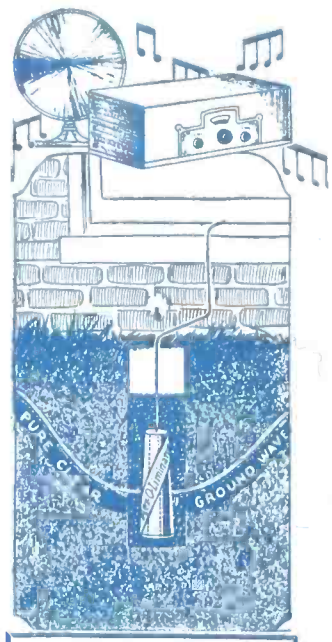
GROUND ANTENNA

Gets Winter Reception in Summer!



EASY TO INSTALL
Just dig a small hole about 6 inches in diameter and drop Aer-O-Liminator into it.

Clearer Ground Wave Reception Allows Greater Distance

Hundreds of satisfied users of the sensational Ground Antenna — Aer-O-Liminator — are wondering how they ever got along without it. All over the country radio owners are finding marvelous satisfaction in freedom from static and noise interference. This revolutionary improvement of reception comes from hooking your receiver to Ground Wave Reception. Radio engineers tell you that the broadcast wave through the ground is in most cases almost static-free and with rare exception carries no noise interference.

The rapidly increasing army of Aer-O-Liminator owners also enjoy and appreciate the natural human tone and clarity of this Ground Wave Reception. If you haven't tried it you can't imagine the difference!

Another advantage users have found with Aer-O-Liminator is the surprising DX they get. Distant stations formerly drowned out by static or noise interference of air waves now come in clear as a bell. Selectivity is improved because, with pure, clear Ground Wave Reception, you can pick up and log signals that before were lost in the jumble of shrieks and howls so common in DX reception through air waves.

You shouldn't deprive yourself of the new thrill of pure, clear ground wave reception a day longer than necessary. We let you prove it for yourself.

FREE TRIAL

Make this thrilling test at our risk!

Install an Aer-O-Liminator (Ground Antenna). Leave your old overhead aerial up. Try out on a night when static is bad. If you do not get a wonderful improvement in freedom from static, greater selectivity and clear, sweet tone without interfering noises, if you can't get good reception on stations that are drowned out by static on your old aerial, you need not pay us a red cent for this test! Send coupon at once for scientific explanation of Aer-O-Liminator (Ground Antenna), proof of performance and our conclusive iron-bound guarantee, and remarkable Free Trial Offer—Mail Coupon TODAY!

Read this Proof

From 208 Golf Terrace
Wilmette, Ill.

"Your Aer-O-Liminator works fine. You could hardly believe what a difference it makes in the clearness and tone of my set. It certainly seems to take out nearly all the static and power noises that have been bothering me, too.

"Mine is only a three tube set, but with the Aer-O-Liminator I can pick up outside stations every night, clear and with volume. You must be right about the static-free ground waves."

L. Beauvais.

From Kimberly Radio Corp.,
328 N. Michigan Ave., Chicago.

"We have used the Aer-O-Liminator with great satisfaction. It removes the necessity of the unsightly outside aerial and improves reception materially. It reduces static and outside interference, and produces very clear tones on distant stations, with good volume. It increases selectivity greatly. We would recommend it to anyone for the best results on his set."

P. R. Kimberly, President.

If all the Radio sets I've "fooled" with in my time were piled on top of each other, they'd reach about half-way to Mars. The trouble with me was that I thought I knew so much about Radio that I really didn't know the first thing. I thought Radio was a plaything—that was all I could see in it for me.

I Thought Radio Was a Plaything

But Now My Eyes Are Opened, And I'm Making Over $100 a Week!

$50 a week! Man alive, just one year ago a salary that big would have been the height of my ambition.

Twelve months ago I was scrimping along on starvation wages just barely making both ends meet. It was the same old story—a little job, a salary just as small as the job—while I myself had been dragging along in the rut so long I couldn't see over the sides.

If you'd told me a year ago that in twelve months' time I would be making $100 and more every week in the Radio business—whew! I know I'd have thought you were crazy. But that's the sort of money I'm pulling down right now—and in the future I expect even more. Why only today—

But I'm getting ahead of my story. I was hard up a year ago because I was kidding myself, that's all—not because I had to be. I could have been holding then the same sort of job I'm holding now, if I'd only been wise to myself. If you've fooled around with Radio, but never thought of it as a serious business, maybe you're in just the same boat I was. If so, you'll want to read how my eyes were opened for me.

When broadcasting first became the rage, several years ago, I first began my dabbling with the new art of Radio. I was "nuts" about the subject, like many thousands of other fellows all over the country. And no wonder! There's a fascination — something that grabs hold of a fellow—about twirling a little knob and suddenly listening to a voice speaking a thousand miles away! Twirling it a little more and listening to the mysterious dots and dashes of steamers far at sea. Even today I get a thrill from this strange force. In those days, many times I stayed up almost the whole night trying for DX. Many times I missed supper because I couldn't be dragged away from the latest circuit I was trying out.

I never seemed to get very far with it, though. I used to read the Radio magazines and occasionally a Radio book, but I never understood the subject very clearly, and lots of things I didn't see through at all.

So, up to a year ago, I was just a dabbler—I thought Radio was a plaything. I never realized what an enormous, fast growing industry Radio had come to be—employing thousands and thousands of trained men. I usually stayed home in the evenings after work, because I didn't make enough money to go out very much. And generally during the evening I'd tinker a little with Radio—a set of my own or some friend's. I even made a little spare change this way, which helped a lot, but I didn't know enough to go very far with such work.

And as for the idea that a splendid Radio job might be mine, if I made a little effort to prepare for it—such an idea never entered my mind. When a friend suggested it to me one year ago, I laughed at him.

"You're kidding me," I said.

"I'm not," he replied. "Take a look at this ad."

He pointed to a page ad in a magazine, an advertisement I'd seen many times but just passed up without thinking, never dreaming it applied to me. This time I read the ad carefully. It told of many big opportunities for trained men to succeed in the great new Radio field. With the advertisement was a coupon offering a big free book full of information. I sent the coupon in, and in a few days received a handsome 64-page book, printed in two colors, telling all about the opportunities in the Radio field and how a man can prepare quickly and easily at home to take advantage of these opportunities. Well, it was a revelation to me. I read the book carefully, and when I finished it I made my decision.

What's happened in the twelve months since that day, as I've already told you, seems almost like a dream to me now. For ten of those twelve months, I've had a Radio business of my own. At first, of course, I started it as a little proposition on the side, under the guidance of the National Radio Institute, the outfit that gave me my Radio training. It wasn't long before I was getting so much to do in the Radio line that I quit my measly little clerical job, and devoted my full time to my Radio business.

Since that time I've gone right on up, always under the watchful guidance of my friends at the National Radio Institute. They would have given me just as much help, too, if I had wanted to follow some other line of Radio besides building my own retail business—such as broadcasting, manufacturing, experimenting, sea operating, or any one of the score of lines they prepare you for. And to think that until that day I sent for their eye-opening book, I'd been wailing "I never had a chance!"

Now I'm making, as I told you before, over $100 a week. And I know the future holds even more, for Radio is one of the most progressive, fastest growing business in the world to-day. And it's work that I like—work a man can get interested in.

Here's a real tip. You may not be as bad off as I was. But think it over—are you satisfied? Are you making enough money, at work that you like? Would you sign a contract to stay where you are now for the next ten years—making the same money? If not, you'd better be doing something about it instead of drifting.

This new Radio game is a live-wire field of golden rewards. The work, in any of the 20 different lines of Radio, is fascinating, absorbing, well paid. The National Radio Institute—oldest and largest Radio home-study school in the world—will train you inexpensively in your own home to know Radio from A to Z and to increase your earnings in the Radio field.

Take another tip—No matter what your plans are, no matter how much or how little you know about Radio—clip the coupon below and look their free book over. It is filled with interesting facts, figures, and photos, and the information it will give you is worth a few minutes of anybody's time. You will place yourself under no obligation—the book is free, and is gladly sent to anyone who wants to know about Radio. Just address J. E. Smith, President, National Radio Institute, Dept. 5Q, Washington D. C.

J. E. SMITH, *President*,
NATIONAL RADIO INSTITUTE,
DEPT. 5Q, WASHINGTON, D. C.

Dear Mr. Smith:
Please send me your 64-page free book, printed in two colors, giving all information about the opportunities in Radio and how I can learn quickly and easily at home to take advantage of them. I understand this request places me under no obligation and that no salesman will call on me.

The Thordarson Z-Coupler, a special audio impedance coupler for use with screen grid tubes; price each, $12.

New! SCREEN-GRID Audio Amplification

Screen grid audio amplification, most revolutionary development in audio systems since the introduction of the power tube, is now an established fact.

The Thordarson Z-Coupler is a special audio coupling device designed for use with the screen grid tube UX-222. With the remarkable amplification thus obtained a mere whisper from the detector is stepped up to a point that gives the power tube all it can handle in the way of signal voltage. In fact, one stage Z-Coupled audio has the amplification equivalent of two, or even three, stages of ordinary coupling. Signals barely audible before may now be heard at normal room volume.

In tone quality, too, the Z-Coupler is unexcelled. Despite the high amplification the tonal reproduction is as nearly perfect as any audio amplifier yet developed. Both high and low notes come through with the same volume increase. Even at 60 cycles the amplification is over 95% of maximum.

Regardless of the type of your receiver you can vastly improve its performance by including this new system of amplification. The Z-Coupler replaces the second audio transformer, with very few changes in the wiring. The screen grid tube is used in the first audio stage. No shielding is required.

30 Up-to-Date Selections

With This Portable Phonograph

$1.00 down

A sensational offer. Only $1.00 with coupon below brings this Portable Phonograph with a special assortment of up-to-date high-grade 75c records—30 selections in all, 15 double face records. These records are made by the wonderful **new electric process**—more life like, more volume, less surface noise than ever. And they play longer. Very latest selections, popular songs, dance music, band and instrumental pieces — $11.25 worth of brand new records included with this outfit. We've picked out just the kind of records to please you most. And besides we give you

30 Days Trial

Yes, we'll send this Puritone portable phonograph outfit, with 30 high-grade selections, 15 double face 75c records, to your home on 30 days trial for only $1.00 with the coupon. Use it as your own and see what a wonderful convenience it is to have a phonograph that you can carry from room to room, from place to place, wherever and whenever you want it.

We Guarantee: that you get everything in this phonograph so far as concerns music reproduction that a $250 phonograph can give you. True, you don't get the big furniture, but you do get **(and we guarantee it)** the exact reproducer, the exact style of tone arm and the same grade of records you get in the most expensive phonograph ever made. That's why you get, on this wonderful offer, **absolutely the best** in music that any phonograph ever gave.

$2.60 a Month

If within 30 days you decide not to keep the outfit, send it back and we'll refund your $1.00 plus all transportation charges. If you keep it, pay only $2.60 a month until you have paid that sensational price on this special sale—only $26.85. Think of it, a first class high grade phonograph and 15 high grade, up-to-date, double face records—[30 selections] a complete outfit, ready to play, only **$26.85**! Seize this opportunity on this special sale, while it lasts. Send the coupon NOW!

FREE Catalog of home furnishings sent on request with or without order. See coupon.

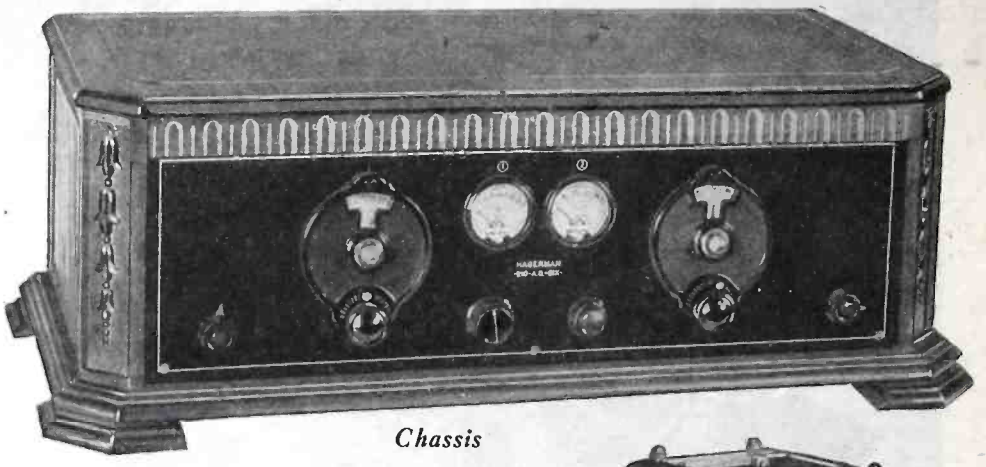
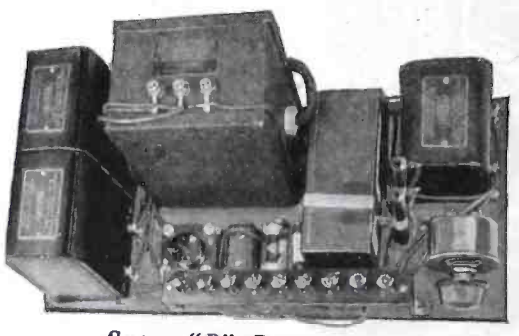
HAGERMAN ENSE

The Perfect Custom-Built Ensemble!



Chassis

Molded Wood Speaker Tone Chamber



Super "B" Power Supply

"A" Supply

These Leading Manufacturers Make This

MUTER

Power Condensers—Resistances, Etc.

The filter condensers of a power circuit are its most critical constants. Muter precision manufacturing methods assure the custom set builder, when he uses Muter Power Condensers, as well as chokes, resistances, transformers, etc., that the set he builds will be perfect in every detail.—Leslie F. Muter Co., 76th and Greenwood Ave., Chicago

JEWELL

Voltmeters

In the Hagerman 210-A.C.-Six Ensemble, Jewell instruments were chosen because of the years of experience of the manufacturer and because of the special fitness of these instruments for adaption to this circuit; Jewell instruments are accurate, sturdy and good looking, and will give untold satisfaction in their use.—Jewell Electrical Instrument Co., 1650 Walnut St., Chicago.

THORDARSON

Power Compact

"Transformers" and "Thordarson" are almost synonymous. The reliability and efficiency of the radio set or power supply is directly in ratio to the theoretical and mechanical perfection of the voltage supply or amplifying transformers. The R-171 and R-210 Power Compacts are the heart of any power amplifier or "B" supply.—Thordarson Electric Mfg. Co., 500 W. Huron St., Chicago.

MOLDED WOOD

Speaker Tone Chamber

The finest type of loud speaker as acknowledged by such great authorities as Dr. Lee De Forest. A natural choice for use in conjunction with the powerful 210-A.C.-Six. Equally as adaptable to any set with or without power amplification. Ready mounted for installation in any console or speaker table.—Moided Wood Products Company, 219 West Chicago Avenue, Chicago.

ANNOUNCEMENT

The new Balkite AC set will retail in the table model at a price between $175 and $200 without tubes. A complete line of console cabinets will be available. Showing will be made at an early date. The set will be worthy of the name Balkite, and well worth waiting for.

For your present radio set Balkite Radio Power Units furnish all power from the light socket and convert it into an electric receiver

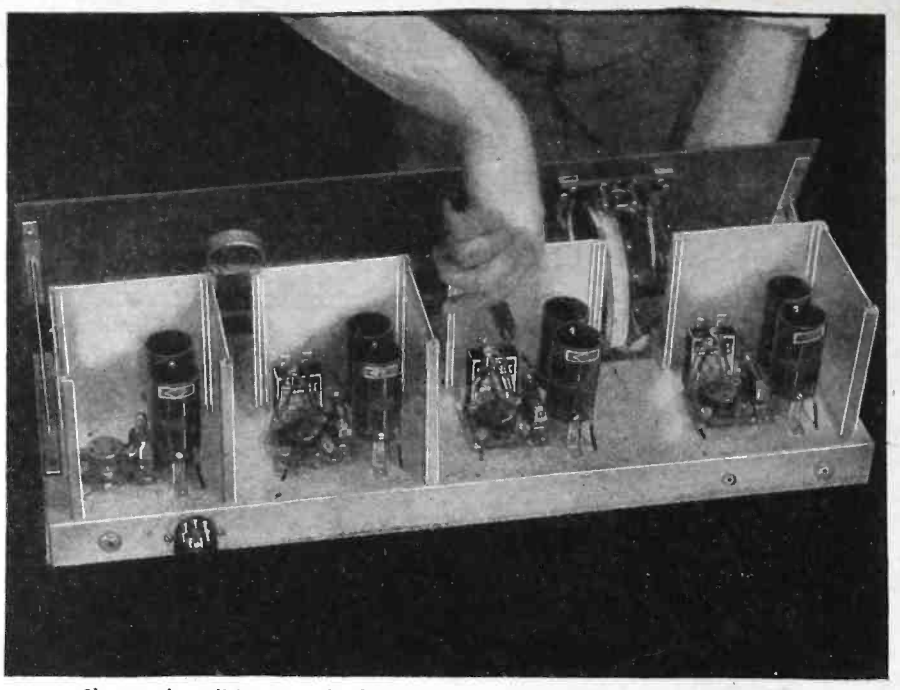
FANSTEEL

Balkite RADIO

FANSTEEL PRODUCTS COMPANY, Inc., *North Chicago, Illinois*

"I have used ACME PARVOLT *Condensers for many years and have never had one break down."*

E. W. Ackerday



Showing the well-known L. C. 28 wired for A. C. power supply. Only the finest parts are specified in this high class set, including PARVOLT *By-Pass Condensers.* ACME PARVOLT *Filter Condensers are also recommended for use in the power end.*

Whether You Buy or Build

a Power Supply Unit for Your Radio

PLAY SAFE WITH PARVOLTS!

WHEN you buy an electrified radio or power supply unit for your receiver, look for ACME PARVOLT Condensers; they are your guide to quality in all other parts. They cost the manufacturer a trifle more, but they are both his and your guarantee against costly condenser break-down.

Should you build your own power supply, be sure to use ACME PARVOLT Condensers and be safeguarded against the possibility of break down. Remember that poor filter condensers have caused untold thousands of dollars worth of loss in the past year or two, for blown out condensers mean blown tubes, burned out transformers and frequently the ruination of speaker units.

Just as PARVOLT By-Pass Condensers have been used for years in high grade receivers, so are PARVOLT Filter Condensers rapidly replacing ordinary condensers in electrified radio. These condensers are wound with the very finest insulating papers combined with highest grade foils. Every detail produced in one of America's most modern plants and under the supervision of experts in condenser design and manufacture.

Uniformity of capacity and uniformity of sizes are two big features. Accuracy of all ratings, based upon the R.M.A. standards, is another guarantee of uninterrupted service. Play safe with PARVOLTS!

Made by THE ACME WIRE CO., New Haven, Conn., manufacturers of magnet and enameled wire, varnished insulations, coil windings, insulated tubing and radio cables.

ACME PARVOLT FILTER CONDENSERS
In all required mfd. capacities for 200, 400, 600, 800, 1000, and 1500 Volt D C requirements. Supplied singly or in complete wired blocks for the important power supply units.

ACME PARVOLT BY-PASS CONDENSERS
Supplied in all required mfd. capacities and for all standard working voltages.

ACME PARVOLT CONDENSERS

Made by the Manufacturers of

ACME CELATSITE WIRE

ENAMELED AERIAL WIRE
Enameled copper wire in both stranded and solid types. Also Acme Lead-ins, Battery Cables, Indoor and Loop Aerial Wire.

CELATSITE FLEXIBLE and SOLID
For all types of radio wiring. High insulation value; non-inflammable. 10 colors.

ACME SPAGHETTI
A superior cambric tubing for all practical radio and other electrical requirements. Supplied in 10 colors.

Licenses Required for Both Transmitters and Receivers in Canada

All radio stations, whether used for transmitting or receiving purposes are required to be licensed in Canada The penalty on summary conviction for operating an unlicensed radio station is a fine not exceeding $50.00, and on conviction or indictment a fine not exceeding $500.00, with imprisonment for a term not exceeding 12 months. in addition to forfeiture of all unlicensed apparatus. The different classes of stations for which licenses are issued and their license fees vary from $1.00 for a private receiving set to $50.00 for a public commercial station.

The issue of licenses for transmitting stations is limited to British subjects or to companies incorporated under the laws of the Dominion of Canada or its provinces. Licenses for private receiving sets are issued to any person irrespective of nationality. Licenses for receiving sets are obtained from the Postmaster of the larger towns and cities in the Dominion, radio dealers, Royal Canadian Mounted Police, Department of Radio Inspectors, Departmental Agencies or from the Department of Marine and Fisheries. Licenses for all other classes of stations are obtained from the Department of Marine and Fisheries at Ottawa.

ARE YOU REPRESENTED IN THE RADIO MARKET

Custom Setbuilders! RADIO LISTENERS' GUIDE and CALL BOOK has inaugurated a new service to help you increase your sale of radio receivers. The Spring issue carried the first of a series of articles the purpose of which was to acquaint our readers with your work and to show you an easy way to start in business for yourself. To this end we offered the service of the RADIO LISTENERS' GUIDE and CALL BOOK to you. In our effort to co-operate further we have opened a section of our magazine in which we carry in geographical order the advertisements of as many setbuilders as wish to avail themselves of this service. Your ad will be inserted at no cost and it is our hope that it will prove a big help in boosting your sales and in making more money for you.

CONDITIONS

Each advertisement will be keyed and listed geographically in the "RADIO SET MARKET" section as seen on page 136.

No advertisement more than fifty words. Each must be clearly written on a piece of white paper and attached to the coupon herewith. No request will be considered without the coupon.

No ad will be accepted from persons merely desiring to sell a set and who are not bonafide custom setbuilders.

We invite you to take advantage of this service. Fill in the coupon and mail it to us with your ad.

Radio Listeners' Guide and Call Book
230 Fifth Avenue, N. Y. C., N. Y.

Radio Listeners' Guide and Call Book,
230 Fifth Avenue, New York, N. Y.

Gentlemen:—Without cost or obligation to me kindly insert the attached custom made set offer in your next issue.

From Radio Amateur to Custom Set Builder

TWENTY years ago, H. G. Horneij started as a radio amateur. Today he is at the head of a prosperous concern, Schneider-Horneij Radio Research Laboratories, Inc., New York, that produces custom-built receivers and radio apparatus for laboratories, and sells service for home radio outfits.

Mr. Horneij lays no claim to being a radio wizard, although he has a national reputation. He was merely one of those young men with a natural liking for mechanical and experimental work. There are thousands of such men, all wishing that they could get away from routine jobs where they are but cogs in the wheels of industry, and longing to be independent business men, free to do the kind of work that they like best and able to make a good living at it. The main difference between them and Mr. Horneij is that he went ahead and did the things which the others only think about.

Any man who looks back over his past must realize that the path of opportunity always has been right in front of him, but that he often was too blind to see it. A lot of us are like pigs and somebody has to hold a board on each side of us to make us think that we are going up the right alley. The trouble with that arrangement is that the fellow who holds the boards brings home the bacon.

We are like the radio operator who wrote a bitter letter criticizing an article because it had stated that there were good opportunities in radio. He said he had been an operator for three long years and all the opportunity he had, was to make monotonous trips on a bad smelling tanker and lie for days in a hot harbor surrounded by mosquito-breeding marshes. A bird like that would sit all the evening in a bunch of old maids without seeing a chance to get married!

The story of this man Horneij appeals to the average man more, we believe, than accounts of men such as Dubilier and Sarnoff. Most of us would like their positions and incomes but we could not stand the work they do. They were good radio men, but either they liked executive work better than construction and experiment or else they went into it merely because there was more money in it.

The born mechanic and experimenter does not enjoy executive work as a rule. He may get a thrill out of it the first few times that he sits at the head of a conference table and steers a board of directors, but after a few weeks of it the mention of a conference is likely to make him sick enough to lose his lunch.

Mr. Horneij became interested in radio—wireless it was called then—in 1908. He says that he built what was then a receiver. Old-timers will remember what that was, with a "coherer" that served as a detector, when it cohered. He also built a coil transmitter, one of those old "rock crushers" that would drown out hundreds of broadcast, ship and shore stations if it should open up today, but would shoot only a few miles.

As the various types of magnetic and crystal detectors came along, Horneij tried them out. Then came the vacuum tube receiver and transmitter. By that time he was ready

for a commercial operator's job and he joined the Marconi Company.

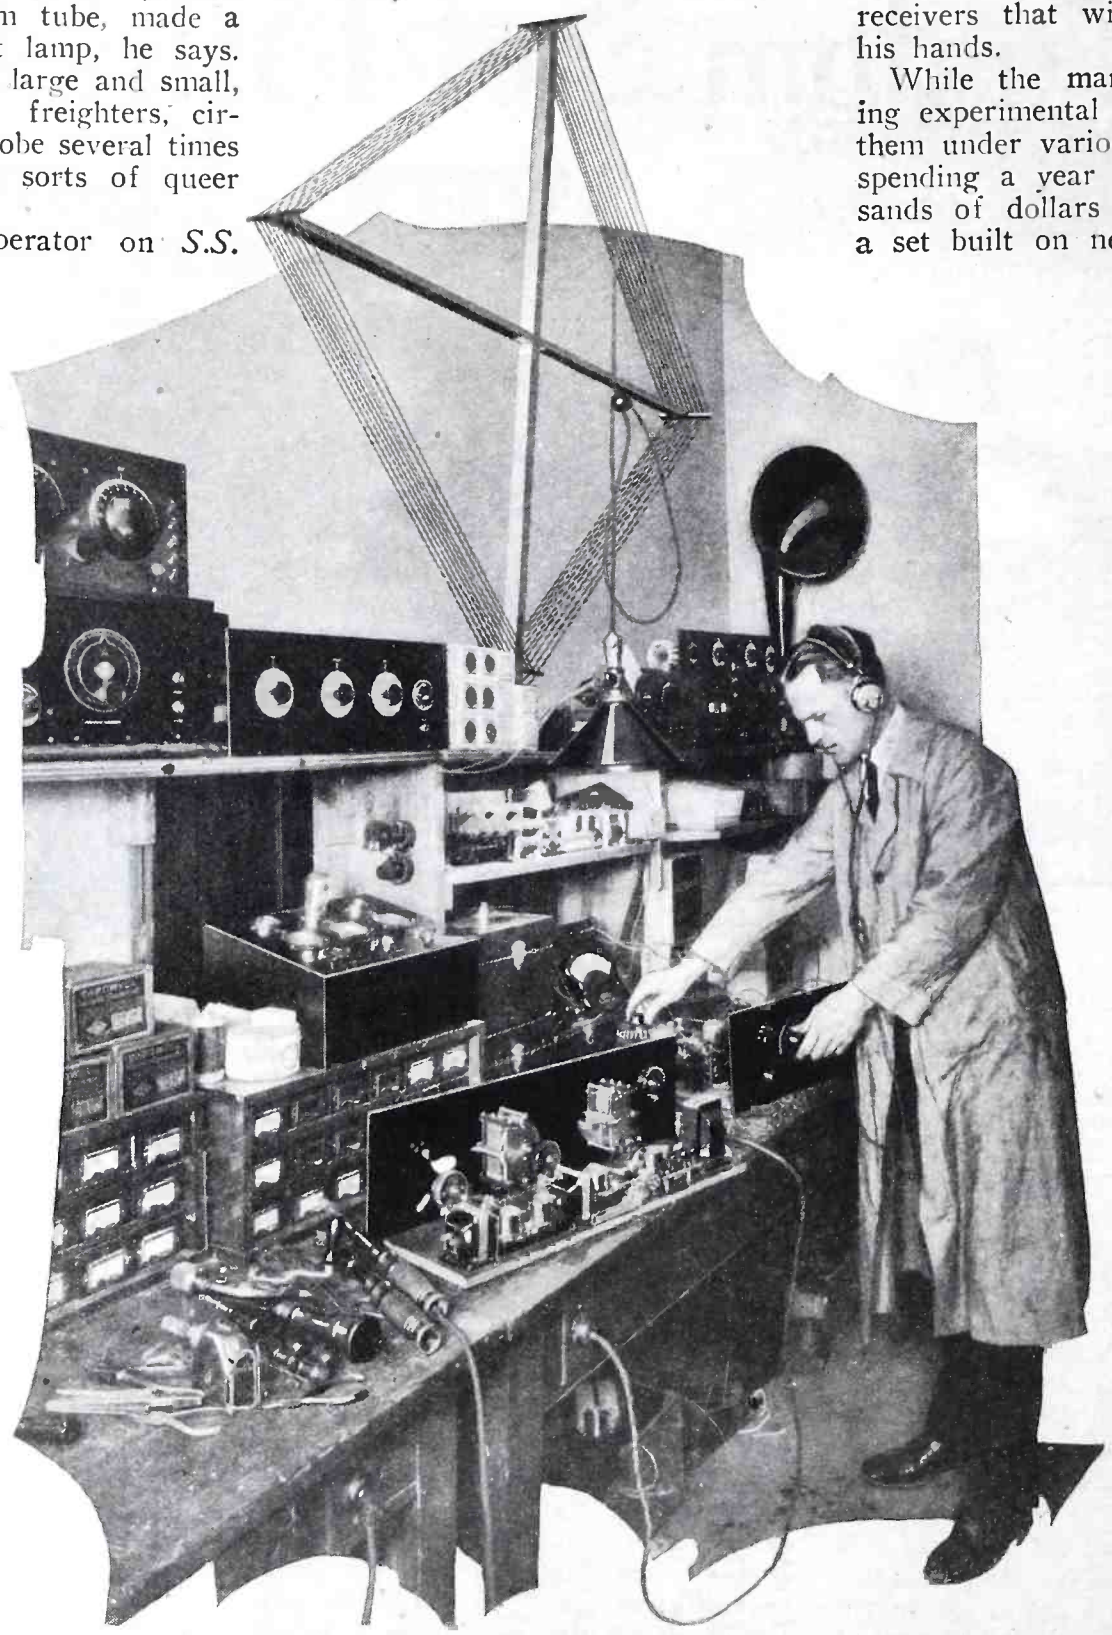
He sailed the Seven Seas, as thousands of men would like to do, with all expenses paid and a fair salary to put in the bank or spend on shore trips. His experience increased as he worked all types of transmitters and receivers. The old Fleming valve, the forerunner of the present three-element vacuum tube, made a perfectly good night lamp, he says. He sailed on vessels large and small, passenger ships and freighters, circumnavigating the globe several times and poking into all sorts of queer places.

He was chief operator on *S.S. New York* of the American Line, call letters KSN, when she was mined off the coast of England. Admiral Sims was on board, en route to England to take command of the American Navy in British waters. Horneij was on watch when the mine exploded, and he broadcast his first and only SOS.

While at sea, Mr. Horneij always was experimenting with different circuits. He carried a trunk full of apparatus and this helped him to pass the time and also laid the foundation for his present thorough knowledge of radio. He read books, too, all the radio books he could find. He still has the reading habit.

He resigned from the Marconi Company in 1920 and was elected secretary and organizer of the Commercial Radio Operators' Association. During the two years that he served this organization he started building high wave receivers and amplifiers to be used on shipboard, and relays to be used with "bug" transmitting keys. He found ready sale for these among the operators.

During the same period he built a tube transmitter at home and began to broadcast "canned" music. He was one of the first amateurs to do this. Then broadcasting suddenly captured the attention of the public and he started to build complete receivers. He met with fair success, but partnership troubles interfered with the business. He had learned that there were certain classes of radio buyers who preferred custom built receivers, just as there are men who buy only custom made clothes no matter how good the factory-made product may be, so he decided to go into the business of building radio sets to order.



Mr. Horneij, the aggressive custom set builder, continually experiments on up-to-date developments and new receivers in order to keep ahead of the manufactured sets.

As a builder of custom sets, Mr. Horneij found that he could keep a year ahead of manufactured sets. The reasons are easy to see. Every day new ideas are presented to manufacturers. However good an idea may be, a manufacturer cannot afford to put it into his product until he has tested it thoroughly. He is working on a mass production basis. He must produce sets that will give average results under average conditions. He cannot adapt sets to the peculiar conditions of certain localities and certain homes. Therefore, he must acquire a considerable volume of experience or he runs a chance of putting out thousands of receivers that will come back onto his hands.

While the manufacturer is making experimental models and testing them under various conditions, often spending a year or more and thousands of dollars before he can sell a set built on new lines, Mr. Horneij and other custom set builders can be making and selling sets that embody every new idea. He builds a set in his shop, tests it in his home, demonstrates it in the home of a customer and sells it, possibly all within a week. If it gives satisfaction in that home, that is all that is necessary. If conditions in the next home are against it, some other type can be installed there.

The manufacturers raise no objections. Where there are patent rights involved, of course they are respected. The custom set builder's volume of sales is as small, compared with the manufacturer's volume, as the custom tailor's output is beside the output of the great clothing factory. No manufacturer fears his competition. On the other hand, the manufacturer reaps the benefit of the experience of the custom set builder, who can tell him what results are obtained with new hook-ups and new types of apparatus right in the homes of the ultimate consumers.

The manufacturers of radio parts welcome the custom set builder and give him wholesale prices. Their business grows as his grows.

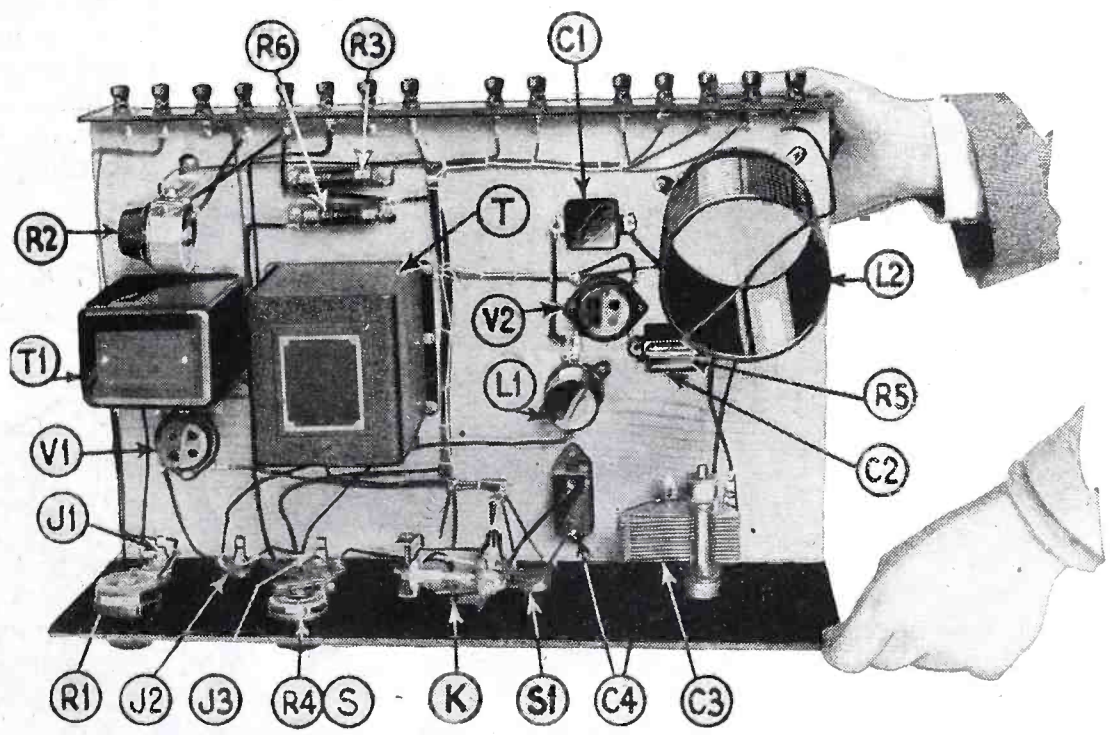
In the early days of his business venture, Mr. Horneij confided his

(*Continued on page* 152)

Building a Radio Picture Receiver

IF, some day while tuning idly around, you pick up peculiar signals that sound like a badly greased grinding stone turning over at a fairly rapid rate, let your curiosity find out what it is all about. The chances are that you accidentally tuned in a radio photograph transmission broadcast. There are several stations, in the United States and in Canada, that are "on the air" with radio pictures. Now, the sport is building a special set that will pick these up, and enable the amateur to receive his own radio-photos in his home.

Radio pictures are being broadcast within the wave bands assigned by the Government for program and entertainment use. This means that the receiving set now ordinarily employed for the reception of broadcast programs can be used to pick up picture impulses without any change. To operate various devices that make it possible to record the picture transmitted, some additional material, to be described further on, will be needed.



This photo shows a top view of the radio picture receiver. All parts are indicated to correspond with components listed in the text of this article.

Receiving a radio picture is practically reversing the process of transmission. At the sending station, an original photograph is wrapped around a cylinder that turns over at a very definite rate of speed, say 100 revolutions per minute. A beam of light is made to strike the surface of the photograph, the reflected ray being directed against the aperture of a photo-electric system, connecting to the transmitting apparatus. The mechanism is so arranged that the entire photograph will be scanned by this narrow beam, revolving and progressing axially before it.

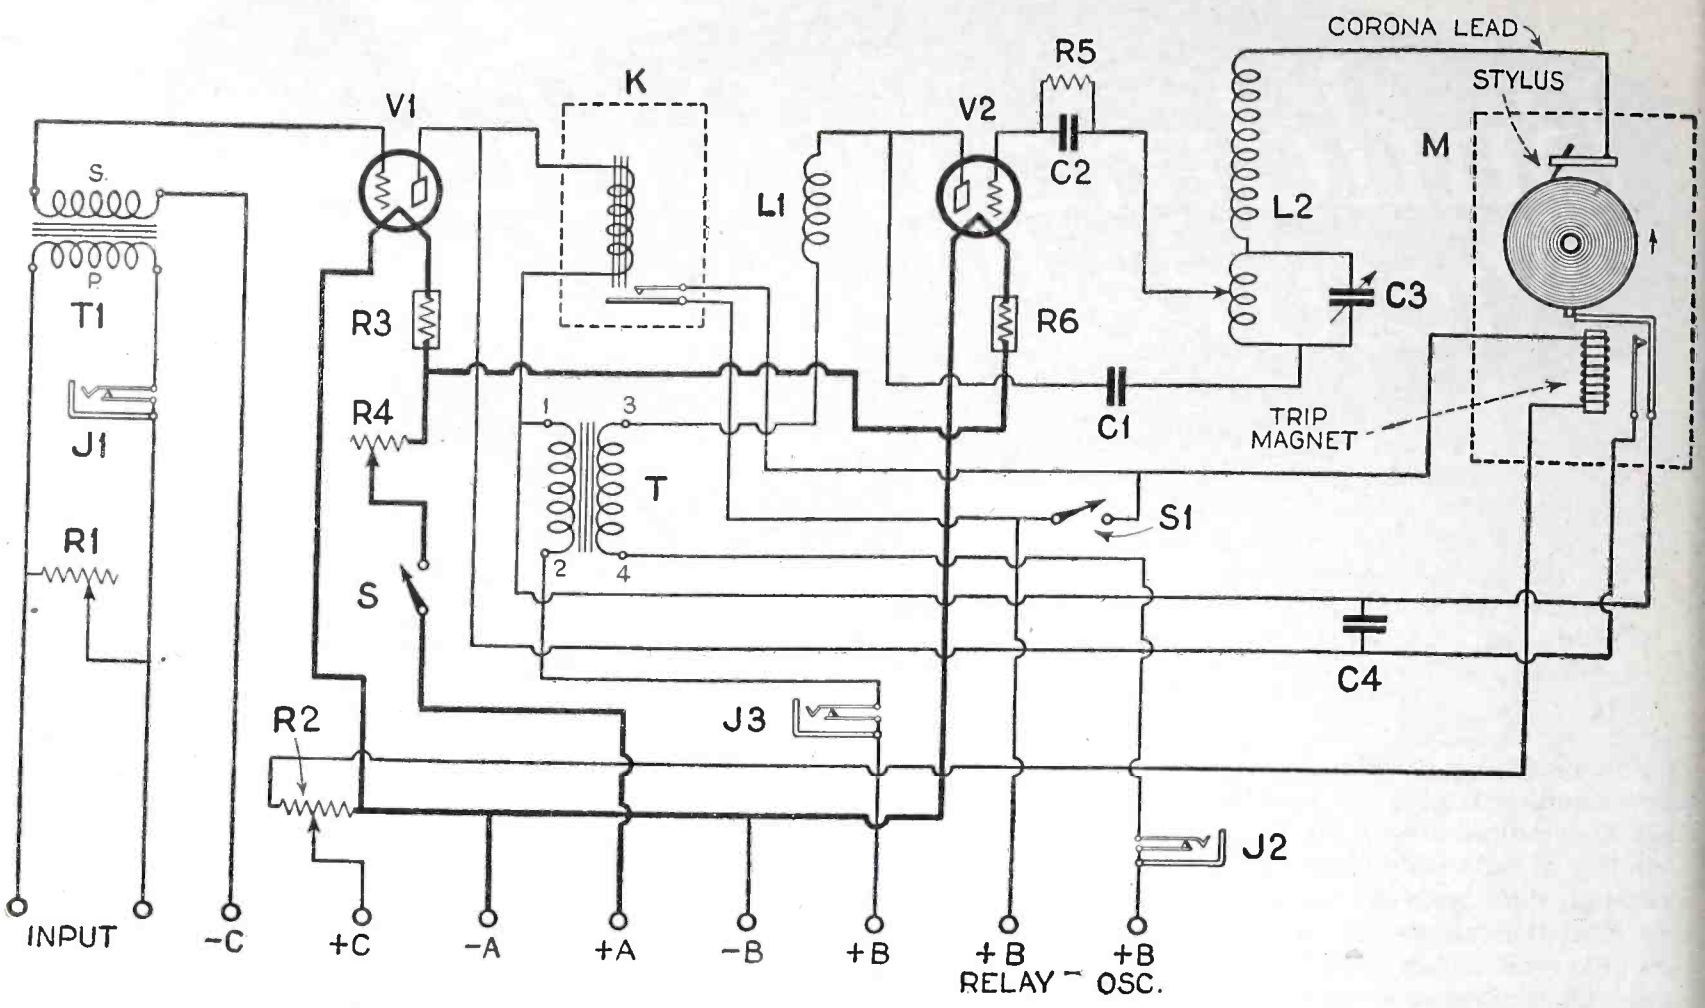
As the beam meets different values of light and shade on the photograph, a greater or lesser amount of light will be reflected to the photo-electric cell. This device, in turn, regulates the intensity of the picture impulse sent.

At the receiving end, the wave is tuned in, and the impulses amplified as though they were ordinary broadcast signals. Then, they are fed into a special amplifying and oscillating arrangement, and after reaching high voltages, are led to a stylus, or recording point on a travelling carriage that is part of a recording cylinder mechanism.

One of the most important considerations in picture transmission and reception is that the both systems operate in absolute synchronism. In this case, it is necessary to have the receiving cylinder turn over at the same rate of speed as the sending one, i.e.—100 revolution per minute.

This may seem an impossible feat, when it is considered that the receiving and sending stations are probably hundreds of miles apart, and with no connecting circuits, except the radio channel. Enginers have, a number of years ago, solved this problem in a more or less satisfactory way. It is called the "stop-start" method, and was used by an Englishman nearly twenty years ago for picture telegraph work between Paris and London. It is the simplest and most practical perhaps, for amateur picture work, and is the idea worked into this system to be described.

The method is simply to have the receiving cylinder travel at a slightly higher rate of speed than that of the sending station. A spring stops the receiving cylinder automatically at the end of each revolution, and a separate but distinct impulse from the transmitter reacts on a relay that permits the receiving cylinder to begin its next revolution at exactly the same time that it does. Thus, the two cylinders begin each



Schematic wiring diagram of the radio picture apparatus described in the article.

revolution on exactly the same instant, and the receiving cylinder is synchronized at every revolution.

Putting together the mechanism that will enable any amateur that can tune in to a picture broadcast to record his own photographs by radio is not complicated. In fact, anyone that can build any of the standard types of multi-tube sets can construct a radio picture receiver.

Standard parts are used throughout. With the exception of the special recorder, and one or two additional parts, all of the apparatus may be purchased from your local radio dealer. The character of parts needed are given as follows:

- 1 Variable gain control resistance, 10,000 ohms, R1.
- 1 Potentiometer, 200 ohms, high current capacity, R2.
- 1 Filament rheostat, 10 ohms, high current, with filament switch, R4, S.
- 1 Fixed condenser 0.1 mfd., C4.
- 2 Fixed condensers 0.0005 mfd., C1, C2.
- 1 Variable condenser 0.0005 mfd., C3.
- 1 R.F. choke, 85 millihenries, L1.
- 1 Switch, filament circuit type, S1.
- 3 Jacks short circuiting short jacks, double contacts, J1, J2, J3.
- 2 Filament ballast resistances, R3, R6.
- 1 Phone plug, P.
- 1 Milliameter 0 to 25 mils, MA.
- 2 Tube sockets, V1, V2.
- 14 Binding posts.
- 1 Panel 16½x7 in.
- 1 Binding post strip 16½x2 in.
- 1 Wood Baseboard 10½x16½ in.
- 1 Grid leak.
- 1 Corona coil, L2.
- 1 Low ratio audio amplifying transformer, T1.
- 1 Modulation transformer, T.
- 1 Relay, K.
- 1 Recording machine, M.

The radio picture set receiving a photograph with the aid of a victrola motor as the driving device. Experiments are being conducted daily with radio picture sets such as described in this article.

With a view to minimizing as much as possible any bad feed-back effects that are most undesirable in this machine, and also, to give maximum room for adjustment, wiring, and replacement, a large board is used for the base. The panel is of standard size, and will accommodate all of the controls that are of immediate importance in the working of the machine.

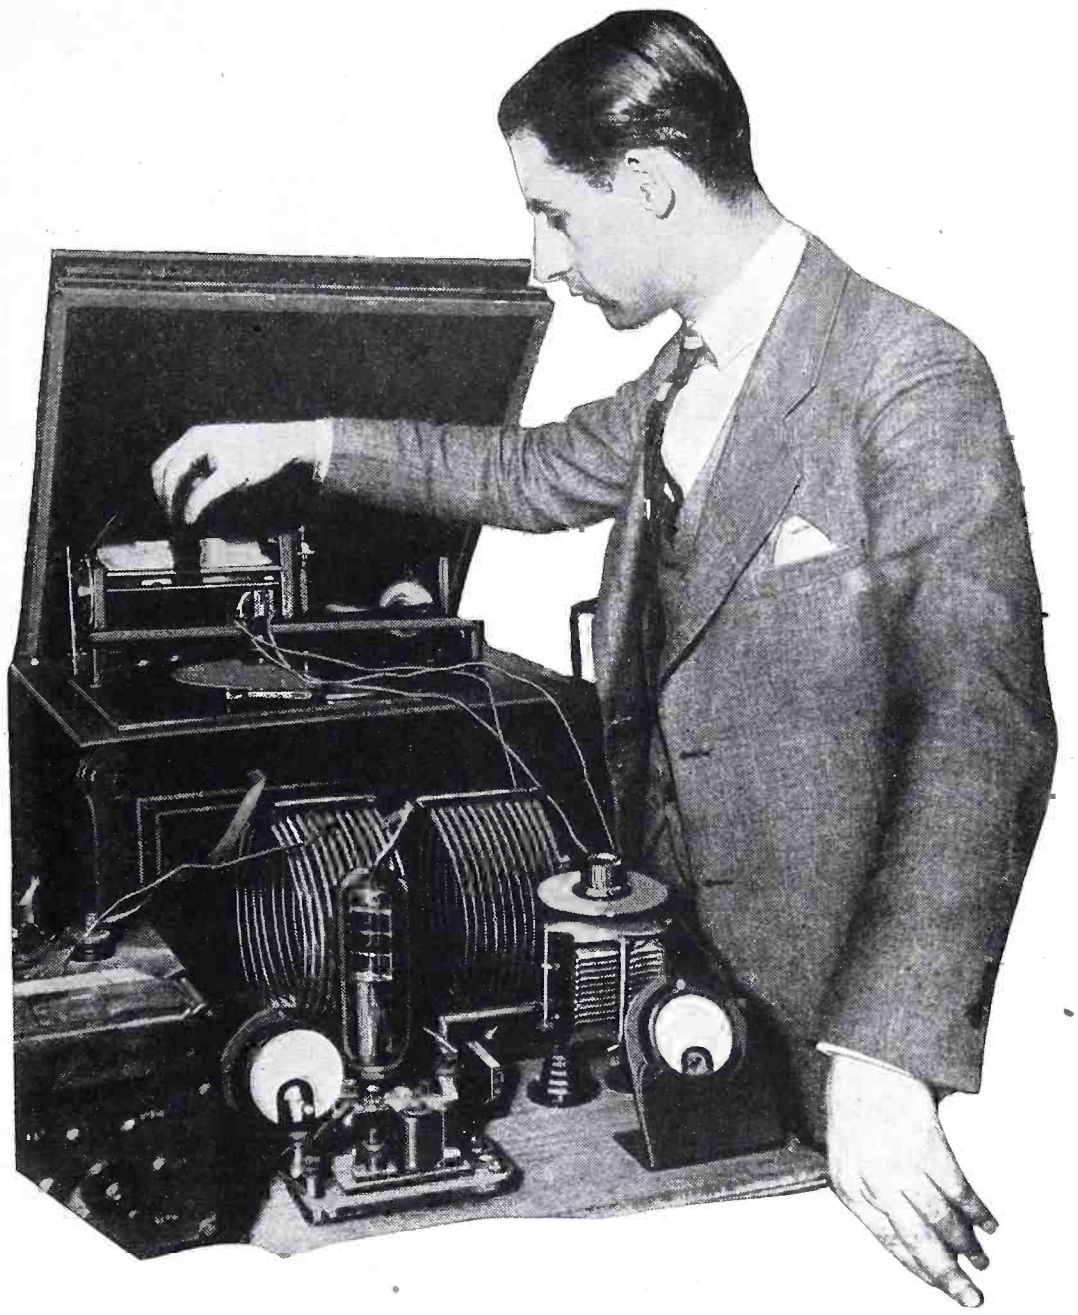
Much of the success of the picture set will depend on the way it is assembled. First, the audio and modulation transformers are located and fastened down with large screws. Then, the sockets, fixed condensers, choke, filament controls, and the coil. The suggested layout can be followed. Experienced amateurs only will attempt to change it greatly.

Work on the panel can now be started. On it are placed the filament and gain controls, several jacks, the special relay, and a variable condenser. Any symetrical arrangement can be designed for the panel. A convenient and practical layout is the one suggested here in the model.

A binding post strip, with the binding posts readily accessible is screwed on the rear end of the baseboard. The preliminary wiring can now proceed.

First, it is suggested that the filament circuits be tackled. The grid, and then, the plate circuits can be done in succession. Before this is done, the front panel should be mounted on the front edge of the baseboard with wood screws.

Every circuit should be checked over carefully. Specially is it important that the relay circuit be watched. Notice the numbers on the transformer terminals, and connect them to the correct jack, relay, and other points in the modulation and oscillating circuits.



Above is the picture transmitter showing simplicity of equipment, hooked up to ordinary victrola. A short wave transmitter is used in conjunction with a photo pick-up device. Experimental tests are being conducted daily over a broadcast station in New York.

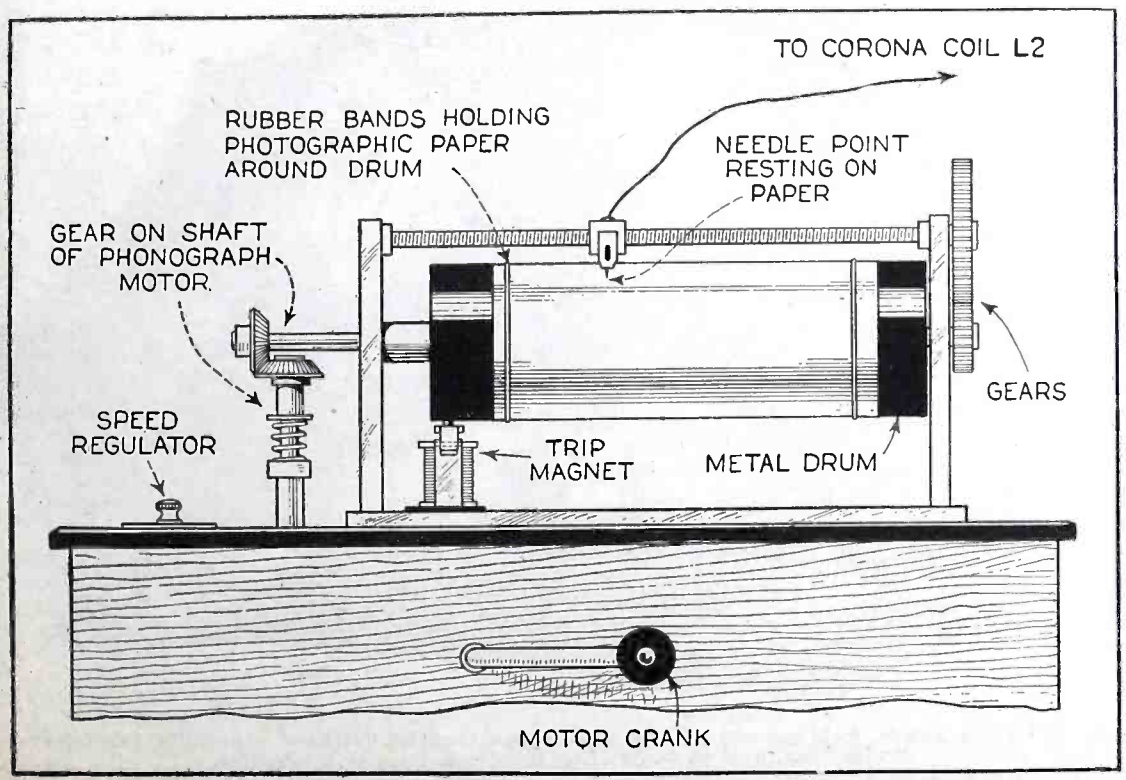
Modulation transformer posts are numbered 1, 2, 3 and 4 in the accompanying schematic diagram. The input goes to terminals 1 and 2. The first terminal connects with the winding of the relay, which in turn, goes to the plate of the first tube. The second post connects with a jack, and to the B plus post on the rear strip.

Then, secondary connections are made, for post three, to the choke coil feeding to the plate of the oscillator; post four goes to high plate voltage terminal on the strip, through a jack. Although the connections from the receiving set into the input transformer are not of prime importance as to direction, they may be reversed if necessary.

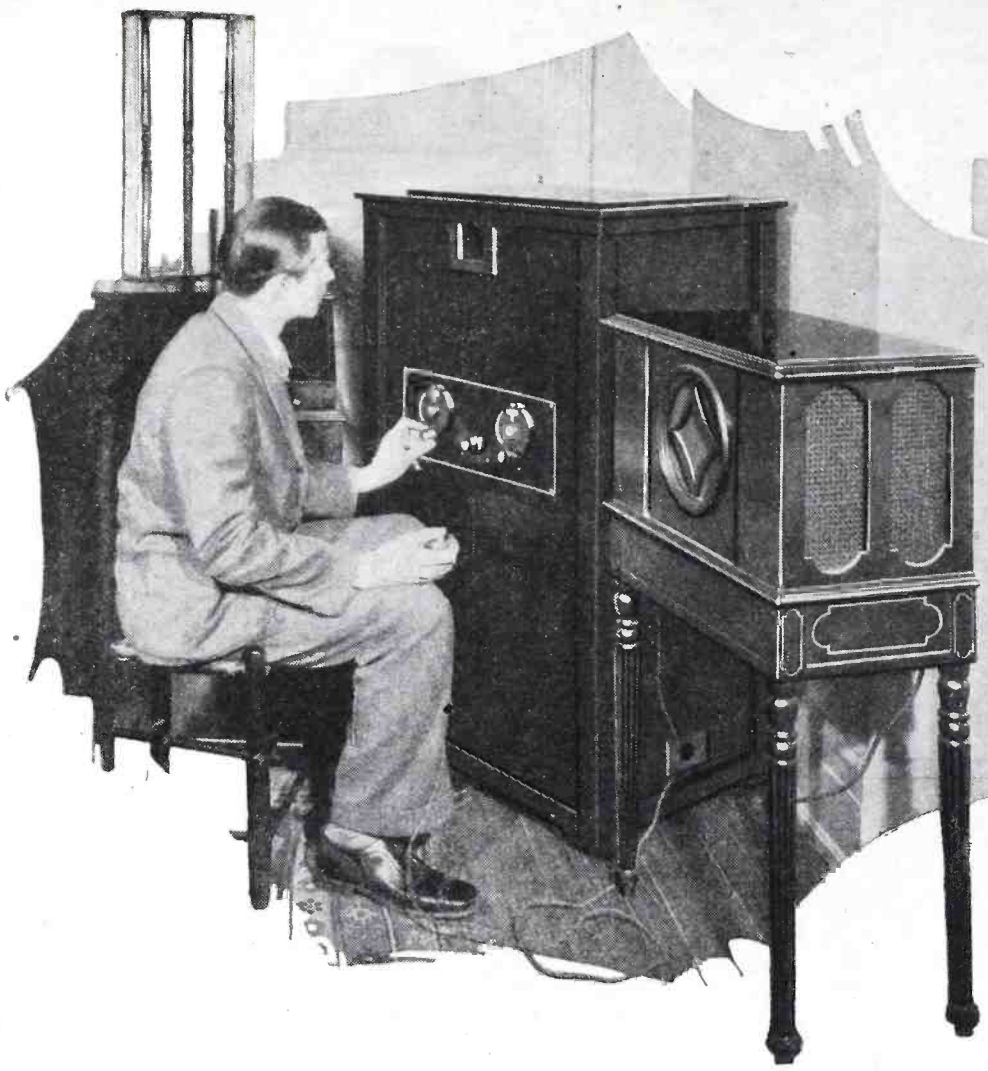
To produce a neat wiring job, wires may be cabled, in the telephone manner, and carefully tied together. Needless to say, all connections should be soldered, and individually tested. All parts should be inspected before using in the circuits. This work may save hours of time later, when it is found that trouble has developed.

Attention may now be given the recorder shown in a sketch herewith. It consists of a cylinder, about two inches in diameter, and six inches long. It is driven, through

(*Continued on page* 144)



Details of the recorder. A device of this type is available completely assembled, or it can be built by the experienced machinist.



EXPERIMENTAL TELEVISION

ALTHOUGH the art of television is not a new one, as compared with its sister science, radio telephony, it has been dormant for many years. while radio telephony has increased in scope with leaps and bounds. Television in the laboratry was an established fact many years ago, but the physical, electrical and mechanical difficulties of bringing it out of that stage were so many, and so seemingly unsurmountable, that it was only recently that several improvements in the art were announced, and interest in television received a great impetus.

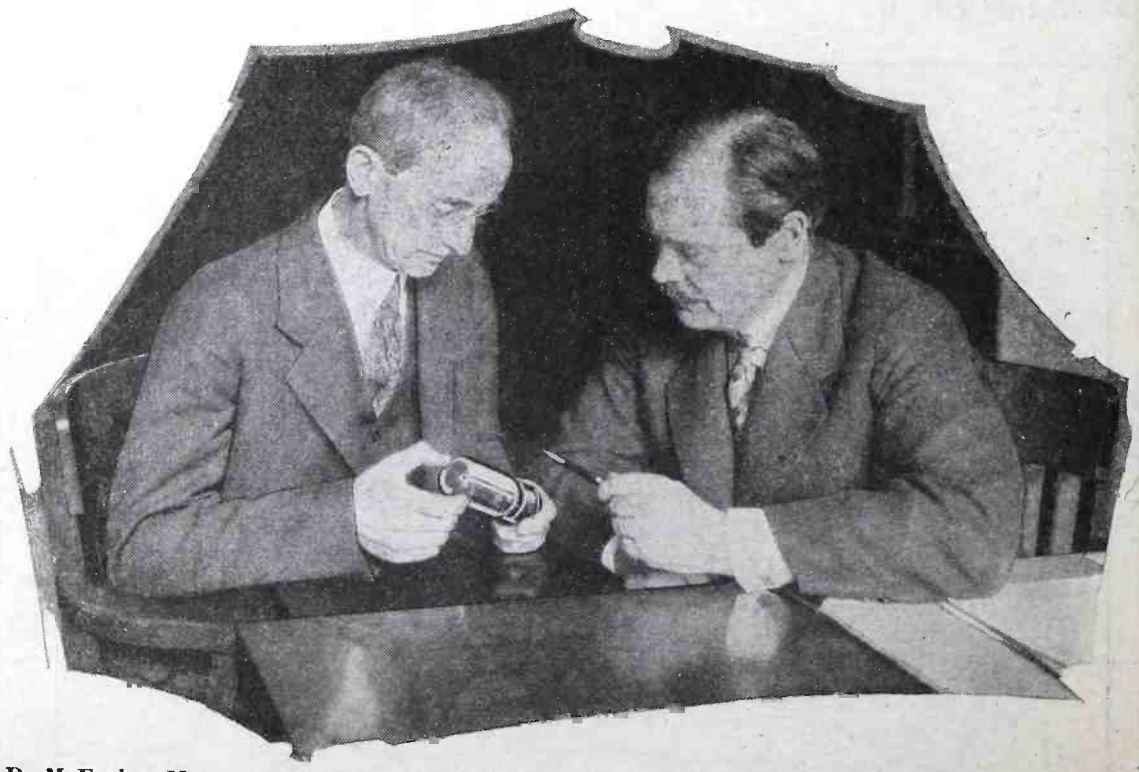
Recently the Bell Laboratories, and then the General Electric Company, have come forth with television systems that have been exhibited and pronounced successful. Baird, a British experimenter, has received much publicity for his method of transmission and reception, and it is quite popular on the other side of the ocean. Even in this country, a demonstration was given recently of the Baird instruments, and the favored few who witnessed it declared hat the results were quite satisfactory. And we could go on and on, telling of this and of that experiment, all backed by money—some of the large companies interested in the work have spent fortunes in research.

But the reader is undoubtedly more interested in what *he* can do with television. The purpose, therefore, of this article is to put before the amateur the simple facts of television transmission and reception, and to give to him some basis for his own work, so that he can, in his own laboratory, and with a minimum of apparatus, learn something of the mysteries of television, and even demonstrate it to his friends.

Before entering into a discussion of the actual construction of the instruments themselves, it will be well to review the theory of the perforated disk system of television. Reverting to a familiar subject, we should bear in mind the motion picture. Here we all know that a series of individaul photographs are projected on a screen at a speed of approximately 16 per second, and that the ability of the eye to retain vision for a fraction of a second makes the pictures blend together. Thus we get the effect of continuous motion.

In television, if we are apparently to see motion, we must produce a series of individual pictures or images, and transmit them to the eye with about the same rapidity that motion pictures are thrown on the screen. Just how this is done will be made plain by the illustrations in Figures 1 and 2. The process consists of picking up the light reflected from the image to be transmitted, taking the light from only a small area at a time, and allowing that light to affect a photo-electric cell.

Let us consider the photo-electric cell for a moment. It is a delicate



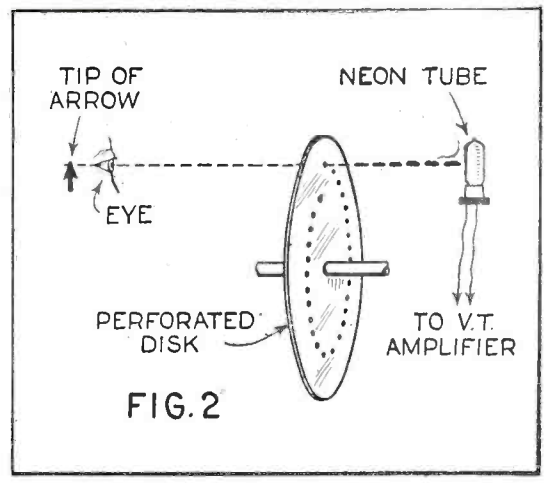
D. McFarlan Moore, holding one of the neon tubes that he designed especially for television reception, and E. F. W. Alexanderson, television inventor.

piece of apparatus, the electrical resistance of which is changed by the action of light. When a powerful light falls on one of these cells that is connected in a circuit, the resistance of the cell falls, and the current in the circuit rises.

Referring specifically to Figure 1, we find a much simplified diagrammatic sketch of a television transmitter. The object to be "televised" is placed in front of a revolving disk, which is pierced with a series of holes, arranged in a spiral, as will be more fully described later. The object, shown here as an arrow for the sake of simplicity, is illuminated by a powerful source of light. This light is, of course, reflected from all parts of the object, in amounts varying with the shade of the particular part of the object that is being considered. These reflected beams, concentrated by a short-focus lens, strike the revolving disk, and when they pass through the holes, they affect the photo-electric cell. The holes in the disk are so arranged that light from only a small portion of the object can reach the cell at one time, and so it will be plain that as the disk revolves, light from each part of the object will reach the cell in its turn, and change the resistance of the cell in a degree governed by the shade of the part.

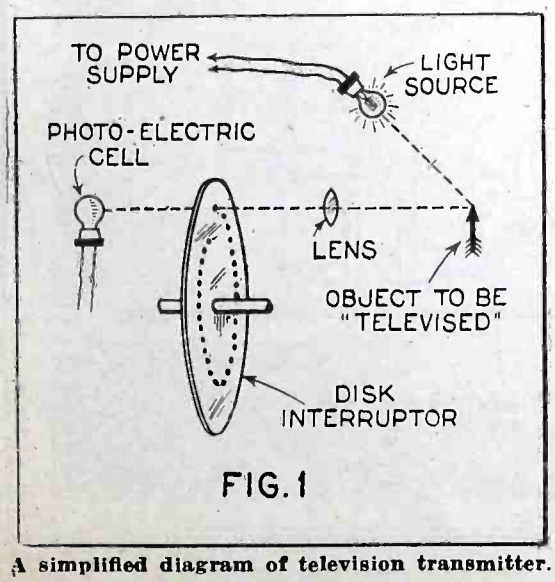
These rapid changes of resistance on the part of the photo-electric cell will set up a current that will fluctuate in accord with the shades of the object. This current is then amplified and used to operate a radio transmitter in much the same way that the voice current in a radio telephone transmitter is employed.

It will be obvious that this system is capable of being worked in the opposite manner. That is, the light source may be in back of the revolving, perforated disk, whereupon the object to be "televised" will be "painted" or "scanned" with a moving beam of light. This light will then be reflected from the object, and this reflected light will be picked up by one or more photo-electric cells. However, for experimental purposes, it is the writer's opinion that the system outlined first will be the best. For commercial work on a large scale, the latter method is probably to be preferred, because more than one photo-electric cell may be employed.



The principle of the television receiver.

Dr. Alexanderson is shown here tuning the television receiver: the image is seen through the small square opening on a level with the operator's eyes. Notice the broadcast receiver and loud speaker.

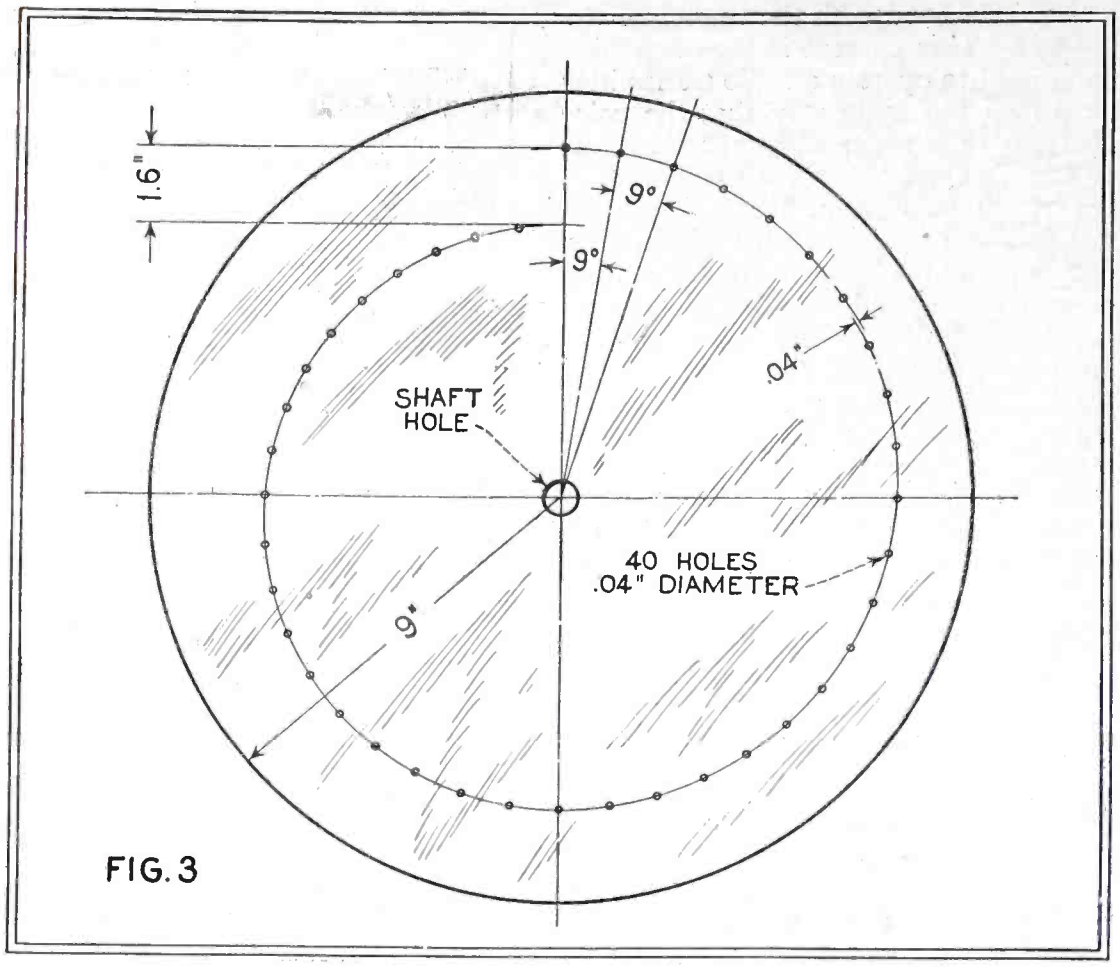


A simplified diagram of television transmitter.

Now, turning to the receiving end, shown diagrammatically in Figure 2, we find another revolving disk, identical with the one used in the transmitter. On one side of this disk is a neon tube of special construction. On the other side is the eye of the observer, or a screen. The current received from the transmitter is rectified and amplified in the usual manner, whereupon the picture current is fed to the neon tube. The latter must be capable of responding rapidly and accurately to a fluctuating current—that is, it must vary quickly in its emitted light when the current fed to it varies.

Let us now follow the sequence of operations through from beginning to end. At the transmitter the illuminated arrow reflects light to the disk. The latter is in such a position that the beam from only the tip of the arrow enters and strikes the photo-electric cell. The latter therefore causes a current to flow, the value of which will correspond with the shade of the tip of the arrow. This current will be transmitted and received and the neon tube will be illuminated to a brightness that was determined at the transmitter by the picture current. Therefore the eye of the observer will record a light intensity from the neon tube that will correspond with the relative shade of the arrow tip. The light will reach the eye through one of the holes in the perforated disk, and therefore the location of the tip will be fixed relatively. Due to the speed of the disk, the received images follow each other so rapidly that the observer sees the image of the entire object, seemingly all at the same time, although actually in series of small portions of the complete object.

The two disks, one at the tansmitter and the other at the receiver, must rotate in absolute synchronism, and here is one of the stumbling blocks that television has always had. For example, they must be rotated so that



Layout of holes in the revolving disc.

the hole that is at the top of the disk at the transmitter will be in the same portion of the spiral series as the hole in the receiver disk that is at the top at the same instant. Any variation of this will destroy the entire system, and if any picture is produced at all, it will be distorted beyond recognition.

Since synchronism of the two disks is a difficult mechanical and electrical problem, the experimenter will be better off if he starts his work with a combination transmitter and receiver working from the same driving motor, and disregards, for the time being, the actual radio transmission and reception. In this way, he will not have to struggle with synchronization and can concentrate his energies on the building of a good, distortionless amplifier, and the rest of the necessary apparatus. Such a combination unit is illustrated in Figure 4, and more will be said of it later.

The first parts of the apparatus that should receive consideration are the revolving disks, two of which will be required for the combination unit. A suitable disk is shown in detail in Figure 3. It may be made of any stiff sheet metal, or even of fibre. The metal is preferable, as the fibre will tend to warp. However, for a temporary installation, fibre will be satisfactory for a time.

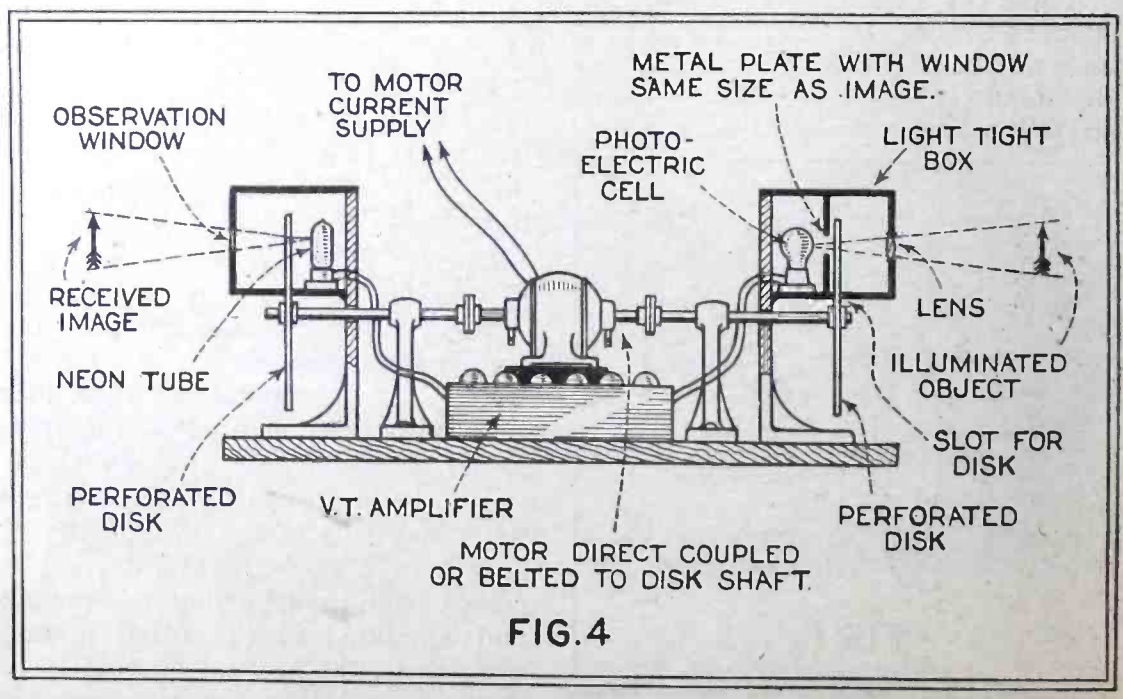
The disk as illustrated, is 18 inches in diameter, and is pierced with a series of 40 holes, each .04 inches in diameter. These dimensions are for a received image of about 1 by .6 inches. The first part of the job is to lay the disk out with 40 equal radii. These will be nine degrees apart. Draw them from the center to the circumference, and drill the first hole on one of them, about ½ inch from the edge. The second hole is drilled on the next radius line, but is .04 inches farther from the edge of the disk than the first. The third hole comes next, and is .04 inches farther in than the second, and so on, until the 40 holes are drilled.

The drilling must be done carefully, with a medium or low-speed drill, and the holes must be true. The drill must not "wobble" during the drilling, and it must be held at right angles to the face of the disk. If the holes are not clean cut, they should be carefully reamed out, and the ends smoothed off with a fine file or abrasive stone. These cleaning operations should be repeated until each hole is perfectly clean, and free from fuzzy edges.

The next step is to procure a motor suitable for rotating the two disks. This should be about ¼ horsepower, and so wound that on the current available, it will turn over at about 1,000 R.P.M. One method of driving the disks from this motor is shown in Figure 4, wherein extension shafts from each end of the motor shaft have the disks fastened to them. However, with most commercial types of motors, this is not possible, so alternative methods are to drive, by a belt or gears from the motor, a solid shaft that connects the disks.

The disks, regardless of the method of driving that is used, must be fastened solidly to the shaft. This can best be done by procuring or making two flanges, and bolting or riveting them fast to the disks. These can then be fastened solidly to the shaft by pins or bolts. Before fastening the disks to the shafts, be very sure that they are in register—that is, that the outer hole in one disk is in the same position in relation to the shaft as the outer hole in the other disk. Thus, the disks will rotate in synchronism and the hole corresponding to the one opposite the object at the transmitting end will be opposite the neon tube in the receiving end at the same instant.

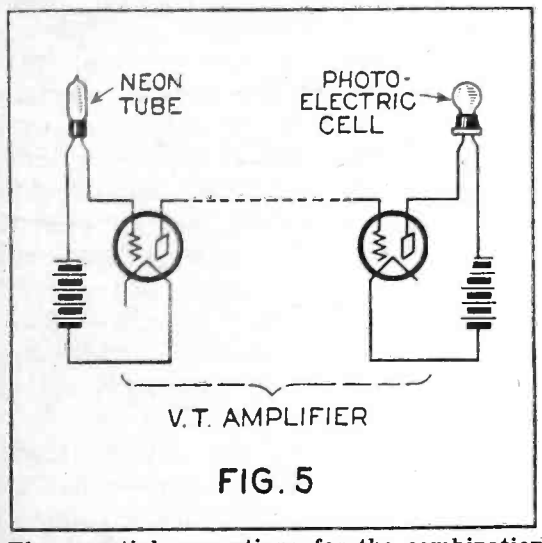
The rest of the details will be obvious from Figure 4. The photo-electric cell and the neon tube are mounted behind their respective disks as shown, and a rectangular hole 1 by 1.6 inches is cut in the face of the receiving enclosures. This window must be placed so that the upper edge is exactly in line with the outer hole in the disk, when this hole is in its



The experimental television apparatus can be arranged as shown above.

upper-most position. Then, of course, the same will be true of the lower edges and the inner-most holes. In the transmitter enclosure a short-focus line is placed in the front, and a metal shield is situated between the disk and the photo-electric cell. In this is cut a 1 by 1.6 inch hole, and it is lined up with the holes in the disk as described for the receiver window.

The amplifier in a television outfit is a very important factor. If it distorts the picture currents, the resulting received image will be distorted.



The essential connections for the combination television unit described in this article.

Even an amplifier that seems to give perfect reproduction when amplifying voice currents, will not always be good enough for television work. Therefore, build your amplifier with a generous leeway. Five or six stages of resistance or impedance-coupled amplification will be necessary. Using

THE HAGERMAN 210-A-C-SIX

THE desire for something better in radio reception, which is one of the chief incentives for extensive research, has been richly gratified during the last year.

Three far-reaching improvements have been applied to radio reception that will have a very lasting and beneficial effect. These are: the long tone chamber speaker; the super-power amplifier, utilizing the new power tubes of the 210 type; and distinct improvements in mechanical design of all parts used in radio construction. This latter is rather general, but is nevertheless very important and includes features that have been badly needed since the inception of radio.

To detail just what effect these will have on the radio industry as a whole, would be rather complicated. Two things have been definitely accomplished. The radio set has evolved from a mechanical reproducer of sound into a true musical instrument, and the custom-built receiver is now the finest example of radio receiver from every standpoint; mechanically, theoretically, and from a standpoint of dollars and cents value for money invested.

The Hagerman 210-A. C.-Six was created for the express purpose of providing for the custom builder and home builder, a radio receiver that incorporates every desirable new feature and can be built at a cost much less than a manufactured set capable of producing even comparable results.

It was found that to obtain satisfactory results from any radio circuit it was essential that the power supply and speaker be of a type fully adapted to the characteristics of the set. A great percentage of the difficulty experienced by custom and home builders can be directly traced to ineffeciencies in the power or speaker circuits. This does not necessarily mean that they were defective, but that they were not designed to operate the set to which they were attached.

Therefore, a special power supply and speaker circuit were designed for the 210-A. C.-Six. The complete receiver should preferably be employed in conjunction with these for best results. This eliminates the gamble in selecting power supplies and further insures the builder against failure.

LIST OF PARTS

- 4 Benjamin 2¼-in. R. F. transformers, L1, L2, L3, L4.
- 6 Benjamin base mounting sockets, V1, V2, V3, V4, V5, V6.
- 4 Karas .00037 mfd. SLF condensers, type 17, C1, C2, C3, C4.
- 2 Karas audio transformers, type 28, T1, T2.
- 1 Set Karas brackets.
- 1 Jewell 0-8 D. C. voltmeter type 135, M1.
- 1 Jewell 0-100 D. C. voltmeter type 135 M2.
- 3 Carter .5 mfd. by-pass condensers, C10, C11, C12.
- 1 Muter .002 mfd. fixed condenser, C14.
- 1 Muter .00025 mfd. condenser and clips, C13.
- 1 Muter .0005 mfd. fixed condenser, C15.
- 1 Muter 6 ohm rheostat, R4.
- 2 Muter ¼ amp. tubestats, R2,. R3.
- 4 Aluminum Co. of America box shields 5x9x6 inches.
- 1 Celoron 7x24x3/16 inch front panel.
- 1 Celoron 10x23x3/16 inch sub-panel.
- 4 Hammarlund 85 m.h. R. F. chokes, L5, L6, L7, L8.
- 2 Hammarlund midget condensers, C8, C9.
- 3 X-L variodensers, Model N, C5, C6, C7.
- 1 Midget Clarostat, R5.
- 1 Muter 3 megohm grid leak, R1.
- 2 National illuminated vernier dials.
- 1 Belden 7-wire cable.
- 1 Belden indoor or outdoor antenna kit.
- 1 Roll Belden colorubber wire.
- 1 Molded wood tone chamber with Fidelity Speaker Unit.
- 2 Brass ¼ inch shafts 10 inches long.
- 1 X-L binding post.
- 1 Pkg. Kester rosin core solder.

The chassis of the set is a six-tube radio frequency circuit, consisting of three stages of radio frequency amplification, detector, one stage of simple audio amplification and a stage of super-power amplification using the type 210 tube.

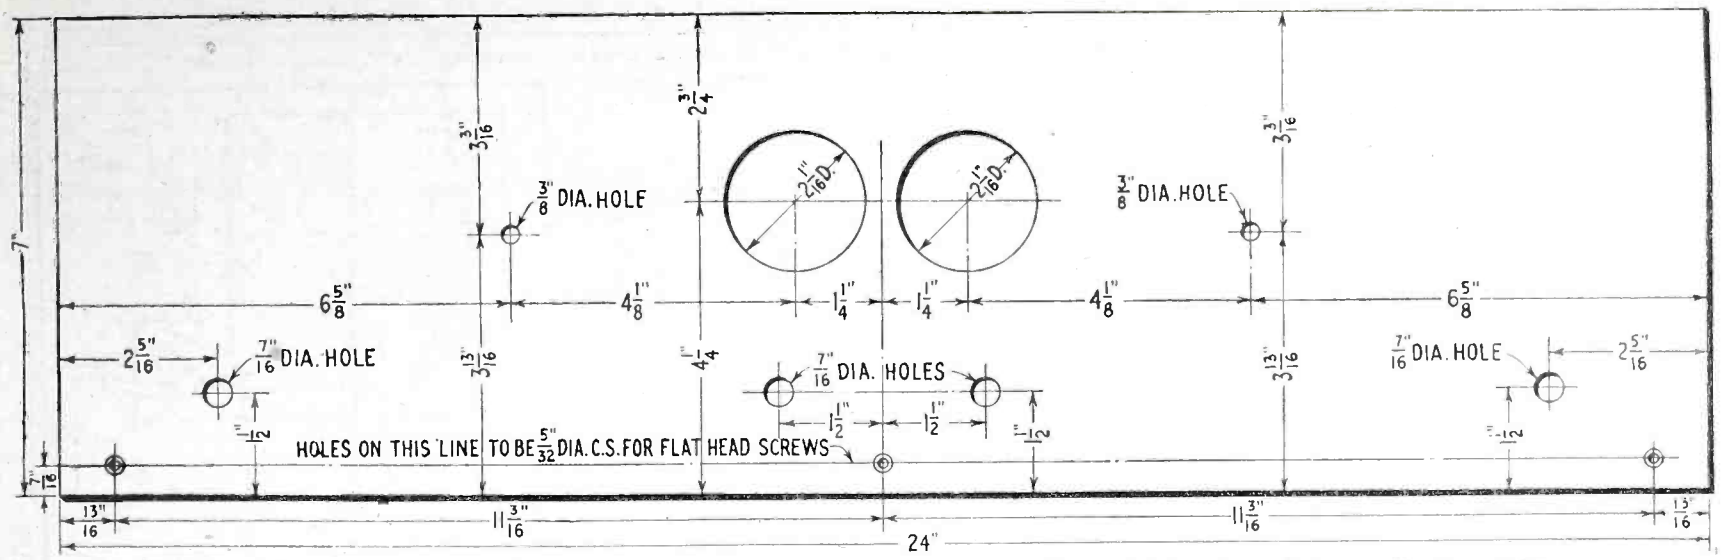
The circuit is not new in principle, but decidedly new in mechanical design and in the control of oscillation. This latter is the greatest problem of the radio set designer. Developing a circuit that is selective and sensitive and still not over critical is simple enough, but to find one that can be built by anyone with limited facilities, and still retain these all essential features is really an accomplishment.

The circuit of the 210-A. C.-Six is shown in the accompanying diagrams. Each individual stage is completely shielded and individually balanced with variable controls. This allows the builder to peak each stage so that it exactly matches the others. The result is a tremendous increase in overall amplification and selectivity. No attempt is made at lining up the dual variable condensers. Trimmers are provided allowing instant hair-line adjustment that is absolutely necessary in the reception of far distant or weak signals. These are critical but positive and need only be made once. They do not enter into the everyday operation of the set.

Attention is called to the audio circuit employed in this set. The 210-power tube is built into the set itself. The "B" power supply is strictly a source of plate voltage. The alternating current filament voltage and direct current grid bias and plate potential are brought to the set through the common power cable. This isolates every circuit in the set from the power supply, reducing the possibility of audio frequency regeneration to a minimum.

There may be some question as to the desirability of the new 250-type tube over the 210. It is not advisable to substitute. The 210 is fully capable of handling the entire output and will give results equally as good as the 250.

Using the 210 tube built into the set necessitated the designing of a power supply of special design. The voltages required are approximately 450 volts on the plate of the 210 tube, 40 volts on the grid, and 7½



Front panel layout for the receiver giving all dimensions for holes to be drilled. The two large holes are for the meters.

volts A. C. on the filament. The power unit for the 210-A. C.-Six supplies these voltages, as well as the intermediate voltages for the set itself.

In it is also incorporated a special condenser-choke output arrangement using a choke capable of handling over 85 milliamperes, and a condenser rated at 600 volts working voltage. This latter is very important. Should this condenser break down, the speaker unit will be burnt out and possible injury result to the set and power supply. There is no danger if the specified condenser is used.

The rectifier tube employed is the 281 type, a very sturdy and reliable tube. Filament voltage is supplied by the Thordarson power pack.

