SPECIFICATIONS

Picture Tube

Direct View Electromagnetic. See Model Identification Chart for different picture tubes used.

Operating Voltage

110-120 volts. 60 cycles, AC.

Wattage

185 watts for all models.

Input Impedance and Transmission Line

300-ohm balanced (between antenna terminals).

Note that 72 ohm coaxial cable may be used by connecting the outer conductor to the chassis and the inner conductor to either antenna terminal. In weak signal areas, the use of coaxial cable should be avoided.

Antenna

All models equipped with a built-in TV antenna. TV-Radio models equipped with a built-in radio antenna.

Intermediate Frequencies

Video 25.75 MC. Sound 21.25 MC.
Intercarrier Sound 4.5 MC.
Radio 455 KC. (TV-Radio models).

Fuse Location

The horizontal output circuit is fused with a 3/8 amp., 250 volt fuse, part number 84A4-3. The fuse is located on the top side of the chassis. See tube location illustrations.

Record Changer

Model RC600 record changer is used in combination models. The changer model number is on the top rear of the changer pan and also on the changer model label on the underside of the changer.

TELEVISION CHASSIS DIFFERENCES

All 19 series chassis employ the same basic television circuitry. The 19B1, 19C1, 19F1, 19F1A, 19H1 and 19K1 chassis are used in "television only" models. The 19E1, 19G1 and 19N1 chassis are used in "combination" models.

The 19B1 chassis uses a 17″ rectangular picture tube (17BP4A). The 19C1 and 19E1 chassis use a 20″ rectangular picture tube (20DP4A). The 19F1, 19F1A, and 19G1 chassis use a 21″ rectangular picture tube (21WP4 or 21WP4X). The 19H1 chassis uses a 21″ cylindrical faced rectangular picture tube (21EP4A). The 19K1 and 19N1 chassis use a 21″ rectangular picture tube (21ZP4A).

A tone control is used in all 19 series chassis with exception of the 19B1 and 19F1A chassis. The 19E1, 19G1 and 19N1 chassis use a PM speaker. The 19B1, 19C1, 19F1, 19F1A and 19H1 chassis use an EM speaker or a PM speaker with a filter choke mounted to it. All chassis use PM focusing.

The 19B1 chassis uses the 94D52-1 or 94D52-2 TV tuner having a 6BC5 pentode tube as an RF amplifier. All other chassis in the 19 series chassis use the 94D46-2 or 94D46-3 cascode TV tuner using a twin triode 6BZ7 tube as an RF amplifier.

TUBE COMPLEMENT

V101	*6BZ7 or 6BC5	RF Amplifier
V102	6J6	Oscillator and Mixer
V201	6AU6	Sound IF Amplifier
V202	6AL5	Ratio Detector
V203	6AV6	AM Detector, AVC, Sound Amplifier in combination sets; Sound Amplifier in TV only sets
V204	†6Y6G or 6AS5	Sound Output
V301	6CB6	1st IF Amplifier
V302	6CB6	2nd IF Amplifier
V303	6U8	3rd IF Amplifier; Vertical Oscillator
V304	6AL5	Video Detector, AGC
V305	6CB6	Video Amplifier
V306	§	Picture Tube
V401	12AU7	Sync Separator, Sync Clipper
V402	6S4	Vertical Output
V403	6SN7GT	Hor. Oscillator Control, Horizontal Oscillator
V404	6BQ6GT	Horizontal Output
V405	1B3GT	High Voltage Rectifier
V406	6AX4GT	Damper
V501	5U4G	Rectifier
V701	6BE6	Converter (AM Radio)
V702	6BA6	IF Amplifier (AM Radio)

* 6BZ7 tube used in 94D46-2 and 94D46-3 tuners. 6BC5 tube used in 94D52-1 and 94D52-2 tuners.

† 6Y6G tube used in combination sets. 6AS5 tube used in TV only sets.

§ See "Model Identification Chart" on front page for different picture tubes used.

NEW FEATURES

New TV Tuners (part Nos. 94D52-1, 94D52-2, 94D46-2 and 94D46-3): New improved TV tuners are used. The 94D52-1 and 94D52-2 (pentode type) TV tuners are used in models having a 17″ picture tube. The 94D46-2 and 94D46-3 tuners (cascode type) are used in models having a 20″ or 21″ picture tube.

These new improved TV tuners feature high sensitivity and high signal to noise ratio. This is made possible by improved tuner circuitry. The circuits in the RF stage of the 94D52-1 and 94D52-2 tuners have been optimized for the 6BC5 tube and the circuits of the 94D46-2 and 94D46-3 tuners have been optimized for the 6BZ7 tube.

The 94D46-3 cascode TV tuner is used in all later production chassis (Run 6 and higher), with exception of the 19B1 chassis. The 94D52-2 pentode TV tuner is used in later production 19B1 chassis (Run 6 and higher).

TV tuners 94D46-2 and 94D46-3 are identical, with exception of shaft length. TV tuners 94D52-1 and 94D52-2 are identical with exception of shaft length.

DX Range Finder Control: A DX Range Finder control (AGC delay circuit) is used in all 19 series chassis. This control is a potentiometer located at the rear of the chassis to enable adjustment of receiver sensitivity to suit the signal conditions in any local or fringe area.

Improved Video Amplifier: Improved circuitry and use of the 6CB6 tube as a video amplifier have resulted in improved picture definition with greater range of contrast.

Tone Control: A tone control is used in all chassis with exception of the 19B1 and 19F1A.

Horizontal Oscillator Circuit: Pulse Width Modulation is used for control or horizontal oscillator frequency. Better control of oscillator frequency has increased the "hold-in" range of the oscillator and improved noise immunity and sync stability in weak signal high noise level areas over previous circuits of this type. The improved horizontal oscillator circuit also provides better drive to the horizontal output stage.

Horizontal Output Circuit: An improved horizontal output circuit, using a high efficiency auto-transformer provides second anode voltage (approximately 15,000 volts) for good picture definition. A new tube (6AX4GT) is used in the damper circuit.

Improved Width and Linearity Control: The width control and horizontal linearity controls are of the slider type. Use of slider type controls has made adjustment faster and more accurate.

PM Focus: A PM focus assembly is used in all 19 series chassis. Use of the PM focus assembly provides good line focus and minimizes the defocusing effect on the electron beam due to voltage variation.

Vertical Retrace Blanking Circuit: A vertical retrace blanking circuit is used in later production sets (stamped Run 5 and higher). Vertical retrace blanking is achieved by applying the pulse voltage appearing at the secondary of the output transformer to the grid of the picture tube.

HIGH VOLTAGE WARNING

High voltages are present throughout the horizontal output, damper and second anode supply circuits. No attempt should be made to make measurements from high voltage points in these circuits with ordinary test equipment. See Voltage Data.

Warning: Operation of the set outside of the cabinet or with cabinet back removed involves a shock hazard. Exercise normal high voltage precautions.

PICTURE TUBE REPLACEMENT

Picture tube replacement for these receivers is similar to that of other chassis using a rectangular glass picture tube. Make picture adjustments as instructed on pages 3 to 4. Instructions for adjusting curvature correcting magnets used with 21EP4A (21" cylindrical faced) picture tube in 19H1 sets is given on page 3.

REMOVABLE PICTURE WINDOW

All models using the 19 series television chassis have picture windows which can be easily removed from the front of the cabinet for cleaning the inside of the window, picture tube and picture tube mask. Two types of picture window mountings are used. A removable molding in used in wood cabinet models. Removable corner brackets are used in plastic cabinet models. Instructions for removing and cleaning the picture window, picture tube and picture tube mask is given below.

REMOVING PICTURE WINDOW FOR CLEANING

If the picture window has a removable molding (at the top), remove the window by first removing the Phillips head screws and molding at the top of the picture window. Pull the top of the window away from the cabinet slightly and lift it up out of the channel at the bottom.

After cleaning the window, picture tube and picture tube mask as instructed below, install the window by placing the bottom edge in the channel and replace the molding. Use care when tightening screws on molding to prevent stripping.

If the picture window has removable corner brackets, first remove the two brackets at the top of the window. Then, while holding the window, loosen the screws on the bottom brackets. Allow the window to tilt out slightly at the top until it can be grasped and lifted free of the cabinet.

After cleaning, install the window by setting it in position and mounting the corner brackets. Use care when tightening bracket mounting screws to prevent stripping or cracking glass.

CLEANING GLASS PICTURE WINDOW

Clean the picture mask using a soft cloth, dampened in mild soapy water. Clean the picture window and the face of the picture tube using a soft cloth, dampened with your favorite window cleaner. Wipe dry using a chamois or soft, lint free cloth. Only use cloths which are just dampened as presence of moisture or water inside the set may cause damage. Install the window as instructed above.

INSTALLATION and SERVICE ADJUSTMENTS

When installing, each set should be checked for DX Range Finder adjustment (generally set on zero), picture centering, picture tilt, shaded corners, proper size, linearity, etc., to insure best performance. It is especially important that Ion Trap adjustment be checked, and that the Channel Slugs be adjusted upon installation or servicing of every set to insure ease of tuning. Make all checks and adjustments as instructed on the following pages.

For best results, all checks or adjustments should be made using a transmitted television test pattern. A mirror placed in front of the picture tube screen will be of help in observing the picture while making adjustments at the rear of the chassis. Removing the TV back disconnects the interlocking line cord; use a separate line cord (part number 89A22-1) when servicing. See "High Voltage Warning" on page.

INDIVIDUAL CHANNEL SLUG ADJUSTMENT USING A TELEVISION SIGNAL

Individual channel oscillator adjustment of every receiver should be checked upon installation or servicing. If this adjustment is properly made, it is possible to tune from one station to another by merely turning the CHANNEL control. With correct channel adjustment, best picture will be located at the approximate center of the range of the TUNING control. However, this may not necessarily be maximum sound output.

Channel slug adjustment can be made without removing the chassis from the cabinet. Adjust as follows:

a. Turn the set on and allow 15 minutes to warm up.

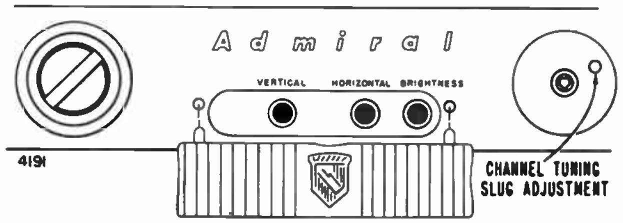

Figure 1. Control Panel on 19B1 Sets. Channel knob is removed.

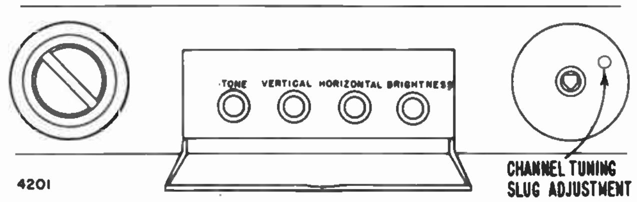

Figure 2. Control Panel on 19C1, 19F1, *19F1A, 19H1 and 19K1 sets. Channel knob is removed.
****19F1A sets have no Tone control.***

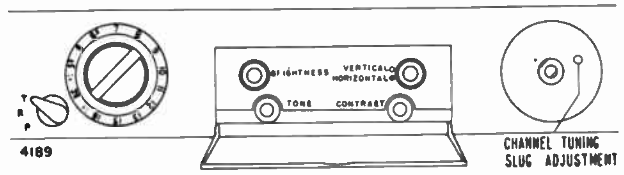

Figure 3. Control Panel on 19E1, 19G1 and 19N1 Sets. Channel knob is removed.

b. Set the CHANNEL knob for a station in operation. Set all other controls for a normal picture.

c. Remove the CHANNEL knob.

d. Set TUNING control at center of its range by rotating it approximately half-way. At this setting, the hole in the TUNING knob will coincide with the hole in the control panel.

e. Insert a 1/8" blade, NON-METALLIC tool in the hole adjacent to the channel tuning shaft (see illustration). For each channel in operation, carefully adjust the channel slug for best picture with clear detail. (Note that this may not be the point at which the sound is loudest.) Be sure that the Tuning control is set at the center of its range before adjusting each channel slug. Generally, only slight rotation of the slug will be required; turning the slug in too far will cause it to fall into the coil. (If the slug falls into the coil, remove the chassis from the cabinet and remove the coil. Move the retaining spring aside, lightly tap the open end of the coil until the slug slips out. Replace slug and reset retaining spring.)

ION TRAP ADJUSTMENT

To prolong the life of the picture tube, it is important that this adjustment be made upon installation, after adjusting the picture positioning lever, or after repositioning the focus coil.

Set the BRIGHTNESS control (at front of set) for normal brightness.

Position the ion trap on the picture tube close to the base. Starting from this point, very carefully move the ion trap forward or backward and at the same time, rotate it slightly in either direction until maximum brightness is produced.

Reset the BRIGHTNESS control for normal brightness. Adjust the FOCUS control (at the rear of set) for good focus. Readjust the ion trap for maximum brightness.

Note that there may be two locations where the brightest picture can be produced. The second ion trap location, which is further away from the tube base, should not be used or tube damage will result.

Important: If the corners of the picture are shaded, be sure the ion trap has been properly adjusted. Do not sacrifice picture brightness when adjusting the ion trap to remove shaded corners. To eliminate shaded corners, see the discussion under "Check Picture Centering". Be sure to readjust the ion trap each time after adjusting the picture positioning lever or repositioning the focus assembly. Tighten the ion trap mounting screw (if used).

DX RANGE FINDER ADJUSTMENT

This control is at the rear of the set, near the right side.

This control is used to improve TV reception in fringe areas and in areas where there is interference.

The DX RANGE FINDER should be at the "0" position, if satisfactory pictures can be obtained by using the operating controls on the front of the set.

Where the TV signal strength is weak, the picture can often be improved by turning the DX RANGE FINDER part way to the right or, if necessary, all the way to "300".

Snow (noise) in the picture can sometimes be minimized by careful adjustment of the DX RANGE FINDER.

Caution: If the DX RANGE FINDER is turned too far to the right for a strong signal, the picture may bend (overload).

If the signal strength changes, it may be desirable to change the setting of the DX RANGE FINDER; however, it is generally possible to set it at a single compromise position which gives reasonable reception for the different signal strengths.

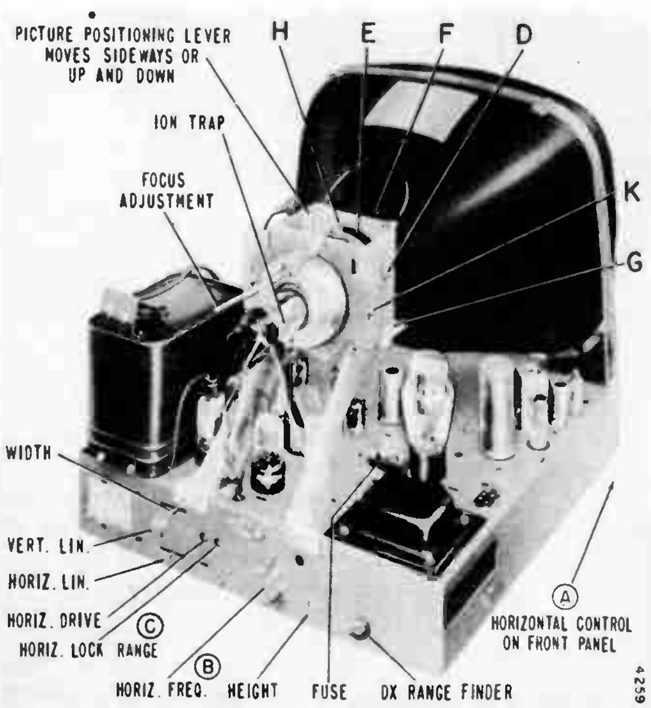

Figure 4. Rear View of Chassis Showing Adjustment Locations.

It is important to keep the DX RANGE FINDER setting as low as possible consistent with satisfactory pictures.

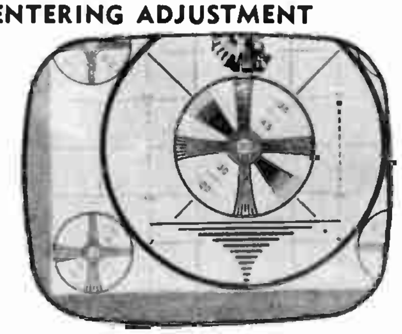
ADJUSTING CURVATURE CORRECTING MAGNETS FOR SETS USING A 21EP4A (21") PICTURE TUBE

If either side of the picture has excessive curvature (pin cushion effect) or if corners of the picture are bent inwardly, this can be minimized by adjustment of the correcting magnets located on the yoke bracket. Either side of the picture can be adjusted individually by using the magnet on that side of the picture tube. A picture or test pattern having straight vertical lines near the sides can be used for making adjustment; the pattern from a cross-hatch generator is preferable. IMPORTANT: A cross-hatch generator which is not capable of locking the picture in both horizontal and vertical sync is not suitable. Adjust as follows:

a. Set the receiver controls for normal picture. Be sure that the picture is centered properly and vertical linearity adjustment is made.
b. Check the radial position of the magnet brackets. The magnet brackets are generally set so that the mounting screw is centered in the curved slot. It should only be necessary to change from this setting if the curvature at the side of the picture is not centered with respect to the side of the picture tube.
c. Move the correcting magnet against the deflection yoke bracket. While observing the vertical lines on the same side of the picture that the magnet is located, slowly move the magnet forward until curvature of vertical lines near the side is minimized. If the magnets are moved too far forward, the corners of the picture will bend inwardly or become shaded.

PICTURE CENTERING ADJUSTMENT

If the picture is off center, it can be centered by using the picture positioning lever, and when necessary, repositioning the focus assembly around the picture tube neck. Follow the instructions given below. ***Note that the picture positioning lever can be moved sideways, or up and down.***



Picture Not Centered; Adjust Picture Positioning Lever.

Centering the Picture

a. Adjust ion trap as instructed on preceding page.
b. Adjust the picture positioning lever (sideways, or up and down) for correct picture centering. If centering is not done with a test pattern, it may be necessary to reduce picture height and width to determine correct centering.
c. Readjust the ion trap.

Difficulty in Centering the Picture

a. Adjust ion trap as instructed on preceding page.
b. Slightly loosen the two screws "K" which hold the focus assembly to the yoke bracket. Center focus assembly around the tube neck; tighten screws.
c. Center the picture with the picture positioning lever. If the picture cannot be centered with the lever, it may be necessary to locate the focus assembly slightly off center and then center the picture with picture positioning lever.
d. Readjust the ion trap.

Difficulty in Eliminating Shaded Corners

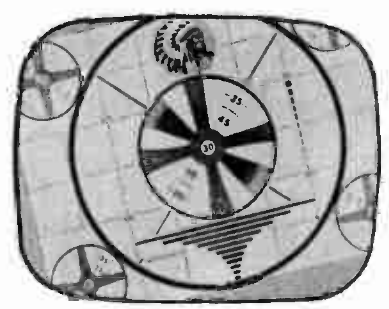
a. Loosen screws "G", then move the yoke support bracket forward until rubber grommet "F" is firmly against the flare of the picture tube.
b. Move the deflection yoke coil "E" as far forward as possible. In some cases, it may be necessary to loosen the two screws "D", move the bracket up or down, and then move the deflection yoke coil as far forward as possible.
c. Adjust ion trap as instructed on preceding page.
d. Shaded corners may also result from use of the wrong ion trap. These picture tubes use ion trap 94A15-3. The part number is stamped on the magnet.

FOCUS ADJUSTMENT

Focus adjustment can be made without removing the cabinet back from the receiver by rotating the shaft extending from the rear of the focus assembly. Set the Picture control for normal picture and the Brightness control at slightly above average brightness. Rotate the control shaft to the right or to the left until the picture is in sharp focus. Slight rotation in either direction should generally bring the picture into focus. If the picture was greatly off focus, readjust the ion trap.

PICTURE TILT ADJUSTMENT

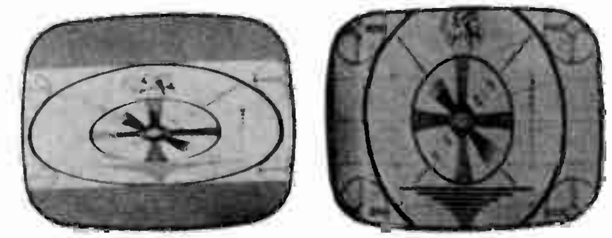
If the picture is tilted, loosen the wing screw "H" on the deflection yoke coil "E" and slightly rotate the yoke until the picture is straight. Before tightening the wing screw, be sure that the yoke is moved as far forward as possible, otherwise corners of the picture may become shaded.



Picture Tilted; Adjust Deflection Yoke Coil.

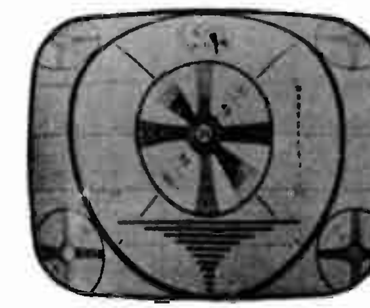
HEIGHT AND VERTICAL LINEARITY ADJUSTMENT

If the picture is of incorrect height (vertical size), adjust the HEIGHT control. This adjustment will affect the vertical linearity of the picture. If necessary, alternately adjust the VERT. LIN control and HEIGHT control. Note that the upper portion of the picture is affected mostly by the Vertical Linearity control; the lower portion by the Height control.



Incorrect Height; Alternately Adjust HEIGHT and VERT. LIN. Controls.

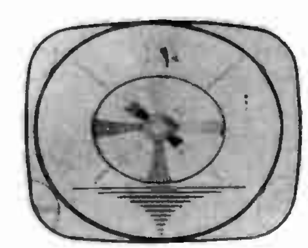
If the large circle in the test pattern appears cramped or flattened at top or bottom (non-linear vertically), correct by alternately adjusting the VERT. LIN. control and the HEIGHT control.



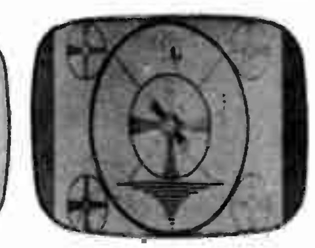
Top or Bottom of Picture Cramped or Flattened; Adjust VERT. LIN. and HEIGHT.

WIDTH ADJUSTMENT

If the picture is too wide or too narrow, adjust the WIDTH adjustment lever by moving it to the left or to the right until the picture just fills the picture tube screen.



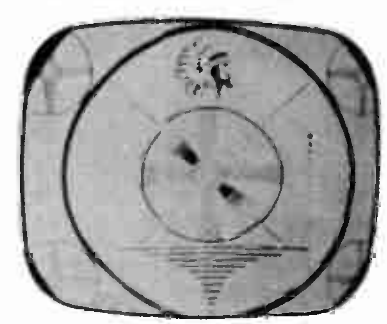
Too Much Width; Adjust WIDTH.



Not Enough Width; Adjust WIDTH.

HORIZONTAL LINEARITY ADJUSTMENT

If the large circle in the center of the test pattern has a cramped or flattened appearance at either side (non-linear horizontally), adjust the HORIZ. LIN. by moving it to the left or to the right as required. Note that the Horizontal Drive and



Side of Picture Cramped or Flattened; Adjust HORIZ. LIN.

the Width adjustment also affect linearity. Be sure that these adjustments are set correctly if difficulty is encountered when making the horizontal linearity adjustment.

HORIZONTAL DRIVE ADJUSTMENT

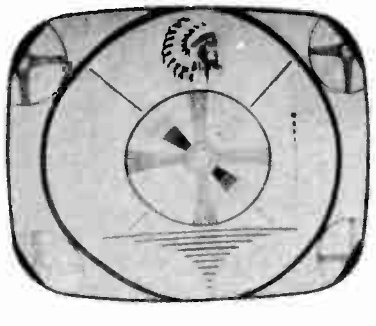
If this adjustment is not properly made, it may be difficult to obtain sufficient picture width and brightness. Adjust as follows:

a. Turn the CHANNEL control to an unused channel. (This adjustment may be made on a channel in operation, but results will not be as accurate.)

b. Set BRIGHTNESS control at a lower than average setting. Turn PICTURE control completely to the left.

c. Turn the HORIZONTAL control (front panel) completely to the left.

d. Turn the HORIZ. DRIVE screw out (to the left) as far as possible while still maintaining slight tension



Vertical Line; Adjust HORIZ. DRIVE.

on the trimmer plate. If a white vertical line (or lines) appears on the screen, slowly turn the HORIZ. DRIVE screw in, until the line(s) just disappears.

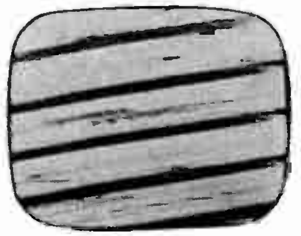
Do not use the Horizontal Drive to obtain correct width or linearity. If necessary, make the Width and Horizontal Linearity adjustments.

SIMPLIFIED HORIZONTAL SYNC ADJUSTMENT

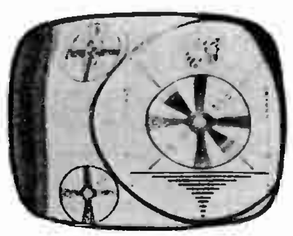
A receiver which requires horizontal sync adjustment can be corrected only by following in exact detail the step-by-step procedure given here.

Check whether adjustment is necessary by rotating the HORIZONTAL control (A) on the front panel from one end to the other; the picture should hold as follows:

a. For strong or medium signals, the picture should remain in sync over the entire rotation of the HORIZONTAL control. Horizontal sync adjustment is required if the picture falls out of sync, bends at the top (jitters), or doubles up on the side. See illustrations below.



Picture Out of Horizontal Sync.



Bending or Jitter at Top of Picture.

b. For weak or fringe area signals, the picture should remain in sync over ½ to ¾ of the rotation of the HORIZONTAL control. Horizontal sync adjustment is required if the picture falls out of sync, bends at the top (jitters), or doubles up on the side. See illustrations below.

Adjust Horizontal Sync as follows:

1. Set the DX Range Finder at "0" position (see figure 5) and set the PICTURE control (contrast on front panel) for normal picture.

2. Important: Before making these adjustments, be sure that the picture can be made to sync vertically (remain stationary up and down) as lack of both vertical and horizontal sync is an indication of trouble in the sync circuits. If replacement of tubes V401 and V403 does not eliminate sync trouble; see Service Hints For Horizontal Sync on page 5.

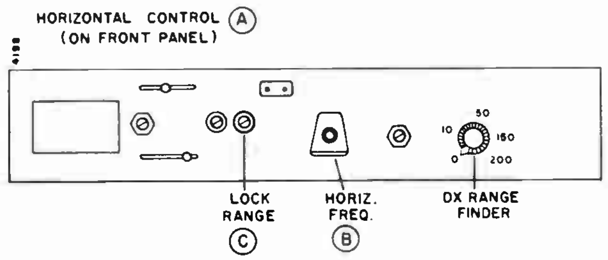


Figure 5. Rear View of Chassis Showing Horizontal Sync Adjustments.

3. With the picture in sync, rotate HORIZONTAL control (A) on front panel from one end to the other. If picture does not hold sync as described in paragraphs "a" or "b" at left, set the HORIZONTAL control (A) at the point where the picture just loses sync or becomes unstable, and slowly adjust the HORIZONTAL FREQUENCY (B) until the picture just falls back into sync. It may require several turns of adjustment (B). Repeat this procedure until the picture holds as described in paragraphs "a" or "b" at left. If the picture can be made to hold sync with adjustment of (B), adjustment is complete; otherwise proceed with step 4.

4. If the picture cannot be made to hold sync as described in paragraphs "a" or "b" at left, turn the LOCK RANGE adjustment (C) clockwise until tight, then back it out ½ turn for strong and medium signals. If signals are generally very weak, turn it out a full turn from the tight position.

5. Recheck step 3.

6. If horizontal sync is still unsatisfactory, carefully repeat entire procedure. Try replacing tube V403. It may be necessary to make complete Horizontal Oscillator Alignment (using an oscilloscope) as instructed.

COMPLETE HORIZONTAL OSCILLATOR ALIGNMENT
(Requires Oscilloscope)

1. IMPORTANT: Set the DX RANGE FINDER at "0" position (see figure 5) and set the PICTURE control (contrast on front panel) for normal picture.

2. In some chassis (stamped Run 1 or lower), the HORIZONTAL control (A) may be wired in reverse. If so, it will be impossible to make adjustment properly by following the instructions below.

   To determine whether the control wiring is reversed, check the lug to which blue wire is connected. The blue wire should connect to the lug nearest bottom edge of the chassis and the 68,000 ohm resistor R425 should connect to the lug nearest the top of the chassis. If wiring is reversed, change the two connections in accordance with the information given here.

3. IMPORTANT: Connect oscilloscope high side through a **10 mmfd. condenser** to terminal marked "C" or "2" on the horizontal blocking transformer T404. (See figure 6.) It is important to use short leads and a very low capacity condenser (at least 10 mmfd.) to avoid loading the circuit and thus distorting the waveform.

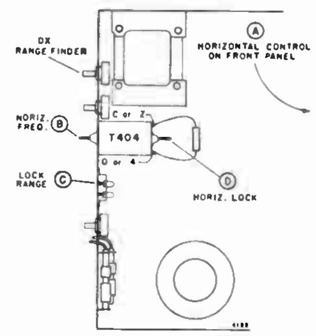

Figure 6. Bottom View of Chassis Showing Horizontal Sync Adjustments.

4. Set the oscilloscope sweep to 15.75 KC or a submultiple of it.

5. Adjust the HORIZONTAL LOCK slug (D) (see figure 6) until the oscilloscope waveform pattern appears as in figure 7. The rounded and pointed peaks

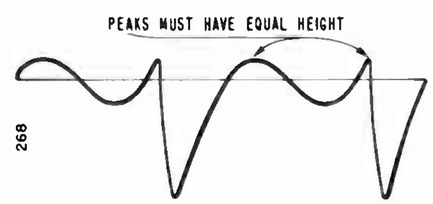

Figure 7. Horizontal Oscillator Waveform.

of the waveform must have equal height. The picture must be kept in sync to obtain the proper oscilloscope waveform pattern. Keep the picture in sync by adjusting the HORIZONTAL FREQUENCY (B) and/or the LOCK RANGE trimmer (C). If the picture still will not sync, check for a defective tube, components, or wiring, before continuing further. See Service Hints on Horizontal Instability And Tearing In Picture on page 5.

6. Disconnect the oscilloscope leads.

7. Set the HORIZONTAL control (A) fully counterclockwise to break sync. If the picture does not go out of sync, momentarily interrupt the channel selector, or adjust the HORIZONTAL FREQUENCY (B) until several bars appear sloping downward to the left. (See figure 8.)

8. Slowly turn the HORIZONTAL control (A) clockwise and note the least number of bars present before the picture falls into sync. If two or three bars are present, the LOCK RANGE trimmer is set properly, so reset the HORIZONTAL control (A) to maximum counterclockwise and adjust the HORIZONTAL FREQUENCY (B) until the picture falls back into sync.

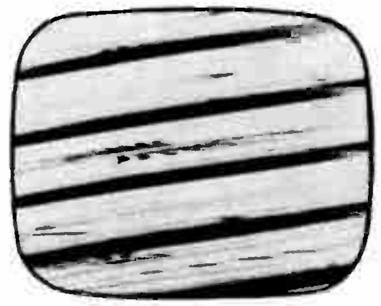

Figure 8. Picture Out of Horizontal Sync.

9. If more than three bars are present, adjust the LOCK RANGE trimmer (C) slightly clockwise. If less than 2 bars are present, adjust the LOCK RANGE trimmer (C) counterclockwise. Repeat steps 7 and 8.

10. Rotate HORIZONTAL control (A) on the front panel from one end to the other. The picture should hold sync as follows:

    a. For strong or medium signals, the picture should remain in sync over the entire rotation of the HORIZONTAL control. If it falls out of sync, bends at the top (jitters), or doubles up on the side; sync adjustment is required; see step 11 below.

    b. For weak or fringe area signals, the picture should remain in sync over ½ to ¾ of the rotation of the HORIZONTAL control. If it falls out of sync, bends at the top (jitters), or doubles up on the side; sync adjustment is required; see step 11 below.

11. If picture does not hold sync as described in paragraphs "a" or "b" above, set the HORIZONTAL control (A) at the point where the picture just loses sync or becomes unstable and adjust the HORIZONTAL FREQUENCY (B) until the picture just falls back into sync. It may require several turns of adjustment (B). Repeat this procedure until the picture holds as described in paragraphs "a" or "b" of step 10.

SERVICE HINTS

Also see Production Changes in this Manual.

TROUBLE SHOOTING

The television chassis covered in this Service Manual are newly designed sets incorporating the latest in television circuitry. New features incorporated in the 19 series chassis are outlined in paragraph on "New Features" on page 1. Important: Since there are many differences in these chassis over earlier model Admiral receivers, it is important to remember the following when servicing or installing these receivers.

All chassis have a "DX Range Finder Control" (AGC delay circuit). This control is a potentiometer located at the rear of the chassis to enable adjustment of receiver sensitivity to suit the signal conditions in any local or fringe area. Incorrect adjustment of this control in a strong signal area, may result in picture bending, excessive contrast and poor sync. Information on the adjustment of the DX Range Finder control is given on page 3.

The sound output tube V204 (6Y6G or 6AS5) functions as a voltage dropping tube in addition to being a sound output tube. The cathode of the sound output tube operates at approximately 140 volts above chassis ground for TV operation. If the sound output stage becomes defective, B+ voltage to the TV tuner, sync separator and clipper, video amplifier and AGC delay circuit will be affected.

In chassis stamped Run 2 or lower, the first and second IF amplifiers V301 and V302 are in series. The cathode of V302 is operated at approximately 120 volts above chassis ground. If either V301 and V302 become defective, B+ voltage to the other stage will be affected.

In chassis stamped Run 3 and higher (except 19B1), B+ voltage to the first and second IF amplifiers V301 and V302 is in parallel. When making voltage measurements in chassis (except 19B1) stamped Run 3 and higher, it is important to note that the plate and screen voltages at the first and second IF amplifier stages V301 and V302, may vary over a wide range, depending on the strength of the TV signal. The voltages shown on the schematics are taken with the antenna disconnected and antenna terminals shorted; see Voltage Data on schematic pages.

In sets using the 94D46-2 or 94D46-3 cascode tuner, the triode sections of the RF stages (V101) are in series. The cathode of the second triode section is operated at approximately 130 volts above chassis ground. If the tube should be come defective or be removed from the socket, there will be no B+ voltage on the plate of the first triode section. See B+ distribution diagrams, figures 9 and 10.

The horizontal oscillator circuit utilizes pulse width modulation for control of the horizontal oscillator frequency. Information on servicing the horizontal oscillator and horizontal oscillator control circuit is given in paragraph "Service Hints for Horizontal Sync". Note: An oscilloscope is required for alignment of the horizontal oscillator waveform. Information on alignment of the horizontal oscillator is given on page 4.

When servicing these chassis in the shop, it is important that the correct type of speaker or speaker substitute be used. The 19B1, 19C1, 19F1, 19F1A and 19H1 chassis use an EM speaker with output transformer, or a PM speaker with an output transformer and filter choke mounted to it. 19E1, 19G1 and 19N1 chassis stamped with the letter "T" at the rear of the chassis, use a permanent magnet (PM) speaker with the output transformer mounted on the television chassis. 19E1, 19G1 and 19N1 chassis without the letter "T" use a permanent magnet (PM) speaker with the output transformer mounted directly on the speaker. Use of an incorrect speaker will result in no B+ voltage or weak and distorted sound.

B+ DISTRIBUTION IN TELEVISION CHASSIS

Figures 9 and 10 illustrate the basic B+ distribution used in these chassis. The B+ distribution in chassis stamped Run 2 or lower is shown in figure 9. The B+ distribution in chassis stamped Run 3 and higher is shown in figure 10. Note: There are variations in the B+ circuits of TV and combination models and TV models using a different RF amplifier tube (V101) in the TV tuner. Alternate connections for the RF amplifier tube (V101) is shown in figure 9. See "Television Chassis Differences", and "Trouble Shooting" information.

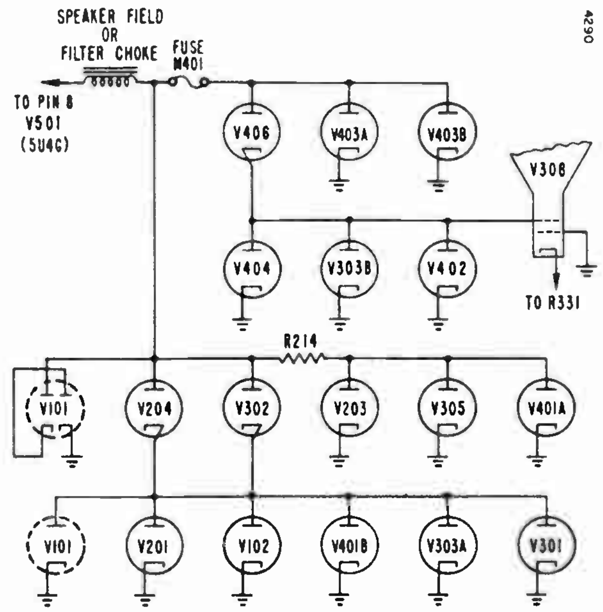

Figure 9. B+ Distribution in Chassis Stamped Run 2 or Lower.

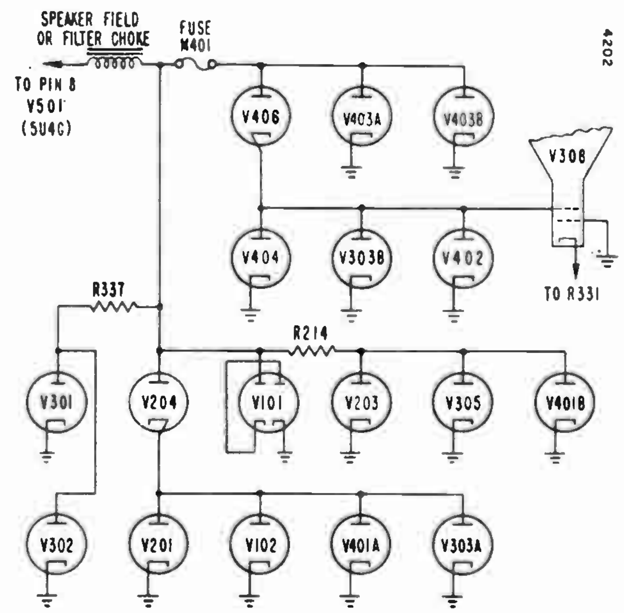

Figure 10. B+ Distribution in All Chassis (except 19B1) Stamped Run 3 and Higher.

SERVICE HINTS FOR HORIZONTAL SYNC

The horizontal oscillator control circuit controls the horizontal oscillator by a method called "Pulse Width Modulation". This method is so called, because the width of the pulse applied to the grid of the horizontal oscillator control section determines the length of time that current flows through this section. The duration of current flow through the control section determines the DC control voltage applied to the grid of horizontal oscillator, thereby controlling the frequency.

The waveshape applied to the grid of the horizontal oscillator control section is formed by combining a partially integrated pulse from the horizontal oscillator output and the horizontal sync pulse. If these two pulses combine properly, the waveshape shown in figure 11 will be developed and the horizontal oscillator will be in sync.

With no sync input, the waveform at the horizontal oscillator control grid should appear as shown in figure 12. Since the horizontal oscillator control voltage is dependent upon a waveshape formed at the horizontal output stages (V404, V405 and V406), a defective component in one of these stages may cause sync trouble. If the waveform shown in figure 12 can be obtained, this will indicate proper operation of the horizontal sweep circuit.

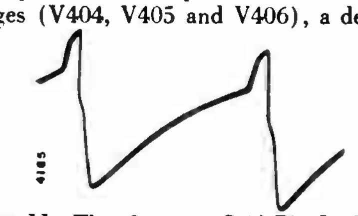

Figure 11. Waveform on Grid Pin 1 of V403 With Sync Pulse.

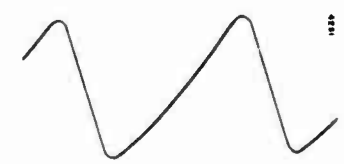

Figure 12. Waveform on Grid Pin 1 of V403 Without Sync Pulse.

When the horizontal oscillator is out of sync, it may be difficult to observe this waveform (figure 12) on an oscilloscope due to the presence of out-of-phase sync pulses. In this case, remove the sync separator and sync clipper tube V401. If the waveshape shown in figure 12 is obtained, place the sync and separator tube back into its socket. Then, remove the horizontal oscillator and control tube V403 (6SN7GT). Conventional, well-shaped sync pulses should appear at control grid (pin 1) of V403.

If there are no sync pulses, or the pulses are of low or varying amplitude, accompanied with noise, the sync circuits should be checked. However, if the sync pulses are well-shaped and of constant amplitude, the horizontal oscillator may be misaligned. Place V403 back into its socket and make the "Horizontal Oscillator Alignment" given on page 4.

If it is impossible to sync the picture, or obtain the correct waveform at terminal "C", check for a defective component. See the following paragraphs.

HORIZONTAL INSTABILITY AND TEARING IN PICTURE

Horizontal instability, tearing or bending may be due to misadjustment of the DX Range Finder or horizontal sync adjustments; or it may be due to a faulty tube or defective components. If causes of trouble have been checked as instructed in the following steps and the chassis is Run 2 or lower, make the circuit changes described under the heading below on "Circuit Changes to Reduce Bending and Improve Horizontal Sync".

Make checks as follows:

a. Check to see if trouble is due to misadjustment of the DX Range Finder control. Set control at "0", use this setting unless a higher setting gives better results. See figure 5.

b. Check horizontal sync adjustment as instructed under "Simplified Horizontal Sync Adjustment" on page 7. If difficulty is experienced in making Horizontal Sync adjustment, continue with the following steps.

c. Replace the horizontal oscillator tube V403 (6SN7GT). Try tubes of different brands. Repeat Horizontal Sync adjustment.

d. Check resistors (R420, R421, R422, R423, R424 and R428). These resistors should be within 5% tolerance of the values shown in the parts list and on the schematic. Also, check condenser C418 (.01 mfd.) for correct capacity. If this condenser is suspected as being faulty, it should be replaced with a .01 mfd, 400 volt, 10% condenser, part number 64A2-16.

e. Check condenser C417 by substitution. Use a 270 mmfd, 10% mica condenser, part numbr 65B21-271.

f. Check condensers C413 and C416 for either open or short.

g. If tapping the horizontal oscillator transformer T404 causes erratic operation, a cracked adjustment slug in the transformer may be the cause. If transformer T404 is suspected as being the cause of the trouble, it should be replaced.

h. If after following each of the above steps, horizontal difficulties are still present, and the set is Run 2 or lower, it is suggested that circuit changes be made as described in the section below.

CIRCUIT CHANGES TO REDUCE BENDING AND IMPROVE HORIZONTAL SYNC

(Applies to chassis stamped Run 2 or lower.)

Making the following circuit changes to an early production chassis, will minimize bending of the picture at high contrast control settings in strong signal areas and improve horizontal sync in medium fringe areas.

IMPORTANT: Before making changes below, check whether bending or sync trouble is due to faulty tubes, defective components, misadjustment of the DX Range Finder control, or horizontal sync adjustment. See pages 3 and 4 for information on adjustment.

Add changes as follows:

1. Check connections to the DX Range Finder control R315. Be sure that the center terminal is grounded and that the white wire goes to the terminal of the DX Range Finder nearest the bottom edge of the chassis. Connect a wire lead from pin 1 of V304 (6AL5) to the remaining terminal of the Range Finder control. See figure 14.

2. In chassis using a 6AS5 sound output tube (V204), change resistor R212 from 3,600 ohms to 1,500 ohms, ½ watt, 5%. In chassis using a 6Y6G sound output tube (V204), change resistor R212 from 4,700 ohms to 2,000 ohms, ½ watt, 5%.

3. In chassis using a 6AS5 sound output tube (V204), change resistor R213 from 1,100 ohms to 910 ohms, ½ watt, 5%. In chassis using a 6Y6G sound output tube, change resistor R218 from 2,000 ohms to 1,500 ohms, ½ watt, 5%.

4. In some areas, it may be beneficial to increase the sync pulse level by changing the sync take-off on the video amplifier plate load. Disconnect resistor R327 (2,700 ohms) from the junction of resistors R325 and R326 (2,700 ohms). Reconnect R327 to the junction of R325 (2,700 ohms) and peaking coil L306. See figure 14.

5. Make the Run 4 change, which consists of connecting a 8,200 ohm resistor (R443) in series with resistor R407 (between terminal 3 of the vertical integrator couplate and pin 1 of V401B). See figure 14.

6. Since step 1 above is effective only with the DX Range Finder set at "0", use this setting unless a higher setting gives better results.

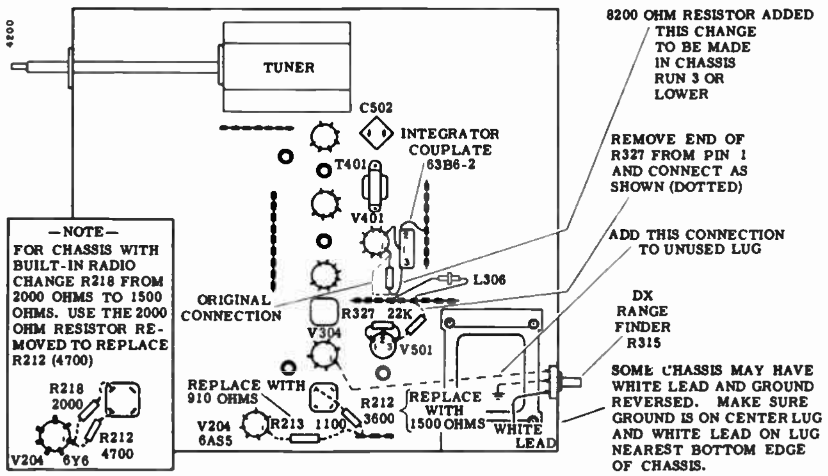

Figure 14. Bottom View of Chassis Showing Simplified Circuit Changes for Reducing Bending and Improving Horizontal Sync in Chassis Stamped Run 2 or Lower.

EXCESSIVE SNOW IN PICTURE DUE TO FAULTY TUBES

Excessive snow in the picture can be caused by faulty tubes in the receiver. Check receiver as follows:

Short circuit the antenna terminals and turn the Picture control (contrast) fully clockwise.

Connect a vacuum tube voltmeter from test point "V" to chassis. Set the channel selector on an unassigned channel. If the voltmeter reading exceeds .6 volt negative, excessive receiver (tube) noise is indicated. This condition can usually be corrected by tube substitution. Substitute tubes in the following order: Video detector tube V304, RF oscillator tube V102, RF amplifier tube V101 and IF amplifier tubes V301, V302 and V303.

Corona or arcing in the second anode supply can also cause a high noise reading at the video detector resulting in excessive snow in weak signal areas.

If the above does not eliminate excessive snow and the chassis is stamped Run 2 or lower, see the "Snow Changes" listed under Run 3 Production Change on page 16. Note: Since this portion of the Run 3 change is rather involved, we do not recommend that it be made in the field. However, if it is desired to make the changes, complete instructions can be obtained by writing the Service Department of the Admiral Corporation at 201 E. North Water Street, Chicago 2, Illinois.

MISCELLANEOUS TROUBLE DUE TO FAULTY TUBES

Faulty tubes cause the majority of receiver troubles. The list below contains most common troubles which are generally due to faulty tubes.

a. Poor fringe area reception due to low B plus voltage. Check the 5U4G tube.

b. Poor fringe area reception due to low sensitivity. Check the 6BC5 and 6BZ7 tubes, if used in the receiver.

c. Picture and sound separated due to IF oscillation. Check the 6CB6 and 6U8 tubes.

d. Picture bending caused by leakage between tube elements. Check the 6BC5 and 6CB6 tubes.

e. Poor sync stability, usually more noticeable in vertical circuit. Check 12AU7 tube.

f. Washed out picture due to negative grid current. Check 6CB6 tube.

VERTICAL JITTER AND POOR INTERLACE

Vertical jitter and poor interlace may occur in early production receivers, if the red lead (terminal 3) of the deflection yoke T403B is dressed too close to the grid circuit of the vertical output tube V402 (6S4). The red lead to the deflection yoke should be dressed against the chassis and as far away from the grid circuit of the vertical output tube as possible.

ADDING VERTICAL RETRACE BLANKING CIRCUIT TO AN EARLY PRODUCTION CHASSIS

All 19 series chassis stamped Run 5 and higher, have a vertical retrace blanking circuit incorporated for eliminating retrace lines. A schematic of the retrace blanking circuit and detailed instructions for adding this change to an early production receiver, is given in the paragraphs below. The following parts are required:

Sym.	Description	Part No.
C427	.01 mfd, 600 volts, condenser	64B 9-13
C428	.01 mfd, 400 volts, condenser	64B 9-32
R445	56,000 ohms, ½ watt, resistor	60B 8-563
R444	2700 ohms, ½ watt, resistor	60B 8-272

1. Locate the red wire between pin 10 of the picture tube and the junction of the black lead of T403A (vertical deflection yoke) and the red lead of T402 (vertical output transformer).

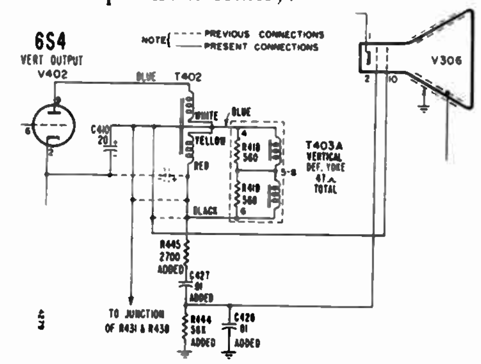

Figure 13. Vertical Output and Picture Tube Circuit With Vertical Blanking Added.

2. Locate the bare wire between the junction of R431 (820,000 ohms) and R438 (1200 ohms) and the junction of the black lead of T403A and red lead of T402.

3. Disconnect the red wire and the bare wire from their common junction point. Reconnect both of these leads to the junction of the 7.5 ohm winding and the 100 ohm winding of T402 (common point of the white and yellow leads). See figure 13.

4. Locate the red (positive) lead from C410 (20 mfd) and the junction of the black lead of T403A and red lead of T402. Disconnect the red wire from this junction and reconnect to junction of 7.5 ohm and 100 ohm winding of T402.

5. Locate the green wire from pin 2 of the picture tube and disconnect from chassis ground. Connect green wire to a .01 mfd., 600 volt condenser. Connect the other end of this condenser to a 2700 ohm, ½ watt resistor. Connect the other end of the resistor to the junction of the red lead of T402 and the black lead of T403A.

6. At the junction of the .01 mfd., 600 volt condenser and the green wire from pin 2 of the picture tube (connected in step 5) connect a 56,000 ohm resistor to chassis ground. Connect a .01 mfd., 400 volt across the 56,000 ohm resistor.

WARNING: Do not use any of the unused lugs of V402 (6S4) tube socket for the points. These lugs are connected to the internal tube structure of the 6S4 tube.

INSUFFICIENT HEIGHT

If adjustment of the Height and Vertical Linearity controls does not provide sufficient height, try replacing the vertical output tube V402 (6S4). Insufficient height can also be due to a weak vertical oscillator tube V303 (6U8).

ELIMINATING AUDIO HUM

Strong (60 cycle) audio hum in these receivers can be due to any one of the causes listed below, which can easily be corrected.

1. Hum may be due to coupling between components in the audio input circuit and the AC wiring. Check the 117 volt AC leads to the On-Off switch. These leads should dress away as far as possible from the grid circuit of the sound amplifier V203. In models using tone control R214, dress the lead between the control and the plate (pin 7) of V203 away from the AC leads.
2. Check position of condenser C209 (.01 mfd.) in the sound amplifier circuit (V203) to make certain that it is not too close to the 117 volt AC wiring or On-Off switch. If C209 is a tubular paper condenser, the outside foil terminal should be connected to the junction of resistor R207 (47,000 ohms) and condenser C208 (.0022 mfd.).
3. Check the B+ (power supply) circuits for an open or under capacity electrolytic condenser. Especially check filter condenser C501, 60 mfd., 350 volts.
4. If the receiver is a TV only model using a 10″ electro-magnetic (EM) speaker, it may be possible that the speaker is the cause of excessive hum. The speaker may be checked by substituting another speaker of the same type. The original 10″ electro-magnetic (EM) speaker part number 78B75-1, can be checked by substituting a permanent magnet (PM) speaker with the filter choke attached such as part number 78B80-1.

SOUND BARS IN PICTURE

Sound bars noticeable at high volume levels, may be caused by heavy audio currents being induced in the B+ circuits. This can be due to the location or the routing of leads to electrolytic condenser C215. Condenser C215 is the single section electrolytic condenser (80 mfd, 350 volts) which is mounted at the center of the chassis.

To minimize the possibility of sound bars in the picture, the mounting and routing of leads to electrolytic condenser C215 were changed. In later production sets, electrolytic condenser C215 is mounted in parallel and in front of the 9 lug terminal strip near the center of the chassis. When mounted this way, the terminals of condenser C215 face away from the TV tuner, thus permitting the negative lead C215 to connect directly to the cathode of the sound output tube V204.

TOUCH-UP OF RATIO DETECTOR SECONDARY USING TELEVISION SIGNAL (A8, BOTTOM SLUG OF T201)

*Adjustment A8 is accessible through the ¼″ hole (just below T201) in bottom of the cabinet or the chassis mounting shelf, located toward the left side facing the rear of the set. See figure 22. Removal of the chassis is therefore not required. ***Adjustment need be made on one channel only.*** Proceed as follows:

a. Turn set on and allow about 15 minutes for warm up.
b. Tune set for normal picture and sound.
c. Carefully insert a non-metallic alignment tool through the opening in cabinet bottom below T201. An alignment tool with a screwdriver blade or hexagonal end is required depending on the transformer used, see * note below. When the alignment tool engages the bottom tuning slug A8, adjust the slug for best sound with minimum buzz level. Do this carefully as only slight rotation in either direction will generally be required. Correct adjustment point is located between the two maximum buzz peaks that will be noticed when turning the slug back and forth about ¼ to ½ turn.

ALIGNMENT OF 4.5 MC TRAP A9, USING A TELEVISION SIGNAL

Beat interference (4.5 MC) appears in picture as very fine vertical or diagonal lines, very close together, having a "gauze-like" appearance, the pattern will vary with speech, forming a very fine herringbone pattern.

The trap can be tuned by watching the picture and adjusting slug A9 for minimum 4.5 MC interference. If greater accuracy is required, the trap should be adjusted as instructed in step 3 of the "4.5 MC Sound IF and Trap Alignment" procedure on page 11.

SERVICING RADIO TUBES AND DIAL LIGHT IN COMBINATION MODELS

The radio tubes can be serviced without removing the TV chassis from the cabinet. The radio tubes can be reached through the opening in the underside of the chassis shelf.

The dial light can be serviced by removing the tuning knobs and plastic control panel. A number 44 dial light (part number 81A1-5) is used in sets stamped Run 5 or lower; a number 47 dial light (part number 81A1-8) is used in sets stamped Run 6 or higher.

* If ratio detector transformer (T201) has hollow hexagonal core slugs, bottom slug adjustment A8 can be made from top of chassis, if you use alignment tool (part number 98A30-7; available at Admiral Distributor). Bottom slug (A8) can be reached through the hole in the core of the upper slug (A10).

TELEVISION TUNER SERVICE

SERVICING TV TUNER CHANNEL COILS

The cabinets of later production sets have been provided with a rectangular cut-out in the chassis shelf just below the TV tuner. This access opening will permit servicing of the tuner channel coils or for installing UHF channel coils without removal of the chassis from the cabinet.

To gain access to the underside of the tuner, it is necessary to remove the screen covering from over the cut-out in the chassis shelf. Then remove the bottom shield from the bottom of the tuner. After servicing the channel coils, carefully replace the tuner shield. Replace the metal screen, using staples or thumb tacks to secure it to the cabinet.

SERVICING STATIONARY CONTACTS OF TV TUNER

A rectangular opening is provided at the side of the chassis for convenience in servicing the stationary contacts of the TV tuner or for making voltage or resistance measurements.

To gain access to the stationary contacts of the TV tuner, it is necessary to remove the mounting screws from the side cover plate on the tuner and unsolder the soldered joint grounding the cover plate to the tuner. Reassemble the cover plate in the same manner.

REMOVING CHANNEL COILS

Insert a screwdriver blade between the coil retainer spring and the turret end plate. Twist the blade away from the turret and lift the end of the coil upward.

CLEANING CONTACTS

Remove several sets of coils from turret and rotate turret to position making contact points of contact plate accessible for cleaning.

Using a small, stiff brush and carbon tetrachloride, clean contact surfaces of stationary contacts.

Remove accumulated dust or grease from stationary contacts and contact plate with a soft canvas cloth dampened with carbon tetrachloride. Accumulated rosin may be removed with a soft cloth dampened with alcohol.

Clean contact surfaces of rotating coils in same manner.

TUNER LUBRICATION

In general the lubrication applied to points of wear or friction at time of manufacture should make lubrication seldom, if ever necessary. However, should tuner lubrication become necessary, it is important that the correct amount and type of lubricant be used.

Using a clean brush, apply a film of switch contact oil (Admiral part number 98A64-1 or Viscosity Oil Co.

4282

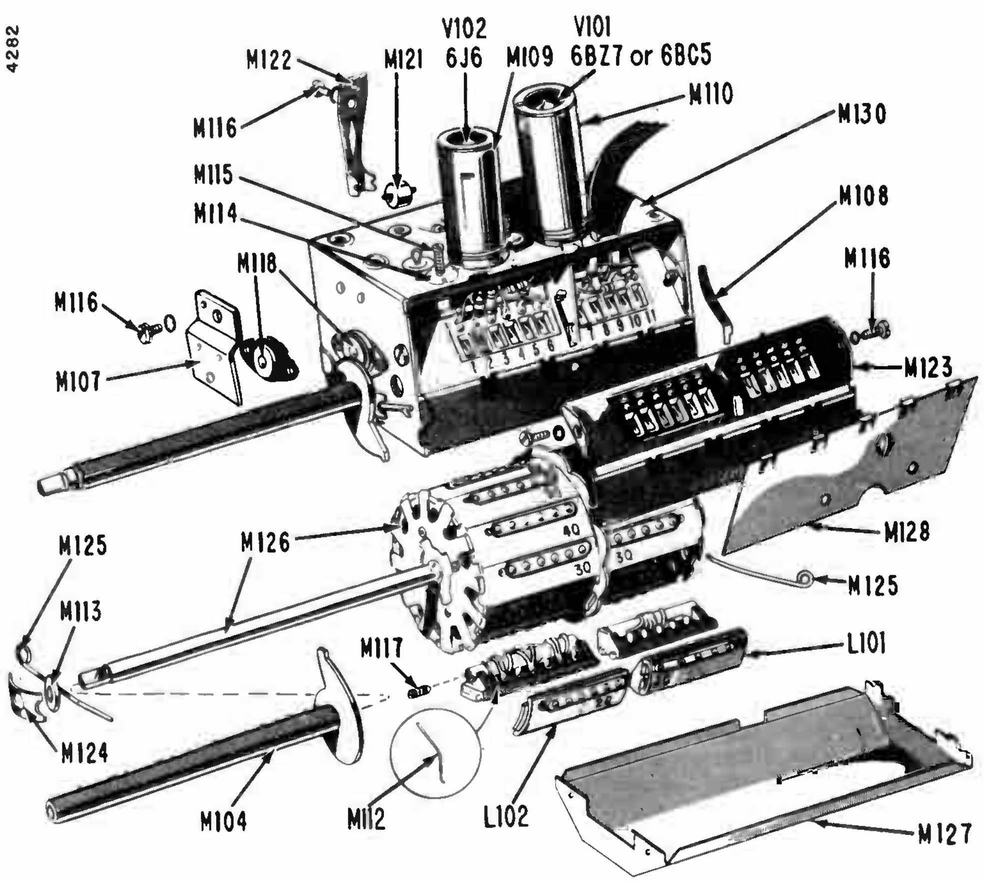

Figure 15. Exploded View. TV Tuners 94D52-1, 94D52-2, 94D46-2 and 94D46-3. For description of parts, see page 14.

#7069) to the surfaces of the coil contacts and stationary contact points.

Lubricate bearing surfaces of all other moving parts with light vaseline or preferably Admiral part #98A64-2 or Viscosity Oil Co. #8857 lubricant.

CAUTION: ***Do not use lubriplate or any similar lubricant containing zinc or cadmium.***

ADJUSTING CONTACT SPRINGS

Should the stationary contact springs make poor contact due to insufficient tension, remove several sets of coils from the turret. Rotate the turret to position making the bottom of the contact strip accessible for observation. With a narrow blade screwdriver, adjust the contact spring tension by carefully bending the spring inward until highest point on the spring extends about 9/64 of an inch above the plastic surface of the contact plate. With correct tension of the contact spring, the spring should clear the flat surface of the turret coil by about 1/64 of an inch.

OSCILLATOR SLUGS IN TOO FAR

If HF oscillator slugs "fall into" coil form, remove the channel coil, move the slug retaining spring M112 aside, and tap the coil assembly until the slug slips forward. Set the slug retaining spring into position; it should rest firmly against the slug.

REMOVING TUNER TURRET ASSEMBLY

a. Remove retaining bracket M107 in front of the tuner.
b. Remove rotor shaft assembly M104, rotor contact spring M124 and fibre washer M113. For reassembly, note order of parts removal.
c. Remove front and rear turret retaining springs M125 by pressing straight end away from tab on chassis.
d. Using a screwdriver blade at the side of the tuner, press the detent spring M122 and roller M121 away from the turret detent plate.
e. Grasp tuner shaft and slip out of end plate bearings.

REPLACEMENT OF THE UNGROUNDED STATOR PLATE OF TUNING CONTROL

Stator plate M118 (part number 94A45-86) is replaced with wiring lead and trimmer condenser C110 attached, because it is difficult to solder the wire lead to the silver plated surface on the ceramic stator plate disc.

To replace the stator plate, remove the turret assembly. Remove mounting rivets from stator plate by drilling out or clipping them out with diagonal wire cutters. Remove trimmer screw M115 and locking nut M114 from trimmer condenser C110. Unsolder wiring lead connecting trimmer to terminal on contact plate.

Assemble the replacement stator plate (M118) by placing the ceramic button over the 3/8" hole in the chassis with the wiring lead extending into the chassis. Place the mounting bracket over the ceramic button and mount securely using #4x3/16 round head machine screws with #4-40x3/16 hex nuts and #4 shake proof lock washers. Mount trimmer condenser C110 in chassis and solder wire lead to its original terminal on the contact plate making this lead as short as possible. Dress wiring lead from ceramic stator plate to trimmer condenser C110 so it does not come in contact with the turret drum. After replacement of the stator plate, adjust trimmer condenser C110 (overall oscillator adjustment).

REMOVING CONTACT PLATE ASSEMBLY M123

a. Remove turret.
b. Remove the mounting screws at the front and rear of Contact Plate and Bracket Assembly M123.
c. Unsolder both ends of contact plate assembly. Press outward the front and rear tuner chassis end plates.
d. To free contact plate assembly, release the contact plate tabs by pushing them away from the slots in the end plates.
e. Unsolder all connections to contact plate. Unsolder the solder joint holding contact plate to the center partition of the tuner chassis.
f. Reassemble in the same manner.

INTERCHANGEABILITY OF 20DP4A, 21ZP4A, 21WP4 and 21WP4X PICTURE TUBES

Some of the above picture tubes can be used as interchangeable replacements and others cannot, as described below.

The 21EP4A picture tube used in the 19H1 chassis and the 21ZP4A picture tube used in 19K1 and 19N1 chassis are not interchangeable with other tubes because of the larger cabinet space required by these tubes.

The 21WP4 or 21WP4X picture tubes used in 19F1, 19F1A and 19G1 chassis and the 20DP4A picture tube used in the 19C1 and 19E1 chassis can all be used as interchangeable replacements. However, the front tube supports may have to be cut down or padded to keep the tube the same distance above chassis as the original tube. Use the measured distance between the original tube and chassis for obtaining proper alignment of the replacement tube and the picture mask. Final alignment should be checked with chassis installed in the cabinet.

The deflection yoke housing must be moved forward or backward so that the rubber neck grommet will fit tightly against the cone of the picture tube. If it cannot be moved forward far enough, the slots in the yoke housing may have to be elongated or new holes can be drilled in the diagonal yoke housing support brackets.

The original tube mounting strap can generally be used.

PRODUCTION CHANGES

Production changes are coded RUN 1, RUN 2, etc., as given in the headings below. Run number (stamped on chassis) indicates that this chassis has the change(s) incorporated which are explained under that particular run number heading below, as well as all changes (lower run numbers) made prior to that time. At the start of production chassis were stamped RUN 1; a few chassis were not stamped with a Run number.

CHANGE TO INCREASE BRIGHTNESS

Run 2 and higher in all 19 series chassis

The following changes were made in the cathode circuit of picture tube V306 for increased brightness.

Resistor R330 was changed from 470,000 ohms to 180,000 ohms, 1/2 watt, part number 60B8-184. Condenser C316 was changed from .01 mfd. to .22 mfd. 400 volts, part number 64B8-24.

CHANGE TO ELIMINATE BENDING AND IMPROVE HORIZONTAL SYNC AND CHANGE TO REDUCE SNOW IN FRINGE AREAS

Run 3 in 19B1, 19C1, 19E1, 19F1, 19F1A, 19G1, 19H1, and 19K1 Chassis

Bending and Sync Changes

The following changes were made to eliminate possible bending at the top of the picture and to improve horizontal sync. If it is desired to make these changes to chassis stamped Run 2 or lower, see heading on "Circuit Changes to Reduce Bending and Improve Horizontal Sync" on page 6.

In early production chassis (with exception of 19B1), the B+ voltage to the 1st and 2nd IF amplifiers V301 and V302 is effectively in series. In later production sets, B+ voltage to the 1st and 2nd IF amplifier stages is in parallel. This makes it possible to apply AGC voltage to the 1st and 2nd IF amplifiers of later production sets, thus allowing the receiver to operate under a wider range of signal conditions without the possibility of overloading.

The circuit changes that were made to the IF amplifiers and AGC circuit of later production sets are as follows: The screen (pin 6) of 2nd IF tube V302 and terminal 2 of 2nd IF transformer T302 connect to common B+ through resistor R312 (1,000 ohms). Condenser C319 (.001 mfd.) is connected from terminal 2 of T302 to chassis.

The control grid (pin 1) of 2nd IF amplifier V302 is returned to AGC through T301 and decoupling resistor R309 (1,000 ohms). Condenser C318 (.001 mfd.) is connected from terminal 3 of T301 to chassis. The suppressor grid (pin 7) of V302 is connected directly to chassis. The cathode (pin 2) of V302 returns to chassis through R336 (68 ohms).

Overloading of the video amplifier and possible sync instability has been eliminated by the following circuit changes:

The B+ voltage at the screen (pin 6) of the video amplifier V305 (6CB6) was increased by lowering the value of resistors R212 and R213 in the grid and cathode circuits of sound output tube V204.

Resistor R212 was changed from 3,600 ohms to 1,500 ohms in sets using a 6AS5 tube for V204, and was changed from 4,700 ohms to 2,000 ohms in sets using a 6Y6 G tube for V204.

Resistor R213 was changed from 1,100 to 910 ohms in sets using a 6AS5 tube for V204 and from 2,000 ohms to 1,500 ohms in sets using a 6Y6G tube for V204.

Increased sync pulse input to the sync circuits is obtained by the following changes made to the video amplifier plate circuit. Resistor R326 was changed from 2,700 ohms to 5,600 ohms, 1 watt. Resistor R325 (2,700 ohms) was omitted.

Snow Changes

(This portion of Run 3 production change does not apply to the 19B1 chassis.)

The circuit changes described below are rather involved. Generally, we do not recommend that they be made in the field. However, if snow is still excessive after making the checks given under the heading of "Excessive Snow Due to Faulty Tubes" on page 6, and it is desired to make the changes below, instructions may be obtained by writing the Service Department of the

Admiral Corporation at 201 E. North Water street, Chicago 2, Illinois.

To reduce the amount of snow (front end noise) in the picture the AGC voltage to the tuner has been reduced with respect to the AGC voltage to the 1st and 2nd IF stages by applying a small positive voltage from voltage divider network.

The voltage divider network consisting of R301 (3.3 megohms), R333 (15 megohms), R334 (2.2 megohms) and R338 (56,000 ohms) was added in the circuit between B+, the AGC diode V304 and the DX Range Finder control R315.

One terminal of DX Range Finder R315 connects to the R338 (56,000 ohms). Resistor R317 connecting to pin 7 of diode V304 was changed from 820,000 ohms to 470.000 ohms. The delayed AGC bias developed at the AGC diode (½ of V304) is thus controlled by both the Contrast (picture) control and the DX Range Finder control. This provides a means of eliminating entirely the delay on the AGC diode in a very strong signal area and also a means of adjusting the AGC delay to a suitable value for best picture with minimum of snow in weak signal or intermediate fringe areas.

RESISTOR R443 ADDED TO IMPROVE HORIZONTAL SYNC STABILITY

Run 4 in all 19 Series Chassis

Later production sets using vertical integrator couplate, part number 63B6-2, have an 8,200 ohm, ½ watt resistor (R443) connected between terminal 3 of the couplate and pin 1 of sync separator tube V401 (12AU7). The integrator couplate contains components R407, R408, R409, C403, C404 and C405.

Adding resistor R443 to the circuit has increased the sync level by squaring up the sync pulses, thereby improving horizontal sync instability.

To install resistor R443 (8,200 ohms) remove the number three lead of integrator couplate 63B6-2 from pin 1 of V401 (12AU7). Connect resistor R443 between the number three lead of the couplate and pin 1 of V401 (12AU7).

VERTICAL RETRACE BLANKING CIRCUIT ADDED

Run 5 in all 19 Series Chassis

A vertical retrace blanking circuit was added to eliminate retrace lines. The vertical retrace blanking circuit consisting of components R444 (2,700 ohms), R445 (56,000 ohms), C427 (.01 mfd.) and C428 (.01 mfd.), is shown in schematic figure 13.

Vertical retrace blanking is achieved by applying the pulse voltage appearing at the low side (red lead) of the vertical output transformer T402 to the grid (pin 2) of the picture tube V306.

Detailed instructions for eliminating retrace lines in early production receivers are given on page 6.

TV TUNER SHAFT LENGTH INCREASED

Run 6 in All 19 Series Chassis

The TV tuners used in chassis stamped Run 6 and higher, have a longer shaft length. This increase in shaft length was made to make the chassis adaptable for installation of a separate UHF tuner.

The 94D46-3 cascode TV tuner is used in all later production chassis (Run 6 and higher), with exception of the 19B1 chassis. The 94D52-2 pentode TV tuner is used in later production 19B1 chassis (Run 6 and higher).

TV tuners 94D46-2 and 94D46-3 are identical, with exception of shaft length. TV tuners 94D52-1 and 94D52-2 are identical, with exception of shaft length.

DIFFERENT INTEGRATOR AND SYNC COUPLATE USED

Run 7 in All 19 Series Chassis

Integrator couplate, part number 63B6-11 has replaced integrator couplate, part number 63B6-2 used in earlier production sets. The circuit of both couplates is the same with the exception that resistor R407 (22,000 ohms), is not contained in couplate 63B6-11. Resistor R407 is connected externally from terminal 3 of couplate 63B6-11 to pin 1 of V401B. This change in integrator couplates has improved horizontal sync stability by increasing the amplitude and squaring up the sync pulses.

To replace couplate 63B6-2 with couplate 63B6-11, omit resistor R443 (8.200 ohms) if used between pin 1 of V401B and terminal 3 of the couplate. Connect resistor R407 (22,000 ohms, ½ watt) between pin 1 of V401B and terminal 3 of couplate 63B6-11.

Sync couplate, part number 63B6-8 has replaced sync couplate part number 63B6-4 used in early production sets. Couplate 63B6-4 contains resistors R328, R329 and condenser C315. Couplate 63B6-8 contains resistor R329 and condensers C315 and C317. This change in sync couplates has simplified circuit wiring by reducing the number of components.

To replace couplate 63B6-4 with couplate 63B6-8, change resistor R327 from 22,000 ohms to 27,000 ohms. Remove condenser C317 (.01 mfd.). Connect couplate 63B6-8 between resistor R327 and pin 7 of V401A.

CHANGE IN TOLERANCE OF COMPONENTS IN THE HORIZONTAL OSCILLATOR CIRCUIT V403

In some Run 2 Chassis and all Chassis Run 3 and higher

Changes were made to horizontal oscillator circuit V403 of later production sets to minimize possible variation of horizontal oscillator performance due to parts tolerances and variation in electrical characteristics of some brands of 6SN7 tubes. By reducing the permissible tolerance of components R422, R423, R428 and C418, the operation of the horizontal oscillator circuit becomes less critical.

In later production sets (stamped Run 3 and higher), tolerance of resistors R422 (330,000 ohms), R423 (82,000 ohms) and R428 (150,000 ohms) were changed from 10% to 5% tolerance. Condenser C418 (.01 mfd.) was changed from 20% to 10% tolerance.

In cases where it is difficult to make satisfactory Horizontal Sync Adjustment, the components in the horizontal oscillator circuit should be checked for correct value as mentioned in the preceding paragraph and on page 5, under Horizontal Instability And Tearing In Picture.

RESISTORS R214 AND R215 REPLACED BY ONE RESISTOR IN SOME LATER PRODUCTION 19E1, 19G1 and 19N1 CHASSIS

In later production chassis, resistors R214 and R215, 2,200 ohms, 2 watt, were replaced by a single wire wound resistor, 1,200 ohms, 5 watt, part number 61A1-10.

CHANGE TO PREVENT FUSE FAILURE IN TV-RADIO CHASSIS

Run 8 in 19E1, 19G1 and 19N1 Chassis

The circuit location of fuse M401 (⅜ amp. 250 V.) has been changed to prevent possible fuse failure when function switch S701 is rotated from Radio to TV position. Fuse failure may occur if all contacts of switch section S701C make simultaneous contact, thus applying a sudden surge of current through the fuse.

Schematic figure 33 shows the fuse location in early sets and schematic figure 35 shows the fuse location in later sets having this production change. This change can be made to an early set by simply interchanging the red and blue leads connecting to switch section S701C. With this change made, the red lead should connect to terminal "h" of S701C and the blue lead should connect to terminal "g" of S701C.

CHANGE IN SIZE OF FUSE M401

To prevent possibility of fuse failure, due to momentary line voltage surges, fuse M401 was changed from a ¼ ampere, 250-volt fuse to a ⅜ ampere, 250-volt fuse, part number 84A4-3. Fuse replacement should be made only with a ⅜ ampere, 250-volt fuse, part number 84A4-3.

CHANGE IN PILOT LIGHT AND VOLTAGE DROPPING RESISTOR R707

In later production combination sets, a different pilot light and pilot light series dropping resistor is used.

Early production sets stamped Run 5 or lower use a number 44 pilot light (part number 81A1-5) and voltage dropping resistor R707 is 4.7 ohms, ½ watt, part number 60B28-11. In later production sets stamped Run 6 and higher, a number 47 pilot light (part number 81A1-8) is used and voltage dropping resistor R707 is 10 ohms, ½ watt, part number 60B28-100.

MECHANICAL CHANGE IN RADIO TUNER USED IN 19E1, 19G1 and 19N1 CHASSIS

Mechanical changes were made to the later production radio tuner sub-chassis used in combination models. The dimensions of the radio chassis were altered slightly and the mounting position of the gang condenser was changed.

Early production radio tuners used gang condenser (part number 68B53) which mounts in a vertical position. Later production radio tuners use gang condenser (part number 68B53-1) which mounts in a horizontal position.

TELEVISION ALIGNMENT PROCEDURE

GENERAL

Complete alignment consists of the following individual procedures and should be performed in this sequence.

a. IF Amplifier and Trap Alignment.
b. IF Response Curve Check.
c. 4.5 MC Sound IF and Trap Alignment.
d. RF and Mixer Alignment.
e. Over-all RF and IF Response Curve Check.
f. HF Oscillator Adjustment.

TEST EQUIPMENT

To properly service this receiver, it is recommended that the following test equipment be available.

IMPORTANT: Many service instruments do not meet the requirements given below. A list of recommended equipment is available from Admiral Distributor.

Oscilloscope

Standard oscilloscope, preferably one with a wide band vertical deflection, vertical sensitivity at least .5 volt (RMS) per inch.

Signal (Marker) Generator

4.5 MC frequency.
18 to 30 MC frequency range.
50 to 90 MC frequency range.
170 to 225 MC frequency range.

Must have a built-in calibration crystal for checking dial accuracy.

Sweep Generator

Sweep generator must provide sweep frequencies from
18 to 30 MC range: } with at least
50 to 90 MC range: } 10 MC sweep width.
170 to 225 MC range: }
Output: adjustable; at least one-tenth volt maximum.
Output impedance: 300 ohms balanced to ground.

A sweep generator not having constant output voltage over the swept range and linear sweep, will produce curves which are widely different from the ideal curves shown in the following pages. If repeated difficulty is encountered in obtaining these curves, the sweep generator should be checked. A simple check is to observe the response curve for a set that is in alignment.

Before suspecting the generator, be sure the alignment instructions in this manual have been followed carefully.

Vacuum-Tube Voltmeter

Preferably with low range (3 volt) DC zero center scale and a high voltage probe (30,000 volt range).

ALIGNMENT TOOLS

The following alignment tools are required. They can be obtained from the Admiral Distributor under the part numbers listed below:

Metal alignment screwdriver part number 98A30-9.
Non-metallic (fiber) alignment screwdriver (11½" long, ⅛" diameter) part number 98A30-10.

Non-metallic alignment wrench (9" long, for hexagon core IF slugs) part number 98A30-12.

IMPORTANT ALIGNMENT HINTS

The following suggestions should be performed if difficulty is experienced during the alignment procedure.

1. IF CIRCUIT INSTABILITY: When spot frequency aligning the IF amplifiers, the VTVM pointer may swing when the hand is placed too near the IF transformers. When viewing the IF response curve on an oscilloscope, the curve may change shape with hand capacity, especially when aligning A2 (3rd IF transformer T303). To correct either of these conditions, the following alignment hints should be tried:

(a) Check the generator output leads to be certain that the unshielded portion (especially the grounded lead) be as short as practicable.

(b) Be sure that a decoupling network is used at the video detector output and that the leads on the network are kept as short as possible (See figure 21).

(c) Construct a special tube shield as shown in figure 16. This is made from an ordinary tube shield and four 10,000 ohm resistors. Keep the spacing between the two halves of the shield at a minimum (1/8 inch).

(d) The use of a non-metallic alignment tool, approximately eight inches long (part number 98A30-12), will permit adjustment without coming too near to the transformers.

2. RECEIVER OVERLOADING WHEN CHECKING THE OVER-ALL RESPONSE CURVE: Due to the inherent high sensitivity of these receivers, it is very easy to cause overloading in the third IF amplifier stage. In some cases, generator leakage alone is enough to produce a response curve on the oscilloscope. To prevent overloading, do the following:

(a) Be certain that the generator output attenuators are set at a minimum.

(b) Some generators have a built-in pad in the output table to be used when viewing the over-all response curve. Be sure that the pad in the cable is properly connected in the circuit. Refer to the generator instruction manual for details.

(c) If a pad is not built in, the 12 db pad shown below in figure 17 can be constructed and connected between the generator and the antenna terminals.

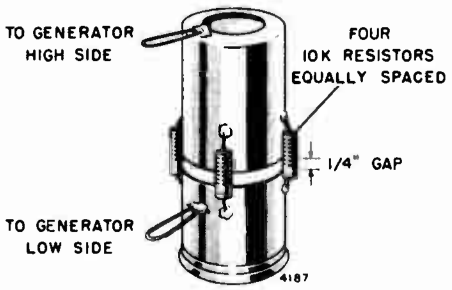

Figure 16. Special Tube Shield for IF Alignment and IF Response Curve Check.

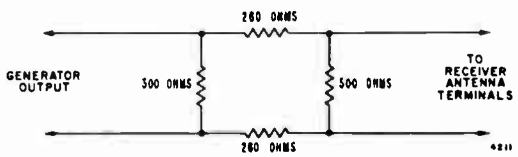

Figure 17. Illustration of 12 db Attenuation Pad for Viewing Over-all RF-IF Response Curve.

IF RESPONSE CURVE CHECK

(Using sweep generator and oscilloscope)

Receiver Controls and Bias Battery	Sweep Generator	Marker Generator	Oscilloscope	Instructions
Set Channel selector on Channel 12 or an unassigned high channel. Picture control fully to the left. Connect negative of 4½ volt bias battery to test point "T"; positive to chassis.	Connect high side to 6J6 mixer-osc. special tube shield, see fig. 16. Connect low side to bottom part of tube shield. Set sweep frequency to 23MC, and sweep width approximately 7MC.	If an external marker generator is used, loosely couple high side to sweep generator lead on tube shield, low side to chassis. Marker frequencies indicated on IF Response Curve.	Connect to test point "V" through a decoupling filter, see figs. 21 and 22. Marker pips on scope will be more distinct if a condenser from 100 mmfd. to 1000 mmfd. is connected across the oscilloscope input.	Check curve obtained against ideal response curve in fig. 18. Note tolerances on curve. Keep marker and sweep outputs at very minimum to prevent overloading. A reduction in sweep output should reduce response curve amplitude without altering the shape of the response curve. If the curve is not within tolerance or the markers are not in the proper location on the curve, touchup with IF slugs as instructed below. *Important:* If curve changes shape with hand capacity, see section 1 of "Alignment Hints" on page *10*.

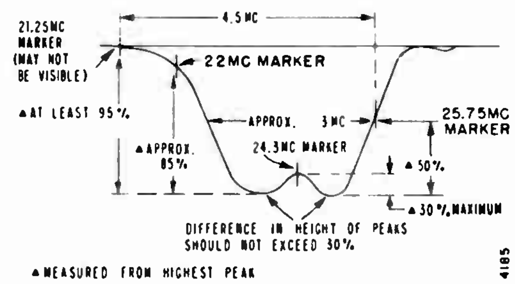

Figure 18. Ideal IF Response Curve.

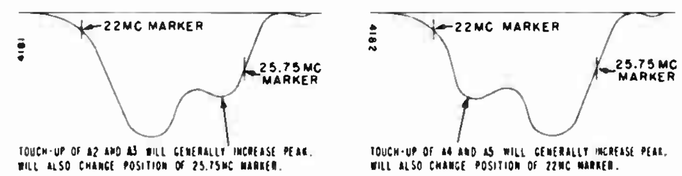

Figure 19. IF Response Curves, Incorrect Shape.

If it is necessary to adjust for approximate equal peaks and marker location, carefully adjust alignment slugs as instructed under the above figures. It should not be necessary to turn the slugs more than one turn in either direction.

If the curve cannot be made to resemble the response curve shown at left, repeat all steps under "IF Amplifier and Trap Alignment" making sure that generator frequencies are accurate and adjustments are carefully made. If a satisfactory curve cannot be obtained after repeating these steps, it may be necessary to change IF amplifier tubes or check for a defective circuit component to be sure that each stage is operating properly.

IF AMPLIFIER AND TRAP ALIGNMENT

- Connect bias battery; negative to test point "T", see figure 22, positive to chassis. A 4½ volt battery is required for all steps below.
- Disconnect antenna. Connect a jumper wire across the antenna terminals.
- Set Channel selector to Channel 12 or other unassigned high channel, to prevent interference during alignment.
- Set the Picture control fully to the left (counterclockwise).
- Allow about 15 minutes for receiver and test equipment to warm up.
- Use lowest DC scale on VTVM.

Step	Signal Gen. Freq.	VTVM and Signal Generator Connections	Instructions	Adjust
1	*27.25 MC	VTVM high side to test point "V" through a decoupling filter; see figs. 21 and 22, common to chassis. Generator high side to 6J6 (V102) special tube shield. Connect low side to bottom part of the tube shield, see figure 16.	Connect a 4½ volt bias battery to test point "T".	A1 for minimum.
2	25.3 MC		Use lowest DC scale on VTVM. When peaking, keep reducing generator output for VTVM reading of approx. 1 volt or less. If unstable, refer to section 1 of the "Alignment Hints" above.	A2 and A3 for maximum.
3	23.1 MC			A4 and A5 for maximum.
4	*27.25 MC			Repeat step 1 above.
5	To insure correct IF alignment, make the "IF Response Curve Check" given on opposite page.			

* Before proceeding, be sure to check the signal generator used in alignment against a crystal calibrator or other frequency standard for absolute frequency calibration required for this operation.

ALIGNMENT HINT

After becoming familiar with alignment procedure, some servicemen simplify subsequent alignment of sets by merely using the essential alignment data given in figures below.

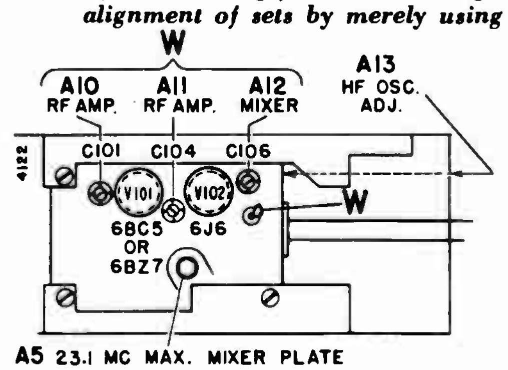

Figure 20. Top View of TV Tuner Showing Adjustment Locations.

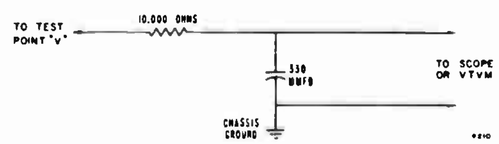

Figure 21. Decoupling Filter.

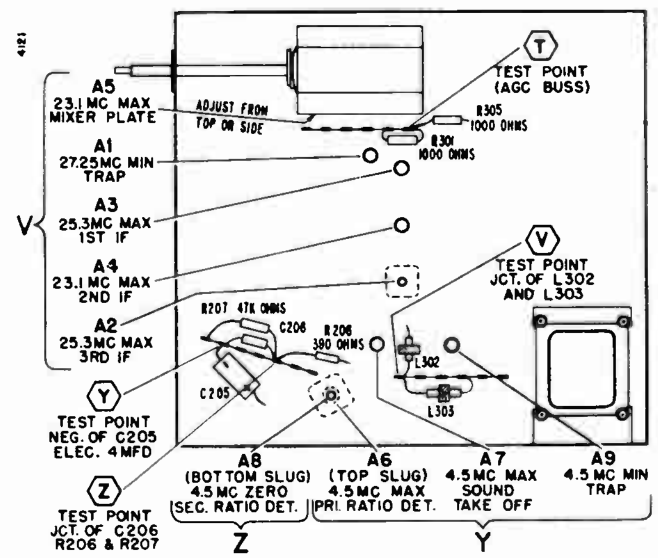

Figure 22. Bottom View of Chassis Showing Test Point Connections and IF Alignment Data.

4.5 MC SOUND IF AND TRAP ALIGNMENT

See page 7 for touch-up of ratio detector using television signal without test equipment.

a. Connect signal generator high side to pin 2 of V304 (6AL5) through a .01 mfd. condenser, connect low side to chassis.

b. Allow about 15 minutes for receiver and test equipment to warm up.

c. Set Picture control fully to the left (counterclockwise).

d. Use a NON-METALLIC alignment tool. If Ratio Det. Transformer (T201) has hollow core slugs, bottom slug adjustment A8 can be made from top of chassis, if you use alignment tool #98A30-12 obtainable from Admiral Distributor.

Step	Signal Gen. Freq. (MC)	VTVM Connections	Instructions	Adjust
	When using a signal generator, be sure to check it against a crystal calibrator or other frequency standard for accurate frequency calibration at 4.5 MC. Accuracy required is within one kilocycle. IMPORTANT: If a signal generator and frequency standard are not available, alignment can be made using a TV station signal. Tune in a station and follow steps 1, 2 and 3 below. If necessary use a higher scale on the VTVM.			
1	Set to exactly 4.5 MC	High side to test point "Y"; common to chassis.	Use lowest DC scale on VTVM.	A6 and A7 for maximum (keep reducing generator output to keep VTVM at approx. 1 volt).
2		High side to test point "Z"; common to chassis.	Use zero center scale on VTVM, if available.	A8 for zero on VTVM (the correct zero point is located between a positive and a negative maximum). If A6 was far off, repeat step 1.
3		High side to test point "Y"; common to chassis.	Connect a 10 mmfd. condenser from pin 5 of V305 (6CB6) to pin 7 of V201 (6AU6). Use lowest DC scale on VTVM.	A9 for minimum.

RF AND MIXER ALIGNMENT FOR SETS USING TV TUNERS 94D52-1 AND 94D52-2

(These tuners use a 6BC5 tube for RF amplifier V101.)

a. Connect negative of 4½ volt bias battery to test point "T", positive to chassis. If it is difficult to obtain a curve of sufficient amplitude, remove battery and connect a wire jumper from test point "T" to chassis.

b. Connect sweep generator (with 300 ohm output) to antenna terminals. If sweep generator does not have a built-in marker generator, loosely couple a marker generator to the antenna terminals. To avoid distortion of the response curve, keep sweep generator output at a minimum, marker pips just barely visible.

c. Connect oscilloscope through a 10,000 ohm resistor to test point "W" on tuner (fig. 24). Keep scope leads away from chassis.

d. Set channel selector to Channel 10.

e. Allow about 15 minutes for receiver to warm up and test equipment.

Step	Marker Gen. Freq. (MC)	Sweep Gen. Frequency	Instructions
1	193.25 MC (Video Carrier) 197.75 MC (Sound Carrier)	Sweeping Channel 10. See frequency table at right.	Alternately adjust A10, A11 and A12 (figure 24) as required. Adjusting A11 will generally shift the center of the response curve in relation to the video and sound carrier markers. A10 and A12 should be alternately adjusted for best gain with flat top appearance. Consistent with proper band width and correct marker location, response curve should have maximum amplitude and flat top appearance; see figure 23.
2	Set the sweep generator to sweep the channel to be checked. Set the marker generator for the corresponding video carrier frequency and sound carrier frequency.		Check each channel operating in the service area for curve shown in fig. 23. In general, the adjustment performed in step 1 is sufficient to give satisfactory response curves on all channels. However, if reasonable alignment is not obtained on a particular channel, (a) check to see that coils have not been intermixed, or (b) try replacing the pair of coils for that particular channel, or (c) repeat step 1 for the weak channel as a compromise adjustment to favor this particular channel. If a compromise adjustment is made, other channels operating in the service area should be checked to make certain that they have not been appreciably affected.

RF AND MIXER ALIGNMENT FOR SETS USING TV TUNERS 94D46-2 AND 94D46-3

(These tuners use a 6BZ7 tube for RF amplifier V101.)

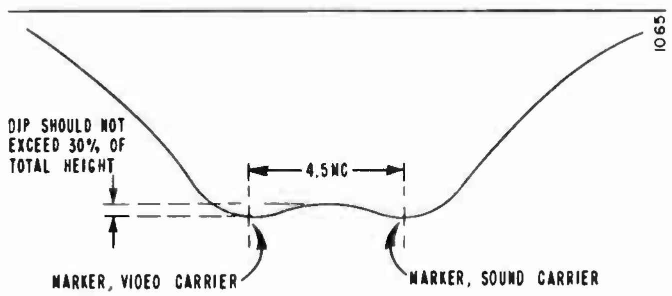
a. Connect negative of 4½ volt bias battery to AGC buss (test point "T"), positive to chassis. If it is difficult to obtain a curve of sufficient amplitude, remove battery and connect a wire jumper from test point "T" to chassis.

b. Connect sweep generator (with 300 ohm output) to antenna terminals. If sweep generator does not have a built-in marker generator, loosely couple a marker generator to the antenna terminals. To avoid distortion of the response curve, keep sweep generator output at a minimum, marker pips just barely visible.

c. Connect oscilloscope through a 10,000 ohm resistor to test point "W" on tuner (figure 24). Keep scope leads away from chassis.

d. Allow about 15 minutes for receiver and test equipment to warm up.

Step	Marker Gen. Freq. (MC)	Sweep Gen. Frequency	Instructions
1	193.25 MC (Video Carrier) 197.75 MC (Sound Carrier)	Sweeping Channel 10. See frequency table below.	Alternately adjust A11 and A12 (figure 24) as required to obtain equal peak amplitudes and symmetry, consistent with flat top appearance, proper band width and correct marker location; see figure 23.
2	83.25 MC (Video Carrier) 87.75 MC (Sound Carrier)	Sweeping Channel 6. See frequency table below.	Adjust A10 as required to obtain curve having maximum amplitude and flat top appearance consistent with proper band width and correct marker location; see figure 23. After completing adjustment, recheck adjustment of step 1.
3	Set the sweep generator to sweep the channel to be checked. Set the marker generator for the corresponding video carrier frequency and sound carrier frequency.		Check each channel operating in the service area for curve shown below. In general, the adjustment performed in steps 1 and 2 are sufficient to give satisfactory response curves on all channels. However, if reasonable alignment is not obtained on a particular channel, (a) check to see that coils have not been intermixed, or (b) try replacing the pair of coils for that particular channel, or (c) repeat step 1 for a weak high channel as a compromise adjustment to favor the particular channel. Repeat step 2 for the weak low channel to favor the particular low channel. If a compromise adjustment is made, other channels operating in the service area should be checked to make certain that they have not been appreciably affected.



Full skirt of curve will not be visible unless generator sweep width extends beyond 10 MC.
Figure 23. RF Response Curve.

FREQUENCY TABLE

Channel Number	Channel Freq., MC	Video Carrier, MC	Sound Carrier, MC	HF Osc., MC
2	54- 60	55.25	59.75	81
3	60- 66	61.25	65.75	87
4	66- 72	67.25	71.75	93
5	76- 82	77.25	81.75	103
6	82- 88	83.25	87.75	109
7	174-180	175.25	179.75	201
8	180-186	181.25	185.75	207
9	186-192	187.25	191.75	213
10	192-198	193.25	197.75	219
11	198-204	199.25	203.75	225
12	204-210	205.25	209.75	231
13	210-216	211.25	215.75	237

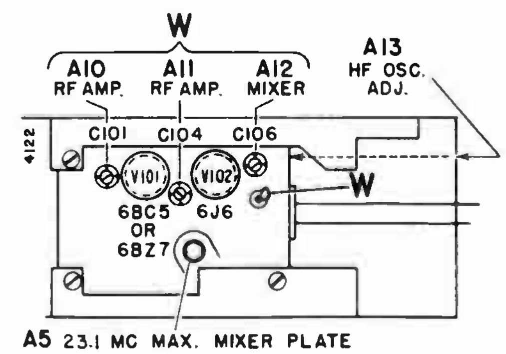


Figure 24. Top of TV Tuner, Showing Adjustment Location.

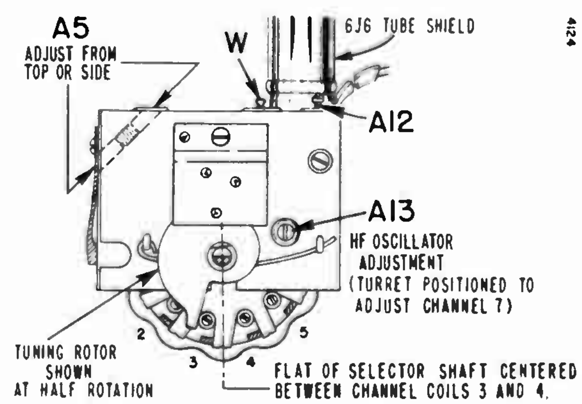

Figure 25. Front View of TV Tuner.

OVER-ALL RF AND IF RESPONSE CURVE CHECK

(Using sweep generator and oscilloscope)

Receiver Controls and Bias Battery	Sweep Generator	Marker Generator	Oscilloscope	Instructions
Picture control fully to the left. Channel selector on Channel 10 or other unassigned high channel. Connect negative of 4½ volt bias battery to test point "T", positive to chassis.	Connect to antenna terminals. Set generator to sweep channel selected. See frequency table on page 11. Keep generator output as low as possible, to prevent overloading. See section 2 of "Alignment Hints" on page 10.	If an external marker generator is used, loosely couple high side to sweep generator lead. Marker frequencies are shown in frequency table on page 11.	Connect to point "V" through a decoupling filter; see figs. 21 and 22.	Compare the response curve obtained against the ideal curve shown in figure 26. If the curve is not within tolerance, touch up the IF slug as instructed below. It should never be necessary to turn slugs more than one turn in either direction. If the curve is satisfactory on the channel checked, all other channels should also be satisfactory. IMPORTANT: When sweep output is reduced, response curve amplitude on scope should also decrease, but curve shape should remain the same. If curve shape changes, reduce sweep output and/or the scope gain until the shape does not change. See section 2 of "Alignment Hints", on page 10.

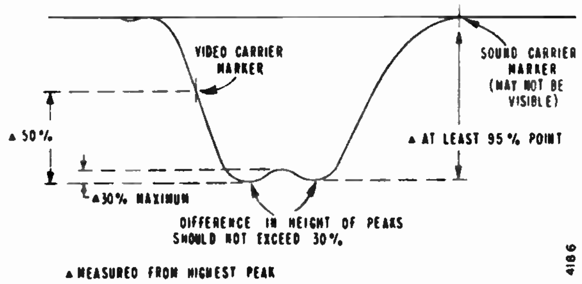

Figure 26. Ideal Over-all RF and IF Response Curve.

Note that video carrier (marker) on the "Over-all RF-IF Response Curve" will appear on the opposite side of the curve as compared to the "IF Response Curve" figure 18. This is due to action of the mixer tube.

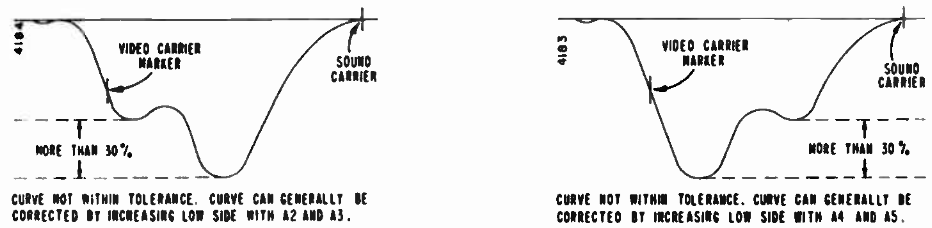

Figure 27. Over-all RF and IF Response Curves, Incorrect Shape.

HF OSCILLATOR ADJUSTMENT

(Using a signal generator)

It is always advisable to make HF oscillator adjustments using a Television Signal as instructed on page 2. If a Television Signal is not available, HF oscillator adjustment can be made using a crystal calibrated signal generator. Make adjustments as follows:

Receiver Control Settings	Signal Generator	Instructions
Set Channel selector for each channel to be adjusted. Set "Tuning" control at half rotation. Turn volume control fully to the right (clockwise).	Connect to antenna terminals. Set generator to exact frequency of HF oscillator. See frequency table on page 11. *Set generator for maximum output.*	Connect a wire jumper from test point "W" on the tuner to test point "Z". See figure 22. Remove the ratio detector tube V202 (6AL5). Carefully adjust the oscillator slug A13 on each channel until a whistle (beat) is heard in the speaker of the receiver.

SERVICING RADIO TUNER IN 19E1, 19G1 AND 19N1 MODELS

SERVICING RADIO TUBES AND DIAL LIGHT

The radio tubes and radio dial light can be serviced without removing the TV chassis from the cabinet. The radio tubes can be reached through the opening cut in the underside of the chassis shelf.

The dial light can be serviced by removing the tuning knobs and plastic control panel.

A number 44 dial light (part number 81A1-5) is used in sets stamped Run 5 or lower; a number 47 dial light (part number 81A1-8) is used in sets stamped Run 6 and higher.

REMOVING RADIO TUNER

The radio tuner is mounted at the front apron of the chassis. Alignment, taking voltage readings or an inspection of the underside of the radio tuner can be performed without complete removal of the radio tuner from the TV chassis. To gain access to the underside of the radio tuner, disconnect the tuning drive cord, remove the self-tapping screws at the rear of the radio tuner.

DIAL STRINGING

Dial stringing for the gang tuning control is shown below.

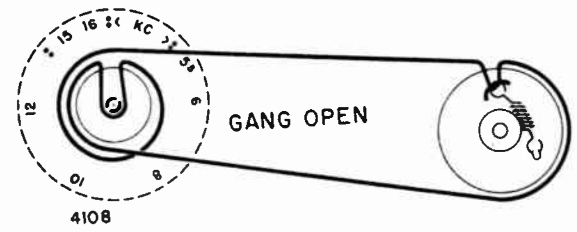

Figure 28. Dial Stringing for 19E1, 19G1 and 19N1 Chassis.

ALIGNMENT OF RADIO TUNER

The radio tuner in television and radio chassis should be aligned as instructed under "Radio Alignment Procedure" below.

The radio alignment trimmers are accessible without disassembly of the radio tuner from the TV chassis. The figure at right shows the locations of radio alignment trimmers.

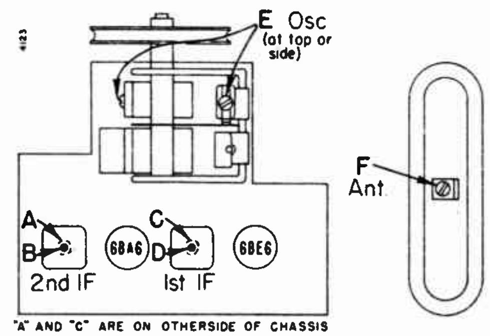

Figure 29. Radio Trimmer Locations.

RADIO ALIGNMENT PROCEDURE

- Connect output meter across speaker voice coil.
- Turn receiver Volume control fully on.
- Function switch in "Radio" position.
- Use lowest output setting of signal generator that gives a satisfactory reading on meter.
- Use a NON-METALLIC alignment tool for IF adjustments.
- Repeat adjustments to insure good results.

Step	Connect Signal Generator	Dummy Antenna Between Radio and Signal Generator	Signal Generator Frequency	Receiver Dial Setting	Adj. Trimmers in Following Order to Max.
1	Gang condenser antenna stator	.1 MFD	455 KC	Tuning gang wide open	*A-B (2nd IF) *C-D (1st IF)
2	"	"	1620 KC	"	E (oscillator)
3	Place generator lead close to loop of set to obtain adequate signal. No actual connection (signal by radiation).		1400 KC	Tune in signal	§F (antenna)

* Adjustments A and C made from underside of chassis. See figure 29 for trimmer locations.
§ AM antenna trimmer may not peak if antenna leads are not properly routed or separated.

PARTS LIST

Electrical components have symbols in 100 series, 200 series, etc., according to location on schematic. Order parts by part number and description from Admiral Distributor.

CHASSIS PARTS

RESISTORS

Sym.	Description	Part No.
R101	15,000 ohms, ½ watt	98A 45-67
R102	47,000 ohms, ½ watt	98A 45-17
R103	100,000 ohms, ½ watt in 94D46-2 and 94D46-3 tuners	94C 37-87
	2,200 ohms, ½ watt in 94D52-1 and 94D52-2 tuners	98A 45-19
R104	1,500 ohms, ½ watt in 94D46-2 and 94D46-3 tuners	60B 8-152
	1,000 ohms, ½ watt in 94D52-1 and 94D52-2 tuners	94C 37-86
R105	10,000 ohms, ½ watt in 94D46-2 and 94D46-3 tuners	98A 45-18
	4,700 ohms, ½ watt in 94D52-1 and 94D52-2 tuners	98A 45-20
R106	220,000 ohms, ½ watt	98A 45-21
R107	10,000 ohms, ½ watt	98A 45-18
R108	8,200 ohms, ½ watt in 94D46-2 and 94D46-3 tuners	60B 8-822
	6,800 ohms, ½ watt in 94D52-1 and 94D52-2 tuners	60B 8-682
R109	15,000 ohms, ½ watt	98A 45-67
R110	100,000 ohms, ½ watt	94C 37-87
R111	160,000 ohms, ½ watt	60B 8-164
R201	470,000 ohms, ½ watt	60B 8-474
R202	68 ohms, ½ watt, carbon only	60B 28-44
R203	330 ohms, ½ watt	60B 8-331
R204	10,000 ohms, ½ watt	60B 8-103
R205	10,000 ohms, ½ watt	60B 8-103
R206	390 ohms, ½ watt	60B 8-391
R207	47,000 ohms, ½ watt	60B 8-473
R208A	1 megohms, **Volume**	75B 11-21
R208B	1,000 ohms, **Picture** (R208 includes switch S501)	
‡R209	4.7 megohms, ½ watt	60B 8-475
†R210	470,000 ohms, ½ watt	60B 8-474
†R211	1 megohm, ½ watt	60B 8-105
R212	4,700 ohms, ½ watt, 5% (in comb. sets, stamped Run 2 or lower)	60B 7-472
	2,000 ohms, ½ watt, 5% (in comb. sets, stamped Run 3 and higher)	60B 7-202
	3,600 ohms, ½ watt, 5% (in TV only sets, stamped Run 2 or lower)	60B 7-362
	1,500 ohms, ½ watt, 5% (in TV only sets, stamped Run 3 and higher)	60B 7-152
R213	1,100 ohms, ½ watt, 5% (in chassis stamped Run 2 or lower)	60B 7-112
	910 ohms, ½ watt, 5% (in chassis stamped Run 3 and higher)	60B 7-911

† Component may be part of couplate, part number 63B6-5. Replace with exact duplicate or individual componets.
‡ Component may be part of couplate, part number 63B6-10. Replace with exact duplicate or individual components.

Sym.	Description	Part No.
R214	2,200 ohms, 2 watt in early comb. sets	60B 20-222
	1,200 ohms, 5 watt in later comb. sets	61A 1-10
	1,200 ohms, 1 watt in TV only sets	60B 14-122
	(R214 and R215 are single resistor in later 19E1, 19G1 and 19N1 sets, see production change).	
R215	2,200 ohms, 2 watt	60B 20-222
R216	2 megohms, **Tone control**	75B 13-22
R217	82,000 ohms, ½ watt	60B 8-823
R218	2,000 ohms, ½ watt, 5% (in chassis stamped Run 2 or lower)	60B 7-202
	1,500 ohms, ½ watt, 5% (in chassis stamped Run 3 and higher)	60B 7-152
R219	2,500 ohms, 7.5 watt	61A 1-23
R220	15,000 ohms, ½ watt	60B 8-153
R221	15,000 ohms, 5 watt	61A 1-7
R222	1,000 ohms, 2 watt	60B 20-102
R223	470 ohms, ½ watt	60B 8-471
R224	47,000 ohms, ½ watt	60B 8-473
R225	1 megohm, **Volume** (R225 includes switch S501)	75C 2-16
R301	1,000 ohms, ½ watt (in chassis stamped Run 2 or lower)	60B 8-102
	3.3 megohms, ½ watt (in chassis stamped Run 3 and higher)	60B 8-335
R302	8,200 ohms, ½ watt, 5%	60B 7-822
R303	47 ohms, ½ watt, carbon only	60B 28-45
R304	330 ohms, ½ watt	60B 8-331
R305	1,000 ohms, ½ watt	60B 8-102
R306	22,000 ohms, ½ watt	60B 8-223
R307	330 ohms, ½ watt	60B 8-331
R309	330 ohms, ½ watt (in chassis stamped Run 2 or lower)	60B 8-331
	1,000 ohms, ½ watt (in chassis stamped Run 3 and higher)	60B 8-102
R310	100 ohms, ½ watt, in sets using 94D46-2 and 94D46-3 tuners	60B 28-19
	68 ohms, ½ watt, in sets using 94D52-1 and 94D52-2 tuners (R310 is carbon resistor only)	60B 28-44
R311	10,000 ohms, ½ watt, 5%	60B 7-103
R312	330 ohms, ½ watt (in chassis stamped Run 2 or lower)	60B 8-331
	1,000 ohms, ½ watt (in chassis stamped Run 3 and higher)	60B 8-102
R313	100 ohms, ½ watt	60B 8-101
R314	330 ohms, ½ watt	60B 8-331
R315	2 megohms, **DX Range Finder control**	75B 1-53
R316	33,000 ohms, ½ watt	60B 8-333
R317	820,000 ohms, ½ watt (in chassis stamped Run 2 or lower)	60B 8-824
	470,000 ohms, ½ watt (in chassis stamped Run 3 and higher)	60B 8-474

Sym.	Description	Part No.
R318	4,700 ohms	Part of L302
R319	5,600 ohms, ½ watt	60B 8-562
R320	1 megohm, ½ watt	60B 8-105
R321	1,000 ohms, **Picture control**	See R208B
R322	33,000 ohms, ½ watt	60B 8-333
R323	33,000 ohms	Part of L305
R324	10,000 ohms	Part of L306
R325	2,700 ohms, ½ watt	60B 8-272
R326	2,700 ohms, ½ watt (in chassis stamped Run 2 or lower)	60B 8-272
	5,600 ohms, 1 watt (in chassis stamped Run 3 and higher)	60B 14-562
R327	22,000 ohms, ½ watt	60B 8-223
	27,000 ohms, ½ watt	60B 8-273
	(R327 is 22,000 ohms when couplate 63B6-4 is used and 27,000 ohms when couplate 63B6-8 is used. See Run 7 production change on page 17.)	
*R328	15,000 ohms, ½ watt	60B 8-153
*R329	270,000 ohms, ½ watt	60B 8-274
R330	180,000 ohms, ½ watt (R330 was 470,000 ohms in early sets)	60B 8-184

R402	12,000 ohms, ½ watt	60B 8-123
R403	47,000 ohms, ½ watt	60B 8-473
R404	2.7 megohms, ½ watt	60B 8-275
R405	33,000 ohms, 2 watt in comb. sets	60B 20-333
	18,000 ohms, 1 watt in "TV only" sets	60B 14-183
R406	15,000 ohms, ½ watt in comb. sets	60B 8-153
	22,000 ohms, ½ watt in "TV only" sets	60B 8-223
§R407	22,000 ohms, ½ watt (See Run 7 production change on page 17.)	60B 8-223
§R408	8,200 ohms, ½ watt	60B 8-822
§R409	8,200 ohms, ½ watt	60B 8-822
R410	1.2 megohms, ½ watt	60B 8-125
R411	1.5 megohms, **Vertical Hold**	75B 13-26
R412	10,000 ohms, ½ watt, 5%	60B 7-103
R413	1 megohm, ½ watt	60B 8-105
R414	2.5 megohms, **Height**	75B 13-3
R415	1 megohm, ½ watt	60B 8-105
R416	3,000 ohms, **Vert. Lin.**	75B 13-7
R417	820 ohms, ½ watt	60B 8-821
R418	560 ohms, ½ watt	60B 8-561
R419	560 ohms, ½ watt	60B 8-561
R420	330,000 ohms, ½ watt	60B 8-334
R421	820,000 ohms, ½ watt	60B 8-824
R422	330,000 ohms, ½ watt, 5%	60B 7-334
R423	82,000 ohms, ½ watt, 5%	60B 7-823
R424	3,900 ohms, ½ watt	60B 8-392
R425	68,000 ohms, ½ watt	60B 8-683
R426	50,000 ohms, **Hor. Hold**	75B 13-23
R427	22,000 ohms, ½ watt	60B 8-223
R428	150,000 ohms, ½ watt, 5%	60B 7-154
R429	8,200 ohms, ½ watt	60B 8-822
R430	150,000 ohms, ½ watt	60B 8-154
R431	820,000 ohms, ½ watt	60B 8-824
R432	82,000 ohms, ½ watt	60B 8-823

Sym.	Description	Part No.
R433	1 megohm, ½ watt	60B 8-105
R434	68 ohms, ½ watt, carbon only	60B 28-44
R435	47 ohms, 1 watt	60B 14-470
R436	82 ohms, ½ watt, carbon only	60B 28-31
R437	8,200 ohms, 2 watt	60B 20-822
R438	1,200 ohms, 2 watt	60B 20-122
R439	1,000 ohms, 2 watt	60B 20-102
R440	1,000 ohms, ½ watt	60B 8-102
R441A	1.5 megohms, **Vert. Hold**	75B 17-3
R441B	50,000 ohms, **Hor. Hold**	
R442	4.7 ohms, ½ watt, carbon only	60B 28-11
R443	8,200 ohms, ½ watt	60B 8-822
	(R443 used only when couplate is part number 63B6-2.) See Run 7 production change on page 17.)	
R444	2,700 ohms, ½ watt	60B 8-272
R445	56,000 ohms, ½ watt	60B 8-563
R501	270,000 ohms, 1 watt	60B 14-274
R701	22,000 ohms, ½ watt	60B 8-223
R702	10,000 ohms, 1 watt	60B 14-103
R703	150 ohms, ½ watt	60B 8-151
R704	27,000 ohms, 1 watt	60B 14-273
R706	1 megohm, ½ watt	60B 8-105
R707	4.7 ohms, ½ watt	60B 28-11
	10 ohms, ½ watt	60B 28-100
	(R707 is 4.7 ohms when #44 pilot light is used and 10 ohms when #47 pilot light is used. See production change on page 9.)	

CONDENSERS

Sym.	Description	Part No.
C101	3 to 9 mmfd, ceramic trimmer	98A 45-96
C102	.001 mfd, min, ceramic	98A 45-24
C103	800 mmfd, min, ceramic feed-thru in 94D46-2 and 94D46-3 tuners	94C 37-90
	150 mmfd, ceramic N470 in 94D52-1 and 94D52-2 tuners	94D 52-86
C104	.5 to 3 mmfd, N470 ceramic trimmers	98A 45-23
C105	47 mmfd, ceramic, N1400 temp. coeff. in 94D46-2 and 94D46-3 tuners	94D 47-50
	120 mmfd, 5% ceramic, N750 temp. coeff. in 94D52-1 and 94D52-2 tuners	98A 45-25
C106	.5 to 3 mmfd, ceramic trimmer	98A 45-23
C107	10 mmfd, 5% ceramic, N750 temp. coeff.	98A 45-64
C108	10 mmfd, 5%, cer, N750 temp. coeff.	98A 45-64

	for Channel #7	94D 46-77
	for Channel #8	94D 46-78
	for Channel #9	94D 46-79
	for Channel #10	94D 46-80
	for Channel #11	94D 46-81
	for Channel #12	94D 46-82
	for Channel #13	94D 46-83
L101	Antenna Coil (Stamped 2H, 3H, etc.) — For 94D 52-1 and 94D 52-2 TV tuners only	
	for Channel #2	94D 52-52
	for Channel #3	94D 52-53
	for Channel #4	94D 52-54
	for Channel #5	94D 52-55
	for Channel #6	94D 52-56
	for Channel #7	94D 52-57
	for Channel #8	94D 52-58
	for Channel #9	94D 52-59
	for Channel #10	94D 52-60
	for Channel #11	94D 52-61
	for Channel #12	94D 52-62
	for Channel #13	94D 52-63
L102	Mixer—Osc. Coil (Stamped 2H, 3H, etc.) — For 94D 52-1 and 94D 52-2 TV tuners only	
	for Channel #2	94D 52-72
	for Channel #3	94D 52-73
	for Channel #4	94D 52-74
	for Channel #5	94D 52-75
	for Channel #6	94D 52-76
	for Channel #7	94D 52-77
	for Channel #8	94D 52-78
	for Channel #9	94D 52-79
	for Channel #10	94D 52-80
	for Channel #11	94D 52-81
	for Channel #12	94D 52-82
	for Channel #13	94D 52-83
L103	Mixer Plate Coil	94D 46-85
L104	Heater RF Choke	98A 45-13
L105	Heater RF Choke	98A 45-14
L109	Mixer Plate Choke	94D 46-86
L201	Sound Take-Off Coil	72B 99-7
L301	Trap Coil includes (C303, C304)	72C 96-23
L302	Video Peaking Coil (wound on R318)	73A 5-15
L303	Video Peaking Coil	73A 5-7
L304	Trap Coil	72B 99-6
L305	Video Peaking Coil (wound on R323)	73A 5-13
L306	Video Peaking Coil (wound on R324)	73A 5-9
L307	Heater RF Choke	73A 2-5
L401	**Hor. Lock control**	Part of T404
L402	**Width control**	94A 49-1
L403	**Hor. Linearity control**	94A 50-1
L501	Filter Choke	74B 18-2
L702	Oscillator Coil	69A 52-4
L704	AM Antenna, Iron Core	69C 155-2
T201	Ratio Detector Transformer	72B 68-1
T202	Audio Output Transformer	79A 8
T301	1st IF Transformer in sets using 94D46-2 and 94D46-3 tuners	72C 96-25
	1st IF Transformer in sets using 94D52-1 and 94D52-2 tuners	72C 96-21
T302	2nd IF Transformer	72C 96-22
T303	3rd IF Transformer	72B 107-1
T401	Vert. Blocking Oscillator Transformer	79A 18-4
T402	Vert. Output Transformer	79D 40-2
T403	Deflection Yoke	94C 51-1
T404	Hor. Blocking Oscillator Transformer (includes **Hor. Freq. control L401**)	69B 110
T405	Hor. Output Transformer	79D 41-1
T501	Power Transformer	80C 35-1
T701	1st IF Transformer	72B 28-7
T702	2nd IF Transformer	72B 28-7

MISC. PARTS FOR 94D46-2, 94D46-3, 94D52-1 and 94D52-2 TV TUNERS

See page 7 for parts illustration.

Sym.	Description	Part No.
M104	Shaft Shell & Rotor Assy. (Sharp Tuning) with 6" long shaft shell for 94D46-2 and 94D52-1 tuners	94D 46-87
	with 6¾" long shaft shell for 94D46-3 and 94D52-2 tuners	94D 46-90
M107	Bracket, Sharp Tuning Rotor Retaining	98A 45-95
M108	Spring, Detent Plate Grounding	98A 45-94
M109	Shield, Tube (Slotted) for 6J6	98A 45-73
M110	Shield, Tube plain, for 6BC5	87A 7-7
	plain, for 6BZ7	94C 37-94
M112	Spring, Slug Retaining (Osc. coil)	98A 45-52
M113	Washer, Fibre Spacer (¼" ID x ½" OD)	98A 45-63
M114	Nut, Locking Spring (for trimmers)	98A 45-31
M115	Screw, Trimmer (4-36 x ⅝")	98A 45-33
M116	Screw, Bracket Mtg. (6-32 x ¼")	98A 45-62
M117	Slug, Oscillator Coil Tuning	98A 45-88
M118	Stator Plate (ungrounded); Silver with Ceramic Insulator, for Sharp Tuning C111 (includes mtg. bracket)	98A 45-86
M121	Roller, Detent (⅜" dia., 3/32" dia. bearing)	98A 45-82
M122	Spring, Detent (2 1/16" long)	98A 45-81
M123	Contact Plate and Bracket Assembly	98A 45-84
M124	Spring, Sharp Tuning Rotor Contact (Flat bronze 1 1/16" x ½")	98A 45-83
M125	Spring, Front and Rear Turret Shaft (Wire 2¾" long, 3/16" dia.)	98A 45-85
M126	Turret and Shaft Assembly (less coils) with 6⅞" shaft for 94D46-2 and 94D52-1 tuners	94D 46-88
	with 7¾" shaft for 94D 46-3 and 94D52-2 tuners	94D 46-91
M127	Shield, Bottom	94C 37-92
M128	Shield, Side	94C 37-93
	Socket, Tube (mica filled) miniature, 7 pin	94C 37-95
	miniature, 9 pin	94C 37-96
M130	Tuner, Television (complete) cascode type (in sets with 20" or 21" picture tube) for sets Run 5 or lower	94D 46-2
	for sets Run 6 and higher	94D 46-3
	pentode type (in sets with 17" picture tube) for sets Run 5 or lower	94D 52-1
	for sets Run 6 and higher	94D 52-2
	(See Run 6 production change on page 9.)	

MISCELLANEOUS CHASSIS PARTS

For picture tube mtg. parts, see separate headings.

Sym.	Description	Part No.
M201	Speaker Socket	87A 4-1
M202	Speaker Plug (2 pin)	88A 5-5
	Speaker Plug (4 pin)	88B 22-1
M203	Speaker	See Cabinet Parts List
M401	Horiz. Output Fuse, ⅜ amp, 250 volts	84A 4-3
	Fuse Holder	84A 5-1
M501	Interlock Socket (Male)	89A 22-2
M502	Line Cord, with interlock socket	89A 22-1
M701	Socket, Phono Input	88A 1
S501	Switch, On-Off Power (S.P.S.T.)	Part of R208 or R225
S701	Switch, Function (complete)	77C 43
	Bracket, Tuner Shaft (Bakelite)	32A 170-1
	Clip, Tube Cap for 6BQ6GT tube	88A 16-17
	for 1B3GT tube	19A 54
	Corona Ring	15A 853
	Connector Lead, 2nd Anode for 17" Picture tube	88A 16-16
	for 20" Picture tube	88A 16-18
	Control Shaft, Focus Assembly (nylon)	94C 53-50
	Focus Assembly, PM	94C 53-1
	Fuse, ⅜ amp, 250 volts	84A 4-3
	Fuse Holder	84A 5-1
	Ion Trap	94A 15-3

* Component may be part of couplate, part number 63B6-4 or 63B6-8. Replace with exact duplicate or individual components.

§ Component may be part of couplate, part number 63B6-2 or 63B6-11. Replace with exact duplicate or individual components.

† Component may be part of couplate, part number 63B6-5. Replace with exact duplicate or individual componets.

‡ Component may be part of couplate, part number 63B6-10. Replace with exact duplicate or individual components.

Description	Part No.
Knob, DX Range Finder	33A 23-4
Plastic Tubing (for 2nd anode lead)	96B 18-2-16-0
Pilot Light (#44)	81A 1-5
Pilot Light Socket	82A 18-1
Shield, Tube	
for 7 pin miniature tube	
plain type	87A 7-17
slotted type	98A 45-73
for 9 pin miniature tube	87A 7-12
Shield, H.V. Compartment	15D 855
Shield, Mica Filled (for mtg. 1B3GT tube socket)	33B 91
Socket, Tube	
miniature bakelite (7 pin)	87A 3-7
miniature bakelite (7 pin) for 6AS5	87A 33-1
octal, plain	87A 5-1
octal, twist-lock (for 1B3GT)	87A 36
miniature (9 pin) for 6S4	87A 14-2
miniature (9 pin) for 6U8 and 12AU7	87A 37-1
picture tube (17")	87A 32-6
picture tube (20")	87A 32-7
Tuner, Television (complete)	
cascode type (in sets with 20" or 21" pic. tube)	
for sets Run 5 or lower	94D 46-2
for sets Run 6 and higher	94D 46-3
pentode type (in sets with 17" picture tube)	
for sets Run 5 or lower	94D 52-1
for sets Run 6 and higher	94D 52-2
(See Run 6 production change on page 9.)	

MISC. RADIO PARTS FOR 19E1, 19G1 and 19N1 CHASSIS

Sym.	Description	Part No.
M701	Socket, Phono Input	88A 1
M706	Socket, Phono Motor	88A 8-7
S701	Switch, Function (complete)	77C 43
	Clip, IF Transformer Mounting	72B 28-10
	Dial Cord (30" length needed)	50A 1-3
	Drum, Gang	A3797
	Grommet, Gang Mounting	12B 1-2
	Lock Washer, Osc. Coil & Gang (#6 I.T.)	3B 1-25-24
	Pilot Light #44	81A 1-5
	Pilot Light #47	81A 1-8
	Pilot Light Shield	82A 5-3
	Screw, Drum Set (#6-32x⅛ Allen Hd.)	1A 43-14
	Sleeve, Tuning (includes drum)	AA231
	Socket, Pilot Light	82A 18-1
	Socket, Tube, 7 pin miniature	87A 3-7
	Spacer Sleeve (for gang mounting)	29A 2-1-24
	Spring, Dial Cord Tension	19C 1-5
	Spring, Tube Retaining	19A 56-4
	Washer, Vellutex (oscillator coil mtg.)	5A 1-21

PARTS FOR MOUNTING 17BP4 (17") PICTURE TUBE

Description	Part No.
Bracket, Web Strap Clamping	15A 787
Bracket, Strap (supports yoke coil)	15A 572
Bracket, Tie Rod Mounting	15B 859
Bracket, Tube Stop	15A 856
Bracket, Yoke Housing	15C 613-1
Bracket, Yoke Housing Support	
right side (facing rear)	15C 860-1
left side (facing rear)	15C 860-2
Connector Lead, 2nd Anode	88A 16-16
Fibre Support (for 2nd anode lead)	32A 178-1
Ion Trap	94A 15-3
Nut (#8-32x⅛) for threaded end of tie rod	2A 1-15-24
Plastic Tubing (used between 2nd anode lead and chassis)	96B 18-2-16-0
Rubber Collar (mounts over picture tube neck)	12B 40
Rubber Strip, Adhesive (1/16x¾x2)	12B 5-6
Rubber Strip, Adhesive (1/32x2¾x1¼)	12A 39-12
Rubber Strip, Adhesive (1/16x1⅝x1⅝)	12A 39-17
Screw, Wing (for deflection yoke)	1A 101-1-24
Tie Rod (#8-32 thread)	28A 63-1
Tube Support (front of tube)	33B 93
Webbing, Picture Tube Mounting Strap (44" length)	50A 3-6

PARTS FOR MOUNTING 20DP4A (20") PICTURE TUBE

Description	Part No.
Bracket, Strap and Spade Bolt Mounting	15A 858
Bracket, Strap (supports yoke coil)	15A 572
Bracket, Tie Rod Mounting	15B 862
Bracket, Tube Stop	15A 857
Bracket, Yoke Housing	15C 613-1
Bracket, Yoke Housing Support	
right side (facing rear)	15C 861-1
left side (facing rear)	15C 861-2
Connector Lead, 2nd Anode	88A 16-18
Fibre Support (for 2nd anode lead)	32A 178-2
Ion Trap	94A 15-3
Nut, Tube Mounting Strap (¼-20 Hex.)	2A 1-23-24
Nut for threaded end of tie rod (#8-32x⅛)	2A 1-15-24
Plastic Tubing (used between 2nd anode lead and chassis)	96B 18-2-16-0
Rubber Channel (used under metal strap)	
36" length	12A 47-4
Rubber Collar (used over picture tube neck)	12B 40
Rubber Strip, Adhesive (1/32x2¾x1¼)	12A 39-12
Rubber Strip, Adhesive (1/16x1⅝x1⅝)	12A 39-17
Screw, Wing (for deflection yoke)	1A 101-1-24
Strap and Spade Bolt Assembly	A3762
Tie Rod (#8-32 thread)	28A 64-1
Tube Front Support	33B 89

PARTS FOR MOUNTING 21WP4 OR 21WP4X (21") PICTURE TUBE

Description	Part No.
Bracket, Strap and Spade Bolt Mounting	15A 858
Bracket, Strap (supports yoke coil)	15A 572
Bracket, Tie Rod Mounting	15B 862-1
Bracket, Tube Stop	15A 857
Bracket, Yoke Housing	15C 613-1
Bracket, Yoke Housing Support	
for 21WP4 tube	
right side (facing rear)	15C 867-2
left side (facing rear)	15C 867-1
for 21WP4X tube	
right side (facing rear)	15C 861-1
left side (facing rear)	15C 861-2
Connector Lead, 2nd Anode	88A 16-18
Fibre Support (for 2nd anode lead)	32A 183
Ion Trap	94A 15-3
Nut, Tube Mounting Strap (¼-20 Hex.)	2A 1-23-24
Nut for threaded end of tie rod (#8-32x⅛)	2A 1-15-24
Plastic Tubing (used between 2nd anode lead and chassis)	96B 18-2-16-0
Rubber Channel (used under metal strap)	
36" length	12A 47-4
Rubber Collar (mounts over picture tube neck)	12B 40
Rubber Strip, Adhesive (1/32x2¾x1¼)	12A 39-12
Rubber Strip, Adhesive (1/16x1⅝x1⅝)	12A 39-17
Screw, Wing (for deflection yoke)	1A 101-1-24
Strap and Spade Bolt Assembly	
for 21WP4 tube	A3846
for 21WP4X tube	A3742
Tie Rod (#8-32 thread)	
for 21WP4 tube	28A 40-4
for 21WP4X tube	28A 64-1
Tube Support (front of tube)	33B 108

PARTS FOR MOUNTING 21EP4A (21") PICTURE TUBE

Description	Part No.
Bracket, Strap (supports yoke coil)	15A 572
Bracket, Strap and Spade Bolt Mounting	15B 878
Bracket, Tie Rod Mounting	15B 862-1
Bracket, Tube Stop	
on sides of tube	15A 808
on front of chassis	15B 876
Bracket, Yoke Housing	15C 613-1
Bracket, Yoke Housing Support	
right side (facing rear)	15C 877-1
left side (facing rear)	15C 877-2
Connector Lead, 2nd Anode	88A 16-18
Fibre Support (for 2nd Anode lead)	32A 183
Ion Trap	94A 15-3
Lever, Picture Positioning	15B 574
Magnet, Correcting (with mtg. bracket)	A3614
Nut, Tube Mounting Strap (¼-20 Hex.)	2A 1-23-24
Nut for threaded end of tie rod (8-32x⅛ Hex.)	2A 1-15-24
Plastic Tubing (used between 2nd anode lead and chassis)	96B 18-12-16-0
Rubber Channel (used under metal strap)	
26" length	12B 47-2
5" length	12B 47-7
Rubber Collar (used over picture tube neck)	12B 40
Rubber Strip, Adhesive (1/32x2¾x1¼)	33A 39-12
Rubber Strip, Adhesive (1/32x1½x½)	12A 39-14
Rubber Strip, Adhesive (1/32x3½x1½)	12A 39-16
Rubber Strip, Adhesive (1/16x1¼x3)	12B 5-36
Screw, Wing (for deflection yoke)	1A 101-1-24
Spring, Tube Grounding	19A 23-2
Strap and Spade Bolt Assembly	A3617
Tie Rod	
sides of tube (#8-32 thread)	28B 52-6
bottom of tube (#8-32 thread)	28A 64-3
Tube Support (front)	33B 97

PARTS FOR MOUNTING 21ZP4A (21½") PICTURE TUBE

Description	Part No.
Bracket, Strap and Spade Bolt Mounting	15B 878
Bracket, Strap (supports yoke coil)	15A 572
Bracket, Tie Rod Mounting	15B 862-1
Bracket, Tube Stop	15B 896
Bracket, Yoke Housing	15C 613-1
Bracket, Yoke Housing Support	
right side (facing rear)	15C 877-1
left side (facing rear)	15C 877-2
Connector Lead, 2nd Anode	88A 16-18
Fibre Support (for 2nd anode lead)	32A 183
Ion Trap	94A 15-3
Nut, Tube Mounting Strap (¼-20 HH)	2A 1-23-24
Nut for threaded end of tie rod (#8-32 x ⅛)	2A 1-15-24
Plastic Tubing (used between 2nd anode lead and chassis)	96B 18-2-16-0
Rubber Channel (used under metal strap)	
26" length	12A 47-2
5" length	12A 47-7
Rubber Collar (used over picture tube neck)	12B 40
Rubber Strip, Adhesive (1/32 x 2¾ x 1¼)	12A 39-12
Rubber Strip, Adhesive (1/32 x 3½ x 1½)	12A 39-16
Rubber Strip, Adhesive (1/16 x 1¼ x 3)	12B 5-36
Screw, Wing (for deflection yoke)	1A 101-1-24
Spring Tube Grounding	19A 23-2
Strap and Spade Bolt Assembly	A3909
Tie Rod (#8-32 thread)	
bottom tube	28A 64-3
sides of tube	28B 52-6
Tube Front Support	33B 97

TUNING KNOBS and ASSOCIATED PARTS

Description	Part No.
Knob, Radio Tuning	
"Tuning"	33D 88-19
"T-R-P" (TV-Radio-Phonograph)	33B 90-4
Knob, Television Tuning	
maroon, "Channel"	
with gold inserts	33C 53-23
less inserts	33C 53-26
less inserts for 17DX12 only	33C 53-5
maroon, "Tuning"	
with gold ring	33D 88-21
less gold ring	33D 88-23
less gold ring for 17DX12 only	33C 53-6
maroon, "Off-Volume"	
2¼" diameter, with gold inserts	33C 53-24
2⅛" diameter, with gold inserts	33C 53-25
less inserts	33C 53-27
less inserts for 17DX12 only	33C 53-7
maroon, "Picture"	
with gold ring	33D 88-20
less gold ring	33D 88-22
less gold ring for 17DX12 only	33C 53-8
maroon, "Vertical"	33A 92-3
brown, "Channel" (with gold insert)	33C 53-29
brown, "Tuning"	33C 53-18
brown, "Off-Volume" (with gold insert)	33C 53-31
brown, "Picture"	33C 53-20
ebony, "Channel"	33C 53-1
ebony, "Tuning"	33C 53-2
ebony, "Off-Volume"	33C 53-3
ebony, "Picture"	33C 53-4
ebony, "DX Range Finder"	33A 23-4
Spring, TV Knob Tension	
for "Off-Volume" knob	18A 43-2
for "Tuning" knob	18A 43-1
for "Channel" knob	18A 43-3
Washer, Felt (used behind Tuning knob)	5A 4-14
Washer, Fibre (used behind Volume knob)	
for TV only models	5A 1-36
for combination models	5A 1-38

CABINET PARTS

Description	17DX10 Walnut	17DX11 Ebony	17DX12 Mahog.	121DX10 Walnut	121DX11 Ebony	121DX12 121DX12A Mahog.

SCHEMATIC NOTES

Run numbers are rubber stamped at the rear of the chassis.

Numerical symbols ①, ②, ③, etc. indicate run numbers for all 19 series chassis.

A1, A2,.....Y, Z, etc. indicate alignment points and alignment connections.

IMPORTANT: Before making waveform and voltage measurements, see instructions below.

WAVEFORM DATA
(Waveforms given on schematic)

Waveforms taken with PICTURE control set fully to the right, all other controls set for normal picture (in sync). DG Range Finder control set fully to the left (at "0" position). WARNING: Incorrect adjustment of the DX Range Finder control will cause waveform distortion.

Waveforms at video and sync stages obtained with transmitted signal input to receiver.

Waveform at pins 1 and 4 of V403 and terminal "C" (2) of T404 taken with a 10 mmfd. condenser connected in series with the oscilloscope high side.

The oscilloscope sweep is adjusted for 30 cycles (which is one-half of the vertical frequency), or for 7875 cycles (which is one-half of the horizontal frequency) so that two pulses appear on the screen.

The peak-to-peak voltage readings shown are subject to some variations due to response of the oscilloscope and parts tolerances.

CAUTION

Pulsed high voltage is present on the caps of V404 and V405 and at pin 3 of V406. Do not make direct connection to these points with ordinary test equipment. Waveform and peak-to-peak voltage at pin 3 of V406 taken, using an oscilloscope with a capacitive voltage divider probe. Waveform at V406 can also be taken by clipping or twisting the lead from the oscilloscope high side over the insulation on the lead connecting to pin 3. When taking the waveform this way, the shape of waveform will be the same but the peak-to-peak voltage will be much lower, depending upon the degree of coupling.

TV VOLTAGE DATA
(Voltages given on schematic)

- PICTURE control turned fully clockwise. CHANNEL control set on an unused channel. Other front controls set at approximately half rotation. Vert. Lin. and Height set at approximately half rotation. DX Range Finder control set fully to the left (at "0" position).
- Antenna disconnected from set with terminals shorted.
- Voltages marked with an asterisk * will vary widely with control setting.
- Line voltage 117 volts AC.
- Voltages measured with a vacuum-tube voltmeter between tube socket terminals and chassis, unless otherwise indicated.
- Voltages at V101 and V102 (TV Tuner) are measured with tube in socket. Use an adapter or lift tube out of socket just high enough to allow a needle point probe to contact tube pins.

  In tuners using a 6BZ7 tube, voltages taken at pins 1 and 8 must be taken as described above or no voltage reading will be obtained.
- Voltages at V306 measured from top of socket with tube removed.

CAUTION

Pulsed high voltages are present on the cap of V404, pin 3 of V406 and on the filament terminals and cap of the 1B3GT tube. NO ATTEMPT SHOULD BE MADE TO TAKE MEASUREMENTS FROM THESE POINTS WITHOUT SUITABLE TEST EQUIPMENT.

Picture tube 2nd anode voltage can be measured from the 2nd anode connector and should be taken only with a high voltage instrument such as a kilovoltmeter. 2nd anode voltage is approximately 15 KV. Proper filament voltage check of the 1B3GT tube may be made by observing filament brilliancy as compared with that obtained with a 1.5 volt dry cell battery.

SPECIFICATIONS

Picture Tube

Direct View Electromagnetic. See Model Identification Chart for different picture tubes used.

Operating Voltage

110-120 volts. 60 cycles, AC.

Wattage

200 watts for all models.

Input Impedance and Transmission Line

300-ohm balanced (between antenna terminals).

Note that 72 ohm coaxial cable may be used by connecting the outer conductor to the chassis and the inner conductor to either antenna terminal. In weak signal areas, the use of coaxial cable should be avoided.

Antenna

All models equipped with a built-in TV antenna. TV-Radio models equipped with a built-in radio antenna.

Intermediate Frequencies

Video 25.75 MC. Sound 21.25 MC.

Intercarrier Sound 4.5 MC.

Radio 455 KC. (TV-Radio models).

Fuse Location

The horizontal output circuit is fused with a ¼ amp., 250 volt fuse, part number 84A4-2. The fuse is located at the rear of the high voltage compartment.

Record Changer

The model RC600 record changer is used in combination models. The changer model number is on the top rear of the changer pan and also on the changer model label on the underside of the changer.

TELEVISION CHASSIS NOTES

The 22C2 and the 22E2 chassis employ the same basic television circuitry. The 22C2 chassis is a 22 tube television only set. The 22E2 chassis is a 24 tube television and radio set used in combination models. Both the 22C2 and 22E2 chassis use a 21EP4A (cylindrical faced) picture tube which mounts directly on the chassis.

NEW FEATURES IN 22C2 AND 22E2 CHASSIS

New TV Tuner (part number 94D47-2): This tuner uses the same basic cascode RF amplifier and oscillator mixer circuit as used in earlier cascode TV tuners. The principal differences in the 94D47-2 tuner over earlier cascode TV tuners are confined mainly to the RF amplifier circuit and coupling between the RF mixer and the IF amplifier circuit. An overall HF oscillator adjustment is omitted from the tuner since it is not required.

Some of the principal features of this new improved TV tuner are high sensitivity, high signal to noise ratio and built-in adjacent channel sound and picture traps (19.75MC and 27.25MC). Design of the cascode RF amplifier circuit has been optimized for use of the 6BZ7 tube.

Improved IF Amplifier: Increased gain, greater bandwidth, higher and more uniform sound level and greater elimination of 4.5MC beat interference are some of the features of this new IF amplifier.

A 12AT7 tube is used as the video detector and 1st sound IF amplifier. Some early production sets used a 12AU7 as video detector and 1st sound IF amplifier.

DX Range Finder Control: A DX Range Finder control (AGC delay circuit) is used. This control is a potentiometer located at the rear of the chassis to enable precision adjustment of the receiver sensitivity to suit the signal conditions of any local or fringe area. Use of this control has greatly improved reception in high noise level and weak signal areas.

Tone Control: A Tone control is used in all 22C2 and 22E2 chassis.

Picture Tube Mounted on Chassis: The picture tube is mounted directly on the chassis for servicing convenience. Mounting the picture tube on the chassis has also eliminated possibility of trouble due to poor plug connection.

TUBE COMPLEMENT

V101	6BZ7	RF Amplifier
V102	6J6	Oscillator and Mixer
V201	6AU6	Sound IF
V202	6AL5	Ratio Detector
V203	6AV6	AM Detector, AVC / Sound Amplifier
V204	6V6GT	Sound Output
V301	6CB6	1st IF
V302	6CB6	2nd IF
V303	6AG5	3rd IF
V304	*12AU7 or 12AT7	Video Detector / 1st Sound IF
V305	6AC7	Video Amplifier
V306	21EP4A	Picture Tube
V307	6AU6	Gated AGC
V401A / V401B	6SN7GT	Vertical Oscillator / Sync Inverter
V402	6S4	Vertical Output
V403	12AU7	Sync Separator and Clipper
V404	6AL5	Sync Discriminator
V405	6SN7GT	Horizontal Oscillator
V406	6CD6G	Horizontal Output
V407	1B3GT	2nd Anode Rectifier
V408	6W4GT	Damper
V501	5U4G	Rectifier
V701	6BE6	Converter (AM Radio)
V702	6BA6	IF Amplifier (AM Radio)

* Tubes not directly interchangeable. See schematic.

INSTALLATION AND SERVICE ADJUSTMENTS

Instructions for making installation and service adjustments are given on the following pages.

When installing, adjust the DX Range Finder control, check picture for centering, tilt, shaded corners, proper size, linearity, etc., to insure best performance. It is especially important that the ion trap be checked, and that the channel slugs be adjusted upon installation or servicing of every set to insure ease of tuning. Procedure for making "Individual Channel Slug Adjustment Using A Television Signal" is given at right.

In sets using the 21EP4A (21" cylindrical faced) picture tube, check for excessive curvature (pin cushion effect) at the sides of the picture. Information on correcting curvature is given on page 30.

DX RANGE FINDER ADJUSTMENT

Incorrect adjustment of this control in a strong signal area may result in bending of the picture, excessive contrast and poor sync.

In normal signal strength areas, the DX Range Finder Control will generally be set at the "0" position. In intermediate areas, where the TV signal strength is lower and the noise level is higher, the DX Range Finder control will generally be set within the 10 to 150 position. In fringe areas or areas where long distance "DX" reception is possible, the DX Range Finder control will generally be set within the 150 to 300 position. In weak signal and high noise level areas, adjust the DX Range Finder for minimum noise (snow) and flashing in the picture.

Adjust the DX Range Finder as follows:

a. Rotate the DX Range Finder control fully to the left (to the "0" setting).

b. Tune in a picture, preferably on the strongest TV channel.

c. Set the Picture (contrast) control fully to the right (clockwise).

d. While observing a test pattern or picture, slowly rotate the DX Range Finder control to the right for best contrast with a minimum of snow and flashing in the picture.

Check for bending of vertical objects (overloading) in the picture. Also check to see that the picture locks in sync properly when switching off and on channel. If necessary, rotate the DX Range Finder control to the left or to the right until the operation is satisfactory.

In some fringe areas where long range reception is possible, TV signals may be subject to excessive fading. This may vary with season and time of day. If the signal in the area concerned is subject to excessive fading and the Range Finder is adjusted during the time the signal is weakest, overloading (picture bending) will take place when the signal is stronger. For this reason be sure that the customer is instructed on the adjustment of this control for periodic variations in signal strength.

INDIVIDUAL CHANNEL SLUG ADJUSTMENT USING A TELEVISION SIGNAL

Individual channel oscillator adjustment of every receiver should be checked upon installation or servicing. If this adjustment is properly made, it is possible to tune from one station to another by merely turning the CHANNEL control. With correct oscillator channel adjustment, best picture will be located at the approximate center of the range of the TUNING control. However, this may not necessarily be maximum sound output.

Channel slug adjustment can be made without removing the chassis from the cabinet. Adjust as follows:

a. Turn the set on and allow 15 minutes to warm up.

b. Set the CHANNEL knob for a station in operation. Set all other controls for a normal picture.

c. Set TUNING control at center of its range by rotating it approximately half-way.

d. Remove the CHANNEL and TUNING knobs.

e. Insert a 1/8" blade, NON-METALLIC screwdriver (kit consisting of one metallic and one non-metallic screwdriver is available under part number 98A30-3) in the 1/4" hole adjacent to the channel tuning shaft. For each channel in operation, carefully adjust the channel slug for best picture with clear detail. Be sure that the Tuning control is set at the center of its range before adjusting each channel slug. Only slight rotation of the slug will be required; turning the slug in too far will cause it to fall into the coil. (If the slug falls into the coil, remove the coil, move the retaining spring aside, lightly tap the open end of the coil until the slug slips out. Replace slug and reset retaining spring.)

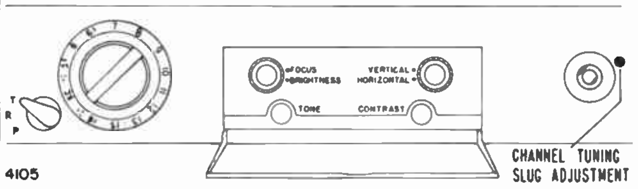

Figure 1. Control Panel in 22E2 Sets. Channel and Tuning Knobs Removed.

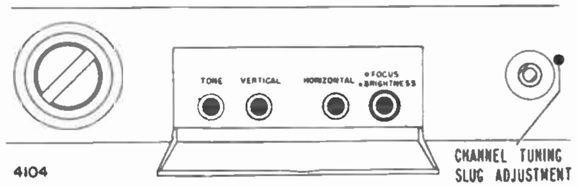

Figure 2. Control Panel in 22C2 Sets. Channel and Tuning Knobs Removed.

TOUCH-UP OF RATIO DETECTOR SECONDARY USING TELEVISION SIGNAL (A12, BOTTOM SLUG OF T201)

*This adjustment is accessible through the 1/4" hole (just below T201) in bottom of the cabinet or the chassis mounting shelf, located toward the left side facing the rear of the set. Removal of the chassis is therefore not required. ***Adjustment need be made on one channel only.*** Proceed as follows:

a. Turn set on and allow about 15 minutes for warm up.

b. Tune set for normal picture and sound.

c. Carefully insert a non-metallic alignment tool through the opening in cabinet bottom below T201. An alignment tool with a screwdriver blade or hexagonal end is required depending on the transformer used, see * note below. When the alignment tool engages the bottom tuning slug A12, adjust the slug for best sound with minimum buzz level. Do this carefully as only slight rotation in either direction will generally be required. Correct adjustment point is located between the two maximum buzz peaks that will be noticed when turning the slug back and forth about 1/4 to 1/2 turn.

d. If necessary, repeat individual channel slug adjustment and conclude with retouching the ratio detector secondary. Note: If oscillator adjustment is required for other channels, it will ***not*** be necessary to repeat the ratio detector secondary adjustment after ***once*** correctly adjusting it.

ALIGNMENT OF 4.5 MC TRAP A13, USING A TELEVISION SIGNAL

Beat interference (4.5 MC) appears in picture as very fine vertical or diagonal lines, very close together, having a "gauze-like" appearance, the pattern will vary with speech, forming a very fine herringbone pattern.

The trap can be tuned by watching the picture and adjusting the slug for minimum 4.5 MC interference. If greater accuracy is required, the trap should be adjusted as shown on page 32 under "4.5 MC Sound IF and Trap Alignment".

ADJUSTING CURVATURE CORRECTING MAGNETS FOR SETS USING A 21EP4 (21") PICTURE TUBE

If either side of the picture has excessive curvature (pin cushion effect) or if corners of the picture are bent inwardly, this can be minimized by adjustment of the correcting magnets located on the yoke bracket. Either side of the picture can be adjusted individually by using the magnet on that side of the picture tube. A picture or test pattern having straight vertical lines near the sides can be used for making adjustment; the pattern from a cross-hatch generator is preferable. IMPORTANT: A cross-hatch generator which is not capable of locking the picture in both horizontal and vertical sync is not suitable. Adjust as follows:

a. Set the receiver control for normal picture. Be sure that the picture is centered properly and vertical linearity adjustment is made.

b. Check the radial position of the magnet brackets. The magnet brackets are generally set so that the mounting screw is centered in the curved slot. It should only be necessary to change from this setting if the curvature at the side of the picture is not centered with respect to the side of the picture tube.

c. Move the correcting magnet against the deflection yoke bracket. While observing the vertical lines on the same side of the picture that the magnet is located, slowly move the magnet forward until curvature of vertical lines near the side is minimized. If the magnets are moved too far forward, the corners of the picture will bend inwardly or become shaded.

SERVICING RADIO TUBES AND DIAL LIGHT IN 22E2 SETS

The radio tubes can be serviced without removing the TV chassis from the cabinet. The radio tubes can be reached through the opening in the underside of the chassis shelf.

The dial light can be serviced by removing the tuning knobs and plastic control panel.

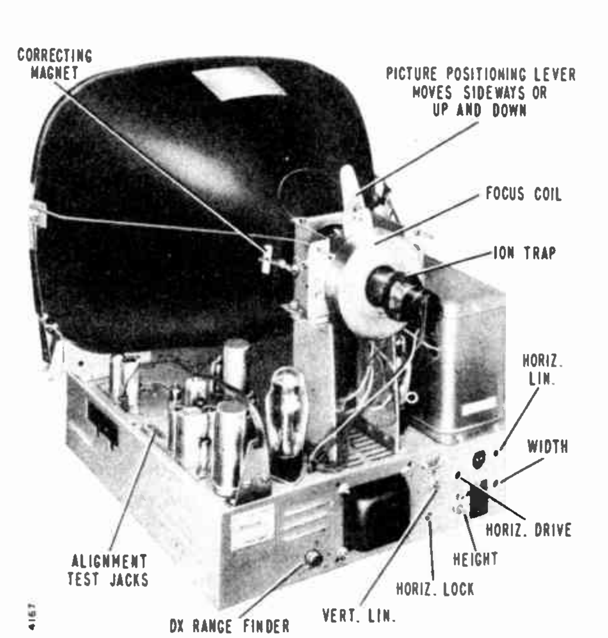

Figure 3. Chassis View Showing Adjustment Locations.

* If ratio detector transformer (T201) has hollow hexagonal core slugs, bottom slug adjustment A12 can be made from top of chassis, if you use alignment tool (part number 98A30-7; available at Admiral Distributor). Bottom slug A12 can be reached through the hole in the core of the upper slug (A11).

SERVICE HINTS

Also see Production Change

TROUBLE SHOOTING

The 22C2 and 22E2 chassis described in this manual are similar to other chassis in the 22 series with respect to the sync, sweep and power supply circuit. The basic differences in the 22C2 and 22E2 chassis over other 22 series are outlined under "New Features in 22C2 and 22E2 Chassis".

In general, the trouble shooting of the 22C2 and 22E2 chassis will be similar to that of other chassis in the 22 series which use a cascode TV tuner.

It is important, however, to remember the following trouble shooting hints which apply to the 22C2 and 22E2 chassis.

No picture or sound: Raster OK. Incorrect adjustment of the DX Range Finder control in a weak signal area may result in complete loss of picture and sound. In strong signal areas, incorrect adjustment may also result in picture bending, excessive contrast and poor sync. See instructions for adjustment.

No sound and no raster. In the 22C2 chassis, no sound and no raster or distorted sound and no raster can be due to a blown fuse M401. See paragraph on "Replacing Fuse M401".

Excessive curvature at the sides of the picture (pin cushion effect) or bending of corners. Excessive curvature at the sides of the picture (pin cushion effect) or bending of corners can be due to misadjustment of the curvature correcting magnets. See "Adjusting Curvature Correcting Magnets Used With 21EP4A (21") Picture Tube".

Picture bending, excessive contrast or poor sync. Incorrect adjustment of the DX Range Finder control in a strong signal area, may result in picture bending, excessive contrast and poor sync. Incorrect adjustment in a weak signal area may also result in complete loss of picture and sound. Instructions for adjustment is given.

MISCELLANEOUS TROUBLES DUE TO FAULTY TUBES

Faulty tubes cause the majority of receiver troubles. The list below contains most common troubles which are generally due to faulty tubes.

a. Poor fringe area reception due to low B plus voltage. Check the 5U4G tube.

b. Poor fringe area reception due to low sensitivity. Check the 6CB6, 6AG5 and 6BZ7 tubes.

c. Picture and sound separated due to IF oscillation. Check the 6CB6 and 6AG5 tubes.

d. Picture bending caused by leakage between tube elements. Check the 6CB6 tubes.

e. Poor sync stability, usually more noticeable in vertical circuit. Check 12AU7 tube.

f. Washed out picture due to negative grid current. Check 6AC7 tube.

EXCESSIVE SNOW IN PICTURE

Excessive snow in the picture can be caused by faulty tubes in the receiver. Check receiver as follows:

Short circuit the antenna terminals and turn the picture control (contrast) fully clockwise.

Connect a vacuum tube voltmeter from test point "V" to chassis. Set the channel selector on an unassigned channel. If the voltmeter reading exceeds .6 volt negative, excessive receiver (tube) noise is indicated. This condition can usually be corrected by tube substitution. Substitute tubes in the following order: Video detector tube V304, RF oscillator tube V102, RF amplifier tube V101 and IF amplifier tube V301, V302 and V303.

Corona or arcing in the second anode supply can also cause a high noise reading at the video detector resulting in excessive snow in weak signal areas.

DISTORTED SOUND

Distorted sound can be caused by misalignment of the ratio detector transformer T201. This misalignment is sometimes due to frequency drift of the ratio detector transformer. If realignment of the ratio detector transformer does not correct this trouble permanently, a permanent remedy for this trouble is to connect a 20 mmfd, —750 temperature coefficient, ceramic condenser (part number 65C6-26) in parallel with condenser C204 (180 mmfd, ceramic, connected across the secondary of the ratio detector transformer T201). Realign ratio detector after adding the 20 mmfd. condenser.

IMPORTANT NOTE ON 27.25 MC AND 19.75 MC TRAP ALIGNMENT

If difficulty is experienced in aligning the 27.25 MC and 19.75 MC traps (A7 and A8), using the method outlined in the alignment procedure on page 8, make trap alignment as follows:

1. Connect an oscilloscope between pin 8 (plate) of video amplifier V305 (6AC7) and chassis.
2. Make all connections and receiver control settings as instructed in steps 5 and 6 of the alignment procedure on page 32.
3. Operate the signal generator with AM (audio) modulation turned on. Full generator output may be required.

   Note: If a termination resistor is used in the generator output cable, increased generator output can be obtained by disconnecting the terminating resistor. Connect a condenser (.002 mfd. or larger) in series with the generator high side.
4. Adjust A7 (27.25 MC trap) and A8 (19.75 MC trap) for minimum amplitude of the waveform on the oscilloscope.

REPLACING FUSE M401

The horizontal output circuit of these receivers is protected by fuse M401 (.25 amp., 250 volts). This fuse is located in the rear of the high voltage compartment. To replace the fuse, remove the two screws at the base of the high voltage compartment and lift the cover away from the base; see figure 3. Carefully remove or insert the fuse so as to avoid damage to the horizontal output transformer.

REMOVABLE PICTURE WINDOW

All models using the 22C2 or 22E2 television chassis have picture windows which can be easily removed from the front of the cabinet for cleaning the inside of the window, picture tube and picture tube mask. A removable picture window molding is used in wood cabinet models. Instructions for removing and cleaning the picture window, picture tube and picture tube mask are given below.

REMOVING PICTURE WINDOW FOR CLEANING

If the picture window has a removable molding (at the top), remove the window by first removing the Phillips head screws and molding at the top of the picture window. Pull the top of the window away from the cabinet slightly and lift it up out of the channel at the bottom.

After cleaning the window, picture tube and picture tube mask as instructed below, install the window by placing the bottom edge in the channel and replace the molding. Use care when tightening screws on molding to prevent stripping.

CLEANING GLASS PICTURE WINDOW

Clean the picture mask using a soft cloth, dampened in mild soapy water. Clean the picture window and the face of the picture tube using a soft cloth, dampened with your favorite window cleaner. Wipe dry using a chamois or soft, lint free cloth. Only use cloths which are just dampened as presence of moisture or water inside the set may cause damage. Install the window as instructed above.

PICTURE TUBE REPLACEMENT

Picture tube replacement for the 22 series receivers is similar to that of other chassis using a rectangular glass picture tube. Instructions for adjusting curvature correcting magnets used with 21EP4A (21" cylindrical faced) picture tube is given on page 30.

PRODUCTION CHANGES

The production changes given below appear in later production sets.

At the start of production, chassis were not stamped with a run number, therefore some chassis will not have a run number stamp.

Production changes are coded RUN 1, RUN 2, etc., as given in the headings below. Run number (stamped on chassis) indicates that this chassis has the change(s) incorporated which are explained under that particular run number heading below, as well as all changes (lower run numbers) made prior to that time.

CHANGE FOR INCREASED SOUND LEVEL

Run 1 in 22C2 and 22E2 chassis

Early production sets used a 12AU7 tube for video detector and first sound IF amplifier V304. Later production sets stamped Run 1 or higher used a 12AT7 tube for V304. The schematic figure 16 shows a partial circuit of the first IF amplifier in sets using the 12AU7 tube. Important: The 12AU7 and 12AT7 tubes are not directly interchangeable. Replace with same type tube used in receiver.

MECHANICAL CHANGE IN RADIO TUNER USED IN 22E2 CHASSIS

Mechanical changes were made to the later production radio tuner sub-chassis used in 22E2 combination models. The dimensions of the radio chassis were altered slightly and the mounting position of the gang condenser was changed.

Early production radio tuners used gang condenser (part number 68B53) which mounts in a vertical position. Later production radio tuners use gang condenser (part number 68B53-1) which mounts in a horizontal position.

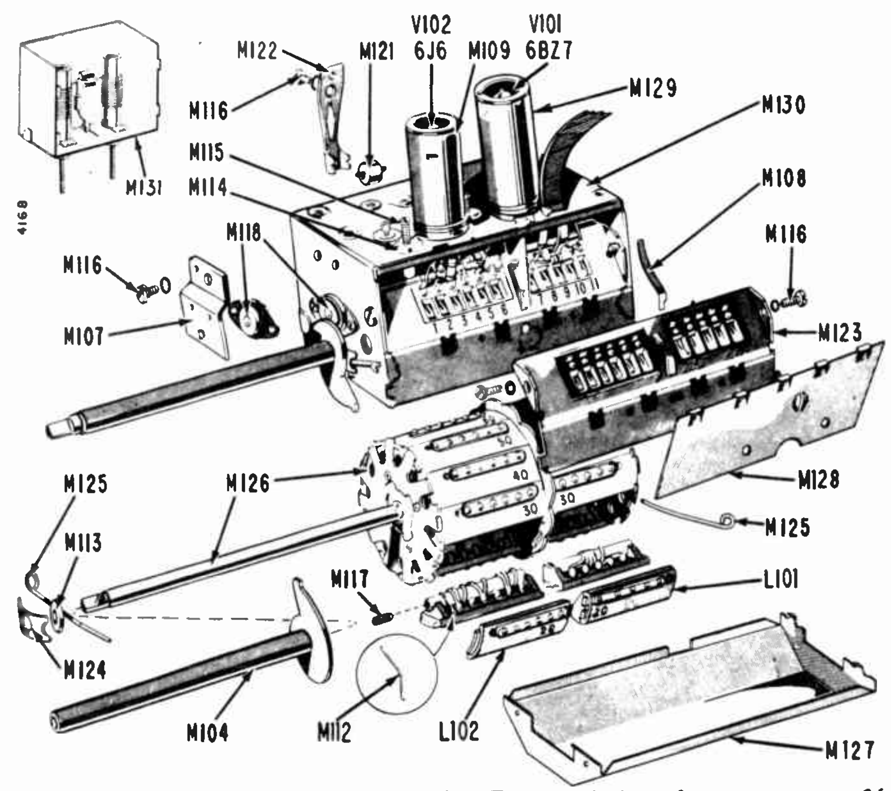

Figure 4. Exploded View, TV Tuner 94D47-2. (For description of parts, see page 36.)

TELEVISION ALIGNMENT PROCEDURE

GENERAL

Complete alignment consists of the following individual procedures and should be performed in this sequence.

a. IF Amplifier and Trap Alignment.
b. IF Response Curve Check.
c. 4.5 MC Sound IF and Trap Alignment.
d. RF and Mixer Alignment.
e. Over-all RF and IF Response Curve Check.
f. HF Oscillator Adjustment.

TEST EQUIPMENT

To properly service this receiver, it is recommended that the following test equipment be available.

IMPORTANT: Many service instruments do not meet the requirements given below. A list of recommended equipment is available from Admiral Distributor.

Oscilloscope

Standard oscilloscope, preferably one with a wide band vertical deflection, vertical sensitivity at least .5 volt (RMS) per inch.

Signal (Marker) Generator

4.5 MC frequency.
18 to 30 MC frequency range.
50 to 90 MC frequency range.
170 to 225 MC frequency range.

Must have a built-in calibration crystal for checking dial accuracy.

Sweep Generator

Sweep generator must provide sweep frequencies from

18 to 30 MC range:
50 to 90 MC range:
170 to 225 MC range:
} with at least 10 MC sweep width.

Output: adjustable; at least one-tenth volt maximum.

Output impedance: 300 ohms balanced to ground.

A sweep generator not having constant output voltage over the swept range and linear sweep, will produce curves which are widely different from the ideal curves shown in the following pages. If repeated difficulty is encountered in obtaining these curves, the sweep generator should be checked. A simple check is to observe the response curve for a set that is in alignment.

Before suspecting the generator, be sure the alignment instructions in this manual have been followed carefully.

Vacuum Tube Voltmeter

Preferably with low range (3 volt) DC zero center scale and a high voltage probe (30,000 volt range).

ALIGNMENT TOOLS

An alignment tool kit consisting of one metallic and one non-metallic screwdriver is available under part number 98A30-3. A non-metallic alignment tool with a screwdriver point at one end and hexagonal wrench (for hollow hexagonal core slugs) at the other is available under part number 98A30-7.

IF AMPLIFIER AND TRAP ALIGNMENT

- Connect bias battery; negative to test point "T", see figure 7, positive to chassis. A 3 volt battery is required for steps 1, 2, 3, 4 and 7. A 1½ volt bias battery is required for steps 5 and 6.
- Disconnect antenna. Connect a jumper wire across the antenna terminals.
- Set Channel selector to channel 12 or other unassigned high channel, to prevent interference during alignment.
- Set the Picture control fully to the left (counterclockwise).
- Allow about 15 minutes for receiver and test equipment to warm up.
- Use lowest DC scale on VTVM.

Step	Signal Gen. Freq.	VTVM and Signal Generator Connections	Instructions	Adjust
1	25.3 MC	VTVM high side to test point "V", common to chassis. Generator high side to 6J6 (V102) tube shield; insulate shield from chassis. Connect low side to chassis near 6J6 tube base.	Use 3 volt bias battery. Use lowest DC scale on VTVM. When peaking, keep reducing generator output for VTVM reading of approx. 1 volt or less. Set channel switch to channel 12 or other unassigned high channel.	A1, A2 and A3 for maximum.
2	22.3 MC			A4 for maximum.
3	23.5 MC			A5 for maximum.
4	21.25 MC			A6 for minimum.
5	*27.25 MC	Connect Generator and VTVM same as in step 1.	Use 1½ volt bias battery. Set channel switch between channels to break channel coil contact: VTVM reading will change when coil contact is broken.	A7 for minimum.
6	*19.75 MC			A8 for minimum.
7	25.3 MC	Connect Generator and VTVM same as in step 1.	Use 3 volt bias battery. Set channel switch same as in step 1.	Readjust A1 and A2 for maximum.
8	To insure correct IF alignment, make the "IF Response Curve Check" given			

IF RESPONSE CURVE CHECK

(Using sweep generator and oscilloscope)

Receiver Controls and Bias Battery	Sweep Generator	Marker Generator	Oscilloscope	Instructions
Set Channel selector on channel 12 or an unassigned high channel. Picture control fully to the left. Connect negative of 3 volt bias battery to test point "T"; positive to chassis.	Connect high side to 6J6 mixer-osc. tube shield. Insulate tube shield from chassis, low side to chassis ground. Set sweep frequency to 23MC, and sweep width approximately 7MC.	If an external marker generator is used, loosely couple high side to sweep generator lead on tube shield, low side to chassis. Marker frequencies indicated on IF Response Curve.	Connect to test point "V". See figures 7 and 8. Marker pips on scope will be more distinct if a condenser from 100 mmfd to 1000 mmfd is connected across the oscilloscope input.	Check curve obtained against ideal response curve in fig. 5. Note tolerances on curve. Keep marker and sweep outputs at very minimum to prevent overloading. A reduction in sweep output should reduce response curve amplitude without altering the shape of the response curve. If the curve is not within tolerance or the markers are not in the proper location on the curve, touch-up with IF slugs as instructed below.

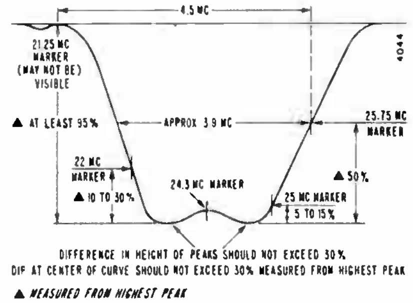

Figure 5. Ideal IF Response Curve.

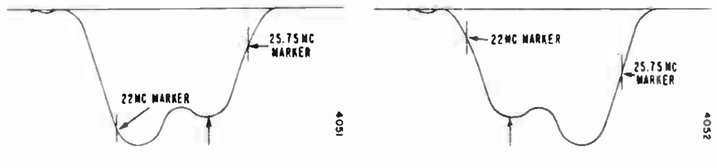

Figure 6. IF Response Curves, Incorrect Shape.

If it is necessary to adjust for approximate equal peaks, carefully adjust slug A5 (23.5 MC). It should not be necessary to turn slug A5 more than one turn in either direction.

If the curve cannot be made to resemble the response curve shown at left, repeat all steps under "IF Amplifier and Trap Alignment" making sure that generator frequencies are accurate and adjustments are carefully made. If a satisfactory curve cannot be obtained after repeating these steps, it may be necessary to change IF amplifier tubes or check for a defective circuit component to be sure that each stage is operating properly.

* Before proceeding, be sure to check the signal generator used in alignment against a crystal calibrator or other frequency standard for absolute frequency calibration required for this operation. Also see "Important Note On 27.25 MC and 19.75 MC Trap Alignment" on page 31.

4.5 MC SOUND IF AND TRAP ALIGNMENT

See page 30 for touch-up of ratio detector using television signal without test equipment.

a. Connect signal generator high side to Pin 1 of V304 (12AU7 or 12AT7) through a .01 mfd. condenser, connect low side to chassis.
b. Allow about 15 minutes for receiver and test equipment to warm up.
c. Set Picture control fully to the left (counterclockwise).
d. Use a NON-METALLIC alignment tool. If Ratio Det. Transformer (T201) has hollow core slugs, bottom slug adjustment A11 can be made from top of chassis, if you use alignment tool #98A30-7 obtainable from Admiral Distributor.

Step	Signal Gen. Freq. (MC)	VTVM Connections	Instructions	Adjust
	When using a signal generator, be sure to check it against a crystal calibrator or other frequency standard for accurate frequency calibration at 4.5 MC. Accuracy required is within one kilocycle. IMPORTANT: If a signal generator and frequency standard are not available, alignment can be made using a TV station signal. Tune in a station and follow steps 1, 2 and 3 below. If necessary use a higher scale on the VTVM.			
1	Set to exactly 4.5 MC	High side to test point "Y"; common to chassis.	Use lowest DC scale on VTVM.	A9, A10 and A11 for maximum (keep reducing generator output to keep VTVM at approx. 1 volt).
2		High side to test point "Z"; common to chassis.	Use zero center scale on VTVM, if available.	A12 for zero on VTVM (the correct zero point is located between a positive and a negative maximum). If A12 was far off, repeat step 1.
3		High side to test point "Y"; common to chassis.	Connect a 10 mmfd. condenser from pin 8 of V305 (6AC7) to pin 8 of V304 (12AU7 or 12AT7). Use lowest DC scale on VTVM.	A13 for minimum.

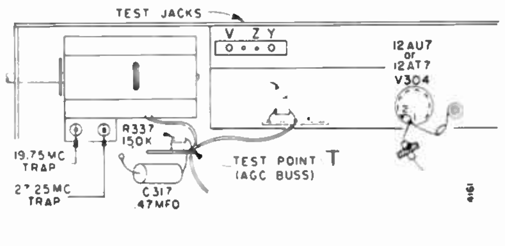

Figure 7. Bottom View Showing Test Point Connections.

ALIGNMENT HINT

After becoming familiar with alignment procedure, some servicemen simplify subsequent alignment of sets by merely using the essential alignment data given in figures 7 and 8.

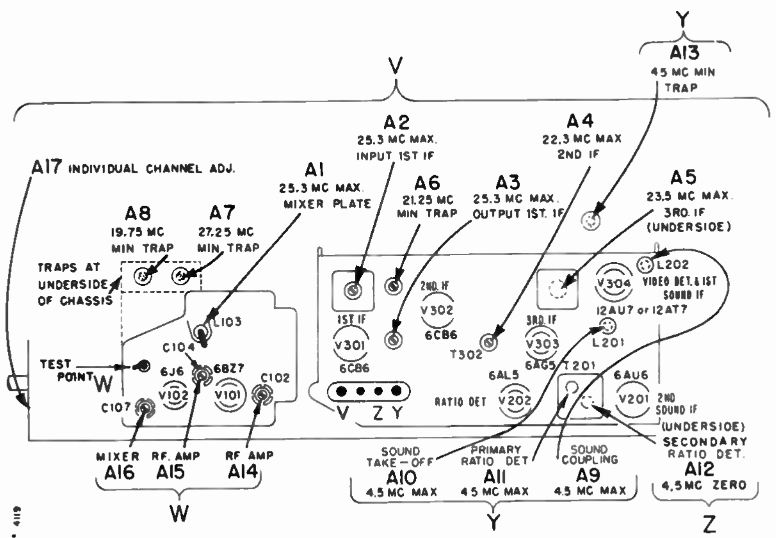

Figure 8. Top View of Chassis Showing Alignment Data.

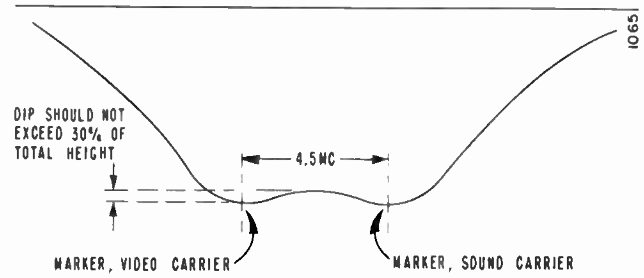

Full skirt of curve will not be visible unless generator sweep width extends beyond 10 MC.

Figure 9. RF Response Curve.

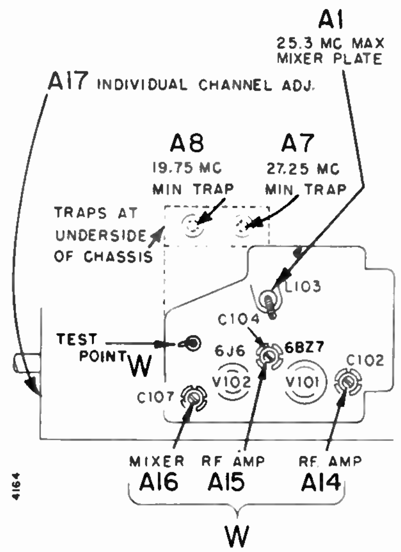

Figure 10. Top of TV Tuner, Showing Adjustment Location.

FREQUENCY TABLE

Channel Number	Channel Freq., MC	Video Carrier, MC	Sound Carrier, MC	HF Osc., MC
2	54- 60	55.25	59.75	81
3	60- 66	61.25	65.75	87
4	66- 72	67.25	71.75	93
5	76- 82	77.25	81.75	103
6	82- 88	83.25	87.75	109
7	174-180	175.25	179.75	201
8	180-186	181.25	185.75	207
9	186-192	187.25	191.75	213
10	192-198	193.25	197.75	219
11	198-204	199.25	203.75	225
12	204-210	205.25	209.75	231
13	210-216	211.25	215.75	237

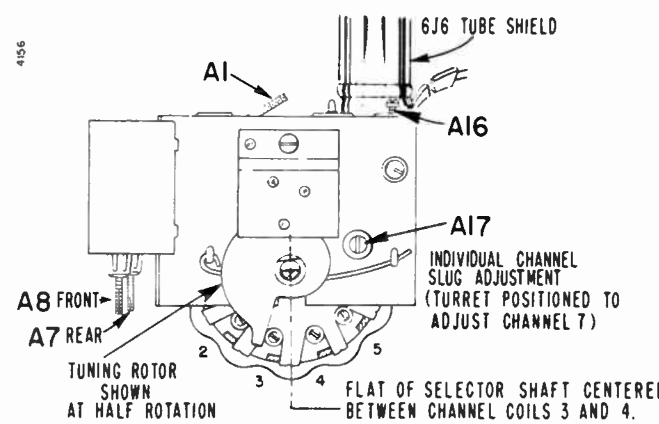

Figure 11. Front View of TV Tuner.

RF AND MIXER ALIGNMENT

a. Connect negative of 3 volt bias battery to AGC buss (test point "T"), positive to chassis. If it is difficult to obtain a curve of sufficient amplitude, remove battery and connect a wire jumper from test point "T" to chassis.

b. Connect sweep generator to antenna terminals. If sweep generator does not have a built-in marker generator, loosely couple a marker generator to the antenna terminals. To avoid distortion of the response curve, keep sweep generator output at a minimum, marker pips just barely visible.

c. Connect oscilloscope through a 10,000 ohm resistor to test point "W" on tuner (figure 10). Keep scope leads away from chassis.

d. Allow about 15 minutes for receiver and test equipment to warm up.

Step	Marker Gen. Freq. (MC)	Sweep Gen. Frequency	Instructions
1	193.25 MC (Video Carrier) 197.75 MC (Sound Carrier)	Sweeping Channel 10. See frequency table below.	Check for RF response curve below. Alternately adjust A15 and A16 (figure 10) as required to obtain equal peak amplitudes and symmetry consistent with proper bandwidth and correct marker location.
2	83.25 MC (Video Carrier) 87.75 MC (Sound Carrier)	Sweeping Channel 6. See frequency table below.	Check for RF response curve below. Adjust A14 as required to obtain curve having maximum amplitude and flat top appearance consistent with proper bandwidth and correct marker location. After completing adjustment, recheck adjustment of step 1.
3	Set the sweep generator to sweep the channel to be checked. Set the marker generator for the corresponding video carrier frequency and sound carrier frequency.		Check each channel operating in the service area for curve shown below. In general, the adjustment performed in steps 1 and 2 are sufficient to give satisfactory response curves on all channels. However, if reasonable alignment is not obtained on a particular channel, (a) check to see that coils have not been intermixed, or (b) try replacing the pair of coils for that particular channel, or (c) repeat step 1 for a weak high channel as a compromise adjustment to favor the particular channel. Repeat step 2 for the weak low channel to favor the particular channel. If a compromise adjustment is made, other channels operating in the service area should be checked to make certain that they have not been appreciably affected.

OVER-ALL RF AND IF RESPONSE CURVE CHECK

(Using sweep generator and oscilloscope)

Receiver Controls and Bias Battery	Sweep Generator	Marker Generator	Oscilloscope	Instructions
Picture control fully to the left. Channel selector on channel 12 or other unassigned high channel. Connect negative of 3 volt bias battery to test point "T", positive to chassis.	Connect to antenna terminals. Set generator to sweep channel selected. Keep generator output as low as possible, to prevent overloading. See frequency table on opposite page.	If an external marker generator is used, loosely couple high side to sweep generator lead. Marker frequencies are shown in frequency table on opposite page.	Connect to point "V". See figure 8.	Compare the response curve obtained against the ideal curve shown in figure 12. If the curve is not within tolerance, touch up the IF slug as instructed below. It should never be necessary to turn slugs more than one turn in either direction. If the curve is satisfactory on the channel checked, all other channels should also be satisfactory. IMPORTANT: When sweep output is reduced, response curve amplitude on scope should also decrease, but curve shape should remain the same. If curve shape changes, reduce sweep output and/or the scope gain until the shape does not change.

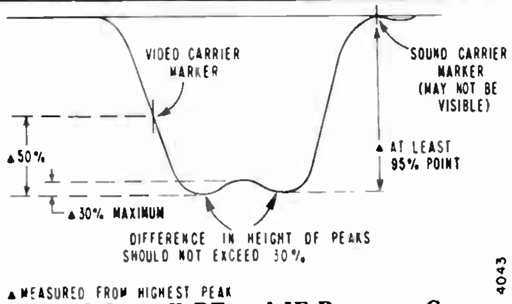

Figure 12. Ideal Over-all RF and IF Response Curve.

Note that video carrier (marker) on the "Over-all RF-IF Response Curve" will appear on the opposite side of the curve as compared to the "IF Response Curve" figure 5. This is due to action of the mixer tube.

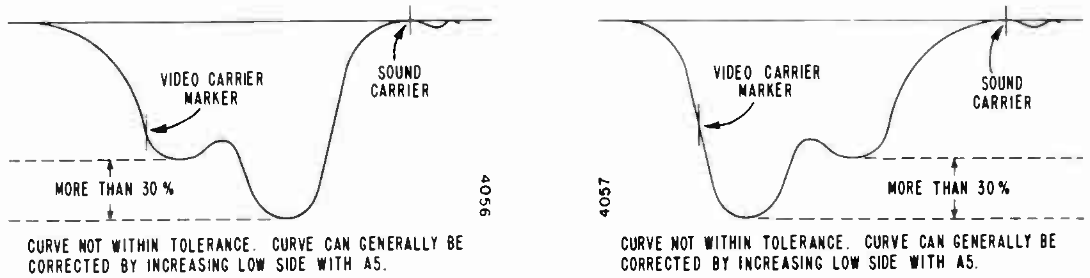

Figure 13. Over-all RF and IF Response Curves, Incorrect Shape.

HF OSCILLATOR ADJUSTMENT

(Using a signal generator)

It is always advisable to make HF oscillator adjustments using a Television Signal as instructed on page 30. If a Television Signal is not available, HF oscillator adjustment can be made using a crystal calibrated signal generator. Make adjustments as follows:

Receiver Control Settings	Signal Generator	Instructions
Set channel selector for each channel to be adjusted. Set "Tuning" control at half rotation. Turn volume control fully to the right (clockwise).	Connect to antenna terminals. Set generator to exact frequency of HF oscillator. See frequency table on opposite page. *Set generator for maximum output.*	Connect a wire jumper from test point "W" on the tuner to test jack "Z". See figure 8. Remove the ratio detector tube V202 (6AL5). Carefully adjust the individual oscillator slug A17 until a whistle (beat) is heard in the speaker of the receiver.

SERVICING RADIO TUNER IN 22E2 MODELS

SERVICING RADIO TUBES AND DIAL LIGHT

The radio tubes and radio dial light can be serviced without removing the TV chassis from the cabinet. The radio tubes can be reached through the opening cut in the underside of the chassis shelf.

The dial light (in models with wood cabinet only) can be serviced by removing the tuning knobs and control panel.

REMOVING RADIO TUNER

The radio tuner is mounted at the front apron of the chassis. Alignment, taking voltage readings or an inspection of the underside of the radio tuner can be performed without complete removal of the radio tuner from the TV chassis. To gain access to the underside of the radio tuner, disconnect the tuning drive cord, remove the two self-tapping screws at the chassis front and back and move the tuner as far as the connecting leads permit. The radio tuner can be completely removed from the TV chassis by unsoldering the leads to the main chassis (including the leads from the radio loop antenna).

DIAL STRINGING

Dial stringing for the radio tuning control is shown below.

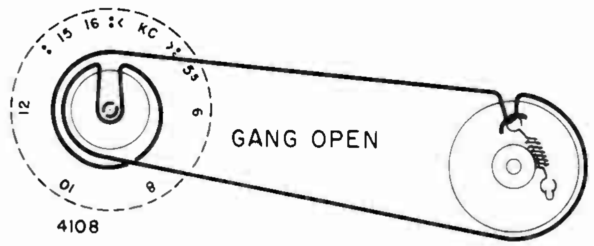

Figure 14. Dial Stringing for the 22E2 Chassis.

ALIGNMENT OF RADIO TUNER

The radio tuner in television and radio chassis should be aligned as instructed under "Radio Alignment Procedure" below.

The radio alignment trimmers are accessible without disassembly of the radio tuner from the TV chassis.

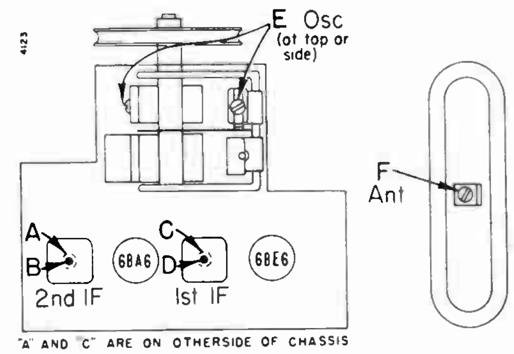

Figure 15. Trimmer Locations for AM Radio Tuner in 22E2 Chassis.

RADIO ALIGNMENT PROCEDURE

- Connect output meter across speaker voice coil.
- Turn receiver Volume control fully on; Tone control fully clockwise.
- Function switch in "Radio" position.
- Use lowest output setting of signal generator that gives a satisfactory reading on meter.
- Use a non-metallic alignment tool for IF adjustments.
- Repeat adjustments to insure good results.

Step	Connect Signal Generator	Dummy Antenna Between Radio and Signal Generator	Signal Generator Frequency	Receiver Dial Setting	Adj. Trimmers in Following Order to Max.
1	Gang condenser antenna stator	.1 MFD	455 KC	Tuning gang wide open	*A-B (2nd IF) *C-D (1st IF)
2	"	"	1620 KC	"	E (oscillator)
3	Place generator lead close to loop of set to obtain adequate signal. No actual connection (signal by radiation).		1400 KC	Tune in signal	§F (antenna)

* Adjustments A and C made from underside of chassis. See figure 15 for trimmer locations.
§ AM antenna trimmer may not peak if antenna leads are not properly routed or separated.

PARTS LIST

Electrical components have symbols in 100 series, 200 series, etc., according to location on schematic. Order parts by number and description from Admiral Distributor.

CHASSIS PARTS

RESISTORS

Sym.	Description	Part No.

C428	.047 mfd, 200 volts, paper	64A 2-14
C429	500 mmfd, 20,000 volts, ceramic	65B 18-5
C430	47 mmfd, 5%, 1,500 volts, mica	65B 1-64
C431	.1 mfd, 400 volts, paper	64A 2-6
C432	Electrolytic	See C307C
C434	.0068 mfd, 600 volts, paper	64A 2-15
C701	5 mmfd, mica (C701 not supplied with set)	65B 1-62

* Component may be part of couplate, part number 63B6-3 or 63B6-5. Part number 63B6-3 used in 22E2 chassis, part number 63B6-5 used in 22C2 chassis. Order exact duplicate or individual components.
‡ Component may be part of couplate, part number 63B6-4. Order exact duplicate or individual components.
§ Component may be part of couplate, part number 63B6-2. Order exact duplicate or individual components.

Sym.	Description	Part No.
C702	2 to 20 mmfd. trimmer	66B 8-5
C704	47 mmfd. ceramic	65C 6-79
C705	.1 mfd. 400 volts, paper	64A 3-15
C706	.1 mfd, 400 volts, paper (C706 was .1 mfd, 200 volts in early sets)	64A 3-15
C707	.005 mfd, min, ceramic	65C 10-1
C708	.1 mfd, 400 volts, paper	64A 3-15
C709	100 mmfd, min, ceramic	65C 6-3
C716A / C716B	420 mmfd, max. / 105 mmfd, max. } gang (mounts horiz.)	68B 53-1
C716A / C716B	420 mmfd. max. / 105 mmfd, max. } gang (mounts vert.) (Note: Dial drum spot welded to gang.)	68B 53

COILS, TRANSFORMERS

Sym.	Description	Part No.
L101	Antenna Coil (Stamped 2Q, 3Q, etc.)	
	for Channel #2	94D 46-52
	for Channel #3	94D 46-53
	for Channel #4	94D 46-54
	for Channel #5	94D 46-55
	for Channel #6	94D 46-56
	for Channel #7	94D 46-57
	for Channel #8	94D 46-58
	for Channel #9	94D 46-59
	for Channel #10	94D 46-60
	for Channel #11	94D 46-61
	for Channel #12	94D 46-62
	for Channel #13	94D 46-63
L102	Mixer—Osc. Coil (Stamped 2Q, 3Q, etc.)	
	for Channel #2	94D 46-72
	for Channel #3	94D 46-73
	for Channel #4	94D 46-74
	for Channel #5	94D 46-75

	for Channel #9	94D 46-79
	for Channel #10	94D 46-80
	for Channel #11	94D 46-81
	for Channel #12	94D 46-82
	for Channel #13	94D 46-83

For 94D 47-2 TV Tuner only

Sym.	Description	Part No.
L103	Mixer Plate Coil	98A 45-77
L104	Heater RF Choke	98A 45-13
L105	Heater RF Choke	98A 45-14
L106	Peaking Coil	94C 37-89
L107	Coil, 27.25 MC Trap } Part of trap assem.	94D 47-56
L108	Coil, 19.75 MC Trap } Part of trap assem.	94D 47-56
L109	Mixer Plate Choke	94D 46-86
L110	Coil, Bandpass Coupling — Part of trap assem.	94D 47-56
L201	Sound Take-off Coil	72B 99-4
L202	Sound Coupling Coil	72B 99-4
L203	Peaking Coil (wound on R219)	73A 5-2
L301	Video Peaking Coil (wound on R341)	73A 5-15
L302	Video Peaking Coil	73A 5-7
L303	Video Peaking Coil (wound on R320)	73A 5-14
L304	Video Peaking Coil (wound on R321)	73A 11-1
L305	Heater RF Choke	73A 2-5
L306	Heater RF Choke	73A 2-5
L308	Trap Coil (includes C322)	72B 99-3
L309	Coil, 1st IF Input	72B 106
L310	Coil, 21.25 MC Trap (includes C327, C324 and R345)	72C 96-24
L401	Horizontal Lock Coil (includes C418, R431)	94A 17
L402	Width Control Coil	94A 39-1
L403	Horizontal Linearity Coil	94A 28
L404	Focus Coil	69C 117-3
L406	Choke Coil	73B 8-2
L702	Oscillator Coil	69A 52-4
L704	AM Antenna	69C 155-2

Sym.	Description	Part No.
T201	Ratio Detector Transformer	72B 68-2
T202	Audio Output Transformer	
	for 22C2	79C 33-3
	for 22E2	79C 33-4
T301	1st IF Transformer	72C 96-14
T302	2nd IF Transformer (includes R309)	72C 96-16
T303	3rd IF Transformer (includes C305 and C325)	72B 105-1
T401	Blocking Oscil. Transformer	79A 18-4
T402	Vertical Output Transformer	79B 40-1
T403	Deflection Yoke (includes R412, R413, R445, C430)	94C 30-1
T404	Horizontal Output Transformer	79C 38-1
T501	Power Transformer	80C 26-1
T701	1st IF Transformer	72B 28-7
T702	2nd IF Transformer	72B 28-7

MISC. PARTS for 94D47-2 TV TUNER

See page 31 for parts illustration.

Sym.	Description	Part No.
M104	Shaft Shell & Rotor Assy. (Sharp Tuning) (with 4 1/16" long brass shaft shell)	98A 45-92
M107	Bracket, Sharp Tuning Rotor Retaining	98A 45-95
M108	Spring, Detent Plate Grounding	98A 45-94
M109	Shield, Tube (Slotted) for 6J6	98A 45-73
M112	Spring, Slug Retaining (Osc. coil)	98A 45-52
M113	Washer, Fibre Spacer (¼" IDx½" OD)	98A 45-63
M114	Nut, Locking Spring (for trimmers)	98A 45-31
M115	Screw, Trimmer (4-36x⅝")	98A 45-33
M116	Screw, Bracket Mtg. (6-32x¼")	98A 45-62
M117	Slug, Brass Tuning	98A 45-88
M118	Stator Plate (ungrounded); Silver with Ceramic Insulator, for Sharp Tuning C111 (includes mtg. bracket)	98A 45-86
M121	Roller, Detent (⅜" dia., 3/32" dia. bearing)	98A 45-82
M122	Spring, Detent (2 5/16" long)	98A 45-81
M123	Contact Plate and Bracket Assembly (uses Wiping Contacts)	98A 45-84
M124	Spring, Sharp Tuning Rotor Contact (flat bronze 1 7/16"x½")	98A 45-83
M125	Spring, Front and Rear Turret Shaft (wire 2¾" long, 3/64" dia.)	98A 45-85
M126	Turret, and Shaft Assembly (less coils) (5⅜" shaft and 3/16" rounded detent depression)	98A 45-91
M127	Shield, Bottom	94C 37-92
M128	Shield, Side	94C 37-93
	Socket, Tube (mica filled)	
	miniature, 7 pin	94C 37-95
	miniature, 9 pin	94C 37-96
M129	Shield, Tube (plain; for 6BZ7)	94C 37-94
M130	Tuner, Television (complete)	94D 47-2
M131	Adjacent Channel Trap Assembly (Trap assem. includes C121, C122, C124, L107, L108 and L110.)	94D 47-56

MISCELLANEOUS CHASSIS PARTS

For picture tube mtg. parts, see separate headings.

Sym.	Description	Part No.
M201	Speaker Socket	88A 5-6
M202	Speaker Plug	88A 5-5
M203	Speaker	See Cabinet Parts List
M401	Horiz. Output Fuse, ¼ amp, 250 volts	84A 4-2
M401	Fuse Holder	84A 5-1
M501	Interlock Socket (Male)	89A 22-2
M502	Line Cord, with interlock socket	89A 22-1
M701	Socket, Phono Input	88A 1
SW501	Switch, On-Off Power (S.P.S.T.)	Part of R208 or R224
SW703	Switch, Tel-Radio-Phono	77C 42

Description	Part No.
Bracket, Tuner Shaft (Bakelite)	32A 111-1
Clip, Tube Cap	
for 6CD6G tube	88A 16-6
for 1B3GT tube	19A 54
Connector Lead, 2nd Anode	88A 16-12
Cover, IF Strip	15B 640
Fuse, ¼ amp, 250 volts	84A 4-2
Fuse Holder	84A 5-1
Ion Trap	94A 15-2
Insulating Plate (for 2nd anode filter condenser mtg.)	32A 135-3
Knob, DX Range Finder	33A 23-4
Lock, 1B3GT Mounting Shell Disc	15A 589
Pilot Light (#44)	81A 1-5
Pilot Light Socket	82A 11-59
Plastic Tubing (for 2nd anode lead)	96B 18-2-16-0
Shield, Tube	
for 7 pin miniature tube	
plain type	87A 7-7
slotted type	98A 45-73
for 9 pin miniature tube	87A 7-10
Shield, HV Compartment	15D 815-2
Shield Cover, HV Compartment	15D 815-1
Socket, Shell (cover for 1B3GT tube socket)	88A 27-1
Socket, Test (4 terminal)	10A 28
Socket, Tube	
miniature bakelite (7 pin)	87A 24-5
octal, plain	87A 5-1
octal, ringmount (mica filled)	87A 20-2
miniature (9 pin)	87A 25-4
picture tube	87B 31-8
Tuner, Television (complete)	94D 47-2
Washer, Spring (for mounting picture positioning lever)	4A 5-10

MISC. RADIO PARTS for 22E2 CHASSIS

Sym.	Description	Part No.
M701	Socket, Phono Input	88A 1
M706	Socket, Phono Motor	88A 8-7
SW703	Switch, Function (complete)	77C 42
	Clip, IF Transformer Mounting	72B 28-10
	Dial Cord (30" length needed)	50A 1-3
	Drum, Gang	A3797
	Grommet, Gang Mounting	12B 1-2
	Lock Washer, Osc. Coil & Gang (#6 I.T.)	3B 1-25-24
	Pilot Light (#44 Mazda)	81A 1-5
	Pilot Light Shield	82A 5-3
	Screw, Drum Set (#6-32x¼ Allen Hd.)	1A 43-14
	Sleeve, Tuning (includes drum)	AA231
	Socket, Pilot Light	82A 18-1
	Socket, Tube, 7 pin miniature	87A 3-7
	Spacer Sleeve (for gang mounting)	29A 2-1-24
	Spring, Dial Cord Tension	19C 1-3
	Spring, Tube Retaining	19A 56-4
	Washer, Vellutex (oscillator coil mtg.)	5A 1-21

PARTS for MOUNTING 21EP4A (21") PICTURE TUBE on CHASSIS

Description	Part No.
Brace, Tie Rod Mtg.	15A 778
Bracket, Picture Tube Mounting (supports front of picture tube)	
right side (facing front)	A3788
left side (facing front)	A3789
Bracket, Strap (supports yoke coil)	15A 572
Bracket, Top and Bottom (for mounting picture tube and focus coil)	
top	15C 613-1
bottom (tube mtg. housing)	43B 183
Bracket	
tube front stop	
for right side facing front	15A 807-1
for left side facing front	15A 807-2
Connector Lead, 2nd Anode	88A 16-12
Insulator Strip, Fibre	
support for 2nd anode lead	32A 143
for deflection yoke	32A 75-1
Ion Trap	94A 15-2
Lever, Picture Positioning	15B 574
Magnet, Correcting (with mtg. bracket)	A3614
Nut, for threaded end of tie rod (#8-32)	2A 1-15-24
Nut, for clamping tube support band (¼-20x7/16)	2A 1-23-24
Plastic Tubing, eliminates corona between 2nd anode lead and HV housing	96B 18-2-16-0
Rubber Channel (used under metal strap), 26" length	12A 47-2
Rubber Collar (supports flare of picture tube)	12B 40
Rubber Insert	
1" dia. (for tube support bracket)	12A 16-4
1 3/16" wide (for tube support bracket)	12A 46-1
Rubber Strip, Adhesive (3/16"x1¼"x3")	12B 5-36
Rubber Strip, Adhesive (1/16"x½"x1¾")	12B 5-35
Screw	
for mounting upper to lower bracket (#10-24x½ H.H.M.S.)	1A 109-31-24
for supporting deflection yoke (8-32x¾ wing head)	1A 101-1-24
Spacer Sleeve (⅛" in length)	29A 2-3-24
Spring, Tube Grounding	19A 23-2
Strap, Bracket and Spade Bolt Assembly	A3617
Tie Rod (#8-32 thread, 20" long, supports sides of tube mtg.)	28B 52-4
Tie Rod (#8-32 thread, 10½" long)	28A 51-1
Washer, Spring	
for mtg. picture positioning lever	4A 5-10
for mtg. correcting magnet	4A 5-18
Washer, Steel (for mtg. correcting magnet)	4B 1-29-24

TUNING KNOBS and ASSOCIATED PARTS

Description	Part No.
Knob, Radio Tuning	
"Tuning"	33D 88-19
"Tel-Rad-Pho"	33B 90-4
Knob, Television Tuning	
black, "DX Range Finder"	33A 23-4
maroon, "Channel" (with gold inserts)	33C 53-23
maroon, "Off-Volume" (with gold inserts)	33C 53-24
maroon, "Off-Volume" (with gold inserts, 22E2 only)	33C 53-25
maroon, "Picture"	33D 88-20
maroon, "Tuning"	33D 88-21
maroon, "Vertical-Focus"	33A 92-3
Washer, Fibre used behind Volume and Picture knob	5A 1-36

CABINET PARTS for MODELS 222DX48 and 222DX49

Description	222DX48 (Maple)	222DX49 (Silver Fox)
Back, Cabinet	A3773	A3773
*Cabinet, Wood	*35E 236-1	*35E 236-2

Window Mask, Plastic	23E 132	23E 132	23E 132	23E 132	23E 132

* To insure proper matching and fit, also specify cabinet manufacturer's code letters (usually burned or stamped on back rail of cabinet). Wood parts are supplied only if old part cannot be repaired; when ordering, describe condition of old part in detail.

§ Order these parts using the part number given in Cabinet Hinge Ordering Data, Form No. S379. Otherwise, return old part, or send an outline tracing (exact size) of part and note finish (brass, bronze, etc.).

PHONOGRAPH PARTS

Model RC600 record changer is used. The changer model number is on the top rear of the changer pan and also on the changer model label on the underside of the changer.

Sym.	Description	Part No.
M702	Cable, Shielded (includes plug)	413A 11-1
M703	Cartridge, Phono Pickup (includes needle)	409A 13
M704	Motor (3 speed)	407C 20
M705	Plug, Motor (Male)	88A 8-1
	Adapter, 45 RPM Record (envelope of 12)	48A 8-2
	Base, Changer (wood, gold finish)	35E 209-3
	Belt, Rubber Drive	406A 20
	Cable, Audio Extension (66" long)	89A 27-4
	Centerpost Assembly	G400B 601
	Escutcheon, Plastic (changer front)	23D 123-1

Sym.	Description	Part No.
	Idler Wheel Assembly (includes tire)	G400A 279
	Manual, Record Changer Service	S454
	Needle, Phonograph for 409A13 cartridge	98A 15-19

WAVEFORM DATA
(Waveforms given on schematic)

Waveforms taken with PICTURE control set fully to the right, all other controls set for normal picture (in sync). Warning: Incorrect adjustment of the DX Range Finder control will cause waveform distortion.

Waveforms at video and sync stages obtained with transmitted signal input to receiver.

The oscilloscope sweep is adjusted for 30 cycles (which is one-half of the vertical frequency), or for 7875 cycles (which is one-half of the horizontal frequency) so that two pulses appear on the screen.

The peak-to-peak voltage readings shown are subject to some variations due to response of the oscilloscope and parts tolerances.

VOLTAGE DATA
(Voltages given on schematic)

- TV voltages taken with function switch on "TV" position. PICTURE control turned fully clockwise. CHANNEL control set on an unused channel. Other front controls set at approximately half rotation. Vert. Lin. and Height set at approximately half rotation. DX Range Finder control set fully to the left (at "O" position). TV antenna disconnected from set with terminals shorted.
- Radio voltages V701 and V702 taken with function switch on "Rad" position; voltages measured from underside of tube sockets. When measured from top of tube sockets (with tube removed), B plus voltage at pins 5 and 6 of V701 and V702 will be approximately 275 volts.
- B plus voltages at V203 and V204, will be slightly higher when set is switched to "Rad" position. Voltages marked with an asterisk * will vary widely with control setting.
- Line voltage 117 volts AC.
- Voltages measured with a vacuum tube voltmeter between tube socket terminals and chassis, unless otherwise indicated.
  Voltages at V306 measured from top of socket with tube removed.

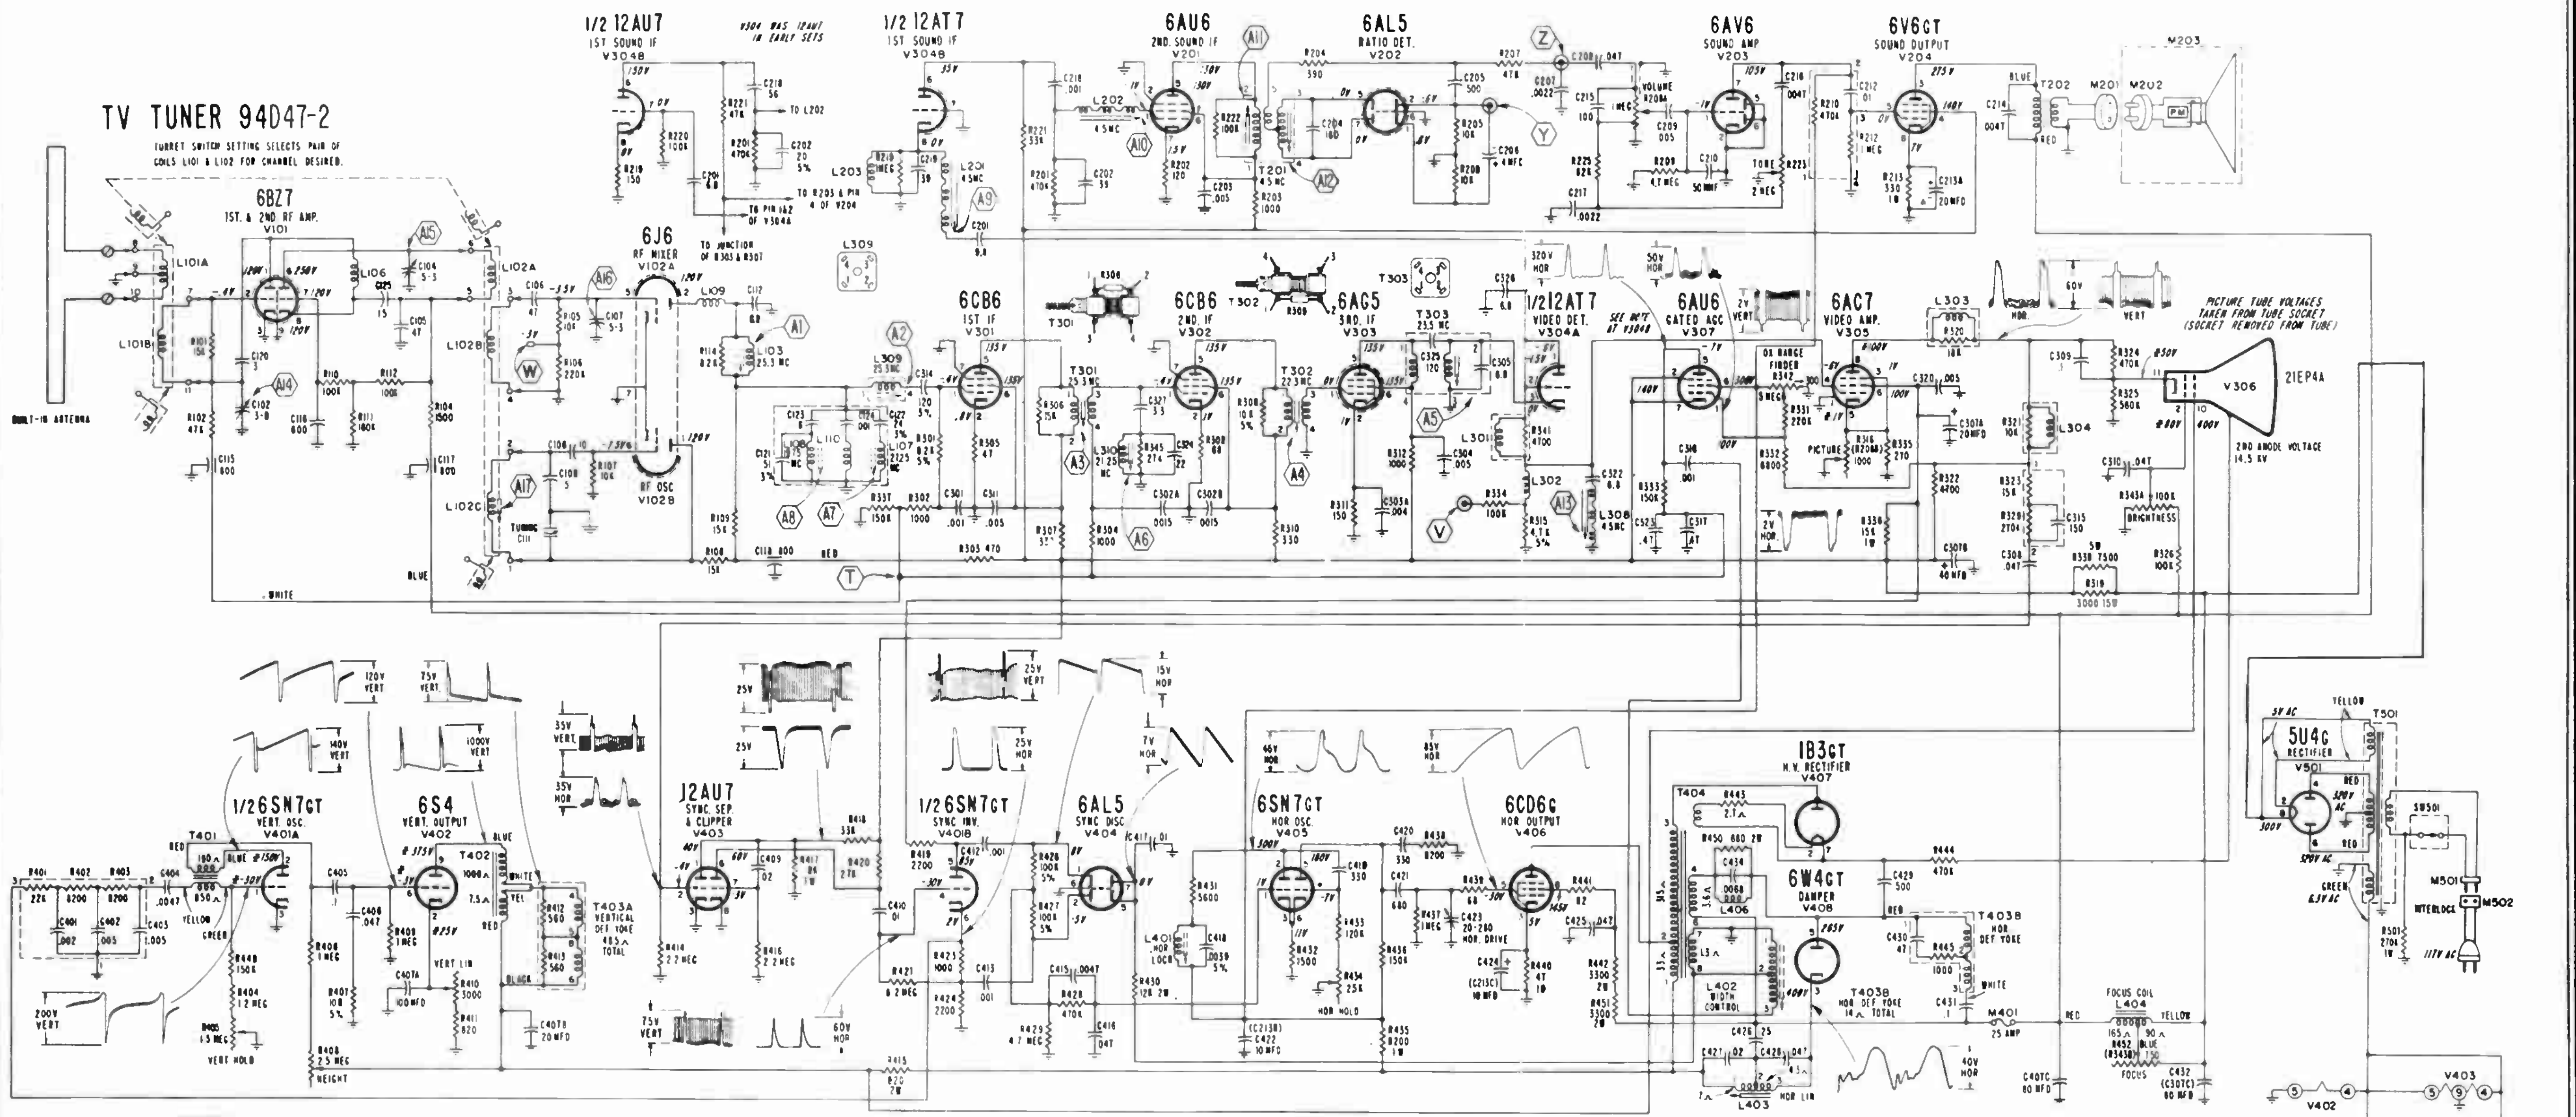

Figure 16. Schematic for 22C2 Television Chassis.

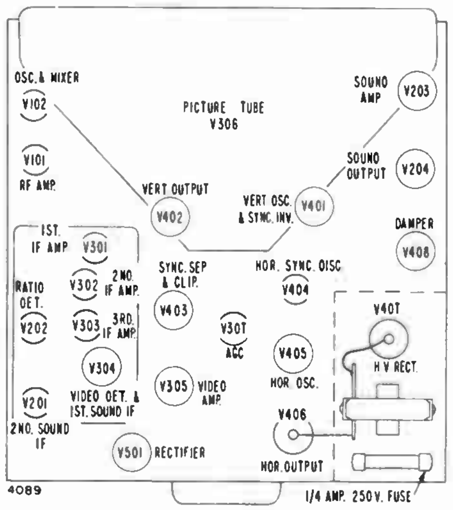


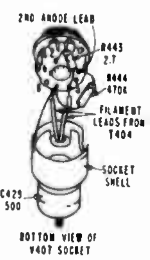
Top View of 22C2 Chassis.

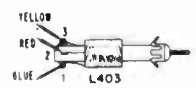
TV VOLTAGE DATA

(Voltages given on schematic)

- PICTURE control turned fully clockwise. CHANNEL control set on an unused channel. Other front controls set at approximately half rotation. Vert. Lin. and Height set at approximately half rotation. DX Range Finder control set fully to the left (at "O" position).
- Antenna disconnected from set with terminals shorted.
- Voltages marked with an asterisk * will vary widely with control setting.
- Line voltage 117 volts AC.
- Voltages measured with a vacuum tube voltmeter between tube socket terminals and chassis, unless otherwise indicated.

Voltages at V306 measured from top of socket with tube removed.





SCHEMATIC NOTES

(A1), (A2),......(Y), (Z), etc. indicate alignment points and alignment connections.

CAUTION

Pulsed high voltages are present on the cap of V406, and on the filament terminals and cap of the 1B3GT tube. NO ATTEMPT SHOULD BE MADE TO TAKE MEASUREMENTS FROM THESE POINTS WITHOUT SUITABLE TEST EQUIPMENT.

Picture tube 2nd anode voltage can be measured from the 2nd anode connector and should be taken only with a high voltage instrument such as a kilovoltmeter. 2nd anode voltage is approximately 14.5 KV. Proper filament voltage check of the 1B3GT tube may be made by observing filament brilliancy as compared with that obtained with a 1.5 volt dry cell battery.

MODEL NUMBERS Model numbers may have suffix letter "N"	TV Chassis	Picture Tube	TV Tuner	Record Changer	Radio	Tone Control
228DX16, 228DX17	23A1	27EP4	94D47-2	......	......	Yes

SPECIFICATIONS FOR 23A1 CHASSIS

Picture Tube
Type 27EP4 (27") rectangular picture tube with aluminum coated screen. Magnetic deflection and focus.

Operating Voltage
110-120 volts, 60 cycles, AC.

Wattage
265 watts for all models.

Input Impedance and Transmission Line
300-ohm balanced (between antenna terminals).
Note that 72-ohm coaxial cable may be used by connecting the outer conductor to the chassis and the inner conductor to either antenna terminal. In weak signal areas, the use of coaxial cable should be avoided.

Antenna
All models equipped with a built-in TV antenna.

Intermediate Frequencies
Video 25.75 MC. Sound 21.25 MC.
Intercarrier Sound 4.5 MC.

Fuse Location
The horizontal output circuit is fused with a 3/8 amp., 250-volt fuse, part number 84A4-3. The fuse is located at the rear of the high voltage compartment.

V502	5U4G	High Voltage Rectifier

23A1 CHASSIS NOTES

The 23A1 chassis is a 23 tube television receiver using a 27 inch (27EP4) rectangular picture tube. The picture tube is mounted separately from the chassis. Circuitry of the 23A1 chassis is similar to that of the 22 series chassis with the exception of the video amplifier, vertical output, horizontal output, damper and power supply circuits. See paragraphs below on "New Features In 23A1 Chassis."

NEW FEATURES IN 23A1 CHASSIS

New Video Amplifier: A 6CL6 tube (9-pin miniature pentode) is used as a video amplifier. This tube is capable of higher output, thereby providing greater peak-to-peak output voltage with high efficiency and low amplitude distortion.

New 27" Picture Tube: A 27EP4 (27" rectangular) picture tube is used. This picture tube features a high quality neutral density face plate which produces increased picture contrast and detail under high ambient light conditions. A reflective metal back (aluminized screen backing) increases the light output and contrast.

Vertical Retrace Blanking Circuit: A vertical retrace blanking circuit is used to eliminate vertical retrace lines. Vertical retrace blanking is achieved by applying the pulse voltage appearing at the secondary of the output transformer to the grid of the picture tube.

New Vertical Output Tube: A 6AV5GT beam power amplifier is used as the vertical output tube. This tube is capable of greater output currents at low plate and screen voltages. Use of the 6AV5GT tube and other circuit improvements made to the vertical output stage has resulted in increased vertical output and improved interlace.

Improved Horizontal Output Circuit: A new high efficiency auto-transformer with a ferrite core is coupled directly to a high efficiency 90 degree deflection yoke. A potentiometer type Horizontal Drive control is used for the drive adjustment. A new Width control (having two windings) permits more effective and increased range of width adjustment.

Circuit improvements made to the horizontal output stage have resulted in increased output, capable of producing full 90 degrees deflection and increased 2nd anode voltage (approximately 19,000 volts).

New Damper Tube: A 6V3 tube (9-pin miniature) is used as the damper tube. This tube features a higher heater to cathode breakdown voltage rating, higher peak inverse plate voltage rating and greater ability to handle high peak currents. Use of this new damper tube minimizes possibility of tube failure in the damper circuit.

Improved Deflection Yoke: A newly designed deflection yoke, provides the 90 degree deflection angle required for the 27 inch picture tube.

Use of this new deflection yoke eliminates the need for pin cushion correction magnets as used with some 21 inch picture tubes.

Improved Focusing Circuit: The focus coil in this receiver is of the shunt type, being connected across the filtered output of the low voltage power supply. This new circuit provides better range of focus, minimizing defocusing effects due to loading of other circuits and variation in power line voltage.

Improved Power Supply: Two 5U4G rectifier tubes are used. One 5U4G (V502) tube is used as the high voltage B+ rectifier, the other 5U4G (V501) tube is used as the low voltage B+ rectifier. Use of two rectifier tubes and other changes in the B+ circuits have provided more efficient B+ distribution with better voltage regulation.

Twin 10" Speakers: Two high qaulity 10" PM speakers are used to provide increased audio frequency response (higher fidelity). The response of the speakers is staggered to produce widest possible range of audio response.

INSTALLATION and SERVICE ADJUSTMENTS

NOTE: Except for DX Range Finder adjustments, all adjustments described on this page and those which follow are for the 23A1 chassis only. For general service information, alignment, etc., see 22C2 and 22E2 chassis.

When installing, each set should be checked for DX Range Finder adjustment (generally set on zero), picture centering, picture tilt, shaded corners, proper size, linearity, etc., to insure best performance. It is especially important that Ion Trap adjustment be checked, and that the Channel Slugs be adjusted upon installation or servicing of every set to insure ease of tuning. Make all checks and adjustments as instructed on the following pages.

For best results, all checks or adjustments should be made using a transmitted television test pattern. A mirror placed in front of the picture tube screen will be of help in observing the picture while making adjustments at the rear of the chassis. Removing the TV back disconnects the interlocking line cord; use a separate line cord (part number 89A22-1) when servicing. See "High Voltage Warning"

INDIVIDUAL CHANNEL SLUG ADJUSTMENT USING A TELEVISION SIGNAL

Individual channel slug adjustment of every receiver should be checked upon installation or servicing. If this adjustment is properly made, it is possible to tune from one station to another by merely turning the CHANNEL control. With correct channel slug adjustment, best picture and satisfactory sound will be located at the approximate center (half rotation) of the range of the Tuning control.

Channel slug adjustment can be made without removing the chassis from the cabinet. Adjust as follows:

a. Turn the set on and allow 15 minutes to warm up.
b. Set the CHANNEL knob for a station; set other controls for normal picture and sound.
c. Remove the CHANNEL knob.
d. Set TUNING control at center of its range by rotating it approximately half-way. At this setting, the hole in the TUNING knob will coincide with the hole in the control panel.
e. Insert a 1/8" blade, NON-METALLIC tool in the hole through the TUNING knob (see illustration). For each channel in operation, carefully adjust the channel slug for best picture with clear detail. (Note that this may not be the point at which the sound is loudest.) Be sure that the Tuning control is set at the center of its range before adjusting each channel slug. Generally, only slight rotation of the slug will be required; turning the slug in too far will cause it to fall into the coil. (If the slug falls into the coil, remove the chassis from the cabinet and remove the coil. Move the retaining spring aside, lightly tap the open end of the coil until the slug slips out. Replace slug and reset retaining spring.)

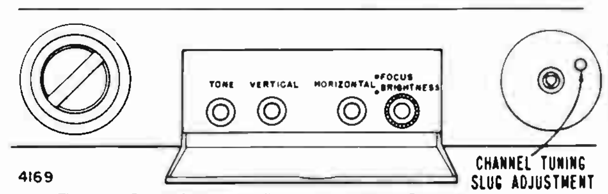

Figure 18. Control Panel for 23A1 Chassis. CHANNEL Knob Removed.

ION TRAP ADJUSTMENT

To prolong the life of the picture tube, it is important that this adjustment be made upon installation, after adjusting the picture positioning lever, or after repositioning the focus coil.

Set the BRIGHTNESS control (at front of set) for normal brightness.

Position the ion trap on the picture tube close to the base. Starting from this point, very carefully move the

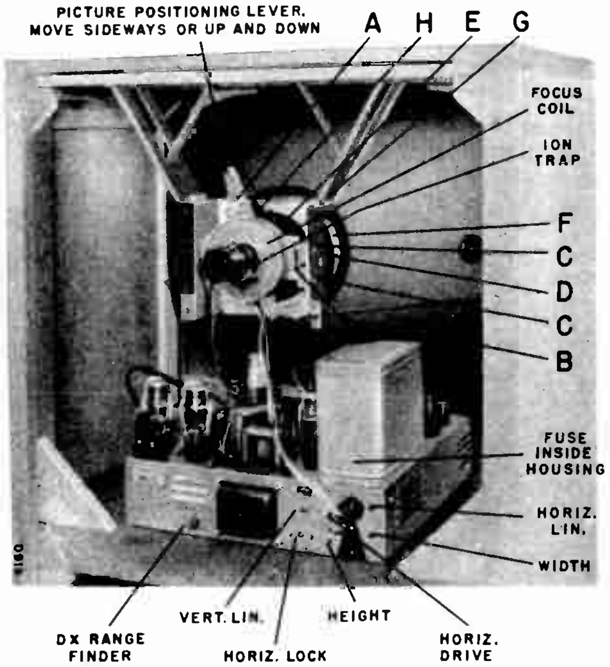

Figure 19. Rear View of 23A1 Chassis Showing Adjustment Locations.

ion trap forward or backward and at the same time, rotate it slightly in either direction until maximum brightness is produced.

Reset the BRIGHTNESS control for normal brightness. Adjust the FOCUS control (at front of set) for good focus. Readjust the ion trap for maximum brightness.

Note that there may be two locations where the brightest picture can be produced. The second ion trap location, which is further away from the tube base, should not be used or tube damage will result.

Important: If the corners of the picture are shaded, be sure the ion trap has been properly adjusted. Do not sacrifice picture brightness when adjusting the ion trap to remove shaded corners. To eliminate shaded corners, see the discussion under "Check Picture Centering". Be sure to readjust the ion trap each time after adjusting picture positioning lever or repositioning the focus coil. Tighten the ion trap mounting screw after adjustment.

LATEST DX RANGE FINDER ADJUSTMENT INFORMATION FOR 22C2, 22E2 AND 23A1 CHASSIS

(Supersedes adjustment information given on page 21.)

This control is at the rear of the set, near the left side.

This control is used to improve TV reception in fringe areas and in areas where there is interference.

The DX RANGE FINDER should be at the "0" position, if satisfactory pictures can be obtained by using the operating controls on the front of the set.

Where the TV signal strength is weak, the picture can often be improved by turning the DX RANGE FINDER part way to the right or, if necessary, all the way to "300".

White flashes across the picture can sometimes be minimized by careful adjustment of the DX RANGE FINDER.

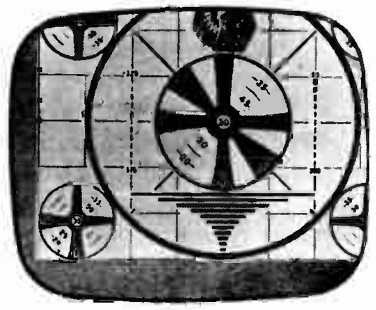
Caution: If the DX RANGE FINDER is turned too far to the right for a strong signal, the picture may disappear completely.

If the signal strength changes, it may be desirable to change the setting of the DX RANGE FINDER; however, it is generally possible to set it at a single compromise position which gives reasonable reception for the different signal strengths.

It is important to keep the DX RANGE FINDER setting as low as possible consistent with satisfactory pictures.

PICTURE CENTERING ADJUSTMENT

If picture is off center, it can be centered by using the picture positioning lever, and when necessary, repositioning the focus coil around picture tube neck. ***Note picture positioning lever can be moved sideways, or up and down.***



Picture Not Centered; Adjust Picture Positioning Lever.

Centering the Picture

a. Adjust ion trap as instructed on preceding page.
b. Slightly loosen the screw "A" which locks the picture positioning lever to the focus coil, and adjust the lever (sideways, or up and down) for correct picture centering. If centering is not done with a test pattern, it may be necessary to reduce picture height and width to determine correct centering.
c. Readjust the ion trap.

Difficulty in Centering the Picture

a. Adjust ion trap as instructed on preceding page.
b. Slightly loosen the two screws "B" which hold the focus coil to the yoke bracket. Center focus coil around the tube neck; tighten screws.
c. Loosen the screw "A" and center the picture with the picture positioning lever. If the picture cannot be centered with the lever, it may be necessary to locate the focus coil slightly off center and then center the picture with picture positioning lever.
d. Readjust the ion trap.

Difficulty in Eliminating Shaded Corners

a. Loosen screws "G", then move the yoke support housing forward until rubber grommet "F" is firmly against the flare of the picture tube.
b. Move the deflection yoke coil "E" as far forward as possible. If the deflection yoke coil cannot be moved forward far enough, it may be necessary to loosen the two screws "D", move the bracket up or down, and then move the deflection yoke coil forward.
c. Adjust ion trap as instructed on preceding page.
d. Shaded corners may also result from use of the wrong ion trap. These picture tubes use iron trap 94A15-2. The part number is stamped on the magnet.

REPOSITIONING FOCUS COIL

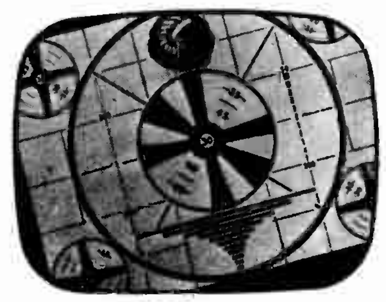
Adjustment of focus coil location in the deflection yoke support housing is made at the factory. Readjustment should not generally be required except when making picture replacement or if difficulty in focusing is encountered.

To adjust the position of the focus coil, proceed as follows:

a. Check to see that the deflection yoke housing and deflection yoke coil are moved forward as far as possible. See paragraph on "Difficulty In Eliminating Shaded Corners".
b. Loosen screws "C" at the sides of the yoke housing. Move the focus coil forward or backward as required. The spacing between the focus coil and the windings of the deflection yoke coil (not the fibre insulator disc) should be about 3/8 of an inch minimum. Moving the focus coil too far away from the deflection yoke coil may cause difficulty in focusing. Moving the focus coil too close to the deflection yoke coil will cause a reduction in picture width and make it impossible to properly focus the picture with the focus control.

PICTURE TILT ADJUSTMENT

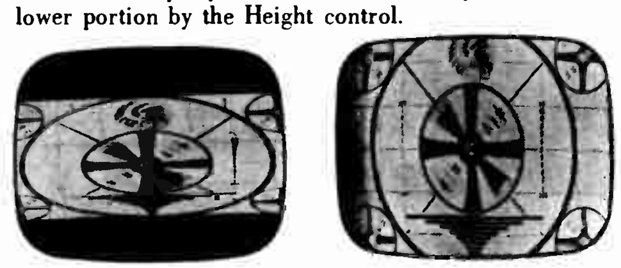
If picture is tilted, loosen wing screw "H" on deflection yoke coil "E" and slightly rotate yoke until the picture is straight. Before tightening the wing screw, be sure yoke is as far forward as possible, otherwise corners of picture may become shaded.



Picture Tilted; Adjust Deflection Yoke Coil.

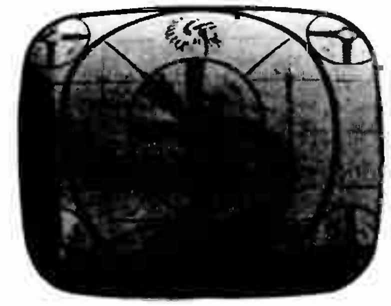
HEIGHT AND VERTICAL LINEARITY ADJUSTMENT

If the picture is of incorrect height (vertical size), adjust the HEIGHT control with BRIGHTNESS control set for normal brightness. This adjustment may affect the vertical linearity of the picture. If necessary, alternately adjust the VERT. LIN. control and HEIGHT control. Note that the upper portion of the picture is affected mostly by the Vertical Linearity control; the lower portion by the Height control.



Incorrect Height; Alternately Adjust HEIGHT and VERT. LIN. Controls.

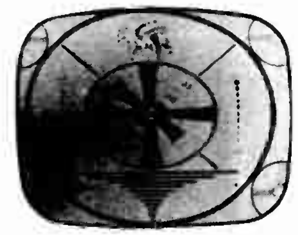
If the large circle in the test pattern appears cramped or flattened at top or bottom (non-linear vertically), correct by alternately adjusting the VERT. LIN. control and the HEIGHT control.



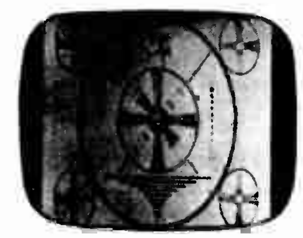
Top or Bottom of Picture Cramped or Flattened; Adjust VERT. LIN. and HEIGHT.

WIDTH ADJUSTMENT

If the picture is too wide or too narrow, adjust the WIDTH adjustment screw until the picture just fills the picture tube screen. Make this adjustment with the BRIGHTNESS control set for normal brightness.



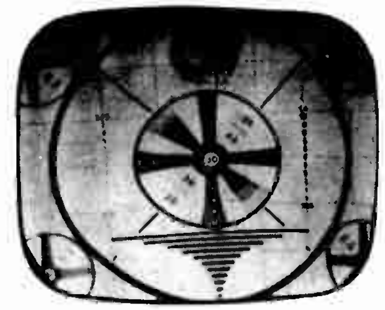
Too Much Width; Adjust WIDTH.



Not Enough Width; Adjust WIDTH.

HORIZONTAL LINEARITY ADJUSTMENT

If the large circle in the center of the test pattern has a cramped or flattened appearance at either side (non-linear horizontally), adjust the HORIZ. LIN. adjustment screw by turning it out (fully to the left). Then slowly turn it in (to the right) until linearity is best. Note that there are two settings of the HORIZ. LIN. adjustment that appear to give good linearity. The correct adjustment setting is the one with the adjustment screw further out (to the left). Note also, that the Horizontal Drive and the Width adjustments also affect linearity. Be sure that these adjustments are set correctly if difficulty is encountered when making the horizontal linearity adjustment.

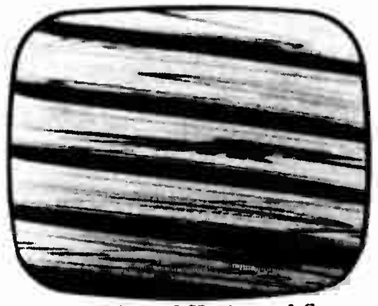


Side of Picture Cramped or Flattened; Adjust HORIZ. LIN.

HORIZONTAL OSCILLATOR and HORIZONTAL DRIVE ADJUSTMENT

A receiver which requires horizontal oscillator or horizontal drive adjustment can be corrected only by following in exact detail the step-by-step procedure given here.

NOTE: *If HORIZ. DRIVE adjustment is not properly made, it may be difficult to obtain sufficient picture width and brightness.*



Picture Out of Horizontal Sync.

Check to see if the HORIZONTAL control (on front panel) keeps the picture in "horizontal sync" through half of its range so that the picture does not "break up" when switching channels. Note: Since there is some interaction between the HORIZ. LOCK adjustment and the HORIZ. DRIVE control, adjustment of these controls are combined in one procedure.

If the picture will not stay in "horizontal sync" through half of the range of the HORIZONTAL control (on front panel), it will be necessary to make HORIZ. LOCK and HORIZ. DRIVE adjustments. However, before making these adjustments, be sure that the picture can be made to remain stationary up and down (sync vertically) as lack of both vertical and horizontal sync is an indication of trouble in the sync circuits such as a defective tube or other component.

Make the HORIZ. LOCK and HORIZ. DRIVE adjustments exactly as follows:

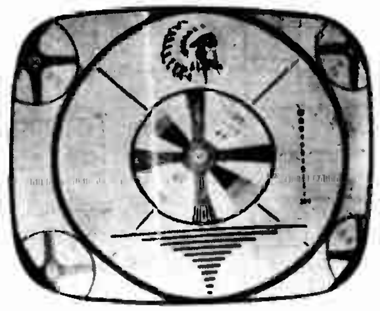
a. Allow the receiver to warm up for a few minutes. Tune in the station, set the BRIGHTNESS control at a lower than average setting. Turn PICTURE control fully to the left. Important: Before proceeding, be sure that the DX Range Finder control (AGC) is adjusted according to the instructions given in this manual.

b. Turn the HORIZONTAL control (front panel) completely to the left. Turn the HORIZ. DRIVE control fully to the right.

c. Turn the HORIZ. LOCK adjustment to the right until the picture falls out of sync. If the picture cannot be made to fall out of sync, momentarily interrupt the signal by switching the CHANNEL control off channel and then back on.

d. With the picture out of sync, turn the HORIZ. LOCK adjustment slowly to the left until the picture just falls in sync.

e. Turn the CHANNEL control to an unused channel. If a white vertical line(s) appears near the center of the screen, slowly turn the HORIZ. DRIVE control to the left until the line(s) just disappears.



Vertical Line;
Adjust HORIZ. DRIVE.

f. If, in step "e", the HORIZ. DRIVE control required readjustment, tune in a station and repeat steps "c" and "d" to be sure of proper Horizontal Oscillator adjustment.

g. Adjustment should now be satisfactory. However, check adjustment by slowly rotating the HORIZONTAL control in either direction while interrupting the television signal by switching the CHANNEL control off channel and then back on. The picture should automatically fall in sync through at least half of the range of the HORIZONTAL control. If necessary, repeat the above step.

h. Do not use the HORIZ. DRIVE control to obtain correct width or linearity. If necessary, make Width and Horizontal Linearity adjustments.

SERVICE HINTS

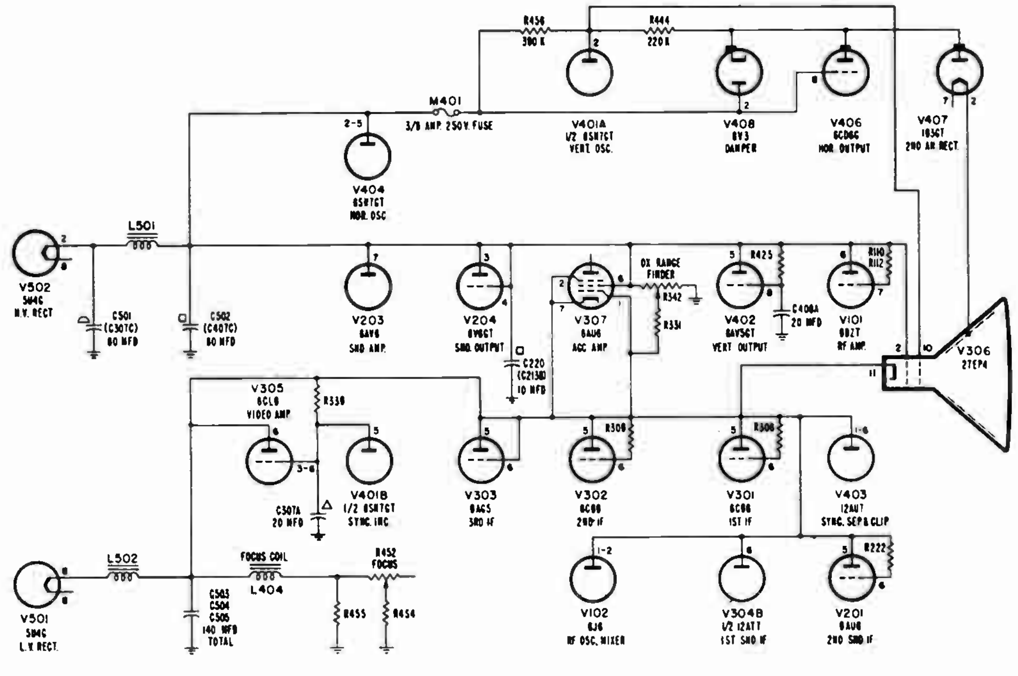
TELEVISION ALIGNMENT

Alignment for the 23A1 chassis is the same as for the 22C2 and 22E2 chassis. For alignment information, see page 32 and page 33

Important: The focus coil and the deflection yoke coil must be connected to chassis during alignment.

TROUBLE SHOOTING

The 23A1 chassis described in this manual is similar to the 22 series chassis with the exception of the video amplifier, picture tube, vertical output, horizontal output, damper and power supply circuits. The basic differences in the 23A1 chassis over the 22 series is outlined under "New Features In 23A1 Chassis".



NOTE: This diagram applies only to chassis which are not stamped with a run number.

Figure 20. Simplified Diagram Showing B+ Distribution in 23A1 Chassis.

In general, the trouble shooting of the 23A1 chassis will be similar to that of the 22 series chassis

It is important, however, to remember the following trouble shooting hints which apply to the 23A1 chassis. Note: Some hints also apply to the 22C2 and 22E2 chassis.

Improper Focus (control focuses at extreme end of rotation, 23A1 chassis): This may be caused by a weak 5U4G rectifier tube V501. Try another rectifier tube.

It may also be impossible to obtain good focus with FOCUS control if the focus coil is spaced too far away from the deflection yoke coil. Spacing between the focus coil and the deflection yoke coil should be 3/8 of an inch minimum. The deflection yoke coil should be as far forward on the neck of the tube as possible. See paragraph "Repositioning Focus Coil" on page 25.

Insufficient Picture Width (23A1 chassis). This may be caused by a weak rectifier tube V502, a weak horizontal output tube V406 or a weak damper tube V408.

Insufficient picture width may also be caused by incorrect adjustment of the Horizontal Drive control R447, or improper positioning of the focus coil on the deflection yoke housing. Moving the focus coil too close to the deflection yoke coil will result in reduction of picture width. The spacing between the focus coil and the deflection yoke coil should be 3/8 of an inch minimum.

White Flashes Across Picture (22C2, 22E2 and 23A1 chassis): In weak signal, high noise level areas, white flashes across the picture can sometimes be minimized by careful adjustment of the DX Range Finder control. Caution: Turning the DX Range Finder control too far to the right for a strong signal may cause the picture to disappear completely. See instructions for DX Range Finder Adjustment on page 41.

No Picture; Sound Normal (22C2, 22E2 and 23A1 chassis): If the DX Range Finder control is turned too far to the right for a strong signal, the picture may disappear completely. Advancing the DX Range Finder control too far to the right for a strong signal area will cause excessive delay in AGC bias thereby blocking the video amplifier. See instructions for DX Range Finder Adjustment on page 41.

TROUBLE SHOOTING B+ CIRCUITS

The power supply and B+ distribution circuits of the 23A1 chassis are different from previous model television receivers. A simplified diagram, showing the B+ distribution in the 23A1 chassis, is shown in figure 20.

REDUCING SNOW IN INTERMEDIATE FRINGE AREAS

(Applies to 22C2, 22E2 Chassis Below Run 2 and 23A1 Chassis without a Run Number)

To reduce snow (front end noise) in intermediate fringe areas, it is recommended that the tuner AGC voltage be reduced to 1½ or 2 volts. This reduction in AGC voltage can be accomplished by removing resistor R337 (150,000 ohms) and replacing it with a 100,000 ohm resistor and a 47,000 ohm resistor connected in series. Connect the 47,000 ohm resistor to chassis ground and the 100,000 ohm resistor to resistor R302, 1,000 ohms (test point "T"). Remove the tuner AGC lead (usually white) from test point "T" and connect it to the junction of the 100,000 ohm resistor and 47,000 ohm resistor. To reduce the possibility of unstable operation, it is recommended that the tuner AGC lead be by-passed to chassis by a .005 mfd. ceramic condenser.

CHANGE IN SIZE OF FUSE M401

To prevent possibility of fuse burn-out, due to momentary overload, the horizontal output fuse was changed from a ¼ ampere, 250-volt fuse to a ⅜ ampere, 250-volt fuse, part number 84A4-3. Fuse replacement should be made only with a ⅜ ampere, 250-volt fuse, part number 84A4-3.

REPLACING FUSE M401

The horizontal output circuit of these receivers is protected by fuse M401 (⅜ amp., 250 volts, part number 84A4-3). This fuse is located in the rear of the high voltage compartment. To replace the fuse, remove the two screws at the base of the high voltage compartment and lift the cover away from the base; see figure 19. Carefully remove or insert the fuse so as to avoid damage to the horizontal output transformer.

CLEANING GLASS PICTURE WINDOW

The picture window and the picture tube should be cleaned whenever the television chassis is removed from the cabinet.

Clean the picture window and the face of the picture tube with a soft cloth dampened with clear water or window cleaner. Dry the glass with a chamois or a lint-free cotton cloth.

The plastic tube mask is held in place with the picture window in a channel along the top and by brackets at the sides and the bottom edge. The tube mask may be removed when it requires cleaning. Mild soap and water applied with a soft cloth will safely remove any dirt on the plastic tube mask.

HIGH VOLTAGE WARNING

High voltages are present throughout the horizontal output, damper and second anode supply circuits. No attempt should be made to make measurements from high voltage points in these circuits with ordinary test equipment.

Caution: Operation of the set outside of the cabinet or with cabinet back removed involves shock hazard. Exercise normal high voltage precautions.

27EP4 PICTURE TUBE REPLACEMENT

Important: Make all deflection adjustments — Repositioning Focus Coil, Picture Centering, Picture Tilt and Ion Trap — whenever replacing the picturing tube. These adjustments are described on pages 41 to 42.

Warning: Before removing or replacing the picture tube, note the following precautions:

- Before handling the picture tube, remove any residual charge on the second anode connector and the second anode socket on the tube.
- Due to the high vacuum and large surface area of the picture tube, great care must be exercised when handling. Do not pick up the picture tube by the neck. Do not scratch or subject the picture tube to excessive pressure as fracture of the glass will result in an explosion of considerable violence which may cause serious personal injury. Shatterproof goggles and heavy gloves should be worn while handling or installing a picture tube.

The picture tube, deflection yoke and focus coil mounting assembly are mounted on a removable board which slides in place along the rails under the cabinet top. Mounting for the 27" picture tube is shown in figure 19.

To remove the picture tube, proceed as follows:

1. Disconnect the ground strap and all plugs which connect between the picture tube assembly, the chassis and the cabinet.
2. Remove the television chassis.
3. Remove the Phillips head screws at the sides and back which fasten the mounting board to the top of the cabinet. Slide the picture tube assembly out of the cabinet.
4. Remove the ion trap.
5. Remove the tube stops on the front tube support brackets. Loosen the tie rod nut and disconnect the tie rods at each side of the picture tube. Remove the nuts on the spade bolts at each end of the picture tube strap and carefully remove the strap assembly.
6. Carefully move the tube straight out from the deflection yoke and focus coil to avoid any damage to either the picture tube neck or the deflection coil. Use care so the fibre insulating disc, which is between the focus coil and the deflection yoke, does not slip down and catch on the tube socket. To facilitate picture tube removal and installation, the fibre insulating disc may be taped to the focus coil.

To install a new picture tube, proceed as follows:

a. Loosen the four hexagonal head screws "G" and slide the deflection yoke housing as far back as it will move; see figure 19. Carefully insert the picture tube, fitting the fibre insulating disc (between deflection yoke and focus coil) over the tube base. Move the picture tube in until it is positioned properly on the front support brackets.
b. Install the tube stops on the front support brackets and move the picture tube forward and snug against these stops.
c. Loosen deflection yoke wing nut "H" and move yoke coil back.
d. Slide the deflection yoke housing forward until the tube ring is snug against the flare of tube and tighten screws.
e. Move deflection coil forward as far as it will go and tighten wing nut "H".
f. Install the strap assembly and tighten the nuts on the spade bolts. Install each tie rod and tighten the tie rod nuts. Be sure that the strap is fitted squarely over the top of the picture tube, that the picture tube rests squarely and snug in the front tube support brackets.
g. Dampen a soft cotton cloth with water and wipe away any finger marks. Polish the tube surface with a dry cotton cloth.
h. Install the ion trap.
i. Install picture tube assembly and chassis in cabinet.
j. Make all picture tube adjustments described on pages 41 to 42.

SUPPLEMENTARY PARTS LIST FOR 23A1 CHASSIS

This parts list includes parts used in the 23A1 chassis which are not used in the 22C2 or 22E2 chassis. Parts which have the same symbol number but have different values in either the 22C2, 22E2 or the 23A1 chassis are also listed. For parts used in the 23A1 chassis, use this parts list FIRST; then refer to the parts list for the 22C2 and 22E2.

RESISTORS

Sym.	Description	Part No.
*R210	150,000 ohms, ½ watt (22E2 chassis)	60B 8-154
	470,000 ohms, ½ watt (22C2, 23A1 chassis)	60B 8-474
R215	560 ohms, 2 watt	60B 20-561

COILS, TRANSFORMERS

Sym.	Description	Part No.
L401	Horizontal Lock Coil (includes C418, R431)	
	for 22C2 and 22E2 chassis	94A 17
	for 23A1 chassis	94B 48-1
L402	Width Control Coil	
	for 22C2 and 22E2 chassis	94A 39-1
	for 23A1 chassis	94A 56-1
L403	Horizontal Linearity Coil	
	for 22C2 and 22E2 chassis	94A 28
	for 23A1 chassis	94A 55-1
L404	Focus Coil	
	for 22C2 and 22E2 chassis	69D 117-3
	for 23A1 chassis (includes plug M404)	69D 117-10
L501	Filter Choke (2 Henry)	74B 18-6
L502	Filter Choke (6 Henry)	74B 18-5
T202	Audio Output Transformer	
	for 22C2 chassis	79C 33-3
	for 22E2 chassis	79C 33-4
	for 23A1 chassis	79C 33-5
T402	Vertical Output Transformer	
	for 22C2 and 22E2 chassis	79B 40-1
	for 23A1 chassis	79B 43-1
T403	Deflection Yoke	
	for 22C2 and 22E2 chassis (includes R412, R413, R445 and C430)	94C 30-1
	for 23A1 chassis (includes R412, R413, R445, C430 and plug M406)	94D 54-1
T404	Horizontal Output Transformer	
	for 22C2 and 22E2 chassis	79C 38-1
	for 23A1 chassis	79D 44-1
T501	Power Transformer	
	for 22C2 and 22E2 chassis	80C 26-1
	for 23A1 chassis	80C 36-1

MISCELLANEOUS CHASSIS PARTS

Sym.	Description	Part No.
M201	Speaker Socket	88A 5-6
M202	Speaker Plug	88A 5-5
M203	Speaker	See Cabinet Parts List
M204	Speaker	See Cabinet Parts List
M205	Speaker Plug	88A 5-5
M206	Speaker Socket	Part of M203
M401	Horiz. Output Fuse	
	¼ Amp. 250 V. (in 22C2, 22E2)	84A 4-2
	⅜ Amp. 250 V. (in 23A1)	84A 4-3
M403	Socket, Focus Coil	87A 4-4
M404	Plug, Focus Coil	88A 3-5
	Cover & Insulator (for 88A3-5 plug)	88A 3-4
M405	Socket, Deflection Yoke	87A 2-7
M406	Plug, Deflection Yoke	88B 23-3
M503	Pilot Light Socket (includes leads)	82A 11-59
	Clip, Tube Cap	
	for 6CD6G tube	88A 16-20
	for 6V3 tube	88A 16-21
	Connector Lead, 2nd Anode, 17" long	88A 16-15
	Pilot Light (#44)	81A 1-5
	Socket, Picture tube	87A 32-8

PARTS for 27EP4 (27") PICTURE TUBE ASSEMBLY

Sym.	Description	Part No.
M403	Socket, Focus Coil	87A 4-4
M404	Plug, Focus Coil	88A 3-5
	Cover and Insulator (for 88A3-5 plug)	88A 3-4
M405	Socket, Deflection Yoke	87A 2-7
M406	Plug, Deflection Yoke	88B 23-3
	Board, Deflection Assembly and Tube Mtg.	46D 37
	Bracket	
	Deflection Yoke Adjustment	15B 871
	Deflection Yoke Support (includes rear tube support bracket)	A3878
	Focus Coil Mounting	15A 872
	Front Tube Stop	15A 807
	Front Tube Support	
	for right side (facing front)	A3788
	for left side (facing front)	A3789
	Rear Base	15C 868
	Cable Assembly, Grounding	A3883
	Connector Lead, 2nd Anode, 17" long	88A 16-15
	Insulating Disc, Fibre (between focus coil and deflection yoke)	32A 181
	Insulator Strip, Fibre (support for 2nd anode lead)	32A 143
	Ion Trap	94A 15-2
	Lever, Picture Positioning	15B 574
	Nut, for mounting focus coil (#8-32)	2A 8-18-24
	Nut, for threaded end of tie rod (#8-32)	2A 1-15-24
	Nut, for tube support strap (¼-20)	2A 1-23-24
	Rubber Bumper	
	for tube stop (⅝" dia. x ½" high)	12A 16-3
	for tube support (1" dia. x 3/16" high)	12A 16-4
	Rubber Channel (for strap assembly)	
	9" long	12A 47-5
	31" long	12A 47-6
	Rubber Pad	
	for tie rod bracket (1¼" wide x 3½" long)	12B 5-37
	for tube support (1¾" wide x 1⅝" long)	12A 46-1
	Rubber Strip (for pict. wind. mtg. bracket)	12B 5-22
	Rubber Support (for flare of picture tube)	
	Rubber Strip Adhesive (¼"x1¼"x3½") 8 req.	15B 5-37
	Rubber Collar	12B 50
	Screw	
	for deflection yoke (#8-32x⅜ wing)	1A 101-1-24
	for mounting deflection yoke adjustment bracket and focus coil (#8-½ B.H.M.S.)	85-500-C2-24
	for mounting deflection yoke support bracket (#10-24x½ H.H.M.S. with lockwasher)	1A 109-31-24
	for mounting focus coil bracket (#6x⅜ B.H.M.S.)	85-375-C2-24
	for mounting front tube stop (#6-32x¼ H.H.S.T.)	1A 51-2-24
	for mounting picture positioning lever (#6-⅜ B.H.M.S.)	65-375-C2-24
	Spacer Sleeve (for picture positioning lever)	29A 2-3-24
	Strap Assembly (includes tie rod brackets and ¼x20x1" spade bolt at each end)	A3879
	Tie Rod (#8-32 threaded end)	28B 65-1
	Washer, Spring (for mtg. picture positioning lever)	4A 5-10

TUNING KNOBS and ASSOCIATED PARTS

Description	Part No.
Knob, Television Tuning	
black, "DX Range Finder"	33A 23-4
maroon, "Channel" (with gold inserts)	33C 53-23
maroon, "Off-Volume" (with gold inserts)	33C 53-24
maroon, "Picture"	33D 88-20
maroon, "Tuning"	33D 88-21
maroon, "Focus"	33A 92-3
Spring, TV Knob Tension	
for "Off-Volume" knob	18A 43-2
for "Tuning" knob	18A 43-1
for "Channel" knob	18A 43-3
Washer, Fibre	
between Volume and Picture knob	5A 1-36

CABINET PARTS for MODELS 228DX16, 228DX17

These model numbers may have the suffix letter "N".

Description	228DX16 Mohog.	228DX17 Blond
Back, TV (complete)	A3882	A3882
Bracket, for mtg. picture window		
1 3/16" wide (used at sides)	15A 763-1	15A 763-1
1 1/16" wide (used at bottom)	15A 763-2	15A 763-2
*Cabinet, Wood	*35E 234-2	*35E 234-3
*Cabinet Doors (matched set of 2 front doors)	*35E 234-50	*35E 234-51
Carton and Fillers	44B 267	44B 267
Caster, Swivel	37A 77-1	37A 77-1
Control Panel (less door)	23D 133-1	23D 133-1
Control Panel Door	23D 133-5	23D 133-5
Control Panel Door Spring	19A 70	19A 70

CABINET PARTS (Continued)

Description	228DX16 Mohog.	228DX17 Blond
§Door Catch and Strike Plate	See § footnote below.	
Door Handle	37A 84	37A 84
†Gasket, Sponge Rubber for pic. window)	12A 32-13	12A 32-13
Grille Cloth	36C 3-140	36C 3-141
Grille, Metal	36C 43	36C 43
§Hinge, Cabinet Door (pair)	See § footnote below.	
Jewel, Pilot Light	82A 10-8	82A 10-8
Knobs, Tuning	See "Tuning Knobs and Associated Parts".	
Light, Pilot #44	81A 1-5	81A 1-5
Line Cord and Interlock Socket	89A 22-1	89A 22-1
Rubber Strip, Adhesive (1/16"x¼"x4")	12B 5-22	12B 5-22
Screw, for mounting control panel (#4x¼" R.H.W.S. P.H.)	1A 7-9-57	1A 7-9-57
Screw, for mounting TV chassis (¼-20x1¼ M.S.)	1A 67-44-24	1A 67-44-24
Speaker, 10" PM (M204; includes 12" leads and plug M205)	78C 78-1	78C 78-1
Speaker, 10" PM (M203; includes 38" leads, plug M202 and socket M206)	78C 78-2	78C 78-2
Speed Nut (for mtg. speaker)	2B 10-8-59	2B 10-8-59
Tubing, Plastic (1⅜" long, used over 19A70 door spring)	96B 19-3-20-0	96B 19-3-20-0
Washer (for mtg. speaker)	4B 1-56-24	4B 1-56-24
Window, Picture, Glass	21B 49-25	21B 49-25
Window Mask, Plastic	23E 134	23E 134

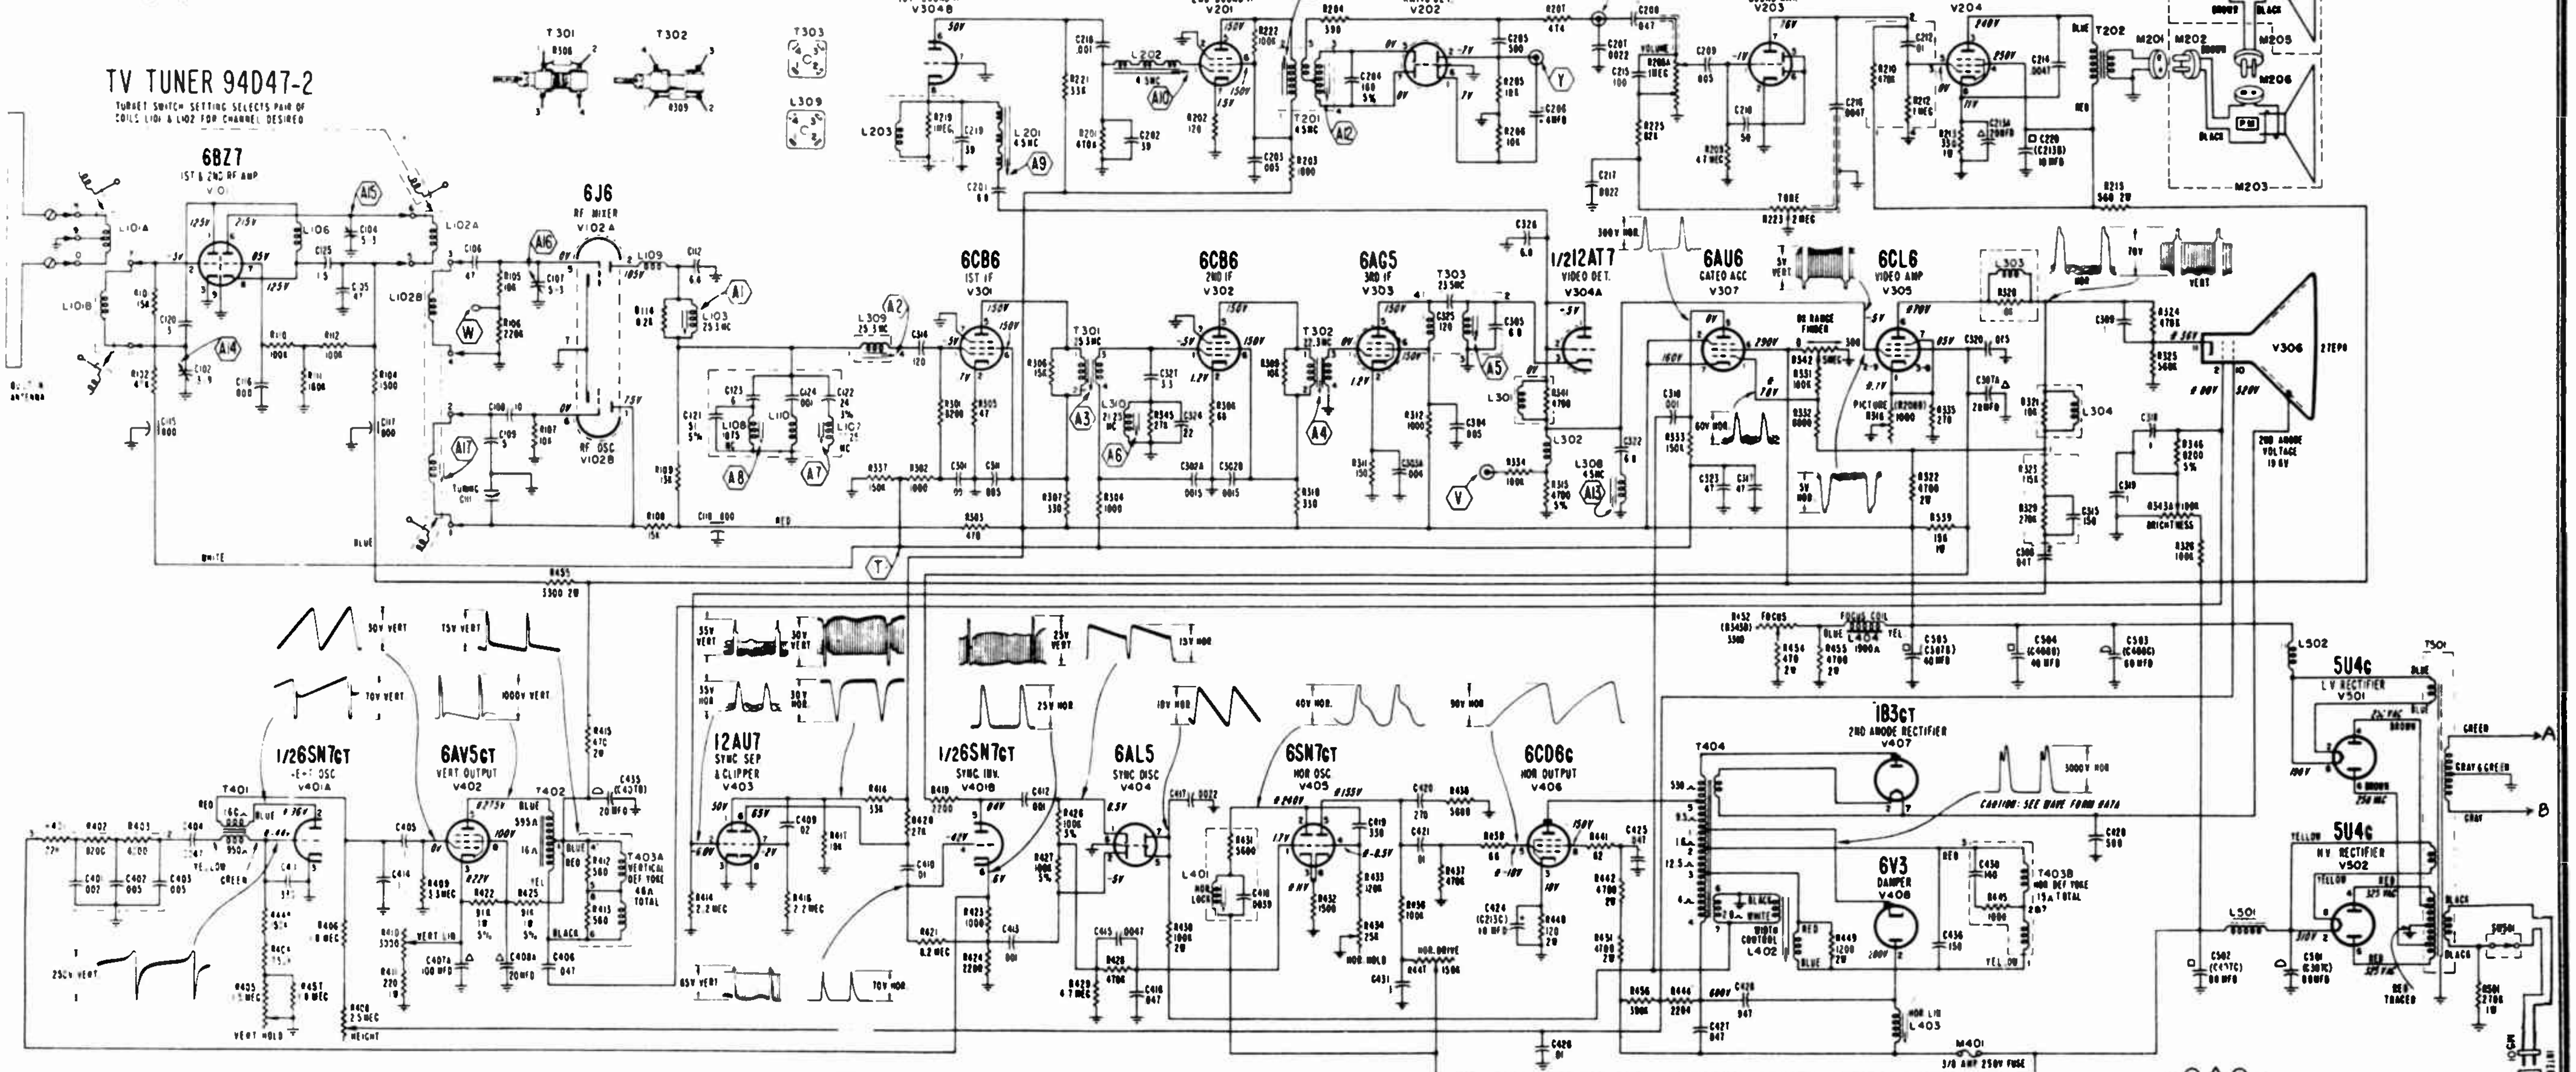
* To insure proper matching and fit, also specify cabinet manufacturer's code letters (usually burned or stamped on back rail of cabinet). Wood parts are supplied only if old part cannot be repaired; when ordering, describe condition of old part in detail.

§ Order these parts using the part number given in Cabinet Hinge Ordering Data, Form No. S379. Otherwise, return old part, or send an outline tracing (exact size) of part and note finish (brass, bronze, etc.).

† Use only rubber cement when mounting sponge rubber gasket.

SCHEMATIC NOTES

(A1), (A2), ... (Y), (Z), etc. indicate alignment points and alignment connections.



CAUTION

Picture tube 2nd anode voltage can be measured from the 2nd anode connector and should be taken only with a high voltage instrument such as a kilovoltmeter or a vacuum-tube voltmeter with a high voltage probe. 2nd anode voltage is approximately 19 KV. Proper filament voltage check of the 1B3GT tube may be made by observing filament brilliancy as compared with that obtained with a 1.5 volt dry cell battery.

Figure 22. Schematic for 23A1 Television Chassis.

NOTE: This schematic applies only to chassis which are not stamped with a run number.

