
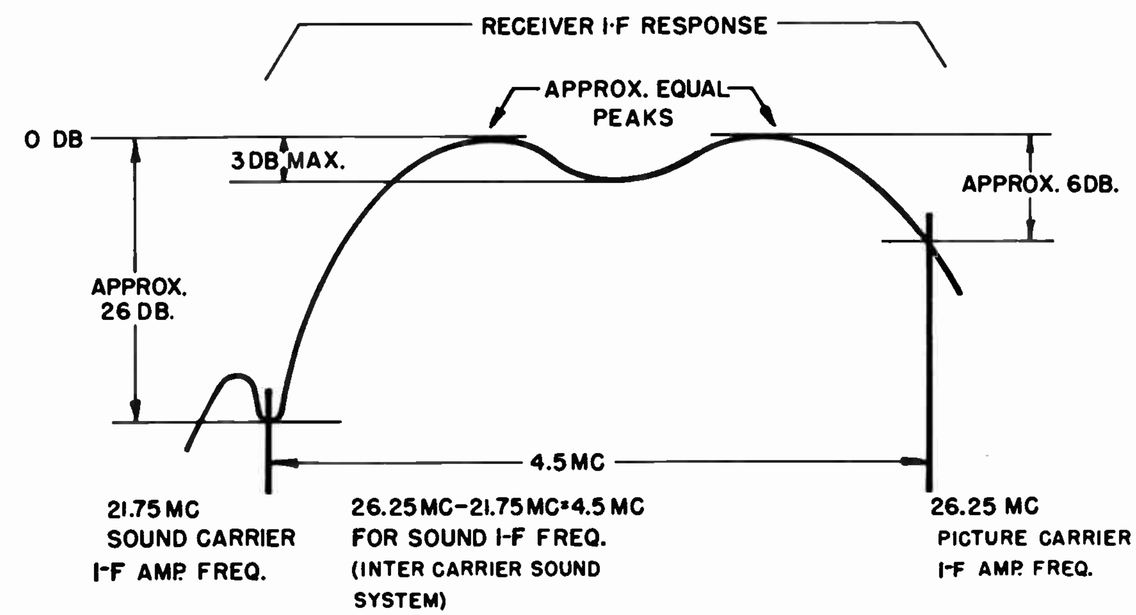

Fig. 54A. Typical I-F Amplifier Response

1E1441 SUPERDYNAMIC TV TUNER ALIGNMENT (ANT. & RF CIRCUITS)

The tuner was carefully aligned at the factory and should not require complete realignment under normal operating conditions. A slight readjustment of the individual oscillator slugs may be required as the tubes in the tuner age or are replaced. In some rare cases it will be necessary to realign the tuner after replacing either of the two tubes. If any service work is performed on the tuner, realignment may or may not be required. NO ATTEMPT TO REALIGN THE TUNER SHOULD BE MADE UNTIL THE BALANCE OF THE TV RECEIVER IS KNOWN TO BE IN PROPER OPERATING CONDITION AND IS PROPERLY ALIGNED.

EQUIPMENT REQUIRED

1. Sweep generator covering all 12 television channels.
2. Marker generator covering the same range as the sweep generator.
3. Oscilloscope.
4. Vacuum tube voltmeter (VTVM)

SET-UP PROCEDURE

1. Set the CHANNEL SELECTOR switch to channel 12.
2. Connect the oscilloscope through a 10,000 ohm resistor to test point TP-9. (See Schematic Diagram and Fig. 56A).
3. Connect the negative pole of a 3 volt dry battery to the terminal where the delayed AGC lead (white wire) from the tuner is connected. Connect the positive pole of the dry battery to the receiver chassis. (See Schematic Diagram).
4. Set the FINE TUNING control at the approximate midpoint of its tuning range.
5. Connect the sweep generator to the antenna terminals and adjust the output to sweep channel 12.
6. Loosely couple the output from the marker generator to the antenna terminals. Use the minimum amount of coupling and signal from the marker generator required to give a good marker or pip on the oscilloscope pattern.

ANTENNA AND RF CIRCUIT ALIGNMENT

7. Adjust C-13, C-3 and C-6 for a flat-top response curve and maximum gain. Check markers on all channels. They should fall in automatically on each channel. Correct marker frequencies for each channel are given in the Picture Carrier and Sound Carrier columns of the chart. Refer to Fig. 56B.
8. Disconnect the battery used to obtain negative bias.
9. Disconnect the test equipment and air check the receiver on all active channels. If it is possible to receive a normal picture on all active channels by adjusting the FINE TUNING control, further alignment will not be necessary.

1E1441 SUPERDYNAMIC TV TUNER ALIGNMENT (OSC. CIRCUIT)

1. Set the FINE TUNING control at the approximate midpoint of its tuning range.
2. Place a non-metallic screwdriver through the openings provided in the front of the chassis and the tuner assembly and adjust the oscillator coil slug for each active channel to give the best possible picture.

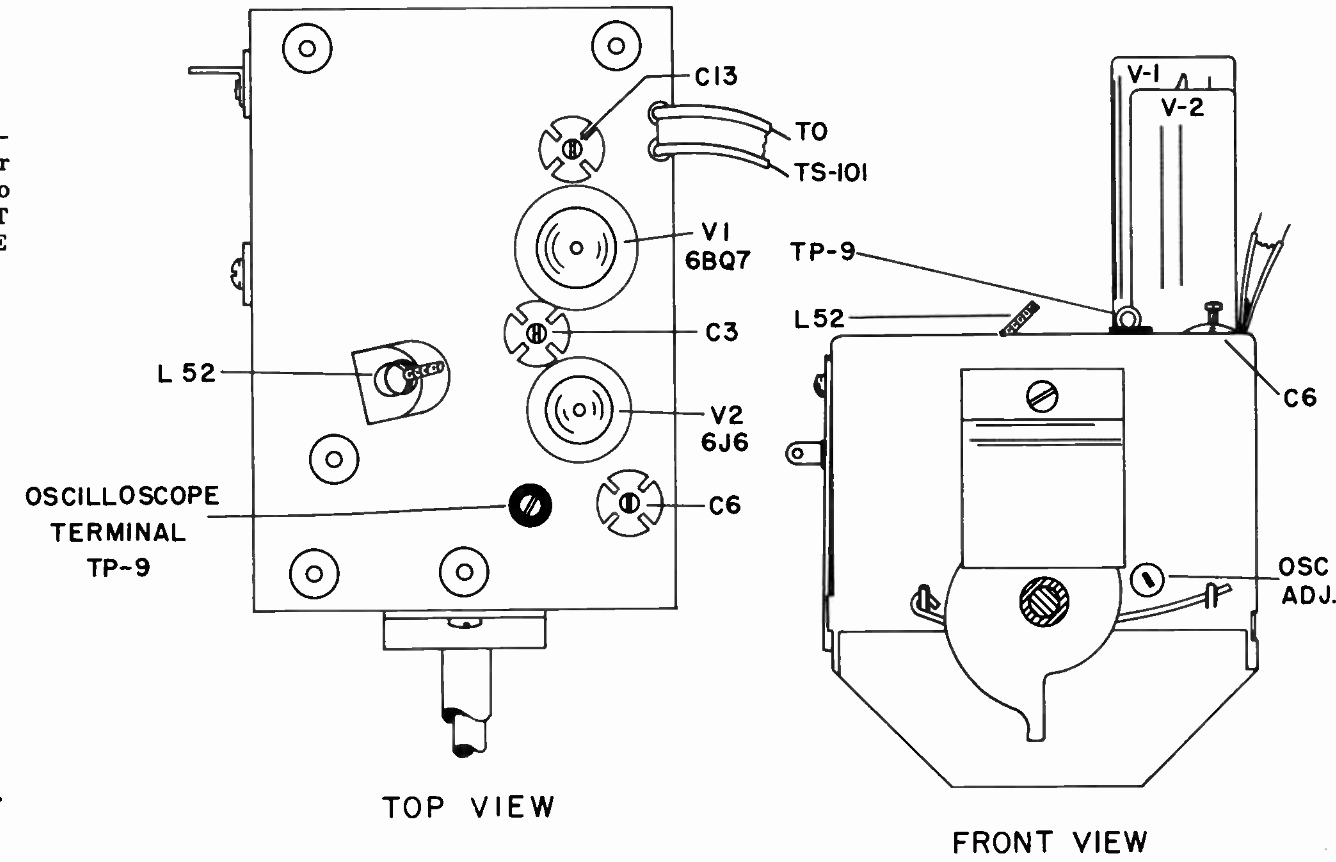

Fig. 56A. Top View Alignment Adjustments for TV Tuner with L-52 & L-113 Coupling Circuit

TYPICAL OSCILLOSCOPE PATTERNS FOR L1100D CHASSIS

The patterns given on the following pages are presented as a guide when using an oscilloscope to locate trouble in the video amplifier, sync., horizontal oscillator, horizontal output, vertical oscillator, and vertical output stages of the tv receiver.

Considerable variation may be noted in the amplitude and shape of some of the various waveforms from one receiver to the next. As long as the waveform obtained from the receiver under test contains the same general characteristics as those shown in the illustrations and the relative amplitude is within approximately 25% of the peak to peak voltage or relative amplitude shown below each waveform the pattern obtained may be assumed to be correct. The patterns are observed with the tv receiver tuned to an active channel and the controls adjusted for the best possible picture.

The waveforms shown in the illustrations were obtained on a Dumont type 304 oscilloscope which was used in conjunction with a low capacity 10 to 1 probe such as the Tel-Instrument Co. type 1610. Other types of oscilloscopes will account for a certain amount of variation in the amplitude and shape of the patterns obtained from the actual receiver under test. A low capacity probe must be used in order to obtain satisfactory results.

With the exception of the test pattern obtained across the vertical yoke all patterns are taken with the ground side of the oscilloscope connected to the ground or chassis of the tv chassis and the 10 to 1 probe connected to the specific points in the tv chassis as specified by each pattern.

The patterns obtained from the horizontal amplifier plate, damper cathode, and the high voltage rectifier tube must be observed by means of the high voltage probe which is made from a type 1X2-A tube as shown in Fig. 60A. The tube is used as a high voltage coupling capacitor. Use a new tube for this application because the loose filament of a burned out one may touch the plate. These patterns are also shown with their relative amplitudes indicated with respect to the pattern obtained at the cathode (topcap) of the damper tube, V-118, which is given a unit value of one.

At certain points throughout the tv receiver the oscilloscope pattern obtained will be dependent upon the frequency of the horizontal sweep oscillator in the oscilloscope. The oscilloscope sweep frequency must be either 30 cps (1/2 of the tv vertical oscillator frequency) or 7875 cps (1/2 of the tv horizontal oscillator frequency) depending upon the pattern desired. The sweep frequency required to obtain the patterns shown is given with each pattern.

VIDEO AMPLIFIER

SERVICE PARTS LIST

The following parts list may be used to determine replacement parts for the chassis L1200D. To determine the correct replacement parts, first refer to the schematic and determine the correct schematic symbol for the part. Refer to the Service Parts List for the part number and description of the component with the same schematic symbol.

The picture tube and its associated mounting components are listed in a separate parts list. Cabinet parts may be determined by referring to the pages devoted to individual models.

COILS AND TRANSFORMERS

Schematic Symbol	Description	Hallicrafters Part Number

SO-103	Socket, speaker	10A373
S-101	Switch, OFF-ON; part of R-225	---------
TS-101	Terminal strip, antenna	88A020 or 88A679
	VHF TUNING UNIT ASSEMBLY, complete; includes tubes	1E1441

V-1 & V-2 (REFER TO PART NUMBER STAMPED ON SIDE OF TUNER CHASSIS)

PICTURE TUBE AND MOUNTING COMPONENTS

Schematic Symbol	Description	Hallicrafters Part Number
	Picture Tube, 27 inch rectangular; glass	90X27EP4
	Board, pix tube mtg.	78D990
	Bracket, deflection yoke mtg.; upper	67C2124
	Bracket, deflection yoke support	67-2126
	Bracket, yoke mtg. & rear pix tube support (mounts on board)	67D2125
	Bracket, PM focus and centering assembly mtg.	67C2123
	Bracket, pix tube mtg., front	67C2122
	Bracket, pix tube stop	67-2133
	Channel, rubber, pix tube stop	16A297
	Collar, rubber, pix tube mtg.	16-323
	Cushion, rubber, pix tube mtg. strap	16-325
L-120	Deflection yoke assembly (includes leads & plug, PL-104)	53-277
	Focus (PM) & centering assembly	51-1638
	Ion Trap	21-151
	Keeper, anode lead	8A1375
	Pad, rubber; front pix tube mtg. bracket	16-324
	Rod, round steel, bracket support	74-585
	Spring, anode keeper, 3¼" long	75A203
	Spring, anode keeper, 1½" long	75A202
	Spring, flat; pix tube ground	75B246
	Strap, pix tube mtg., with end brackets	76A1043
	Screw, pix tube mtg. strap	3BRCH/A
	Screw, wing, deflection yoke adj.	3A1610
	Spacer, deflection yoke adj.	73A580

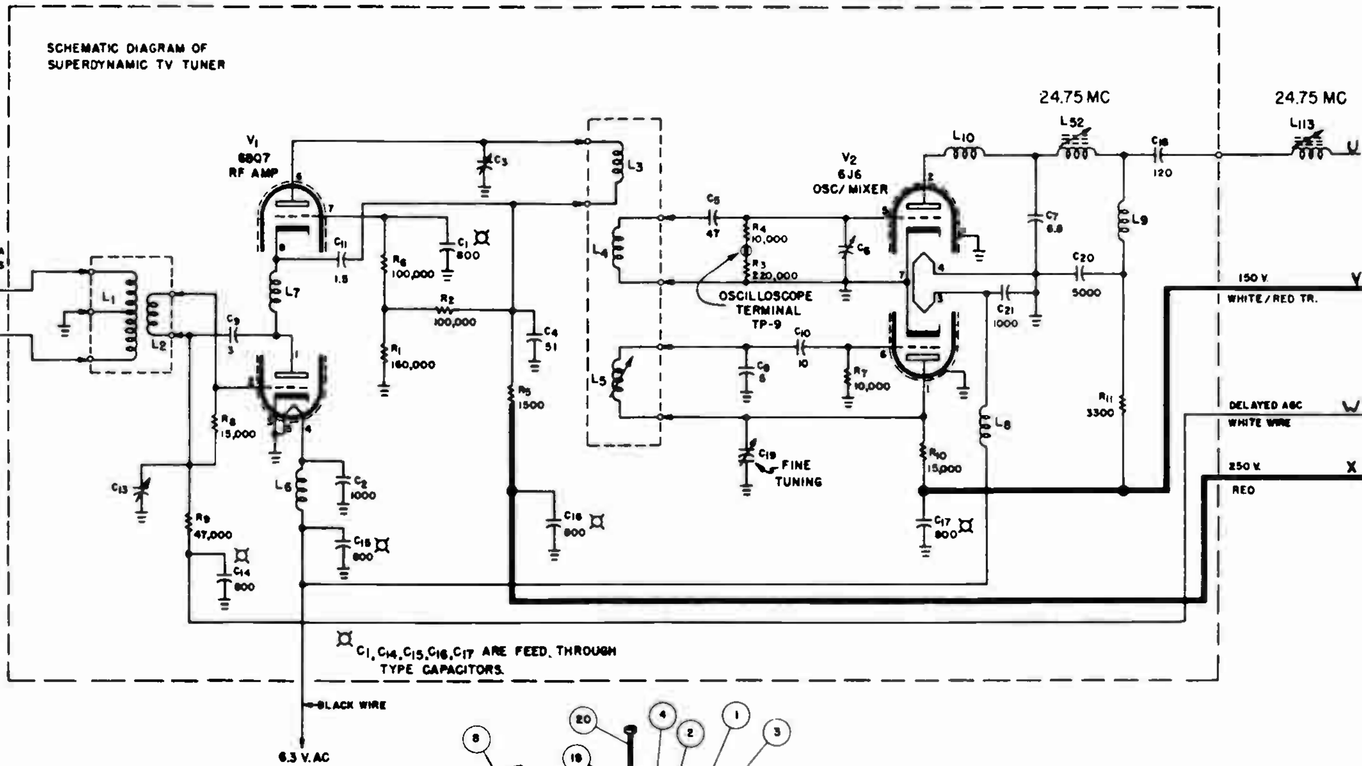

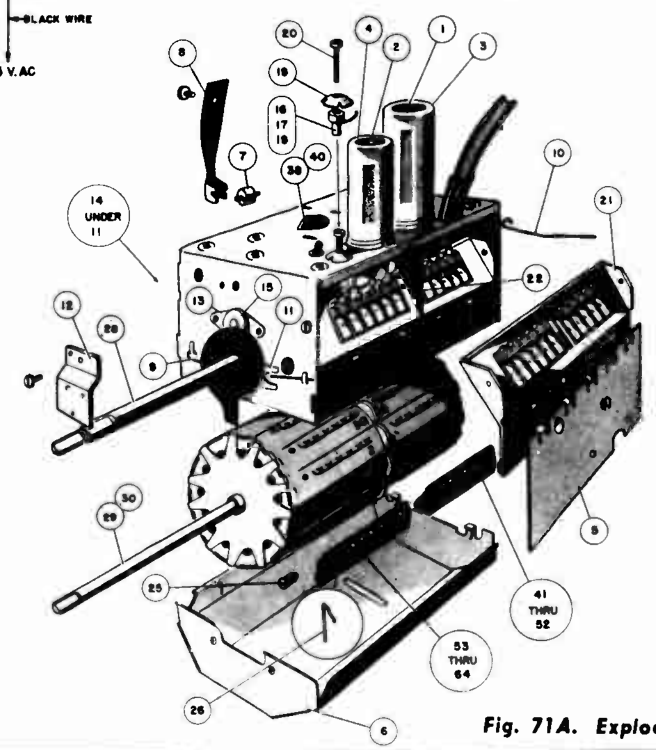

Fig. 71A. Exploded View of TV Tuner 1E1441

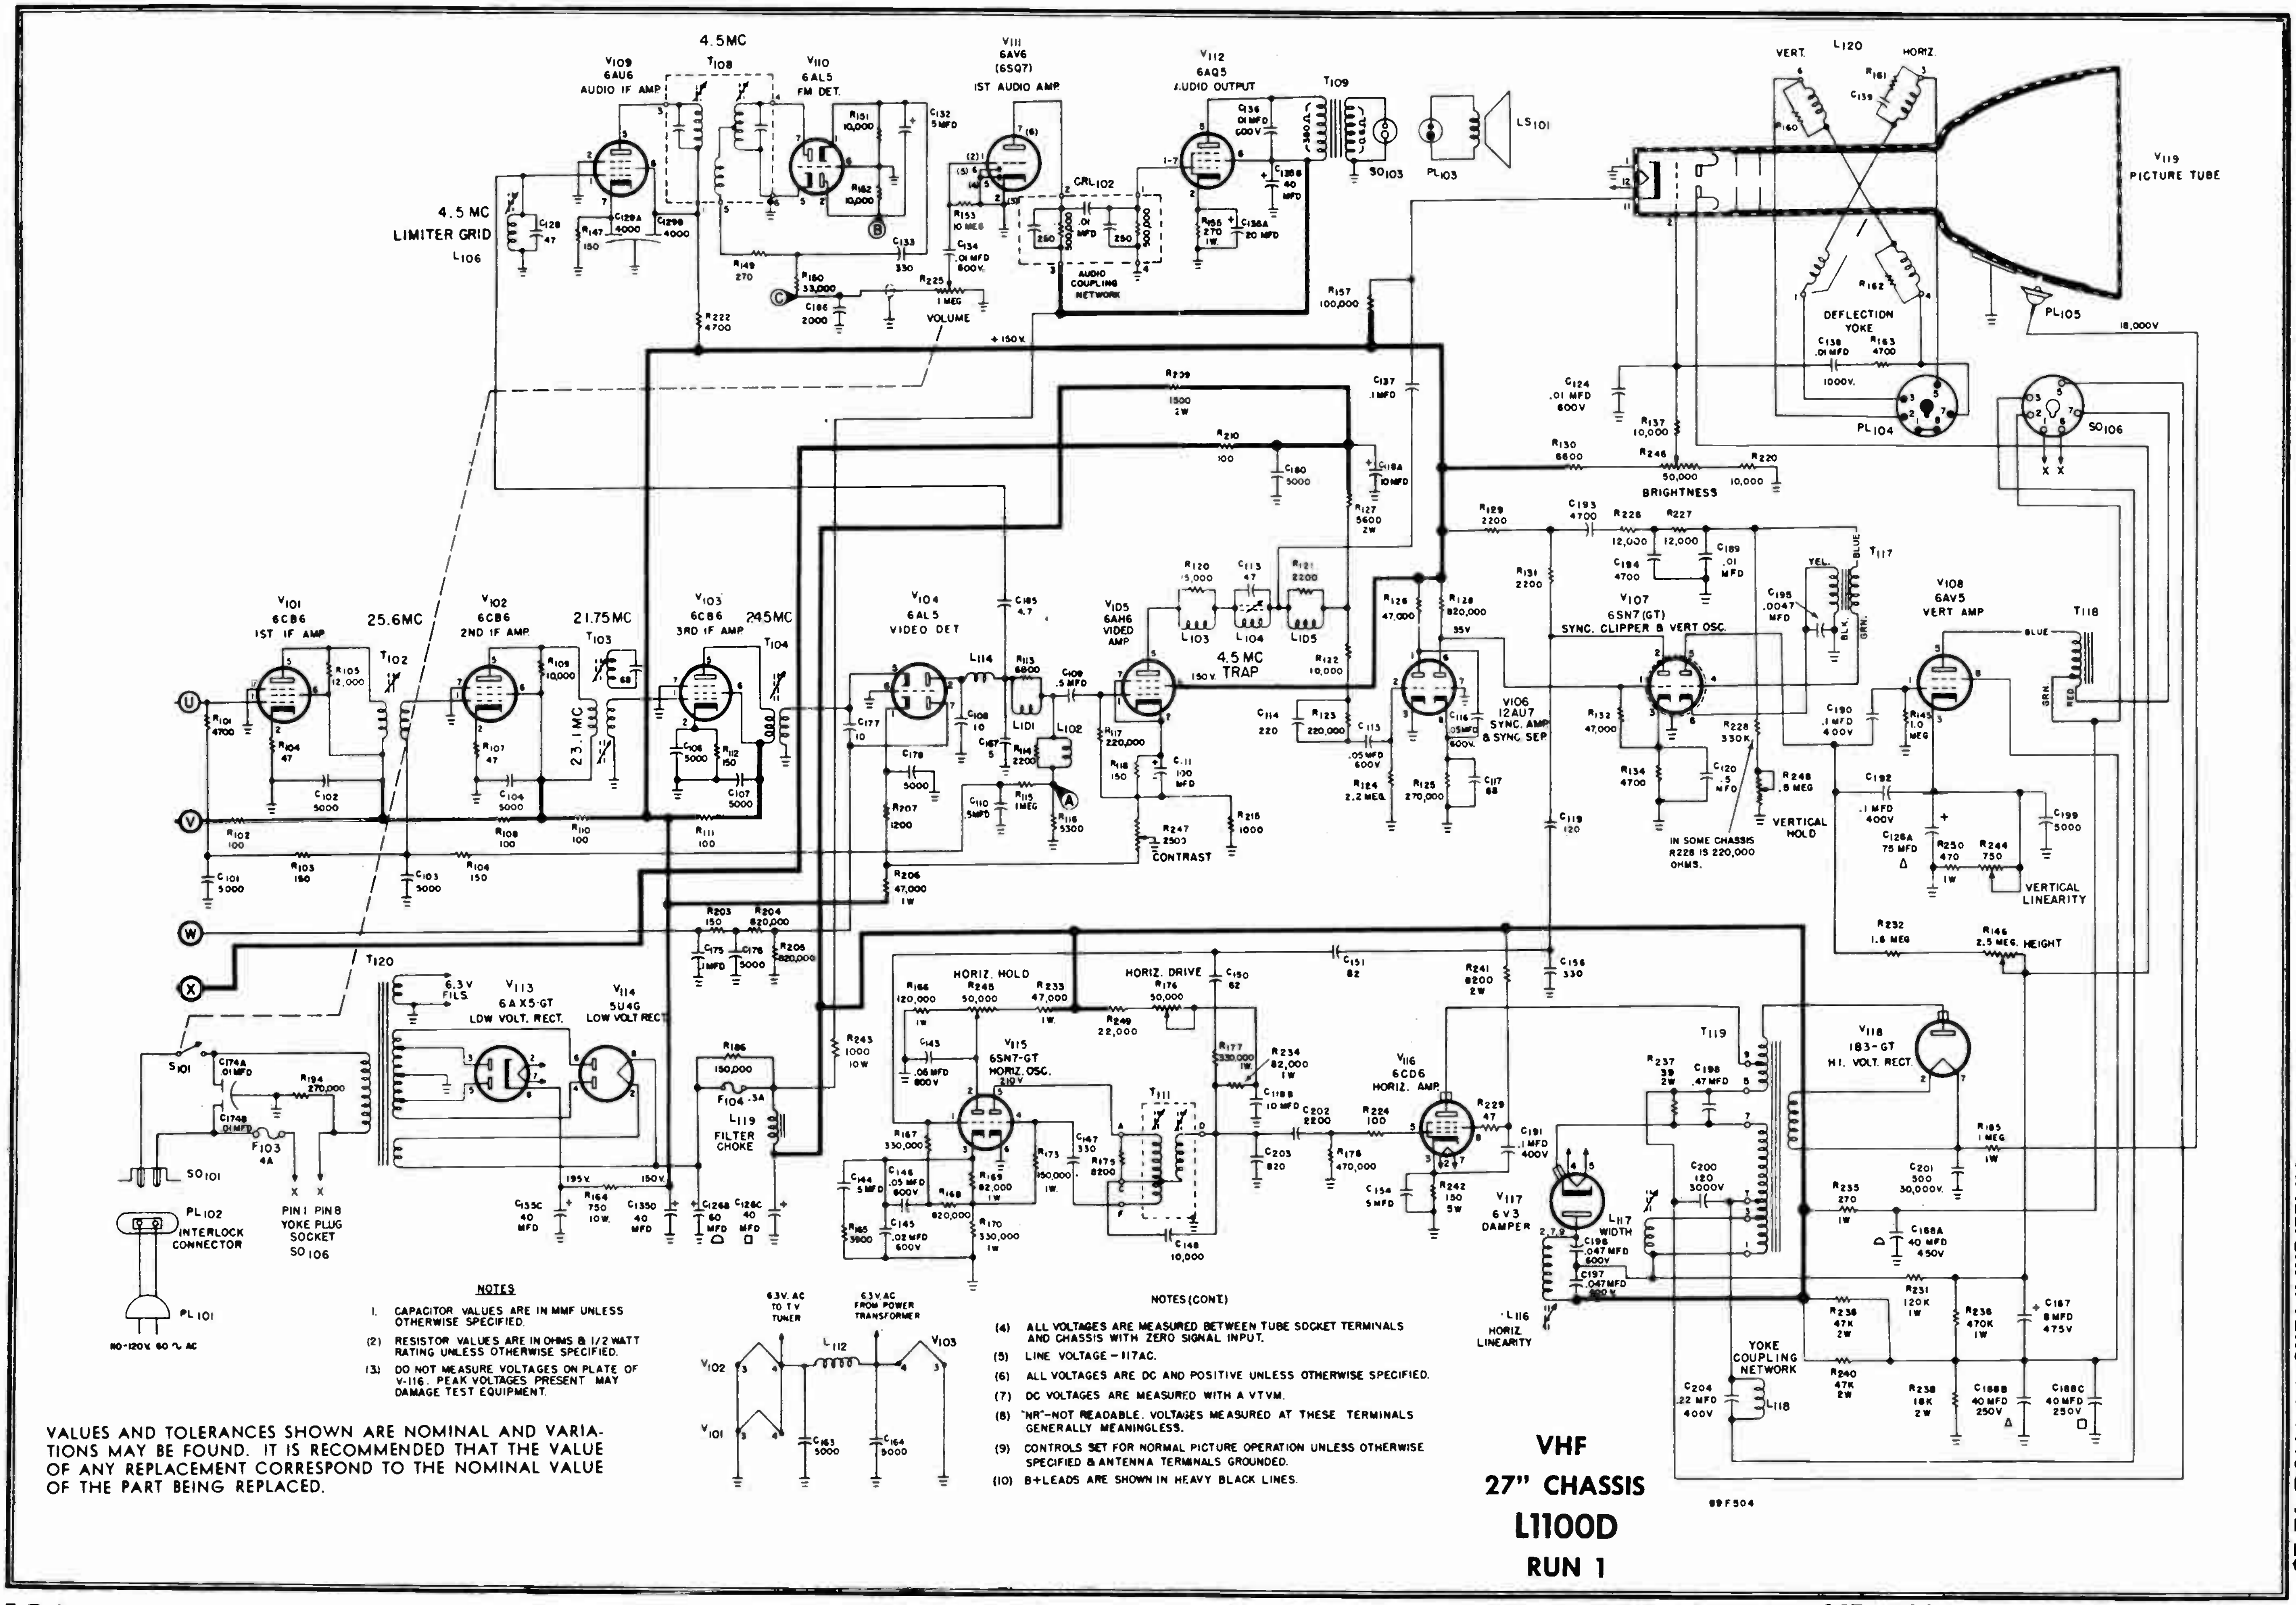

NOTES

1. CAPACITOR VALUES ARE IN MMF UNLESS OTHERWISE SPECIFIED.
(2) RESISTOR VALUES ARE IN OHMS & 1/2 WATT RATING UNLESS OTHERWISE SPECIFIED.
(3) DO NOT MEASURE VOLTAGES ON PLATE OF V-116. PEAK VOLTAGES PRESENT MAY DAMAGE TEST EQUIPMENT.

NOTES (CONT.)

(4) ALL VOLTAGES ARE MEASURED BETWEEN TUBE SOCKET TERMINALS AND CHASSIS WITH ZERO SIGNAL INPUT.
(5) LINE VOLTAGE - 117AC.
(6) ALL VOLTAGES ARE DC AND POSITIVE UNLESS OTHERWISE SPECIFIED.
(7) DC VOLTAGES ARE MEASURED WITH A VTVM.
(8) "NR"-NOT READABLE. VOLTAGES MEASURED AT THESE TERMINALS GENERALLY MEANINGLESS.
(9) CONTROLS SET FOR NORMAL PICTURE OPERATION UNLESS OTHERWISE SPECIFIED & ANTENNA TERMINALS GROUNDED.
(10) B+LEADS ARE SHOWN IN HEAVY BLACK LINES.

VALUES AND TOLERANCES SHOWN ARE NOMINAL AND VARIATIONS MAY BE FOUND. IT IS RECOMMENDED THAT THE VALUE OF ANY REPLACEMENT CORRESPOND TO THE NOMINAL VALUE OF THE PART BEING REPLACED.

CHASSIS IDENTIFICATION

A chassis stamp, located on the right side of the rear apron of the chassis, provides the necessary information to identify the chassis and thereby determine the applicable service data and schematic diagram. The first letter of this chassis stamp indicates the chassis type and the number with letter suffix designates the chassis series. A production run number is stamped directly below or to one side of the chassis identification stamp. At the start of production, chassis are stamped RUN 1. Whenever a major production change is made in the chassis, the run number changes to the next higher number.

CHASSIS NO.	MODELS CHASSIS MAY BE USED IN
A1200D, K1200D or W1200D	1010P, 1012P
D1200D, L1200D or X1200D	1021P, 1026P
F1200D	1013C

COMPARISON OF 1200 SERIES CHASSIS

The A1200D may be considered the basic chassis in the series 1200 chassis. The D, F, G, J, K, L, P, R, T, W, X, Y and Z1200D chassis are all based on the A1200D chassis with any one or more of the modifications shown on the following pages. See chart below for modifications used in any particular chassis.

COMPARISON CHART FOR 1200 SERIES

CHASSIS	PIX TUBE SIZE See Modification I	HEATER CIRCUIT See Modification IV	TUNER TYPE See Modification VII	MODIFICATIONS USED and/or NOTES FOR RUN 1
A1200D	17" glass	Series-parallel	1C1345 Pentode	Basic 1200 series chassis.
D1200D	20" glass	Series-parallel	1C1345 Pentode	I except step D & II
F1200D	17" glass	Transformer	1C1376 Cascode	II, III, IV, VI & VII
G1200D	20" glass	Transformer	1C1376 Cascode	I, II, IV, VI & VII On some chassis, R-181 is 270,000 ohms and R-194 value is 100,000 or 120,000 ohms.
J1200D	21" metal	Transformer	1E1380 Cascode	I, IV, VI, VII, IX, X, XI, XII & XIV*
K1200D	17" glass	Transformer	1C1345 Pentode	IV & V
L1200D	20" glass	Transformer	1C1345 Pentode	I except step D, II, IV & V
P1200D	17" glass	Series-parallel	1C1345 Pentode	VI, IX & X
R1200D	21" metal or glass	Series-parallel	1C1345 Pentode	I, VI, VIII, IX, X, & XIV*
T1200D	21" metal	Transformer	1C1376 Cascode	I, IV, VI, VII, VIII, IX, X, XII & XIV*
W1200D	17" glass	Series-parallel	1C1345 Pentode	II & VI
X1200D	20" glass	Series-parallel	1C1345 Pentode	I, II & VI
Y1200D	17" glass	Transformer	1E1483 VHF Cascode & 1E1484 UHF	IV, VI, IX, X, XIII & XIV ★
Z1200D	21" metal	Transformer	1E1483 VHF Cascode & 1E1484 UHF	I, IV, VI, VIII, IX, X,• XII, XIII & XIV• ★

* Modification XIV will be found only in J, R, & T1200D chassis which have a RUN 1A chassis stamp.
• Only Run 1A and later Z1200D chassis have modifications X and XIV.
★ See page 33 for changes in Runs 2, 3, 4 and 5 of the Y1200D and Z1200D UHF chassis.

COMPARISON OF 1200 SERIES CHASSIS (Cont.)

LIST OF MODIFICATIONS

MODIFICATION I

To change from a 17 inch to a 20 or 21 inch picture tube the following changes are made:

LOCATION OF CHANGE	CHANGE MADE
A. High side of Horizontal Hold control	82,000 ohms, $\frac{1}{2}$ watt resistor (R-178) added.
B. Plate (pin 2) circuit of Horizontal Oscillator	220,000 ohms, $\frac{1}{2}$ watt resistor (R-179) added.
C. Plate supply decoupling of Horizontal Oscillator (pin 2)	.1 mfd., 600 v. paper capacitor (C-162) added.
D. Plate supply decoupling of Horizontal Oscillator (pin 2)	120,000 ohms, $\frac{1}{2}$ watt resistor (R-156) replaced by 180,000 ohms, $\frac{1}{2}$ watt resistor (R-194). The bottom of R-194 is returned to terminal 1 of T-109.
E. Plate (pin 2) circuit of Horizontal Oscillator	4700 ohms, $\frac{1}{2}$ watt resistor (R-157) replaced by 8200 ohms, $\frac{1}{2}$ watt resistor (R-180).
F. Plate (pin 2) circuit of Horizontal Oscillator	470 mmf. silver mica capacitor (C-145) replaced by 390 mmf. silver mica capacitor (C-163).
G. Horizontal Output stage grid coupling	5000 mmf. disc ceramic capacitor (C-146) replaced by 560 mmf. silver mica capacitor (C-164).
H. Horizontal Output stage grid leak	330,000 ohms, $\frac{1}{2}$ watt resistor (R-158) replaced by 390,000 ohms, $\frac{1}{2}$ watt resistor (R-181).
I. Horizontal Output stage screen bypass	.047 mfd., 400 v. paper capacitor (C-165) added
J. Horizontal Output stage screen resistor	10,000 ohms, 2 watts resistor (R-182) added.
K. Horizontal Output stage output transformer	Horizontal output transformer T-106 (55D193) replaced by T-109 (55D197).
L. Servo Loop feedback from Horizontal Output to AFC tube	Two 150,000 ohms, 1 watt resistors (R-151 & R-152) series connected replaced by 33,000 ohms, 1 watt resistor (R-177).
M. Series capacitor in doubler power supply	140 mfd., 150 v. electrolytic capacitor (C-135) replaced by 200 mfd., 150 v. electrolytic capacitor (C-161).
N. Audio voltage amplifier cathode resistor	1500 ohms, $\frac{1}{2}$ watt resistor (R-169) replaced by 1200 ohms, $\frac{1}{2}$ watt resistor (R-176)
O. Speaker	Speaker with field coil resistance of 85 ohms replaced by speaker with field coil resistance of 61 ohms

MODIFICATION II

The 75 mmf., 500 V. ceramic capacitor (C-142) connected from plate pin 5 to ground of the Horizontal Oscillator, V-108, is replaced by a 100 mmf., 500 v. silver mica capacitor (C-170). Some chassis have neither C-142 or C-170. The 100 mmf. capacitor, C-170, is the preferred capacitor.

MODIFICATION III

The horizontal integrating network in the grid circuit (pin 4) of the Horizontal Oscillator is changed as follows:

A. 4.7 megohms, $\frac{1}{2}$ watt resistor (R-149) is replaced by 470,000 ohms, $\frac{1}{2}$ watt resistor (R-189).
B. .003 mfd., 400 v. paper capacitor (C-139) is replaced by .005 mfd., 400 v. paper capacitor (C-167).
C. .01 mfd., 400 v. paper capacitor (C-141) is replaced by .05 mfd., 400 v. paper capacitor (C-168).