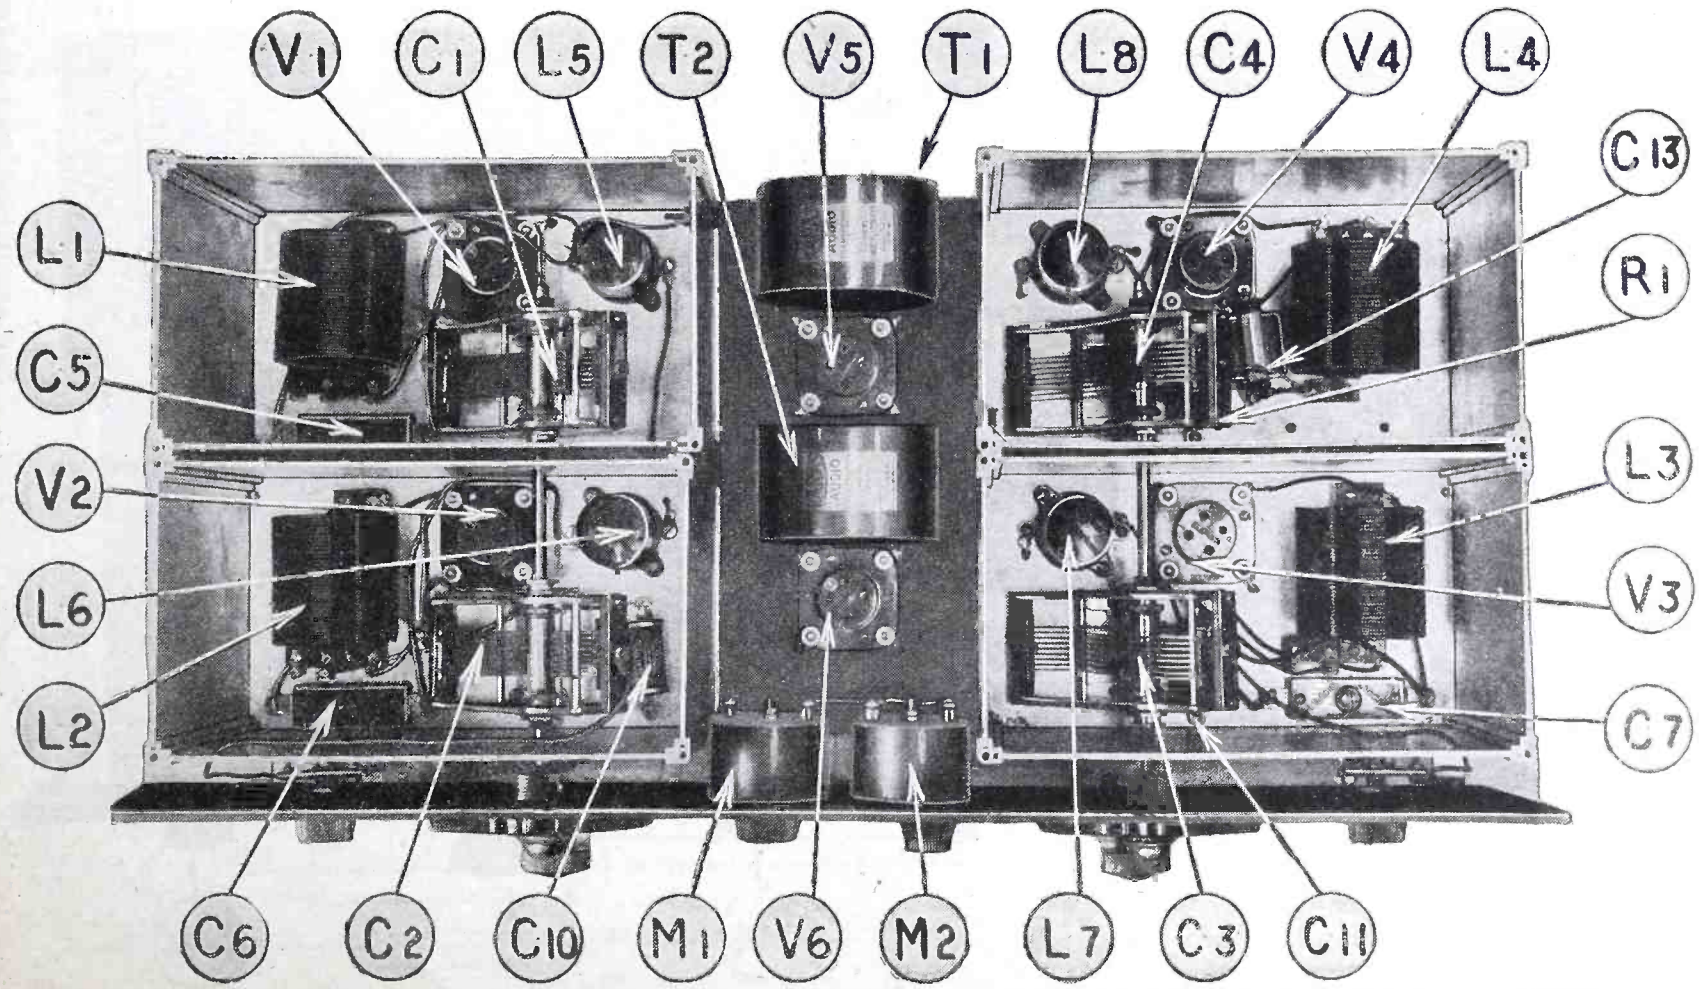
Considerable attention was given the question of the type tubes to be employed. There are three ways of obtaining complete A. C. operation: by the use of A. C. tubes; standard tubes with the filaments in series operated from a rectifier tube with high output; or standard tubes hooked up in the customary manner with filaments in parallel, deriving filament voltages from an A. C. converter.

The latter method was selected as being the most satisfactory from a custom-builder's standpoint. The results obtained with standard tubes are equally as good, if not better than with A. C. types. The original cost is much less, and all possibility of an A. C. hum, which is very objectionable with super-power amplification, is eliminated.

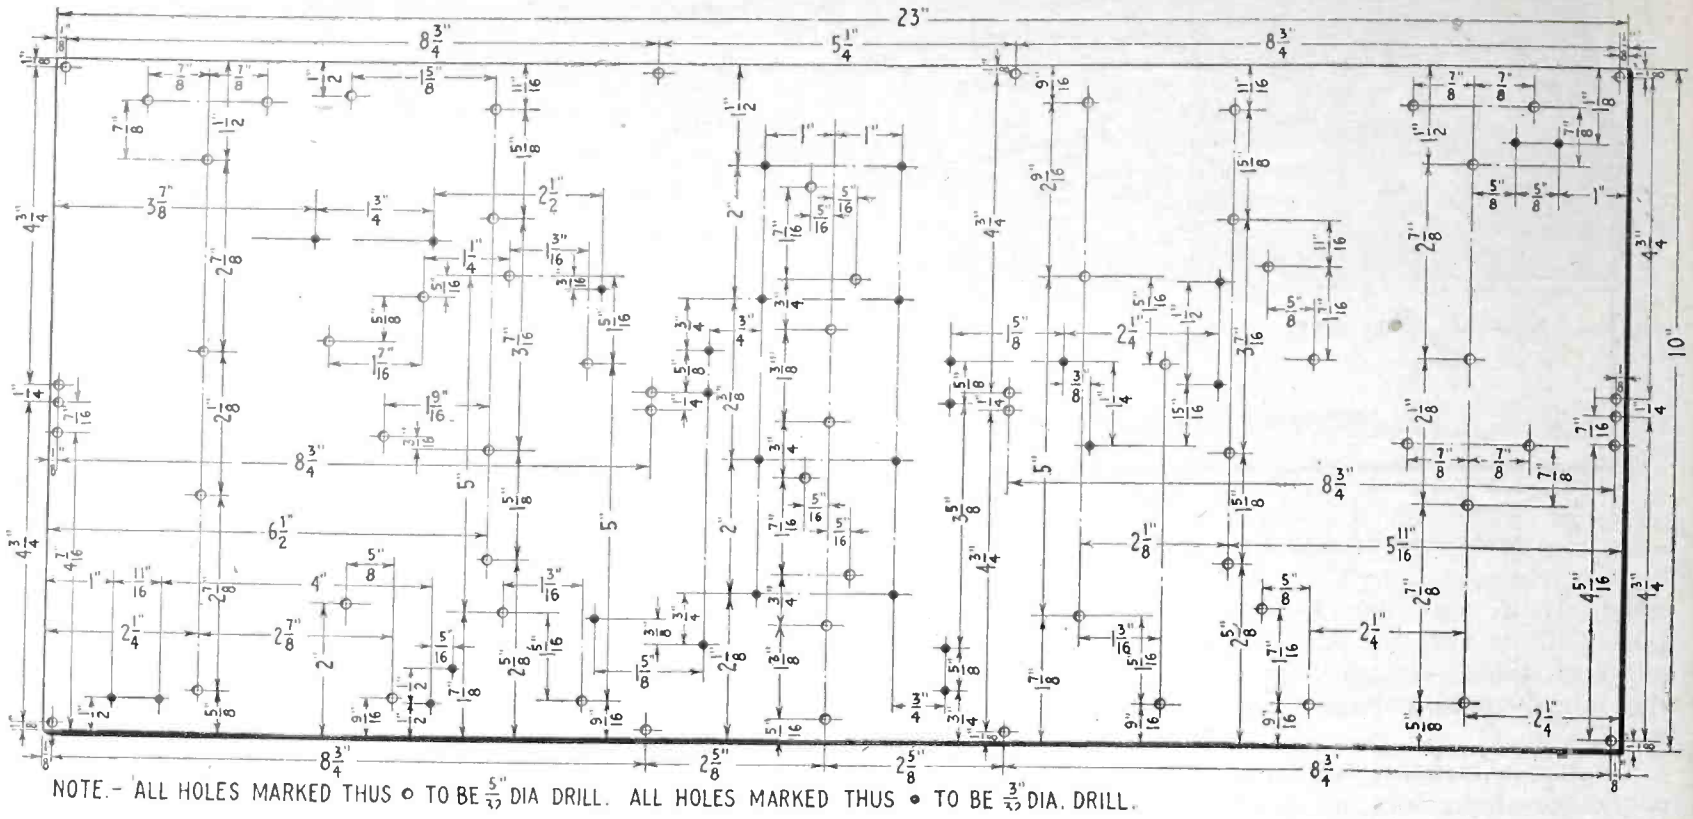
The A. C. converter specified was selected because of its extremely high capacity filter as "A" supply. This unit lights the filaments of the tubes directly from the A. C. line by changing alternating current into pulsating current and smoothing this into pure, hum-free direct current by means of a filter having two condensers with a capacity of over 200,000 microfarads.

The speaker employed is of the new long tone chamber type and is equipped with a special speaker unit which was specially designed to work with it. Many variations and inflections of tone that are inaudible to the human ear are brought out with this combination horn and unit.

The speaker chamber shown in a photo accompanying this article is preferably constructed in a box, ready for mounting in a console or speaker table. This depends on the desire and pocketbook of the constructor and is left to his selection.



A top view of the Hagerman 210-A.C.-Six Receiver showing the arrangement of parts within the four shielded compartments.



Sub-panel drilling layout of the Hagerman receiver described herewith.

The general assembly, wiring, etc., is comparatively simple. There is surprisingly little wiring, and as the circuits in the radio frequency end of the set are almost identical to one another, the set is very easily hooked up.

The chassis assembly is self explanatory from the layout herewith. There are several precautions to be taken. The holes for mounting the Variodensers should be larger in the aluminum shields than in the sub-panel. This is to prevent the mounting screws from shorting the condensers.

Wherever possible, the shields are used as wiring connections to the negative filament circuit. The variable condensers are mounted directly on the aluminum, which automatically connects them to the negative filament. The by-pass condensers are connected in the same way. One end of these is mounted on a short stilt, raising the other end so that it can be wired to the plate circuit.

It should be noted that the power leads are conducted to the set by means of a seven-wire cable that

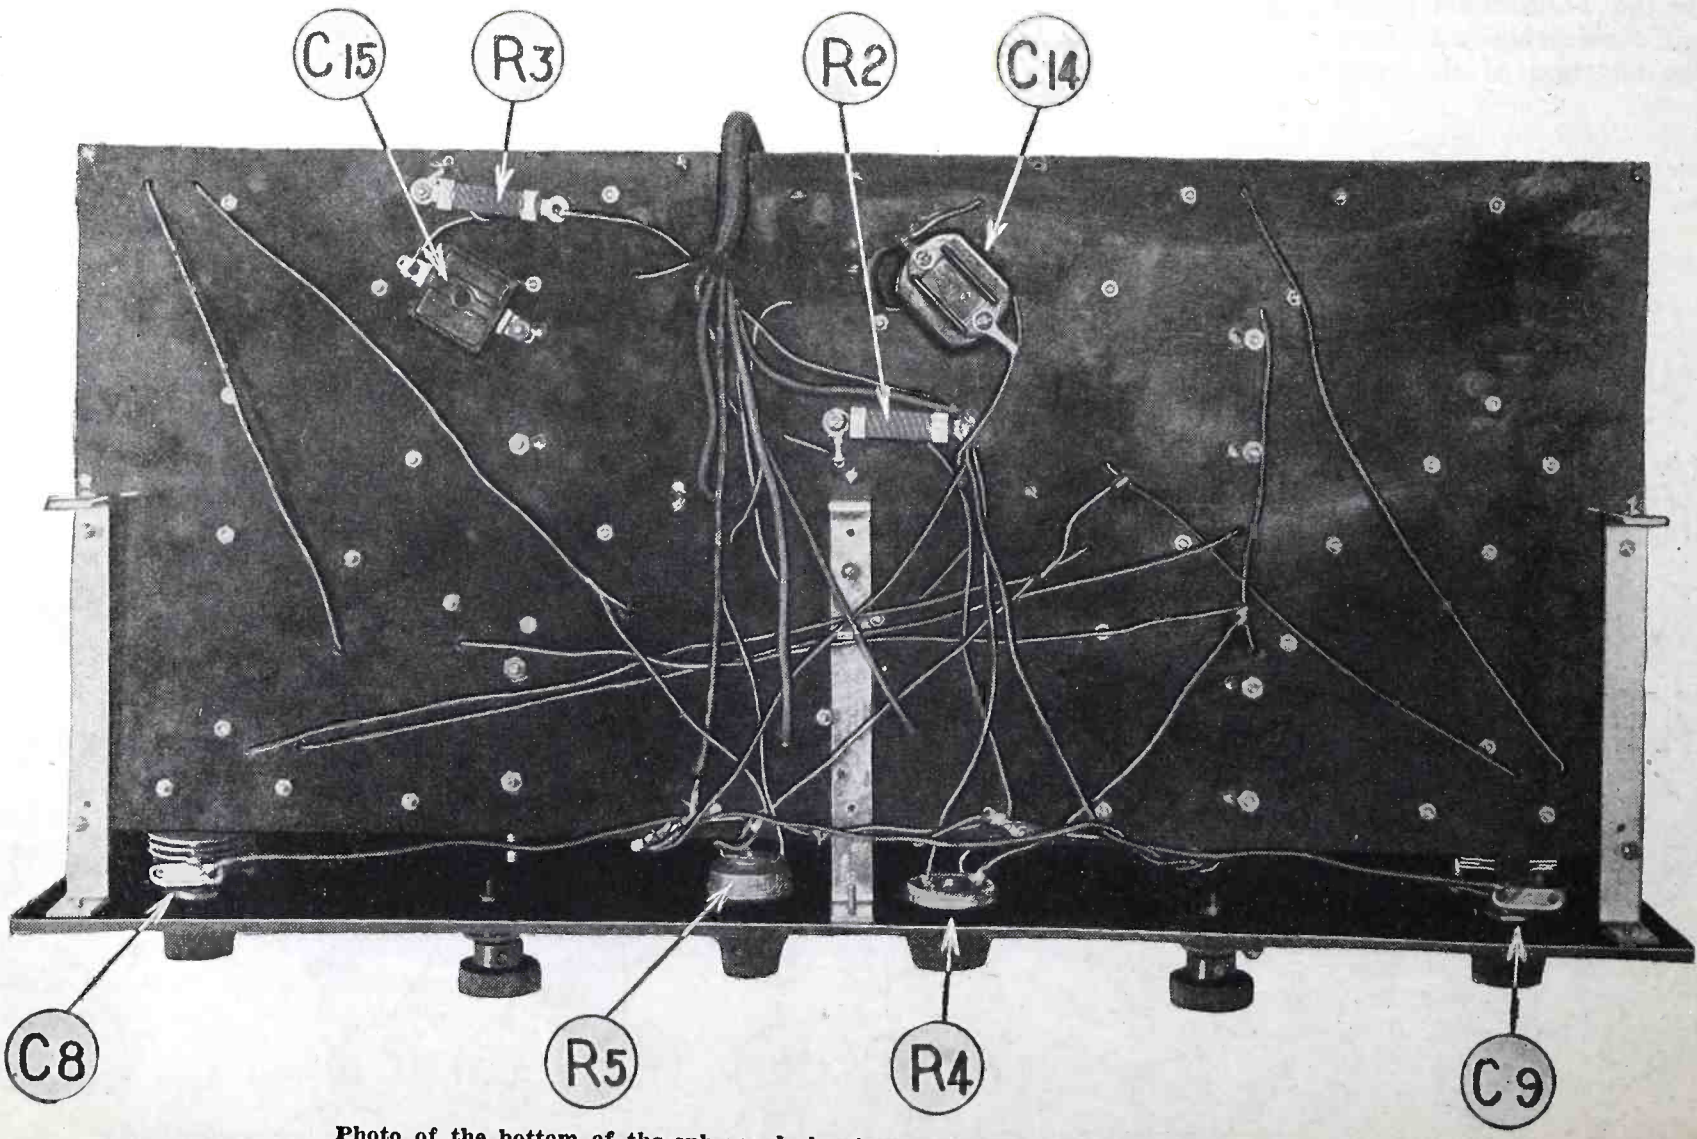


Photo of the bottom of the sub-panel showing condensers, fixed resistors and wiring.

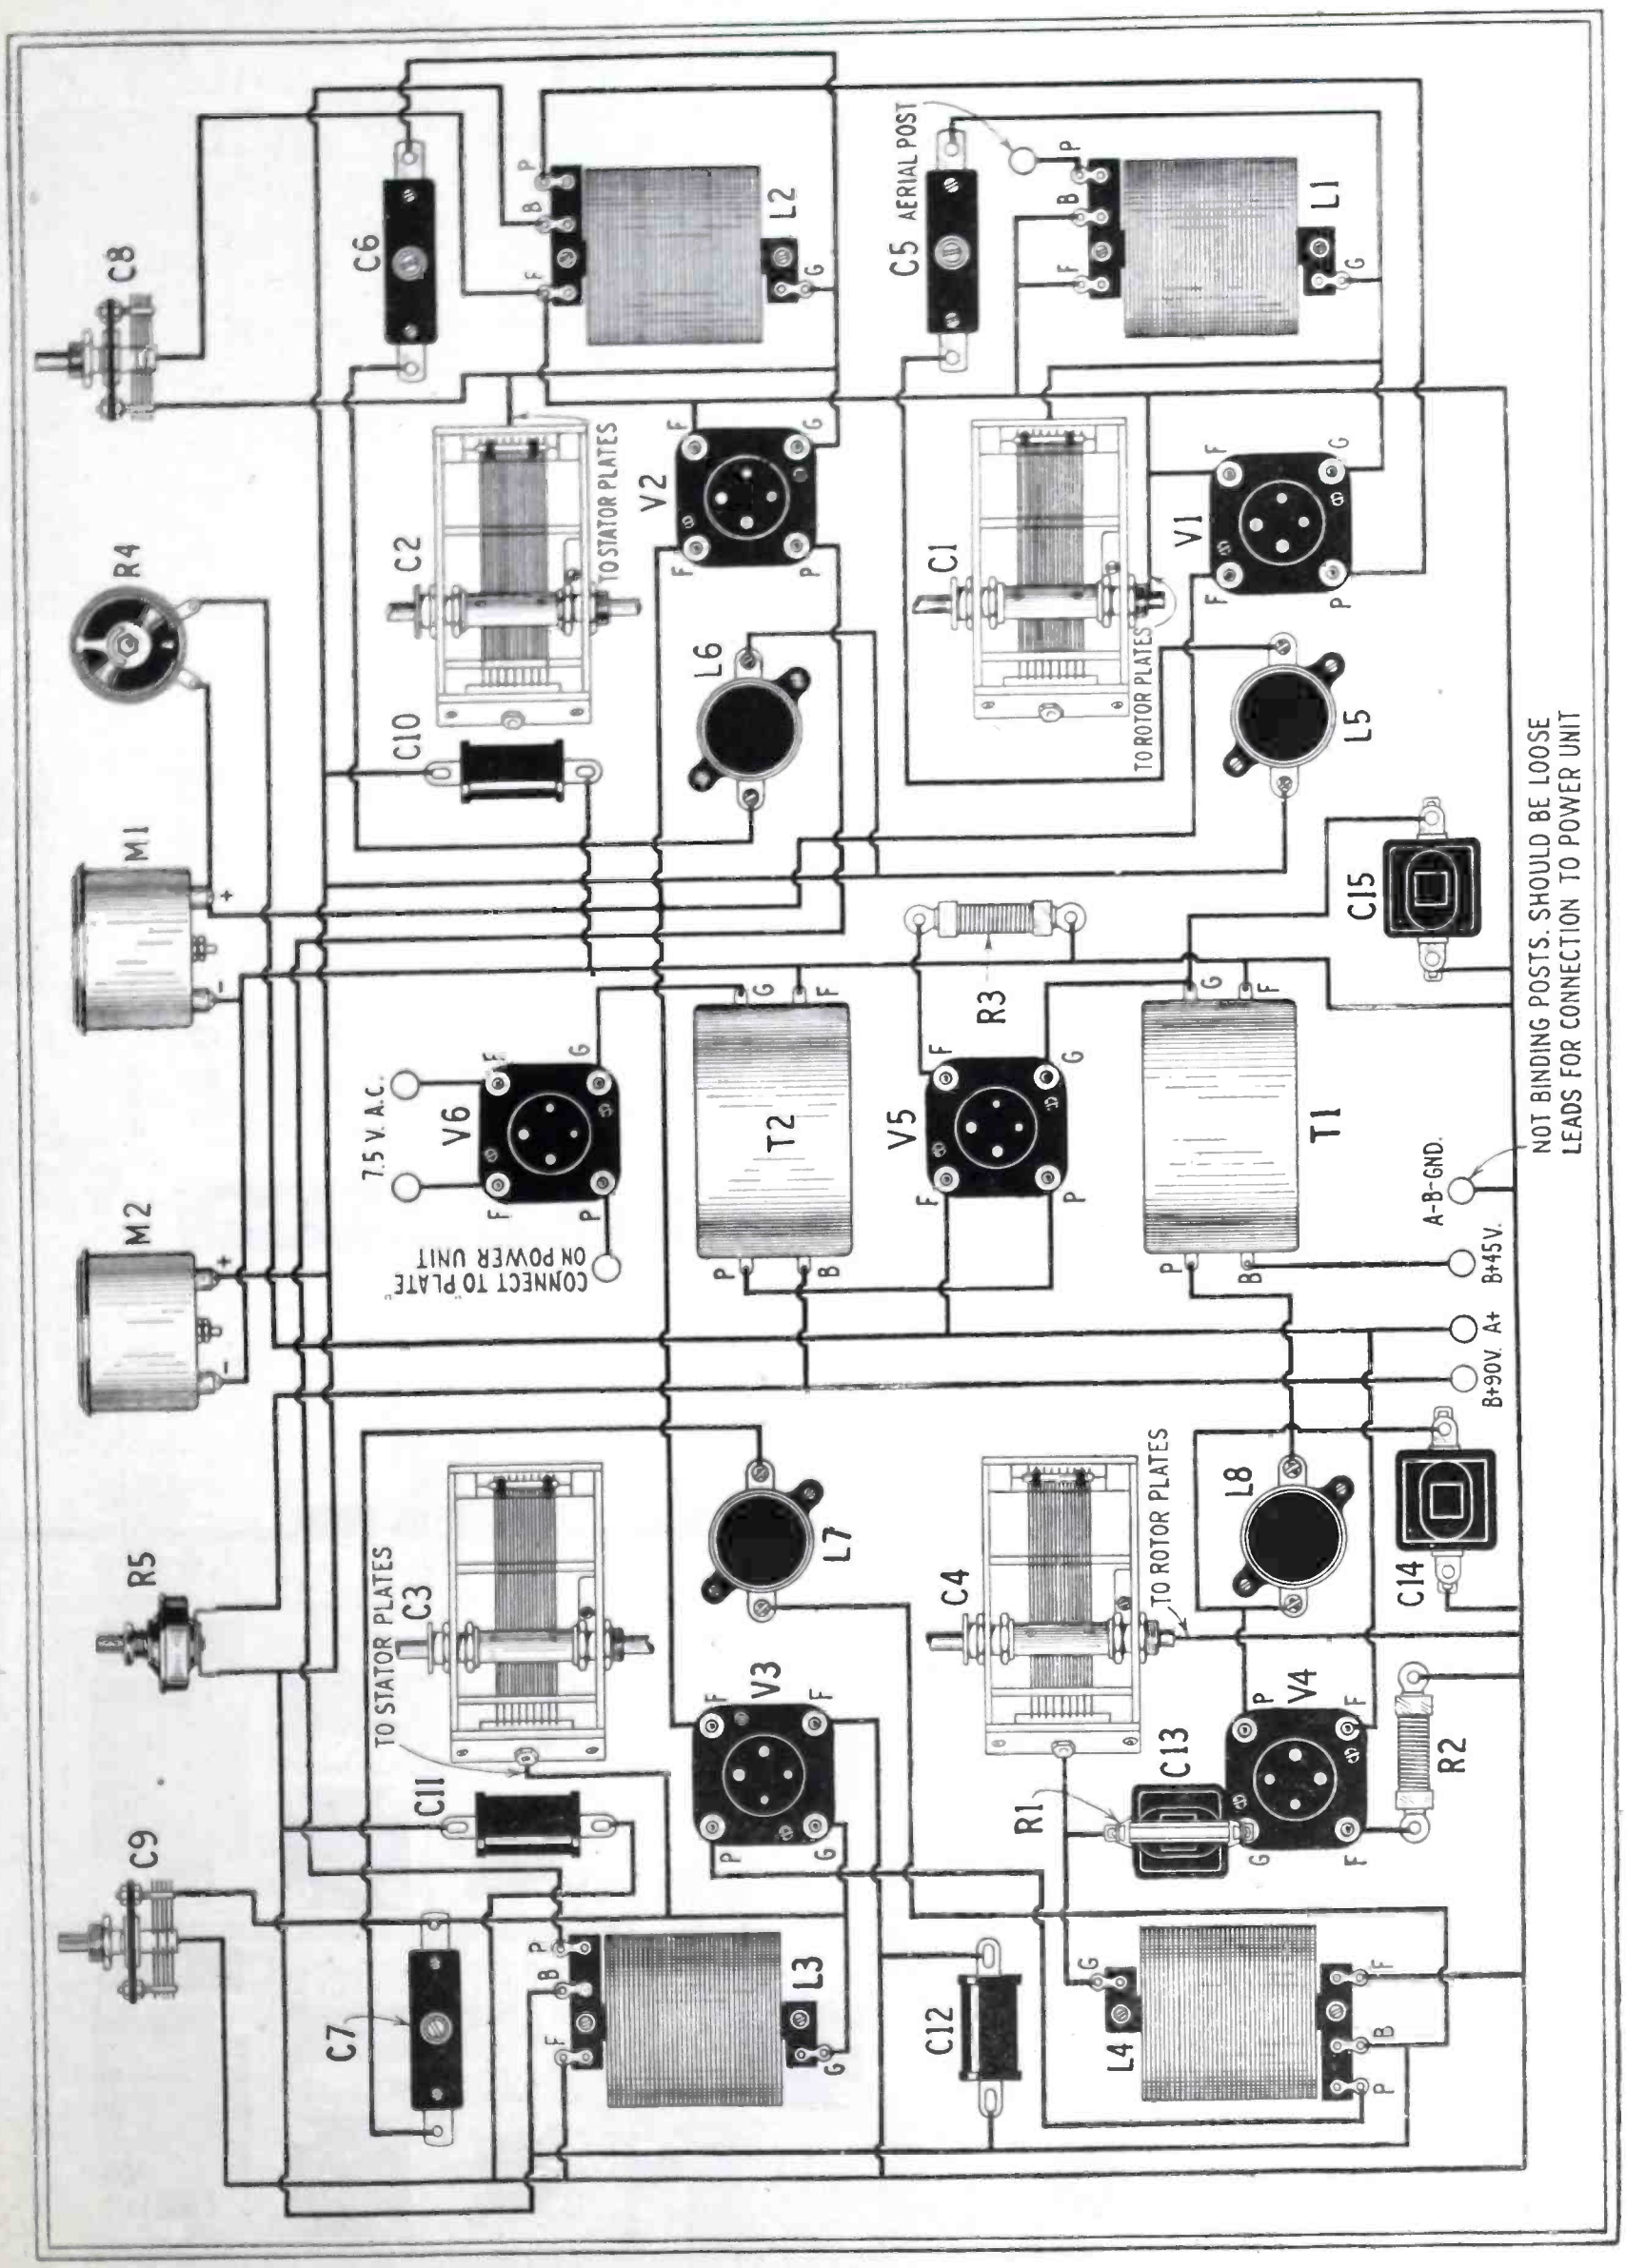
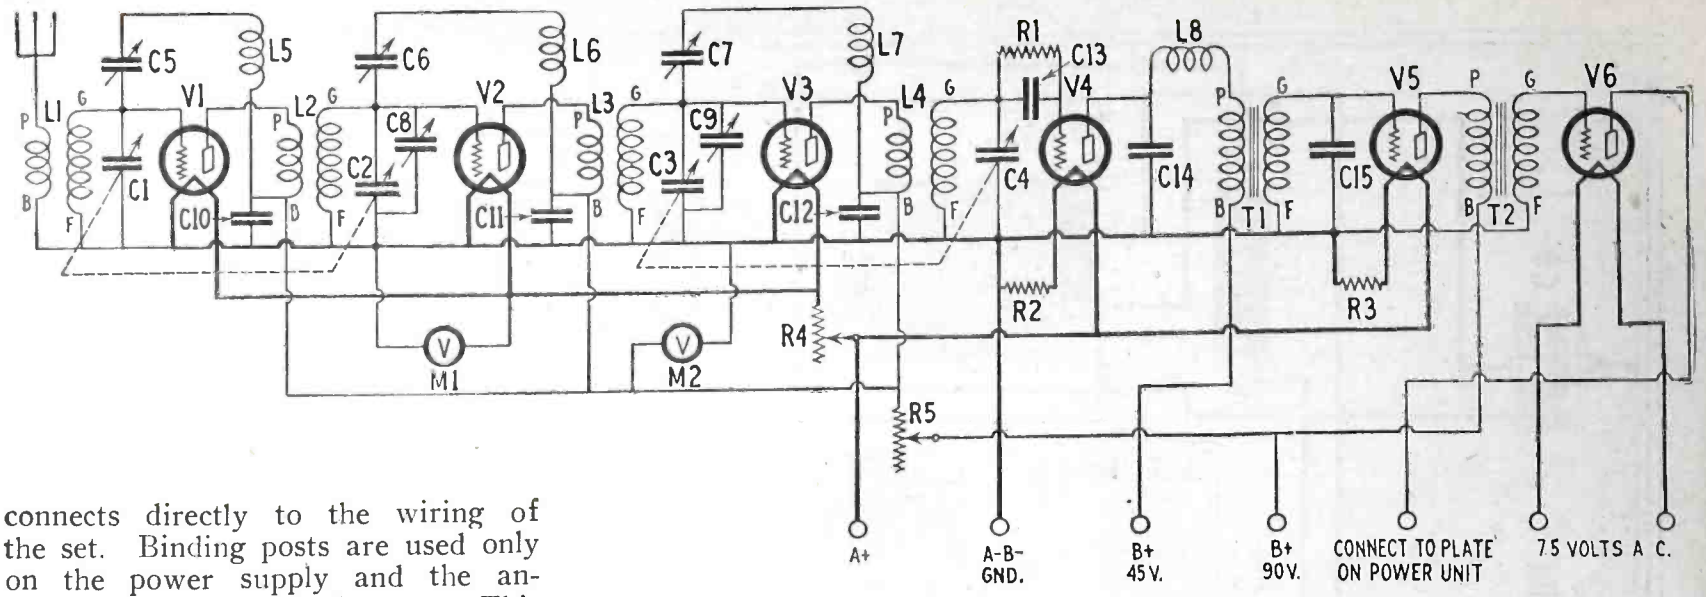




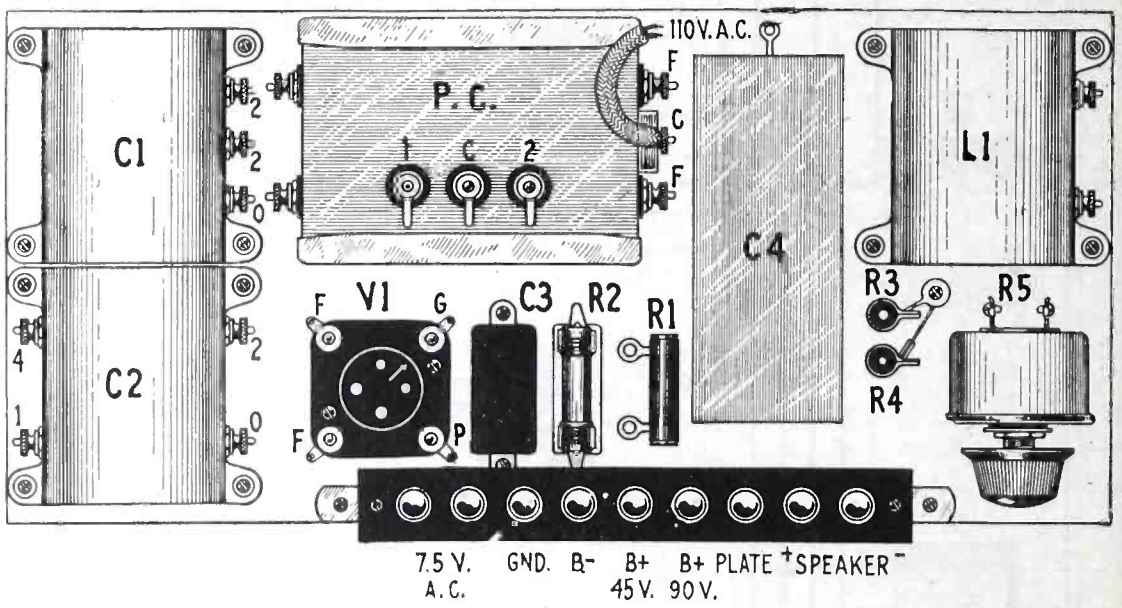
Schematic wiring diagram of the six tube A.C. operated receiver described herewith. Variable condensers C1 and C2 are operated on one shaft and condensers C3 and C4 on another shaft.

connects directly to the wiring of the set. Binding posts are used only on the power supply and the antenna connection to the set. This cable connection simplifies wiring the set to the power unit and prevents to a great extent the possibility of making an error in hooking up.

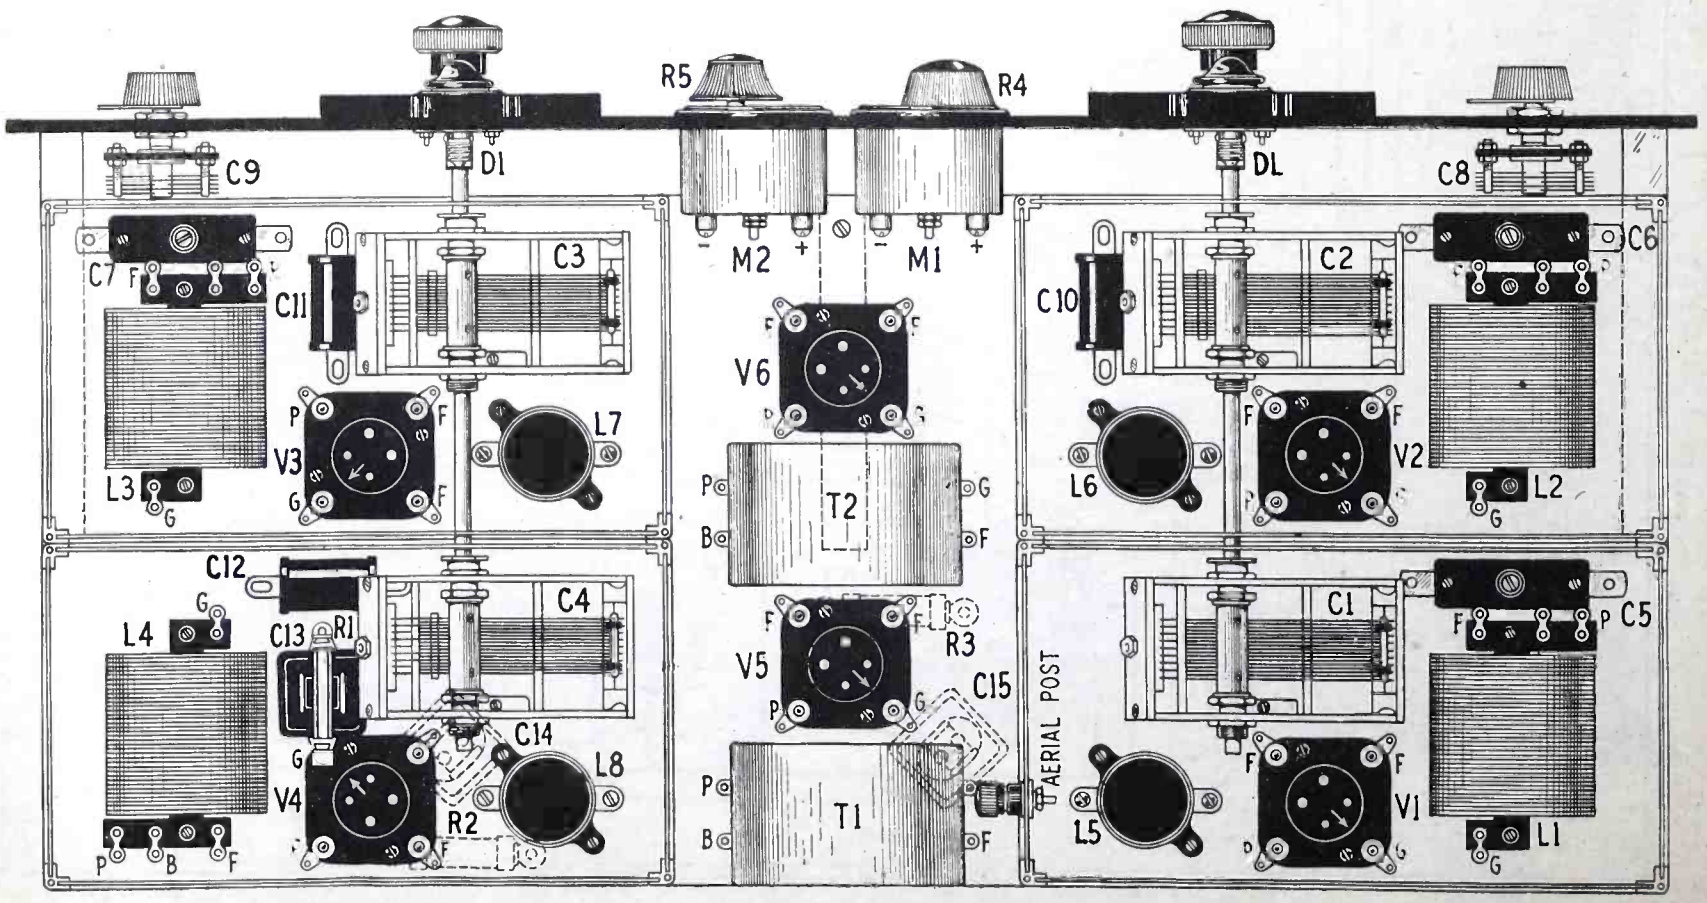
The wiring of the power supply is not like any other power unit. If there are connections that do not seem exactly in accordance with your previous experience, make them as shown. The diagrams explain the circuit.

The Hagerman 210-A. C.-Six operates on either an indoor or outdoor antenna. This should be given every consideration. For an indoor antenna, a length of wire fifty to seventy-five feet in length around the molding or rug is sufficient. The outdoor antenna, which is much to be desired, should be from thirty-five to fifty feet in length in congested localities, and longer where there are few nearby stations.

Putting the set into operation merely consists of connecting the



Layout of parts for the power unit employed in conjunction with the Hagerman 210-A.C. Six Receiver. Parts are indicated in symbols to correspond with diagrams.



Instrument layout of the receiver indicating the exact location of all components. Parts mounted beneath the sub-panel are shown in dotted lines.

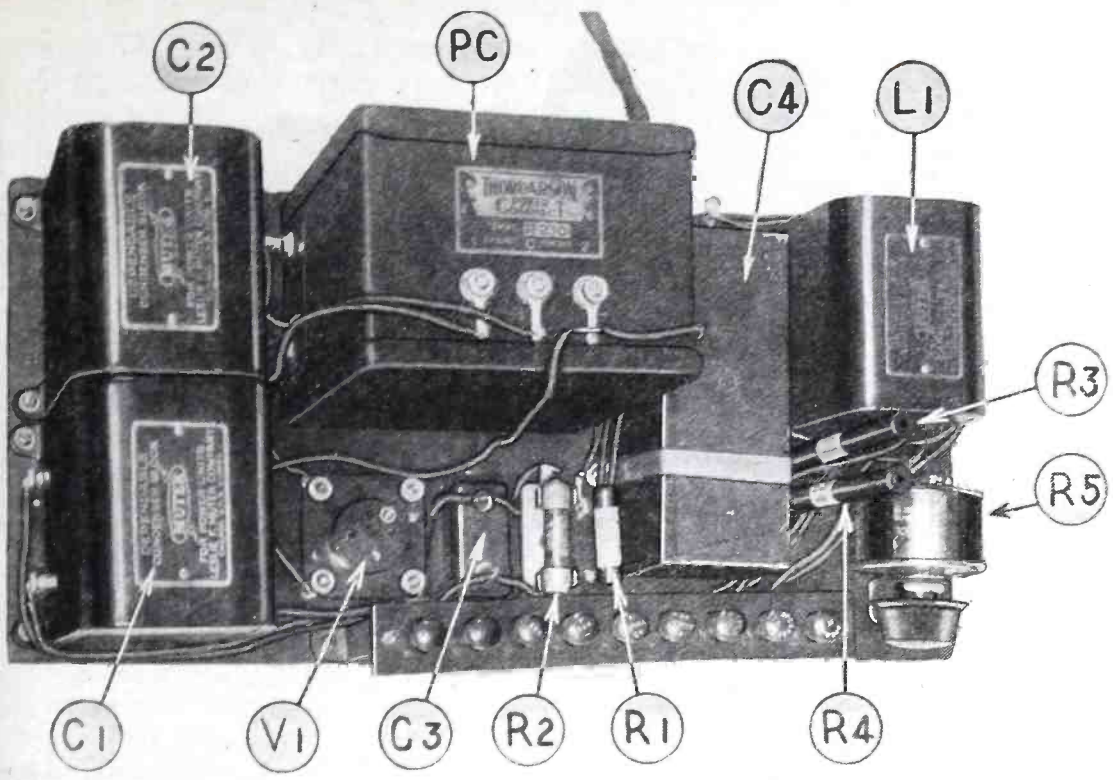


Photo of the power unit. All parts are indicated to correspond with wiring diagrams.

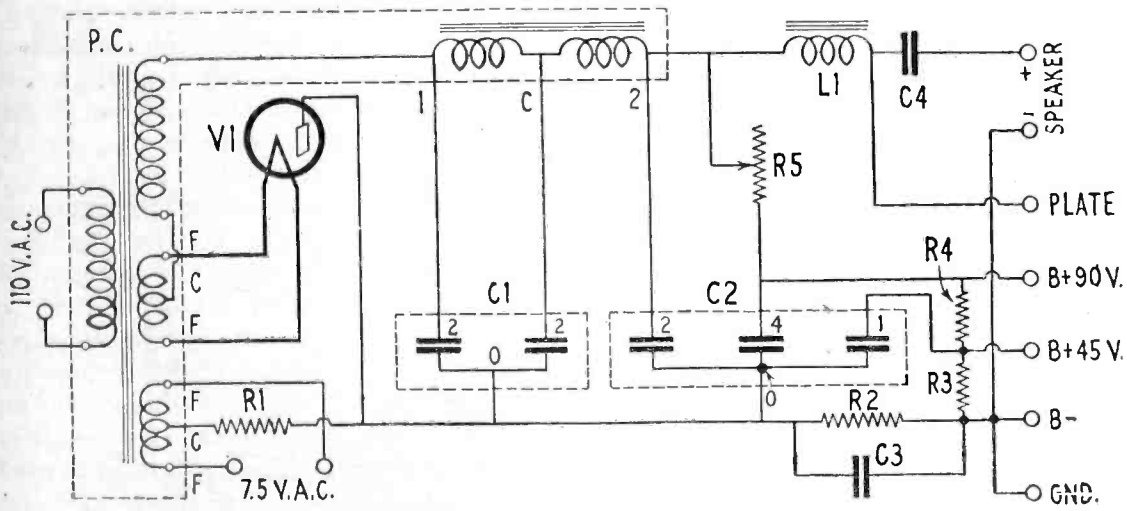
cable to the power supply, attaching the loud speaker, inserting the tubes and plugging into the light socket. Be sure that the power Clarostat in the power supply is screwed all the way out.

When the set is turned on, the meters on the panels should show a deflection. Adjust the rheostat so that the 0-8 voltmeter reads about 4 volts and screw the knob of the power supply Clarostat in until the reading with the volume control all the way in is about 100 volts. Then decrease it with the volume control to about 50 volts.

Turning the dials should now bring in a station. Adjust the trimmer and the volume controls for best results. Do not use the rheostat or filament control constantly. The ideal setting for this will vary for different tubes, but once determined, should be fairly constant.

If the set has good volume, tunes fairly sharp and shows the customary response to superficial tuning, with a long screw driver or, better yet, a pointed stick, screw the Variodensers all the way down.

Now, using the trimmers carefully, tune in a distant station. Adjust the Variodensers in the first stage so as to bring in the station with the greatest volume, and so on through the entire group. Do this with several stations and the best adjustments will be found.



Schematic wiring diagram of the power unit.

The 0-100 voltmeter can be used as a very valuable adjunct to tuning. The setting of the volume control can be recorded as well as the dial setting, by jotting down the voltage reading at which the set was most sensitive to receive a certain station on a certain frequency. This is very valuable in logging new stations that you had before, because you know not only the dial readings on which they should be received, but also the proper voltage setting of the volume control.

It might be noted that this voltmeter is a standard type; not a high-resistance meter, even though it is used to measure the output of a "B" supply. Being constantly in the circuit, the small amount of energy it consumes is of no consequence to the "B" supply, which has an output quite in excess of that required, and the small drain means a drop of but about 2 per cent of the total output.

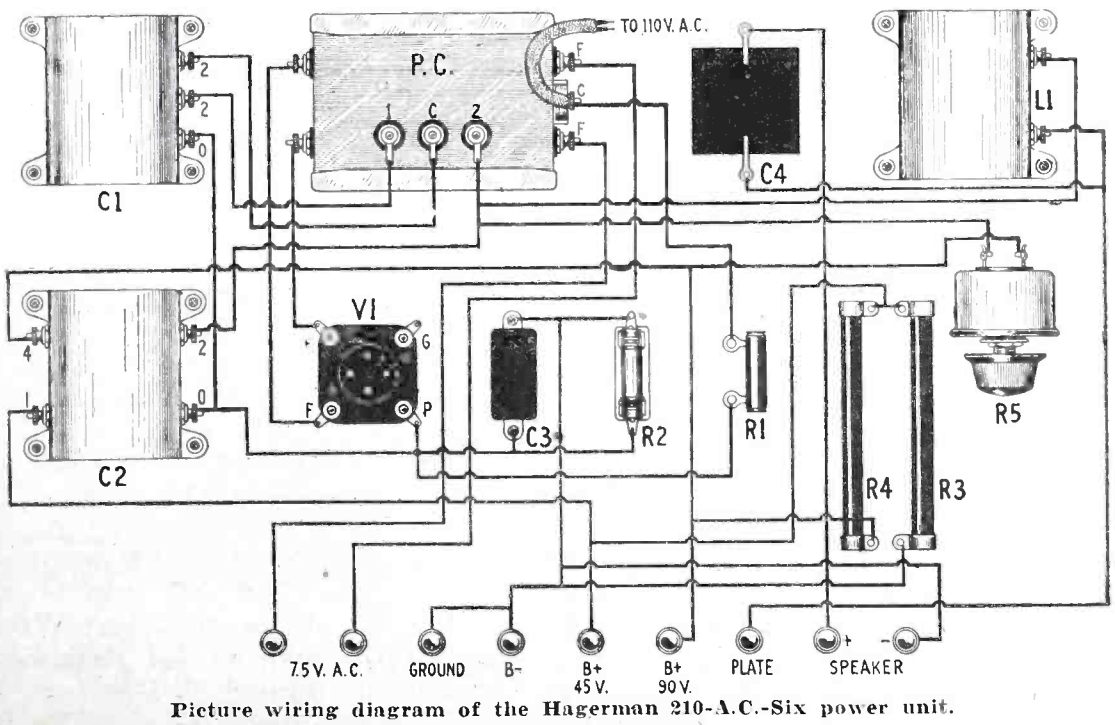
PARTS FOR POWER SUPPLY

- 2 Muter power condenser blocks No. 598, C1, C2.
- 2 Muter 10,000 ohm resistors No. 2910, R3, R4.
- 1 Muter 1000 ohm resistor No. 2901, R1.
- 1 Muter audio power choke No. 3130, L1.
- 1 Muter 2 mfd. power condenser 600 volt, C4.
- 1 Benjamin base mounting socket, V1.
- 1 Thordarson power compact, type R210, PC.
- 1 Heavy duty high range Clarostat, R5.
- 9 X-L binding posts.
- 1 Amsco 100 ohm resistor and mounting, R2.
- 1 Muter ½ mfd. condenser No. 507, C3.
- 1 Abox 6 volt A unit.
- 1 Celoron strip 1x9x¾ inches.



Picture wiring diagram of the Hagerman 210-A.C.-Six power unit.

The Four-Tube Roberts A-C Receiver

THE Four-Tube Roberts A. C. Receiver was designed for that large class of people who do not care to spend more than a hundred dollars for a complete "all-electric" installation. It was designed to permit easy assembly for both the novice and the custom set builder. The simplicity of its layout and the inclusion of everything necessary for operation in one unit, is bound to appeal to those who do not care to be troubled by such annoyances as recharging "A" batteries, replacing "B" and "C" batteries or the knowledge required to connect innumerable wires from a receiver to the proper terminals of batteries or "A" and "B" eliminators.

All that is necessary to put the Four-Tube Roberts A. C. set in operation is to insert the plug of the unit into an electric light socket, connect up antenna, ground and speaker and tune the set.

In spite of the fact that both receiver and power pack are included in a single unit, careful design and placement of parts have made possible a compact unit with a panel size of 7 inches by 21 inches with a depth of 12 inches. This size will fit into most of the standard table cabinets or consoles and is easily adaptable for mounting in desks, secretaries, bookcases and other odd pieces of furniture.

Although the list price of the parts for making the combined receiver and power pack has been kept under $100.00, no attempt was made to skimp on the quality of parts employed. A glance at the list of parts will attest to the high quality of the parts selected.

Economy, both in first cost and in operating expense was achieved through the design of a really efficient circuit and by trimming off all non-essentials.

It is impossible, of course, to make any guarantees regarding the receiving range or operating efficiency of a receiver under unknown conditions, but a brief statement of the performance of this receiver in New York City, a test location which is as trying to the best radio receivers as Pike's Peak is to the best automobiles, should prove interesting.

In a test during the early evening between eight and ten o'clock when the local stations were on full blast, KDKA, Pittsbugh on 315 meters was brought in through the local stations WABC on 309 meters and WRNY on 325 meters. Soon after, WSM, Nashville, Tenn., on 337 meters was brought in through stations WRNY on 325 meters and WGBS on 348 meters. Next WSAI, Cincinnati, Ohio, on 361 meters was brought in through WGBS on 348 meters and WMCA on 370 meters. Finally WGY, Schenectady, N. Y., on 379 meters and station WBBM, Chicago, Ill., on 389 meters were brought in through WMCA on 370 meters and WPAP on 394 meters.

LIST OF PARTS

2 Hammarlund .0005 mfd. Midline condensers, .0005 mfd., C1, C2.
1 Aerovox .00025 mfd. molded condenser with grid leak clips.
1 Aerovox .001 mfd. molded condenser, C4.
2 Acme Parvolt 1 mfd. condenser, series A, C5, C6.
1 Acme Parvolt, No. R-171 condenser block, CB.
1 Electrad type F, Royalty variable resistance, 0-2,000 ohms, R1.
1 Durham metalized grid leak, 2 megohms, R2.
1 Electrad type B-1, Truvolt fixed resistance, 100 ohms, R3.
1 Electrad type C-130-S Truvolt tapped resistor, R4.
1 Set of Hammarlund HR-23 coils, T1, T2.
2 Thordarson R-200 audio frequency transformers, T3, T4.
1 Thordarson R-76 output transformer, T5.
1 Thordarson type T-2504 transformer, T6.
1 Thordarson type R-171 power compact, T7.
3 Amperites, No. 227, or Elkay Equalizers for A.C. tubes.
3 Eby 5-prong sockets, VT1, VT2, VT3.
2 Eby standard 4-prong sockets, VT4, RT.
1 Hammarlund illuminated drum dial, model DD-2.
1 Formica or Micarta panel 7x21x 3/16".
4 X-L binding posts for Ant., Ground, and Loud Speaker.
1 Pkg. Acme Celatsite wire.
1 Pkg. Kester rosin core solder.

The remarkable part of the whole performance was the fact that these distant stations came pounding in so strongly that it was necessary to turn down the volume control. Such performance might well be the envy of many six- and seven-tube sets under the same difficult conditions of reception as are found in the New York City locality in which the Four-Tube Roberts A. C. Receiver was tested.

A casual study of the circuit will reveal the reasons for its really remarkable performance. A very efficient non-radiating and non-interfering circuit is employed, making possible the utilization of the tremendous sensitivity of the regenerative circuit without any interference to neighboring receivers. The circuit is a modification of the old tried and true Roberts Circuit consisting of a stage of tuned radio frequency amplification, a regenerative detector and two stages of transformer-coupled audio frequency amplification.

To simplify the transformer requirements and the wiring, A. C. heater type tubes such as the UY-227 and C-327 tubes are used in all except the last audio stage. This arrangement eliminates the necessity for a large and comparatively expensive heater transformer. In its place a standard power transformer designed to supply a secondary voltage of 3 volts is employed. A 100-ohm fixed resistor is connected in the primary circuit of this transformer to cut down the seconday voltage to the proper value.

A variable resistance, having a resistance range of from 0 to 2,000 ohms, connected across the primary

winding of the R. F. transformer serves the double purpose of a very efficient volume and oscillation control.

One of the most common sources of trouble when using A. C. tubes is that resulting from the application of excessive voltages to the filaments of the tubes. Such overloading of the filaments usually results in shortening the life of the tubes and impaired reception during the time that the tubes are used.

In the Four-Tube Roberts A. C. set special automatic filament controls are used in the filament circuit of each A. C. tube to prevent any possiblity of harm to the tubes when the line voltage becomes excessive. This means of regulating the filament voltage applied to the tubes increases the useful life of the tubes and the overall efficiency of the receiver.

Two stages of high grade transformer-coupled audio frequency amplification, complete the circuit itself. An output transformer is used to keep the heavy direct current in the plate circuit of the last tube out of the loud speaker. This serves both to improve tone quality and prevent damage to the loud speaker windings.

The plate current supply for the unit is obtained very efficiently without taking up undue space, by using the power compact and condenser specified in the accompanying list of parts. The power compact contains, in a single unit, the power transformer winding which supplies the high voltage to the rectifier electrodes and the 5-volt winding required for the filament of the UX-171A or CX-371A tube of the last audio stage. It also includes the two choke coils necessary for the filter system and the two buffer condensers which are required across each half of the high voltage winding.

The condenser block includes the three filter condensers required for the filter system and two additional 1-mfd. by-pass condensers for use across the resistances of the voltage divider system.

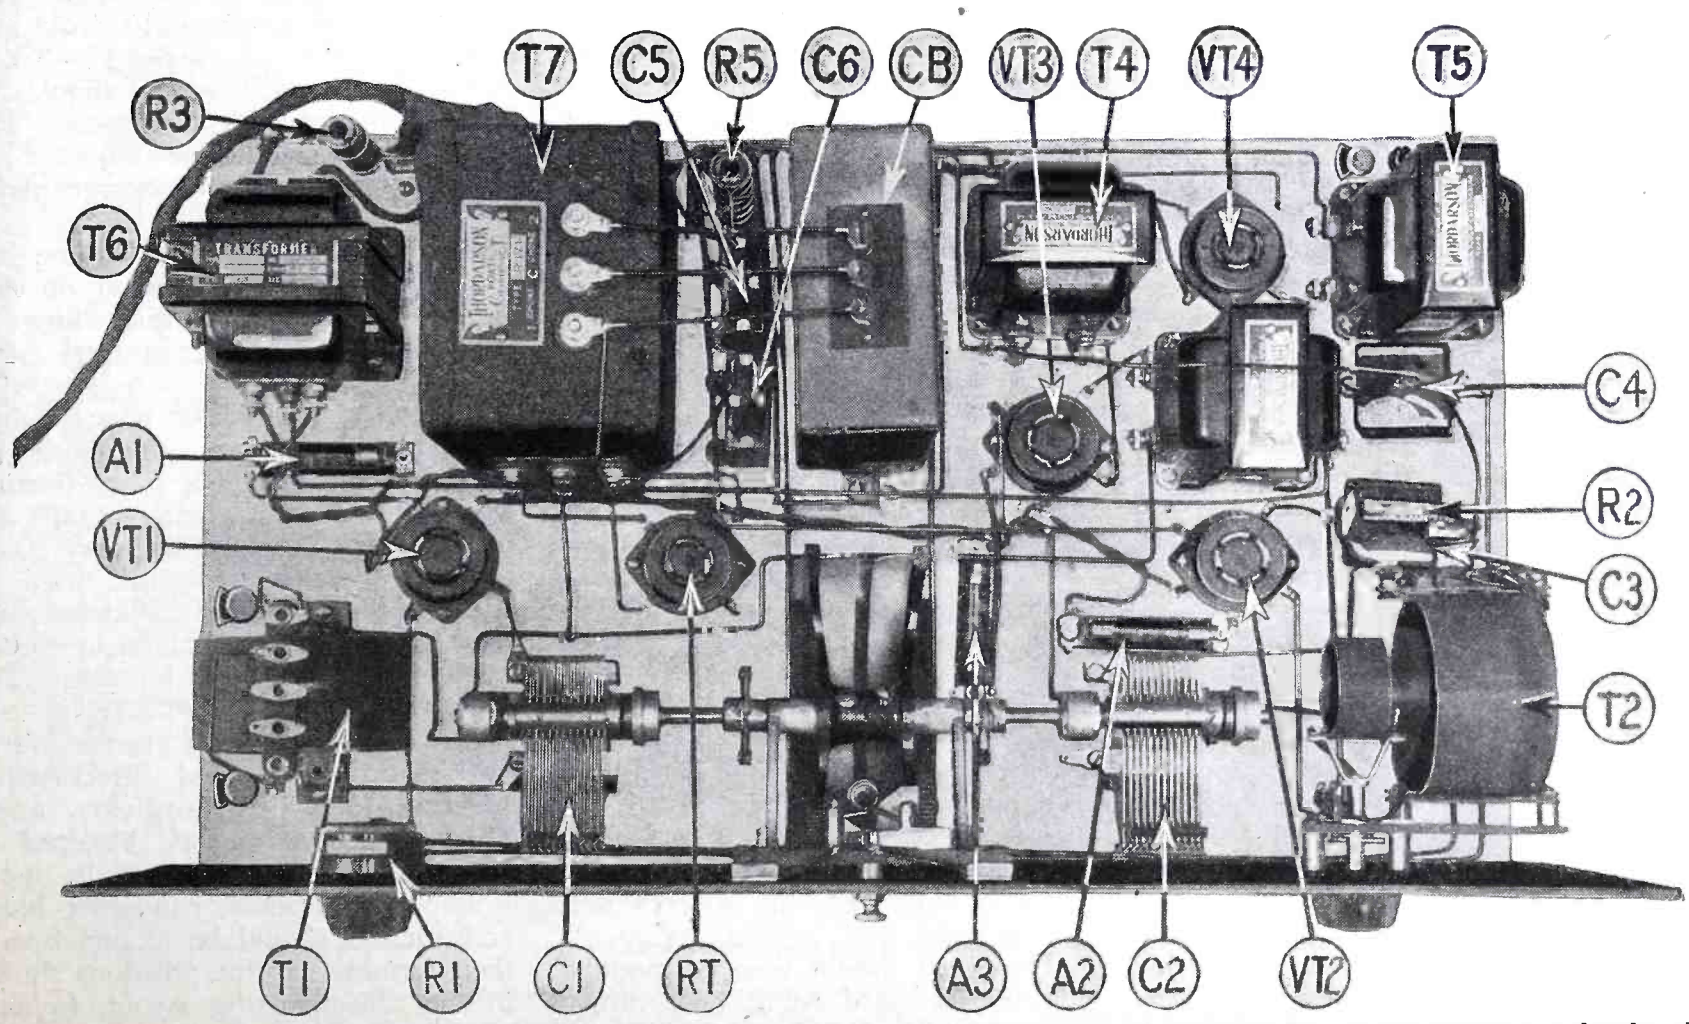
Simplified operation has been attained by using only two tuning controls which are centralized so that both controls may be operated together as a single control. The knob at the left of the panel is used simply to adjust the volume to the amount desired while the knob at the right is used to set the regeneration control at the required position for maximum sensitivity and selectivity.

To avoid any possibility of confusion regarding the proper terminals to be connected together, each instrument has been assigned a distinctive symbol such as C1, T1, etc., and the same symbol has been used to designate the corresponding parts on both the schematic and the pictorial wiring diagrams. In addition, where there would be any likelihood of confusion between the terminals on any particular part, the letters or numbers stamped on those terminals ae shown on both wiring diagrams. Where no numbers or letters are given on the parts themselves, numbers or letters have been assigned to those terminals on the drawings so that corresponding terminals on both diagrams and photos may be located without trouble.

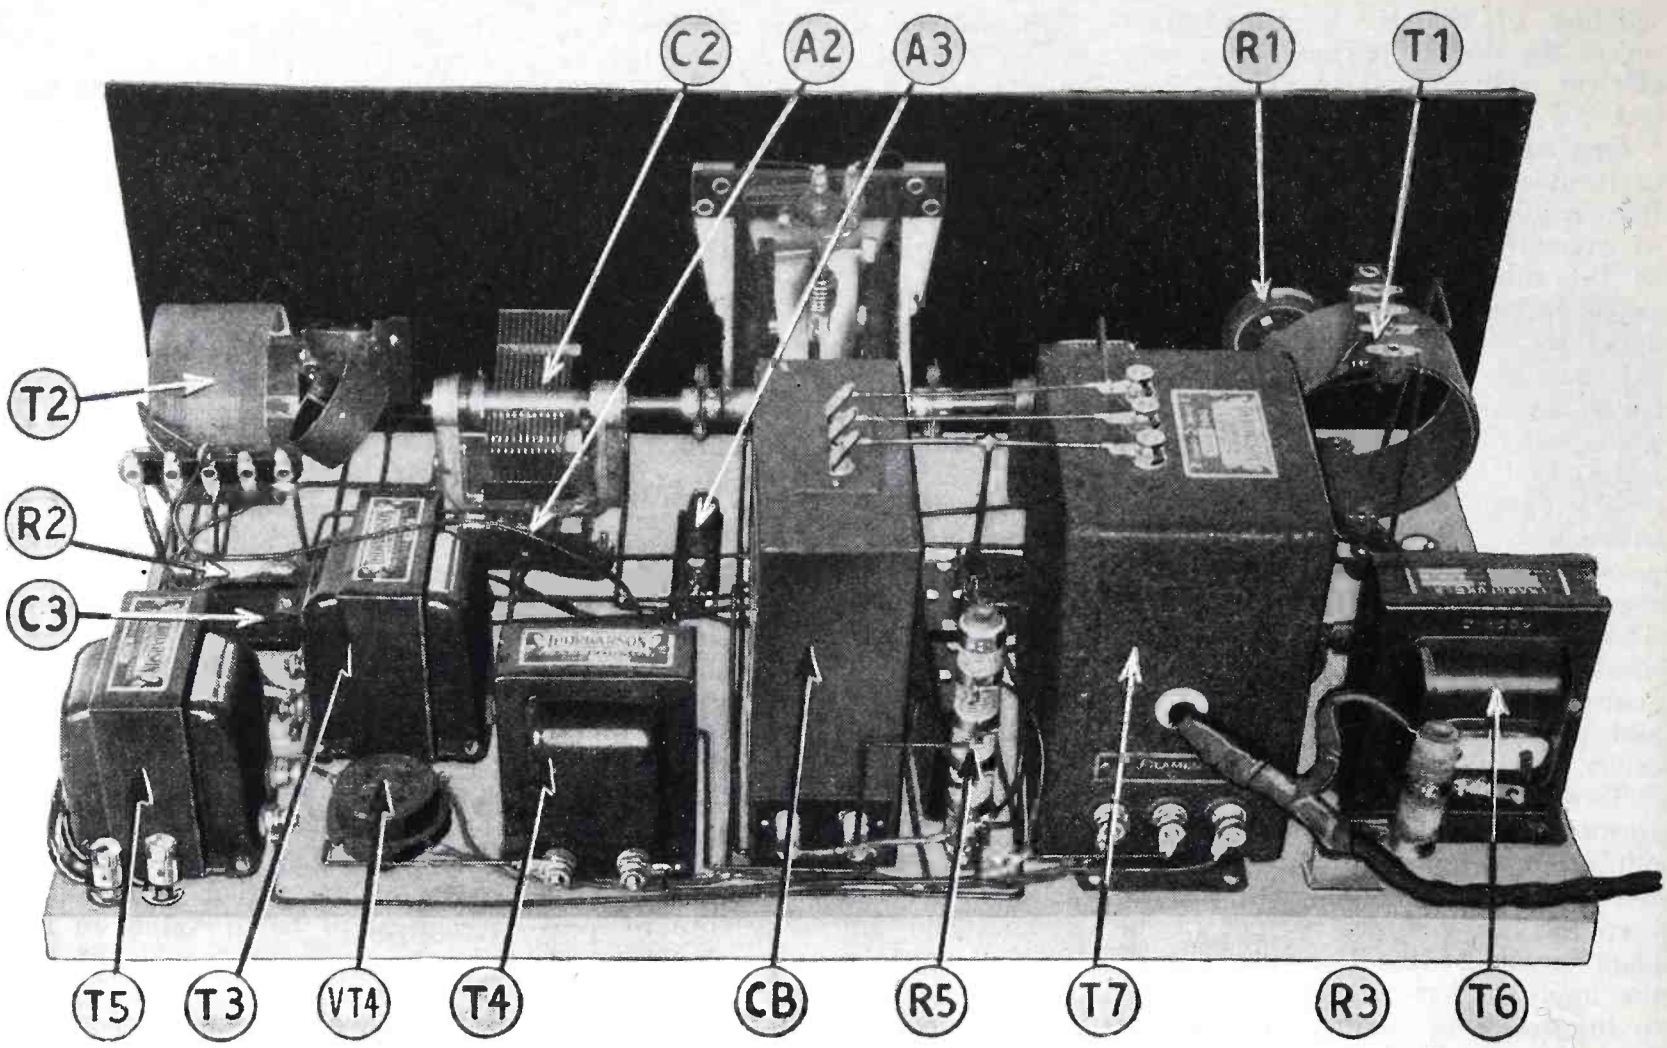
The exact relative location of the parts on the panel and baseboard are shown in the rear view photograph of the receiver. While the pictorial wiring diagram shows the relative location of the parts, it was necessary for the sake of clearness and to avoid confusion where lack of space would otherwise have necessitated crowding of the wiring, to show the spaces between the parts out of true proportion to permit the wiring to show clearly.

The first step, after gathering all the parts together is to mount them on the panel and baseboard. The mounting of the parts is a comparatively simple matter but a few suggestions gathered from the experience of the author in building the receiver will be of value, in lessening the time and trouble of assembling the receiver.

Much trouble and annoyance will be spared if the proper number of screws necessary to mount the parts are obtained when purchasing the rest of the material. The screws required for mounting the transformers, sockets and fixed condenses to the baseboard should be ¾"—No. 6 round head wood screws. In all, 36 of these screws will be required.



How the set appears looking down on the baseboard from top. Note that complete parts for the "B" supply are also mounted on baseboard.



A rear view of the set showing the "B" supply condenser block, CB, power compact, T7, filament transformer, T6 and resistors, R3, R5, as well as other parts of the set.

To fasten the variable condensers and the antenna coupler to the baseboard, four 1"—No. 6 round head wood screws should be provided. Four, 1"—No. 6 flat head wood screws will be necessary to fasten the front panel to the baseboard.

If the ready-drilled panel is used, no trouble at all will be experienced in mounting the double drum dial, the R. F. transformer, T2, and the variable resistance R1.

If a plain panel is employed, the first step will be to drill the panel for the dial, R. F. transformer and the volume control mounting holes and provide also, four holes at the bottom of the panel for use in fastening the panel to the baseboard.

In drilling the panel, use the template provided with the drum dial to lay out the dial cut out and necessary mounting holes. The holes for the dial, the R. F. transformer T2, the volume control R1 and the holes for use in mounting the panel on the baseboard should be laid out to correspond with the measurements given on the panel drilling template given herewith.

A baseboard 20 inches long and 11½ inches deep is required in building the receiver. A well-seasoned board, not more than three-quarters of an inch thick, should be used for this purpose. A board exactly three-quarters of an inch thick will bring the shafts of the variable condensers to the proper height to fit the drum dial bushings. If a thinner board is used the top surface of the board should be brought to a distance of three-quarters of an inch from the bottom edge of the panel before fastening the panel to the baseboard.

This can be done by building up the thickness of the board by gluing cardboard of the required thickness to the bottom of the baseboard or by using a wood screw at each corner of the bottom side of the baseboard with the head allowed to project just far enough to bring the height of the top surface of the baseboard to three-quarters of an inch.

No matter what method is used, it is important that the distance from the surface on which the condensers are mounted and the axis of the drum dial bushings be kept to exactly 2-1/16 inches to prevent any strain on the dial or the condensers.

A notch 2⅛ inches wide and 4 inches deep should be cut in the front edge of the baseboard to allow clearance for the drums of the dial.

The next step is to mount the dial in accordance with the instructions furnished with it, being careful to use the two spacers provided if the dial is to be used with a one-eighth inch panel. If a three-sixteenths inch panel is employed, the spacers need not be used.

The panel should then be mounted on the baseboard being very careful that the distance between the top surface of the baseboard and the axis of the drum dial bushings is exactly 2-1/16 inches before fastening the panel and sub-panel together.

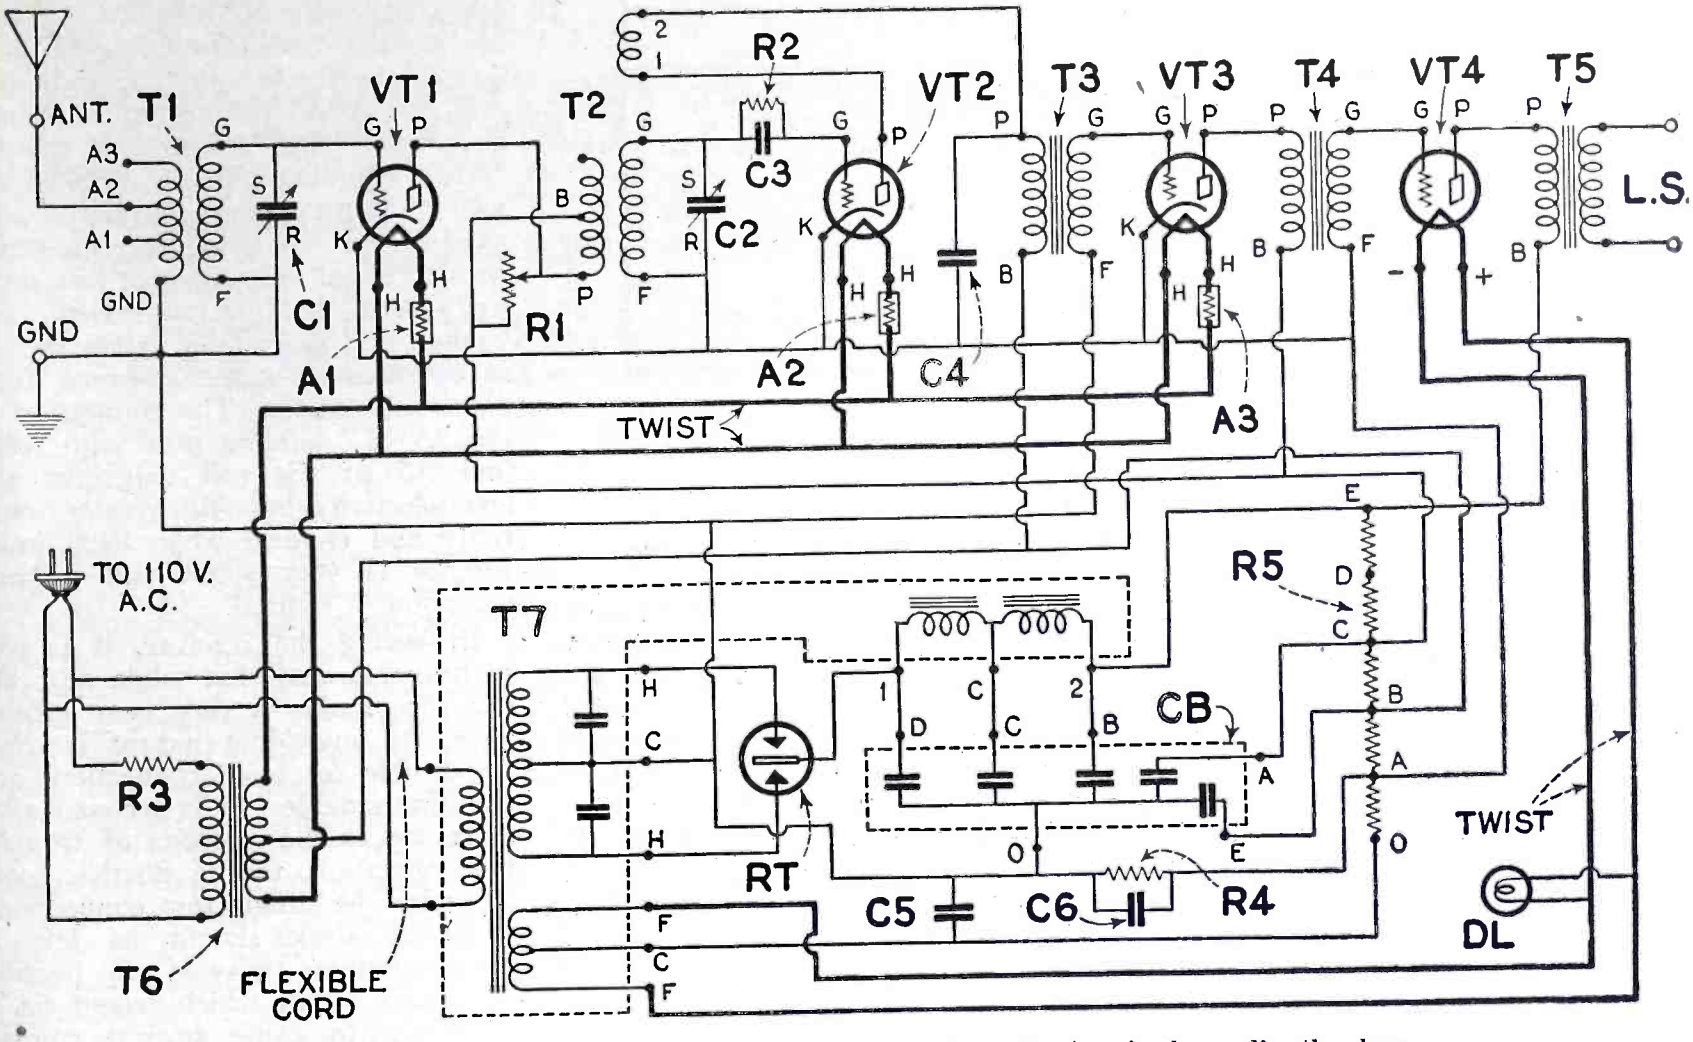
Care should be used in mounting the condensers to make sure that their shafts are in alignment with the dial couplings so as to avoid any possible strain. A single, 1"—No. 6 round head wood screw should be used to mount each condenser. The dial drums should be adjusted to read 100 when the condenser plates are all in mesh.

The two by-pass condensers, C5 and C6 should be mounted on end by bending the mounting lugs at right angles to their original positions.

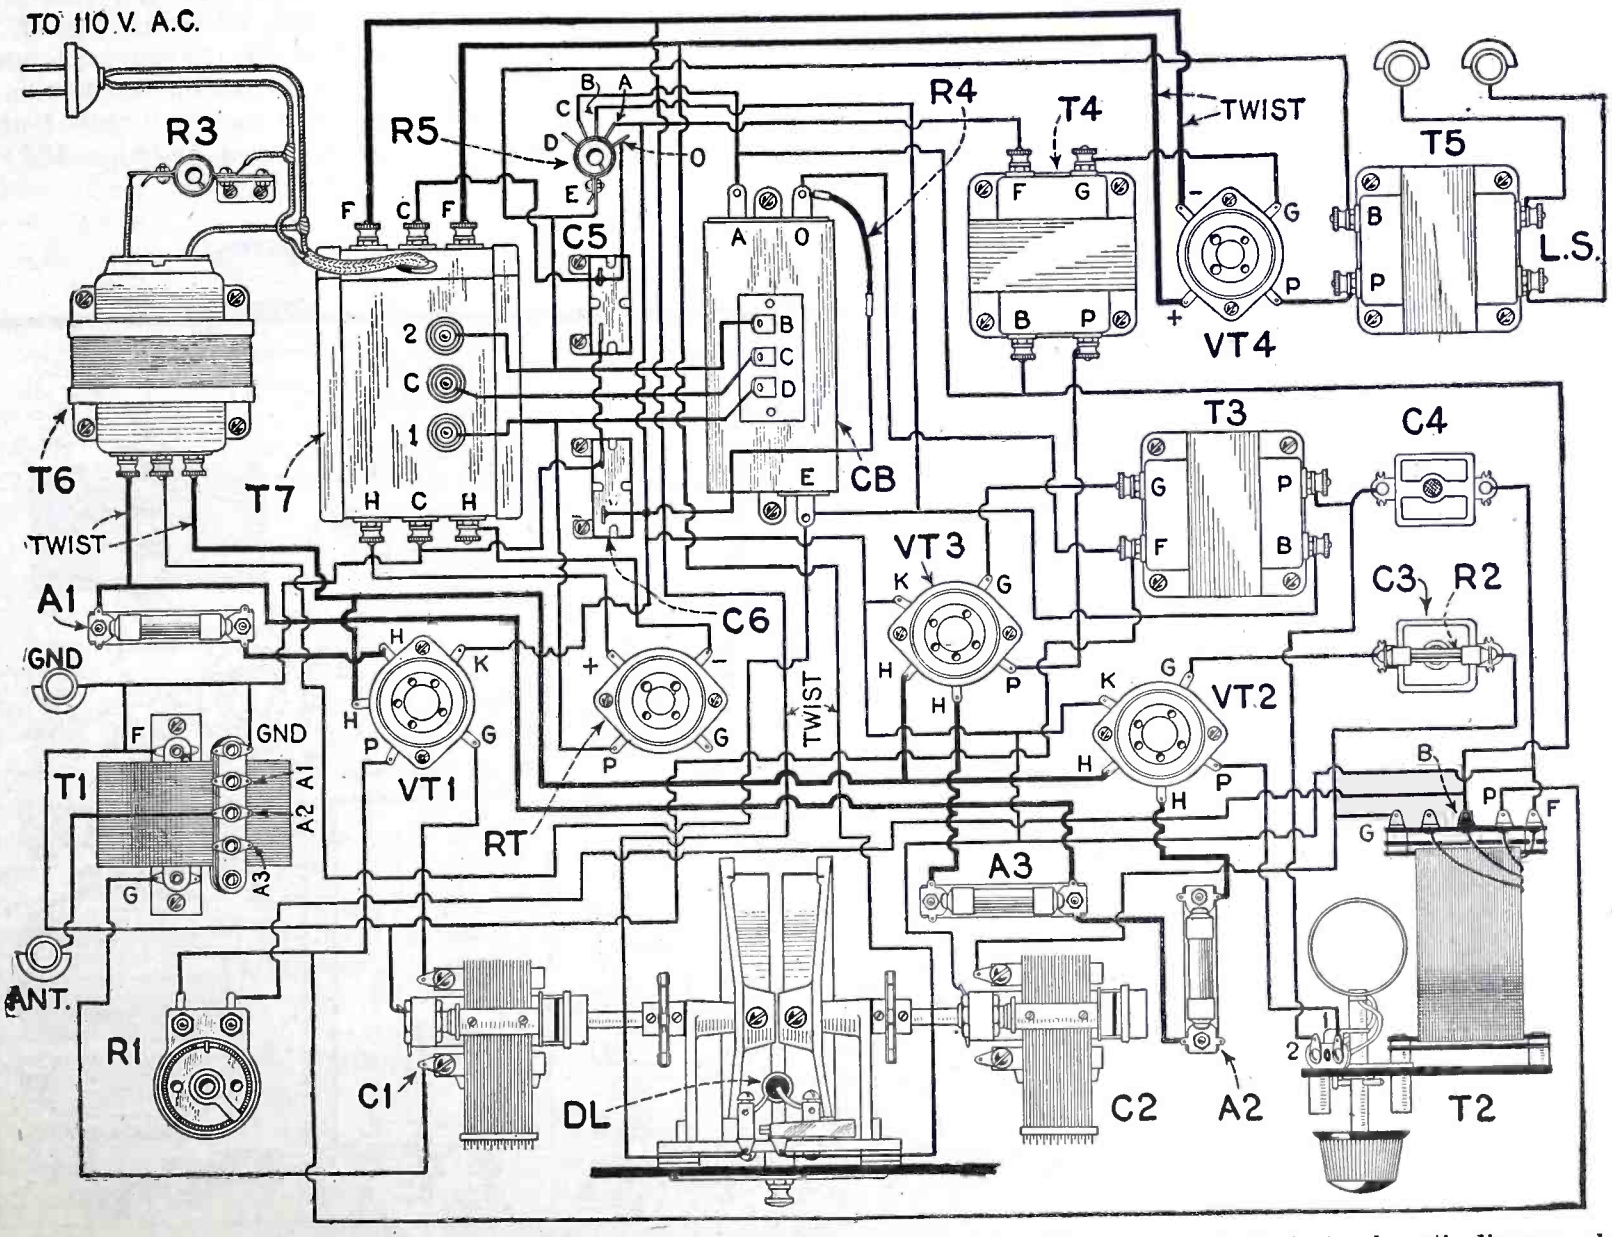
The tapped resistance unit R5 may be mounted on end. It makes no difference which end is down because the resistance units between taps are of the same values either way.

The resistance unit R3, used in the primary lead of the filament supply transformer is mounted by means of a small mounting bracket. The required mounting bracket is not generally available at radio stores but may be obtained direct from Electrad, Inc. An ordinary angle bracket such as can be obtained at most hardware stores may be used.

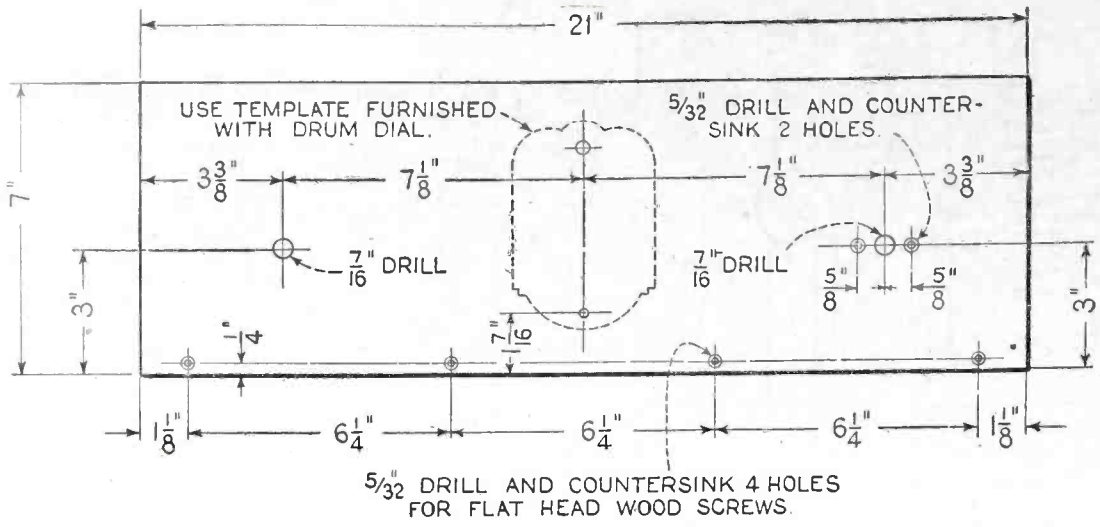
The transformers, condenser block and sockets should be mounted with their terminals in the positions shown in the accompanying layout, to simplify connections.



Schematic wiring diagram of the Four-Tube Roberts A. C. Receiver is shown directly above.



Picture wiring diagram for the Roberts A. C. set. All parts are indicated to correspond with references in the text, schematic diagram, photos, instrument layout and list of parts.



Dimensions for drilling the front panel of the Four-Tube Roberts A. C. Receiver.

Practically all of the wiring is so self-evident from the schematic wiring diagram, and the pictorial wiring diagram, that detailed instructions or step-by-step wiring instructions are unnecessary.

In the case of the antenna coupler T1, the R. F. transformer T2 and the resistance unit R5, the positions of the terminals have been altered slightly so as to bring all of them into view. In the resistance unit for instance, the bottom terminal or zero point is marked "O." The taps from that point up are marked respectively "A", "B", "C", "D" and "E" in order. Tap "D" is not used as shown in both the schematic diagram and the pictorial diagram.

In the R. F. transformer T2, the terminal between the terminals marked "G" and "B" is not used. The tickler coil connections must be made with the proper polarity to produce results. The tickler coil terminals are shown marked 1 and 2, the terminal nearest the baseboard being number 2 and that towards the top of the panel being number 1.

When the coil is mounted in the position shown, the upper terminal, number 1 should be connected to the "P" terminal of socket VT2 while the lower terminal, number 2 goes to the "P" terminal of transformer T3.

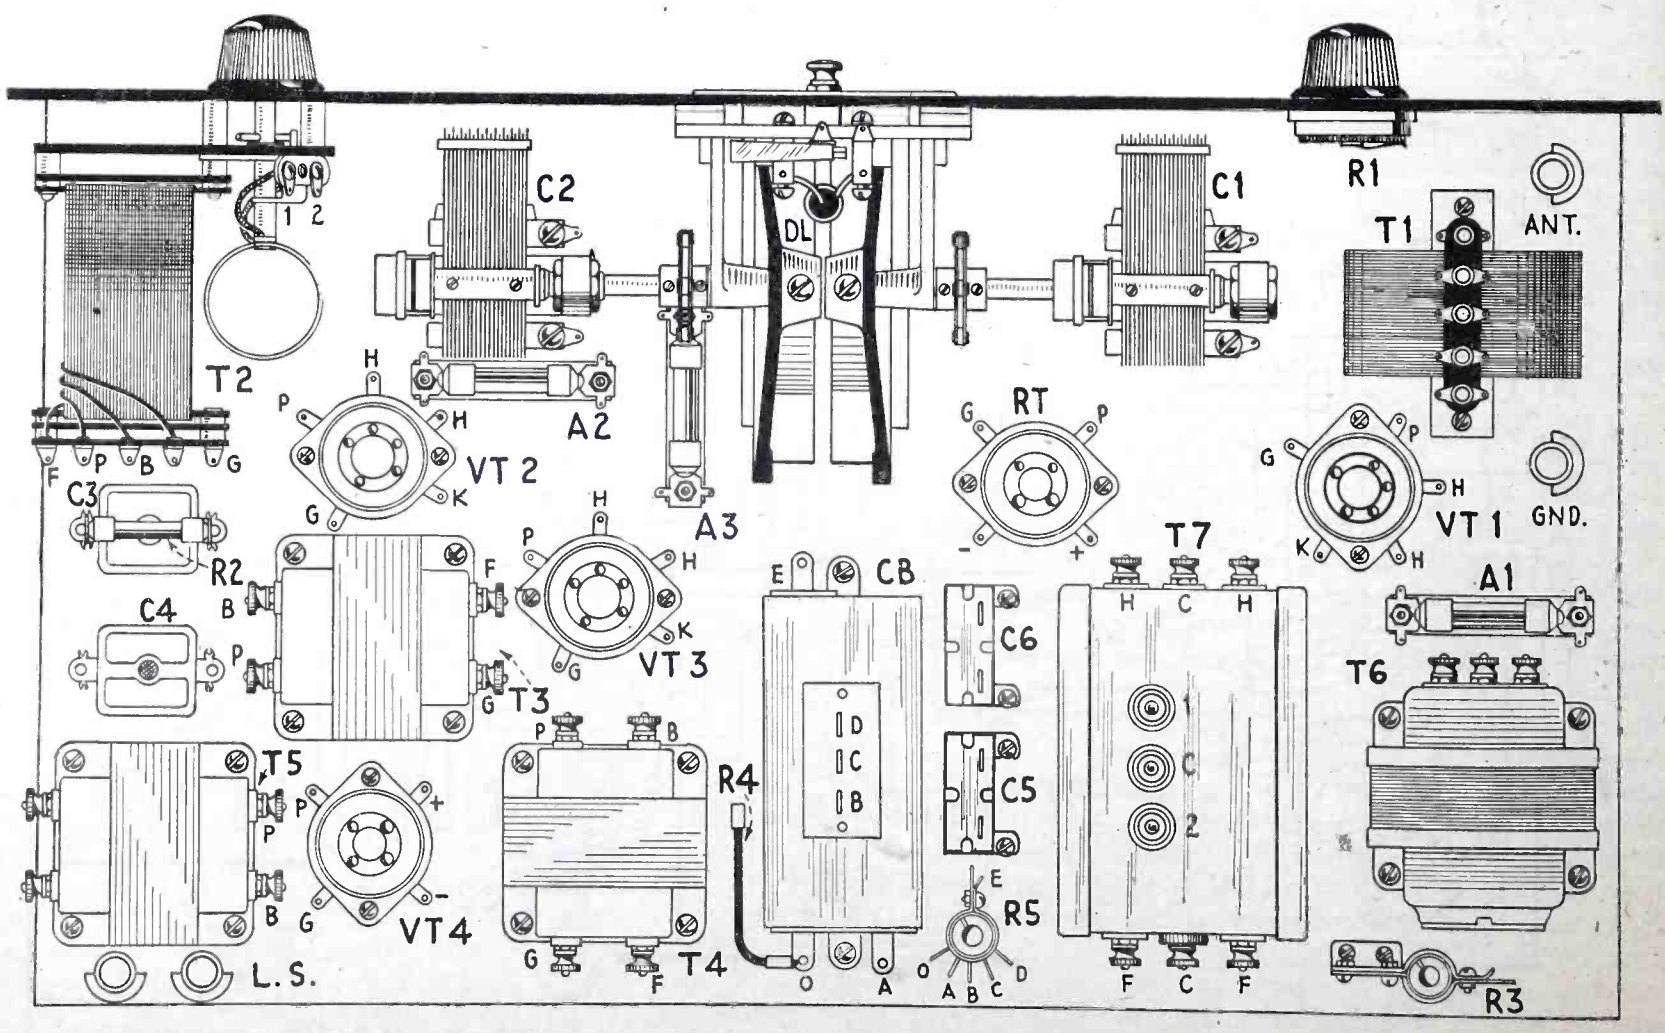
Be sure that the antenna coupler, T1, is mounted so that its primary coil is towards the back of the receiver. In this position, the terminal at the end of the top strip is in the position shown, marked "GND."