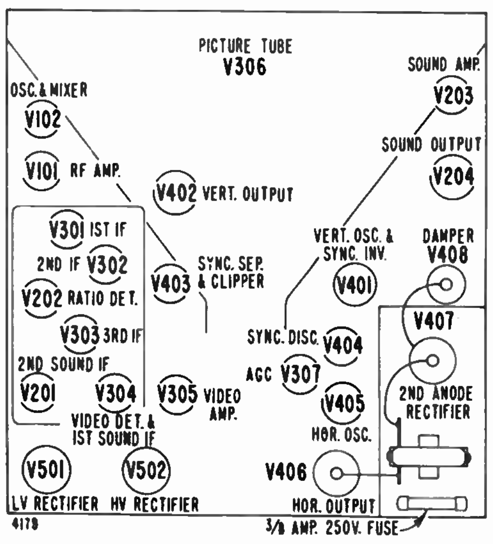


Figure 21. Top View of 23A1 Chassis.

TV VOLTAGE DATA

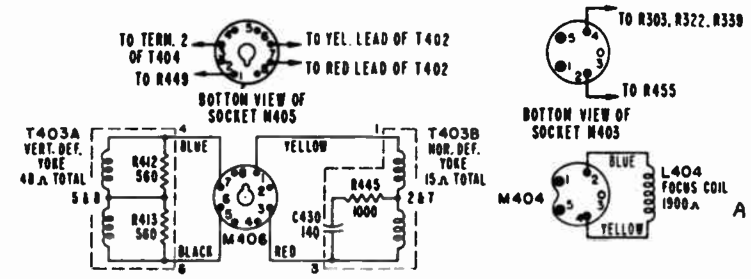
(Voltages given on schematic)

- Picture control turned fully clockwise. Channel control set on an unused channel. Other front controls set at approximately half rotation. Vert. Lin. and Height set at approximately half rotation. DX Range Finder control set fully to the left (at "0" position).
- Antenna disconnected from set with terminals shorted.
- Line voltage 117 volts AC.
- Voltages measured with a vacuum-tube voltmeter between tube socket terminals and chassis, unless otherwise indicated. Voltages at V306 measured from top of socket with tube removed.
- Voltages marked with an asterisk * will vary widely with control setting.

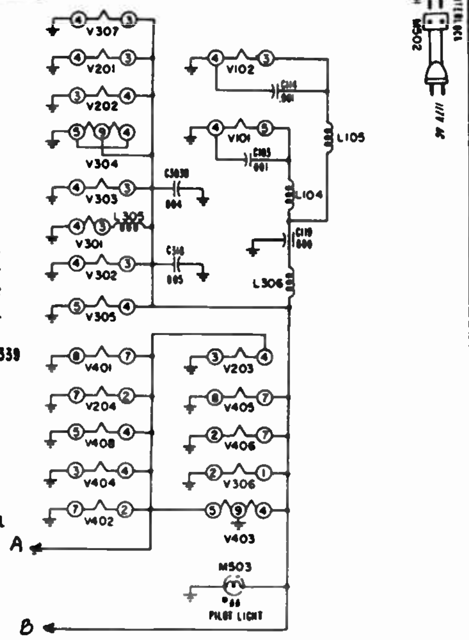
WAVEFORM DATA

(Waveforms given on schematic)

Waveforms taken with Picture control set fully to the right, all other controls set for normal picture (in sync). Important: Incorrect adjustment of the DX Range Finder control will cause waveform distortion. DX Range Finder should be at zero setting.



DEFLECTION YOKE AND FOCUS COIL CONNECTORS FOR 23A1 CHASSIS.



NOTE: Both 16" and 17" rectangular glass picture tubes are used. They require different mechanical mountings and mask and therefore are not interchangeable. When replacing tubes in service use identical tube sizes.

Electrical and Mechanical Specifications

Radio Frequency Ranges

Channel Number	Channel Freq. MC	Picture Carrier Freq. MC	Sound Carrier Freq. MC	Receiver RF Osc. Freq. MC
2	54-60	55.25	59.75	81

ALIGNMENT

Equipment Required

1) RF signal generator to provide the following accurate frequencies. If the accuracy of the generator frequencies is not known, some type of crystal calibrator should be utilized to check the correct settings of the RF generator for each particular frequency.

(a) 4.5 MC Video Amplifier Trap

(b) IF Frequencies

21.25 MC	Sound IF, Sound Discriminator and Sound Traps
22.25 MC	Converter Coil
22.5 MC	Marker Frequency
23.0 MC	First Pix IF Coil
26.5 MC	Second Pix IF Coil
25.0 MC	Third Pix IF Coil
25.75 MC	Picture Carrier Marker

(c) RF Frequencies

Channel Number	Picture Carrier Freq. MC	Sound Carrier Freq. MC
2	55.25	59.75
3	61.25	65.75
4	67.25	71.75
5	77.25	81.75
6	83.25	87.75
7	175.25	179.75
8	181.25	185.75
9	187.25	191.75
10	193.25	197.75
11	199.25	203.75
12	205.25	209.75
13	211.25	215.75

(d) Output on these ranges should be adjustable and capable of providing at least .1 volt.

2) Electronic Voltmeter
3) Cathode Ray Oscilloscope, 3" minimum screen
4) RF Sweep Generator, meeting the following requirements:

(a) Frequency Ranges
18 to 30 MC., 1 MC. sweep width
40 to 90 MC., 10 MC. sweep width
170 to225 MC., 10 MC. sweep width

(b) Output adjustable to .1 volt.

The chassis may be removed from the cabinet with the kinescope tube in place and servicing and alignment work can be accomplished without removing the kinescope tube. This work is most conveniently performed by placing the chassis on its left side (power supply cage resting on work bench) and the controls facing the operator.

To remove chassis from cabinet remove
(1) Line cord from power outlet
(2) Masonite back
(3) Antenna Lead-in from terminal posts
(4) Speaker plug from rear of chassis
(5) Knobs from front of cabinet
(6) Four mounting screws and washers from bottom of cabinet

In sliding chassis out of cabinet be careful that the kinescope tube does not strike against cabinet or any other obstruction.

Order of Alignment

When complete receiver alignment is necessary it should be performed in the following sequence.

(1) Pix IF Traps
(2) Sound IF Transformers
(3) Sound Discriminator
(4) Pix IF Coils
(5) Retouch Pix IF Transformers
(6) 4.5 MC Trap

After removing chassis from cabinet, connect power and speaker plugs.

If a local station is not operating on channel #9 set the tuner to this channel, turn on power switch and proceed as follows: (If #9 is a local station channel use channel #8 or #10).

Picture I-F Trap Adjustment

Insert 100,000 ohm resistor in series with hot lead of electronic voltmeter and connect to Pin #7 of V11 with meter range switch set to lowest scale and observing polarity for negative readings.

Couple hot lead of RF SignalGenerator to converter tube V2 by means of a loop consisting of two turns of insulated hook-up wire. Connect ground lead of RF Signal Generator to chassis.

Note: If the converter tube V2 is shielded - remove shield.

Set the generator frequency accurately to 21.25 MC, and adjust L7 cathode sound trap (see tube and trimmer layout drawing) for minimum reading on voltmeter.

By means of a clip lead, short circuit condenser C26 on cathode trap.

Increase generator output to maximum (recheck 21.25 MC generator setting) and adjust L5 for minimum reading of voltmeter.

Sound IF Transformer Adjustment

Change hot lead connection of electronic voltmeter (with 100,000 ohm resistor connected in series) to terminal marked "C" of sound discriminator transformer. Reduce output of the signal generator to give approximately 2 volts reading on voltmeter scale.

Adjust L1 and L2 for maximum reading.

Sound Discriminator Adjustment

Change hot lead connection of voltmeter to pin #1 of V5 and adjust L3 for zero reading on voltmeter. This zero setting is very critical and the adjustment must be made with extreme care.

Repeat adjustments for L2 and L3 in the same manner indicated above.

Pix IF Coil Adjustment

Connect hot lead of voltmeter to pin #7 of V11 and adjust the following slugs for maximum output at frequencies indicated:

L301 - - - - - - - - - - - - -22.25 MC
L4 (Bottom of can) - - -23.0 MC
L6 - - - - - - - - - - - - -26.5 MC
L8 - - - - - - - - - - - - -25.0 MC

If oscillation occurs during alignment, temporarily lower frequency of L8 by turning screw clockwise until screw projects approximately $\frac{1}{4}$". After properly adjusting L301, L4 & L6 then set L8 to proper frequency. Oscillation is evidenced by high reading on voltmeter (-10v to -20v) with signal generator OFF and no signal coming in through the antenna terminals.

Retouch Pix IF Transformer Adjustment

Disconnect RF signal generator leads and connect hot lead of sweep generator to coupling loop on converter tube and ground lead to chassis.

Connect vertical input terminal of oscilloscope to pin #7 of V11 (Pix Dectector) and connect ground lead of scope to chassis.

Connect $1\frac{1}{2}$ V flashlight battery with positive terminal to chassis and negative terminal to #2 pin of V11.

Set tuner to channel 9 unless local station is operating on this frequency, in which case an adjacent channel should be used.

Set sweep generator frequency to IF sweep on the 20 to 30 MC range.

Adjust sweep generator output to produce a curve on the scope which is approximately 2/3 of the screen diameter.

Loosely couple output of RF signal generator to hot lead of sweep generator and set frequency of RF signal generator to 25.75 MC (marker).

Curve shown on scope should be similar to the standard response curve shown below. For proper setting of the pix carrier the 25.75 MC marker should appear on the curve at a point approximately 50% to 60% of the vertical height of the curve.

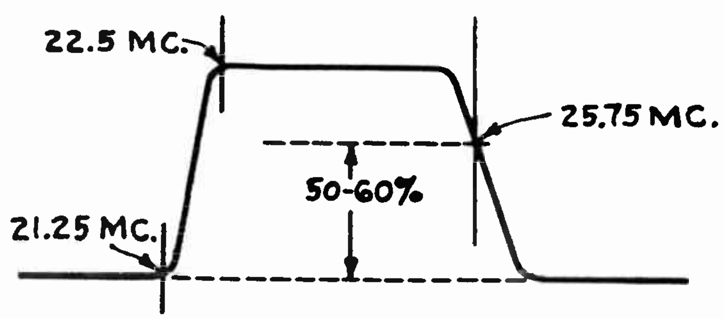
To obtain this setting retouch L6 and L8.

Reset RF signal generator frequency to 22.5 MC and retouch L301 and L4 for correct positioning of marker on shoulder of curve.

The curve may now be flat topped by retouching L8 & L4.

Recheck setting of 25.75 MC marker to make sure that position has not shifted on curve.

Disconnect bias battery.



Note: If the curve cannot be made to appear as above due to a local station or other interference, or multiple markers appear, remove (V1) 6BC5 RF tube from tuner.

Tuner Adjustments for Models using Tuner Part #CL-2262

Note: Before making a complete tuner adjustment it is essential that the Sound I.F. and discriminator circuits be aligned at their proper frequencies as described above. WHEN CHANGING THE CONVERTER TUBE IT IS NECESSARY TO REALIGN THE OSCILLATOR ADJUSTMENT ON ALL CHANNELS WITH THE V2 TUBE SHIELD IN PLACE.

RF and Converter Alignment

1) Set channel selector switch to #12
2) Connect oscilloscope through 10,000 ohms to test point on tuner (bare tinned copper loop wire located between V1 and V2)
3) Set fine tuning control at approximate mid-point of its tuning range. Temporarily connect jumper wire from pin #7 of V11 to chassis.
4) Feed Sweep generator into antenna terminals, sweeping channel 12.
5) Adjust C301, C302, and C304 for flat top response curve. Check picture and sound carrier markers corresponding to frequencies shown on Page 2 for all respective channels.
6) Remove jumper from pin #7 of V11 to chassis.

Oscillator Alignment

1) Set channel selector switch to #12
2) Connect signal generator to one antenna terminal and ground. Set to sound carrier frequency 209.75 MC.
3) Connect electronic voltmeter to pin #1 of V5 (6AL5) sound discriminator.
4) Adjust C303 for zero reading on electronic voltmeter between a positive and negative peak.
5) Check all channels for zero reading on voltmeter. It is usually not necessary to make any further adjustments. If it is found necessary to touch up the oscillator coils, the following procedure should be observed.

Oscillator Coil Touch-up

(a) Center fine tuning control, as described in Note A below.
(b) Place a non-metallic screwdriver through opening, and adjust oscillator coil on channel 12 (L312)
(c) Turn channel selector switch to channel 13 and adjust L313.
(d) This adjustment can be repeated for all channels or if necessary on any single channel.

ADJUSTMENTS

Ion Trap Magnet Adjustment

Turn the brightness control fully clockwise and the contrast control fully counter-clockwise. Adjust the ion trap magnet by moving it forward or backward and at the same time rotating it slightly around the neck of the kinescope until the raster on the screen is brightest. Reduce the brightness control setting until the raster is slightly above average brilliance. Adjust focus control until the line structure of the raster is clearly visible (sharp). Readjust the ion trap magnet again for maximum raster brilliance. The final touches on this adjustment should be made with the brightness control at the maximum position with which good line focus can be maintained

Focus Coil Adjustments:

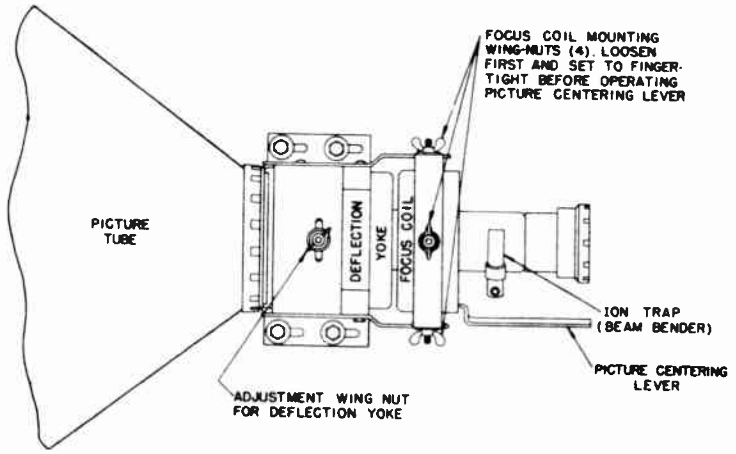
The focus coil is mounted within a frame to permit movement about its horizontal and vertical axis. The four wing nuts holding the focus coil to the frame are tightened at the factory to prevent movement during shipment. Upon installation of the receiver these wing nuts should be loosened and then adjusted finger tight. Centering of the picture within the mask is accomplished by gently moving the lever welded to the focus coil up and down or from left to right until the entire raster or picture is visible on the screen.

Deflection Yoke Adjustment:

If the lines of the raster are not horizontal or squared with the picture mask, loosen the deflection yoke adjustment screw and rotate the deflection yoke until this condition is obtained, and retighten the yoke adjustment screw.

If neck shadow is evident or the corners of the raster are dark, the deflection yoke must be moved forward as far as possible and the wing screw retightened. After observing that the picture tube is brought forward as far as possible to rest against the two tube stop brackets, loosen the four screws holding the rear tube support bracket to the chassis and move the entire bracket forward so that the rubber cup presses firmly against the cone of the picture tube. Where an additional reinforcing bracket is used to hold the rear tube support to the high voltage power supply cage it will be necessary to remove the power supply cover and remove the mounting screws in the bracket prior to making the above adjustment. After the rear tube support bracket has been properly adjusted and the screws retightened the reinforcing bracket can be reassembled using another set of mounting holes on the side of the power supply cage which will maintain a firm pressure of the rubber cup against the cone of the picture tube.

Note A - The mid-point of the fine tuning range is attained when the point of the bakelite cam (which is attached to the fine tuning control) faces directly downward.)



Check of Horizontal Oscillator Alignment

(Any adjustments or check of horizontal oscillator alignment should be made after a fifteen to thirty minute chassis warm-up period.)

Obtain a test pattern and turn the horizontal hold control to the extreme clockwise position. The picture should remain in synchronization or shift slightly to the right with the blanking bar becoming visible. The blanking bar may be unstable and move from side to side. Turn hold control counter-clockwise and the picture should remain in synchronization unless the signal is weak and in which case 3 or 4 bars may be seen sloping downward to the left.

If the receiver behaves in this manner and the test pattern is normal and stable, the horizontal oscillator is properly adjusted. Skip the "Adjustment of Horizontal Oscillator" and proceed with Height and Vertical Linearity adjustments.

Horizontal Oscillator

The horizontal oscillator is adjusted at the factory to provide the wave shape shown on the following page and normally can be adjusted by means of the horizontal frequency threaded brass screw (L16) at rear of chassis, and by means of the horizontal lock trimmer (C57).

(a) Turning the horizontal lock trimmer (C57) clockwise decreases the range of the horizontal hold control, and turning the trimmer counter-clockwise increases the range of the hold control. Normal setting is about one turn counter-clockwise from the tight position. In "Fringe" or weak signal areas the trimmer may be set two turns counter-clockwise from the tight position resulting in somewhat better range on the hold control.

(b) Turning the horizontal frequency screw (L16) clockwise lowers the frequency, (bars sloping downward to left). Turning the screw counter-clockwise increases frequency (bars sloping downward to right).

Adjustment of Horizontal Oscillator (with the use of an oscilloscope)

1) Allow set to warm up to operating temperature. Select station operating normally.
2) Connect vertical input lead of oscilloscope to terminal "C" of horizontal oscillator transformer (TR-2294) and ground oscilloscope to chassis. Set frequency of scope to approximately 5 KC.
3) Set horizontal lock trimmer (C57) one turn from tight.
4) Short terminals "C" & "D" on TR-2294 by means of clip lead.
5) **Set horizontal hold control at maximum clockwise rotation.**
6) **Adjust horizontal frequency screw (L16) until picture falls into sync. Then turn screw slightly counter-clockwise until blanking bar shows, or three or four bars show sloping downward to right.**
7) **Remove short from terminals "C" & "D" of TR-2294 and adjust screw (L17) at terminal end of TR-2294 (under chassis) until wave shape as observed on scope is like that shown in sketch.**

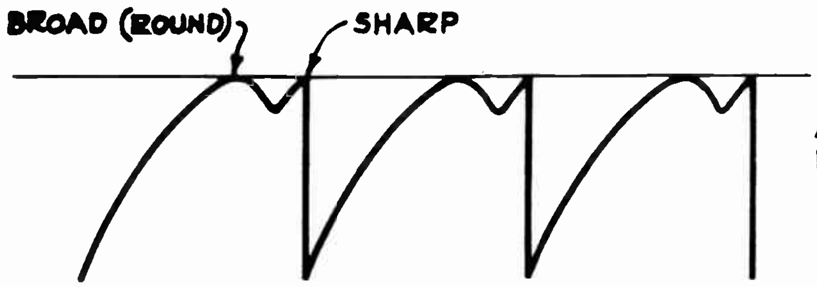
NOTE: Due to variations in oscilloscope input characteristics it may be necessary to insert a 50,000 ohm resistor in the vertical input lead. This will prevent the loading of the scope from affecting the frequency of the horizontal circuit.

8) **Some further adjustment of horizontal frequency screw (L16) may be necessary to keep picture in sync while L17 is being adjusted for proper wave shape.**
9) **Remove scope from terminal "C".**
10) **Turn horizontal hold control through entire range. Picture should remain in sync except in clockwise position when "blanking bar" will appear, or two or three bars will show sloping downward to the right.**
11) **If picture falls out at left or condition described in "10" is not obtained, adjust horizontal frequency screw (L16) slightly. Observe paragraphs "a" & "b" under "Horizontal Oscillator"**

NOTE: Some manufacturers types of 6SN7GT may perform better than others in the horizontal oscillator socket and excessive drift of the horizontal oscillator circuit may be caused by a weak or defective 6SN7GT tube.

After the horizontal oscillator circuit has been adjusted in the manner outlined above, any subsequent touch-up may be made with the horizontal frequency screw L16.

Caution: It is important that the picture be centered in the mask properly with the horizontal hold control in the mid-position, otherwise the set user may attempt to center the picture by means of the hold control. Under this condition the control may be on "edge" and impulse noise or change of camera will cause the picture to fall out of synchronization.



ADJUST L17 FOR EQUAL HEIGHTS OF ROUND AND SHARP PORTIONS OF PULSE.

Height and Vertical Linearity Adjustments:

Adjust the height control until the picture fills the mask vertically. Adjust vertical linearity until the test pattern is symmetrical from top to bottom.

Adjustment of one control will require readjustment of the other. Then adjust focus coil lever to align the picture within the mask.

Width, Drive and Horizontal Linearity:

Turn the width control L19 (accessible through a hole in the rear of chassis) clockwise until the picture fills the entire width of the tube. Adjust the trimmer "horizontal drive" C67 (rear of chassis) to give the best degree of brightness and linearity. Adjust the horizontal linearity control L18 (rear of chassis) for best linearity of the right half of the picture. Readjust the width control until the picture fills the mask and again adjust the focus coil lever to align the picture within the mask.

NOTE: It is advisable to adjust both the height and width of the picture to a size slightly larger than the mask opening so that during periods of low line voltage or subsequent aging of tubes adequate deflection to fill the mask opening is obtained.

IMPORTANT:

The horizontal oscillator frequency must be checked for proper range of horizontal hold control after any adjustment of horizontal drive (C67) and horizontal lock (C57) trimmers. Some interaction is present between these trimmers and any adjustment of either one will usually require resetting of the horizontal frequency adjustment screw (L16).

FOCUS:

Adjust the focus control for maximum definition of the vertical wedge of the test pattern and uniform focus over face of picture tube.

Sensitivity Switch

A two-position switch is provided at the rear of the chassis for increasing the gain of the receiver which may be required for proper operation in fringe areas. Where sound and picture reception is weak with the sensitivity switch set in LOCAL position, switching to "FRINGE" position will improve the performance of the receiver.

Phono-Television Switch

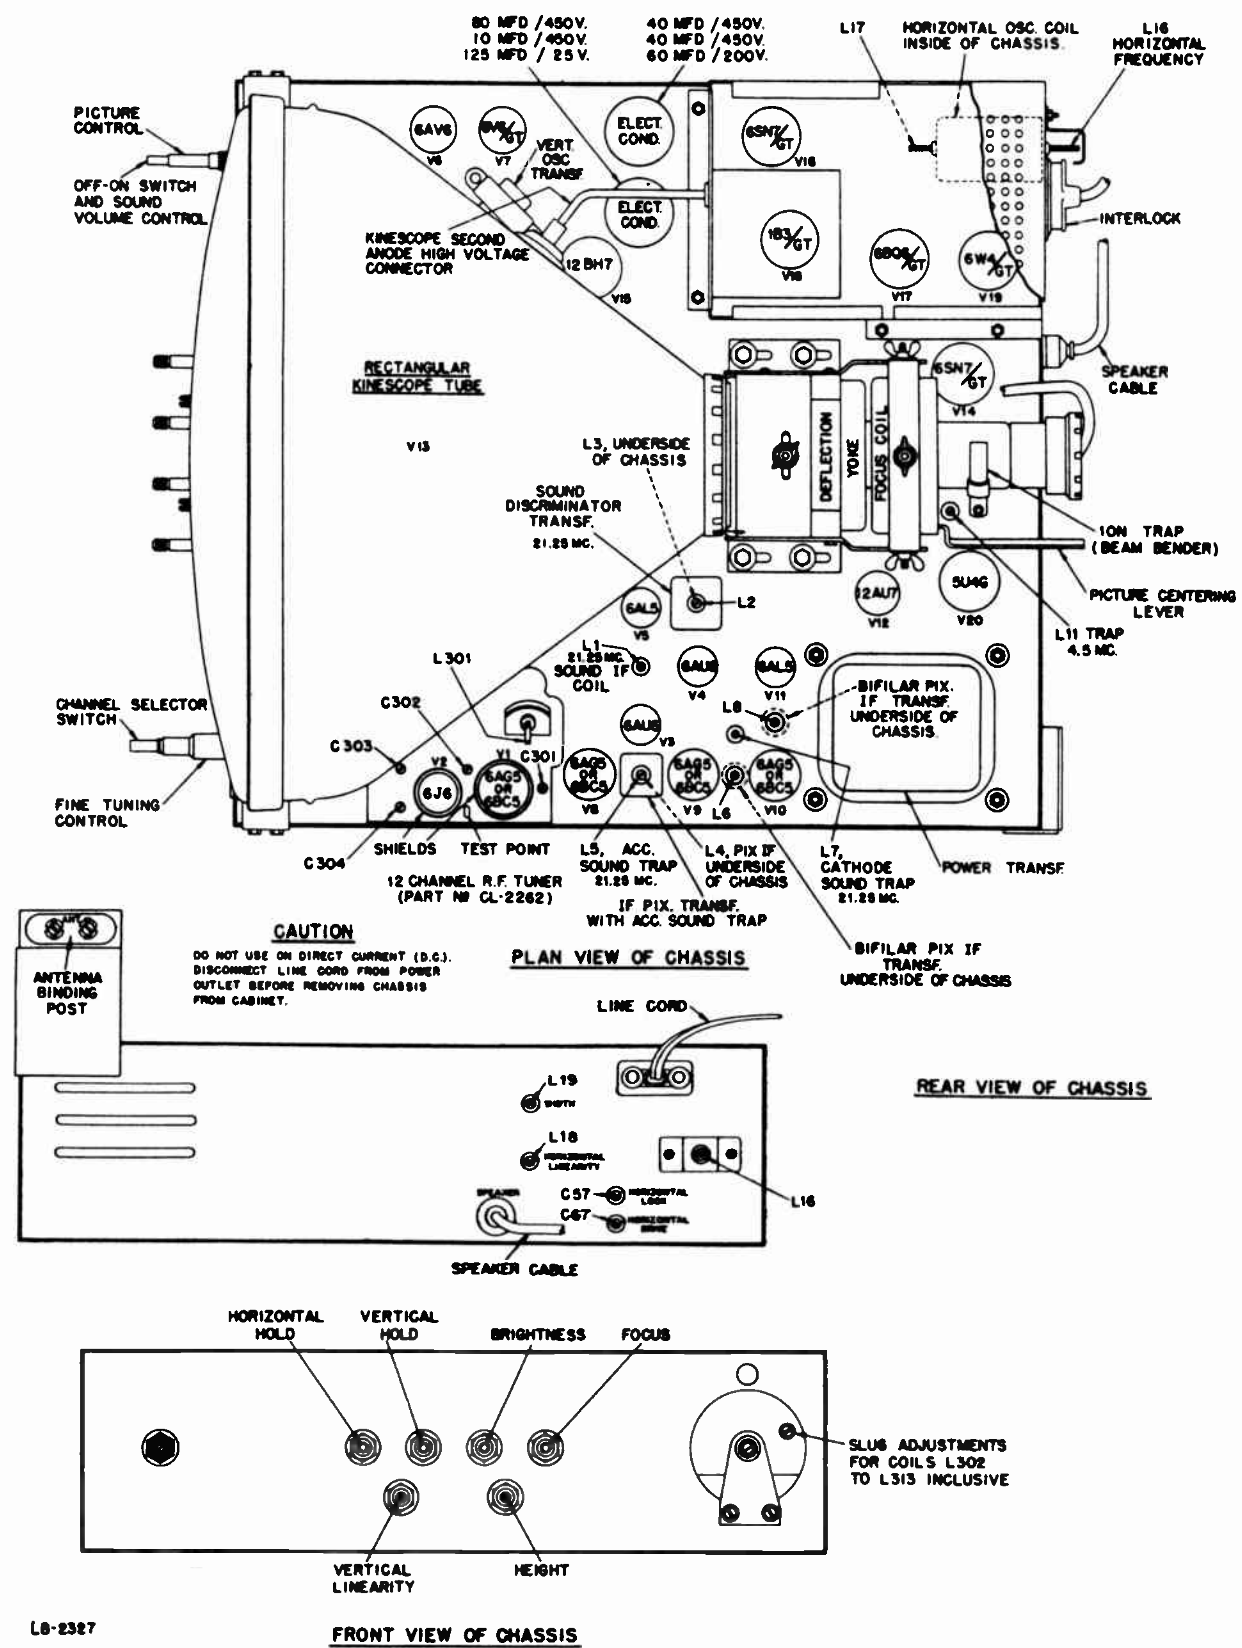
A two-position slide switch is provided at the rear of the chassis together with a pick-up socket for plug-in of an external record changer.

Built-In Antenna

All models are equipped with a built-in antenna which will provide satisfactory ...eption in many locations. In areas of weak reception an outside antenna will substan... improve the performance of the receiver. An antenna post is provided at the rear of ...is and is accessible through the opening in the masonite back to permit the con... ...n outside aerial. The built-in antenna is normally connected to the antenna ...ust be disconnected when attaching the outside aerial. To prevent the lead-in ...e built-in antenna from contacting chassis parts and tubes it is recommended that the lead-in wire be folded and held in place by tape or a rubber band. In some cases reception can be improved by changing the location of the receiver in the room.

Note: The text in this manual applies to television receivers wired in accordance with enclosed schematic diagram DG-2346-1.

TUBE AND TRIMMER LAYOUT



rouble: Fuse blows on line voltage surge, etc. resulting in small picture, fold over on both sides and damping bars.
Remedy: Remove fuse from present circuit and then remove green lead from terminal #1 on TR-2293 horizontal output transformer and connect to #8. Connect fuse between #8 and #1. Remove yellow wire from #8 and connect to #7. Dress fuse away from high voltage terminals.

Trouble: Insufficient width.
Remedy: Connect an .05-400 volt condenser across width control (terminals #5 and #6 on transformer). In severe cases of low line voltage, etc. a .1-400 condenser may be used. Change 6BQ6GT.

Trouble: Vertical retrace lines visible at low contrast. May be due to low transmitter sync level, or variations in picture tube characteristics.
Remedy: Connect .05-600 volt condenser from green lead of vertical output transformer (TR-2189) to yellow lead (pin #11 V13 Kinescope). These leads run to adjacent tie points on terminal strip near vertical output transformer.

Trouble: Beat interference, hash in picture or sound, or separation of sound and picture on high band. Oscillation in sound I.F.
Remedy: Ground cathode resistor (R1 150 ohms) directly to center shield of V3 socket 1st sound IF amplifier, instead of terminal strip ground. Connect 1500 mmf ceramic condenser between pin #7 cathode and socket center shield. Check alignment of sound IF, sound traps, and distriminator.

1. Tube Changes
Due to the critical shortage of 12AU7 tubes, the first and second video amplifier V12 will at times be replaced by a 6SN7GT tube. Due to inability to obtain adequate supplies of 12BH7 tubes, the vertical oscillator tube V15 is now being replaced by a 6SN7GT and all further production will use the latter type of tube.

2. Circuit Change
Condenser No. C18 .01/600 volts is being returned to the 6V6 screen, pin #4 instead of ground to reduce possibility of voltage breakdown.
Resistor No. R50, 6.8 Meg. going to the vertical hold control is not being used in all sets. It is often eliminated for better range of the vertical hold control.

3. Horizontal Tearing (Defective Parts)
If tearing occurs, especially in fringe areas resulting in a distorted picture, when contrast control is advanced, check for a short, leaky or open .05 condenser (C37) and low capacity in 220 MMF mica condenser (C38).

4. Color Converter
A color converter socket is now being wired in on the rear of the chassis for use with color converters -- when available.

5. Underwriters' Changes
In accordance with U/L requirements, a 120,000 ohm 1 watt resistor is being placed across condenser C48 in the primary of the power transformer -- connecting one side of the A.C. line to ground.

6. Picture Width
To increase picture width for low line voltage areas, a .05/600 W.V. paper condenser is now used on all models across terminals 5 and 6 of the flyback transformer TR-2293.

7. Vertical Height
To improve vertical height, try replacing the vertical output tube V15 which may be either a 6SN7GT or a 12BH7. As noted in paragraph one, both 6SN7GT and 12BH7 have been used in V15 socket.
Due to resistor shortages, R55 and R56, 3300 ohms each respectively in series have been replaced on some receivers by one 6500 ohm 5 watt wire wound resistor. To obtain increased height where R55 and R56 are used, short out either one of them. Where a 6500 ohm resistor is used, shunt another 6500 ohm 2 to 5 watt resistor across the present one or replace it by a 3300 ohm 2 watt resistor.

8. Width Control
Due to the scarcity of power transformers, Olympic Part No. TR-1966, it has been necessary to substitute another specification TR-1688 giving slightly lower B+ voltages. On all models where TR-1688 have been substituted and to secure sufficient width, the width control has been removed from the circuit by connecting both width control leads to terminal #1 of the 6BQ6GT tube. (V17 socket).
If it is necessary to reduce the width of the picture, restore connections of the width control by re-wiring to terminals 5 and 6 of the flyback transformer.

9. Vacuum Tubes
It appears that component parts manufacturers standards have been appreciably lowered lately. Therefore -- always check tubes first in case of performance and operation troubles. Some manufacturers types are better than others especially in 6BQ6 and 6SN7 types.

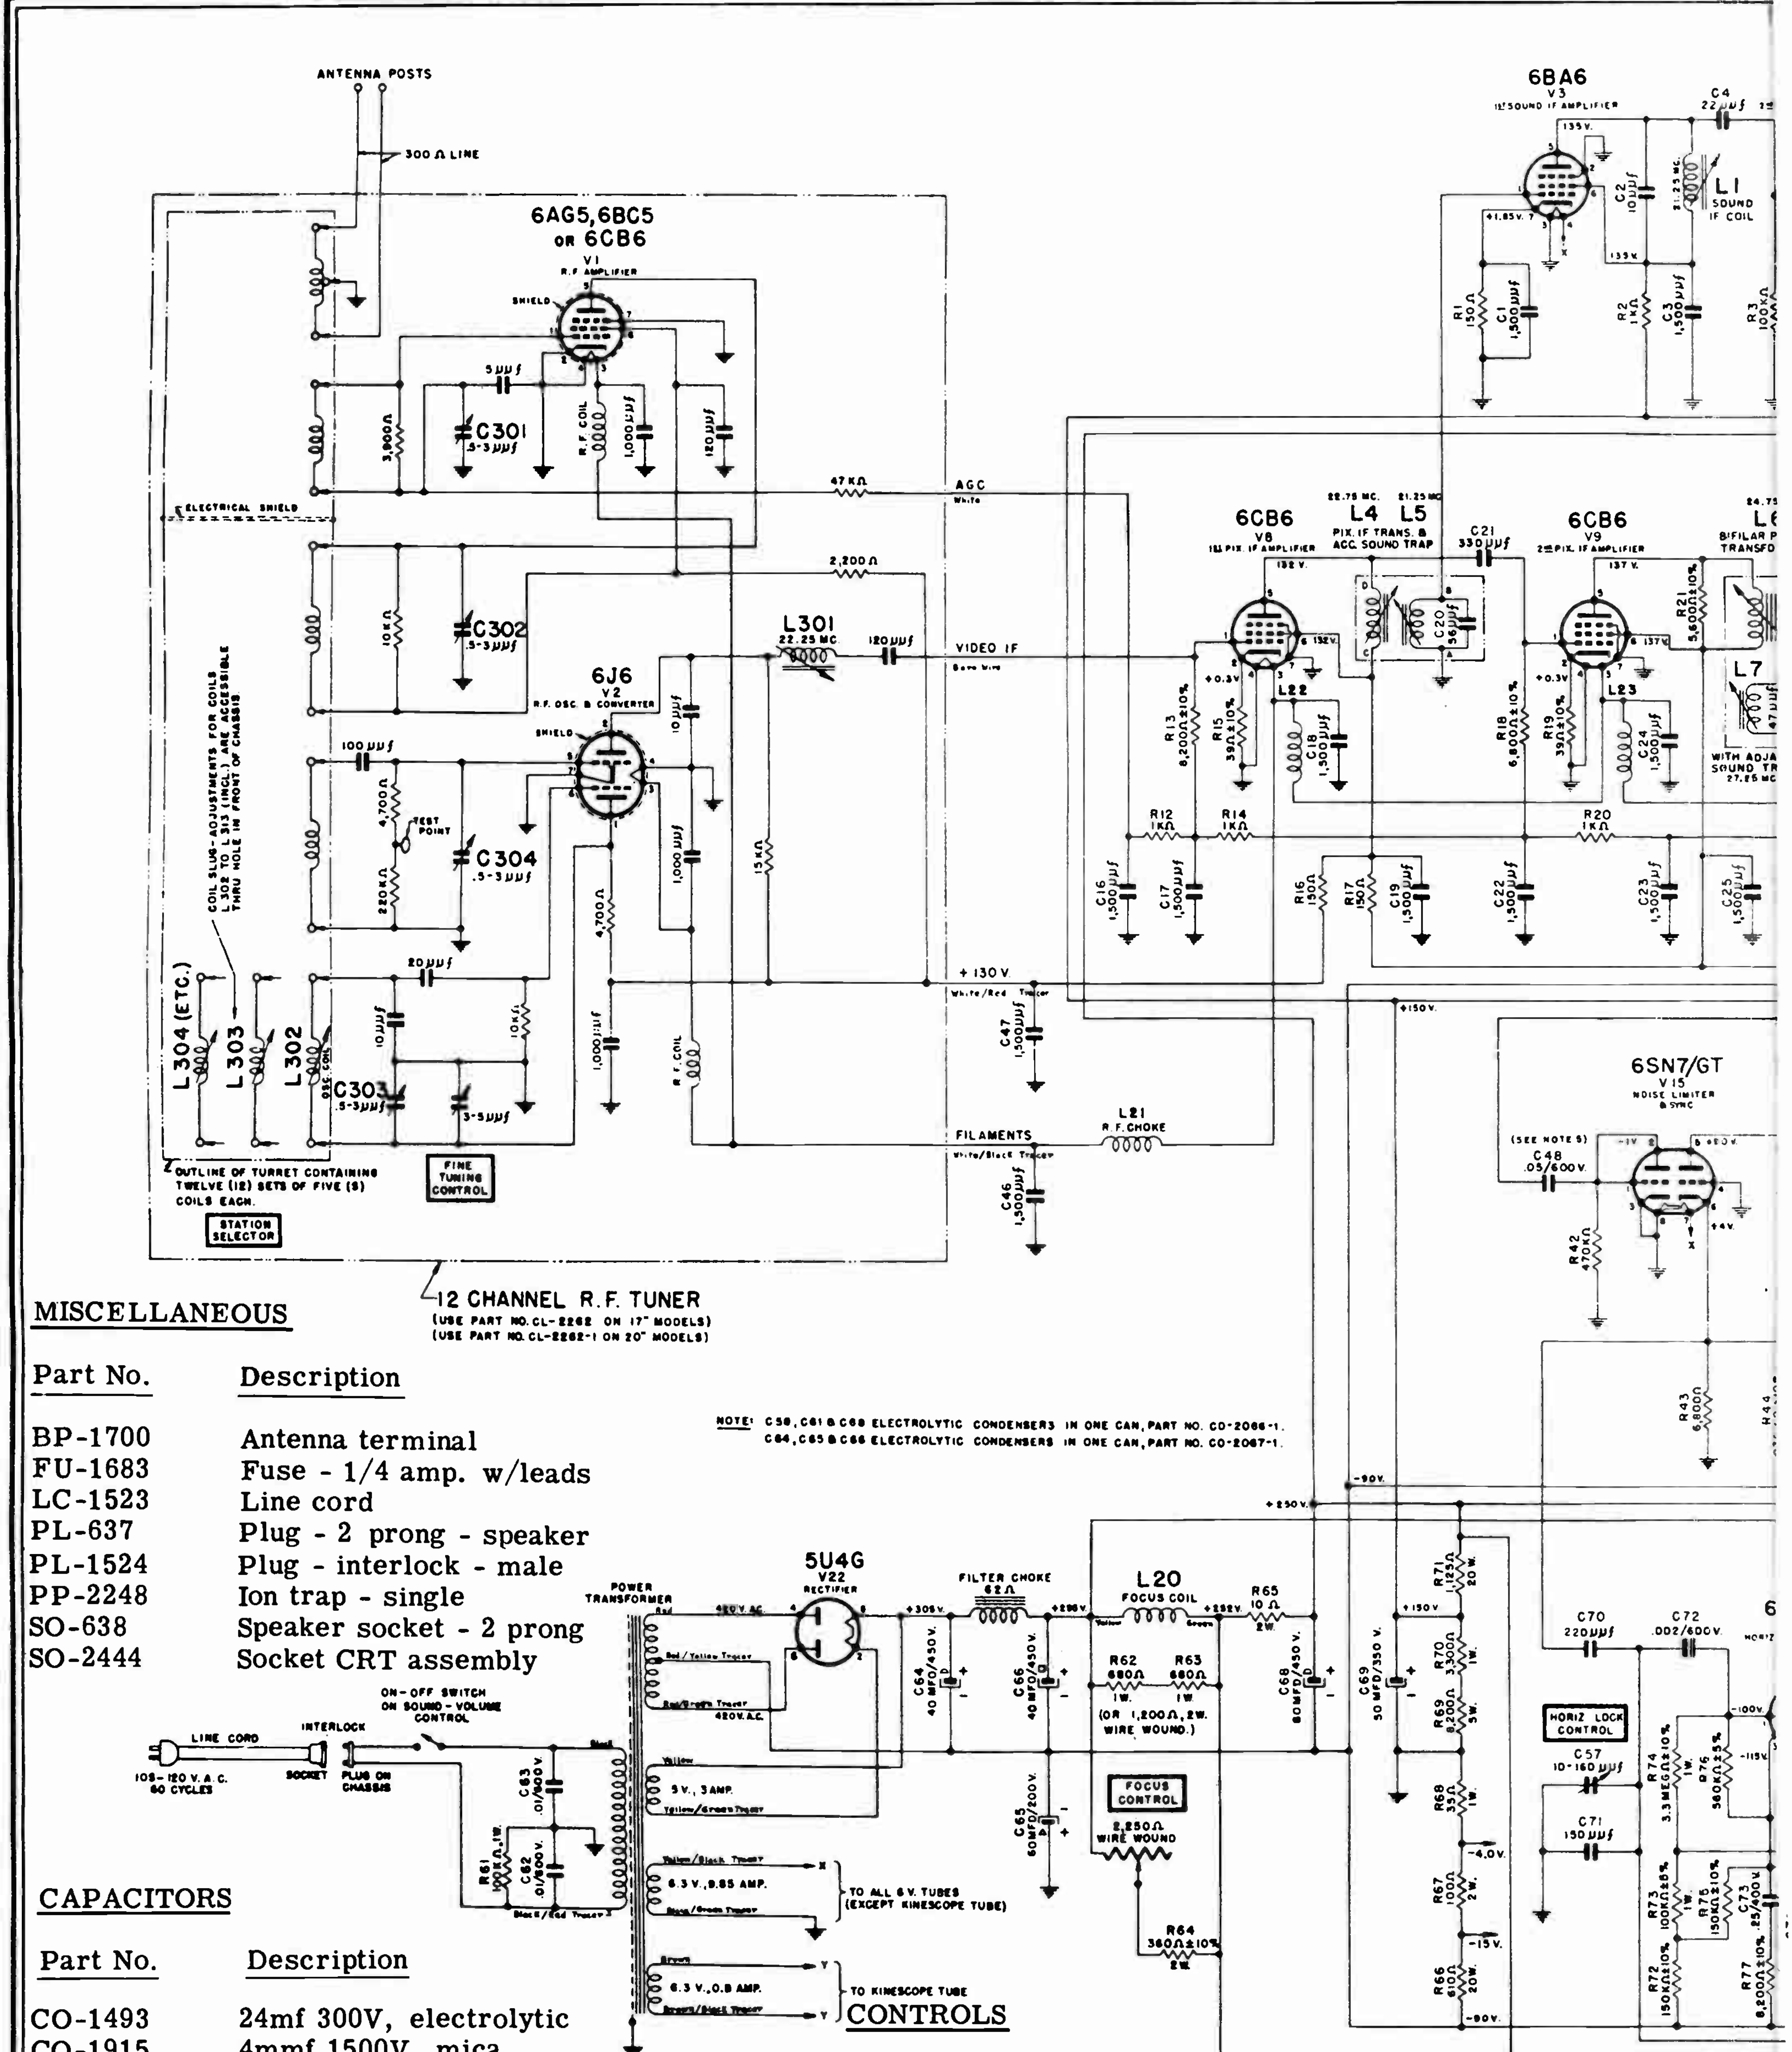
10. Resistors
Because of the critical shortage of this item, we and other manufacturers are compelled to develop new sources of supply even using resistors of foreign manufacture. While foreign resistors are properly rated as to wattage and resistance, the majority of them are of the un-insulated type. In production, these resistors are dressed away from contact with other parts. Transportation shock may cause them to shift, causing shorts. In case of trouble, check for short circuits and re-dress resistors so that they do not touch adjacent parts or components.

11. Horizontal Tearing (Modification)
When tearing of picture occurs at high or medium contrast control setting, R36 1000 ohm should be reduced to 700 or 800 ohms. When tearing or distortion occurs at low contrast setting R36 is too low and should be increased to 1200 ohms.

Production Changes

Pix Width: R76 56,000 ohm 1 watt resistor changed to 22,000 ohm ±20% 1 watt.

Pix Height: R55 and R56 3,300 ohm 2 watt, (actually 6500 ohm 10 watt in production) replaced by one 3300 ohm 2 watt. A parallel resistor combination may be used as an equivalent of a 3300 ohm 2 watt resistor.



MISCELLANEOUS

Part No.	Description
BP-1700	Antenna terminal
FU-1683	Fuse - 1/4 amp. w/leads
LC-1523	Line cord
PL-637	Plug - 2 prong - speaker
PL-1524	Plug - interlock - male
PP-2248	Ion trap - single
SO-638	Speaker socket - 2 prong
SO-2444	Socket CRT assembly

CAPACITORS

Part No.	Description

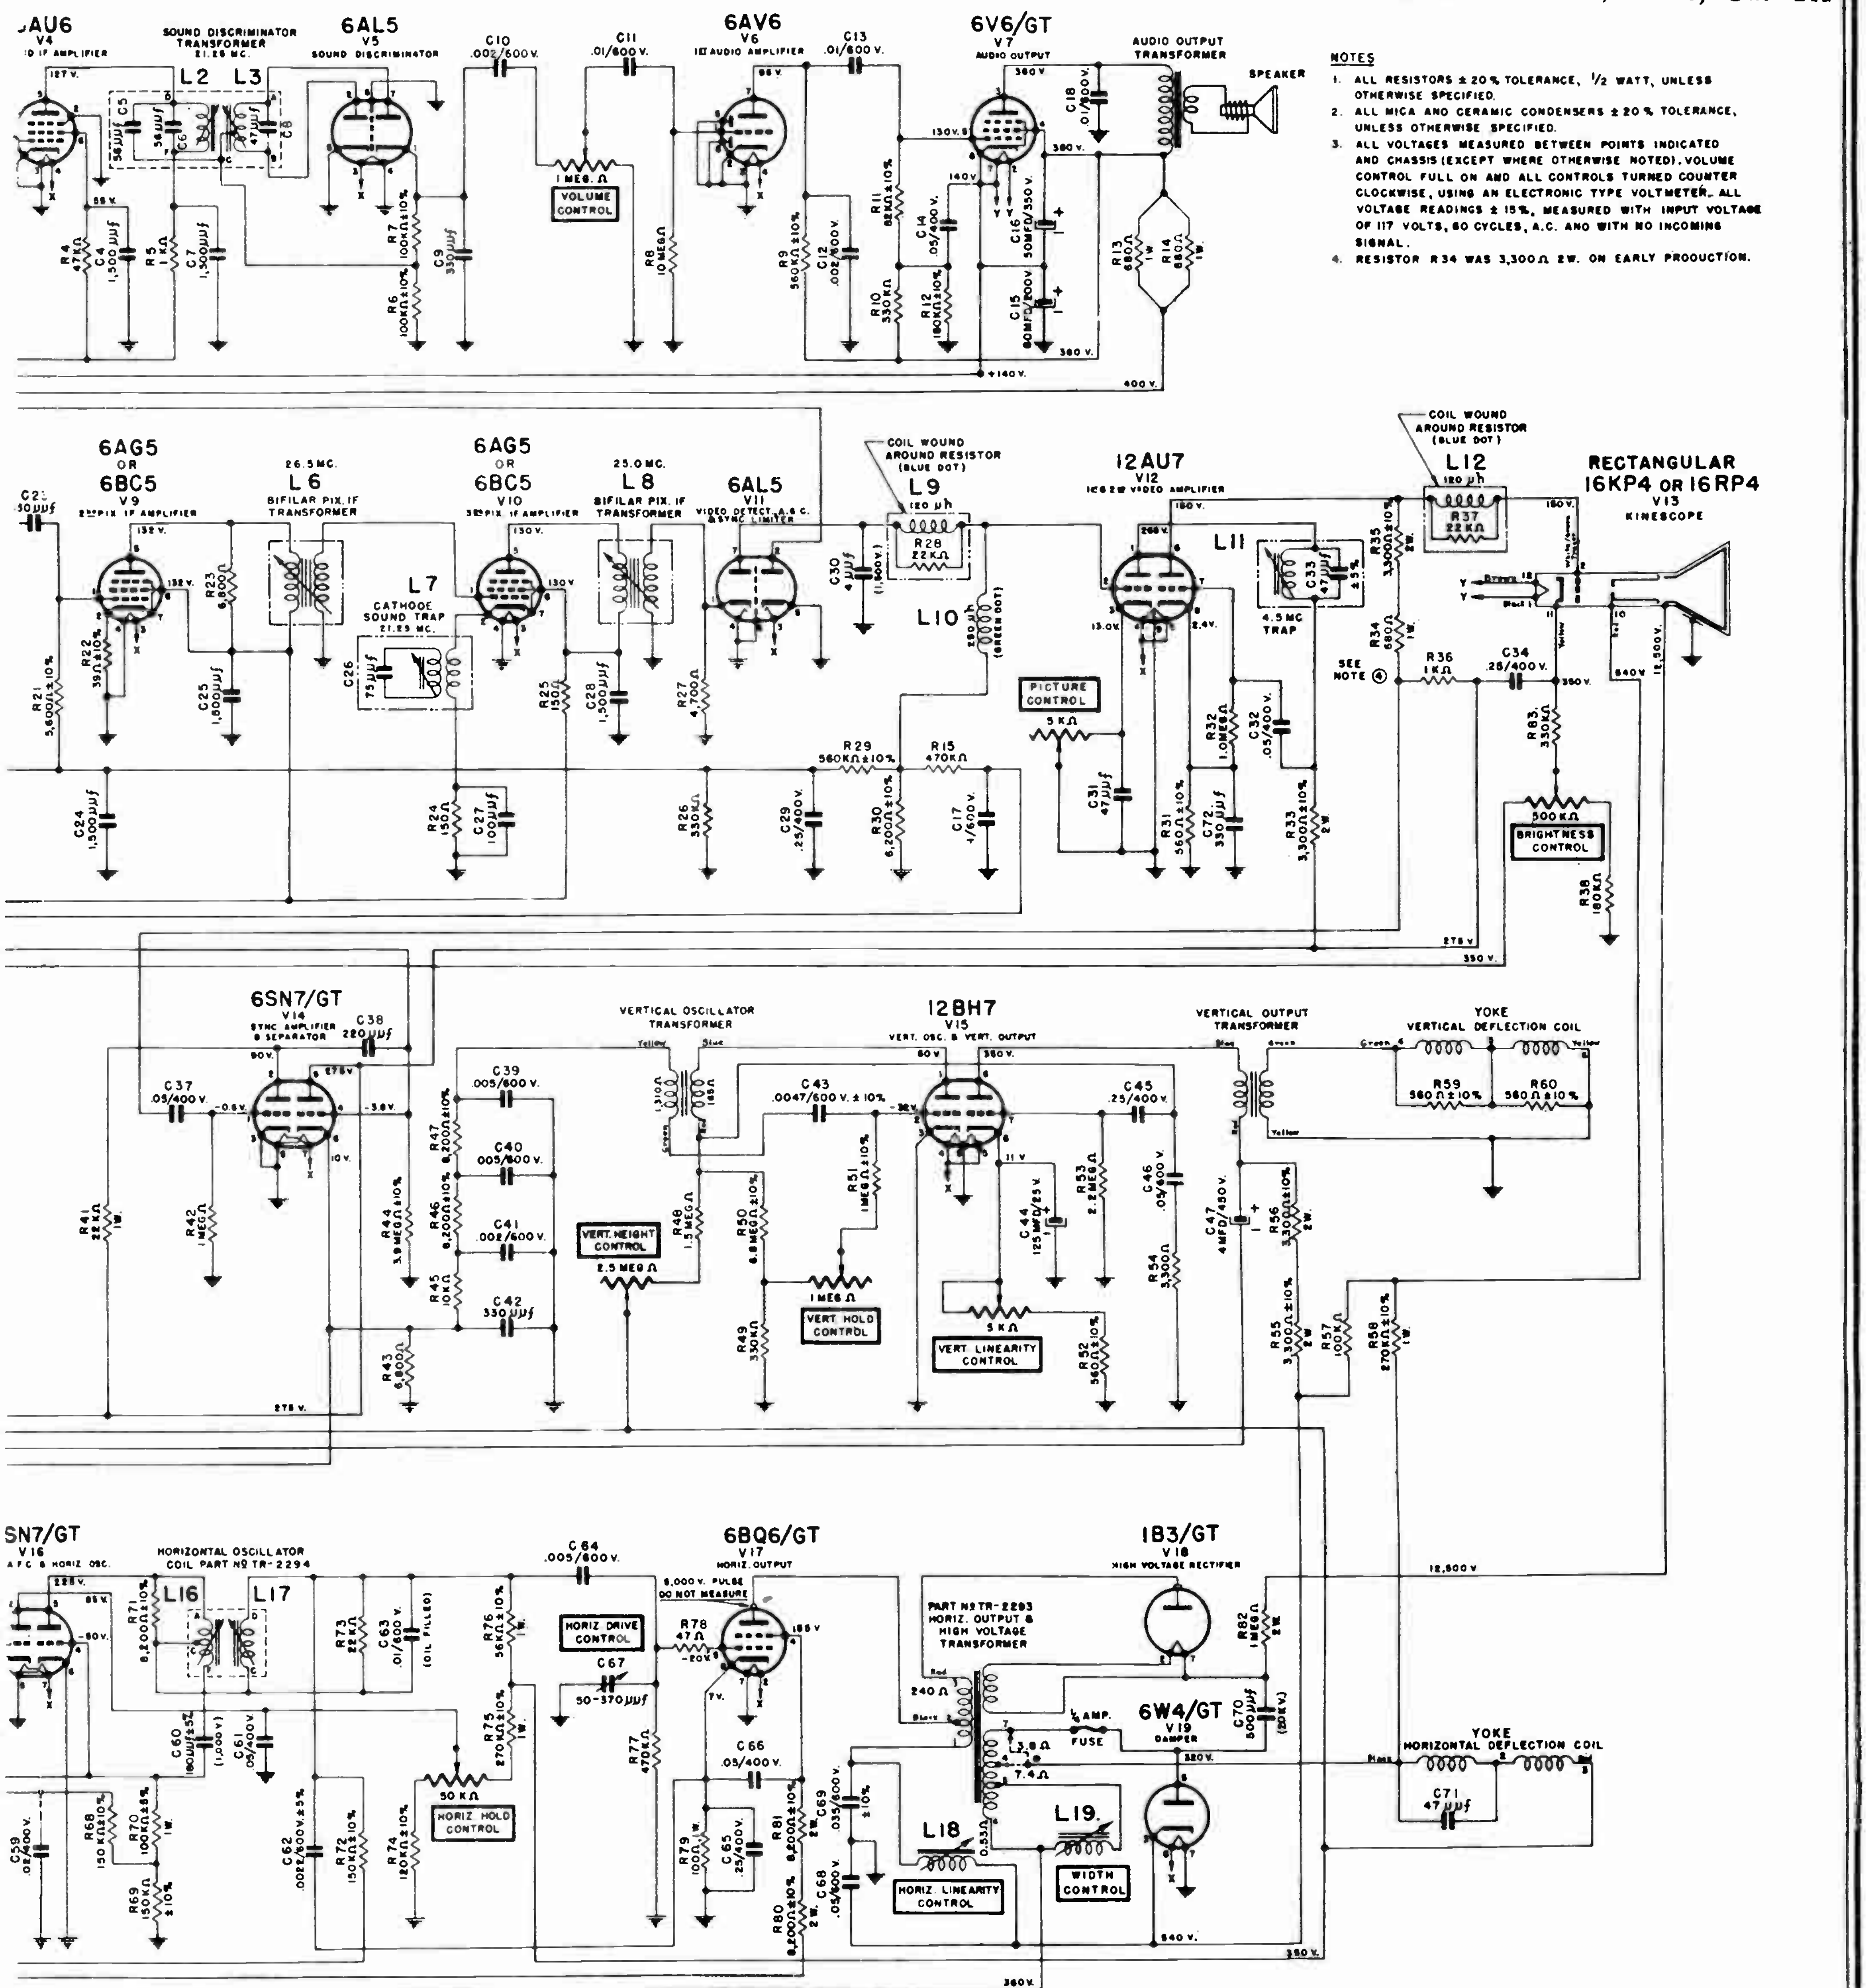
MODELS 1C72, 1T71, Ch. TA



NOTES

1. ALL RESISTORS ± 20% TOLERANCE, 1/2 WATT, UNLESS OTHERWISE SPECIFIED.
2. ALL MICA AND CERAMIC CONDENSERS ± 20% TOLERANCE, UNLESS OTHERWISE SPECIFIED.
3. ALL VOLTAGES MEASURED BETWEEN POINTS INDICATED AND CHASSIS (EXCEPT WHERE OTHERWISE NOTED). VOLUME CONTROL FULL ON AND ALL CONTROLS TURNED COUNTER CLOCKWISE, USING AN ELECTRONIC TYPE VOLTMETER. ALL VOLTAGE READINGS ± 15%, MEASURED WITH INPUT VOLTAGE OF 117 VOLTS, 60 CYCLES, A.C. AND WITH NO INCOMING SIGNAL.
4. RESISTOR R34 WAS 3,300Ω 2W. ON EARLY PRODUCTION.

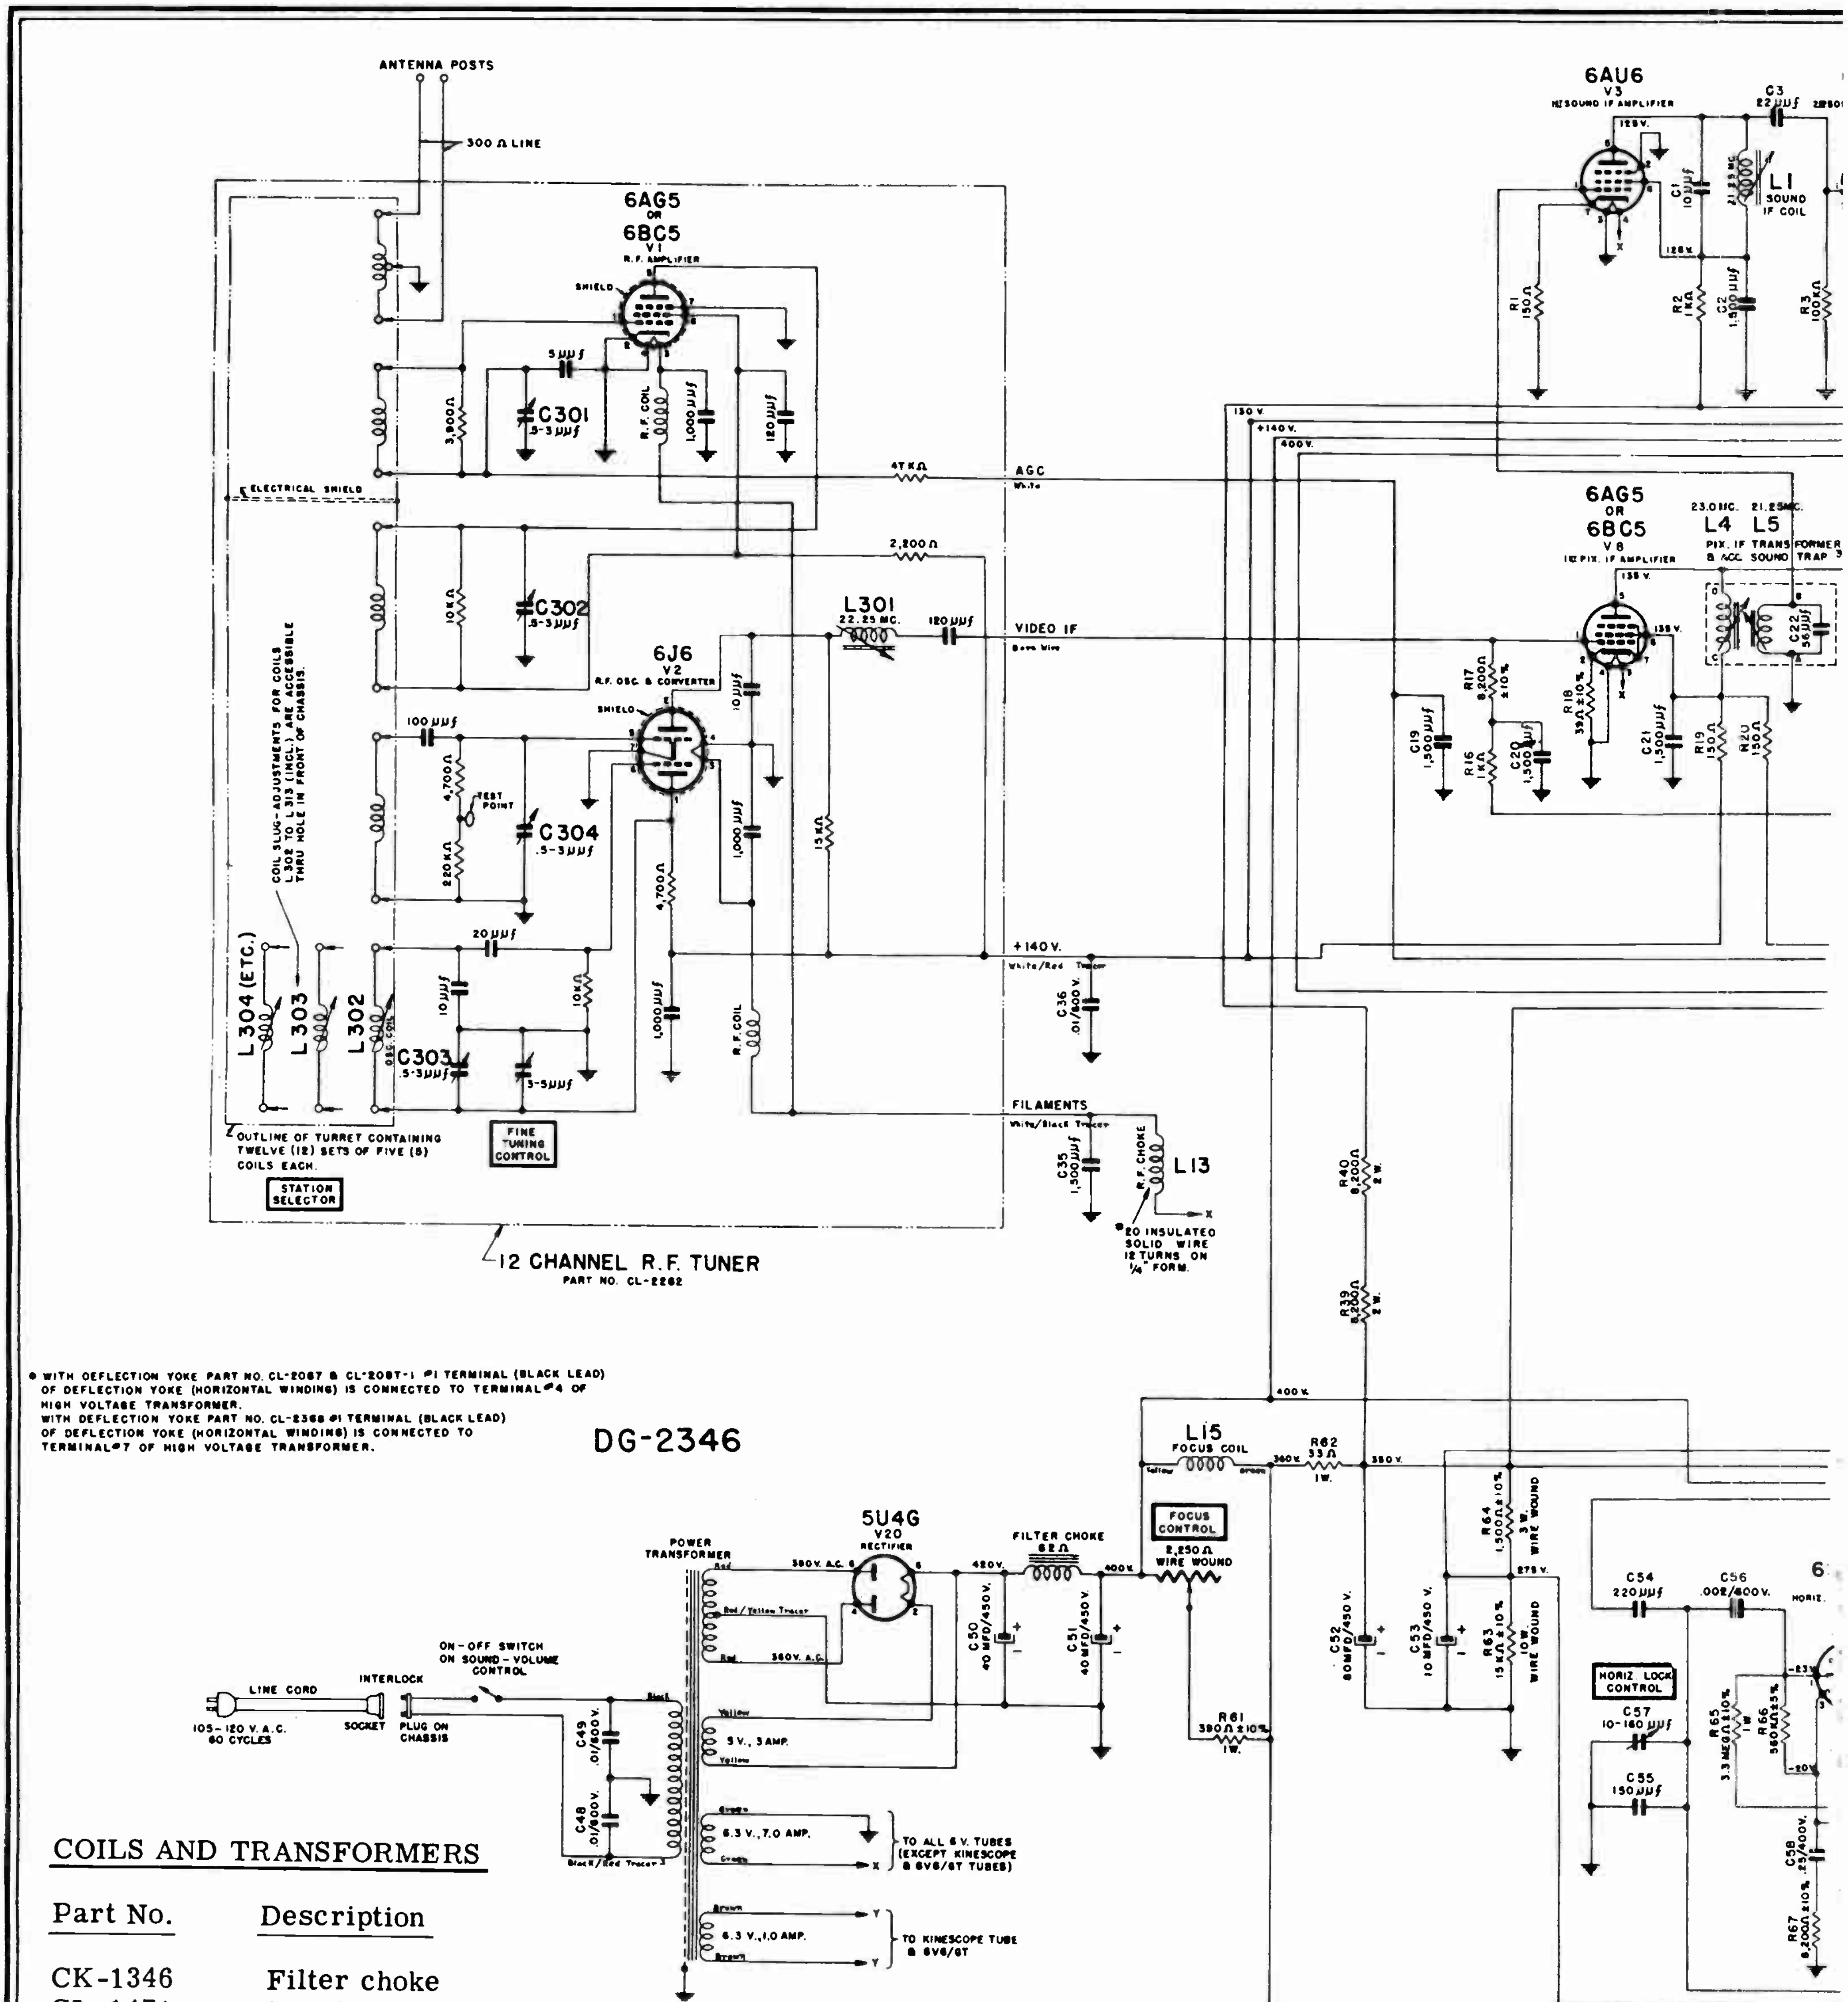
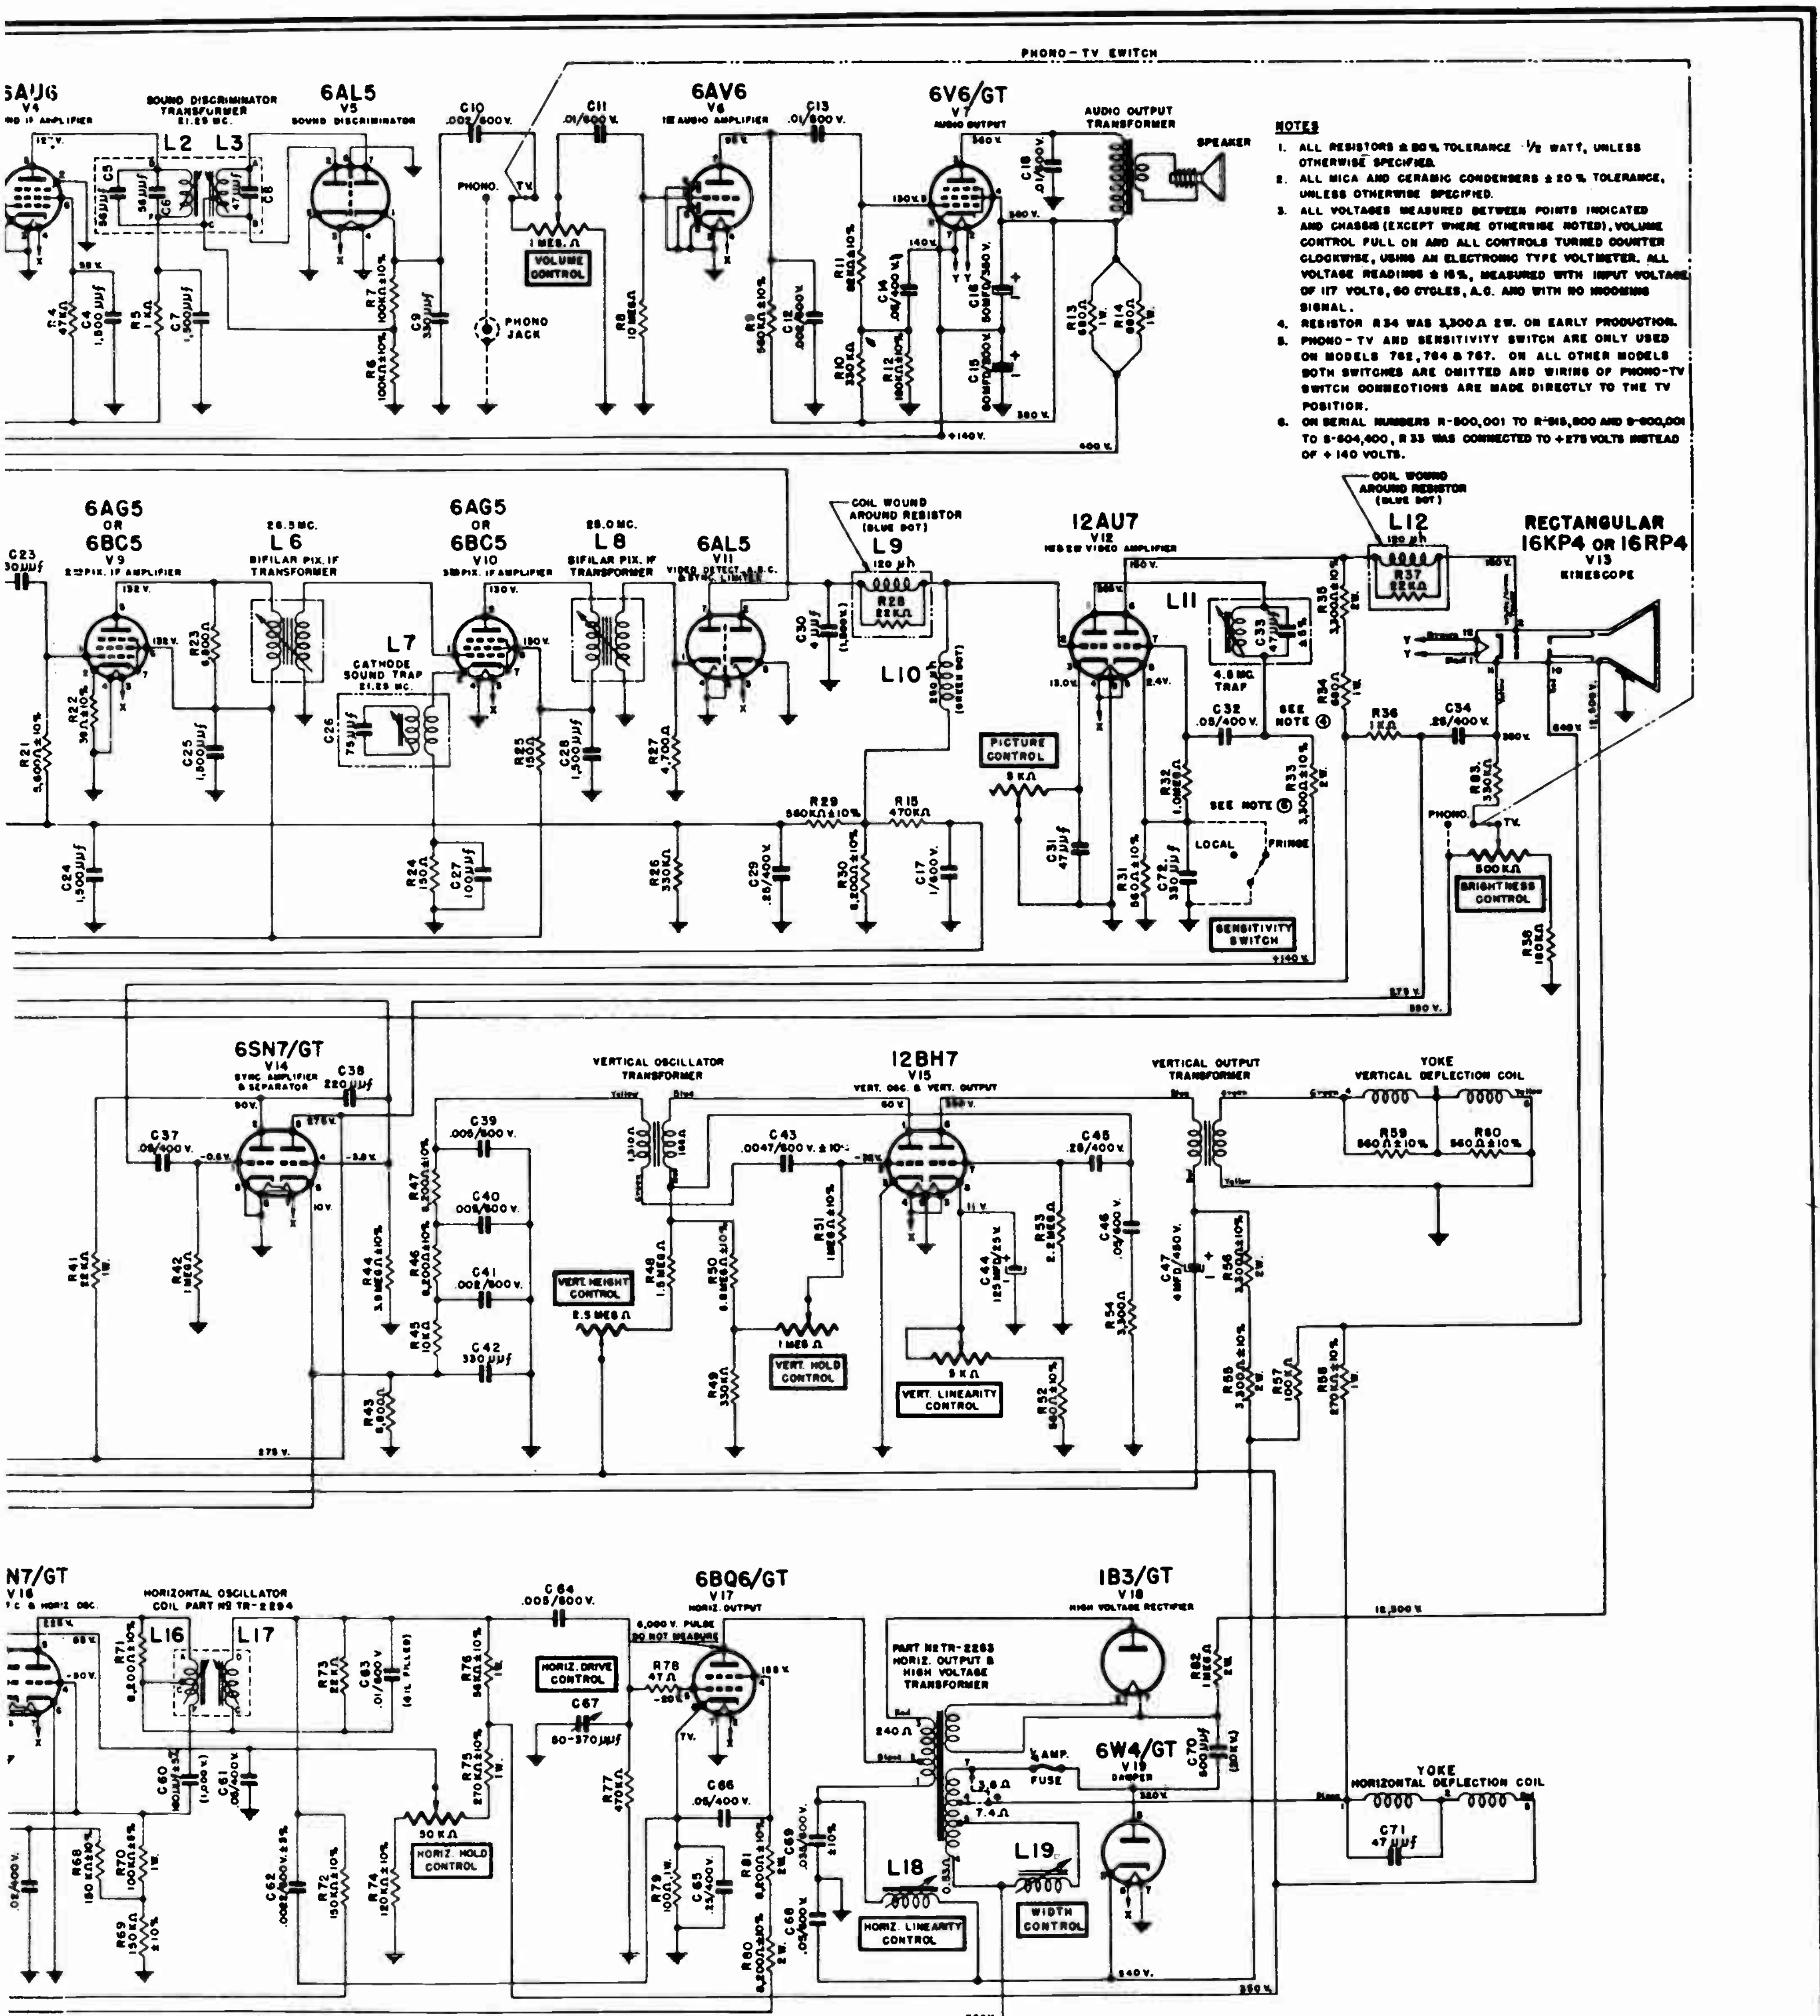
CAPACITORS

Part No.	Description
CO-1056	4mf, 450V, electrolytic
CO-1915	4mmf 1500V, mica
CO-2066	80/450V, 10/450V, 125/25V, elec.
CO-2067	40/450V, 40/450V, 60/200V, elec.
CO-2266	500mmf 20KV
CO-2344	50/350V, electrolytic
CO-2560	20/450V, electrolytic
CT-2261	10-160mmf & 50-370mmf, trimmer
PC-2435	Vertical inter. network



COILS AND TRANSFORMERS

Part No.	Description
CK-1346	Filter choke
CL-1471	Sound IF coil
CL-1472	Cathode sound trap w/75mmf cond.
CL-1502	Width control
CL-1503	Horiz. lin. control
CL-1535	Peaking coil 36μh (black dot)
CL-1536	Peaking coil 120μh (blue dot)
CL-2073	Peaking coil 250μh (green dot)
CL-2087-1	Deflection yoke 70^{o}
CL-2262	Tuner - standard coil
CL-2300	Focus coil
CL-2309	Pix IF transformer
CL-2331	Sound coil 4.5 mc trap
CL-2427	Filament choke (RF)
TR-1469	Transformer - disc.
TR-1473	Transformer - vert osc.
TR-1506	Transformer - audio output
TR-1966	Transformer - power
TR-2117	Transformer - pix IF w/adj. sound trap
TR-2189	Transformer - vert. output
TR-2293	Transformer - flyback
TR-2294	Transformer - horiz. osc.
	UHF osc./ant. strips (pair) for Standard Coil Tuners



* WITH DEFLECTION YOKE PART NO. CL-2087 & CL-2087-1 #1 TERMINAL (BLACK LEAD) OF DEFLECTION YOKE (HORIZONTAL WINDING) IS CONNECTED TO TERMINAL #4 OF HIGH VOLTAGE TRANSFORMER.
WITH DEFLECTION YOKE PART NO. CL-2366 #1 TERMINAL (BLACK LEAD) OF DEFLECTION YOKE (HORIZONTAL WINDING) IS CONNECTED TO TERMINAL #7 OF HIGH VOLTAGE TRANSFORMER.

DG-2346-1

Knob - blonde fine tuning
Knob - blonde volume
Knob - blonde contrast cont.
TV antenna loop
Escutcheon - plastic
Door - plastic
Safety glass
Mask - 16"
Mask - 17"
Speaker - 5" PM
Back
Back

MISCELLANEOUS

Part No.	Description
BP-1700	Antenna terminal
FU-1683	Fuse - 1/4 amp. w/leads
LC-1529	Line cord
PL-637	Plug - 2 prong - speaker
PL-1524	Plug - Interlock - male
PP-2248	Ion trap - single
PP-2352	Sec. anode conn.
SO-638	Speaker socket - 2 prong

All chassis are provided with a sensitivity switch and a phono-TV switch with phonojack.

NOTE: Both 17" and 20" rectangular glass picture tubes are used. They require different mechanical mountings and mask and therefore are not interchangeable. When replacing tubes in service use identical tube sizes.

ALIGNMENT

Equipment Required

1) RF signal generator to provide the following accurate frequencies. If the accuracy of the generator frequencies is not known, some type of crystal calibrator should be utilized to check the correct settings of the RF generator for each particular frequency.

(a) 4.5 MC Video Amplifier Trap

(b) IF Frequencies

19.75 MC	Adjacent Pix Trap
21.25 MC	Sound IF, Sound Discriminator and Sound Traps
22.25 MC	Converter Coil
22.5 MC	Marker Frequency
22.75 MC	First Pix IF Coil
24.25 MC	Fourth Pix IF Coil
24.75 MC	Second Pix IF Coil
25.75 MC	Picture Carrier Marker
27.0 MC	Third Pix IF Coil
27.25 MC	Adjacent Sound Trap

(c) RF Frequencies

Channel Number	Picture Carrier Freq. MC	Sound Carrier Freq. MC
2	55.25	59.75
3	61.25	65.75
4	67.25	71.75
5	77.25	81.75
6	83.25	87.75
7	175.25	179.75
8	181.25	185.75
9	187.25	191.75
10	193.25	197.75
11	199.25	203.75
12	205.25	209.75
13	211.25	215.75

(d) Output on these ranges should be adjustable and capable of providing at least .1 volt.

2) Electronic Voltmeter
3) Cathode Ray Oscilloscope, 3" minimum screen
4) RF Sweep Generator, meeting the following requirements:

(a) Frequency Ranges

18 to 30 MC.,	10 MC. sweep width
40 to 90 MC.,	10 MC. sweep width
170 to 225 MC.,	10 MC. sweep width

(b) Output adjustable to .1 volt.

The chassis may be removed from the cabinet with the kinescope tube in place and servicing and alignment work can be accomplished without removing the kinescope tube. This work is most conveniently performed by placing the chassis on its left side (power supply cage resting on work bench) and the controls facing the operator.

To remove chassis from cabinet remove
(1) Line cord from power outlet
(2) Masonite back
(3) Antenna Lead-in from terminal posts
(4) Speaker plug from rear of chassis
(5) Knobs from front of cabinet
(6) Four mounting screws and washers from bottom of cabinet

In sliding chassis out of cabinet be careful that the kinescope tube does not strike against cabinet or any other obstruction.

Order of Alignment

When complete receiver alignment is necessary it should be performed in the following sequence.

(1) Adjacent Channel Traps
(2) Accompanying Sound Traps
(3) Sound IF Transformers
(4) Sound Discriminator
(5) Pix IF Coils
(6) Retouch Pix IF Transformers
(7) 4.5 MC Trap

After removing chassis from cabinet, connect power and speaker plugs.

If a local station is not operating on channel #9 set the tuner to this channel, turn on power switch and proceed as follows: (If #9 is a local station channel use channel #8 or #10).

NOTE: Before proceeding with alignment set sensitivity switch in LOCAL position.

Picture IF Trap Adjustment

Insert 100,000 ohm resistor in series with hot lead of electronic voltmeter and connect to junction of peaking coils L12 & L13, with meter range switch set to lowest scale and observing polarity for negative readings.

Couple hot lead of RF Signal Generator to converter tube V2 by means of a loop consisting of two turns of insulated hook-up wire. Connect ground lead of RF Signal Generator to chassis.

NOTE: If the converter tube V2 is shielded - remove shield.

Refer to tube and trimmer layout drawing. Set the generator frequency accurately to 27.25 MC and adjust L7 adjacent sound trap for minimum reading on voltmeter. Set generator to 19.75 MC and adjust L11 adjacent pix trap for minimum reading on voltmeter.

Set the generator frequency accurately to 21.25 MC, and adjust L9 cathode sound trap (see tube and trimmer layout drawing) for minimum reading on voltmeter.

By means of a clip lead, short circuit condenser C29 on cathode trap.

Increase generator output to maximum (recheck 21.25 MC generator setting) and adjust L5 for minimum reading of voltmeter.

Sound IF Transformer Adjustment

Change hot lead connection of electronic voltmeter (with 100,000 ohm resistor connected in series) to terminal marked "C" of sound discriminator transformer. Reduce output of the signal generator to give approximately 2 volts reading on voltmeter scale.

Adjust L1 and L2 for maximum reading.

Sound Discriminator Adjustment

Change hot lead connection of voltmeter to pin #1 of V5 and adjust L3 for zero reading on voltmeter. This zero setting is very critical and the adjustment must be made with extreme care.

Repeat adjustments for L2 and L3 in the same manner indicated above.

Pix IF Coil Adjustment

Connect hot lead of voltmeter to pin #7 of V12 and adjust the following slugs for maximum output at frequencies and sequence indicated:

L301	22.25 MC
L4 (Bottom of Can)	22.75 MC
L6	24.75 MC
L8	27.0 MC
L10	24.25 MC

If oscillation occurs during alignment, temporarily raise frequency of L8 by turning screw counterclockwise until screw projects approximately 3/4". After properly adjusting L301, L4, L6 & L10 then set L8 to proper frequency. Oscillation is evidenced by high reading on voltmeter (-10v to -20v) with signal generator OFF and no signal coming in through the antenna terminals.

Retouch Pix IF Transformer Adjustment

Disconnect RF signal generator leads, replace V2 tube shield, connect hot lead of sweep generator through a 330 mmf condenser to test point on tuner and ground lead to chassis.

Connect vertical input terminal of oscilloscope to junction of peaking coils L12 and L13, and connect ground lead of scope to chassis.

Connect 3v. flashlight battery with positive terminal to chassis and negative terminal to junction of C34 (.25-400v) and R30 (560k). This point is origin of AGC bias voltage.

Set tuner to channel 9 unless local station is operating on this frequency, in which case an adjacent channel should be used.

Set sweep generator frequency to IF sweep on the 20 to 30 MC range.

Adjust sweep generator output to produce a curve on the scope which is approximately 2/3 of the screen diameter.

Loosely couple output of RF signal generator to hot lead of sweep generator and set frequency of RF signal generator to 25.75 MC (marker).

Curve shown on scope should be similar to the standard response curve shown on following page. (See note below). For proper setting of the pix carrier the 25.75 MC marker should appear on the curve at a point approximately 50% of the vertical height of the curve.

To obtain this setting retouch L6 and L8.

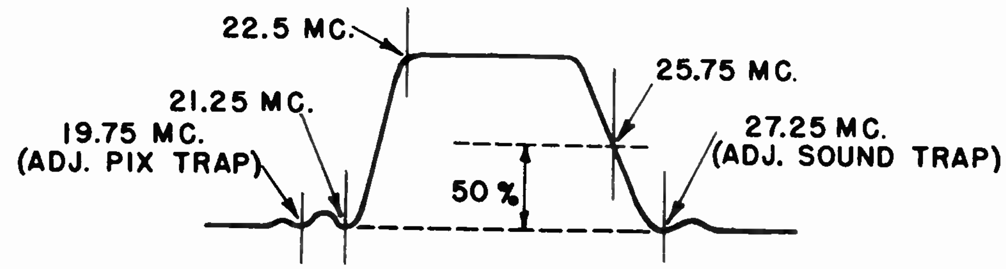
Reset RF signal generator frequency to 22.5 MC and retouch L301 and L4 for correct positioning of marker on shoulder of curve.

The curve may now be flat topped by first retouching L10 and then L6.

Recheck setting of 25.75 MC marker to make sure that position has not shifted on curve.

NOTE: To obtain increased sensitivity for fringe reception the response curve should be modified as shown on page 11.

Disconnect bias battery.



STANDARD RESPONSE CURVE

Note: If the curve cannot be made to appear as above due to a local station or other interference, or multiple markers appear, remove (V1)* 6BC5 RF tube from tuner.

4.5 MC TRAP ADJUSTMENT

Connect hot lead of 4.5 MC generator to pin #7 of V12 (6AL5) video detector tube, and ground lead to chassis.

Connect voltmeter lead to pin #7 of V13 (12AU7) video amplifier, and ground lead to chassis. Turn Picture Control full "ON" (clockwise).

Adjust L14 4.5 MC trap for minimum reading on voltmeter.

NOTE: If generator does not have sufficient output (1 volt at 4.5 MC), to provide indication on electronic voltmeter, adjust L14 by observing raster on screen of picture tube as follows:

Turn L14 "out" (counterclockwise) so that the 4.5 MC "beat" is observed on screen which will appear as if a fine meshed screen was superimposed on the raster. Turn L14 "in" clockwise until the beat disappears. Adjust Brightness and Focus controls for sharpest line definition. Do not turn trap further "clockwise" than is necessary to remove "beat" or picture quality will suffer.

Tuner Adjustments for Models using Tuner Part #CL-2262 and CL-2262-1

Note: Before making a complete tuner adjustment it is essential that the Sound I.F. and discriminator circuits be aligned at their proper frequencies as described above. WHEN CHANGING THE CONVERTER TUBE IT IS NECESSARY TO REALIGN THE OSCILLATOR ADJUSTMENT ON ALL CHANNELS WITH THE V2 TUBE SHIELD IN PLACE.

RF and Converter Alignment

1) Set channel selector switch to #12
2) Connect oscilloscope through 10,000 ohms to test point on tuner (bare tinned copper loop wire located between V1 and V2)
3) Set fine tuning control at approximate mid-point of its tuning range. Temporarily connect jumper wire from pin #7 of V12 to chassis.
4) Feed Sweep generator into antenna terminals, sweeping channel 12.
5) Adjust C301, C302, and C304 for flat top response curve. Check picture and sound carrier markers corresponding to frequencies shown on Page 2 for all respective channels.
6) Remove jumper from pin #7 of V12 to chassis.

* This may also be a 6AG5 or 6CB6

Oscillator Alignment

1) Set channel selector switch to #12
2) Connect signal generator to one antenna terminal and ground. Set to sound carrier frequency 209.75 MC.
3) Connect electronic voltmeter to pin #1 of V5 (6AL5) sound discriminator.
4) Adjust C303 for zero reading on electronic voltmeter between a positive and negative peak.
5) Check all channels for zero reading on voltmeter. It is usually not necessary to make any further adjustments. If it is found necessary to touch up the oscillator coils, the following procedure should be observed.

Oscillator Coil Touch-up

(a) Center fine tuning control, as described in Note A below.
(b) Place a non-metallic screwdriver through opening, and adjust oscillator coil on channel 12 (L312)
(c) Turn channel selector switch to channel 13 and adjust L313.
(d) This adjustment can be repeated for all channels or if necessary on any single channel.

ADJUSTMENTS

Ion Trap Magnet Adjustment

Turn the brightness control fully clockwise and the contrast control fully counter-clockwise. Adjust the ion trap magnet by moving it forward or backward and at the same time rotating it slightly around the neck of the kinescope until the raster on the screen is brightest. Reduce the brightness control setting until the raster is slightly above average brilliance. Adjust focus control until the line structure of the raster is clearly visible (sharp). Readjust the ion trap magnet again for maximum raster brilliance. The final touches on this adjustment should be made with the brightness control at the maximum position with which good line focus can be maintained.

Focus Coil Adjustments:

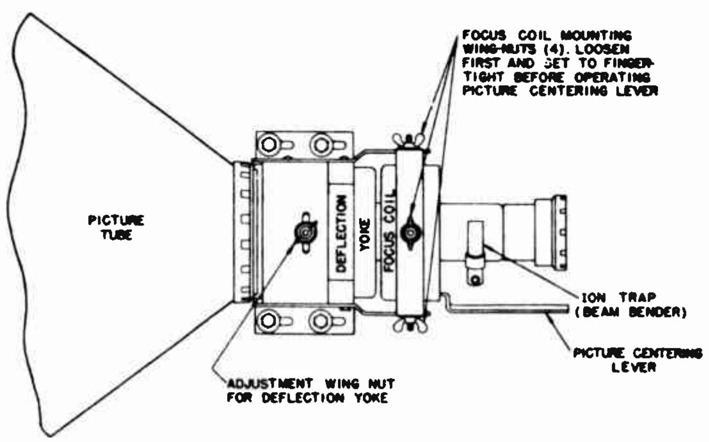
The focus coil is mounted within a frame to permit movement about its horizontal and vertical axis. The four wing nuts holding the focus coil to the frame are tightened at the factory to prevent movement during shipment. Upon installation of the receiver these wing nuts should be loosened and then adjusted finger tight. Centering of the picture within the mask is accomplished by gently moving the lever welded to the focus coil up and down or from left to right until the entire raster or picture is visible on the screen.

Deflection Yoke Adjustment:

If the lines of the raster are not horizontal or squared with the picture mask, loosen the deflection yoke adjustment screw and rotate the deflection yoke until this condition is obtained, and retighten the yoke adjustment screw.

If neck shadow is evident or the corners of the raster are dark, the deflection yoke must be moved forward as far as possible and the wing screw retightened. After observing that the picture tube is brought forward as far as possible to rest against the two tube stop brackets, loosen the four screws holding the rear tube support bracket to the chassis and move the entire bracket forward so that the rubber cup presses firmly against the cone of the picture tube. Where an additional reinforcing bracket is used to hold the rear tube support to the high voltage power supply cage it will be necessary to remove the power supply cover and remove the mounting screws in the bracket prior to making the above adjustment. After the rear tube support bracket has been properly adjusted and the screws retightened the reinforcing bracket can be reassembled using another set of mounting holes on the side of the power supply cage which will maintain a firm pressure of the rubber cup against the cone of the picture tube.

Note A - The mid-point of the fine tuning range is attained when the point of the bakelite cam (which is attached to the fine tuning control) faces directly downward.)



Check of Horizontal Oscillator Alignment

(Any adjustments or check of horizontal oscillator alignment should be made after a fifteen to thirty minute chassis warm-up period.)

Obtain a test pattern and turn the horizontal hold control to the extreme clockwise position. The picture should remain in synchronization or shift slightly to the right with the blanking bar becoming visible. The blanking bar may be unstable and move from side to side. Turn hold control counter-clockwise and the picture should remain in synchronization unless the signal is weak and in which case 3 or 4 bars may be seen sloping downward to the left.

If the receiver behaves in this manner and the test pattern is normal and stable, the horizontal oscillator is properly adjusted. Skip the "Adjustment of Horizontal Oscillator" and proceed with Height and Vertical Linearity adjustments.

Horizontal Oscillator

The horizontal oscillator is adjusted at the factory to provide the wave shape shown on the following page and normally can be adjusted by means of the horizontal frequency threaded brass screw (L16) at rear of chassis, and by means of the horizontal lock trimmer (C57).

(a) Turning the horizontal lock trimmer (C57) clockwise decreases the range of the horizontal hold control, and turning the trimmer counter-clockwise increases the range of the hold control. Normal setting is about one turn counter-clockwise from the tight position. In "Fringe" or weak signal areas the trimmer may be set two turns counter-clockwise from the tight position resulting in somewhat better range on the hold control.

(b) Turning the horizontal frequency screw (L16) clockwise lowers the frequency, (bars sloping downward to left). Turning the screw counter-clockwise increases frequency (bars sloping downward to right).

Adjustment of Horizontal Oscillator (with the use of an oscilloscope)

1) Allow set to warm up to operating temperature. Select station operating normally.
2) Connect vertical input lead of oscilloscope to terminal "C" of horizontal oscillator transformer (TR-2294) and ground oscilloscope to chassis. Set frequency of scope to approximately 5 KC.
3) Set horizontal lock trimmer (C57) one turn from tight.
4) Short terminals "C" and "D" on TR-2294 by means of clip lead.
5) Set horizontal hold control at maximum clockwise rotation.
6) Adjust horizontal frequency screw (L16) until picture falls into sync. Then turn screw slightly counter-clockwise until blanking bar shows, or three or four bars show sloping downward to right.
7) Remove short from terminals "C" & "D" of TR-2294 and adjust screw (L17) at terminal end of TR-2294 (under chassis) until wave shape as observed on scope is like that shown in sketch.

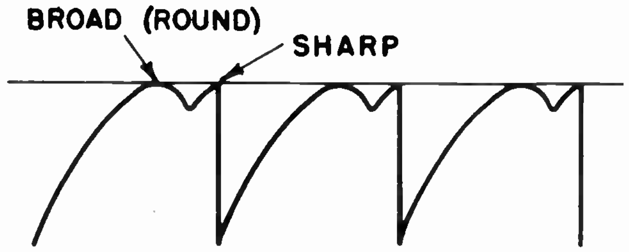
NOTE: Due to variations in oscilloscope input characteristics it may be necessary to insert a 50,000 ohm resistor in the vertical input lead. This will prevent the loading of the scope from affecting the frequency of the horizontal circuit.

8) Some further adjustment of horizontal frequency screw (L16) may be necessary to keep picture in sync while L17 is being adjusted for proper wave shape.
9) Remove scope from terminal "C".
10) Turn horizontal hold control through entire range. Picture should remain in sync except in clockwise position when "blanking bar" will appear, or two or three bars will show sloping downward to the right.
11) If picture falls out at left or condition described in "10" is not obtained, adjust horizontal frequency screw (L16) slightly. Observe paragraphs "a" & "b" under "Horizontal Oscillator"

NOTE: Some manufacturers types of 6SN7GT may perform better than others in the horizontal oscillator socket and excessive drift of the horizontal oscillator circuit may be caused by a weak or defective 6SN7GT tube.

After the horizontal oscillator circuit has been adjusted in the manner outlined above, any subsequent touch-up may be made with the horizontal frequency screw L16.

Caution: It is important that the picture be centered in the mask properly with the horizontal hold control in the mid-position, otherwise the set user may attempt to center the picture by means of the hold control. Under this condition the control may be on "edge" and impulse noise or change of camera will cause the picture to fall out of synchronization.



Height and Vertical Linearity Adjustments:

Adjust the height control until the picture fills the mask vertically. Adjust vertical linearity until the test pattern is symmetrical from top to bottom.

Adjustment of one control will require readjustment of the other. Then adjust focus coil lever to align the picture within the mask.

Width, Drive and Horizontal Linearity:

Turn the width control L19 (accessible through a hole in the rear of chassis) clockwise until the picture fills the entire width of the tube. Adjust the trimmer "horizontal drive" C67 (rear of chassis) to give the best degree of brightness and linearity. Adjust the horizontal linearity control L18 (rear of chassis) for best linearity of the right half of the picture. Readjust the width control until the picture fills the mask and again adjust the focus coil lever to align the picture within the mask.

NOTE: It is advisable to adjust both the height and width of the picture to a size slightly larger than the mask opening so that during periods of low line voltage or subsequent aging of tubes adequate deflection to fill the mask opening is obtained.

IMPORTANT:

The horizontal oscillator frequency must be checked for proper range of horizontal hold control after any adjustment of horizontal drive (C67) and horizontal lock (C57) trimmers. Some interaction is present between these trimmers and any adjustment of either one will usually require resetting of the horizontal frequency adjustment screw (L16).

FOCUS:

Adjust the focus control for maximum definition of the vertical wedge of the test pattern and uniform focus over face of picture tube.

Sensitivity Switch

A two-position switch is provided at the rear of the chassis for increasing the gain of the receiver which may be required for proper operation in fringe areas. Where sound and picture reception is weak with the sensitivity switch set in LOCAL position, switching to "FRINGE" position will improve the performance of the receiver.

Phono-Television Switch

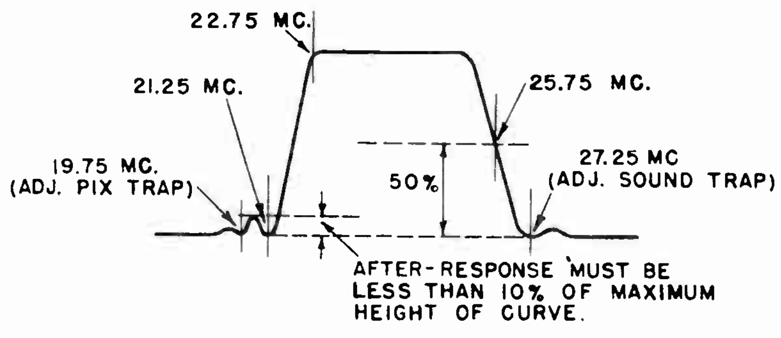
A two-position slide switch is provided at the rear of the chassis together with a pick-up socket for plug-in of an external record changer.

Built-In Antenna

All models are equipped with a built-in antenna which will provide satisfactory reception in many locations. In areas of weak reception an outside antenna will substantially improve the performance of the receiver. An antenna post is provided at the rear of the chassis and is accessible through the opening in the masonite back to permit the connection of an outside aerial. The built-in antenna is normally connected to the antenna posts and must be disconnected when attaching the outside aerial. To prevent the lead-in wires of the built-in antenna from contacting chassis parts and tubes it is recommended that the lead-in wire be folded and held in place by tape or a rubber band. In some cases reception can be improved by changing the location of the receiver in the room.

Special Alignment Procedure for Fringe Reception

All adjustments are the same as for standard alignment except that the curve and marker frequency 22.75 MC (instead of 22.5 MC) are as shown below during "Retouch Pix IF Transformer Adjustment" and a $1\frac{1}{2}$v bias battery is used instead of a 3v bias battery.



FRINGE RESPONSE CURVE

The "after response" shown on the curve should not exceed 10% of the maximum curve to prevent adjacent channel interference in areas where a weak signal is on the low frequency side of a powerful local station. The adjustment of L301 and L4 will have the greatest effect on "after response". However L301 and L4 must not be set to a higher frequency (counterclockwise) than is necessary to reduce "after response" otherwise the sound sensitivity will suffer.

GENERAL DESCRIPTION

The model 630FA-2 chassis is a 31 tube receiver including picture and three rectifiers. Features include: full 12 channel coverage: latest Standard Coil Cascode circuit RF tuner, with a high signal to noise ratio. Adaptable to UHF by just changing a channel strip. Limiter-discriminator FM sound system, automatic frequency control of the horizontal oscillator (Syncroloc), full 4Mc band width, noise saturation circuits, fast action keyed AGC, threshold control, Hi-fidelity push pull audio output, Phonograph connection and switch, color connection, front focus control, all molded plastic condensers.

Line Voltage	117VAC, 60 Cycle
Power Consumption	320 Watts
Tuner input impedence	300 Ohms
Video IF carrier Freq.	26.4MC
Sound IF carrier Freq.	21.9MC
Band width of Video IF.	4MC
Band width of Sound Discriminator	350KC
Adjacent channel trap (picture)	20.4MC
Adjacent channel trap (sound)	27.9MC
Video sensitivity	4 Microvolts
Video IF amplifier	4 stages
Video amplifier	2 stages
Sound IF amplifier	3 stages
Audio amplifier	2 stages
Overall gain of Video Amplifier	40 times
Audio Output undistorted	5 watts
Audio Output maximum	10 watts

TUBE COMPLEMENT

Circuit Symbol	Tube Type	Function
V-1	5U4	Low voltage rectifier
V-2	5U4	Low voltage rectifier
V-3	6CB6	1st Sync Amplifier
V-4	6CB6	Sync Separator
V-5a	6SN7	2nd Sync Amplifier
V-5b	6SN7	Horizontal discharge
V-6	6AL5	Horiz. Sync. Discr.
V-7	6AC7	Horiz. Oscillator control
V-8	6K6	Horizontal Oscillator
V-9	6CD6	Horizontal Output
V-10	1B3	High Voltage Rectifier
V-11	6W4	Horizontal Damper
V-12	6J5	Vert. Osc. & Discharge
V-13	6S4	Vertical Output
V-14 to 17	6CB6	1st, 2nd, 3rd, 4th Video IF
V-18a	6AL5	2nd Video Detector
V-18b	6AL5	DC Restorer
V-19	6AU6	1st Video Amplifier
V-20	6V6	2nd Video Amplifier
V-21	6AU6	AGC Control
V-22	6BA6	1st Sound IF
V-23	6BA6	2nd Sound IF
V-24	6AU6	3rd Sound IF & Liminator
V-25	6AL5	Sound Disc. Detector
V-26a	6SL7	1st Audio Amplifier
V-26b	6SL7	Phase Inverter
V-27&28	6AQ5	Audio Output

VIDEO I.F. ALIGNMENT

1. Connect the common lead of the VTVM to chassis ground. Set the meter on -volts setting and connect the DC probe to the junction of PC-2 and R28. This is the load resistor of the 2nd pix detector.

2. Remove the 6AU6 AGC control tube VT-21.

3. Apply a bias of -3 volts to the AGC line. This is the junction of C-35, R22B and R-22. For fringe areas -1.5V should be used.

4. Turn the tuner channel selector to a station that does not have a local signal.

5. Apply the IF signal with an accurate generator to the 6J6 tube in the tuner. This may be done by placing an ungrounded shield cover over the tube and applying the signal to the shield. The ground connection for the generator should be as short as possible.

6. Set the generator to 24.05MC with high output and adjust L2 for maximum reading on the VTVM. Keep the meter on the lowest scale. Always keep the generator output low enough to prevent the VTVM from reading over 1.5 volts during all alignment steps.

7. Set signal generator to 25.85MC and adjust L1 for maximum reading.

8. Set signal generator to 21.9MC and adjust T7 for minimum reading.

9. Set signal generator to 22.95MC and adjust T2 bottom for maximum.

10. Set signal generator to 21.9MC and adjust T2 top for minimum.

11. Repeat steps 9 and 10.

12. Set signal generator to 27.9MC and adjust T1 top for minimum.

13. Set signal generator to 25.95MC and adjust T1 bottom for maximum.

14. Set signal generator to 22.45MC and adjust converter on tuner for maximum reading.

SOUND I.F ALIGNMENT

1. Connect the signal generator to pin 1 of VT-24 and set it on 21.9MC. This setting should not be touched during the entire alignment. Reduce output of generator where necessary to keep meter reading within the specified scale.

2. Connect the VTVM common lead to ground and the other lead in series with a 1 megohm resistor to the junction of the diode resistors R-110 and R-111. Do not remove the discriminator shield to make these connections as they can be made by making a hook on the resistor and making connection to the transformer lug C through the hole provided for the adjusting tool. Set the meter on the +10 scale and the top of T-10 should be adjusted for maximum reading.

3. Connect the meter common lead to ground and the other lead to the junction of R-113 and C-111. The VTVM should be set to plus 3 or 5 volt scale. Adjust T-10 bottom for zero reading on the meter.

4. Connect the probe of the VTVM to terminal A of T-9. Set the meter on -3 or 5 volt scale and adjust both the top and bottom of T-9 for maximum reading.

5. Apply a 21.9MC signal to the 6J6 tube in the same manner as that done in step 5 of the Video IF Alignment Section. Adjust T-8 top and bottom for maximum reading on VTVM.

RF OSCILLATOR ALIGNMENT

The RF unit or tuner is factory pre-aligned and the alignment screws on the top of the tuner should not be touched. Only the converter coil on the tuner should be adjusted as in step number 14 of the Video IF Alignment.

The only adjustment that you can make on the tuner is the oscillator adjustment for the channel slugs.

1. Connect an antenna to the tuner and turn the set on.

2. Select the channels that are on the air. Set the fine tuning control to its midway position and do not touch again. A 1/4 inch hole to the right of the control shaft will be exposed.

3. Insert a fiber or plastic screwdriver not larger than 3/16" through the oscillator adjustment hole and slightly turn the slug in or out until maximum volume without distortion is obtained. Do not screw the slug more than a couple of turns or it will fall into the coil and you will have to remove the coil and reset the slug.

4. Turn the channel selector to the stations that you can receive and repeat step 3 for each channel.

OVERALL ALIGNMENT

While it is generally unnecessary to use a sweep generator, it may be desirable to view the overall response curve. This curve is similar to that drawn below. To obtain it a 50-216 MC sweep generator is used together with a standard signal generator and an oscilloscope.

1. In a normal area the -3V bias should be applied to the IF strip as in steps 2 and 3 of the Video Alignment section. For fringe area the -1.5 volt bias should be used.

2. Connect the IF sweep generator to the antenna terminals and set to channel 12 or 13. Set the receiver channel selector to the same channel.

3. Connect the common lead of the VTVM to ground and the DC probe to the junction of PC-2 and R-28. Set the meter to the -3 or -5V scale.

4. Set the sweep generator output to high output and adjust the fine tuning control on the receiver until a response curve appears on the scope screen. Reduce the generator output until a reading of .3 volts is obtained on the VTVM. Readjust the oscilloscope gain if necessary to get an adequate size pattern.

5. Connect the signal generator to the antenna terminals through a small capacitor and feed in a 26.4MC IF picture carrier marker.

6. Observe and analyze the response curve obtained. If necessary the IF adjustments should be slightly retouched in order to obtain a curve similar to the one illustrated.

7. If T-2 bottom requires any adjustment it may be necessary to readjust T-2 top. When all the final adjustments are made the picture carrier marker 26.40MC should be at approximately 50% response. The curve must be approximately flat top with a 22.95MC marker at approximately 100% response, a 22.95MC marker may be obtained by readjusting the signal generator as in step 5.

Throughout the video IF alignment care should be taken to see that no two transformers are tuned to the same frequency. Replace 6AU6 tube, VT-21 and remove bias batteries.

INSTALLATION NOTES

If the set is to be used in a custom cabinet, mounting brackets are always supplied with the cabinet for the mounting of the picture tube. If the set is to be used in a wall installation then metal mounting brackets are available for this purpose.

After mounting the picture tube, the deflection yoke should be placed all the way up on the neck of the tube as far as it will go. Mount the focus coil with the gap forward. The focus coil should be about 1/4" behind the yoke. It is understood that the brackets that hold the yoke and focus coil are already fastened to the board or brackets.

Mount the ion trap on the neck of the tube near the cap. Make sure that you are using the correct ion trap with the particular tube you are using. Most tubes today use single magnet ion traps and that is what is supplied with the set.

Connect the high voltage lead to the picture tube. Turn on the set. Adjust the brightness control to about 3/4 of the way and slowly bring the ion trap forward and back slowly rotating at the same time until maximum brightness can be obtained on the picture tube. There might be two positions where maximum brightness can be obtained. The correct position is nearest the cap of the picture tube.

Connect the antenna to the set. Turn the AGC level control 3/4 clockwise. Turn up the contrast until a picture is on the screen. If the picture tears or has a venetian blind effect, adjust the synchroloc T-5 until the picture becomes steady. If it is rolling up or down, adjust the vertical hold control on the front of the chassis.

Adjust the width and horizontal drive control until the picture fills the tube. Then adjust the vertical height and linearity control to fill the tube vertically. If shadows are on the corners of the picture tube, tilt the focus coil slightly. This will remove the shadows and readjust the ion trap slightly. If the picture tube is centered in the yoke and focus coil there should be very little adjusting to be done.

If the picture is tilted, loosen the wing nut on top of the yoke and move it to the left or right. This will level the picture. Tighten up the wing nut after this setting.

SERVICE HINTS

POOR BRIGHTNESS
1. Width coil
2. Ion trap adjustment
3. VT-5, 8, 9, 10, 11
4. Deflection yoke
5. Picture tube
6. R-81 too high in value
7. Setting of Horiz. drive
8. HV arcing or corona

SOUND BUT NO RASTER
1. Deflection yoke
2. No high voltage
3. Picture tube
4. R-88
5. High voltage fuse
6. Ion trap adjustment
7. Coil LL-1
8. Flyback transformer
9. VT-5, 8, 9, 10, 11

NO RASTER OR SOUND
1. VT-1, 2
2. Supply voltages
3. AC input

INSUFFICIENT WIDTH
1. Deflection yoke
2. Low line voltage
3. VT-5, 8, 9, 10, 11
4. R-88
5. Horiz. drive control

NO SOUND
1. Speaker or leads
2. Output transformer
3. Volume control
4. VT-22, 23, 24, 25, 26A, 26B, 27, 28

VERTICAL LINE, NO RASTER
1. Deflection yoke
2. VT-11
3. Flyback transformer

HORIZONTAL LINE, NO RASTER
1. Deflection yoke
2. T-4 Vertical output transformer
3. VT-12, 13

RASTER BUT NO PICTURE
1. Picture tube socket connections
2. Continuity of width & AGC coils
3. VT-14, 15, 16, 17, 18, 19, 20, 21
4. Bias of AGC lines, should be -.6 to -4 volts depending on signal
5. Contrast control
6. PC-1, 2, 3, 4, 5, 6 in video circuit

INSUFFICIENT HEIGHT
1. Deflection yoke
2. VT-12, 13
3. Vert lin & height control

NO SYNC
1. VT-18A, 3, 4, 5

NO HORIZONTAL SYNC
1. Horizontal hold control
2. VT-6, 7
3. C-45, C-66
4. Sync discr. transformer T-5

NO VERTICAL SYNC
1. C-51, C-52, C-53, C-54
2. R-51, R-52, R-53, R-54, R-58
3. VT-12
4. T-3
5. Vertical hold control

IMPROPER FOCUS
1. Adjustment of focus control
2. Defective picture tube
3. Low high voltage
4. Focus coil should be 470 ohms
5. R-7 and focus control
6. Improper adjustment of ion trap

HORIZONTAL JITTER
1. Yoke leads too close to kine. grid lead
2. Minus 2 volts supply line
3. T-5
4. VT-7

POOR VERTICAL LINEARITY
1. Deflection yoke
2. VT-12, 13
3. Height, Vertical Lin & vertical hold

BURN OUT SPOT ON SCREEN
1. Picture tube

DARK LINES ON LEFT SIDE OF PICTURE
1. 6CD6 tube VT-9
2. Yoke wires too close to picture grid lead
3. C-82 in yoke

SOUND BARS IN PICTURE
1. Sound IF Alignment

LIGHT LINE LEFT SIDE OF PICTURE
1. Horizontal drive control
2. VT-5
3. Value of R-81 to be increased to 560K or 680K

ONE HALF OF RASTER DARKER
1. VT-14, 15, 16, 17, 18, 19, 20
2. All low voltage electrolytics

VERTICAL JITTER
1. VT-12
2. Increase value of C-3B to 1mfd.
3. C-54 or R-58
4. T-3

RASTER OFF CENTER
1. Focus coil & vertical centering control
2. Reverse focus coil leads
3. Incorrect setting of ion trap

TILTED RASTER
1. Adjustment of deflection yoke
2. Reverse leads of focus coil

CORNERS OF RASTER CUT OFF
1. Defective picture tube
2. Focus coil too far back
3. Deflection yoke too far back
4. Improper ion trap or ion trap adjustment

POOR PICTURE DETAIL
1. VT-18A, 19, 20
2. PC-1, PC-2, PC-3, PC-4, PC-5, PC-6
3. IF alignment

TRAPEZOIDAL RASTER-KEYSTONE
1. Defective deflection yoke
2. C-82 in yoke defective

POOR HORIZONTAL LINEARITY
1. VT-8, 5, 9, 10, 11
2. Deflection yoke
3. C-80, C-83
4. Improper ion trap for picture tube

RESISTORS

All resistors are 1/2 watt plus or minus 10% unless otherwise stated

GENERAL INFORMATION

SPECIFICATIONS

OPERATING VOLTAGE
105-125 volts, 60 cycles.

POWER CONSUMPTION
215 watts.

FUSE
Located at rear of chassis.
(5 amp. 3AG)

RECEIVER INPUT IMPEDANCE
300 OHM balanced (between terminals). If 72 OHM coaxial cable is used, connect outer conductor to chassis and inner conductor to either antenna terminal.

INTERMEDIATE FREQUENCIES
Video Carrier - - - - - - - 24.75 MC.
Sound Carrier - - - - - - - 20.25 MC.
Intercarrier Sound- - - - - 4.5 MC.

SPEAKER
10" P.M. (all models except 21" T.M.)
Voice Coil Impedance - - 3.2 ohms.
Audio Power Output - - - 2.5 watts. (Undistorted)

DEFLECTION
Electromagnetic

FOCUS
Electrostatic or Magnetic.

CAUTION NOTICE

HIGH VOLTAGE; (18,000 VOLTS) EXISTS AT THE HIGH VOLTAGE LEAD TO THE PICTURE TUBE, AND GREAT CARE MUST BE TAKEN WHEN REMOVING THE CHASSIS FOR SERVICING.

PICTURE TUBE HANDLING; GOGGLES AND HEAVY GLOVES SHOULD BE WORN WHEN HANDLING THE PICTURE TUBE. NEVER LIFT THE PICTURE TUBE BY ITS NECK OR STRIKE THE NECK IN ANY WAY.

BACK COVER; THIS SHOULD ONLY BE REMOVED BY A QUALIFIED SERVICE TECHNICIAN.

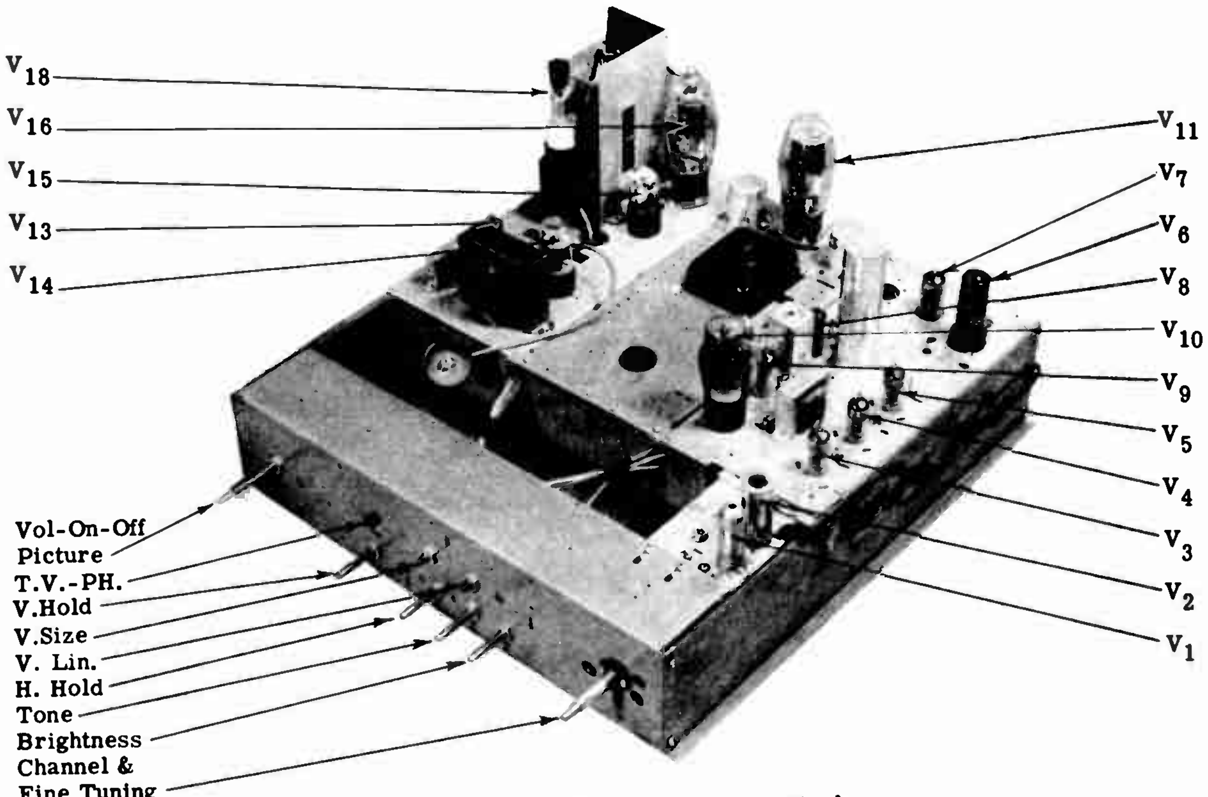

Fig. 2. Tubes and Front Controls.

INSTALLATION INSTRUCTIONS

This receiver is normally shipped ready for operation. After unpacking and removing wooden shipping base the following operational checks should be performed; Connect either an Indoor or Outside Antenna to the Receiver Antenna Terminals and plug in the line cord. The OPERATING INSTRUCTIONS given below should now be followed.

Controls for customer adjustment are located on the front panel behind the small control door. Controls at the rear of receiver should be adjusted (if necessary) only by the installation technician.

OPERATING INSTRUCTIONS

The receiver is adjusted at the factory and is ready for operation after installation. To place the receiver in operation attach the cord to any 117 volt 60 cycle AC outlet and proceed as follows:

1. Turn the OFF-ON, VOLUME control knob clockwise about one half turn and wait for tubes to warm to operating temperature.
2. Turn the CHANNEL selector knob to the desired channel.
3. The picture control should be turned to a point near half way rotation.
4. The FINE TUNING control located behind the channel selector knob is then adjusted for the clearest picture.
   NOTE: This may also require readjustment of the PICTURE control for maximum picture quality.
5. The VOLUME control is then adjusted for desired sound level.

PRE-SET CONTROL ADJUSTMENTS

VERTICAL SIZE AND LINEARITY ADJUSTMENTS
Adjust the SIZE control until the picture completely fills the mask. Adjust the VERTICAL LINEARITY control until the picture is symetrical from top to bottom. Adjustment of one control will effect the adjustment of the other, therefore, readjustment may be required for correct setting.

VERTICAL HOLD CONTROL
Rotate the VERTICAL HOLD control until the picture moves slowly downward. Turn the control back until the picture moves upward and locks in.

PICTURE CONTROL
Adjust this control for best contrast with a test pattern or good picture.

BRIGHTNESS CONTROL
This control must be operated in conjunction with the PICTURE control for best picture contrast.

HORIZONTAL HOLD
Adjust this control to mid position.

PHONO TV SWITCH
Place switch in downward position for T.V. operation.

TONE CONTROL
Adjust control for desired sound range.

LOCAL FRINGE SWITCH
Place switch in upward position for local stations.

SERVICE INFORMATION

PICTURE TUBE ADJUSTMENTS

- IMPORTANT -
"Read (caution notice) on page 1.".

These adjustments to be made by Qualified Service Technicians only.

ION TRAP ADJUSTMENT
It is important that this adjustment be made upon installation and repeated after "Focus" or "Positioning" adjustments.

When adjusting the ION TRAP have the BRIGHTNESS control set for normal brightness. Start with the ION TRAP close to the picture tube socket and move it slowly in the direction of the yoke while rotating it to find the position which gives maximum raster brilliance.

Reset BRIGHTNESS control for normal brilliance. There may exist two positions of the trap where maximum brightness occurs. The ION TRAP should always be placed at the position closest to the picture tube base.

CAUTION: Never set the ION TRAP to the forward position.

If shadows now appear in the corner of the raster do not attempt to eliminate them by adjusting the ION TRAP and sacrificing raster brilliance. Remove shadows by adjusting the CENTERING DEVICE and DEFLECTION YOKE. The ION TRAP should always be readjusted after the CENTERING, FOCUS or YOKE adjustments.

FOCUS ADJUSTMENT
For receivers using electrostatically focused picture tubes a fixed 300 volts (positive) DC is applied to the focusing anode and no focusing provision is provided. With ion trap and centering adjustments correctly made, proper focus will result.

For receivers using magnetically focused picture tubes a combination permanent magnet focusing device and centering assembly is provided. The magnetic field is varied by placing a non-magnetic screw driver in slot provided as a screw driver adjustment on the PM focalizer unit. This unit is located behind the deflection yoke on the neck of the picture tube. Focus adjustment is made at the factory, but if necessary, this adjustment should be made while viewing the raster with normal picture brilliance. Optimum focus results when the horizontal lines are clearly defined.

PIN CUSHION CORRECTOR MAGNET ADJUSTMENT
Two CORRECTOR MAGNETS are used to eliminate curvature of the top and bottom edges of the raster. These magnets are mounted on the deflection coil mounting bracket and can be moved in an out or up and

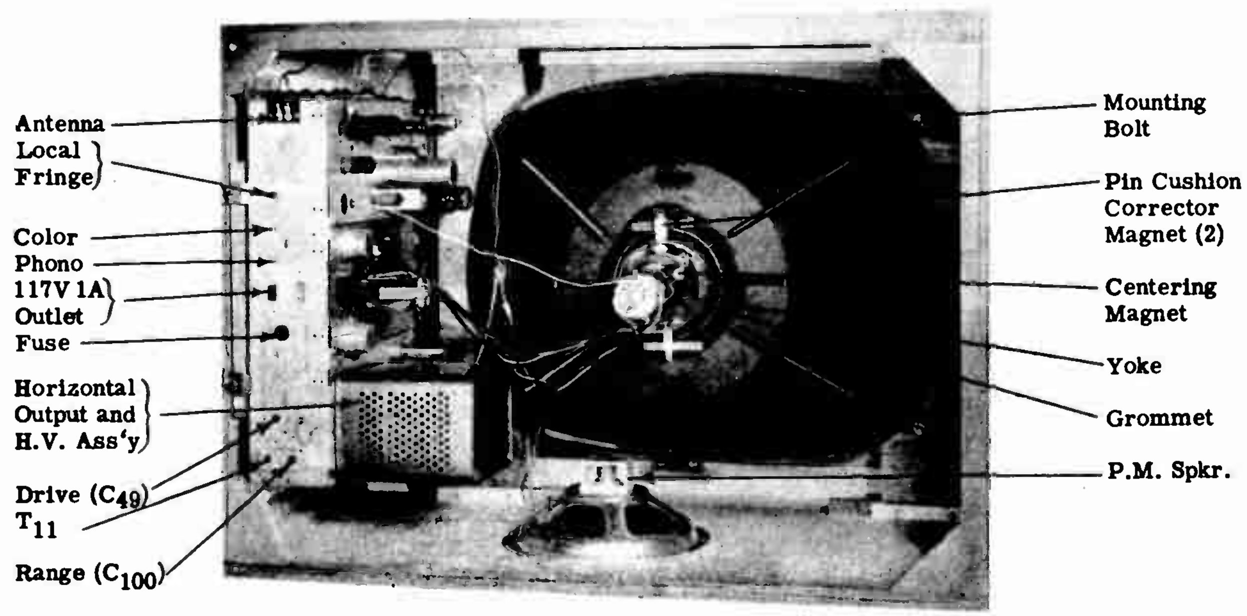

Fig. 3. View Showing Rear of Cabinet.

down by moving the holding arm.

To make adjustment;

1. Turn the VERTICAL SIZE control until both the top and bottom edges of the raster are visable.
2. Loosen the screw that holds the magnet arm in place and adjust the magnet position by moving the arm forward and/or rotate it around the screw until the top and bottom edges are straight and parallel to each other.

NOTE: Mis-adjustment of the CORRECTOR MAGNETS may cause keystoning, poor linearity, etc.

CENTERING ADJUSTMENTS

Two types of centering assemblies have been used in production.

One assembly utilizes a small bar type magnet which can be turned by means of a knurled shaft. This assembly is adjusted by turning the knurled shaft and by rotating the entire unit until the picture is centered on the screen.

One assembly consists of two magnetic rings mounted as two movable washers. The washers are provided with tabs to enable rotating the magnets independently of each other to vary the magnetic field. This unit is installed about 3/4 inch behind the yoke to prevent the yoke from demagnetizing the ring magnets. Adjustment is made by gradually rotating them with respect to each other and by rotating the entire unit until the picture is centered.

TO REMOVE AND REPLACE PICTURE TUBE

REMOVING THE PICTURE TUBE

1. The vertical wooden bar (located at right of the screen) is secured by a holding screw inserted from inside the cabinet. After the holding screw has been removed, grasp the vertical wooden bar and force upward until the bottom of the bar is clear of the framework. Bar can now be removed by pulling at the bottom with an outward and downward motion.
2. Remove the safety glass front by placing palms of hands on the glass and forcing it to the right and then upward until the glass edge is clear of the bottom and left side of the cabinet. Hold the glass carefully and remove by bringing the bottom edge forward.
3. Using the same general rule as in step 2 remove the mask.
4. Remove the cathode ray tube socket and the yoke plug, ion trap, centering device, the second anode wire and cathode lead.
5. Remove the yoke and rubber grommet by first removing the yoke retaining springs from the eye bolts on the cabinet. The springs should be removed in this order; top left, bottom right, top right and bottom left. The yoke and grommet may now be taken from the neck of the CRT.
6. Return to the front of cabinet and remove the nuts and washers from the bottom CRT retaining bolts. Remove the nuts and washers from the top CRT retaining bolts and the CRT can be removed while taking great care not to drop or jar it.
7. Remove the metal strap around the CRT by loosening the bolts on each side of the screen until the strap will slide off the picture tube.

REPLACING THE PICTURE TUBE

1. Place the metal strap around the picture tube and tighten the side bolts, being sure that bolts are midway along the side of picture and then tighten for equal spacing. The picture tube should fit against the four small curved retaining brackets. Tighten the strap securely.
2. Replace the springs and washers as shown:

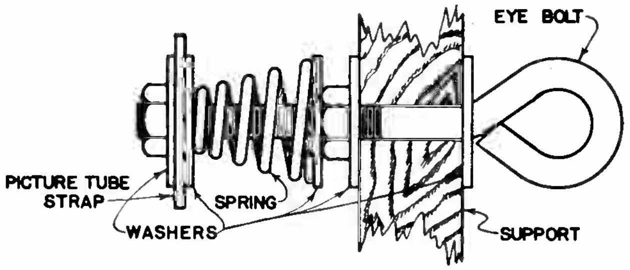

Fig. 4. Picture Tube Mounting Bolt.

and place picture tube in position with the two top nuts and washers being replaced before the two bottom nuts and washers.

3. Tighten the mounting nuts to bring the picture screen just against the picture mask. Check position by putting picture mask in place by first fitting it in the top groove, lowering it in place and then sliding it to the left. If the picture tube is too far back remove the mask and loosen proper mounting nuts. If the picture tube is too far forward mask will not fit and the mounting nuts must be tightened.
4. Replace the rubber grommet and then the yoke. Replace the four springs on the yoke with the short end toward the neck of the picture tube and the hook toward the tube base. Then attach the springs of the eye-bolts on the tube mount in this order; top left, bottom right, top right and bottom left.
5. Replace centering device, ion trap (see ion trap adjustments), yoke plug, picture tube socket, cathode lead and second anode lead.
6. Replace the safety glass by placing it in the upper groove first then lowering it in the bottom groove and then sliding it to the left as was done with the mask.
7. Replace wooden bar by moving top end up into the hole provided and pushing it down into the bottom hole. Insert the holding screw from inside the cabinet.

SEMI-REMOVAL OF CHASSIS

The receiver chassis may be partially removed from cabinet for minor service and adjustments. The chassis may be moved out from cabinet approximately one foot after removing the two rear retaining brackets.

LIMIT OF CHASSIS REMOVAL DEPENDS UPON SLACK IN LEAD WIRES FROM THE CHASSIS TO PICTURE TUBE.

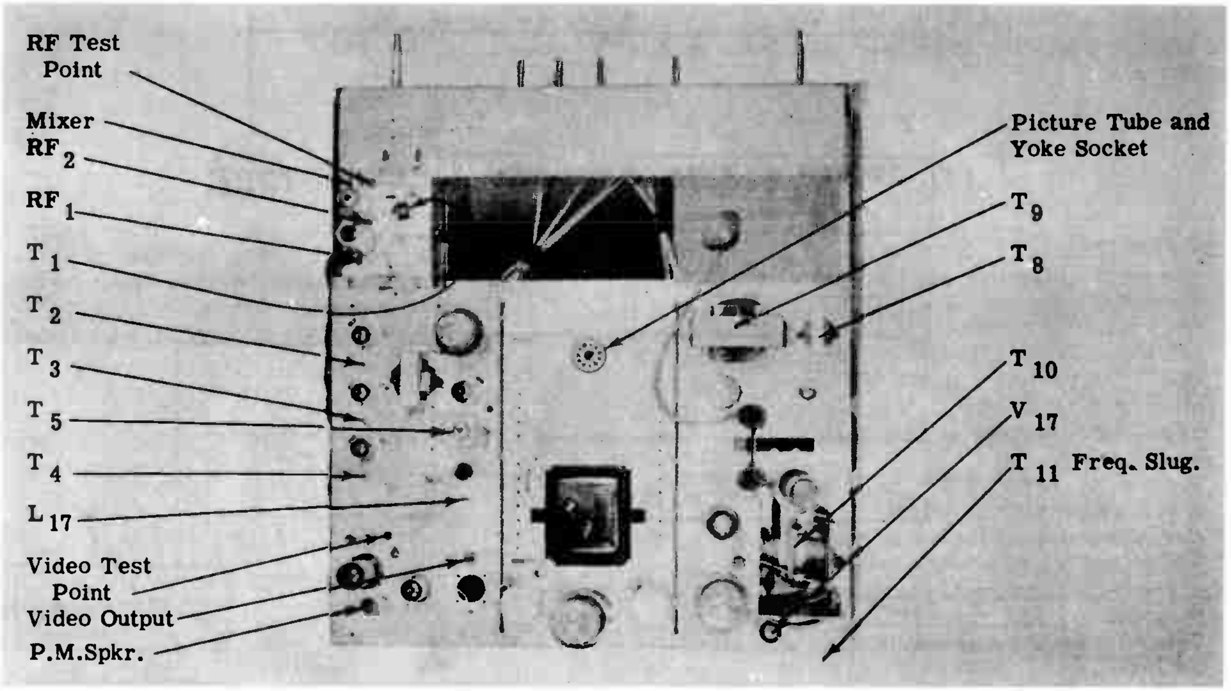

Fig. 5. Top View of Chassis.

HORIZONTAL OSCILLATOR ADJUSTMENTS

A) "HORIZONTAL FREQUENCY ADJUSTMENT"

1. Short circuit terminals "C" and "D" of the horizontal oscillator transformer "T_{11}". Tune in a station and sync in the picture if possible. Set PICTURE control to mid position. Set RANGE control "C_{100}" to approximately one turn from full in position.
2. Turn the HORIZONTAL HOLD control R_{65} to the extreme clockwise position. If picture is out of sync adjust frequency slug on "T_{11}" (back of chassis). NOTE; There may be two settings at which picture syncs, so use the one with screw farthest out of the coil. After this position has been correctly located readjust the frequency adjustment slug counter clockwise until picture is just out of sync.
3. Turn the HOLD control approximately 1/4 turn from the extreme clockwise position, to just sync picture horizontally.(It may be necessary to slightly readjust "T_{11}" back of chassis). Adjust the HORIZONTAL DRIVE control "C_{49}" (back of chassis) counter clockwise, to point where vertical drive line appears near center of raster. If this throws picture out of sync readjust "T_{11}" (back of chassis) and then turn "C_{49}" so that line just disappears. This is the proper adjustment of "C_{49}". Now, turn the HORIZONTAL HOLD control "R_{65}" to the extreme clockwise position and if picture loses sync readjust "T_{11}".

(B) "HORIZONTAL STABILIZER ADJUSTMENT"

1. Remove the short circuit from "C" and "D" of

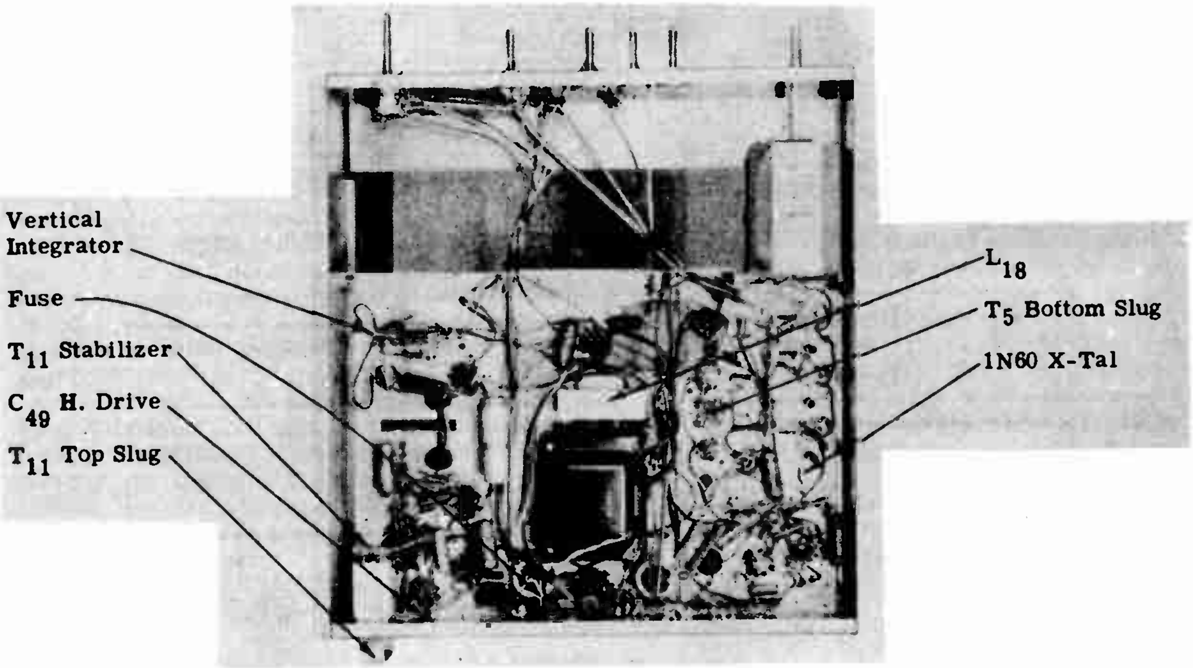

Fig. 6. Bottom View of Chassis.

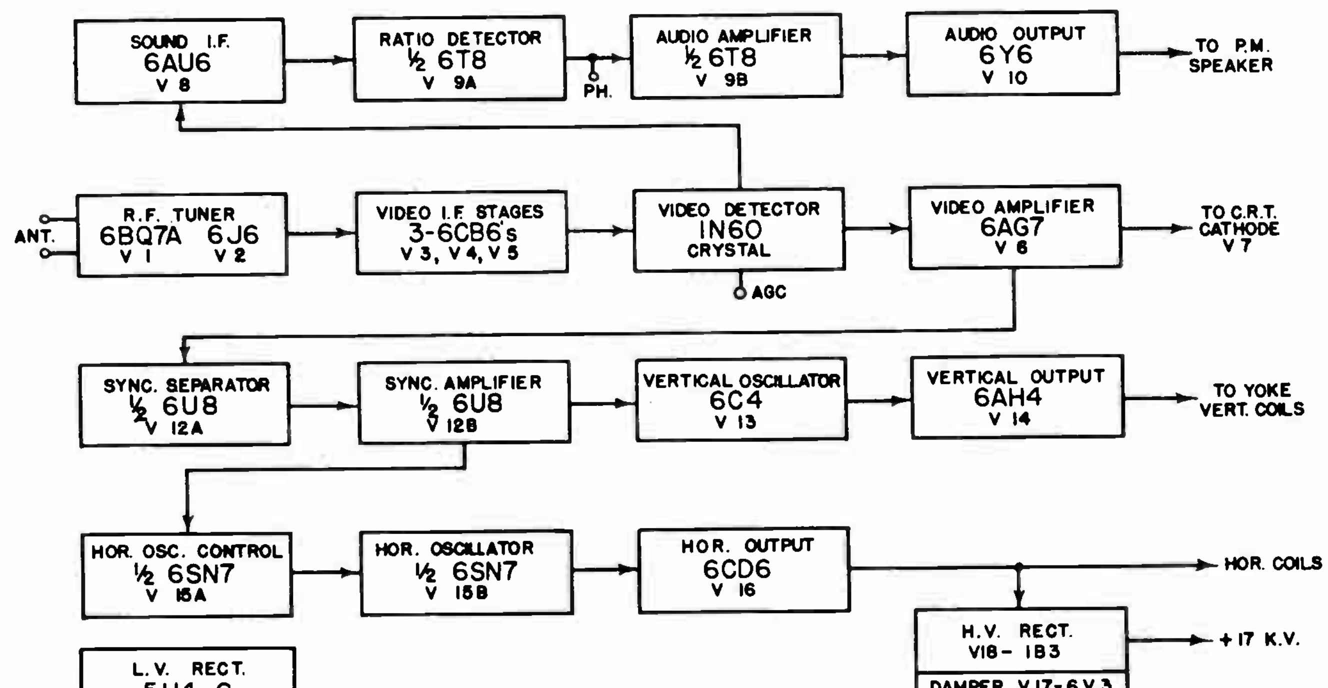

Fig. 8. Block Diagram.

"T_{11}". If picture loses sync slightly adjust the stabilizer adjustment of "T_{11}" (under chassis). NOTE; There may be two settings that sync picture, use the one which is obtained with the screw farther out of the coil.

2. Connect the low capacity probe of an oscilloscope to terminal "C" of "T_{11}". If scope upsets sync adjustment readjust frequency adjustment of "T_{11}" (back of chassis). The pattern on the scope should be as shown in Figure (7).

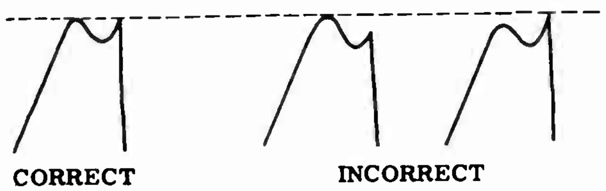

Fig. 7. Horizontal Stabilizer Waveforms.

3. Adjust the stabilizer adjustment "T_{11}" (under chassis) for above waveforms. The correct adjustment of this slug is when the two peaks are of equal height. During this adjustment the picture must be kept in sync by readjusting the HOLD control or "T_{11}" frequency adjustment (back of chassis). This adjustment is very important for correct operation of the circuit from the stand-point of oscillator drift and noise immunity.
4. Remove scope.

(C) "HORIZONTAL LOCKING - RANGE - ADJUSTMENT"

1. Set the horizontal HOLD control fully counter clockwise. The picture may remain in sync. If so turn "T_{11}" frequency adjust (back of chassis) slightly and momentarily switch channel until picture falls out of sync with diagonal lines sloping down to the left. Momentarily remove the signal by switching CHANNEL selector to next channel and back again. Slowly turn the HORIZONTAL HOLD control clockwise and note the least number of diagonal bars obtained as the picture pulls into sync.
2. If more than 7 bars are present as the picture pulls into sync, adjust the horizontal LOCKING RANGE trimmer "C_{100}" (back of chassis) slightly clockwise. If less than 3 bars are present, adjust "C_{100}" (range control) slightly counter clockwise; momentarily remove the signal, and then, again rotate the HOLD control clockwise noting the least number of horizontal bars obtained as the picture pulls into sync, repeating this procedure until 3 to 5 bars are present.
3. Replace scope and readjust "T_{11}" stabilizer control for the waveforms of Figure (7).
4. Remove scope and set HOLD control to the extreme clockwise position. Adjust frequency slug "T_{11}" (back of chassis) counter-clockwise so that the vertical blanking bar just appears on the screen and then turn slug clockwise until blanking bar just disappears. The HOLD control can now be rotated either way without loss of sync.

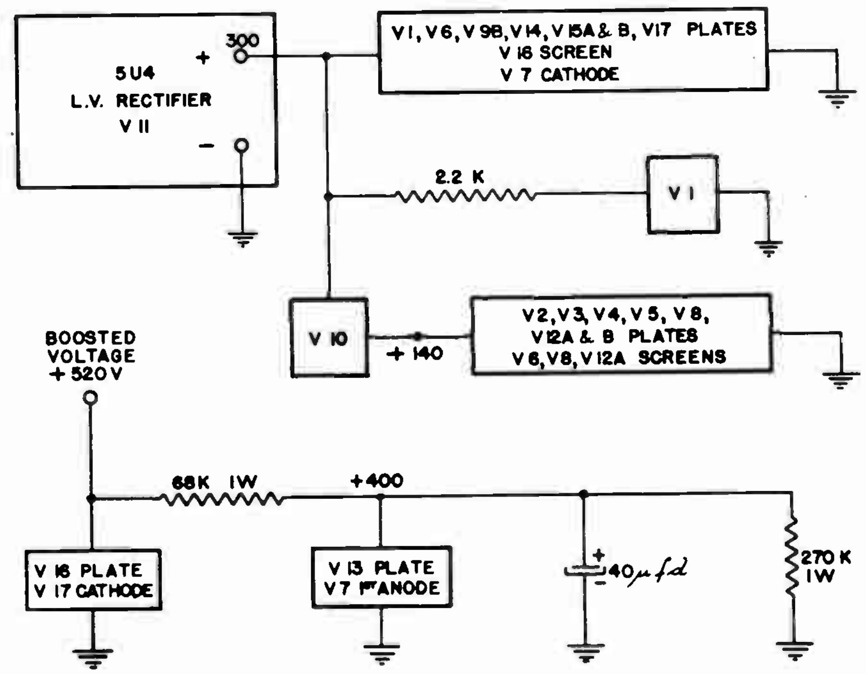

Fig. 9. D.C. Distribution Diagram.

The distribution of the D.C. plate and screen voltages is shown in Figure 9. This diagram will serve as an aid in servicing the D.C. circuits. It will be noted that V10 serves the dual function of an Audio Power Amplifier and a voltage divider. In this manner 140 volts is obtained at the cathode of V10.

ALIGNMENT PROCEDURES

I.F. AMPLIFIER ALIGNMENT

PREALIGNMENT INSTRUCTIONS

1. Connect negative side of bias battery (4V) to white lead entering R.F. tuner sub chassis and positive lead to chassis. IMPORTANT; Be sure local-fringe switch is in local position. A method of obtaining 4V DC for AGC bias is shown in Figure (10).

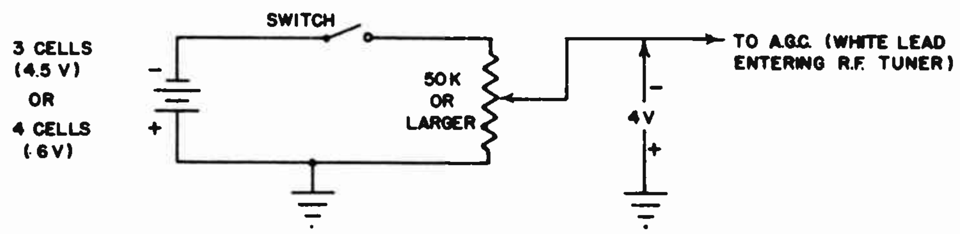

Fig. 10. Suggested Circuit for Adjusting AGC Bias.

2. Disconnect antenna and short antenna terminals.
3. Set channel selector to unused channel.
4. Set picture control at mid position.
5. Allow reasonable warming period for receiver and test equipment.
6. Connect V.T.V.M. (5V.D.C. scale or less) to video "test point" at video detector, near V-6 (positive side of V.T.V.M. to chassis).
7. Connect RF signal generator high side to 6J6 shield. (Be sure to raise shield on the 6J6 to insulate it from chassis). Connect low side of generator to chassis at 6J6 base.

PROCEDURE

IMPORTANT:
The following adjustments are made keeping the R.F. generator output low enough to give a V.T.V.M. reading of less than one volt at the video "test point".

1. Set the signal generator to 23.9 M.C. and adjust T_4 for maximum on the V.T.V.M.
2. Set the signal generator to 24.7 M.C. and adjust T_3 for maximum on the V.T.V.M.
3. Set the signal generator to 21.9 M.C. and adjust T_2 for maximum on the V.T.V.M.
4. Set the signal generator to 22.7 M.C. and adjust T_1 for maximum on the V.T.V.M.
5. Repeat procedure.

IF RESPONSE CURVE (Visual Check)
The preceeding procedure should result in a reasonable IF response characteristic. However, a visual check of the IF response curve will insure correct alignment. The response curve should appear as in Figure (11).

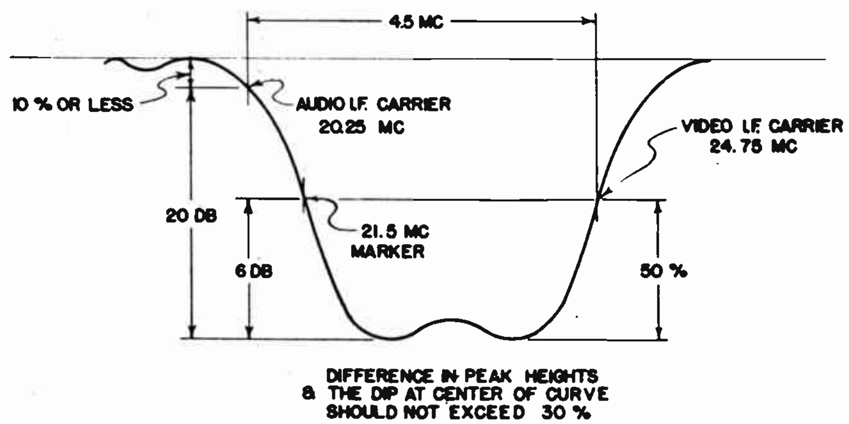

Fig. 11. Ideal I.F. Response Curve.

PROCEDURE:

1. Follow prealignment instructions, steps 1 thru 6.
2. Connect sweep generator high side to the 6J6 tube shield. Raise shield on 6J6 tube to prevent it from shorting the generator signal to ground.
3. If a separate marker generator is used, loosely couple high side to sweep generator lead on tube shield, low side to chassis. Marker frequencies are indicated on IF response curve Figure (11).
4. Connect oscilloscope to "Video test point". Marker pips on scope will be more distinct if a condenser between 100 MMFD and 1000 MMFD is connected across the oscilloscope input.
5. Check curve obtained against response curve of Figure (11). Note tolerance on curve. To prevent overloading keep sweep and marker outputs at very minimum. If response varies from tolerance given, or the markers are not in the proper location on the curve, improve the response by making the following adjustments:
   a. If peaks are not equal, carefully adjust T4 (23.9mc). It should not be necessary to adjust more than one turn in either direction.
   b. If the curve cannot be made to resemble the ideal response curve of Figure (11), repeat all steps under "IF" amplifier alignment. Be sure that generator frequencies are accurate and adjustments carefully made. If a satisfactory curve cannot be obtained after the steps have been repeated, stages may not be operating properly due to defective tube or other circuit component.

R.F. AMPLIFIER AND MIXER ALIGNMENT

TEST EQUIPMENT: Oscilloscope, RF Marker Generator, and RF Sweep Generator.

1. Allow receiver and test equipment to warm up for approximately 15 minutes.
2. Repeat step 1 of IF prealignment instructions (pertaining to bias battery).
3. Connect sweep generator to antenna terminals on the receiver. If sweep generator does not have an internal marker generator, loosely couple an external marker generator through a 2 or 3 MMFD capacitor to the antenna terminals as shown in Figure (12).
4. Connect the oscilloscope vertical input to the RF test point on the RF tuner through a 10K resistor. A .002 MFD condenser placed across scope vertical input will remove stray pickup.
5. Connect the "scope output" on the sweep generator to the horizontal input of the scope.

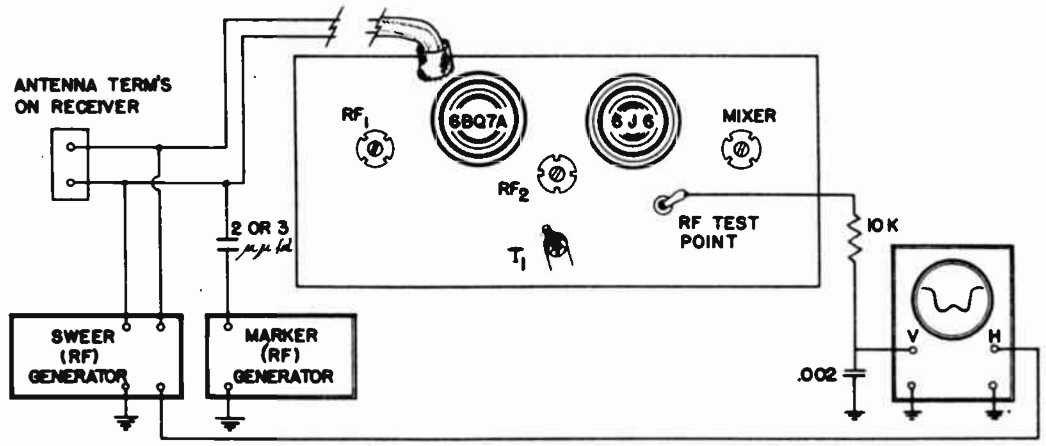

Fig. 12. Connections for R.F. Tuner Alignment.

PROCEDURE

IMPORTANT:
The following adjustments are made while keeping the sweep generator output at a minimum and the marker pips are just barely visible on the oscilloscope. The alignment of the standard RF tuner used in American Television receivers can be simplified by the alignment of one HIGH and one LOW frequency channel. This is possible because the same trimmer condensers are used on all channels.

ALIGNMENT CHART

CHANNEL SELECTOR	SWEEP GENERATOR	MARKER FREQ.		ADJUSTMENTS	
		Sound (MC)	Picture (MC)	(Step 1) Mixer & RF_2	(Step 2) RF_1
5	79MC (15 MC sweep)	81.75	77.25	Adjust for equal peak amplitudes. Peaks should occur at proper marker points as shown in Figure (13).	no adjustment
10	195 MC (20 MC sweep)	197.75	193.25	no adjustment	Adjust maximum amplitude and maximum flatness while keeping markers properly located as in Fig. (13).

With the above procedure the alignment of all channels will now be sufficiently correct.

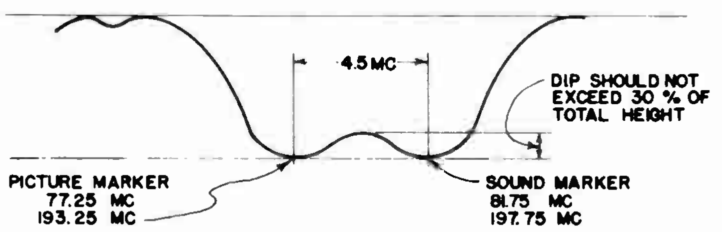

Fig. 13. R.F. Response Curve.

As a final check of tuner alignment, turn channel selector to each of the channels in the area where the receiver will operate. Use the above alignment chart in conjunction with the frequencies given in Figure (14) on the following page. The adjustments being, step 1 for channels 2 to 6, and step 2 for channels 7 to 13. If a compromise adjustment must be made, favor the weaker channels.

Channel		Sweep Gen. M.C.	Marker Gen.		OSC M.C.
			Sound M.C.	Picture M.C.	
L	2	57	59.75	55.25	81
	3	63	65.75	61.25	87
O	4	69	71.75	67.25	93
	5	79	81.75	77.25	103
W	6	85	87.75	83.25	109
	7	177	179.75	175.25	201

G	10	195	197.75	193.25	219
H	11	201	203.75	199.25	225
	12	207	209.75	205.25	231
	13	213	215.75	211.25	237

Fig. 14. Alignment Frequencies.

OVER-ALL ALIGNMENT

RF and IF section)

1. Use the same setup as shown in Figure (12) except that the oscilloscope is connected to "video test point" instead of the "RF test point". (The 10K resistor and .002 cap. are not necessary).
2. Set the CHANNEL selector to an unassigned HIGH channel and set the sweep generator to sweep this channel. See sweep generator frequency Figure (14).
3. Set marker to proper sound and picture carriers for unassigned HIGH channel chosen. See Figure (14).
4. If the response curve obtained does not compare with that shown in Figure (15), adjust T_4 for proper response curve. An adjustment of more than one turn in either direction should not be necessary.

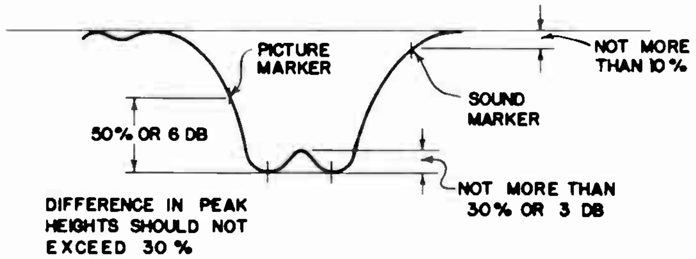

Fig. 15. Overall Response Curve.

R.F. OSCILLATOR ADJUSTMENT

(Using Television Station)

It is suggested, that RF oscillator adjustments be made using an "on the air television station".

1. Allow at least 15 minutes warm up time.
2. Set the "FINE TUNING" control at the center of rotation.
3. Set the CHANNEL selector to the channel whose oscillator frequency you wish to adjust.
4. Remove the CHANNEL selector and TUNING control knobs.
5. Using a non-metalic screw driver of (1/8) inch diameter, adjust the oscillator slug in the hole provided near the CHANNEL selector shaft.

6. Proper adjustment of this slug is for best picture clarity and detail.
NOTE: The proper adjustment of the oscillator slug will not be where maximum sound level occurs.

IMPORTANT: The oscillator slug need not be rotated very much. Turning the slug in too far will cause it to drop into the coil form. In the event that this occurs move the retaining spring aside, remove the coil, and lightly tap the open end of the coil until the slug slips out. Replace the slug and coil, reset the retaining spring, and repeat adjustment as above.

(Using a Signal Generator)

It is suggested that the RF oscillator adjustments be made using an on-the-air television station. However, if a television station signal is not available, the following procedure may be used.

1. Set CHANNEL selector to channel to be adjusted.
2. Set "FINE TUNING" at mid position.
3. Set VOLUME control fully clockwise.
4. Connect a crystal calibrated signal generator to the antenna terminals. Adjust the signal generator for maximum output.
5. Set crystal calibrated signal generator to exact frequency that the receiver oscillator should be in the channel being adjusted. See Figure (14).
6. With a clip lead and a .01 MFD capacitor connect the "RF test point" on the tuner to the center lug on the VOLUME control, or pin 8 of V_9.
7. Adjust the RF oscillator slug on the tuner until a whistle or beat note is heard in the speaker.
8. Repeat for all channels to be adjusted.

SOUND I.F. ALIGNMENT

IMPORTANT:

The following adjustments are made using a non-metalic screw driver with a 1/8 inch blade.

1. Connect two 100K OHM resistors in series from pin 2 of V9 to chassis ground. See Figure (16).
2. Connect a V.T.V.M. (50v scale) to points A and B as in Figure (16). Note polarity of Connections.

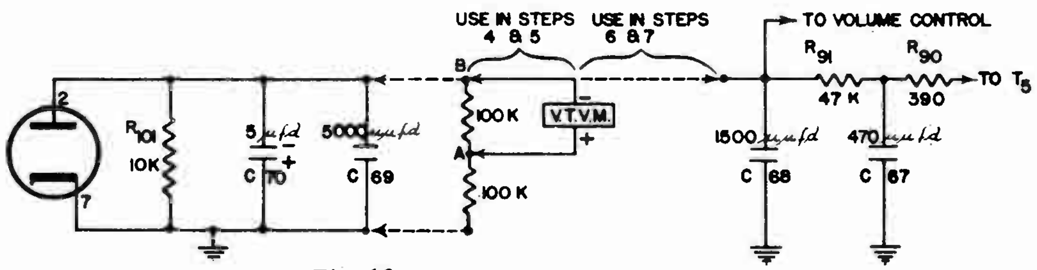

Fig. 16. Ratio Detector Alignment.

3. Tune in a T.V. station, adjust the receiver front controls for a good picture. (Set volume control fully counter clockwise.)
4. Adjust T5 primary (bottom slug) for maximum deflection of the V.T.V.M.
5. Adjust L_{17} for maximum deflection of the V.T.V.M. and repeat step 4 then readjust L_{17} for maximum deflection.
6. Remove negative lead of the V.T.V.M. from point B in Figure (16) and connect it to the junction of R_{91} (47K) and C_{68} (1500 MMF). The positive lead remains at point A in Figure (16).
7. Adjust the quardrature slug (top slug) on T5 for a null on the V.T.V.M.

NOTE: Misalignment of T_5 (top slug) may make reading either negative or positive depending on direction T_5 is turned. T_5 (top slug) should be adjusted for zero. Adjustment should be made using the 50V range of the V.T.V.M. and then succeedingly lower ranges to obtain the most sensitive null.

PARTS LIST

List of Resistors, Condensers, Coils, and Transformers

AMERICAN TELEVISION TV PAGE 12-9

CHASSIS Series "D"

MODEL 1127

MODEL 621CM

MODEL 721CDM

GENERAL DESCRIPTION

30 tube receivers (including picture tube and three rectifiers). Features include: full 12 channel coverage; latest Standard Coil Cascode Circuit RF tuner, with high signal to noise ratio, UHF adaptable; limiter-discriminator FM sound system; high second anode potential for full picture brilliance and definition; automatic frequency control of the horizontal oscillator (Syncrolok); full 4 mc. bandwidth of the picture channel; noise saturation circuits; keyed A.G.C.; and a phonograph input connector by means of which the sound section may be used as an audio amplifier. Reference is made to the overall *Circuit Diagram*

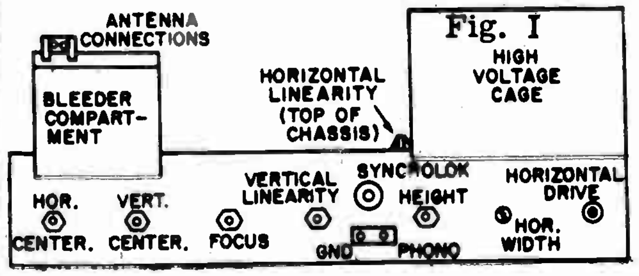

Fig. I

ELECTRICAL SPECIFICATIONS

RF Frequency Range: Channels 2 to 13 in 12 steps.

Power Supply Rating: 117 Volts, 60 Cycles, 275 Watts.

Audio Power Rating: Undistorted—2.5 Watts.
Maximum—4 Watts.

Antenna Input Impedance: 300 Ohms.

RF amplifier and RF oscillator-Mixer tubes are also supplied. These are the 6J6, oscillator and mixer, and 6BK7 or 6BQ7, RF amplifier in the tuner.

TUBE COMPLEMENT

Circuit Symbol	Tube Type	Function
V101	6BA6	1st Sound IF Amplifier
V102	6BA6	2nd Sound IF Amplifier
V103	6AU6	3rd Sound IF Amplifier (Limiter)
V104	6AL5	Sound Discriminator
V105	6AT6	1st Sound Amplifier and Syncrolok Damper
V106	6K6	Audio Output Tube
V107	6AG5	1st pix IF Amplifier
V108	6AG5	2nd pix IF Amplifier
V109	6AG5	3rd pix IF Amplifier
V110	6AG5	4th pix IF Amplifier
V111	6AL5	Pix 2nd Det. and D.C. Restorer
V112	6AU6	1st Video Amplifier
V113	6K6	2nd Video Amplifier
V114	6AU6	AGC Keying Tube
V115	6J5-GT	High Frequency Sync Clipper
V116	6J5-GT	Low Frequency Sync Clipper
V117	6SN7-GT	2nd Sync Amplifier and Horizontal Discharge
V118	6J5-GT	Vertical Oscillator and Discharge Tube
V119	6K6	Vertical Output Tube
V120	6AL5	Horizontal Sync Discriminator
V121	6K6-GT	Horizontal Oscillator
V122	6BG6-G	Horizontal Output—
V123	6AC7	Horizontal Oscillator Control
V124	1B3-GT/8016	High Voltage Rectifier
V125	6W4-GT	Damper
V126	5U4-G	Rectifier
V127	5U4-G	Rectifier

INSTALLATION NOTES

Adjust the Ion Trap

In order to prolong the life of the picture tube, it is important that the following adjustment be made on every receiver upon installation and every time the receiver is serviced:

Very carefully move the ion trap forward or backward, and at the same time, rotate it in either direction; adjust for the brightest picture possible with the brightness control set for average brightness.

Note that there may be two locations where the brightest picture can be produced. The ion trap location that is further forward on the picture tube neck should *not* be used; use the location nearer the rear.

IMPORTANT:—If the corners of the picture are shaded, be sure the ion trap has been properly adjusted. Do not sacrifice picture brightness when adjusting the ion trap to remove shaded corners. To eliminate shaded corners, see the discussion under "Check Picture Centering". Be sure to re-adjust the ion trap *each time after adjusting the focus coil.*

If the picture or raster is off-center with respect to the mask, to the right or left, or too high or too low, it may readily be repositioned by adjustment of the Horizontal and Vertical centering controls located on the rear apron of the chassis. (See Fig. I).

If the picture has a slightly blurred or fuzzy appearance, this may be cleared up by adjustment of the FOCUS control on the rear panel. The focus control should be adjusted for sharpest and clearest picture while viewing the face of the picture tube at close range, using a mirror if necessary. A good indication can be gotten by closely observing the scanning lines of the picture and adjusting for the sharpest and thinnest lines across the entire face of the picture tube.

When the height of the picture is not sufficient to fill the mask, or if vertical non-linearity is present (evidenced by unequal heights of the vertical wedges in the test pattern, or heads and bodies being out of proportion in a picture), the VERTICAL LINEARITY AND HEIGHT controls must be adjusted. These two controls affect each other, and when one is adjusted, it is usually necessary to readjust the other to obtain a satisfactory picture. The HEIGHT CONTROL has its greatest effect on the bottom half of the picture, while the LINEARITY CONTROL mostly affects the top half. If the picture width is not right, or if horizontal non-linearity is present, (i.e., one side of the picture expanded and the other side squeezed in), adjustment of the HORIZONTAL WIDTH, HORIZONTAL LINEARITY and/or HORIZONTAL DRIVE controls will be necessary. (See Fig. I).

Check Picture Tilt

If the picture is tilted, loosen the wing screw on the deflection yoke coil and slightly rotate the yoke until the picture is straight. Before tightening the wing screw, be sure that the yoke is moved as far forward as possible, otherwise corners of the picture may become shaded.

If the picture does not hold in sync throughout the range of the HORIZONTAL HOLD control, it may be possible to make it do so by adjusting the SYNCROLOK control on the rear panel. If this cannot be done, a detailed adjustment of the sync system, must be made.

9. Using a Record Player

Provision is made on the chassis for playing a record player throughout the receiver. The record player may be placed at a remote point, or near the set. The means of connecting the record player to the receiver is as follows:

A terminal link board at the central rear chassis apron is the external means for connecting the record player through the audio amplifier of the television receiver. This is so labeled on the rear chassis apron. Also, see Fig. I. Use a *shielded* phono lead between the player and the television chassis. This is to minimize extraneous pickup into the sensitive audio system of the chassis. Connect the shield end of the phono lead to the link board Terminal No. 1, which is at ground. Connect the phono *output* lead to Terminal No. 3.

Operation: The procedure for using the record player through the television receiver after the preceding connections are installed is as follows:

A phono switch is provided on the Brightness Control. When the Brightness Control is turned to its extreme *counter-clockwise* position, a click will be heard at this point, as the phono switch is thus turned on. With this simple motion all reception and light are entirely extinguished from the picture tube, and the phono circuit is put into operation. Reference may be made to the Schematic Circuit Diagram for the simple circuit involved.

The record player is now ready to be used. To adjust the phono volume, use the regular volume control on the television receiver.

When resumption of television reception is desired, simply turn and reset the Brightness Control clockwise in the normal manner.

ALIGNMENT PROCEDURE

Equipment Needed

Signal generator (or sweep signal generator with internal Sweep signal generator) marker generator.

Cathode Ray Oscilloscope.

Plastic aligning tool having a recessed metal blade.

Adjustable low voltage source (0-6V).

Pre-Alignment—Fixed Frequency

1. Connect the RF output leads of the signal generator between the shield of the 6J6 in the tuner and ground. Raise the shield slightly so that it no longer contacts the chassis. Switch to modulated RF.
2. Attach the vertical amplifier leads of the Cathode Ray Oscilloscope to the picture 2nd detector load resistor (R139—3900 Ohms). Use high vertical amplifier gain.
3. Disable the AGC system by connecting the low voltage supply across the AGC condenser C134 (0.47 Mfd). (Positive side to ground) and removing the AGC tube in the H.V. cage.
4. Adjust the signal generator to produce each of the listed frequencies using *barely sufficient* RF output to produce a usable 400 cycle sine wave pattern on the screen of the oscilloscope in each case. Make sure that there is no over-loading by raising and lowering the RF output and observing that the sine-wave pattern varies in amplitude accordingly. Use sufficient AGC voltage to prevent over-loading.
5. At each listed setting of the signal generator, adjust the specified screw for maximum or minimum amplitude of the sine-wave pattern as indicated.

Adjustment	Frequency	Coil	Location	Amplitude
A	25.7 MC.	Converter Coil (Tuner)	Top	Max.
B	22.3 MC.	1st Pix IF (T103)	Bottom	Max.
C	22.8 MC.	2nd Pix IF (T104)	Bottom	Max.
D	25.7 MC.	3rd Pix IF (L183)	Top	Max.
E	23.9 MC.	4th Pix IF (T105)	Top	Max.
F	21.75 MC.	1st Pix IF (T103)	Bottom	Min.
G	21.75 MC.	4th Pix IF (T105)	Bottom	Min.
H	20.25 MC.	2nd Pix IF (T104)	Top	Min.
I	27.75 MC.	3rd Pix IF (L183)	Bottom	Min.

6. It is advisable to repeat step 5 if the adjustments required resetting by more than a few turns from their original position.
7. Now connect the oscilloscope leads to Terminal A of the 2nd sound IF transformer T112 and ground.
8. Set the signal generator to 21.75 mc. and adjust the top and bottom screws of the 1st and 2nd sound IF transformers T111 and T112 for maximum amplitude of the sine wave pattern.
9. Connect the oscilloscope leads to the junction of R111 (22 K ohm resistor emerging from shield over sound discriminator socket) C116 at the output of the sound discriminator. The junction is at the end lug of a terminal strip mounted on the inner side apron of the chassis.
10. Still using 21.75 mc. adjust the primary of the sound discriminator transformer T113 (Top) for maximum amplitude and then adjust the bottom for zero amplitude. This zero should be quite critical with a sharp rise of amplitude to either side of the zero amplitude position.

Sweep Alignment

1. Connect RF output of the sweep signal generator to the antenna terminals. Set the frequency to 85 mc. and the sweep width to 10 mc. Switch tuner to Channel 6. Set AGC voltage to −2 volts.

NOTE: — Steps 1 and 3 apply if separate sweep and signal generators are available. This is the preferable method. If a sweep generator with internal marker generator is the available instrument, connect as per step 1 of the pre-alignment instructions. Use a sweep frequency of about 24 mc. and disable the local oscillator of the tuner by using a 6J6 with Pin No. 1 broken off or carefully balancing the Standard Coil Tuner switching mechanism between channels. With the Dumont tuner only the former method can be used.

Be careful not to use excessive sweep signal output or marker injection as mis-shaping of the response curve will result.

2. Attach the oscilloscope leads to the terminals of the pix 2nd detector load resistor (R139-3900). Connect the Hor. amplifier input of the oscilloscope to the horiz. sweep output of the sweep signal generator. Switch off the internal sweep of the oscilloscope.

NOTE: — Excessive marker injection will alter the shape of the response curve. Use as little RF output as is necessary to produce a "birdie".

3. Clip the signal generator output lead to the "body" (no electrical connection) of the grid resistor of the 1st pix IF amplifier (R119-22 K ohms) near the AGC end. This serves to inject a weak signal capacitively into the pix IF amplifier. If this method of coupling doesn't produce a "birdie" or marker on the response curve, try clipping the signal generator leads between various points of the tuner chassis.
4. Use sufficient RF output of the sweep generator to produce a sweep pattern on the oscilloscope screen. Be very careful not to use excessive RF output or overloading will result. This will flatten the bottom of the response curve as viewed on the scope.
5. If 85 mc. input is being used, rotate the fine tuning control of the television chassis until the entire response curve comes into view. Use that portion of the fine tuning range where the response curve remains uniform. If some portion of the response curve is still off the horizontal trace, try changing the sweep generator or using greater sweep width.
6. The various adjustments should be touched up as follows to produce a response curve to conform with figure 2.

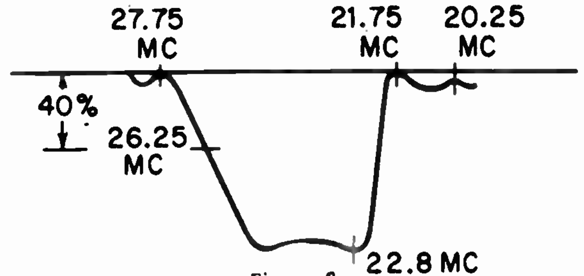

Figure 2
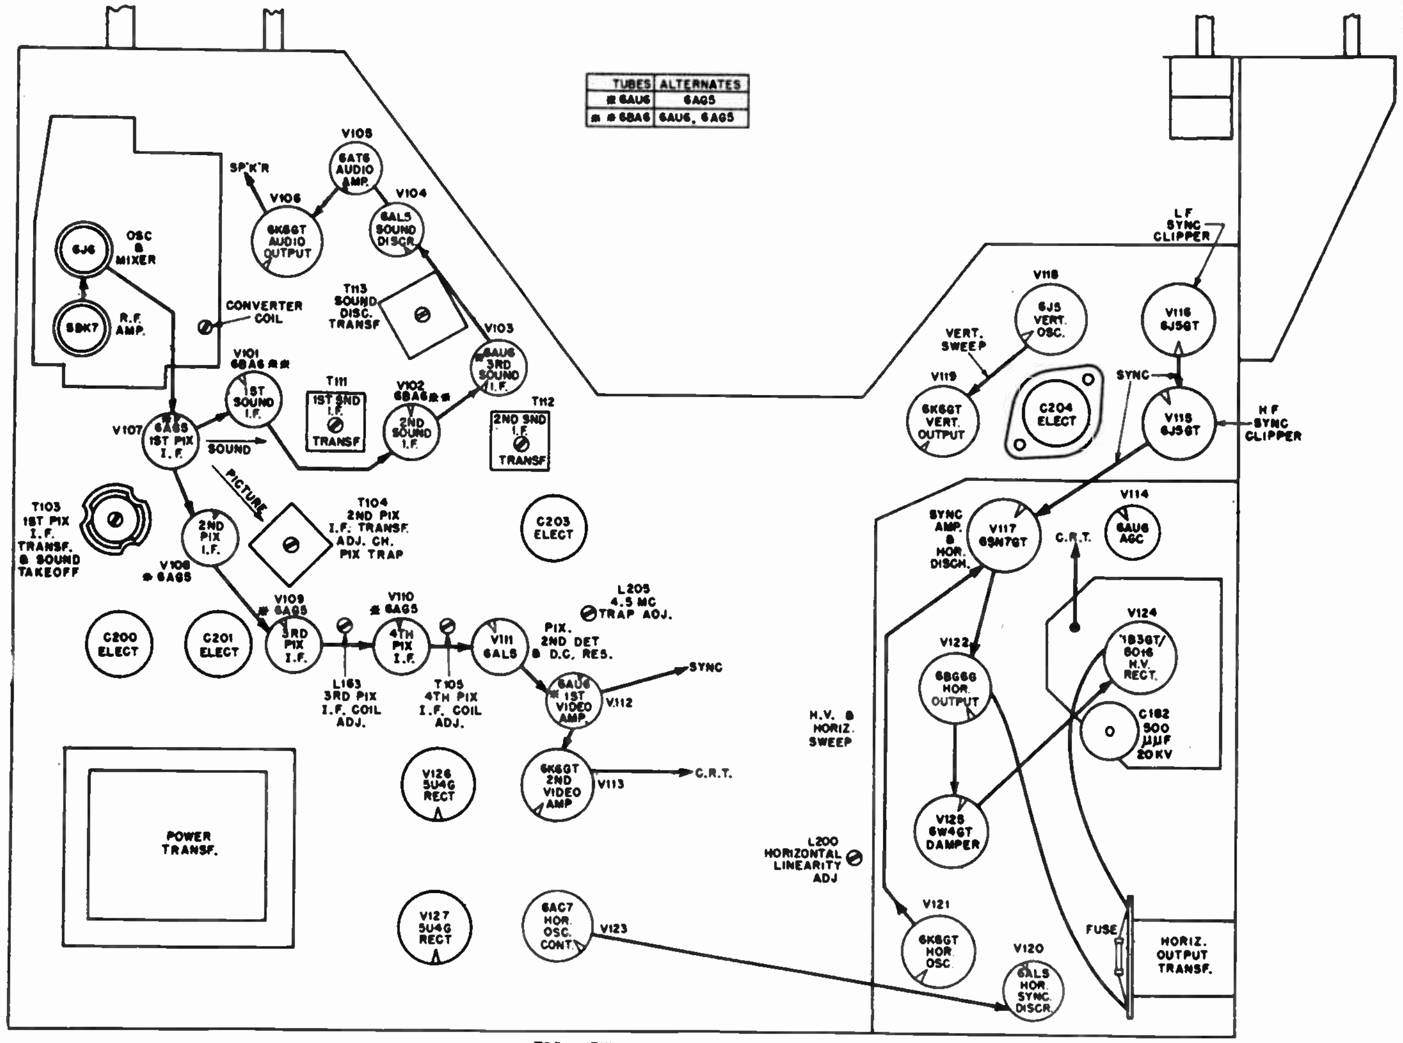
I.F. Alignment Curve

7. If any of the adjustments were changed substantially from their pre-alignment position, repeat adjustments F-I of step 5, pre-alignment instructions.
8. Remove oscilloscope leads and connect to the 2nd sound IF transformer, lug A. Set the sweep and signal generators to 21.75 mc. and reduce the sweep width to about 1 mc.
9. Readjust the 1st and 2nd sound IF coils (Top and Bottom) for a symmetrical response curve to either side of 21.75 mc.



Marker	Frequency	Coils	Location	Function
A	22.8 MC.	1st Pix IF (T103)	Bottom	Max. response at 22.8 MC.
		2nd Pix IF (T104)	Bottom	Min. response between 21.75 MC. and 20.75 MC. traps. Low frequency shaper.
B	26.25 MC. (Pix carrier)	Converter (Tuner)	Top	Marker (26.25 MC.) Adjustment at 30-40% of max. amplitude.
		3rd Pix IF (L183)	Top	High frequency shaper.
C	26.25 MC.	4th Pix IF (T105)	Top	Balance response curve.

10. Now attach the oscilloscope leads to the end of the 22K Ohm resistor emerging from the shield over the socket of the sound discriminator tube. The "S" curve should now appear. Adjust the primary of the sound discriminator transformer (T113) for equal upper and lower peaks without excessive loss of amplitude.

Tuner Channel Slug Adjustment

Individual channel tuner oscillator adjustments of the television receiver should be checked, upon its installation or servicing. If such adjustments are properly made, it is possible to tune from one station to another by merely turning the CHANNEL Selector and, if necessary, slightly readjusting the fine TUNING control. With correct oscillator channel adjustment, best picture and satisfactory sound will be located at the approximate center (half rotation) of the range of the FINE TUNING control.

Channel slug adjustment can be made without removing the chassis from the cabinet. Adjust as follows:

a. Turn the set on and allow 15 minutes to warm up.

b. Set the CHANNEL SELECTOR knob for a station; set other controls for normal picture and sound.

c. Set FINE TUNING control at center of its range by rotating it approximately half way.

d. Remove the CHANNEL Selector and FINE TUNING knobs.

e. Insert a 1/8" blade, non-metallic screwdriver in the 1/4" hole (to the right of the channel tuning shaft). For each channel in operation, carefully adjust the channel slug for best picture with clear detail and best sound. Be sure that the FINE TUNING control is set at the center of its range before adjusting each channel slug. Generally, only a slight rotation of the slug will be required, turning the slug in too far will cause it to fall into its coil. (If the slug falls into the coil, remove the coil strip from the tuner, move the retaining spring aside, lightly tap the open end of the coil until the slug slips out. Replace slug and re-set retaining spring.)

GENERAL TROUBLE-SHOOTING NOTES

The lay-out diagram shows the various "strings" or chains of vacuum tubes that control the pix, sound, "sync" signals, vertical and horizontal sweeps. In the event of failure of any portion of the chassis, trouble-shooting should be undertaken in the following order:

1. Replace the tubes in the involved "string" in sequence.
2. Check the voltage readings against those listed on the schematic diagram for the involved "string".
3. Compare the wave-forms against those shown. An approximate method for measuring the peak voltages as listed is to use the 6.3 volt heater supply as a reference. The method consists of observing the desired pattern on the oscilloscope screen and then comparing the amplitude with that obtained by connecting to the heater voltage without altering the vertical amplifier gain sitting. The overall amplitude, (top to bottom of the observed heater voltage) represents approximately 18 volts.

AGC System

The AGC system keeps the voltage across the 2nd detector load resistor (R139-3900 Ohms) at a reasonably constant level (−1.8) volts for all signals of reasonable signal strength. Defects in the system can cause this voltage to rise or fall excessively.

The AGC voltage as measured across the AGC condenser (C134-47 Mfd) ranges from a fraction of a volt (−) to a little over −4 volts.

As a rough check of the system, if trouble is suspected, remove the 6AU6, 1st video amplifier. The AGC voltage should rise to well over −40 volts and the sound should disappear as the tuner and 1st pix IF amplifier are cut-off.

Sympton of AGC Defects

(a) *Picture appears on weak signal or without antenna but strong signal produces black white raster. Sound normal* — this is due to lack of AGC voltage and may be due to a defective AGC tube (6AU6) in the high voltage cage or a defective width control (mounted above flyback transformer on rear of cage).

(b) *Absence of picture and sound, raster normal*— Replace the tubes that are common to the picture and sound "strings". If this doesn't help try replacing the 1st video amplifier and the AGC tube (6AU6). If the trouble lies in the AGC system, there will be an excessively high AGC voltage across C134, and the AGC condenser (.47 Mfd).

Barkhausen Oscillations

Under certain operating conditions, the horizontal output circuit may produce spurious signals of a type known as "Barkhausen oscillations". These signals cause one or more dark vertical stripes to appear in the picture on some channels usually on the left-hand side.

In order to eliminate them, take the following steps in order:

1. Reduce the horizontal drive (turn the horizontal drive trimmer screw clockwise).
2. Dress the antenna lead-in away from the H.V. cage and power line-cord.
3. Replace the 6BG6-G horizontal output tube.
4. Replace the deflection yoke.
5. Replace the horizontal output (Flyback) transformer.

Insufficient Height Consistent with Good Linearity

1. Replace tubes in the vertical sweep "string".
2. Replace the vertical output transformer T107.
3. Check voltages and waveforms.

Picture Twists Horizontally

1. Replace tubes in the sync "string".
2. Replace the 6AC7, hor. osc. control and the hor. sync discriminator, 6AL5.
3. Check the cathode resistors and condensers of the 6J5 sync clippers, V115, V116 according to the schematic diagram.
4. Check the voltages and waveforms.

Buzz in Sound which Disappears when Contrast Control is Rotated Fully Clock-wise

1. Redress white wire to center arm of the contrast control away from other leads and up against side apron of chassis.

Picture Over-loads (Picture excessively black and white with almost no grays)

This sometimes occurs in a very strong signal area due to the very high signal strength over-loading the tuner beyond the limits of the AGC system. In that case, it is necesary to reduce the signal strength by the insertion of a suitable pad in series with the antenna terminals. A sketch of a recommended type is shown below constructed from small carbon resistors. In the event that the over-loading occurs in a weak or normal signal area, trouble in the AGC system should be suspected.

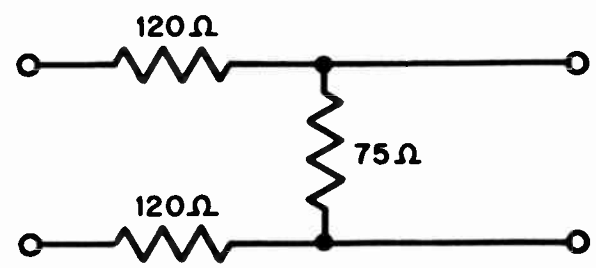


Fig. 5

Several Vertical White Stripes in the Left Side of the Picture (disappears when the width switch is snapped to wide position)

Replace R219, 470 resistor across width control. Use a 5 Watt resistor.

Incorrect Vertical Frequency

1. Replace 6J5 vertical oscillator.
2. Check all the resistors and condensers of the vertical oscillator and discharge circuit.
3. Check the integrating network (R167, 168, 169, C160, 161, 162, etc. contained in a printed circuit wafer).
4. Check the vertical blocking oscillator transformer—T106.

Lack of Vertical Hold

1. Replace the tubes of the sync "string".
2. Check the integrating network (R167, 168, 169, C160, 161, 162, etc. contained in a printed circuit wafer).
3. Check the cathode resistors and condensers of the 6J5 sync clippers V115 and V116.

IN CHASSIS USING 5V4G IN PLACE OF 6W4GT (V125) THE POWER TRANSFORMER (T110) HAS A 5.0 VOLT WINDINGS IN PLACE OF THE 6.3 VOLT WINDING DESIGNATED "Z-Z"

** IN CHASSIS USING 6AU6 IN PLACE OF 6BA6 (V101 & V102) RESISTORS R100 & R103 BECOME 330 IN PLACE OF 100

ALL RESISTANCE VALUES ARE IN OHMS K=1000
CAPACITANCE VALUES UNDER 1.0 ARE IN MF OVER 1.0 ARE IN MMF UNLESS OTHERWISE NOTED
DIRECTION OF ARROWS AT CONTROLS INDICATE CLOCKWISE ROTATION
POWER SUPPLY VOLTAGES MEASURED WITH 117V LINE VOLTAGE USING RCA VOLTOHMYST VOLTAGES SHOULD HOLD WITHIN ±10%
SECOND ANODE POTENTIAL MEASURED AT 200 MICRO AMPERE LOAD WITH A 50 MICRO AMPERE METER AND A 400 MEGOHM MULTIPLIER.

MODEL TV-5020

TV-5120

OPERATION

This television receiver is designed to operate on a 105-125 Volt AC, 60 cycle power line.

The receiver should not be installed near a radiator or any other area where it will be exposed to excessive heat. The position in a room will depend on the seating and lighting arrangements available. Best performance can be realized in a dim or moderately lit room.

The receiver is equipped with a built-in antenna which will afford excellent reception in most areas. A simple folded dipole antenna with reflectors used with a 300 ohm transmission line can be used in weak signal areas.

CONTROLS

VOLUME CONTROL AND ON-OFF SWITCH

The outer knob on the left side of the cabinet puts the receiver on or off and controls the sound. It has no affect on the picture quality.

CONTRAST CONTROL

The inner knob on the left side of the cabinet controls the picture contrast. Turning this control too far to the right will result in stark pictures with extreme black and white images. Turning it back too far will make the picture appear weak and washed out. The control should be adjusted until the picture appears natural with good black and white definitions.

CHANNEL SELECTOR

The bar knob on the right side of the receiver is used to select the required channel as indicated by the numbers on the channel selector escutcheon. The fine tuning inner knob should then be adjusted for the best picture and sound.

INSTALLATION

The deflection yoke, "Focalizer", and ion trap settings may have shifted during transit. These components and all other controls should be re-adjusted at the time of installation. Make all the following adjustments.

DEFLECTION YOKE

Loosen the two screws securing the yoke mounting bracket. Push yoke to the closest possible position on the "bell" of the cathode ray tube. Tighten screws. Loosen the screw on the bottom of the deflection yoke. With a test pattern visible on the screen, rotate yoke so that top of picture runs parallel with the cabinet top. Tighten screw.

ION TRAP

Turn the back panel brilliance control to the almost full position. Move the ion trap backwards and forwards carefully rotating it at the same time for the best possible brilliance on the screen.

FOCUS AND POSITIONING

This receiver is equipped with a newly designed device known as a "focalizer". It provides for all magnetic means of focusing and positioning.

POSITIONING

Loosen the two nuts securing the "focalizer" to the mounting bracket. Slide the "focalizer" up or down and from one side to the other until a position is located that centers the test pattern on the picture tube. In some cases it may be necessary to re-adjust ion trap if neck shadowing occurs.

NOTE "A"

Some models are manufactured with a "Focalizer" equipped with a "shutter" assembly. This shutter assembly is actuated by a rod extending out near the Cathode Ray Tube neck. Rotating this rod will also rotate the picture on the picture tube screen, thereby adding to the ease of picture centering.

Fig. 2

FOCUS

Turn the channel selector to an inoperative channel. Turn brilliance control up until the raster is visible. Adjust variable magnetic shunt by turning large screw on top of "Focalizer" until raster lines are in focus. Re-adjust ion trap and repeat variable magnetic shunt adjustment.

REAR CHASSIS CONTROLS

VERTICAL LINEARITY AND HEIGHT CONTROLS

Adjust these controls so that the entire picture screen is filled vertically, and that the test pattern measures the same from center to top and from center to bottom. There is normally some interaction between these controls and the adjustments should be repeated several times.

HORIZONTAL DRIVE

This control should be adjusted to obtain additional horizontal size. Improper adjustment of this control may result in two bright lines showing on the left hand side of the picture screen. Re-adjust this control until the lines disappear.

HORIZONTAL LINEARITY

Proper adjustment of this control will fill out the left side of the test pattern so that the pattern will be round and not flattened on one side.

VERTICAL HOLD

This control should be adjusted so that picture does not roll vertically. Re-adjust control if picture rolls when channel selector is turned on or off an active channel.

HORIZONTAL HOLD

Adjust this control so picture does not roll horizontally. Check this adjustment by putting channel selector on or off channel. If picture rolls horizontally, re-set control.

BRILLIANCE

Adjust the brilliance control so that picture appears natural with good black and white contrast. Turning up this control too far may result in diagonal white re-trace lines showing on the picture screen. The control should be turned back until these lines disappear. It may also be necessary to re-adjust the contrast control on the front panel while this adjustment is made.

GENERAL DATA

TUBE COMPLIMENT

V1.	6AG5	RF Amplifier
V2.	6J6	RF Oscillator and mixer
V3.	6AU6	1st Video IF Amplifier

R.F. TUNER

This receiver is equipped with a tuner designed to operate satisfactorily in any local or fringe areas. The tuner has rugged turret style construction and features very high sensitivity and a high signal to noise ratio. All oscillator and RF coils are snapped into position on a drum and can be readily replaced if necessary. Oscillator adjustments are accessible from the receiver front and adjustment can be made without removing the receiver from the cabinet.

VIDEO I. F.

The video IF amplifier consists of 3 6AU6 stages with four IF transformers. A powdered iron slug adjustment for each coil is available on the top of the chassis. The IF transformers are stagger tuned to two frequencies. The fourth and second IFs are tuned to 25.6 MC and the third and first IFs are tuned to 23.4 MC.

SYNC. CIRCUIT

This receiver employs a new and improved "Sync. Amplifier, Phase Splitter, and DC Restorer" circuit. The AFC circuit in conjunction with this new circuit minimizes picture disturbances caused by ignition and similar types of interference. The improved sync. circuit also prevents vertical rolling in high interference or fringe areas.

VIDEO AMPLIFIER

The video amplifier in the receiver consists of a 12AU7 dual triode. The output of the video detector is fed into the first section of the video amplifier. The output stage of the 12AU7 is connected to the sound take-off coil where the sound is sent to the ratio detector driver, ratio detector, audio amplifier and finally to the speaker. Picture information is fed to the picture tube grid. Sync. pulses are also separated at the end of this stage and sent to their respective circuits.

SOUND SYSTEM

This receiver uses the Inter-Carrier Sound System. The difference between this system and other systems is that the sound and picture information are both carried through a single I. F. amplifier channel. The sound carrier is taken off the video amplifier by a 4.5 megacycle sound "take-off" coil and fed through a 4.5 MC amplifier to the Ratio Detector, and the audio amplifier. The advantage of this system is that the necessity of two IF amplifiers is avoided and that drift in the local oscillator does not distort or cut off "sound" reception.

VIDEO I. F. ALIGNMENT

(Refer to Fig. 3 and Fig. 8 for reference points)

1. A fixed battery bias should be applied to the AGC circuit for proper IF alignment. Connect negative terminal of 3-volt battery to reference point "B" the junction of 2.2 meg resistor (R31), 330 ohm resistor (R27), and 11,000 ohm resistor (R28).
2. Connect positive terminal of 3-volt battery to chassis ground.
3. Connect hot terminal of VTVM (set for negative voltage reading) to reference point "A", the junction of the video detector 700 MH peaking coil and 4.7 K resistor (R37).
4. Connect ground terminal of VTVM to chassis ground.
5. Lift 6J6 tube shield above ground and connect AM signal generator (unmodulated) to tube shield. Connect signal generator ground to nearest chassis ground. Keep signal generator leads short to avoid regeneration.
6. Align IF-24 and IF-22 at 25.6 MC for maximum output as indicated by the VTVM.
7. Align IF-23 and IF-21 at 23.4 MC for maximum output.

The over all IF response may be observed on a Cathode Ray oscilloscope in the following manner:

1. Connect the synchronizing sweep voltage from a sweep Generator to the horizontal input of an oscilloscope for horizontal deflection.
2. Loosely couple sweep generator by connecting to ungrounded tube shield floating over 6J6 tube and nearby ground. (Keep all leads short to avoid re-generation due to stray coupling.)
3. Set sweep generator to 24.5 MC frequency and 10 MC sweep width.
4. Connect vertical amplifier of scope to same point as VTVM, reference point "A", remove VTVM.
5. Set marker to 21.25 MC and 25.75 MC.

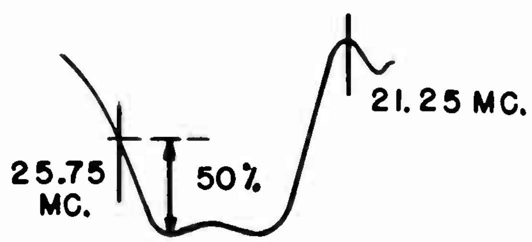

Fig. 4

Response curve should be similar to curve shown in Fig. 4.

Response curve may be flattened out and improved by re-adjusting IF 21 on front end.

OSCILLATOR ADJUSTMENT

The oscillators may be adjusted without removing the chassis from the cabinet by the following procedure:

1. Remove channel selector knobs.
2. Remove channel selector escutcheon.
3. Turn channel selector to desired station.
4. Set fine tuning control to the middle of its range.
5. Adjust oscillator screw through a hole located just to the right of the channel selector shaft. This adjustment should be made with a fibre or bakelite screwdriver. Set oscillator for best compromise between picture and sound.

The oscillators may all be adjusted by using an All Channel Television sweep generator, a Marker Generator and a Cathode Ray Oscilloscope.

The output of the sweep generator should be connected to the antenna terminals. Loosely couple marker generator to antenna terminals also.

Connect high side of oscilloscope to same point "A" as VTVM connection and ground side of scope to nearest chassis ground.

Frequency settings for each channel can be determined from the chart below.

SOUND IF FREQUENCY 21.25 MC.
PICTURE IF FREQUENCY 25.75 MC.

Frequency Chart

Channel	*Frequency*	*Picture Marker Frequency*	*Sound Marker Frequency*
2	54-60	55.25	59.75
3	60-66	61.25	65.75
4	66-72	67.25	71.75
5	76-82	77.25	81.75
6	82-88	83.25	87.75
7	174-180	175.25	179.75
8	180-186	181.25	185.75
9	186-192	187.25	191.75
10	192-198	193.25	197.75
11	198-204	199.25	203.75
12	204-210	205.25	209.75
13	210-216	211.25	215.75

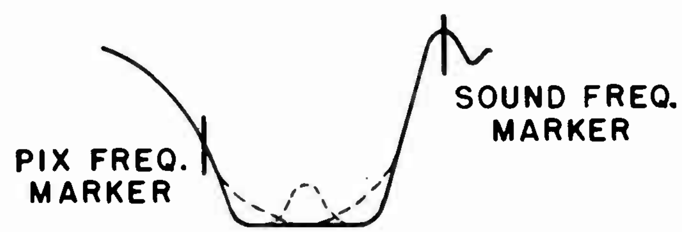

Fig. 5

Set Sweep Generator to approximately mid-frequency of each channel and tune until response curve is centered on oscilloscope screen. Adjust picture and sound markers to the exact frequency as indicated on the Frequency Chart.

Adjust oscillator screw so that sound carrier falls in notch as shown in Fig. 5. This adjustment should place the picture carrier at a point approximately 50% up on the opposite side of the response curve. Some variations in location of picture carrier and wave shapes are permissable. The position of the picture carrier may vary from 45% to 60% up on the slope. A 15% valley is also acceptable in the overall wave shape response.

SOUND ALIGNMENT

(See Fig. 3, Fig. 6 and Fig. 8 for reference points)

1. Connect AM signal generator (unmodulated) to reference point "C", pin 7 of 12AU7 (V 7) video amplifier.
2. Connect hot terminal of VTVM, set for negative voltage reading, to reference point "D", pin 7 of 6AL5 (V9) ratio detector.
3. Connect ground terminal of VTVM to chassis ground.
4. Set signal generator to 4.5 MC and adjust top and bottom of sound take-off coil (ST-10) and bottom of ratio detector coil (RD-416 or RD-7B) for maximum output.
5. Connect VTVM to reference point "E", junction of 47,000 ohm resistor (R16) and .0015 MFD condenser (C41).
6. Adjust top of ratio detector coil for zero reading.

NOTE: Top of ratio detector may be re-adjusted for minimum "buzz" while a channel is in operation and a test pattern tone signal is being received.

CHASSIS SPECIFICATIONS

Power Requirements

117 volts, 60 cycles AC

Power Consumption

250 Watts

Fine Tuning

Plus & minus 1 MC on Channel 2
Plus & minus 1.6 MC on Channel 13

Audio Power Output

2.8 watts

Band Width

Video amplifier 3.8 MC within 3 db
IF Amplifiers 4 MC within 6 db
Antenna input to picture tube 3.5 MC at 6 db
Ratio detector, peak to peak 200 KC

Deflection

Horizontal & Vertical	Magnetic
Focus	Electro Magnetic
Scanning	Interlaced, 525 Lines
Horiz. Freq.	15750 CPS
Vert. Freq.	60 CPS
Frame Freq.	30 CPS

MODEL IDENTIFICATION TABLE

MODELS FM27C, HB27C

Model Number	Chassis	Picture Tube	Focus	VHF Tuner	UHF Tuner	Speaker
FM27C, HB27C	T14-3	27EP4	Electro-Magnetic	258051-2	258052-1	10″ PM
TM24DS, TB24DS	T14-10	24CP4	Electro-Magnetic	258051-2	–	6″ PM
TM24DU, TB24DU	T14-11	24CP4	Electro-Magnetic	258051-2	258052-1	6″ PM

The T14-10 Chassis has all of the necessary mechanical provisions for accommodating the 258052-1 UHF Tuner. Please order by type No. CT-14.

VHF FREQUENCY CHART

Chan. No.	Chan. Freq.	Picture Carrier	Sound Carrier	RF Osc. Freq.
2	54-60	55.25	59.75	101MC
3	60-66	61.25	65.75	107MC
4	66-72	67.25	71.75	113MC
5	76-82	77.25	81.75	123MC
6	82-88	83.25	87.75	129MC
7	174-180	175.25	179.75	221MC
8	180-186	181.25	185.75	227MC
9	186-192	187.25	191.75	233MC
10	192-198	193.25	197.75	239MC
11	198-204	199.25	203.75	245MC
12	204-210	205.25	209.75	251MC
13	210-216	211.25	215.75	257MC

The UHF band of frequencies has been placed between 470MC and 890MC. Each channel from 14 to 83 has been alloted, in succession, a band 6MC wide within this spectrum.

IF Frequencies: Picture Carrier – 45.75 MC
Sound Carrier – 41.25 MC

ALIGNMENT PROCEDURE

VISUAL ALIGNMENT OF THE RF AND MIXER STAGES

CAUTION: Always determine by suitable tests, the causes of unsatisfactory operation before attempting to align portions of this receiver. Necessity for realignment will, in all cases, be rare.

PROCEDURE:

1. Connect an RF sweep generator with at least a 10MC sweep width to the antenna terminals through the test circuit shown in Figure 1.

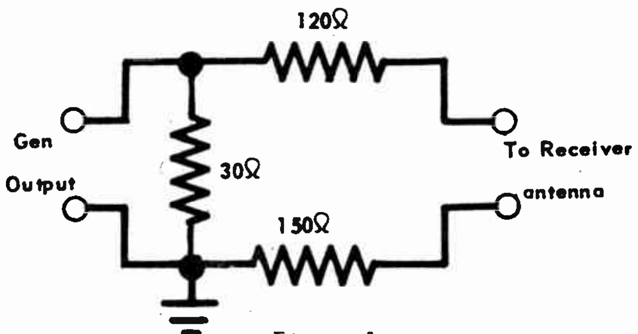

Figure 1

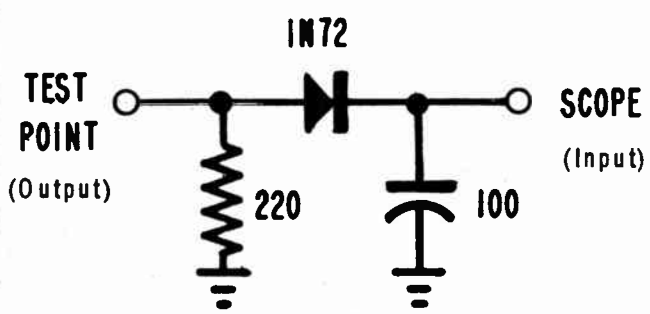
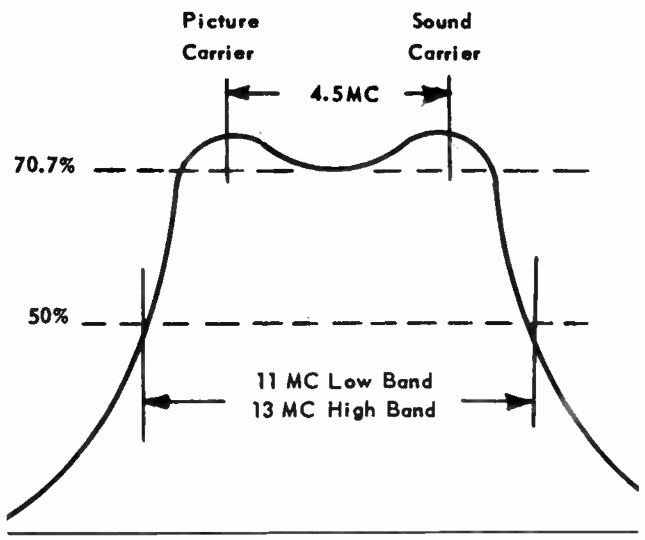
2. Remove the keyed AGC Amplifier tube V12. (This is necessary in order to eliminate AGC action which would interfere with RF alignment.)
3. Connect the positive terminal of a 3 volt dry cell supply to chassis ground and the negative terminal to the RF AGC test point.
4. Attach the high side of the vertical input of an oscilloscope to the input of the detector test circuit shown in Figure 2, and the output to the test point located on the tuner – see Figure (4). In order to synchronize the sweep of the oscilloscope with the RF sweep, connect the horizontal amplifier terminals on the RF sweep generator labeled "oscilloscope sweep voltage."



Test Circuit for Oscilloscope Observation of Tuner Response
Figure 2

5. Turn the station selector to Channel 13 and adjust the sweep generator until it sweeps from 208MC to 218MC. (NOTE: If the sweep generator does not supply marker signals at picture and sound carrier frequencies, an external source, such as a CW signal generator should be used to supply them. For method of marker injection, refer to instructions supplied by the manufacturer of sweep generator being used.
6. Adjust L913, L929, L930 until the viewed response curve is similar to that shown in Figure 3. Check all other channels readjusting L913, L929 and L930 as necessary to obtain optimum response on all twelve channels.



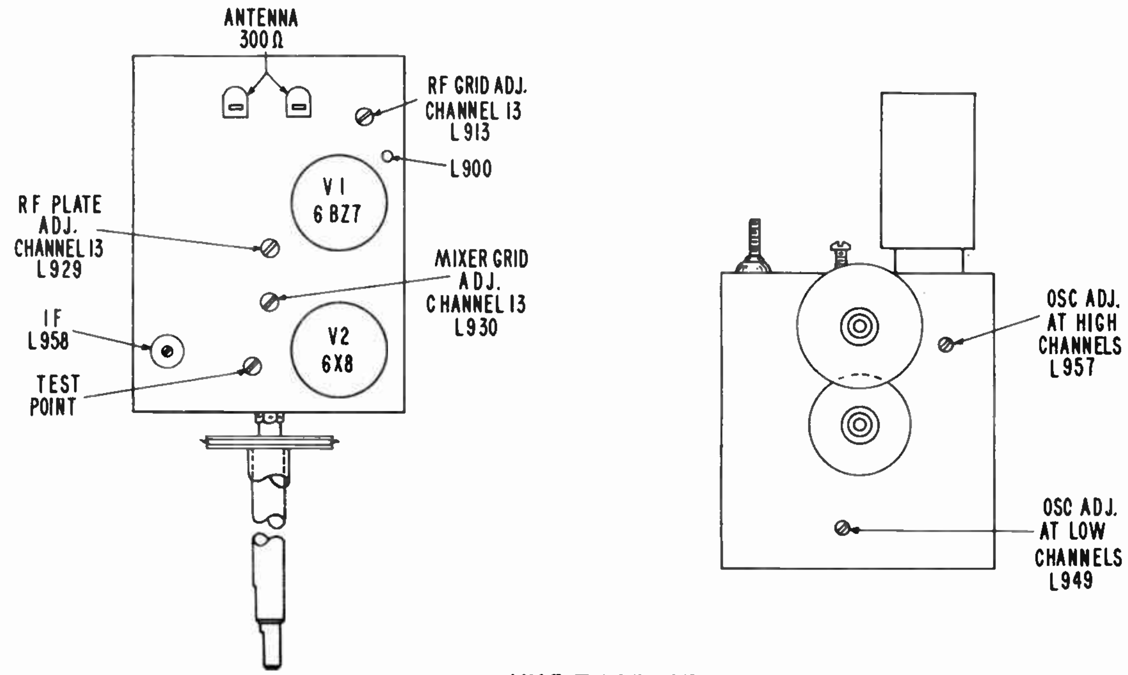
RF Response Curve
Figure 3

The dip in the curve between picture and sound carriers should not fall below 70.7% of the response peak and the bandwidth at 50% down should not exceed 11MC on the low band and 13MC on the high band.

RF OSCILLATOR ALIGNMENT

CW METHOD

1. Remove V12 from its socket and connect the negative terminal of a 3 volt dry cell bias supply to the RF and IF AGC test points. (This can best be accomplished by tieing the two points together.)
2. Apply the CW signal to the antenna terminals through the pad shown in Figure 1.
3. Connect the DC probe of a vacuum tube voltmeter to test point C.



VHF TUNER VIEWS

Figure 4

4. Turn the fine tuning control to approximately the center of its rotating range, and proceed as follows:

For low band alignment

– Turn channel selector to Channel No. 6.
– Tune signal generator to the sound carrier frequency of Channel 6 – see frequency chart on page 2.
– Adjust the lowband oscillator slug (see Figure 4) until a sharp dip in the voltage reading on the VTVM is reached.

For high band alignment

– Turn channel selector to Channel No. 13.
– Tune signal generator to the sound carrier frequency of Channel 13 – see frequency chart on page 2.
– Adjust the high band oscillator slug (see Figure 4) until a sharp dip in the voltage reading on the VTVM is reached.

IF ALIGNMENT

Remove the AGC Amplifier (V12) from its socket. Connect the negative terminal of a 3 volt dry cell supply to the IF AGC test point and the positive terminal to chassis ground. Raise the tube shield of V2 so that it is not grounded and apply the signal to it.

Generator Frequency	VTVM Connections	Adjustment	Remarks
45 MC	To Test Point (C) and Ground	T3-T2-L958*	Adjust for Max.
42 MC	To Test Point (C) and Ground	L5-T1-L2*	Adjust for Max.
41.25 MC	To Test Point (C) and Ground	L1-L3	Adjust for Min. with output of Signal Gen. at Max.
39.75 MC	To Test Point (C) and Ground	L4	Adjust for Min. with output of Signal Gen. at Max.

NOTE: To insure correct IF Alignment follow the procedure outlined under Visual Check of IF Alignment.

* The designated frequencies for L958 and L2 are to be used for preliminary alighment only. Since these two coils compromise a band pass circuit, final alignment should be made with a sweep generator.

VISUAL CHECK OF IF ALIGNMENT

1. Lift the shield of the oscillator mixer tube V2 until it becomes ungrounded. Connect the high side of a sweep generator to the ungrounded tube shield and the ground lead to chassis ground. Connect a lead from the sweep synchronizing terminal on the sweep generator to the external sweep terminal on the oscilloscope.
2. Connect high side of oscilloscope to pin 7 of V13 video amplifier tube and ground lead to chassis ground. (Set contrast control at minimum.)
3. Remove the keyed AGC amplifier tube V12.
4. Connect the negative terminal of a 3 volt dry cell to the IF AGC test lead and the positive terminal to chassis ground.
5. Adjust sweep generator to sweep from 40 to 50MC.
6. Connect a vacuum tube voltmeter between pin #1 of V13 and ground and adjust the sweep generator output until a reading of −2 volts is obtained.
7. Adjust the oscilloscope until the IF response curve is centered.
8. Place a lead from an AM signal generator near the IF strip and adjust it to cover from 40 to 50MC.
9. Observe the response curve and the position of the markers (see nominal response curve Figure 5). A slight deviation from this response curve is permissible; however, complete realignment of the IF will be necessary if a great deviation is noted. Some improvement in the shape of the response curve may be accomplished by slightly readjusting L2 on the main chassis and L958 on the tuner.

For best performance the difference in height of peaks should not exceed 30% nor should the dip drop more than 30% below the peak of the response curve.

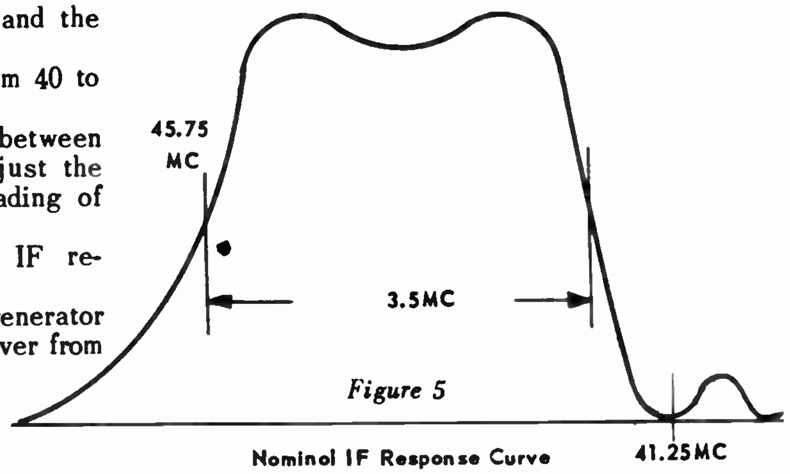


Figure 5

Nominal IF Response Curve

SOUND ALIGNMENT

Connect the Negative Terminal of a 9 volt dry cell supply to the IF AGC test point and the Positive Terminal to Chassis ground.

Signal Generator Coupling	*Frequency*	*Connect*	*Adjust*	*Remarks*
High side to Pin 1 of V13 (Video Amp)	4.5 MC	DC probe of VTVM to "PT.E." Common lead to chassis.	L9 T10 (top & bottom)	Adjust for Max. reading keeping output of Generator high enough to produce about 4V at "PT.E."
SAME	4.5 MC	Parallel R38 with two 100K resistors which are within 1% of each other. DC probe of VTVM of "PT.A." Common lead to chassis.	L11	Adjust for Max. reading.
SAME	4.5 MC	DC probe of VTVM to "PT.B." Common lead to "PT.A."	L13	Adjust for zero reading at cross-over.

NOISE INVERTER ADJUSTMENT

NOTE: The noise inverter control is adjusted at the factory to give optimum performance under varied conditions, therefore, only upon rare occasions would any adjustment be necessary. If the receiver is to be operated in an extremely weak signal area having a high noise level, or this control becomes maladjusted by one means or another, it can be satisfactorily set by the following procedure:

Select and properly tune in the strongest station in the area.

Turn the contrast control to its maximum position (full clockwise).

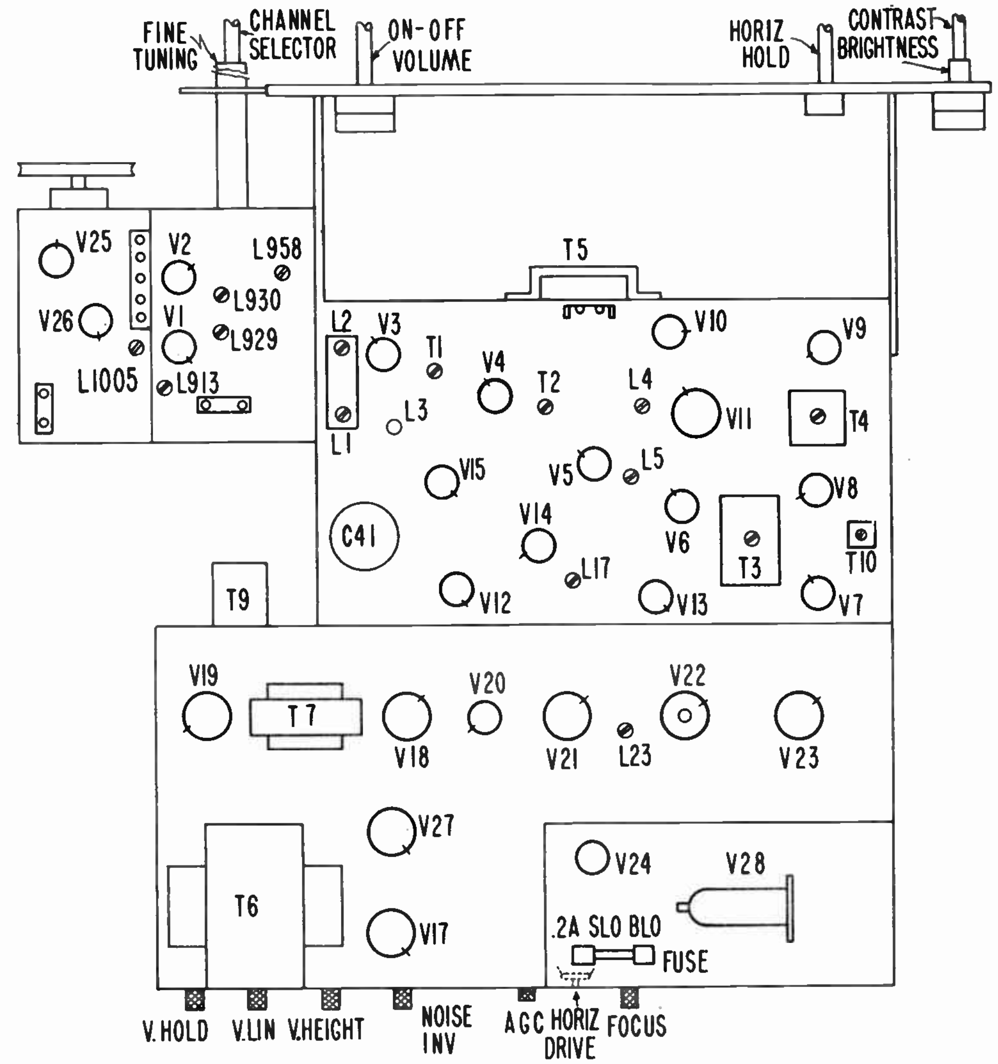

Figure 6

With the noise inverter control set at minimum, slowly turn it in the clockwise direction until a slight shifting of the picture in the horizontal plane is observed, then back off (counterclockwise) 1/8 of a turn.

CAUTION: If this control is set too far in the clockwise position an erratic jumping of the picture will be encountered when switching channels.

HORIZONTAL OSCILLATOR ADJUSTMENT

This adjustment may be satisfactorily performed with any received program signal.

Set the Horizontal Hold control, R115, at approximately mid-position.

Set the Contrast control to the normal operating position.

Adjust the Horizontal Oscillator control, L23, until the diagonal streaks on the screen decrease in number and become erect (picture locks in sync).

The setting obtained by the preceding steps may not give optimum range on the Horizontal front panel hold control, therefore, further adjustment by the trial and error method should be performed. When L23 is properly adjusted, the H. Hold control can be slowly rotated to its stops in either direction without losing picture sync.

HORIZONTAL DRIVE ADJUSTMENT

Allow the receiver to warm up for at least five minutes.

Adjust the contrast and brightness for a normal picture.

Adjust the horizontal drive trimmer until there is no indication of horizontal foldover in the picture.

ANTI-PIN CUSHIONING MAGNETS

Pin cushioning is an effect caused by the use

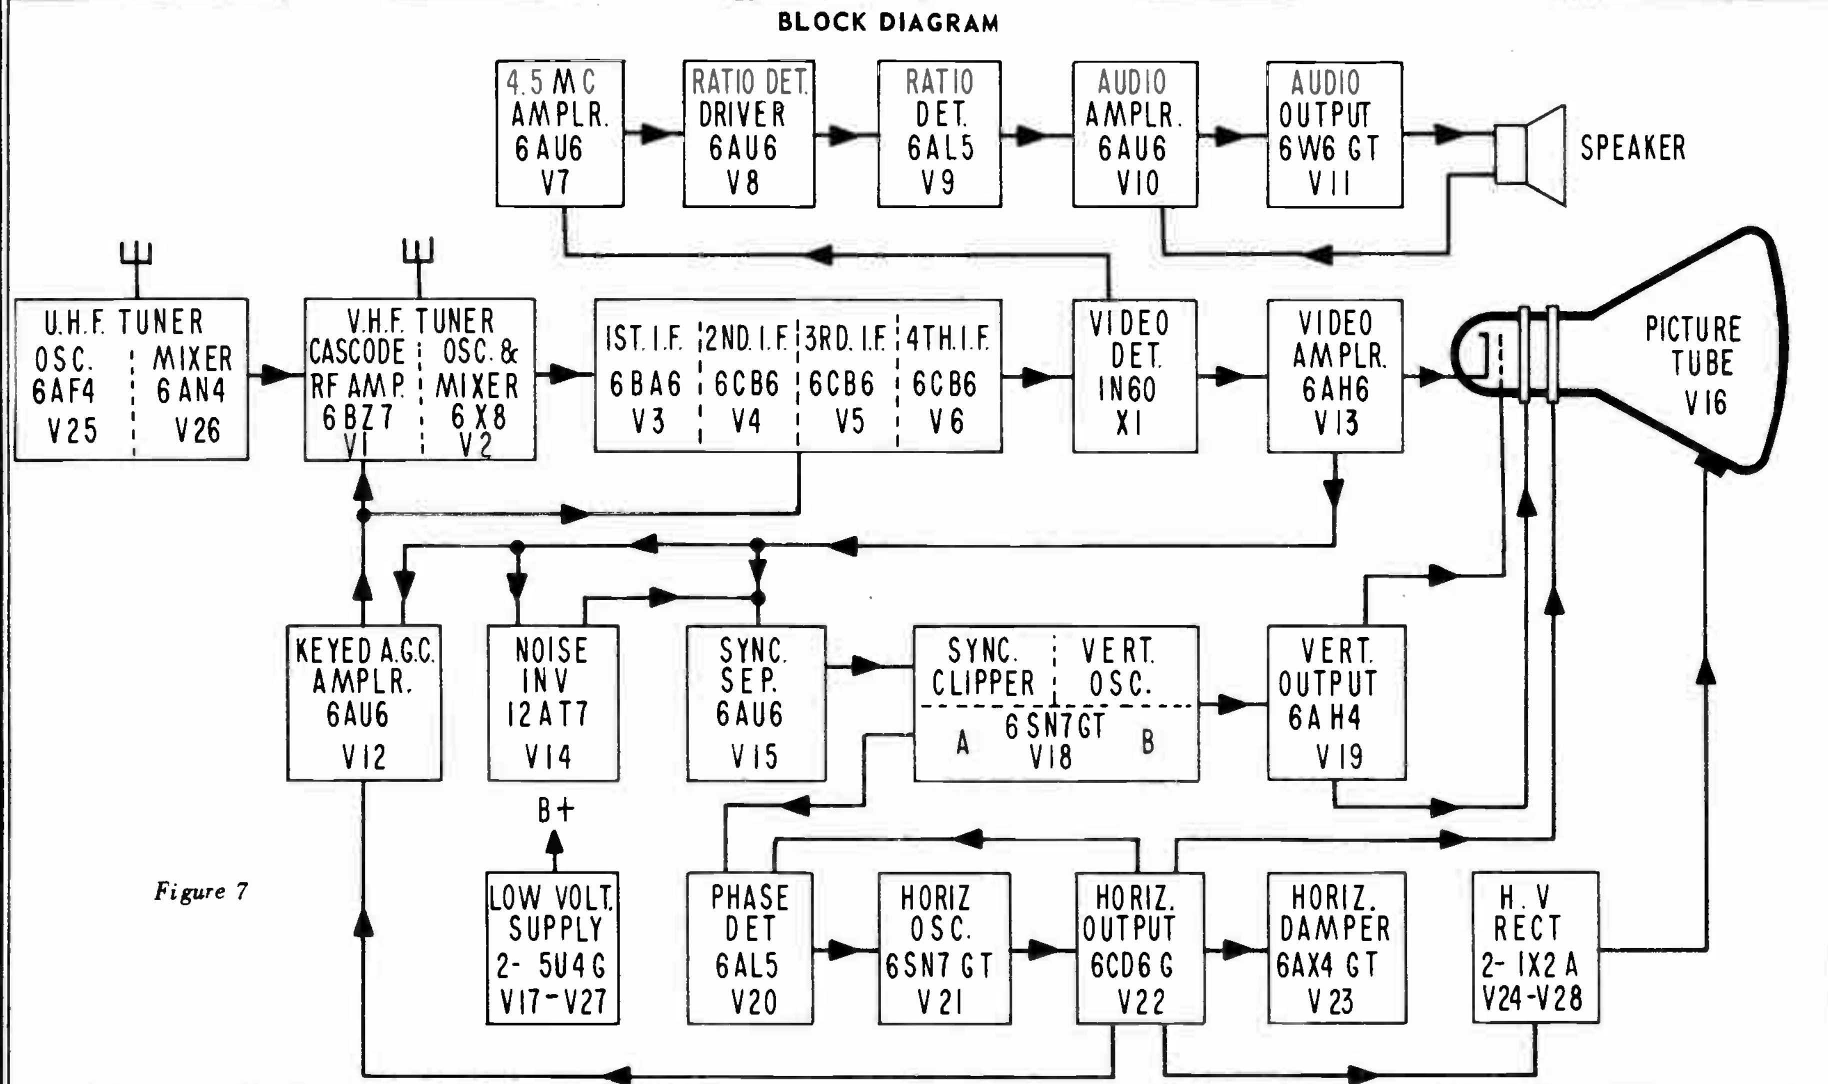

Figure 7

of the cosine-deflection yoke and is apparent by the *"bowing in"* along the edges of the raster. In order to compensate for this condition two anti-pin cushioning magnets have been mounted to the picture tube mounting brackets. For ease of adjustment these magnet brackets are hinged in two places; thus allowing the magnet to be moved either forward or backward at various distances from the picture tube surface. The proper adjustment of each magnet may be observed by moving the raster off center far enough to see the side of the picture that is being straightened.

NOTE: These magnets are properly set at the factory and should require no further adjusting unless a new picture tube is installed.

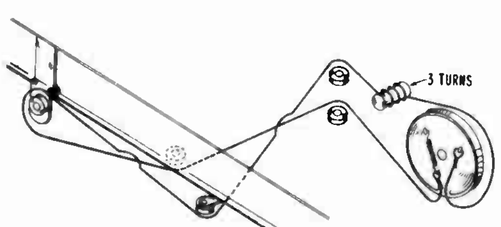

Figure 8

UHF DIAL CORD STRINGING

ION TRAP ADJUSTMENT

Reduce the *contrast* and raise the *brightness* to a point where a blank raster is just visible on the picture tube. Rotate the ion trap while moving it either forward or backward until the *brightest* raster is obtained.

WARNING: It is extremely important that the ion trap be adjusted properly as soon as the set is turned on. A trap even slightly maladjusted can cause severe damage to the CR tube, and this type of damage is not covered by the factory warranty. *NEVER ADJUST THE ION TRAP TO REMOVE SHADOW.*

LOW VOLTAGE POWER SUPPLY

A straight AC power supply utilizing two 5U4G rectifier tubes is used. The input voltage is stepped up in the secondary of the power transformer (T6) and fed to the plates of the rectifier tubes, (V17) and (V27). The output of the rectifiers is fed to the filter section consisting of C55A, L26, L18, and C42B. Tubes V11 and V12 are in series with V5 and 8, V2, V4, V7, V14, V15, V25 and V26 serving as voltage regulators for these tubes. When the current through these amplifiers change due to changes in signal strength the cathode voltage of V11 and V12 vary accordingly. This causes the impedance of V11 and V12 to change maintaining a constant voltage of +165 volts at the cathode of V11.

NOTE: No DC voltage from the low voltage rectifiers is supplied to V9, V20 or the plate of V12.

REMOVAL AND INSTALLATION OF PICTURE TUBE

CAUTION: Be sure the power is off. Wear goggles whenever a picture tube is being handled.

1. Place the cabinet face down taking all precautions necessary to keep from marring the finish.
2. Remove the high voltage lead from its socket.
3. Remove the tube socket from the base of the tube.
4. Remove the ion trap from the neck of the tube.
5. Loosen and remove the two 1/4″ bolts that hold the yoke and hood assembly to the mounting straps.
6. Remove this assembly from the neck of the tube.
7. Bend the two straps away from the tube as far as possible.
8. Grasp the rim of the picture tube face and gently lift the tube out of its harness. Do not allow the tube to rest on its neck or base, and do not under any circumstances carry or handle the tube by its neck alone.
9. To replace the tube, reverse the above procedure paying particular attention to the fact that the two 1/4″ bolts which hold the yoke and hood assembly should be tightened with equal pressure.

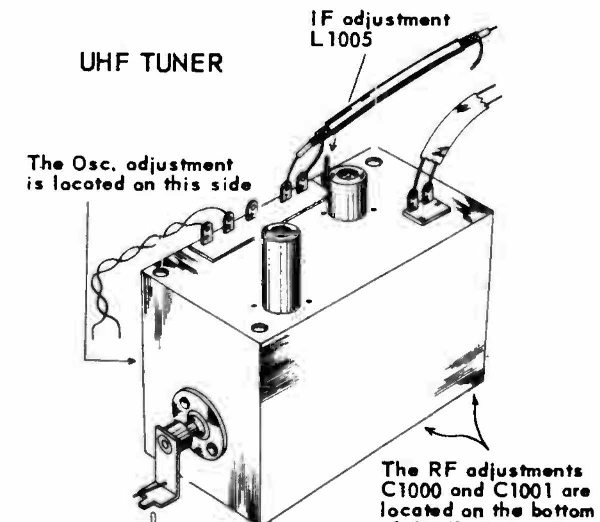

Figure 9

NOTE: No attempt should be made to align this UHF Tuner without the aid of a UHF Generator.

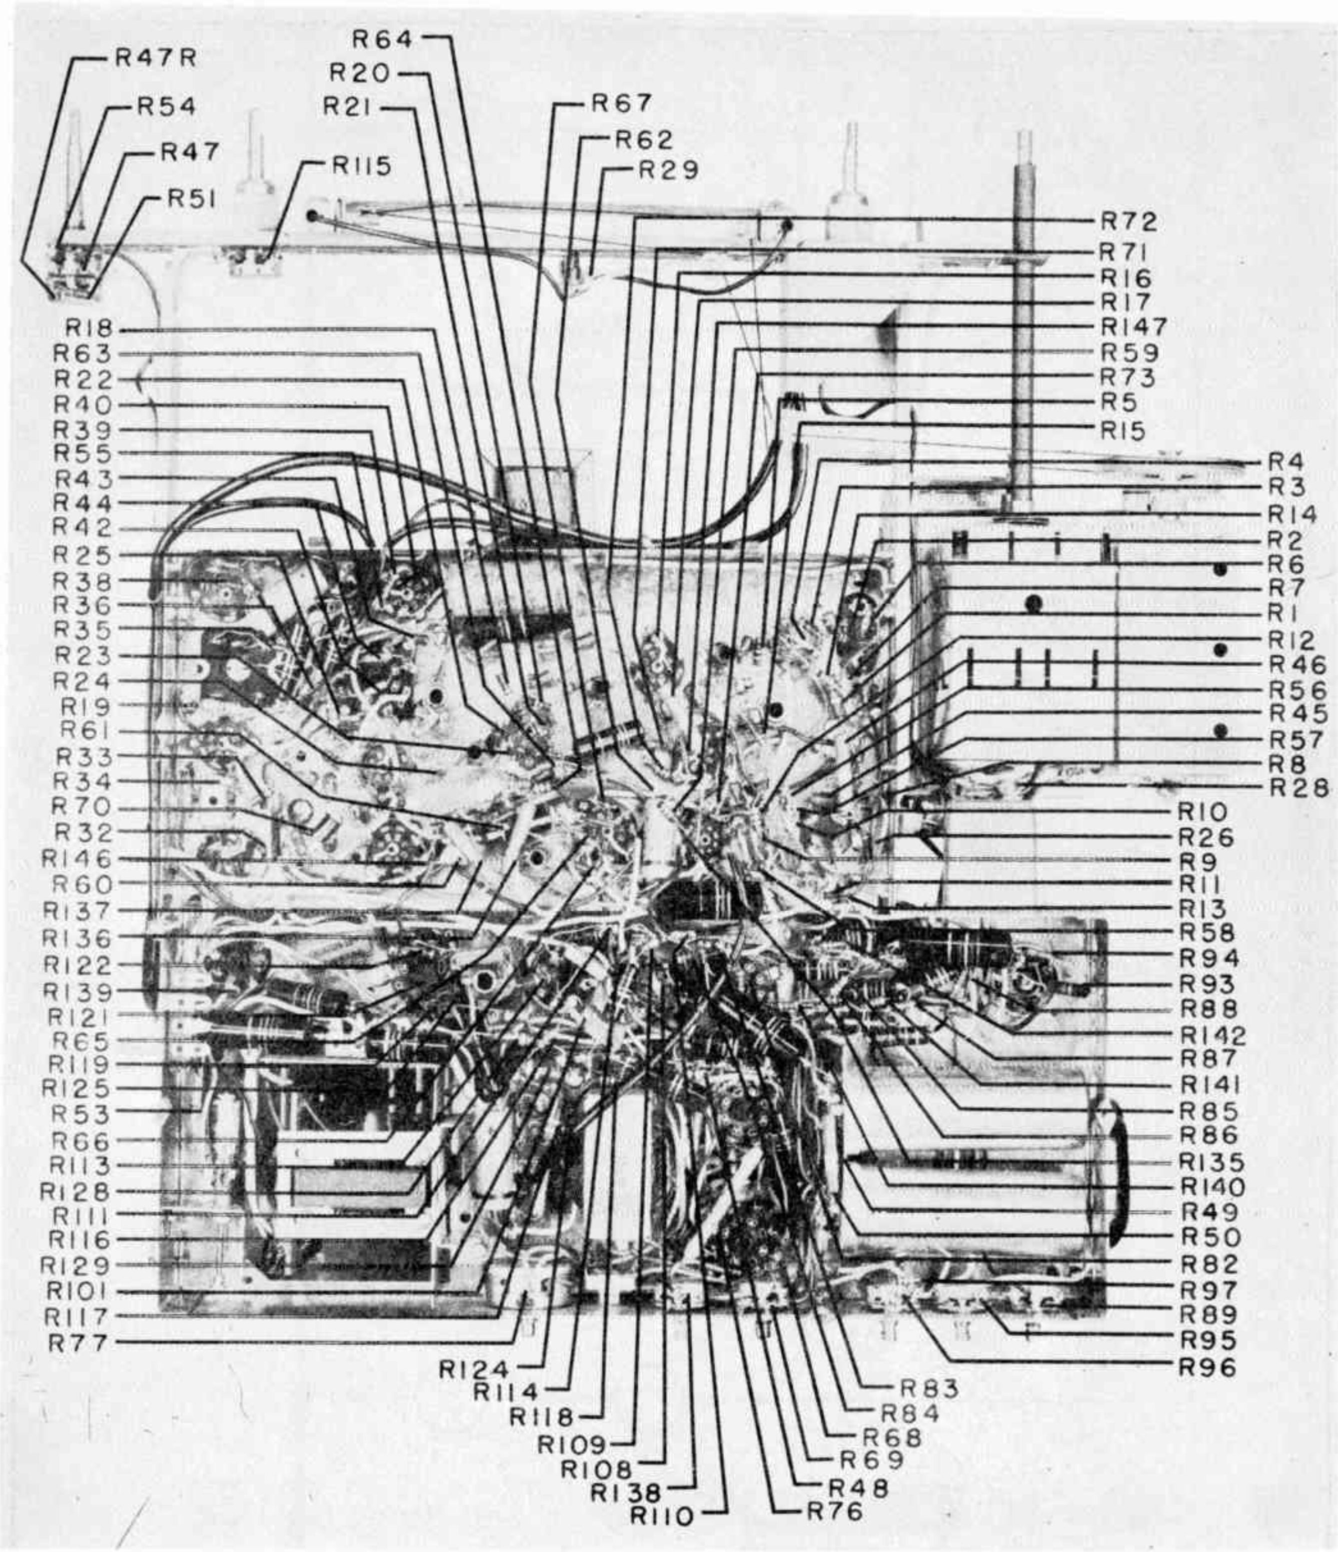

Figure 12

CIRCUIT DESCRIPTION

UHF TUNER

This tuner covers the entire UHF range of 470 to 890MC continuously by means of a three section tuning element. Two of these elements are used for tuning the band-pass or preselector input circuits while the other is for oscillator tuning. A bandwidth of approximately 10MC is realized in this band-pass circuit. The received signal from this point is fed into a grounded-grid mixer stage V26 a 6AN4 where it beats with the local oscillator signal. Injection of the oscillator voltage is through C1012 to the filament of V26. V25 a 6AF4 is the UHF local oscillator, the frequency of which, is maintained and tracked at a difference of 41MC from the incoming signal by the tuning element. Since the IF system of the TV receiver is tuned to 41MC, single conversion is accomplished within this tuner. The 41MC output is applied through L960 and L900 to the VHF tuner circuits which have been altered to operate as 41MC IF amplifiers by the switching arrangement. When the channel selector is in the UHF position the VHF local oscillator is inoperative allowing both the cascode amplifier and mixer stage to act as IF amplifiers thereby increasing the overall sensitivity during UHF reception.

VHF – RF SYSTEM

The tuner is of the rotary switch type, made up of a series of coils in cascade, bridging the contacts of the channel selector switch. The selector switch has 16 positions. Two positions of this switch are utilized to switch the necessary B+ and bias circuits to operate the accompanying UHF tuner, and alter the VHF tuner to provide additional amplification in the IF range. All of the step-tuned coils are preadjusted with the final overall tuning adjustments made in the Bendix factory with the use of a sweep generator. Adjustment of the tuner in the field should not be attempted unless a sweep generator is used; and the instructions that are included under *Alignment Procedure* followed very carefully.

The antenna input circuit is designed to give optimum performance with 300 ohms balanced impedance. The signal is inductively coupled through T900 to the input grid of the RF amplifier. This grid also has applied to it the AGC voltage which controls the gain through both sections of the RF amplifier and 1st IF stage.

The RF amplifier, V1, is a 6BZ7, twin triode type of tube connected in what is known as a series "cascode" circuit. In using a circuit of this design the noise figure which accompanies a conventional pentode amplifier has been greatly reduced and yet equivalent gain has been maintained. The input section of the RF stage is connected as a grounded cathode type amplifier. Its output is fed through L914 to the cathode of a grounded grid amplifier – the output section of the RF stage. All of the preselector coils are preadjusted and matched to a standard, therefore the only adjustments made available for overall RF alignment are L913, L929 and L930. The amplified RF signal is capacitively coupled through C908 to a pentode mixer stage – 1/2 of a 6X8 (V2). Tuning of the mixer grid is accomplished by the same step-tuning method that is utilized throughout the preselector stages. Grid leak bias for this stage is developed across R905 a 220K resistor. A test point for checking the tuner response curve has been made available at the top of the tuner. This point is coupled to the mixer plate by C915 making it necessary to detect the signal before applying it to the oscilloscope.

The other half of V2 a triode is used in a Colpitts type oscillator circuit. There are two oscillator adjustments accessible from the front of the tuner, L957 for the high band of frequencies and L949 for the low band. The fine tuning capacitor has sufficient range to compensate for any further tuning which is required for the individual channels. Capacitive coupling (C913) is used to inject the oscillator output into the grid of the mixer stage.

The output of the mixer is fed to the first IF amplifier through a series double tuned band pass circuit consisting of L958, C28 and L2. This type of circuit accomplishes two purposes – a high degree of oscillator frequency isolation plus optimum transfer of energy. The tunable tank circuit L1 and C2 is used as a sound trap capacitively coupled to the grid of the first IF amplifier. This IF trap along with the one located in the plate circuit of the first IF amplifier reduces the IF gain at the sound carrier frequency approximately 32db, providing satisfactory sound attenuation.

IF SYSTEM

Five stagger-tuned circuits employing one 6BA6 and three 6CB6 tubes along with a crystal detector comprises the interstage IF amplifier system.

Three of the IF transformers used in this system are of the Bifilar wound type – two windings interwound on a single form. A winding of this type approximates unity coupling and gives the effect of a single tuned coil. The following advantages are derived from such an arrangement. Improved filtering of all plate and grid returns can be achieved because the bypass condensers are returned to the same ground as their associated cathode thus eliminating circulating ground currents. It is also possible to keep the time constant in the grid circuit of each amplifier to a very low value therefore minimizing the possibility of a charge building up on the grid of these stages during heavy noise pick up. This latter advantage permits the IF system to operate at optimum performance at all times. Unbypassed cathode resistors are used in the first two stages to reduce the variations of input capacity with AGC voltage changes. Within this IF strip there are two cases of voltage cascading which means that two or more tubes are connected in what can be termed as "plate current series" with one another. The first case involves the first IF (V3) and the RF amplifier V1, while a similar hook-up encases V6, V5 and V8. In each case the tube at the top of the line-up has applied to its plate approximately the maximum voltage available and is so biased that the voltage drop across it is sufficient to reduce the voltage at its cathode to a value that is proper for operating the next stage. This continues to happen right on down the line until the tube at the bottom of the string has its cathode D.C. connected to the ground. A hook-up of this kind consumes less power due to the fact that the tubes at the top of the string are effectively used as the plate load resistor for the pursuing stage, therefore the dissipation that normally takes place across a load resistor is utilized for amplification. This IF system has been designed to provide an overall response curve which is flat topped with a nominal bandwidth of 4MC 6db down from peak response. The IF output is fed into the video detector can T3 which encases the third IF amplifier plate transformer, sound take off coil, the crystal video detector IN60, and its associated peaking coils necessary to extend the frequency response to the desired bandwidth.

Various test points have been indicated on the schematic diagram in order to facilitate the making of checks on the operation of the IF system. One is located in the AGC string at the junction of R56 and R57 while another is located at the junction of R10 and R12. These two points have been made available from the top of the chassis for checking developed AGC voltage and for applying bias potentials when making sweep tests on the RF or IF systems. Another test point "C" has been designated at Pin 7 of V14, the noise inverter, for connecting a VTVM when measuring the voltage developed by the crystal detector during alignment with a CW signal.

SOUND SECTION

Intercarrier sound reproduction is used. By this method both the picture and sound carriers are amplified by the same IF amplifiers and beat together in the Video Detector, giving a 4.5MC FM carrier that is fed to the sound amplifier V7. The 4.5 megacycle beat is constant since it is always the fixed difference between the Video and Sound coming from the TV Station. Therefore, the Sound will not be affected by any normal oscillator drift, since both the Video and Sound carriers will drift equal amounts and the difference will always be 4.5MC. The 4.5MC signal is taken off at L9 and amplified by V7, which in turn is transformer coupled to the ratio detector driver V8. This tube has low DC voltages on the plate and screen and, while there is some amplification, its chief function is that of limiting. The Ratio Detector (V9) is of the conventional type. The 33 ohm (R35) resistor in series with the coupling line of the detector transformer (T4) stabilizes the impedance presented by the diodes. If this resistor was deleted, the variation in impedance between individual tubes would cause the AM rejection to vary between receivers.

The output of the Detector is amplified in the 1st Audio stage (V10) and then directly coupled to the grid of the output tube (V11). This DC coupling is possible since V11 is part of the voltage regulating system. (See Current Distribution Diagram.)

About 10db of negative feedback is provided by R55 which is connected between the secondary of the Audio output transformer and the cathode of the 1st Audio amplifier (V10) to reduce output distortion.

VIDEO AMPLIFIER

The Video amplifier is a 6AH6, with the associated wide band, low pass filters. The output of the crystal detector is DC connected to the grid of the Video amplifier through a filter circuit comprising a series (L7) and a shunt (L8) peaking coils. L16 is a shunt plate peaking coil used to extend the frequency response of the Video amplifier to its desired value and compensate for any incurred phase shift. The response of the Video system is flat to 1MC and down 3db at 3.8MC.

The contrast is controlled by changing the amount of degeneration in the Video amplifier. This is accomplished by varying the control R47 in the cathode circuit.

No DC restoration is necessary at the output of the Video amplifier because the entire Video amplifier is direct coupled from the output of the crystal detector to the cathode of the picture tube. Therefore, the rectified video signal does not vary about an AC axis.

Notice that the polarity of the detector is such that a negative signal is applied to the grid of the Video amplifier, resulting in a positive video signal at the plate which is applied directly to the cathode of the picture tube.

KEYED AGC

V12 is the AGC amplifier whose function is to keep the sensitivity automatically adjusted in accordance with the strength of the received signal. This is accomplished by the negative voltage which is developed at the plate of the AGC amplifier V12 tube and applied to the grids of the RF and IF amplifiers. The plate voltage for V12 is in the form of a positive pulse taken from terminal #5 on the horizontal output Transformer T8.

This pulse is developed by the collapsing of the field in the horizontal deflection coils and its duration is about 5% of the horizontal period. Plate current can flow only during the application of this pulse and the amount of current flow is controlled by the amplitude of the sync pulse on the grid, pin #1 of V12, and the setting of R138, the AGC control which serves as a variable grid resistor. The grid is DC connected to the video amplifier output at the junction of R62 and R63, the plate load resistors for the video amplifier. The bias level for V12 is a function of the video amplifier plate current. The AGC cathode potential is +165 volts, taken from the source which also supplies the plate of V13. The screen potential is approximately +340 volts, thus maintaining the required potential difference with respect to the cathode. The screen and plate voltages are approximately the same at the time the pulse occurs.

When current flows in the plate circuit of V12 it will develop a negative voltage across resistors R56, R57 and R58. This voltage is filtered by the RC network R56, R57 and C43 to rid it of the horizontal frequency component (15,750cps). Therefore, the time constant required to filter frequencies of this kind can be made very short as compared to the time constant used in conventional AGC systems, which had to filter out a 60 cycle component. The control voltage for the IF stages is taken from the junction of the dividing network, R56 and R57. The control voltage for the RF amplifier is taken from the junction of R57 and R58 and fed through R9 with a delay voltage being applied by means of a voltage dividing network from the +165 supply. The circuit constants are such that the IF bias reaches a value of approximately −4.5 volts before the RF delay is overcome.

The keyed AGC system has good noise immunity because its duty cycle is only about 5% of the total time, and any noise pulses occurring during the other 95% of the time do not affect its operation. The developed AGC voltage is a function of sync pulse amplitude only and is not affected by picture content. Hence, the AGC action can be made fast, practically eliminating the flutter caused by airplanes.

NOISE INVERTER

The noise inverter, V14, provides a major improvement in signal-noise ratio for both horizontal and vertical synchronization.

This new circuit requires the use of a Hi-Mu twin triode tube. Its purpose is to prevent the noise that is normally present in the sync region of the composite video signal from appearing at the input of the sync limiter, V15. In this chassis the circuit has been designed around a 12AT7. The way this circuit accomplishes its purpose is by amplifying and inverting the noise that appears at the screen of the video amplifier and superimposing its negative output upon the positive noise pulses that are normally prevalent in the composite signal at this point. This out-of-phase component will cancel out and eliminate any noise at the input of the sync separator that would ordinarily appear in the sync region of the composite video signal.

The first section of this twin triode is connected in parallel with R65, the screen resistor for the video amplifier, V13. It is so biased by the voltage divider network, R66, R68 and R69 that it will conduct at varying degrees corresponding to the signal level applied to its cathode from the screen of V13. This variation causes the tube to act as a variable low impedance shunt across R65 holding the voltage on the screen of V13 fairly constant until the desired moment – *the arrival of a noise pulse*. The same video signal that is being applied to the cathode of Unit #1 is also being coupled through C47 to the grid of Unit #2, but its amplitude is insufficient to overcome the bias of that section which is set by R69 the noise inverter control. It is important that the bias be set high enough to keep this section from conducting on sync peaks because that would cancel out the sync signal entirely allowing both vertical and horizontal to fall out of step. The next step is to follow the chain of reactions that is set up by a noise pulse which has great enough amplitude to ride well above the sync peaks. A noise pulse of this amplitude will, due to design, drive the grid of the video amplifier into cutoff thus allowing the voltage on both the plate and screen of that stage to rise rapidly. This pulse being of a positive polarity on the screen will also cutoff unit #1 of V14, doing away with its affect as a low impedance shunt across R65 allowing the voltage at its cathode to rise rapidly to the potential of the supply source. This wave front has been increased sufficiently, due to this chain of reactions, to overcome the bias of Unit #2 when applied to its grid through C47. The overcoming of this bias allows Unit #2 of V14 to conduct and amplify this noise pulse, superimposing it at the junction of R64 and R67 exactly upon the same noise pulse that created it within the composite video signal. Since the output of the noise inverter is negative in polarity the noise peak is cancelled to the point where it is placed well below the sync pulse region before the composite video signal reaches the sync separator.

ANTI-LOCKOUT MEASURES

When using the noise inverter circuit in a receiver employing keyed AGC, there is an important problem of "lockout" to be taken into consideration. The term "lockout" refers to a condition which may take place in the receiver upon the loss of horizontal synchronism. When the receiver loses horizontal sync, the keyed AGC will not function properly removing the bias from the IF amplifiers, thus permitting an excessive signal to be applied to the video amplifier V13. This increased signal is sufficient to drive the grid of V13 into cutoff causing the noise inverter to function continuously inverting the sync pulses, thereby preventing the receiver from pulling back into horizontal or vertical sync. Therefore anti-lockout measures have been designed with this circuit. C48 and R67 located in the plate circuit of Unit #2 of V14 plays an important part in this function. When the receiver is out of sync, the vertical sync pulse causes C48 to charge sufficiently to reduce the effective plate voltage on the second half of V14 enough that the noise inverter approaches an inoperative condition. Another measure which aids the one just mentioned consists of placing an RC time constant, C47 and R70 in the grid circuit of Unit #2 of V14. C47 becomes negatively charged due to the grid current that will flow during the vertical sync pulse while the receiver is out of sync. Here again this charge reaches proportions that approach grid cutoff of this section of the tube. The charges that build up on both C47 and C48 will remain only long enough to enable the receiver to regain synchronism due to the value of their respective resistors. Still another anti-lockout measure has been employed. This one consists of connecting the video detector output to the grid of Unit #2 of V14 through R70 a 2.2 meg resistor. Since the negative output of the video detector reaches several volts in amplitude, without the application of AGC voltage to the IF amplifiers, this connection aids to further the negative bias on the grid of the output section of V14. In view of the fact that each measure tends to place this stage in an inoperative condition, their combined effects completely eliminate any tendency of the receiver to lockout during the loss of horizontal sync.

SYNC LIMITER

Video signals are applied to the grid of the Sync Limiter tube (V15) from the plate of the Video amplifier (V13) through an isolating resistor R64 and capacitor C49. This isolation is required to avoid adding excessive capacity to the Video plate circuit, which would reduce the bandwidth. Limiting is accomplished in the grid of V15. The signal is amplified and then clipped again in the plate of V15. The grid develops its own bias and the plate is operated at a low DC potential. The output is fed to the Sync Clipper (V18A). From the plate of V18A, the positive vertical pulse is fed through an integrating network to the Vertical Oscillator and Output, V18B and V19. Both a positive and a negative horizontal sync pulse are taken from V18A, the positive pulse is coupled through C71 to pin 7 of V20 and the negative one through C70 to pin 5 of V20.

THE VERTICAL DEFLECTION SYSTEM

The vertical deflection system consists of a blocking oscillator (V18B) and vertical output (V19) which is locked into synchronism by the vertical integrated sync pulse. The output of V19 is coupled to the vertical deflection coils (L19 and L20) by the vertical output transformer (T7).

For a discussion of the circuit operation it will be assumed that no triggering pulses are present. Following this, the triggering pulses will be added and their effect upon the operation discussed.

For any linear magnetic deflection system, the waveform of voltage which must be present across the deflection coils (L19 and L20) is as shown in Figure 13, where A is the trace time and B is the retrace time.

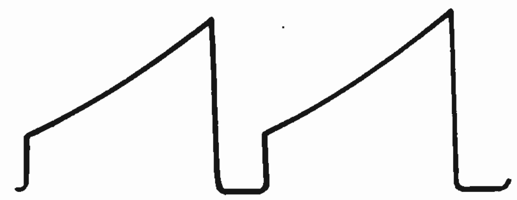

Figure 13

The procedure for obtaining this waveform is as follows:

In common with all oscillators, feedback of energy from plate to grid must occur. A transformer (T9) is employed for this purpose. Any change in plate current will induce a voltage in the grid circuit which will act to aid this change. For instance, an increase in plate current will induce a positive voltage in the grid circuit through the blocking oscillator transformer T9 (See Schematic Diagram). As the grid becomes more positive, more plate current will flow, resulting in the grid becoming rapidly very positive. This will cause electrons to flow in the circuit, charging (C58). The electrons reaching the grid, pile-up on the negative side of condenser (C58). The resistances in this circuit are made large enough so that in combination with condenser (C58) they create a sufficient time constant for the oscillator to block out at a frequency slightly lower than 60 CPS. The electrons stored on C58 discharge slowly to ground.

Because of the slow discharge of (C58) caused by the high value of resistance in the circuit, electrons which have accumulated on the grid remain there in sufficient numbers to give it a large negative bias, sufficient to block or stop the plate current flow. Gradually the charge built up on (C58) passes through the resistance in the circuit back to the positive plate of (C58). The negative bias on the grid then becomes less. When (C58) is almost completely discharged, electrons again begin to flow from the cathode to the plate, the tube begins to draw plate current very fast, and reaches its high value, which drives the grid positive and the whole process is repeated. From the above explanation we can see that during every cycle there is a sharp pulse of plate current, followed by a period during which the tube blocks itself until the accumulated negative charge built up on the grid leaks off again. The frequency of these pulses is determined by C58 and the associated resistance in the circuit.

Figure 14 shows the voltage waveform across the resistance in the circuit. Figure 15 shows the plate current waveform which occurs once in every cycle.

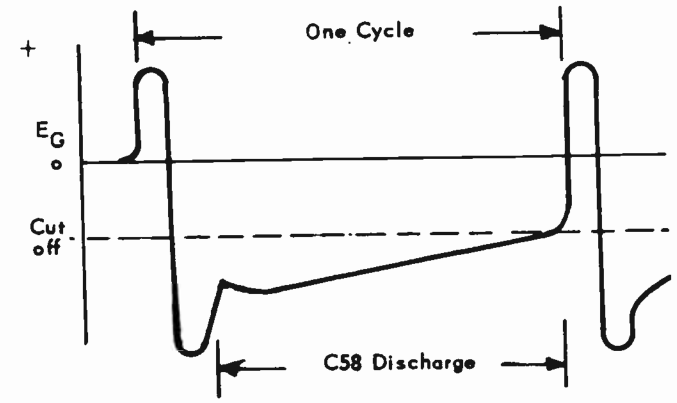

Figure 14

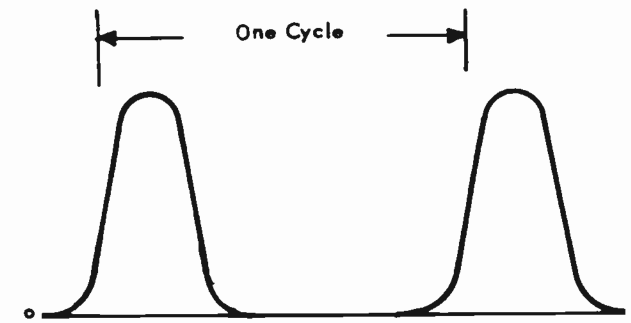

Figure 15

The combination of resistor R142 and capacitor C59 forms the sawtooth waveform needed to drive the vertical output tube (V19). This sawtooth waveform is amplified in V19 and coupled to the deflection coils (L19 and L20) through the vertical output transformer (T7).

A pulse is taken from the junction of C59 and R142 and fed to the suppressor grid (Pin 2 of V15) sync separator. This pulse arrives at the suppressor grid immediately after the blocking oscillator is fired by the leading edge of the integrated vertical sync pulse.

The pulse fed to the suppressor grid is of sufficient amplitude (approximately 100 volts) to cut off the tube. This pulse is formed by the vertical blocking oscillator fly-back and is negative in polarity. This negative pulse cuts the tube off for the remainder of the vertical sync and post equalizing pulse interval and the tube starts to conduct when the preparatory horizontal pulses arrive. Gating off the sync separator tube during most of the vertical and all of the post equalizing pulse interval prevents these pulses from being coupled to the vertical circuit which would impair interlace.

HORIZONTAL SWEEP SYSTEM

The horizontal sweep system consists of a free running multivibrator (V21) coupled to a horizontal output tube (V22) which drives the horizontal deflection coils (L21, L22). The phase detector tube (V20) is used to synchronize the multivibrator. The horizontal generator employs a 6SN7GT tube as a multivibrator, whose frequency is controlled by the L, R and C in the circuit. The amount of charge placed on C80 will determine the multivibrator frequency. The synchronizing system used to lock the oscillator in step with the synchronizing pulses employs a 6AL5 (V20) as a balanced phase detector.

The operation of the multivibrator and associated circuits will be discussed first of all in the completely unsynchronized state. This condition would exist if V20 was removed from the circuit. The operation will then be discussed in the synchronized state.

UNSYNCHRONIZED STATE

The multivibrator used in the horizontal sweep system is of the cathode coupled type. Feedback between unit 1 and unit 2 is accomplished through coupling condenser C80 and the unbypassed cathode resistor R112 which is common to both sections. Now let us apply power to this circuit and follow the chain of reactions as they take place. Any disturbance within the circuit would very likely cause an increase in the plate current of V21B, which in turn will increase the voltage at the top of the common cathode resistor R112. In an unsynchronized condition the bias on V21A can be thought of as being fixed, therefore a substantial increase in cathode voltage will drive the unit into plate current cutoff. Since both units commence conducting upon the application of voltage, this cutoff point of V21A is reached very rapidly. When the cathode voltage cuts-off this unit, the plate voltage immediately approaches the potential of the supply voltage, thereby forming a very steep wave front. C80 couples this positive wave front to the grid of V21B causing the plate current to flow freely offering a very low impedance discharge path for the voltage which has built up on C82. The grid of Unit #2, due to the positive pulse coupled through C80, is driven sufficiently positive to make it draw current. This grid current is being drawn through R114 and R115 consequently building up a negative charge on the grid side of C80 to proportions that will cut off conduction within V21B. With V21B cut-off, the voltage at the top of R112 will drop to a level that will allow V21A to start drawing current. Its plate voltage will then drop sharply applying the developed negative wave front through C80 to the grid of Unit #2, pushing it even more negative than it was when first cutting-off. V21 remains in this condition, that is – Unit #1 drawing current and Unit #2 cut-off, until the negative charge on C80 drains off through R114 and R115. The time required for this negative charge to become small enough to allow V21B to conduct again is determined by the RC time constant of the circuit and has been designed to be approximately 15750 cycles per second. Consequently when this point is reached the first cycle will be completed only to be repeated.

The frequency of this multivibrator is controlled by two separate circuits. One is an RC circuit consisting of R114, R115 (Hor. Hold Control) and C80 while the other is a LC circuit made up of L23 (Hor. Osc. Adjustment) and C75. The latter one is a tank circuit which should be tuned to be resonant at approximately 15750 CPS in order to aid in keeping the multivibrator oscillating at the correct frequency. The function of the RC circuit was discussed in the previous paragraph.

In order to produce the necessary current flow in the horizontal deflection yoke a sawtooth voltage must be applied to the grid of the horizontal output tube. An RC circuit comprised of R118, a 18K resistor and C82, a 330 mmf condenser is used to properly shape the voltage to produce a linear sweep. This sawtooth voltage is amplified by V22 (6CD6G) and since the high voltage transformer is its plate load, produces a sawtooth current which is fed to the horizontal deflection coils, L21 and L22.