MODIFICATION IV

To replace series parallel heater arrangement with a heater transformer the following changes are made:

LOCATION OF CHANGE	CHANGE MADE
A. Between power line and Damper heater pin 8	190 ohms cold/19 ohms hot, 5 watts negative temperature coefficient resistor (R-143) deleted.
B. Heater string shunt	80 ohms, 10 watts, 5% resistor (R-144) deleted.
C. Heater string shunt	42 ohms, 3 watts, 5% resistor (R-145) deleted.
D. Heater string choke	Air core r-f choke (L-113) deleted.
E. First I.F. Amplifier heater bypass	4000 mmf. dual disc ceramic capacitor (C-104) deleted.
F. Ratio Detector heater bypass	5000 mmf. disc ceramic capacitor (C-106) deleted.
G. Video Amplifier heater bypass	5000 mmf. disc ceramic capacitor (C-158) deleted.
H. 4.5 MC Amplifier heater bypass	5000 mmf. disc ceramic capacitor (C-159) deleted.
I. Heater transformer	Auto transformer T-110 (52C258) added.
J. Sync. Clipper V-105	12SN7GT tube replaced by 6SN7GT tube.
K. Horizontal Output V-109	25BQ6GT tube replaced by 6BQ6GT tube.
L. Audio Output V-115	25L6GT tube replaced by 6W6 tube.
M. Audio Output tube socket wiring	Cathode pin 8 connected directly to heater pin 7 to place both heater and cathode at the same potential.

MODIFICATION V

LOCATION OF CHANGE	CHANGE MADE
A. Integrating network in Vert. Osc. grid circuit	22,000 ohms, $\frac{1}{2}$ watt resistor (R-133) replaced by 47,000 ohms, $\frac{1}{2}$ watt resistor (R-183).
B. AGC divider network in Sync. Clip. plate circuit	3300 ohms, $\frac{1}{2}$ watt resistor (R-132) replaced by 2200 ohms, $\frac{1}{2}$ watt resistor (R-184).
C. Horizontal Oscillator cathode resistor	1200 ohms, $\frac{1}{2}$ watt resistor (R-153) replaced by 1500 ohms, $\frac{1}{2}$ watt resistor (R-185).
D. Horizontal Oscillator plate circuit (pin 2)	4700 ohms, $\frac{1}{2}$ watt resistor (R-157) replaced by 8200 ohms, $\frac{1}{2}$ watt resistor (R-180).
E. Horizontal Oscillator plate circuit (pin 2)	470 mmf. silver mica capacitor (C-145) replaced by 390 mmf. silver mica capacitor (C-163).
F. Horizontal Oscillator Adjustment	Test point (A) removed and the Horizontal Oscillator Adjustment procedure changed. See page 1952-78.

MODIFICATION VI

This modification is composed of MODIFICATION V plus the following changes:

LOCATION OF CHANGE	CHANGE MADE
A. Sync. Clipper plate circuit (pin 2)	680,000 ohms, $\frac{1}{2}$ watt resistor (R-127) replaced by 1.2 megohms, $\frac{1}{2}$ watt resistor (R-190).
B. Sync. Clipper grid leak (pin 4)	22,000 ohms, $\frac{1}{2}$ watt resistor (R-130) replaced by 47,000 ohms, $\frac{1}{2}$ watt resistor (R-191).
C. High side of Horizontal Hold control	82,000 ohms, $\frac{1}{2}$ watt resistor (R-178) added.
D. Sync. Clipper plate (pin 5) circuit supply	10,000 ohms, 1 watt resistor (R-192) added.
E. Sync. clipper plate (pin 5) circuit supply	22,000 ohms, 1 watt resistor (R-193) added.
F. Sync. Clipper plate (pin 5) circuit supply	10 mfd., 150 v. electrolytic capacitor (C-169) added.
G. AGC Control Switch	Switch S-102 (60B500) replaced by S-103 (60B507).
H. AGC Control Switching	22,000 ohms, 1 watt resistor (R-188) added.

MODIFICATION VII

To use a 1C1376 Cascode tuner in place of the 1C1345 Pentode tuner the following changes are made:

A. The 1C1345 Pentode tuner is removed and replaced by the 1C1376 Cascode tuner. These two tuners do not have the same terminal connections. Refer to schematic diagram. The 1C1376 Cascode tuner may be used only with chassis which have a heater transformer.
B. A wire to supply 260 volts d-c is added between tuner terminal 4 of the Cascode tuner and the junction of R-120 (33,000 ohms, 1 watt, the video amplifier screen resistor) and the 260 volt "B" supply.

MODIFICATION VIII

Whenever the picture tube used has a metal cone which eliminates the high voltage filter capacitor built into tubes with an outer aquadag coating, C-166 (500 mmf. 20,000 volts) is required between pin 7 and ground of the 1B3GT high voltage rectifier. Resistor R-210 (1 megohm 1 watt) was added in series with the anode lead on some chassis with metal cone picture tubes.

MODIFICATION IX

A. A deeper chassis with a depth of 3 3/4" instead of 3" is used.
B. The tuner, three i-f amplifiers, video detector, video amplifier, 4.5 MC amplifier and the ratio detector are mounted on a separate sub-chassis.
C. Test socket SO-101 is deleted.
D. The 6C4 audio amplifier tube, V-114, is moved to a new location slightly forward and to one side of the vertical output transformer.

MODIFICATION X

The horizontal stabilizer coil L-108 (55B1536) is replaced by coil 51B1642 and its mounting plate 63A902. When coil 51B1642 is used for L-108, plate 63A902 must also be used and either C-142 (75 mmf.) or C-170 (100 mmf.) connected between pin 5 of the horizontal oscillator and ground is deleted. Coil 51B1642 is preferred. However, the 55B1536 coil will be found in some chassis. Use coil 51B1642 and plate 63A902 for replacement purposes.

MODIFICATION XI

To use a 1E1380 Cascode tuner in place of the 1C1345 Pentode tuner the following changes are made:

A. The 1C1345 Pentode tuner is removed and replaced by the 1C1380 Cascode tuner. The 1E1380 tuner does not have terminal lugs on the back. The wire leads from this tuner must be connected to the correct points in the chassis as shown in the schematic diagram. The 1E1380 tuner also requires a supply voltage of approximately 250 volts as shown in the schematic diagram. The 1E1380 tuner may be used only with 3 3/4" deep chassis which have a heater transformer.
B. Resistor R-101 (100,000 ohms, ½ watt) in the A.G.C. bus is not required.

MODIFICATION XII

The vertical and horizontal hold controls are moved from the rear apron of the chassis to a removable plate mounted on the front apron of the chassis.

MODIFICATION XIII

A 16 position VHF Cascode tuner (1E1483) is used along with the 1E1484 UHF tuner. At the same time, the i-f frequency is shifted to a higher frequency covering 41.25 MC to 45.75 MC instead of 21.75 MC to 26.25 MC. The associated circuit changes are easily identified in the schematic diagram by the schematic symbols in the 200 catagory which were assigned to those components required to make this change in i-f frequency.

MODIFICATION XIV

To improve vertical and horizontal sync particularly under extreme fringe area receiving conditions the following changes will be found in chassis which have a RUN 1A chassis stamp except the Y1200D which has this change in RUN 1.

A. 10,000 ohms, ½ watt resistor (R-124) replaced by 22,000 ohms, ½ watt resistor (R-195).
B. 470,000 ohms, ½ watt resistor (R-125) replaced by 220,000 ohms, ½ watt resistor (R-196).
C. 47,000 ohms, ½ watt resistor (R-183) replaced by 33,000 ohms, ½ watt resistor (R-197).
D. 22 mmf. 500 V., ceramic tubular capacitor (C-124) replaced by 47 mmf. 500 V., ceramic tubular capacitor (C-172).
E. 1000 mmf. 500 V., ceramic disc capacitor (C-171) added between pin 5 and ground of the 12AX4 damper tube V-110.

CHANGES FOR RUN 2 OF THE Y1200D & Z1200D CHASSIS

1. A 100 ohm ½ watt resistor (R-211) was added in series with the +B bus feeding V-101 and the tuner.

2. A 1000 mmf. ceramic disc capacitor (C-176) was added between the power supply side of R-211 and ground.

3. A 1000 mmf. ceramic disc capacitor (C-175) was added between the power supply side of R-209 and ground. The other side of R-209 is connected to pin 10 of the VHF tuner.

4. The UHF input coil in the VHF tuner (L-1 in the schamctics) was made adjustable by either one of two methods. The first method used was to insert a small self-supporting coil in series with the co-axial cable from the UHF tuner where it connects to pin 7 of the VHF tuner. This coil was adjusted by spreading or squeezing the turns. The next method used consisted of replacing L-1 in the VHF tuner with a coil having an adjustable iron core.

5. Capacitor C-308 (100 mmf. ceramic tubular) at the UHF tuner end of the co-axial cable between the UHF and VHF tuners had an additional 120 mmf. ceramic tubular capacitor connected in parallel with it. The value of this additional parallel capacitor was varied in some chassis in order to obtain the desired bandwidth in this coupling circuit. If replacement is necessary be sure to use a capacitor with the same value as the one found in the chassis.

CHANGES FOR RUN 3 OF THE Y1200D & Z1200D CHASSIS

1. Changes 1 through 5 shown above for the Run 2 changes were incorporated except that in change 4 the only coil used for L-1 had an adjustable iron core.

2. Heater choke (L-205) was inserted in series with the brown heater lead to the UHF tuner.

3. Pin 9 of the VHF tuner was by-passed by a 1000 mmf. ceramic disc capacitor C-178.

4. The position of R-207 (100 ohms 1 watt) was changed so that the plate current for the VHF tuner, V-101 and V-102 flows through it instead of the plate current for V-103 plus the VHF tuner, V-101 and V-102.

5. The junction of R-207 (100 ohms 1 watt moved in the above step) and R-205 (470 ohms ½ watt) was by-passed by the addition of capacitor C-177 (1000 mmf. ceramic disc).

6. In the Video Detector circuit the junction of R-116 and R-117 was moved from the junction of C-114, L-102 and L-103 to the junction of R-114 and L-103.

7. Resistor R-212 (10,000 ohms ½ watt) was added to the AGC circuit for V-101 and V-102.

CHANGES FOR RUN 4 OF THE Y1200D & Z1200D CHASSIS

1. Run 4 for both of these chassis is the same as the Run 3 chassis except that the video peaking coil L-107 and resistor R-123 on which L-107 is wound are replaced by a wire jumper.

CHANGES FOR RUN 5 OF THE Y1200D & Z1200D CHASSIS

A. In the grid circuit (pin 1) of V-105 resistor R-195 (22,000 ohms, ½ watt) is replaced by R-124 (10,000 ohms, ½ watt) and R-196 (220,000 ohms, ½ watt) is replaced by R-125 (470,000 ohms, ½ watt).

B. In the plate circuit (pin 2) of V-105 resistor R-190 (1.2 megohms, ½ watt) is replaced by R-213 (820,000 ohms, ½ watt).

C. In the grid and cathode circuits of V-105 (pins 1 & 3) capacitor C-172 (47 mmf.) is replaced by C-124 (22 mmf.).

D. In the plate circuit of V-106A (pin 1) resistors R-136 (3300 ohms, ½ watt) and R-137 (1800 ohms, ½ watt) are transposed so that R-136 goes to ground and R-137 connects to C-130 and C-131. The junction of the two resistors connects as before.

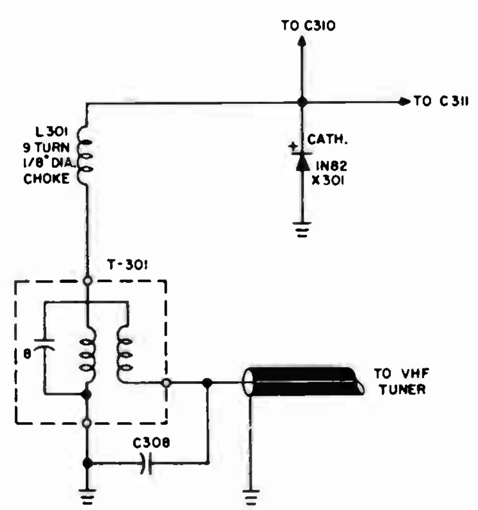
E. In the plate circuit of V-104 (video amp.) peaking coil L-107 and resistor R-123 on which it is wound is added to the circuit in series with the power supply and R-121.

F. In the Servo Loop feedback from the horizontal output to the AFC tube (V-107 pins 5 & 7), capacitor C-140 (.001 mfd. 1000 V. molded tubular) is replaced by two .01 mfd. ceramic disc capacitors (C-179 & C-180).

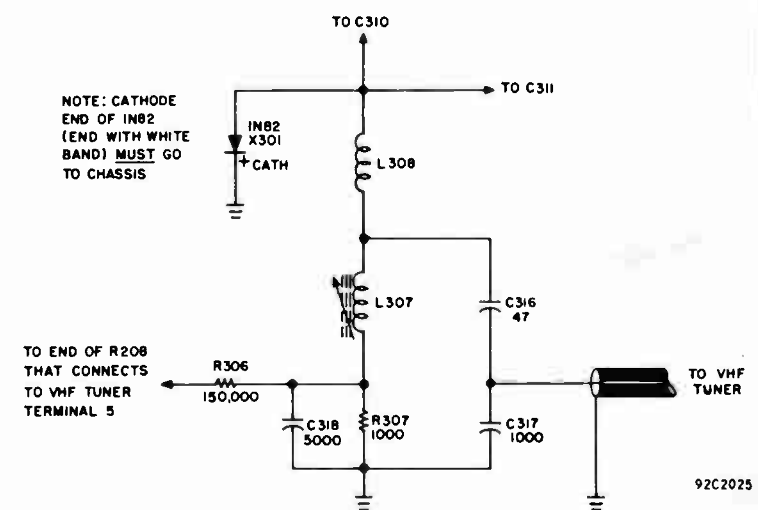
G. Capacitor C-181 (1000 mmf. 500 V., ceramic disc) was added between the positive terminal of C-119A (200 mfd. 150 V., electrolytic) and ground.

H. A shield was placed over the bottom of the video detector transformer T-203.

I. The i-f output coupling circuit of the 1E1484 or 1E1659 UHF tuner was changed at the factory as shown in the following partial schematics:



CIRCUIT BEFORE MODIFICATION



CIRCUIT AFTER MODIFICATION

T-301	I-F coupling tranformer	50A600
L-301	r.f. choke	53A290
C-308	100 mmf. ceramic (1E1484)	47A351
C-308	150 mmf. ceramic (1E1659)	47A394

L-307	I-F coupling coil	51-1708
L-308	r.f. choke	53-302
C-316	47 mmf. tubular ceramic	47B20470K5
C-317	100 mmf. tubular ceramic	47B20101K5
C-318	5000 mmf. disc ceramic	47A168
R-306	150,000 ohms ½ watt	23X20X154K
R-307	1000 ohms ½ watt	23X20X102K

SERVICE ADJUSTMENTS

Note: The controls whose adjustment is outlined below are all located on the rear apron of the chassis with the exception of the centering device which is located on the neck of the picture tube. The sequence of "SERVICE ADJUSTMENTS" outlined herein is suggested as a convenient method of approach and is not an arbitrary procedure. Variations of the procedure are permitted to obtain the desired final results. The operating controls, located on the front panel, should be set for as good a pattern as possible before making any of the following adjustments.

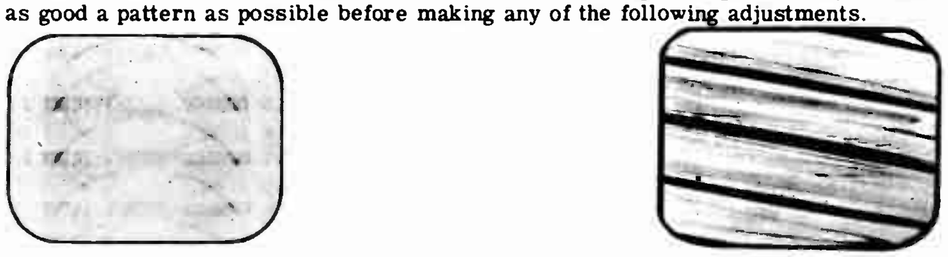


Fig. 73A. Improper Hold Control Adjustments

VERTICAL AND HORIZONTAL HOLD CONTROLS - These two controls should be adjusted until a single steady picture is obtained. With average signal strength it should be possible to switch from one active channel to another without losing sync when these two controls are properly adjusted. These two controls will be found on the front apron of some chassis.

Fig. 73B. Improper Centering Adjustments

CENTERING - Place the horizontal centering control, located on the rear apron of the chassis, in the approximate center of the range over which it may be rotated. Rotate the two ring magnets of the centering device around the neck of the picture tube until the picture is properly centered. Each ring magnet is provided with an ear for making this adjustment. The centering device should contact the rear of the deflection yoke. A slight readjustment of the ion trap may be necessary after adjusting the centering device. The horizontal centering control may now be adjusted as required for a fine adjustment of the horizontal picture centering.

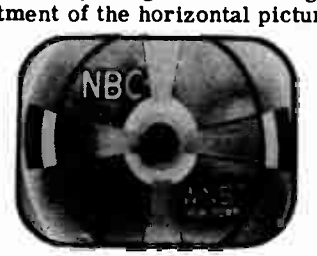

Fig. 73C. Improper Height Control Setting

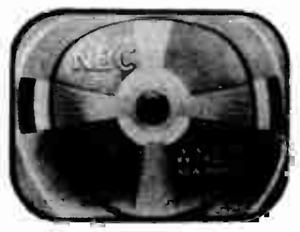

Fig. 73D. Improper Vertical Linearity Control Setting

HEIGHT CONTROL AND VERTICAL LINEARITY ADJUSTMENT - A test pattern will be required for the proper adjustment of these two controls. The height control has a pronounced effect on the overall picture height and at the same time the adjustment of this control will expand or contract the top of the picture more than the bottom. The vertical linearity control will affect the height somewhat but will have a more pronounced effect on the bottom portion of the picture. The interaction between these two controls makes it necessary to adjust both for proper picture height and vertical linearity.

A.G.C. CONTROL SWITCH - The A.G.C. control switch should be adjusted for the best average performance on all active channels.

With this switch set in the 0-10 MILE position (counterclockwise) maximum AGC voltage is applied to the tuner. The video amplifier will not be overloaded by strong signals.

With this switch set in the OVER 30 MILES position (clockwise) minimum AGC voltage is applied to the tuner. Snow in the picture will be at minimum when the switch is in this position under weak signal or fringe area receiving conditions. If the AGC control switch is left in this position in areas where strong signals are received, poor picture quality will result along with a probable intercarrier buzz in the speaker. In some cases the sync pulses will be clipped and trouble will be encountered which will appear like a loss of sync unless this switch is properly adjusted.

WIDTH CONTROL - The width control should be adjusted until the picture fills the screen horizontally. Rotating this control in the clockwise direction will increase picture width while counterclockwise rotation will decrease picture width.

BRIGHTNESS CONTROL - This control should be adjusted in any given location for the best average picture from the various active channels which may be received.

FOCUS CONTROL - Adjust this control until the fine horizontal lines which make up the picture are clearly visible. Use the lines in the center portion of the picture for this adjustment.

HUM ADJUSTMENT - A small rheostat will be found mounted on the frame of some of the speakers. Adjust this rheostat with a small screw driver for minimum audible hum in the speaker.

PICTURE TUBE REMOVAL

1. Remove the chassis from the cabinet. Note that on chassis with the horizontal and vertical hold controls on the rear apron the knobs on the control shafts and the A.G.C. control switch must be removed before the cabinet back may be removed. These are push-on type knobs.
2. Insure the discharge of the high voltage power supply by disconnecting the anode plug and shorting it to the chassis. Also short the anode socket or metal cone of the picture tube to the chassis.
3. Remove the picture tube socket from the base of the tube.
4. Slip the ion trap and the centering device from the neck of the tube. On some chassis, the centering device is an integral part of the deflection yoke assembly.
5. Carefully remove the rear support tension spring on each side of the picture tube. If a glass cone picture tube is involved, remove the metalized paper picture tube shield and ground by unhooking the springs on each side and the hook on the top center of the picture tube mounting strap.
6. Remove the mounting strap from the front rim of the picture tube.
7. Lift the front of the picture tube just far enough to clear the front mounting brackets and slip the tube forward until the neck is clear of the deflection yoke and the rubber collar. Use a slight twisting pull to break the cone of the tube from the rubber collar if the two are stuck together. Loosen the deflection yoke adjustment screw if required for clearance when raising the front of the picture tube over the front mounting brackets.

CAUTION - IF THE TUBE FAILS TO SLIP OUT EASILY, INVESTIGATE AND REMOVE THE CAUSE OF TROUBLE. DO NOT USE FORCE AS THE NECK OF THE PICTURE TUBE IS EASILY BROKEN.

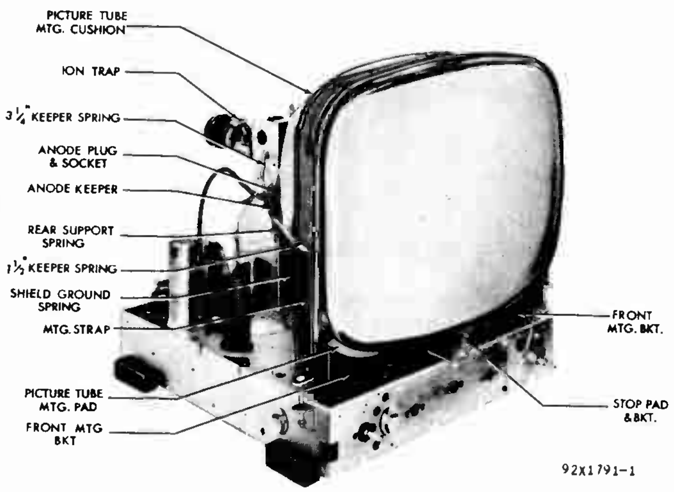

Fig. 75A. 17" Glass Pix Tube Mounting

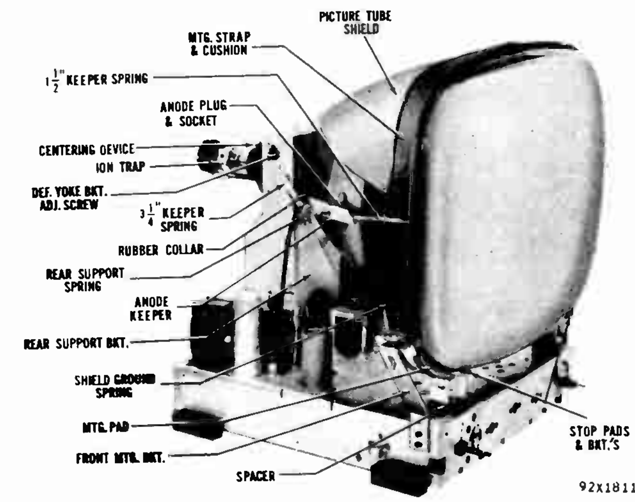

Fig. 75B. 20 or 21" Glass Pix Tube Mounting

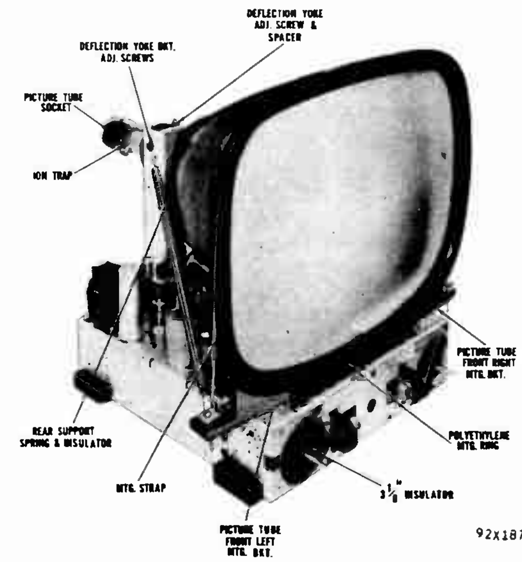

Fig. 75C. 21" Metal Pix Tube Mounting

PICTURE TUBE INSTALLATION AND ADJUSTMENT

1. Position the tube so that the anode socket is located at the left side of the tube when viewed from the front face. A metal cone tube will not have an anode socket but will require the polyethylene mounting ring around the front rim of the tube with the joint in the ring on the bottom center of the tube.

2. Insert the neck of the tube through the rubber collar and the deflection yoke. Seat the front of the tube on the front mounting brackets. The groove in the polyethylene mounting ring fitting over the front mounting brackets or the picture tube face resting against the front stop pad will determine the forward position of the tube. Be sure that the face of the picture tube rests against the stop pad and not against the bracket for this pad which is provided on chassis which use glass cone picture tubes.

3. Place the mounting strap around the front of the tube. On metal cone tubes place the 4" rubber strip in the top center of the groove in the polyethylene mounting ring. At the same time be sure that the copper anode connector strap is inserted under the polyethylene mounting ring on the left side of the tube when viewed from the front. Be sure the picture tube mounting cushion is placed under the mounting strap for glass cone tubes.

4. Tighten the screws on each end of the mounting strap and replace the rear support tension spring on each side of the picture tube. On glass cone picture tubes replace the metalized paper picture tube shield and ground with the metalized surface next to the tube. The hook in the center of this shield should be hooked over the top center of the picture tube mounting strap and the springs on each end should be hooked around the screws on each end of the mounting strap. If the replacement glass pix tube does not have an outer aquadag coating it will be necessary to install C-166 (500 mmf. 20 KV.). See schematic. This capacitor will already be installed in chassis with metal cone picture tubes.

5. Press the deflection yoke firmly forward against the cone of the picture tube and tighten the deflection yoke adjusting screw.

6. The picture tube neck should pass through the approximate center of the deflection yoke. If it does not, loosen the deflection yoke bracket adjustment screws and reposition the yoke.

7. Slide the centering device over the neck of the tube. This device should be installed directly behind and contacting the deflection yoke with the adjusting ears for the two ring magnets as near to the deflection yoke as possible. On some chassis the centering device is an integral part of the deflection yoke assembly.

8. Check the ion trap for any marking and slip the trap over the neck of the tube. If the trap is marked with an arrow, the arrow should point towards the face of the tube.

9. Connect the picture tube anode plug and replace the anode keeper and springs if a glass pix tube is being installed.

10. Connect the picture tube socket and turn the receiver on. Don't forget the chassis is "hot" - use an isolation transformer.

11. Turn up the brightness control and set the ion trap for maximum raster brilliance, backing off the brightness control as the maximum point is approached. The ion trap must be rotated about the axis of the tube as well as shifted along the neck to obtain the proper setting.

12. Tune in a test pattern and set the focus, brightness and contrast controls for as good a picture as possible.

13. Check the position and appearance of the test pattern. If it is off center or shadowed at the corners, adjust the ears of the centering device by rotating them about the axis of the picture tube until proper centering is obtained. An additional horizontal centering control is located on the rear apron of the chassis. This control should be in the approximate center of the range over which it may be rotated before adjusting the centering device.

14. If the lines of the raster are not horizontal or square with respect to the escutcheon, loosen the deflection yoke adjustment screw and rotate the deflection yoke until the proper raster position is obtained. Press the deflection yoke firmly against the cone of the picture tube and tighten the adjustment screw.

15. Follow the procedure under "SERVICE ADJUSTMENTS" and make any minor adjustments necessary to obtain a properly adjusted pattern.

HIGH VOLTAGE WARNING

OPERATION OF THE RECEIVER CHASSIS OUTSIDE OF THE CABINET INVOLVES DANGER OF ELECTRICAL SHOCK. USE A POWER LINE ISOLATION TRANSFORMER AND EXERCISE ALL NORMAL HIGH VOLTAGE PRECAUTIONS WHEN WORKING WITH THIS RECEIVER.

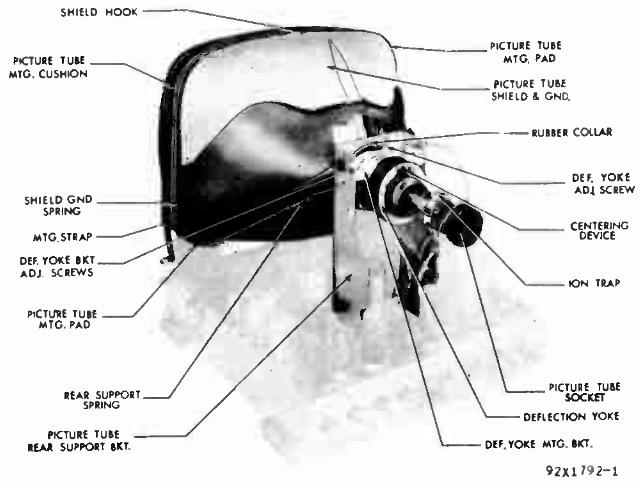

Fig. 77A. 17" Glass Pix Tube Mounting

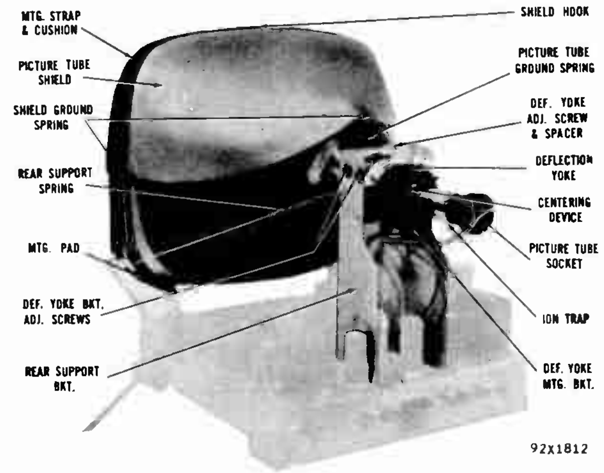

Fig. 77B. 20 or 21" Glass Pix Tube Mounting

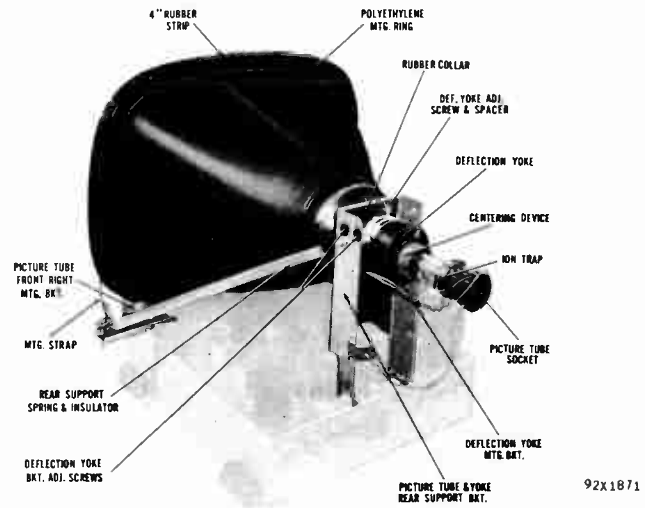

Fig. 77C.! 21" Metal Pix Tube Mounting.

PICTURE TUBE ANODE HIGH VOLTAGE MEASUREMENT

The second anode potential for a 17 inch tube will be approximately 11,500 volts and approximately 14,000 volts for a 20 or 21 inch tube. If it is possible to obtain good picture brilliance, the second anode potential is correct and need not be measured.

The setting of the width control will affect the high voltage on the second anode. If the width control is set for excessive width, the second anode potential will be low.

If it is necessary to measure the voltage present on the second anode, a meter specifically designed for high voltage measurements should be used. The contrast and brightness controls should be rotated to the minimum position and the anode plug should be connected to the tube. Under these conditions the test meter will load the high voltage power supply approximately the same amount as the picture tube would during normal operation.

SAFETY FIRST

DO NOT USE HAND HELD FLEXIBLE TEST LEADS WHEN MAKING SECOND ANODE HIGH VOLTAGE MEASUREMENTS. ANY ACCIDENTAL CONTACT WITH THE HIGH VOLTAGE PRESENT IN THIS CIRCUIT MAY CAUSE A SEVERE BURN OR IN SOME CASES BE FATAL.

HORIZONTAL OSCILLATOR ADJUSTMENT FOR CHASSIS A1200D & X1200D

If the horizontal hold control fails to restore synchronization, the horizontal stabilizer coil (L-108) should be adjusted. Procedure for this adjustment is as follows:

1. Set the brightness control for normal picture brightness and turn the contrast control as low as possible with a picture still visible on the screen.
2. Turn the horizontal centering control, located on the rear apron of the chassis, full clockwise. The right side of the raster should now be visible. If not, reduce the width of the picture by turning the width control counterclockwise until the right edge of the raster does become visible.
3. Connect a .1 mfd. 600 V. tubular capacitor between test point (A) and the chassis. See Fig. 78B.
4. Adjust the horizontal hold control for a single steady picture whose right edge is approximately ¼ inch to the left of the right edge of the raster. See Fig. 78A.
5. Remove the .1 mfd. 600 V. capacitor installed in step 3.
6. Adjust the horizontal stabilizer coil, (L-108) until the right edges of the picture and the raster are the same distance apart as they were set in step 4. See Fig. 78A.
7. Readjust the horizontal centering control and the width control for normal operation.

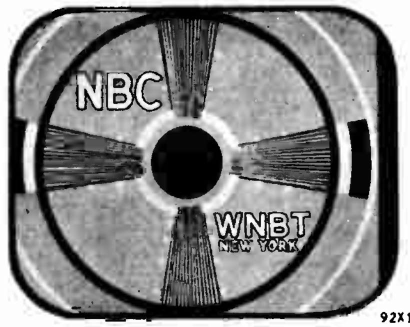

Fig. 78A. Test Pattern for Horizontal Stabilizer Adjustment

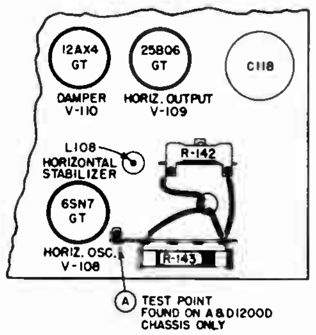

Fig. 78B. Horizontal Oscillator Adjustment Point for Chassis with Series—Parallel Heaters

HORIZONTAL OSCILLATOR ADJUSTMENT FOR CHASSIS F, G, J, K, L, P, R, T, W, X, Y AND Z1200D

If the horizontal hold control fails to restore synchronization, the horizontal stabilizer coil (L-108) should be adjusted. Procedure for this adjustment is as follows:

1. Set the horizontal hold control in the approximate center of the range over which it may be rotated.
2. Set the channel selector to an active channel and adjust the horizontal stabilizer for a single steady picture. See Fig. 78B or 78C.
3. Rotate the horizontal hold control full clockwise. The picture may or may not remain in sync. If it does, momentarily switch the channel selector to another channel and return it to the original channel. The picture should now be slightly out of sync.
4. Rotate the horizontal hold control full counterclockwise. The picture may or may not remain in sync. If it does, momentaril switch the channel selector to another channel and return it to the original channel. The picture should now be slightly out of sync.

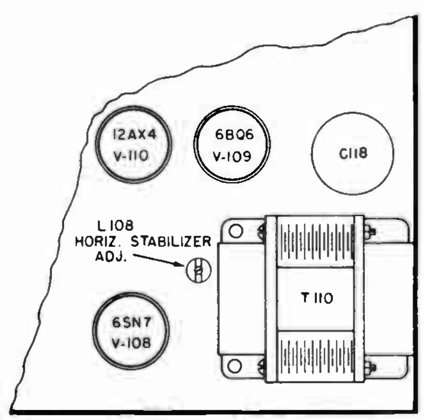

Fig. 78C. Horizontal Oscillator Adjustment Point for Chassis with Heater Transformer

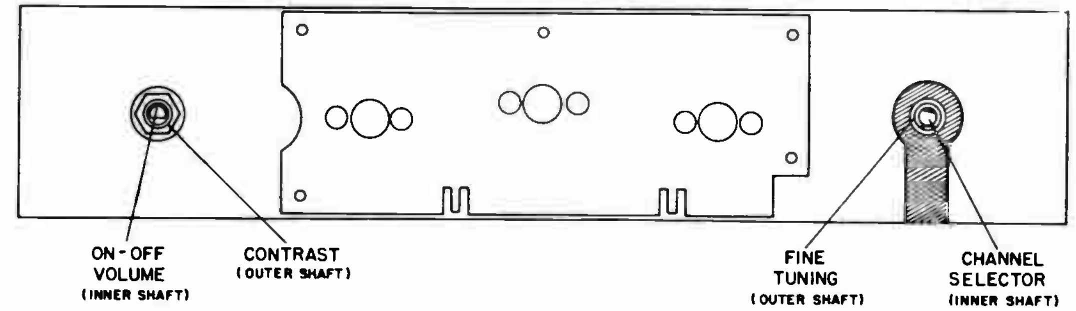
When the horizontal stabilizer coil is properly adjusted the results outlined in steps 3 and 4 will be obtained. If the correct results are not obtained, repeat steps 2, 3 and 4 until they are.



THE P & R1200D ARE DEEP CHASSIS. SEE MODIFICATION IX ON PAGE 1952-72D.

Fig. 79A. Front Controls for Chassis A, D, F, G, K, L, P, R, W, and X1200D

FM SOUND CHANNEL ALIGNMENT FOR 1200 SERIES CHASSIS

EQUIPMENT REQUIRED

Signal generator covering 4 to 30 mc. unmodulated.

Vacuum tube voltmeter (VTVM).

Sound alignment test circuit shown in Fig. 80A.

Power line isolation transformer.

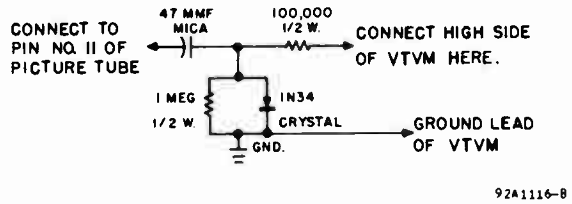

Fig. 80A. Sound Alignment Test Circuit

PROCEDURE

1. Connect all test equipment to a common ground. Connect the TV chassis to this same ground after installing an isolation transformer between the power line and the TV chassis. One side of the line cord connects directly to the TV chassis and an isolation transformer must be used for safety.

2. Set the channel selector to any vacant channel and the contrast control at minimum.

3. Connect the signal generator output through a .005 mfd. capacitor to terminal 2 of test socket SO-101 shown in Figs. 79AA, 79AB, 81A & 81B or test point (D) shown in schematic diagram. Ground the shield of the generator output cable to terminal 1 of the test socket or the chassis.