Various degrees of selectivity and sensitivity may be obtained by connecting the "ANT" binding posts to one of the three remaining terminals, A1, A2, or A3 of the antenna coupler, T1. The connection of the "ANT" binding post to terminal A1 will give maximum selectivity with good signal strength. Its connection with terminal A2 will give less selectivity but greater sensitivity and volume and is suitable when the set is operated at some distance from powerful stations. The connection of the "ANT" binding post with terminal A3 of the coil will give still less selectivity but still greater sensitivity and is ideal when local interference is very slight and distance reception is desired.

In wiring the receiver, it is well to bear in mind that while stiff bus bar wire makes a very neat appearance, its unyielding nature is often responsible for loose connections and resulting trouble. It is recommended therefore, in the interests of trouble-free operation, that a flexible hook-up wire be used for connections. Sufficient slack should be left in the connections to avoid any possible chance of strain which would be at all likely to cause broken connections.

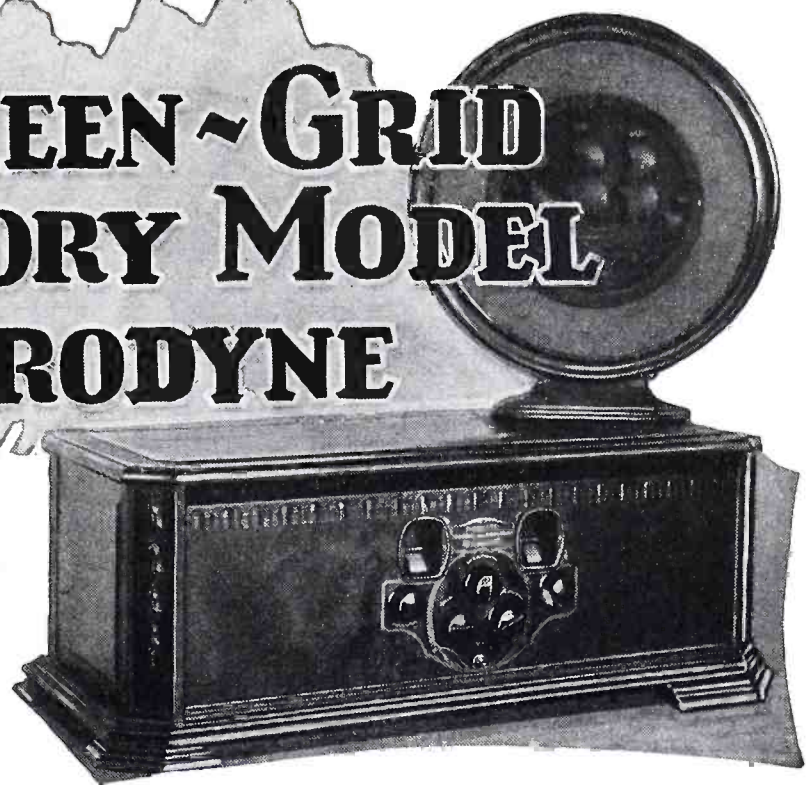
By using flexible insulated wire and by threading the end of the wire into the soldering lug or twisting the end of the wire around any other wire to which connection is to be made, the main source of possible

(*Continued on page* 163)



Instrument layout showing the placement of all parts on the baseboard and front panel.

The Improved Screen-Grid Laboratory Model Super-Heterodyne



THE receiver pictured and described herewith is an eight-tube superheterodyne employing three of the new screen-grid R. F. amplifier tubes in the intermediate-frequency amplifier, which is a laboratory-assembled and tested shielded unit, and which effectively eliminates all possibility of anything less than peak performance in the hands of even the most inexperienced builder.

The real value of the screen-grid tubes in this receiver can best be realized from the statement that the amplification factor in the three-stage 112-kc. intermediate amplifier approaches 40 per stage, as compared to about 20 per stage for 201A-type tubes. Thus, for the three R. F. stages, the amplification when using screen-grid tubes is approximately 40x40x40, or 64,000, as against 20x20x20, or 8,000 gain for the same amplifier using 201A-type tubes. These values of amplification were obtained under conditions of equal *apparent* selectivity; for it must be borne in mind that, as the sensitivity or amplification of a radio set is increased, the selectivity must go up far faster to maintain the same apparent selectivity in tuning the set. Actually, if the receiving range is doubled, selectivity must go up four times, merely to hold the apparent selectivity constant. Therefore, in designing a screen-grid amplifier, great care must be used to prevent the loss of selectivity from accompanying the increased amplification.

In the receiver described herewith, not only have the factors of increased amplification and increased selectivity been given careful consideration, but also that of tone quality, so generally neglected or, of necessity, slighted in very sensitive superheterodynes. Through the use of an intermediate frequency of 112 kilocycles, high amplifier selectivity has been obtained and the cutting of side bands is brought entirely within the operator's control. Either he may have medium range, ultra-high-quality reception or, by sacrificing tone slightly, he can boost the sensitivity of the set to a point where local noise and static, ordinarily very weak, comes in as a roar, and stations not ordinarily heard come in loudly

Another advantageous feature of the 112-kc. intermediate frequency is that, for all stations below 215 meters or above 455 meters, the receiver is a "one-spot" set; that is, stations outside of the 215—455-meter range are tuned in at but one point on the oscillator drum dial. Though stations between 215 and 455 meters can be tuned in at two points on the oscillator dial, by taking 25 grid turns off a standard oscillator coil, the set is made "one-spot" for all stations outside the 215-390-meter band. A further advantage of the 112-kc. intermediate frequency is that the two oscillator dial readings, for those stations that do come in at two dial settings, are widely separated; so that, with the sharp tuning of the regenerative first detector, the set is in operation practically "one-spot." Of course, all stations are received at but one setting of the antenna dial, and either a loop or a short antenna may be used. It is also possible to cut out one of the intermediate amplifier stages and one of the audio stages at will, if desired.

The set employs a regenerative first-detector circuit (S1) using a 201A- or 200A-type first detector tube (V1), with a plug-in antenna coil (L1), or loop, tuned by a .00035-mf. variable condenser (C1) which is controlled by an illuminated drum dial. Regeneration is effected thorugh a small .000075-mf. midget condenser (C3) adjusted by the "sensitivity" knob on the panel. The second tube (V2) is the oscillator, also using a plug-in coil (L2) and a .00035-mf. variable condenser (C2). The oscillator is coupled to the first-detector grid circuit. The use of plug-in coils allow different sizes of standard oscillator and antenna coils to be plugged into the set, thus covering all waves from about 30 to 3,000 meters. Following the first detector and oscillator, which may be shielded as shown at S1 and S2 or not, as desired (depending upon

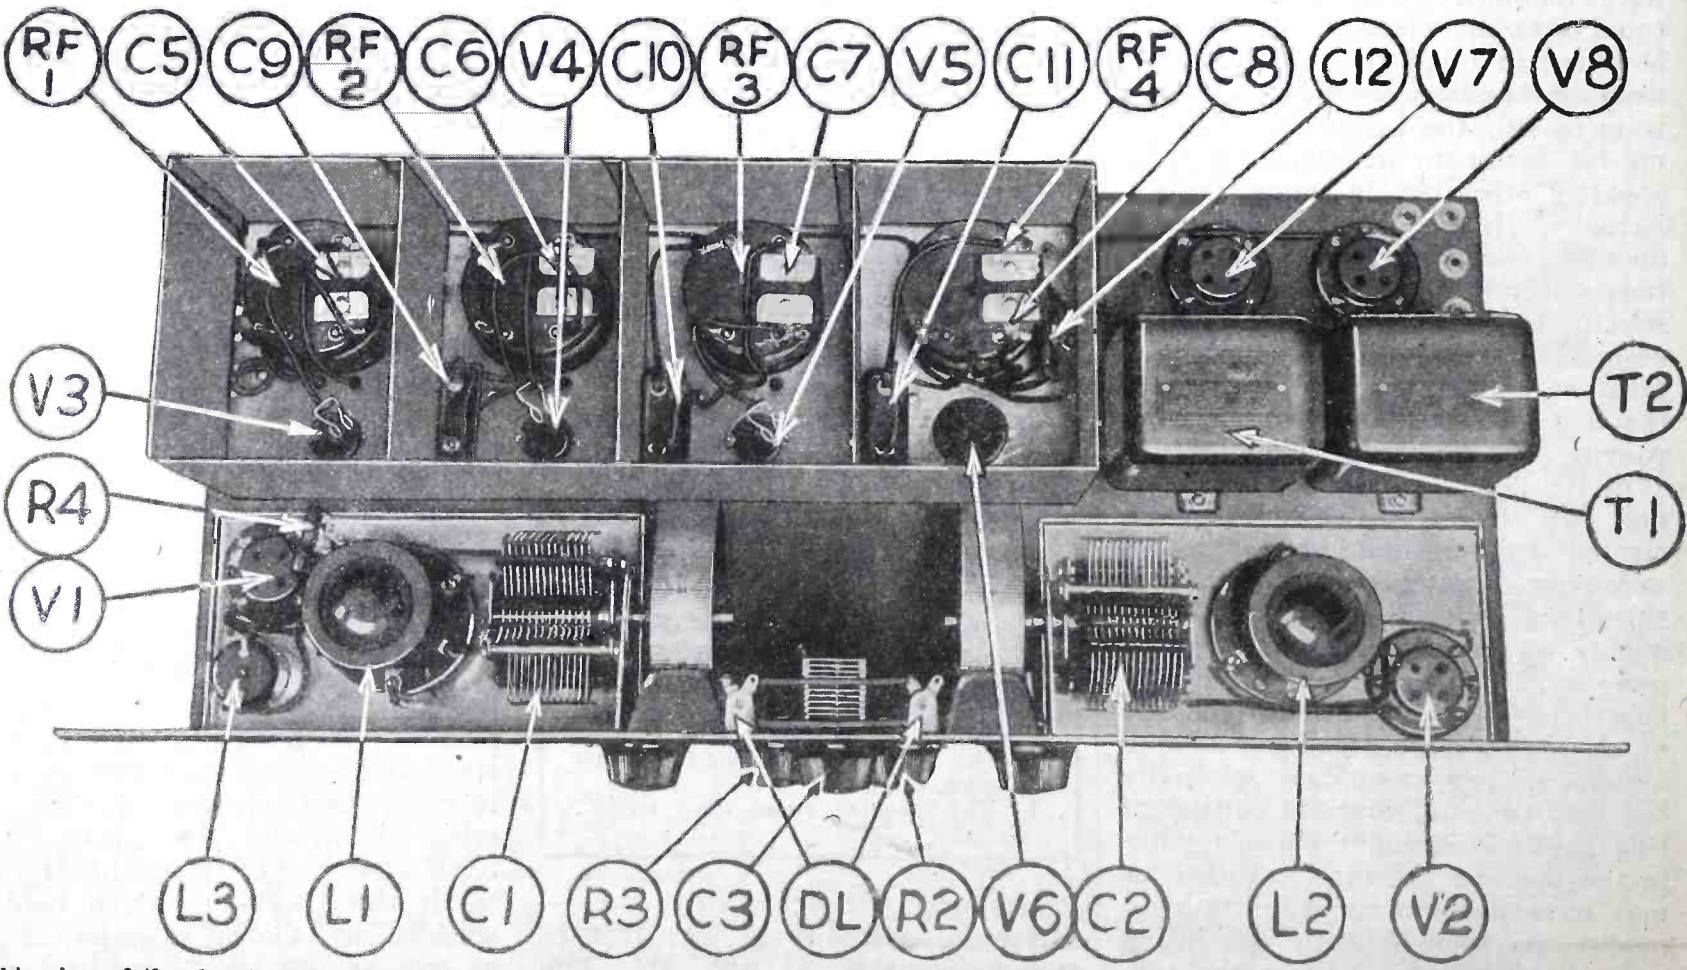
Schematic wiring diagram of the Improved Screen-Grid Laboratory Model Super-Heterodyne.

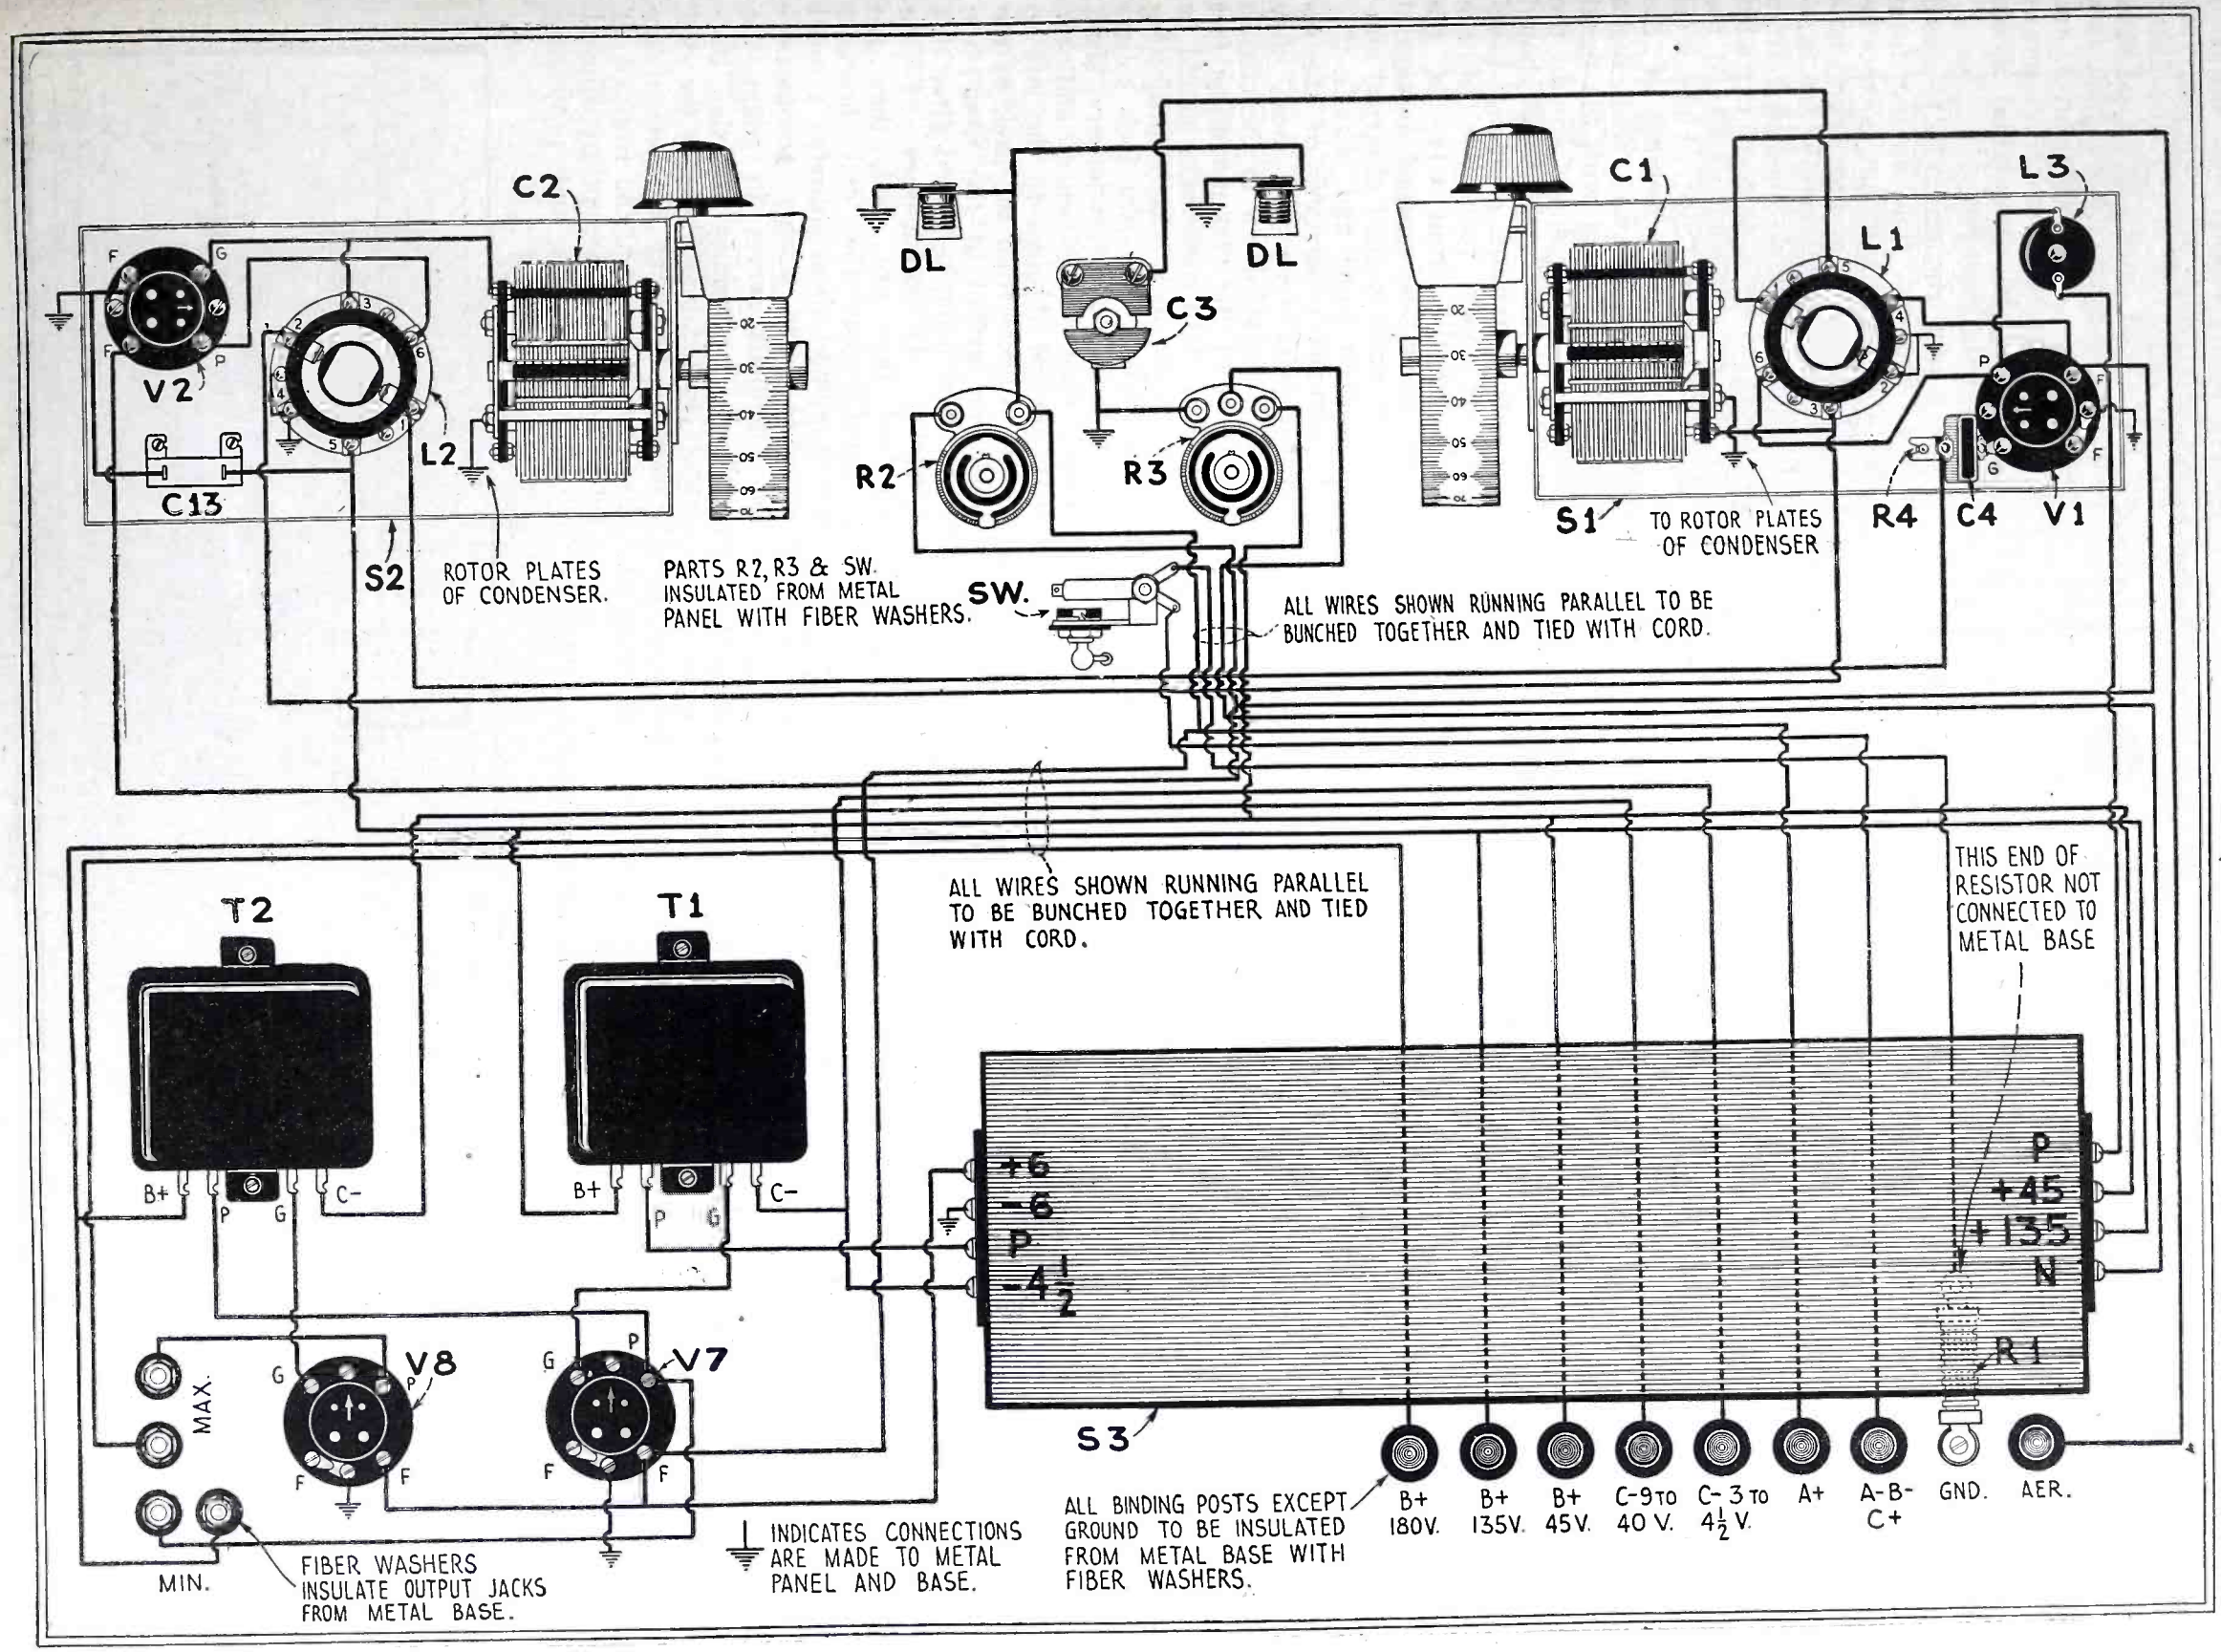
whether the set is to be operated in a congested broadcasting center or in the country) is the four-tube long-wave amplifier (S3) containing the three 112-kc. amplifier circuits and screen-grid tubes (V3, V4 and V5) and the second detector circuit and tube (V6). Each transformer and tube is in a separate compartment in the copper shielding, which is 15 inches long, 5 inches wide, and 5½ inches high, with a cover removable to allow tube insertion and removal. To the right of this I. F. unit (which is actually a complete amplifier for time-signal reception), is the two-stage audio amplifier, using a pair of high quality audio transformers (T1 and T2). This amplifier gives uniform amplification to all frequencies between 30 and 5,000 cycles. Above the highest frequency it cuts off to keep down background noise and the all-too-prevalent heterodyne squeals which are caused by over 600 broadcasting stations being crowded into channels, which would adequately accommodate 95 stations without interference.

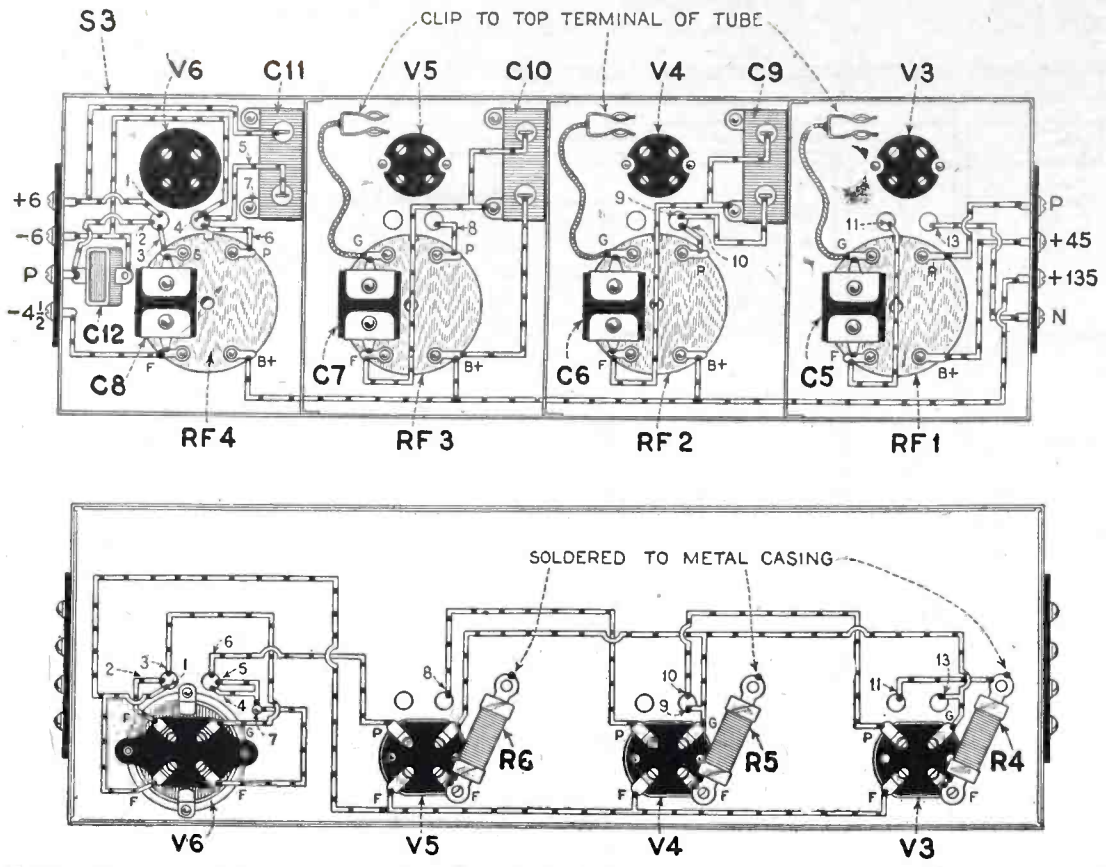
The entire set is mounted on a pierced steel chassis 10 inches wide, 1½ inches high, and 23 inches long, to which is attached a 7x24-inch metal panel carrying the control knobs. The actual controls are the vernier knobs actuating the two drum dials; an "On-Off" switch (Sw); a regeneration control (C3) for the first detector (the "Sensitivity" knob); a "Gain" control potentiometer (R3) regulating volume of the screen-grid amplifiers; and a filament rheostat (R2) for the first detector and oscillator.

In a number of tests the Improved Screen-Grid Laboratory Model receiver has been found to have no equal for DX ability; for it will reach out from Chicago on a small ten or twenty-foot aerial, bringing in with loud-speaker volume stations on the east and west coasts that many other receivers will not bring in at all. One I. F. amplifier stage can be dropped from the eight-tube



This view of the chassis, with stage shields removed, clearly shows the location of all apparatus: C1 and C2, variable condensers; L1 and L2, R.F. coils; R2, rheostat; R3, potentiometer; C3, midget condenser; L3, R.F. choke coil; T1 and T2, A.F. transformers; V1, V2, V7 and V8, tube sockets; DL, dial lights; R4, grid condenser. The remaining parts shown are located inside the intermediate-amplifier unit S3. By-pass condenser, C13 is not shown in this photo but is placed in the bottom of the shield at the right in back of socket, V2. See instrument layout.





Wiring diagram of the top and under side of the long-wave shielded time amplifier, S3. V3, V4 and V5 are screen-grid tubes. This amplifier is available only as a complete, ready-wired unit. Its wiring is shown as a matter of technical interest.

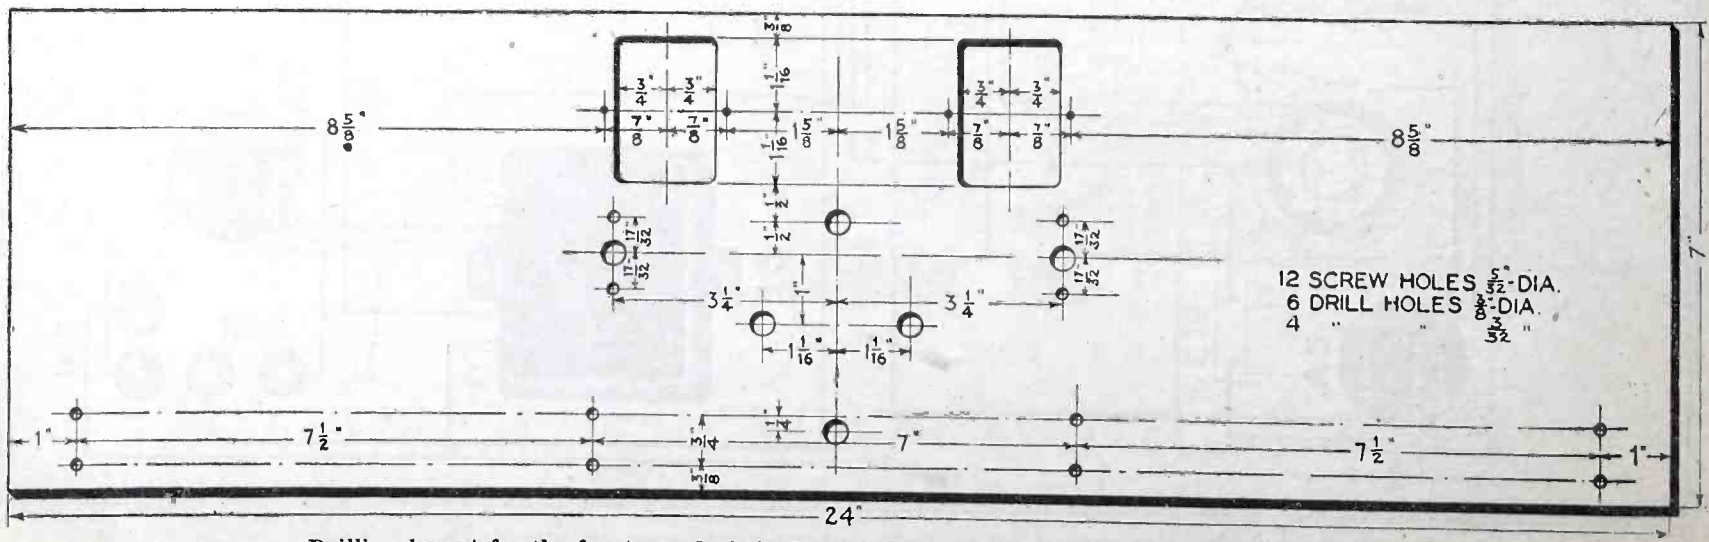
circuit by simply pulling the grid lead from the left compartment of the amplifier (S3) over the partition and clipping it to the top cap of the second tube (V4), whose clip lead is ignored. So connected and using but two I. F. amplifier stages, the set will produce results for distance, tone quality, and selectivity that will equal those obtained from other nine- and ten-tube supers. Even using only seven tubes the set will bring east and west coast stations into Chicago almost like locals on a twenty foot length of wire. Truly, the set is one fully deserving of the name "superheterodyne," for even in the hands of a novice, it tunes in distant station after distant station through a maze of locals with a simplicity that is delightful, while an expert can make it run rings around ordinary sets.

The parts used for the Improved Screen-Grid Laboratory receiver are named in the list of apparatus which accompanies this article and are all of standard manufacture. It will be found that the different parts bear the same symbols as in the drawings and photographs. The two aluminum stage shields (S1 and S2) are not absolutely necessary, but should be used to house the detector and oscillator circuits if the set is to be operated near any powerful broadcast stations. Brass-plate variable condensers of the more expensive type are illustrated in the set, as these allow the dials to turn in the same direction for simultaneous capacity increase or decrease by means of removable shafts. Though the cheaper type made by the same manufacturer are equally satsifactory, the dials turn in opposite directions for simultaneous oscillator and antenna increase or decrease of wavelengths.

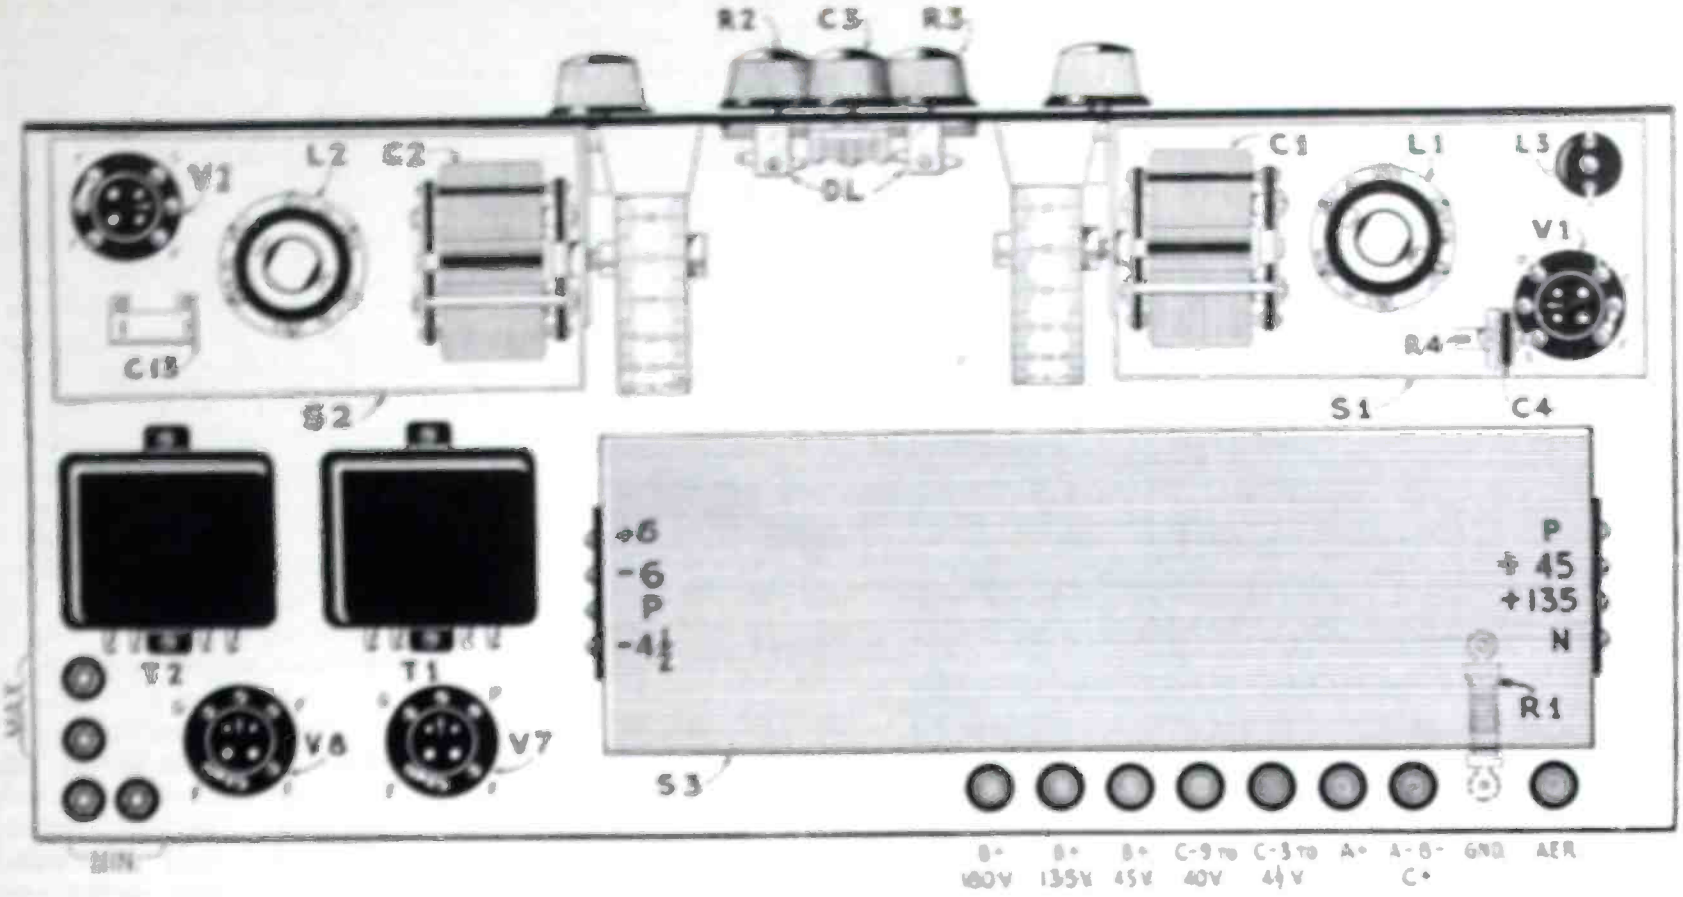
The construction of the Improved Screen-Grid Laboratory receiver is a simple task, indeed; for the steel chassis and panel are completely and accurately pierced so that the different parts need simply be placed upon them, in the positions in which they appear in the different pictures, and bolted down with machine screws and nuts. A few precautions should be observed, however.

The 6-ohm rheostat (R2) placed in the "filament" hole of the front panel and the 5000 ohm potentiometer (R3) placed in the "gain" hole of the front panel should be carefully and thoroughly insulated from the panel, using a pair of extruded fiber washers for each as should the "On-Off" switch (Sw), while it is desirable that the bushing of the midget condenser (C3) shall make good, positive contact with the metal panel and a small space around the "sensitivity" hole in the panel should be scraped free of enamel. Likewise, the lower rear side of the panel and the front edge of the chassis should be scraped at several points to make a good electrical contact between panel and chassis.

If variable condensers of the removable-shaft type are used, they may be screwed down to the chassis by means of the two mounting feet provided. Both condensers should be put in with their shafts projecting to the right. The two lock collars on the oscillator-condenser shaft should then be loosened and the shaft pushed through to the left so that it projects from the back of the condenser instead of the front; the lock collars being tightened after this operation. If condensers of the standard type are used, they are mounted upon the dial brackets which support them entirely; a small extruded brass washer accompanying the dials serves to adapt the small shaft bushing of the condensers to the large hole in the dial brackets. The dial brackets themselves are fastened to the front panel with the drive mechanism slipped into their bushings and projecting



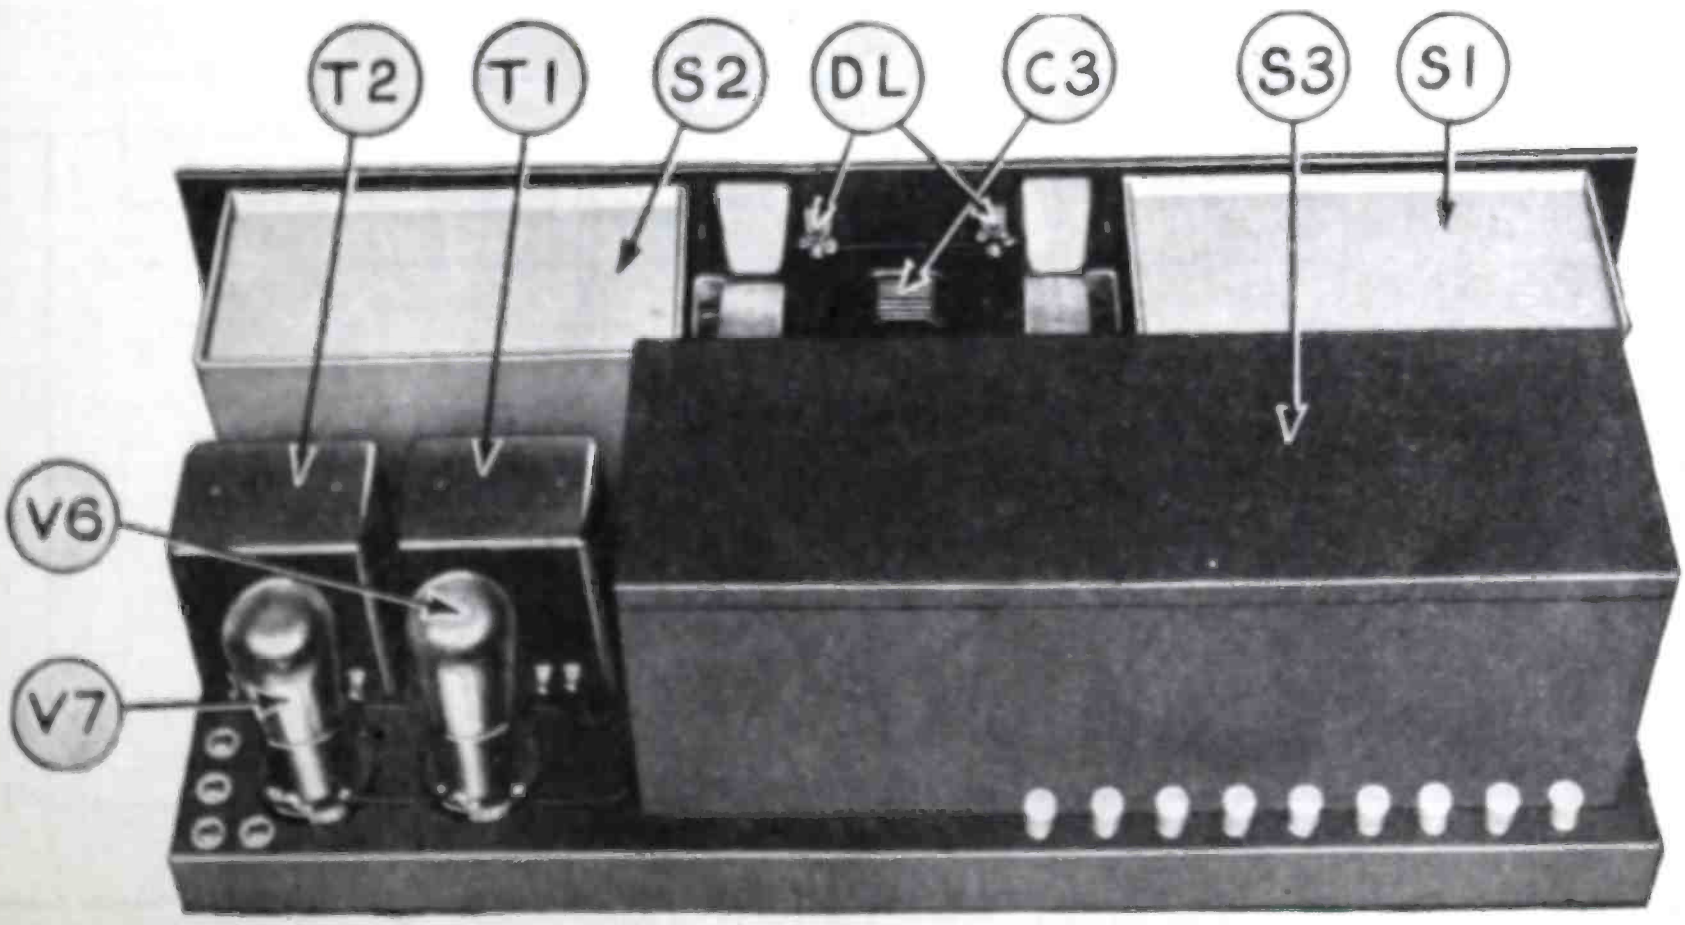
Drilling layout for the front panel of the Improved Screen-Grid Laboratory Super-Heterodyne.



Instrument layout of parts for the set. All binding posts are insulated from the metal chassis with the exception of the ground terminal. Note how parts are mounted within the two stage shields.

through the front panel. The drum scales should be fitted on the condenser shafts to read 100 when the condensers are entirely interleaved, so that readings will increase with the wavelength.

The location of the different parts upon the chassis is very clearly illustrated in the layout accompanying this article. If oscillator and first-detector stage shields (S1 and S2) are used, they are held to the chassis by the different parts mounted in them. It is important to elevate the coil sockets for L1 and L2 above the chassis by means of the ½-inch hollow brass studs slipped over the mounting screws. Terminal 3 of the antenna coil (L1) socket should be to the rear; and terminal 3 of the oscillator coil (L2) socket to the front. The positions of the four tube sockets are clearly illustrated in the top view photo and instrument layout, and the "A—" connection of each tube socket is grounded to the chasis by means of a lug under the head of the nearest socket mounting screw. The positions of the audio transformers (T1 and T2), choke coil (L3), and time-signal amplifier (S3) are clearly illustrated and their mounting needs little explanation, other than to state that the amplifier is held to the chassis by four long 8/32 screws tapped into the corners of its chasis. Each binding post should be mounted, using a pair of extruded fiber washers to insulate it thoroughly from the chassis, with the exception only of the "ground"



A rear view of the set with the covers of shields, S1 and S2 closed.

binding post, which should be grounded to the chassis. The simplest way of doing this is to use one lug of the the 0.57-ohm filament resistor (R1) as a washer for the "ground" binding post, the binding-post screw going through the resistor lug, up through the chassis, and into the binding post. This connection serves to ground one end of the resistor, the other end being connected directly to the "A—" binding post (this connection can be seen in the schematic diagram—the resistor should be mounted, not as in the under-view picture, but as explained above.)

The wiring of the receiver is done entirely with flexible fabric-insulated hook-up switch-board wire, with the exception of the three leads, which are put in with bus-bar in spaghetti. One of these bus-bar leads serves to connect post 5 of the antenna coil socket (4) to the stator lug of the midget "sensitivity" condenser (C3); while the other two leads serve to connect posts 1 and 2 of the oscillator coil socket (L2) to post 3 of the antenna coil socket (L1) and the first-detector grid condenser (C4). All three of these leads should be made of bus-bar in spaghetti, put in in such a way that they are at least ¾-inch away from the metal chassis or receiver assembly at any point where they run parallel. All the rest of the wiring, with the exception only of grid and plate leads, should be bunched together as far as possible and, after final assembly and testing, may be laced or cabled, using heavy waxed shoemaker's thread, thus providing a very neat and workmanlike job, as seen in the pictures. The receiver can, of course, be wired with bus-bar in spaghetti throughout, if desired.

The wiring and assembly of the receiver having been completed, all previous operations should be very carefully checked, and the wiring compared with the schematic and pictorial diagrams to make absolutely sure that no errors, which might result in tube burn-out, or other damage, have been allowed to creep in. This done, the set is ready for operation.

The necessary accessories should be connected to the receiver in accordance with the markings on the binding posts, and all tubes placed in the set. With both filament rheostats (R2 and R3) turned to the left or "Off" position, and the "On-Off" switch turned on, the two audio amplifier tubes (V7 and V8) and the detector tube (V6) in the time-signal amplifier should light. With the filament rheostat (R2) turned slowly to the right, the first detector and oscillator tubes (V1 and V2) should light; and with the "Gain" knob to the right, the three 222-type tubes in the screen-grid amplifier should light. The three flexible leads with clips should, of course, be attached to the top caps of the 222-type tubes in the amplifier.

To operate the receiver, the filament rheostat (R2) should be turned half-way on, the "Sensitivity" knob of the midget condenser (C3) should be turned absolutely all the way out, and the "Gain" or potentiometer knob (R3) turned in a central position. If the oscillator dial is now rotated, no squeals should be heard; should they be, it will indicate oscillation of the intermediate amplifier. This would possibly be correct in the case of certain individual tube variations, in which event the "Gain" knob should be turned slightly to the left or right, until oscillation stops and rotation of the oscillator drum produces no squeals. The receiver may now be tuned as a regular superheterodyne, the Antenna and Oscillator dials serving to select stations. As mentioned previously, stations between approximately 215 and 455 meters will be heard at two points upon the oscillator dial. In preliminary testing, some station between 440 and 460 meters should be tuned in for best response on both dials. It will be observed that while the station can be heard at two points on the Oscillator dial, one point will be stronger than the other. Which of these points is strongest is de-

(*Continued on page* 158)

The Supreme A.C. Six Receiver

IT seems as if every important development is preceded by an enormous public demand, and the batteryless radio receiver is no exception to this rule. Even in the early days of radio, the set owners grumbled about battery troubles. As a result, "B" eliminators were introduced and perfected, but the storage "A" battery still remained to cause bother and annoyance. Trickle chargers helped the situation somewhat, but the advent of the new A. C. tubes has now made it possible to operate the radio receiver direct from the lamp socket without the help, or one might say the hindrance, of any batteries at all.

While it has been the purpose of the tube manufacturer to design the A. C. tubes with characteristics similar to those of the battery operated tubes, it is natural to assume that a circuit planned to take advantage of the peculiarities of the new tubes would give especially good results. This happens to be the case with the set described herewith. The fundamental circuit of this receiver consists of two stages of balanced tuned radio frequency amplification, a detector, one stage of transformer coupled amplification and a push-pull amplifier in the last stage. Standard apparatus is used throughout and parts have been selected especially for their adaptability for use in connection with the A. C. tubes. Slight differences between stages may be compensated for by the three small compensating condensers. A phasatrol is used in each R. F. stage to eliminate any tendency to radio frequency oscillation or distortion. Volume is controlled by means of a 75-ohm rheostat shunted around a portion of the primary of the first R. F. coil.

The combination of transformer, and 171 push-pull amplifier in the last audio stage, gives the receiver plenty of volume, while the superior tone quality furnishes another reason for naming this set. "The Supreme A. C. Six."

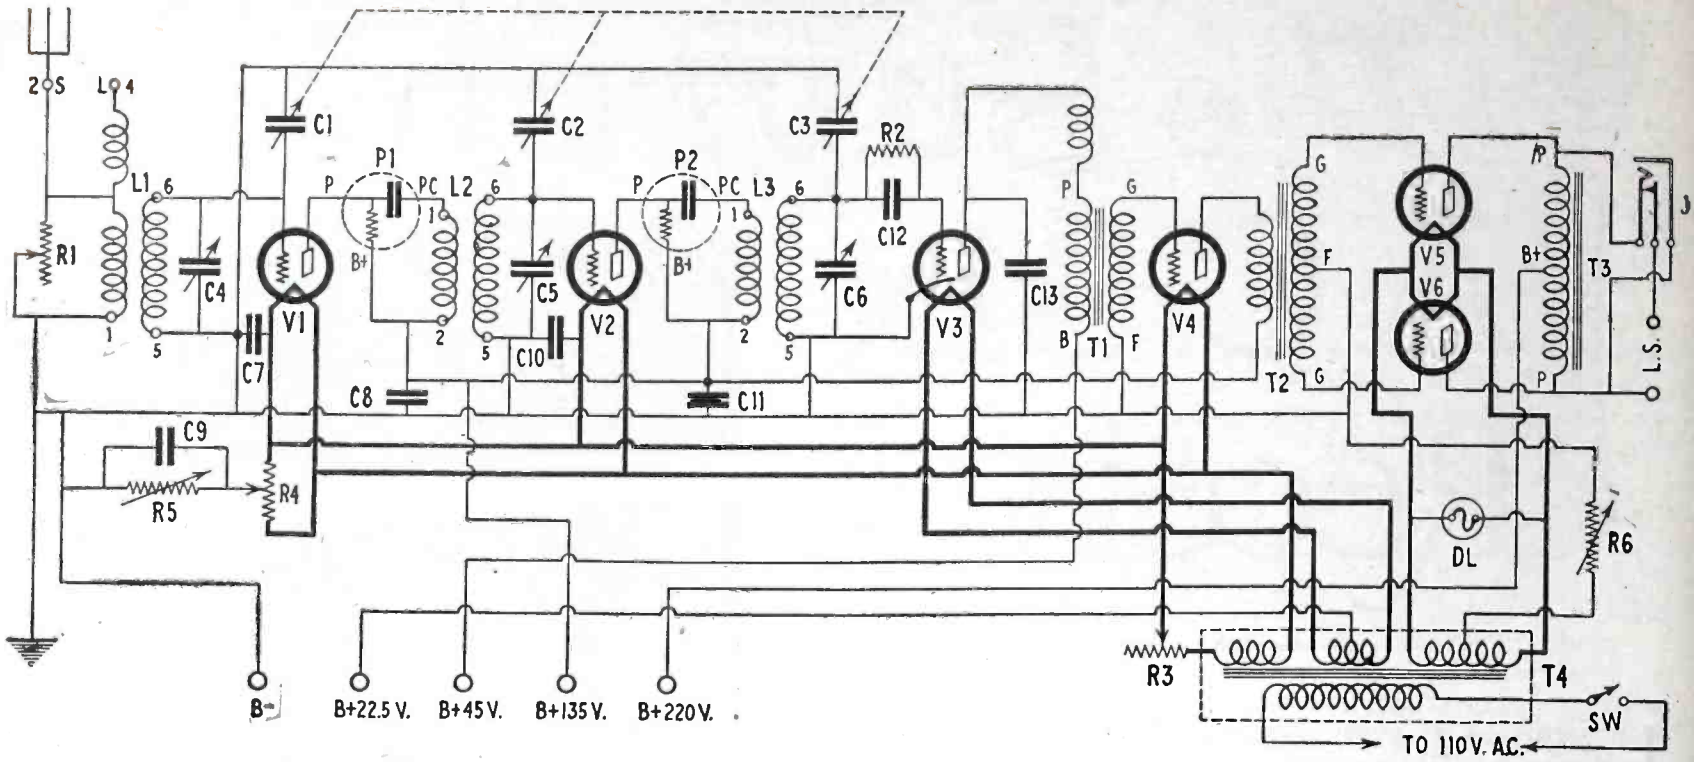
LIST OF PARTS

- 3 Aero R. F. coils, type U-12, L1, L2, L3.
- 1 Hammarlund Mid-Line condenser, .0005 mfd., C1.
- 1 Hammarlund Dual Mid-Line condenser, .0005 mfd., C2, C3.
- 1 National or Mar-Co vernier dial.
- 3 X-L variodensers, model "N," C4, C5, C6.
- 1 Thordarson, type R-200 transformer, T.
- 1 Thordarson input transformer, type T-2408, T2.
- 1 Thordarson output choke, type T-2420, T3.
- 1 Thordarson A. C. tube filament transformer, type T-2445, T4.
- 2 Electrad Phasatrols, P1, P2.
- 2 Electrad variable resistors, type "F," R5, R6.
- 5 Acme by-pass condensers, ½ mfd., C7, C8, C9, C10, C11.
- 1 Polymet by-pass condenser, .001 mfd., C13.
- 1 Samson R. F. choke, No. 85, L4.
- 1 Polymet grid condenser, .00025 mfd., C12.
- 1 Durham metallized grid leak with mounting, 2 meg., R2.
- 1 Yaxley 10 ohm rheostat, type 110-K used as potentiometer, R4.
- 1 Yaxley 2-circuit jack, No. 2-A, J.
- 2 Yaxley Pup jacks.
- 5 Eby tube sockets UX type.
- 1 Eby tube socket, UY type.
- 2 Rolls Acme Celatsite wire.
- 1 Carter ½ ohm rheostat type IR-X5, R3.
- 1 Carter 75 ohm rheostat type IR-75, R1.
- 1 Carter power switch, SW.
- 3 X-L binding posts.
- 6 Ft. Cornish 5-wire cable.
- 1 Can Kester rosin core solder.
- 1 Formica panel, 7x26x3/16 in.
- 1 Formica sub-panel, 10x24½x3/16 in.
- 4 Benjamin or Karas brackets.

A special filament supply transformer furnishes correct voltages to the various tubes. Since the 227 detector tube is not critical as to filament voltage, no variable resistance is used in this portion of the circuit for voltage control. Due to the separate heater element, the grid return is not critical, so that a center tap on the transformer winding is used for this purpose.

A ½-ohm rheostat is placed in series with the 1½-volt winding to compensate for line voltage differences, since the 226 tubes are quite critical as to filament voltage. Grid return for these tubes must be brought to the point of exact potential balance of the filament voltage, thus necessitating the use of the 10-ohm potentiometer. Negative grid bias for the 226 tubes is secured by means of a 2,000-ohm variable resistance connected between the mid-tap of the potentiometer and "B" minus. A negative grid bias of 40 volts is obtained for the 171 tubes by means of the 2,000-ohm variable resistance, R6, connected between the center tap of the input transformer and the center tap of the 5-volt winding supplying the filaments of the 171 tubes. With 220 volts applied to the plates of the 171 tubes, the net voltage across plate and filament of these tubes will be 180 volts.

A power switch is connected in series in the primary circuit of the



Schematic wiring diagram of the set. Variable condensers, C1, C2 and C3 operate on the one shaft, making the set uni-controlled.

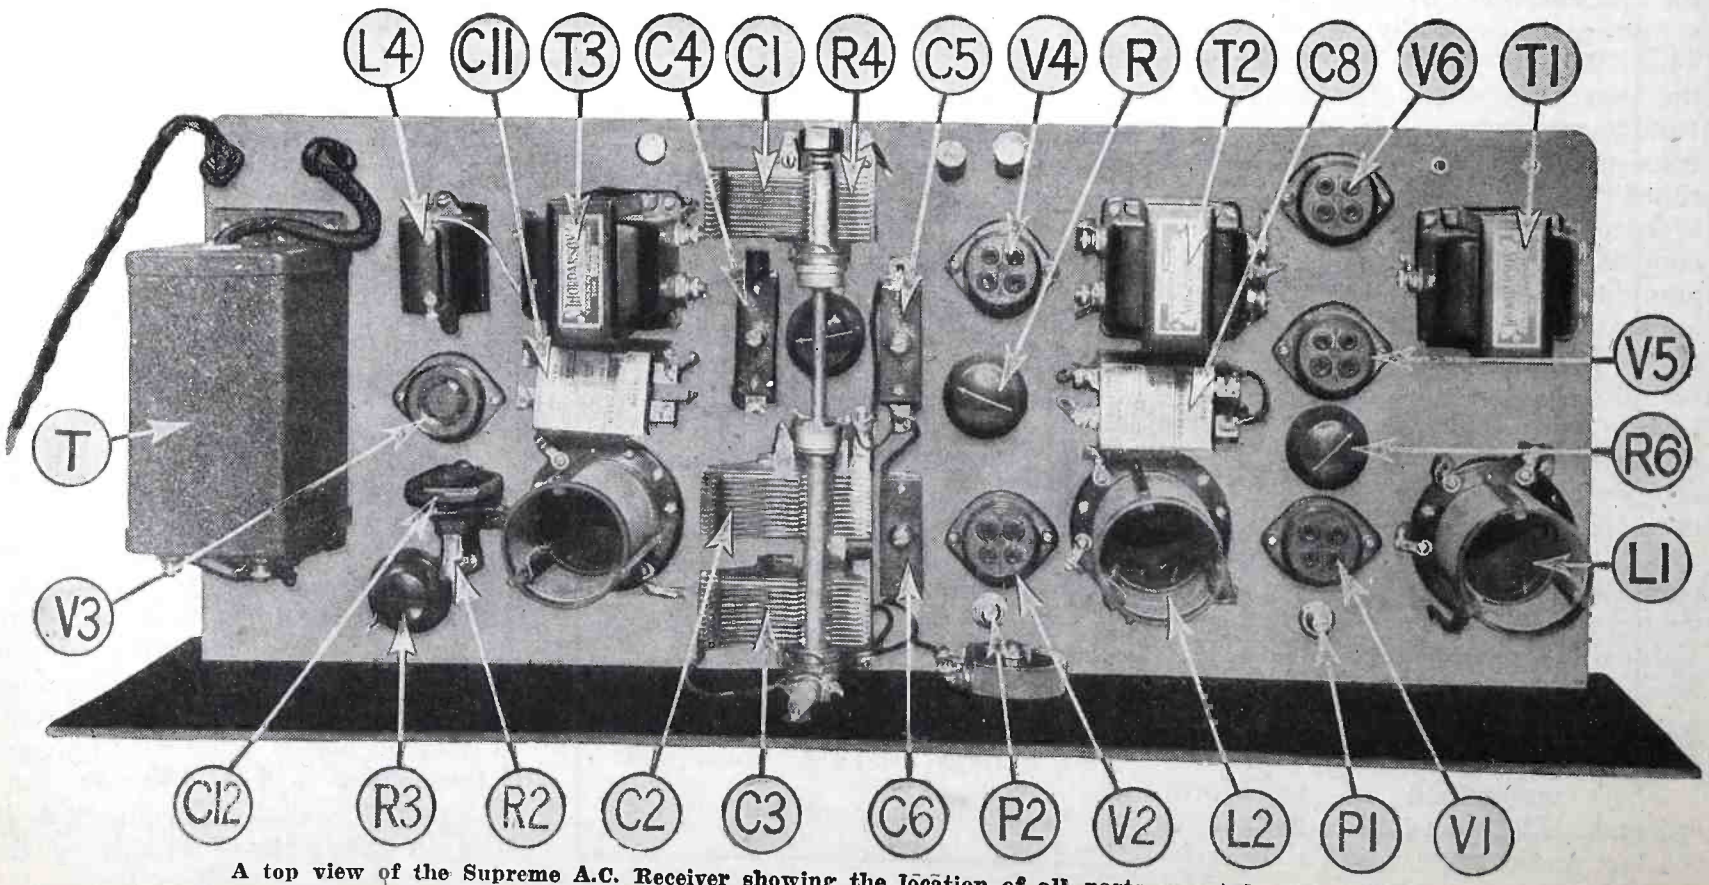
filament supply transformer. Filament leads are twisted separately and it is desirable to use a heavier gauge wire for these leads to prevent voltage drop, due to the resistance of small diameter wire.

The first step in assembling the Supreme A. C. Six, is to cut the sub-panel to the correct length of 24½ inches. The four low brackets are next fastened to the sub-panel. Two of the brackets are placed at the ends of the sub-panel (at a distance of approximately 1¼ inches from each end), while the other two are located 7¾ inches from each end, respectively.

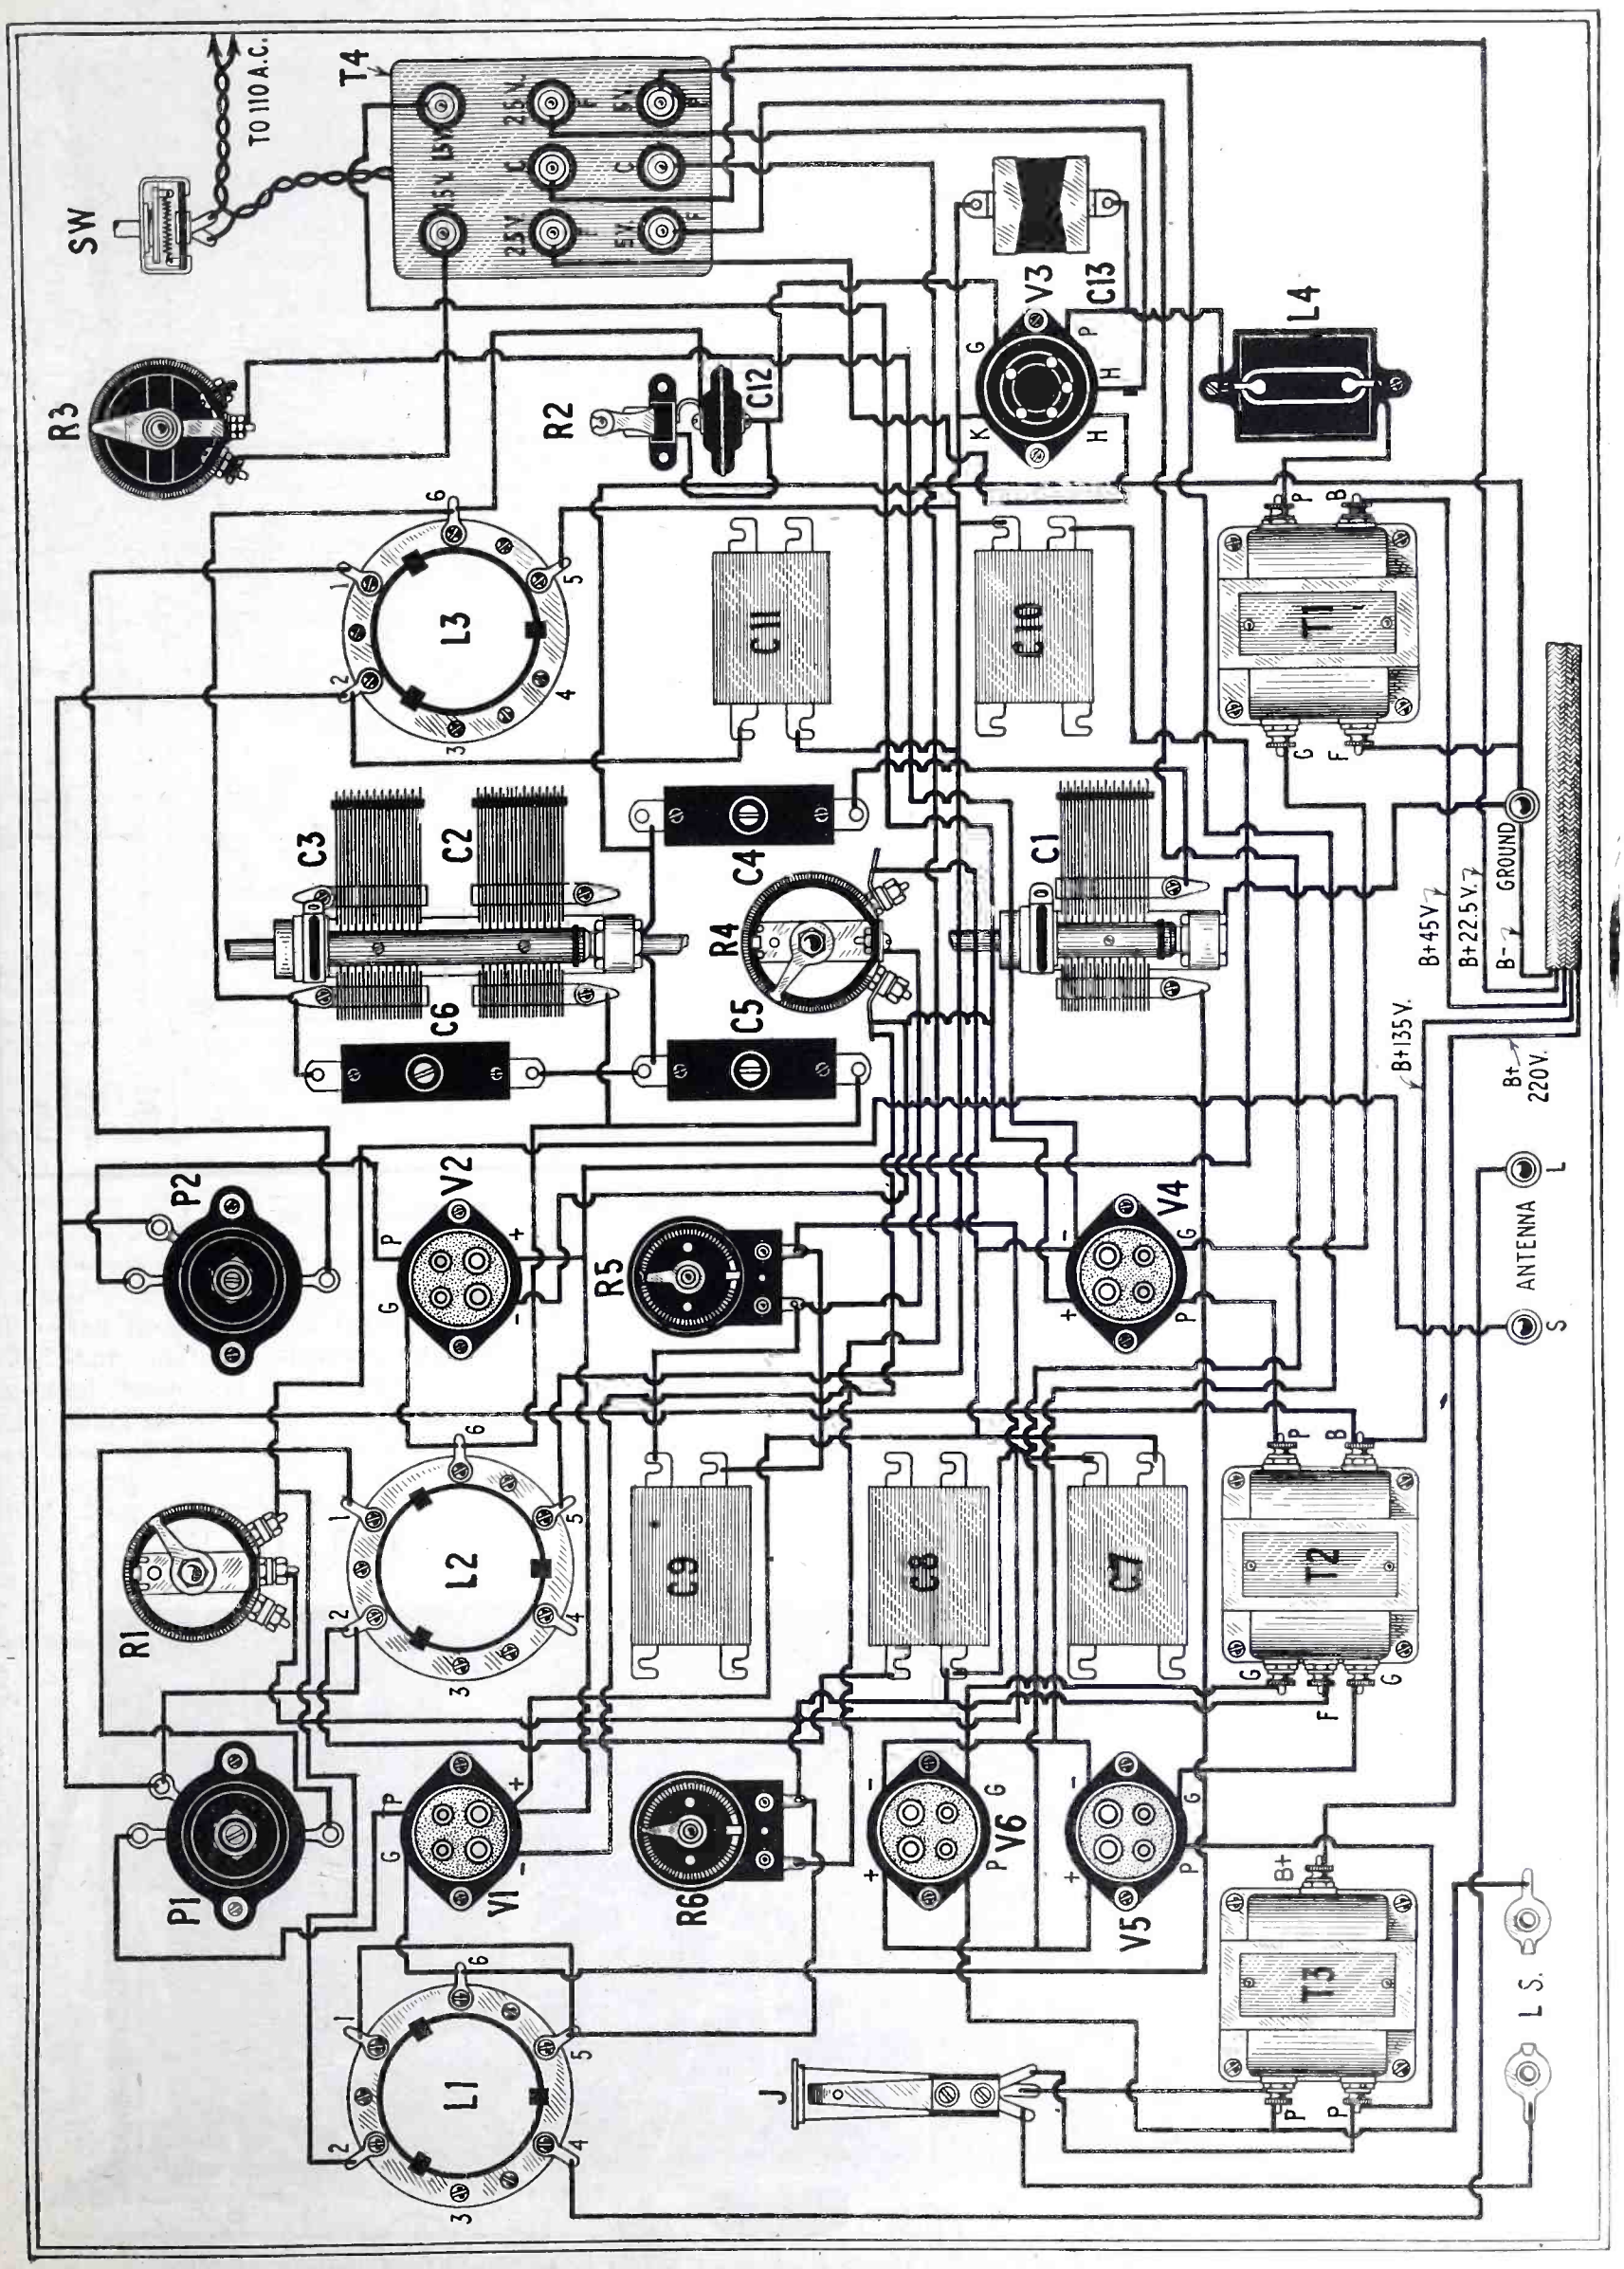
The variable condensers are then mounted with the shaft centers on a line 11½ inches from the right edge of the sub-panel (facing rear of panel). The dual condenser is located with its front bearing flush with the (panel) edge of the sub-panel, while the single condenser is mounted with its rear bearing flush with the rear edge of the sub-panel. This leaves a distance of about 2⅜ inches between the condensers. The shaft of the dual condenser is moved forward, while the shaft of the single condenser is replaced by a longer shaft, which is rigidly attached to the dual condenser by means of the rear shaft set screw on the dual condenser. In this way the condensers are "ganged" for single dial control.

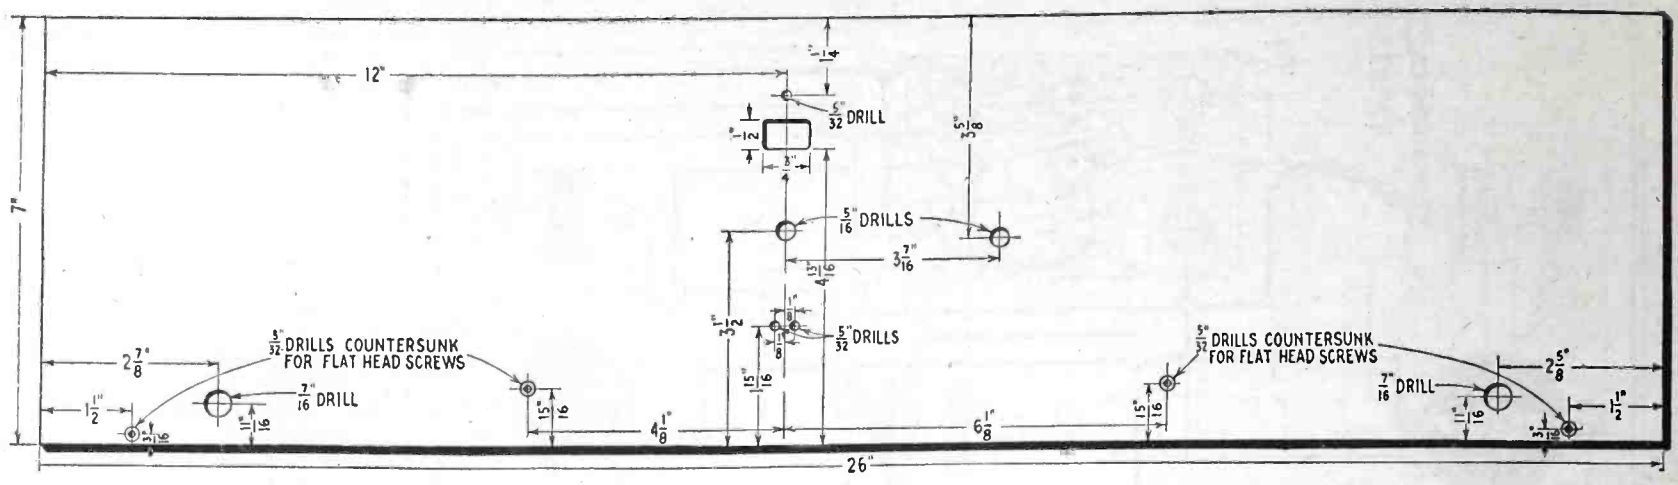
The tube sockets and the two phasatrols are mounted as shown in the photo and diagram of the top view. The audio transformer, the input transformer and the output choke are mounted in a row at the rear of the sub-panel, about 1⅜ inches from the rear edge. The compensating condensers are placed at each side of the variable condensers, as shown.

The four by-pass condensers are next mounted. Condenser, C8 is placed directly on top of C7, while C11 is placed on top of C10. Next a R. F. choke may be mounted between transformer, T and choke, T3, as seen in the photo. The single resistor mounting for the grid leak, R2, is then mounted. The by-pass grid condenser, C12, is fastened to the mounting.

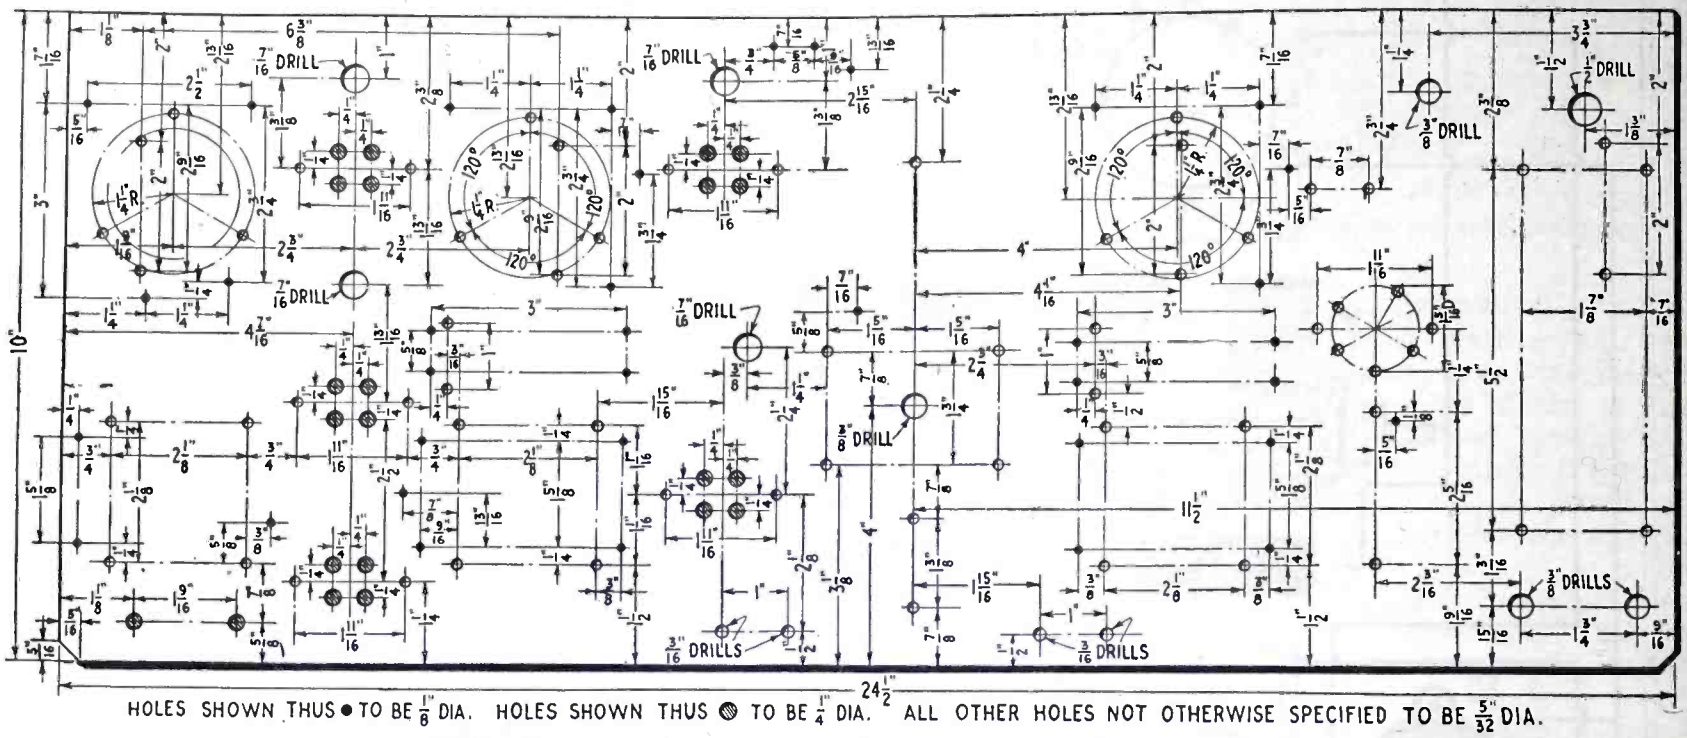


A top view of the Supreme A.C. Receiver showing the location of all parts mounted on the sub-panel.





Directly above is the layout for drilling the front panel.



HOLES SHOWN THUS ● TO BE 1/8" DIA. HOLES SHOWN THUS ⊘ TO BE 1/4" DIA. ALL OTHER HOLES NOT OTHERWISE SPECIFIED TO BE 5/32" DIA.

Drilling layout for the sub-panel of the Supreme A. C. Six Receiver.

Holes are now drilled for resistances and potentiometer and these parts are then mounted. Holes for the binding posts are also drilled at this time and posts are mounted. Next the holes are drilled for the filament supply transformer. The two fixed condensers are fastened beneath the sub-panel as shown by the dotted lines on layout herewith.

The panel is then placed flat, with the sub-panel in position, and holes are drilled for fastening brackets to panels, and also for fastening dual condenser to panel. Holes are also

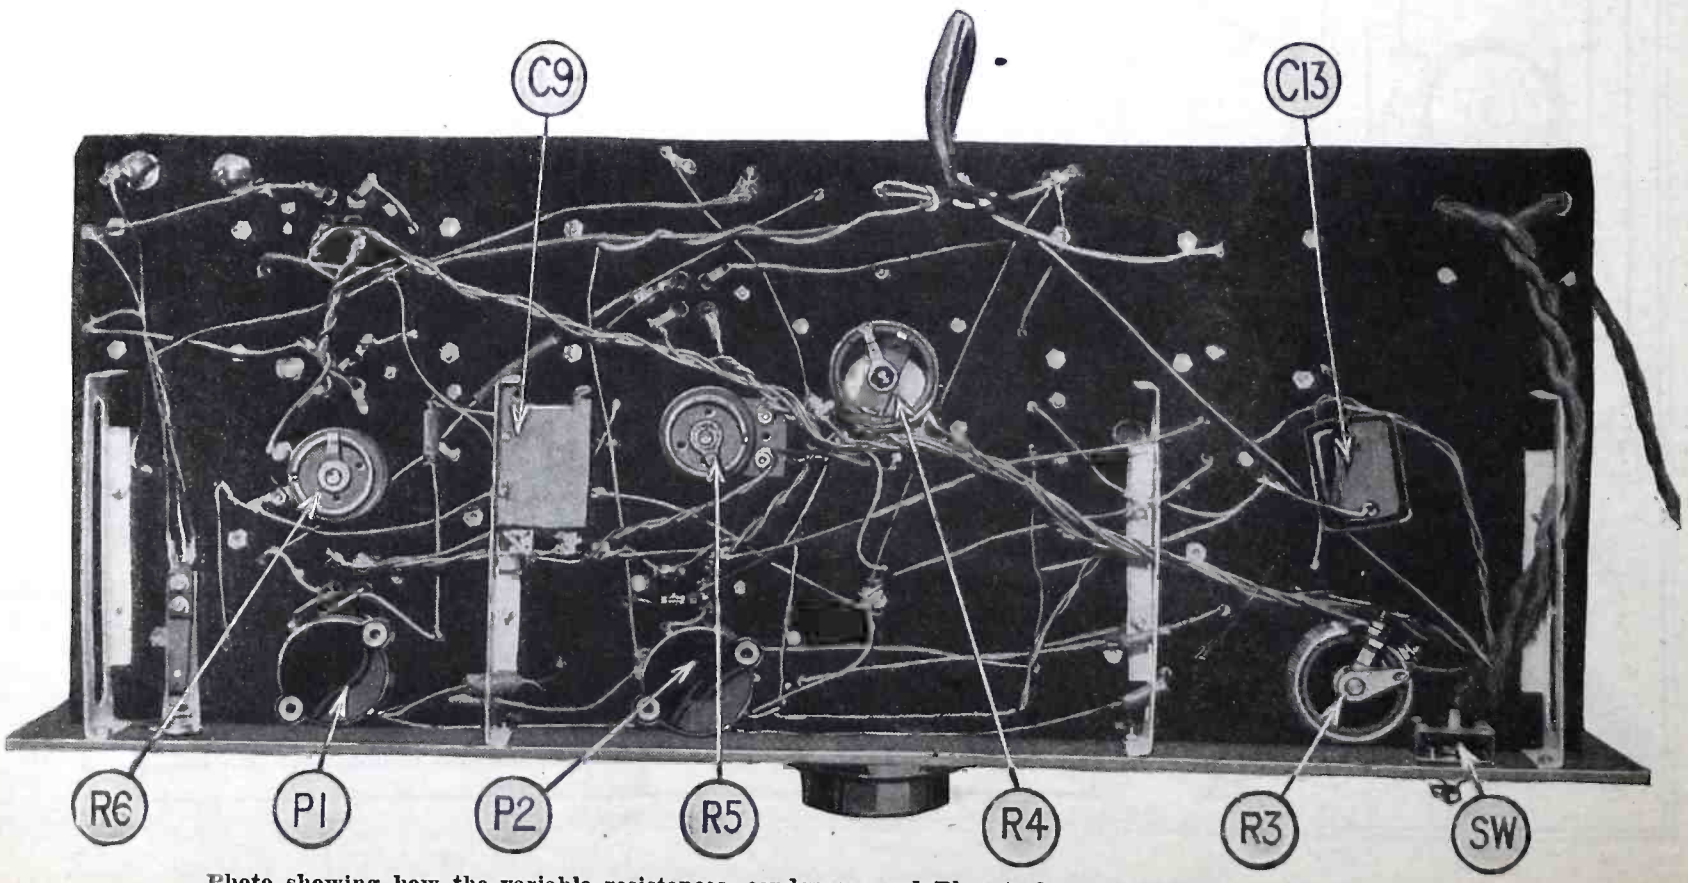


Photo showing how the variable resistances, condensers and Phasatrols are mounted beneath the sub-panel.