OPERATION WITH SYNCHRONIZATION

The Phase Detector (V20) provides automatic frequency control for the horizontal oscillator (V21). This is accomplished by comparing the phase of two different waveforms: both polarities of the incoming horizontal sync pulse and a sawtooth waveform taken from the horizontal output transformer. The positive and negative polarities of the incoming sync pulse kept approximately equal in amplitude, are taken from the plate and cathode of V18A. See Figure 16 (a and b). They are coupled through C70 and C71 to pins 5 and 7 respectively of V20. The second waveform consists of a sawtooth voltage obtained from terminal 5 of the horizontal output transformer. The integrating network C72 and R124 correctly shapes the desired sawtooth waveform revolving about an AC axis. The sawtooth voltage thus developed is both positive and negative, and is applied to pins 1 and 2 of the phase detector tube (V20). See Figure 16 (c).

The sync pulses and the sawtooth waveform are superimposed on each other in the phase

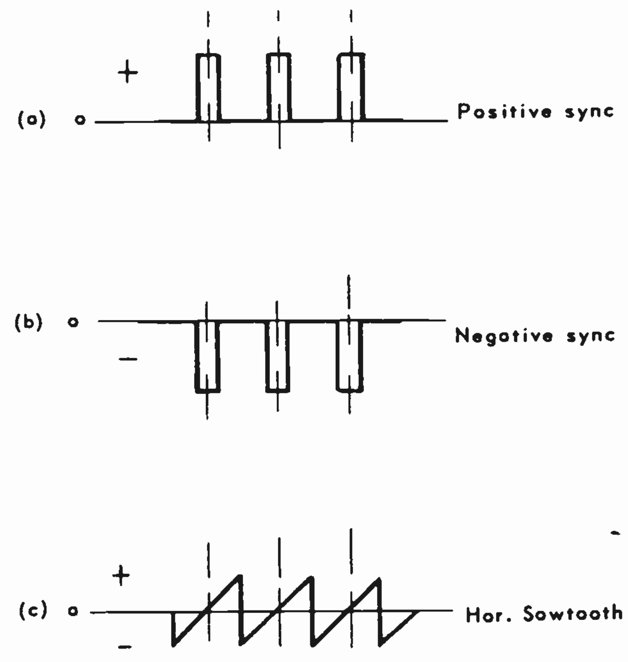

Figure 16

detector. The amplitude of each sync pulse and the sawtooth wave remain the same, but any phase shift between the two will cause a variation in the DC voltage developed at the junction of R108 and R109.

When both the horizontal oscillator and incoming sync are at the same frequency, they are properly phased and the amplitudes of the waveforms in each section of the phase detector are equal. See Figure 17 (a). Each diode, therefore, conducts equally and the DC voltages across the two load resistors, R108 and R109, are equal but opposite in polarity. The voltage developed at the junction of these resistors is therefore zero. Since the output is zero, no change in grid bias takes place and there is no change in the oscillator frequency.

If the horizontal oscillator is ***higher*** in frequency than the incoming sync pulse, the sawtooth voltage being applied to pins 1 and 2 of V20 will be in the positive portion of its cycle by the time the sync pulses arrive on pins 5 and 7. See Figure 17 (b). This places a negative sync pulse on pin 5, equal amounts of positive sawtooth voltage on pins 1 and 2 and a positive sync pulse on pin 7, allowing more current to flow through the pin 2 and 5 section of V20. The result of this is a ***positive*** voltage at the junction of R108 and R109, [see Figure 18 (a)] which makes the grid (pin 1 of V21) more positive and ***slows down*** the oscillator frequency.

If the horizontal oscillator is lower in frequency than the incoming sync pulse, the sawtooth voltage being applied to pins 1 and 2 of V20 will now be in the negative portion of its cycle at the time the sync pulses arrive on pins 5 and 7. See Figure 17 (c). This places a negative voltage on pins 1 and 2, instead of the positive potential that was there in the previous example, and more current will flow through the

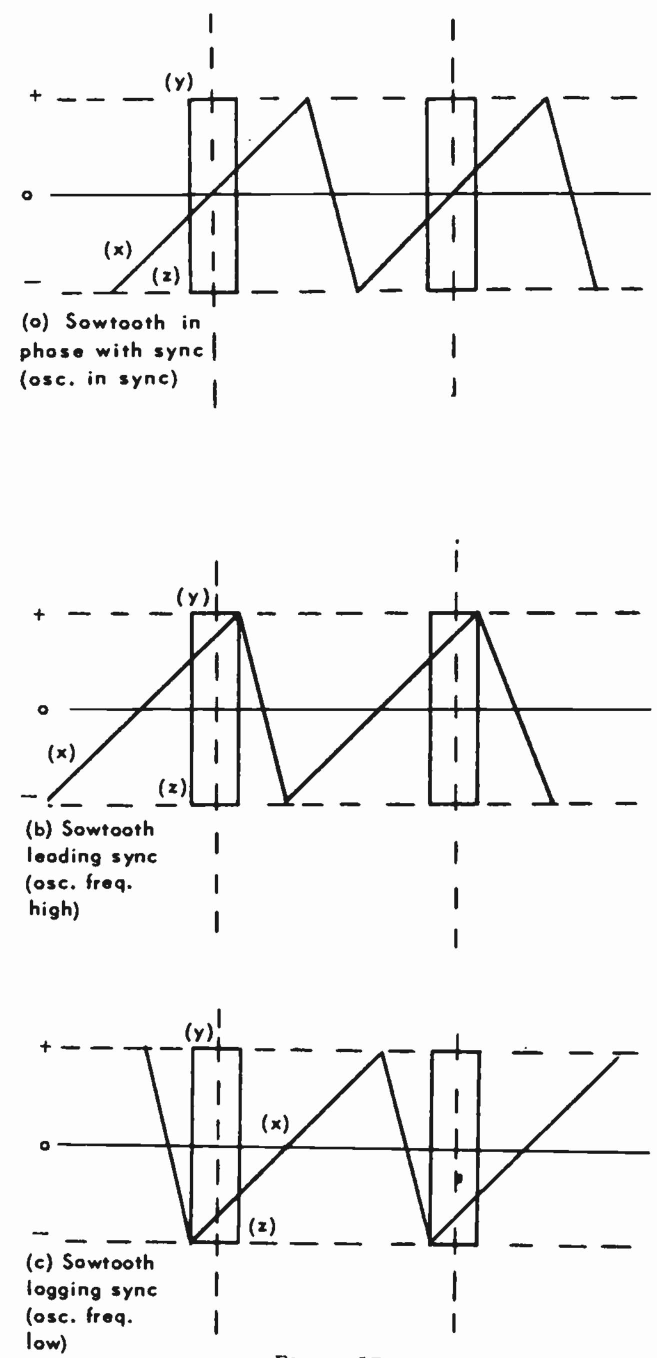

Figure 17

pin 1 and 7 section of the diode. The voltage developed at the junction of R108 and R109 will now be at a negative potential, [see Figure 18 (b)], making the grid (pin 1 of V21) more negative and ***speeding up*** the oscillator frequency. R110 provides a DC return for the grid of V21 in the event V20 should fail or be removed from the socket.

CHASSIS SPECIFICATIONS

Power Requirements
117 volts, 60 cycles AC

Power Consumption
240 watts

Fine Tuning
Plus & minus 600 KC on Channel 2
Plus & minus 1 MC on Channel 13

Audio Power Output
2.8 watts

Band Width
Video amplifier 3.8 MC within 3 db
IF Amplifiers 3.5 MC within 6 db
Antenna input to picture tube 3.25 MC at 6 db
Ratio Detector, peak to peak 200 KC

Deflection
Horizontal & Vertical — Magnetic

Focus — Magnetic (PM)

Scanning — Interlaced, 525 lines
Horiz. Freq. — 15750 CPS
Vert. Freq. — 60 CPS
Frame Freq. — 30 CPS

MODEL IDENTIFICATION TABLE

Model Numbers	Chassis	Picture Tubes	Focus	Tuner	Speaker
KM17CD, SKM17C	T17-1	17QP4A	PM	258050-1	10″ PM
TM17CD, STM17C TS17C	T17-1	17QP4A	PM	258050-1	6″ PM
KS21C	T17	21EP4A	PM	258050-1	8″ PM
TS21C	T17	21EP4A	PM	258050-1	6″ PM

These receivers are adaptable to UHF reception by the insertion of Channel Strips. Please order the UHF strips by the basic part number 275105- making the dash number the same as the channel number desired.

TUBE COMPLEMENT

Tube	Type	Function	Tube	Type	Function
V1	6BQ7	Cascode RF Amplifier	V13	17QP4A or 21EP4A	Picture Tube
V2	6J6	Mixer & Oscillator	V14	5U4G	Low Voltage Rectifier
V3	6BA6	1st IF Amplifier	V15A	1/2 6SN7GT	Sync Clipper
V4	6CB6	2nd IF Amplifier	V15B	1/2 6SN7GT	1/2 Vertical Oscillator
V5	6CB6	3rd IF Amplifier	V16	6W6GT	1/2 Vertical Oscillator & Vertical Output

Sound Carrier – 41.25 MC

ALIGNMENT PROCEDURE

VISUAL ALIGNMENT OF THE RF AND MIXER STAGES

NOTE:

CAUTION: Always determine by suitable tests, the causes of unsatisfactory operation before attempting to align portions of this receiver. Necessity for realignment will, in all cases, be rare.

PROCEDURE:

1. Connect an RF sweep generator with at least a 10 MC sweep width to the antenna terminals through the test circuit shown in Figure 1.

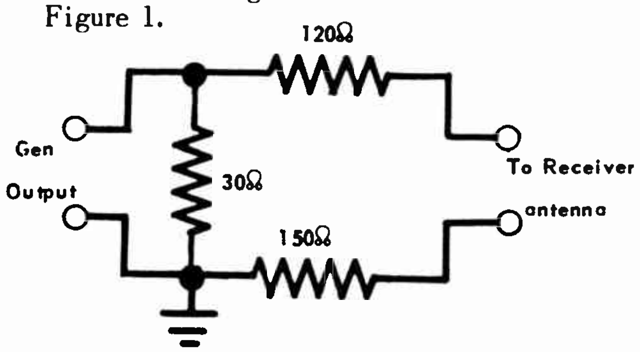

Figure 1

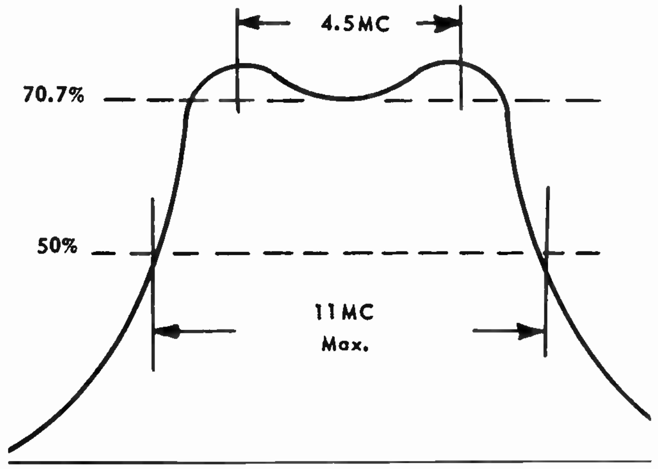
2. Remove the keyed AGC Amplifier tube V10 (This is necessary in order to eliminate AGC action which would interfere with RF alignment).
3. Connect the positive terminal of a 3 volt dry cell supply to chassis ground and the negative terminal to the RF AGC test point.
4. Attach the high side of the vertical input of an oscilloscope through a 10,000 OHM resistor to the test point located at the junction of R806 and R807. In order to synchronize the sweep of the oscilloscope with the RF sweep, connect the horizontal amplifier terminals of the oscilloscope to the terminals on the RF sweep generator labeled "oscilloscope sweep voltage."
5. Turn the station selector to Channel 12 and adjust the sweep generator until it sweeps from 202MC to 212MC. (NOTE: If the sweep generator does not supply marker signals at picture and sound carrier frequencies, an external source, such as a CW signal generator should be used to supply them. For method of marker injection, refer to instructions supplied by the manufacturer of sweep generator being used.
6. Adjust C802, C808 and C811 until the viewed response curve is similar to that shown in Figure 2. Check all other channels readjusting C802, C808 and C811 as necessary to obtain optimum response on all twelve channels as shown.



RF Response Curve

Figure 2

The dip in the curve between picture and sound carriers should not fall below 70.7% of the response peak and the bandwidth at 50% down should not exceed 11MC on any channel.

RF OSCILLATOR ALIGNMENT

CW METHOD

1. Remove V10 from its socket and connect the negative terminal of a 3 volt dry cell bias supply to the RF and IF AGC test points. (This can best be accomplished by tieing the two points together.)
2. Apply the CW signal to the antenna terminals through the pad shown in Figure 1.
3. Connect the DC probe of a vacuum tube voltmeter to test point C.
4. Set the signal generator to the sound carrier frequency of each channel that is to be aligned.
5. Turn the fine tuning control to approximately the center of its rotating range.
6. Adjust the oscillator coil slug that is accessible through a hole in the front panel of the tuner until a sharp dip in the voltage reading on the VTVM is reached. Repeat this procedure for all channels. Precautions should be taken not to turn the oscillator slug into the coil form too far – to do so will allow the slug to pass beyond the clip which acts as a thread guide thus necessitating the removal of the channel strip in order to return the slug to its proper tuning position.

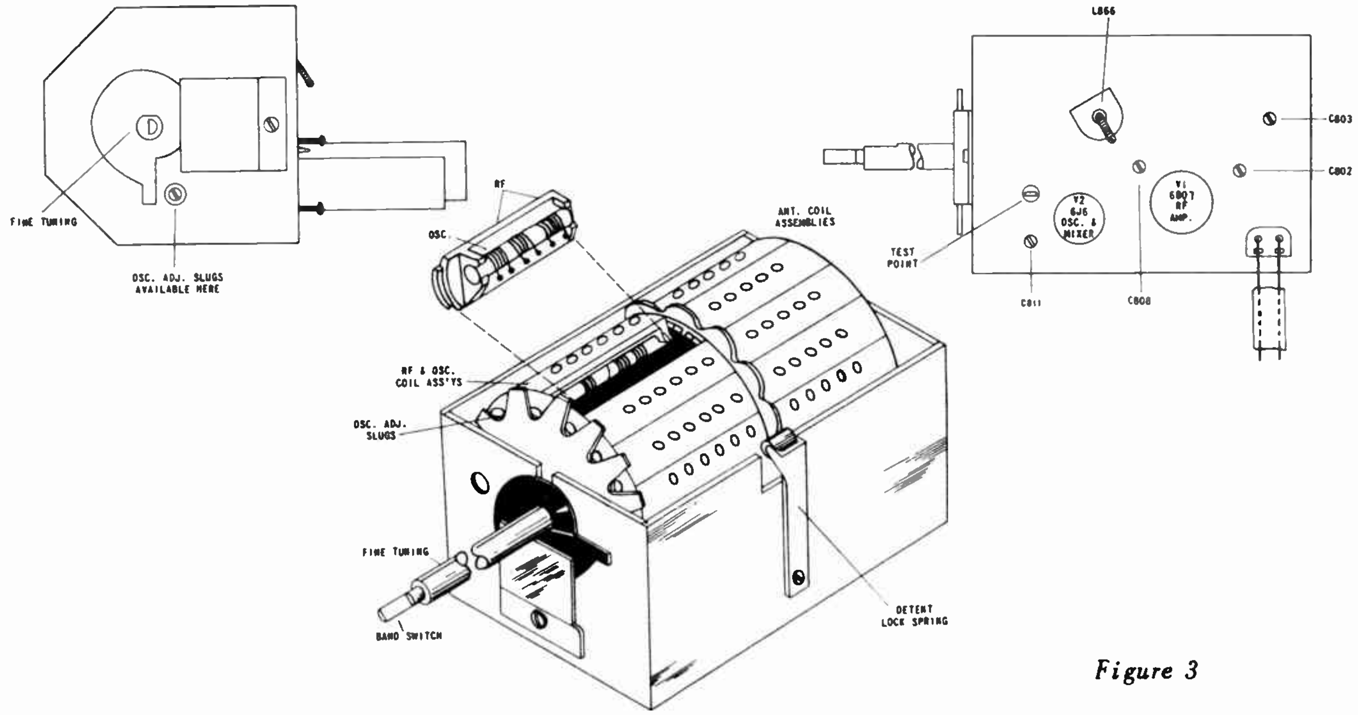


Figure 3

RECEIVED SIGNAL METHOD

There is also another satisfactory method for adjusting the RF oscillator in the turret type tuner. This may be accomplished without removing the chassis from the cabinet by the following procedure:

1. Allow the receiver to warm-up for approximately 10 minutes.
2. Turn the channel selector to a station which is in operation making sure that all other controls are adjusted for normal picture.
3. Set the fine tuning control at the center of its range.
4. Remove both the channel selector and fine tuning knobs.

IF ALIGNMENT

Remove the AGC Amplifier (V10) from its socket.

Connect the negative terminal of a 3 volt dry cell supply to the IF AGC test point and the positive terminal to chassis ground.

Raise the tube shield of V2 so that it is not grounded and apply the signal to it.

Turn channel selector to an unassigned high channel position, to reduce the possibility of interference during alignment.

Generator Frequency	VTVM Connections	Adjustment	Remarks
44.3 MC	To Test Point (C) and Ground	T3	Adjust for Max.
42.7 MC	To Test Point (C) and Ground	T2-L2	Adjust for Max.
45.0 MC	To Test Point (C) and Ground	T1-L866	Adjust for Max.
41.25 MC	To Test Point (C) and Ground	L1	Adjust for Min. with output of Signal Gen. at Max.

NOTE: To insure correct IF Alignment follow the procedure outlined under visual check of IF Alignment.

5. Adjust the brass slug which is accessible through a 1/4″ hole beside the tuning shaft first in a counterclockwise direction for the clearest detailed picture. If best detail is not reached then screw in clockwise direction. Here again caution must be taken not to rotate the slug too far into the coil form. (For best results a non-metallic screwdriver approximately 8 inches long must be used.)
6. Repeat this procedure for each local station making sure that the fine tuning control is in the center of its range.

VISUAL CHECK OF IF ALIGNMENT

1. Lift the shield of the oscillator mixer tube V2 until it becomes ungrounded. Connect the high side of a sweep generator to the ungrounded tube shield and the ground lead to chassis ground. Connect a lead from the sweep synchronizing terminal on the sweep generator to the external sweep terminal on the oscilloscope.
2. Connect high side of oscilloscope to pin 7 of V11 video amplifier tube and ground lead to chassis ground. (Set contrast control at minimum.)
3. Remove the keyed AGC amplifier tube V10.
4. Connect the negative terminal of a 3 volt dry cell to the IF AGC test lead and the positive terminal to chassis ground.
5. Adjust sweep generator to sweep from 40 to 50MC.
6. Connect a vacuum tube voltmeter between pin #1 of V11 and ground and adjust the sweep generator output until a reading of −2 volts is obtained.
7. Adjust the oscilloscope until the IF response curve is centered.
8. Place a lead from an AM signal generator near the IF strip and adjust it to cover from 40 to 50MC.
9. Observe the response curve and the position of the markers (see nominal response curve Figure 4). A slight deviation from this response curve is permissible; however, complete realignment of the IF will be necessary if a great deviation is noted. Some improvement in the shape of the response curve may be accomplished by slightly re-adjusting L2 on the main chassis and L866 on the Standard Coil (strip type) tuner or L958 on the Sarkes-Tarzian (switch type) tuner.

For best performance the difference in height of peaks should not exceed 30% nor should the dip drop more than 30% below the peak of the response curve.

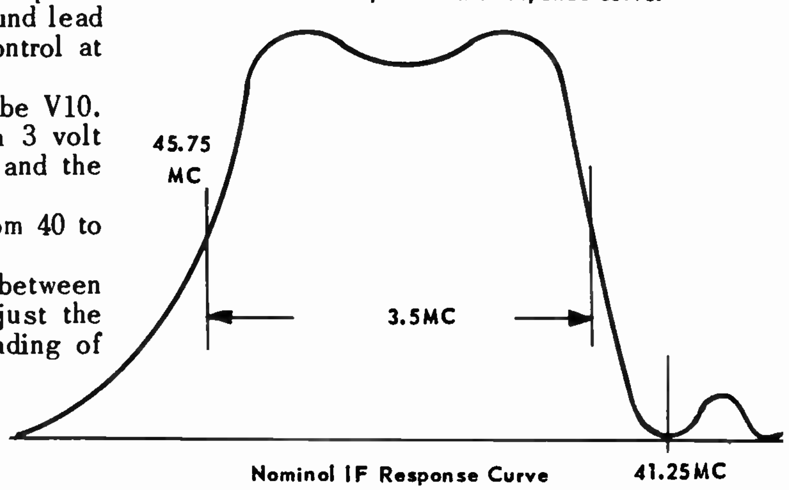

Figure 4

SOUND ALIGNMENT

Connect the negative terminal of a 9 volt dry cell supply to the IF AGC test point and the positive terminal to chassis ground.

Signal Generator Coupling	Frequency	Connect	Adjust	Remarks
High side to Test Point (C). Low Side to Chassis.	4.5MC	Parallel R23 with two 100K resistors which are within 1% of each other. DC probe of VTVM to PT. A. Common lead to chassis.	L5 L6	Adjust for maximum reading in order given, then repeat.
SAME	4.5MC	DC probe of VTVM to PT. B. Common lead to PT. A.	L8	Adjust for zero reading at cross-over.

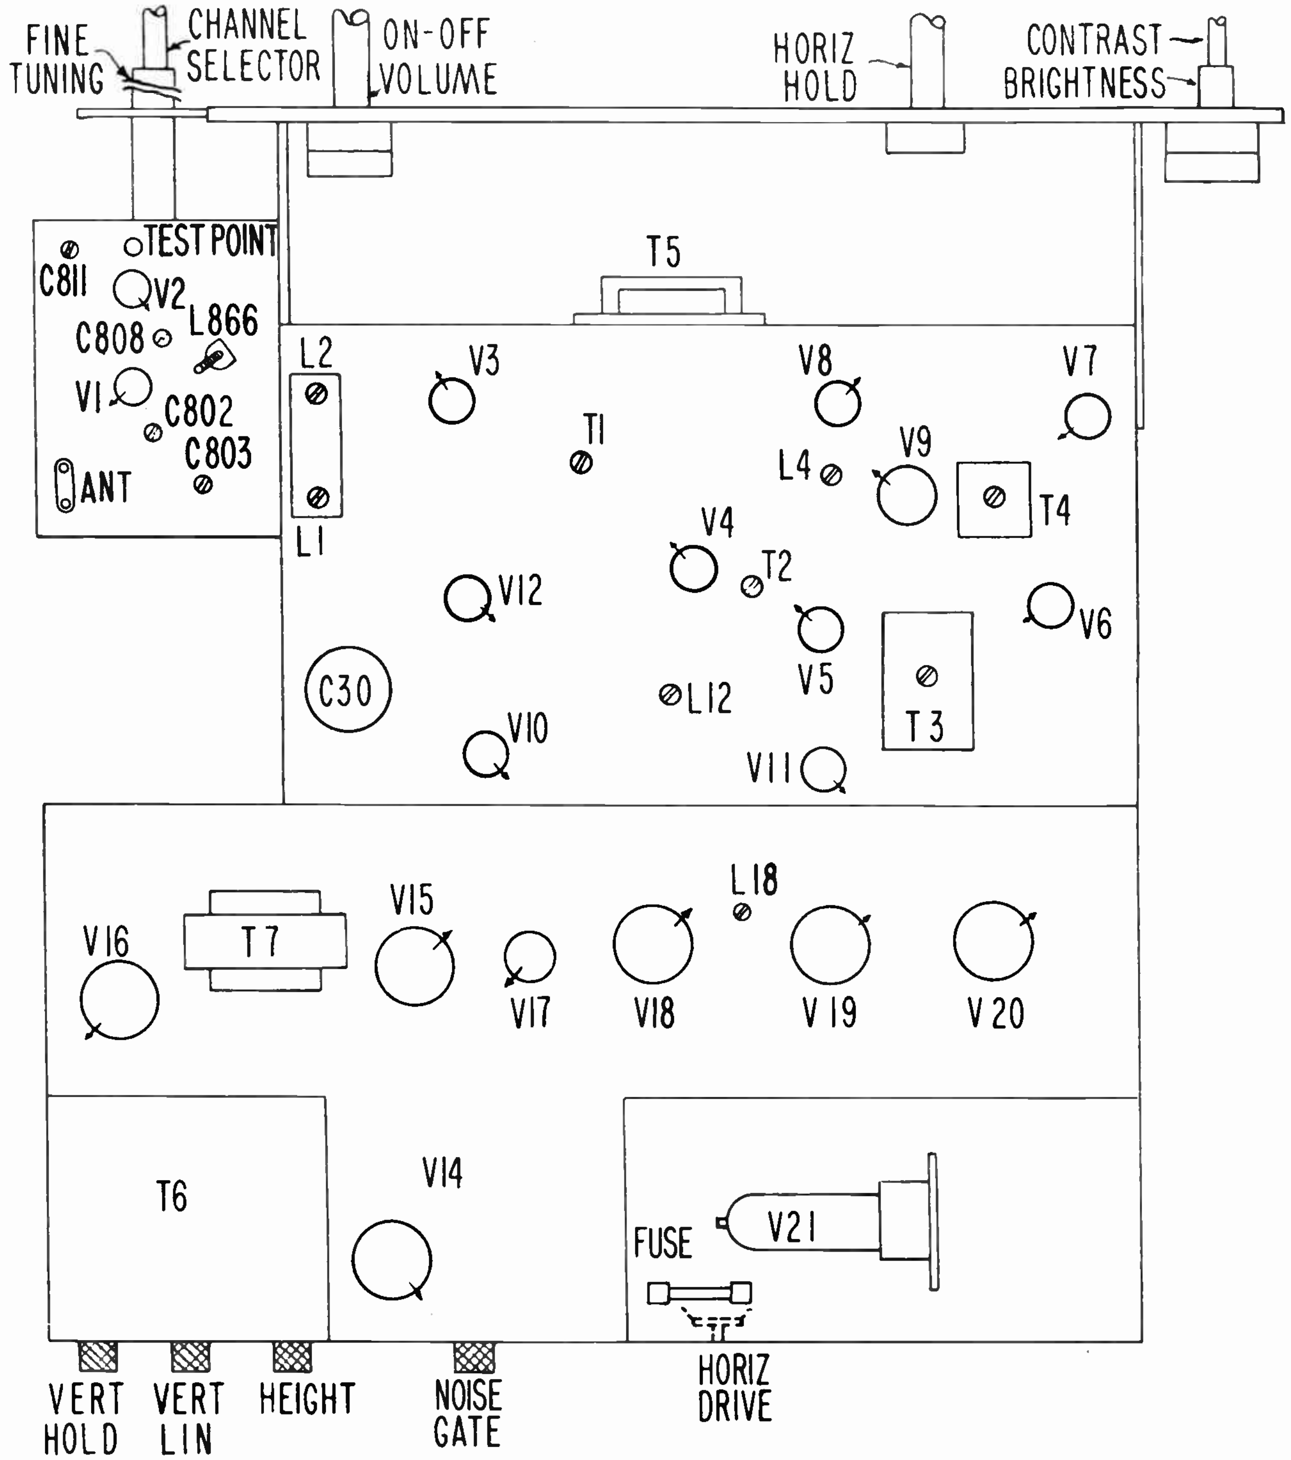

Figure 5

NOISE GATE ADJUSTMENT

NOTE: The noise gate control is adjusted at the factory to give optimum performance under varied conditions. Therefore, only upon rare occasions would any adjustment be necessary. If the receiver is to be operated in an extremely weak signal area where a high noise level is encountered, or this control becomes maladjusted by one means or another it can be satisfactorily set by the following procedure:

– Select and properly tune in the strongest station in the area.

– Turn the contrast control to its maximum position (full clockwise).

– With the noise gate control set at minimum, slowly turn it in the clockwise direction until a slight shifting of the picture in the horizontal plane is observed, then back off (counterclockwise) 1/8 of a turn.

CAUTION: If this control is set too far in the clockwise direction either the receiver will lose sync entirely or an erratic jumping of the picture will be encountered.

HORIZONTAL OSCILLATOR ADJUSTMENT

This adjustment may be satisfactorily performed with any received program signal.

– Set the Horizontal Hold control, R99, at approximately mid-position.

– Set the Contrast control to the normal operating position.

– Adjust the Horizontal Oscillator control, L18, until the diagonal streaks on the screen decrease in number and become erect (picture locks in sync).

The setting obtained by the preceding step may not give optimum range on the Horizontal front panel hold control, therefore, further adjustment by the trial and error method should be performed. When L18 is properly adjusted, the H. Hold control can be slowly rotated to its stops in either direction without losing picture synchronization.

HORIZONTAL DRIVE ADJUSTMENT

CAUTION: Maladjustment of this control may cause unstable Horizontal sync or Horizontal pulling throughout the picture.

– Rotate the selector to an unassigned channel position.

– Turn the contrast control to its extreme counterclockwise position.

– Connect the DC probe of a VTVM to pin #8 of V19 (6BQ6GT).

– Observing the voltmeter reading, turn the horizontal drive control (C70) clockwise not allowing the maximum voltage to exceed 15 volts (on some sets this much voltage may not be obtained).

– The correct setting will be reached by turning the drive control counterclockwise until the rapid voltage drop of approximately 1½ volts suddenly ends. (Further counterclockwise adjusting of the drive control will only cause a slow tapering off in voltage reading).

IMPORTANT: DO NOT adjust for minimum voltage reading. To do so may overdrive the horizontal output stage causing foldover in the picture.

ANTI-PIN CUSHIONING MAGNETS

Pin cushioning is an effect caused by the use of the cosine-deflection yoke and is apparent by the "bowing in" along the edges of the raster. In order to compensate for this condition two anti-pin cushioning magnets have been mounted to the picture tube mounting bracket. For ease of adjustment these magnet brackets are hinged in two places; thus allowing the magnet to be moved either forward or backward at various distances from the picture tube surface. The proper adjustment of each magnet may be observed by moving the raster off center far enough to see the side of the picture that is being straightened.

NOTE: These magnets are properly set at the factory and should require no further adjusting unless a new picture tube is installed.

ION TRAP ADJUSTMENT

Reduce the *contrast* and raise the *brightness* to a point where a blank raster is just visible on the picture tube. Rotate the ion trap while moving it either forward or backward until the *brightest* raster is obtained.

BLOCK DIAGRAM

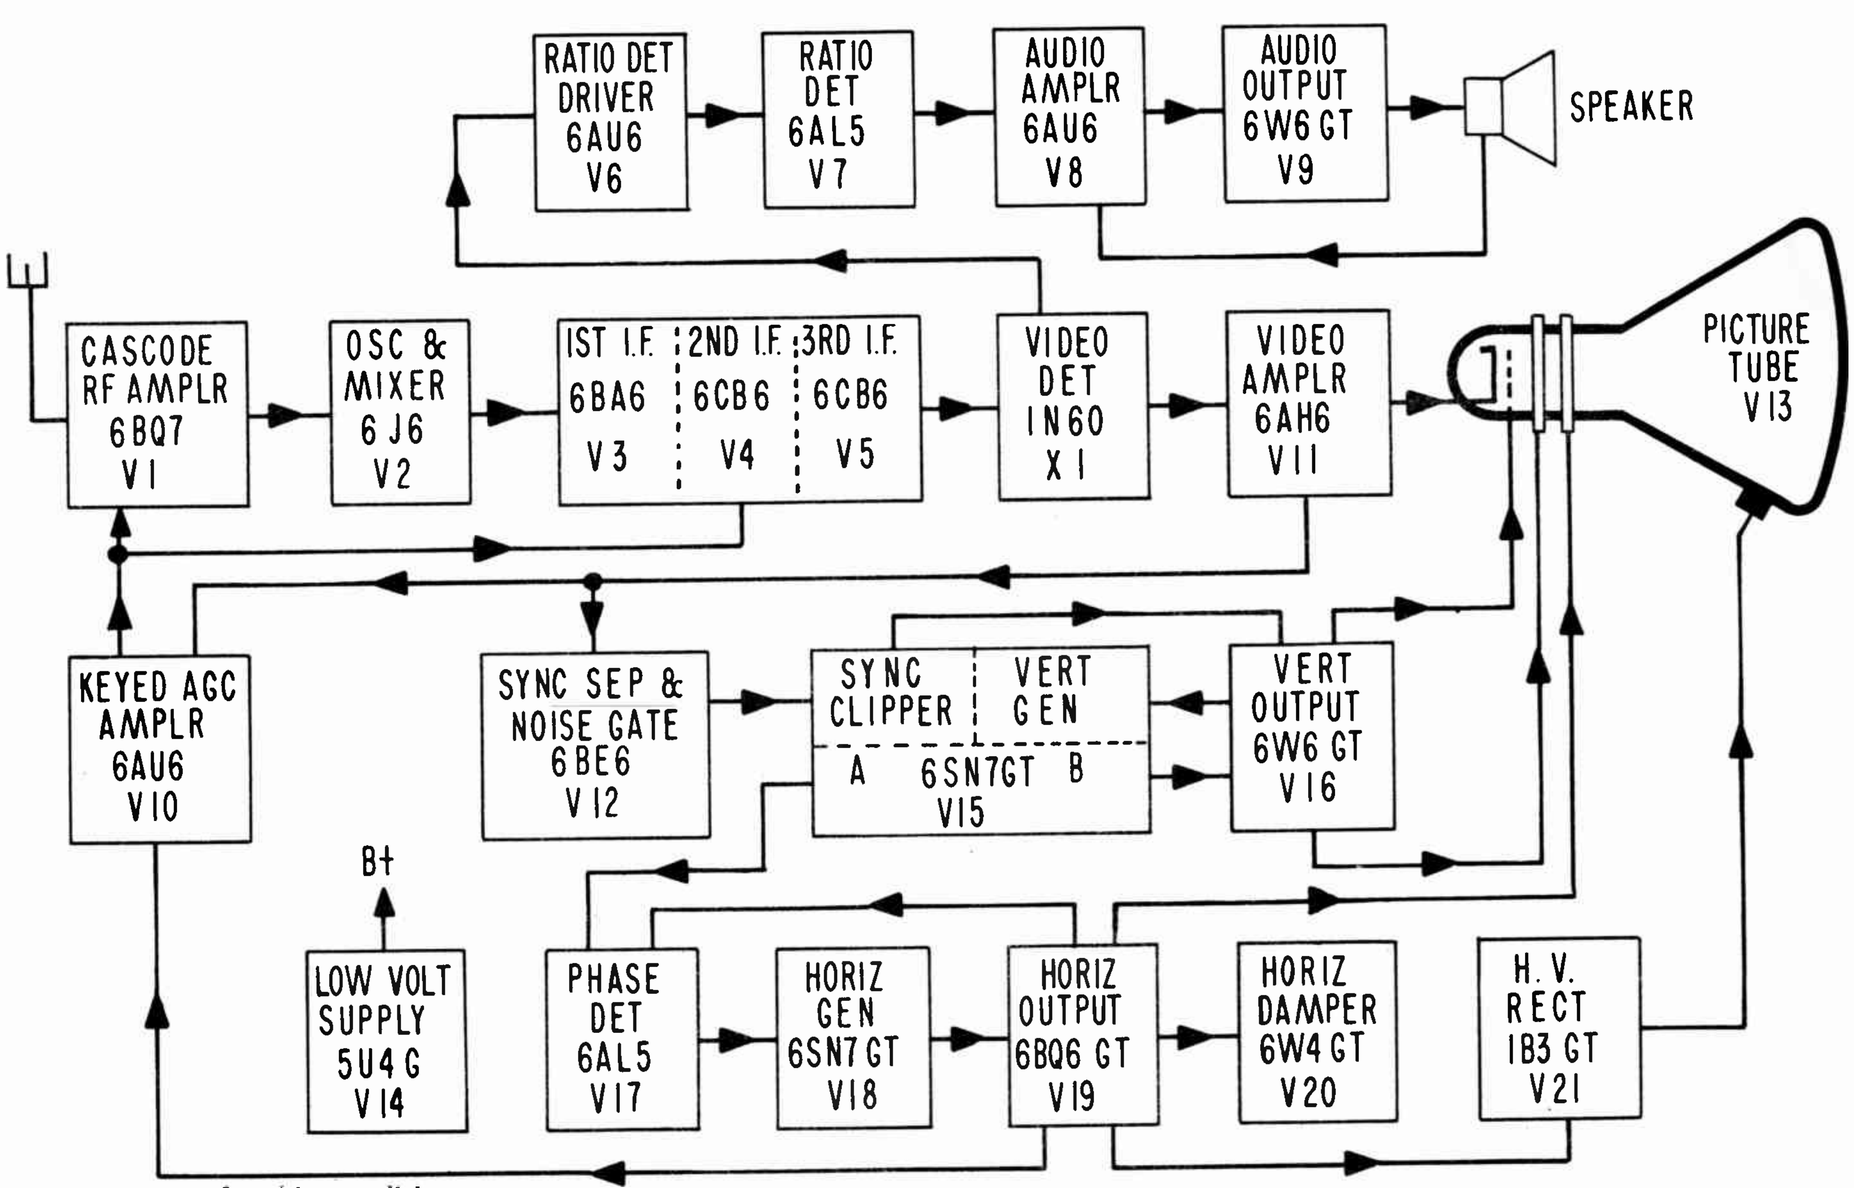

Figure 6

WARNING: It is extremely important that the ion trap be adjusted properly as soon as the set is turned on. A trap even slightly maladjusted can cause severe damage to the CR tube, and this type of damage is not covered by the factory warranty. *NEVER ADJUST THE ION TRAP TO REMOVE SHADOW.*

REMOVAL AND INSTALLATION OF PICTURE TUBE

CAUTION: Be sure the power is off. Wear goggles whenever a picture tube is being handled.

– Place the cabinet face down taking all precautions necessary to keep from marring the finish.

– Remove the high voltage lead from its socket.

– Remove the tube socket from the base of the tube.

– Remove the ion trap from the neck of the tube.

– Loosen and remove the two 1/4″ bolts that hold the yoke and hood assembly to the mounting straps.

– Remove this assembly from the neck of the tube.

– Bend the two straps away from the tube as far as possible.

– Grasp the rim of the picture tube face and gently lift the tube out of its harness. Do not allow the tube to rest on its neck or base, and do not under any circumstances carry or handle the tube by its neck alone.

– To replace the tube, reverse the above procedure paying particular attention to the fact that the two 1/4″ bolts which hold the yoke and hood assembly should be tightened with equal pressure or tightness.

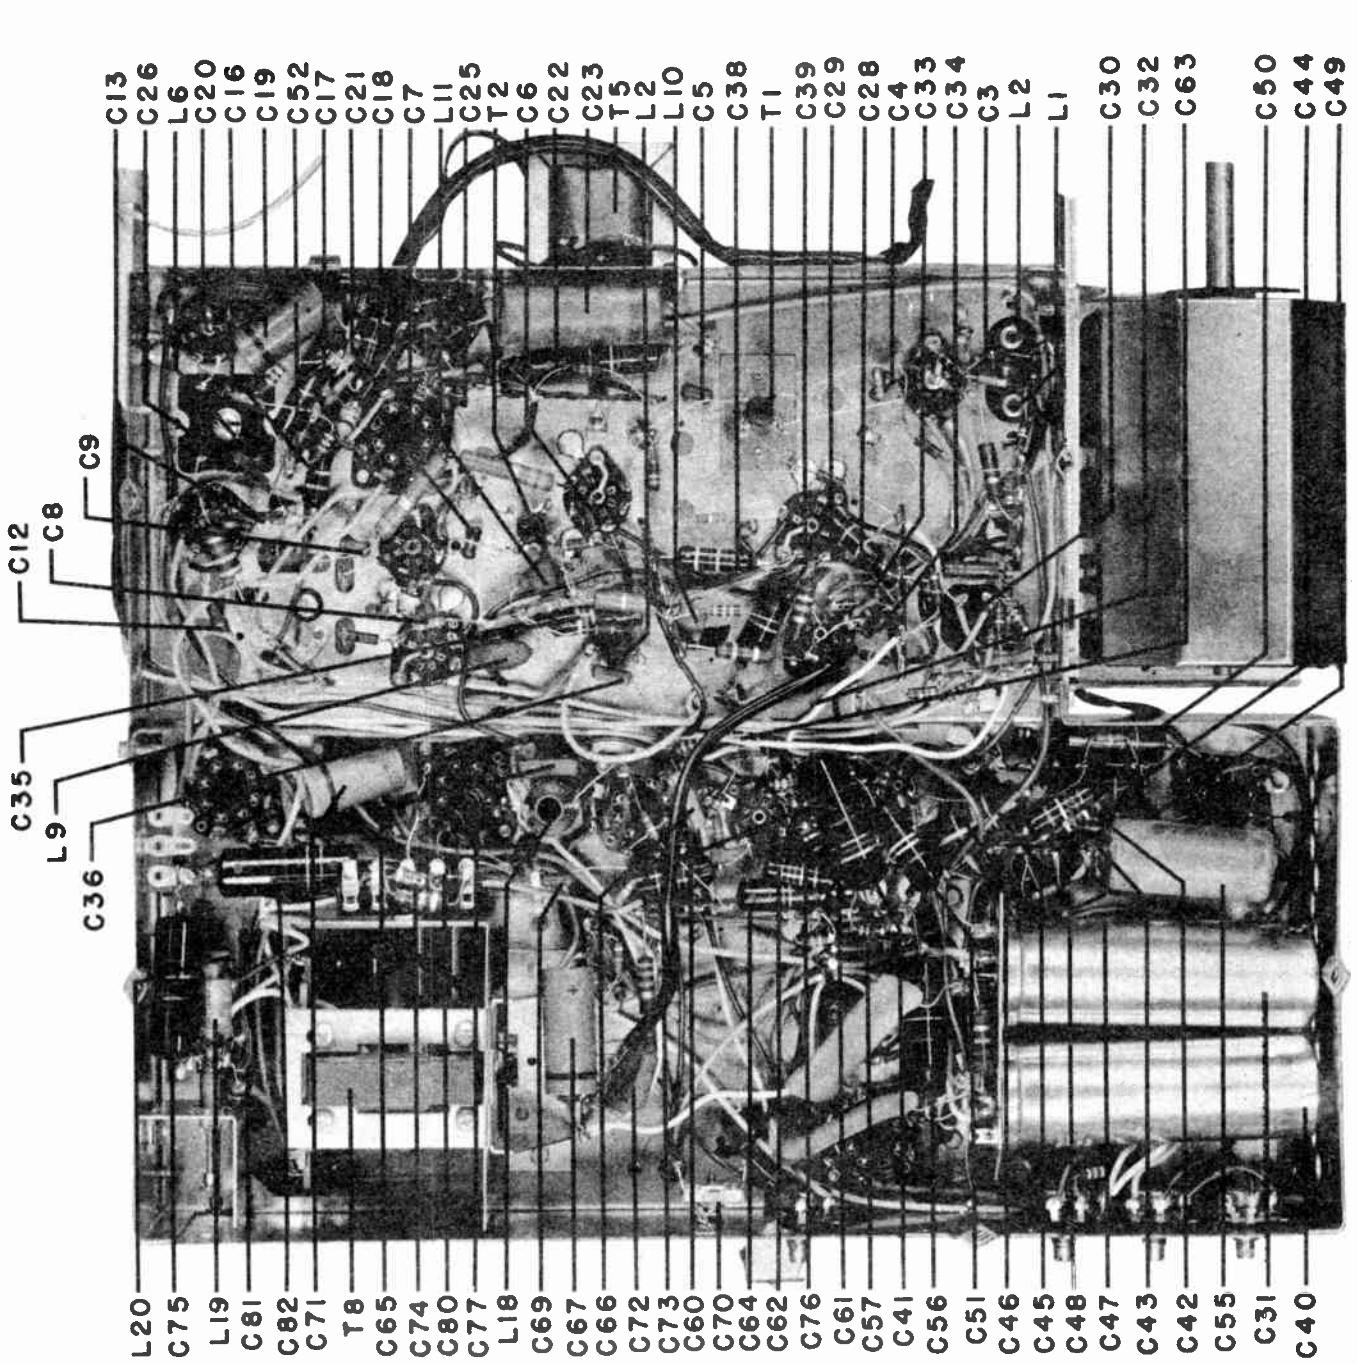

Figure 8

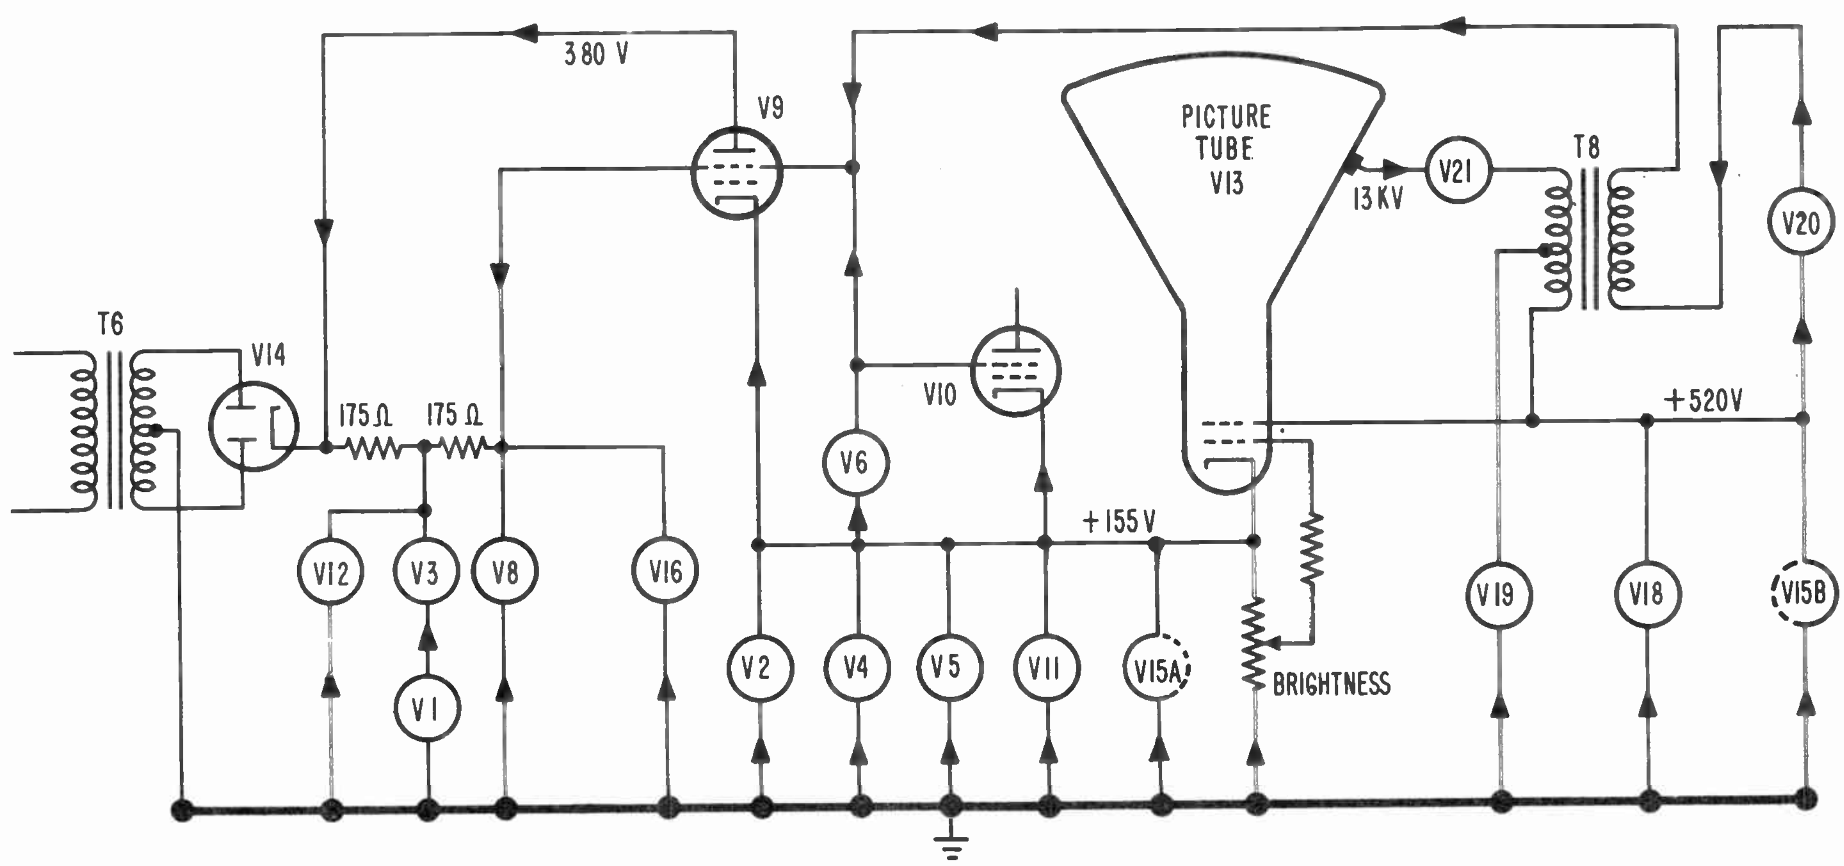
CURRENT DISTRIBUTION DIAGRAM



NOTE: There is no DC voltage applied to V9, V20 or to the plate of V12.

Figure 7

CIRCUIT DESCRIPTION

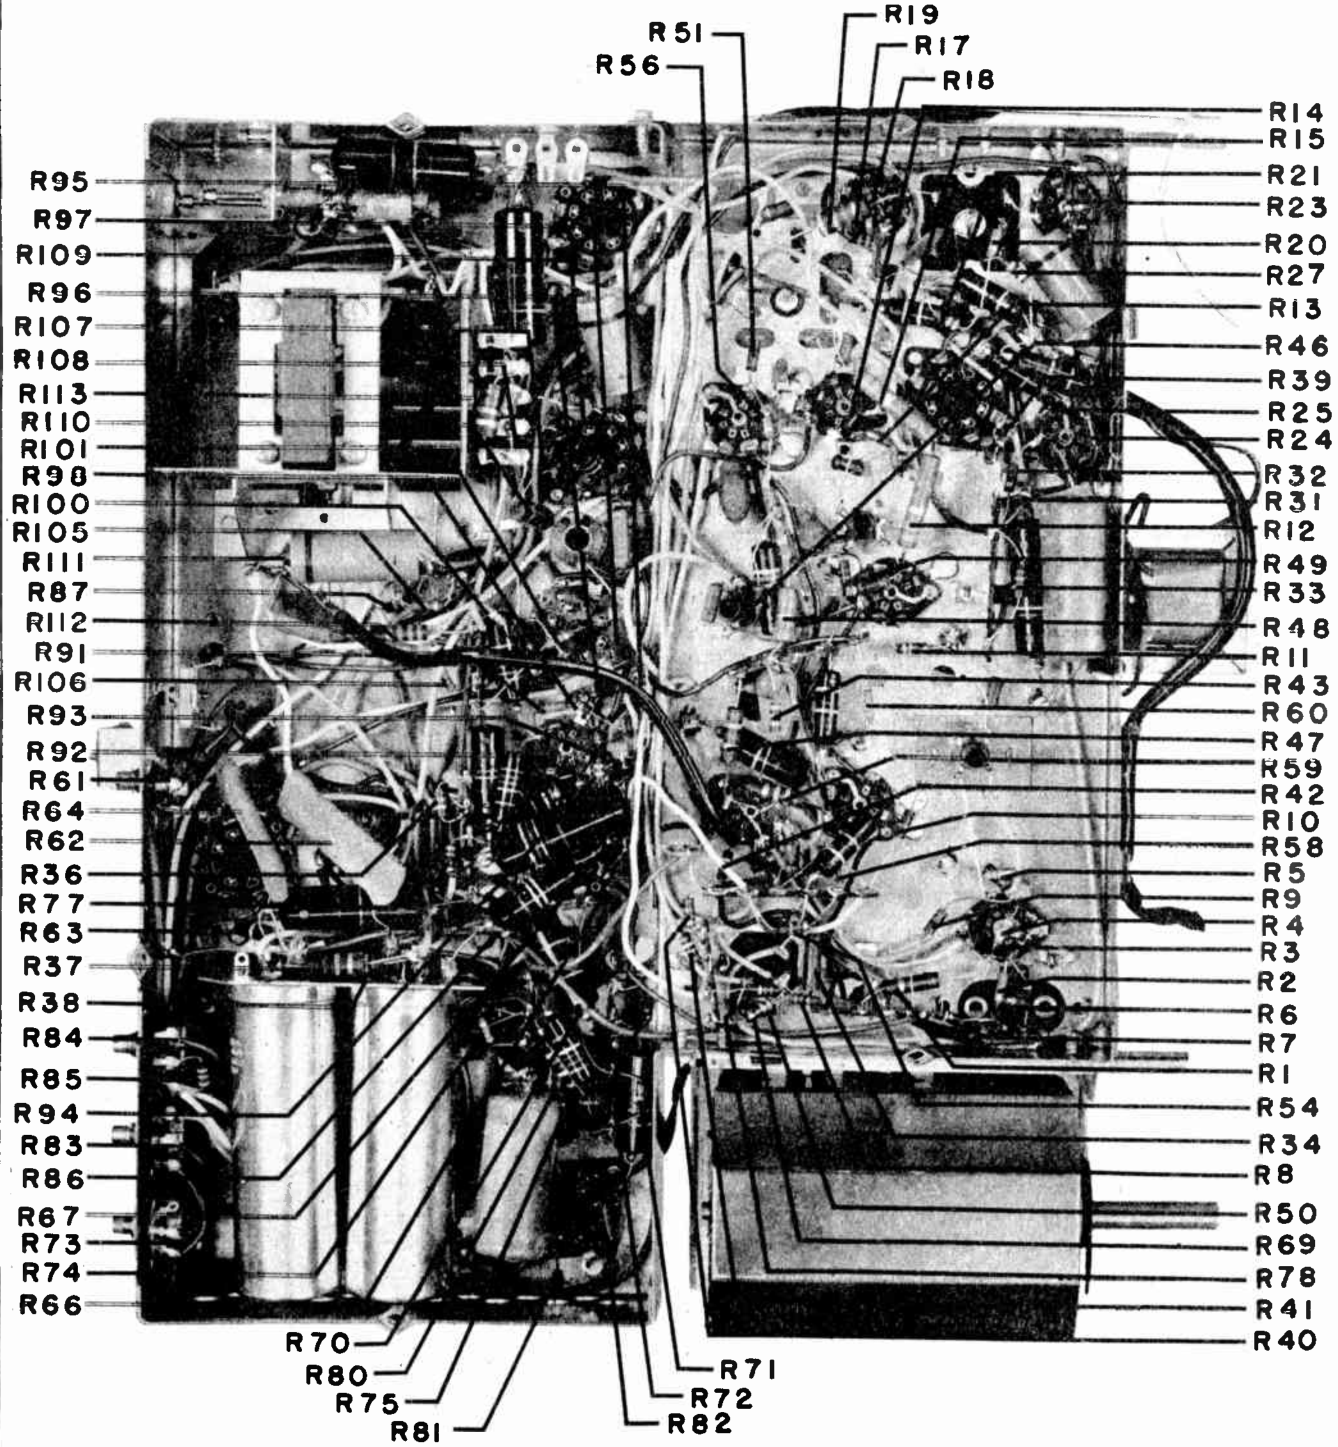


Figure 9

RF SYSTEM

The tuner used in this receiver is a rotary turret type which is made up of separate coil assemblies mounted in a rotating drum. These assemblies are of the snap-in design, therefore can be very readily replaced if and when such a necessity arises. All of the tuning adjustments were made with the aid of a sweep generator in the Bendix factory. Any further adjustment of the tuner in the field is not recommended unless a sweep generator is used and the instructions included under *Alignment Procedure* are followed very carefully. The antenna input circuit is designed to give optimum performance with 300 ohms balanced impedance. The signal is inductively coupled to the input grid of the RF amplifier which is controlled by an AGC voltage.

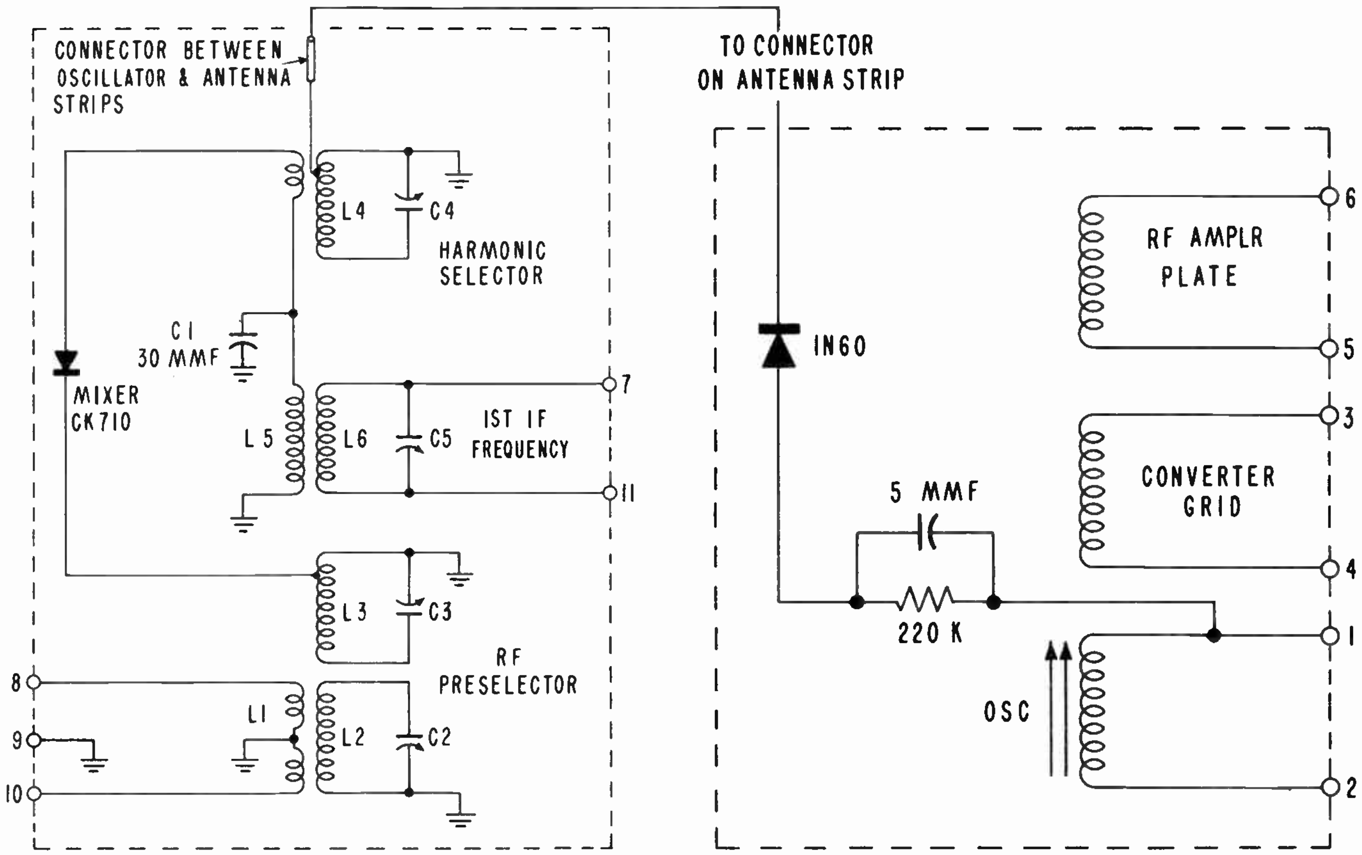
The RF amplifier, V1, is a 6BQ7, twin triode type of tube connected in what is known as a series "Cascode" circuit. In using a circuit of this design the noise figure which accompanies a conventional pentode amplifier has been greatly reduced and yet equivalent gain has been maintained. The input section of the RF stage is connected as a grounded cathode type amplifier. Its output is fed through L827 to the cathode of a grounded grid amplifier – the output section of the RF stage. All of the RF coils are preadjusted and matched to a standard, therefore the only adjustments made available for overall RF alignment are C802, C808 and C811. Two over-coupled tuned circuits couple the plate of the RF amplifier to the grid of the mixer stage, V2, one-half of a 6J6. These circuits are so loaded that the overall response of the RF system is flat over a maximum band width of 11MC, to within 6db of the peak response. R806 connected in series with R807 forms the grid leak resistor for the mixer stage. The test point located at the junction of these two resistors provides a very convenient point for checking a portion of the D.C. voltage developed by the injected oscillator signal and also for connecting an oscilloscope to examine the response characteristic of the RF system with a sweep generator. (A 10,000 ohm resistor should be connected in series with the oscilloscope to avoid adding excessive capacity to the mixer grid circuit.)

The other half of V2 is used in a Colpitts type oscillator circuit. There is an adjustable brass slug assembled in each oscillator coil for ease of correcting its frequency for each channel as it is selected. Inductive coupling is used to inject the oscillator output into the grid of the mixer stage. The DC voltage developed at the test point by the injected oscillator signal should be at least −2.5 volts on all of the channels. C810 and L864 form the neutralizing circuit for the mixer stage. L865 is an RF peaking coil.

The output of the mixer is fed to the first IF amplifier through a band pass double tuned circuit consisting of L866, C822 and L2. This type of circuit accomplishes two purposes – a high degree of oscillator frequency isolation plus optimum transfer of energy. The tunable tank circuit L1 and C2 is used as a sound trap capacitively coupled to the grid of the first IF amplifier. This IF trap reduces the IF gain at the sound carrier frequency approximately 32db, providing satisfactory sound attenuation.

UHF ADAPTION TO THIS SYSTEM

The separate snap-in coil design of this tuner makes it very readily adaptable to UHF reception. The UHF snap-in coils commonly called "strips" are of such design to fit into the turret drum in the same manner as the VHF coils. Therefore an unused VHF position is utilized for UHF reception. The circuitry of these strips is shown in Figure 10. Double conversion is the method used to convert the UHF signal to the 41MC IF frequency of this receiver. The antenna coil L1 is center tapped for a balanced 300 ohms Z input and inductively coupled to the RF preselector circuit. This preselector circuit consists of two separately tuned tank circuits L2, C2 and L3, C3 which are inductively coupled to one another and pretuned to the designated channel frequency. This type of circuit is used to insure a high degree of signal selectivity to the crystal mixer CK710. The signal required for the first conversion of the received UHF is obtained from the VHF local oscillator. In order to insure that the local oscillator's output is rich enough in harmonics to produce the necessary signal, a IN60 is employed as a harmonic generator. This output is fed to the Harmonic Selector Circuit L4 and C4. A predetermined harmonic of the local oscillator selected by this tuned tank circuit is fed to the crystal mixer so as to produce in L5 the signal titled 1st IF frequency. This signal is inductivity coupled into the input section of the 6BQ7 cascode RF amplifier. Since the signal is now in the VHF region, it is amplified and converted in the tuner just as if it were received at the antenna as a VHF station. The circuitry which has just been discussed is mounted on the strip which snaps into this antenna coil section of the removed VHF strips. The oscillator section of the UHF strips appears to be very similar in construction to the VHF strip, with the addition of the harmonic generator circuit.



UHF Antenna Strip

Figure 10

UHF Osc. and Converter Strip

IF SYSTEM

Four stagger-tuned circuits employing one 6BA6 and two 6CB6 tubes along with a crystal detector comprises the interstage IF amplifier system. Three of the IF transformers used in this system are of the Bifilar wound type – two windings interwound on a single form. A winding of this type approximates unity coupling and yet tunes as readily as a single tuned coil. The following advantages are derived from such an assembly. Improved filtering of all plate and grid returns can be achieved because the bypass condensers are returned to the same ground as their associated cathode thus eliminating circulating ground currents. It is also possible to keep the time constant in the grid circuit of each amplifier to a very low value therefore minimizing the possibility of a charge building up on the grids of these stages during heavy noise pick up. This latter advantage permits the IF system to operate at optimum performance at all times. Unbypassed cathode resistors are used in the first two stages to reduce the variations of input capacity with AGC voltage changes. Within this IF strip there is a case of voltage cascading which means that two or more tubes are connected in what may be termed as "plate current series" with one another. This hook-up involves the first IF (V3) and the RF amplifier (V1). In such an arrangement the tube at the top of the line-up has applied to its plate approximately the maximum voltage available and is biased so that the voltage drop across it is sufficient to reduce the voltage at its cathode to a value that is proper for operating the next stage. This continues to happen right on down the line until the tube at the bottom of the string has its cathode D.C. connected to ground. A hook-up of this kind consumes less power due to the fact that the tubes at the top of the string are effectively used as the plate load resistor for the pursuing stage, therefore the dissipation that normally takes place across a load resistor is utilized for amplification. This IF system has been designed to provide an overall response curve which is flat topped with a nominal band width of 3.5MC 6db down from peak response. The IF output is fed into the video detector can T3 which encases the third IF amplifier plate transformer, sound take off coil, the crystal video detector IN60, and its associated peaking coils necessary to extend the frequency response to the desired band width.

Various test points have been indicated on the schematic diagram in order to facilitate the making of checks on the operation of the IF system. One is located in the AGC string at the junction of R40 and R41 while another is located at the junction of R40 and R42. These two points have been made available from the top of the chassis for checking developed AGC voltage and for applying bias potentials when making sweep tests on the RF or IF systems. Another test point "C" has been designated at the grid of the video amplifier V11. This point may be used for connecting a VTVM when measuring the voltage developed by the crystal detector during alignment with a CW signal, and it may also be used for applying a 4.5MC signal with which to align the sound IF's and ratio detector transformer.

SOUND SECTION

Intercarrier sound reproduction is used. By this method both the picture and sound carriers are amplified by the same IF amplifiers and beat together in the Video Detector, giving a 4.5MC frequency modulated signal that is fed to the Ratio Detector Driver V6. The 4.5 megacycle beat is constant since it is always the fixed difference between the video and sound carriers coming from the TV station. Therefore, the sound will not be effected by any normal oscillator drift, since both the video and sound carriers will drift equal amounts making the difference always 4.5MC. This 4.5MC signal is captured by a high impedance tank circuit, L5 and its distributed capacity located inside of the video detector can, and applied to the ratio detector driver V6 through C12. V6 as its name implies amplifies and drives the Ratio Detector hard enough to produce a charge on C19 great enough in amplitude to render V7 inoperative to an amplitude modulated signal of short duration. The Ratio Detector V7 is of conventional design. R20, a 180 ohms resistor, in series with the coupling link of the detector transformer T4 stabilizes the impedance presented by the diodes. If this resistor were omitted, the variation in impedance between individual tubes would cause the AM rejection to vary between receivers.

The output of the Detector is amplified in V8 first audio stage and then directly coupled to the grid of the audio output tube V9. This DC coupling is possible and necessary because V9 plays an intricate part in the voltage regulating system. (See Current Distribution Diagram)

About 10db of negative feedback is provided by R39 which is connected between the secondary of the audio output transformer and the cathode of the first audio amplifier V8 to reduce output distortion.

VIDEO AMPLIFIER

The Video amplifier is a 6AH6, with the associated wide band, low pass filters. The output of the crystal detector is DC connected to the grid of the Video amplifier through a filter circuit comprising a series (L3) and a shunt (L4) peaking coil. L11 is a shunt plate peaking coil used to extend the frequency response of the Video amplifier to its desired band width and compensate for any incurred phase shift. The response of the Video system is flat to 1MC and down 3db at 3.8MC.

The contrast is controlled by changing the amount of degeneration in the Video amplifier. This is accomplished by varying the control R35 in the cathode circuit. The video stage gain is 34db measured at 100KC with the contrast control set at maximum.

No DC restoration is necessary at the output of the Video amplifier because the entire Video amplifier is direct coupled from the output of the crystal detector to the cathode of the picture tube. Therefore, the rectified video signal does not vary about an AC axis.

Notice that the polarity of the detector is such that a negative signal is applied to the grid of the Video amplifier, resulting in a positive video signal at the plate which is applied directly to the cathode of the picture tube.

KEYED AGC

V10 is the AGC amplifier whose function is to keep the sensitivity automatically adjusted in accordance with the strength of the received signal. This is accomplished by the negative voltage which is developed at the plate of V10 and applied to the grids of the RF and IF amplifiers.

The plate voltage for this circuit is a positive pulse taken from terminal 8 of the horizontal output transformer T8. This pulse is developed by the collapsing of the field in the horizontal deflection coils and its duration is about 5% of the horizontal period. Plate current can flow only during this pulse and is controlled by the amplitude of the sync pulse being applied to the grid. The grid is DC connected to the video amplifier output at the junction of R45 and R48. Therefore, the bias level for V10 is a function of the video amplifier plate current. The AGC cathode potential is +150 volts, taken from the source which also supplies the plate and screen of V11. The screen potential is approximately 300 volts, thus maintaining the required potential difference with respect to the cathode. The screen and plate voltages are approximately the same at the time the pulse occurs.

When current flows in the plate circuit of V10 it will develop a negative voltage across resistors R40, R41 and R42. This voltage is filtered by the RC network R40, R41 and C32 to rid it of the horizontal frequency component (15,750cps). Therefore, the time constant required to filter frequencies of this kind can be made very small as compared to the time constant used in conventional AGC systems, which had to filter out a 60 cycle component. The control voltage for the 2nd IF stage is taken from the junc ion of the dividing network, R40 and R41. The control voltage for the RF amplifier and 1st IF stage is taken from the junction of R40 and R42. The reason why bias on V3 can be controlled merely by applying AGC voltage to V1 is because these two tubes are connected in plate current series with one another. In order to increase the effect that this AGC voltage has upon the 1st IF amplifier, it has been shunted by a 470K resistor R4. The manner in which R4 aids this condition is, as the impedance of V3 increases, R4 passes more and more of V1's plate current, therefore effectively reducing the gain in V3 to a much greater extent than in V1.

The keyed AGC system has good noise immunity because its duty cycle is only about 5% of the total time, and any noise pulses occurring during the other 95% of the time do not affect its operation. The developed AGC voltage is a function of sync pulse amplitude only and is not effected by picture content. Hence, the AGC action can be made fast, practically eliminating the flutter caused by airplanes.

SYNC SEPARATOR & NOISE GATE

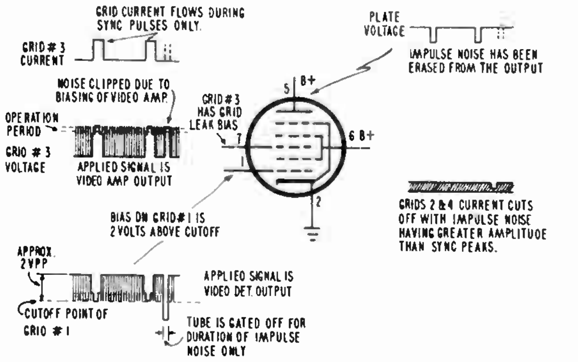
This circuit just as its name implies performs two important functions. It separates the sync pulses from the composite video signal and erases all effects of noise pulses which are greater in amplitude than the incoming sync pulses. The manner in which this pentagrid tube accomplishes its purpose can best be portrayed by following the composite signal accompanied by impulse noise through this stage (see Figure 11). Without a signal the plate current of V12 is cut off due to the negative bias on grid #3, while at the same time a positive bias on grid #1 is allowing grids #2 and #4 which are tied together, to draw maximum current. R61 controls the amount of positive bias being placed on grid #1 which determines at what point the tube will gate off. The negative output of the video detector is being applied to grid #1 as well as to the video amplifier V11. Since V11 has a gain of about 20 the inverted or positive signal which is being coupled through C38 to grid #3 of V12 is of a much greater amplitude than that of the signal being impressed upon grid #1. It can be seen that during normal operation this tube has a negative signal on grid #1 and a positive signal on grid #3. As long as the amplitude of the noise pulses is not greater in amplitude than sync tips, the positive bias on grid #1 is not overcome. Therefore, each sync pulse appearing at grid #3 drives it sufficiently positive to overcome its bias and allow plate current to flow. The presence of noise pulses having greater amplitude than sync peaks drive grid #1 beyond cutoff, preventing the tube from amplifying the noise which would otherwise pass on to the sync circuits. The tube remains in this cutoff condition only for the duration of the impulse noise. This composite characteristic of the noise – immune sync separator shows how the amplitude of the signal at the video detector determines whether or not the pulse is suppressed or amplified.

SYNC SEPARATION

Complete separation of the horizontal and vertical sync pulses from the video composite signal is accomplished in V12 a 6BE6 and V15A 1/2 6SN7 GT.

The manner in which V12 aids in this operation has been presented in the preceding paragraph titled sync separator and noise gate.

The output of V12 consisting entirely of sync pulses wiped clean of all video information, is applied to a triode sync clipper stage V15A. This signal which is now of a negative polarity must be inverted as well as further clipped to insure proper operation of the vertical and horizontal sync circuits. Since the amplitude of these pulses are sufficiently strong to drive V15A into cutoff, the signal is further clipped. The result provides a more constant, flat topped sync pulse with which to control the sweep oscillators.



Detailed Illustration of Noise Gate Operation using either the 6BE6 or 6C56

Figure 11

THE VERTICAL DEFLECTION SYSTEM

The vertical deflection system consists of a free-running multivibrator (V15B and V16) which is locked into synchronism by the vertical integrated sync pulse. The output of the multivibrator (V16) is fed to the vertical output transformer (T7), and then to the vertical deflection coils (L14), (L15) without the use of further amplification. The coupling network consisting of R74, R75, C47 and C48 is used between the two sections of the multivibrator to filter out any 15 KC horizontal pulses that may get through the integrating network, thus improving the interlace.

For a discussion of the circuit operation, it will be assumed that no triggering pulses are present. Following this, the triggering pulses will be added and their effect upon the operation discussed.

For any linear magnetic deflection system, the waveform of voltage which must be present across the deflection coils (L14, L15) is as shown in Figure 12, where A is the trace time and B is the retrace time.

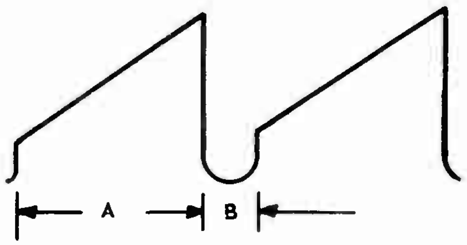


Figure 12

The procedure for obtaining this waveform is as follows:

If the circuit is thought of as starting from a static condition where V15B and V16 are conducting, it can be seen from the schematic diagram, that the circuit is very unstable and will readily break into oscillation. If V16 should have a slight increase in plate current, due to "shot effect," "thermal agitation," or any of many possible reasons, its plate voltage would decrease, driving the grid of V15B in a negative direction. This would, in turn, decrease the plate current of V15B, causing the plate voltage to increase. Under these circumstances the grid of V16 would swing in a positive direction, further increasing the plate current. The process is cumulative and V15B is almost instantaneously driven into cutoff. The period of cutoff for V15B is determined by the time constant of the coupling network. When the charge of C46 decreases sufficiently, V15B starts to conduct and V16 is driven almost instantly to cutoff. The circuit will remain in this condition just long enough for the grid current flowing in V15B to charge C46 sufficiently negative to again cut off this section of the multivibrator. Then V16 begins to conduct and the cycle is repeated. The time constant is so adjusted that the waveform from grid of V15B to ground appears as in Figure 13. During the period of time that V15B is cut off, the waveform at the plate of V15B tries to rise to the B+ voltage, but C45 and R72 form an integrating circuit which causes the plate voltage waveform to appear as shown in Figure 14. The waveform of

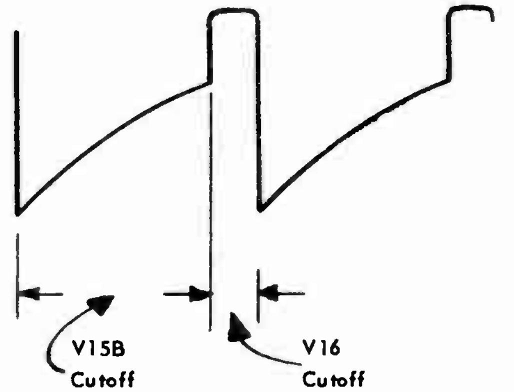

Figure 13

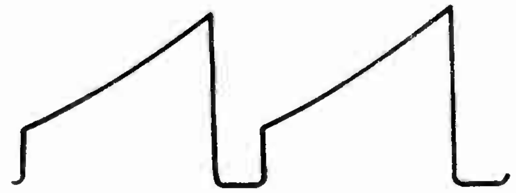

Figure 14

Figure 14 is fed to the grid of V16 which is conducting and capable of amplifying during the trace time. The waveform appearing between the plate of V16 and ground is shown in Figure 15. The waveform appearing between V15B plate and B+ is shown in Figure 16. This is the desired waveform as shown in Figure 12 for the voltage appearing across the deflection coils (L14, L15). The effect of the synchronizing pulses can now be discussed.

The sync pulses appear at the grid of V16

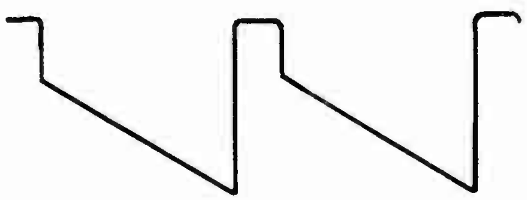

Figure 15

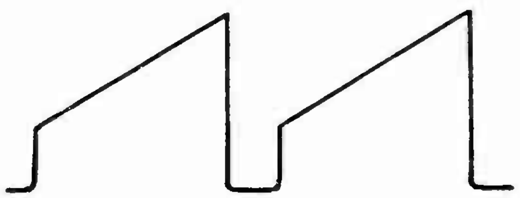

Figure 16

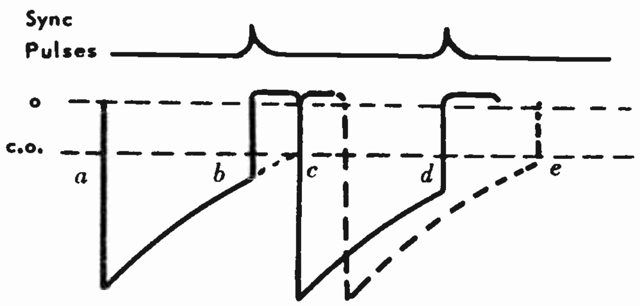

Figure 17

with a negative polarity. They are amplified by V16 and sent to the grid of V15B as positive pulses. The effect is shown in Figure 17 which represents the voltage waveform appearing at the grid of V15B. Without sync pulses V15B would start to conduct at c and e in their respective cycles, but with the sync pulses the grid is driven far enough positive at b and d to cause V15B to conduct and thereby lock the sweep in step with the sync pulses. Vertical hold is obtained by varying R73 which in turn varies the unsynchronized cutoff period of V15B. When R73 is increased the cutoff period is increased and vice-versa. See Figure 18. With the sync pulses as shown in Figure 18, no sync action will occur if R73 is made too large. On the other hand, if R73 is made sufficiently small sync action will take place on every other cycle. This explains why erratic operation is encountered with *too little* "hold," while a double image is sometimes observed with *too much* "hold."

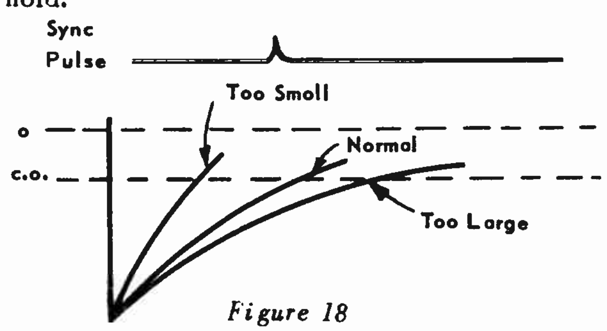

Figure 18

The multivibrator employs a coupling circuit between V15B and V16 consisting of two RC networks in cascade, instead of the usual single RC network. This system makes the vertical sweep circuit much less likely to be triggered by noise and much more smoothly triggered by the sync pulses. The use of cascade coupling causes the grid voltage curve of V15B to cross the cutoff voltage line at a much steeper angle than it would with a single coupling circuit. See Figure 19. It will be observed that R75 and R80 are effectively across the vertical deflection coils (L14, L15) and in conjunction with R89 and R90 provide the dampening action across the deflection coils during the retrace period. Height is controlled by varying the plate load resistance (R84) of V15B, which in turn varies the magnitude of the waveform which is fed to

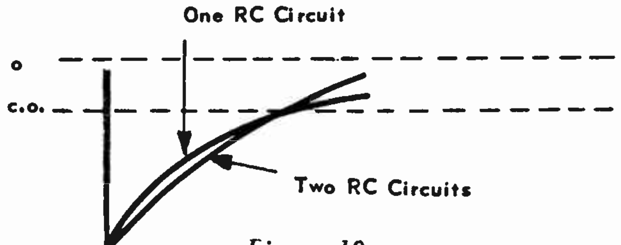

Figure 19

V16. Vertical linearity control, R83, varies the bias of V16, shifting the operating point of the tube up and down its dynamic curve.

NOTE: Vertical height, linearity and hold controls all interact one upon the other. Therefore, it may be necessary to adjust these controls simultaneously for the best test pattern.

HORIZONTAL SWEEP SYSTEM

The horizontal sweep system consists of a multivibrator (V18) coupled to a horizontal output tube (V19) which drives the horizontal deflection coils (L16, L17). The phase detector tube (V17) is used to synchronize the multivibrator. The horizontal generator employs a 6SN7GT tube as a multivibrator, whose frequency is controlled by the L, R and C in the circuit. The amount of charge placed on C66 will determine the multivibrator frequency. The synchronizing system used to lock the oscillator in step with the synchronizing pulses employs a 6AL5 (V17) as a balanced phase detector.

The operation of the multivibrator and associated circuits will be discussed first of all in the completely unsynchronized state. This condition would exist if V17 was removed from the circuit. The operation will then be discussed in a synchronized state.

UNSYNCHRONIZED STATE

The multivibrator used in the horizontal sweep system is of the cathode coupled type. Feedback between unit 1 and unit 2 is accomplished through coupling condenser C66 and the unbypassed cathode resistor R96 which is common to both sections. Now let us apply power to this circuit and follow the chain of reactions as they take place. Any disturbance within the circuit could very likely cause an increase in the plate current of V18B, which in turn will increase the voltage at the top of the common cathode resistor R96. In an unsynchronized condition the bias on V18A can be thought of as being fixed, therefore a substantial increase in cathode voltage will drive the unit into plate current cutoff. Since both units commence conducting upon the application of voltage, this cutoff point of V18A is reached very rapidly. When the cathode voltage cuts-off this unit, the plate voltage immediately climbs toward the voltage level of its source forming a very steep wave front. C66 couples this positive wave front to the grid of V18B causing the plate current to flow freely offering a very low impedance discharge path for the voltage which has built up on C68. In fact, the grid of Unit #2, due to the positive pulse coupled through C66, is driven sufficiently positive to make it draw current. This grid current is being drawn through R98 and R99 consequently building up a negative charge on the grid side of C66 to proportions that will cut off conduction within V18B. With V18B cut off the voltage at the top of R96 will drop to a level that will allow V18A to start drawing current. Its plate voltage will then drop sharply applying the developed negative wave front through C66 to the grid of Unit #2, pushing it even more negative than it was when first cutting-off this section. V18 remains in this condition, that is – Unit #1 drawing current and Unit #2 cutoff, until the negative charge on C66 drains off through R98 and R99. The time required for this negative charge to become small enough to allow V18B to conduct again is determined by the RC time constant of the circuit and has been designed to be approximately 15750 cycles per second. Consequently when this point is reached the first cycle will be completed only to be repeated.

The frequency of this multivibrator is controlled by two separate circuits. One is an RC circuit consisting of R98, R99 (Hor. Hold Control) and C66 while the other is a LC circuit made up of L18 (Hor. Osc. Adjustment) and C65. The latter one is a tank circuit which should be tuned to be resonant at approximately 15750 CPS in order to aid in keeping the multivibrator oscillating at the correct frequency. How the RC circuit fits into the picture was discussed in the previous paragraph.

In order to produce the necessary current flow in the horizontal deflection yoke a sawtooth voltage must be applied to the grid of the horizontal output tube. An RC circuit comprised of R106, a 5600 ohm resistor and C68, a 330 uuf condenser is used to properly shape the voltage in this case. This sawtooth voltage is amplified by V19 (6BQ6) and since the primary of the high voltage transformer is its plate load, produces a sawtooth current which is fed to the horizontal deflection coils, L16 and L17. From pin 7 of the high voltage transformer (T8) a negative pulse is coupled through C80 to the unbypassed screen of V19 driving it down toward its normal B+ voltage, thus allowing the horizontal output tube to draw current much sooner than it normally would. This measure tends to smooth out any oscillation or ringing effect not entirely eliminated by the horizontal damper tube, V20.

OPERATION WITH SYNCHRONIZATION

The Phase Detector (V17) provides automatic frequency control for the horizontal oscillator (V18). This is accomplished by comparing the phase of two different waveforms: the incoming horizontal sync pulse and a pulse taken from the horizontal output transformer. The first waveform is made up of sync pulses, approximately equal in amplitude, taken from the plate and cathode of V15A. See Figure 20 (a and b).

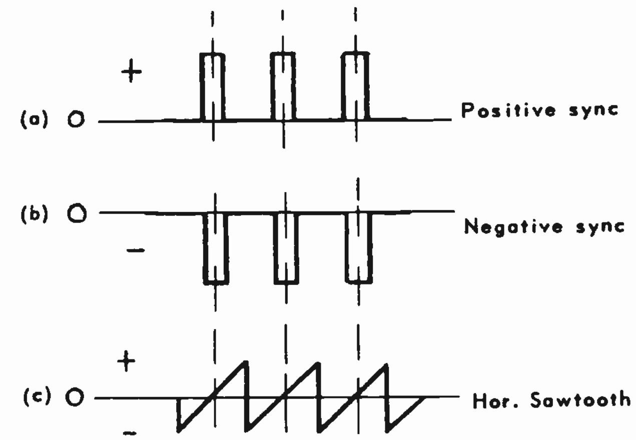

Figure 20

They are coupled through C60 and C61 to pins 5 and 7 respectively of V17. The second waveform consists of a positive component from terminal 8 and a negative component from terminal 7 of the horizontal output transformer. Capacitor C74 along with the network R102 and R77 shifts the phase of these two components to the correct operating point and the integrating network of C62 and R91 gives the correct sawtooth waveform revolving around a zero axis. The sawtooth voltage thus developed is both positive and negative, and is applied to pins 1 and 2 of the phase detector tube (V17). See Figure 20 (c).

The sync pulses and the sawtooth waveform are superimposed on each other in the phase detector. The amplitude of each sync pulse and the sawtooth wave remain the same, but any phase shift between the two will cause a variation in the DC voltage developed at the junction of R92 and R93.

When both the horizontal oscillator and incoming sync are at the same frequency, they are properly phased and the amplitudes of the waveform in each section of the phase detector are equal. See Figure 21 (a). Each diode, therefore, conducts equally and the DC voltages across the two load resistors, R92 and R93, are equal but opposite in polarity. The voltage developed at the junction of these resistors is therefore zero. Since the output is zero, no change in grid bias takes place and there is no change in the oscillator frequency.

If the horizontal oscillator is *higher* in frequency than the incoming sync pulse, the sawtooth voltage being applied to pins 1 and 2 of V17 will be in the positive portion of its cycle by the time the sync pulses arrive on pins 5 and

7. See Figure 21 (b). This places a negative sync pulse on pin 5, equal amounts of positive sawtooth voltage on pins 1 and 2 and a positive sync pulse on pin 7, allowing more current to flow through the pin 2 and 5 section of V17. The result of this is a positive voltage at the junction of R92 and R93, [see Figure 22 (a)] which makes the grid (pin 1 of V18) more positive and slows down the oscillator frequency.

If the horizontal oscillator is lower in frequency than the incoming sync pulse, the sawtooth voltage being applied to pins 1 and 2 of V17 will now be in the negative portion of its cycle at the time the sync pulses arrive on pins 5 and 7. See Figure 21 (c). This places a negative voltage on pins 1 and 2, instead of the positive potential that was there in the previous condition, and more current will flow through the pin 1 and 7 section of the diode. The voltage developed at the junction of R92 and R93 will now be at a negative potential, [see Figure 22 (b)], making the grid (pin 1 of V18) more negative and *speeding up* the oscillator frequency. R94 provides a DC return for the grid of V18 in the event V17 should fail or be removed from the socket.

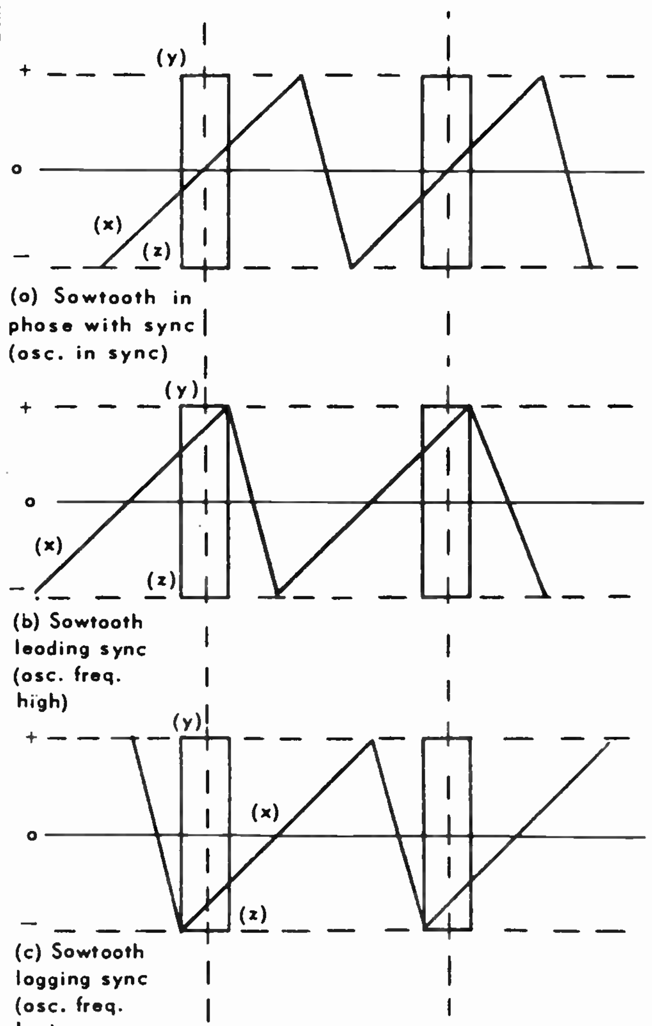

Figure 21

POWER SUPPLY

A transformer power supply is used. The transformer T6 steps up the voltage in its secondary to about 350V AC. This AC voltage is rectified by a 5U4G (V14) and applied to a capacitive input filter network which aids in placing approximately 370V DC on the plate of V9. V9 and V10 are connected in series with several of the other amplifiers serving as voltage regulators. This particular application is carried out in the following manner: when the current through these amplifiers change, the cathode voltage on V9 and V10 varies accordingly. This causes the impedance of these tubes to change, maintaining a fairly constant voltage drop across them at all times.

NOTE: There is no DC voltage applied to V7, V17 or to the plate of V10 from the low voltage power supply.

T17 CHASSIS ACCOMODATES 21" TUBE
T17–1 CHASSIS ACCOMODATES 17" TUBE

NOTES:

1. ALL RESISTORS ARE 1/2W WITH VALUES IN OHMS UNLESS OTHERWISE NOTED. K = 1,000 OHMS MEG = MEG OHMS
2. ALL CAPACITORS ARE IN MMF UNLESS OTHERWISE NOTED. MFD = MICROFARAD
3. HEAVY LINES INDICATE SIGNAL PATH, ARROWS INDICATE DIRECTIONS.
4. VOLTAGES MEASURED WITH VACUUM TUBE VOLTMETER. VOLUME, CONTRAST AND BRIGHTNESS CONTROLS SET AT MINIMUM, ALL OTHER CONTROLS IN NORMAL OPERATING POSITIONS. ANTENNA TERMINALS SHORTED AND CHANNEL SELECTOR SET AT AN UNUSED CHANNEL.
5. WAVEFORMS TAKEN AND PEAK TO PEAK VOLTAGES MEASURED WITH A 5 MC BANDWIDTH OSCILLOSCOPE. (TEKTRONIX)

The Bogen Broad Band Television Booster Model BB-1A is a double tuned push-pull broad band amplifier designed to increase the signal strength on television channels 2 to 13 by as much as 10 times, without introducing noise or reducing picture quality. Automatic power turn-on is built in, and is controlled by the power switch of the TV receiver.

INSTALLATION:

1. Connect the short length twin lead supplied, between the booster terminals marked "output" and the receiver antenna terminals.

2. Connect the antenna lead-in to the booster terminals marked "input".

3. The rear of the chassis clearly indicates which terminals to use for the 300 or 75 ohm lines.

4. Plug the TV set power plug into the receptacle on the rear of the booster and connect the booster to the 117 v cycle A. C. line. (Do not plug into D. C.) The Booster outlet will accomodate TV receivers which draw from 150 to 350 watts.

5. For best results, the input and output twin leads should be straight and short. They should be located so that they neither cross each other, nor run near each other. This may cause oscillation, which will be evidenced either by horizontal black bars appearing on the picture or by complete erasure of the picture.

OPERATION: Turn Booster Dial to "OFF". Turn on the TV power. (Booster power will then turn on automatically in about 30 seconds.) Tune in the desired TV channel number and tune the booster for best results on the TV set. The channel numbers on the booster dial are for reference only and best results frequently may be obtained at settings of the booster tuning dial slightly off the selected channel number.

When the Television Receiver is switched off, the booster will shut off automatically about a minute later.

NOTE: When using the Model BB-1A Booster with a console assembly whose total power drain exceeds the maximum rating of 350 watts, remove the line cord of the TV portion of the console from the receptacle within the console and plug it instead into the receptacle on the booster. The line cord of the booster should be plugged into the receptacle intended for the TV portion of the console.

MODEL 12F272M

27" C.R.T. TV RECEIVER

SERVICE INFORMATION

TV Chassis CT-74

GENERAL DESCRIPTION

The CT-74 Chassis is the 27 inch CRT Version of the "CX-36" Series. The chassis itself employs 26 tubes, just one more than that employed in the standard "CX-36" Series. The additional tube is used as a second Damper Tube. Basic differences in this chassis are in the sweep circuits which are revised to operate with the larger picture tube. These revisions are as follows:

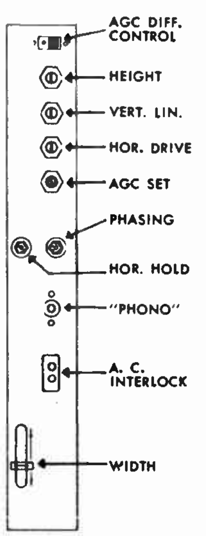
1. A type 6AV5GT tube is used in place of the 6V6 as Vertical Output Tube. Circuit components including the Vertical Output Transformer are also changed in this circuit.
2. A type 6CD6G tube is used in place of the 6BQ6 as Horizontal Output tube.
3. Two 6AX4GT tubes, connected in parallel, are used as Dampers instead of a single 6W4GT.
4. The Horizontal Output Transformer and Width Coil are revised to function with the 90° Deflection Yoke which is required for the 27 inch Rectangular CRT.
5. The video peaking circuits have been revised to provide additional "snap" and "sparkle" in this picture.

The chassis and picture tube are mounted separately in the cabinet. Special Instructions for removal of both the chassis and the CRT are included.

LOCATION OF CONTROLS

There are six (6) primary operating controls accessible from the front of this receiver. These are (from bottom to top) On-Off, Volume (front), Shading (rear), Contrast, Vertical Hold, Fine Tuning (rear) and Channel Selector (front).

Mounted on the rear chassis apron and accessible from the rear of the instrument are the Height, Vertical Linearity, Horizontal Drive and AGC Set. These are all potentiometer controls and with exception of AGC Set are easily adjustable by hand. The AGC Set is a recessed screw-driver adjustment. Also mounted on the rear apron is the Width control which is provided with a sliding adjustment for quick set-up. The Horizontal Oscillator "Frequency" (or "Hold") and "Phasing" slugs are accessible through two small holes in the rear of the chassis apron. The slugs are provided with hex-nuts for adjustment with a ¼" Spintite type wrench.



In addition to these controls a slide type switch referred to as the AGC Differential Control is located on the rear of the chassis. This control provides a variation of the differential bias applied to the R-F and I-F stages, thus permitting the signal circuits to be operated with an optimum signal-to-noise ratio under varying circuit conditions.

TUBE COMPLEMENT

Ref. No.	Type	Function
V101	6BQ7	R. F. Amplifier
V102	6J6	Osc. & Mixer
V201	6CB6	1st I.F. Amplifier
V202	6CB6	2nd I.F. Amplifier
V203	6CB6	3rd I.F. Amplifier
V204	6CB6	4th I.F. Amplifier
V205	6X8	Triode Section, 1st Video Amplifier; Pentode Section, 1st Sound I.F. Amplifier
V206	6AQ5	Video Output
V208	27GP4 or 27EP4	Picture Tube
V301	6AU6	2nd Sound I.F. Amplifier
V302	6AL5	Ratio Detector
V303	6AV6	1st Audio Amp. & AGC Clamp
V304	6AQ5	Audio Output
V401	6AU6	Keyed A.G.C. Amplifier
V402	6BA6	Sync Amplifier
V403	6BE6	Sync Sep. & Noise Clipper
V404	12AT7	1st Triode, Sync Clipper; 2nd Triode, Reactance Tube
V501	6AL5	Horizontal A.F.C.
V502	12AU7	1st Triode, Horizontal Oscillator; 2nd Triode, Horizontal Discharge
V505	1B3	H.V. Rectifier
V506	6C4	Vertical Multibibrator
V508	6CD6	Horizontal Output
V509	6AX4	Damper
V510	6AX4	Damper
V511	6AV5	Vertical Output
V601	5U4	L. V. Rectifier
V602	5U4	L. V. Rectifier
CR201	1N64 (Germanium Diode)	Video Detector

REMOVAL OF SAFETY GLASS ESCUTCHEON

Should it be necessary, the safety glass is removable from the front of this instrument. The glass is fitted into slots in the chassis mounting shelf and the sides of the cabinet. It is held firmly in place at the top by a removable wood strip.

TO REMOVE THE GLASS:

1. Remove the small wood screw from the wood strip at the top of the safety glass and remove the strip.
2. Slide the glass to the right until it is free of the cabinet slot at the left of the cabinet.
3. Slide the glass upward until it is free of the bottom slot and tilt the glass forward at the left. Note: A small rubber suction cup (such as a CRT H.V. anode cup) can be used to assist in removing the glass from the cabinet.

To replace the glass the above procedure should be followed in reverse.

Removing the Picture Tube From the Cabinet

CAUTION — Due to the weight and bulk of the 27" CRT it is recommended that more than normal precautions be exercised in handling. One suggested procedure to facilitate removal of the CRT is to first place the instrument face down on the floor, using a heavy blanket or other padding to protect the cabinet, then proceed with the removal of the CRT as outlined below. Using this method one man can remove the tube without assistance.

To Remove the CRT:

1. Remove the cabinet rear door assembly (held in place by twelve (12) wood screws).
2. Remove the CRT socket from the CRT base.
3. Disconnect the Deflection Yoke Cable.
4. Disconnect the H.V. Anode Connector from the CRT.
5. Remove the rear braces from the deflection yoke support assembly.
6. Remove the four (4) nuts which fasten the front CRT strap assembly to the cabinet. NOTE: Unless the instrument is in the face down position (as described above) the CRT should be supported from the rear while the mounting nuts are being removed.
7. Lift the tube out of the cabinet tilting it slightly to avoid striking the H.V. Section of the TV Chassis.

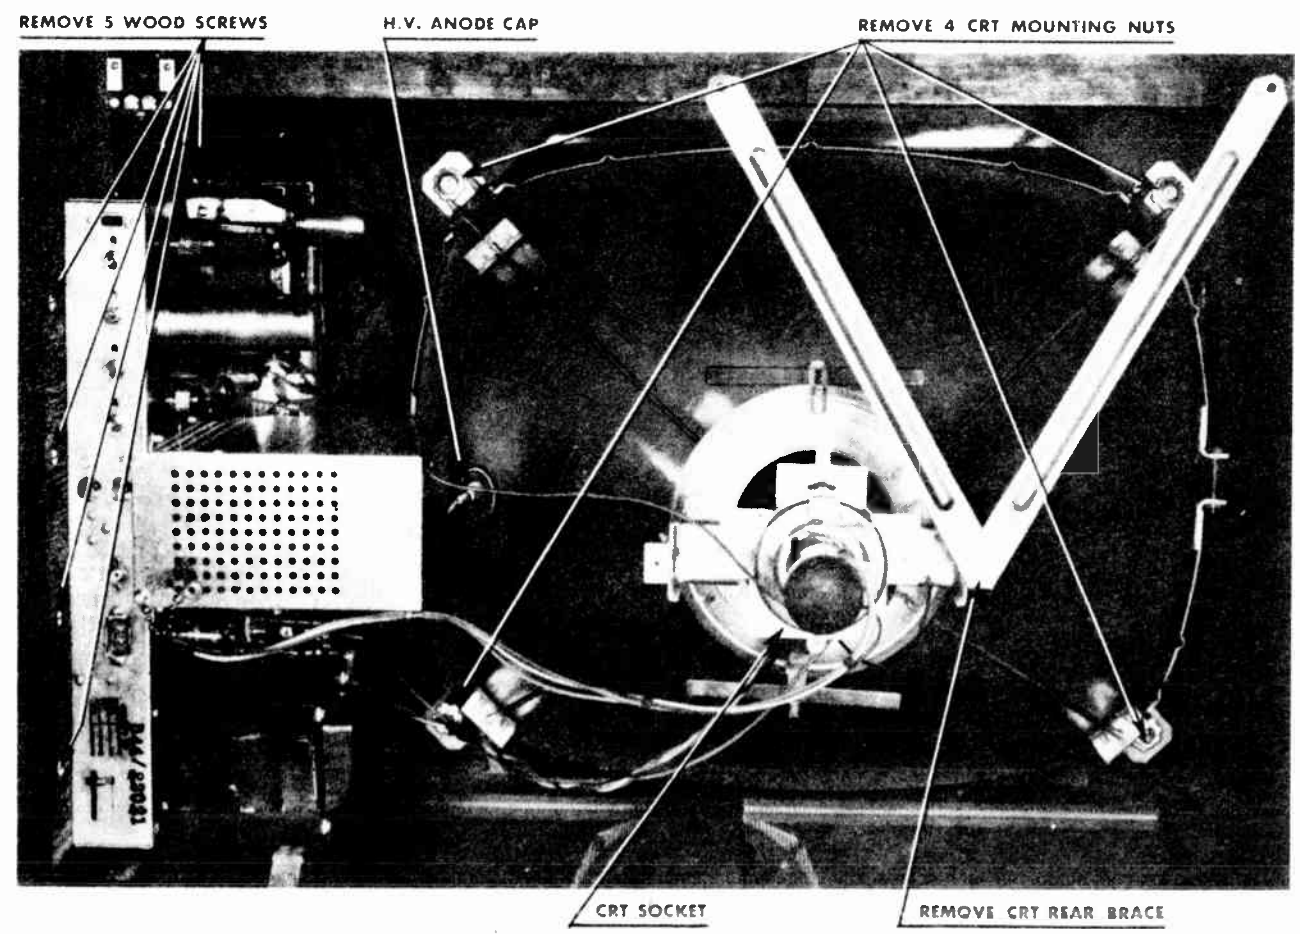
After removing the CRT assembly from the cabinet place it face down on a pad (to protect the CRT face) and remove the Ion Trap, Focus Magnet and Deflection Yoke. When installing a new CRT be certain that the rubber collar, which is used to hold the deflection yoke in place against the bell of the tube, is solidly in place.

Removing the Chassis From the Cabinet

The chassis used in this model is bolted to a sliding skid which fits in grooves provided in the cabinet construction. For maintenance the chassis can be removed from the rear of the instrument as follows:

1. Remove the control knobs from the front of the instrument.
2. Remove the cabinet rear door assembly (held in place by twelve (12) wood screws).
3. Remove the Antenna Terminal strip (fastened to cabinet by two (2) wood screws).
4. Remove the CRT Socket from the CRT base.
5. Disconnect the Deflection Yoke Cable.
6. Disconnect H.V. Anode Connector from the CRT.
7. Remove the Speaker plug from the TV chassis.
8. Remove the wood screws which fasten the chassis mounting skid to the cabinet (four screws at the rear and one at the front near the R-F Unit.)
9. Slide the chassis on the sliding skid from the rear of the instrument.
10. Remove the wooden skid from the chassis to facilitate service.

To replace the chassis in the cabinet, follow this procedure in reverse. Make certain that all interconnecting cables are properly connected and see that the chassis and sliding skid are securely fastened.



SET-UP ADJUSTMENTS

Final adjustment of the various secondary (or set-up) controls should be made at the time of installation of the receiver. The receiver should be given a thorough operating test at the same time, and, of course, the owner should be instructed as to the operation of the various controls on the front panel. The owner should be cautioned that the secondary controls should be adjusted only by an experienced television service man.

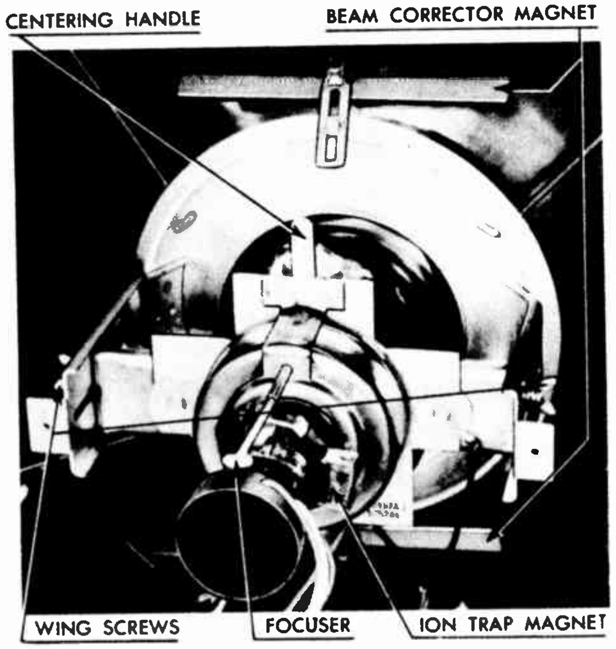
Adjustments of the Horizontal A.F.C. circuits and setting the Local Oscillator of the R.F. Tuner should be made as outlined

Preliminary Checks:

1. Remove the cabinet back and connect the receiver to an AC source, using a "cheater cord" (A line cord that can be plugged into the AC Interlock receptacle on the rear of the chassis).
2. Turn the receiver on and adjust the Shading and Contrast controls to approximately half rotation. If a raster is not seen after allowing time for the tubes to warm up, immediately adjust the Ion Trap Magnet to obtain a raster. Upon obtaining a raster, continue to adjust the magnet (by sliding back and forth and rotating about the neck of the CRT) to obtain maximum brightness.
3. Check to see that the Deflection Yoke is flush against the bell of the CRT. If the raster is tilted, rotate the yoke to correct the tilt.
4. Connect the lead wire from an antenna to the terminals on the rear of the set. Be sure to remove the lead wire from the "built-in" antenna from these terminals when using an outside antenna.
5. Set the Channel knob to a channel on which a program is being transmitted.
6. Adjust the Fine Tuning and Contrast controls to obtain the best reception. Tune for the sharpest detail in the picture, but not necessarily the brightest picture or loudest sound.
7. Adjust the Shading control for the desired brightness and the Volume control for the desired volume. Check the Sound quality.
8. Adjust the Vertical Hold control if the picture rolls vertically.

Picture Centering and Focus:

9. To center the picture on the CRT screen move the centering handle on the Focusing Magnet.



If proper horizontal centering cannot be obtained with this adjustment, check the Horizontal Phasing Adjustment as outlined under "Adjustment of Horizontal A.F.C. Circuit."

10. To provide over all good focus adjust the Focuser adjustment which extends from the rear of the Focusing Magnet. The magnet should be approximately ½ inch from rear of the yoke.

ADJUSTMENT OF HORIZONTAL A.F.C. CIRCUIT

There is no Horizontal Hold front panel control provided on this chassis. The picture should lock in synchronism automatically when switching from channel to channel. In event, however, that adjustment of this circuit is required, because of tube or component replacement, the following procedure should be followed:

1. Remove the Horizontal A.F.C. Detector Tube (6AL5) from its socket and adjust the Horizontal Frequency slug until the picture is syncronized horizontally. When properly adjusted the picture will move slowly back and forth horizontally with one vertical blanking bar.
2. Re-insert the 6AL5 tube, and as soon as the tube reaches its normal operating temperature, the picture should fall in sync.
3. After making the frequency adjustment, check the horizontal phasing. This can best be done by decentering the picture so that the right hand edge of the raster is visible. Adjust the Shading control for maximum brilliance and reduce the Contrast control until the raster edge can be seen. There should be approximately 3/16 inch between the edge of the raster on 17 inch tubes and 1/4 inch on 21 inch tubes. If the picture is out of phase, adjust the Horizontal Phasing "slug" on the rear of the chassis.

If considerable amount of change is required in the phasing adjustment, it may be necessary to re-adjust the horizontal frequency as in Step 1, above.

Picture Size and Linearity:

11. Adjust the Horizontal Drive and Width controls to obtain the proper picture width and horizontal linearity. The Horizontal Drive control should be adjusted first to provide maximum scan and then the Width control should be used to adjust for the proper horizontal size. If a vertical white line (or lines) appears in the picture, back off the Horizontal Drive control slightly.
12. Adjust the Height and Vertical Linearity controls to obtain proper height and vertical linearity. It may be necessary to adjust the Vertical Hold control while making these adjustments, if the picture should roll. (Refer to "Beam Corrector Magnet Adjustment").

Final Check:

13. In sequence, set the Channel knob to all channels on which reception is obtained. Adjust the receiver for operation as outlined in the Owner Operating Instructions. Check the quality of reception, picture and sound on all available TV stations in the area.

NOTE: If a degree of "background noise" is noticed on moderate signals the AGC Differential Control (switch on rear chassis apron) should be placed in the DOWN position. If no background noise is apparent with the switch in the UP position, it should be left in this position.

14. Recheck the focuser adjustment and Ion Trap Magnet setting for good picture focus.
15. Check to see that the best reception is obtained on all channels with the Fine Tuning control set to the approximate center of its range. This can be obtained by making the adjustments outlined under "Oscillator Adjustments Using a TV Signal
16. Remove the "cheater cord" and replace the cabinet back.

OSCILLATOR ADJUSTMENT USING A TELEVISION SIGNAL

1. Turn set on and allow sufficient time for set to reach normal operating temperature.
2. Turn Channel selector to the channel to be adjusted and adjust Shading, Contrast and Volume controls for normal sound and picture. Set the Fine Tuning control to the midpoint of its range.
3. Remove Channel and Fine Tuning knobs and adjust the oscillator slug for that channel, using a small non-metallic screwdriver. When the CHANNEL selector is set for a particular channel, the oscillator "slug" for that channel is accessible through a small hole in the front of the tuner chassis.

Adjust the oscillator slug for the clearest and sharpest detail in the picture. At this point the sound should be best, but not necessarily the loudest.

NOTE: BE CAREFUL NOT TO TURN THE SLUG TOO FAR, AS IT MAY FALL COMPLETELY OUT OF ITS MOUNTING.

Beam Corrector Magnet Adjustment

Adjust the Height Control so that the top and bottom edges of the raster are just visible and check to see if the raster lines near the top and bottom are sufficiently straight. If the lines are bent adjust the two Beam Corrector Magnets (attached to the CRT metal support ring, one above and the other below the bell of the CRT) to remove the bend. These magnets are adjusted at the factory and should not require re-adjustment unless they have been accidently bent out of position.

These magnets can be adjusted by moving them closer to or further from the bell of the CRT or by moving them from side to side. As the magnet is moved closer to the tube, the raster lines will be pulled toward the magnet. Likewise as the magnet is moved away from the tube, it will have less effect on the raster lines. If the magnets have been shifted either to the left or right, an irregular bend may appear in the raster lines near the top or bottom.

ALIGNMENT INSTRUCTIONS

General Information

Before attempting either complete or partial alignment of the receiver circuits it is recommended that all of the alignment data included here be read thoroughly. After becoming familiar with the procedure it will probably be necessary to refer to the alignment charts only. Note that there are two methods given for alignment of the I-F Stages. The method to be used will depend upon the type of equipment available. If a Sweep Generator having a 40 - 50 MC range is not available, the I-F Stages (with exception of the over-coupled transformer) can be accurately aligned with a Signal Generator having a 40-50 MC range and a VTVM. In this case the over-coupled stage can be aligned while observing the over-all R-F, I-F curve on a channel which is known to have a fairly flat response.

A suggested list of Test Equipment needed for proper alignment of the receiver is listed here. Under no circumstances should alignment be attempted without the proper equipment. When connecting the test equipment to the various points in the receiver, be certain that a good connection is made and that the leads are as short as possible.

In alignment of the R-F Amplifier in particular the Sweep Generator must be properly terminated in order to prevent distortion of the response curve caused by reflections and losses on the lines. All equipment used must be adequately grounded on the receiver chassis. Always allow sufficient time for both test equipment and receiver to warm up before starting the alignment.

Test Equipment Specifications

1. R-F Sweep Generator
   a. Frequency Ranges
      4.5 Mc with .5 and 2 MC Sweep Width, 40 - 50 MC with approximately 10 MC Sweep Width 50 - 90 MC, 170 - 220 MC with at least 10 MC Sweep Width.
   b. Constant Output within the sweep range.
   c. Signal Output not less than 0.1 volt maximum.
2. Marker Generator
   a. Frequency Ranges
      41.25 - 47.25MC — I-F Markers
      55.25 - 215.75MC — Picture Sound Carrier Markers
      4.5 MC — Sound I-F and 4.5 MC Trap
   b. Modulated Signal over I-F Range (optional)

R-F AMPLIFIER ALIGNMENT

1. Connect the sweep generator output cable to the receiver antenna input terminals through the proper terminating network. If the sweep generator used has a 300 ohm balanced output use the matching pad shown in Figure 1A. For other generators use the proper values of R_o and R_i for the output cable impedance of the particular generator. Adjust the generator to sweep Channel 10.
2. Couple an accurately calibrated marker generator into the antenna input to provide picture and sound carrier markers. In most cases the marker generator can be connected across the sweep generator terminals. A 10K isolating resistor should be used in series with the marker output cable. Maintain the output of the marker generator at a low level to prevent distortion of the response curve.
3. Connect the oscilloscope (high side) through a 10K isolating resistor to the test point (small wire loop) on top of R-F Tuner Chassis. If necessary to provide a clean trace on the scope, connect a 270 uuf. (approx. value) capacitor across the vertical input terminals of the scope.
4. Remove the AGC Amplifier tube (V401, 6AU6) and connect a bias source (see note 2 of Video I-F Alignment) from terminal 2 of the R-F, I-F Chassis Power Cable Plug to chassis. Set the bias on terminal 2 at −3 volts.
5. Remove the 1st I-F Amplifier tube (V201) and detune the mixer plate transformer, T101.
6. Set the receiver Channel Selector for Channel 10. A trace should appear on the scope similar to that shown in Figure 2. Adjust the trimmers C117, C107 and C111 on top of the R-F Tuner Chassis for maximum amplitude and to locate the sound and picture carrier markers within the limit shown in Figure 2.
7. Adjust the sweep and marker generators progressively for each channel. Check the response curve obtained on each channel. The curve should be within the following limits: neither side of the curve should be down more than 30% and the valley of the curve should not be down more than 30% of the total amplitude. If the response of a particular channel does not come within these limits, check to see that the correct coils for that channel are being used and try replacing the antenna coil for that channel. As a final step, a compromise can be made by adjusting the trimmer C117, C107 and C111 to improve the response of the channel that is off. The response on all other channels should then be rechecked to determine the extent to which they were affected by the compromise.

LOCAL OSCILLATOR ALIGNMENT CHART

Step No.	Set Sweep Generator to:	Set Marker Generator to:	Connect Generator Output Cable to:	Connect Oscilloscipe to:	Set Channel Selector to:	Adjust	Refer to Note/s:
1	Sweep Channel 13	211.25MC, 215.75MC	Receiver Antenna Input Terminals	Junction of R219 and pin 2 of V205A through 10K Resistor	Channel 13	Channel 13 Oscillator Slug	1, 2, 3 4, 5, 6 7
2	Sweep Channel 12	205.25MC, 209.75MC			Channel 12	Channel 12 Oscillator Slug	
3	Sweep Channel 11	199.25MC, 203.75MC			Channel 11	Channel 11 Osc. Slug	
4	Sweep Channel 10	193.25MC, 197.75MC			Channel 10	Channel 10 Osc. Slug	
5	Sweep Channel 9	187.25MC, 191.75MC			Channel 9	Channel 9 Osc. Slug	
6	Sweep Channel 8	181.25MC, 185.75MC			Channel 8	Channel 8 Osc. Slug	
7	Sweep Channel 7	175.25MC, 179.75MC			Channel 7	Channel 7 Osc. Slug	
8	Sweep Channel 6	83.25MC, 87.75MC			Channel 6	Channel 6 Osc. Slug	
9	Sweep Channel 5	77.25MC, 81.75MC			Channel 5	Channel 5 Osc. Slug	
10	Sweep Channel 4	67.25MC, 71.75MC			Channel 4	Channel 4 Osc. Slug	
11	Sweep Channel 3	61.25MC, 65.75MC			Channel 3	Channel 3 Osc. Slug	
12	Sweep Channel 2	55.25MC, 59.75MC			Channel 2	Channel 2 Osc. Slug	

NOTE: The individual oscillator slugs are accessible from the front of the cabinet, therefore, if the R-F and I-F circuit are properly aligned, "touch up" of the oscillator alignment on any channel can be accomplished without removing the chassis from the cabinet. For further information, refer to "Oscillator Alignment Using a TV Signal" on Page 3.

LOCAL OSCILLATOR ALIGNMENT

1. Connect the sweep generator output cable to the receiver antenna input terminals through the proper terminating network. If the sweep generator used has a 300 ohm balanced output use the matching pad shown in Figure 1A. For other generators use the proper values of R_o and R_i for the output cable impedance of the particular generator. Adjust the generator to sweep Channel 13.
2. Couple an accurately calibrated marker generator into the antenna input to provide picture and sound carrier markers for Channel 13.
3. Connect the oscilloscope (high side) through a 10K isolating resistor to the junction of R219 and pin 2 of V205A.
4. Remove the AGC Amplifier tube (V401, 6AU6) and connect a short test lead from pin 2 of the R-F, I-F Chassis Power Cable plug to chassis. This places the R-F Amplifier bias at zero. Also, connect a bias battery (a 4.5 Volt battery with a 1K pot connected across its terminals can be used), negative side to terminal 3 of the same plug and positive side to chassis. Adjust the pot to provide −3 volts bias at terminal 3 of the R-F, I-F Chassis Power Cable plug.
5. Set the Channel Selector to Channel 13 and check the response curve obtained against the ideal curve shown in Figure 4. If the shape of the curve is not within these limits, it will be necessary to repeat the R-F and I-F Amplifier Alignments. The R-F and I-F Amplifiers must be properly aligned before the oscillator adjustments can be correctly made.
6. Set the Fine Tuning control to the approximate center of its mechanical range and leave it set in this position for the entire alignment.
7. Adjust the individual oscillator "slug" for Channel 13 to properly position the markers on the curve. This adjustment should be made with a non-metallic screwdriver having an ⅛ inch blade approximately. If one of the slugs should "fall into" the coil form, first remove the metal shield which covers the lower portion of the turret (to remove the shield pull down at the front and slide it out of its hinges at the rear) and then remove the particular oscillator coil from the turret. To reposition the slug, move the slug retaining spring aside and tap the coil until the slug slides forward, then replace the spring so that the slug is held in place. Replace the coil in the turret and proceed with its alignment.
8. Set the sweep and marker generators, progressively for each channel and check the position of the markers on the curves. Adjust the individual oscillator "slug" wherever necessary to properly locate the markers.

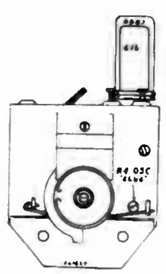

Figure 3

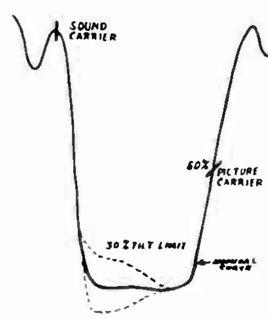

Figure 4

VIDEO I-F ALIGNMENT

1. Connect the sweep generator output cable (properly terminated in its characteristic impedance) to pin 1 of V201 (grid of 1st I-F Amplifier) through a .001 ufd. isolating capacitor and adjust it to sweep from 40 to 50 MC. If a separate marker generator is used it should be coupled to the same point through a 10K resistor.
2. Remove the AGC Amplifier tube (V401, 6AU6) and connect a bias source from terminal 3 of the R-F, I-F Chassis Power Cable plug to chassis. A bias source may be obtained from a 4.5 volt battery with a 1K pot connected across its terminals. Connect the positive end of the battery to chassis ground and connect the arm of the pot to terminal 3 of the R-F, I-F plug. Connect a VTVM to terminal 3 of the plug and adjust the pot for a minus 3 volt reading on the VTVM.
3. Connect the oscilloscope high side to the junction of R219 and pin 2 of V205A through a 10K isolating resistor.
4. Check the response curve for evidence of local oscillator influence by adjusting the fine tuning control. If the shape of the curve changes, switch to another channel where oscillator influence is not present or else adjust the Channel Selector so that it is between channels.
5. Adjust the marker generator to provide a marker at 41.25 MC and adjust the top slug of T202 (Co-Channel Sound I-F Trap) for minimum response at the marker frequency. This adjustment may be made easier by running the sweep generator output high so that the trap "dips" are easily visible.
6. Adjust the marker generator to 47.25 MC and adjust the top slugs of T203 and T204 (Adjacent Channel Sound I-F Traps) for minimum response at the marker frequency.
7. Reduce the sweep generator output so that a normal curve is seen. Adjust the marker generator to 42.65 MC and then adjust the bottom slugs of T202 and T204 to obtain maximum amplitude of the 42.65 MC marker.
8. Adjust the marker generator to 45.3 MC and adjust the bottom slugs of T203 and T205 to obtain maximum amplitude of the 45.3 MC marker. To obtain access to the bottom slug of T205 remove the contrast control from the front panel. Use a thin blade alignment tool for the adjustment.
9. Connect the sweep and marker generators to the test point on the R-F Tuner through a .001 ufd., isolating capacitor. Set Channel Selector to Channel No. 9. If the available equipment allows, markers at both 42.25 MC and 45.75 MC should be provided simultaneously.
10. Adjust the overcoupled I-F circuit, T101 (on top of the R-F Tuner) and the bottom slug of L211 to obtain a curve similar to that shown in Figure 5. With certain types of sweep generators this method is not usable due to the spureous response curves obtained on the scope which are caused by the various harmonic of the generator. Under these conditions the overcoupled stage should be aligned as in step 6 of alternate method of I-F alignment. The 42.25 MC marker must fall within 30% to 70% of maximum amplitude of the curve on one side and the 45.75 MC marker must fall within 40% to 60% of maximum on the other side. The valley of the curve should not exceed 10% and the tilt should not be greater than + or −10%. A 45 MC marker should fall within 5% of maximum amplitude on the high frequency side of the curve.

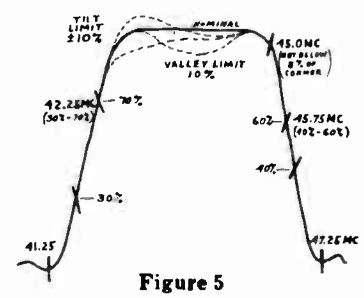

Figure 5

VIDEO I-F ALIGNMENT CHART

Step No.	Set Sweep Generator to:	Set Marker Generator to:	Connect Generator Output Cables to:	Connect Oscilloscope to:	Adjust	Refer
1.	Sweep from 40 to 50MC	41.25MC	pin 1 of V201 (grid of 1st I-F Stage) through a .001 ufd. capacitor	Junction of R219 and pin 2 of V205A through a 10K resistor	Top slug of T202 for min. response at 41.25MC	1, 2, 3, 4
2.		47.25MC			Top slugs of T203 & T204 for min. response at 47.25MC	1, 2, 4, 6
3.		42.65MC			Bottom slugs of T202 & T204 for max. amplitude of marker	1, 2, 4, 7
4.		45.3MC			Bottom slugs of T203 & T205 for max. amplitude of marker	1, 2, 4, 8
5.		Repeat Steps 1 & 2 after completing Steps 3 & 4				
6.		42.25MC 45.0 MC 45.75MC	Test Point on R-F Tuner through a .001 ufd., capacitor		T101 (on top of R-F tuner) and Bottom slug of L211 for curve shown in Fig. 5	2, 4, 9, 10

ALTERNATE METHOD OF VIDEO I-F ALIGNMENT

1. Connect the signal generator output cable to pin 1 of V201 through .001 ufd., isolating capacitor. If an oscilloscope is used for indication, the generator should be AM modulated with a 400 c.p.s. signal.
2. Set the bias at the I-F grids to minus 3 volts (refer to note 2 of Video I-F Alignment).
3. Connect the VTVM to the junction of R219 and pin 2 of V205 through a 10K resistor.
4. Set the signal generator to 41.25 MC and adjust the top slug of T202 for minimum indication on the VTVM.
5. Set the signal generator to 47.25 MC and adjust the top slugs of T203 and T204 for minimum indication on the VTVM.
6. Set the signal generator to 42.65 MC and adjust the bottom slugs of T202 and T204 for maximum indication on the VTVM.
7. Set the signal generator to 45.3 MC and adjust the bottom slugs of T203 and T205 for maximum indication on the VTVM. To obtain access to the bottom slug of T205, remove the Contrast Control from the front panel. Use a thin blade alignment tool for this adjustment.
8. Connect the Sweep Generator output cable to the receiver antenna input terminals through the proper terminating network. (Refer to note 1 of R-F Amplifier Alignment).
9. Connect the marker generator to pin 1 of V201 through a .001 ufd., capacitor.
10. Set the I-F Bias to minus 3 volts (Refer to Note 2 of Video I-F Alignment).
11. Connect the oscilloscope high side to the junction of R219 and pin 2 of V205A through a 10K resistor.
12. Set the receiver Channel Selector to Channel 12 and adjust the sweep generator to sweep Channel 12. A curve should appear on the scope similar to that shown in Figure 6. The marker generator should be adjusted to provide markers at 42.25 MC and 45.75 MC.
13. Adjust T101 (on top of the R-F Tuner) and the bottom slug of L211 for location of the markers as stated in Note 10 of Video I-F Alignment.

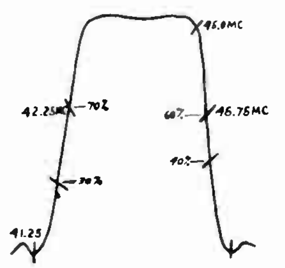

Figure 6

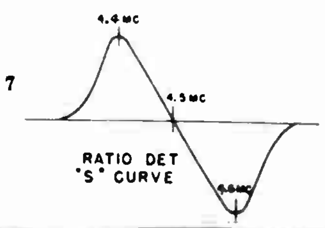
SOUND (4.5MC) I-F ALIGNMENT

1. Connect the sweep generator output cable to the junction of L205 and R218 through a .001 ufd., isolating capacitor and adjust it for 1 MC sweep, with center frequency at 4.5MC.
2. If a separate marker generator is used it may be coupled to the sweep generator cable through a 10K isolating resistor. The marker must be accurately calibrated at 4.5MC.
3. Connect the oscilloscope (high side) to the junction of R306, R307 and C310.
4. Adjust L301 for maximum amplitude of the response curve such as shown in Figure 7.
5. Adjust the secondary (top) of T301 to center the marker on the curve and to provide as straight a slope as possible between the negative and positive peak.
6. Adjust the primary (bottom) of T301 for maximum and equal amplitude of the peaks. Remove the Volume Control from the front panel and insert a long "thin blade" alignment tool through the mounting hole for this adjustment.
7. Recheck the adjustment of L301 for maximum amplitude and also the adjustment of T301 (secondary) to center the marker on the curve.

Figure 7



VIDEO I-F ALIGNMENT CHART (ALTERNATE METHOD)

Step No.	Set Sweep Generator to:	Set Signal Generator to:	Connect Generator Output Cables to:	Connect Oscilloscope or VTVM to:	Adjust	Refer to Note/s

*Values obtained on chassis coded "D-3" or earlier with the noise limiting switch in the "OFF" position.

†Measured with zero brilliance

MEASUREMENT CONDITIONS

All voltages measured with no signal input on a vacuum tube voltmeter from tube socket pin to chassis unless otherwise indicated. All voltages should be within ± 20% of the above stated values with line voltage of 117 volts, 60 cycle AC. Voltages on V206 vary with setting of Contrast. Voltages on V401 vary with setting of AGC Set. Voltages on V507 and V506 vary with settings of Vert. Hold, Vert. Lin. and Height. Voltages on V207 vary with setting of Shading.

PARTS LIST

RESISTORS

All Resistors are ½ watt 10% unless otherwise noted.

SPECIFICATIONS

Power Source Rating:

Frequency .... 60 cycles
Voltage .... 117 volts
Wattage (TV Operation) .... 210 watts

R-F Tuning Range:

VHF TV Channels .... Nos. 2 through 13
UHF TV Channels .... (Refer to "Adaptability to UHF")

Intermediate Frequencies:

Picture I-F Carrier .... 45.75 MC
Sound I-F Carrier .... 41.25 MC
Intercarrier Sound I-F .... 4.5 MC

Antenna Input:

Impedance .... Balanced 300 ohms

Audio System:

Type Speaker .... PM Dynamic
Voice Coil Impedance .... 3.2 ohms
Power Output (Max. Undistorted) .... 2.0 watts

Tube Complement:

REF NO.	TYPE	FUNCTION

*The 17LP4 is used in Chassis No. CT-75 and the 21FP4 is used in Chassis No. CT-77 & CT-81.
†Not included in Chassis No. CT-81.

GENERAL INFORMATION

CHASSIS PRODUCTION RUN CODING

To facilitate and coordinate the handling of production changes both in the factory and in the field a production run coding system has been established for these chassis. The initial production is coded as follows:

The R.F-I.F. chassis will be stamped just forward of the R.F. Tuner with either R-1 or CR-1. Both designations will indicate the first production run.

The Deflection Chassis will be stamped on the rear apron above the width control with a D-1.

Minor circuit changes will not affect this coding, however, when a major change is made, for example in the Deflection Chassis, the code will be changed to D-2.

REMOVING CHASSIS FROM CABINET

To gain access to the chassis the cabinet back must first be removed. The back is held in place by several small wood screws. When shipped from the factory, the chassis is bolted to the cabinet shelf by six mounting bolts. These are ⅜" head, hex-head machine bolts. The two bolts near the center of the chassis are shipping bolts and it is not necessary that these be replaced after servicing the chassis. After removing the chassis mounting bolts, the control knobs and the speaker cable, the chassis may be slid out of the rear of the cabinet. On some table model sets it will be necessary to remove the speaker from the cabinet before removing the chassis.

For servicing, it is suggested that the chassis be placed on the bench on its left side.

CAUTION — The normal safety precautions should be taken when handling this chassis since the picture tube is highly evacuated. Any weakening of the picture tube glass caused by chipping, scratching or abnormal pressure may cause implosion.

Installation Instructions

After the instrument has been unpacked the following inspection checks and adjustments should be made before placing the instrument in operation.

1. General appearance and condition of cabinet.
2. All tubes in place in their respective sockets.
3. Mechanical operation of all front panel controls.
4. Inter-connections, speaker cable, picture tube H.V. Anode cap and socket connector.

POWER SOURCE

This instrument is designed to operate from an alternating current (AC) power source of 117 volts, 60 cycles. It is suggested that in all cases it be determined in advance that the power source available will meet these requirements.

ANTENNA CONNECTIONS

These instruments incorporate a "built-in" television antenna which will provide good reception on all VHF television channels in areas where signal strength is sufficient. When installing an external antenna, either indoor or outdoor type, the lead from the "built-in" TV antenna must be disconnected from the antenna terminal at the rear of the cabinet and the lead-in from the antenna in use must be connected in its place.

For information concerning antenna installation for UHF reception refer to page 17.

REMOVAL OF SAFETY GLASS ESCUTCHEON

Should it be necessary, the safety glass is removable from the front of this instrument. The glass is fitted into slots in the sides of the cabinet and held solidly in place by a strip of felt which is inserted in the right hand slot between the glass and the cabinet.

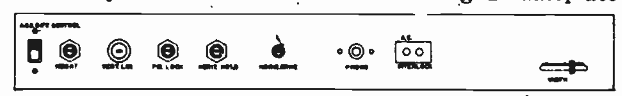
TO REMOVE THE GLASS:

1. Slide back the small catch, located at the right front of the cabinet (facing front of the cabinet) on the underside of the chassis shelf. It will be necessary to loosen the screw which holds the catch in place before it can be slid back. Note: On table model sets a metal plug button is used instead of the catch, on these sets the plug can be pried loose with a screwdriver.
2. From the exposed hole (formerly covered by the catch) pull out the strip of felt.
3. After removing the felt, slide the glass to the right until it is free of the cabinet slot at the left.
4. Tilt the glass forward at the left and remove from the cabinet. With the glass removed the CRT mask can also be removed.

NOTE: A small rubber suction cup (such as a CRT H.V. Anode cup) can be used to assist in removing the glass from the cabinet.

LOCATION OF SECONDARY CONTROLS AND ADJUSTMENTS

There are four primary operating controls and four secondary controls (concealed by the hinged nameplate) accessible to the owner from the front of the instrument. The primary controls on the left are: Off-On Volume (front) and Contrast (rear) and on the right: Channel Selector (front) and Fine Tuning (rear). The secondary controls located behind the hinged nameplate



are: TV-Phono Tone control, Shading, Vertical Hold and Horizontal Hold (top). On sets not having a TV-Phono Tone Control the secondary controls are from left to right Shading, Horizontal Hold and Vertical Hold.

Mounted on the rear chassis apron and accessible from the rear of the instrument are the Height, Vertical Linearity, Picture Lock and Rear Horiz. Hold. These are all potentiometer controls and with exception of Vert. Lin. are easily adjustable by hand. The Vert. Lin. is a recessed screwdriver adjustment. Also mounted on the rear apron is the Width control which is provided with a sliding adjustment for quick set-up. The Horizontal Drive is a trimmer which is accessible through a small hole in the rear of the chassis apron. In addition to these controls a Switch referred to as the AGC Differential Control is located on the rear apron.

SET-UP ADJUSTMENTS

Final adjustment of the various "set-up" controls should be made at the time of installation of the receiver. The receiver should be given a thorough operating test at the same time, and, of course, the owner should be instructed as to the operation of the various controls on the front panel. The owner should be cautioned that the "set-up" controls should be adjusted only by an experienced television serviceman.

Preliminary Checks:

1. Remove the cabinet back and connect the receiver to an AC source, using a "cheater cord" (A line cord that can be plugged into the AC Interlock receptacle on the rear of the chassis).
2. Turn the receiver on and adjust the TV-Phono-Tone switch to either the TV Bass or TV Treble position. The Shading and Contrast controls should be adjusted to approximately one half of full rotation. If a raster is not seen after allowing time for the tubes to warm up, immediately adjust the Ion Trap Magnet to obtain a raster. Upon obtaining a raster, continue to adjust the magnet (by sliding back and forth and rotating about the neck of the CRT) to obtain maximum brightness and good focus.
3. Check to see the Deflection Yoke is flush against the bell of the CRT. If the raster is tilted, loosen the wing screw on top of the yoke and rotate the yoke to correct the tilt.
4. Connect the lead wire from an antenna to the terminals on the rear of the set. Be sure to remove the lead wire from the "built-in" antenna from these terminals when using an outside antenna.
5. Set the Channel knob to a channel on which a program is being transmitted.
6. Adjust the Fine Tuning and Contrast controls to obtain the best reception. Tune for the sharpest detail in the picture.
7. Adjust the Shading control for the desired brightness and the Volume control for the desired volume. Check the Sound quality.
8. Adjust the Vertical Hold control if the picture rolls vertically.
9. Adjust the (Front) Horizontal Hold control from one extreme to the other and note the amount of picture shift. The picture should be properly phased when the front Horizontal Hold control is in the center of its mechanical range. When adjusted to both extremes the control should vary the picture phasing by an equal amount. If these conditions do not exist, follow the procedure listed under "Adjustment of Horizontal Oscillator".

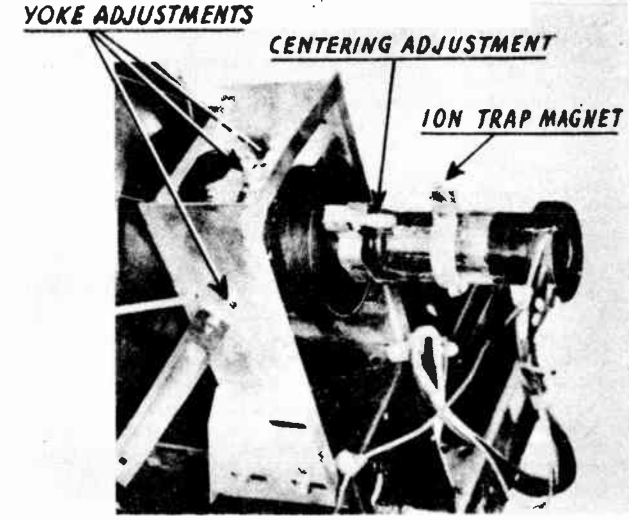
Picture Lock Adjustment:

10. Rotate the PIX. LOCK control to the extreme clockwise position and then back it off slowly while observing the picture. As the control is backed off the picture will shift slightly to the left. The control should be set to the position immediately prior to the point where it causes the picture to shift.
In extreme noisy and weak signal areas the Pix Lock control should be adjusted in conjunction with the sync controls to provide the most stable operation.

Picture Centering:

11. To center the picture on the CRT screen, adjust the knurled knob on the centering magnet, and, if necessary, rotate the centering magnet on the CRT neck.

YOKE ADJUSTMENTS



If the picture cannot be centered, loosen the wing screw on the centering magnet and reset its location on the CRT neck until centering can be achieved with the centering adjustment.
The centering magnet should be located as close to the yoke as possible. If corner cutting is experienced, loosen the two adjustment screws on either side of the deflection yoke and push the yoke as far up on the bell of the CRT as possible. Also center the yoke on the tube neck and tighten the adjustment screws.

Picture Size and Linearity:

12. Adjust the Horizontal Drive Trimmer and Width control to obtain the proper picture width and horizontal linearity. The Horizontal Drive should be adjusted first to provide maximum scan and then the Width control should be used to adjust for the proper horizontal size. If a vertical white line (or lines) appears in the picture, turn the Horizontal Drive Trimmer in slightly.

13. Adjust the Height and Vertical Linearity controls to obtain proper height and vertical linearity. It may be necessary to adjust the Vertical Hold control while making these adjustments, if the picture should roll. (On sets employingBeam Corrector Magnets refer to instructions for adjustment on page 18.

Final Check:

14. In sequence, set the Channel knob to all channels on which reception is obtained. Adjust the receiver for operation as outlined in the Owner Operating Instructions. Check the quality of reception, picture and sound on all available TV stations in the area.
    NOTE: If a degree of "background noise" is noticed on moderate signals the AGC Differential Control should be placed in the DOWN position. If no background noise is apparent with the control in the UP position, it should be left in this position.
15. Recheck the Ion Trap Magnet setting for good picture focus.
16. On receivers using the turret type R-F unit check to see that best reception is obtained on all channels with the Fine Tuning control set to the approximate center of its range. This can be obtained by making the adjustments outlined under "Oscillator Adjustments Using a TV Signal."
17. Remove the "cheater cord" and replace the cabinet back.

ADJUSTMENT OF HORIZONTAL OSCILLATOR

The procedure outlined here should be followed if the adjustment described in Step 9 cannot be properly made:

1. Remove the cover from the rear of the H.V. compartment and connect a shorting jumper between the two terminals which are provided on a lug strip just inside the H. V. compartment. This jumper is used to short out L501, the Horiz. Ringing Coil during the following adjustment.
2. Remove the 6BE6 tube (V402) and adjust the Rear Horizontal Hold control so that when the front Horizontal Hold control is set to the center of its range there is approximately 1/4" between the edge of the picture and the right edge of the raster.
3. Remove the short from across L501. Adjust the slug of the ringing coil (L501) so that with the Front Horizontal Hold control set to the center of its range the picture is properly phased as outlined in step 2.
4. Replace the 6BE6 tube and check the pull-in range of the circuit by setting the Front Horizontal Hold control to extreme clockwise position and switching off channel momentarily to interrupt the signal. If the picture breaks sync horizontally, slowly rotate the Front Horizontal Control and observe the least number of diagonal blanking bars visible before the picture synchronizes. Pull-in should occur at 1½ to 2½ bars. Repeat this adjustment with the Front Horizontal Hold control in the opposite extreme position.

OSCILLATOR ADJUSTMENT USING A TELEVISION SIGNAL

1. Turn set on and allow sufficient time for set to reach normal operating temperature.
2. Turn Channel selector to the channel to be adjusted and adjust Shading, Contrast and Volume controls for normal sound and picture. Set the Fine Tuning control to the midpoint of its range.
3. Remove Channel and Fine Tuning knobs and adjust the oscillator slug for that channel, using a small non-metallic screwdriver. When the CHANNEL selector is set for a particular channel, the oscillator "slug" for that channel is accessible through a small hole in the front of the tuner chassis.

Adjust the oscillator slug for the clearest and sharpest detail in the picture. At this point the sound should be best, but not necessarily the loudest.

NOTE: BE CAREFUL NOT TO TURN THE SLUG TOO FAR, AS IT MAY FALL COMPLETELY OUT OF ITS MOUNTING.

ADJUSTMENT OF QUADRATURE COIL AND NOISE REJECTION CONTROL

Adjustment of the Quadrature Coil (L302) and Noise Rejection Control (R307) should be made at the time the instrument is installed to insure the best sound reproduction. Access to these adjustments has been provided from the front of the instrument. With a station properly tuned in remove the Volume and Contrast Knobs.

Adjustment of the Quadrature Coil can be made by inserting an alignment tool through the bottom hole that is located behind the Volume and Contrast Knobs. Adjustment of this control should be made for the strongest and clearest sound.

The Noise Rejection Control can best be set with the signal attenuated until background noise is apparent in the sound. With the signal attenuated adjust the control for minimum background hiss and noise. This control is located behind the top hole that is exposed by removing the Volume and Contrast Knobs.

General Description

The Capehart "CX-37" TV Chassis is a two-piece chassis containing 21 tubes, including the Picture Tube and two Rectifiers. The front section of the chassis, the R-F - I-F Unit, bolts to the rear section of the chassis which is the Sync Deflection Unit. The chassis features a tilted I-F strip for ease in adjustment and replacing tubes. Complete isolation is obtained between the R-F - I-F Stages and the Deflection circuits.

The front portion of the R-F - I-F Unit forms a solid mount for the picture tube while the H.V. Section serves as a rear mount for the CRT and Deflection Yoke. The H.V. Section is a separate unit which is easily removable from the chassis for servicing.

The chassis is designed for use with the new low-voltage electrostatic focus picture tubes which employ the new cylindrical face for reduced reflection. Mounting arrangement of the CRT allows removal from the front of the cabinet without removing the chassis.

There are three versions of the "CX-37" TV Chassis. These are the basic units, Chassis No. CT-75 and CT-77 (using 17" and 21" rectangular picture tubes, respectively), and Chassis No. CT-81 (similar to CT-77 except for the deletion of the audio circuits. This chassis is designed for use in conjunction with a separate radio chassis). The following circuit descriptions refer to the basic units, the CT-75 and CT-77.

The R-F Tuning Unit

The R-F Tuner used in this chassis is the "Cascode" Tuner employing two tubes; a type 6BQ7 tube and a type 6J6 tube. The 6BQ7 tube is used as a driven-grounded grid (Cascode) R-F Amplifier. Effectively this is a two-stage amplifier which combines the equivalent gain of a pentode with the low-noise factor of a triode. This combination results in a greatly improved signal-to-nosie ratio which means less "snow" in weak and low signal areas.

There are two traps connected in series with the antenna input. These are parallel-resonant traps formed by L112 & C101 (fixed tuned to 45.1 MC) and L113 & C102 (fixed tuned to 44.75 MC) which provide the desired amount of attenuation of signals within the I-F pass band at the input to the R-F Amplifier. In addition to these traps, a series-resonant adjustable trap (formed by L111 and C116) is provided in the input grid circuit of the R-F Amplifier. The capacitor, C116 (the variable portion of the trap) can be adjusted to provide maximum rejection of any interfering signal within the I-F pass band. Thus, the R-F circuits are highly selective and provide maximum rejection of unwanted signals. In addition to this, the tuner is completely shielded to prevent radiation from the local oscillator and also, to prevent pickup of unwanted signals in the various tuned circuits.

The 6J6 tube is used as a mixer and oscillator in circuits very similar to those used in the earlier Standard Coil Tuners. The mechanical arrangement and switching on this tuner is also the same as the earlier tuner.

Common I-F Amplifier Stages

The Capehart CX-37 chassis employs four stages (4 type 6CB6 tubes) of common I-F amplification. In accord with present RTMA Recommendations, the frequency of the I-F stages is in the 40 MC region. The use of the higher intermediate frequency eliminates the problem of local oscillator radiation in the existing television channels. The principles of intercarrier sound are employed wherein both the picture and sound information are amplified simultaneously throughout the I-F stages and are then separated after heterodyning in the Video Detector.

Using the intercarrier sound principle, the sound I-F carrier must be kept at a considerably low level with reference to the picture carrier level. In order to maintain the proper difference in amplitude between the two carriers, a 41.25 MC trap is included in the coupling transformer (T202) between the 1st and 2nd I-F stages.

Coupling between the mixer and the 1st I-F stage is by means of a low impedance overcoupled circuit. The coil in the grid circuit of the 1st stage and the mixer plate transformer form a tuned overcoupled circuit centered at 43.5 MC. The 2nd, 3rd and 4th stages and the Video Detector are coupled by means of Bifilar I-F coils. The "Staggered-Pairs" system of tuning is used wherein the 2nd and 4th coils are tuned to the low-frequency side of the I-F bandpass (42.65 MC) and the 3rd and 5th coils are tuned to the high side (45.3 MC) while the 1st coil in the grid of the 1st stage is tuned near the center of the pass band.

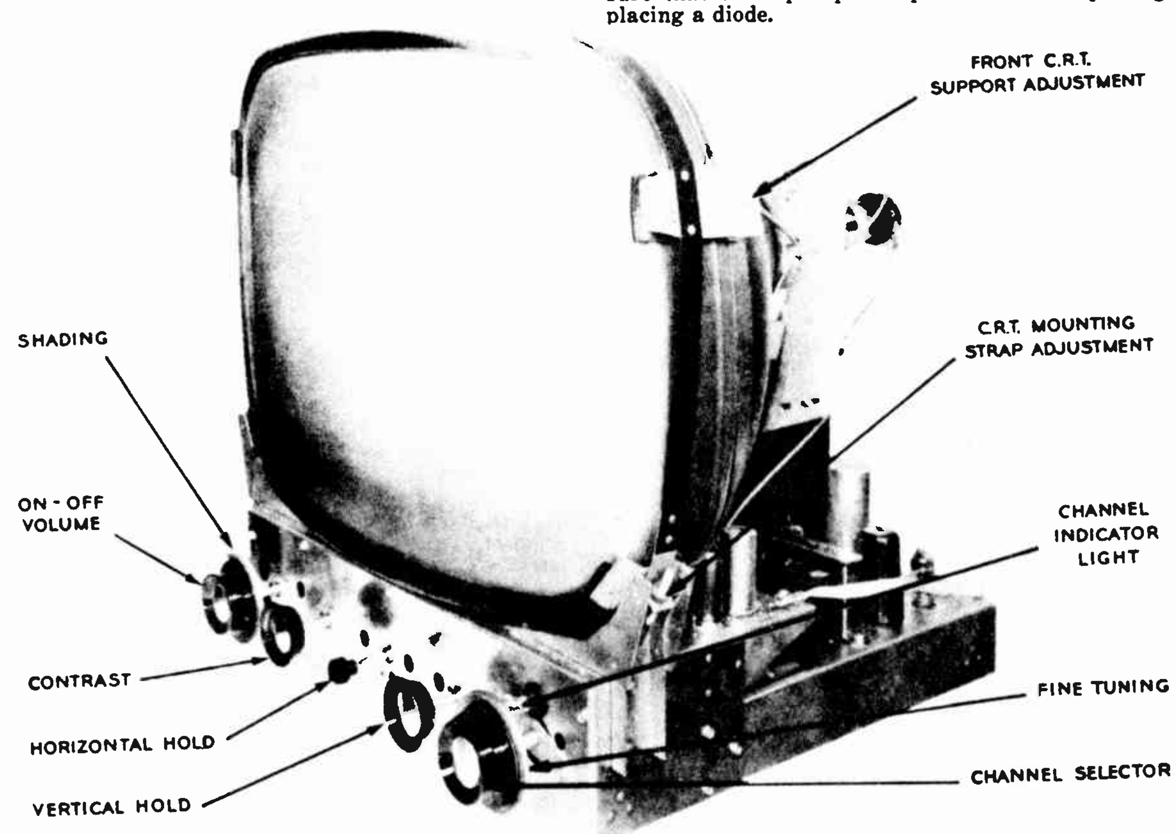
The use of bifilar-wound transformers allows a coefficient of coupling to be achieved which approaches unity. The coupling capacitor such as used with impedance coupling is not necessary with this type of transformer. The bifilar coils provide improved noise immunity due to the low resistance presented in the grid circuits by the secondary winding. Noise pulses of sufficient amplitude would develop a charge on a coupling capacitor, if used, which in turn would cause a momentary increase in bias and subsequent reduction in stage gain. The noise pulse itself, which modulates the carrier toward the black level, is not objectionable; however, each pulse is followed by a white tail (or streak) which has an undesirable effect both on picture and sync.

Each bifilar coil is tuned by a threaded powdered-iron core which is adjustable from the underside of the chassis. All trap adjustments are available from the top of the chassis and are provided with hex-nuts for easy adjustment by hand. The 1st trap is tuned to the Co-Channel Sound I-F and the 2nd and 3rd traps are both tuned to the Adjacent Channel Sound I-F.

The 1st and 2nd I.F. stages are actually connected in series DC-wise as can be seen from the current distributor diagram on the schematic diagram; the stages are, therefore, referred to as being "stacked". B plus for all of the I.F. tubes is taken from the +300 volt source. The cathodes of the 3rd and 4th stages are returned to +135 volts while the 2nd stage is returned through the 1st to chassis ground. AGC voltage is applied to the grid of the 1st stage and due to its series DC connection, the 2nd stage is also AGC controlled.

Video Detector

The Video Detector is a germanium crystal diode, type 1N64. The diode is mounted on the top terminals of the last I-F transformer (T205). The diode is readily accessible by removing (pull-off) the top cap of the I-F shield can. By enclosing the diode within the shield can harmonic radiation from the crystal is prevented. The Detector Circuit is filtered to eliminate harmonic feedback also. Because of its accessibility, the diode can be replaced, if need be, with the chassis in the cabinet. When replacing a crystal diode, care should be taken not to apply excess heat which may possibly damage the crystal. Always be sure that the top cap is replaced after inspecting or replacing a diode.



Video Amplifier

Two stages of video amplification are employed in this chassis; the pentode section of a 6X8 and a pentode 6AQ5 tube. The rectified output of the Video Detector developed across the video detector load resistor is coupled directly into the grid of the 1st Video Amplifier (V205A). The amplified output of this tube is then coupled through a peeking network into the grid of the 2nd Amplifier, a 6AQ5 tube (V206).

Variation of contrast is provided by a potentiometer in the cathode circuit of the 2nd amplifier. The output of this tube is coupled through a series peaking coil and a coupling capacitor into the grid of the picture tube.

By providing a 2 volt signal at the output of the video detector a signal of 125 volts peak-to-peak or more is available at the CRT grid through the use of two video amplifier stages. The method of selective peaking employed in these stages is designed to provide emphasis of certain portions of the video response. This emphasis assures reception of sharp, clear pictures even though the transmitted signal may not contain high definition video.

A slug tuned 4.5 MC trap is included in the plate circuit of the 2nd Video Amplifier to prevent the beat signal, developed in the detector, from reaching the CRT grid.

The new cylindrical face Electrostatic Focus picture tube is used with this chassis. The CRT is the low voltage focus type which requires a voltage of approximately 550 volts at the focus anode. Focus is completely automatic—no focus control is needed. Variation of brightness is accomplished by a potentiometer (Shading control) in the cathode circuit of the CRT.

Sound I-F Circuits

The Sound I.F. Circuits are of the 4.5 Mc. intercarrier type. The 4.5 Mc. beat between the picture and sound carriers that is produced in the video detector is amplified with the video information by the pentode section of the 6X8 (V205). The 4.5 Mc. signal is removed from the video amplifier by a 4.5 Mc. Trap consisting of L301 and C306. This trap effectively couples the 4.5 Mc. information from the video amplifier plate circuit to the grid of the sound I.F. amplifier (V205B) for additional amplification.

Detection of the 4.5 Mc. FM signal takes place in the 6BN6 Gated Beam Detector (V301). The 6BN6 provides FM detection through an unusual constructional feature. The tube is so constructed that a beam of electrons flowing from cathode to plate can be cut off with a small amount of signal applied to either the first (limiter) grid or the third (quadrature) grid. By connecting the quadrature grid to a 4.5 Mc. resonant circuit the signal is coupled to the quadrature grid through the electron stream of the tube with a phase shift of 90°. As the frequency of the applied signal is varied around 4.5 Mc. (as with FM) the phase shift between the limiter grid and quadrature grid will vary. As the phase shift varies the electron stream will be allowed to flow to the plate for a longer or shorter length of time. The length of time that plate current flows is exactly in step with the phase shift variations and thus follows the frequency shift of the incoming signal. The audio signal appears across R309 as a result of the plate current flow of V301. Limiting to reject any AM signal is achieved in the tube when the signal exceeds an amplitude of bias set by the Noise Rejection Control (R307).

Audio Amplifier

The audio signal that is present across R309 is coupled through the TV-Phono switch mounted on the Contrast Control, coupling capacitor C312 and the Volume control R311 to the grid of the audio output tube (V302). Through the large audio signal that is supplied by the detector and the high sensitivity of the 6BK5 output tube no first audio amplifier stage is required. The output of the audio amplifier is supplied to a speaker connector on the chassis through the output transformer T301.

A phono input jack is mounted on the rear panel so that a record changer can be connected and used if desired. The phono input is connected to the amplifier when switch S301 is actuated by turning the contrast control to its maximum counter-clockwise position.

Keyed Automatic Gain Control

A type 6AU6 Tube (V401) is employed as a Keyed AGC Amplifier. The grid of this tube is DC coupled to the plate of the 1st Video Amplifier tube (V205A). The signal appearing at this point is a sync-positive composite video signal. The white portions of the signal may be crushed, but this does not affect the AGC action because of direct coupling from the second detector to the AGC amplifier).

The screen voltage of the first video amplifier (V205A) is supplied from +300V through a 33K resistor (R241) and the AGC control (R238). By varying the screen voltage on the video amplifier the amplification of that stage and thus the amount of signal that is aplied to the grid of the AGC amplifier is set.

The plate of the AGC amplifier is pulsed with a 700 volt positive pulse, derived from a secondary winding on the horizontal width coil. The duration of this pulse is only for the retrace time of the horizontal deflection system. This coincides with the received sync pulse applied to the grid of the AGC amplifier tube, provided the horizontal oscillator is in sync, and properly phased. Thus the AGC amplifier tube operates as a keyed rectifier tube.

During the time of conduction of this tube, the capacitor C403 is charged negatively. When the tube stops conducting (during the interval between horizontal pulses) C403 discharges through R406 and R407 developing a voltage across these resistors which is divided and applied to the controlled stages as bias.

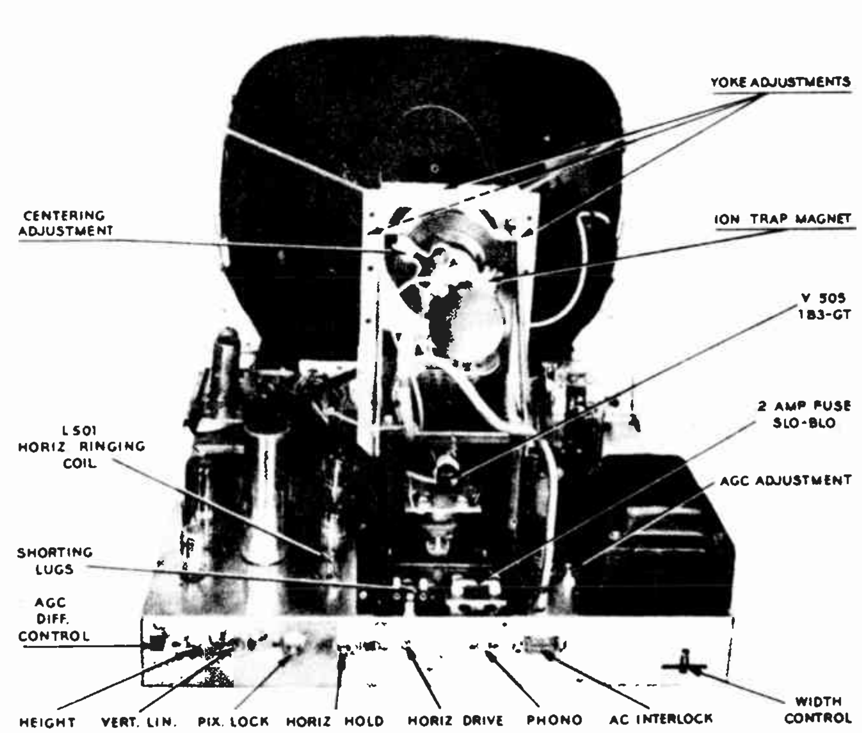
As the strength of the received signal increases, the peak sync voltage developed at the plate of the video amplifier tube (V205A) increases and thus increases the current output of the AGC amplifier tube. This results in a more negative AGC voltage being developed, which reduces the gain of the controlled stages.

Bias for the R.F. Amplifier is taken off across both R406 and R407, while bias for the I.F. stage is taken off at their junction. The diode section of V501, 6BF6 tube is used as an AGC clamp. The plate of this diode is connected to the R.F. bias point. The plate of this tube is also connected, through R409 & R410 (in series) to +300 volts. With a weak signal input, this diode holds the R.F. bias at zero or just above. If the signal were to be increased gradually the voltage developed across R406 and R407 would eventually become sufficiently negative to cause the diode plate to go negative. With the diode negative it no longer controls the R-F bias and hence the bias is allowed to increase rapidly. The circuit is so designed that the diode will hold the R.F. bias to zero until the signal becomes strong enough to provide a snow-free picture without maximum R-F Amplifier gain. The switch, S401 is used to vary the point at which the diode loses its control and in this manner affords a compensation for circuit variables.

SYNC SEPARATION AND NOISE CANCELLATION

The amplification and shaping of the horizontal and vertical sync pulses plus the removal of noise bursts that would be harmful to the stability of the scanning circuits is accomplished by the 6BE6 Sync Separator (V402) and one section of a 12AU7 (V403A) used as a Phase Splitter.

The composite video signal is applied to the signal grid (pin 7) of the 6BE6 through a .01 mfd. coupling capacitor (C406). Through a combination of no fixed bias, low plate voltage and a positive going sync pulse, grid current flows charging C406 to the amplitude of the sync pulses. Capacitor C406 partially discharges through 1.5 megohm grid resistor (R417) during the interval between pulses, setting a bias on the grid that is equal to the amplitude of the pulse. This bias effectively clamps the tip of the sync pulses to ground potential. Since the video information is negative with respect to the sync pulses, this portion of the applied signal cuts the tube off permitting no plate current to flow at the intervals between pulses. Thus the sync pulses are effectively stripped from the composite signal.



To eliminate positive going noise pulses that could be passed through the sync separator and cause unstable sync a noise cancellation circuit is used. A small amount of the video information is coupled from the video detector load through a 47K isolation resistor (R221) to the first grid of the 6BE6 (pin 1). This signal is 180° out of phase with the signal applied to the signal grid (pin 7). The bias on the first grid is set so that with a normal signal, plate current is allowed to flow all of the time. If a noise pulse arrives at this grid that is of the same polarity and of greater amplitude than the sync pulses then the plate current is cutoff for the period of time that the noise pulse is actually present. During this time no sync information is passed to the control circuits of the oscillators but the stability of the oscillators is such that they will remain in sync during this short time interval.

The sync information that is present at the 6BE6 plate load (R419) is coupled to one-half of a 12AU7 (V403A). The vertical control pulses are amplified and passed on to the vertical integrating circuit (PC501). The horizontal pulses are removed from both the cathode and plate circuit of the tube in a phase splitting action. By removing the horizontal pulses across balanced load resistors (R422 and R423) pulses are supplied to the Horizontal Phase Detector (V403B) that are of equal amplitude and opposite in phase.

Vertical Multivibrator & Output

The vertical scanning pulses are developed in a conventional two-tube multivibrator and discharge circuit using a 6V6 (V502) and a 6BF6 (V501) height necessitating readjustment of the Height control. This circuit provides the sharp pulse which is required to develop a sawtooth of current in the vertical winding of the deflection yoke.

Vertical sync pulses are coupled into the vertical MV circuit from the output of the Phase Splitter through the vertical integrator network and injected at the grid of the 6BF6 (V501).

The free-running frequency of the MV is controlled by the setting of the Vertical Hold control which is connected in the grid circuit of the 6BF6 tube. The Vertical Hold is provided as an owner operating control on the front panel.

The Height control (R531) varies the amplitude of the sawtooth wave on the plate of the 6BF6 by controlling the rate of charge of the capacitor C533.

The Vertical Linearity control (R529) varies the cathode bias on the output tube (V502). The grid voltage-plate current curve of this tube is not a straight line over its entire range; therefore, the effect of varying R529 produces variations in the shape of the sawtooth wave by shifting the operating point of the tube to different points along its characteristic. The effective gain of this tube will be varied as the operating point is shifted: therefore, adjustment of the Linearity control will affect picture height necessitating readjustment of the height control.

Horizontal Oscillator and AFC Circuit

Automatic control of the Horizontal Oscillator is accomplished by the Horizontal Phase Detector circuit which employs one-half of a type 12AU7 tube. The plate of this tube (V403B) is pulsed by a 15750 cycle pulse which is coupled from the plate of the AGC Amplifier tube (V401). Before application to the plate of V403B the pulse is integrated and reduced in amplitude by the combination of R507, R502, C510 and C509 and, therefore, appears as a sawtooth pulse of approx. 20 volts peak-to-peak amplitude. In the grid-cathode of V403B is a balanced resistor circuit composed of two 82K resistors (R503 & R504). A positive going sync pulse is applied through C506 to the grid of this tube. The positive pulse on the grid causes the tube to draw grid current which in turn develops a potential across the two 82K resistors. Circuit values are chosen such that when the sync pulse applied to the grid and the sawtooth (derived from the Horiz. Oscillator) applied to the plate are in step, the resultant voltage at the center of the two 82K resistors will be approximately zero (position of Hor. Hold Control will affect this voltage due to AFC action). If the oscillator should shift slightly, an out-of-phase condition will result. As a result of the difference in phase between the plate and grid, the potential on the plate at the instant of arrival of the sync pulse at the grid will be either more or less positive depending on the direction of the shift. The change in plate potential will cause a corresponding change in plate current and as a result cause the potential at the center of the two 82K resistors to shift in either a positive or negative direction from zero. The voltage obtained at the center of these two resistors is fed through a filtering network to the Horizontal Oscillator and is used to control the oscillator frequency.

R506 is used as the DC plate return for V403B. The capacitor C505 feeds a negative going sync pulse into the cathode of V403B. This negative pulse serves to cancel the positive pulse, at the center of the two 82K resistors, which otherwise would be coupled through to the oscillator. In addition to the noise immunity afforded by the Noise Cancellation circuit employed in the sync circuit a certain amount of immunity to noise is provided by this arrangement. A further advantage is provided by this circuit design in that should the sync pulses be interrupted for a period of time, there will be no grid current drawn in the tube and hence the point of take-off of the control voltage will be zero. This leaves the oscillator free-running and it is sufficiently stable to maintain its frequency until control is re-established.

The Horizontal Oscillator V503, a 12AU7 type tube is connected as a cathode-coupled multivibrator, with an L-C circuit (L501 and C515) in series with the plate-load resistor R509 of the first triode section. This type of oscillator combines the pull-in sensitivity of the multivibrator with the stability of a sinusoidal circuit.

The operating frequency is set at 15,750 cycles with the L-C circuit shorted out. With the Front Horizontal Hold control (R511) set to the center of its range, the rear Horizontal Hold control (R512) is adjusted so that a picture or test pattern is properly synchronized horizontally. After removing the short from the L-C circuit, the Ringing Coil (L501) is adjusted to a natural resonant frequency of 15,750 cycles to stabilize the frequency of the circuit beyond that of a conventional multivibrator. R511, the front Horizontal Hold control, is actually a fine horizontal frequency adjustment that is provided for use by the owner.

The DC control voltage that is developed in the AFC Detector circuit (previously described) is applied to the grid of the first triode section of the oscillator. This control voltage either adds to or subtracts from the normal bias on the grid of this tube causing it to remain cut-off either a longer or shorter period of time. By changing the time interval of conduction, naturally, the frequency of the multivibrator will be changed.

The operation of the multivibrator may be briefly summed up as follows: As a point to start from assume that the plate current of the second triode section is rising rapidly. This current flow will develop a voltage across the common cathode resistor R510 which is sufficient to cut-off the first section. The second section does not cut-off, however, because of the feedback capacitor C516 which maintains the grid of this tube sufficiently positive to counteract the negative cathode bias. During this time when the second section is conducting heavily the discharge capacitor, C517 discharges through this tube. During this instant of heavy current flow the grid of this tube will start to draw current. This immediately biases the grid to cut-off and allows the first section to conduct again and C517 to charge again. At this point the cycle commences again where the second section, no longer biased by grid current, is allowed to start conducting.

The modified sawtooth appearing across the output of the multivibrator is coupled to the grid of the Horizontal Output tube from a capacitor voltage divider circuit. The lower portion of this divider is the Horizontal Drive trimmer C519. Adjustment of this trimmer will vary the amplitude of the pulse applied to the Horizontal Output tube and hence the drive.

Horizontal Output & High Voltage

The Horizontal Output stage employs a type 6BQ6-GT beam power amplifier. This tube produces the horizontal deflection current and is the source of the high voltage supply for the CRT second anode. The amplitude of the pulse applied to the 6BQ6 tube is varied by a trimmer (C519, the Horizontal Drive Control) connected in the grid circuit of V504.

When the plate current in the 6BQ6 tube is suddenly cut-off by the sharp negative pulse applied to its control grid, the magnetic field which is created in the primary of the Horizontal Output transformer collapses, developing a very high voltage pulse. This voltage tends to oscillate in the 6BQ6 plate circuit, but it is rapidly damped out by the Damper tube, a 6W4-GT (V506). The B+ "Boost" is a combination of the +300 volt supply voltage plus the charge that is developed across C524 during the retrace time (duration of the high voltage pluse developed in the 6BQ6 plate circuit). This "Boost" voltage is used as plate supply for the Horizontal Output tube and also for the CRT first anode and focus voltage.

A high-efficiency ferrite core transformer is used to couple the output of the 6BQ6 to the horizontal winding of the deflection yoke and also to step up the high voltage pulse for rectification by the 1B3-GT H.V. Rectifier (V505). The deflection yoke is coupled off across two intermediate points on the horizontal output transformer secondary. This method of coupling provides an optimum impedance match and tends to reduce the effect of high frequency "ringing" which would show up in the raster as light and dark vertical bars.

The 1B3-GT tube rectifies the high voltage pulses which are applied to its plate during the horizontal retrace time. The 15,750 cycle ripple is filtered out by C525 in the 1B3 filament circuit and R523 (330K) in conjunction with the capacitance provided by the external coating on the CRT.

Variation of picture width is provided by a slug tuned inductance (T503) connected across a portion of the horizontal output transformer secondary. The Width Coil is provided with a "speed-slide" adjustment which allows for quick set-up.

Low Voltage Power Supply

A transformer-type power supply is employed using a 5U4G Rectifier (V601). Adequate filtering is provided by an inductance-capacitance type filter circuit. The B+ supplies 300 volts and a tap is provided for 135 volts. All circuits are returned to chassis ground.

The power transformer (T601) is equipped with a copper shield passing completely around the winding and core. This shield eliminates "snaking" in the picture which may result from a difference between the transmitted vertical sync frequency and the local power source frequency.

General Information

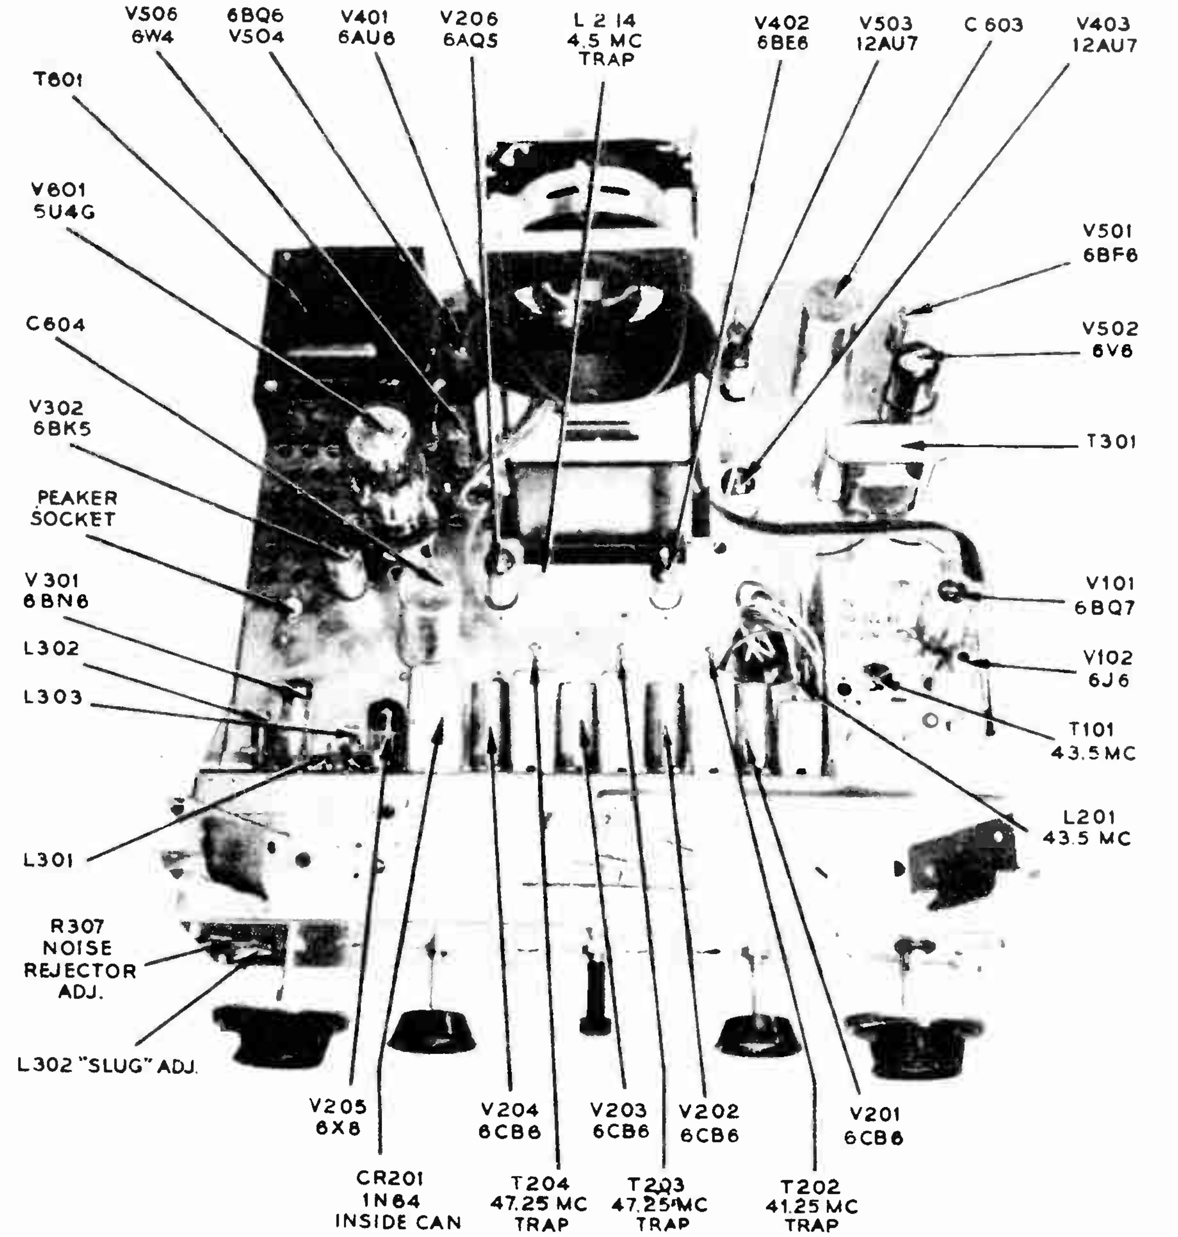
Before attempting either complete or partial alignment of the receiver circuits it is recommended that all of the alignment data included here be read thoroughly. After becoming familiar with the procedure it will probably be necessary to refer to the alignment charts only. Note that there are two methods given for alignment of the I-F Stages. The method to be used will depend upon the type of equipment available. If a Sweep Generator having a 40 - 50 MC range is not available, the I-F Stages (with exception of the over-coupled transformer) can be accurately aligned with a Signal Generator having a 40-50 MC range and a VTVM. In this case the over-coupled stage can be aligned while observing the over-all R-F, I-F curve on a channel which is known to have a fairly flat response.

A suggested list of Test Equipment needed for proper alignment of the receiver is listed here. Under no circumstances should alignment be attempted without the proper equipment. When connecting the test equipment to the various points in the receiver, be certain that a good connection is made and that the leads are as short as possible.

In alignment of the R-F Amplifier in particular the Sweep Generator must be properly terminated in order to prevent distortion of the response curve caused by reflections and losses on the lines. All equipment used must be adequately grounded on the receiver chassis. Always allow sufficient time for both test equipment and receiver to warm up before starting the alignment.

Test Equipment Specifications

1. R-F Sweep Generator
   a. Frequency Ranges
      4.5 MC with 25 KC Sweep Width, 40 - 50 MC with approximately 10 MC Sweep Width 50 - 90 MC, 170 - 220 MC with at least 10 MC Sweep Width.
   b. Constant Output within the sweep range.
   c. Signal Output not less than 0.1 volt maximum.
2. Marker Generator
   a. Frequency Ranges
      41.25 - 47.25MC — I-F Markers
      55.25 - 215.75MC — Picture-Sound Carrier Markers
      4.5 MC — Sound I-F and 4.5 MC Trap
   b. Modulated Signal over I-F Range (optional)
   c. 50% AM modulation at 4.5 MC.



3. Oscilloscope
   a. Good sensitivity in Vertical Amplifier
   b. Preferably a 5 inch screen or larger
4. Vacuum Tube Voltmeter
   a. High input resistance
   b. Accurate low voltage range
5. Crystal Detector Network
   a. Refer to construction detail in figure 7.

R-F AMPLIFIER ALIGNMENT

Note:

1. Connect the sweep generator output cable to the receiver antenna input terminals through the proper terminating network. If the sweep generator used has a 300 ohm balanced output use the matching pad shown in Figure 1A. For other generators use the proper values of R_t and R_1 for the output cable impedance of the particular generator. Adjust the generator to sweep Channel 10.
2. Couple an accurately calibrated marker generator into the antenna input to provide picture and sound carrier markers. In most cases the marker generator can be connected across the sweep generator terminals. A 10K isolating resistor should be used in series with the marker output cable. Maintain the output of the marker generator at a low level to prevent distortion of the response curve.
3. Connect the oscilloscope (high side) through a 10K isolating resistor to the test point (small wire loop) on top of R-F Tuner Chassis. If necessary to provide a clean trace on the scope, connect a 270 uuf. (approx. value) capacitor across the vertical input terminals of the scope.
4. Remove the AGC Amplifier tube (V401, 6AU6) and connect a bias source (see note 2 of Video I-F Alignment) from terminal 2 of the R-F, I-F Chassis Power Cable Plug to chassis. Set the bias on terminal 2 at 3 volts.
5. Remove the 1st I-F Amplifier tube (V201) and detune the mixer plate transformer, T101.

R-F AMPLIFIER ALIGNMENT CHART

Step No.:	Set Sweep Generator to:	Set Marker Generator to:	Connect Generator Output Cable to:	Connect Oscilloscope to:	Set Channel Selector to:	Adjust	Refer to Note/s:
1	Sweep Channel 10	193.25MC 197.75MC	Receiver Antenna Input Terminals	Test Point on R-F Tuner through 10K Resistor	Channel 10	C117, C107 & C111 for response curve shown in Fig. 2.	1, 2, 3, 4, 5, 6
2	Sweep Channel 13	211.25MC, 215.75MC			Channel 13	Check Response Curve on all Channels	7
3	Sweep Channel 12	205.25MC 209.75MC			Channel 12		
4	Sweep Channel 11	199.25 MC 203.75MC			Channel 11		
5	Sweep Channel 9	187.25MC, 191.75MC			Channel 9		
6	Sweep Channel 8	181.25MC, 185.75MC			Channel 8		
7	Sweep Channel 7	175.25MC, 179.75MC			Channel 7		
8	Sweep Channel 6	83.25MC, 87.75MC			Channel 6		
9	Sweep Channel 5	77.25MC, 81.75MC			Channel 5		
10	Sweep Channel 4	67.25MC, 71.25MC			Channel 4		
11	Sweep Channel 3	61.25MC, 65.75MC			Channel 3		
12	Sweep Channel 2	55.25MC, 59.75MC			Channel 2		

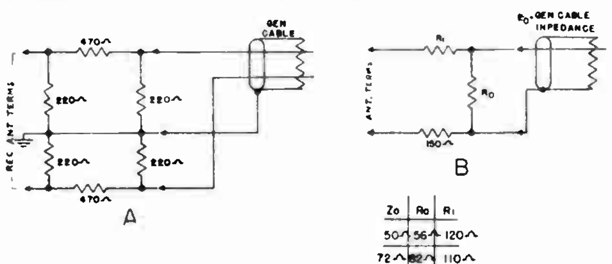


Figure 1

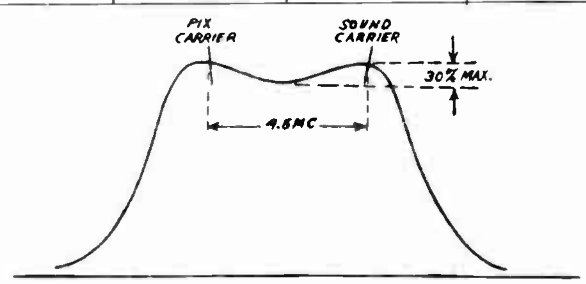

Figure 2

6. Set the receiver Channel Selector for Channel 10. A trace should appear on the scope similar to that shown in Figure 2. Adjust the trimmers C117, C107 and C111 on top of the R-F Tuner Chassis for maximum amplitude and to locate the sound and picture carrier markers within the limit shown in Figure 2.
7. Adjust the sweep and marker generators progressively for each channel. Check the response curve obtained on each channel. The curve should be within the following limits: neither side of the curve should be down more than 30% and the valley of the curve should not be down more than 30% of the total amplitude. If the response of a particular channel does not come within these limits, check to see that the correct coils for that channel are being used and try replacing the antenna coil for that channel. As a final step, a compromise can be made by adjusting the trimmer C117, C107 and C111 to improve the response of the channel that is off. The response on all other channels should then be rechecked to determine the extent to which they were affected by the compromise.

LOCAL OSCILLATOR ALIGNMENT

Note:
1. Connect the sweep generator output cable to the receiver antenna input terminals through the proper terminating network. If the sweep generator used has a 300 ohm balanced output use the matching pad shown in Figure 1A. For other generators use the proper values of R_o and R_i for the output cable impedance of the particular generator. Adjust the generator to sweep Channel 13.
2. Couple an accurately calibrated marker generator into the antenna input to provide picture and sound carrier markers for Channel 13.
3. Connect the oscilloscope (high side) through a 10K isolating resistor to the junction of R219 and pin 7 of V205A.
4. Remove the AGC Amplifier tube (V401, 6AU6) and connect a short test lead from pin 2 of the R-F, I-F Chassis Power Cable plug to chassis. This places the R-F Amplifier bias at zero. Also, connect a bias battery (a 4.5 Volt battery with a 1K pot connected across its terminals can be used), negative side to terminal 3 of the same plug and positive side to chassis. Adjust the pot to provide −3 volts bias at terminal 3 of the R-F, I-F Chassis Power Cable plug.
5. Set the Channel Selector to Channel 13 and check the response curve obtained against the ideal curve shown in Figure 4. If the shape of the curve is not within these limits, it will be necessary to repeat the R-F and I-F Amplifier Alignments. The R-F and I-F Amplifiers must be properly aligned before the oscillator adjustments can be correctly made.
6. Set the Fine Tuning control to the approximate center of its mechanical range and leave it set in this position for the entire alignment.
7. Adjust the individual oscillator "slug" for Channel 13 to properly position the markers on the curve. This adjustment should be made with a non-metallic screwdriver having an ⅛ inch blade approximately. If one of the slugs should "fall into" the coil form, first remove the metal shield which covers the lower portion of the turret (to remove the shield pull down at the front and slide it out of its hinges at the rear) and then remove the particular oscillator coil from the turret. To reposition the slug, move the slug retaining spring aside and tap the coil until the slug slides forward, then replace the spring so that the slug is held in place. Replace the coil in the turret and proceed with its alignment.
8. Set the sweep and marker generators, progressively for each channel and check the position of the markers on the curves. Adjust the individual oscillator "slug" wherever necessary to properly locate the markers.

VIDEO I-F ALIGNMENT

Note:
1. Connect the sweep generator output cable (properly terminated in its characteristic impedance) to pin 1 of V201 (grid of 1st I-F Amplifier) through a .001 ufd. isolating capacitor and adjust it to sweep from 40 to 50 MC. If a separate marker generator is used it should be coupled to the same point through a 10K resistor.
2. Remove the AGC Amplifier tube (V401, 6AU6) and connect a bias source from terminal 3 of the R-F, I-F Chassis Power Cable plug to chassis. A bias source may be obtained from a 4.5 volt battery with a 1K pot connected across its terminals. Connect the positive end of the battery to chassis ground and connect the arm of the pot to terminal 3 of the R-F, I-F plug. Connect a VTVM to terminal 3 of the plug and adjust the pot for a minus 3.8 volt reading on the VTVM.
3. Connect the oscilloscope high side to the junction of R219 and pin 7 of V205A through a 10K isolating resistor.
4. Check the response curve for evidence of local oscillator influence by adjusting the fine tuning control If the shape of the curve changes, switch to another channel where oscillator influence is not present or else adjust the Channel Selector so that it is between channels.

LOCAL OSCILLATOR ALIGNMENT CHART

Step No.	Set Sweep Generator to:	Set Marker Generator to:	Connect Generator Output Cable to:	Connect Oscilloscipe to:	Set Channel Selector to:	Adjust	Refer to Note/s:
1	Sweep Channel 13	211.25MC, 215.75MC	Receiver Antenna Input Terminals	Junction of R219 and pin 7 of V205A through 10K Resistor	Channel 13	Channei 13 Oscillator Slug	1, 2, 3 4, 5, 6 7
2	Sweep Channel 12	205.25MC, 209.75MC			Channel 12	Channel 12 Oscillator Slug	
3	Sweep Channel 11	199.25MC, 203.75MC			Channel 11	Channel 11 Osc. Slug	
4	Sweep Channel 10	193.25MC, 197.75MC			Channel 10	Channel 10 Osc. Slug	
5	Sweep Channel 9	187.25MC, 191.75MC			Channel 9	Channel 9 Osc. Slug	
6	Sweep Channel 8	181.25MC, 185.75MC			Channel 8	Channel 8 Osc. Slug	
7	Sweep Channel 7	175.25MC, 179.75MC			Channel 7	Channel 7 Osc. Slug	
8	Sweep Channel 6	83.25MC, 87.75MC			Channel 6	Channel 6 Osc. Slug	
9	Sweep Channel 5	77.25MC, 81.75MC			Channel 5	Channel 5 Osc. Slug	
10	Sweep Channel 4	67.25MC, 71.75MC			Channel 4	Channel 4 Osc. Slug	
11	Sweep Channel 3	61.25MC, 65.75MC			Channel 3	Channel 3 Osc. Slug	
12	Sweep Channel 2	55.25MC, 59.75MC			Channel 2	Channel 2 Osc. Slug	

NOTE: The individual oscillator slugs are accessible from the front of the cabinet, therefore, if the R-F and I-F circuit are properly aligned, "touch up" of the oscillator alignment on any channel can be accomplished without removing the chassis from the cabinet. For further information, refer to "Oscillator Alignment Using a TV Signal" as outlined in the Installation Instructions.

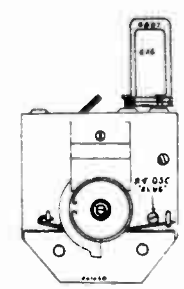

Figure 3

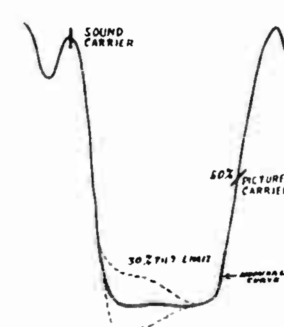

Figure 4

5. Adjust the marker generator to provide a marker at 41.25 MC and adjust the top slug of T202 (Co-Channel Sound I-F Trap) for minimum response at the marker frequency. This adjustment may be made easier by running the sweep generator output high so that the trap "dips" are easily visible.
6. Adjust the marker generator to 47.25 MC and adjust the top slugs of T203 and T204 (Adjacent Channel Sound I-F Traps) for minimum response at the marker frequency.
7. Reduce the sweep generator output so that a normal curve is seen. Adjust the marker generator to 42.65 MC and then adjust the bottom slugs of T202 and T204 to obtain maximum amplitude of the 42.65 MC marker.
8. Adjust the marker generator to 45.3 MC and adjust the bottom slugs of T203 and T205 to obtain maximum amplitude of the 45.3 MC marker. To obtain access to the bottom slug of T205 remove the contrast control from the front panel. Use a thin blade alignment tool for the adjustment.
9. Connect the sweep and marker generators to the test point on the R-F Tuner through a .001 ufd., isolating capacitor. Set Channel Selector to Channel No. 9. If the available equipment allows, markers at both 42.25 MC and 45.75 MC should be provided simultaneously.
10. Adjust the overcoupled I-F circuit, T101 (on top of the R-F Tuner) and the slug of L201 to obtain a curve similar to that shown in Figure 5. With certain types of sweep generators this method is not usable due to the spureous response curves obtained on the scope which are caused by the various harmonics of the generator. Under these conditions the overcoupled stage should be aligned as in step 6 of alternate method of I-F alignment. The 42.25 MC marker must fall within 30% to 70% of maximum amplitude of the curve on one side and the 45.75 MC marker must fall within 40% to 60% of maximum on the other side. The valley of the curve should not exceed 10% and the tilt should not be greater than + or −10%. A 45 MC marker should fall within 5% of maximum amplitude on the high frequency side of the curve.

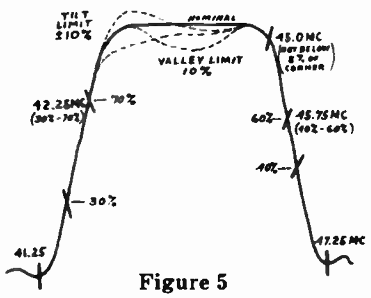

Figure 5

ALTERNATE METHOD OF VIDEO I-F ALIGNMENT

Note:

1. Connect the signal generator output cable to pin 1 of V201 through .001 ufd., isolating capacitor. If an oscilloscope is used for indication, the generator should be AM modulated with a 400 c.p.s. signal.
2. Set the bias at the I-F grids to minus 3.8 volts (refer to note 2 of Video I-F Alignment).
3. Connect the VTVM to the junction of R219 and pin 7 of V205A through a 10K resistor.
4. Set the signal generator to 41.25 MC and adjust the top slug of T202 for minimum indication on the VTVM.
5. Set the signal generator to 47.25 MC and adjust the top slugs of T203 and T204 for minimum indication on the VTVM.
6. Set the signal generator to 42.65 MC and adjust the bottom slugs of T202 and T204 for maximum indication on the VTVM.
7. Set the signal generator to 45.3 MC and adjust the bottom slugs of T203 and T205 for maximum indication on the VTVM. To obtain access to the bottom slug of T205, remove the Contrast Control from the front panel. Use a thin blade alignment tool for this adjustment.
8. Connect the Sweep Generator output cable to the receiver antenna input terminals through the proper terminating network. (Refer to note 1 of R-F Amplifier Alignment).
9. Connect the marker generator to pin 1 of V201 through a .01 ufd., capacitor.
10. Set the I-F Bias to minus 3 volts (Refer to Note 2 of Video I-F Alignment).
11. Connect the oscilloscope high side to the junction of R219 and pin 7 of V205A through a 10K resistor.
12. Set the receiver Channel Selector to Channel 12 and adjust the sweep generator to sweep Channel 12. A curve should appear on the scope similar to that shown in Figure 6. The marker generator should be adjusted to provide markers at 42.25 MC and 45.75 MC.
13. Adjust T101 (on top of the R-F Tuner) and the slug of L201 for location of the markers as stated in Note 10 of Video I-F Alignment.

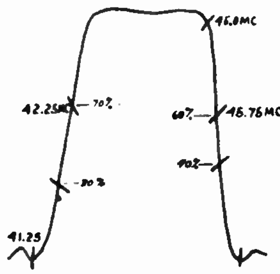

Figure 6

4.5 MC. SOUND I-F ALIGNMENT

Note:

1. Connect generator output cables to junction of L206 and R219 (pin 2 of V205A).
2. Connect vertical input leads of oscilloscope to detector network shown in fig. 7. Clip the alligator clip of the detector input over the insulated wire between pin 2 of the 6BN6 and L303 so that there is no direct electrical connection between the input to the detector network and the circuit under test. The ground connection of the detector circuit, however, should be connected to the chassis.
3. Short pin 1 to pin 2 of tube V202.
4. Inject 4.5 Mc. Signal with 50% AM modulation and adjust L301 for maximum. Use full vertical amplifier oscilloscope gain so that the signal level from the generator is kept as low as possible.
5. Adjust L303 for maximum indication and then recheck the adjustment of L301.
6. Remove crystal detector network and connect the oscilloscope directly to the junction of R308 and R309.
7. Inject 4.5 Mc. FM signal with 25 kc. deviation and using full generator output to insure limiting in the 6BN6, adjust L302 (quadrature coil — accessible through bottom hole in back of Shading Control) for maximum output.
8. Remove short from V202 and connect receiver to antenna through a signal attenuator (Centralab PCH-4, IRC QJ-3 or Equivalent). Adjust set for reception of a local TV signal. By attenuating the incoming signal so that background noise is just noticeable at all times a more exact setting can be obtained. Adjust Noise Rejection Control (R307 — accessible through top hole in back of Shading Control) for minimum background noise and hiss.
9. Remove attenuator and with full signal adjust L302 for clearest sound.

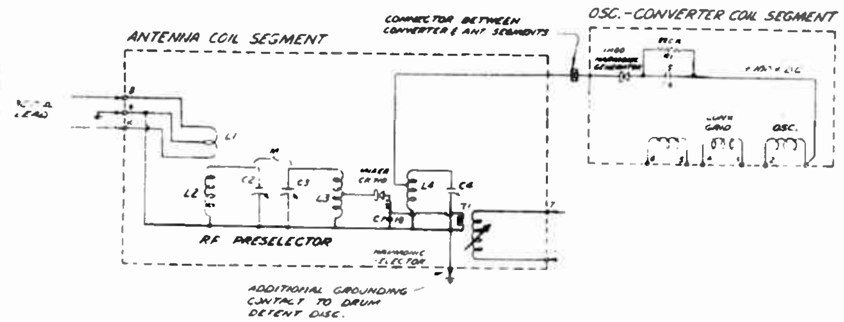
ADAPTABILITY TO UHF

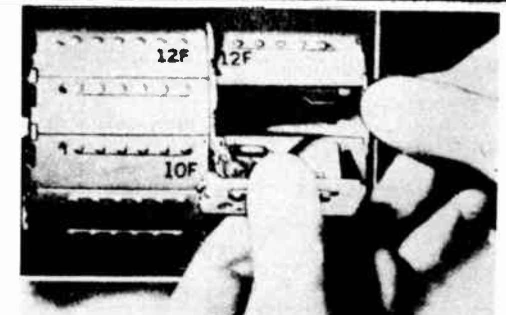
Conversion of the tuner incorporated in the CX37 chassis to reception of UHF stations can be accomplished by merely removing coil strips from the tuner (for channels that are not locally received) and inserting a set of UHF strips for each UHF channel that is locally available. Due to the physical dimensions of the UHF strips it is not possible to place them adjacent to each other. If strips for more than one UHF channel are to be installed, there should be the space of at least one channel strip between them. The UHF strips are in two sections (as is the VHF strip) and contain all of the required components to complete the conversion.

One section of the UHF strip includes the antenna input circuit, a crystal mixer and its tuned circuit and a 1st I-F grid coil. The second section consists of the coils for the 1st I-F plate, converter grid and the Oscillator.

In operation, the UHF signal is fed into the balanced antenna input coil and is then coupled into the mixer circuit where it is mixed with an oscillator frequency (a harmonic of the fundamental oscillator frequency) to produce an I-F frequency which falls in the spectrum between the two present VHF television bands. This I-F frequency is then coupled into the grid of the R-F Amplifier which in this case acts as a 1st I-F Amplifier. The amplified I-F signal is then coupled into the mixer circuit where the fundamental oscillator frequency mixes with it to produce the regular I-F frequency of the receiver. The functions of the receiver from this point on then are the same as for VHF reception.

Channel strips to convert this tuner to UHF reception are available through your local Capehart parts distributor. At the time of ordering it is essential that the exact UHF channel number desired and the exact tuner that the strips are to fit, be specified.





ELIMINATION OF TELEVISION INTERFERENCE

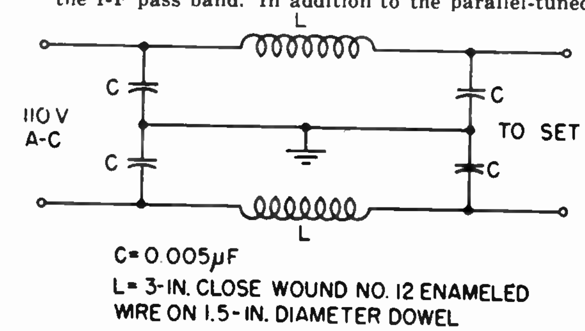
Everyone is familiar with the types of interference that have continually plagued the radio listener—it has merely been accepted as "static." Unfortunately for television viewers, the eyes are much more critical with respect to interference than the ears. In addition to this, there are other factors which add to the interference problem. Television, having a relatively wide band width, provides a greater range over which interference can be received. Also, the problem of weak signals in many areas permits types of interferences which otherwise would not be noticeable.

Many types of television interference are beyond the scope of elimination within the receiver especially in weak signal areas. The design of the CX-37 series chassis takes into consideration, wherever possible, the elimination or minimization of TVI. Use of the 40MC I-F itself eliminates a sizeable amount of interference resulting from images, oscillator radiation from other TV sets and, of course, signals in the 21 to 27MC range. High selectivity in the R-F amplifier is supplemented with the incorporation of parallel-tuned wave traps in the antenna input circuit. These traps are tuned to provide rejection of signals within the I-F pass band. In addition to the parallel-tuned traps, a series-tuned trap is provided in the input grid circuit of the R-F Amplifier. This trap can be adjusted to provide maximum rejection at any frequency within the I-F pass band.

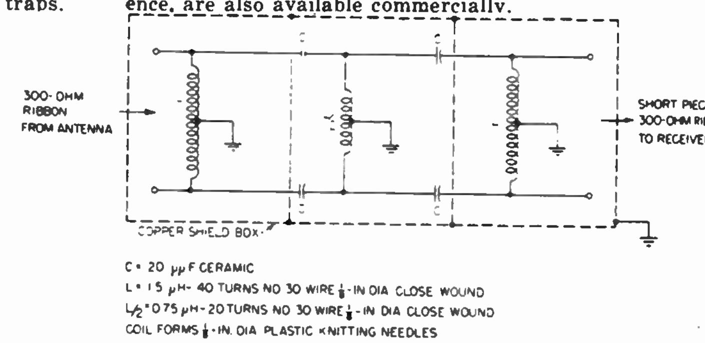
In addition to the rejection built into these instruments, additional rejection of certain types of TVI can be obtained through the use of external devices such as the High-Pass Filter, which is shown below. This high-pass filter provides additional attentuation of all frequencies below the television band. The device can be constructed as shown in the diagram; however, similar devices are available commercially for such use.

In the case of interference from household electrical appliances entering the receiver through the AC line, a power-line filter such as shown below may be of some help. Interference of this type is best eliminated at the source, however it is not always possible to do so. Some difficulty may be encountered in locating the source and also in obtaining the cooperation of the owner of the interfering appliance.

Powerline filters, for eliminating this type of interference, are also available commercially.



Power-line filter for appliance interference



Typical high-pass filter to attenuate interference below television frequencies

†Measured with zero brilliance.

MEASUREMENT CONDITIONS

All voltages measured with no signal input on a vacuum tube voltmeter from tube socket pin to chassis unless otherwise indicated. All voltages should be with ± 20% of the above stated values with line voltage of 117 volts, 60 cycle AC. Voltages on V206 vary with setting of Contrast. Voltages on V401 vary with setting of AGC Set. Voltages on V501 and V502 vary with settings of Vert. Hold, Vert. Lin. and Height. Voltages on V207 vary with setting of shading.

A. G. C. Adjustment

Adjustment of the AGC control (R238) should only be made with the aid of a calibrated oscilloscope. Connect the vertical input of the scope to pin 1 of the 2nd Video Amplifier (V206). With the set connected to an antenna and adjusted for normal reception adjust the AGC control (on top of chassis between power transformer and high voltage cage) for an indication of 12 volts peak-to-peak.

The AGC control is properly adjusted at the factory and the setting is marked with colored cement across the shaft and bushing of the control. If the control should become misadjusted and a calibrated oscilloscope is not available, the control can be set approximately by resetting to its original position, as indicated by the cement.

Production Changes

Early production chassis may vary from the schematic shown in the following ways:

C209, C239, C240, C241 were not used.
R225, R242, R306 were not used.
R315 was 470K instead of 100K.
R226 was 1800 instead of 820.
R238 was 250K instead of 100K and was connected between pin No. 1 and pin No. 7 with a 4.7K in series. C526 (.047 mfd 400V) was connected from junction of C524-R519 to +300V and H. V. fuse was .15 amp.
C525 was grounded instead of connected to pin No. 8 of V502.

Special Instructions for UHF Installation

These receivers are manufactured with two types of R-F Units. The standard models employ a chassis using the turret type tuner (Part No. 850222) which can be adapted to UHF by addition of UHF Channel Strips. The second version incorporates a chassis which employs a UHF/VHF Tuner assembly.

Models Employing the UHF/VHF Tuner Assembly

These models can be identified by the marking "CX-37-1" on the chassis rear apron, also the model number as appears on the model number label on the cabinet back will contain the suffix "-1". Separate antenna input terminals are provided on the rear of the cabinet on these models for UHF and VHF antennas. These are properly marked, VHF and UHF. If separate UHF and VHF antennas are used in the installation with individual transmission lines for each, the individual lines should be attached to the corresponding input terminals. If a single transmission line is used for both UHF and VHF as would be the case if a combination antenna is employed a UHF/VHF antenna coupler (such as the Vee DX Mighty Match MM-30) can be used to separate the signals at the receiver. In this case the common transmission line from the antenna should be connected to the center terminals of the coupler, the UHF terminals on the receiver should be connected to the UHF terminals on the coupler and the VHF terminals on the receiver should be connected to the VHF terminals on the coupler. The UHF/VHF tuner is completely pre-adjusted at the factory and should require no adjustments upon installation of the receiver.

Models Employing the Turret Type Tuner

The chassis used in these models will be marked "CX-37R" on the chassis rear apron. (Note: Early CX-37 Series Chassis were not marked as such). These models have a single antenna input terminal on the rear of the cabinet which is used for both VHF and UHF. It is advisable to use a common transmission line, however, if separate lines are employed an antenna coupler can be used to feed the two lines into the common input terminals.

Installation of UHF Channel Strips

To install UHF Channel Strips it is not necessary to remove the chassis from the cabinet. The installation can be made from the bottom of the instrument, as follows:

(1) Turn the instrument over on its top, placing it on a suitable protective pad or cloth. Remove a few staples and fold back a portion of the ventilating screen on the tuner side of the chassis mounting shelf. This provides easy access to the tuner in most instruments. On the smaller table models it may be necessary to loosen the chassis mounting bolts and allow the chassis to slip down a fraction of an inch.

(2) Remove the anti-radiation shield, prying up with a screw driver.

(3) Remove a set of unused VHF strips (either adjacent or preferably, one channel away from a locally received VHF station).

(4) Insert the UHF Strips as follows:
- (A) UHF Antenna segment first.
- (B) Oscillator segment last. Make certain that a good connection is made at the inter-connector wire between segments.
- (C) Make sure that the spring clips hold the segments securely in place.

(5) Replace the anti-radiation shield and tack down the ventilating screen.

(6) Return the instrument to the upright position and proceed with the set-up adjustments as outlined on page 1 of this folder. The local oscillator adjustment for the UHF strip is similar to that for VHF. As a final check set the channel selector to the channel position in which the UHF strip has been installed and set the fine tuning control to the center of its range. Insert an insulated alignment screw driver through the oscillator adjustment hole in the front of the chassis and adjust the oscillator slug slowly (either in or out) until the picture begins to distort (sound in picture). Rotate the slug just slightly from this position to the point of best picture definition.

Caution: Do not make any other adjustments to the UHF strips. When more than one set of strips are installed they must be spaced on the turret at least one VHF strip apart. Due to the physical size of the strips, they cannot be installed adjacent to each other in the turret. After the installation is completed, the proper UHF channel indicator tab should be cemented in place on the Channel Selector to identify the position (or positions) in which UHF strips have been inserted. Sets of UHF and VHF channel tabs are available from your Capehart Distributor. The set contains VHF tabs which can be cemented in place also on the Channel Selector to present a symetrical appearance.

Beam Corrector Magnet Adjustment

Adjust the Height Control so that the top and bottom edges of the raster are just visible and check to see if the raster lines near the top and bottom are sufficiently straight. If the lines are bent adjust the two Beam Corrector Magnets (attached to the yoke support bracket, one on each side of the CRT) to remove the bend. These magnets are adjusted at the factory and should not require re-adjustment unless they have been accidentally bent out of position.

These magnets can be adjusted by moving them closer to or further from the bell of the CRT or by moving them from side to side. As the magnet is moved closer to the tube, the raster lines will be pulled toward the magnet. Likewise as the magnet is moved away from the tube, it will have less effect on the raster lines. If the magnets have been shifted considerbly from their correct adjustment an irregular bend may appear in the raster at the sides.

NOTES

THE FLEETWOOD MODEL 600 REMOTE TUNING TELEVISION SYSTEM

The FLEETWOOD Remote Receiver is designed for custom installation in a special cabinet, in the wall of a room, or into a recess or nook which may exist in the television viewing area. Its flexibility frees it from the usual requirement that the entire set be accessible for tuning. With the FLEETWOOD Remote system, it is quite practicable to place the viewing screen over a stairway, or over a buffet. The tuner, measuring only 7 x 11 1/2 inches, may be built into an end table, into a magazine rack, or placed wherever it may be of service with a minimum of effort on the part of the viewer. It may be mounted in any position, and its beautifully edgelit dial, in perfect taste, will add warmth and color to any room.

The system employs 27 tubes, and will accommodate any of the standard 21" or 24" magnetic focus picture tubes. The high voltage system employed will supply 18,000 volts nominally, resulting in extremely good spot focus and high brilliance. A cosine squared yoke insures uniform focus over the entire screen.

The picture chassis, when fitted with a 21" tube, can be mounted in a space 21" wide and 21" high. The 21AP4 picture tube is only 22 3/4" long, from the faceplate to the outside of the tube socket. This tube is recommended wherever space is at a premium; for installation in an existing cabinet, or an enclosure of limited size. When fitted with a 24" tube, the chassis can be mounted in a space 26" wide and 30" high. The 24" tube is 24" long from faceplate to the outside of the socket.

The following Kits are available as accessories to your Fleetwood Receiver:

601 A Kit for mounting a type 21AP4 Metal rectangular tube. This Kit includes:

1 - Plastic ring for the front of the picture tube.
1 - Plastic sleeve for the picture tube, with anode connector.
1 - Rubber band for the plastic ring.
1 - Tie down cable for the picture tube, 49" long.
1 - Set of blocks for the front of the picture tube.
4 - 8-32 x 3/4" self-threading screws for the blocks.
2 - Nuts for the tie down cable.

601 B Kit for mounting a 21" glass tube, either cylindrical or spherical faced. This Kit includes:

1 - Pair of support blocks for the front of the picture tube.
1 - Tie down strap for the front of the picture tube.
1 - Anode connector for the picture tube.
4 - 8-32 x 3/4" self-threading screws for the support blocks.
2 - Pieces of cork for the face of the support blocks.
2 - Phosphor Bronze Strips 1/4" x 2".
2 - #6-32 Self-threading screws.

604 A Kit for mounting a 24AP4 round metal tube. This Kit contains:

1 - Pair of side panels to support the yoke and focus coil.
1 - Pair of front tube support assemblies.
2 - 6-32 x 1/4" self-threading screws for the front support assemblies.
2 - 8-32 x 1/4" self-threading screws for the front support assemblies.
1 - Tie down cable for the front of the tube - 64" long.
1 - Plastic ring for the front of the tube
1 - Insulating sleeve for the tube, with anode connector.
1 - Rubber band for the plastic ring.

621 A Kit for framing a 21" metal picture tube. This Kit is assembled at the factory and is composed of the following items:

1 - Picture frame of Pacific Coast Birch, unfinished, sanded smooth, approximately 18 1/2" x 24 1/2" outside dimensions.
1 - Safety glass, 16" x 22" x 7/32", laminated.
1 - Mask for a 21AP4 type tube, gray-green in color.
4 - Clips for holding the assembled frame to the wall.

621 B Kit for framing a 21" Cylindrical Faced glass tube. This kit is assembled at the factory, and is identical with the 621 A Kit except for the mask, which will fit a Cylindrical Faced glass tube instead of the metal tube.

624 Kit for framing a 24" Round Metal Tube. This kit is assembled at the factory, and is composed of the following items:

1 - Picture Frame of Pacific Coast Birch, unfinished, sanded smooth, approximately 22" x 28" outside dimensions.
1 - Safety Glass, 20" x 26" x 7/32", laminated.
1 - Mask for a 24AP4 tube, gray-green in color.
4 - Clips for holding the assembled frame to the wall.

ELECTRICAL SPECIFICATIONS

PICTURE TUBE:	21AP4 Metal Rectangular or 24AP4 Metal Round
REMOTE PANEL CONTROLS:	Station Selector Fine Tuning Contrast Off-On-Volume

PICTURE CHASSIS CONTROLS: FRONT:	Height Vertical Linearity Brightness Focus Horizontal Hold Vertical Hold	
REAR:	Width Horizontal Drive Horizontal Linearity	
I. F. FREQUENCIES:	Video 25.75 mc Audio 21.25 mc	
BANDWIDTH:	4 mc	
AUDIO OUTPUT:	1. 4.5 watts at terminals on Picture Chassis with volume control on remote tuner; 2. Ratio detector output; no volume control.	
POWER:	117 Volts, 60 Cycle Picture tube chassis: 180 watts Remote tuner chassis: 55 watts	
PICTURE TUBE ANODE VOLTAGE:	18 kv, design center	

TUBE COMPLEMENT:
(Remote Tuner)

1 - 6BQ7/6BK7	Cascode R.F. Amplifier
1 - 6J6	First Detector and Local Oscillator
1 - 6CB6	First I. F. Amplifier
3 - 6AU6	2nd, 3rd, and 4th I. F. Amplifiers
1 - 12AU7	Video Detector, AGC Rectifier, and 1st sound I. F. Amplifier
1 - 6AU6	2nd sound I. F. Amplifier
1 - 6AL5	Sound Ratio Detector
1 - 6AB4	Sound Cathode Follower
1 - 12AT7	Video Cathode Follower
1 - 6X4	Rectifier

TUBE COMPLEMENT:
(Picture Chassis)

1 - 6AB4	Grounded Grid Video Input Stage
1 - 6AC7	Video Output Stage
1 - 6BE6	Sync Stripper and Noise Inverter
1 - 6SN7	Sync Phase Inverter and D.C. Restorer
1 - 6AL5	Horizontal Discriminator
1 - 6SN7	Vertical Oscillator
1 - 6S4	Vertical Output Amplifier
1 - 6SN7	Horizontal Oscillator
1 - 6CD6	Horizontal Amplifier
1 - 6W4	Horizontal Damper
1 - 1B3	High Voltage Rectifier
1 - 6AV6	Audio Input Amplifier
1 - 6V6	Audio Power Amplifier
1 - 5U4	Plate Supply Rectifier

WARNING — HIGH VOLTAGE

Extremely high voltages are used in the operation of this set. To avoid personal injury, extreme care should be exercised so that no contact is made with any components connected to the high voltage circuits. Do not operate the receiver with the high voltage compartment shield removed.

WARNING — PICTURE TUBE HANDLING

Particular care must be exercised when handling picture tubes due to their high vacuum and large surface area. The picture tube must not be struck, scratched, or subjected to more than moderate pressure at any time as fracture of the glass will result in an implosion of considerable violence capable of damaging both property and person.

PICTURE CHASSIS			
21" Chassis:	20 1/4	14 1/2	20 1/4
21" Chassis, tube mounted:	20 3/4	21	23 1/4
24" Chassis:	20 1/4	19	22 1/2
24" Chassis, tube mounted:	26	30	25 1/4
TUNER CHASSIS	11 1/2	7	8 1/2

INSTALLING A 21" METAL PICTURE TUBE (21AP4) USING 601 A KIT

1. Mount the front support blocks on the chassis, ridges forward, screwing the 8-32 x 3/4" self-threading screws through the blocks and into the holes found 1/2" from the front of the chassis.

2. Unpack the type 21AP4 picture tube and place it face down on a soft pad to protect it from being scratched. Place plastic sleeve over the tube away from the socket key. Bend the clip around the front edge of the rim of the picture tube.

3. With the plastic sleeve snug against the tube, wrap the plastic ring around the front rim of the tube, over the sleeve. Work the ring tightly around the tube. Secure the ring with the rubber band, which must lie flat in the groove.

4. Loosen the screws which hold the yoke mounting hood on top of the mounting panels, allowing the yoke to slip toward the rear of the chassis.

5. Set the picture tube, complete with its ring and plastic cover, in place on the chassis, using extreme caution not to damage the deflection yoke windings with the prongs of the picture tube as the base of the tube is guided through the yoke. The high voltage clip should be on your left as you face the tube. The ridges on the front mounting blocks should fit into the groove in the mounting ring.

6. Place the tie down cable in the groove in the plastic ring and pass the ends through the holes in the front corners of the chassis. Screw the nuts on the ends and tighten MODERATELY. These nuts need be only "finger tight" to secure the tube.

7. Solder anode connector to the end of the white wire extending through the front of the high voltage box. Snap this connector into the terminal in the plastic sleeve.

8. Loosen the wing screw protruding from the top of deflection yoke. Push the yoke mounting hood forward until the rubber rims engage the flare of the picture tube firmly. While holding the hood forward under moderate tension, tighten the two screws which fasten the hood to the top of the upright panels.

9. Push the deflection yoke forward until it also engages the flare of the picture tube, and tighten the wing screw in the top of the deflection yoke.

10. Clamp the Ion Trap Magnet around the neck of the picture tube, about 1/2" forward of the tube base.

11. Place the picture tube socket on the base of the picture tube. Dress the leads away from the tubes on the chassis, and also away from the picture tube.

INSTALLING A 21" GLASS TUBE USING A 601 B KIT

1. Mount the front support blocks on the chassis, screwing the 8-32 x 3/4" screws through the blocks and into the holes found 1/2" from the front of the chassis.

2. Remove the four screws which hold the yoke mounting panels to the chassis. Move the entire assembly (yoke, focus coil and panels) back 1 1/4", by putting the screws into the front set of holes in the panels.

3. Fasten the 2" x 1/4" grounding strips to front of yoke mounting panels, using 6-32 x 1/4" self-threading screws.

4. Place the pieces of cork on the faces of the front blocks. If desired, the cork may be cemented to the blocks.

5. Loosen the screws which hold the yoke mounting hood on top of the mounting panels, allowing the yoke to slide toward the rear of the chassis.

6. Set the picture tube in place on the blocks, using extreme caution not to damage the deflection yoke windings with the prongs of the picture tube as the base of the tube is guided through the yoke. The anode connection on the side of the picture tube should be on your left as you face the tube. The grounding strips must make connection with the coating on the outside of the tube.

7. Place the tie down strap over the top of the picture tube and pass the ends through the holes in the front corners of the chassis Screw the nuts onto the ends of the strap MODERATELY. These nuts need be only "finger tight" to properly secure the tube.

8. Loosen the wing screw protruding from the top of the deflection yoke. Push the yoke mounting hood forward until the rubber rim engages the flare of the picture tube firmly. While holding the hood forward under moderate tension, tighten the two screws which fasten the hood to the top of the upright panels.

9. Push the deflection yoke forward until it also engages the flare of the picture tube, and tighten the wing screw on top of the deflection yoke.

10. Clamp the ION TRAP MAGNET around the neck of the tube, about 1/2" forward of the base.

11. Place the picture tube socket on the base of the picture tube.

12. Dress the leads away from the tubes on the chassis, and also away from the picture tube.

13. Solder the anode connector onto the end of the white wire extending through the front wall of the high voltage box, and press connector into place on the picture tube.

INSTALLING A 24" TUBE USING A 604 A KIT

1. Mount the front support brackets on the chassis. Each front support bracket is mounted (wood side forward) with one 8-32 and one 6-32 self-threading screws. The screws are driven upward from beneath the chassis. The 8-32 screw goes through the hole in the corner of the chassis and engages the center hole in the bracket.

2. Remove the deflection yoke hood and the focus magnet assembly from the upright panels at the rear of the chassis. Remove the panels, and replace them with the taller panels supplied with the 24" mounting kit. Replace the deflection yoke and hood, leaving it loose and free to slip toward the rear of the chassis. Remount the focus magnet on the new panels.

3. Unpack the type 24AP4 tube and place it face down on a soft pad to protect it from being scratched. Place the plastic sleeve over the tube, with high voltage clip on the side of the tube away from the socket key. Bend the high voltage clip around the front edge of the rim of the tube.

4. With the plastic sleeve snug against the tube, wrap the plastic ring around the front of the tube, over the sleeve. Secure the ring with the rubber band, which must lie flat in the groove.

5. Set the picture tube, complete with its ring and sleeve on the chassis, using extreme caution not to damage the deflection yoke windings with the prongs of the picture tube as the base of the tube is guided through the yoke. The high voltage clip should be on your left as you face the tube. The front mounting pieces should fit into the groove in the mounting ring.

6. Place the tie down cable in the groove in the plastic ring, and pass the ends through the holes in the outside ends of the front mounting assemblies. Screw the nuts on the ends of the rod and tighten moderately.

7. Solder anode connector to the end of the white wire extending through the front of the high voltage box. Snap this connector into the terminal in the plastic sleeve.

8. Loosen the wing screw which holds the deflection yoke in the yoke mounting hood. Push the yoke mounting hood forward until the rubber rims engage the flare of the picture tube firmly. While holding the hood forward under moderate tension, tighten the two screws which fasten the hood to the top of the upright panels.

9. Push the deflection yoke forward until it also engages the flare of the picture tube, and tighten the wing screw which holds it in the yoke mounting hood.

10. Clamp the Ion Trap Magnet around the neck of the picture tube about 1/2" forward of the tube base.

11. Place the picture tube socket on the base of the picture tube. Dress leads away from the tubes on the chassis, and away from the picture tube.

ELECTRICAL CONNECTIONS

Connect the tuner chassis with the picture chassis, using the 40-foot cable provided. Connect a P.M. Type speaker to the speaker terminals on the picture tube chassis. Plug each unit into a 117 volt, 60 cycle source of power. Turn the system "ON" by clockwise rotation of the center control on the tuner chassis. The tubes in both chassis should now be lighted.

Set the brightness control on the picture chassis to maximum. Adjust the Ion Trap Magnet until the screen of the picture tube lights up. The Ion Trap may be rotated completely, and moved back and forth along the neck of the picture tube. Proper adjustment has been attained when the light on the face of the picture tube is at its maximum.

Connect an antenna to the antenna terminals on the tuner chassis, using 300 ohm twin lead. It should now be possible to tune in a station.

CENTERING THE PICTURE

Each FLEETWOOD system is operated at the factory with a standard picture tube and is properly adjusted. However, picture tubes vary slightly and, when first set up, the picture on your set may not be properly centered. Around the neck of the picture tube, to the rear of the deflection yoke, will be found a focus magnet. It is mounted on a shelf with a single wing nut and is adjustable laterally on the shelf. The shelf in turn is mounted with two wing nuts and is adjustable vertically. These adjustments permit centering the picture. If the picture must be raised, the focus coil must be raised. Similarly, if the picture must be moved to one side in order to be centered, the focus magnet must be moved in the same direction as it is necessary to move the picture.

After the picture has been centered, it will be necessary to readjust the Ion Trap. The Ion Trap MUST BE ADJUSTED FOR MAXIMUM SCREEN BRIGHTNESS ONLY, OR THE PICTURE TUBE WILL BE DAMAGED, OVER A PERIOD OF TIME. MAKE ALL CENTERING ADJUSTMENTS WITH THE FOCUS COIL.

To level the picture, loosen the wing screw above the deflection yoke and turn the yoke slightly. Keep the yoke pushed forward against the flare of the picture tube when tightening the wing screw.

HEIGHT AND VERTICAL LINEARITY ADJUSTMENTS: These adjustments should be made only if a reliable test pattern is available from a station. During some parts of the day several stations may be transmitting test patterns, and their individual differences may be "averaged." Generally speaking, the "Vertical Linearity" controls the top portion of the picture, and can make the test pattern "flat headed" or "egg headed." After changing the Vertical Linearity, the height will probably have to be reset.

HORIZONTAL HOLD: If the stations should come in as a series of black and white bars running diagonally across the screen, adjust the Horizontal Hold. Do not center the picture with this control.

VERTICAL HOLD: Proper adjustment of this control will prevent the picture from "rolling" either up or down. When the Horizontal and Vertical Hold controls have been adjusted, they should not require re-setting for many months.

BRIGHTNESS: With no station tuned in, adjust this control so that the screen is nearly dark.

NORMAL OPERATION OF THE SYSTEM:

Select a station desired with the Station Selector Knob. Behind this knob is a FINE TUNING CONTROL. Turn this control counter-clockwise until the picture appears to be covered with a fine mesh pattern, or has "sound" in it. Turn the fine tuning control clockwise until this effect just disappears. This will be the point at which the picture will have a maximum of fine detail.

Adjust the CONTRAST control for the most pleasing picture. Too much contrast will give the picture a coarse appearance, while too little contrast will give the picture a "washed out" appearance.

OPERATION OF THE SYSTEM WITH A SEPARATE AUDIO SYSTEM:

On the rear of the tuner chassis is a jack marked DETECTOR OUTPUT, which may be used to supply audio to an external amplifier. In this case, the volume control in the tuner will not function, and the loudness or volume control in the external system must be used. It is important that the speaker terminals on the picture tube chassis be shorted with a wire at all times if there is no speaker connected to these terminals. Failure to do so may result in damage to the audio output transformer in the picture tube chassis.

CABINET CONSIDERATIONS

The FLEETWOOD picture chassis should always be mounted in a cabinet, or in an enclosure behind a wall. In either case, the face of the picture tube should be protected by a safety glass window. Suitable laminated safety glass, together with a Royalite Picture Mask and a mounting frame are available in the FLEETWOOD 621 Accessory Kit (for 21" tube); and the FLEETWOOD 624 Accessory Kit (for 24" tube). This safety glass should be mounted on a plywood panel not less than 1/4" thick. Panel layout drawings will be found in the back of this manual.

A piece of the plywood 2-1/2" x 10-1/2" should be salvaged from the panel cutout to make a matching cover for the secondary controls. Two spring clips are provided to hold the cover in place. This cover will rarely have to be opened after the set has been properly adjusted. If the set is housed in a cabinet, the back of the cabinet should be masonite. Ventilation should be provided by piercing the masonite with holes not larger than 1/4" in diameter, on centers not greater than 1/2".

In order that the longest possible life may be expected from the tubes and other components in the system, it is imperative that both chassis be installed in a manner that will provide adequate ventilation. The shelf on which the picture chassis is mounted should have an opening approximately ten inches square, near the center of the chassis. This opening should be covered with hardware cloth, or heavy screen.

MOUNTING THE TUNER

If the tuner is to be installed in a piece of furniture, check the thickness of the panel behind which it is to be installed. If the panel is not over 1/2" thick, the front panel and the bottom of the tuner may be removed and the dial bezel may be mounted directly on the panel.

An opening approximately 4" x 6" should be made in the shelf beneath the chassis for ventilation, and the opening should be covered with hardware cloth or heavy screen. Provision must also be made for ventilating the top of the chassis. At least 30 square inches of opening is recommended, at either the top, back, or sides of the tuner.

SERVICE NOTES

OSCILLATOR ADJUSTMENT

If the fine tuning control knob does not turn far enough to properly bring in a particular station, set the fine tuning control at the middle of its range. Turn the oscillator adjusting slug clockwise until the picture has "sound interference" in it. Turn slug counter-clockwise until this interference just disappears. This slug can be adjusted through the hole located one inch to the right of, and 1/4 inch above the station selector shaft. As the station selector is turned to a different station, a different slug will appear in the hole. Use a non-metallic screw driver. A fraction of a turn should be sufficient.

Should the slug "fall into" the coil form, remove the bottom tuner cover by pulling downward on its forward end, and remove the forward channel coil cartridge of the station concerned. Move the slug retaining spring out of its slot, and tap the coil assembly until slug slips forward. Set the retaining spring in place so that it rests firmly against the slug, and reassemble the tuner.

If the fine tuning is off in the same direction on all stations, due to replacing V2 (6J6), set the station selector on a station in the "high group" (11-13), set the fine tuning knob in the middle of its range. Turn C15 counter-clockwise until the picture has "sound interference" in it, then turn it clockwise until this interference just disappears.

I. F. ALIGNMENT — VIDEO

1. Connect the negative terminal of a 3-volt battery to the junction of C118 and R105; positive grounded.

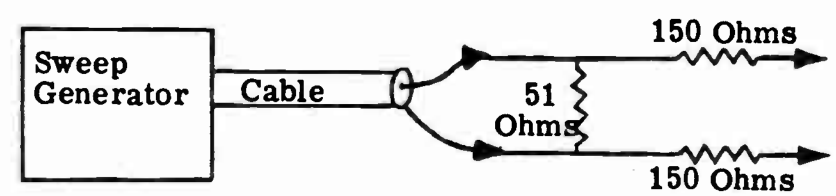
2. Connect the negative probe of a VTVM to point "A" at the "high" end of the contrast potentiometer; positive meter terminal to ground.

3. Connect signal generator having a 21-28 mc range, to pin #1 of V101 (6CB6) through a D.C. blocking condenser.

Adjust the following:

Coil	Frequency	Indication
T105 - Bottom Slug	27.25	Null
T101 - Bottom Slug	21.1	Null
T102	21.25	Null
T105 - Top Slug	25.5	Maximum
T101 - Top Slug	22	Maximum
L104	23	Maximum
L105	24.5	Maximum

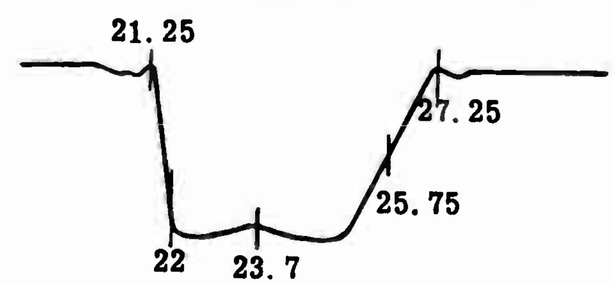
Replace the VTVM with an oscilloscope, and the signal generator with a sweep generator, adjusted to sweep 20-28 M.C. If necessary, re-adjust T101 (top), T105 (top), L104 and L105 to produce a curve approximately as shown:



Set marker generator to 23.7 and adjust L9 so that the dip produced by it is at 23.7 mc. Move the sweep generator lead to the output terminal of the tuner and adjust L101 for maximum response at 23.7 m.c.

TUNER ADJUSTMENT

Set sweep generator on channel 12 and feed the antenna terminals through a balancing network as shown:



Set station selector on channel 12 and adjust C6, C2 and C7 for maximum output and minimum tilt on top of curve.

I. F. ALIGNMENT – SOUND CHANNEL

1. Connect a voltmeter from the junction of R125 and R126 (point D) to ground. Tune in a station. Adjust T103, top and bottom, and T104 bottom for maximum reading. Connect the voltmeter between points C and D and adjust T104 top for zero voltage.

4 1/2 M.C. VIDEO TRAP ADJUSTMENT

With a station tuned in, turn the fine tuning control knob counter-clockwise until "sound interference" can be seen in the picture. Adjust L107 for a minimum of this interference.

HORIZONTAL OSCILLATOR ADJUSTMENTS:

1. Horizontal Linearity, L604:

   Connect a voltmeter across the cathode resistor of the 6CD6, R609, and adjust the Horizontal Linearity Coil, L604 for minimum voltage, while watching a standard test pattern. Proper adjustment will be attained when the two halves of the pattern are similar, and will be close to the point of minimum cathode voltage.

2. Horizontal Frequency, L603:

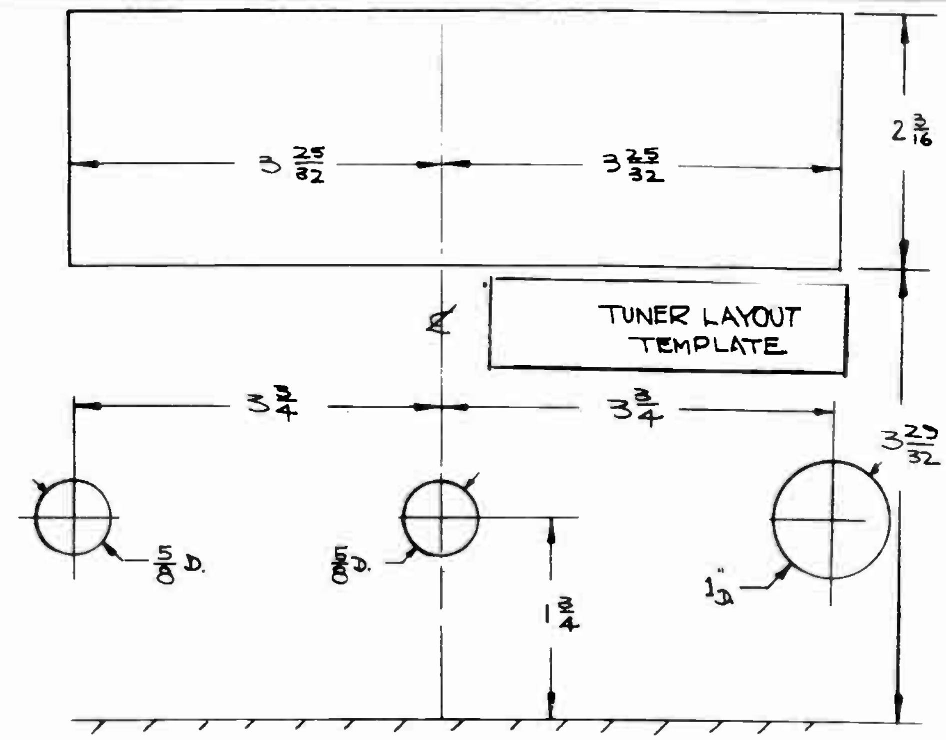
   With a station tuned in, temporarily ground the grid, pin #1, of V601, the horizontal oscillator. Set the horizontal hold in the middle of its range, and adjust L603 until the picture is nearly stopped. Remove temporary ground from pin #1, V601.

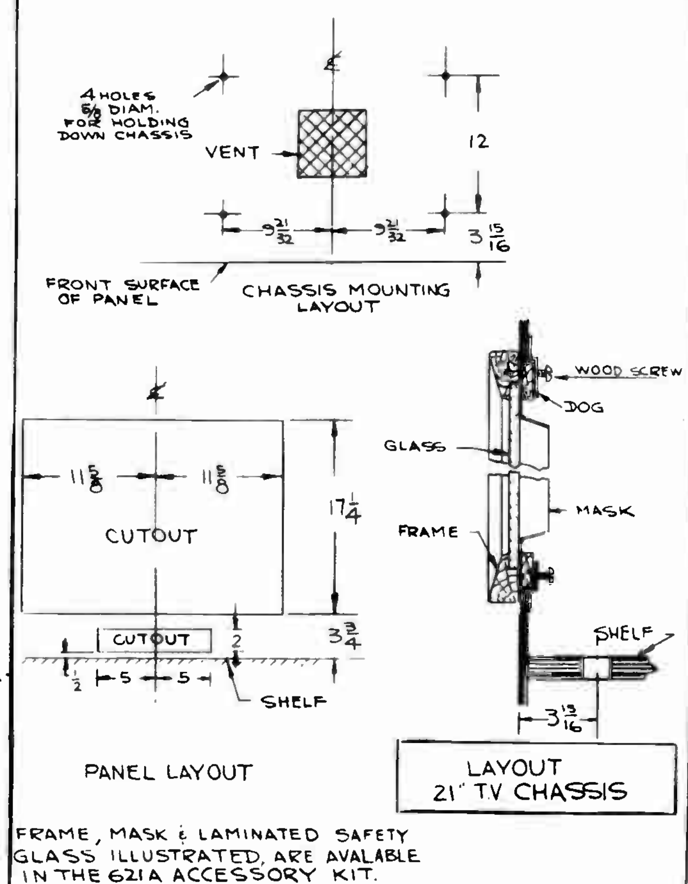
3. Horizontal Drive, C609:

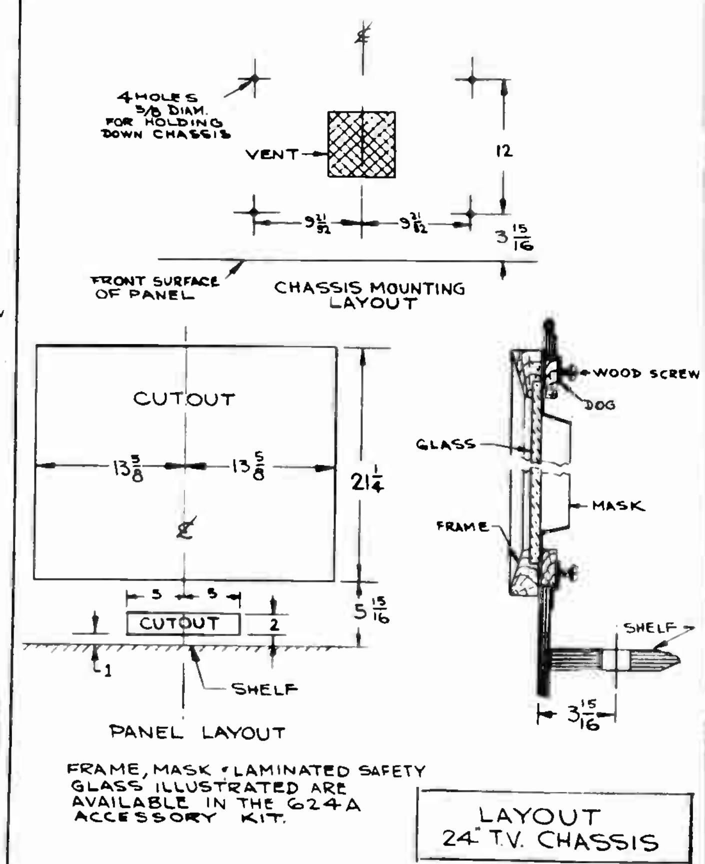
   With a station tuned in, set contrast at its minimum, and brightness so that the screen is lighted. Turn C609 clockwise from the rear of the chassis (loosen) until a white vertical bar appears near the middle of the screen. Tighten (counter-clockwise) until the bar just disappears.

4. Width:

   Adjust so that 1/8" to 1/4" of the picture is off the screen on each side.







All resistors are 1/2 watt, 10% composition except as noted.

CONRAC TV PAGE 12-9

FLEETWOOD MODEL 610 TELEVISION RECEIVER

The Fleetwood Model 610 Television Receiver is a Custom Quality chassis designed for installation into a wall, or for use in a special cabinet. It is especially suited for installations which include high fidelity sound systems and record players. Two types of audio output are provided, making it possible to connect the receiver into almost any sound system without circuit changes, or to operate a loud-speaker from the amplifier which is included in the 610 Receiver.

The Fleetwood 610 Receiver will accommodate a 21" or a 24" picture tube, either metal or glass. Kits are available, which will mount any of the standard types of tubes. When the Receiver has been fitted with the desired type of picture tube, it makes a complete package, with everything except the loud-speaker firmly mounted onto a single chassis The chassis may be mounted in any position. A set of knobs is supplied with the Fleetwood 610.

UHF Tuner strips are available which will enable the FLEETWOOD to receive any of the new Ultra High Frequency stations. A set of these strips replaces a set of coils which are not used in a particular locality. The Super Cascode turret type tuner with which your Fleetwood is equipped insures maximum sensitivity on any channel, in both the VHF and UHF bands. When properly fitted with the strips for the UHF stations in your locality, these channels can be tuned in as easily as the regular VHF channels. An extra position on the dial is provided to show UHF when such a station is tuned in. The panel light associated with the replaced coils can easily be moved to this UHF position behind the dial panel.

ELECTRICAL SPECIFICATIONS

PICTURE TUBE: (Not Supplied)	21AP4 21EP4 24AP4
CONTROLS:	Off-Volume Contrast Brightness Station Selector-fine tuning
SECONDARY CONTROLS:	Vertical Hold Horizontal Hold Height Vertical Linearity
SECONDARY CONTROLS: (Rear of Chassis)	Width Horizontal Drive Horizontal Linearity Focus
I. F. FREQUENCIES:	Video 25.75 Mc. Audio 4.5 Mc.
BANDWIDTH:	Video 4 Mc.
AUDIO OUTPUT:	1. Ratio detector output; no volume control. 2. 6V6 Power Amplifier with inverse feedback.
POWER:	117 Volts, 60 Cycles 210 Watts
PICTURE TUBE ANODE VOLTAGE:	18 kv, design center, 20.5 kv max.

TUBE COMPLEMENT:

1 - 6BQ7	Cascode RF Amplifier
1 - 6J6	First Detector & Local Oscillator
1 - 6CB6	First I. F. Amplifier
3 - 6AU6	2nd, 3rd, and 4th I. F. Amplifiers
1 - 12AU7	Video Detector, AGC Rectifier and 1st I. F. Amplifier
1 - 6AU6	2nd Sound I. F. Amplifier
1 - 6AL5	Ratio Detector
1 - 6AV6	1st Audio Amplifier
1 - 6V6	Audio Power Amplifier
1 - 6AC7	Video Amplifier
1 - 6BE6	Sync Stripper and Noise Inverter
1 - 6SN7	Sync Phase Inverter
1 - 6AL5	Horizontal Phase Discriminator
1 - 6SN7	Horizontal Oscillator
1 - 6CD6	Horizontal Amplifier
1 - 6W4	Horizontal Damper
1 - 1B3	High Voltage Rectifier
1 - 6SN7	Vertical Oscillator
1 - 6S4	Vertical Output Amplifier
1 - 5U4	Plate Supply Rectifier

WARNING - HIGH VOLTAGE

Extremely high voltages are used in the operation of this set. To avoid personal injury, extreme care should be exercised so that no contact is made with any components connected to the high voltage circuits. Do Not Operate the receiver with the high voltage compartment shield removed.

WARNING - PICTURE TUBE HANDLING

Particular care must be exercised when handling picture tubes due to their high vacuum and large surface area. The picture tube must not be struck, scratched, or subjected to more than moderate pressure at any time as fracture of the glass will result in an implosion of considerable violence capable of damaging both property and person.

DIMENSIONS

	Width	Height	Depth
Chassis:	20 1/4	14 1/2	20 1/4
Chassis, 21" tube mounted:	20 3/4	21	23 1/4
Chassis, 24" tube mounted:	26	30	25 1/4

UNPACKING

Remove the chassis from the shipping carton. A small package will be found in the carton, which contains a set of knobs, the Ion Trap for the neck of the picture tube, a pair of clips for holding a trap door in position over the secondary controls, and some small wood screws for mounting the clips onto the back side of the trap door. As soon as the receiver has been unpacked, examine it for any apparent damage which may have occurred in shipment. Should any damage be found, file a claim immediately with the carrier, stating the extent of the damage.

INSTALLING A 21" METAL PICTURE TUBE (21AP4) USING 601 A KIT

1. Mount the front support blocks on the chassis, ridges forward, screwing the 8-32 x 3/4" self-threading screws through the blocks and into the holes found 1/2" from the front of the chassis.

2. Unpack the type 21AP4 picture tube and place it face down on a soft pad to protect it from being scratched. Place plastic sleeve over the tube away from the socket key. Bend the clip around the front edge of the rim of the picture tube.

3. With the plastic sleeve snug against the tube, wrap the plastic ring around the front rim of the tube, over the sleeve. Work the ring tightly around the tube. Secure the ring with the rubber band, which must lie flat in the groove.

4. Loosen the screws which hold the yoke mounting hood on top of the mounting panels, allowing the yoke to slip toward the rear of the chassis.

5. Set the picture tube, complete with its ring and plastic cover, in place on the chassis, using extreme caution not to damage the deflection yoke windings with the prongs of the picture tube as the base of the tube is guided through the yoke. The high voltage clip should be on your left as you face the tube. The ridges on the front mounting blocks should fit into the groove in the mounting ring.

6. Place the tie down cable in the groove in the plastic ring and pass the ends through the holes in the front corners of the chassis. Screw the nuts on the ends and tighten MODERATELY. These nuts need be only "finger tight" to secure the tube.

7. Solder anode connector to the end of the white wire extending through the front of the high voltage box. Snap this connector into the terminal in the plastic sleeve.

8. Loosen the wing screw protruding from the top of deflection yoke. Push the yoke mounting hood forward until the rubber rims engage the flare of the picture tube firmly. While holding the hood forward under moderate tension, tighten the two screws which fasten the hood to the top of the upright panels.

9. Push the deflection yoke forward until it also engages the flare of the picture tube, and tighten the wing screw in the top of the deflection yoke.

10. Clamp the Ion Trap Magnet around the neck of the picture tube, about 1/2" forward of the tube base.

11. Place the picture tube socket on the base of the picture tube. Dress the leads away from the tubes on the chassis, and also away from the picture tube.

INSTALLING A 21" GLASS TUBE USING A 601 B KIT

1. Mount the front support blocks on the chassis, screwing the 8-32 x 3/4" screws through the blocks and into the holes found 1/2" from the front of the chassis.

2. Remove the four screws which hold the yoke mounting panels to the chassis. Move the entire assembly (yoke, focus coil and panels) back 1 1/4", by putting the screws into the front set of holes in the panels.

3. Fasten the 2" x 1/4" grounding strips to front of yoke mounting panels, using 6-32 x 1/4" self-threading screws.

4. Place the pieces of cork on the faces of the front blocks If desired, the cork may be cemented to the blocks.

5. Loosen the screws which hold the yoke mounting hood on top of the mounting panels, allowing the yoke to slide toward the rear of the chassis.

6. Set the picture tube in place on the blocks, using extreme caution not to damage the deflection yoke windings with the prongs of the picture tube as the base of the tube is guided through the yoke. The anode connection on the side of the picture tube should be on your left as you face the tube. The grounding strips must make connection with the coating on the outside of the tube.

7. Place the tie down strap over the top of the picture tube and pass the ends through the holes in the front corners of the chassis. Screw the nuts onto the ends of the strap MODERATELY. These nuts need be only "finger tight" to properly secure the tube.

8. Loosen the wing screw protruding from the top of the deflection yoke. Push the yoke mounting hood forward until the rubber rim engages the flare of the picture tube firmly. While holding the hood forward under moderate tension, tighten the two screws which fasten the hood to the top of the upright panels.

9. Push the deflection yoke forward until it also engages the flare of the picture tube, and tighten the wing screw on top of the deflection yoke.

10. Clamp the ION TRAP MAGNET around the neck of the tube, about 1/2" forward of the base.

11. Place the picture tube socket on the base of the picture tube.

12. Dress the leads away from the tubes on the chassis, and also away from the picture tube.

13. Solder the anode connector onto the end of the white wire extending through the front wall of the high voltage box, and press connector into place on the picture tube.

INSTALLING A 24" TUBE USING A 604 A KIT

1. Mount the front support brackets on the chassis. Each front support bracket is mounted (wood side forward) with one 8-32 and one 6-32 self-threading screws. The screws are driven upward from beneath the chassis. The 8-32 screw goes through the hole in the corner of the chassis and engages the center hole in the bracket.

2. Remove the deflection yoke hood and the focus magnet assembly from the upright panels at the rear of the chassis. Remove the panels, and replace them with the taller panels supplied with the 24" mounting kit. Replace the deflection yoke and hood, leaving it loose and free to slip toward the rear of the chassis. Remount the focus magnet on the new panels.

3. Unpack the type 24AP4 tube and place it face down on a soft pad to protect it from being scratched. Place the plastic sleeve over the tube, with high voltage clip on the side of the tube away from the socket key. Bend the high voltage clip around the front edge of the rim of the tube.

4. With the plastic sleeve snug against the tube, wrap the plastic ring around the front of the tube, over the sleeve. Secure the ring with the rubber band, which must lie flat in the groove.

5. Set the picture tube, complete with its ring and sleeve on the chassis, using extreme caution not to damage the deflection yoke windings with the prongs of the picture tube as the base of the tube is guided through the yoke. The high voltage clip should be on your left as you face the tube. The front mounting pieces should fit into the groove in the mounting ring.

6. Place the tie down cable in the groove in the plastic ring, and pass the ends through the holes in the outside ends of the front mounting assemblies. Screw the nuts on the ends of the rod and tighten moderately.

7. Solder anode connector to the end of the white wire extending through the front of the high voltage box. Snap this connector into the terminal in the plastic sleeve.

8. Loosen the wing screw which holds the deflection yoke in the yoke mounting hood. Push the yoke mounting hood forward until the rubber rims engage the flare of the picture tube firmly. While holding the hood forward under moderate tension, tighten the two screws which fasten the hood to the top of the upright panels.

9. Push the deflection yoke forward until it also engages the flare of the picture tube, and tighten the wing screw which holds it in the yoke mounting hood.

10. Clamp the Ion Trap Magnet around the neck of the picture tube about 1/2" forward of the tube base.

11. Place the picture tube socket on the base of the picture tube. Dress leads away from the tubes on the chassis, and away from the picture tube.

ELECTRICAL CONNECTIONS

Connect a PM type speaker to the speaker terminals on the chassis Connect an antenna to the antenna terminals, using 300 ohm twin lead. Plug the unit into a 117 volt, 60 cycle source. Turn the receiver on by clockwise rotation of the "off-volume" control. The tubes in the receiver should now be lighted. Set the brightness control to maximum (clockwise rotation). Adjust the Ion Trap Magnet until the screen of the picture tube lights up. The Ion Trap may be rotated completely, and moved back and forth along the neck of the picture tube. Proper adjustment has been attained when light of the face of the tube is at its maximum. It should now be possible to tune in a station.

CENTERING THE PICTURE

Each FLEETWOOD system is operated at the factory with a standard picture tube and is properly adjusted. However, picture tubes vary slightly and, when first set up, the picture on your set may not be properly centered. Around the neck of the picture tube, to the rear of the deflection yoke, will be found a focus magnet. It is mounted on a shelf with a single wing nut and is adjustable laterally on the shelf. The shelf in turn is mounted with two wing nuts and is adjustable vertically. These adjustments permit centering the picture. If the picture must be raised, the focus coil must be raised. Similarly, if the picture must be moved to one side in order to be centered, the focus magnet must be moved in the same direction as it is necessary to move the picture.

After the picture has been centered, it will be necessary to readjust the Ion Trap. The Ion Trap MUST BE ADJUSTED FOR MAXIMUM SCREEN BRIGHTNESS ONLY, OR THE PICTURE TUBE WILL BE DAMAGED, OVER A PERIOD OF TIME. MAKE ALL CENTERING ADJUSTMENTS WITH THE FOCUS COIL.

To level the picture, loosen the wing screw above the deflection yoke and turn the yoke slightly. Keep the yoke pushed forward against the flare of the picture tube when tightening the wing screw.

HEIGHT AND VERTICAL LINERARITY ADJUSTMENTS: These adjustments should be made only if a reliable test pattern is available from a station. During some parts of the day several stations may be transmitting test patterns, and their individual differences may be "averaged." Generally speaking, the "Vertical Linearity" controls the top portion of the picture, and can make the test pattern "flat headed" or "egg headed." After changing the Vertical Linearity, the height will probably have to be reset.

HORIZONTAL HOLD: If the stations should come in as a series of black and white bars running diagonally across the screen, adjust the Horizontal Hold. Do not center the picture with this control.

VERTICAL HOLD: Proper adjustment of this control will prevent the picture from "rolling" either up or down. When the Horizontal and Vertical Hold controls have been adjusted, they should not require re-setting for many months.

NORMAL OPERATION OF THE SYSTEM: Select a station desired with the Station Selector Knob. Behind this knob is a FINE TUNING CONTROL. Turn this control counter-clockwise until the picture appears to be covered with a fine mesh pattern, or has "sound" in it. Turn the fine tuning control clock-wise until this effect just disappears. This will be the point at which the picture will have a maximum of fine detail.

Adjust the CONTRAST CONTROL for the most pleasing picture. Too much contrast will give the picture a coarse appearance, while too little contrast will give the picture a "washed out" appearance.

Adjust the BRIGHTNESS for the amount of light desired.

OPERATION OF THE SYSTEM WITH A SEPARATE AUDIO SYSTEM: On the rear of the chassis is a jack marked DETECTOR OUTPUT, which may be used to supply audio to an external amplifier. In this case, the volume control on the receiver will not function, and the loudness or volume control in the external system must be used. It is important that the speaker terminals on the picture tube chassis be shorted with a wire at all times if there is no speaker connected to these terminals. Failure to do so may result in damage to the audio output transformer in the picture tube chassis.

CABINET CONSIDERATIONS

The FLEETWOOD picture chassis should always be mounted in a cabinet, or in an enclosure behind a wall. In either case, the face of the picture tube should be protected by a safety glass window. Suitable laminated safety glass, together with a Royalite Picture Mask and a mounting frame are available in the FLEETWOOD 621 Accessory Kit (for 21" tube); and the FLEETWOOD 624 Accessory Kit (for 24" tube). This safety glass should be mounted on a plywood panel not less than 1/4" thick. Panel layout drawings will be found in the back of this manual.

A piece of the plywood 2 1/2" x 10 1/2" should be salvaged from the panel cutout to make a matching cover for the secondary controls. Two spring clips are provided to hold the cover in place. This cover will rarely have to be opened after the set has been properly adjusted. If the set is housed in a cabinet, the back of the cabinet should be masonite. Ventilation should be provided by piercing the masonite with holes not larger than 1/4" in diameter, on centers not greater than 1/2".

In order that the longest possible life may be expected from the tubes and other components in the system, it is imperative that both chassis be installed in a manner that will provide adequate ventilation. The shelf on which the picture chassis is mounted should have an opening approximately ten inches square, near the center of the chassis. This opening should be covered with hardware cloth, or heavy screen.

SERVICE NOTES

OSCILLATOR ADJUSTMENT

If the fine tuning control knob does not turn far enough to properly bring in a particular station, set the fine tuning control at the middle of its range. Turn the oscillator adjusting slug clockwise until the picture has "sound interference" in it. Turn slug counter-clockwise until this interference just disappears. This slug can be adjusted through the hole located one inch to the right of, and 1/4 inch above the station selector shaft. As the station selector is turned to a different station, a different slug will appear in the hole. Use a non-metallic screw driver. A fraction of a turn should be sufficient.

Should the slug "fall into" the coil form, remove the bottom tuner cover by pulling downward on its forward end, and remove the forward channel coil cartridge of the station concerned. Move the slug retaining spring out of its slot, and tap the coil assembly until slug slips forward. Set the retaining spring in place so that it rests firmly against the slug, and reassemble the tuner.

If the fine tuning is off in the same direction on all stations, due to replacing V2 (6J6), set the station selector on a station in the "high group" (11-13), set the fine tuning knob in the middle of its range. Turn C15 counter-clockwise until the picture has "sound interference" in it, then turn it clockwise until this interference just disappears.

I. F. ALIGNMENT - VIDEO

1. Connect the negative terminal of a 3-volt battery to the junction of C118 and R105; positive grounded.

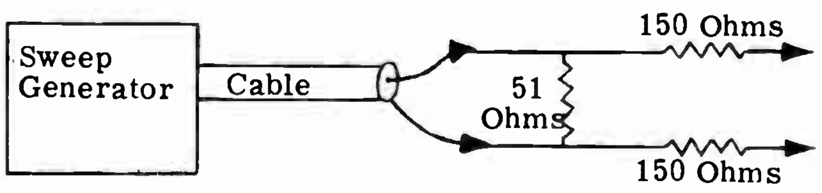
2. Connect the negative probe of a VTVM to pin #4 of the 6AC7 tube; positive meter terminal to ground.

3. Connect signal generator having a 21-28 mc range, to pin #1 of V101 (6CB6) through a D.C. blocking condenser.

Adjust the following:

Coil	Frequency	Indication
T105 - Bottom Slug	27.25	Null
T101 - Bottom slug	21.1	Null
T102	21.25	Null
T105 - Top Slug	25.5	Maximum
T101 - Top Slug	22	Maximum
L104	23	Maximum
L105	24.5	Maximum

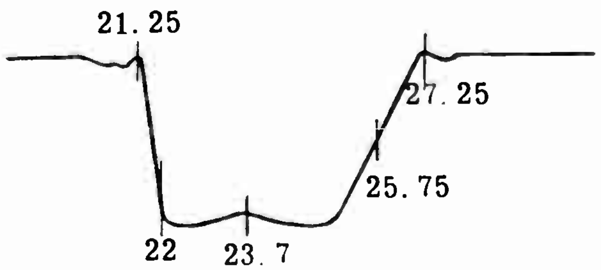
Replace the VTVM with an oscilloscope, and the signal generator with a sweep generator, adjusted to sweep 20-28 M.C. If necessary, re-adjust T101 (top), T105 (top), L104 and L105 to produce a curve approximately as shown:



Set marker generator to 23.7 and adjust L9 so that the dip produced by it is at 23.7 mc. Move the sweep generator lead to the output terminal of the tuner and adjust L101 for maximum response at 23.7 m.c.

TUNER ADJUSTMENT

Set sweep generator on channel 12 and feed the antenna terminals through a balancing network as shown:



Set station selector on channel 12 and adjust C6, C2 and C7 for maximum output and minimum tilt on top of curve.

I. F. ALIGNMENT - SOUND CHANNEL

1. Connect a voltmeter from the junction of R125 and R126 (point D) to ground. Tune in a station. Adjust T103, top and bottom, and T104 bottom for maximum reading. Connect the voltmeter between points C and D and adjust T104 top for zero voltage.

4 1/2 M.C. VIDEO TRAP ADJUSTMENT

With a station tuned in, turn the fine tuning control knob counter-clockwise until "sound interference" can be seen in the picture. Adjust L107 for a minimum of this interference.

HORIZONTAL OSCILLATOR ADJUSTMENTS:

1. Horizontal Linearity, L604:

Connect a voltmeter across the cathode resistor of the 6CD6, R609, and adjust the Horizontal Linearity Coil, L604 for minimum voltage, while watching a standard test pattern. Proper adjustment will be attained when the two halves of the pattern are similar, and will be close to the point of minimum cathode voltage.

2. Horizontal Frequency, L603:

With a station tuned in, temporarily ground the grid, pin #1, of V601, the horizontal oscillator. Set the horizontal hold in the middle of its range, and adjust L603 until the picture is nearly stopped. Remove temporary ground from pin #1, V601.

3. Horizontal Drive, C609:

With a station tuned in, set contrast at its minimum, and brightness so that the screen is lighted. Turn C609 clockwise from the rear of the chassis (loosen) until a white vertical bar appears near the middle of the screen. Tighten (counter-clockwise) until the bar just disappears.

4. Width:

Adjust so that 1/8" to 1/4" of the picture is off the screen on each side.

These receivers are equipped with twenty (20) tubes including a picture tube, and two (2) selenium rectifiers.

They have a switch type tuner which tunes the twelve V.H.F. television channels (2 to 13), also a U.H.F. converter which covers the seventy (70) U.H.F. television channels (14 to 83).

TUBE COMPLEMENT (VHF Chassis 393,394)

Symbol	Tube	Function	Symbol	Tube	Function

V1	6AF4	U.H.F. Oscillator
V2	6BQ7, 6BQ7A or 6BZ7	IF Amplifier

POWER SUPPLY: 117 volts, 60 cycle, a.c.

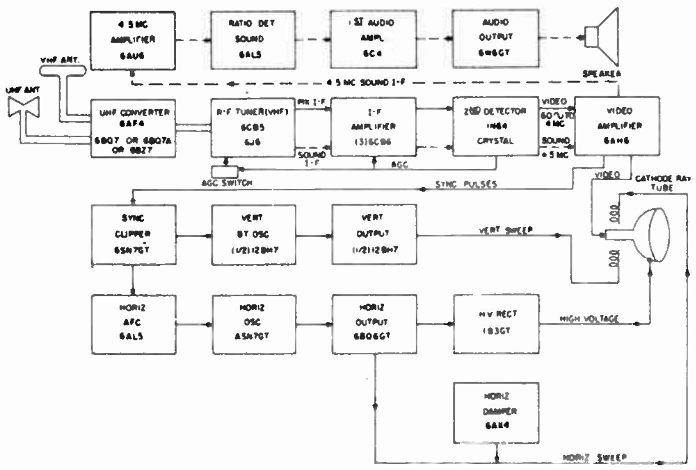
POWER CONSUMPTION: 140 watts.

AUDIO POWER OUTPUT: 2 watts maximum.

ANTENNA INPUT IMPEDANCE:
300 ohms balanced.

INTERMEDIATE FREQUENCY:
Video Carrier — 26.4 mc.
Sound Carrier — 21.9 mc.
Intercarrier Sound — 4.5 mc.
U.H.F. Output — Channels 5 or 6.

BLOCK DIAGRAM:



DEFLECTION: Electromagnetic.

FOCUS: Electrostatic.

ION TRAP: Single Permanent Magnet.

HORIZONTAL SCANNING FREQ.: 15,750 c.p.s.

VERTICAL SCANNING FREQ.: 60 c.p.s.

FRAME FREQUENCY: 30 c.p.s.

SCANNING: Interlaced, 525 lines.

SPEAKER:
21" Console Models 10" P.M.
21" Table Models 5¼" P.M.

VOICE COIL IMPEDANCE: 3.2 ohms at 400 cycles.

CAUTION

HIGH VOLTAGE--Operation of a television receiver with the back open involves a shock hazard. When making adjustments other than adjusting the controls at the front panel, all precautions for working near high voltage should be exercised.

HIGH TEMPERATURE OF TUBES--Some tubes in the receiver operate at extremely high temperatures. To avoid serious burns, do not touch these tubes while the receiver is operating, or until the tubes have cooled after the set is shut off.

HANDLING OF PICTURE TUBES--Breakage of the picture tube, which contains a high vacuum, may result in injury from flying glass. Do not scratch tube face or subject to more than moderate pressure. DO NOT REMOVE OR HANDLE THE PICTURE TUBE IN ANY MANNER UNLESS HEAVY GLOVES AND PROTECTIVE GOGGLES ARE WORN. Persons not so equipped should be kept away while handling the tube. NEVER GRASP THE TUBE BY THE NECK OR ALLOW PRESSURE TO BE EXERTED ON THE NECK. In installation, if the tube sticks or fails to slip smoothly through the deflection yoke, investigate and remove the cause of the trouble. DO NOT FORCE TUBE.

ANTENNAS

BUILT-IN ANTENNAS--The receiver is equipped with two antennas; one for VHF reception is enclosed in the cabinet and one for UHF reception is attached to the UHF antenna terminal board at the rear of the cabinet. These antennas will eliminate the need of an external antenna in some areas where the signal strength is sufficient. If you are in a location where the signal strength is not sufficient and it is impossible to obtain satisfactory results with the built-in antennas due to the above effect, or if the receiver is too far from the television station, it will be necessary to install an external antenna which is designed for both VHF and UHF, or two separate antennas - one designed for VHF and the other for UHF. Sometimes it is possible for VHF reception to be satisfactory on the built-in VHF antenna, but the reception of UHF on the built-in UHF antenna may be unsatisfactory; of vice versa. In these cases it is only necessary to install one external antenna designed for VHF or for UHF, depending on which built-in antenna is not providing satisfactory reception.

EXTERNAL ANTENNA--The choice of the proper type of antenna and its location are very important. Of equal importance is the installation of the antenna. In some localities where there are a number of stations operating, it may be impossible to eliminate all reflections.

CONNECTING EXTERNAL VHF ANTENNA--The antenna terminal board for the VHF antenna is located on a metal plate at the rear of the cabinet. Remove the wires of the built-in antenna that are fastened under the screws of the terminal board. Fasten the lead-in wires of the external VHF antenna under these two screws. Cover bare ends of the wires from the built-in antenna with tape.

CONNECTING EXTERNAL UHF ANTENNA--The antenna terminal board for the UHF antenna is also located on the metal plate at the rear of the cabinet. Remove the UHF dipole antenna (wire loop) leads that are fastened under the two screws and attach the lead-in from the external UHF antenna. Do not drape or coil the lead-in wire and keep it away from the power cord (and also the speaker cable on console models).

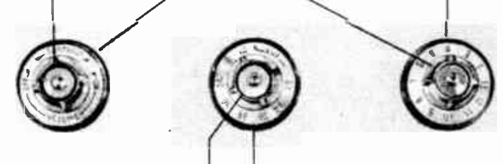
FRONT PANEL CONTROLS

CONTRAST CONTROL- Varies the picture output (increases or decreases the variations between light and dark areas of the picture) similar to the manner in which sound output is varied by the volume control.

OFF-ON-VOLUME- Turns the power off or on and varies the output of sound.

CHANNEL SELECTOR (VHF)- Selects the channel number of the desired VHF station. When tuning for VHF stations be sure the COURSE TUNING (UHF) is set to the VHF position (rotated completely counterclockwise).