4. Connect the sound alignment detector circuit and VTVM as shown in Fig. 80A. Adjust the 4.5 mc. generator output (unmodulated) to give a 1 volt reading on the VTVM.

5. Adjust the 4.5 mc. trap adjustment (L-105) at 4.5 mc. for a minimum VTVM reading.

6. Disconnect the test circuit and connect the VTVM to test terminal (B) (Pin 2 of FM detector, V-113). See schematic diagram.

7. Adjust the 4.5 mc. amplifier grid adjustment (L-110) and the primary of T-107 (bottom core) at 4.5 mc. for a maximum VTVM reading.

8. Connect the VTVM to test terminal (C), shown in the schematic diagram. Adjust the secondary of T-107 (top core) at 4.5 mc. for the zero reading which occurs between the positive and negative peaks. If the zero reading occurs at more than one setting, use the position nearest the top limit of the core.

9. Shift the signal generator an equal amount on either side of 4.5 mc. and touch up the primary of T-107 (bottom core) for approximately equal peaks. Use just enough signal output to obtain one volt peaks for best results.

I-F AMPLIFIER ALIGNMENT FOR 1200 SERIES CHASSIS EXCEPT Y & Z1200D (See Page 48.)

EQUIPMENT REQUIRED

SWEEP GENERATOR	RCA type WR-59B or equivalent.
MARKER GENERATOR	RCA type WR-39C Television Calibrator or equivalent.
OSCILLOSCOPE	RCA type WO-56A or equivalent.
VACUUM TUBE VOLTMETER (VTVM)	RCA type WV-97A or equivalent.
BIAS SOURCE	Three volt battery.
TEST CIRCUIT	Shown in Fig. 82A.
ISOLATION TRANSFORMER	150 watt rating or higher.

PROCEDURE

1. Connect all test equipment to a common ground. Connect the TV chassis to this same ground after installing an isolation transformer between the power line and the TV chassis. One side of the line cord connects directly to the TV chassis and an isolation transformer must be used for safety. Allow a 15 minute warm up period.

2. Set the AVC switch on the rear chassis apron to the 0-10 MILE (counterclockwise) position.

3. Connect the negative side of a 3 volt battery supply to pin 3 of test socket SO-101 or test point Ⓔ. Connect the positive side of the supply to the TV chassis.

4. Connect a VTVM to pin 2 of test socket SO-101 or test point Ⓓ through a 47,000 ohm carbon resistor. Connect the ground side of the meter to the TV chassis.

5. Connect the high side of a marker generator to the shield of the osc./mixer tube. This connection will capacitively couple the generator output to the tube. Make sure the shield is ungrounded by raising it above the grounded clips that hold it in place.

6. Set the channel selector to any vacant channel.

7. Set the marker generator output (unmodulated) for a two volt negative dc reading on the VTVM and adjust the three i-f transformers, L-9, and L-101 according to the I-F AMPLIFIER ALIGNMENT CHART shown below. Readjust the signal generator output as required to maintain the two volt VTVM reading.

I-F AMPLIFIER ALIGNMENT CHART

Signal Generator Frequency (No Modulation)	Adjustment	Location	VTVM Indication
25.4 MC	T-101 (bottom)	See Fig. 81A	Maximum
23.4 MC	T-102 (bottom)	Under Chassis	Maximum
24.5 MC	T-103 (bottom)	See Fig. 81A	Maximum
21.75 MC	T-102 (top)	See Fig. 81A	Minimum
23.4 MC	T-102 (bottom)	See Fig. 81A	Maximum
24.75 MC	*L-101	See Fig. 81A	Maximum
24.75 MC	#L-9	See Fig. 81A	Maximum

IMPORTANT — The wax in the end of the coil forms holding the iron core in position may be softened for adjustment of the core by means of a heated screwdriver or a small pencil type soldering iron inserted into the wax. Remelt wax after adjustment.

* NOTE: On chassis with the 1E1345 Pentode and 1E1376 Cascode tuners, temporarily connect the series resistor-capacitor combination shown in Fig. 82A to the tuner test point TP-2 when making this adjustment. On chassis with the 1E1380 Cascode tuner, hold the channel selector between channels when making this adjustment.

#NOTE: Temporarily connect the series resistor-capacitor combination shown in Fig. 82A to the grid (pin 1) of V-101 the 6CB6 first i-f amplifier when making this adjustment.

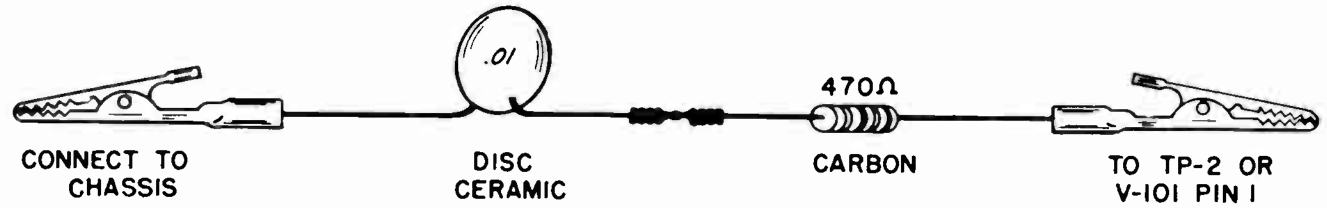

Fig. 82A. Test Circuit for I-F Amplifier Alignment

8. Disconnect the VTVM and marker generator connected in steps 4 and 5. The balance of the set-up should be as directed in steps 1, 2, 3 and 6.

9. Capacitively couple the high side of the sweep generator r-f output to the osc./mixer tube by connecting to the tube shield which has been raised above its grounding clips. The ground side of the sweep generator should be connected to the receiver chassis. Adjust the generator to sweep from 19 to 29 MC.

10. Loosely couple the high side of the marker generator to the high side of the sweep generator by clipping the marker generator r-f lead over the insulation of the sweep generator r-f lead. The ground side of the marker generator should be connected to the receiver chassis.

IMPORTANT - To prevent overloading of the i-f amplifier keep the output of the sweep and marker generators as low as possible. The marker generator output should be just high enough to produce visible pips on the pattern. In some cases the 21.75 MC pip will not be visible unless the r-f. output of the marker generator is increased to overcome the attenuation of the 21.75 MC signal by the trap in the top of T-102.

11. Connect the sweep output terminals on the sweep generator to the input of the horizontal amplifier in the oscilloscope.

12. Connect one side of a 47,000 ohm 1/2 watt resistor to test socket, SO-101, pin 2 or to test point Ⓓ shown in the schematic diagrams for chassis which do not have the test socket. Connect the other end of the resistor to the high side of the input terminals for the vertical amplifier in the oscilloscope. The scope ground terminal connects to the receiver chassis. Keep the scope leads away from the internal chassis wiring, particularly the horizontal output section.

13. Reduce the r-f output of the sweep generator and increase the gain of the vertical amplifier in the oscilloscope as much as possible without introducing an excessive amount of noise on the test pattern. This will prevent overloading of the i-f system.

14. Check the position of the markers shown in Fig. 84A. Adjust only the bottom cores of T-101, T-102 and T-103 for a response curve of maximum amplitude with a slightly tilted flat topped appearance as shown in Fig. 84A. This tilt is required to compensate for the capacitive coupling used for the signal generators. The actual response obtained will be flat when the pattern viewed on the oscilloscope has this tilt. The bottom core of T-103 will primarily control the tilt of this central portion of the curve.

The bottom core of T-101 should be adjusted to position the 26.25 MC marker in the 50% position shown in Fig. 84A.

The bottom core of T-102 should be adjusted to determine the slope of the curve between 21.75 MC and 23.4 MC with the 22.75 MC marker down 50% on the curve as shown in Fig. 84A.

Under no circumstances should an attempt be made to adjust L-9, L-101 and the 21.75 MC trap in the top of T-102 by means of an oscilloscope and sweep generator. Maladjustment of these coils does not give a noticeable indication on the oscilloscope. Align these coils by following the procedure given in steps 1 through 7 only.

MEASUREMENT OF I-F AMPLIFIER SENSITIVITY

To determine the i-f amplifier sensitivity, disconnect the r-f output lead from the tuner where it connects to L-101. Temporarily connect one side of a .005 mfd. ceramic or mica capacitor to grid pin 1 of the 6CB6 first i-f amplifier tube V-101. Connect the unmodulated r-f output of a marker generator to the other side of the capacitor and the ground side of the generator to the TV chassis. Set the marker generator to 24.75 MC. Connect a VTVM as directed in step 4 of the alignment procedure. The three volt battery must be removed. If a generator output of 200 to 400 microvolts produces a 1 volt reading on the VTVM, the i-f amplifier sensitivity is normal.

TELEVISION CHANNELS vs. CARRIER, OSCILLATOR AND I-F FREQUENCIES

Channel No.	Channel Freq. (mc)	Picture Carrier Freq. (mc)	Sound Carrier Freq. (mc)	Receiver Osc. Freq. (mc)	Picture I-F Freq. (mc)	Sound I-F Freq. (mc)	Picture I-F less Sound I-F (mc)
2	54-60	55.25	59.75	81.5	26.25	21.75	4.5
3	60-66	61.25	65.75	87.5	26.25	21.75	4.5
4	66-72	67.25	71.75	93.5	26.25	21.75	4.5
5	76-82	77.25	81.75	103.5	26.25	21.75	4.5
6	82-88	83.25	87.75	109.5	26.25	21.75	4.5
7	174-180	175.25	179.75	201.5	26.25	21.75	4.5
8	180-186	181.25	185.75	207.5	26.25	21.75	4.5
9	186-192	187.25	191.75	213.5	26.25	21.75	4.5

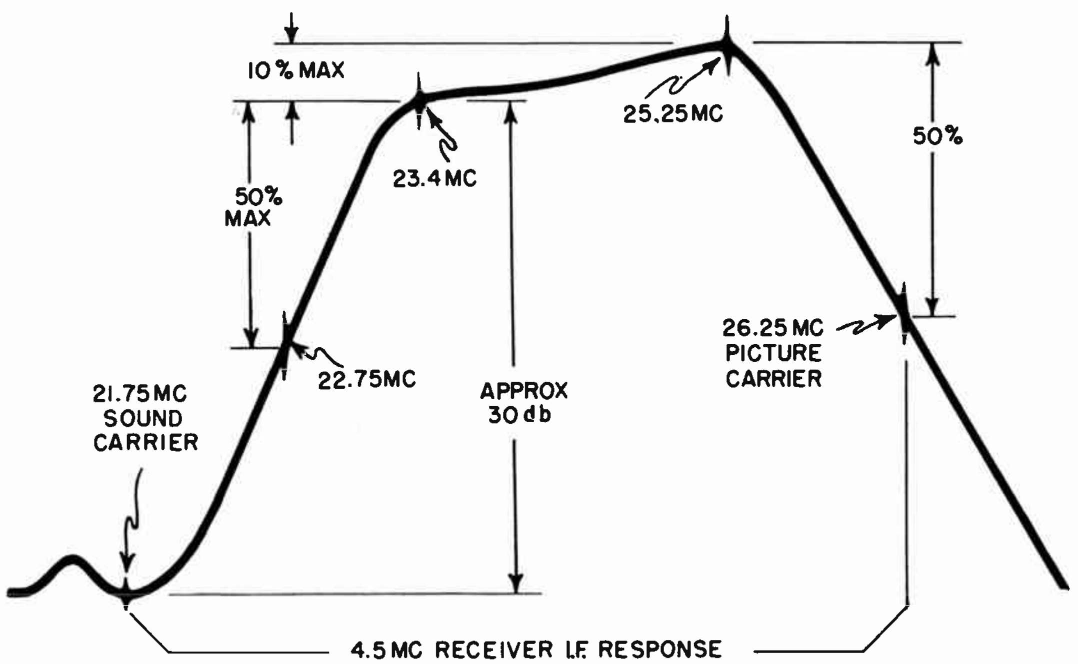
13	210-216	211.25	215.75	237.5	26.25	21.75	4.5

Fig. 84A. Typical Response for 21.75 to 26.25 MC I-F Amplifier



ALIGNMENT FOR 1C1345 PENTODE & 1C1376 CASCODE TV TUNERS

These tuners have been carefully aligned at the factory by personnel using precision equipment. Minor alignment adjustments of the tuner may be necessary after making tube or part replacements. When replacing tubes in a tuner use the same tube type as the original tube which was removed from the tuner and also try several different tubes and select the one which gives best performance. Realignment of the tuner probably will not be required if a selected tube is used for replacement. Use of an alternate tube may require a complete realignment of the TV tuner. For those service engineers who are properly equipped as specified, the following alignment procedure is included. Balance of TV receiver must be functioning properly before aligning tuner.

EQUIPMENT REQUIRED FOR TV TUNER ALIGNMENT

1. Sweep generator ______ RCA type WR-59B or equiv.
2. Marker Generator ______ RCA type WR-39C Television Calibrator or equivalent.
3. Oscilloscope ______ RCA type WO-56A or equiv.
4. Bias Source ______ 1.5 volt battery.
5. Isolation Transformer ______ 150 watt rating or higher

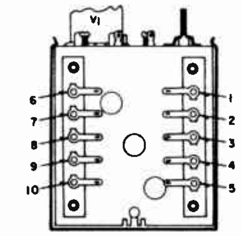


Fig. 85A. Numbering of Tuner Terminals

SET-UP PROCEDURE FOR TUNER ALIGNMENT

1. Check to be sure that the tube shields and the bottom cover for the tuner are in place.
2. Connect all test equipment and the television chassis to a common ground. Be sure to use an isolation transformer for the receiver chassis. Allow at least a 5 minute warm-up period for the receiver chassis.
3. Connect the negative terminal of a 1.5 volt bias source to terminal 8 of the TV tuner. See Fig. 85A for terminal numbering. Connect the positive side of the bias source to any convenient ground point on the chassis.
4. Connect the hot lead from the oscilloscope through a 10,000 ohm carbon resistor to test point T.P.-1 (See page 1952-86). Connect the ground lead from the oscilloscope to any convenient ground point on the TV tuner chassis. Set the scope sweep oscillator to roughly 120 cycles.

OSCILLATOR ADJUSTMENT

1. Turn the channel selector to channel 13.
2. Set the marker generator to 237.5 mc. and connect generator leads to the antenna terminals.
3. Rotate the fine tuning control until a zero beat is indicated on the scope. When the fine tuning control is rotated a band will appear across the face of the scope. As the point of zero beat is approached this band will increase in amplitude and then decrease sharply until a minimum is reached which is the point of zero beat. If the fine tuning control is rotated farther in the same direction the amplitude of the band will increase sharply and then decrease. The point of zero beat should fall in the approximate center of the range over which the fine tuning control may be rotated. If it does not, set the fine tuning control at the approximate center of its range and adjust L-7 (Channel 13 Oscillator Adjustment) for the zero beat. Do not disturb the setting of the fine tuning control after this adjustment.
4. Set the channel selector to channel 6.
5. Set the marker generator to 109.5 mc.
6. Adjust L-8 (Channel 6 Oscillator Adjustment) for the zero beat indication on the scope.

NOTE: Adjustment of the channel 13 and channel 6 oscillator coils automatically brings all other channel into adjustment. The adjustment screws cover their entire electrical range within eight full revolutions counterclockwise from the tight position. Any further rotation of these screws may cause them to fall out. Counterclockwise rotation of the screws will decrease the oscillator frequency. Best results will be obtained if a non-metallic screwdriver is used.

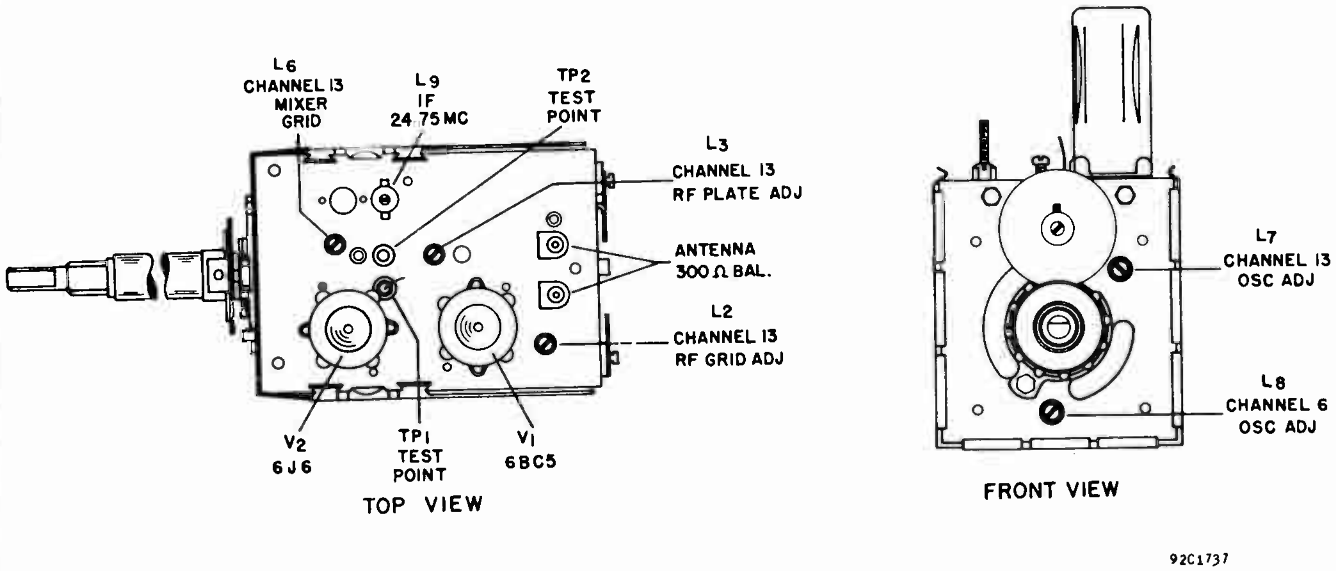

Fig. 86A. 1C1345 Pentode TV Tuner Alignment Adjustments

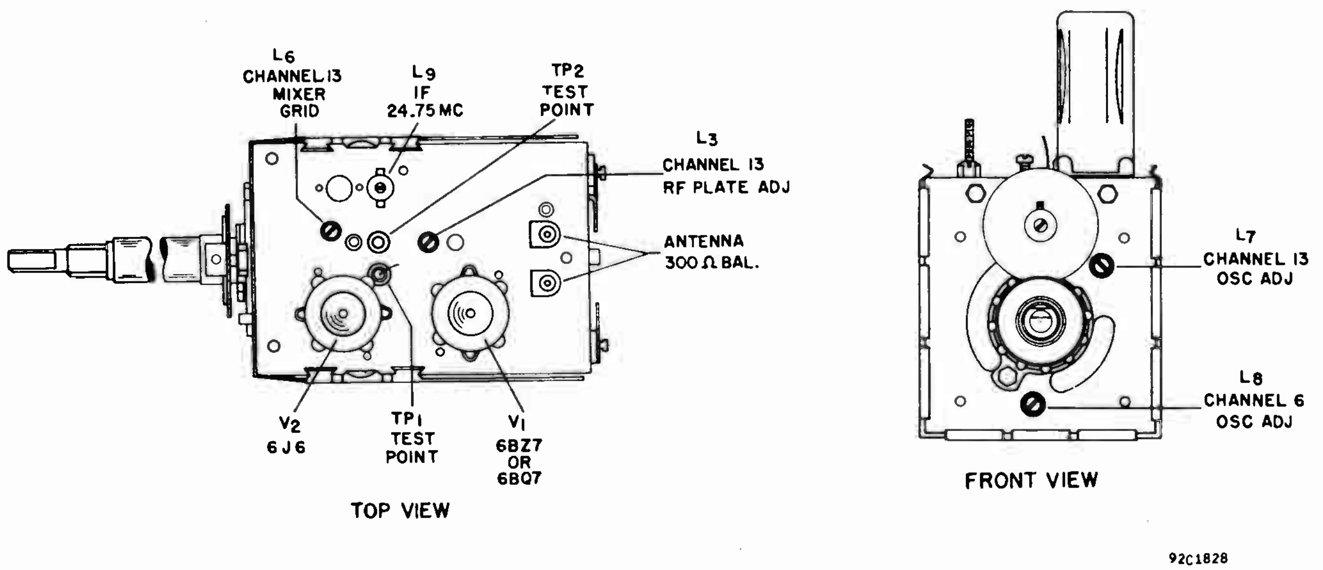

Fig. 86B. 1C1376 Cascode TV Tuner Alignment Adjustments

BAND PASS ALIGNMENT OF 1C1345 & 1C1376 TV TUNERS

CAUTION: Band pass alignment is carefully made at the factory. Attempt this alignment only with proper equipment and set-up. The tube shields and the bottom cover for the tuner must be in place. The oscillator adjustment given on page 39 must be completed before the band pass alignment is started.

1. Complete the set-up procedure given on page 39.
2. Connect the leads from the sweep and marker generators to the tuner antenna terminals.
3. Turn the channel selector to channel 13. Adjust the generators to the correct frequencies for channel 13 as shown in the chart on page 39.
4. Adjust L-3 (channel 13 rf plate), L-2 (channel 13 rf grid), and L-6 (channel 13 mixer grid) adjusting screws (see Fig. 86A or 86B for a band pass characteristic containing both carriers with steep sides and maximum gain. The 1C1376 cascode tuners do not require adjustment of the channel 13 rf grid coil (L-2) and hence a screw for this adjustment will not be found on the top of these tuners.

If the factory adjustment of the incremental loops and coils has not been disturbed, alignment of the rf plate, rf grid, and mixer grid should be complete after the completion of step 4 unless extensive repairs have been made on the tuner. Check the other channels for a similar band pass characteristic as shown in Fig. 87A. If they have the correct characteristics further alignment is not necessary. If they do not, procede with step 5. When aligning the 1C1376 cascode tuners it will first be necessary to repeat step 4 and adjust L-2 by spreading or compressing the turns of the coil before continuing with steps 5 and 6.

5. Adjust the coils of the rf plate, rf grid, and mixer grid for channels 12 through 7 starting with channel 12. Adjust the signal generators for each channel to the frequencies given in the chart on page 39. Pushing the half turn coil loops towards the center of the switch so that they are closer to the switch wafer will increase the frequency while pulling them out and away from the switch wafer will decrease the frequency. Adjust for a band pass characteristic containing both carriers with steep sides and maximum gain.
6. Adjust the coils of the rf plate, rf grid, and mixer grid for channels 6 through 2 starting with channel 6. Adjust the signal generators for each channel to the frequencies given in the chart on page 39. Spreading the turns of the coils will increase the frequency while squeezing the turns together will decrease the frequency. Adjust for a band pass characteristic containing both carriers with steep sides and maximum gain. A tuning wand may be used to determine what change is necessary.

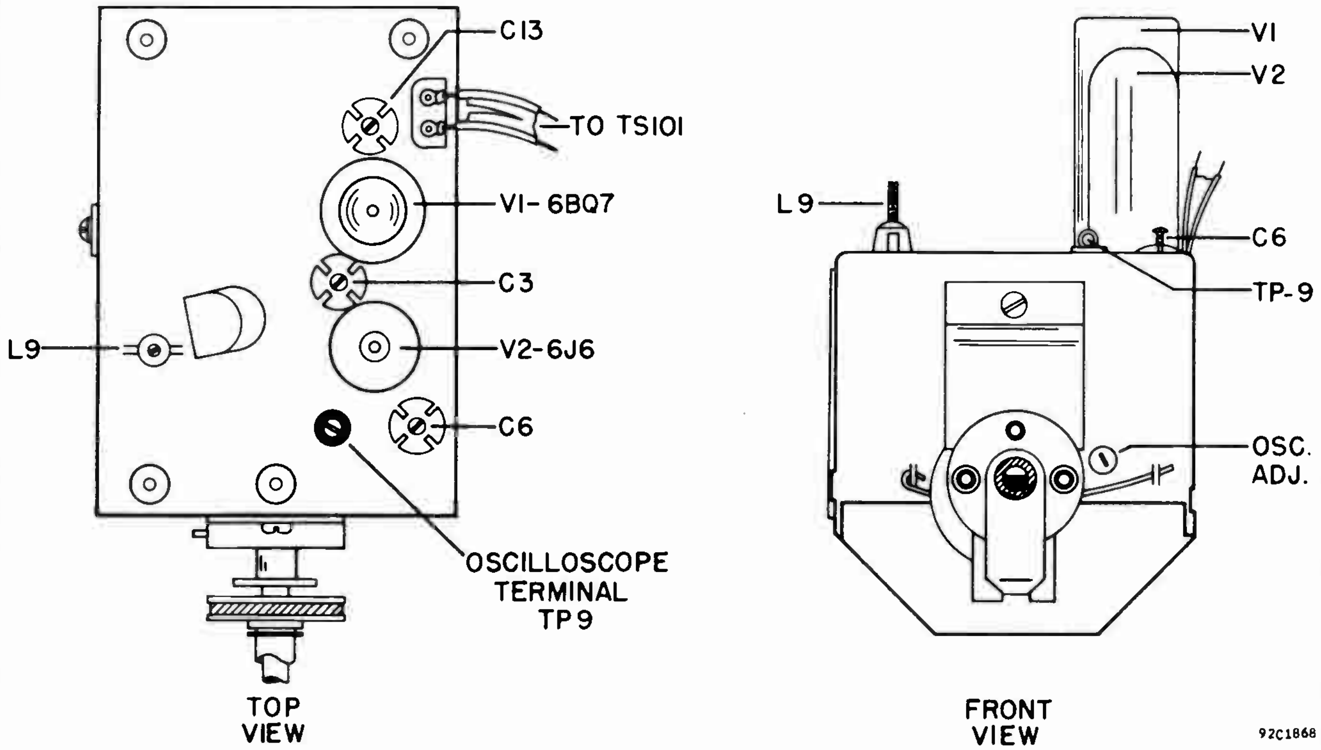

Fig. 88B. 1E1380 Cascode TV Tuner Alignment Adjustments

1E1380 CASCODE TV TUNER ALIGNMENT (ANT. & RF CIRCUITS)

The tuner was carefully aligned at the factory and should not require complete realignment under normal operating conditions. A slight readjustment of the individual oscillator slugs may be required as the tubes in the tuner age or are replaced. In some rare cases it will be necessary to realign the tuner after replacing either of the two tubes. If any service work is performed on the tuner, realignment may or may not be required. NO ATTEMPT TO REALIGN THE TUNER SHOULD BE MADE UNTIL THE BALANCE OF THE TV RECEIVER IS KNOWN TO BE IN PROPER OPERATING CONDITION AND IS PROPERLY ALIGNED.

EQUIPMENT REQUIRED

1. Sweep generator covering all 12 television channels.
2. Marker generator covering the same range as the sweep generator.
3. Oscilloscope.
4. Vacuum tube voltmeter (VTVM).

SET-UP PROCEDURE

1. Set the CHANNEL SELECTOR switch to channel 12.
2. Connect the vertical amplifier input of the oscilloscope through a 10,000 ohm resistor to test point TP-9 on the tuner. (See Schematic Diagram and Fig. 88B). The horizontal amplifier in the oscilloscope should be connected to the oscilloscope sweep voltage output from the sweep generator.
3. Connect the negative pole of a 1.5 volt dry cell to the terminal where the AGC lead (white wire) from the tuner is connected. (Connect the positive pole of the dry cell to the receiver chassis. (See Schematic Diagram).
4. Set the FINE TUNING control at the approximate midpoint of its tuning range.
5. Connect the sweep generator to the antenna terminals and adjust to sweep channel 12. Keep the output of the sweep generator as low as possible to prevent overloading the r-f stage.
6. Loosely couple the r-f output from the marker generator to the antenna terminals. Use the minimum amount of coupling and signal from the marker generator required to give a good marker on pipe on the oscilloscope pattern.

ANTENNA AND RF CIRCUIT ALIGNMENT

7. Adjust C-13, C-3 and C-6 for a flat-top response curve and maximum gain. Check markers on all channels. They should fall in automatically on each channel. Correct marker frequencies for each channel are given in the Picture Carrier and Sound Carrier columns of the chart on page 39. Refer to Fig. 87.
8. Disconnect the battery used to obtain negative bias.
9. Disconnect the test equipment and air check the receiver on all active channels. If it is possible to receive a normal picture on all active channels by adjusting the FINE TUNING control, further alignment will not be necessary.

1E1380 CASCODE TV TUNER ALIGNMENT (OSC. CIRCUIT)

1. Set the FINE TUNING control at the approximate midpoint of its tuning range.
2. Place a non-metallic screwdriver through the openings provided in the front of the chassis and the tuner assembly and adjust the oscillator coil slug for each active channel to give the best possible picture.

TYPICAL OSCILLOSCOPE PATTERNS

The patterns given on the following pages are presented as a guide when using an oscilloscope to locate trouble in the video amplifier, sync., horizontal oscillator, horizontal output, vertical oscillator, and vertical output stages of the television receiver.

Considerable variation may be noted in the amplitude and shape of some of the various waveforms from one receiver to the next. As long as the waveform obtained from the receiver under test contains the same general characteristics as those shown in the illustrations and the relative amplitude is within approximately 25% of the peak to peak voltage or relative amplitude shown below each waveform the pattern obtained may be assumed to be correct. The patterns are observed with the tv receiver tuned to an active channel and the controls adjusted for the best possible picture. The line voltage should be set to 117 volts.

The waveforms shown in the illustrations were obtained on a Dumont type 304 oscilloscope which was used in conjunction with a low capacity 10 to 1 probe such as the Tel-Instrument Co. type 1610. Other types of oscilloscopes will account for a certain amount of variation in the amplitude and shape of the patterns obtained from the actual receiver under test. A low capacity probe must be used in order to obtain satisfactory results. A power line isolation transformer should also be used for safety since the chassis is "hot".

With the exception of the test patterns obtained across the vertical yoke and horizontal yoke all patterns are taken with the ground side of the oscilloscope connected to the ground or chassis of the tv receiver and the 10 to 1 probe connected to the specific points in the tv chassis as specified by each pattern.

The patterns obtained from the horizontal amplifier plate, damper cathode, horizontal deflection yoke, and the high voltage rectifier tube must be observed by means of the high voltage probe which is made from a type 1X2-A tube as shown in Fig. 94A. The tube is used as a high voltage coupling capacitor. Use a new tube for this application because the loose filament of a burned out one may touch the plate and damage the probe or input circuit of the scope. These patterns are shown with their relative amplitudes indicated with respect to the pattern obtained at pin 3 (cathode) of the damper tube (V-110) which is given a unit value of one.

At certain points throughout the tv receiver the oscilloscope pattern obtained will be dependent upon the frequency of the horizontal sweep oscillator in the oscilloscope. The oscilloscope sweep frequency must be either 30 cps (1/2 of the tv vertical oscillator frequency) or 7875 cps (1/2 of the tv horizontal oscillator frequency) depending upon the pattern desired. The sweep frequency required to obtain the patterns shown is given with each pattern.

*On some 17" chassis the picture tube is mounted with a forward tilt of approximately four degrees. This tilt causes the bottom of the rear picture tube and yoke support bracket to raise up and at the same time move toward the rear of the chassis. The odd shape of the bracket used to mount the rear support bracket in this position is easily recognized. An additional spacer is also placed under the front picture tube mounting brackets on some chassis as indicated below.

The following parts are used when the picture tube is tilted:

	CHASSIS A,F,K & W1200D	CHASSIS P1200D & Y1200D
Socket assembly, pix tube	6A454	None
Spacer, extra; front pix tube support	8A1985	None
Bracket, right rear support	67C2081	67C2081
Bracket, left rear support	67C2080	67C2080
Bracket, rear pix tube & yoke support	No change	67A2083
Bracket, stop pad; center mounting	No change	None

When a chassis with a tilted picture tube is installed in a cabinet a different mask, cabinet back and sometimes safety glass are used. These different cabinet parts are listed on the model data sheets for each individual model when applicable.

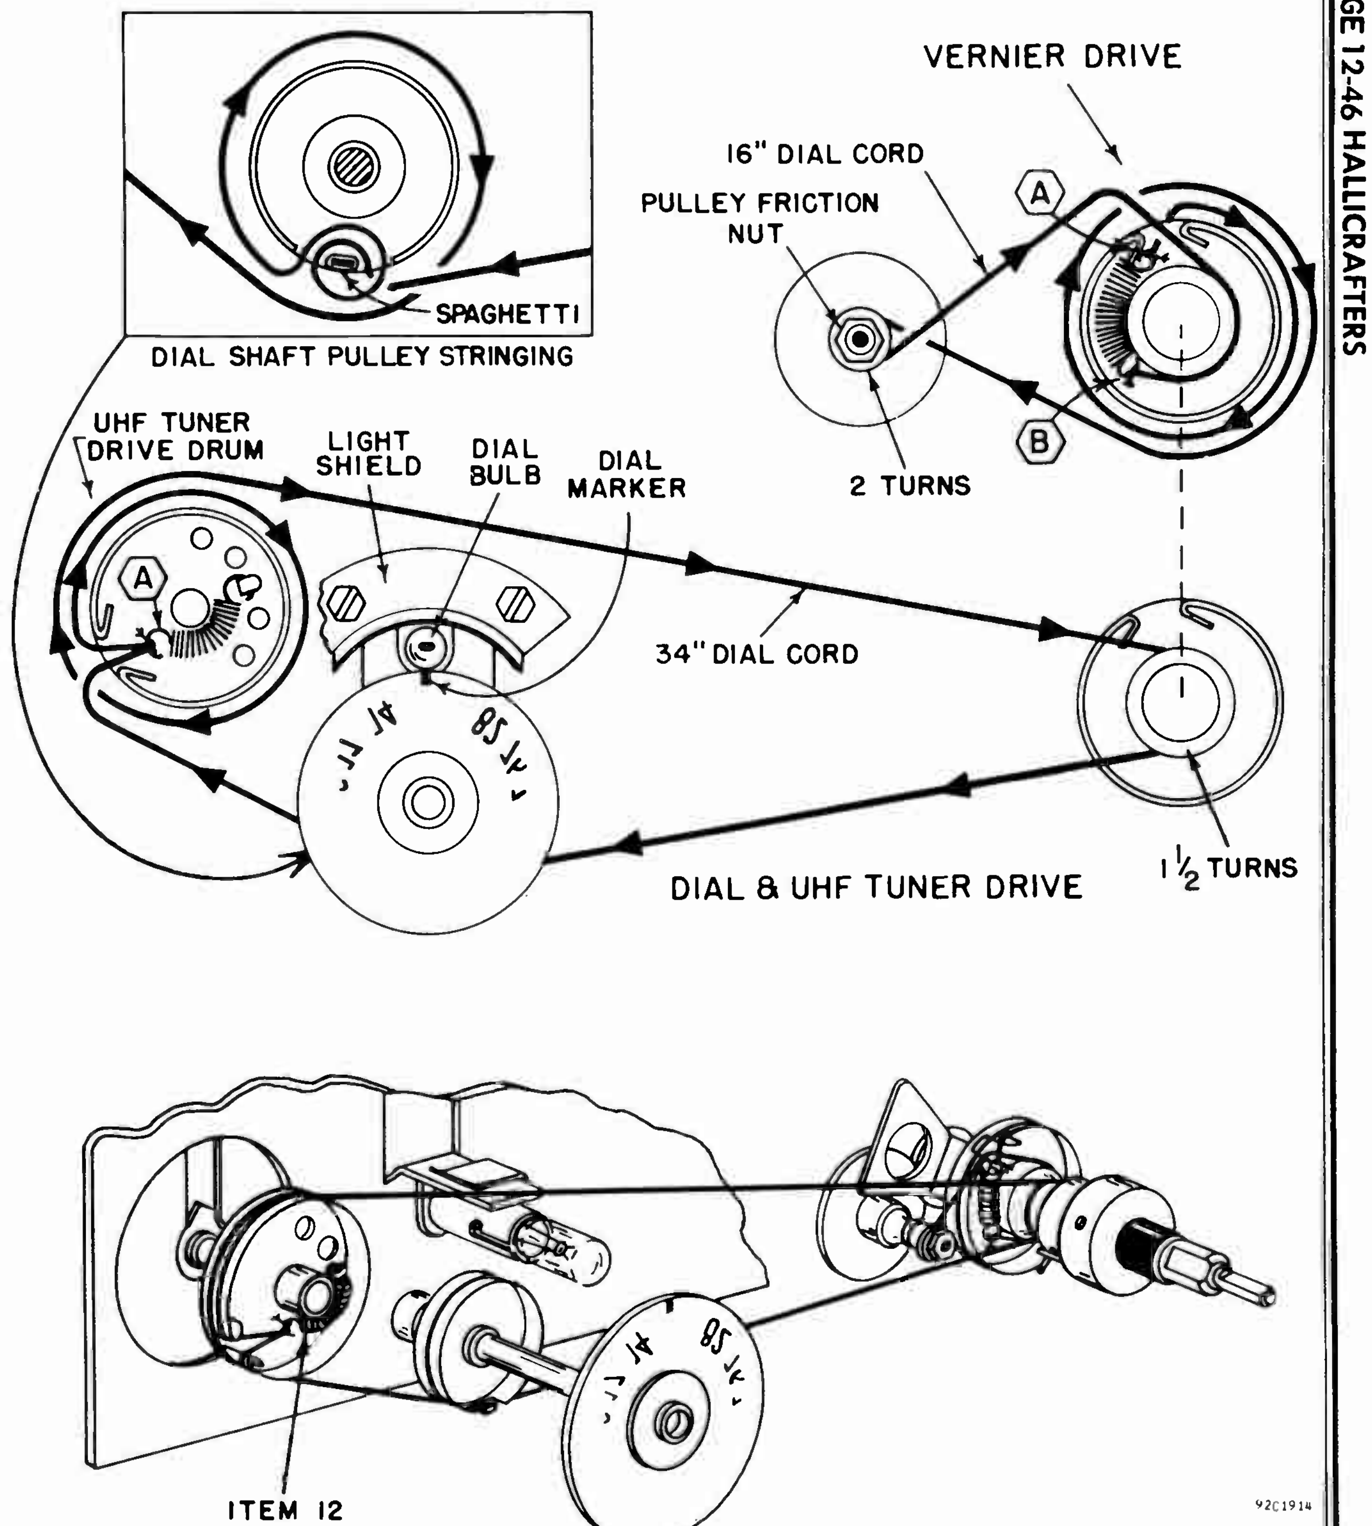

Fig. 104A. 1E1484 UHF Tuner Drive Mechanism Stringing

STRINGING & ADJUSTMENT OF VERNIER DRIVE, DIAL & UHF TUNER DRIVE

STRINGING VERNIER DRIVE

Tie one end of a 16" or longer dial cord to tension spring at "A" and position the spring as shown in Fig. 104A so that a slight tension on the dial cord will hold the spring in place.