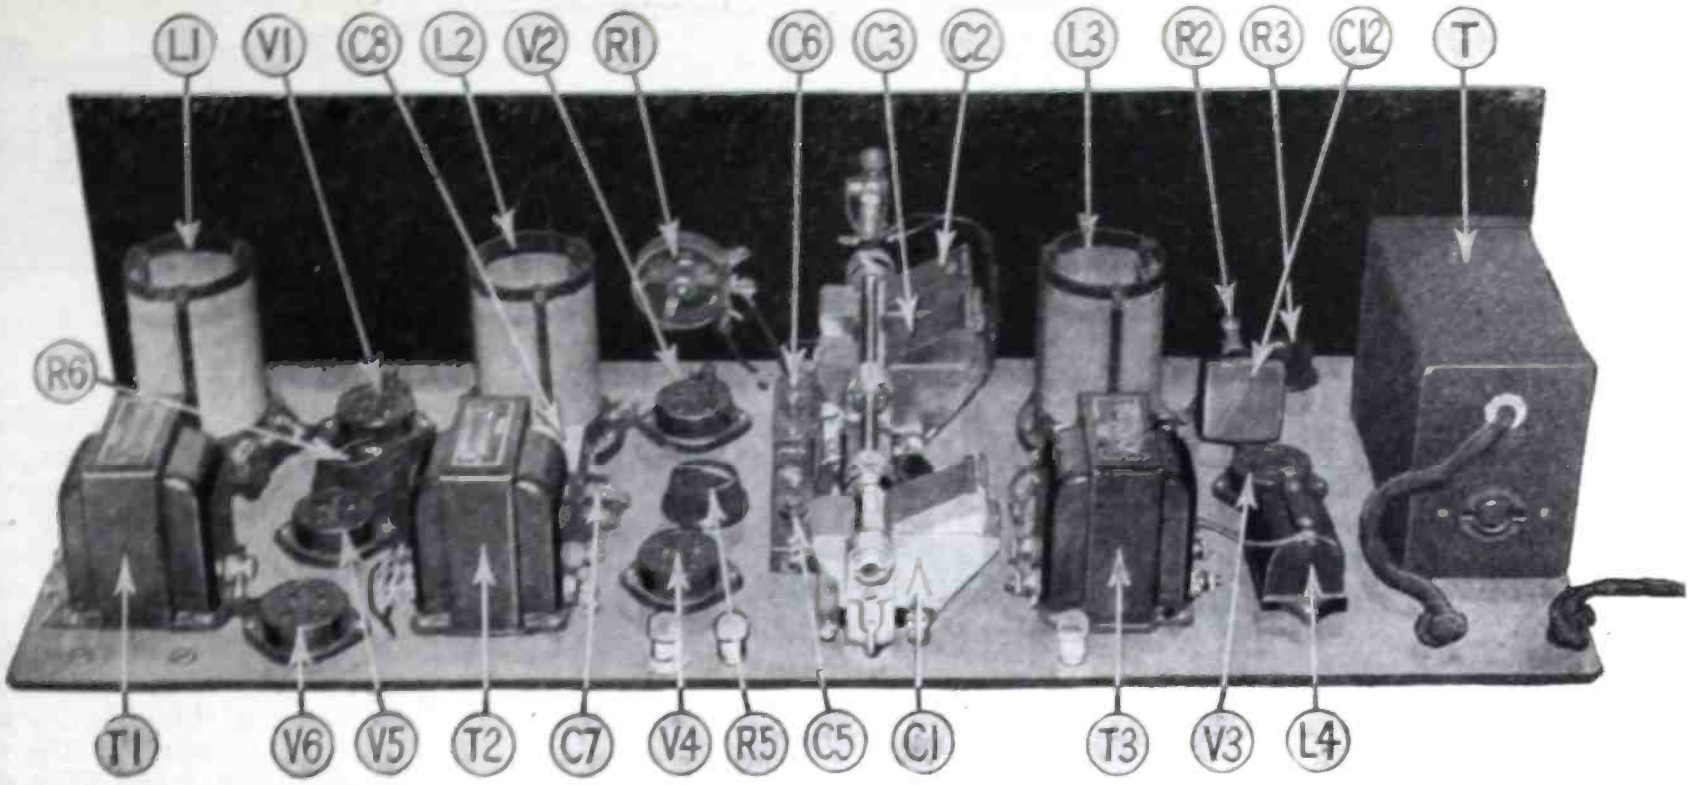

A rear view of the set. All parts are lettered to correspond with diagrams and list of parts.

drilled in the panel for the volume control rheostat, the power switch and jack. The volume control is located at 3½ inches to the right of the dial center line.

The three R. F. coils, L1, L2 and L3 are mounted on the sub-panel as shown. Holes are then drilled for the phone tip jacks and these are mounted. Holes are also drilled for the power cord and filament leads.

The panel is fastened to the sub-panel and the filament transformer is mounted on the sub-panel. Holes are drilled in the panel for the panel light and for the dial fastening screw and the dial is fastened to the panel. Practically any well made dial can be used on the set providing it gives vernier adjustment.

The wiring should be performed with flexible hook-up wire, using rosin core solder in making joints. The following sequence should be followed:

First: Wire all grid circuits, up to negative return.

Second: Wire all plate circuits to "B" plus terminals of apparatus.

Third: Wire "B" minus and all negative returns.

Fourth: Connect the twisted 1.5 volt filament leads to the first and second R. F. and first audio sockets.

Fifth: Connect the twisted 3-volt lead to the detector socket.

Sixth: Wire in the twisted filament leads to sockets V5 and V6.

Seventh: Wire all the "B" plus leads from apparatus terminals to the cable mounting.

Eighth: Connect the by-pass condensers in the circuit.

Ninth: Wire in the jack and phone tip jacks.

Tenth: Wire in the antenna circuit, with volume control and ground binding post.

Eleventh: Wire in the panel light with twisted leads.

It should be noted that the small figures shown at coil terminals of L1, L2 and L3 correspond to the same markings on the R. F. coils.

To place the Supreme A. C. Six in adjustment, first tighten up the compensating condensers C4, C5, C6, as much as possible. Then unscrew all of them four turns each. Turn all the phasatrols all the way to the right. Set the potentiometer, R4 to approximately mid-point. Turn bias resistor R5 to about mid-point. Next, turn the power switch "on" and rotate the dial until a station is heard. A hum may be present. If there is no hum, turn the R. F. bias resistance, R5, until hum is heard.

(*Continued on page* 157)

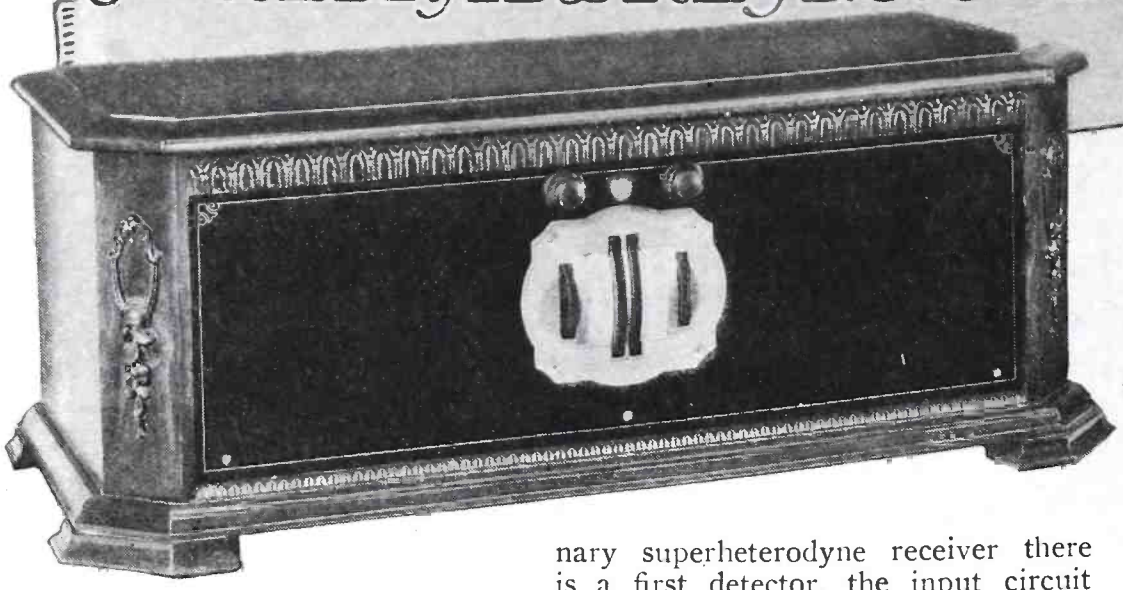
The ULTRADYNE A.C. COMMANDER



ONE of the greatest tests of a radio receiving circuit is that of time. Those readers who have been in the game since the beginning of broadcasting will remember the deluge of new circuits that were continually forthcoming, but how many of those circuits are remembered today, and furthermore, how many of the remembered circuits are being used? You could count them on the fingers of your hands.

As has been said this matter of time is an important one by which a circuit can be judged. If a circuit or a principle has remained in use when the field has been flooded with new circuits and principles, then that old timer must be something of real worth. And that is exactly the case with the set described in this article. The principle underlying the whole thing is good and having been proved good has been in use for four or five years, which incidentally is a long time for such a thing in the realm of radio.

The circuit in this set has as its underlying principle the superimposition of one frequency upon another —the superheterodyne. However, there are some features of this receiver not found in the usual run of superheterodyne sets. For example, instead of feeding the signals from the antenna directly to the first detector, there is a stage of tuned radio-frequency amplification in the input circuit. This increases the efficiency greatly. Then, too, the "modulation" system is employed, replacing the first detector. Above all this, though, the set has been adapted to the use of alternating-current tubes, which fact in itself is a boost for any set.

Let us examine this system of modulation more closely. In the ordinary superheterodyne receiver there is a first detector, the input circuit of which is coupled directly to the antenna circuit and whose plate circuit is connected to the input of the intermediate-frequency amplifier. To this tube is coupled the oscillator tube through a pick-up coil or some other means. Now the frequency of the oscillator circuit must be such that when it is beat with the incoming signal-frequency, the result will be a frequency for which the intermediate transformers have been especially designed, i.e., they operate most efficiently at that frequency or rather band of frequencies. The first detector tube has to fulfill more than one function; it must mix, as it were, the signal frequency with that of the oscillator, rectify the resulting beat note and then transfer it to the intermediate-frequency amplifier.

The modulation system employed in this receiver operates differently and more efficiently. It will be seen upon reference to the circuit diagram of the receiver that the plate of the modulator tube is not connected to a "B" battery but to the grid circuit of the oscillator tube through the primary of the first intermediate-frequency transformer. Therefore the frequency of the oscillator is impressed directly on the plate of the modulator. Now the signal frequency after being first amplified in the radio-frequency tube modulates the oscillator frequency and produces a band of frequencies for which the intermediate transformers are designed. Therefore, it can be seen that no rectification occurs in the modulator tube. By this system a very minute amount of current will cause the system to function and therefore the set will respond to distant signals, which an ordinary superheterodyne receiver would never detect.

Another interesting fact is that the sensitivity is greatly increased by the use of the stage of tuned radio-frequency amplification. Also the selectivity is increased.

The intermediate-frequency amplifier is designed to function at 113 kilocycles (2650 meters). The intermediate-frequency transformers (Ultraformers) are of the air-core type, having their secondaries tuned to the designated frequency by small condensers.

The first thing to do when laying out the receiver is to drill the sides of the aluminum shields for the mounting of the variable condensers. The greatest care should be exer-

LIST OF PARTS

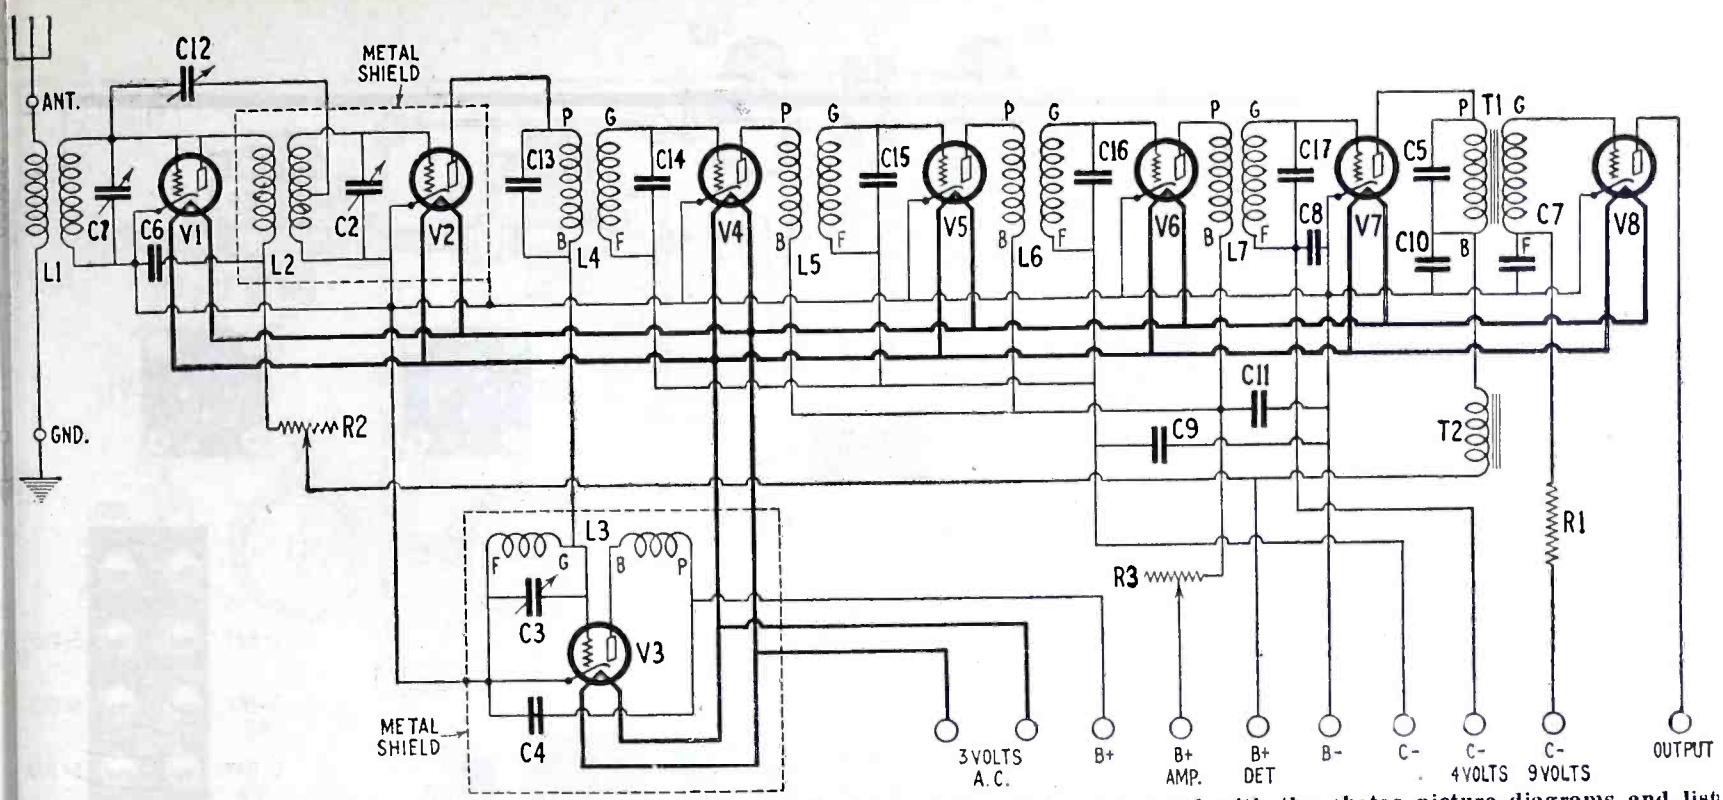
- 2 Hammarlund extension shafts.
- 1 Hammarlund flexible shaft coupling.
- 1 Wooden baseboard, 12x25½ in.
- 1 Carter switch No. 110, S.
- 8 Sovereign A. C. tubes, V1, V2, V3, V4, V5, V6, V7, V8.

Miscellaneous lugs, nuts, screws, bolts.

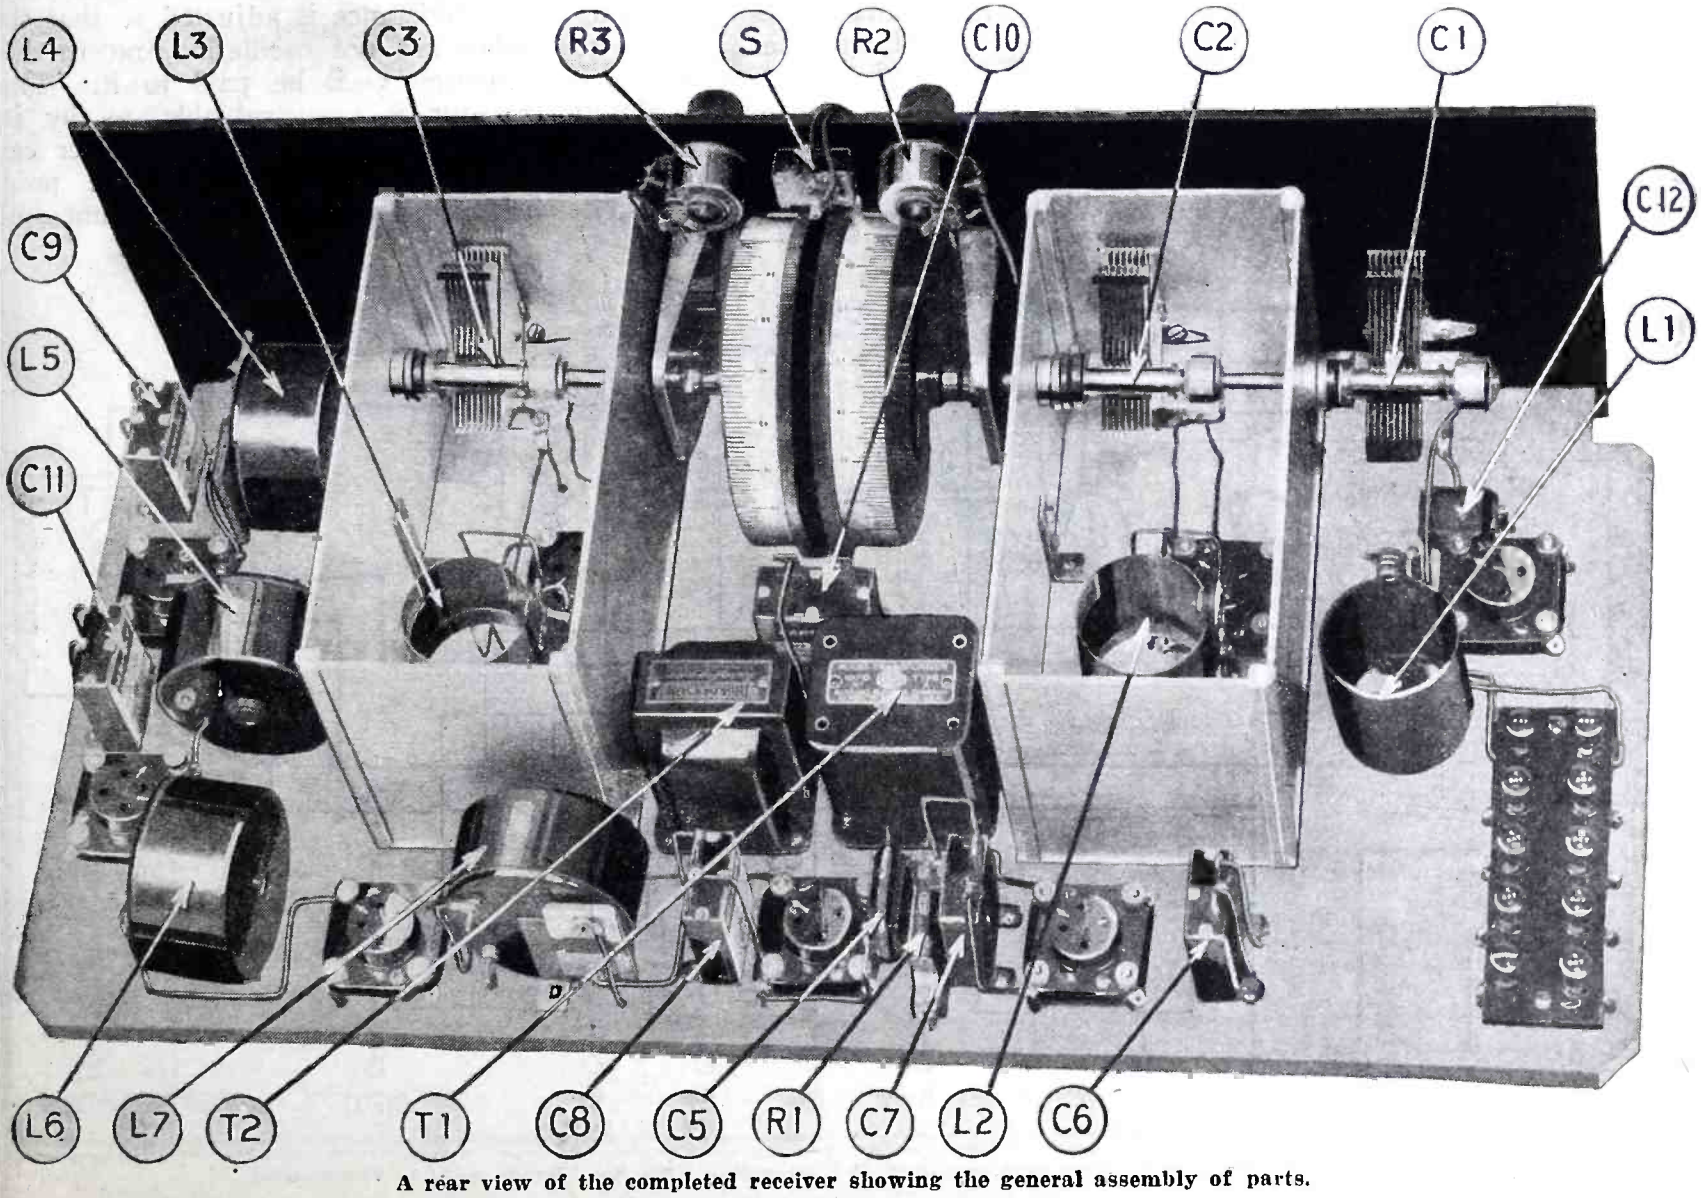


Schematic wiring diagram of the Ultradyne A. C. Commander. All parts are indicated to correspond with the photos picture diagrams and list of parts for the set.

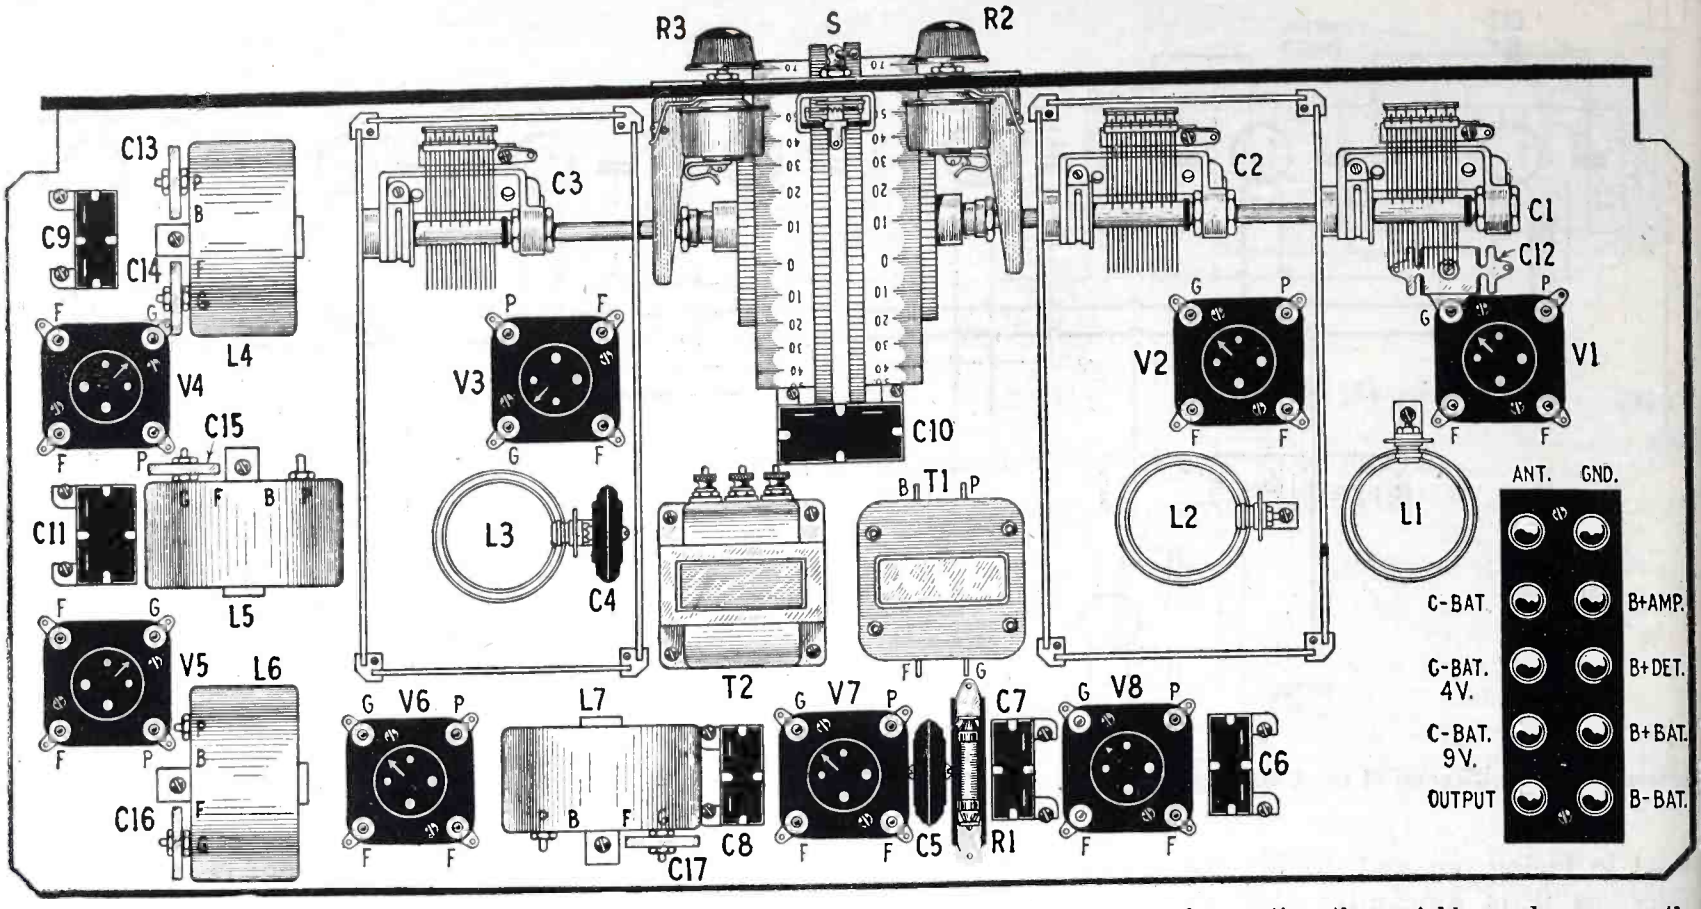
cised in laying out and drilling these holes, as it is imperative that they line up exactly. Use an accurate scale when measuring the distances, for if these holes are not aligned accurately the condensers' shaft will not fit into the drum dial.

The next step is to drill the front panel, but this is not difficult as there are comparatively few holes. The hole for the drum dials, if no "fly cutter" is available, may be made by drilling a series of small holes around a circle inscribed on the panel and then cutting out with a small saw the remaining spaces between them. The hole can be trued up by using a half round file. The various pieces of apparatus are next placed on the wooden baseboard and mounted in place by means of wood screws. The baseboard should be one-half inch thick.

The apparatus that is mounted on the front panel should be fastened to it after the panel has been mounted on the wooden baseboard which should be at least one-half inch thick. Care must be taken in the mounting of the condensers and



A rear view of the completed receiver showing the general assembly of parts.



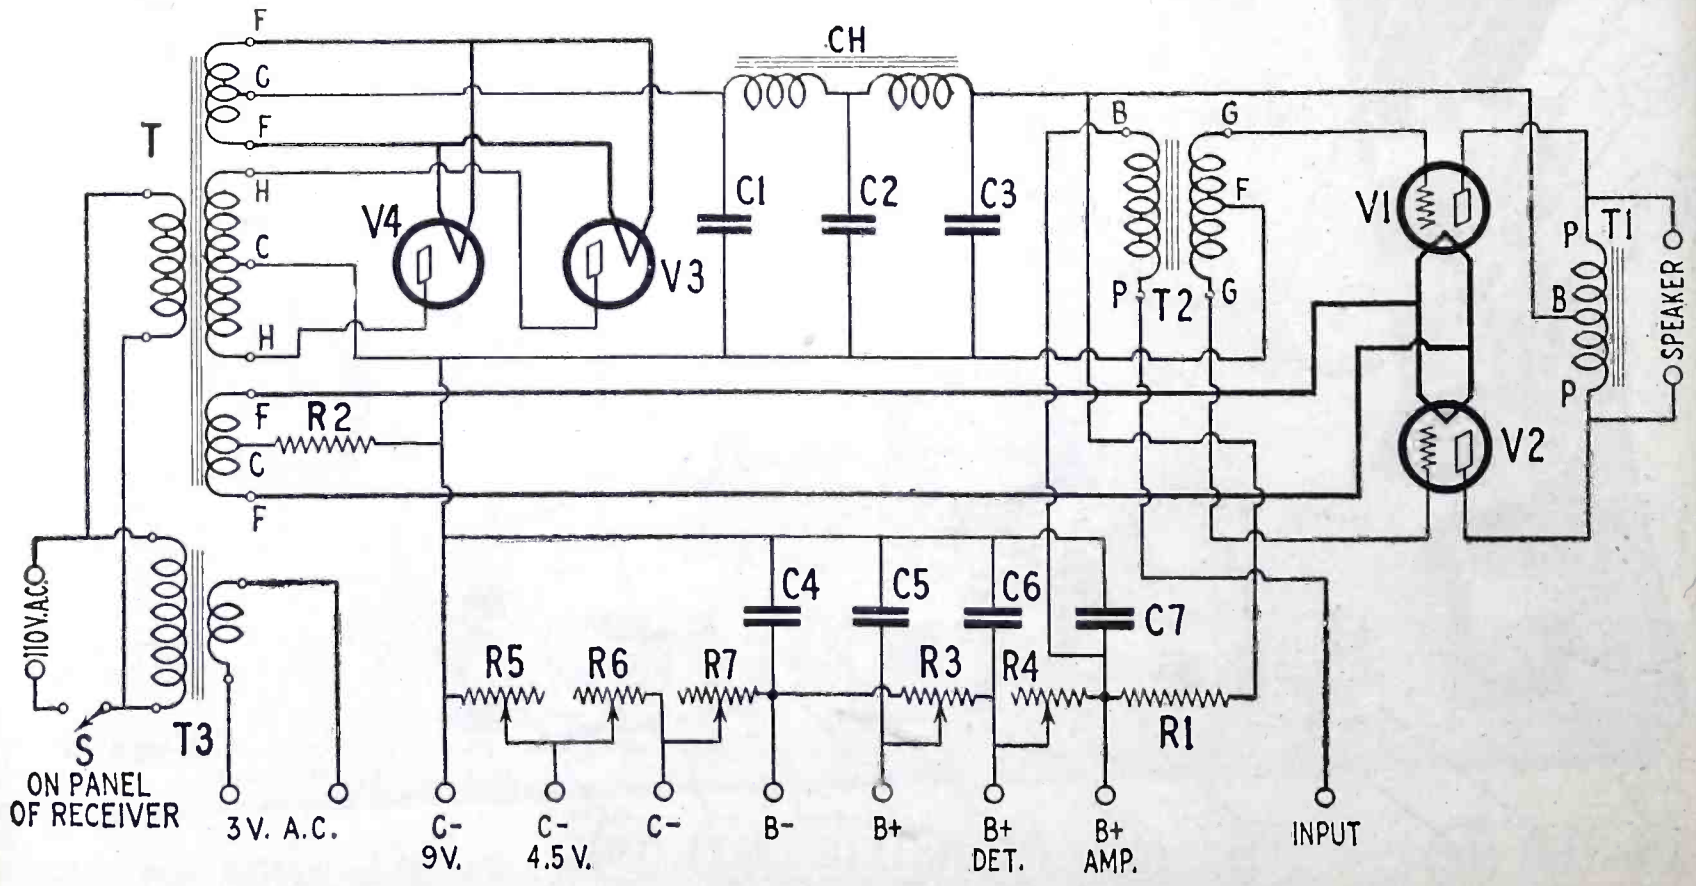
The above layout shows how all parts are mounted on the baseboard and panel. Note the method of mounting the variable condensers on the walls of the aluminum shields.

drum dials so that they line up perfectly and therefore will operate smoothly. Next the other apparatus is mounted by means of wood screws to the baseboard, following the layout that is shown herewith. As may be seen some of the wiring is run under the baseboard and therefore holes have to be drilled at the proper places to permit this.

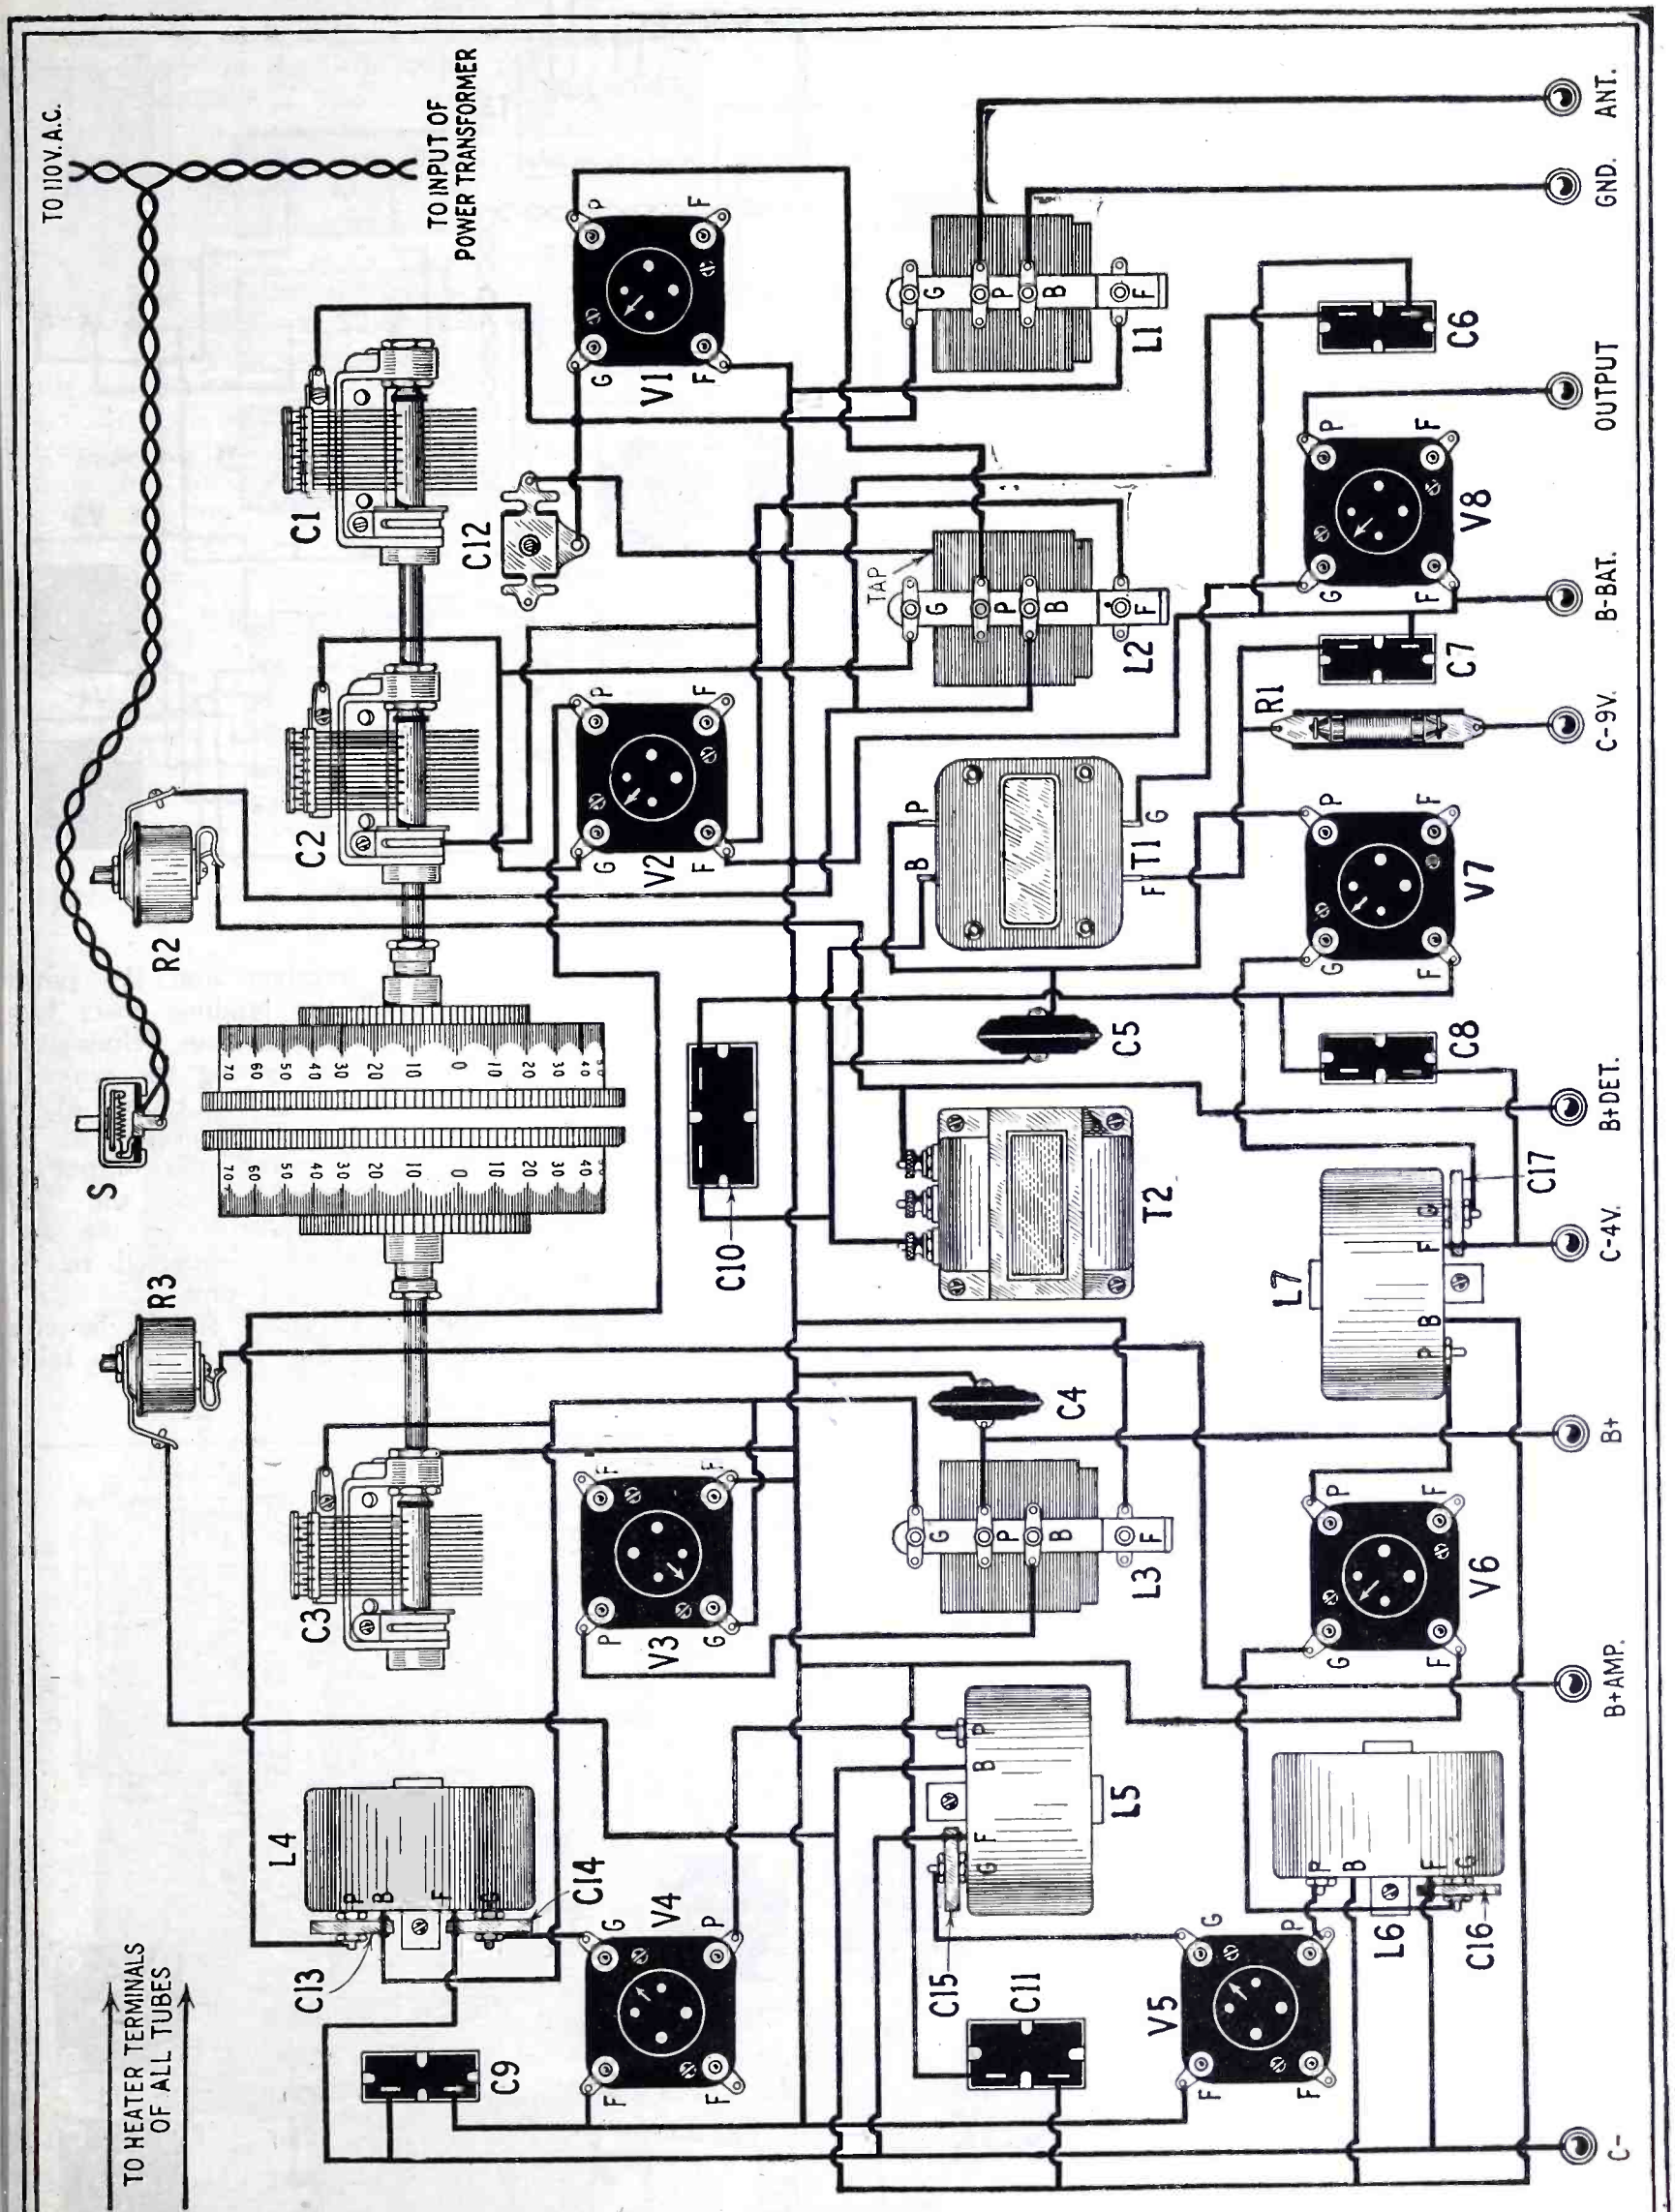
The constructor will find that the wiring diagram given is a great aid. When the set was designed and built thought was given as to just how each wire should be run in order to get the best results. Therefore the constructor is advised to follow this diagram as closely as possible.

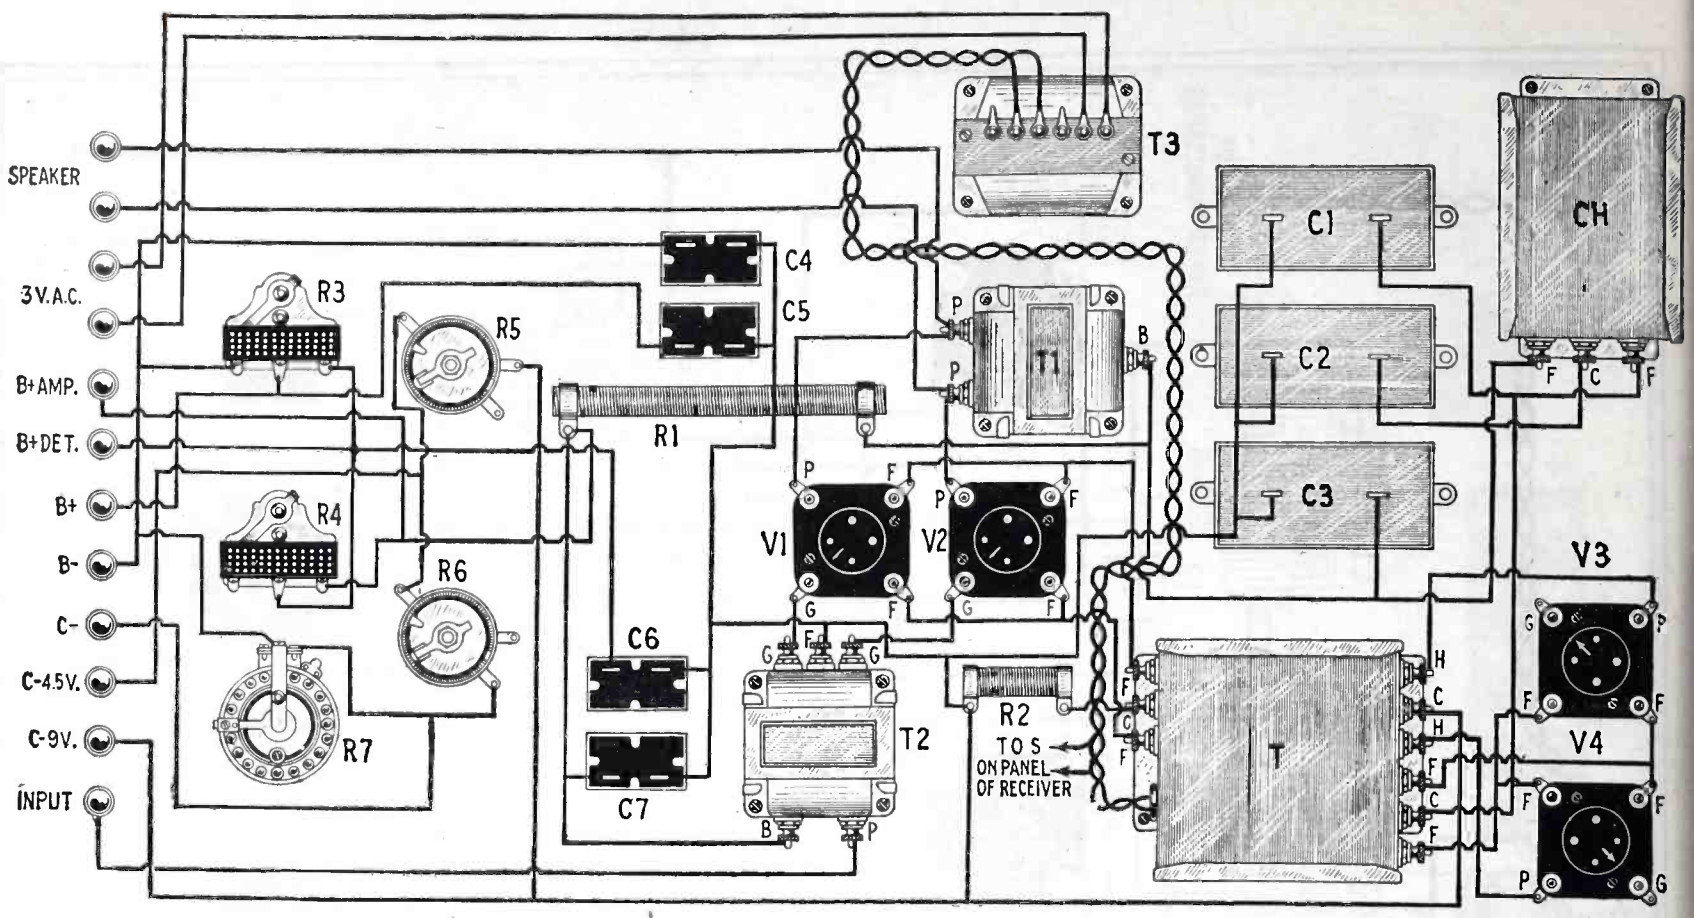
Since the volume cannot be varied by changing the filament current of the tubes, a variable resistor is placed in the plate circuit of the radio-frequency amplifier tube. This is an ideal position for the control as it cuts down the signal energy almost at the very start and so does not overload any of the following tubes, which might be the case when listening to a local station, and thereby cause distortion.

In order to eliminate all chance of the tubes in the intermediate amplifier oscillating, another variable resistor is incorporated in the plate circuit of these tubes. When once this resistance is adjusted so that the tubes are not oscillating, no further attention need be paid to it. This resistor is very valuable, as by its means the tubes in the amplifier can be brought right up to the point of oscillation, but they will not spill



Schematic diagram of the power unit employed in conjunction with the Ultradyne A. C. Commander.





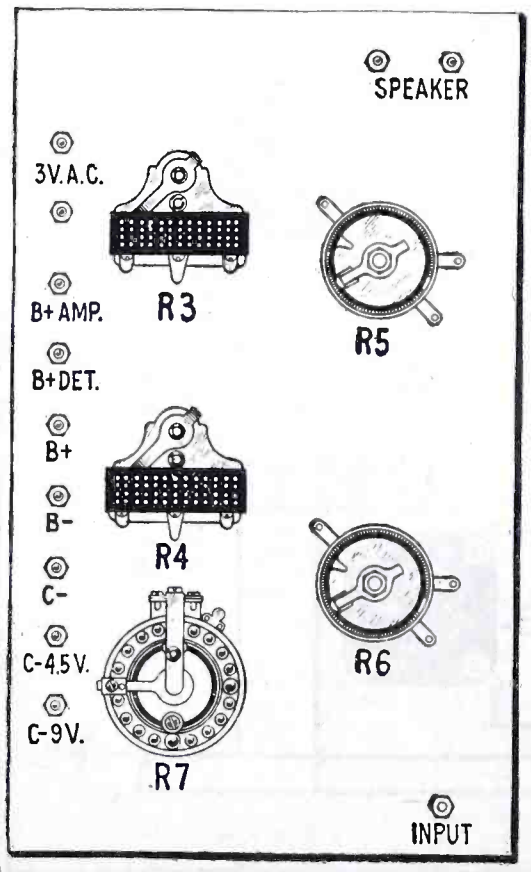
The diagram above shows in picture form how parts of the power unit are wired.

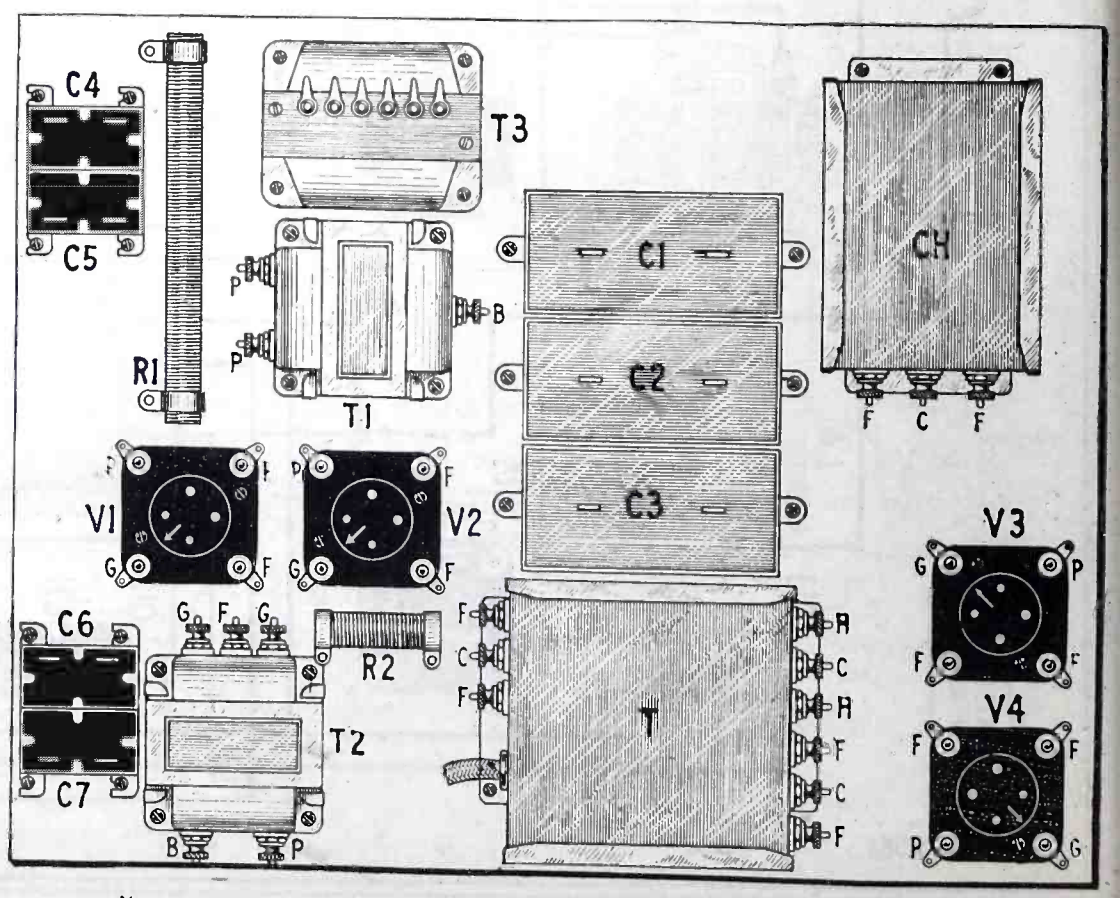
over. As this will aid greatly when hunting for DX stations this is really a sensitivity control.

The first step in building the power unit for operating this receiver is to drill the front panel on which are mounted the resistors and binding posts. This panel is then mounted on a wooden baseboard on which the rest of the apparatus is placed. Here none of the wiring need be run beneath the baseboard, as there is comparatively little to do. Follow carefully the layout plans shown, as in this way the wires carrying the power will be in the best place.

It is a good idea to use busbar when wiring the unit as it is stiff and will therefore stay in place. Also connections carrying high voltage should be covered with spaghetti tubing, eliminating any danger of getting a shock if they should be touched accidentally. There is little work in making the connections between the receiver and the power unit as all the binding posts have similar markings, thus eliminating any chance of getting the wires in the wrong place. The output of the set is of course connected to the input of the unit, the output of which is connected to the loud speaker. The heaters of the set's A. C. tubes are connected to the A. C. posts on the unit.

The A. C. tubes should be connected with the supply leads taken





At the left shows how the variable resistors of the power unit are mounted on the panel while at the right shows the arrangement of parts on on the baseboard.

in the center so that four tubes are connected to each side of the main leads. This is done in order that the distribution of the current can be evened up along these leads.

To operate the set, all the resistors on the power unit are adjusted so that the arm is about in the middle of each one. This should permit the set to operate at first. When the tubes are functioning correctly then the resistors can be readjusted in accordance with the voltage on the line. This can be determined by the quality of the music coming from the loud speaker.

On the set itself the upper left knob controls the volume and also the sensitivity of the radio-frequency amplifier. It is advantageous to readjust this knob when trying for weak stations, so that this amplifier will function at the highest possible efficiency. The other control is in the intermediate amplifier circuit and should be adjusted until the signals are loudest and clearest. Then the rheostat on the power unit panel should be reset for optimum results.

PARTS FOR POWER UNIT

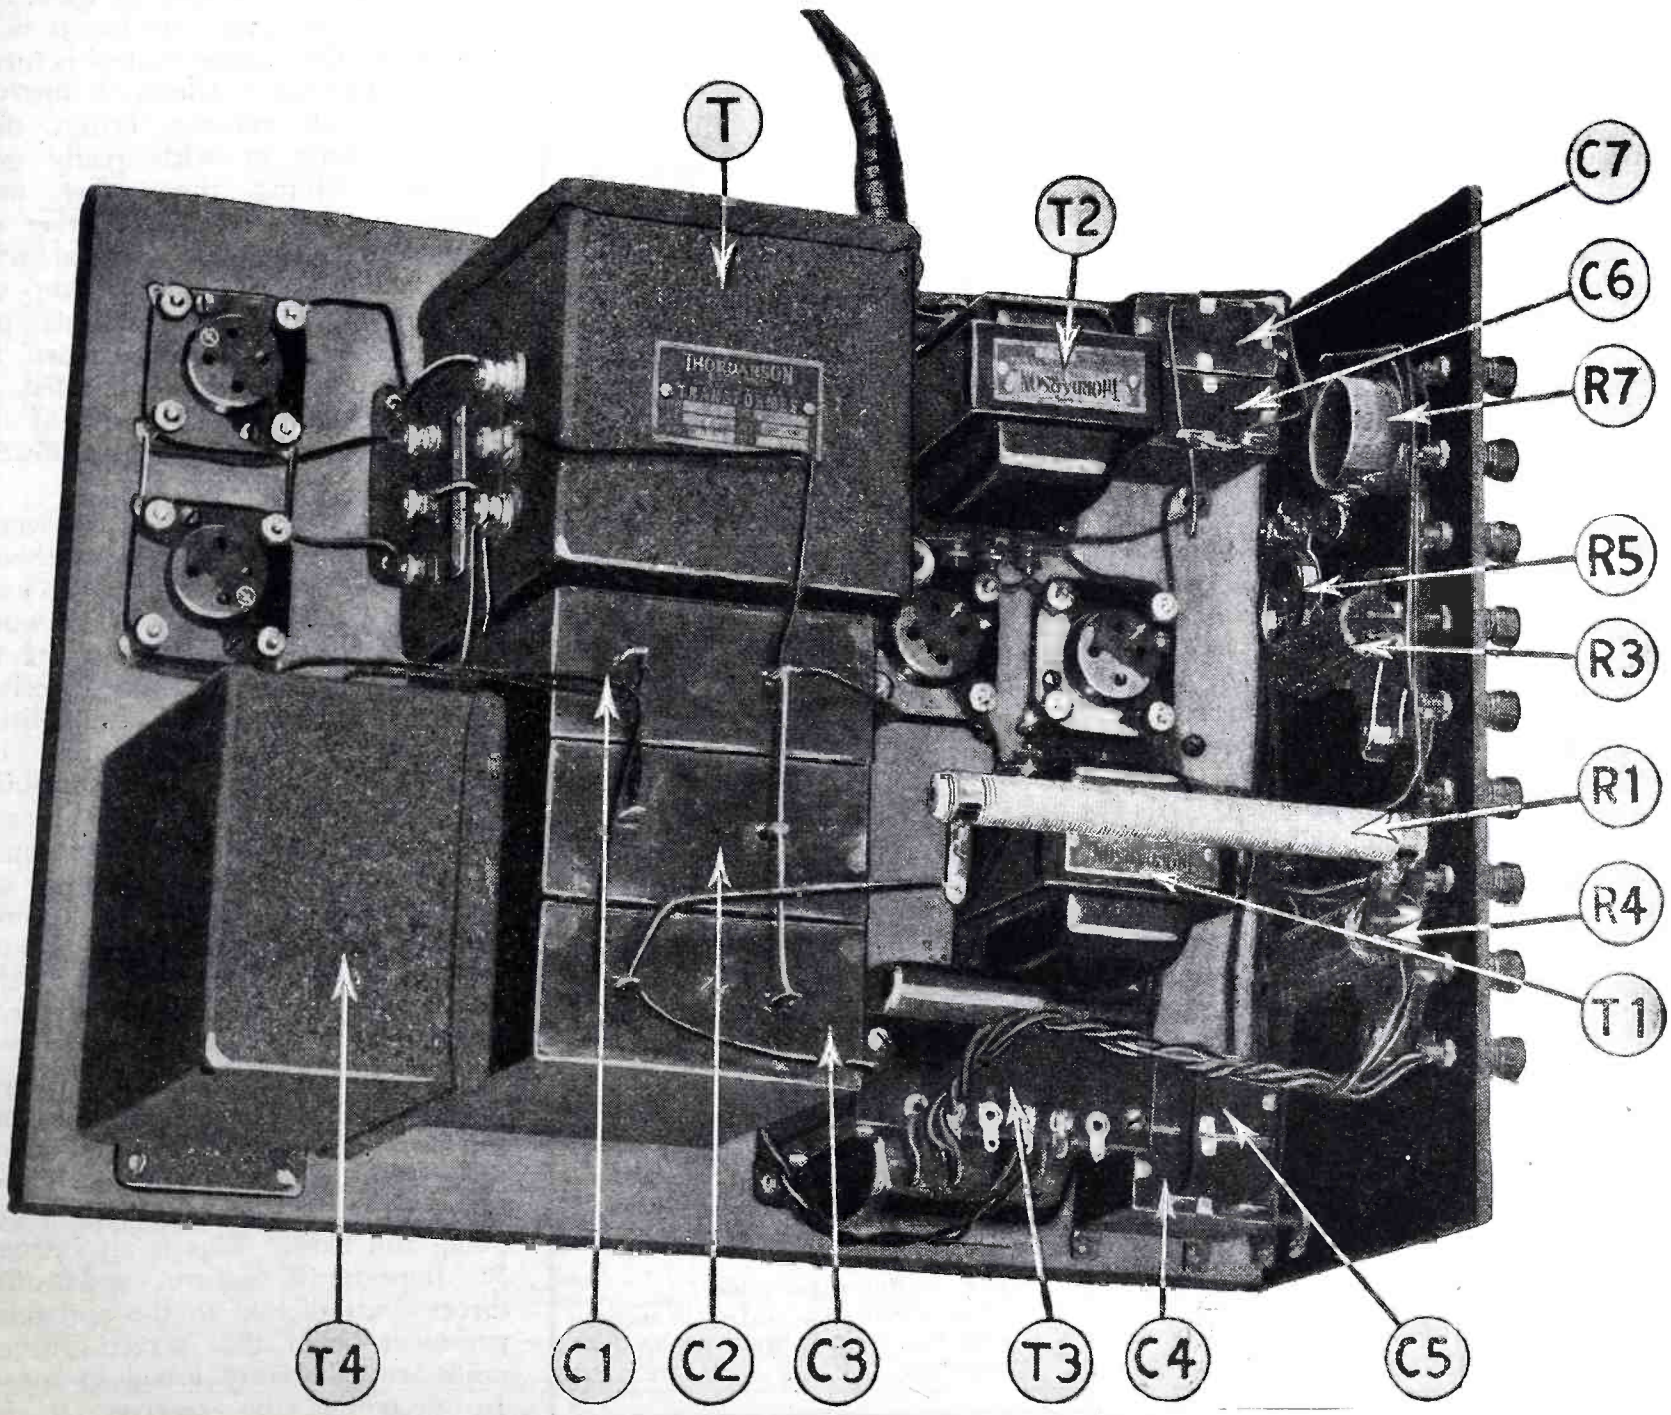
- 4 Acme Parvolt type A, 1 mfd. by-pass condensers, C4, V5, C6, C7.
- 3 Acme Parvolt type C, 2 mfd. by-pass condensers, 1,000 volts, C1, C2, C3.
- 1 Thordarson push-pull transformer, type T2408, T2.
- 1 Thordarson output choke, type T2420, T1.
- 1 Thordarson high voltage transformer type T2098, T.
- 1 Transformer Co. of America A. C. heater transformer. T3.
- 1 Thordarson double choke coil, type T2099, CH.
- 1 Eelectrad Truvolt fixed resistor, type D70, R1.
- 1 Electrad Truvolt fixed resistor, type B7.5, R2.
- 2 Electrad Truvolt variable resistors, type T50, R3, R4.
- 2 Carter 200 ohm potentiometers, R5, R6.
- 1 Carter 50 ohm rheostat, R7.
- 12 Eby engraved binding posts.
- 1 Panel 7x12x3/16 inches.
- 1 Wood baseboard, 12x15 inches.
- 20 Feet Acme Celatsite wire.
- 2 CeCo tubes, type L10, V1, V2.
- 2 CeCo tubes, type R81, V3, V4.
- 4 Benjamin spring sockets.

This receiver will operate on any type of antenna, either indoor or outdoor, but it almost goes without saying that the best results will be from an outdoor antenna. Any single wire between 75 and 120 feet long will be sufficient. Be sure that you have a good ground connection on either a water pipe or a radiator.

A word of caution should be added here. Before trying this out or better yet before building this set, be sure that you have 60-cycle alternating current in your home. This set will operate only on that.

In order to get the full benefit of the high-quality audio amplifier and push-pull second stage, a good loud speaker must be used; because quite a few loud speakers will rattle or distort and will not do justice to the quality of the amplifier.

In tests conducted at our laboratory, a dynamic type speaker was used which gave exceptionally good results. However, the constructor has a wide variety of good speakers to choose from, but is advised to select a high grade product.



A photographic view of the power unit showing the layout of parts and wiring.

How to Build The Cosmopolitan Screen-Grid Receiver

IN designing this receiver, the collaboration was obtained of a Research Engineer who has not only spent many years in developing receivers but who has also made exhaustive tests with screen-grid tubes. There is probably no engineer today who has had more practical experience with or first-hand information on this tube and the circuits employing it. It was a privilege indeed to be able to call upon his vast store of information on the peculiarities of this tube in working out the design for this receiver. While his affiliations in the radio industry make it impossible to give him due credit by divulging his name, we wish to take this opportunity of acknowledging indebtedness to his kindly interest and helpful suggestions.

The outstanding feature of this receiver of course, is its sensitivity. During a demonstration recently staged in New York City between the hours of 8 and 9:30 P. M., stations at Schenectady, N. Y., Pittsburgh, Pa., and Nashville, Tenn., were brought in using only a four-foot wire for an an antenna. These stations came pounding in with sufficient volume to make conversation in the same room difficult. With a 30-foot antenna, the volume was so great, on stations up to 1,000 miles away, as to overload the tube in the last audio stage when the volume control was turned up.

In tests covering several evenings, KFI, Los Angeles, has been brought in regularly on a 30-foot antenna. On a 75-foot antenna, KFI has been brought in with sufficient volume to be heard several rooms away. Such reception was not a matter of unusually favorable conditions but a night after night reception in the hours after WRC, Washington, D. C., which operated on the same wavelength has signed off.

The receiver is so thoroughly shielded that there is no signal pick-up without an antenna except on two or three of the low-wave stations. Even in the case of these low-wave stations signals are barely heard only when the volume control is turned all the way on. Adding a one-foot wire for an antenna brings these same stations in with really good volume. Adding three feet more brings in all the locals and other stations up to several hundred miles distant with good loud-speaker volume. This really remarkable performance on extremely short antennae of a perfectly shielded receiver is conclusive proof of the high degree of R. F. amplification attained in the design.

The construction of the receiver is by no means complicated although somewhat greater care must be exercised in its construction than would be given to the construction of the ordinary type of five-tube receiver. Tuning is simple, being accomplished with two main controls and one auxilliary control. The auxilliary control however, is used only to provide exact resonance when tuning in distant stations, when maximum sensitivity and selectivity are required. For normal reception this control need not be used. The only other adjustment is that for volume control.

Through careful design, adequate selectiviity has been obtained to permit bringing in innumerable out of town stations during the early evening when the local stations are going full blast. This is an extremely important feature and offers direct contradiction to the apparently prevalent belief that screen-grid circuits are inherently broad in tuning. In designing the receiver it was

LIST OF PARTS

- 3 Hammarlund No. ML-17. .00035 mfd. Midline variable condensers, C1, C2, C3.
- 1 General Radio, type 368, .000015 mfd. variable condenser, C4.
- 1 Hammarlund No. EC, Equalizer adjustable condenser, C5.
- 4 Aerovox .02 mfd. fixed condensers, C6, C7, C8, C9.

- 1 CX-371A tube in socket VT5.
- 1 Formica or Lignole panel, 7x21 inches.
- 1 Wood baseboard 20x12x½ inches.
- 1 Pkg. Acme Celatsite flexible hook-up wire.
- 1 Pkg. Kester radio solder.
- 1 Composition strip, 4x1x3/16 inches with two 1 inch brass angles for mounting.

found necessary to design special coils because none of the coils on the market would supply either the maximum amplification or maximum selectivity made possible by the tubes. Therefore it is of vital importance that the coils specified be used in the construction of this set. In preliminary test circuits a voltage amplification (average at all broadcast frequencies) of 39 per stage and running as high as 49 per stage at 1,500 kilocycles was obtained when employing these coils, much higher than any of the other coils available for use with these tubes.

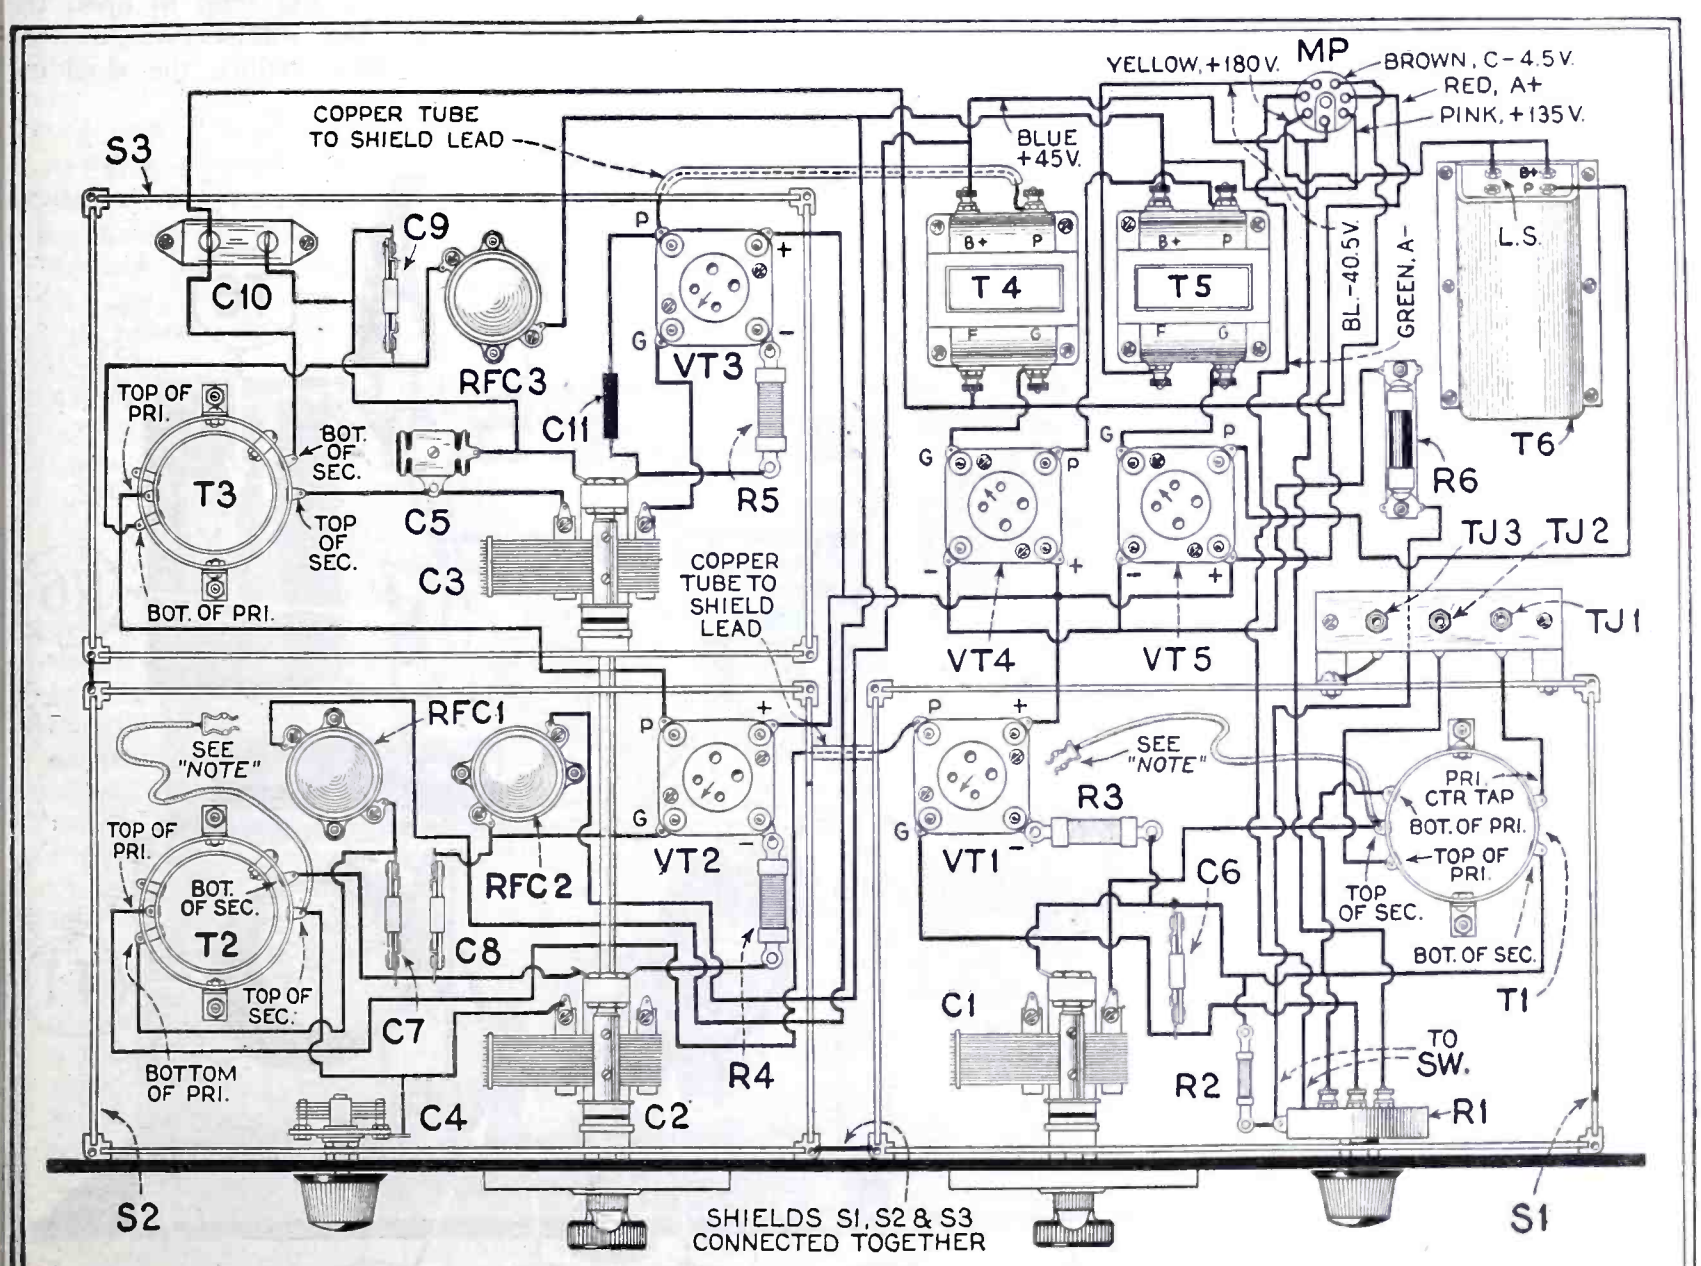
The turn ratio of the R. F. coupling transformers is approximately 1 to 1, yet the receiver cannot be made to oscillate except on the very low wavelengths and there the oscillation is under absolute control by means of the volume control knob. This stability is accomplished through proper coil and circuit design and not through the usual lesser methods. Had the coils been made slightly less efficient it would have been possible to completely eliminate the possibility of making the receiver oscillate even on the low wavelengths, but this would have meant a sacrifice of amplification, especially at the long waves. This would not be desirable, especially as it is never necessary to turn up the volume control to a point where the amplifier will oscillate.

Needless to say, careful attention has been given to the matter of tone quality. The stability of the R. F. amplifier prevents any tendency toward distortion in that portion of the circuit and high grade transformers in the audio stages insure quality reproduction at that end.

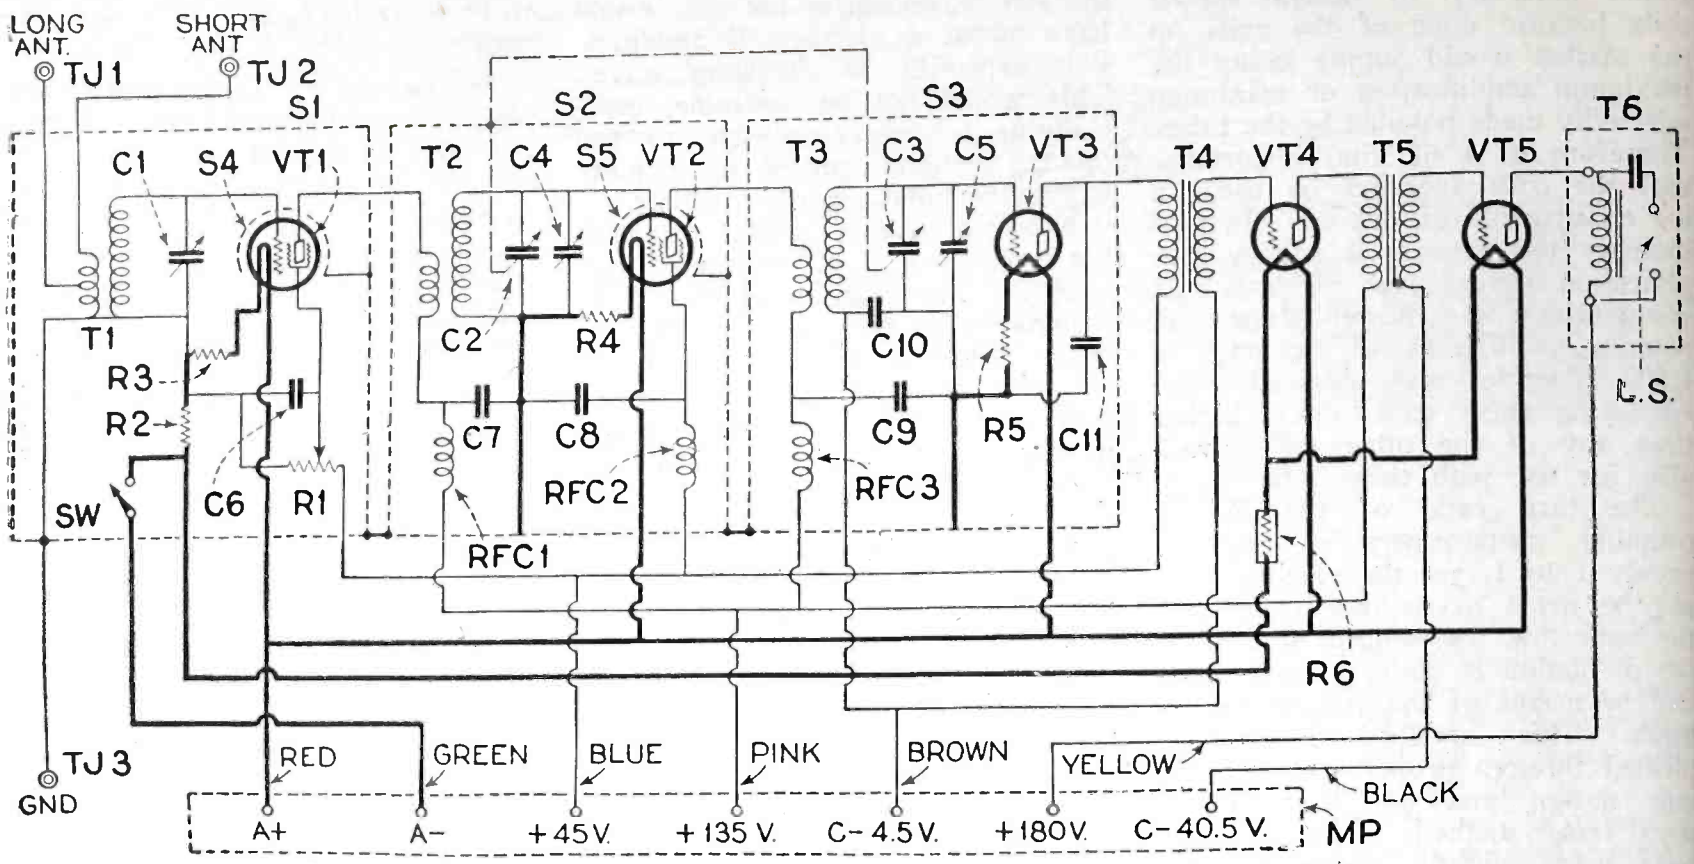
A study of the illustrations will disclose that extensive precautions have been taken to avoid any undesirable coupling between stages. The two R. F. stages and the detector stage are individually enclosed in aluminum box shields to reduce electro-static and electro-magnetic coupling. Direct coupling through the leads and batteries or "B" eliminator is reduced through the use of chokes and by-pass condensers. The two screen-grid tubes are shielded from their circuits by the use of individual tube shields of copper. These shields are provided with removable caps and shielded connectors.

The method of volume control employed is unique and has the advantage that it neither broadens tuning nor causes microphonic disturbance as would be the case with shunt resistances or filament rheostats respectively. Neither of these older methods has any place in circuits employing screen-grid tubes.

The "C" bias for the screen-grid tubes is obtained through the drop in the 10-ohm resistors inserted in the negative side of the individual filament circuits. This arrangement has the advantage that the "C" bias varies with the tube plate current which in turn varies with the tube plate voltage. In this way, the correct bias is automatically maintained regardless of the amount of plate voltage applied to the tubes. In the case of the detector tube, a bias is also used but this is obtained from an external "C" battery or from the battery eliminator as the case may be. The grid bias method was used for several reasons. The most obvious was to prevent over-



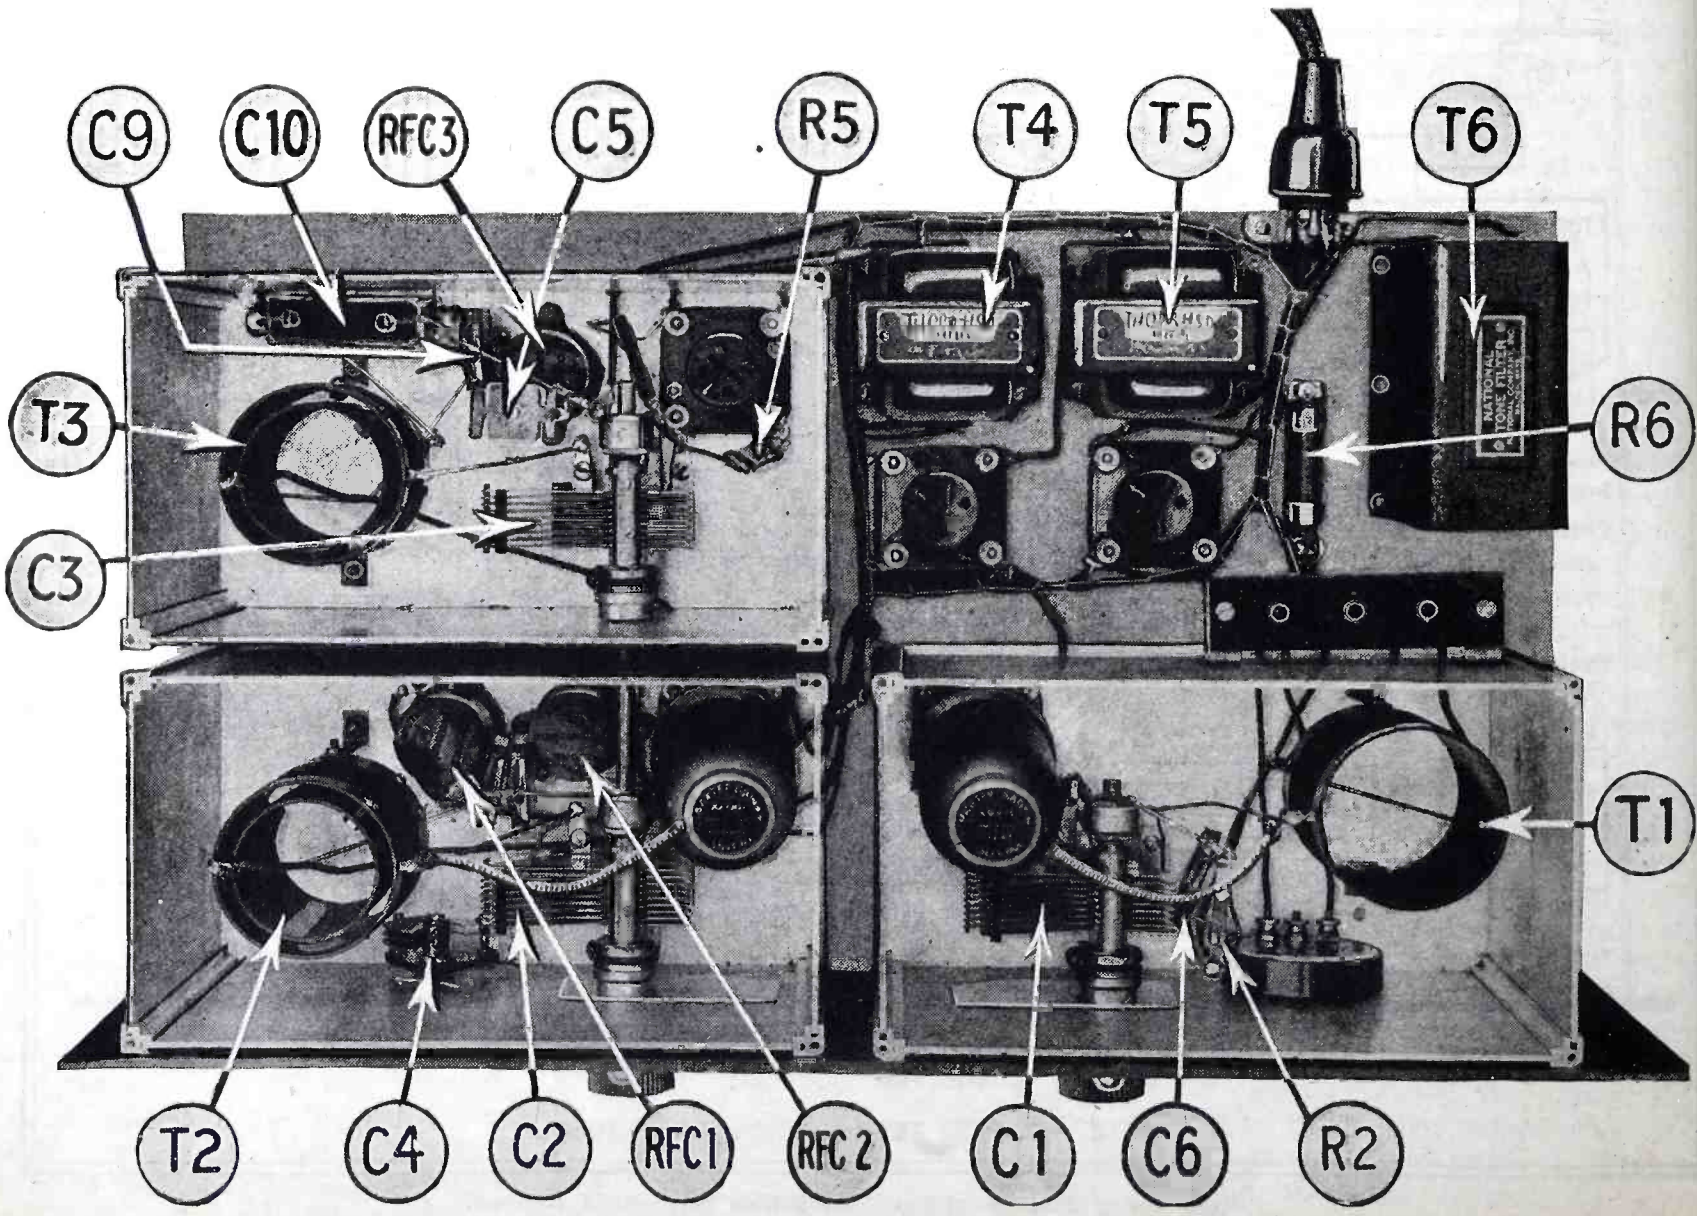
Picture wiring diagram of the Cosmopolitan Screen-Grid Receiver.