FINE TUNING (VHF)- Tunes in the best picture, at which point sound is also received.



COURSE TUNING (UHF)-* Selects the channel number of the desired UHF station. To tune in a UHF station set the CHANNEL SELECTOR (VHF) to channel 5 or 6 as determined by the setting of the slide switch (see note below). Then set the COURSE TUNING (UHF) to the channel number of the desired UHF station.

FINE TUNING (UHF)-Tunes in the best picture, at which point sound is also received. Sometimes a slight adjustment of the Fine Tuning (VHF) will improve reception of a station.

*NOTE - The slide switch operated by a wire looped around the Contrast control shaft should be set, at the time of installation, to its forward position if a VHF station is not assigned to channel 5 in the area in which the receiver is being installed. To set the switch in it forward position, pull the Contrast and Off-On Volume knobs from their shafts. Then pull the wires loop forward on the Contrast control shaft. If a VHF station is assigned to channel 5, set the switch toward the rear by pushing back on the wire loop. In this position the UHF stations can be tuned-in with the COURSE TUNING (UHF) and FINE TUNING (UHF) control knobs, when the CHANNEL SELECTOR (VHF) is set to channel 6. If no VHF station is assigned to channel 5 or to channel 6, set the switch for operation on either channel, whichever may provide the best reception. Be sure to inform the customer as to which channel (5 or 6) the switch has been set to operate on.

ADJUSTMENTS (Chassis 393)

Off Center and Neck Shadow

CENTERING MAGNET ADJUSTMENT — If the picture is off center and/or has neck shadow as shown in the illustration at the left, rotate either or both centering magnet levers to the right or left until the picture is centered on the screen and the picture is free of all neck shadow.

ION TRAP ADJUSTMENT — With the brightness control advanced just enough to dimly light up the face of the picture tube, slide the ion trap backward or forward and at the same time rotate it to the right or left until maximum brightness is obtained. If a neck shadow appears at any of the corners, refer to "Centering Magnet Adjustment" above.

Misadjusted Height

HEIGHT CONTROL—This control increases the overall height of the picture. When making this adjustment it is sometimes necessary to also adjust the VERTICAL LINEARITY to obtain a picture that is correctly proportioned.

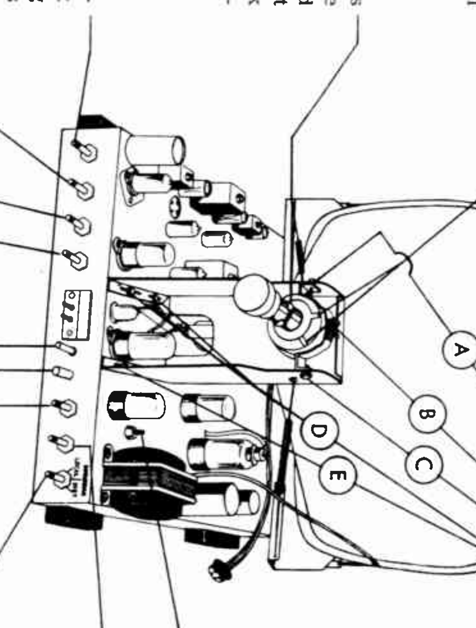
Misadjusted Vertical Linearity

VERTICAL LINEARITY CONTROL — This control increases or decreases the height of the upper portion of the picture.

FOCUS CONTROL — Rotate to the right or left until the sharpest picture, or sharpest horizontal lines, are obtained.

BRIGHTNESS CONTROL — Turn clockwise to increase brightness. To decrease brightness, turn counter-clockwise.

CONNECTING EXTERNAL ANTENNAS — Refer to User's Instruction Booklet furnished with the receiver.



DEFLECTION YOKE ADJUSTMENTS — The deflection yoke must be positioned as far forward as possible on the neck of the picture tube. To make this adjustment, loosen screws "D" and "E" enough to permit the yoke bracket to be pushed forward. While holding the bracket in the forward position, tighten screws "D" and "E". Screws "A" and "C" are for shifting the yoke up or down to center it around the picture tube neck. If the picture is tilted as illustrated at right, loosen wing nut "B". Then, rotate the yoke to left or right as required to make the picture parallel with respect to top and bottom of window frame. Be sure to hold the yoke in position while tightening the wing nut.

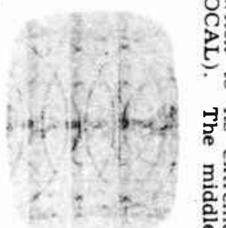
Picture Tilted

HORIZONTAL STABILIZER ADJUSTMENT — See "HORIZONTAL HOLD CONTROL".

Misadjusted Vertical Hold

HORIZONTAL HOLD CONTROL — If the picture appears as shown in the illustration, adjust the horizontal hold control to right or left as required to lock in a single stationary picture. If the range of the control is not sufficient to lock in picture, set the control to its midway position and then adjust the horizontal stabilizer adjustment until the picture locks in.

LOCAL - SUBURBAN - DISTANCE SWITCH — In strong signal areas set this switch to its extreme counter-clockwise position (LOCAL). The middle position (SUBURBAN), and extreme clockwise position (DISTANCE) are used in areas where the signal is weak or medium strength. Set the switch in the position which provides the most satisfactory picture with minimum overloading when the contrast control is advanced.



Misadjusted Horizontal Hold

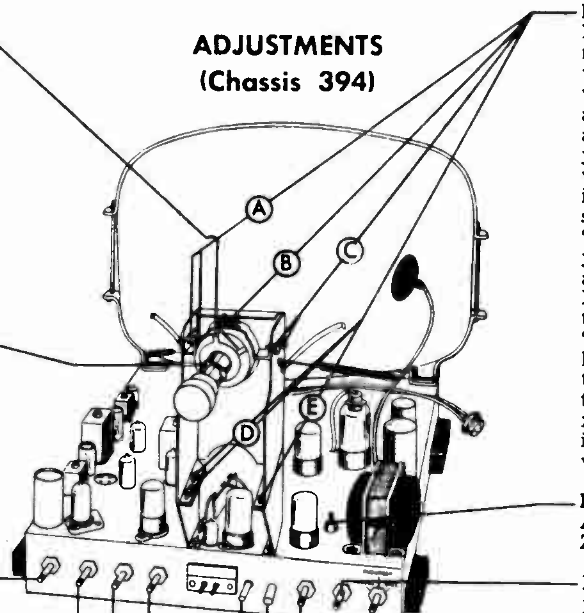
VERTICAL HOLD CONTROL — If the picture is moving up or down as illustrated at right, adjust the vertical hold control until a single stationary picture is obtained.

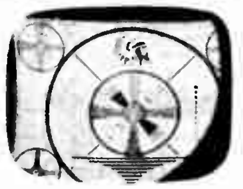
HORIZONTAL CENTERING CONTROL — If the picture is off center to the right or left, rotate this control in either direction as required to center the picture. The picture should become centered when this control is approximately at the middle of its range of adjustment. If not, then set the control at the middle of its range. Then center the picture on the screen by adjusting the centering magnet levers as explained under "CENTERING MAGNET ADJUSTMENT"

WIDTH CONTROL — If the picture is too narrow as illustrated, or too wide, turn the width control clockwise or counter-clockwise as required to adjust the picture to the proper width of the viewing area on the screen.

Picture Too Narrow

ADJUSTMENTS (Chassis 394)





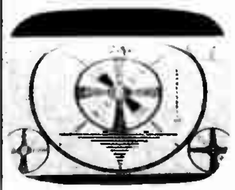
Off Center and Neck Shadow

CENTERING MAGNET ADJUSTMENT — If the picture is off center and/or has neck shadow as shown in the illustration at the left, rotate either or both centering magnet levers to the right or left until the picture is centered on the screen and the picture is free of all neck shadow.

ION TRAP ADJUSTMENT — With the brightness control advanced just enough to dimly light up the face of the picture tube, slide the ion trap backward or forward and at the same time rotate it to the right or left until maximum brightness is obtained. If a neck shadow appears at any of the corners, refer to "Centering Magnet Adjustment" above.

Misadjusted Height

HEIGHT CONTROL—This control increases the overall height of the picture. When making this adjustment it is sometimes necessary to also adjust the VERTICAL LINEARITY to obtain a picture that is correctly proportioned.



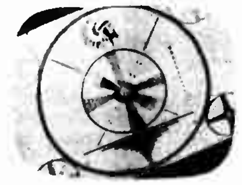
Misadjusted Vertical Linearity

VERTICAL LINEARITY CONTROL — This control increases or decreases the height of the upper portion of the picture.

FOCUS CONTROL — Rotate to the right or left until the sharpest picture, or sharpest horizontal lines, are obtained.

BRIGHTNESS CONTROL — Turn clockwise to increase brightness. To decrease brightness, turn counter-clockwise.

DEFLECTION YOKE ADJUSTMENTS — The deflection yoke must be positioned as far forward as possible on the neck of the picture tube. To make this adjustment, loosen screws "D" and "E" enough to permit the yoke bracket to be pushed forward. While holding the bracket in the forward position, tighten screws "D" and "E". Screws "A" and "C" are for shifting the yoke up or down to center it around the picture tube neck. If the picture is tilted as illustrated at right, loosen wing nut "B". Then, rotate the yoke to left or right as required to make the picture parallel with respect to top and bottom of window frame. Be sure to hold the yoke in position while tightening the wing nut.



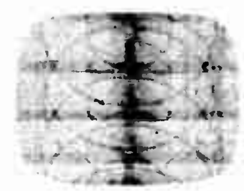
Picture Tilted

Misadjusted Horizontal Hold

HORIZONTAL STABILIZER ADJUSTMENT — See "HORIZONTAL HOLD CONTROL".

HORIZONTAL HOLD CONTROL — If the picture appears as shown in the illustration, adjust the horizontal hold control to right or left as required to lock in a single stationary picture. If the range of the control is not sufficient to lock in picture, set the control to its midway position and then adjust the horizontal stabilizer adjustment until the picture locks in.

LOCAL - SUBURBAN - DISTANCE SWITCH — In strong signal areas set this switch to its extreme counter-clockwise position (LOCAL). The middle position (SUBURBAN), and extreme clockwise position (DISTANCE) are used in areas where the signal is weak or medium strength. Set the switch in the position which provides the most satisfactory picture with minimum overloading when the contrast control is advanced.

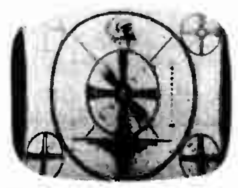


Misadjusted Vertical Hold

VERTICAL HOLD CONTROL — If the picture is moving up or down as illustrated at right, adjust the vertical hold control until a single stationary picture is obtained.

HORIZONTAL CENTERING CONTROL — If the picture is off center to the right or left, rotate this control in either direction as required to center the picture. The picture should become centered when this control is approximately at the middle of its range of adjustment. If not, then set the control at the middle of its range. Then center the picture on the screen by adjusting the centering magnet levers as explained under "CENTERING MAGNET ADJUSTMENT".

WIDTH CONTROL — If the picture is too narrow as illustrated, or too wide, turn the width control clockwise or counter-clockwise as required to adjust the picture to the proper width of the viewing area on the screen.



Picture Too Narrow

ADJUSTMENTS

1. ION TRAP ADJUSTMENT:

Adjust the BRIGHTNESS control for normal brightness. With the ION TRAP positioned close to the base of the picture tube, move the trap forward or backward and at the same time rotate in either direction until maximum brightness of the raster is obtained. Readjust the BRIGHTNESS control until the raster is slightly above average brilliance. Adjust the FOCUS CONTROL until the line structure of the raster is clearly visible. Readjust the ION TRAP again for maximum brightness.

There may be two locations on the tube neck where the ION TRAP will produce maximum brightness. Never set the trap to the forward position, always use the position closest to the tube base.

If there is a shadow in the corners of the raster, be sure the ION TRAP is properly adjusted. Do not sacrifice picture brilliance when adjusting the ION TRAP to overcome shadows in corner of picture. If corner shadows are present, be sure the DEFLECTION YOKE and CENTERING MAGNET are properly adjusted.

2. DEFLECTION YOKE AND BRACKET:

The DEFLECTION YOKE should be positioned as far forward as possible on the picture tube neck and rotated to the left or right as required to make the picture parallel with respect to the top and bottom of window frame.

3. CENTERING RASTER:

If the picture is off center and/or has neck shadow, rotate either or both CENTERING MAGNET levers to the left or right until the picture is centered on the screen and is free of neck shadow. The CENTERING MAGNET is located on the back cover of the DEFLECTION YOKE. To determine the correct picture centering, it may be necessary to reduce the size of the picture with the HEIGHT and WIDTH adjustments. After making adjustment of CENTERING MAGNET, readjust ION TRAP.

4. HEIGHT AND WIDTH ADJUSTMENTS:

The linearity and corresponding size controls will have to be adjusted together and with care to maintain picture symmetry. For this reason it is best to use a test pattern when making these adjustments. Adjust size of picture to fill the screen by means of the HEIGHT, WIDTH, VERTICAL LINEARITY.

5. VERTICAL LINEARITY ADJUSTMENTS:

The VERTICAL LINEARITY control has the effect of expanding the picture at an increasing rate from the bottom to the top of the picture. Adjustment of this control has the greatest effect on the top portion of the picture, some effect on the middle and very little effect on the bottom of the picture. The HEIGHT and FOCUS controls may need readjustment as a result of the change in position of the VERTICAL LINEARITY control.

6. HORIZONTAL HOLD CONTROL:

The HORIZONTAL HOLD CONTROL is adjusted with a weak picture to the center of its pull-in range. If the pull-in range is insufficient or the horizontal sync is unstable, see Horizontal Hold Adjustment" under "Alignment".

7. VERTICAL HOLD CONTROL:

The VERTICAL HOLD CONTROL is also adjusted to the center of its pull-in range with the contrast control set to obtain a weak picture.

8. FOCUS CONTROL:

Adjust the FOCUS CONTROL for best focus of the vertical and horizontal wedges at the center of the test pattern. If corner focus is poor, check position of DEFLECTION YOKE and ION TRAP. While observing the test pattern (or picture), make a slight readjustment of the VERTICAL HOLD control until the horizontal lines are least noticeable. This adjustment is very critical and will require only a very slight movement of the control shaft to obtain proper adjustment.

9. BRIGHTNESS CONTROL:

BRIGHTNESS CONTROL and CONTRAST control should be set to obtain as much shading in the picture as possible. If the Brightness control is set too low, the black and grays of the picture are black and if set too high, the black and grays of the picture will appear light and faded.

10. LOCAL-DISTANCE (AGC) SWITCH:

The LOCAL-DISTANCE SWITCH can be set to prevent the receiver from overloading in strong signal areas or to reduce "snow" in the picture in weak signal areas. In strong signal areas, the "LOCAL" (counter-clockwise) position of the switch must be used. The second and third positions "SUBURBAN" and "DISTANCE" are to be used in medium to weak signal areas. Use the position with which the best picture is obtained with a minimum of overloading of the receiver when the CONTRAST control is advanced.

11. OSCILLATOR ADJUSTMENT USING A TELEVISON SIGNAL:

Do not make any adjustments on the two oscillator adjusting screws unless the FINE TUNING control range is insufficient to properly tune-in the station. The adjusting screws are accessible through holes in the front of the chassis after the chassis is removed from the cabinet.

To make the adjustment, proceed as follows:

(a) Turn the receiver on and allow a warm-up period of approximately five minutes.

(b) For stations from channel 13 to channel 7, set the Station Selector Switch to the highest channel received and adjust the Contrast and Volume control for normal sound and picture. Set the Fine Tuning Control in the center of its range.

(c) Using a small non-metallic screwdriver, adjust the slotted head brass screw located to the left of shaft and above the fiber disc for the clearest and sharpest detail in the picture. This adjustment will be effective on all channels between 13 and 7. If other stations are operating in this range, it may be necessary to compromise slightly on the high channel adjustment so the other channels may be properly tuned-in.

(d) For Stations on channel 6 and below, set the station Selector Switch to the channel received closest to channel 6 and adjust the Contrast and Volume control for normal sound and picture. Set the Fine Tuning control in the center of its range.

(e) Using a small non-metallic screwdriver, adjust the slotted head brass screw located to the right of the shaft for the clearest and sharpest detail in the picture. This adjustment will effect all channels between 6 and 2.

I. F. ALIGNMENT

All lead connections from the signal generator and wobbulator must be shielded. Keep the exposed ends and ground leads as short as possible (about one inch). Always locate the ground lead connections as close as possible to their respective "hot" leads in the television receiver chassis. The wobbulator, signal generator output, and contrast control must be kept low enough to prevent overloading the television receiver circuits.

CAUTION: One side of the chassis is connected to the power line. Therefore, test equipment should not be connected to the receiver unless an isolation transformer is used between the power line and the receiver. DO NOT GROUND THE RECEIVER CHASSIS UNLESS AN ISOLATION TRANSFORMER IS USED.

1. To Check I. F. Alignment on Oscilloscope:

(a) Lift the shield of the Oscillator - Mixer tube V2 sufficiently to clear the socket ground clips. Connect sweep signal generator "hot" lead to the underground tube shield and generator ground lead to the tuner chassis.

(b) Connect high side of oscilloscope to high side of contrast control (pin 2 and 7 of V108), and the low side to chassis.

(c) Apply - 3.0 volts D.C. bias to lug 4 of S103 (See sketch "Variable Bias Control"). Contrast control should be set in the maximum counter-clockwise position.

(d) With the generator sweep set at zero, connect an electronic voltmeter between lug 2 of S103 and chassis. Adjust the output of the generator to obtain a reading of 2 volts D.C. on the meter.

(e) Set generator to sweep from 20 mc. to 30 mc.

(f) Connect marker generator to sweep generator output leads and adjust to provide markers that appear in the curve on page 5.

(g) Observe curve and position of markers (see nominal response curve). Slight deviation in shape from the nominal response curve is permissible, but if any great deviation is noted, it will be necessary to realign the I-F Amplifier.

2. Alignment, I. F. & Tuner Assembly (with electronic voltmeter):

(1) Connect - 3.5 Volts D.C. bias supply to lug 4 of S103 or to junction of C115 and R144.

(2) Connect signal generator "hot" lead through a 1000 mmf. capacitor to TP-1 (wire protruding from tuner directly adjacent to the oscillator mixer tube V2) and ground lead to the R. F. tuner case.

(3) Connect high side of Electronic Voltmeter to lug 2 of S103 and low side to chassis.

(4) Set signal generator to 25.0 mc. and adjust bottom of T103 for maximum meter deflection, limiting meter deflection to 2 volts D.C. by adjusting input attenuator.

(5) Set signal generator to 23.3 mc. and adjust bottom to T102 for maximum D.C. meter indication. Adjust signal generator amplitude to make this peak indication approximately 2 volts D.C.

(6) Reset signal generator to 21.9 mc. and adjust the top of T102 for minimum D.C. meter deflection. Signal generator amplitude must be sufficiently high to produce a definite null. Meter must read at least 0.5 volts at null.

(7) Repeat steps (5) and (6).

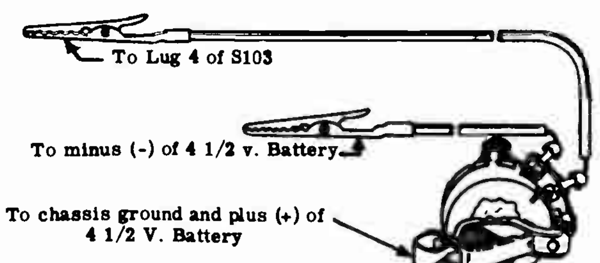
(8) Next set signal generator to 25.2 mc. and adjust bottom of T101 for maximum meter indication, limiting output of generator so peak reading will not exceed 2 volts D.C.

(9) Reset signal generator to 23.3 mc. Connect a 100 ohm resistor in series with a 100 mmf. capacitor from TP-2 (wire protruding from the tuner through the insulated eyelet between the brass adjusting screws) on the R-F Tuner to the Tuner case. Adjust L101 for maximum meter deflection, but limit output of generator so this reading does not exceed 2 volts D.C. Remove the 100 ohm resistor and the 100 mmf. capacitor.

(10) Set signal generator to 24.65 mc. Connect the 100 ohm resistor and the 100 mmf. series capacitor across L101 and adjust mixer output (L9) on R-F Tuner for maximum meter indication. Adjusting amplitude of signal generator to make this maximum indication approximately 2 volts D.C. Remove the 100 ohm resistor and the 100 mmf. capacitor.

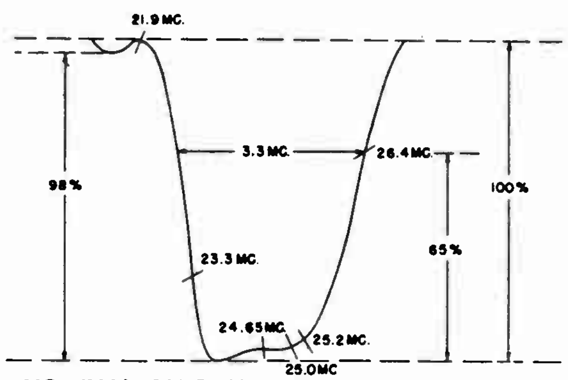
(11) Check sensitivity. The input for 2 volts D.C. output and zero bias should not exceed 150 microvolts at 24.65 mc. with a generator internal resistance of 1.5 ohms or less, and the local oscillator set to properly tune in channel 5.

(12) Remove the signal generator and electronic voltmeter.



5000 Ohm Control only, Part No. 144260

VARIABLE BIAS CONTROL ASSEMBLY



NOMINAL OVERALL I. F. RESPONSE CURVE
NOTE: Response as Seen by Means of Sweep Generator

SOUND ALIGNMENT

1. Connect crystal controlled 4.5 mc. 400 cycle amplitude modulated signal, modulated 30% or greater, to lug 2 of S103 and chassis.
2. Connect high side of scope through detector probe to the picture tube cathode (pin 11). Connect low side of scope to chassis. Adjust 4.5 mc. trap, L105 for minimum 400 cycle deflection on scope.
3. Connect electronic voltmeter to lug 2 of ratio detector, V106, and adjust 4.5 mc. sound take-off (L110) and bottom of ratio transformer (T107) for peak reading on voltmeter. Adjust input to make this peak reading 4 volts.
4. Adjust input to obtain 12 volts output. Transfer electronic voltmeter to junction of R167 and C153 (refer to Schematic Wiring Diagram). Adjust top of T107 for zero balance of electronic voltmeter.
5. Recheck steps 2, 3 and 4 above.
6. Remove input signal, scope and electronic voltmeter.

HORIZONTAL HOLD ADJUSTMENT

1. Tune in a local television signal and adjust contrast control for normal picture.
2. Connect electronic voltmeter between TP-3 (green lead) and chassis.
3. Short TP-4 (orange lead) to chassis and adjust electronic voltmeter to zero.
4. Remove short from TP-4. Do not change zero on electronic voltmeter.
5. Connect a 0.1 mfd., 20%, 600 volt capacitor between TP-5 (red lead) and chassis.
6. Adjust Horizontal Hold control for zero reading on the meter.
7. Remove the 0.1 mfd. capacitor from TP-5 and chassis. Do not disturb setting of horizontal hold control.
8. Adjust Horizontal Stabilizer coil (L108) for zero reading on the meter.
9. Remove electronic voltmeter from TP-3.
10. Check horizontal pull-in range. The pull-in range should be approximately 50° of the controls rotation.

TV CHASSIS BOTTOM VIEW
(Tube Socket and Alignment Locations)

UHF ALIGNMENT

NOTES:

1. Remove the UHF Converter from the VHF receiver chassis.
2. Disengage the toggle coupling from the switch throw arm on the front of the UHF chassis.

   To accomplish this: -

   a. Turn the UHF tuning control clockwise until the pin located on the rear of the drive pulley is free from the toggle coupling.

   b. Turn the switch throw arm to a vertical position to disengage fork of toggle coupling.

   c. Turn the toggle coupling counter-clockwise to a vertical position so that it does not interfere with the movement of the drive pulley.

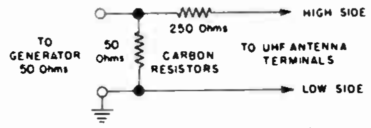
   d. Turn the switch throw arm counter-clockwise to the UHF position; top contact blade on switch rotor must contact and center on the two top switch fingers with the red wires attached. Leave switch in this position while aligning.
3. Connect the output leads of the UHF converter to the R-F input terminals of the VHF Tuner.
4. Connect the B- and filament leads of the tuner to the VHF receiver. Connect UHF Converter chassis to B- (VHF receiver chassis).
5. Set VHF Tuner to Channel 6.
6. Keep all leads as short as possible.
7. Alignment should be followed in the order shown.

I.F. ALIGNMENT:

1. Set I-F slide switch on the UHF Converter to Channel 6 (pushed toward the rear of chassis position).
2. Connect an electronic voltmeter or oscilloscope across the second detector load resistor, R114 on the VHF chassis.
3. Turn on the power.
4. Apply an 82.5 mc. (amplitude modulated if a scope is used) signal to the junction of C2 and C9.
5. Adjust I-F input coil (T2) for peak reading on meter (or maximum indication on scope).
6. Change signal generator frequency to 88.5 mc. and adjust I-F output coil (T1) for maximum reading or indication.
7. Repeat steps 4 through 6 until maximum readings are obtained.
8. Remove the generator connections from the junction of C2 and C9.

OSCILLATOR ALIGNMENT:

1. Connect an electronic voltmeter or scope across the second detector load resistor, R114.
2. Apply a 460 mc. (amplitude modulated when scope is used) signal to the UHF antenna terminals through the antenna matching network. (See Antenna Matching Network sketch.)
3. With the tuner shaft at maximum counter-clockwise position, adjust the oscillator trimmer, C13 for peak reading on the electronic voltmeter (or maximum indication on scope).



Antenna Matching Network

4. Set the signal generator to 904 mc.
5. Rotate the tuner shaft to maximum clockwise position and adjust the oscillator end inductor, L13 for maximum reading on the voltmeter (or scope).
6. Repeat steps 2 through 5 until maximum reading is obtained.

R-F CIRCUIT ALIGNMENT:

1. With the signal generator and electronic voltmeter or scope connected as for the Oscillator Alignment above, set the R-F coupling trimmer, C1 and C2 to minimum capacity by turning the screw counter-clockwise.
2. Set the signal generator to 460 mc. (amplitude modulated when scope is used).
3. With the tuner shaft at maximum counter-clockwise position, adjust the antenna and mixer trimmers, C8 and C11 for maximum meter reading (or scope indication).
4. Reset signal generator to 904 mc.
5. Rotate the tuner shaft to maximum clockwise position and adjust the antenna and mixer end inductors, L1 and L2 for maximum reading on meter (or scope).
6. Repeat steps 2 through 5 until maximum reading is obtained.
7. Reset signal generator to 460 mc.
8. Turn the tuner shaft to maximum counter-clockwise position and adjust the coupling trimmer, C1 and C2 for peak reading.
9. Turn the power switch to the "OFF" position.
10. Disconnect the generator and electronic voltmeter, or scope.
11. Re-engage the toggle coupling in the pin on the switch throw arm and the pin on the drive pulley as follows:

    a. Rotate the tuning control shaft clockwise until the pin on the rear of the drive pulley is toward the base of the chassis.

    b. Turn the switch throw arm to a vertical position.

    c. Turn the toggle coupling approximate 45° clockwise from a vertical position.

    d. Turn the switch throw arm counter-clockwise until pin engages the upper fork on the toggle coupling.

    e. Turn the tuning shaft counter-clockwise and guide the pin on the rear of drive pulley into the lower fork of the coupling. The coupling is now in the proper operating position and when the tuning shaft is turned completely counter-clockwise, the switch will be thrown to the VHF position.
12. Replace the UHF Converter on the VHF receiver chassis.

CRITICAL LEAD AND COMPONENT DRESS VHF RECEIVER CHASSIS

R-F TUNER:

The brown AGC lead from the terminal board to the tuner should be dressed flat down to chassis.

I-F SECTION:

The component leads and wires in the video I-F section must be kept as short as possible.

CRITICAL LEAD AND COMPONENT DRESS VHF RECEIVER CHASSIS (Continued)

R-F CHOKE:

The end of the R-F choke L113 which is wired to T103 lug 6, shall be as short as possible.

LEADS:

The black wire from T103, lug 4 to chassis must be as short as possible. All leads must be kept away from the plates of the selenium rectifiers, SR101 and SR102. Dress the red and blue leads of Audio Output Transformer, T108 away from the high voltage shield so they will not be pinched under it.

COMPONENTS:

Keep all components, particularly peaking coils, away from R121 which is wired between the terminal boards adjacent to V110.

RESISTORS:

Dress the fuse resistor R142 attached to the terminal board, up away from the chassis. On the 396 chassis, dress the two 150K ohm resistors, R151 and R152, in such a manner as not to short against the high voltage shield.

CAPACITORS:

The .006 mfd. capacitor, C138, wired from V114, pin 6, to ground lug of C118, should be dressed down close to the chassis. The .005 mfd. capacitor, C162, which is wired from the case of R118 thru the center lug of R118A to chassis, must have a very short lead on the end wired to the case of R118 so the body of the capacitor prevents any shorting to the shield wired to R118.

CONTROLS:

All controls and the local-distance switch must be kept from shorting to the chassis. Make sure the control does not turn when the nut is tightened.

HIGH VOLTAGE SECTION:

The plate cap of the 1B3GT, V115, should be put on so the lead comes away from it in a vertical direction. The vinyl tape that is applied to the corona ring should cover the entire outside edge of the ring and as much of the socket area as possible.

YOKE COUPLING NETWORK:

The yoke coupling newtwork, L109, wired from T106 lug 3 to V112, lug 1, should be kept away from lug 4 of T106.

CRITICAL LEAD AND COMPONENT DRESS UHF CONVERTER

As the UHF Converter used in this receiver operates over a range (470 mc. to 890 mc.) of frequencies that are from approximately two to four times higher than the highest frequencies encountered in VHF tuners, placement of parts and component lead lengths in the circuit have considerable effect upon the performance of the unit. When replacing components or wiring, special note should be taken of the position of the part or wire to be replaced, before removal. New parts or wires should be located in the same position as those removed. Extremely critical points that require special attention are listed below.

Capacitors:

C3, C6, C7 — The capacitors C3, C6 and C7 in the antenna circuit must be placed with their leads as short and direct as possible.

C9, C10 — The capacitors C9 and C10, 3.3 mmf., must be placed with their leads as short and direct as possible.

C12 — The capacitor C12, 12 mmf., must be placed with only the silvered surface in contact with the lug to which it is soldered. They must be at right angles to the inductor. In order to avoid burning off the silver plating of the unit, the tip temperature of the iron used for soldering should not exceed 500°F. (260°C).

C13 — When the oscillator trimmer assembly, C13 is soldered to the socket contacts, base of trimmer must be firmly held flat against ribs in socket body while socket contacts are firmly seated in the socket body so that this construction is mechanically rigid. Failure to maintain mechanical rigitity in this assembly will result in difficult alignment and poor oscillator frequency stability.

C14 — Capacitor C14, 2.2 mmf., must be placed away from the chassis.

C19, C20 — Capacitors C19 and C20, should be dressed up and away from the function switch.

C21 — Capacitor C21, 27 mmf. must be connected with shortest possible leads.

C22 — Capacitor C22, 1000 mmf. must be oriented so that the flat side of lug is toward pin 2 on the V2 tube socket, in order that the lug may be bent over to the socket contact. If capacitor is not turned quite far enough when threads first begin to tighten, it may be rotated up to about a 1/2 turn further by application of greater torque to wrench. Care should be exercised to prevent stripping threads by turning too far.

RESISTOR:

R5 — The resistor R5, 10,000 ohms, must be placed away from the chassis.

CHOKES:

L4, L6 — The chokes L4 and L6 must be placed away from the chassis.

LEADS:

a. The B+ and heater leads leaving the oscillator radiation shield should be dressed down flat against the R-F chassis.

b. The short red lead joining slide switch terminal and terminal on I-F output transformer should be dressed in form of loop, up and away from chassis.

c. The red lead joining the crystal holder terminal and slide switch terminal should be as short and direct as possible, and dressed down against the chassis. There should be no excess lengths to be looped or doubled up.

R-F COUPLING TRIMMER:

Plates forming the R-F coupling trimmer (C1 and C2) must be placed so that the plates are parallel in both planes when trimmer screw is adjusted so that the plates are 1/32 inch apart. Plates should overlap 1/8 inch minimum. In order to accomplish this overlap, it may be necessary to decenter the parts on the UHF tuner tabs. If so, such decentering should be equally divided between the two parts.

OSCILLATOR:

a. The oscillator plate strap A-154740 (C02) must be assembled with its bottom edge (as viewed from bottom of chassis) resting on the tube socket ribs and with the plane of part of the piece joining the two socket contacts perpendicular to chassis. In order to realize this condition, socket contacts must be firmly seated down against body of socket and "ears" on this piece must be inserted their full length into holes in socket contacts. Solder should be flown between socket contact and the piece for full length of socket contact, in order to avoid possibility of intermittent contact between socket contact and edge of this piece extending beyond "ears". Tab should be soldered flat against and of C12.

b. A dummy plug with hardened steel pins should be inserted in the oscillator socket before components are placed and soldered to socket lugs, to insure alignment of contacts.

CRYSTAL HOLDER:

When soldering connections to the crystal holder terminals, al-

CRITICAL LEAD AND COMPONENT DRESS (Continued)

UHF CONVERTER

low solder to flow between eyelet and terminal proper to insure a consistent electrical connection.

FUNCTION SWITCH:

The function switch must have all VHF position contacts fully and firmly made and all UHF position contacts fully broken when the UHF tuner shaft is at full counter-clockwise rotation. All VHF position contacts must be fully broken and all UHF position contacts must be fully and firmly made at 7-1/2° or more from full counter-clockwise rotation as tuner shaft is rotated in a clockwise direction.

TV CHASSIS 393

Symbol No.	Part No.	Description
	154794	Barrier, Volume Control
	154275-5	Bracket (Frame), Deflection Yoke Mtg.
	154273	Bracket, Deflection Yoke Mtg.
	154368-2	Bracket,(L.H.), Picture Tube Support
	154368-1	Bracket (R.H.), Picture Tube Support
	154190	Bracket, Tuner Mtg.
	154318	Cable, Shielded (18" long) Twin Lead
	154349-1	Cable, Shielded (9" long)
	154349-2	Cable, Shielded (6-1/2" long)
	154180	Coil (High Voltage), Horizontal Deflection Assy.
	154989	Coil (Primary), Horizontal Deflection Assy.
	154276-2	Channel (Rubber 10-5/16"), Deflection Yoke Assy.
	154363	Clip, Picture Tube Anode
	154124	Coupling, Shaft Width Control
	154353	Cushion (Rubber), Picture Tube Support
	154122-1	Grid Cap (V114)
	154134	Grommet (4 used), Tube Mtg. (V105, V113)
	154259	Insulator, Antenna Lead
	154260	Insulator (1-3/16" x 1-7/32" Phenolic), Controls
	154264	Insulator, Interlock
	154268	Insulator (1-13/16" x 19/32 x 1/6" Armite), R. F. Tuner Shaft
	154025	Insulator (Ring), Picture Tube
	154730	Insulator, Volume Control
	154109-2	Ion Trap
	39012-102	Iron Core
	39012-95	Iron Core
	39012-96	Iron Core
	154073	Iron Core, Horizontal Deflection Assy.
	39012-115	Iron Core
	154274	Key & Centering Control Shaft Assy.
	154314	Plate (Bearing), R. F. Tuner Shaft
	154075	Plate, Horizontal Width Control
	154129	Plate, Tube Mtg. (V105, V113)
	154079-1	Ring (Retaining, 3 used), Width Control Shaft Assy.
	154119	Ring (Retaining), Centering Control Shaft Key
	144957	Screw (Wing), Deflection Yoke
	155027	Shaft, RF Pentode Assy.
	154267	Shaft, Width Control
	154077	Shaft, Width Control (Horizontal Deflection Assy.)
	154152	Shield, Corona
	154195	Shield, High Voltage
	39008-37	Shield (Spiral), R. F. Tuner Assy.
	149572	Sleeving (36" lengths), Plate Lead V113, 6-1/2" long
	149572	Sleeving (36" lengths), Anode Lead 4" Long
	154148-2	Socket & Cable Assy., Picture Tube
	154203	Socket, Tube (V113)
	154192	Socket, Tube (V105)
	154092	Socket, Tube (V115)
	154117	Socket, Tube (V110)
	154146	Socket, Tube (V101, V102, V103, C107)
	154131	Socket, Tube (V109, V111, V114)
	154130	Socket, Tube (V112)
	154127	Socket, Tube (V104, V106, V108)
	154381	Spring, Capacitor Mtg. (C165)
	154072	Spring (Clip), Horizontal Deflection Assy.
	154071	Spring (Strap), Horizontal Deflection Assy.
	154120	Spring, Horizontal Centering Control Shaft
	153972-2	Strap, Picture Tube
	154991	Terminal Board, Horizontal Deflection Assy.
	154116	Tuner, R. F. Pentode Assy.
	91595-1	Washer (Flat), Width Control Shaft
	154140	Washer (Protruded) Controls
	149180	Washer (Spring), Width Control Shaft

TV CHASSIS 394

Symbol No.	Part No.	Description
	154794	Barrier, Volume Control
	154275-1	Bracket (Frame), Deflection Yoke Mtg.
	154253	Bracket, Deflection Yoke Mtg.
	154514	Bracket (Lower), Deflection Yoke Mtg.
	154190	Bracket, R. F. Tuner Mtg.
	154358	Bracket (2 used), Picture Support
	154359	Bracket, Picture Tube Stop
	154318	Cable, Shielded (18" long) Twin Lead
	154349-1	Cable, Shielded (9" long)
	154349-2	Cable, Shielded (6-1/2" long)
	154276-2	Channel (Rubber 10-5/16" long), Deflection Yoke Assy.
	154180	Coil (High Voltage), Horizontal Deflection Assy.
	154989	Coil (Primary), Horizontal Deflection Assy.
	155102-2	Connector, Picture Tube Anode
	154124	Coupling, Width Control Shaft
	153424-1	Cushion (Rubber), Picture Tube Strap
	153424-4	Cushion (Rubber), Picture Tube Stop
	154122-1	Grid Cap (V114)
	154134	Grommet (Rubber 4 used), Tube Mtg. (V105, V113)
	154259	Insulator, Antenna Lead
	154260	Insulator (1-13/16" x 17/32", Phenolic), Controls
	154264	Insulator, Interlock
	154268	Insulator, (1-13/16" x 9/32" x 1/6" Armite), R. F. Tuner Shaft
	154730	Insulator, Volume Control
	153109-2	Ion Trap
	39012-102	Iron Core
	39012-114	Iron Core
	154073	Iron Core, Horizontal Deflection Assy.
	39012-115	Iron Core
	155298	Key, Centering Control Shaft
	154314	Plate (Bearing), R. F. Tuner Shaft
	154075	Plate, Horizontal Width Control
	154079-1	Ring (Retaining, 3 used), Width Control Shaft Assy.
	154119	Ring (Retaining), Centering Control Shaft Key
	153423	Rod (2 used), Picture Tube Tie Down
	144957	Screw (Wing), Deflection Yoke
	155299	Shaft, Centering Control
	155027	Shaft, R F Pentode Assy.
	154267	Shaft, Width Control
	154077	Shaft, Width Control (Horizontal Deflection Assy.)
	154152	Shield, Corona
	154197	Shield, High Voltage
	39008-37	Shield (Spiral), R. F. Tuner Assy.
	149572	Sleevings (36" lengths), Plate Lead V113, 6-1/2" long
	154148-2	Socket & Cable Assy., Picture Tube
	154203	Socket, Shock Mtg. Tube (V113)
	154192	Socket, Shock Mtg. Tube (V105)
	154092	Socket, Tube (V115)
	154117	Socket, Tube (V110)
	154146	Socket, Tube (V101, V102, V103, V107)
	154131	Socket, Tube (V109, V111, V114)
	154130	Socket, Tube (V112)
	154127	Socket, Tube (V104, V106, V108)
	154072	Spring (Clip), Horizontal Deflection Assy.
	154414	Spring (2 used), Picture Tube Mtg.
	149671-1	Spring, (Grounding)
	154071	Spring (Strap), Horizontal Deflection Assy.
	154120	Spring, Horizontal Centering Control Shaft
	153422	Strap, Picture Tube
	149322	Support, Picture Tube Anode
	154991	Terminal Board, Horizontal Deflection Assy
	154116	Tuner, R. F. Pentode Assy.
	91595-1	Washer (Flat), Width Control Shaft
	154140	Washer (Protruded), Controls

Chassis 393 and 394 Code letter E, incorporate the one tube converter, Part No. 155499. Chassis 393 and 394 coded prior to Code letter E use converter, Part No. 154848.

ALIGNMENT PROCEDURE

Oscillator Alignment:

1. Connect an electronic voltmeter or scope across the second detector load resistor, R114.
2. Turn on the power.
3. Apply a 460 mc. (amplitude modulated when scope is used) signal to the UHF antenna terminals through the antenna matching network (Fig. 3).
4. Turn out the adjusting screw of the mixer circuit trimmer C4 so that the flat side of the head is 5/8" above the chassis before aligning oscillator.
5. With the tuner shaft at maximum CCW position, adjust the oscillator trimmer, C18 for peak reading on the electronic voltmeter (or maximum indication on scope).
6. Set the signal generator to 904 mc.
7. Rotate the tuner shaft to maximum CW position and adjust the oscillator end inductor, L4 for maximum reading on the voltmeter (or scope).
8. Repeat steps 3 through 6 until maximum reading is obtained.

R. F. Circuit Alignment:

1. With the signal generator and electronic voltmeter or scope connected as for the Oscillator Alignment above, set the R-F coupling trimmer, C1 and C2 to minimum capacity by turning the screw CCW.
2. Set the signal generator to 460 mc. (amplitude modulated when scope is used).
3. With the tuner shaft at maximum CCW position, adjust the antenna and mixer trimmers, C3 and C4 for maximum meter reading (or scope indication).
4. Reset signal generator to 904 mc.
5. Rotate the tuner shaft to maximum CW position and adjust the antenna and mixer end inductors, L2 and L3 for maximum reading on meter (or scope).
6. Repeat steps 2 through 5 until maximum reading is obtained.
7. Turn the tuner shaft to maximum CW position and adjust the coupling trimmer, C1 and C2 for peak reading at 904 MC.
8. Turn the power switch to the "OFF" position.
9. Disconnect the generator and electronic voltmeter, or scope.
10. Re-engage the toggle coupling in the pin on the switch throw arm and the pin on the drive pulley as follows.
    a. Rotate the tuning control shaft clockwise until the pin on the rear of the drive pulley is toward the base of the chassis.
    b. Turn the switch throw arm to a vertical position.
    c. Turn the toggle coupling approximate 45° CW from a vertical position.
    d. Turn the switch throw arm CCW until pin engages the upper fork on the toggle coupling.
    e. Turn the tuning shaft CCW and guide the pin on the rear of drive pulley into the lower fork of the coupling. The coupling is now in the proper operating position and when the tuning shaft is turned completely CCW, the switch will be thrown to the VHF position.
11. Replace the UHF Converter on the VHF receiver chassis.

These receivers are equipped with seventeen (17) tubes, two (2) selenium rectifiers, and a picture tube.

They have a switch type tuner which tunes the twelve V.H.F. television channels (2 to 13). The receivers may be converted to receive both V.H.F. and U.H.F. stations with the use of an external converter.

POWER SUPPLY: 117 volts, 60 cycle, a.c.

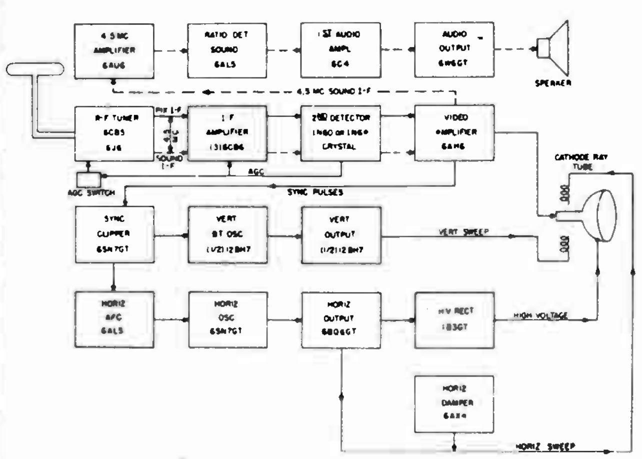
POWER CONSUMPTION: 130 watts.

AUDIO POWER OUTPUT: 2 watts maximum.

ANTENNA INPUT IMPEDANCE:
300 ohms balanced.

INTERMEDIATE FREQUENCY:
Video Carrier — 26.4 mc.
Sound Carrier — 21.9 mc.
Intercarrier Sound — 4.5 mc.

BLOCK DIAGRAM:



DEFLECTION: Electromagnetic.

FOCUS: Electrostatic.

ION TRAP: Single Permanent Magnet.

HORIZONTAL SCANNING FREQ.: 15,750 c.p.s.

VERTICAL SCANNING FREQ.: 60 c.p.s.

FRAME FREQUENCY: 30 c.p.s.

SCANNING: Interlaced, 525 lines.

SPEAKER:
21" Console Models 10" P.M.
Table Models 5¼" P.M.

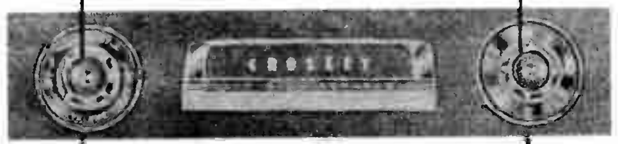
VOICE COIL IMPEDANCE: 3.2 ohms at 400 cycles.

E.M. SPEAKER FIELD COIL, D.C. RESISTANCE:
50 ohms.

FRONT PANEL CONTROLS

OFF-ON VOLUME — Turns the power off or on and varies the output of sound.

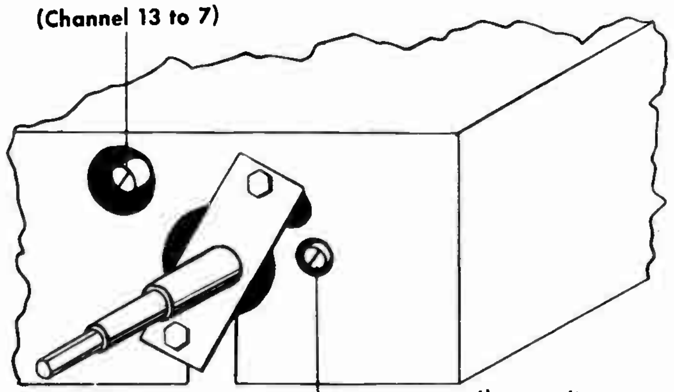
CHANNEL SELECTOR—Selects the channel number of the desired station.



CONTRAST CONTROL — Varies the picture output (increases or decreases the variations between light and dark areas of the picture) similar to the manner in which sound output is varied by a volume control.

FINE TUNING CONTROL — Tunes in the best picture, at which point sound is also received.

R. F. TUNER OSCILLATOR ADJUSTMENT



CHASSIS FRONT VIEW
(OSCILLATOR ADJUSTMENTS)

Generally, the two oscillator adjusting screws do not require adjusting. However, if the range of the FINE TUNING CONTROL is insufficient to permit the station to be tuned in satisfactorily before the control reaches the end of its range (clockwise or counter-clockwise), then it will be necessary to remove the chassis from the cabinet to adjust these oscillator adjusting screws. To remove the chassis, pull the front panel control knobs off their shafts, remove the cabinet back, and the four chassis hold-down bolts.

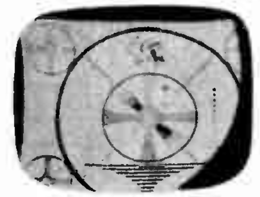
With a service type power cable connected to the inter-lock connector on the rear of the chassis and the antenna connected to its terminals, turn the receiver on, and allow it to operate for at least five minutes before attempting to adjust the oscillator screws.

The upper left screw is used to adjust the oscillator for stations which operate on channels 13 to 7, and the lower right screw adjusts for stations on channels 6 to 2 (See Sketch). When it is necessary to adjust either or both of these screws, proceed as follows:

1. Set the CHANNEL SELECTOR switch to the channel number of the station that is operating on the highest assigned channel number in either the 13 to 7 or the 6 to 2 channel range, depending upon which needs adjusting. (Example: In the 13 to 7 channel range, if stations are operating on channels 11 and 7, set the CHANNEL SELECTOR to channel 11).
2. Adjust the CONTRAST and VOLUME controls for normal sound and picture.
3. Set the FINE TUNING control to the center of its range.
4. With a non-metallic screwdriver adjust the oscillator adjusting screw until the clearest picture is obtained.

NOTE: If other stations are operating in the area in the channel range that is being adjusted (13 to 7 or 6 to 2), it may be necessary to compromise slightly on the oscillator adjustment so as to permit the FINE TUNING to be equally effective on all stations.

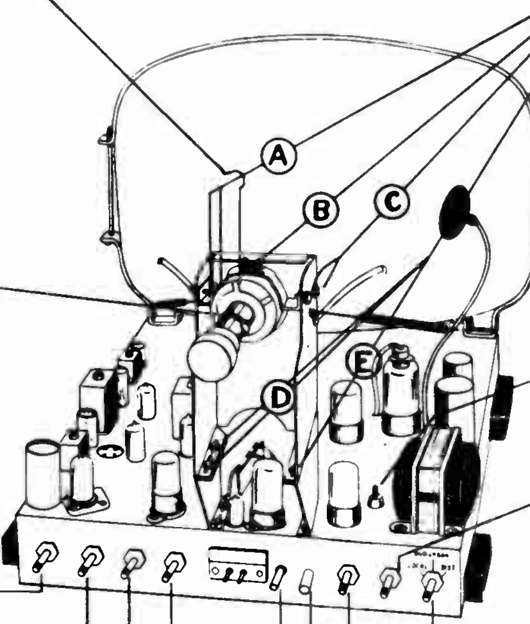
ADJUSTMENTS
Chassis 387

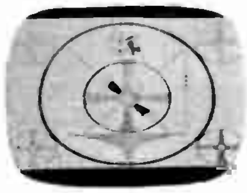


Off Center and Neck Shadow

CENTERING MAGNET ADJUSTMENT — If the picture is off center and/or has neck shadow as shown in the illustration at the left, rotate either or both centering magnet levers to the right or left until the picture is centered on the screen and the picture is free of all neck shadow.

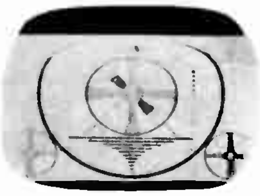
ION TRAP ADJUSTMENT — With the brightness control advanced just enough to dimly light up the face of the picture tube, slide the ion trap backward or forward and at the same time rotate it to the right or left until maximum brightness is obtained. If a neck shadow appears at any of the corners, refer to "Centering Magnet Adjustment" above.





Misadjusted Height

HEIGHT CONTROL — This control increases the overall height of the picture. When making this adjustment it is sometimes necessary to also adjust the VERTICAL LINEARITY to obtain a picture that is correctly proportioned.



Misadjusted Vertical Linearity

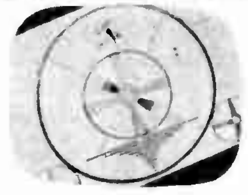
VERTICAL LINEARITY CONTROL — This control increases or decreases the height of the upper portion of the picture.

FOCUS CONTROL — Rotate to the right or left until the sharpest picture, or sharpest horizontal lines, are obtained.

BRIGHTNESS CONTROL — Turn clockwise to increase brightness. To decrease brightness, turn counter-clockwise.

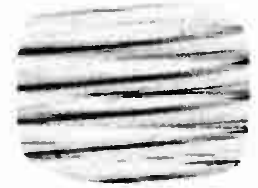
CONNECTING EXTERNAL ANTENNA — Disconnect the built-in antenna wires from the two screw terminals on the back of the receiver, and tape the bare ends of the wires. Fasten the lead-in wires from the external antenna under these screws.

DEFLECTION YOKE ADJUSTMENTS — The deflection yoke must be positioned as far forward as possible on the neck of the picture tube. To make this adjustment, loosen screws "D" and "E" enough to permit the yoke bracket to be pushed forward. While holding the bracket in the forward position, tighten screws "D" and "E". Screws "A" and "C" are for shifting the yoke up or down to center it around the picture tube neck. If the picture is tilted as illustrated at right, loosen wing nut "B". Then, rotate the yoke to left or right as required to make the picture parallel with respect to top and bottom of window frame. Be sure to hold the yoke in position while tightening the wing nut.



Picture Tilted

HORIZONTAL STABILIZER ADJUSTMENT — See "HORIZONTAL HOLD CONTROL".



Misadjusted Horizontal Hold

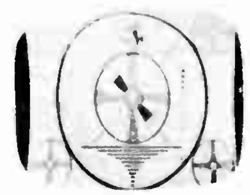
HORIZONTAL HOLD CONTROL — If the picture appears as shown in the illustration, adjust the horizontal hold control to right or left as required to lock in a single stationary picture. If the range of the control is not sufficient to lock in picture, set the control to its midway position and then adjust the horizontal stabilizer adjustment until the picture locks in

LOCAL-SUBURBAN-DISTANCE SWITCH — In strong signal areas set this switch to its extreme counter-clockwise position (LOCAL). The middle position (SUBURBAN), and extreme clockwise position (DISTANCE) are used in areas where the signal is weak or medium strength. Set the switch in the position which provides the most satisfactory picture with minimum over-loading when the contrast control is advanced.

Misadjusted Vertical Hold

VERTICAL HOLD CONTROL — If the picture is moving up or down as illustrated at right, adjust the vertical hold control until a single stationary picture is obtained.

HORIZONTAL CENTERING CONTROL — If the picture is off center to the right or left, rotate this control in either direction as required to center the picture. The picture should become centered when this control is approximately at the middle of its range of adjustment. If not, then set the control at the middle of its range. Then center the picture on the screen by adjusting the centering magnet levers as explained under "CENTERING MAGNET ADJUSTMENT".



Picture Too Narrow

WIDTH CONTROL — If the picture is too narrow as illustrated, or too wide, turn the width control clockwise or counter-clockwise as required to adjust the picture to the proper width of the viewing area on the screen.

1. GENERAL DESCRIPTION

These Crosley television receivers are equipped with seventeen (17) tubes, two (2) selenium rectifiers, and a picture tube. They are designed to operate on 117 volts, 60 cycle alternating current. The chassis 386 is designed for a 21-inch (21MP4) metal picture tube; and chassis 387 is designed to use a 21-inch (21FP4A) glass picture tube.

The receivers will produce high definition pictures with fine detail and excellent brilliance and contrast on all twelve VHF (Very High Frequency) television channels (2 to 13), and may be converted to receive both VHF and UHF (Ultra High Frequency-(channels 14 to 82) stations. However, in no one area are there stations operating on all channels.

Symbol numbers contained in this description are listed on the schematic diagram for the 386 and 387 chassis.

In later production models using the 386 and 387 chassis, some alterations were made in the horizontal deflection circuit that required changing certain components. As the basic operation has not been changed, this description will still apply.

2. Automatic Gain Control reduces interference from flying aircraft and other sources of brightness fluctuations. It also eliminates readjustment of the brightness and contrast controls when tuning from one station to another and minimizes fading in areas of low signal strength.

3. Specially designed built-in antenna that needs no tuning.

4. Tempered safety glass picture tube window.

5. Wide angle viewing and "Procenium Arch" styling of the picture tube window.

6. Electrostatic "Black Face" picture tube provides better contrast, sharper picture and less glare.

7. FM sound system provides true, clear sound.

8. Electronically controlled circuit to erase vertical retrace lines that normally appear during dark scenes, or changes of scenes.

Features Include:

1. Automatic Frequency control, with "Stabilock" circuits, holds picture firm and steady even through electrical disturbances.

1.01 Specifications:

Power Requirements: 117 volts, 60 cycle, a.c.
Power Consumption: 130 watts at 117 volts 60 cycles.
Audio Power Output: 2 watts maximum
Receiver Antenna Input Impedance: 300 ohms balanced.

Picture Area:
Chassis 386; Chassis 387; 239 sq. inches
Picture Size:
Chassis 386; Chassis 387; 19-1/8" x 13-7/8"

Intermediate Frequency:
Video Carrier . . . . 26.4 mc.
Sound Carrier . . . . 21.9 mc.
Intercarrier Sound . . . . 4.5 mc.

Frequency Range:

Channel Number	Channel Frequency (mc)	Video Carrier Freq. (mc)	Audio Carrier Freq. (mc)	Receiver Oscillator Freq. (mc)
2	54-60	55.25	59.75	81.65

PRECAUTIONS

HIGH VOLTAGE WARNING—Operation of this receiver with the interlock by-passed, or the chassis removed from the cabinet involves a shock hazard from the receiver power supplies. Work on the receiver should not be attempted by anyone not thoroughly familiar with the precautions necessary when working on high voltage equipment. When handling the high voltage lead to the picture tube the receiver power plug should be disconnected from the power receptaclé.

HANDLING PICTURE TUBE—Do not remove or handle the picture tube in any manner unless heavy gloves and protective goggles are worn. Persons not so equipped should be kept away while handling picture tube. Keep the tube away from the body while handling. NEVER GRASP THE TUBE BY ITS NECK OR ALLOW PRESSURE TO BE EXERTED ON THE NECK.

HIGH TEMPERATURE OF TUBES—Some tubes operate at extremely high temperatures. To avoid serious burns, do not touch the tubes while the receiver is operating, or until the tubes have cooled after the receiver is shut off.

2. CIRCUIT DESCRIPTION

2.01 Preliminary:

The "intercarrier" sound system used in this receiver differs from the "conventional" type of television circuit where the video and sound RF carriers are converted to their respective intermediate frequencies in the mixer tube. The video and sound IF are usually divided into two separate IF channels of different frequencies, separated by 4.5 mc. after leaving the plate of the mixer tube or at the plate of the 1st. IF amplifier. As it is important to keep the audio component off the picture tube grid, traps must be inserted in the video IF and/or video amplifier circuits to absorb the sound frequency.

In the "intercarrier" sound system the RF carriers are converted to their respective intermediate frequencies in the same manner as above (in the mixer tube), but the video and sound IF frequencies are not separated after leaving the mixer plate; instead they are amplified together in a common IF channel and both signals appear at the input to the video detector. As the video and sound carriers are always separated by a fixed difference frequency of 4.5 megacycles that must be maintained by the transmitting station in accordance with FCC regulations, both IF signals that appear at the cathode of the video detector are separated exactly 4.5 megacycles. The video detector not only functions as a detector, but also as a mixer for the two IF signals. In the mixing process of the sound IF carrier with the video IF carrier, a 4.5 mc. beat signal is produced. This beat signal is frequency modulated in unison with the sound IF carrier.

The manner in which the 4.5 mc. beat signal is obtained, is comparable to the mixer action in a superheterodyne radio receiver.

In place of a local oscillator, the incoming video IF carrier beats against the incoming sound IF carrier to produce the sum and difference frequencies at the output of the detector. As the sum frequency falls outside the range of the pass-band of the video amplifier, only the difference frequency need be considered.

After being amplified in the video amplifier, the 4.5 mc. signal is trapped or "sucked out" of the video signal and fed to the sound driver stage by means of the sound take-off transformer. The transformer serves a dual purpose of providing a 4.5 mc. trap to reduce sound interference in the picture and providing a sharp pass band for 4.5 mc. injection to the grid of the sound driver stage. The 4.5 mc. signal is amplified and limited in the sound driver which provides sufficient signal to operate the sound detector. FM demodulation of the sound IF signal is accomplished by the two diode sections of V106, that function as an unbalanced ratio detector which converts frequency deviations of the IF carrier to audio frequencies and suppresses amplitude modulation interference. The IF input is applied to the diodes by mutual coupling between the tuned primary and secondary of the ratio detector transformer T107. The applied IF carrier rectified by the diodes, charges the electrolytic capacitor C151. The bias voltage developed across R165 and R166 holds the conduction level of the diodes at a definite value determined by the applied carrier. Any sudden change, such as may be caused by instantaneous noise impulses, cannot change the bias due to the relatively long time constant of R165-R166-C151. The rectified audio frequencies pass through the tertiary winding that is connected to the center tap of the secondary, and through the sound volume control to the grid of the 1st. Audio Amplifier tube V104. The audio amplifier consists of two stages of amplifications, a triode 1st stage V104 coupled to a beam power output stage V111 that drives the speaker.

2.02 RF Unit: (V1,V2)

The RF Unit comprises an RF stage, mixer and oscillator all in one compact unit. Its function is to amplify the received signal and to convert the sound and picture carriers to the correct intermediate frequencies.

The tuner assembly consists of four, twelve position wafer switches mounted on a common shaft. Pretuned coils are mounted between the contacts on each wafer and form a series of coils, tapped at each contact. The channel to which the switch is set, is determined by the amount of inductance (number of coils) in the circuit.

The antenna is matched to the input circuit of the receiver by the transformer T1. As the chassis is at power line potential, isolating capacitors C163 and C164 are inserted between the transformer T1, and the antenna. The antenna circuit is tuned by the first (closest to rear of RF unit) wafer switch connected to the grid of the RF Amplifier V1. The RF coils on the second wafer switch tune the plate circuit of V1. Two variable inductors L2 and L3 are connected in series with the RF coils on the respective wafer switches for alignment of the high channels (7 to 13). To obtain the proper band width, the coils on the antenna switch are tuned to the video carrier and the RF coils in the plate circuit of V1 are tuned to the sound carrier.

The VHF oscillator utilizes one section of the twin triode, V2, in a modified Colpitts oscillator circuit. The feedback voltage from the plate to the grid is obtained by means of the capacitor C12 and the interelectrode capacity of the tube. The oscillator is tuned to frequency by the coils on the front wafer switch and the trimmer capacitor C11, the Fine Tuning control. Two variable inductors are included in this circuit for alignment of the oscillator. Oscillator adjustment at channel 13 is made by L7 and at channel 6 by L8.

The series of coils on the third (from rear) wafer switch, connected to the grid of the mixer through L6, tends to increase the bandwidth of the circuit. The variable inductor L6 is used to align the high channels, the adjustment being made at channel 13.

The incoming signal to which the receiver is tuned, is amplified by V1 and applied to the grid of the mixer section of V2 through the coupling capacitors C8 and C9, while the signal from the local oscillator is injected through the capacitor C14. Feedback voltage from the grid of the mixer is applied to the plate of the RF Amplifier V1, through the capacitor C7. The output of the mixer, contains a wide band of frequencies. It includes both the video and sound intermediate frequencies that are transferred to the grid of the 1st IF amplifier V101, through the mixer plate coil L9, the coupling capacitor C101 and mixer coupling coil L101.

2.03 IF Amplifier: (V101, V102, V103)

The If amplifier consists of three stagger-tuned stages using three sharp-cutoff, high gain pentodes. Stagger-tuning of the IF system provides a simple means of securing adequate gain and a sufficiently broad pass-band that is needed to accept both the video and sound IF carriers.

Each IF coupling network consists of a variable iron core tuned inductance with closely coupled secondary windings over the primary of the coil. The secondaries of the 1st. and 2nd. If coil are coupled directly to the grids of the following tubes and the secondary of the 3rd. IF coil is coupled directly to crystal diode, second detector. An additional winding, tuned with a fixed capacitor, C159, and iron core, on the 2nd. IF transformer coil form, functions as a 21.9 megacycle sound trap.

Decoupling resistors and capacitors are used in the plate, screen and grid circuits to prevent coupling between the stages which might otherwise cause oscillation.

To provide stabilizing degenerative feedback, the cathode resistors R104 and R107 of V101 and V102 are unbypassed.

As an intercarrier sound system is used in this receiver, both the video and sound carriers are amplified together in a common IF channel and both signals appear at the input of the second detector.

2.04 2nd. Detector: (CR101)

The 2nd. detector is a germanium crystal diode and is located in the shield can of T103. The IF carriers are applied to the cathode of the crystal to produce a video signal of the proper polarity. The signal from the anode is applied to the grid of the Video Amplifier V108 through L113, L102 and the coupling capacitor C114.

A low pass filter circuit composed of C112, L113 and C113 in the output of the 2nd. detector, rejects the IF carriers.

To compensate for loss of high frequencies and phase shift, due to the capacity of the circuit, peaking coils, L102 and L103 are inserted in the circuit in series with the detector load resistor R114.

As a fixed difference of 4.5 megacycles always exists between the video and sound carriers, and must be maintained by the transmitting station in accordance with F.C.C. regulations, both IF signals that appear at the input of the detector, are separated exactly 4.5 megacycles.

Besides functioning as a detector, the crystal also functions as a mixer for the two IF signals. In the mixing process of the sound IF carrier with the video IF carrier, a 4.5 megacycle beat signal is produced. This beat signal is frequency modulated in unison with the sound IF carrier.

2.05 A G C Circuit:

The purpose of the AGC circuit is to maintain a constant output at the picture tube as the signal input varies due to different field strengths of the television station or flutter of field strength due to the interference from flying aircraft. As the voltage appearing across the detector load resistor R114 is always negative and varies according to the strength of the incoming signal, this voltage is used for automatic gain control. This potential is applied to the grids of the 1st. and 2nd. IF amplifier tubes V101 and V102 through the resistor R116 and to the grid of the RF amplifier tube V1 through R117.

A three position Local-Distance switch at the rear of the chassis is used to control the gain of the receiver. When the switch is in the "Local" position, the switch is open and the developed AGC voltage is unaffected. When the switch is in the "Suburban" position, a voltage divider network, R112 and R113, is thrown into the circuit. These resistors tend to decrease the applied AGC voltage, thus, increasing the gain. For fringe area reception, the "Distant" position of the switch should be used. This position shorts out a portion (R113) of the voltage divider network so a minimum AGC potential is applied to the tubes.

2.06 Video Amplifier: (V108)

The Video Amplifier V108, functions as an amplifier for the 60 cycle to 4 megacycles video signal. the 4.5 megacycle sound IF signal and the synchronizing pulse signal for control of the deflection circuits.

The video signal is applied to the cathode of the picture tube V116, through L104, L105 and C121. L105 and C117 functioning as a 4.5 megacycle trap prevents sound modulation from reaching the cathode of the picture tube.

L104, L106 and L107 are peaking coils which with their respective damping resistors, R119, R122 and R123 compensate for losses of the higher frequencies. To minimize attenuation of low frequency gain, the screen is bypassed by a large capacitor C118B.

The cathode of V108 is connected to one end of the Contrast Control R118A, with the arm of the control returning to chassis. Connected in this manner, the setting of the control determines the bias on the Video Amplifier and thus, sets the black level of the picture.

The 4.5 mc. sound IF signal is applied to the grid of the 4.5 mc. Amplifier (Sound Driver) tube V107 through the capacitor C116. An absorbtion trap formed by L110 and C149 is tuned to the 4.5 mc. Sound IF frequency and provides a sharp pass-band for 4.5 mc. injection to the grid of V107.

2.07 Sound Channel: (V107, V106, V104, V111)

See last paragraph of "Preliminary Circuit Description" (2.01).

2.08 1st. & 2nd. Sync Clipper: (V109)

A portion of the composit video signal is taken from the plate side of the Video Amplifier plate load resistor R121 and fed to the grid (pin 1) of the 6SN7GT, 1st. Sync Clipper section of V109 through R124, R125 and C123. The signal that appears at the grid is positive in polarity and drives the grid (pin 1) of the 1st. Sync Clipper very positive, the grid current charging C123 negatively.

The tube bias is obtained by grid rectification of the video signal. The voltage developed across R126 biases the tube so that plate conduction occurs only on the peaks of the video signal. Since the maximum amplitude of the video signal is actually the sync pulses, only the sync pulses will appear at the plate (pin 2) of the 1st. Sync Clipper.

The signal from the plate of the 1st. Sync Clipper is applied to the grid (pin 4) of the 2nd. Sync Clipper through C125, and is negative in polarity. Any noise pulses, that would appear as irregularities at the most negative portion of the pulses, would drive the tube beyond cut-off and therefore are limited.

Very little amplification (close to unity) is obtained from the Sync Clipper stage, its primary purpose being to limit the amplitude of the sync pulses, clip the peaks caused by noise pulses, and to couple the sync signals of the proper polarity to the deflection circuits.

2.09 Picture Tube: (V116)

The picture tube is a rectangular electrostatic focus tube. Electromagnetic fields are used for vertical and horizontal deflection.

The high voltage for the anode of the tube is furnished by the high voltage power supply at approximately 12 kilovolts. The Brightness control R170 varies the cathode bias and thus, the tube screen illumination.

The permanent magnet Ion Trap must be properly positioned on the neck of the picture tube for maximum brightness.

2.10 Integrating Network:

To separate the vertical from the horizontal sync pulses, an integrating network composed of R133, R134, C127 and C128, is coupled between the plate of the 2nd. Sync Clipper (through C126) and the grid of the Vertical Oscillator V105A (through T104). This RC network acting as a low pass filter will pass the low frequency of the vertical synchronizing pulse, while the higher frequency of the horizontal sync is attenuated.

2.11 Vertical Oscillator & Amplifier: (V105)

The purpose of these circuits is to provide a sawtooth current of the proper amplitude and frequency to move the scanning beam across the picture tube screen slowly from top to bottom, during the time the image is being placed on the screen, and rapidly from bottom to top during retrace time. A blocking oscillator and discharge circuit is formed by one triode section, V105A, and its associated components. The Vertical Hold Control R135 in series with T104, adjusts the free running frequency of the oscillator.

Cathode to grid feed back induces a current which charges C129 causing bias voltage to be applied momentarily to the tube. When this occurs, plate current begins to flow, and C131 discharges rapidly until plate current saturation is reached. The plate current begins to decay, reversing the direction of the induced cathode voltage which in turn causes C129 to discharge. The grid is then driven negative, cutting off the plate current and slowly charging C131. The cycle is repeated as soon as the voltage across C129 reaches a value that will again cause plate current to flow. This slow charging and rapid discharging of C131 causes a sawtooth voltage to be generated.

The peaking action of R136 and R137 provides a sharp negative pulse to insure that the Vertical Amplifier section (V105B) will remain cut off during retrace time.

A pulse from the junction of R136-R137 is applied to the control grid of the picture tube for the elimination of retrace lines during scene changes.

Although the voltage on the plate of the Vertical Oscillator is of the basic shape to produce a sawtooth current in the vertical deflection yoke, it must be amplified by the Vertical Amplifier (V105B) to obtain sufficient power.

By controlling the plate voltage of the Vertical Oscillator by movement of the arm on the Height Control R138, the amplitude of the sawtooth voltage is varied.

The Vertical Linearity Control R140, varies the cathode bias of the Vertical Amplifier, so that the applied sawtooth voltage is shifted along the operating characteristics of the tube. Impedance match between the plate of the output tube and the deflection yoke is made by the Vertical Output Transformer T105.

2.12 Horizontal AFC: (V110)

The Horizontal AFC tube V110, is connected in a phase discriminator circuit for automatic phase and frequency control of the Horizontal Oscillator and operates in the following manner: A negative pulse from the cathode of the 2nd. Sync Clipper section of V109 is applied to the cathode (pin 1) of the 6AL5 Duo Diode V110, and a positive pulse from the plate of the 2nd. Sync Clipper is fed to the plate (pin 2) of V110.

These pulses are compared, with respect to time, with a wave representative of the Horizontal Oscillator line frequency. This wave is in the form of a sharp pulse and is taken from the Horizontal Deflection Yoke and integrated into a sawtooth by R151, R152, C140 and C138 and applied to the cathode (pin 5) and the plate (pin 7) of V110.

Voltages developed across the diode load resistors, R146 and R147 oppose each other due to the method of connecting the diodes to the output of the 2nd. Sync Clipper.

When the rectified output of the diodes is equal, the voltage developed on the filter network R149-C139, R150 and C141 is zero, and a condition of stable operation exists.

If the oscillator frequency is too fast, the current in the diode section, pins 1 and 7, will increase and the current in the diode section, pins 5 and 2 will decrease. If too slow, the action is reversed.

The difference voltage that is developed at the junction of R146-R147 varies the bias applied to the grid of the Horizontal Oscillator through the filter network R149, C139, R150 and C141, and corrects its frequency.

The long time constant of the filter network retards rapid AC pulses and prevents them from reaching the grid of the Horizontal Oscillator and only D.C. changes will govern the frequency.

2.13 Horizontal Oscillator: (V113)

A cathode coupled multivibrator type of oscillator is employed to generate the sawtooth pulses used for horizontal deflection.

The operation of the circuit is as follows: When V113A starts conducting, the voltage drop across R154 causes the grid of V113B to be driven negative. C144 then discharges through the Horizontal Hold control R155 and holds V113B at cutoff. During this period, C145 charges toward B+ and a voltage is developed across C145 and R157. As the current that is being discharged through R155 starts to diminish, the grid of V113B reaches cutoff, conduction starts, and C145 discharges through R157 and V113B, developing the retrace portion of the sweep voltage.

The sudden pulse of current which occurs in the common cathode resistor R153 when C145 discharges will bias V113A beyond cutoff. The plate current of V113B gradually diminishes until the bias developed across the cathode resistor R153 no longer holds V113A at cutoff, conduction again begins and the cycle is repeated.

As the multivibrator is not very stable, due to its sensitivity to bias changes, a Horizontal Stabilizer (L108-C143) is inserted in the circuit. This tuned circuit resonates at 15,750 c.p.s. and tends to stabilize the oscillator

2.14 Horizontal Output. Damper & High Voltage Rectifier: (V114, V112. V115)

The Horizontal Output tube V114, amplifies the output of the Horizontal Oscillator so that sufficient current of the proper wave shape is available to excite the horizontal deflection yoke for horizontal scanning in the picture tube.

During the return trace of the sweep, the current which was flowing in the horizontal deflection yoke reverses. The induced voltage pulse in the primary winding (lugs 1 and 2) of the Horizontal Output Transformer. T106 appears in the form of a very sharp positive pulse. This pulse is increased by auto transformer action to approximately 12 kilovolts and is applied to the plate of V115, and rectified. When a glass envelope picture tube is used the capacity between the inner and outer coating of the tube is sufficient to store this rectified energy that is used to accelerate the electron beam in the picture tube. When a metal envelope picture tube is used, a capacitor (C165) is added for this purpose. Picture width is increased or decreased by an adjustable iron core that is part of T106, the adjustment being made by the width control on the rear apron of the chassis. This adjustment changes the width of the air gap of the core and permits more or less flux to flow, in this manner, the voltage fed to the plate of V115 is raised or lowered. The Damper tube V112 assists in providing a linear trace by damping out oscillations of the energy stored in the deflection yoke and critically dampens the ringing in the yoke that occurs just at the end of the line retrace period. The plate current of V114 flows through the damper tube for the major portion of the trace.

Capacitor C148 is fully charged during this period and supplies the plate current to V114 during the time the damper tube V112 is not conducting. An average voltage developed across the yoke decoupling network, L109-C148, is used to boost the B+ voltage applied to the plate of the Horizontal Output tube V114 and the Vertical Output tube V105B.

2.15 Low Voltage Power Supply:

The low voltage power supply consists of a voltage doubler circuit using two selenium rectifiers with conventional filtering. Booster voltage from the cathode of the Damper tube V112, supplements the B+ voltage that is delivered to V114, the Horizontal Output tube; the plate of the Vertical Output, V105B and the 1st. anode of the picture tube.

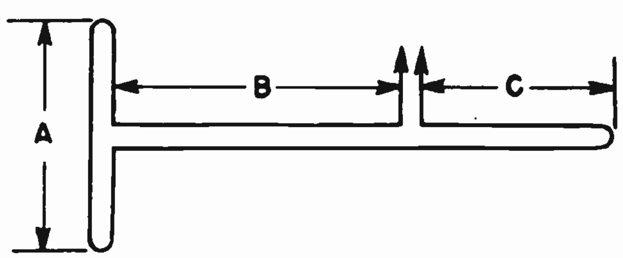
A Filament Transformer, T109 supplies the filament voltage for all the tubes except the H.V. Rectifier V115. Two additional windings on the transformer supply the filament voltage for the Audio Output tube V111 and the Sync Clipper tube V109, as the cathodes of these tubes are at a relatively high positive voltage.

3. ANTENNAS

3.01 Built-in Antenna:

An antenna, that in some localities will eliminate the need of an external TV antenna, is built into the receiver. The built-in antenna serves both the low (channel 2 to 6) and the high (channel 7 to 13) television bands.

For the high band, section "A" of the Built-in Antenna Schematic shown below, is the 1/2 wave folded dipole resonating at 200 mc. Section "B" is the lead-in, and section "C" a 1/2 wave shorted stub resonating at 200 mc. For the low band, A, B, and C resonate at 70 mc.



Schematic of Built-in Antenna

The antenna is mounted, or printed, on a cardboard form fastened in the cabinet. For proper operation of the antenna, do not shorten or lengthen the leads as this will change the resonating frequencies. The results obtained by using the built-in antenna are limited by the distance between the receiver and the transmitter and the location and type of building in which the receiver is used.

Unless the signal transmitted by the television station is of sufficient strength to reach the area where the receiver is located, NO television receiver can reproduce the picture. Due to the high frequencies used for television transmission, the signals reach only to the "line of sight". This is determined by the height of the transmitting and receiving antennas. In addition, steel frame work buildings, mountains, hills etc. reflect the television signals so that even though the television station is only a short distance away, the built-in antenna may not function satisfactorily.

In locations where it is impossible to obtain satisfactory results with the built-in antenna, due to shielding effects of buildings or mountains or if the receiver is located too far from the television station, it will be necessary to install an external indoor or outdoor antenna.

3.02 External Antenna:

A proper antenna installation is the most important factor in avoiding reflections in a picture, or a weak picture, although, in some localities where there are a number of stations operating, it may be impossible to eliminate all reflections. The Service Man should suggest the proper type of antenna to be used in the specific location and install and adjust the antenna for the best picture quality.

This television receiver has been designed to operate from a 300 ohm parallel lead transmission line.

3.03 Connecting External Antenna to Receiver:

Remove the two wires from the built-in antenna fastened to the two screws on the terminal board mounted on the rear of the cabinet and fasten the lead-in from the external antenna under these screws. Tape the loose ends of the wires from the built-in antenna, as noisy reception will result if these wires come in contact with the antenna terminal screws.

4. INSTALLATION

4.01 Unpacking:

The cabinet of this receiver is shipped in first class condition with considerable attention given to protecting the finish. Handle With Care. To remove the cabinet from the shipping container, turn the carton on its side and tear open the carton bottom flaps. Fold the flaps up along the side of the carton and turn the carton back up. Lift the carton up and off the cabinet. Tilt cabinet and carefully knock off the skid that is nailed to the bottom of the cabinet (console models only). Remove the screws in the cabinet back and swing back open. Check to see that all tubes are in place and firmly seated in their sockets. Check high voltage lead to see that it is connected to the CRT second anode connector socket on the bell of the tube. After inspection, close cabinet back and reinsert and tighten the screws.

4.02 Location of the Receiver:

The selection of a proper location for placing the receiver in the room should be given careful consideration. Be guided by the following considerations.

Choose a location:

(1) Where no bright light will fall directly on the picture. (Some ilumination in the room is desirable).

(2) That will provide easy access for operation and comfortable viewing.

(3) Where the built-in antenna will pick up the strongest signal for clearest picture. Due to the variation of the station's signal strength throughout the room, all practical locations should be tried or if an outside antenna is used, choose a location that will permit a convenient connection to the antenna.

(4) Convenient to an electrical outlet of the proper voltage and frequency (117 volts, 60 cycles alternating current).

CAUTION: -- The receiver cabinet is provided with adequate ventilation openings. Do not obstruct the ventilation by placing too close to a wall or placing objects too close to the openings. Do not place close to sources of heat, such as radiators.

5. OPERATING INSTRUCTIONS

The receiver is adjusted at the factory and is ready for operation after being connected to a 117 volt, 60 cycle a.c. outlet. To set the receiver in operation, follow the procedure outlined under "Normal Operation".

5.01 Normal Operation:

1. Turn the Off-On Volume control knob approximately half-way clockwise; this will turn the receiver "on". Wait one minute for the tubes to warm-up to the proper operating temperature.

2. Turn the Channel Selector Knob to the desired station's channel number.

3. Turn the Contrast control knob approximately half-way clockwise.

4. Adjust the Fine Tuning control until a clear picture is obtained; this may require a readjustment of the Contrast control to get the correct picture shading.

5. Turn the Volume control to obtain the desired sound level. On some stations it may be necessary to make a slight readjustment of the Fine tuning control to minimize noise in the sound.

6. To turn the receiver "Off", turn the Off-On-Volume control completely counterclockwise. Normally, only the main controls need be adjusted. At rare intervals it may be necessary to adjust the Auxiliary Controls due to the normal ageing of the tubes and other components.

5.02 Auxiliary Control Adjustment:

1. Turn the receiver "On" as described in paragraph "1" of "Normal Operation".

2. Adjust the Brightness control for moderate brightness, below the point where the raster size increases.

NOTE: If normal brilliance is not obtained at this point it may be necessary to adjust the Ion trap on the neck of the picture tube. For Ion trap adjustment, see "Ion Trap Magnet Adjustment" in section 6.01

3. Turn the Brightness control counter-clockwise until the raster just becomes invisible.

4. Rotate the Channel Selector to the desired channel and move the Fine Tuning Control slowly over this point until the best quality picture is obtained. This may require adjustment of the Contrast control to obtain the proper contrast between the blacks and whites of the picture, or adjustment of the Focus control located on rear of chassis to sharpen the picture. Adjust the focus control for greatest clarity of the lines in the center of the raster.

5. Adjust the Volume control to obtain the desired sound level. On some stations, the readjustment of the Fine Tuning control may be necessary to minimize the noise in the sound.

6. If the picture rolls or jumps vertically, turn Contrast control counter-clockwise to obtain a weak picture and adjust the Vertical Hold control until the picture remains stationary. Then readjust Contrast control.

7. If the picture pulls to the right or tears, adjust the Horizontal Hold control until the picture remains stationary on the screen then set the control in the center of the range in which it makes the picture stationary. This adjustment should also be made with the Contrast control set to obtain a weak picture.

6. SERVICE NOTES

All controls are adjustable without removing the chassis from the cabinet. The back of the cabinet must be opened for the Horizontal Stabilizer adjustment which is on the top of the chassis.

WARNING

An A.C. interlock is provided at the rear of the receiver so that when the back is removed, the power is off. Bypassing the interlock involves a shock hazard from the receiver high voltage power supply and the anode lead to the picture tube. Work on the receiver should not be attempted by anyone not thoroughly familiar with the precautions necessary when working on high voltage equipment.

6.01 Adjustments & Operating Check:

Remove the screws in the cabinet back and swing open the back. Connect an auxiliary power cord with suitable socket to the interlock receptacle on the rear of the receiver chassis.

1. ION TRAP MAGNET ADJUSTMENT - When making this adjustment, do not exert pressure on the neck of the picture tube. Adjust the BRIGHTNESS control for normal brightness. With the ION TRAP positioned close to the base of the picture tube, move the trap forward or backward and at the same time rotate in either direction until maximum brightness of the raster is obtained. Readjust the BRIGHTNESS control until the raster is slightly above average brilliance. Adjust the FOCUS CONTROL until the line structure of the raster is clearly visible. Readjust the ION TRAP again for maximum brightness.

There may be two locations on the tube neck where the ION TRAP will produce maximum brightness. Never set the trap to the forward position, always use the position closest to the tube base.

If there is a shadow in the corners of the raster, be sure the ION TRAP is properly adjusted. Do not sacrifice picture brilliance when adjusting the ION TRAP to overcome shadows in corner of picture. If corner shadows are present, be sure the DEFLECTION YOKE and CENTERING MAGNET are properly adjusted.

2. DEFLECTION YOKE ADJUSTMENT - Position the Deflection Yoke as far forward as possible on the picture tube. If the lines of the raster are not horizontal, rotate the Deflection Yoke so as to make the top of the raster parallel with the top of the chassis, then tighten the yoke adjusting screws.

3. CENTERING RASTER - Center the raster by turning the levers of the CENTERING MAGNET in either direction until the raster is centered. The CENTERING MAGNET is located on the back cover of the deflection yoke. To determine the correct picture centering, it may be necessary to reduce the size of the picture with the HEIGHT and WIDTH adjustments. After making this adjustment, readjust ION TRAP.

4. HEIGHT AND WIDTH ADJUSTMENTS - Height, width and linearity adjustments must be made only when necessary. The linearity and corresponding size controls will have to be adjusted together and with care to maintain picture symmetry. For this reason it is best to use a test pattern when making these adjustments. Adjust size of picture to fill the screen by means of the HEIGHT, WIDTH, VERTICAL LINEARITY and the HORIZONTAL centering control.

5. VERTICAL LINEARITY ADJUSTMENT - The Vertical Linearity control has the effect of expanding the picture at an increasing rate from the bottom to the top of the picture. Adjustment of this control has the greatest effect on the top portion of the picture, some effect on the middle and very little effect on the bottom of the picture. The Height Control and Focus control may need readjustment as a result of the change in position of the Vertical Linearity Control.

6. FOCUS CONTROL - Adjust the FOCUS CONTROL for best focus of the vertical and horizontal wedges at the center of the test pattern. If corner focus is poor, check position of DEFLECTION YOKE and ION TRAP. While observing the test pattern (or picture), make a slight readjustment of the VERTICAL HOLD control until the horizontal lines are least noticeable. This adjustment is very critical and will require only a very slight movement of the control shaft to obtain proper adjustment.

6.02 Oscillator Adjustment Using A Television Signal:

Do not make any adjustments on the two oscillator adjusting screws unless the FINE TUNING control range is insufficient to properly tune-in the station. The adjusting screws are accessible through holes in the front of the chassis after the chassis is removed from the cabinet.

To make the adjustment, proceed as follows:

(a) Turn the receiver on and allow a warm-up period of approximately five minutes.

(b) For stations from channel 13 to channel 7, set the Station Selector Switch to the highest channel received and adjust the Contrast and Volume control for normal sound and picture. Set the Fine Tuning Control in the center of its range.

(c) Using a small non-metallic screwdriver, adjust the slotted head brass screw located to the left of shaft and above the fiber disc for the clearest and sharpest detail in the picture. This adjustment will be effective on all channels between 13 and 7. If other stations are operating in this range, it may be necessary to compromise slightly on the high channel adjustment so the other channels may be properly tuned-in.

(d) For Stations on channel 6 and below, set the station Selector Switch to the channel received closest to channel 6 and adjust the Contrast and Volume control for normal sound and picture. Set the Fine Tuning control in the center of its range.

(e) Using a small non-metallic screwdriver, adjust the slotted head brass screw located to the right of the shaft for the clearest and sharpest detail in the picture. This adjustment will effect all channels between 6 and 2.

6.03 Local-Distance (AGC) Switch:

The Local-Distance Switch can be set to prevent the receiver from overloading in strong signal areas or to reduce "snow" in the picture in weak signal areas. In strong signal areas, the Local (counterclockwise) position of the switch must be used. The second and third positions Suburban and Distance are to be used in medium to weak signal areas. Use the position with which the best picture is obtained with no overloading of the receiver when the Contrast control is advanced.

6.04 Horizontal Lock-in Adjustment:

See "HORIZONTAL HOLD ADJUSTMENT".

6.05 To Clean Picture Tube and Window:

The chassis must be removed from cabinet. (See Section 6.06 Removal of the chassis from the cabinet)

6.06 Removal of the Chassis from the Cabinet:
(Be sure Power is Disconnected)

1. Remove the (slip-on type) knobs from the front panel controls.

2. Remove the screws in the cabinet back and swing open the back.

3. Remove the built-in antenna leads from the antenna terminal board screws.

4. Disconnect the speaker plug from the speaker socket on the rear of the speaker.

5. Remove the hex head machine screws that secure the chassis in the cabinet. These are accessible from the bottom of the chassis shelf on the console models and from the bottom of the cabinet on the table models.

6. Slide the chassis from the cabinet.

7. To reinsert the television chassis in the cabinet, repeat steps 2 to 6 in reverse order, then proceed as follows:

(a) Replace the large and small knobs on the Volume Control and Off-On-Contrast control shafts.

(b) Replace the large and small knobs on the Fine Tuning and Channel Selector control shafts.

6.07 Removal and Replacement of the Picture Tube:

Do not remove or handle the picture tube in any manner unless heavy gloves and protective goggles are worn. KEEP THE TUBE AWAY FROM THE BODY WHILE HANDLING.

1. Disconnect the tube socket and high voltage anode lead from the picture tube. Remove the Ion Trap from the neck of the tube.

2. Remove Picture tube strap.

3. Grasp the picture tube firmly with both hands along the outer edge and gently slide it out of the deflection coils.

CAUTION: NEVER GRASP THE PICTURE TUBE BY ITS NECK OR ALLOW PRESSURE TO BE EXERTED ON THE NECK.

4. Place the picture tube face down, on a flat surface covered by a clean cloth, in a location where it will not be disturbed.

5. When the picture tube is ready to be replaced in the receiver chassis, slide the picture tube gently back into the deflection coils.

6. Bottom of tube should rest on the rubber strip on the bracket fastened to the front of the chassis. Also, see that the neck of the tube is centered in the deflection coil. This centering must be accomplished by adjusting the deflection yoke bracket. DO NOT ALLOW PRESSURE TO BE EXERTED ON THE NECK OF THE TUBE. Fasten the picture tube strap.

7. Slide the deflection coil bracket forward as far as possible until the rubber cushion fits snugly against the flare of the picture tube. Also make sure that the deflection coils are positioned firmly against the flare of the tube.

8. Replace the Ion Trap.

9. Connect the anode (high voltage) lead to tube.

10. Connect the tube socket to base of tube.

6.08 Removal and Replacement of the RF Unit:

1. Unsolder: (a) Black and Yellow lead from lug #3 on rear of Tuner.
(b) R143, 220 ohm resistor from lug #2 on rear of Tuner.
(c) C101, 330 mmf. capacitor from lug #1 on rear of Tuner.
(d) Spiral shield from ground lance on rear of Tuner.
(e) C102, .05 mfd. capacitor and R101, 100,000 ohm resistor from lug #8 on rear of Tuner.
(f) R101, 100,000 ohm resistor and Brown lead from lug #9 on rear of Tuner.

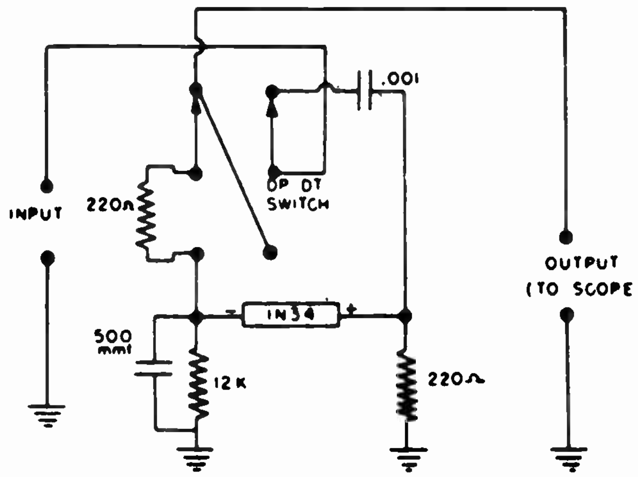
2. Remove CA101 antenna lead from terminal board CO102.

3. Remove two self tapping screws that fasten the tuner shaft support bracket to the front of the chassis. Then remove the two screws that fasten the tuner mounting bracket to the underneath side of the chassis and carefully remove the unit from the bottom of the chassis.

4. To install the new R.F. TUNER UNIT, reverse steps "1" to "3".

6.09 Test Equipment:

Equipment Needed	Required Characteristics
Cathode-Ray Oscilloscope	Very high input impedance. Must readily synchronize with "Y" axis signal. Must have excellent frequency and phase response from 10 cycles to at least two megacycles and should be capable of passing a 60 cycle square wave without appreciable distortion. Must not compress input signal until a reasonably size wave form appears. Wide range input attenuator.
Voltage Calibrator	Suitable for calibrating the amplitude of the wave shapes on the "Y" axis of the oscilloscope.
Electronic Voltmeter	Very high input impedance for d.c. voltage measurements. Having at least one megohm of d.c. resistance on the 3 volt scale.
R. F. Sweep Generator or Wobbulator	Frequency range 20 to 250 megacycles, sweep width 10-12 megacycles (adjustable). Output adjustable with at least .1 volt maximum. Output constant on all ranges. Center frequency variable over the complete television spectrum of channels 2-13. Output impedance 150 ohms unbalanced.
Signal Generator	High frequency signal generator; minimum frequency range 40-250 mc.; frequency calibrations reliable to better than 100 KC. Attenuator should be adjustable and very accurate; modulation up to 30%.
Cathode-Ray Oscilloscope	Same as in "A".
Probe Detector	For connecting scope to circuits ahead of second detector. (Probe Detector Schematic.)
Non-Capacitive Screwdriver	Made of 1/4" fiber rod having screwdriver ends.



Probe Detector Schematic

6.10 Possible Failures:

NOTE: The following failures and possible solutions will aid the serviceman to locate and remedy the trouble.

Tubes should be changed first and if this will not remedy the trouble, check voltages.

1. DEAD RECEIVER:
   a. A.C. interlock not making connection.
   b. Power cord broken, check cord at interlock.
   c. Power switch SW101 contacts open.

2. NO RASTER OR SOUND BUT TUBES LIGHT UP:
   a. Low voltage selenium rectifiers SR101, SR102.
   b. Speaker plug disconnected.
   c. Open choke L111.
   d. Open R142 Fuse type Resistor.

3. PICTURE BUT NO SOUND:
   a. Audio Tubes (V104, V111).
   b. Sound Det. Driver tube (V107).
   c. Defective Speaker voice coil.
   d. Receiver not tuned properly.
   e. T108 or C157 defective.
   f. Sound Detector tube (V106).

4. NO RASTER WITH SOUND PRESENT:
   a. Ion trap magnet not set properly.
   b. No high voltage caused by 1B3 GT rectifier, T106 Horizontal Output transformer, V110, V112, V113, or V114.
   c. Defective Picture tube.

5. NO PICTURE OR SOUND WITH RASTER PRESENT:
   a. I.F. tubes V101, V102, V103.
   b. Crystal detector CR101 or Video amplifier V108; peaking coils open.
   c. R.F. Unit.
   d. Antenna Lead-in.

6. NO VERTICAL DEFLECTION:
   a. Open Vert. Osc. Transformer T104.
   b. Vertical Output Transformer T105 open.
   c. Open deflection coil L112A.
   d. V105 tube defective or burnt out.
   e. C132 shorted.
   f. C131 or C118D shorted or R137 open.

7. NO HORIZONTAL DEFLECTION:
   a. Tubes V112, V113, V114.
   b. Horizontal Stabilizer Coil L108.
   c. Open deflection coil L112B.

8. SOUND BARS OR GRAIN IN PICTURE:
   a. Station not "tuned-in" properly.
   b. Ratio Detector Trans. T107 primary not adjusted properly.
   c. Microphonic tubes. (V2, V101, V102, V103).
   d. Oscillation in I.F. system due to lead dress or open by-pass capacitor.
   e. R.F. or I.F. not aligned properly.

9. SIGNAL BUT NO VERTICAL SYNC:
   a. Defective vertical oscillator Trans. T104.
   b. V105 tube.
   c. Integrator network, C126, open or shorted.
   d. Vertical Hold Control R135 arm not making good contact.

10. SIGNAL BUT NO HORIZONTAL SYNC:
   a. V110
   b. Capcitors C136 and C137 open.
   c. R149 open, or C139 defective.
   d. Horizontal frequency adjustment of L108 not properly adjusted.
   e. Horizontal Hold control R155.

11. SIGNAL BUT NO VERT. OR HORIZ. SYNC:
   a. Tube V109.
   b. C123 or C125 open.
   c. R127 open.

12. SHADOWS IN CORNERS OF PICTURE:
   a. Ion trap magnet adjustment.
   b. Misadjusted centering magnet.

13. "SNOW" IN PICTURE:
   a. Weak signal; check antenna and lead-in.
   b. Noisy tube V2 in R.F. Unit.
   c. Corona discharge from High Voltage power supply due to improper lead dress.

14. SMALL PICTURE:
   a. Low line voltage.
   b. Weak Selenium Rectifiers SR101, SR102.
   c. V112 tube.

15. PICTURE WITH VERTICAL LINES: AND HORIZONTAL NON-LINEARITY:
   a. V112 tube.

6.11 Critical Lead Dress:

CIRCUIT OR LEAD:

R.F. TUNING UNIT:

RF Tuner:

The brown AGC lead from the terminal board to the tuner should be dressed flat down to chassis.

IF Section:

The component leads and wires in the video IF section must be kept as short as possible.

RF Choke:

The end of the RF choke L113 which is wired to T103, lug 6, shall be as short as possible.

LEADS:

The black wire from T103, lug 4 to chassis must be as short as possible. All leads must be kept away from the plates of the selenium rectifiers, SR101 and SR102. Dress the red and blue leads of Audio Output Transformer, T108 away from the high voltage shield so they will not be pinched under it.

Components:

Keep all components, particularly peaking coils, away from R121 which is wired between the terminal boards adjacent to V110.

Resistors:

Dress the fuse resistor R142 attached to the terminal board, up away from the chassis. On the 385 chassis, dress the two 150K ohm resistors, R151 and R152, in such a manner as not to short against the high voltage shield.

Capacitors:

The .006 mfd. capacitor, C138, wired from V114, pin 6, to ground lug of C118, should be dressed down close to the chassis. The .005 mfd. capacitor, C162, which is wired from the case of R118 thru the center lug of R118A to chassis, must have a very short lead on the end wired to the case of R118 so the body of the capacitor prevents any shorting to the shield wired to R118.

Controls:

All controls and the local-distance switch must be kept from shorting to the chassis. Make sure the control does not turn when the nut is tightened.

High Voltage Section:

The plate cap of the 1B3GT, V115, should be put on so the lead comes away from it in a vertical direction. The vinyl tape that is applied to the corona ring should cover the entire outside edge of the ring and as much of the socket area as possible.

Yoke Coupling Network:

The yoke coupling network, L109, wired from T106 lug 3 to V112, lug 1, should be kept away from lug 4 of T106.

6.12 Alignment and Adjustment Notes:

1. The sound I.F. and video I.F. carriers of this receiver are 21.9 megacycles and 26.4 megacycles respectively. Sound I.F. frequency 4.5 mc.

2. When the television receiver is repaired or aligned, always turn the chassis on its side with I.F. strip and R.F. Tuning unit up and block up the deflection coil mounting bracket to prevent the tube from resting on the bench.

3. Never disconnect the speaker while the power is on as the filter choke mounted on the speaker is in the B+ circuit.

4. If the television receiver must be operated with the picture tube removed from the chassis, tape or cover the exposed end of the high voltage anode lead.

5. All lead connections from the signal generator and wobbulator must be shielded. Keep the exposed ends and ground leads as short as possible (about one inch).

6. Always locate the ground lead connections as close as possible to their respective "hot" leads in the television receiver chassis.

7. The wobbulator, signal generator output, and contrast control must be kept low enough to prevent over loading the television receiver circuits.

CONNECTING EXTERNAL ANTENNA

Remove the two wires from the built-antenna fastened to the two screws on the antenna terminal board mounted at the rear of the receiver. Tape bare ends of wires from the built-in antenna. Keep the lead-in from the external antenna away from the power cord and speaker leads. Fasten the lead-in wires under the two screws on the antenna terminal board.

ADJUSTMENTS

1. ION TRAP ADJUSTMENT:

Adjust the BRIGHTNESS control for normal brightness. With the ION TRAP positioned close to the base of the picture tube, move the trap forward or backward and at the same time rotate in either direction until maximum brightness of the raster is obtained. Readjust the BRIGHTNESS control until the raster is slightly above average brilliance. Adjust the FOCUS CONTROL until the line structure of the raster is clearly visible. Readjust the ION TRAP again for maximum brightness.

There may be two locations on the tube neck where the ION TRAP will produce maximum brightness. Never set the trap to the forward position, always use the position closest to the tube base.

If there is a shadow in the corners of the raster, be sure the ION TRAP is properly adjusted. Do not sacrifice picture brilliance when adjusting the ION TRAP to overcome shadows in corner of picture. If corner shadows are present, be sure the DEFLECTION YOKE and CENTERING MAGNET are properly adjusted.

2. DEFLECTION YOKE AND BRACKET:

The DEFLECTION YOKE should be positioned as far forward as possible on the picture tube neck and rotated to the left or right as required to make the picture parallel with respect to the top and bottom of window frame.

3. CENTERING RASTER:

If the picture is off center and/or has neck shadow, rotate either or both CENTERING MAGNET levers to the left or right until the picture is centered on the screen and is free of neck shadow. The CENTERING MAGNET is located on the back cover of the DEFLECTION YOKE. To determine the correct picture centering, it may be necessary to reduce the size of the picture with the HEIGHT and WIDTH adjustments. After making adjustment of CENTERING MAGNET, readjust ION TRAP.

4. HEIGHT AND WIDTH ADJUSTMENTS:

The linearity and corresponding size controls will have to be adjusted together and with care to maintain picture symmetry. For this reason it is best to use a test pattern when making these adjustments. Adjust size of picture to fill the screen by means of the HEIGHT, WIDTH, VERTICAL LINEARITY.

5. VERTICAL LINEARITY ADJUSTMENTS:

The VERTICAL LINEARITY control has the effect of expanding the picture at an increasing rate from the bottom to the top of the picture. Adjustment of this control has the greatest effect on the top portion of the picture, some effect on the middle and very little effect on the bottom of the picture. The HEIGHT and FOCUS controls may need readjustment as a result of the change in position of the VERTICAL LINEARITY control.

6. HORIZONTAL HOLD CONTROL:

The HORIZONTAL HOLD CONTROL is adjusted with a weak picture to the center of its pull-in range. If the pull-in range is insufficient or the horizontal sync is unstable, see "Horizontal Hold Adjustment" under "Alignment".

7. VERTICAL HOLD CONTROL:

The VERTICAL HOLD CONTROL is also adjusted to the center of its pull-in range with the contrast control set to obtain a weak picture.

8. FOCUS CONTROL:

Adjust the FOCUS CONTROL for best focus of the vertical and horizontal wedges at the center of the test pattern. If corner focus is poor, check position of DEFLECTION YOKE and ION TRAP. While observing the test pattern (or picture), make a slight readjustment of the VERTICAL HOLD control until the horizontal lines are least noticeable. This adjustment is very critical and will require only a very slight movement of the control shaft to obtain proper adjustment.

CAUTION

HIGH VOLTAGE--Operation of a television receiver with the back open involves a shock hazard. When making adjustments other than adjusting the controls at the front panel, all precautions for working near high voltage should be exercised.

HIGH TEMPERATURE OF TUBES--Some tubes in the receiver operate at extremely high temperatures. To avoid serious burns, do not touch these tubes while the receiver is operating, or until the tubes have cooled after the set is shut off.

HANDLING OF PICTURE TUBES--Breakage of the picture tube, which contains a high vacuum, may result in injury from flying glass. Do not scratch tube face or subject to more than moderate pressure. DO NOT REMOVE OR HANDLE THE PICTURE TUBE IN ANY MANNER UNLESS HEAVY GLOVES AND PROTECTIVE GOGGLES ARE WORN. Persons not so equipped should be kept away while handling the tube. NEVER GRASP THE TUBE BY THE NECK OR ALLOW PRESSURE TO BE EXERTED ON THE NECK. In installation, if the tube sticks or fails to slip smoothly through the deflection yoke, investigate and remove the cause of the trouble. DO NOT FORCE TUBE.

ADJUSTMENTS (Continued)

9. BRIGHTNESS CONTROL:

BRIGHTNESS CONTROL and CONTRAST control should be set to obtain as much shading in the picture as possible. If the Brightness control is set too low, the black and grays of the picture are black and if set too high, the black and grays of the picture will appear light and faded.

10. LOCAL-DISTANCE (AGC) SWITCH:

The LOCAL-DISTANCE SWITCH can be set to prevent the receiver from overloading in strong signal areas or to reduce "snow" in the picture in weak signal areas. In strong signal areas, the "LOCAL" (counter-clockwise) position of the switch must be used. The second and third positions "SUBURBAN" and "DISTANCE" are to be used in medium to weak signal areas. Use the position with which the best picture is obtained with a minimum of overloading of the receiver when the CONTRAST control is advanced.

11. OSCILLATOR ADJUSTMENT USING A TELEVISION SIGNAL:

Do not make any adjustments on the two oscillator adjusting screws unless the FINE TUNING control range is insufficient to properly tune-in the station. The adjusting screws are accessible through holes in the front of the chassis after the chassis is removed from the cabinet.

To make the adjustment, proceed as follows:

(a) Turn the receiver on and allow a warm-up period of approximately five minutes.

(b) For stations from channel 13 to channel 7, set the Station Selector Switch to the highest channel received and adjust the Contrast and Volume control for normal sound and picture. Set the Fine Tuning Control in the center of its range.

(c) Using a small non-metallic screwdriver, adjust the slotted head brass screw located to the left of the shaft and above the fiber disc for the clearest and sharpest detail in the picture. This adjustment will be effective on all channels between 13 and 7. If other stations are operating in this range, it may be necessary to compromise slightly on the high channel adjustment so the other channels may be properly tuned-in.

(d) For Stations on channel 6 and below, set the station Selector Switch to the channel received closest to channel 6 and adjust the Contrast and Volume control for normal sound and picture. Set the Fine Tuning control in the center of its range.

(e) Using a small non-metallic screwdriver, adjust the slotted head brass screw located to the right of the shaft for the clearest and sharpest detail in the picture. This adjustment will effect all channels between 6 and 2.

I. F. ALIGNMENT

All lead connections from the signal generator and wobbulator must be shielded. Keep the exposed ends and ground leads as short as possible (about one inch). Always locate the ground lead connections as close as possible to their respective "hot" leads in the television receiver chassis. The wobbulator, signal generator output, and contrast control must be kept low enough to prevent overloading the television receiver circuits.

CAUTION: One side of the chassis is connected to the power line. Therefore, test equipment should not be connected to the receiver unless an isolation transformer is used between the power line and the receiver. DO NOT GROUND THE RECEIVER CHASSIS UNLESS AN ISOLATION TRANSFORMER IS USED.

1. To Check I. F. Alignment on Oscilloscope:

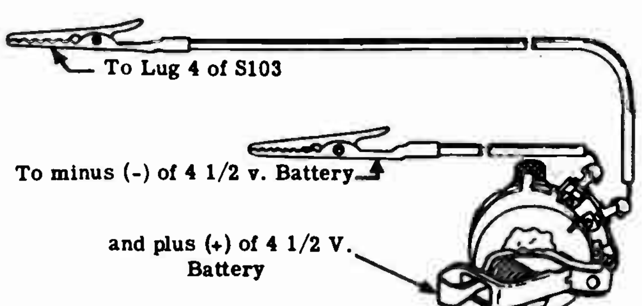
(a) Lift the shield of the Oscillator - Mixer tube V2 sufficiently to clear the socked ground clips. Connect sweep signal generator "hot" lead to the underground tube shield and generator ground lead to the tuner chassis.

(b) Connect high side of oscilloscope to high side of contrast control (pin 2 and 7 of V108), and the low side to chassis.

(c) Apply - 3.0 volts D.C. bias to lug 4 of S103 (See sketch "Variable Bias Control"). Contrast control should be set in the maximum counter-clockwise position.

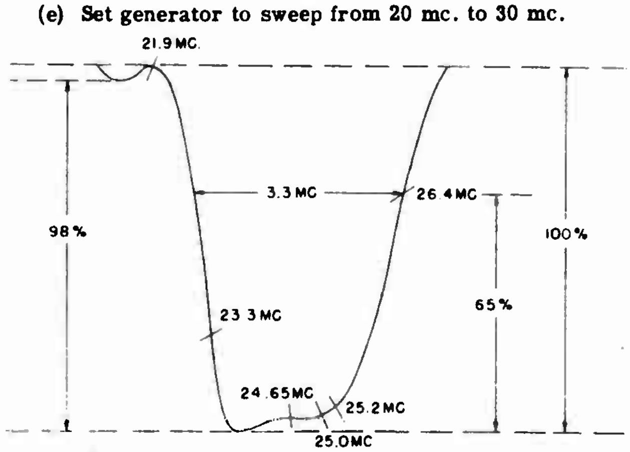
(d) With the generator sweep set at zero, connect an electronic voltmeter between lug 2 of S103 and chassis. Adjust the output of the generator to obtain a reading of 2 volts D.C. on the meter.

(e) Set generator to sweep from 20 mc. to 30 mc.



5000 Ohm Control only, Part No. 144260

VARIABLE BIAS CONTROL ASSEMBLY



NOMINAL OVERALL I. F. RESPONSE CURVE

NOTE: Response as Seen by Means of Sweep Generator

I. F. ALIGNMENT (Continued)

(f) Connect marker generator to sweep generator output leads and adjust to provide markers that appear in the curve.

(g) Observe curve and position of markers (see nominal response curve). Slight deviation in shape from the nominal response curve is permissible, but if any great deviation is noted, it will be necessary to realign the I-F Amplifier.

2. Alignment, I. F. & Tuner Assembly (with electronic voltmeter):

(a) Connect - 3.0 Volts D.C. bias supply to lug 4 of S103.

(b) Connect signal generator "hot" lead through a 1000 mmf. capacitor to TP-1 (wire protruding from tuner directly adjacent to the oscillator mixer tube V2) and ground lead to the R. F. tuner case.

(c) Connect high side of Electronic Voltmeter to lug 2 of S103 and low side to chassis.

(d) Set signal generator to 25.0 mc. and adjust bottom of T103 for maximum meter deflection, limiting meter deflection to 2 volts D.C. by adjusting input attenuator.

(e) Set signal generator to 23.3 mc. and adjust bottom of T102 for maximum D.C. meter indication. Adjust signal generator amplitude to make this peak indication approximately 2 volts D.C.

(f) Reset signal generator to 21.9 mc. and adjust the top of T102 for minimum D.C. meter deflection. Signal generator amplitude must be sufficiently high to produce a definite null. Meter must read at least 0.5 volts at null.

(g) Repeat steps 5 and 6.

(h) Next set signal generator to 25.2 mc. and adjust bottom of T101 for maximum meter indication, limiting output of generator so peak reading will not exceed 2 volts D.C.

(i) Reset signal generator to 24.65 mc. Connect a 500 ohm resistor in series with a 500 mmf. capacitor from TP-2 (wire protruding from the tuner through the insulated eyelet between the brass adjusting screws) on the R-F Tuner to the Tuner side of C101. Adjust L101 for maximum meter deflection, but limit output of generator so this reading does not exceed 2 volts D.C. Remove the 500 ohm resistor and the 500 mmf. capacitor.

(j) Set signal generator to 24.65 mc. Connect the 500 ohm resistor and the 500 mmf. series capacitor across L101 and adjust mixer output (L9) on R-F Tuner for maximum meter indication. Adjusting amplitude of signal generator to make this maximum indication approximately 2 volts D.C. Remove the 500 ohm resistor and the 500 mmf. capacitor.

(k) Check sensitivity. The input for 2 volts D.C. output and zero bias should not exceed 150 microvolts at 24.65 mc. with a generator internal resistance of 1.5 ohms or less, and the local oscillator set to properly tune in channel 5.

(l) Remove the signal generator and electronic voltmeter.

SOUND ALIGNMENT

1. Connect crystal controlled 4.5 mc. 400 cycle amplitude modulated signal, modulated 30% or greater, to lug 2 of S103 and chassis.
2. Connect high side of scope through detector probe to the picture tube cathode (pin 11). Connect low side of scope to chassis. Adjust 4.5 mc. trap, L105 for minimum 400 cycle deflection on scope.
3. Connect electronic voltmeter to lug 2 of ratio detector, V106, and adjust 4.5 mc. sound take-off (L110) and bottom of ratio transformer (T107) for peak reading on voltmeter. Adjust input to make this peak reading 4 volts.
4. Adjust input to obtain 12 volts output. Transfer electronic voltmeter to junction of R167 and C153 (refer to Schematic Wiring Diagram). Adjust top of T107 for zero balance on electronic voltmeter.
5. Recheck steps 2, 3 and 4 above.
6. Remove input signal, scope and electronic voltmeter.

HORIZONTAL HOLD ADJUSTMENT

1. Tune in a local television signal and adjust contrast control for normal picture.
2. Connect electronic voltmeter between TP-3 (green lead) and chassis.
3. Short TP-4 (orange lead) to chassis and adjust electronic voltmeter to zero.
4. Remove short from TP-4. Do not change zero on electronic voltmeter.
5. Connect a 0.1 mfd. plus 20%, 600 volt capacitor between TP-5 (red lead) and chassis.
6. Adjust Horizontal Hold control for zero reading on the meter.
7. Remove the 0.1 mfd. capacitor from TP-5 and chassis. Do not disturb setting of horizontal hold control.
8. Adjust Horizontal Stabilizer coil (L108) for zero reading on the meter.
9. Remove electronic voltmeter from TP-3
10. Check horizontal pull-in range. The pull-in range should be approximately 50° of the controls rotation.

R104	39374-9	Resistor, 47 ohm, 10%, 1/2 w.

TV CHASSIS 386-387 (Schematic Parts)

Symbol No.	Part No.	Description
R105	39374-25	Resistor, 1000 ohm, 10%, 1/2 w.
R106	39375-73	Resistor, 10,000 ohm, 5%, 1/2 w.
R107	39374-9	Resistor, 47 ohm, 10%, 1/2 w.
R108	39374-25	Resistor, 1000 ohm, 10%, 1/2 w.
R109	39375-75	Resistor, 12,000 ohm, 5%, 1/2 w.
R110	39374-15	Resistor, 150 ohm, 10%, 1/2 w.
R111	39374-25	Resistor, 1000 ohm, 10%, 1/2 w.
R112	39374-56	Resistor, 390,000 ohm, 10%, 1/2 w.
R113	39374-67	Resistor, 1.8 megohm, 10%, 1/2 w.
R114	39375-67	Resistor, 5600 ohm, 5%, 1/2 w.
R115	39374-61	Resistor, 1 megohm, 10%, 1/2 w.
R116	39374-65	Resistor, 1.5 megohm, 10%, 1/2 w.
R117	39374-69	Resistor, 2.2 megohm, 10%, 1/2 w.
R118A	154085	Control (Contrast), 2500 ohm } Assembly
R118B		Control (Volume), 1 megohm }
R119	Part of L104	Resistor, 8200 ohm, 10%, 1/2 w.
R120	39374-131	Resistor, 33,000 ohm, 10%, 1 w.
R121	39375-361	Resistor, 4700 ohm, 5%, 2 w.
R122	Part of L106	Resistor, 6800 ohm, 10%, 1/2 w.
R123	Part of L107	Resistor, 3300 ohm, 10%, 1/2 w.
R124	39374-37	Resistor, 10,000 ohm, 10%, 1/2 w.
R125	39374-57	Resistor, 470,000 ohm, 10%, 1/2 w.
R126	39374-69	Resistor, 2.2 megohm, 10%, 1/2 w.
R127	39374-59	Resistor, 680,000 ohm, 10%, 1/2 w.
R128	39374-29	Resistor, 2200 ohm, 10%, 1/2 w.
R129	39374-146	Resistor, 560,000 ohm, 10%, 1/2 w.
R130	39374-41	Res'stor, 22,000 ohm, 10%, 1/2 w.
R131	39374-35	Resistor, 6800 ohm, 10%, 1/2 w.
R132	39374-31	Resistor, 3300 ohm, 10%, 1/2 w.
R133	39374-41	Resistor, 22,000 ohm, 10%, 1/2 w.
R134	39374-37	Resistor, 10,000 ohm, 10%, 1/2 w.
R135	154087	Control, Vertical Hold (850,000 ohm)
R136	39374-31	Resistor, 3300 ohm, 10%, 1/2 w.
R137	39374-28	Resistor, 1800 ohm, 10%, 1/2 w.
R138	154086	Control, Height (5 megohm)
R139	39374-14	Resistor, 120 ohm, 10%, 1/2 w.
R140	154088	Control, Vertical Linearity (750 ohm)
R141	154084	Resistor, 8700 ohm, 5%, 5 W. Wire Wound
R142	154089	Resistor, 7.5 ohm, 10%, 5 W. Wire Wound (Fuse type)
R143	39374-17	Resistor, 220 ohm, 10%, 1/2 w.
R144	39374-25	Resistor, 1000 ohm, 10%, 1/2 w.
R146	39374-49	Resistor, 100,000 ohm, 10%, 1/2 w.
R147	39374-49	Resistor, 100,000 ohm, 10%, 1/2 w.
R148	39374-41	Resistor, 22,000 ohm, 10%, 1/2 w.
R149	39374-77	Resistor, 4.7 megohm, 10%, 1/2 w.
R150	39374-77	Resistor, 4.7 megohm, 10%, 1/2 w.
R151	39374-131	Resistor, 33,000 ohm, 10%, 1 w.
R152	39374-133	Resistor, 47,000 ohm, 10%, 1 w.
R153	39374-26	Resistor, 1200 ohm, 10%, 1/2 w.
R154	39374-34	Resistor, 5600 ohm, 10%, 1/2 w.
R155	154093	Control, Horizontal Hold (120,000 ohm)
R156	39374-53	Resistor, 220,000 ohm, 10%, 1/2 w.
R157	39374-36	Resistor, 8200 ohm, 10%, 1/2 w.
R158	39374-55	Resistor, 330,000 ohm, 10%, 1/2 w.

Symbol No.	Part No.	Description
R159	39374-121	Resistor, 4700 ohm, 10%, 1 w.
R160	154083	Control, Horizontal Centering (50 ohm)
R161	39303-12	Resistor, 2.2 ohm, 10%, 1/2 w. Wire Wound
R162	39374-15	Resistor, 150 ohm, 10%, 1/2 w.
R163	39374-29	Resistor, 2200 ohm, 10%, 1/2 w.
R164	39374-18	Resistor, 270 ohm, 10%, 1/2 w.
R165	39375-73	Resistor, 10,000 ohm, 5%, 1/2 w.
R166	39375-73	Resistor, 10,000 ohm, 5%, 1/2 w.
R167	39374-43	Resistor, 33,000 ohm, 10%, 1/2 w.
R168	39374-27	Resistor, 1500 ohm, 10%, 1/2 w.
R169	39374-43	Resistor, 33,000 ohm, 10%, 1/2 w.
R170	154095	Control, Brightness (5 megohm)
R171	154094	Control, Focus (1.5 megohm)
R172	39374-45	Resistor, 47,000 ohm, 10%, 1/2 w.
R173	39374-50	Resistor, 120,000 ohm, 10%, 1/2 w.
R174	39374-213	Resistor, 10,000 ohm, 10%, 2 w.
L101	154287	Coil, Converter I. F.
L102	154171	Coil, Video Peaking (168 microhenry, 5%)
L103	154184	Coil, Video Peaking (335 microhenry, 5%)
L104	154194	Coil, Video Peaking (412 microhenry, 5%)
L105	154158	Trap (4.5 megacycle)
L106	154206	Coil, Video Peaking (106 microhenry, 5%)
L107	154176	Coil, Video Peaking (840 microhenry, 5%)
L108	154220	Coil, Horizontal Osc.
L109	154156	Network, Yoke Decoupling
L110	154183	Coil, Sound Take Off
L111	154442	Choke, Filter (used on SP 101)
L112	154221-6	Yoke, Deflection
L113	154376	Coil, R. F. Choke
L114	154442	Choke, Filter (used on SP 102)
T101	154307	Transformer, 1st. I. F.
T102	154319	Transformer, 2nd. I. F.

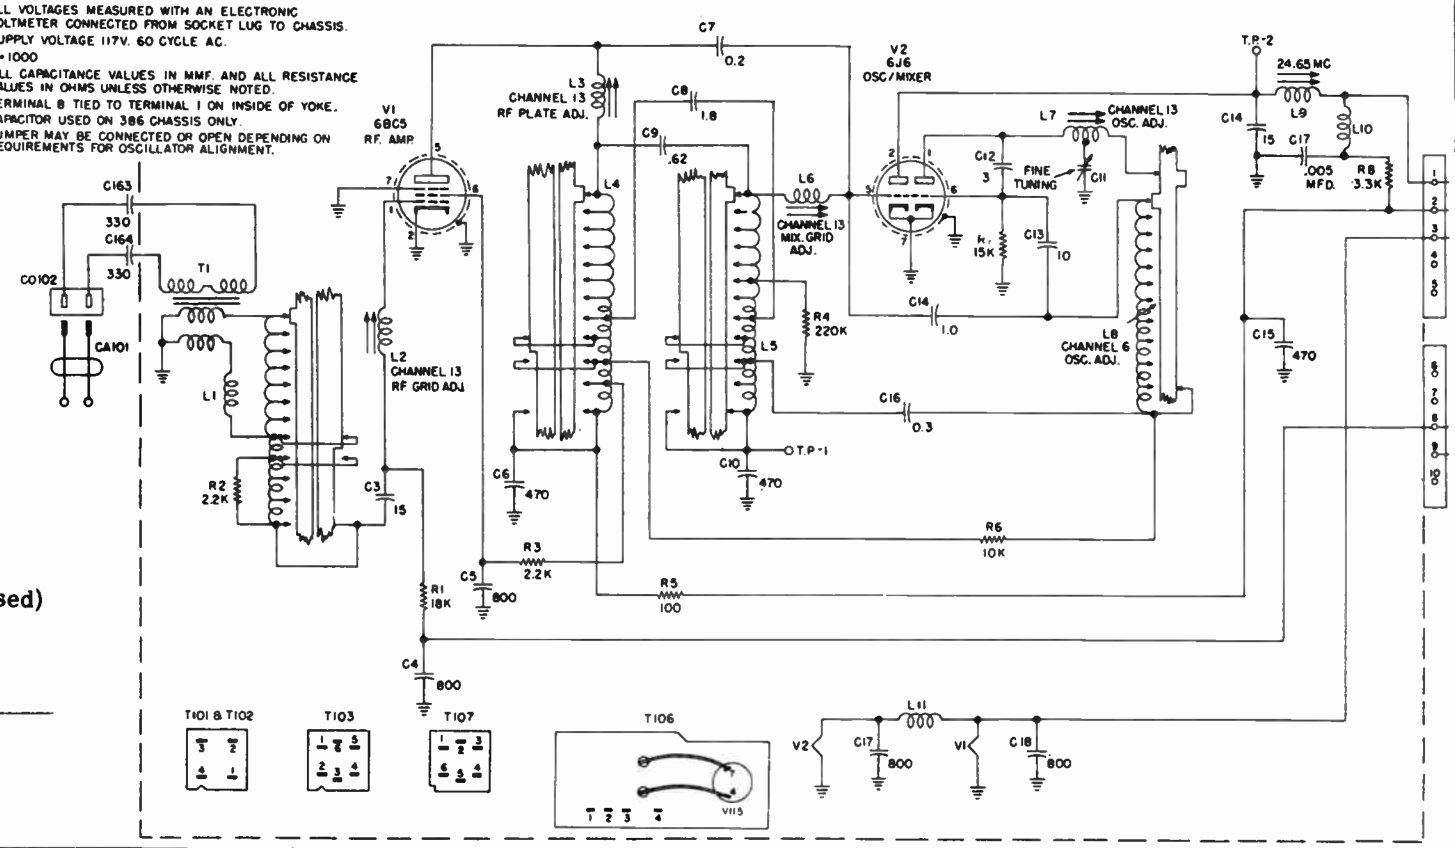
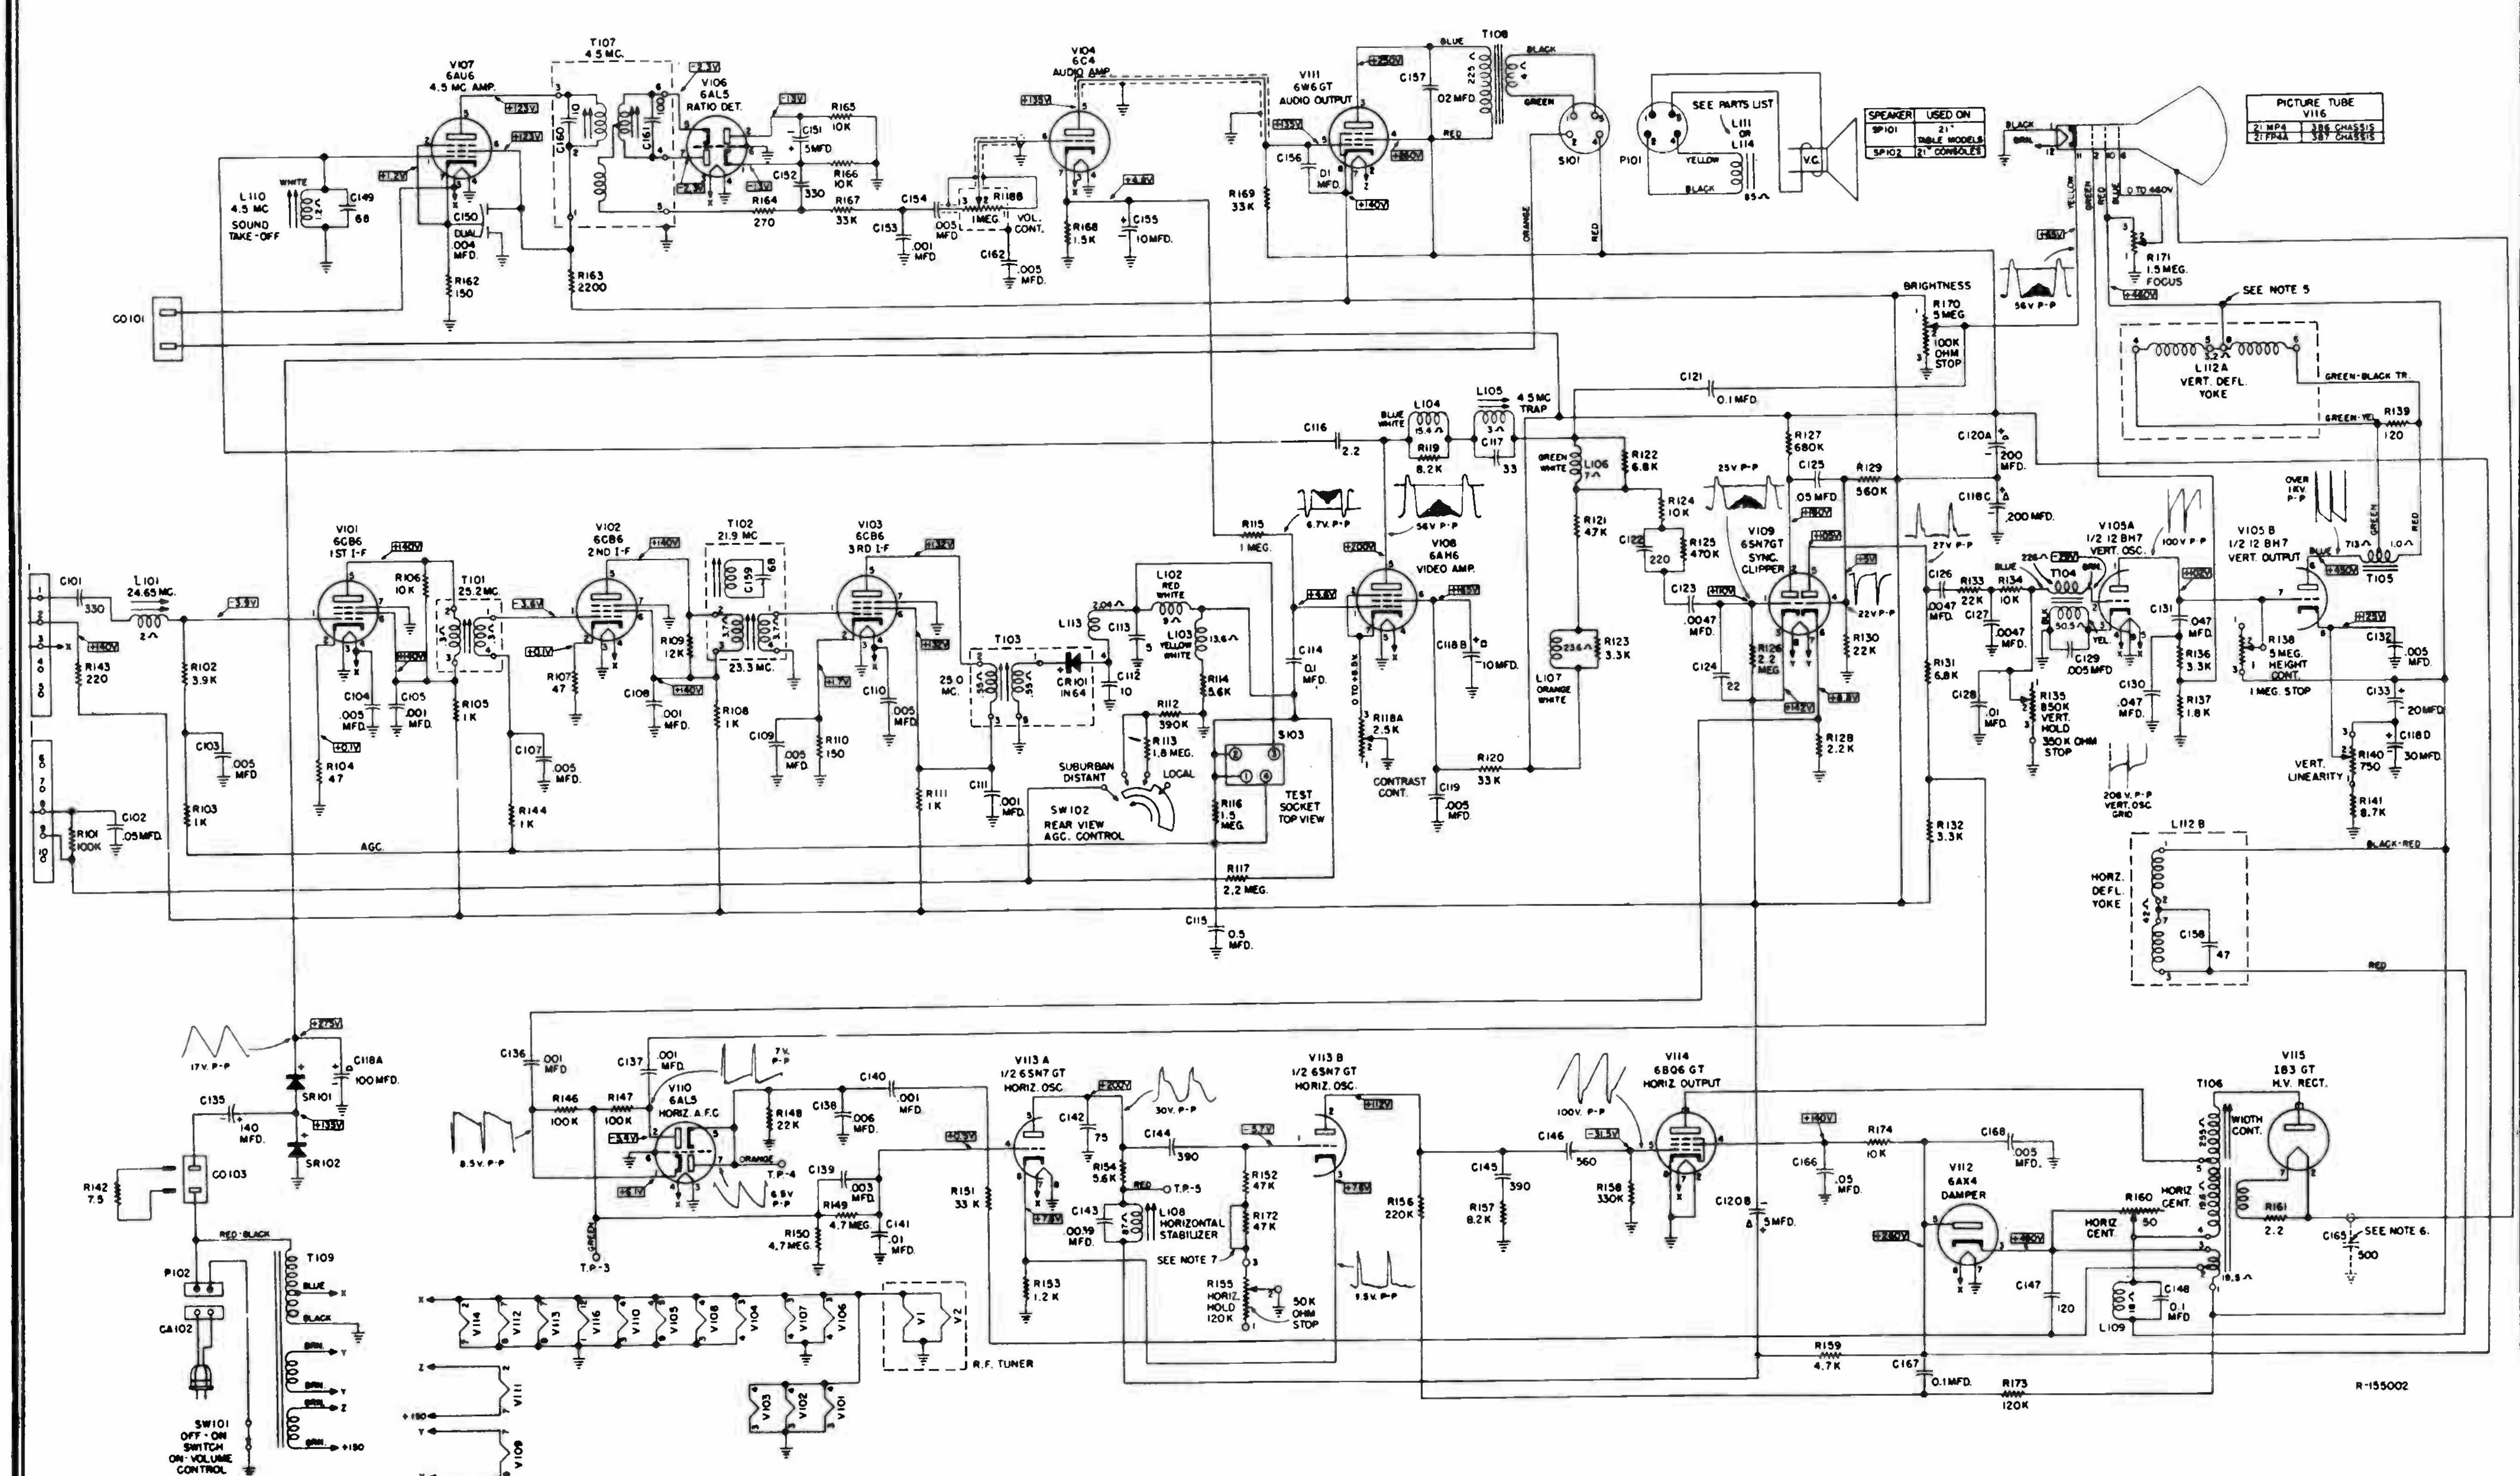
NOTES:

1. ALL VOLTAGES MEASURED WITH AN ELECTRONIC VOLTMETER CONNECTED FROM SOCKET LUG TO CHASSIS.
2. SUPPLY VOLTAGE 117V. 60 CYCLE AC.
3. K=1000
4. ALL CAPACITANCE VALUES IN MMF. AND ALL RESISTANCE VALUES IN OHMS UNLESS OTHERWISE NOTED.
5. TERMINAL 8 TIED TO TERMINAL 1 ON INSIDE OF YOKE.
6. CAPACITOR USED ON 386 CHASSIS ONLY.
7. JUMPER MAY BE CONNECTED OR OPEN DEPENDING ON REQUIREMENTS FOR OSCILLATOR ALIGNMENT.



SCHEMATIC WIRING DIAGRAM - REVISED CHASSIS 386-387

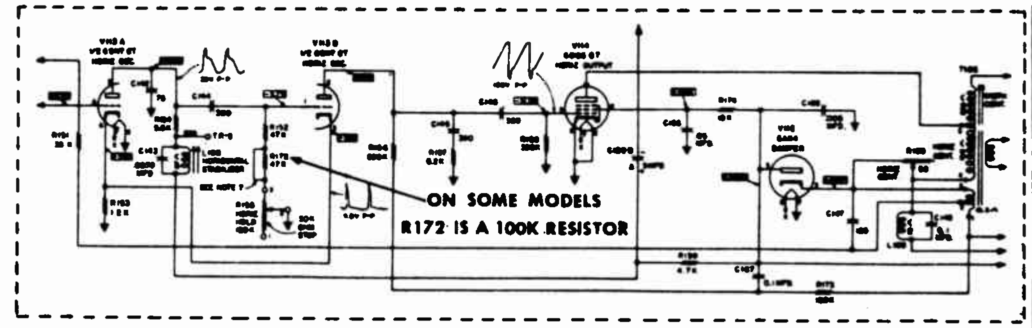


CROSLEY TV PAGE 12-25

Chassis identified by a code letter later than the letter A also incorporate the changes in the previous coded chassis. For example a chassis identified by code letter D incorporates the changes in codes A, B, C & D.

CHASSIS 386 & 387 HORIZONTAL DEFLECTION TRANSFORMERS AND ASSOCIATED CODE LETTERS

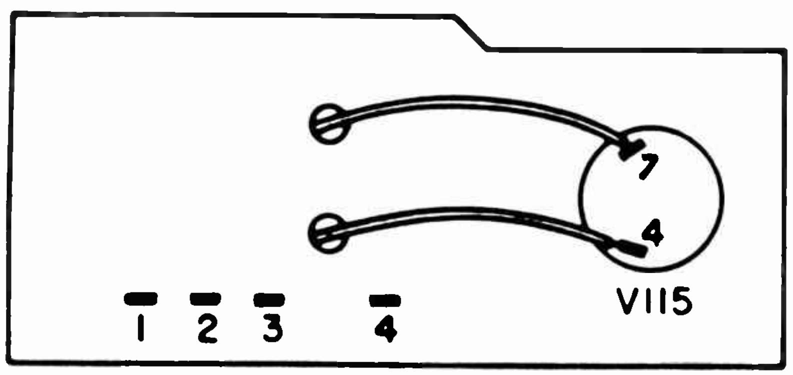
CHASSIS 386 & 387 (CODE LETTER B)
Increase High Voltage and Improve Stability



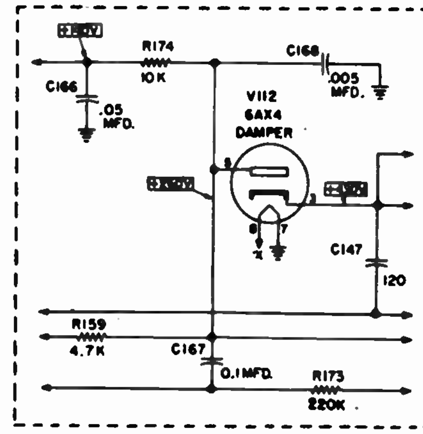
Chassis 386 & 387 (Code Letter A) - For Horizontal Deflection Transformer T106 (Part No. 154069-1), the terminal numbering sequence is as shown in sketch A.

T106

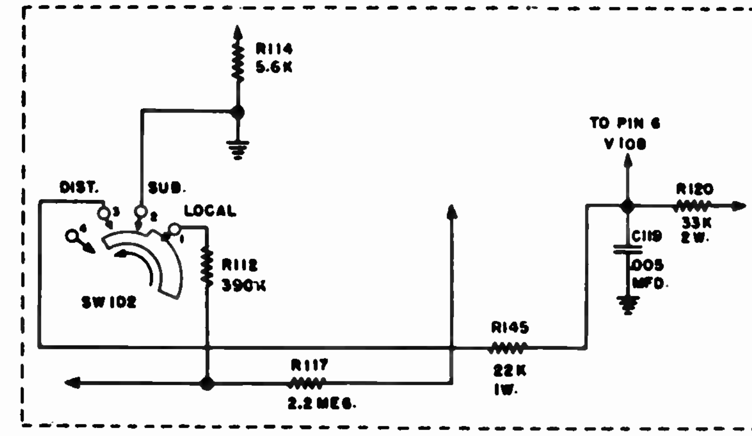
SKETCH A



Chassis 386 & 387 (Code Letter C)
To Reduce Horizontal fold over



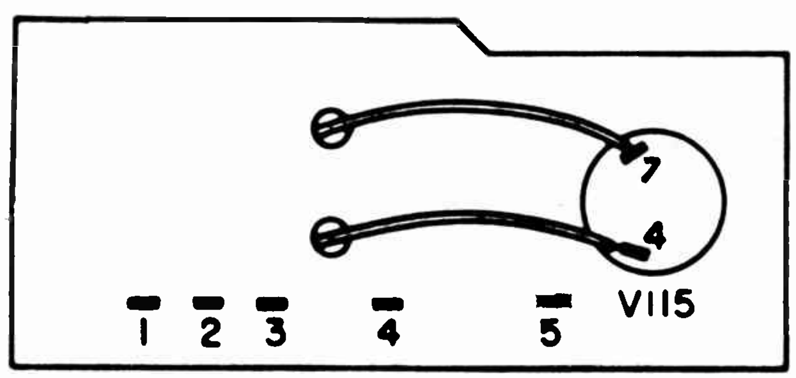
Chassis 386 (Code Letter E), and Chassis 387 (Code Letter D)
To Increase Vertical Sync. Stability



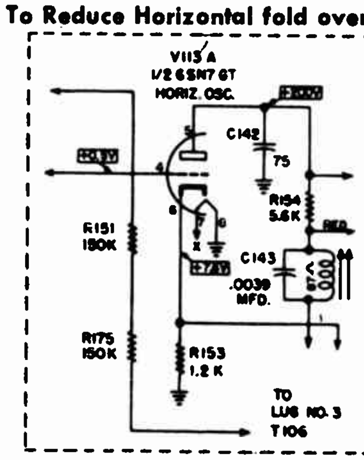
Chassis 386 & 387 (Code Letters B thru E) - For Horizontal Deflection Transformer T106 (Part No. 154990-1), the terminal numbering sequence is as shown in sketch B.

T106

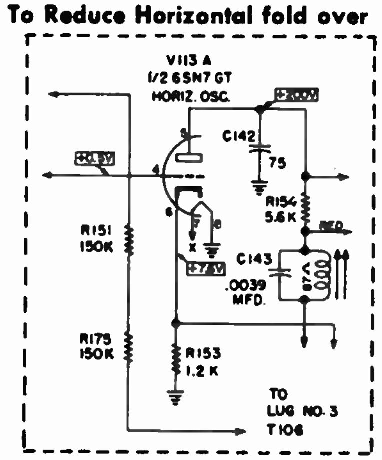
SKETCH B



Chassis 386 (Code Letter D)
To Reduce Horizontal fold over

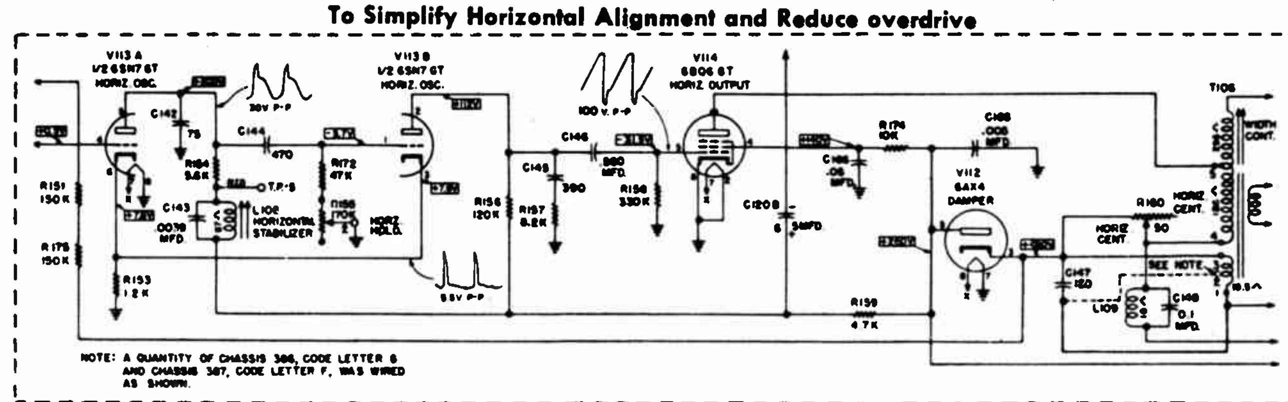


Chassis 386 (Code Letter F), and Chassis 387 (Code Letter E)
To Reduce Horizontal fold over



Chassis 386 (Code Letter H), and Chassis 387 (Code Letter G) - The Horizontal Deflection Transformer (Part No. 154990-1) can be used by omitting lug #2 and by wiring capacitor C147, 120 mmf., between lug #1 and #3.

Chassis 386 (Code Letter H), and Chassis 387 (Code Letter G)
To Simplify Horizontal Alignment and Reduce overdrive



New Part Numbers for Chassis Code Letters H&G

Symbol No.	Part No.	Description
C144	137499-46	Capacitor, 470 mmf., 10%, 500 v., mica
R155	155511	Control, Horizontal Hold (170,000 ohm)

CAUTION

HIGH VOLTAGE--Operation of a television receiver with the back open involves a shock hazard. When making adjustments other than adjusting the controls at the front panel, all precautions for working near high voltage should be exercised.

HIGH TEMPERATURE OF TUBES--Some tubes in the receiver operate at extremely high temperatures. To avoid serious burns, do not touch these tubes while the receiver is operating, or until the tubes have cooled after the set is shut off.

HANDLING OF PICTURE TUBES--Breakage of the picture tube, which contains a high vacuum, may result in injury from flying glass. Do not scratch tube face or subject to more than moderate pressure. DO NOT REMOVE OR HANDLE THE PICTURE TUBE IN ANY MANNER UNLESS HEAVY GLOVES AND PROTECTIVE GOGGLES ARE WORN. Persons not so equipped should be kept away while handling the tube. NEVER GRASP THE TUBE BY THE NECK OR ALLOW PRESSURE TO BE EXERTED ON THE NECK. In installation, if the tube sticks or fails to slip smoothly through the deflection yoke, investigate and remove the cause of the trouble. DO NOT FORCE TUBE.

These receivers are equipped with twenty (20) tubes, two (2) selenium rectifiers, and a picture tube. They have a switch type tuner which tunes the twelve (12) VHF television channels (2 to 13), also a UHF Converter which covers the seventy (70) UHF television channels (14 to 83).

TUBE COMPLEMENT (VHF Chassis 396)

Symbol	Tube	Function	Symbol	Tube	Function
V1	6BC5	R-F Amplifier	V108	6AH6	Video Amplifier
V2	6J6	VHF Oscillator & Mixer	V109	6SN7GT	Sync. Clipper & Sync. Output
V101	6CB6	1st I-F Amplifier	V110	6AL5	Horizontal A.F.C.

EU-17COLU (Mahogany)
EU-17COLBU (Blond)

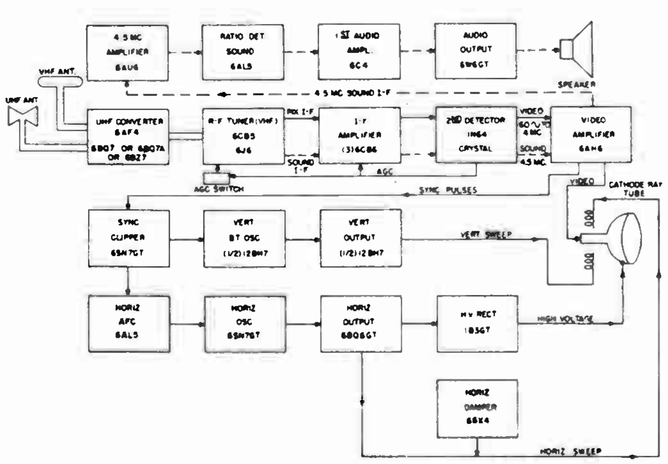
POWER SUPPLY: 117 volts, 60 cycle, a.c.

POWER CONSUMPTION: 140 watts.

AUDIO POWER OUTPUT: 2 watts maximum.

ANTENNA INPUT IMPEDANCE:
300 ohms balanced.

BLOCK DIAGRAM:



DEFLECTION: Electromagnetic.

FOCUS: Electrostatic.

ION TRAP: Single Permanent Magnet.

HORIZONTAL SCANNING FREQ.: 15,750 c.p.s.

VERTICAL SCANNING FREQ.: 60 c.p.s.

FRAME FREQUENCY: 30 c.p.s.

SCANNING: Interlaced, 525 lines.

SPEAKER:
17" Console Models 5¼" P.M.
17" Table Models 5¼" P.M.

VOICE COIL IMPEDANCE: 3.2 ohms at 400 cycles.

ANTENNAS

BUILT-IN ANTENNAS--The receiver is equipped with two antennas; one for VHF reception is enclosed in the cabinet and one for UHF reception is attached to the UHF antenna terminal board at the rear of the cabinet. These antennas will eliminate the need of an external antenna in some areas where the signal strength is sufficient. If you are in a location where the signal strength is not sufficient and it is impossible to obtain satisfactory results with the built-in antennas due to the above effects, or if the receiver is too far from the television station, it will be necessary to install an external antenna which is designed for both VHF and UHF, or two separate antennas--one designed for VHF and the other for UHF. Sometimes it is possible for VHF reception to be satisfactory on the built-in VHF antenna, but the reception of UHF on the built-in UHF antenna may be unsatisfactory; or vice versa. In these cases it is only necessary to install one external antenna designed for VHF or for UHF, depending on which built-in antenna is not providing satisfactory reception.

EXTERNAL ANTENNA--The choice of the proper type of antenna and its location are very important. Of equal importance is the installation of the antenna. In some localities where there are a number of stations operating, it may be impossible to eliminate all reflections.

CONNECTING EXTERNAL VHF ANTENNA--The antenna terminal board for the VHF antenna is located on a metal plate at the rear of the cabinet. Remove the wires of the built-in antenna that are fastened under the screws of the terminal board. Fasten the lead-in wires of the external antenna under these two screws. Cover bare ends of the wires from the built-in antenna with tape.

CONNECTING EXTERNAL UHF ANTENNA--The antenna terminal board for the UHF antenna is also located on the metal plate at the rear of the cabinet. Remove the UHF dipole antenna (wire loop) leads that are fastened under the two screws and attach the lead-in from the external UHF antenna. Do not drape or coil the lead-in wire and keep it away from the power cord (and also the speaker cable on console models).

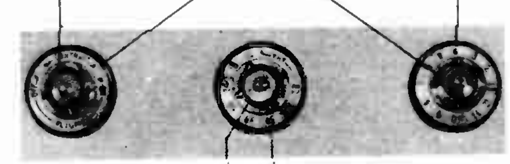
FRONT PANEL CONTROLS

CONTRAST CONTROL- Varies the picture output (increases or decreases the variations between light and dark areas of the picture) similar to the manner in which sound output is varied by the volume control.

OFF-ON-VOLUME- Turns the power off or on and varies the output of sound.

CHANNEL SELECTOR (VHF)- Selects the channel number of the desired VHF station. When tuning for VHF stations be sure the COURSE TUNING (UHF) is set to the VHF position (rotated completely counterclockwise).

FINE TUNING (VHF)- Tunes in the best picture, at which point sound is also received.



COURSE TUNING (UHF)-* Selects the channel number of the desired UHF station. To tune in a UHF station set the CHANNEL SELECTOR (VHF) to channel 5 or 6 as determined by the setting of the slide switch (see note below). Then set the COURSE TUNING (UHF) to the channel number of the desired UHF station.

FINE TUNING (UHF)- Tunes in the best picture, at which point sound is also received. Sometimes a slight adjustment of the Fine Tuning (VHF) will improve reception of a station.

*NOTE - The slide switch operated by a wire looped around the Contrast control shaft should be set, at the time of installation, to its forward position if a VHF station is not assigned to channel 5 in the area in which the receiver is being installed. To set the switch in its forward position, pull the Contrast and Off-On-Volume knobs from their shafts. Then pull the wires loop forward on the Contrast control shaft. If a VHF station is assigned to channel 5, set the switch toward the rear by pushing back on the wire loop. In this position the UHF stations can be tuned-in with the COURSE TUNING (UHF) and FINE TUNING (UHF) control knobs, when the CHANNEL SELECTOR (VHF) is set to channel 6. If no VHF station is assigned to channel 5 or to channel 6, set the switch for operation on either channel, whichever may provide the best reception. Be sure to inform the customer as to which channel (5 or 6) the switch has been set to operate on.

ADJUSTMENTS

1. ION TRAP ADJUSTMENT:

Adjust the BRIGHTNESS control for normal brightness. With the ION TRAP positioned close to the base of the picture tube, move the trap forward or backward and at the same time rotate in either direction until maximum brightness of the raster is obtained. Readjust the BRIGHTNESS control until the raster is slightly above average brilliance. Adjust the FOCUS CONTROL until the line structure of the raster is clearly visible. Readjust the ION TRAP again for maximum brightness.

There may be two locations on the tube neck where the ION TRAP will produce maximum brightness. Never set the trap to the forward position, always use the position closest to the tube base.

If there is a shadow in the corners of the raster, be sure the ION TRAP is properly adjusted. Do not sacrifice picture brilliance when adjusting the ION TRAP to overcome shadows in corner of picture. If corner shadows are present, be sure the DEFLECTION YOKE and CENTERING MAGNET are properly adjusted.

2. DEFLECTION YOKE AND BRACKET:

The DEFLECTION YOKE should be positioned as far forward as possible on the picture tube neck and rotated to the left or right as required to make the picture parallel with respect to the top and bottom of window frame.

3. CENTERING RASTER:

If the picture is off center and/or has neck shadow, rotate either or both CENTERING MAGNET levers to the left or right until the picture is centered on the screen and is free of neck shadow. The CENTERING MAGNET is located on the back cover of the DEFLECTION YOKE. To determine the correct picture centering, it may be necessary to reduce the size of the picture with the HEIGHT and WIDTH adjustments. After making adjustment of CENTERING MAGNET, readjust ION TRAP.

4. HEIGHT AND WIDTH ADJUSTMENTS:

The linearity and corresponding size controls will have to be adjusted together and with care to maintain picture symmetry. For this reason it is best to use a test pattern when making these adjustments. Adjust size of picture to fill the screen by means of the HEIGHT, WIDTH, VERTICAL LINEARITY.

5. VERTICAL LINEARITY ADJUSTMENTS:

The VERTICAL LINEARITY control has the effect of expanding the picture at an increasing rate from the bottom to the top of the picture. Adjustment of this control has the greatest effect on the top portion of the picture, some effect on the middle and very little effect on the bottom of the picture. The HEIGHT and FOCUS controls may need readjustment as a result of the change in position of the VERTICAL LINEARITY control.

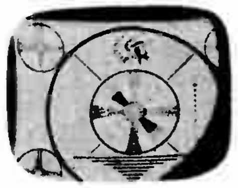
6. HORIZONTAL HOLD CONTROL:

The HORIZONTAL HOLD CONTROL is adjusted with a weak picture to the center of its pull-in range. If the pull-in range is insufficient or the horizontal sync is unstable, see "Horizontal Hold Adjustment" under "Alignment"

7. VERTICAL HOLD CONTROL:

The VERTICAL HOLD CONTROL is also adjusted to the center of its pull-in range with the contrast control set to obtain a weak picture.

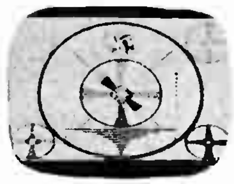
ADJUSTMENTS (Chassis 396)



Off Center and Neck Shadow

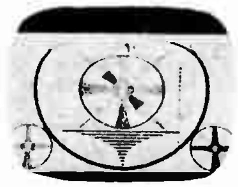
CENTERING MAGNET ADJUSTMENT — If the picture is off center and/or has neck shadow as shown in the illustration at the left, rotate either or both centering magnet levers to the right or left until the picture is centered on the screen and the picture is free of all neck shadow.

ION TRAP ADJUSTMENT — With the brightness control advanced just enough to dimly light up the face of the picture tube, slide the ion trap backward or forward and at the same time rotate it to the right or left until maximum brightness is obtained. If a neck shadow appears at any of the corners, refer to "Centering Magnet Adjustment" above.



Misadjusted Height

HEIGHT CONTROL — This control increases the overall height of the picture. When making this adjustment it is sometimes necessary to also adjust the VERTICAL LINEARITY to obtain a picture that is correctly proportioned.

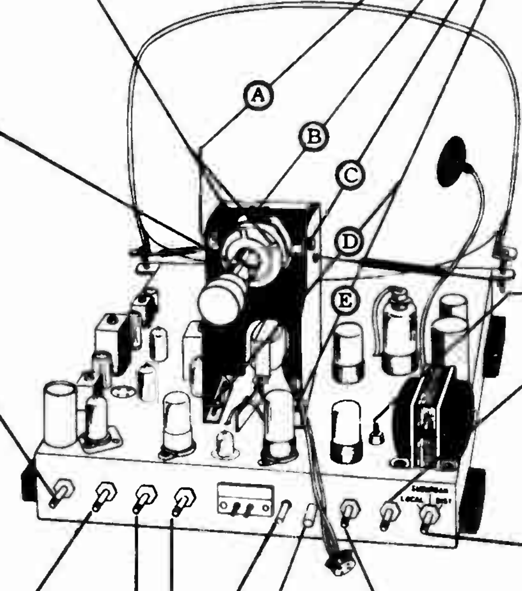


Misadjusted Vertical Linearity

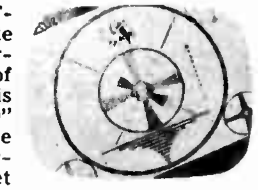
VERTICAL LINEARITY CONTROL — This control increases or decreases the height of the upper portion of the picture.

FOCUS CONTROL — Rotate to the right or left until the sharpest picture, or sharpest horizontal lines, are obtained.

BRIGHTNESS CONTROL — Turn clockwise to increase brightness. To decrease brightness, turn counter-clockwise.



DEFLECTION YOKE ADJUSTMENTS — The deflection yoke must be positioned as far forward as possible on the neck of the picture tube. To make this adjustment, loosen screws "D" and "E" enough to permit the yoke bracket to be pushed forward. While holding the bracket in the forward position, tighten screws "D" and "E". Screws "A" and "C" are for shifting the yoke up or down to center it around the picture tube neck. If the picture is tilted as illustrated at right, loosen wing nut "B". Then, rotate the yoke to left or right as required to make the picture parallel with respect to top and bottom of window frame. Be sure to hold the yoke in position while tightening the wing nut.



Picture Tilted

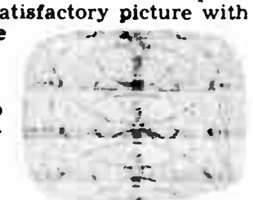
HORIZONTAL STABILIZER ADJUSTMENT — See "HORIZONTAL HOLD CONTROL".

Misadjusted Horizontal Hold

HORIZONTAL HOLD CONTROL — If the picture appears as shown in the illustration, adjust the horizontal hold control to right or left as required to lock in a single stationary picture. If the range of the control is not sufficient to lock in picture, set the control to its midway position and then adjust the horizontal stabilizer adjustment until the picture locks in.

LOCAL - SUBURBAN - DISTANCE SWITCH — In strong signal areas set this switch to its extreme counter-clockwise position (LOCAL). The middle position (SUBURBAN), and extreme clockwise position (DISTANCE) are used in areas where the signal is weak or medium strength. Set the switch in the position which provides the most satisfactory picture with minimum overloading when the contrast control is advanced.

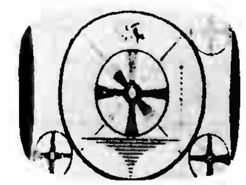
VERTICAL HOLD CONTROL — If the picture is moving up or down as illustrated at right, adjust the vertical hold control until a single stationary picture is obtained.



Misadjusted Vertical Hold

HORIZONTAL CENTERING CONTROL — If the picture is off center to the right or left, rotate this control in either direction as required to center the picture. The picture should become centered when this control is approximately at the middle of its range of adjustment if not, then set the control at the middle of its range. Then center the picture on the screen by adjusting the centering magnet levers as explained under "CENTERING MAGNET ADJUSTMENT"

WIDTH CONTROL — If the picture is too narrow as illustrated, or too wide, turn the width control clockwise or counter-clockwise as required to adjust the picture to the proper width of the viewing area on the screen.



Picture Too Narrow

8. FOCUS CONTROL:

Adjust the FOCUS CONTROL for best focus of the vertical and horizontal wedges at the center of the test pattern. If corner focus is poor, check position of DEFLECTION YOKE and ION TRAP. While observing the test pattern (or picture), make a slight readjustment of the VERTICAL HOLD control until the horizontal lines are least noticeable. This adjustment is very critical and will require only a very slight movement of the control shaft to obtain proper adjustment.

9. BRIGHTNESS CONTROL:

BRIGHTNESS CONTROL and CONTRAST control should be set to obtain as much shading in the picture as possible. If the Brightness control is set too low, the black and grays of the picture are black and if set too high, the black and grays of the picture will appear light and faded.

10. LOCAL-DISTANCE (AGC) SWITCH:

The LOCAL-DISTANCE SWITCH can be set to prevent the receiver from overloading in strong signal areas or to reduce "snow" in the picture in weak signal areas. In strong signal areas, the "LOCAL" (counter-clockwise) position of the switch must be used. The second and third positions "SUBURBAN" and "DISTANCE" are to be used in medium to weak signal areas. Use the position with which the best picture is obtained with a minimum of overloading of the receiver when the CONTRAST control is advanced.

11. OSCILLATOR ADJUSTMENT USING A TELEVISON SIGNAL:

Do not make any adjustments on the two oscillator adjusting screws unless the FINE TUNING control range is insufficient to properly tune-in the station. The adjusting screws are accessible through holes in the front of the chassis after the chassis is removed from the cabinet.

To make the adjustment, proceed as follows:

(a) Turn the receiver on and allow a warm-up period of approximately five minutes.

(b) For stations from channel 13 to channel 7, set the Station Selector Switch to the highest channel received and adjust the Contrast and Volume control for normal sound and picture. Set the Fine Tuning Control in the center of its range.

(c) Using a small non-metallic screwdriver, adjust the slotted head brass screw located to the left of shaft and above the fiber disc for the clearest and sharpest detail in the picture. This adjustment will be effective on all channels between 13 and 7. If other stations are operating in this range, it may be necessary to compromise slightly on the high channel adjustment so the other channels may be properly tuned-in.

(d) For Stations on channel 6 and below, set the station Selector Switch to the channel received closest to channel 6 and adjust the Contrast and Volume control for normal sound and picture. Set the Fine Tuning control in the center of its range.

(e) Using a small non-metallic screwdriver, adjust the slotted head brass screw located to the right of the shaft for the clearest and sharpest detail in the picture. This adjustment will effect all channels between 6 and 2.

ADJUSTMENTS

All lead connections from the signal generator and wobbulator must be shielded. Keep the exposed ends and ground leads as short as possible (about one inch). Always locate the ground lead connections as close as possible to their respective "hot" leads in the television receiver chassis. The wobbulator, signal generator output, and contrast control must be kept low enough to prevent overloading the television receiver circuits.

CAUTION: One side of the chassis is connected to the power line. Therefore, test equipment should not be connected to the receiver unless an isolation transformer is used between the power line and the receiver. DO NOT GROUND THE RECEIVER CHASSIS UNLESS AN ISOLATION TRANSFORMER IS USED.

1. To Check I. F. Alignment on Oscilloscope:

(a) Lift the shield of the Oscillator - Mixer tube V2 sufficiently to clear the socket ground clips. Connect sweep signal generator "hot" lead to the underground tube shield and generator ground lead to the tuner chassis.

(b) Connect high side of oscilloscope to high side of contrast control (pin 2 and 7 of V108), and the low side to chassis.

(c) Apply - 3.0 volts D.C. bias to lug 4 of S103 (See sketch "Variable Bias Control"). Contrast control should be set in the maximum counter-clockwise position.

(d) With the generator sweep set at zero, connect an electronic voltmeter between lug 2 of S103 and chassis. Adjust the output of the generator to obtain a reading of 2 volts D.C. on the meter.

(e) Set generator to sweep from 20 mc. to 30 mc.

(f) Connect marker generator to sweep generator output leads and adjust to provide markers that appear in the curve (see nominal overall I. F. response curve).

(g) Observe curve and position of markers (see nominal overall I. F. response curve). Slight deviation in shape from the nominal response curve is permissible, but if any great deviation is noted, it will be necessary to re-align the I. F. Amplifier.

2. Alignment, I. F. & Tuner Assembly (with electronic voltmeter):

(1) Connect - 3.0 Volts D.C. bias supply to lug 4 of S103.

(2) Connect signal generator "hot" lead through a 1000 mmf. capacitor to TP-1 (wire protruding from tuner directly adjacent to the oscillator mixer tube V2) and ground lead to the R. F. tuner case.

(3) Connect high side of Electronic Voltmeter to lug 2 of S103 and low side to chassis.

(4) Set signal generator to 25.0 mc. and adjust bottom of T103 for maximum meter deflection, limiting meter deflection to 2 volts D.C. by adjusting input attenuator.

(5) Set signal generator to 23.3 mc. and adjust bottom of T102 for maximum D.C. meter indication. Adjust signal generator amplitude to make this peak indication approximately 2 volts D.C.

(6) Reset signal generator to 21.9 mc. and adjust the top of T102 for minimum D.C. meter deflection. Signal generator amplitude must be sufficiently high to produce a definite null. Meter must read at least 0.5 volts at null.

(7) Repeat steps 5 and 6.

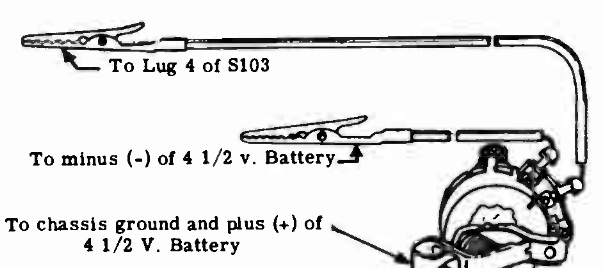
(8) Next set signal generator to 25.2 mc. and adjust bottom of T101 for maximum meter indication, limiting output of generator so peak reading will not exceed 2 volts D.C.

(9) Reset signal generator to 24.65 mc. Connect a 500 ohm resistor in series with a 500 mmf. capacitor from TP-2 (wire protruding from the tuner through the insulated eyelet between the brass adjusting screws) on the R. F. Tuner to the Tuner case. Adjust L101 for maximum meter deflection, but limit output of generator so this reading does not exceed 2 volts D.C. Remove the 500 ohm resistor and the 500 mmf. capacitor.

(10) Set signal generator to 24.65 mc. Connect the 500 ohm resistor and the 500 mmf. series capacitor across L101 and adjust mixer output (L9) on R.F. Tuner for maximum meter indication. Adjusting amplitude of signal generator to make this maximum indication approximately 2 volts D.C. Remove the 500 ohm resistor and the 500 mmf. capacitor.

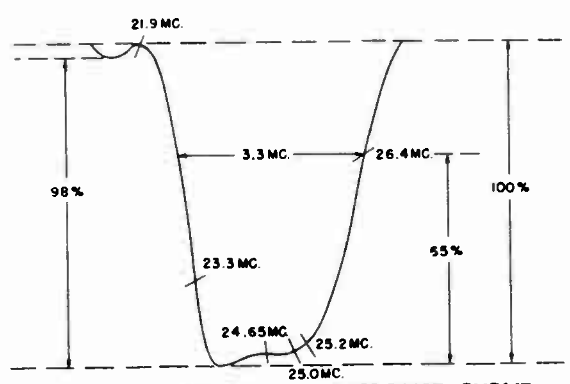
(11) Check sensitivity. The input for 2 volts D.C. output and zero bias should not exceed 150 microvolts at 24.65 mc. with a generator internal resistance of 1.5 ohms or less, and the local oscillator set to properly tune in channel 5.

(12) Remove the signal generator and electronic voltmeter.



5000 Ohm Control only, Part No. 144260

VARIABLE BIAS CONTROL ASSEMBLY



NOMINAL OVERALL I. F. RESPONSE CURVE
NOTE: Response as Seen by Means of Sweep Generator

SOUND ALIGNMENT

1. Connect crystal controlled 4.5 mc. 400 cycle amplitude modulated signal, modulated 30% or greater, to lug 2 of S103 and chassis.
2. Connect high side of scope through detector probe to the picture tube cathode (pin 11). Connect low side of scope to chassis. Adjust 4.5 mc. trap, L105 for minimum 400 cycle deflection on scope.
3. Connect electronic voltmeter to lug 2 of ratio detector, V106, and adjust 4.5 mc. sound take-off (L110) and bottom of ratio transformer (T107) for peak reading on voltmeter. Adjust input to make this peak reading 4 volts.
4. Adjust input to obtain 12 volts output. Transfer electronic voltmeter to junction of R167 and C153 (refer to Schematic Wiring Diagram). Adjust top of T107 for zero balance on electronic voltmeter.
5. Recheck steps 2, 3 and 4.
6. Remove input signal, scope and electronic voltmeter.

HORIZONTAL HOLD ADJUSTMENT

1. Tune in a local television signal and adjust contrast control for normal picture.
2. Connect electronic voltmeter between TP-3 (green lead) and chassis.
3. Short TP-4 (orange lead) to chassis and adjust electronic voltmeter to zero.
4. Remove short from TP-4. Do not change zero on electronic voltmeter.
5. Connect a 0.1 mfd. plus 20%, 600 volt capacitor between TP-5 (red lead) and chassis.
6. Adjust Horizontal Hold control for zero reading on the meter.
7. Remove the 0.1 mfd. capacitor from TP-5 and chassis. Do not disturb setting of horizontal hold control.
8. Adjust Horizontal Stabilizer coil (L108) for zero reading on the meter.
9. Remove electronic voltmeter from TP-3.
10. Check horizontal pull-in range. The pull-in range should be approximately 50^{0} of the controls rotation.

TV CHASSIS BOTTOM VIEW
(Tube Socket and Alignment Locations)

UHF ALIGNMENT

NOTES:

1. Remove the UHF Converter from the VHF receiver chassis.
2. Disengage the toggle coupling from the switch throw arm on the front of the UHF chassis.

   To accomplish this: -

   a. Turn the UHF tuning control clockwise until the pin located on the rear of the drive pulley is free from the toggle coupling.

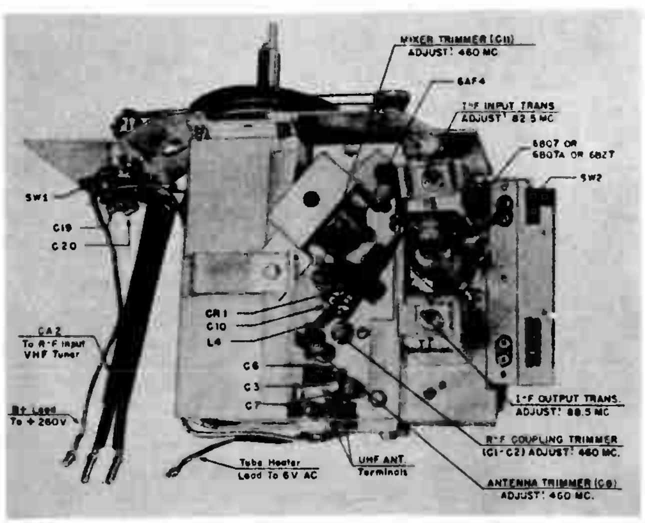
   b. Turn the switch throw arm to a vertical position to disengage fork of toggle coupling.

   c. Turn the toggle coupling counter-clockwise to a vertical position so that it does not interfere with the movement of the drive pulley.

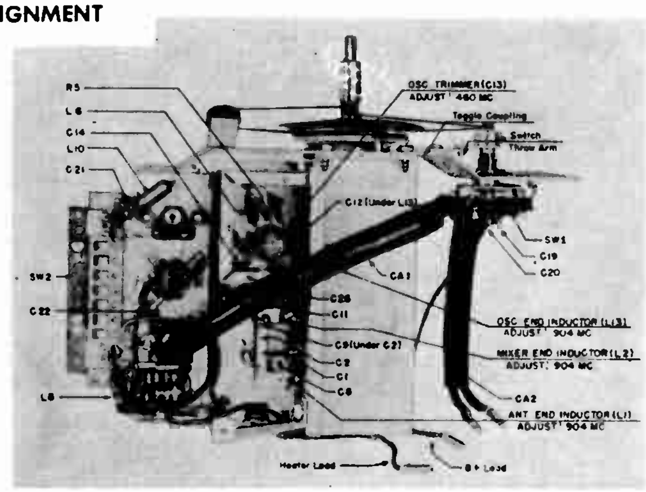
   d. Turn the switch throw arm counter-clockwise to the UHF position; top contact blade on switch rotor must contact and center on the two top switch fingers with the red wires attached. Leave switch in this position while aligning.
3. Connect the output leads of the UHF converter to the R-F input terminals of the VHF Tuner.
4. Connect the B+ and filament leads of the tuner to the VHF receiver. Connect UHF Converter chassis to B- (VHF receiver chassis).
5. Set VHF Tuner to channel 6.
6. Keep all leads as short as possible.
7. Alignment should be followed in the order shown.

I.F. ALIGNMENT:

1. Set I-F slide switch on the UHF Converter to Channel 6 (pushed toward the rear of chassis) position.
2. Connect an electronic voltmeter or oscilloscope across the second detector load resistor, R114 on the VHF chassis.
3. Turn on the power.
4. Apply an 82.5 mc. (amplitude modulated if a scope is used) signal to the junction of C2 and C9.
5. Adjust I-F input coil (T2) for peaking reading on meter (or maximum indication on scope).



Top View, UHF Converter

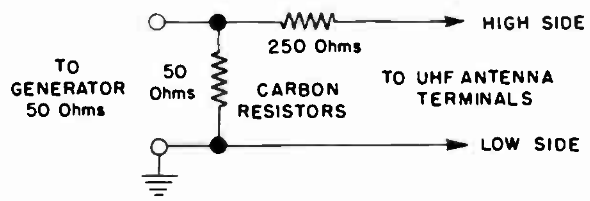


Bottom View, UHF Converter

6. Change signal generator frequency to 88.5 mc. and adjust I-F output coil (T1) for maximum reading or indication.
7. Repeat steps 4 through 6 until maximum readings are obtained.
8. Remove the generator connections from the junction of C2 and C9.

OSCILLATOR ALIGNMENT:

1. Connect an electronic voltmeter or scope across the second detector load resistor, R114.
2. Apply a 460 mc. (amplitude modulated when scope is used) signal to the UHF antenna terminals through the antenna matching network. (See Antenna Matching Network Sketch.)



Antenna Matching Network

3. With the tuner shaft at maximum counter-clockwise position, adjust the oscillator trimmer, C13 for peak reading on the electronic voltmeter (or maximum indication on scope).
4. Set the signal generator to 904 mc.
5. Rotate the tuner shaft to maximum clockwise position and adjust the oscillator end inductor, L13 for maximum reading on the voltmeter (or scope).
6. Repeat steps 2 through 5 until maximum reading is obtained.

R-F CIRCUIT ALIGNMENT:

1. With the signal generator and electronic voltmeter or scope connected as for the Oscillator Alignment above, set the R-F coupling trimmer, C1 and C2 to minimum capacity by turning the screw counter-clockwise.
2. Set the signal generator to 460 mc. (amplitude modulated with scope is used.)
3. With the tuner shaft at maximum counter-clockwise position, adjust the antenna and mixer trimmers, C8 and C11 for maximum meter reading (or scope indication).

UHF ALIGNMENT (Continued)

4. Reset signal generator to 904 mc.
5. Rotate the tuner shaft to maximum clockwise position and adjust the antenna and mixer end inductors, L1 and L2 for maximum reading on meter (or scope).
6. Repeat steps 2 through 5 until maximum reading is obtained.
7. Reset signal generator to 460 mc.
8. Turn the tuner shaft to maximum counter-clockwise position and adjust the coupling trimmer, C1 and C2 for peak reading.
9. Turn the power switch to the "OFF" position.
10. Disconnect the generator and electronic voltmeter, or scope.
11. Re-engage the toggle coupling in the pin on the switch throw arm and the pin on the drive pulley as follows:

    a. Rotate the tuning control shaft clockwise until the pin on the rear of the drive pulley is toward the base of the chassis.

    b. Turn the switch throw arm to a vertical position.

    c. Turn the toggle coupling approximately 45° clockwise from a vertical position.

    d. Turn the switch throw arm counter-clockwise until pin engages the upper fork on the toggle coupling.

    e. Turn the tuning shaft counter-clockwise and guide the pin on the rear of drive pulley into the lower fork of the coupling. The coupling is now in the proper operating position and when the tuning shaft is turned completely counter-clockwise, the switch will be thrown to the VHF position.
12. Replace the UHF Converter on the VHF receiver chassis.

CRITICAL LEAD AND COMPONENT DRESS VHF RECEIVER CHASSIS

R-F TUNER:

The brown AGC lead from the terminal board to the tuner should be dressed flat down to chassis.

I-F SECTION:

The component leads and wires in the video I-F section must be kept as short as possible.

R-F CHOKE:

The end of the R-F choke L113 which is wired to T103 lug 6, shall be as short as possible.

LEADS:

The black wire from T103, lug 4 to chassis must be as short as possible. All leads must be kept away from the plates of the selenium rectifiers, SR101 and SR102. Dress the red and blue leads of Audio Output Transformer, T108 away from the high voltage shield so they will not be pinched under it.

COMPONENTS:

Keep all components, particularly peaking coils, away from R121 which is wired between the terminal boards adjacent to V110.

RESISTORS:

Dress the fuse resistor R142 attached to the terminal board, up away from the chassis. On the 396 chassis, dress the two 150K ohm resistors, R151 and R152, in such a manner as not to short against the high voltage shield.

CAPACITORS:

The .006 mfd. capacitor, C138, wired from V114, pin 6, to ground lug of C118, should be dressed down close to the chassis.

The .005 mfd. capacitor, C162, which is wired from the case of R118 through the center lug of R118A to chassis, must have a very short lead on the end wired to the case of R118 so the body of the capacitor prevents any shorting to the shield wired to R118.

CONTROLS:

All controls and the local-distance switch must be kept from shorting to the chassis. Make sure the control does not turn when the nut is tightened.

HIGH VOLTAGE SECTION:

The plate cap of the 1B3GT, V115, should be put on so the lead comes away from it in a vertical direction. The vinyl tape that is applied to the corona ring should cover the entire outside edge of the ring and as much of the socket area as possible.

YOKE COUPLING NETWORK:

The yoke coupling network, L109, wired from T106 lug 3 to V112, lug 1, should be kept away from lug 4 of T106.

CRITICAL LEAD AND COMPONENT DRESS UHF CONVERTER

As the UHF Converter used in this receiver operates over a range (470 mc. to 890 mc.) of frequencies that are from approximately two to four times higher than the highest frequencies encountered in VHF tuners, placement of parts and component lead lengths in the circuit have considerable effect upon the performance of the unit. When replacing components or wiring, special note should be taken of the position of the part or wire to be replaced, before removal. New parts or wires should be located in the same position as those removed. Extremely critical points that require special attention are listed below.

Capacitors:

C3 C6 C7 — The capacitors C3, C6 and C7 in the antenna circuit must be placed with their leads as short and direct as possible.

C9 C10 — The capacitors C9 and C10, 3.3 mmf., must be placed with their leads as short and direct as possible.

C12 — The capacitor C12, 12 mmf., must be placed with only the silvered surface in contact with the lug to which it is soldered. They must be at right angles to the inductor. In order to avoid burning off the silver plating of the unit, the tip temperature of the iron used for soldering should not exceed 500°F. (260°C).

C13 — When the oscillator trimmer assembly, C13 is soldered to the socket contacts, base of trimmer must be firmly held flat against ribs in socket body while socket contacts are firmly seated in the socket body so that this construction is mechanically rigid. Failure to maintain mechanical rigidity in this assembly will result in difficult alignment and poor oscillator frequency stability.

C14 — Capacitor C14, 2.2 mmf., must be placed away from the chassis.

C19 C20 — Capacitors C19 and C20, should be dressed up and away from the function switch.

CRITICAL LEAD AND COMPONENT DRESS (Continued)
UHF CONVERTER

C21 Capacitor C21, 27 mmf. must be connected with shortest possible leads.

C22 Capacitor C22, 1000 mmf. must be oriented so that the flat side of lug is toward pin 2 on the V2 tube socket, in order that the lug may be bent over to the socket contact. If capacitor is not turned quite far enough when threads first begin to tighten, it may be rotated up to about a 1/2 turn further by application or greater torque to wrench. Care should be exercised to prevent stripping threads by turning too far.

RESISTOR:

R5 The resistor R5, 10,000 ohm, must be placed away from the chassis.

CHOKES:

L4 L6 The chokes L4 and L6 must be placed away from the chassis.

LEADS:

a. The B+ and heater leads leaving the oscillator radiation shield should be dressed down flat against the R-F chassis.

b. The short red lead joining slide switch terminal and terminal on I-F output transformer should be dressed in form of loop, up and away from chassis.

c. The red lead joining the crystal holder terminal and slide switch terminal should be as short and direct as possible, and dressed down against the chassis. There should be no excess lengths to be looped or doubled up.

R-F COUPLING TRIMMER:

Plates forming the R-F coupling trimmer (C1 and C2) must be placed so that the plates are parallel in both planes when trimmer screw is adjusted so that the plates are 1/32 inch apart. Plates should overlap 1/8 inch minimum. In order to accomplish this overlap, it may be necessary to decenter the parts on the UHF tuner tabs. If so, such decentering should be equally divided between the two parts.

OSCILLATOR:

a. The oscillator plate strap A-154740 (CO2) must be assembled with its bottom edge (as viewed from bottom of chassis) resting on the tube socket ribs and with the plane of part of the piece joining the two socket contacts perpendicular to chassis. In order to realize this condition, socket contacts must be firmly seated down against body of socket and "ears" on this piece must be inserted their full length into holes in socket contacts. Solder should be flown between socket contact and the piece for full length of socket contact, in order to avoid possibility of intermittent contact between socket contact and edge of this piece extending beyond "ears". Tab should be soldered flat against end of C12.

b. A dummy plug with hardened steel pins should be inserted in the oscillator socket before components are placed and soldered to socket lugs, to insure alignment of contacts.

CRYSTAL HOLDER:

When soldering connections to the crystal holder terminals, allow solder to flow between eyelet and terminal proper to insure a consistent electrical connection.

FUNCTION SWITCH:

The function switch must have all VHF position contacts fully and firmly made and all UHF position contacts fully broken when the UHF tuner shaft is at full counter-clockwise rotation. All VHF position contacts must be fully broken and all UHF position contacts must be fully and firmly made at 7 1/2° or more from full counter-clockwise rotation as tuner shaft is rotated in a clockwise direction.

PARTS LIST
TV CHASSIS 396 (Schematic Parts)

Symbol No.	Part No.	Description
C101	137727-129	Capacitor, 330 mmf., 500 v., ceramic

R118A	154085	Control (Contrast), 2500 ohm } Assembly
R118B		Control (Volume), 1 megohm } Assembly
R119	Part of L104	Resistor, 8200 ohm, 10%, 1/2 w.
R120	39374-131	Resistor, 33,000 ohm, 10%, 1 w.
R121	39375-361	Resistor, 4700 ohm, 5%, 2 w.
R122	Part of L106	Resistor, 6800 ohm, 10%, 1/2 w.
R123	Part of L107	Resistor, 3300 ohm, 10%, 1/2 w.
R124	39374-37	Resistor, 10,000 ohm, 10%, 1/2 w.
R125	39374-57	Resistor, 470,000 ohm, 10%. 1/2 w.
R126	39374-69	Resistor, 2.2 megohm, 10%, 1/2 w.
R127	39374-59	Resistor, 680,000 ohm, 10%, 1/2 w.
R128	39374-29	Resistor, 2200 ohm, 10%, 1/2 w.
R129	39374-146	Resistor, 560,000 ohm, 10%, 1 w.
R130	39374-41	Resistor, 22,000 ohm, 10%, 1/2 w.
R131	39374-35	Resistor, 6800 ohm, 10%, 1/2 w.
R132	39374-31	Resistor, 3300 ohm, 10%, 1/2 w.
R133	39374-41	Resistor, 22,000 ohm, 10%, 1/2 w.
R134	39374-37	Resistor, 10,000 ohm, 10%, 1/2 w.
R134	154087	Control, Vertical Hold (850,000 ohm)
R136	39374-31	Resistor, 3300 ohm, 10%, 1/2 w.
R137	39374-28	Resistor, 1800 ohm, 10%, 1/2 w.
R138	154086	Control, Height (5 megohm)
R139	39374-14	Resistor, 120 ohm, 10%, 1/2 w.
R140	154088	Control, Vertical Linearity (750 ohm)
R141	154084	Resistor, 8700 ohm, 5%, 5 W. Wire Wound
R142	154089	Resistor, 7.5 ohm, 10%, 5 W. Wire Wound (Fuse type)
R143	39374-17	Resistor, 220 ohm, 10%, 1/2 w.
R144	39374-25	Resistor, 1000 ohm, 10%, 1/2 w.
R146	39374-49	Resistor, 100,000 ohm, 10%, 1/2 w.
R147	39374-49	Resistor, 100,000 ohm, 10%, 1/2 w.
R148	39374-41	Resistor, 22,000 ohm, 10%, 1/2 w.

PARTS LIST
TV CHASSIS 396 (Schematic Parts)

Symbol No.	Part No.	Description
R149	39374-77	Resistor, 4.7 megohm, 10%, 1/2 w.
R150	39374-77	Resistor, 4.7 megohm, 10%, 1/2 w.
R151	39374-139	Resistor, 150,000 ohm, 10%, 1 w.
R152	39374-139	Resistor, 150,000 ohm, 10%, 1 w.
R153	39374-26	Resistor, 1200 ohm, 10%, 1/2 w.
R154	39374-34	Resistor, 5600 ohm, 10%, 1/2 w.
R155	154093	Control, Horizontal Hold (120,000 ohm)
R156	39374-50	Resistor, 120,000 ohm, 10%, 1/2 w.
R157	39374-34	Resistor, 5600 ohm, 10%, 1/2 w.
R158	39374-57	Resistor, 470,000 ohm, 10%, 1/2 w.
R159	39374-121	Resistor, 4700 ohm, 10%. 1 w.
R160	154083	Control, Horizontal Centering (50 ohm)
R161	39303-12	Resistor, 2.2 ohm, 10%, 1/2 w. Wire Wound
R162	39374-15	Resistor, 150 ohm, 10%, 1/2 w.
R163	39374-29	Resistor, 2200 ohm, 10%, 1/2 w.
R164	39374-18	Resistor, 270 ohm, 10%, 1/2 w.
R165	39375-73	Resistor, 10,000 ohm, 5%, 1/2 w.
R166	39375-73	Resistor, 10,000 ohm, 5%, 1/2 w.
R167	39374-43	Resistor, 33,000 ohm, 10%, 1/2 w.
R168	39374-27	Resistor, 1500 ohm, 10%, 1/2 w.
R169	39374-43	Resistor, 33,000 ohm, 10%, 1/2 w.
R170	154095	Control, Brightness (5 megohm)
R171	154094	Control, Focus (1.5 megohm)
L101	155178	Coil, Converter I. F.
L102	154171	Coil, Video Peaking (168 microhenry, 5%)
L103	154184	Coil, Video Peaking (335 microhenry, 5%)
L104	154194	Coil, Video Peaking (412 microhenry, 5%)
L105	154158	Trap, (4.5 megacycle)
L106	154206	Coil, Video Peaking (106 microhenry, 5%)
L107	154176	Coil, Video Peaking (840 microhenry, 5%)
L108	154220	Coil, Horizontal Osc.
L109	154156	Network, Yoke Decoupling

Symbol No.	Part No.	Description
L110	154183	Coil, Sound Take Off
L111	154799	Choke, Filter (used on SP 101)
L112	154221-5	Yoke, Deflection
L113	154376	Coil, R. F. Choke
L114	154799	Choke, Filter (used on SP 103)
T101	155174	Transformer, 1st. I. F.
T102	155173	Transformer, 2nd. I. F.
T103	155179	Transformer, Diode I. F.
T104	154105-1	Transformer, Vertical Blocking Osc.
T105	154106	Transformer, Vertical Output
T106	154069-1	Transformer, Horizontal Output
T107	154108	Transformer, Ratio Detector
T108	154109-1	Transformer, Audio Output
T109	154720	Transformer, Filament
CA102	132300-6	Cable & Plug Assy., Power
SW101	Part of R118B	Switch, ON-OFF (Power)
SW102	154115	Switch, A.G.C. Control
SP101	138762-7	Speaker, P. M. (5-1/4")
SP103	138762-7	Speaker, P. M. (5-1/4")
S101	154178	Cable & Connector Assy., (used with SP103)
S102	154113	Socket, Test (Connector)
P101	154243	Plug, Speaker Cable (used with SP103)
P102	154125	Plug, Interlock
SR101	154112	Selenium Rectifier
SR102	154112	Selenium Rectifier
CR101	154111	Crystal (1N64)
CO101	155049	Terminal Boards & Bracket Assy., Antenna (VHF, UHF)
CO102	154114	Connector
CO103	154114	Connector
CO104	154114	Connector

TV CHASSIS 396

Symbol No.	Part No.	Description
	154256	Block, Chassis Mtg.
	154275-1	Bracket (frame), Deflection Yoke Mtg.
	154253	Bracket, Deflection Yoke Mtg.
	154190	Bracket, Tuner Mtg.
	154255-2	Bracket, Picture Tube Stop
	154318	Cable, Shielded (18" long) Twin Lead
	154349-1	Cable, Shielded (9" long)
	154349-2	Cable, Shielded (6-1/2" long)
	154266-1	Channel (Rubber 3"), Picture Tube Strap
	155052	Channel (Rubber 3/4"), Picture Tube Stop Bracket
	154276-2	Channel (Rubber 10 5/16"), Deflection Yoke Assy.
	154180	Coil (High Voltage), Horizontal Deflection Assy.
	154181	Coil,(Primary), Horizontal Deflection Assy.
	155102-1	Connector, Picture Tube Anode
	154124	Coupling Shaft Width Control
	153424-3	Cushion (Rubber, 1/6" x 1-1/4" x 23"), Picture Tube
	154122-1	Grid Cap (V114)
	154134	Grommet (Rubber, 4 used) Tube Mtg. (V105, V113)
	154259	Insulator, Antenna Lead
	154260	Insulator (1-3/16" x 1-7/32" Phenolic), Controls
	154264	Insulator, Interlock
	154268	Insulator (1-13/16" x 19/32" x 1/16" Armite), R. F. Tuner Shaft
	153109-2	Ion Trap
	39012-102	Iron Core
	39012-95	Iron Core
	39012-96	Iron Core
	154073	Iron Core, Horizontal Deflection Assy.
	39012-115	Iron Core
	155298	Key, Centering Control Shaft
	153580	Nut (Wing), Deflection Yoke
	154257-2	Picture Tube Rest (2 used)
	154314	Plate (Bearing), R. F. Tuner Shaft
	154075	Plate, Horizontal Width Control
	154129	Plate, Tube Mtg. (V105, V113)
	154079-1	Ring, (Retaining, 3 used), Width Control Shaft Assy.
	154119	Ring (Retaining), Centering Control Shaft Key
	155299	Shaft, Centering Control
	154267	Shaft, Width Control
	154077	Shaft, Width Control (Horizontal Deflection Assy.)
	155027	Shaft, R. F. Pentode Assy.
	154152	Shielded Corona
	154195	Shield, High Voltage
	39008-37	Shield (Spiral) R. F. Tuner Assy.
	149572	Sleeving (36" Lengths), Plate Lead V113, 6-1/2" long
	149572	Sleeving (36" Lengths), Anode Lead 4" long
	154148-2	Socket & Cable Assy., Picture Tube
	154203	Socket, Tube (V113)
	154192	Socket, Tube (V105)
	154092	Socket, Tube (V115)
	154117	Socket, Tube (V110)
	154146	Socket, Tube (V101, V102, V103, V107)
	154131	Socket, Tube (V109, V111, V114)
	154130	Socket, Tube (V112)
	154127	Socket, Tube (V104, V106, V108)
	149671	Spring (Grounding), Deflection Yoke Assy.
	154072	Spring (Clip), Horizontal Deflection Assy.
	154071	Spring (Strap), Horizontal Deflection Assy.
	154120	Spring, Horizontal Centering Control Shaft
	154205	Strap, Picture Tube
	154170	Terminal Board, Horizontal Deflection Assy.
	154116	Tuner, R. F. Pentode Assy.
	91595-1	Washer (Flat), Width Control Shaft
	154140	Washer (Protruded), Controls
	149180	Washer (Spring), Width Control Shaft

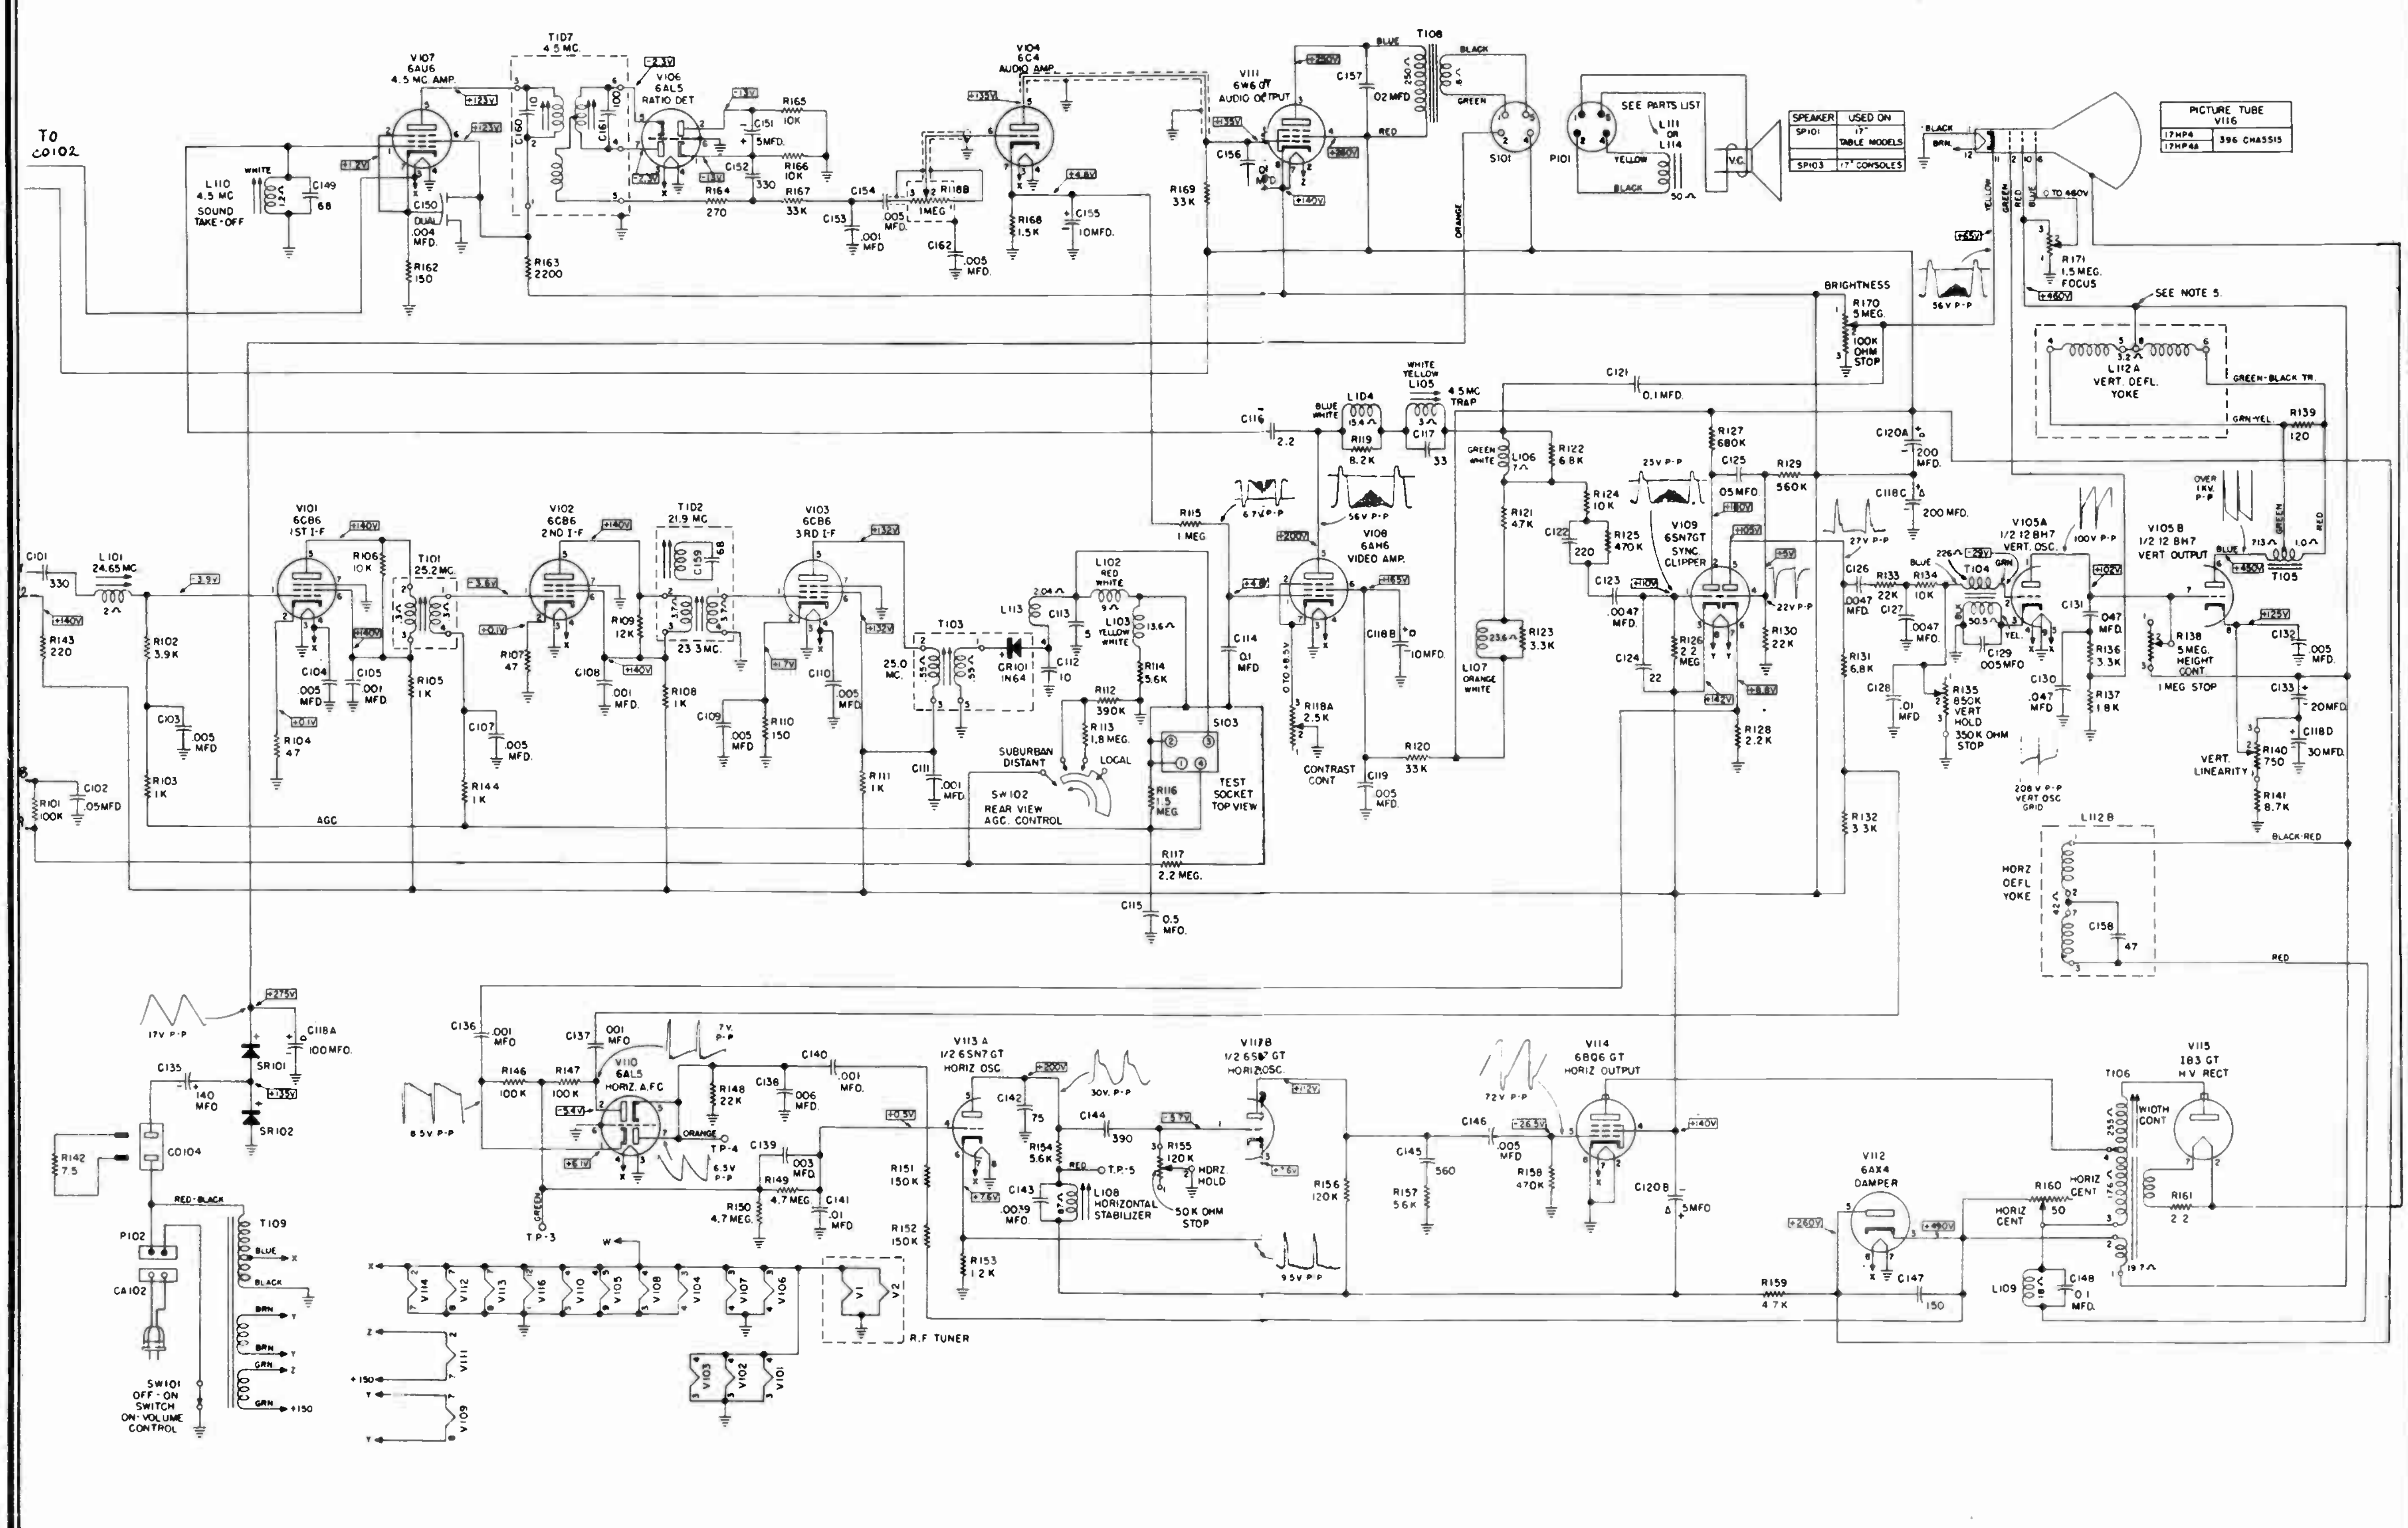
SCHEMATIC WIRING DIAGRAM-CHASSIS 396



CROSLEY TV PAGE 12-35

SUBJECT: TO ADD ALIGNMENT PROCEDURE AND PARTS LIST FOR ONE TUBE CONVERTER PART NO. (155499)

Chassis 396, Code letter C incorporates the one tube converter, part no. 155499. Chassis 396 coded prior to Code letter C use converter, Part No. 154848.

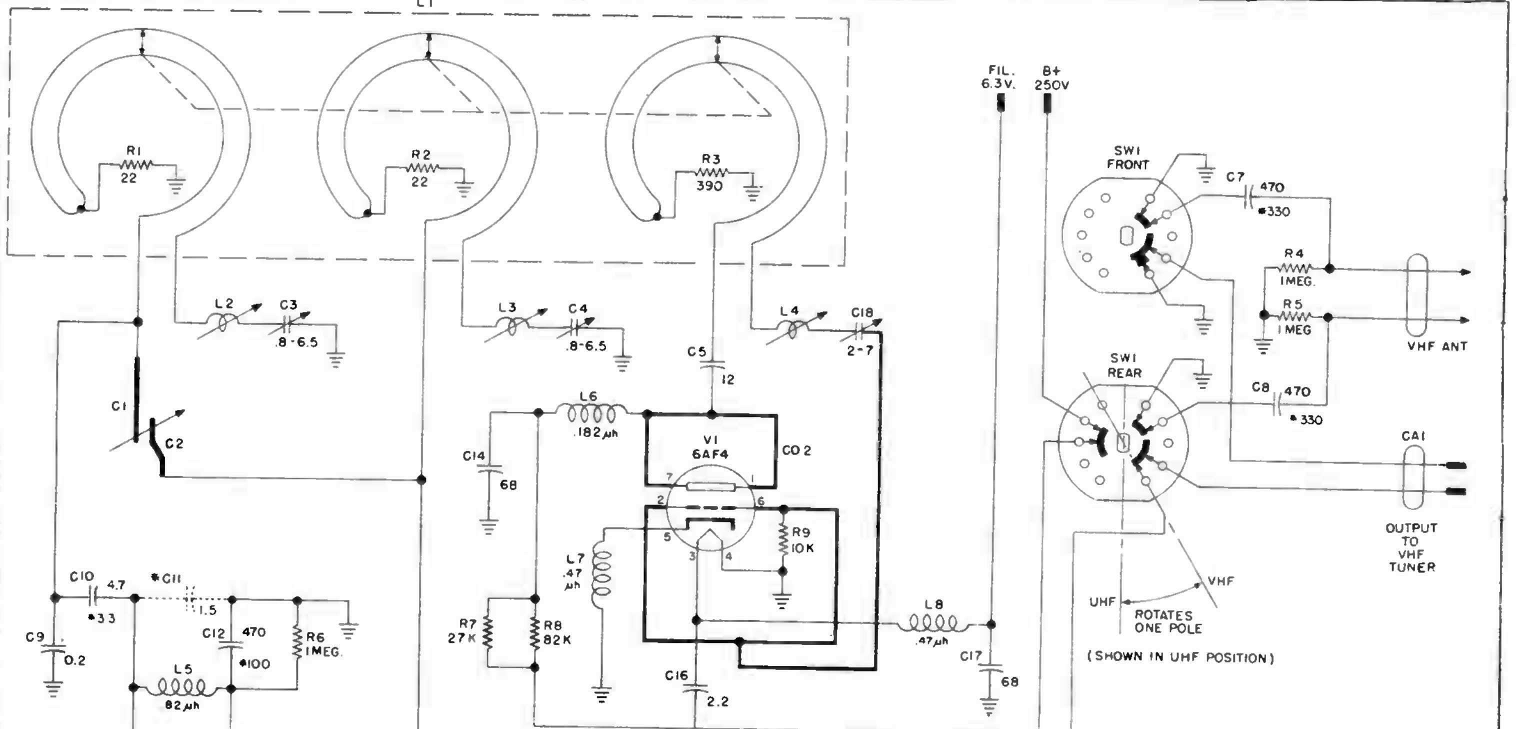
ALIGNMENT PROCEDURE

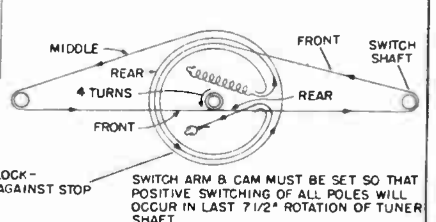
Oscillator Alignment:

1. Connect an electronic voltmeter or scope across the second detector load resistor, R114.
2. Turn on the power.
3. Apply a 460 mc. (amplitude modulated when scope is used) signal to the UHF antenna terminals through the antenna matching network (Fig. 3).
4. Turn out the adjusting screw of the mixer circuit trimmer C4 so that the flat side of the head is 5/8" above the chassis before aligning oscillator.
5. With the tuner shaft at maximum CCW position, adjust the oscillator trimmer, C18 for peak reading on the electronic voltmeter (or maximum indication on scope).
6. Set the signal generator to 904 mc.
7. Rotate the tuner shaft to maximum CW position and adjust the oscillator end inductor, L4 for maximum reading on the voltmeter (or scope).
8. Repeat steps 3 through 6 until maximum reading is obtained.

R. F. Circuit Alignment:

1. With the signal generator and electronic voltmeter or scope connected as for the Oscillator Alignment above, set the R-F coupling trimmer, C1 and C2 to minimum capacity by turning the screw CCW.
2. Set the signal generator to 460 mc. (amplitude modulated when scope is used).
3. With the tuner shaft at maximum CCW position, adjust the antenna and mixer trimmers, C3 and C4 for maximum meter reading (or scope indication).
4. Reset signal generator to 904 mc.
5. Rotate the tuner shaft to maximum CW position and adjust the antenna and mixer end inductors, L2 and L3 for maximum reading on meter (or scope).
6. Repeat steps 2 through 5 until maximum reading is obtained.
7. Turn the tuner shaft to maximum CW position and adjust the coupling trimmer, C1 and C2 for peak reading at 904 MC.
8. Turn the power switch to the "OFF" position.
9. Disconnect the generator and electronic voltmeter, or scope.
10. Re-engage the toggle coupling in the pin on the switch throw arm and the pin on the drive pulley as follows.
    a. Rotate the tuning control shaft clockwise until the pin on the rear of the drive pulley is toward the base of the chassis.
    b. Turn the switch throw arm to a vertical position.
    c. Turn the toggle coupling approximate 45° CW from a vertical position.
    d. Turn the switch throw arm CCW until pin engages the upper fork on the toggle coupling.
    e. Turn the tuning shaft CCW and guide the pin on the rear of drive pulley into the lower fork of the coupling. The coupling is now in the proper operating position and when the tuning shaft is turned completely CCW, the switch will be thrown to the VHF position.
11. Replace the UHF Converter on the VHF receiver chassis.





NOTES:
1. K=1000
2. ALL CAPACITANCE VALUES IN MMF AND ALL RESISTANCE VALUES IN OHMS UNLESS OTHERWISE NOTED.
* EARLY PRODUCTION ONE TUBE CONVERTERS USED THESE VALUES. IN THE EVENT THAT ANY OF THESE COMPONENTS FAIL, REPLACE THEM WITH THE SAME VALUE.

PLACEMENT OF DIAL DRIVE CORD

TUBE COMPLEMENT (UHF Converter)

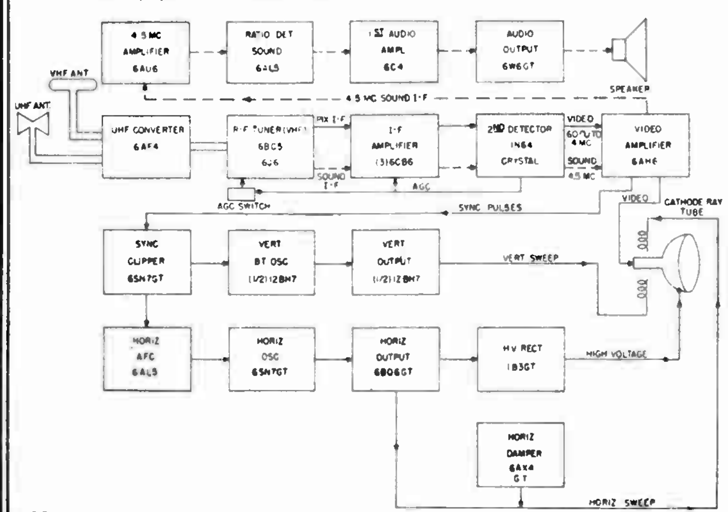
Symbol	Tube	Function
V1	6AF4	UHF Oscillator

POWER SUPPLY: 117 volts, 60 cycle, a.c.

POWER CONSUMPTION: 145 watts. (VHF)
150 watts. (UHF)

AUDIO POWER OUTPUT: 1.4 watts maximum.

BLOCK DIAGRAM:



ANTENNA INPUT IMPEDANCE:
300 ohms balanced.

INTERMEDIATE FREQUENCY:
Video Carrier — 26.4 mc.
Sound Carrier — 21.9 mc.
Intercarrier Sound — 4.5 mc.
UHF Output — Channels 5 or 6.

DEFLECTION: Electromagnetic.

FOCUS: Electrostatic, 402 chassis.
Magnetic, 403 and 404 chassis.

ION TRAP: Single Permanent Magnet

HORIZONTAL SCANNING FREQ.: 15,750 c.p.s.

VERTICAL SCANNING FREQ.: 60 c.p.s.

FRAME FREQUENCY: 30 c.p.s.

SCANNING: Interlaced, 525 lines.

SPEAKER:
21" Console Models 10" P.M.
17" and 21" Table Models 5¼" P.M.

VOICE COIL IMPEDANCE: 3.2 ohms at 400 cycles.

CAUTION

HIGH VOLTAGE--Operation of a television receiver with the back open involves a shock hazard. When making adjustments other than adjusting the controls at the front panel, all precautions for working near high voltage should be exercised.

HIGH TEMPERATURE OF TUBES--Some tubes in the receiver operate at extremely high temperatures. To avoid serious burns, do not touch these tubes while the receiver is operating, or until the tubes have cooled after the set is shut off.

HANDLING OF PICTURE TUBES--Breakage of the picture tube, which contains a high vacuum, may result in injury from flying glass. Do not scratch tube face or subject to more than moderate pressure. DO NOT REMOVE OR HANDLE THE PICTURE TUBE IN ANY MANNER UNLESS HEAVY GLOVES AND PROTECTIVE GOGGLES ARE WORN. Persons not so equipped should be kept away while handling the tube. NEVER GRASP THE TUBE BY THE NECK OR ALLOW PRESSURE TO BE EXERTED ON THE NECK. In installation, if the tube sticks or fails to slip smoothly through the deflection yoke, investigate and remove the cause of the trouble. DO NOT FORCE TUBE.

CONNECTING EXTERNAL ANTENNA

Remove the two wires from the built-in antenna fastened to the two screws on the antenna terminal board mounted at the rear of the receiver. Tape bare ends of wires from the built-in antenna. Keep the lead-in from the external antenna away from the power cord and speaker leads. Fasten the lead-in wires under the two screws on the antenna terminal board.

ADJUSTMENTS

1. ION TRAP ADJUSTMENT:

With the ION TRAP positioned close to the base of the picture tube, and the BRIGHTNESS control at low to medium setting, move the trap forward or backward and at the same time rotate in either direction until maximum brightness of the raster is obtained. Readjust the BRIGHTNESS control until the raster is slightly above average brilliance. Adjust the FOCUS CONTROL until the line structure of the raster is clearly visible. Readjust the ION TRAP again for maximum brightness.

There may be two locations on the tube neck where the ION TRAP will produce maximum brightness. Never set the trap to the forward position, always use the position nearest the tube base.

If there is a shadow in the corners of the raster, be sure the ION TRAP is properly adjusted. Do not sacrifice picture brilliance when adjusting the ION TRAP to overcome shadows in corner of picture. If corner shadows are present, be sure the DEFLECTION YOKE and CENTERING MAGNET are properly adjusted.

2. DEFLECTION YOKE AND BRACKET:

The DEFLECTION YOKE BRACKET should be positioned as far forward as possible so that the rubber cushion on the front of the bracket rests on the flare of the tube.

The DEFLECTION YOKE should be positioned as far forward as possible on the picture tube neck and rotated to the left or right as required to make the picture parallel with respect to the top and bottom of window frame.

3. FOCUSING MAGNET BRACKET ADJUSTMENT:
(403 & 404 chassis)

This bracket should be adjusted so that the magnet is centered around the neck of the picture tube. Do not remove the cardboard spacer between the neck of the tube and the magnet. Adjustment can be made after loosening the two screws in the sloted holes of the bracket on either side of the magnet housing.

4. CENTERING RASTER:

If the picture is off center and/or has neck shadow on receivers using the 402 chassis, rotate either or both CENTERING MAGNET levers to the left or right until the picture is centered on the screen and is free of neck shadow. The CENTERING MAGNET is located on the back cover of the DEFLECTION YOKE. On receivers using the 403 or 404 chassis, move the centering lever (woggle arm) up or down or to the right or left. Some of the Focusing Magnet Brackets have a sloted head screw or a wing screw to lock lever in position. Before adjusting, loosen the screw, retighten screw after adjustment is made. To determine the correct picture centering, it may be necessary to reduce the size of the picture with the HEIGHT and WIDTH adjustments. After making adjustment of CENTERING MAGNET, readjust ION TRAP.

5. HEIGHT AND WIDTH ADJUSTMENTS:

The linearity and corresponding size controls will have to be adjusted together and with care to maintain picture symmetry. For this reason it is best to use a test pattern when making these adjustments. Adjust size of picture to fill the screen by means of the HEIGHT, WIDTH, VERTICAL LINEARITY.

6. VERTICAL LINEARITY ADJUSTMENTS:

The VERTICAL LINEARITY control has the effect of expanding the picture at an increasing rate from the bottom to the top of the picture. Adjustment of this control has the greatest effect on the top portion of the picture, some effect on the middle and very little effect on the bottom of the picture. The HEIGHT and FOCUS controls may need re-adjustments as a result of the change in position of the VERTICAL LINEARITY control.

7. HORIZONTAL HOLD CONTROL:

The HORIZONTAL HOLD CONTROL is adjusted with a weak picture to the center of its lock-in range. If the lock-in range is insufficient or the horizontal sync is unstable, see "Horizontal Hold Adjustment" under "Alignment".

ADJUSTMENTS (Continued)

8. VERTICAL HOLD CONTROL:

The VERTICAL HOLD CONTROL is also adjusted to the center of its lock-in range with the contrast control set to obtain a weak picture.

9. FOCUS CONTROL

Adjust the FOCUS CONTROL for best focus of the vertical and horizontal wedges at the center of the test pattern. If corner focus is poor, check position of DEFLECTION YOKE and ION TRAP.

10. BRIGHTNESS CONTROL:

BRIGHTNESS CONTROL and CONTRAST control should be set to obtain as much shading in the picture as possible. If the Brightness control is set too low, the black and grays of the picture are black and if set too high, the black and grays of the picture will appear light and faded.

11. LOCAL-DISTANCE (AGC) SWITCH:

The LOCAL-DISTANCE SWITCH can be set to prevent the receiver from overloading in strong signal areas or to reduce "snow" in the picture in weak signal areas. In strong signal areas, the "LOCAL" (counter-clockwise) position of the switch must be used. The second and third positions "SUBURBAN" and "DISTANCE" are to be used in medium to weak signal areas. Use the position with which the best picture is obtained with a minimum of overloading of the receiver when the CONTRAST control is advanced.

12. NOISE GATE CONTROL:

This control makes it possible to obtain improved picture stability in the presence of electrical interference (noise), when the Local-Distance switch is in the "Suburban" or "Distance" position. When the control is turned completely counter-clockwise, it is out of the circuit and has no effect. Adjust the control by turning it clockwise until the picture is stable. The limiting factor of this adjustment is the buzz or noise that may be introduced, if the control is turned too far in the clockwise direction.

13. OSCILLATOR ADJUSTMENT USING A TELEVISION SIGNAL:

Do not make any adjustments on the two oscillator adjusting screws unless the FINE TUNING control range is insufficient to properly tune-in the station. The adjusting screws are accessible through holes in the front of the chassis after the tuning knobs are removed.

To make the adjustment, proceed as follows:

(a) Turn the receiver on and allow a warm-up period of approximately five minutes.

(b) For stations from channel 13 to channel 7, set the Station Selector Switch to the highest channel received and adjust the Contrast and Volume control for normal sound and picture. Set the Fine Tuning Control in the center of its range.

(c) Using a small non-metallic screwdriver, adjust the slotted head brass screw located above and to the right of shaft and above the fiber disc for the clearest and sharpest detail in the picture. This adjustment will be effective on all channels between 13 and 7. If other stations are operating in this range, it may be necessary to compromise slightly on the high channel adjustment so the other channels may be properly tuned-in.

(d) For Stations on channel 6 and below, set the station Selector Switch to the channel received closest to channel 6 and adjust the Contrast and Volume control for normal sound and picture. Set the Fine Tuning control in the center of its range.

(e) Using a small non-metallic screwdriver, adjust the slotted head brass screw located below the shaft for the clearest and sharpest detail in the picture. This adjustment will effect all channels between 6 and 2.

I. F. ALIGNMENT

All lead connections from the signal generator and wobbulator must be shielded. Keep the exposed ends and ground leads as short as possible (about one inch). Always locate the ground lead connections as close as possible to their respective "hot" leads in the television receiver chassis. The wobbulator, signal generator output, and contrast control must be kept low enough to prevent overloading the television receiver circuits.

CAUTION: One side of the chassis is connected to the power line. Therefore, test equipment should not be connected to the receiver unless an isolation transformer is used between the power line and the receiver. DO NOT GROUND THE RECEIVER CHASSIS UNLESS AN ISOLATION TRANSFORMER IS USED.

1. To Check I. F. Alignment on Oscilloscope:

(a) Lift the shield of the Oscillator-Mixer tube V2 sufficiently to clear the socket ground clips. Connect sweep signal generator "hot" lead to the ungrounded tube shield and generator ground lead to the tuner chassis.

(b) Connect high side of oscilloscope to high side of contrast control (pin 2 and 7 of V108), and the low side to chassis.

(c) Apply -3.0 volts D.C. bias to I-F Bias line (See sketch "Variable Bias Control"). Contrast control should be set in the maximum counter-clockwise position.

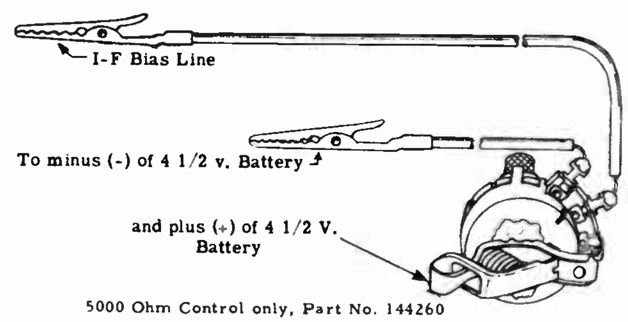
(d) With the generator sweep set at zero, connect an electronic voltmeter between top of detector load resistor, R116 and chassis. Adjust the output of the generator to obtain a reading of 2 volts D.C. on the meter.

(e) Set generator to sweep from 20 mc. to 30 mc.

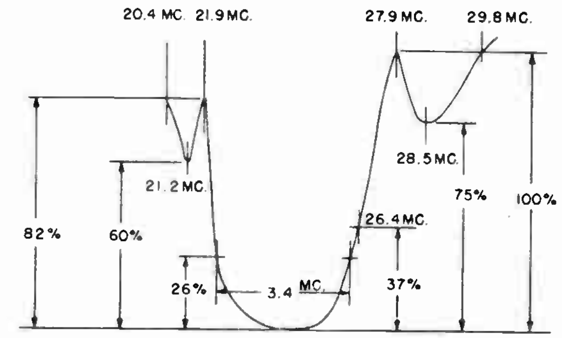
(f) Connect marker generator to sweep generator output leads and adjust to provide markers that appear in the curve.

(g) Observe curve and position of markers (see nominal response curve). Slight deviation in shape from the nominal response curve is permissible, but if any great deviation is noted, it will be necessary to realign the I-F Amplifier.

ADJUSTMENTS (Continued)



VARIABLE BIAS CONTROL ASSEMBLY



NOMINAL OVERALL I. F. RESPONSE CURVE

Note: Response as Seen by Means of Sweep Generator

2. Alignment, I. F. & Turner Assembly (with electronic voltmeter):

(a) Connect -3.0 Volts D.C. bias supply to I-F Bias line.

(b) Connect signal generator "hot" lead through a 1000 mmf. capacitor to TP-1 (wire protruding from tuner directly adjacent to the oscillator mixer tube V2) and ground lead to the R. F. tuner case.

(c) Connect high side of Electronic Voltmeter to top of detector load resistor, R116, and low side to chassis; zero meter.

(d) Set signal generator to 24.4 mc. and adjust top of T101 for maximum D.C. meter indication on voltmeter. Adjust the signal generator amplitude to make this peak indication 2 volts D.C., approximately.

(e) Set signal generator to 22.9 mc. and adjust top of L103 for maximum D.C. meter indication, limiting meter deflection to 2 volts D.C. by adjusting input of attenuator.

(f) Set the signal generator to 21.9 mc. and adjust bottom of L103 for minimum D.C. meter deflection. Input should be high enough to permit a definite null to be observed on the meter.

(g) Repeat steps e and f.

(h) Set signal generator to 25.5 mc. and adjust top of L102 for maximum meter deflection, limiting meter deflection to 2 volts D.C. by adjusting input attenuator.

(i) Reset signal generator to 24.4 mc. Connect a 100 ohm resistor in series with a 1000 mmf. capacitor across L101. Adjust converter output, L11, of R.F. Tuner for maximum meter deflection, but limit output of generator so this reading does not exceed 2 volts D.C. Remove the 100 ohm resistor and the 1000 mmf. capacitor.

(j) Reset signal generator to 27.9 mc. and adjust the bottom of L101 for minimum D.C. meter deflection. Signal generator amplitude must be sufficiently high to produce a definite null.

(k) Set signal generator to 25.5 mc. Connect the 100 ohm resistor and the 1000 mmf. series capacitor from TP-2 (wire protruding from the tuner through the insulated eyelet between the brass adjusting screws) on the R-F Tuner to the tuner case and adjust L101 for maximum D.C. meter indication. Adjusting amplitude of signal generator to make this maximum indication approximately 2 volts D.C. Remove the 100 ohm resistor and the 1000 mmf. capacitor.

(l) Repeat steps j and k.

(m) Check sensitivity. The input for 2 volts D.C. output and zero bias should not exceed 650 microvolts at 24.4 mc. with generator properly terminated, and generator fed into grid of first I-F amplifier.

(n) Remove the signal generator and electronic voltmeter.

(o) Note: When aligning bottom of L103 and bottom of L101 the first null obtained when running the core into the trap winding from the Tinnermann Clip end of the trap winding is the proper alignment null.

SOUND ALIGNMENT

1. Connect crystal controlled 4.5 mc. 400 cycle amplitude modulated signal, modulated 30% or greater, between grid of video amplifier and chassis.

2. Connect high side of scope through detector probe to the picture tube cathode (pin 11). Connect low side of scope to chassis. Adjust 4.5 mc. trap, L109, for minimum 400 cycle deflection on scope.

3. Connect electronic voltmeter to lug 2 of ratio detector, V106, and adjust 4.5 mc. sound take-off (L112) and bottom of ratio transformer (T102) for peak reading on voltmeter. Adjust input to make this peak reading 4 volts.

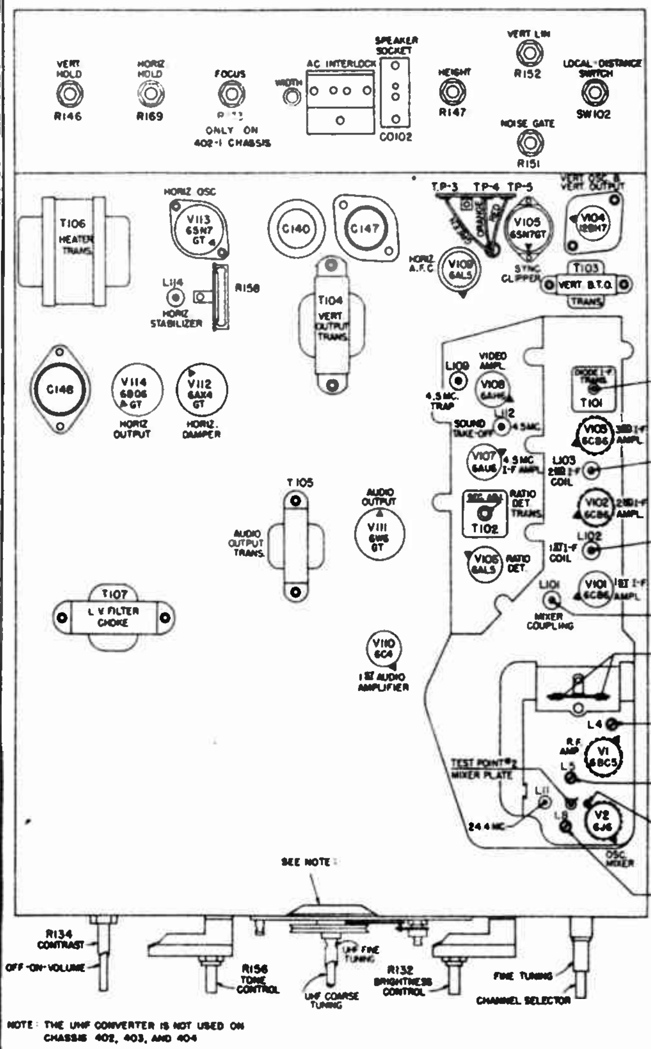
4. Adjust input to obtain 12 volts output. Transfer electronic voltmeter to junction of R129 and C128 (refer to Schematic Wiring Diagram). Adjust top of T102 for zero balance on electronic voltmeter.

5. Recheck steps 2, 3 and 4.

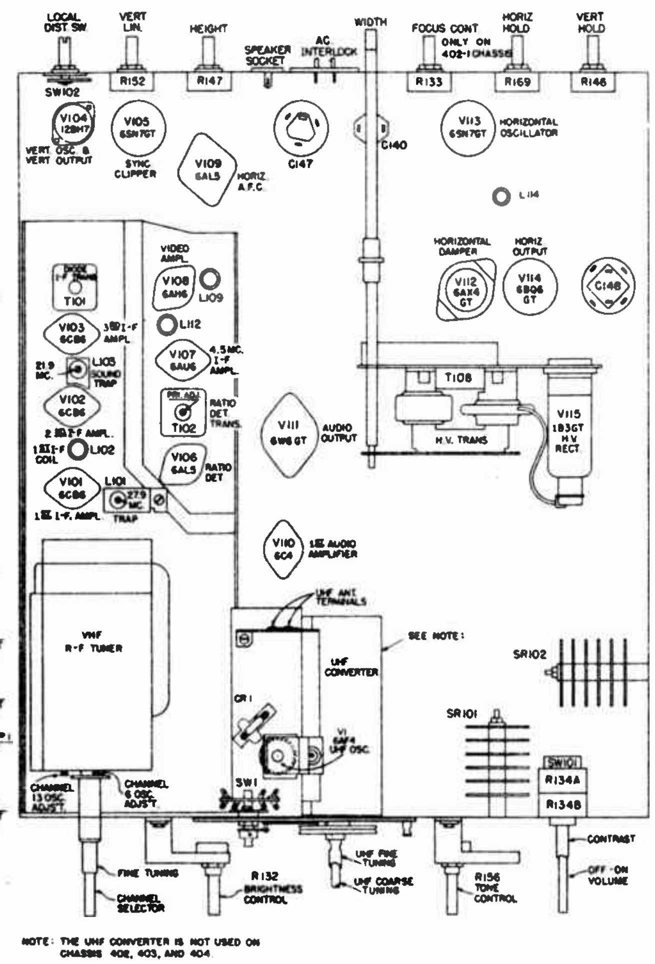
6. Remove input signal, scope and electronic voltmeter.

HORIZONTAL HOLD ADJUSTMENT

1. Tune in a local television signal and adjust contrast control for normal picture.
2. Connect electronic voltmeter between TP-3 (green lead) and chassis.
3. Short TP-4 (orange lead) to chassis and adjust electronic voltmeter to zero.
4. Remove short from TP-4. Do not change zero on electronic voltmeter.
5. Connect a 0.1 mfd., 600 volt capacitor between TP-5 (red lead) and chassis.
6. Adjust Horizontal Hold control for zero reading on the meter.
7. Remove the 0.1 mfd. capacitor from TP-5 and chassis. Do not disturb setting of horizontal hold control.
8. Adjust Horizontal Stabilizer coil (L114) for zero reading on the meter.
9. Remove electronic voltmeter from TP-3.
10. Check horizontal pull-in range. The pull-in range should be approximately 50° of the control's rotation.



TOP VIEW 402-1, 403-1, 404-1 CHASSIS



BOTTOM VIEW 402-1, 403-1, 404-1 CHASSIS

CIRCUIT DESCRIPTION (UHF CONVERTER)

This UHF Converter employs a 1N72 crystal mixer and a 6AF4 UHF oscillator tube. The continuous tuner covers the UHF Commercial Television Band, Channels 14 through 83. The filament and B+ voltages are supplied by the Crosley VHF television receiver with which the converter is used.

The converter is designed to operate from a 300 ohm, balanced or unbalanced line antenna.

Provisions are made for connecting and switching of separate antennas for UHF and VHF. This switching is accomplished by movement of the UHF coarse or fine tuning knob. When the knob is turned completely counter-clockwise (to "VHF") a link coupling throws a switch which in turn connects the VHF antenna to the receiver input. By a slight movement of the knob in a clockwise direction (toward channel "14") the link coupling throws the switch to the UHF position, connecting the UHF antenna to the receiver input and shorting out the VHF antenna. This function is performed before the UHF converter is tuned to any channel in the UHF commercial television band.

The UHF Tuner assembly consists of three variable (tuned line) inductors mounted on a common shaft. The first two inductors tune the UHF antenna preselector circuit. This circuit passes the signal to which the UHF dial is set and attenuates all other signals, thus acting to reduce interference. These inductors in conjunction with the associated capacitors and end inductors, tune to any desired frequency between 465 and 902 megacycles, while the third inductor, used to tune the local UHF oscillator, covers a range of approximately 376 to 820 megacycles.

The antenna preselector circuit is shunted by the choke L5, this provides additional attenuation to unwanted signals and acts as a high-pass radio-frequency filter to suppress broadcast and other low frequency cross modulation interference that may be encountered when the television receiver is located in an extremely intense field of a local AM Broadcast station or other R-F radiators.

The end inductors L2, L3, L4 and the capacitors, C3, C4 and C18, provide a means of aligning the tuner at the high and low end. The UHF oscillator utilizes a 6AF4 tube. Feedback voltage from the plate to the grid is obtained by means of the capacitor C5 and the interelectrode capacity of the tube. The oscillator circuit (and the preselector circuits) is tuned to frequency by movement of a shorting contact on the tuned line inductors. Position of this contact determines the resonant frequency of the inductance.

Both the tuned incoming signal from the antenna and the local oscillator signal are applied to the crystal mixer. The antenna preselector circuit is capacity coupled (through C1, C2 and C15) to the germanium crystal mixer. The local oscillator is coupled to the mixer through capacitor C16. The output of the crystal mixer is coupled through R-F choke L9, to the switch, SW1. When SW1 is in the UHF position, the output of the crystal mixer is fed to the R-F input of the VHF tuner.

Proper operation of the television receiver on the UHF channels require that the VHF Channel Selector be set to either channel 5 or 6, depending upon the locality in which the receiver is used and must be set to the channel not in use by a VHF station in the area. If both channel 5 and 6 are clear, the one with the least interference should be used.

UHF ALIGNMENT

Alignment Notes:

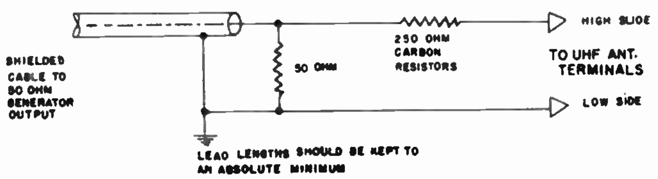
CAUTION: This UHF converter unit is used with a VHF receiver that has one side of the chassis connected to the power line. DO NOT CONNECT TEST EQUIPMENT TO ANY PART OF THE RECEIVER OR GROUND THE CHASSIS UNLESS AN ISOLATION TRANSFORMER IS USED BETWEEN THE POWER LINE AND RECEIVER.

1. Remove the UHF Converter from the VHF receiver chassis.
2. Disengage the toggle coupling from the switch throw arm on the front of the UHF chassis.
   To accomplish this: -
   a. Turn the UHF tuning control clockwise until the pin located on the rear of the drive pulley is free from the toggle coupling.
   b. Loosen the two set screws in switch throw arm collar and remove from switch shaft.
   c. Turn the switch clockwise to the UHF position; contact blade on switch rotor must contact and center on the two switch fingers with the red wires attached. Leave switch in this position while aligning.
3. Connect the output leads of the UHF converter to the R-F input terminals of the VHF Tuner.
4. Connect the B+ and filament leads of the tuner to their respective points from which they were removed on the VHF receiver. Connect UHF Converter chassis to B- (VHF receiver chassis).
5. Keep all leads as short as possible, one way to accomplish this is to mount the UHF converter at right angles to the TV chassis with one mounting screw. Most of the leads on the converter will then require no additional length.
6. Set VHF Tuner to Channel 6.
7. Alignment should be followed in the order shown.

UHF ALIGNMENT (Continued)

OSCILLATOR ALIGNMENT

1. Connect an electronic voltmeter or scope across the second detector load resistor.
2. Turn on the power
3. Apply a 460 mc. (amplitude modulated, when scope is used) signal to the UHF antenna terminals through the antenna matching network (See Sketch).

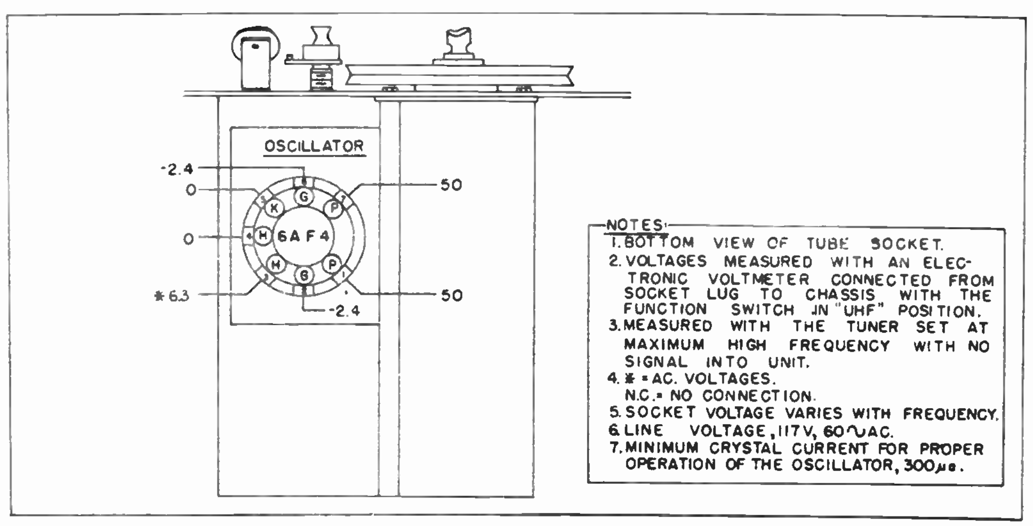


Antenna Matching Network

4. Turn out the adjusting screw of the mixer circuit trimmer C4 so that the flat side of the head is 5/8" above the chassis before aligning oscillator.
5. With the tuner shaft at maximum CCW position, adjust the oscillator trimmer C18 for peak reading on the electronic voltmeter or maximum indication on the scope (oscillator frequency is set to 84 mc below the carrier frequency).
6. Set the signal generator to 904 mc.
7. Rotate the tuner shaft to maximum CW position and adjust the oscillator end inductor, L4 up or down for maximum reading on the voltmeter.
8. Repeat steps 3 through 6 until maximum reading is obtained.

R-F CIRCUIT ALIGNMENT

1. With the signal generator and electronic voltmeter or scope connected as for the Oscillator Alignment above, set the R-F coupling trimmer, C1 and C2 to minimum capacity by turning the screw CCW.
2. Set the signal generator to 460 mc. (Amplitude modulated when scope is used).
3. With the tuner shaft at maximum CCW position, adjust the antenna and mixer trimmers, C3 and C4 for maximum meter reading. (or scope indication)
4. Reset signal generator to 904 mc.
5. Rotate the tuner shaft to maximum CW position and adjust the antenna and mixer end inductors, L2 and L3, for maximum reading on meter or scope, by forming larger or smaller loop
6. Repeat steps 2 through 5 until maximum reading is obtained.
7. Turn the tuner shaft to maximum CW position and adjust the coupling trimmer, C1 and C2 for peak reading at 904 MC.
8. Turn the power switch to the "OFF" position.
9. Disconnect the generator and electronic voltmeter, or scope.
10. Re-engage the toggle coupling in the pin on the switch throw arm and the pin on the drive pulley as follows:
    a. Rotate the tuning control shaft clockwise until the pin on the rear of the drive pulley is toward the base of the chassis.
    b. Turn the tuning shaft CCW and guide the pin on the rear of drive pulley into the fork of the toggle coupling, then continue to turn tuning shaft CCW to stop. The coupling is now in the proper operating position.
    c. With the switch set to the VHF position (CCW) replace the switch throw arm so that the pin on the arm engages the fork of the toggle coupling. In this position it is approximately 30° CW from horizontal. Tighten the two set screws in the switch throw arm collar.
    d. Function switch should be checked for proper operation under conditions of customer use.

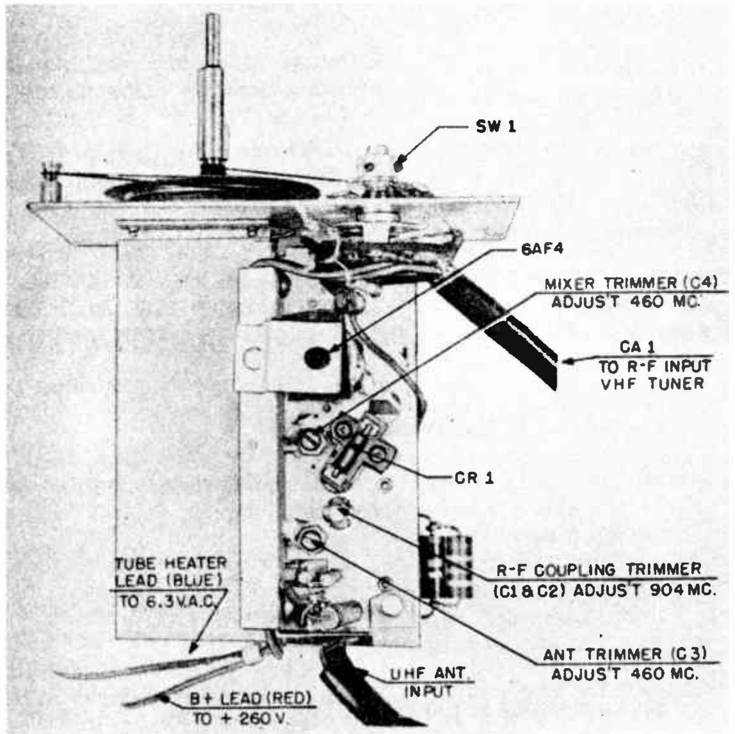


Socket Voltage Chart

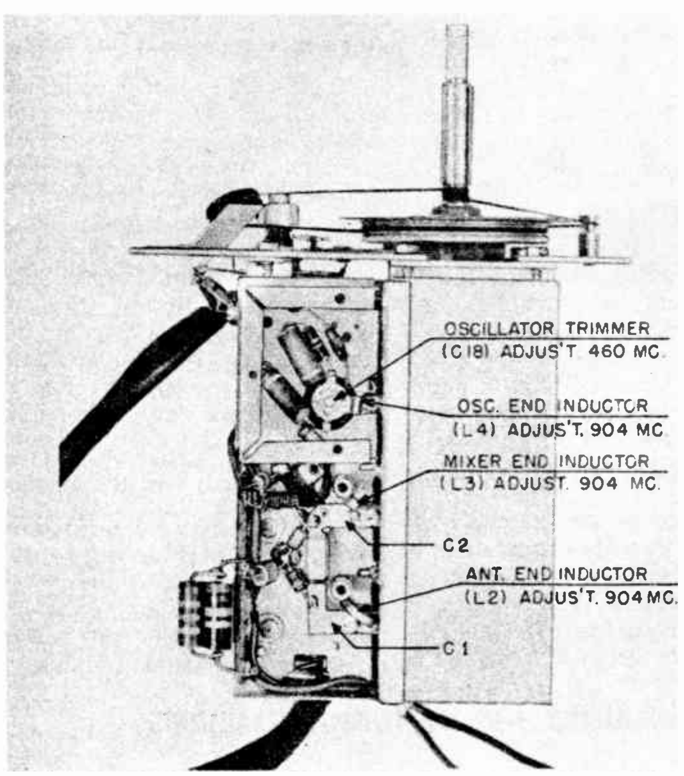
UHF ALIGNMENT (Continued)

At full CCW rotation of tuner shaft, all VHF position contacts must be fully and firmly made and all UHF position contacts must be fully broken. All UHF position contacts must be fully and firmly made and all VHF position contacts must be fully broken, when tuner shaft is 7-1/2° or more from full CCW, as tuner shaft is rotated toward stop from UHF position.

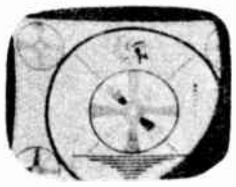
11. Replace the UHF Converter on the VHF receiver chassis.



UHF CONVERTER CHASSIS, (Top View)



UHF CONVERTER CHASSIS, (Bottom View)



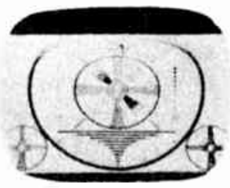
Off Center and Neck Shadow

CENTERING MAGNET ADJUSTMENT — If the picture is off center and/or has neck shadow as shown in the illustration at the left, loosen screw "G" and rotate the centering magnet lever "H" to the right, left, up, down, or a combination of these directions until the picture is centered on the screen and the picture is free of all neck shadow. While holding lever in position tighten screw "G".

ION TRAP ADJUSTMENT — With the ion trap magnet positioned close to the base of the picture tube and the Brightness Control at a low to medium setting, slide the ion trap backward or forward and at the same time rotate it to the right or left until maximum brightness is obtained. Readjust the brightness control until the raster is slightly above average brilliance. Adjust the focus control until the line structure of the raster is clearly visible. Readjust the Ion Trap again for maximum brightness. There may be two locations on the tube neck where the ion trap will produce maximum brightness. Never set the trap to the forward position, always use the position closest to the tube base. If there is a shadow in the corner of the raster, be sure the ion trap is properly adjusted; when adjusting the ion trap, do not sacrifice picture brilliance to overcome shadows in corners. When shadows are present, be sure the deflection yoke and centering magnet are properly adjusted.

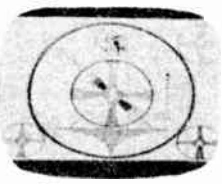
NOISE GATE CONTROL — In areas that have strong electrical interference and the Local-Suburban-Distance Switch can be set to "Suburban" or "Distance" without overloading the receiver, picture stability can be improved by turning the control clockwise to a position where the picture is most stable with no buzz or noise introduced into the sound output.

LOCAL - SUBURBAN - DISTANCE SWITCH — In strong signal areas set this switch to its extreme counter-clockwise position (LOCAL). The middle position (SUBURBAN), and extreme clockwise position (DISTANCE) are used in areas where the signal is weak or medium strength. Set the switch in the position which provides the most satisfactory picture with minimum overloading when the contrast control is advanced.



Misadjusted Vertical Linearity

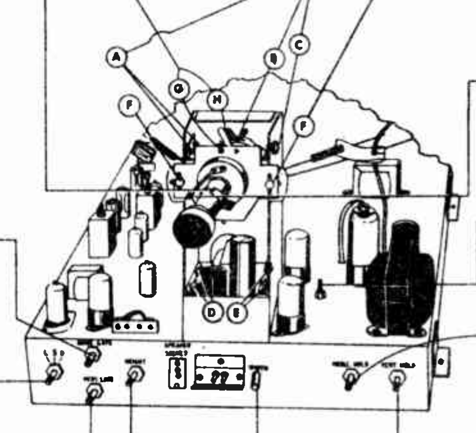
VERTICAL LINEARITY CONTROL — This control increases or decreases the height of the upper portion of the picture.



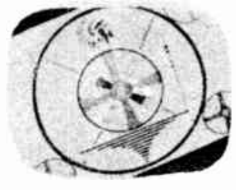
Misadjusted Height

HEIGHT CONTROL — This control increases the overall height of the picture. When making this adjustment it is sometimes necessary to also adjust the VERTICAL LINEARITY to obtain a picture that is correctly proportioned.

REAR VIEW — CHASSIS 404, 404-1 — (Chassis 403, 403-1 are similar to chassis 404, 404-1 except that the 403 and 403-1 chassis are equipped with a metal picture tube and a deflection yoke mounting bracket which is mounted directly to the chassis with the four screws "D" and "E").



CONNECTING EXTERNAL ANTENNA — When connecting an external antenna to the terminals at the rear of the receiver be sure to disconnect the built-in antenna which is being replaced by the external antenna.

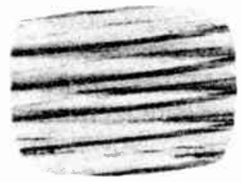


Picture Tilted

DEFLECTION YOKE ADJUSTMENTS — The deflection yoke must be positioned as far forward as possible on the neck of the picture tube. To make this adjustment, loosen screws "D" and "E" enough to permit the yoke bracket to be pushed forward. While holding the bracket in the forward position, tighten screws "D" and "E". Screws "A" and "C" are for shifting the yoke up or down to center it around the picture tube neck. If the picture is tilted as illustrated at right, loosen wing nut "B". Then, rotate the yoke to left or right as required to make the picture parallel with respect to top and bottom of window frame. Be sure to hold the yoke in position while tightening the wing nut.

FOCUS ASSEMBLY — To Center the Focus Assembly around the neck of the picture tube, loosen screws "F" and shift the assembly to right, left, up, or down until paper shim around tube neck can be moved freely. Then tighten screws "F".

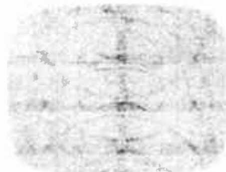
FOCUS CONTROL — Rotate to the right or left until the sharpest picture, or sharpest horizontal lines, are obtained.



Misadjusted Horizontal Hold

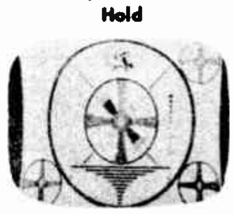
HORIZONTAL STABILIZER ADJUSTMENT — See "HORIZONTAL HOLD CONTROL".

HORIZONTAL HOLD CONTROL — If the picture appears as shown in the illustration, adjust the horizontal hold control to right or left as required to lock in a single stationary picture. If the range of the control is not sufficient to lock in picture, see "Horizontal Hold Control" adjustment.



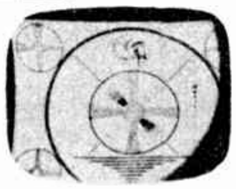
Misadjusted Vertical Hold

VERTICAL HOLD CONTROL — If the picture is moving up or down as illustrated at right, adjust the vertical hold control until a single stationary picture is obtained.



Picture Too Narrow

WIDTH CONTROL — If the picture is too narrow as illustrated, or too wide, turn the width control clockwise or counter-clockwise as required to adjust the picture to the proper width of the viewing area on the screen.



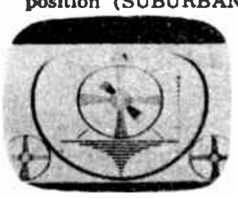
Off Center and Neck Shadow

CENTERING MAGNET ADJUSTMENT — If the picture is off center and/or has neck shadow as shown in the illustration at the left, rotate either or both centering magnet levers to the right or left until the picture is centered on the screen, and the picture is free of all neck shadow.

ION TRAP ADJUSTMENT — With the ion trap magnet positioned close to the base of the picture tube and the brightness control at a low to medium setting, slide the ion trap backward or forward and at the same time rotate it to the right or left until maximum brightness is obtained. Readjust the brightness control until the raster is slightly above average brilliance. Adjust the focus control until the line structure of the raster is clearly visible. Readjust the ion trap again for maximum brightness. There may be two locations on the tube neck where the ion trap will produce maximum brightness. Never set the trap to the forward position, always use the position closest to the tube base. If there is a shadow in the corner of the raster, be sure the ion trap is properly adjusted; when adjusting the ion trap, do not sacrifice picture brilliance to overcome shadows in corners. When shadows are present, be sure the deflection yoke and centering magnet are properly adjusted.

NOISE GATE CONTROL — In areas that have strong electrical interference and the Local-Suburban-Distance Switch can be set to "Suburban" or "Distance" without overloading the receiver, picture stability can be improved by turning the control clockwise to a position where the picture is most stable with no buzz or noise introduced into the sound output.

LOCAL - SUBURBAN - DISTANCE SWITCH — In strong signal areas set this switch to its extreme counter-clockwise position (LOCAL). The middle position (SUBURBAN), and extreme clockwise position (DISTANCE) are used in areas where the signal is weak or medium strength. Set the switch in the position which provides the most satisfactory picture with minimum overloading when the contrast control is advanced.



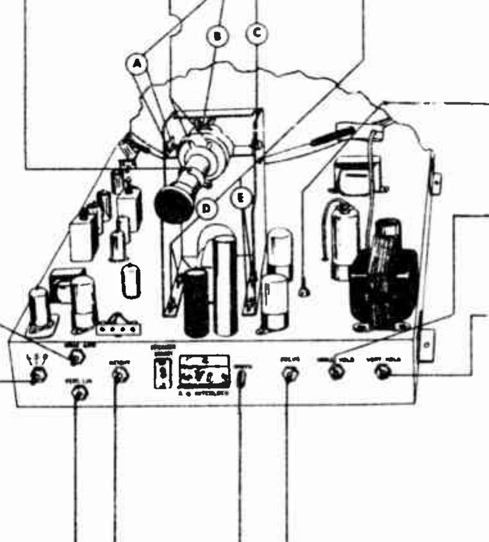
Misadjusted Vertical Linearity

VERTICAL LINEARITY CONTROL — This control increases or decreases the height of the upper portion of the picture.

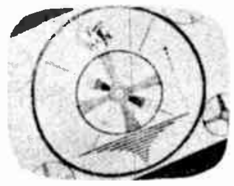
Misadjusted Height

HEIGHT CONTROL — This control increases the overall height of the picture. When making this adjustment it is sometimes necessary to also adjust the VERTICAL LINEARITY to obtain a picture that is correctly proportioned.

REAR VIEW — CHASSIS 402, 402-1



CONNECTING EXTERNAL ANTENNA — When connecting an external antenna, be sure to disconnect the built-in antenna, which is being replaced by the external antenna.



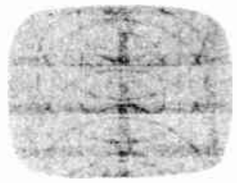
Picture Tilted

DEFLECTION YOKE ADJUSTMENTS — The deflection yoke must be positioned as far forward as possible on the neck of the picture tube. To make this adjustment, loosen screws "D" and "E" enough to permit the yoke bracket to be pushed forward. While holding the bracket in the forward position, tighten screws "D" and "E". Screws "A" and "C" are for shifting the yoke up or down to center it around the picture tube neck. If the picture is tilted as illustrated at right, loosen wing nut "B". Then, rotate the yoke to left or right as required to make the picture parallel with respect to top and bottom of window frame. Be sure to hold the yoke in position while tightening the wing nut.

Misadjusted Horizontal Hold

HORIZONTAL STABILIZER ADJUSTMENT — See "HORIZONTAL HOLD CONTROL".

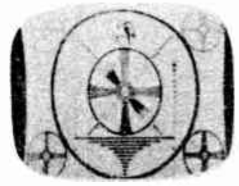
HORIZONTAL HOLD CONTROL — If the picture appears as shown in the illustration, adjust the horizontal hold control to right or left as required to lock in a single stationary picture. If the range of the control is not sufficient to lock in picture, see "Horizontal Hold Control" adjustment.



Misadjusted Vertical Hold

VERTICAL HOLD CONTROL — If the picture is moving up or down as illustrated at right, adjust the vertical hold control until a single stationary picture is obtained.

FOCUS CONTROL — Rotate to the right or left until the sharpest picture or sharpest horizontal lines are obtained.



Picture Too Narrow

WIDTH CONTROL — If the picture is too narrow as illustrated, or too wide, turn the width control clockwise or counter-clockwise as required to adjust the picture to the proper width of the viewing area on the screen.

R125	39374-15	Resistor, 150 ohm, 10%, 1/2 w.
R126	39374-49	Resistor, 100,000 ohm, 10%, 1/2 w.
R127	39374-29	Resistor, 2200 ohm, 10%, 1/2 w.
R128	39374-18	Resistor, 270 ohm, 10%, 1/2 w.
R129	39374-43	Resistor, 33,000 ohm, 10%, 1/2 w.
R130	39375-73	Resistor, 10,000 ohm, 5%, 1/2 w.
R131	39375-73	Resistor, 10,000 ohm, 5%, 1/2 w.
R132	155352	Control, Brightness (5 megohm)
R133	154094	Control, Focus (1.5 megohm used on 402 chassis only)
R134A	154085	Control, Volume (1 megohm) } Assembly
R134B		Control, Contrast (2500 ohm) } Assembly
R135	39374-57	Resistor, 470,000 ohm, 10%, 1/2 w.
R136	39374-69	Resistor, 2.2 megohm, 10%, 1/2 w.
R137	39374-61	Resistor, 1 megohm, 10%, 1/2 w.
R138	39374-146	Resistor, 560,000 ohm, 10%, 1 w.
R139	39374-41	Resistor, 22,000 ohm, 10%, 1/2 w.
R140	39374-31	Resistor, 3300 ohm, 10%, 1/2 w.
R141	39374-35	Resistor, 6800 ohm, 10%, 1/2 w.
R142	39374-29	Resistor, 2200 ohm, 10%, 1/2 w.
R143	39374-41	Resistor, 22,000 ohm, 10%, 1/2 w.
R144	39374-37	Resistor, 10,000 ohm, 10%, 1/2 w.
R145	39374-56	Resistor, 390,000 ohm, 10%, 1/2 w.
R146	155610	Control, Vertical Hold
R147	154086	Control, Height
R148	39374-125	Resistor, 10,000 ohm, 10%, 1 w.