Pass cord around pulleys as shown in Fig. 104A in the direction indicated by the arrows. Maintain a slight tension on the free end of the cord and rotate the large pulley counterclockwise to the position shown in Fig. 104A.

Tie the free end of the dial cord to the tension spring at "B" after stretching the spring.

Place a drop of quick drying cement on the knots to prevent them from working loose.

STRINGING UHF TUNER DRIVE AND DIAL

Set UHF tuner drive drum and vernier drive fully counterclockwise as shown in Fig. 104A.

Tie one end of a 34" or longer dial cord to tension spring at "A" and hook other end of spring on the pulley, stretch the spring and pass the cord around pulleys as shown in Fig. 104A in the direction indicated by the arrows until the dial shaft pulley is reached.

Carefully set the position of the dial so that the dial marker is directly above the center of the shaft as shown in Fig. 104A. Pass dial cord around spaghetti covered pin through notches in pulley rim and take one turn around pulley before passing free end of cord through notch in drive drum pulley and tying to the tension spring at "A". Cement knots to prevent them from working loose.

ADJUSTMENT OF PULLEY FRICTION NUT

The vernier drive is designed with a fast and slow tuning speed. During slow speed tuning the friction nut must be tightened so that the friction developed by the spring washer will not allow the idler pulley (Item 6, Fig. 104AA) to slip. If it does slip, it will not be possible to accurately tune in a UHF station.

During high speed tuning the idler pulley must slip. If the friction nut is set too tight the dial cord will slip on the idler pulley causing excessive cord wear necessitating frequent cord replacement. The dial will also be hard to turn.

SERVICE PARTS LIST FOR UHF TUNER VERNIER DRIVE MECHANISM

The items in the following parts list are identified in Fig. 104AA, except item 12 shown in Fig. 104A, by means of the item numbers. WHEN ORDERING REPLACEMENT PARTS ORDER BY PART NUMBER ONLY.

74	830-836	831.25	835.75	877
75	836-842	837.25	841.75	883
76	842-848	843.25	847.75	889
77	848-854	849.25	853.75	895
78	854-860	855.25	859.75	801
79	860-866	861.25	865.75	807
80	866-872	867.25	871.75	813
81	872-878	873.25	877.75	819
82	878-884	879.25	883.75	825
83	884-890	885.25	889.75	931

On all channels the Picture I-F frequency is 45.75 MC and the Sound I-F frequency is 41.25 MC which gives a difference between these two frequencies of 4.5 MC for the inter-carrier sound system.

I-F AMPLIFIER ALIGNMENT FOR Y AND Z1200D CHASSIS

EQUIPMENT REQUIRED

SWEEP GENERATOR	RCA type WR-59B or equivalent.
MARKER GENERATOR	RCA type WR-39C Television Calibrator or equivalent.
OSCILLOSCOPE	RCA type WO-56A or equivalent.
VACUUM TUBE VOLTMETER (VTVM)	RCA type WV-97A or equivalent.
BIAS SOURCE	Three volt battery.
TEST CIRCUIT	Shown in Fig. 104DA
ISOLATION TRANSFORMER	150 watt rating or higher.

PROCEDURE

1. Connect all test equipment to a common ground. Connect the TV chassis to this same ground after installing an isolation transformer between the power line and the TV chassis. One side of the line cord connects directly to the TV chassis and an isolation transformer must be used for safety. Allow a 15 minute warm up period.

2. Set the AVC switch on the rear chassis apron to the 0-10 MILE (counterclockwise) position.

3. Connect the negative side of a 3 volt battery supply to test point Ⓔ. Connect the positive side of the supply to the TV chassis. See schematic diagram.

4. Connect a VTVM to test point Ⓓ through a 47,000 ohm carbon resistor. Connect the ground side of the meter to the TV chassis. See Fig. 104CA.

5. Connect the high side of a marker generator to the shield of the osc./mixer tube. This connection will capacitively couple the generator output to the tube. Make sure the shield is ungrounded by raising it above the grounded clips that hold it in place.

6. Set the channel selector to channel 3 or 4, whichever is vacant.

7. Set the marker generator output (unmodulated) for a two volt negative dc reading on the VTVM and adjust the three i-f transformers, L-9, and L-201 according to the I-F AMPLIFIER ALIGNMENT CHART shown below. Readjust the signal generator output as required to maintain the two volt VTVM reading.

I-F AMPLIFIER ALIGNMENT CHART

Signal Generator Frequency (No Modulation)	Adjustment	Transformer or Coil Location	VTVM Indication
45.0 MC	T-201 (bottom)	See Fig. 104CA	Maximum
42.8 MC	T-202 (bottom)	Under Chassis	Maximum
44.0 MC	T-203 (bottom)	See Fig. 104CA	Maximum
41.25 MC	T-202 (top)	See Fig. 104CA	Minimum
42.8 MC	T-202 (bottom)	See Fig. 104CA	Maximum
44.25 MC	*L-201	See Fig. 104CA	Maximum
44.25 MC	#L-9	See Fig. 104CA	Maximum

IMPORTANT — The wax in the end of the coil forms holding the iron core in position may be softened for adjustment of the core by means of a heated screwdriver or a small pencil type soldering iron inserted into the wax. Remelt wax after adjustment.

* NOTE: Temporarily connect the series resistor-capacitor combination shown in Fig. 104DA to the tuner test point TP-2 when making this adjustment.

\# NOTE: Temporarily connect the series resistor-capacitor combination shown in Fig. 104DA to the grid (pin 1) of V-101 the 6CB6 first i-f amplifier when making this adjustment.

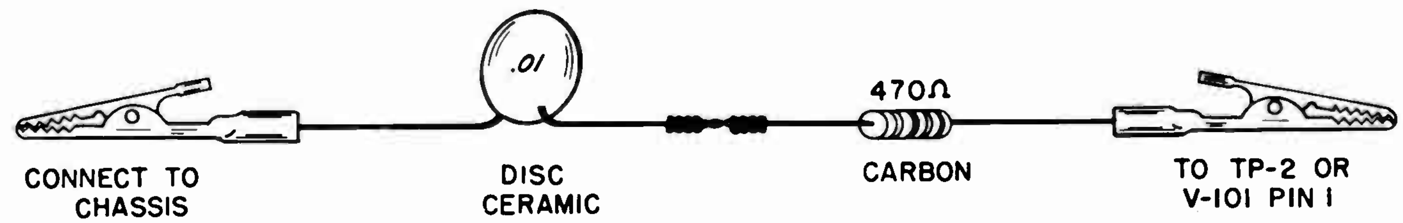

Fig. 104DA. Test Circuit for I-F Amplifier Alignment

8. Disconnect the VTVM and marker generator connected in steps 4 and 5. The balance of the set-up should be as directed in steps 1, 2, 3 and 6.

9. Capacitively couple the high side of the sweep generator r-f output to the osc./mixer tube by connecting to the tube shield which has been raised above its grounding clips. The ground side of the sweep generator should be connected to the receiver chassis. Adjust the generator to sweep from 40.5 to 46.5 MC.

10. Loosely couple the high side of the marker generator to the high side of the sweep generator by clipping the marker generator r-f lead over the insulation of the sweep generator r-f lead. The ground side of the marker generator should be connected to the receiver chassis.

IMPORTANT — To prevent overloading of the i-f amplifier keep the output of the sweep and marker generators as low as possible. The marker generator output should be just high enough to produce visible pips on the pattern. In some cases the 41.25 MC pip will not be visible unless the r-f output of the marker generator is increased to overcome the attenuation of the 41.25 MC signal by the trap in the top of T-202.

11. Connect the sweep output terminals on the sweep generator to the input of the horizontal amplifier in the oscilloscope.

12. Connect one side of a 47,000 ohm 1/2 watt resistor to test point (D) shown in the schematic diagrams. Connect the other end of the resistor to the high side of the input terminals for the vertical amplifier in the oscilloscope. The scope ground terminal connects to the receiver chassis. Keep the scope leads away from the internal chassis wiring, particularly the horizontal output section.

13. Reduce the r-f output of the sweep generator and increase the gain of the vertical amplifier in the oscilloscope as much as possible without introducing an excessive amount of noise on the test pattern. This will prevent overloading of the i-f system.

14. Check the position of the markers shown in Fig. 104EA. Adjust only the bottom cores of T-201, T-202 and T-203 for a response curve of maximum amplitude with a slightly tilted flat topped appearance as shown in Fig. 104EA. This tilt is required to compensate for the capacitive coupling used for the signal generators. The actual response obtained will be flat when the pattern viewed on the oscilloscope has this tilt. The bottom core of T-203 will primarily control the tilt of this central portion of the curve.

The bottom core of T-201 should be adjusted to position the 45.75 MC marker in the 50% position shown in Fig. 104EA.

The bottom core of T-202 should be adjusted to determine the slope of the curve between 41.25 MC and 42.8 MC with the 42.25 MC marker down 50% on the curve as shown in Fig. 104EA.

Under no circumstances should an attempt be made to adjust L-9, L-201 and the 41.25 MC trap in the top of T-202 by means of an oscilloscope and sweep generator. Maladjustment of these coils does not give a noticeable indication on the oscilloscope. Align these coils by following the procedure given in steps 1 through 7 only.

I-F AMPLIFIER SENSITIVITY MEASUREMENT

To determine the i-f amplifier sensitivity, disconnect the r-f output lead from the tuner where it connects to L-201. Temporarily connect one side of a .005 mfd. mica or ceramic capacitor to grid pin 1 of the first 6CB6 i-f amplifier tube V-101. Connect the unmodulated r-f output of a marker generator to the other side of the capacitor and the ground side of the generator to the TV chassis. Set the marker generator to 43.75 MC. Connect a VTVM as directed in step 4 of the alignment procedure. The 3 volt battery must be removed. If a generator output of 200 to 400 microvolts produces a 1 volt reading on the VTVM, the i-f amplifier sensitivity is normal.

I-F ALIGNMENT OF THE COUPLING BETWEEN THE 1E1483, 1E1582, OR 1E1670 VHF AND 1E1484 OR 1E1659 UHF TUNERS.

The following alignment procedure is suitable for use with any series 1200D chassis equipped with the 1E1483, 1E1582 or 1E1670 sixteen position cascode VHF tuner and a 1E1484 or 1E1659 UHF tuner.

NO ATTEMPT SHOULD BE MADE TO PERFORM THE FOLLOWING ALIGNMENT PROCEDURE UNTIL THE VHF TUNER AND THE BALANCE OF THE TV RECEIVER IS KNOWN TO BE IN PROPER OPERATING CONDITION.

EQUIPMENT REQUIRED

Sweep Generator	RCA type WR-59B or equiv.
Marker Generator	RCA type WR-39C or equiv.
Oscilloscope	RCA type WO-56A or equiv.
Bias Source	$1\frac{1}{2}$ volt battery or equiv.
Detector Circuit	See Fig. 104HA.
Isolation Transformer	150 watt rating or higher

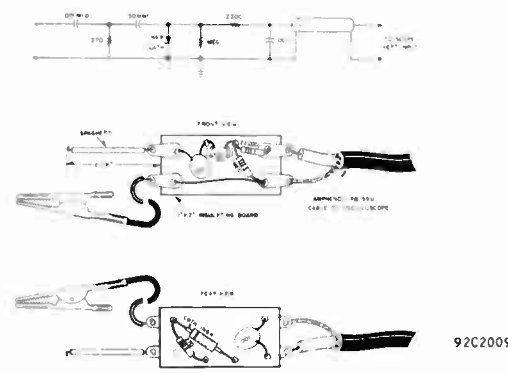

Fig. 104HA. Detector Circuit for UHF-VHF Coupling I-F Alignment

SET-UP PROCEDURE & ADJUSTMENT

1. Check to be sure that all tube shields are in place on both tuners. Open the bottom shield cover of the 16 position VHF tuner and connect the test circuit of Fig. 104HA to the plate pin 1 of the 6BZ7 r-f amplifier in the VHF tuner.
2. Connect all test equipment and the television chassis to a common ground. Be sure to use an isolation transformer for the receiver chassis. Allow at least a 5 minute warm up period for the receiver chassis with the channel selector in the UHF position.
3. Connect the negative side of the bias source to terminal 8 of the VHF tuner and the positive side to the chassis.
4. Connect the vertical input terminals of the oscilloscope to the test circuit as shown in Fig. 104HA.
5. Set the sweep generator to sweep an 8 MC band from 40 to 48 MC. Connect the r-f output hot lead through a .005 mfd. disc ceramic capacitor to the junction of the diode X-301, L-301, C-310 and C-311 in the UHF tuner. This point is the 1N82 diode clip which is farthest away from the 6AF4 oscillator tube in the UHF tuner. The ground lead from the sweep generator should be connected to the UHF tuner chassis. See Fig. 104IA.
6. Loosely couple the high side of the marker generator r-f lead to the high side of the sweep generator by connecting the marker generator r-f lead to the sweep generator r-f lead through a 22 mmf. capacitor. The ground side of the marker generator should be connected to the receiver chassis.
7. Connect the sweep output terminals on the sweep generator to the input of the horizontal amplifier in the oscilloscope.

IMPORTANT—To prevent possible overloading of the tuned circuits and the r-f amplifier tube in the VHF tuner keep the output of the sweep generator as low as possible with a useable pattern remaining on the oscilloscope. The oscilloscope vertical gain should be close to maximum. The marker generator output should be set just high enough to produce visible pips on the pattern viewed on the oscilloscope.

8. Adjust the I.F. output coil (T-301) in the UHF tuner and the I.F. input coil (L-1) (*) in the VHF tuner for peaks of equal amplitude with the 45.75 MC picture carrier marker appearing exactly on one peak of the curve. The 42.25 MC marker should appear somewhere within the 10% limits on the other peak of the curve shown in Fig. 104IB. The coil adjustments must be made so that the two peaks are of the same amplitude regardless of the 42.25 MC marker position.

(*) In some of the early versions of the 1E1483 sixteen position VHF tuner, the I.F. input coil is not adjustable by means of an iron core. On these tuners it will be necessary to spread or compress the turns of this coil within tuner. Some tuners had an additional coil on the outside of the tuner connected in series with the co-axial link from the UHF tuner. This coil may be adjusted as well as the coil inside the VHF tuner.

SPECIAL NOTE: The capacitor (C-308) connected across the r-f output terminals of the UHF tuner determines the bandwidth of the coupling circuits between the UHF and VHF tuners. If this capacitor is increased in value the bandwidth will decrease while a decrease in the value of this capacitor will increase the bandwidth. In some of the 1E1484 tuners C-308 will have a ceramic tubular capacitor connected in parallel with it so that the total effective value will range from 100 to 220 mmf. Some 1E1484 tuners have a variable capacitor (Part No. 44A347) connected in parallel with a 150 mmf. ceramic capacitor (Part No. 47B20151M5) across C-308. This variable capacitor is factory set to give the desired bandwidth. If the bandwidth determined in step 8 is found to be not correct this capacitor may be adjusted. Determine from step 8 whether the bandwidth should be increased or decreased and adjust the variable capacitor accordingly. Repeat step 8. If the bandwidth requires further adjustment, again change the setting of the variable capacitor and repeat step 8. Repeat this procedure until the desired bandwidth is obtained. The value of C-308 is 150 mmf. in the 1E1659 tuners.

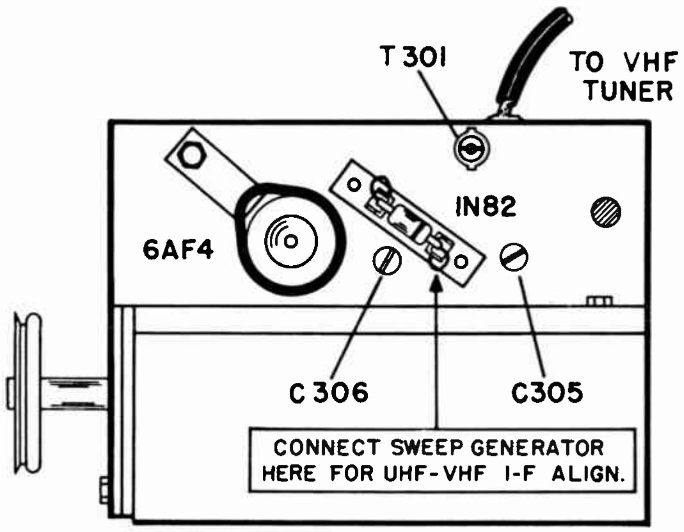

Fig. 104IA. Alignment Adjustments for 1E1484 & 1E1659 UHF Tuners

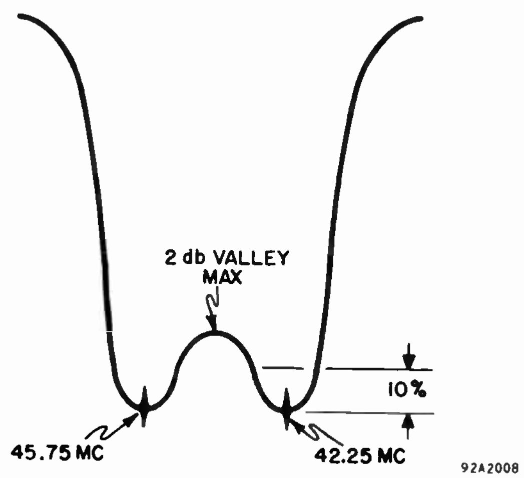

Fig. 104IB. Response Curve for VHF-UHF I-F Coupling Alignment

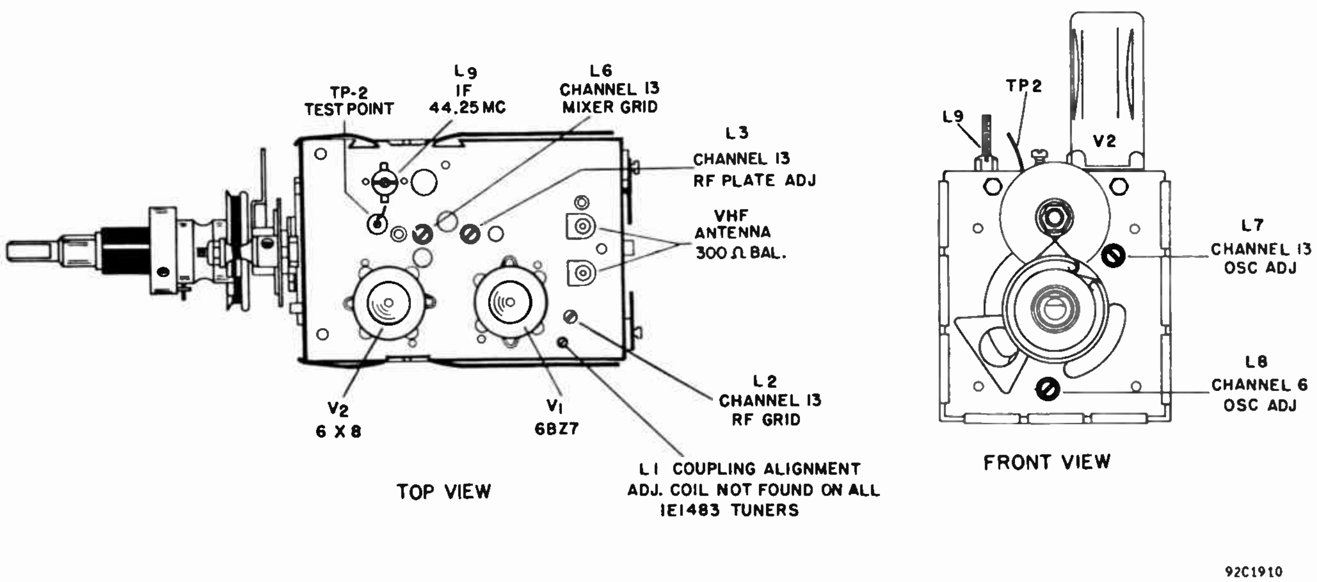

Fig. 104IC. Alignment Adjustments for 1E1483, 1E1582 or 1E1670 VHF Tuners

ALIGNMENT FOR 1E1483, 1E1582 OR 1E1670 VHF 16 POSITION CASCODE TUNERS

These tuners have been carefully aligned at the factory by personnel using precision equipment. Minor adjustments of the tuner may be necessary after making tube or part replacement. When replacing tubes in a tuner use the same tube type as the original tube which was removed from the tuner and also try several different tubes and select the one which gives best performance. Realignment of the tuner probably will not be required if a selected tube is used for replacement. For those service engineers who are properly equipped as specified, the following alignment procedure is included. DO NOT ATTEMPT TUNER ALIGNMENT UNTIL THE TV RECEIVER IS KNOWN TO BE FUNCTIONING PROPERLY AND THE I-F ALIGNMENT OF THE RECEIVER IS CORRECT.

EQUIPMENT REQUIRED FOR VHF TUNER ALIGNMENT

Sweep Generator	RCA type WR-59B or equiv.
Marker Generator	RCA type WR-39C or equiv.
Oscilloscope	RCA type WO-56A or equiv.
Bias Source	$1\frac{1}{2}$ volt battery or equiv.
Detector Circuit	See Fig. 104HA.
Isolation Transformer	150 watt rating or higher.

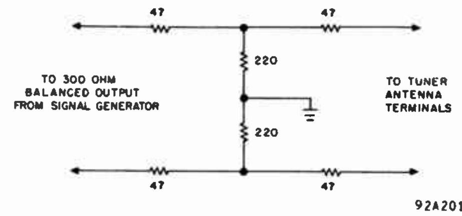

Fig. 104JA. Sweep Generator 300 Ohm Pad

OSCILLATOR ADJUSTMENT FOR 16 POSITION TUNERS

1. Connect the balanced sweep output from a signal generator to the VHF tuner antenna terminals through the 300 ohm pad shown in Fig. 104JA. Set sweep generator for 10 MC sweep.
2. Connect the negative side of $1\frac{1}{2}$ volt bias supply to terminal 8 of the VHF tuner. Connect the positive side of the bias supply to the chassis.
3. Connect the oscilloscope and band-pass detector circuit shown in Fig. 104HA to Test Point TP-2 shown in Fig. 104IC.
4. Set the VHF tuner channel selector to channel 13.
5. Loosely couple the high side of the marker generator to the antenna input terminals by clipping the lead over the insulation of one sweep generator lead. Connect the ground side of the generator to the chassis of the VHF tuner. Set the marker generator to the channel 13 picture carrier frequency of 211.25 MC.
6. Carefully note the position of the marker pip on the response curve. Use a grease pencil if necessary to mark the position on the face of the cathode ray tube.
7. Loosely couple the high side of the marker generator to the band-pass detector circuit by clipping the lead over the germanium diode in the detector circuit. Connect the ground side of the generator to the chassis of the VHF tuner. Set the marker generator to 45.75 MC.
8. Rotate the fine tuning control of the VHF tuner until the 45.75 MC marker is in the same spot as the marker in steps 5 and 6. If this cannot be accomplished by adjustment of the fine tuning control, adjust the channel 13 oscillator adjustment (L-7) to position the 45.75 MC marker. DO NOT DISTURB THE SETTING OF THE FINE TUNING CONTROL AFTER THIS ADJUSTMENT.
9. Switch the VHF tuner channel selector and sweep generator to channel 12.
10. Repeat steps 5 and 6 except use the picture carrier frequency for channel 12 (205.25 MC) in step 5.
11. Repeat step 7 using the same marker frequency of 45.75 MC.
12. Adjust the incremental oscillator coil for the channel until the 45.75 MC marker pip is in the same position on the curve as the marker pip for the picture carrier was in step 10.
13. Repeat steps 9, 5, 6, 7 and 12 for channels 11, 10, 9, 8 and 7 in that order. In each case switch the channel selector and sweep generator to the channel being aligned. The marker generator frequency for step 5 will be the picture carrier frequency for the channel being aligned. See the chart on page 39 for the picture carrier frequency of each channel.
14. Switch the channel selector and sweep generator to channel 6 and repeat steps 5 and 6 except use the picture carrier frequency for channel 6 (83.25 MC) in step 5.

15. Repeat step 7 using the same marker frequency of 45.75 MC.

16. Adjust the channel 6 oscillator adjustment until the 45.75 MC marker pip is in the same position on the curve as the marker pip in Step 14. See Fig. 104IC.

17. Repeat steps 9, 5, 6, 7 and 12 for channels 5, 4, 3 and 2 in that order. In each case switch the channel selector and sweep generator to the channel being aligned. The marker generator frequency for step 10 will be the picture carrier frequency for the channel being aligned. See the chart on page 39 for the picture carrier frequency of each channel.

NOTE: If two marker generators are available the alignment can be greatly simplified by using one generator for the picture carrier marker and the other for the 45.75 MC marker. Both generators are connected to the receiver at all times as directed in the above instructions. The use of two generators will produce two pips on the pattern. The adjustments outlined above will make these two pips coincide on the oscilloscope pattern.

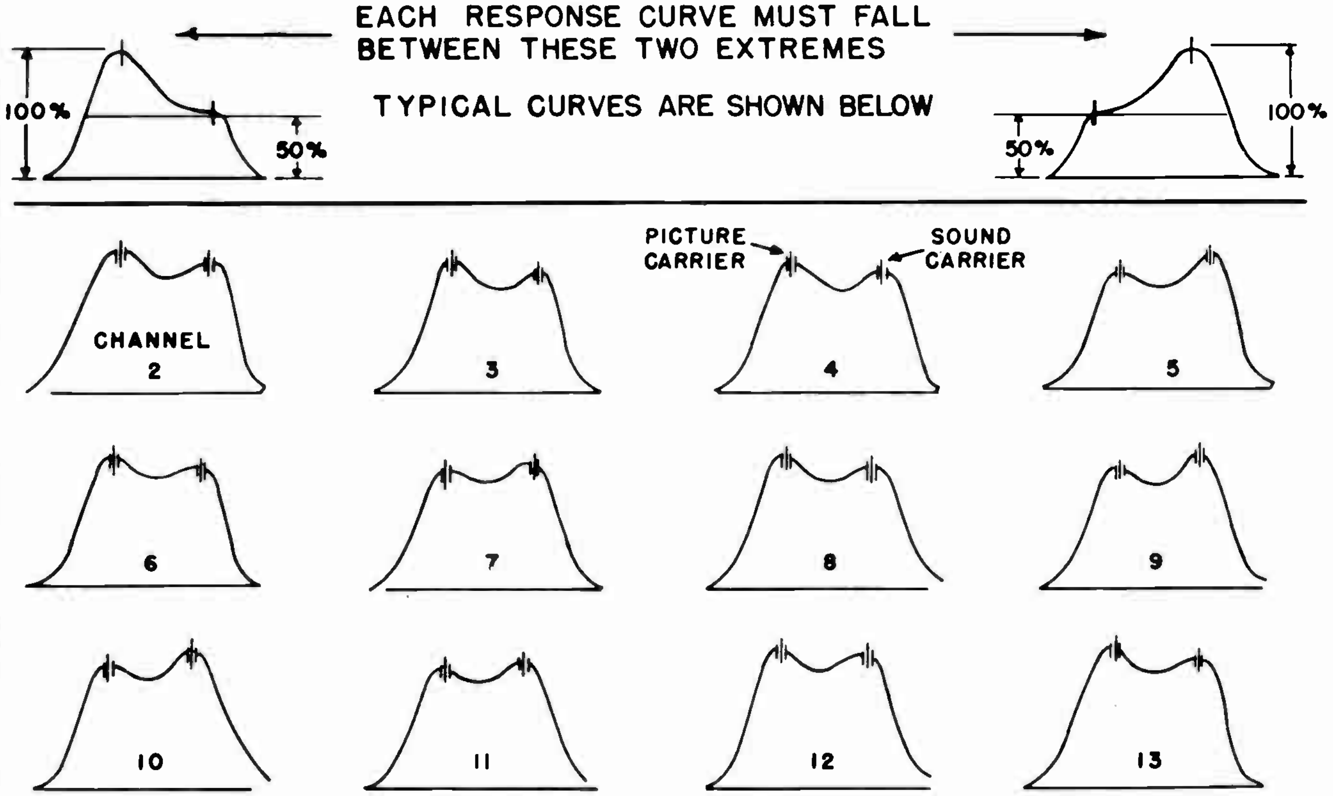

Fig. 104KA. Typical Channel Response Curves 9281956

BAND-PASS ALIGNMENT FOR 16 POSITION VHF TUNERS 1E1483, 1E1582 & 1E1670

DO NOT ATTEMPT THIS ALIGNMENT UNTIL THE I-F ALIGNMENT OF THE RECEIVER HAS BEEN CHECKED AND IS KNOWN TO BE CORRECT. THE OSCILLATOR ADJUSTMENT PROCEDURE GIVEN ON PAGE 39 MUST ALSO BE COMPLETED BEFORE STARTING THIS ALIGNMENT.

1. Connect the balanced sweep output from a signal generator to the VHF tuner antenna terminals through the 300 ohm pad shown in Fig. 104JA. Set the sweep generator for 10 MC sweep.

2. Connect the negative side of the 1½ volt bias supply to terminal 8 of the VHF tuner. Connect the positive side of the bias supply to the chassis.

3. Connect the oscilloscope and band-pass detector circuit shown in Fig. 104HA to Test Point TP-2 shown in Fig. 104IC.

4. Set the VHF tuner channel selector to channel 13.

5. Loosely couple the high side of the marker generator to the band-pass detector circuit by clipping the lead over the germanium diode in the detector circuit. Connect the ground side of the generator to the chassis of the VHF tuner.

6. Set the sweep generator for channel 13 and turn the VHF tuner channel selector to channel 13.

7. Adjust L-2 (channel 13 r-f grid), L-3 (channel 13 r-f plate), and L-6 (channel 13 mixer grid) adjusting screws (see Fig. 104IC) for a band pass characteristic containing both carriers with steep sides and maximum gain. See curves shown on page • The mixer grid adjustment (L-6) must be adjusted for maximum mid-band gain regardless of the shape of the skirts. The slope and position of the skirts are primarily controlled by the r-f plate adjustment (L-3) while the r-f grid adjustment (L-2) controls the slope of the flat topped portion of the curve. Always adjust to place the picture carrier marker on a peak of the curve.

If the factory adjustment of the incremental loops and coils has not been disturbed, alignment of the r-f plate, r-f grid and mixer grid should be complete after the completion of step 7, unless extensive repairs have been made on the tuner. Check the other channels for a similar band-pass characteristic as shown in Fig. 104KA. If they have the correct characteristics further alignment is not necessary. If they do not, proceed with the following steps.

8. Adjust the coils of the r-f plate, r-f grid and mixer grid for channels 12 through 7 starting with channel 12. Adjust the signal generators for each channel to the frequencies given in the chart on page 39. Pushing the half turn incremental loops toward the center of the switch so that they are closer to the switch wafer will increase the frequency while pulling them out and away from the switch wafer will decrease the frequency. Always adjust the mixer grid coils for maximum mid-band gain and the r-f plate and r-f grid coil loops as outlined in step 7.

9. Adjust the coils of the r-f plate, r-f grid and mixer grid for channels 6 through 2 starting with channel 6. Adjust the signal generators for each channel to the frequencies given in the chart on page 39. Spreading the turns of the coils will increase the frequency while squeezing the turns together will decrease the frequency. Always adjust the mixer grid coils for maximum mid-band gain and the r-f plate and r-f grid coils as outlined in step 7.

10. Repeat step 7 as a final adjustment for channel 13.

ALIGNMENT OF UHF POSITION IN 16 POSITION VHF TUNERS

1. Complete the oscillator and band-pass alignment given on pages 51 and 52.

2. Turn the channel selector switch in the VHF tuner to the UHF position which will turn on the UHF dial light.

3. Complete the I-F Amplifier Coupling Alignment given on page 50 and 51 and leave the sweep and marker generators connected as for the coupling alignment.

4. Connect the oscilloscope and band-pass detector shown in Fig. 104HA, to Test Point TP-2 on the VHF tuner as shown in Fig. 104IC.

5. Adjust the incremental coils on S-1C and S-1D in the VHF tuner for the same general characteristics obtained for the I-F coupling alignment between the VHF and UHF tuners. The two peaks of the curve should be adjusted so that they are of equal amplitude with the picture carrier marker on one peak of the curve as shown in Fig. 104IB. Only a slight adjustment of these coils is required to produce considerable change. Adjust the coils with a non-metallic instrument and replace the cover on the VHF tuner before viewing the waveform on the oscilloscope.

Fig. 104MB. Channel Selector Switch Positions

ALIGNMENT OF THE 1E1484 AND 1E1659 UHF TUNERS

It is recommended that the alignment of the 1E1484 and 1E1659 UHF tuners not be disturbed in the field. If it is definitely established that realignment of the tuner is absolutely necessary the UHF tuner will have to be removed from the main TV chassis in order to get at the adjustments. Electrical connections to the main TV chassis will have to be maintained in order to use amplifiers in the TV chassis to obtain a useable oscilloscope indication and prevent loading of the UHF tuner output circuit by the necessary test equipment. A heavy ground braid must also be connected between the UHF tuner chassis and the main TV chassis.

THE HALLICRAFTERS SERVICE DEPARTMENT PROVIDES A TUNER EXCHANGE SERVICE FOR A NOMINAL FEE. THE SERVICE TECHNICIAN IS URGED TO AVAIL HIMSELF OF THIS SERVICE RATHER THAN TO ATTEMPT FIELD ALIGNMENT OF THESE TUNERS.

SET-UP PROCEDURE

1. Complete the I-F coupling alignment given on page 1952-104H.
2. Connect the band-pass detector circuit given in Fig. 104HA to an oscilloscope and the plate (6BZ7 pin 1) of the r-f amplifier in the VHF tuner.
3. Connect the output of a UHF sweep generator to the UHF tuner antenna terminals through the 300 ohm resistor network shown in Fig. 104JA.
4. Loosely couple the r-f output of a UHF marker generator to the leads from the sweep generator.

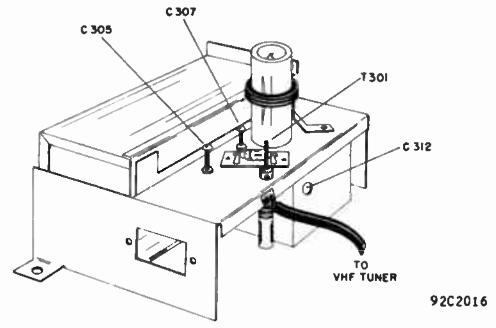

Fig. 104NA. UHF Tuner Adjustment Points

OSCILLATOR ADJUSTMENT

1. Rotate the UHF tuning control to the full counterclockwise position.
2. Set the marker and sweep generators to 465 MC.
3. Adjust the oscillator trimmer capacitor (C-312 shown in Fig. 104NA) until the marker appears on the top portion of the curve.
4. Rotate the UHF tuning control to the full clockwise position.
5. Set the marker and sweep generators to 900 MC.
6. Carefully spread or pinch together the legs of the oscillator end inductor (LI-3 shown in Fig. 104OA) until the marker appears on the top portion of the curve.
7. Repeat the above steps until no further improvement is apparent. The oscillator adjustment figures of 465 and 900 megacycles are approximate only, and may not fall precisely at the dial settings specified; in every case, however, the oscillator must be aligned so that both frequencies can be tuned by normal manipulation of the tuning control.

R-F ALIGNMENT

1. Rotate the UHF tuning control to the full counterclockwise position.
2. Set the marker and sweep generators to 465 MC.
3. Adjust the r-f trimmer (C-305 & C-307 shown in Fig. 104NA) for maximum gain and a flat top response curve. The marker should be in the top center portion of the curve.
4. Rotate the UHF tuning control to the full clockwise position.
5. Carefully spread or pinch together the legs of the r-f end inductors (LI-1 & LI-2 shown in Fig. 104OA) for maximum gain and a flat top response curve. The marker should appear in the top center portion of the curve.
6. Repeat the above steps until no further improvement is apparent.

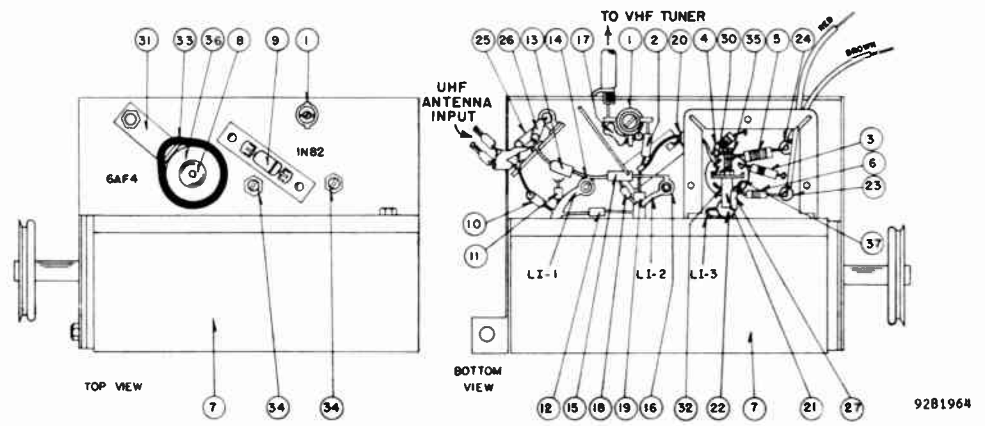

Fig. 104O. Parts Identification for 1E1484 & 1E1659 UHF Tuners

SERVICE PARTS LIST FOR 1E1484 & 1E1659 UHF TUNERS

The parts in the following list may be identified by reference symbols shown in the above figure.