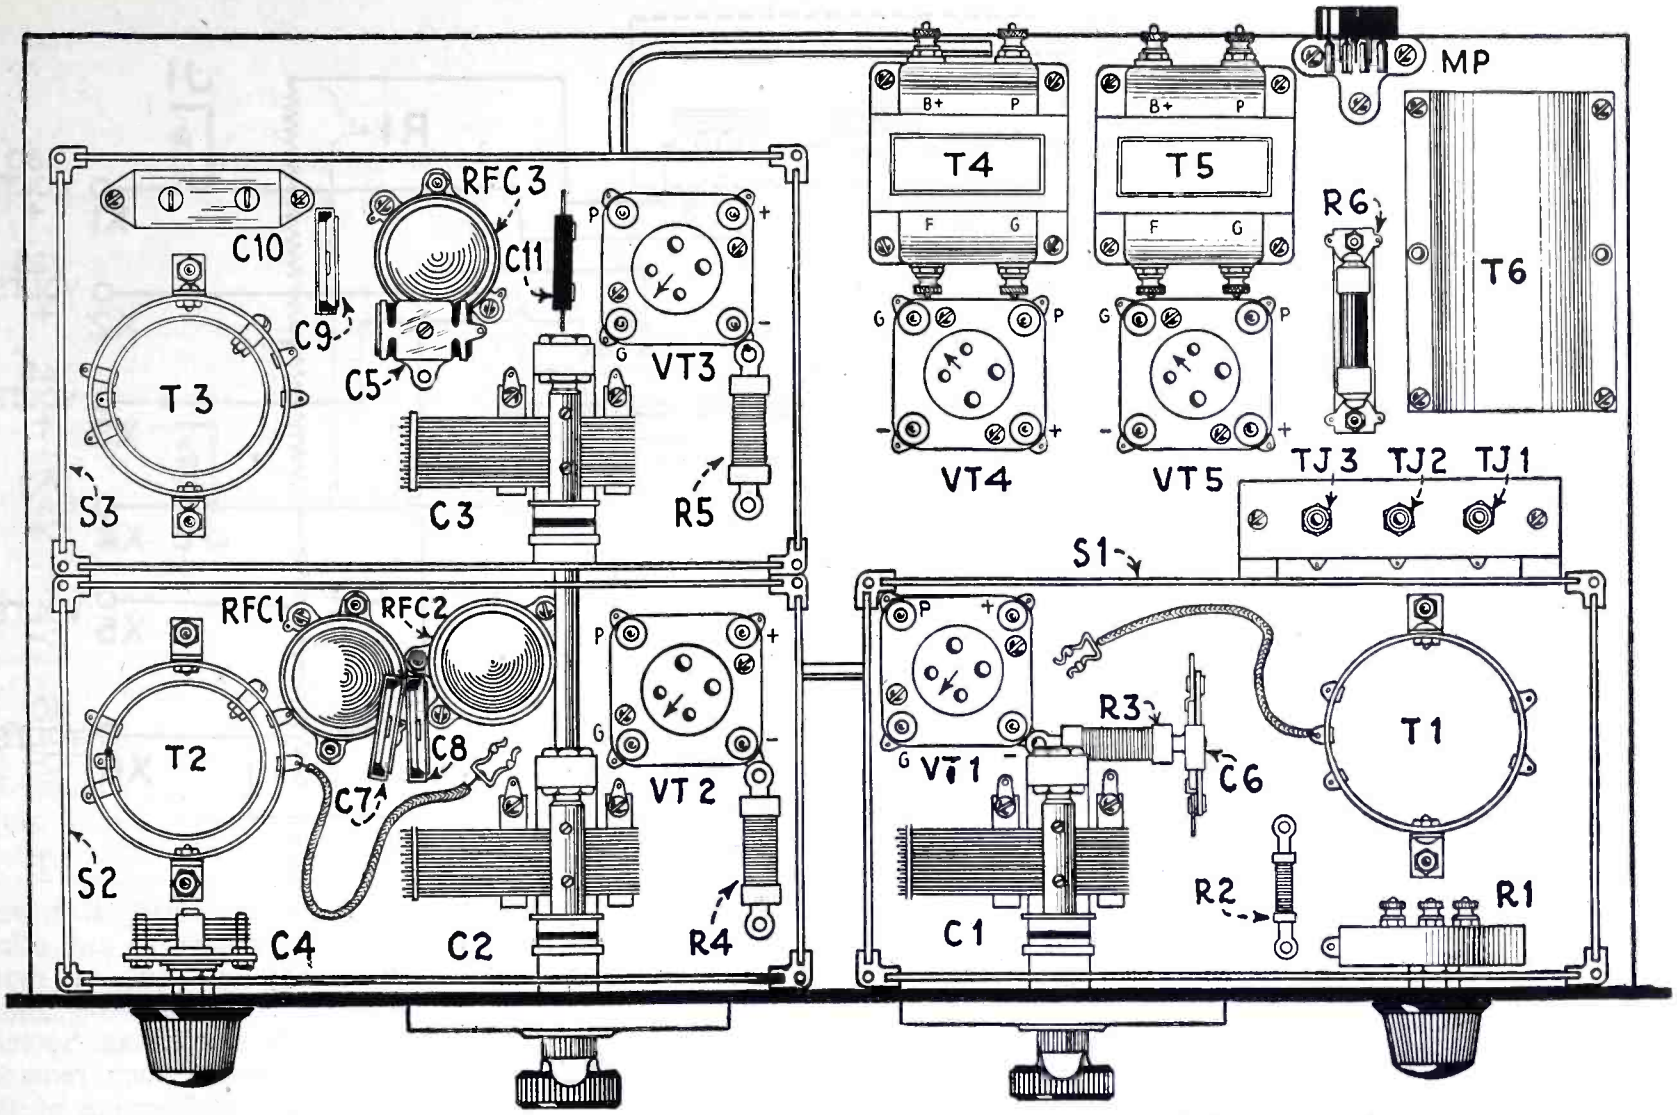
Schematic diagram of the wiring. All parts within dotted lines are enclosed in shields.

loading the detector—a precaution made necessary by the high amplification of the R. F. amplifier system.

In assembling the receiver shown in the illustrations, the sheilds were mounted with ¼ inch bushing between baseboard and shield bases and were attached to the baseboard at only three corners of each shield. This precaution was taken to prevent warping of the shield bases in case the baseboard is not absolutely flat. If this is not done, any warping of the baseboard and of the shield bases would tend to open the shields at the intersection of the edges and thus reduce the shielding effect.



A top view of the set showing how the screen-grid tube shields are mounted and connected.



Instrument layout of the set showing the placement and position of all parts.

Contact with the grid terminal stem of the screen-grid tubes is made by means of small caps of the connectors provided with shields which fits snugly over the brass ferrule of the tubes. Special insulating bushings are provided to prevent any possibility of contact between the caps and shields after connecting the leads to the terminals on top of the tubes, the caps may be placed on the tube shields and the flexible shields slipped over the leads.

In order to gang the tuning condensers of the second R. F. and detector stages on a single shaft, it is necessary to use a small, extra balancing capacity if exact resonance is to be obtained. The second R. F. stage requires slightly higher capacity than the detector stage and the amount of this extra capacity increases with the wavelength. At the low wavelengths the capacity difference is less than the minimum capacity of a midget condenser, whereas at the highest broadcast wavelengths a balancing capacity of approximately half that of the balancing condenser "C4" is needed. Inasmuch as a midget type of movable plate condenser is required in the second stage for control from the panel, and inasmuch as the minimum capacity of such a condenser is too high to obtain resonance at the low wavelengths, it has been found necessary to add a very small capacity across the tuning condenser of the detector stage. This is a small spring type neutarilizing condenser "C5" which need be adjusted only once.

This receiver will function very well with either "B" batteries or a "B" eliminator. A very desirable type of eliminator designed especially for this set will be described in detail later in this article.

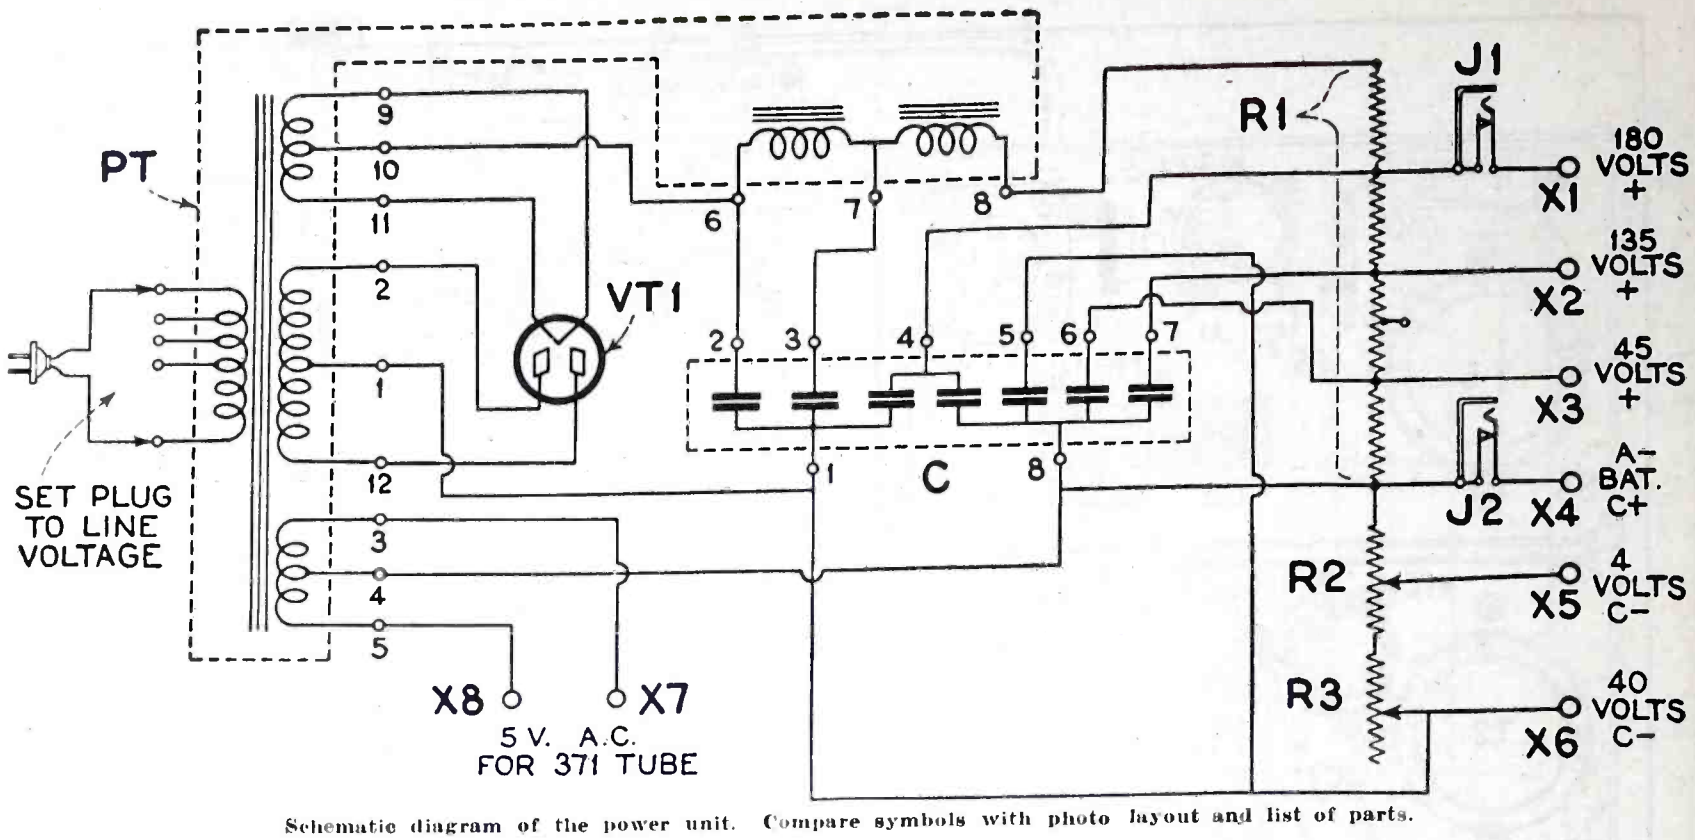
PARTS FOR POWER UNIT

1 Aerovox No. BC-280 condenser block, C.
2 Carter No. 2-A short jacks, J1, J2.
1 Samson No. 713 power block, PT.
1 Electrad type C-130-S "Truvolt" tapped resistance unit, R1.
1 Electrad type T-5 "Thruovlt." 500 ohm variable resistor, R2.
1 Electrad type T-10 "Truvolt," 1000 ohm variable resistor, R3.
1 Benjamin vacuum tube socket.
8 Eby binding posts, X1, X2, X3, X4, X5, X6, X7, X8.
1 CX-380, rectifier tube, VT1.
1 Composition panel, 10x4x3/16 inches.
1 Wood baseboard, 10x11½x¾ inches.
1 Pkg. Acme Celatsite flexible hookup wire.

It will be noted that the volume control potentiometer is connected directly across the detector plate supply source, whether the receiver is turned on or off. This would seem, at first glance to be wasteful of current when "B" batteries are used. Actually it provides no cause for worry because the current drain through this resistance is only about one-tenth of a milliampee and probably would not reduce the useful life of a set of batteries by one per cent.

In putting the receiver into operation, the usual practices are followed, except in the adjustment of the balancing condensers C4 and C5. This is therefore the only point that requires discussion. The adjustment is made with the covers of shields S2 and S3 removed.

The first step is to adjust the knob of C4 so that its arrow is in a horizontal position, pointing to the left when the plates are entirely unmeshed. Then turn the screw of C5 all the way in and then back one full turn. Next put the receiver into operation and tune in a low wave station at around 10 on the tuning dials, the left-hand tuning dial is then readjusted with different settings of the balancing condenser C4 until the best position for the balancing condenser is found for that particular station. If the condenser C5 is properly adjusted, the best position for C4 at this wavelength should be with the head of the arrow on the knob about ¼ inch above the horizontal. If it is less than this, turn the screw of C5 one-

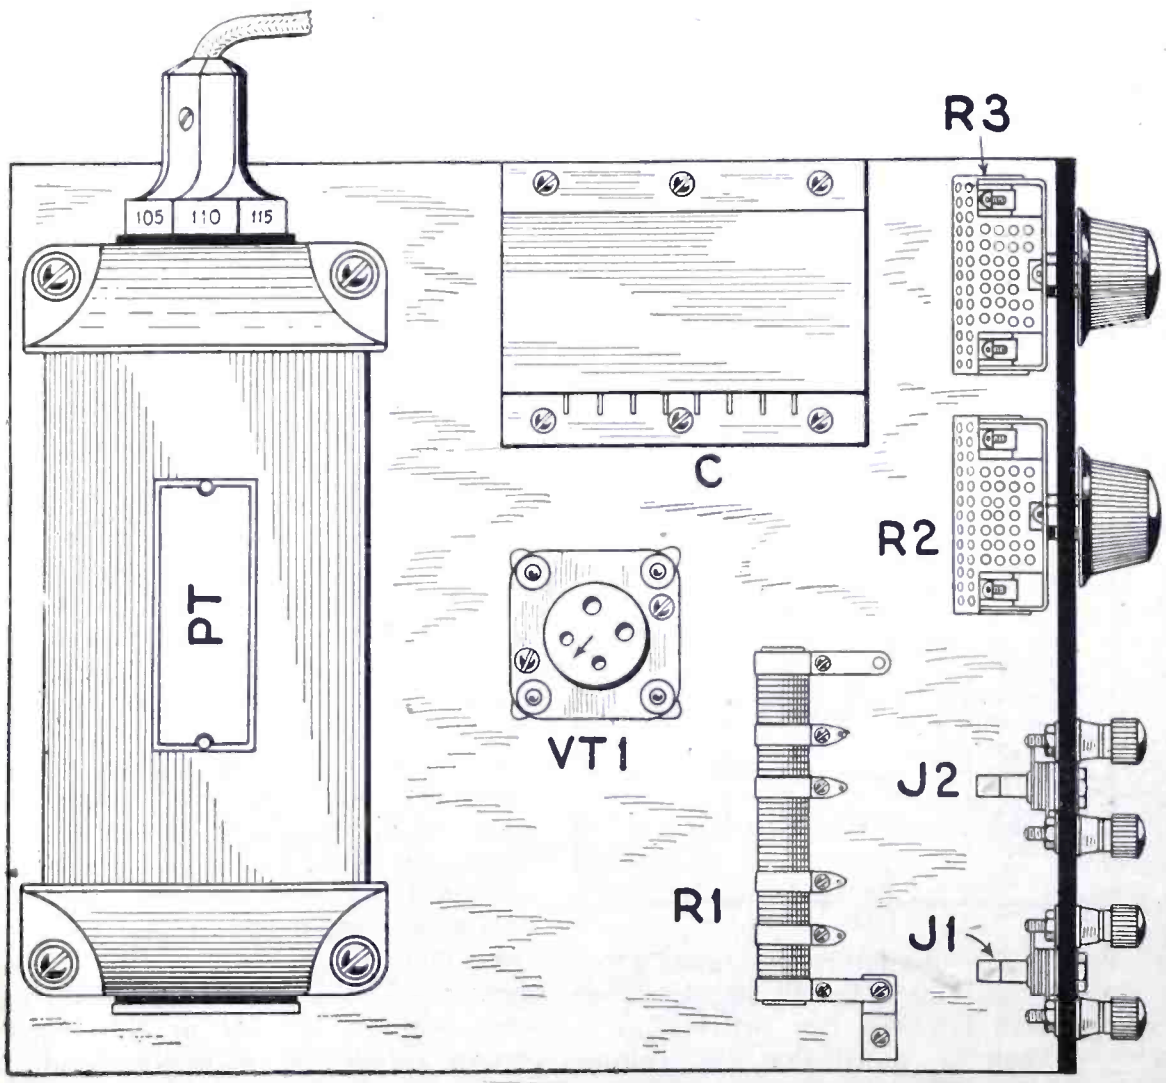


Schematic diagram of the power unit. Compare symbols with photo layout and list of parts.

quarter turn to the right (clockwise) and repeat the process.

When the proper adjustment of C5 has thus been found, it need not be changed again. When maximum sensitivity and selectivity are desired on distant stations, C5 should be adjusted. For 200 meter stations, its adjustment will be about horizontal with the arrow pointing to the left (minimum capacity) while for 545 meter stations, the arrow will point almost directly up. Its useful range therefore represents only a a quarter turn of the knob and its adjustment is therefore not critical and adds very little complication to the tuning.

The eliminator illustrated was designed particularly for use with the Cosmopolitan Screen-Grid Receiver, but is equally applicable to any other receiver that employs one or more 371-type power tubes in the audio amplifier. The Cosmopolitan Screen-Grid set is capable of such remarkable results that it is deseving of the best of power supply units as a run ning mate and it is for that reason that this, the present unit, was de-



TOP VIEW-

Layout of parts on the baseboard of the power unit is shown at the left. At the right is given a layout of the small bakelite panel on which the variable resistors, jacks and binding posts are mounted.

signed and is being described here.

This power pack is small in size, consists of few parts and is easy to construct and wire. While the parts employed are all standard and are of the highest possible standard, the cost of the whole job is little if any higher than the cost of the "B" batteries that would be required to do the same work over a period of one year.

The transformer employed provides secondary voltages of 300 for each side of the full wave rectifier circuit; a five-volt, center-tapped winding for the filament supply for the CX-380 type full wave rectifier tube; and another five-volt center-tapped winding for operation of the filament of one or two CX-371 type tubes used in the last audio stage of the receiver with which this power unit is to be used.

A unique feature of the transformer is the primary plug connection by means of which the transformer primary is matched up with the pevailing local line voltage by the position of the plug. This scheme eliminates the necessity for voltage adjusting rheostats, switches, etc.,

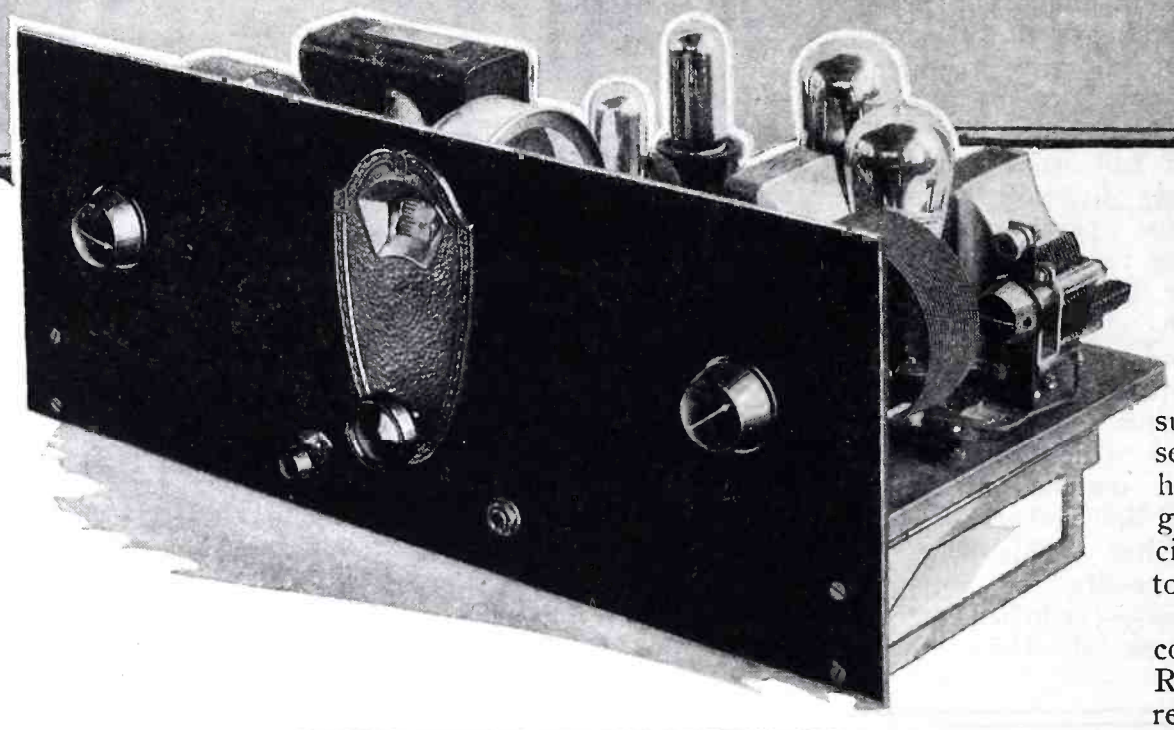
HOW · TO · BUILD
THE · ADVENTURER · FOUR



IT has long been the desire on the part of those interested in short-wave work to evolve a circuit wherein it was possible to employ satisfactorily a stage of radio frequency amplification. Efforts to incorporate in the circuit a regular tuned stage of R. F. amplification ahead of the detector have not been very successful, due largely to uncontrollable oscillation in the R. F. stage and the extreme difficulty often encountered in satisfactorily tuning an exceedingly sharp or selective circuit.

The circuit featured in the design of the receiver described in this article has none of these drawbacks and in fact is so flexible in operation as to allow of the ganging together of the two tuning condensers.

Referring to the accompanying schematic diagram, the first tube, V1, is the radio frequency amplifier, the antenna being coupled to the tuned circuit L2-C3 through the midget condenser C1. Another condenser, C6 is employed to feed energy from the plate of the R. F. tube to the grid circuit of the detector tube. When C6 is correctly adjusted a very easy control of oscillation is thereby obtained. Capacity feedback is employed in the detector circuit thereby eliminating the necessity for a separate tickler coil. If the capacity of C6 is fairly large in comparison to the feedback condenser C5 then the R. F. amplifier will oscillate strongly and the detector only feebly, a condition which is rather undesirable. However, if the capacity of C5 be made large and C6 be made small in comparison a desirable condition results and it will be seen that what we have is a tuned grid-tuned plate circuit in the detector circuit.

Since the circuit comprises a good R. F. amplifier and regenerative detector, the receiver is extremely satisfactory in the reception of short-wave broadcast programs.

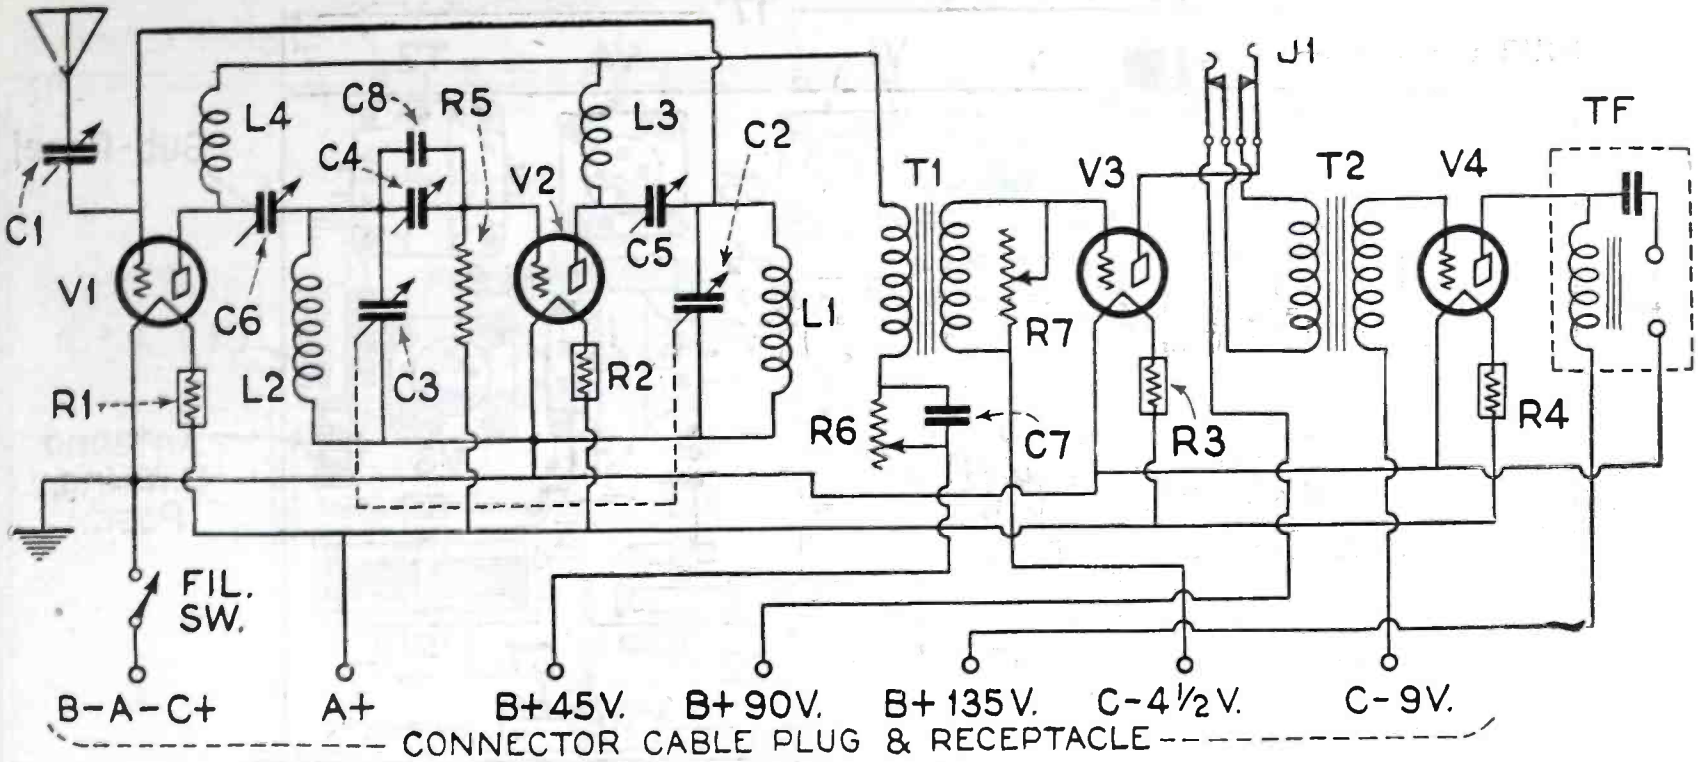
L3 and L4 are choke coils which provide a means for applying the plate potential to the plates of the R. F. and detector tubes without detriment to their satisfactory operation. The two tuning condensers C2 and C3 are actuated by one dial of the drum type and which, due to the natural sharpness of tuning at the short wavelengths must be of the vernier type. Regeneration in the detector circuit is controlled quite smoothly by a variable resistance unit, R6. So that the audio component in the plate circuit of the detector tube may be by-passed around this variable resistance a fixed condenser of 1 mfd. capacity is shunted across the resistance unit. This also helps to reduce the tendency of the resistance unit to be noisy in operation.

Two stages of transformer coupled audio frequecy amplification are employed to build up the received signal to a point where it will operate a loud speaker. The last of the audio stages is a power stage employing a 112 type of tube.

The tuning inductances which are of the plug-in type are situated at the extreme ends of the receiver and are mounted at right angles to each other to reduce to a minimum the chances for electromagnetic coupling.

LIST OF PARTS

1 Hammarlund midget condenser, 100 mmfd., C1.
2 Hammarlund midline condensers, .0001 mfd., C2, C3.
2 Hammarlund equalizer condensers, 35 mmfd., C4, C5.
1 Hammarlund midget condenser, 35 mmfd., C6.
1 Tobe by-pass condenser, 1 mfd., type 301, C7.
1 Tobe fixed condenser, .0001 mfd., C8.
2 Aero interchangeable coils, type INT-2 (for 30 to 70 meters), L1, L2.
2 Samson choke coils, No. 85.
2 Amperites, type 6V-199, or Elkay Equalizors, type No. 50, R1, R2.
2 Amperites, type 1A and 112, or Elkay Equalizors types Nos. 4 and 2, R3, R4.
3 Durham grid leaks, 8, 9 and 10 megohms, R5.
1 Electrad royalty variable resistance, 0-200,000 ohms, R6.
1 Electrad tonatrol, R7.
1 Durham grid leak mount.
1 National drum dial.
1 National tone filter, TF.
4 Eby or Benjamin UX type tube sockets.
2 Benjamin sub-panel brackets, type 8629.
1 Yaxley battery switch, No. 10.
1 Yaxley interstage junior jack, type 704.
1 Yaxley connector cable plug.
2 Samson audio transformers.
1 Formica panel. 7x18x3/16 in.
1 Sub-base, 9x17x3/8 in.
1 Pkg. Kester rosin core solder.
3 Rolls Corwico Braidite wire.

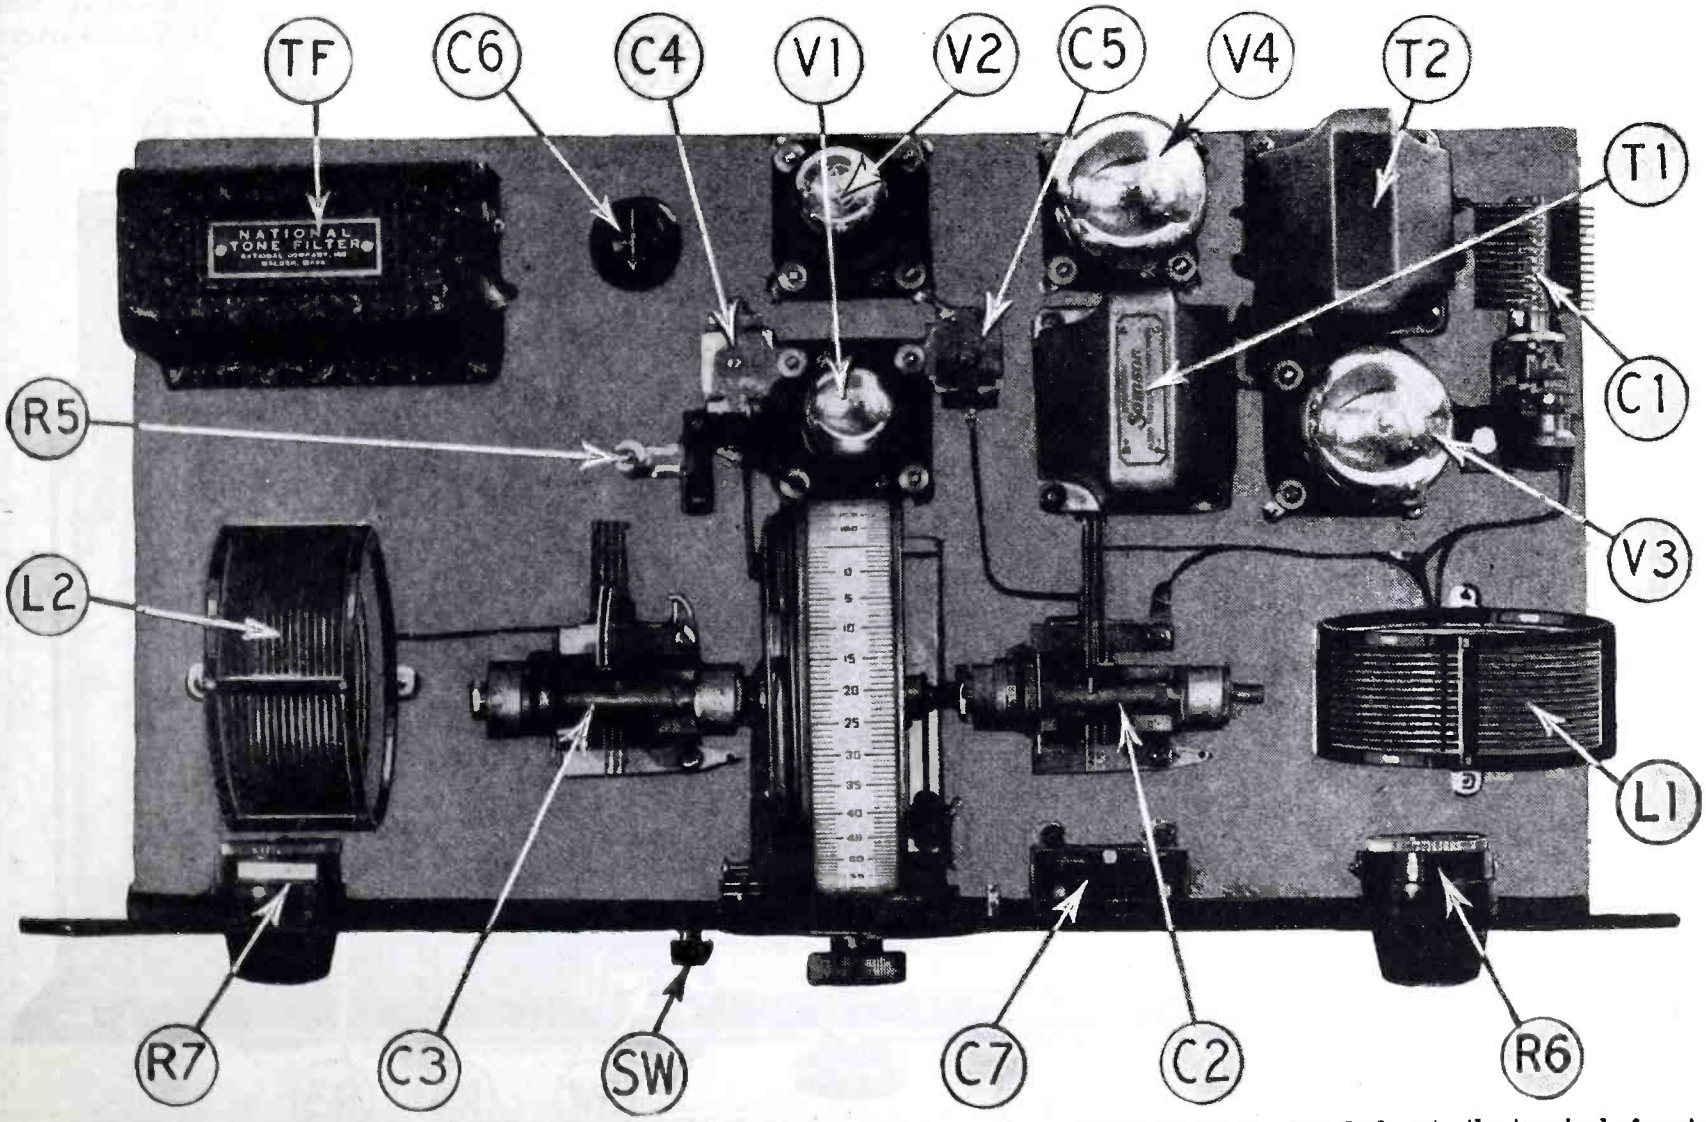


Schematic diagram of the Adventurer Four receiver. Variable condensers C2 and C3 are operated on the single control drum dial.

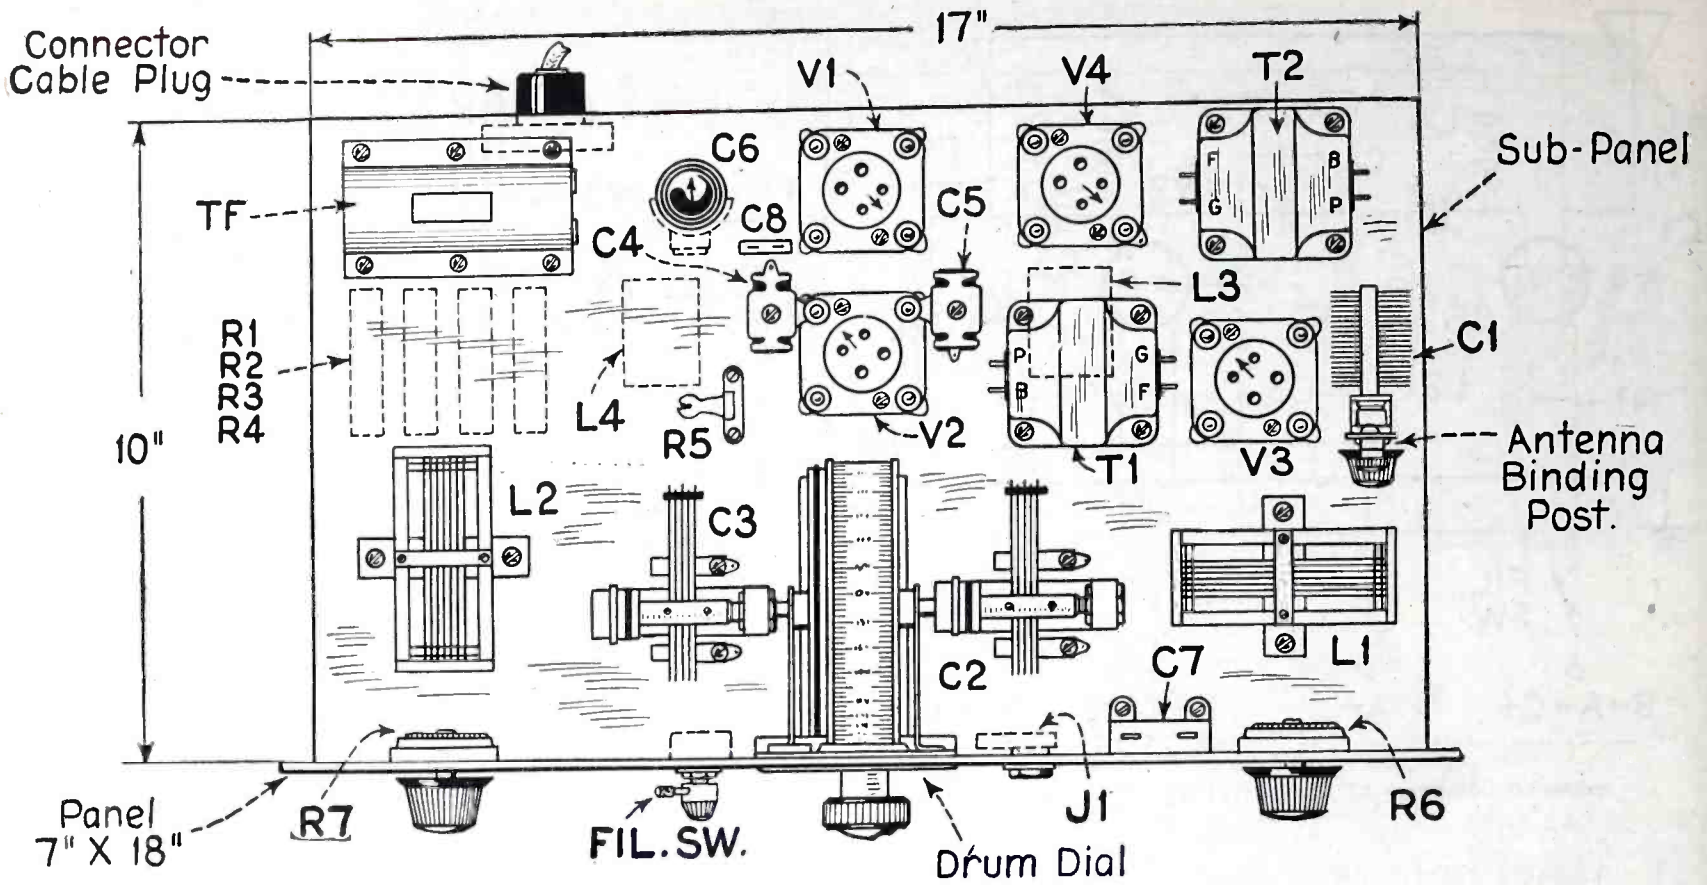
A variable resistance shunted across the secondary of the first audio transformer permits a ready control of the volume obtainable. A double circuit jack in the output of this stage makes possible the reception of a signal suitable for headphones.

In the receiver shown home-made coils were first used, but were later replaced by manufactured coils. Those who wish to make their own coils may do so, but it is far preferable to use the manufactured product as specified in the accompanying list of parts. Home-made coils can be wound on three-inch forms using No. 16 D. C. C. wire separated by the width of the wire. Both coils consist of the same number of turns and for the 20 meter band 4 turns should be wound. For the 30-55 meter band 7 tubes are required. For the 80 meter band 15 turns are required.

If it were merely the intention of the experimenter to play with this circuit it might be quite all right to hastily throw the necessary parts together on any old baseboard. However, if it is desired to build a receiver which will be patterned along sound constructional lines it



A top view of the set. The best part of the wiring is beneath the baseboard. Holes are drilled in the baseboard close to the terminal of parts and wires are passed through the board to the underneath side.

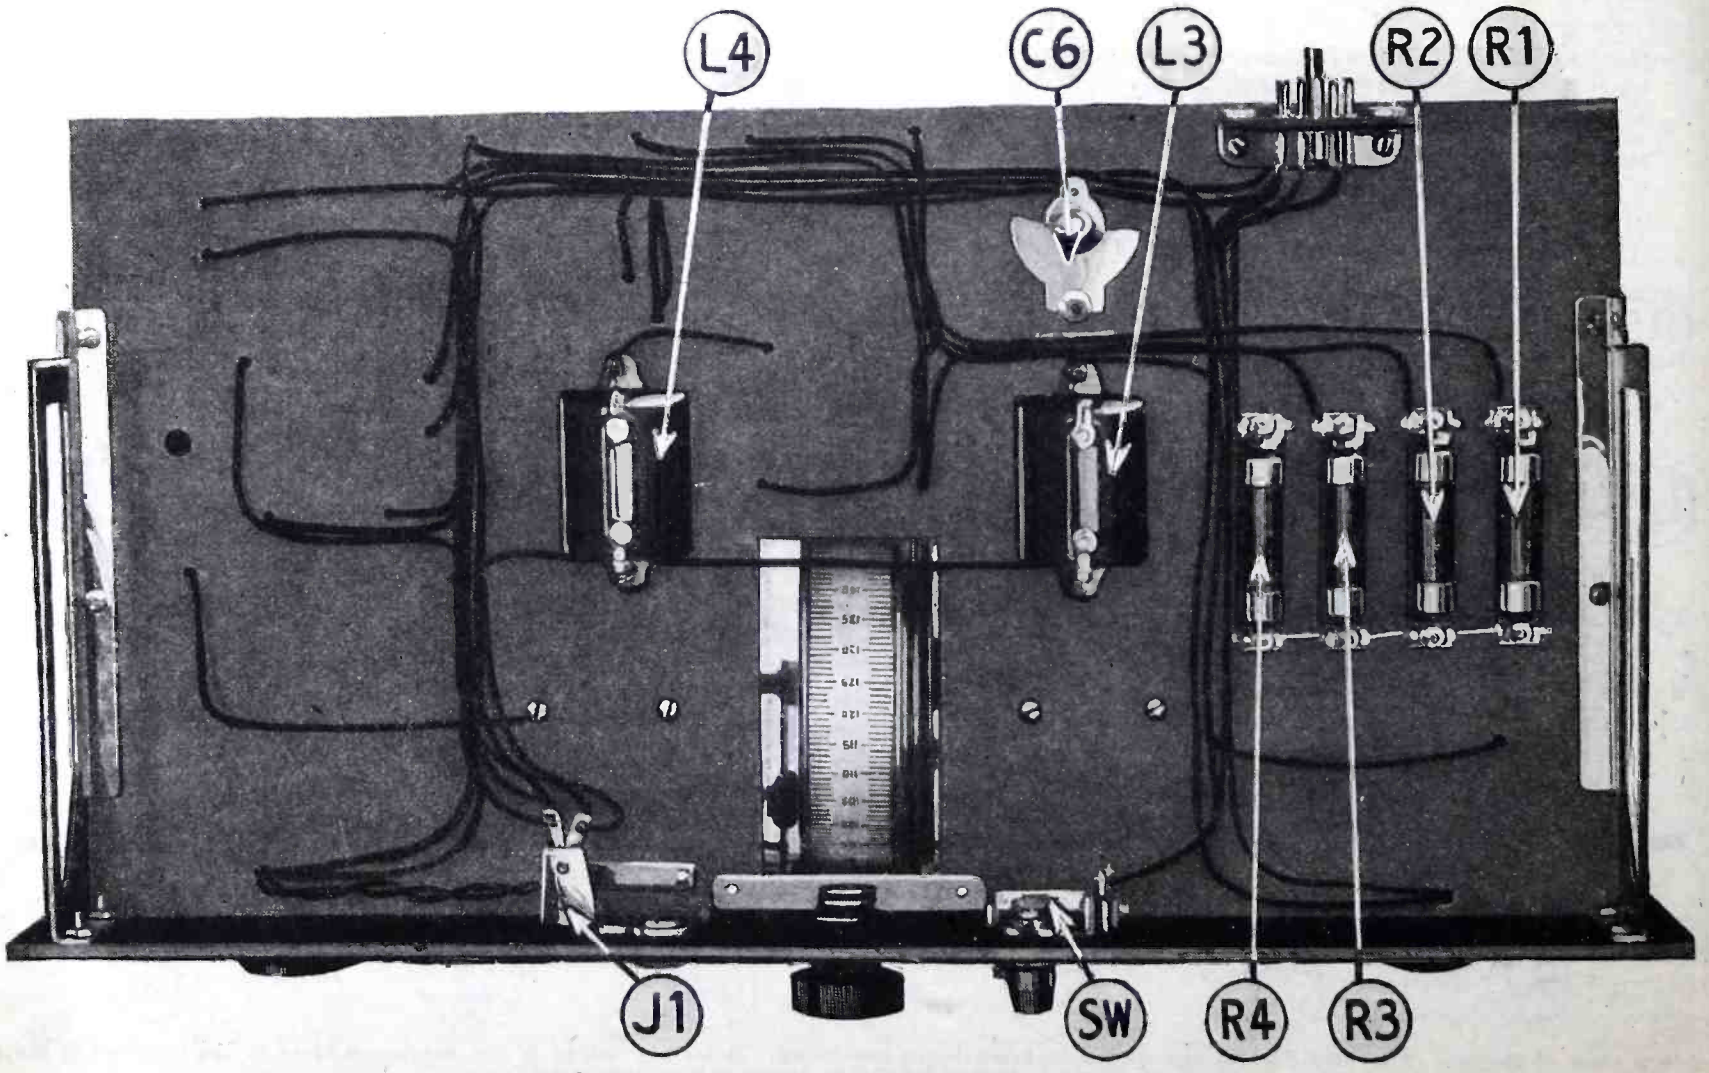


Instrument layout of the set. Parts to be mounted beneath the baseboard are indicated in dotted lines.

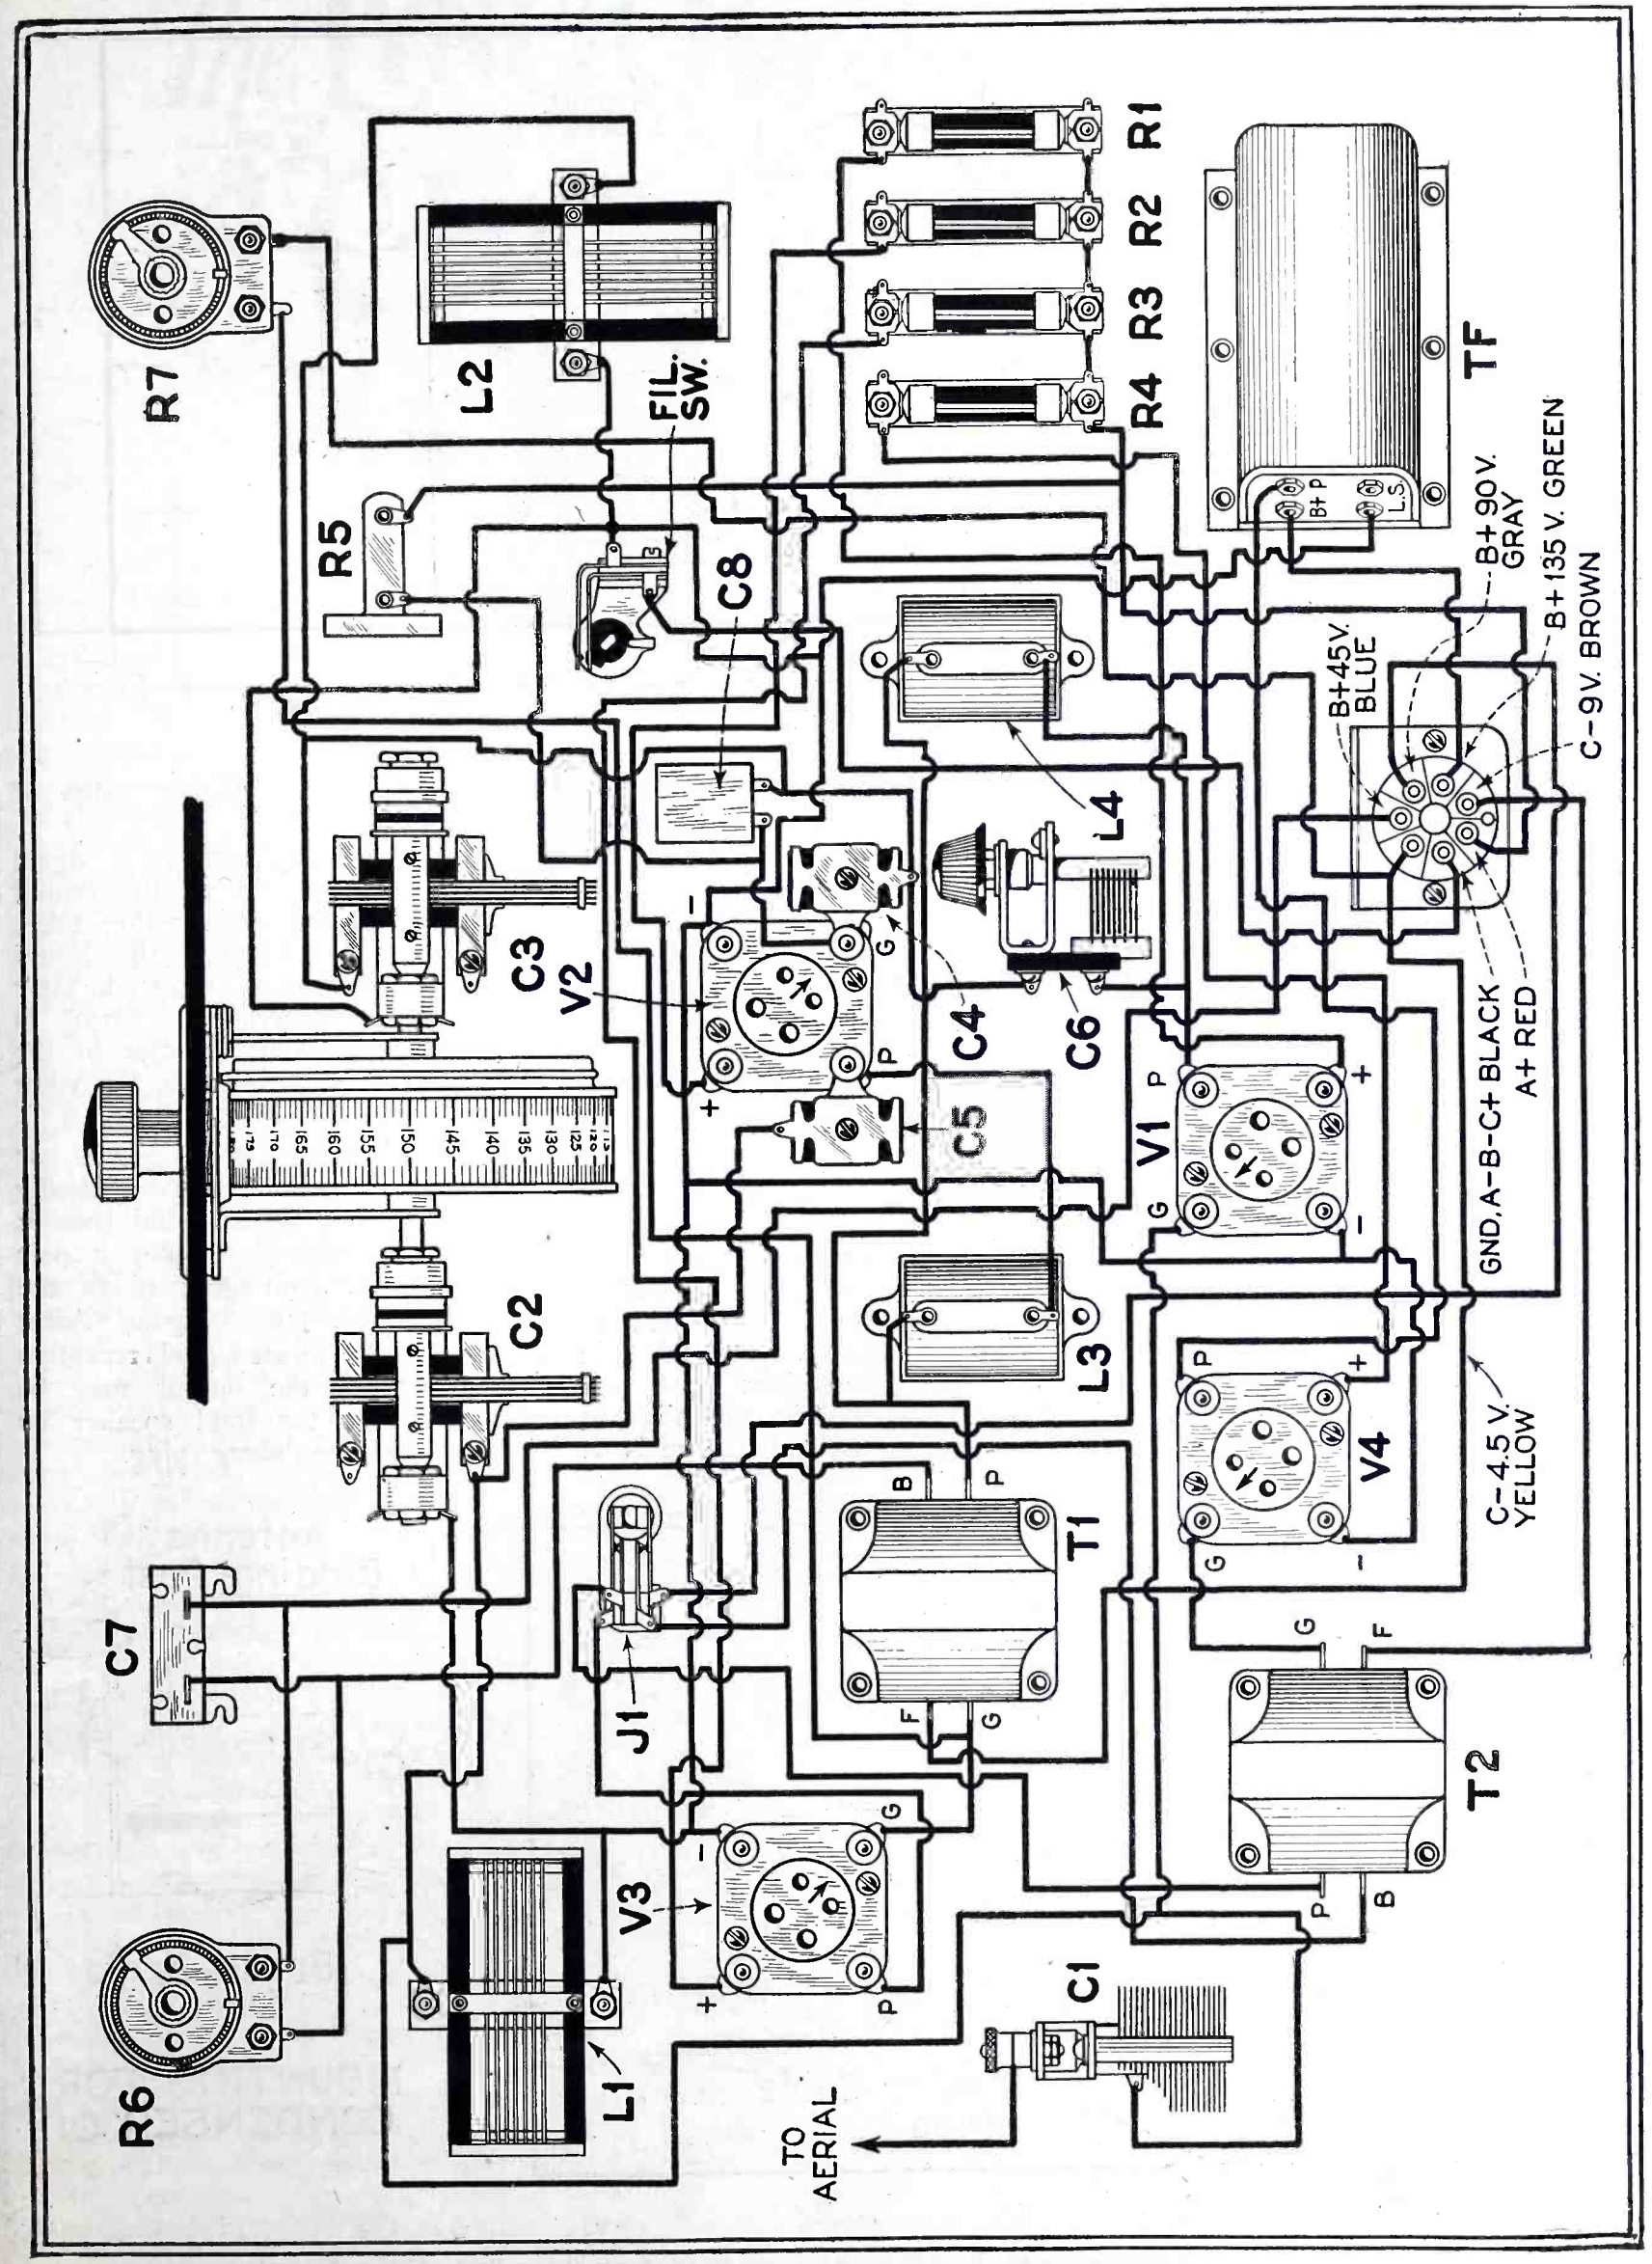
is well for the constructor to heed the instructions given here as to the particular placement of parts. Deviation of the list of parts as listed herein will naturally result in a necessary deviation form the proper placement of these individual parts to the ultimate detriment and inferior operation of the receiver.

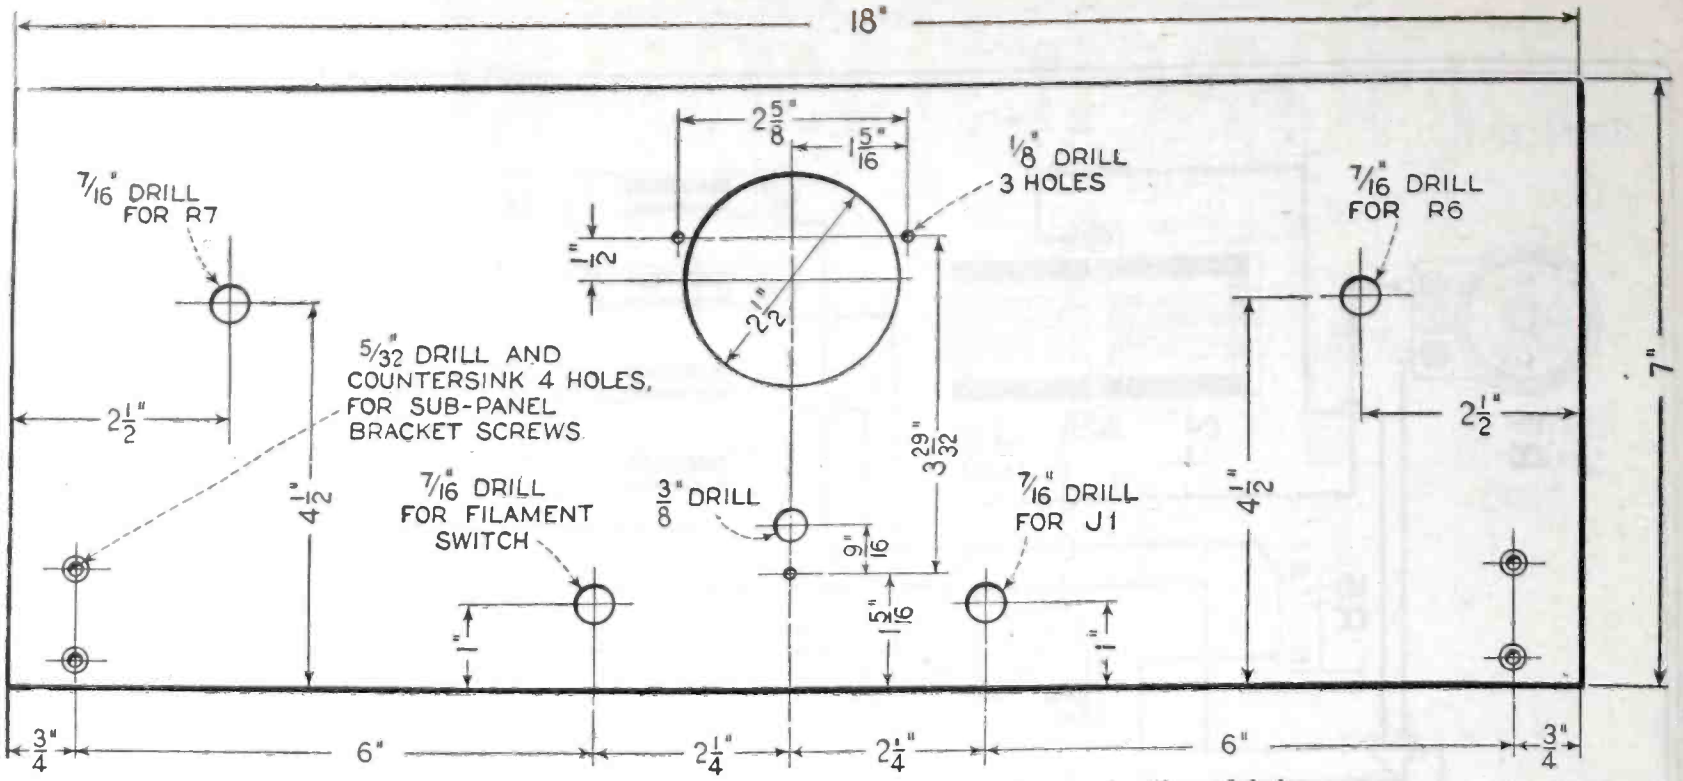
Practically all of the apparatus employed in the construction, with the exception of the two variable resistances, the filament switch and the interstage jack are mounted directly on the sub-base. The actual layout of the parts is shown in the accompanying illustration. The choke coils, cable connector receptacle and amperites are mounted below the sub-base as shown in the sub-base layout. The dotted line outlined in layout show the relative positions of these pieces of apparatus in respect to the placement of the others above the baseboard.

Perhaps the most difficult operation in the whole construction is the placement and mounting of the two tuning condensers and the drum dial. After the sub-base has been cut away to take the drum dial it should be temporarily placed in position and the mount holes for the condensers



A photographic view of the set from beneath the baseboard showing parts and wiring.





The front panel drilling layout giving all dimensions for the location of holes.

marked off and drilled. Then the condensers may be fastened in place after which the mounting of the dial may be accomplished.

The accompanying panel drilling layout gives the dimensions for laying out the mounting holes for the various panel controls.

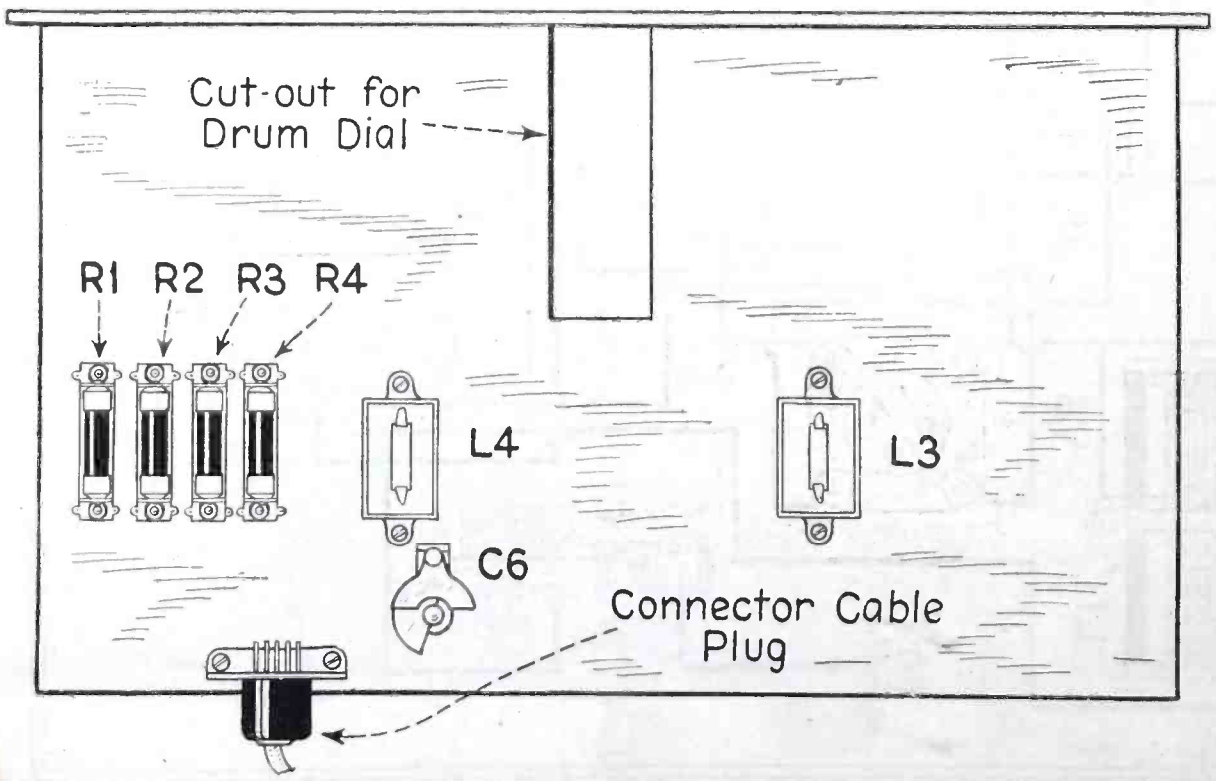
In the wiring of any short-wave receiver it is well to dispense with pretty right angle bus bar wiring and employ instead flexible hook-np wire which will allow of short, direct point-to-point wiring. This is especially true of the tuning circuits.

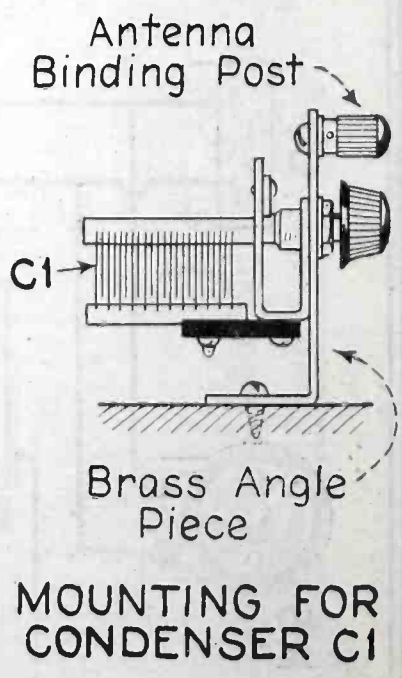
It has been found that for most suitable operation the grid condenser should be variable over a small range and therefore the equalizer condenser, C4, is shunted by a fixed condenser of .0001 mfd. This condenser is soldered in place, its terminals directly shunting those of the equalizer condenser.

After the receiver is completely wired in accordance with the picture or schematic diagram the batteries, antenna-ground and loud speaker may be connected to their respective terminals and the filament switch thrown to the "on" position. The capacity of C5 and C6 should be varied, making that of C5 quite large in comparison to C6. When operating on the wavelengths between 20 and 40 or 50 meters it may be found necessary to adjust the grid condenser C4 to a comparatively low value while for the higher wavelengths a larger value will be found more suitable. Several grid leaks between the values of 8 and 10 megohms should be available, as better reception of weak signals is obtained when the higher value of resistance is used.

To satisfactorily tune in a signal the regeneration control R6 should be adjusted until regeneration takes place—then by turning the drum dial a signal may be received, after which the regeneration control is retarded until, as in the case of the reception of 'phone signals, the voice or music is clearly received.

For the reception of code, or where the operator must actually find the station on the dial then it is most advisable to employ a pair of headphones, plugging in to the jack on the front of the panel. After the station is located and reception is satisfactory the output may be transferred to the loud speaker by withdrawing the 'phone plug.





The above sketches show how parts are mounted under the baseboard and at the right shows the method of mounting variable condensers C1.

The LYNCH-HAMMARLUND A-C-FIVE RECEIVER

THE battery operated Lynch-Hammarlund Five receiver was described in the preceding number of this publication. The remarkable popularity of this receiver following its introduction to the radio enthusiast has more than justified a revision of the circuit to adapt it to the use of alternating current tubes.

The general acclaim accorded this receiver may be credited to its electrical efficiency and mechanical convenience. The electrical characteristics of the set, as far as the radio frequency channel is concerned, are practically identical with those of the original Roberts circuit which remains today probably the only receiving system introduced during the hey-dey of circuit production that has maintained its popularity for almost five years.

The Roberts receiver has always been controlled by two dials tuning one stage of radio frequency amplification and a regenerative detector. It may be remarked in passing, that no really efficient receiver has ever been produced that did not owe its efficiency to the combination of radio frequency amplification and regeneration. The Roberts receiver effects with a minimum of tubes the requirements and specifications of an ideally selective and sensitive receiver.

The mechanical convenience of the Lynch-Hammarlund design is the result of the chassis or "deck" arrangement in which practically all the components of the audio and detecting systems are premounted on a simple sub-panel eliminating at least 50% of the mechanical effort generally associated with receiver construction.

The conversion of the Lynch-Hammarlund Five to A.C. operation is a relatively simple matter necessitating comparitively few and elementary variations from the direct current procedure. However, this article is not written merely for the enthusiast who has already constructed the battery operated model and who now desires to convert it to A.C. operation. The general excellence of the receiver is such as to justify a complete new construction on an A.C. basis by thousands of interested fans who at present are in ignorance of the excellencies of this general arrangement. However, the electrical features of the A.C. model are best illustrated in a description of the steps necessary to alter the D.C. set to A.C. operation.

The conversion has been accomplished by the use of Arcturus A.C. tubes. While it is possible to convert a Lynch-Hammarlund receiver to the use of alternating current tubes of other manufacture, Arcturus tubes have been chosen for this particular set, in consideration of the mechanical and electrical characteristics which particularly recommend them for conversion purposes. The Arcturus A.C. tubes are all of the relatively humless heater type and plug into the standard UX sockets without adaptors of any kind. A common cathode heater connection makes this possible. This particular feature holds for all types of Arcturus tubes, including the detector. Also, Arcturus tubes are made in a hi-mu type "the A.C. 32" inch which particularly recommends them for use in resistance coupled circuits. The A.C. 32 tube has an amplification constant of 30 and is comparable in its electrical characteristics with the R.C.A. and Cunningham hi-mu tubes.

Assuming that the reader has a battery operated model of the Lynch-Hammarlund Five receiver, the following additional parts will be required in effecting the conversion:

1 volume control Clarostat, R5

1 Arcturus type A.C 28 amplifying tube

1 Arcturus type A.C. 26 detector tube

1 Arcturus type A.C. 32 hi-mu tube

1 Arcturus type A.C. 30 power tube

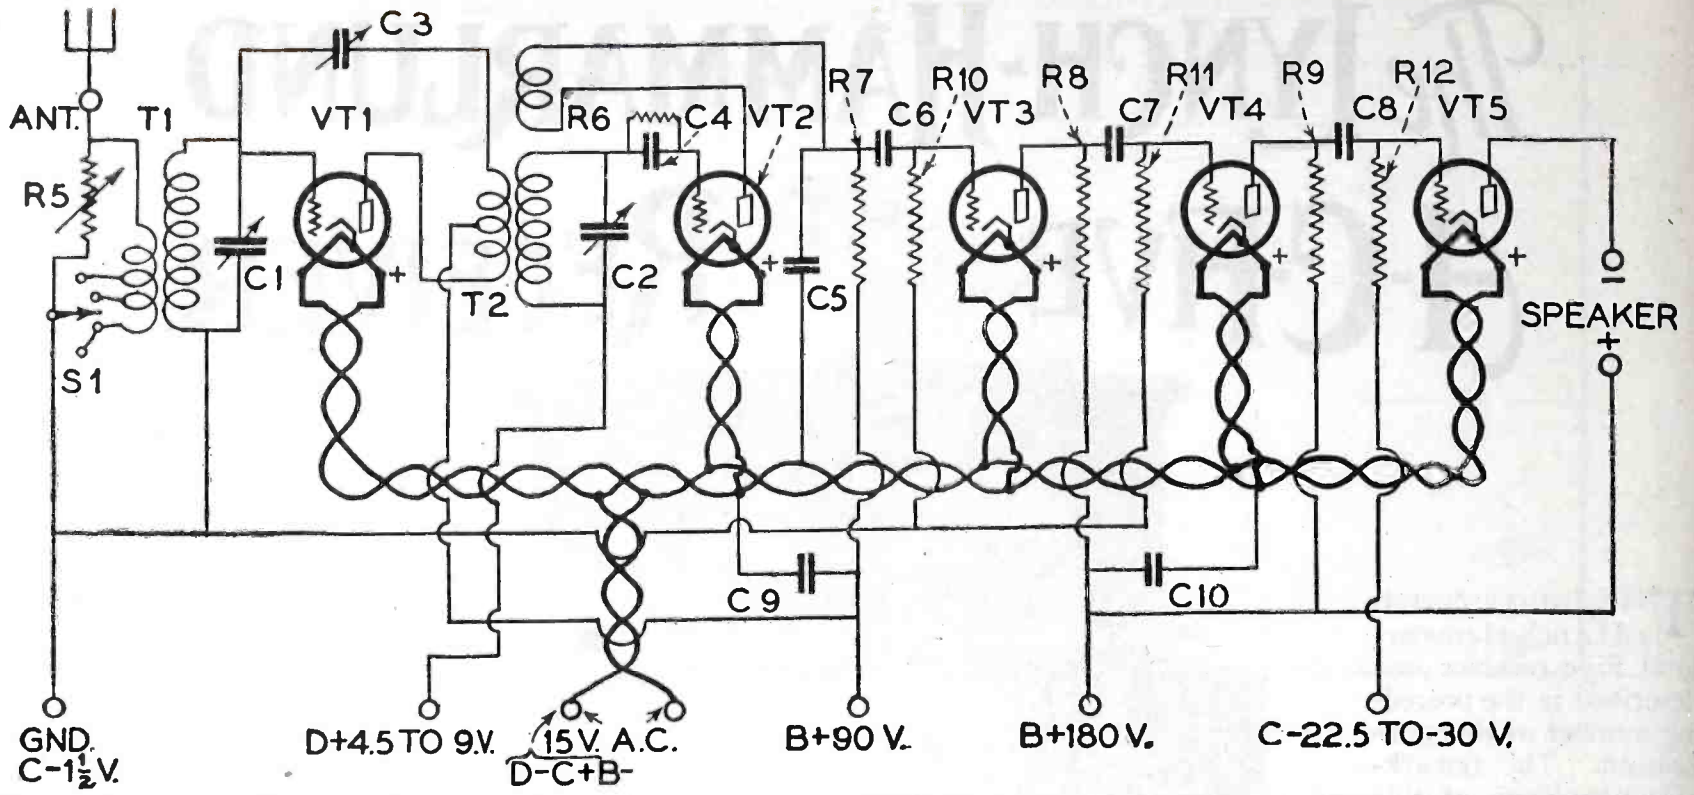
(Arcturus type 28 amplifier tubes may also be used in place of the hi-mu tubes with satisfactory results.)

2 Polymet 2. mfd. by-pass condensers, C10, C11

1 Filament lighting transformer with a 15 volt secondary such as the Thordarson type TY 121.

The mechanical appearance of the A.C. receiver converted from the battery set remains identical with that of the original design as will be observed from the accompanying photographs. The circuit changes are as follows resulting in the arrangement shown in the accompanying diagrams.

Turn the receiver upside down and clip all wires running to the filament terminals of the sockets at the point

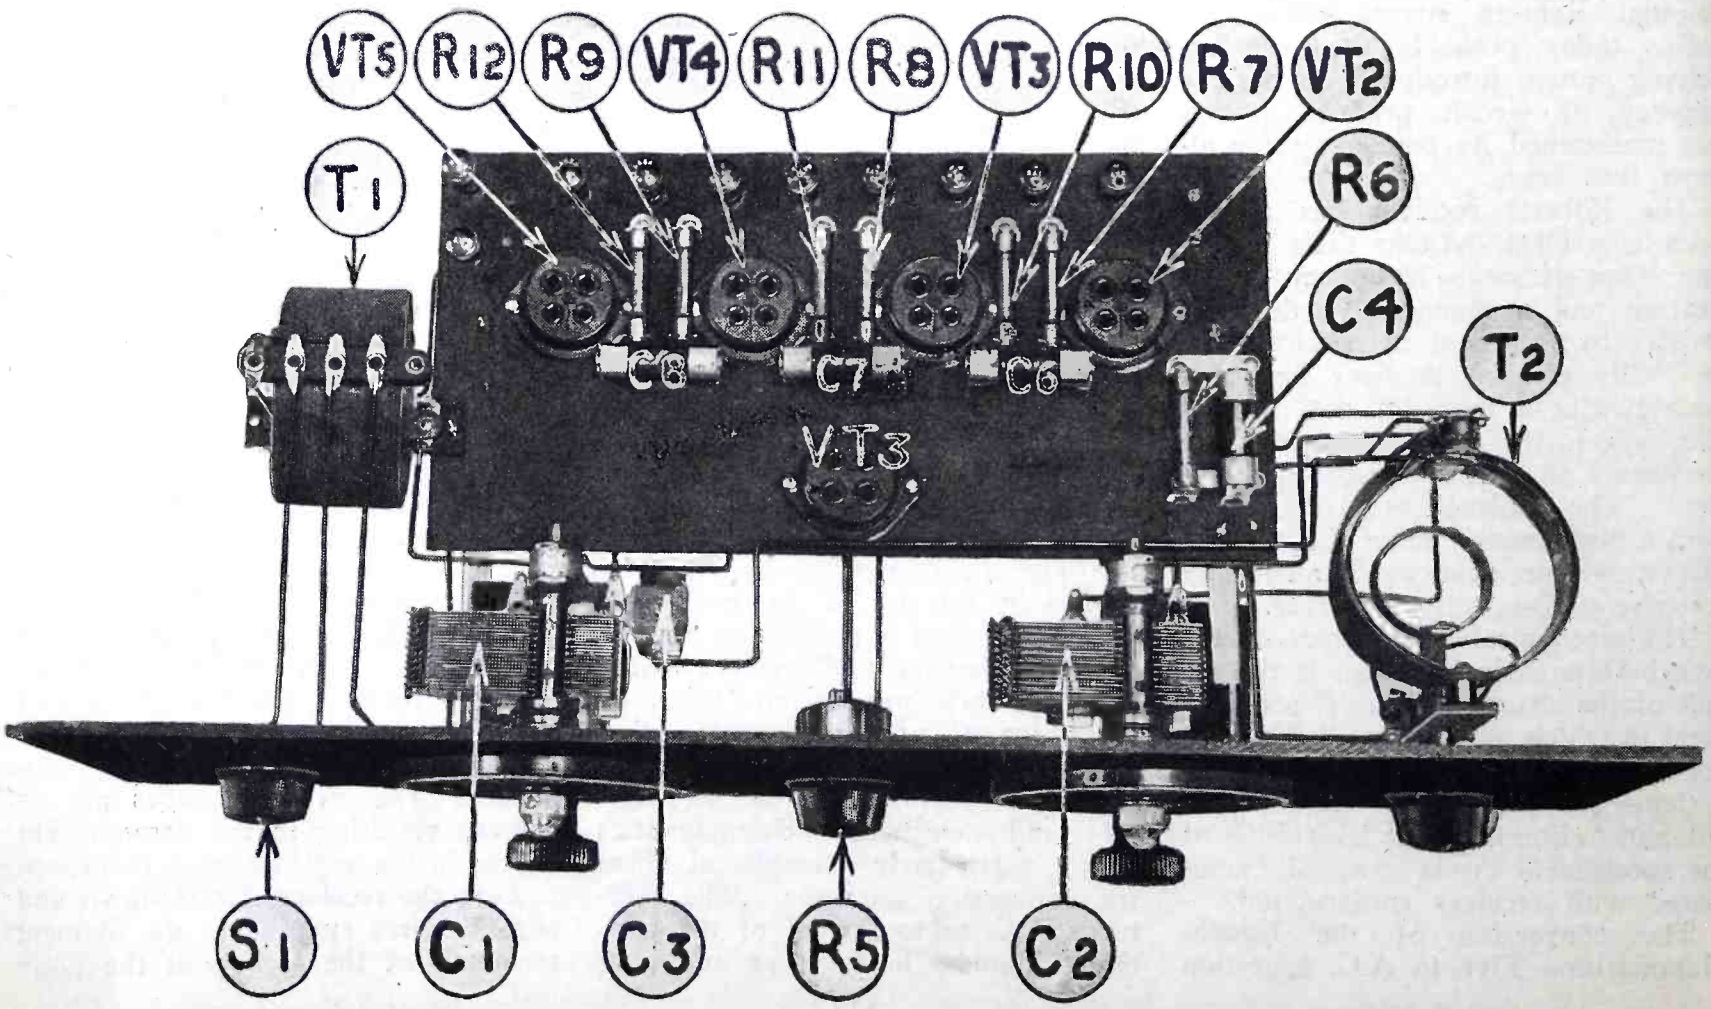


Above shows a schematic wiring diagram of the Lynch-Hammarlund set wired for A.C. operation. All parts of the circuit are indicated to correspond with photos, picture wiring diagram and list of parts.

where they connect to the lugs on the socket. Also disconnect the lead running to the A plus B minus post and likewise the lead running to the A minus C plus post at the posts. Short circuit all connections at the terminals of the 20 ohm rheostat and filament switch. Run a wire from this short circuited connection to the wire running from the ground post to the inductance switch. Now rewire the filament or heater circuit with twisted flexible cable. Twisted red and black Celatsite is recommended for this purpose as the coding facilitates the correct connections. As a matter of consistency connect the red wire to the plus filament post of all sockets. The twisted heater conductor is then led to the posts originally marked A plus and A minus. Coding is immaterial at this point. The effect of these alterations is such that the filament or heater circuit is now completely isolated from the rest of the receiver while the two radio frequency secondaries are grounded on the low potential sides.

Remove the grid leak in the detector circuit from its clip mounting. Replace it so that only side makes contact with the clip nearest to the socket, that is, the clip that is electrically wired to the grid terminal of the socket. The grid leak will now stick out past the detector socket being held in position only by one clip, the free terminal being unsupported. A wire is easily connected, by mechanical pressure, in the groove on this free end. This wire provides an extra lead to the receiver and is designated on the wiring diagram as "plus D 4.5 to 9 volts."

The grid returns from the first two



A top view of the set showing all parts mounted on the "deck" and front panel. The Clarostat, R5 is mounted directly in the center of the front panel and is connected in the antenna circuit of the set as shown in the diagrams accompanying this article.

audio frequency tubes have automatically been grounded by the connection effected between the 20 ohm rheostat (which has been shorted out of the electrical significance) and the ground post. No additional changes are made in the audio frequency amplifier.

With A. C. tubes the volume control or regenerative control of volume is seldom adequate on local stations. To provide satisfactory variations of signal intensity the Clarostat volume control is connected to antenna and ground posts. This has not been indicated on the circuit diagram. The volume control Clarostat is a table mounting device requiring no mechanical or electrical alterations in the receiver itself

It is desirable that two additional by-pass condensers be used in the A.C. job. The Polymet type C905 are particularly well suited mechanically and electrically to the designated use in the Lynch-Hammarlund receiver. These are connected between ground and plus 90 and 180 volts potential points. They are designated as "C" on the wiring diagram.

An additional lead is wired to the plus filament prong on the detector socket (which, incidentally, is the cathode to the detector tube) through which the B return is effected. This extra lead is designated on the wiring diagram as "minus B, minus D and plus C." It is important that an extra lead be wired for this purpose rather than use the red coded heater wire. An amplification plate potential of 180 is supplied to the post marked "B plus 135 volts" on the battery operated receiver. Plus 90 volts is tapped off to the indicated post and likewise, 45 volts for the detector circuit. The minus side of the B battery is connected to the special lead designated on the diagram. If it is possible to tap the B battery between 4.5 to 9 volts, this tap may be connected to the special lead designated as "plus D." If, however, it is impracticable to secure this special potential from the B battery, an extra battery may be connected between the D minus lead and the D plus lead. A "C" potential of 1.5 volts is connected between the B minus lead and the ground post—negative to the ground. If convenient and practicable this may be tapped off from a larger C. battery supplying from 22.5 to 30 volts to the grid of the power tube, (the C minus 9 volt post on the battery operated set.) Fifteen volts A.C. potential are applied to the heaters for the Arcturus tubes. The tubes may be turned on and off by a switch placed in the primary circuit of the heater lighting transformer.

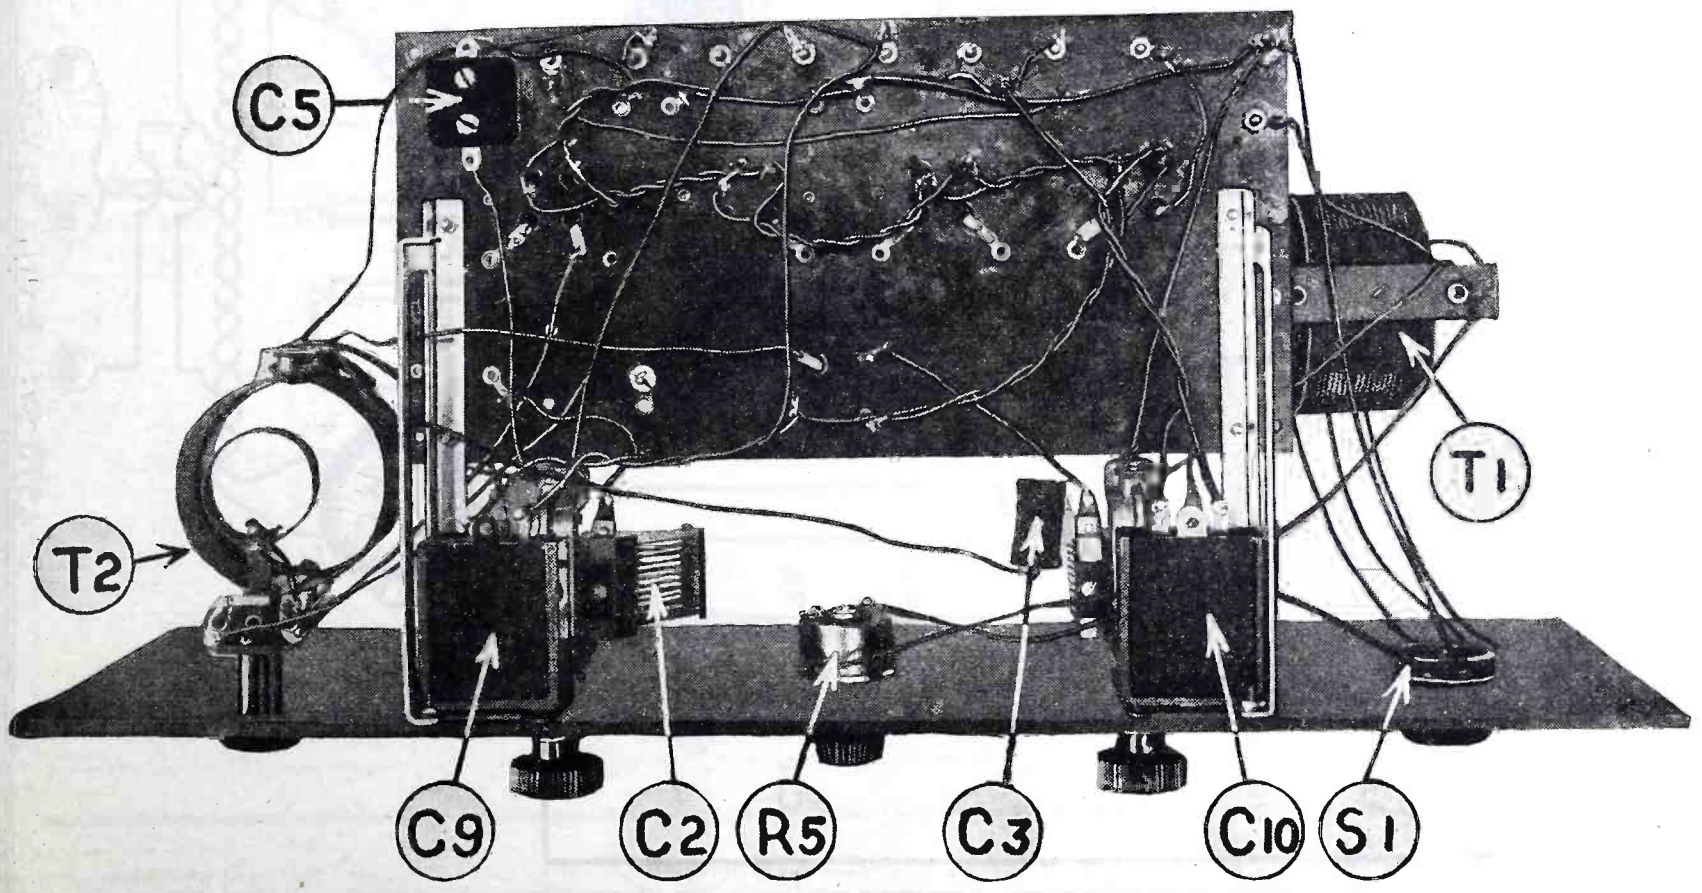
Any efficient eliminator, such as can be found advertised in this publication, supplying the necessary potentials, can be used in place of the batteries.