PARTS LIST

CHASSIS 402, 403 & 404 (Schematic Parts)

402-1, 403-1 & 404-1

Symbol No.	Part No.	Description
R149	39374-60	Resistor, 820,000 ohm, 10%, 1/2 w.
R150	39374-33	Resistor, 4700 ohm, 10%, 1/2 w.
R151	155576	Control, Noise Gate (90,000 ohm)
R152	154088	Control, Vertical Linearity
R153	154084	Resistor, 8700 ohm, 5%, 5 w. wire wound
R154	39374-14	Resistor, 120 ohm, 10%, 1/2 w.
R155	39374-27	Resistor, 1500 ohm, 10%, 1/2 w.
R156	155389	Control, Tone (250,000 ohm)
R157	39374-43	Resistor, 33,000 ohm, 10%, 1/2 w.
R158	154089	Resistor, 7.5 ohm, 10%, 5 w. wire wound
R159	39374-49	Resistor, 100,000 ohm, 10%, 1/2 w.
R160	39374-49	Resistor, 100,000 ohm, 10%, 1/2 w.
R161	39374-41	Resistor, 22,000 ohm, 10%, 1/2 w.
R162	39374-139	Resistor, 150,000 ohm, 10%, 1 w.
R163	39374-77	Resistor, 4.7 megohm, 10%, 1/2 w.
R164	39374-77	Resistor, 4.7 megohm, 10%, 1/2 w.
R165	39374-26	Resistor, 1200 ohm, 10%, 1/2 w.
R166	39374-34	Resistor, 5600 ohm, 10%, 1/2 w.
R167	39374-33	Resistor, 4700 ohm, 10%, 1/2 w.
R168	39374-45	Resistor, 47,000 ohm, 10%, 1/2 w.
R169	155511	Control, Horizontal Hold
R170	39374-36	Resistor, 8200 ohm, 10%, 1/2 w.
R171	39374-50	Resistor, 120 ohm, 10%, 1/2 w.
R172	39374-55	Resistor, 330,000 ohm, 10%, 1/2 w.
R173	39374-213	Resistor, 10,000 ohm, 10%, 2 w.
R174	39374-6	Resistor, 27 ohm, 10%, 1/2 w. (used on 403, 404 chassis only)
R175	39303-12	Resistor, 2.2 ohm (Part of T108)
R176	39374-139	Resistor, 150,000 ohm, 10%, 1 w.
R177	39374-23	Resistor, 680 ohm, 10%, 1/2 w.
R179	39374-57	Resistor, 470,000 ohm, 10%, 1/2 w. (used on 402 only)
R180	39374-57	Resistor, 470,000 ohm, 10%, 1/2 w.
L101	155304	Coil, Converter IF (1.98 to 4.5 microhenries)
L102	155319	Coil, 1st IF (1.95 to 4.5 microhenries)
L103	155348	Coil, 2nd IF (2.4 to 4.5 microhenries)
L104	154376	Coil, Diode Choke (15.5 microhenries)

Symbol No.	Part No.	Description
L105	156035	Coil, Video Peaking (117 microhenries)
L106	156036	Coil, Video Peaking (464 microhenries)
L107	155256	Choke, Filament RF (.576 microhenries)
L108	154194	Coil, Video Peaking (414 microhenries)
L109	155446	Coil, 4.5 MC. Trap (27 to 57 microhenries)
L110	154206	Coil, Video Peaking (106 microhenries)
L111	154176	Coil, Video Peaking (840 microhenries)
L112	155442	Coil, Sound Take-Off (12 to 23 microhenries)
L113A	154221-6	Yoke, Deflection } Assembly (used on 402 only)
L113B		Yoke, Deflection
L113A	154221-9	Yoke, Deflection } Assembly (used on 403, 404 chassis)
L113B		Yoke, Deflection
L114	154220	Coil, Horizontal Oscillator (18 to 37 microhenries)
L115	154156	Network, Yoke Coupling (3 microhenries, used on 403, 404 chassis only)
L116	156035	Coil, Video Peaking (117 microhenries)
T101	155594	Transformer, Diode IF
T102	154108	Transformer, Ratio Detector
T103	155255-1	Transformer, Vertical Oscillator
T104	155572	Transformer, Vertical Output
T105	154109-2	Transformer, Audio Output
T106	155390	Transformer, Filament
T107	155529-1	Choke, Filter
T108	155514-1	Transformer, Horizontal Deflection
CO102	138352	Socket, Speaker
CO103	154114	Socket, Terminal Strip
SW101	Part of R134A&B	Switch, ON-OFF Power
SW102	155554	Switch, Rotary (AGC Control)
CR101	154111	Crystal, 1N64
SR101	155575-2	Rectifier, Selenium
SR102	155575-2	Rectifier, Selenium
SP101	138762-7	Speaker, PM (5-1/4")
SP102	138762-7	Speaker, PM (5-1/4")
SP103	138762-5	Speaker, PM (10")
CA101	132300-6	Cable & Plug Assembly, AC Power
P101	154125	Receptacle, AC Power
P102	131983	Plug (Male), 2 Prong

CHASSIS 402 & 402-1

Part No.	Description
154495	Antenna Terminal Board & Bracket Assembly
155462	Barrier, Brightness Control
155375	Barrier, Tone Control
155750-1	Bracket (Frame), Deflection Yoke Assembly
155222	Bracket (Front), VHF Tuner Shaft
154255-2	Bracket, Picture Tube Stop
154238-2	Bracket, Picture Tube Strap Tie Down
154253	Bracket, (Saddle), Deflection Yoke Assembly
155199	Bracket, Tone & Brightness Controls
155558	Cable, Twin Shielded
154276-2	Channel (Rubber), Deflection Yoke Assembly
154266-1	Channel (Rubber), Picture Tube Mounting Foot
156009	Coil (High Voltage), Horizontal Deflection Assembly
154180	Coil (Primary), Horizontal Deflection Assembly
155102-2	Connector, Picture Tube Anode
154124	Coupling, Width Control Shaft
153424-3	Cushion (Rubber), Picture Tube Strap
155194	Disc, Fine Tuning (VHF)
156045	Foot, Picture Tube Mounting (2 used)
154134	Grommet (4 used), Tube Mounting (V104, V113)
155553	Insulator, Antenna Lead
138853	Insulator, Controls (8 used)
154264	Insulator, Interlock
154268	Insulator, VHF Tuner Shaft
153109-3	Ion Trap
39012-102	Iron Core
39012-116	Iron Core (6 used on IF Strip)
154073	Iron Core, Horizontal Deflection Assembly
154122-2	Plate Cap, Tube (V115)
154122-3	Plate Cap, Tube (V114)
155253	Plate (Bearing), VHF Tuner Shaft
154075	Plate, Horizontal Width Control
154079-1	Ring (Retaining), Width Control Shaft (3 used)

Part No.	Description
154079-2	Ring (Retaining), Width Control Shaft Key
153580	Screw (Thumb), Deflection Yoke Assembly
39296-84	Screw (2 used), Picture Tube Strap
155195	Shaft, Width Control
154077	Shaft, Width Control (Horizontal Deflection Assembly)
155027	Shaft, VHF Tuner
155276	Shield, Corona
155241	Shield, High Voltage
154143	Shield, Tube (2 used)
154148-3	Socket & Cable Assembly, Picture Tube
154203	Socket, Tube Shock Mounted (V113)
154192	Socket, Tube Shock Mounted (V104)
154127	Socket, Tube (V106, V107, V108, V110)
39388	Socket, Tube (V111)
154131	Socket, Tube (V105, V114)
154117	Socket, Tube (V109)
154130	Socket, Tube (V112)
154146	Socket, Tube (V101, V102, V103)
149322	Support, Anode Connector
154074	Support, High Voltage Lead (Horizontal Deflection Assembly)
149671-1	Spring (Grounding), Deflection Yoke Assembly
154135	Spring, Picture Tube Mounting (2 used)
154072	Spring (Clip), Horizontal Deflection Assembly
154071	Spring (Strap), Horizontal Deflection Assembly
154205	Strap, Picture Tube
155351	Terminal Board, Horizontal Deflection Assembly
155398	VHF Tuner, Complete
154123	Wafer, Capacitor Mounting (C148)
154126	Wafer, Capacitor Mounting (C140)
155394	Washer (Extruded), Tone & Brightness Controls
138976	Washer (Extruded), Auxillary Controls (8 used)
155339	Washer, Picture Tube Mounting Foot (2 used)
149180	Washer (Spring), Width Control Shaft

NOTE: For Replacement Parts List for Chassis 403, 403-1, 404 & 404-1, see page 20.

PARTS LIST

CHASSIS 403 & 403-1

Part No.	Description
154495	Antenna Terminal Board & Bracket Assembly
155462	Barrier, Brightness Control
155375	Barrier, Tone Control
154722	Barrier, Picture Tube
155750-2	Bracket (Frame), Deflection Yoke Assembly
155222	Bracket (Front), VHF Tuner Shaft
155330-1	Bracket (R.H.), Picture Tube Support
155330-2	Bracket (L.H.), Picture Tube Support
155741	Bracket (2 used), Focuser Mounting
154253	Bracket (Saddle), Deflection Yoke Assembly
155199	Bracket, Tone & Brightness Controls
155558	Cable, Twin Shielded
154276-2	Channel (Rubber), Deflection Yoke Assembly
155579	Clip, Anode Connector
156009	Coil (High Voltage), Horizontal Deflection Assembly
154180	Coil (Primary), Horizontal Deflection Assembly
154124	Coupling, Width Control Shaft
155999-1	Cushion (Rubber), Picture Tube Support (2 used)
155194	Disc, Fine Tuning (V.H.F.)
155788-1	Focuser (P.M.)
154134	Grommet (4 used), Tube Mounting (V104, V113)
155553	Insulator, Antenna Lead
138853	Insulator, Controls (8 used)
154264	Insulator, Interlock
154268	Insulator, VHF Tuner Shaft
154025	Insulator (Ring), Picture Tube
153109-1	Ion Trap
39012-102	Iron Core
39012-116	Iron Core (6 used on IF Strip)
154073	Iron Core, Horizontal Deflection Assembly
154122-2	Plate Cap, Tube (V115)
154122-3	Plate Cap, Tube (V114)
155253	Plate (Bearing), VHF Tuner Shaft
154075	Plate, Horizontal Width Control

Part No.	Description
154079-1	Ring (Retaining), Width Control Shaft (3 used)
154079-2	Ring (Retaining), Width Control Shaft Key
153580	Screw (Thumb), Deflection Yoke Assembly
155195	Shaft, Width Control
154077	Shaft, Width Control (Horizontal Deflection Assembly)
155027	Shaft, VHF Tuner
155851	Shim, used between Focuser & Picture Tube Neck
155276	Shield, Corona
155241	Shield, High Voltage
154143	Shield, Tube (2 used)
155842-1	Socket & Cable Assembly, Picture Tube
154203	Socket, Tube Shock Mounted (V113)
154192	Socket, Tube Shock Mounted (V104)
154127	Socket, Tube (V106, V107, V108, V110)
39388	Socket, Tube (V111)
154131	Socket, Tube (V105, V114)
154117	Socket, Tube (V109)
154130	Socket, Tube (V112)
154146	Socket, Tube (V101, V102, V103)
154074	Support, High Voltage Lead (Horizontal Deflection Assembly)
154381	Spring, Capacitor Mounting (C166)
154414-4	Spring (2 used), Deflection Yoke Assembly to Picture Tube Support
154072	Spring (Clip), Horizontal Deflection Assembly
154071	Spring (Strap), Horizontal Deflection Assembly
153979-2	Strap, Picture Tube
155398	VHF Tuner, Complete
154123	Wafer, Capacitor Mounting (C148)
154126	Wafer, Capacitor Mounting (C140)
155394	Washer (Extruded), Tone & Brightness Controls
138976	Washer (Extruded), Auxillary Controls (8 used)
149180	Washer (Spring), Width Control Shaft

CHASSIS 404 & 404-1

Part No.	Description
154495	Antenna Terminal Board & Bracket Assembly
155462	Barrier, Brightness Control
155375	Barrier, Tone Control
155750-1	Bracket (Upper Frame), Deflection Yoke Assembly
155514	Bracket (Lower Frame), Deflection Yoke Assembly
155199	Bracket, Tone & Brightness Controls
155741	Bracket (2 used), Focuser Mounting
154253	Bracket (Saddle), Deflection Yoke Assembly
155891	Bracket (R.H.), Picture Tube Support
155892	Bracket (L.H.), Picture Tube Support
155558	Cable, Twin Shielded
154276-2	Channel (Rubber), Deflection Yoke Assembly
156009	Coil (High Voltage), Horizontal Deflection Assembly
154180	Coil (Primary), Horizontal Deflection Assembly
155102-3	Connector, Picture Tube Anode
154124	Coupling, Width Control Shaft
153424-1	Cushion, Picture Tube Strap
153424-5	Cushion, Picture Tube Support (2 used)
155194	Disc, Fine Tuning (V.H.F.)
155788-1	Focuser (P.M.)
154134	Grommet (4 used), Tube Mounting (V104, V113)
155553	Insulator, Antenna Lead
138853	Insulator, Controls (7 used)
154264	Insulator, Interlock
154268	Insulator, VHF Tuner Shaft
153109-1	Ion Trap
39012-102	Iron Core
39012-116	Iron Core (6 used on IF Strip)
154073	Iron Core, Horizontal Deflection Assembly
154122-2	Plate Cap, Tube (V115)
154122-3	Plate Cap, Tube (V114)
155253	Plate (Bearing), VHF Tuner Shaft
154075	Plate, Horizontal Width Control
154079-1	Ring (Retaining), Width Control Shaft (3 used)

Part No.	Description
154079-2	Ring (Retaining), Width Control Shaft Key
153580	Screw (Thumb), Deflection Yoke Assembly
155195	Shaft, Width Control
154077	Shaft, Width Control (Horizontal Deflection Assembly)
155027	Shaft, VHF Tuner
155276	Shield, Corona
155241	Shield, High Voltage
154143	Shield, Tube (2 used)
155851	Shim, Used between Focuser & Picture Tube Neck
155842-1	Socket & Cable Assembly, Picture Tube
154203	Socket, Tube Shqck Mounted (V113)
154192	Socket, Tube Shock Mounted (V104)
154127	Socket, Tube (V106, V107, V108, V110)
39388	Socket, Tube (V111)
154131	Socket, Tube (V105, V114)
154117	Socket, Tube (V109)
154130	Socket, Tube (V112)
154146	Socket, Tube (V101, V102, V103)
149322	Support, Anode Connector
154074	Support, High Voltage Lead (Horizontal Deflection Assembly)
149671	Spring (Grounding), Deflection Yoke Assembly
154414-3	Spring, Picture Tube Mounting (2 used)
154072	Spring (Clip), Horizontal Deflection Assembly
154071	Spring (Strap), Horizontal Deflection Assembly
155887	Strap, Picture Tube
155351	Terminal Board, Horizontal Deflection Assembly
155398	VHF Tuner, Complete
154123	Wafer, Capacitor Mounting (C148)
154126	Wafer, Capacitor Mounting (C140)
155394	Washer (Extruded), Tone & Brightness Controls
138976	Washer (Extruded), Auxillary Controls (7 used)
149180	Washer (Spring), Width Control Shaft

PARTS LIST

Final Assembly and Cabinet - Models F-17TOLH & F-17TOLU

Part No.	Description	Part No.	Description
154377-2	Antenna Assembly (VHF)	154216-1	Knob, Contrast Control
154965	Antenna Assembly (UHF)	154265	Knob, Local-Distance-Suburban Switch
155709	Back & Power Cable Assembly (F-17TOLH)	154270	Knob, (2 used), Vertical & Horizontal Hold Controls
155493	Back & Power Cable Assembly (F-17TOLU)		
155163	Bracket (4 used), Chassis Mounting	155513-1	Knob, (2 used), Tone & Brightness Controls
155302-1	Cabinet	156206-1	Knob, Channel Selector (UHF)
153751	Clip (4 used), Window Retaining	156209-1	Knob, Volume Control
156234-1	Escutcheon (F-17TOLH)	156217-1	Knob, Channel Selector (VHF)
156234-2	Escutcheon (F-17TOLU)	154154	Mask, Window
144600	Grille Cloth	145211-22	Nut (Wing), Speaker Mounting
155306	Insulation (4 pieces used), Chassis Mounting Bracket	154210-10	Screw (4 used), Chassis Mounting
		155162	Washer (Extruded), Chassis Mounting Bracket
154214-1	Knob, Fine Tuning (VHF & UHF)	154101	Window, Tempered Glass

Final Assembly and Cabinet - Models F-17TOLBH & F-17TOLBU

Part No.	Description	Part No.	Description
154377-2	Antenna Assembly (VHF)	154216-2	Knob, Contrast Control
154965	Antenna Assembly (UHF)	154265	Knob, Local-Distance-Suburban Switch
155709	Back & Power Cable Assembly (F-17TOLBH)	154270	Knob (2 used), Vertical & Horizontal Hold Controls
155493	Back & Power Cable Assembly (F-17TOLBU)		
155163	Bracket (4 used), Chassis Mounting	155513-2	Knob (2 used), Tone & Brighiness Controls
155302-2	Cabinet	156206-2	Knob Channel Selector (UHF)
153751	Clip (4 used), Window Retaining	156209-2	Knob, Volume Control
156234-1	Escutcheon (F-17TOLBH)	156217-2	Knob, Channel Selector (VHF)
156234-2	Escutcheon (F-17TOLBU)	154154	Mask, Window
145472	Grille Cloth	145211-22	Nut (Wing), Speaker Mounting
155306	Insulation (4 pieces used), Chassis Mounting Bracket	154210-10	Screw (4 used), Chassis Mounting
		155162	Washer (Extruded), Chassis Mounting Bracket
154214-2	Knob, Fine Tuning (VHF & UHF)	154101	Window, Tempered Glass

Final Assembly and Cabinet - Models F-21TOLH & F-21TOLU

Part No.	Description	Part No.	Description
154377-2	Antenna Assembly (VHF)	155513-1	Knob (2 used), Tone & Brightness Controls
154965	Antenna Assembly (UHF)	156206-1	Knob, Channel Selector (UHF)
155995	Back & Power Cable Assembly (F-21TOLH)	156209-1	Knob, Volume Control
155996	Back & Power Cable Assembly (F-21TOLU)	156217-1	Knob, Channel Selector (VHF)
155163	Bracket (4 used), Chassis Mounting	154333-3	Mask, Window
155890	Bracket, Window Reinforcing	155257-1	Moulding (Rubber), Window
155250-1	Cabinet	145211-22	Nut (Wing), Speaker Mounting
156234-1	Escutcheon (F-21TOLH)	156028	Nut (Wing), Trim Strip Mounting
156234-2	Escutcheon (F-21TOLU)	148464-7	Screen, Speaker Baffle
144600	Grille Cloth	154210-10	Screw (4 used), Chassis Mounting

154214-2	Knob, Fine Tuning	155464	Wood Anchor
154216-2	Knob, Contrast Control	155350-5	Window, Tempered Glass

TURRET TUNERS

Because tuners operate at very high frequencies, considerable care must be taken when working on them. If the following simple precautions are observed no difficulty should be encountered:

1. Don't assume the tuner is at fault until the other circuits of the receiver have been carefully checked.
2. Always use exact replacement parts.
3. When troubleshooting a tuner do not disturb the parts or lead position-ing.
4. When making a replacement, duplicate the positioning and lead dress of the original part.
5. Do not disturb any of the tuner adjustments unless you are familiar with the proper adjustment procedure.

REPLACING TUNER COIL STRIPS. — TU-1, TU-2, TU-3, TU-4, TU-6, TU-8, TU-10

1. Remove the tuner bottom cover by pulling its front end away from the tuner and unhooking its rear edge.
2. Using a screwdriver pry the spring finger, holding the strip, away from the turret end plate and lift out the strip.
3. To install the new strip, insert the two projections into the holes in the detent ring.
4. Pry the spring finger away from the end plate, push the strip in place, and let the spring finger snap over the end of the strip.

TU-5, TU-7, TU-9

1. Remove the four screws holding the tuner bottom cover and remove the cover.
2. Using a screwdriver, push the spring finger holding the strip toward rear of tuner and lift out strip.
3. To install new strip, insert end having smaller projection into the hole in the detent plate.
4. Pry the spring finger away from rear of drum and push the strip into place. Let spring finger snap back into place making sure that projection on end of strip seats correctly in hole in spring finger.

CLEANING THE TUNER CONTACTS. — Remove the tuner bottom cover and several of the coil strips as described in the previous paragraph. Rotate the turret so that the wiping contacts are accessible through the opening made by removing the strips. Clean the coil strip and wiping contacts with a soft cloth moistened with "No Noise".

ADJUSTING THE TENSION OF THE WIPING CONTACTS.—Remove the tuner bottom cover and several of the coil strips. Rotate the turret to permit access to the contacts through the opening thus provided. Using a small screwdriver bend each contact spring until it extends approximately ⅛ inch inward from the surface of the plastic contact-mounting plate.

To check the tension of the spring contacts, place the turret in a position between channels and note the clearance between the contact spring and the surface of the coil strip. The clearance should be approximately 1/64 inch.

REMOVING THE TUNER TURRET DRUM.—

1. Remove the tuner bottom cover.
2. Remove the fine tuning bracket from front of tuner.
3. Remove the front and rear retainer springs by pushing the straight end of each spring toward the top of tuner.
4. Slip the turret drum out of the tuner.

OSCILLATOR TUBE REPLACEMENT. —Due to differences in interelectrode capacitance, replacement of the oscillator tube may result in considerable oscillator frequency shift. This condition can be avoided by trying several tubes and selecting the one which causes the least frequency shift. If it is necessary to use a tube which causes excessive frequency shift the oscillator frequency must be adjusted.

INDIVIDUAL CHANNEL OSCILLATOR ADJUSTMENT.—When the oscillator frequency is correct for some channels but not for others, the individual-channel slugs should be used to correct the oscillator frequency on channels requiring adjustment. Adjust the slugs as follows:

1. Tune the set to the channel requiring adjustment.
2. Remove the Fine-Tuning and Station Selector knobs. If set has a UHF dial, remove the dial.
3. Set the Fine-Tuning control in the center of its mechanical range. If the Fine-Tuning control does not have a stop, turn the control so that the flat on the shaft faces down.
4. Using an insulated alignment tool adjust the slug for best picture and sound. The slug is accessible through the hole just to the right of the tuning shaft.

OVERALL OSCILLATOR ADJUSTMENT.—TU-5, TU-7 and TU-9 are provided with an overall oscillator adjustment. When replacement of the oscillator tube, or components other than a channel strip, causes a change in oscillator frequency, this adjustment may be used to correct the oscillator frequency. The adjustment should be made as follows:

1. Tune the set to the highest channel station available.
2. Set the Fine-Tuning at the center of its mechanical range. If the Fine-Tuning control does not have a stop, turn the control so that the flat on the shaft faces down.
3. Adjust G (figure 2) for best picture and sound.
4. Check the tuning on all available channels and adjust the individual channel slugs if necessary.

TUNER IDENTIFICATION

Chassis	Tuner		Input Impedance	Tubes		Turret Positions	Shaft Lengths, Inches	Output I. F.	Channel Strips

TUNER INTERCHANGEABILITY

All tuners that are used on the same chassis are interchangeable. In a few cases special instructions are required. For the technician's convenience an interchangeability chart is shown below which contains these instructions. When a tuner is interchanged the mixer output coil (E in figure 2) of the new tuner should be readjusted. The alignment procedure for the mixer output coil will be found on the service data sheet for the chassis involved.

Chassis	Symbol	Tuner Part Number	Remarks
RA-160-162-162B	TU-1 TU-2	21 009 121 21 009 122	TU-1 and TU-2 are directly interchangeable.
RA-164-165	TU-3 TU-4 TU-5	21 010 781 21 010 782 89 012 601	TU-3, TU-4 and TU-5 are directly interchangeable.
	TU-6	21 010 783	TU-6 may be interchanged with TU-3, TU4 or TU-5 by adding L220 (see production change 6552074 in this issue). TU-3, TU-4 and TU-5 may be interchanged with TU-6 by removing L220.
RA-166-167-170	TU-7 TU-8	89 012 901 89 012 971	TU-7 and TU-8 are directly interchangeable.
RA-168-169-171	TU-9 TU-10	89 012 911 89 013 021	TU-9 and TU-10 are directly interchangeable.

TUNER ALIGNMENT

TEST EQUIPMENT. — To properly align a Du Mont switch turret tuner the following test equipment is required:

Oscillograph

Vertical amplifier must have good 60 cycle response and a vertical deflection sensitivity of at least 0.1 rms volts per inch.

Sweep Signal Generator

Frequency range—54 to 216 mc.
Sweep—At least 10 mc.

Marker Signal Generator

Frequency range—54 to 216 mc.
Should have built-in calibrator crystal.

BENCH SET-UP.— The following precautions should be observed when setting up equipment for tuner alignment purposes:

1. Connect all equipment to a common ground. A metal topped bench is preferred, however heavy bonding straps may be used.
2. The sweep generator output *must* be properly matched to the tuner input. A suitable matching device is shown in figure 1. It consists of a connector plug, which fits the generator output and three half-watt resistors.
3. Before attempting to perform an actual alignment check the bench set-up by connecting the test equipment to a chassis which is operating properly and observe the tuner curves. If the curves are correct it can be assumed that the bench set-up is functioning properly.

FREQUENCY TABLE

Channel Number	Channel Freq., MC	Video Carrier, MC	Sound Carrier, MC	21.25 MC HF Osc., MC	41.25 MC HF Osc., MC
2	54-60	55.25	59.75	81	101
3	60-66	61.25	65.75	87	107
4	66-72	67.25	71.75	93	113
5	76-82	77.25	81.75	103	123
6	82-88	83.25	87.75	109	129
7	174-180	175.25	179.75	201	221
8	180-186	181.25	185.75	207	227
9	186-192	187.25	191.75	213	233
10	192-198	193.25	197.75	219	239
11	198-204	199.25	203.75	225	245
12	204-210	205.25	209.75	231	251
13	210-216	211.25	215.75	237	257

The oscillator frequencies shown in the above table are for reference only. Final oscillator frequency adjustments should always be made with the available TV station signals.

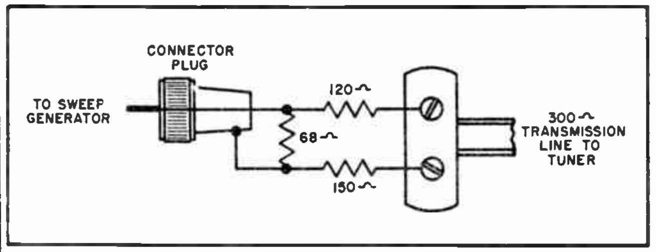

Figure 1. Matching device suitable for tuner alignment work. Keep the lead lengths between the connector plug and the resistor network as short as possible.

Turret Tuner ALIGNMENT PROCEDURE

a. Apply −3 volts to the tuner green a-g-c lead by connecting two small flashlight batteries in series between the tuner a-g-c lead and ground.

b. Connect the tuner antenna transmission line terminal board to the generator matching network.

c. Connect the vertical amplifier terminals of the oscillograph to the tuner look point (D in figure 2) using a short length of coax. Connect a 10K resistor between the look point and the center lead of the coax. Ground the coax outer conductor to the tuner chassis.

d. Disable the horizontal sweep circuits by removing the horizontal oscillator and deflection amplifier tubes.

STEP	SWEEP GEN.	MARKER FREQ.	ADJUST
1	Adjusted to sweep channel 13.	215.75 mc sound 211.25 mc video	Check for curve shown below. If necessary, adjust A and B in figure 2 for proper bandpass, and C in figure 2 for maximum amplitude with equal peaks.
2	Adjust to sweep each channel in turn.	Correct markers for each channel (see frequency table on page 19).	Above adjustment sufficient for all channels. Individual channels may be favored if desired.
3	Tune to each channel on which a TV signal is available.		Set fine tuning control in the center of its mechanical range. If fine tuning control does not have a stop turn control shaft so that flat on shaft faces downward and adjust oscillator slugs. Adjust each oscillator slug for best picture and sound using non-metallic alignment tool.

NOTES

Slug A adjusts low frequency side of curve, slug B the high frequency side and slug C adjusts the r-f stage bandpass.

Some tuners have slug F which adjusts a 40 mc i-f trap. This slug may be reset if additional i-f rejection is required. Its adjustment affects the low channel curves slightly.

Some tuners have slug G which adjusts the oscillator frequency. It should be reset only if a channel strip oscillator slug cannot be properly set for its channel.

Failure to obtain the proper curves can be caused by a misadjusted oscilator slug or mixer output coil E. The adjustment of the mixer output coil is included in the i-f alignment procedure.

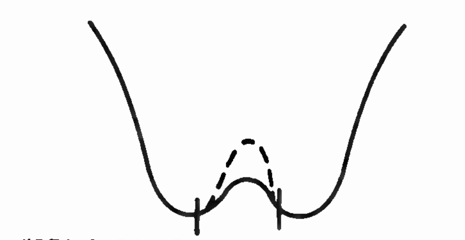

Figure 3—Set video carrier just inside peak. Sound carrier position may vary somewhat. On channel 13 the two peaks may be equal, varying slightly in amplitude on other channels.

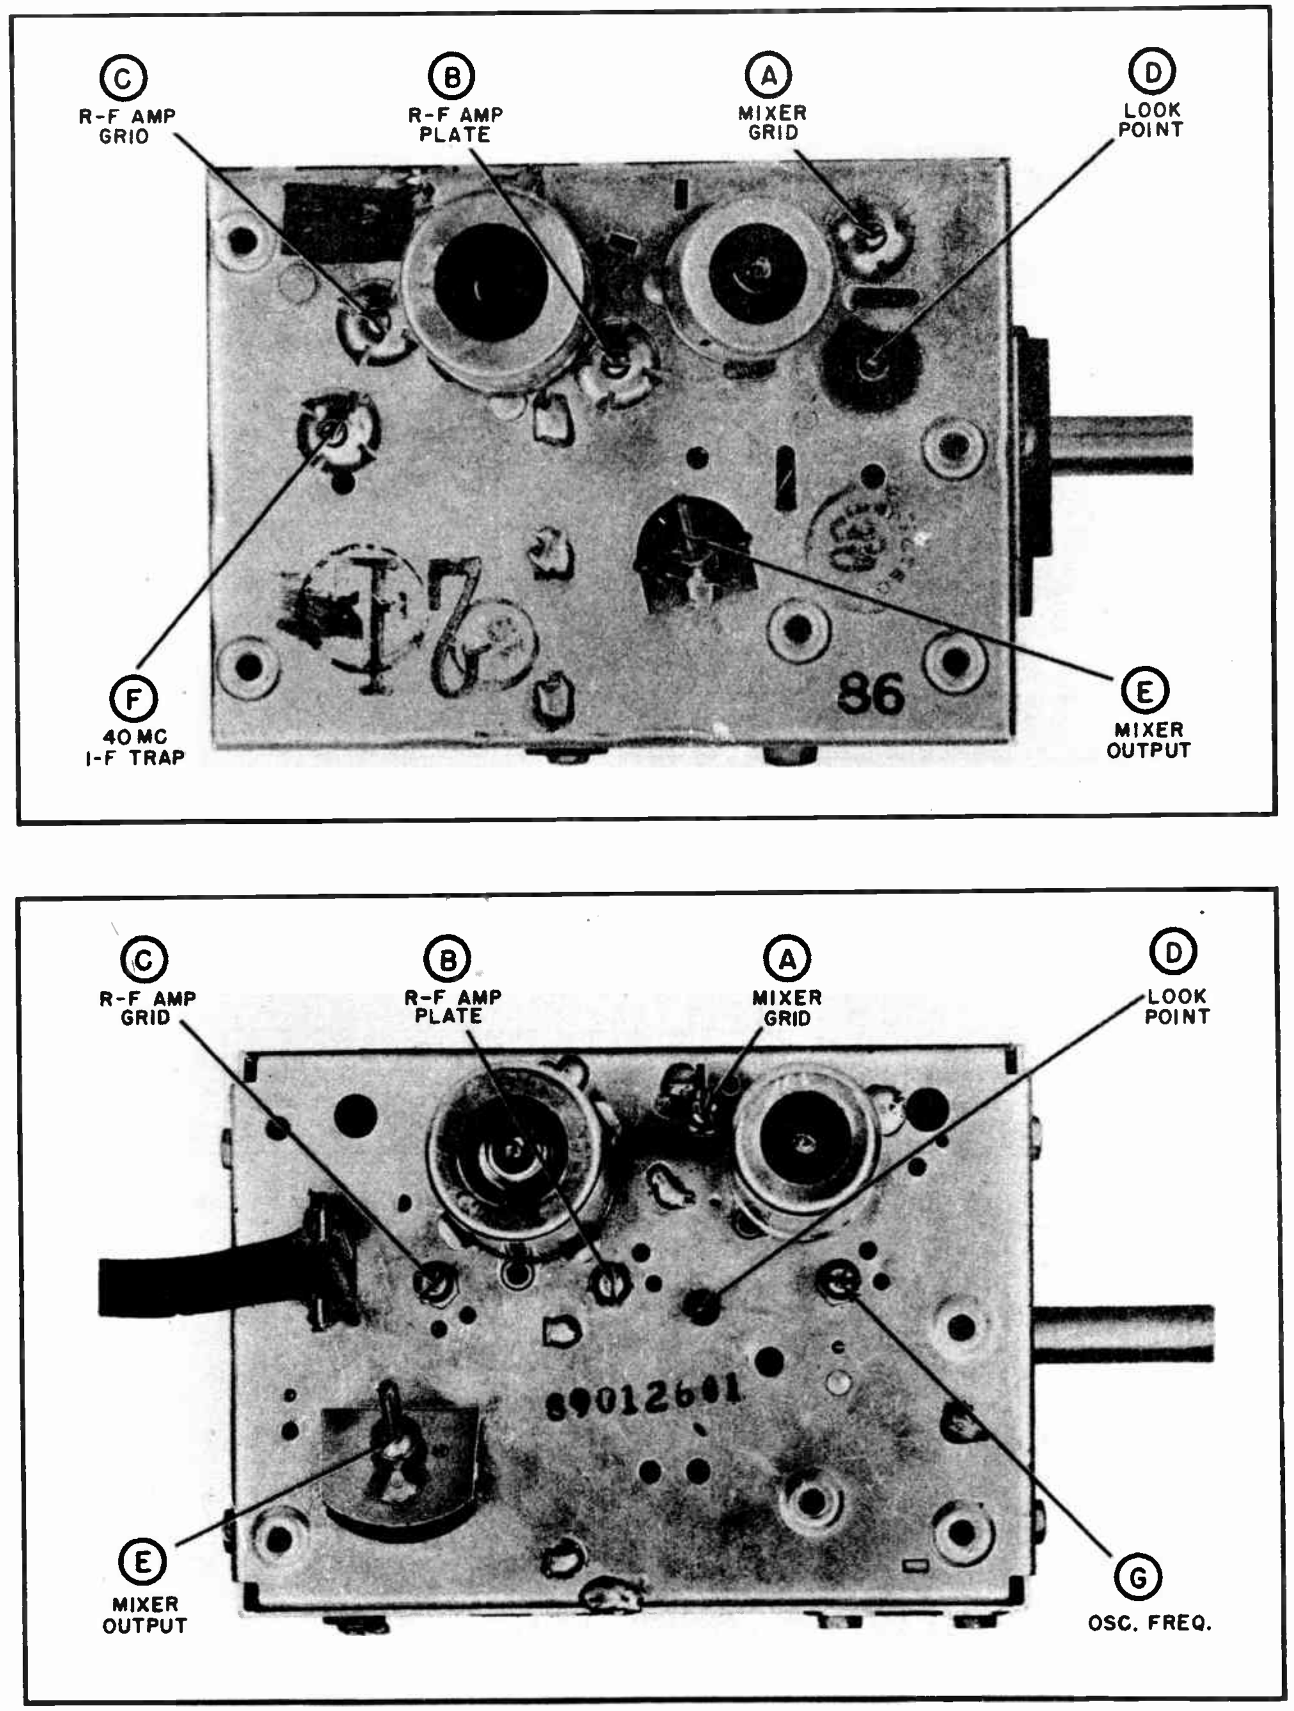

Figure 2. The two basic turret tuners and their adjustment slugs. The upper illustrations is for TU-1, 2, 3, 4, 6, 8 and 10 and the lower is for TU-5, 7 and 9. An explanation of the tuner slug functions will be found on the next page.

SERVICING TURRET TUNERS

PART II

A faulty tuner may produce any of the following symptoms; weak picture and sound, no picture and sound, microphonics, and intermittent noise.

When the picture and sound are weak or completely absent the tuner tubes may be checked by substitution. If the tubes are not at fault return the *original* ones to their sockets and check the video i-f and detector stages of the receiver before troubleshooting the tuner.

After it has been determined that the balance of the receiver is not at fault proceed to check the tuner in the following manner:

1. Measure the voltages at the socket pins. The undersides of the sockets can be reached by removing the tuner side plate. A quick check can be made by removing each tube from its socket and checking the voltages from the top of the socket. Using the latter method the voltages will not agree with those shown in the tables; however a quick check for the presence of the B+ voltages can be made.

2. Measure the resistances at the socket pins.

3. Remove the tuner bottom cover and turret drum and inspect for burnt parts, broken leads, parts touching turret drum, etc.

4. Check resistances of suspected parts.

5. Replace defective parts, clean all contacts, check the tension of the wiping contacts and reassemble the tuner for final check.

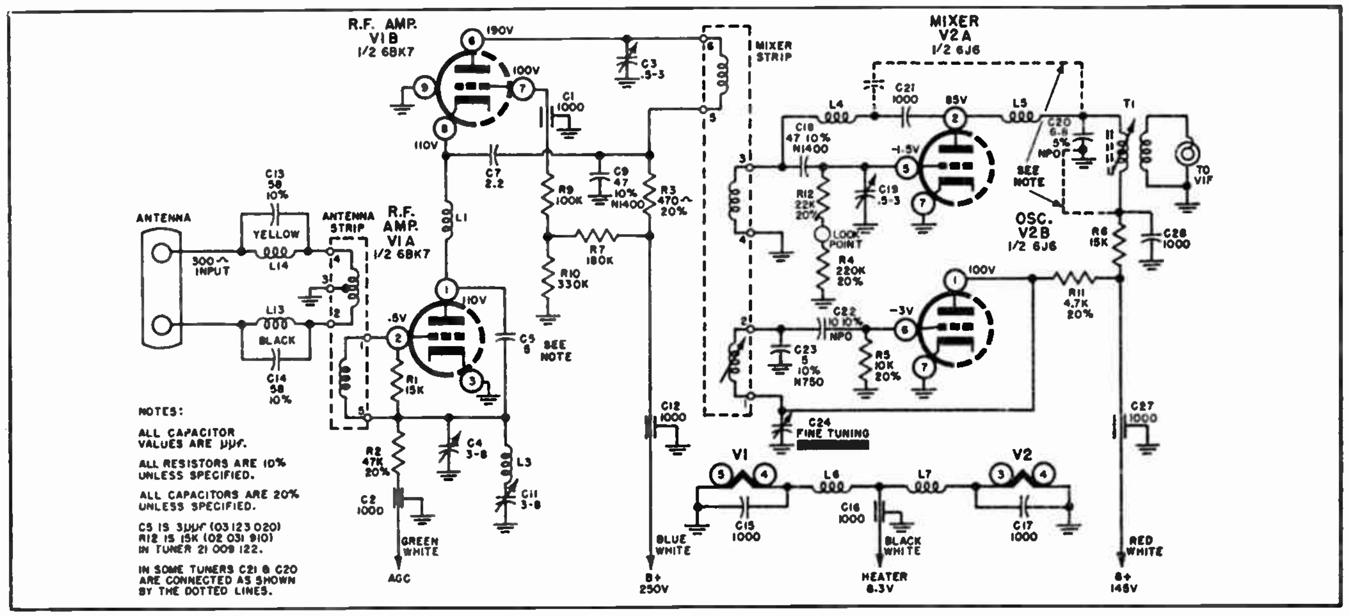
The cause of microphonics or intermittent noise can usually be located by substituting tubes and by careful inspection of all parts and contacts. The chart below outlines the procedures to be followed for various tuner faults.

TROUBLESHOOTING PROCEDURES

Symptom	Procedure
Weak or No Sound and Picture (all channels)	1. Check V1 and V2 by substitution. 2. Check tuner voltage and resistance readings, and associated components. (21 mc Tuners) Check mixer output capacitor and output tab for leakage or shorts.
Weak or No Sound and Picture (one channel)	1. Check incorrect or defective channel strip in tuner drum. 2. Check tension and clean contact springs.
Inoperative-Tubes, Component Check OK	1. Remove coil drum. Inspect for components rubbing against the coil drum, especially at the mixer output coil.
Microphonics	1. Check 6J6 properly seated in its socket. 2. Check 6J6 by substitution. 3. Tighten the 6J6 socket pins.
Oscillator Slugs Do Not Adjust Properly (all channels)	1. Check 6J6 by substitution. 2. Check capacitors in oscillator circuit.
Oscillator Slug Turned Too Far In—Cannot Be Adjusted	1. Remove bottom cover. 2. Rotate the tuner drum and remove the affected coil strip. 3. Loosen slug thread spring. 4. Tap slug back in position and reset its thread spring.
Channel 13 Oscillator Slug Will Not Adjust Properly (21 mc tuner)	1. Check mixer output coil adjustment.
Channel 2 Oscillator Slug Will Not Adjust Properly (21 mc tuner)	1. Check mixer output circuit.
Flashing When Tapped (2-section strip tuners)	1. Check position of fiber washer on drum shaft. The washer should be between the drum retaining spring and the Fine Tuning control spring.
Heavy Picture Beat (all channels)	1. Check adjustment of mixer output coil.

TURRET TUNER SERVICE DATA

TUNERS TU-1 (21 009 121) AND TU-2 (21 009 122)

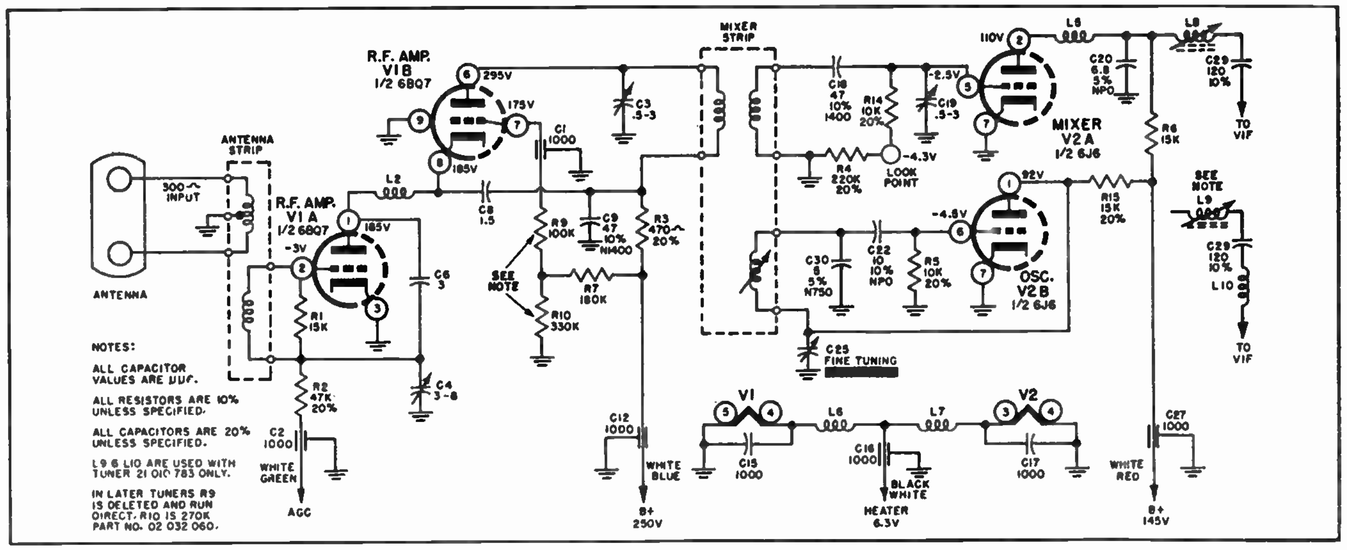


Resistance readings for TU-1 and TU-2 are shown below. All resistance measurements were taken with the tuner wired in the chassis. Voltage readings are shown above in the schematic.

		1	2	3	4	5	6	7	8	9
V1	**6BK7/ 6BQ7**	INF	90K/200K*	0	.1	0	11K	220K	INF	0
V2	**6J6**	18K	28K	.1	0	240K	10K	0		

*Depends upon High-Low Signal Switch position.

TUNERS TU-3 (21 000 781), TU-4 (21 000 782) AND TU-6 (21 000 783)



Resistance readings for TU-3, TU-4 and TU-6 are shown below. All resistance measurements were taken with the tuner wired in the chassis. Voltage readings are shown above in the schematic.

		1	2	3	4	5	6	7	8	9
V1	**6BQ7**	90K	85K	.05	0	230K	10K	0

The new Du Mont RA-166, 167, 170 and 171 chassis are high-performance units designed to provide high-definition pictures and outstanding fringe area reception. RA-166, 167 and 170 chassis are designed to receive all VHF channels and are easily adapted for UHF. The RA-171 chassis is designed to receive all 82 VHF and UHF channels. The circuitry of all chassis is of similar design. The RA-170 and RA-171 are Custom chassis and include a tone control, plus provisions for attachment of a phonograph with a conveniently located Phono-TV switch.

Among the many outstanding features found in these new chassis are:

1. Low-noise cascode 12-channel switch-turret VHF tuner for superior fringe area performance.
2. One dial tuning of all 82 VHF and UHF channels on VHF-UHF models.
3. Non-UHF models easily adapted for UHF by substitution of tuner strips.
4. Du Mont's Selfocus* Teletron*—provides fully automatic focus—eliminates focus control.
5. Four-stage, 41-mc, stagger-tuned, intercarrier video i-f strip for maximum sensitivity and high-definition pictures.
6. Fast acting keyed and delayed AGC, provides instantaneous control of receiver gain and automatically adjusts for both strong and weak signals.
7. Vertical retrace blanking circuit—eliminates retrace lines at all control settings.
8. Conveniently located controls—the most used controls are on the front panel, rear controls are easily accessible.
9. Shipped completely adjusted ready for installation.

ELECTRICAL AND MECHANICAL SPECIFICATIONS

POWER RATING
- Source .... 105-129 volts, 60 cycle a-c
- Consumption
  - RA-166, 167 .... 225 watts
  - RA-170, 171 .... 240 watts (phono included)

NUMBER OF TUBES
- RA-166, 167, 170 .... 22 plus 3 Rectifiers and 1 CRT
- RA-171 .... 23 plus 3 Rectifiers, 2 Crystals and 1 CRT

OPERATING CONTROLS .... Station Selector, Fine Tuning and UHF Tuning, Contrast, Volume and On-Off.

HIDDEN FRONT PANEL CONTROLS
- RA-166, 167
  - Operating .... Brightness, Vertical Hold and Horizontal Hold
  - Service .... Vertical Size and Vertical Linearity
- RA-170, 171
  - Operating .... Brightness, Tone, Vertical Hold, Horizontal Hold and Phono-TV Switch
  - Service .... Vertical Size and Vertical Linearity

ANTENNA INPUT IMPEDANCE
- VHF .... Balanced 300 ohm
- UHF .... Balanced 300 ohm

FREQUENCY RANGE
- RA-166, 167, 170 .... Channels 2 through 13
- RA-171 .... Channels 2 through 83

INTERMEDIATE FREQUENCIES
- Video I-F Carrier .... 45.75 mc
- Sound I-F Carrier .... 41.25 mc
- Sound Intercarrier Frequency ... 4.5 mc
- Adjacent Channel Sound Trap ... 47.25 mc

PICTURE TUBE
- Type RA-166: 17HP4; RA-167, 170, 171: 21FP4A
- Dimensions .... RA-166: 11 x 14¼; RA-167, 170, 171: 13⅞ x 19⅛

CRT HIGH VOLTAGE .... 14.5 kv

SWEEP DEFLECTION .... Magnetic

FOCUS .... Automatic Electrostatic

LOUDSPEAKER
- Size .... Table Model: 5 inch; Console: 10 inch
- Impedance .... 3.2 ohm at 400 cycles

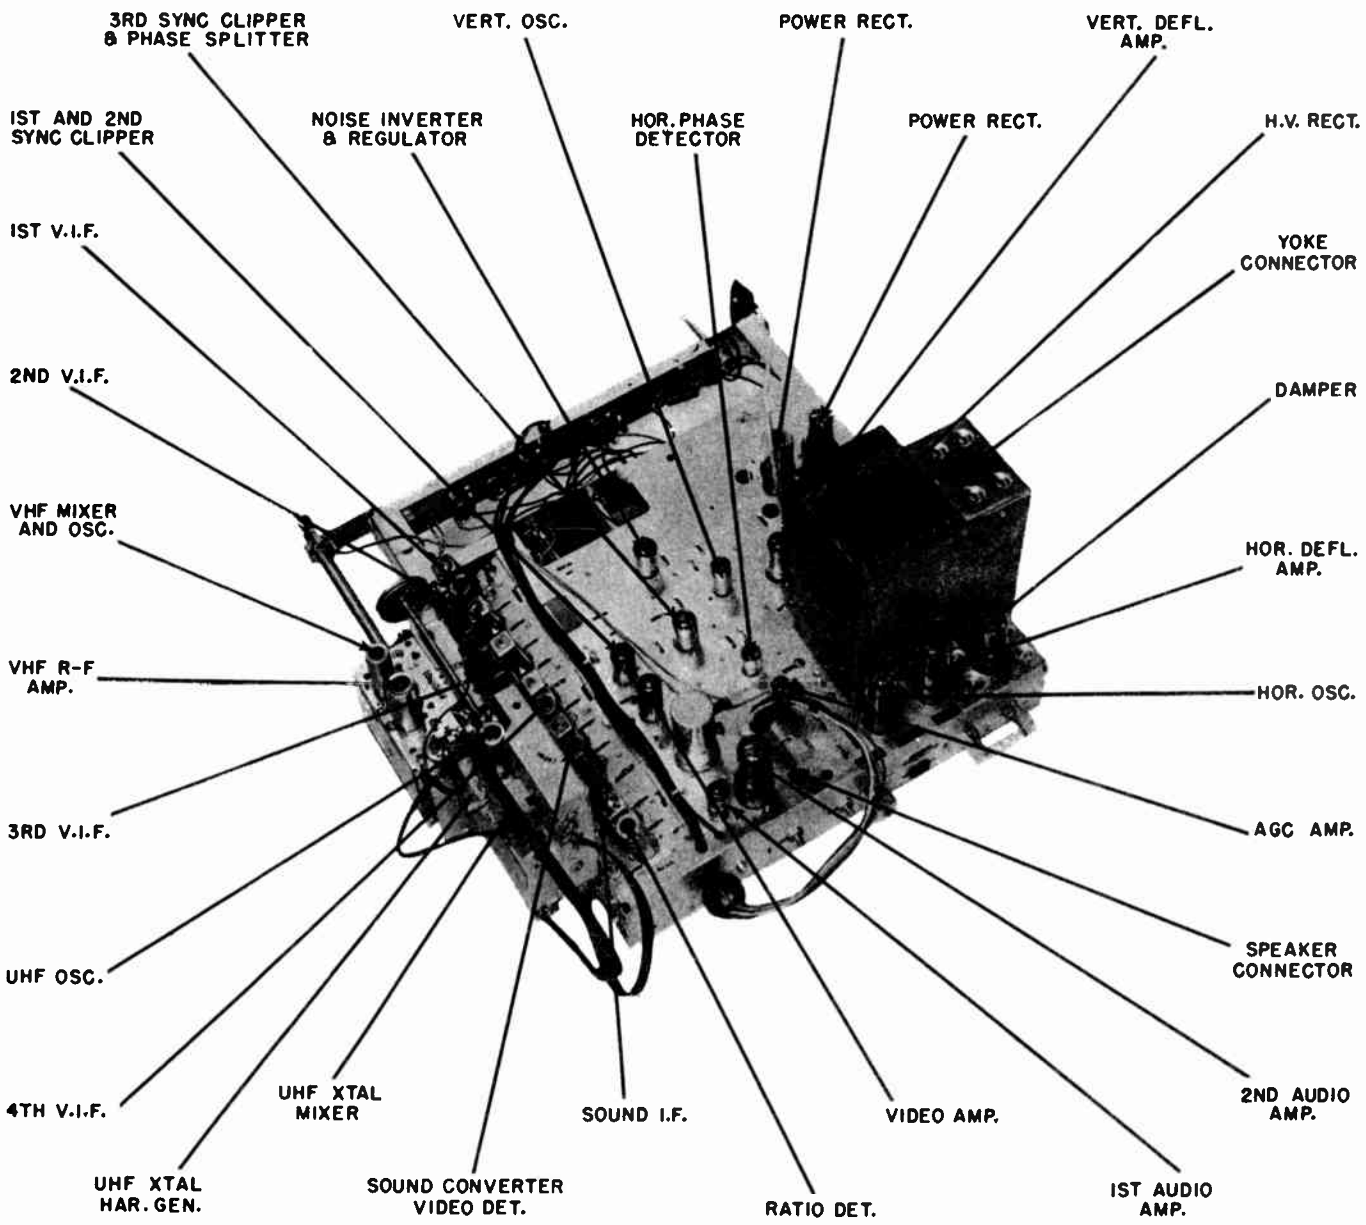
CIRCUIT DESCRIPTION

GENERAL. — A block diagram of the RA-166-167, RA-170-171 chassis is shown in figure 1. The RA-171 is a UHF-VHF receiver equipped with separate UHF and VHF tuners coupled to a single control shaft. In the RA-166, 167 and 170, only the VHF tuner is provided. The VHF tuners in all models are of similar design.

The VHF tuner is of the switch-turret type. 13 switch positions are provided. When the tuner is switched to the thirteenth position, in receivers equipped with UHF tuners, the input of the VHF tuner is switched to the output of the UHF tuner, and the necessary circuits are switched to enable the VHF tuner to operate as a 41 mc i-f amplifier.

The video i-f strip consists of four stagger-tuned 6CB6 amplifier stages. The video i-f is 45.75 mc and the sound i-f is 41.25 mc. Separate video detector and sound



The RA-171 Chassis

converter diodes are provided. This provision increases the amount of signal available at the input of the sound i-f amplifier, as compared to that obtained when a single diode is used. A single high-gain video-amplifier stage is employed.

The sync takeoff is in the plate circuit of the video amplifier. Three sync-clipper stages are used. The output of the third sync clipper is fed to a phase-splitter stage which provides out-of-phase sync signals required for operation of the horizontal phase detector. A multivibrator type horizontal-oscillator circuit is employed. A ringing circuit is provided in the oscillator circuit for improved stability.

A single 6BQ6-GT is used in the horizontal-output stage. A high-efficiency flyback-type high-voltage supply provides 14.5 kv for application to the CRT.

A keyed a-g-c circuit similar to that employed in RA-164-165 chassis is used. The a-g-c system also includes a tuner a-g-c delay circuit to provide a wide range of control for maximum performance in fringe - and strong - signal areas. A voltage regulator tube is provided in the a-g-c amplifier circuit to improve a-g-c stability.

The vertical-sync signal is taken off at the cathode of the phase-splitter stage and applied to a printed-circuit integrator network. A multivibrator circuit performs the combined functions of vertical oscillator and output stage.

As previously mentioned a separate sound-converter diode is provided. The output of the sound converter is applied to the input of a 4.5 mc intercarrier sound i-f stage. A ratio sound detector is employed. To secure optimum sound quality two stages of audio amplification are used.

In the following paragraphs a more detailed description is given of those circuits which are not familiar to the technician.

UHF - VHF TUNERS. — RA-171 chassis are designed to receive all 82 UHF and VHF channels and are equipped with both UHF and VHF tuners. RA-166, RA-167 and RA-170 chassis are designed to receive the 12 VHF channels and are easily converted for UHF reception. The VHF tuners used in all models are of similar design. They are of the conventional switch-turret type, similar to those used in RA-160-162 and RA-164-165 Telesets. Since most technicians are familiar with this type of tuner it will not be described in detail here.

A block diagram of the VHF and UHF tuners, showing the circuit arrangement when receiving the UHF channels, is shown in figure 2. The UHF tuner is of the continuous-tuning type and provides coverage of the complete UHF television band (470-890 mc). 300-ohm balanced input is used. The incoming UHF signal is coupled to a tuned preselector. The preselector consists of two tuned circuits which pass the desired channel and attenuate all other signals. The output of the preselector is applied to a crystal mixer.

The UHF tuner oscillator operates at one half the required frequency and its second harmonic is injected into the mixer circuit. The second-harmonic signal is obtained by applying the oscillator fundamental to a crystal harmonic generator. A tuned circuit is provided to select the proper harmonic.

The oscillator frequency is chosen to provide a second harmonic 41.25 mc higher than the incoming sound carrier, in order to produce a sound i-f of 41.25 mc and a video i-f of 45.75 mc in the output of the mixer. A link-coupling network is provided in the mixer output circuit. The UHF tuner output signals are fed from this coupling circuit to the input of the VHF tuner by means of a short length of 73-ohm coax.

The VHF tuner is provided with 13 switch-turret positions. To receive the UHF channels the tuner is switched to the thirteenth, or UHF position. In this position the tuner oscillator is disabled and the r-f and mixer stages operate as 41-mc i-f amplifiers. Note that the incoming signal is converted only once and that the UHF tuner is a true tuner, not a converter.

When receiving VHF signals the B+ is removed from the UHF tuner and the input of the VHF tuner is connected to the VHF antenna. This is accomplished by a slide switch which is actuated by the Station Selector knob.

PRESELECTOR CIRCUITS. — As previously mentioned the preselector consists of two inductively-coupled tuned circuits. Conventional tuned-circuit construction cannot be used in the UHF tuned circuits, consequently a special type high-Q low-loss circuit referred to as a capacitively-tuned, shorted coaxial line is used as shown in figure 3.

To aid in explanation of the preselector a low-frequency equivalent circuit is shown in figure 4A. The circuit configuration of the preselector is shown at B. The preselector tuned circuits are labeled 1 and 2.

The construction of these circuits is based upon the fact that transmission lines exhibit the same properties as do tuned circuits. For this reason the preselector circuits are referred to as transmission-line tuned circuits. For the benefit of the technician who is not familiar with this property of transmission lines a brief discussion follows.

An ordinary parallel-resonant circuit consists of an inductance and a capacitance as shown in figure 5A. At its resonant frequency this circuit presents a very high impedance. At frequencies above its resonant frequency the inductive reactance, X_L, is greater than the capacitive reactance, X_C. Since the greatest current flows through the smallest reactance, the capacitor current is greater than the inductor current, and the circuit is predominantly capacitive.

At frequencies below the resonant frequency of the circuit the capacitive reactance, X_C, is greater than the inductive reactance, X_L, the current through the inductor

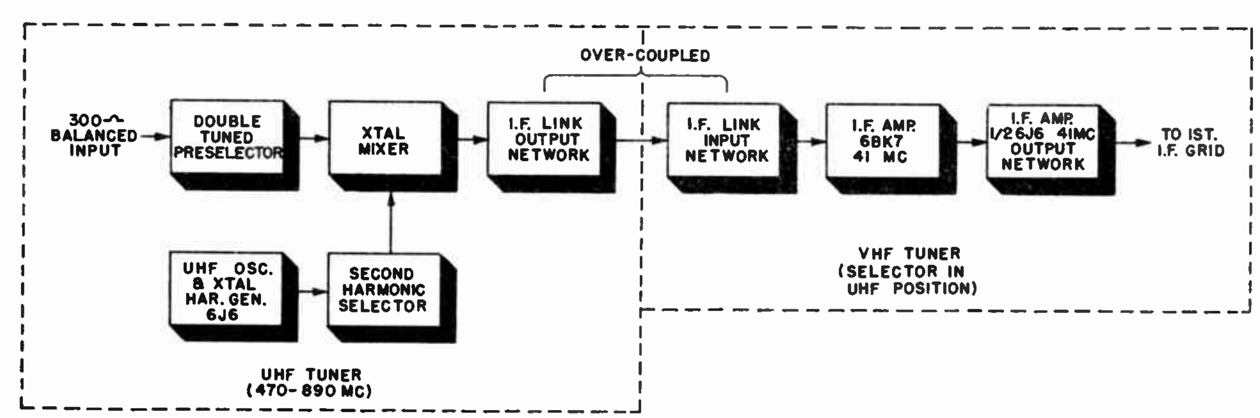


Figure 2. Block diagram of UHF-VHF Tuners.

is greater than that through the capacitor, and the circuit is predominantly inductive.

A section of transmission line an exact electrical quarter-wave length long, shorted at one end, acts just the same as a parallel-resonant circuit. This property of transmission lines is due to the fact that it has both capacitance and inductance, as shown in figure 5B. The line shown is of the coaxial type. When current passes through the inner lead a field is set up around the lead, conseqently the lead has inductance. The capacitance necessary to complete the tuned circuit exists between the inner and outer conductors and is represented by the dotted capacitors in figure 5B. This capacitance is referred to as distributed capacitance and while it is not a "lumped constant" capacitor, as we ordinarily expect to find in a tuned circuit, it performs the same function.

As in the parallel-resonant circuit in figure 5A, the quarter-wave line is a high impedance at its resonant frequency. Above its resonant frequency it is predominantly capacitive, while *below its resonant frequency it is predominantly inductive.* Stating it another way, a transmission line shorter than a quarter wavelength at a given frequency is inductive at that frequency. The fact that a shorted section of transmission line is inductive under certain conditions is important because this characteristic is taken advantage of in the design of the UHF tuner.

A transmission line less than a quarter-wavelength long can therefore be used as the inductor in a parallel-resonant circuit. By adding sufficient capacitance between the inner and outer conductors, as shown in figure 5C, it can be resonated at the desired frequency. If the capacitor is made variable the circuit will be tunable over a band of frequencies.

Comparing figure 5C with the preselector tuned circuits in figure 4B we can see that they are the same. A form of link coupling is used between the preselector tuned circuits. Since the inductance for the circuits is supplied primarily by the inner conductor of the transmission line, the link must be located inside of the line. Partial turns of wire serve as the two links required (3 and 4 in figure 4B). They are brought out through holes in the outer conductors.

The same type of inductive coupling is also used between the input tuned circuit and the antenna. Two coupling loops are used to provide a 300-ohm balanced input (5 in figure 4B).

The output of the second preselector circuit is coupled to the mixer by means of a tap on the inner conductor (6 in figure 4B). This method of coupling is the same as the tapped coil of figure 4A.

The physical construction of the preselector tuned circuits is shown in figure 6. The box in which the tuner is mounted forms parts of the outer conductors of the tuned lines. The inner conductors are hollow U's, as shown in the figure. The inner conductors also serve as the stator plates of the tuning capacitors.

A shield located between the first and second preselector circuits forms one side of the outer conductors of the tuned lines.

The tuning-capacitor rotor plates are of the straight-line frequency type. Four rotor plates are used in each capacitor. The end plates are slotted so that they may be bent in sections to correct tracking and passband characteristics over the tuning range.

Each line section is provided with a metal tab attached to the inner surface of the outer conductor. These tabs are used as trimmer capacitors to correct for normal production variations. They are adjusted by bending them closer to or farther from the inner conductors of the tuned lines, and are adjusted with the tuning-capacitor rotors completely unmeshed, to establish the high end of the tuning range.

As shown in figure 3, two coupling loops are used between the preselector tuned circuits. The upper loop, L162, is effective primarily at the low-frequency end of the band, while the lower loop, L163, is effective primarily at the high-frequency end of the band.

THE UHF OSCILLATOR. — The UHF oscillator uses a push-pull, tuned-plate, tuned-grid circuit. To avoid the need for a special tube type, and permit the use of an existing type of known reliability, the oscillator is operated at one half the required frequency. Operation in this manner also results in greater stability and uniformity in manufacture.

A 6J6 dual triode is used in the oscillator. The plate tank coil is a flat piece of sheet metal shaped as shown in figure 6. This type of construction results in greater uniformity of inductance and lead dress.

Plate-circuit tuning is accomplished by means of split-stator capacitor C4. The rotor of this capacitor is ganged with those of the preselector and harmonic selector circuits. The grid circuit is tuned by L153 which is self resonant at the lower end of the tuning range and maintains the proper oscillator signal amplitude at these frequencies.

C156 and C157 provide the feedback necessary to maintain oscillation. Coil L2 is provided to permit adjustment of the plate circuit inductance. C152 is used to adjust the oscillator tracking at the high end of the tuning range.

In order to produce a 41.25-mc sound i-f and a 45.75-mc video i-f the local-oscillator signal must be tunable from 517 mc to 931 mc. Since the oscillator operates at half the required frequency it tunes from 258.5 mc to 465.5 mc.

The oscillator output is applied to a crystal harmonic generator, CR101, by means of coupling link L164. The crystal distorts the oscillator signal making it rich in harmonics. From the harmonic generator the signal is fed to a harmonic-selector circuit. The harmonic selector is a tuned circuit identical to the preselector circuits, except for frequency range. It is tuned to the second harmonic of the oscillator, the frequency required for mixer injection.

The oscillator second harmonic is applied to the crystal mixer, CR102, by means of a tap on the inner conductor of the harmonic-selector tuned line. L158 is an r-f choke.

The mixer output appears across i-f coil L155. This coil is slug tuned to permit adjustment for proper bandpass. From this point the signal is link coupled (L156) to a short length of 72-ohm coax, through which the signal is fed to the VHF tuner input.

The look point in the mixer-output circuit is used in production to observe the tuner bandpass and check the mixer injection current.

To minimize feedback from the i-f strip to the UHF tuner, the tuner is insulated from the main chassis and

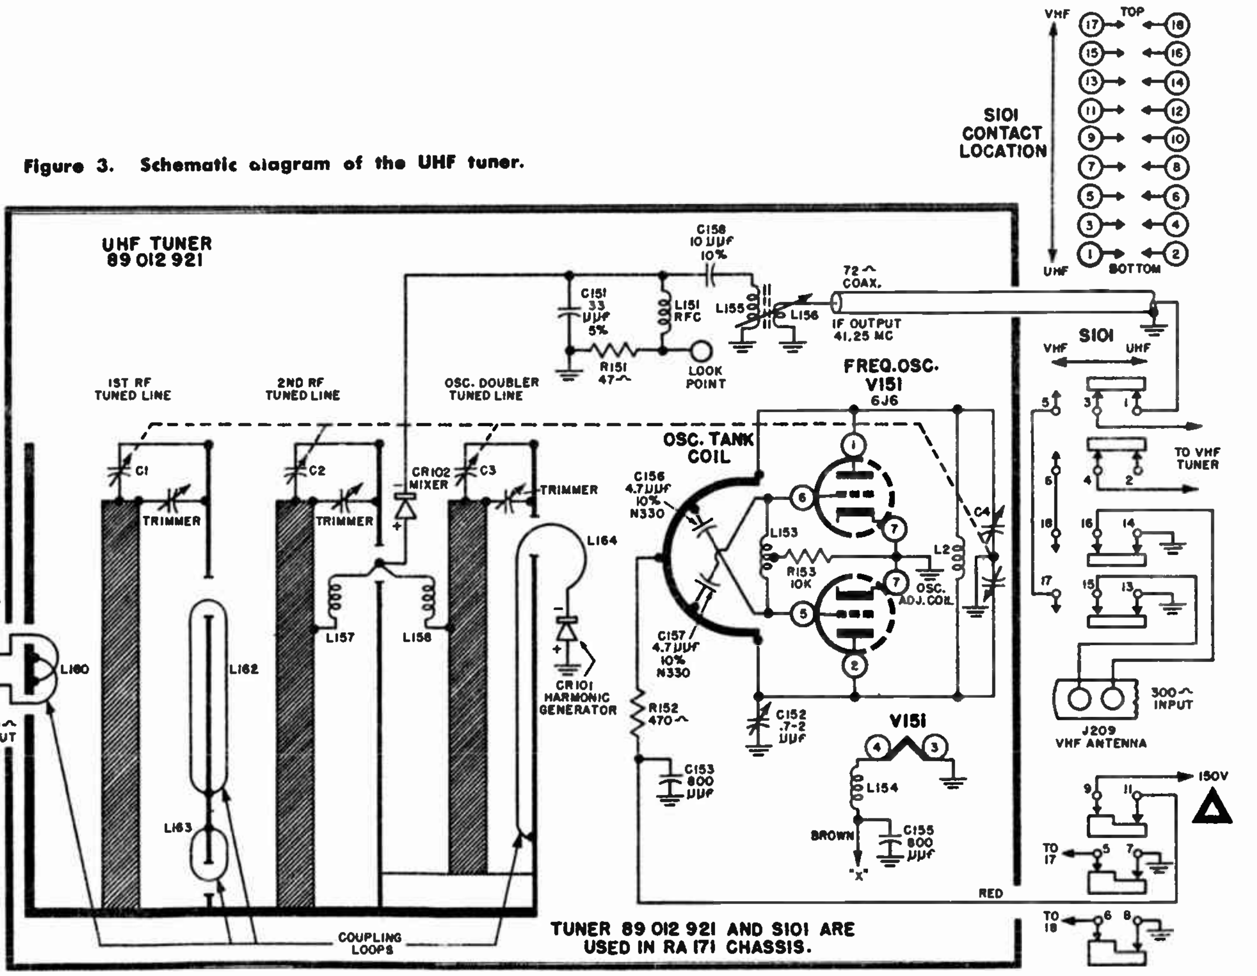

Figure 3. Schematic diagram of the UHF tuner.

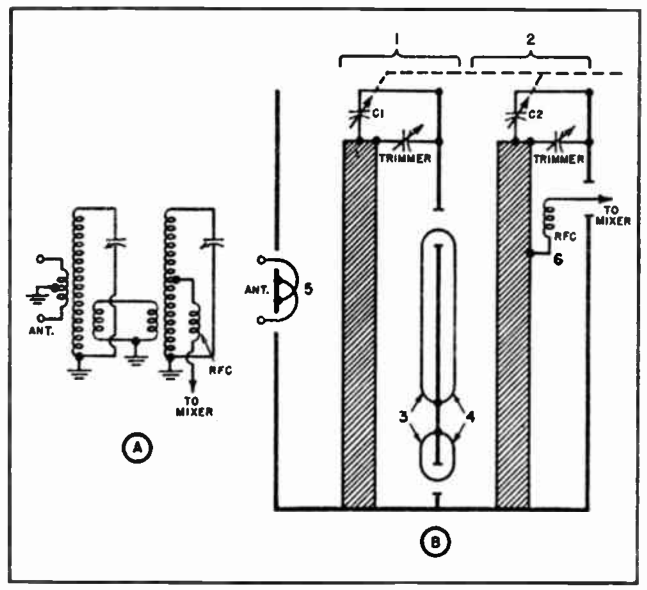

Figure 4. A—Low frequency equivalent of the preselector circuits. B—The actual preselector using tuned coaxial lines.

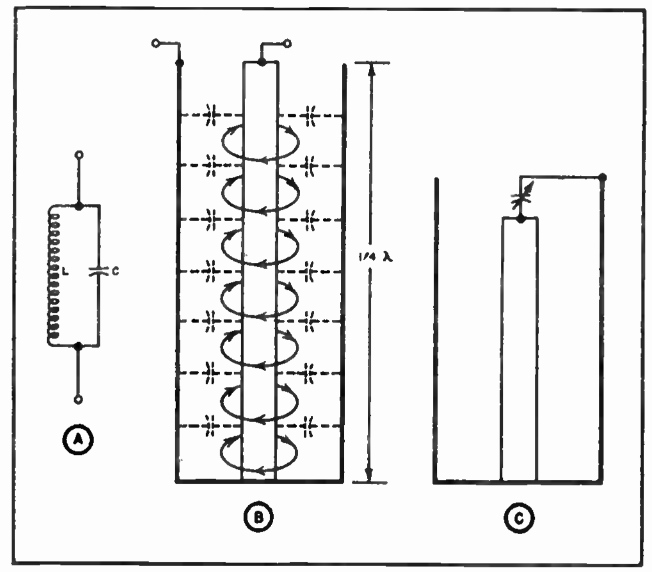

Figure 5. A—Parallel tuned resonant circuit. B—Resonant quarter-wave coaxial line. C—Shorted coax line less than quarter-wave long used as resonant circuit by the addition of capacitance.

grounded at one point by means of a short length of metallic braid. This type of grounding, called "single point grounding," is much more effective than simply mounting the tuner directly on the main chassis.

As pointed out previously the VHF tuner is provided with 13 switch-turret positions. To receive the UHF channels the Station Selector is placed in the thirteenth position. When this is done the VHF oscillator is disabled, and the necessary tuned circuits are switched in the VHF tuner so that the r-f amplifier and the mixer operate as 41 mc i-f stages.

In addition to the above, placing the Station Selector in the thirteenth position actuates a slide switch, S101 in figure 3, which applies B+ to the UHF tuner and connects the VHF tuner input to the UHF tuner output.

VIDEO I-F STRIP. — Four 41-mc stagger-tuned video i-f stages, employing 6CB6 tubes, are used. The grid circuit of the first video i-f stage is double tuned. All other coupling circuits are single tuned. A 47.25 mc adjacent-channel sound trap is provided. This trap is of the absorption type and is located in the plate circuit of the second video i-f stage. A-g-c voltage is applied to the first three stages.

VIDEO DETECTOR AND AMPLIFIER. — One-half of a 6AL5 twin diode serves as the video detector. D-c coupling is used between the detector and the video amplifier, as well as between the video amplifier and the CRT. A single high-gain video-amplifier stage employing a 12BY7 tube, is used.

The contrast control is located in the video-amplifier stage and consists of a potentiometer, connected between the cathode of the tube and ground. This potentiometer varies the bias and hence the gain of the video-amplifier stage.

A-G-C CIRCUITS. — A keyed a-g-c system with provisions to delay application of a-g-c voltage to the tuner r-f amplifier is used. The system posseses the excellent noise immunity and rapidity of action characteristic of keyed systems. In addition the delay provision greatly improves performance in both weak and strong-signal areas.

The tuner a-g-c voltage remains at the minimum permissible value (−.5 volts) on weak signals. This permits the tuner r-f amplifier to operate at full gain, maintaining maximum signal-to-noise ratio and minimizing picture snow. Adequate a-g-c is maintained on weak signals by the voltage applied to the i-f stages.

The tuner a-g-c delay also makes it possible to select component values in the a-g-c circuit which permit the tuner a-g-c voltage to rise rapidly at higher signal levels. As a result maximum performance is obtained over a wider range of input signal levels, with a given a-g-c control setting.

The a-g-c circuit is shown in figure 7. A 6AU6 sharp cut-off pentode is used as a keyed a-g-c amplifier (V212). The composite video signal, at the plate of the video amplifier, is applied to the grid of V212, through R256. Since d-c coupling is used, a portion of the plate voltage of the video amplifier appears at V212's grid, making it positive with respect to ground.

A positive d-c potential is applied to the cathode of V212. This positive voltage is obtained from the cathode of the regulator tube, V223. The positive voltage applied to V212's cathode is greater than the voltage at its grid, consequently the tube is negatively biased.

The composite video signal on the grid of V212 is positive. The grid is biased sufficiently beyond cut off so that only the sync pulses drive the grid out of cut off.

A positive pulse, obtained from terminal 4 of the horizontal output transformer, is applied to the plate of V212 through C238, R239 and R241. This positive horizontal pulse occurs at the same time as the sync pulse at the grid, causing the tube to conduct. As a result a negative voltage is developed at the plate of V212. The a-g-c amplifier is similar to the one used in the RA-164-165 chassis, and the reader is referred to the October, 1952 issue of the Service News for a more detailed description of its operation.

R264 and C245, at the plate of V212, function as a filter which removes most of the horizontal pulse component. The total a-g-c voltage is developed across R245 and R263. This voltage is appplied to the tuner a-g-c delay network, shown in figure 7 within the dotted lines.

To simplify the explanation of the delay network it has been shown in figure 8 with the diodes and capacitors removed. The negative a-g-c voltage produced by V212 appears at point A, causing a current to flow through R245 and R263 in the direction indicated by the dotted arrows. If we assume that this current is 225μa (.000225 amps), point A will be approximately −55 volts with respect to ground. As shown in the figure a bucking voltage of +270 volts is applied to R215, producing a current through the circuit as indicated by the solid arrows. The total resistance of R263, R245, R210 and R215 is 2,667,000 ohms, therefore the current due to the +270 volts is approximately 100 μa. (.0001 amps).

Since the direction of the current due to the bucking voltage is opposite that due to V212, the currents subtract and the resultant current through R263 and R245 is 125 μa (225 μa minus 100 μa), flowing from point A to ground. As a result point A becomes approximately 31 volts negative with respect to ground. The a-g-c voltage for the i-f stages is taken off at the junction of R245 and R263. The voltage at point A divides across these resistors producing approximately −5.9 volts at the i-f a-g-c take off.

Since point A is 31 volts negative and point C is 270 volts positive, the total drop across R210 and R215 is 301 volts. This voltage divides across the resistors producing a drop across R210 of approximately 27 volts. Thus point B is 27 volts positive with respect to point A, making it 4 volts negative with respect to ground. The tuner a-g-c voltage is taken off at point B and is applied to the tuner r-f amplifier through R205.

So far we have explained how the bucking voltage reduces the a-g-c voltage. The delay action of the circuit will be described with reference to figure 9. Referring to figure 9A assume that the same conditions exist as in figure 8. Point A is −31 volts and point B is −4 volts. Now assume that the voltage at point A is gradually made less negative. This will cause the voltage at point B to also gradually become less negative.

When the a-g-c voltage at point A is reduced to approximately −27 volts, the voltage at point B will be zero. A further reduction in the voltage at point A will cause the voltage at point B to become positive. Provisions have been made in the a-g-c circuit to prevent point B from becoming positive. This is accomplished by the addition of diode V214, as shown in figure 9B.

When the voltage at point A is sufficiently negative to produce a negative voltage at point B the plate of the diode is negative and it does not conduct. Therefore it has no effect on the circuit. However, when the voltage at point A is reduced, so that point B tends to become positive, the diode begins to conduct. Under these conditions the diode acts as a very low resistance to ground (practically a short circuit) and point B remains at zero potential.

Now let's examine what occurs as the signal level at the input of the receiver changes. If the signal is very weak the a-g-c voltage at point A is not very negative. Point B tends to become positive but the action of the diode keeps it at zero potential. As the signal strength rises the voltage at point A becomes more negative. However, point B remains at zero until the signal level is great enough to produce approximately −27 volts at point A. The diode now ceases to conduct and as the input signal level continues to increase, making point A more negative, point B also becomes negative and a-g-c voltage is applied to the tuner r-f amplifier.

In this way application of a-g-c voltage to the tuner is delayed until the input signal reaches a pre-determined level. It should be noted that negative a-g-c voltage is being applied to the i-f stages at all times because point A is always negative.

To prevent the plate current of the r-f amplifier from exceeding the maximum tube ratings, a minimum grid bias of −.5 volts must be maintained on the tube. This

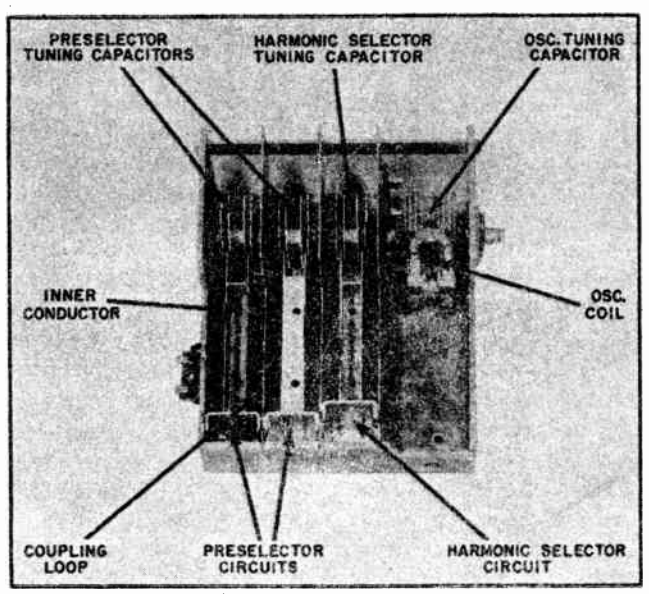

Figure 6. The UHF tuned circuits.

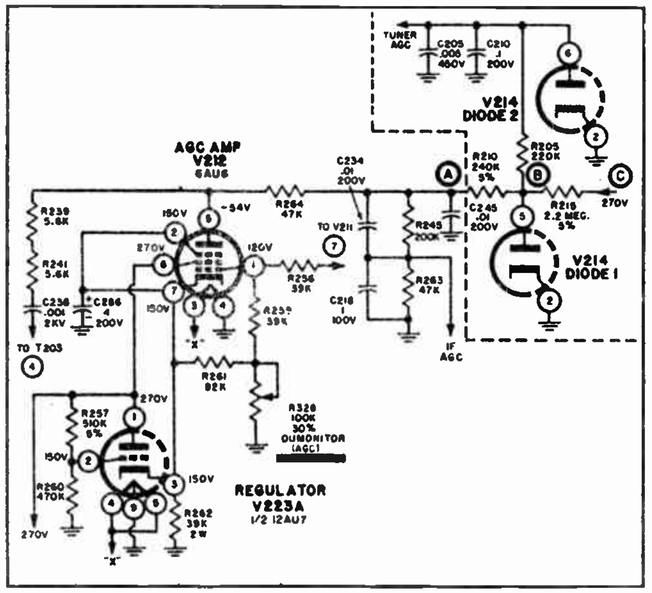

Figure 7. The a-g-c circuit.

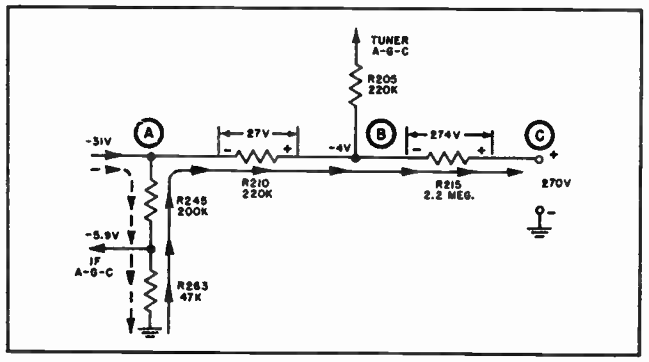

Figure 8. Simplified schematic of a-g-c delay net work showing currents produced by the a-g-c amplifier and the bucking voltage.

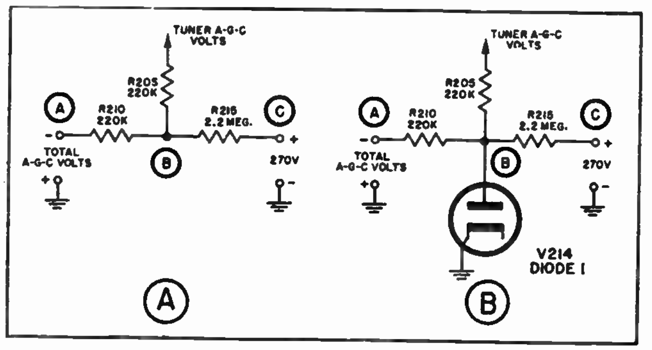

Figure 9. Operation of the delay circuit.

bias is obtained from the plate of diode number 2 in figure 7. When the voltage at point B, in figure 7, is zero the plate of diode 2 assumes a potential of –.5 volts, due to contact potential. This contact potential is produced by random electrons which strike the plate of the diode and create a current flow in R205.

C205 and C210 at the plate of diode 2 are bypass capacitors. C205 prevents r-f signals from the tuner from entering the a-g-c circuits. C210 eliminates the remaining horizontal pulse component from the a-g-c voltage.

As shown in figure 7 a voltage regulator tube (V223A) is provided to stabilize the cathode voltage on the a-g-c amplifier. The addition of this tube prevents line voltage, or power supply load fluctuations from affecting the a-g-c voltage.

When the current through the a-g-c amplifier (V212) increases, the drop across R262 and the bias on V223A also increases. This results in a drop in current through V223A and R262 which tends to compensate for the original change. As a result the bias on V212 is held at a comparatively constant value.

SYNC CIRCUITS. — The sync circuits consist of a noise inverter, three sync-clipper stages and a phase splitter, as shown in the block diagram of figure 10.

The composite-video signal is applied to the grids of the noise inverter and the first and second sync clippers. The noise inverter is biased so that it is normally cut off. When a noise pulse occurs, whose amplitude exceeds that of the sync signal, the noise inverter is driven out of cut off and the noise pulse appears at its plate. The output of the noise inverter is coupled to the grids of the first and second sync clippers. Since a phase reversal occurs in the noise inverter, the noise pulse arrives at the first and second sync clipper grids 180° out-of-phase with the composite-video signal and the noise pulse is cancelled at the grids.

The first sync clipper passes only horizontal sync information and the second sync clipper only vertical sync information. The separated horizontal and vertical sync signals are recombined in the output of the sync clippers and fed to the input of the third sync clipper. The third sync clipper is biased so that it clips near sync tip, to remove noise present on the sync pulse.

The output of the third sync clipper is fed to the grid of the phase splitter. This stage provides additional clipping action and in addition provides out-of-phase sync signals for application to the horizontal phase detector. The vertical sync is taken off at the cathode of the phase splitter.

NOISE INVERTER. — The composite-video signal at the plate of the video amplifier is applied to the upper end of R238 in figure 11. R238, R302 and R303 form a voltage divider. That portion of the signal which appears across R303 is applied to the grid of the noise inverter, V223B. Since d-c coupling is used between the video-amplifier plate and the grid of V223B, part of the video-amplifier plate voltage is applied to the grid, making it positive. A positive potential, obtained from the cathode of V208A, is applied to the cathode of V223B through R305. The positive cathode voltage is sufficiently greater than the positive grid voltage to bias the tube beyond cut off and prevent it from conducting on any part of the composite-video signal, as shown in figure 12. Therefore under normal operating conditions there is no signal at the plate of this stage.

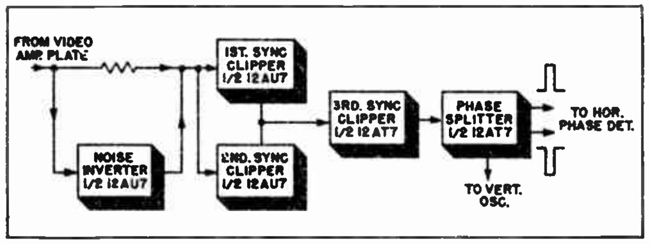

Figure 10. Block diagram of sync circuits.

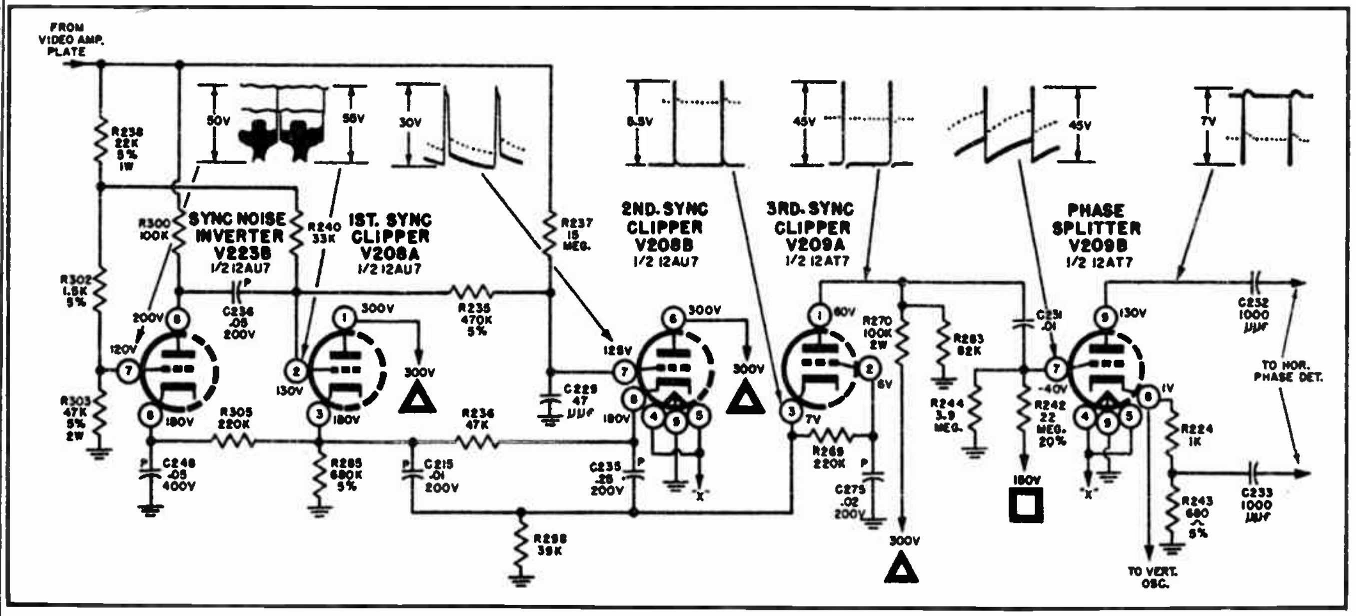

Figure 11. Schematic of sync circuits.

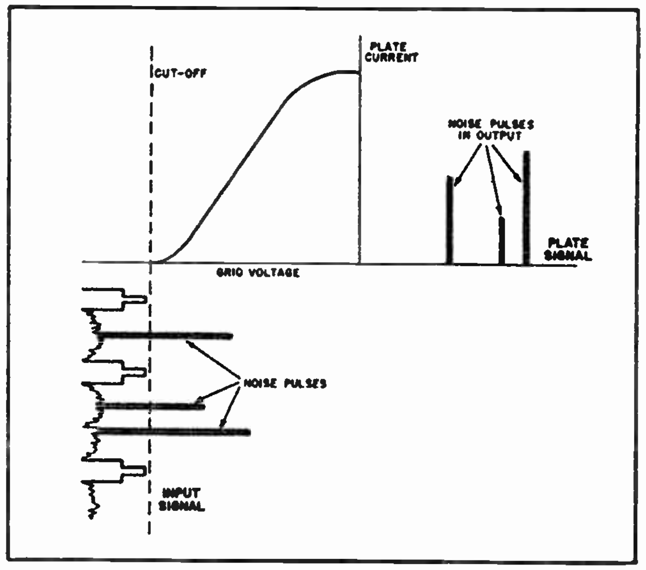

Figure 12. V223B grid-voltage, plate-current waveforms.

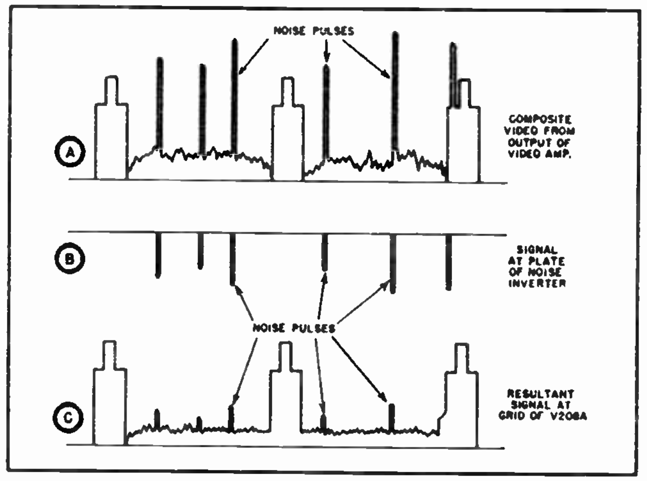

Figure 13. Signal at grid of V208A.

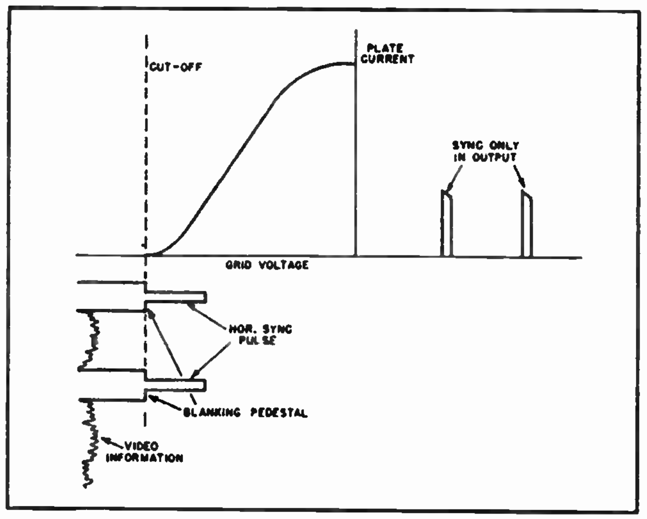

Figure 14. V208A grid-voltage, plate-current waveforms.

When a noise pulse occurs whose amplitude exceeds that of the sync, it drives the tube into conduction and appears in its output, as shown in figure 12. The output of the noise inverter is coupled to the grid of the first sync clipper. The signal at this point is shown in figure 13. A shows the composite-video signal obtained from the junction of R238-R302 and applied to the grid of the first sync clipper (V208A) through R240. B shows the noise pulses which are coupled from the plate of V223B to the grid of V208A, through C236. Note that the polarity of the noise pulses from the plate of V223B is opposite that of those in the composite-video signal. As a result the noise pulses cancel and the resultant signal appears as shown at C. Only a small portion of the noise still remains. In this way a large portion of the noise in the composite video signal is eliminated before application to the sync clippers.

FIRST SYNC CLIPPER. — That portion of the composite-video signal which appears across R302 and R303 is applied to the grid of the first sync clipper in conjunction with the output of the noise inverter. The noise cancellation action previously described takes place at this grid. Since the video-amplifier plate is d-c coupled to V208A, the grid is positive. A positive cathode voltage, exceeding this positive grid voltage, is developed across R285-C215, negatively biasing the tube. The operating conditions of the tube are shown in figure 14. The grid bias point of V208A is well beyond cut off, so that the tube conducts only on the horizontal-sync pulse, and the video and blanking information do not appear in its output.

In addition to eliminating the video and blanking information V208A removes most of the vertical-sync signal. This occurs as a result of the cathode-bias network, R285, C215 and R268. The signal at the grid of V208A is shown in figure 15A. Since the tube does not conduct on the video and blanking portions of the signal they have not been shown.

The horizontal sync pulses have a duration of 5 microseconds. During each horizontal sync pulse the tube conducts, as shown in figure 15C, charging C215 as shown at B. Since the interval between horizontal pulses is 58 microseconds (approximately 12 times the duration of each horizontal pulse), the charge due to each pulse is dissipated before the next pulse occurs, and the bias on V208A is substantially equal to that produced by the static current through the tube. V208A continues to conduct on each horizontal pulse producing current through R268, as shown in figure 15C.

Since the equalizing pulses are only 2.5 microseconds in duration and the interval between them is long (32 microseconds), the charges on C215 due to each pulse is dissipated before the next pulse occurs. Consequently, the equalizing pulses also produce a signal across R268.

As shown in figure 15A the vertical sync pulses are of much longer duration (27 microseconds) and are not as widely separated (4 microseconds) as are the horizontal and equalizing pulses.

As a result the vertical-sync pulses develop a large charge across C215, as shown in figure 15B. This charge is added to the static cathode bias on V208A, causing the tube to remain near cut off for the duration of the vertical-sync interval. Therefore, after the first vertical pulse occurs there is very little current through V208A, and the cathode resistor, R268.

V208A operates as a cathode follower with output taken off across R268. As a result of the operating conditions just described, only the horizontal sync, the equalizing and the leading vertical sync pulses appear in its output.

The advantage of this type of sync-clipper circuit lies in the fact that noise pulses do not affect the bias on the stage. Noise pulses are normally of short duration. As noted in the previous discussion short duration pulses do not develop a significant charge on the cathode capacitor, C215, and therefore do not change the bias on V208A.

In the usual grid-leak biased sync clipper the bias is determined by the peak amplitude of the signal. As a result high-amplitude noise pulses increase the grid bias, changing the clipping level and compressing, or completely eliminating, the sync information.

SECOND SYNC CLIPPER. — As noted in the preceding discussion the first sync clipper, V208A, does not pass the vertical sync signal. As a result other provisions have been made to separate the vertical sync from the composite-video signal. This is accomplished in the second sync clipper, V208B in figure 11.

The composite-video signal at the grid of the first sync clipper is applied to the grid of the second sync clipper through R235. Since noise cancellation takes place at the grid of V208A a large portion of the noise present in the composite-video signal is cancelled before it reaches the grid of V208B.

Bias for V208B is obtained from the cathode of V208A, through resistor R236. R236 and C235 function as a filter to prevent the horizontal and equalizing pulse components, present at the cathode of V208A, from reaching the cathode of V208B. The filter produces a slightly higher positive voltage at the cathode of V208B. Since the grids of V208A and V208B are at approximately the same potential, this causes the negative bias on V208B. to exceed the bias on V208A. To equalize the bias on both tubes R237 has been connected between the video take-off line and the grid of V208B. The addition of the resistor produces a slightly higher voltage at the grid, to compensate for the slightly higher cathode voltage. In this manner V208B is negatively biased beyond cut off. The operating conditions of the tube are shown in figure 16. Cut off corresponds to the blanking-pedestal level.

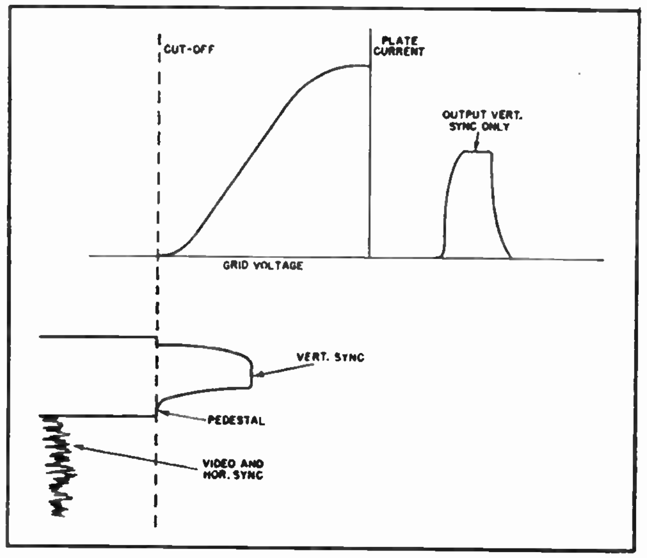

Figure 16. V208B grid-voltage, plate-current waveforms.

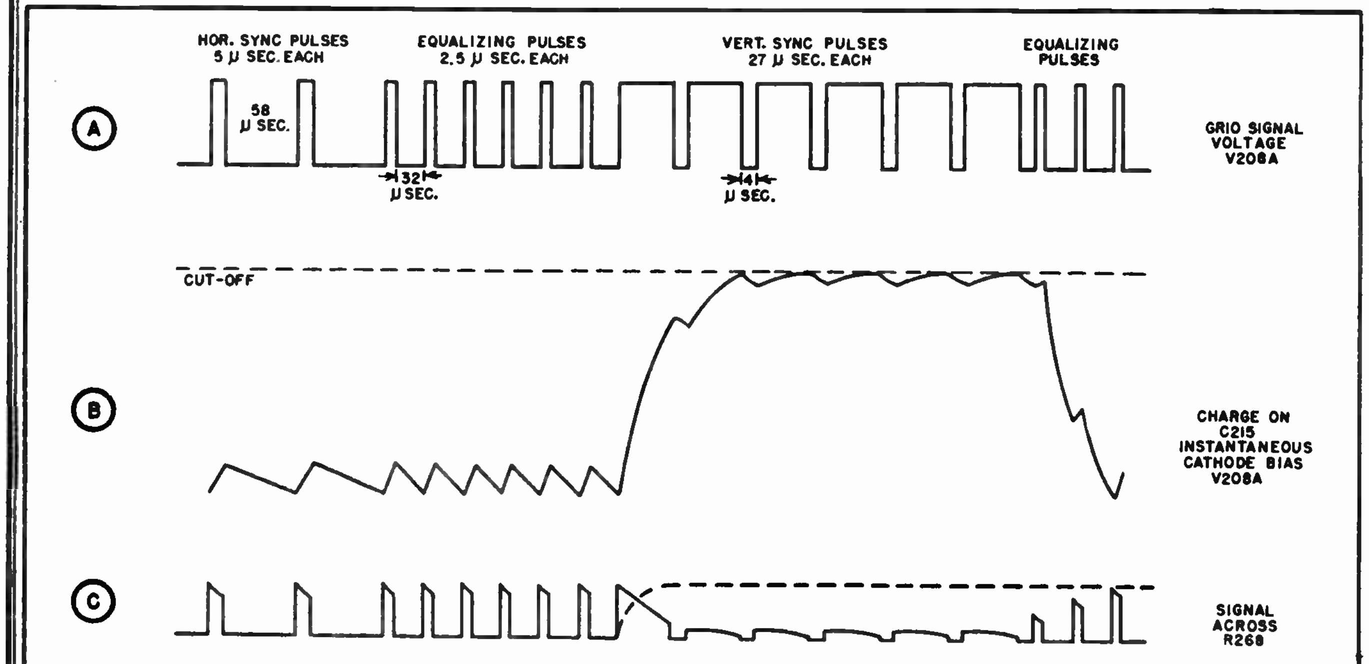

Figure 15. Operation of the first sync clipper, V208A. A—Sync portion of the composite video signal at grid. B—Instantaneous cathode voltage. C—Signal voltage across R-268. The dash line is due to V208B.

As previously mentioned the input signal is applied to the grid of V208B through R235. The time constant of R235-C229 in the grid circuit is approximately 25 microseconds. As a result the 5 microsecond horizontal and the 2.5 microsecond equalizing pulses produce very little voltage at the grid and do not drive the tube into conduction. The 27 microsecond vertical sync pulses, being of much longer duration, are integrated and drive the tube into conduction as shown in figure 16, producing a vertical-sync pulse across cathode resistor R268. This resistor is common to V208A and V208B and both the horizontal and vertical sync signals appear across it.

THIRD SYNC CLIPPER. — The composite-sync signal (horizontal, equalizing and vertical pulses) appearing across R268 is applied to the cathode of the third sync clipper, V209A in figure 11. R269 maintains the grid and cathode at approximately the same d-c potential, while the addition of C275 prevents the input signal from appearing at the grid. The operating conditions of the stage are shown in figure 17. Since the positive input signal is applied to the cathode it has the same effect as a negative signal applied to the grid, therefore the sync pulses drive the tube into cut off. As a result the upper 40% of the sync signal is clipped and does not appear at the plate. This clipping action removes noise superimposed on the sync signal.

PHASE SPLITTER. — The phase splitter, V209B in figure 11, provides additional clipping and out-of-phase sync signals for application to the horizontal a-f-c phase detector.

The sync signal at the plate of V209A is applied to the grid of V209B through coupling capacitor C231. C231 in combination with R244 form a grid-leak bias network which biases the grid negatively. The comparatively long vertical-sync pulse tends to charge C231 and increase the bias on the tube, so that the sync information immediately following the vertical-sync pulse is reduced in amplitude at the output of the stage. To overcome this condition a small positive voltage, obtained from the +150 volt line, is applied to the grid through R242. This permits the charge on C231 to leak off more rapidly so that the amplitude of the horizontal sync information is not reduced.

V209B operates as a conventional triode phase splitter. Output is obtained from both the plate and cathode circuits. The plate and cathode signals are of opposite polarity as required for operation of the horizontal a-f-c phase detector.

The vertical-sync signal is taken off at the cathode of V209B and applied to an integrator network before application to the vertical oscillator.

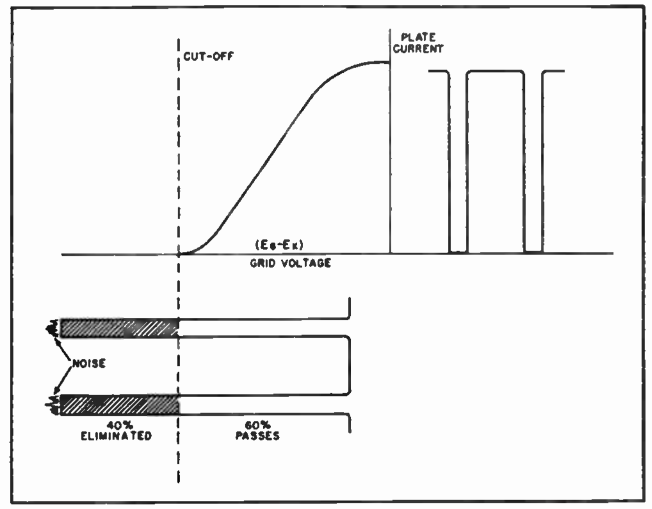

Figure 17. V209A grid-voltage, plate-current waveforms.

SERVICING PROCEDURES

ION-TRAP MAGNET ADJUSTMENT. —

1. Position the ion-trap approximately as shown in figure 18.

NOTE: A small magnetic shunt may have been clipped on the ion-trap magnet at the factory. Do not disturb this shunt.

2. Turn the set on and allow 30 seconds for warm-up. Set the Contrast control at the middle of its range and set the brightness so that a raster is just visible on the screen.

NOTE: Do not operate the Teleset with the ion-trap magnet improperly positioned for any longer than necessary.

3. Slide the magnet slowly back and forth along the neck of the tube, while at the same time rotating it slightly to the left and right. As the raster becomes brighter, turn down the Brightness control until there is just enough brightness to permit the adjustment to be made. When the position giving maximum *brightness* and optimum *focus* has been located, turn up the Brightness control until the raster begins to increase in size. Adjust the ion-trap magnet again, for maximum brightness and optimum focus.

DEFLECTION YOKE ADJUSTMENT. — If the picture is tilted, squeeze the ends of the yoke spring clip (A in Figure 18) together and lift them off the CRT support ring. Rotate the yoke until the picture is horizontal. The deflection yoke retainer (B in Figure 18) may rotate with the yoke. If this occurs the retainer should be held in position while the yoke is rotated, making sure that the yoke end cover rotates with the yoke. When the deflection yoke has been properly adjusted, reset the spring clip to hold the yoke in position.

POSITIONING ADJUSTMENT. — If the picture is not properly positioned, readjust the positioning magnet using the following procedure:

1. Push the positioning magnet assembly forward until it touches the rear of the yoke retainer.
2. Bring the protruding adjustment tabs (C in Figure 18) together.
3. Rotate the entire positioning magnet assembly around the neck of the tube until the picture is properly positioned.
4. If the picture cannot be properly positioned in this manner, separate the tabs slightly and rotate the entire assembly around the tube again. Continue to repeat this step, increasing the separation of the tabs each time, until the picture is properly positioned. When this adjustment has been made, a slight readjustment of the ion-trap magnet may be necessary.

VHF TUNER OSCILLATOR ADJUSTMENT. — Individual oscillator adjustment slugs are provided in the VHF tuner to permit precise adjustments to suit the receiving condition for each channel in your area. These slugs are set at the factory for average conditions and do not require adjustment when the receiver is installed. However, it is often possible to obtain better reception by readjusting the oscillator slugs to suit the particular conditions at the location where the receiver is installed.

The following procedure should be used:

1. Turn the Station Selector to the channel on which the oscillator is to be adjusted.
2. Remove the Fine Tuning and Station Selector knobs (and the RA-171 UHF channel dial).
3. Set the Fine Tuning control so that the flat on the shaft faces downward. The oscillator slug is accessible through the hole just to the right of the tuning shaft.
4. Using an insulated alignment tool. adjust the slug for best picture and sound.

DUMONITOR ADJUSTMENT. — The Dumonitor control is adjusted at the factory and normally does not require readjustment in the field. However, in some cases better reception can be obtained by adjusting the control to suit the conditions in your area.

In weak signal areas the Dumonitor control should be adjusted for best contrast and picture stability.

In strong signal areas the control should be set to prevent overloading on the strongest signal received, using the following procedure:

1. Set the front panel Horizontal Hold control for minimum whip (straight vertical wedge on test pattern) at the top of the picture.
2. Adjust the Dumonitor control until no overload is observed.
3. Switch the Station Selector on and off channel. If this causes overload to occur reset the Dumonitor until the overload does not reappear when switching on and off channel.

In areas where both very strong and very weak signals are received the Dumonitor control should always be adjusted to prevent overloading on the strongest signal.

UHF-VHF ANTENNA CROSSOVER NETWORK. — If a combination UHF-VHF antenna having a single transmission line is used with RA-171 chassis, an antenna crossover network is required to terminate the transmission line at the receiver's UHF and VHF antenna terminals. Crossover network, Du Mont Part No. 88 000 681, should be used. This network is available from your Du Mont distributor.

The UHF-VHF transmission line should be connected to the terminals provided on the crossover network and the separate UHF and VHF output leads should be connected to their respective antenna terminals on the receiver.

REPLACING THE VHF TUNER COIL STRIPS

1. Remove the four screws holding the tuner bottom cover and remove the cover.
2. Using a screw driver, push the spring finger holding the strip toward rear of tuner and lift out strip.
3. To install new strip, insert end having smaller projection into the hole in the detent plate.
4. Pry the spring finger away from rear of drum and push the strip into place. Let spring finger snap back into place making sure that projection on end of strip seats correctly in hole in spring finger.

CLEANING THE TUNER CONTACTS. — Remove the tuner bottom cover and several of the coil strips as described in the previous paragraph. Rotate the turret so that the wiping contacts are accessible through the opening made by removing the strips. Clean the coil strip and wiping contacts with a soft cloth moistened with "No Noise."

ADJUSTING THE TENSION OF THE WIPING CONTACTS. — Remove the tuner bottom cover and several of the coil strips. Rotate the turret to permit access to the contacts through the opening thus provided. Using a small screw driver bend each contact spring until it extends approximately ⅛ inch inward from the surface of the plastic contact-mounting plate.

REMOVING VHF TUNER

1. Unplug the coax lead connection near 1st VIF transformer.
2. Remove the dial cord.
3. Unsolder the four VHF tuner leads from the terminal strip on top of VHF tuner bracket.
4. Unsolder lead from terminal strip at slide switch.
5. Unsolder lead from UHF tuner at slide switch.
6. Unsolder center coax lead from slide switch.

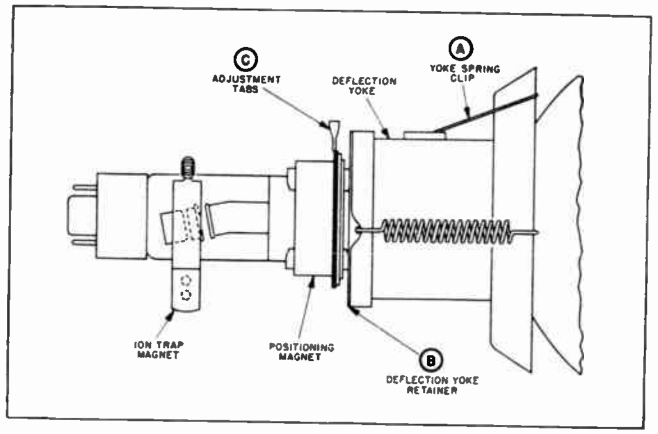

Figure 18.

7. Remove the bracket supporting the front end of the tuning shafts.
8. Remove the three screws mounting the VHF tuner to the support bracket.

REMOVING UHF TUNER

1. Unsolder the center lead of coax from slide switch, and remove ground lug fastening outside lead of coax to bracket.
2. Unsolder red lead from UHF tuner at slide switch.
3. Unsolder brown lead from UHF tuner at terminal strip.
4. Loosen UHF tuner-shaft coupling screw.
5. Remove three screws fastening tuner to mounting bracket.

UHF DIAL CALIBRATION

If a UHF channel is available tune to channel and adjust the UHF dial for proper calibration.

If no UHF channel is available, calibrate the dial so that it tunes below the channel 20 marker and above the channel 80 marker.

DIAL STRINGING PROCEDURE

1. Rotate the UHF pulley shaft fully clockwise.
2. Rotate the UHF tuning control so that the opening of the tuner shaft drum is positioned to the left.
3. Hook end of the dial cord on the pulley drum, marked START in figure 19, and string dial cord as shown.

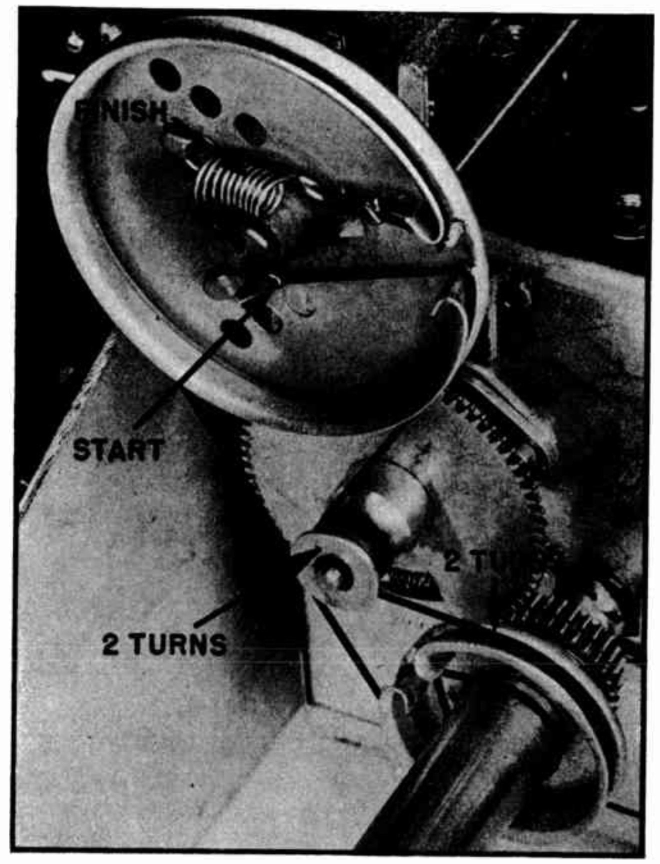

Figure 19.

TROUBLESHOOTING PROCEDURES

PICTURE

Symptom	Procedure
Bright Horizontal Line **Loss of Vertical Size**	1. Substitute V213 and V216 2. Check voltages, waveforms and associated components of V213 and V216 3. Check yoke and vertical output transformer, T201
Critical Vertical Hold	1. Check waveforms in integrator network
Drive Line in Center	1. Check setting of drive control
Insufficient Horizontal Size	1. Check settings of horizontal size and linearity controls 2. Substitute V220, V221 and V219 3. Check boosted B+ and associated components 4. Check C279 and C278
Insufficient Vertical Size	1. Check setting of vertical-size control **Control Has No Effect** 2. Check vertical size pot. R324 **Control Does Not Give Normal Size** 2. Substitute V213 and V216 3. Check voltages, waveforms and associated components of V213 and V216

PICTURE (con't)

Symptom	Procedure
Loss of Horizontal and Vertical Hold Probable Cause: Faulty sync clipper stage	1. Check settings of front panel hold controls 2. Substitute V208 and V209 3. Check voltages, waveforms and associated components of V208 and V209
Loss of Vertical Hold Only	1. Substitute V208 2. Check associated components of V208B
Microphonics - Visual Probable Cause: Mechanical modulation of tube in picture circuits.	1. Check control shafts and knobs for binding against cabinet 2. Substitute V101 and V102 3. Substitute V201, V202, V203, V204 and V211
No Brightness	1. Check for presence of high voltage at CRT connector **High Voltage OK** 2. Check CRT for open filament (look for glow) 3. Check adjustment of ion trap 4. Check voltages and associated components of CRT **No High Voltage** 2. Check the ¼ amp. fuse (F201) in high voltage cage 3. Substitute V222, V221, V220 and V219 4. If a picture of reduced size with heavy horizontal fold-over appears when V221 is removed, replace C278 5. Check voltages, waveforms and associated components of V222, V221, V220 and V219
No Horizontal Hold - or Critical Horizontal Hold Probable Cause: Defective a-f-c circuit	1. Check setting of front panel horizontal hold control 2. Substitute V210 and V219 3. Check setting of L210 horizontal-stabilizer control located on rear of chassis 4. Check voltages, waveforms and associated components of V210 and V219
Picture Oversize - Low Brightness Probable Cause: Insufficient high voltage	1. Substitute V222 2. Check h-v rectifier components
Picture Too Small (Horizontal and Vertical) Probable Cause: B+ low	1. Substitute V217 and V218 2. Check B+ line and associated components
Poor Focus	1. Check setting of ion trap
Poor Horizontal Linearity	1. Check setting of horizontal-linearity control 2. Substitute V220 and V221 3. Check voltages, waveforms and components associated with V220 and V221
Poor Vertical Linearity	1. Check setting of vertical-linearity control 2. Substitute V216 3. Check voltages, waveforms and associated components of V216 and 213
Sound Bars In Picture Probable Cause: Misalignment	1. Check fine tuning adjustment 2. Check video i-f alignment
Vertical Instability Probable Cause: Faulty vertical oscillator	1. Check setting of front panel vertical hold control 2. Substitute V213 and V216 3. Check voltages, waveforms and associated components of V213 and V216
Weak Picture	1. Substitute V211 2. Check voltages and components associated with V211

SOUND

Symptom	Procedure
Buzz Probable Cause: Vertical sync in sound	1. Check fine tuning adjustment 2. Substitute V206 and V207 3. Check sound i-f alignment
Cannot Be Tuned In Properly Probable Cause: H-f oscillator frequency misadjusted	1. Check oscillator slug adjustment 2. Substitute V102
Dead or Weak Probable Cause: Loss of gain in audio or sound i-f stage	1. Substitute, V205, V206, V207, V214 and V215 2. Check speaker plug and speaker audio transformer 3. Check voltages on V205, V206, V207, V214 and V215 4. Check components associated with V205, V206, V207, V214 and V215 5. Check sound i-f alignment
Distorted	1. Check fine tuning adjustment 2. Substitute V206, V207, V214 and V215 3. Check alignment of Z206 4. Check voltages on V214 and V215 5. Check components in 1st and 2nd audio amp.
Microphonics - Audible Probable Cause: Mechanical modulation of h-f oscillator (V102) or audio amplifier tubes.	1. Check for binding knobs or control shafts 2. Substitute V102 3. Substitute V214 and V215
Poor Quieting Probable Cause: Improper operation of ratio detector or sound i-f stage	1. Check fine tuning adjustment 2. Substitute V207 3. Check alignment of Z206 4. Substitute V206 5. Check components of ratio detector, V207

PICTURE AND SOUND

Symptom	Procedure
No Picture, No Sound, Brightness OK	1. Substitute V101, V102, V201, V202, V203, V204, V205, V215 (see note) and V223 2. Check voltages on V101, V102, V201, V202, V203, V204 and V205 and speaker plug connection. NOTE: The 150V source is the cathode of V215, the 2nd audio amp., therefore, a defective tube, speaker plug connection, or output transformer will result in loss of the 150V
No Picture, No Sound, Low Brightness (brightness control set at maximum)	1. Substitute V211 2. Check voltages and components associated with V211
Overload in Picture - Buzz in Sound Probable Cause: Loss of a-g-c voltage	1. Check setting of the a-g-c potentiometer 2. Substitute V212, V201, V202 and V203 3. Check voltages, waveforms and components associated with V212
UHF OK, VHF Inoperative	1. Substitute V102. 2. Check operation of cam and slide switch, S101. 3. Check voltages and components associated with V102.
VHF OK, UHF Inoperative	1. Substitute V151, CR101 and CR102. 2. Check operation of cam and slide switch, S101. 3. Check VHF tuner 40 mc i-f strip.

VIDEO IF ALIGNMENT RA-166/167, 170/171

Place STATION SELECTOR between channels to disable oscillator. Remove fuse, F201. Connect a short length of wire to pin 5 of V101 (see Figure 1). Use the lowest VTVM range for all steps.

Step	Signal Generator Frequency	Signal Generator Connect to	Output Indicator	Connect to	Adjust	Remarks
1	44.5 mc No Sweep	Pin 5 V101 1	VTVM	Pin 2, V211 1VTVM	Z205 for maximum reading	Set signal generator output to maintain reading on lowest range of VTVM.
2	42.5 mc No Sweep	As Above 2	VTVM	As Above 2VTVM	Z204 for maximum reading	Same
3	46.1 mc No Sweep	As Above 3	VTVM	As Above 3VTVM	Z203 (bottom) for maximum reading	Same
4	43.75 mc No Sweep	As Above 4	VTVM	As Above 4VTVM	Z202 for maximum reading	Same
5	47.25 mc	As Above 5	VTVM	As Above 5VTVM	Z203 (top) for minimum reading	Increase signal generator output to obtain reading on VTVM.
6	43.5 mc center freq. 10 mc deviation (min.)	As Above 6	Oscillograph through XTAL	Pin 5 V201 6XTAL	Mixer Plate Coil (L109) and Z201 (top) for 44.8 mc marker on one peak Z201 (bottom) for 42.5 mc marker on other peak.	Adjust for waveform below. 42.5 MC 44.8 MC
7	4.5 mc 400 CPS AM	Pin 2 V211 7	Oscillograph through XTAL	Junction R266, R267, and C239 7XTAL	L207 for minimum reading	

SOUND IF ALIGNMENT

Step	Signal Generator Frequency	Signal Generator Connect to	Output Indicator	Connect to	Adjust	Remarks
8	4.5 mc Approx. 1 MC sweep	Pin 5 V205B 8	Oscillograph through XTAL	Pin 7 V207 8XTAL	L204 and Z206 (bottom)	Adjust for waveform below. 4.5
9	As Above	As Above 9	Oscillograph Direct	Junction R232, C228 9DIR	Z206 top	Adjust for waveform below. 4.5

ALTERNATE SOUND IF ALIGNMENT — USING TV SIGNAL

Step	Signal Source	Output Indicator	Connect to	Adjust	Remarks
8	TV Signal	VTVM	Pin 7, V207 8XTAL	L204 Z206 (bot.) for maximum reading	Teleset must be tuned for best picture.
9	As Above	VTVM	Ratio Det. Test Point P206	Z206 Top for zero reading	As Above

ALIGNMENT TEST POINTS

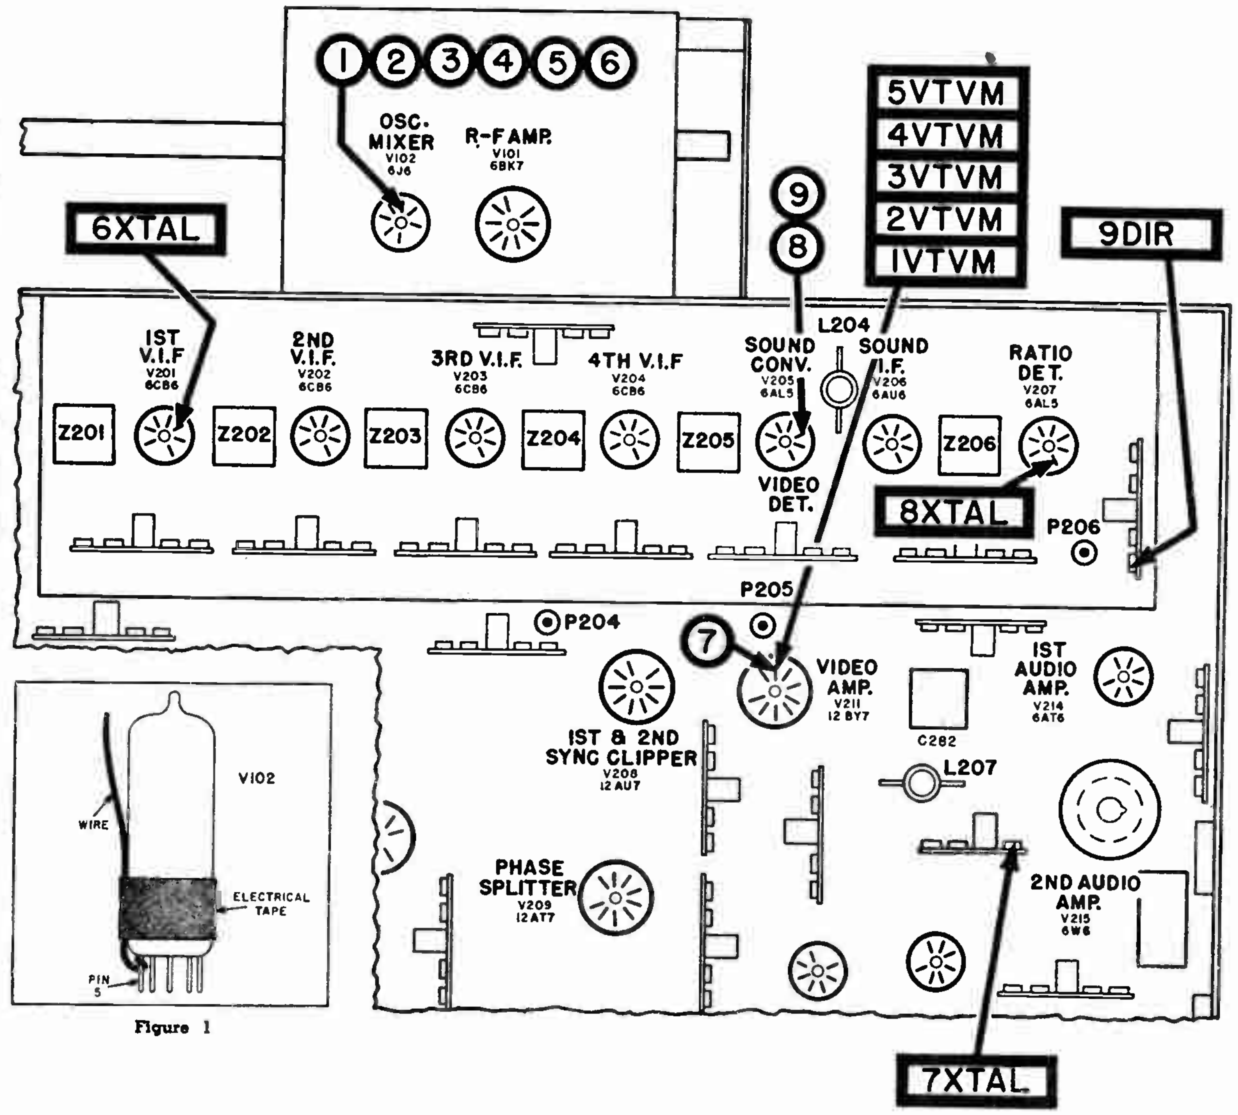

Figure 1

PHASING

When the alignment procedure has been completed, the phasing of the video IF strip should be checked and corrected if required.

1. Tune the receiver to the best signal available, preferably a station transmitting a test pattern.
2. Adjust the Fine Tuning control until the sound in the picture is eliminated.
3. Carefully examine the picture for trailing whites, or the presence of spurious black response (smear) following black elements of the picture.
4. If either of these conditions is encountered, adjust the top slug of Z201 not more than ½ turn to eliminate the condition.

USE OF SYMBOLS

Solid symbol indicates source of voltage.

Open symbol indicates point to which voltage is applied.

Solid bar indicates an adjustable control.

NOTES

1. All voltages are shown with the Contrast control rotated fully clockwise, and the Du-monitor (agc) control adjusted for −6.5 volts at P204, the agc test point.
2. Voltages ± 20% of those shown are normal.
3. All resistors are 10%, one-half watt, unless otherwise indicated.
4. All capacitors are 20%, 500V, unless otherwise indicated.
5. All capacitors are ceramic, unless indicated as follows:
   M—mica, P—paper, ±—electrolytic

RA-166/167, 170/171 C

ALIGNMENT TEST POINTS

NOTE: V205 IS A 6AL5 IN SOME SETS. USE PIN 5 OF THIS TUBE FOR CONNECTIONS 8 AND 9.

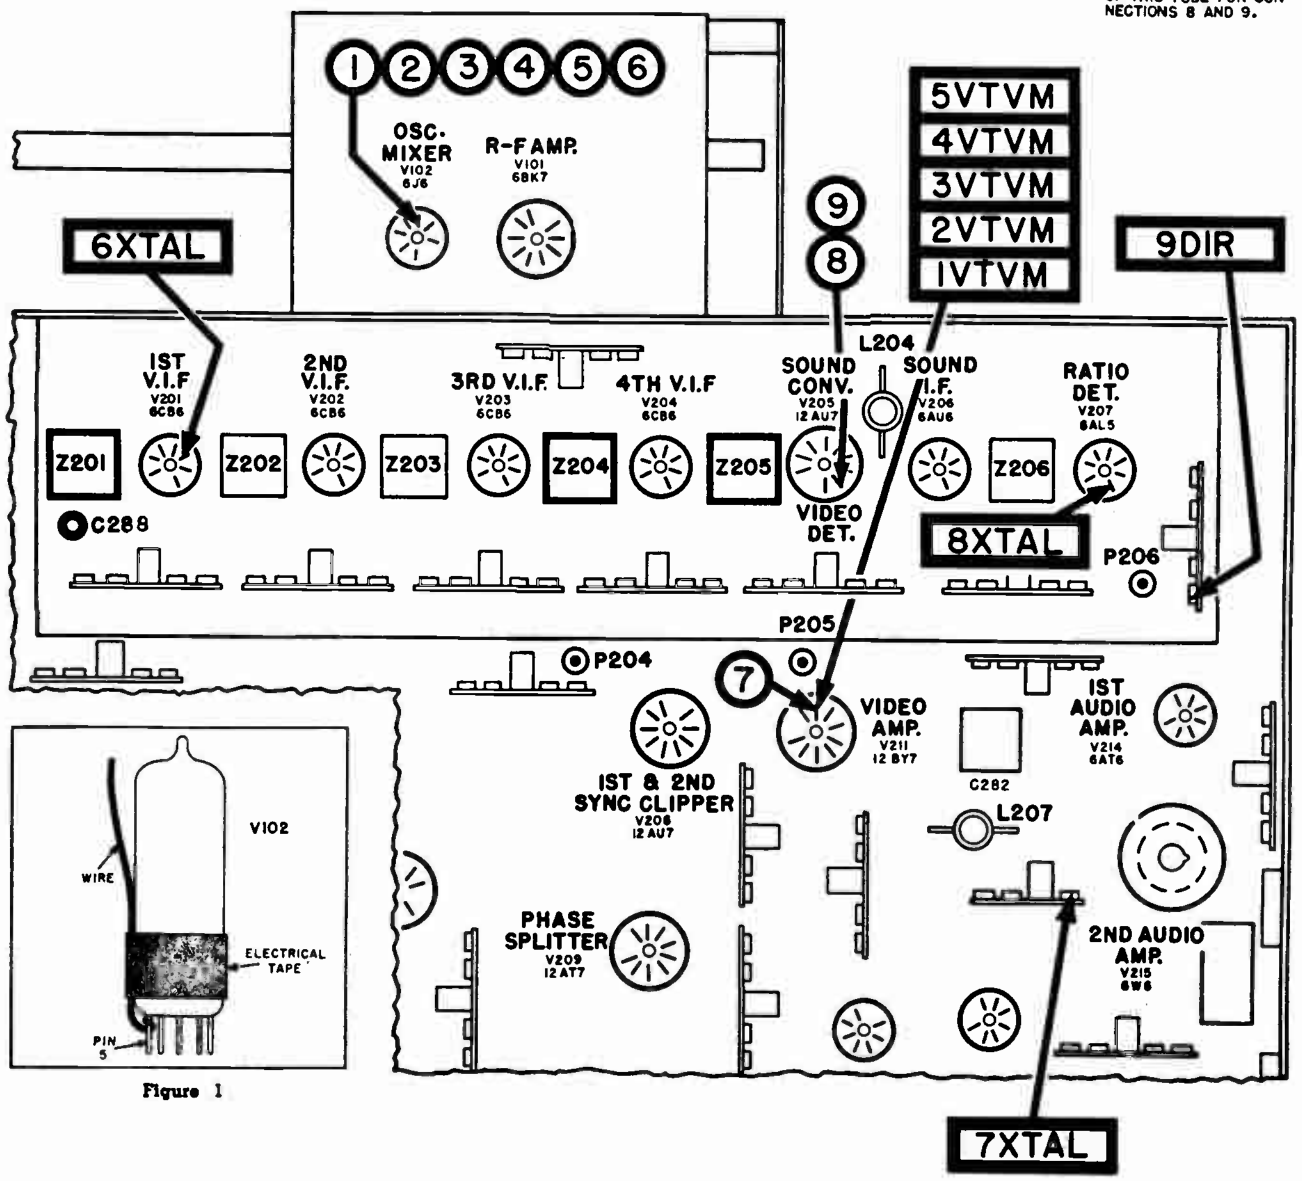

Figure 1

PHASING

When the alignment procedure has been completed, the phasing of the video IF strip should be checked and corrected if required.

1. Tune the receiver to the best signal available, preferably a station transmitting a test pattern.
2. Adjust the Fine Tuning control until the sound in the picture is eliminated.
3. Carefully examine the picture for trailing whites, or the presence of spurious black response (smear) following black elements of the picture.
4. If either of these conditions is encountered, adjust the top slug of Z201 not more than ½ turn to eliminate the condition.

VIDEO IF ALIGNMENT RA-166/171

Place STATION SELECTOR between channels to disable oscillator. Remove fuse, F201. Connect short length of wire to pin 5 of V102, Fig. 1. Use lowest VTVM range.

Step	Signal Generator Frequency	Signal Generator Connect to	Output Indicator	Connect to	Adjust
1	44.25 mc No Sweep	Pin 5 V102 ①	VTVM	Pin 2, V211 1VTVM	Z205 for maximum reading. Set signal generator output to maintain reading on lowest range of VTVM.
2	42 mc No Sweep	As Above ②	VTVM	As Above 2VTVM	Z204 for maximum reading
3	46.1 mc No Sweep	As Above ③	VTVM	As Above 3VTVM	Z203 (bottom) for maximum reading

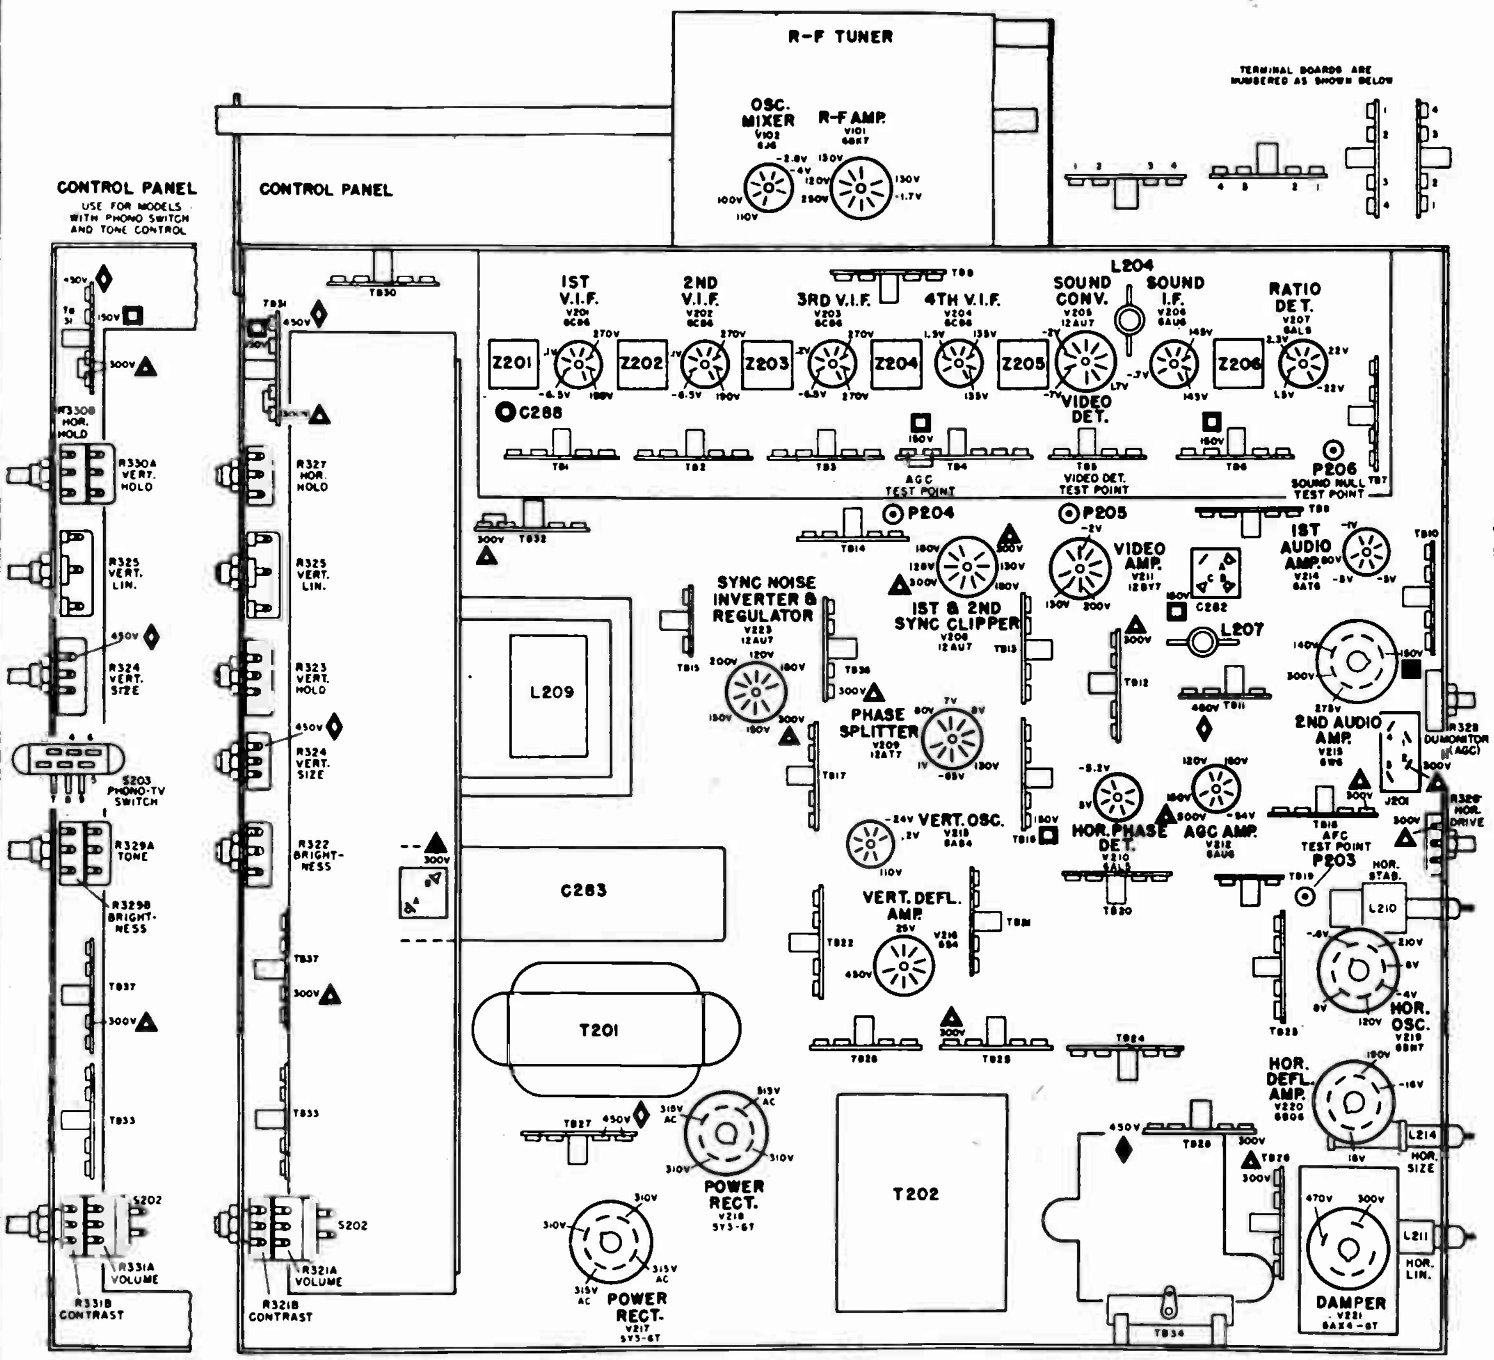
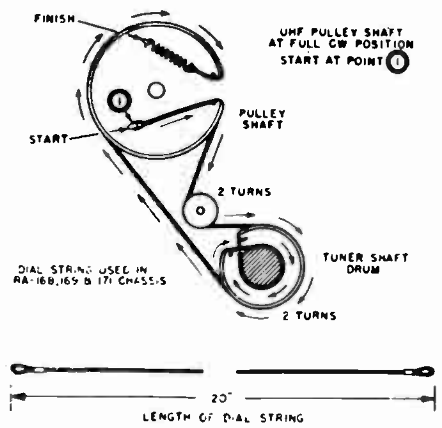
ALTERNATE SOUND IF ALIGNMENT — USING TV SIGNAL

Step	Signal	Output Indicator	Connect to	Adjust
8	TV Signal Teleset must be tuned for best picture.	VTVM	Pin 7, V207 8XTAL	L204 Z206 (bot.) for maximum reading
9	As Above	VTVM	Ratio Det. Test Point P206	Z206 (top) for zero reading

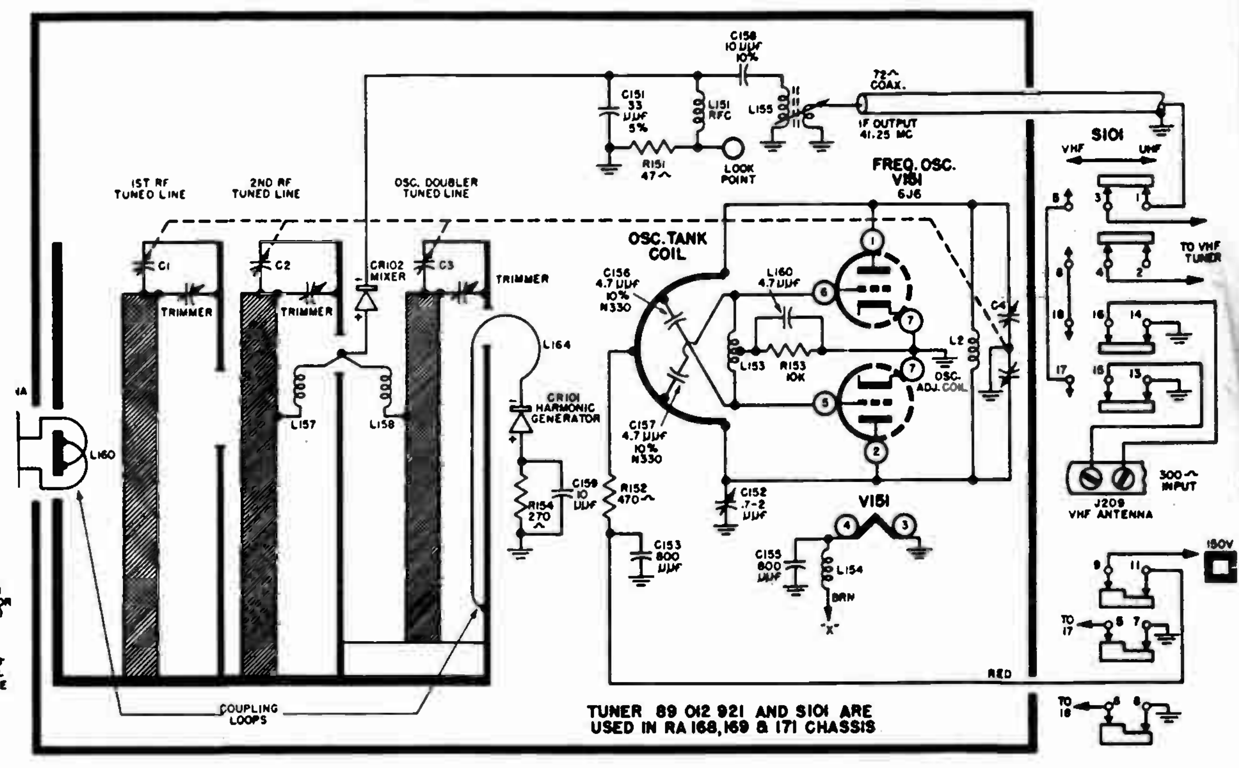


NOTES

1. All voltages are shown with the Contrast control rotated fully clockwise, and the Du-monitor (agc) control adjusted for −6.5 volts at P204, the agc test point.
2. Voltages ± 20% of those shown are normal.
3. All resistors are 10%, one-half watt, unless otherwise indicated.
4. All capacitors are 20%, 500V, unless otherwise indicated.
5. All capacitors are ceramic, unless indicated as follows:
   M—mica, P—paper, ±—electrolytic,
   MP — molded paper
6. Tuner 89 012 901 is used in RA-166, 167 and 170 chassis. Tuner 89 012 911 is used with UHF tuner 89 012 921 in RA-168, 169 and 171 chassis.

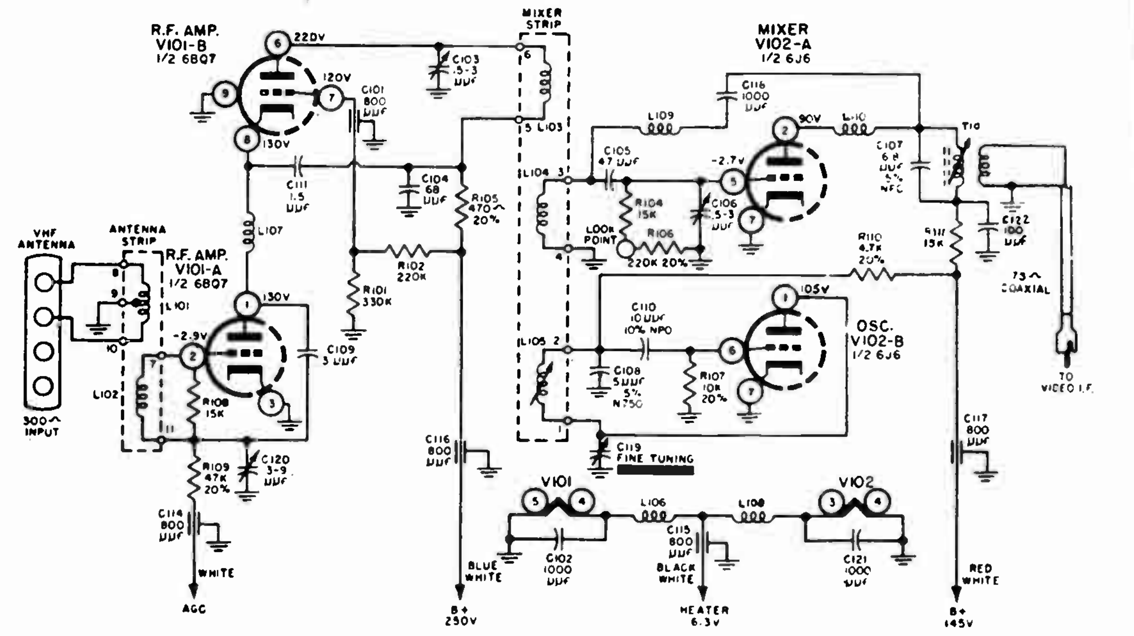


UHF TUNER 89 012 921

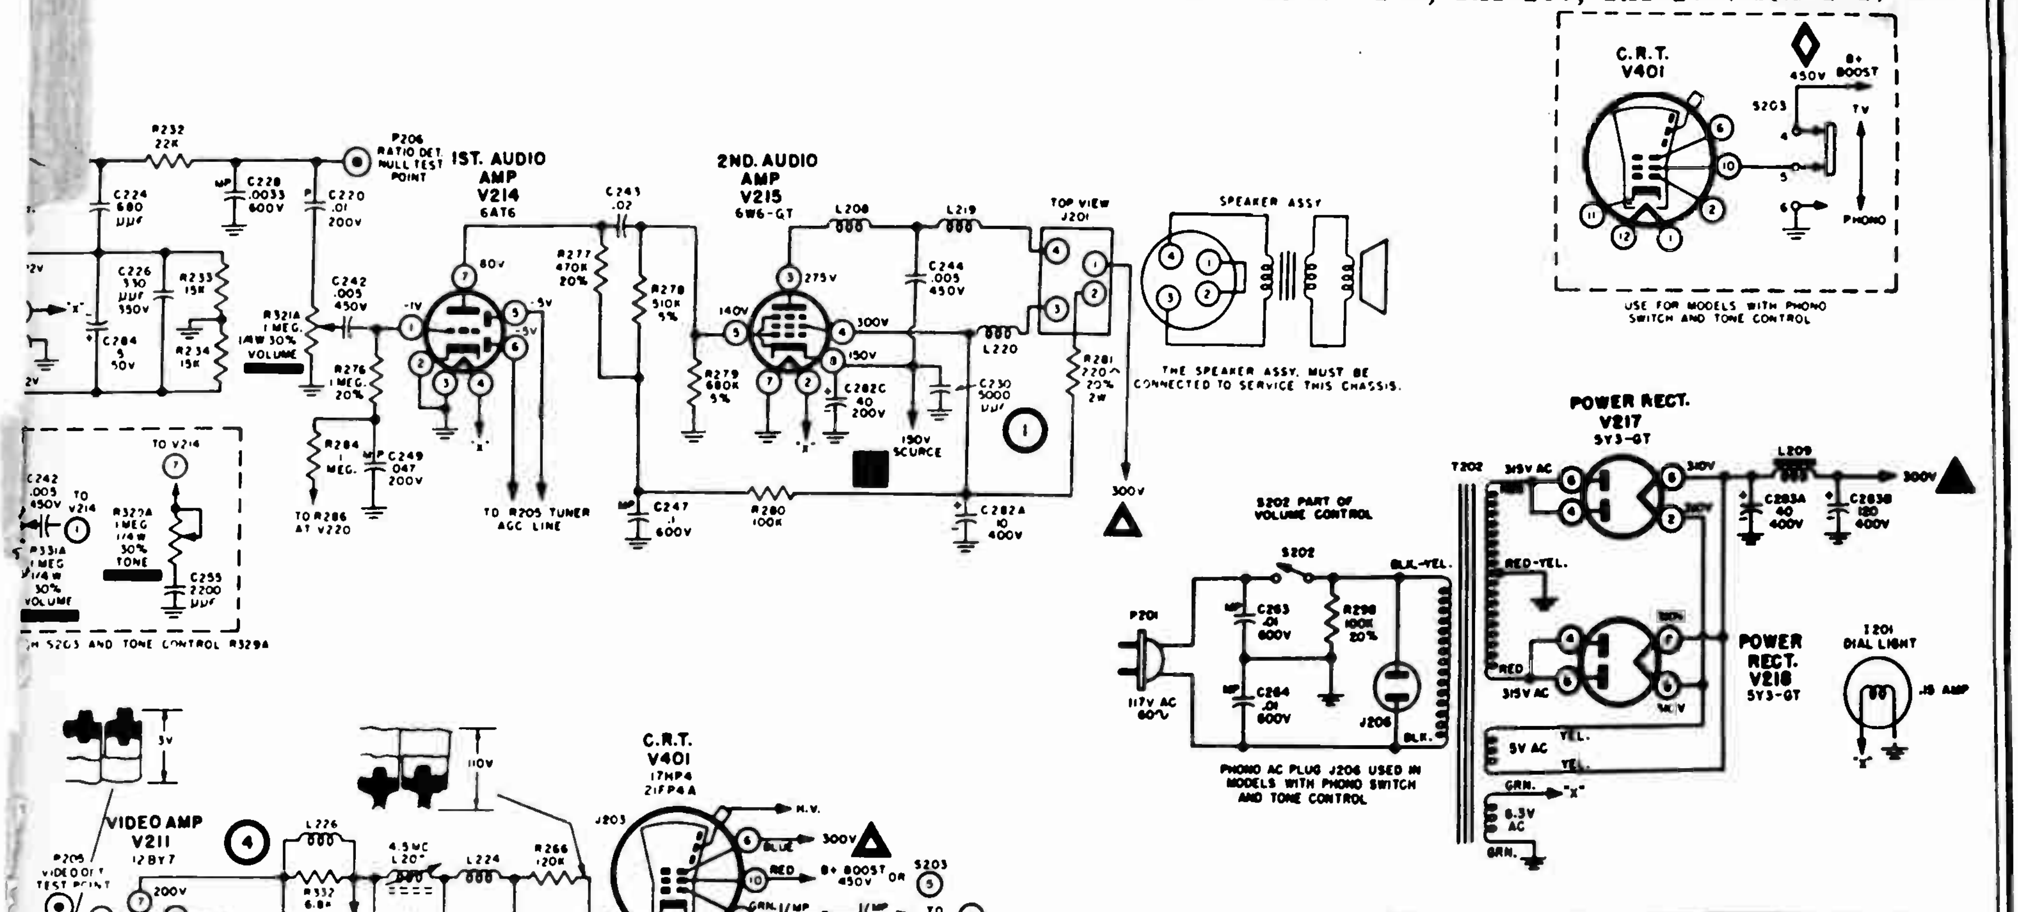


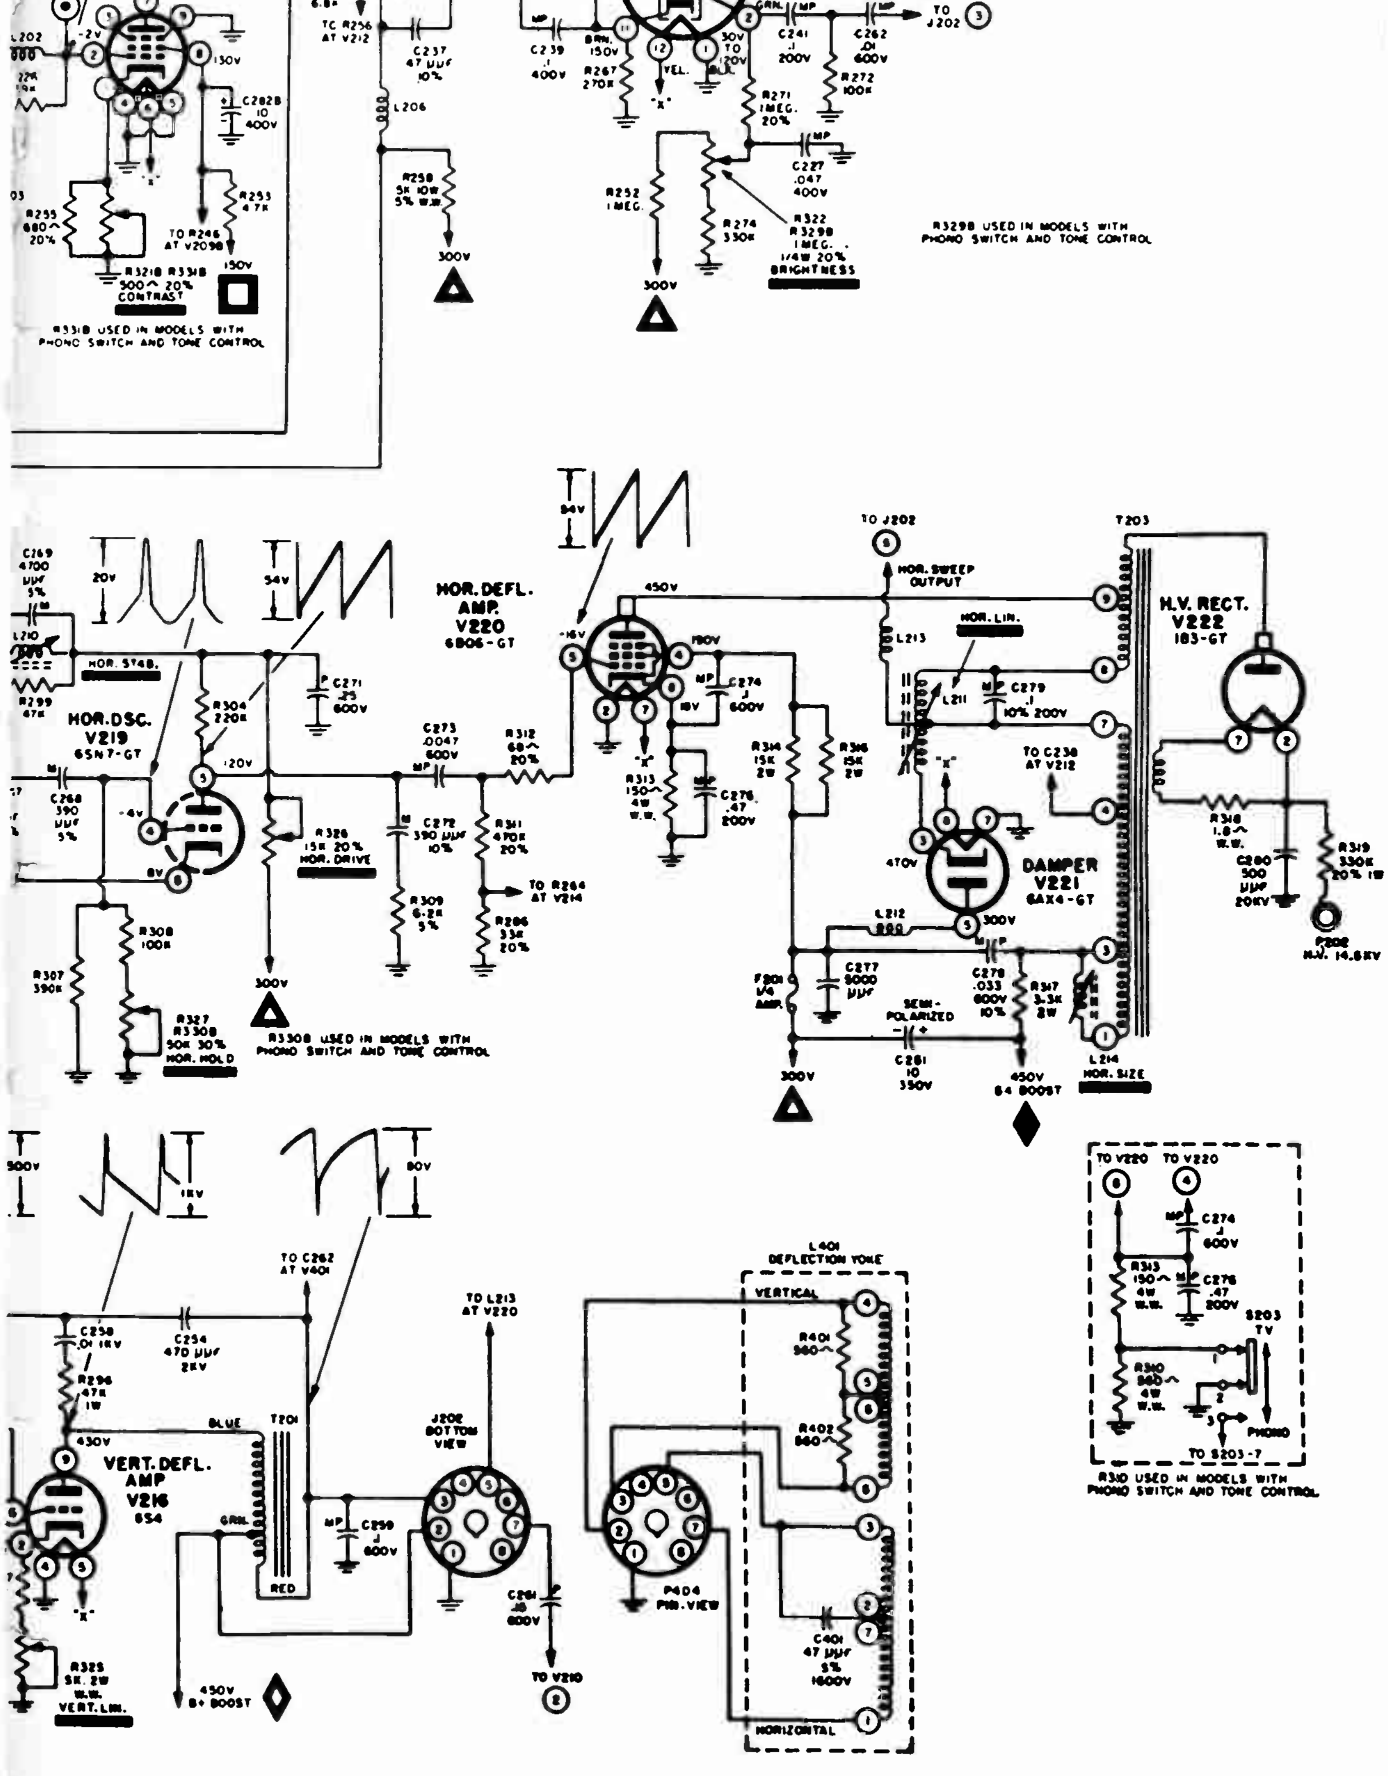
TUNER 89 012 971

USED ALTERNATELY WITH TUNER 89 012 901.



CHASSIS RA-166, RA-167, RA-170, RA-171, Late



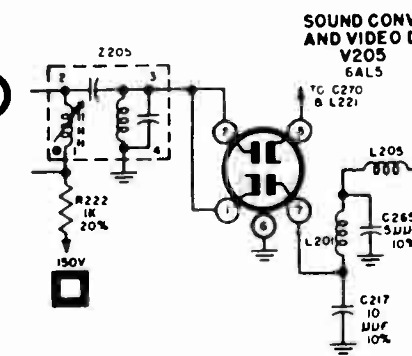


PRODUCTION CHANGES

RA-166/171

(1) C230 is not used in RA-166/171 chassis prior to serial number 666426.

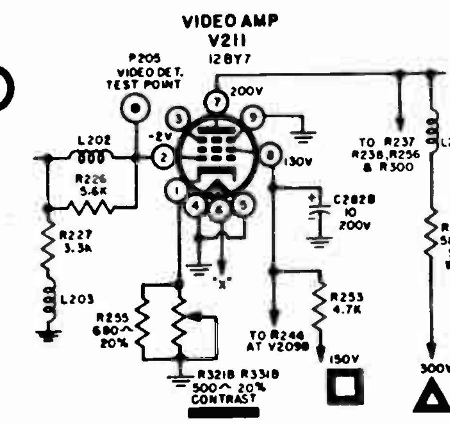
(2)



V205 is a 6AL5 in chassis prior to those coded Run 1. The early circuit is shown above. R265 is 1K and is connected between the junction of C219, L221 and ground.

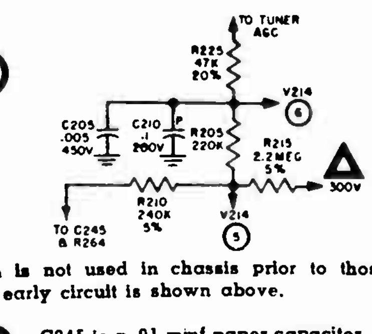
(3) C209, C260, C287 and R320 are not used in RA-166 and RA-167 chassis prior to serial number 668401 or RA-170 chassis prior to serial number 704201.

(4)



In chassis prior to those coded Run 4 the video amplifier circuit shown above is used. In these chassis L225, C288 are not used and R228 is 100K.

(5)

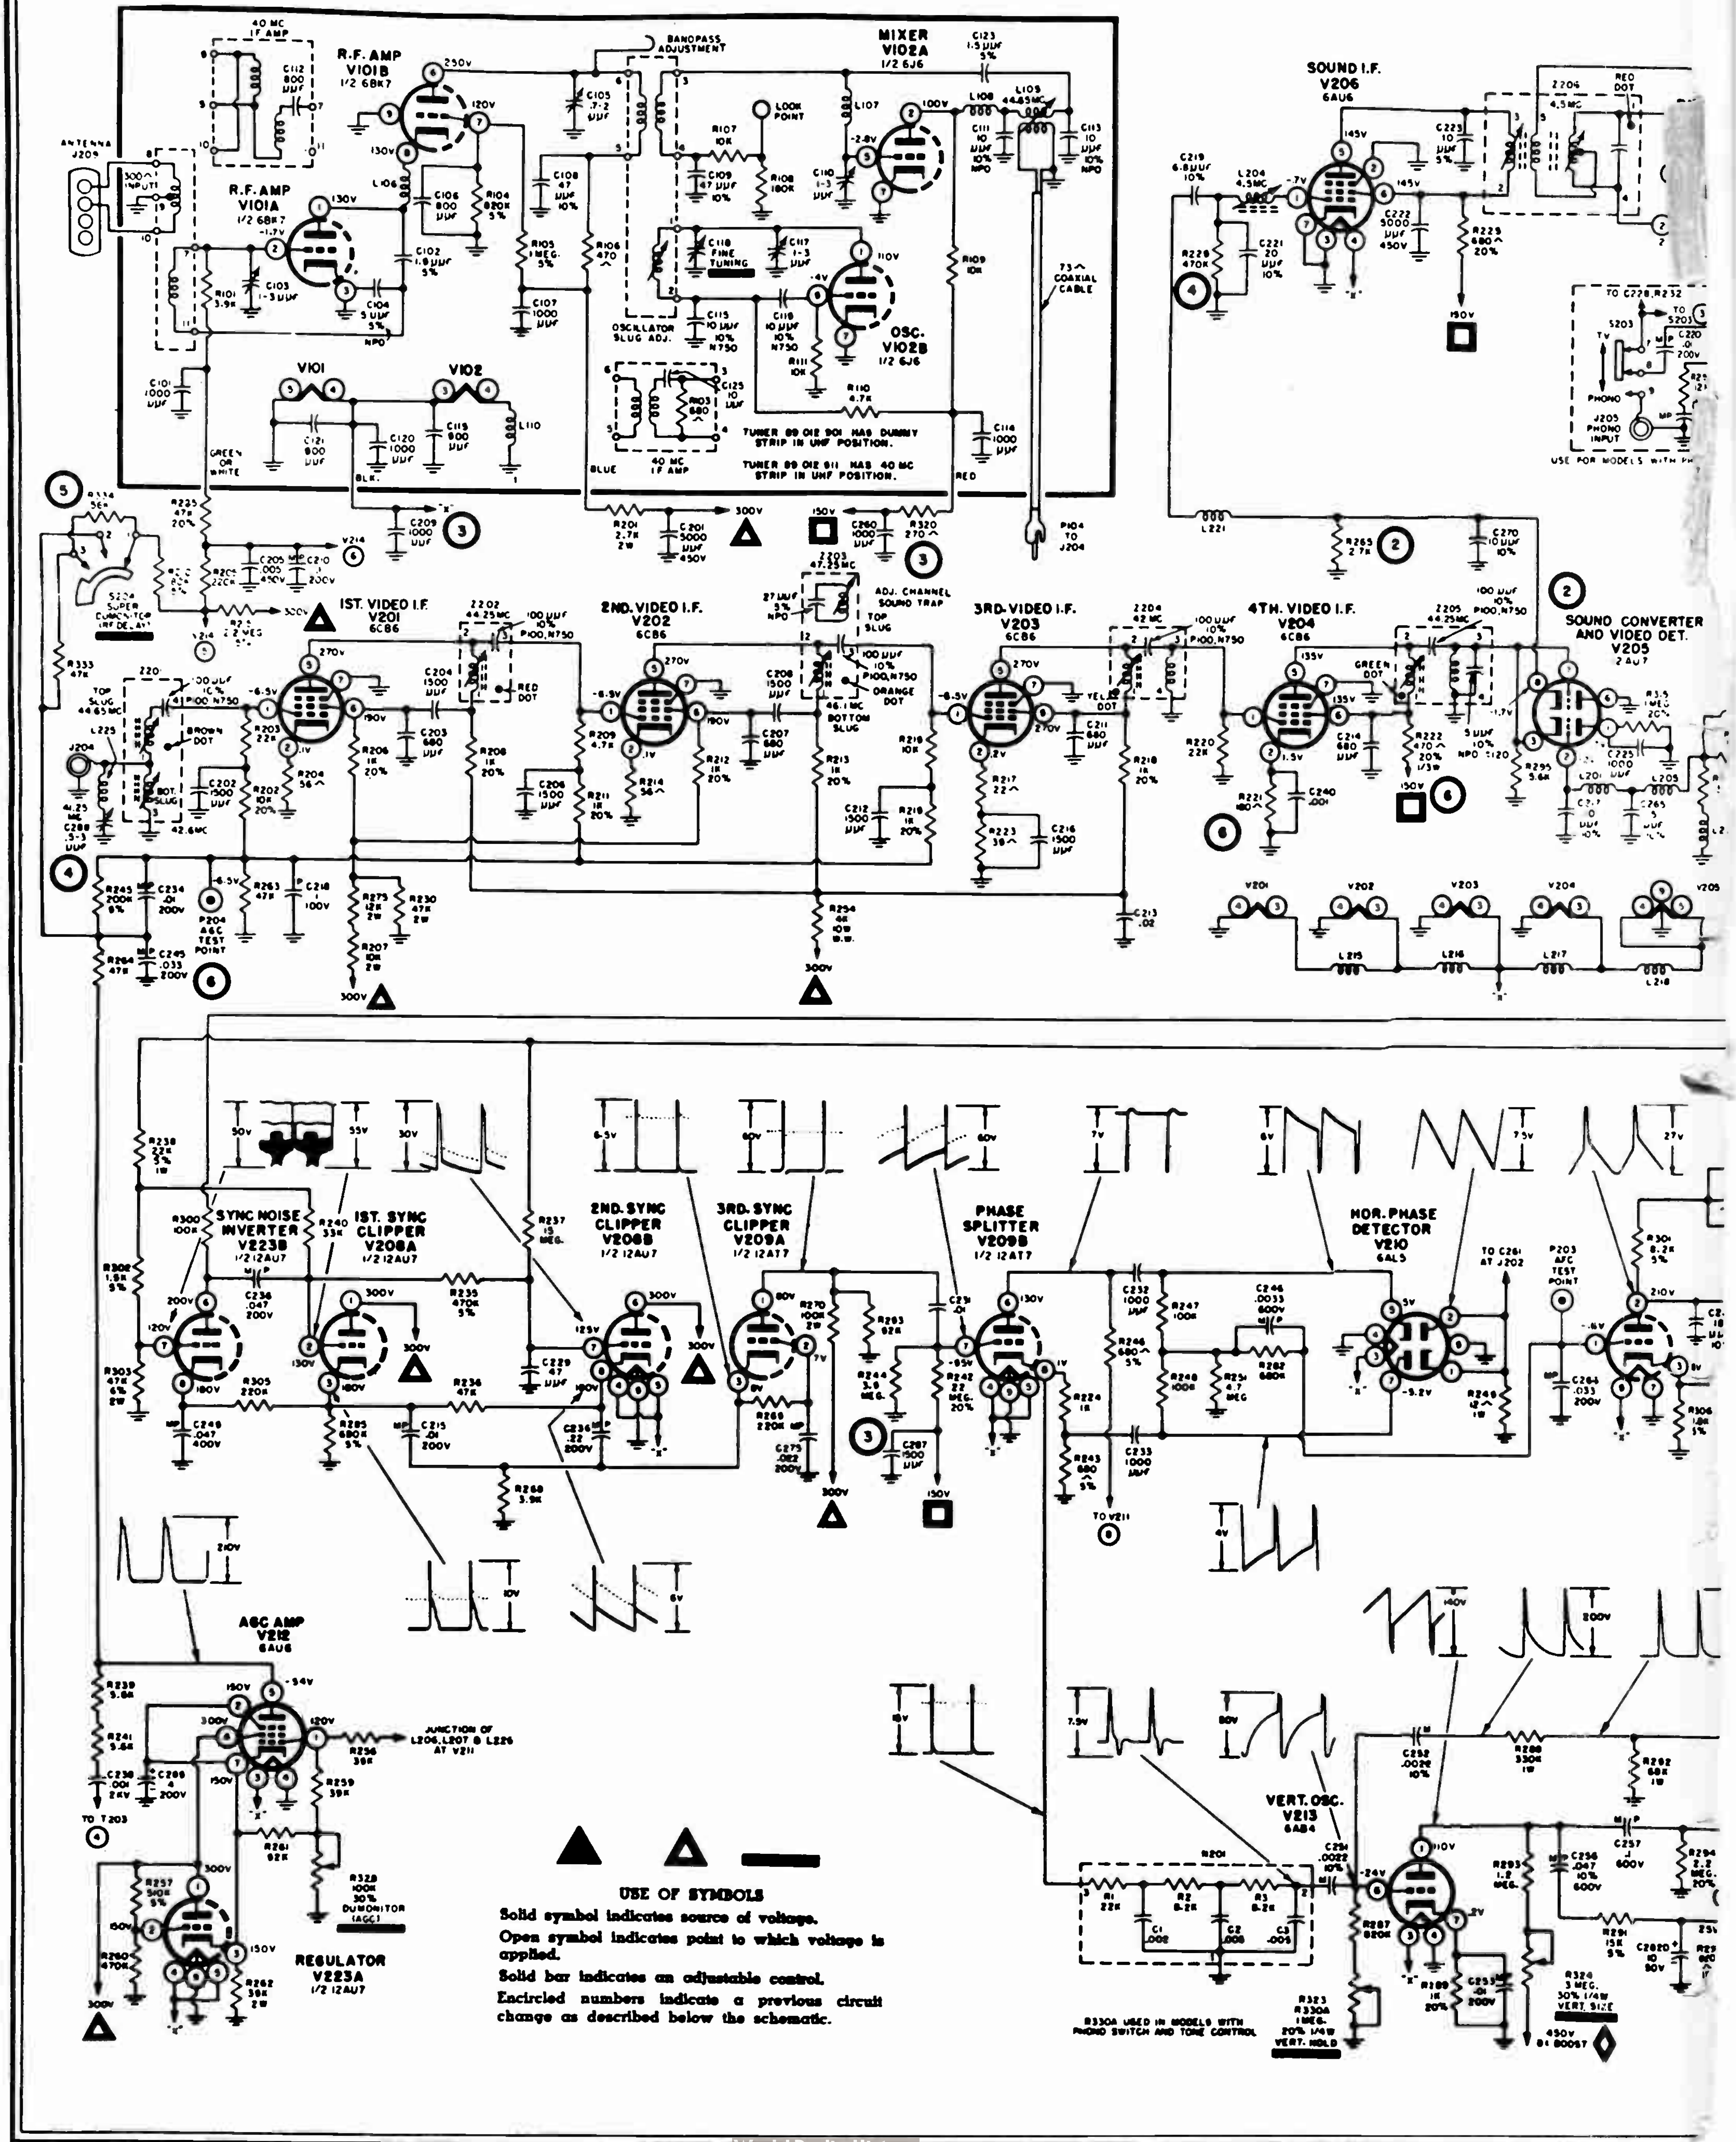


S204 is not used in chassis prior to those coded Run 5. The early circuit is shown above.

(6) C245 is a .01 mmf paper capacitor, R221 is 100 ohms and R222 is 1K in chassis prior to those listed below.

RA-166/167	6619866
RA-168/169	681901
RA-170	7027381
RA-171	719501

RA-166/171 CHASSI



RA-166/171 PRODUCTION CHANGES

Reason:

To eliminate high audio frequency harmonics, present on the 150 volt line. In some cases these harmonics enter other stages of the receiver causing streaks in the picture.

Procedure:

Connect a 5000 mmf ceramic capacitor from pin 8 to pin 7 of the audio output tube, V215.

Parts Required:

SYMBOL	PART NUMBER	DESCRIPTION
C230	03 015 610	Cap. ceramic 5000 mmf.

The first chassis so modified are:

RA-166/167	No. 666426
RA-168/169	No. 681
RA-170	No. 701
RA-171	No. 711

Run 1

Reason:

To reduce radiation of harmonics of the sound and video i-f signals, generated in the video detector and sound converter, V205. Under some conditions these harmonic signals enter the tuner causing interference in the picture. A dual triode is used in place of the 6AL5 dual diode. The triode sections operate as diodes

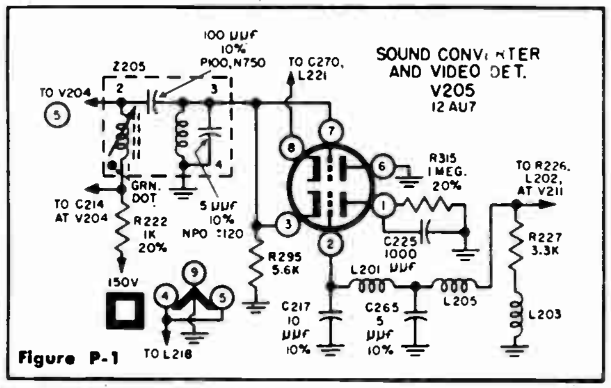


Figure P-1

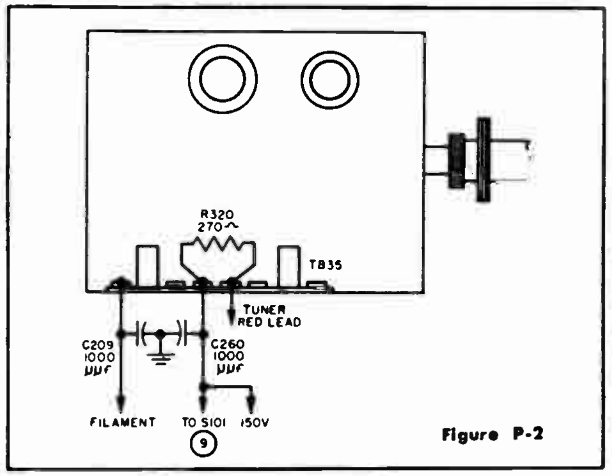

Figure P-2

with the grids acting as the diode plates. The triode plates are used as shields to reduce radiation.

The sound-converter section plate is grounded directly. The video-detector section plate is grounded through a parallel RC network. The network places the plate at ground potential to r-f, while avoiding the loading effect on the video detector which would occur if the plate were grounded directly.

Procedure:

1. Remove the 6AL5 and its socket. Replace the socket with a 9-pin miniature socket. Rewire the circuit as shown in figure P-1.
2. Remove R265, connected between the junction of C219-L221 and ground. Connect R265, 2.7K 10% ½W resistor, from the junction of L221, C270 and pin 8 of V205, to ground.

Parts Required:

SYMBOL	PART NUMBER	DESCRIPTION
R265	02 031 820	Res 2.7K 10% ½W
R295	02 031 860	Res. 5.6K 10% ½W
R315	02 032 600	Res. 1 Meg 20% ½W
V205	25 000 130	Tube, 12AU7
	34 003 590	Socket, 9 prong
	42 009 040	Shield (for 12AU7)
	42 007 110	Base, tube shield

The first chassis so modified are:

RA-166/167	No. 666972
RA-168/169	No. 681
RA-170	No. 70966
RA-171	No. 711

Run 2

Reason:

To reduce the possibility of regeneration in models equipped with a UHF tuner. An RC decoupling network has been added between the +150 volt line and the tuner red lead.

To eliminate r-f components on the tuner filament and +150 volt line two r-f bypass capacitors have been added.

Procedure:

1. Disconnect the yellow lead, and the red lead between S101 and TB-35, from terminal 3 of TB-35 and reconnect them to terminal 4 (see figure P-2).
2. Connect a 270 ohm, ½ watt, resistor between terminals 3 and 4 of TB-35, and connect a 1000 mmf ceramic disc capacitor between terminal 4 of TB-35 and ground. The capacitor ground lead should be soldered to the tuner bracket directly below terminal 4 of TB-35.
3. Connect a 1000 mmf ceramic capacitor between terminal 6 of TB-35 and the ground point in step 2.
4. Connect a 1500 mmf ceramic disc capacitor between terminal 1 of TB-16 and the nearest ground lug.

Parts Required:

SYMBOL	PART NUMBER	DESCRIPTION
C209	03 100 490	Cap. ceramic 1000 mmf
C260	03 100 490	Cap. ceramic 1000 mmf
C287	03 017 850	Cap. ceramic 1500 mmf
R320	02 031 700	Res. 270 ohm 10% ½W

The first chassis so modified are:

RA-166/167	No. 668401
RA-168/169	No. 681
RA-170	No. 704201
RA-171	No. 711

Run 2

Reason:

To increase the long term stability of the vertical oscillator.

Procedure:

Remove C252 and replace it with a 2200 mmf mica capacitor.

Parts Required:

SYMBOL	PART NUMBER	DESCRIPTION
C252	03 029 480	Cap. mica 2200 mmf 10% 500V

The first chassis so modified are:

RA-166/167	No. 6614876
RA-168/169	No. 68795
RA-170	No. 7014100
RA-171	No. 71121

Run 4

Reason:

To provide improved picture quality and very weak signal sound performance. An accompanying sound trap C288-L225 is added, see figure P-3, the video amplifier plate load and sync take off circuits are changed, as shown in figure P-4, and new i-f alignment frequencies are specified.

Procedure:

1. Mount C288 a .5 to 3 mmf capacitor in the rectangular chassis hole located between Z201, the first video i-f transformer and the input jack J204. Solder the capacitor's spring lock nut to the chassis.
   NOTE: A few chassis do not have this hole. In this case drill a ⅛" hole in the chassis midway between Z201-1 and J204, and file the sides to fit C288.
2. Connect L225 between C288 and J204.
3. Remove the black lead connecting pin 7 of V211, the video amplifier, and L207, the 4.5 mc trap.
4. Remove the black lead connected between TB-13-3 (junction of R237, 15 Meg ½W, and R238, 22K 5% 1W) and pin 7 of V211.
5. Connect L226 between pin 7 of V211 and L207. Connect R332, a 6.8K 10% ½W resistor, in parallel with L226.
6. Connect a lead from TB-12-3 (junction of L208 and R258, 5K 5% 10W resistor) to the junction of TB-13-3 noted in step 4.
7. Replace R228 at V206 with a 470K 10% ½W resistor.
8. Replace R220 at V204 with a 22K 10% ½W resistor.
9. Replace R226 at V211 with a 3.9K 10% ½W resistor.
   The frequencies in the alignment procedure should be changed as follows:
   Step 1—44.25 mc (Z205)
   Step 2—42 . mc (Z204)
   Step 4—44.25 mc (Z202)
   Step 6—Adjust mixer plate coil (L109) and Z201 (top) for 44.65 mc marker on one peak and Z201 (bottom) for 42.6 marker on the other peak of waveform shown in figure P-5. Adjust C288 for 41.25 mc dip.

Parts Required:

SYMBOL	PART NUMBER	DESCRIPTION
C288	03 019 871	Cap. cer. var. .5 to 3 mmf

L226	21 006 623	Coil video peaking
R220	02 031 930	Res. 22K 10% ½W
R226	02 031 840	Res. 3.9K 10% ½W
R228	02 032 090	Res. 470K 10% ½W
R320	02 031 700	Res. 270 ohm 10% ½W
R332	02 031 870	Res. 6.8K 10% ½W

The first chassis so modified are:

RA-166/167	No. 6618456
RA-168/169	No. 681201
RA-170	No. 7023315
RA-171	No. 716174

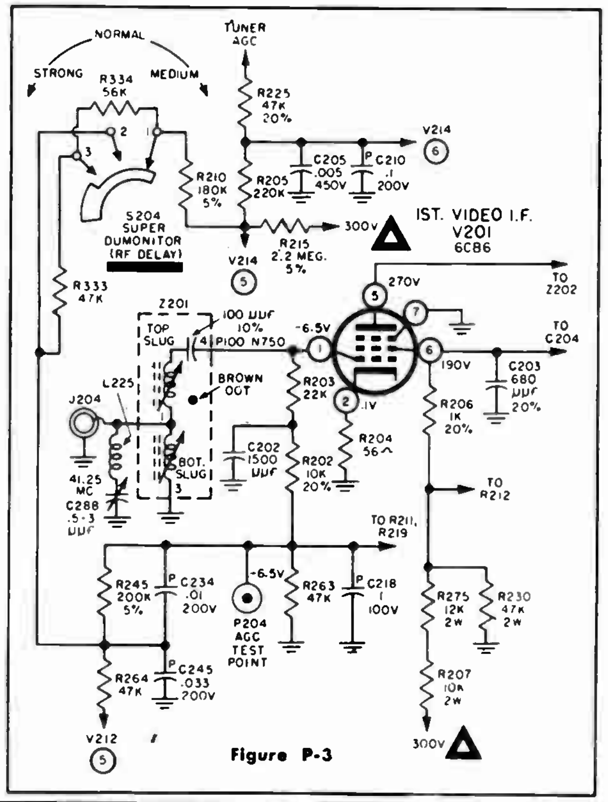

Figure P-3

Run 5

Reason:

To provide a field adjustment of the r-f a-g-c delay in order to obtain improved strong and very weak signal performance. The new control is named the Super Dumonitor.

Procedure:

1. Mount S204, a single-pole three-position rotary switch, on rear of chassis above L210.
2. Remove R210. Connect a 180K ½ watt 5% resistor, between terminal 1 of S204 and terminal 3 of TB-18. Cover the leads of this resistor with spaghetti. The new resistor is shown as R210 in figure P-3.

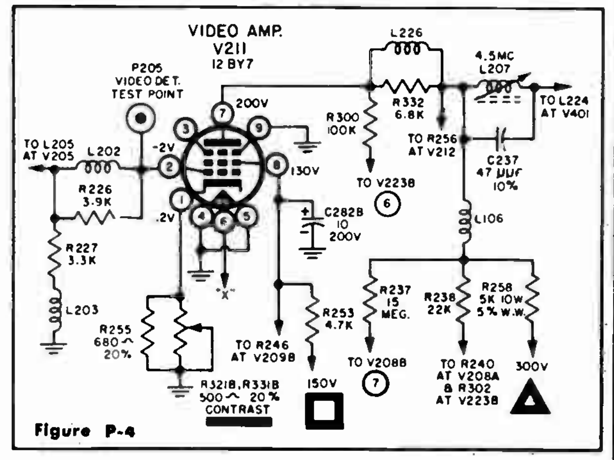

Figure P-4

3. Connect R333, a 47K ½W resistor, between terminals 2 and 3 of S204.
4. Connect R334, a 56K ½ watt resistor, between terminals 1 and 3 of S204.
5. Connect a lead between terminal 2 of S204 and terminal 2 of TB-19.

Parts Required:

SYMBOL	PART NUMBER	DESCRIPTION
R210	02 031 020	Res. 180K 5% ½W
R333	02 031 970	Res. 47K 10% ½W
R334	02 031 980	Res. 56K 10% ½W
S204	05 008 731	Switch 3 position

The first chassis so modified are:

RA-166/167	No. 6619556
RA-168/169	No. 681901
RA-170	No. 7025737
RA-171	No. 719001

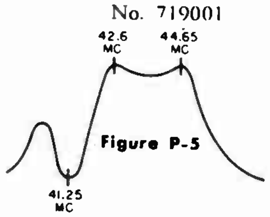

Figure P-5

Run 5

Reason:

To improve the horizontal lock-in range and minimize the possibility of overload in the 4th video i-f stage.

Procedure:

1. Remove C245, the a-g-c filter capacitor (see figure P-3), and replace it with a .033 mf 20% 200V capacitor.
2. Remove R221 in the cathode circuit of V204 and replace it with a 180 ohm 10% ⅓W resistor.
3. Remove R222 in the plate circuit of V204 and replace it with a 470 ohm 10% ⅓W resistor.

Parts Required:

SYMBOL	PART NUMBER	DESCRIPTION
C245	03 126 830	Cap. paper .033 mf 20% 200V
R221	02 031 680	Res. 180 ohm 10% ⅓W
R222	02 201 700	Res. 470 ohm 10% ⅓W

The first chassis so modified are:

RA-166/167	No. 6619866
RA-168/169	No. 681901
RA-170	No. 7027381
RA-171	No. 719501

GENERAL DESCRIPTION

Emerson models 711F, 712F, 720D, 732B, 734B and 733F are television receivers providing direct view high definition pictures on a twenty-one inch glare free kinescope. Many advanced circuit designs have been incorporated in these models including built-in antenna, black magic contrast, miracle picture lock, automatic horizontal frequency control, automatic gain control, electrostatic focusing minimum operating controls and many other features.

The 120169-B and 120164-B chassis are similar except for the horizontal frequency control and oscillator circuits which are explained in this note.

Model 733F (chassis 120169-F) in addition to these differences also incorporates a 3-speed phonograph (pt. no. 819069), and an independent 5-tube AM radio (chassis 120152-F). The 120169-F chassis is the same as the 120169-B chassis except where necessary to accommodate this radio and phonograph, which is explained in this note.

HORIZONTAL AUTOMATIC FREQUENCY CONTROL

In modern day receivers it is necessary to use some form of automatic frequency control so that the horizontal sync. pulses do not directly trigger the horizontal oscillator. This is necessary since occasional noise bursts may prematurely trigger the oscillator, causing the picture to either spear or tear out.

By using A.F.C. the average of a group of sync. pulses are used to control the frequency of the oscillator, therefore, if a sync. pulse is distorted or masked by noise little effect will be observed on the screen.

This type of system is especially useful in the fringe areas where the signal to electrical noise interference is very poor.

This particular chassis uses a comparison of phase between the sync. signal and the generated sawtooth as a basis for automatic frequency control (A.F.C.). Such a system is little influenced by changes in sync. amplitude or occasional noise and, therefore, operates extremely well.

A Phase Detector V-12B compares the difference in phase between transmitted horizontal sync. pulse and the horizontal sawtooth voltage which is generated in the receiver. Whenever the frequency of the horizontal multivibrator (V-13) changes, the sawtooth frequency generated by this tube also changes. This effect changes the phase between the sync. and sawtooth voltages which is detected by V-12B (Horizontal Phase Detector).

When the frequency and phase of the sync. and sawtooth is correct the negative grid voltage developed across R-66 (82K) is equal to the positive cathode voltage developed across R-65 (100K), therefore, the net output voltage to the grid of V-13 (Horizontal Oscillator) is zero.

If the oscillator slows up, the phasing is such to cause the grid current to increase more than the plate current with a resultant negative output control voltage.

If the oscillator speeds up the plate current increases more than the grid current and the net output control voltage is positive.

R-77, R-69, C-47, R-64, C-46 are used to couple and shape the negative going pulse to a negatively phased sawtooth.

C-54, C-53 Divide the generated horizontal sawtooth which is further reduced in amplitude by the voltage division of C-48 in series with C-45.

The network of R-68 (2.2 meg) in parallel with C-50 (.001) used in conjunction with C-49 (.015) tends to filter unwanted high frequency pulses, while permitting the low frequency control voltage to pass.

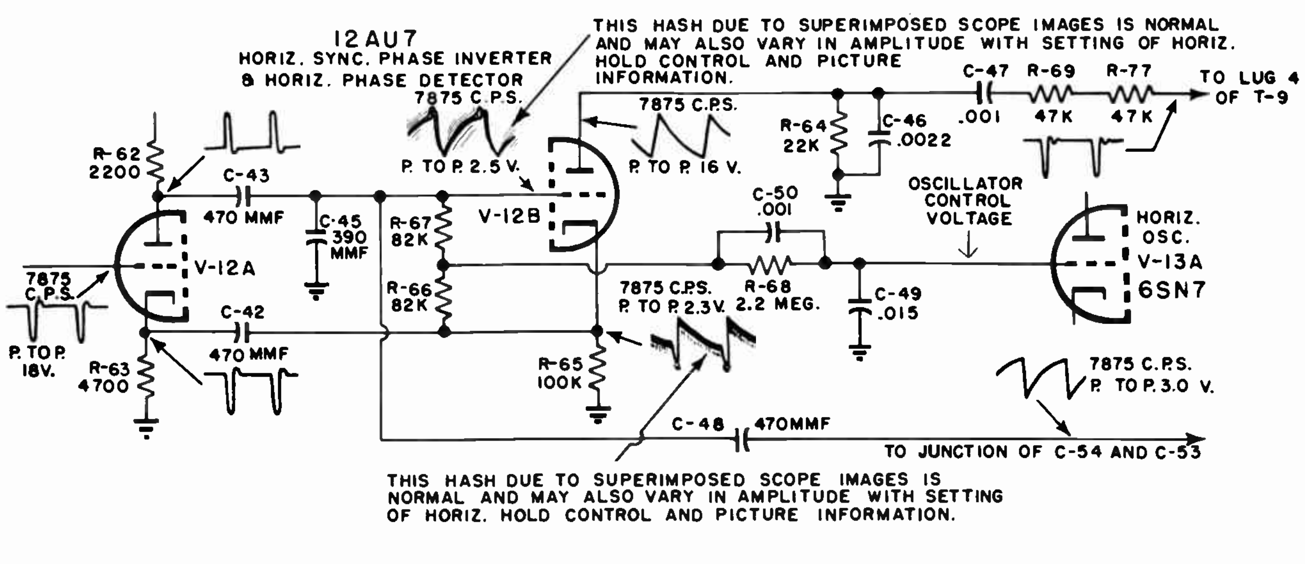

Figure 2 - HORIZONTAL AUTOMATIC FREQUENCY CONTROL NETWORK

HORIZONTAL OSCILLATOR, SWEEP, AND OUTPUT

V-13 6SN7 is a cathode coupled multivibrator whose free running frequency depends upon such factors as setting of R-72 (Horizontal Balance), R74 (Horizontal Hold), adjustment of L-10 (Horizontal Phase Coil) and the applied plate and grid voltages. Since automatic frequency control is to be used in this circuit, one of the above factors will have to be automatically varied. Since the grid of V-13A offers a convenient control point its voltage will be varied automatically to control the oscillation frequency of V-13. The method of control is outlined under "Horizontal Automatic Frequency Control."

The horizontal phase coil (L-10) is adjusted so that its natural resonant frequency is the same as the horizontal sync. rate (15,750 C.P.S.). The abrupt voltage changes in the plate circuit of V-13A shock this circuit into oscillation. Since the frequency of L-10 and C-52 is not effected by voltage changes or other component changes, it greatly stabilizes the operation of the circuit by modulating the plate voltage of V-13A with a 15,750 C.P.S. sine wave. The polarity and phase of this sine wave is such that it maintains the free running frequency at 15,750 C.P.S.

The sweep voltage is developed across C-56, C-54, C-53 which is charged through R-75 (120K) and is then coupled to the grid of the 6BQ6GT horizontal output tube. The 6BQ6GT (V-14) is used as a power amplifier so as to supply the necessary horizontal deflection current to the deflection yoke. The horizontal output transformer (T-9) matches the relatively low impedance of the horizontal deflection yoke winding (L-13) to the plate circuit of the 6BQ6GT (V-14) for maximum efficiency. The damper tube V-16 (6W4GT) is effectively connected across the horizontal deflection yoke to damp out oscillations which occur over part of the horizontal scanning cycle. The resultant energy from these damped oscillations provides the boosted B+ voltage.

PHONO TV SWITCH

In the phono position, the phono-TV switch removes B plus voltages from the screen of the horizontal output tube, plate of the damper tube and removes screen and plate voltages from V-1, V-2 and V-3 (video IF tubes). This renders the TV sweep, H.V. and signal circuits inoperative. At the same time the input to the volume control is disconnected from the discriminator output and connected to the output of the phono crystal.

RADIO CHASSIS 120152F (Model 733F)

This radio is an independent 5 tube superheterodyne A.M. receiver which utilizes the same speaker as the television receiver. This is achieved by means of a relay operated switch which is mounted on the television chassis. This relay also prevents the TV and radio from being operated at the same time. A pilot light incorporated in this chassis indicates when the radio is on. (For service information on Radio see page 7.)

RELAY OPERATED SWITCH (Model 733F Chassis 120169F)

A two pole double throw switch is operated by this relay. When the TV "ON-OFF" switch is in the "OFF" position, the relay is unenergized, (as shown on schematic), thus terminal F is shorted to terminal G and terminal I is shorted to terminal K. Since terminals F and G are connected together, the speaker (SP-1) is connected to the radio's audio output transformer. Since terminals I and K are connected together, power is supplied to the radio outlet (X-9) permitting the radio receiver to be turned on.

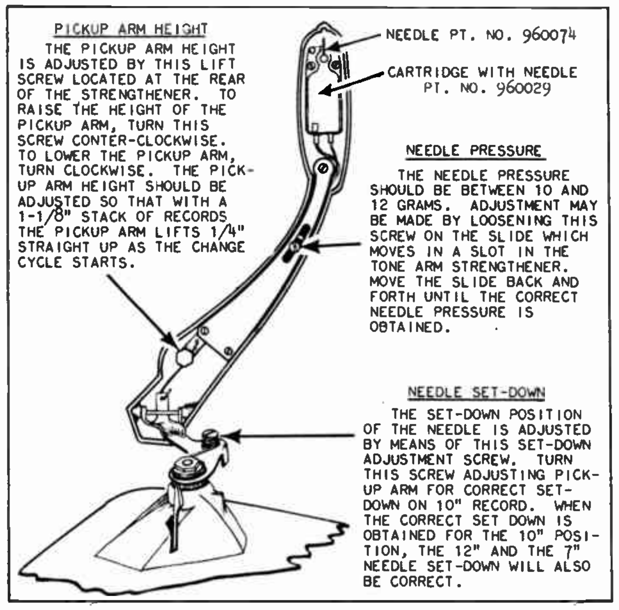
When the TV receiver is turned "ON" the relay is energized, thus shorting terminal E to F and also H to I. This removes the power from the radio outlet (X-9) and connects the speaker (SP-1) to the TV audio output transformer (T-8) instead of the radio's.

3 SPEED (78, 45, 33-1/3 R.P.M.) AUTOMATIC RECORD CHANGER pt#819069 (MODEL 733F)

This changer plays records through the sound portion of the TV chassis when the "Phono-TV switch" is placed in the phono position.

Features of this changer include playing and automatically changing as many as ten – 12", twelve – 10", twelve – 7", or any assortment of intermixed 10" and 12" records of the same R.P.M. (78, 45, 33-1/3 R.P.M.).

This changer shuts off automatically after the last record has been played.



PREPARING FOR OPERATION

1. SHIPPING BOLTS
   Before placing in operation, the changer must be floated freely on the mounting springs. During shipment, the mechanism is secured by means of two shipping bolts. To float the changer, remove the turntable* by lifting it straight up the spindle. Turn the two shipping bolts in a clockwise direction as far as they will go and replace the turntable. Before the turntable can be fully seated, the idler wheel must be gently pushed back out of the way to prevent damage to the rubber tire.

* When shipped turntable is secured to the back of the cabinet.

2. LEVELING RECORD CHANGER
   It is essential to have the record changer absolutely level. Use a torpedo or similar type level on the record changer baseplate. Use adequate shims to level the record changer pan or radio combination cabinet to achieve perfect level.

For additional service information refer to the manual on the 819053 changer which was issued at an earlier date. These changers are the same except 819069 has the addition of an equalizing circuit in series with the pickup arm (2.2 meg ohm in parallel with a 68 mmfd. condenser). See top of page 7.

BEAM BENDER (ION TRAP)

A single magnet type of beam bender is used and should always be adjusted by sliding and rotating the unit for maximum brightness. Do not adjust the trap for removing corner shadows if in so doing the brightness is reduced.

If two positions of maximum brightness are found use the one closer to the picture tube socket.

USE OF THE FRINGE COMPENSATOR

In fringe areas there is generally a higher ratio of electrical impulse noise (ignition, neon signs, electrical motors, etc.) to signal which might tend to effect sync. operation. To reduce this condition this chassis has been equipped with a "Fringe Compensator and Switch". This compensator is located at the rear of the chassis, and can be adjusted to handle the effects of electrical interference in most fringe locations. This compensator is provided with an on-off switch so that it can be disconnected when not required.

NOTE: In most locations this added protection will not be necessary and the fringe compensator should remain in the "off" position.

Improper adjustment or application of the fringe compensator may result in excessive audio buzz and/or picture wiggle. This device is designed to give added performance in fringe areas and will result in satisfactory operation only if instructions are carefully adhered to.

ADJUSTMENT OF THE FRINGE COMPENSATOR

1.) Tune set to a low frequency channel in a normal fashion. If low channels are not available use a higher channel.

2.) Turn fringe compensator switch to the "ON" position and adjust the potentiometer to the center of its mechanical range.

3.) Check all channels normally received in the area and re-adjust compensator if necessary for best performance.

CENTERING PROCEDURE

1. Set the unit, magnets forward, on the tube so that the magnets are about 1/4" behind the yoke. Adjust the clamp so that the unit is a sliding fit on the tube.
2. Set the magnets so that the adjusting arms are approximately 120° apart (figure 3).
3. Adjust the ion trap magnet for maximum brightness.
4. Rotate the whole unit, this will cause the picture to move around a circle. Stop where the picture is most nearly centered.
5. Rotate the magnets separately, in equal distances but in opposite directions to complete the centering.
6. Repeat Steps 3, 4 and 5, if necessary.
7. Tighten clamp.
8. Readjust ion trap magnet to give maximum brightness.

CAUTION: It is important that the centering magnets not be operated too close to the yoke as the A-C field from the yoke may cause the centering magnets to become demagnetized.

NOTE: Some slight improvement in focus may be obtained by adjusting the ion trap magnet within the range of the maximum brightness.

On no account should the trap magnet be adjusted to give good focus at the expense of brightness, as this condition produces ion "burns" on the screen in the course of time.

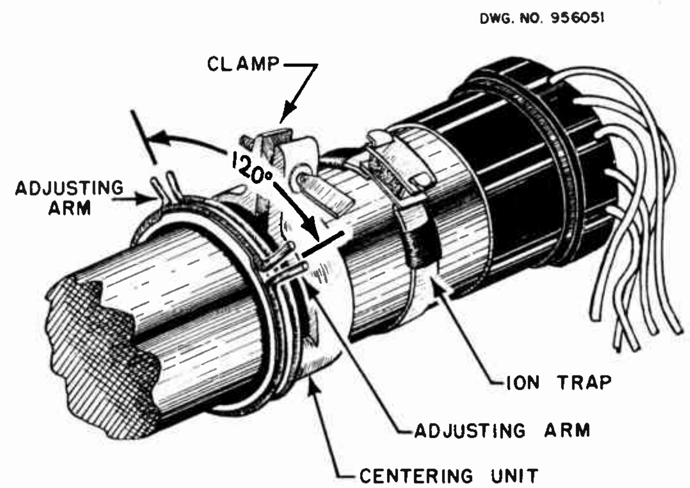


Figure 3 – CENTERING UNIT LOCATION DRAWING

ALIGNMENT

a. Equipment Required - A sweep generator, (10 MC. sweep with center frequency of 44 MC. plus all necessary R.F. sweep frequencies as listed in R.F. Table), accurate marker generator, oscilloscope and V.T.V.M. are required for alignment. The marker generator must supply frequencies of 4.5 MC., 40 to 48 MC. and 50 to 216 MC.

b. Alignment Points - The location of all I.F. transformers, Tuned Circuits, and trimmers shown in Figure 8.

TV R.F. & MIXER ALIGNMENT

Connect 3 volt bias battery to both I.F. and R.F. AGC. circuits, positive terminal to chassis, negative terminal to junction of R-16, C-19, C-18. Add a jumper wire from this junction to junction of R-8, R-14, C-7 so that the bias battery is also applied to I.F. AGC.

	#4 69 MC.	* 71.75 MC. ** 67.25 MC.		Set Channel Selector to #4 (See Note Above)		
	#3 63 MC.	* 65.75 MC. ** 61.25 MC.		Set Channel Selector to #3 (See Note Above)		
	#2 57 MC.	* 59.75 MC. ** 55.25 MC.		Set Channel Selector to #2 (See Note Above)		

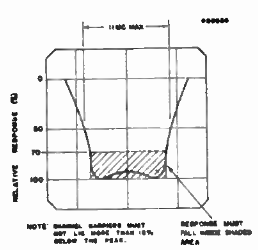

Figure 5 -- TUNER RESPONSE CURVE SHOWING BAND-PASS LIMITS.

The response for all channels should meet with the requirements of Fig. 5. To do so it may be necessary to compromise by slightly changing the initial channel #12 adjustments of C-2, C-5 and C-6 while switched to channel which does not conform.

*Sound Carrier Marker
**Picture Carrier Marker

NOTE: C-1 IS AN I.F. TRAP AND CAN BE ADJUSTED IN THE FIELD TO REDUCE ANY INTERFERENCE WHICH MAY AFFECT CHANNEL #2 FROM A NEARBY TRANSMITTER OPERATING IN THE 40 MC. BAND.

I.F. ALIGNMENT

1) Tune receiver to unused Channel 10 or 12.

2) Connect 3 volt bias battery with negative terminal to I.F. AGC. (Junction R-8, C-7, R-14) positive terminal to chassis.

3) Connect D.C. V.T.V.M. to video test point (see location in Fig. 7 and 8)

4) Connect terminated marker generator to floating shield of converter tube V-23 6J6. (Shield raised slightly so that it does not make contact with chassis). Use unmodulated marker. See Fig. 7.

MARKER GENERATOR	ADJUST	PROCEDURE
45.75 MC. Unmodulated	T-4	Peak for maximum response. Adjust output of signal generator so that maximum response does not produce more than -2V. D.C. on V.T.V.M.
43.2 MC. Unmodulated	T-3	
42.0 MC. Unmodulated	T-2	
45.0 MC. Unmodulated	L-3 T-1	
41.25 MC. Unmodulated	L-2	Adjust trap for minimum response. Increase output from signal generator so that a true minimum position can be found.

5) Connect vertical input of an oscilloscope instead of V.T.V.M. to video test point with vertical scope gain set at, or near, maximum. (Horizontal scope sweep set at 400 cycles).

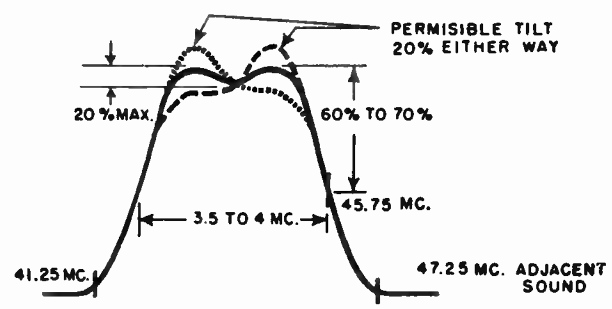
MARKER GENERATOR	ADJUST	PROCEDURE
47.25 MC. 400 Cycles Amp. Mod.	L-1	With signal generator set at maximum output, adjust L-1 for minimum vertical response on scope.

6) Now that all the I.F. coils and transformers have been set, the overall response can be observed and adjusted if necessary.

SIGNAL GENERATOR INPUT			MEASURING INSTRUMENT	ADJUST	PROCEDURE
CONNECTION	FREQUENCY				
	SWEEP	MARKER			
Connect terminated sweep and marker as shown in Fig. 7.	Center frequency 44 MC. 10 MC. Sweep	45.75 MC.	Scope connected to Video Test Point	T-4	If 45.75 MC. doesn't lie from 60 to 70% down adjust T-4 (see fig. 6) for tolerances. *

Providing overall curve is within tolerances as shown below, no further adjustments are needed. If band width or tilt is not as specified, repeat entire alignment procedure. If still out then a slight retouching is permissible. TRAPS L-1 and L-2 MUST BE ADJUSTED AS INDICATED ABOVE. DO NOT RE-ADJUST WHILE OBSERVING OVERALL I.F. RESPONSE CURVE.

*KEEP OUTPUT SIGNAL GENERATOR AS LOW AS POSSIBLE WHEN OBSERVING THE OVERALL I.F. SHAPE SINCE TUBE OVERLOAD MIGHT RESULT AND THE RESPONSE WILL APPEAR INCORRECTLY FLAT AND WIDE.



NOTE: It may be impossible to observe the 47.25 MC. marker with the average service equipment due to the high attenuation of trap L-1 (adjacent sound).

Figure 6. OVERALL I.F. RESPONSE CURVE

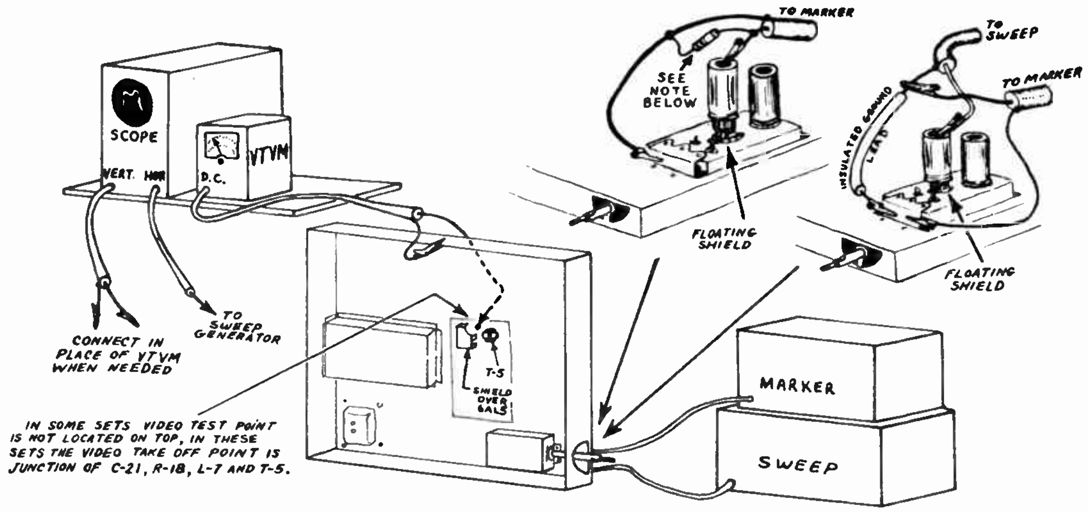


Figure 7. CONNECTIONS FOR I.F. ALIGNMENT.

All instrument leads should be dressed as directed and as short as possible to prevent interaction between input and output leads. Failure to do this may result in an unstable response indication.

NOTE It is important that the output cable of the sweep and marker generator be properly terminated in their characteristic impedance which is usually from 50 to 75 ohms. If this termination has not been built into the end of the cable by the instrument manufacturer * then a resistor of the proper value (characteristic impedance) should be connected across the output of each generator cable as shown above.

* If in doubt check your instruction book which is issued by the test equipment manufacturer.

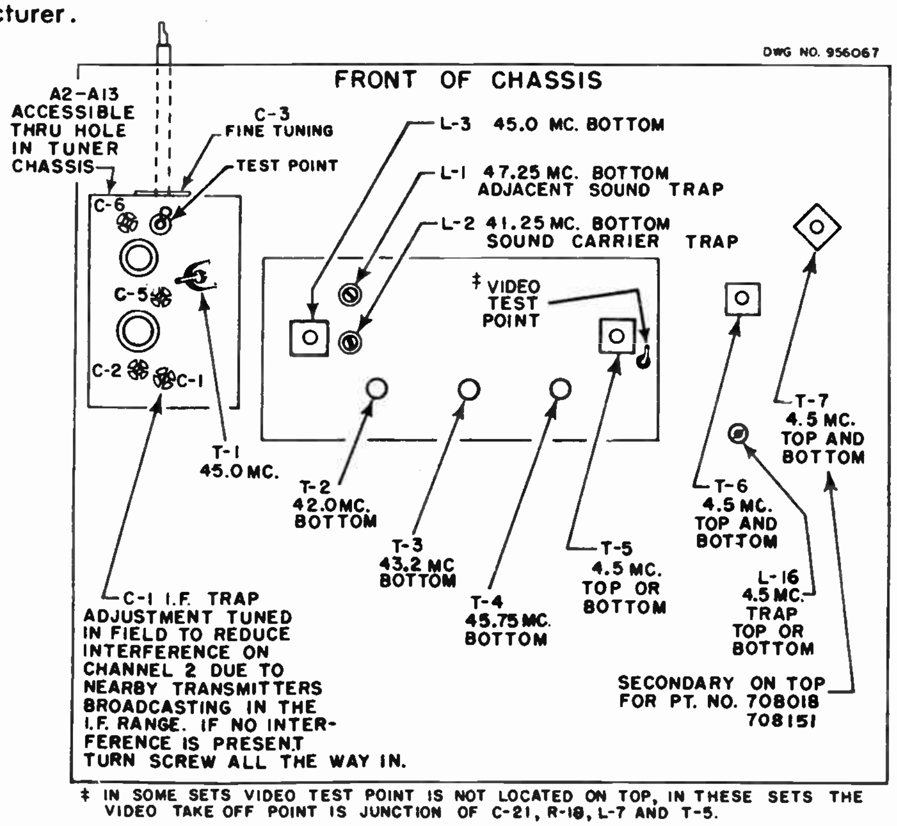

Figure 8 - LOCATION OF ALIGNMENT POINTS (TOP VIEW)

R.F. OSCILLATOR ALIGNMENT

1. Connect marker and sweep generator as shown in Figure 4, low side to chassis.
2. Connect scope to video test point (see location Fig. 7 and 8).
3. Connect 3 volt bias battery as described under R.F. Alignment Page 4.
4. Before undertaking oscillator alignment be sure I.F. circuits are correctly aligned for band pass characteristic and trap settings.
5. During oscillator alignment, it is necessary to set the fine tuning control so that the tooth on the fine turning cam points downword.

MARKER SIGNAL GENERATOR FREQUENCY	SWEEP GENERATOR FREQUENCY	MISCELLANEOUS INSTRUCTIONS	TRIMMER OR SLUG	TYPE OF ADJUSTMENT AND OUTPUT INDICATION
*209.75 MC. **205.25 MC.	Channel #12 Center Frequency 207 MC. 10 MC. Sweep	Be sure that fine tuning control has been properly positioned (tooth on the cam pointing down) NOTE During this step and thru-out all succeeding steps it is necessary to: 1. Keep output of sweep generator at a level that does not allow the reading on a VTVM to exceed minus 1 volt when connected across video detector load at minimum sweep width. 2. Keep output of standard signal generator at a level that provides a readable marker but does not distort the curve that is being observed on the scope.	Adjust Slug A-12	NOTE: Before making the following adjustment, advance the vertical gain control on the scope in order to magnify the sound trap portion of the response curve. Then, use a non-metallic screwdriver to adjust channel #12 oscillator slug (accessible thru hole on front of r-f tuner unit and shift response curve so that sound carrier marker is located at the position indicated below. Now reduce gain control setting of scope to restore pattern to normal amplitude and observe position of picture carrier marker. This marker should appear on the high frequency side of the characteristic curve. The amplitude of the picture carrier should be between 60 and 70% down from peak response.
*215.75 MC. **211.25 MC.	Channel #13 213 MC.	Set Channel Selector to #13 (See note above)		Adjust the r-f sweep generator and marker generator for operation on other television channels; set marker generator to sound carrier frequency. After setting Channel Selector to corresponding channel, adjust oscillator slug thru hole on front of r-f tuner unit. (A-2 to A-13) This permits response curve to be shifted so that sound carrier marker will appear at the position indicated below.
*203.75 MC. **199.25 MC.	Channel #11 201 MC.	Set Channel Selector to #11 (See note above)		
*197.75 MC. **193.25 MC.	Channel #10 195 MC.	Set Channel Selector to #10 (See note above)		
*191.75 MC. **187.25 MC.	Channel #9 189 MC.	Set Channel Selector to #9 (See note above)		
*185.75 MC. **181.25 MC.	Channel #8 183 MC.	Set Channel Selector to #8 (See note above)		 TYPICAL OVERALL RESPONSE CURVE
*179.75 MC. **175.25 MC.	Channel #7 177 MC.	Set Channel Selector to #7 (See note above)		
* 87.75 MC. ** 83.25 MC.	Channel #6 85 MC.	Set Channel Selector to #6 (See note above)		
* 81.75 MC. ** 77.25 MC.	Channel #5 79 MC.	Set Channel Selector to #5 (See note above)		
* 71.75 MC. ** 67.25 MC.	Channel #4 69 MC.	Set Channel Selector to #4 (See note above)		
* 65.75 MC. ** 61.25 MC.	Channel #3 63 MC.	Set Channel Selector to #3 (See note above)		
* 59.75 MC. ** 55.25 MC.	Channel #2 57 MC.	Set Channel Selector to #2 (See note above)		NOTE: Make sure that cam on fine tuning control shaft remains properly positioned during this step (tooth on the cam pointing downward).

NOTE: If an unsatisfactory overall response is obtained for a particular channel, observe R-F amp. and Mixer response curve for that channel (as described in R-F Amp. and Mixer Alignment Table). If characteristic does not conform reasonably well within the typical curve shown in Figure 5, then do the following things:

1. Check method of connecting scope, voltmeter and generator leads to eliminate possible distortion of observed response, or:
2. Attempt to obtain a better compromise for R.F. response on all channels by realigning R-F Amp. and Mixer circuits, or:
3. Try replacing Antenna, R-F and Oscillator coils for the particular channel.

*Sound Carrier Marker
**Picture Carrier Marker

R.F. OSCILLATOR ALIGNMENT PROCEDURE

SOUND ALIGNMENT

(A) USING 4.5MC UNMODULATED SIGNAL GENERATOR

1) Short pin #1 of V-3 to chassis with short jumper wire.
2) Keep output of signal generator low so as to provide a sharp meter indication with adjustment of transformers.

(B) USING TRANSMITTED TV AIR SIGNAL

1) Connect antenna and tune to a good on the air TV station.
2) Adjust fine tuning control for best picture.
3) Adjust antenna coupling for moderate signal so as to provide a sharp meter indication with adjustment of transformer.
4) Meter reading may pulsate due to changes in signal strength; do not confuse with a peak adjustment.

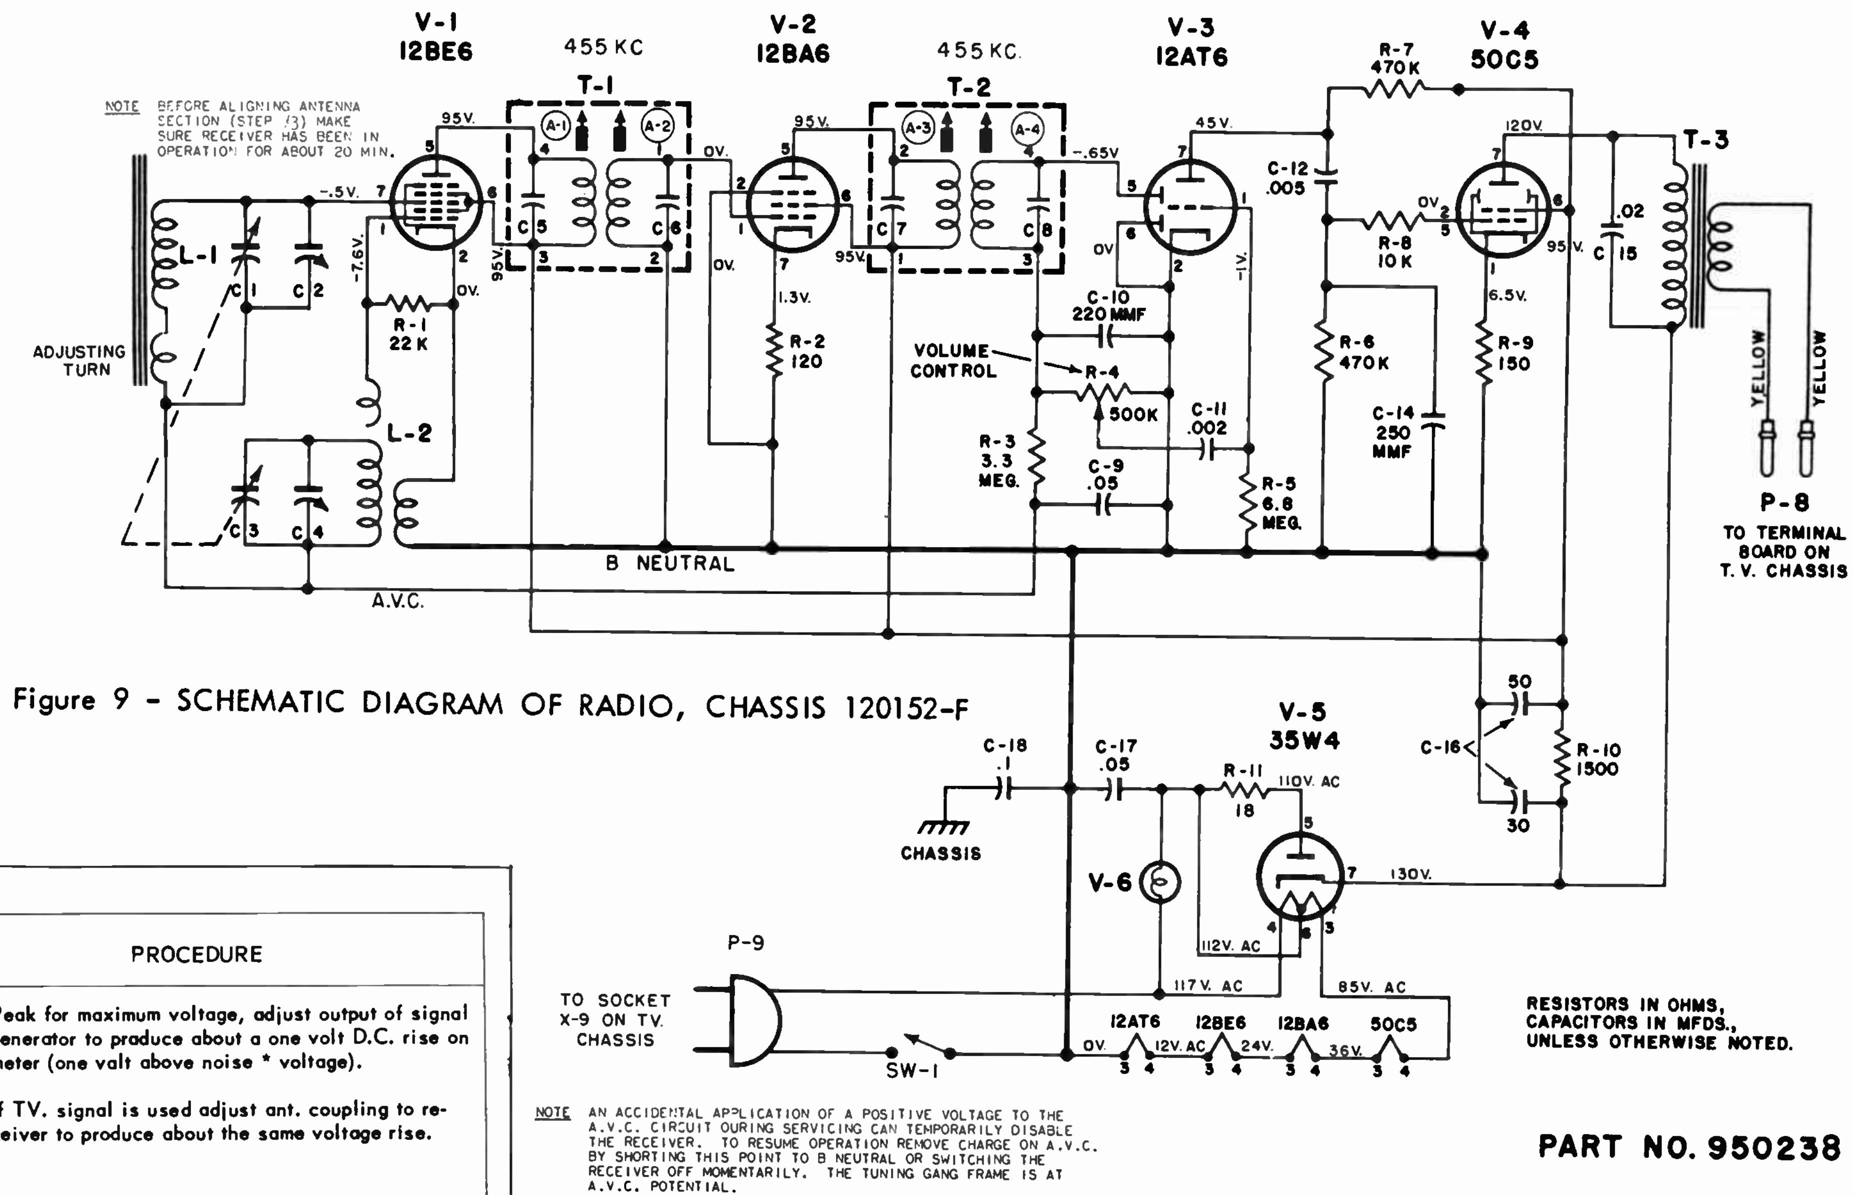

Figure 9 - SCHEMATIC DIAGRAM OF RADIO, CHASSIS 120152-F

PART NO. 950238

STEP	SIGNAL GENERATOR INPUT CONNECTION	SIGNAL GENERATOR INPUT FREQUENCY	MEASURING INSTRUMENT	ADJUST	PROCEDURE
1	Marker gen. through .01 mf. to Pin 7 of V-4 low side to chassis. -or- Connect antenna and tune in a good transmitted TV signal (any channel)	4.5 mc. (unmodulated) -or- a good on the air TV. channel	Connect D.C. V.T.V.M. (negative scale) through 10K resistor to junction of C-29, R-33, R-34 Low side to chassis.	T-5 top or bottom T-6 top and bottom	Peak for maximum voltage, adjust output of signal generator to produce about a one volt D.C. rise on meter (one volt above noise * voltage). If TV. signal is used adjust ant. coupling to receiver to produce about the same voltage rise.
2	Same as above	Same as above	Connect V.T.V.M. through 10K resistor to junction of R-48, C-78 Low side to chassis	T-7 top and bottom discriminator	A) Detune discriminator secondary (T-7 top Pt. #708018, 708151; bottom Pt. #708017) for maximum negative meter reading. B) Adjust primary T-7 for maximum negative meter reading. C) Readjust discriminator secondary (towards original setting) for zero D.C. reading on V.T.V.M. D) Check audio, if distorted repeat steps A to C.

* The noise voltage is measured under no signal conditions (ant. terminals shorted directly at tuner by means of a short jumper wire; or disconnect 4.5 mc. generator if procedure (A) above is followed).

4.5MC. VIDEO TRAP ALIGNMENT (L-16)

1) Short Pin 1 of V-3 to chassis by means of a short jumper wire.
2) Connect a 4.5MC. signal generator (unmodulated and crystal calibrated) through a .01 MF condenser between cathode of V-5 (Pin 2) and chassis.
3) Connect a D.C. V.T.V.M. (neg. scale) between junction of R-33, T-6, C-29 and chassis.
4) With contrast control set at minimum contrast (counter clockwise) adjust L-16 (see Fig. 8) for negative dip on V.T.V.M. (minimum negative reading). Keep output of signal generator low so as to produce a sharp voltage dip on the V.T.V.M.

NOTE Whenever the 4.5MC. Video trap (L-16) is adjusted, repeak the sound take off transformer (T-5) as shown above.

ALIGNMENT OF MIRACLE PICTURE LOCK

1) Tune set to a good channel.
2) Short phase coil (L-10), leads have been brought to top of chassis on a terminal strip near fuse (see tube location diagram figure 11).
3) Short horizontal control grid to chassis. This point has also been brought to top of chassis on same strip as mentioned in step 2.
4) Rotate horizontal hold control (R-74) to center of its mechanical range.
5) Adjust horizontal balance control (R-72) (rear of chassis) until picture pulls into synchronism (in most cases picture will sway from side to side).
6) Remove short from horizontal phase coil (L-10) and adjust L-10 for same synchronous condition as step 5 above.
7) Remove short from horizontal control grid. Horizontal frequency circuits are now properly aligned.
8) When properly adjusted (steps 1-7) the horizontal hold control can be moved slowly over most of its range without throwing the picture out of sync.

ALIGNMENT INSTRUCTIONS

1. Use isolation transformer if available. If not, connect a .1 mfd. condenser in series with low side of signal generator and B neutral.
2. Volume control should be at maximum position. Output of signal generator should be no higher than necessary to obtain an output reading. Use an insulated screw driver for adjusting.

STEP	DUMMY ANTENNA	SIGNAL GENERATOR COUPLING	SIGNAL GENERATOR FREQUENCY	RADIO DIAL SETTING	OUTPUT METER	ADJUST	REMARKS
1	.1 mfd.	High side to grid (pin 7) of V1 (12BE6). Low side to B neutral.	455 KC	Variable condenser fully open.	Across voice coil.	T2, T1 (A3, A4, A1, A2)	Adjust for maximum output. If isolation transformer is not used, reduce dummy ant. to .001 mfd. to reduce hum modulation.
2		Form loop of several turns and radiate signal into receiver	1620 KC	"	Across voice coil.	Trimmer C-4 (Osc.)	Adjust for maximum output.
3		"	1400 KC	Tune for maximum output.	Across voice coil.	Trimmer C-2 (Ant.)	Adjust for maximum output.

CONDITIONS FOR VOLTAGE AND RESISTANCE READINGS

1. Voltages indicated are positive d.c., resistances are in ohms, unless otherwise indicated.
2. Measurements made with voltohmyst or equivalent.
3. Line voltage maintained at 117 volts a.c. for voltage measurements.
4. Socket connections are shown as bottom views, with measurements from pin to common negative.
5. Volume control at maximum; no signal applied for voltage measurements.
6. Nominal tolerance on component values makes possible a variation of ± 15% in voltage and resistance readings.
7. NC denotes no connection, K is kilohms, MEG is megohms. Resistances marked * are measured to pin 7 of rectifier (B +).

DESCRIPTION
RADIO CHASSIS 120152-F

TYPE: Single-band (AM) superheterodyne.

FREQUENCY RANGE: Broadcast 540-1620 kc

TYPES OF TUBES:

- V-1 – 12BE6, converter
- V-2 – 12BA6, i-f amplifier
- V-3 – 12AT6, detector, a.v.c. a-f amplifier
- V-4 – 50C5, power output
- V-5 – 35W4, rectifier

VOLTAGE RATING: 105-125 volts.

POWER SUPPLY: Power from T.V. Outlet X-9

POWER CONSUMPTION: 30 watts.

CURRENT DRAIN: 0.24 amp. at 117 volts a.c.

TUBE TROUBLE ANALYSIS CHART

SYMPTOM	CHECK
Weak or no sound nor video (picture) raster normal	V-22, V-23, V-1, V-2, V-3, V-4 *
Weak or no sound - Video and raster normal	V-6, V-7, V-8, V-9, V-10
Weak or no video - Sound and raster normal	V-5, V-24
Poor or no horizontal nor vertical sync. Sound and video normal (contrast control makes video darker or lighter)	V-11
Poor or no horizontal nor vertical sync. - video weak or distorted, raster normal - sound may or may not be normal	V-22, V-23, V-1, V-2, V-3, V-4
Poor or no horizontal sync - raster and sound normal (Picture locks in vertically)	V-11, V-12, V-13
Poor or no vertical sync - raster and sound normal. (Picture locks in horizontally)	V-11, V-17, V-18
Horizontal line (no vertical sweep) - sound normal	V-18, V-19
Insufficient horizontal size, sound and video normal	V-14, V-16, V-20, V-21
Insufficient vertical size or white horizontal bar in picture	V-19
No sound, no raster - tubes lit	Fuse, V-20, V-21
No sound, no raster - tubes not lit	Plug connection in wall socket, on-off switch, line cord

* Another very common fault is a shorted or open circuit antenna connection to set. By raster we mean illuminated scanning lines.

VALUE OF C-62 (120169-B, F CHASSIS NOT BEARING ANY CODE TRIANGLE LETTER)

Each 708162 deflection yoke used in this chassis has been individually balanced at the factory to prevent objectionable yoke ringing (rippling of horizontal raster lines at left third of picture). To accomplish this, a ceramic capacitor, C-62, of 2000 volt rating has been used with each of these yokes. In the unlikely event that C-62 should fail, it must be replaced with one of the same individually identical value, construction and voltage rating. Since the yoke was previously perfectly balanced at the factory, the commercially available 5% tolerance of the first replacement condenser tried may yield a condenser sufficiently different from the original so as to fail to balance perfectly the horizontal windings in this yoke. A cut and try procedure will pay off in performance.

The following yoke balancing condensers may be tried:

VALUE	TOLERANCE + OR −	TYPE	VOLTAGE RATING	PART #	SUGGESTED LIST PRICE
38 mmf	5%	CERAMIC DISCAP	2000 volts	960640	.30
41 mmf	5%	CERAMIC DISCAP	2000 volts	960641	.30
43 mmf	5%	CERAMIC DISCAP	2000 volts	960642	.30
44 mmf	5%	CERAMIC DISCAP	2000 volts	960643	.30
47 mmf	5%	CERAMIC DISCAP	2000 volts	928065	.30
50 mmf	5%	CERAMIC DISCAP	2000 volts	960644	.30
52 mmf	5%	CERAMIC DISCAP	2000 volts	928085	.30
57 mmf	5%	CERAMIC DISCAP	2000 volts	960645	.30
62 mmf	5%	CERAMIC DISCAP	2000 volts	960646	.30

If the deflection yoke itself should fail and a replacement is ordered from your Emerson Distributor, this replacement yoke will have been factory balanced for optimum results, therefore, C-62 and R-85 (390 ohms) are shipped as part of this yoke.

VALUE OF C-62 (120169-B, F CHASSIS CODED TRIANGLE A)

A A circuit change has been incorporated in these chassis which effectively eliminates the necessity to match the value of C-62 for each yoke. See schematic diagram for details of change.

The deflection yoke used may be one of three (3) part numbers, 708137, 708162, 708163. These yokes are all interchangeable when used in a chassis with TRIANGLE A circuit modifications.

Since the value of C-62 is now non-critical, the range of condensers used is from 38 to 62 mmfd. For replacement purposes, however, it is recommended that a value of 47 to 52 mmfd. be used. The part numbers of these condensers are shown above. In some chassis a 390 ohm ½ watt resistor is connected in series with C-62 as indicated on the schematic.

CONDITIONS FOR TAKING VOLTAGE AND RESISTANCE READINGS

The resistance measurements listed below are for chassis 120169-B and 120169-F with a triangle code △B.

Due to component variations, voltage and resistance readings may vary slightly from those given here. Slight variations may also be noticed if chassis is not coded as mentioned above.

The picture tube, deflection yoke and high voltage circuits were connected to take the following readings and waveshapes.

1. Antenna disconnected and antenna terminals shorted on tuner and connected to chassis (use short leads).
2. Line voltage 117 volts (Disconnect power for resistance readings).
3. 3 volt bias battery connected to both I.F. and R.F. A.G.C. circuits, positive terminal to chassis, negative terminal to junction of R-16, C-19, C-18. Add a jumper wire from this junction to junction of R-8, C-7, R-14 so that bias battery is also applied to I.F. A.G.C. BIAS BATTERY USED FOR VOLTAGE READINGS ONLY.
4. All controls in position for normal picture. (Varied when it directly effects reading).
5. All measurements taken with a vacuum tube voltmeter and ohmmeter.
6. All readings listed in tables were taken between points shown and chassis.
7. Resistance readings are given in ohms unless otherwise noted.
8. N.C. denotes no connection.

WAVE SHAPE ANALYSIS CHART FOR CHASSIS 120169-B AND 120169-F

For models 711F, 712F, 720D, 732B, 733F and 734B. The information listed was taken from a chassis code marked △B.

Slight peak to peak voltage differences may be noticed if chassis is not triangle code marked as mentioned above.

The wave shapes shown here are arranged so as to give the serviceman an easy method of signal tracing. The peak to peak voltage given may vary slightly depending on signal strength and component variations.

To accurately observe the wave shapes, the relatively high input capacity of an oscilloscope must be reduced so as not to change the operating characteristics of the television set. Failure to do this will result in wrong wave shape readings.

Connect antenna and tune receiver to channel where best reception has been obtained in the past.

Low end of the probe is connected to CHASSIS and the contrast control is set at MAXIMUM CONTRAST.

The 30 and 7875 C.P.S. oscilloscope sweep settings are used so as to permit the serviceman to observe two cycles of the wave shape.

NOTE: A wave shape seen in your oscilloscope may be upside down from same wave shape shown here. This will depend on the number of stages of amplification in the oscilloscope used.

TUNER PART NO. 470696 or 470689

MECHANICAL PARTS CAN BE ORDERED BY NAMING PARTS FUNCTION AND NOTING THE TUNER PT. NO.

SCHEMATIC PART NO. 950219

Figure 14 - SCHEMATIC DIAGRAM OF TURRET TYPE TUNER USED ON CHASSIS 120169-B & F

REPAIR OF TUNERS

The majority of tuner troubles which are not due to defective tubes can usually be detected by a physical examination of the tuner (turret removed), such as burnt resistors, broken parts, bent or dirty contact fingers, cold solder joints, broken socket pins, etc.

If the tuner checks out physically it should then be checked according to the following trouble shooting chart.

It should always be borne in mind that a burnt tuner resistor is usually the result of a shorted condenser or tube.

The part numbers of items which are not generally commercially available are given on the tuner schematic. When replacing parts, leads should be kept as short as possible and components replaced in the same position as the original parts.

TUNER TROUBLE SHOOTING CHART

Measurements taken under same conditions as listed on top of Page 10. To take measurements from 6BQ7 socket, remove 6BQ7 tube but leave 6J6 tube in its socket, likewise when taking measurements from the 6J6 socket leave 6BQ7 tube in its socket.

	PIN NO.	NORMAL READINGS		POSSIBLE TROUBLES IF READINGS NOT NORMAL

PRODUCTION CHANGES

In the course of production various changes were incorporated in the order shown below. Changes as listed under a particular letter also include changes as listed under all previous letters unless otherwise noted.

Triangle Code Letter	F.S.B. No.	Supp. No.	Purpose
A	Service Note	O	See Schematic and Page 9.
B	Service Note	O	See Schematic
C	Service Note	O	See Schematic
D	Service Note	O	See Schematic

SUPPLEMENT NO. 1
MODEL – 742B
CHASSIS – 120169-B
MODEL – 720F
CHASSIS – 120169-D

Model Numbers	TV Chassis	Tube Size	TV Tuner
742B	120169-B	21MP4 (Metal-Rect.)	470689
720F	120169-D	21FP4A (Glass - Rect.)	470689

The model 720F is the same as the 720D except that it uses a 21 inch glass picture tube (21FP4A, chassis 120169-D) instead of a metal 21 inch picture tube (chassis 120169-B). The 120169-B & D chassis are identical except for the type of picture tube used.

With the exception of the cabinet parts list (below), all technical information pertaining to the models listed above will be found in the service note covering models 711F, 712F, 720D, 732B, 733F and 734B using chassis 120169-B & 120169-F

READY FOR U.H.F.

As in all Emerson Television Receivers, this model provides for reception of all V.H.F. Stations as well as new U.H.F. Stations, by means of easily interchanged tuning strips or an external converter.

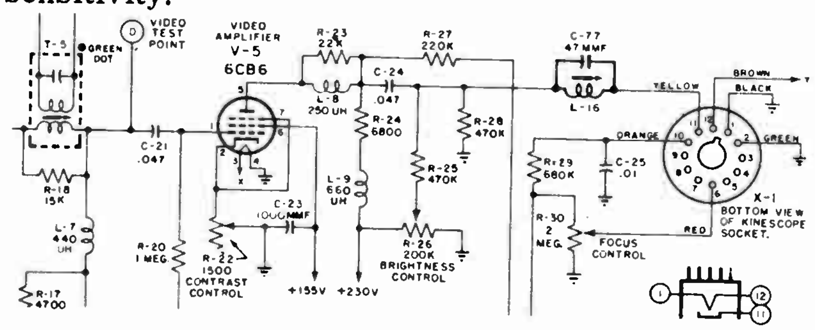
MODEL – 742B
CHASSIS – 120169-B

PRODUCTION CHANGES ON THE 120169-D CHASSIS

The Service Note covers production changes dealing with TRIANGLES A to D so for information concerning these changes, refer to schematic diagram in the Service Note.

△E Sets Coded TRIANGLE E have the 4.5 mc (L-16) trap electrically changed from the grid to the plate circuit of the video amplifier as shown below. The physical mounting of this trap remains the same.

This change has been incorporated to increase the 4.5 mc trap rejection ratio and increase the audio sensitivity.



The procedure for aligning this trap is now different from what is indicated. On all Chassis Coded TRIANGLE E or higher this trap should be aligned in the following manner:

a) Connect a crystal controlled 4.5 mc signal generator through a .01mf. condenser to the grid of the video amplifier tube (pin #1 of V-5 6CB6) low side to chassis.

b) Set contrast control for maximum contrast (fully clockwise).

c) Connect a V.T.V.M. (D.C. scale) through an R.F. probe to the cathode of the picture tube (pin #11 yellow lead) low side to chassis.

d) Adjust the 4.5 mc trap L-16 for minimum reading on the V.T.V.M.

If a crystal controlled generator is not available the video trap can be adjusted in the field by setting the fine tuning control for maximum 4.5 mc in picture and adjusting the 4.5 mc trap (L-16) until this 4.5 mc beat note is reduced. Be sure that video ringing is not introduced from this adjustment since this indicates the trap was aligned at too low a frequency.

SERVICE HINTS ON THE 120169-B, F & D CHASSIS

1) REPEATED FUSE FAILURE IN THESE CHASSIS - REPLACE WITH 1/2 AMP SLOW BLOWING TYPE FUSE. This condition can be caused by momentary arcs in tubes or components which occur intermittantly and soon heal themselves. These causes of fuse failure can be easily overcome by replacing the burnt out fuse with a 1/2 amp slow blowing type fuse.

2) LEAD DRESS TO PREVENT PICTURE WIGGLE ON CHASSIS BEARING NO TRIANGLE CODE.

a) The yellow lead to the cathode of the picture tube should be dressed away from the horizontal oscillator tube to prevent stray pickup of video information by the oscillator tube. This can be done by securing the yellow picture tube lead to the deflection yoke support bracket.

b) The white lead to the fringe compensator ON-OFF switch should be dressed away from the horizontal phase coil and the grid of the horizontal oscillator tube (V-13).

3) USE OF A 6BQ7A or 6BZ7 IN PLACE OF 6BQ7 ON TUNERS. The tuner used with this chassis may now incorporate either a 6BQ7, 6BQ7A or a 6BZ7 tube. These tubes are interchangeable but due to possible variations in interelectrode capacities, several tubes may have to be tried for best results.

GENERAL TUNER INFORMATION

In some tuners R-4 (180K) and R-3 (370K) may be changed to R-4 (150K) and R-3 (270K). Since the ratio of these resistors remain about the same there is no change in performance.

4) IMPROVEMENT OF SOUND IN THE FRINGE AREAS. Under certain conditions of reception or transmission, it may be advisable to touch up the alignment of the sound circuits in the field using an "on the air" TV station as the signal instead of the generator. By doing this, it is possible to improve the audio signal to noise ration.

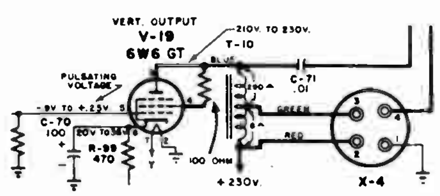
The Service Note shows how this can be done in the field. As a final step the sound transformers should be retouched (while listening to the sound) for best audio and minimum noise.

Chassis Coded TRIANGLES A to D can be further improved if desired, by either shorting out the 4.5 mc trap (jumper wire across L-16) or reconnecting the trap from the grid to the video amplifier plate circuit as shown under TRIANGLE E.

NOTE: If you short out the trap be sure to repeak the sound take-off transformer (T-5).

5) POPPING SOUND IN THE AUDIO WHEN PICTURE STARTS TO ROLL VERTICALLY OR WHEN THE VERTICAL HOLD CONTROL IS ADJUSTED.

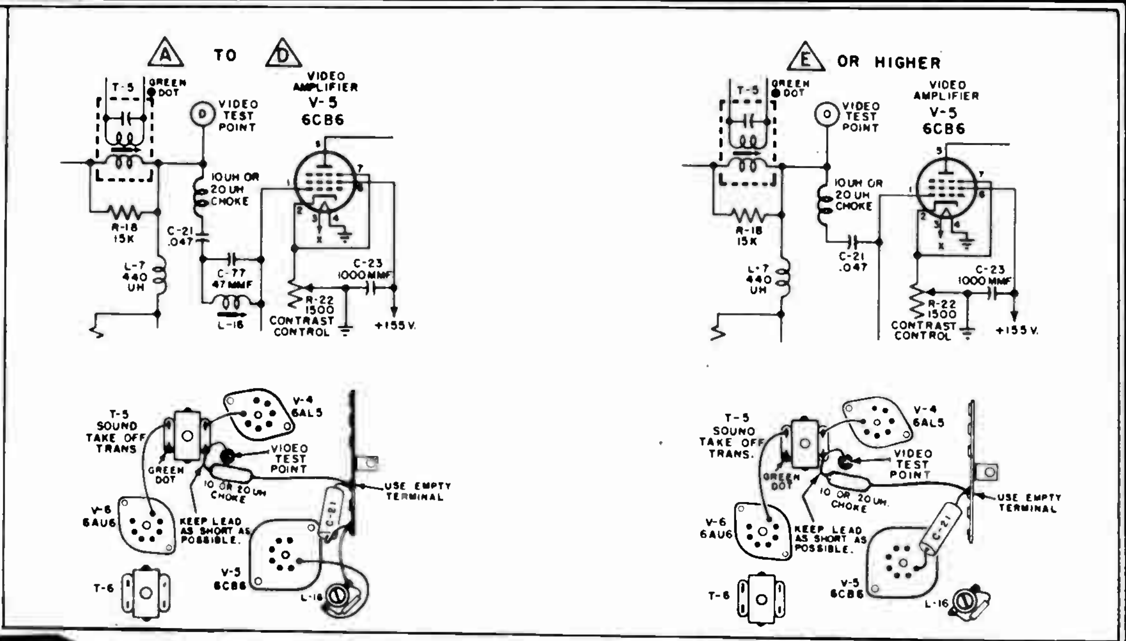
F



This can be eliminated by installing a 100 ohm 1/2 watt resistor between the plate and screen of the vertical output tube (V-19 6W6) as shown here and on schematic in Service Note. Above chassis incorporating this change are coded Triangle F.

6) BLACK HORIZONTAL STREAKS OVER PICTURE WHEN TUNED TO CHANNEL #6. This condition is usually only apparent in the fringe areas and is caused by harmonics of the picture I. F. which is generated in the video detector coupling to the front end, causing regeneration of certain frequencies. This condition is tunable with fine tuning and can sometimes effect Channels 5 or 7.

If this condition exists it can be easily eliminated by connecting a 10 uh R. F. choke part #705021 or a 20 uh R. F. choke part #705014 is series with the condenser (C-21) connected to the grid of the 6CB6 Video Amplifier Tube. This choke should be connected and dressed as shown below:



MODEL 752H

ALL CHANNEL
UHF-VHF RECEIVER

TV Chassis	Tube Size	TV Tuner
120169-H	21MP4 (Metal-Rect.)	470712-VHF 470713-UHF

Model 752H using chassis 120169-H is a 21" direct view television receiver which is designed to receive both V.H.F. channels 2 to 13 and U.H.F. channels 14 to 83.

Combination V.H.F. and U.H.F. tuning is achieved through the use of two tuners which are connected to the same tuning knobs making V.H.F. or U.H.F. channel tuning very simple. The V.H.F. cascode turret tuner has 13 positions (one more than the conventional type), 12 being used for V.H.F. reception, (Channels 2 to 13), while the 13th or U.H.F. position is used to activate the proper U.H.F. circuits and provides additional amplification for the converted 40 mc. U.H.F. signal. In this position, a window is provided to observe the continuous tuning of the U.H.F. channels.

This receiver incorporates a built in U.H.F. - V.H.F. antenna. It has provisions for connecting separate external V.H.F. and U.H.F. antennas, or a combination U.H.F.-V.H.F. antenna which uses a common lead in wire.

Except for the use of a special 13th position V.H.F. turret tuner and a separate U.H.F. continuous tuner and associated circuits, the 120169-H V.H.F.-U.H.F. chassis and the 120169-B V.H.F. chassis are the same. Refer to the Service Note on the 120169-B chassis for all information not included in this addendum service note.

GENERAL DESCRIPTION

The U.H.F. tuner in this chassis utilizes continuous tuning from Channels 14 to 83 and is mounted adjacent to the special V.H.F. cascode turret tuner. This V.H.F. tuner is special in that it is provided with 13 positions (Channels 2 to 13 and a U.H.F. position). The U.H.F. tuner is coupled to the fine tuning control of the V.H.F. tuner by a dial cord. This arrangement allows for simple tuning since both V.H.F. fine tuning and U.H.F. continuous tuning are accomplished by the same knob.

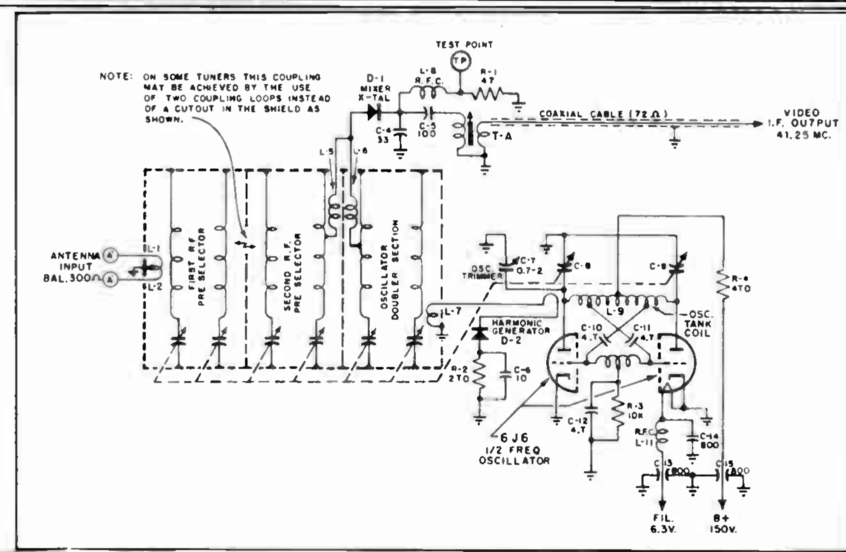
When tuned to V.H.F. (Channels 2 to 13) the U.H.F. tuner is inoperative and, therefore, the set performs as a conventional V.H.F. receiver.

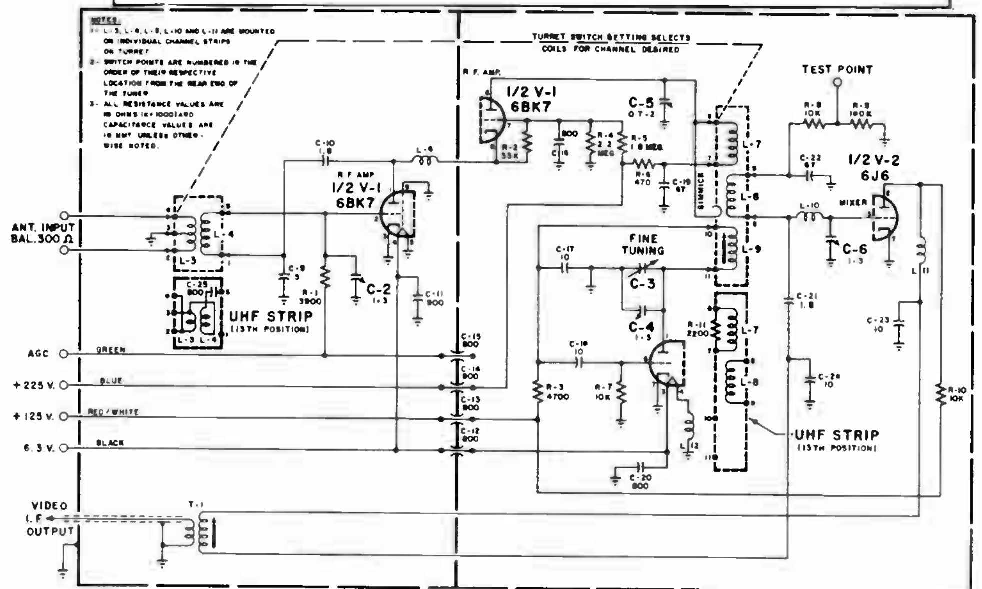
When the channel selector is set to the 13th or U.H.F. position, a window on the channel selector knob displays the U.H.F. channel calibration and a cam located on the V.H.F. turret tuner shaft activates a switch which performs the following functions:

1) Applies B+ to the U.H.F. tuner causing it to function.
2) Connects the V.H.F. or combination of V.H.F.-U.H.F. antenna to the input of the U.H.F. tuner providing one antenna lead in is used.
3) Disconnects the V.H.F. antenna from the V.H.F. tuner.
4) Connects the output of the U.H.F. tuner to the input of the V.H.F. tuner.

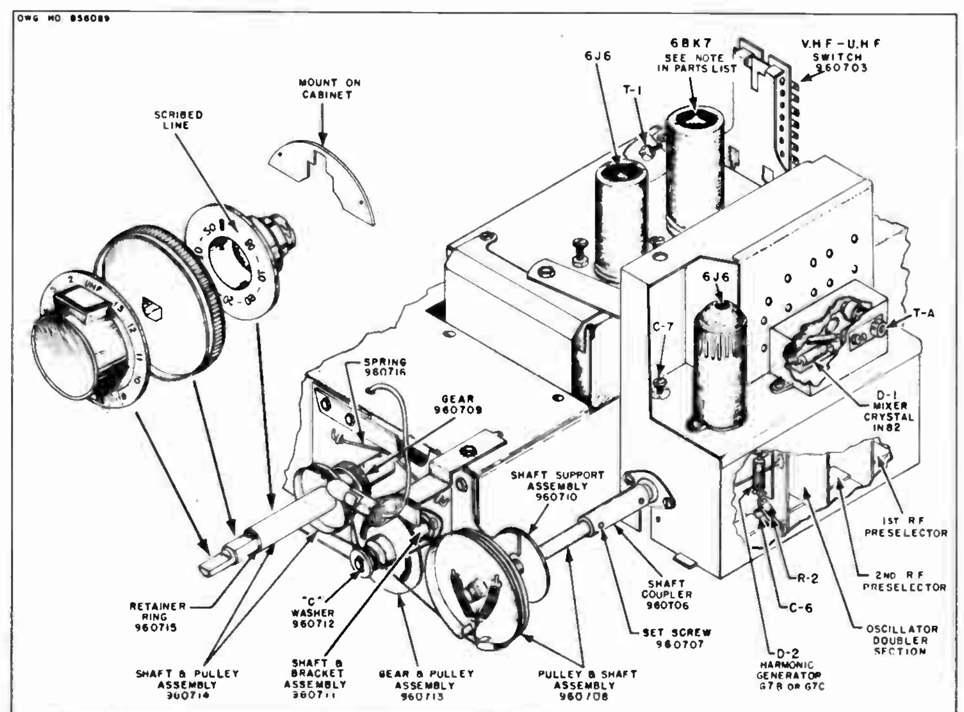
The U.H.F. tuning system is designed for a single conversion, therefore, the I.F. frequencies (40 mc range) are the same from both the V.H.F. and U.H.F. tuners.

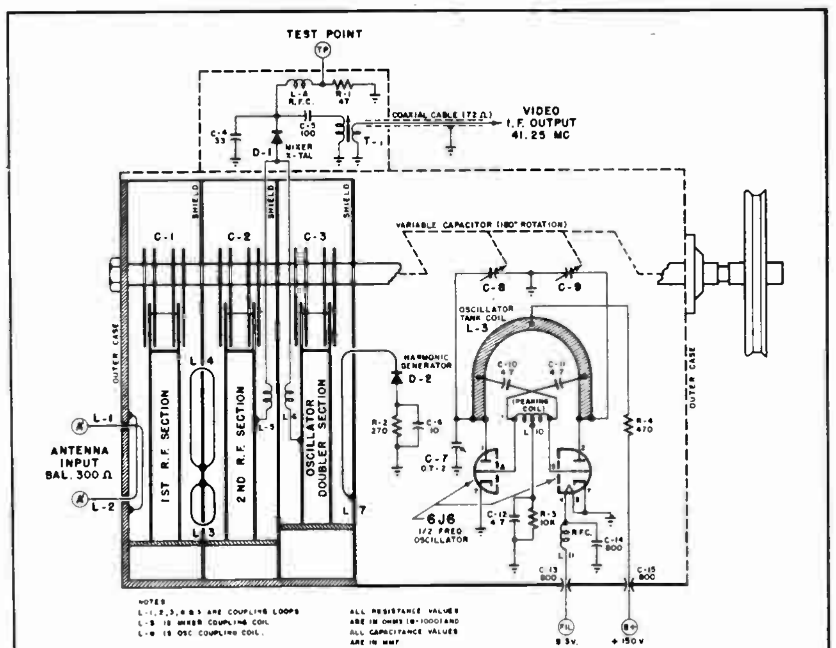
In the 13th or U.H.F. position, the turret tuner strips in the V.H.F. tuner are designed to accept 40 mc signals. This means that the 40 mc I.F. signal from the U.H.F. tuner will be further amplified by the V.H.F. tuner which acts as an additional two stage low noise cascode amplifier preceding the receiver's I.F. system.





TUNER PART NO. 470712 SCHEMATIC PART NO. 950246



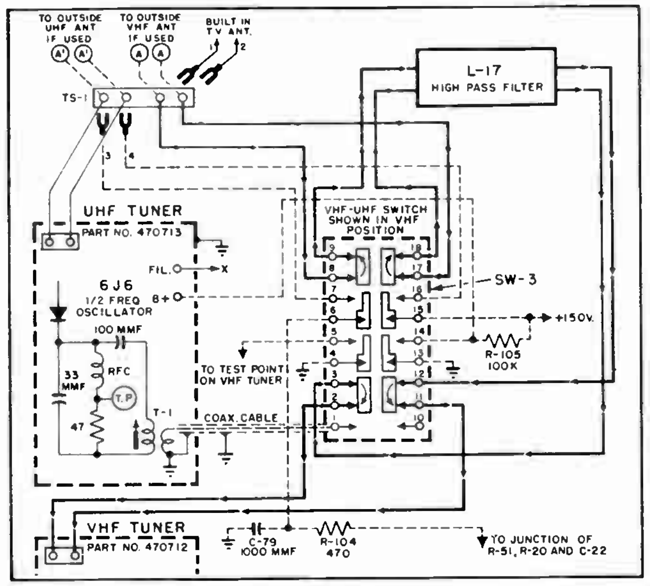


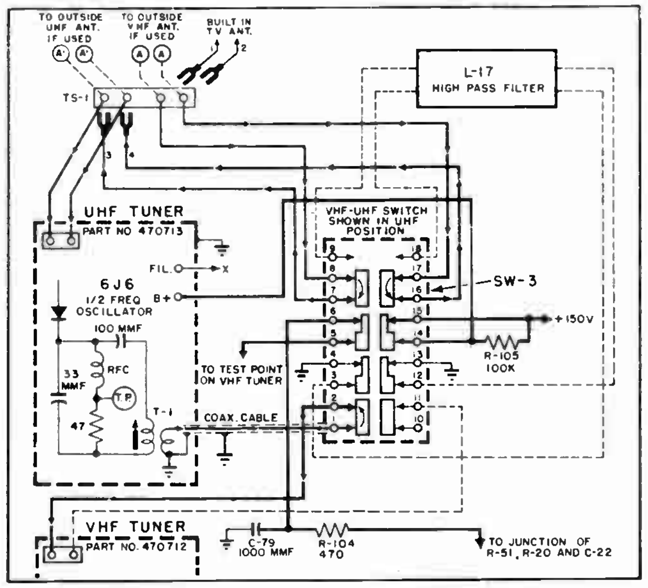
TUNER PART NO. 470713 SCHEMATIC PART NO. 950245

OPERATION OF VHF-UHF SWITCH

This switch is automatically operated by a cam located on the V.H.F. tuner shaft. This cam changes the switch from its V.H.F. position to U.H.F. whenever the V.H.F. tuner is set for U.H.F. operation.

The following diagram and description should make the operation of this switch clear.





VHF POSITION

The V.H.F. antenna is connected through the switch to the input of the high pass filter L-17. The output of this filter is connected to the input of the V.H.F. tuner through this same switch. B+ is supplied to the U.H.F. tuner through a 100K ohm resistor (R-105) preventing it from oscillating but allowing some current to flow through the 6J6 so that its cathode will not be poisoned during long periods of inoperation (V.H.F. reception).

UHF POSITION

The V.H.F. antenna or combination V.H.F.-U.H.F. antenna is disconnected from the V.H.F. tuner and connected to the input of the U.H.F. tuner through the switch and terminals 3 and 4 (providing they are connected. See installation instructions for more information). If a separate lead in is used for U.H.F., then terminals 3 and 4 should not be connected to the U.H.F. antenna terminals.

The single ended output of the U.H.F. tuner is fed through the switch to the input of the V.H.F. tuner.

The 100K resistor R-105 is shorted out by the switch so that full B+ is applied to the U.H.F. tuner.

Since the V.H.F. mixer tube functions as a 40 mc amplifier when tuned to U.H.F., fixed grid bias is applied to it (test point V.H.F. tuner) through the switch.