Schematic Symbol	Description	Reference Symbol	Mfgrs. Cross Reference	Hallicrafters Part Number
	TRANSFORMERS & COILS			
T-301	r-f output transformer	1	B-630160-1	50-600
L-301	Choke; 9 turns, 1/8" diameter	2	A-600407-1	53-290
L-302	0.38 uh. cathode choke	3	A-600240-3	53-285
L-303	0.47 uh. heater choke	4	A-600033-1	53-293
L-304	0.47 uh. heater choke	5	A-600033-1	53-293
L-305	0.38 uh. plate choke	6	A-600240-3	53-285
L-306A,B,C	UHF Inductuner complete with R-304 & R-305	7	A-600414-1	1-1645
	TUBES & RECTIFIERS			
V-301	6AF4 triode, UHF oscillator	8	A-600210-1	90X6AF4
X-301	1N82 silicon diode	9	A-600413	19A1883
	CAPACITORS			
C-301	1.0 mmf. ceramic gimmick	10	A-600025-6	47-339
C-302	2.5 mmf. ceramic gimmick	11	A-600389-7	47-350
C-303	0.25 mmf. ceramic gimmick	12	A-600025-12	47-345
C-304	1.0 mmf. ceramic gimmick	13	A-600025-6	47-339
C-305	0.8 to 6.5 mmf. tubular ceramic trimmer	14	A 600220-1	44-428
C-306	0.25 mmf. ceramic gimmick	15	A-600025-12	47-345
C-307	0.8 to 6.5 mmf tubular ceramic trimmer	16	A-600220-1	44-428
C-308	100 mmf. tubular ceramic (1E1484 tuner)	17	A-600026-6	47-351
C-308	150 mmf. tubular ceramic (1E1659 tuner)	17	A-600026-12	47-394
C-309	2.5 mmf. ceramic gimmick	18	A-600025-17	47-353
C-310	2.2 mmf. ceramic gimmick	19	A-600025-10	47-338
C-311	0.4 mmf. ceramic gimmick	20	A-600389-2	47-346
C-312	3.0 to 10 mmf. tubular ceramic trimmer	21	A-600282-3	44-427
C-313	6.0 mmf. ceramic disc	22	A-600463-2	47-352
C-314	68 mmf. ceramic gimmick	23	A-600281-1	47-336
C-315	68 mmf. ceramic gimmick	24	A-600281-1	47-336
	RESISTORS			
R-301	470,000 ohms 1/2 watt, carbon	25	A-6000029-9	23X20X474K
R-302	470,000 ohms 1/2 watt, carbon	26	A-6000029-9	23X20X474K
R-303	12,000 ohms 1/2 watt, carbon	27	A-200116-12	23X20X123K
R-304	22,000 ohms 1/2 watt, carbon	28	None	23X20X223K
R-305	22,000 ohms 1/2 watt, carbon	29	None	23X20X223K
	MISCELLANEOUS PARTS			
	Bracket, mounting for C-312	30	A-600280-1	67-2220
	Bracket, oscillator tube clamp	31	A-600465-1	67-2221
	Connector, oscillator plate	32	A-600446-1	76-1073
	Grommet, oscillator tube clamp	33	A-600466-1	16-336
	Screw, adj.; for C-305 and C-307	34	A-11511-62	3-3136
	Screw, adj.; for C-312	35	A-15717-12	3-3137
	Shield, 7 pin tube	36	A-600035-1	69-577
	Socket, 7 pin molded mica filled	37	A-600215-1	6-471

SERVICE PARTS LIST

The following combined parts list may be used to determine replacement parts for the 1200 series TV chassis. To determine the correct replacement part, first refer to the correct schematic for the particular chassis involved and determine the correct schematic symbol for the part. Refer to the Service Parts List for the part number and description of the component with the same schematic symbol. Some components with the same schematic symbol vary from one type of chassis to another due to mechanical changes. These exceptions are also shown in the Service Parts List.

The part number will be found stamped on most components with the exception of carbon resistors, capacitors, tube sockets, and other small components not large enough to be stamped.

Picture tubes and their associated mounting components are listed in a separate parts list. Cabinet parts may be determined by referring to the pages devoted to individual models.

TRANSFORMERS AND COILS

Schematic Symbol	Description	Hallicrafters Part Number
T-101	Transformer, first i-f amplifier	50B561
T-102	Transformer, second i-f amplifier	50B568
T-103	Transformer, diode detector	50B562
T-104	Transformer, vertical blocking oscillator	55B190
T-105	Transformer, vertical output	55C192
T-106	Transformer, horizontal output (for 17" chassis)	55D193
T-107	Transformer, ratio detector	50C473
T-108	Transformer, audio output	55C191
T-109	Transformer, horizontal output (for 20" chassis)	55D197
T-110	Transformer, Heater	52C258
T-201	Transformer, first i-f amplifier	50B573
T-202	Transformer, second i-f amplifier	50B574
T-203	Transformer, diode detector	50B575
L-101	Coil, converter i-f	51B1301
L-102	Coil, video peaking	51A1578
L-103	Coil, video peaking	51A1579
L-104	Coil, video peaking (wound on R-119)	51A1580
L-105	Coil, 4.5 MC trap	51B1541
L-106	Coil, video peaking (wound on R-122)	51A1581
L-107	Coil, video peaking (wound on R-123)	51A1582
§L-108	Coil, horizontal stabilizer	51B1642 or 51B1536
L-109	Coil, yoke coupling (wound on C-148)	53B264
L-110	Coil, 4.5 MC amplifier grid adjustment	51B1542
L-111	Coil, speaker field (part of speaker)	---------
L-112	Deflection yoke (for 17" chassis)	53A271 or 53C263
L-112	Deflection yoke (for 20" chassis)	53A271 or 53A268
L-112	Deflection yoke (for 21" chassis)	53A271
L-113	Choke, heater	53A266
L-114	Choke, r-f (channel 5 tweet filter)	53B008
L-201	Coil, converter i-f	51C1643
L-202	Choke, heater	53A282
L-203	Choke, heater	53A282
L-204	Choke, heater	53A282
L-205	Choke, heater	53B266

§Either one of the two different horizontal stabilizer coils listed above for L-108 may be found in the 1200 series chassis. The 51B1642 coil is easily identified by the 63A902 aluminum plate which must be used for mounting this coil. Neither C-142 (75 mmf) nor C-170 (100 mmf) are required between pin 5 and ground of the horizontal oscillator when the 51B1642 coil is used.

SERVICE PARTS LIST (Cont.)

TUBES & RECTIFIER COMPLEMENT

Schematic Symbol	Description	Hallicrafters Part Number: CHASSIS WITH HEATER TRANSFORMER	Hallicrafters Part Number: CHASSIS WITH SERIES-PARALLEL HEATER CIRCUIT
V-1	R-F amplifier (part of VHF tuner)	---------	---------
V-2	Oscillator/mixer (part of VHF tuner)	---------	---------
V-101	First i-f amplifier	90X6CB6	90X6CB6
V-102	Second i-f amplifier	90X6CB6	90X6CB6
V-103	Third i-f amplifier	90X6CB6	90X6CB6
V-104	Video amplifier	90X6AH6	90X6AH6
V-105	Sync clipper	90X6SN7GT	90X12SN7GT
V-106	Vertical oscillator and output	90X12BH7	90X12BH7
V-107	Horizontal A.F.C.	90X6AL5	90X6AL5
V-108	Horizontal oscillator	90X6SN7GT	90X6SN7GT
V-109	Horizontal output	90X6BQ6GT	90X25BQ6GT
V-110	Damper	90X12AX4	90X12AX4
V-111	High voltage rectifier	90X1B3GT	90X1B3GT
V-112	Sound i-f amplifier (4.5 MC)	90X6AU6	90X6AU6
V-113	Ratio detector	90X6AL5	90X6AL5
V-114	Audio amplifier	90X6C4	90X6C4
V-115	Audio output amplifier	90X6W6	90X25L6GT/G
V-116	Picture tube	----------	----------
X-101	Selenium rectifier (300 ma.)	27A173	27A173
X-102	Selenium rectifier (300 ma.)	27A173	27A173
X-103	Video detector (1N60 germanium diode) or Video detector (1N64 germanium diode)	19B1246	19B1246
V-301	UHF Oscillator (part of UHF tuner)	----------	----------

VHF & UHF TUNING UNITS

	A, D, K, L, P, R, W & X1200D CHASSIS	F, G & T1200D CHASSIS	J1200D CHASSIS	Y & Z 1200D CHASSIS
VHF tuning unit assembly, complete with tubes. Refer to part number stamped on top of tuner chassis.	1C1345 Pentode type with 90X6BC5 r-f amplifier and 90X6J6 oscillator/mixer.	1C1376 Cascode type with 90X6BZ7 or 90X6BQ7 r-f amplifier and 90X6J6 oscillator/mixer.	1E1380 Cascode type with 90X6BQ7 r-f amplifier and 90X6J6 oscillator/mixer.	1E1483, 1E1582 or 1E1670 Cascode 16 position type with 90X6BZ7 r-f amplifier and 90X6X8 oscillator/mixer.
UHF tuning unit assembly, complete with tube and crystal diode.	None	None	None	1E1484 or 1E1659 with 6AF4 oscillator and 1N82 crystal mixer.

CAPACITORS

SPEAKERS

DESCRIPTION		HALLICRAFTERS PART NUMBER
Speaker, 6½" Electrodynamic; 85 Ohms Field (Cold Resistance)	1010P	85C128
Speaker, 8" Electrodynamic; 61 ohms field (cold resistance)	1012P	85C136
Speaker, 8" Electrodynamic; 85 ohms field (cold resistance)	1013C	85C136
Speaker, 8" Electrodynamic; 61 ohms field (cold resistance)	1026P, 1027P	85A133
Speaker, 6-1/2" Electrodynamic; 85 Ohms Field (Cold Resistance)	1051P 1052P	85C128
Speaker, 6-1/2" Electrodynamic; 61 ohms field (cold resistance)	1053P 1054P	85A135
Speaker, 6-1/2" Electrodynamic; 61 ohms field (cold resistance)	1055C, 1056C, 1060C, 1061C	85C135
Speaker, 8" Electrodynamic; 61 ohms field (cold resistance)	1055C, 1056C, 1060C, 1061C	85A133
Speaker, 8" Electrodynamic; 61 ohms field (cold resistance)	1062C, 1063C	85A133

* USE EXACT REPLACEMENT PART ONLY

CABINET SERVICE PARTS FOR MODEL 1058U

For parts other than those listed below refer to the appropriate chassis and picture tube mounting parts list and any supplementary material that has been added thereto.

DESCRIPTION	HALLICRAFTERS PART NUMBER
Antenna, Built-in VHF Silver Vortex	57D171
Antenna, Built-in UHF	57C182
VHF or UHF Antenna Terminal strip	88A456
Board, Speaker Baffle	32C625
Bolt, Ornamental Head; Speaker Mounting	3B1790
Bracket, Built In Antenna Support	67A2121
Bracket, Glass & Mask Retainer; Top and Bottom	67A2138
Bracket, Glass & Mask Retainer; Left Side	67B2139
Bracket, Glass & Mask Retainer; Right Side	67B2140
Bracket, Cabinet Back Upper Corner Support	67B2009
Bracket, UHF Prism Mounting	67B2147
Cabinet, Table; Mahogany Brown Plastic	116F029
*Cabinet Back Only	8E2040
*Cabinet Back Assembly	41A15453
Cabinet Foot	16A315
Dust Seal	16B343
*Glass, Safety	22A371
Grille, Speaker	7C424
¶Knob, Channel Selector	15C578
¶Knob, Contrast Control	15C517
¶Knob, VHF Fine Tuning & UHF Tuning	15C573
¶Knob, Off-On-Volume Control	15C577
Line Cord and Plugs	87B1668-1
*Mask, Picture Tube	7D395
Nameplate	13A1046
Pad, Glass and Mask Retainer Brackets	16A313
Plug, Speaker, With Leads	6A442
Prism, UHF Dial Indicator	83D434
Prism Mounting clips	76A415
Shield, Picture Tube; Mounted On Cabinet Back	69A411
•Speaker, 6-1/2" Electrodynamic; 85 Ohms Field (Cold Resistance)	85C128
Screw, Plastic; For Mounting Cabinet Back, Safety Glass and Mask	3A266

*When the chassis has a tilted picture tube all of the following parts are used in place of the components listed in the above parts list:

Cabinet Back Only	8B2041
Cabinet Back Assembly	41A15454
Glass, Safety	22E380
Mask, Picture Tube	7D438

¶The following knobs may be used for replacement provided they are replaced as a set:

Knob, Channel Selector	15C588
Knob, Contrast Control	15C587
Knob, VHF Fine Tuning & UHF Tuning	15C590
Knob, Off-On-Volume Control	15C586

• In some models the speaker used is part number 85A135 with a 61 ohms field. When this speaker is used a 20 ohms, 10 watt, flat wirewound resistor 24-927 is connected in series between the red speaker field cable lead and the point from which field voltage is obtained.

CH. Y1200D, Runs 1, 2, 3, 4, 5
CH. Z1200D, Runs 1, 1A, 2, 3, 4

THE FOLLOWING INFORMATION IS INTENDED TO BE USED IN CONJUNCTION WITH ANY TELEVISION CHASSIS INCORPORATING THIS TYPE OF UHF TUNING UNIT.

IDENTIFICATION

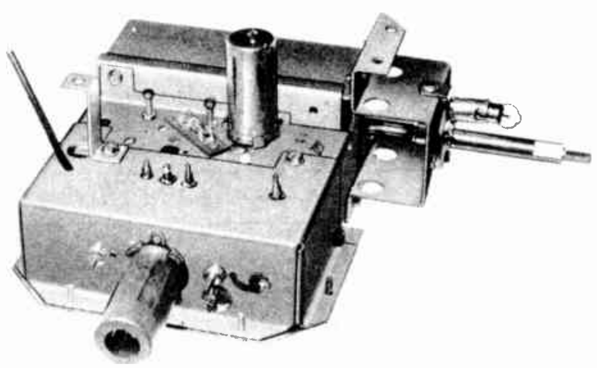

Figure 1. UHF Tuner Assembly

INTRODUCTION

This UHF tuner is of continuous design. In other words, tuning for a UHF channel is not unlike tuning a radio for a radio station. The tuning range is from channel 14 through 83. There are two parts to the tuner; the R-F Section (Mallory Tuning Unit) and the Pre-Amp Section. The tuner is located under the chassis pan and is accessible only by removing the chassis from the cabinet. Circuit operation is described below.

CIRCUIT OPERATION OF THE UHF TUNER

The method of operation may be best understood by referring to the block diagram of the UHF Tuner Assembly, Figure 2. As shown in the upper left of the diagram, the antenna, a UHF-VHF combination type, is connected to the input of the preselector when function switch is in the UHF position. The line connecting the antenna has a normal impedance of 300 ohms.

ELECTRICAL AND MECHANICAL DATA

Antenna Input Impedance	300 Ohms balanced
Output	Single output for sound and picture
R-F Amplifier	6BQ7 or 6BZ7
Mixer-Oscillator	6AF4
Tuning Range	Channels 14 - 83
Tuning Mechanism	Continuous

The signal may be traced to the first tuned circuit, which is resonated to the channel to be received. It is then coupled capacitively to the second tuned circuit, which has the same resonant frequency. The coupling between the circuits is such that a bandpass of 6 mc or more is obtained. The output of the second tuned circuit is matched to the Xtal which is also fed by a voltage from the oscillator shown to the right. The oscillator frequency is so arranged that it is higher than the signal by the I-F frequency and by being connected to the tuning shaft, remains spaced by this amount throughout the band.

A connection from the Xtal circuit to the cascode I-F section contains a filter which passes the difference in frequency of the I-F but rejects the signal frequency.

This I-F signal is now amplified through the cascode stage approximately twenty-five times. However, in the mixing process, the resulting I-F signal is three times down as compared to the R-F signal. This then gives an overall gain of eight times or slightly more.

Lastly, the output of the cascode stage is link-coupled to the first I-F grid coil of the main video I-F amplifier and from there on, the usual circuit actions take place as in the VHF television receiver.

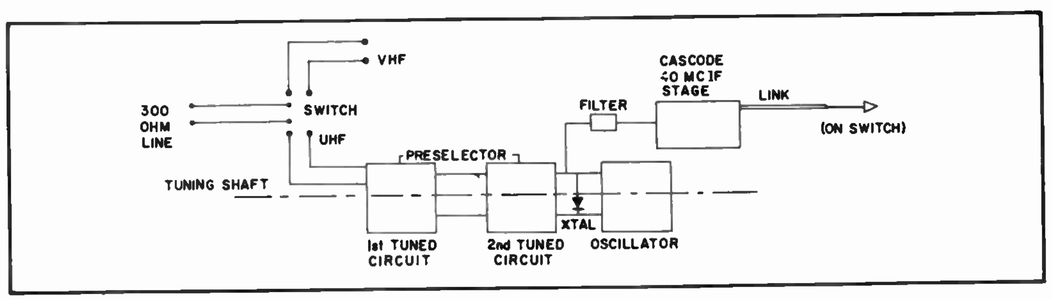

Figure 2. Block Diagram, UHF Tuner Assembly

ALIGNMENT PROCEDURE:

1. Perform the usual VHF alignment of the set with the function switch control shaft turned to the counter-clockwise position (VHF position). Use the standard alignment procedure. Be sure that the four inter-stage video I-F coils and the traps are tuned accurately to the fixed frequencies specified so that a minimum amount of staggering of the mixer plate coil and 1st grid I-F coil is required to obtain a flat I-F response curve.

2. Throw the function switch to its UHF position by turning control shaft in a clockwise direction. Attach a signal generator to ground (make ground lead as short as possible) and to UHF test point lead through a 120 ohm resistor. Shunt a 10 ohm resistor to ground off test point (see Figure 5). Turn the neutralizing trimmer approximately 3 turns out from its maximum clockwise position, using a center frequency of approximately 44 mc. Adjust the two UHF I-F transformers so as to obtain a flat response between the frequency limits given for the VHF bandwidth.

   When necessary, turn the neutralizing trimmer to broaden the response curve of the first circuit.

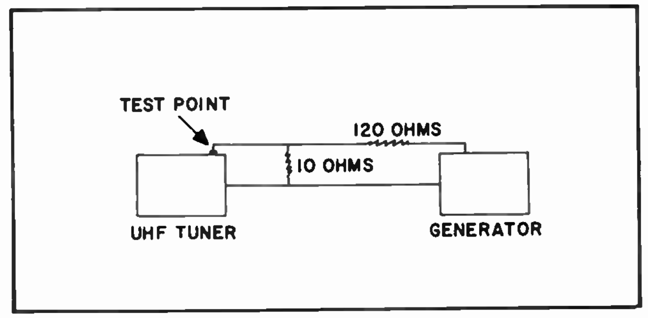

Figure 5. Alignment Test Set-up

NOTE

Each time the neutralizing trimmer is turned, it changes the tuning of the adjacent coil which must be recentered.

3. Close the test point through a meter (0-10) ma dc and check to see that the injection current runs 1 to 2 ma over the band. This should be approximately 1.5 ma over 500 to 750 mc.

4. Solder test point lead to chassis and check to see that shields are fastened tightly.

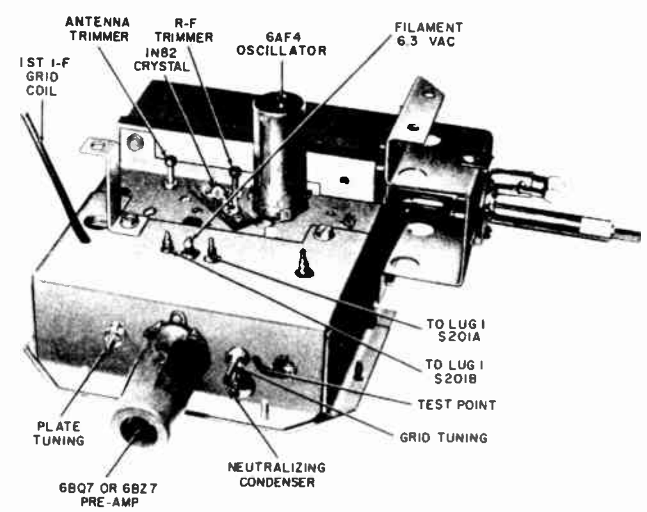

Figure 4. UHF Tuner Assembly

IDENTIFICATION

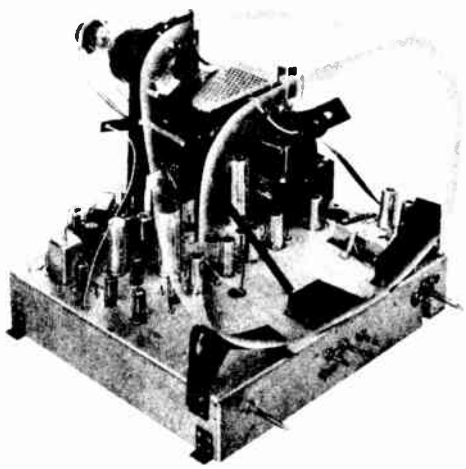

Figure 1. Chassis 195 TV Chassis

Chassis 195 receiver incorporates a low radiation "40 megacycle" cascode type tuner, the RF-11, that comprises the R-F stages.

Both picture and sound output from the tuner is fed to the first of four stages of stagger-tuned I-F amplification. The picture carrier frequency is 45.75 mc. An intercarrier type sound system is employed, the 4.5 mc sound take-off occuring at the output of the video detector. The sound is fed into the first of two 4.5 mc sound I-F stages. A 39.75 mc adjacent channel picture trap, a 41.25 mc co-sound trap, and a 47.25 mc adjacent channel sound trap are employed in the video I-F stages.

A ratio detector is used as the sound second detector. This stage is followed by a stage of voltage amplification which drives a stage of power amplification. The beam power output tube is coupled to the speaker through an audio output transformer which is located on top of the receiver chassis.

The video detector is one-half of a miniature dual diode vacuum tube. The output from this detector is coupled directly to the video amplifier through high frequency compensating shunt and series peaking coils. The single stage of video amplification is directly coupled to the cathode of the picture tube through high frequency compensating shunt and series peaking coils. Since direct coupling is employed, no DC restoration circuit is needed in the receiver.

ELECTRICAL AND MECHANICAL DATA

TABLE I - ELECTRICAL AND MECHANICAL DATA

Operating Voltage	115 Volts AC, 60 cps
Power Consumption	200 Watts
Tuning Range	Channels 2-13
Maximum Audio Power Output	3 Watts
Audio Output Impedance	6.4 Ohms tapped at 3.2 Ohms at 400 cps
Intermediate Frequencies	
Picture Carrier	45.75 Mc
Sound Carrier	4.5 Mc
Antenna Input Impedance	300 Ohms, balanced
Picture Tube Size	17" Rectangular

TABLE II - TUBE COMPLEMENT

TUBE	TYPE	FUNCTION
V1	6BZ7 or 6BQ7	R-F Amplifier
V2	6J6	Oscillator-Mixer
V101	6AU6	1st Sound I.F.
V102	6AU6	2nd Sound I.F.
V103	6AL5	Ratio Detector
V104	1/2-6SQ7	Audio Amplifier

V202	6CB6	2nd Picture I.F.
V203	6CB6	3rd Picture I.F.
V204	6CB6	4th Picture I.F.
V205	1/2-6AL5	Video Detector
V301	6AH6	Video Amplifier
V302	17HP4 (Chassis 195)	Picture Tube
V401	6AU6	AGC Keyer
V402	1/2-6SQ7	Delayed AGC
V501	6AU6	1st Sync Separator
V502	1/2-6SN7GT	2nd Sync Separator
V601	6SN7GT	Vertical Oscillator
V602	6S4	Vertical Output
V701	1/2-6AL5	Horiz. Phase Det.
V702	1/2-6SN7GT	
V703	6SN7GT	Horiz. Oscillator
V704	6BQ6GT	Horiz. Output
V705	6W4GT	Damper
V706	1B3GT	H.V. Rectifier
V801	5U4G	L.V. Rectifier

Two stages of sync separation are designed into the receiver. They receive the composite video signal from a tap on the video amplifier load resistor.

The second sync separator serves the additional function of a phase splitter for feeding approximately equal and opposite sync pulses to the balanced horizontal phase detector. A negative sync pulse is taken from a tap on cathode resistor, and this pulse is fed to the vertical integrating network, Z501, for the purpose of synchronizing the vertical oscillator.

The vertical oscillator is the cathode-coupled multivibrator type. It drives a single power triode output stage which is coupled to the vertical deflection coils through an output transformer. The positive pulse of the retrace portion of the vertical sweep output voltage is reversed in phase by the transformer action of the output transformer, and the resulting negative voltage pulse is coupled to the picture tube control grid through a .022 uf condenser which also serves to sharpen the pulse so that it is only effective during the retrace portion of the sweep. The negative voltage pulse biases the picture tube beyond cut-off during the retrace portion of the vertical sweep, and the bright retrace lines are blanked out.

The horizontal oscillator is a cathode-coupled type of multivibrator. The stabilizing influence of a parallel tuned L-C circuit is used as part of the plate load of one of the triodes in the multivibrator circuit. The natural frequency of the tuned circuit is made very close to the horizontal sweep frequency. The frequency of the horizontal multivibrator is further stabilized by a balanced horizontal phase detector circuit which consists of one-half of a dual diode and one-half of a dual triode which has its plate and grid tied together so that the triode serves as a diode. The horizontal oscillator drives a stage of power amplification that is coupled to the horizontal deflection coils through an output transformer. The horizontal output transformer is also an active member of the high voltage supply. In addition the horizontal output transformer supplies positive keyer pulses to the plate of the keyed AGC tube and it furnishes a reference saw-tooth voltage in conjunction with the horizontal deflection coil circuit for the horizontal phase detector.

The high voltage section is a high efficiency fly-back type which uses a single half-wave rectifier. The approximately 200 volts that results from the rectification of the fly-back potential across the damper tube is

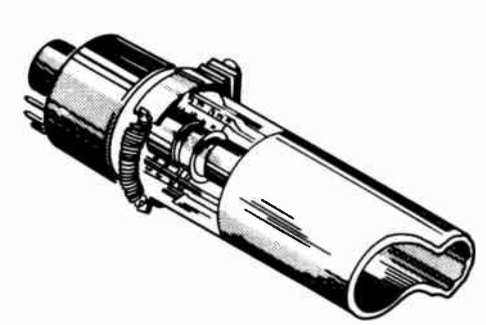

Figure 2. Ion Trap Position

added to the 280 volt bus potential, and this boost voltage of approximately 480 volts is applied to the vertical sweep circuits and electrostatic focus circuit through voltage divider networks which supply the necessary voltage to their respective circuits.

The low voltage power supply is the conventional full-wave rectifier type which delivers power into a condenser input RC filter voltage divider network that supplies the required bus voltage for the circuits throughout the receiver.

Chassis 195 is a 24-tube TV receiver, including the rectangular picture tube.

The picture tube is seated in a support bracket which mounts directly on the receiver chassis of all three chassis types.

Provision is made for phono input on Chassis 195. The phono reproduction may be selected by the use of a double-pole double-throw switch once a record player has been connected to the TV chassis. The selector switch performs the functions of switching the audio amplifier from the ratio detector output to phono input and switching the picture tube control grid from the brightness control circuit to ground, cutting off the picture tube raster when the phonograph is being played. Phono motor power is provided through an AC outlet at the rear of the receiver chassis. A color converter receptacle is also available at the rear apron of the chassis. When the converter is not being utilized, a five-pin plug is inserted in the receptacle. Pins 1 and 5 of the plug are jumpered together, and it is essential that the plug be inserted in the receptacle in order that the B+ circuit to the brightness control be complete.

FUSE PROTECTION

Two sources of fuse protection are provided in the chassis. The entire receiver is protected against over-loading due to short circuiting that results in excessive input current being drawn by the power transformer. The fuse used for this purpose is a 3-ampere Slo-Blo type that is housed in a fuse holder mounted on the chassis rear apron. The second source of fuse protection is in the horizontal output screen circuit and damper circuit. A 1/4-ampere fuse is held in a fuse clip located inside of the high voltage cage at the left rear corner.

MAINTENANCE

The 195 chassis and its complete model assembly is designed to facilitate receiver servicing. The chassis is mounted in a horizontal position within the cabinet. It is held in position within the cabinet by four bolts which thread into four mounting brackets located at the corners of the chassis. The four bolts are inserted from below the mounting shelf in the cabinet. Removal of the backboard exposes the top of the chassis. The removal of one screw from the bottom rear of the high voltage cage allows the back and top of the cage to be rotated away for servicing inside of the cage. The bottom of the chassis is made accessible by removing the bottom cover board which is held in place by several wood screws. Tuner oscillator adjustments may be made by removing the channel selector knob and inserting a non-metallic screw-driver through the access hole located at the right-hand side of the tuner shaft.

OPERATING INSTRUCTIONS

Front Panel Controls

Refer to Figure 3 for location of front panel controls.

OFF-ON VOLUME CONTROL

The VOLUMF control is part of a dual type potentiometer being associated with the CONTRAST control. The chassis power switch is mechanically linked to the volume potentiometer. This switch opens the 115V power line to the receiver power transformer and AC RECEPTACLF when the VOLUME control shaft is turned to the extreme counterclockwise position. The initial rotation of the shaft in the clockwise direction closes the AC switch and causes the sound level to start increasing toward maximum audio power output. The smaller, outer, left-hand knob is the one that turns the VOLUME control shaft when the knobs are in place.

CONTRAST CONTROL

The CONTRAST control varies the gain of the video amplifier. With the AGC system used for maintaining constant signal level, the CONTRAST control becomes primarily useful in setting background level for best viewing under various room lighting levels or different average program contrast levels. To increase picture contrast turn the CONTRAST control clockwise. The large, inner, left-hand knob is the one that turns the CONTRAST control shaft when the knobs are in place.

TUNING CONTROLS

The tuning controls are the dual type. To select a desired channel, turn the CHANNEL SFLECTOR shaft in either direction until the desired channel's coils are in operating position in the tuner. Once a channel has been chosen, tune the FINE TUNING control shaft counterclockwise until the picture starts to become wavy and variable dark horizontal lines and bars appear in the picture. Turn the shaft clockwise until the lines and bars just disappear and the picture appears clear and sharp. Do not turn too far in the clockwise direction or definition will start to decrease. Picture and sound tuning are synchronized so that the best picture will come in with best sound when alignment is correct.

The remaining three front panel controls are located behind the front controls cover plate when the chassis is in position in its cabinet. Pull the cover plate down from the front panel to reach these controls.

BRIGHTNESS CONTROL

The BRIGHTNESS control sets the average background illumination of the picture.

1. Temporarily turn the CONTRAST control to minimum setting (extreme counterclockwise).
2. Turn the BRIGHTNESS control so that a medium illumination is visible on the screen.

This setting produces a picture with average background characteristics at about three-quarters contrast setting. For individual tastes that vary from this recommendation, the BRIGHTNESS control may be set so that the picture is most pleasing to the customer.

VFRTICAL HOLD CONTROL

The Vertical Hold control has a hold-in range over which the picture will stay in vertical sync. Turn the control so that the picture is brought from a downward moving picture into sync and best interlace of the sweep lines is observed.

TONE CONTROL AND TV-PHONO SWITCH

The control is dual control. A double pole double throw switch is mounted at the rear of the tone potentiometer. The switch is activated when the tone control shaft is turned to either the extreme clockwise position or the extreme counterclockwise position. Extreme counterclockwise rotation of the tone control switches the receiver for TV operation and provides maximum bass response. Clockwise rotation of the control provides continuous increase in treble response. Maximum clockwise rotation switches the receiver to PHONO operation. When changing from one function to the other, turn the control in the appropriate direction until a click is heard. Then turn the control until the desired tone is obtained.

Rear Adjustments

The rear chassis controls are intended to be adjusted by the dealer or his service representative at the time of installation in the customer's home or during a service call. Once adjusted correctly, these controls need not be changed over long periods of time or unless a specific service problem develops. Refer to Figure 3 for location of rear controls.

ION TRAP

The effects of the FOCUS control, ion trap, and centering magnet orientation are slightly interdependent and one or two sequential adjustments of each may be necessary for optimum setting of these controls. Always set the ion trap for maximum raster brightness.

CAUTION

Never attempt to center the picture by misadjustment of the ion trap.

Set the BRIGHTNESS and CONTRAST controls about midrange, never at maximum setting, to avoid damaging the picture tube. Move the ion trap over the "flags" of the picture tube first anode. Refer to Figure 2. Rotate the ion trap on the picture tube neck until light appears on the screen. After initial light has been obtained, move the ion trap back and forth and further rotate it to obtain the brightest raster. If the receiver is equipped with a Rauland picture tube, the optimum ion trap setting is indicated by minimum green glow inside the tube neck.

FOCUS ADJUSTMENT

Electrostatic focusing is used. The picture tube is designed for optimum focus at some fixed potential relative to its cathode, the potential value depending chiefly upon tube type, but the variation of focus with several hundred volts change in focus potential is very slight. The FOCUS control is a 2 megohm potentiometer connected between boost voltage (approx. 480 volts) and ground. The arm of the potentiometer is connected to the focusing electrode in the picture tube.

With a picture on the picture tube screen, turn the FOCUS control until the sharpest picture is obtained at the center of the picture.

HORIZONTAL DRIVE ADJUSTMENT

1. Turn the HORIZ. DRIVE control counterclockwise until a drive bar (thin, light vertical line) appears.
2. Turn the control clockwise until the drive bar just disappears. If no drive bar is obtained, set the control at the maximum counterclockwise position.

HORIZONTAL HOLD CONTROL

The HORIZONTAL HOLD control provides a vernier adjustment for the horizontal multivibrator operating frequency. Proper setting depends on correct adjustment of the HORIZ. FREQ. and HORIZ. DRIVE controls.

Turn the Horizontal Hold control until bending of the top portion of the picture is eliminated. This is best determined by noting the vertical lines in the picture.

HORIZONTAL FREQUENCY CONTROL

1. Turn the Horizontal Hold control to mid-range.
2. Turn the HORIZ. FREQ. control counterclockwise while switching the CHANNEL SELECTOR on and off channel until sync is lost.
3. Turn the control clockwise and check the number of bars which appear just before pull-in of the picture. Check circuit for abnormal operation if less than two bar pull-in occurs.
4. Continue turning control clockwise while switching the CHANNEL SELECTOR on and off channel until sync is lost.
5. Turn the control counterclockwise and check the point where picture pull-in occurs.
6. Turn the control an additional 1/2 turn counterclockwise.

HORIZONTAL LINEARITY

Adjust for best Horiz. Linearity with a test pattern. This is generally obtained when the slug is nearly all the way in.

WIDTH ADJUSTMENT

To adjust picture width, turn WIDTH control, L705 clockwise to increase width, counterclockwise to decrease width. When adjusting picture width, remember to take line voltage into consideration if it differs by more than several volts from the value usually existing when and/or where the receiver is to be operated. Make allowance for voltage difference when adjusting width. Width increases with increase in line voltage.

VERTICAL SIZE AND LINEARITY ADJUSTMENTS

The VERT. SIZE and VERT. LINEARITY controls adjust the height and vertical proportion of the picture. The VERT. SIZE control affects the height of the entire picture but not in a linear manner. The bottom portion of the picture is expanded at a greater rate than the top portion, and the picture center tends to move toward the top of the picture tube.

1. Turn the VERT. SIZE control counterclockwise to increase the height of the picture and clockwise to decrease the picture height.

The VERT. LINEARITY control affects the upper portion of the picture and compensates for non-linearity created by changes made by the VERT. SIZE control.

2. Turn the VERT. LINEARITY control clockwise to expand the upper portion of the picture and counterclockwise to compress the upper portion of the picture.

After adjustment of the picture height and/or vertical linearity, check the VERT. HOLD adjustment; the three controls are interdependent. The same caution that was given for picture width and line voltage applies equally well to vertical picture size.

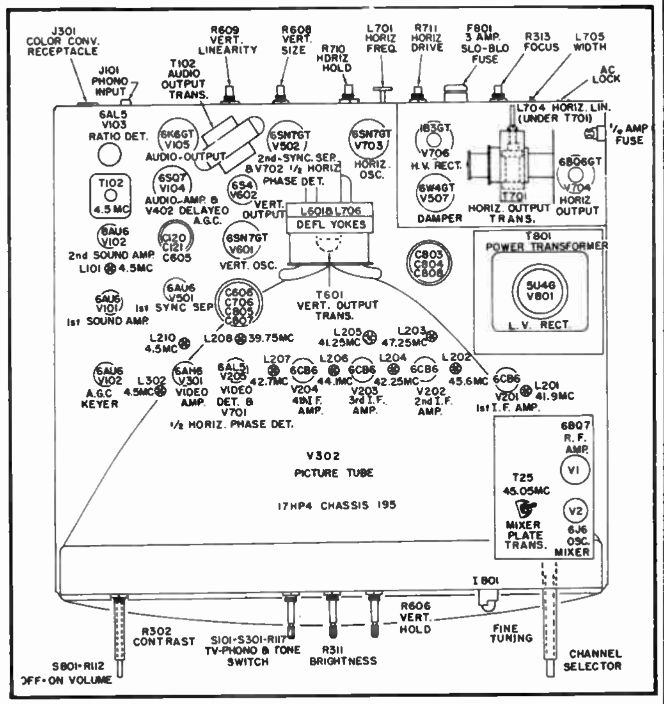

Figure 3. Top View Parts Layout

RASTER CENTERING

It is best to adjust the picture linearity and size, using a test pattern, before centering the picture. If picture tilt exists, temporarily loosen the wing screw at the top of the deflection yoke and rotate the yoke until the tilt is eliminated. Make certain that the deflection yoke is seated as far forward on the picture tube neck as it is possible to move the yoke.