If it is desired to build a complete receiver of the Lynch-Hammarlund A.C. Five design rather than converting an already existing battery operated set, the accompanying list of parts will be required in addition to the parts listed previously.

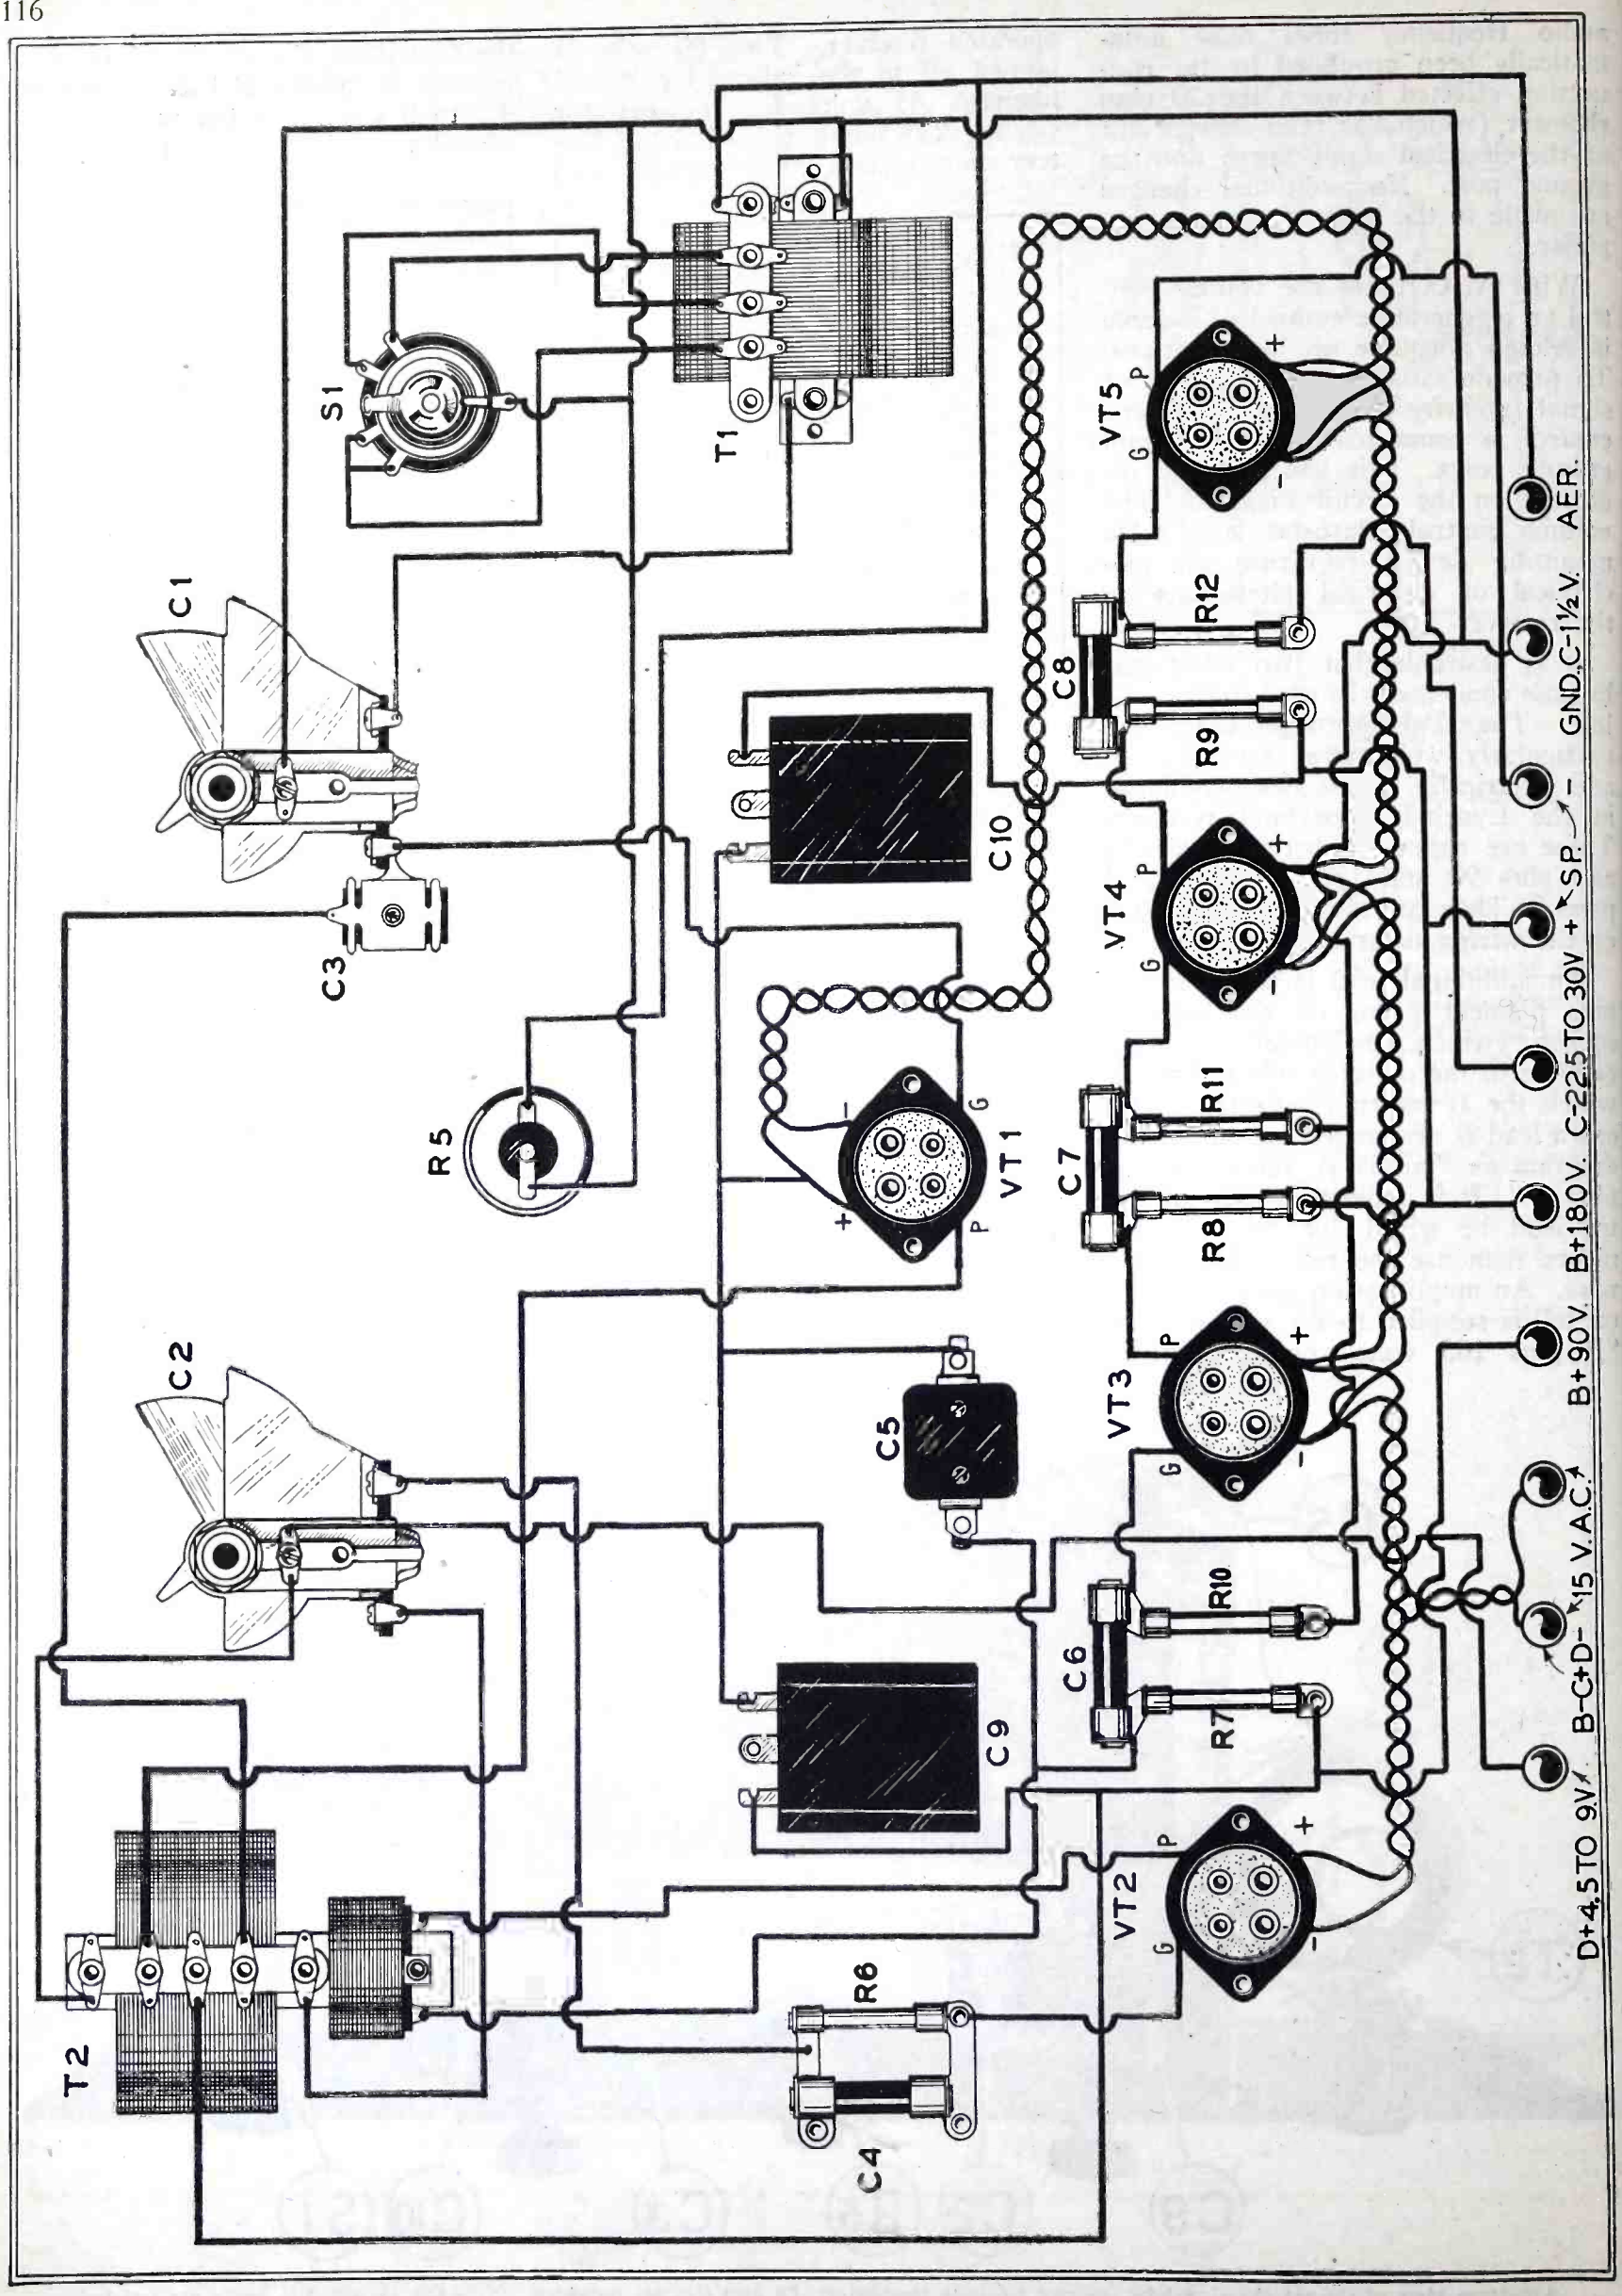
The operation of the Lynch-Hammarlund A.C. Five receiver is identical with that of the battery operated model. A slight readjustment of the neutralizing condenser may be necessary. While the design of the heaters on the Arcturus tubes is such as to provide for reasonable variations

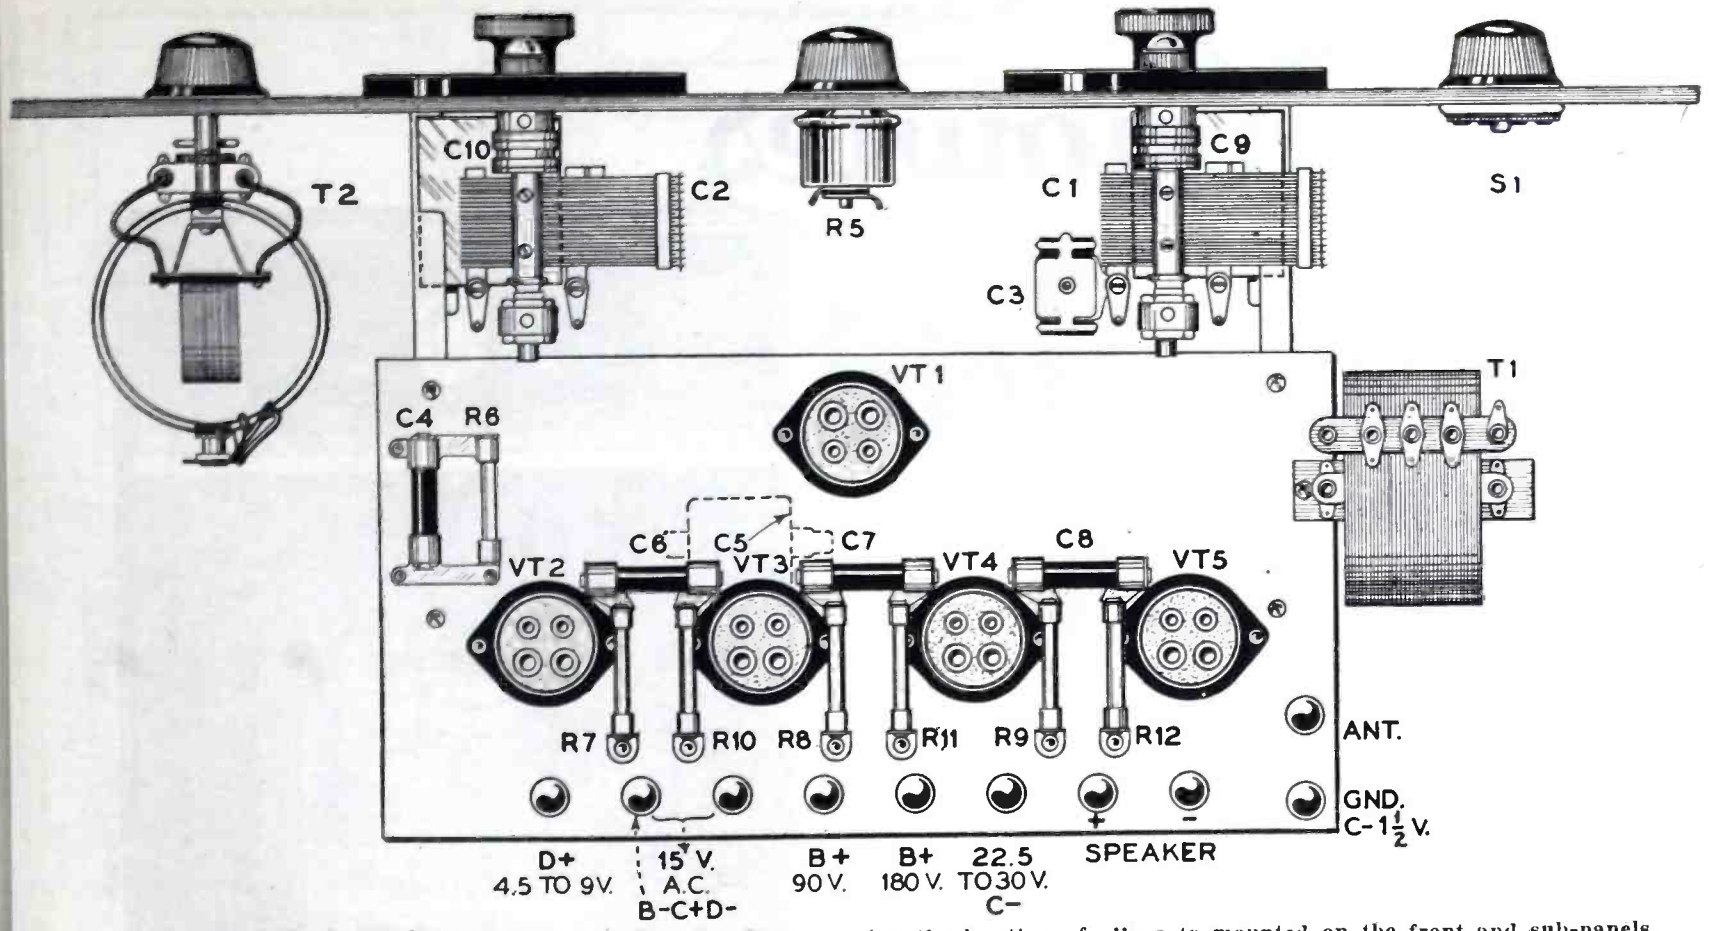
LIST OF PARTS

1 Lynch five tube DeLuxe kit which includes the following:
1 Lynch .00025 mfd. cartridge type fixed condenser, C4
3 Lynch .006 mfd. cartridge type fixed condensers, C6, C7, C8
1 Lynch 2.5 megohm metallized resistor, R6
3 Lynch .1 megohm metallized resistors, R7, R8, R9
3 Lynch .5 megohm metallized resistors, R10, R11, R12
5 Eby universal sockets, VT1, VT2, VT3, VT4, VT5
1 Formica or Micarta 6x12 3/16-inch sub-panel
4 Sets special mountings
All of the above material is completely assembled on the sub-panel ready for wiring.
2 Hammarlund ML-23 .0005 mfd. variable condensers, C1, C2
1 Hammarlund EC. equalizing balancing condenser, C3
1 Polymet .001 mfd. fixed condenser, C5
2 Polymet 2. mfd. by-pass condensers, C9, C10
1 Carter inductance switch No. 404, S1
1 Hammarlund antenna coupler HR-23, T1.
1 Hammarlund coupler coil, TCT-23, T2
1 Formica panel 7x21x3/16 inch
2 Benjamin sub-panel brackets
2 Marco vernier dials
10 X-L or Eby binding posts
1 Can of Kester radio solder
1 Package of Acme Celatsite hook-up wire



A bottom view of the set showing how the two by-pass condensers, C9 and C10 are mounted. Note the 15-volt A.C. leads are twisted.





Instrument layout of the Lynch-Hammarlund A.C. Five Receiver, showing the location of all parts mounted on the front and sub-panels.

in line voltage, it is desirable that the heaters be lighted across a potential of 15 volts. This assurance is best effected by using a Jewell A. C. voltmeter. However, if such an instrument is not available, the proper adjustment to the transformer voltage (generally effected by variable taps) can be achieved by noting the length of time it requires for the cold filaments to heat to normal operation. At 15 volts it will require exactly 30 seconds from the time the current is turned on to when satisfactory reception is secured.

One of the most important details in the construction of the home-built or custom-made receiver is the installation of the completed ensemble in a suitable cabinet to fill the requirements of home surroundings as well as the convenience of installing incidental equipment. The cabinet to the radio set is therefore just as important as the body of an automobile is to the chassis.

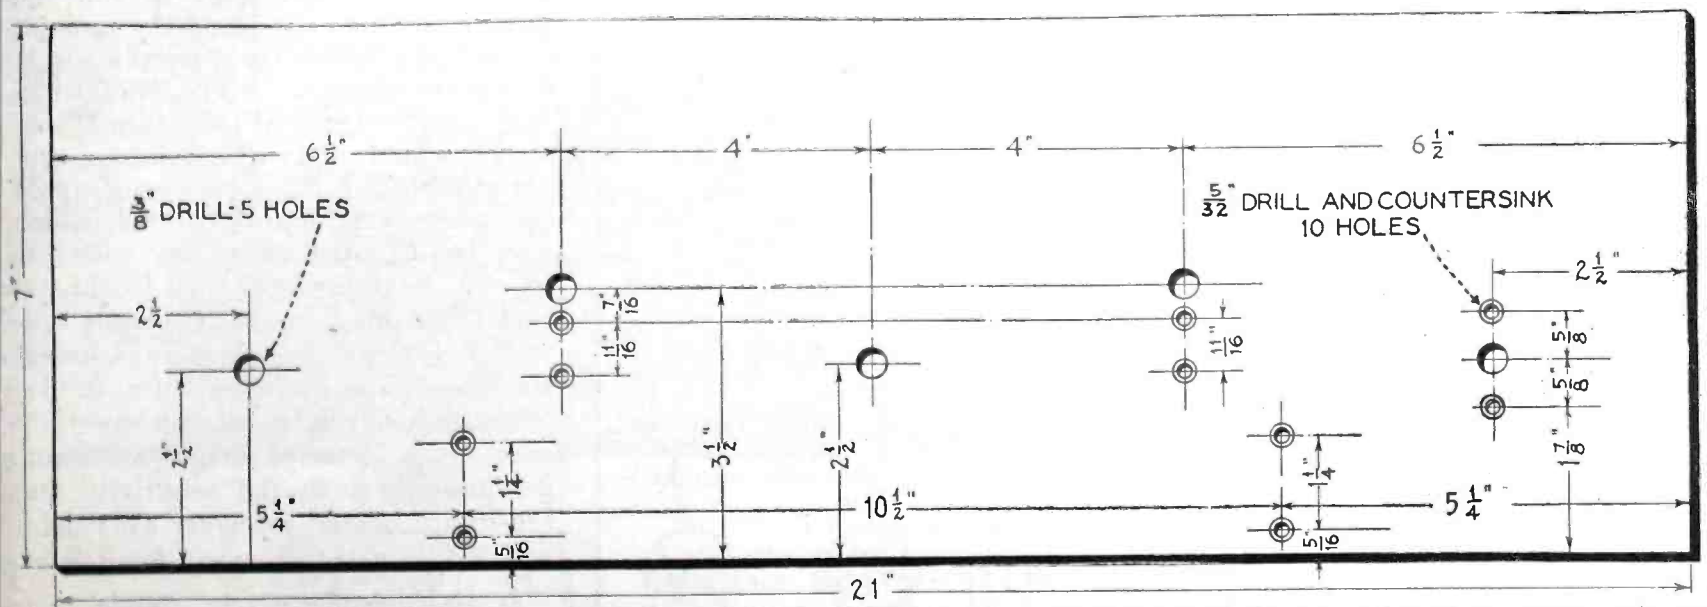
For this reason we cannot recommend too highly the advisability of installing the set in a cabinet or console which will be in keeping with the furnishings of the home.

The Lynch-Hammarlund A.C. Five as described in the preceding paragraphs is shown in the heading of this article installed in an Excello wall type console. This particular type of cabinet is available in various designs. The upper portion of the cabinet into which the set is placed also provides ample space for installing other incidental equipment employed with the set. The lower portion is fitted with a decorative grill backed with a silken mesh fabric, and a cone or aeroplane cloth speaker can easily be installed in this part of the cabinet.

There are several types of loud speaker kits and speaker units available on the market, but if the constructor hopes to be repaid for his time and efforts as well as expense, it would be well to select a speaker unit which will handle all that this receiver will deliver and exercise care in the construction of the cone or aeroplane cloth diaphragm.

Among the most efficient types of speaker units recommended in connection with the construction of a loud speaker suitable for installing in the lower portion of the Excello console are the Ensco, Accusti-cone, Fan-speaker or the G.R.P. units.

The "B" eliminator unit to be used in connection with the Lynch-Hammarlund A.C. receiver can also be installed in the lower portion of the cabinet just behind the speaker diaphragm.



Layout for drilling the front panel. The hole at the extreme left is for mounting switch, S1 and hole at the extreme right for coupler coil, T2, either side are for mounting the variable condensers, C1 and C2. The hole directly in the center of the panel is for the Clarostat variable resistor, R5, and holes on either side are for mounting the variable condensers, C1 and C2.

The Knowles Screen-Grid Four

WE are continually told that the radio industry is "in its infancy" and that things in radio quickly become obsolete. While this would seem to be true, judging from the "new" and "revolutionary" designs that appear from time to time, there are numerous exceptions. Probably the most outstanding exception to this tendency, in circuit combinations, is that of a stage of tuned-radio-frequency amplification with a regenerative detector and an audio-frequency amplifier. This type of circuit has appeared under numerous different names—each variation calling for a new name.

The fact that this circuit arrangement is still very popular, although it has been in common use for four years or more, indicates that it has definite survival value. With the advent of the screen-grid (222-type) tube, which promises to mark a new era in radio-frequency amplification, it is very natural to ask whether this popular circuit arrangement can still be used advantageously and, if so, just what modifications are necessary. Because of the very different characteristics of this new tube it is important to modify the circuit, and not merely to insert the new tube in the old circuit with the expectation of getting greatly-improved results.

The receiver we are about to discuss is one which combines the features of this well-known circuit arrangement with the modifications made necessary by the use of the 222 tube. The merits which have been carried over may be summed up in the word "performance." This is due to the fact that each tube is made to operate at its maximum efficiency — a thing which is much more difficult in a receiver using five or more tubes.

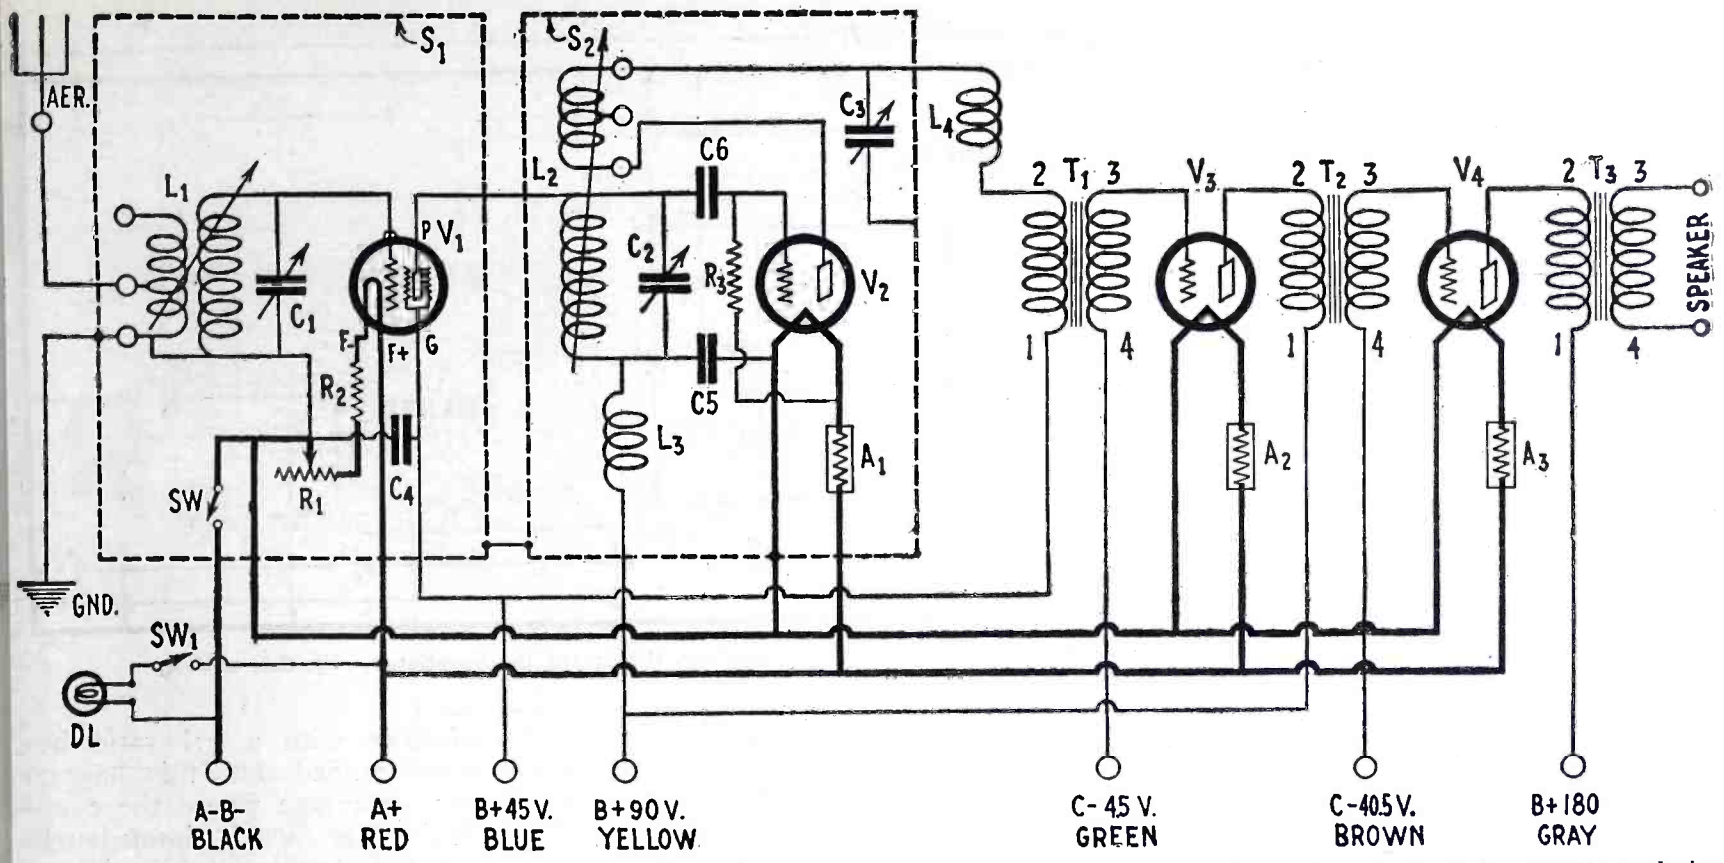
LIST OF PARTS

2 Hammarlund .00035 mfd. variable condensers, C1, C2.
1 Hammarlund 65 mmfd. midget condenser, C3.
2 Polymet or Tobe 0.5 mfd. bypass condensers, C4, C5.
1 Polymet .00025 mfd. grid condensers, C6.
2 S-M audio frequency transformers, 3 to 1 ratio, T1, T2.
1 S-M output transformer, 1 to 1 ratio, T3.
2 Hammarlund coupling coils, L1, L2.
2 Hammarlund R. F. choke coils, 85 millihenry, L3, L4.
2 Amperites, 5 volt, ¼ ampere type, A1, A2.
1 Amperite, ½ ampere type, A3.
1 Yaxley switch-rheostat, 40 ohms, R1, SW.
1 Yaxley fixed resistor, 15 ohms, R2.
1 Polymet or Durham grid leak, 8 megohms, R3.
1 Screen-grid tube, type 222, V1.
1 CeCo type H special detector tube, V2.
1 CeCo type A tube, V3.
1 CeCo type 171 tube, V4.
2 Hammarlund aluminum stage shields, S1, S2.
1 Yaxley 7 wire cable plug P.
1 Hammarlund double type drum dial.
1 Polymet grid leak mounting.
3 X-L binding posts.
4 Benjamin UX type sockets.
1 Formica or Micarta front panel, 7x21x½ in.
1 Formica or Micarta terminal strip, 3x¾x⅛ in.
1 Wood baseboard.
1 Pkg. Acme Celatsite wire.
1 Pkg. Kester rosin core solder.

In performance the receiver combines the features that have made the sets using the 201A-type tube popular, and those that are made possible only by the use of the new 222-type tube. It combines simplicity of operation on local stations with a flexibility of control which permits the more experienced operator to get remarkable results on distant stations. The 222-type tube has made greater radio-frequency amplification possible; with the result that this set's sensitivity is equal to that of the average five- or even six-tube receiver in which controlled regeneration and individual-stage control are not used.

The antenna coupling may be varied (in the coil L1) to suit the type of antenna used and the amount of interference that prevails in a particular locality. The radio-frefrequency stage (S1) is tuned separately; which insures maximum amplification. The detector circuit (S2) has a separate tunning control, which may be operated in unison with the R. F. stage control on local stations, but may be more closely adjusted for the reception of distant stations. The judicious use of regeneration by means of condenser C3 makes the detector stage contribute its quota to both the selectivity and sensitivity of the receiver. This point will be discussed in more detail later.

It is a comparatively simple matter to make one laboratory model of



The schematic diagram of the Knowles screen-grid receiver described in the article herewith. The dotted lines indicate the shields enclosing R. F. portions of the circuit.

a receiver which has exceptional performance; but it is a very different thing to build a receiver which may be duplicated by the thousands in the homes of set constructors, not only in parts of appearance, but in performance as well. When this is considered we have a clue to the popularity of the R. F.-stage, regenerative detector combination. Such a circuit normally has no component parts which have critical values; in other words, it is a *production receiver* in the sense that it is easy to duplicate and can be relied upon for excellent results consistently.

One of the most important motives in building a receiver is the economic one. Since the set builder is usually willing to use only the best parts obtainable, to insure corresponding performance, it is important to build a receiver which is simple and which uses as few com-

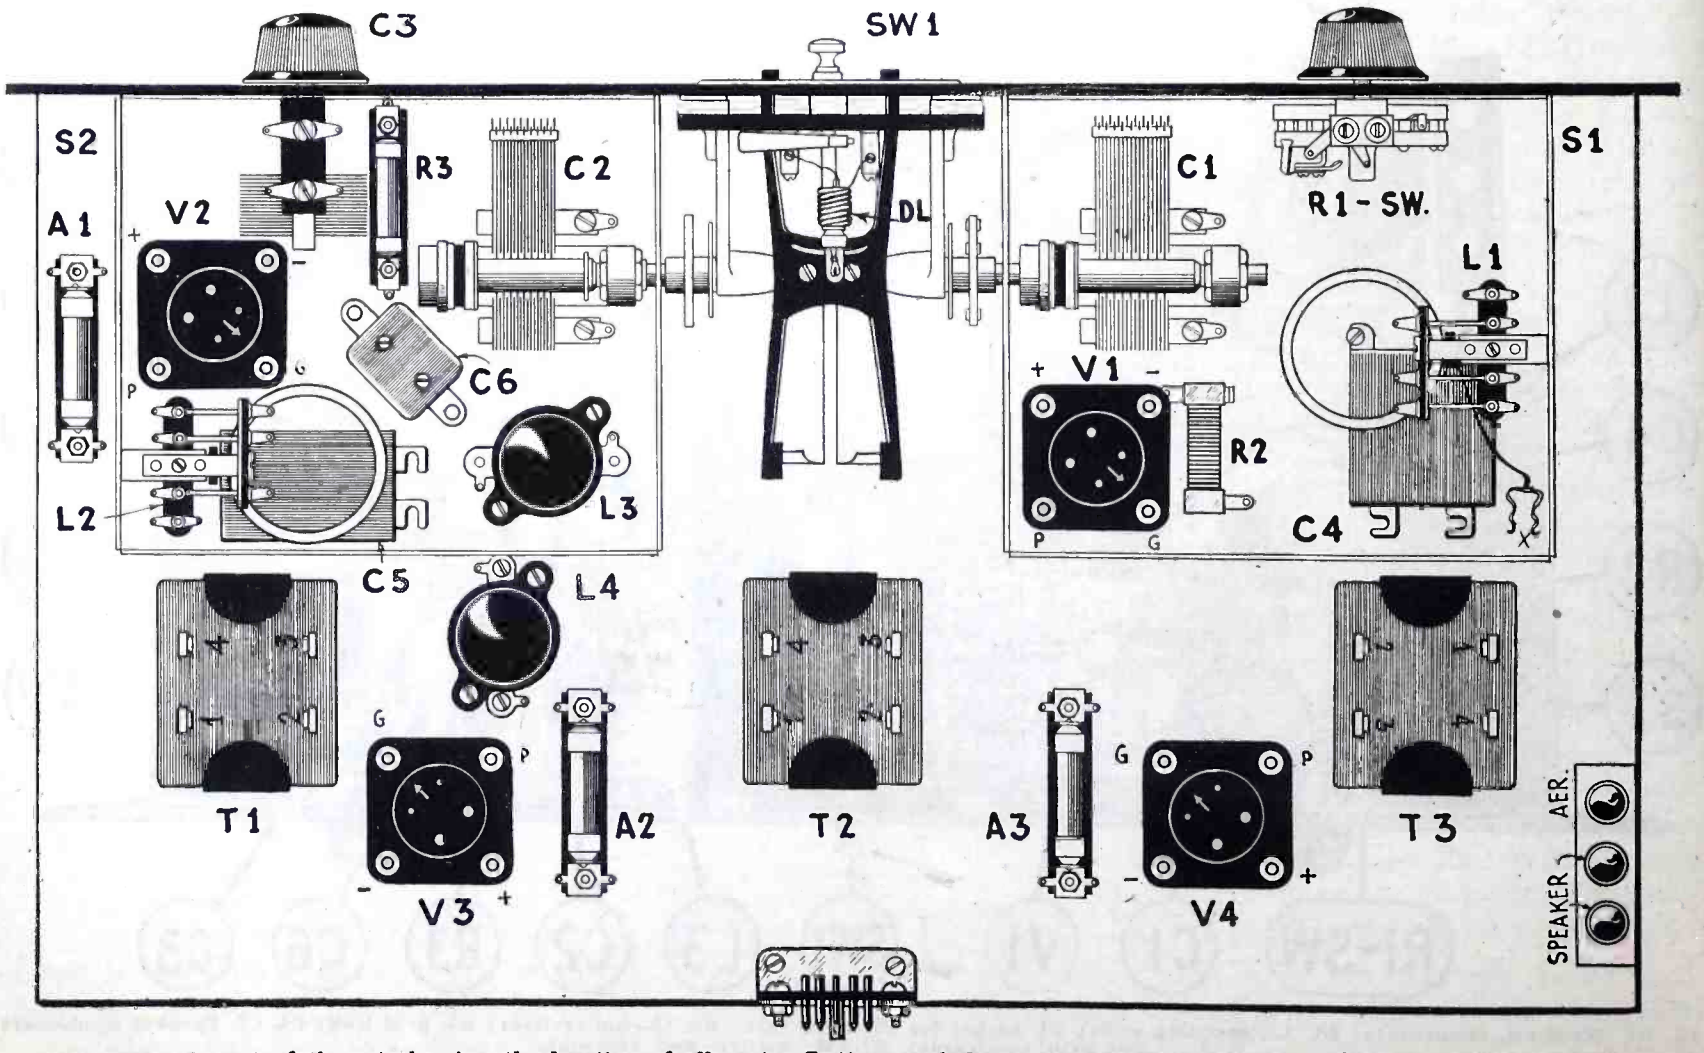
ponents and tubes as possible. This is another important reason for the survival and popularity of the circuit combination we have in mind.

An inspection of the wiring diagram of the receiver will show that two principal changes are made necessary by the use of the new screen-grid tube, V1. These are the omission of the balancing circuit, which is a distinct advantage resulting from the low inter-electrode capacity (from control grid to plate) in this tube; and the use of a tuned circuit instead of a transformer to couple the radio-frequency stage to the detector.

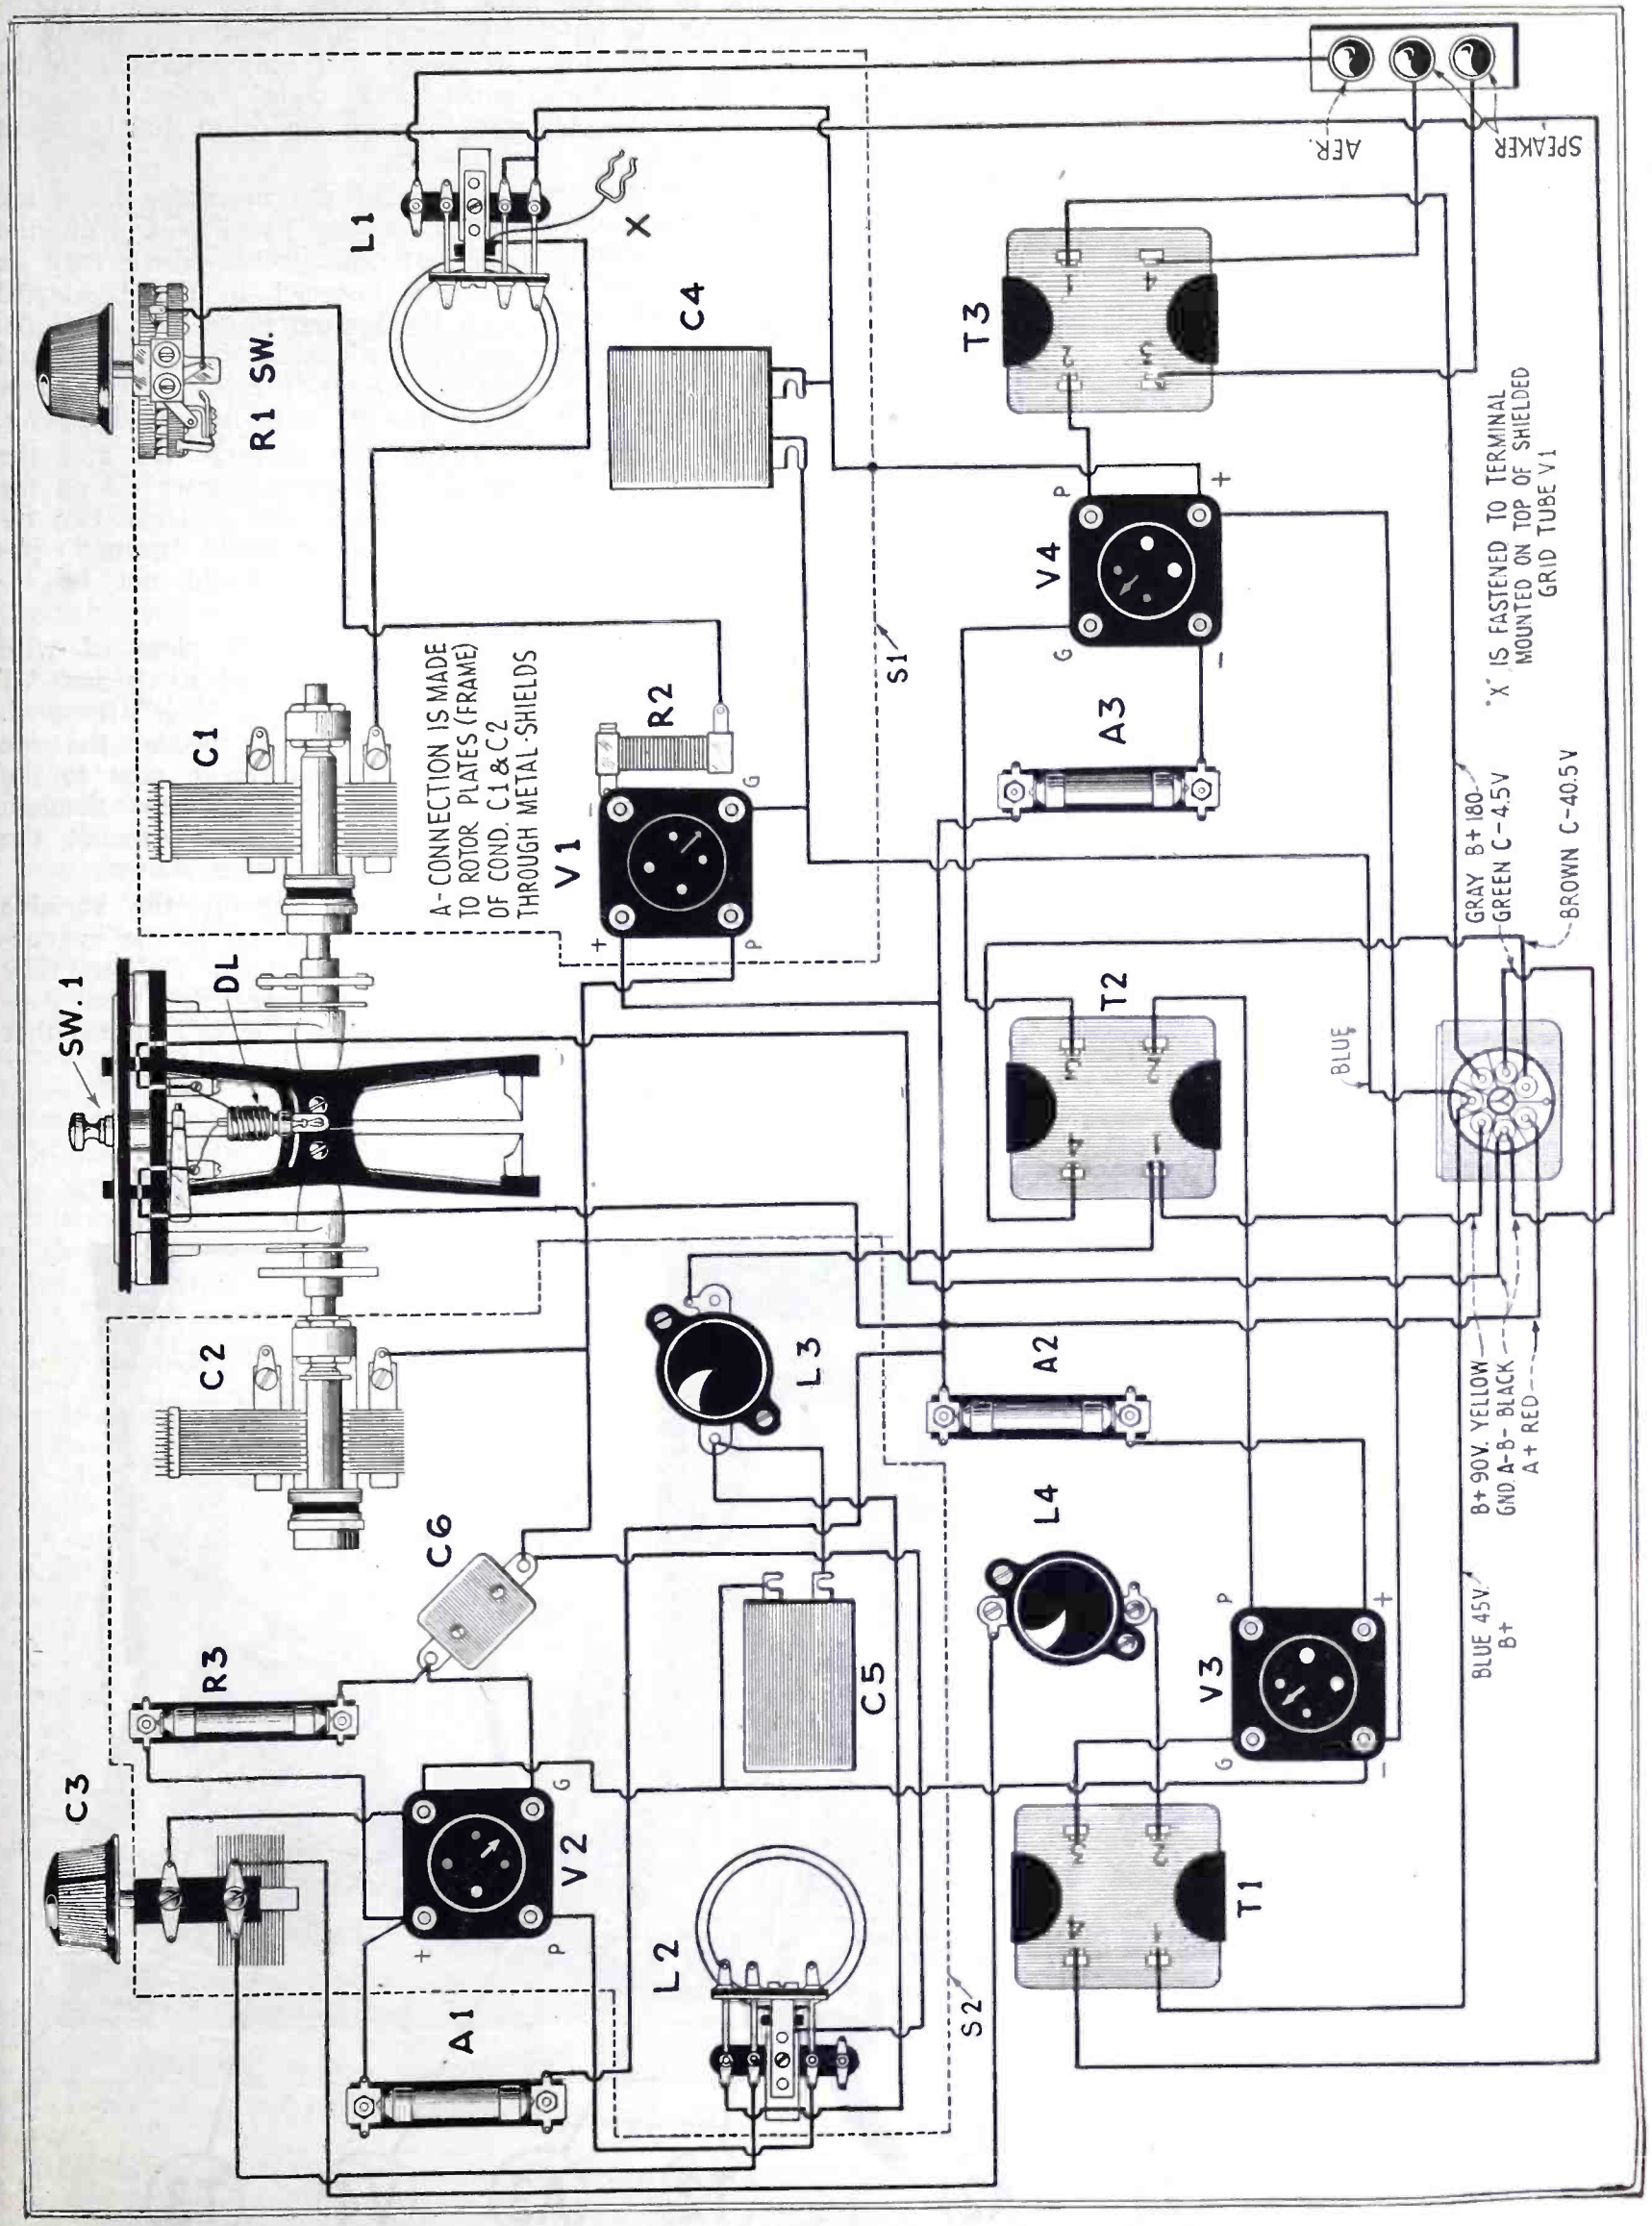
Although no balancing circuit is used, certain precautions must be observed. It is important to minimize the capacity between the plate of the screen-grid tube and the control-grid. In this arrangement, it will be seen that the plate lead leaves the shield compartment within half an inch of the terminal. To prevent any coupling through the common battery, or through the battery leads, a radio-frequency choke and a by-pass condenser are used.

Because of the high plate impedance of the 222-type tube it is important to use a coupling device of high impedance. This is most readily obtainable, without the use of a special coil, by using a tuned circuit such as recommended by the manufacturer of the tube. In some cases a transformer with a 1:1 ratio has been recommended, but this has no particular advantage where the coupling device is used immediately ahead of the detector tube. When such a transformer gives perfect coupling between the primary and secondary, it is similar to the tuned-impedance stage. When increased selectivity is obtained, it is due to looser coupling or to the omission of the grid leak; and this cannot be omitted in the detector stage without making the detector itself much less efficient.

This circuit normally tunes very broadly. This is due partly to the fact that the grid leak is connected across the tuned circuit; but prin-



Instrument layout of the set showing the location of all parts. Letter symbols correspond with diagrams, photos and list of parts.



cipally to the fact that the 201A-type tube must be operated with a positive bias on the grid to secure efficient rectification in the grid circuit (that is, with a condenser-leak arrangement). This positive bias is obtained by connecting the leak (R3) to the positive A filament terminal. Under these conditions the grid attracts electrons and this greatly decreases the grid-to-filament resistance, resulting in loss of sensitivity and selectivity.

To insure good quality reproduction the radio-frequency circuits need not pass more than about ten kilocycles. When the tuned circuit "looks into" the detector, the band it will pass depends on the frequency but is from 30 to 60 kilocycles wide; indicating that it contributes little or nothing to the selectivity. Furthermore what is known as the "dynamic" resistance of the circuit is decreased to such a low value that the 222-type tube gives only moderate amplification.

To offset these effects regeneration has been used. The effect of regeneration is to decrease the losses in the circuit or to increase the resistance across the circuit. When used in moderation it results merely in bringing this stage up to par without impairing the quality. In other words, sufficient regeneration may be used to increase the amplification considerably and to narrow the band the circuit passes to approximately 10 kilocycles. The adjustment is made by the operator, who can regulate it until he detects no appreciable distortion.

When the radio-frequency stages are adjusted so they do not discriminate against the higher audio frequencies, then the problem of good reproduction rests with the audio-frequency amplifier and speaker. A high quality audio-frequency amplifier has been used together with an output transformer, which makes it possible to use the 171 or 171A-type tube in the last stage.

The receiver may very easily be constructed by following the instrument layout, picture and schematic wiring diagrams.

A few general precautions will permit the constructor to duplicate the receiver quite easily. If three hours are available in which to assemble the receiver, one of them will be well spent in considering the sequence that is to be followed in the assembly, and in becoming familiar with the various parts and leads.

Partially assemble the two shields by holding the sides together and forcing the corner pieces down about half way. Place the bottom of the shield in what seems to be the proper position and then hold the assembled side walls immediately over it. The shields should be so placed that they are next to the panel and their sides clear the couplings on the drum dial by about 3/16-inch.

After all the necessary holes are drilled in the panel and drum-dial sides of the shields, these may be securely fastened to the baseboard with the bottom piece in place. An ice pick or similar tool may be used very conveniently to locate the screw holes and to start the wood screws.

Mount the rheostat R1 and the variable midget condenser C3 on the panel. The shafts of these two instruments are at shield (ground) potential so they should not be insulated.

Solder an 18-inch piece of wire to the "P" terminal of socket V1 and another to the "F+" terminal. These two leads go through the side of the left-hand shield, next to the drum dial. Thread them through the holes provided and mount the socket in the position shown.

Details for aligning the variable condensers are given in the instructions with the drum dial so they need not be repeated. The condenser C1 should be so mounted that

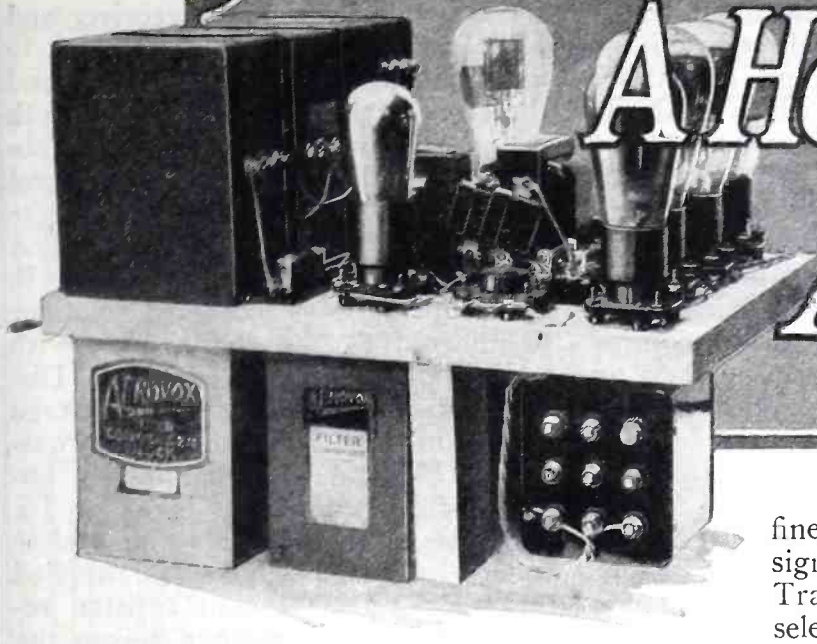
A Home Concert Amplifier



THE last two years have seen greater advances in the perfection of broadcast reception equipment than any other like period since the inception of broadcasting. It is less than two years since we thought that a push-pull amplifier utilizing two 201A tubes with 90 volts of B battery gave us real good reproduction. Perhaps it did, but when the first of the power tubes were brought out there was no question as to their superiority. The 71 followed the 112 and finally the old 5-watt transmitting tube was dressed up into the 7½-watt amplifier and seemed the culmination of amplification effort.

The last of these tubes drew from 20 to 30 milliamperes each, which, in consideration of the voltage required for their operation, absolutely prohibited the continuance of batteries except by millionaires; and eliminators became the order of the day.

Ever progressing, however, the last three months or so have seen the announcement of a new amplifier tube which dwarfs the 210—we now have available tubes of the UX-250 type. These tubes require no higher voltage than did the 210 and have at last enabled us to reproduce music on a scale which makes it possible to imagine that we have the singer or orchestra in our own home. In the past we have not been able to bring in the full performance of a symphony orchestra with real fidelity—in fact, even the base notes of the piano have betrayed the burring dissonance which is a sure sign of overloading. The new tubes change all this. They will reproduce all the volume which can be desired for home entertainment without any distortion whatever and we can now listen to the whispering notes of the upper register or the deep boom of a tuba with equal pleasure.

Owing to the much larger amounts of power required for the operation of the new valves, a great many refinements in circuit design prove necessary. Transformers must be selected which will carry the greater drain. Filter chokes which were all right for 35 M.A. have no reactance at all at 135. Filter systems must be designed with a view towards much improved regulation even with the heavier load. Amplifiers must be designed with greater care, for we no longer can be helped by corrective distortion.

LIST OF PARTS

1 Thordarson power transformer, type T-2098, T1
1 Karas A.C. Former, T2
1 Aerovox Pyrohm type 992-900, R1
1 Aerovox Pyrohm type 992-750, R2
2 Aerovox condensers type 202, 1 mfd., C1, C2
2 Thordarson chokes type 2099, L1, L2
2 Aerovox condensers type 1002, 2 mfd., C3, C6
2 Aerovox condensers, type 1002, 4 mfd., C4, C5
1 Aerovox Pyrohm type 992-10,000, C7
3 Aerovox condensers type 202, 4 mfd., C8, C9, C10
1 Aerovox Lavite resistor, 100,000 ohms with mounting, R3
1 Aerovox Pyrohm type 992-15000, R4
1 Aerovox Pyrohm type 992-8000, R5
1 Aerovox Pyrohm type 992-10000, R6
1 Aerovox Pyrohm type 992-250, R7
1 Thordarson output impedance type 2420, L3
1 Thordarson push-pull transformer type 2408, L4
2 Aerovox moulded mica condensers, .006 mfd., C11, C12
2 Aerovox Metalohms, 2 megohm, R8, R9
2 Aerovox Lavites, 500,000 ohms with mounting, R10, R11
1 Aerovox Lavite, 100,000 ohms with mounting, R12
8 Benjamin sockets
1 Yaxley plug and cable
1 Wood baseboard 12x15x1"
2 CeCo rectifying tubes, type R-81
2 CeCo amplifying tubes, type G
2 CeCo amplifying tubes, type L-250
1 Voltage regulator, type CX-374
1 Pkg. Kester rosin core solder
50 Ft. Corwico rubber covered hook-up wire.

The combined power unit and amplifier which will be described in the following paragraphs has been worked out with an eye to all these conditions and if instructions are followed carefully, the result will be a power block supplying up to 140 M.A. at 475 volts at the rectifier output.

The non-motor-boating voltage divider system cut this down to 45 and 90 volts for the receiver and 100 volts for the external first stage audio amplifier tube, which energizes the 4 tube power amplifier.

The voltage regulator tube, without which the unit nonoperative, protects the tubes and condensers from dangerous surges. The simplicity of construction is obvious, all parts except the filter condensers and resistances being mounted on the upper side of the foundation board while the condensers and power resistances are underneath. All wiring from one to the other is carried through one large hole and two small ones in the wooden baseboard.

To simplify construction of the functions of the various parts, we shall divide our description of the unit into the following sections. 1.—Power Converter; 2.—Filter and, 3.—Amplifier.

Mount the transformer, Lavite resistors and grid-leaks with the tube sockets on one side of the board taking care to locate them carefully as in the illustrations. Then turn the board over and mount the condensers and Pyrohm resistors with the Karas A.C. Former on the lower side of the board.

The .006 mfd. coupling condensers are mounted directly on the ends of the ½-megohm Lavite resistors.

The 110 volt A.C. Leads from the glow tube are carried around the outside of the board, twisted together and well away from all parts of the set; finally being led up directly to their terminals at the glow tube through a hole alongside of the socket. The same hole can be used to conduct the A.C. filament lead from the 5-volt section of the A.C. Former to the high-mu tube sockets.

All D.C. leads should be cabled to-

gether wherever possible and each pair or triplet of A.C. leads should be twisted separately. A.C. and D.C. leads should be as far apart as possible and the loud speaker leads from L3 to the Yaxley plug should also be twisted and can be somewhat separated from the other leads. All cases of transformers and condensers must be grounded in order to prevent any possible 120 cycle pick-up.

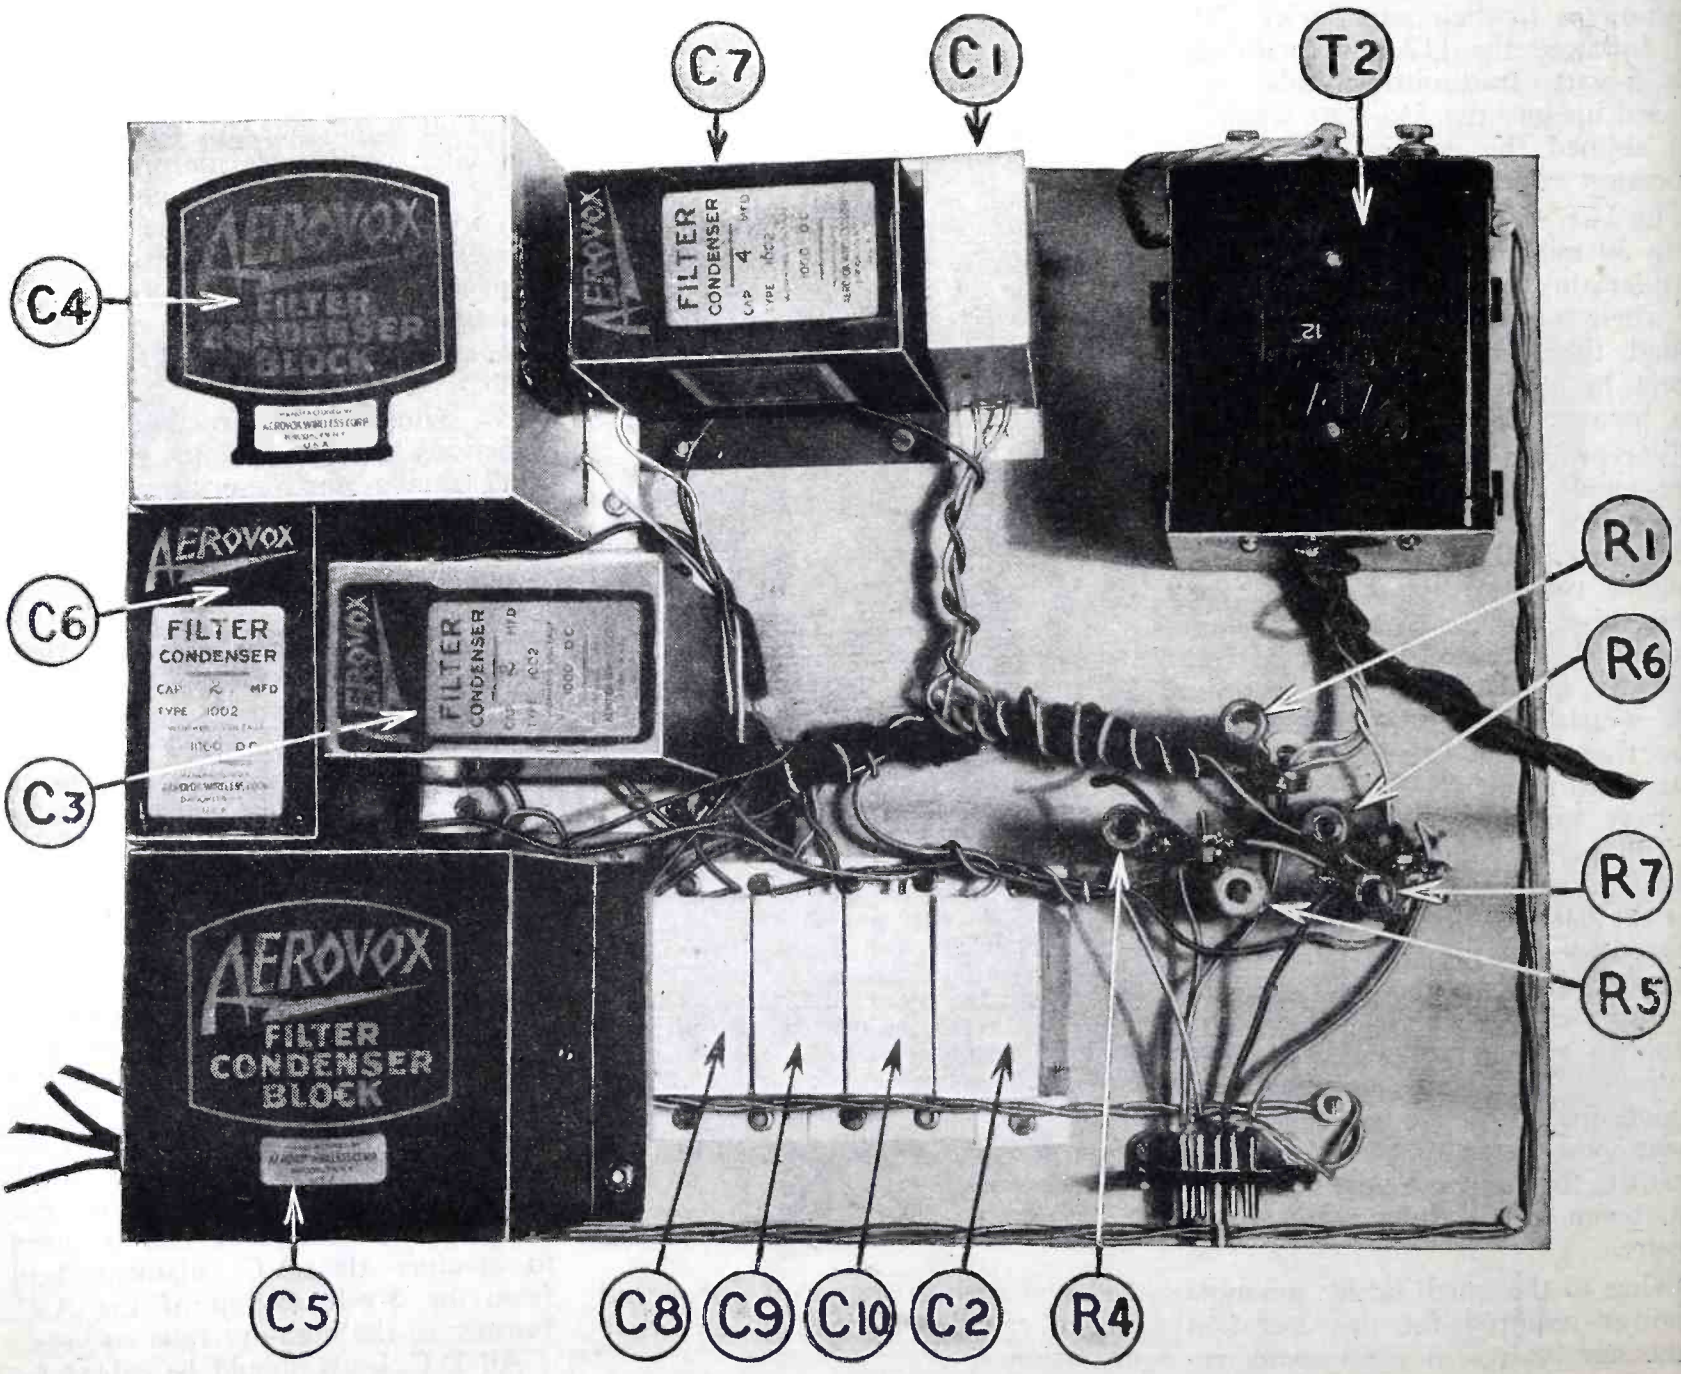
A reference to the circuit diagram will show a number of unusual features. For example, a great deal of care has been taken in designing the unit to prevent any possible audio frequency feed-back to plate supply taps, for all taps of more than 90-volts are taken direct from the maximum plus "B" terminal. The first sections of the double chokes are connected in parallel in order to increase their current carrying capacity and keep the voltage drop in them to a minimum. The plate supply for the two high-mu tubes is carried through a filter choke system which is separate from the supply for the balance of the tubes and isolates any possible trouble from reactance here.

The plate lead to the input transformer is also tapped directly off the major plus "B" through a 100,000 ohm Lavite resistor, which with its by-pass condenser forms an isolator circuit for the audio frequency component of the input tube plate current.

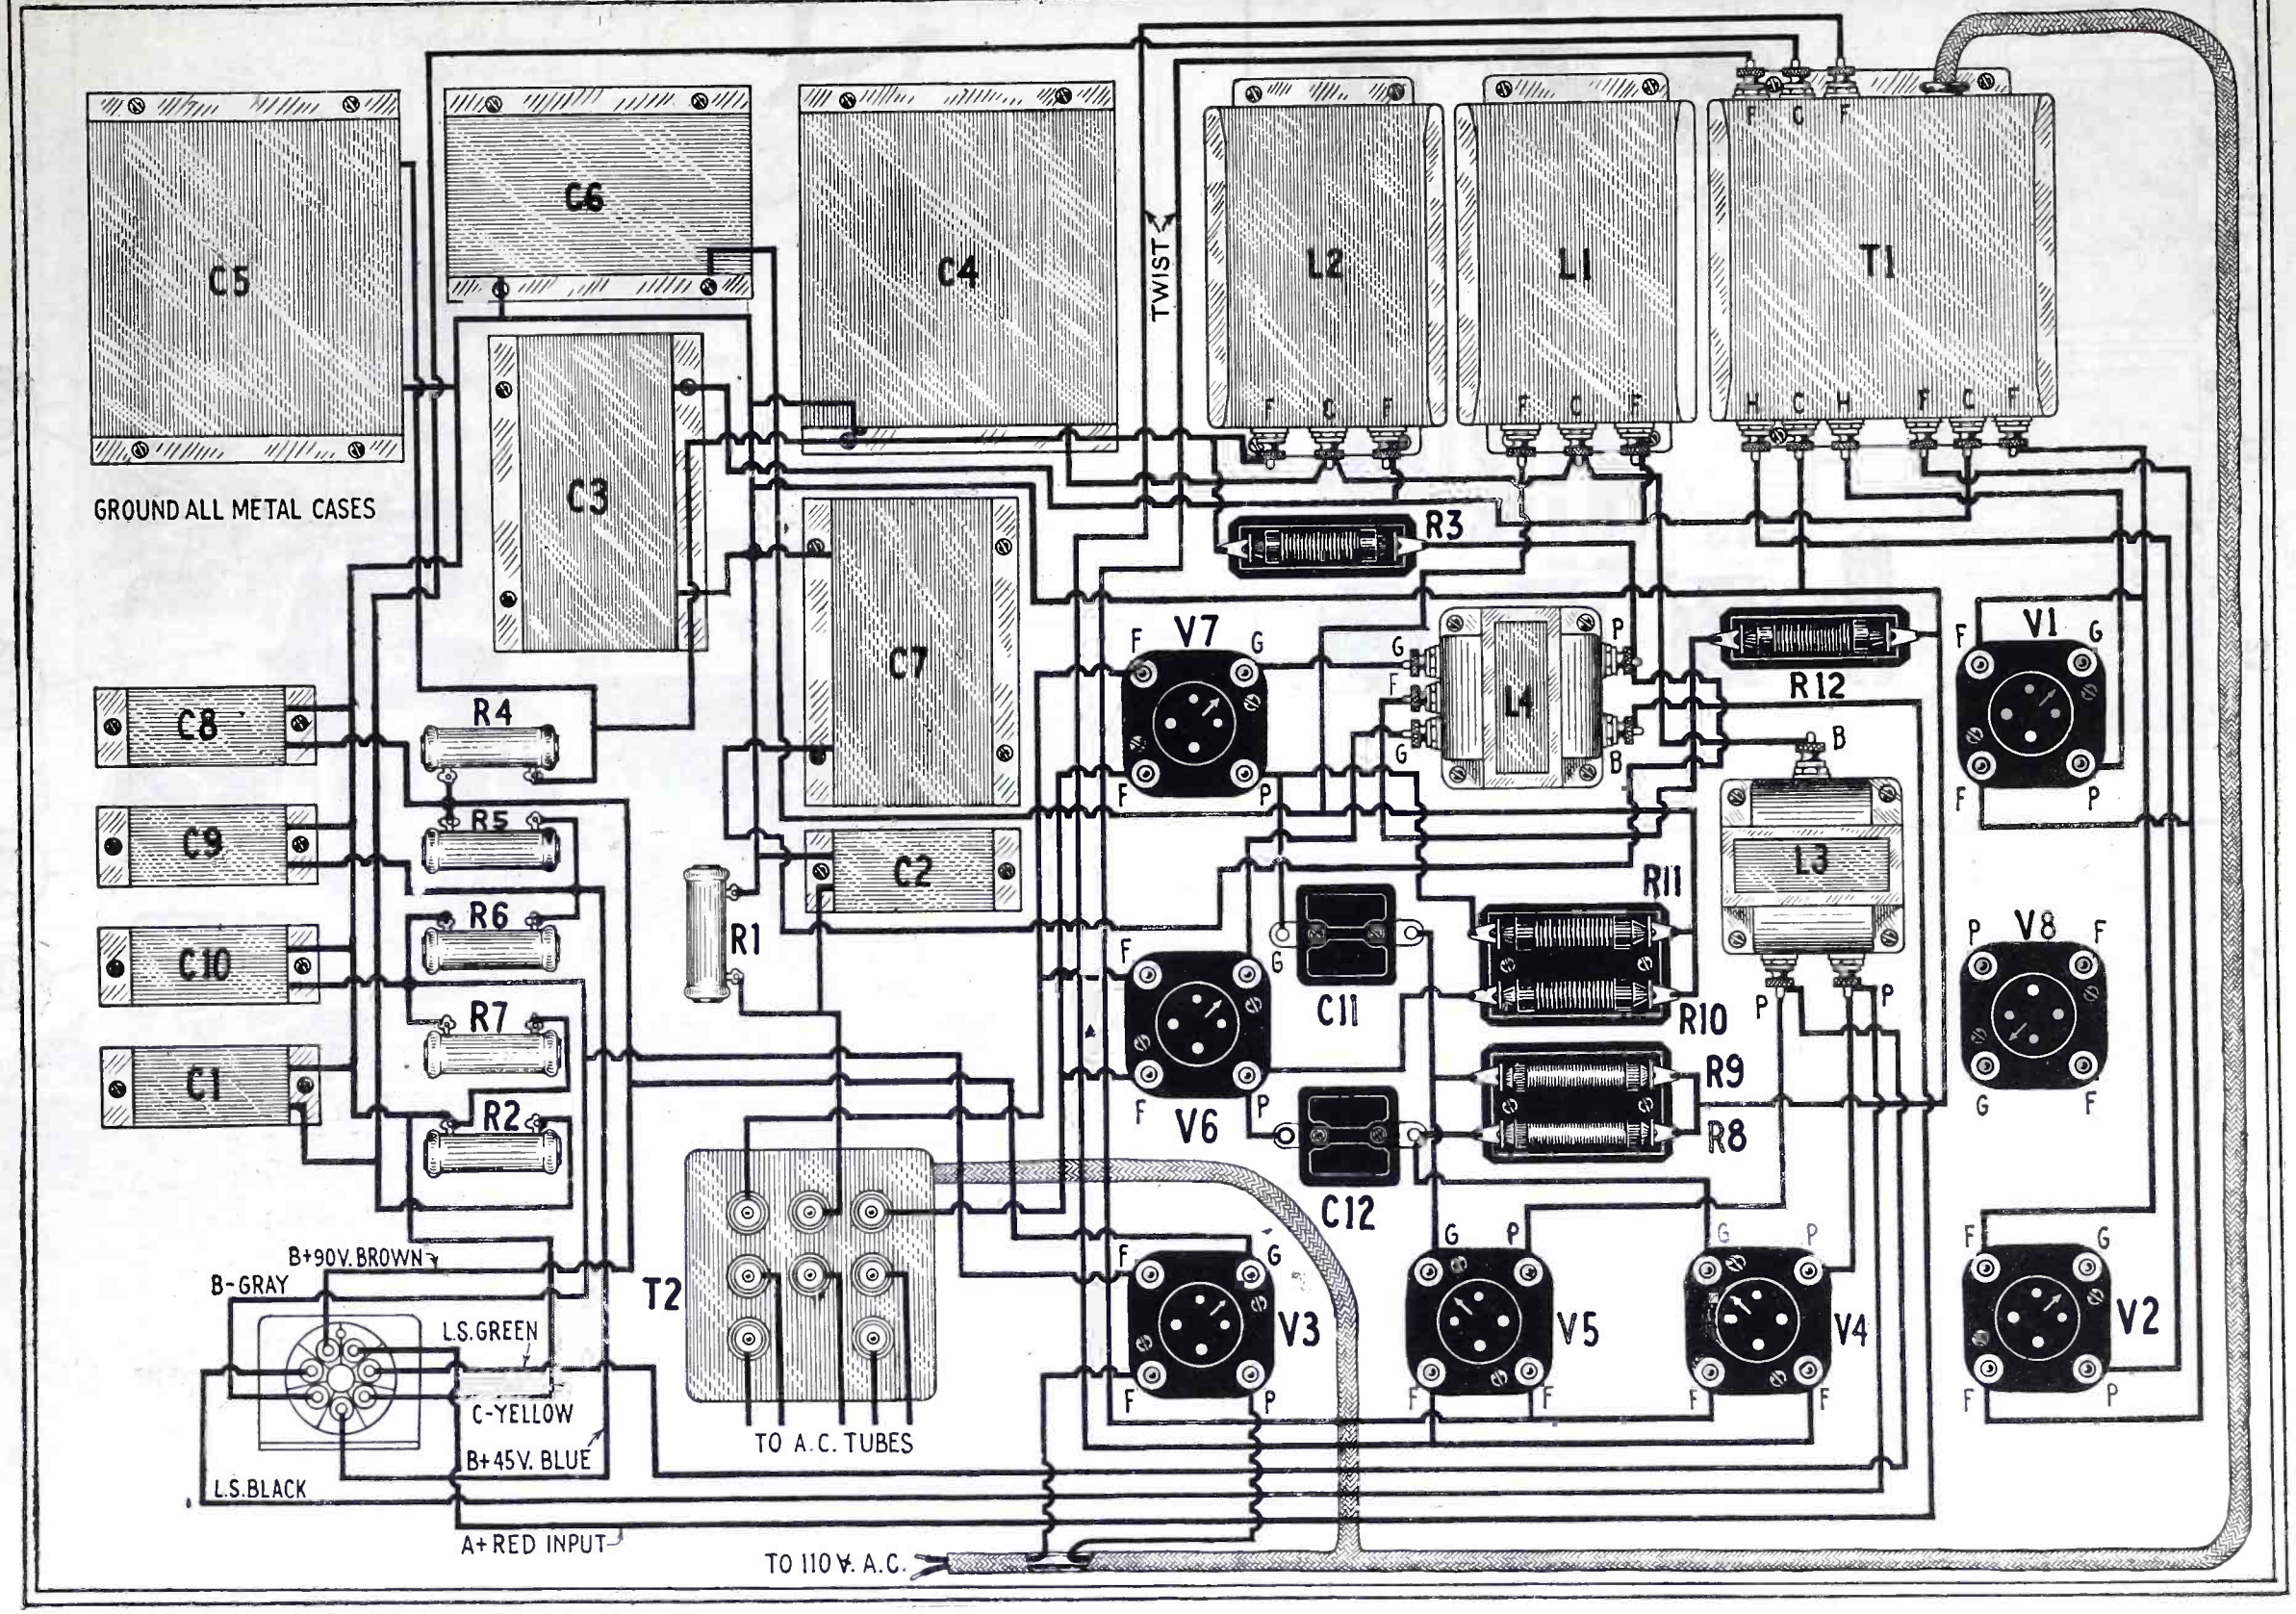
The glow tube holds the voltages for the detector and amplifying tubes in the receiver to their exact requirements regardless of the number of tubes used in the receiver and also serves as a protection for the by-pass condensers if the amplifier is turned on without any load, but if any other tube is by accident inserted in the socket of the glow tube, the cut-off will not function and power will not be applied to the transformer primaries, thus protecting the user against burning out tubes if he accidentally gets them in the wrong sockets.

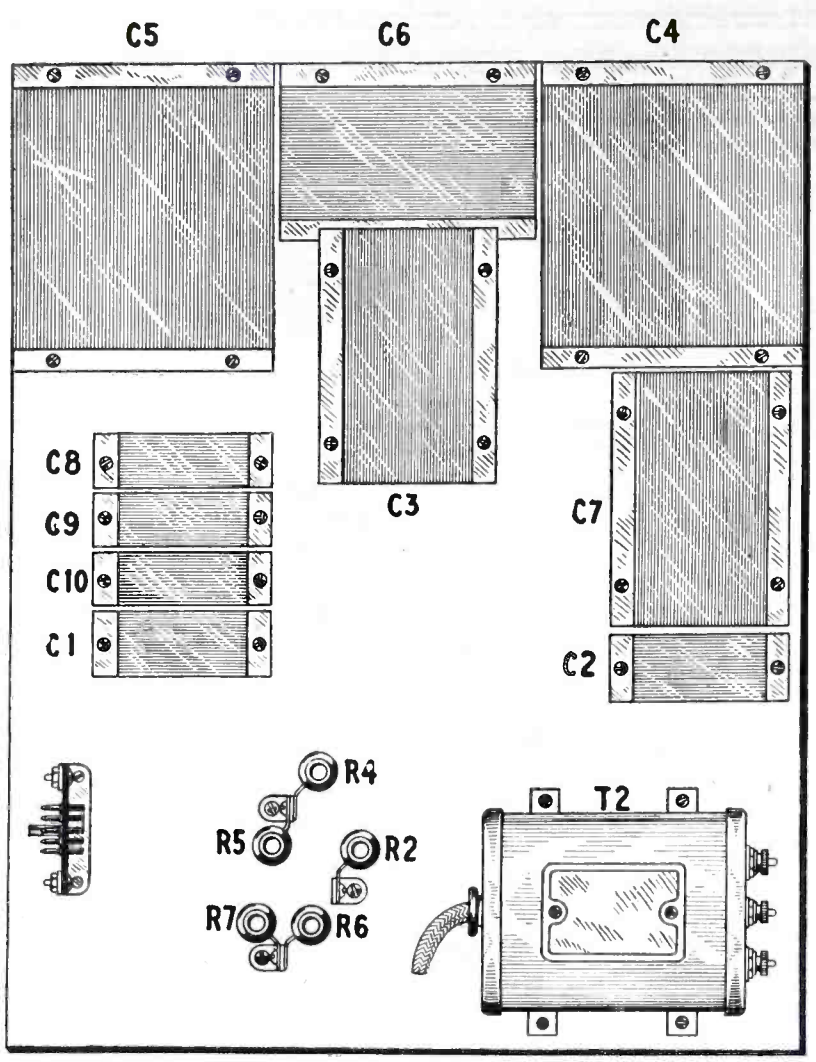
The system of amplification (push-pull input to two high-mu voltage amplifier tubes, each operating one type L-250 amplifier) has several reasons. In the first place in order to get the proper amounts of current for best operation of the receiver and 350's, we are working very close to the limit of the rectifier tubes and therefore if equal amplification both in quality and quantity can be ob-obtained with tubes drawing a total of 1.6 M.A. to that which can be gotten with 7 or 8 M.A. we have made a perceptable gain. It is customary in the ordinary resistor coupled amplifier to utilize 135-volts plate supply with resistor of about 200,000 ohms. Under this condition, the D.C. voltage across the tube terminals is approximately 118 and the amplification obtained from one stage is about 16. We have available in this unit a plate voltage of 425. This is applied through a 500,000 ohm resistor resulting in a D.C. voltage across the tube of about 170 volts and an overall amplification of about 26 which is better than can be obtained with an ordinary tube and a 3 to 1 transformer; besides which the distortion which a transformer might possibly introduce is avoided.