DESCRIPTION OF UHF TUNER

The tuned elements in this tuner are of the modified coaxial transmission line type. As you can see from the enclosed mechanical schematic, the U.H.F. incoming signal is tuned by means of two R.F. preselectors. These preselectors are quarter wave end tuned coaxial lines. Capacitive tuning is employed at the open ends to electrically adjust the line to 1/4 wave length and, therefore, effect a resonant condition at any frequency within the U.H.F. band. Two identical preselector circuits are coupled together to provide the proper band pass characteristic. The ganged variable capacitors adjust the two preselector lines and are similar to those used in conventional low frequency circuits. Each line is tuned by four rotor plates. Capacitor trimmers are located behind the coaxial line to preset the high frequency end of the R.F. preselectors. The antenna input in this tuner is coupled to the 1st preselector circuit and is designed to match a balanced 300 ohm transmission line. The output from the preselector stages is fed through an R.F. choke (L-5) to the mixer crystal D-1.

The U.H.F. local oscillator uses a 6J6 in a conventional push pull circuit using lumped circuit constants. This oscillator operates at 1/2 the desired frequency which greatly stabilizes the circuit and permits the use of a thoroughly field tested and debugged tube (6J6). The two outer oscillator capacitor plates are slotted to allow for factory corrections of pass band characteristics.

The output from this oscillator is loop coupled to the oscillator doubler section through L-7. A crystal diode (D-2) is employed in series with this coupling loop to provide rectification of the oscillator signal and thus effect more efficient doubling action. The output from this doubler is fed through L-6 to the mixer crystal D-1 where it beats with the preselected incoming U.H.F. signal. A picture I.F. of 45.75 mc and a sound I.F. of 41.25 mc are generated in this fashion. When the receiver is tuned to any V.H.F. channel a 100K ohm resistor is inserted in series with the B+ to the U.H.F. tuner as shown in the switch diagram on page three of this note. This is done to prevent weak operation of the U.H.F. oscillator after long periods of inoperation (set used on V.H.F.).

C-7 is used to set the high end of the oscillator and can be used in the field to compensate for slight variations in 6J6s. The range of this trimmer has been limited so as not to effect tuner tracking. Because of this, several 6J6s may have to be tried if adjustment of C-7 does not produce the desired results. Complete tuner shielding is provided to reduce oscillator radiation and stray pickup to a minimum.

The advantage of using a crystal mixer is its simplicity of design. Since a crystal generally has a higher conversion loss than V.H.F. mixer tubes, it becomes desirable to insert additional I.F. amplification so that the sensitivity of V.H.F. and U.H.F. will be of similar magnitudes.

This is accomplished by feeding the I.F. output from the U.H.F. tuner (T-A) to the input of the V.H.F. tuner. In the 13th or U.H.F. position, the V.H.F. tuner becomes a two stage low noise cascode I.F. amplifier. The tuner input changes from 300 ohm balanced to a 72 ohm unbalanced line to match the I.F. output of the U.H.F. tuner. Since this U.H.F. strip (13th position) does not have any coil section for the V.H.F. oscillator, plate voltage is removed from this section of the 6J6 tube causing it to be inoperative.

ALIGNMENT

The alignment of the tuner is factory set and will usually not require any additional adjustments other than to compensate for differences in 6J6 oscillator tubes. Because of this fact, the only adjustment to be made in the field is trimmer C-7 which is located next to the 6J6 oscillator tube.

This trimmer is normally set at the factory to track the highest U.H.F. Channel (83-). This must be done with a U.H.F. sweep and marker generator. In the field, however, this equipment is not readily available and C-7 should, therefore, be used to track the highest U.H.F. channel received in the area. It is usually best to try a few 6J6 tubes until one is found which more nearly resembles the original, thus requiring only a slight adjustment of C-7.

In the event T-A has been tampered with or replaced, it should be adjusted for best results on all U.H.F. channels received in the area. This I.F. sometimes has only a slight effect on the picture or sound.

Before doing any alignment on this U.H.F. tuner, whether in the field or shop, be sure that the V.H.F. I.F. and R.F. circuits have been properly set up. Information pertaining to this can be found in the Service Note to which this is an addendum.

GENERAL TROUBLE SHOOTING INFORMATION

Since the operation of this tuner is dependent almost entirely on its mechanical configuration, all component parts whether lumped constants or transmission line section, have been manufactured and mounted as rigid as possible. If it is necessary to replace a component, the exact replacement part should be used. Be sure it is mounted in the same position using the same lead lengths as the original. This is very important since at U.H.F. frequencies a small piece of wire has an appreciable inductance. Stray capacitances between components and chassis also tend to affect the circuit's operation to a marked degree.

Due to the simplicity of design and manufacture of this tuner, little trouble is to be expected. In the event that this tuner becomes defective in any way, the trouble shooting chart in this note can be used to good advantage.

If the crystal D-2 is open or shorted, or the oscillator is inoperative, there will be no bias developed across R-2. If replacing D-2 does not rectify this condition, then it can be assumed that the oscillator is not functioning. Be sure that the harmonic generator coupling loop (L-7) is not touching the shield. A voltage and resistance check of the 6J6 oscillator circuit should soon locate the trouble.

If the correct bias is measured across the R-2 and the set still operates poorly on U.H.F., then it can be assumed that the mixer crystal D-1 is defective in some way. This can easily be determined by lifting R-1 off chassis and inserting a D.C. milliammeter between it and chassis. In the event that the current readings are abnormally low or high, a new crystal known to be good should be inserted (see trouble shooting chart). If it is desired to localize the difficulty further, C-4 and, or C-5, can be disconnected. When soldering near crystals, be sure to use a small tipped, low wattage iron, placing the pliers between the crystal and the connection so as to absorb the heat thus protecting the crystal. This is important, since excessive heat can easily damage it.

Do not attempt to repair or adjust this tuner by adjusting any of the coupling loops or by moving various components. The only adjustment that can be made in the field is C-7 to compensate for a change in interelectrode capacities when a new 6J6 is used. The proper procedure for this is shown under alignment.

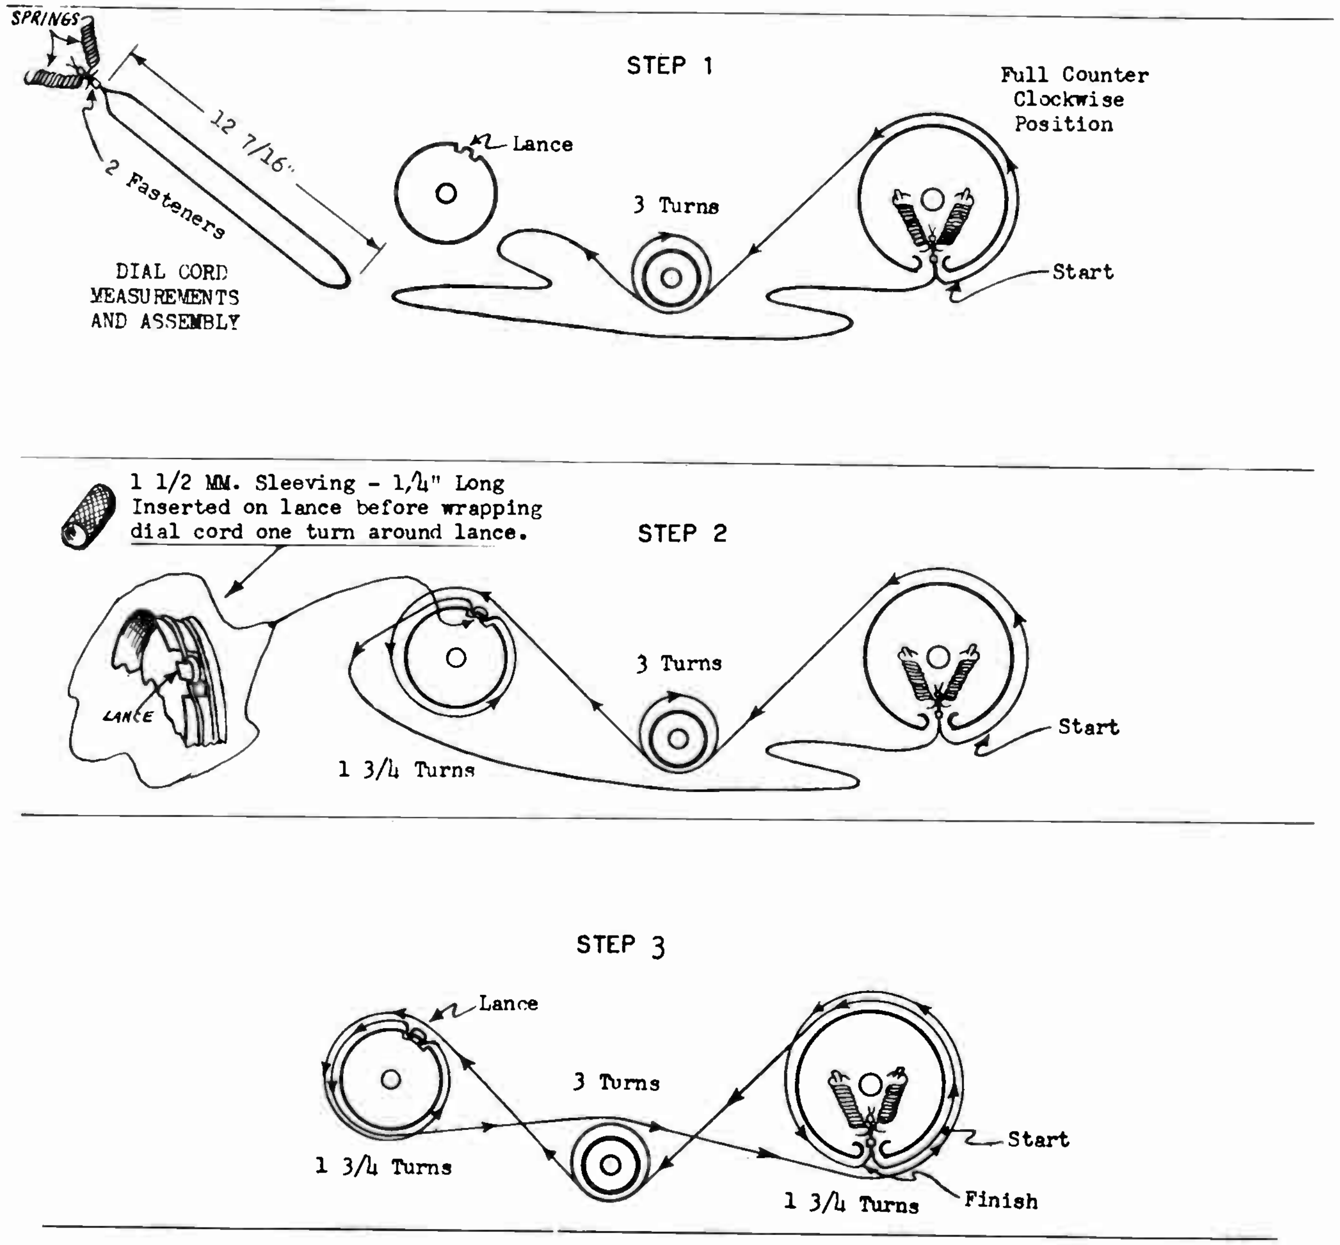
Components which are not a part of the R.F. or oscillator tuned circuits such as feed thru condensers, B+ resistors, T-A, etc., can usually be replaced with little difficulty providing the above precautions are observed.

NOTE: In the event that this tuner needs an over all alignment or service of parts, the defective tuner should be returned for repairs through your Emerson distributor.

TROUBLE SHOOTING CHART

Component		Variations Low to High Frequency	POSSIBLE TROUBLE (If voltage readings not normal)
	B+	+150V.	C-10, C-15, C-11 shorted, the V.H.F.-U.H.F. switch.
6J6	Filament	6.3V. A.C.	L-11 open, C-14, C-13 shorted.
	R-3	-20V. to -3V.	R-3 open, C-12 shorted, L-10 open or shorted.
D-2 Harmonic Gen. Crystal	R-2	±1.5V. to ±2.6V.	Crystal defective, L-7 shorted to chassis, C-7 shorted. Voltage polarity depends upon crystal polarity.
D-1 Mixer Crystal	Current thru R-1 Insert Milliammeter	0.6 thru 3.7 to 1.00 ma. (current)	D-1 defective, C-4 shorted, L-8 open.

DIAL CORD STRINGING



GENERAL V.H.F. INSTALLATION INSTRUCTIONS

(A) ANTENNA

This chassis is designed to operate from either its built in U.H.F.-V.H.F. antenna, an external combination U.H.F.-V.H.F. antenna or separate U.H.F. and V.H.F. antennas using one or two sets of antenna lead in wires.

The set as delivered is ready to operate from its built in U.H.F.-V.H.F. antenna. In most strong signal areas this will suffice.

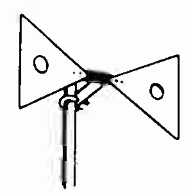
If it is necessary to install an external antenna, disconnect the built in one by removing the spade lugs (1 and 2) from the V.H.F. antenna terminals.

If one antenna lead in is used for both U.H.F. and V.H.F. reception, it should be connected to the V.H.F. input terminals. When the receiver is set for U.H.F. reception, the U.H.F.-V.H.F. switch automatically transfers the single antenna lead in to the input of the U.H.F. tuner removing it from the V.H.F. tuner. This transfer will only take place providing the jumper twin lead, connected to terminals 7 and 16 of the U.H.F.-V.H.F. switch is also connected to the U.H.F. input terminal strip by means of spade lugs 3 and 4.

If separate U.H.F. and, or V.H.F. antenna lead in wires are used, they should be connected to their respective antenna input terminals. Under these conditions, spade lugs 3 and 4 must be removed from the U.H.F. input antenna terminals.

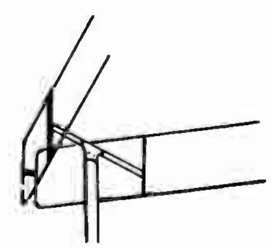
For new installations, it would be desirable and economical to install a combination U.H.F.-V.H.F. antenna providing, of course, that a V.H.F. station has been allocated to that area. In the event that the terrain is hilly or in a metropolitan area, ghosts may present quite a problem and it may be better to install separate U.H.F. and V.H.F. antennas. This may be necessary since combination antennas usually have poor directivity at U.H.F. Separate U.H.F. and V.H.F. antennas can be connected to one lead in if desired through a printed commercially available circuit filter.

U.H.F. ANTENNAS WHICH WILL TAKE CARE OF MOST PRESENT DAY INSTALLATIONS.



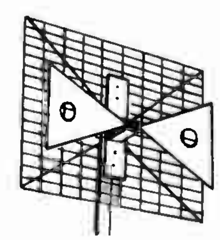
SINGLE BOW TIE

For use in strong signal areas where ghosts do not present a problem.



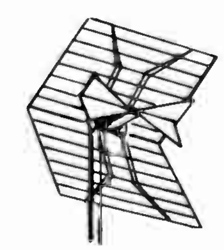
STACKED V

For use in weak signal areas where ghosts do not present much of a problem. Can also be used for strong V.H.F. signals.



BOW TIE SCREEN REFLECTOR

For use in weak signal areas where ghosts present a problem.



FOLDED BOW TIE CORNER REFLECTOR

For use in fringe areas where ghosts present a problem.

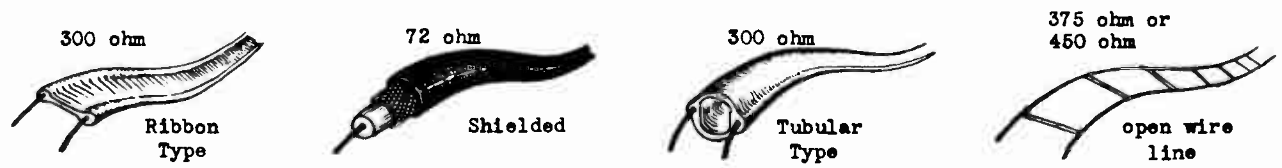
NOTE: All of the above four antennas will operate over all 70 U.H.F. channels.

In U.H.F. the use of free space terminals and rigid construction is an important detail. By free space terminals we mean air insulation between the terminals of each antenna section instead of bakelite or poly. The use of an insulation other than air, tends to collect moisture which creates a signal leakage path thus reducing the signal.

Since U.H.F. frequencies have relatively short wave lengths, rigid elements are very important. The slightest movement could easily become an appreciable part of a wave length which may affect signal pickup.

(B) ANTENNA WIRE

The common type 300 ohm ribbon line will work out satisfactorily only in strong signal areas, since when wet, line losses increase by almost 8 times at the high end of the U.H.F. band. The tubular 300 ohm line is much better in this respect as the leakage path is not as readily affected by moisture and can, therefore, be used in most signal areas. When wet, tubular line losses increase slightly more than two times at the high end of the U.H.F. band. In the extreme fringe areas the use of open wire line may be best, but it is more difficult to work with. Shielded 72 ohm or 300 ohm transmission line is not at all affected by weather conditions but these lines generally have a higher loss to start with and are comparatively expensive.



Transmission lines other than the shielded type should be mounted away (6 to 7 inches) from all nearby metal objects by use of stand-offs, as the closer these lines are to metal, the greater are the losses. In the event that it is impractical to use stand-offs, shielded lines such as RG-59U or RG-11U should be used. Never rest unshielded lines next to metal objects over any appreciable distance as losses will be exceptionally high and depend to a great extent on humidity variations.

If tubular line is used, be sure that the ends are sealed to prevent moisture from entering the line. This is easily done by heating the ends and pressing them together to form a good seal.

(C) HEIGHT AND ORIENTATION OF ANTENNAS AT U.H.F.

Since the wave lengths at U.H.F. are much shorter than at V.H.F., objects which did not appreciably reflect the V.H.F. wave will now reflect U.H.F. waves. Because of this, orientation and the use of directive antennas is much more important to minimize the pickup of reflected or ghost signals.

Another effect of these shorter wave lengths is to cause a more rapid variation of signal pickup with antenna height. Because of this fact, it is important that antenna height be probed for maximum signal pickup. A foot higher or lower may yield a marked increase in the signal pickup.

SETTING OF TUNING KNOBS

1) Make sure chassis has been adjusted in the cabinet so that the tuning shafts are perfectly centered through the cabinet hole.

2) Insert fine tuning knob on shaft and rotate fully counter clockwise (no further rotation of outer U.H.F. dial shaft).

3) Remove fine tuning knob and insert the U.H.F. dial (contains U.H.F. Channel #s) on U.H.F. dial shaft. Set the scribed line at 12 o'clock before placing on shaft. Do not twist or turn when inserting U.H.F. dial. The scribe line is a hair thickness and is located about 3/16" to the right of the heavy black line near 0 of Channel 20.

4) Place fine tuning and selector knobs on their respective shafts.

NOTE: Leave enough space between knobs so that there will not be any binding.

REPLACEMENT OF TUNERS

If it becomes necessary to return a U.H.F. tuner to your distributor for repair or replacement, remove and retain the extension shaft and pulley. When returning the V.H.F. tuner, remove and retain the V.H.F.-U.H.F. switch and the front plate which consists of a pulley and gear combination. This is important since replacement tuners will not come equipped with the above devices.

Under no conditions are both the V.H.F. and U.H.F. tuners to be returned as a unit. Before returning for replacement or repair, an honest effort should be made to repair the unit since all parts will be available through your Emerson distributor.

NEW PARTS

Part #	Description	Part #	Description
587040	Dial Cord Spring	470712	V.H.F. Tuner
541005	Dial Cord Fastener	470713	U.H.F. Tuner
530002	Dial Cord (specify length)	960703	V.H.F.-U.H.F. Switch

565264	Fish Paper Mask for Dial	960704	T-A I.F. Coil on U.H.F. Tuner
	(mounted to cabinet)	960705	T-1 I.F. Coil on V.H.F. Tuner
547507	Escutcheon Pin for Mask	720173	High Pass Filter L-17

NOTE: The R.F. amplifier tube presently used is a 6BK7. In the future a 6BQ7, 6BQ7A or a 6BZ7 may be used. These three tubes are interchangeable, but due to possible variations in interelectrode capacities, several tubes may have to be tried for best results.

ADDENDUM SERVICE NOTE

NOTE: This information should be considered as part of the Service Note for models 711F, 712F, 720D, 732B, 733F and 734B using chassis 120169-B & 120169-F

G

June 1953

Supplement No. 2

Models - 767C, 771C

Chassis - 120169-B

Model Numbers	TV Chassis	Tube Size	TV Tuner
767C, 771C	120169-B	21MP4 (Metal-Rect.)	470689

With the exception of the cabinet parts list (below), all technical information pertaining to the models listed above will be found in the service note covering models 711F, 712F, 720D, 732B, 733F and 734B using chassis 120169-B & 120169-F

READY FOR U.H.F.

As in all Emerson Television Receivers, this Model provides for reception of all V.H.F. stations as well as new U.H.F. stations, by means of easily inter-changed tuning strips or an external converter.

Model 767C

Model 771C

HIGH VOLTAGE WARNING

Operation of this receiver outside its cabinet or with covers removed involves a shock hazard from the power supplies. No work should be attempted on this receiver by anyone not thoroughly familiar with the precautions necessary when working on high voltage equipment.

CATHODE RAY TUBE HANDLING PRECAUTIONS

Extreme care must be used in handling the picture tube. The tube is highly evacuated and, due to its large size, is subjected to a considerable amount of atmospheric pressure. The handler should wear safety goggles and gloves for protection. Avoid nicking or scratching the glass by rough contact with other objects.

Before removing the picture tube, discharge the capacitor formed by the inner and outer aquadag coatings on the tube by shorting the anode contact on the side of the tube to the outer surface with a well insulated piece of wire.

GENERAL INFORMATION

TUNING RANGE: Channels 2 through 13.

INSTALLATION INSTRUCTIONS

SHIPPING BLOCK

The shipping block and bolt located on the top rear inside portion of the cabinet must be removed when the receiver is installed. Models 17C2, 17C4.

RECEIVER LOCATION

The receiver may be placed anywhere in the room, but for greatest satisfaction it should be located:

1. Away from any bright light that may fall directly on the screen or be reflected from it. This includes windows and lamps. Some illumination in the room, off to one side, is desirable to prevent eye-strain.

2. To provide comfortable viewing and ease in operation.

3. At least one inch away from a wall to allow for cabinet ventilation. This is very important.

ANTENNAS

The choice of a television antenna depends entirely upon the location of the receiver with respect to all television station transmitting antennas in any locality. Maximum pick-up is obtained when the receiving antenna is directly in line of sight with the transmitting antenna.

"BUILT-IN-ANTENNA"

The receiver is normally shipped with the FADA built-in-antenna connected. This antenna is a stationary folded dipole which is used for both the high and low frequency channels. It is fastened to the top underside of the cabinet, and connected to the antenna terminals on the back of the cabinet.

When this antenna is used, the following requirements should be observed for best reception:

1. In order to get maximum performance and satisfactory pictures from the "BUILT-IN-ANTENNA," ample signals from the television station must be present at the location of the receiver. Normally, the strength of the signals will vary throughout the room in which the receiver is located. For this reason, better pictures will be obtained if the receiver is tried in all possible locations in the viewing room and is then placed where the clearest pictures are received from all stations. Avoid large metallic objects, such as radiators, metal panels, etc.

2. Lamps, vases, and metallic objects, when placed on top of the receiver, may affect the efficiency of the "BUILT-IN-ANTENNA."

3. The Fada "BUILT-IN-ANTENNA" will give satisfactory reception in strong signal areas, but if the receiver is located in a fringe or weak signal area, an outdoor antenna is recommended.

OUTDOOR ANTENNA

The "BUILT-IN-ANTENNA" must be disconnected from the antenna terminal strip before connecting the outdoor antenna leads. It is immaterial which lead is connected to which terminal.

OPERATING INSTRUCTIONS

(Refer to Figure 1)

(1) Turn OFF-ON SOUND volume control clockwise about a half turn. This turns the receiver on and sets the sound volume to a reasonable level.

(2) Allow a brief warm-up period.

(3) Set Station Selector to desired channel.

(4) Adjust the Fine Tuning control to where music or speech is heard, assuming that the station is broadcasting.

(5) Turn picture control fully counter clockwise.

(6) Turn the brightness control fully clockwise and then slowly counter clockwise until light is just visible on the screen.

(7) Turn the picture control clockwise until activity or a definite form is just noted on the screen. Do not advance control any further until steps 8, 9, and 10 are completed.

(8) If the pattern is moving up or down adjust Vertical control until pattern is stationary in vertical direction.

(9) If picture appears as black and white diagonal lines or seems to be moving sideways, adjust Horizontal control until a proper picture is obtained.

(10) Readjust Fine Tuning control for best picture.

(11) Adjust Picture control until picture is suitable for brightness and contrast. If the control is advanced to maximum clockwise position, overloading of the picture will occur on strong signals. This will be noted by excessive contrast, bending of picture and raspy noise in the sound output. When this occurs rotate the picture control slowly in a counter clockwise direction until the picture and sound distortion disappears. The brightness and details of a picture are controlled by the Brightness and Picture knobs. Adjust Tone Control for desired quality of sound.

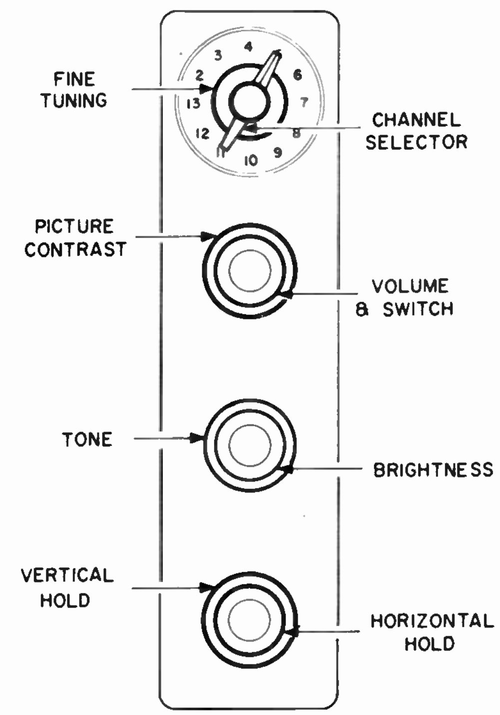
(12) Recheck the Fine Tuning control for best picture.

NOTE: If any difficulty is experienced with steps number 8 or 9, turn the PICTURE control ¼ turn counter clockwise, readjust the Fine Tuning control and then repeat these adjustments.

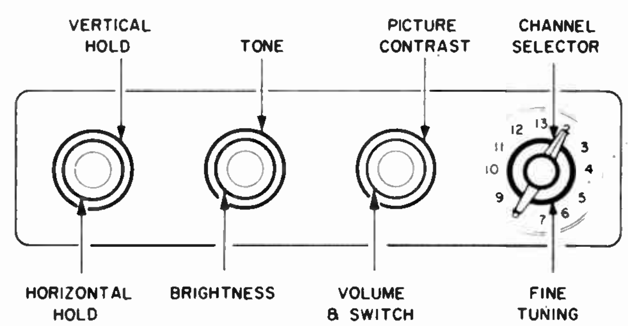
If the receiver has been in previous operation and no controls disturbed except for turning the on-off knob to "off" position, then subsequent operation should require the previous steps 1 through 3 and, if necessary, steps 13 and 14 as follows:

(13) Adjust the FINE TUNING control for best picture quality. Readjust the SOUND volume control to desired level.

(14) Adjust PICTURE and BRIGHTNESS controls to obtain desired level of contrast and brightness.



17C2 - 17C4



17T6 - 17T9

FIG. 1. OPERATING CONTROLS

SERVICE ADJUSTMENTS

The receiver is completely adjusted at the factory, so normally none other than the front panel operating instructions need be followed to put the receiver in operation. However, to provide for any misadjustment of the service controls due to handling, the following instructions are in order.

ION TRAP, FOCUSER AND DEFLECTION YOKE ADJUSTMENTS

Before any adjustments can be made the back of the cabinet will have to be removed. Remove all screws holding back cover to cabinet, and pull cover away from cabinet. Since the power cord circuit is broken by the interlock when the cabinet back is removed, an extra television power cord will be necessary to make a power connection to the receiver. A mirror placed in front of the receiver will help in making the adjustments.

FOR MAGNETIC FOCUS KINESCOPES:

ION TRAP ADJUSTMENTS

Turn on the receiver and switch to one of the television channels not in use in your area. With the brightness control in the maximum clockwise position and the picture control fully counter-clockwise adjust the ion trap by moving it forward or backward at the base of the tube, at the same time rotating it slightly around the neck of the cathode ray tube for the brightest raster on the screen. Reduce the brightness control setting until the raster is just visible on the screen, readjust the ion trap for maximum brilliance. Adjust the focuser adjustment control (shown in Figure 2 or 3) until the line structure of the raster is clearly visible. Readjust the ion trap for maximum raster brilliance. The final touches of the adjustment should be made with the brightness control at the maximum position with which good line focus can be maintained.

FOCUSER MAGNET ADJUSTMENT

The focuser magnet should be adjusted so that there is approximately one-eighth inch of space between the rear shell of the deflection yoke and the front face of the focuser magnet. This spacing gives best average focus over the face of the tube.

The axis of the hole through the focuser magnet should be parallel with the axis of the cathode ray tube neck. See Figure 2 or 3.

NOTE: The cardboard insert between the focuser magnet and the neck of the cathode ray tube must not be removed.

DEFLECTION YOKE ADJUSTMENT

If the lines of the raster are not horizontal or squared with the picture mask, loosen the yoke centering wing screw (shown in Figure 2, 3) and rotate the yoke until this condition is obtained. Tighten the wing screw making sure the deflection yoke is as far forward on the neck of the cathode ray tube as possible.

CENTERING ADJUSTMENTS

No electrical centering controls are provided. Centering is accomplished by means of a separate plate on the focus magnet as shown in Fig. 2 or 3. The centering plate has a locking screw which must be loosened before centering. Up and down adjustment of the plate moves the picture side to side and sidewise adjustment moves the picture up and down.

If a corner of the raster is shadowed, check the position of the ion trap. Reposition the ion trap within the range of maximum raster brightness to eliminate the shadow and recenter the picture by adjustment of the focus centering plate. In no case should the ion trap be adjusted to cause any loss of brightness since such operation may cause immediate or eventual damage to the cathode ray tube. In some cases it may be necessary to shift the position of the focuser magnet in order to eliminate a corner shadow.

FOR ELECTROSTATIC FOCUS KINESCOPES:

ION TRAP ADJUSTMENTS

Turn on the receiver and switch to one of the television channels not in use in your area. With the brightness control in the maximum clockwise position and the picture control fully counter-clockwise adjust the ion trap by moving it forwards or backwards at the base of the kinescope, at the same time rotating it slightly around the neck of the kinescope for the brightest raster on the screen.

DEFLECTION YOKE ADJUSTMENT

If the lines of the raster are not horizontal or squared with the picture mask, loosen the yoke centering wing screw (shown in figure 4) and rotate the yoke until this condition is obtained. Tighten the wing screw making sure that the deflection yoke is as far forward on the neck of the cathode ray tube as possible.

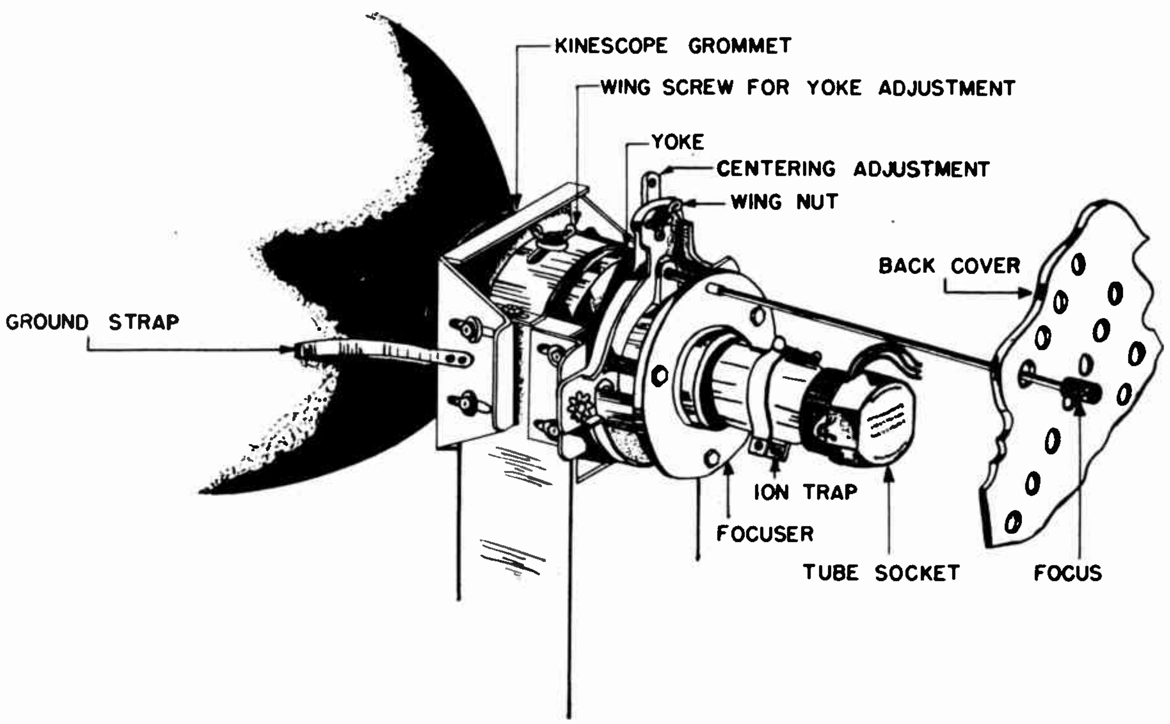


FIG. 2. SERVICE ADJUSTMENT AND CONTROLS
ELECTROMAGNETIC FOCUS KINESCOPES
17T6 — 17T9

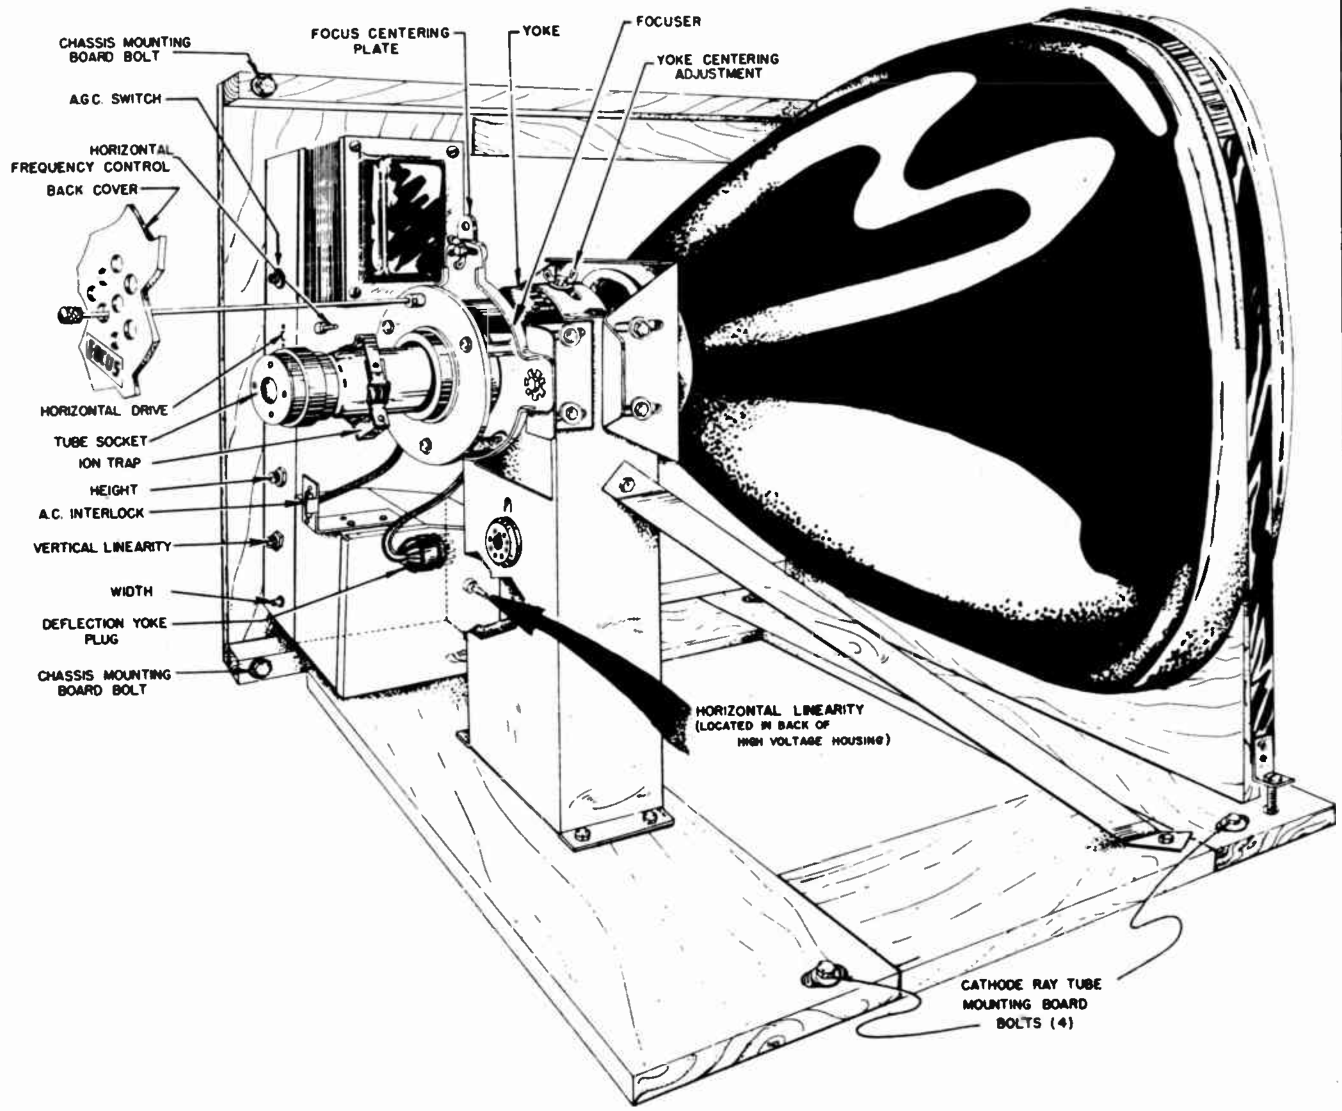

FIG. 3. SERVICE ADJUSTMENTS AND CONTROLS
ELECTROMAGNETIC FOCUS KINESCOPES
17C2 —17C4

CENTERING ADJUSTMENTS:

No electrical centering controls are provided. Centering is accomplished by the adjustment of a P.M. centering device located close to the back of the yoke (see figure 4). Two types of centering magnets are shown. With the rotatable magnet type, centering is achieved by rotating the entire unit as well as the centering control. With the contrarotatable magnet type, centering is achieved by rotating one magnet (or disc) with respect to the other. When the centering is satisfactory, readjust the ion trap for maximum raster brilliance keeping the brightness control at the maximum position with which good line focus can be maintained.

NOTE: As all electrostatic focus kinescopes used are essentially of the self-focus variety, good focusing will automatically be obtained throughout the life of the kinescope. In most receivers utilizing the electrostatic focus kinescope, there is a focus control (see figure 5) for optimizing the focus. See step No. 8 under Service Control Adjustments for adjusting this control.

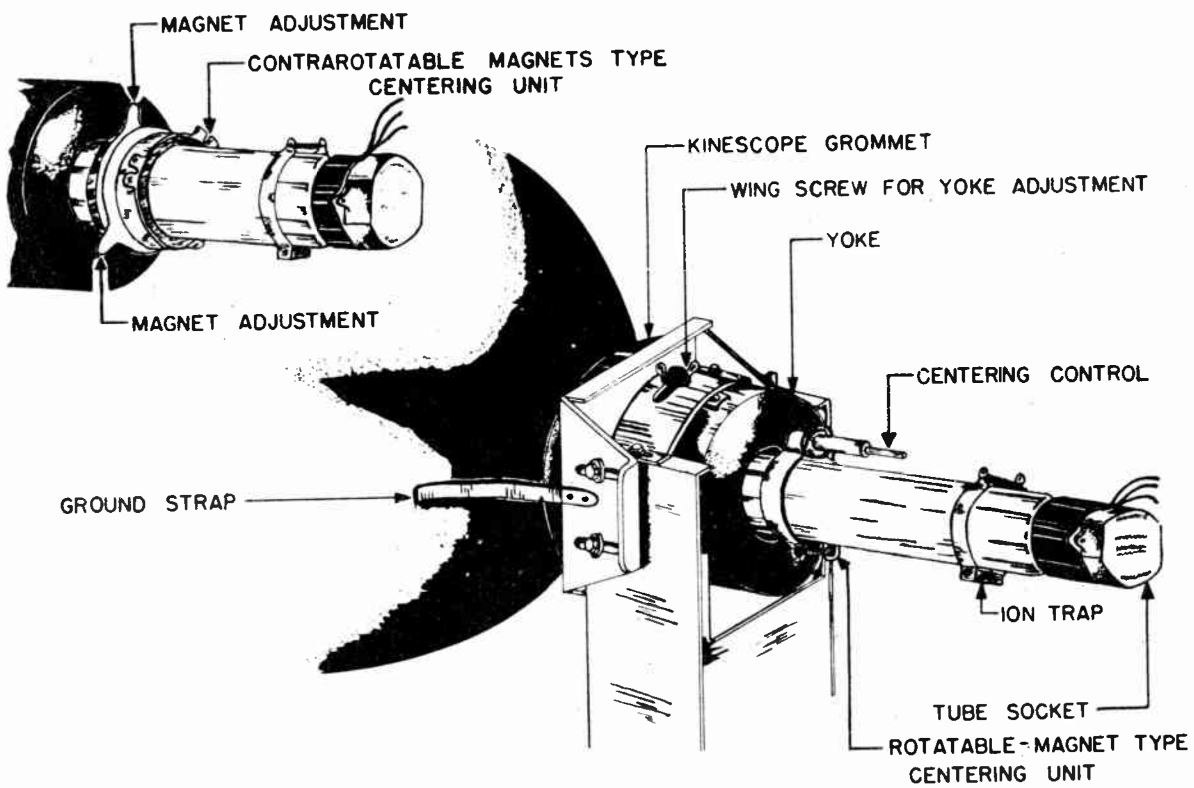

FIG. 4. SERVICE ADJUSTMENTS AND CONTROLS
ELECTROSTATIC FOCUS KINESCOPES
17T6 - 17T9 - 17C2 - 17C4

SERVICE CONTROL ADJUSTMENTS

With the deflection system in proper mechanical alignment, the service controls may be adjusted. The mechanical adjustments ordinarily will not require further attention until the cathode ray tube is replaced. Normal picture contrast and brightness should be maintained during adjustments with the AGC switch in its normal position (max. clockwise position). Using a test pattern from a local television station, make the service control adjustments as follows: (Refer to Figure 3 or 5.)

1. Set the horizontal and vertical hold controls on the front panel for a steady test pattern. If horizontal synchronization cannot be effected within the normal range of the horizontal hold control, set the control in the center of its range and adjust the horizontal frequency coil for a steady picture. This screw driver adjustment is reached from the top rear section of the chassis.

2. Set the picture control on the front panel to minimum, counter-clockwise, and advance the brightness control on the front panel clockwise to maximum. Fully open the horizontal drive trimmer adjustment located on the center rear apron of chassis. If no vertical white line appears in the center of the test pattern, leave it at full drive and proceed to the next step. If a vertical white line does appear in the center of the test pattern, gradually tighten up on the trimmer screw until the white line is eliminated. Insufficient horizontal drive will cause the raster to fall short of filling the mask horizontally or cause the picture to lack the brilliance normally obtained with a correct adjustment.

3. Reset the picture control for the desired picture contrast. If necessary, readjust the brightness control for a most desirable picture.

4. Set the width coil screw-driver adjustment so that the test pattern fills the kinescope mask horizontally. If necessary recenter the pattern.

5. Set the horizontal linearity coil screw-driver adjustment so that the test pattern is symmetrical from left to right. A slight readjustment of the horizontal drive may be necessary after making this adjustment.

6. Set the height control on the rear apron of the chassis so that the test pattern fills the kinescope mask vertically. Recenter the pattern if necessary.

7. Set the veterical linearity control on the rear apron of the chassis for a symmetrical test pattern vertically. A slight readjustment of the height control may be required after making this adjustment.

8. In receivers with electromagnetic focus kinescopes, set the brightness and picture controls for a normal test pattern and adjust the focus adjustment until the line horizontal line structure of the raster is clearly visible over the picture area. The control should be turned through the correct point several times so that optimum focus is obtained.

In receivers with electrostatic focus kinescopes, set the brightness and picture controls for a normal test pattern and adjust the focus control for the clearest horizontal and vertical wedges. Readjust the ion trap for maximum brightness.

TO REMOVE FRONT SAFETY GLASS ON MODEL 17T9 ONLY

The front glass may be removed to allow cleaning of its rear face and of the picture tube face.

The top edge of the glass fits into a groove on the inside surface at the top of the cabinet. The bottom edge rests on a metal bracket attached to the cabinet. The bracket is covered by a snap-on FADA nameplate.

Place fingers over top and bottom of the FADA nameplate and pull. The nameplate will snap off to expose two screws in the bracket. Press bracket in towards cabinet with one hand and remove the two screws with the other hand. After removing screws, hold the bottom edge of the glass with free hand. Remove bracket. While holding glass at bottom allow it to slide down gently, until its top edge comes below cabinet top. With other hand grasp top edge of glass and remove glass from cabinet.

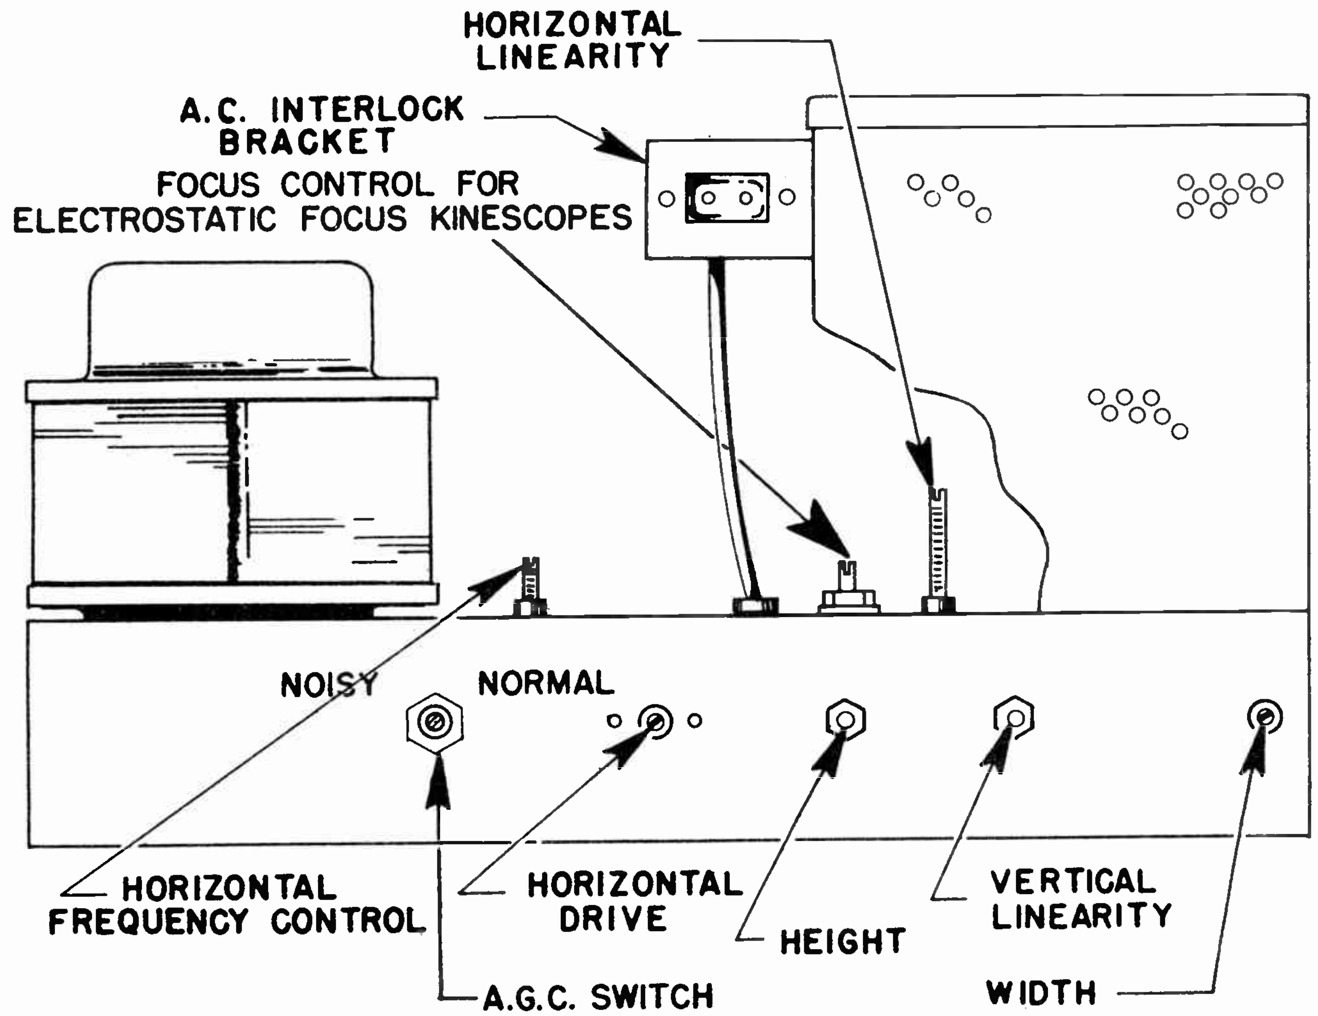

FIG. 5. SERVICE ADJUSTMENTS

ALIGNMENT

GENERAL

If the receiver must be aligned or some portion serviced, the chassis and kinescope must be removed from the cabinet. Remove the knobs from the front panel, remove all screws holding back cover to cabinet, and pull cover away from cabinet to disengage interlock. Remove the two screws holding the antenna terminal strip to cabinet. Remove speaker plug.

For table model receivers the chassis and kinescope must be removed as one unit. Remove the four chassis mounting bolts from the underside of the cabinet. Slide the chassis back out of the cabinet.

For console model receivers the chassis must be removed first and separately from the kinescope (see fig. 3). Disengage the kinescope socket, the kinescope high voltage lead, and the yoke plug. Remove the two bolts on the back top and bottom of the chassis mounting board. Slide the chassis board with chassis out of the cabinet. To remove the kinescope, remove the four bolts holding the tube mounting board to the cabinet and slide the complete assembly out of the cabinet.

EQUIPMENT REQUIRED

RF SWEEP GENERATOR meeting the following requirements:

(a) Frequency Ranges

18 to 30 mc	10 mc sweep width
40 to 90 mc	10 mc sweep width
170 to 225 mc	10 mc sweep width

(b) Output adjustable with at least 1 volt maximum.

(c) Output constant on all ranges.

(d) "Flat" output on all attenuator positions.

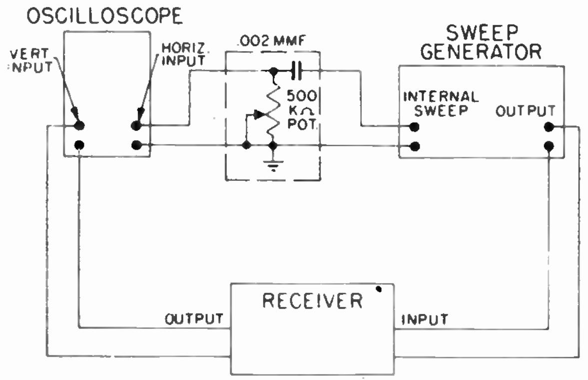

FIG. 6. SWEEP SETUP EXTERNAL PHASING

If the sweep generator does not have an internal blanking control or a phasing control, then it will be necessary to connect a phasing network between the sweep output of the sweep generator and the horizontal input to the oscilloscope. See Fig. 6 SWEEP-SET-UP EXTERNAL PHASING.

CATHODE RAY OSCILLOSCOPE preferably one with a wide band vertical deflection, input calibrating source, and a low capacity probe.

SIGNAL GENERATOR to cover all IF frequencies of from 4.5mc to 28mc and all picture and sound carrier frequencies.

ELECTRONIC VOLTMETER of Junior "Voltohmyst" type and a high voltage multiplier probe for use with this meter to permit measurements up to 20KV.

Bias supply made of batteries to give 4.5 volts.

ORDER OF ALIGNMENT

Sound Ratio Detector.

Sound IF Transformers.

Picture IF Transformers (preliminary and flat topping).

Oscillator and RF sections.

PRECAUTIONS

Before proceeding with IF Alignment, the following precautions should be observed:

Disconnect the antenna. Set picture control for minimum. Remove R.F. unit bottom shield. Remove channel 11 oscillator coil section. This is the coil strip nearest the fine-tuning control. Short the coil nearest the oscillator tuning slug, by soldering a bare wire across the coil terminals. Use extreme care so as not to short the oscillator coil to any other coil and also not to deform any of the coils. Reinsert channel 11 oscillator coil section and set R.F. unit to channel 11. Now the local oscillator is deactivated and you may proceed with the alignment without interference from local television stations.

For all IF Alignment, insert a 47K ohm resistor in series with the VTVM probe; also, a 47K ohm resistor should be inserted between the take-off point and the oscilloscope lead for decoupling.

SOUND RATIO DETECTOR AND IF ALIGNMENT

1. Connect probe of the VTVM to the diode plate of the ratio detector tube V20B (6T8, pin 2). Common to ground. See Figure 8.

2. Connect high side of the signal generator to the grid of the ratio detector driver. V21 (6AU6, pin 1). Common to ground. See Figure 8.

3. Tune the signal generator to exactly 4.5mc and attenuate the generator so it does not exceed 8 volts on the VTVM.

4. Peak L16 bottom core (FIG. 8) for maximum.

5. Peak L17 top core (FIG. 9) for maximum.

6. Adjust attenuator of signal generator to give exactly eight volts on the VTVM.

7. Move probe of VTVM to junction of R35, C28 and C29. (FIG. 8).

8. Adjust L17 top core (FIG. 9) for exactly 4 volts on the VTVM.

9. Move signal generator to video output tube V8 (6AG7, pin 4) (FIG. 8) and repeat steps number 1 and 3.

10. Peak L12 bottom (FIG. 8) and L13 top (FIG. 9) for maximum.

11. Repeat with care steps 1-3-4-5-6-7-8.

ALTERNATIVE PROCEDURE FOR STEPS 6-7-8:

1. Connect common lead of VTVM to junction of R33 and R34. (FIG. 8).

2. Connect probe of VTVM to junction of R35, C28, and C29. (FIG. 8).

3. Adjust L17 top (FIG. 9) for zero reading on the VTVM.

PICTURE I.F. (ROUGH ALIGNMENT)

1. Connect the bias battery as shown in fig. 8. The negative side of the bias battery to the junction of R4, R5, and C80, and the positive side to ground. Disconnect the white wire, that goes to the center terminal of the AGC switch (S2), from the junction of R4, R5, and C80. Connect the output of the signal generator between the test point on the R.F. unit (see fig. 9) and ground.

2. Connect the probe of the VTVM to the junction of L11 and R16 (fig. 8). Common to ground. When 12BY7 is used connect to junction of L11 and R118.

3. Set the signal generator to 21.6 mc. and adjust L25, co-channel sound trap, (fig. 9) for minimum output on V T V M.

4. Reset the signal generator to 23.25 mc. Adjust the output of the signal generator for approximately 2.5 volts on the VTVM.

5. Peak first Picture I.F. coil (located on R.F. Unit) and the third Picture I.F. coil L6 (fig. 9) for maximum. Maintain approximately 2.5 volts on the VTVM by adjusting the generator output.

6. Reset signal generator to 25.7 mc.

7. Peak second Picture I.F. coil L3 and the fourth Picture I.F. coil L9 (fig. 9) for maximum.

PICTURE I.F. (FLAT-TOPPING)

1. Remove signal generator and VTVM.

2. Connect the sweep generator between the R.F. test point and ground.

3. Connect the oscilloscope probe to the junction of L11 and R16 (or L11 and R118 in sets using 12BY7).

4. Connect the hot side of the signal generator to the chassis side apron nearest the first I.F. stage. Leave the ground side disconnected.

5. With most sweep generators, there is enough output to give an I.F. response curve of sufficient height on the oscilloscope. If there is insufficient output use 3 volts bias instead of 4.5 volts. In adjusting the output of the sweep generator, make sure you do not overload the I.F.'s. This can be ascertained by noticing that the relative shape of the I.F. response does not change with small variations in sweep generator output.

6. Set the signal generator to 26.1 mc. and advance the output until a marker pip is visible on the Picture I.F. curve on the oscilloscope. Be careful not to distort the I.F. curve by advancing the generator output too far. Adjust L3 and L9 so that the marker pip is at the 50% point. See Fig. 7 Picture I.F. curves and Markers.

7. Set the signal generator to 22.7 mc. Adjust the first Picture I.F. coil (located on the R.F. Tuner) and L6 so that the marker pip is at the 50% point. See Fig. 7.

8. Repeat steps 6 and 7 until an acceptable curve is achieved.

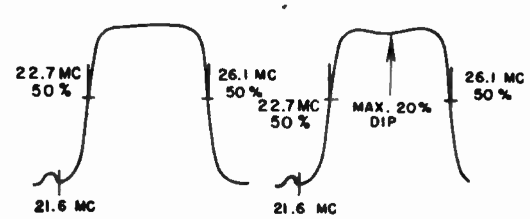

FIG. 7. TYPICAL PICTURE I.F. CURVES AND MARKERS

OSCILLATOR AND R.F. ALIGNMENT

The R.F. Unit is a turret type tuner with separate coil segments for each channel. Normal channel sequence is progressive in a clockwise direction covering channels 2 to 13. The R.F. amplifier is of the cascode type utilizing a 6BQ7 or 6BK7. The converter stage utilizes a 6J6.

OSCILLATOR ALIGNMENT

It should be possible to tune in all channels with the fine tuning control C212 (see figs. 8 and 9) in the middle third of its range. When V3 ages, the oscillator may shift slightly in frequency requiring adjustment. If V3 is defective and must be replaced, several tubes should be tried to find one that requires the least oscillator adjustment.

If an accurately calibrated signal generator that covers all the R.F. frequencies is available then continue with step 1. If not go on to step 10.

1. Remove tube shield on 6J6, V3.

2. Modify a tube shield which will fit snugly over the 6J6 and still remain ungrounded.

3. Remove shorting wire from channel 11 oscillator coil and replace segment and R.F. unit bottom shield.

4. Turn channel selector to channel 12.

5. Set generator to the oscillator frequency which is 231.35 mc. for channel 12.

6. With reference to figure 10 connect the generator to one of the 10 mmf capacitors and connect the other 10 mmf capacitor to the ungrounded tube shield over the 6J6. Connect remaining terminal on probe to vertical input on oscilloscope.

7. Set fine tuning control C212 (fig. 9) to center of its range. Adjust C211 for zero beat pattern on the oscilloscope screen. (The oscillator coil slug which is accessible from the chassis front apron should be in its mechanical mid-position. If the slug should fall in during adjustment, the oscillator coil segment will have to be removed from the turret housing, the little wire spring which normally fits into the slug threads lifted up, and the slug brought forward to its mean position.)

8. Reset the generator for the oscillator frequency of channel 11. Adjust the oscillator coil slug for zero beat on the oscilloscope screen. Use a non-metallic screw-driver in adjusting the oscillator coil slug.

9. Repeat step 8 for the remaining channels, making sure the signal generator is set for the proper frequency on each channel.

When an accurately calibrated generator is not available, then oscillator alignment can only be accomplished when the local T.V. transmitters are on the air.

10. Remove bias battery and replace AGC lead to junction of R4, R5, and C80 (fig. 8).

11. Set fine tuning control C212 (fig. 9) to center of its range.

12. Rotate channel selector control to one of the local T.V. stations and adjust the oscillator coil slug, which is accessible from the front chassis apron (fig. 9), for best picture.

13. Check remaining local stations by rotating the channel selector switch to each channel in turn and adjusting the oscillator slug for best picture.

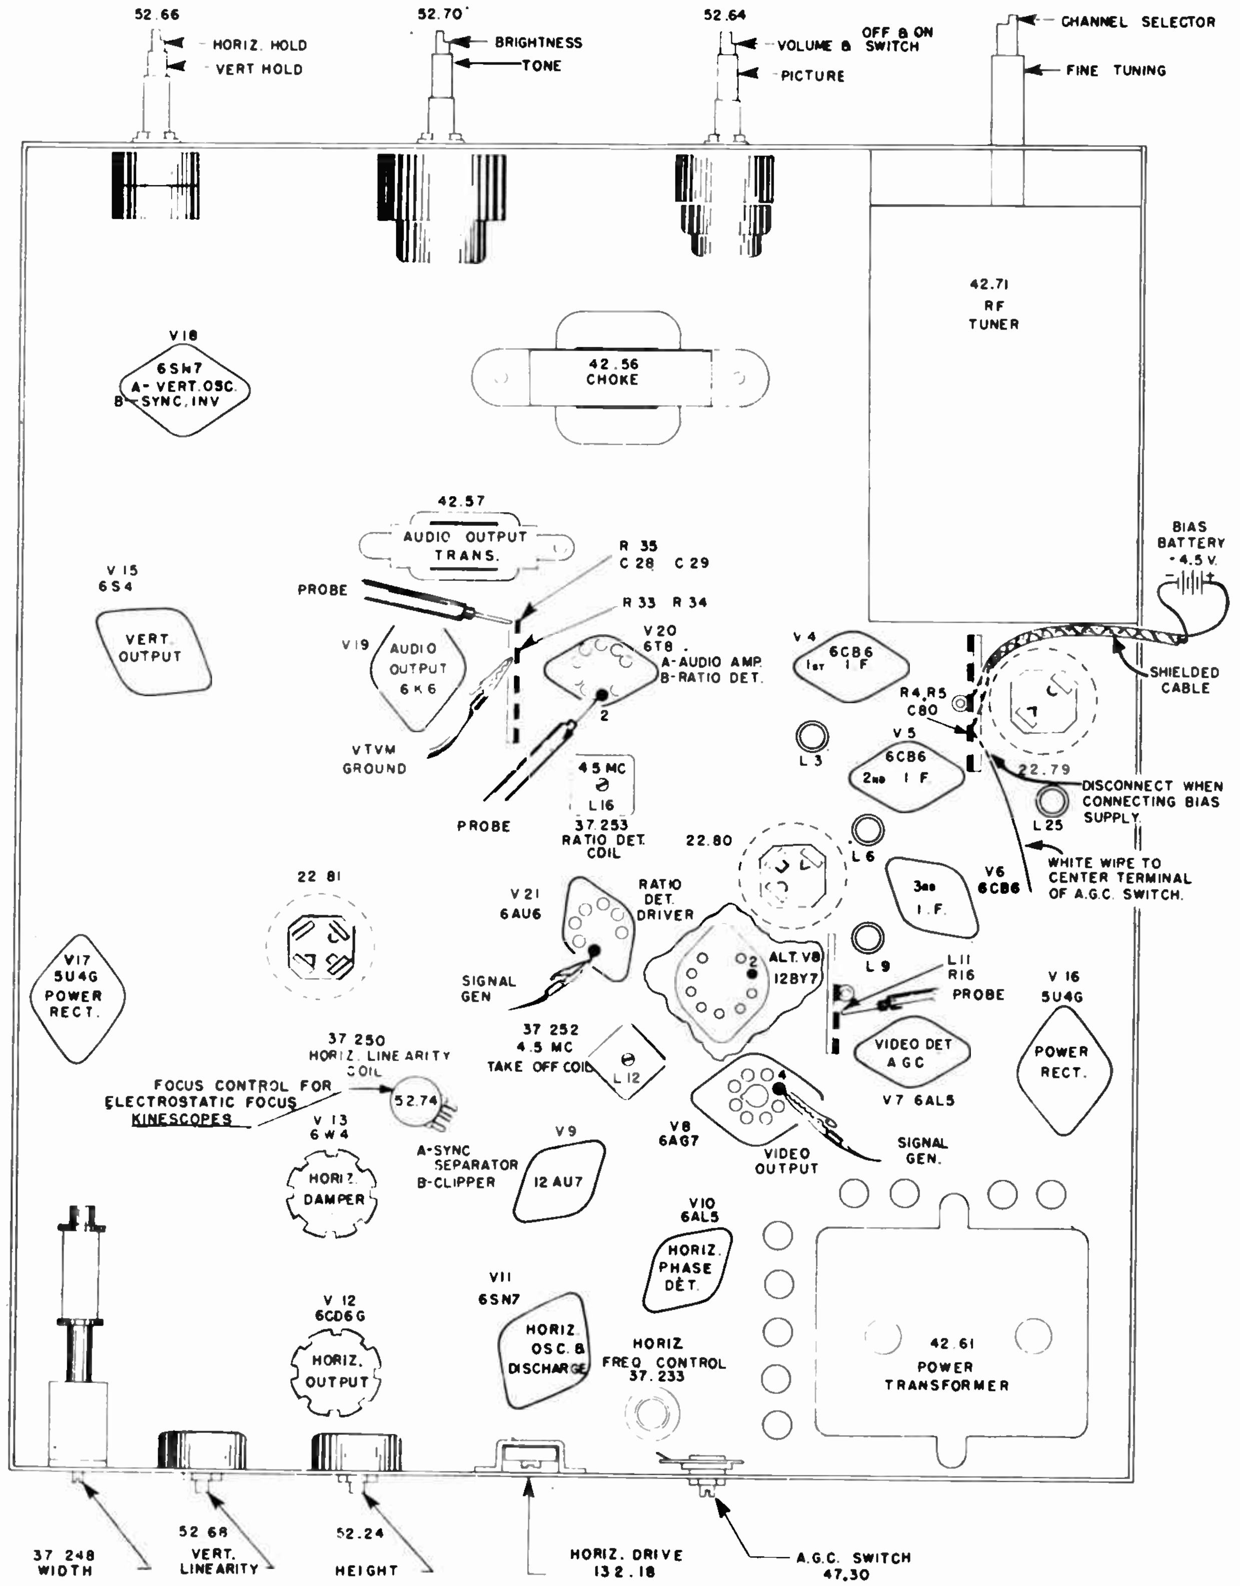

FIG. 8. BOTTOM VIEW OF CHASSIS

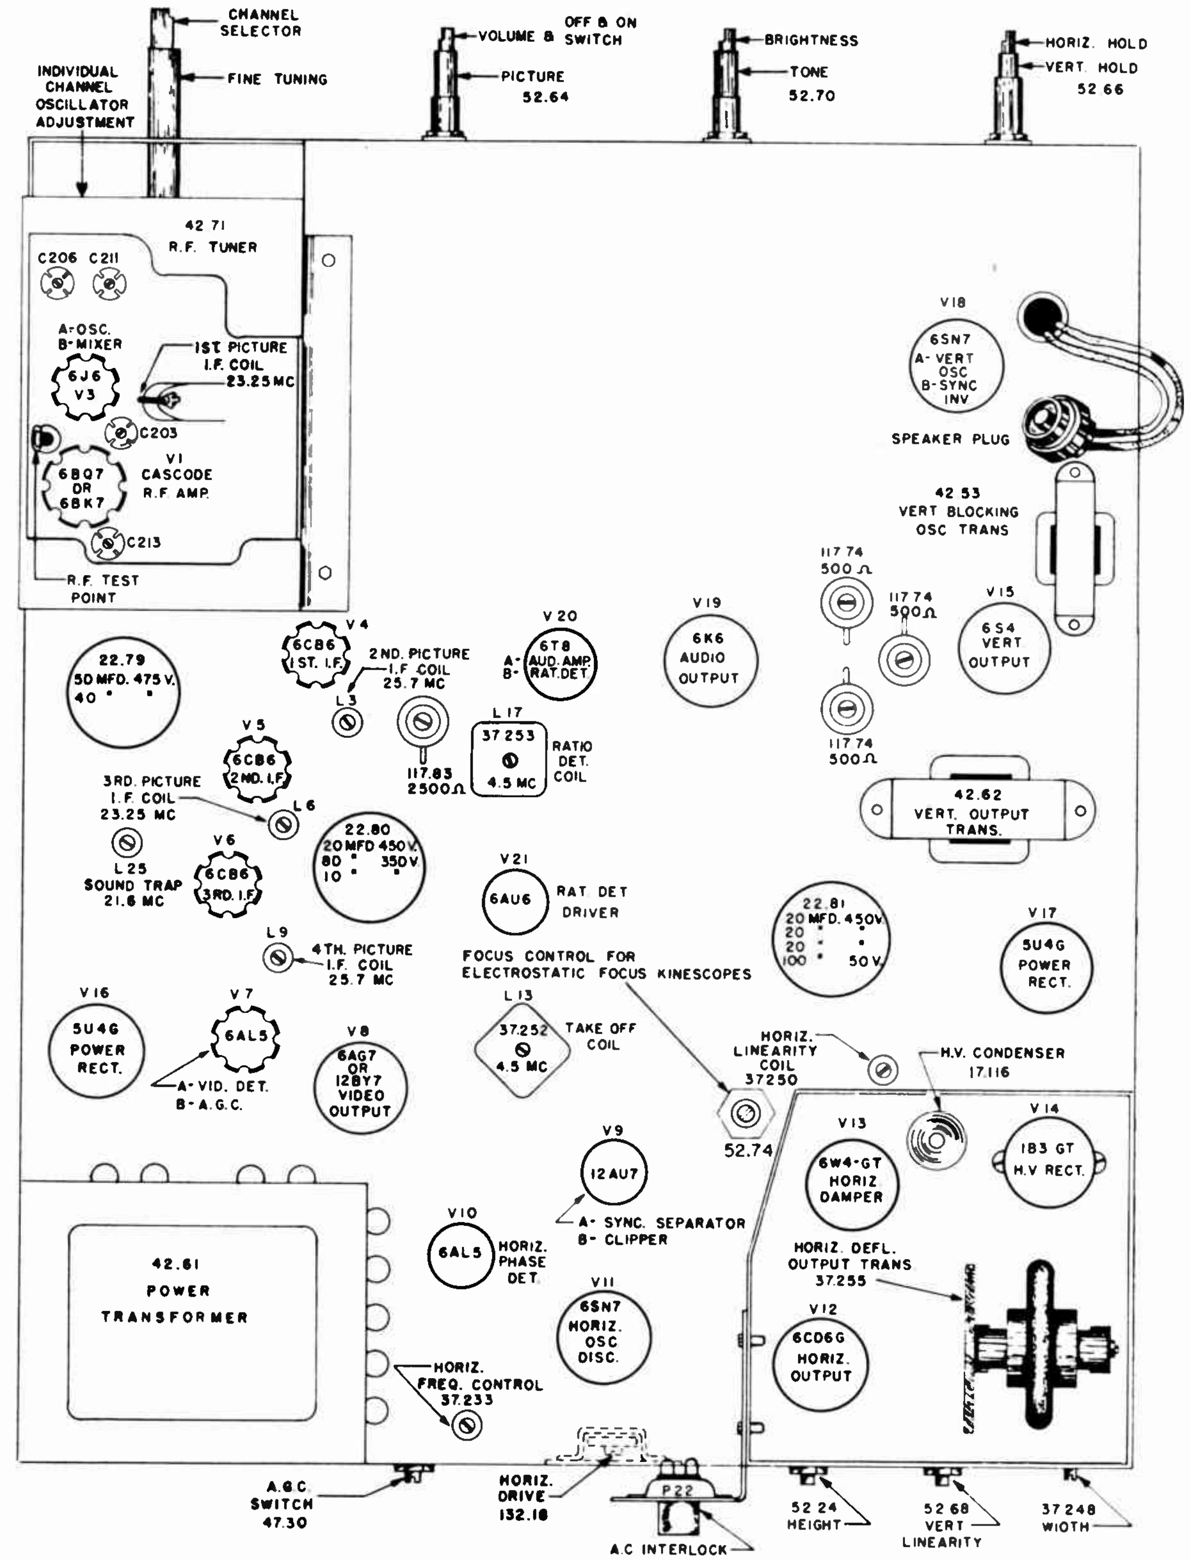

FIG. 9. TOP VIEW OF CHASSIS

14. If on one or two of the channels you do not have enough oscillator range, readjust C211 and repeat steps 12 and 13.

It is possible to adjust the oscillator channel slugs without removing the chassis from the cabinet. The slugs are made accessible by removing the channel selector and fine tuning knobs and by moving the escutcheon plate to one side. Use a long thin fibre or bakelite screwdriver for making adjustments.

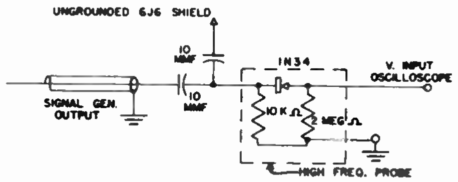

FIG. 10.

R.F. ALIGNMENT

1. Reconnect bias battery as in step 1. Picture I.F. (Rough alignment). Disconnect white AGC wire. Set bias for 3 volts.

2. Connect oscilloscope through 10,000 ohms to test point on R.F. Unit. Connect sweep generator to antenna terminals. If the sweep generator is not terminated for balanced 300 ohms, insert the network shown in fig. 11 below.

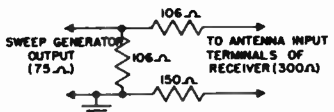

FIG. 11.

3. Set fine tuning control at approximately the midpoint of its tuning range and rotate channel selector to channel 12.

4. Adjust sweep generator to channel 12 and loosely couple signal generator to sweep generator in order to obtain picture carrier and sound carrier markers.

5. Adjust C206, C203, and C213 for flat top response curve. See figure 12 for acceptable R.F. passbands.

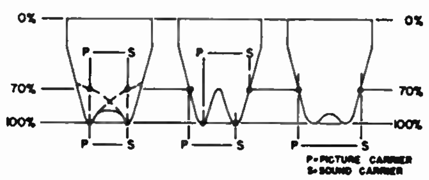
6. Check remaining channels. If the response curves obtained on any channel is not acceptable, it might be necessary to return to channel 12 and make a compromise of its response. If one channel is extremely out, that coil section should be repaired or replaced. It is not necessary to remove the tuner from the chassis in order to repair or replace a coil section.

"POWER PLUS" SWITCH, ITS FUNCTION AND USE

The new Fada television receiver with "Power Plus" control has been designed for optimum performance in all areas. This has been achieved by the utilization of two types of automatic gain control (AGC) circuits. The AGC circuit in use is controlled by the AGC "Power Plus" switch located on the rear apron of the receiver chassis.

In normal or strong signal areas, the AGC switch is rotated to its maximum clockwise position. This introduces a peak detector type of AGC which is fast acting, has good limiting and prevents overloading, all of which are desirable features for superior reception in these areas.

In weak and noisy signal areas, the AGC switch is rotated to its maximum counterclockwise position. This introduces an average detector type of AGC which is completely immune to the impulse type of noises prominent in weak signal areas. Another desirable feature of this type of AGC for weak signal areas is that a lower value of bias is developed for a fixed signal strength, thereby giving better noise factor and superior contrast. These characteristics give a picture which has a minimum of snow, which is free of noise, and which is free of horizontal and vertical jitter.



ACCEPTABLE R.F. PASSBAND
FIG. 12.

SERVICE SUGGESTIONS

No Raster Kinescope
Incorrect adjustment of ion trap magnet.
Defective Kinescope.
No high voltage. Check V11, V12, V13, V14. Check all voltages and waveforms associated with these tubes.
Incorrect setting of horizontal drive control (C51).
Check fuse F1.

Horizontal Deflection Only
Check V15, V18A, T5, T6, L18, L19, R60 and R66.
Check voltage and waveforms on grids and plates of V15, V18A.

Poor Horizontal Linearity
Check V12, V13, L21, L23, L24, C56, C57 and C58.

Small Raster
Low B or low line voltage.
Check V16 and V17.

Raster—No Sound No Picture with Control Over Brightness
Check V4, V5, V6, V7, V8 and their associated circuits.
Check R. F. Unit.

Raster — No Sound No Picture and No Control Over Brightness
Check 130 volts supply and R87.

Raster Picture and No Sound
Check V19, V20 A and B, V21.
Check alignment of L12, L13, L16, and L17.

Poor or No Horizontal Sync.
Check for gassy Kinescope.
Check V9, V10, V18B and their associated circuits.

Poor or No Vertical Sync.
Check V9, V18B and their associated circuits.

Picture Smear
Check Video peaking coils L10, L11, L14, and L15.
Check V7, V8, and their associated circuits.
Check video I. F. Alignment.

Arcing in High Voltage Supply
When replacing a component in the high voltage supply all soldered connections should be made round so that there are no sharp ends. This will eliminate any possibility of corona.

CATHODE RAY TUBE HANDLING PRECAUTIONS

Extreme care must be used in handling the picture tube. The tube is highly evacuated and, due to its large size, is subjected to a considerable amount of atmospheric pressure. The handler should wear safety goggles and gloves for protection. Avoid nicking or scratching the glass by rough contact with other objects.

Before removing the picture tube, discharge the capacitor formed by the inner and outer aquadag coatings on the tube by shorting the anode contact on the side of the tube to the outer surface with a well insulated piece of wire.

GENERAL INFORMATION

Channel Number	Channel Freq. Mc.	Picture Carrier Freq. Mc.	Sound Carrier Freq. Mc.	Receiver R-F Osc. Freq. Mc.
2	54-60	55.25	59.75	81.35
3	60-66	61.25	65.75	87.35
4	66-72	67.25	71.75	93.35
5	76-82	77.25	81.75	103.35
6	82-88	83.25	87.75	109.35
7	174-180	175.25	179.75	201.35

13	210-216	211.25	215.75	237.35

TUNING RANGE: Channels 2 through 13.

SOUND RATIO DETECTOR FREQUENCY: 4.5MC.

SOUND IF FREQUENCY: 4.5MC.

PICTURE IF FREQUENCY: 26.1MC.

ANTENNA: "Built-in-Antenna" with provisions for connection of external antenna where necessary.

EXTERNAL ANTENNA IMPEDANCE: Balanced 300 ohms.

POWER SUPPLY: 117 volts, 60 cycles A.C.

POWER CONSUMPTION: 250 watts.

AUDIO OUTPUT: 3.2 watts.

INSTALLATION INSTRUCTIONS

SHIPPING BLOCK

The shipping block and bolt located on the top rear inside portion of the cabinet must be removed when the receiver is installed Model 21C2 only

RECEIVER LOCATION

The receiver may be placed anywhere in the room, but for greatest satisfaction it should be located:

1. Away from any bright light that may fall directly on the screen or be reflected from it. This includes windows and lamps. Some illumination in the room, off to one side, is desirable, however, to prevent eye-strain.

2. To provide comfortable viewing and ease in operation.

3. At least one inch away from a wall to allow for cabinet ventilation. This is very important.

ANTENNAS

The choice of a television antenna depends entirely upon the location of the receiver with respect to all television station transmitting antennas in any locality. Maximum pick-up is obtained when the receiving antenna is directly in line of sight with the transmitting antenna.

"BUILT-IN-ANTENNA"

The receiver is normally shipped with the FADA built-in-antenna connected. This antenna is a stationary folded dipole which is used for both the high and low frequency channels. It is fastened to the top underside of the cabinet, and connected to the antenna terminals on the back of the cabinet.

When this antenna is used, the following requirements should be observed for best reception:

1. In order to get maximum performance and satisfactory pictures from the "BUILT-IN-ANTENNA," ample signals from the television station must be present at the location of the receiver. Normally, the strength of the signals will vary throughout the room in which the receiver is located. For this reason, better pictures will be obtained if the receiver is tried in all possible locations in the viewing room and is then placed where the clearest pictures are received from all stations. Avoid large metallic objects, such as radiators, metal panels, etc.

2. Lamps, vases, and metallic objects, when placed on top of the receiver, may effect the efficiency of the "BUILT-IN-ANTENNA."

3. The Fada "BUILT-IN-ANTENNA" will give satisfactory reception in strong signal areas; but if the receiver is located in a fringe or weak signal area, an outdoor antenna is recommended.

OUTDOOR ANTENNA

The "BUILT-IN-ANTENNA" must be disconnected from the antenna terminal strip before connecting the outdoor antenna leads. It is immaterial which lead is connected to which terminal.

OPERATING INSTRUCTIONS

(Refer to Figure 1)

(1) Turn OFF-ON SOUND volume control clockwise about a half turn. This turns the receiver on and sets the sound volume to a reasonable level.

(2) Allow a brief warm-up period.

(3) Set Station Selector to desired channel.

(4) Adjust the Fine Tuning control to where music or speech is heard, assuming that the station is broadcasting.

(5) Turn picture control fully counter clockwise.

(6) Turn the brightness control fully clockwise and then slowly counter clockwise until light is just visible on the screen.

(7) Turn the picture control clockwise until activity or a definite form is just noted on the screen. Do not advance control any further until steps 8, 9, and 10 are completed.

(8) If the pattern is moving up or down adjust Vertical control until pattern is stationary in vertical direction.

(9) If picture appears as black and white diagonal lines or seems to be moving sideways, adjust Horizontal control until a proper picture is obtained.

(10) Readjust Fine Tuning control for best picture.

(11) Adjust Picture control until picture is suitable for brightness and contrast. If the control is advanced to maximum clockwise position, overloading of the picture will occur on strong signals. This will be noted by excessive contrast, bending of picture and raspy noise in the sound output. When this occurs rotate the picture control slowly in a counter clockwise direction until the picture and sound distortion disappears. The brightness and details of a picture are controlled by the Brightness and Picture knobs. Adjust Tone Control for desired sound quality.

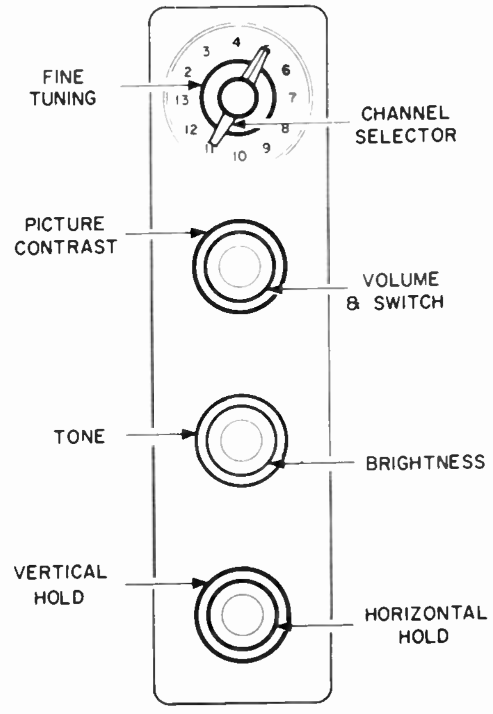
(12) Recheck the Fine Tuning control for best picture.

NOTE: If any difficulty is experienced with steps number 8 or 9, turn the PICTURE control ¼ turn counter clockwise, readjust the Fine Tuning control and then repeat these adjustments.

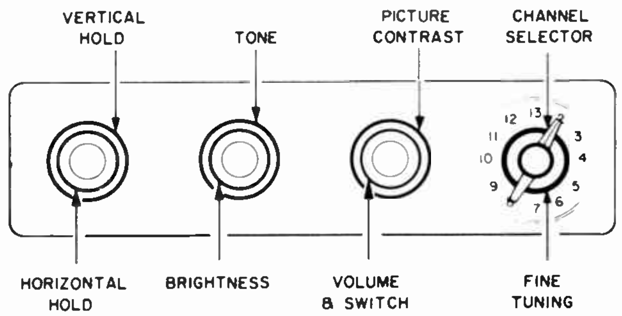
If the receiver has been in previous operation and no controls disturbed except for turning the on-off knob to "off" position, then subsequent operation should require the previous steps 1 through 3 and, if necessary, steps 13 and 14 as follows:

(13) Adjust the FINE TUNING control for best picture quality. Readjust the SOUND volume control to desired level.

(14) Adjust PICTURE and BRIGHTNESS controls to obtain desired level of contrast and brightness.



21C2 - 24T2



21T - DL21T

FIG. 1. OPERATING CONTROLS

SERVICE ADJUSTMENTS

The receiver is completely adjusted at the factory, so normally none other than the front panel operating instructions need be followed to put the receiver in operation. However, to provide for any misadjustment of the service controls due to handling, the following instructions are in order.

ION TRAP, FOCUSER AND DEFLECTION YOKE ADJUSTMENTS

Before any adjustments can be made the back of the cabinet will have to be removed. Remove all screws holding back cover to cabinet, and pull cover away from cabinet. Since the power cord circuit is broken by the interlock when the cabinet back is removed, an extra television power cord will be necessary to make a power connection to the receiver. A mirror placed in front of the receiver will help in making the adjustments.

ION TRAP ADJUSTMENTS

Turn on the receiver and switch to one of the television channels not in use in your area. With the brightness control in the maximum clockwise position and the picture control fully counter-clockwise adjust the ion trap by moving it forward or backward at the base of the tube, at the same time rotating it slightly around the neck of the cathode ray tube for the brightest raster on the screen. Reduce the brightness control setting until the raster is just visible on the screen, readjust the ion trap for maximum brilliance. Adjust the focuser adjustment control (shown in Figure 2, 3 or 4) until the line structure of the raster is clearly visible. Readjust the ion trap for maximum raster brilliance. The final touches of the adjustment should be made with the brightness control at the maximum position with which good line focus can be maintained.

FOCUSER MAGNET ADJUSTMENT

The focuser magnet should be adjusted so that there is approximately one-eighth inch of space between the rear shell of the deflection yoke and the front face of the focuser magnet. This spacing gives best average focus over the face of the tube.

The axis of the hole through the focuser magnet should be parallel with the axis of the cathode ray tube neck. See Figure 2, 3 or 4.

NOTE: The cardboard insert between the focuser magnet and the neck of the cathode ray tube must not be removed.

DEFLECTION YOKE ADJUSTMENT

If the lines of the raster are not horizontal or squared with the picture mask, loosen the yoke centering wing screw (shown in Figure 2, 3 or 4) and rotate the yoke until this condition is obtained. Tighten the wing screw making sure the deflection yoke is as far forward on the neck of the cathode ray tube as possible.

CENTERING ADJUSTMENTS

No electrical centering controls are provided. Centering is accomplished by means of a separate plate on the focus magnet as shown in Fig. 2, 3 or 4. The centering plate has a locking screw which must be loosened before centering. Up and down adjustment of the plate moves the picture side to side and sidewise adjustment moves the picture up and down.

If a corner of the raster is shadowed, check the position of the ion trap. Reposition the ion trap within the range of maximum raster brightness to eliminate the shadow and recenter the picture by adjustment of the focus centering plate. In no case should the ion trap be adjusted to cause any loss of brightness since such operation may cause immediate or eventual damage to the cathode ray tube. In some cases it may be necessary to shift the position of the focuser magnet in order to eliminate a corner shadow.

SERVICE CONTROL ADJUSTMENTS

With the deflection system in proper mechanical alignment, the service controls may be adjusted. The mechanical adjustments ordinarily will not require further attention until the cathode ray tube is replaced. Normal picture contrast and brightness should be maintained during adjustments. Using a test pattern from a local television station, make the service control adjustments as follows: (Refer to Figure 2, 3 or 4.)

1. Set the horizontal and vertical hold controls on the front panel for a steady test pattern. If horizontal synchronization cannot be effected within the normal range of the horizontal hold control, set the control in the center of its range and adjust the horizontal frequency coil for a steady picture. This screw driver adjustment is reached from the top rear section of the chassis.

2. Set the picture control on the front panel to minimum, counter-clockwise, and advance the brightness control on the front panel clockwise to maximum. Fully open the horizontal drive trimmer adjustment located on the center rear apron of chassis. If no vertical white line appears in the center of the test pattern, leave it at full drive and proceed to the next step. If a vertical white line does appear in the center of the test pattern, gradually tighten up on the trimmer screw until the white line is eliminated. Insufficient horizontal drive will cause the raster to fall short of filling the mask horizontally or cause the picture to lack the brilliance normally obtained with a correct adjustment.

3. Reset the picture control for the desired picture contrast. If necessary, readjust the brightness control for a most desirable picture.

4. Set the width coil screw-driver adjustment so that the test pattern fills the horizontal dimensions of the cathode ray tube mask. A minor adjustment of the focuser centering plate may be necessary to recenter the pattern.

5. Set the horizontal linearity coil screw-driver adjustment so that the test pattern is symmetrical from left to right. A slight readjustment of the horizontal drive may be necessary after making this adjustment.

6. Set the height control on the rear apron of the chassis so that the test patern fills the vertical dimensions of the cathode ray tube mask. A minor adjustment of the focuser centering plate may be required to recenter the pattern.

7. Set the vertical linearity control on the rear apron of the chassis for a symmetrical test pattern in the vertical dimensions. A slight readjustment of the height control may be required after making this adjustment.

8. Set the brightness and picture controls for a normal test pattern and adjust the focus adjustment until the fine horizontal line structure of the raster is clearly visible over the picture area. The control should be turned through the correct point several times so that optimum focus is obtained.

FIG. 2. SERVICE ADJUSTMENT AND CONTROLS

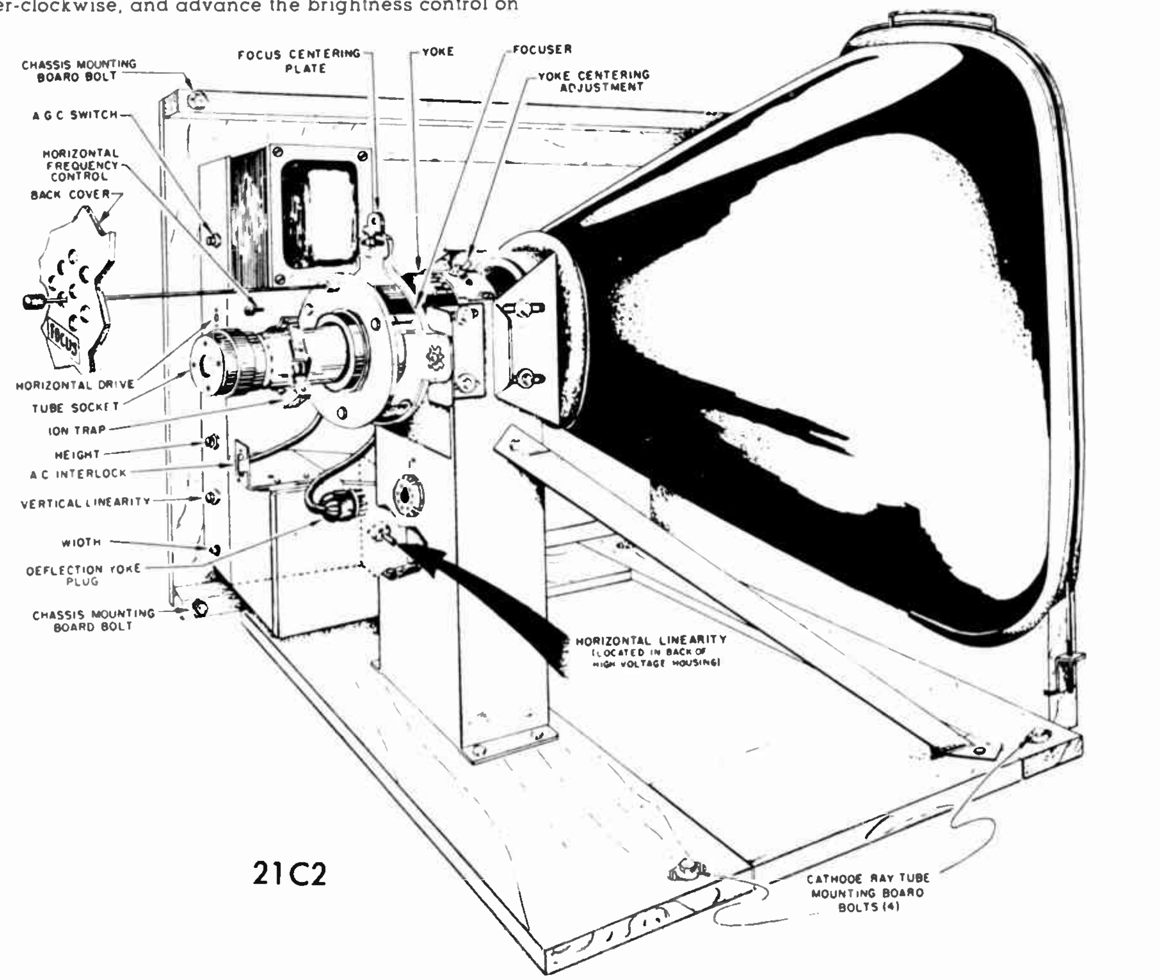

FIG. 3. SERVICE ADJUSTMENTS AND CONTROLS

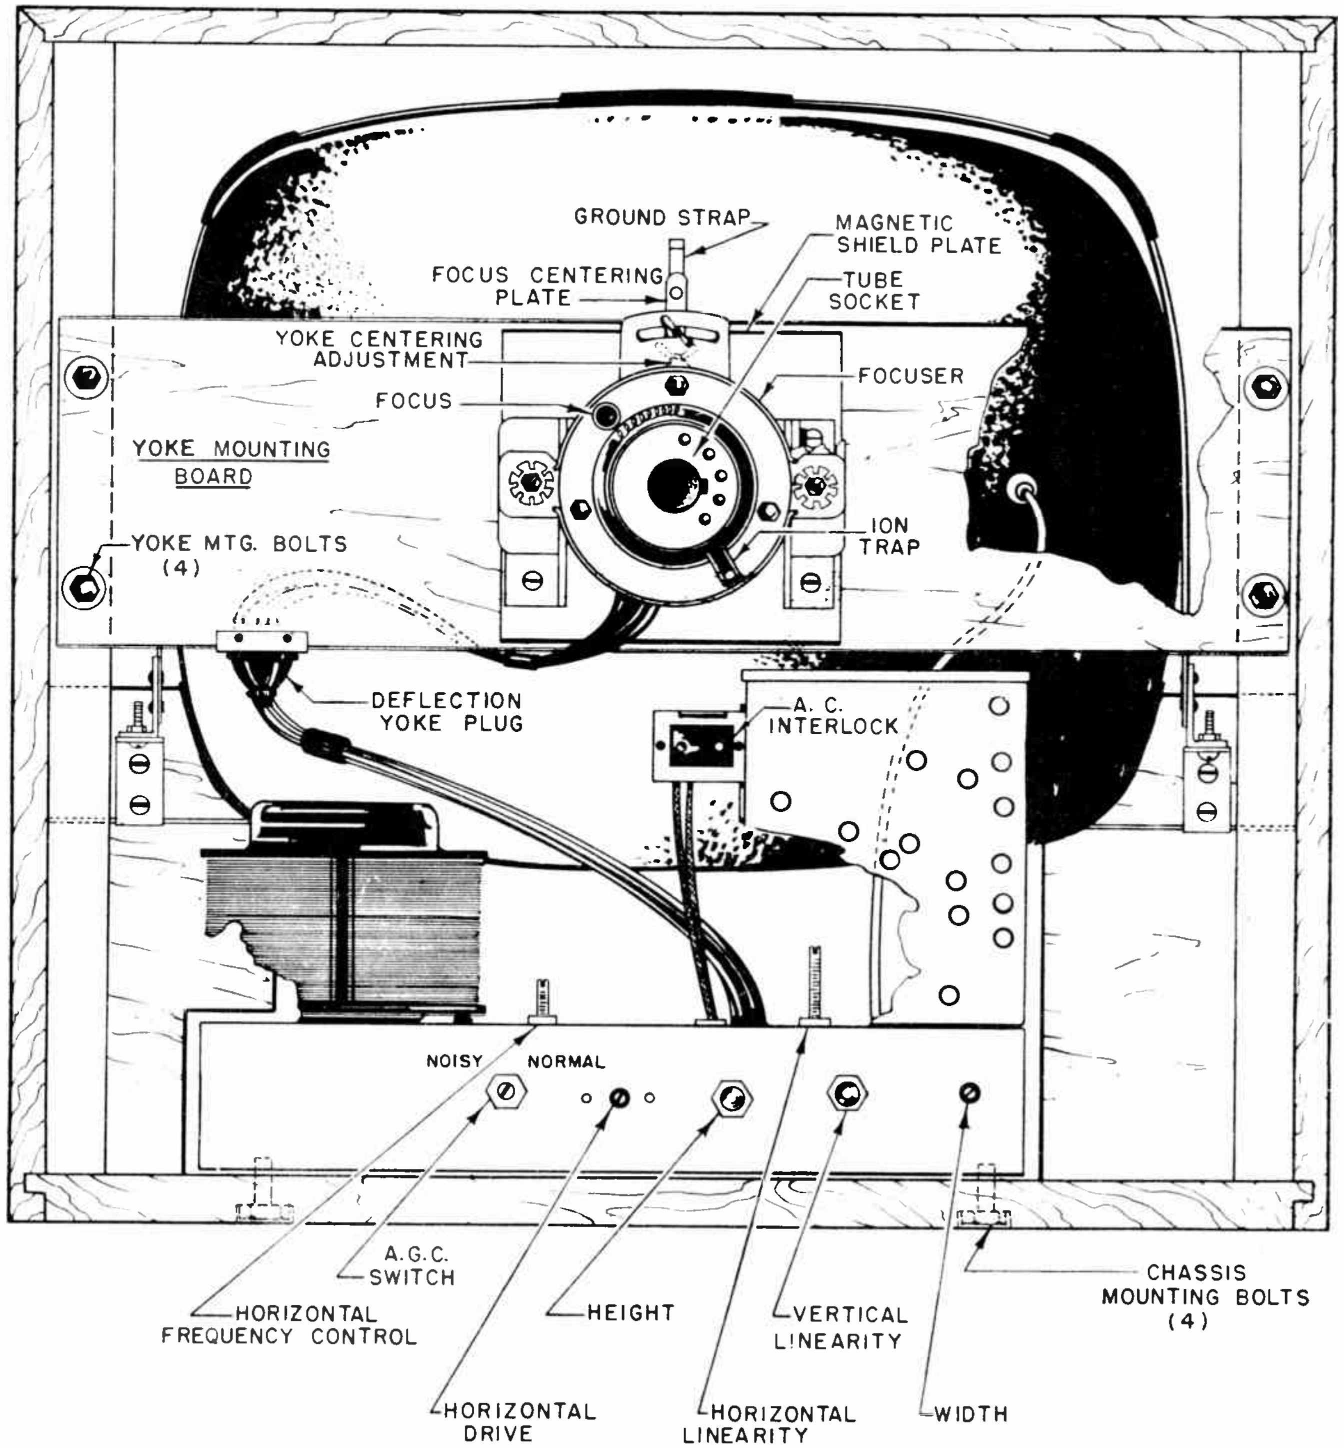

FIG. 4. SERVICE ADJUSTMENTS AND CONTROLS

21T DL21T

TO REMOVE FRONT SAFETY GLASS ON MODEL 21T ONLY

The front glass may be removed to allow cleaning of its rear face and of the picture tube face.

The top edge of the glass fits into a groove on the inside surface at the top of the cabinet. The bottom edge rests on a metal bracket attached to the cabinet. The bracket is covered by a snap-on decorative plate.

Place fingers over top and bottom of the decorative plate and pull. The nameplate will snap off to expose two screws in the bracket. Press bracket in towards cabinet with one hand and remove the two screws with the other hand. After removing screws, hold the bottom edge of the glass with free hand. Remove bracket. While holding glass at bottom allow it to slide down gently, until its top edge comes below cabinet top. With other hand grasp top edge of glass and remove glass from cabinet.

TO REMOVE FRONT SAFETY GLASS ON MODEL DL21T ONLY

The top edge of the glass fits into a groove on the inside surface at the top of the cabinet. The bottom edge of the glass fits into a groove on the inside surface at the bottom of cabinet and rests on a push-up bar which passes through the bottom (near front and center) of the cabinet. A screw holds this push bar to the underside of the cabinet bottom.

Move cabinet forward until the felt feet at the front portion of the cabinet bottom just touch the edge of the table. The front edge of the cabinet will overhang the table. There will now be sufficient room to reach the screw holding the push bar to the bottom of the cabinet.

Place one hand on the top portion of the safety glass. With the free hand remove the screw holding the push bar. Place the free hand on glass next to the other hand. Press gently forward and down on glass which will slide down to expose top edge. Grasp top edge with either hand and bring glass out and then up from bottom groove.

ALIGNMENT

GENERAL

If the receiver must be aligned or some portion serviced, the chassis must be removed first and separately from the kinescope. (See figures 2, 3, or 4.) To remove the chassis, remove the knobs from the front panel, remove all screws holding back cover to cabinet and pull cover away from cabinet to disengage interlock. Disengage the kinescope socket, the kinescope high voltage lead, the yoke plug, and the speaker plug. Remove the two screws holding the antenna terminal strip to the top of the cabinet.

For Models 21T and DL21T, remove the four chassis mounting bolts from the underside of the cabinet, (See Figure 4) and slide the chassis back out of the cabinet.

For Model 21C2 remove the two bolts on the back top and bottom of the chassis mounting board. A third bolt which runs through the bottom board underneath the front of the chassis must be loosened. (This bolt is used to align the control shafts with the holes on the front panel.) Slide chassis board with chassis out of the cabinet. (See Fig. 3). For Model 24T2 remove the two bolts on the back top and bottom and one bolt on the top front of the chassis mounting board, (See Figure 2) and slide the chassis mounting board with the chassis out of the cabinet.

To remove the kinescope on Models 21C2 and 24T2 remove the bolts (four on 21C2 and three on 24T2) holding the tube mounting board to the cabinet. For the 24T2, also remove the kinescope holding blocks. Slide the complete assembly out of the cabinet.

To remove the kinescope on Models 21T and DL21T place the cabinet front down and remove the four bolts holding the yoke mounting board. Lift the yoke mounting board off the tube, being careful not to exert any force on neck of tube, and then loosen the two screws holding the kinescope holding strap to free tube. Kinescope can then be lifted free from cradle. **Warning:** Do not attempt to lift kinescope by grasping neck of tube.

EQUIPMENT REQUIRED

RF SWEEP GENERATOR meeting the following requirements:

(a) Frequency Ranges

18 to 30 mc	10 mc sweep width
40 to 90 mc	10 mc sweep width
170 to 225 mc	10 mc sweep width

(b) Output adjustable with at least 1 volt maximum.

(c) Output constant on all ranges.

(d) "Flat" output on all attenuator positions.

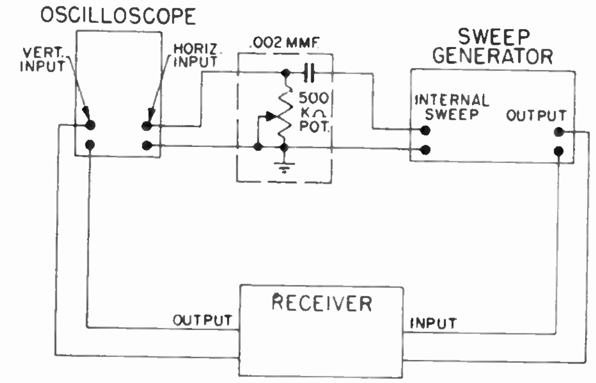

FIG. 5. SWEEP SETUP EXTERNAL PHASING

If the sweep generator does not have an internal blanking control or a phasing control, then it will be necessary to connect a phasing network between the sweep output of the sweep generator and the horizontal input to the oscilloscope. See Fig. 5 SWEEP-SET-UP EXTERNAL PHASING.

CATHODE RAY OSCILLOSCOPE preferably one with a wide band vertical deflection, input calibrating source, and a low capacity probe.

SIGNAL GENERATOR to cover all IF frequencies of from 4.5mc to 28mc and all picture and sound carrier frequencies.

ELECTRONIC VOLTMETER of Junior "Voltohmyst" type and a high voltage multiplier probe for use with this meter to permit measurements up to 20KV.

Bias supply made of batteries to give 4.5 volts.

ORDER OF ALIGNMENT

Sound Ratio Detector.

Sound IF Transformers.

Picture IF Transformers (preliminary and flat topping).

Oscillator and RF sections.

PRECAUTIONS

Before proceeding with IF Alignment, the following precautions should be observed:

Disconnect the antenna. Set picture control for minimum. Remove R.F. unit bottom shield. Remove channel 11 oscillator coil section. This is the coil strip nearest the fine-tuning control. Short the coil nearest the oscillator tuning slug, by soldering a bare wire across the coil terminals. Use extreme care so as not to short the oscillator coil to any other coil and also not to deform any of the coils. Reinsert channel 11 oscillator coil section and set R.F. unit to channel 11. Now the local oscillator is deactivated and you may proceed with the alignment without interference from local television stations.

For all IF Alignment, insert a 47K ohm resistor in series with the VTVM probe; also, a 47K ohm resistor should be inserted between the take-off point and the oscilloscope lead for decoupling.

SOUND RATIO DETECTOR AND IF ALIGNMENT

1. Connect probe of the VTVM to the diode plate of the ratio detector tube V20B (6T8, pin 2). Common to ground. See Figure 11.

2. Connect high side of the signal generator to the grid of the ratio detector driver. V21 (6AU6, pin 1). Common to ground. See Figure 11.

3. Tune the signal generator to exactly 4.5mc and attenuate the generator so it does not exceed 8 volts on the VTVM.

4. Peak L16 bottom core (FIG. 11) for maximum.

5. Peak L17 top core (FIG. 12) for maximum.

6. Adjust attenuator of signal generator to give exactly eight volts on the VTVM.

7. Move probe of VTVM to junction of R28, C31 and C29. (FIG. 11).

8. Adjust L17 top core (FIG. 12) for exactly 4 volts on the VTVM.

9. Move signal generator to video output tube V8 (6AG7, pin 4) (FIG. 11) and repeat steps number 1 and 3.

10. Peak L12 bottom (FIG. 11) and L13 top (FIG. 12) for maximum.

11. Repeat with care steps 1-3-4-5-6-7-8.

ALTERNATIVE PROCEDURE FOR STEPS 6-7-8:

1. Connect common lead of VTVM to junction of R29 and R30 (FIG. 11).

2. Connect probe of VTVM to junction of R28, C31, and C29. (FIG. 11).

3. Adjust L17 top (FIG. 12) for zero reading on the VTVM.

12. Connect detector probe shown in figure 6 between kinescope cathode (junction of R37 and R38) and ground.

13. Rotate the contrast control to its maximum clockwise position. Connect probe of VTVM to detector.

14. Adjust L12 (bottom slug) for minimum output on VTVM.

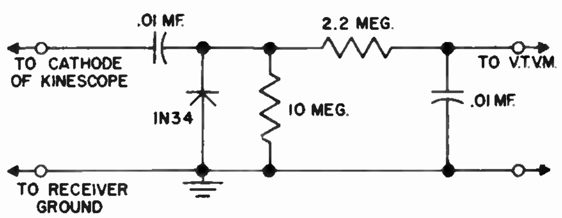

FIG. 6. DETECTOR PROBE

PICTURE I.F. (ROUGH ALIGNMENT)

1. Connect the bias battery as shown in fig. 11. The negative side of the bias battery to the junction of R8, R5, and C81, and the positive side to ground. Disconnect the white wire, that goes to the center terminal of the AGC switch (S2), from the junction of R8, R5, and C81. Connect the output of the signal generator between the test point on the R.F. unit (see fig. 12) and ground.

2. Connect the probe of the VTVM to the junction of L11 and R16 (fig. 11). Common to ground.

3. Set the signal generator to 21.6 mc. and adjust L25, co-channel sound trap, (fig. 12) for minimum output on VTVM.

4. Reset the signal generator to 23.25 mc. Adjust the output of the signal generator for approximately 2.5 volts on the VTVM.

5. Peak first Picture I.F. coil (located on R.F. Unit) and the third Picture I.F. coil L6 (fig. 12) for maximum. Maintain approximately 2.5 volts on the VTVM by adjusting the generator output.

6. Reset signal generator to 25.7 mc.

7. Peak second Picture I.F. coil L3 and the fourth Picture I.F. coil L9 (fig. 12) for maximum.

PICTURE I.F. (FLAT-TOPPING)

1. Remove signal generator and VTVM.

2. Connect the sweep generator between the R.F. test point and ground.

3. Connect the oscilloscope probe to the junction of L11 and R16.

4. Connect the hot side of the signal generator to the chassis side apron nearest the first I.F. stage. Leave the ground side disconnected.

5. With most sweep generators, there is enough output to give an I.F. response curve of sufficient height on the oscilloscope. If there is insufficient output use 3 volts bias instead of 4.5 volts. In adjusting the output of the sweep generator, make sure you do not overload the I.F.'s. This can be ascertained by noticing that the relative shape of the I.F. response does not change with small variations in sweep generator output.

6. Set the signal generator to 26.1 mc. and advance the output until a marker pip is visible on the Picture I.F. curve on the oscilloscope. Be careful not to distort the I.F. curve by advancing the generator output too far. Adjust L3 and L9 so that the marker pip is at the 50% point. See Fig. 7 Picture I.F. curves and Markers.

7. Set the signal generator to 22.7 mc. Adjust the first Picture I.F. coil (located on the R.F. Tuner) and L6 so that the marker pip is at the 50% point. See Fig. 7.

8. Repeat steps 6 and 7 until an acceptable curve is achieved

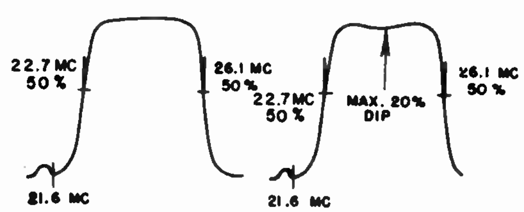

FIG. 7. TYPICAL PICTURE I.F. CURVES AND MARKERS

OSCILLATOR AND R.F. ALIGNMENT

The R.F. Unit is a turret type tuner with separate coil segments for each channel. Normal channel sequence is progressive in a clockwise direction covering channels 2 to 13. The R.F. amplifier is of the cascode type utilizing a 6BQ7 or 6BK7. The converter stage utilizes a 6J6.

OSCILLATOR ALIGNMENT

It should be possible to tune in all channels with the fine tuning control C212 (see figs. 11 and 12) in the middle third of its range. When V3 ages, the oscillator may shift slightly in frequency requiring adjustment If V3 is defective and must be replaced, several tubes should be tried to find one that requires the least oscillator adjustment.

If an accurately calibrated signal generator that covers all the R.F. frequencies is available then continue with step 1. If not go on to step 10.

1. Remove tube shield on 6J6, V3.

2. Modify a tube shield which will fit snugly over the 6J6 and still remain ungrounded.

3. Remove shorting wire from channel 11 oscillator coil and replace segment and R.F. unit bottom shield.

4. Turn channel selector to channel 12.

5. Set generator to the oscillator frequency which is 231.35 mc. for channel 12.

6. With reference to figure 8 connect the generator to one of the 10 mmf capacitors and connect the other 10 mmf capacitor to the ungrounded tube shield over the 6J6. Connect remaining terminal on probe to vertical input on oscilloscope.

7. Set fine tuning control C212 (fig. 12) to center of its range. Adjust C211 for zero beat pattern on the oscilloscope screen. (The oscillator coil slug which is accessible from the chassis front apron should be in its mechanical mid-position. If the slug should fall in during adjustment, the oscillator coil segment will have to be removed from the turret housing, the little wire spring which normally fits into the slug threads lifted up, and the slug brought forward to its mean position.)

8. Reset the generator for the oscillator frequency of channel 11. Adjust the oscillator coil slug for zero beat on the oscilloscope screen. Use a non-metallic screw-driver in adjusting the oscillator coil slug.

9. Repeat step 8 for the remaining channels, making sure the signal generator is set for the proper frequency on each channel.

When an accurately calibrated generator is not available, then oscillator alignment can only be accomplished when the local T.V. transmitters are on the air.

10. Remove bias battery and replace AGC lead to junction of R8, R5, and C81 (fig. 11).

11. Set fine tuning control C212 (fig. 12) to center of its range.

12. Rotate channel selector control to one of the local T.V. stations and adjust the oscillator coil slug, which is accessible from the front chassis apron (fig. 12), for best picture.

13. Check remaining local stations by rotating the channel selector switch to, each channel in turn and adjusting the oscillator slug for best picture.

14. If on one or two of the channels you do not have enough oscillator range, readjust C211 and repeat steps 12 and 13.

It is possible to adjust the oscillator channel slugs without removing the chassis from the cabinet. The slugs are made accessible by removing the channel selector and fine tuning knobs and by moving the escutcheon plate to one side. Use a long thin fibre or bakelite screwdriver for making adjustments.

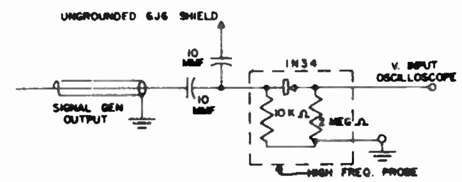

FIG. 8.

R.F. ALIGNMENT

1. Reconnect bias battery as in step 1. Picture I.F. (Rough alignment). Disconnect white AGC wire. Set bias for 3 volts.

2. Connect oscilloscope through 10,000 ohms to test point on R.F. Unit. Connect sweep generator to antenna terminals. If the sweep generator is not terminated for balanced 300 ohms, insert the network shown in fig. 9 below.

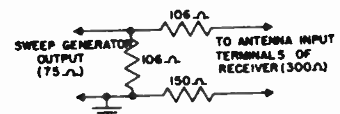

FIG. 9.

3. Set fine tuning control at approximately the midpoint of its tuning range and rotate channel selector to channel 12.

4. Adjust sweep generator to channel 12 and loosely couple signal generator to sweep generator in order to obtain picture carrier and sound carrier markers.

5. Adjust C206, C203, and C213 for flat top response curve. See figure 10 for acceptable R.F. passbands.

6. Check remaining channels. If the response curves obtained on any channel is not acceptable, it might be necessary to return to channel 12 and make a compromise of its response. If one channel is extremely out, that coil section should be repaired or replaced. It is not necessary to remove the tuner from the chassis in order to repair or replace a coil section.

"POWER PLUS" SWITCH, ITS FUNCTION AND USE

The new Fada television receiver with "Power Plus" control has been designed for optimum performance in all areas. This has been achieved by the utilization of two types of automatic gain control (AGC) circuits. The AGC circuit in use is controlled by the AGC "Power Plus" switch located on the rear apron of the receiver chassis.

In normal or strong signal areas, the AGC switch is rotated to its maximum clockwise position. This introduces a peak detector type of AGC which is fast acting, has good limiting and prevents overloading, all of which are desirable features for superior reception in these areas.

In weak and noisy signal areas, the AGC switch is rotated to its maximum counterclockwise position. This introduces an average detector type of AGC which is completely immune to the impulse type of noises prominent in weak signal areas. Another desirable feature of this type of AGC for weak signal areas is that a lower value of bias is developed for a fixed signal strength, thereby giving better noise factor and superior contrast. These characteristics give a picture which has a minimum of snow, which is free of noise, and which is free of horizontal and vertical jitter.

SERVICE SUGGESTIONS

No Raster on Kinescope
Incorrect adjustment of ion trap magnet.
Defective Kinescope.
No high voltage. Check V11, V12, V13, V14. Check all voltages and waveforms associated with these tubes.
Incorrect setting of horizontal drive control (C61).
Check fuse F1.

Horizontal Deflection Only
Check V15, V18A, T5, T6, L18, L19, R60 and R68
Check voltage and waveforms on grids and plates of V15, V18A.

Poor Horizontal Linearity
Check V12, V13, L21, L23, L24, C65 and C66.

Small Raster
Low B or low line voltage.
Check V15 and V17.

Raster—No Sound No Picture with Control Over Brightness
Check V4, V5, V6, V7, V8 and their associated circuits.
Check R. F. Unit.

Raster — No Sound No Picture and No Control Over Brightness
Check 130 volts supply and R95.

Raster Picture and No Sound
Check V19, V20 A and B, V21.
Check alignment of L12, L13, L16, and L17.

Poor or No Horizontal Sync.
Check for gassy Kinescope.
Check V9, V10, V18B and their associated circuits.

Poor or No Vertical Sync.
Check V9, V18B and their associated circuits.

Picture Smear
Check Video peaking coils L10, L11, L14, and L15.
Check V7, V8, and their associated circuits.
Check video I. F. Alignment.

Arcing in High Voltage Supply
When replacing a component in the high voltage supply all soldered connections should be made round so that there are no sharp ends. This will eliminate any possibility of corona.

4.5 mc Beat in Picture
Check L25, L12, L13 and their associated circuits.
Check alignment of L25, L12, L13.

TELEVISION ALIGNMENT PROCEDURE

Aligning a television receiver is an exacting procedure and involves the use of bench space, test equipment and skilled personnel at the service shop, as well as the cost of making two trips to the customer's home. Before deciding that the chassis must be pulled and aligned at the shop, the serviceman should check these very common sources of trouble:

1 – The antenna and installation.
2 – Front panel and rear chassis controls, including picutre tube adjustments.
3 – Reception on all available channels.
4 – Tube failures. Substitute from your kit of known good replacements.
5 – Visual inspection of underside of chassis for obvious faults, such as loose connections, etc.

TEST EQUIPMENT REQUIRED FOR ALIGNMENT

The equipment specified below is desirable, but in cases where this equipment is not available, it is possible to align the receiver by use of a 20 to 30 mc. modulated r-f signal generator, using the picture and speaker as indication of alignment.

1 – Signal Generator with an output variable between 100 and 100,000 microvolts, and crystal controlled or crystal-calibrated at the following frequencies:
  a– 4.5 megacycles
  b– 22.8 megacycles
  c– 25.4 megacycles
  d– 21.25 megacycles
2 – DC Vacuum Tube Voltmeter with 5 volt and 10 volt scales.
3 – A pair of balanced (± 1%) 100K carbon resistors.

TEST EQUIPMENT
REQUIRED FOR SWEEP ALIGNMENT CHECK

1 – R-F sweep generator with frequencies ranging from 40 to 220 megacycles, having sweep width of approximately 10 megacycles, and having adjustable output to approximately 0.1 volt.
2 – Crystal-controlled or crystal-calibrated markers for the picture and sound carriers of each channel.
3 – Cathode Ray Oscilloscope with good low frequency response.

CAUTION: THE SECOND ANODE LEAD TO THE PICTURE TUBE HAS A HIGH POTENTIAL. DURING THIS ALIGNMENT IT IS ADVISABLE TO REMOVE THE COLOR PLUG FROM ITS SOCKET, THUS ELIMINATING THIS HIGH VOLTAGE HAZARD.

I.F. ALIGNMENT PROCEDURE

1 – Connect "high" lead of signal generator to the test point located on the top of the RF tuner unit (Refer to the R-F tuner location diagram located on inside of cabinet). Connect ground to chassis.
2 – Connect DC VTVM lead (through 10K isolating resistor) to 4.7K diode load resistor (R113); ground to chassis. Set VTVM to 5 volt scale, negative polarity.
3 – Set I.F. generator to 25.4 megacycles with sufficient output to read approximately 3 volts on the VTVM.
4 – Carefully adjust L101 and L104 (see tube and tuner location) for maximum deflection on VTVM. Adjust sweep generator output to keep meter reading approximately 3 volts.
5 – Set I.F. signal generator to 22.8 megacycles with sufficient output to read approximately 3 volts on the VTVM.
6 – Carefully adjust L404, L103 (see tube and tuner location) for maximum deflection on VTVM. Adjust signal generator output to keep meter reading approximately 3 volts.
7 – Set I.F. signal generator to 21.25 megacycles, set VTVM to 10 volt scale (negative polarity), and adjust signal generator output for convenient deflection on VTVM.
8 – Adjust L114 for minimum deflection on VTVM.

SWEEP ALIGNMENT CHECK

Although not essential, a sweep alignment check is a desirable verification of good R-F and I.F. response. Proceed as follows:

1 – Connect R-F sweep generator to antenna terminals (antenna impedance 300 ohms.)
2 – Calibrate oscilloscope for convenient 5 volts peak-to-peak vertical deflection (5 volts peak-to-peak is approximately 1/4 of the peak-to-peak voltage of the 6.3V A.C. filament).
3 – Connect vertical input of oscilloscope (through 10K isolating resistor) to 4.7 diode load resistor (R113); ground to chassis. Connect horizontal input of oscilloscope to "scope" terminals of R-F generator; adjust for convenient horizontal sweep.
4 – Set R-F sweep generator to channel 3, television receiver to channel 3, and if necessary, adjust sweep generator output, sweep width, and scope horizontal setting for convenient band-pass display having 5 volts vertical deflection as previously calibrated. (If you must touch scope vertical settings during these adjustments recalibrate scope for 5 volts peak-to-peak as in step 2 above).
5 – Couple crystal-controlled R-F carrier markers very loosely to antenna terminals, adjust receiver FINE TUNING control till video carrier marker is 1/2 down on curve. Turn up marker output till R-f sound carrier is visible on bandpass and adjust sound trap (L114) to minimize effect of sound carrier marker.
6 – Check all channels as above.

SOUND ALIGNMENT

1 – Connect 4.5 megacycle signal generator to pin 2 of 12BH7 (V7) video amplifier.
2 – Connect DC V.T.V.M. lead to pin 7 of 6AL6 (V9) ratio detector, negative polarity.
3 – Adjust signal generator to precisely 4.5 megacycles; adjust output to read approximately 5 volts on V.T.V.M.
4 – Adjust L113 and bottom of T100 for maximum deflection on V.T.V.M. Keep V.T.V.M. reading below 10 volts at all times.
5 – Attach two series-connected 100K(± 1%) resistors across R126 (Ratio Detector Load Resistor). Connect DC V.T.V.M. to center-tap of 100K resistors, and connect ground wire of V.T.V.M. to junction of C119 and C120 (Audio Take-Off of T100).
6 – Adjust top of T100 for zero reading on V.T.V.M. between a plus and a minus peak.

VIDEO AMPLIFIER TRAP

When necessary, the video amplifier 4.5 mc trap (L110) should be adjusted as follows:

1 – Connect 4.5 mc signal generator "high" lead to picture tube grid; ground to chassis.
2 – Connect DC V.T.V.M. to pin 7 of 6AL5 (V9) ratio detector, 10 volt scale, negative polarity.
3 – Adjust L110 for minimum deflection on V.T.V.M.

R-F OSCILLATOR

If all channels are not within range of FINE TUNING control, adjust two screws located in front of r-f tuner unit for adjustment of either low or high band. CAUTION: Do not touch adjustments on top of r-f tuner unit, other than converter plate coil, L404, during IF Alignment.

HORIZONTAL OSCILLATOR ALIGNMENT

If the Horizontal Hold control fails to maintain sync, the horizontal oscillator should be reset. To reset this screwdriver adjustment, set the horizontal hold control in the center of its range and sync the picture with the horizontal A.F.C. adjustment screw. Check the hold control action on various channels and alter the screw adjustment as required to provide sync on all channels.

DEFLECTION YOKE, ION TRAP AND FOCUS ADJUSTMENT

Following is the proper procedure for adjusting the Deflection Yoke, Ion Trap and Focus.

The receiver should be turned on but not connected to an antenna. These steps should then be taken in the following order:

1 – The Deflection Yoke should be moved as far forward as possible on the neck of the CRT.
2 – The Brightness control should be turned to maximum (clockwise) and the Contrast control should be turned to minimum (counterclockwise).
3 – The Ion Trap should be rotated and at the same time moved forward and backward to find the position which produces the brightest raster on screen.
4 – The Deflection Yoke should be rotated so that the top and bottom edges of the raster are parallel to the top of the chassis.
5 – The Brightness control should now be reduced (ccw) to a point where the raster is slightly above normal brilliance.
6 – With Brightness and Contrast controls at normal positions, adjust the Focus control (rear of chassis) for well-defined scanning lines.

HEIGHT, WIDTH AND LINEARITY

To adjust the overall size and linearity of the picture it is almost mandatory that a test pattern transmitted from a local station be used. It should also be remembered that in areas where more than one station is being received, that pictures transmitted from different stations will vary slightly in size. The smallest transmitted picture should be made to fill the area outlined by the mask.

The Width control (rear of H.V. cage) should be adjusted to give a picture that will fill the mask horizontally.

The Height and Vertical Linearity controls (both rear of chassis) should then be adjusted for a linear picture that will fill the mask vertically.

PICTURE TUBE HANDLING PRECAUTIONS

The picture tube encloses a high vacuum and with the large surface area of glass involved, the stresses set up, particularly at the front rim of the tube, are considerable. An abnormal handling stress, accidental blow of a highly stressed surface, or even a scratch on the surface of the tube could cause it to implode or collapse with destructive violence.

HIGH VOLTAGE WARNING

Operation of this receiver outside the cabinet or with covers removed involves a shock hazard from the receiver power supplies. Work on the receiver should not be attempted by anyone who is not thoroughly familiar with the precautions necessary when working on high voltage equipment.

[E] Varies with Horizontal Hold setting.
[F] Pins 7 and 8 are filament terminals.
[G] Varies with height setting.

NO. 13-G-118 CODE NO. 105-2-82100

The safety glass of this receiver is removable so that the face of the picture tube may be cleaned. To accomplish this remove power cord from wall socket. Remove the upper strip that holds the safety glass in place by removing the five screws which secure the strip, supporting the safety glass so that it does not fall forward. Remove the safety glass by tilting it forward and lifting it out of the slot in the lower glass retaining strip. Be careful not to scratch or strike the surface of the picture tube with any object. Carefully clean face of picture tube and the inside surface of the safety glass with a soft, clean, dry cloth. DO NOT ATTEMPT TO REMOVE THE PICTURE TUBE MASK. Reassemble by inserting glass in slot of lower strip. Replace upper strip and tighten the screws securely.

20" Mahogany Console Combination

TELEVISION ALIGNMENT PROCEDURE

Aligning a television receiver is an exacting procedure and involves the use of bench space, test equipment and skilled personnel at the service shop, as well as the cost of making two trips to the customer's home. Before deciding that the chassis must be pulled and aligned at the shop, the serviceman should check these very common sources of trouble:

1 – The antenna and installation.

2 – Front panel and rear chassis controls, including picutre tube adjustments.

3 – Reception on all available channels.

4 – Tube failures. Substitute from your kit of known good replacements.

5 – Visual inspection of underside of chassis for obvious faults, such as loose connections, etc.

TEST EQUIPMENT REQUIRED FOR ALIGNMENT

The equipment specified below is desirable, but in cases where this equipment is not available, it is possible to align the receiver by use of a 20 to 30 mc. modulated r-f signal generator, using the picture and speaker as indication of alignment.

1 – Signal Generator with an output variable between 100 and 100,000 microvolts, and crystal controlled or crystal-calibrated at the following frequencies:

a– 4.5 megacycles
b– 22.8 megacycles
c– 25.4 megacycles
d– 21.25 megacycles

2 – DC Vacuum Tube Voltmeter with 5 volt and 10 volt scales.

3 – A pair of balanced (± 1%) 100K carbon resistors.

TEST EQUIPMENT REQUIRED FOR SWEEP ALIGNMENT CHECK

1 – R-F sweep generator with frequencies ranging from 40 to 220 megacycles, having sweep width of approximately 10 megacycles, and having adjustable output to approximately 0.1 volt.

2 – Crystal-controlled or crystal-calibrated markers for the picture and sound carriers of each channel.

3 – Cathode Ray Oscilloscope with good low frequency response.

CAUTION: THE SECOND ANODE LEAD TO THE PICTURE TUBE HAS A HIGH POTENTIAL. DURING THIS ALIGNMENT IT IS ADVISABLE TO REMOVE THE COLOR PLUG FROM ITS SOCKET, THUS ELIMINATING THIS HIGH VOLTAGE HAZARD.

I.F. ALIGNMENT PROCEDURE

1 – Connect "high" lead of signal generator to the test point located on the top of the RF tuner unit (Refer to the R-F tuner location diagram located on inside of cabinet). Connect ground to chassis.

2 – Connect DC VTVM lead (through 10K isolating resistor) to 4.7K diode load resistor (R113); ground to chassis. Set VTVM to 5 volt scale, negative polarity.

3 – Set I.F. generator to 25.4 megacycles with sufficient output to read approximately 3 volts on the VTVM.

4 – Carefully adjust L101 and L104 (see tube and tuner location) for maximum deflection on VTVM. Adjust sweep generator output to keep meter reading approximately 3 volts.

5 – Set I.F. signal generator to 22.8 megacycles with sufficient output to read approximately 3 volts on the VTVM.

6 – Carefully adjust L404, L103 (see tube and tuner location) for maximum deflection on VTVM. Adjust signal generator output to keep meter reading approximately 3 volts.

7 – Set I.F. signal generator to 21.25 megacycles, set VTVM to 10 volt scale (negative polarity), and adjust signal generator output for convenient deflection on VTVM.

8 – Adjust L114 for minimum deflection on VTVM.

SWEEP ALIGNMENT CHECK

Although not essential, a sweep alignment check is a desirable verification of good R-F and I.F. response. Proceed as follows:

1 – Connect R-F sweep generator to antenna terminals (antenna impedance 300 ohms.)

2 – Calibrate oscilloscope for convenient 5 volts peak-to-peak vertical deflection (5 volts peak-to-peak is approximately 1/4 of the peak-to-peak voltage of the 6.3V A.C. filament).

3 – Connect vertical input of oscilloscope (through 10K isolating resistor) to 4.7 diode load resistor (R113); ground to chassis. Connect horizontal input of oscilloscope to "scope" terminals of R-F generator; adjust for convenient horizontal sweep.

4 – Set R-F sweep generator to channel 3, television receiver to channel 3, and if necessary, adjust sweep generator output, sweep width, and scope horizontal setting for convenient band-pass display having 5 volts vertical deflection as previously calibrated. (If you must touch scope vertical settings during these adjustments recalibrate scope for 5 volts peak-to-peak as in step 2 above).

5 – Couple crystal-controlled R-F carrier markers very loosely to antenna terminals, adjust receiver FINE TUNING control till video carrier marker is 1/2 down on curve. Turn up marker output till R-f sound carrier is visible on bandpass and adjust sound trap (L114) to minimize effect of sound carrier marker.

6 – Check all channels as above.

SOUND ALIGNMENT

When necessary, the video amplifier 4.5 mc trap (L110) should be adjusted as follows:

1 – Connect 4.5 mc signal generator "high" lead to picture tube grid; ground to chassis.

2 – Connect DC V.T.V.M. to pin 7 of 6AL5 (V9) ratio detector, 10 volt scale, negative polarity.

3 – Adjust L110 for minimum deflection on V.T.V.M.

R-F OSCILLATOR

1 – Connect 4.5 megacycle signal generator to pin 2 of 12BH7 (V7) video amplifier.

2 – Connect DC V.T.V.M. lead to pin 7 of 6AL6 (V9) ratio detector, negative polarity.

3 – Adjust signal generator to precisely 4.5 megacycles; adjust output to read approximately 5 volts on V.T.V.M.

4 – Adjust L113 and bottom of T100 for maximum deflection on V.T.V.M. Keep V.T.V.M. reading below 10 volts at all times.

5 – Attach two series-connected 100K(± 1%) resistors across R126 (Ratio Detector Load Resistor). Connect DC V.T.V.M. to center-tap of 100K resistors, and connect ground wire of V.T.V.M. to junction of C119 and C120 (Audio Take-Off of T100).

6 – Adjust top of T100 for zero reading on V.T.V.M. between a plus and a minus peak.

VIDEO AMPLIFIER TRAP

If all channels are not within range of FINE TUNING control, adjust two screws located in front of r-f tuner unit for adjustment of either low or high band. CAUTION: Do not touch adjustments on top of r-f tuner unit, other than converter plate coil, L404, during IF Alignment.

HORIZONTAL OSCILLATOR ALIGNMENT

If the Horizontal Hold control fails to maintain sync, the horizontal oscillator should be reset. To reset this screwdriver adjustment, set the horizontal hold control in the center of its range and sync the picture with the horizontal A.F.C. adjustment screw. Check the hold control action on various channels and alter the screw adjustment as required to provide sync on all channels.

DEFLECTION YOKE, ION TRAP AND FOCUS ADJUSTMENT

Following is the proper procedure for adjusting the Deflection Yoke, Ion Trap and Focus.

The receiver should be turned on but not connected to an antenna. These steps should then be taken in the following order:

1 – The Deflection Yoke should be moved as far forward as possible on the neck of the CRT.

2 – The Brightness control should be turned to maximum (clockwise) and the Contrast control should be turned to minimum (counterclockwise).

3 – The Ion Trap should be rotated and at the same time moved forward and backward to find the position which produces the brightest raster on screen.

4 – The Deflection Yoke should be rotated so that the top and bottom edges of the raster are parallel to the top of the chassis.

5 – The Brightness control should now be reduced (ccw) to a point where the raster is slightly above normal brilliance.

6 – With Brightness and Contrast controls at normal positions, adjust the Focus control (rear of chassis) for well-defined scanning lines.

HEIGHT, WIDTH AND LINEARITY

To adjust the overall size and linearity of the picture it is almost mandatory that a test pattern transmitted from a local station be used. It should also be remembered that in areas where more than one station is being received, that pictures transmitted from different stations will vary slightly in size. The smallest transmitted picture should be made to fill the area outlined by the mask.

The Width control (rear of H.V. cage) should be adjusted to give a picture that will fill the mask horizontally.

The Height and Vertical Linearity controls (both rear of chassis) should then be adjusted for a linear picture that will fill the mask vertically.

PICTURE TUBE HANDLING PRECAUTIONS

The picture tube encloses a high vacuum and with the large surface area of glass involved, the stresses set up, particularly at the front rim of the tube, are considerable. An abnormal handling stress, accidental blow at a highly stressed surface, or even a scratch on the surface of the tube could cause it to implode or collapse with destructive violence.

HIGH VOLTAGE WARNING

Operation of this receiver outside the cabinet or with covers removed involves a shock hazard from the receiver power supplies. Work on the receiver should not be attempted by anyone who is not thoroughly familiar with the precautions necessary when working on high voltage equipment.

Knob, AM/FM Chassis w/Marker	A39247-1
Knob, AM/FM Chassis	A39246-1
Record Changer	A6426-4

INSTALLATION

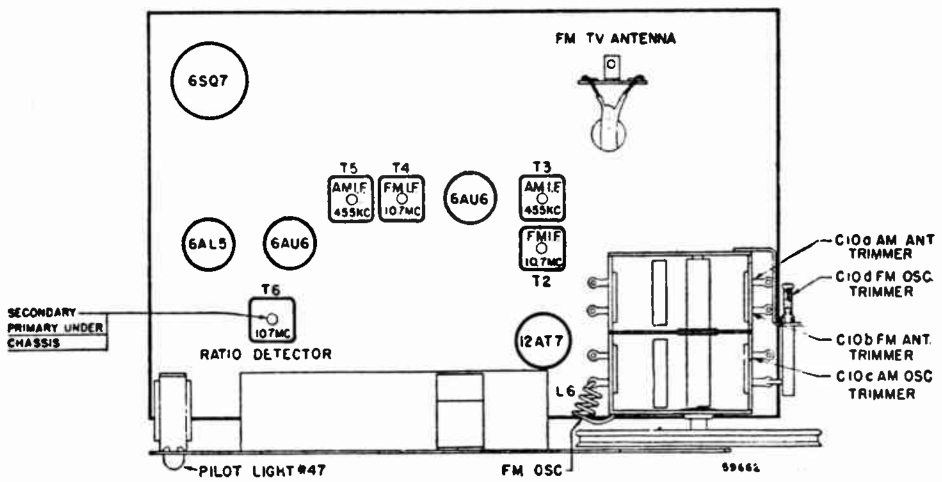
PREPARING THE RECEIVER FOR INSTALLATION:

Do not connect this unit to an electric outlet until these unpacking instructions have been followed and rechecked.

1. Remove shipping Bracket which is located at the rear of the record changer compartment drawer.
2. The record changer is floated on spring mountings. For shipping purposes only, these mountings are made rigid. To float the changer, remove the turntable by lifting it straight up the spindle. Turn the two shipping bolts (identified by large, round heads) in a clockwise direction as far as possible and replace the turntable. Replace the turntable with a counterclockwise turning motion, making sure that the driver wheel is in position against the inside flange of the turntable.
3. For proper operation, the radio chassis must be allowed to float on the rubber shock mounts on which it is mounted. This is done by loosening the two bolts which hold the shock mounts secure. These bolts are at the ends of the chassis with a cardboard "Shim" under them. The bolts can be reached from the underside of the compartment, and from the television compartment.

TUBES:

The receiver is shipped with all of the tubes in their respective sockets. Be sure that each tube is pushed all the way down in its socket. The location of the tubes are shown below.



TUBE-TRIMMER LOCATION

ELECTRICAL AND MECHANICAL DATA

Frequency Range .... (AM) 535 KC to 1620 KC
(FM) 87 MC to 109 MC

Intermediate Frequency .... (AM) 455 KC (FM) 10.7 MC

Power Supply .... 117 volts AC, 60 cycles

Speaker .... PM

TUBE COMPLEMENT

1	12AT7	Oscillator-Converter
1	6AU6	1st IF Amplifier
1	6AU6	2nd IF Amplifier
1	6SQ7	AM Detector—1st Audio (AM-FM)
1	6AL5	FM Detector

SOCKET VOLTAGES

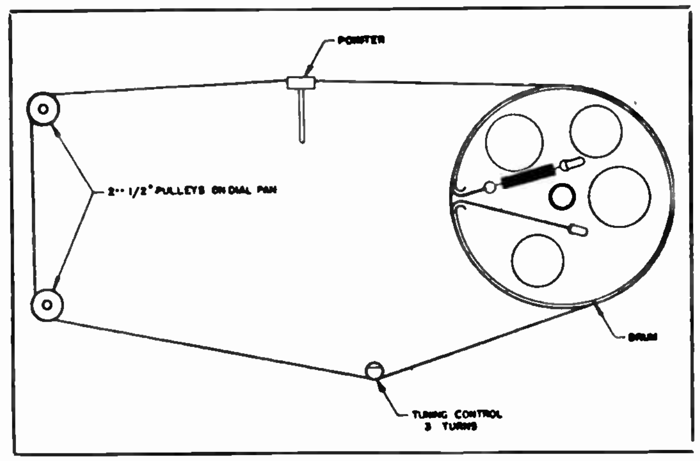
TUBE	POSITION	1	2	3	4	5	6	7	8
12AT7	Oscillator-Converter	245	0	4.2 AC	6.3 AC	6.3 AC	245	−4.5	0
6AU6	1st IF. Amplifier	−0.5	0	0	6.3 AC	250	155	1.1	....
6AU6	2nd IF. Amplifier	0	0	0	6.3 AC	225	160	1.2	....
6SQ7	AM Detector 1st Audio (AM-FM)	0	0.8	0	0	−0.5	92	6.3 AC	0
6AL5	FM Detector	−1.6	−1.4	6.3 AC	0	0	0	−2.5	....

NOTE: All DC voltages measured with V.T.V.M. from Chassis to socket contact indicated. All voltages are positive DC unless otherwise marked.
Volume control full on. Zero signal input.
Tone control in counter-clockwise position.
Band switch in "AM" position.
Variable condenser set at minimum.
Line voltage 117 volts, 60 cycle AC.

CHASSIS REMOVAL

Remove the power cord from the electrical outlet before starting to remove chassis.

1. Remove the four knobs.
2. Remove the back cover.
3. Remove loop and dipole antenna leads from their respective terminals.
4. Detach the phono-motor cord. (Plug and socket connection.)
5. Remove the phono-input lead from the receptacle on the chassis.
6. Remove the interconnecting cables from receptacle in T.V. chassis.
7. Remove chassis mounting screws. The chassis may now be removed from the cabinet.



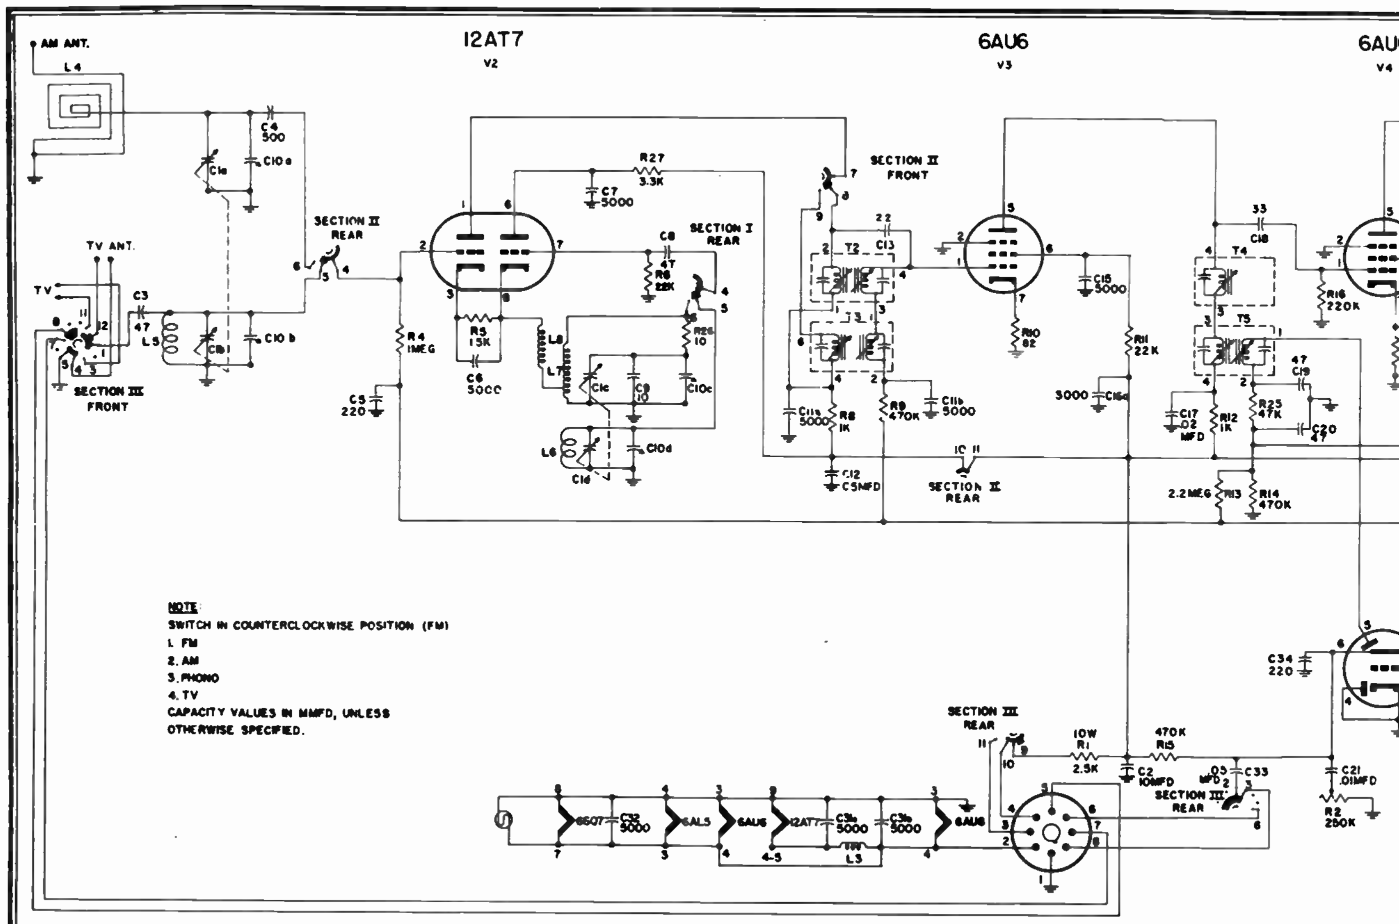
DIAL STRINGING

ALIGNMENT PROCEDURE

The following equipment is necessary to properly align this receiver:

1. AM signal generator with frequency coverage from 455 kc. to 1700 kc.
2. FM or CW signal generator covering the FM band from 87 mc. to 109 mc. and the 10.7 mc. for FM IF alignment.
3. Vacuum Tube Voltmeter (VTVM).
4. Output meter—to match 4 ohms, 5 watts maximum.
5. Insulated alignment screwdriver.
6. Dummy antenna—0.1 mfd. capacitor, 300 ohm carbon resistor and inductive loop (fashioned from several turns of wire).

NOTE: Oscilloscope equipment not required if aligned according to the following procedure:



Reference Notes to Alignment Chart

Note A: Put two 100,000 ohm resistors in series across R-23 (30,000 ohms). Negative lead of V.T.V.M. is attached to the junction of these two resistors. Positive lead of V.T.V.M. is ground. V.T.V.M. on 3 volt scale.

Note B: Negative lead of V.T.V.M. same as in Note A, positive lead of V.T.V.M. at junction of R-22 (27K ohm) and shielded lead, on terminal strip at ratio detector.

Note C: The FM R.F. and OSC. coils are made of stiff wire. To adjust these coils for bandwidth and tracking move coils together or apart as required.

Note D: Tune F.M. antenna trimmer (ClOb) and at the same time rock the signal generator frequency back and forth for maximum deflection on the meter.

Before starting alignment, painter must be set 87.5 MC. mark with gang fully closed.

ALIGNMENT CHART

Step No.	Band Switch in Position	Dummy Antenna	Signal Generator Freq.	Signal Generator Connection	Dial Position	Output Meter	Adjust C or L	Adjust For	Remarks

INSTALLATION

PREPARING THE RECORD CHANGER FOR OPERATION

Do not connect this unit to a power outlet until all shipping items on the record changer have been removed.

The record changer is floated on spring mountings. For shipping purposes only, these mountings are made rigid. To float the changer, remove the turntable by lifting it straight up the spindle. Turn the two shipping bolts (identified by large, round heads) in a clockwise direction as far as possible and replace the turntable. Replace the turntable with a counterclockwise turning motion, making sure that the driver wheel is in position against the inside flange of the turntable.

It is essential to have the record changer absolutely level. Use a torpedo or similar type level on the changer baseplate. Use adequate shims under the radio combination cabinet to achieve perfect level.

RECORD CHANGER CONNECTION

See that the connections from the pickup arm and from the turntable motor are plugged into their sockets on the radio chassis.

POWER SUPPLY

The record changer is designed for operation from 105-125 volt, 60 cycle, alternating current (AC) supply only. Never connect to a supply having a different frequency or voltage than that specified.

OPERATION

This Intermix Record Changer is designed to automatically play standard 78 RPM records, and 45 RPM and 33 1/3 RPM records of standard commerical dimensions. Any of these type records up to 12″ in diameter may be played manually.

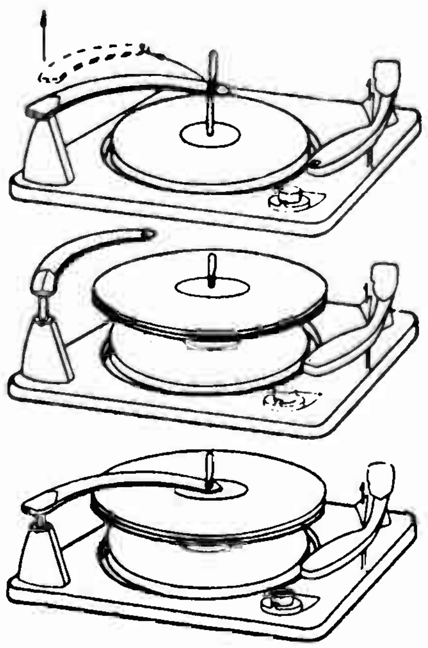
The changer will automatically play as many as ten 12″, twelve 10″, or any assortment of ten records intermixed. However, only intermix records of the same type—either standard (78 RPM) or long play (33 1/3 RPM).

A full stack of twelve 7″, 33 1/3 RPM, long-play records, a full stack of twelve 7″, 45 RPM, fine-groove records (with the proper adapter inserted in the record), or a full stack of twelve 7″ 78 RPM records (children's records) with lead-in and finishing grooves will also automatically play on this changer. Changer shuts off after the last record has been played.

Those children's records and home recordings that do not have lead-in and finishing grooves must be played manually.

LOADING THE RECORDS FOR AUTOMATIC OPERATION

1. Lift up on the record support knob until it clears the spindle and swing it to the left.
2. Carefully place the records on the spindle and lower them to the off-set shoulder. Steady the records with one hand and replace the record support over the spindle. Gently push down on the record support knob until the records are held parallel with the turntable.
3. The record to be played first should be at the bottom of the stack; the second record to be played next, etc. The side of the record to be played should face upward.

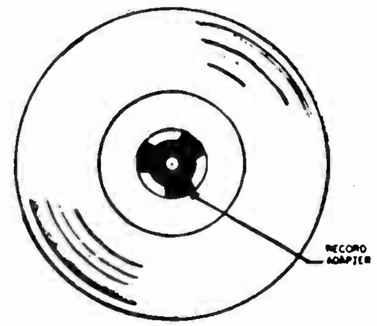


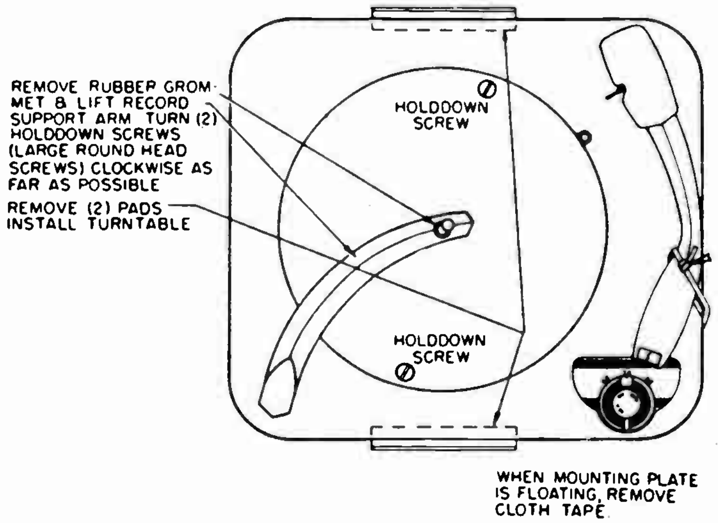
TO PLAY STANDARD RECORDINGS (78 RPM)

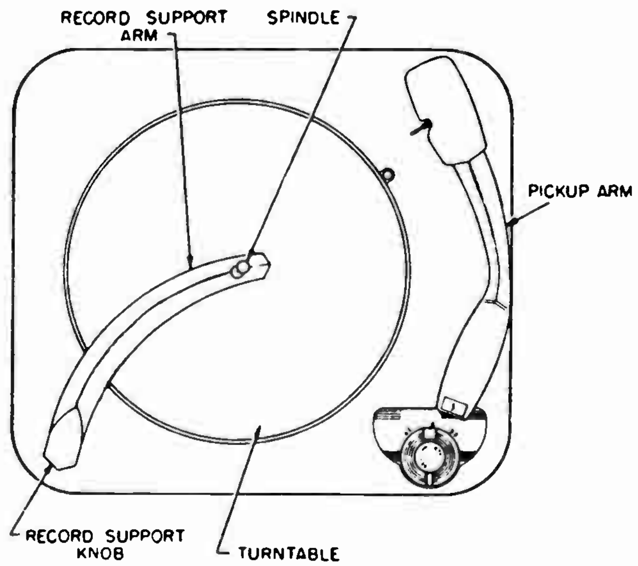
1. Motor speed control knob must be in the 78 position. A stack of 10″ and 12″ standard records (78 RPM) may be intermixed.

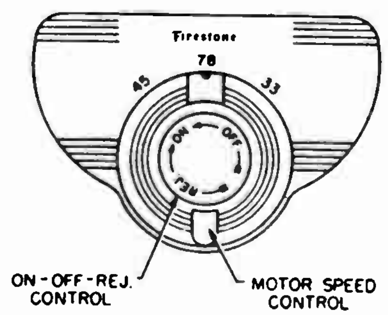
TO PLAY LONG-PLAY (33 1/3 RPM) RECORDS

1. Motor speed control knob must be in the "33" position a stock of 10″ and 12″ long play records (33 1/3 RPM) may be intermixed, or a full stack of 7″ long play records (33 1/3 RPM) may be played.









TO PLAY FINE-GROVE (45 RPM) RECORDS

1. Motor speed control knob must be in the "45" position. Your fine-groove 45 RPM records are manufactured with a 1½″ spindle hole. Because of this it is essential before playing these records that a record adapter be inserted (as shown in the illustration) in each 45 RPM record to be played. A full stack of 7″ Fine Groove (45 RPM) records may be played.

STARTING THE MECHANISM

The pickup arm should be in place on the pickup arm rest.

1. Turn the receiver on and set the selector switch to phono position.
2. Turn the changer control knob clockwise (to the right) to "REJ." and release it. This will release the bottom record from the stack and will cause the pickup arm to come to its proper position on the record and start playing. When the record is finished, the mechanism will automatically lift the pickup arm and drop the next record into position for playing. When the last record is played, the mechanism will automatically shut off.

NOTE: If when the line cord is first connected to an A.C. outlet, the turntable does not revolve and the ON-OFF Reject Control cannot be turned to its "ON" position it will be necessary to rotate the turntable in a clockwise direction by hand until the pickup arm is on its rest.

TO REJECT A RECORD

To reject a record you don't want to hear, turn the changer control knob to "REJ." and release it. This will lift the pickup arm from the record and drop the next record into position for playing.

TURNING OFF

To turn off the changer before the last record has been played, turn the changer control knob to "OFF," lift the pickup arm from the record and place it on the rest.

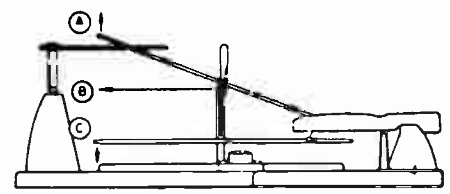
TO REMOVE RECORDS

Lift and turn the record support arm to the left. Lift the records from the turntable.

MANUAL OPERATION

To play records one at a time as with an ordinary phonograph:

1. Lift up on the record support knob until it clears the spindle. Swing it to the left until the pin in the shaft drops into the locating groove.
2. Place the record on the off-set shoulder of the spindle and tilt it toward the back of the pickup arm (A).



This will guide the push-off finger into the center hole of the record. Pull the record (B) so the center hole is over the main part of the spindle. The record can now drop to the turntable (C) and be played in the usual manner.

3. Turn the changer control knob to "ON".
4. Place the needle in the starting grooves of the record.

TONE AND VOLUME CONTROLS

The tone and the volume controls will affect record reproduction and volume in the manner as for the radio.

CARE OF RECORDS

To insure long life for your records requires only slight effort. Do not expose them to heat from the sun or from nearby stoves or radiators. Store them preferably in albums, but in any case keep them always in a cool, dry place, resting vertically. Remove dust and dirt, using a soft cloth and a light circular motion.

SUGGESTIONS

When loading and unloading the changer use care to prevent bending of spindle. Records should not be left on the spindle except during operation of changer. Records will warp. When machine is not in use, it is suggested that the motor control be left in the "78" position. For best reproduction keep needle and records clean.

IF NOISE DEVELOPS

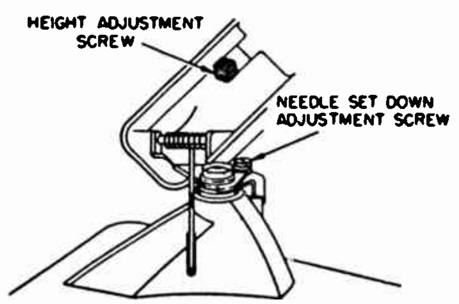
Noisy scratching indicates worn records. Some records will wear longer than others, even if kept equally clean. This is due not only to quality of manufacture and care given the records but also to the kind of music recordered.

SELECTION OF NEW RECORDS

When buying records inspect them carefully to be sure that they do not have chipped edges and that they are perfectly flat. Records that are warped or "saucer shaped" or that have chipped edges may not operate properly in the record changer.

SPECIAL INSTRUCTIONS

1. The set-down position of the needle is adjusted by means of an adjusting screw. See illustration. Turn this screw in either direction until correct set-down is obtained for a 10" record. When correct set-down is obtained for the 10" position, the 12" and 7" set-down positions also will be correct.



2. The pickup arm height is adjusted by the height adjustment screw. See illustration. Turn the screw in or out until the underneath side of the pickup arm lifts 1/4" above a 1 1/8" stack of records on the turntable during start of cycle.
3. The pickup arm is equipped with a cartridge having a osmium tipped unipoint needle. Insert new needle and tighten thumb nut firmly by hand.

The replacment needle will have to be adjusted before it is tightened in the pickup cartridge to insure that the needle shank is securely held by the knurled thumb nut.

***CAUTION:* DO NOT USE PLIERS ON KNURLED THUMB NUT.**

TIGHTEN WITH FINGERS ONLY.

13	210-216	211.25	215.75	237.45

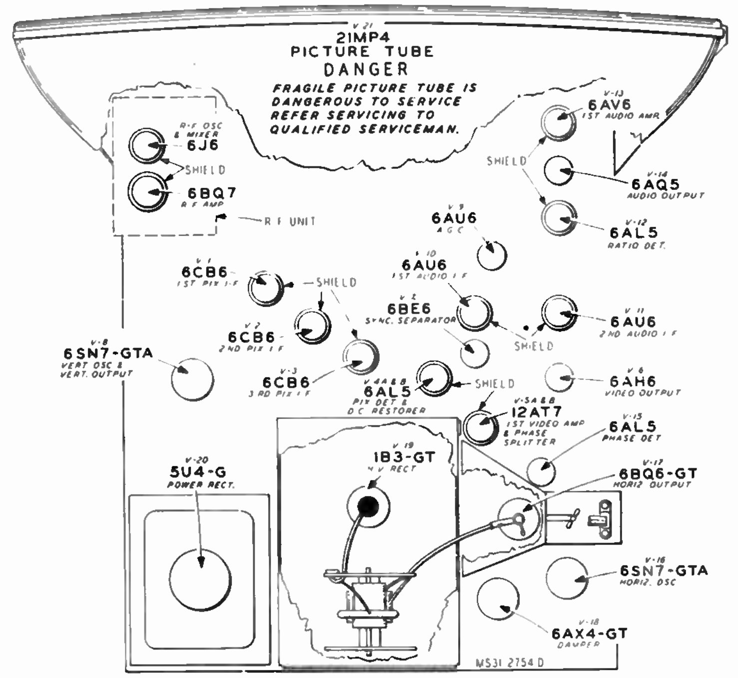

Fig. 1—Tube Layout.

RECEIVER LOCATION — Advise the owner as to the proper location for the television receiver. The following may be used as a guide:

1. Choose an area in the home where sunlight or light from lamps does not strike the face of the picture tube and cause glare.
2. Remember the necessity of an electrical outlet and the location of the point at which the antenna leads enter the room.
3. The receiver should be placed a short distance from the wall to allow adequate ventilation.
4. The receiver should be placed to permit easy access for operation and comfortable viewing from all angles.

ANTENNA — This receiver has been designed to use an antenna with a 300 ohm balanced transmission line. This line must be as short as possible because the longer the line the greater the chances are for picking up electrical disturbances. Stand-off insulation should be used to keep the line away from the mast, metal or walls. Twist this line about one turn per foot throughout the line to cancel out direct signal and/or noise pickup by the transmission line. It should also be securely anchored in place so that a change in weather will not affect its position.

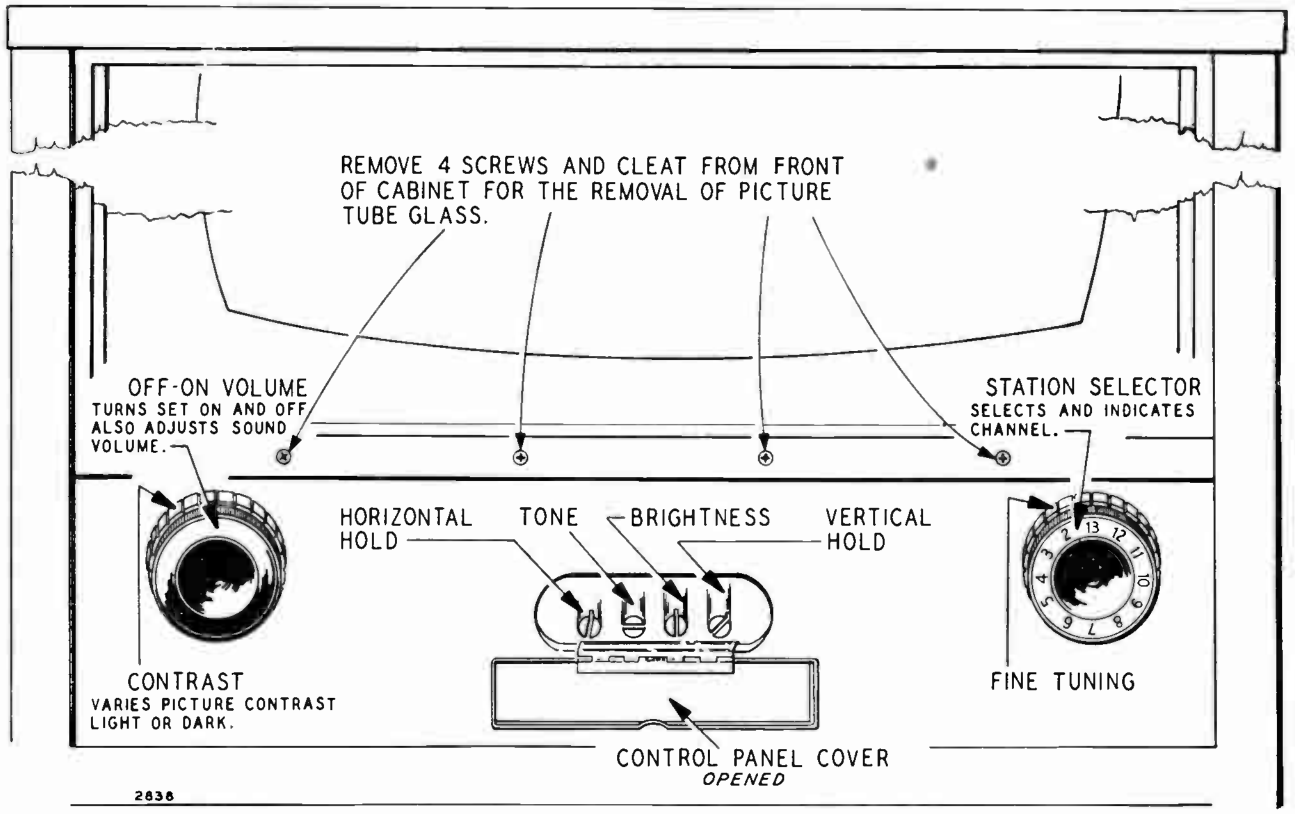
HIGH VOLTAGE WARNING

This television receiver contains high voltages which are dangerous to life. Never operate or service the receiver outside of the cabinet or with the covers removed until all the safety precautions necessary for working with high voltage equipment have been observed.

PICTURE TUBE HANDLING PRECAUTIONS

Shatterproof goggles and heavy gloves must be worn by individuals while handling the picture tube or installing the picture tube into the receiver.

The picture tube encloses a high vacuum and due to the large surface area, is subjected to very high air pressure. Therefore, care should be taken not to bump or scratch the picture tube accidentally as it may cause the tube to implode resulting in damage to property or injury to an individual.



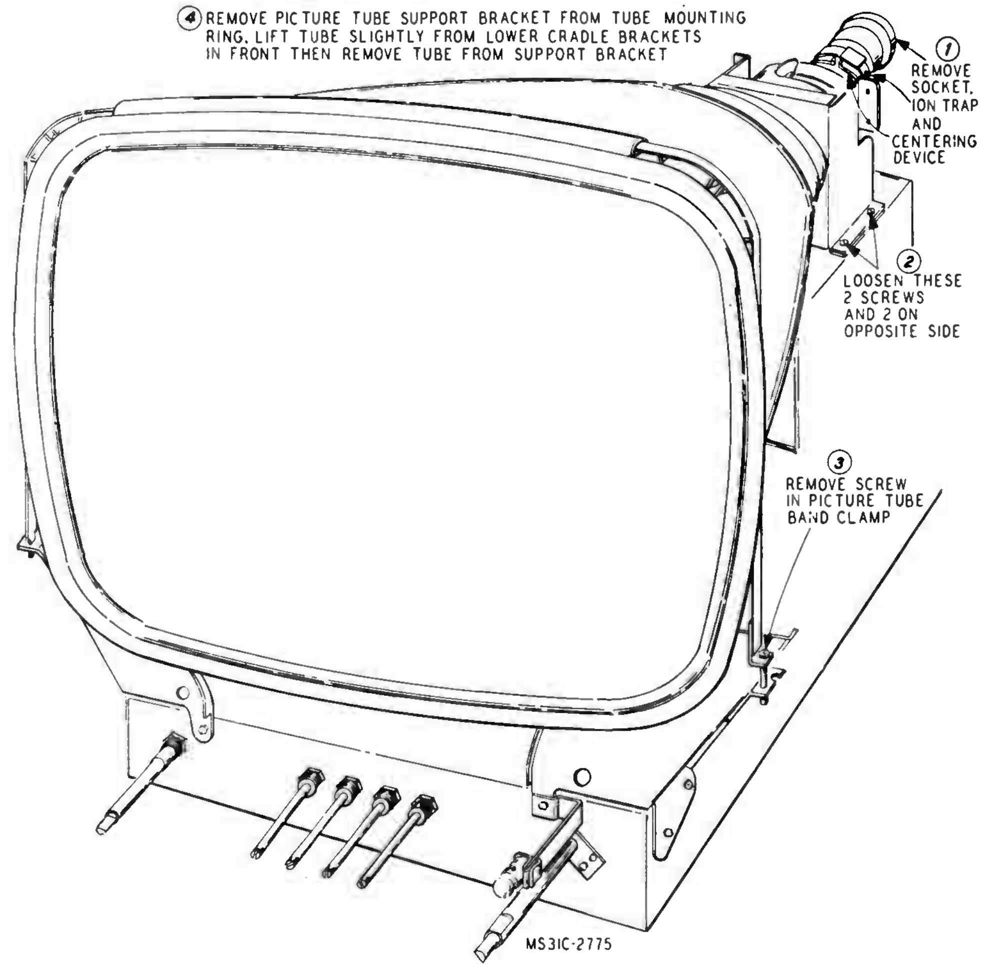


Fig. 3—Removal of Picture Tube

TUNING PROCEDURE

1. To turn the television receiver on, turn the OFF-ON VOLUME control clockwise until a click is heard. Allow approximately 30 seconds for the tubes to warm up.
2. Turn the STATION SELECTOR control to the desired channel. This control may be turned in either direction.
3. Turn the CONTRAST control clockwise until activity or definite form is noted on the screen.
4. Adjust the FINE TUNING control for clearest picture and the VOLUME control for desired volume.
5. To turn off the receiver, turn only the OFF-ON VOLUME control counterclockwise until a click is heard.

OCCASIONAL ADJUSTMENTS TO IMPROVE PICTURE RECEPTION

There are four controls at the front of the chassis which are accessible when the hinged control panel is pulled downword. See illustration (Figure 2). These controls are pre-set at the factory and may occasionally need adjustment due to aging of the components in the receiver and the fluctuating line voltages in different areas.

If any adjustments are necessary follow the instructions under "Controls and Functions."

IMPORTANT — Be sure that the FINE TUNING control has been set for the clearest picture before adjusting any controls.

CONTROLS AND FUNCTIONS

HORIZONTAL HOLD—Stops horizontal movement (diagonal bars.)

TONE—Adjusts for tonal quality bass or treble.

BRIGHTNESS—Adjusts for desired picture brilliance.

VERTICAL HOLD—Stops upward or downward picture movement.

PICTURE TUBE SAFETY GLASS

It will be necessary to clean the picture tube safety glass and the face of the picture tube occasionally. Remove the screws and cleat as outlined in the illustration. Insert your fingers into the opening at the center of the frame and carefully lift up and pull out the safety glass. Clean the safety glass and the face of the picture tube with a soft lint-free cloth dampened with water or mild soapsuds.

WARNING — Before handling the picture tube, it will be necessary to remove the static charge. In receivers with glass picture tubes, ground the anode lead to chassis, and insert an insulated wire from the well in the tube to chassis. In receivers with metal picture tubes, remove the static charge by grounding an insulated wire from the chassis to the metal portion of the tube.

PICTURE TUBE REPLACEMENT — To replace the picture tube it is necessary to remove the chassis from the cabinet. This may be accomplished in the following manner:

1. Remove the front panel control knobs by pulling them straight from their shafts.
2. Remove the cabinet back.
3. Disconnect the leads from the speaker, remove the antenna terminal board at the rear of the cabinet and then the five chassis mounting bolts. Pull chassis CAREFULLY out of the cabinet.
4. Remove the picture tube as shown and outlined in the illustration. To install a new picture tube, reverse the procedure making sure that the picture tube fits close against the picture tube cushion. If the picture tube sticks or fails to slip into place smoothly, investigate and remove the source of the trouble. Never force the tube. It is important that all the clips and shims used in mounting the tube be replaced, otherwise difficulty may be encountered when horizontal or vertical centering is required.

FRONT OF CHASSIS

(Accessible After Opening Front Panel Control Cover)

Horizontal Hold	R-94
Brightness	R-25
Vertical Hold	R-51
Tone	R-72

NON-OPERATING CONTROLS REAR OF CHASSIS

Horizontal Centering	Centering Device
Vertical Centering	Centering Device
Ion Trap Magnet	Wing Nut Adjustment
Deflection Yoke	Wing Screw
Width	L-15
Horizontal Linearity	L-16
Horizontal Drive	R-89
Horizontal Frequency	L-14
Vertical Linearity	R-49
Height	R-54
Sync Stability	R-39
AGC Threshold Control	R-108

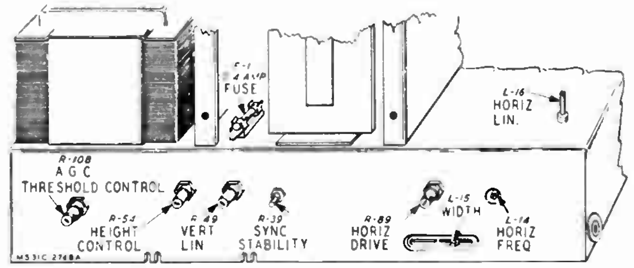

Fig. 4—Adjustments Rear of Chassis

ION TRAP MAGNET ADJUSTMENT—The ion trap magnet should be positioned close to the base of the tube with the magnet of the ion trap on the side where the electron gun is nearest the glass neck of the picture tube. From this position adjust the magnet by moving it back and forth and at the same time rotating it slightly around the neck of the picture tube until the brightest raster is obtained on the picture screen. Reduce the brightness control setting until the raster is slightly above average brilliance. Readjust the ion trap magnet for maximum raster brilliance and best focus. MAXIMUM RASTER BRILLIANCE AND BEST FOCUS OCCUR AT THE SAME POINT. Do not sacrifice brilliance for best focus. The ion trap magnet adjustment is a very critical one especially with the electrostatic type zero focus picture tube. Consequently, great care should be taken to make sure that the ion trap magnet is correctly adjusted.

DEFLECTION YOKE ADJUSTMENT — If the lines of the raster are not horizontal or squared with the picture mask, rotate the deflection yoke until this condition is obtained. Tighten the yoke adjustment wing screw.

CENTERING ADJUSTMENT — If horizontal or vertical centering is required, adjust each ring in the centering device until proper centering is obtained. If a clamp type centering device is used, rotate the device to the left or right and turn the knob located at the top of the device until the picture is centered correctly.

PICTURE ADJUSTMENT — For further adjustments, obtain a test pattern on the receiver. Turn on receiver and follow tuning procedure on page 16. When a test pattern is obtained it may be necessary to slightly re-adjust the fine tuning control for clearest picture.

ADJUSTMENT OF AGC THRESHOLD CONTROL — Tune the receiver to the strongest station in the area in which the receiver will be used. While observing the picture and listening to the sound, turn the control clockwise until signs of overloading (buzz in sound, washed-out picture) appear. Then turn the control a few degrees counter-clockwise from the point at which overloading occurs. (The stronger the signal input, the more counter-clockwise this setting will be.) In areas where the strongest signal does not exceed 10,000 uv the setting will usually be maximum clockwise. With the control set correctly, the AGC will automatically adjust the bias on the R.F. and I.F. amplifiers so that the best possible signal to noise ratio (Minimum snow) will be obtained for any signal input to the receiver.

ADJUSTMENT OF SYNC STABILITY CONTROL — When receiving strong (500 MV or more) signals, set hold controls so that the picture is locked in. Turn the sync control fully counter-clockwise, then, while observing the picture, turn the control slowly clockwise until a minimum amount of bending occurs. If the control is set incorrectly bending, tearing, etc., will be present and when switching from channel to channel the picture will not lock in quickly.

In weak signal areas the control should be set for maximum picture stability. In general the weaker the signal the more clockwise the control should be turned.

When the sync stability control is correctly adjusted the receiver will hold sync without tearing or rolling under even the most adverse noise conditions.

CHECK OF HORIZONTAL OSCILLATOR ALIGNMENT — Tune in a station and adjust the horizontal hold control until the picture falls into sync. Momentarily remove the signal by switching off channel and then back. The picture should pull into sync over a range of 90° rotation of the horizontal hold control. If in the above check the receiver fails to hold sync or the pull-in range is at the extreme end of the control, it will be necessary to make the following adjustment.

HORIZONTAL FREQUENCY ADJUSTMENT — With the horizontal hold control set to the center of its range of rotation, adjust the horizontal frequency control (L-14) until the picture pulls into sync. Recheck the "Horizontal Oscillator Alignment."

HEIGHT AND VERTICAL LINEARITY ADJUSTMENT — Adjust the height control (R-54) until the picture fills the mask vertically. Adjust the vertical linearity control (R-49) until the picture is symmetrical from top to bottom. Adjust the picture centering device to align picture with the mask. Adjustment of any control will require a re-adjustment of the other control.

WIDTH, DRIVE AND LINEARITY ADJUSTMENTS— While receiving a signal from a station (with picture locked in sync) turn contrast control fully counter-clockwise, turn the brightness control (R-25) up so that the picture appears washed out. Adjust width control (L-15) until the picture fills the mask. Turn the horizontal drive control (R-89) clockwise until white bars appear in the left center portion of the raster, then turn counter-clockwise until the white bars just disappear. This adjustment will allow the horizontal system to operate at maximum efficiency. Adjust horizontal linearity control (L-16) for best linearity. If adjustment of the horizontal drive (R-89) or horizontal linearity (L-16) is required, it usually will be necessary to recheck the horizontal oscillator alignment. If adjustment of the horizontal linearity control (L-16) is required, readjustment of the horizontal drive control (R-89) will be necessary. Adjust the picture centering device to align the picture with the mask.

CHECK OF R-F OSCILLATOR ADJUSTMENTS

The oscillator is preset at the factory and normally needs no adjustment. However, if adjustments are required, they can be made without removing the chassis from the cabinet. Remove the channel selector and fine tuning knobs from the tuning shaft.

TEST PROCEDURE:

1. Set channel selector to receive desired station.
2. Set fine tuning control in center of its range.
3. Adjust oscillator slug, with bakelite type screwdriver, for best picture resolution.
4. Repeat steps 1, 2 and 3 on all channels used.

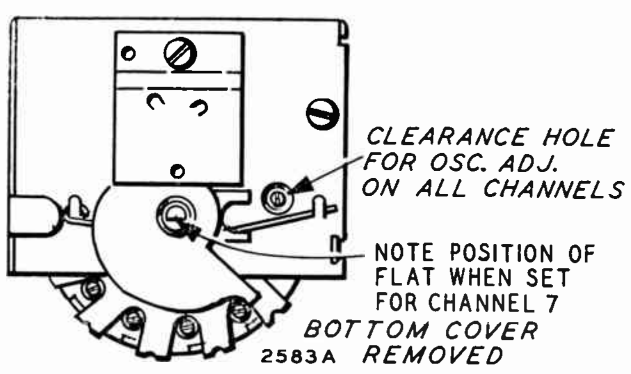

Fig. 5—Tuner Oscillator Adjustments

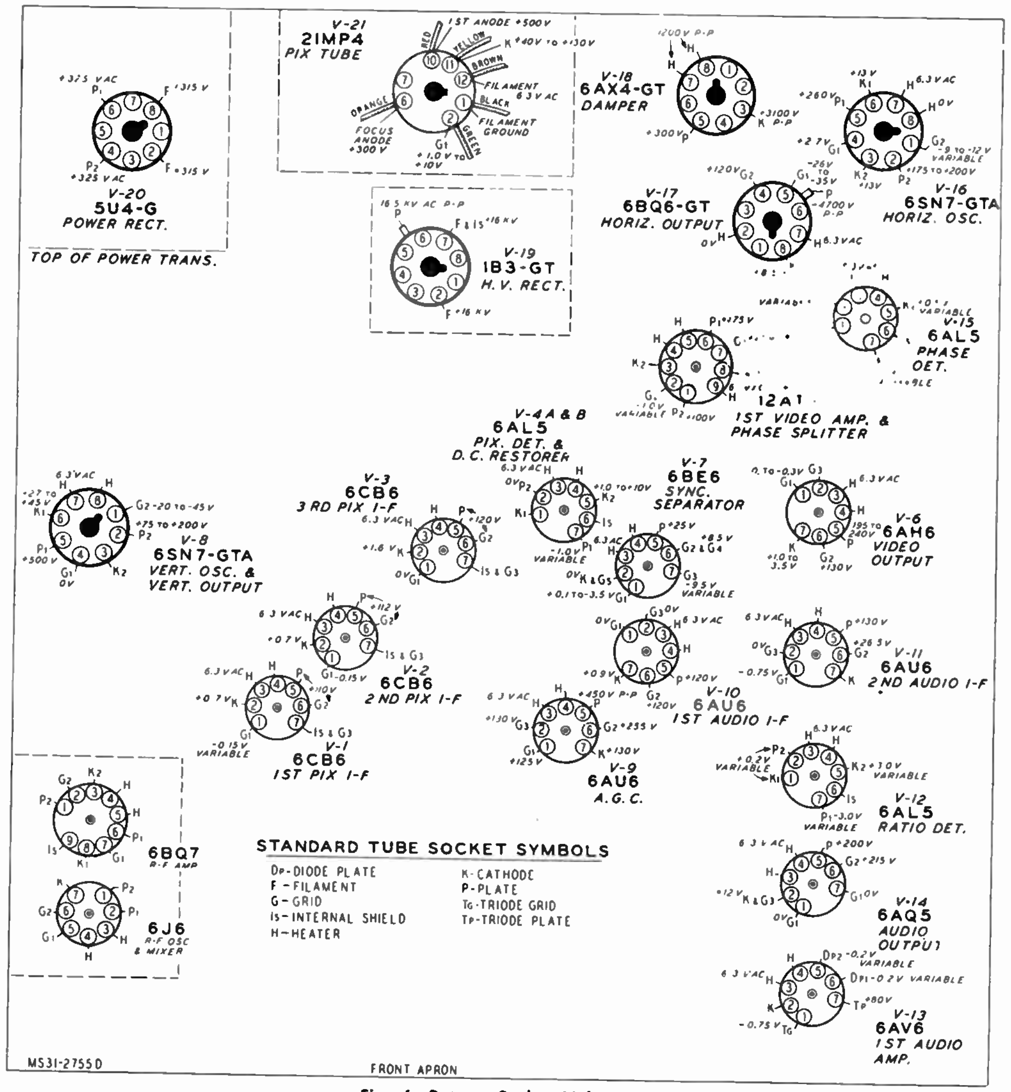

Fig. 6—Bottom Socket Voltages

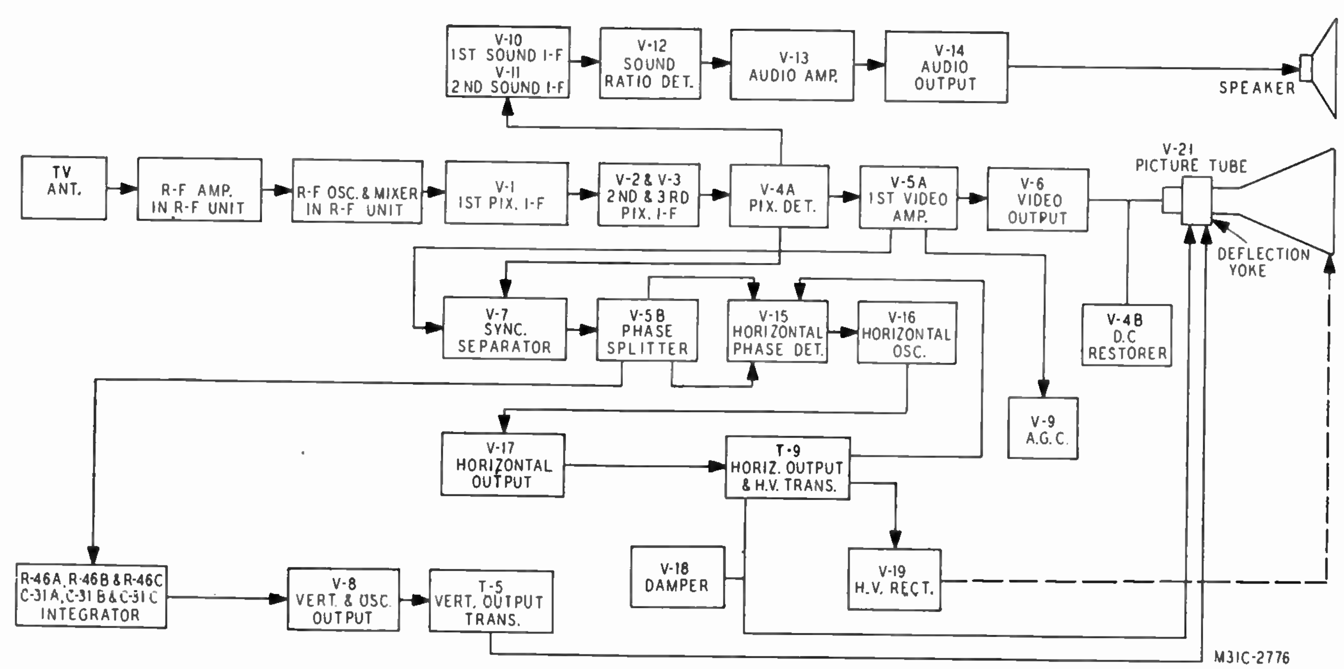

Fig. 7—Block Diagram

SERVICE SUGGESTIONS

NO RASTER ON PICTURE TUBE — If raster cannot be obtained check below for the possible causes.
1: Ion trap magnet adjustment is incorrect.
2: No +B voltage. Check 4/10 ampere fuse. Replace if defective. If fuse continually burns out, check
(A) Horizontal output tube V-17 (6BQ6-GT)
(B) Check damper tube V-18 (6AX4-GT).
(C) Check horizontal oscillator tube V-16 (6SN7-GTA) for proper operation.
(D) With an ohm meter, check for a short between terminal 1 of the horizontal output transformer (T-9) and the chassis.
(E) Check DC resistance of T-9.
3: No high voltage. Check V-17, V-18 and V-19 tubes and circuits. If the horizontal deflection circuits are operating as evidenced by the correct voltage (600V) measured on terminal No. 1 of T-9, the trouble can be isolated to the high voltage rectifier circuit. Either the high voltage winding to the 6BQ6-GT plate and 1B3 plate is open, tube V-19 is defective, its filament circuit is open, R-99 and C-78 defective or pix tube elements shorted internally.
4: Defective picture tube heater open or cathode return circuit open.

HORIZONTAL DEFLECTION ONLY — If only horizontal deflection is obtained as evidenced by a straight line across the face of the picture tube, it can be caused by the following:
1: Vertical oscillator and vertical output tube V-8 inoperative. Check socket voltages.
2: Vertical oscillator transformer (T-4) defective.
3: Vertical output transformer (T-5) open or shorted.
4: Yoke vertical coils open or shorted.
5: Vertical hold, height or linearity controls may be defective.

POOR VERTICAL LINEARITY — If adjustment of the height and linearity controls will not correct this condition, any of the following may be the cause.
1: Check variable resistors R-49 and R-54.
2: Vertical output transformer (T-5) defective.
3: Capacitors C-35A, C-39 or C-70 defective.
4: V-8 defective, check voltages.
5: Excess leakage or incorrect value of capacitor C-37, or open or incorrect value of resistors R-55 & R-56.
6: Low plate voltages. Check rectifier tube and capacitors in +B supply circuits.
7: Capacitor C-36 defective.
8: Vertical deflection coils (L-12) defective.

POOR HORIZONTAL LINEARITY — If adjustment of the Horizontal drive and linearity controls does not correct this condition, check the following:
1: Check or replace horizontal output tube V-17.
2: Check or replace damper tube V-18 (6AX4-GT).
3: Check capacitors C-74, C-76, C-77 and horizontal linearity control (L-16) for defects.
4: Horizontal deflection coils (L-17) defective.

TRAPEZOIDAL OR NONSYMMETRICAL RASTER
1: Defective yoke.

WRINKLES ON LEFT SIDE OF RASTER — This condition can be caused by:
1: Defective yoke due to C-75 or R-98 (internal in yoke assembly) being wrong value or open. These components are mounted in rear of yoke assembly.
2: V-18 (6AX4-GT) defective.

SMALL RASTER — This condition can be caused by:
1: Low +B or line voltage. Check V-20 (5U4G).
2: Insufficient output from horizontal output tube V-17. Replace tube.
3: Insufficient output from vertical oscillator and vertical output tube V-8. Replace tube.
4: Incorrect setting of horizontal drive control R-89.
5: V-18 (6AX4-GT) defective.
6: Incorrect setting of (L-15) width control.

RASTER; NO IMAGE, BUT ACCOMPANYING SOUND — This condition can be caused by:
1: No signal on picture tube grid. Check V-5A (12AT7) and V-6 (6AH6) tubes and associated circuits.
2: Bad contact to picture tube grid (lead to socket broken).
3: AGC tube (V-9) may be defective. Check tube and its associated circuit.

SIGNAL APPEARS ON PICTURE TUBE GRID BUT IMPOSSIBLE TO SYNCHRONIZE THE PICTURE VERTICALLY AND HORIZONTALLY — A condition of this nature can be caused by:
1: Defective sync separator V-7 or phase splitter V-5B.
2: If tubes are O.K. check voltages, and associated circuits.
3: AGC system inoperative. Check V-9 (6AU6) AGC tube and associated circuits.

SIGNAL ON PICTURE TUBE GRID AND HORIZONTAL SYNC ONLY — If this condition is encountered, check:
1: Vertical integrating network capacitors C-31A, B & C, and resistors R-46 A, B & C.
2: Vertical hold control (R-51) defective.

SIGNAL ON PICTURE TUBE GRID AND VERTICAL SYNC ONLY
1: V-15 or V-16 defective.
2: Improper setting of (L-14) horizontal frequency control.
3: Check setting of horizontal drive control and horizontal linearity control.
4: Check V-15 and V-16 socket voltages.

PICTURE STABLE BUT WITH POOR RESOLUTION — If the picture resolution is not up to standard, it may be caused by any of the following:
1: Defective pix I-F tubes V-1, 2 & 3, (6CB6's).
2: Defective picture detector V-4A, (6AL5) or video amplifier V-5A or video output V-6 (6AH6).
3: Defective picture tube.
4: Open video peaking coil. Check all peaking coils L-5, L-6, L-8, L-9, L-10 and L-11 for continuity. Note that L-5, L-9 and L-10 have shunting resistors.
5: Leakage in V-6 (6AH6) grid capacitor C-11. If the capacitor is not found to be defective, check the following:
  1: Check all potentials in video circuits.
  2: Check picture tube grid circuit for poor or dirty contact.
  3: Check and realign, if necessary, the picture I-F and R-F circuits.

SERVICE SUGGESTIONS—(continued)

PICTURE SMEAR:
1: A smear can be attributed to phase shift at the low or high frequency end of the video characteristic. This can be caused by improper values of resistors and capacitors in the video circuits. Check for grid current on video output tube V-6 (6AH6), open or shorted peaking coils, video amplifier load resistors are of improper value (high).
2: This trouble can also originate at the transmitter. Check reception from another station.
3: Check and realign, if necessary, the picture I-F and R-F circuits.

MAN MADE NOISE IN SOUND (Ignition, etc)
1: Check sound I-F tubes V-10, 11 & 12 and associated circuits.
2: Check sound I-F alignment.

BENDING OR S-ING
1: Check sync stability control adjustment.
2: Check capacitors C-35B and C-79B.
3: V-17 (6BQ6-GT) defective or V-16 (6SN7-GTA) defective.
4: Check sync separator tube V-7 (6BE6) and phase splitter V-5B (12AT7) and V-5A (12AT7) video amplifier.
5: Check AGC threshold control.

PICTURE NORMAL—NO SOUND OR WEAK OR DISTORTED SOUND
1: Check sound I-F alignment.
2: Check V-10 (6AU6) V-11 (6AU6) V-12 (6AL5) V-13 (6AV6) V-14 (6AQ5) and associated circuits.

POOR FOCUS
1: Improper setting of Ion Trap magnet.
2: Defective picture tube or picture tube socket.

PICTURE JITTER:
1: If regular sections at left of the picture are displaced, replace the horizontal oscillator tube V-16.
2: Vertical instability may be due to loose connections or noise received with the signal.
3: Horizontal instability may be due to unstable transmitted sync.
4: Check receiver AGC system for proper operation.
5: Check phase splitter V-5B, (12AT7) and sync separator V-7 (6BE6).
6: Check for improper setting of sync stability control.
7: Picture tube grid lead not held in position by support spring, ie: close proximity of grid lead to sync and horizontal tubes will cause picture to jitter at high contrast setting.
8: Check AGC threshold control.

ALIGNMENT PROCEDURE

TEST EQUIPMENT — To service this receiver properly, it is recommended that the following test equipment be available:

R-F SWEEP GENERATOR meeting the following requirements:
(a) Frequency ranges:
  18 to 30 mc, 10 mc sweep width
  40 to 90 mc, 10 mc sweep width
  170 to 225 mc, 10 mc sweep width
(b) Output adjustable with at least .1 volt maximum.
(c) Output constant on all ranges.
(d) Flat output in all attenuator positions.

CATHODE-RAY OSCILLOSCOPE preferably one with a wide band vertical deflection and an input calibrating source.

SIGNAL GENERATOR to provide the following frequencies: (Output on these ranges should be adjustable and at least .1 volt maximum.)
(a) Intermediate alignment frequencies.
  23.1 mc first picture I-F coil.
  24.1 mc third picture I-F coil.
  25.9 mc second picture I-F coil.
  21.7 mc sound trap.
  4.5 mc video trap & sound I-F.
  25.2 mc converter plate coil (Tuner).

HETERODYNE FREQUENCY METER with crystal calibrator if the signal generator is not crystal controlled.

ELECTRONIC VOLTMETER and a high voltage probe for use with this meter to permit measurements up to 20 kilovolts.

SERVICE PRECAUTIONS — To service the receiver remove the chassis from the cabinet. To do so, remove the knobs, the cabinet back, disconnect the leads from the speaker, remove the antenna terminal board at rear of cabinet, and then the 5 chassis mounting bolts. The chassis may be serviced with the picture tube in place provided the chassis is turned on its side with the power transformer on the bottom. The weight of the chassis will be supported against the power transformer and pix tube brackets.

CAUTION: Do not permit the kinescope second-anode lead to become shorted to the chassis. To do so will cause a considerable overload on the high voltage filter resistor R-99.

ALIGNMENT PROCEDURE
PIX I-F

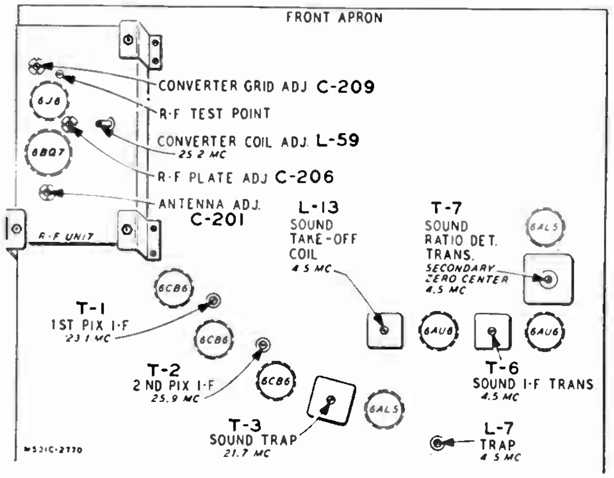

Fig. 8—Top Chassis Video and Audio I-F Adjustments

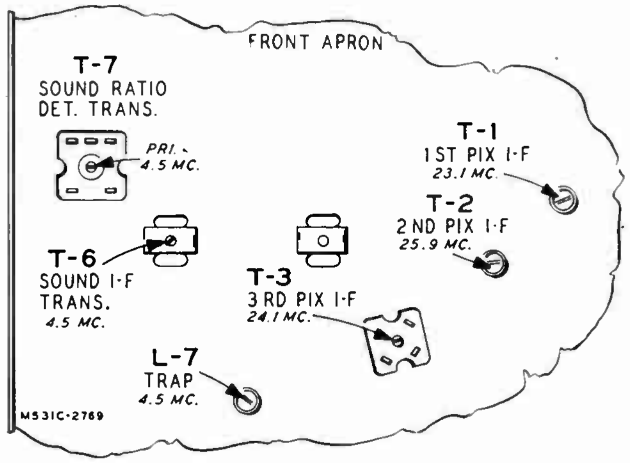

Fig. 9—Bottom Chassis Video and Audio I-F Adjustments.

A. Unmodulated R-F signal into Converter Grid by means of tube shield insulated from base. VTVM with filter in lead of 22 K ohms and 5000 mmf connected to pic. det. load resistor, (R-100) 4700 ohms, in series with peaking coil (L-6) from Pin 7 of 6AL5. Input signal level should be such that output is less than 2 volts DC. Apply -4.5V battery bias on AGC line.

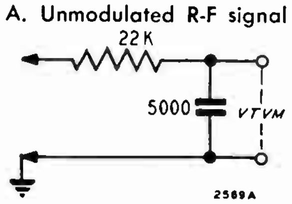

Fig. 10—VTVM Connections

	FREQUENCY	ADJUST
1.	25.2 MC	Converter plate coil on top of tuner for maximum dc at picture detector.
2.	23.1 MC	1st picture I-F coil (T-1) for maximum dc at picture detector.
3.	25.9 MC	2nd picture I-F coil (T-2) for maximum dc at picture detector.
4.	24.1 MC	3rd picture I-F coil (T-3 below chassis) for maximum dc at picture detector.
5.	21.7 MC	3rd picture I-F trap (T-3 in can above chassis) for minimum dc at picture detector.

B. I-F Sweep Generator into converter grid by means of tube shield insulated from base.

Connect oscilloscope across R-100 (in place of VTVM). Apply -4.5V bias (DC) to AGC line (battery).

Tuner should be switched to dead channel so as not to cause interference.

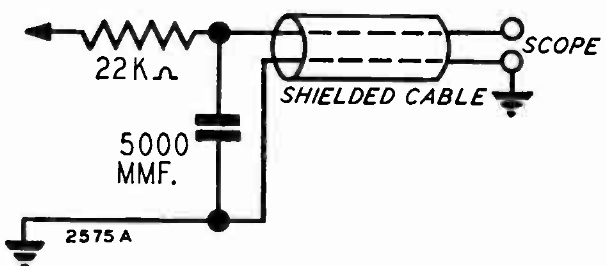

Fig. 11—Oscilloscope Connections

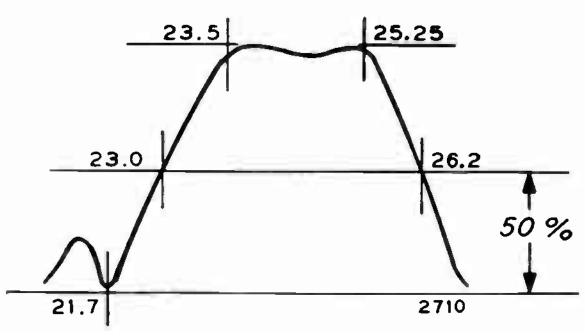

Fig. 12—Overall Response Curve

Observe overall I-F response, which should be as shown above: A slight touch-up may be required. At no time should the trap coil be re-adjusted, nor should it be necessary to turn any of the picture I-F coils more than 1/2 turn of the slug. The following comments are suggestions only:

ALIGNMENT PROCEDURE (Continued)

1. The height of the 26.2 MC marker is controlled by the 25.2 MC (Converter Plate Coil on tuner) and the 25.9 MC (2nd P.I.F.) coils.
2. The uniformity of response (flatness across top and position of 23.5 MC) marker is controlled for the most part by the 24.1 MC third picture I-F coil.
3. The 23.0 MC marker position is controlled by the first picture I-F (23.1 MC coil). However, it is NOT advisable to change the setting of the coil, due to its effect on sound rejection. Its adjustment should be avoided unless believed to be absolutely necessary.

VIDEO

With 4.5 MC unmodulated signal from a high impedance source, (10,000 ohms in series with the generator) into plate of the picture detector tube (Pin 7-6AL5) and VTVM on picture tube grid, tune 4.5 MC trap (L-7 Top) for minimum response. VTVM on 0-10 V AC scale. This adjustment can also be made while observing a picture from a station. Tune trap for least 4.5 MC beat in picture.

AUDIO I-F

1: With signal generator set to 4.5 MC and dc VTVM connected to junction of R-62 and C-46, adjust sound take-off coil (L-13 Top) and sound I-F transformer slugs (T-6 Top & Bottom) for maximum.

2: With VTVM connected to pin 7 of V-12 (6AL5) adjust the ratio detector primary (T-7 Bottom) for maximum.

3: With VTVM connected to junction of R-66, R-69 and C-50, adjust ratio detector secondary (T-7 Top) for cross over (zero voltage) on lowest scale.

NOTE — If no signal generator is available, the procedure above may be followed by tuning in a station and using the 4.5 MC beat between picture and sound carrier.

TUNER ALIGNMENT

A. Sweep generator with balanced 300 ohm output to antenna terminals. Marker generator output to antenna terminals. Oscilloscope to "test point" (Figure 13) on tuner. Connect 1½ V bias to AGC line at junction of R-33 and C-20 on the receiver.

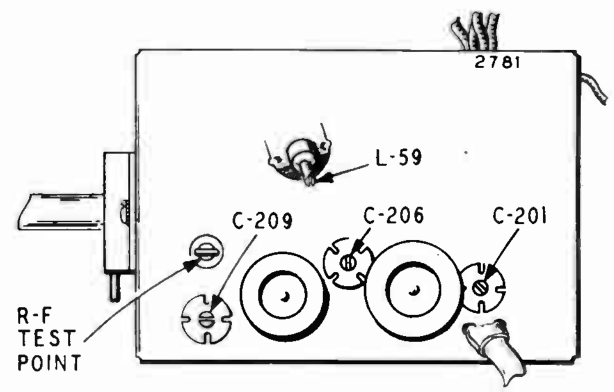

Fig. 13—Top Tuner Adjustments

B. RF AND CONVERTER ADJUSTMENT.

1. With channel selector on Channel 12, adjust C-201 slightly favoring the Pix carrier, then adjust C-206 and C-209 for response as in Figure 14. Picture and sound markers at 90% maximum response.
2. Check response on all channels. If markers are below 70% on any channels, readjust C-201, C-206, and C-209. Recheck all channels.

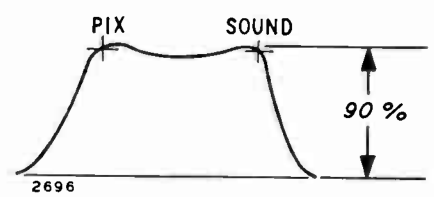

Fig. 14—Pix & Audio Markers

C. OSCILLATOR ADJUSTMENT.

1. Apply -4.5 volts on I-F AGC line at junction of R-1 and C-21.
2. Connect oscilloscope to output of video detector. Place fine tuning in center of range. Check response on all channels. Sound marker should be in notch and picture marker at 50%. (See Figure 12).
3. If markers are off, individual oscillator coil slugs will require adjustment. Adjust each channel slug, accessible through hole in front of chassis with a non-metallic screwdriver to bring sound marker to correct position.

TUNER ASSEMBLY INFORMATION

OSCILLOSCOPE WAVEFORM PATTERNS

The waveforms on this page were taken with the receiver tuned to a normal picture. The numbers on the waveforms correspond to the numbers on the schematic diagram which identifies each test point.
The voltages shown on each waveform are the approximate peak to peak amplitudes. The frequencies shown indicates the repetition rate of the waveform, not the sweep rate of the oscilloscope. If the waveforms are observed on the oscilloscope with a poor high frequency response, the corners of the pulses will tend to be more rounded than those shown below and the amplitudes of any high frequency pulse will tend to be less.

PARTS LIST

Use only GENUINE factory tested parts to insure service jobs you can depend on and to obtain original set performance.

PRICES SUBJECT TO CHANGE WITHOUT NOTICE

ORDERING PARTS

Order parts from your nearest Firestone Home and Auto Supply Warehouse. When ordering parts, it is important that the correct code number and stock number, be given with the correct part name and part number as shown in the parts list. You will find the stock number and code number stamped on the chassis pan. The stock and code number also appears on the front cover of this booklet.

RETURNING DEFECTIVE PARTS

All parts on adjustments must be returned to your District Office Service Department with claim form completely filled out. This receiver is so constructed that it can be repaired locally by an experienced repairman.

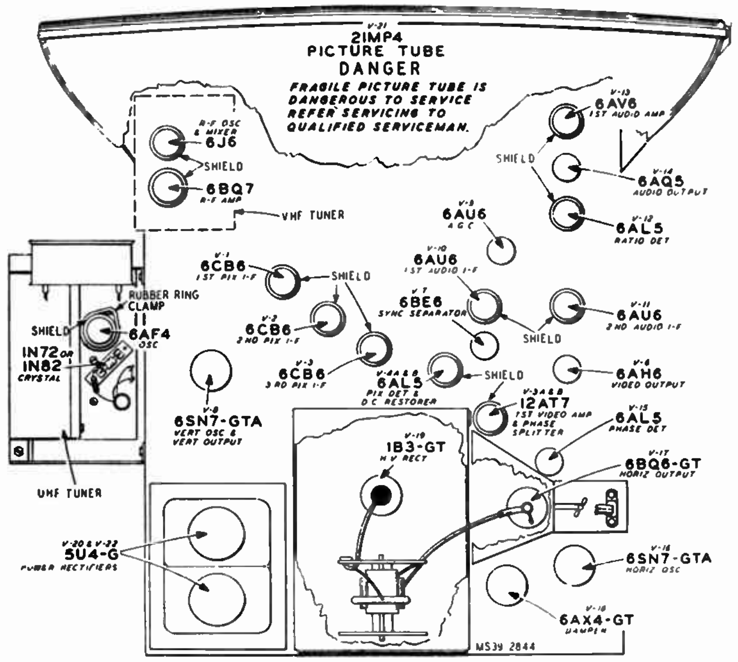

Fig. 1—Tube Layout.

RECEIVER LOCATION — Advise the owner as to the proper location for the television receiver. The following may be used as a guide:

1. Choose an area in the home where sunlight or light from lamps does not strike the face of the picture tube and cause glare.
2. Remember the necessity of an electrical outlet and the location of the point at which the antenna leads enter the room.
3. The receiver should be placed a short distance from the wall to allow adequate ventilation.
4. The receiver should be placed to permit easy access for operation and comfortable viewing from all angles.

ANTENNA — This receiver has been designed to use an antenna with a 300 ohm balanced transmission line. This line must be as short as possible because the longer the line the greater the chances are for picking up electrical disturbances. Stand-off insulation should be used to keep the line away from the mast, metal or walls. Twist this line about one turn per foot throughout the line to cancel out direct signal and/or noise pickup by the transmission line. It should also be securely anchored in place so that a change in weather will not affect its position.

HIGH VOLTAGE WARNING

This television receiver contains high voltages which are dangerous to life. Never operate or service **the receiver outside of the cabinet or with the covers removed until all the safety precautions necessary for working with high voltage equipment have been observed.**

PICTURE TUBE HANDLING PRECAUTIONS

Shatterproof goggles and heavy gloves must be worn by individuals while handling the picture tube or installing the picture tube into the receiver.

The picture tube encloses a high vacuum and due to the large surface area, is subjected to very high air pressure. Therefore, care should be taken not to bump or scratch the picture tube accidentally as it may cause the tube to implode resulting in damage to property or injury to an individual.

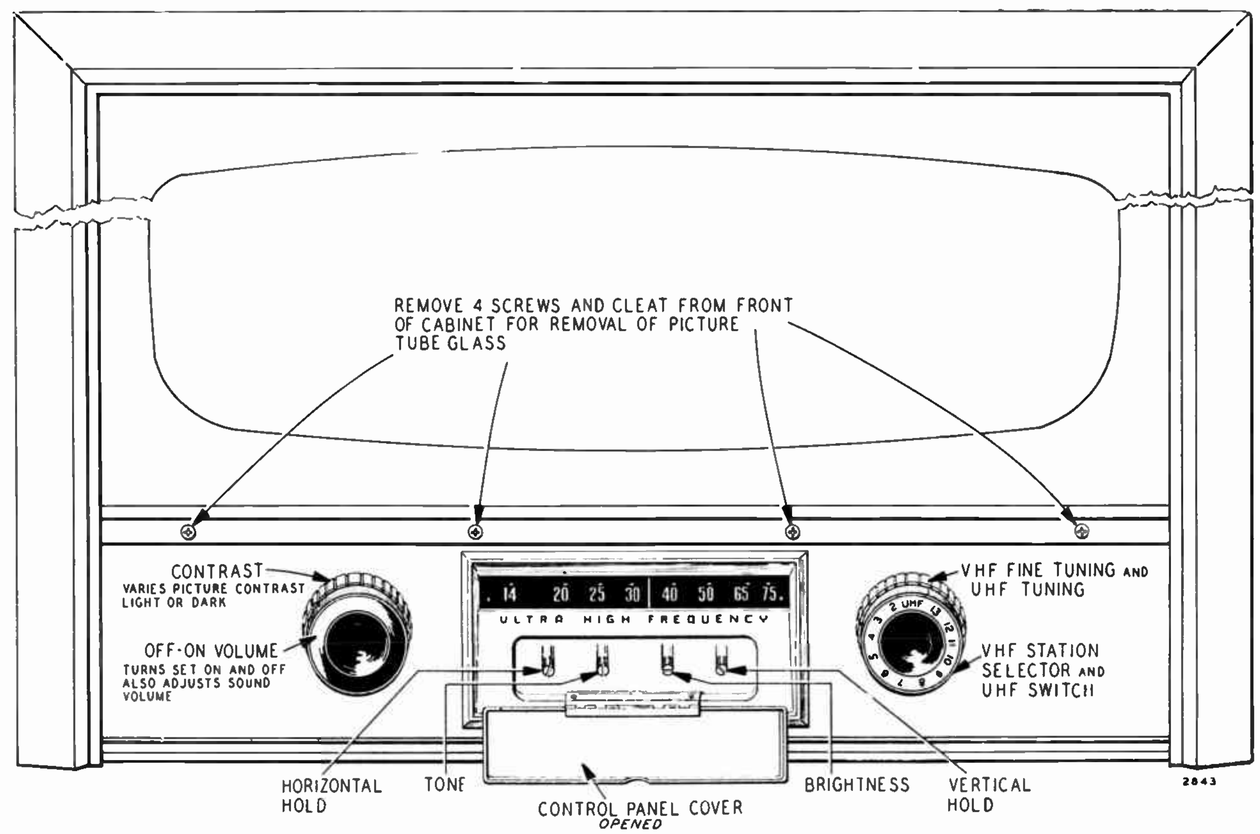

Fig. 2—Front Panel Controls

TUNING PROCEDURE

1. To turn the television receiver on, turn the OFF-ON VOLUME control clockwise until a click is heard. Allow approximately 30 seconds for the tubes to warm up.
2. Turn the STATION SELECTOR control to the desired channel. This control may be turned in either direction.
3. Turn the CONTRAST control clockwise until activity or definite form is noted on the screen.
4. Adjust the FINE TUNING control for clearest picture and the VOLUME control for desired volume.
5. To turn off the receiver, turn only the OFF-ON VOLUME control counterclockwise until a click is heard.
6. TONE CONTROL — When this Control is turned clockwise, the high notes will predominate and when turned counterclockwise, a deep bass effect will result.
7. In localities where UHF programs are available, turn the STATION SELECTOR control to the UHF position and tune in the desired station with the UHF Tuning Control. The dial scale is calibrated in channel numbers and covers the entire UHF range of channels 14 through 83.

OCCASIONAL ADJUSTMENTS TO IMPROVE PICTURE RECEPTION

There are four controls at the front of the chassis which are accessible when the hinged control panel is pulled downward. See illustration Figure 2. These controls are pre-set at the factory and may occasionally need adjustment due to aging of the components in the receiver and the fluctuating line voltages in different areas. If any adjustments are necessary follow the instructions under "Controls and Functions."

IMPORTANT — Be sure that the FINE TUNING control has been set for the clearest picture before adjusting any controls.

CONTROLS AND FUNCTIONS

HORIZONTAL HOLD—Stops horizontal movement (diagonal bars.)

TONE—Adjusts for tonal quality bass or treble.

BRIGHTNESS—Adjusts for desired picture brilliance.

VERTICAL HOLD—Stops upward or downward picture movement.

PICTURE TUBE SAFETY GLASS

PICTURE TUBE SAFETY GLASS — It will be necessary to clean the picture tube safety glass and the face of the picture tube occasionally. Remove the screws and cleat as outlined in the illustration. Insert your fingers into the opening at the center of the frame and carefully lift up and pull out the safety glass. Clean the safety glass and the face of the picture tube with a soft lint-free cloth dampened with water or mild soapsuds.

For models that have the cleat and screws at the top of the cabinet the following caution must be observed.

CAUTION — UPON REMOVAL OF THE LAST SCREW AND THE CLEAT THE GLASS MAY FALL FORWARD. SUPPORT THE GLASS WITH ONE HAND AS YOU LIFT IT GENTLY FROM THE CABINET.

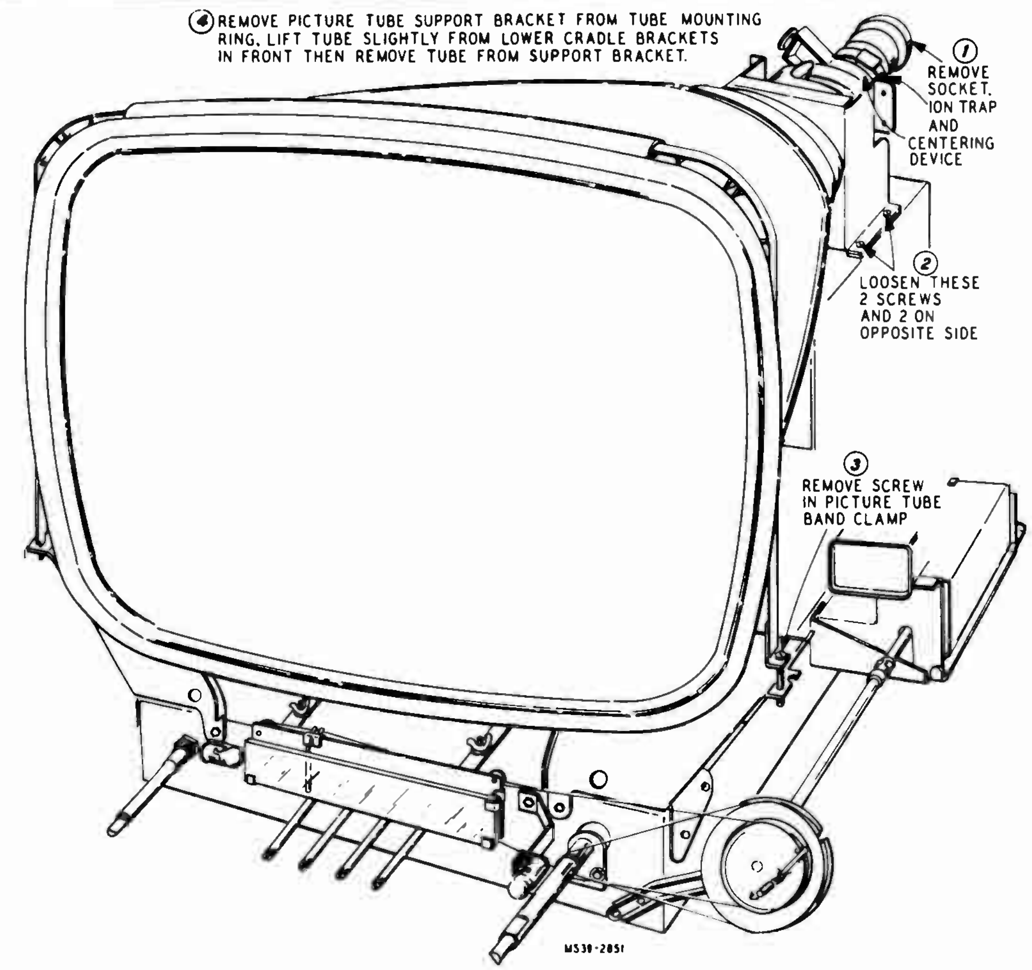

Fig. 3—Removal of Picture Tube

WARNING — Before handling the picture tube, it will be necessary to remove the static charge. In receivers with glass picture tubes, ground the anode lead to chassis, and insert an insulated wire from the well in the tube to chassis. In receivers with metal picture tubes, remove the static charge by grounding an insulated wire from the chassis to the metal portion of the tube.

PICTURE TUBE REPLACEMENT — To replace the picture tube it is necessary to remove the chassis from the cabinet. This may be accomplished in the following manner:

1. Remove the front panel control knobs by pulling them straight from their shafts.
2. Remove the cabinet back.
3. Disconnect the leads from the speaker, remove the antenna terminal board at the rear of the cabinet and then the five chassis mounting bolts. Pull chassis CAREFULLY out of the cabinet.
4. Remove the picture tube as shown and outlined in the illustration. To install a new picture tube, reverse the procedure making sure that the picture tube fits close against the picture tube cushion. If the picture tube sticks or fails to slip into place smoothly, investigate and remove the source of the trouble. Never force the tube. It is important that all the clips and shims used in mounting the tube be replaced, otherwise difficulty may be encountered when horizontal or vertical centering is required.

FRONT OF CHASSIS

(Accessible After Opening Front Panel Control Cover)

Horizontal Drive	R-89
Horizontal Frequency	L-14
Vertical Linearity	R-49
Height	R-54
Sync Stability	R-39
AGC Threshold Control	R-108

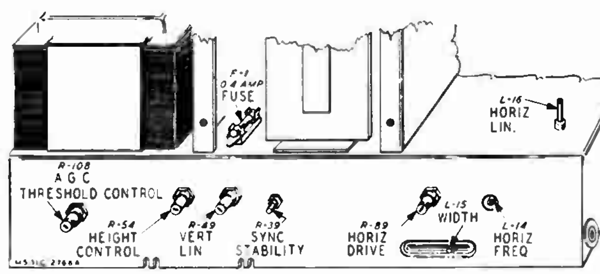

Fig. 4—Adjustments Rear of Chassis

ION TRAP MAGNET ADJUSTMENT—The ion trap magnet should be positioned close to the base of the tube with the magnet of the ion trap on the side where the electron gun is nearest the glass neck of the picture tube. From this position adjust the magnet by moving it back and forth and at the same time rotating it slightly around the neck of the picture tube until the brightest raster is obtained on the picture screen. Reduce the brightness control setting until the raster is slightly above average brilliance. Readjust the ion trap magnet for maximum raster brilliance and best focus. MAXIMUM RASTER BRILLIANCE AND BEST FOCUS OCCUR AT THE SAME POINT. Do not sacrifice brilliance for best focus. The ion trap magnet adjustment is a very critical one especially with the electrostatic type zero focus picture tube. Consequently, great care should be taken to make sure that the ion trap magnet is correctly adjusted.

DEFLECTION YOKE ADJUSTMENT — If the lines of the raster are not horizontal or squared with the picture mask, rotate the deflection yoke until this condition is obtained. Tighten the yoke adjustment wing screw.

CENTERING ADJUSTMENT — If horizontal or vertical centering is required, adjust each ring in the centering device until proper centering is obtained. If a clamp type centering device is used, rotate the device to the left or right and turn the knob located at the top of the device until the picture is centered correctly.

PICTURE ADJUSTMENT — For further adjustments, obtain a test pattern on the receiver. Turn on receiver and follow tuning procedure . When a test pattern is obtained it may be necessary to slightly re-adjust the fine tuning control for clearest picture.

ADJUSTMENT OF AGC THRESHOLD CONTROL — Tune the receiver to the strongest station in the area in which the receiver will be used. While observing the picture and listening to the sound, turn the control clockwise until signs of overloading (buzz in sound, washed-out picture) appear. Then turn the control a few degrees counter-clockwise from the point at which overloading occurs. (The stronger the signal input, the more counter-clockwise this setting will be.) In areas where the strongest signal does not exceed 10,000 uv the setting will usually be maximum clockwise. With the control set correctly, the AGC will automatically adjust the bias on the R.F. and I.F. amplifiers so that the best possible signal to noise ratio (Minimum snow) will be obtained for any signal input to the receiver.

ADJUSTMENT OF SYNC STABILITY CONTROL — When receiving strong (500 MV or more) signals, set hold controls so that the picture is locked in. Turn the sync control slowly clockwise until bending occurs at top of picture. Then turn the control a few degrees counter-clockwise until bending disappears. If the control is set incorrectly bending, tearing, etc., will be present and when switching from channel to channel the picture will not lock in quickly.

In weak signal areas the control should be set for maximum picture stability. In general the weaker the signal the more clockwise the control should be turned.

When the sync stability control is correctly adjusted the receiver will hold sync without tearing or rolling under even the most adverse noise conditions.

CHECK OF HORIZONTAL OSCILLATOR ALIGNMENT — Tune in a station and adjust the horizontal hold control until the picture falls into sync. Momentarily remove the signal by switching off channel and then back. The picture should pull into sync over a range of 90° rotation of the horizontal hold control. If in the above check the receiver fails to hold sync or the pull-in range is at the extreme end of the control, it will be necessary to make the following adjustment.

HORIZONTAL FREQUENCY ADJUSTMENT — With the horizontal hold control set to the center of its range of rotation, adjust the horizontal frequency control (L-14) until the picture pulls into sync. Recheck the "Horizontal Oscillator Alignment."

HEIGHT AND VERTICAL LINEARITY ADJUSTMENT — Adjust the height control (R-54) until the picture fills the mask vertically. Adjust the vertical linearity control (R-49) until the picture is symmetrical from top to bottom. Adjust the picture centering device to align picture with the mask. Adjustment of any control will require a re-adjustment of the other control.

WIDTH, DRIVE AND LINEARITY ADJUSTMENTS— While receiving a signal from a station (with picture locked in sync) turn contrast control fully counter-clockwise, turn the brightness control (R-25) up so that the picture appears washed out. Adjust width control (L-15) until the picture fills the mask. Turn the horizontal drive control (R-89) clockwise until white bars appear in the left center portion of the raster, then turn counter-clockwise until the white bars just disappear. This adjustment will allow the horizontal system to operate at maximum efficiency. Adjust horizontal linearity control (L-16) for best linearity. If adjustment of the horizontal drive (R-89) or horizontal linearity (L-16) is required, it usually will be necessary to recheck the horizontal oscillator alignment. If adjustment of the horizontal linearity control (L-16) is required, readjustment of the horizontal drive control (R-89) will be necessary. Adjust the picture centering device to align the picture with the mask.

CHECK OF R-F OSCILLATOR ADJUSTMENTS

The oscillator is preset at the factory and normally needs no adjustment. However, if adjustments are required, they can be made without removing the chassis from the cabinet. Remove the channel selector and fine tuning knobs from the tuning shaft.

TEST PROCEDURE:

1. Set channel selector to receive desired station.
2. Set fine tuning control in center of its range.
3. Adjust oscillator slug, with bakelite type screwdriver, for best picture resolution.
4. Repeat steps 1, 2 and 3 on all channels used.

Caution — These adjustments are intended only for VHF Channels. For information regarding UHF alignment, see paragraph "Tuner Alignment",

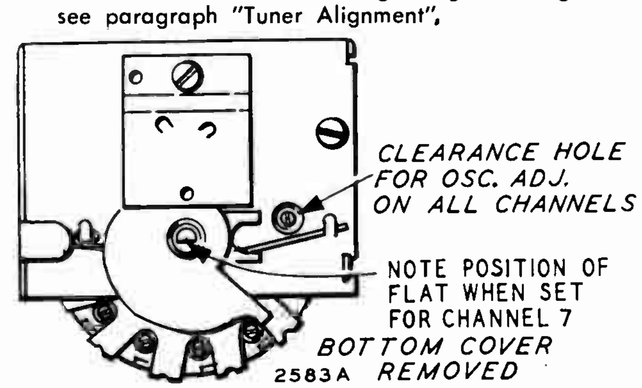

Fig. 5—Tuner Oscillator Adjustments

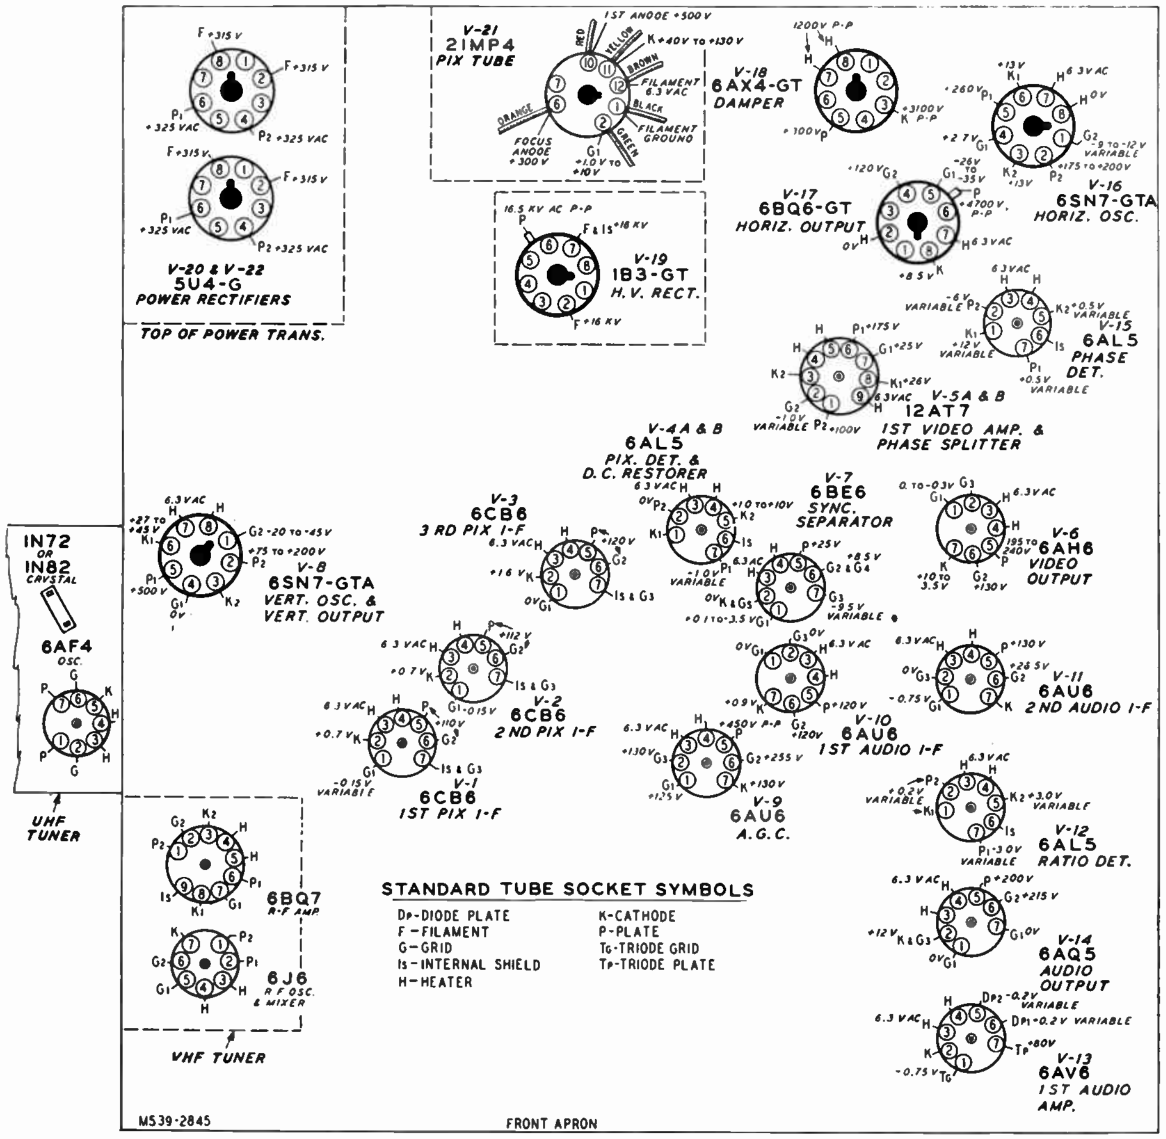

Fig. 6—Bottom Socket Voltages

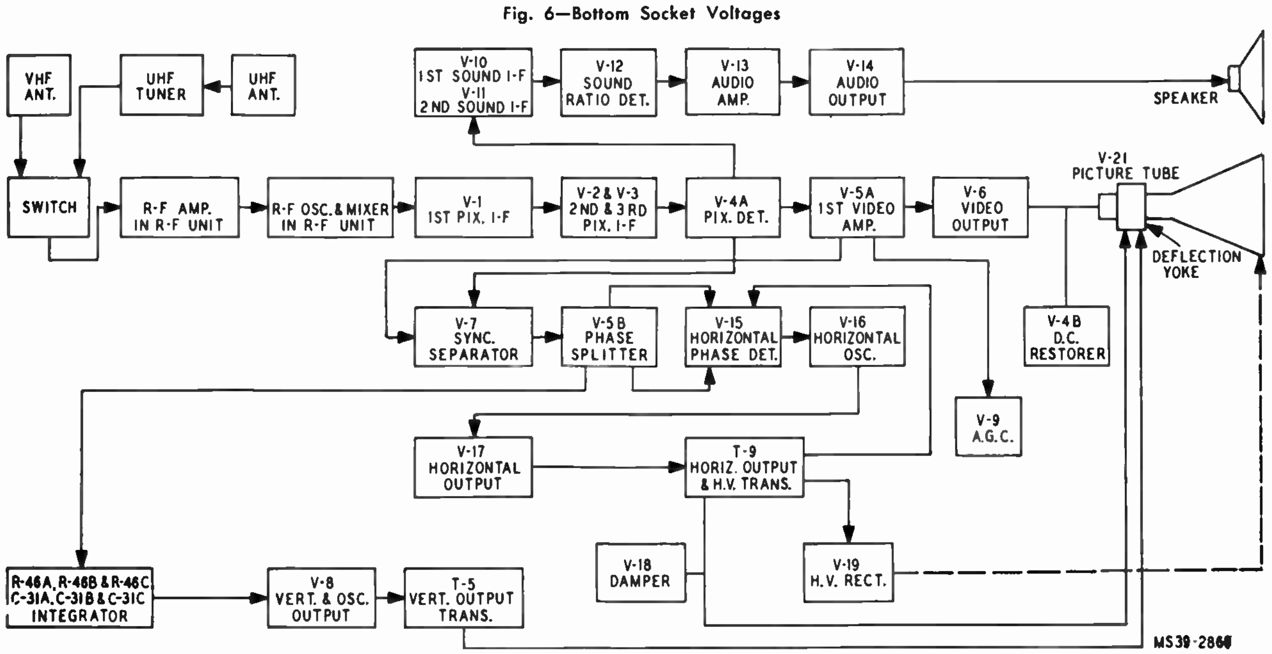

Fig. 7—Block Diagram

SERVICE SUGGESTIONS

NO RASTER ON PICTURE TUBE — If raster cannot be obtained check below for the possible causes.
1: Ion trap magnet adjustment is incorrect.
2: No +B voltage. Check 4/10 ampere fuse. Replace if defective. If fuse continually burns out, check
(A) Horizontal output tube V-17 (6BQ6-GT)
(B) Check damper tube V-18 (6AX4-GT).
(C) Check horizontal oscillator tube V-16 (6SN7-GTA) for proper operation.
(D) With an ohm meter, check for a short between terminal 1 of the horizontal output transformer (T-9) and the chassis.
(E) Check DC resistance of T-9.
3: No high voltage. Check V-17, V-18 and V-19 tubes and circuits. If the horizontal deflection circuits are operating as evidenced by the correct voltage (600V) measured on terminal No. 1 of T-9, the trouble can be isolated to the high voltage rectifier circuit. Either the high voltage winding to the 6BQ6-GT plate and 1B3 plate is open, tube V-19 is defective, its filament circuit is open, R-99 and C-78 defective or pix tube elements shorted internally.
4: Defective picture tube heater open or cathode return circuit open.

HORIZONTAL DEFLECTION ONLY — If only horizontal deflection is obtained as evidenced by a straight line across the face of the picture tube, it can be caused by the following:
1: Vertical oscillator and vertical output tube V-8 inoperative. Check socket voltages.
2: Vertical oscillator transformer (T-4) defective.
3: Vertical output transformer (T-5) open or shorted.
4: Yoke vertical coils open or shorted.
5: Vertical hold, height or linearity controls may be defective.

POOR VERTICAL LINEARITY — If adjustment of the height and linearity controls will not correct this condition, any of the following may be the cause.
1: Check variable resistors R-49 and R-54.
2: Vertical output transformer (T-5) defective.
3: Capacitors C-35A, C-39 or C-70 defective.
4: V-8 defective, check voltages.
5: Excess leakage or incorrect value of capacitor C-37, or open or incorrect value of resistors R-55 & R-56.
6: Low plate voltages. Check rectifier tube and capacitors in +B supply circuits.
7: Capacitor C-36 defective.
8: Vertical deflection coils (L-12) defective.

POOR HORIZONTAL LINEARITY — If adjustment of the Horizontal drive and linearity controls does not correct this condition, check the following:
1: Check or replace horizontal output tube V-17.
2: Check or replace damper tube V-18 (6AX4-GT).
3: Check capacitors C-74, C-76, C-77 and horizontal linearity control (L-16) for defects.
4: Horizontal deflection coils (L-17) defective.

TRAPEZOIDAL OR NONSYMMETRICAL RASTER
1: Defective yoke.

WRINKLES ON LEFT SIDE OF RASTER — This condition can be caused by:
1: Defective yoke due to C-75 or R-98 (internal in yoke assembly) being wrong value or open. These components are mounted in rear of yoke assembly.
2: V-18 (6AX4-GT) defective.

SMALL RASTER — This condition can be caused by:
1: Low +B or line voltage. Check V-20 & V-22 (5U4G).
2: Insufficient output from horizontal output tube V-17. Replace tube.
3: Insufficient output from vertical oscillator and vertical output tube V-8. Replace tube.
4: Incorrect setting of horizontal drive control R-89.
5: V-18 (6AX4-GT) defective.
6: Incorrect setting of (L-15) width control.

RASTER; NO IMAGE, BUT ACCOMPANYING SOUND — This condition can be caused by:
1: No signal on picture tube grid. Check V-5A (12AT7) and V-6 (6AH6) tubes and associated circuits.
2: Bad contact to picture tube grid (lead to socket broken).
3: AGC tube (V-9) may be defective. Check tube and its associated circuit.

SIGNAL APPEARS ON PICTURE TUBE GRID BUT IMPOSSIBLE TO SYNCHRONIZE THE PICTURE VERTICALLY AND HORIZONTALLY — A condition of this nature can be caused by:
1: Defective sync separator V-7 or phase splitter V-5B.
2: If tubes are O.K. check voltages, and associated circuits.
3: AGC system inoperative. Check V-9 (6AU6) AGC tube and associated circuits.

SIGNAL ON PICTURE TUBE GRID AND HORIZONTAL SYNC ONLY — If this condition is encountered, check:
1: Vertical integrating network capacitors C-31A, B & C, and resistors R-46 A, B & C.
2: Vertical hold control (R-51) defective.

SIGNAL ON PICTURE TUBE GRID AND VERTICAL SYNC ONLY
1: V-15 or V-16 defective.
2: Improper setting of (L-14) horizontal frequency control.
3: Check setting of horizontal drive control and horizontal linearity control.
4: Check V-15 and V-16 socket voltages.

PICTURE STABLE BUT WITH POOR RESOLUTION — If the picture resolution is not up to standard, it may be caused by any of the following:
1: Defective pix I-F tubes V-1, 2 & 3, (6CB6's).
2: Defective picture detector V-4A, (6AL5) or video amplifier V-5A or video output V-6 (6AH6).
3: Defective picture tube.
4: Open video peaking coil. Check all peaking coils L-5, L-6, L-8, L-9, L-10 and L-11 for continuity. Note that L-5, L-9 and L-10 have shunting resistors.
5: Leakage in V-6 (6AH6) grid capacitor C-11. If the capacitor is not found to be defective, check the following:
1: Check all potentials in video circuits.
2: Check picture tube grid circuit for poor or dirty contact.
3: Check and realign, if necessary, the picture I-F and R-F circuits.

PICTURE SMEAR:

1: A smear can be attributed to phase shift at the low or high frequency end of the video characteristic. This can be caused by improper values of resistors and capacitors in the video circuits. Check for grid current on video output tube V-6 (6AH6), open or shorted peaking coils, video amplifier load resistors are of improper value (high).

2: This trouble can also originate at the transmitter. Check reception from another station.

3: Check and realign, if necessary, the picture I-F and R-F circuits.

MAN MADE NOISE IN SOUND (Ignition, etc)

1: Check sound I-F tubes V-10, 11 & 12 and associated circuits.

2: Check sound I-F alignment.

BENDING OR S-ING

1: Check sync stability control adjustment.

2: Check capacitors C-35B and C-79B.

3: V-17 (6BQ6-GT) defective or V-16 (6SN7-GTA) defective.

4: Check sync separator tube V-7 (6BE6) and phase splitter V-5B (12AT7) and V-5A (12AT7) video amplifier.

5: Check AGC threshold control.

PICTURE NORMAL—NO SOUND OR WEAK OR DISTORTED SOUND

1: Check sound I-F alignment.

2: Check V-10 (6AU6) V-11 (6AU6) V-12 (6AL5) V-13 (6AV6) V-14 (6AQ5) and associated circuits.

RASTER ON TUBE BUT NO PICTURE OR SOUND

This condition can be caused by,

1: Defective pix I-F Amplifier tubes V-1, V-2 or V-3

2: Defective pix detector tube V-4A (6AL5). Check tube and its associated circuit.

3: Defective R-F Amplifier or oscillator mixer tubes in the tuner.

4: UHF-VHF switch defective.

POOR FOCUS

1: Improper setting of Ion Trap magnet.

2: Defective picture tube or picture tube socket.

PICTURE JITTER:

1: If regular sections at left of the picture are displaced, replace the horizontal oscillator tube V-16.

2: Vertical instability may be due to loose connections or noise received with the signal.

3: Horizontal instability may be due to unstable transmitted sync.

4: Check receiver AGC system for proper operation.

5: Check phase splitter V-5B, (12AT7) and sync separator V-7 (6BE6).

6: Check for improper setting of sync stability control.

7: Picture tube grid lead not held in position by support spring, ie: close proximity of grid lead to sync and horizontal tubes will cause picture to jitter at high contrast setting.

8: Check AGC threshold control.

NO PICTURE OR SOUND OR WEAK PICTURE OR SOUND IN UHF POSITION

If this condition is encountered

1: Check to see whether or not a UHF station is operating in the vicinity.

2: The 6AF4 oscillator tube or the IN72 (or IN82) crystal may be defective.

3: Pre-selector in UHF tuner defective.

4: Low pass filter defective.

5: The UHF antenna and oscillator strips in the VHF tuner defective.

6: Defective switch on UHF tuner.

ALIGNMENT PROCEDURE

TEST EQUIPMENT — To service this receiver properly, it is recommended that the following test equipment be available:

R-F SWEEP GENERATOR meeting the following requirements:

(a) Frequency ranges:
- 18 to 30 mc, 10 mc sweep width
- 40 to 90 mc, 10 mc sweep width
- 120 to 130 mc, 10 mc sweep width
- 170 to 225 mc, 10 mc sweep width
- 470 to 890 mc, 10 mc sweep width

(b) Output adjustable with at least .1 volt maximum.
(c) Output constant on all ranges.
(d) Flat output in all attenuator positions.

CATHODE-RAY OSCILLOSCOPE preferably one with a wide band vertical deflection and an input calibrating source.

SIGNAL GENERATOR to provide the following frequencies: (Output on these ranges should be adjustable and at least .1 volt maximum.)

(a) Intermediate alignment frequencies.
- 23.1 mc first picture I-F coil.
- 24.1 mc third picture I-F coil.
- 25.9 mc second picture I-F coil.
- 21.7 mc sound trap.
- 4.5 mc video trap & sound I-F.
- 25.2 mc converter plate coil (Tuner).

HETERODYNE FREQUENCY METER with crystal calibrator if the signal generator is not crystal controlled.

ELECTRONIC VOLTMETER and a high voltage probe for use with this meter to permit measurements up to 20 kilovolts.

SERVICE PRECAUTIONS — To service the receiver remove the chassis from the cabinet. To do so, remove the knobs, the cabinet back, disconnect the leads from the speaker, remove the antenna terminal board at rear of cabinet, and then the 5 chassis mounting bolts. The chassis may be serviced with the picture tube in place provided the chassis is turned on its side with the power transformer on the bottom. The weight of the chassis will be supported against the power transformer and pix tube brackets.

CAUTION: Do not permit the kinescope second-anode lead to become shorted to the chassis. To do so will cause a considerable overload on the high voltage filter resistor R-99.

ALIGNMENT PROCEDURE
PIX I-F

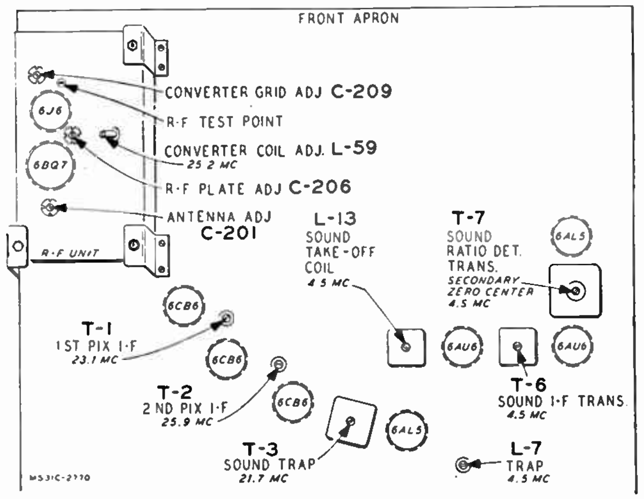

Fig. 8—Top Chassis Video and Audio I-F Adjustments

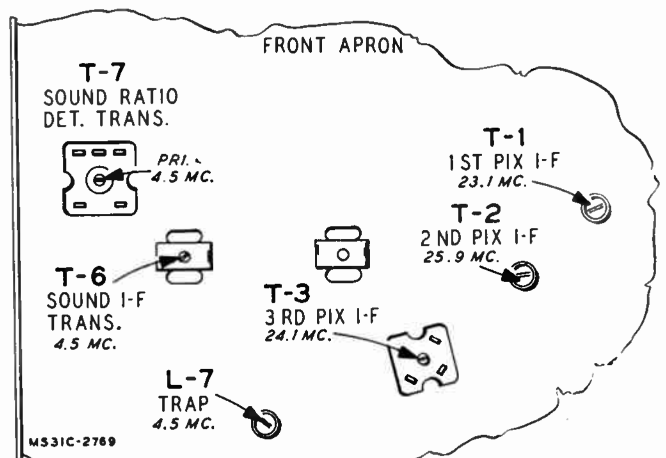

Fig. 9—Bottom Chassis Video and Audio I-F Adjustments.

A. Unmodulated R-F signal into Converter Grid by means of tube shield insulated from base. VTVM with filter in lead of 22 K ohms and 5000 mmf connected to pic. det. load resistor, (R-100) 4700 ohms, in series with peaking coil (L-6) from Pin 7 of 6AL5. Input signal level should be such that output is less than 2 volts DC. Apply -4.5V battery bias on AGC line.

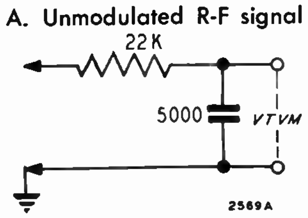

Fig. 10—VTVM Connections

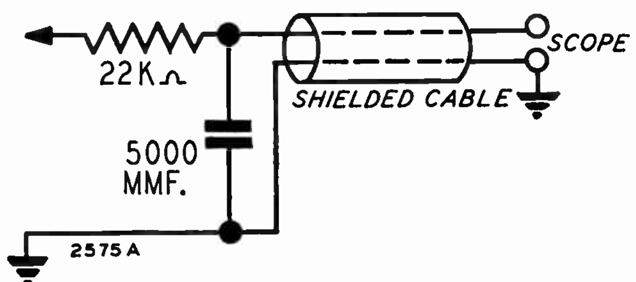

Fig. 11—Oscilloscope Connections

	FREQUENCY	ADJUST
1.	25.2 MC	Converter plate coil on top of tuner for maximum dc at picture detector.
2.	23.1 MC	1st picture I-F coil (T-1) for maximum dc at picture detector.
3.	25.9 MC	2nd picture I-F coil (T-2) for maximum dc at picture detector.
4.	24.1 MC	3rd picture I-F coil (T-3 below chassis) for maximum dc at picture detector.
5.	21.7 MC	3rd picture I-F trap (T-3 in can above chassis) for minimum dc at picture detector.

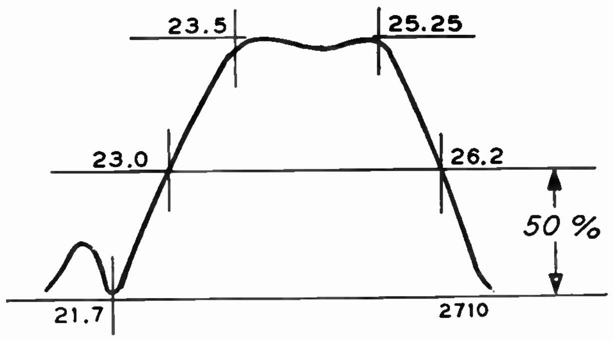

Fig. 12—Overall Response Curve

B. I-F Sweep Generator into converter grid by means of tube shield insulated from base.

Connect oscilloscope across R-100 (in place of VTVM). Apply -4.5V bias (DC) to AGC line (battery). Tuner should be switched to dead channel so as not to cause interference.

Observe overall I-F response, which should be as shown above: A slight touch-up may be required. At no time should the trap coil be re-adjusted, nor should it be necessary to turn any of the picture I-F coils more than 1/2 turn of the slug. The following comments are suggestions only:

1. The height of the 26.2 MC marker is controlled by the 25.2 MC (Converter Plate Coil on tuner) and the 25.9 MC (2nd P.I.F.) coils.
2. The uniformity of response (flatness across top and position of 23.5 MC) marker is controlled for the most part by the 24.1 MC third picture I-F coil.
3. The 23.0 MC marker position is controlled by the first picture I-F (23.1 MC coil). However, it is NOT advisable to change the setting of the coil, due to its effect on sound rejection. Its adjustment should be avoided unless believed to be absolutely necessary.

VIDEO

With 4.5 MC unmodulated signal from a high impedance source, (10,000 ohms in series with the generator) into plate of the picture detector tube (Pin 7-6AL5) and VTVM on picture tube grid, tune 4.5 MC trap (L-7 Top) for minimum response. VTVM on 0-10 V AC scale. This adjustment can also be made while observing a picture from a station. Tune trap for least 4.5 MC beat in picture.

AUDIO I-F

1: With signal generator set to 4.5 MC and dc VTVM connected to junction of R-62 and C-46, adjust sound take-off coil (L-13 Top) and sound I-F transformer slugs (T-6 Top & Bottom) for maximum.

2: With VTVM connected to pin 7 of V-12 (6AL5) adjust the ratio detector primary (T-7 Bottom) for maximum.

3: With VTVM connected to junction of R-66, R-69 and C-50, adjust ratio detector secondary (T-7 Top) for cross over (zero voltage) on lowest scale.

NOTE — If no signal generator is available, the procedure above may be followed by tuning in a station and using the 4.5 MC beat between picture and sound carrier.

TUNER ALIGNMENT

A. Sweep generator with balanced 300 ohm output to antenna terminals. Marker generator output to antenna terminals. Oscilloscope to "test point" (Figure 13) on tuner. Connect 1½ V bias to AGC line at junction of R-33 and C-20 on the receiver.

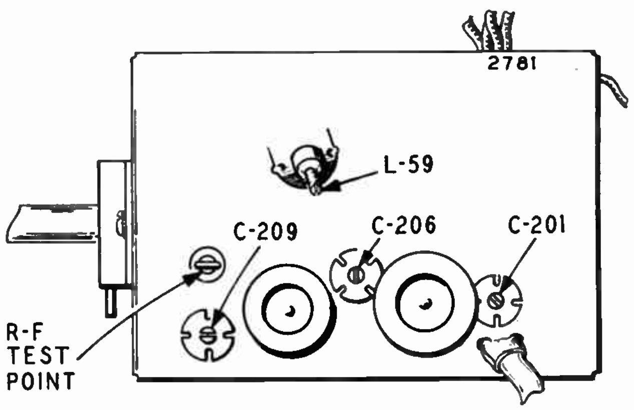

Fig. 13—Top Tuner Adjustments

B. RF AND CONVERTER ADJUSTMENT.

1. With channel selector on Channel 12, adjust C-201 slightly favoring the Pix carrier, then adjust C-206 and C-209 for response as in Figure 14. Picture and sound markers at 90% maximum response.
2. Check response on all channels. If markers are below 70% on any channels, readjust C-201, C-206, and C-209. Recheck all channels.

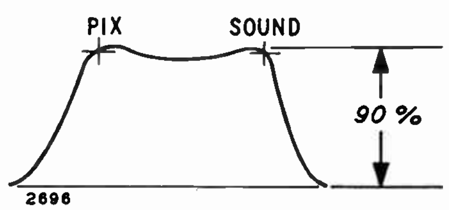

Fig. 14—Pix & Audio Markers

C. OSCILLATOR ADJUSTMENT.

1. Apply -4.5 volts on I-F AGC line at junction of R-1 and C-21.
2. Connect oscilloscope to output of video detector. Place fine tuning in center of range. Check response on all channels. Sound marker should be in notch and picture marker at 50%. (See Figure 12).
3. If markers are off, individual oscillator coil slugs will require adjustment. Adjust each channel slug, accessible through hole in front of chassis with a non-metallic screwdriver to bring sound marker to correct position.
4. To adjust oscillator on UHF position, feed the sweep generator with center frequency of 124 MC and markers at 121.75 and 126.25 into the input of the low pass filter (output of UHF tuner). Adjust oscillator slug in the VHF tuner so that the 121.75 pix carrier marker is at 50% and that 126.25 marker is in the sound notch. If a sweep generator is not available, a single frequency generator set to 126.25 MC and VTVM may be used. Connect VTVM to the pix detector load resistor R-100. Feed generator into the low pass filter. Adjust oscillator slug in the VHF tuner so that the 126.25 marker is in the sound notch of the I-F curve.

If the 6AF4 oscillator tube in the UHF tuner is replaced, it may be necessary to adjust the oscillator trimmer C-309 on the UHF tuner located underneath the chassis. (See Figure 15). Adjust this trimmer until the tuner will cover a range of below 470 MC to above 890 MC.

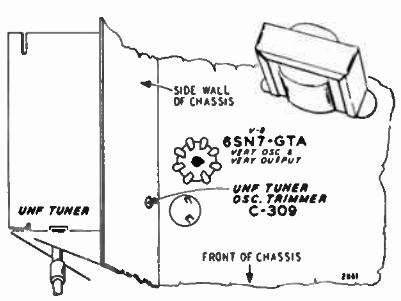

Fig. 15—UHF Tuner Adjustment.

VHF TUNER ASSEMBLY INFORMATION

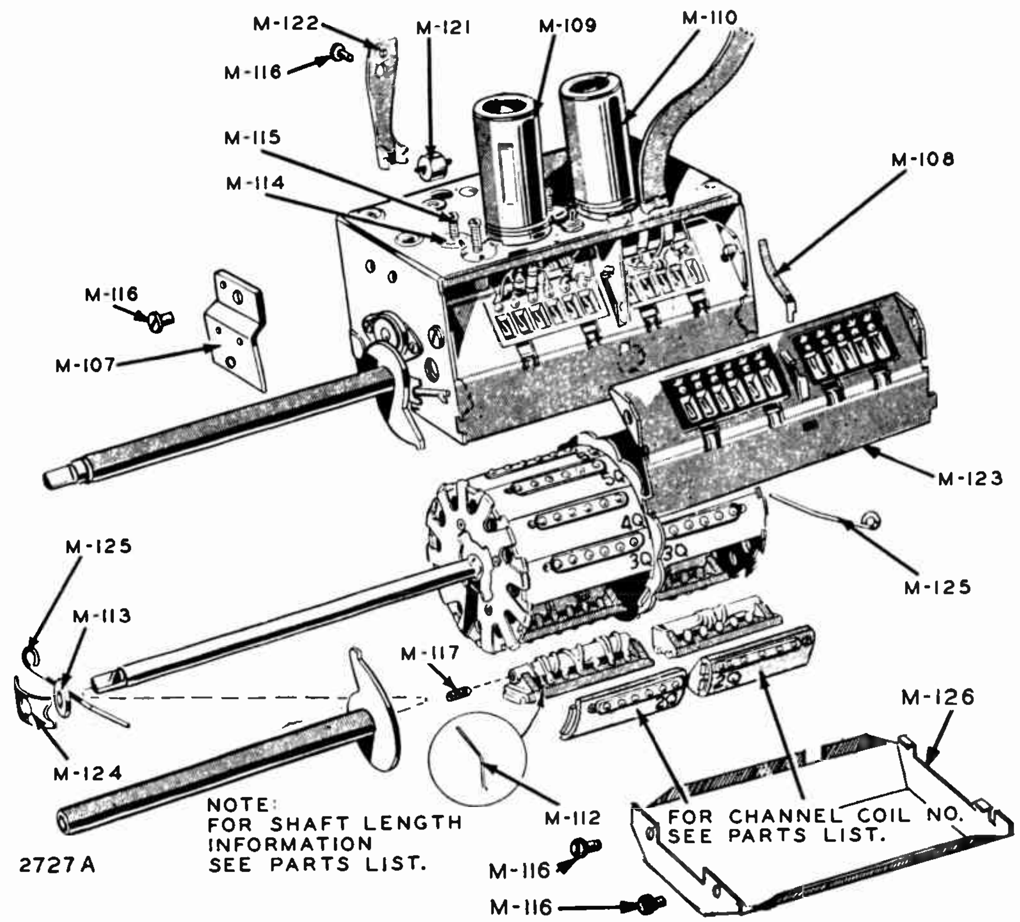

Fig. 16—"Q" Tuner Pictorial.

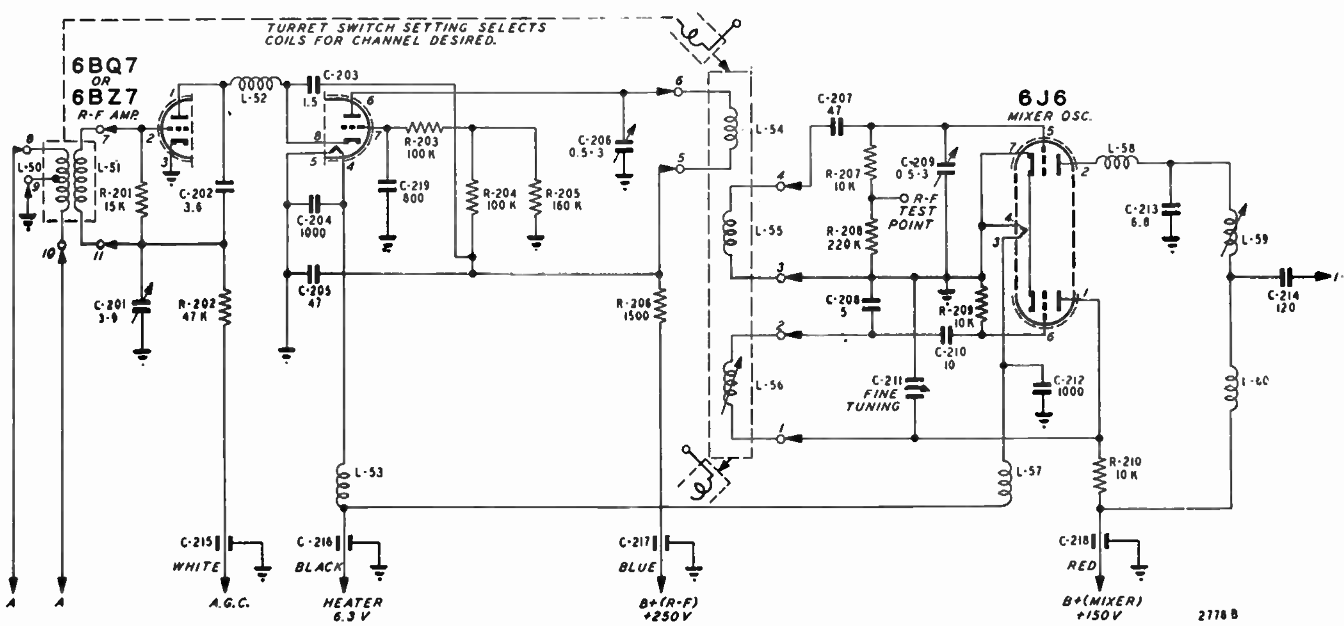

Fig. 17—"Q" Tuner Schematic Diagram.

UHF TUNER INFORMATION

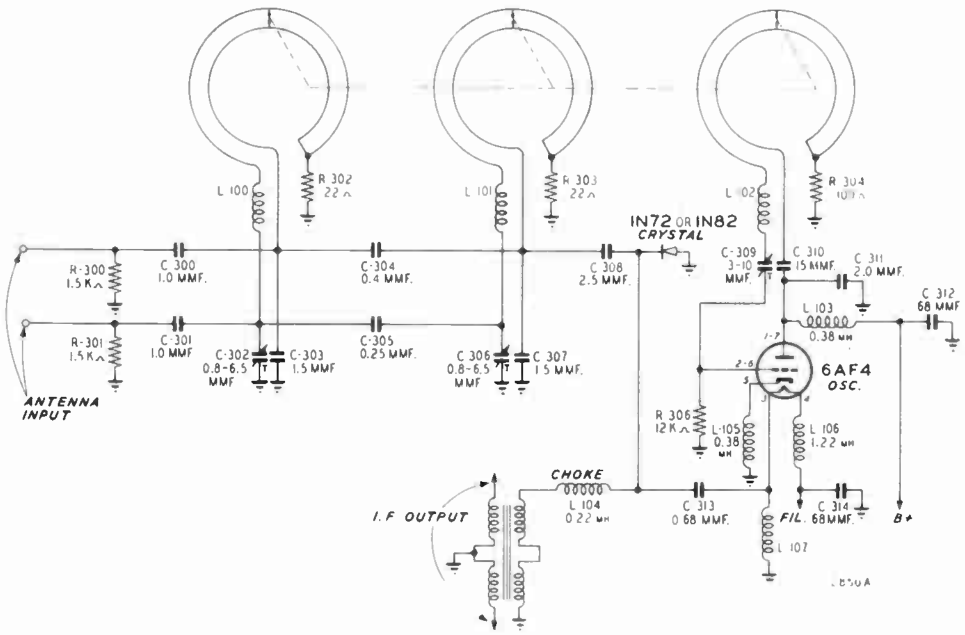

Fig. 18—UHF Tuner Schematic Diagram.

Due to the complexity of the UHF tuner, neither servicing nor aligning is encouraged in the field because replacement of any component within the R-F circuit may disturb the band-pass characteristics of the tuner. However, the 6AF4 tube or the 1N72 (or 1N82) crystal may be replaced in the field if found to be defective. A schematic diagram of this tuner is shown only for the purpose of outlining the circuit used.

If the UHF tuner does not operate satisfactorily after the tube or crystal replacement, disconnect the tuner and return it to the factory for repair.

DRIVE CORD REPLACEMENT

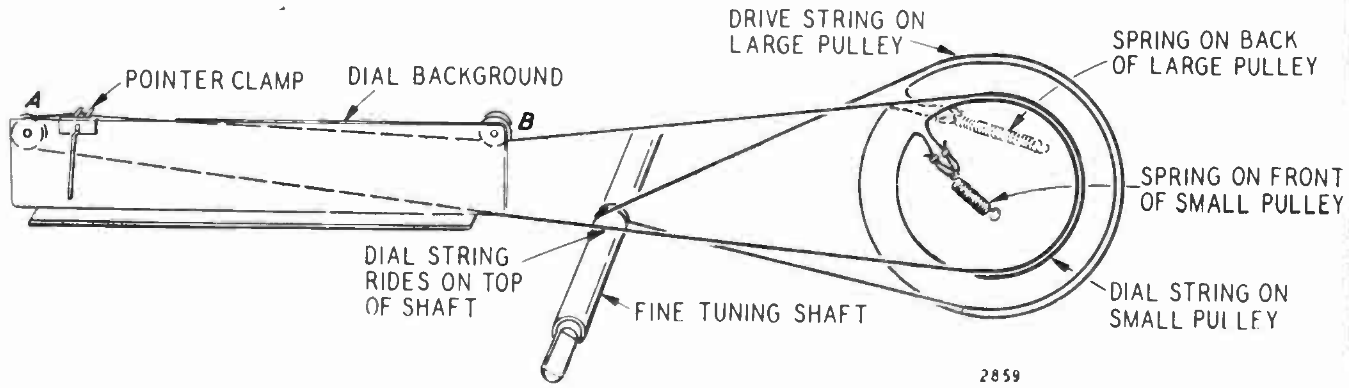

Fig. 19—Drive Cord Stringing.

You will note that there are two cords used for the pointer drive system on this receiver. Part number 10X88 Drive Cord assembly and part number 28X603 Spring are used on the tuning shaft and large pulley, while part number 10X89 Drive Cord and a part number 28X603 Spring are used on the small pulley system and the pointer. Install the cords as shown in the illustration. After completing the installation rotate the fine tuning shaft a few turns to take up the slack in the cord.

OSCILLOSCOPE WAVEFORM PATTERNS

The waveforms on this page were taken with the receiver tuned to a normal picture. The numbers on the waveforms correspond to the numbers on the schematic diagram which identifies each test point.

The voltages shown on each waveform are the approximate peak to peak amplitudes. The frequencies shown indicates the repetition rate of the waveform, not the sweep rate of the oscilloscope. If the waveforms are observed on the oscilloscope with a poor high frequency response, the corners of the pulses will tend to be more rounded than those shown below and the amplitudes of any high frequency pulse will tend to be less.