Raster centering is accomplished by adjusting two permanent magnet rings on the neck of the picture tube just behind the deflection yoke. The centering assembly should be positioned very near the deflection yoke (never more than an inch behind). Due to inter-action it will be necessary to rotate both magnets to obtain correct centering in most instances.

MAXIMUM PERFORMANCE SELECTOR

This control and its associated circuits regulate R-F and I-F AGC voltages (within the limits of the AGC system). When the AGC control is turned full clockwise the greatest bias appears on the I-F AGC bus and the lowest bias appears on the R-F AGC bus for a given signal. When the control is reversed the I-F AGC bias voltage is minimum and the R-F AGC bias is maximum for a given signal. This source of high R-F bias is very useful when strong signals cause the video stages to overload, clipping the sync pulses. In very strong signal areas turn the AGC control counterclockwise until loss of sync is eliminated. Do not turn more than necessary because increase bias on the R-F amplifier with simultaneous decrease in I-F bias will lead to excessive noise in the picture after a certain point. Conversely, in weaker signal areas the control should be turned clockwise so that the R-F bias is reduced and the I-F bias is increased. This condition will improve the signal to noise ratio, minimizing "snow", in the picture. Again, do not over control or the I-F stages may be overdriven. The optimum point is a function of signal strength. Use picture quality as an indicating device and adjust for optimum performance.

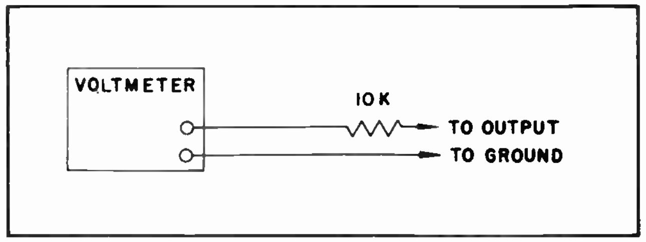

Figure 6. Voltmeter Isolation

Ratio Detector Alignment

Equipment: Generator input remains unchanged from the level that produced 6.5 to 7 volts in the preceding step. Connect the voltmeter across the junction of R111 and R112 and the switch side of R110; polarity will depend upon which side of resonance the secondary winding of T101 is tuned. If a VTVM is being used, set the zero voltage point up scale so that plus and minus readings may be observed without changing the polarity selector switch on the VTVM. Start with one of the higher scales of the VTVM and decrease the scale setting as the null point is obtained.

Procedure: Tune the secondary (top) of T101 for a zero reading on the voltmeter. Do not change the generator output level from that which produced the 6.5 to 7 volts in the first step. Repeat tuning of T101 primary and secondary until adjustments do not change.

Trap and Picture I-F Alignment

TUNING 4.5 MC TRAP

Equipment: Connect the CW generator through the .005 uf isolating condenser, to pin 7 of V205 (plate of video detector) and tune the generator to 4.5 mc. Connect the detector network and voltmeter between ground and the cathode of the picture tube as shown in Figure 7.

Procedure: Tune L302 (4.5 mc trap in plate circuit of video amplifier) for minimum indication on voltmeter.

TUNING 39.75 MC, 41.25 MC, AND 47.25 MC TRAPS

Equipment: Couple the CW generator "hot" lead to the tuner mixer grid. This may be done in several ways. The .5-3 uuf trimmer condenser (C12 in Bulletin 301) located in front of the 6J6 and nearest the contact side of the tuner is connected to pin 5 of the 6J6, the mixer grid. This plate of the trimmer condenser is accessible through a hole in the side cover plate. The "hot" generator lead may be coupled to this point through a .005 uf isolating condenser, the condenser pigtail being clipped to the trimmer by some convenient means. Another method of coupling the generator is to remove the 6J6, wrap the isolating condenser pigtail around pin 5 of this tube, and replace it in its socket. In either method take care that the pigtail lead does not short to ground. A third method of coupling is to pull the 6J6 tube shield up on the tube until it is not grounded. Clip the "hot" lead of the generator directly to the tube shield. The tube shield and the tube electrodes form a condenser which capacitively couples the signal to the mixer grid. The capacity is much less than .005 uf, and a much higher level of generator output will be required if this method is utilized.

Connect the negative lead of the voltmeter to pin 1 of V301, the video amplifier grid, using the 10K ohm isolating resistor at the end of the lead; connect the voltmeter positive lead to ground. Connect the negative terminal of the 3 volt bias source to the AGC bus; connect the bias source positive lead to ground.

Procedure: Turn the CONTRAST control to its maximum position (extreme clockwise) for remainder of alignment. Tune the traps by setting the trap frequency on the CW generator and adjusting the trap slug for a minimum voltmeter reading. The order of tuning the traps is given in Table III. Keep signal low to avoid overloading I-F circuits.

TUNING PICTURE I-F COILS

Equipment: Instruments and set-up remain the same as for trap alignment during the first part of the procedure. For final adjustment the sweep frequency generator is also used and the voltmeter should be replaced by the oscilloscope. See Figure 8 for oscilloscope isolation details.

Procedure: Tune the I-F coils by setting the coil frequency on the CW generator and adjusting the coil for maximum voltmeter reading. The CW generator output must be attenuated so that the DC output voltage of the video detector (indicated on the voltmeter), remains at 1 volt as the I-F coils are tuned. The order of tuning is from the last I-F stage toward the tuner. Before tuning the grid coil of the 1st I-F stage, temporarily tune the tuner mixer plate coil for a minimum reading on the voltmeter at 41.90 mc. After the 1st picture I-F grid coil has been tuned, tune the mixer plate coil to 45.05 mc and repeat the trap and I-F alignment procedure until no additional change in adjustments is necessary.

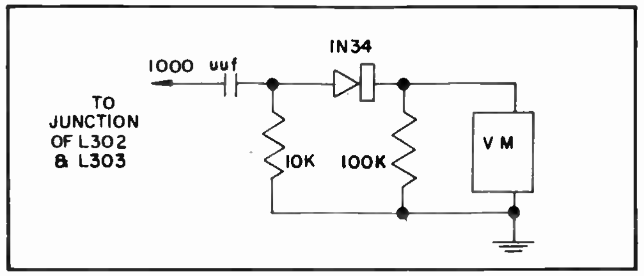

Figure 7. Detector Network

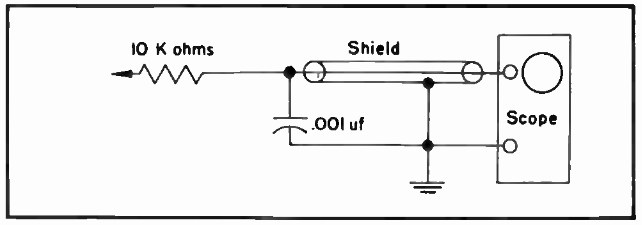

Figure 8. Oscilloscope Isolation

When no further change takes place, replace the voltmeter with the oscilloscope and replace the CW generator with the sweep frequency generator. Use the same isolating condenser and input connection to the mixer grid. Loosely couple the CW generator (marker) to the input by clipping or touching the CW generator "hot" lead to the unshielded insulated end of the sweep generator "hot" lead. This will afford a small amount of capacitive coupling. If the CW and sweep generators are contained in the same instrument, it will only be necessary to switch on the sweep frequency generator in order to continue the procedure. Tune the sweep frequency generator to a center frequency of approximately 43.8 mc. Use a sweep width of approximately 10 mc so that the base of each of the two response curve skirts is well within the ends of the oscilloscope trace. Check the overall bandwidth, position of the picture carrier, dip in bandpass, and trappage by using the marker pip to locate frequency points on the response curve. See Figure 9. Tune the CW generator to 45.75 mc. The marker pip should appear at approximately the 50% point on the response curve skirt. Adjust the 1st I-F grid coil, L201, to eliminate any tilt of the response curve and adjust the mixer plate transformer T25 to set the picture carrier at the 50% response point. It should not be necessary to readjust the other picture I-F coils. Once the picture carrier has been correctly positioned, tune the CW generator so that the marker pip moves to the 50% response point on the opposite skirt. Note the frequency calibration of the CW generator dial and subtract this value from 45.75 mc. The difference should be between 3.6 mc and 3.8

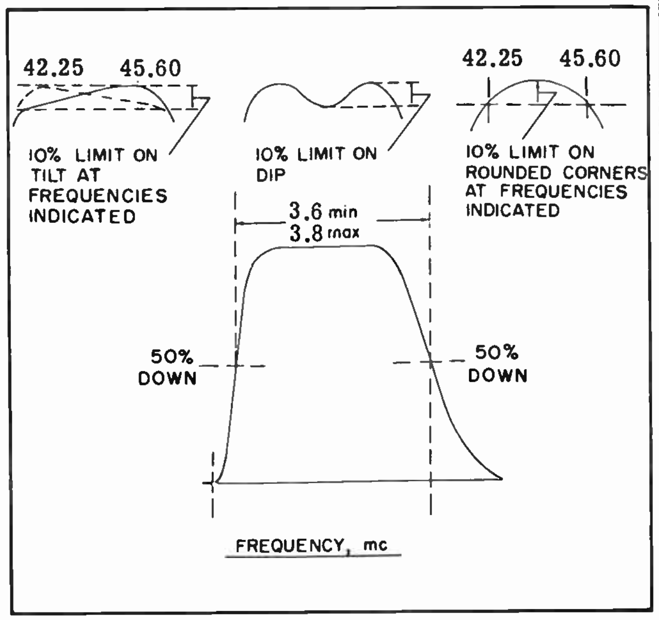

Figure 9. Picture I-F Response Curve

mc, the bandpass limits taken between 50% point of picture carrier and 50% point of opposite skirt. If the bandpass does not lie within these limits, touch up the other I-F coils until the correct curve is obtained. Any appreciable touch-up requirement should be taken as an indication that the I-F Section is not operating normally and should be checked for abnormalities.

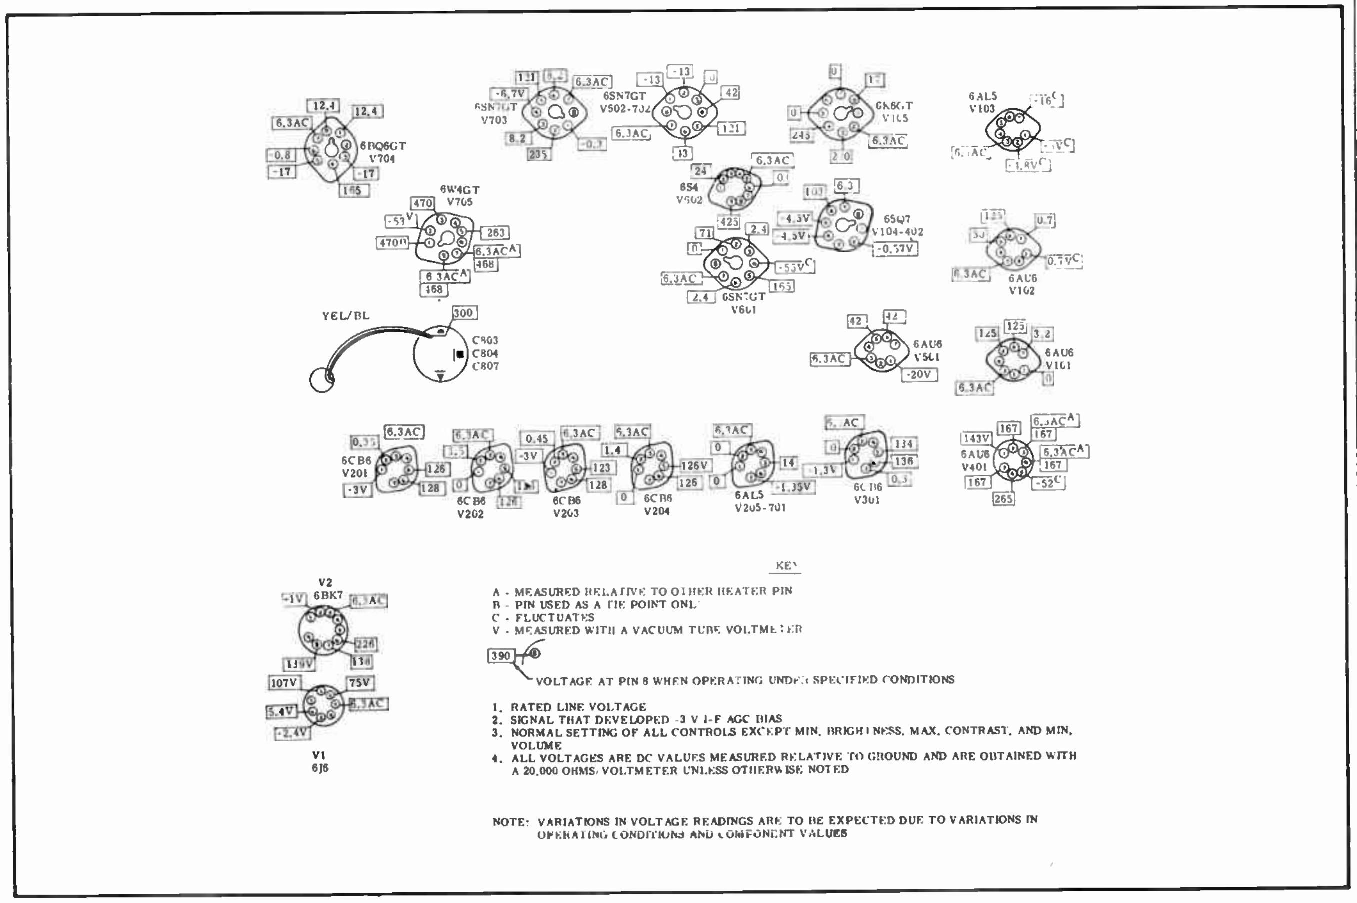

TABLE III - TV ALIGNMENT PROCEDURE

STEP NO.	SIGNAL GENERATOR FREQUENCY, MC	CONNECT SIGNAL TO	OUTPUT INDICATOR	ADJUST	INSTRUCTIONS	SPECIAL CONNECTIONS AND SETTINGS
			SOUND I-F AND RATIO DETECTOR			
1	4.5 CW	Pin 7 of V205	Meter across pin 7 of V103 and ground.	T101 Pri. (bottom) L101 L210	Tune for maximum reading on meter.	Signal level should be low enough to obtain approximately 6.5 to 7 volts on meter. Use isolation networks shown in Figures 5 and 6.
2	4.5 CW	"	Meter across junction of R111 and R112 and switch side of R110.	T101 Sec. (top)	Tune for zero meter reading; use same signal level as in step 1.	Repeat tuning of T101 primary and secondary until adjustments do not change.
			TRAPS AND PICTURE I-F			
3	4.5 CW	Pin 7 of V205	Meter connected through detector network to picture tube cathode lead.	L302	Tune for minimum reading on meter.	Detector and isolating networks shown in Figures 5 and 7. Temporarily detune L210.
4	39.75 CW	Mixer grid	Voltmeter across pin 1 of V301 and ground.	L208	Tune for maximum reading on meter.	Apply -3V bias to AGC bus. See text for connection to mixer grid. Use isolating resistor between negative voltmeter lead and pin 1 of V301. Keep generator output low. Remove 1/4 amp. fuse or bias V704 with -60V for remainder of procedure.
5	41.25 CW	"	"	L205	"	
6	47.25 CW	"	"	L203	"	
7	42.70 CW	Mixer grid	"	L207	Tune for maximum reading on meter.	Set CONTRAST control for maximum contrast. Adjust signal level throughout I-F alignment so that a 1 volt DC output is maintained at pin 1 of V301.
8	44.10 CW	"	"	L206	"	
9	41.25 CW	"	"	L204	"	
10	45.60 CW	"	"	L202	"	
11	41.90 CW	"	"	L201	"	Temporarily tune mixer plate transformer for minimum voltmeter reading at 41.90 mc.
12	45.05 Cw	"	"	Mixer Plate Coil, L4	"	
13		Repeat steps 4 through 12 until adjustments do not change.				
14	Approximately 43.8 with 10-mc sweep. Marker required.	Mixer grid	High gain scope to pin 1 of V301.	Mixer Plate Coil and L201 1st. Other coils if necessary.	Set 45.75 mc marker at 50% point with Mixer Plate transformer T25. Eliminate tilt with L201	See Figure 8 for isolation network. Use markers to determine bandpass between picture carrier and 50% point on opposite skirt. Bandpass should be between 3.8 mc and 3.6 mc. Adjust other I-F coils to obtain proper curve only when absolutely necessary.

ALIGNMENT

The following alignment procedure describes alignment of the stagger-tuned video I-F amplifier stages and the 4.5 mc sound I-F amplifier stages.

The following discussion describes recommended methods and equipment to be used and precautions to be observed during the alignment procedure. Table III offers a ready reference alignment guide to be followed after the more detailed procedure has been studied.

For best results it is important that alignment be performed on a metal topped bench with all instruments and equipment securely bonded together and to ground. All leads should be as short as is practicable, particularly in the input grid circuits. Allow about fifteen minutes for the test equipment and receiver to warm before beginning the alignment. Isolation circuits will be required for both the input and output connections. It is important that composition resistors, preferably the half-watt size, and disc type ceramic condensers be used in making up these isolation networks so that a minimum amount of external inductance is added to the tuned circuits being adjusted.

The following equipment* will be required in order to align the picture and sound I-F stages of the receiver properly.

1. Accurate CW signal generator covering the following frequencies:

4.5 mc	44.10 mc
39.75 mc	45.60 mc
41.25 mc	45.75 mc
42.25 mc	47.25 mc
42.70 mc	

The generator must have an attenuation control which can be used to vary its output signal level.

2. Sweep frequency generator with a sweep center frequency of approximately 43.8 mc and a 10 mc sweep width.
3. Cathode Ray Oscilloscope with at least a moderately high vertical gain. Must have external sweep input or internal sweep frequency equal to the sweep generator sweep frequency and capable of phase control.
4. DC voltmeter with sensitivity of 20,000 ohms per volt or higher and voltage scale ranges which include approximately 10 volts and 3 volts (full scale deflection). VTVM with zero center scale adjustment is an ideal type.
5. 3 volt bias source such as a battery.
6. Detector network shown in Figure 7.
7. .005 uf isolating condenser.
8. 10K ohm, 1/2 watt composition resistor.
9. .001 uf condenser for shunting oscilloscope input.

*Several instrument manufacturers combine the first three items of the equipment list into one compact instrument assembly.

Before alignment is begun, tune the tuner off-channel by turning the tuner CHANNEL SELECTOR shaft so that the detent roller rests on one of the high points of the drum disc. Remove the 1/4 amp. fuse or bias pin 5 of V704 with -60 volts, in order to eliminate spurious signals and possibility of high voltage shock hazard.

ORDER OF ALIGNMENT

1. Sound I-F and Ratio Detector Primary
2. Ratio Detector Secondary
3. 4.5 mc Sound Take-off
4. 4.5 mc Beat Trap
5. 39.75 mc Adj. Channel Picture Trap
6. 41.25 Co-channel Sound Trap
7. 47.25 Adj. Channel Sound Trap
8. 42.70 mc 4th Picture I-F Coil
9. 44.10 mc 3rd Picture I-F Coil
10. 41.25 mc 2nd Picture I-F Coil
11. 45.6 mc 1st Picture I-F Coil
12. 41.9 mc 1st Picture I-F Grid Coil
13. 45.05 mc Mixer Plate Coil

It is important that the alignment be performed in order listed, with the exception of items 1 and 2, because there is some interaction within the various stages. It is for this reason that step 13 is included in the alignment table.

Sound I-F Alignment

Equipment: Connect the "hot" lead of the CW signal generator to the grid, pin 1, of V101, the 1st sound I-F tube, through a .005 uf isolating condenser as shown in Figure 5. Tune the generator frequency to 4.5 mc, unmodulated. Connect the voltmeter negative lead in series with a 10K isolating resistor to pin 7 of V103, one plate of the ratio detector, as shown in Figure 6. It is important that the 10K ohm isolating resistor be at the very end of the meter lead to avoid regeneration. Connect the positive voltmeter lead to ground.

Procedure: Adjust L101, L210 and T101 primary (bottom), to obtain a maximum voltmeter reading. The maximum voltage reading should be held at about 6.5 to 7 volts by decreasing the generator output as the transformer windings are turned to resonance.

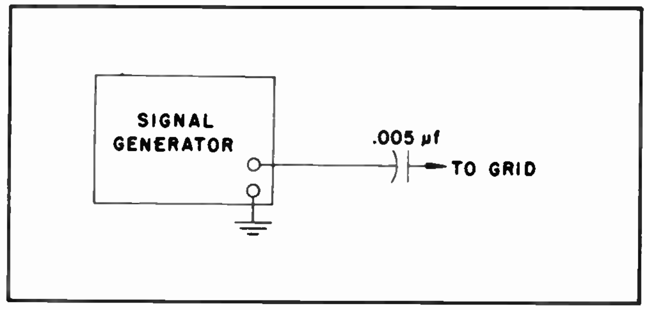

Figure 5. Signal Generator Isolation

PARTS LIST

NOTE: Unless otherwise noted all resistors are 1/2 watt, composition type, ±10% tolerance with values given in ohms.

MODELS 7M140, 7B141
CHASSIS 300-21
MODELS 21M143, 21B144, 21P145, 21M317, 21B318, 21M718, 21B719, 21P720

NOTE

This information also covers the 300 series chassis, incorporating the "All-Wave Tuner".
Chassis incorporating the "All-Wave Tuner" can be identified by a "U" following the model number. (Example 7M140U)

IDENTIFICATION

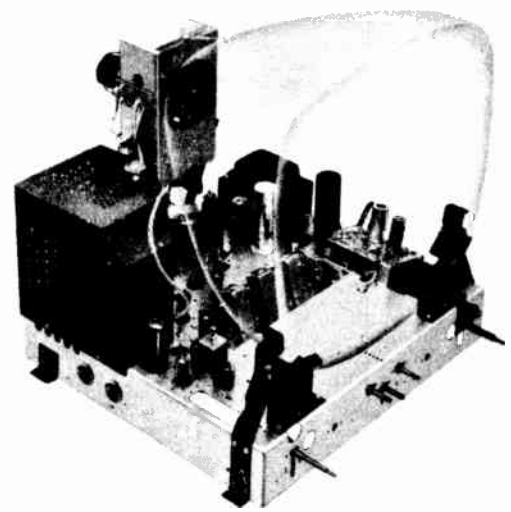

Figure 1. Chassis 300 TV Chassis

Chassis 300-17 and 300-21 will come under the collective heading of the 300 series chassis.

The 300 series chassis will incorporate either a 9786 VHF tuner or a 9795 All-Wave tuner which comprises the RF stages of the receiver.

This tuner is identical to the 9758 tuner except that the coupling is changed. If a 9795 All-Wave tuner is used refer to this bulletin. Both picture and sound output from the tuner is fed to the first of three stages of stagger-tuned I-F amplification. The picture carrier frequency is 45.75 mc. An intercarrier type sound system is employed, the 4.5 mc sound takeoff occurring at the output of the video amplifier. The sound is fed into a single 4.5 mc sound I-F stage.

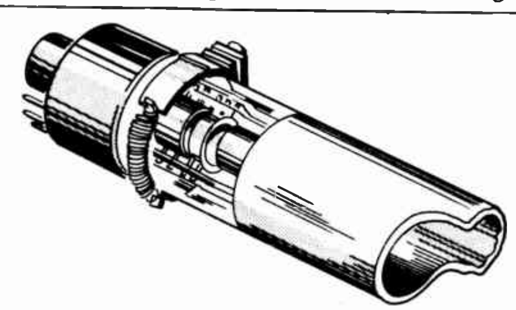

Figure 2. Ion Trap Position

ELECTRICAL AND MECHANICAL DATA

TABLE I - ELECTRICAL AND MECHANICAL DATA

Operating Voltage	115 Volts AC, 60 cps
Power Consumption	155 Watts
VHF Tuning Range	Channels 2-13
Maximum Audio Power Output	1.6 Watts
Audio Output Impedance	3.2 Ohms at 400 cps
Intermediate Frequencies Picture Carrier Sound Carrier	 45.75 mc 4.5 mc
Antenna Input Impedance	300 Ohms, balanced
Picture Tube Size	17" and 21" Rectangular

HORIZONTAL DRIVE ADJUSTMENT

1. Turn the HORIZ. DRIVE control counterclockwise until a drive bar (thin, light vertical line) appears.
2. Turn the control clockwise until the drive bar just disappears. If no drive bar is obtained, set the control at the maximum counterclockwise position.

HORIZONTAL FREQUENCY CONTROL

1. Turn the Horizontal Hold control to mid-range.
2. Turn the HORIZ. FREQ. control counterclockwise while switching the CHANNEL SELECTOR on and off channel until sync is lost.
3. Turn the control clockwise and check the number of bars which appear just before pull-in of the picture. Check circuit for abnormal operation if less than two bar pull-in occurs.
4. Continue turning control clockwise while switching the CHANNEL SELECTOR on and off channel until sync is lost.
5. Turn the control counterclockwise and check the point where picture pull-in occurs.
6. Turn the control an additional 1/2 turn counterclockwise.

WIDTH ADJUSTMENT

To adjust picture width, turn WIDTH control, L705 clockwise to increase width, counterclockwise to decrease width. When adjusting picture width, remember to take line voltage into consideration if it differs by more than several volts from the value usually existing when and/or where the receiver is to be operated. Make allowance for voltage difference when adjusting width. Width increases with increase in line voltage.

VERTICAL SIZE AND LINEARITY ADJUSTMENTS

The VERT. SIZE and VERT. LINEARITY controls adjust the height and vertical proportion of the picture. The VERT. SIZE control affects the height of the entire picture but not in a linear manner. The bottom portion of the picture is expanded at a greater rate than the top portion, and the picture center tends to move toward the top of the picture tube.

1. Turn the VERT. SIZE control counterclockwise to increase the height of the picture and clockwise to decrease the picture height.

The VERT. LINEARITY control affects the upper portion of the picture and compensates for non-linearity created by changes made by the VERT. SIZE control.

2. Turn the VERT. LINEARITY control clockwise to expand the upper portion of the picture and counterclockwise to compress the upper portion of the picture.

After adjustment of the picture height and/or vertical linearity, check the VERT. HOLD adjustment; the three controls are interdependent. The same caution that was given for picture width and line voltage applies equally well to vertical picture size.

RASTER CENTERING

It is best to adjust the picture linearity and size, using a test pattern, before centering the picture. If picture tilt exists, temporarily loosen the wing screw at the top of the deflection yoke and rotate the yoke until the tilt is eliminated. Make certain that the deflection yoke is seated as far forward on the picture tube neck as it is possible to move the yoke.

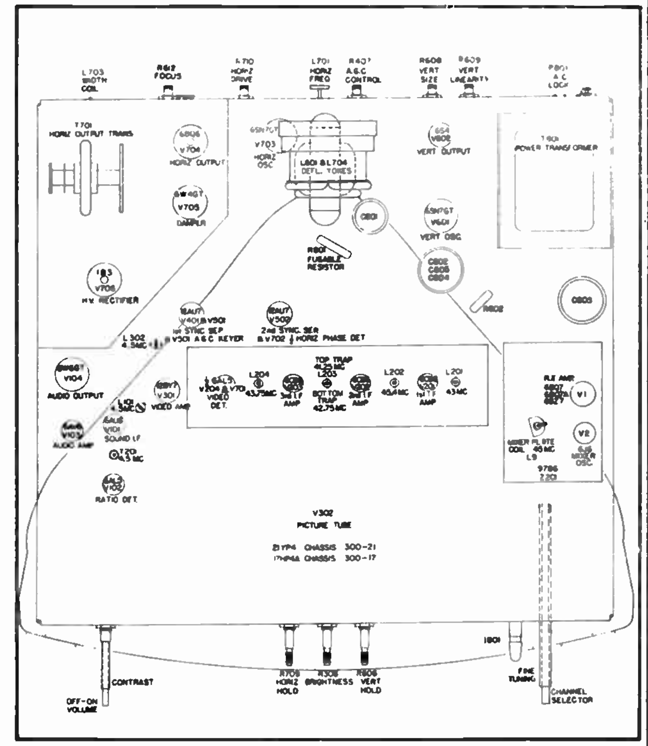

Figure 3. Top View Parts Layout

Raster centering is accomplished by adjusting two permanent magnet rings on the neck of the picture tube just behind the deflection yoke. The centering assembly should be positioned very near the deflection yoke (never more than an inch behind). Due to inter-action it will be necessary to rotate both magnets to obtain correct centering in most instances.

AUTOMATIC GAIN CONTROL

This control and its associated circuits regulate R-F and I-F AGC voltages (within the limits of the AGC system). When the AGC control is turned full clockwise the greatest bias appears on the I-F AGC bus and the lowest bias appears on the R-F AGC bus for a given signal. When the control is reversed the I-F AGC bias voltage is minimum and the R-F AGC bias is maximum for a given signal. This source of high R-F bias is very useful when strong signals cause the video stages to overload, clipping the sync pulses. In very strong signal areas turn the AGC control counterclockwise until loss of sync is eliminated. Do not turn more than necessary because increase bias on the R-F amplifier with simultaneous decrease in I-F bias will lead to excessive noise in the picture after a certain point. Conversely, in weaker signal areas the control should be turned clockwise so that the R-F bias is reduced and the I-F bias is increased. This condition will improve the signal to noise ratio, minimizing "snow", in the picture. Again, do not over control or the I-F stages may be overdriven. The optimum point is a function of signal strength. Use picture quality as an indicating device and adjust for optimum performance.

TABLE III - TV ALIGNMENT PROCEDURE

STEP NO.	SIGNAL GENERATOR FREQUENCY, MC	CONNECT SIGNAL TO	OUTPUT INDICATOR	ADJUST	INSTRUCTIONS	SPECIAL CONNECTIONS AND SETTINGS
			SOUND I-F AND RATIO DETECTOR			
1	4.5 CW	Pin 2 of V301	Meter across pin 7 of V102 and ground.	T101 Pri. (bottom) L101	Tune for maximum reading on meter	Signal level should be low enough to obtain approximately 4 to 7 volts on meter. Use isolation networks shown in Figures 4 and 5.
2	4.5 CW	"	Meter across ground and junction of R105 and C108.	T101 Sec. (top)	Tune for zero meter reading; use same signal level as in step 1.	Repeat tuning of T101 primary and secondary until adjustments do not change.
			TRAPS AND PICTURE I-F			
3	4.5 CW	Pin 2 of V301	Meter connected through detector network to picture tube cathode lead.	L302	Tune for minimum reading on meter.	Detector and isolating networks shown in Figures 4 and 6.
4	41.25 CW	Mixer grid	Voltmeter across R215.	Top of L203	Tune for minimum reading on meter.	Apply -3V bias to AGC bus. See text for connection to mixer grid. Use isolating resistor between negative voltmeter lead and R213. Keep generator output low. Either bias V704 with A-60 volts or remove tube. Set CONTRAST control for maximum contrast. Adjust signal level throughout I-F alignment so that a 1 volt DC output is maintained across R215.
5	43.75 CW	"	"	L204	Tune for maximum.	
6	42.75 CW	"	"	L203	"	
7	45.4 CW	Mixer grid	"	L202	Tune for maximum reading on meter.	
8	43 CW	"	"	L9	Tune for minimum reading on meter.	
9	43 CW	"	"	L201	Tune for maximum.	
10	45 CW	"	"	L9	Tune for maximum.	
11	Repeat steps 4 through 10 until adjustments do not change.					
12	Approximately 43.5 with 10-mc sweep. Marker required.	Mixer grid	High gain scope across R215	Adjust L202, L203 and L204 if necessary.	Set 45.75 mc marker at 50% point with L202. Eliminate tilt with L204.	See Figure 7 for isolation network. Use markers to determine bandpass between picture carrier and 50% point on opposite skirt. Bandpass should be between 3.4 mc and 3.6 mc. Adjust L9 and L201 only when absolutely necessary.

ALIGNMENT

The following alignment procedure describes alignment of the stagger-tuned video I-F amplifier stages and the 4.5 mc sound I-F amplifier stages. The alignment procedure for the VHF TV tuner is described in the 1952 Service Manual. Bulletin No. 301 and 301A covers the tuner. The following discussion describes recommended methods and equipment to be used and precautions to be observed during the alignment procedure. Table III offers a ready reference alignment guide to be followed after the more detailed procedure has been studied.

For best results it is important that alignment be performed on a metal topped bench with all instruments and equipment securely bonded together and to ground. All leads should be as short as is practicable, particularly in the input grid circuits. Allow about fifteen minutes for the test equipment and receiver to warm before beginning the alignment. Isolation circuits will be required for both the input and output connections. It is important that composition resistors, preferably the half-watt size, and disc type ceramic condensers be used in making up these isolation networks so that a minimum amount of external inductance is added to the tuned circuits being adjusted.

The following equipment* will be required in order to align the picture and sound I-F stages of the receiver properly.

1. Accurate CW signal generator covering the following frequencies:

4.5 mc	43.75 mc
41.25 mc	45 mc
42.25 marker freq	45.4 mc
42.75 mc	47.25 marker freq
43 mc	

The generator must have an attenuation control which can be used to vary its output signal level.

2. Sweep frequency generator with a sweep center frequency of approximately 43.5 mc and a 10 mc sweep width.
3. Cathode Ray Oscilloscope with at least a moderately high vertical gain. Must have external sweep input or internal sweep frequency equal to the sweep generator sweep frequency and capable of phase control.
4. DC voltmeter with sensitivity of 20,000 ohms per volt or higher and voltage scale ranges which include approximately 10 volts and 3 volts (full scale deflection). VTVM with zero center scale adjustment is an ideal type.
5. 3 volt bias source such as a battery.
6. Detector network shown in Figure 7.
7. .005 uf isolating condenser.
8. 10K ohm, 1/2 watt composition resistor.
9. .001 uf condenser for shunting oscilloscope input.

*Several instrument manufacturers combine the first three items of the equipment list into one compact instrument assembly.

Before alignment is begun, tune the tuner off-channel by turning the tuner CHANNEL SELECTOR shaft so that the detent roller rests on one of the high points of the drum disc. Bias the grid of V704 with a -60 volts or remove the tube. This is done in order to eliminate spurious signals and the possibility of high shock hazard.

ORDER OF ALIGNMENT. (Use a non-metallic alignment tool or one with a small metal insert.)

1. Ratio Detector Primary
2. 4.5 mc Sound Take-Off
3. Ratio Detector Secondary
4. 4.5 mc Video Trap
5. Tune Co-Sound Trap (L203) for minimum output indication at 41.25 mc
6. Tune 3rd I-F Coil (L204) for maximum output indication at 43.75 mc
7. Tune 2nd I-F Coil (L202) for maximum output indication at 42.75 mc
8. Tune 1st I-F Coil (L202) for maximum output indication at 45.4 mc
9. Tune Converter Coil (L9) for minimum output indication at 43 mc
10. Tune Input Coil (L201) for maximum output indication at 43 mc
11. Tune Converter Coil (L9) for maximum output indication at 45 mc

Repeat steps (5) to (11) until adjustments do not change.

NOTE

In all steps of video I-F alignment, the input signal should be maintained to a level of approximately one (1) volt DC output across video detector load. This is to insure against false tuning due to overloading.

It is important that the alignment be performed in order listed, with the exception of items 1 and 2, because there is some interaction within the various stages.

Sound I-F Alignment

Equipment: Connect the "hot" lead of the CW signal generator to the grid, pin 2, of V301, the video amplifier tube, through a .005 uf isolating condenser as shown in Figure 4. Tune the generator frequency to 4.5 mc, unmodulated. Connect the voltmeter negative lead in series with a 10K isolating resistor to pin 7 of V102, one plate of the ratio detector, as shown in Figure 5. It is important that the 10K ohm isolating resistor be at the very end of the meter lead to avoid regeneration. Connect the positive voltmeter lead to ground.

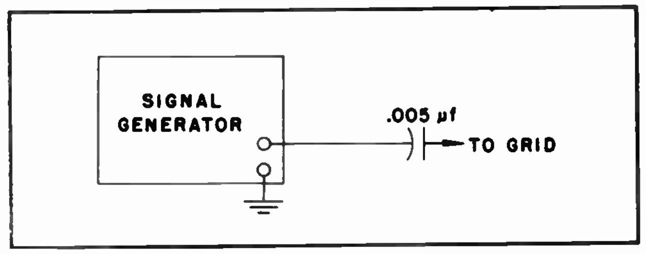

Figure 4. Signal Generator Isolation

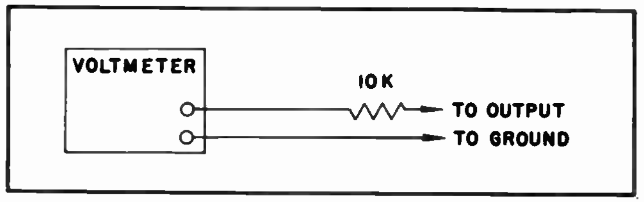

Figure 5. Voltmeter Isolation

Procedure: Adjust L101 and T101 primary (bottom), to obtain a maximum voltmeter reading. The maximum voltage reading should be held at about 4 to 7 volts by decreasing the generator output as the transformer windings are turned to resonance.

Ratio Detector Alignment

Equipment: Generator input remains unchanged from the level that produced 4 to 7 volts in the preceding step. Connect the voltmeter across the junction of R105 and C108; polarity will depend upon which side of resonance the secondary winding of T101 is tuned. If a VTVM is being used, set the zero voltage point up scale so that plus and minus readings may be observed without changing the polarity selector switch on the VTVM. Start with one of the higher scales of the VTVM and decrease the scale setting as the null point is obtained.

Procedure: Tune the secondary (top) of T101 for a zero reading on the voltmeter. Do not change the generator output level from that which produced the 4 to 7 volts in the first step. Repeat tuning of T101 primary and secondary until adjustments do not change.

Trap and Picture I-F Alignment

TUNING 4.5 MC TRAP

Equipment: Connect the CW generator through the .005 uf isolating condenser, to pin 2 of V301 (plate of video detector) and tune the generator to 4.5 mc. Connect the detector network and voltmeter between ground and the cathode of the picture tube as shown in Figure 6.