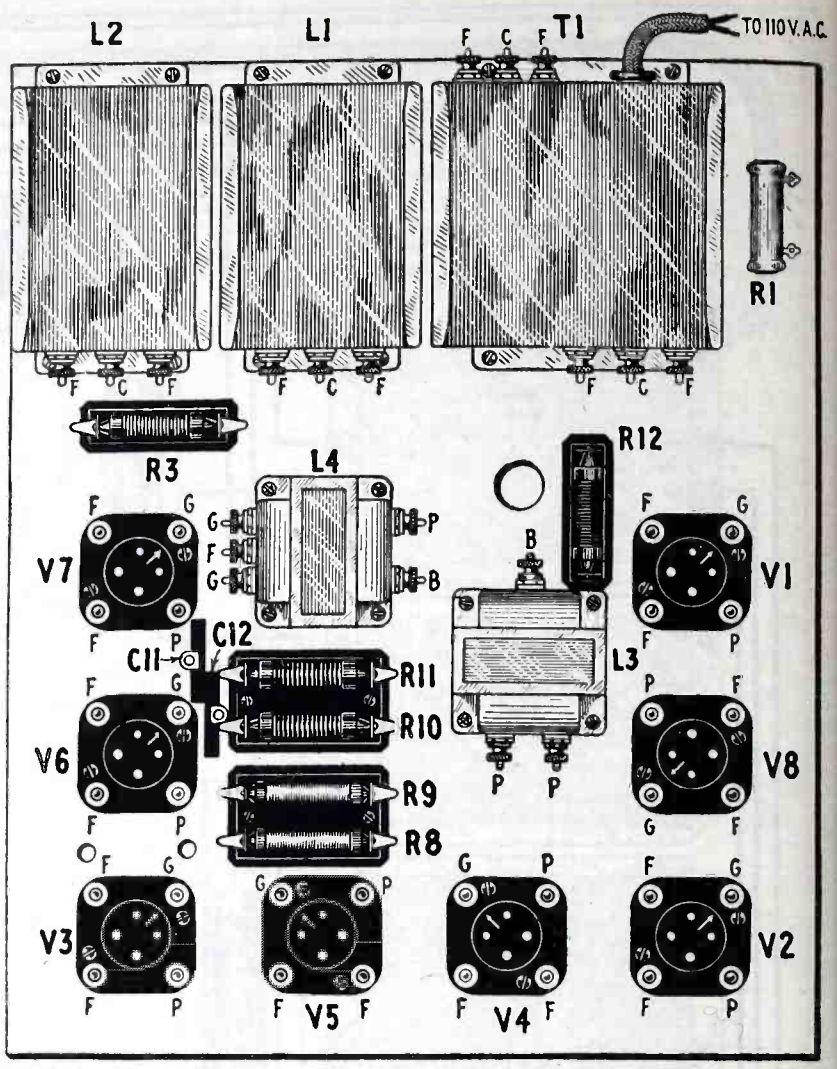
The output impedance selected to couple the CX-350 to the loud speaker has been carefully checked as to its



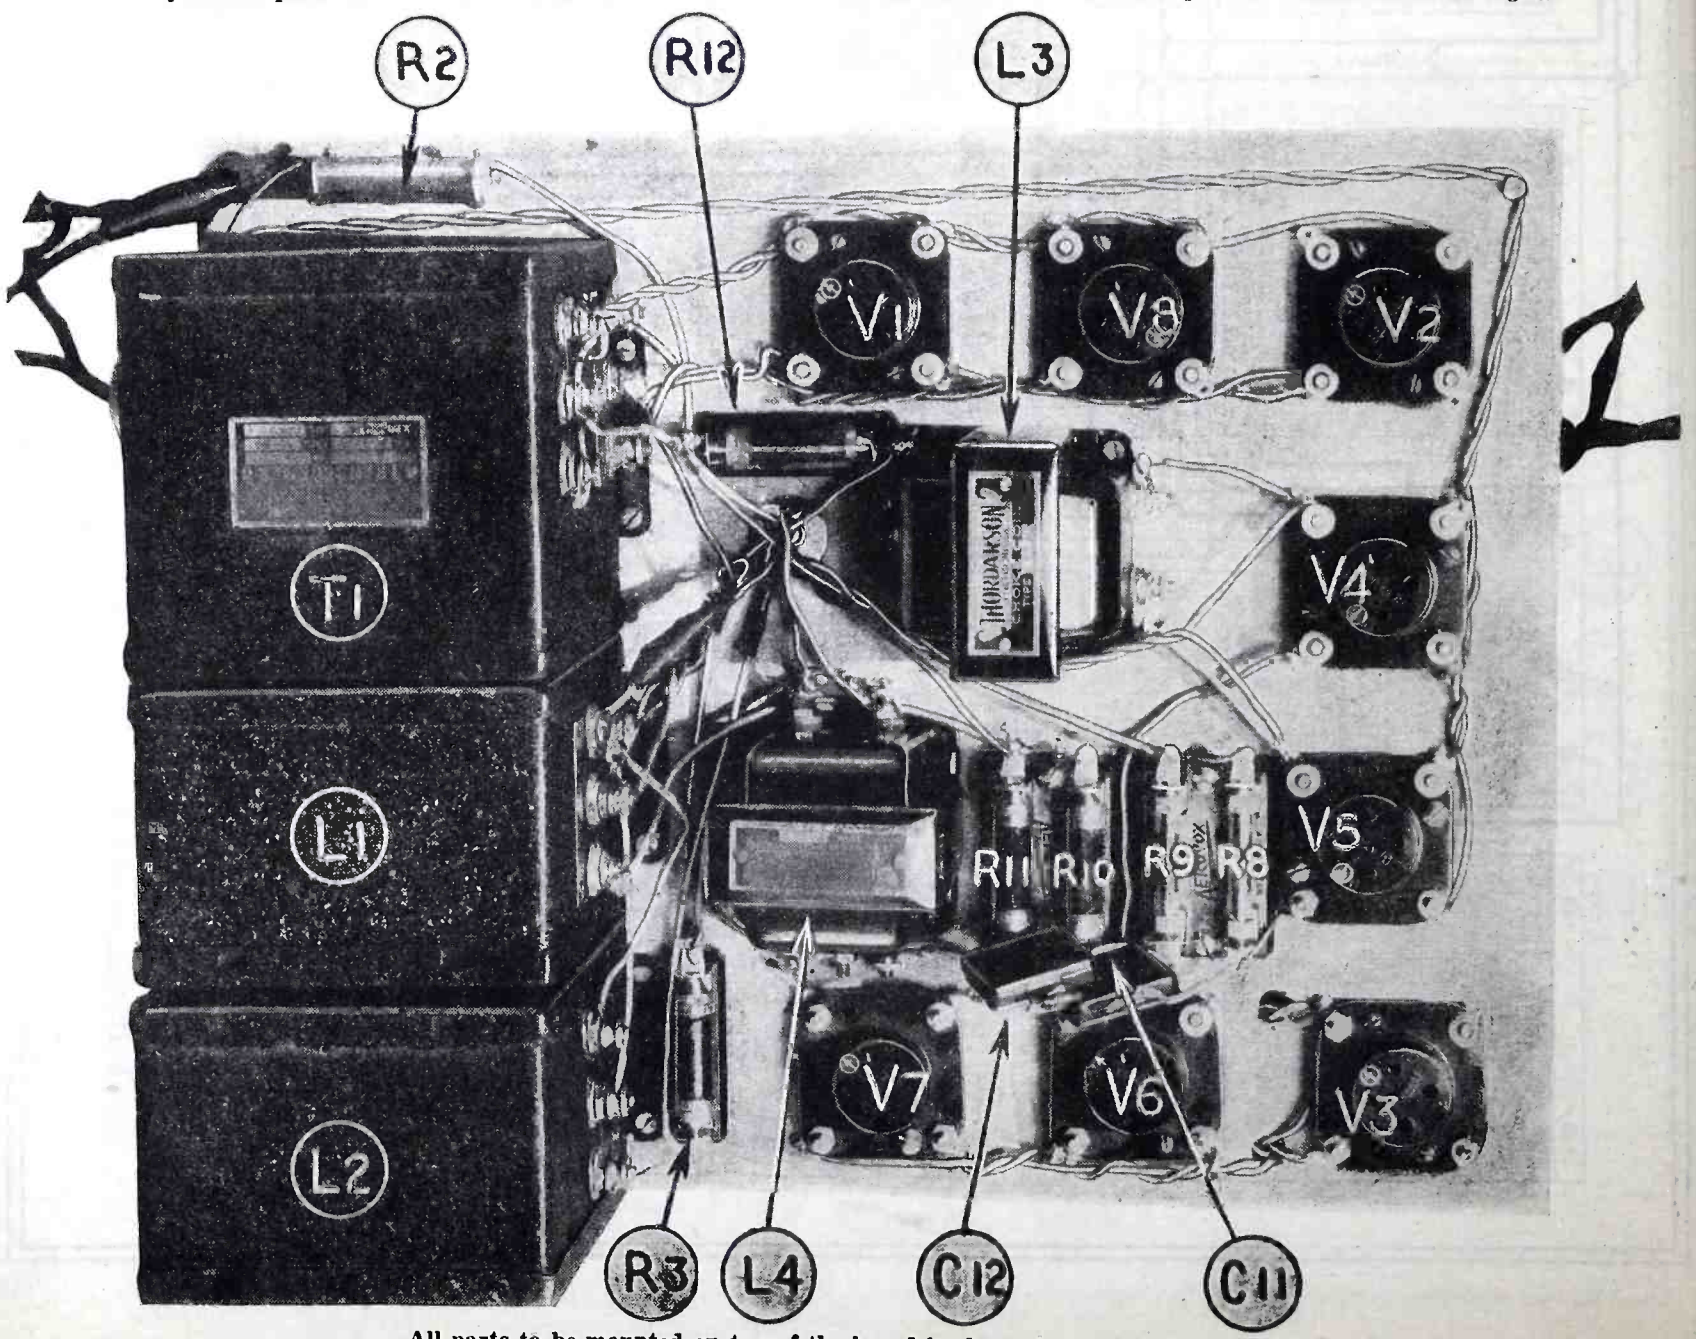
A bottom view of the completed Home Concert Amplifier showing how the condensers, fixed resistors and cable-plug connector are mounted and wired.







Layout for parts on the bottom of the board is shown at the left and layout for the top of the board is at the right.



All parts to be mounted on top of the board is shown in the above photo.

mpedance in combination with that f the average loud speaker and it will roduce in most tases the optimum oad at sonic frequencies.

The whole unit may be expected to ive an overall amplification of about 00 to 325 and its undistorted power utput should be in the neighborhood f seven and a half watts.

In operation with a receiver the econd audio tube should be left out nd the input lead of the Yaxley able should be connected to the plate erminal of the first audio amplifying ube. When used with a phonograph, special impedance mating transormer should be used between the honograph pick-up and the amplifier. The secondary of the latter should e connected on one side to the inut lead and the other side through 4 mfd. filter condenser to the minus B" lead.

Under no circumstances should the nit be operated with less than its ull complement of tubes as the reistances have been calculated to give he proper bias when all the tubes re in their sockets and if it is operted under other conditions serious lamages may result.

Attention is called to the fact that there are no knobs to turn. All voltages have been arranged exactly to give the best operation with existing receivers and variable resistors can do very little to improve and a great deal to harm the operation of the unit as an eliminator.

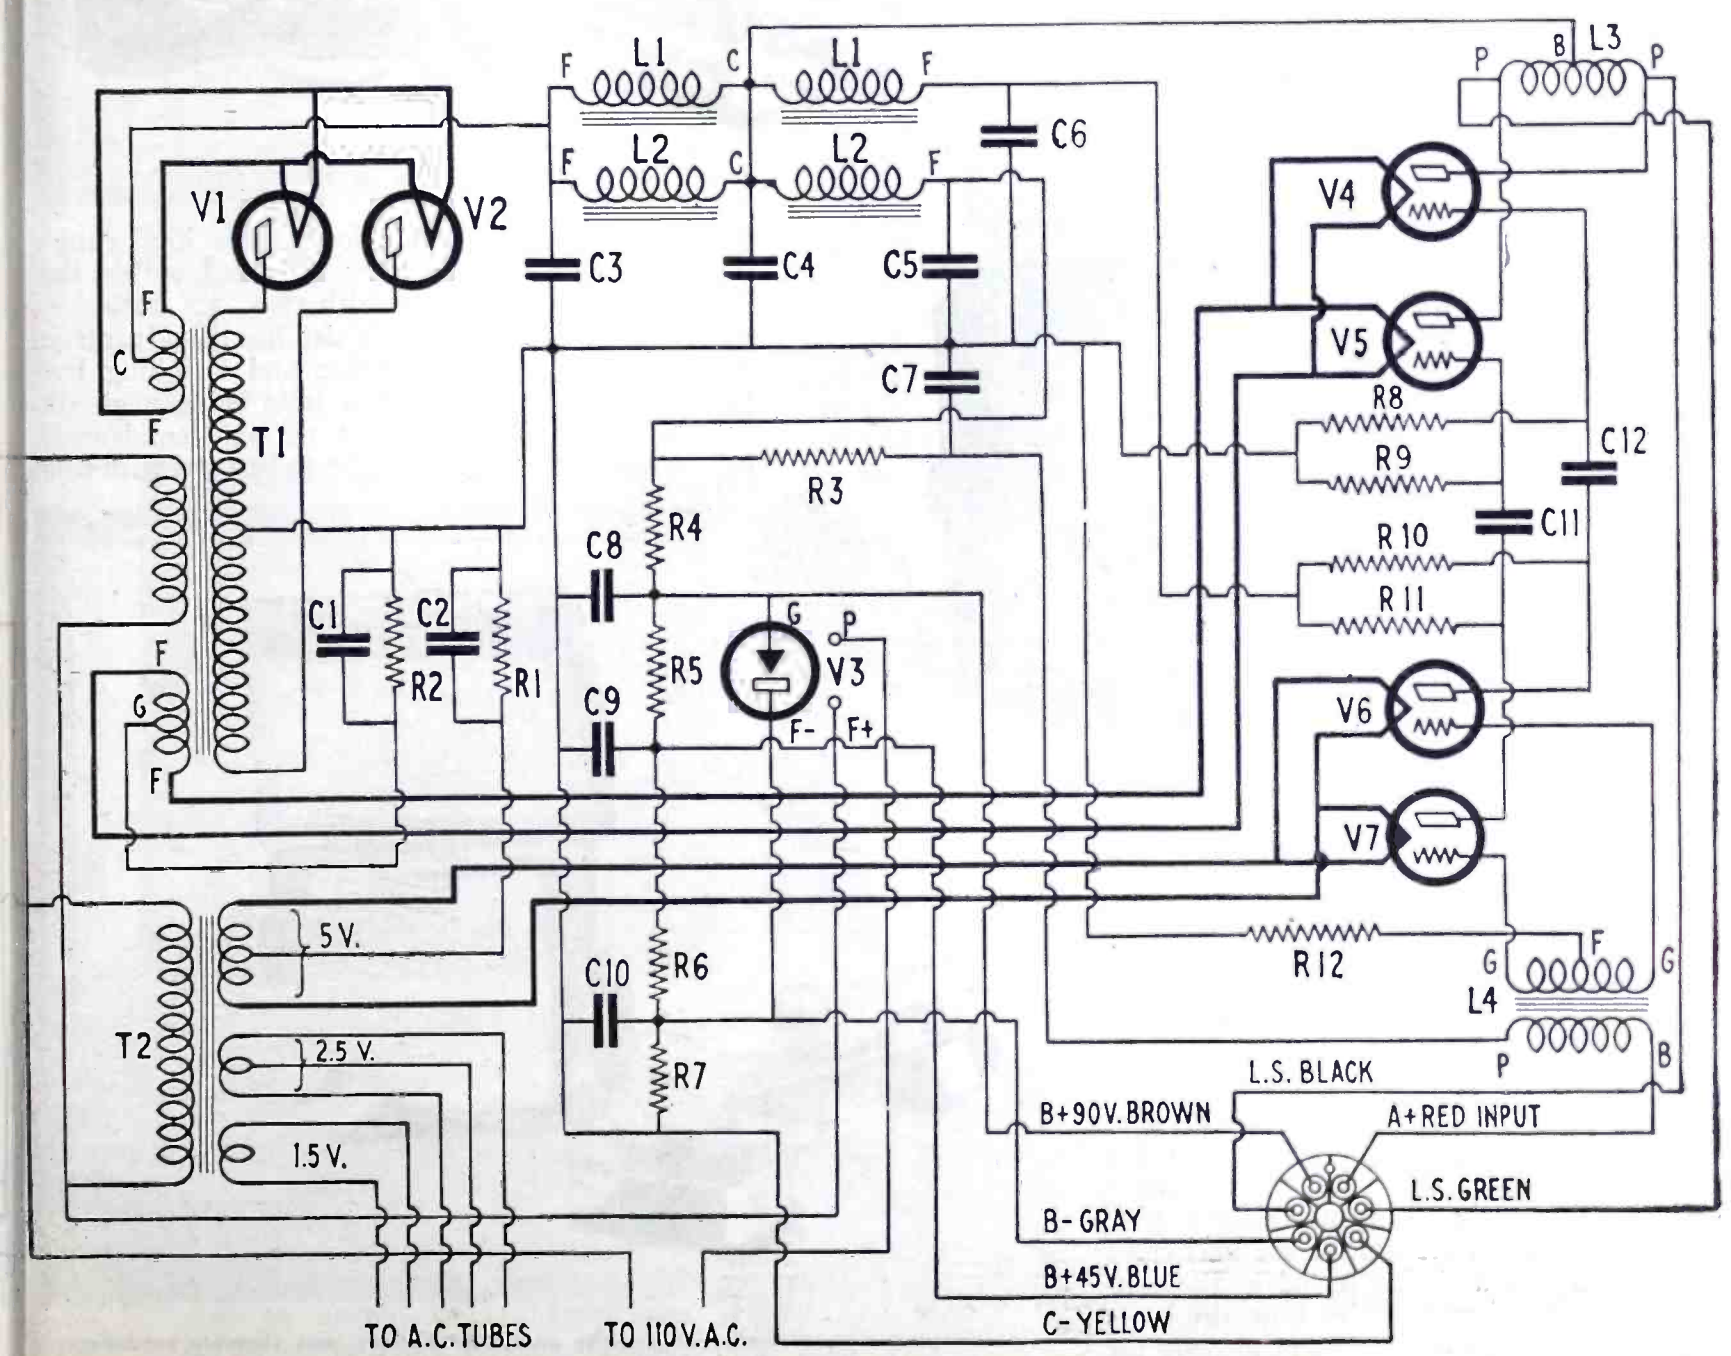
If the unit is to be used with an A.C. receiver or if it is desired to convert a battery set to complete A.C. operation, filament windings are provided on the Karas A.C. Former for type 226 and 227 tubes. The Carter A.C. Adapter will simplify the conversion of existing sets.

After completing the assembly of the unit it may be encased in a metal container both for appearance sake and general convenience in handling. Practically any local tinsmith will make a metal box to fit this unit at a reasonable cost.

The metal box should cover the over-all size of the unit allowing from one to one and a half inches in height above the top of the L-250 tube, and large ventilating holes should be made in a removable cover for the top of the box. If the box is made so that the wood board fits flush with the inside, two chest handles can be screwed to either side of the box. The box may then be given a few coats of lacquer and the finished product will have every appearance of a fine factory-made job.

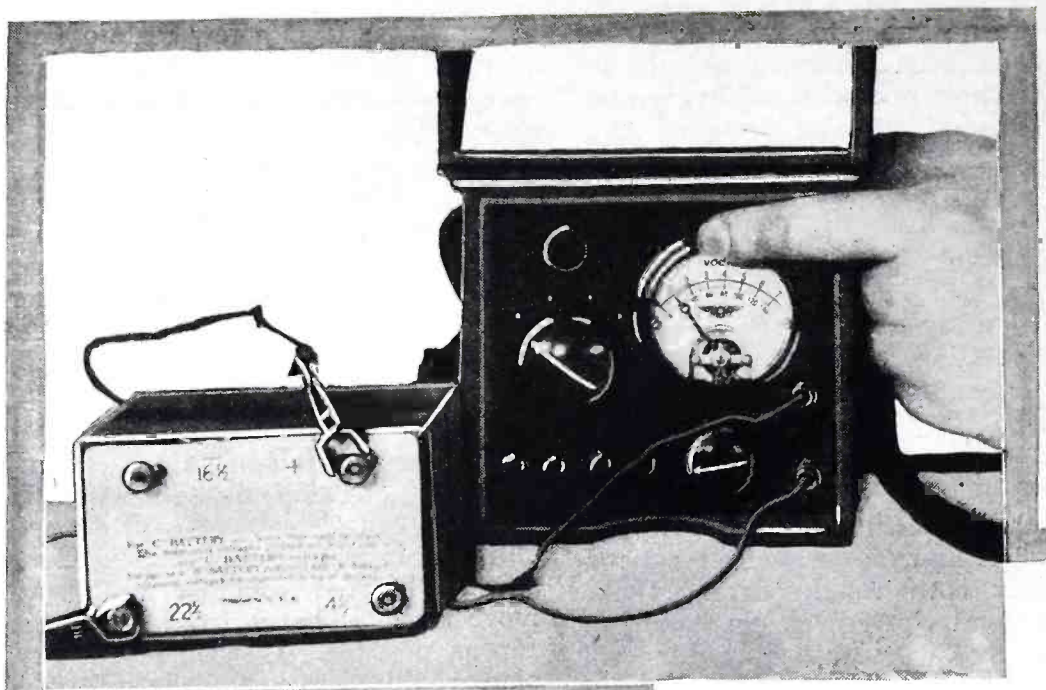
This unit is particularly effective when used in conjunction with aeroplane cloth speakers such as the Dynatone speaker, Accousti-cone, or an aeroplane cloth diaphragm speaker using the Brielle B-A motor. These speakers are specially designed to handle a heavy output and give exceptionally natural tone reproduction.

The completed Home Concert Amplifier can conveniently be installed in the radio console cabinet with the set, although if trouble is experienced by an A.C. hum, it would be well to remove the unit away from the set as far as possible. Of course the best plan would be to install the unit in a separate cabinet with the loud speaker. Thus, if a dynamic type speaker is employed a cabinet can be so constructed as to allow for a suitable baffle for the speaker unit. The amplifier can then be installed in the cabinet either above or below the speaker, and leads for the power supply can be connected to the set by means of the cable and twisted lamp cord for the A.C. tube leads.

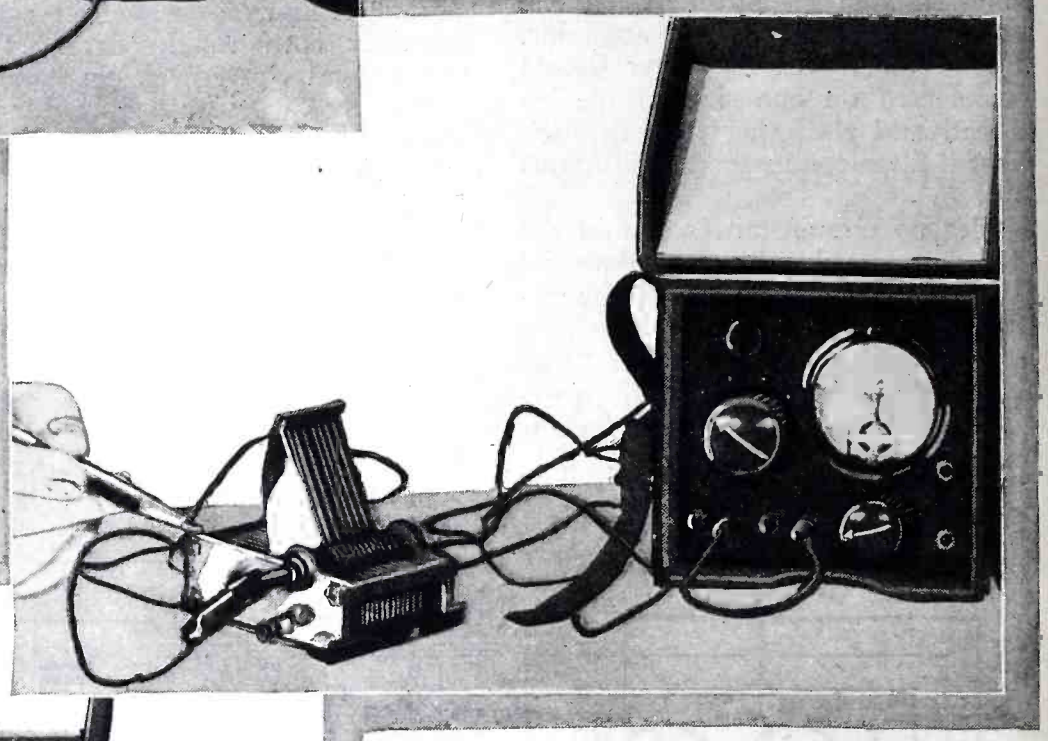


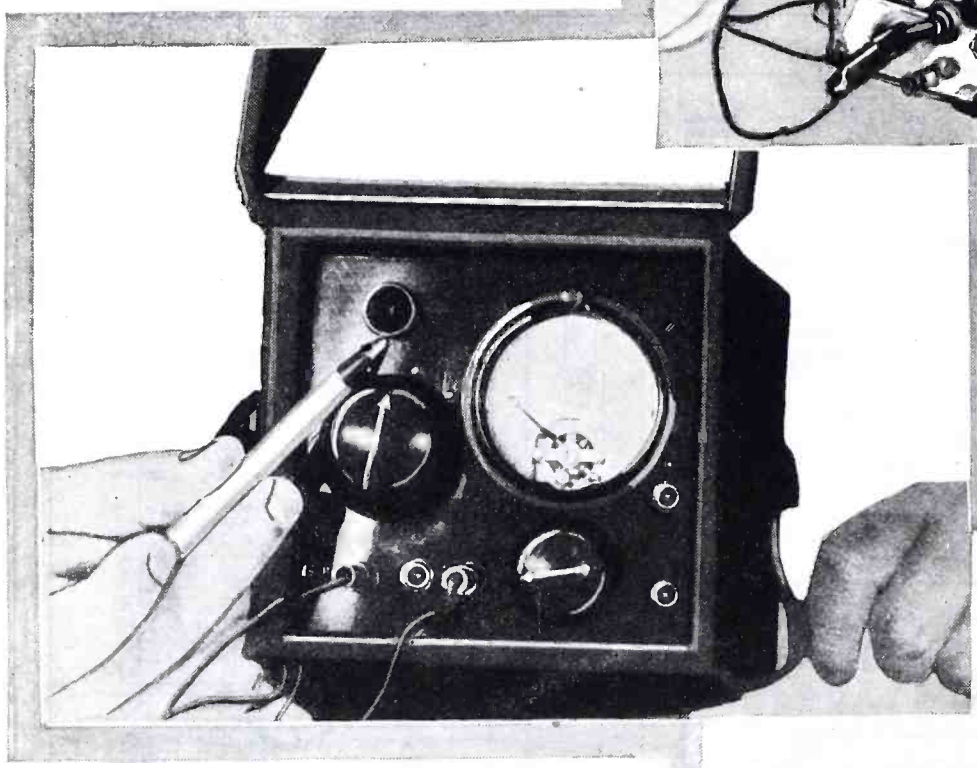
Schematic wiring diagram of the Home Concert Amplifier.

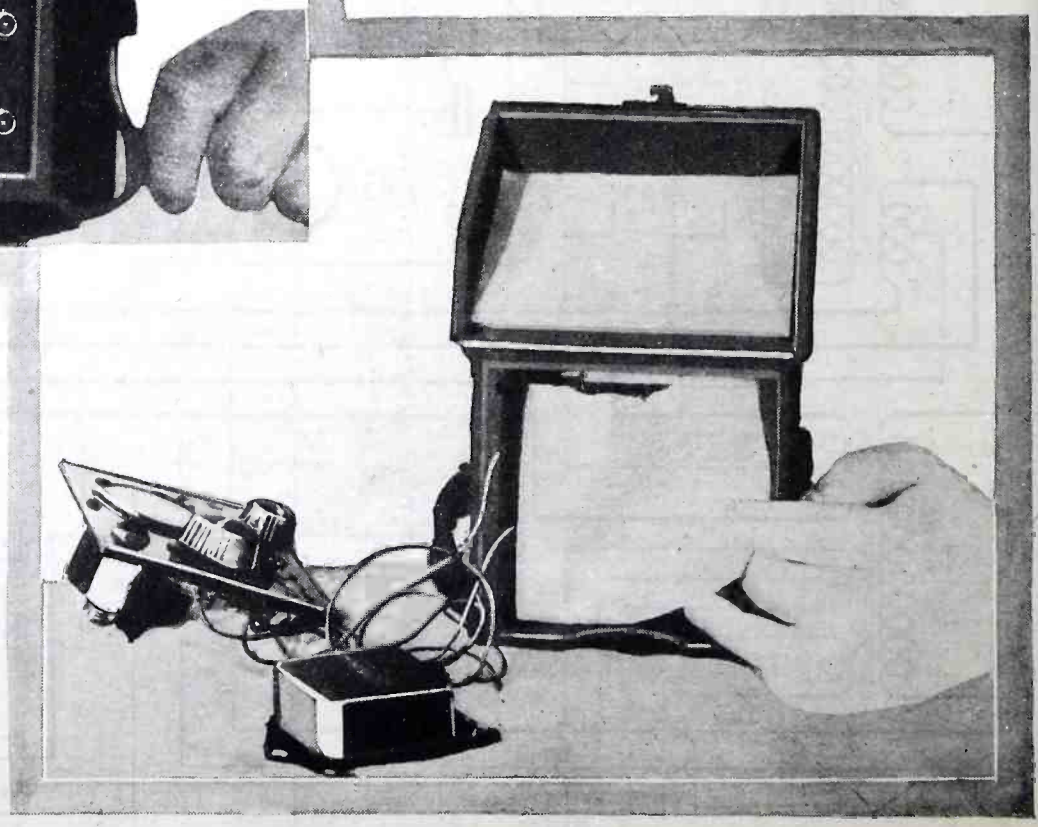
A COMPACT TEST SET



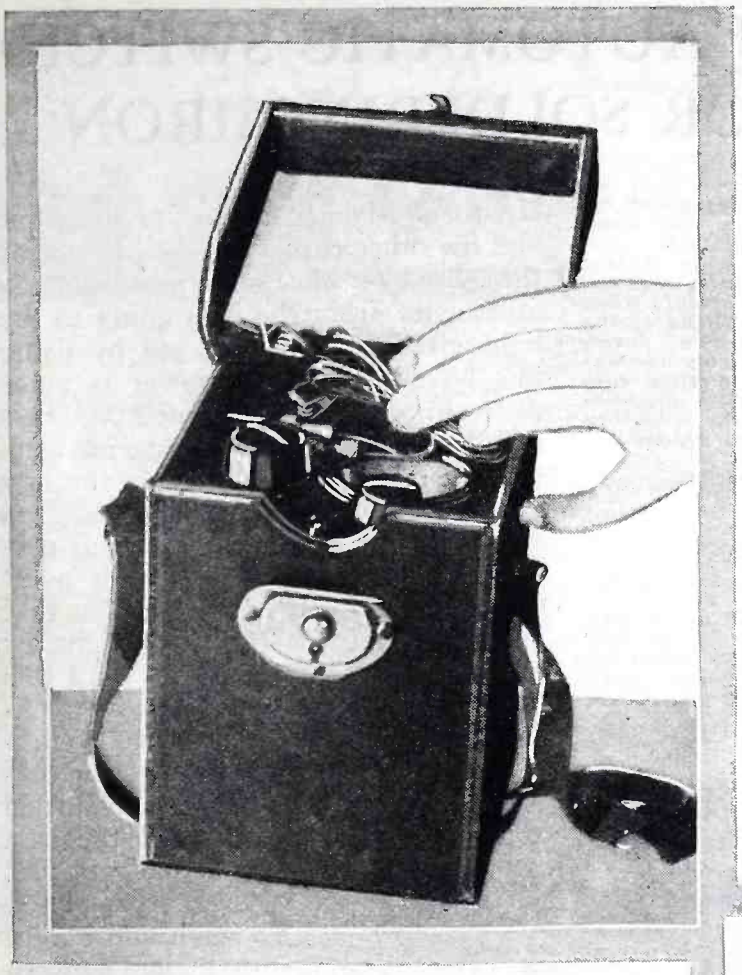
THIS compact radio set tester is exceptionally useful for measuring the various voltages of batteries at the battery terminals of the tube sockets in a radio set when trouble occurs. It may also be used for testing the continuity of the various circuits and the condition of the various components used in radio set construction. By means of a multi-pointed switch, a buzzer voltmeter or test lamp may be used as an indicator. The completed instrument is readily portable, as it is housed in a discarded camera case. Two "C" batteries are also included with the testing outfit and furnish the necessary current for testing radio circuits and parts. As may be seen from the photos, the potentiometer, voltmeter, four point switch, tip jacks and test lamp are mounted on the panel. A voltmeter giving a double range reading should be used. By means of the four point switch, the buzzer, test lamp or voltmeter may be cut into the circuit and used to give indication of the condition of the particular piece of apparatus being tested or the continuity of the circuit. The four tip jacks arranged on the panel as shown, provide for the insertion of the two test leads. Various combinations can be obtained by simply plugging-in the test leads in the different tip jacks. The circuit diagram of the meter is also given here. A 2,000 ohm potentiometer is used as the rheostat. The tip jacks numbered 1, 2, 3 and 4 are used for ordinary testing, and numbers 5 and 6 are used when testing "B" batteries or higher voltages as they connect with the high reading portion of the dual range voltmeter. The buzzer is placed within the meter case together with two "C" batteries. This small testing outfit also has the advantage of being readily portable and weighing but little. The photos show tests being made on a "B" battery and on a variable condenser. The best type of test light to be used with this



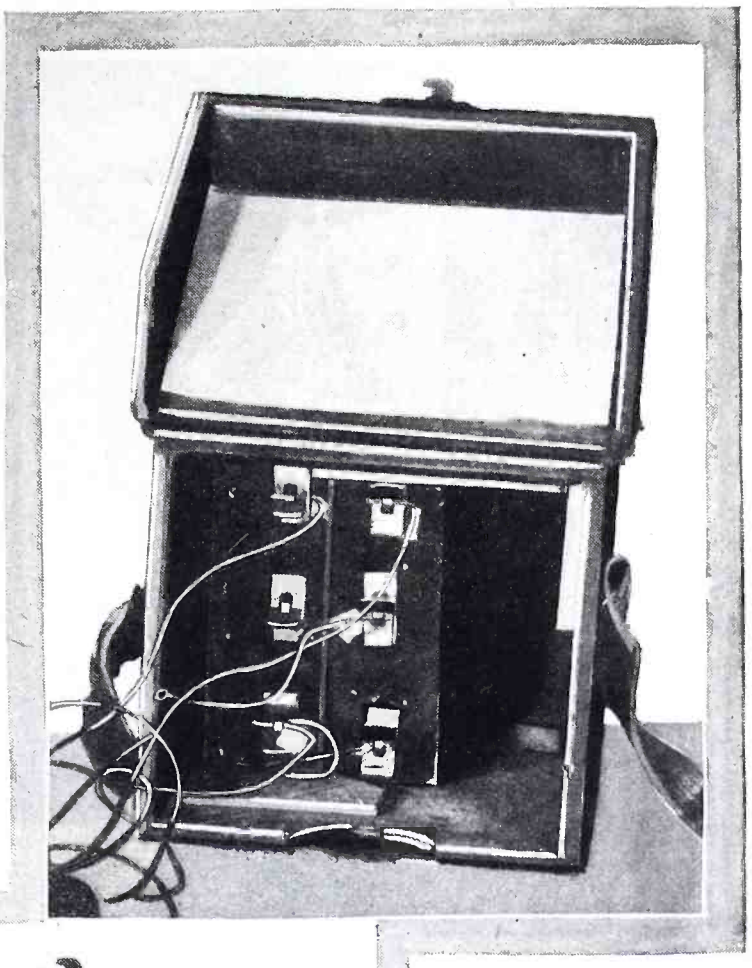


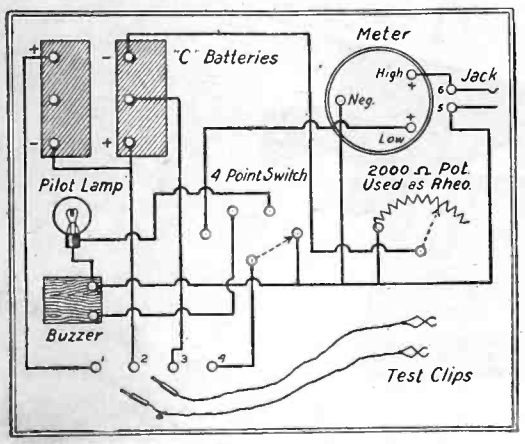


Above photos show tests being made on a "B" battery and variable condenser. The lower photo shows the parts removed from camera case.

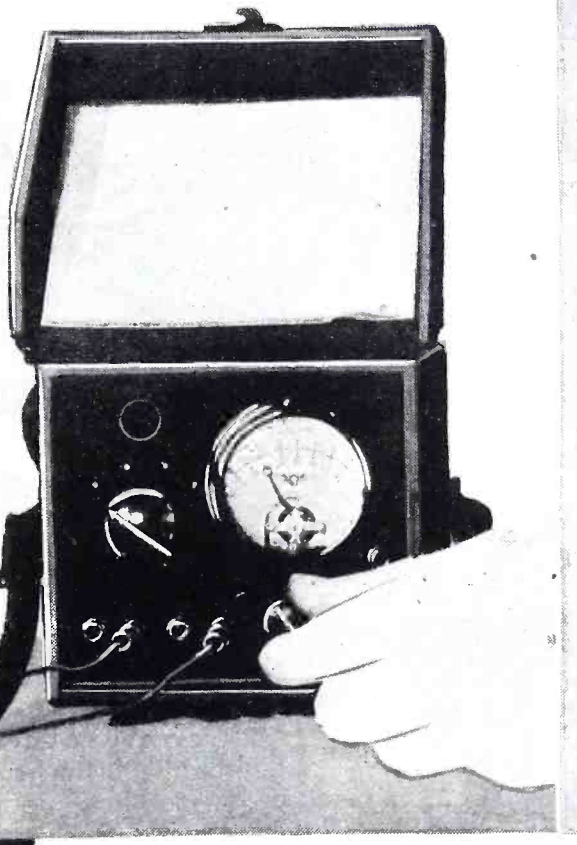


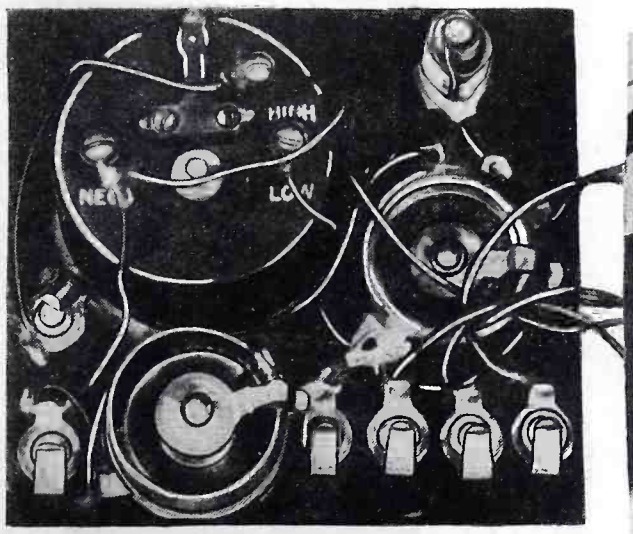
The photos on this page show various details of the radio test set. At the left is complete test set with test cords placed in the top of the camera carrying case. At the right shows how the two "C" batteries are placed in the bottom of the carrying case. The three photos directly below show a top view, a rear view of the panel, and the lower right hand photo indicates the location of the small pilot light.

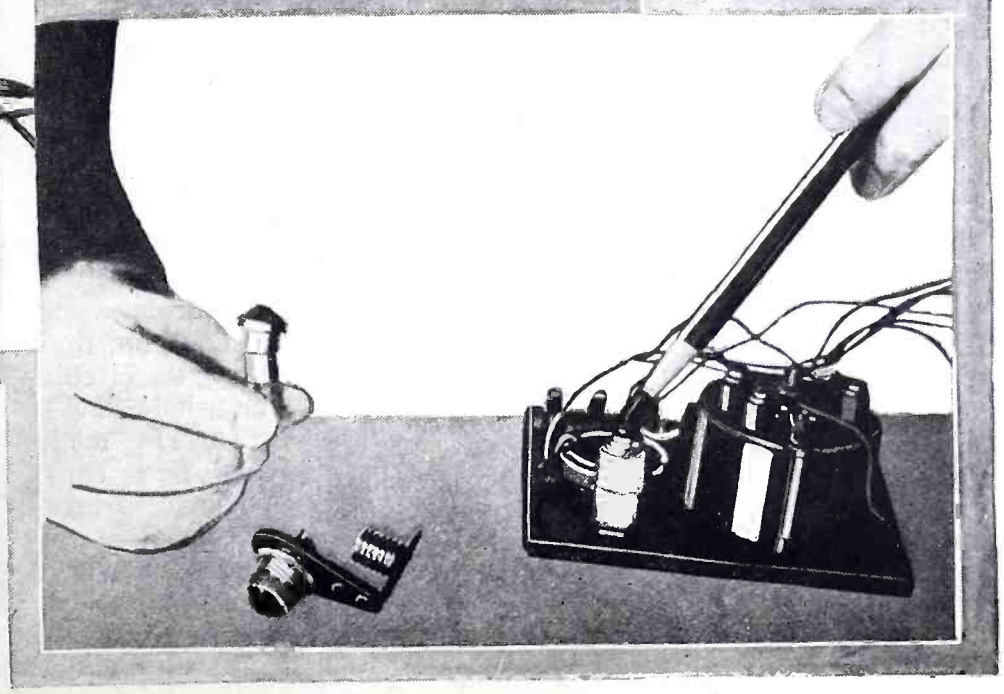




Wiring diagram of the testing set.



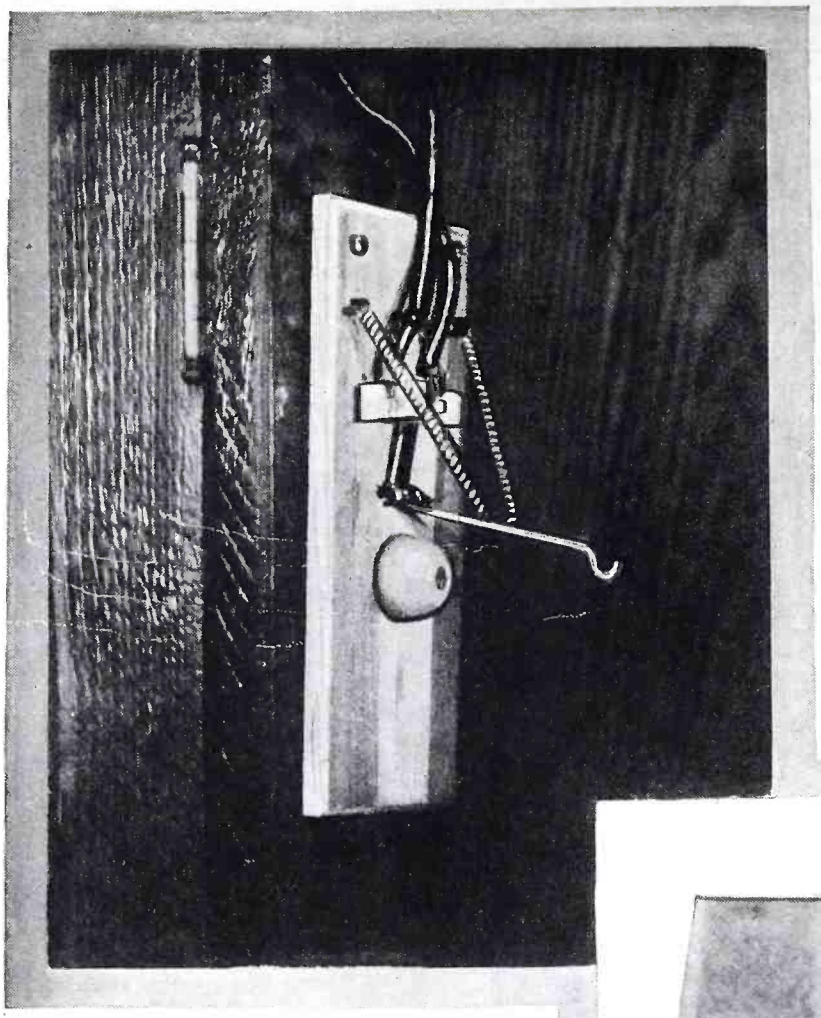




outfit is also shown. This light has a colored glass front with the small electric bulb placed in an upright position in back of it. A testing device of this nature is particularly helpful to the builder while making tests of a receiver on the work bench, since it is possible to immediately ascertain which circuit is faulty or incomplete. The testing outfit is also valuable in determining wheth-

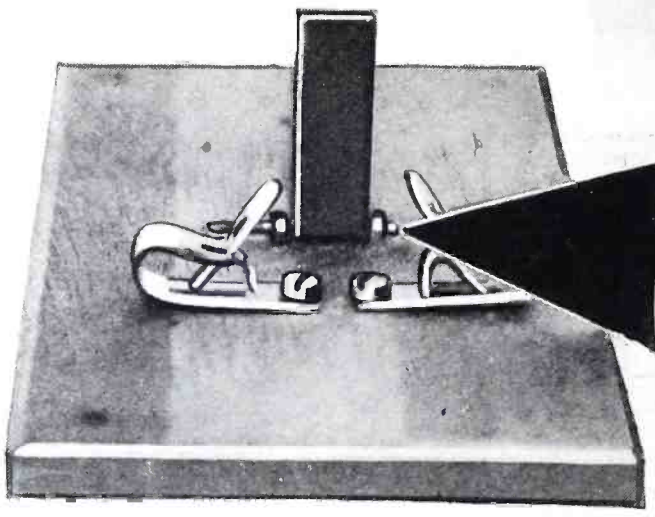
er condensers have been short circuited or broken down, or if the windings on transformers and coils have become broken or injured in any way. The cost of the outfit is really low compared to the valuable service which it renders and is particularly valuable to the custom setbuilder or service man who does not have the money to invest in a more elaborate outfit.

AN AUTOMATIC SWITCH FOR SOLDERING IRON

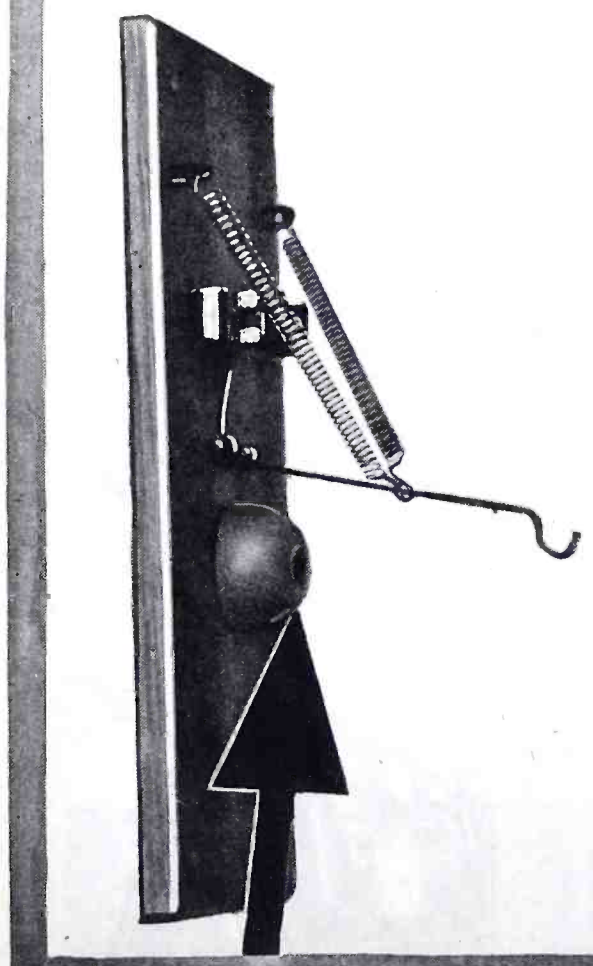


The photograph at the left shows the completed automatic soldering iron holder which shuts off the electric current when the iron is hung on the hook. This device saves not only the expense of electric current but also prevents the electric soldering iron from oxidizing.

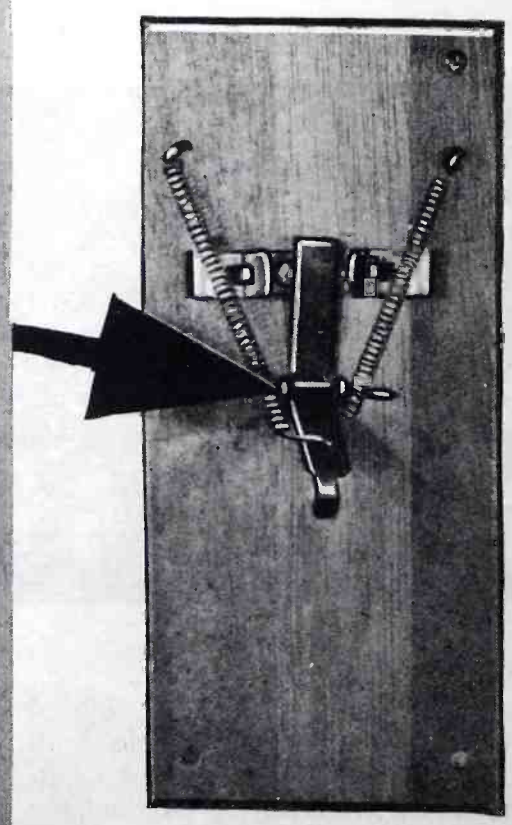
Directly below an arrow points to the contacts which are merely the heads of the two wood screws fastening the spring terminals to the baseboard.



THE soldering iron holder shown in the photographs should find much use in the laboratory and radio workshop, inasmuch as it is automatic in its action. When the iron is taken from the holder, the current is automatically turned on, and when it is hung up, the switch shuts off the supply. The construction is simple and the completed arrangement may be mounted upon a wooden base as shown. The hook for the iron also acts as the switch. The weight of the iron keeps this switch in an off position, but when the iron is lifted, the springs pull the hook up, thus closing the circuit. The whole device is easily made from two clips, two small springs, and a piece of metal upon which the iron is hooked. One of the wires from the light circuit is attached to one of the clips, and the other clip is attached to one of the wires on the soldering iron, the other wire from the iron going to the light circuit. Thus we see by using this novel device, the power is automatically shut off and turned on. This will do much to save the soldering iron, for when the iron is left on for any length of time the tip becomes oxidized and encrusted with scales which prevent the heat from reaching the point to be soldered. It often happens that the iron is left attached overnight, or for a long period of time. With this device described here, the above mentioned troubles will be entirely eliminated, as the current is only turned on when the iron is actually in use. The completed switch and holder may be conveniently mounted on the wall near the work bench. This simple device serves very nicely in the workshop of the custom set-builder and will save expense on the electric bill.



A rubber bumper stop is fastened below the hook.



The arrow points to the hinge of the hook arm.

Remote Volume Control For Speakers, Etc.

PROVIDING precise variable resistance in the form of an accessory rather than as a radio part, together with sufficient current-handling capacity for reliable and long-life operation, the device shown in the photo herewith has a wide range of applications in radio and laboratory work.

Photo by courtesy American Mechanical Labs.
This device can be placed on the tea table or any remote location for control of tone.

Briefly, the device comprises a micrometric variable resistor or from zero to 500,000 ohm range, mounted in a neat metal stand, together with two flexible conducting cords provided with standard cord tips as well as a connection block to take the usual loud speaker cord tips. The metal case is handsomely finished in nickel and bronze, with a neat bakelite knob to complete the attractive appearance of this accessory. The bottom is provided with a soft felt pad to protect the finest furniture.

There are various ways in which this device may be employed. First of all, it may be employed as a through connection, with one cord to the receiver and the other, by means of the connection block, to the loud speaker. Again, it may be employed to cut in resistance in any given circuit, by using just one cord, since the resistance is shunted across the cords. It provides an ideal volume control for the usual loud speaker, either alongside or as a remote control. It may be employed as a volume control for electric phonographs. It may be used in connection with A. C. tube harness. It may be applied in many experimental and laboratory set-ups.

A Full Automatic Power Control

THREE systems are now available to the set owner who wishes to operate the filament circuits of his radio receiver with power obtained from the light socket. The first method employs a storage battery, a battery charger and an automatic power-control switch; and the battery is automatically charged while the receiver is not in use. The second system uses an "A" power-supply unit which converts the 110-volt A. C. into pure 6-volt D.C., which may be used for heating the filaments of the tubes. The third way is to use special A.C. tubes, which have electrical characteristics similar to standard tubes, but are designed for operation with a low-voltage source of A.C., which may be obtained from a transformer. It is possible to operate a receiver at high efficiency with any one of these systems; but each has features which render it unsuitable under certain conditions.

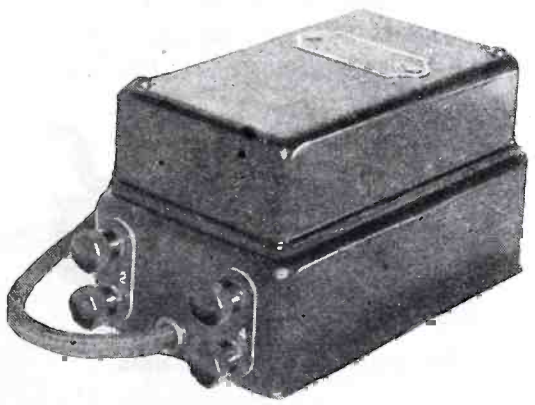


Photo by courtesy Yaxley Mfg. Co.
The full automatic power control is completely encased in metal and fool-proof in every way.

In a properly-designed receiver A.C. tubes are capable of giving excellent performance, and the characteristic A.C. hum may be reduced to a very low minimum. However, the receiver must be designed especially for these tubes or, if originally D.C. operated it must be rewired before these tubes may be used. Also, the characteristics of the A.C. supply must be good, or line noises will be heard in the receiver. "A" power supply units also give excellent satisfaction; but they necessitate discarding the storage battery and purchasing a unit which is as expensive as a battery and a charger. As in the case of A.C. tubes, these units may be used only where a good A.C. supply is available.

There are a large number of radio fans, who already own an "A" battery, to whom the use of a charger with an automatic power-control relay strongly appeals; as this is a very inexpensive method of electrifiying a receiver. With this system the "trickle" type of charger is most commonly used, and this supplies the battery with current at a very slow rate. In twenty hours, chargers of this type replace approximately the same amount of current that is consumed by the average receiver during an evening's operation. Therefore, where a receiver is used consistently, this method keeps the battery in good condition at all times.

There are also two classes of listeners who wish to use a trickle charger, but find it unsuitable for their needs. The first use the receiver a great deal and, as a result, are constantly discharging the battery; the second class use the set very little and therefore overcharge the battery. This problem may be solved by a new type of power-control relay recently placed on the market. With this relay a full-rate charger is used; the relay turns on the charger when the set is turned off, and turns off the charger when the battery is fully charged. If the set is used a great many hours during the day the full-rate charger is able to bring the battery back to full charge before the set is used the next time. When the set is seldom used, the charger does not operate after the battery has been charged. In other words, the charger keeps the battery fully charged at all times, but never overcharges it. Also, the battery requires practically no attention; as it is necessary only to add water to the cells, at very infrequent intervals.

In construction, the new relay is the same as a previous model, but with an extra coil added. The schematic wiring diagram will be found on this page and shows that the device really comprises two relays, A and B. Relay A, connected in series with the "A" battery lead to the set, causes the

"B" power unit to be turned on when the set is in use, and connects the charger when the set is turned off. Relay B is connected in shunt with the battery at all times and turns off the charger when the battery is charged.

"A" Power With Charger and Filter Unit

THE photo herewith shows a new dry "A" filter unit which can be employed in conjunction with practically any type of battery charger to furnish the filament lighting current of battery operated receivers. In this way the efficiency of direct current type tubes or the newer screen-grid tubes can be had along with the advantage of A. C. operation.

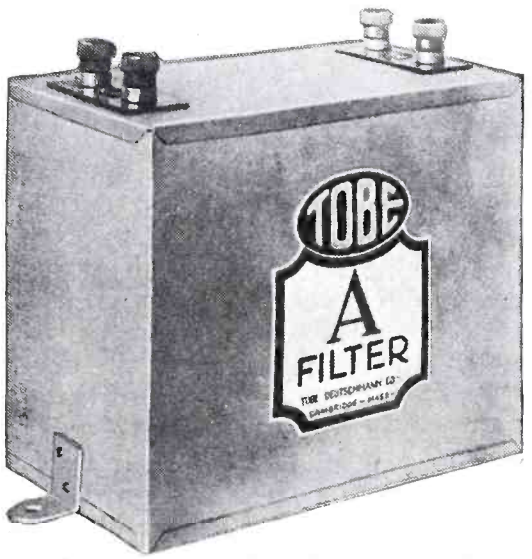

Photo by courtesy Tobe Deutschmann Co.

This device can be connected to the battery charger as a filter for the "A" battery supply from the A.C. line.

The major difficulty with a number of "A" battery eliminators has been primarily that of an efficient high capacity condenser or filter system. The unit herewith employs a dry type condenser of the usual construction which has a capacity of 3,600 mfd., and with it two specially designed choke coils are combined in a metal casing.

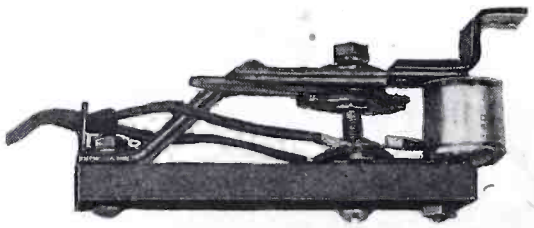
All that is necessary to complete the "A" battery eliminator is a charger of the two ampere type to which this unit is connected as though it were a battery. The radio set owner who does not have a charger needs only a rectifier, transformer and a high voltage rheostat, and in a few minutes can assemble an efficient "A" eliminator, as practically all the wiring is made within the filter unit. A 10 ohm heavy duty variable resistor is connected to the positive lead of the set in order to control the voltage from the eliminator to compensate for the line voltage variations. The transformers tested in connection with this unit and which have been found to be most efficient were those of the 75-watt types with a secondary output of 10 to 14 volts. A voltmeter is recommended to be employed in conjunction with this unit to keep accurate check on the current flow, as line voltage variations are common in most A. C. current sources.

The Piano As a Radio Loud Speaker

A FUNDAMENTAL fact in the musical production of tones is the naturalness and beauty of wood as a reproducing medium. The two instruments that play an indespensable role in musical creation are the violin and piano.

The manufacturers of the unit pictured in an accompanying photo have taken advantage of this fact in the development of this simple device which can be readily attached to the sound-board of the piano with the resultant production or reproduction of broadcast music of astonishing quality. The pole-piece or armature of the unit is flat and fairly rigid, allowing no free vibration and responding only to the impressed vibrations from the radio receiver. In order to do away with the distortion inherent in the average cone unit or driving mechanism, the motion here is direct. There is no side-sway. The air gap being in the center of the flux field there is practically no loss of flux and no great loss of energy.

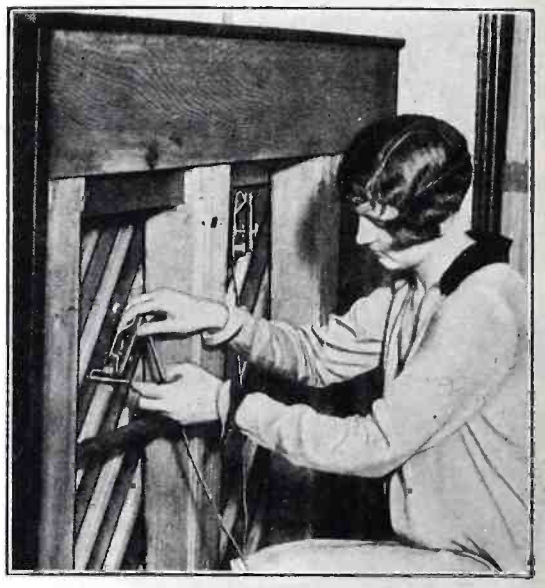
Another photo herewith shows how the unit is attached to the sound-board of an upright piano. The vibrating portion of the upper



The piano loud speaker unit.

armature is fitted with a bracket which is fastened to a cross rib of the sound-board by means of two screws. The unit is self-supported on its own armature and consequently there is no loss of energy, every impulse being transmitted direct to the vibrating medium or sound-board.

In operation the unit is adjusted to the right point for the particular set and in the exact location on the sound-board to give the pitch and range you individually prefer. By means of a small pin attached to the bracket it is possible to test for the best location before mounting the unit. The unit is merely connected to the set and the pin pressed against the sound-board at various points. In this manner the proper point can readily be determined. This will vary with different conditions but for general use and in the case of the average set and piano, about the middle of the sound-board will be found best. This allows a novel feature in that one can make the loud speaker suit his ear. If extreme bass accentuation is preferred, the unit is placed low down at right rear, over the bass strings of the



Photos by courtesy Engineers Service Co.

Method of fastening the unit to the sound board of an upright type piano.

piano. If a higher pitch is preferred it can be placed to the left rear over the high strings, or if an average pitch is desired, which will give a wide range of tone over the entire scale of audible frequencies, it is placed about the center of the sound-board.

A Socket-Power Unit For Four-Volt Tube Sets

THE "A" power unit illustrated in the photo herewith was designed especially for use in the battery compartment of a popular superheterodyne receiver, which employs tubes of the 199 type; but it may be used to advantage for electrifying any receiver using 4-volt dry-cell-type tubes.

A large majority of the receivers using 199-type tubes obtain their filament power from three No. 6 dry-cell batteries connected in series; and these batteries are usually located in the receiver cabinet. Therefore, an "A" power unit for sets of this type should be small in size, in

order that it may fit in the space formerly occupied by the batteries. The "A" power unit under discussion answers this requirement. It is housed in a metal case 4 by 9 inches by 6 inches high and weighs only 11½ pounds. It will provide pure direct current of 0.6 amperes at 4 volts, which is ample for the operation of any receiver using 10 tubes or fewer.

There are on the power unit no knobs or dials which require adjustment. Two binding posts are provided, for connecting wires to the battery posts of the set, and there is a filler hole where distilled water is added at rare intervals; in addition, there is the wire and plug which connects with the lamp socket. To install the unit it is necessary only to connect two wires to the posts and insert the plug in the socket. After it has been installed it is necessary to add water to the filler hole on an average of only once every six months. It should also be remembered that the unit is

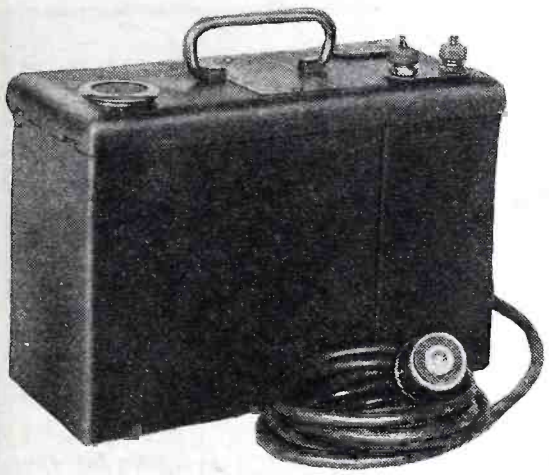


Photo by courtesy the Abox Co.

This compact unit may be used to provide filament power for sets using up to ten 199-type receiving tubes. It supplies 0.6 amperes at 4 volts D.C.

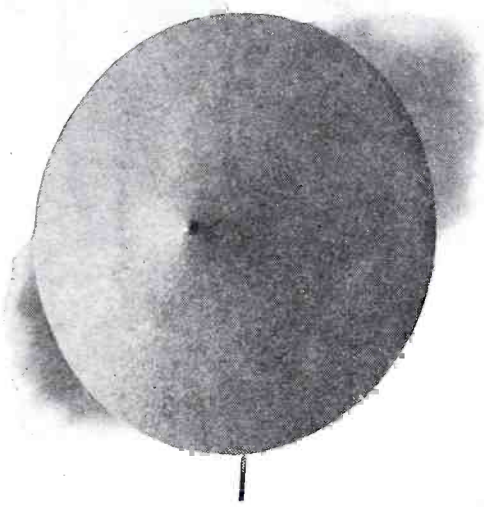
turned on and off at the lamp socket and *not* by the filament switch on the panel of the receiving set.

Electrically, the unit consists of a stepdown transformer, a rectifier of the electrolytic type, and a filter system consisting of a heavy-duty choke coil and a high-capacity electrolytic condenser bank. Power units of this type, which were designed to supply filament current to receivers using 6-volt tubes, have been described previously in the "Listeners' Accessory Guide" section of RADIO LISTENERS' GUIDE AND CALL BOOK.

It should be explained that this unit does not supersede *all* batteries. It provides filament power for 4-volt tubes and replaces the "A" battery; but "B" batteries or a "B" power unit are still required. It should also be pointed out that the unit may be operated only with 110-volt, 60-cycle house current.

A Double-Cone Loud Speaker Kit

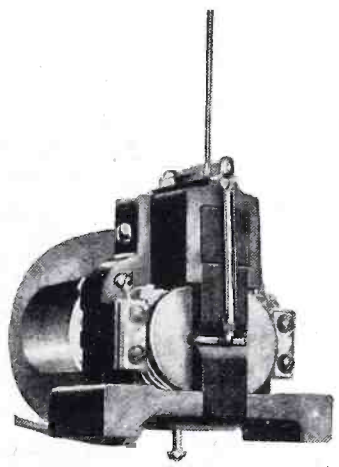
THE loud speaker shown in a photo herewith is of the double cone type and is furnished in kit form for home assembly. The unit employed in this speaker is shown in another photo and is of the balanced-armature type. It has laminated pole pieces made of silicon steel and are cast into an iluminum frame.



The completely assembled double-cone loud speaker.

A heavy horseshoe permanent magnet, which has one side 5/8" longer than the other, is held in position with regard to the pole pieces by set screws in the aluminum frame; so that drilling the magnet is not required. The two coils, which are of eliptical section, are relatively large and are clamped into the pole pieces; two special holes in the frame allow easy mounting of this unit on the mounting piece provided with the kit.

The kit consists of the unit as described; two large sheets of special paper for the front and back cone which are marked and can be cut for three sizes up to 36 inches in diameter; two aluminum back



Photos by courtsy G. R. Penn Mfg. Co.

A special speaker unit is used in the construction of the speaker.

rings; a bridge piece for mounting the unit; bolts, nuts, tube of cement; apex fittings, etc.

The process of assembling this speaker is remarkably simple as instructions furnished with each kit are easily understood and each step in assembly is illustrated. The usual method of cutting out the two cones is followed and the assembly of the cones as well as mounting of unit can be accomplished by practically untrained hands.

The tone qualities of this speaker are excellent; the reproduction has naturalness and great volume.

An "A" Power Unit For Rural Sections

WHEN designing accessories for radio receivers, a large percentage of the manufacturers in this country have considered only the demands of the broadcast listeners who reside in the cities and towns, and have ignored almost entirely the needs of the farmers, who wish also to enjoy radio programs. In more than nine cases out of ten the socket-power units, chargers, automatic relays, etc., designed for the benefit of the city user are of no value to the farmer whose house is not supplied

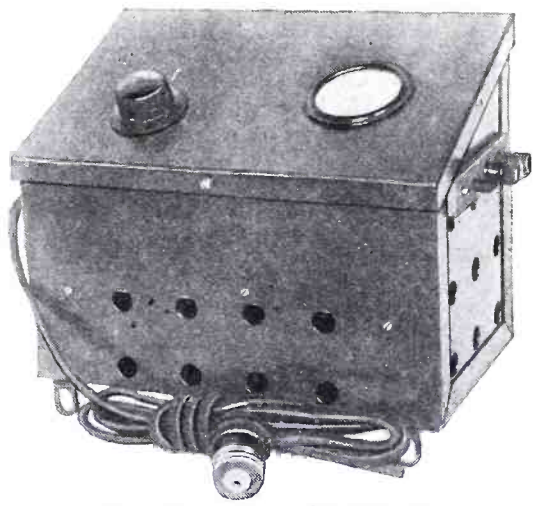


Photo by courtesy the Kato Co.

General view of farm "A" power unit housed in a compact metal case.

with electricity from the city power stations.

In a large number of modern farm and rural houses electric power is obtained fom a 32-volt farm-lighting plant; this consists of a bank of storage batteries, which are charged each day with current from a small electric generator driven by a gasoline motor. Such an outfit provides an ideal source of filament power for a radio receiver, and recently a manufacturer has placed on the market an "A" current-supply unit which, when connected to a 32-volt D. C. supply, reduces the voltage to the 6 required for operating the average set. The unit will be found pictured in the photo herewith.

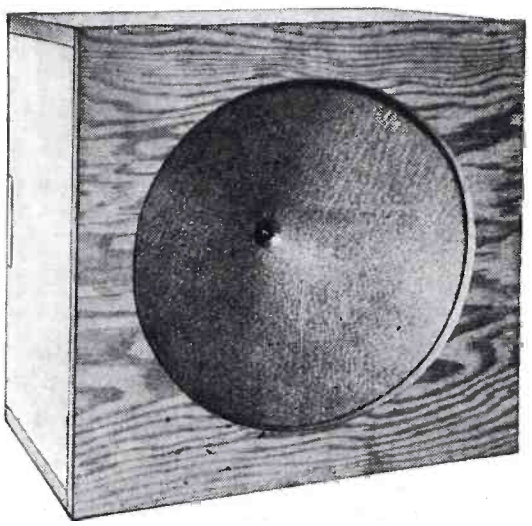
Essentially this unit consists of a bank of resistance units, a multi-point switch, a voltmeter and a cir-

cuit-breaker. The resistors are connected in series and reduce to a suitable amount the voltage applied to the filament. A switch connects various portions of the resistance bank into the circuit and in this way adjusts the output voltage to the required value. A voltmeter registers accurately the exact voltage at all times; and a circuit-breaker prevents the possibility of applying accidentally an excessively high voltage to the tubes, as it is so adjusted that it opens the circuit when the potential difference is over 6½ volts between the output terminals.

The voltage control knob and the voltmeter are mounted on the top. The plug is connected into the 32-volt supply circuit, and the binding posts on the side provide the 6-volt supply to the receiver. An adjustment knob on the side with the binding posts may be used to prevent the circuit-breaker from operating.

Loud-Speaker Unit Employs Powerful Electro-Magnetic Field

THE speaker illustrated in the accompanying photographs is a new type of power unit especially designed for operation from the "A" battery source of the radio set. It is also designed to match the new power tubes and faithfully reproduces natural tones over the entire range of the musical scale.



The assembled speaker can be housed in a wood box as shown above.

The outstanding feature of the unit which differs from the usual run of speaker units, is in the use of an electromagnet instead of a permanent magnet for polarization.

This unit is designed for cone speaker operation and is not adapted for use with the exponential horn type of speaker. It weighs about 4 pounds and is so shaped that it will fit into and 18-inch double cone speaker. The electromagnet draws about .4 of an ampere from the 6-volt "A" battery, or a little less than that required to light a power tube, which is not enough current

Photos by courtesy the Fanspeaker Radio Co.

The assembly of the cone showing the electro-magnetic power unit.

to be alarmed at. Where an "A" battery is not available, a trickle charger connected to the 110-volt A. C. lighting line may be used to supply the low voltage direct current needed. No filter is required. Under 200 volts "B" battery, no protective device is required between set and speaker.

A unit of this type will operate large and small cones, wood, airplane cloth, and other types of large diaphragm speakers. However, the most practical type of speaker seems to be the one shown in the illustration using a small cone mounted in a baffle box or chamber. This construction gives us a small sized speaker having a wide frequency response curve that may be placed in the average console cabinet.

This box may be constructed out of a good grade of wood at least ½-inch thick having a 11-inch diameter opening in the front to accommodate the 12-inch cone. The back of the box is open with the exception of the 3-inch strip of hard wood across the center for supporting the unit. The rim of the cone should be covered with felt; it is merely pressed against the front of the box behind the opening as shown. For the 12-inch cone the box must measure at least 12x12x6 inches deep inside. In building this speaker it is advisable to make the box as large as is possible to fit within a console cabinet or other space alloted for it.

In operation, it is possible to feed the speaker all that the set will deliver, whether using 100 volts or 700 volts, and rest assured that the speaker will stand the full blaze of the set without blasting or choking or otherwise distorting the musical tones.

Adapter Harness Converts Battery Sets For A.C. Operation

THE adapter harness shown in the accompanying photograph has recently been introduced to the radio public and makes it possible to convert practically any type of battery operated set to A. C. tube operation. When the conversion is made, no alterations in the wiring of the set is necessary.

The method of connecting the harness in standard battery operated sets is as follows:

The battery type tubes are removed from the A and C batteries disconnected. The tube adapters are then placed in the tube sockets of the set and the A. C. tubes are inserted in the adapters. The leads of the harness are connected to the binding post of a filament transformer designed for the A. C. tubes employed. All leads of the harness

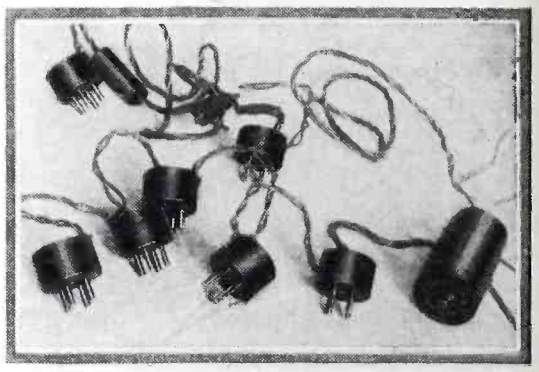


Photo by courtesy Carter Radio Co.

The A.C. adapter harness is made for four, five, six and seven tube sets. The seven tube harness is pictured above.

are clearly marked and there is little possibility of making error. Since the A and C batteries were disconnected from the set, the A battery terminals are of course not used. The C— binding post of the receiver should then be connected to the C+ binding post with a short piece of wire. The receiver is then ready to operate without batteries.

After the set is thus converted for A. C. operation, the old volume control usually becomes inoperative and an auxiliary volume control or variable resistor is connected across the aerial and ground terminals of the receiver which serves most effectively for the purpose.

Standard harnesses of this type are available for five, six and seven tube sets, both with or without power tubes. No tools are required to install this harness and the wiring of the set itself is not disturbed or altered in any way.

(*Continued on page* 169)

S. GERNSBACK'S RADIO ENCYCLOPEDIA

New limp Suede Edition!

S. Gernsback's Radio Encyclopedia is the first radio encyclopedia ever compiled. The many ramifications entering into collecting the vast amount of information required to make this work a complete, dependable and accurate guide can be better appreciated when one realizes that it took over two and one-half years to gather the material that it contains.

Every development, each circuit, prominent people of the radio world, every word used in radio practice—this is what you will find in S. GERNSBACK'S RADIO ENCYCLOPEDIA — NOT JUST A DICTIONARY.

There are 1,930 definitions, 549 photographs, diagrams of circuits and drawings. A complete cross index is just one of the many features of this remarkable book.

S. GERNSBACK'S RADIO ENCYCLOPEDIA can be had in either of two beautiful bindings. The luxurious limp suede edition sells for $5.00 the copy. It was made to meet the demand for a more handsomely bound volume. This edition is a masterpiece of bindery art, and is unquestionably designed for those eclectics who have a flare for the best of everything and a true appreciation for the art of printing. The Keratol Bound edition of this master Radio Encyclopedia can still be had for the price of $2.00. This is printed from the same plates as the beautiful suede bound edition and is not only a valuable source of information but also an exceptionally good printing job.

The value of S. GERNSBACK'S RADIO ENCYCLOPEDIA is well attested to by the fact that there are more than 25,000 copies of the Keratol edition already sold.

Mail this coupon now. No radio enthusiast can well afford to be without this authentic guide—S. GERNSBACK'S RADIO ENCYCLOPEDIA. Large 9" x 12" size—Gold embossed titles—large clean type.

The RADIO SET MARKET

This department is conducted in the interest of our readers who either build sets for sale or desire to have sets built to order. Anyone desiring to communicate with setbuilders whose notices appear in these advertisements can do so by addressing correspondence to the key number of each setbuilder in care of RADIO LISTENERS' GUIDE AND CALL BOOK, *230 Fifth Avenue, New York City.*

All advertisements of custom set-builders appearing in the radio set market are published without cost or obligation. However, the publishers reserve the right to reject any advertisement which in their opinion appears illegitimate or cases where concerns merchandising parts would take advantage of this offer to custom set-builders. No more than fifty words to each advertisement and only one advertisement is allowed to each party or concern. Each request must be written on a separate sheet of paper to which must be attached the special coupon given in the notice appearing on another page preceding the feature articles in this issue.

MIDDLE ATLANTIC STATES
New York, New Jersey, Pennsylvania

No. 119—Setbuilder in Brewerton, N. Y., has Bremer-Tully and Victoreen sets for sale. Specializes in Super-Heterodynes and all difficult circuits. Guarantees perfect satisfaction on any type of set built.

No. 221—Setbuilder in Bronx, N. Y., has custom built 3-tube radio set for sale. Price complete $25.00. Take it along with you on your vacation. Only one dial and very compact. Uses small loop aerial which is contained in the set. Has excellent volume and tone quality with a hundred mile range.

No. 124—Radio Rex of Bronx, N. Y., will build any set to order. Specializes in Magnaformer 9-8. All inquiries answered promptly.

No. 192—Custom setbuilder in Bronx, N. Y., will wire all popular circuits (with special improvements if desired). Standard sets wired for A.C. tubes. Specializes in Hi-Q 5 or 6.

No. 175—Professional custom setbuilder of Brooklyn, N. Y., has facilities for construction of all high grade sets, irrespective of type. Specified equipment only considered in assembly. Specializes in Hammarlund-Roberts, Browning-Drake, Super-Hilodyne and Super-Heterodyne receivers.

No. 268—Setbuilder in Brooklyn, N. Y., has for sale the following, One Freshman Masterpiece, one three tube portable also an R.E.L. short wave receiver and some Ham parts and will build any short wave set or any type of set to order. All work guaranteed.

No. 253—Setbuilder in Brooklyn, N. Y., will build any make of set to order with standard parts and circuits used. Will rematch condensers which improve reception and selectivity on one-dial sets. Seven years experience.

No. 148—Setbuilder in Brooklyn, N. Y., can build latest sets to order. 50 per cent deposit on all orders.

No. 125—Setbuilder in Buffalo, N. Y., can build any set you wish at right prices. Fully equipped with accurate test instruments. Also maker of famous power antenna for more stations and distance.

No. 179—Custom setbuilder and radio consultant in Buffalo, N. Y., will build or design any circuit to order. Modernizing sets a specialty. 12 years' practical experience. Associate of Institute of Radio Engineers. Will build anything from a 1-tube receiver to broadcast station. All work guaranteed.

No. 151—Setbuilder in Buffalo, N. Y., can build any make of set to order. Victoreen Super-Heterodyne specialist.

No. 110—Custom setbuilder in Cohoes, N. Y., will construct any nationally known circuit at very reasonable prices. Write for quotation on any set you are interested in.

No. 262—Setbuilder in Corona, L. I., N. Y., builds all popular late model sets, "B" eliminators and power amplifiers to order.

No. 118—Setbuilder in Elmira, N. Y., has for sale an 8-tube Super-Heterodyne and a Bremer-Tully Nameless—$20.00 each. Experimental work a specialty. Any kit custom built. Also special circuits for screen grid tubes. All work guaranteed.

No. 250—Custom setbuilder in Frankfort, N. Y., specializes in building and repairing radio sets. Have a special custom built 5 and 6-tube set known as "The Clarke Special," at a very moderate price.

No. 180—Custom setbuilder in Hastings-on-Hudson, N. Y., specializes in Silver-Marshall and Hammarlund-Roberts sets. All types of sets built, remodeled and repaired. All complete kits and accessories for sale.

No. 240—Radio expert and professional setbuilder in Jamestown, N. Y., will convert all sets for A.C. operation. Kits wired and sets tested. Antennas erected and sets installed.

No. 132—Four or five-tube sets with cabinet made by setbuilder in New Rochelle, N. Y. Wonderful DX "go-getters." Price $45.

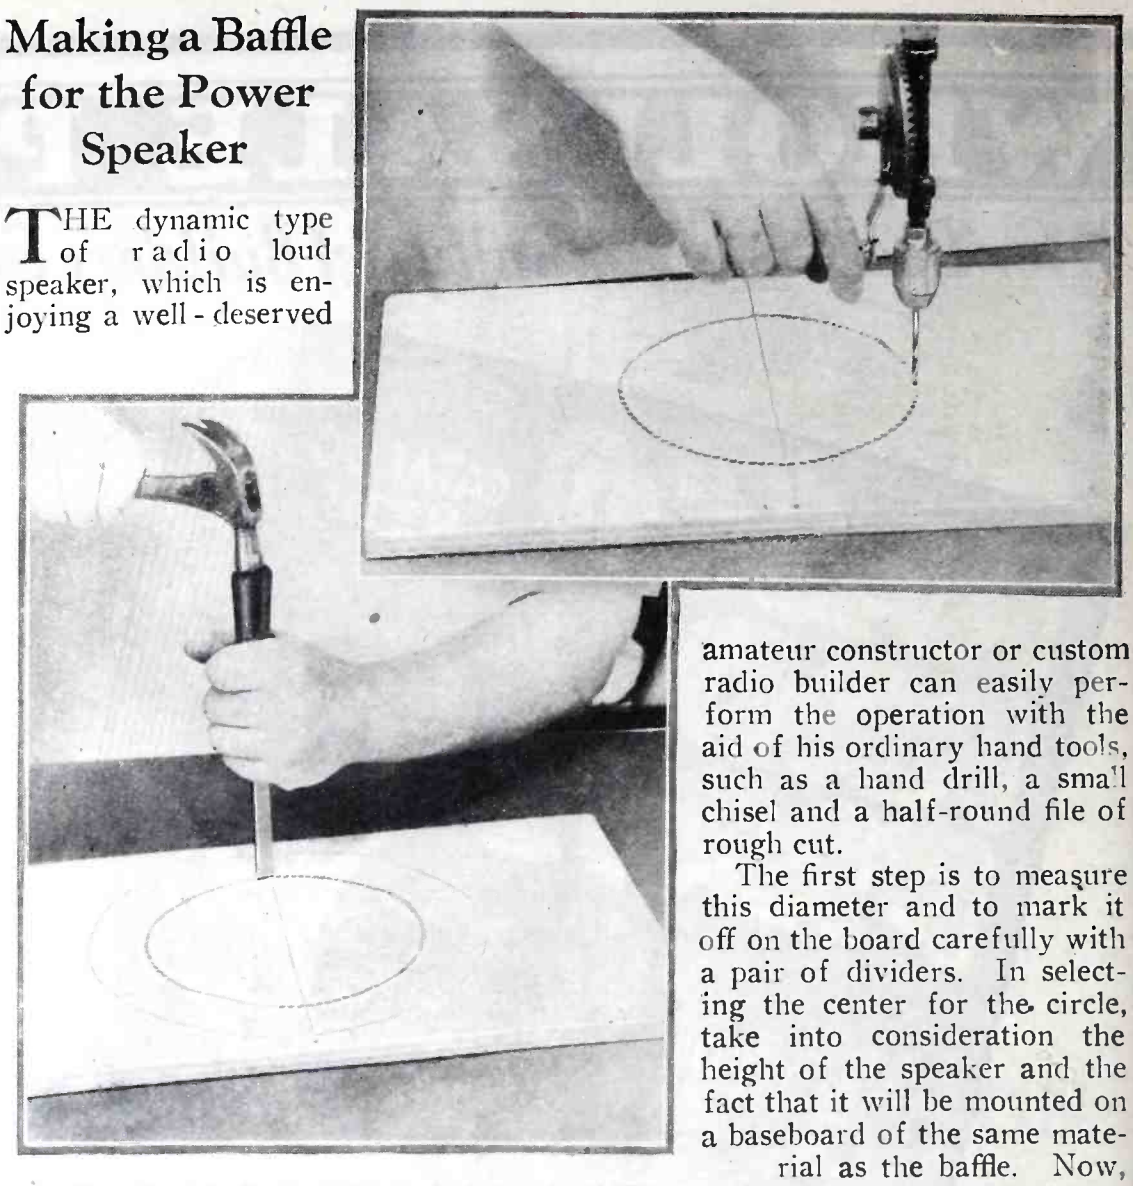
No. 193—Setbuilder in Toronto, Canada, builds all popular circuits, more sensitive, selective, powerful and cheaper than equivalent circuit in manufactured set. Specializes in 5-tube receiver which has received verifications from Cuba, Mexico and Pacific Coast.

Making a Baffle for the Power Speaker

THE dynamic type of radio loud speaker, which is enjoying a well-deserved popularity, requires a baffle board for its most satisfactory operation. This baffle is merely a plain board about three times the area of the mouth of the speaker, with a hole cut in it to accommodate the latter.

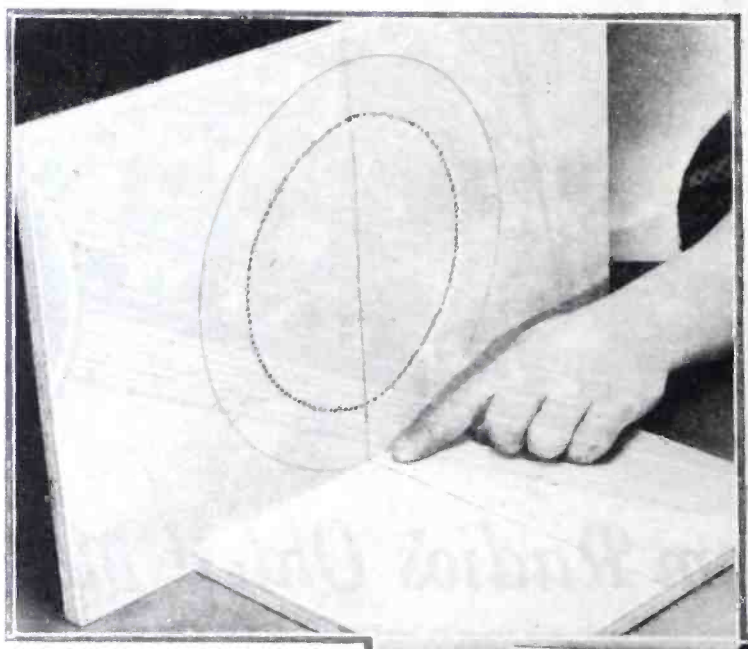
The main job in making such a baffle is the cutting of the large hole, which must be of the same diameter as the speaker opening. The amateur constructor or custom radio builder can easily perform the operation with the aid of his ordinary hand tools, such as a hand drill, a small chisel and a half-round file of rough cut.

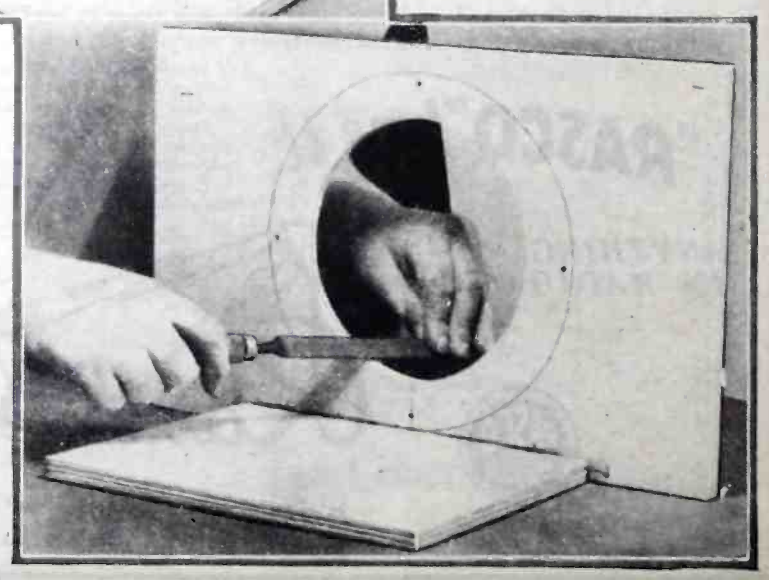


How the hole in the baffle is drilled and cut out.

The first step is to measure this diameter and to mark it off on the board carefully with a pair of dividers. In selecting the center for the circle, take into consideration the height of the speaker and the fact that it will be mounted on a baseboard of the same material as the baffle. Now, with a hand drill and a drill about 3/16 inch in diameter, drill a circle of closely-spaced holes just inside the circle you have marked. Work slowly and carefully, and allow the drill to cool after every eight or ten holes.

Then take the chisel, and working it with a hammer, carefully cut through the small spaces between the drilled holes, so that a rough disc will eventually fall out. Now clamp the baffle in a vise, and smooth off the big hole with the half-round





Fitting and filing the hole in the baffle.

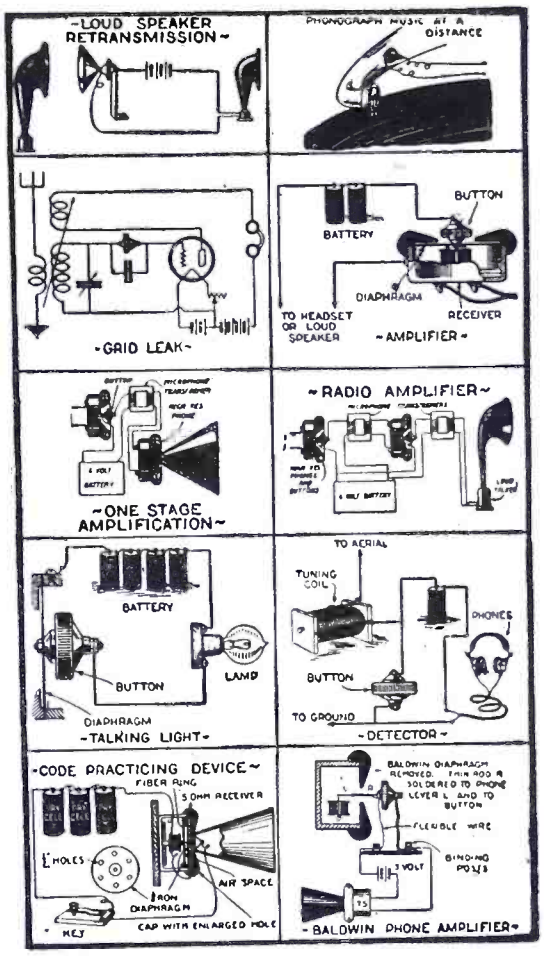
Thousands Use The *SKINDERVIKEN TRANSMITTER UNIT*

95c Or Two for $1.75

This famous and popular unit has been adapted to hundreds of different uses. Its application to radio, to electrical phenomena and to many unusual and practical household uses is limitless. It is essentially a very powerful amplifier as well as an efficient and dependable transmitter.

The Skinderviken transmitter units are, at the present time, used in numerous radio circuits, they are used for radio transmission, for radio amplification permitting the operation of a loud speaker from a crystal receiver, for phonograph and loud speaker amplification, for stethescopes, detectaphones, telephone transmission, etc., etc. Every amateur should have two or three of these units in his laboratory.

A FEW USES FOR THESE UNITS



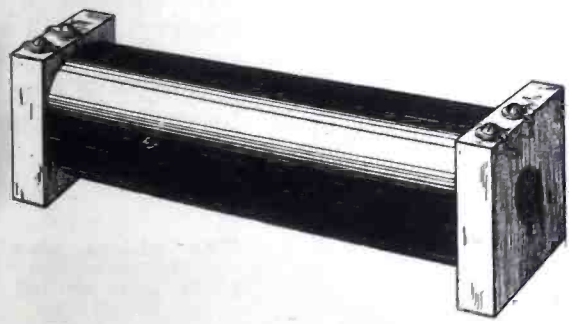
12 Page Instruction Booklet Furnished with Each Unit

With each unit is furnished a twelve-page instruction booklet, containing suggestions and diagrams for innumerable uses. Each use in the booklet is explained carefully and illustrated with clear diagrams. The booklet alone is worth the price of the unit.

We Pay $5.00 In Cash

for every new use developed for this unit and accepted and published by us. There is no limit to the uses to which the Skinderviken Transmitter Unit can be put. Experimenters are always finding new ones. There still remains hundreds of undiscovered applications that can be developed by a little experimentation. Here is your chance to make some money.