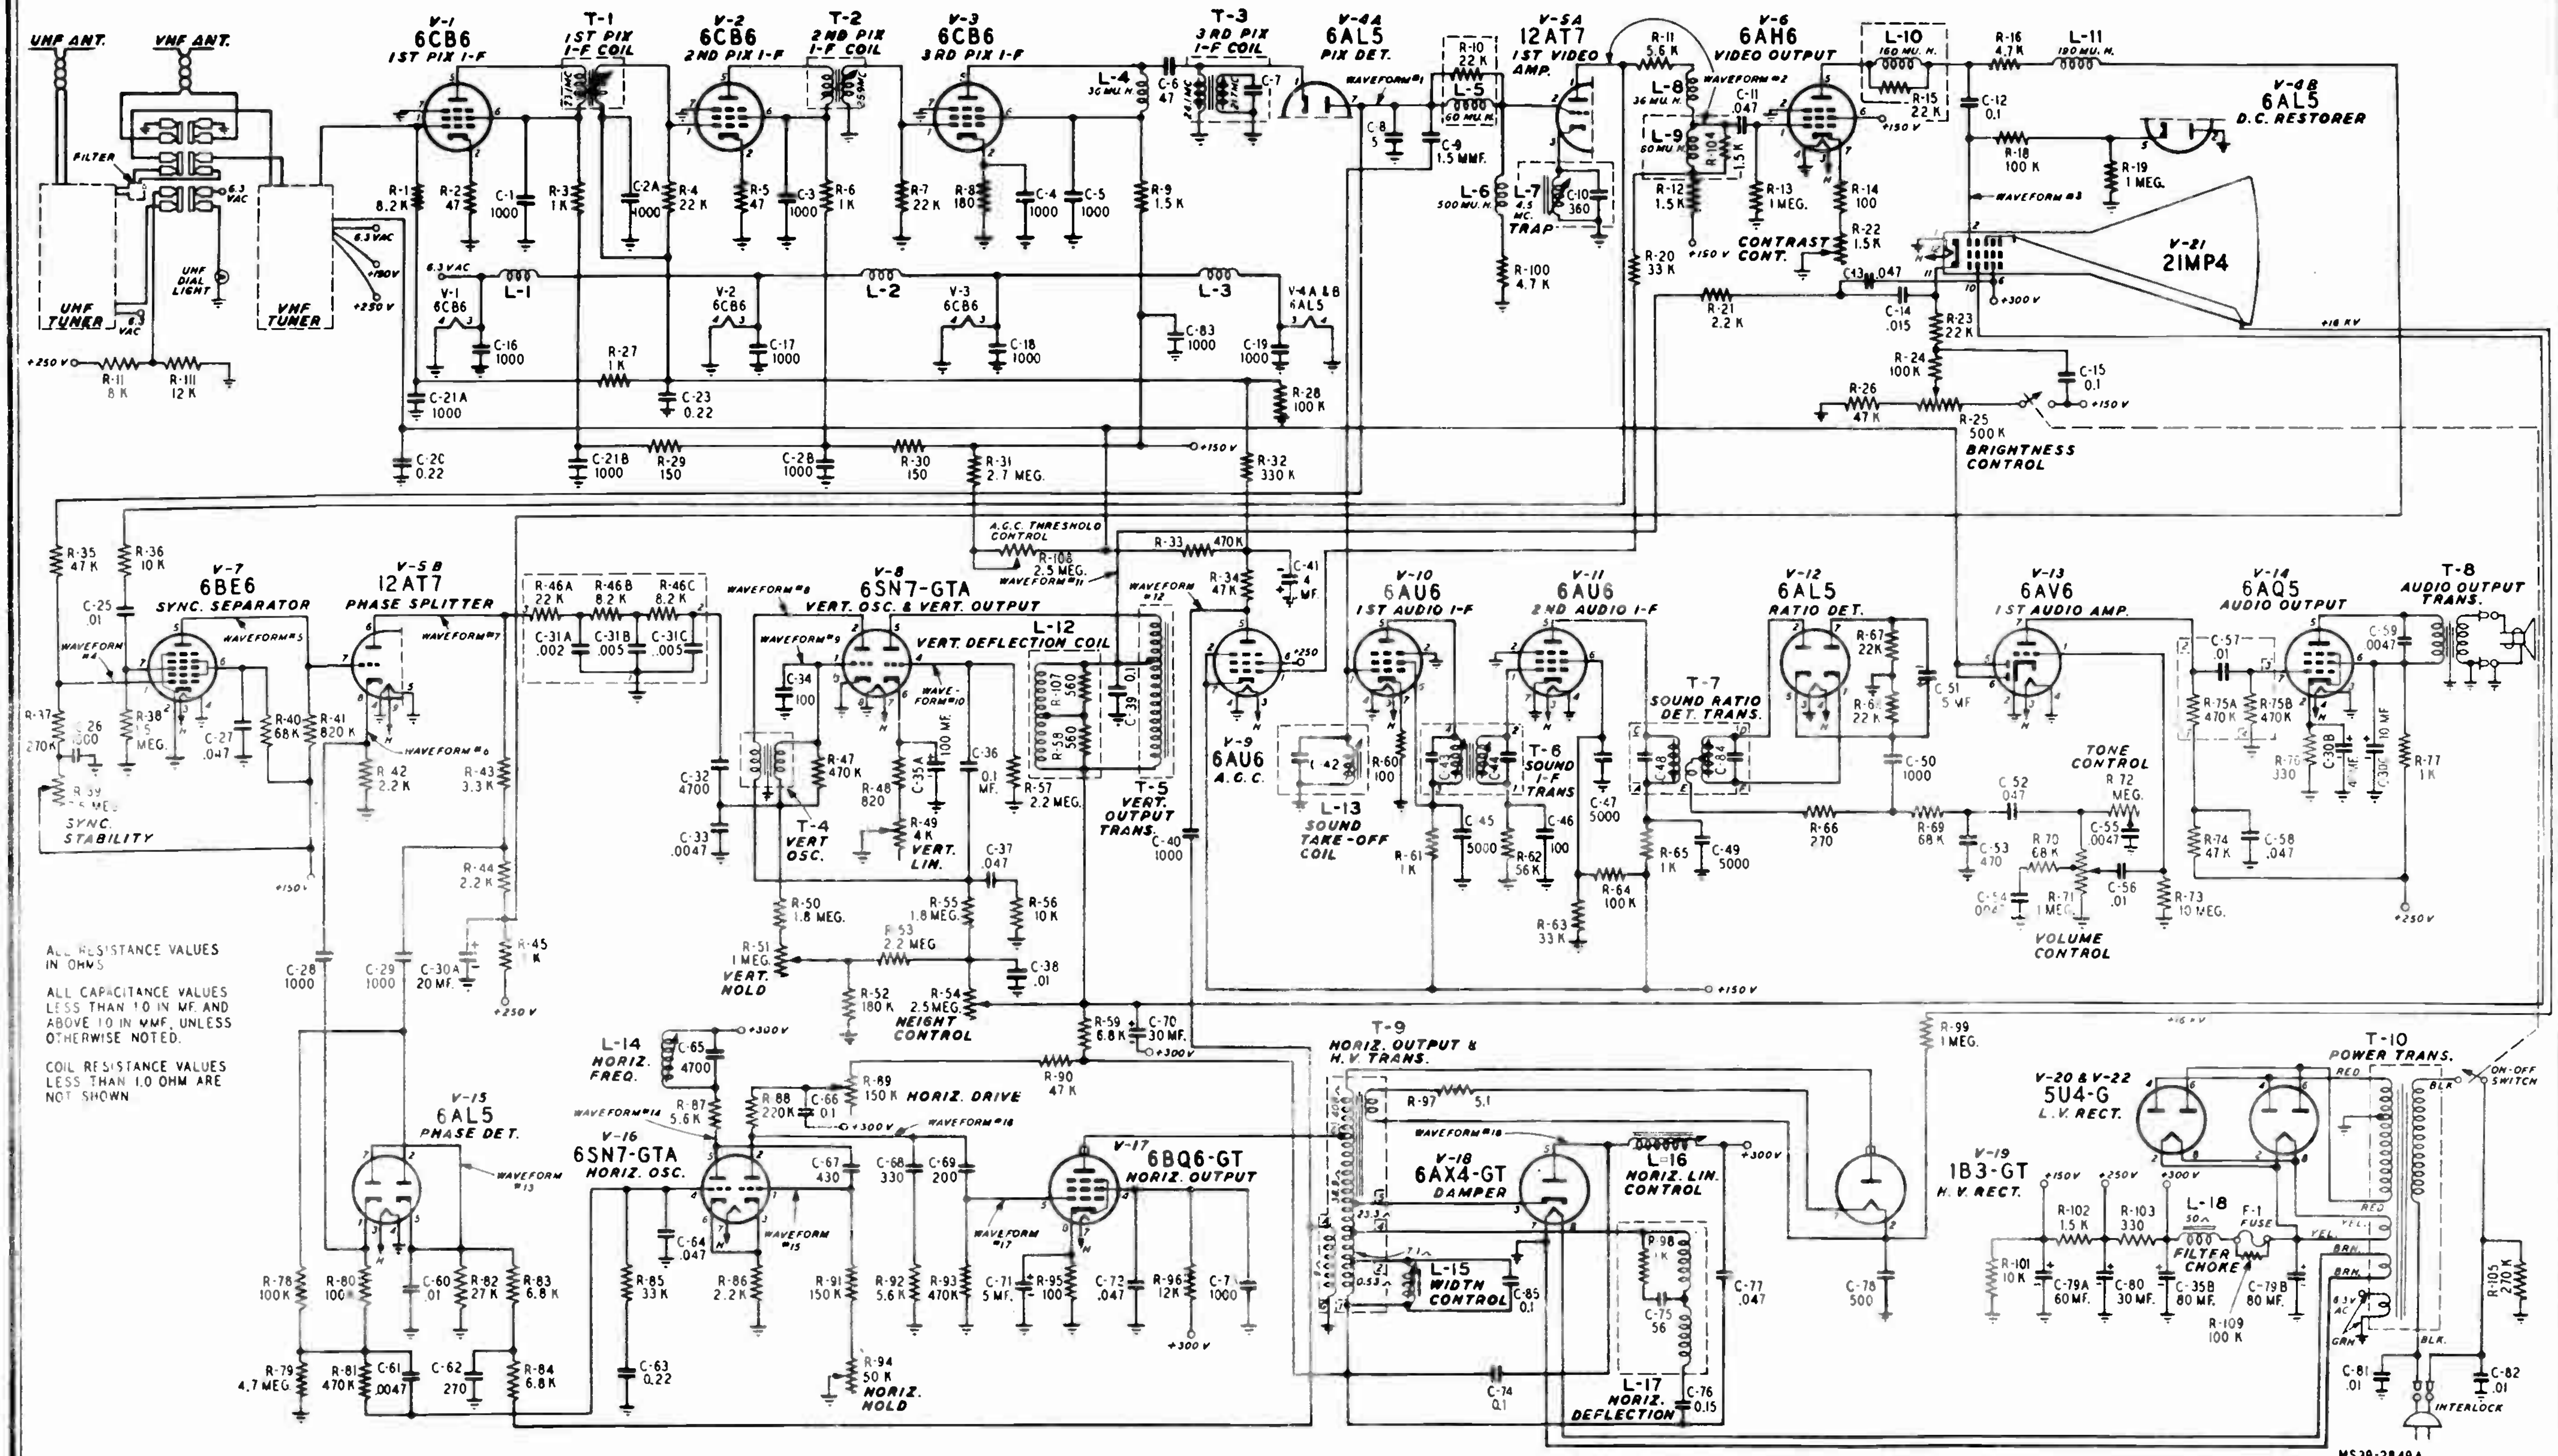
21" UHF-VHF TELEVISION RECEIVER



PRODUCTION CHANGES

There are two different ratio detector transformers (T-7) used in these receivers, Part Numbers 9A2269 and 9A2295. The T-7 circuit shown in this schematic diagram covers the 9A2269 ratio detector. Receivers using the 9A2295 ratio detector can be identified by the following changes:

C-50 becomes 47X570 330 mmf molded mica condenser

R-64 becomes B84333 33K ohm 0.5 W carbon resistor

R-67, R-68 } become B83103 10K ohm 0.5 W carbon resistors

In addition, the 9A2295 ratio detector has terminals with numerical identification (1, 2, 3 etc.) whereas the 9A2269 ratio detector has terminals with alphabetical identification (A, B, C etc.)

IMPORTANT

Models 35TV2-43-9023A and 45TV2-43-9023B are identical except for a few minor changes in cabinet construction and design. For differences between the "A" & "B" models, see the replacement parts list section.

ELECTRICAL SPECIFICATIONS

Power Supply	105-125 Volts AC 60 Cycles Only
Power Consumption	200 Watts
Power Output	2.4 Watts (Max.) 1.8 Watts (10% Distortion)
Tuning Ranges	VHF — Channels 2 thru 13 UHF — Channels 14 thru 83
Antenna Input Imp.	300 Ohms Balanced
Intermediate Frequencies	Picture 26.20 MC Sound 21.70 MC
I-F (UHF Position Only)	Picture 121.75 Sound 126.25
Intercarrier Sound System . . .	4.5 MC
Loud Speaker	See Parts List
Voice Coil Imp.	3.2 Ohms 400 Cycles

TUBE COMPLEMENT

Symbol	Type	Function
VHF Tuner	6J6	R-F Osc. and Mixer
*VHF Tuner	6BQ7	R-F Amplifier
UHF Tuner	6AF4	R-F Osc.
UHF Tuner	1N72 or 1N82	Crystal Mixer

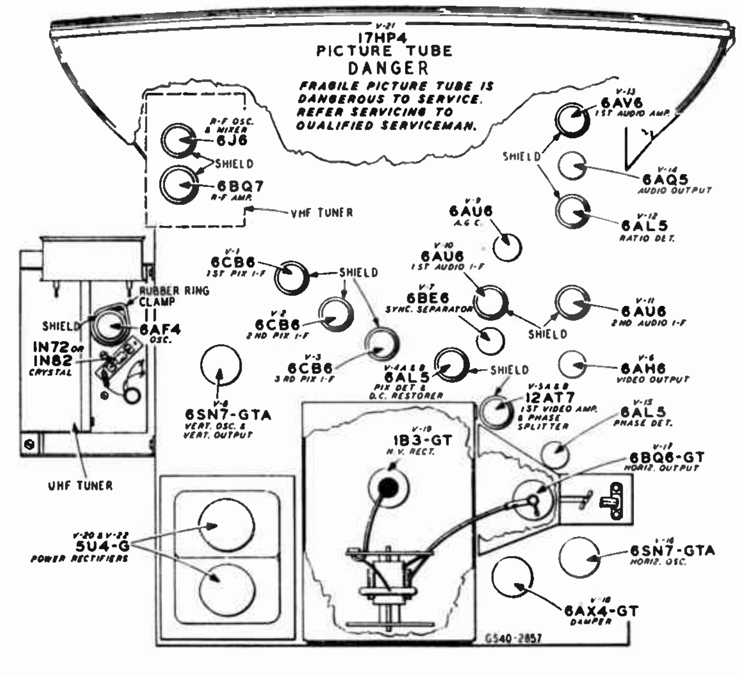

Fig. 1—Tube Layout.

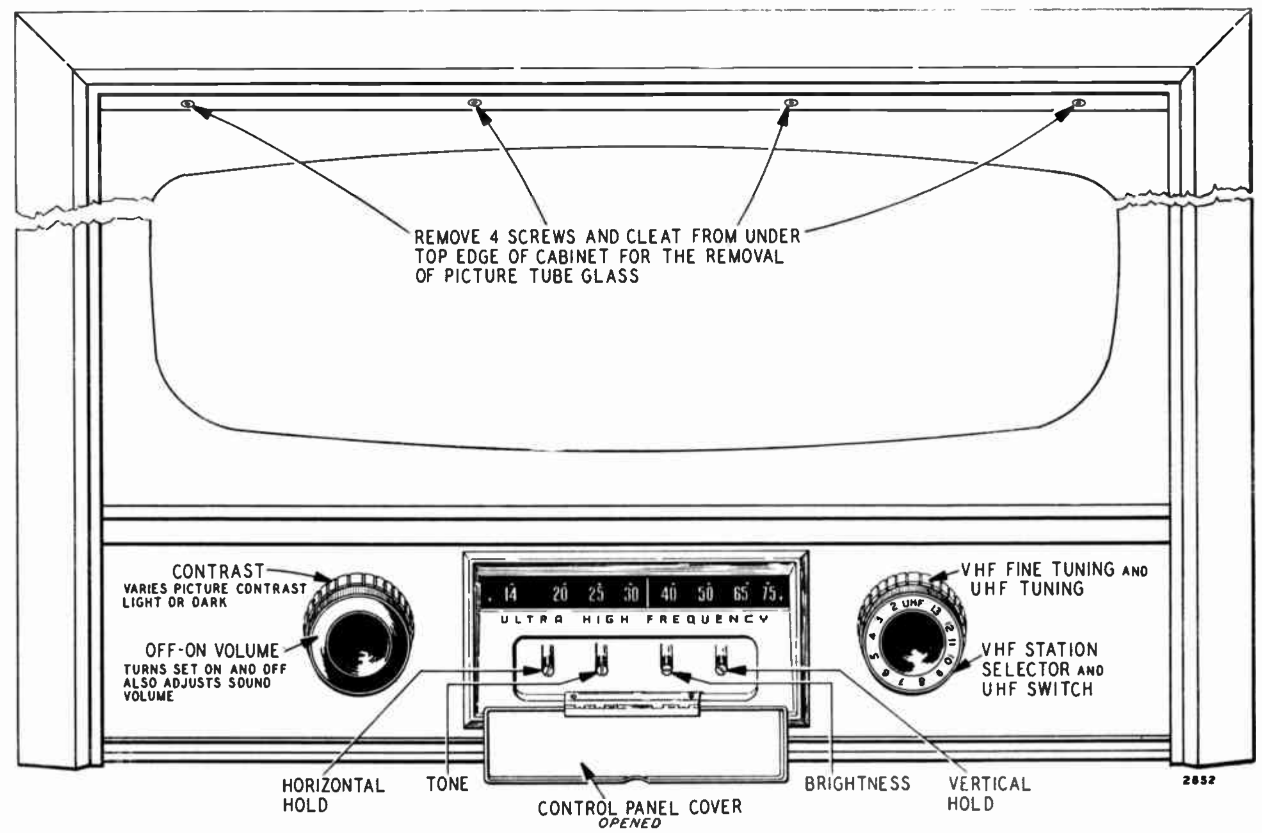

NOTE — In some receivers it may be necessary to remove 5 screws and cleat from under top edge of cabinet for the removal of picture tube glass.

Fig. 2—Front Panel Controls

RECEIVER LOCATION — Advise the owner as to the proper location for the television receiver. The following may be used as a guide:

1. Choose an area in the home where sunlight or light from lamps does not strike the face of the picture tube and cause glare.
2. Remember the necessity of an electrical outlet and the location of the point at which the antenna leads enter the room.
3. The receiver should be placed a short distance from the wall to allow adequate ventilation.
4. The receiver should be placed to permit easy access for operation and comfortable viewing from all angles.

ANTENNA — This receiver has been designed to use an antenna with a 300 ohm balanced transmission line. This line must be as short as possible because the longer the line the greater the chances are for picking up electrical disturbances. Stand-off insulation should be used to keep the line away from the mast, metal or walls. Twist this line about one turn per foot throughout the line to cancel out direct signal and/or noise pickup by the transmission line. It should also be securely anchored in place so that a change in weather will not affect its position.

HIGH VOLTAGE WARNING

This television receiver contains high voltages which are dangerous to life. Never operate or service the receiver outside of the cabinet or with the covers removed until all the safety precautions necessary for working with high voltage equipment have been observed.

PICTURE TUBE HANDLING PRECAUTIONS

Shatterproof goggles and heavy gloves must be worn by individuals while handling the picture tube or installing the picture tube into the receiver.

The picture tube encloses a high vacuum and due to the large surface area, is subjected to very high air pressure. Therefore, care should be taken not to bump or scratch the picture tube accidentally as it may cause the tube to implode resulting in damage to property or injury to an individual.

TUNING PROCEDURE

1. To turn the television receiver on, turn the OFF-ON VOLUME control clockwise until a click is heard. Allow approximately 30 seconds for the tubes to warm up.
2. Turn the STATION SELECTOR control to the desired channel. This control may be turned in either direction.
3. Turn the CONTRAST control clockwise until activity or definite form is noted on the screen.
4. Adjust the FINE TUNING control for clearest picture and the VOLUME control for desired volume.
5. To turn off the receiver, turn only the OFF-ON VOLUME control counterclockwise until a click is heard.
6. TONE CONTROL — When this Control is turned clockwise, the high notes will predominate and when turned counterclockwise, a deep bass effect will result.
7. In localities where UHF programs are available, turn the STATION SELECTOR control to the UHF position and tune in the desired station with the UHF Tuning Control. The dial scale is calibrated in channel numbers and covers the entire UHF range of channels 14 through 83.

OCCASIONAL ADJUSTMENTS TO IMPROVE PICTURE RECEPTION

There are four controls at the front of the chassis which are accessible when the hinged control panel is pulled downward. See illustration Figure 2. These controls are pre-set at the factory and may occasionally need adjustment due to aging of the components in the receiver and the fluctuating line voltages in different areas.

If any adjustments are necessary follow the instructions under "Controls and Functions."

IMPORTANT — Be sure that the FINE TUNING control has been set for the clearest picture before adjusting any controls.

CONTROLS AND FUNCTIONS

HORIZONTAL HOLD—Stops horizontal movement (diagonal bars.)

TONE—Adjusts for tonal quality bass or treble.

BRIGHTNESS—Adjusts for desired picture brilliance.

VERTICAL HOLD—Stops upward or downward picture movement.

PICTURE TUBE SAFETY GLASS

PICTURE TUBE SAFETY GLASS — It will be necessary to clean this glass and the face of the picture tube occasionally. Remove the safety glass carefully as outlined in the illustration.

CAUTION — UPON REMOVAL OF THE LAST SCREW AND THE CLEAT THE GLASS MAY FALL FORWARD. SUPPORT THE GLASS WITH ONE HAND AS YOU LIFT IT GENTLY FROM THE CABINET. Clean the safety glass and the face of the picture tube with a soft lint-free cloth dampened with water or mild soapsuds.

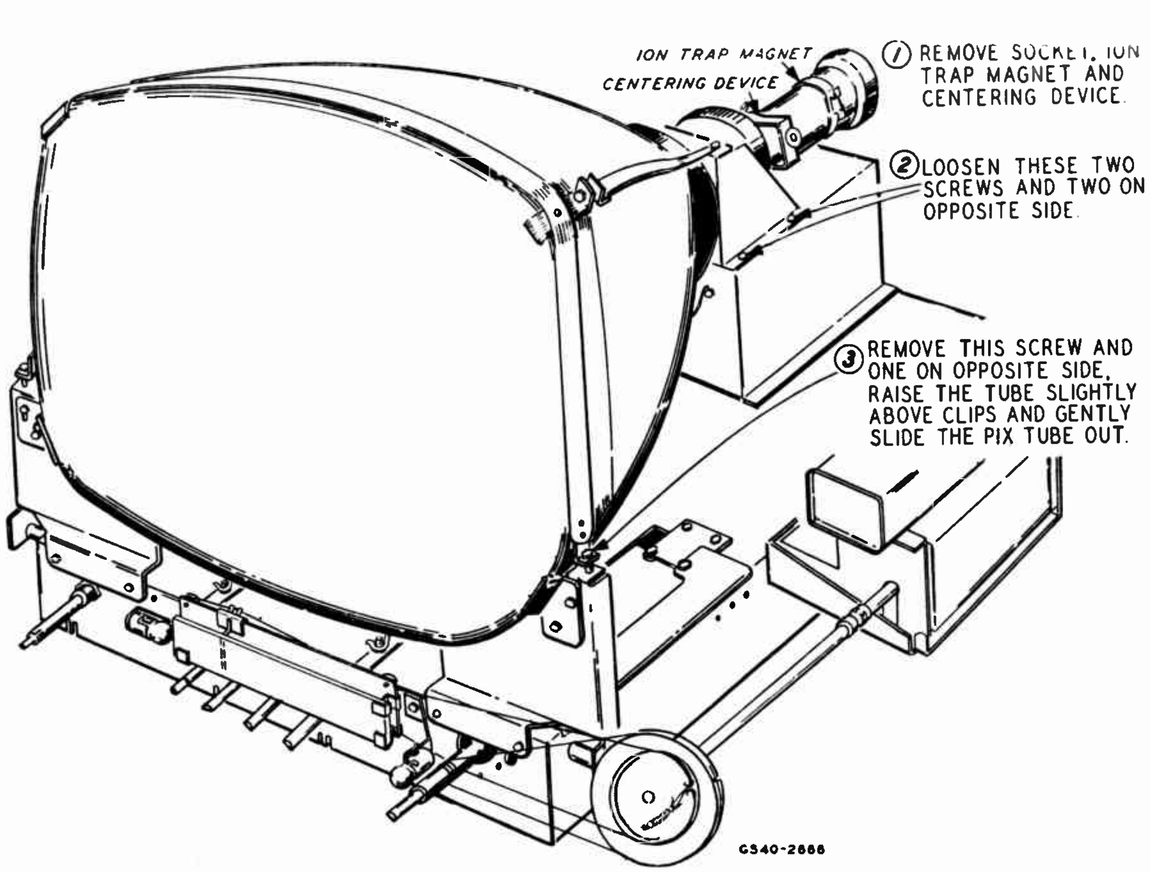

Fig. 3—Removal of Picture Tube

WARNING — Before handling the picture tube, it will be necessary to remove the static charge. In receivers with glass picture tubes, ground the anode lead to chassis, and insert an insulated wire from the well in the tube to chassis. In receivers with metal picture tubes, remove the static charge by grounding an insulated wire from the chassis to the metal portion of the tube.

PICTURE TUBE REPLACEMENT — To replace the picture tube it is necessary to remove the chassis from the cabinet. This may be accomplished in the following manner:

1. Remove the front panel control knobs by pulling them straight from their shafts.
2. Remove the cabinet back.
3. Disconnect the leads from the speaker, remove the antenna terminal boards at the rear of the cabinet and then the five chassis mounting bolts. Pull chassis CAREFULLY out of the cabinet.
4. Remove the picture tube as shown and outlined in the illustration. To install a new picture tube, reverse the procedure making sure that the picture tube fits close against the picture tube cushion. If the picture tube sticks or fails to slip into place smoothly, investigate and remove the source of the trouble. Never force the tube. It is important that all the clips and shims used in mounting the tube be replaced, otherwise difficulty may be encountered when horizontal or vertical centering is required.

FRONT OF CHASSIS

(Accessible After Opening Front Panel Control Cover)

Horizontal Hold	R-94
Brightness	R-25
Vertical Hold	R-51
Tone	R-72

NON-OPERATING CONTROLS REAR OF CHASSIS

Vertical Centering	Centering Device
Ion Trap Magnet	See paragraph.
Deflection Yoke	Wing Screw
Width	L-15
Horizontal Linearity	L-16
Horizontal Drive	R-89
Horizontal Frequency	L-14
Vertical Linearity	R-49
Height	R-54
Sync Stability	R-39
AGC Threshold Control	R-108

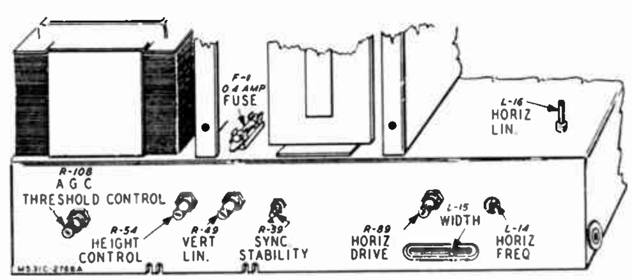

Fig. 4—Adjustments Rear of Chassis

ION TRAP MAGNET ADJUSTMENT—The ion trap magnet should be positioned close to the base of the tube with the magnet of the ion trap on the side where the electron gun is nearest the glass neck of the picture tube. From this position adjust the magnet by moving it back and forth and at the same time rotating it slightly around the neck of the picture tube until the brightest raster is obtained on the picture screen. Reduce the brightness control setting until the raster is slightly above average brilliance. Readjust the ion trap magnet for maximum raster brilliance and best focus. MAXIMUM RASTER BRILLIANCE AND BEST FOCUS OCCUR AT THE SAME POINT. Do not sacrifice brilliance for best focus. The ion trap magnet adjustment is a very critical one especially with the electrostatic type zero focus picture tube. Consequently, great care should be taken to make sure that the ion trap magnet is correctly adjusted.

DEFLECTION YOKE ADJUSTMENT — If the lines of the raster are not horizontal or squared with the picture mask, rotate the deflection yoke until this condition is obtained. Tighten the yoke adjustment wing screw.

CENTERING ADJUSTMENT — If horizontal or vertical centering is required, adjust each ring in the centering device until proper centering is obtained. If a clamp type centering device is used, rotate the device to the left or right and turn the knob located at the top of the device until the picture is centered correctly.

PICTURE ADJUSTMENT — For further adjustments, obtain a test pattern on the receiver. Turn on receiver and follow tuning procedure. When a test pattern is obtained it may be necessary to slightly re-adjust the fine tuning control for clearest picture.

ADJUSTMENT OF AGC THRESHOLD CONTROL — Tune the receiver to the strongest station in the area in which the receiver will be used. While observing the picture and listening to the sound, turn the control clockwise until signs of overloading (buzz in sound, washed-out picture) appear. Then turn the control a few degrees counter-clockwise from the point at which overloading occurs. (The stronger the signal input, the more counter-clockwise this setting will be.) In areas where the strongest signal does not exceed 10,000 uv the setting will usually be maximum clockwise. With the control set correctly, the AGC will automatically adjust the bias on the R.F. and I.F. amplifiers so that the best possible signal to noise ratio (Minimum snow) will be obtained for any signal input to the receiver.

ADJUSTMENT OF SYNC STABILITY CONTROL — When receiving strong (500 MV or more) signals, set hold controls so that the picture is locked in. Turn the sync control slowly clockwise until bending occurs at top of picture. Then turn the control a few degrees counter-clockwise until bending disappears. If the control is set incorrectly bending, tearing, etc., will be present and when switching from channel to channel the picture will not lock in quickly.

In weak signal areas the control should be set for maximum picture stability. In general the weaker the signal the more clockwise the control should be turned.

When the sync stability control is correctly adjusted the receiver will hold sync without tearing or rolling under even the most adverse noise conditions.

CHECK OF HORIZONTAL OSCILLATOR ALIGNMENT — Tune in a station and adjust the horizontal hold control until the picture falls into sync. Momentarily remove the signal by switching off channel and then back. The picture should pull into sync over a range of 90° rotation of the horizontal hold control. If in the above check the receiver fails to hold sync or the pull-in range is at the extreme end of the control, it will be necessary to make the following adjustment.

HORIZONTAL FREQUENCY ADJUSTMENT — With the horizontal hold control set to the center of its range of rotation, adjust the horizontal frequency control (L-14) until the picture pulls into sync. Recheck the "Horizontal Oscillator Alignment."

HEIGHT AND VERTICAL LINEARITY ADJUSTMENT — Adjust the height control (R-54) until the picture fills the mask vertically. Adjust the vertical linearity control (R-49) until the picture is symmetrical from top to bottom. Adjust the picture centering device to align picture with the mask. Adjustment of any control will require a re-adjustment of the other control.

WIDTH, DRIVE AND LINEARITY ADJUSTMENTS— While receiving a signal from a station (with picture locked in sync) turn contrast control fully counter-clockwise, turn the brightness control (R-25) up so that the picture appears washed out. Adjust width control (L-15) until the picture fills the mask. Turn the horizontal drive control (R-89) clockwise until white bars appear in the left center portion of the raster, then turn counter-clockwise until the white bars just disappear. This adjustment will allow the horizontal system to operate at maximum efficiency. Adjust horizontal linearity control (L-16) for best linearity. If adjustment of the horizontal drive (R-89) or horizontal linearity (L-16) is required, it usually will be necessary to recheck the horizontal oscillator alignment. If adjustment of the horizontal linearity control (L-16) is required, readjustment of the horizontal drive control (R-89) will be necessary. Adjust the picture centering device to align the picture with the mask.

CHECK OF R-F OSCILLATOR ADJUSTMENTS

The oscillator is preset at the factory and normally needs no adjustment. However, if adjustments are required, they can be made without removing the chassis from the cabinet. Remove the channel selector and fine tuning knobs from the tuning shaft.

TEST PROCEDURE:

1. Set channel selector to receive desired station.
2. Set fine tuning control in center of its range.
3. Adjust oscillator slug, with bakelite type screwdriver, for best picture resolution.
4. Repeat steps 1, 2 and 3 on all channels used.

Caution — These adjustments are intended only for VHF Channels. For information regarding UHF alignment, see paragraph "Tuner Alignment".

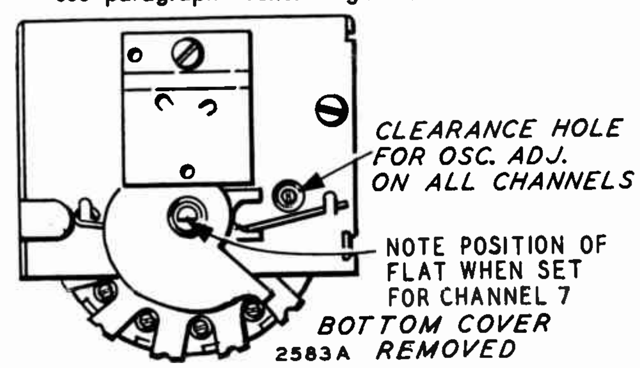

Fig. 5—Tuner Oscillator Adjustments

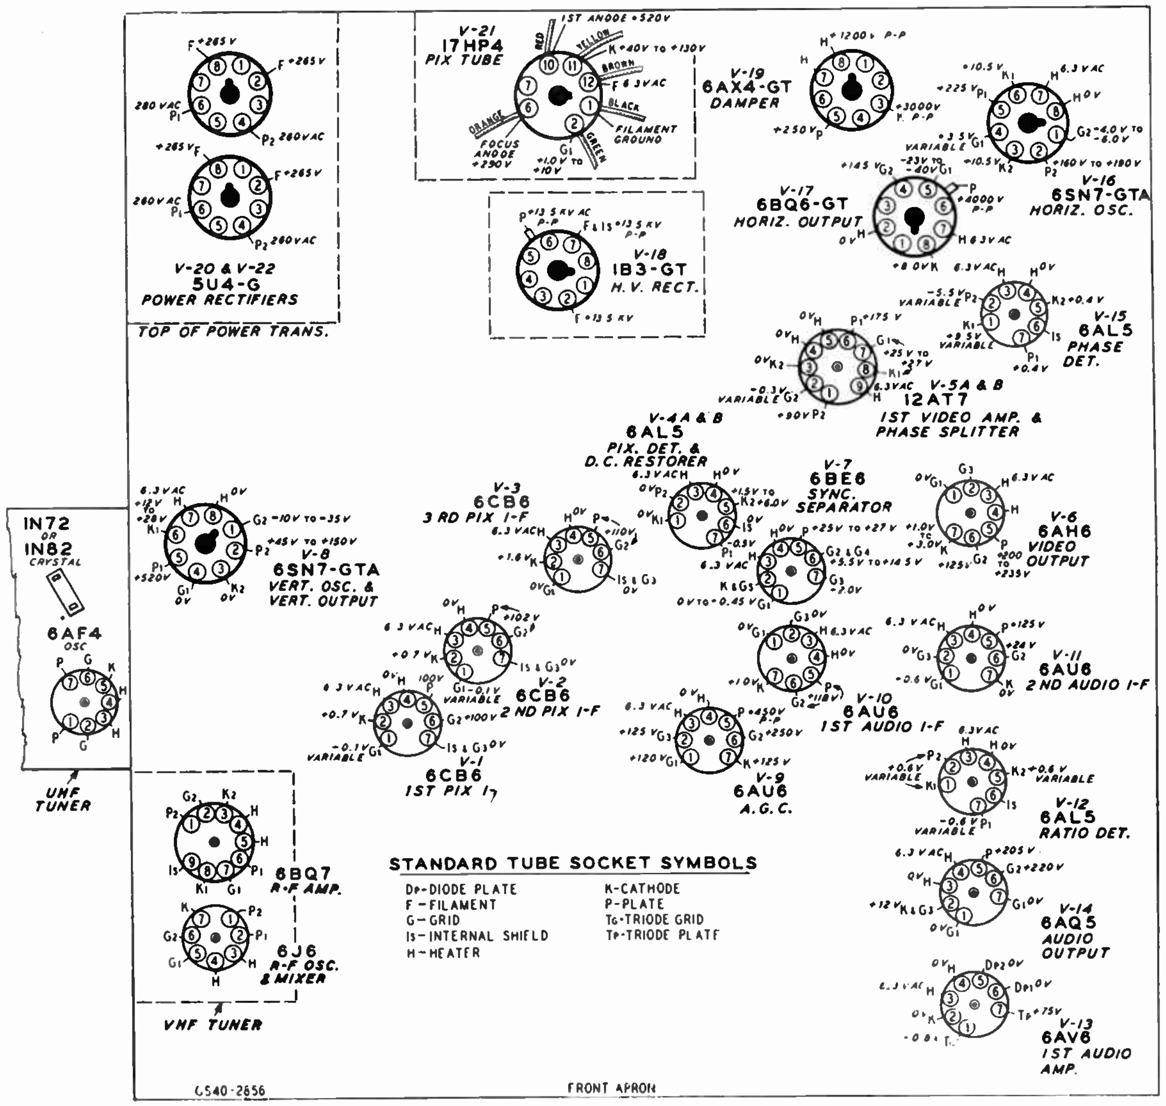

Fig. 6—Bottom Socket Voltages

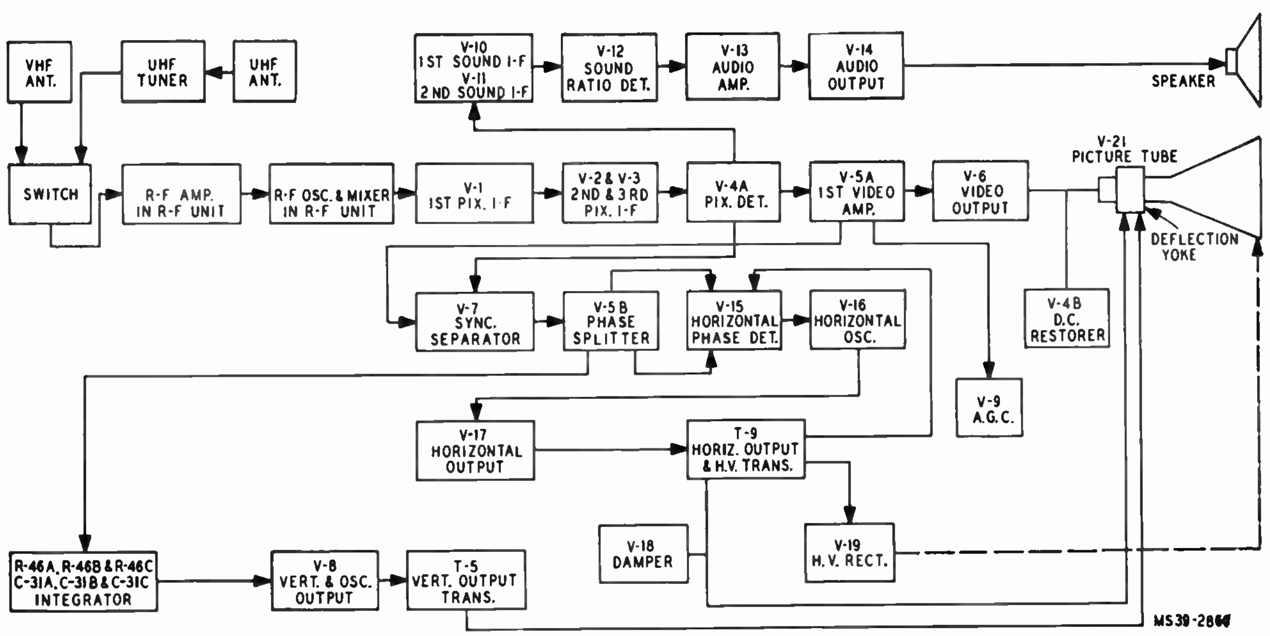

Fig. 7—Block Diagram

SERVICE SUGGESTIONS

NO RASTER ON PICTURE TUBE — If raster cannot be obtained check below for the possible causes.

1: Ion trap magnet adjustment is incorrect.
2: No +B voltage. Check 4/10 ampere fuse. Replace if defective. If fuse continually burns out, check
   (A) Horizontal output tube V-17 (6BQ6-GT)
   (B) Check damper tube V-18 (6AX4-GT).
   (C) Check horizontal oscillator tube V-16 (6SN7-GTA) for proper operation.
   (D) With an ohm meter, check for a short between terminal 1 of the horizontal output transformer (1-9) and the chassis.
   (E) Check DC resistance of T-9.
3: No high voltage. Check V-17, V-18 and V-19 tubes and circuits. If the horizontal deflection circuits are operating as evidenced by the correct voltage (600V) measured on terminal No. 1 of T-9, the trouble can be isolated to the high voltage rectifier circuit. Either the high voltage winding to the 6BQ6-GT plate and 1B3 plate is open, tube V-19 is defective, its filament circuit is open, R-99 and C-78 defective or pix tube elements shorted internally.
4: Defective picture tube heater open or cathode return circuit open.

HORIZONTAL DEFLECTION ONLY — If only horizontal deflection is obtained as evidenced by a straight line across the face of the picture tube, it can be caused by the following:

1: Vertical oscillator and vertical output tube V-8 inoperative. Check socket voltages.
2: Vertical oscillator transformer (T-4) defective.
3: Vertical output transformer (T-5) open or shorted.
4: Yoke vertical coils open or shorted.
5: Vertical hold, height or linearity controls may be defective.

POOR VERTICAL LINEARITY — If adjustment of the height and linearity controls will not correct this condition, any of the following may be the cause.

1: Check variable resistors R-49 and R-54.
2: Vertical output transformer (T-5) defective.
3: Capacitors C-35A, C-39 or C-70 defective.
4: V-8 defective, check voltages.
5: Excess leakage or incorrect value of capacitor C-37, or open or incorrect value of resistors R-55 & R-56.
6: Low plate voltages. Check rectifier tube and capacitors in +B supply circuits.
7: Capacitor C-36 defective.
8: Vertical deflection coils (L-12) defective.

POOR HORIZONTAL LINEARITY — If adjustment of the Horizontal drive and linearity controls does not correct this condition, check the following:

1: Check or replace horizontal output tube V-17.
2: Check or replace damper tube V-18 (6AX4-GT).
3: Check capacitors C-74, C-76, C-77 and horizontal linearity control (L-16) for defects.
4: Horizontal deflection coils (L-17) defective.

TRAPEZOIDAL OR NONSYMMETRICAL RASTER

1: Defective yoke.

WRINKLES ON LEFT SIDE OF RASTER — This condition can be caused by:

1: Defective yoke due to C-75 or R-98 (internal in yoke assembly) being wrong value or open. These components are mounted in rear of yoke assembly.
2: V-18 (6AX4-GT) defective.

SMALL RASTER — This condition can be caused by:

1: Low +B or line voltage. Check V-20 & V-22 (5U4G).
2: Insufficient output from horizontal output tube V-17. Replace tube.
3: Insufficient output from vertical oscillator and vertical output tube V-8. Replace tube.
4: Incorrect setting of horizontal drive control R-89.
5: V-18 (6AX4-GT) defective.
6: Incorrect setting of (L-15) width control.

RASTER; NO IMAGE, BUT ACCOMPANYING SOUND — This condition can be caused by:

1: No signal on picture tube grid. Check V-5A (12AT7) and V-6 (6AH6) tubes and associated circuits.
2: Bad contact to picture tube grid (lead to socket broken).
3: AGC tube (V-9) may be defective. Check tube and its associated circuit.

SIGNAL APPEARS ON PICTURE TUBE GRID BUT IMPOSSIBLE TO SYNCHRONIZE THE PICTURE VERTICALLY AND HORIZONTALLY — A condition of this nature can be caused by:

1: Defective sync separator V-7 or phase splitter V-5B.
2: If tubes are O.K. check voltages, and associated circuits.
3: AGC system inoperative. Check V-9 (6AU6) AGC tube and associated circuits.

SIGNAL ON PICTURE TUBE GRID AND HORIZONTAL SYNC ONLY — If this condition is encountered, check:

1: Vertical integrating network capacitors C-31A, B & C, and resistors R-46 A, B & C.
2: Vertical hold control (R-51) defective.

SIGNAL ON PICTURE TUBE GRID AND VERTICAL SYNC ONLY

1: V-15 or V-16 defective.
2: Improper setting of (L-14) horizontal frequency control.
3: Check setting of horizontal drive control and horizontal linearity control.
4: Check V-15 and V-16 socket voltages.

PICTURE STABLE BUT WITH POOR RESOLUTION — If the picture resolution is not up to standard, it may be caused by any of the following:

1: Defective pix I-F tubes V-1, 2 & 3, (6CB6's).
2: Defective picture detector V-4A, (6AL5) or video amplifier V-5A or video output V-6 (6AH6).
3: Defective picture tube.
4: Open video peaking coil. Check all peaking coils L-5, L-6, L-8, L-9, L-10 and L-11 for continuity. Note that L-5, L-9, L-10 and L-11 have shunting resistors.
5: Leakage in V-6 (6AH6) grid capacitor C-11. If the capacitor is not found to be defective, check the following:
   1: Check all potentials in video circuits.
   2: Check picture tube grid circuit for poor or dirty contact.
   3: Check and realign, if necessary, the picture I-F and R-F circuits.

SERVICE SUGGESTIONS—(continued)

PICTURE SMEAR:

1: A smear can be attributed to phase shift at the low or high frequency end of the video characteristic. This can be caused by improper values of resistors and capacitors in the video circuits. Check for grid current on video output tube V-6 (6AH6), open or shorted peaking coils, video amplifier load resistors are of improper value (high).
2: This trouble can also originate at the transmitter. Check reception from another station.
3: Check and realign, if necessary, the picture I-F and R-F circuits.

MAN MADE NOISE IN SOUND (Ignition, etc)

1: Check sound I-F tubes V-10, 11 & 12 and associated circuits.
2: Check sound I-F alignment.

BENDING OR S-ING

1: Check sync stability control adjustment.
2: Check capacitors C-35B and C-79B.
3: V-17 (6BQ6-GT) defective or V-16 (6SN7-GTA) defective.
4: Check sync separator tube V-7 (6BE6) and phase splitter V-5B (12AT7) and V-5A (12AT7) video amplifier.
5: Check AGC threshold control.

PICTURE NORMAL—NO SOUND OR WEAK OR DISTORTED SOUND

1: Check sound I-F alignment.
2: Check V-10 (6AU6) V-11 (6AU6) V-12 (6AL5) V-13 (6AV6) V-14 (6AQ5) and associated circuits.

RASTER ON TUBE BUT NO PICTURE OR SOUND

This condition can be caused by,
1: Defective pix I-F Amplifier tubes V-1, V-2 or V-3
2: Defective pix detector tube V-4A (6AL5). Check tube and its associated circuit.
3: Defective R-F Amplifier or oscillator mixer tubes in the tuner.
4: UHF-VHF switch defective.

POOR FOCUS

1: Improper setting of Ion Trap magnet.
2: Defective picture tube or picture tube socket.

PICTURE JITTER:

1: If regular sections at left of the picture are displaced, replace the horizontal oscillator tube V-16.
2: Vertical instability may be due to loose connections or noise received with the signal.
3: Horizontal instability may be due to unstable transmitted sync.
4: Check receiver AGC system for proper operation.
5: Check phase splitter V-5B, (12AT7) and sync separator V-7 (6BE6).
6: Check for improper setting of sync stability control.
7: Picture tube grid lead not held in position by support spring, ie: close proximity of grid lead to sync and horizontal tubes will cause picture to jitter at high contrast setting.
8: Check AGC threshold control.

NO PICTURE OR SOUND OR WEAK PICTURE OR SOUND IN UHF POSITION

If this condition is encountered
1: Check to see whether or not a UHF station is operating in the vicinity.
2: The 6AF4 oscillator tube or the IN72 (or IN82) crystal may be defective.
3: Pre-selector in UHF tuner defective.
4: Low pass filter defective.
5: The UHF antenna and oscillator strips in the VHF tuner defective.
6: Defective switch on UHF tuner.

ALIGNMENT PROCEDURE

TEST EQUIPMENT — To service this receiver properly, it is recommended that the following test equipment be available:

R-F SWEEP GENERATOR meeting the following requirements:
(a) Frequency ranges:
18 to 30 mc, 10 mc sweep width
40 to 90 mc, 10 mc sweep width
120 to 130 mc, 10 mc sweep width
170 to 225 mc, 10 mc sweep width
470 to 890 mc, 10 mc sweep width
(b) Output adjustable with at least .1 volt maximum.
(c) Output constant on all ranges.
(d) Flat output in all attenuator positions.

CATHODE-RAY OSCILLOSCOPE preferably one with a wide band vertical deflection and an input calibrating source.

SIGNAL GENERATOR to provide the following frequencies: (Output on these ranges should be adjustable and at least .1 volt maximum.)
(a) Intermediate alignment frequencies.
23.1 mc first picture I-F coil.
24.1 mc third picture I-F coil
25.9 mc second picture I-F coil.
21.7 mc sound trap.
4.5 mc video trap & sound I-F.
25.2 mc converter plate coil (Tuner).

HETERODYNE FREQUENCY METER with crystal calibrator if the signal generator is not crystal controlled.

ELECTRONIC VOLTMETER and a high voltage probe for use with this meter to permit measurements up to 20 kilovolts.

SERVICE PRECAUTIONS — To service the receiver remove the chassis from the cabinet. To do so, remove the knobs, the cabinet back, disconnect the leads from the speaker, remove the antenna terminal boards at rear of cabinet, and then the 5 chassis mounting bolts. The chassis may be serviced with the picture tube in place provided the chassis is turned on its side with the power transformer on the bottom. The weight of the chassis will be supported against the power transformer and pix tube brackets.

CAUTION: Do not permit the kinescope second-anode lead to become shorted to the chassis. To do so will cause a considerable overload on the high voltage filter resistor R-99.

ALIGNMENT PROCEDURE
PIX I-F

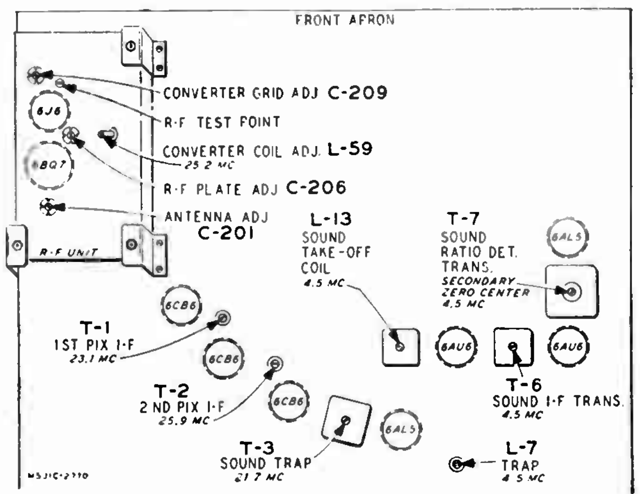

Fig. 8—Top Chassis Video and Audio I-F Adjustments

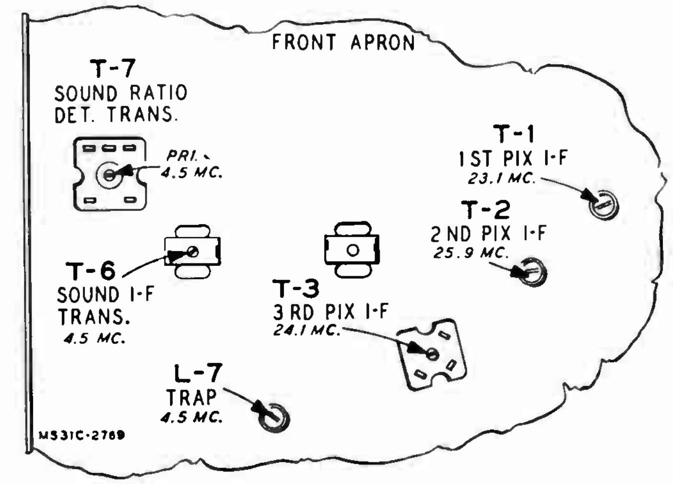

Fig. 9—Bottom Chassis Video and Audio I-F Adjustments.

A. Unmodulated R-F signal into Converter Grid by means of tube shield insulated from base. VTVM with filter in lead of 22 K ohms and 5000 mmf connected to pic. det. load resistor, (R-100) 4700 ohms, in series with peaking coil (L-6) from Pin 7 of 6AL5. Input signal level should be such that output is less than 2 volts DC. Apply -4.5V battery bias on AGC line.

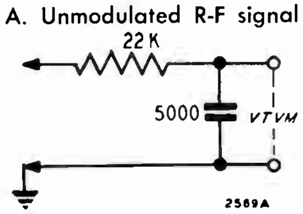

Fig. 10—VTVM Connections

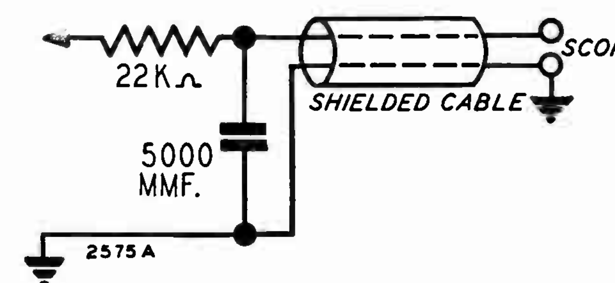

Fig. 11—Oscilloscope Connections

	FREQUENCY	ADJUST
1.	25.2 MC	Converter plate coil on top of tuner for maximum dc at picture detector.
2.	23.1 MC	1st picture I-F coil (T-1) for maximum dc at picture detector.
3.	25.9 MC	2nd picture I-F coil (T-2) for maximum dc at picture detector.
4.	24.1 MC	3rd picture I-F coil (T-3 below chassis) for maximum dc at picture detector.
5.	21.7 MC	3rd picture I-F trap (T-3 in can above chassis) for minimum dc at picture detector.

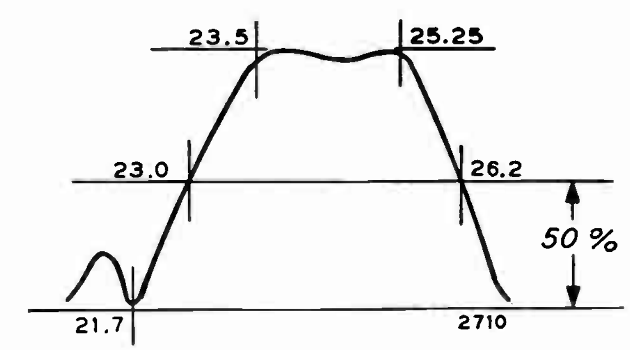

Fig. 12—Overall Response Curve

B. I-F Sweep Generator into converter grid by means of tube shield insulated from base.

Connect oscilloscope across R-100 (in place of VTVM). Apply -4.5V bias (DC) to AGC line (battery).

Tuner should be switched to dead channel so as not to cause interference.

Observe overall I-F response, which should be as shown above: A slight touch-up may be required. At no time should the trap coil be re-adjusted, nor should it be necessary to turn any of the picture I-F coils more than 1/2 turn of the slug. The following comments are suggestions only:

1. The height of the 26.2 MC marker is controlled by the 25.2 MC (Converter Plate Coil on tuner) and the 25.9 MC (2nd P.I.F.) coils.
2. The uniformity of response (flatness across top and position of 23.5 MC) marker is controlled for the most part by the 24.1 MC third picture I-F coil.
3. The 23.0 MC marker position is controlled by the first picture I-F (23.1 MC coil). However, it is NOT advisable to change the setting of the coil, due to its effect on sound rejection. Its adjustment should be avoided unless believed to be absolutely necessary.

VIDEO

With 4.5 MC unmodulated signal from a high impedance source, (10,000 ohms in series with the generator) into plate of the picture detector tube (Pin 7-6AL5) and VTVM on picture tube grid, tune 4.5 MC trap (L-7 Top) for minimum response. VTVM on 0-10 V AC scale. This adjustment can also be made while observing a picture from a station. Tune trap for least 4.5 MC beat in picture.

AUDIO I-F

1: With signal generator set to 4.5 MC and dc VTVM connected to junction of R-62 and C-46, adjust sound take-off coil (L-13 Top) and sound I-F transformer slugs (T-6 Top & Bottom) for maximum.

2: With VTVM connected to pin 7 of V-12 (6AL5) adjust the ratio detector primary (T-7 Bottom) for maximum.

3: With VTVM connected to junction of R-66, R-69 and C-50, adjust ratio detector secondary (T-7 Top) for cross over (zero voltage) on lowest scale.

NOTE — If no signal generator is available, the procedure above may be followed by tuning in a station and using the 4.5 MC beat between picture and sound carrier.

TUNER ALIGNMENT

A. Sweep generator with balanced 300 ohm output to antenna terminals. Marker generator output to antenna terminals. Oscilloscope to "test point" (Figure 13) on tuner. Connect 1½ V bias to AGC line at junction of R-33 and C-20 on the receiver.

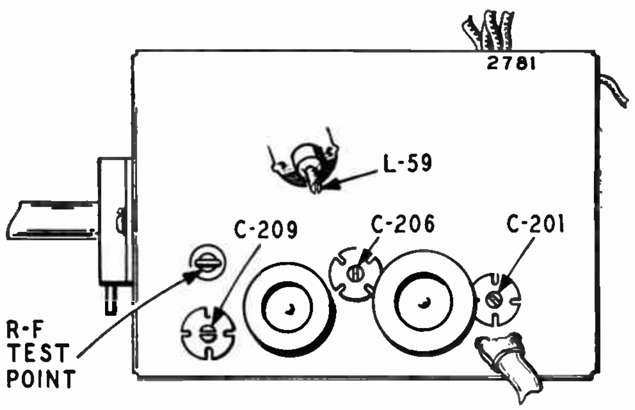

Fig. 13—Top Tuner Adjustments

B. RF AND CONVERTER ADJUSTMENT.

1. With channel selector on Channel 12, adjust C-201 slightly favoring the Pix carrier, then adjust C-206 and C-209 for response as in Figure 14. Picture and sound markers at 90% maximum response.
2. Check response on all channels. If markers are below 70% on any channels, readjust C-201, C-206, and C-209. Recheck all channels.

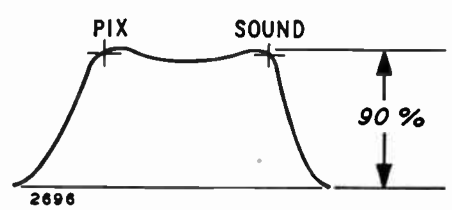

Fig. 14—Pix & Audio Markers

C. OSCILLATOR ADJUSTMENT.

1. Apply -4.5 volts on I-F AGC line at junction of R-1 and C-21.
2. Connect oscilloscope to output of video detector. Place fine tuning in center of range. Check response on all channels. Sound marker should be in notch and picture marker at 50%. (See Figure 12).
3. If markers are off, individual oscillator coil slugs will require adjustment. Adjust each channel slug, accessible through hole in front of chassis with a non-metallic screwdriver to bring sound marker to correct position.
4. To adjust oscillator on UHF position, feed the sweep generator with center frequency of 124 MC and markers at 121.75 and 126.25 into the input of the low pass filter (output of UHF tuner). Adjust oscillator slug in the VHF tuner so that the 121.75 pix carrier marker is at 50% and that 126.25 marker is in the sound notch. If a sweep generator is not available, a single frequency generator set to 126.25 MC and VTVM may be used. Connect VTVM to the pix detector load resistor R-100. Feed generator into the low pass filter. Adjust oscillator slug in the VHF tuner so that the 126.25 marker is in the sound notch of the I-F curve.
5. If the 6AF4 oscillator tube in the UHF tuner is replaced, it may be necessary to adjust the oscillator trimmer C-309 on the UHF tuner located underneath the chassis. (See Figure 15). Adjust this trimmer until the tuner will cover a range of below 470 MC to above 890 MC.

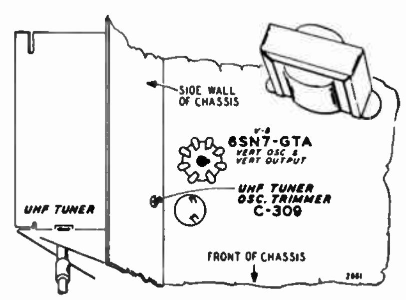

Fig. 15—UHF Tuner Adjustment.

VHF TUNER ASSEMBLY INFORMATION

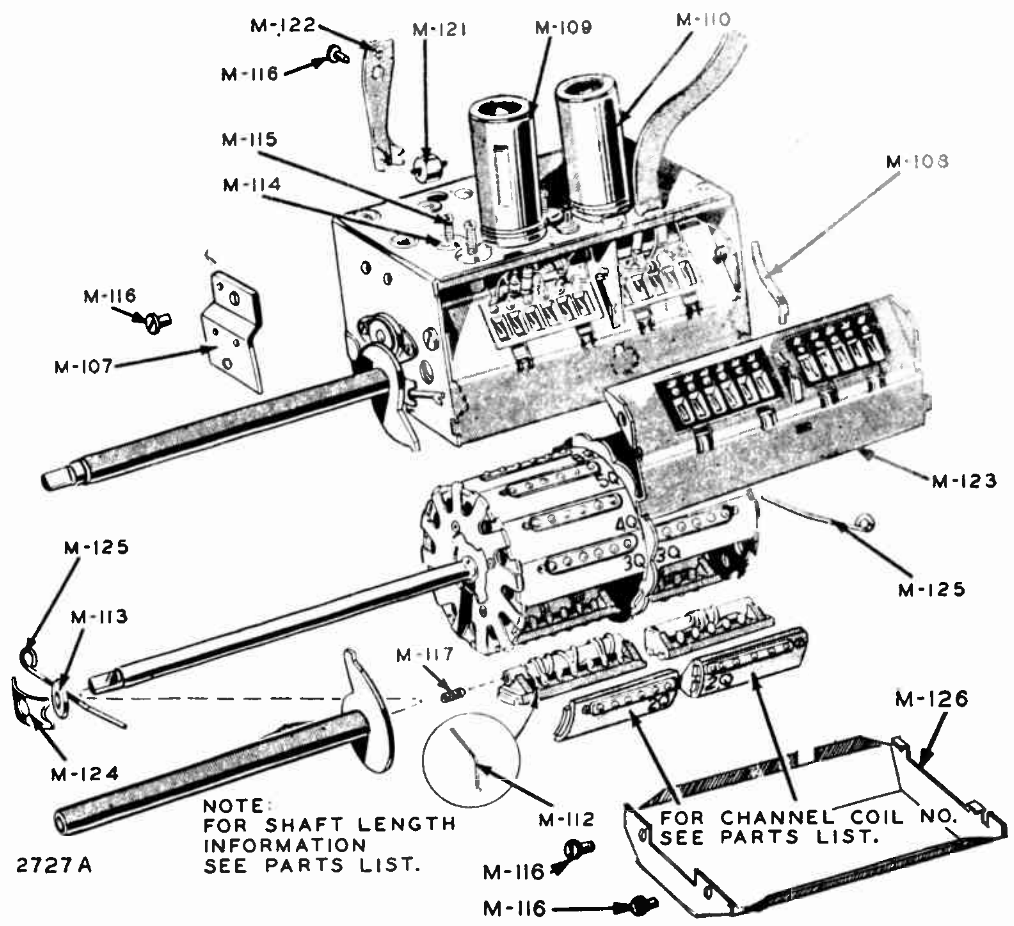

Fig. 16—"Q" Tuner Pictorial.

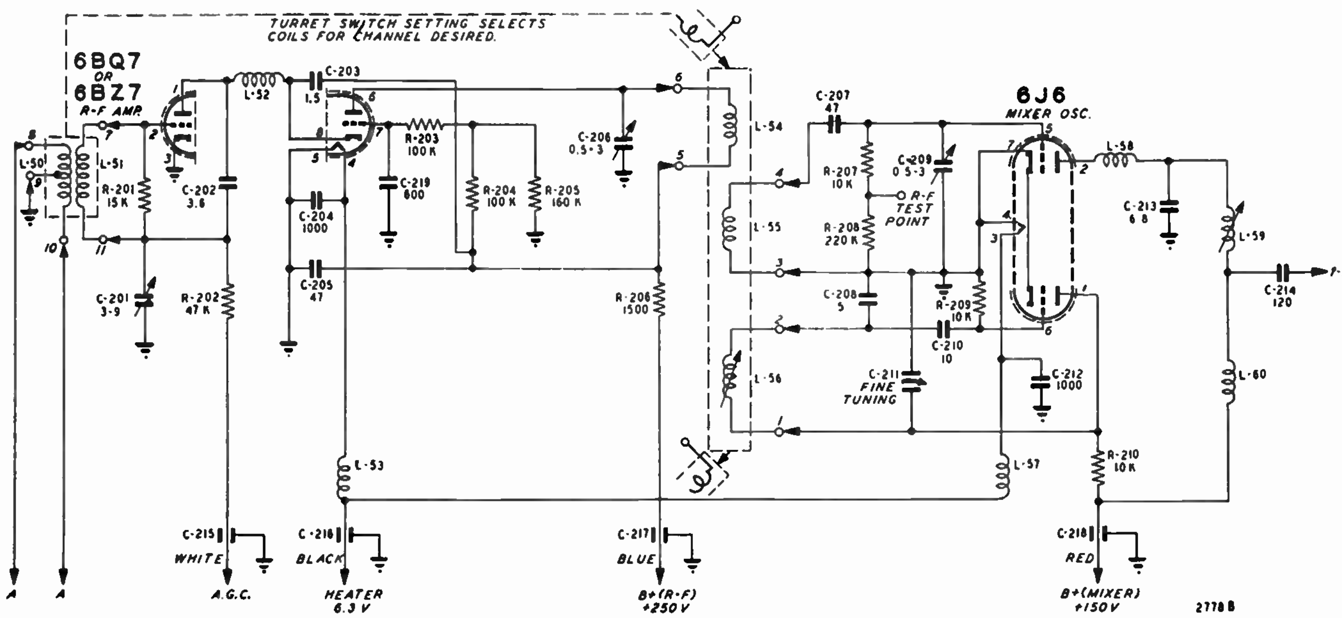

Fig. 17—"Q" Tuner Schematic Diagram.

UHF TUNER INFORMATION

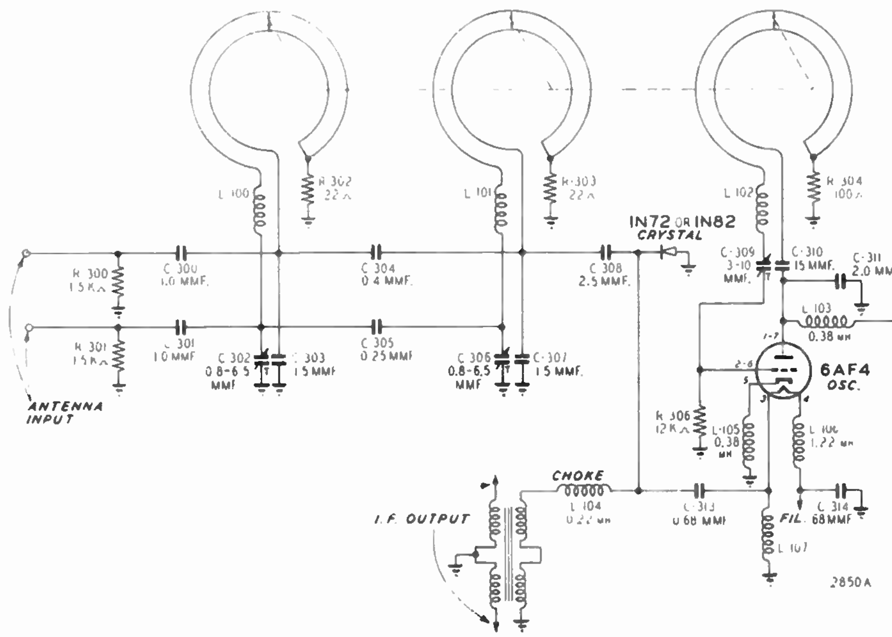

Fig. 18—UHF Tuner Schematic Diagram.

Due to the complexity of the UHF tuner, neither servicing nor aligning is encouraged in the field because replacement of any component within the R-F circuit may disturb the band-pass characteristics of the tuner. However, the 6AF4 tube or the 1N72 (or 1N82) crystal may be replaced in the field if found to be defective. A schematic diagram of this tuner is shown only for the purpose of outlining the circuit used.

If the UHF tuner does not operate satisfactorily after the tube or crystal replacement, disconnect the tuner and return it to the factory for repair.

DRIVE CORD REPLACEMENT

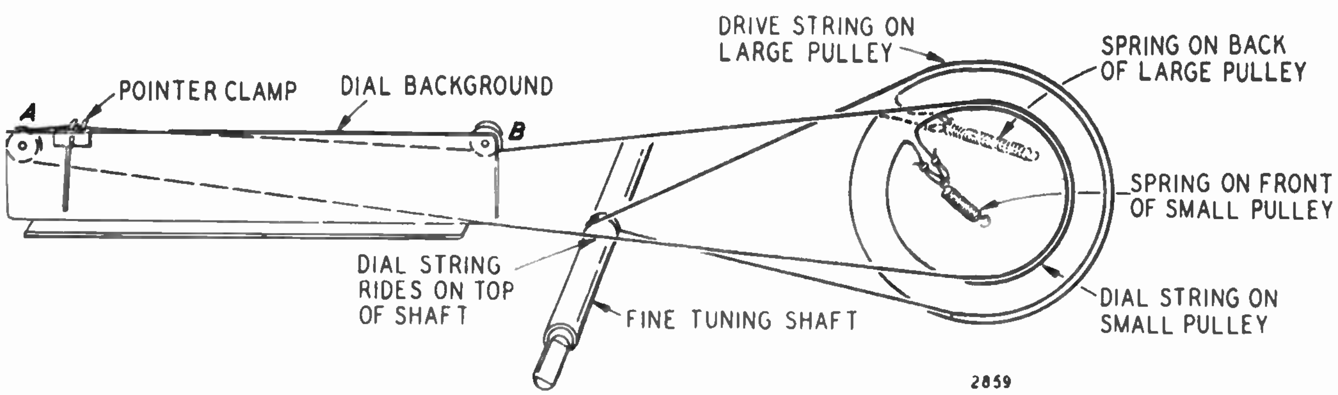

Fig. 19—Drive Cord Stringing.

You will note that there are two cords used for the pointer drive system on this receiver. Part number 10X88 Drive Cord assembly and part number 28X603 Spring are used on the tuning shaft and large pulley, while part number 10X89 Drive Cord and a part number 28X603 Spring are used on the small pulley system and the pointer. Install the cords as shown in the illustration. After completing the installation rotate the fine tuning shaft a few turns to take up the slack in the cord.

OSCILLOSCOPE WAVEFORM PATTERNS

The waveforms on this page were taken with the receiver tuned to a normal picture. The numbers on the waveforms correspond to the numbers on the schematic diagram which identifies each test point.
The voltages shown on each waveform are the approximate peak to peak amplitudes. The frequencies shown indicates the repetition rate of the waveform, not the sweep rate of the oscilloscope. If the waveforms are observed on the oscilloscope with a poor high frequency response, the corners of the pulses will tend to be more rounded than those shown below and the amplitudes of any high frequency pulse will tend to be less.

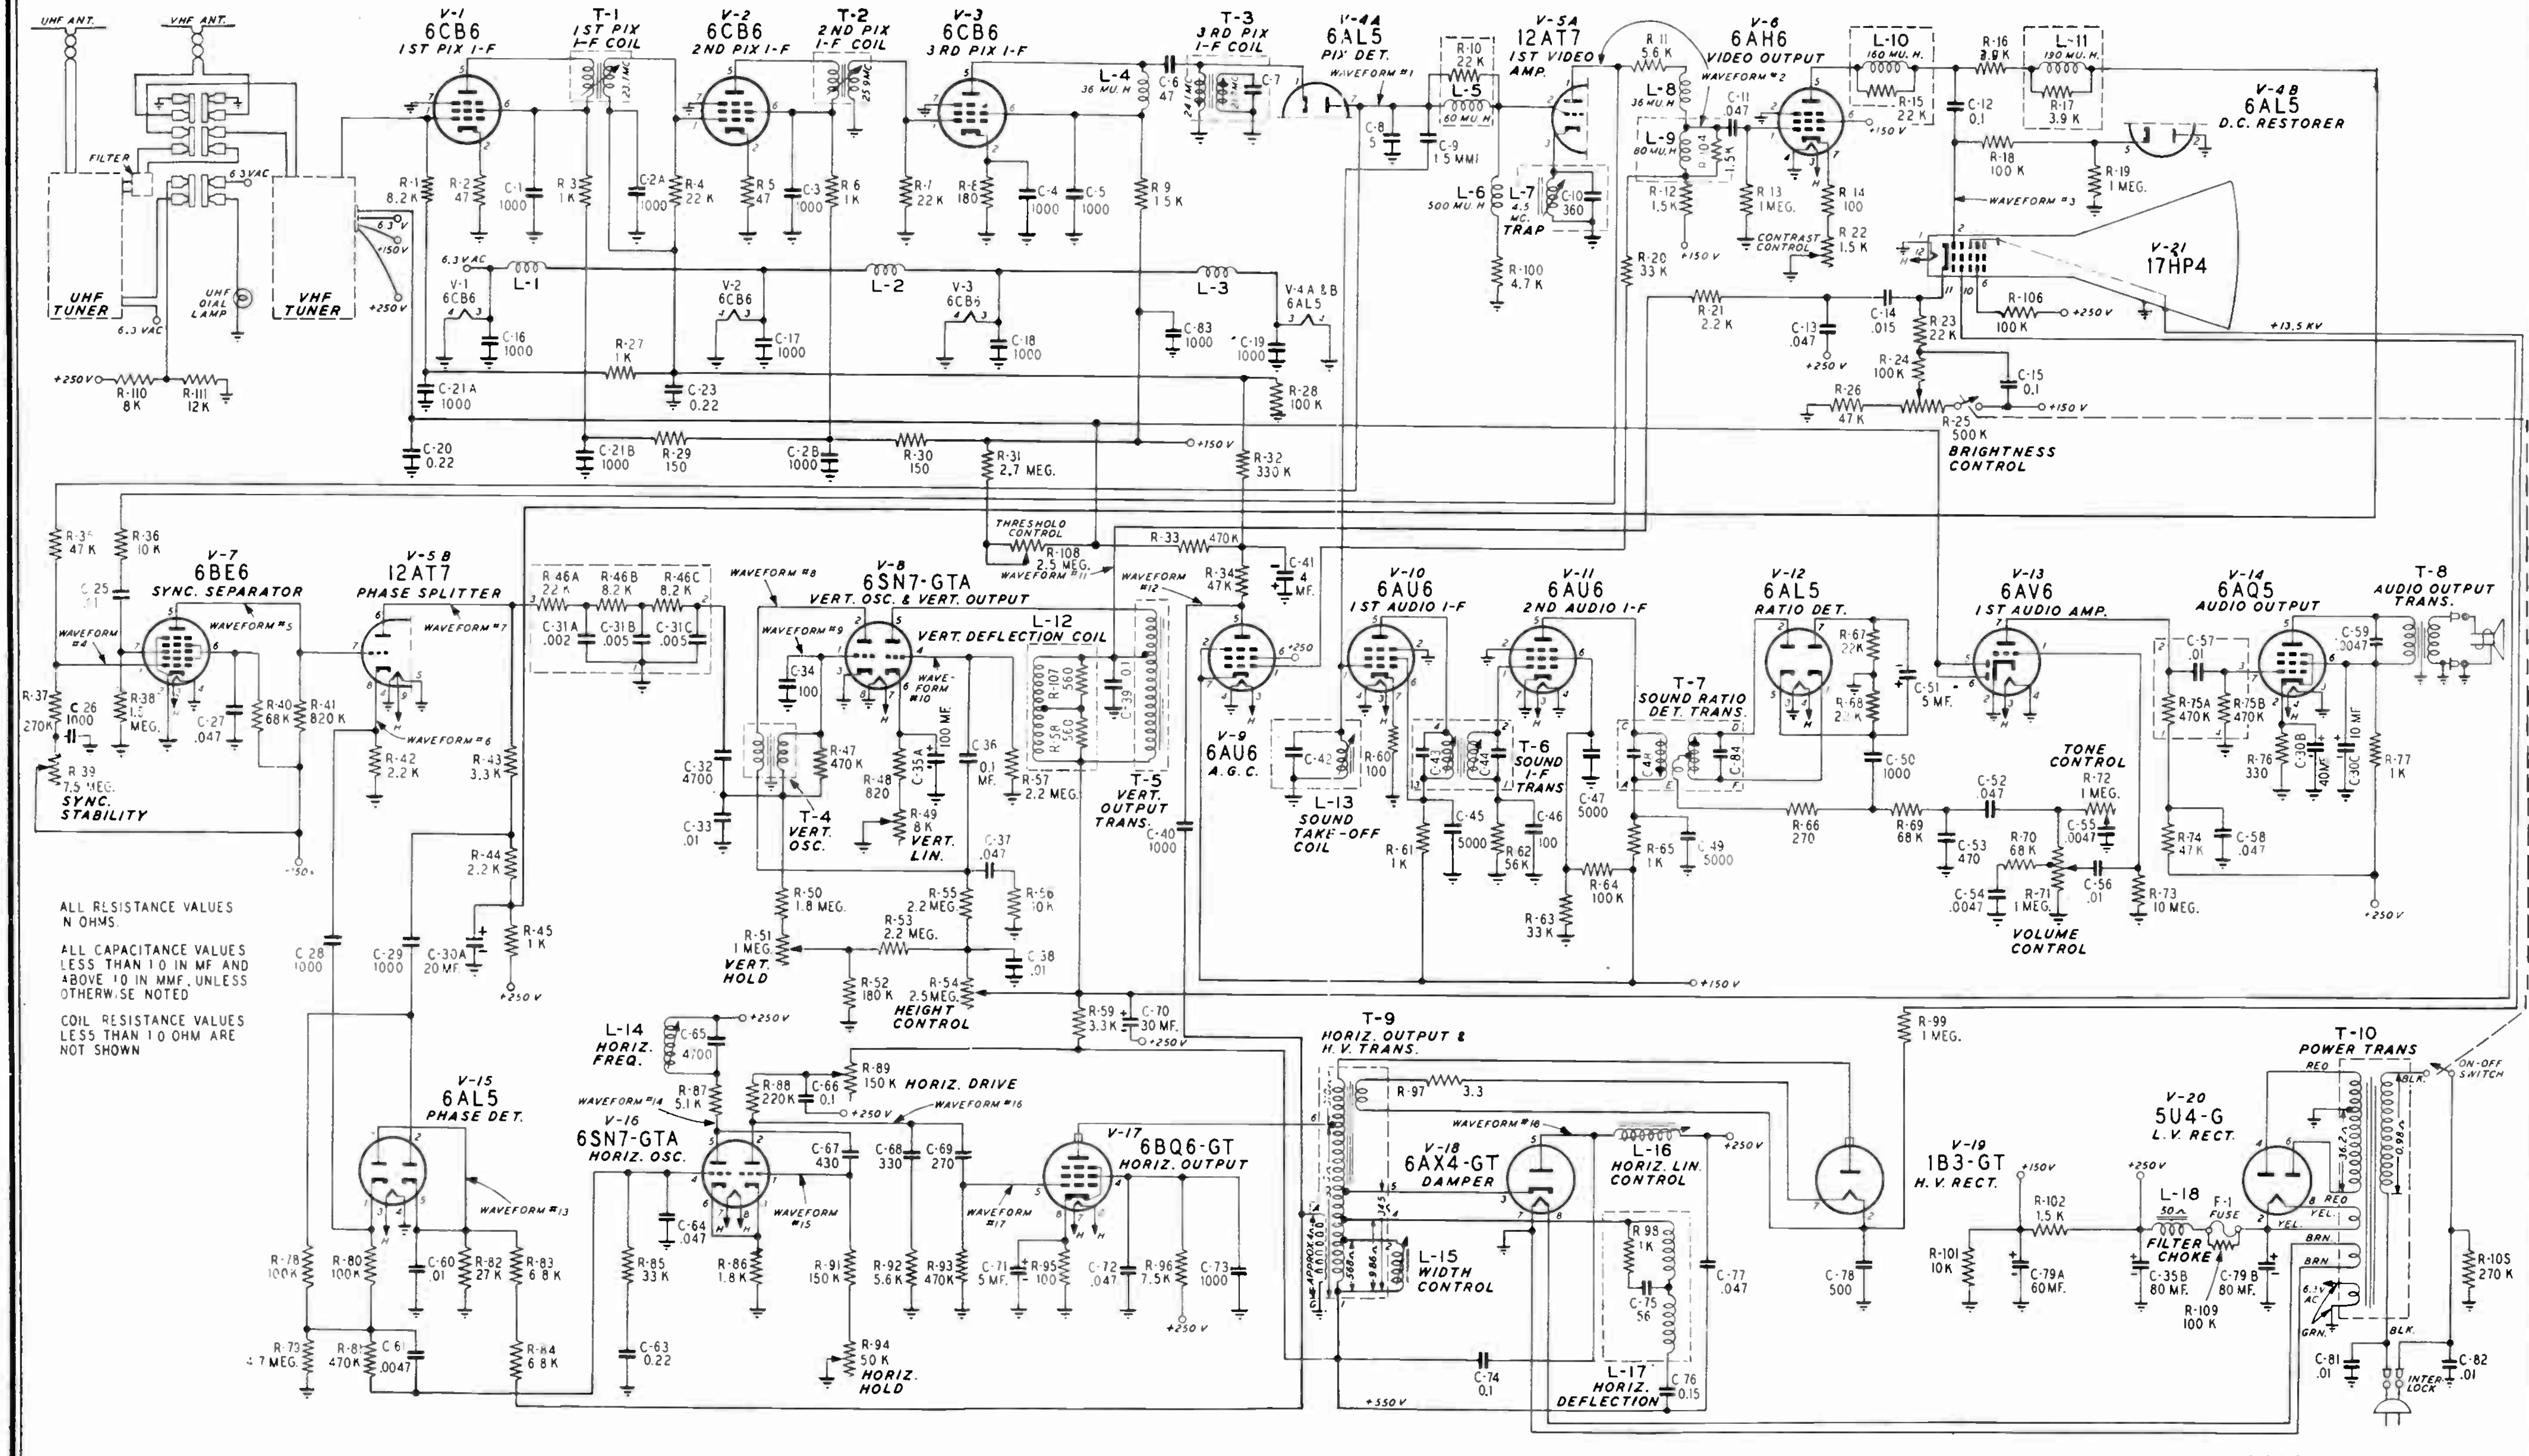
17" UHF-VHF TELEVISION RECEIVER



PRODUCTION CHANGES

There are two different ratio detector transformers (T-7) used in these receivers, Part Numbers 9A2269 and 9A2295. The T-7 circuit shown in this schematic diagram covers the 9A2269 ratio detector. Receivers using the 9A2295 ratio detector can be identified by the following changes:

C-50 becomes 47X570 330 mmf molded mica condenser

R-64 becomes B84333 33K ohm 0.5 W carbon resistor

R-67, R-68 become B83103 10K ohm 0.5 W carbon resistors

In addition, the 9A2295 ratio detector has terminals with numerical identification (1, 2, 3 etc.) whereas the 9A2269 ratio detector has terminals with alphabetical identification (A, B, C etc.)

VHF TUNER ASSEMBLY PARTS LIST

Use only GENUINE factory tested parts to insure service jobs you can depend on and to obtain original set performance.

RESISTORS

Ref. No.	Part No.	Ohms	Tolerance	Watts
R-201	12A-004	15 K	±10%	0.5
R-202	12A-039	47 K	±20%	0.5
R-203	12A-094	100 K	±10%	0.5
R-204	12A-166	100 K	±5%	0.5
R-205	12A-167	160 K	±5%	0.5
R-206	12A-183	1500	±10%	0.5
R 207, R 209, R 210	12A-040	10 K	±10%	0.5
R 208	12A-041	220 K	±20%	0.5

CAPACITORS

Ref. No.	Part No.	Capacity	Tolerance

V-18	6AX4-GT	Damper
V-19	1B3-GT	High Voltage Rectifier
V-20 & V-22	5U4-G	Low Voltage Rectifier
V-21	21MP4	Picture Tube 21" Metal Rectangular (Electrostatic)

*For replacement purposes a 6BZ7 tube may be used in place of a 6BQ7 tube.

PICTURE TUBE SAFETY GLASS

PICTURE TUBE SAFETY GLASS — It will be necessary to clean the picture tube safety glass and the face of the picture tube occasionally. Remove the screws and cleat as outlined in the illustration. Insert your fingers into the opening at the center of the frame and carefully lift up and pull out the safety glass. Clean the safety glass and the face of the picture tube with a soft lint-free cloth dampened with water or mild soapsuds.

For models that have the cleat and screws at the top of the cabinet the following caution must be observed. CAUTION — UPON REMOVAL OF THE LAST SCREW AND THE CLEAT THE GLASS MAY FALL FORWARD. SUPPORT THE GLASS WITH ONE HAND AS YOU LIFT IT GENTLY FROM THE CABINET.

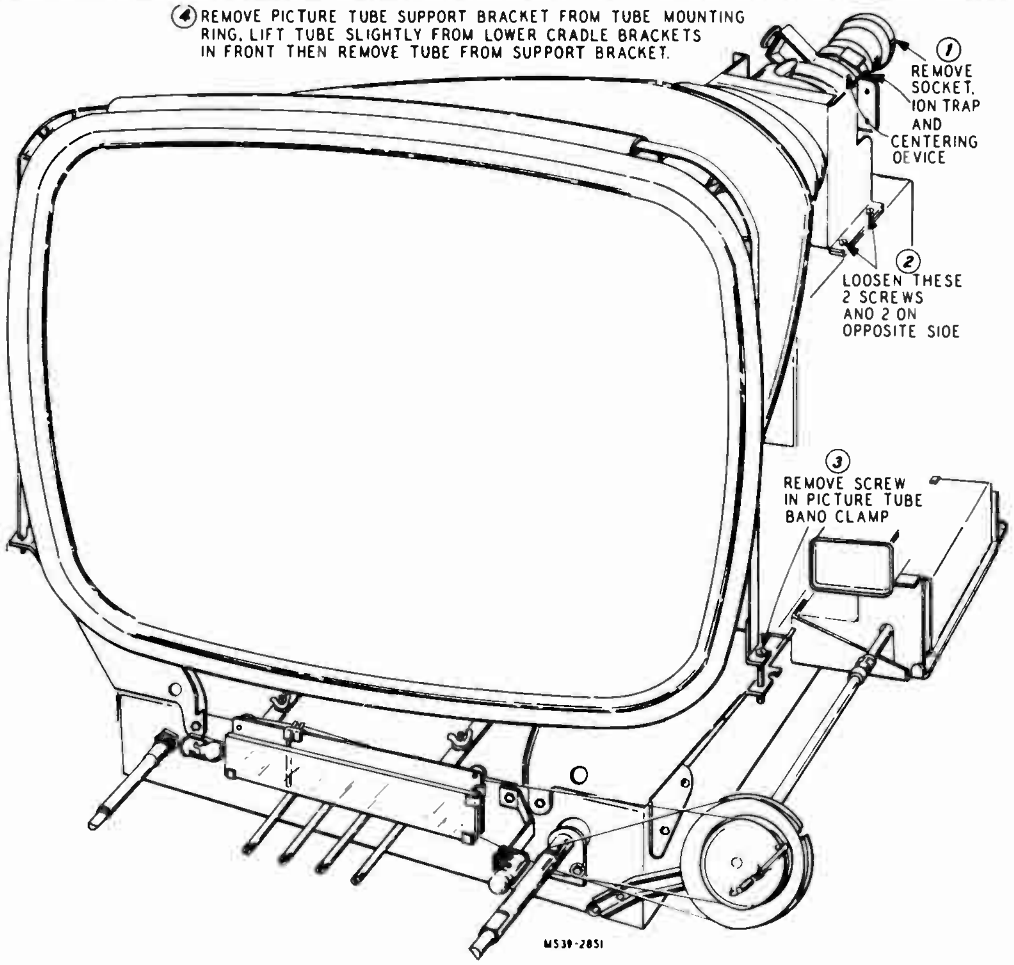

Fig. 3—Removal of Picture Tube

WARNING — Before handling the picture tube, it will be necessary to remove the static charge. In receivers with glass picture tubes, ground the anode lead to chassis, and insert an insulated wire from the well in the tube to chassis. In receivers with metal picture tubes, remove the static charge by grounding an insulated wire from the chassis to the metal portion of the tube.

PICTURE TUBE REPLACEMENT — To replace the picture tube it is necessary to remove the chassis from the cabinet. This may be accomplished in the following manner:

1. Remove the front panel control knobs by pulling them straight from their shafts.
2. Remove the cabinet back.
3. Disconnect the leads from the speaker, remove the antenna terminal board at the rear of the cabinet and then the five chassis mounting bolts. Pull chassis CAREFULLY out of the cabinet.
4. Remove the picture tube as shown and outlined in the illustration. To install a new picture tube, reverse the procedure making sure that the picture tube fits close against the picture tube cushion. If the picture tube sticks or fails to slip into place smoothly, investigate and remove the source of the trouble. Never force the tube. It is important that all the clips and shims used in mounting the tube be replaced, otherwise difficulty may be encountered when horizontal or vertical centering is required.

FRONT OF CHASSIS

(Accessible After Opening Front Panel Control Cover)

Height	R-54
Sync Stability	R-39
AGC Threshold Control	R-108

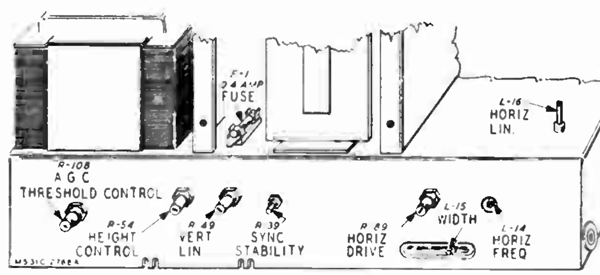

Fig. 4—Adjustments Rear of Chassis

ION TRAP MAGNET ADJUSTMENT—The ion trap magnet should be positioned close to the base of the tube with the magnet of the ion trap on the side where the electron gun is nearest the glass neck of the picture tube. From this position adjust the magnet by moving it back and forth and at the same time rotating it slightly around the neck of the picture tube until the brightest raster is obtained on the picture screen. Reduce the brightness control setting until the raster is slightly above average brilliance. Readjust the ion trap magnet for maximum raster brilliance and best focus. MAXIMUM RASTER BRILLIANCE AND BEST FOCUS OCCUR AT THE SAME POINT. Do not sacrifice brilliance for best focus. The ion trap magnet adjustment is a very critical one especially with the electrostatic type zero focus picture tube. Consequently, great care should be taken to make sure that the ion trap magnet is correctly adjusted.

DEFLECTION YOKE ADJUSTMENT — If the lines of the raster are not horizontal or squared with the picture mask, rotate the deflection yoke until this condition is obtained. Tighten the yoke adjustment wing screw.

CENTERING ADJUSTMENT — If horizontal or vertical centering is required, adjust each ring in the centering device until proper centering is obtained. If a clamp type centering device is used, rotate the device to the left or right and turn the knob located at the top of the device until the picture is centered correctly.

PICTURE ADJUSTMENT — For further adjustments, obtain a test pattern on the receiver. Turn on receiver and follow tuning procedure. When a test pattern is obtained it may be necessary to slightly re-adjust the fine tuning control for clearest picture.

ADJUSTMENT OF AGC THRESHOLD CONTROL — Tune the receiver to the strongest station in the area in which the receiver will be used. While observing the picture and listening to the sound, turn the control clockwise until signs of overloading (buzz in sound, washed-out picture) appear. Then turn the control a few degrees counter-clockwise from the point at which overloading occurs. (The stronger the signal input, the more counter-clockwise this setting will be.) In areas where the strongest signal does not exceed 10,000 uv the setting will usually be maximum clockwise. With the control set correctly, the AGC will automatically adjust the bias on the R.F. and I.F. amplifiers so that the best possible signal to noise ratio (Minimum snow) will be obtained for any signal input to the receiver.

ADJUSTMENT OF SYNC STABILITY CONTROL — When receiving strong (500 MV or more) signals, set hold controls so that the picture is locked in. Turn the sync control slowly clockwise until bending occurs at top of picture. Then turn the control a few degrees counter-clockwise until bending disappears. If the control is set incorrectly bending, tearing, etc., will be present and when switching from channel to channel the picture will not lock in quickly.

In weak signal areas the control should be set for maximum picture stability. In general the weaker the signal the more clockwise the control should be turned.

When the sync stability control is correctly adjusted the receiver will hold sync without tearing or rolling under even the most adverse noise conditions.

CHECK OF HORIZONTAL OSCILLATOR ALIGNMENT — Tune in a station and adjust the horizontal hold control until the picture falls into sync. Momentarily remove the signal by switching off channel and then back. The picture should pull into sync over a range of 90° rotation of the horizontal hold control. If in the above check the receiver fails to hold sync or the pull-in range is at the extreme end of the control, it will be necessary to make the following adjustment.

HORIZONTAL FREQUENCY ADJUSTMENT — With the horizontal hold control set to the center of its range of rotation, adjust the horizontal frequency control (L-14) until the picture pulls into sync. Recheck the "Horizontal Oscillator Alignment."

HEIGHT AND VERTICAL LINEARITY ADJUSTMENT — Adjust the height control (R-54) until the picture fills the mask vertically. Adjust the vertical linearity control (R-49) until the picture is symmetrical from top to bottom. Adjust the picture centering device to align picture with the mask. Adjustment of any control will require a re-adjustment of the other control.

WIDTH, DRIVE AND LINEARITY ADJUSTMENTS— While receiving a signal from a station (with picture locked in sync) turn contrast control fully counter-clockwise, turn the brightness control (R-25) up so that the picture appears washed out. Adjust width control (L-15) until the picture fills the mask. Turn the horizontal drive control (R-89) clockwise until white bars appear in the left center portion of the raster, then turn counter-clockwise until the white bars just disappear. This adjustment will allow the horizontal system to operate at maximum efficiency. Adjust horizontal linearity control (L-16) for best linearity. If adjustment of the horizontal drive (R-89) or horizontal linearity (L-16) is required, it usually will be necessary to recheck the horizontal oscillator alignment. If adjustment of the horizontal linearity control (L-16) is required, readjustment of the horizontal drive control (R-89) will be necessary. Adjust the picture centering device to align the picture with the mask.

CHECK OF R-F OSCILLATOR ADJUSTMENTS

The oscillator is preset at the factory and normally needs no adjustment. However, if adjustments are required, they can be made without removing the chassis from the cabinet. Remove the channel selector and fine tuning knobs from the tuning shaft.

TEST PROCEDURE:

1. Set channel selector to receive desired station.
2. Set fine tuning control in center of its range.
3. Adjust oscillator slug, with bakelite type screwdriver, for best picture resolution.
4. Repeat steps 1, 2 and 3 on all channels used.

Caution — These adjustments are intended only for VHF Channels. For information regarding UHF alignment, see paragraph "Tuner Alignment".

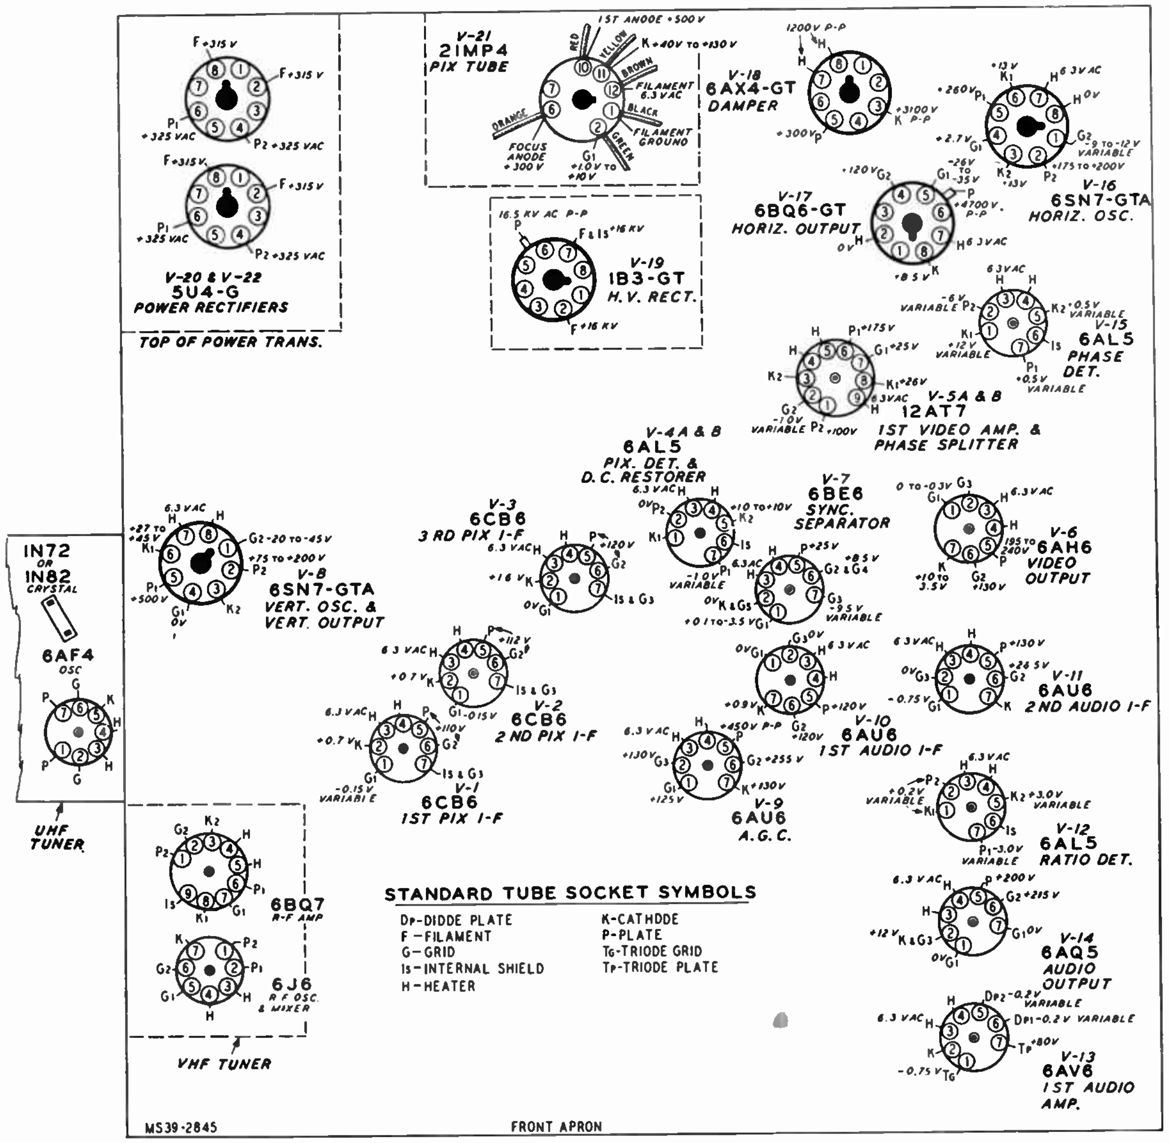

Fig. 6—Bottom Socket Voltages

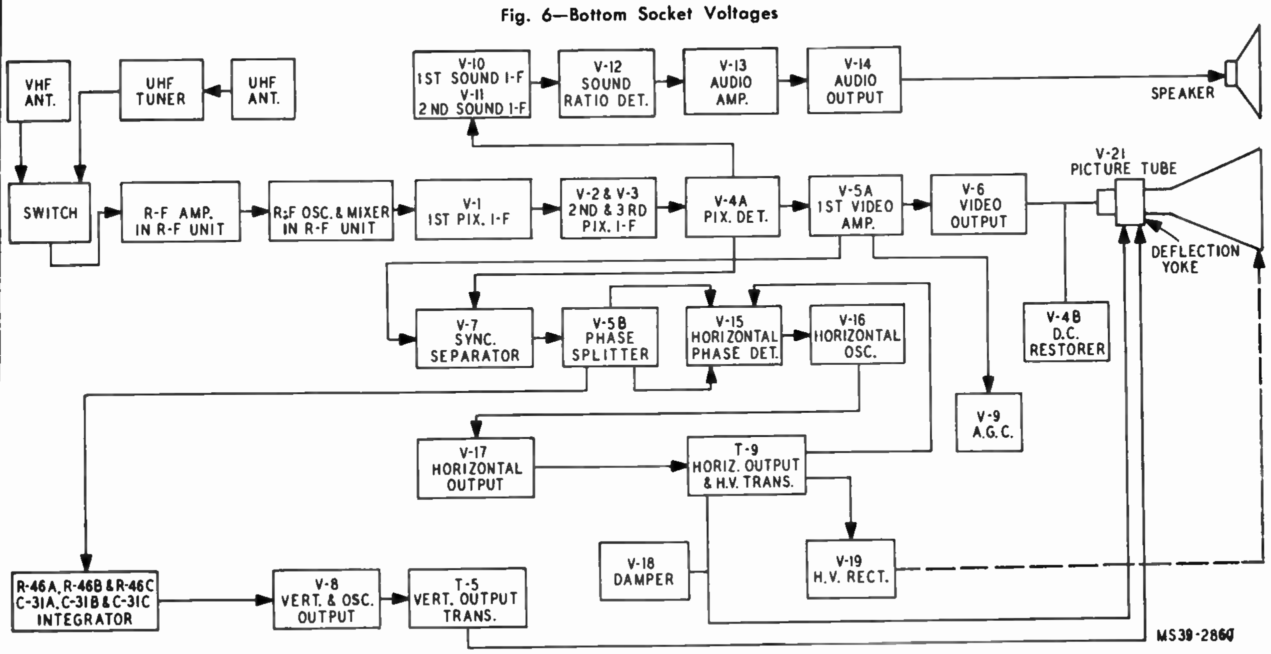

Fig. 7—Block Diagram

SERVICE SUGGESTIONS

NO RASTER ON PICTURE TUBE — If raster cannot be obtained check below for the possible causes.

1: Ion trap magnet adjustment is incorrect.
2: No +B voltage. Check 4/10 ampere fuse. Replace if defective. If fuse continually burns out, check
   (A) Horizontal output tube V-17 (6BQ6-GT)
   (B) Check damper tube V-18 (6AX4-GT).
   (C) Check horizontal oscillator tube V-16 (6SN7-GTA) for proper operation.
   (D) With an ohm meter, check for a short between terminal 1 of the horizontal output transformer (T-9) and the chassis.
   (E) Check DC resistance of T-9.
3: No high voltage. Check V-17, V-18 and V-19 tubes and circuits. If the horizontal deflection circuits are operating as evidenced by the correct voltage (600V) measured on terminal No. 1 of T-9, the trouble can be isolated to the high voltage rectifier circuit. Either the high voltage winding to the 6BQ6-GT plate and 1B3 plate is open, tube V-19 is defective, its filament circuit is open, R-99 and C-78 defective or pix tube elements shorted internally.
4: Defective picture tube heater open or cathode return circuit open.

HORIZONTAL DEFLECTION ONLY — If only horizontal deflection is obtained as evidenced by a straight line across the face of the picture tube, it can be caused by the following:

1: Vertical oscillator and vertical output tube V-8 inoperative. Check socket voltages.
2: Vertical oscillator transformer (T-4) defective.
3: Vertical output transformer (T-5) open or shorted.
4: Yoke vertical coils open or shorted.
5: Vertical hold, height or linearity controls may be defective.

POOR VERTICAL LINEARITY — If adjustment of the height and linearity controls will not correct this condition, any of the following may be the cause.

1: Check variable resistors R-49 and R-54.
2: Vertical output transformer (T-5) defective.
3: Capacitors C-35A, C-39 or C-70 defective.
4: V-8 defective, check voltages.
5: Excess leakage or incorrect value of capacitor C-37, or open or incorrect value of resistors R-55 & R-56.
6: Low plate voltages. Check rectifier tube and capacitors in +B supply circuits.
7: Capacitor C-36 defective.
8: Vertical deflection coils (L-12) defective.

POOR HORIZONTAL LINEARITY — If adjustment of the Horizontal drive and linearity controls does not correct this condition, check the following:

1: Check or replace horizontal output tube V-17.
2: Check or replace damper tube V-18 (6AX4-GT).
3: Check capacitors C-74, C-76, C-77 and horizontal linearity control (L-16) for defects.
4: Horizontal deflection coils (L-17) defective.

TRAPEZOIDAL OR NONSYMMETRICAL RASTER

1: Defective yoke.

WRINKLES ON LEFT SIDE OF RASTER — This condition can be caused by:

1: Defective yoke due to C-75 or R-98 (internal in yoke assembly) being wrong value or open. These components are mounted in rear of yoke assembly.
2: V-18 (6AX4-GT) defective.

SMALL RASTER — This condition can be caused by:

1: Low +B or line voltage. Check V-20 & V-22 (5U4G).
2: Insufficient output from horizontal output tube V-17. Replace tube.
3: Insufficient output from vertical oscillator and vertical output tube V-8. Replace tube.
4: Incorrect setting of horizontal drive control R-89.
5: V-18 (6AX4-GT) defective.
6: Incorrect setting of (L-15) width control.

RASTER; NO IMAGE, BUT ACCOMPANYING SOUND — This condition can be caused by:

1: No signal on picture tube grid. Check V-5A (12AT7) and V-6 (6AH6) tubes and associated circuits.
2: Bad contact to picture tube grid (lead to socket broken).
3: AGC tube (V-9) may be defective. Check tube and its associated circuit.

SIGNAL APPEARS ON PICTURE TUBE GRID BUT IMPOSSIBLE TO SYNCHRONIZE THE PICTURE VERTICALLY AND HORIZONTALLY — A condition of this nature can be caused by:

1: Defective sync separator V-7 or phase splitter V-5B.
2: If tubes are O.K. check voltages, and associated circuits.
3: AGC system inoperative. Check V-9 (6AU6) AGC tube and associated circuits.

SIGNAL ON PICTURE TUBE GRID AND HORIZONTAL SYNC ONLY — If this condition is encountered, check:

1: Vertical integrating network capacitors C-31A, B & C, and resistors R-46 A, B & C.
2: Vertical hold control (R-51) defective.

SIGNAL ON PICTURE TUBE GRID AND VERTICAL SYNC ONLY

1: V-15 or V-16 defective.
2: Improper setting of (L-14) horizontal frequency control.
3: Check setting of horizontal drive control and horizontal linearity control.
4: Check V-15 and V-16 socket voltages.

PICTURE STABLE BUT WITH POOR RESOLUTION — If the picture resolution is not up to standard, it may be caused by any of the following:

1: Defective pix I-F tubes V-1, 2 & 3, (6CB6's).
2: Defective picture detector V-4A, (6AL5) or video amplifier V-5A or video output V-6 (6AH6).
3: Defective picture tube.
4: Open video peaking coil. Check all peaking coils L-5, L-6, L-8, L-9, L-10 and L-11 for continuity. Note that L-5, L-9 and L-10 have shunting resistors.
5: Leakage in V-6 (6AH6) grid capacitor C-11. If the capacitor is not found to be defective, check the following:
   1: Check all potentials in video circuits.
   2: Check picture tube grid circuit for poor or dirty contact.
   3: Check and realign, if necessary, the picture I-F and R-F circuits.

SERVICE SUGGESTIONS—(continued)

PICTURE SMEAR:

1: A smear can be attributed to phase shift at the low or high frequency end of the video characteristic. This can be caused by improper values of resistors and capacitors in the video circuits. Check for grid current on video output tube V-6 (6AH6), open or shorted peaking coils, video amplifier load resistors are of improper value (high).
2: This trouble can also originate at the transmitter. Check reception from another station.
3: Check and realign, if necessary, the picture I-F and R-F circuits.

MAN MADE NOISE IN SOUND (Ignition, etc)

1: Check sound I-F tubes V-10, 11 & 12 and associated circuits.
2: Check sound I-F alignment.

BENDING OR S-ING

1: Check sync stability control adjustment.
2: Check capacitors C-35B and C-79B.
3: V-17 (6BQ6-GT) defective or V-16 (6SN7-GTA) defective.
4: Check sync separator tube V-7 (6BE6) and phase splitter V-5B (12AT7) and V-5A (12AT7) video amplifier.
5: Check AGC threshold control.

PICTURE NORMAL—NO SOUND OR WEAK OR DISTORTED SOUND

1: Check sound I-F alignment.
2: Check V-10 (6AU6) V-11 (6AU6) V-12 (6AL5) V-13 (6AV6) V-14 (6AQ5) and associated circuits.

RASTER ON TUBE BUT NO PICTURE OR SOUND

This condition can be caused by,
1: Defective pix I-F Amplifier tubes V-1, V-2 or V-3
2: Defective pix detector tube V-4A (6AL5). Check tube and its associated circuit.
3: Defective R-F Amplifier or oscillator mixer tubes in the tuner.
4: UHF-VHF switch defective.

POOR FOCUS

1: Improper setting of Ion Trap magnet.
2: Defective picture tube or picture tube socket.

PICTURE JITTER:

1: If regular sections at left of the picture are displaced, replace the horizontal oscillator tube V-16.
2: Vertical instability may be due to loose connections or noise received with the signal.
3: Horizontal instability may be due to unstable transmitted sync.
4: Check receiver AGC system for proper operation.
5: Check phase splitter V-5B, (12AT7) and sync separator V-7 (6BE6).
6: Check for improper setting of sync stability control.
7: Picture tube grid lead not held in position by support spring, ie: close proximity of grid lead to sync and horizontal tubes will cause picture to jitter at high contrast setting.
8: Check AGC threshold control.

NO PICTURE OR SOUND OR WEAK PICTURE OR SOUND IN UHF POSITION

If this condition is encountered
1: Check to see whether or not a UHF station is operating in the vicinity.
2: The 6AF4 oscillator tube or the IN72 (or IN82) crystal may be defective.
3: Pre-selector in UHF tuner defective.
4: Low pass filter defective.
5: The UHF antenna and oscillator strips in the VHF tuner defective.
6: Defective switch on UHF tuner.

ALIGNMENT PROCEDURE

TEST EQUIPMENT — To service this receiver properly, it is recommended that the following test equipment be available:

R-F SWEEP GENERATOR meeting the following requirements:
(a) Frequency ranges:
18 to 30 mc, 10 mc sweep width
40 to 90 mc, 10 mc sweep width
120 to 130 mc, 10 mc sweep width
170 to 225 mc, 10 mc sweep width
470 to 890 mc, 10 mc sweep width
(b) Output adjustable with at least .1 volt maximum.
(c) Output constant on all ranges.
(d) Flat output in all attenuator positions.

CATHODE-RAY OSCILLOSCOPE preferably one with a wide band vertical deflection and an input calibrating source.

SIGNAL GENERATOR to provide the following frequencies: (Output on these ranges should be adjustable and at least .1 volt maximum.)
(a) Intermediate alignment frequencies.
23.1 mc first picture I-F coil.
24.1 mc third picture I-F coil.
25.9 mc second picture I-F coil.
21.7 mc sound trap.
4.5 mc video trap & sound I-F.
25.2 mc converter plate coil (Tuner).

HETERODYNE FREQUENCY METER with crystal calibrator if the signal generator is not crystal controlled.

ELECTRONIC VOLTMETER and a high voltage probe for use with this meter to permit measurements up to 20 kilovolts.

SERVICE PRECAUTIONS — To service the receiver remove the chassis from the cabinet. To do so, remove the knobs, the cabinet back, disconnect the leads from the speaker, remove the antenna terminal board at rear of cabinet, and then the 5 chassis mounting bolts. The chassis may be serviced with the picture tube in place provided the chassis is turned on its side with the power transformer on the bottom. The weight of the chassis will be supported against the power transformer and pix tube brackets.

CAUTION: Do not permit the kinescope second-anode lead to become shorted to the chassis. To do so will cause a considerable overload on the high voltage filter resistor R-99.

ALIGNMENT PROCEDURE
PIX I-F

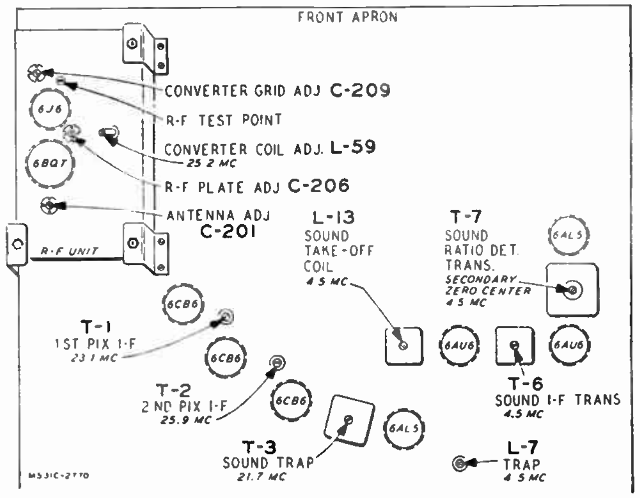

Fig. 8—Top Chassis Video and Audio I-F Adjustments

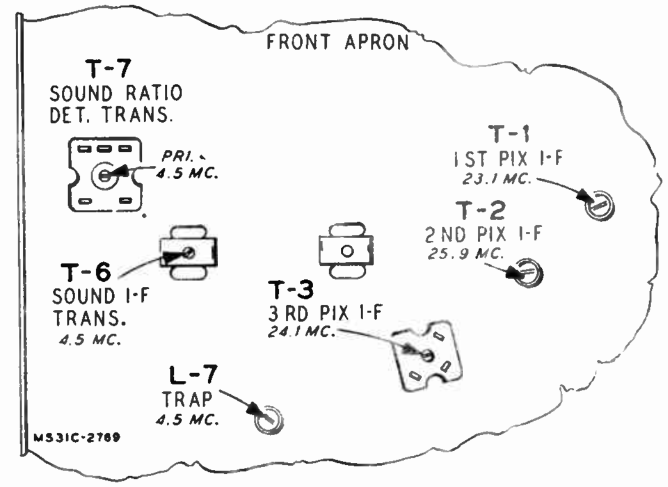

Fig. 9—Bottom Chassis Video and Audio I-F Adjustments.

A. Unmodulated R-F signal into Converter Grid by means of tube shield insulated from base. VTVM with filter in lead of 22 K ohms and 5000 mmf connected to pic. det. load resistor, (R-100) 4700 ohms, in series with peaking coil (L-6) from Pin 7 of 6AL5. Input signal level should be such that output is less than 2 volts DC. Apply -4.5V battery bias on AGC line.

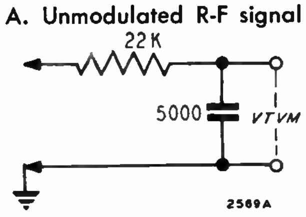

Fig. 10—VTVM Connections

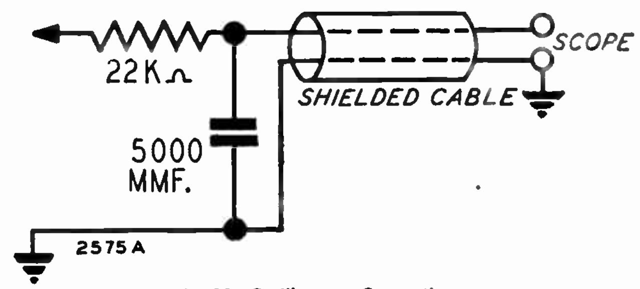

Fig. 11—Oscilloscope Connections

	FREQUENCY	ADJUST
1.	25.2 MC	Converter plate coil on top of tuner for maximum dc at picture detector.
2.	23.1 MC	1st picture I-F coil (T-1) for maximum dc at picture detector.
3.	25.9 MC	2nd picture I-F coil (T-2) for maximum dc at picture detector.
4.	24.1 MC	3rd picture I-F coil (T-3 below chassis) for maximum dc at picture detector.
5.	21.7 MC	3rd picture I-F trap (T-3 in can above chassis) for minimum dc at picture detector.

B. I-F Sweep Generator into converter grid by means of tube shield insulated from base.

Connect oscilloscope across R-100 (in place of VTVM). Apply -4.5V bias (DC) to AGC line (battery). Tuner should be switched to dead channel so as not to cause interference.

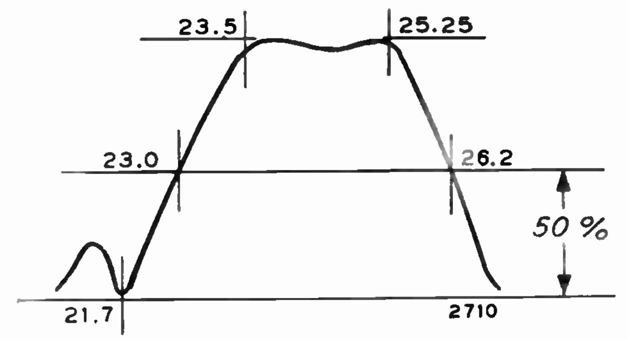

Fig. 12—Overall Response Curve

Observe overall I-F response, which should be as shown above: A slight touch-up may be required. At no time should the trap coil be re-adjusted, nor should it be necessary to turn any of the picture I-F coils more than 1/2 turn of the slug. The following comments are suggestions only:

ALIGNMENT PROCEDURE (Continued)

1. The height of the 26.2 MC marker is controlled by the 25.2 MC (Converter Plate Coil on tuner) and the 25.9 MC (2nd P.I.F.) coils.
2. The uniformity of response (flatness across top and position of 23.5 MC) marker is controlled for the most part by the 24.1 MC third picture I-F coil.
3. The 23.0 MC marker position is controlled by the first picture I-F (23.1 MC coil). However, it is NOT advisable to change the setting of the coil, due to its effect on sound rejection. Its adjustment should be avoided unless believed to be absolutely necessary.

VIDEO

With 4.5 MC unmodulated signal from a high impedance source, (10,000 ohms in series with the generator) into plate of the picture detector tube (Pin 7-6AL5) and VTVM on picture tube grid, tune 4.5 MC trap (L-7 Top) for minimum response. VTVM on 0-10 V AC scale. This adjustment can also be made while observing a picture from a station. Tune trap for least 4.5 MC beat in picture.

AUDIO I-F

1: With signal generator set to 4.5 MC and dc VTVM connected to junction of R-62 and C-46, adjust sound take-off coil (L-13 Top) and sound I-F transformer slugs (T-6 Top & Bottom) for maximum.

2: With VTVM connected to pin 7 of V-12 (6AL5) adjust the ratio detector primary (T-7 Bottom) for maximum.

3: With VTVM connected to junction of R-66, R-69 and C-50, adjust ratio detector secondary (T-7 Top) for cross over (zero voltage) on lowest scale.

NOTE — If no signal generator is available, the procedure above may be followed by tuning in a station and using the 4.5 MC beat between picture and sound carrier.

TUNER ALIGNMENT

A. Sweep generator with balanced 300 ohm output to antenna terminals. Marker generator output to antenna terminals. Oscilloscope to "test point" (Figure 13) on tuner. Connect 1½ V bias to AGC line at junction of R-33 and C-20 on the receiver.

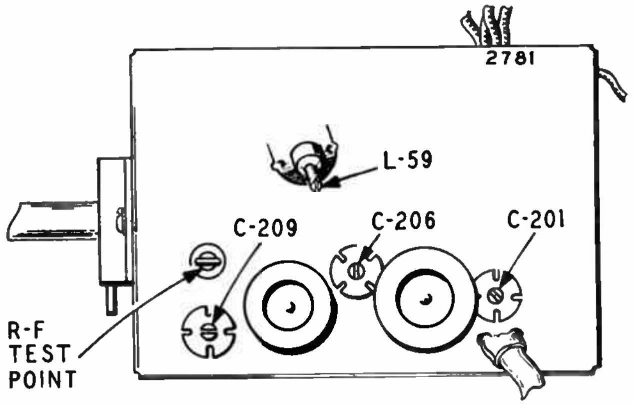

Fig. 13—Top Tuner Adjustments

B. RF AND CONVERTER ADJUSTMENT.

1. With channel selector on Channel 12, adjust C-201 slightly favoring the Pix carrier, then adjust C-206 and C-209 for response as in Figure 14. Picture and sound markers at 90% maximum response.
2. Check response on all channels. If markers are below 70% on any channels, readjust C-201, C-206, and C-209. Recheck all channels.

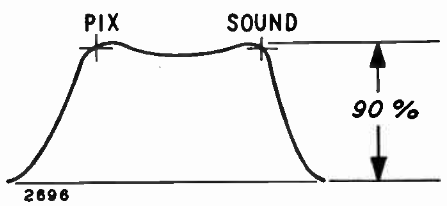

Fig. 14—Pix & Audio Markers

C. OSCILLATOR ADJUSTMENT.

1. Apply -4.5 volts on I-F AGC line at junction of R-1 and C-21.
2. Connect oscilloscope to output of video detector. Place fine tuning in center of range. Check response on all channels. Sound marker should be in notch and picture marker at 50%. (See Figure 12).
3. If markers are off, individual oscillator coil slugs will require adjustment. Adjust each channel slug, accessible through hole in front of chassis with a non-metallic screwdriver to bring sound marker to correct position.
4. To adjust oscillator on UHF position, feed the sweep generator with center frequency of 124 MC and markers at 121.75 and 126.25 into the input of the low pass filter (output of UHF tuner). Adjust oscillator slug in the VHF tuner so that the 121.75 pix carrier marker is at 50% and that 126.25 marker is in the sound notch. If a sweep generator is not available, a single frequency generator set to 126.25 MC and VTVM may be used. Connect VTVM to the pix detector load resistor R-100. Feed generator into the low pass filter. Adjust oscillator slug in the VHF tuner so that the 126.25 marker is in the sound notch of the I-F curve.
5. If the 6AF4 oscillator tube in the UHF tuner is replaced, it may be necessary to adjust the oscillator trimmer C-309 on the UHF tuner located underneath the chassis. (See Figure 15). Adjust this trimmer until the tuner will cover a range of below 470 MC to above 890 MC.

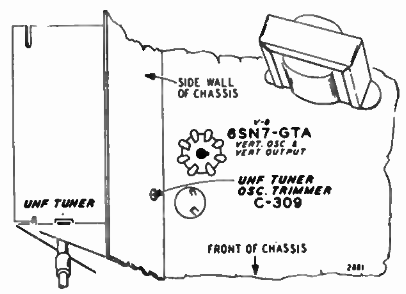

Fig. 15—UHF Tuner Adjustment.

VHF TUNER ASSEMBLY INFORMATION

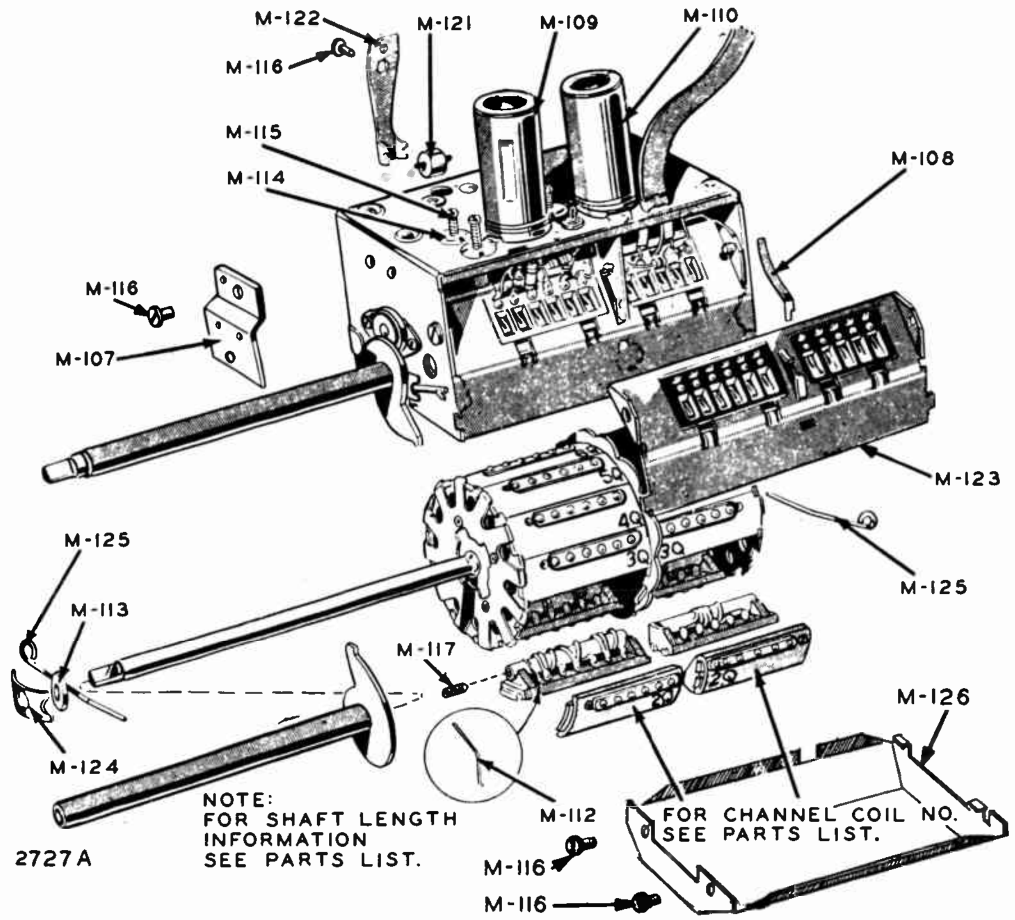

Fig. 16—"Q" Tuner Pictorial.

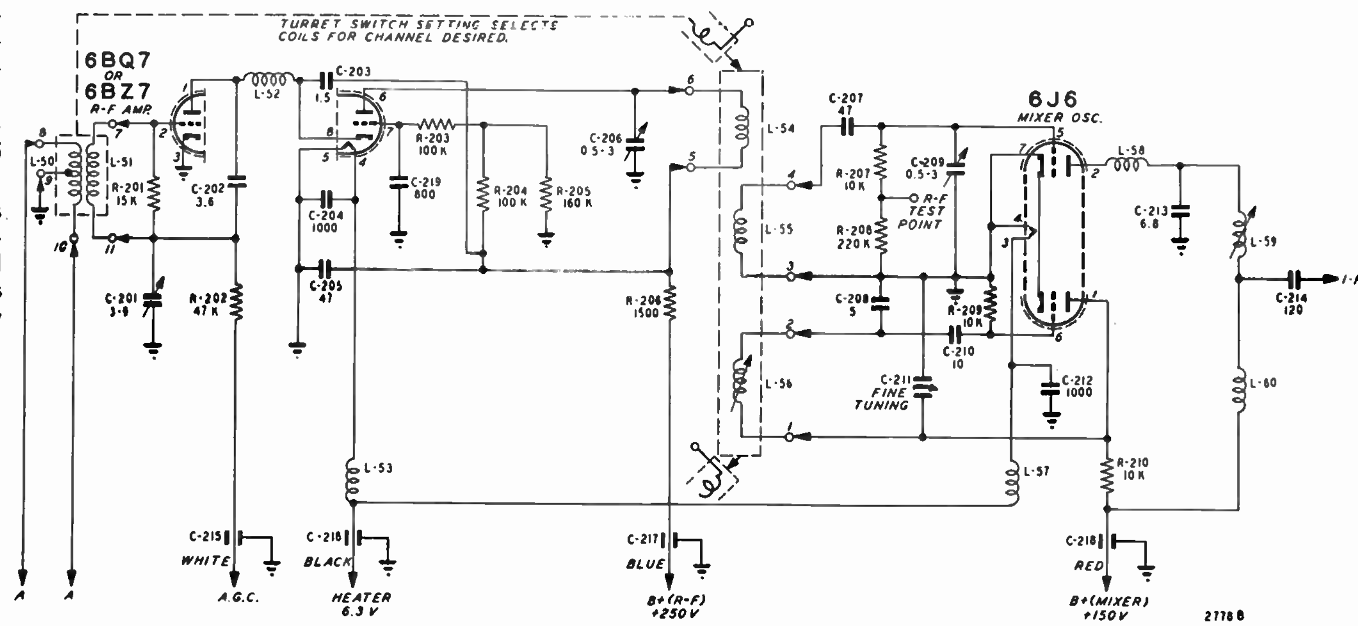

Fig. 17—"Q" Tuner Schematic Diagram.

UHF TUNER INFORMATION

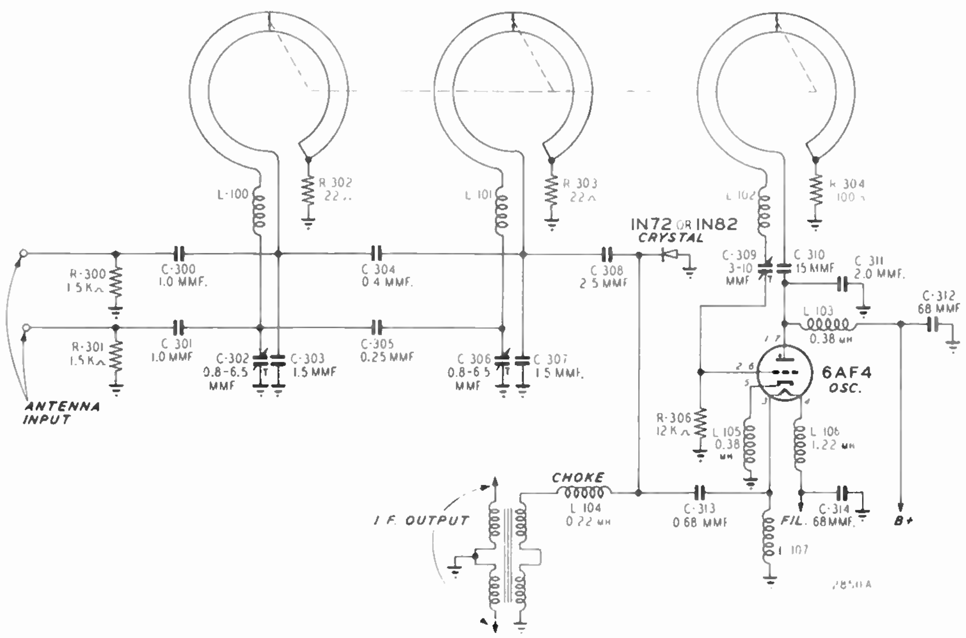

Fig. 18—UHF Tuner Schematic Diagram.

Due to the complexity of the UHF tuner, neither servicing nor aligning is encouraged in the field because replacement of any component within the R-F circuit may disturb the band-pass characteristics of the tuner. However, the 6AF4 tube or the 1N72 (or 1N82) crystal may be replaced in the field if found to be defective. A schematic diagram of this tuner is shown only for the purpose of outlining the circuit used.

If the UHF tuner does not operate satisfactorily after the tube or crystal replacement, disconnect the tuner and return it to the factory for repair.

DRIVE CORD REPLACEMENT

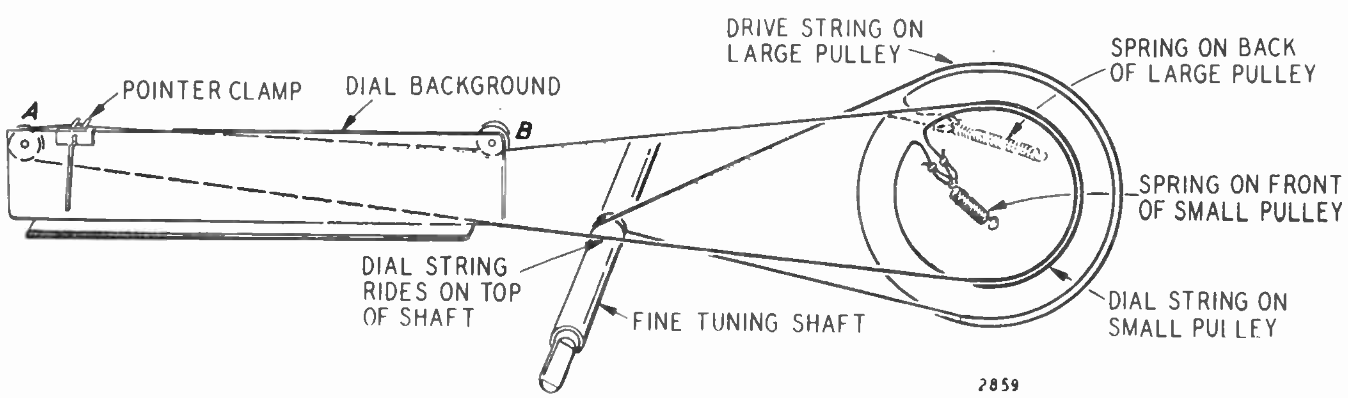

Fig. 19—Drive Cord Stringing.

You will note that there are two cords used for the pointer drive system on this receiver. Part number 10X88 Drive Cord assembly and part number 28X603 Spring are used on the tuning shaft and large pulley, while part number 10X89 Drive Cord and a part number 28X603 Spring are used on the small pulley system and the pointer. Install the cords as shown in the illustration. After completing the installation rotate the fine tuning shaft a few turns to take up the slack in the cord.

OSCILLOSCOPE WAVEFORM PATTERNS

The waveforms on this page were taken with the receiver tuned to a normal picture. The numbers on the waveforms correspond to the numbers on the schematic diagram which identifies each test point.

The voltages shown on each waveform are the approximate peak to peak amplitudes. The frequencies shown indicates the repetition rate of the waveform, not the sweep rate of the oscilloscope. If the waveforms are observed on the oscilloscope with a poor high frequency response, the corners of the pulses will tend to be more rounded than those shown below and the amplitudes of any high frequency pulse will tend to be less.

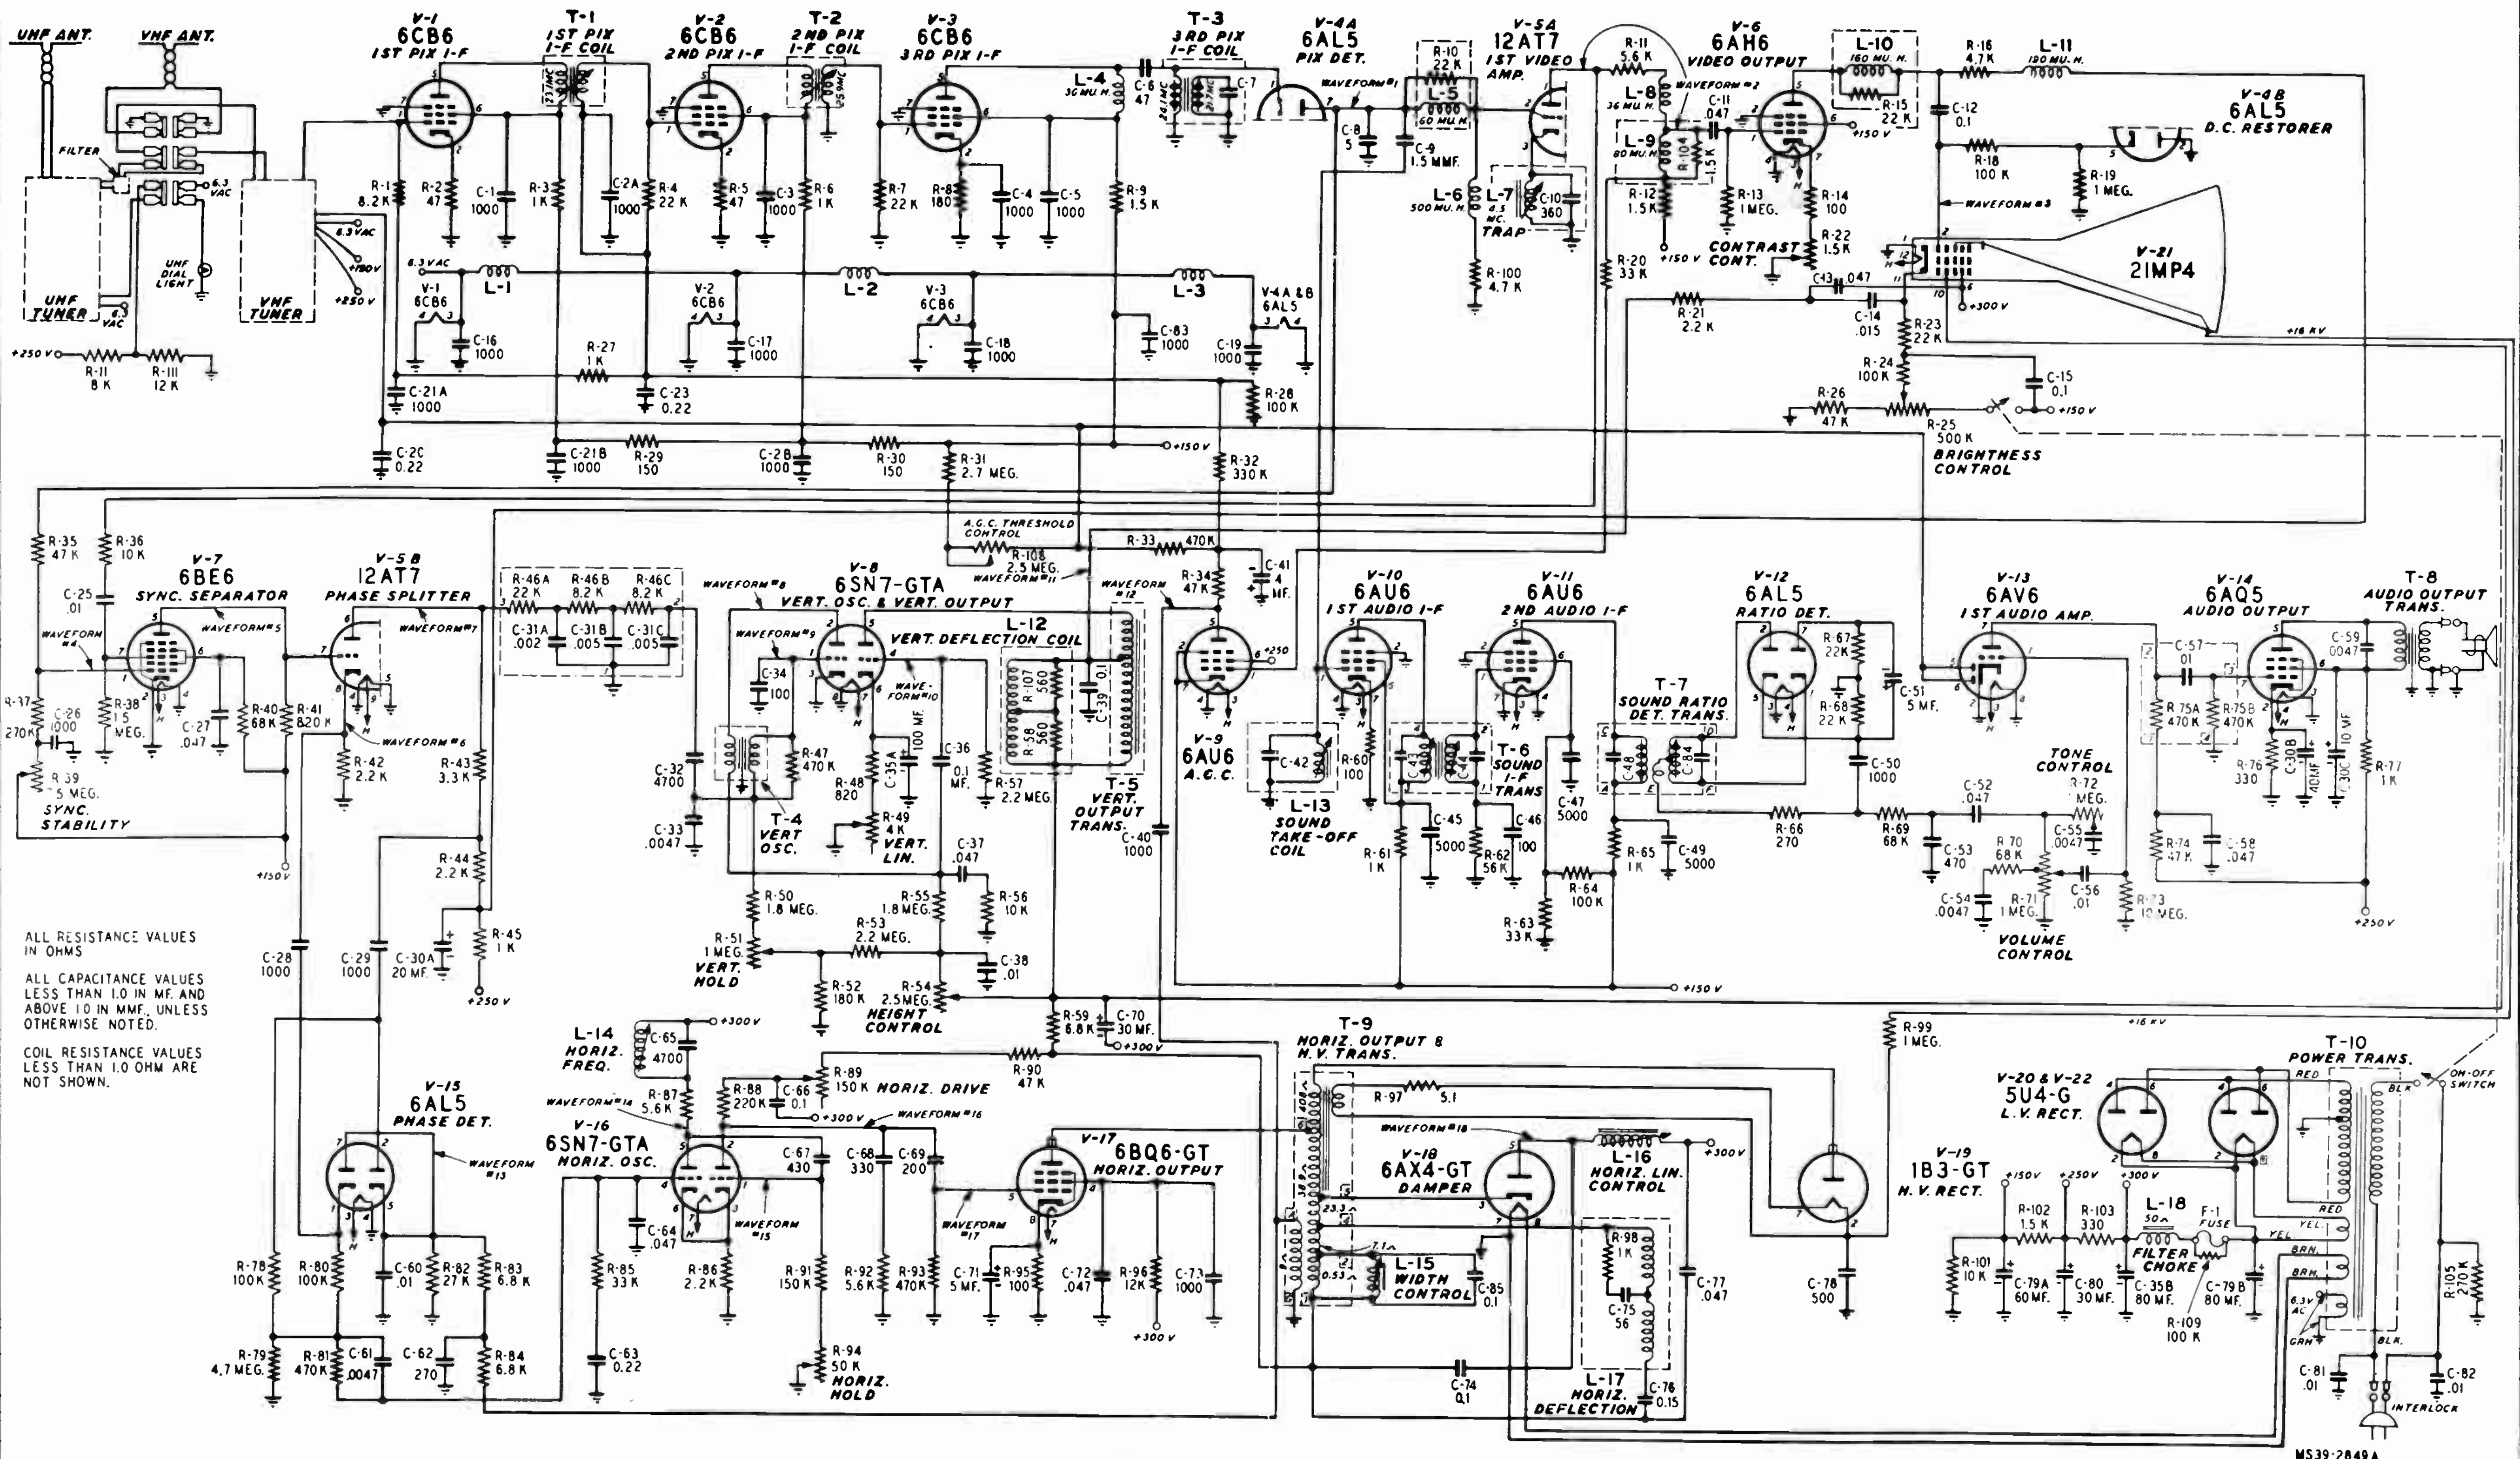
21" UHF-VHF TELEVISION RECEIVER



ALL RESISTANCE VALUES IN OHMS

ALL CAPACITANCE VALUES LESS THAN 1.0 IN MF. AND ABOVE 1.0 IN MMF., UNLESS OTHERWISE NOTED.

COIL RESISTANCE VALUES LESS THAN 1.0 OHM ARE NOT SHOWN.

PRODUCTION CHANGES

There are two different ratio detector transformers (T-7) used in these receivers, Part Numbers 9A2269 and 9A2295. The T-7 circuit shown in this schematic diagram covers the 9A2269 ratio detector. Receivers using the 9A2295 ratio detector can be identified by the following changes:

C-50 becomes 47X570 330 mmf molded mica condenser

R-64 becomes B84333 33K ohm 0.5 W carbon resistor

R-67 } R-68 } become B83103 10K ohm 0.5 W carbon resistors

In addition, the 9A2295 ratio detector has terminals with numerical identification (1, 2, 3 etc.) whereas the 9A2269 ratio detector has terminals with alphabetical identification (A, B, C etc.)

Rear View, All Receivers

CAUTION NOTICE

HIGH VOLTAGES ARE USED IN THE OPERATION OF THIS TELEVISION RECEIVER. THE BACK COVER PREVENTS ACCIDENTAL CONTACT WITH THESE HIGH VOLTAGES AND SHOULD NOT BE REMOVED EXCEPT BY A QUALIFIED TELEVISION TECHNICIAN.

THE PICTURE TUBE IS A HIGH VACUUM TUBE AND, IF BROKEN, PIECES OF GLASS MAY FLY WITH FORCE IN ALL DIRECTIONS. ANY WEAKENING OF THE GLASS BULB CAUSED BY CHIPPING, SCRATCHING OR ABNORMAL PRESSURE MAY CAUSE BREAKAGE. THE USE OF SAFETY GLASSES IS RECOMMENDED WHEN EXPOSING THE PICTURE TUBE.

IMPORTANT NOTE: WHEN SERVICING OR ALIGNING THIS RECEIVER ALWAYS USE AN ISOLATION TRANSFORMER TO PROTECT TEST EQUIPMENT.

POWER SHOULD NOT BE APPLIED TO THE RECEIVER FOR ANY GREAT LENGTH OF TIME WITHOUT THE ION TRAP (SEE FIG. 2) SET FOR BEST ILLUMINATION.

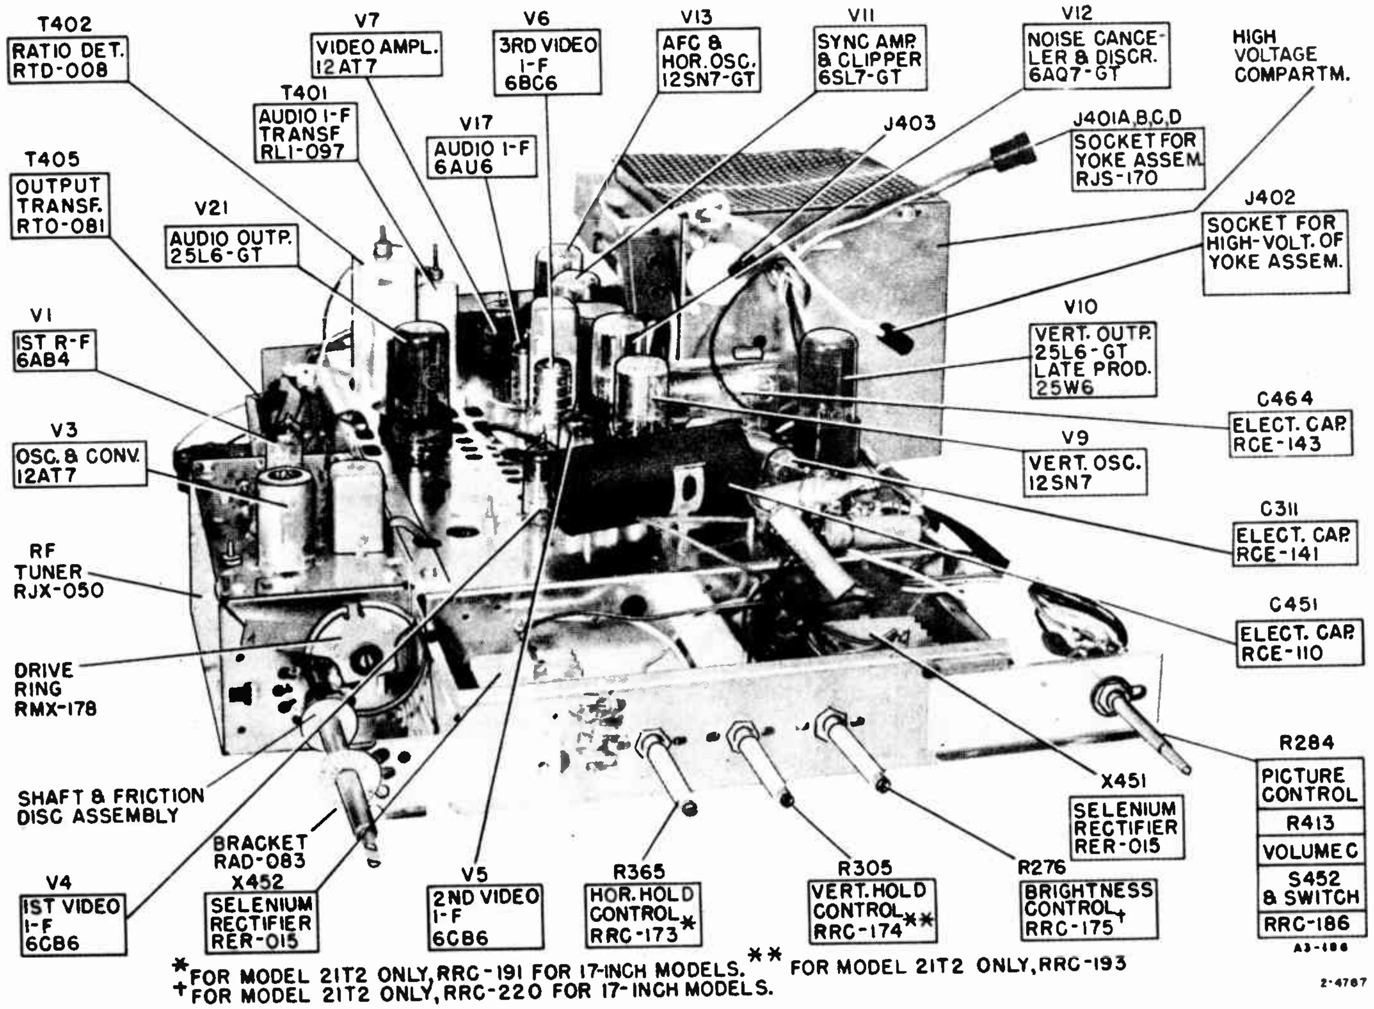
GENERAL INFORMATION

Features of this series include a balanced input to a two-stage r-f amplifier, intercarrier sound, ratio-detector, B+ boost circuit, automatic frequency control for horizontal sweep synchronization, noise canceller circuit with picture stabilizer control, selenium type rectifiers, electromagnetic deflection, PM focus unit and power outlet for an UHF translator.

The models 17T10-UHF, 17T11-UHF and 17T12-UHF contain an ultra-high frequency tuner, Model UHF-103, for reception of stations in the UHF spectrum. The tuner has three switch positions, which can be preset to any channel in the entire UHF spectrum. The tuner employs a heterodyne circuit consisting of a crystal diode, a beat oscillator and an I-F amplifier which are energized by a separate power supply.



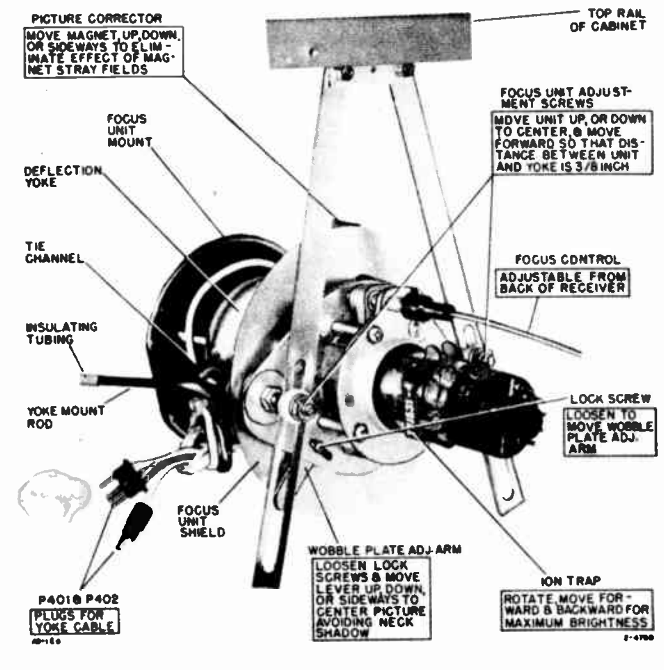
Note: Front apron is insulated from chassis.

Fig. 1. Front View of Chassis

RECEIVER INSTALLATION

The receiver is shipped from the factory with the picture tube installed and all controls pre-adjusted for normal operation. However, if in checking receiver performance, it is evident that one or more of the preset controls are out of adjustment due to handling, it is necessary to readjust the affected controls.

1. Remove cabinet back.
2. With power applied to the receiver set the Brightness control on the front panel to a maximum clockwise position.
3. Set the Horizontal and Vertical Hold control in the middle of their respective ranges.
4. Check to make sure that the deflection yoke is seated firmly against bell of picture tube.
5. Alternately turn and slide ion trap along picture tube neck for maximum brilliance of raster.
6. Tilt deflection yoke slightly left or right, using yoke lever to position picture within mask.
7. Tune in a television signal.
8. With the front panel Horizontal Hold control set at the center of its range, adjust the core of the horizontal oscillator coil, L351, until picture is synced horizontally.
9. Adjust the Horizontal Drive control on the back apron of chassis for maximum width of picture with good linearity and without foldover.
10. Adjust P.M. Focus unit to center and focus picture and to eliminate neck shadow.
11. Readjust ion trap for maximum brightness.
12. Adjust Height and Vertical Linearity controls on the back apron of chassis for correct height and best vertical linearity.
13. Adjust Width and Linearity controls on back apron of chassis for correct width and best horizontal linearity.
14. Recheck adjustments of steps 10 through 13 and tighten all screws properly.



NOTE: Late production receivers do not use flexible focus control but use crimp funnel instead

Fig. 2. Picture Tube Adjustment

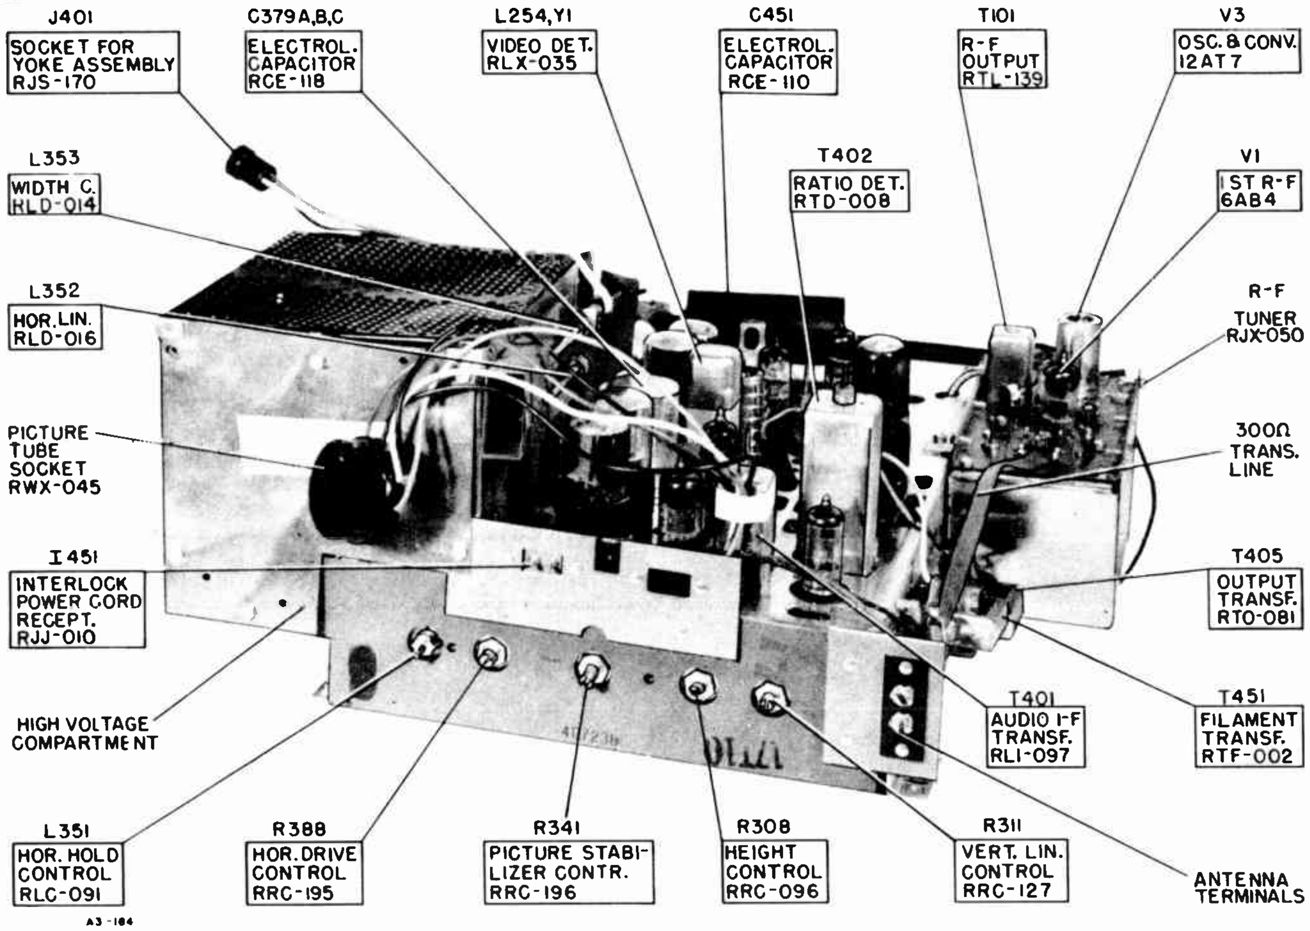


Fig. 3. Rear View of Chassis

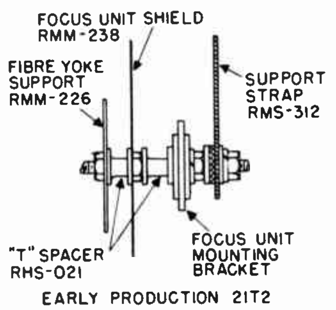
Late production 17-inch models incorporate a screwdriver method of adjustment instead of the earlier flexible shaft and knob as illustrated in Fig. 2.

It is important when adjusting this new focus unit that a non-magnetic screwdriver be used. When inserting the screwdriver, be sure that it enters the screw funnel, otherwise the ion trap may become disturbed which would require removal of the cabinet back to allow readjustment of the ion trap.

REPLACEMENT OF PICTURE TUBE

MODELS 17T10, 17T11, 17T12, 17T10-UHF, 17T11-UHF AND 17T12-UHF

1. Remove chassis.
2. Place cabinet on its front, being sure not to scratch it.
3. Remove ion trap (see Fig. 2).
4. Remove the two mounting screws fastening the support straps to the support bracket.
5. Remove the two mounting draw nuts and pull out the two yoke mount rods.
6. Slide out complete yoke assembly with attached PM focus unit.
7. Remove the two nuts which press the tube strap assembly against picture tube and remove the strap assembly.
8. Lift picture tube out of the cabinet and remove dust seal.
9. Place dust seal into notches located around the tube mask.
10. Place picture tube into cabinet and reposition tube strap assembly and tighten nuts holding tube strap assembly so that picture tube is held in place.
11. Release the dust seal from notches so that it contacts both tube and tube mask.
12. Install yoke and PM focus unit assembly and fasten the two yoke mounting rods to the picture-tube mounting rods. Be sure that yoke and PM focus unit are perpendicular to and concentric with picture-tube neck.
13. Install ion trap.
14. Replace chassis and connect picture-tube socket to base of tube, high-voltage lead to picture tube anode, two yoke plugs and loudspeaker leads.
15. Install knobs and chassis mounting screws and cabinet back.



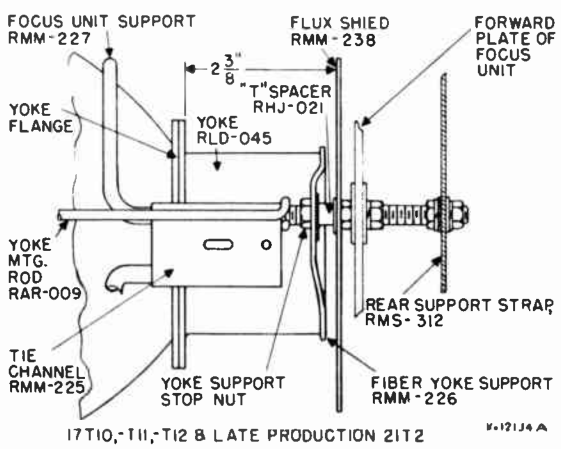


Fig. 4. Side View of Yoke and Focus Assembly

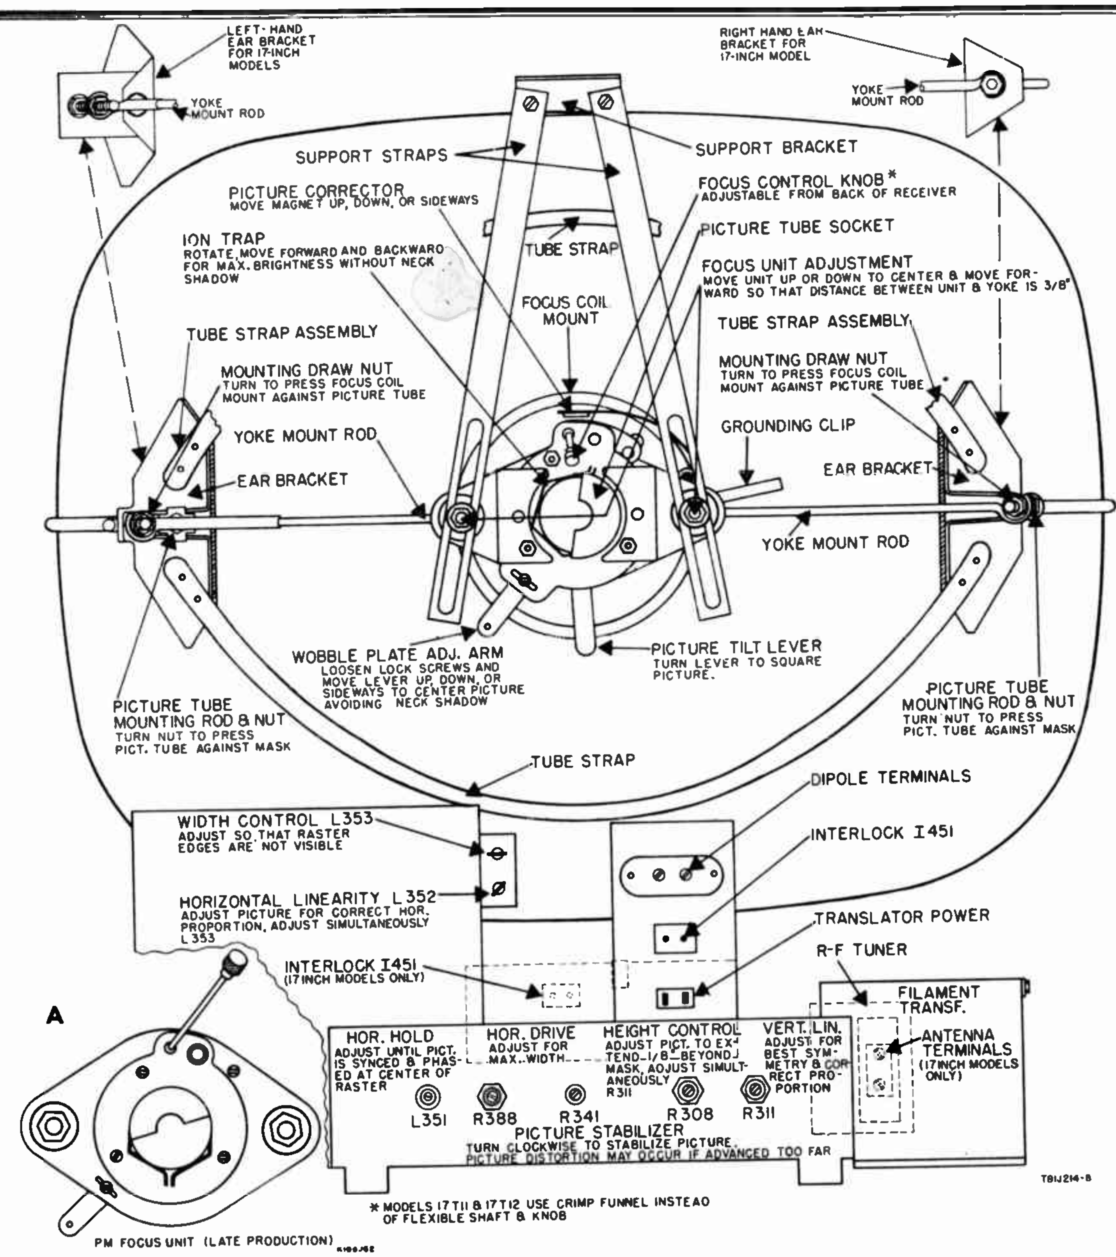

Fig. 5. Preset Controls and Picture Tube Adjustments

REPLACEMENT OF PICTURE TUBE MODEL 21T2

1. Follow steps 1 through 9 of preceding paragraph.
2. Place picture tube into cabinet, reposition tube strap assembly, assemble left picture-tube mounting nut flush with end of mounting rod, see Fig. 6.
3. Tighten the right picture-tube mounting nut.
4. Tighten the left picture-tube mounting nut.
5. Place yoke mount rod as indicated in Fig. 5 and tighten with nut provided.
6. Make sure that the focus unit is perpendicular to and concentric with the picture-tube neck.

REPLACEMENT OF YOKE AND PM FOCUS UNIT

There are two types of PM focus units: the early type with riveted-on bracket, Fig. 5, and the later production type which is identical to that used on Model 21T4, Fig. 5A. When reassembling follow this procedure (see Fig. 4):

1. Turn nut on the fiber yoke support by fingers fully forward.
2. The nut immediately to the rear of the focus unit shield should be set for 2⅜ inches between the disk and the yoke flange.
3. The yoke support stop nut is now unscrewed towards the fiber yoke support and suitably tightened.
4. Make sure that the focus unit is placed perpendicular and concentric about the picture-tube neck.
5. The two rear assembly supporting straps should be positioned on the focus unit support rods as far back from the focus unit as possible while still maintaining their vertical position, see Fig. 4.

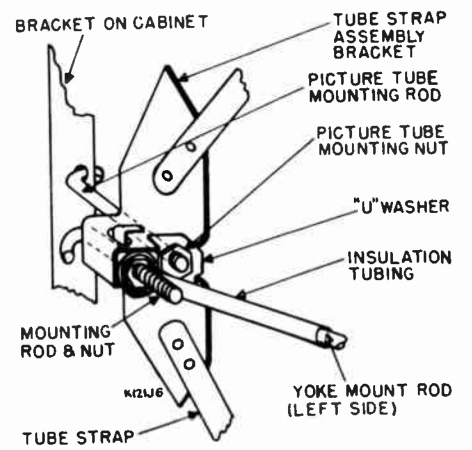

Fig. 6. Tube Strap Assembly Mount, Model 21T2

RECEIVER ALIGNMENT

GENERAL:

In most cases the circuits in the receiver should need realignment only when components have been replaced in the tuned circuits or the adjustments have been tampered with. When the decision is reached that the trouble lies in improper alignment of the circuits, the alignment should be undertaken only if proper test equipment is available.

The alignment procedure described follows the sweep method using General Electric test equipment. When other than General Electric sweep equipment is used, make sure that it meets the requirements listed below. If an accurately calibrated marker generator is not available, a conventional signal generator may be used to supply the markers. Its output should be loosely coupled to the sweep generator output terminals and must be kept as low as possible to prevent distortion of the sweep waveform.

Before proceeding with the alignment make sure to read all notes and consult the connection diagrams. Allow the test equipment and receiver to warm up for at least 15 minutes before starting the alignment. It is often advisable to perform the alignment with the picture tube disconnected. The filament circuit can be completed by using a type 6SN7 tube with all pins clipped off except pins No. 7 and No. 8 which must be plugged in to pins No. 1 and No. 12 of the picture tube socket.

TEST EQUIPMENT

The following test equipment is necessary in order to effect alignment of the tuned circuits of the receiver:

1. ***R-F SWEEP GENERATOR***

   (G-E Type ST-4A or Equivalent)

   a. Frequency requirements:
      4.5 MC with 500 KC and 2 MC sweep width.
      40–50 MC with approximately 10 MC sweep width.
      50–90 MC, 170–220 MC with 15 MC sweep width.

   b. Constant output in the sweep range.

   c. Minimum output 0.1 volt.

2. ***MARKER GENERATOR***

   (G-E Type ST-5A or Equivalent)

   The marker generator must have good frequency stability, accurate calibration and must cover the following frequencies:

   a. 41.25 MC for video IF
      42.50 MC for video IF
      44.10 MC for video IF
      45.00 MC for video IF
      45.75 MC for video IF
      47.25 MC for video IF

   b. 4.5 MC for sound IF and trap alignment.

   c. Picture and sound carrier frequencies for Channel No. 2 through No. 13.

3. ***BALANCED OUTPUT ADAPTER***

   (G-E ST-8A or Equivalent)

   See R-F Alignment, note 2.

4. ***OSCILLOSCOPE***

   (G-E Type ST-2A or Equivalent)

   The oscilloscope should have good sensitivity and preferably a 5-inch screen with a good wide-band frequency response in the vertical deflection circuits. Although the high frequency response is not necessary for alignment, it is imperative when making waveform measurements.

5. ***DETECTOR NETWORK***

   A crystal detector network as shown in Fig. 19 is necessary when aligning the 4.5 mc trap, L260.

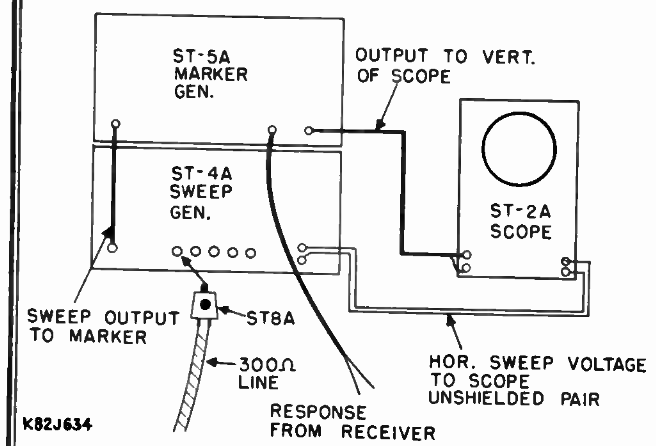

Fig. 7. R-F Alignment Equipment Connections

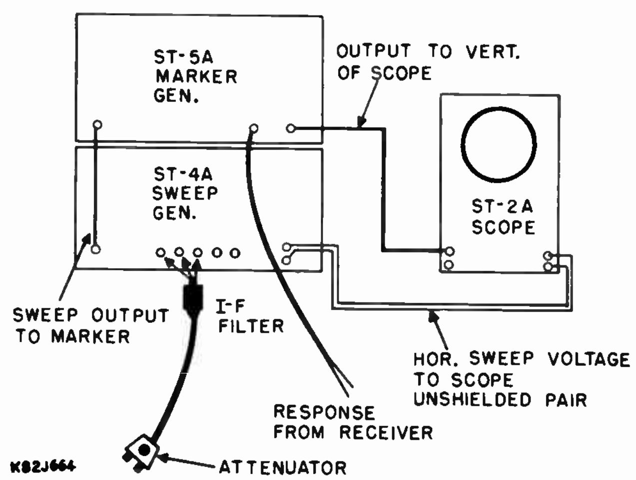

Fig. 8. I-F Alignment Equipment Connections

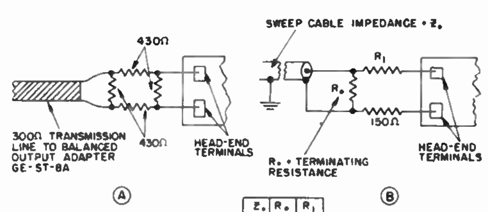

Z_o	R_o	R_1
50Ω	56Ω	120Ω
72Ω	82Ω	110Ω
92Ω	110Ω	100Ω

Fig. 9. Sweep Generator Termination

R-F Tuner Alignment

Notes:

1. The R-F tuner may be aligned without removing it from the main chassis. Disconnect the 300-ohm transmission line from the antenna input transformer, T100 and disconnect the B+ to the oscillator. To do this remove the self-tapping screws which hold the rear shield, so that the terminal boards are exposed. Unsolder the jumper between terminals 3 and 4 of the top terminal (see Fig. 14) and connect choke L141 to terminal 3.
2. Connect the sweep generator to the R-F tuner antenna input transformer using the G-E ST8A balanced adapter to obtain 300 ohms output, see Fig. 7. The adapter should be connected to the R-F tuner through approximately three feet of 300-ohm transmission line and a resistor pad, as shown in Fig. 9A. When using other test equipment of the unbalanced output type, a pad as shown in Fig. 9B should be used instead.
3. Connect a 3-volt battery to the AGC terminal of the R-F tuner, see Fig. 14, with the positive lead of the battery connected to the main chassis.
4. The inductance of the coils is adjusted by means of brass screws. In general, good tracking can be obtained by this adjustment. On the high channels proper tracking can be achieved by dressing the coil L122, Fig. 13. This coil is available through the opening obtained by removing a self-tapping screw and bending up the flap on the tuner shield, see Fig. 11. Use an insulated tool for dressing this coil, since it is connected to B+.
5. It is possible to obtain two different settings of C105, Fig. 11, that will give the proper R-F band width. The correct setting may be determined by switching from Channel 13 to Channel 12 and observing the change in band width. The correct setting will result in a slightly greater band width on Channel 12.
6. When proper tracking on the low channels cannot be achieved with the provided screw adjustments, the inductance of the coils L110, L111, L117, L118, L125 and L126 (Fig. 12, 13, and 16) may be varied by inserting a knife blade between the windings. This method of adjustment requires the removal of the tuner shield, a procedure which will detune the circuits. However, in most cases the provided screw-type adjustments will suffice to achieve proper tracking through all channels after the shield has been replaced.
7. The picture and sound carrier marker should not be less than 75% of the peak of the R-F response curve. Refer to the "limits" curves shown in the accompanying alignment chart.
8. Seal trimmer screw of C105 and the brass cores in the coils L114, L112, L109, L119, L116, L127 and L124, Fig. 11, with wax to prevent detuning. Seal the tuning screws in trimmers C104, C106 and C108, Fig. 10, with glue. Reconnect the jumper on the R-F tuner terminal board and connect the transmission line to R-F tuner input transformer. Mount the rear R-F tuner shield.
9. For over-all alignment check see page 6.

OSCILLATOR ALIGNMENT

GENERAL—Two methods of oscillator frequency adjustment are given below. The first method uses a transmitting station for the adjustment while the second method uses a sweep generator to align the oscillator coils.

A. *"On Station Signal" Alignment*

R-F and video I-F alignment must be correct before attempting oscillator alignment. An operating transmitting station is needed for each one of the coils being adjusted. Tune in the station starting with the higher channels and adjust the tuning screws for all available stations so that with the fine tuning control in the full clockwise position, audio is just visible in the picture. Then, check to see that best picture response on all channels takes place approximately in the center of the oscillator tuning range.

B. *Sweep Alignment*

1. R-F and video I-F must be properly aligned before aligning the oscillator.
2. Connect a 3-volt battery to the AGC terminal of the R-F tuner, see Fig. 14, with the positive lead of the battery connected to the main chassis.
3. Disconnect the 300-ohm transmission line from the antenna terminals to the R-F terminals and connect the sweep generator to the R-F tuner terminals as described in note 2 on page 4.
4. Set the fine tuning knob 180° (½ turn) from the counterclockwise limit of its rotation, i.e. rotate the fine tuning knob counterclockwise to the end of its travel, then turn the fine tuning control knob 180° (½ turn) clockwise. This setting of the fine tuning control should be maintained for all oscillator adjustments.
5. Make the indicated adjustments so that the picture carrier marker for the channel falls at 50% on the high frequency side of the response curve.

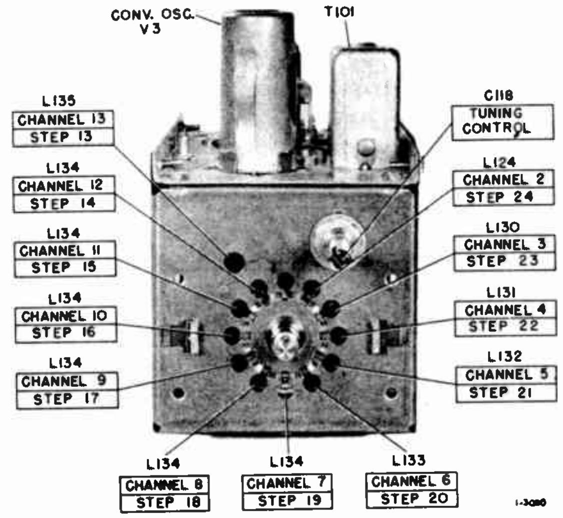

Fig. 15. Oscillator Adjustments

OSCILLATOR ALIGNMENT CHART

Sweep Generator Sweep Width 10-15 MC

Step No.	Receiver and Marker Position	Marker Generator Frequency	Signal Input Point	Observe Response Curve at	Adjust	See Note

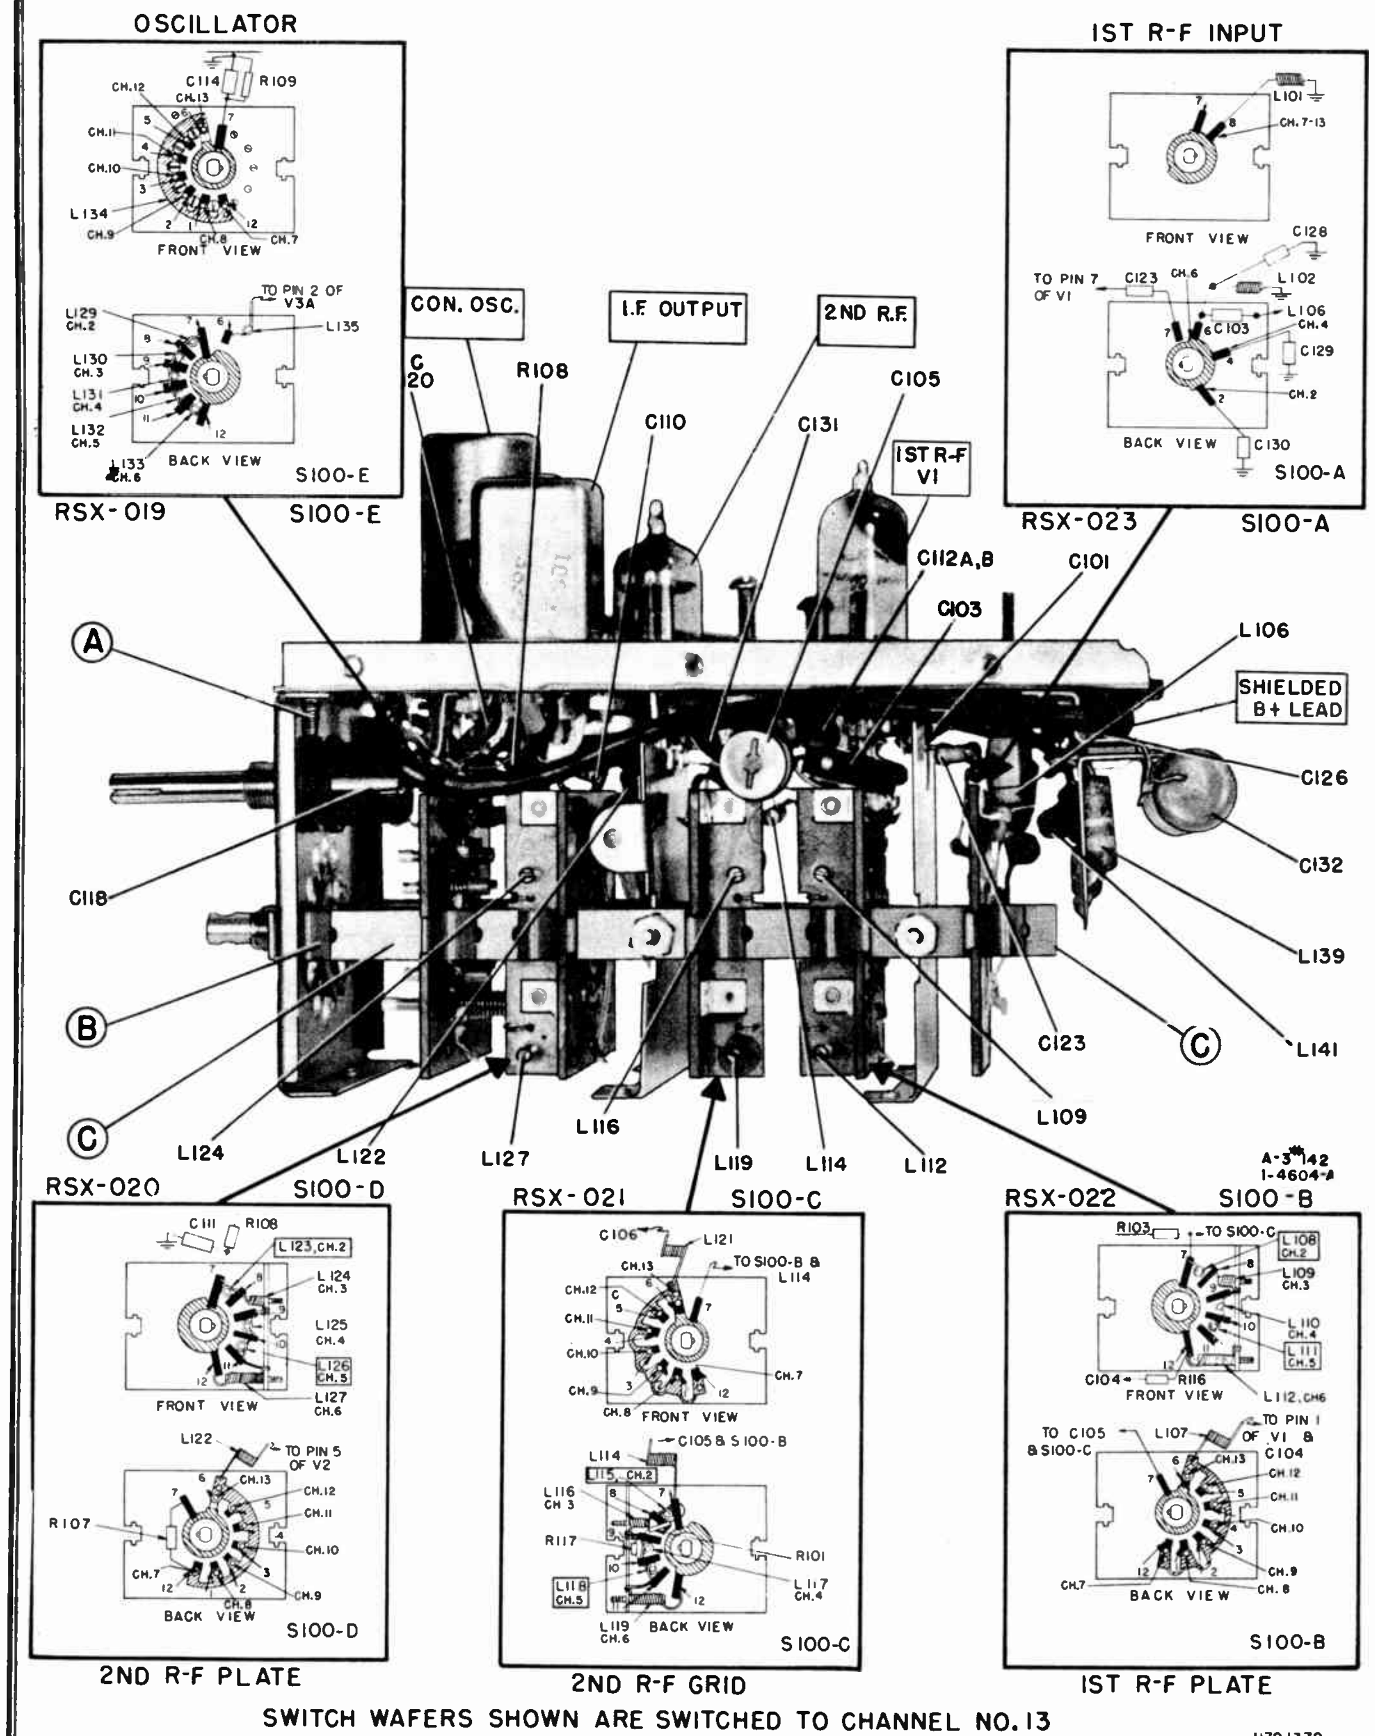

Fig. 16. R-F Tuner with Switch Wafer Wiring

VIDEO I-F ALIGNMENT

NOTES:

1. Connect a 3-volt bias battery from the junction C284, R288 and picture control, R284 to chassis, see Fig. 27.
2. Set channel switch to Channel No. 11 and turn Fine Tuning control to the counterclockwise stop.
3. The noise canceller V12 should be biased off during alignment by rotating the Picture Stabilizer at the rear of the receiver to the counterclockwise stop.
4. The sweep generator should be properly terminated in its characteristic impedance. Couple the signal to the point of input through the capacitor specified and adjust signal input to give a video response curve of ¾ volts.
5. In most cases it is only necessary to perform an over-all alignment of the video i-f to obtain the final curve. L251 will adjust the marker 42.5 mc of the audio or low-frequency side of the response curve; coil L266 will adjust the marker 45.75 mc of the video or high-frequency side of the curve. T101 and L254 should be adjusted simultaneously to obtain maximum gain and flatness of the curve, see Fig. 17. Then L266 is readjusted to give the final curve as in step 5.
6. It is necessary to detune the i-f coils by shorting as noted in the alignment chart to prevent the coil preceding the signal input point from influencing the response curve.
7. It is important that the cores of all coils, including traps, be tuned on the outside of their respective coils.

VIDEO I-F ALIGNMENT

(a) SWEEP GENERATOR FREQUENCY 40 TO 50 MC.
(b) OBSERVE RESPONSE CURVE AT JUNCTION L256, R292, AND L268 THROUGH 10,000 OHMS RESISTOR AND CHASSIS.

Step	Marker Generator Frequency	Signal Points Between	Adjust	Remarks
1	47.25 MC	Test Point "A" on head-end thru 100 mmf capacitor and head-end chassis.	Cores of L265 and L267 for minimum output at 47.25 MC.	Make this adjustment with high scope gain.
2	42.50 MC 44.10 MC 45.75 MC	V6 grid (pin 1) thru .01 mf capacitor and chassis; short L266.	Core of L254, 3rd- if for proper curve.	3	41.25 MC 42.50 MC 45.00 MC 45.75 MC	V5 grid (pin 1) thru .01 mf capacitor and chassis, short L251 and remove short on L266.	Core of L266, 2nd i-f for proper curve.	4		V4 grid (pin 1) thru .01 mf capacitor and chassis, remove short on L251.	Core of L251, 1st i-f for proper curve.	5	41.25 MC 42.50 MC 45.00 MC 45.75 MC 47.25 MC	Test Point "A" on head-end thru 100 mmf capacitor and head-end chassis.	Core of T201, T101 and L254.	 41.25 mc-Marker should be at 7% with 45.0 mc marker at 100%. 45.75 mc marker may vary between the limits 25% and 35% (nominal 30%). 42.5 mc marker may vary between 50% and 90% (nominal 70%). Peak of the curve should approximately equal 150% referred to the 100% 45 mc marker.

OVER-ALL (RF-IF) ALIGNMENT CHECK

A receiver which has been properly R-F aligned and I-F aligned must not be considered as a properly aligned receiver until the over-all check and adjustments have been made. Because the converter grid and cathode are utilized as a detector diode in the R-F alignment process, a certain degree of "tilt" or R-F detuning will occur. The only method of determining the degree of introduced "tilt" and the correction thereof must be done by observing the over-all curve.

In general, a receiver which has been properly R-F aligned will display an over-all curve (antenna to diode) which will duplicate the I-F system curve, since the major portion of the receiver selectivity occurs in the I-F system. It is to be expected, however, that minor variations in the over-all curve will occur when checking each of the various channels.

The procedure given here is quite simple, and assures optimum picture detail and receiver sensitivity. After the receiver has been properly aligned according to the data given for R-F and I-F alignment, proceed as follows:

a. Couple R-F sweep and channel marker signals to antenna input terminals.

b. Connect oscilloscope to junction of L256, R292 and L268 through 10,000 ohms, see Fig. 27.

c. Sweep each channel, starting with channel #13, and observe resulting curve. Adjust the Fine Tuning control so that the resulting sound and picture I-F markers fall in the approximate positions shown in Fig. 17.

d. Should the observed curve not agree with that shown in Fig. 17, the following adjustments should be made:

I. On channels 7–13, adjust C108 (Fig. 10) to produce desired curve shape and amplitude. CAUTION: Do not move C108 adjustment core more than three turns in either direction—usually one turn will suffice to produce the desired curve compensation.

II. On channels 4, 5 and 6 adjust L127 for proper curve compensation if required (Fig. 11).

III. On channels 2 and 3 adjust L124.

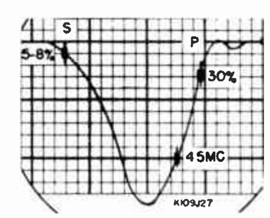

Fig. 17. Over-all Curve

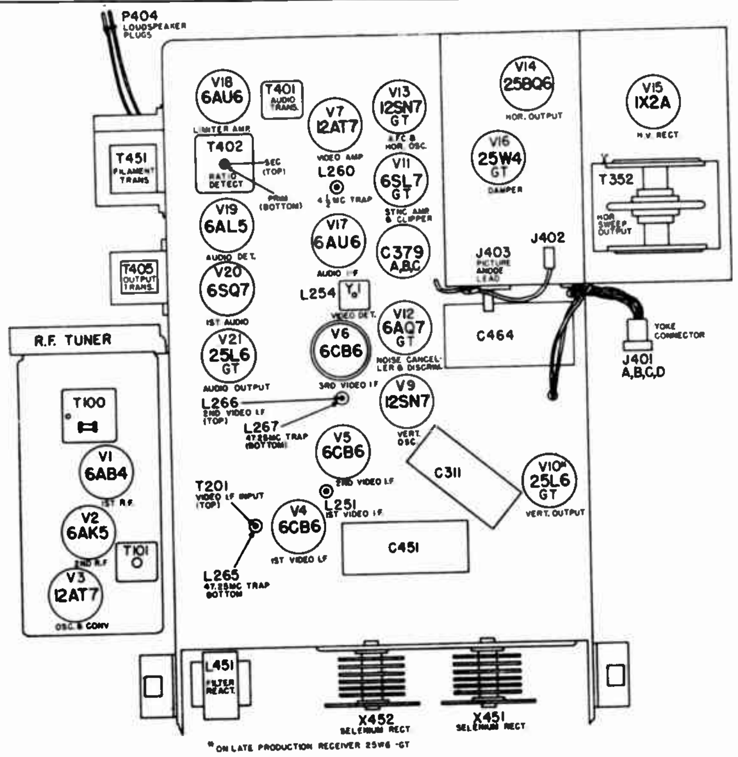

Fig. 18. Tube and Trimmer Location

TRAP ADJUSTMENTS

Alignment of L106 I-F Trap (R-F Tuner)

The trap, L106, Fig. 10, is for the purpose of removing any frequency in the i-f range which may cause interference and it should be aligned for minimum interference.

The trap, L106, may be aligned by tuning for minimum i-f channel interference pattern on the screen.

If the interference frequency is known, L106 may also be aligned for minimum interference as outlined below.

1. Connect 3 volts bias from the AGC line on head-end terminal board, Fig. 14, to chassis. Connect the positive of the bias battery to chassis.

2. Use an accurate marker generator to furnish marker of the same frequency as the interfering frequency.

Connect the scope to view the response curve at output of the video detector.

Use a sweep generator with its center frequency set approximately at the interference frequency.

3. Do not tune L106 so it will attenuate Channel No. 2.

4. Use the GE-ST8A balanced adapter and a 3-foot piece of 300-ohm transmission line to couple the r-f sweep to the antenna terminals of the receiver, to properly match the input impedance of this receiver.

If the shape of the response curve changes when you grasp the 300-ohm transmission line, a resistor pad, as shown in Fig. 9, should be inserted at the head-end antenna terminals. In most cases as you grasp the 300-ohm transmission line the amplitude of the response curve will decrease, the shape will not change.

L106 ALIGNMENT CHART

Marker Frequency	Sweep Frequencies and Input Points	Observe Response Curve at	Channel Switch Setting	Adjust	See Note
Interference frequency	40 to 50 MC to antenna terminals	Junction R292, L256 and L268	2	Core of L106 for minimum amplitude of curve at marker.	1, 2, 3, 4

AUDIO I-F ALIGNMENT

1. Feed a 4.5 mc signal with a 500 kc sweep and adjust for proper response curve as indicated in the chart.

2. Keep the input signal of the sweep generator low enough so that limiting does not take place, otherwise the response curve will broaden out, preventing correct adjustment. Check by increasing the output of the generator: the response curve should increase in amplitude.

3. An alternate method to the visual alignment is the sound output method using an operating television station, preferably when transmitting tone modulation during test pattern transmission.

(a) Tune the receiver for best detail.

(b) Set the picture control to give reduced contrast or by using a resistor pad in the antenna circuit.

(c) Adjust transformer T401 and primary of T402 for maximum sound output.

(d) Adjust the secondary of T402 for best quality audio reception and for minimum buzz in the output.

AUDIO I-F ALIGNMENT CHART

(a) MARKER GENERATOR FREQUENCY 4.5 MC
(b) SWEEP GENERATOR FREQUENCY 4.5 MC ±500 KC
KEEP SIGNAL BELOW LIMITING LEVEL OF RECEIVER.

Step No.	Signal Input Points Between	Observe Response Curve at	Adjust	
1	Pin 1 of V17 thru .01 mf capacitor and chassis	Junction of R404, C404, and secondary of T401 thru 10 K-ohm resistor and chassis.	Primary and secondary of T401 for max. amplitude and symmetry of curve.	2			Secondary of T402 to place zero beat of 4.5 mc marker and sweep at the cross-over of the curve and base line.	
3	Pin 1 of V18 thru .01 mf capacitor and chassis	Junction of R408, C411, and R411 thru 10 K-ohm resistor and chassis.	Primary of T402 for equal amplitude of the positive and negative peaks with a straight line connecting these peaks.	4			Secondary of T402 to place zero beat of 4.5 mc marker at cross-over point of curve and the base line.	
5	Recheck alignment of Step 4 on operating station as in Note 3.			

ADJUSTMENT OF VIDEO AMPLIFIER 4.5 MC TRAP (L260)

NOTES:

This trap is used to remove 4.5 mc audio i-f from the video amplifier which shows up in the picture as a cross-hatch pattern. This trap will very rarely require adjustment. If adjustment is necessary, proceed as follows:

1. The trap (L260, C271) is adjusted for minimum amplitude of the 4.5 mc marker. Use a detector network as shown in Fig. 19, connected from junction of L271 and C275 to chassis to detect the signal.

2. Adjust the Vertical Hold control to remove the vertical pulses from the response curve.

L260 ALIGNMENT CHART

UHF-TUNER MODEL UHF-103

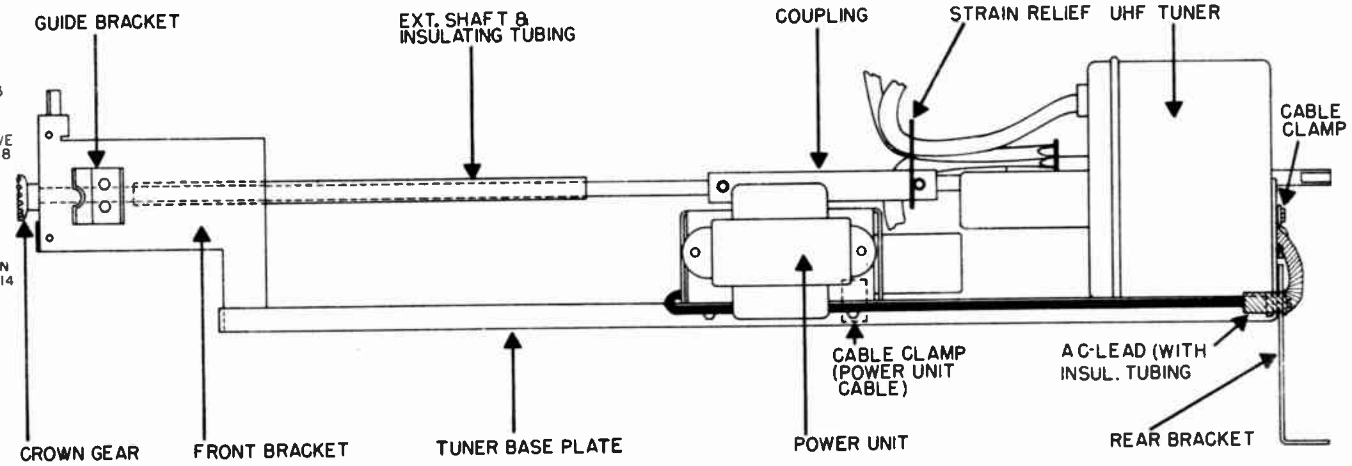

Fig. 23. UHF-103 Tuner Assembly

Installation

The tuner unit consists of a turret tuner and a power unit mounted to a base plate, see Fig. 23. The tuner is switched from the front of the receiver by means of a switch knob or knob ring which engages a crown gear, see Fig. 24. The movement of knob is transferred to the turret tuner by means of an extension shaft and coupling.

The tuner is held in place in front by a locating plate and locating pin and in the rear by a rear bracket fastened to the cabinet.

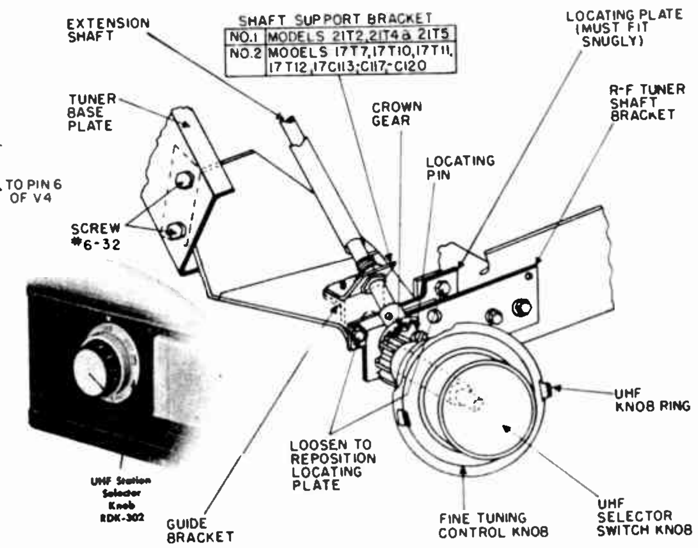

Fig. 24. UHF-Tuner Front Assembly

UHF Tuner Adjustments

General

The UHF Tuner, as shipped from the factory, has its output stage tuned to Channel No. 5, to which the television receiver must be tuned. This output stage may need realignment for Channel No. 6 operation for reasons given below. The actual realignment is very simple and can be done without the use of test equipment.

The service technician must individually adjust each of the three UHF positions for operation upon the local active UHF channels. This may be done without the use of special test equipment. The tuning ranges of the three UHF positions are all identical and cover the entire UHF spectrum.

UHF—I-F Adjustments

Before making the I-F adjustments it will probably be more convenient to remove the tuner unit from the cabinet.

The I-F preamplifier in the UHF Tuner has been factory-aligned to Channel No. 5. If there is a station operating on Channel No. 5, the Tuner I-F preamplifier should be adjusted to function on Channel No. 6. For example, it is not desirable to convert the UHF signal to Channel No. 5 if there is a strong television station operating on Channel No. 5 in your area. It is quite obvious that if the VHF station signal on Channel No. 5 is fairly strong, it will be picked up by the television receiver even when the Tuner is operating and thereby impairing the quality of the UHF picture.

To readjust the preamplifier for operation on Channel No. 6 instead of No. 5, as shipped from the factory, proceed as follows:

(a) Turn core "A" (see Fig. 25) approximately three turns counterclockwise.

(b) Turn core "B" approximately two and a half turns counter-clockwise.

The UHF Tuner is now ready for operation on Channel No. 6.

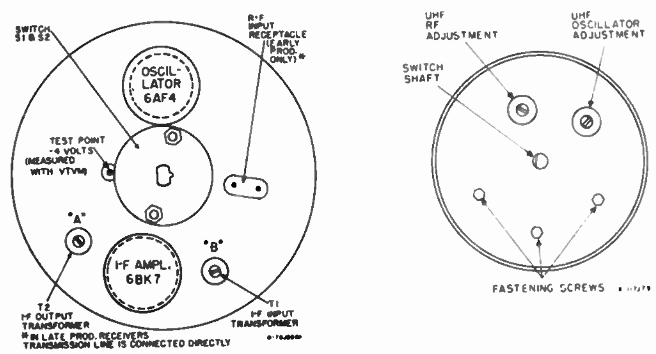

Fig. 25. UHF Adjustments

UHF Channel Adjustments

Notes:

(a) Always allow approximately 15 minutes warm-up time before proceeding with the adjustments.

(b) Set the Tuner knob ring to "UHF-1" position and the television receiver channel selector knob on either Channel No. 5 or No. 6 according to preceding information. Set the Fine Tuning control on the television receiver to the middle of its range.

ALIGNMENT PROCEDURE

1. Turn the oscillator tuning core (see Fig. 25) fully counter-clockwise.
2. From this "starting point," gradually turn the oscillator tuning core clockwise into the coil until a UHF picture and accompanying sound signal are received. While turning the oscillator core clockwise into the coil, two strong picture responses may be noticed. However, the first response to be noted while turning the core clockwise from its maximum counterclockwise position is the response to be used. Be careful not to exert any pressure when turning the core into the coil, to avoid any damage to the coil.
3. Adjust the R-F tuning core for maximum picture signal.
4. The oscillator tuning core should now be readjusted so that the Fine Tuning control on the television receiver will permit tuning slightly into accompanying audio bars or "beats." Be sure that you can tune away from any adjacent channel interference.
5. The Tuner is now aligned for operation on one UHF channel. Repeat steps 1 to 4 on the two remaining UHF positions, if more than one UHF channel is available in your area.

UHF-103 CIRCUIT DESCRIPTION

Refer to diagram, Fig. 27, page 11.

Conversion of UHF to VHF is achieved by mixing the incoming UHF signal with a signal which is generated by a local high-frequency 6AF4 oscillator. This mixing takes place in a 1N72 crystal diode, the output of which is amplified by the low-noise 6BK7 cascode amplifier. The output of this amplifier is then link-coupled to the television receiver antenna terminals.

Two antenna inputs are provided; one for the VHF antenna and one for the UHF antenna. Switches S1 and S2 are mechanically ganged with the UHF coil plate. The switch, S1 permits switching of the VHF receiver antenna input lead to either the VHF antenna directly, or to the Translator output link.

On the VHF position, switch S2 un-shorts R11. Thus, a small amount of current is permitted to flow through the tubes, even while on the VHF position.

In the UHF-1 position, as shown, the signal is fed into the input circuits consisting of C1, C2, C3, C4 and L1. L1 is a ¼-wave shorted line, the electrical length of which is varied by adjustment of the shorting core. For mechanical convenience, this ¼-wave line is wound into a spiral form and should not be considered as a conventional "coil."

The values of C1, C2, C3, C4 are chosen so that the input circuit impedance closely approximates 300 ohms across the UHF band, while the impedance at the junctions of C1 and C4 and the ends of the transmission line L1, is very high—in the order of several thousand ohms. C7, C8, L7 and L8 maintain accurate balance of the input circuits. C9 and the 1N72 diode are tied in series across the line. Their midpoint is used for extraction of the VHF converted signal as well as for injection of the local UHF oscillator signal. C9 is critical in value since together with the diode it also affects the balance of the line.

The oscillator, a 6AF4 tube, is connected in an ultra-audion oscillator circuit. Its plate voltage is "shunt-fed" through L17 which presents a high impedance at frequencies above approximately 250 mc. The oscillator tank circuit, L2, is also a tunable shorted ¼-wave line. Oscillator output is taken from the cathode circuit across L14 and coupled through C11 into the 1N72 diode.

L9 furnishes the d-c return path for rectified diode current, while C18 resonates with other circuit constants to the VHF output frequency. The converted UHF signal is coupled through C19 into the cascode 6BK7 amplifier.

This amplifier consists of two stages. The first stage is a conventional triode, grounded-cathode stage, whose input circuit is tuned to the VHF frequency, (approximately 79 to 85 mc). The cathode circuit, consisting of R1 and C20, is only used to obtain d-c bias. L12 is a high-impedance, shunt-fed R-F choke. The output of the first stage is capacity-coupled into the second triode which is a grounded-grid amplifier. In the cathode of the second stage is connected a conventional bias resistor, R4, and its R-F bypass capacitor, C23. L11 provides the d-c cathode return through T1 to ground and also provides neutralization of the first triode stage to prevent it from oscillating. This neutralizing coil is somewhat critical in value and must, if damaged, be replaced by a proper coil if the low-noise advantages of this circuit are to be maintained.

SERVICING THE UHF-103 TUNER

Before replacing components check first the tubes. Check to see that the oscillator is working properly: the voltage on test point (see Fig. 25) should read −4 volt as measured with VTVM. With the exception of the oscillator socket, the components thereon and the UHF coils, the replacement of components in the tuner is comparatively simple, requiring no special considerations other than the usual lead dress precautions common in VHF practice. However, because of the small size of most components be sure to prevent overheating of components by using a small soldering iron.

The oscillator circuit wiring and the UHF coils are critical and require special attention.

Replacement of Oscillator Tube Socket

1. Remove the coil turret assembly by loosening the four set screws in the long coupling (Fig. 23) and the one set screw in the short coupling. Then, by lifting the detent roller and turning the assembly so one of the detent slots matches the bracket screw, the turret can be slid out of the unit.
2. Unsolder all connections to the V-shaped contactor board. Remove contactor board from the assembly by removing the one Phillips-head screw.
3. Carefully unsolder the components to the tube socket, not disturbing their position any more than necessary.
4. Drill out the two rivets holding the detent roller bracket. After removing this bracket the oscillator tube socket can be removed.
5. When reinstalling new socket be sure to place components in the original position (see Fig. 26). Positioning is so critical that it is not advisable to wiggle the tube back and forth when removing or inserting it but to pull or push it straight from the socket.

Replacement of UHF Coils

1. Remove small spring split washer (Truarc clip) on turret shaft that holds textolite coil bracket. To facilitate this operation a set of Truarc pliers should be used which may be obtained at your General Electric dealer (order number WH 50 x 58).
2. After removing old coil solder new coil assembly in place with the coil leads in their normal position. Flow the solder between the lead and the contact, making sure that the iron does not put any stress on the lead which might deform it.

The tuning cores for the coils are of different sizes and are selected to fit the coils. Therefore, do not interchange cores from one coil to another. Coils are supplied from the factory complete with their cores; be sure to replace as such.

3. With proper care it is possible to replace coil without removing coil bracket. Bend carefully the textolite plate upward just above the coil to be removed. Push the coil to the right until the top of the coil clears the retaining hole.
4. Gently release the textolite plate, and while holding the coil in this cocked position, apply the soldering iron to the two coil terminals simultaneously. As soon as the solder melts tilt the coil still further to the right and remove it. Wipe the contacts clean of all solder.
5. When replacing new coil bend textolite plate gently upward and put the new coil into position, being careful not to even slightly bend the coil leads in any direction. This precaution is very important as poor frequency stability will probably result if it is not followed. In soldering the new coil leads in place use the same precaution as outlined above.

PRODUCTION CHANGES

1. Vertical Sweep Circuit (Models 17T10-T11-T12 only).

(a). To reduce height changes with different settings of the Brightness control, R276, the resistor in the cathode of the picture tube was changed from R289, 150,000 ohms (URD-101) to R277, 220,000 ohms (URD-105).

(b). To eliminate compression at the top of the picture, the resistor across the vertical output transformer, T302, was changed from R330, 82,000 ohms (URD-095) to R374, 180,000 ohms, (URD-103).

2. Horizontal Sync Circuit (Models 17T10-T11-T12 only).

To improve horizontal sync stability under various conditions of signal strength levels, the feed-back resistor connected from the grid of the horizontal oscillator (V13B) to the discriminator (V12) plate was changed from R279, 180,000 ohms (URD-103) to R390, 330,000 ohms (URD-109).

3. Vertical Output Circuit.

To improve the vertical linearity, the vertical output tube was changed from 25L6-GT to 25W6-GT. These tubes are interchangeable and no change in tube socket wiring was necessary.

4. UHF-103 in Metal Cabinet 17T10, 21T2

When the UHF-103 Tuner is installed in a metal cabinet-type receiver, there is a tendency for the cabinet to induce horizontal sync pulses into the vertical system. The condition is recognized by the fact that the vertical sync is weak and unstable.

To eliminate this trouble, connect a .01 mf. 600 v molded paper capacitor between the front control apron and chassis.

A convenient location for this capacitor is on the right-hand side of the chassis looking at the front. Connect one lead of the capacitor to the center ground lug of the existing terminal board and the other lead to a soldering lug to be mounted under one of the screws fastening the front chassis mounting foot.

*RLI-145	L136	CHOKE—1.4 μh., V3A oscillator cathode	.35
*RLI-152	L141	CHOKE—R-F choke	.65
*RLI-154	L138, 139	CHOKE—3.3 μh., choke coil, orange, molded	.25
*RLI-159	L106	TRAP—I-F trap coil and tuning core in head-end	.75
*RLI-161	L262, R271	CHOKE—Video compensating	.70
*RLI-162	L257, 263	CHOKE—Video compensating, 165 μh.	.45
*RLI-165	L100	CHOKE—R-F input	.35
RLI-173	L266, 277	COIL—3rd. video I-F coil and tuning core	1.75
RLI-174	L269, R294	CHOKE—Video comp. 80 μh and 3300-ohm resistor	.50
RLI-185	L271, R291	CHOKE — Video comp. choke, 130 μh. and 22,000-ohm resistor	.60
*RLX-035	C265, 267, L254, 255, 256	VIDEO DETECTOR ASS'Y.—In shield can includes 1N64 diode, capacitors, coils and tuning slugs	6.00
*RTD-008	T402, C407, 408	TRANSFORMER — Ratio detector transformer assembly with capacitors and cores	5.25
*RTF-002	T451	TRANSFORMER — Filament for V1, V2, and V3	3.60
RTL-137	T201, C281, L265	TRANSFORMER—I-F input with tuning core in shield can	2.90
*RTL-139	T101	TRANSFORMER — Video I-F head end output with tuning core in shield can	1.95
RTO-081	T405	TRANSFORMER — Audio output	2.25
*RTO-116	T352	TRANSFORMER — Horizontal sweep output	12.65
*RTO-117	⊢302	TRANSFORMER — Vertical sweep output	7.60

MISCELLANEOUS ELECTRICAL

Cat. No.	Symbol	Description	List Price
*REC-006		CAP—High voltage rectifier	
*REF-008	F459	FUSE—1.6 amp., 125 v., slo blo line fuse	.05
*REI-014		CORE—Brass (screw type) tuning core for R-F tuner coils	.05
*REI-016		CORE—Tuning core composition iron with screw stud for RLI-097, RLI-100, RLX-035	.20
*REI-027		CORE — Width control, composition iron with screw stud	.60
*REI-033		CORE—Tuning core for ratio detector transf., RTD-008	.25
*REI-034		CORE—Brass (screw type), large head, for RSX-019	.10
*REI-035		CORE—Brass (screw type, ½ inch long) tuning slug for oscillator coils L129, L130, L131, L132, or R-F coilsL105,L109,L116,L124	.10
*REI-036		CORE—Brass (screw type. ¾ inch long tuning, slug for R-F tuner coils L112, L119, L127 and L133	.10
*REI-038		CORE—Tuning core composition iron with screw stud for trap coil T201	.20
*REI-040		CORE—Tuning core composition iron with screw stud for T101	.20
RER-015	X451, 452	RECTIFIER—350 ma., selenium	
*RET-014		ION TRAP—PM magnet ring on neck of picture tube	1.45
*RII-057		STRIP—Head-end switch wafer mounting insulator, textolite side rails	.25

MISCELLANEOUS ELECTRICAL (Cont'd)

Cat. No.	Symbol	Description	List Price
*RII-067		INSULATOR — Textolite bushing insulates volume control shaft from chassis	$0.05
RII-072		INSULATOR—For rear apron potentiometers.	.35
*RII-074		INSULATOR GUIDE—On channel switch bracket	.15
RII-075		INSULATOR—Left hand control mounting bracket	.15
RII-076		INSULATOR—Right hand control mounting bracket	.15
*RJC-015	P402	PLUG—Single connector male plug for deflection yoke	.30
*RJC-019	P404	SPEAKER PIN — Loudspeaker lead connector	.02
*RJC-020		CONNECTOR — Anode, Model 17T10-T11-T12	.60
RJC-025		CONNECTOR — Anode connector 17T11 and 17T-12	.70
*RJJ-008	S452	RECEPTACLE — Translator power	.35
*RJJ-010	I451	RECEPTACLE — Power cord	.20
RJP-039	P401	PLUG—Yoke connector, male, 4 pins	.15
*RJS-003		SOCKET—Tube socket, octal 1 5/16 inch for 6SQ7	.20
*RJS-025		SOCKET—Molded octal socket, wax impregn. for 25W4	.20
*RJS-026		SOCKET—Tube socket, octal, 1 1/16 inch for V21	.20
*RJS-031		SOCKET—Octal tube socket for tube V14	.25
*RJS-118		SOCKET Wafer socket, 9 pins, 1⅛ inch mtg., for 12AT7	.35
*RJS-132		SOCKET—Seven pin tube socket, 1 1/16 inch for V12 and V9	.20
*RJS-133		SOCKET—Tube socket, 7 pin shielded for V5, V6, V18	.20
*RJS-135		SOCKET — Octal shock mount for V13	.25
RJS-145		SOCKET—Miniature, 7 pin, wafer for 6CB6	.30
*RJS-148		SOCKET—Molded, tube socket, 9 pin, for high voltage rectifier V15	.25
*RJS-159	J402, 403	SOCKET — Female receptacle, 1 pin, for hi-voltage lead of yoke assy., and pix anode connector	.20
*RJS-160		SOCKET—Miniature 7 pin, for V1 and V2	.25
*RJS-161		SOCKET—Miniature 9 pin for V3	.30
*RJS-170	J401	SOCKET—Yoke connector, 4 pin female receptacle.	.25
*RJS-179		SOCKET—7 pin, shielded for 6AU6	.20
RLF-059		PM FOCUS ASSEMBLY—Less flexible shaft, 17T10 and 21T1	11.00
RLF-060		PM FOCUS ASSEMBLY—17T11 and 17T12	11.00
*RSX-019	S100-E, L134	SWITCH WAFER—Channel switch wafer with oscillator coils (first from knob)	7.00
*RSX-020	S100-D, L128	WAFER COIL ASSY.—Switch wafer - channel switch wafer with 2nd R-F plate coil (2nd from knob)	7.00
*RSX-021	S100-C, L120	SWITCH WAFER—With 2nd R-F grid coils (3rd from knob)	7.00
*RSX-022	S100-B, L113	SWITCH WAFER—With 1st R-F. plate coils (4th from knob)	6.50
*RSX-023	S100-A	SWITCH WAFER—Channel switch wafer with capacitors and coils (5th from knob)	5.75
*RWL-027		POWER CORD—A-c power cord and plug	1.20
*RWX-045		SOCKET—Picture tube socket	.90
S-527D-7	LS1	SPEAKER—PM, 5¼ inch	4.60

PRICES ARE SUGGESTED LIST PRICES AND SUBJECT TO CHANGE WITHOUT NOTICE.
*Parts used on previous receivers.
††Without C132 and jumper lead across terminals 3 and 4, see Fig. 14.

MISCELLANEOUS MECHANICAL

Cat. No.	Description	List Price
*RAD-083	BRACKET—For On-Off, volume and switch control	$0.25
RAD-096	BRACKET—Focus unit support bracket, Model 21T2	.25
*RAP-023	DETENT PLATE—Detent index plate for channel switch	.60
RAR-009	ROD—Pix tube mounting rod, Model 21T2	.85
RAR-010	ROD—Picture tube mounting rod, 17-inch models	.75
RAR-011	ROD—Yoke mount rod, Model 21T2	.65
RAR-012	ROD—Yoke mount rod, Model 17T10	.60
RAR-015	ROD—Picture tube mounting rod 17-inch models	.70
RAR-023	ROD—Yoke mounting rod, Model 17T12	.30
RAR-024	ROD—Yoke mounting rod, 17T10 and 17T11	.30
REA-002	PICTURE CORRECTOR—Bar magnet mounted on tie channel, Model 17T10 and 21T2	.65
RET-014	ION TRAP—PM magnet ring on neck of picture tube	1.45
RHC-008	CLIP—Mounting clip, 1 inch for elect. cap.	.10
RHG-010	GROMMET—Shock mount for tube V10	.05
RHG-021	GROMMET—Rubber grommet for speaker mounting	.05
RHJ-021	SPACER—"T" spacer on PM focus mount assy.	.10
RHM-072	FUNNEL—Crimp funnel on focus adjustment screw, Models 17T11 and 17T12	.15
RHN-016	NUT—Coupling nut for screws in channel selector shaft coupling RMK-006	.15
RHS-088	SHIELD—For tube V3	.30
RHS-089	BASE—Tube shield base for RHS-088 clip-on type	.15
*RHW-032	WASHER—Shoulder washer on head-end mounting	.02
RHW-033	WASHER—Rubber washer for loudspeaker mounting	.02
*RHW-038	WASHER—"U" washer on tube mounting rod, Model 21T2	.02
RHW-043	WASHER—Rubber washer for speaker mounting	.05
*RMC-017	CLIP—Mtg., clip, 1⅜ inch for electrolytic cap.	.10
*RMK-006	COUPLING—Shaft coupling (composition), less screws and nuts, couples head-end selector switch assembly shaft to control knob shaft	.35
RMM-222	CUSHION—Tube cushion Model 21T2	.25
RMM-225	CHANNEL—Tie channel, metal piece to hold PM focus unit mount	.15
RMM-226	SUPPORT—Yoke support plate, fibre	.25
RMM-227	MOUNT—Focus coil mount brass rod	1.20
RMM-228	CUSHION—Tube cushion, Models 17T11, 17T12	.15
RMM-234	SUPPORT—Anode lead support Model 21T2	.40
RMM-235	SUPPORT—Anode lead support 17-inch models	.35
RMM-238	DISC—Focus unit disc	1.20
RMS-310	SPRING—For head-end fine tuning control, for 17-inch models	.10
RMS-311	SPRING—Picture tube ground spring, Model 21T2	.10
RMS-312	STRAP—Support strap for focus coil, 17T10 and 21T2	.40
RMS-313	ASSEMBLY—Tube strap assembly, Model 21T2	2.75
RMS-314	ASSEMBLY—Tube strap assembly, Model 17T10	2.10
RMS-315	SPRING—Grounding spring, Model 21T2	.10
*RMS-316	STRAP—Support strap for focus coil, Models 17T11 and 17T12	.40
*RMU-055	SHAFT—Extension shaft for RLD-014 and RLD-016	.25
RMU-084	SHAFT—Switch shaft for channel switch, Model 21T2 only	.75
*RMU-087	SHAFT—Flexible shaft for PM focus unit, 17T10 and 21T2	1.85
RMU-089	SHAFT—Switch shaft for channel switch, 17-inch models only	.75
*RMX-178	RING ASSEMBLY—Ring, hub-flange assembly on fine tuning control shaft	.55
*RMX-211	SHAFT ASSEMBLY—Front panel tuning shaft (tubular) assembly, includes spacer and friction disc, Model 21T2 only	1.70
RMX-228	SHAFT ASSEMBLY—Front panel tuning shaft (tubular) assembly, includes space and friction disc, 17-inch models only	1.85
RMX-230	STRAP—Picture tube strap assembly, models 17T11 and 17T12	1.35

CABINETS AND CABINET PARTS

Cat. No.	Description	List Price
RAB-196	BACK—Cabinet back, Model 21T2	2.30
RAB-197	BACK—Cabinet back, Model 17T10	2.20
RAB-204	BACK—Cabinet back, Model 17T12	2.20
RAB-207	BACK—Cabinet back, Model 17T11	
*RAC-115	CAP—For cabinet back, Model 21T2	1.80
RAC-120	CAP—For cabinet back, Model 17T10	1.90
RAC-122	CAP—For cabinet back, Models 17T11-T12	
*RAD-084	DOOR—Trap door for knob escutcheon, Model 21T2	2.40
RAG-054	BAFFLE—Baffle and grille assy. for loudspeaker, 17T10 and 21T2	.95
RAV-204	CABINET—Metal cabinet, less mask and safety glass, Model 21T2	95.00†
RAV-205	CABINET—Metal cabinet, less mask and safety glass, Model 17T10	70.00†
RAV-209	CABINET—Mahog. cabinet, less mask and safety glass, 17T12	85.00†
RAV-213	CABINET—Mahog. cabinet, less mask and safety glass, Model 17T11	65.00†
*RDE-125	ESCUTCHEON—Control knob escutcheon less springs and clips, Model 21T2	1.25

CABINETS AND CABINET PARTS (Cont'd)

Cat. No.	Description	List Price
*RDK-244	KNOB—Concealed knobs, fawn for Model 21T2	.15
*RDK-263	KNOB—Knob for Off-On and volume control	.30
*RDK-291	KNOB—Knob for picture stabilizer	.15
RDK-299	KNOB—Knob for selector switch	1.20
RDK-300	KNOB—Secondary knobs, Models 17T10-T11-T12	.15
*RDK-308	KNOB AND SKIRT ASSY.—For tuning control	1.10
*RDK-309	KNOB AND SKIRT ASSY.—For picture control	1.20
*RDM-032	MASK—Picture tube mask, metal Model 21T2	17.50
RDM-033	MASK—Picture tube mask, Model 17T10	11.50
RDM-039	MASK—Picture tube mask, Model 17T12	
RDM-040	MASK—Picture tube mask, Model 17T11	15.95
*RDW-061	GLASS—Safety glass for picture tube, Model 21T2	11.95
RDW-062	GLASS—Safety glass for picture tube, Models 17T10-T11-T12	8.00
RMM-232	CUSHION—For safety glass 17 1/16-inch long, Models 17T10-T11-T12	$0.30
RMM-233	CUSHION—For safety glass 12 11/16-inch long, 17-inch models	.20
RMM-246	CUSHION—For picture tube	
*RMS-222	SPRING—Right hand spring for knob escutcheon, Model 21T2	.05
*RMS-223	SPRING—Left hand spring for knob escutcheon, Model 21T2	.05
*RMS-272	COMPRESSION RING—For tuning knob assembly	.05
*RMS-273	COMPRESSION RING—For picture knob assembly	.04
*RHC-036	CLIP—For escutcheon door pin springs, Model 21T2	$0.05
RHW-033	WASHER—Cup washer for escutcheon mounting 21T2	.02
*RIG-010	DUST SEAL—Rubber ring, Model 21T2, located between picture tube and safety glass	1.60
RIG-011	DUST SEAL—Rubber ring Models 17T10-T11-T12 located between picture tube and safety glass	1.40
*RMM-222	CUSHION—Picture tube cushion, Model 21T2	.25
RMM-228	CUSHION—Picture tube cushion, Models 17T10-T11-T12	.15
RMM-230	CUSHION—For safety glass 21⅛-inch long, Model 21T2	.25
RMM-231	CUSHION—For safety glass 15⅝-inch long, Model 21T2	.20

PARTS LIST—MODEL UHF-103

RESISTORS

Cat. No.	Symbol	Description	List Price
*URD-025	R1, 4	RESISTOR—100 ohms, ½ w., carbon	$0.13
*URD-033	R2, 3, 9, 13	RESISTOR—220 ohms, ½ w., carbon	.13
*URD-069	R5	RESISTOR—6800 ohms, ½ w., carbon	.13
*URD-073	R10	RESISTOR—10,000 ohms, ½ w., carbon	.13
*URD-081	R11	RESISTOR—22,000 ohms, ½ w., carbon	.13
URD-101	R6, 7	RESISTOR—150,000 ohms, ½ w., carbon	.13
*URD-117	R14	RESISTOR—680,000 ohms, ½ w., carbon	.13
URE-033	R8	RESISTOR—220 ohms, 1 w., carbon	.13

CAPACITORS

Cat. No.	Symbol	Description	List Price
RCE-150	C25, 26, 27	CAPACITOR—50 mf., 150 v. —20 mf., 150 v. —20 mf., 150 v.	3.00
*RCN-001	C11, 25	CAPACITOR—1 mmf., ceramic, min.	.20
*RCW-3037	C12, 13, 20, 21, 23, 24	CAPACITOR—800 mmf., ceramic	.25
*RCW-3070	C1, 2, 3, 4	CAPACITOR—2-2-5-5 mmf., ±.5 mmf. ceramic	1.75
RCW-3082	C5, 6	CAPACITOR—2 mmf., ceramic	.25
RCW-3083	C7, 8	CAPACITOR—1 mmf., ceramic, ±.25 mmf	.25
RCW-3084	C9	CAPACITOR—1.5 mmf., ±.25 mmf	.25
RCW-3085	C19	CAPACITOR—10 mmf., ±10%, ceramic	.25
RCW-3086	C18	CAPACITOR—18 mmf., ±10%, ceramic	.25
RCW-3087	C22	CAPACITOR—47 mmf., ceramic	.25
RCW-3088	C10, 14	CAPACITOR—6 mmf., ±5%, ceramic	.25

COILS AND TRANSFORMERS

Cat. No.	Symbol	Description	List Price
*RLI-122	L9	CHOKE—I-F choke, molded 2.2 mh.	.25
*RLI-168	L7, 8	CHOKE—R-F choke, 10 turns	.35
RLI-187	L11	COIL—Neutralizer coil	.85
RLI-188	L12	COIL—Interstage tuning coil	.60
RLI-189	L14, 15, 16, 17	COIL—Filament choke coil, 15 turns	
RLX-037	L1, 2, 3, 4, 5, 6	ASSEMBLY—Coil form assembly, including tuning core	4.25
RTL-140	T1	TRANSFORMER—I-F input transformer	1.20
RTL-141	T2	TRANSFORMER—I-F output transformer	1.65
RTP-313	T3	TRANSFORMER—Power transformer	4.75

MISCELLANEOUS ELECTRICAL

Cat. No.	Symbol	Description	List Price
RER-016	X1	RECTIFIER—Selenium rectifier	3.00
RJB-023		TERMINAL BOARD—2 terminals	.25
RJB-024		TERMINAL BOARD—3 terminals	.25
RJB-025		TERMINAL BOARD—5 terminals	.35
RJB-026		BOARD—Antenna terminal board and bracket, 4 terminals	2.00
RJP-046	P1	PLUG—Power plug, 7 pin	$0.20
RJP-047		PLUG—2 pin, for transmission lines, early production	.25
RJS-174		SOCKET—Tube socket for I-F tube 6BK7, 9 pin	.40
RJS-185	J1	SOCKET—Power socket, 7 pin	.30
RJS-186		SOCKET—Tube socket for oscillator tube, 6AF4	.40
RJS-187		SHELL—Connector shell for RJP-046	.25
RMM-245		ASSEMBLY—Crystal board assembly	.90
RSW-095	S1, 2	SWITCH—Wafer switch	.80
*RWL-009	P2	POWER CORD—6 feet long, with plug	.70

MISCELLANEOUS MECHANICAL

Cat. No.	Description	List Price
RAC-127	CAP—Retaining cap washers	$0.05
RAD-105	BRACKET—Front bracket, Models 21T2, 21T4	3.10
*RAD-106	BRACKET—Front bracket, Models 17T10, 17T11, and 17T12	3.00
RAD-107	BRACKET—Front bracket, Model 20T2	3.25
RAD-108	BRACKET—Guide bracket, "AK" line	.30
RAD-109	BRACKET—Rear bracket, Model 21T2	1.25
RAD-110	BRACKET—Rear bracket, Model 17T10	1.15
RAD-113	BRACKET—Rear bracket, Model 20T2	1.30
RAD-115	BRACKET—Rear bracket, Models 17T11 and 17T12	.90
*RDK-261	KNOB—Tuning knob	.15
RDK-302	KNOB—Knob ring, UHF selector	1.20
RDK-307	KNOB—Side mount knob assembly	1.75
RHC-059	RING—Truarc grip ring	.10
RHG-039	GROMMET—For switch shaft	.05
*RHI-017	STRAIN RELIEF—Two piece insulator, power unit	.15
RHJ-019	SPACER—To mount switch in tuner	.05
RHJ-022	SPACER—Knob ring spacer	.05
*RHM-043	"C" WASHER—Retaining ring to hold switch shaft	.01
RHS-091	SHIELD—Tube shield for 6BK7	.20
RHS-103	SCREW—For switch contact mount, ⅛ inch long	.02
RHS-105	SHIELD—Tube shield for 6AF4	.15
RHS-106	SCREW—Set screw for shaft coupling, No. 6-32	.15
RHS-107	SCREW—Set screw, No. 8-32	.15
RMB-030	BUSHING—Front bushing for "AK" line	.15
RMC-055	COLLAR—On turret tuner shaft	.35
RMG-014	GEAR—Crown gear, "AK" line	1.00
RMK-008	COUPLING—Switch shaft coupling	1.20
RMM-244	SUPPORT—Coil top support, round metal plate	.35
RMR-013	ROLLER—Detent roller, tuner	.15
*RMS-272	RING—Compression ring for knob	.05
RMS-318	SPRING—Detent spring, tuner	.35
RMS-320	SPRING—Short detent spring, tuner	.35
RMU-090	SHAFT—Switch shaft	.75
RMU-091	SHAFT—For large gear wheel	.15
RMU-092	SHAFT—Idler gear wheel	.15
RMX-234	SHAFT—Shaft and rotor assembly	2.90

PRICES ARE SUGGESTED LIST PRICES AND SUBJECT TO CHANGE WITHOUT NOTICE.
Mica and ceramic capacitors are 500 volts unless otherwise specified.
Resistor value tolerance is ±10% unless otherwise specified.

GENERAL INFORMATION

These Stratopower receivers are 12 channel models, into some of which the General Electric model UHF-103 UHF Tuner has been installed. Located at the rear of the receiver is a power outlet receptacle designated "UHF TRANSLATOR" into which the UHF Tuner should be plugged.

The 21-inch Stratopower chassis contains 20 tubes plus 6 receifiers (3 high-voltage rectifiers, 2 selenium power rectifiers and a crystal diode detector). The 17- and 20-inch models contain only two high-voltage rectifiers. Receivers equipped with a UHF Tuner Unit contain 2 additional tubes and one additional crystal diode.

Some of the features of these receivers are: Two r-f amplifiers, automatic noise cancellation, automatic horizontal frequency control, vertical and horizontal retrace blanking and automatic gain control.

The receiver performance may be optimized for weak or strong signal areas by the adjustment of the labeled control located at the rear of the receiver.

An i-f interference trap is incorporated in the r-f tuner unit. This trap is effective on channels 2 through 6 and may be adjusted to offending signals in the 40 to 50 mc i-f range. In most cases, this trap has been factory preset to 43.0 mc.

CAUTION NOTICE

THE NORMAL B+ VOLTAGES IN THIS RECEIVER ARE DANGEROUS. USE EXTREME CAUTION WHEN SERVICING THIS RECEIVER. THE HIGH VOLTAGE AT THE PICTURE TUBE ANODE (16,000 VOLTS) WILL GIVE AN UNPLEASANT SHOCK BUT DOES NOT SUPPLY ENOUGH CURRENT TO GIVE A FATAL BURN OR SHOCK. HOWEVER, SECONDARY HUMAN REACTIONS TO OTHERWISE HARMLESS SHOCKS HAVE BEEN KNOWN TO CAUSE INJURY. ALWAYS DISCHARGE THE PICTURE TUBE ANODE TO THE CHASSIS BEFORE HANDLING THE TUBE.

THE PICTURE TUBE IS HIGHLY EVACUATED AND IF BROKEN, IT WILL VIOLENTLY EXPEL GLASS FRAGMENTS. WHEN HANDLING THE PICTURE TUBE, ALWAYS WEAR GOGGLES.

INSTALLATION INSTRUCTIONS

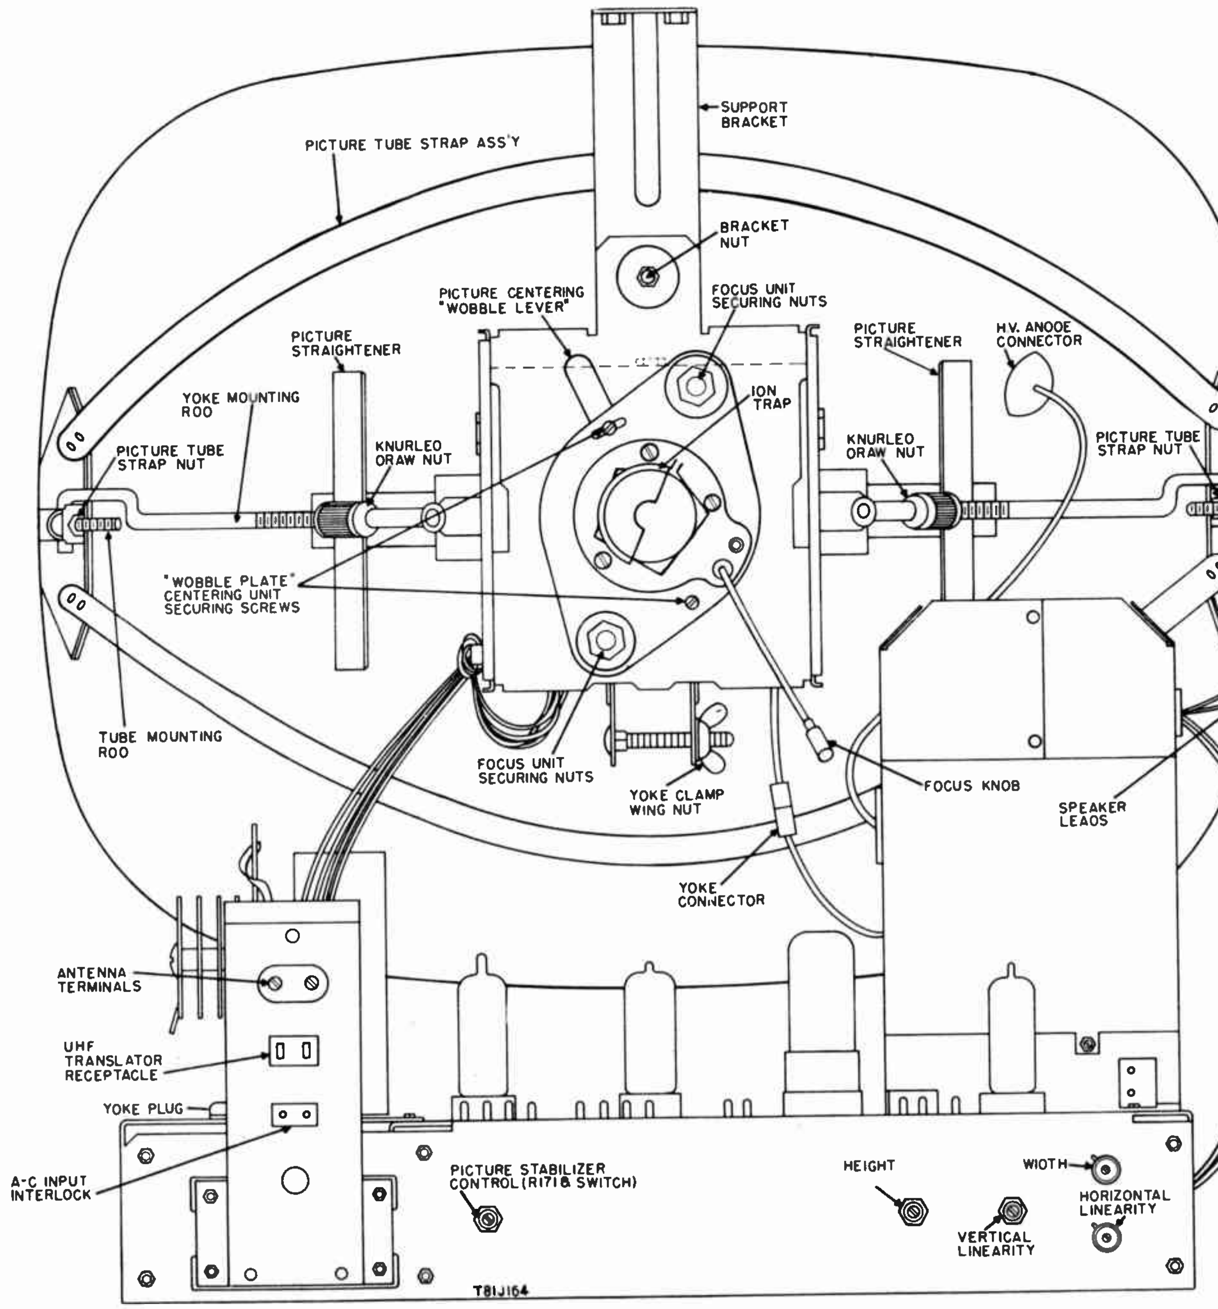

Fig. 1. Chassis and 21-inch Picture Tube Assembly, Rear View (Early Production)

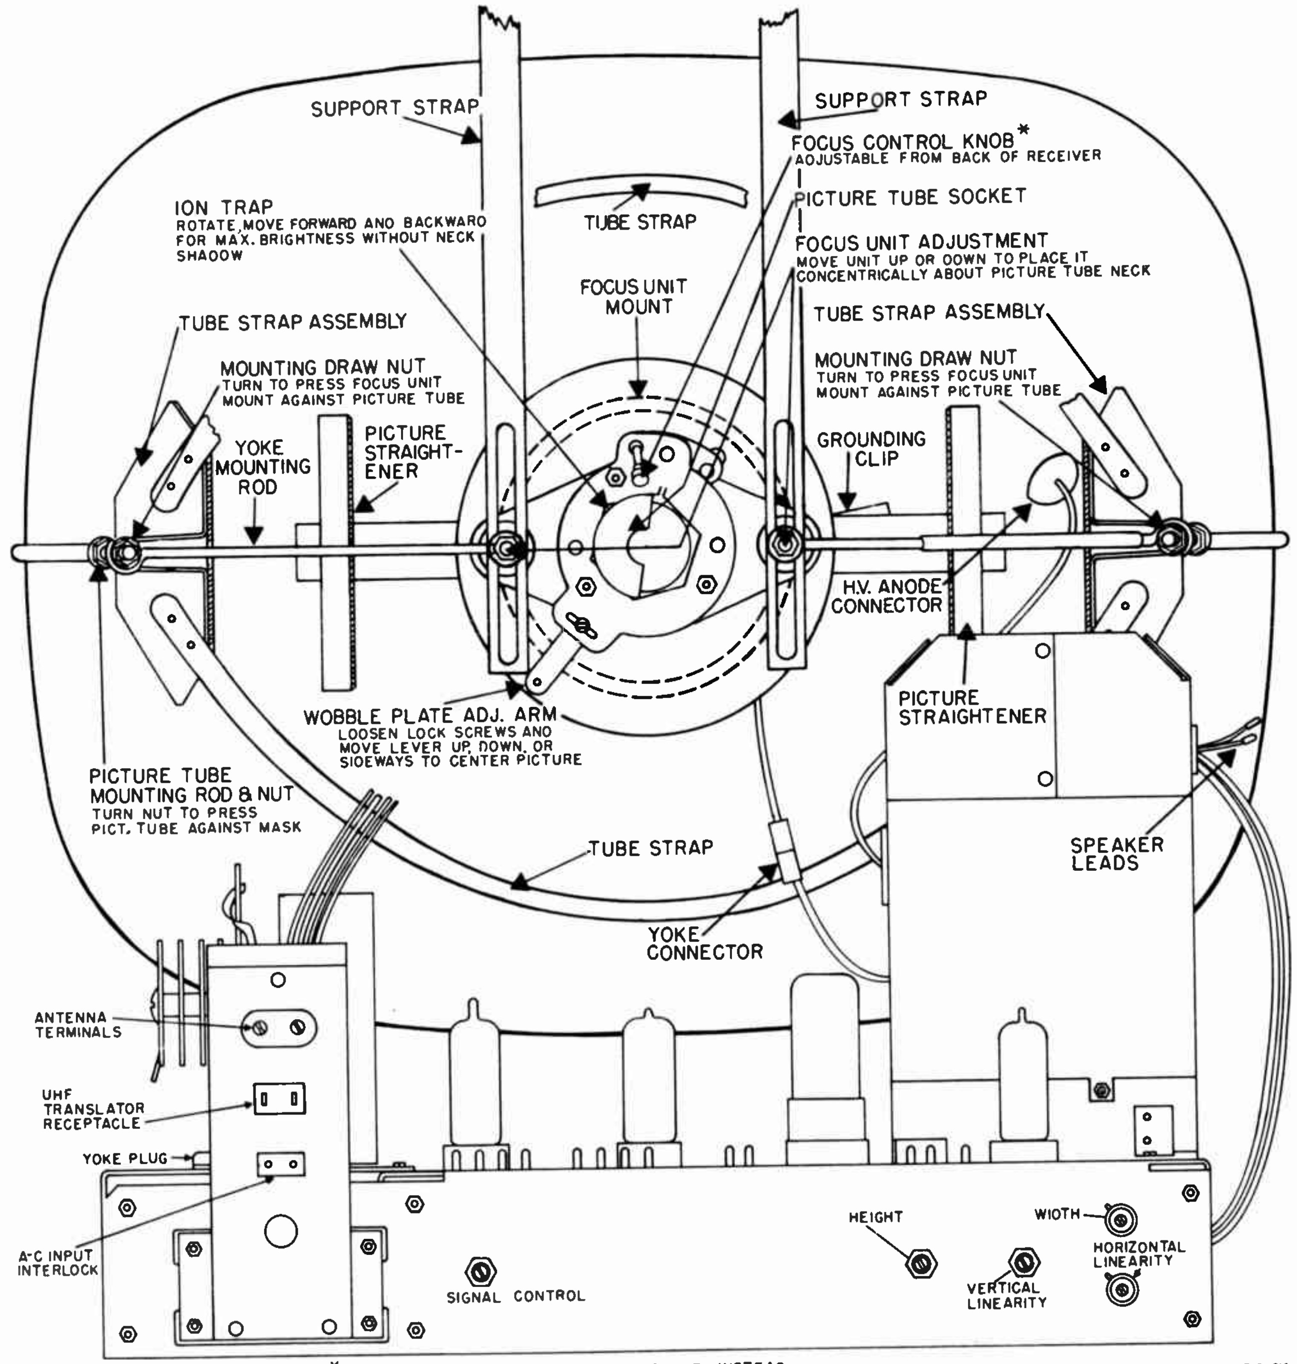

*LATE PRODUCTION MODELS USE GUIDE FUNNEL INSTEAD OF FLEXIBLE SHAFT

Fig. 2. Chassis and 21-inch Picture Tube Assembly, Rear View (Middle and Late Production)

IMPORTANT—PRODUCTION CHANGE NOTICE

Because these models have undergone several mechanical and electrical changes during production, frequent reference is made herein to first, second, third and fourth production versions. NOTE: References made to various versions refer only to the portion of the receiver under discussion. Changes in early production, mid-production and late production of the picture tube assembly do not necessarily coincide chronologically with electrical circuit changes in the chassis. See page 31 for a review of major production changes.

INSTALLATION ADJUSTMENTS

GENERAL: These receivers are shipped from the factory with the picture tube installed and all controls pre-adjusted for normal operation. It is necessary therefore, to merely plug in the receiver and, where required, connect it to a suitable antenna system. The various operating controls should then be checked for proper operation. The rear apron signal control should be adjusted for optimum receiver performance as indicated by its label.

If it becomes evident that one or more of the preset controls are out of adjustment due to handling, adjust the necessary controls according to the following information.

ELECTRICAL INSTALLATION ADJUSTMENTS

The following information is applicable to all Stratopower receivers. It is recommended that the receiver be permitted to operate for at least 15 minutes before the final raster adjustments are made.

HEIGHT AND VERTICAL LINEARITY: These controls should be adjusted simultaneously to provide proper picture height consistent with good vertical linearity. The final adjustment should extend the picture approximately 1/8 inch beyond the mask limits.

HORIZONTAL SIZE (WIDTH) & HORIZONTAL LINEARITY: These controls should be adjusted simultaneously to provide proper picture width, consistent with good horizontal linearity. The adjustments, when completed, should extend the picture approximately 1/4 inch beyond the mask limits.

HORIZONTAL HOLD: The coil, L351, see Fig. 30, should be adjusted so that the horizontal sync will remain locked over the entire range of the horizontal hold control, R363. Also, the "pull-in" range of sync should be evenly distributed on each end of the horizontal hold control range. This may be checked by switching off and on a station and observing the "pull-in" ability at either extreme of the control.

I-F INTERFERENCE TRAP: The R-F Tuner unit incorporates a tunable I-F interference trap in the 40–50 mc range. This trap should be adjusted after it has been determined that interfering signals in the I-F range are causing picture degradation. This trap adjustment is the rear-most adjustment on the top of the R-F Tuner. See Fig. 25 on page 23 for the location of this trap. It is designated as L106. If there is a station in the area on Channel 2, check to see that the tuning of the i-f trap has not affected the Channel 2 response. For complete adjustment instruction refer to page 27.

ADJUSTMENT OF THE AGC & SYNC GAIN CONTROL: (EARLY AND MID-PRODUCTION ONLY): This control is located at the rear of the receiver and should be adjusted at the time of the receiver installation. On some receivers, this control is labeled "Signal Control," "Signal Strength Compensator," or "Picture Stabilizer."

Adjust this control so that the strongest signal to be received does not cause picture sync distortion. The extreme clockwise "switch" position of the control should be used in the weaker signal areas to improve the sync stability in the presence of ignition and similar interferences.

SYNC GAIN CONTROL: Late production Stratopower receivers incorporating "Delayed AGC" are equipped with a simple two-position rotary switch instead of the above mentioned control.

INSTALLATION INSTRUCTIONS (Cont'd)

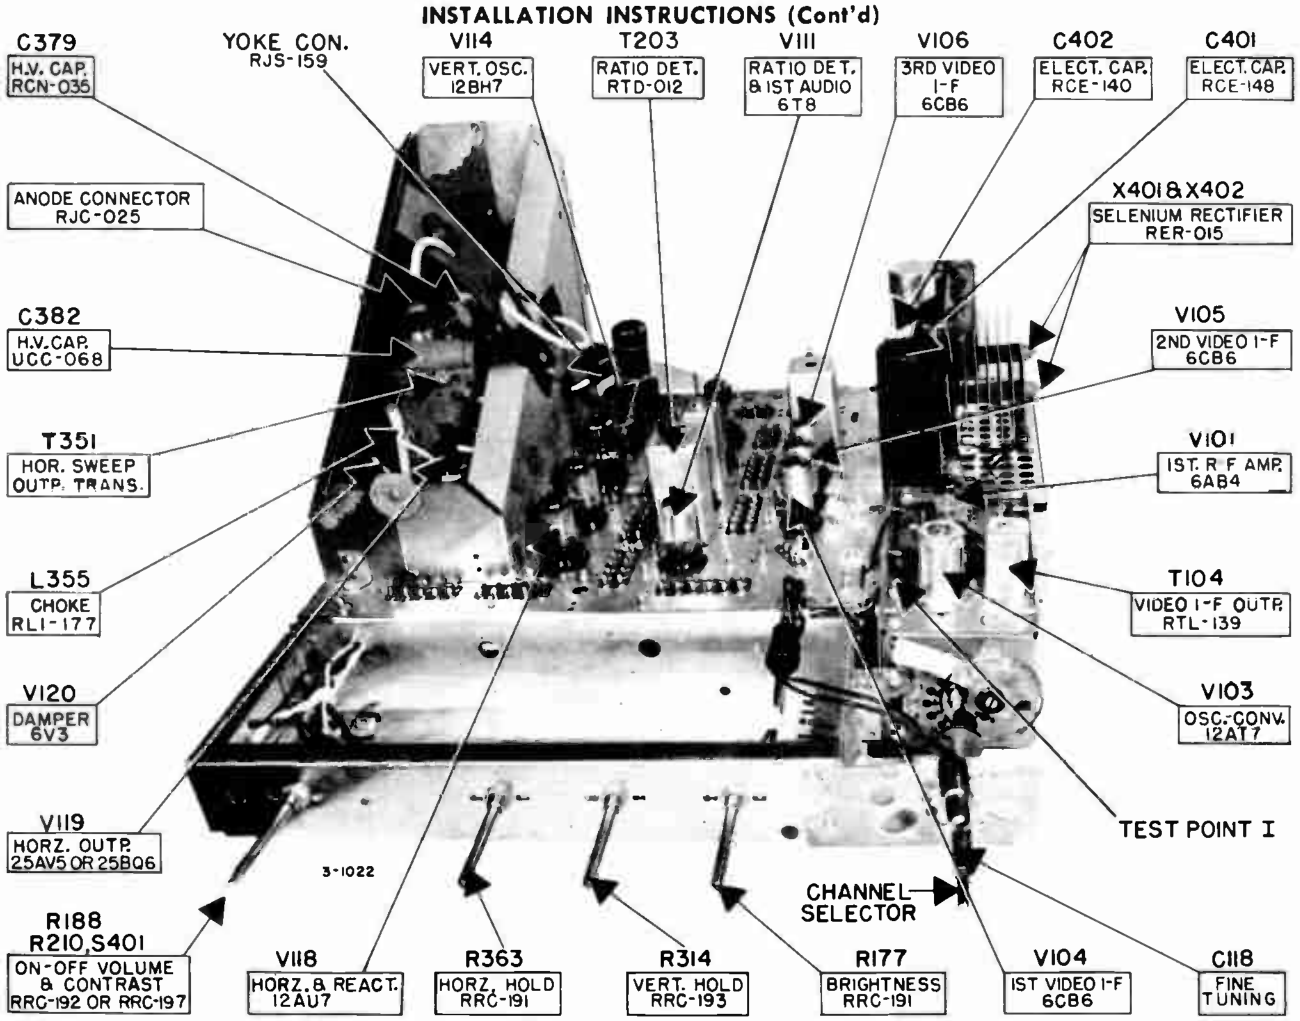

Fig. 3. Front View of Chassis

This switch (Normal-Fringe) increases or decreases the sync gain thus permitting optimum sync system operation under strong or weak signal conditions.

OVER-LOAD PROTECTION: A "slow-blow" 1.6 ampere fuse is incorporated in this receiver to protect the power supply rectifiers from overload. Should the receiver fail to operate, the fuse should be checked and the cause of overload remedied. This fuse is wired into the power supply compartment beneath the chassis, see Figure 33, page 90.

THE PICTURE TUBE ASSEMBLY

GENERAL: Two basic types of picture tube assemblies have been used in the production of the STRATOPOWER family of receivers. Figures 4 and 8 indicate the differences between these units. Both assemblies are similar in that the picture tube is held forward against the mask by a strap assembly which, in turn, is secured to the cabinet or mask assembly. The yoke and focus unit are held in position against the bell of the picture tube by side rods which engage the picture tube strap assembly. The yoke and focus assembly is also top supported by a bracket or, in the "late" unit, by two vertical straps. Note that the picture tube need not be removed when the yoke is removed for service, providing that the picture tube strap assembly is properly tightened.

In order to avoid neck shadow, the focus unit in both the "early" and "late" assembly must be perpendicular to the picture tube neck and concentric about it. Also, the deflection yoke must be properly positioned in the "early" unit, as described below.

Since the picture tube in 21-inch models is of the "cylindrical face" type, picture straightening magnets are used to avoid a "pincushioning" effect in the raster. These magnets should be perfectly vertical in their position and be centered about the center line of the picture tube as shown in Fig. 1, 2, 4 and 6. Failure to properly position these magnets will result in either a "pincushioning" or "parallelogramming" of the picture.

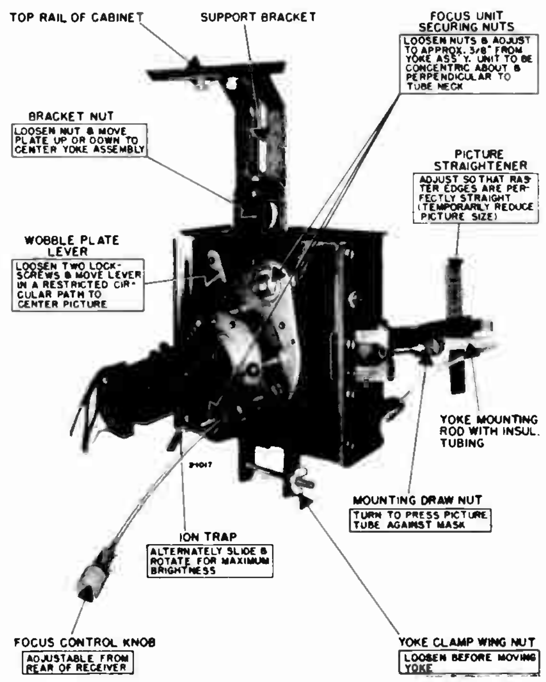

Fig. 4. Picture Tube Adjustments, (Early Production)

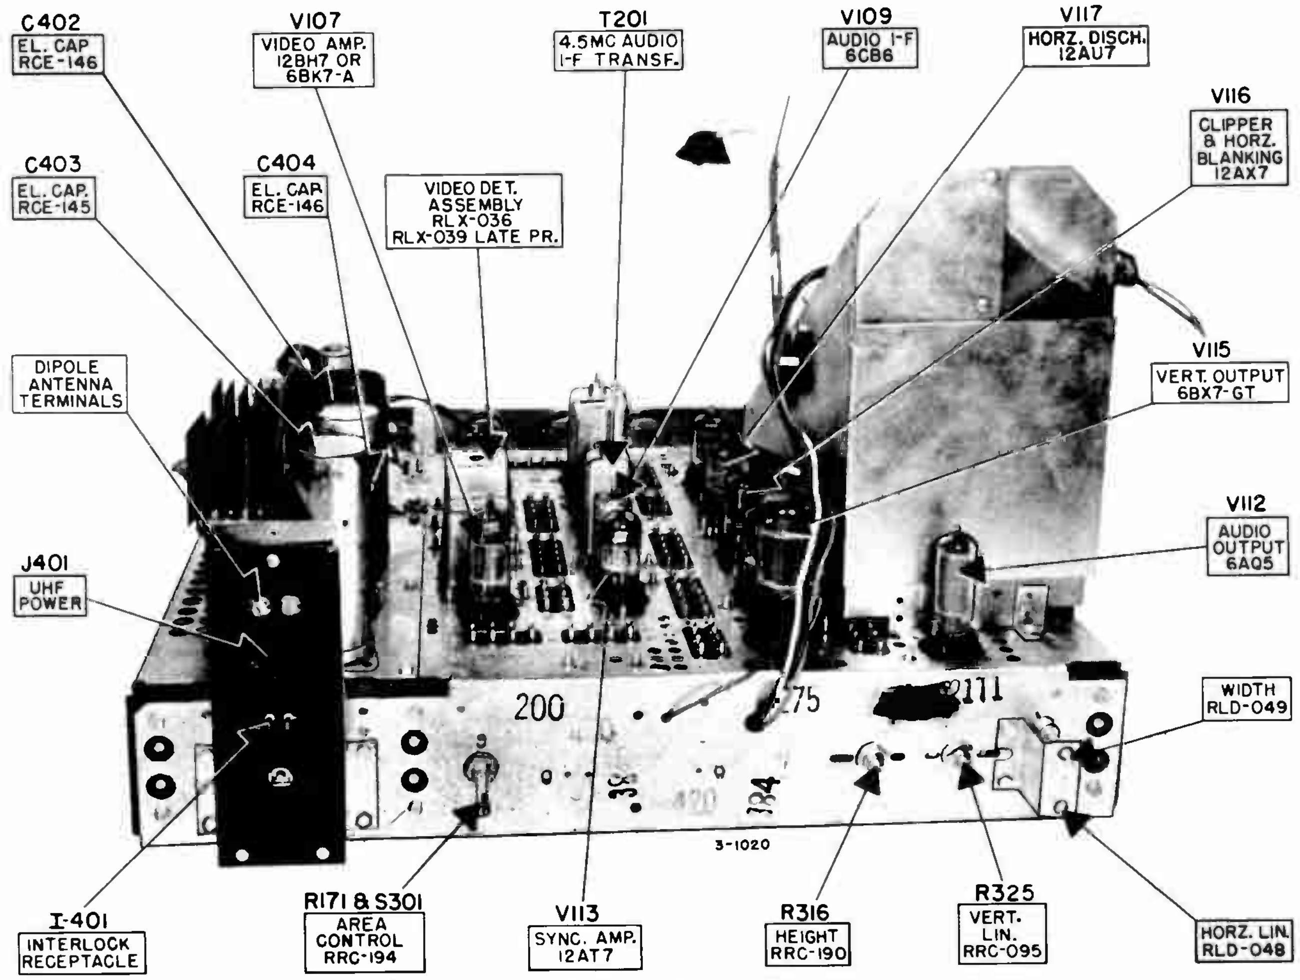

Fig. 5. Rear View of Chassis (1st, 2nd and 3rd Production)

PICTURE TUBE ASSEMBLY ADJUSTMENTS (EARLY ASSEMBLY)

The following data refers to the early assembly shown in Fig. 1 and 4.

1. Remove cabinet back.
2. Apply power to the receiver, turn set on and tune in a test pattern.
3. Adjust the necessary controls to correct any existing maladjustments. These control functions are as follows:

ION TRAP: Set the brightness control (under front panel control door) to its maximum clockwise position and alternately slide and rotate the ion trap for maximum brightness.

YOKE POSITIONING: Loosen the yoke clamp wing nut and make sure that the yoke is firmly seated against the bell of the picture tube. Picture tilt may be corrected by rotating the yoke to square the picture within the mask. Retighten the clamp wing nut after completing this adjustment.