Procedure: Tune L302 (4.5 mc trap in plate circuit of video amplifier) for minimum indication on voltmeter.

TUNING 41.25 MC TRAP

Equipment: Couple the CW generator "hot" lead to the tuner mixer grid. This may be done in several ways. The .5-3 uuf trimmer condenser (C12 in 1952 Bulletin 301) located in front of the 6J6 and nearest the contact side of the tuner is connected to pin 5 of the 6J6, the mixer grid. This plate of the trimmer condenser is accessible through a hole in the side cover plate. The "hot" generator lead may be coupled to this point through a .005 uf isolating condenser, the condenser pigtail being clipped to the trimmer by some convenient means. Another method of coupling the generator is to remove the 6J6, wrap the isolating condenser pigtail around pin 5 of this tube, and replace it in its socket. In either method take care that the pigtail lead does not short to ground. A third method of coupling is to pull the 6J6 tube shield up on the tube until it is not grounded. Clip the "hot" lead of the generator directly to the tube shield. The tube shield and the tube electrodes form a condenser which capacitively couples the signal to the mixer grid. The capacity is much less than .005 uf, and a much higher level of generator output will be required if this method is utilized.

Connect the negative lead of the voltmeter across R215, the video amplifier load, using the 10K ohm isolating resistor at the end of the lead; connect the voltmeter positive lead to ground. Connect the negative terminal of the 3 volt bias source to the AGC bus; connect the bias source positive lead to ground.

Procedure: Turn the CONTRAST control to its maximum position (extreme clockwise) for remainder of alignment. Tune the traps by setting the trap frequency on the CW generator and adjusting the trap slug for a minimum voltmeter reading. The order of tuning the traps is given in Table III. Keep signal low to avoid overloading I-F circuits.

TUNING PICTURE I-F COILS

Equipment: Instruments and set-up remain the same as for trap alignment during the first part of the procedure. For final adjustment the sweep frequency generator is also used and the voltmeter should be replaced by the oscilloscope. See Figure 7 for oscilloscope isolation details.

Procedure: Tune the I-F coils by setting the coil frequency on the CW generator and adjusting the coil for maximum voltmeter reading. The CW generator output must be attenuated so that the DC output voltage of the video detector (indicated on the voltmeter), remains at 1 volt as the I-F coils are tuned. The order of tuning is from the last I-F stage toward the tuner. Before tuning the grid coil of the 1st I-F stage, temporarily tune the tuner mixer plate coil for a minimum reading on the voltmeter at 43 mc. After the 1st picture I-F grid coil has been tuned, tune the mixer plate coil to 45 mc and repeat the trap and I-F alignment procedure until no additional change in adjustments is necessary.

When no further change takes place, replace the voltmeter with the oscilloscope and replace the CW generator with the sweep frequency generator. Use the same isolating condenser and input connection to the mixer grid. Loosely couple the CW generator (marker) to the input by clipping or touching the CW generator "hot" lead to the unshielded insulated end of the sweep generator "hot" lead. This will afford a small amount of capacitive coupling. If the CW and sweep generators are contained in the same instrument, it will only be necessary to switch on the sweep frequency generator in order to continue the procedure. Tune the sweep frequency generator to a center frequency of approximately 43.5 mc. Use a sweep width of approximately 10 mc so that the base of each of the two response curve skirts is well within the ends of the oscilloscope trace. Check the overall bandwidth, position of the picture carrier, dip in bandpass, and trappage by using the marker pip to locate frequency points on the response curve. See Figure 8. Tune the CW generator to 45.75 mc. The marker pip should appear at approximately the 50% point on the response curve skirt. Readjust individual coils to give proper band pass. Adjust 1st I-F coil to set video carrier (45.75 mc) at 50% (6db) response point. Adjust 2nd I-F coil to set the 50% (6db) bandwidth point (42.25 mc) on sound side. Adjust 3rd I-F coil to eliminate any tilt in the response shape. It should not be necessary to adjust converter or input coil. Once the picture carrier has been correctly positioned at the 50% response point, tune the CW generator to 42.25 mc, which should be the 50% point on the sound side. This will give the proper bandwidth of 3.5 mc. The second I-F coil, L202, may be adjusted slightly to achieve the correct bandwidth.

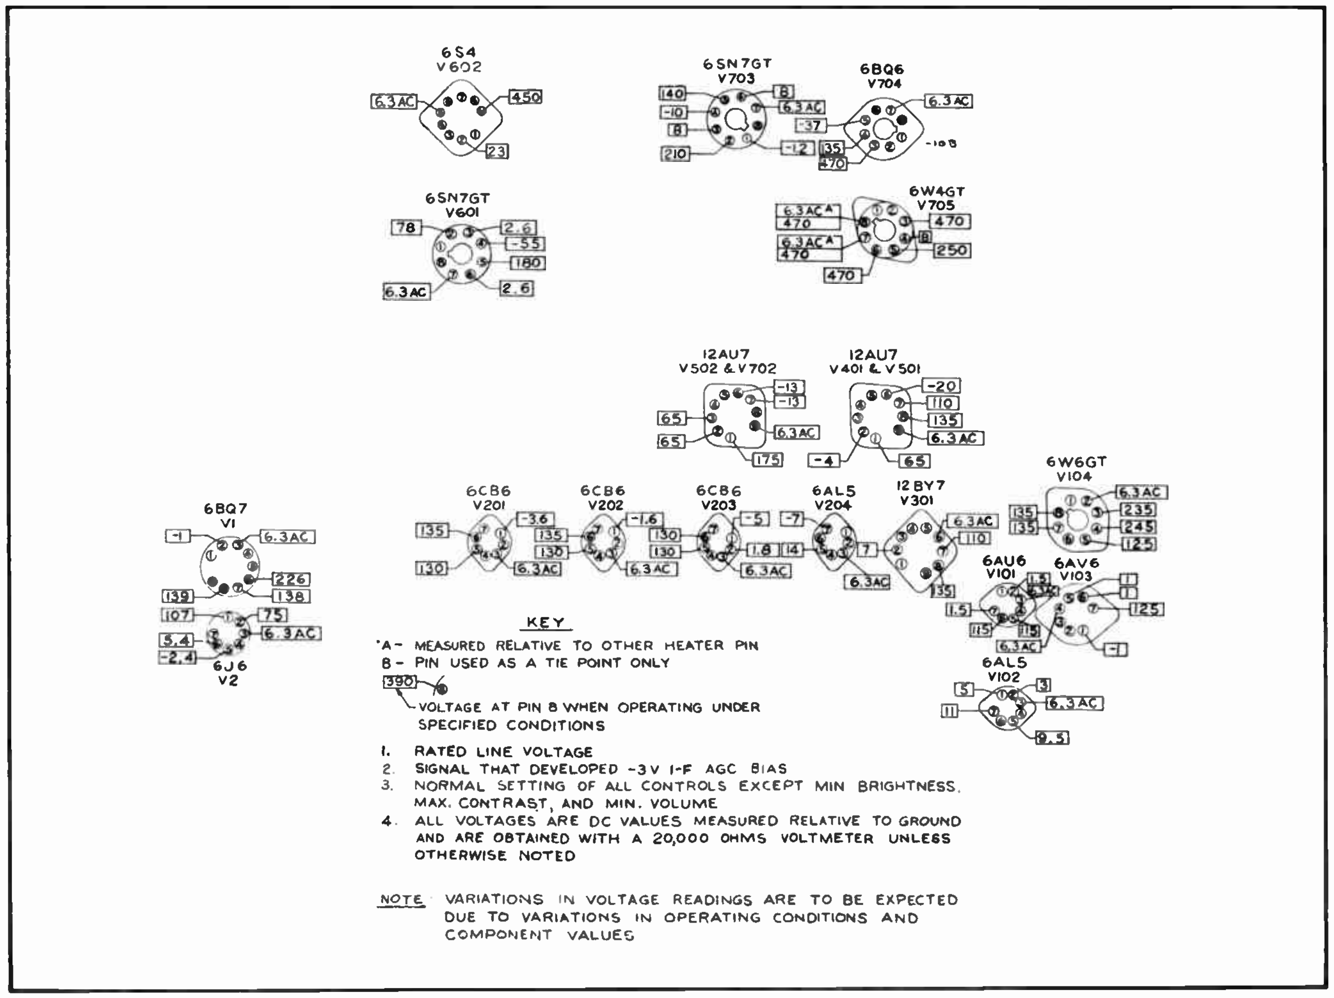

Figure 9. Bottom View Parts Tube Layout

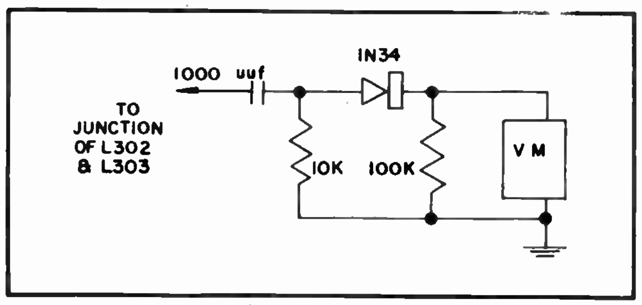

Figure 6. Detector Network

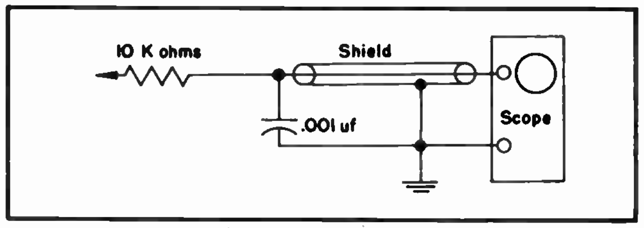

Figure 7. Oscilloscope Isolation

ALL WAVE TUNER

The 9795 is the All-Wave tuner. This tuner incorporates a 6BQ7, a 6BQ7A or a 6BZ7 for an RF amplifier; a 6T4 or 6AF4 as a UHF oscillator with a 6U8 acting as a mixer and VHF oscillator. Refer to Figure 12 for a complete diagram of the 9795.

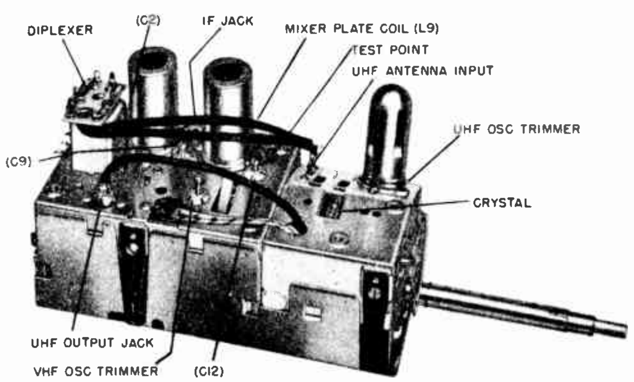

Figure 10. All Wave Tuner

In general, the combination tuner consists of two major units, as noted in the block diagram; the UHF subassembly, and VHF subassembly.

Referring to the block diagram, Figure 11, the antenna is seen to be connected to a diplexer which provides separation of signals above 470 mc for the UHF tuner, and signals below 300 mc for the VHF tuner.

The operation may best be followed by tracing the path of the signal from the antenna through the corresponding tuner and then to the I-F amplifier at its output. When the combination tuner is in UHF position, the signal from the common antenna passes down the twin-lead to the diplexer and continues on to the UHF tuner. Here it goes through two preselector circuits and into a Xtal mixer. The Xtal is supplied with a local oscillator voltage, differing by 40 mc above the signal frequency. After mixing, it becomes a 40 mc signal (I-F frequency) and passes into the VHF tuner. Since the combination tuner has been set for UHF operation, the 40 mc amplifier, which is noted in a block below the VHF tuner, is now in place of one of the VHF channels. In this manner, the signal is amplified again at 40 mc and passes on through the output to the I-F stage.

When the combination tuner is in the VHF position, the following path of signal may be traced: as previously noted, the signal travels from the common antenna to the diplexer, but now, since its frequency is below 300 mc, it is diverted directly to the VHF tuner input. At this point, it is connected to one of the channels (2 - 13) as in the usual TV band, and is amplified at this corresponding frequency. At the end of this amplification, it is mixed (in the VHF tuner) by a 6U8 stage. This provides the local oscillator, again 40 mc above the signal, and the result in output is then the 40 mc signal which is coupled by the output plate coil to the I-F strip.

The various components of the major subassemblies may be seen from the circuit diagram (figure). In the UHF tuner, L22 and L23 are the preselector circuits. L24 and L25 make up the oscillator inductance. The oscillator tube is either a 6AF4 or 6T4, as shown. It should be noted that the coils, L20 and L21, along with C30, C31 and C32, comprise the high-pass filter portion of the diplexer. The low-pass filter, consisting of coils La and Lb, along with the two 1.5 mmfd condenser, is the other portion of the diplexer which diverts signals lower than 300 mc to the VHF tuner.

Shaft Function

1. FINE TUNING - Outer shaft for VHF and UHF oscillators fine tuning.

2. SWITCHING - Center shaft includes nine detent positions, eight for UHF decade coil board strips covering frequency channels 14 to 19; 20 to 29; 30 to 39; 40 to 49; 50 to 59; 60 to 69; 70 to 79 and 80 to 83. VHF channels 10 through 13 may be received on first UHF decade position. The ninth position allows VHF reception.

3. SWITCHING - Inner shaft includes twelve detent positions, ten for UHF unit digits (individual channel selection included within the above eight decades), twelve positions for VHF channels 2 to 13.

4. VHF TUNING - To receive VHF channels 2 through 13, set middle section of tuning knob assembly so that "VHF" and channel numbers are directly in front of pilot light. These VHF channel numbers will be found on the inner circles of numbers. To switch VHF channels, rotate front crown control knob only.

5. UHF TUNING - To receive UHF channels, rotate middle section either right or left from VHF position. First half of UHF channel number is controlled by middle knob. Second half of UHF channel number is controlled by front crown knob; example, channel 56 - the middle knob will place the first half of the UHF channel number (5) in front of the pilot light. The front crown knob will place the second half of this UHF channel number (6) in front of the pilot light, thus reducing UHF channel 56.

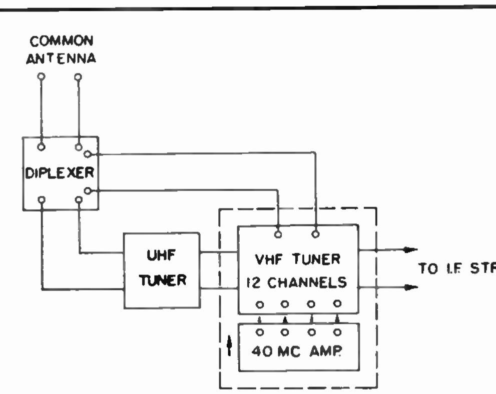

Figure 11. All Wave Tuner Block Diagram

ALL-WAVE I-F ALIGNMENT PROCEDURE - GENERAL

The combination All-Wave tuner contains two sections - the first (front section) contains the UHF portion. The second (rear section) is the usual 12-channel VHF turret tuner. There is one difference in the VHF section, in that it contains a contact board or cascode strip. This provides the equivalent of a 13th position, and is held out when the decade knob is in the VHF position. The units front knob then operates the rear turret from channel 2 to 13. It is also held out when the decade knob is in the 10's position for channels 10, 11, 12 and 13. UHF operation is obtained when the decade center knob is in the 10's position for channels 14 to 19 and for all succeeding decade positions, up to 83.

I-F ALIGNMENT

Set the tuner in the VHF position (on channel 10) and insert a signal at the test point (refer to Figure 10) through a .005 capacitor with the proper termination for the generator being used. Use a -3 volts for the AGC bias. Observe the output of the video detector with a 10K resistor and a .001 capacitor isolation network which is connected to the oscilloscope vertical terminals or a voltmeter.

A. Apply a 43 mc signal and align the 1st I-F grid coil until a maximum indication is observed.

B. Apply a 45 mc signal and align the output plate coil (L9) of the tuner for maximum indication. A sweep may then be applied and the I-F touched up for proper response. It is preferable to adjust coils in the I-F strip slightly, rather than accommodate discrepancies in the curve with changes in the settings of the adjustments mentioned in A and B.

R-F ALIGNMENT - CHECK VHF

Set the tuner to the VHF position on the decade center knob and the units front knob on channel 10. Connect a sweep to the VHF or the antenna point of the diplexer. Note overall wave shape and position of sound in video carrier. Adjust local oscillator slug to proper frequency with fine tuning in center of scale. A bias of 3 volts is applied to AGC during the above operation.

R-F ALIGNMENT - CHECK UHF

With the tuner at channel 19, with three or four volts of bias on the I-F AGC and three volts of R-F AGC. Connect a UHF sweep to the antenna terminals with the proper dummy termination (300 ohms total). Observe the output on the video detector with proper isolation network. (10K resistor and a .001 capacitor on scope.) Use a 60 cycle sweep that is phased properly.

A. Check wave shape and operation of channels 14, 21, 31, 41, 51, 61, 71 and 81. These should operate positively and not be intermittent.

B. Note above operation to be made with fine tuner in center of fine tuning range.

NOTE

To adjust VHF local oscillators, place tuner in VHF position, remove knobs, place fine tuner in middle of range so VHF local oscillators can be reached with proper alignment tool through UHF unit.

To adjust UHF local oscillator, place tuner in UHF position, remove knobs, place fine tuner in middle of range. Rotate units front knob. Adjust front screw head.

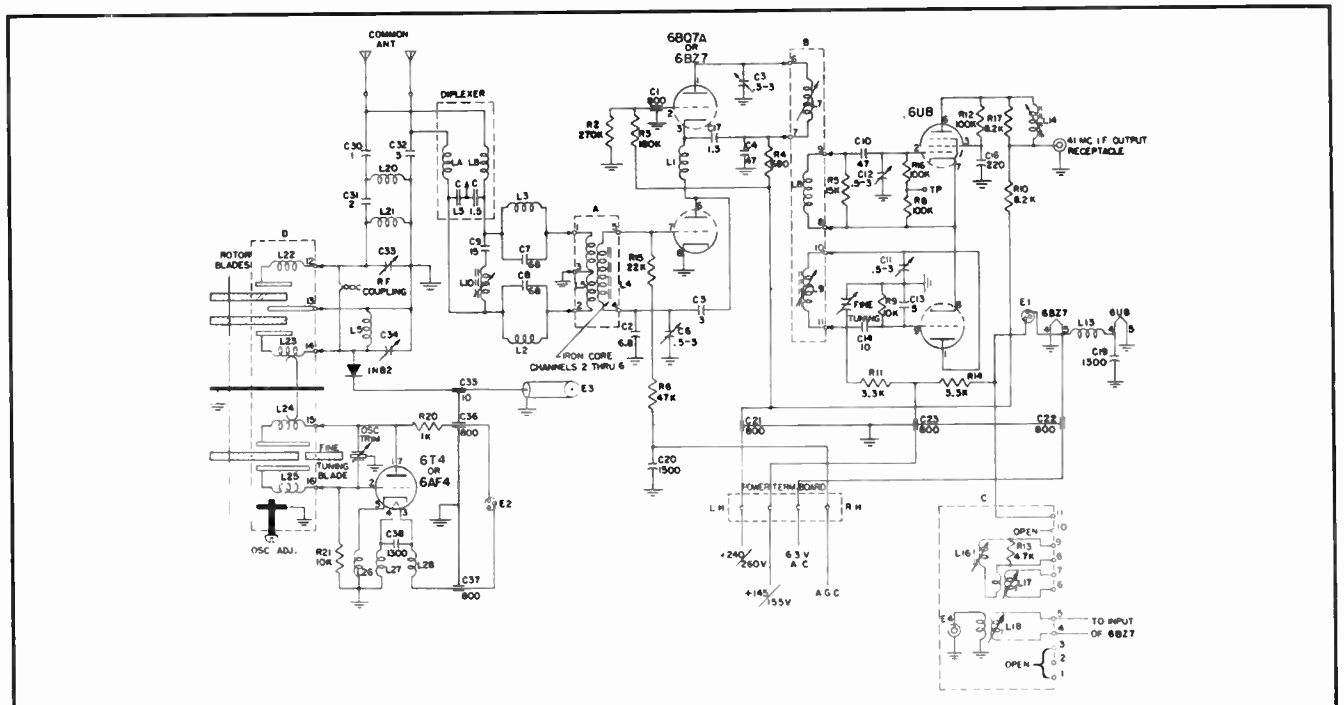

Figure 12. All Wave Tuner Schematic

PARTS LIST

NOTE: Unless otherwise noted all resistors are 1/2 watt, composition type, ±10% tolerance with values given in ohms.

NOTE: Unless otherwise noted all condensers are 600 volt, molded phenolic type, ±20% tolerance with whole number values given in micromicrofarads and decimal fraction values given in microfarads. GMC - guaranteed minimum capacity.

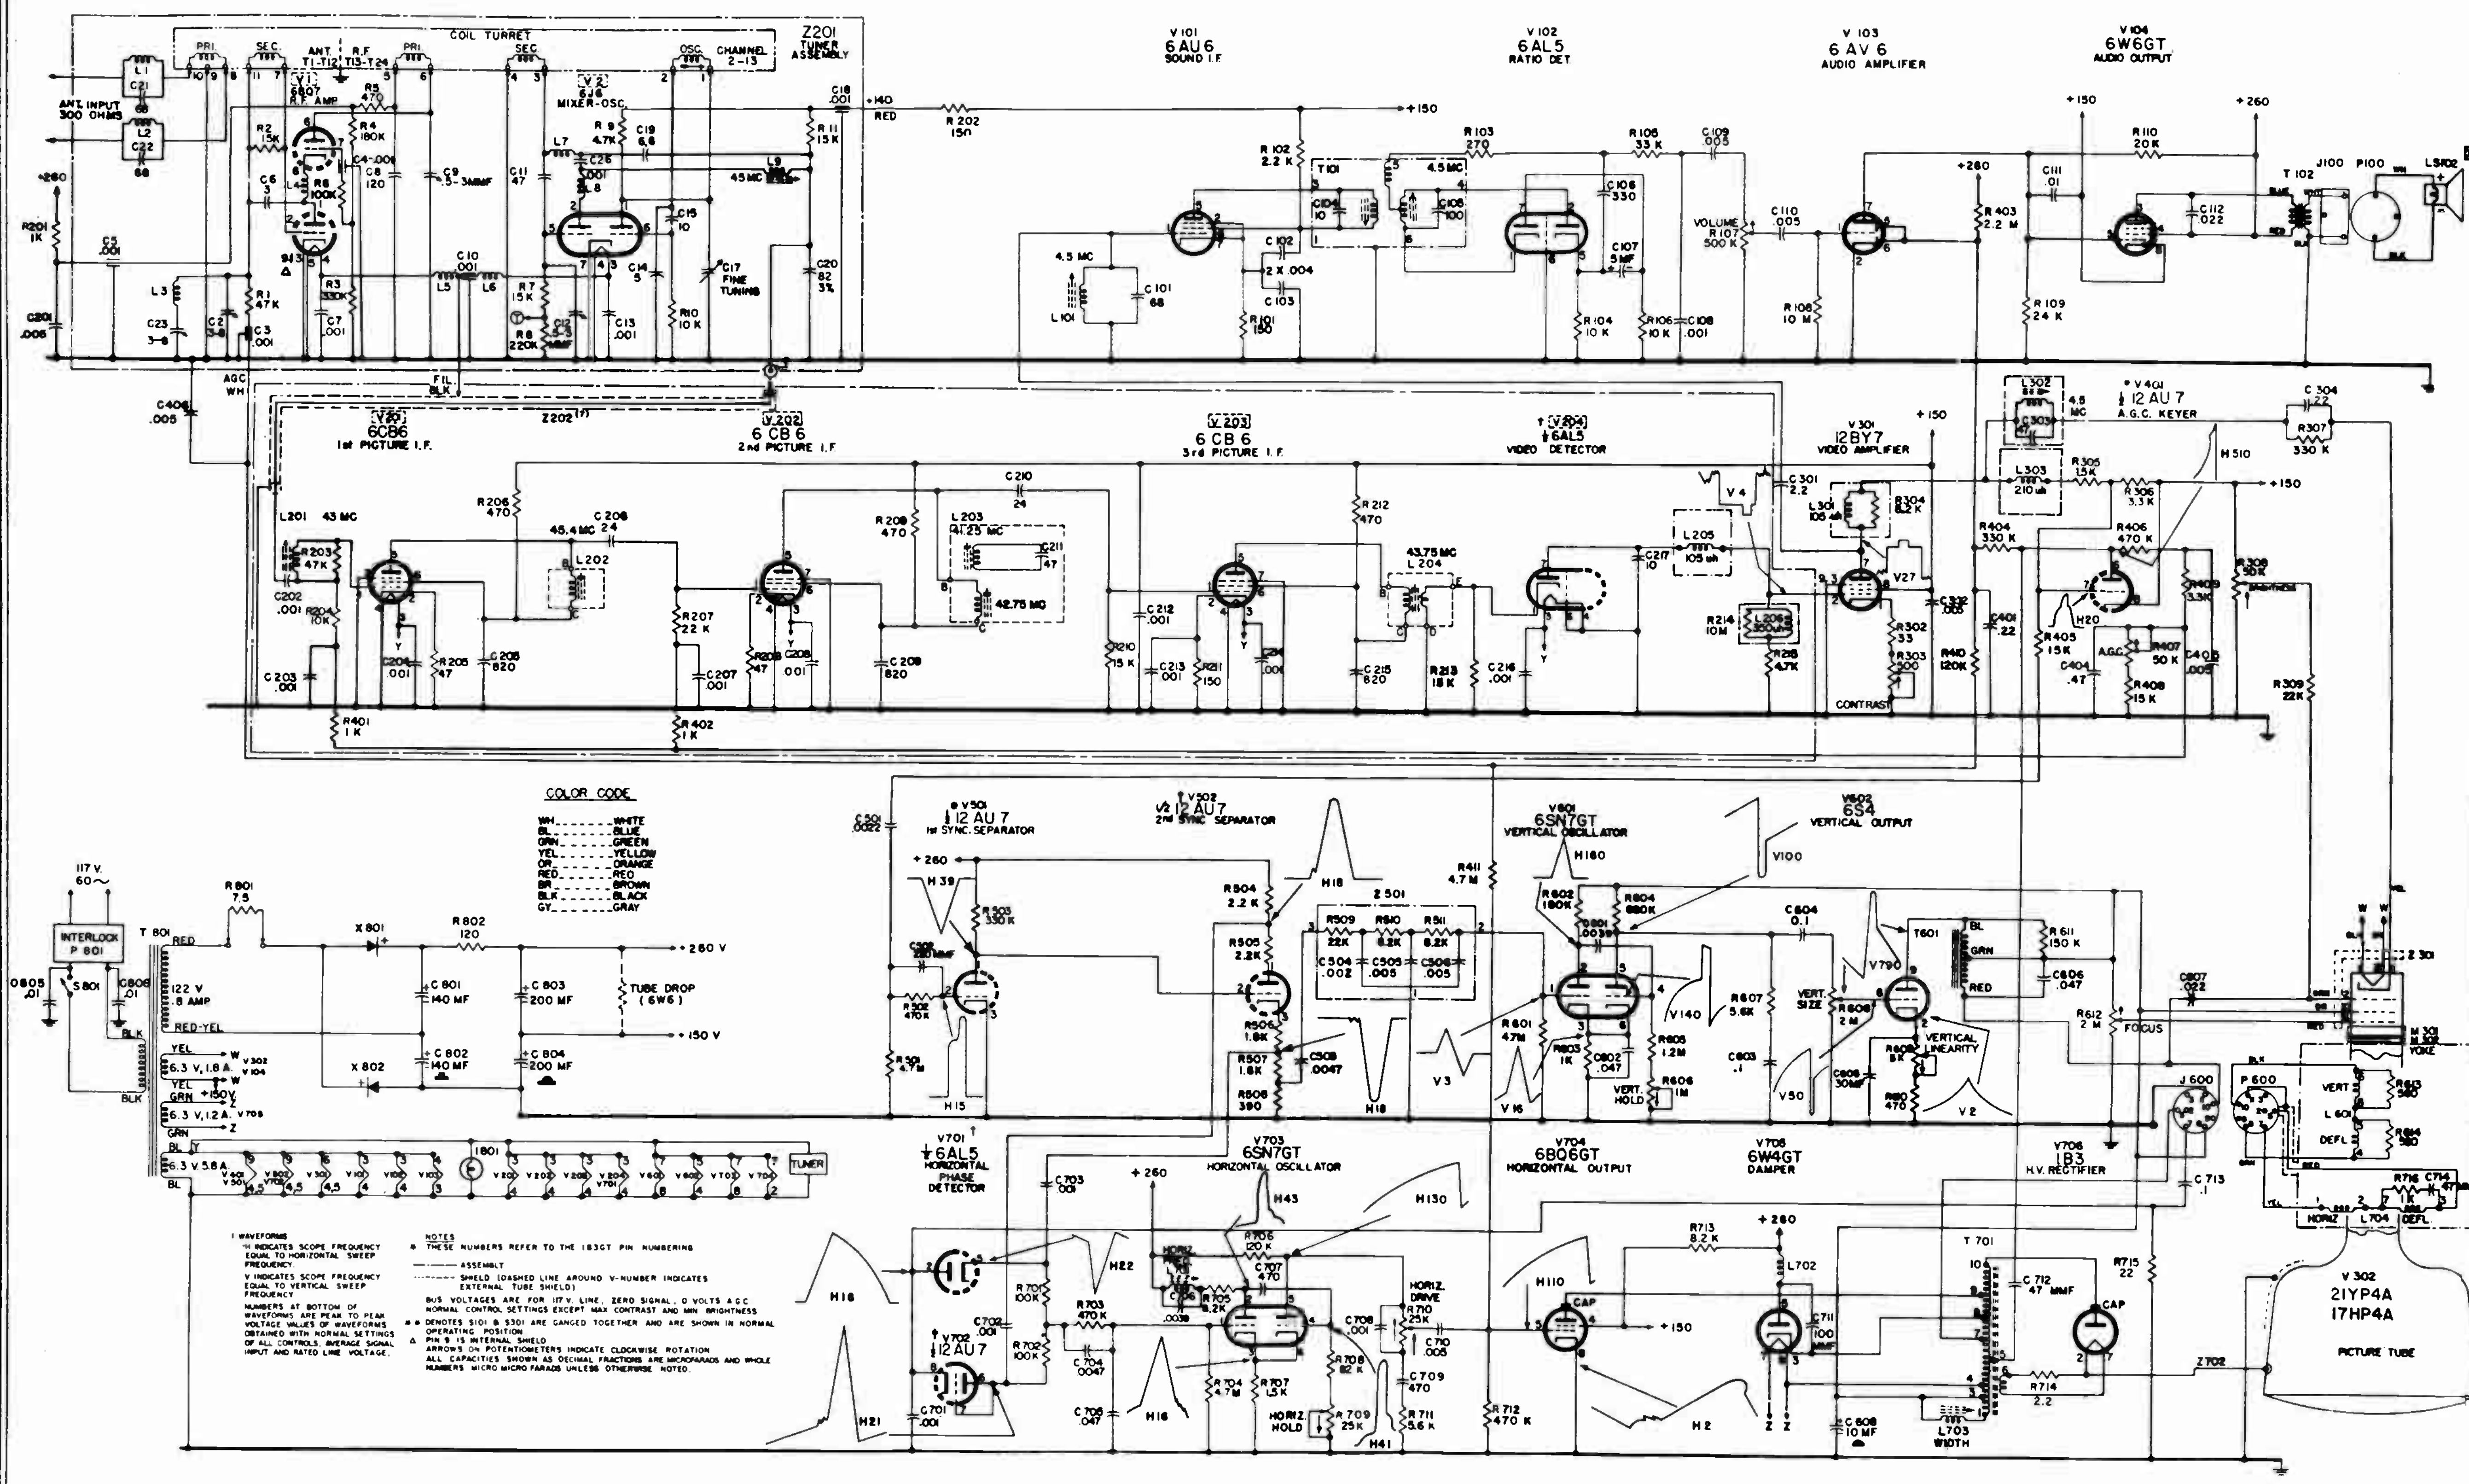

Figure 13. Schematic Diagram for Chassis 300

CHASSIS 375-21

MODELS 21M910, 21B911, 21P912

IDENTIFICATION

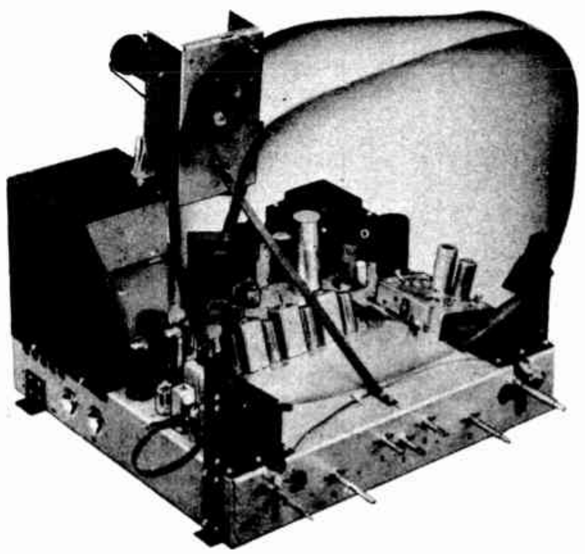

Figure 1. Chassis 375

Chassis 375 is similar to the 300 chassis. The chassis are identical with the exceptions to be pointed out in this bulletin. Chassis 375 includes an AM Radio Tuner. This Tuner employs two tubes; a 6BE6 as a converter and a 6BA6 as an I-F amplifier. In conjunction with the radio, there is an ENTERTAINMENT SELECTOR SWITCH. This switch is used for program selection, RADIO, TV and PHONO. When the switch is in TV position, the chassis operates as would Chassis 300. When the switch is in RADIO-PHONO, parts of the TV CIRCUIT cease to operate, due to an electrical difference which is caused by the switching action. The horizontal oscillator and horizontal output circuit is made inoperative, due to the removal of B+, thus removing the second anode voltage, etc.

ELECTRICAL AND MECHANICAL DATA

NOTE

This information also covers the 400 series chassis, incorporating the "All-Wave Tuner".
Chassis incorporating the "All-Wave Tuner" can be identified by a "U" following the model number. (Example 21M721U)

IDENTIFICATION

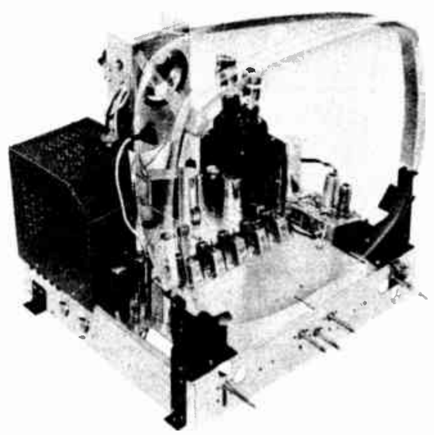

Figure 1. Chassis 401-21

INTRODUCTION

Chassis 400-21, 401-21, 402-24 and 403-24 will come under the collective heading of the 400 series chassis. The 400 series chassis contain all of the outstanding Hoffman features, plus new electrical and mechanical modifications. The same fine workmanship and excellent performance that was typical of the Mark V chassis have been incorporated. All changes, both mechanical and electrical, were made with the service man in mind.

Chassis 400 and 401 are identical in every respect except for the power supply and audio portion of Chassis 400 which incorporates a Push-Pull, Hi-Fi audio circuit.

Chassis 402 and Chassis 403 are identical except for the audio portion of Chassis 403 which incorporates a Push-Pull, Hi-Fi audio circuit. Chassis 400-401 and 402-403 are similar except for the following: Chassis 402 and 403 drive a 24 inch picture tube, whereas Chassis 400 and 401 drive a 21 inch picture tube. The increase in picture tube size on Chassis 402 and 403 require an increase in the amount of energy needed to sweep the larger tube. Therefore the major electrical difference will be found in the high voltage and sweep circuits.

The major mechanical difference, besides the increase in picture tube size, is the use of a 90° deflection yoke assembly.

All	V801	5U4	L.V. Rectifier
All	V802	5U4	L.V. Rectifier

Chassis 400 401 402 and 403 will incorporate either a low radiation "40 megacycle" VHF cascode type tuner (Part #9786 RF-14) or an All-Wave tuner (Part #9795 RF-15) that will comprise the R-F stages.

This tuner is identical to the 9758 tuner, except that the coupling is changed. If a 9795 All Wave tuner is used, refer to this bulletin. Both picture and sound output from the tuner is fed to the first of four stages of stagger-tuned I-F amplification. The picture carrier frequency is 45.75 mc. An intercarrier type sound system is employed, the 4.5 mc sound take-off occurring at the output of the video detector. The sound is fed into the first of two 4.5 mc I-F stages. A 39.75 mc adjacent channel picture trap, two 41.25 mc co-sound traps, and a 47.25 mc adjacent channel sound trap are employed in the video I-F stages.

A ratio detector is used as a second sound detector. This stage is followed by a stage of audio amplification (a dual diode triode on Chassis 401-402 and dual triode on Chassis 400-403 with the second half of the dual triode acting as an audio driver) which drives a single stage of power amplification on Chassis 401-402 and a push-pull network in Chassis 400-403. On Chassis 401-402 the audio amplifier is coupled to the audio output by means of a printed circuit, Z201. The audio output tube or tubes is coupled to the speakers through an audio output transformer. On all chassis, plug-type speaker connection is used. Chassis 400-403 uses a Hi-Fi, push-pull type audio circuit, which incorporates two tetrodes. You will note that a unique phase inversion scheme is being used in that one of the push-pull tubes receives its driving voltage from the audio amplifier in the conventional manner, whereas the second tube receives its equal and opposite phase voltage from a tertiary winding on the audio output transformer, thus eliminating the need for a vacuum tube phase inverter. The video detector is 1/2 of a miniature dual diode vacuum tube, with the second half providing the clamping voltage for the delayed AGC. The output from this video detector is coupled directly to the video amplifier, through high frequency compensating shunt and series peaking coils. The single stage of video amplification is directly coupled to the cathode of the picture tube through high frequency compensating shunt and series peaking coils. Since direct coupling is employed, no DC restoration circuit is needed in the receiver. The keyer tube provides the necessary AGC bias for the first and third I-F stages.