P.G. MICROPHONE TRANSFORMER



A microphone transformer (*modulation transformer*) specially designed for use with the Skinderviken Transmitter. These transformers are used for stepping up the low voltage high-frequency currents from the transmitter circuit, to a slightly higher voltage which will permit transmission over greater distances. The coils have many other uses for experimenters, such as for making small medical coils, etc. Primary resistance 1¼ ohms.

$2.00

The 12-page instruction booklet furnished with each Unit gives details and diagrams for a large number of special uses of the Transformer in conjunction with the unit.

Skinderviken Transmitter Units Are For Sale at Following Dealers

The W. T. Grant Stores
J. Belmuth, 198 Broadway, New York City
Chicago Salvage Stock Store, 509 S. State St., Chicago
Metropolitan Radio Supply, 134 W. 7th St., Los Angeles
Radio Centre Corp., 329 W. Baltimore St., Baltimore
Radio Specialty Co., 98 Park Place, New York City
Conrad Richter, 1284 Market Street, San Francisco
Ben's Tremont Elec. Sup. Co., 228 Tremont St. & 70 Stuart St., Boston
Washington Elec. Sup. Co., 24 Stuart St., Boston
Wedel Co., 520-2nd Ave., Seattle

If Your Dealer Cannot Supply You, Order Direct—Use Coupon

SEND NO MONEY

Order whatever or as many as you want. For your convenience use the coupon. When the postman delivers your order you pay him for whatever you have ordered, plus a few cents postage.

Immediate Shipment Guaranteed

PRESS GUILD, Inc. RLG 6-28
16-18-G East 30th St., New York.

Please mail me at once.....Skinderviken Transmitter Units, for which I will pay the postman 95c, plus postage, or $1.75 plus postage if I order two units.

Please ship me one P. G. Microphone Transformer for which I will pay the postman $2, plus postage.

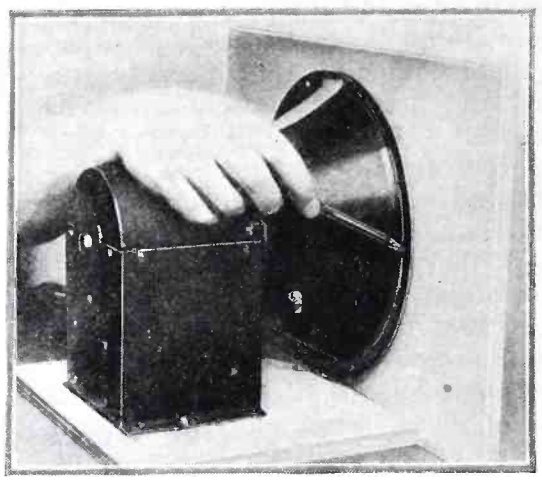
Name .....

Address .....

City .....State .....

file. Use light strokes and rock the file around so that it will not tend to dig beyond the marked circle. Finish the hole by smoothing off the edge with fine sandpaper.

The rest of the operation consists merely of drilling four holes for the mounting screws of the speaker frame, and of fastening the baffle to the baseboard. With the two boards thus joined, the speaker can be screwed in place permanently.



Fastening the baffle to the baseboard.

One length of dowel stick, one-quarter inch in diameter and about a foot long; two smaller pieces of dowel, one-half or five-eighth inch in diameter and each two inches long; a small brass hinge, not over one-quarter inch wide; and a small oil can.

Drill a one-quarter-inch hole in the side of one of the short dowels, so that the long, thin stick will fit tightly in it, forming a sort of little hammer. Then fasten the clamp of the pick-up unit around the end of the thick dowel, and tape the other end, as shown in the picture.

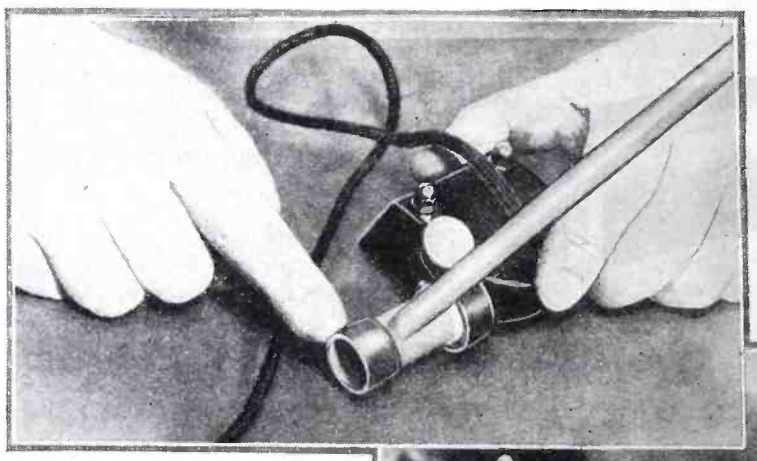
The other illustration shows the arrangement of the end support so clearly that little explanation is necessary. Cut off about half of the nose of the oil can, and drill a hole in the end of the second thick dowel to accommodate the short piece that remains. The hole should be a trifle oversize, so that the stick is free to turn. Screw the hinge to the top of the thick dowel and to the end of the thin one, so that the pick-up unit may be raised off the turn-table when not in use. Then drill two holes through the body of the oil can and screw the latter down to the turntable box in one of its corners.

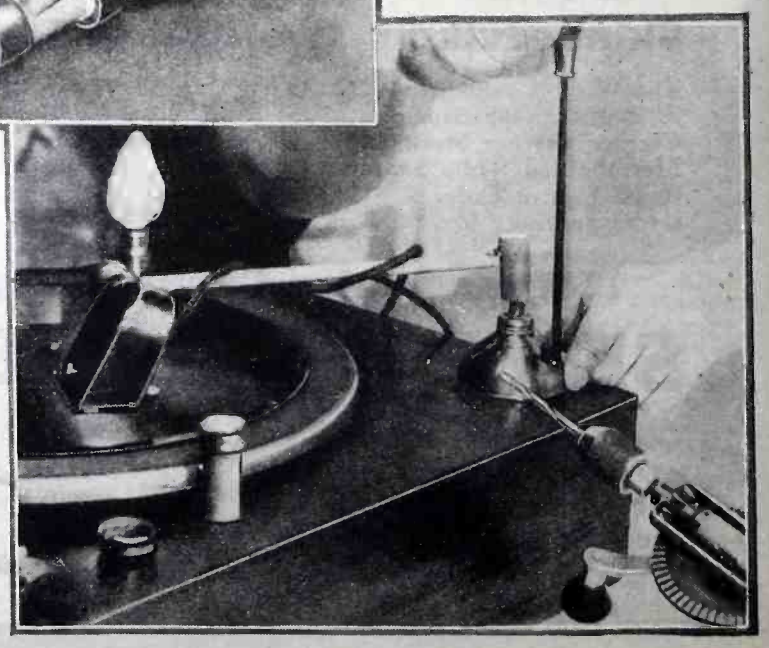
A complete phonograph motor-turntable device can easily be assembled at home as the only parts required are a phonograph motor and record turntable which can be often purchased from a second-hand dealer. The motor is merely mounted in a suitable wooden box with speed regulator and crank handle projecting at the side. Then when the whole unit is mounted in a cabinet all the controls will be readily accessible. The method of connecting the pick-up device to a suitable amplifier is furnished by the manufacturers.

Constructing a "Tone Arm" for the Phonograph Pick-Up Unit

THE man who has built the simple phonograph turntable described in the previous number of RADIO LISTENERS' GUIDE will be interested in this description of a "tone arm" designed to support the electrical pick-up unit in the same manner that the tone arm on a regular phonograph holds the mechanical pick-up device. The two accompanying illustrations make the nature of the device clear.

The parts required are as follows:



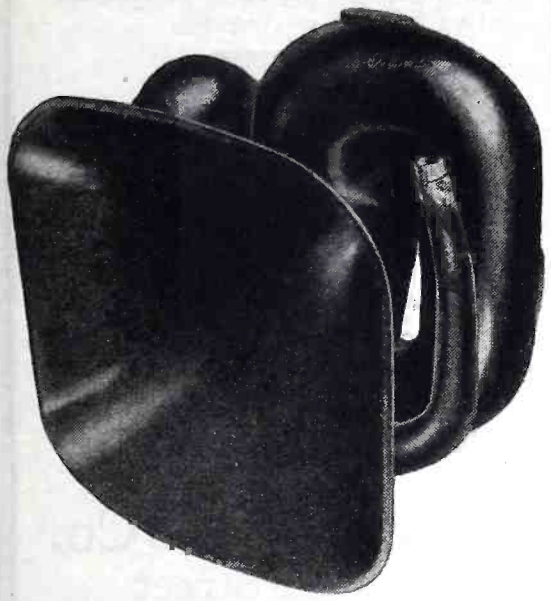


Two photos showing a close-up of the arm piece and method of mounting.

The Hagerman 210-A.C. Six

(*Continued from page 79*)

The success of this set or any other set can be traced directly to the efficiency of the parts employed. Those used in this set were selected after extensive experimentation as to

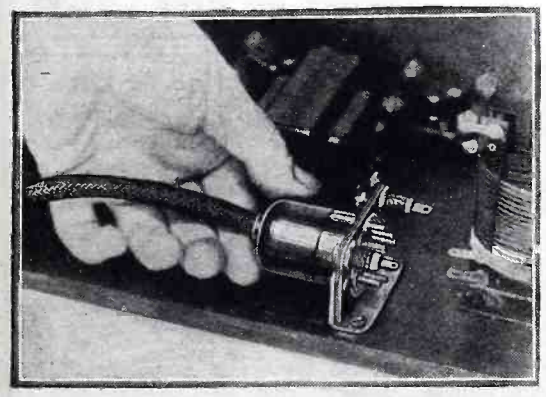


The molded wood horn recommended for use in conjunction with the set.

their electrical and mechanical characteristics. They all work perfectly in the circuit and are of exactly the correct values and physical size to conform to the base and panel layout and theoretical circuit. It is therefore not advisable to substitute any parts for those as specified.

Mounting Cable Connector

MOST radio set builders mount cable connectors on baseboards in such a manner that the multi-point plug, when inserted in the con-



Mount the cable connector at right angles with the edge of the baseboard.

nector itself, protrudes at right angles over the edge of the board. In this position it sometimes proves to be very awkward and inconvenient, as allowance must always be made for the distance the plug hangs over the baseboard.

With some sets and power-supply devices it is a better idea to mount the receptor end of the connector at right angles to the edge of the baseboard, so that the plug, when inserted, will lie *inside* the edge and parallel to it. In this position, the pins of the connector are more accessible for soldering than they were before, and the markings on them can be distinguished with less trouble.

Building a Radio Picture Receiver

(*Continued from page 69*)

a gear arrangement, by a spring motor. An ordinary phonograph motor, or an electric one that has the same speed can be used. A commercial recorder is made so that it can be placed in a standard phonograph for driving.

By means of a train of gears, a carriage moves along the cylinder axially at the rate of about 80 lines to the inch. A sharp stylus, such as a phonograph steel needle is attached to it. This is the terminal electrode of the high voltage corona coil. At this point, a brush discharge of varying intensity takes place, which records the picture on a photographic paper wrapped around the metal cylinder.

There is a stop-start spring arrangement, together with a release magnet, which stops, and again starts the cylinder, according to impulses received and directed through the relay, as explained above for the synchronization process.

The entire recording mechanism looks very much like an old cylinder phonograph, except that it has in addition the synchronizing apparatus. It would be possible to convert such a device into a recorder, by providing the synchronizing means, as in the commercial product. It would, however, be necessary for the amateur to have an elaborate machine shop equipment to do this.

Nevertheless, in a subsequent edition of RADIO LISTENERS' GUIDE AND CALL BOOK we shall make every effort to give our readers complete mechanical details for making a recorder and relay as well as other constructional information on the subject of telephoto reception.

After the final assembly of the picture machine, and the good working of the recorder, either spring or electrically driven, the picture set should be tried out. Tubes of the usual amplifier type are placed in the sockets, the V1, V2, and batteries connected, and a milliameter handy. It is very desirable to use individual batteries for this appara-

tus. Eliminators are best used with the receiving set to be connected to the picture machine. Of course, the ideal experimental set-up is where the entire arrangement is operated from individual sources of current supply.

Certain adjustments will have to be made to the picture set before it will be ready for operation. There is apparatus adjustment, and a bit of tuning. The relay contacts will have to be carefully brought into place, and the tension on the armature regulated to a nicety. Every time this relay trips, it will actuate the magnet of the recorder machine. It must be balanced so that only the synchronizing signal, which precedes each picture impulse once a revolution will trip it.

Then, the biasing resistance R2, must be judged best, so as to give the right amount of negative bias on the amplifier tube grid in order to swing the plate current to the operating point of the relay winding. The best way to adjust this resistance value is by means of a milliameter reading, when the relay and recorder magnets are energized. A reading of 15 mils in the plate circuit of the amplifier tube show a healthy operating condition.

This relay, as explained previously, will cause the recording cylinder magnet to stop its revolving once a revolution, in synchronism with the sending impulse. There may be some sparking at the contacts, which may be minimized by placing a large fixed condenser across them, or by increasing the space between contacts. The relay will trip at approximately 100 or more times a minute. The speed of the phonograph motor, governing that of the recording cylinder will have to be adjusted to strictly that of the sending station, plus a little advance. The revolutions can be readily counted by the tick produced by the trip magnet when it works.

To receive a picture, it will be necessary to see that a corona discharge is actually taking place at the stylus end. The oscillating circuit must perforce be working. A milliameter reading in its plate circuit will determine this. The recorder depends upon the voltage generated in the step-up radio frequency transformer for the spark discharge.

By darkening the room, and placing the stylus on a dark piece of paper, its glow may be seen. By adjusting various parts of the circuits, such as the variable condenser, the intensity of the spark can be regulated. A better method would be to insert a piece of photographic paper on the cylinder, and "expose" it to the spark. After developing, dark spots will indicate the action of the spark.

See page 135 for full information on Gernsback's Radio Encyclopedia.

The oscillating circuit should be regulated so that there is just a visible discharge when there is no modulated picture signal coming through. The intensity of the discharge will vary with that of the picture impulse.

Ordinary photographic paper can be used with the recorder. Azo No. 2 has been suggested, but Velox, or any of the other standard makes can be used. Simply wrap the sheet, which should be about 5 by 7 inches around the cylinder, holding it in place by means of rubber bands, or, if desired, paste along the long edge.

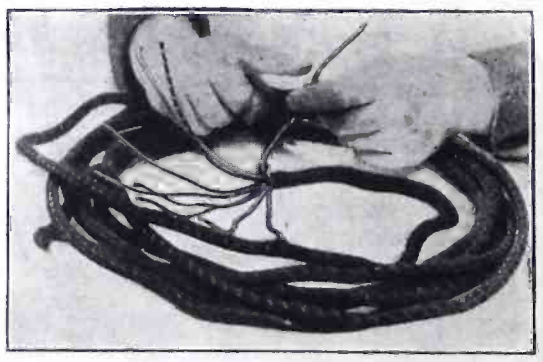
After the picture is run off, it should be developed in the regular way, with a developing and fixing bath. As skill is gained with the apparatus, more sensitive or contrasty papers can be tried, until the best combination is discovered. If the pictures are too dark, it is because the spark discharge is too strong, or the paper too rapid. Adjust the input resistance of the picture set to the amount given above, or use a slower grade of paper, or, again, readjust the oscillating condenser so that the discharge will be smaller.

If the pictures are weak, boost the signal, or use faster paper. Careful adjustment of the oscillating circuit should be made also.

Static and other interference may cause some difficulties in the manipulation of the picture machine. These generally show up in the shape of streaks in the photographs. The skill of the amateur constructor will enter here, to eliminate much of the troubles, and to obtain the finest picture.

Tracing Colors In Connector Cables

CONNECTOR cables which are used between the radio receiver proper and the batteries or socket-power units consist of from five to ten individual wires, covered by a single fabric sleeve. If these wires are examined closely, it will be seen



Each wire is of a distinct color.

hat they are all colored differently. Two or three of them may have their nsulation in solid colors, such as red, rown, yellow and green, while the thers will have vari-colored tracer trings woven into the material. A color scheme of some kind is necesary to enable the set owner to identify the wires and to connect them to the proper binding posts.

The colors used vary greatly. The solid red wires invariably represent the "A" plus leads, the solid black the "A" minus. The experimenter will have to adopt an identifying code of his own f the wires of any particular cable he has on hand do not conform to any standard code. It makes absolutely no difference which wire is selected for any service, as long as the code is adhered to.

If you are "shooting" trouble in a set equipped with an old cable, and find that the colors of the wires faded, merely slice off some of the outer fabric sleeve, so as to reveal an unfaded section of the wire.

The Knowles Screen-Grid Four

(*Continued from page* 122)

its stator plates clear the side of the rheostat R1 by about 3/16-inch. The condenser C2 should be mounted so the frame is ⅛-inch from the side of the shield.

The location of C2 is quite important, since its frame and rotor plates must be insulated from the shield. They are connected to the "B+90" lead. The frame may be insulated from the bottom of the shield by using a thin piece of varnished cambric or empire tape; or two or three pieces of paraffined paper may be used. The holes in the shield bottom should be quite large and the hole through the insulating strip just large enough to clear the screws. The hole in the side of the shield, through which the shaft goes, should be large enough to clear the shaft by 1/16-inch unless a short piece of bakelite shaft is available.

After C2 has been mounted, a test may be made from its frame to the shield by using a battery with a voltmeter, head-set or speaker. There should be no "click" or deflection of the voltmeter.

The sockets and by-pass condensers may then be mounted. A long lead should be soldered to one terminal of the choke L3. This should be threaded through the hole in the shield, after which the two mounting screws may be inserted. The two machine screws on the soldering lugs

Get your copy of 'Gernsback's Radio Encyclopedia now. See page 135 for prices.

should be removed, to prevent the possibility of one's touching the shield bottom.

Flexible rubber-covered wire is used throughout for the wiring. This, together with the use of "bee" or direct-line wiring and cabled battery leads, makes the wiring very simple. Long leads should be soldered to the terminals which are difficult to reach with a soldering iron after the apparatus is mounted. The grid-leak mount is an example of this; after it has been screwed in place the leads may be cut to the proper length and soldered to the grid condenser and to the filament terminal. If a 201A-type detector is to be used the filament connection of the leak should be made to the "A+" terminal. If the 200A-type is used, it should be connected to the "A—" terminal.

The wiring should progress with a view to completing the coil connections just before the shield is to be assembled. No parts are mounted on the rear side of the shields and these may be added after all the connections have been made. This makes it possible to solder the leads to the coils and other parts more easily.

After the wiring in both shielded compartments has been completed the three A. F. transformers (T1, T2 and T3), the A. F. sockets (V3 and V4), and the amperites (A1, A2 and A3) should be mounted. The left-hand shield should have five long leads, which are to be connected externally. They are the following: "A—" lead, which goes to the cable terminal; aerial lead from the primary of L1, which goes to the aerial binding post; plate lead from V1, which goes to the stator of C2; screen-grid lead, which is attached to the "G" terminal of V1 and goes to the "B+45" terminal (blue) on the cable connector, and the "A+" lead, which goes to the red cable terminal.

The right-hand shield should have the following external leads: one from the stator plates of condenser C3 to the choke L4; "A+" battery lead, which goes to A1 (to the right-hand side of the detector shield and not visible in the pictures); from the choke L3 to the yellow terminal on the cable connector; and that which goes across to the other shield and connects the stator plates of C2 with the "P" terminal of V1.

After these leads have been checked, the audio-frequency amplifier may be wired. The bottom leads to the cable terminal should be wired first to simplify the soldering.

There is ample room on the baseboard to permit the use of any type of audio-frequency amplification. If the constructor prefers push-pull amplification a pair of push-pull trans-

formers may be substituted for T2 and T3, and another socket and amperite added.

The amperite used in the last stage will depend on the power tube. The 1A type should be used for all ¼-ampere and the 112 type for all ½-ampere tubes.

To place the receiver in operation, connect the two "A" battery leads to the cable. Insert the 222-type tube in V1, 201A tubes in V2 and V3 (unless a special detector is used in V2), and the power tube on V4. The filament switch (R1-Sw) should break the connection to all the filaments and should control the brilliancy of the 222-type tube. If the rheostat seems to work satisfactorily complete the battery connections. The small initial spark on the blue and yellow leads is due to the current which charges the by-pass condensers. There should be no second spark when it is disconnected and quickly reconnected.

All of the cable markers are correct except that on the yellow lead. This lead should be connected to the "B+90" terminal instead of the "B—."

Connect the aerial, ground and loud speaker and tune in a local station. If the aerial is quite long, the position of the primary of L1 should be adjusted by turning the primary screw (which protrudes through a small hole in the top of the shield) until the primary is near the top of the shield; that is, until the coupling is very loose. If a small indoor aerial is used, the primary should be adjusted so that it is near the secondary. If a very short wire, having a total length of not over 30 feet, is used the connection should be changed so that all of the primary, instead of half of it, is used. The adjustment of the primary will depend on the selectivity and sensitivity wanted. It may be adjusted, while listening to a station, until the desired selectivity is obtained on the left-hand drum.

The right-hand drum will be found to tune broadly, for the reasons previously mentioned. To sharpen up this circuit, the regeneration control must be adjusted. Turn the rotor of the midget condenser (C3) until the plates are fully meshed. Set the rotor knob with the arrow pointing downward, so that thisp osition may be determined after the shield top is replaced. Set both drums at 100 and adjust the regeneration or tickler coil, just as the primary coil was adjusted, until the set begins to make a hissing noise or otherwise shows signs of oscillating.

When short-wave stations are tuned in it will be found that the capacity of the midget condenser must be decreased to stop oscillations.

The tuning is done as follows: move both dials, keeping them in the same relative positions and with about the same setting. When a station is found, tune the left-hand drum, which should be quite sharp, until maximum intensity is found. This should be done with the volume control in the "on" position; that is, with no resistance in the rheostat circuit. If the station is a local, the volume control may be turned to the left until the volume is moderate. Adjust the right-hand dial and gradually increase the capacity of the midget condenser C3 (make the plates intermesh more completely). It will be found that the setting of the drum must be changed slightly to secure maximum volume, and that the tuning becomes sharper. If the regeneration control is tuned too far, the quality becomes poor and there is a piercing whistle which varies in frequency as the drum is rotated. At some intermediate position good volume may be secured without any loss in the quality of the reproduction.

The selectivity of the detector circuit, in all such circuit arrangements, seems particularly poor because no other tuning control is operated from the same drum. If another tuned circuit were operated from the same control and sharply tuned, the "apparent" selectivity would be much better; although the actual selectivity might be the same. The important measure of selectivity is the distance to which *all* frequency controls must be moved in unison to tune out a station; this gives a measure of the over-all selectivity.

In this receiver the overall sensitivity and selectivity are quite high and both may be controlled largely by the regeneration control. In adjusting the receiver *both controls should be rotated together,* before judging that the selectivity is inadequate. If it must be increased, either more regeneration may be used or the aerial coupling may be decreased as explained before.

Both the selectivity and the sensitivity may be increased when this is necessary by employing the 200A-type detector tube; this may be used with an "A—" return or with the filament end of the leak connected to this terminal. This greatly increases the grid-to-filament resistance of the detector tube and results in sharper tuning and increased sensitivity.

After completing the set it can be installed in a suitable cabinet either of the table type variety or a wall type console. The latter is preferable as it contributes to the furnishings of the home.

Experimental Television

(*Continued from page 73*)

this number of tubes, and power tubes in the last stages, the individual tubes will not be overloaded, and there will be little chance of distortion. Run the tubes at their rated plate and grid voltages, and do not try to force them. Then there will be less chance of trouble with the amplifier unit. Use batteries, not eliminators.

In Figure 5 give the essential connections for the combination television unit described above. The photo-electric cell feeds into the first tube of the vacuum-tube amplifier, and the last tube feeds the neon tube. The voltages in the first grid and last plate circuits will depend on the type and make of photoelectric cell and neon tube that you employ. The manufacturers will supply the necessary data.

In presenting the design detailed in Figure 4, dimensions of the various parts are purposely omitted. The builder of a similar unit will have to change the layout to suit the parts available, and he will undoubtedly want to incorporate some of his own ideas in the construction of the apparatus.

When all of the parts have been constructed and assembled, the testing begins. First, start the motor and allow it to gain speed until it is turning the disks at a rate of about 1,000 R.P.M. If the photo-electric cell and the neon tube are "fast" enough, the disks may turn even faster than this, with a consequent increase in the quality of reprodution. A speed of about 960 R.P.M. with the disks built as described, will give about the equivalent of motion-picture speed, as the object to be transmitted will send beams of light from all its parts in succession through the disk to the photo-electric cell 16 times every second.

When the motor is running smoothly, turn on the amplifier and the light at the transmitting end. The latter may be an arc, or one or two 1,000-watt incandescent bulbs. Place an object before the window of the transmitter, and if everything is working properly, an image of the object, more or less perfect, will appear to the observer as he looks directly into the window at the receiving end through the revolving disk, to the neon tube. The position of the lens in the transmitter may have to be varied for best results.

The above description is presented to the amateur more as a series of constructive suggestions than as a definite set of rules that must be followed to the last period. Much still remains to be done before television

will have reached as high a stage of perfection as, say, radio telephone broadcasting.

However, with the experience gained with a combination outfit such as that outlined, the ambitious experimenter will soon be ready to tackle actual radio television. The necessary steps will be obvious to every transmitting "ham" and there is no need to go into details. Furthermore, in a very short time, we may expect to have some of our more prominent broadcasters equipped to transmit television programs. Then the experience gained with this outfit will stand you in good stead, and you will be far advanced toward good television reception.

The problem of synchronization has been but lightly touched upon in the foregoing paragraphs. When television broadcasting is ready for the public, and programs are transmitted, the synchronizing process will undoubtedly be govened by that used by the broadcaster, and this information will then be made public. There is no use of entering into a lengthy discussion of it here, as when the work is started, there is no telling just what system will be employed.

From Radio Amateur To Custom Set Builder

(Continued from page 66)

plans to the editors of several radio magazines. They invited him to submit for publication new circuits and new ideas in set building. When these were published, all inquiries concerning them were turned over to Mr. Horneij. He followed up the inquiries and in many cases turned them into sales.

Soon he had a national reputation for fine work and good receivers at fair prices. He did some national and local advertising, with good results. The early customers recommended him to their friends and satisfied customers gained in this way still keep the business growing. It would be easy in most cases for local set builders to secure co-operation from local papers as Mr. Horneij did from magazines, and the magazine ediotors always like to have a look at good radio stuff.

Mr. Horneij believes that his sets outdo in performance any of the factory sets of similar types. He has tested them against manufactured sets many times, with results favorable to the custom built set. One reason for the success of the

custom set builder is that he goes out among the manufacturers of the best parts, selects the materials for his sets and tests each part before putting a set together.

When a set is finished, he tests it several times before he is satisfied that it is perfect. If it satisfies him, he can be sure that the customer will be satisfied for, with his experience, he can discover defects that the average radio user would overlook.

One thing that is losing money for radio dealers, Mr. Horneij says, is service. He says that his sets require practically no service. He has never had to visit a customer more than once to inspect a set. When tubes or batteries cause trouble the customer may call up, but all needed information can be given over the phone.

The customer pays for the service call, unless inspection proves that the set is at fault. Mr. Horneij points out the cause of the trouble to the customer, and he does not try to duck any responsibility that belongs to him.

As each set is finally tested after installation in the place where it is to be used, and is adjusted for best results in that location, the customer knows what it will do before he accepts it.

Sometimes a prospective customer wants to try a set of a certain type but is not sure that he wishes to purchase one. He is told that there will be a moderate charge for this service, unless he buys a set.

Knowing his field as he does, and having had years of experience in installing receivers in many places, Mr. Horneij can tell what circuits will work best in different localities. If he is not sure what circuit will be best for a certain home, he takes a test set there and makes a reception test in room where the set that is ordered will be used. This eliminates guess work, and is one of the things that make customers. No customer buys a set that will work only half way.

Schneider-Horneij Radio Research Laboratories, Inc., which is the latest development of Mr. Horneij's business, was the first concern, he believes, to be appointed as an authorized service station for radio kits. Home set builders sometimes encounter problems that they cannot solve alone, even with the plans and instructions furnished with the kits, because they know so little of the principles of radio. A number of kit manufacturers were glad to turn such customers over to Schneider-Horneij, who give the necessary help for a reasonable fee.

This concern has no trouble about prices. Its price on a set usually is about the same as that of a similar

ADV.

factory built set. Sometimes it is lower. In any case, the customer receives a better set than one built under factory conditions because it is built of the best parts obtainable and under the eye of the man who is ultimately responsible for its performance.

Mr. Horneij, whose knowledge of human nature has increased with his radio experience, says that in every case where there is an argument about price, he has found a customer ready to pay a little more if he could get a better outfit. That is a good point for set builders to remember.

Besides building sets, Schneider-Horneij have constructed laboratory apparatus for manufacturers. They build and install transmitters and broadcast receivers for pleasure boats of all types. They were the first to put out a tube tester, several years ago. This type now is being used by the Radio Corporation of America.

In the busy season they employ several men to build sets, but Mr. Horneij does all the testing and has the contact with customers. His personal interest in the success of every set, and his desire to make a friend of every customer, are so strong that he will not delegate this important work to anyone else.

It is improbable that any reader has come this far unless he is the kind of man who would like to build up a business as Mr. Horneij has. Why not do it?

It is not necessary to have twenty years of radio experience to start with. Mr. Horneij acquired his a day at a time. Today there is experience available, in printed form and in apparatus, that enables a man to start building sets without personal experience and with reasonable assurance of success.

I have known novices, who never read a radio book or handled a piece of apparatus, who bought parts, built sets and sold them at a profit. Even before kits were on the market they did it. With a kit, a set of plans, an instruction book and a reasonable amount of common sense, any man who is handy with tools can put together a set tha twill bring in broadcast programs.

It would be unfortunate to raise false hopes. I have known men who were fine mechanics but who could not sell $5 gold pieces at a nickel apiece, because they had not learned the simple rudiments of salesmanship. But unless a man's personality is hopelessly weak, he can install a radio set in a home, school or club house and let it sell itself.

One of the most successful radio dealers whom I know talks less than

How to Build Modern Loudspeakers

~ an important book on an important subject!

AMATEURS! Build your own loudspeaker. This book, a complete history of radio accoustics, has been compiled by Clyde J. Fitch and many other eminent authorities on loudspeaker construction. The data thus assembled is now ready to be presented to you in the most comprehensible manner yet achieved—and now you can build any loudspeaker with absolute surety. Way back to the days of "canned music," those hectic days when distance was all engrossing to the radio enthusiast, and up to the present time when true tone reproduction is the objective of every radio fan—thru every phase of this development—to each milestone of progress, this little book will take you.

Every type of speaker—the Exponential Horn—the Cone—the Piezo Electric loudspeaker — Power speakers and Roll type speakers all types fully explained. Complete constructional data, diagrams, etc., assure positive results for the experimenting fan.

any salesman I ever saw. He has a force of salesmen and he has taught them to keep still, too. He started by hunting up a good prospect and asking her if she would like to have a radio set in her home for a few days, for a demonstration. She was delighted. He went to the house, placed the set where she wanted it, ran a ground wire to the radiator, placed a short length of antenna wire somewhere out of the way, plugged into a light socket and—

After the lady had finished her enthusiastic exclamations about how she never knew it was so easy to put in a radio, and how she always thought it was hard to tune one, and so on, she began giving him names of her friends whom she knew would like to have demonstrations. He sold them, too, and they gave him more names. So many names were given to him that he started putting on salesmen. In a short time he had six men trained and at work.

Little capital is needed for a start in set building, just enough to buy the first outfit of parts. The work can be done at home—no factory or office rent to pay. The selling can be done in the evening hours, if a man is busy during the day. It is one of the few kinds of business that a man can start with little money and in his spare time, and find a market for his products in any community.

The Supreme A.C. Six Receiver

(*Continued from page 95*)

Now reduce with this control until the hum just disappears, or nearly does. Next adjust the bias of the power tubes, R6. The next step is to adjust all compensating condensers in turn until the set howls on a station about 50 on the dial. The phasatrols are turned to the left until howl ceases. Begin with phasatrol, P1. The set should then be tuned to a wave length station near 200 meters. Howling will probably be noted again. This can be eliminated by reducing the phasatrols a little. The compensating condensers should again be adjusted to a finer degree. If this makes the set oscillate again, reduce the phasatrols still further to remove the howl. Readjust grid bias of all tubes. If a slight A. C. hum is present, adjust the 1.5 volt power rheostat and readjust the potentiometer.

The Improved Screen-Grid Laboratory Model Super-Heterodyne

(*Continued from page* 90)

termined by the position of the oscillator-coil rotor, which should be turned about 180 degrees in order to make the lower wavelength point (with oscillator-condenser plates least engaged) strongest, and this oscillator-coil rotor should be left set at about 45 degrees with respect to the stator coil. The selectivity of the Antenna dial is determined by the position of the antenna coil rotor; greatest selectivity at least volume being obtained with the antenna rotor at right angles to the stator coil. Antenna selectivity and the sensitivity of the receiver are further affected by the position of the "Sensitivity knob"; this, through the midget regeneration condenser, controls regeneration and oscillation in the first detector and if turned too far in, will naturally cause first-detector oscillation, so that a large number of squeals will be heard in operation. Care should be taken never to use this condenser except on very weak stations, when, after the station is tuned in, it should be turned up gradually to increase signal strength with slight readjustment of the Antenna dial to compensate for the variations in tuning caused by the Sensitivity condenser.

If it is desired to operate the receiver as a seven-tube set, omitting one intermediate stage—and this is really desirable, except for extreme long-range reception—the first R. F. amplifier stage can very easily be dropped by simply pulling the clip lead in the left-hand compartment of the time-signal amplifier over into the next compartment to the right and clipping it on to the top lead of the second 222-type tube. The clip in the second compartment, ordinarily going to the second tube, should be ignored. Thus the first transformer in the intermediate amplifier feeds the second tube, which, in turn, feeds the third transformer; so that the tube in the first compartment and the transformer in the second compartment (from the left) are simply dropped out of the circuit. It will be found in operation that the tone quality will be somewhat better when using only two intermediate stages than when using three; but the sensitivity in the receiver will be greatest using three stages, and, of course, greater sensitivity means greater noise and stronger signals. The last audio-amplifier stage can also be dropped

very easily by simply moving the loud-speaker cord tips from the two "maximum" tip-jacks to the two "minimum" tip-jacks; although this course is not recommended except where an external power amplifier is used, in which case it is best to leave off the second audio stage altogether. An output transformer should be used connected between the output jacks of the set and the loud speaker.

It will be observed in tuning the set that, when using the lower-wavelength heterodyne point of the Oscillator for all signals, both dials will not track. This condition can be remedied by tuning in (say, KYW or KSD) a very high-wave station, and removing turns from the top end of the oscillator coil until the Oscillator dial reading for this high-wave station coincides with that of the Antenna dial. Actually, it may be desirable to remove turns from both oscillator and antenna coils so that KYW or any other 535-meter station will come in with both Oscillator and Antenna condensers interleaved to within all but five degrees of their maximum position. If this stripping of oscillator and antenna coils, which is done in steps of two or three turns at a time, is carried out, it is possible to extend the range of the receiver down so that it will actually go a little below 200 meters. In stripping the coils, only the enamel wire winding at the top end of the stator forms should be touched, the rotors and slot windings being O. K. Generally 10 turns may be removed from the antenna and 25 turns from the oscillator coil.

The receiver will, of course, cover other than the regular broadcast wavelength range, a pair of 111B coils allowing it to tune from about 70 to 210 meters, and a pair of 111C coils covering the range of about 30 to 90 meters. Two type 111D coils will cover the range of 500 to 1,500 meters; while the addition of one 111E coil for the antenna socket (using a 111D oscillator) will allow the set to tune up to about 3,000 meters. All of these coils are interchangeable plug-in types fitting the standard coil socket.

For short wavelength a three-tube regenerative receiver will generally give entire satisfactory results, or even for medium range broadcast reception. It is a simple matter to add a three-contact switch, with all contacts insulated from the frame, on the front panel of the receiver under the detector stage assembly. The lead from post P on the left end of the intermediate amplifier to the R. F. choke coil (L3) should be broken, and the wire from the choke coil led to the blade of the switch. One contact to the switch

8 POPULAR MODERN MOVIE NOVELS $1.00

GREATEST OFFER EVER MADE

Take advantage of this amazing bargain

Eight full size books for one dollar. Never before has an offer of this kind been made. Only quantity production permits us to make this astounding offer now. Take advantage of it while you have the opportunity. Needless to say these modern up-to-date movie hits can not last long at this tremendous bargain price. Each book contains at least two color "stills" of an actual scene from the photoplay. Don't hesitate. Mail this coupon now. Each story based on an actual moving picture triumph. The greatest book bargain of the age.

Titles of this Tremendous Bargain Offer

1. New York
2. The Campus Flirt.
3. Almost a Lady.
10. Sensation Seekers.
11. The Rambling Rangers.
12. Don't Tell the Wife.
14. Tracked by the Police.
15. Tell It to the Marines.
18. Irresistible Lovers.
20. The Cohens and Kellys in Paris.
21. The Divine Woman.
22. Jazz Mad.
23. The Crimson City.
24. You Can't Beat the Law.
25. Tillie's Punctured Romance.
26. Forbidden Hours.

An Addition to Your Library

These books will be a worthwhile addition to your library. You will find many hours of truly enjoyable reading in each beautiful volume. Printed on fine paper with large, clear type. Beautiful colored covers of flexible, durable material. These books are undoubtedly one of the greatest values ever offered at this amazingly low price.

should go to post P on the left of the intermediate amplifier and the other contact should connect to post P on the right of the intermediate amplifier. The switch then serves to throw the output of the regenerative first detector either directly into the audio amplifier or into the intermediate amplifier. Naturally, when the detector output is connected directly to the audio amplifier, the oscillator tube and all tubes in the intermediate amplifier are unused and may be turned out by an extra pair of contacts on the throw-over switch; or the tubes may be removed from the set, if desired.

If any difficulty is experienced in getting the set to function properly in the matter of sensitivity, selectivity, or tone quality, the change above suggested should be made and the lead from the choke (L3) connected directly to terminal P on the right end of the I. F. amplifier. The set should then be operated as a three-tube regenerator, and the results carefully observed, in order that the operator may familiarize himself with the operation of the first detector circuit and the nature of the regeneration control of the "Sensitivity" knob. Naturally, when the intermediate amplifier is added to the circuit, volume, sensitivity and selectivity should increase very much and the oscillator dial would then come into play. In tuning, the oscillator dial should be extremely sharp, requiring only a degree or two at the outside to eliminate practically any station, local or distant. The antenna dial will be broad comparatively, local stations covering as much as 20 to 30 degrees of the Antenna dial when it is rotated alone, and out-of-town stations from 5 to 10 degrees or more.

The real test of the receiver's performance, however, is a comparison against any other standard set—the Improved Screen-Grid Laboratory Model receiver should give greater selectivity and far greater distance range than any other set on the American market, and the tone quality, when using but two intermediate stages, should be on a par with that of the very best T. R. F. receivers. When using three intermediate stages for extreme sensitivity, it should be equal or better than that of practically all other superheterodyne. A loop may be used, connected to antenna coil socket posts 3 and 4, with the antenna coil removed from the set.

It is suggested that a high grade speaker be employed in conjunction with this set if best tone quality is expected. Among the types recommended for use with this set are the Accusti-cone, Ensco, Dynatone and G. R. Penn speakers.

THESE 2 MAGAZINES *for* THE PRICE OF 1

A year's subscription to these two popular magazines for the price of Radio News—alone. If you were to buy Radio News and Radio Listeners' Guide and Call Book individually for one year they would cost you $5.00. By our special combination yearly subscription rate you can get both of these foremost radio periodicals at the tremendous bargain price of $3.00. In order to keep up with the latest developments of Radio, to know the newest sets and how to build them, to find every radio broadcasting station you must read these leading periodicals of radio.

The RADIO LISTENERS' GUIDE AND CALL BOOK is the foremost quarterly magazine in the field. A special feature of this remrakable magazine is the up-to-the-minute log of every station in this country, Canada and in Europe. This list of call letters is carefully checked and corrected in each quarterly edition.

RADIO NEWS is read each month by more radio enthusiasts than any other publication in the field. It contains the latest developments and the most modern circuits of the radio world. Honest, unbiased opinions on every subject of interest—this is what RADIO NEWS gives you.

Write today—insure your receiving each issue of RADIO LISTENERS' GUIDE and CALL BOOK and RADIO NEWS. Take advantage of this special subscription offer—Two magazines for the price of one.

The Four-Tube Roberts A.C. Receiver

(*Continued from page* 84)

trouble, that of loose connections, can be eliminated.

A little extra care spent in making sure that the binding post connections are good and tight and that the soldered connections are really fast will be more than repaid by freedom from trouble.

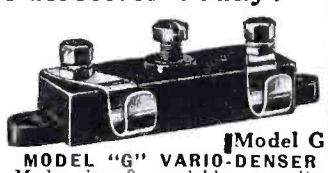
If the parts specified are employed and ordinary care is taken in the construction of the receiver, the resulting job will be one of which any professional set builder or radio experimenter may well be proud and the receiver may be counted upon to put many much more expensive receivers to shame.

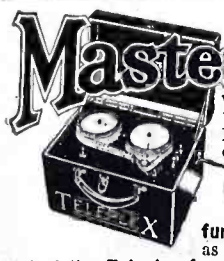
A good idea in wiring up the set is to put in the filament wiring to the tubes first. The leads for making the filament connections to the power tube, in socket VT4 and to the heater ("H") terminals of sockets VT1, VT2 and VT3 should be twisted pair wire or parallel leads twisted together. This twisting is important in avoiding troublesome hum through interacting fields around the wires.

The next step in the wiring is to make the connections to the cathode ("K") terminals of sockets VT1, VT2 and VT3 and to the terminals of the other instruments which are joined with the "K" terminals of the sockets.

The rest of the wiring can then be done, following the scheme of connections as shown in the schematic and pictorial diagrams.

In making the connections to the primary of the power transformers, T6 and T7, cut the braid which covers the twisted pair leads which come out of the porcelain outlet, just above the filament terminals of transformer T7, so as to separate the two leads. These two leads should then be bared (a short distance apart as shown in the pictorial diagram, to avoid any possibility of short circuit). One of the leads from transformer T6 should be connected with one of the bared leads of transformer T7, shown in pictorial wiring diagram. The other lead from transformer T6 should be connected with one of the terminals of resistor R3 as shown. The other terminal of resistor R3 should be connected with the other bared lead of transformer T7. After the connections have been made, the joints to the leads from transformer T7 should be taped up to insulate them.





This scheme of connections connects the primary of transformer T7 directly across the A. C. line but connects the primary of transformer T6 across the A. C. line with the resistance R3 in series with the primary of transformer T6 to cut down the voltage to the required value.

Binding posts should be mounted on the baseboard and connected to the output terminals of the output transformer T5 for connections to the cord tips of the loud speaker.

While the possibilities of trouble have been reduced down to an absolute minimum in this receiver by the selection of high grade parts and by careful design of the circuit and layout, a few hints and cautions on how to avoid trouble or eliminate it will prove helpful.

Regardless of the care taken in the mounting the parts and wiring the receiver, there is always a chance that even the most experienced set-builder might make an error in connecting the terminals.

If after careful checking the set fails to work, it is a good plan to check up each portion of the circuit. The audio unit can be tested out step by step by connecting the loud speaker terminals first across the primary of the first audio transformer, T3 to see whether the signal comes through on the detector stage. If the signal comes through, then proceed to connect the loud speaker across the primary terminals of the second audio transformer T4, to determine whether the first audio stage is functioning. Finally connect the loud speaker across the primary terminals of the output transformer T5 to see whether the last audio stage is operating. If the signal comes through at each stage it indicates that the trouble is farther along in the circuit, until a point is found where the signal does not come through indicating a defective part, tube or connection.

If the signal does not come through on the detector stage, take out the R. F. tube from socket VT1 and connect the antenna to the stator plates terminal of the tuning condenser C2. If signals come through on this connection, the detector stage is all right and the trouble may be located in the R. F. stage.

It is well to keep in mind also, that the volume is increased when the volume control knob is turned in a counterclockwise direction and not in a clockwise direction as is the case with many other sets. Do not therefore expect to hear loud signals if your volume control is turned as far as it will go in a clockwise direction. If these simple precautions are taken excellent results will be obtained.

How to Build the Cosmopolitan Screen-Grid Receiver

(*Continued on page* 107)

and insures best operation of the power unit at all times and in any location.

The filter and by-pass condensers are all enclosed in a single block or "can." These condensers have an ample safety factor in their voltage ratings thus eliminating any possible chance of breakdown. The output resistor network has been the subject of careful consideration and was selected for use only after thorough investigation as to its fitness for inclusion in this job. These resistors are capable of carrying several times the current placed upon them in this circuit, their resistance remains constant and they are capable of providing exactly the output voltages required—to an accuracy of better than five per cent. In fact, with a little care in the first adjustment the output voltages can be brought within one per cent of the receiver requirements.

Binding posts are provided for each required output voltage and jacks are included on the terminal panel so that a milliammeter with a scale range of 0-50 milliamperes may be plugged in by means of an ordinary phone plug to obtain current readings on the plate supply to the power amplifier tube in the receiver and on the total current drain of the receiver.

The fine voltage regulation, by means of which the output voltages are maintained at almost absolute constancy regardless of heavy loads imposed by strong reproduction of low notes is obtained through the use of a power transformer with excellent regulation, a properrly proportioned filter, a rectifier tube capable of handling much geater loads than are imposed upon it in this eliminator—and particularly by the use of an output resistance network of comparatively low resistance. The regulation is so good in fact that the rectifier output varies only 7 per cent when the load of the Cosmopolitan receiver is applied to the output of the eliminator. If the total voltage variation from no load to full load is only 7 per cent it is obvious that the variation with small variations in the load are negligible. The low output resistance also has the advantage that with the receiver disconnected from the eliminator, in other words with no load, the volt-

2 GREAT RADIO CIRCUITS!

The Strobodyne

NEVER, since the basic principles involving superheterodyne construction were first conceived, has there been a greater circuit than the STROBODYNE. The STROBODYNE takes its name from the Stroboscopic Phenomena, on the principle of which it was developed. The French inventor of the STROBODYNE, Lucien Chretien, and this country's greatest authority on superheterodyne construction, R. E. Lacault, have co-operated in introducing this remarkable receiver to the American radio public.

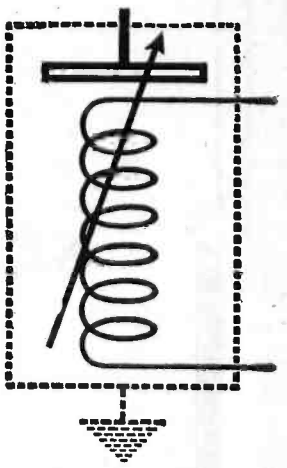
Leading engineers of the radio industry have called the STROBODYNE the greatest of superheterodynes. The STROBODYNE reaches out for the distant stations, locates them and brings them in with such clariety and ease that only by actual operation of this remarkable receiver can you fully appreciate its efficiency. Marvelously clear and faithful tone reproduction is just another feature of this wonderful set. Those radio fans who lean to the superheterodyne as the acme in radio receiving circuits will find in the STROBODYNE the culmination of all their ideals.

The Consrad Company, the famous old pattern publishers of radio, have compiled complete blueprints (full sized) and all the necessary information for building either the STROBODYNE or the PERIDYNE. These complete patterns can be obtained for 50c each. Every question arising in the construction of either of these remarkable sets has been fully and clearly answered. Build one of these famous efficient radio receivers. You are sure to be more than satisfied. Mail this coupon today.

50c Per Pattern

The Peridyne

Designed by Hugo Gernsback



A great deal of valuable time and money has been spent in the last few years in an effort to facilitate the operation of radio receivers by cutting down to a minimum the number of controls required to operate a set efficiently. In this effort many manufacturers have attained a degree of perfection quite laudable but until the development, by Hugo Gernsback, of the PERIDYNE—one-dial radio receiver—each new method, although accomplishing its purpose, did so at the sacrifice of some necessary feature in construction. In the PERIDYNE the solution to the question of efficient operation has been found. THE PERIDYNE IS THE IDEAL ONE-DIAL RECEIVER.

Previous to the PERIDYNE it was impossible to build a one-dial radio receiver that was selective. With the advent of the PERIDYNE, however, not only was selectivity preserved, but all other features required for the successful operation of the receiver did not suffer in the least from the elimination of what previously had been considered necessary controls. Those desiring maximum efficiency and simplicity of operation could find no radio circuit better fitted for their requirements than the PERIDYNE.

CONSRAD COMPANY,
230 Fifth Avenue, New York, N. Y.

Gentlemen:—I desire complete patterns on the———STROBODYNE———PERIDYNE (check which) for which I enclose 50c.

age increase at the filter is so small as to eliminate surges and strains which would otherwise endanger filter condensers and rectifier.

The total available voltage at the output of the eliminator is 300 volts at a drain of 40 milliamperes. The voltage drop in the first section of resistor "R1" drops this to 220 volts which provides 180 volts for the plate supply of the power tube and 40 volts for the grid bias for this tube. The next resistor tap provides a plate voltage of 135 which is the value used for both the R. F. and first A. F. tubes in the Cosmopolitan receiver. The 45-volt supply for the screen grids and for the detector plate are obtained from the next to the bottom tap on the resistor "R1" and the junction between "R1" and "R2" provides the "B—" terminal. The slider arm of "R2" provides the —4.5-volt tap for the first A. F. and detector grid bias and the slider of "R3" provides the —40-volt grid bias for the power tube.

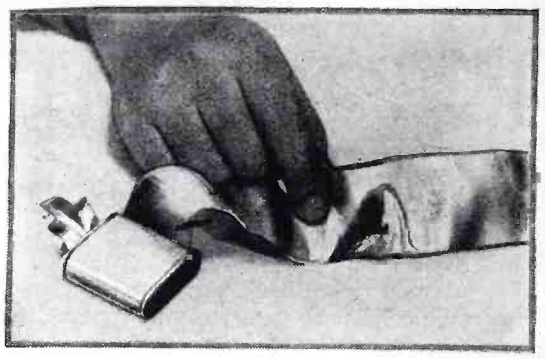
The taps on the resistor "R1" are all adjustable. When the power-pack is first put into operation the taps that provide the 135- and 45-volt terminals (and also the 90-volt terminal if this voltage is required) should be adjusted until they provide exactly the desired voltages. This can only be done with the assistance of a high resistance volt meter which may be borrowed for the occasion inasmuch as it is not required after the adjustment has once been made. Adjustment is made by loosening the screw in the terminal clamp and shifting the clamp band toward the high voltage end of the resistor to secure higher voltage and toward the low end to secure lower voltage.

At first glance the necessity for adjusting the taps of "R1" would seem to be a nuisance but this scheme has the advantage over fixed resistors that the output voltages can be made to exactly fit the requirements of the receiver with which the unit is to be used. It also has the advantage over ordinary variable resistors that it eliminates the tendency to make constant readjustments with resulting doubt as to correct adjustment. In other words the schemes employed here has the advantages of both the fixed and variable resistors but without the outstanding disadvantages of either.

This eliminator is highly recommended to anyone who desires a plate supply source which approaches the ideal, at a moderate investment of money, time and skill. It can be used to maximum advantage with any receiver, using a CX-371A type of tube in the last audio stage, requires no upkeep attention and has an indefinite life.

Effects of a Blown Out Condenser

AT one time or another you probably have asked yourself: "What happens inside a fixed condenser when it blows out?" If you are curious to find out without deliberately blowing a few and disembowelling them, look at the accompanying picture. The black spotch



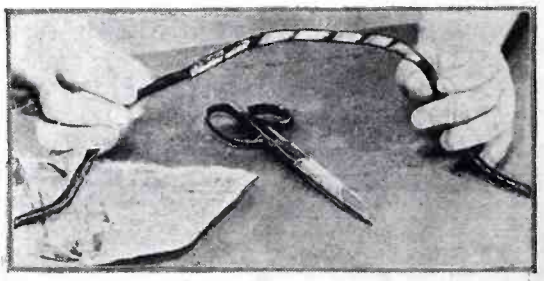
The effect of a blown out by-pass condenser.

indicates the spot where the paper dielectric of the condenser broke down and was burned by the current as it arced between the tinfoil sheets.

Keep this picture in mind the next time you debate the advisability of using a condenser rated at 180 volts in a power circuit carrying 400.

Shielding the Battery Cable With Foil

WITH certain types of sets, it is necessary to shield every exposed part of the equipment, including even the battery cable, which may act as a pick-up of stray R.F. current to a troublesome degree. Receivers employing the 222 (screen-grid tube) are especially critical in this respect.



The foil is wrapped around the battery cable.

Shielded battery cables are not readily obtainable, and if they were, they probably would be very expensive. Fortunately, it is a very simple matter to shield an ordinary cable. Simply cut strips about an inch wide from a sheet of heavy tin or lead foil, and wrap them around the wires in exactly the same manner that you would apply ordinary friction tape. When the job is completed, connect the foil to the ground post of the set.

The Listeners' Accessory Guide

(*Continued from page* 134)

A Short Wave Adapter

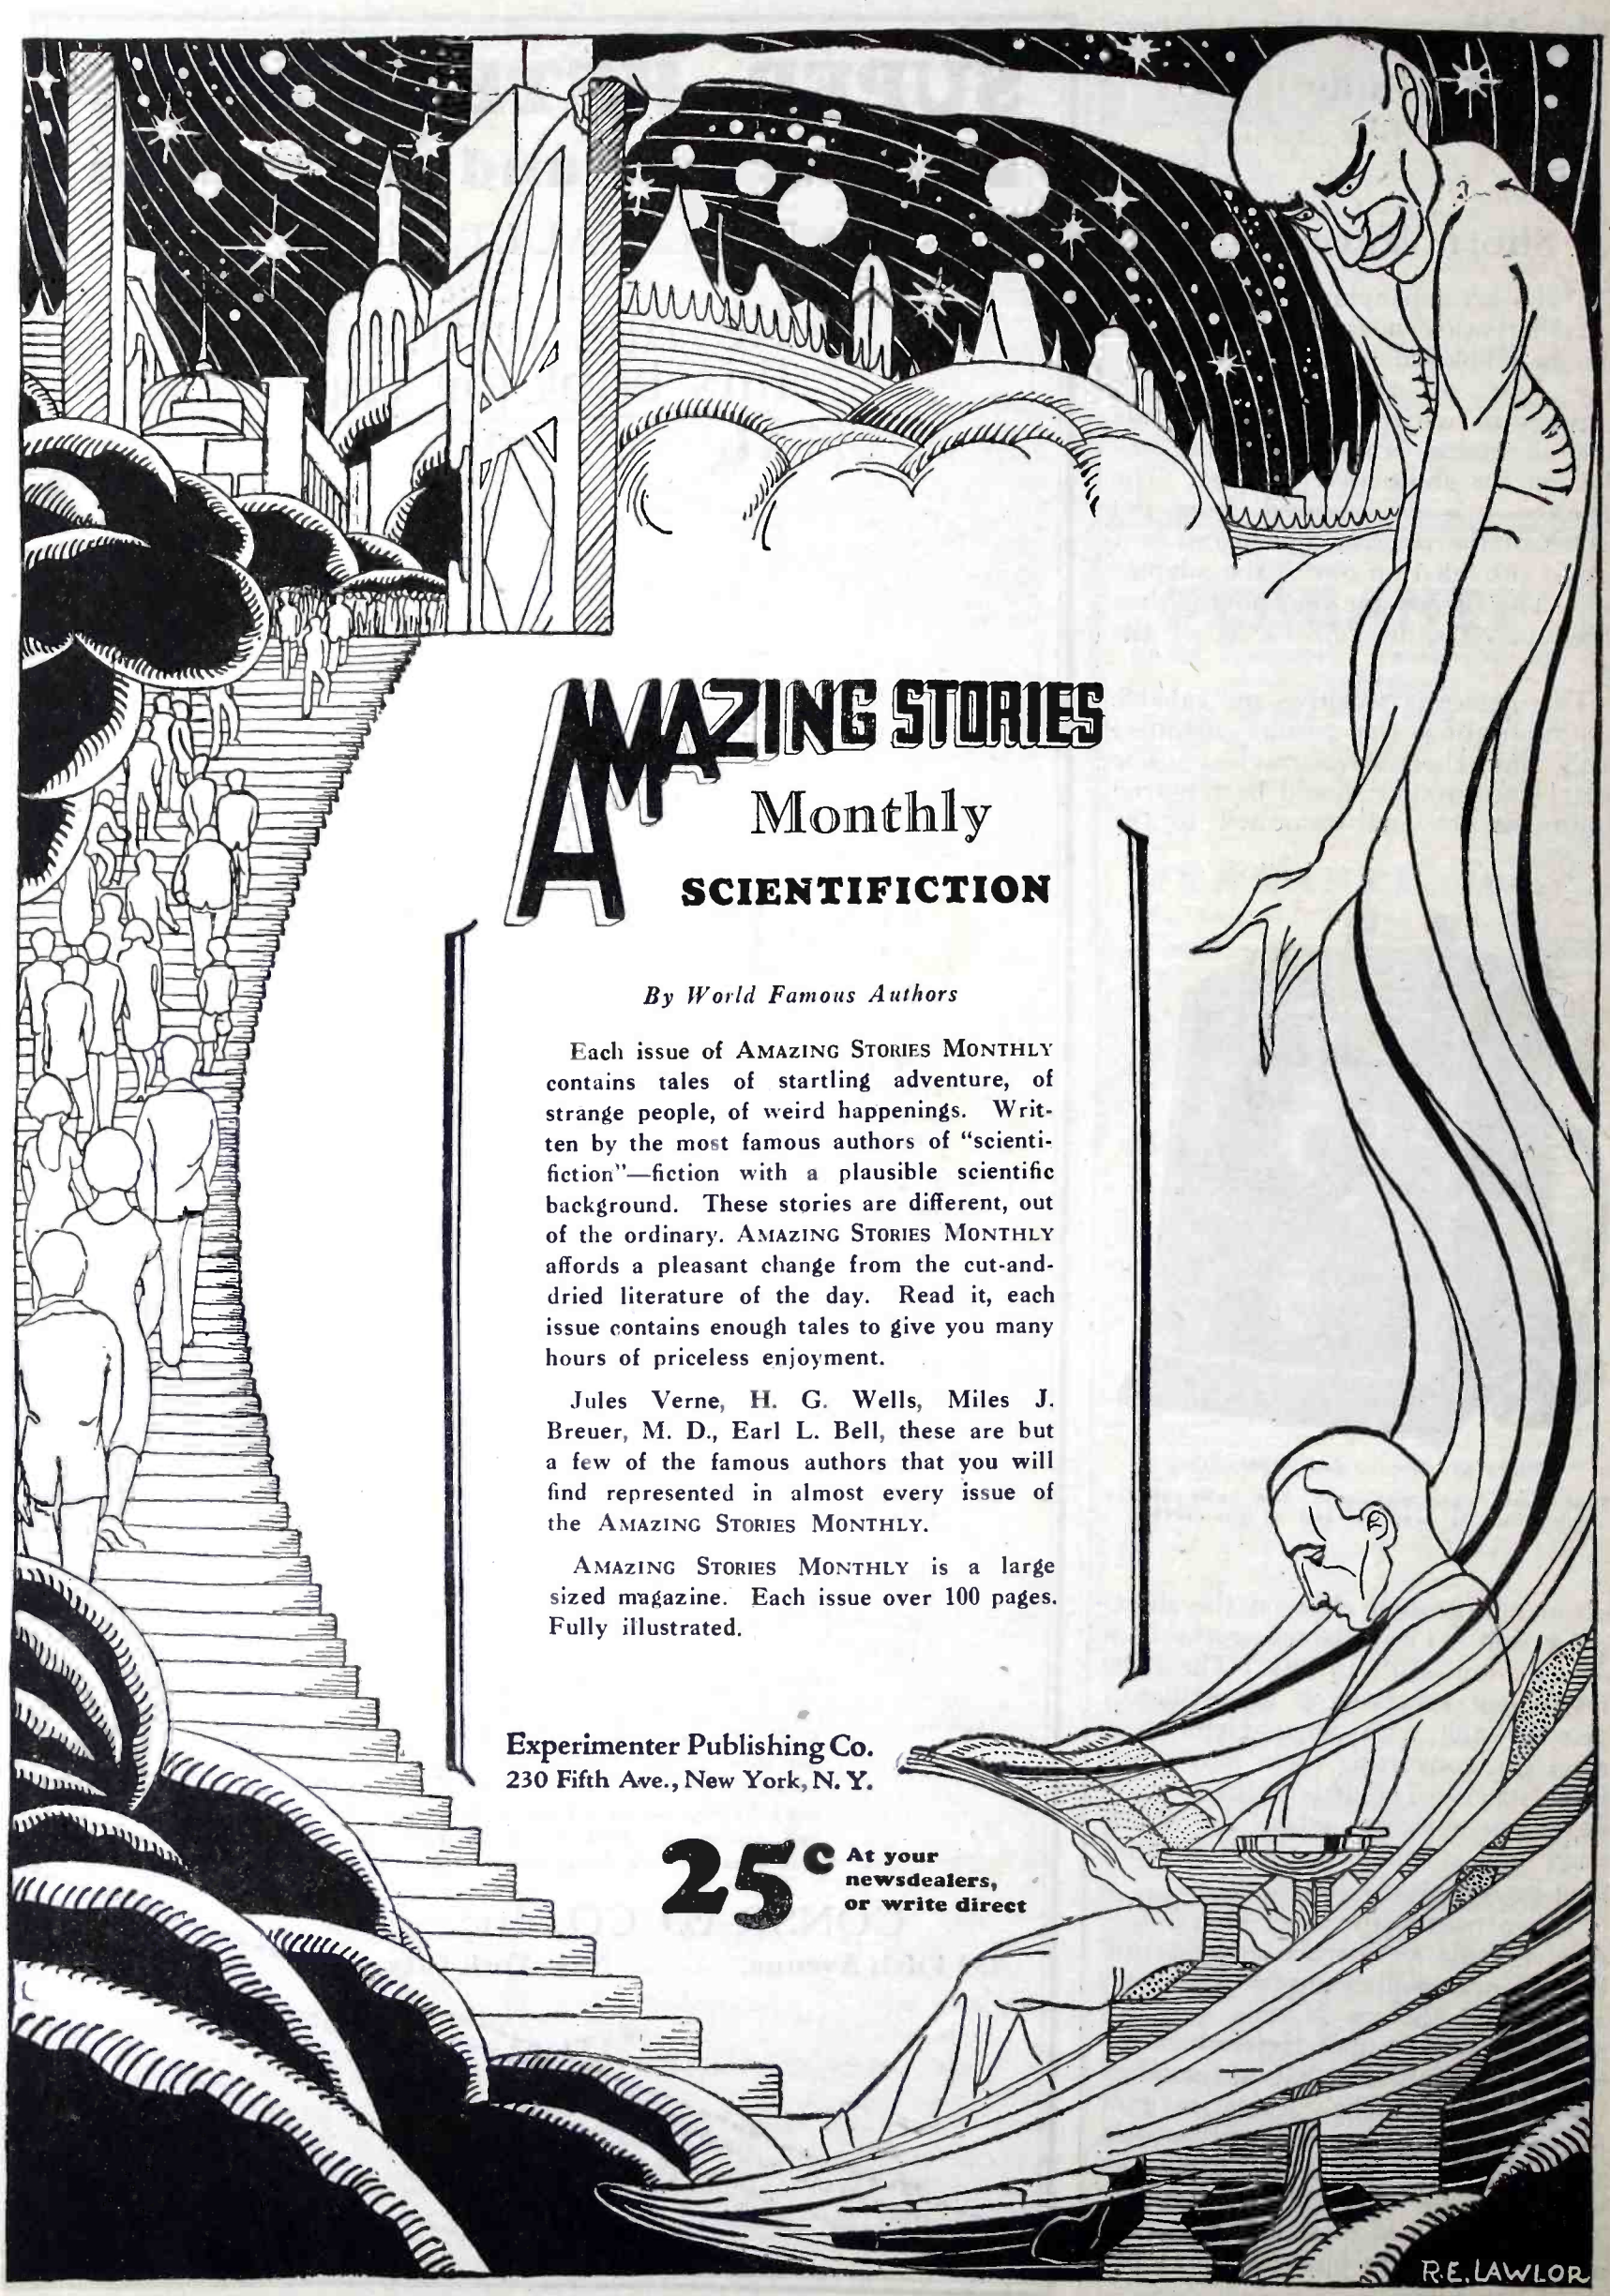
THE accompanying photo shows a short-wave adaptor device which can be employed in conjunction with any type of radio receiver. No changes in wiring have to be made and all tuning is done with the one dial on the short-wave adapter. The detector tube is removed from the socket of the receiver and placed in a socket provided on top of the adapter unit. The short-wave unit plug is then fitted into the detector socket of the set.

This device is sensitive and capable of duplicating the results obtained with any short-wave receiver. The aerial and ground should be removed from the set and connected to the aerial and ground clips on the short-wave unit. This adapter works as a detector unit with all sets. The same instrument functions as an oscillator-detector unit with Super-Heterodyne receivers, converting them into short-wave supers. The dials of the set have no effect in tuning when the short-wave unit is attached, therefore, they may be left at any setting.

Photo by courtesy J-M-P Mfg. Co.

The short wave adapter. The tube socket holes can be seen on top of the device.

When used with Super-Heterodyne receivers the short-wave adapter utilizes all intermediate radio frequency stages and the set is then vertually a short wave Super-Heterodyne receiver with only one dial on the adapter to tune. The device is now available in four additional models, namely: one with interchangeable coils and three for the different type of A.C. tubes. All of these models are exactly the same in appearance as pictured herewith.



An "A. B. and C." Power Supply Unit For A. C. Sets

FOR receivers wired for 226, 227 and 171 or 112 power tubes, the power supply unit shown in the accompanying photograph can be installed without the necessity of adding mid-tap resistors, C bias resistors or filament by-pass condensers. All such connections are provided for in the power unit itself. Where a filament switch and volume control are employed in the set, with which this unit is to be employed, a rheostat of 50,000 ohms can be used in the plate circuit of the radio frequency tubes or a 200,000 ohm potentiometer connected in the aerial circuit. Single switch operation is made automatic by connection to the receiver filament switch, or by external switch, depending on the receiver design. Thus only minimum changes of the set are necessary.

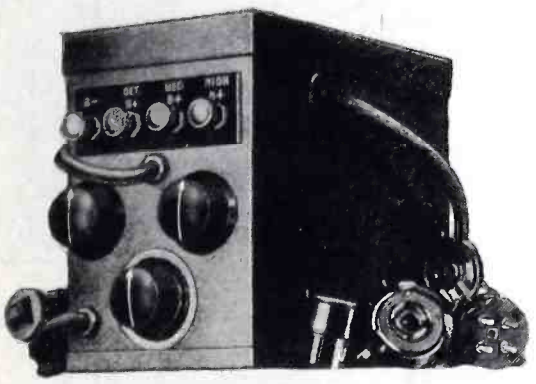


Photo by courtesy Sterling Mfg. Co.

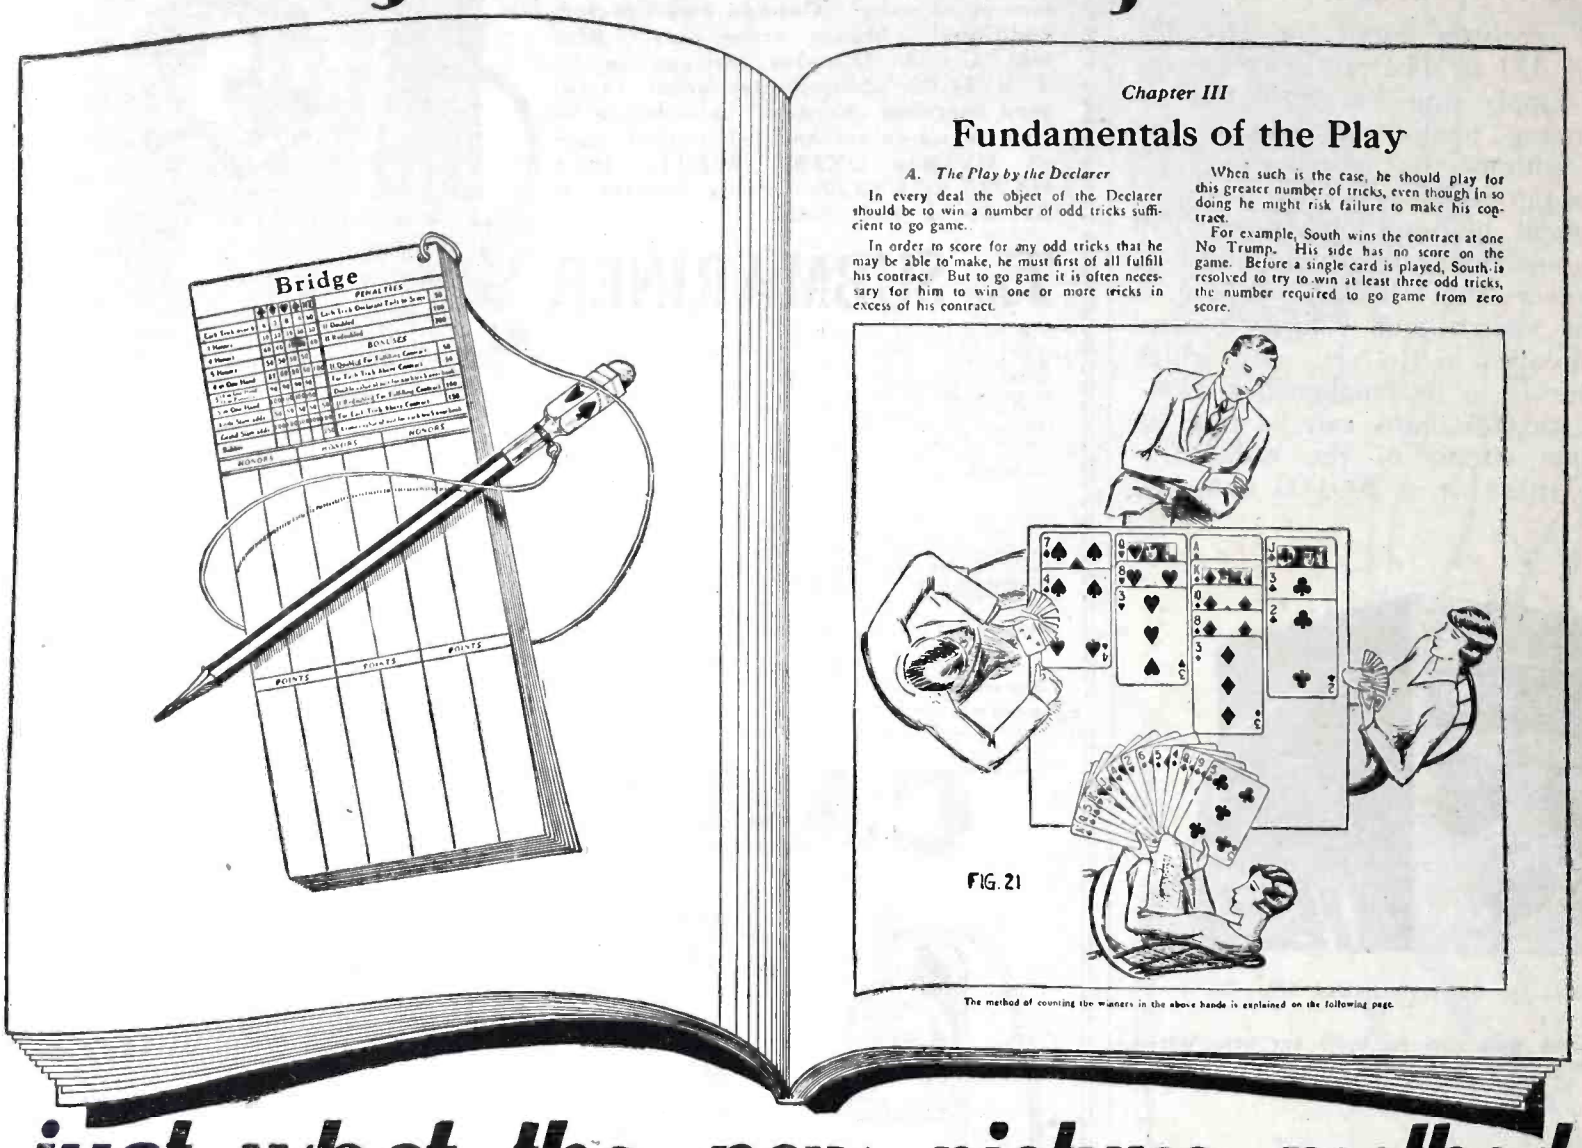
This power unit can be used for sets wired for A.C. tubes. The A.C. adapter harness is also shown in the photo.

Battery operated sets can be converted for A. C. tube operation by means of a special harness which is manufactured by the same concern who makes the unit. This harness also shown in the photograph herewith is especially designed for use in connection with the power unit. The 6-tube adapter is provided with removable grid resistors for the R. F. tubes to prevent execessive oscillation. Special harnesses are also provided for five, seven and eight tube receivers. This power supply unit consists of vacuum tube rectifier system and high voltage condenser filters, the output voltage of which is regulated by means of carbon pressure type variable resistors. The C bias voltage is also furnished within the unit. The entire unit is housed in a metal casing finished in a dark green lacquer, size 7½x4½x5½ inches and is equipped with screw clamps for attaching permanently in a console or radio table.

Bridge —/ —/ —/ —/ by Whitehead



Chapter III

Fundamentals of the Play

A. The Play by the Declarer

In every deal the object of the Declarer should be to win a number of odd tricks sufficient to go game.

In order to score for any odd tricks that he may be able to make, he must first of all fulfill his contract. But to go game it is often necessary for him to win one or more tricks in excess of his contract.

When such is the case, he should play for this greater number of tricks, even though in so doing he might risk failure to make his contract.

For example, South wins the contract at one No Trump. His side has no score on the game. Before a single card is played, South is resolved to try to win at least three odd tricks, the number required to go game from zero score.

FIG. 21

The method of counting the winners in the above hands is explained on the following page.

just what the new picture method can do for you!

The world's greatest bridge player, Wilbur C. Whitehead now reveals the secret of his success in this remarkable instruction book "BRIDGE *by Whitehead.*" Whether you are a beginner or a veteran—it makes no difference—you are never too good a player not to heed his advice nor too poor a player for him to give it. This new picture method makes bridge easy for all. Every play is illustrated—each step thoroughly explained. Follow Radio bridge instruction with greater ease—obtain a copy of "Bridge *by Whitehead*"—you cannot fail to grasp the game.

How efficient are you at the *play?* Do you know what to *bid* and when to bid it? Can you explain the following accurately:—the *auction;* the *book* and *odd tricks; rank of bids;* the *pass;* the *double;* the *redouble;* the *contract;* who is the *declarer;* the *adversaries;* the *dummy?* Can you keep *score?* What are *honors, slams,* the *rubber?* These are but a few of the many component parts of the game of Bridge. Whitehead's new method will make this fascinating game easy for you.

"Bridge *by Whitehead*" will teach you all there is to know by the *new picture method.* Do not fail to get your copy! The most complete book ever prepared. Different from any other on the market. 100 pages—replete with illustrations—beautiful colored cover—large 9" x 12" book.

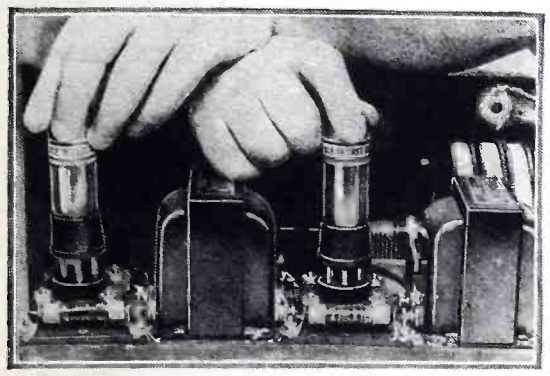
Switching Tubes in the A.F. Amplifier

THE oft-repeated advice about switching tubes back and forth in the radio-frequency sockets of a broadcast receiver applies just as well to the audio portion of the receiver, although, of course, the tubes in this position are not quite as critical.

Application of the advice may be especially helpful if the audio amplifier uses a final stage of the popular push-pull type. After you have tuned in a station put one hand on each of the push-pull tubes, remove them quickly and switch them around. Don't expect any *marked* increase



If the tubes are changed around in the sockets of the set better results are often obtained.

in volume or any *decided* improvement in tone quality; you simply may obtain a little better results. But if the effect of the change is not as good as before the tubes can easily be changed around to their original position.

In switching tubes around, be careful to not interchange tubes of different kinds. For instance, the first stage or first two stages of the A. F. amplifier may use 201A's or high mu's, and the last stage a 112A, 171A or 210. You can exchange the 201A's for each other in the first two sockets, but you must leave the last tube alone.

STATEMENT

Of the ownership, Management, Circulation, Etc., required by the Act of Congress of August 24, 1912, of RADIO LISTENERS' GUIDE AND CALL BOOK, a quarterly published at New York, N. Y., for April 1, 1928.

State of New York,
County of New York, ss.

Before me, a notary public in and for the State and county aforesaid, personally appeared S. Gernsback, who having been duly sworn according to law, deposes and says that he is the Editor of the RADIO LISTENERS' GUIDE AND CALL BOOK, a quarterly magazine, and that the following is, to the best of his knowledge and belief, a true statement of the ownership, management (and if a daily paper, the circulation), etc., of the aforesaid publication for the date shown in the above caption, required by the Act of August 24, 1912, embodied in section 411, Postal Laws and Regulations, printed on the reverse of this form, to wit:

1. That the names and addresses of the publisher, editor, managing editor, and business managers are: Publisher, The Consrad Co., Inc., 230 Fifth Avenue; Editor, S. Gernsback, 230 Fifth Avenue; Managing Editor, W. G. Many, 230 Fifth Avenue; Business Manager, C. E. Rosenfelt, 230 Fifth Avenue.

2. That the owner is: (If owned by a corporation, its name and address must be stated and also immediately thereunder the names and addresses of stockholders owning or holding one per cent or more of total amount of stock. If not owned by a corporation, the names and addresses of the individual owners must be given. If owned by a firm, company, or other unincorporated concern, its name and address, as well as those of each individual members, must be given.) The Consrad Co., Inc., 230 Fifth Avenue; Hugo Gernsback, President, 230 Fifth Avenue; Sidney Gernsback, Vice-President, 230 Fifth Avenue; R. W. DeMott, 230 Fifth Avenue.

3. That the known bondhoders, mortgagees, and other security holders owning or holding 1 per cent or more of total amount of bonds, mortgages, or other securities are: (If there are none, so state.) None.

4. That the two paragraphs next above, giving the names of the owners, stockholders, and security holders, if any, contain not only the list of stockholders and security holders as they appear upon the books of the company but also, in cases where the stockholder or security holder appears upon the books of the company as trustee or in any other fiduciary relation, the name of the person or corporation for whom such trustee is acting, is given; also that the said two paragraphs contain statements embracing affiant's full knowledge and belief as to the circumstances and conditions under which stockholders and security holders who do not appear upon the books of the company as trustees, hold stock and securities in a capacity other than that of a bona fide owner; and this affiant has no reason to believe that any other person, association, or corporation has any interest direct or indirect in the said stock, bonds, or other securities than as so stated by him.

5. That the average number of copies of each issue of this publication sold or distributed, through the mails or otherwise, to paid subscribers during the six months preceding the date shown above is..... (This information is required from daily publications only.)

S. GERNSBACK, Editor.

Sworn to and subscribed before me this 31st day of March, 1928.

[SEAL.] JOSEPH H. KRAUS.

Notary Public, Queens Clerk's No. 985, Queens County Register's No. 2903, New York County Register's No. 9257, New York County Clerk's No. 317. (My commission expires March 30, 1929.)

BRAUN *offers you* SEASONABLE Lines
Radio-Electrical-Auto Supplies
SPORTING Goods

Keep Busy the Year 'Round —Make More Money

NO more Spring and Summer slumps for radio dealers. The W. C. Braun Co., has happily solved the problem for you. Now you can keep busy the year 'round because *Braun* lines round out your stocks and give you merchandise that keeps money rolling in and profits piling up Spring, Summer, Autumn and Winter.

Radio sets, circuits, parts and accessories for the busy Fall and Winter months; auto supplies for Spring and Summer; sporting goods for Summer; household appliances, electrical goods and other stable merchandise for all times and seasons.

Braun service is keeping things moving and rolling in the profits regularly every month—that's the kind of service that counts.

Sketch of W. C. Braun Co. Headquarters in Chicago.

Monroe A-C Sets

A-C is the big thing now. Monroe A-C sets are big sellers—remarkable quality at moderate prices. Everything from table models to deluxe highboys and super-consoles. Electrified, battery-operated and dry cell models in many designs and at money-saving prices. Also a fine line of portable radio sets for Summer use, camping, etc. Big discounts, big profits, fast sellers.

Radio Accessories

The worth-while standard guaranteed radio accessories from leading manufacturers—tubes, batteries, consoles, cabinets, speakers, eliminators, A-supply units, A-C converter harness—everything that a radio user needs to keep up to date.

Parts for All Circuits

We carry the largest stock of radio parts in the world, for all the leading radio A-C and battery-operated circuits—Tyrman, Silver-Marshall, Aero, Scott's World Record, Magnaformer 9-8, Madison-Moore, St. James, LC28, all the new Grid Tube circuits; in fact, everything published in the way of circuits by the Citizens Radio Call Book, Radio News, Radio Broadcast, Radio Listeners' Guide, Popular Radio, Radio Age, Radio, Radio Doings, Radio Digest, QST and all radio magazines. Special combination offers that afford big profits to dealers and custom set builders.

Auto Supplies

The most complete line of auto supplies, including everything needed by the garage, auto dealer and auto supply shop. Standard quality guaranteed tires and tubes, seat covers, tools, tire gauges, pumps, jacks, luggage carriers, shock absorbers, springs, gaskets, replacement parts, special accessories and parts for all Ford models—in fact, everything that a motorist needs for city, country or camping.

Sporting Goods

You will be surprised at our complete line of sporting goods, including golf clubs, bags, golf balls and other golf equipment; tennis goods, outing equipment, fishing tackle, just the kind of merchandise that goes big during the Spring and Summer months. Liberal discounts assure you big profits.

Electrical Goods

Here is a line that is closely affiliated with radio; that will sell in any radio shop at all seasons. Complete assortment of wiring materials, electrical stoves, heaters, grilles, percolators, waffle irons, curling irons, motors, tools, household appliances, vacuum cleaners, washing machines, etc.

In 5 Minutes Stop King Static from spoiling Summer Radio!

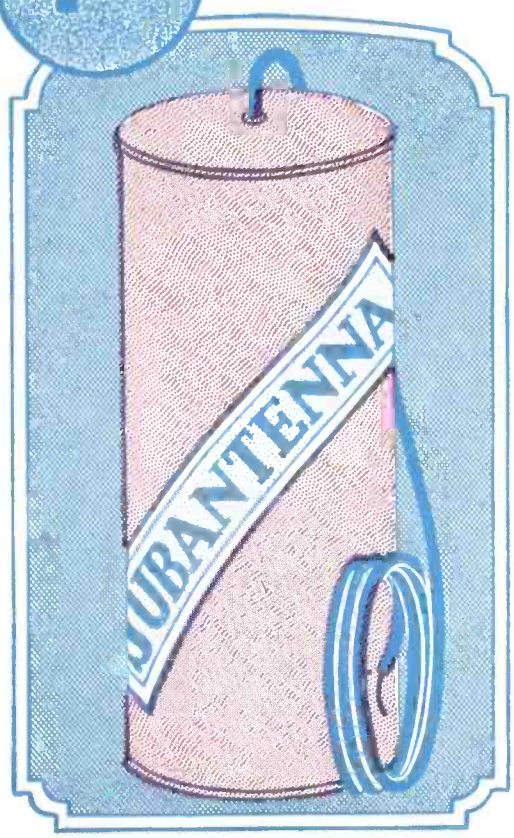
Summer is here. King Static once more resumes his throne as sovereign of the air. There's a hint of his domineering presence even in your local stations—and he's *everywhere*, all-powerful when you try for a bit of DX. But, you CAN avoid Static—you CAN get loud, clear DX right NOW, just as though old King Static never existed.

He Can't Reach Subantenna

The *air* is the realm of Static, because static is caused by the rapid changes always taking place in the summer air. The ground is not so affected; hence, the ground is practically static-free. The broadcast wave travels through the ground just as it does through the air. So there's the answer to summertime DX: intercept the clear, strong ground wave with a new, improved Subantenna, and listen-in on your favorite distant broadcasters at will. Thousands are doing it—thousands have stopped Static from spoiling their summer radio enjoyment, by avoiding the air and taking their radio waves out of the ground with the new, improved, easily installed Subantenna.

Greater Distance, Clarity, Volume Guaranteed!

You'll be amazed when you twist the dials of your set—after Subantenna has been connected. The spaces between the local stations will no longer yield up scratchy noises and shrieking static, but a veritable parade of stations. Turn from one to the other. In they'll come—each one unbelievably clear and loud. You'll have difficulty realizing they're not locals, so clearly will each note be brought to you. What is radio of this kind worth to you? Isn't it worth the mere fraction of time it takes to clip the coupon from this page—and the five minutes it will take you to install the new, improved Subantenna and test it at OUR RISK! You'll agree, after you make the FREE test that Subantenna is worth many times its price. Send coupon NOW.



Make this Underground DX Test at OUR RISK!

Install the new, improved Subantenna in 5 minutes. Wait for a bad night when static is at its worst in the air. Leave your old aerial up. Tune in a distant station on the Subantenna. See how clear and loud it comes in. Then—switch back to your aerial or over to any other antenna device which claims to be as good as the genuine Subantenna. If the new, improved Subantenna does not convince you of its worth in this acid test of direct comparison, the test is FREE, and the Subantenna comes back to us. Mail coupon today for full particulars of this great, new device, and for details of FREE TRIAL GUARANTEE OFFER.

Announcing

A GREAT, NEW RECEIVER

SCOTT CHALLENGES THE WHOLE WORLD OF RADIO TO ANY KIND OF COMPETITIVE TEST

More Actual Amplification • More Distance and Volume than Any Other Existing Receiver Known to Us

This—we believe, is the most powerful, the most selective and the finest toned receiver in existance today. We draw this conclusion from having tested and scientifically measured every other receiver which might claim itself the equal of the SCOTT World's Record Shielded Grid NINE. And there is no question but that this radically new type of receiver will maintain its position of obvious superiority for years to come, for the features of circuit engineering responsible for its amazingly better performance are far ahead of any circuit developed to date.

UNLIMITED RANGE! Without aerial, ground or loop, the SCOTT Shielded Grid NINE brings Pacific Coast Stations to Chicago with loud speaker volume. And so tremendous is the amplification of the *shielded grid* long wave amplifier employed, that it is impossible to determine a range limit for this receiver when used with a short antenna and a connection to ground.

Shielded Grid Tubes Used in an Entirely New Way

Standard circuits commonly in use with the new shielded-grid tubes, provide actual amplification of approximately 40 per stage. The revolutionary new circuit used exclusively in the SCOTT Shielded Grid NINE, gives a practical amplification of 140 per stage, thereby making this receiver many times more powerful than receivers using shielded-grid tubes in a conventional manner. It is this new circuit arrangement developed and used exclusively by us which enables us to challenge the whole world of radio to any kind of competitive test with assurance that the SCOTT Shielded Grid NINE will win.

Only One Stage of Audio Required!

The second detector output of this receiver is so heavy that concert volume and clear, undistorted cathedral tone, even on the most distant stations, is obtained with but a single stage of 2 to 1 audio frequency amplification.

Easy to Build --- Results Guaranteed

Despite the fact that the Scott Shielded Grid NINE is one of the most elaborate receiving systems ever devised — and despite the fact that it embodies many features of circuit arrangement not known to common practice, it is a very easy set to build, and when you buy the kit of parts we positively guarantee that you will get the same results we get from our laboratory model. Both panel and sub-panel are drilled to receive each part and the shield-grid amplifier units come to you fully wired and tested—ready to be connected into the circuit just as though they were a transformer.

Why Pay More *for* Less?

Why pay more than the small cost of the Scott Shielded Grid NINE when no other receiver offers you so much? Why not have a receiver which provides actual 10 Kilocycle selectivity regardless of where located? Why not have a receiver with which you can listen in on all the world—no limit to its distance range. The Scott Shielded Grid NINE is, unquestionably the finest, most powerful, most advanced receiver of the day, and is, beyond all doubt, destined to hold its position of leadership, throughout the coming years. It is the ultimate. Build it—enjoy it NOW.

FREE

Circuit Diagram and Particulars

Find out all particulars of the Scott Shielded Grid NINE. Examine its circuit. See for yourself why it has unlimited range—unlimited power—perfect tone. Proof of the superiority of this great new receiver is FREE to you. Also copies of 6000 and 9000 mile reception verifications and other records made by the Scott World's Record Super 9 and the Super 10, the less powerful predecessors of the new Scott Shielded Grid NINE.