FOCUS UNIT: Loosen the focus unit securing nuts and laterally adjust the focus unit to approximately 3/8 inch from the yoke assembly. Make sure the circular focus magnet remains concentric about and perpendicular to the tube neck. Tighten the focus unit securing nuts. Adjust the focus control for best focus.

PICTURE CENTERING: The wobble plate lever which is located on the forward end of the focus unit is the centering control. Loosen its two securing screws and move the lever in a restricted circular path until the picture is centered. Readjust the focus knob if the picture centering process disturbed the focus adjustment.

NECK SHADOW—IMPORTANT: If, after having made the above mechanical adjustments and it is impossible to eliminate neck shadow, the following procedure should be followed.

It is important that the entire yoke assembly and focus unit be concentric about the tube neck. Also the mounting bracket assembly should be perpendicular to the neck of the picture tube. To accomplish this, loosen the two yoke adjustment nuts on the sides of the yoke assembly, the yoke adjustment nut on the top assembly bracket and the yoke clamp wing screw. Then push the entire assembly towards the bell of the picture tube and tighten the rod draw nuts and the above mentioned nuts. Next, loosen the securing nuts on the focus unit bracket. Set the focus unit flush with the yoke tail and position the focus assembly so that it is perpendicular to and concentric about the tube neck. Tighten the securing nuts and recheck for proper picture centering, focus and ion trap adjustment.

PICTURE STRAIGHTENERS: These are the two anti-pincushioning magnets mounted near the bell of the picture tube. Adjust these magnets as follows:

(a) Reduce the picture size so that the raster edges are visible.
(b) Adjust the straightening magnets so that the raster edges are perfectly straight. These magnets will have an effect upon the width, but their important function is to keep the raster edges from being "bowed" in or out.
(c) Return picture to normal size with the size controls.

A. TO REMOVE PICTURE TUBE (Early Assembly):

1. Remove chassis.
2. Lay cabinet, face down, on a soft, nonscratching surface.
3. Loosen the two knurled draw nuts and move the yoke mounting rods away from yoke assembly.
4. Remove screw holding yoke assembly top supporting bracket.
5. Remove ion trap.
6. Remove yoke assembly from tube.
7. Loosen picture tube strap nuts and remove strap.
8. Remove picture tube.

B. TO REPLACE PICTURE TUBE (Early Assembly):

1. With the cabinet lying on its front, insert the picture tube into mask with its high voltage anode to the right (above volume

INSTALLATION INSTRUCTIONS (Cont'd)

control shaft hole). NOTE: Before replacing picture tube into receivers equipped with a metal mask, place the dust seal into the space between the mask front bezel and the inside rim. The dust seal should then be pulled through the eight tab holes which are arranged around the mask inside rim. Hook the dust seal on the eight provided tabs.

2. Place picture tube strap over tube and secure strap with the provided nuts and "U" washers.

3. Slide yoke assembly over tube neck and secure with screw to top support bracket.

4. Position both yoke mounting rods and tighten knurled draw nuts.

5. Install ion trap.

6. This step applies only to those receivers equipped with a metal mask.

After the side rods have been tightened and the assembly secured so that the picture tube can't possibly move or shift, the dust seal may be positioned. Push the dust seal off of the eight tabs in the mask rim. The dust seal will then fall into its proper place between the picture tube and the mask.

7. Restore cabinet to normal upright position and install chassis.

8. Bolt chassis to cabinet and install knobs.

9. Connect all leads and cables.

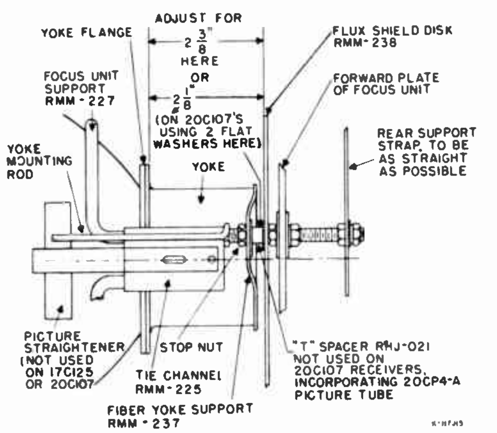

Fig. 6. Side View of Late Picture Tube Mount Assembly

"LATE" 21-INCH PICTURE TUBE ASSEMBLY

GENERAL: This information refers to the assembly shown in Fig. 2, 6, 7, 8, 9 and 10. In mid-production, the yoke and focus unit assembly was changed to incorporate a later design which somewhat simplified the installation adjustments and service procedure. Basically, this assembly is similar to the earlier unit in that the picture tube is held forward by a strap assembly which, in turn, is secured to the cabinet. The yoke and focus assembly is held in position against the bell of the picture tube by side rods in a manner similar to that used in the earlier assembly. The yoke is supported by the tube neck and hence need not be specially positioned to assure lack of neck shadow etc. It is necessary however to make sure that the focus unit is concentric about and perpendicular to the tube neck.

On some receivers using this assembly, the brass focus unit support rods must be "cocked" slightly clockwise (approximately 5 degrees) so that the picture straightening magnets will be reasonably vertical in their position to prevent a "Parallelogram" effect in the picture. See Fig. 7. This is not necessary in later production receivers using the new assembly since the picture straighteners were re-designed with off-set brass supporting straps which will properly position them without "cocking" the entire assembly.

Late production focus units utilize a screw driver method o adjustment rather than the flexible shaft and knob found on earlier versions. It is important when adjusting this new focus unit that a nonmagnetic screw driver be used to simplify the procedure. Also, when attempting to adjust the focus unit through the cabinet back, be sure that the screw driver enters the screw funnel otherwise the ion trap may become disturbed. This would require removal of the cabinet back to allow re-adjustment of the ion trap.

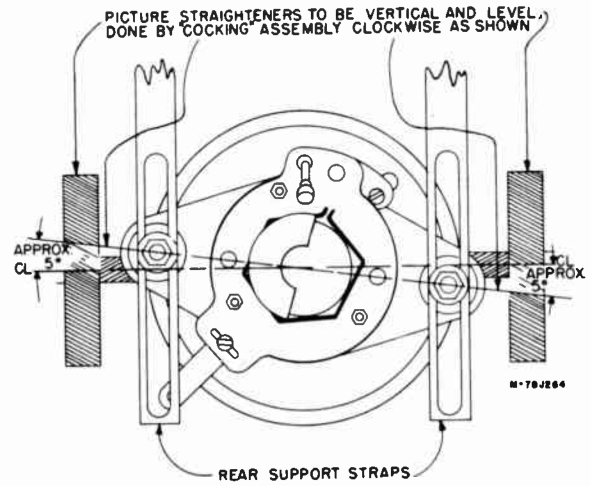

Fig. 7. Rear View, 21-inch Models

PICTURE TUBE ASSEMBLY ADJUSTMENTS (LATE ASSEMBLY)

The following data refers to the late assembly shown in Figures 2, 6, 7 and 8.

1. Remove cabinet back.
2. Apply power to the receiver, turn set on and tune in a test pattern.
3. Adjust the necessary controls to correct any existing mal-adjustments. These control functions are as follows:

ION TRAP: Set the brightness control (under front panel control door) to its maximum clockwise position and alternately slide and rotate the ion trap for maximum brightness.

YOKE POSITIONING: Rotate yoke to square picture within the mask. It is not necessary to loosen any part of the assembly for this operation.

FOCUS UNIT: Loosen the focus unit securing nuts and laterally adjust the focus unit for the dimension shown in Fig. 6. Make sure the circular focus magnet remains concentric about and perpendicular to the tube neck. Tighten the focus unit securing nuts. Adjust the focus control for best focus.

PICTURE CENTERING: The wobble plate lever which is located on the forward end of the focus unit is the centering control. Loosen its two securing screws and move the lever in a restricted circular path until the picture is centered. Readjust the focus knob if the picture centering process disturbed the focus adjustment.

PICTURE STRAIGHTENERS: These are the two anti-pincushioning magnets mounted near the bell of the picture tube. Adjust these magnets as follows:

(a) Reduce the picture size so that the raster edges are visible.
(b) Adjust the straightening magnets so that the raster edges are perfectly straight. These magnets will have an effect upon the width, but their important function is to keep the raster edges from being "bowed" in or out.
(c) Return picture to normal size with the size controls.

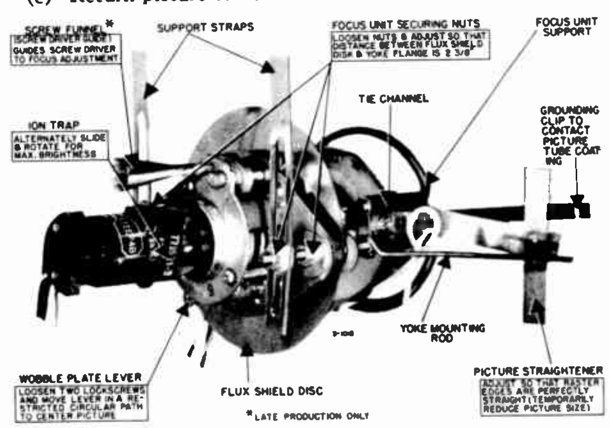

Fig. 8. Picture Tube Adjustments (Late Production)

INSTALLATION INSTRUCTIONS (Cont'd)

A. TO REMOVE PICTURE TUBE (Late Assembly):

1. Disconnect all cables and leads. Remove chassis.
2. Lay cabinet, face down on a soft, nonscratching surface.
3. Remove ion trap.
4. Loosen and remove nuts and washers which secure the yoke mounting rods to the picture tube strap assembly.
5. Remove rear support strap nuts and move straps aside.
6. Remove entire yoke and focus assembly.
7. Remove picture tube strap assembly and picture tube.

B. TO REPLACE PICTURE TUBE (Late Assembly):

1. This step applies only to those receivers equipped with a metal mask. Before inserting picture tube into mask, the sponge rubber dust seal should be placed into the space between the mask front bezel and the inside rim. The dust seal should then be pulled through the eight tab holes arranged around the mask inside rim. Hook the dust seal on the eight tabs.

2. Replace picture tube.

3. Replace, in reverse order, all yoke and focus assembly parts removed in "A" above.

4. After the side rods have been tightened and the assembly secured so that the picture tube can't possibly move or shift, the dust seal may be positioned. Push the dust seal off of the eight tabs in the mask rim. The dust seal will then fall into its proper place between the picture tube and the mask.

5. The nut between the fiber yoke support and the tie channel should be turned by finger fully forward. The nut immediately to the rear of the flux shield (large disc) should be set for $2\frac{3}{8}$ inches between the disc and the flange as shown in Fig. 6. The fiber yoke support stop nut should now be unscrewed toward the fiber yoke support and suitably tightened. Next, tighten the nut behind the forward plate of the focus unit thus maintaining it in its maximum forward position.

6. Replace ion trap.

7. Replace chassis and connect all leads and cables.

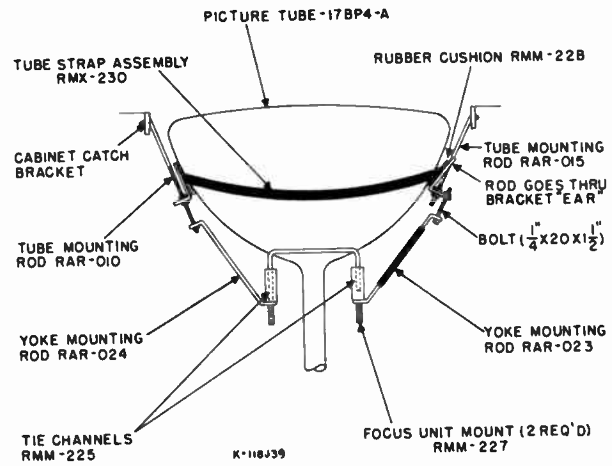

Fig. 9. Picture Tube Assembly, Model 17C125 (Top View) (Yoke and Focus Unit Not Shown)

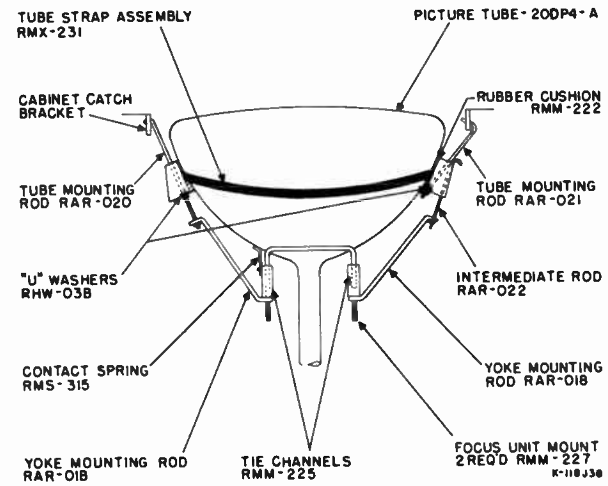

Fig. 10. Picture Tube Assembly, Model 20C107 (Top View) (Yoke and Focus Unit Not Shown)

RECEIVER CIRCUIT ANALYSIS

A brief description of the operation of each circuit is given in the following paragraphs. A block diagram of the receiver is shown in Fig. 11 to better visualize the operation of the receiver.

The incoming signal is amplified by two r-f amplifier stages V101, 6AB4, and V102, 6AK5. The signal is then mixed in the converter V103B, 1/2 12AT7, with a signal developed by the local oscillator V103A, 1/2 12AT7. The resulting intermediate frequencies (both sound and picture) are then coupled via a transmission line into the video i-f strip consisting of the tubes V104, V105 and V106 (6CB6 tubes). After amplification these signals are then rectified or detected by a crystal diode, Y151.

Across the diode load circuit appears a 4.5 mc FM signal containing the sound information. This 4.5 mc FM sound i-f carrier is amplified by V109, 6CB6 and then passed to a limiter, V110, 6AU6. The output of the limiter is detected by a ratio detector V111A, 1/2 6T8. Tubes V111B, 1/2 6T8 and V112, 6AQ5 comprise the remainder of the audio system. The audio signal is then fed to the loudspeaker.

Composite sync and video information also appears across the video detector diode load and is passed to the video amplifier V107 and thence to the grid of the picture tube, V108.

A portion of the composite sync and video voltage appearing across the diode load is picked off and amplified by the sync amplifier V113A, 1/2 12AT7. In order to remove the deleterious effects of strong impulse noise upon picture stability, a noise canceller circuit is incorporated in this receiver. The noise canceller V113B, 1/2 12AT7 is tied across the output of the sync amplifier in such a manner that it will eliminate the noise impulses. This will be more completely described on page 20.

After removal of noise pulses if any the composite video and sync information is passed to the sync clipper wherein the video information and blanking pedestals are stripped off leaving only the vertical and horizontal sync information. Another function of the clipper is to provide an automatic gain control (AGC) voltage which is used in conjunction with diode d-c voltage to control the gain of the r-f and i-f stages.

This is partially accomplished by clipper grid rectification of the sync pulses together with a "minimum" bias developed by the diode detector. Since the sync information is held at a constant level throughout the transmission, these pulses provide an excellent amplitude reference for purposes of AGC operation. The horizontal and vertical sync pulses are separated after the clipper and fed to their respective sweep frequency controlling devices.

The vertical sync information is integrated in the integrator network P301 to form the vertical sync pulse. This pulse is applied to one grid of the vertical multivibrator V114, 12BH7, to control its frequency. The produced vertical sweep pulse is properly shaped and amplified by the vertical amplifier V115, 6BX7. This amplified voltage is then applied to the vertical windings of the deflection yoke. A portion of the vertical sweep pulse is picked off at the output of tube V115, and after proper shaping, is applied to the cathode of the picture tube. This vertical blanking pulse is used to blank or cut off the picture tube during the vertical retrace time, thus eliminating the annoying diagonal white lines that may appear in the picture should the brightness be turned up too far or if the blanking pedestal pulse from the

RECEIVER CIRCUIT ANALYSIS (Cont'd)

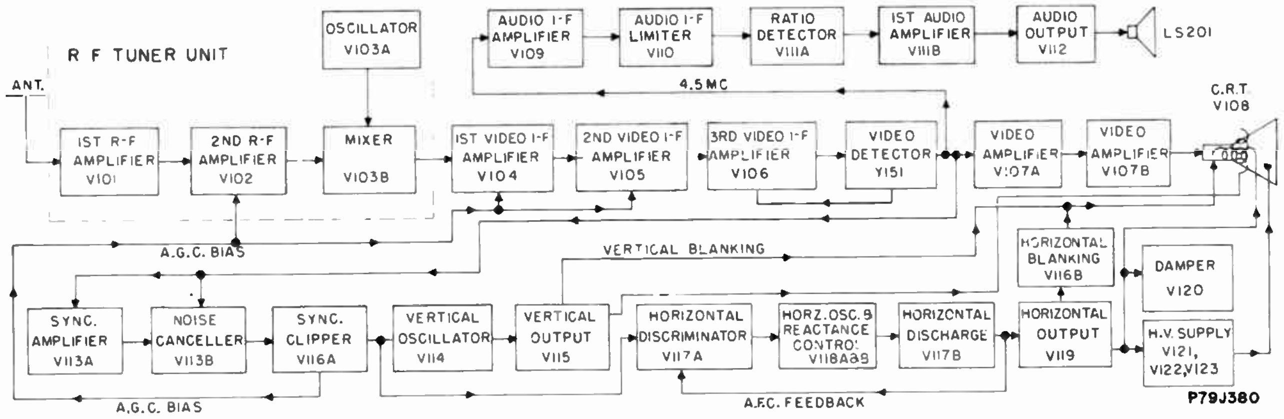

Fig. 11. Block Diagram (21-inch Models)

transmitter is of insufficient amplitude to accomplish vertical blanking.

The horizontal pulse information from the clipper tube, V116A, 1/2 12AX7, is coupled into the horizontal phase detector V117A, 1/2 12AU7, wherein a comparison is made between the phase or frequency of the sync pulses and the horizontal sweep pulse. This comparison results in a d-c correction voltage which is then applied to the reactance control tube V118A, 1/2 12AU7, which in turn controls the frequency and/or phase of the horizontal oscillator, V118B, 1/2 12AU7.

The pulse generated by the horizontal oscillator is properly shaped in the horizontal discharge stage, V117B, 1/2 12AU7, and applied to the horizontal output amplifier V119, 25AV5 or 25BQ6. This tube provides the necessary pulses for horizontal sweep and the development of the high-voltage for the picture tube anode. A damper tube V120, 6V3 is connected in a high-efficiency "flyback" type circuit. Its dual purpose is to dampen out or remove the train of oscillations appearing at the beginning of each sweep pulse and to use these pulses, after rectification, to provide boosted d-c voltage for the plate of the horizontal output tube, V119.

A portion of the horizontal scanning pulse, as it appears across the width coil, is picked off and applied to the grid of a cathode follower stage, V116B, 1/2 12AX7, from which is derived a horizontal retrace blanking pulse. This pulse prevents the appearance of horizontal retrace effects.

The high voltage is derived from a voltage doubler circuit. In the 21-inch models a high-efficiency doubler circuit consisting of V121, V122 and V123 (1X2A tubes) is used. It is the inclusion of V122 as a coupling diode which brings about the higher efficiency and greatly stabilized voltage regulation of the high-voltage rectifier system. Because of the lower high-voltage requirements of tubes smaller than 21 inches, a straight-forward voltage doubler is used in 17- and 20-inch receivers.

In the following paragraphs a detailed description of some new circuits is given.

VIDEO I-F SYSTEM ANALYSIS

The video i-f system consists of three pentode amplifiers, the output of which is detected by a crystal diode, Y151.

The input signal is delivered from the r-f tuner via link coupling. The grid winding or secondary of T151 is tuned approximately to the center of the video i-f pass band. A 38.0 mc series-tuned absorption trap, L152, is tied across the input grid circuit. Also, an absorption trap, L151, is inductively coupled to T151 to reject any adjacent channel audio carrier interference.

The next two plate coils, L153 and L155, are tuned to opposite sides of the pass band center frequency in such a manner as to provide the desired 45–55% response at 42.5 mc and 45.75 mc. Inductive absorption traps are coupled to each of these coils. L154 is the second 47.25 mc trap. L156 is tuned to the "accompanying" sound frequency of 41.25 mc. It is not the purpose of this trap to eliminate the 41.25 mc carrier since this would remove the sound signal when the receiver is properly tuned. Rather, this trap is incorporated to somewhat lower the percentage of audio i-f carrier present in the i-f system to prevent excessive 4.5 mc "crystallization" effects in the picture when the receiver is tuned for best picture detail. (The very high gain of the audio i-f system plus its limiting stage more than compensates for this inserted loss).

The coil, L157, is also tuned to the i-f pass-band center frequency. A 38.0 mc trap, L158, is inductively coupled to L157.

The frequency of the adjacent channel audio i-f carrier traps would normally be expected to fall at 39.75 mc. However, in the fringe areas where the operator will tune for maximum picture gain and hence place the carrier near the peak of the response curve, it becomes necessary to correspondingly shift the adjacent channel audio trap lower in frequency. For this reason the adjacent channel audio carrier traps are tuned to 38.0 mc.

The two i-f carrier signals present at the plate of the third i-f (V106) are capacitively coupled to the crystal diode "shunt-type" detector. L168 is incorporated as a "tweet" filter and eliminates upper-order harmonics of the i-f frequencies present in the crystal output which would cause tuneable interference patterns on some channels.

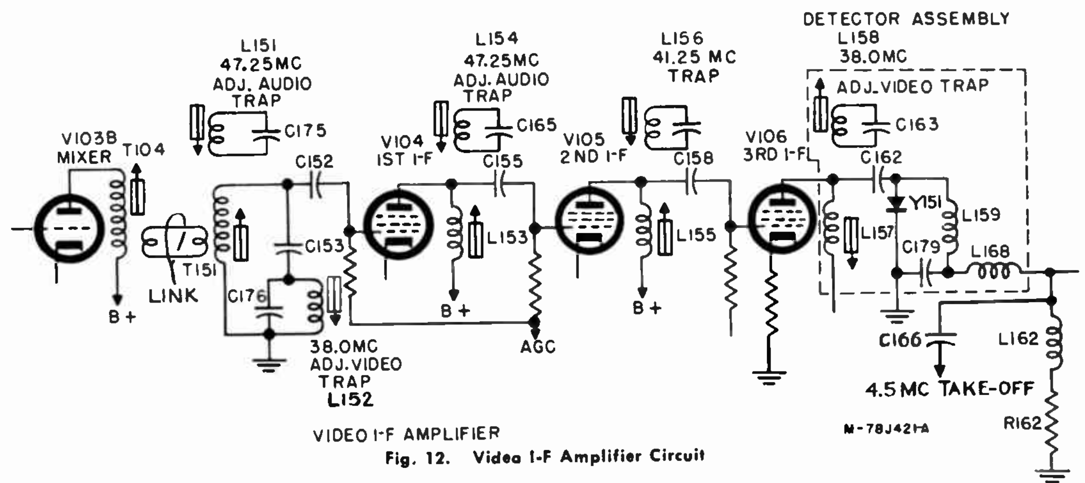

Fig. 12. Video I-F Amplifier Circuit

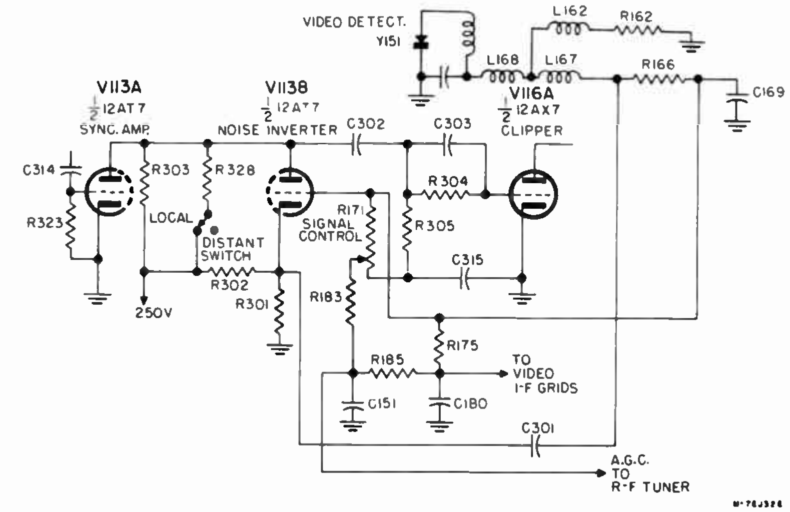

Fig. 13. Noise Canceller Circuit (1st and 2nd Production)

The crystal diode output consists of composite video information (positive white) which is coupled to the video amplifier V107, for further amplification. The crystal diode output also contains a 4.5 mc FM carrier which is coupled to the audio i-f system for further amplification and detection to provide the program sound intelligence.

SYNC AMPLIFIER, CLIPPER AND NOISE CANCELLER

A portion of the crystal diode (Y151) output is picked off and fed to the grid of the sync amplifier, V113A. See Fig. 13. This stage is a voltage amplifier, the output level of which may be adjusted to suit a particular signal area or to optimize the sync stability of the receiver under noisy, weak signal conditions. This may be done by raising or lowering the value of its plate load resistor by closing or opening the local-distant switch. (In some earlier models, this switch was attached to the AGC control potentiometer.)

The output of the sync amplifier is coupled to the clipper grid through C302. The clipper, V116A, strips off all video information leaving only the sync pulses which are then used to synchronize both the vertical and horizontal oscillators in the sweep system.

The noise inverter or canceller, V113B, is tied across the output of the sync amplifier V113A. The cathode of the canceller has a fixed positive bias applied by virtue of R301, R302. Its grid is maintained at some negative bias voltage which is proportional to the strength of the incoming signal. This negative grid bias is obtained from the crystal diode Y151, and is suitably filtered by R166 and C169. These two bias voltages combine to cut off the canceller tube, V113B, so that it will normally not conduct in the presence of a received television signal.

The cathode of the canceller, V113B, is fed a signal consisting of video and negative-going sync as well as impulse noise, if any. Since the canceller is biased off and will not pass any signals less than the sync-tip level, nothing happens until a noise burst of greater-than-sync-tip level occurs. When this happens, the canceller tube, V113B, will conduct heavily, and hence will drop the instantaneous sync amplifier output below the clipping level which has already been established in the clipper V116A.

Because of this, neither sync nor noise will be present in the clipper output for the duration of the noise burst. At these times, the inertia or "fly-wheel" effect of the sweep circuits and the horizontal AFC system is relied upon to maintain proper frequency. After the noise burst ceases, the canceller tube, V113B, no longer conducts and the circuits return to normal operation. (For maximum efficiency, however, the canceller is normally biased in such a manner as to *slightly* wipe sync. This is permissible since the sync information amplitude is more than adequate. This is mentioned here instead of earlier to prevent confusion.)

AGC SYSTEM

In all the included models, AGC bias is derived from the clipper grid circuit by means of grid rectification of the applied video and sync waveform—and partially from the crystal diode detector. Some earlier models incorporated a rear-apron AGC potentiometer, R171, which should be adjusted just below the point of sync overload on the strongest available signal. The AGC voltage is then distributed to the r-f stage and to the first and second video i-f amplifiers.

Later production receivers incorporate a Delayed AGC system which prevents the application of negative AGC bias to the r-f tuner unit on all signals below a predetermined signal level. Thus on weak signals the r-f amplifier operates at maximum gain and hence improves the signal-to-noise ratio. The i-f stages, however, receive the normal nondelayed AGC voltage from the clipper circuit, or from the crystal diode.

AGC delay is achieved as follows: (Refer to Fig. 14.) AGC voltage which originates from the clipper grid circuit is fed through R223 and thence to the r-f tuner through the decoupling filter consisting of R183 and C151. R222 feeds a small positive d-c voltage into the junction of R223 and the by-pass capacitor C181. The diode of V111B is tied between this point and ground, the purpose of which is to prevent the voltage at this point from going positive in the absence of signal or in the presence of weak signals. Hence the voltage appearing on the r-f tuner AGC lead will theoretically remain at zero volts d-c until a sufficiently strong signal is received which will develop enough negative AGC bias voltage to overcome the small applied positive delay voltage. In actual practice, however, the zero signal or weak signal r-f tuner bias voltage is never at absolute zero volts, since a small amount of contact potential is developed by the delay diode and by the 2nd r-f amplifier. This voltage will usually measure from $-\frac{1}{2}$ to $-1\frac{1}{2}$ volts.

Delayed AGC was incorporated in 3rd and 4th-production models, which may be readily identified by the rear apron compensator control which is a simple two-position switch rather than a switch and potentiometer combination, as was used in earlier production receivers.

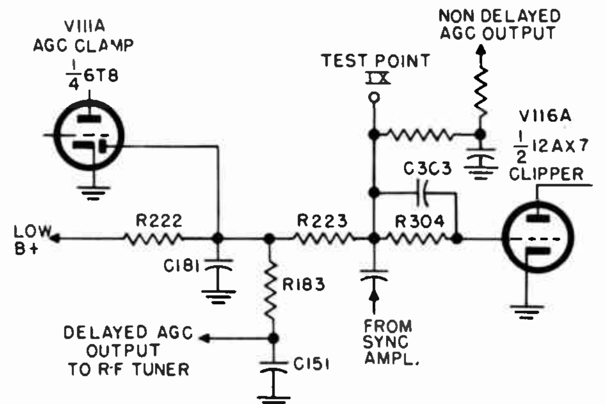

Fig. 14. Delayed AGC Circuit

RETRACE BLANKING

These receivers incorporate both vertical and horizontal retrace blanking which removes the annoying diagonal white lines or the white irregular vertical band frequently noticed on receivers not equipped with retrace blanking facilities.

VERTICAL RETRACE BLANKING—The coupling network consisting of C313 and R329 (see Fig. 38) differentiates the saw-tooth waveform originating at the vertical output stage plate (V115) and forms a steep positive "spike" voltage. This voltage is coupled through C172 into the picture tube cathode and hence drives it to cut-off during the retrace portion of the vertical sweep cycle. (C318 and R326 are required for the horizontal blanking system as explained below. These components have little or no effect on the vertical blanking pulse.)

HORIZONTAL RETRACE BLANKING—Horizontal blanking is also accomplished by the application of a suitable positive pulse to the picture tube cathode.

A "sample" of the width coil pulse is fed to the grid of the horizontal blanking tube, V116B, after suitable shaping. V116B functions as a cathode follower and provides isolation between the pulse source and the picture tube circuits. This system provides a suitably low impedance source of horizontal blanking pulses.

The developed blanking pulses appear across R326. As far as the *horizontal* blanking pulses are concerned, the bottom end of R326 is virtually grounded, since C318 provides a low impedance return path at the 15,750 cps. frequency. C318 is used additionally to prevent the appearance of horizontal pulse information in the vertical output circuits which would otherwise destroy picture interlace.

HORIZONTAL SYNCHRONIZATION

Horizontal synchronization is accomplished by comparing the phase and/or frequency of the incoming horizontal sync pulses with the phase and/or frequency of the horizontal sweep pulses which are generated within the receiver.

This comparison is made in the horizontal phase detector circuit (V117A) which then, by means of this comparison, provides a d-c output voltage. The polarity and amplitude of this voltage will depend upon any difference between the phase or frequency of the sync pulses and the locally generated sweep pulses.

This "correction" voltage is next applied, after suitable filtering, to the reactance tube (V118A) which, in turn, retards or advances the firing time of the horizontal oscillator thus causing it to remain accurately in step with the sync pulses.

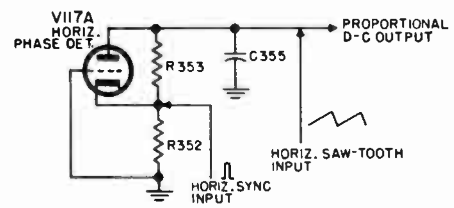

Fig. 15. Basic Horizontal Phase Detector

A triode-type tube is used as the phase detector. In general, the application of a small, identical positive voltage to both the grid and plate will cause identical currents to flow in each element. Figure 15 shows the basic horizontal phase detector circuit. R352 and R353, being nearly equal in value, will have developed across each of them, an equal but opposing d-c voltage due to the application of the negative polarity sync signals to the cathode. (R352 and R353 differ in value only to correct for the slight impedance difference between the grid to cathode and plate to cathode paths.)

A sample of the horizontal saw-tooth voltage, obtained from the discharge stage (V117B) plate circuit, is fed into the plate circuit of the phase detector, V117A, and hence modulates its plate current. The resulting effects are shown in Fig. 16. As indicated in condition 1, if the horizontal oscillator is properly timed, the developed saw-tooth will be so positioned that the sync pulses will occur exactly at the center of the retrace slope. Therefore, the grid and plate currents will be equal, and because they are of opposite polarity, a total of zero d-c volts will appear at the detector output.

Conditions 2 and 3 show the effect of either a leading or lagging saw-tooth pulse. In either case, a current unbalance will exist which will cause a positive or negative d-c voltage to be developed which in turn will be used to correct the oscillator timing. If the

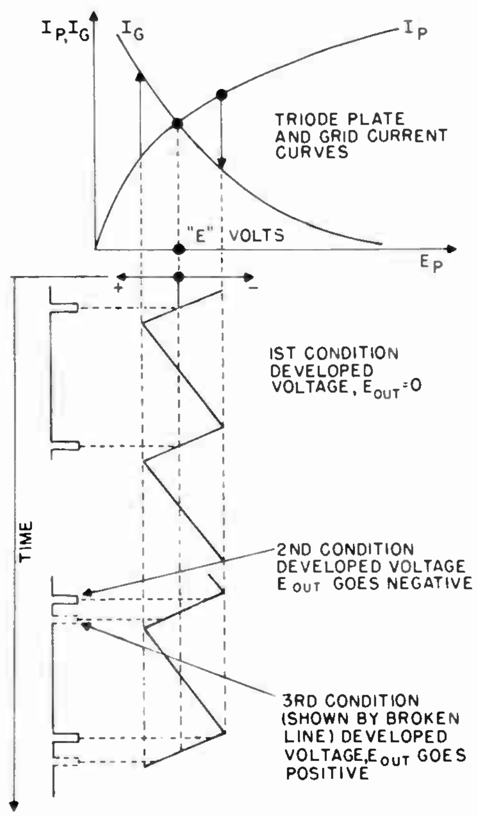

Fig. 16. Phase Detector Operation

horizontal oscillator of the receiver fires too late (i.e. the saw-tooth is "lagging") as shown in condition 2, the plate current increases, causing a negative output voltage. This will cause a speeding up of the horizontal oscillator by virtue of the reactance tube (to be discussed below). If the saw-tooth leads, as shown in condition 3, the negative developed voltage at the plate will be less than the positive voltage appearing at the cathode, thus resulting in a positive output voltage which in turn will retard the oscillator firing time.

The reactance tube, as shown in Fig. 17, acts as a variable resistance which is connected in series with C358 across the oscillator tank circuit to vary its frequency. As the d-c output from the phase detector changes amplitude or polarity, the reactance tube plate resistance will change accordingly. A positive voltage on the grid will cause the tube to conduct more heavily, thereby lowering the resistance between the capacitor C358 and ground. This increases the effective capacitive reactance of C358 across the oscillator tank circuit and causes a consequent lowering of its natural resonant frequency. Conversely, the application of a negative grid correcting voltage will result in a higher natural resonant frequency of the oscillator tank circuit.

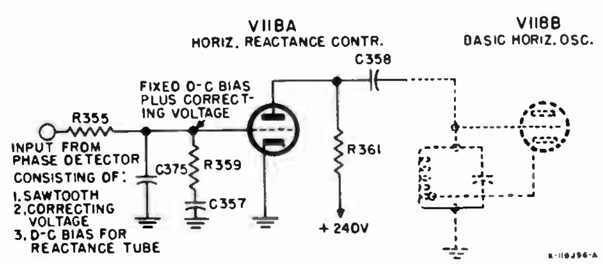

Fig. 17. Reactance Tube Circuit

R-F TUNER UNIT

GENERAL DESCRIPTION

The r-f amplifier, converter and local oscillator are constructed as a complete unit sub-assembly which can be easily dismounted from the main chassis.

This unit is designed and shielded to reduce oscillator radiation to a minimum.

This r-f tuner unit employs two r-f amplifiers, a converter and an oscillator. The intermediate output frequencies are: 45.75 megacycles for picture and 41.25 megacycles for sound.

The circuits are tuned by series coils and their distributed capacity, the tube capacity, and the capacity of three trimmers. As the channel selector is switched to lower channels, coils are added in series to lower the frequency. The oscillator section has a tuning adjustment for each channel so that the oscillator frequency may be correctly adjusted for every channel with one setting of the fine tuning control at the center of its range:

The antenna is coupled to the cathode of the first r-f amplifier by a balanced input transformer to reduce noise pick-up.

The r-f tuner unit includes an intermediate frequency trap in the cathode circuit of the first r-f amplifier to remove interfering frequencies, in the intermediate frequency pass-band, which may be picked by the antenna system. The trap is connected into the circuit when the receiver is tuned to the critical channels, 2 through 6.

Automatic gain control bias is applied to the second r-f amplifier.

The i-f output of the converter is applied to the first i-f amplifier through a transformer link coupled to the i-f input transformer.

A test point is added at the converter grid which is isolated from the grid by a 10,000-ohm resistor.

SERVICE ON R.F. TUNER UNIT

The r-f tuner unit has been carefully designed for trouble-free operation and ease in servicing. All parts including the switch wafers with the coils mounted are readily replaceable.

It is recommended that any trouble be definitely located before removing the r-f tuner unit. Make the following checks to help ascertain whether or not the trouble is in the r-f tuner.

1. If video or sound is present this usually eliminates the r-f tuner unit as a source of trouble. If both video and sound are absent, but the raster is normal, the trouble may be in the video i-f stages as well as in the r-f tuner unit.

2. If a noise pattern is evident on the screen, it usually indicates that the r-f tuner unit, the video i-f and the video amplifier circuits are operating normally. Check for a short or an open circuit in the antenna or antenna input circuits or first r-f stage.

3. Replace head-end tubes with known good tubes. Note: When a new tube is used, slight differences in interelectrode capacities between tubes may cause a slight detuning of r-f circuits. If an oscillator tube is replaced, the fine tuning range should be checked.

4. Check for proper AGC bias voltage at test point No. VII. A or B Normal signal with normal contrast control setting should produce approximately −3 volts VTVM reading.

5. The oscillator may be checked by measuring the voltage at test point No. 1. If the oscillator is functioning it should develop approximately −4 volts as measured by a vacuum tube voltmeter. If the oscillator is inoperative the voltage at test point No. 1 will drop below 1 volt.

6. Check the i-f link output coupling for open or short circuit.

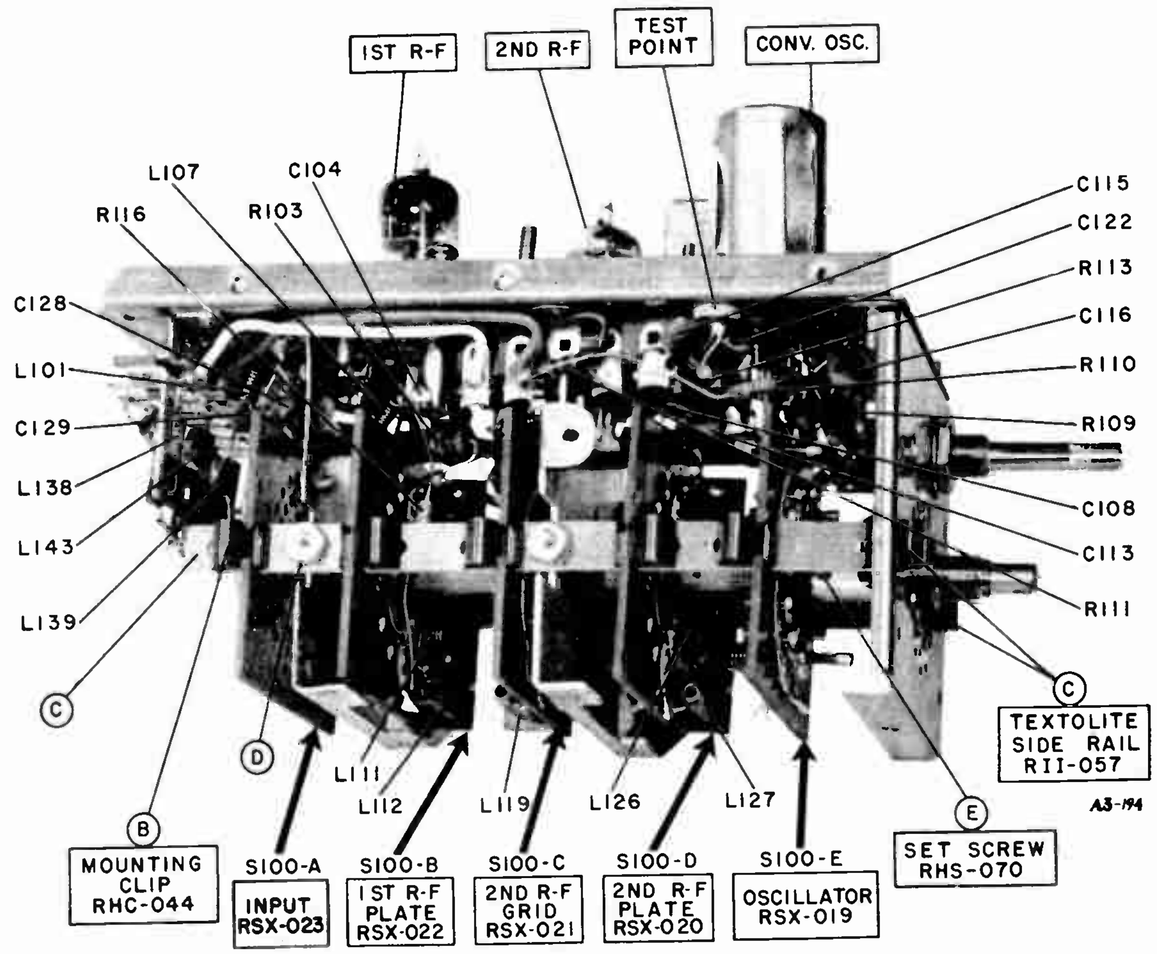

Fig. 18. R-F Tuner, Side View

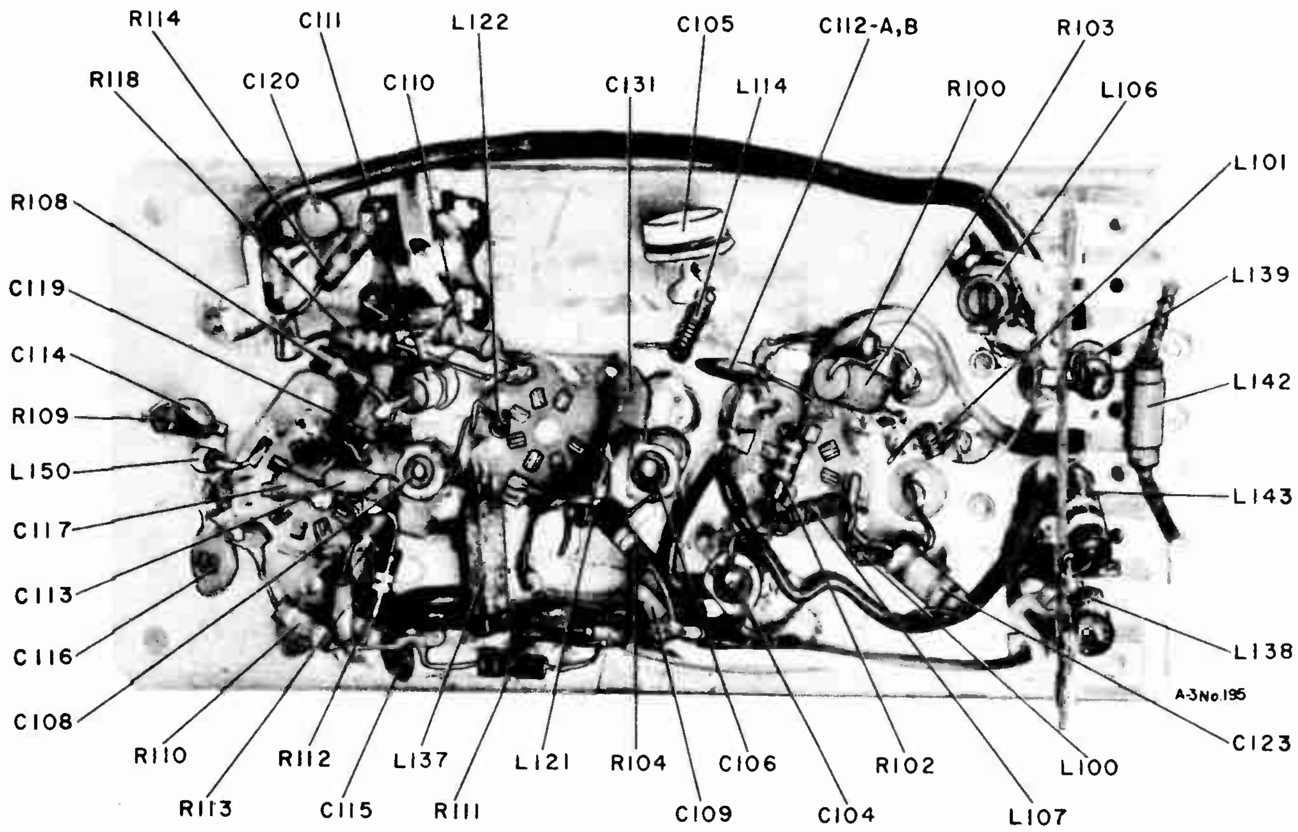

Fig. 19. R-F Tuner, Bottom View, Switch Removed

7. Couple a 44-megacycle 400-cycle amplitude modulated signal to test point No. 1. If the 400-cycle modulation is present at the output of the video amplifier plate as seen on an oscilloscope or observed on the screen of the picture tube in the form of horizontal bars, it is highly probable that the trouble lies somewhere in the R-F tuner unit ahead of the converter, V103B, grid (pin 7). However, should this 400-cycle information fail to appear in the receiver output, a check should be made of the first, second and third viedo i-f amplifier stages, the crystal diode and the video amplifier.

8. Check r-f tuner socket voltages shown in Fig. 36, page 31.

REMOVAL OF TUNER UNIT FROM CHASSIS—

1. Disconnect the antenna transmission line and the tuner output 100-ohm i-f coupling link at the i-f assembly.

2. Remove self-tapping screws holding the tuner to the mounting brackets at the rear and side of the tuner.

3. Disconnect the following leads from the r-f tuner terminal board: AGC, 6.3-volt heater, high B+ and low B+, see Fig. 27.

4. Disconnect the black phenolic coupling from the r-f tuner switch shaft. The tuner assembly is now free for removal.

REPLACEMENT OF SWITCH WAFERS—See Fig. 18 and 20.

1. Remove the r-f tuner unit from the chassis and remove its shield.

2. Loosen setscrew (E) which holds Textolite switch shaft into the brass coupling RMK-006 and slide shaft out of the rear of the switch.

3. Remove the spring clips (B) which secure the switch wafer to the Textolite side rails (C). There are six of these springs on each side. These may be removed by lifting the tab out of the hole in the Textolite side rails.

4. Unscrew the four hex nuts (D) which secure the side rails (C) to the shields. The side rails may be lifted out of the switch wafers.

5. Unsolder the connections to the wafer to be removed and replace with the new wafer.

TO REMOVE THE OSCILLATOR WAFER ONLY—See Fig. 18 and 20.

1. Remove the r-f tuner from the chassis and remove the r-f tuner unit shield.

2. Loosen the Allen setscrew (E) which holds the Textolite switch shaft to the coupling and pull the shaft out of the oscillator wafer.

3. Remove the four spring clips (B) which secure the Textolite side rails (C) to the r-f tuner unit front apron and the oscillator wafer.

4. Remove the two self-tapping screws (A) which hold the r-f tuner unit front apron to the chassis, and pull the front apron forward so that the oscillator wafer may be removed. Use care not to break the connection to the tuning capacitor, C118.

5. Unsolder the connections to the oscillator wafer and remove it by springing up the Textolite side rails (C).

When reassembling the r-f tuner unit and replacing switch wafers, use care not to damage or distort any of the coils mounted on the switch wafers. Reassemble the r-f tuner unit in the reverse order that it was disassembled.

REMOVAL OF TUNING CAPACITOR OR DETENT ASSEMBLY—See Fig. 18 and 20.

1. Remove the r-f tuner unit from the chassis as outlined.

2. Remove the r-f tuner unit shield.

3. Remove the two spring clips (B) which hold the Textolite side rails.

4. Loosen the rear setscrew which holds the Textolite shaft into the brass coupling (RMK-006) and slide the Textolite shaft out of the coupling.

5. Remove the two self-tapping screws which secure the front apron to the r-f tuner unit chassis.

6. Spring up the Textolite side rails (C) to release the front apron for access to the tuning capacitor.

7. Unsolder the tuning capacitor lead at the 12AT7 socket.

8. To remove the detent assembly, remove the "C" washer on brass shaft.

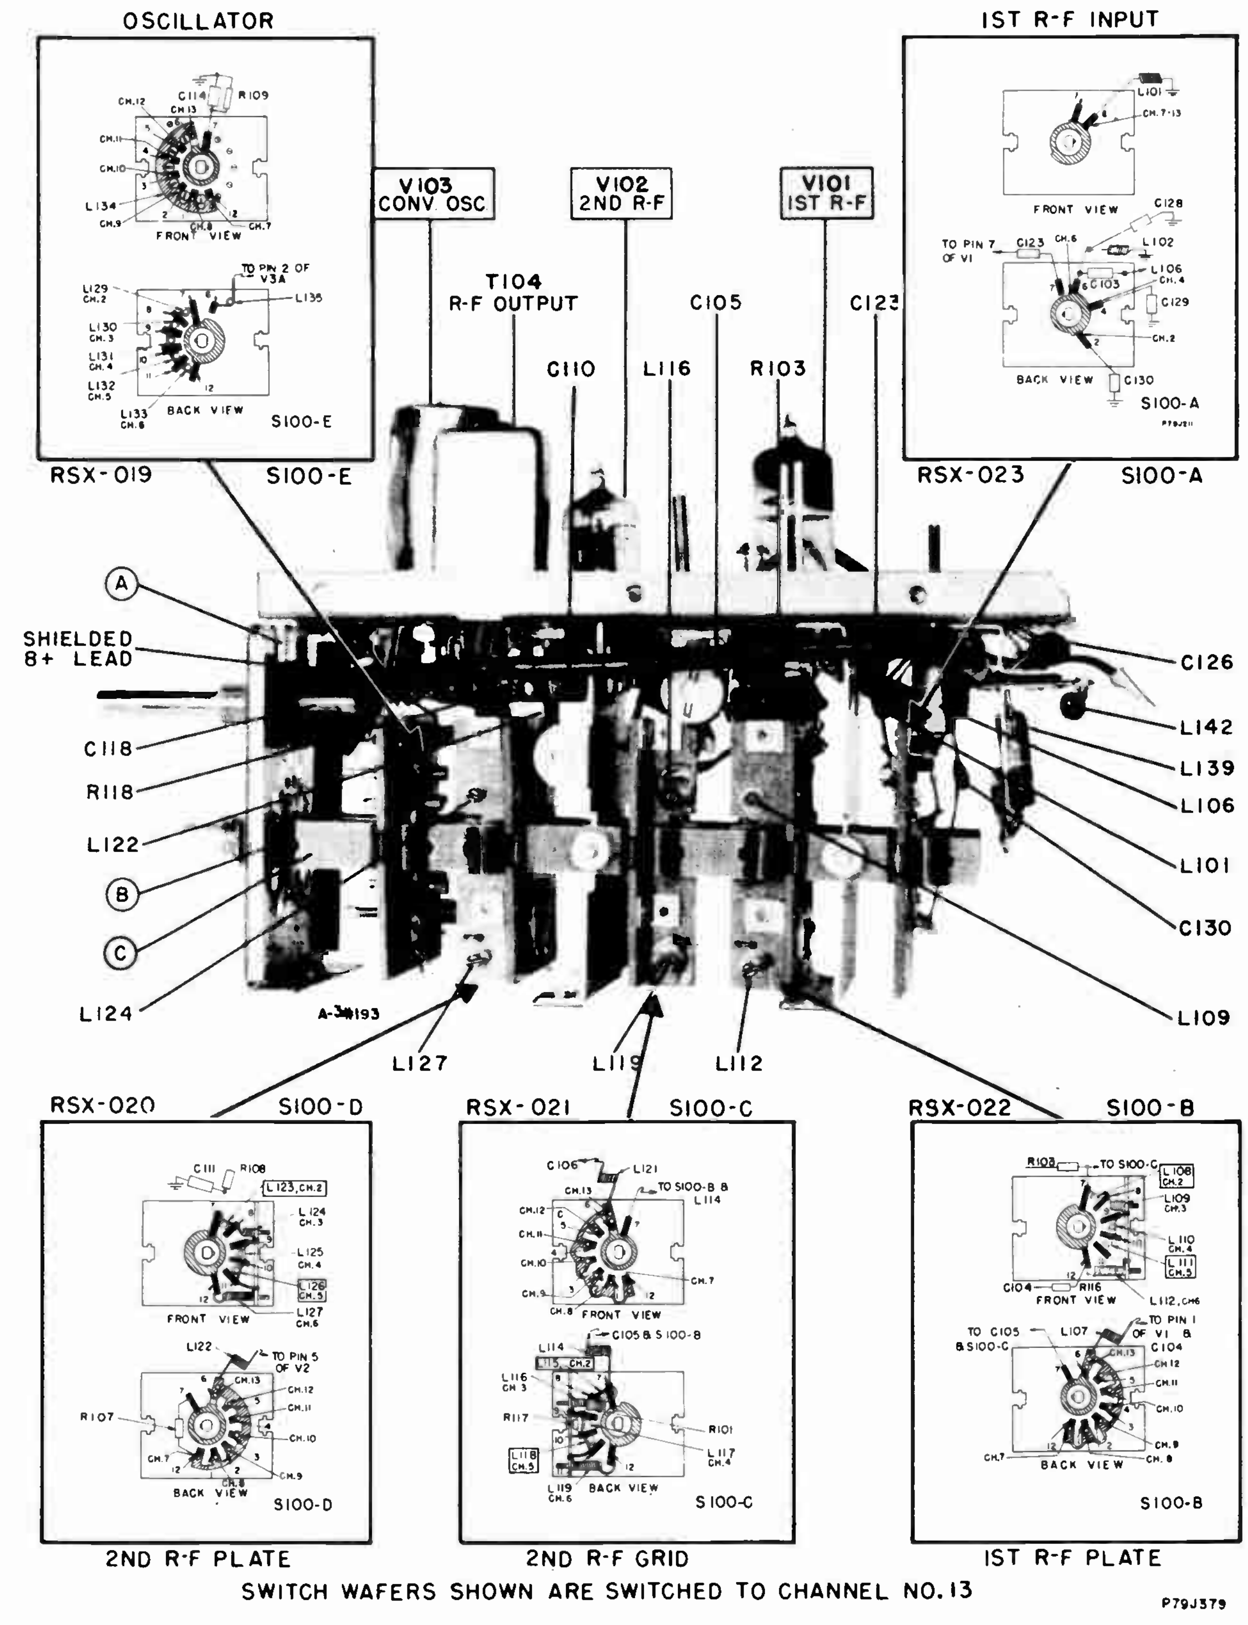

Fig. 20. R-F Tuner and Switch, Wafer Wiring

RECEIVER ALIGNMENT

GENERAL:

The following procedure covers the alignment of the R-F Tuner Unit, Video I-F System, Audio I-F System and Video Amplifier Trap.

In most cases the circuits in the receiver should need realignment only when tubes or components in the tuned circuits have been replaced, or the adjustments have been tampered with. When the decision is reached that the trouble lies in improper alignment of the circuits, the alignment should be undertaken only if proper test equipment is available. In many cases, the "over-all" receiver alignment may be first checked to determine the source of the difficulty.

The alignment procedure described follows the sweep method using General Electric test equipment. When other than General Electric sweep equipment is used, make sure that it meets the requirements listed below. If an accurately calibrated marker generator is not available, a conventional signal generator may be used to supply the markers. Its output should be loosely coupled to the sweep generator output terminals and must be kept as low as possible to prevent distortion of the sweep wave-form.

Before proceeding with the alignment make sure to read all notes and consult the connection diagrams. Allow the test equipment and receiver to warm up for at least 15 minutes before starting the alignment.

ALWAYS USE AN ISOLATION TRANSFORMER TO PROTECT TEST EQUIPMENT

TEST EQUIPMENT

The following test equipment is necessary in order to effect alignment of the tuned circuits of the receiver:

1. R-F SWEEP GENERATOR

(G-E Type ST-4A or Equivalent)

a. Frequency requirements:
   4.5 MC with approximately 2 MC sweep width.
   37-48 MC with approximately 10 MC sweep width.
   50-90 MC, 170-220 MC with 15 MC sweep width.

b. Constant output in the sweep range.

c. Minimum output 0.1 volt.

2. MARKER GENERATOR

(G-E Type ST-5A or Equivalent)

The marker generator must have good frequency stability, accurate calibration and must cover the following frequencies:

a. 38.00 MC
   41.25 MC
   42.50 MC
   45.00 MC
   45.75 MC
   47.25 MC

b. 4.5 MC for video amplifier trap alignment.

c. Picture and sound carrier frequencies for Channel No. 2 through No. 13.

3. BALANCED OUTPUT ADAPTER

(G-E ST-8A or Equivalent)
See R-F Alignment, note 2.

4. OSCILLOSCOPE

(G-E Type ST-2A or Equivalent)

The oscilloscope should have good sensitivity and preferably a 5-inch screen with a good wide-band frequency response in the vertical deflection circuits. Although the high frequency response is not necessary for alignment, it is imperative when observing video waveforms.

5. DETECTOR NETWORK

A crystal detector network as shown in Fig. 31 is necessary when aligning the 4.5 mc video amplifier trap.

R-F Tuner Unit

INTRODUCTION:

Before actually starting the Alignment procedure, it would be well to first comprehend the objectives to be achieved.

In general, the R-F Tuner "channel frequency" response should be "flat" across each channel. As previously noted, the major portion of the receiver selectivity will be found in the I-F system, the desired response of which is predicated upon the characteristics of the transmitted signal. Hence, the R-F Tuner response should permit conversion of the incoming signal to the I-F spectrum without disturbing the amplitude relationship of the two carriers and their associated sidebands.

Additionally, the R-F Tuner must provide a reasonable degree of selectivity to prevent cross-modulation of the television signal by other VHF services and to prevent signals in the 40 to 48 mc band from being passed to the I-F amplifier with a consequent degradation of the picture.

In the following procedure, the tuner may be aligned without removing it from the main chassis. The alignment procedure is in two parts; the first portion deals with alignment and frequency response shaping of the signal frequency circuits and the second portion with the adjustment of the local oscillator. The signal frequency circuits, as may be noted on the schematic diagram, Fig. 36, are brought into resonance by adjustment of some of the inductances and, in some cases, by the adjustment of low value trimmer capacitors.

The only adjustment in the cathode of the first R-F amplifier, V101, is the I-F interference trap, L106. This trap is pre-set at the factory at approximately 43.0 mc and may be readjusted, if required, to any offending signal in the 40-50 mc range. (Caution: when adjusting this trap—make sure that it has not changed the normal channel No. 2 response).

The first R-F amplifier plate and second R-F amplifier grid circuits are tuned by switch-tapped coils and trimmer capacitors C104 and C106. Channels 7-13 are brought into resonance by the adjustment of these trimmers. Channels 2 thru 6 are brought into resonance by the adjustment of inductances L109, L112, L116 and L119. Coupling between these stages is controlled by the common impedances L114 and C105. L114 controls the bandwidth on channels 2–6, while C105 controls the bandwidth on channels 7-13. Although the following procedure indicates the above adjustments are to be made only on a few specific channels, the final adjustment will represent an excellent compromise setting for all channels.

The second R-F plate and Converter grid circuits are tuned by the tank circuits associated with switch wafer S100D. C108 is used to resonate the circuits in channels 7-13. L124 and L127 resonate the circuits on channels 2–6. In the "over-all" receiver alignment procedure, page 26, these three adjustments are used to correct for "Tilt" in the over-all response.

The oscillator frequency is changed from channel to channel by switching additional inductances in series with the channel No. 13 oscillator coil progressively down to channel No. 2. Each of these coils is adjustable through the front detent plate of the Tuner unit.

R-F Alignment

NOTES:

1. The R-F tuner may be aligned without removing it from the main chassis. Disconnect the 300-ohm transmission line from the antenna input transformer, T100 and disconnect the B+ to the oscillator. To do this, on 4th-production R-F tuner units (those incorporating a 470-ohm, R125 resistor on the rear terminal boards) merely open the jumper between the two center terminals on the upper board. On earlier units disconnect this jumper and transpose L142 from terminal 4 to terminal 3 (see Fig. 27). Failure to transpose L142 will remove plate voltage from the 1st R-F amplifier and hence will result in improper alignment and reduced gain.
2. Connect the sweep generator to the R-F tuner antenna input transformer using the G-E ST-8A balanced adapter to obtain 300 ohms output, see Fig. 21. The adapter should be connected to the R-F tuner through approximately three feet of 300-ohm transmission line and a resistor pad, as shown in Fig. 23A. When using other test equipment of the unbalanced output type, a pad as shown in Fig. 23B should be used instead.
3. Connect a 3-volt battery to the AGC terminal of the R-F tuner, see Fig. 27, with the positive lead of the battery connected to the tuner chassis.
4. Should it become difficult to obtain proper tracking on channels 7-13 with the indicated adjustments, proper tracking may be achieved by dressing the coil L122. See Fig. 20. This coil is available through the opening obtained by removing the self-tapping screw on the side flap and bending the flap up. See Fig. 26. This coil should be dressed with an insulated tool to prevent a B+ short.
5. It is possible to obtain two different settings of C105, Fig. 26, that will give the proper R-F bandwidth. The correct setting may be determined by switching from Channel 13 to Channel 12 and observing the change in bandwidth. The correct setting will result in a slightly greater bandwidth on Channel 12.
6. When proper tracking on the low channels cannot be achieved with the provided screw adjustments, the inductance of the coils L110, L111, L117, L118, L125 and L126 (Fig. 18 and 20) may be varied by inserting a knife blade between the windings. This method of adjustment requires the removal of the tuner shield, a procedure which will detune the circuits. However, in most cases the provided screw-type adjustments will suffice to achieve proper tracking through all channels after the shield has been replaced.
7. The picture and sound carrier marker should not be less than 75% of the peak of the R-F response curve. Refer to the "limits" curves shown in the accompanying alignment chart.
8. Seal trimmer screw of C105 and the brass cores in the coils L114, L112, L109, L119, L116, L127 and L124, Fig. 26, with wax to prevent detuning. Seal the tuning screws in trimmers C104, C106 and C108, Fig. 25, with glue. Reconnect the jumper on the R-F tuner terminal board and connect the transmission line to R-F tuner input transformer.
9. For receiver over-all alignment check, see page 26.

Oscillator Alignment

GENERAL. Two methods of oscillator frequency adjustment are given below. The first method uses a transmitting station for the adjustment while the second method requires a sweep generator to align the oscillator coils.

A. "ON Station Signal" Alignment

R-F and video I-F alignment must be correct before attempting oscillator alignment. A transmitted station signal is needed for each one of the coils being adjusted. Tune in the stations starting with the highest frequency channels and adjust the tuning screws for all available stations so that with the fine tuning control in the full-clockwise position, audio is just visible in the picture. Then, check to see that best picture response on all channels takes place approximately in the center of the oscillator fine tuning range.

B. Sweep Alignment

1. R-F and video I-F must be properly aligned before aligning the oscillator.
2. Connect a 3-volt battery to the AGC terminal of the R-F tuner, see Fig. 27, with the positive lead of the battery connected to the tuner chassis.
3. Disconnect the 300-ohm transmission line from the antenna terminals to the R-F terminals and connect the sweep generator to the R-F tuner terminals as described in note 2 on page 18.
4. Set the fine tuning knob 180° (½ turn) from the counter-clockwise limit of its rotation, i.e. rotate the fine tuning knob counterclockwise to the end of its travel, then turn the fine tuning control knob 180° (½ turn) clockwise. This setting of the fine tuning control should be maintained for all oscillator adjustments.
5. Make the indicated adjustments so that the picture carrier marker for the channel falls at 50% on the high frequency side of the response curve.

Audio I-F Alignment

GENERAL:

The preferred method of audio i-f alignment involves the use of the station signal. The 4.5 mc audio i-f circuits are then tuned for proper indication on a d-c voltmeter as indicated below.

Meter Alignment

NOTES:

1. Tune in a television signal. This will provide a 4.5 mc signal source for audio alignment. Keep the volume control turned down unless the speaker is connected.
2. Figure 29 shows a simple resistor network needed for the alignment of T203 secondary. These two 100K resistors should be chosen as accurately as possible, for equal resistance. Be sure to remove these resistors after completing the alignment. Align according to chart below.

IN THE ABSENCE OF TEST EQUIPMENT, the audio I-F System may be aligned by tuning the various circuits for maximum volume output as follows:

1. Tune in a weak station signal—preferably one with test pattern and tone modulation. A strong signal will require sufficient attenuation (by shorting the antenna terminals or similar means), in order to lower the audio I-F Signal Strength below limiting.
2. Adjust L160 and T201 (top and bottom cores) for maximum audio output.
3. Adjust T203 (bottom core) for maximum audio output.
4. Adjust T203 (top core) for maximum audio output and minimum distortion and/or buzz.
5. Repeat steps 3 and 4 above to assure proper final adjustment.
6. Check audio limiting on normal-strength signal. Readjust T203 top core if necessary.

ALIGNMENT CHART

STEP NO.	CONNECT VTVM OR 20,000 OHMS/VOLT METER	ADJUST	METER INDICATION	REMARKS
1	To test point VI and chassis. (Limiter grid)	L160 and T201 (top and bottom cores)	Adjust for Maximum Deflection	Voltage to be read is negative with respect to chassis.

RECEIVER ALIGNMENT (Cont'd)

I-F AMPLIFIER ALIGNMENT

GENERAL:

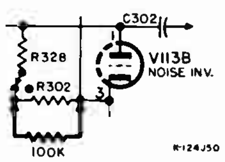
As indicated on the accompanying schematic diagrams, two basically different video amplifiers have been used. Since the frequency and transient response of these amplifiers differ somewhat, the desired i-f response curves must also differ in order to achieve the same over-all frequency and transient response in both systems.

The "Desired Waveform," "Remarks" columns in the following chart are each identified by the designation "12BH7" or "6BK7-A." Before sweep aligning a receiver, determine its video amplifier (V107) tube type and use the corresponding curves to achieve proper alignment.

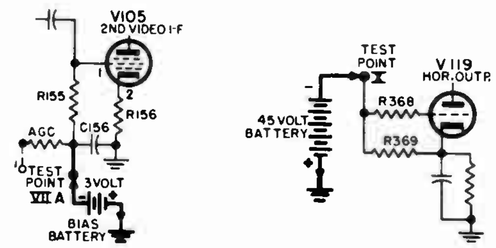
The usual precautions should be observed regarding the proper termination of the sweep output cable, warm-up time, equipment cable dress, etc. Always use an *Isolation Transformer* when servicing these receivers.

NOTES:

1. Connect a 100,000-ohm ½-watt resistor across R302 to bias off the noise inverter which otherwise would cause a false i-f curve indication, see figure below. *Remove this resistor after completing the alignment.*



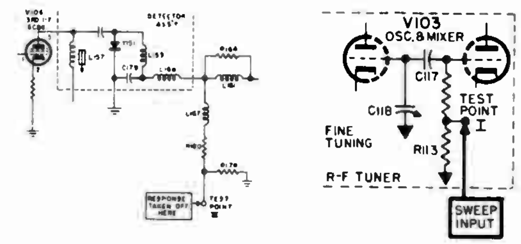
2. Connect the negative lead of a 3-volt bias battery to test point VIIA. Connect the positive lead to the nearest top-chassis ground point. Similarly, insert a 45.0-volt negative bias at test point X to prevent horizontal pulse information from appearing on the sweep waveforms.



3. Set contrast control and rear apron AGC control (if receiver is so equipped) fully counterclockwise.

4. Calibrate the vertical gain of the oscilloscope so that ¾-volt A-C will provide the desired curve size. Receiver response should be observed at test point III as indicated in the following diagram. Connect the ground side of the cable to the nearest top-chassis ground point.

5. Set channel selector switch to Channel 11 position and turn the fine tuning control fully counterclockwise.



6. Refer to Fig. 22 and 23 for proper connection and termination of sweep generator.

7. In many cases, it will only be necessary to start with Step 2 of the procedure below. Step 1 is included only as a "Starting" point for use in cases where the receiver has become seriously misaligned, or when the correct setting of the 38.0 mc trap (L158) is difficult to determine in the "over-all" i-f curve.

8. Note that in the following procedure, the 45.0 mc marker is used as the 100% reference point in the "12BH7" alignment, while the curve peak is used as the 100% reference point in the "6BK7-A" alignment procedure. Align as indicated in the chart below.

Over-all (RF-IF) Alignment Check

A receiver which has been properly r-f aligned and i-f aligned must not be considered as a properly aligned receiver until the over-all check and adjustments have been made. Because the converter grid and cathode are utilized as a detector diode in the r-f alignment process, a certain degree of "tilt" or r-f detuning will occur. The only method of determining the degree of introduced "tilt" and the correction thereof must be done by observing the over-all curve.

In general, a receiver which has been properly r-f aligned will display an over-all curve (antenna to diode) which will closely duplicate the i-f system curve, since the major portion of the receiver selectivity occurs in the i-f system. It is to be expected, however, that minor variations in the over-all curve will occur when checking each of the various channels.

The procedure given below is quite simple, and assures optimum picture detail and receiver sensitivity. After the receiver has been properly aligned according to the data given for r-f and i-f alignment, proceed as follows:

a. Couple r-f sweep and channel marker signals to antenna input terminals.
b. Observe receiver response at Test Point III.
c. Sweep each channel, starting with Channel 13, and observe resulting curve. Adjust the Fine Tuning control so that the resulting sound and picture I-F markers fall in the approximate positions shown in step 3 of the chart below.
d. Should the observed curve not agree with that shown in step 3, the following adjustments should be made:
   I. On Channels 7–13, adjust C108 (Fig. 24) to produce desired curve shape and amplitude.
   CAUTION: Do not move C108 adjustment core more than three turns in either direction—usually one turn will suffice to produce the desired curve compensation.
   II. On Channels 4, 5 and 6 adjust L127 for proper curve compensation if required.
   III. On Channels 2 and 3 adjust L124.

VIDEO I-F ALIGNMENT CHART

STEP	SWEEP INPUT	ADJUST	DESIRED RESPONSE (12BH7)	REMARKS (12BH7)	DESIRED RESPONSE (6BK7-A)	REMARKS (6BK7-A)
1	Into Pin 1 of V106 thru .001 mf capacitor. Center sweep frequency approx. 44 mc. Sweep width approx. 15 mc	L158 (Trap) to 38.0 mc L157 (V106 plate) to peak at 44.6 mc		Use full available sweep width		Use full available sweep width
2	Into Test Point II (refer to schematic diagrams) thru .001 mf capacitor. Center sweep frequency approx. 44 mc. Sweep width approx. 10 mc	L156 (Trap) to 41.25 mc L154 (Trap) to 47.25 mc L153 (V104 plate) set 45.75 mc marker L155 (V105 plate) set 42.5 mc marker L157 (V106 plate) balance curve		Use 45.0 mc as 100% reference Set 45.75 mc @ 60% Set 42.5 mc @ 70% L157 should be peaked @ 44.15 mc		Peak of curve = 100% Set 45.75 mc @ 60% Set 42.5 mc @ 60 % L157 should be adjusted for symmetrical skirt response
3	Into Test Point I (on r-f tuner) thru .001 mf cap. Center sweep frequency approx. 44 mc. Sweep width approx. 10 mc	L152 (Trap) to 38.0 mc L151 (Trap) to 47.25 mc T151 (V104 grid) and T104 (R-F Tuner) for curve shown, check percentages as indicated in "Remarks" column		Use 45.0 mc as 100% reference *simultaneously* "rock" T151 & T104 for symmetrical skirts consistent with optimum gain. Max. curve peak 145%, min. curve peak 115%		Peak of curve = 100% Adjust T151 and T104 for *flat* peak. Adjust L157 to correct for any "Tilt." 45.0 mc may fall between limits of 85–100%

TRAP ADJUSTMENT

ALIGNMENT OF L106 I-F TRAP

The trap, L106 (Fig. 30) is incorporated in the r-f tuner to remove or attenuate any interfering frequency in the i-f range. The trap should be aligned by tuning for minimum i-f channel interference pattern on the screen. If the interference is intermittent and the interfering frequency is known, L106 may also be aligned by the use of a calibrated signal generator.

NOTES:

1. Connect 3 volts bias from the AGC line on the r-f tuner (see Fig. 27) to chassis with the positive terminal of the battery connected to chassis.

2. Use an accurate marker generator to furnish a signal of the same frequency as the interfering frequency and a sweep generator with its center frequency set approximately at the interference frequency. Connect the scope to view the response curve at the output of the video detector.

3. Use the GE-ST-8A balanced adapter and a 3-foot piece of 300-ohm transmission line to couple the r-f sweep to the antenna terminals of the receiver.

4. Be sure not to tune the trap so that it will attenuate channel No. 2.

L106 ALIGNMENT CHART

Marker Frequency	Sweep Frequencies and Input Point	Observe Response Curve at	Channel Switch Setting	Adjust
Interference frequency	40 to 50 mc to antenna terminals	Test Point III	2	Core of L106 for minimum amplitude of curve at marker

ADJUSTMENT OF 4.5 MC TRAP (L163)

ADJUSTMENT NOTES:

This trap is pre-set at the factory and should not require readjustment due to its stable design characteristics. However, should it become damaged, it may require re-alignment. The experienced service technician may, if desired, tune the trap for a minimum 4.5 mc "beat" effect in the picture. This requires that a strong, noise-free television station signal be used. Otherwise the following method given in the procedure of the accompanying alignment chart in accordance with the notes below should be used.

1. Remove tube V103 to remove circuit noise.

2. Inject an accurate amplitude modulated 4.5 mc signal into test point VIII.

3. Connect a diode network as shown in Fig. 31 to test point IV. Ground the bottom of the network (Junction 68K and 100K) to the receiver chassis.

4. Tune the trap for minimum signal amplitude response as observed on the oscilloscope (Fig. 32).

TROUBLE SHOOTING

In many cases a circuit difficulty may be localized by observing the picture or test pattern and by noting the presence or absence of sound. In general, the tubes in defective circuits should be checked first since this check does not take much time and the probability of failure is higher in tubes than in components. When substituting tubes in r-f or video i-f circuits, the original tube should be replaced in the socket if it is found to be satisfactory.

Always make sure that all tubes are making good socket contact. In some cases it may be necessary to clean the tube pins to eliminate intermittances.

To facilitate trouble shooting the waveforms of Figures 38, 39, and 44 should be consulted. Alignment equipment may be used to isolate defective r-f or video i-f stages by checking for the response curves given in the alignment procedure.

For a detailed description of circuit analysis and an illustrated trouble shooting guide refer to General Electric publication RSM4-TV53.

SYMPTOM	CHECK FOR
DEFECTS OF THE R-F AND I-F CIRCUITS	
A. No sound, no picture	1. Inoperative local oscillator, V103A 2. Open video i-f coupling capacitors, C152, C155, C158, C162 3. Improper or no screen or plate voltage at r-f or i-f tubes due to shorted screen by-pass capacitor or open resistor 4. Open video detector crystal, Y151
B. No picture, sound possibly weak, raster satisfactory	1. Shorted capacitor, C166 2. Open coupling capacitor, C162 3. Defective crystal diode, Y151
C. Noisy picture (Low signal strength)	1. Open input circuit and components of antenna input circuit, such as open capacitors, C173, C174, or open transformer, T100 2. Defective antenna, or antenna transmission line 3. Antenna orientation 4. Open filament, V101
D. Wiggles in picture background, trailing whites, sound normal	1. Open capacitors, C412, C413, C414 2. Alignment of i-f amplifier and associated traps
E. "Motorboat" or flutter in picture and/or audio	1. Open by-pass, C151 on AGC bus 2. Open AGC filter capacitor C180 3. Alignment of r-f and video i-f amplifiers
F. Lack of picture detail (Focus satisfactory)	1. Misalignment of video i-f amplifier 2. Misalignment of r-f amplifier 3. Mismatch of input impedances at antenna input terminals of receiver 4. Overloading of r-f stages (also check for leakage in capacitors C155, C158) 5. Defective peaking coil
G. Sound bars in picture	1. For microphonic tubes: V101, V102, V103, V104, V105, V106, V107 and V108 2. For misalignment of adjacent channel sound traps L151 and L154 or misalignment of accompanying sound trap L156

DEFECTS OF THE VIDEO AMPLIFIER

A. No picture, sound satisfactory, raster satisfactory	1. Open compensating choke L165 (1st, 2nd, 3rd prod.) 2. Shorted capacitor, C403C in cathode V107B (1st, 2nd, 3rd prod.) 3. Open input coupling capacitor, C170 to tube V107A 4. Open plate resistors at tube V107A or V107B. Check plate voltages 5. Short of grid to cathode in picture tube
B. Lack of picture detail (focus satisfactory)	1. Shorted peaking coils 2. Open peaking coils (only those coils shunted by resistors) 3. Increase in value of diode load and video amplifier plate resistors
C. Trailing Whites	1. Decrease in value of diode load and/or video amplifier plate resistors

TROUBLE SHOOTING (Cont'd)

DEFECTS OF THE SYNC SECTION

SYMPTOM	CHECK FOR
A. Weak or no horizontal sync; vertical sync, picture and sound satisfactory	1. Sync amplitude at input to discriminator tube, V117A. 2. Bias and plate voltage on control tube V118A 3. Sine-wave oscillator components, L351, C361, C358, C359 and R362 4. Leaky or shorted capacitors, C368 and C355 5. Waveform feedback components, C356, R358, R365 and C352.
B. Weak or composite sync, otherwise picture and sound normal	1. Open or low capacity of input coupling capacitor, C314 2. Defective coupling capacitor C302 or C303, to clipper tube 3. Incorrect value of plate resistor, R307, in clipper 4. Insufficient amplitude of composite signal applied to sync amplifier from video detector; check video detector circuit
C. No vertical sync, hor. sync satisfactory	1. Sync pulse at input of vert. oscillator, check integrator plate P301 2. Vert. oscillator frequency, if far off from 60 cps, check vert. oscillator components such as C309 and R313 3. Leakage in feedback capacitor, C308
D. Picture displaced to left, right edge wavy	1. Open or low value of capacitor, C303
E. Horizontal sync out, bright bar or bars in picture	1. Shorted, open or leaky capacitor, C360 2. Improper value resistor, R364
F. "Gear Tooth" effect	1. Open or low value capacity of C357 2. Open or high resistance of R359
G. Noise "tearing" picture (noise inverter failure)	1. Low value, R302 2. Open C301 3. Open or high value, R301
H. No horizontal or vertical sync Poor composite sync (attributable to noise inverter failure)	1. Open or high value of R302 2. Low value R301 3. Leaky or shorted C301 4. Shorted C169 or C177

DEFECTS OF THE VERTICAL DEFLECTION CIRCUIT

SYMPTOM	CHECK FOR
A. Poor vertical linearity, inadequate height	1. Low emission of sweep output tube, V115 2. Improper grid input "drive" voltage at V115 3. Defective sweep output transformer, T301 4. Low B+ voltage to sweep output tube, V115 5. Low value of cathode capacitor, C403B
B. Inadequate picture height	1. Rise in resistance value of vert. oscillator plate resistor, R315 or R330 2. Leakage in capacitor C317 3. Incorrect value of plate, or grid voltages on output tube, V115 4. Low value capacitor in cathode of vert. output tube, C403B. (This usually results in poor linearity) 5. Weak vertical deflection tube, V114 or V115
C. No vertical deflection	1. Open vertical deflection coils, D301 2. Defective sweep output transformer, T301 3. Vertical sweep tube, V114 or V115 not operating 4. Poor contacts in yoke plug
D. Poor vertical linearity, height satisfactory	1. Linearity control components such as cathode capacitor, C403B, for leakage or improper value or improper value of R318 2. Low value capacitor, C311 3. Leaky capacitor, C316 4. Vertical output tube, V115
E. Excessive height	1. Too low value of resistor R315 or R330 or defective Height control, R316
F. Poor vertical linearity, fold-over at bottom of picture, picture height excessive	1. Low resistance leakage of capacitor, C310 2. Low value of charging capacitor, C311
G. Vertical keystoning	1. External short across vertical deflection coils 2. Defective vertical deflection coil, D301

TROUBLE SHOOTING (Cont'd)

DEFECTS OF THE HORIZONTAL DEFLECTION CIRCUITS

SYMPTOM	CHECK FOR
A. Too great sweep width, reception normal otherwise.	1. Open width control coil 2. Open winding between width coil taps on horizontal output transformer, T351
B. Inadequate sweep width	1. Correct waveshape and amplitude of input "drive" voltage at test point X 2. Shorted Width control L352 or defective deflection coil, D351 3. Defective output transformer T351—shorted turns or arc-over 4. Low emission of damper tube, V120 5. Low B+ voltage to tubes V117B, V118B, V119
C. Single vertical line in center, sound normal	1. Open horizontal deflection coils, D351 2. Open capacitor, C382 3. Open choke, L357 4. Open yoke plug connection
D. Poor horizontal linearity	1. Shorted linearity control 2. Defective feed-back capacitor, C385 3. Defective yoke, D351 4. Defective capacitors C370, C371
E. Poor horizontal linearity, bright vertical bars, inadequate width	1. Open or low value of capacitor, C371 2. Defective damper tube, V120
F. Black "beady" vertical line or lines, receiver normal otherwise	1. Defective output tube, V119 2. Defective output transformer, T351 3. Defective deflection yoke, D351
G. No raster—sound satisfactory	1. Shorted capacitor, C378 2. Defective sweep output tube, V119 or damper tube, V120 3. Defective tubes, V117B, V118B 4. No voltage at T351 primary 5. Shorted capacitor C371 6. No screen voltage on V119 7. Adequate drive at grid of V119 8. Shorted Width control 9. Open Linearity control 10. Defective sweep output transformer, T351

DEFECTS OF THE POWER SUPPLY

SYMPTOM	CHECK FOR
A. No raster, no sound	1. Power supply interlocks and/or fuse open 2. Power cord plug and cable 3. Rectifier components 4. Open filter choke 5. Open tube filament in series filament string 6. Open input capacitor, C401 7. Yoke plug not connected
B. Picture size small, brilliance low, sound normal	1. Open or low value of input filter capacitor, C402 of power supply 2. Defective rectifier, X401 or X402
C. Picture blooms	1. Defective H.V. rectifiers, V121, V122, (21-inch models only), V123 2. Defective picture tube
D. Hum bar in picture, waviness in edges of raster ("Mae West" movement)	1. Open or low value of filter capacitor, C403A
E. Low picture brilliance, sound satisfactory	1. Low voltage at H.V. anode of picture tube, caused by leaky capacitors C378 and C379, defective rectifiers, V121, V122 (21-inch models only) and V123 2. Improper adjustment of ion trap 3. Defective Brightness control circuit 4. Low voltage at 1st anode of picture tube (pin 10) 5. Defective picture tube

MISCELLANEOUS DEFECTS

SYMPTOM	CHECK FOR
A. No raster—sound satisfactory	1. Open or shorted picture tube heater 2. No voltage at 1st anode of picture tube (pin 10) 3. Excessively high bias voltage at cathode of picture tube 4. Defective picture tube, check by substitution.
B. AGC control ineffective (1st, 2nd production receivers only)	1. Shorted capacitor, C302. This will result in excessive RF-IF gain and the AGC control will work backwards 2. Shorted AGC by-pass C151. This will result in no AGC and too much contrast 3. Insufficient signal at clipper. Check for normal voltages with oscilloscope. Check V113 and V116 4. Leaky capacitor C155 and C131 (R-F Tuner unit)

TROUBLE SHOOTING (Cont'd)

SYMPTOM	CHECK FOR
C. Receiver overloads on moderate to strong signals (3rd & 4th production receivers only)	1. AGC clamp tube failure (1/4 V111B) 2. Shorted C151
D. Brightness control partially or completely inoperative	1. Defective Brightness control, R177, or circuit components 2. Defective (short or leaky) capacitor, C171 3. Defective (gassy) picture tube
E. Picture pulled out of shape on one side or corner	1. Proper orientation of the Picture Straighteners
F. Poor focus	1. Proper focus unit adjustment and position 2. Defective picture tube
G. Vertical retrace lines visible	1. Open input capacitor to blanking circuit, C313 2. Check for shorted capacitor in blanking circuit, C318 3. Open coupling capacitor C172 to picture tube cathode
H. Horizontal blanking inoperative	1. Defective horizontal blanking tube, V116B 2. Open capacitor, C381 3. Shorted capacitor, C384
I. Cramping of last 1½ inches on right side of picture	1. Open capacitor, C385
J. Dark shading on left edge of picture	1. Open capacitor, C383

5. NOISE INVERTER CHECK

A simple oscillographic check may be performed which will display the operation of the noise inverter. The procedure is based upon noise pulse inversion in the absence of signal.

1. Turn on receiver. Set channel selector switch to an unoccupied channel.
2. Connect oscilloscope to test point IX (Junction of C302 and C303).
3. Bias off the noise inverter (V113B) by connecting a 100,000 ohm resistor between its pin No. 3 and +250 volts.
4. Supply a moderate-amplitude noise signal to the antenna input terminals. A suitable noise source would be an electric shaver or similar "spark" type noise generator.
5. Observe positive polarity of noise pulses on oscilloscope. Removal of the temporarily added 100,000 ohm resistor should cause the noise signal to reverse itself and hence become negative in polarity.

FILAMENT GLOBAR CHECK

Those tubes having 300 ma. heaters are connected in a series circuit containing a globar resistor R402. This resistor is designed so that its "cold" resistance is in the order of 200 or 300 ohms, and when at operating temperature approximately 31 ohms. A "cold" resistance check is almost valueless since the resistance reading may vary widely between resistors.

The surest method of checking R402 is to read the voltage drop across it. This should be in the vicinity of 10 volts with the receiver operating on a 117 volt A-C line.

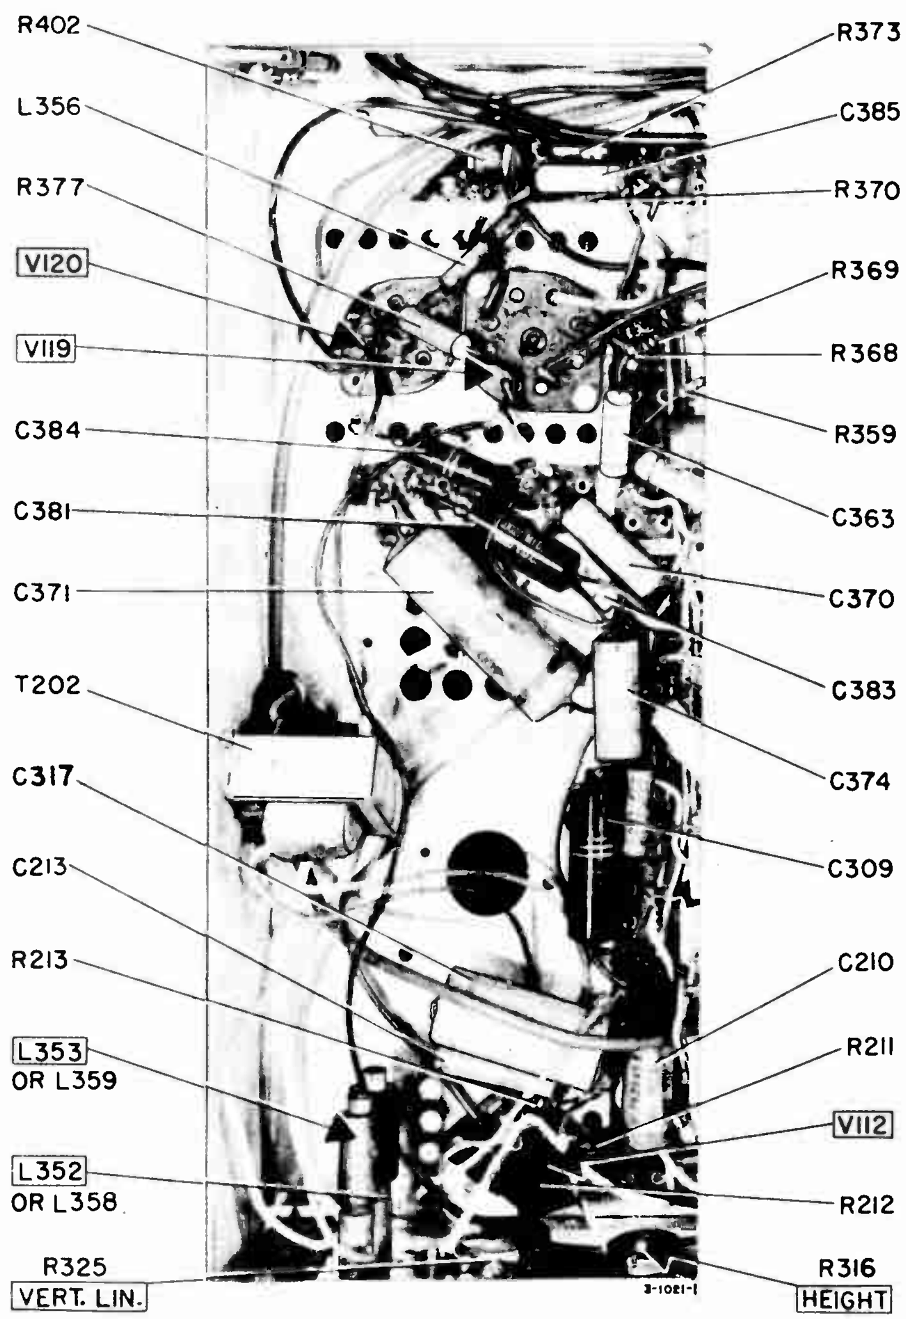
GENERAL SERVICE INFORMATION

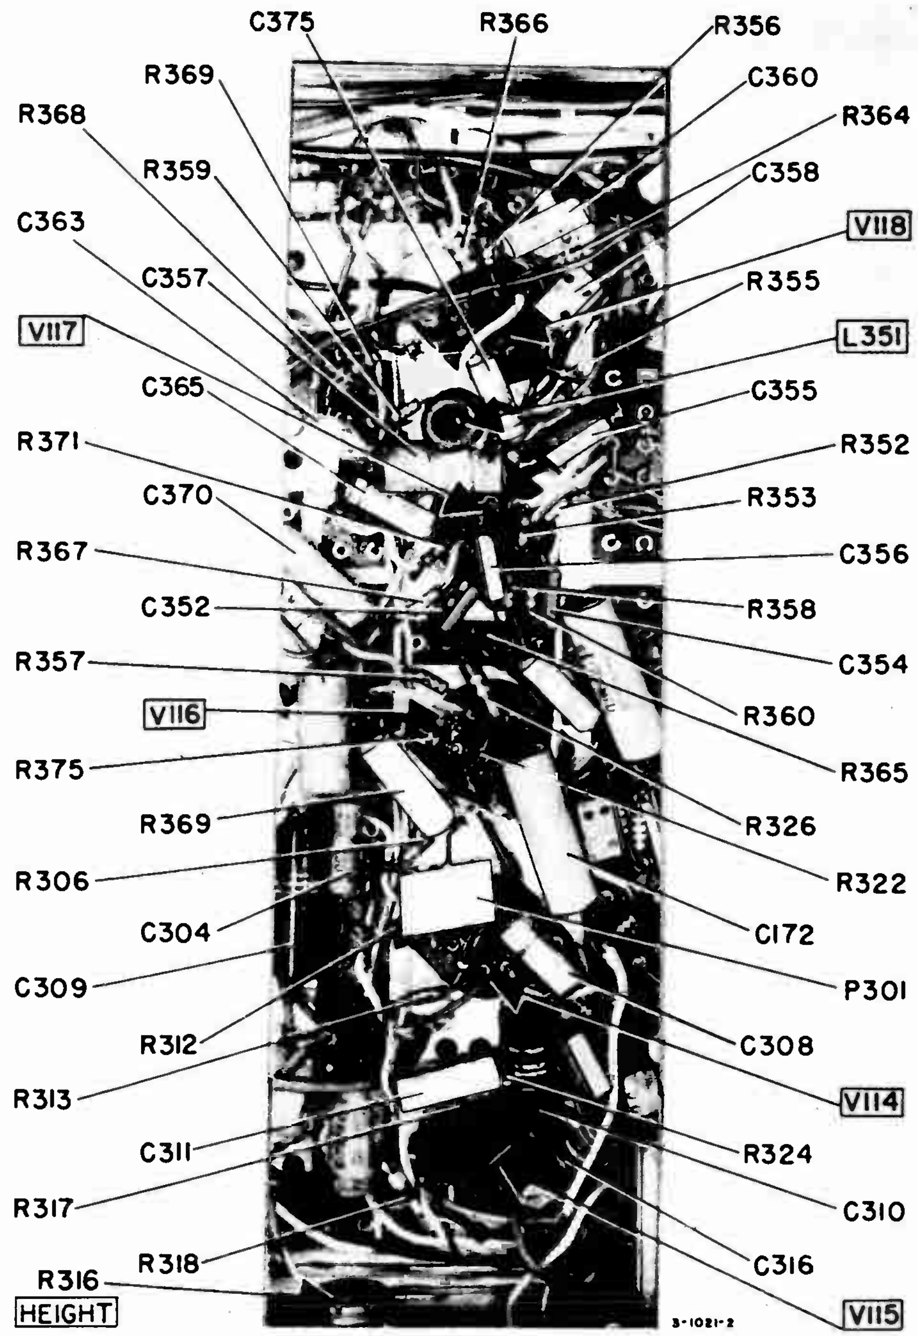
1. *CRITICAL LEAD DRESS*—To prevent the effects of undesired 4.5 mc harmonic radiation, it is essential that all audio and video i-f components be replaced in exactly the same position they occupied when they were wired in at the factory. All r-f, video and sync carrying leads should be made as short as possible. Check lead dress of picture tube anode lead to prevent high-voltage arc-over.

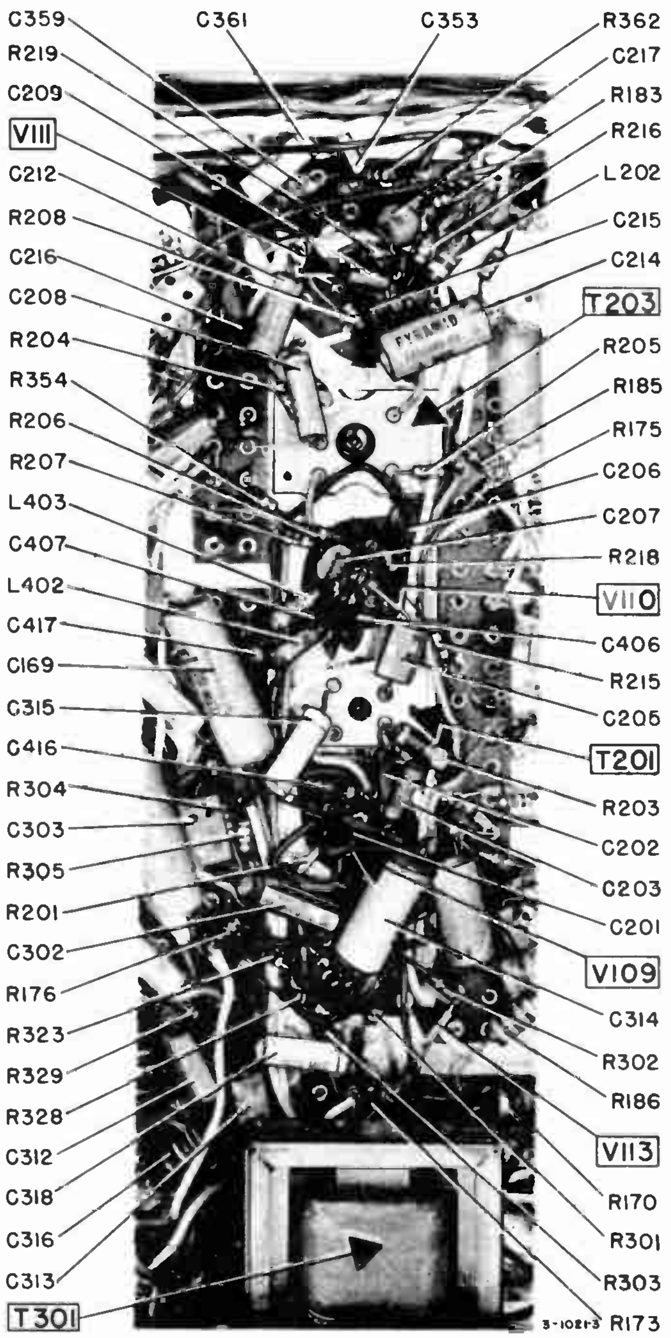
2. *ARC-OVER IN HIGH VOLTAGE COMPARTMENT (21-INCH MODELS)*—Under humid conditions poor lead or component dress on the high-voltage rectifier bracket may cause arc-over. It may occur between the plate cap of input rectifier (V121) and the solder lug which is fastened to the center of the socket of the middle rectifier (V122). To remedy this condition dress tube V121 away from the middle rectifier tube (V122). Also bend the above mentioned solder lug up and away from the plate cap of rectifier tube V121.

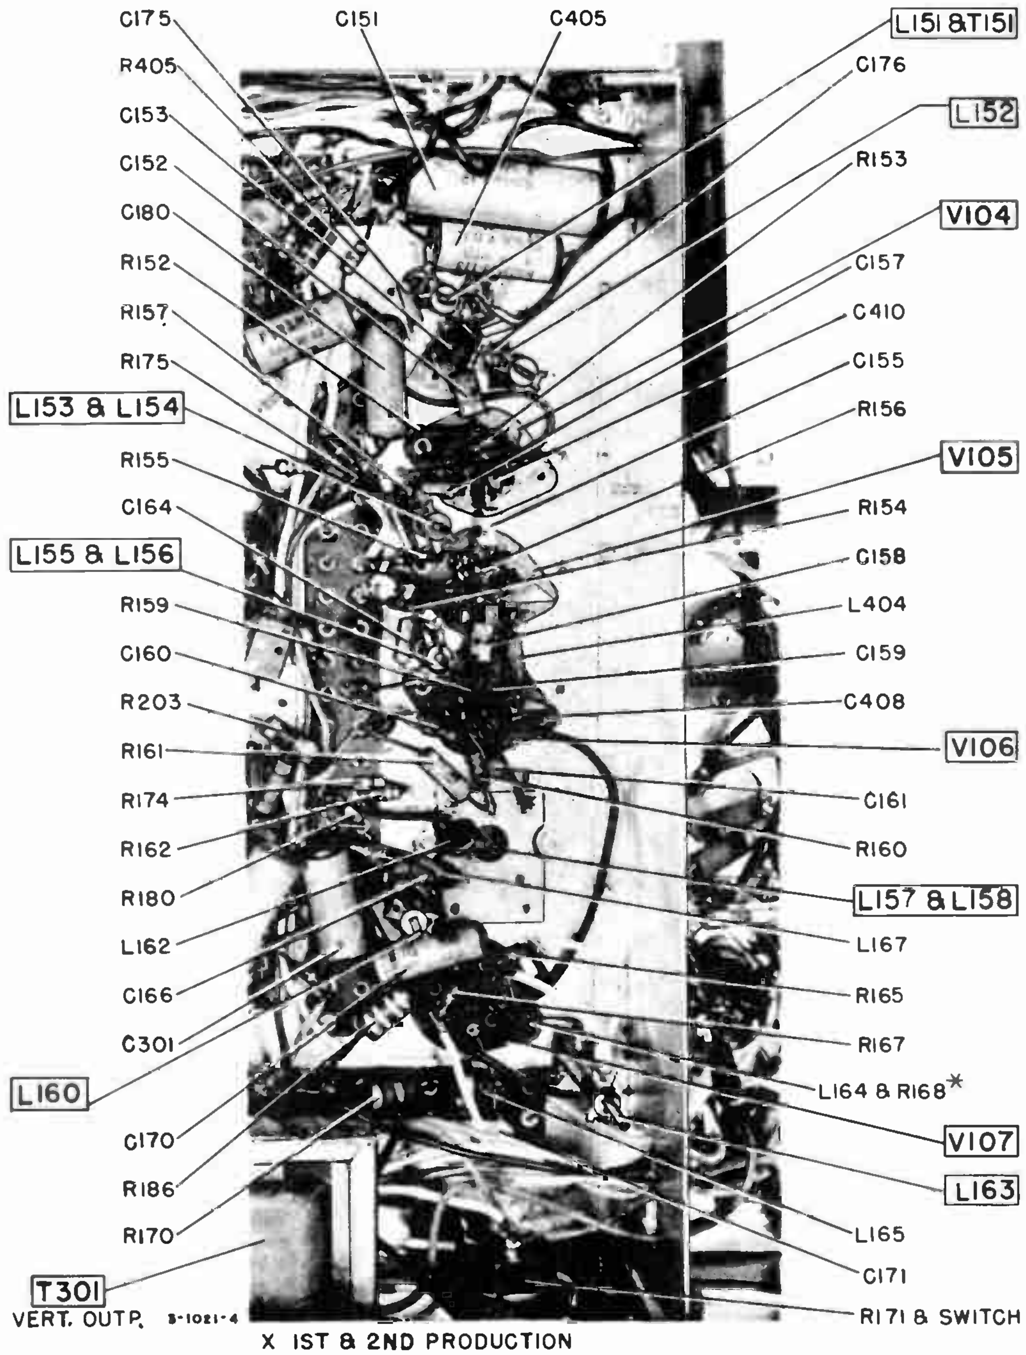
3. *REPLACEMENT OF CRYSTAL DIODE*—For replacement purposes special diodes (Cat. No. RED-001) are being supplied. To insure proper receiver operation it is not recommended that any other type diode be used for replacement purposes.

4. *REPLACEMENT OF FILAMENT TRANSFORMER*—(4th Prod. only) When replacing the filament transformer, T401, be sure to measure the voltage at pin 3 of V106 (3rd video i-f). This voltage should read approximately 12.0 volts. If zero or near zero volts are measured at this point the *primary* leads should be reversed.









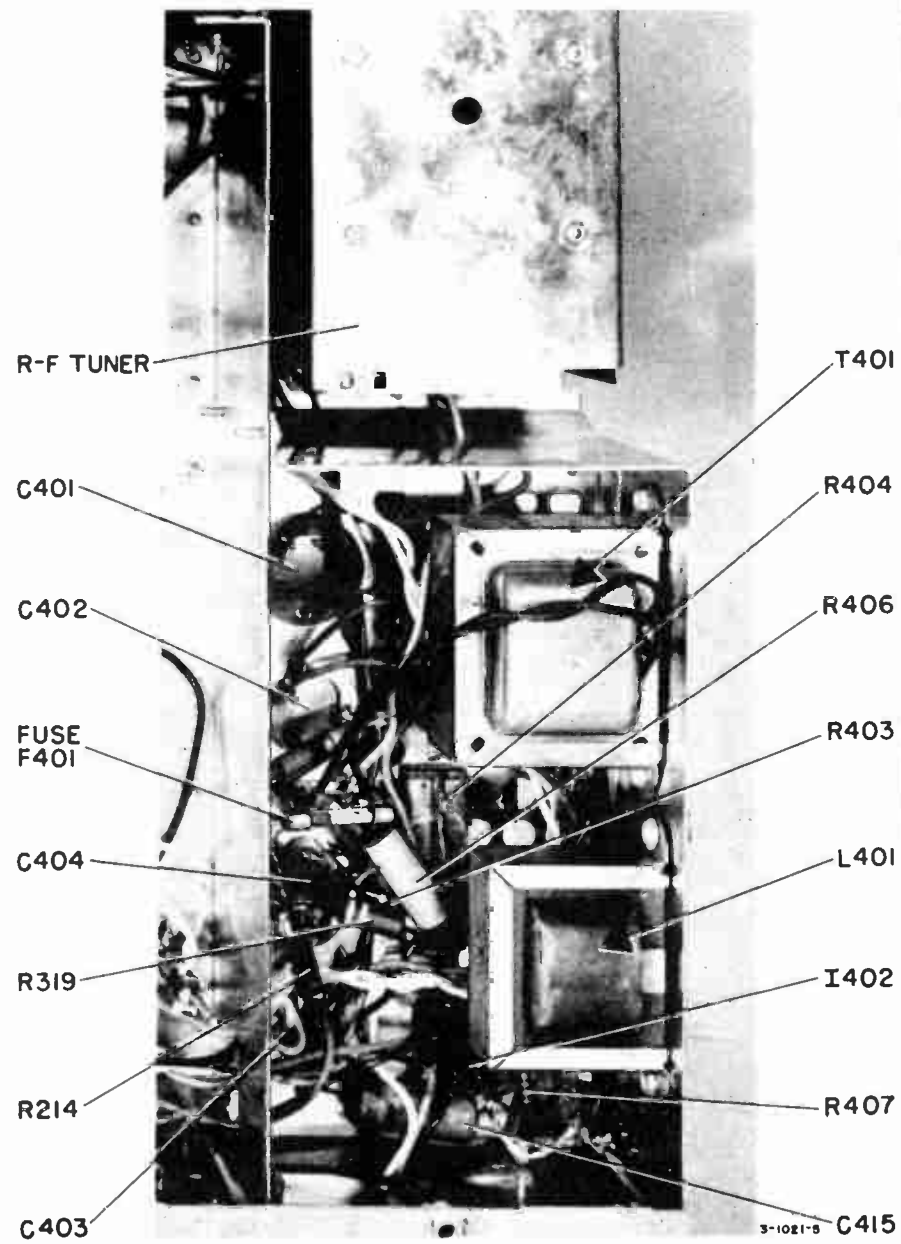


Fig. 33. Bottom View of Chassis (Represents typical layout; minor variations may be encountered)

MAJOR PRODUCTION CHANGES

GENERAL:

As previously noted, several mechanical and electrical changes have occurred during the production of this family of receivers. Listed below are the various items to be considered with reference to specific production versions. It should be noted that electrical circuit changes are not chronologically related to those changes which occurred in the various mechanical assemblies. To prevent confusion, electrical circuit changes shall be denoted as 1st, 2nd, 3rd or 4th production versions, while mechanical assembly changes shall be referred to as "early," "mid" and "late" production items.

MECHANICAL ITEMS

1. PICTURE TUBE ASSEMBLY:

Two basic types of picture tube assemblies have been used during production, each of which is described on pages 5 through 10. The "early" models 21T1, 21C204 and 21C214 use the "square" type assembly depicted on page 5. All later production of these models utilize the "late" type assembly described on page 19.

MASK AND OVERLAY:

Two different masks, one metal and one plastic, have been used in these receivers. These masks are interchangeable. It should be noted however, that the metal type mask requires the use of a rubber dust seal (Cat. No. RIG-010, 011 or 012) between the mask and the picture tube. The dust seal should be installed according to instructions found on pages 18 and 19. The plastic type mask was used in early and midproduction receivers. The metal type mask is to be found in middle and late production units.

2. ANCHORING OF MASK:

On late production metal masks two overlay anchors are projection welded to the lower edge of the mask to permit securing the mask to the cabinet by means of No. 8 x 3/4 inch wood screws. This was done to eliminate shifting of the mask or picture tube during transportation.

3. FOCUS UNIT ASSEMBLY

Early and midproduction focus units utilized a flexible extension shaft and knob assembly which extended out of the rear of the receiver for the purpose of focus adjustment.

Late production focus units utilize a screw driver and associated guide funnel type adjustment. These two focus units are otherwise similar as may be noted in Figs. 4 and 8.

5. DETECTOR CAN ASSEMBLY:

1st and 2nd production chassis incorporated the detector can assembly shown in Fig. 38, page 38. In this assembly, the diode detector is located under the removable "hat."

3rd and 4th production receivers utilize the detector assembly shown in Fig. 44. To change the diode or any other component within this assembly, it is merely necessary to remove the two self-tapping screws at the base of the assembly. The entire assembly may then be pulled off of the mounting plate. The shield can may then be removed from the assembly by compressing the two spring tabs on the top tuning core securing clip.

ELECTRICAL ITEMS

1. HORIZONTAL OUTPUT TUBE—Horizontal output tube was changed from 25AV5 to 25BQ6. The 25AV5 tube was used in first production models only.

2. IMPROVEMENT IN PICTURE QUALITY—The diode load resistor, R162, was changed from 3900 ohms to 3000 ohms. For identification these receivers were rubber-stamped on the back apron of the chassis with No. 420.

3. HORIZONTAL SWEEP OUTPUT TRANSFORMER AND YOKE—In 3rd and 4th production models the horizontal output transformer and yoke were changed. Receivers using these revised sweep components bear a label on the high-voltage compartment rear door which indicates the catalog numbers of the horizontal output transformer and yoke contained therein. Models 17C125 and 20C107 use horizontal output transformer RTO-130, 21 models use RTO-129. The yoke to be used with either of these transformers is RLD-050. These components should not be used in those receivers which used the "early" type transformer and yoke, unless a "late" transformer and a "late" yoke are simultaneously installed. These receivers using these "late" sweep components are rubber-stamped with No. 430 and include changes of No. 420.

4. DELAYED AGC—In order to improve the operation of the receiver a new AGC circuit was incorporated in the 3rd and 4th production. Receivers using this new circuit may be identified by noting the "Local-Fringe Stabilizer" two-position switch label located on the cabinet back. This control replaces the original potentiometer and switch, the label of which reads "Picture Stabilizer" or "Signal Strength Compensator."

The purpose of this new circuit is two-fold:

a. To prohibit the development of AGC bias for the 2nd r-f stage until a sufficiently strong signal is received which will remove all conversion noise in the picture. This results in an improvement of the signal-to-noise ratio on weak signals while still permitting AGC action by virtue of a non-delayed AGC voltage which is applied to the i-f system.

b. To make the AGC fully automatic, thus eliminating the necessity of adjusting an AGC level potentiometer to suit particular installation conditions. For easy identification these receivers were rubber-stamped with No. 401 which also include changes No. 420 and No. 430. See page 20 for detailed description of this circuit.

5. NEW VIDEO AMPLIFIER—A new video amplifier circuit using a 6BK7-A instead of 12BH7 tube was used in the 4th production receivers. Receivers and cartons bearing these receivers are stamped with the number 1140.

This new circuit has been incorporated, to increase the overall receiver bandwidth and to improve the video transient response. Since this circuit change was incorporated after the delayed AGC circuit, all receivers equipped with the new video amplifier also include delayed AGC.

Together with this circuit change, the capacitor C162 in the video detector is changed from 5 mmf to 9 mmf. The new type tube necessitated a change in the filament string wiring which permits the operation of a 450 ma. heater (6BK7-A) partially in series with other filaments and partially from the filament transformer. When replacing the filament transformer, observe the precaution outlined . For detailed circuit analysis and alignment notes refer to pages 20 and 26. For easy identification receivers incorporating this circuit change were rubber-stamped with No. 1140. These receivers include a 3000-ohm diode load resistor and delayed AGC.

6. CHANGE OF PICTURE TUBE IN MODEL 20C107 RECEIVERS—Late production 20C107 receivers were equipped with a 20DP4A picture tube instead of 20CP4A as used in the earlier production. Receivers using a 20CP4A tube require two flat washers on each support rod (see Fig. 6) as a spacing medium between the flux shield disk and the fibre yoke support.

Receivers using a 20DP4 picture tube require a "T" spacer and one flat washer on each support rod as is also required for the 21-inch models.

7. "LATE" TYPE VIDEO DETECTOR ASSEMBLY—First, second and third production receivers incorporate a video detector assembly in which the value of C162 is 5 mmf. The video detector of 4th production receivers incorporate a 9 mmf capacitor, C162. This change appears in all receivers which incorporate the 6BK7-A type video amplifier.

UHF-TUNER MODEL UHF-103

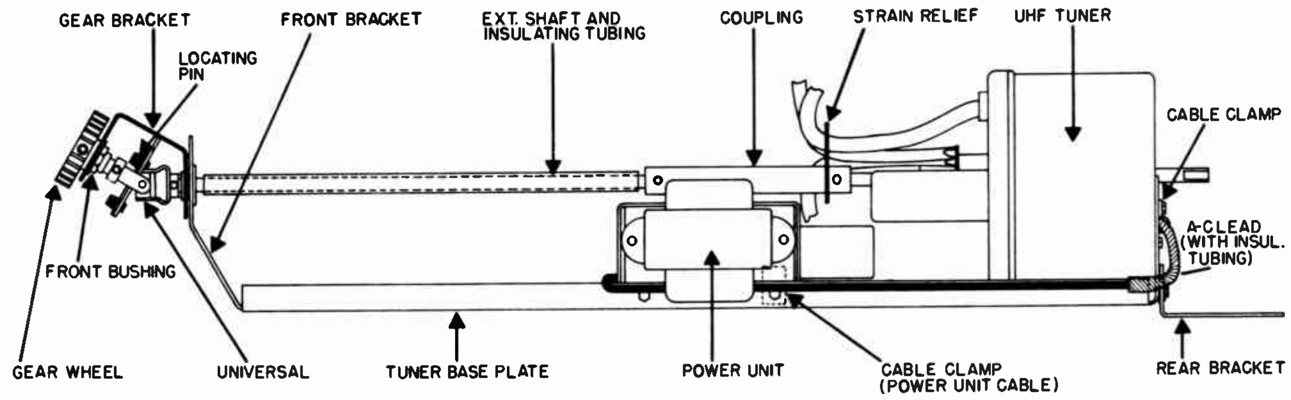

Fig. 40. UHF-103 Tuner Assembly

Installation

All receivers marked with UHF have the UHF Tuner installed in the factory. However, due to the fact that this tuner is also available in kit form, some unmarked receivers may contain this tuner. Each tuner kit includes the detailed installation instruction ER-A-UHF103-1.

If the tuner unit had been removed for service be sure to check for proper meshing of knob gear and gear drive after completing the assembly. In case of improper operation readjust locating pin plate (see Fig. 42). Its position may be adjusted by loosening the two adjustment screws available from the front of the receiver. Make sure that the UHF Selector detent roller locks into each of the four positions without any difficulty.

The tuner unit consists of a turret tuner and a power unit mounted to a base plate, see Fig. 40. The tuner is operated from the front of the receiver by means of a knob ring. The movement of the knob is transferred to the tuner turret by means of a gear, an extension shaft and coupling.

The tuner is held in place in front by a locating pin plate and locating pins and in the rear by a rear bracket fastened to the cabinet.

It is assumed that the television receiver with which the UHF tuner is used is in proper alignment, particularly with respect to adjacent channel attenuation. If the receiver adjacent channel attenuation is unsatisfactory, the converted UHF signal may be interfered with.

UHF Tuner Adjustments

General

The UHF Tuner, as shipped from the factory, has its output stage tuned to Channel No. 5, to which the television receiver should be tuned. This output stage may need realignment for Channel No. 6 operation for reasons given below. The actual realignment is very simple and can be done in most cases without the use of test equipment.

The service technician must individually adjust each of the three UHF positions for operation upon the local active UHF channels. This may be done also without the use of special test equipment. The tuning ranges of the three UHF positions are all identical and cover the entire UHF spectrum.

UHF—I-F Adjustments

Before installing the tuner in the receiver it will probably be more convenient to make the necessary UHF I-F adjustments.

The I-F preamplifier in the UHF Tuner has been factory-aligned to Channel No. 5. If there is a station operating on Channel No. 5, the Tuner I-F preamplifier should be adjusted to function on Channel No. 6. It is not desirable to convert the UHF signal to Channel No. 5 if there is a strong television station operating on Channel No. 5 in your area. It is quite obvious that if the VHF station signal on Channel No. 5 is fairly strong, it will be picked up by the television receiver even when the UHF Tuner is operating and would thereby impair the quality of the UHF picture.

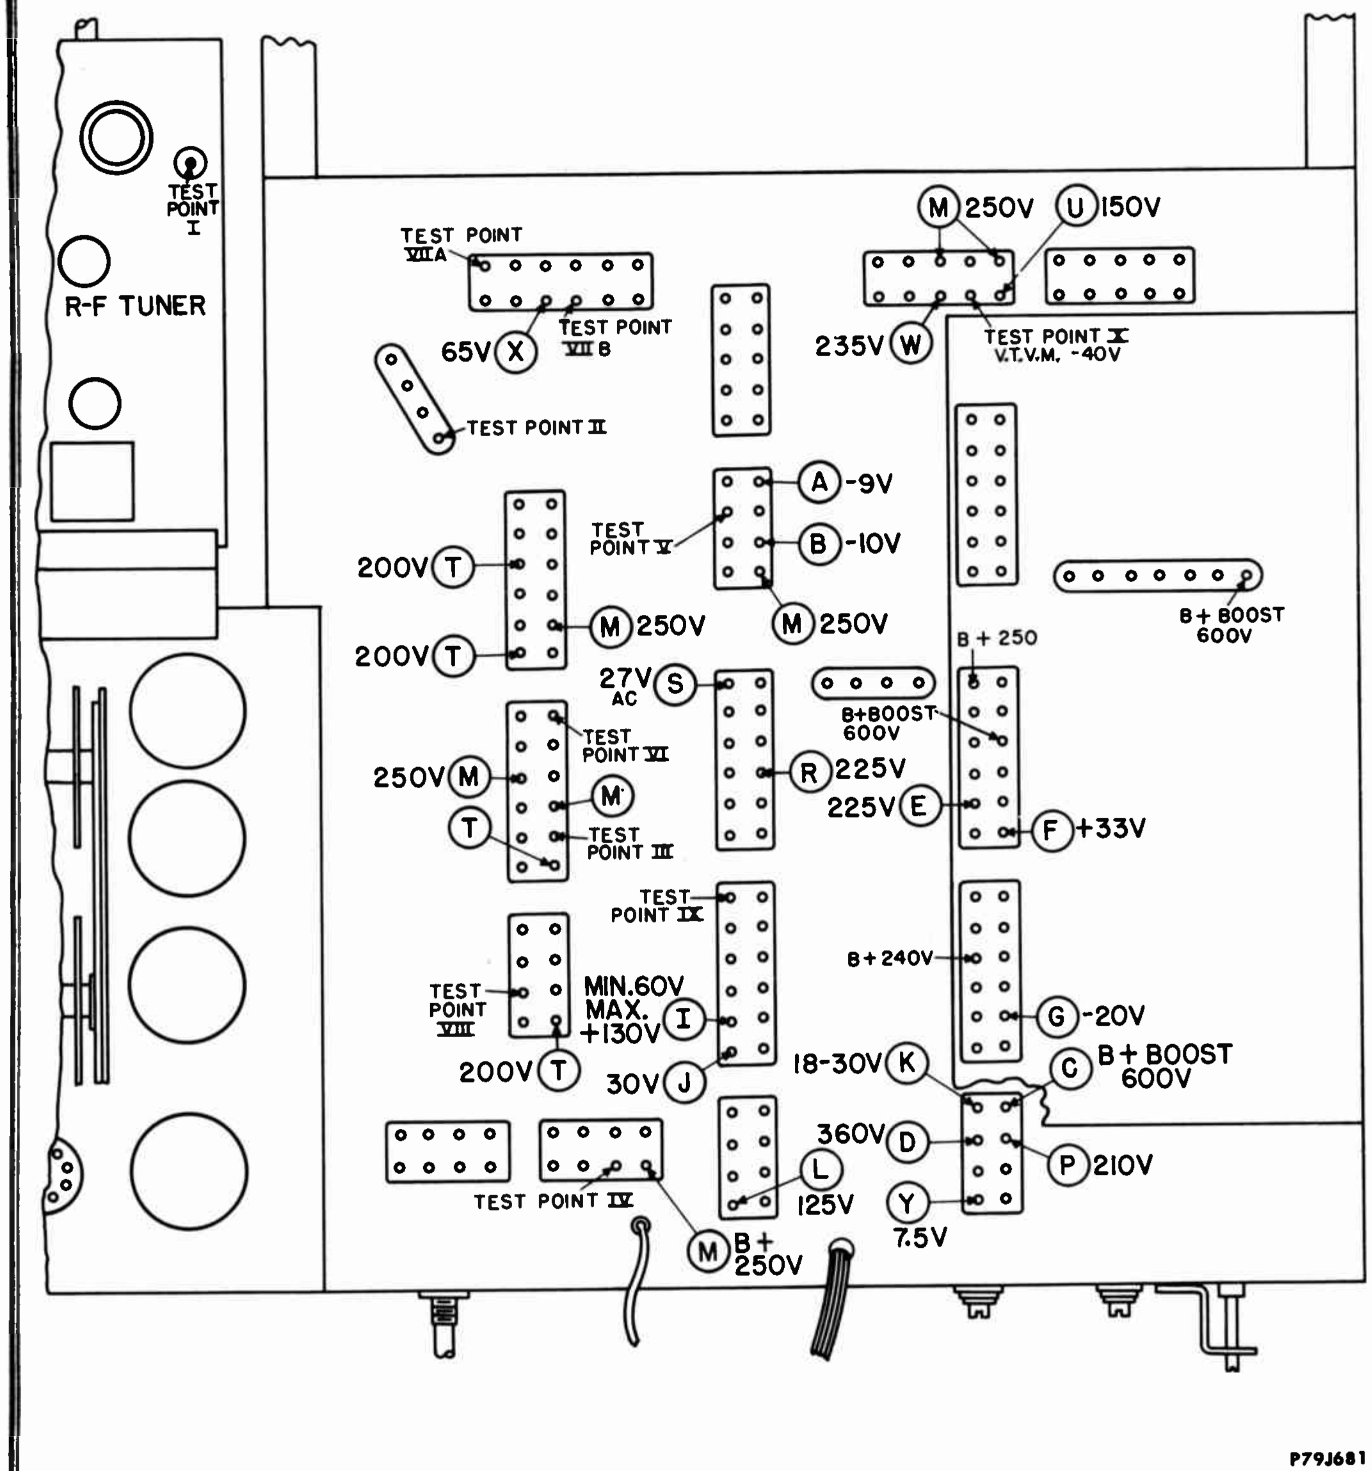

Fig. 43. Test Point Diagram (Represents a typical receiver, though minor variations may be encountered)

To readjust the preamplifier for operation on Channel No. 6 instead of No. 5, as shipped from the factory, proceed as follows:

(a) Turn core "A" (see Fig. 45) approximately three turns counterclockwise.

(b) Turn core "B" approximately two and a half turns counterclockwise.

The UHF Tuner is now ready for operation on Channel No. 6.

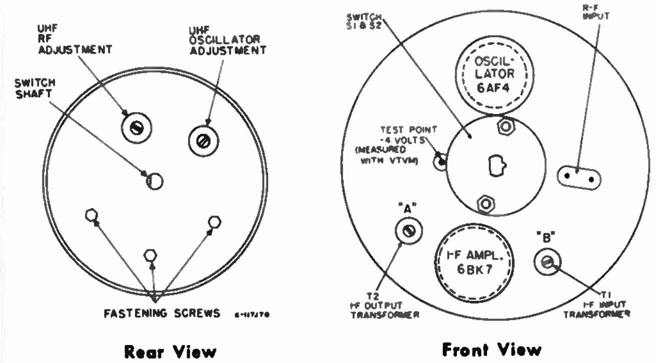

Fig. 45. UHF Adjustments

UHF Channel Adjustments

Notes:

(a) Always allow approximately 15 minutes warm-up time before proceeding with the adjustments.

(b) Set the Tuner knob ring to "UHF-1" position and the television receiver channel selector knob on either Channel No. 5 or No. 6 according to preceding information. Set the Fine Tuning control on the television receiver to the middle of its range.

ALIGNMENT PROCEDURE

1. Turn the oscillator tuning core (see Fig. 45) fully counterclockwise.
2. From this "starting point," gradually turn the oscillator tuning core clockwise into the coil until a UHF picture and accompanying sound signal are received. While turning the oscillator core clockwise into the coil, several minor responses as well as two strong picture responses may be noticed. However, the first strong response to be noted while turning the core clockwise from its maximum counterclockwise position is the response to be used. Be careful not to exert any undue pressure when turning the core into the coil, since damage to the coil may result.
3. Adjust the R-F tuning core for maximum picture signal.
4. The oscillator tuning core should now be readjusted so that the Fine Tuning control on the television receiver will permit tuning slightly into accompanying audio bars or "beats." Be sure that you can tune away from any adjacent channel interference.
5. The Tuner is now aligned for operation on one UHF channel. Repeat steps 1 to 4 on the two remaining UHF positions, if more than one UHF channel is active in your area.

UHF-103 CIRCUIT DESCRIPTION

Refer to diagram, Fig. 47.

Conversion of UHF to VHF is achieved by mixing the incoming UHF signal with a signal which is generated by a local high-frequency 6AF4 oscillator. This mixing takes place in a 1N72 crystal diode, the output of which is amplified by the low-noise 6BK7 cascode amplifier. The output of this amplifier is then link-coupled to the television receiver antenna terminals.

Two antenna inputs are provided; one for the VHF antenna and one for the UHF antenna. Switches S1 and S2 are mechanically ganged with the UHF coil plate. The switch, S1 permits switching of the VHF receiver antenna input lead to either the VHF antenna directly, or to the UHF Tuner output link.

On the VHF position, switch S2 un-shorts R11. Thus, a small amount of current is permitted to flow through the tubes, even while on the VHF position.

In the UHF-1 position, as shown, the signal is fed into the input circuits consisting of C1, C2, C3, C4 and L1. L1 is a ¼-wave shorted line, the electrical length of which is varied by adjustment of the shorting core. For mechanical convenience, this ¼-wave line is wound into a spiral form and should not be considered as a conventional "coil."

The values of C1, C2, C3, C4 are chosen so that the input circuit impedance closely approximates 300 ohms across the entire UHF band, while the impedance at the junctions of C1 and C4 and the ends of the transmission line L1, is very high—in the order of several thousand ohms. C7, C8, L7 and L8 maintain accurate balance of the input circuits. C9 and the 1N72 diode are tied in series across the line. Their midpoint is used for extraction of the VHF converted signal as well as for injection of the local UHF oscillator signal. C9 is critical in value since together with the diode it also affects the balance of the line.

The oscillator, a 6AF4 tube, is connected in an ultra-audion oscillator circuit. Its plate voltage is "shunt-fed" through L17 which presents a high impedance at all frequencies above approximately 250 mc. The oscillator tank circuit, L2, is also a tunable

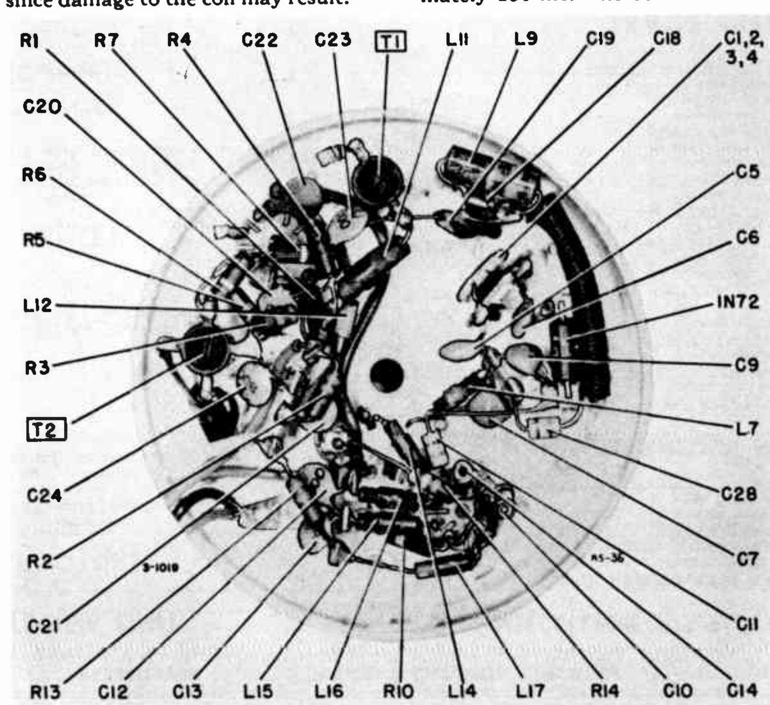

Fig. 46 Bottom View of Turret Tuner Chassis

UHF TUNER (Cont'd)

shorted ¼-wave line. Oscillator output is taken from the cathode circuit across L14 and coupled through C11 into the 1N72 diode.

L9 furnishes the d-c return path for rectified diode current, while C18 resonates with other circuit constants to the VHF output frequency. The converted UHF signal is coupled through C19 into the cascode 6BK7 amplifier.

This amplifier consists of two stages. The first stage is a conventional triode, grounded-cathode stage, whose input circuit is tuned to the VHF frequency (approximately 79 to 85 mc). The cathode circuit, consisting of R1 and C20, is only used to obtain d-c bias. L12 is a high-impedance, shunt-feed R-F choke. The output of the first stage is capacity-coupled into the second triode which is a grounded-grid amplifier. In the cathode of the second stage is connected a conventional bias resistor, R4, and its R-F bypass capacitor, C23. L11 provides the d-c cathode return through T1 to ground and also provides neutralization of the first triode stage. This neutralizing coil is somewhat critical in value and must, if damaged, be replaced by an exact replacement coil if the low-noise advantages of this circuit are to be maintained.

SERVICING THE UHF-103 TUNER

With the exception of the oscillator socket, the components thereon and the UHF coils, the replacement of components in the tuner is comparatively simple, requiring no special considerations other than the usual lead dress precautions common to VHF practice. However, because of the small size of most components be sure to prevent overheating of components by using a small soldering iron.

The oscillator circuit wiring and the UHF coils are critical and require special attention.

Replacement of Oscillator Tube Socket

1. Remove the coil turret assembly by loosening the four set screws in the long coupling (Fig. 40) and the one set screw in the short coupling. Then, by lifting the detent roller and turning the assembly so one of the detent slots matches the bracket screw, the turret can be slid out of the unit.

2. Unsolder all connections to the V-shaped contactor board. Remove contactor board from the assembly by removing the Phillips-head screw.

3. Carefully unsolder the components at the tube socket, being careful to note their exact position.

4. Drill out the two rivets holding the detent roller bracket. After removing this bracket the oscillator tube socket can be removed by drilling out its securing rivets.

5. When reinstalling new socket be sure to place the components in their original positions (see Fig. 46). Positioning is somewhat critical hence is not advisable to wiggle the tube back and forth when removing or inserting it but rather to pull or push it straight from the socket. Even minor distortion of the tube socket pins has a most detrimental effect at ultra high frequencies.

Replacement of UHF Coils

1. Remove small pring split washer (Truarc clip) on turret shaft that holds textolite coil bracket. To facilitate this operation a set of Truarc pliers should be used which may be obtained at your General Electric dealer (order number WH-50 x 59).

2. After removing old coil, solder new coil assembly in place with the coil leads in their normal position. Flow the solder between the lead and the contact, making sure that the iron does not put any stress on the lead which might deform it.

The tuning cores for the coils are of different sizes and are selected to fit the coils. Therefore, do not interchange cores from one coil to another. Coils are supplied from the factory complete with their cores; be sure to replace as such.

3. With reasonable care it is possible to replace a coil without removing the coil bracket. Carefully bend the textolite plate upward just above the coil to be removed. Push the coil to the right until the top of the coil clears the retaining hole.

4. Gently release the textolite plate, and while holding the coil in this cocked position, apply the soldering iron to the two coil terminals simultaneously. As soon as the solder melts, tilt the coil still further to the right and remove it. Wipe the contacts clean of all solder.

5. When replacing new coil gently bend textolite plate upward and put the new coil into position, *being careful not to bend the coil leads in any direction*. This precaution is very important as poor frequency stability will probably result if it is not followed. In soldering the new coil leads in place use the same precaution as outlined above.

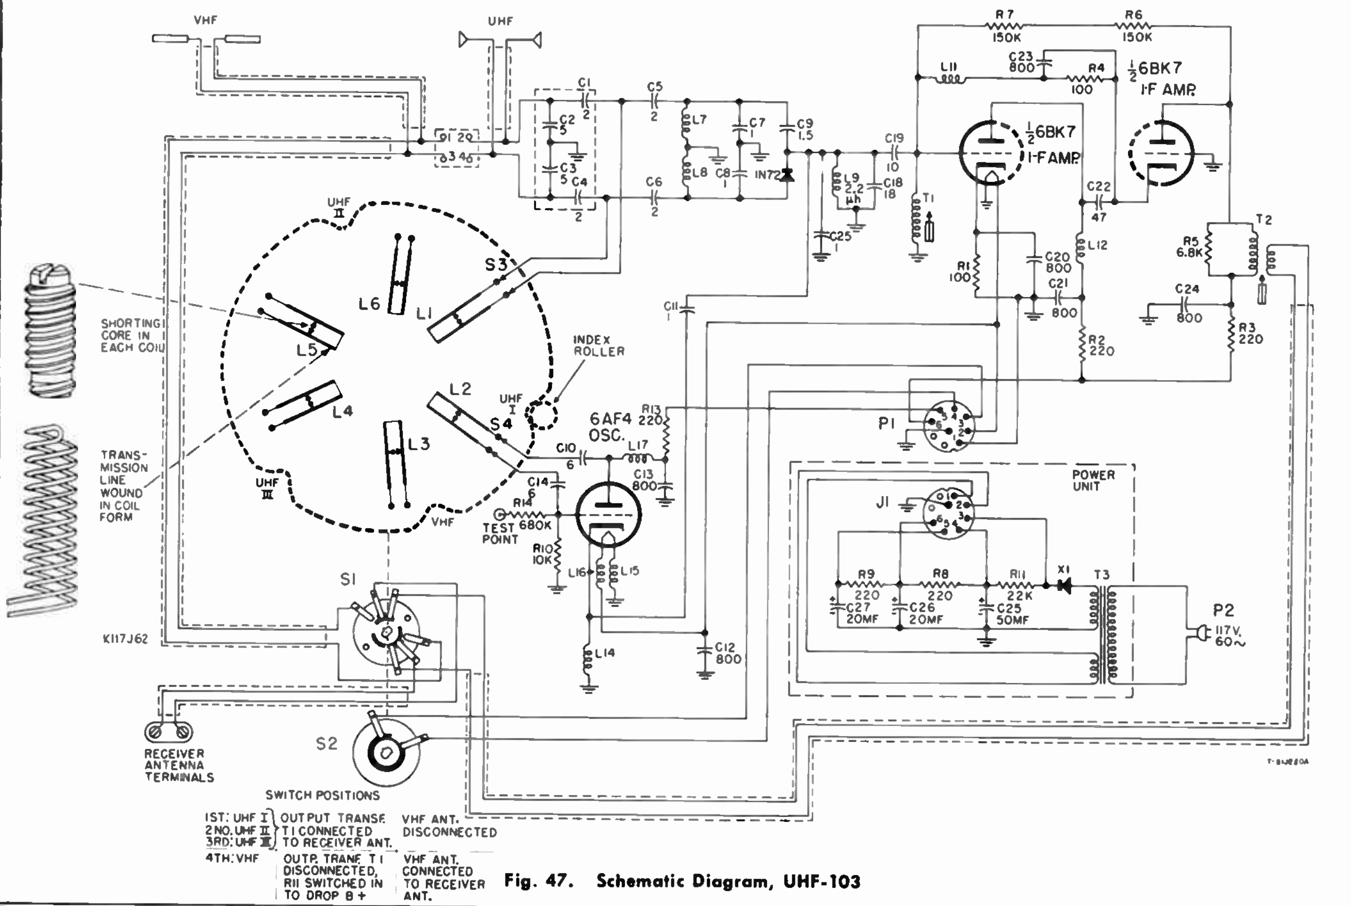

Fig. 47. Schematic Diagram, UHF-103

PARTS LIST

CAT. NO.	SYMBOL	DESCRIPTION	PRICE
R-F TUNER UNIT			
CAPACITORS			
*RCN-001	C100	1 mmf., ceramic	$0.20
*RCN-027	C112 A, B	800-800 mmf., ceramic	.65
*RCN-055	C113	3.9 mmf., mica	.25
*RCW-3027	C111	680 mmf., ceramic	.90

COILS & TRANSFORMERS (Cont'd)

CAT. NO.	SYMBOL	DESCRIPTION	PRICE
*RLI-138	L167, 172†† 356, 357	CHOKE—Choke, 10 uh.	$0.25
*RLI-142	L168, 404	CHOKE COIL—Choke 1.4 uh.	.45
RLI-154	L202	CHOKE—Choke 3.3 uh.	.25
RLI-175	L164, R168	PEAKING COIL—Peaking coil, 120 uh., wound on 3900 ohms, ½ w., resistor, (1st, 2nd and 3rd production)	.80
RLI-176	L161, R164	PEAKING COIL—Peaking coil 120 uh., wound on 15,000 ohms, ½ w., resistor	.70
RLI-177	L355	CHOKE—Choke, 30 uh., flexible	.60
RLI-179	L152, C176	TRAP COIL—38 mc trap coil, with 62 mmf., capacitor & tuning core	2.00
RLI-180	T201, C204	TRANSFORMER—Interstage transformer (4.5 mc) includes tuning cores & 47 mmf. cap	3.25
RLI-181	L163, C178	TRAP—4.5 mc trap, includes tuning core & capacitor, for use in receivers incorporating a 12BH7 video ampl.	2.25
RLI-182	L160, C166, 167	COIL—4.5 mc., audio take-off trap coil, incls. cap. & tuning core	2.10
RLI-183	L166, R172	PEAKING COIL—Peaking coil, 165 uh., wound on 8200 ohms, ½ w., resistor	.60
RLI-184	L162	COIL—Peaking coil, 265 uh.	.50
RLI-186	L165	PEAKING COIL—Peaking coil 425 uh.	.50
RLI-190	L169††	COIL—Choke coil 80 uh.	.40
RLI-191	L170††	COIL—Choke coil 6.8 uh.	.40
RLI-202	L163, C178	COIL—4.5 mc. trap coil, for use in receivers incorporating a 6BK7 video amplifier	2.00
RLP-020	L153, 154, C165	COIL—1st video I-F plate and trap coil, with cap. & tuning cores	2.50
RLP-021	L155*†, 156*†, C164*†, C164**, L155**, 156**	COIL—2nd video I-F plate & trap coil with cap. & tuning cores	2.50
RLP-022	L155††, 156††, C164††	COIL—2nd video I-F plate coil and trap coil with capacitors and tuning cores	2.00
RLX-036	L157*, 158*, C163*, L157**, 158**, C163**, L157†, 158†, C163†	VIDEO DET. ASS'Y.—Assembly complete in shield can, includes 1N64 crystal detector, coils with tuning cores & capacitors for use in receivers incorporating a 12BH7 video amplifier	7.95
RLX-039	L157, 158, C163	VIDEO DET. ASS'Y.—Assembly complete in shield can, for use in receivers incorporating a 6BK7 video amplifier	7.15
RTD-012	T203, C218, 219, R220	TRANSFORMER—4.5 mc ratio detector transformer including cap., resistors and tuning cores	4.25
RTF-003	T401	TRANSFORMER—Filament transformer, 6.3 V., output at 6 amperes	6.15
RTL-138	T151, L151, C175	TRANSFORMER—Video I-F input transf. includes cap., with tuning cores for use in receivers incorporating 12BH7 video amplifier	2.95
RTL-147	T151, L151	TRANSFORMER—Video I-F input transf. includes cap. with tuning cores for use in receivers incorporating 6BK7 video amplifier	
RTO-121	T301	TRANSFORMER—Vertical sweep output transformer	7.00
RTO-123	T202	TRANSFORMER—Audio output transformer, table models only	2.80
RTO-124	T202	TRANSFORMER—Audio output transformer, console models only	3.50
RTO-125	T351*, 351**	TRANSFORMER—Horizontal sweep output transformer for use with yoke RLD-042, for 21" models	13.00
RTO-127	T351	TRANSFORMER—Horizontal sweep output transformer for use with RLD-042 for 17C125 and 20C107 only	14.50
RTO-129	T351†, 351††	TRANSFORMER—Horizontal sweep output transformer for use with RLD-050 yoke for 21" models	13.00
RTO-130	T351†	TRANSFORMER—Horizontal sweep output transformer to be used with yoke RLD-050 for models 17C125 and 20C107 only	12.75

MISCELLANEOUS ELECTRICAL

CAT. NO.	MODEL	DESCRIPTION	PRICE
REA-003	21T1 (early) 21C201-C202-C204-C206-C214	PICTURE STRAIGHTENER—Picture straightener with support (for early "square" type yoke housing)	$0.75
REA-004	21T1 (late) 21T1-U, 21T3-T6, 21C201-C202-C206-C208-C208-U-C210-C214	PICTURE STRAIGHTENER—Picture straightener (for use with "late" type yoke support)	.75
REC-006		GRID CAP—Spring cap for 6V3	.05
REF-008		FUSE—1.6 amp., 125 v., slow-blow line fuse, pigtails (F401)	.45
RED-001		CRYSTAL DIODE—Crystal diode with leads (Y151)	1.90
*REI-016		CORE—Tuning core for L157, T151, T201	.20
REI-037		CORE—Tuning core, composition iron with screw stud for RLI-179	.20
*REI-038		TUNING CORE—For L151, L158	.20
RER-015		SELENIUM RECTIFIER—Selenium rectifier, 350 ma., 6 plates, 2 x 2 in. (X401, 402)	6.50
*RET-013		ION TRAP—Single magnet	1.45
RHB-017		BUTTON—Corona button	.25
*RII-069		INSULATOR—Insulator, fiber for yoke "Hot" lead	.02
RII-080	17C125, 20C107	INSULATOR—Insulator, standoff for 1X2A socket	.25
RJC-015		YOKE PLUG—Male, for yoke horizontal "Hot" lead	.30
RJC-019		PIN—Speaker pin	.02
*RJC-025		ANODE CONNECTOR—Picture tube anode connector	.50
RJJ-008		RECEPTACLE—Translator power receptable	.35
RJJ-010		RECEPTACLE—Power cord receptacle (I401)	.20
RJP-003		PLUG—Pilot light plug, 2-prong	.15
*RJP-031		PLUG—Male plug, 9-pin with locator pin 1-in. dia.	.15
RJP-034		PIN PLATE—Tube socket pin plate, 8-pin	.35
RJP-042		PIN PLATE—Tube socket pin plate, 7-pin	.25
RJP-043		PIN PLATE—Tube socket pin plate, 9-pin	.30
RJP-044		PIN PLATE—Tube socket pin plate, 8-pin	.25
RJS-049		SOCKET—2-prong socket, for RJP-003	.25
*RJS-148		SOCKET—Socket 7-pin miniature for 1X2A	.25
RJS-159		CONNECTOR—Yoke connector female receptacle, 1-pin	.20
RJS-164		SOCKET—Tube adapter socket, 8-pin for V115 or V119	.35
RJS-166		SOCKET ADAPTER—7-pin for tubes V104, V105, V106, V109, V110 or V112	.30
RJS-168		SOCKET—Tube adapter socket 9-pin, black phenolic for V107, V111, V113, V114, V116, V117, V118 or V120	.35
RJS-183		SOCKET—Yoke connector, socket, female 9-pin	.30
RJS-184		SOCKET—Tube socket, 9-pin, 29/32 in. dia., single screw center mtg., mica filled molded phenolic	.25
RLF-055	21T1 (early) 21C204	FOCUS UNIT—PM focus unit	11.00
RLF-058	17C125, 20C107 21T1-U, 21T1 (late) 21C201-C202-C206-C208-C208-U-C210, C214, 21T3-T6	FOCUS UNIT—PM focus unit	11.00
RMX-232	21T1 (early & late), 21C201-C202-C204-C206-C208-C208-U-C214	MOUNT SUB-ASSEMBLY—High-voltage assembly consisting of textolite bracket, high-voltage capacitor, sockets, corona shield & eyelet	1.75

PRICES ARE SUGGESTED LIST PRICES AND SUBJECT TO CHANGE WITHOUT NOTICE.
Mica and ceramic capacitors are 500 volts unless otherwise specified.
Resistor value tolerance is ±10% unless otherwise specified.
*Parts used on previous receivers when referring to "Cat. No." Column.
*Indicates 1st Production.
**Indicates 2nd Production.

MISCELLANEOUS ELECTRICAL (Cont'd)

CAT. NO.	MODEL	DESCRIPTION	PRICE
ROP-025	21T1 (late) 21T1-U, 21T3	SPEAKER—Loudspeaker 8-inch PM, 3.2 ohms	$13.50
RSW-098		SWITCH—Local-distance switch	1.00
RWL-027		POWER CORD—AC power cord assembly	1.20
*RWX-045		SOCKET — Picture tube socket, with leads	1.00
RWX-046		SOCKET—Pilot light socket with leads	.75
*S527D-7	21T1 (early)	SPEAKER—Loudspeaker, 5¼-in. PM, 3.2 ohms	5.00
S650D-7	21T6	SPEAKER—Loudspeaker, 6½-in. Alnico PM, 3.2 ohms	6.10
*S810D-7	17C125	SPEAKER—Speaker 8-in. Alnico PM, 3.2 ohms	13.80
S1012D-7	20C107	SPEAKER—Speaker, 10-in. Alnico PM, 3.2 ohms	11.80
S1212D-7	21C201-C202-C204-C206-C208-C208-U-C210-C214	SPEAKER—Loudspeaker, 12-in. Alnico PM, 3.2 ohms	12.95

MISCELLANEOUS MECHANICAL

CAT. NO.	MODEL	DESCRIPTION	PRICE
*RHG-007		GROMMET — Rubber insulating grommet for white yoke lead	.05
RHG-021	21T1 (early)	GROMMET—Rubber grommet for speaker mounting	.05
RHM-025		WASHER—"C" washer for R-F tuner shaft	.01
*RHN-016		NUT—Coupling nut for screws in channel selector shaft coupling RMK-006	.15
*RHS-010		SHIELD—Miniature tube shield, 1⅜ in. long	.20
RHS-098		SHIELD—Pilot light shield	.20
RHW-044	21T1-T3-T6, 21C201-C202-C204 21C206-C208-C208-U-C210-C214	WASHER—Fiber washer, $^9/_{64}$ x $^7/_{16}$ dia.	.05
RII-077		BUSHING—Insulated bushing	.25
RII-079	17C125, 20C107, 21T1-T3-T6, 21C201-C202-C204-C206-C208-C208-U-C210-C214	GROMMET—Grommet for RJC-025	.10
RJS-004		MOUNTING PLATE—Electrolytic capacitor, mounting plate, textolite, for C401	.10
RJS-012		MOUNTING PLATE—Electrolytic capacitor mounting plate, steel, for C402	.10
*RMK-006		COUPLING — Channel selector coupling	.35
RMU-088		SHAFT—Channel selector shaft	.70
RMX-178		ASSEMBLY—Ring & hub flange assembly	.55
RMX-214		BRACKET ASSEMBLY — R-F tuner shaft bracket, with bearing	.35
RMX-215		SHAFT ASSEMBLY — Tubular tuner shaft with friction drive disk	1.50

YOKE AND FOCUS MOUNT ASSEMBLY

CAT. NO.	MODEL	DESCRIPTION	PRICE
RAD-096	17C125	BRACKET—Focus unit support bracket (screwed to top of cabinet)	.25
RAR-005	21T1 (early) 21C204	ROD—Picture tube mounting rod, 2 x ¼ inch	.60
RAR-006	21T1 (early) 21C204	ROD—Yoke mounting rod, 11¾ x ⅜ inch	.60
*RAR-008	21T1 (late) 21C201-C202-C206-C208-C214-21T3-T6, 21T1-U	ROD—Picture tube mounting, 8¼ x ¼ inch	.65

YOKE AND FOCUS MOUNT ASSEMBLY (Cont'd)

CAT. NO.	MODEL	DESCRIPTION	PRICE
*RAR-010	21T1 (early) & late) 21T1-U, 21T3-T6, 21C201-C202-C206-C208-C208-U-C210-C214	ROD—Picture tube mounting rod, 6¼ x ¼ inch	$0.75
*RAR-014	21T1 (late) 21C201-C202-C206-C208-C208-U-C210-C214	ROD—Yoke mounting rod	.35
RAR-015	17C125	TUBE MOUNTING ROD—Picture tube mounting rod, right side viewing rear of receiver, 5 x ¼ inch	.70
*RAR-017	21T1 (late) 21T1-U, 21T3-T6, 21C201-C202-C206-C208-C208-U-C210-C214	ROD—Yoke mounting rod, 12 x ⅜ in.	.35
*RAR-018	20C107	ROD—Yoke mounting rod, 11⅛ x ⅜ inch	.25
RAR-020	17C125, 20C107	ROD—Tube mounting rod, 7¼ x ¼ inch	.75
RAR-021	20C107	ROD—Right side tube mtg. rod, viewed from rear of receiver, 5 x ¼ inch	.70
RAR-022	20C107	ROD—Intermediate tube mtg. rod, 5¼ x ¼ in.	.70
RAR-023	17C125	YOKE MTG. ROD—Right side, viewing from rear of receiver, 9¼ x ⅜ inch	.30
RAR-024	17C125	YOKE MTG. ROD—Left side, viewing from rear of receiver, 8⅜ x ⅜ inch	.30
RHJ-021	17C125, 20C107 (late), 21T1 (late), 21T1-U, 21T3-T6, 21C201-C202-C206-C208-C208-U-C210-C214	SPACER—For use with "late" 21T1 type picture tube assembly	.10
RHM-072	17C125, 20C107, 21T1 (late) 21T1-U, 21T3-T6, 21C201-C202-C206-C208-C208-U-C210-C214	FUNNEL—Screwdriver guide on focus unit	.15
*RHN-017	21T1 (early) 21C204	NUT—Wing nut, #10, used in picture tube mount assembly	.05
*RHN-026	21T1 (early) 21C204	NUT—Tube mtg. rod nut (knurled)	.65
*RHW-038	21T1 (early & late), 21T1-U 21T3-T6, 21C201-C202-C204-C206-C208-C208-U-C210-C214	WASHER—"U" washer, used with picture tube strap assembly	.02
*RMM-205	21T1 (early) 21C204	CUSHION—Yoke mtg. cushion, rubber	.45
*RMM-225	17C125, 20C107, 21T1 (late) 21T1-U, 21T3-T6, 21C201-C202-C206-C208-C208-U-C210-C214	TIE CHANNEL—Tie channel metal clamp for use with part RMM-227	.15
*RMM-227	17C125 20C107, 21T1 (late), 21T1-U, 21T3-T6, 21C201-C204-C206-C208-C208-U-C210-C214	SUPPORT—Focus unit support, Brass, 5½ in. long	$1.20
RMM-237	17C125, 20C107, 21T1 (late), 21T1-U, 21T3-T6, 21C201-C202-C206-C208-C208-U-C210-C214	SUPPORT—Fiber yoke support	.25
RMM-238	17C125, 20C107, 21T1 (late), 21C201-C202-C206-C208-C208-U-C210-C214, 21T1-U, 21T3-T6	DISK—Focus unit disk, circular plate 5⅝ in., with two holes	1.20
RMM-240	21T1 (early) 21C204	PAD—Rubber pad, around yoke, RLD-042, two required	.75
*RMS-312	20C107, 21T1-(late), 21T3-T6, 21C201-C202-C206-C208-C208-U-C210-C214	STRAP—Picture tube strap	.40
RMS-315	20C107, 21T1 (early & late), 21T1-U, 21T3-T6, 21C201-C202-C204-C206-C208-C208-U-C210-C214	SPRING—Contact spring for picture tube coating	.10
RMS-316	17C125	STRAP—Picture tube support strap, 8$\frac{7}{16}$ inch	.40
*RMU-082	21T1 (early) 21C204	SHAFT—Flexible focus control shaft	1.80
*RMU-087	21T1 (late) 21C201-C202-C206-C208-C214	FLEXIBLE SHAFT—Flexible shaft and knob for PM focus unit ⅛ x 6½ inch, spring steel	1.85
RMX-230	17C125	TUBE STRAP ASSEMBLY—Picture tube mtg. strap assembly, incls. ear bracket & 2 tube straps each 20¾ in. long	1.35
RMX-231	20C107	STRAP ASSEMBLY—Picture tube mtg. strap assy. incls. ear bracket & 2 tube straps—each 23⅞ in. long	1.65
RMX-242	21T1 (early & late), 21T1-U, 21T3-T6, 21C201-C202-C204-C206-C208-C208-U-C210-C214	STRAP ASSEMBLY—Picture tube mtg. strap assy., incls. ear bracket & 2 tube straps, each 25⅝ in. long	

CABINETS, CABINET PARTS AND APPEARANCE ITEMS

CAT. NO.	MODEL	DESCRIPTION	PRICE
RAB-190	21T1-T3	CABINET BACK—Back, less cap, cord & plug	2.30
RAB-191	21C204	CABINET BACK—Less cap, cord & plug	2.85
RAB-192	21C201-C202	CABINET BACK—Less cap, cord & plug	2.85

CABINETS, CABINET PARTS AND APPEARANCE ITEMS (Cont'd)

CAPACITORS

CAT. NO.	SYMBOL	DESCRIPTION	PRICE
RCE-150	C25, 26, 27	CAPACITOR—50 mf, 150 v-20 mf, 150 v-20 mf, 150 v.	$3.00
*RCN-001	C11	CAPACITOR—1 mmf, ceramic, miniature	.20
*RCW-3037	C12, 13, 20, 21, 23, 24	CAPACITOR—800 mmf, ceramic, 500 v	.25
*RCW-3070	C1, 2, 3, 4	CAPACITOR—2-2-5-5 mmf, ±.5 mmf, ceramic	1.75
RCW-3082	C5, 6	CAPACITOR—2 mmf, ceramic	.25
RCW-3083	C7, 8	CAPACITOR—1 mmf, ceramic, ±.25 mmf	.25
RCW-3084	C9	CAPACITOR—1.5 mmf, ±.25 mmf	.25
RCW-3085	C19	CAPACITOR—10 mmf, ±10%, ceramic	.25
RCW-3086	C18	CAPACITOR—18 mmf, ±10%, ceramic	.25
RCW-3087	C22	CAPACITOR—47 mmf, ceramic	.25
RCW-3088	C10, 14	CAPACITOR—6 mmf, ±5%, ceramic	.25

RESISTORS

CAT. NO.	SYMBOL	DESCRIPTION	PRICE
*URD-025	R1, 4	RESISTOR—100 ohms, ½ w, carbon	.13
*URD-033	R2, 3, 9, 13	RESISTOR—220 ohms, ½ w, carbon	.13
*URD-069	R5	RESISTOR—6,800 ohms, ½ w, carbon	.13
*URD-073	R10	RESISTOR—10,000 ohms, ½ w, carbon	.13
*URD-081	R11	RESISTOR—22,000 ohms, ½ w, carbon	.13
URD-101	R6, 7	RESISTOR—150,000 ohms, ½ w, carbon	.13
*URD-117	R14	RESISTOR—680,000 ohms, ½ w, carbon	.13
URE-033	R8	RESISTOR—220 ohms, 1 w, carbon	.13

COILS AND TRANSFORMERS

CAT. NO.	SYMBOL	DESCRIPTION	PRICE
*RLI-122	L9	CHOKE—IF choke, molded 2.2 mh	.25
RLI-167	L14, 15, 16, 17	COIL—Filament choke coil, 15 turns	.35
*RLI-168	L7, 8	CHOKE—RF choke, 10 turns	.35
RLI-187	L11	COIL—Neutralizer coil	.85
RLI-188	L12	COIL—Plate choke	.60
RLX-037	L1, 2, 3, 4, 5, 6	ASSEMBLY—Coil form assembly	4.25
RTL-140	T1	TRANSFORMER—IF input transformer	$1.20
RTL-141	T2	TRANSFORMER — IF output transformer	1.65
RTP-313	T3	TRANSFORMER — Power transformer	4.75

MISCELLANEOUS ELECTRICAL

CAT. NO.	SYMBOL	DESCRIPTION	PRICE
RER-016	X1	RECTIFIER—Selenium rectifier	3.00
RJB-023		TERMINAL BOARD—2 terminals	.25
RJB-024		TERMINAL BOARD—3 terminals	.25
RJB-025		TERMINAL BOARD—5 terminals	.35
RJB-026		BOARD—Antenna terminal board & bracket, 4 terminals	2.00
RJP-046	P1	PLUG—Power plug, 7 pin	.20
RJP-047		PLUG—2 pin, for transmission lines, early production	.25
RJS-174		SOCKET—Tube socket for IF tube 6BK7, 9 pin	.40
RJS-185	J1	SOCKET—Power socket, 7 pin	.30
RJS-186		SOCKET—Tube socket for oscillator tube, 6AF4	.40
RJS-187		SHELL—Connector shell for RJP-046	.25
RMM-245		ASSEMBLY—Crystal board assembly	.90
RSW-095	S1, 2	SWITCH—Wafer switch	.80

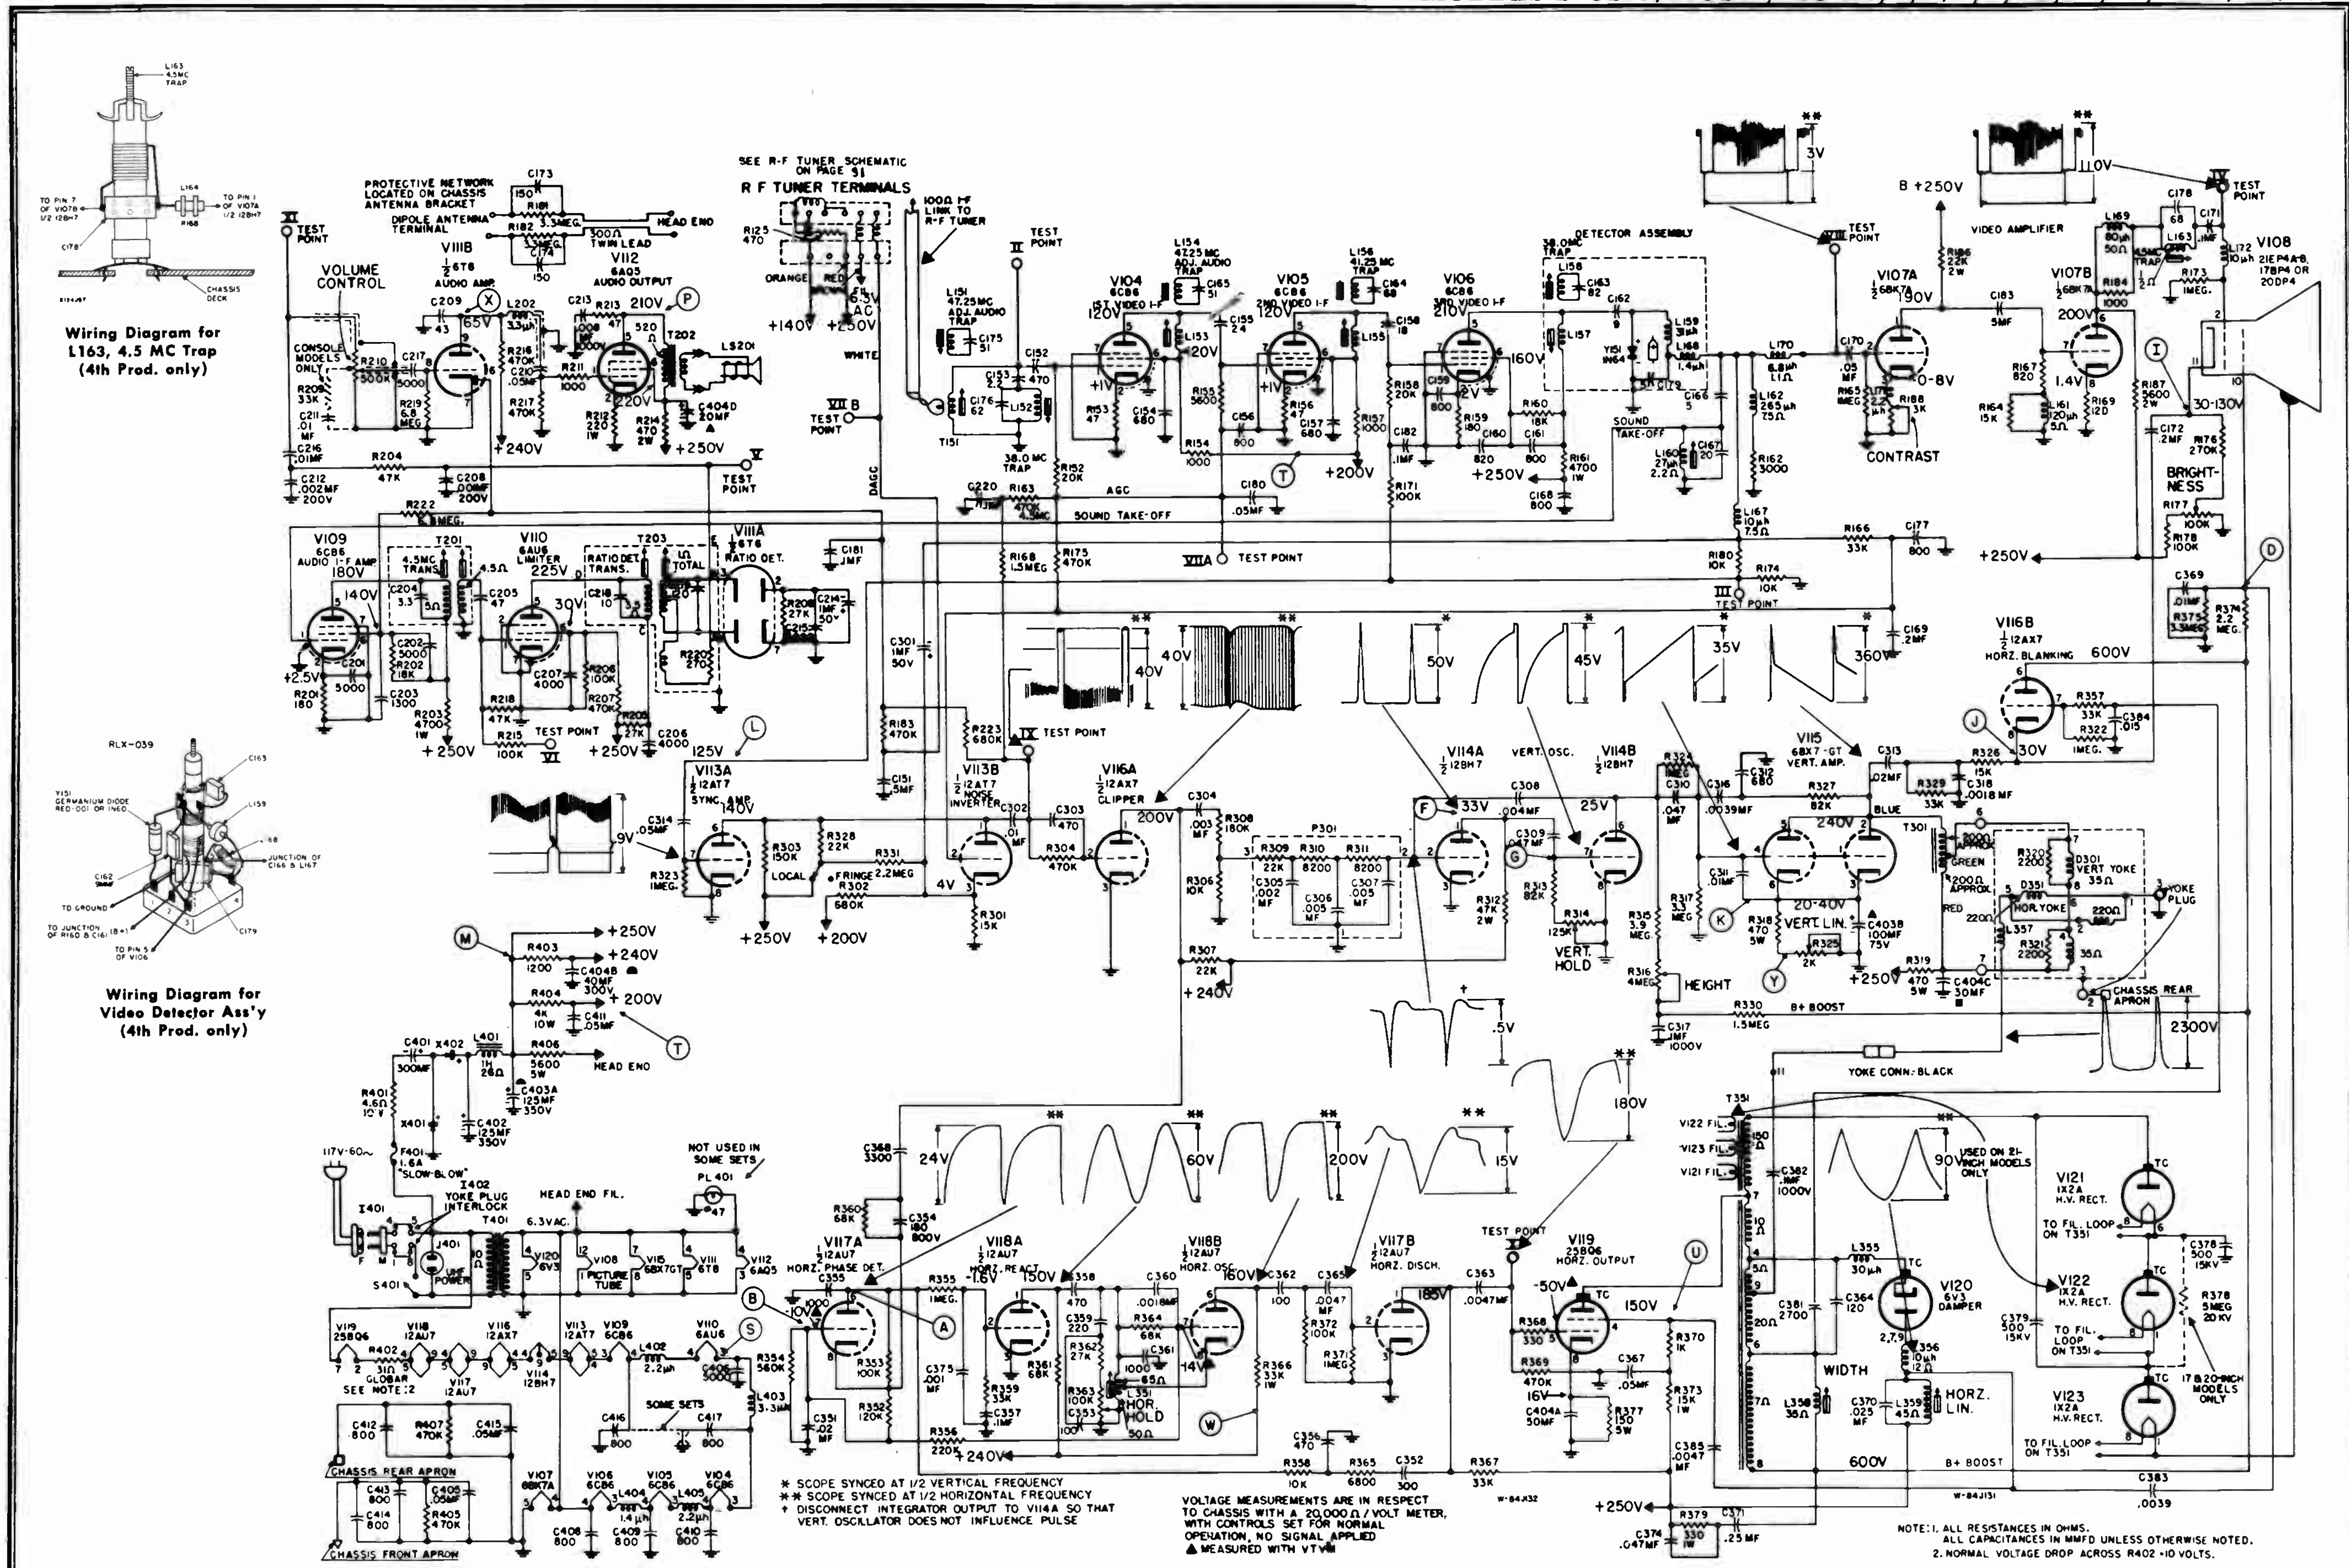

Fig. 44. Schematic Diagram, Fourth Production

GENERAL

The Hallicrafters UHF "Match Box" converter kits are available in two forms. One kit is supplied with a "Match Box" to cover UHF frequencies from 470 to 680 MC (channels 14 thru 48) and the other kit is supplied with a "Match Box" to cover UHF frequencies from 656 to 890 MC (channels 45 thru 83). Thus, it will be possible to receive any single channel in either the upper or the lower range. If reception is desired on a second UHF channel in either the upper or the lower range an additional "Match Box" in either range may be installed in the conversion kit. The "Match Boxes" are easily changed since all necessary connections are made to the "Match Box" by means of a 5 pin plug with the exception of two antenna input connections which must be soldered.

Both kits are supplied completely wired with a heater transformer for supplying the necessary heater voltage for the tube in each Match Box. Only four simple wiring connections are made when wiring the conversion kit into the chassis. Two for the antenna connections, one for the necessary plate voltage and the other for the primary of the heater transformer.

The Hallicrafters UHF Match Box converters consist of a double tuned band pass circuit which couples the 300 ohm UHF antenna input to a crystal diode mixer where the received UHF signal is mixed with the output of a local oscillator. The fundamental frequency of this oscillator may be adjusted so that the output frequency of the Match Box is preset to any VHF channel from 2 through 6.

The local oscillator in each Match Box must be preset by the Service Technician at the time of installation so that the output frequency of the Match Box is the same as the channel frequency for any vacant VHF channel from 2 through 6. For UHF reception the VHF tuner channel selector is set to the selected vacant channel and the VHF-UHF switch in the UHF converter is set in either of the two UHF positions which have a Match Box tuner in place. The fine tuning control in the VHF tuner may then be used as a fine tuner for UHF reception. For VHF reception the VHF tuner channel selector is set to the desired VHF channel and the VHF-UHF switch in the converter is set to the VHF position (full counterclockwise). The set will now operate in the same manner that it did before conversion.

The same antenna terminal on the back of the television receiver is used for both VHF and UHF reception. Either a VHF or a UHF antenna will have to be connected to this terminal depending upon the frequency of the station being received. A multiband VHF-UHF antenna may be used which will eliminate the necessity for changing antennas.

The cabinet modifications required are simple to make on all models. The cabinets for models 1010P, 1012P, 1021P and 1026P require a $1\frac{1}{2}$" hole which must be drilled. A template for the proper location of this hole is provided with the kits. Other cabinets have provisions which require only hand tools for modification. Cabinets for models 1010P, 1012P, 1021P, 1026P, 1051P, 1052P, 1053P and 1054P will require gluing of a small label on the front of the cabinet to cover the four holes left when the Hallicrafters name plate is taken off of the front of the cabinet. This gummed label is supplied with both conversion kits and is coated with a special cement to insure its remaining fixed on the cabinet.

The high voltage power supply shield used in some of the earlier series 1200D chassis was rectangular in shape and must be replaced in order to provide mounting space for the Match Box assembly. The correct replacement shield is available as an accessory under part number 69D547. Before this shield is installed, as directed in the step by step instructions, the inside of it must be covered with "Scotch" #21 electrical tape as specified in the instructions. This tape is available from Hallicrafters under stock number 8A2085. Approximately $16\frac{1}{2}$" of tape 4" wide are required to properly cover one of the 69D547 shields. Tape of narrower width may be used provided the strips are overlapped and the area shown in the instructions is covered.

The A, K, & W1200D chassis used in models 1010P and 1012P and the D, L, & X1200D chassis used in models 1021P and 1026P have a front chassis cover plate which is not easily drilled for the mounting holes necessary for the Match Box sub-chassis. For this reason a new front chassis cover plate part number 63C958 is supplied with the kit for use only on these chassis. Other chassis may or may not require drilling the 7/8" or larger hole and the two 3/16" holes. Templates are supplied for the proper location of these holes on the various other chassis.

INSTALLATION OF UHF MATCH BOX CONVERTER SUB-CHASSIS

Before starting the installation of either the 1X1658 or the 1X1678 conversion kits be sure to read the general instructions given on page 2.

MECHANICAL CHASSIS CHANGES

1. Remove the chassis from the cabinet.
2. On chassis with a removeable front chassis cover plate, remove the plate and drill the necessary mounting holes for the Match Box sub-chassis. Use the chart on page 1953-203 to determine which drilling template should be used. On chassis which do not have a removeable front plate it will not be necessary to drill mounting holes as these chassis already have the necessary provisions for adding the Match Box sub-chassis. A new front chassis plate is provided with the kits for use on A, D, K, L, W & X1200D chassis.
3. Replace the new or drilled front chassis cover plate from step 2.
4. Remove the high voltage compartment shield. If the shield is rectangular in shape (part number 69D492) it should be discarded. It will be replaced in a later step by a new shield part number 69D547. The 69D547 shield must be ordered separately as it is not supplied with either of the Match Box conversion kits.
5. Insert the converter sub-chassis in the TV chassis and secure to the front apron or front chassis cover plate by means of the two 6-32 x $\frac{1}{4}$" hex head self tapping screws supplied with each conversion kit. On chassis with the front cover plate use the two 3/16" holes on each side of the switch shaft. On chassis without the removeable front chassis cover plate use two diagonally opposite holes in the corners of the sub-chassis.
6. The rear mounting bracket for the converter sub-chassis should now be fastened. On some chassis this bracket rests directly on the chassis and should be secured with one of the 8-32 x $\frac{1}{4}$" hex head self tapping screws supplied. If this rear bracket does not rest directly on the chassis use either the 1/2" or the 3/4" spacer supplied along with the 8-32 x 7/8" hex head self tapping screw. The correct spacer will not bend or warp the sub-chassis or the rear mounting bracket.

WIRING

7. Connect and solder the long black heater transformer primary lead to one of the four outer lugs of the power supply series electrolytic capacitor (C-135 in some chassis and C-161 in others). It will be necessary to remove the 1B3-GT high voltage rectifier tube V-111 and raise the plastic insulating tape on the chassis in order to gain access to the bottom of this capacitor. See Fig. 205A.
8. Press the plastic insulating tape back in place after dressing the transformer lead as shown in Fig. 205A.
9. Replace the 1B3-GT high voltage rectifier tube V-111.
10. Replace the high voltage compartment shield. Be careful to dress the wires running under the edges of this shield through the notches provided so that the wires are not pinched under the edges of the shield. A new shield may be required as described on page 1953-202. Insulate the new shield if used as shown in Fig. 205B.
11. Dress the orange wire from the VHF-UHF switch over to the terminal strip directly behind the VHF tuner. Connect and solder to the lug as shown in Fig. 205A. This wire provides 150V. B+ for the converter and is connected to the B+ supply for the three I.F. tubes in the receiver.
12. Remove and discard R-186, R-187, C-100 and C-101 from the VHF tuner input terminals. The Match Box sub-chassis has the same four components mounted on a terminal strip near the front of the sub-chassis next to the VHF-UHF switch. The 300 ohm twin lead for the antenna lead-in should be disconnected from the terminal strip near the VHF tuner terminals and connected to the terminal strip on the Match Box sub-chassis. Solder the connections. Refer to Fig. 205A. for the location of these terminals.

The 1X1658 and 1X1678 UHF Match Box conversion kits for the series 1200D Hallicrafters television chassis will enable the Service Technician to easily and quickly convert any of the models listed in the following chart.

MODELS	CHASSIS	FRONT CHASSIS COVER PLATE MODIFICATIONS	CABINET MODIFICATIONS
1010P, 1012P	A, K or W1200D	Use new plate 63C958 supplied with both conversion kits.	Remove "H" medallion. Use template 95D251 to drill a $1\frac{1}{4}$" hole in the cabinet. See Fig. 208A. Remove Hallicrafters nameplate and replace with 31B3191 metalized label. Wet back of label with water to activate the special cement coating and place label on the cabinet as shown in Fig. 208A.
1021P, 1026P	D, L, or X1200D		
1053P, 1054P	R1200D	Drill cover plate using template 95C249. See Fig. 208B.	
1051P, 1052P	P1200D	Drill cover plate using template 95C252. See Fig. 208C.	Remove "H" medallion. Cut out thin cabinet section in the front center of the cabinet. Remove Hallicrafters nameplate and replace with 31B3191 metalized label. Wet back of label with water to activate the special cement coating and place label on the cabinet as shown in Fig. 208A.
1055C, 1056C 1060C, 1061C	T1200D	Drill cover plate using template 95C249. See Fig. 208B.	Remove "H" medallion. No other modifications are required since the cabinet is provided with the necessary center hole for the shaft of the VHF-UHF switch.
1062C, 1063C	J1200D		
1050	AL1200D		
1081, 1081A 1085, 1085A 1088, 1088A	AJ1200D		
1081B, 1085B 1088B	AZ1200D		
1072, 1074, 1075, 1078	AG1200D	Chassis have the necessary mounting provisions. Do not have a removeable front chassis plate.	Remove "H" medallion. Cut out thin section in the front bottom center of the cabinet.
1072A, 1074A 1075A, 1078A	AR1200D		
1072AT, 1074AT, 1075AT, 1078AT	AY1200D		

13. Connect and solder the $6\frac{1}{2}$" twin line coming from the VHF-UHF switch to the now vacant antenna terminals of the VHF tuner. Refer to Fig. 205A and carefully note how this short length of twin line and the spaghetti covered antenna lead-in twin line must be dressed to prevent any possible coupling between these two lines.

14. Installation of the Match Box sub-chassis is now complete with the exception of inserting either one or two Match Boxes. Instructions for installing and adjusting the individual Match Boxes are given.

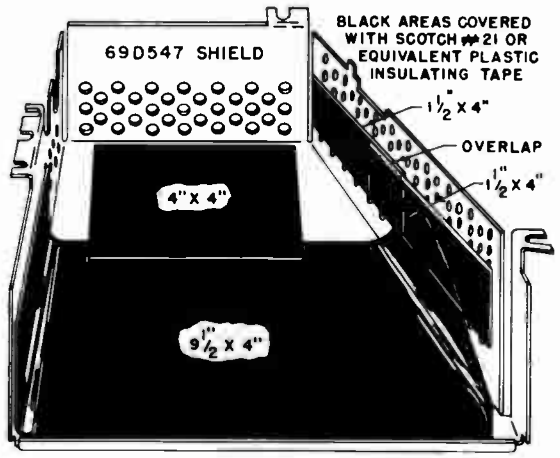

Fig. 205B. Position of Plastic Insulation on 69D547 Shield

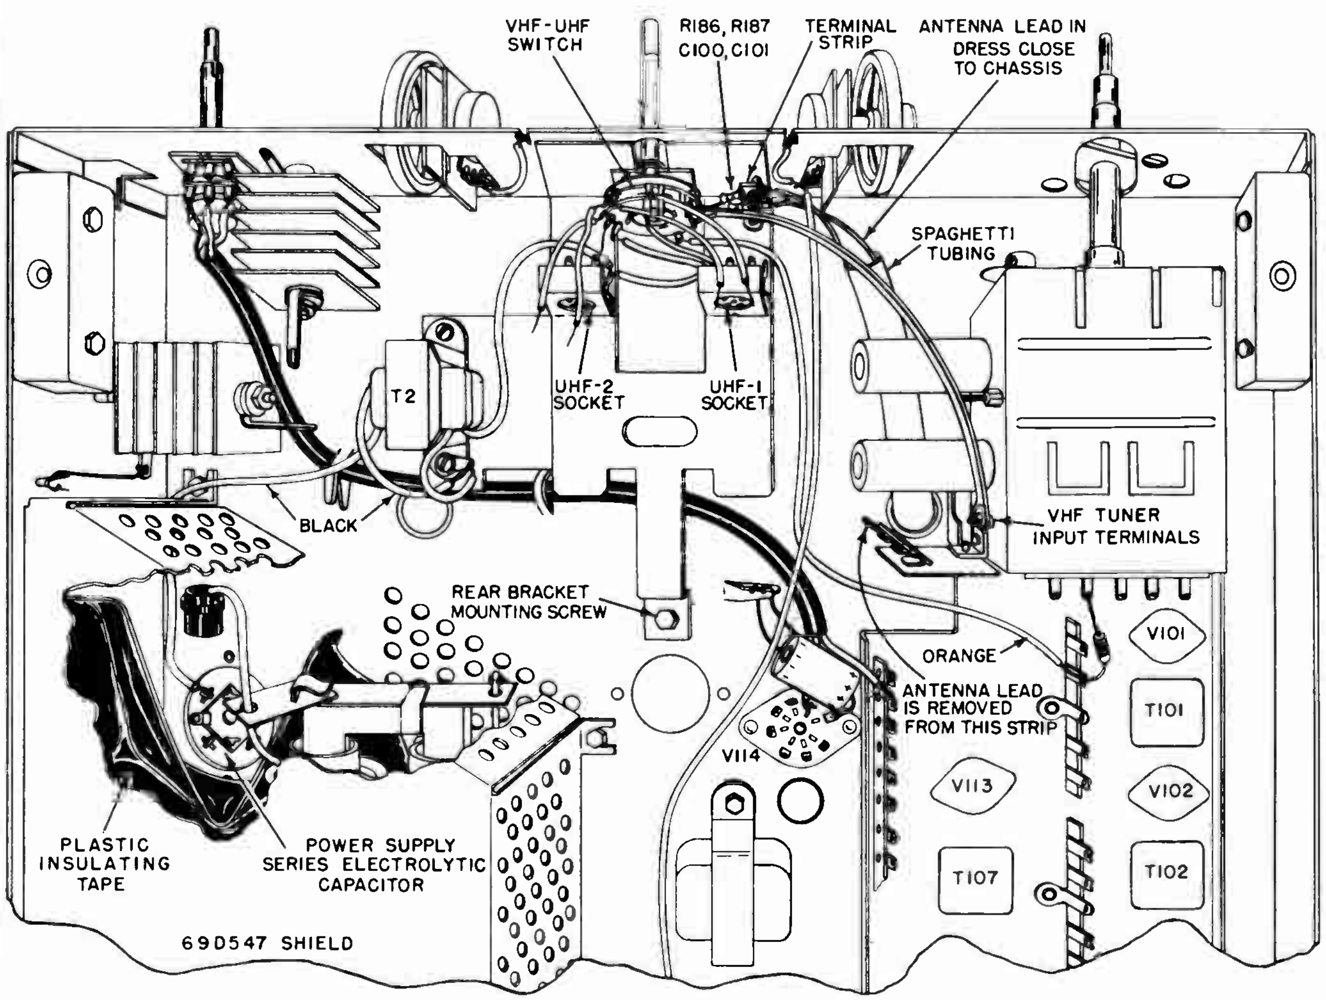

Fig. 205A. Series 1200D Chassis with Match Box UHF Sub-Chassis Installed

INSTALLATION AND ADJUSTMENT OF INDIVIDUAL MATCH BOXES

GENERAL

The UHF Match Box converter sub-chassis is provided with two sockets for plug-in Match Box units. These self contained units operate independently and require oscillator plate supply voltage, obtained from the TV chassis, and heater voltage, obtained from the heater transformer. Each conversion kit is supplied with one Match Box plug-in unit. The Match Box supplied with the 1X1658 kit will cover any UHF channel from 14 through 48 while the one supplied with the 1X1678 kit will cover any channel from 45 through 83.

In order to cover a second UHF channel with either kit, Match Box 1A1664 may be used to cover channels 14 through 48 and Match Box 1A1665 may be used to cover channels 45 through 83.

Each Match Box regardless of the range it covers is supplied with two screws for adjustment of the oscillator. One screw is 5/8" long and the other 7/8" long. The shorter screw must be used to cover the upper half of the tuning range of the Match Box. The longer screw will protrude below the bottom edge of the main TV chassis if used to tune this range. The 5/8" screw will be found taped to the side of each Match Box unit when received in kit form with the sub-chassis or when obtained as an individual unit.

When the VHF-UHF switch is in the UHF-2 position (full clockwise) the Match Box next to the heater transformer is used. With the switch in the UHF-1 position (center) the Match Box next to the VHF tuner is used. In the VHF switch position (full counter-clockwise) neither Match Box is used and the antenna input is connected through C-100 and C-101 to the VHF tuner input terminals.

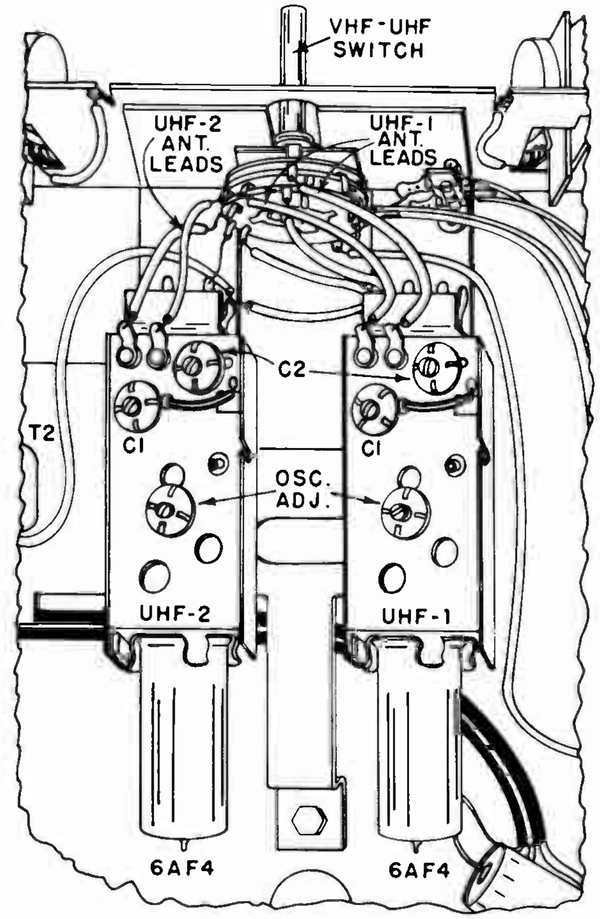

Fig. 206A. Match Box Connections & Adjustments

INSTALLATION

1. Plug the UHF Match Box to be installed into either of the two positions in the conversion sub-chassis. Be sure to hook the two prongs on the Match Box unit over the protrusion on the sub-chassis to support the end of the unit on which the oscillator tube is mounted.
2. Connect and solder the two antenna leads (spaghetti covered) from the VHF-UHF switch to the terminals of the Match Box. See Fig. 206A to determine which pair of leads should be used. If only one Match Box is to be installed, the remaining pair of leads should be dressed over the top of the unused socket bracket as shown in the cover photo and the ends taped.
3. Turn the television receiver on in the usual manner and allow at least a two minute warm up period. Select the most interference free unused channel from 2 through 6 and set the VHF tuner channel selector to this channel. Position the fine tuning control of the VHF tuner to the center of its tuning range.
4. Set the VHF-UHF selector switch in the Match Box converter to the UHF position which corresponds with the position of the Match Box being adjusted. See General text above.
5. Adjust the oscillator tuning screw on the Match Box until the desired UHF channel is received. See Fig. 206A. It is usually possible to receive the desired signal at two different settings of this adjustment. USE THE POSITION THAT PLACES THE ADJUSTMENT SCREW THE FARTHEST INTO THE MATCH BOX. This position places the converter oscillator frequency below the frequency of the incoming signal by an amount equal to the frequency of the VHF channel that was selected in step 3.
6. Adjust the two input tuning adjustment screws (C-1 and C-2) shown in Fig. 206A. for the best possible picture. These adjustments should be carefully made to provide the most desirable compromise between bandwidth (picture definition) and sufficient sensitivity to provide a stable noise free picture.
7. Repeat steps 5 and 6 until reception cannot be further improved.
8. Repeat steps 4 through 7 for a second Match Box if used.

CABINET MODIFICATIONS

The cabinet modifications required for the various receiver models are explained in the chart on page 1953-203.

In some models when the converted chassis is replaced in the cabinet the shaft of the VHF-UHF switch will not pass through the center of the hole in the cabinet. The large knob supplied for the VHF-UHF switch will cover the cabinet hole even if the switch shaft is considerably off of center.

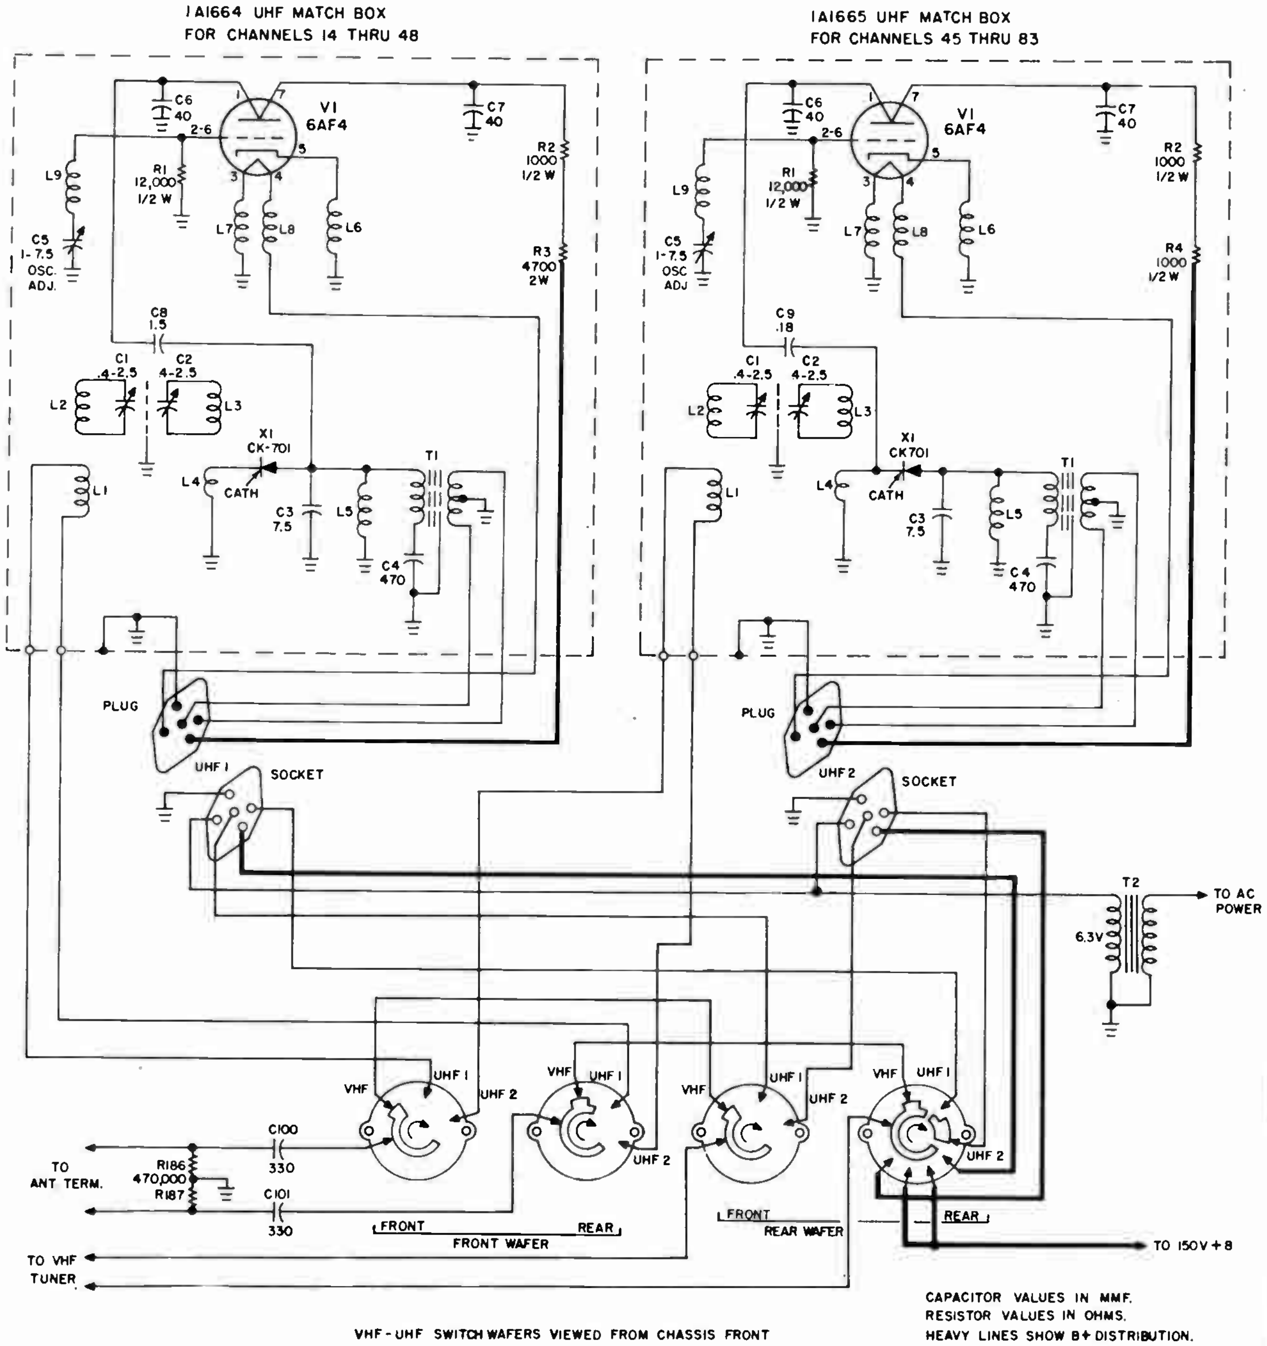

Fig. 207A. Schematic Diagram of Conversion Kit with a 1A1664 and 1A1665 Match Box in Place

SERVICE PARTS LIST

KITS & ACCESSORIES

Wired sub-chassis with Match Box for channels 14 through 48	1X1658

INSTALLATION & OPERATING INSTRUCTIONS

FOR

HALLICRAFTERS SELF POWERED SINGLE CHANNEL UHF CONVERTER
(SUPPLIED IN TWO FREQUENCY RANGES)

HALLICRAFTERS STOCK NO.	COVERS CHANNELS	FREQUENCY RANGE	CODE STAMP
1X1527	14 through 48	470 mc. to 680 mc.	A
1X1679	45 through 83	656 mc. to 890 mc.	B

The model 1X1527 and model 1X1679 converters provide for the reception of any single UHF television channel. The converter is fixed tuned to the desired channel at the time of installation. This unit may be installed on any standard television receiver that has provision for 300 ohm balanced antenna input. This includes all HALLICRAFTERS TELEVISION RECEIVERS. The Hallicrafters converter has been designed for excellent performance as well as simplicity of installation and operation as illustrated by the following features:

- Self contained power supply.
- Convenient power outlet for the television receiver.
- Utilizes the full amplification of the VHF tuner.
- No alteration of the television receiver is required.
- Test equipment is not required for pre-tuning.
- Single switch selects either UHF or VHF operation.
- Output may be tuned to any of the low VHF channels, 2 through 6. This permits selection of the unused channel that is most interference free in any given signal area.

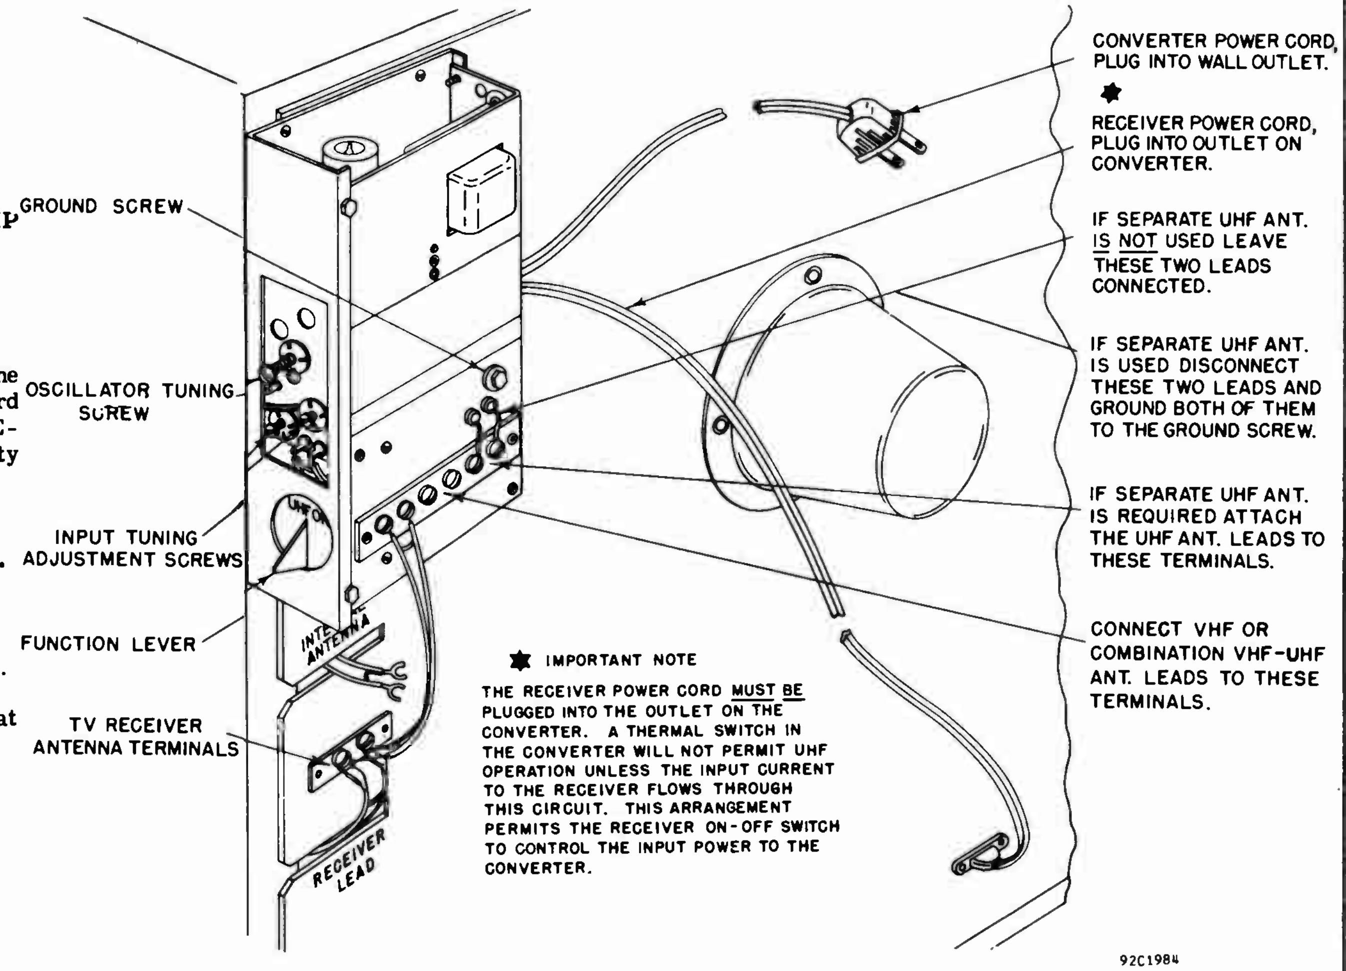

Figure 1.

TO INSTALL AND ADJUST CONVERTER

1. Mount the unit on the cabinet back so that the FUNCTION LEVER protrudes beyond the side of the cabinet as shown in Figure 2.

2. Make the required antenna and power connections as illustrated in Figure 1. The converter is designed to operate from a 115 volt, 60 cycle AC power source.

3. Set the FUNCTION LEVER on the converter to the "UHF ON" (down) position.

4. Turn the television receiver on in the usual manner and allow at least a two minute warm up period. Select the most interference free unused channel (2 through 6) and set the CHANNEL SELECTOR on the television receiver to the channel decided upon. Position the FINE TUNING control to the center of its tuning range.

5. Adjust the OSCILLATOR TUNING screw on the converter until the desired UHF channel is received. It is usually possible to receive the desired signal at two different settings of this adjustment. USE THE POSITION THAT PLACES THE ADJUSTMENT SCREW THE FARTHEST INTO THE CHASSIS. This position places the converter oscillator frequency below the frequency of the incoming signal by an amount equal to the frequency of the VHF channel that has been selected in step 4.

6. Adjust the two INPUT TUNING adjustment screws on the converter for the best reception. These adjustments should be carefully made to provide the most desirable compromise between bandwidth (picture definition) and sufficient sensitivity to provide a stable noise free picture.

7. Repeat steps 5 and 6 until reception cannot be further improved.

OPERATION

1. Turn the television receiver on in the usual manner.

2. Set the converter FUNCTION LEVER to the "UHF ON" (down) position. Allow one minute for the converter tube to reach operating temperature.

3. Set the CHANNEL SELECTOR on the television receiver to the unused channel (2 through 6) that was decided upon at the time the converter was installed. Tune in the UHF channel with the FINE TUNING control on the television receiver.

4. Adjust the other operating controls on the television receiver in the usual manner if required. When UHF operation is completed be sure to retune the converter FUNCTION LEVER to the "VHF ON" (up) position to permit normal operation of the receiver.

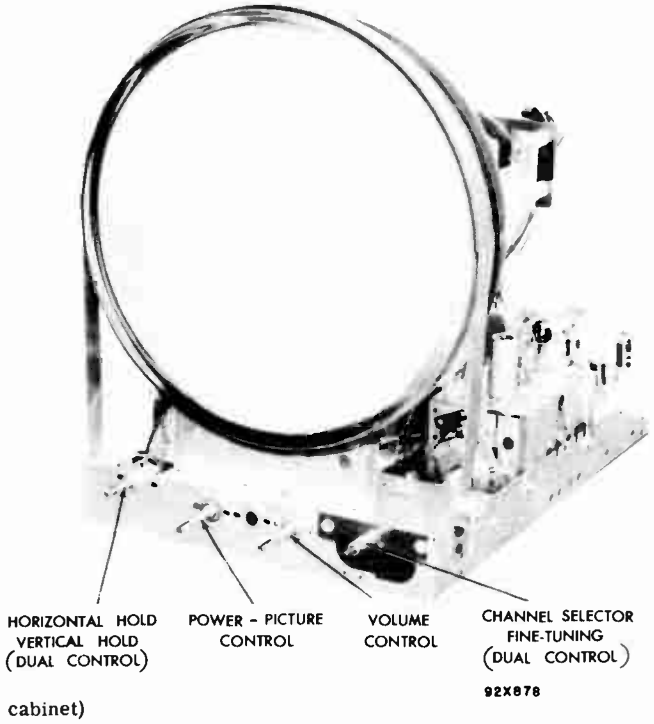
Power Supply . . . . 105-125 V. 60 cycles AC

Power Consumption. . . . . . 180 Watts

Model Differences. . . . . . . Model 518 - Table model (Plastic cabinet)

Model 521 - Custom installation (Chassis unit)



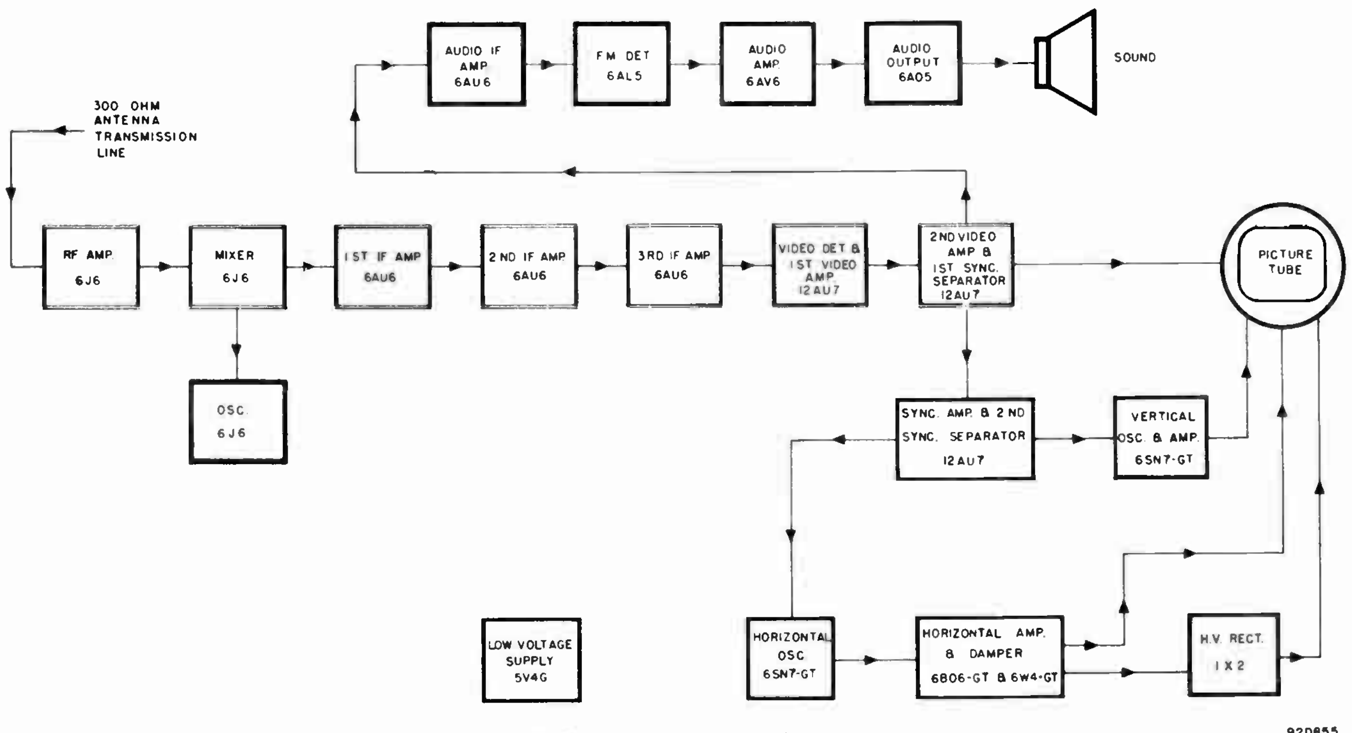


Fig. 1. Functional block diagram.

CARE OF THE KINESCOPE WINDOW

The window in front of the picture tube is made of safety glass, hence may be cleaned by any of the conventional window cleaning processes. Abrasive or strong solvent type cleaning solutions that may scratch the glass or damage the cabinet finish, however, should be avoided.

HIGH VOLTAGE WARNING

Operation of the receiver chassis outside of the cabinet involves a shock hazard. An interlock in the line cord disconnects the power when the back cover is removed. The HIGH VOLTAGE supply, while of low current capacity, operates at a 11,000 volt potential. Exercise all normal HIGH VOLTAGE precautions while working this equipment.

KINESCOPE HANDLING PRECAUTIONS

The kinescope housing provides adequate protection against possible tube implosure while in the cabinet. Do not expose the kinescope or handle it in any way without providing personal protection in the form of shatterproof goggles and heavy gloves. The kinescope should be handled by qualified personnel only.

The kinescope envelope encloses a high vacuum and with the large surface area of glass involved, the stresses set up, particularly at the front rim of the tube, are considerable. An abnormal handling stress, accidental blow at a highly stressed surface, or even a scratch on the surface of the tube could cause it to implode or collapse with destructive violence.

NON-OPERATING CONTROL ADJUSTMENTS

The "non-operating" or screw-driver adjustments normally will require an occasional minor adjustment if any circuit work or tube changing is required. A test pattern, generated either locally in the shop or obtained from a television station is recommended for best results. Normal picture contrast and brightness should be maintained during the following adjustments for best results.

BRIGHTNESS AND FOCUS ADJUSTMENTS

1. Set the HORIZONTAL and VERTICAL HOLD controls for a steady test pattern. Should the HORIZONTAL HOLD control fail to hold the test pattern in the normal manner, set the HORIZONTAL HOLD control in the center of its range and adjust the HORIZONTAL OSC. ADJ. screw for horizontal sync. (See Fig. 11 for location). Note that if horizontal sync. cannot be obtained by adjusting the top slug, turn the top screw approx. two turns down from its top limit and adjust the bottom slug (accessible from the under side of the chassis) for sync.

2. Set the PICTURE control at minimum (counter-clockwise) and advance the BRIGHTNESS control (clockwise) to the point where the retrace lines (widely spaced white lines) on the raster begin to show, then back off the adjustment slightly to eliminate the lines. Reset the PICTURE control for the desired picture brilliance and adjust the FOCUS control for best picture detail. Watch vertical wedges of test pattern for best definition.

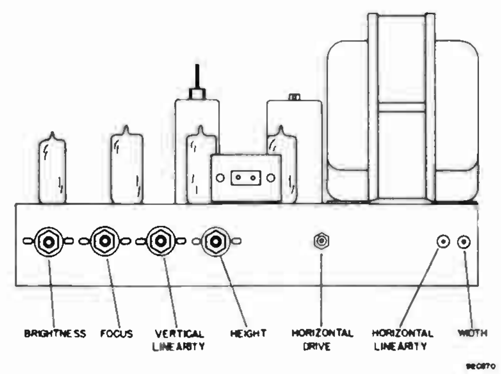

Fig. 2. Rear chassis view, location of "non-operating" controls.

HORIZONTAL — OSC., — DRIVE, — LINEARITY, — CENTERING AND WIDTH ADJUSTMENTS

1. Advance the HORIZONTAL DRIVE control (clockwise) as far as possible without causing fold over of the test pattern. (Vertical white line.) Insufficient horizontal drive will cause the raster to fall short of filling the mask horizontally.

HORIZONTAL DRIVE CONTROL MISADJUSTMENT

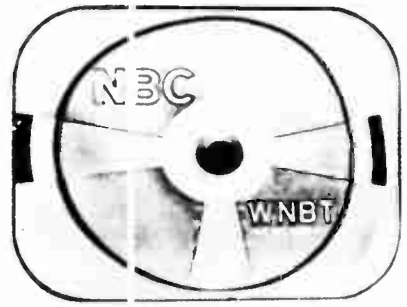

Figure 3.

2. Set the WIDTH control so that the test pattern fits the horizontal dimension of the kinescope escutcheon. A minor adjustment of the focus coil position may be required to recenter the pattern.

WIDTH CONTROL MISADJUSTMENT

Figure 4.

HORIZONTAL CENTERING MISADJUSTMENT

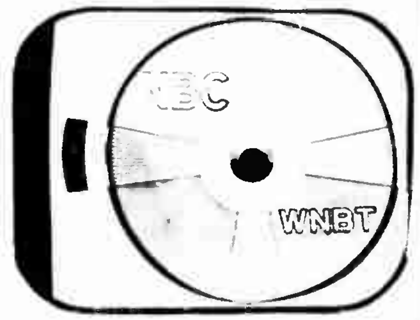

Figure 5.

3. Set the HORIZONTAL LINEARITY control so that the test pattern is symmetrical from left to right. A slight readjustment of the HORIZONTAL DRIVE control may be necessary when making this adjustment.

HORIZONTAL LINEARITY CONTROL MISADJUSTMENT

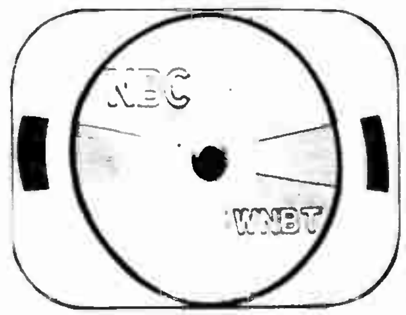

Figure 6.

VERTICAL — CENTERING, — LINEARITY, AND HEIGHT ADJUSTMENTS

HEIGHT CONTROL MISADJUSTMENT

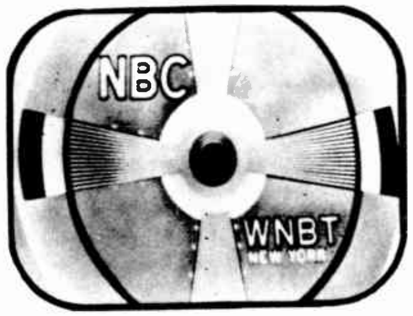

Figure 7.

1. Set the HEIGHT control so that the test pattern fits and centers in the vertical dimension of the kinescope escutcheon. A minor adjustment of the focus coil position may be required to recenter the pattern.

VERTICAL CENTERING MISADJUSTMENT

Figure 8.

VERTICAL LINEARITY CONTROL MISADJUSTMENT

Figure 9.

2. Set the VERTICAL LINEARITY control for a symmetrical test pattern in the vertical dimension. A slight readjustment of the HEIGHT control may be required when making this adjustment.

Note - The sequence of "non-operating" control adjustments outlined above is suggested as a convenient method of approach and not an arbitrary procedure. Variations of the procedure is permitted to obtain the final result.

DISMANTLING FOR KINESCOPE REPLACEMENT OR ALIGNMENT ADJUSTMENTS (MODEL 518)

1. Remove the four front panel control knobs by pulling them straight from their shafts. The dual control knobs must be removed in two pieces, removing the center unit first.

2. Remove the back cover. Note that the line cord and half of the interlock connector come along with the back cover.

3. Unfasten and remove the speaker to clear the KINESCOPE. Remove the two screws holding the antenna terminal strip bracket to the cabinet.

4. Remove the five chassis bolts holding the receiver chassis in the cabinet and slide the entire assembly from the cabinet. The KINESCOPE is now accessible for replacement or adjustment.

REMOVING THE KINESCOPE

Refer to the warning KINESCOPE HANDLING PRECAUTIONS. Read all warning notices on both tube and carton. Follow the dismantling instructions above to expose the KINESCOPE and proceed as follows:

1. Disconnect the KINESCOPE SOCKET at the base of the kinescope.

2. Slip the ION TRAP from the neck of the tube past the kinescope base connector.

3. Measure the distance from the front edge of the steel band to the face of the tube. Keep this dimension handy for installation of a new tube.

4. Remove the steel band at the front rim of the kinescope and carefully slip the neck of the kinescope out of the FOCUS COIL and DEFLECTION YOKE. If the tube fails to slip out smoothly, investigate and remove the cause of the trouble. Do not use force.

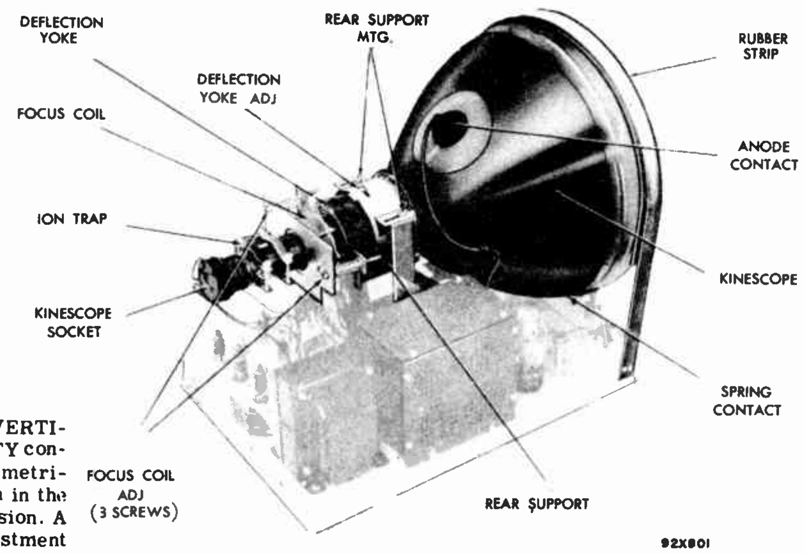

Fig. 10. Kinescope mounting detail.

INSTALLING AND ADJUSTING THE KINESCOPE

1. Wrap the RUBBER STRIP around the front rim of the kinescope and position the tube so that the anode contact is at the top and approximately centered as viewed from the screen.

2. Slip the neck of the kinescope through the REAR SUPPORT, DEFLECTION YOKE and FOCUS COIL and seat the tube firmly against the REAR SUPPORT. If it fails to slip into place smoothly, investigate and remove the cause of the trouble. Do not force the tube. Check the distance from the face of the tube to the front edge of the steel band. Refer to the measurement made in step 3 above. If this dimension is off; loosen the two REAR SUPPORT MTG. screws, position the tube correctly and fasten the steel band firmly about the rim of the tube.

3. The REAR SUPPORT must seat firmly against the flare of the tube and be securely anchored in place by the two REAR SUPPORT MTG. screws. Check the SPRING CONTACT grounding the outer coating of the kinescope tube. A high potential is developed on the outer coating of the tube if this contact is faulty.

4. The DEFLECTION YOKE must seat firmly against the flare of the kinescope. Check by loosening the single DEFLECTION YOKE ADJ. screw and pushing the DEFLECTION YOKE forward as far as it will go. Take up the slack in the screw temporarily to hold the coil in place.

5. Slip the ION TRAP over the neck of the tube. If it is the ring type, the arrow points toward the front of the tube; if it is of the clamp type, the blue coded clamp is toward the front.

6. Reconnect the KINESCOPE SOCKET and anode connector and turn on the receiver.

7. After allowing a few minutes for warm up, turn up the BRIGHTNESS control and set the ION TRAP for maximum raster brilliance, backing off the brightness control adjustment as the maximum point is approached. The ION TRAP must be rotated about the axis of the tube as well as shifted along the neck of the tube to obtain the proper setting. The arrow on the ring type ion trap will generally point at the HV anode connector when properly positioned as far as rotation is concerned, hence a rough setting may be obtained immediately with this type of trap.

With the brightness control set for slightly above average brilliance and the PICTURE control full counter-clockwise, adjust the FOCUS control until the line structure of the raster is clearly visible and readjust the ION TRAP for maximum raster brilliance. The final touches on this adjustment should be made with the BRIGHTNESS control at the maximum position with which good line focus can be maintained, then back off the setting of the BRIGHTNESS control until the retrace lines disappear.

8. Check the position and appearance of the test pattern. If the test pattern is off center or shadowed at the corners (Electron beam striking the neck of the tube), adjust the three FOCUS COIL ADJ. screws for a centered, evenly illuminated raster. Note that the three spring loaded adjustment screws tilt the focus coil to shift the position of the raster on the face of the kinescope. Do not turn all three screws up tight, use them to tilt the FOCUS COIL only.

CAUTION - It is not necessary to tilt the focus coil excessively. Excessive tilt may snap the neck of the kinescope if sufficient force is used. The focus coil may be shifted slightly for additional clearance around the neck of the tube by loosening the two knurled screws holding the coil to the mounting plate. Tighten the screws after the adjustment.

9. If the lines of the raster are not horizontal or square with the escutcheon, loosen the DEFLECTION YOKE ADJ. screw and rotate the DEFLECTION YOKE until this condition is obtained. Tighten the adjustment.

10. Follow the procedure under NON-OPERATING CONTROL ADJUSTMENTS and make any minor adjustments of the FOCUS COIL or DEFLECTION YOKE necessary to obtain the desired results. The final adjustment of the focus coil should leave the test pattern approximately centered.

MEASUREMENT OF H.V. POTENTIAL ON KINESCOPE ANODE

The second anode potential will be approx. 11,000 V., on a receiver that is functioning properly. Since the high potential for the kinescope anode is obtained from the horizontal output transformer, the "non-operating" control adjustments outlined above must be made or be known to be in proper adjustment before the H.V. measurement will have any meaning. Improper operation of the horizontal sweep circuit or circuit faults in the high voltage filter will generally account for an abnormal anode potential. If the anode potential is low, check the HORIZONTAL DRIVE adjustment outlined above.

CAUTION HIGH VOLTAGE

Do not use hand held flexible test leads when making the following measurement. Keep the hands clear of the circuit during measurement. A 11 KV. potential exists in this circuit. Exercise all normal high voltage precautions.

1. Connect a 50-megohm resistor string in series with a 300 microampere meter. Connect the free meter terminal to the chassis and the high side of the resistor string to the anode cap of the kinescope. The connection to the anode cap may be made with a fine wire slipped under the connector. Make up the resistor string with 5-megohm one or two watt resistors to provide a safety factor for voltage breakdown. If 5-megohm resistors are used, a total of ten will be required to obtain the 50 megohms. Make the setup self-supporting and allow adequate clearance between the resistor string and chassis parts to prevent high voltage breakdown.

2. Turn on the receiver and set the BRIGHTNESS and PICTURE controls at minimum. The microammeter will read approx. 220 microamperes for 11,000 V. at the kinescope anode. The anode potential is measured in this manner (PICTURE and BRIGHTNESS control at minimum; meter current approx. 200 microamperes) to simulate the kinescope load on the high voltage power supply.

ALIGNMENT PROCEDURE

Note - The following alignment adjustments do not require the use of the kinescope tube. It is recommended that the tube be removed if extensive alignment adjustments are to be made.

CAUTION - Removal of the kinescope tube exposes the HIGH VOLTAGE anode connector contact. Keep this lead and contact clear of personnel servicing equipment and grounded objects on the service bench. Exercise all normal high voltage precautions while working with the exposed units.

EQUIPMENT REQUIRED

Signal generator covering 4mc to 30 mc
Signal generator covering 40mc to 215 mc
Electronic voltmeter
Two 150-ohm carbon resistors
One .01 mfd. 600 V. tubular paper condenser.

F-M SOUND CHANNEL ALIGNMENT

1. Connect the low frequency signal generator output across resistor (R-118) in the plate circuit of the 12AU7 VIDEO DET. tube (V-104). This resistor is located at the terminal strip near the tube socket.

2. Connect the electronic voltmeter between pin 7 of the 6AL5 FM DET. tube (V-109) and chassis ground.

3. With the signal generator (unmodulated) set at 4.5 mc. set the 4.5 MC LIMITER GRID ADJ. and FM DET PRI. ADJ. (See Fig. 11) for maximum d-c voltage as measured by the electronic voltmeter. Adjust the limiter grid transformer (T-105) before adjusting the f-m detector transformer (T-108) primary. Use just enough signal generator output to obtain approximately one volt at the electronic voltmeter.

4. Connect the electronic voltmeter across the 1000 mmf condenser (C-135) at the output of the f-m detector stage and adjust the FM DET. SEC. ADJ. of the f-m detector transformer (T-108) for the null.

5. Shift the frequency of the signal generator either side of 4.5 mc and touch up the FM DET. PRI. ADJ. for approximately equal peaks. Use just enough signal generator output to obtain one volt peaks for the best results.

6. After completing the alignment procedure and placing the receiver in operation again, carefully tune in a TV test pattern and adjust the 4.5 MC TRAP ADJ. for maximum vertical wedge definition. This adjustment is located on the under side of the chassis and on the same coil form as the 4.5 MC LIMITER GRID ADJ. shown in Fig. 11.

NOTE - The primary adjustment of T-108, the coarse frequency adjustment of T-111 and the 4.5 mc trap adjustment may all be made through the plugged holes in the cabinet bottom if desired.

I-F AMPLIFIER ALIGNMENT

1. Connect the electronic voltmeter across resistor R-118 in the plate circuit of the 12AU7 VIDEO DET. tube (V-104). This resistor is located on the terminal strip near the tube socket.

2. Couple the high side of the signal generator to the mixer tube (V-2) by slipping a tight fitting tube shield or length of copper braid over the bulb of the tube and connecting the generator lead to it. Connect the ground side of the signal generator to the frame of the tuning unit.

3. Set the channel selector at channel 2.

4. Set the signal generator output (unmodulated) to develop one or two volts at the electronic voltmeter and adjust the four i-f amplifier coils, according to the following chart, for maximum d-c voltage as measured by the electronic voltmeter. Readjust the signal generator output as required to maintain the two-volt potential at the electronic voltmeter.

I-F AMPLIFIER ALIGNMENT CHART

Signal Generator Frequency (No Modulation)	Adjustment (Refer to Fig. 11)	Stage Adjusted
23.2 mc	23.2 MC IF ADJ.	1st IF amp
25.2 mc	25.2 MC IF ADJ.	2nd IF amp
26.1 mc	26.1 MC IF ADJ.	3rd IF amp
22.9 mc	22.9 MC IF ADJ.	Video detector

5. Check the i-f amplifier frequency response by tuning the signal generator from 21 mc through 26.25 mc and observing the change in d-c voltage at the electronic voltmeter. If the signal generator output is set for an electronic voltmeter reading of 1.5 volts at the peak i-f amplifier response. the d-c voltage should not drop below one volt between the two peaks normally obtained with this i-f amplifier. If the response is unsatisfactory, repeat the procedure or try slight modifications of the recommended settings to obtain the desired response. Avoid resonating the coils with the iron core at the bottom end of the coil form. (Adjustment screw near limit of its travel.)

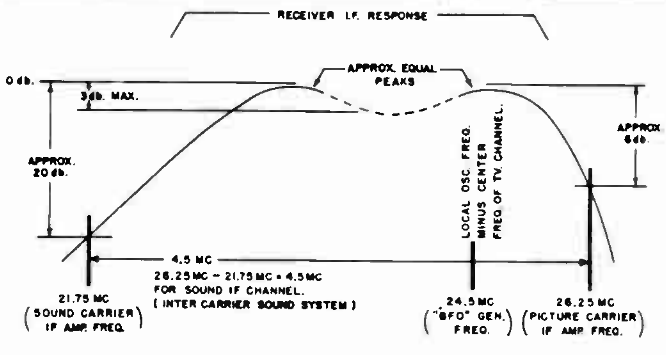

Fig. 12. I-F amplifier response

If a sweep type signal generator and oscilliscope is available the problem of making the final adjustments will be much easier. Check the two carrier i-f responses, 21.75 mc and 26.25 mc. The 21.75 mc response will be approximately 20 db below the peak response (Approx. 0.15 volt) and the 26.25 mc response will fall approximately 6 db below the peak (Approx. 0.4 volt). Refer to Fig. 12.

The average i-f amplifier sensitivity, when feeding the signal generator output through the receiver as described in step 2, will run approx. 1500 to 3000 microvolts for the one volt d-c peak measured at resistor R-118. (Receiver's oscillator operating on channel 2.)

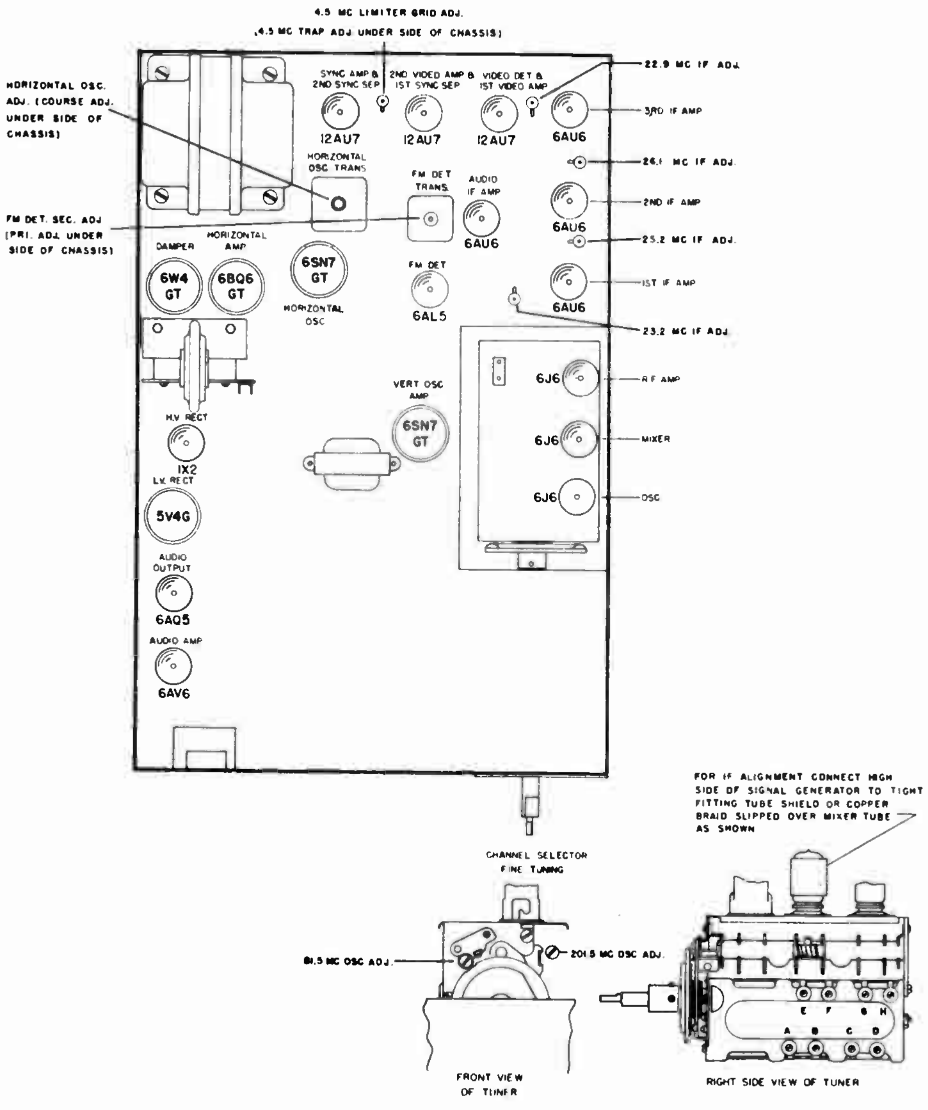

Fig. 11. Top view, alignment points.

STATION CHANNEL ALIGNMENT

1. Due to the broad frequency response of the i-f amplifier, it is necessary to use a 24.5 mc signal generator or oscillator (unmodulated) as a beat frequency oscillator (BFO) in order to locate the center frequency of the i-f amplifier response for the correct local oscillator adjustment. The "BFO" generator should be loosely coupled by means of a wire from the generator output placed in close proximity to the 12AU7 VIDEO DET. tube (V-104).

2. Connect the high frequency signal generator output to the receiver's antenna transmission line through the two 150-ohm carbon resistors, one connected in each conductor of the transmission line.

3 Clip on an .01 mfd condenser between pin 2 of the kinescope (V-117) and pin 1 of the 6AV6 AUDIO AMP tube (V-110). The connection at pin 2 of the kinescope can be made at the terminal strip under the chassis provided for the socket leads of this tube.

4. Set the "BFO" generator at 24.5 mc (No modulation).

5. Set the FINE TUNING control in the center of its range.

*6. Set the channel selector at channel number 2, the high frequency signal generator at 57 mc. and adjust the 81.5 mc OSC. ADJ. screw for a rough audio beat note, using the speaker as a detector.

*7. Set the channel selector at channel number 7, the high frequency signal generator at 177 mc. and adjust the 201.5 MC OSC. ADJ. screw for a rough audio beat note.

8. Disconnect the .01 mfd condenser and connect the electronic voltmeter across resistor R - 118 in the plate circuit of the 12AU7 VIDEO DET. tube (V-104) as for i-f amplifier alignment.

**9. Set the channel selector at channel 6. the high frequency signal generator at 85 mc and adjust trimmers A,B,C and D for maximum voltage as measured by the electronic voltmeter. Use just enough signal generator output to obtain approx. one volt at the electronic voltmeter. Note that trimmers A and B and trimmers C and D must be adjusted simultaneously since the mixer and amplifier tubes are operating in push-pull circuits.

**10. Set the channel selector at channel 13, the high frequency signal generator at 213 mc. and adjust trimmers E,F,G, and H for maximum voltage following the same procedure used in step 9. This completes the alignment of the tuning unit.

The overall sensitivity for the receiver will run approximately 200 microvolts for one volt DC at resistor R-118 when measured in the above manner.

*Note - If local TV stations are operating on channels 2 and 7, the adjustments made in steps 6 and 7 may be made without the use of test equipment. Simply adjust the oscillator for best picture in each case.

**Note - Steps 9 and 10 are not ordinarily required. Adjustment of the trimmers should be undertaken only if the resonant circuits in the tuner have been serviced.

CARRIER vs I-F FREQUENCY CHART

Channel No.	Channel Freq. (mc)	Picture Carrier Freq. (mc)	Sound Carrier Freq. (mc)	Receiver Osc. Freq. (mc)	Picture IF Freq. (mc)	Sound IF Freq. (mc)	Picture IF less Sound IF (mc)

* These tubes are not directly interchangeable. For socket wiring of each type refer to the Schematic Diagram. When tube replacement is required use the same tube types found in the receiver chassis.

COMPARISON CHASSIS L1100D - Runs 1 & 2

Runs 1 & 2 of the L1100D Chassis are identical except for the voltage supply to the plate of V-111, the audio voltage amplifier, and the screen grid of V-112, the audio output stage.

The connection between Pin 3 of CRL-102 (the audio coupling network) and B plus and the connection betwen Pin 6 of V-112 and the B plus are broken. Pin 3 of CRL-102 and Pin 6 of V-112 are then connected together and then to R-156 (10,000 ohms, 1 watt). The other side of R-156 is connected to B plus at the juncture of R-209, L-119, F-104, and R-186. C-140 (20 mfd., 450 V., electrolytic) then is connected with the positive terminal to junction of Pin 3 of CRL-102 and Pin 6 of V-112, and the negative terminal to the chassis.

The additional filtering provided by this circuit has been found to reduce still further the hum level of the set.

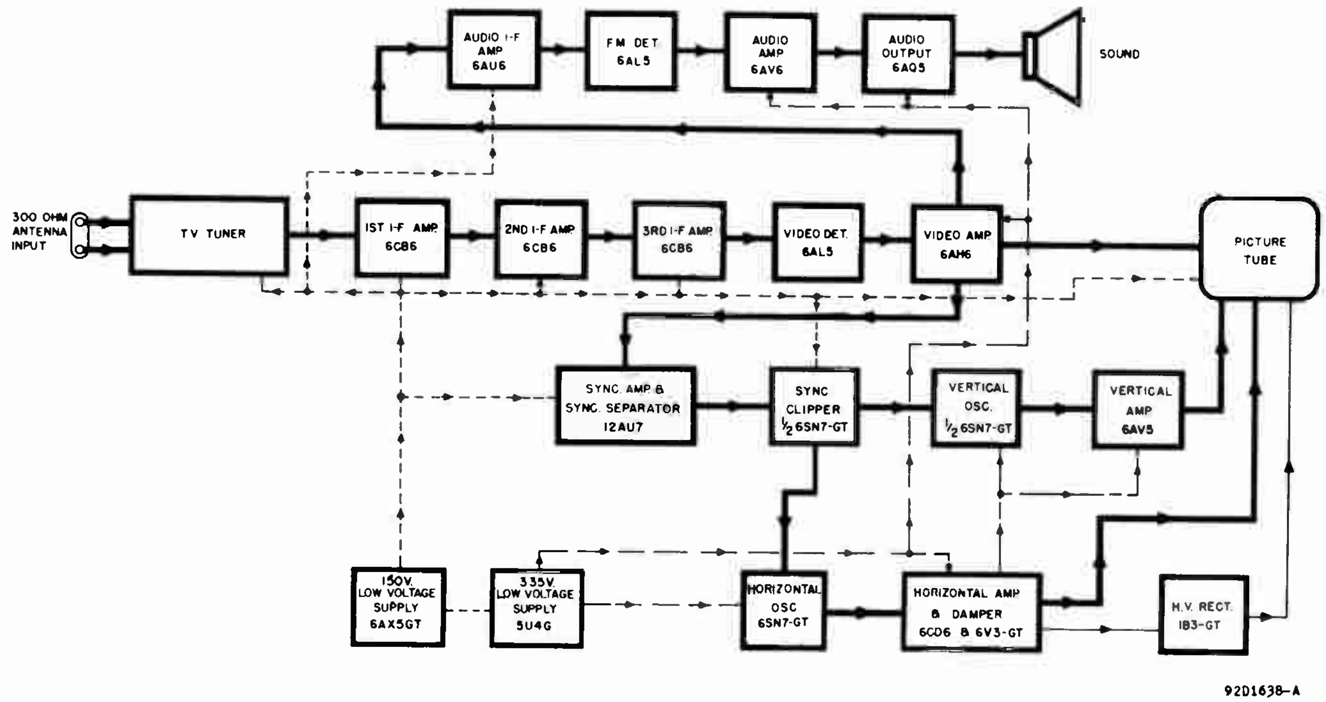

Fig. 44A. Block Diagram of L1100D Chassis

SERVICE ADJUSTMENTS

NOTE: The sequence of "SERVICE ADJUSTMENTS" outlined herein is suggested as a convenient method of approach and is not an arbitrary procedure. Variations of the procedure are permitted to obtain the desired final results. The operating and auxiliary controls, located on the front panel, should be set for as good a pattern as possible before making any of the following adjustments.

Fig. 45A. Improper Centering Adjustments

CENTERING: Loosen the centering lock nut, and adjust the centering lever until the picture is properly centered. Moving the centering lever through the horizontal slot will center the picture vertically. For centering the picture horizontally, grasp the top of the lever, and raise or lower it. If the picture cannot be correctly adjusted by these operations, additional range may be gained by adjusting the screws on each side of the PM focus device. Retighten all adjustment screws and nuts after proper centering has been accomplished.

FOCUS: With the channel selector control tuned to a free channel, adjust the focus control until the lines of the raster are clearly visible. If this operation does not achieve proper focus, the whole PM focus assembly may be moved either backwards or forward by adjustment of the mounting bracket adjustment screws on each side of the rear tube support brackets. Retighten screws after adjustment.

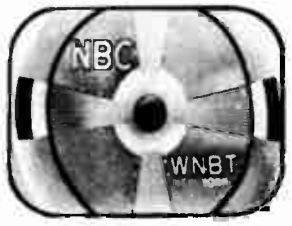

Fig. 45B. Improper Height Control Setting

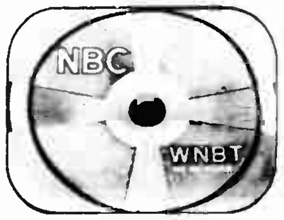

Fig. 45C. Improper Width Control Setting

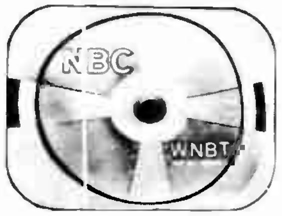

Fig. 45D. Improper Horizontal Drive Control Setting

Adjust the height and width controls so that the picture fills out the dimensions of the screen. A slight readjustment of the centering control may then be necessary.

Adjust the horizontal drive by advancing the control clockwise until a vertical white line appears in the pattern as shown in Fig. 45D. Turn the control in the opposite direction a little further beyond the point at which the line disappears. If a white line does not appear leave the control set to the extreme clockwise position. If, after setting the drive control, the horizontal hold control on the front panel fails to restore synchronization it will be necessary to adjust the horizontal oscillator as described under "HORIZONTAL OSCILLATOR ADJUSTMENT".

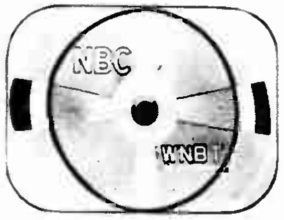

Fig. 45E. Improper Horizontal Linearity Control Setting

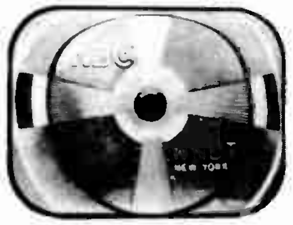

Fig. 45F. Improper Vertical Linearity Control Setting

Adjust the horizontal and vertical linearity controls for a symmetrical pattern. A slight readjustment of the height and width controls may then be necessary.

REMOVAL OF PICTURE TUBE MOUNTING FROM CABINET

1. Remove the 5 Phillips head screws which fasten cabinet back to cabinet. Swing cabinet back open slightly guiding focus control knob through hole in shield cup. Remove internal antenna lead from hole in cabinet back. Swing cabinet back full open.
2. Loosen 6 screws which hold picture tube baseboard to cabinet shelf. (An offset screw driver or other suitable tool will be required to loosen the 2 screws located under the main chassis.)
3. Slide the board out of the cabinet, being careful to protect the tube. (The tube weighs about forty-five pounds.)

NOTE: If no suitable tool is available for loosening the two screws located under the main chassis in the limited clearance available, it will be necessary to remove the chassis. This can be done by pulling off the front knobs, removing the speaker plug, yoke plug, high voltage lead, ground wire lug (black wire) and removing the four screws which hold the chassis mounting board to the side of the cabinet. The chassis can then be pulled back and removed. It can then be replaced after the picture tube adjustment is made.

WARNING!

PICTURE TUBE HANDLING PRECAUTIONS

EXTREME CARE SHOULD BE USED IN REMOVING OR INSTALLING THE PICTURE TUBE. DO NOT FORCE THE NECK OR GRASP THE TUBE BY THE NECK ALONE. THE DESTRUCTIVE EFFECTS OF IMPLOSION INCREASE WITH GREATER SURFACE AREA AND GREATER GLASS THICKNESS.

THE FORTY-FIVE POUND WEIGHT OF THIS TUBE MAKES IT ADVISABLE THAT ITS INSTALLATION OR REMOVAL BE A TWO-MAN OPERATION.

SHATTERPROOF GOGGLES, HEAVY GLOVES, AND PROTECTIVE CLOTHING ARE RECOMMENDED.

REMOVAL OF THE PICTURE TUBE

1. Remove the picture tube from the cabinet according to instructions above.
2. Disconnect the anode plug (PL-105) from the side of the tube and short the plug to the chassis to insure discharge of the high voltage filter capacitor. Discharge the aquadag coating by shorting the anode contact of the tube to the outer tube coating.
3. Remove the anode lead keeper by unhooking the attached springs.
4. Remove the tube socket from the base of the tube.
5. Remove the ion trap from the neck of the picture tube.
6. Remove the two rear support adjustment screws closest to the front of the picture tube.
7. Loosen the two remaining rear support adjustment screws by nine complete turns each but leave them in place.
8. Loosen the three screws which hold the deflection yoke mounting bracket.
9. Loosen the screws for the picture tube mounting strap.
10. Remove mounting strap and rubber strip.
11. Carefully lift tube upward to clear picture tube stop brackets, raising the rear picture tube support to provide enough clearance for the neck. DO NOT FORCE NECK.
12. Move tube forward gently until neck of tube emerges from deflection yoke and rubber collar. Slight twisting motion may be necessary to free neck from the rubber collar.

INSTALLATION AND ADJUSTMENT OF THE PICTURE TUBE

1. With the tube in position so that the anode lead will be located on the right side when viewed from the front face, place the rubber strip across the top and sides along the front rim of the tube.
2. Slide the neck of the picture tube through the rubber collar and the deflection yoke.
3. Seat the tube on the pad so that the face rests against the rubber stop pads, not the brackets for the pads.
4. Place the mounting strap around the rubber strip and tighten the mounting strap screws.
5. Move the rear support so that the rubber collar rests firmly against and supports the cone of the tube. Tighten the rear support adjustment screws.
6. Tighten the three screws on the deflection yoke mounting bracket.
7. Slip the ion trap over neck of tube.
8. Connect the picture tube socket and anode plug (PL-105) and turn on receiver.
9. With the brightness control turned up, adjust the ion trap both along the length of, and around, the neck of the tube. Turn brightness control down as maximum point is approached.
10. With slightly more than normal brightness and the channel selector tuned to a free channel, adjust the focus control until the lines of the raster are most clearly visible. If good focus cannot be obtained in this manner, loosen screws on PM focus mounting bracket, move this bracket forward or back and again adjust the focus control lever. Tighten screws again when perfect focus is obtained.
11. Readjust the brightness control for normal brilliance and touch up ion trap setting.
12. Connect the antenna and tune in a test pattern, if possible.
13. Readjust the contrast control until different shades of the gray scale are clearly visible.

14. If the pattern is off center or shadowed at the corners, loosen the centering lock nut and adjust the centering lever. Rotating this lever through the horizontal slot centers the picture vertically. For moving the picture to right or left, raise or lower this lever. If greater range of adjustment is needed, loosen the screws to the right and left of the focus magnet. Retighten nut and screws after adjustment.

15. If the lines of the raster are not horizontal or square with the escutcheon, loosen the deflection yoke adjustment nut and rotate deflection yoke until proper raster position is obtained. Tighten thumb screw after adjustment.

16. Follow the procedure under "SERVICE ADJUSTMENTS" and make any minor adjustments necessary to obtain properly adjusted pattern.

HIGH VOLTAGE WARNING

OPERATION OF THE RECEIVER CHASSIS OUTSIDE OF THE CABINET INVOLVES DANGER OF ELECTRICAL SHOCK. EXERCISE ALL NORMAL HIGH VOLTAGE PRECAUTIONS WHEN WORKING WITH THIS RECEIVER.

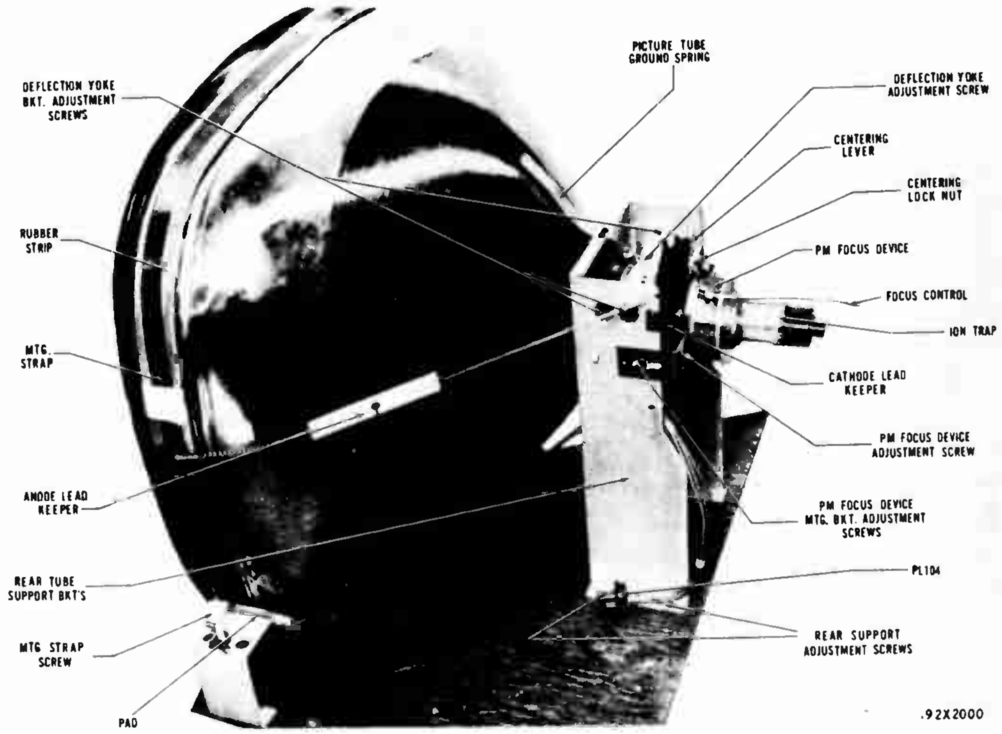

Fig. 48A. 27" Tube Mounting Detail

PICTURE TUBE ANODE HIGH VOLTAGE MEASUREMENT

The second anode potential will be approximately 18,000 volts or higher in a receiver that is functioning properly. If it is possible to obtain good picture brilliance, the second anode potential is correct and need not be measured.

The setting of the horizontal drive control will affect the high voltage on the second anode. Instructions for setting this control are given in the section under the heading of "SERVICE ADJUSTMENTS".

If it is necessary to measure the voltage present on the second anode, a meter specifically designed for high voltage measurements should be used. The contrast and brightness controls should be rotated to the minimum position and PL-105 should be connected to the picture tube. Under these conditions the test meter will load the high voltage power supply approximately the same amount as the picture tube would during normal operation.

SAFETY FIRST

DO NOT USE HAND HELD FLEXIBLE TEST LEADS WHEN MAKING SECOND ANODE HIGH VOLTAGE MEASUREMENTS. ANY ACCIDENTAL CONTACT WITH THE HIGH VOLTAGE PRESENT IN THIS CIRCUIT MAY CAUSE A SEVERE BURN OR IN SOME CASES BE FATAL.

HORIZONTAL OSCILLATOR ADJUSTMENT

If the horizontal hold control on the front panel fails to restore synchronization, the horizontal range adjustment should be reset. Procedure for this adjustment is as follows:

1. Turn the horizontal hold control to the full clockwise position. Adjust the horizontal range adjustment until a vertical bar appears in the pattern as shown in Fig. 49B.

2. Turn the horizontal hold control to the full counterclockwise position. Momentarily set the channel selector to an adjacent channel, and then return it to the original channel being used for adjustment. The resulting picture may or may not be in horizontal synchronization. If it is not in sync., four or less horizontal bars should then appear on the screen as shown in Fig. 49C.

3. If more than four bars appear in step 2, repeat steps 1 and 2.

4. Check the action of the front controls. If the horizontal oscillator is properly adjusted it should be possible to obtain a stable picture on all active channels.

If the above procedure fails to restore stable synchronization, make proper horizontal oscillator waveform adjustments with the aid of an oscilloscope as directed in the following steps.

5. Connect the oscilloscope as shown in Fig. 49A. Adjust the tertiary waveform adjustment until the sine wave is equal in amplitude to the peak of the sawtooth as shown in Fig. 49D. Vary the horizontal range adjustment to keep the picture synchronized.

This adjustment is very important for correct operation of the circuit. If the broad peak of the wave (as seen on the oscilloscope) is lower than the sharp peak, the noise immunity becomes poorer, the stabilizing effect of the tuned circuit is reduced and drift of the oscillator becomes more serious.

On the other hand, if the broad peak is higher than the sharp peak, the oscillator is overstabilized, the pull-in range becomes inadequate and the broad peak can cause double triggering of the oscillator when the hold control approaches the clockwise position.

6. Remove the oscilloscope and repeat steps 1 and 2 if necessary.

7. Check the action of the front controls and repeat the above steps as required to provide positive synchronization on all active channels.

FM SOUND CHANNEL ALIGNMENT

EQUIPMENT REQUIRED

Signal generator covering 4 to 30 mc.
Vacuum tube voltmeter (VTVM).
Sound alignment test circuit shown in Fig. 51A.

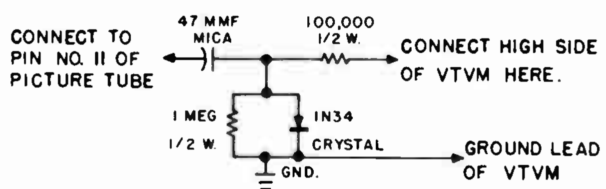

Fig. 51A. Sound Alignment Test Circuit

PROCEDURE

1. Connect the signal generator output through a .005 mfd. capacitor to test terminal (A) which is located on the top of the chassis. This terminal is shown in the chassis top view alignment location illustrations and in the schematic diagrams. Ground the shield of the generator output cable to the chassis near terminal (A).
2. Connect the sound alignment detector circuit and VTVM as shown in Fig. 51A. Adjust the 4.5 mc generator output (unmodulated) to give a 1 volt reading on the VTVM.
3. Adjust the 4.5 mc trap adjustment (L-104) at 4.5 mc for a minimum VTVM reading.
4. Disconnect the test circuit and connect the VTVM to test terminal (B) (Pin 2 of FM detector, V-110).
5. Adjust the 4.5 mc limiter grid adjustment (L-105) and the primary of T-108 (bottom core) at 4.5 mc for a maximum VTVM reading.
6. Connect the VTVM to test terminal (C), shown in the schematic diagram. Adjust the secondary of T-108 (top core) at 4.5 mc for the zero reading which occurs between the positive and negative peaks. If the zero reading occurs at more than one setting, use the position nearest the top limit of the core.
7. Shift the signal generator an equal amount on either side of 4.5 mc and touch up the primary of T-108 (bottom core) for approximately equal peaks. Use just enough signal output to obtain one volt peaks for best results.
8. Disconnect the test equipment and tune in a test pattern. Adjust L-104 for maximum vertical wedge definition.

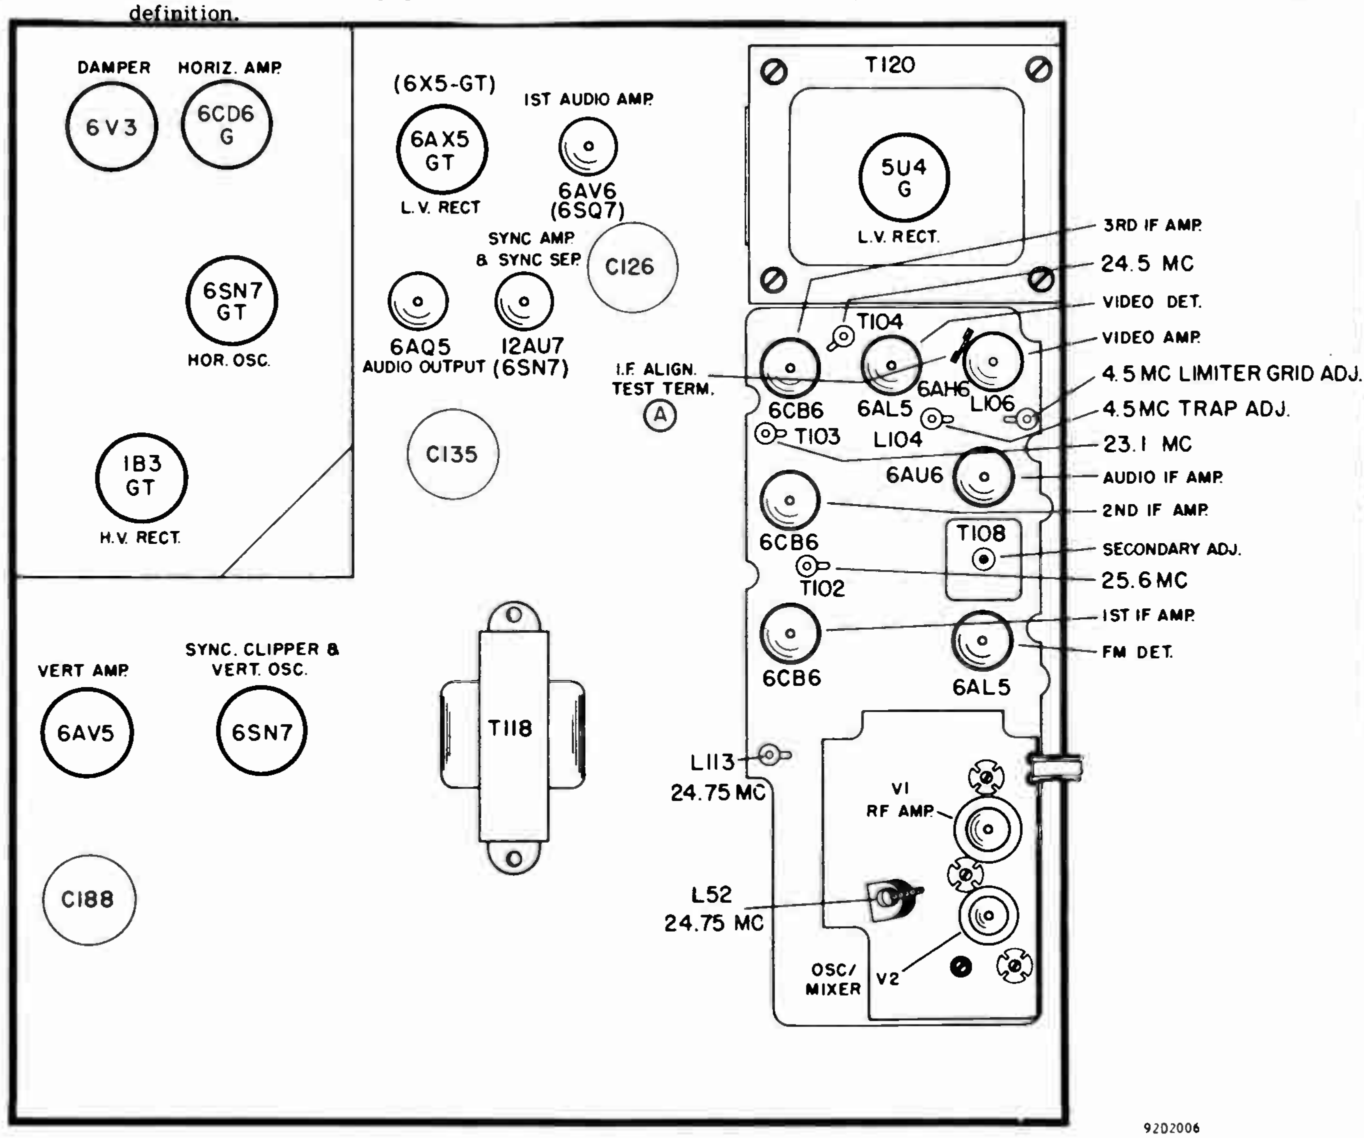

Fig. 52A. Top View Alignment Location

I-F AMPLIFIER ALIGNMENT

1. Connect a VTVM between test terminal (A) and the chassis. Refer to Fig. 52A or the schematic diagram for the particular chassis involved.
2. Connect the high side of a signal generator to the shield of the osc./mixer tube. This connection will capacitively couple the generator output to the tube. Make sure that the shield is ungrounded by raising it above the grounded clips that hold it in place. Connect the ground return of the generator to any chassis point near the base of the tube.
3. Set the channel selector to any vacant channel.
4. Set the signal generator output (unmodulated) for a two volt dc reading on the VTVM and adjust the three i-f transformers, L-113, and L-52 according to the I-F AMPLIFIER ALIGNMENT CHART shown below. Re-adjust the signal generator output as required to maintain the two volt VTVM reading.

I-F AMPLIFIER ALIGNMENT CHART

Signal Generator Frequency (No Modulation)	Adjustment	Location	VTVM Indication
25.6 mc	T-102 (top)	See Fig. 52A	Maximum
23.1 mc	T-103 (top)	See Fig. 52A	Maximum
24.5 mc	T-104 (top)	See Fig. 52A	Maximum
21.75 mc	T-103 (bottom)	Under Chassis	Minimum
24.75 mc	*L-113	See Fig. 52A	Maximum
24.75 mc	**L-52	See Fig. 52A	Maximum

* NOTE: Hold the channel selector between two channels when making this adjustment.

** NOTE: Return the channel selector to the normal position on any vacant channel and shunt the 4700 ohm grid resistor (R-101) of V-101 with a 1000 ohm resistor when making this adjustment. Remove the resistor after adjustment is completed.

5. After adjusting the 21.75 mc sound trap (bottom slug of T-103), recheck the setting of the top core of T-103. Note that the bottom core of T-103 is concealed by wax. Remove and save the wax. After the bottom core has been adjusted, replace the wax and melt it with a soldering iron to secure the core so that the setting will not change when the chassis is subjected to normal operating conditions.
6. Tune the signal generator from 21 mc through 26.25 mc and observe the change in indication on the VTVM. If the generator output is set to the level where a 1.5 volt meter reading is obtained at the peak i-f amplifier response, the reading should not drop below one volt between the two peaks normally obtained with this i-f amplifier. If the band-pass response is not satisfactory, repeat the above procedure or try slight modifications of the recommended settings to obtain the desired results. Avoid resonating the coils with the iron core at the bottom end of the coil form (adjustment screw near the outer limit of its travel). Final adjustments can be made much more easily if a sweep type signal generator and oscilloscope are used.
7. Check the two carrier i-f responses of 21.75 mc and 26.25 mc. The 21.75 mc response will be approximately 26 db below the peak response (approx. 0.075 volt) and the 26.25 mc response will fall approximately 6 db below the peak, (approx. 0.75 volt). Refer to Fig. 54A.

To determine the i-f amplifier sensitivity, connect a signal generator to the osc./mixer tube as directed in step 2 above. Set the generator frequency to either i-f peak. If a generator output of 800 to 1500 microvolts produces a one volt dc reading on a VTVM connected between terminal (A) and ground, the i-f amplifier sensitivity is normal.

TELEVISION CHANNELS vs. CARRIER, OSCILLATOR AND I-F FREQUENCIES

Channel No.	Channel Freq. (mc)	Picture Carrier Freq. (mc)	Sound Carrier Freq. (mc)	Receiver Osc. Freq. (mc)	Picture I-F Freq. (mc)	Sound I-F Freq. (mc)	Picture I-F less Sound I-F (mc)