Two stages of sync separation are designed into the receiver. They receive the composite video signal from a tap on the video amplifier load resistor.

The second sync separator serves the additional function of a phase splitter for feeding approximately equal and opposite sync pulses to the balanced horizontal phase detector. A negative sync pulse is taken from a tap on cathode resistor, and this pulse is fed to the vertical integrating network, Z501, for the purpose of synchronizing the vertical oscillator.

The vertical oscillator is the cathode coupled multivibrator type. It drives a single power output stage which is coupled to the vertical deflection coils through an output transformer. The positive pulse of the retrace portion of the vertical sweep output voltage is reversed in phase by the transformer action of the output transformer, and the resulting negative voltage pulse is coupled to the picture tube control grid through a .022 uf condenser which also serves to sharpen the pulse so that it is only effective during the retrace portion of the sweep. The negative voltage pulse biases the picture tube beyond cut-off during the retrace portion of the vertical sweep, and the bright retrace lines are blanked out.

The horizontal oscillator is a cathode-coupled type of multivibrator. The stabilizing influence of a parallel tuned L-C circuit is used as part of the plate load of one of the triodes in the multivibrator circuit. The natural frequency of the tuned circuit is made very close to the horizontal sweep frequency. The frequency of the horizontal multivibrator is further stabilized by a balanced horizontal phase detector circuit which consists of a dual diode. The horizontal oscillator drives a stage of power amplification that is coupled to the horizontal deflection coils through an output transformer. The horizontal output transformer is also an active member of the high voltage supply. In addition the horizontal output transformer supplies positive keyer pulses to the place of the keyed AGC tube and it furnishes a reference saw-tooth voltage in conjunction with the horizontal deflection coil circuit for the horizontal phase detector.

The high voltage section is a high efficiency fly-back type which uses a single half-wave rectifier. The approximately 200 volts that results from the rectification of the fly-back potential across the damper tube is added to the 280 volt bus potential, and this boost voltage of approximately 480 volts (630 volts on Chassis 402-403) is applied to the vertical sweep circuit.

The low voltage power supply is a dual, full wave rectifier type, which delivers power into a condenser input RC filter voltage divider network that supplies the required bus voltage for the circuits throughout the receiver. The picture tube is seated in a support bracket which mounts directly on the receiver's chassis. Chassis 401-402 is a 25 tube television receiver, including the rectangular picture tube. Chassis 400-403 is a 26 tube television receiver, including the rectangular picture tube. Provision is made for a phono input on the 400 series chassis. The phono reproduction may be selected by the use of a double pull, double throw switch. On Chassis 401-402, this is accomplished by 1/2 of the treble tone control switch, where on Chassis 400-403, this is accomplished by 1/2 of the brightness control switch. This selector switch performs the function of switching the audio amplifier from the ratio detector output to the phono input and switching the picture tube control grid from the brightness control circuit to ground, cutting off the picture tube raster when the phonograph is being played. Phono motor power is provided through an AC outlet at the rear of the receiver's chassis.

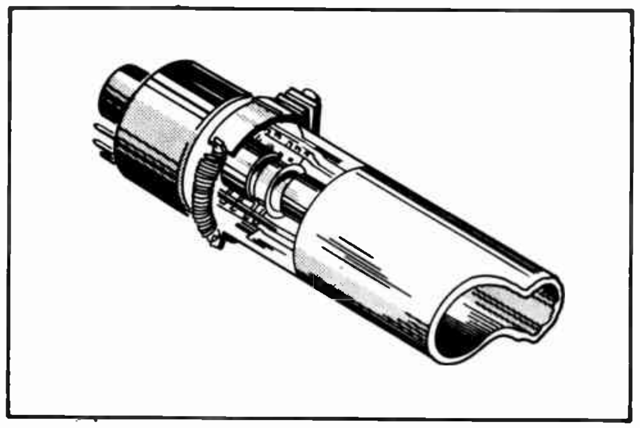

Figure 2. Ion Trap Position

OPERATING INSTRUCTIONS

Front Panel Controls

Refer to Figure 9 for location of front panel controls.

OFF-ON VOLUME CONTROL

The VOLUME control is part of a dual type potentiometer, being associated with a CONTRAST control. The chassis power switch is mechanically linked to the volume potentiometer. This switch opens the 115 volt power line to the receiver's power transformer and AC RECEPTACLE when the VOLUME control shaft is turned to the extreme counterclockwise position. The initial rotation of the shaft in the clockwise direction closes the AC switch and causes the sound level to start increasing toward maximum audio power output. The smaller, outer, left-hand knob is the one that turns the volume control shaft when the knobs are in place. This control also performs the function of automatically removing the bias from the picture tube when the control is in OFF POSITION. (Refer to Focus Operation.)

CONTRAST CONTROL

The CONTRAST control varies the gain of the video amplifier. With the AGC system used for maintaining constant signal level, the CONTRAST control becomes primarily useful in setting background level for best viewing under various room lighting levels or different average program contrast levels. To increase picture contrast turn the CONTRAST control clockwise. The large, inner, left-hand knob is the one that turns the CONTRAST control shaft when the knobs are in place.

TUNING CONTROLS

The tuning controls are the dual type. To select a desired channel, turn the CHANNEL SELECTOR shaft in either direction until the desired channel's coils are in operating position in the tuner. Once a channel has been chosen, tune the FINE TUNING control shaft counterclockwise until the picture starts to become wavy and variable dark horizontal lines and bars appear in the picture. Turn the shaft clockwise until the lines and bars just disappear and the picture appears clear and sharp. Do not turn too far in the clockwise direction or definition will start to decrease. Picture and sound tuning are synchronized so that the best picture will come in with best sound when alignment is correct.

The remaining three front panel controls are located in the middle of the front chassis panel. On chassis 400-403, these controls are visable. On chassis 401-402, the front cover plate must be pulled down in order to view controls.

BRIGHTNESS CONTROL AND PHONO SWITCH (For Chassis 400 and 403 Only)

The BRIGHTNESS control sets the average background illumination of the picture.

1. Temporarily turn the CONTRAST control to minimum setting (extreme counterclockwise).

2. Turn the BRIGHTNESS control so that a medium illumination is visible on the screen.

This setting produces a picture with average background characteristics at about 3/4 contrast setting. For individual tastes that vary from this recommendation, the BRIGHTNESS control may be set so that the picture is most pleasing to the customer.

On chassis 400 and chassis 403 this control performs a dual function. A double pole, double throw switch is mounted at the rear of the brightness potentiometer. This switch is activated when the BRIGHTNESS control shaft is turned either to the extreme clockwise position or the counterclockwise position. Extreme counterclockwise rotation of the BRIGHTNESS control switches the receiver for phono operation and provides minimum brightness. Clockwise rotation of the control provides continuous increase in brightness intensity.

BASS (Chassis 400-403)

As BASS control is turned clockwise, the frequency range is spread to increase reproduction of the lower frequencies, as indicated on the dial. Maximum bass response is achieved when BASS control is in the extreme clockwise position.

VERTICAL HOLD CONTROL (For Chassis 401 and Chassis 402 Only)

The VERTICAL HOLD CONTROL has a hold-in range over which the picture will stay in vertical sync. Turn the control so that the picture is brought from a downward moving picture into sync and best interlace of the sweep lines is observed. Chassis 400 and Chassis 403 utilize a BASE control in place of the VERTICAL HOLD CONTROL.

TREBLE (Chassis 400-403)

As control is turned clockwise, the frequency range is spread to increase the reproduction of the high frequencies, as indicated on the dial. Maximum treble response is achieved when TREBLE control is in the extreme clockwise position.

TONE CONTROL AND PHONO SWITCH (For Chassis 401 and 402 Only)

This control is a dual control on Chassis 401 and 402 only. A double pull, double throw switch is mounted at the rear of the tone potentiometer. The switch is activated when the tone control shaft is turned to either the extreme clockwise position or the extreme counterclockwise position. Extreme counterclockwise rotation of the tone control switches the receiver for PHONO operation and provides maximum base response. Clockwise rotation of the control provides continuous increase in treble response. Maximum clockwise rotation switches the receiver to PHONO operation. When changing from one function to the other, turn the control in the appropriate direction until a click is heard. Then turn the control until the desired tone is obtained.

Rear Adjustments

The rear chassis controls are intended to be adjusted by the dealer or his service representative at the time of installation in the customer's home or during a service call. Once adjusted correctly, these controls need not be changed over long periods of time or unless a specific service problem develops. Refer to Figure 3 for location of rear controls.

ION TRAP

The effects of the FOCUS ADJ, ion trap, and centering control orientation are slightly interdependent and one or two sequential adjustments of each may be necessary for optimum setting of these controls. Always set the ion trap for maximum raster brightness.

CAUTION

Never attempt to center the picture by misadjustment of the ion trap.

Set the BRIGHTNESS and CONTRAST controls about midrange, never at maximum setting, to avoid damaging the picture tube. Move the ion trap over the "flags" of the picture tube first anode. Refer to Figure 2. Rotate the ion trap on the picture tube neck until light appears on the screen. After initial light has been obtained, move the ion trap back and forth and further rotate it to obtain the brightest raster. If the receiver is equipped with a Rauland picture tube, the optimum ion trap setting is indicated by minimum green glow inside the tube neck.

FOCUS ADJUSTMENTS (Refer to Figure 3)

Magnetic focusing is being employed in the 400 series chassis. For correct focus adjustment, adjust focus control for maximum focus range. Readjust ion trap after making the initial focus adjustment. Check neck of picture tube, making sure it is in center of focus coil. Because magnetic focusing is being used, the off-on control switch now performs the function of removing the bias from the picture tube so that when the set is turned off, the small electron beam that is present will be out of focus, therefore preventing damage to the face of the picture tube.

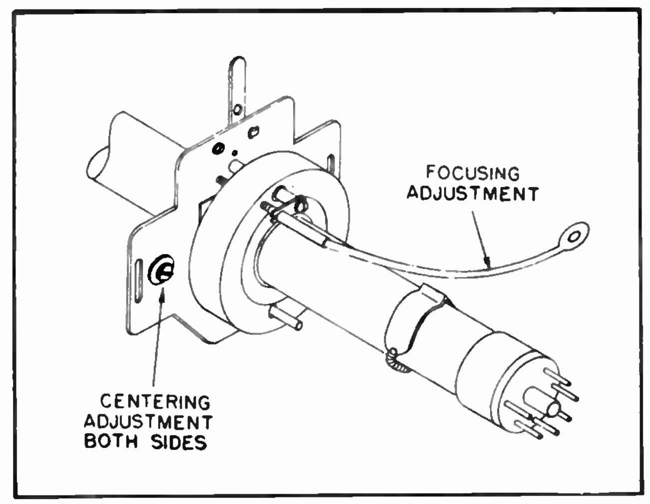

Figure 3. Focus and Centering Adjustment

HORIZONTAL DRIVE ADJUSTMENT

1. Turn the HORIZ. DRIVE control counterclockwise until a drive bar (thin, light vertical line) appears.

2. Turn the control clockwise until the drive bar just disappears. If no drive bar is obtained, set the control at the maximum counterclockwise position.

HORIZONTAL HOLD CONTROL

The HORIZONTAL HOLD control provides a vernier adjustment for the horizontal multivibrator operating frequency. Proper setting depends on correct adjustment of the HORIZ. FREQ. and HORIZ. DRIVE controls.

Turn the Horizontal Hold control until bending of the top portion of the picture is eliminated. This is best determined by noting the vertical lines in the picture.

HORIZONTAL FREQUENCY CONTROL

1. Turn the Horizontal Hold control to mid-range.

2. Turn the HORIZ. FREQ. control counterclockwise while switching the CHANNEL SELECTOR on and off channel until sync is lost.

3. Turn the control clockwise and check the number of bars which appear just before pull-in of the picture. Check circuit for abnormal operation if less than two bar pull-in occurs.

4. Continue turning control clockwise while switching the CHANNEL SELECTOR on and off channel until sync is lost.

5. Turn the control counterclockwise and check the point where picture pull-in occurs.

6. Turn the control an additional 1/2 turn counterclockwise.

WIDTH ADJUSTMENT

To adjust picture width, turn WIDTH control L703 clockwise to increase width, counterclockwise to decrease width. When adjusting picture width, remember to take line voltage into consideration if it differs by more than several volts from the value usually existing when and/or where the receiver is to be operated. Make allowance for voltage difference when adjusting width. Width increases with increase in line voltage.

VERTICAL SIZE AND LINEARITY ADJUSTMENTS

The VERT. SIZE and VERT. LINEARITY controls adjust the height and vertical proportion of the picture. The VERT. SIZE control affects the height of the entire picture but not in a linear manner. The bottom portion of the picture is expanded at a greater rate than the top portion, and the picture center tends to move toward the top of the picture tube.

1. Turn the VERT. SIZE control counterclockwise to increase the height of the picture and clockwise to decrease the picture height.

The VERT. LINEARITY control affects the upper portion of the picture and compensates for non-linearity created by changes made by the VERT. SIZE control.

2. Turn the VERT. LINEARITY control clockwise to expand the upper portion of the picture and counterclockwise to compress the upper portion of the picture.

After adjustment of the picture height and/or vertical linearity, check the VERT. HOLD adjustment; the three controls are interdependent. The same caution that was given for picture width and line voltage applies equally well to vertical picture size.

RASTER CENTERING

It is best to adjust the picture linearity and size, using a test pattern, before centering the picture. If picture tilt exists, temporarily loosen the wing screw at the top of the deflection yoke and rotate the yoke until the tilt is eliminated. Make certain that the deflection yoke is seated as far forward on the picture tube neck as it is possible to move the yoke.

Raster centering is accomplished by adjusting the center control. Refer to Figure 3. By moving the centering control up and down, the raster moves from left to right. By moving the control from left to right, the raster moves up and down.

AUTOMATIC GAIN CONTROL

This control and its associated circuits regulate R-F and I-F AGC voltages (within the limits of the AGC system). When the AGC control is turned full clockwise the greatest bias appears on the I-F AGC bus and the lowest bias appears on the R-F AGC bus for a given signal. When the control is reversed the I-F AGC bias voltage is minimum and the R-F AGC bias is maximum for a given signal. This source of high R-F bias is very useful when strong signals cause the video stages to overload, clipping the sync pulses. In very strong signal areas turn the AGC control counterclockwise until loss of sync is eliminated. Do not turn more than necessary because increase bias on the R-F amplifier with simultaneous decrease in I-F bias will lead to excessive noise in the picture after a certain point. Conversely, in weaker signal areas the control should be turned clockwise so that the R-F bias is reduced and the I-F bias is increased. This condition will improve the signal to noise ratio, minimizing "snow", in the picture. Again, do not over control or I-F stages may be overdriven. The optimum point is a function of signal strength. Use picture quality as an indicating device and adjust for optimum performance.

FUSE PROTECTION

The source of fuse protection is in the horizontal output screen circuit and damper circuit. A 1/4-ampere fuse is held in a fuse clip located inside of the high voltage cage.

ALIGNMENT

The following alignment procedure describes alignment of the stagger-tuned video I-F amplifier stages and the 4.5 mc sound I-F amplifier stages. The alignment procedure for the TV tuner is described in a separate bulletin. Bulletin No. 301 and 301A of the 1952 Service Manual covers the tuner. The following discussion describes recommended methods and equipment to be used and precautions to be observed during the alignment procedure. Table III offers a ready reference alignment guide to be followed after the more detailed procedure has been studied.

For best results it is important that alignment be performed on a metal topped bench with all instruments and equipment securely bonded together and to ground. All leads should be as short as is practicable, particularly in the input grid circuits. Allow about fifteen minutes for the test equipment and receiver to warm before beginning the alignment. Isolation circuits will be required for both the input and output connections. It is important that composition resistors, preferably the half-watt size, and disc type ceramic condensers be used in making up these isolation networks so that a minimum amount of external inductance is added to the tuned circuits being adjusted.

The following equipment* will be required in order to align the picture and sound I-F stages of the receiver properly.

1. Accurate CW signal generator covering the following frequencies:

4.5 mc	44.2 mc
39.75 mc	42.25 mc
41.25 mc	45.5 mc
47.25 mc	43 mc
42.5 mc	45 mc

The generator must have an attenuation control which can be used to vary its output signal level.

2. Sweep frequency generator with a sweep center frequency of approximately 43.5 mc and a 10 mc sweep width.

3. Cathode Ray Oscilloscope with at least a moderately high vertical gain. Must have external sweep input or internal sweep frequency equal to the sweep generator sweep frequency and capable of phase control.

4. DC voltmeter with sensitivity of 20,000 ohms per volt or higher and voltage scale ranges which include approximately 10 volts and 3 volts (full scale deflection). VTVM with zero center scale adjustment is an ideal type.

5. 3 volt bias source such as a battery.

6. Detector network shown in Figure 6.

7. .005 uf isolating condenser.

*Several instrument manufacturers combine the first three items of the equipment list into one compact instrument assembly.

8. 10K ohm, 1/2 watt composition resistor.

9. .001 uf condenser for shunting oscilloscope input.

Before alignment is begun, tune the tuner off-channel by turning the tuner CHANNEL SELECTOR shaft so that the detent roller rests on one of the high points of the drum disc. Bias pin 1 of V703 with -60 volts, in order to eliminate spurious signals and possibility of high voltage shock hazard, or remove high voltage tube.

ORDER OF ALIGNMENT

1. Sound I-F and Ratio Detector Primary
2. Ratio Detector Secondary
3. 4.5 mc Sound Take-off
4. 4.5 mc Beat Trap
5. 39.75 mc Adj. Channel Picture Trap
6. 41.25 Co-channel Sound Traps
7. 47.25 Adj. Channel Sound Trap
8. 42.75 mc 4th Picture I-F Coil
9. 44.2 mc 3rd Picture I-F Coil
10. 42.25 mc 2nd Picture I-F Coil
11. 45.5 mc 1st Picture I-F Coil
12. 43 mc Converter Coil (min)
13. 43 mc Input Coil (max)
14. 45 mc Converter Coil (max)

It is important that the alignment be performed in order listed, with the exception of items 1 and 2, because there is some interaction within the various stages.

Sound I-F Alignment

Equipment: Connect the "hot" lead of the CW signal generator to the grid, pin 1, of V101, the 1st sound I-F tube, through a .005 uf isolating condenser as shown in Figure 5. Tune the generator frequency to 4.5 mc, unmodulated. Connect the voltmeter negative lead in series with a 10K isolating resistor to pin 7 of V103, one plate of the ratio detector, as shown in Figure 5. It is important that the 10K ohm isolating resistor be at the very end of the meter lead to avoid regeneration. Connect the positive voltmeter lead to ground.

Procedure: Adjust L101, L210 and T101 primary (bottom), to obtain a maximum voltmeter reading. The maximum voltage reading should be held at about 4 to 7 volts by decreasing the generator output as the transformer windings are turned to resonance.

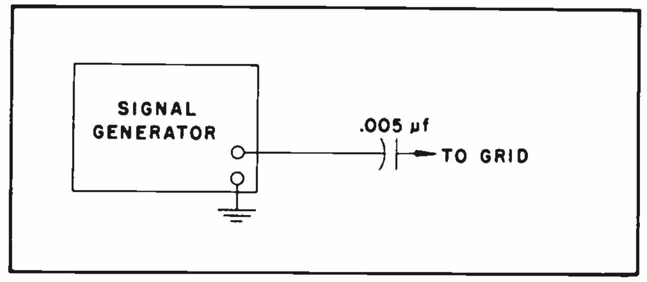

Figure 4. Signal Generator Isolation

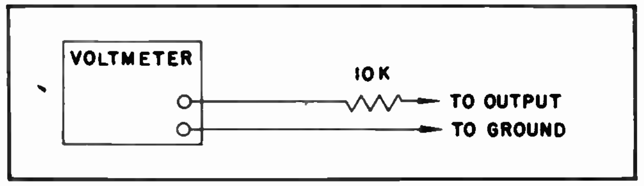

Figure 5. Voltmeter Isolation

Ratio Detector Alignment

Equipment: Generator input remains unchanged from the level that produced 4 to 7 volts in the preceding step. Connect the voltmeter across the junction of R111 and R112 and the switch side of R110; polarity will depend upon which side of resonance the secondary winding of T101 is tuned. If VTVM is being used, set the zero voltage point up scale so that plus and minus readings may be observed without changing the polarity selector switch on the VTVM. Start with one of the higher scales of the VTVM and decrease the scale setting as the null point is obtained.

Procedure: Tune the secondary (top) of T101 for a zero reading on the voltmeter. Do not change the generator output level from that which produced the 4 to 7 volts in the first step. Repeat tuning of T101 primary and secondary until adjustments do not change.

Trap and Picture I-F Alignment

TUNING 4.5 MC TRAP

Equipment: Connect the CW generator through the .005 uf isolating condenser, to pin 7 of V205 (plate of video detector) and tune the generator to 4.5 mc. Connect the detector network and voltmeter between ground and the cathode of the picture tube as shown in Figure 6.

Procedure: Tune L302 (4.5 mc trap in plate circuit of video amplifier) for minimum indication on voltmeter.

TUNING 39.75 MC, 41.25 MC, AND 47.25 MC TRAPS

Equipment: Couple the CW generator "hot" lead to the tuner mixer grid. This may be done in several ways. The .5-3 uuf trimmer condenser (C12 in Bulletin 301 of the 1952 Service Manual) located in front of the 6J6 and nearest the contact side of the tuner is connected to pin 5 of the 6J6, the mixer grid. This plate of the trimmer condenser is accessible through a hole in the side cover plate. The "hot" generator lead may be coupled to this point through a .005 uf isolating condenser, the condenser pigtail being clipped to the trimmer by some convenient means. Another method of coupling the generator is to remove the 6J6, wrap the isolating condenser pigtail around pin 5 of this tube, and replace it in its socket. In either method take care that the pigtail lead does not short to ground. A third method of coupling is to pull the 6J6 tube shield up on the tube until it is not grounded. Clip the "hot" lead of the generator directly to the tube shield. The tube shield and the tube electrodes form a condenser which capacitively couples the signal to the mixer grid. The capacity is much less than .005 uf, and a much higher level of generator output will be required if this method is utilized.

Connect the negative lead of the voltmeter to pin 1 of V301, the video amplifier grid, using the 10K ohm isolating resistor at the end of the lead; connect the voltmeter positive lead to ground. Connect the negative terminal of the 3 volt bias source to the AGC bus; connect the bias source positive lead to ground.

Procedure: Turn the CONTRAST control to its maximum position (extreme clockwise) for remainder of alignment. Tune the traps by setting the trap frequency on the CW generator and adjusting the trap slug for a minimum voltmeter reading. The order of tuning the traps is given in Table III. Keep signal low to avoid overloading I-F circuits.

TUNING PICTURE I-F COILS

Equipment: Instruments and set-up remain the same as for trap alignment during the first part of the procedure. For final adjustment the sweep frequency generator is also used and the voltmeter should be replaced by the oscilloscope. See Figure 7 for oscilloscope isolation details.

Procedure: Tune the I-F coils by setting the coil frequency on the CW generator and adjusting the coil for maximum voltmeter reading. The CW generator output must be attenuated so that the DC output voltage of the video detector (indicated on the voltmeter), remains at 1 volt as the I-F coils are tuned. The order of tuning is from the last I-F stage toward the tuner. Before tuning the grid coil of the 1st I-F stage, temporarily tune the tuner mixer plate coil for a minimum reading on the voltmeter at 43 mc. After the 1st picture I-F grid coil has been tuned, tune the mixer plate coil to 45 mc and repeat the trap and I-F alignment procedure until no additional change in adjustments is necessary.

When no further change takes place, replace the voltmeter with the oscilloscope and replace the CW generator with the sweep frequency generator. Use the same isolating condenser and input connection to the mixer grid. Loosely couple the CW generator (marker) to the input by clipping or touching the CW generator "hot" lead to the unshielded insulated end of the sweep generator "hot" lead. This will afford a small amount of capacitive coupling. If the CW and sweep generators are contained in the same instrument, it will only be necessary to switch on the sweep frequency generator in order to continue the procedure. Tune the sweep frequency generator to a center frequency of approximately 43.5 mc. Use a sweep width of approximately 10 mc so that the base of each of the two response curve skirts is well within the ends of the oscilloscope trace. Check the overall bandwidth, position of the picture carrier, dip in bandpass, and trappage by using the marker pip to locate frequency points on the response curve. See Figure 8. Tune the CW generator to 45.75 mc. The marker pip should appear at approximately the 50% point on the response curve skirt. Adjust individual coils to give proper bandpass. Adjust 1st I-F to set video carrier (45.75 mc) at 50% (6db) response point. Adjust 2nd I-F to set the 50% (6db) bandwidth point (42 mc) on sound side. Adjust 3rd and 4th I-F coils to eliminate any tilt in the response shape. It should not be necessary to adjust converter or input coil.

STEP NO.	SIGNAL GENERATOR FREQUENCY, MC	CONNECT SIGNAL TO	OUTPUT INDICATOR	ADJUST	INSTRUCTIONS	SPECIAL CONNECTIONS AND SETTINGS
12	43 CW	Mixer grid	Voltmeter across pin 1 of V301 and ground.	L201		Temporarily tune mixer plate coil for minimum voltmeter reading at 43 mc.
13	45 CW	"	"	Mixer Plate L9		
14		Repeat steps 4 through 12 until adjustments do not change.				
15	Approximately 43.5 with 10-mc sweep. Marker required.	Mixer grid	High gain scope to pin 1 of V301.	Mixer Plate Coil and L201 1st. Other coils if necessary.	Adjust 1st I-F to set video carrier (47.75 mc) at 50% point. Adjust 3rd and 4th I-F to eliminate any tilt.	See Figure 7 for isolation network. Use markers to determine bandpass between picture carrier and 50% point on opposite skirt. Bandpass should be between 3.8 mc and 3.6 mc. Adjust other I-F coils to obtain proper curve only when absolutely necessary.

ALL-WAVE TUNER

The 9795 is the All-Wave Tuner. This tuner incorporates a 6BQ7, 6BQ7A or a 6BZ7 for an R-F amplifier; a 6T4 or 6AF4 as a UHF oscillator with a 6U8 acting as a mixer and VHF oscillator. Refer to Figure 12 for complete schematic of the 9795.

SHAFT FUNCTION

1. FINE TUNING - Outer shaft for VHF and UHF oscillators fine tuning.

2. SWITCHING - Center shaft includes nine detent positions, eight for UHF decade coil board strips covering frequency channels 14 to 19; 20; 29; 30 to 39; 40 to 49; 50 to 59; 60 to 69; 70 to 79 and 80 to 83. VHF channels 10 through 13 may be received on first UHF decade position. The ninth position allows VHF reception.

3. SWITCHING - Inner shaft includes twelve detent positions, ten for UHF unit digits (individual channel selection included within the above eight decades), twelve positions for VHF channels 2 to 13.

4. VHF TUNING - To receive VHF channels 2 through 13, set middle section of tuning knob assembly so that "VHF" and channel numbers are directly in front of pilot light. These VHF channel numbers will be found on the inner circle of numbers. To switch VHF channels, rotate front crown control knob only.

5. UHF TUNING - To receive UHF channels, rotate middle section either right or left from VHF position. First half of UHF channel number is controlled by middle knob. Second half of UHF channel number is controlled by front crown knob; example, channel 56 - the middle knob will place the first half of the UHF channel number (5) in front of the pilot light. The front crown knob will place the second half of this UHF channel number (6) in front of the pilot light, thus producing UHF channel 56.

Theory of Operation

In general, the combination tuner consists of two major units as noted in the block diagram; the UHF subassembly, and VHF subassembly.

Referring to the block diagram, the antenna is seen to be connected to a diplexer which provides separation of signals above 470 mc for the UHF tuner, and signals below 300 mc for the VHF tuner.

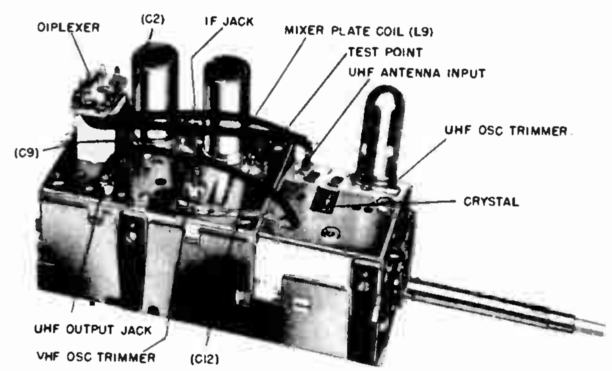

Figure 10. All-Wave Tuner

The operation may best be followed by tracing the path of the signal from the antenna through the corresponding tuner and then to the I-F amplifier at its output. When the combination tuner is in UHF position, the signal from the common antenna passes down the twin-lead to the diplexer and continues on to the UHF tuner. Here it goes through two preselector circuits and into a Xtal mixer. The Xtal is supplied with a local oscillator voltage. differing by 40 mc above the signal frequency. After mixing, it becomes a 40 mc signal (I-F frequency) and passes into the VHF tuner. Since the combination tuner has been set for UHF operation, the 40 mc amplifier, which is noted in a block below the VHF tuner, is now in place of one of the VHF channels. In this manner, the signal is amplified again at 40 mc and passes on through the output to the I-F stage.

When the combination tuner is in the VHF position, the following path of signal may be traced: As previously noted, the signal travels from the common antenna to the diplexer, but now, since its frequency is below 300 mc, it is diverted directly to the VHF tuner input. At this point, it is connected to one of the channels (2 - 13) as in the usual TV band, and is amplified at this corresponding frequency. At the end of this amplification, it is mixed (in the VHF tuner) by a 6U8 stage. This provides the local oscillator, again 40 mc above the signal, and the result in output is then the 40 mc signal which is coupled by the output plate coil to the I-F strip.

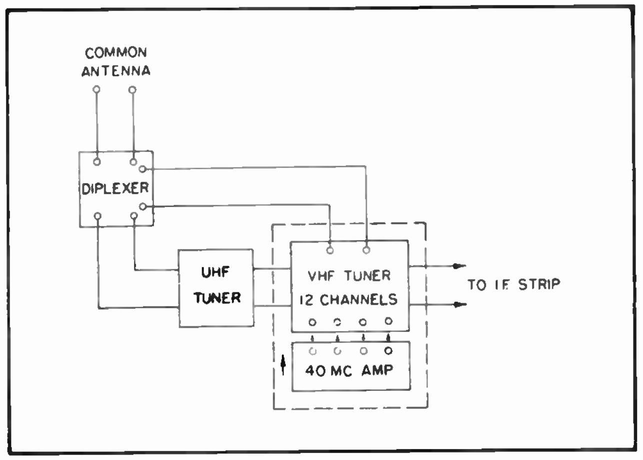

Figure 11. Block Diagram, All-Wave Tuner

The various components of the major subassemblies may be seen from the circuit diagram (figure 12). In the UHF tuner, L22 and L23 are the preselector circuits. L24 and L25 make up the oscillator inductance. The oscillator tube is either a 6AF4 or 6T4, as shown. It should be noted that the coils, L20 and L21, along with C30, C31 and C32, comprise the high-pass filter portion of the diplexer. The low-pass filter, consisting of coils La and Lb, along with the two 1.5 mmfd condensers, is the other portion of the diplexer which diverts signals lower than 300 mc to the VHF tuner.

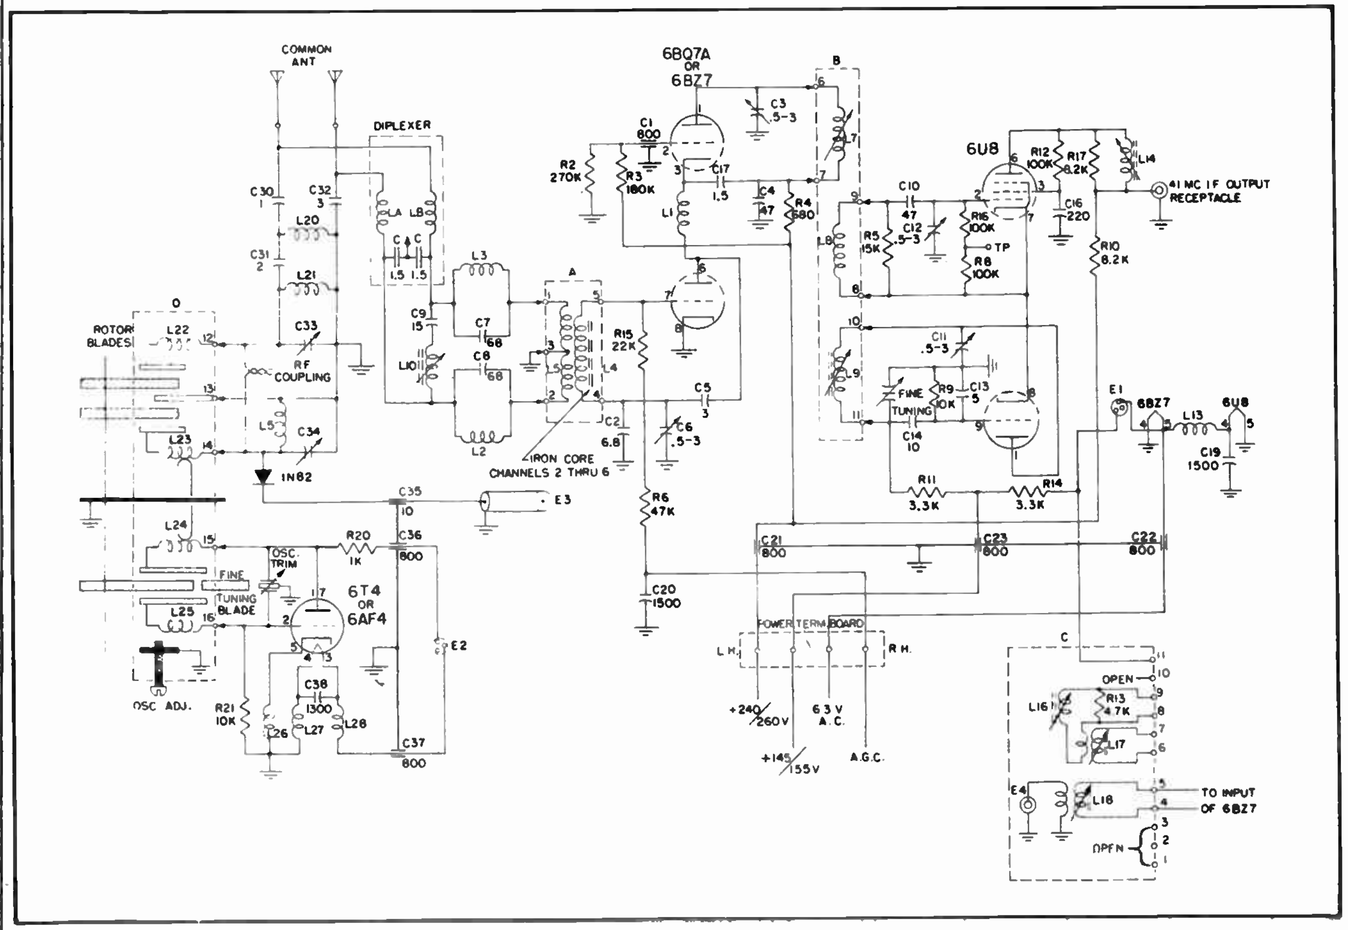

Figure 12. Schematic, All-Wave Tuner

ALIGNMENT

ALL-WAVE I-F ALIGNMENT PROCEDURE - GENERAL

The combination All-Wave tuner contains two sections - the first (front section) contains the UHF portion. The second (rear section) is the usual 12-channel VHF turret tuner. There is one difference in the VHF section, in that it contains a contact board or cascode strip. This provides the equivalent of a 13th position, and is held out when the decade knob is in the VHF position. The units front knob then operates the rear turret from channel 2 to 13. It is also held out when the decade knob is in the 10's position for channels 10, 11, 12 and 13. UHF operation is obtained when the decade center knob is in the 10's position for channels 14 to 19 and for all succeeding decade positions, up to 83.

I-F ALIGNMENT

Set the tuner in the VHF position (on channel 10) and insert a signal at the test point (refer to figure 10) through a .005 capacitor with the proper termination for the generator being used. Use a -3 volts for the AGC bias. Observe the output of the video detector with a 10K resistor and a .001 capacitor isolation network which is connected to the oscilloscope vertical terminals or a voltmeter.

A. Apply a 43 mc signal and align the 1st I-F grid coil until a maximum indication is observed.

B. Apply a 45 mc signal and align the output plate coil (L9) of the tuner for maximum indication. A sweep may then be applied and the I-F touched up for proper response. It is preferable to adjust coils in the I-F strip slightly, rather than accommodate discrepancies in the curve with changes in the settings of the adjustments mentioned in A and B.

R-F ALIGNMENT - Check VHF

Set the tuner to the VHF position on the decade center knob and the units front knob on channel 10. Connect a sweep to the VHF or the antenna point of the diplexer. Note overall wave shape and position of sound in video carrier. Adjust local oscillator slug to proper frequency with fine tuning in center of scale. A bias of 3 volts is applied to AGC during the above operation.

R-F ALIGNMENT - Check UHF

With the tuner at channel 19, with three or four volts of bias on the I-F AGC and three volts of R-F AGC. Connect a UHF sweep to the antenna terminals with the proper dummy termination (300 ohms total.) Observe the output on the video detector with proper isolation network. (10K resistor and a .001 capacitor on scope.) Use a 60 cycle sweep that is phased properly.

A. Check wave shape and operation of channels 14, 21, 31, 41, 51, 61, 71 and 81. These should operate positively and not be intermittent.

B. Note above operation to be made with fine tuner in center of fine tuning range.

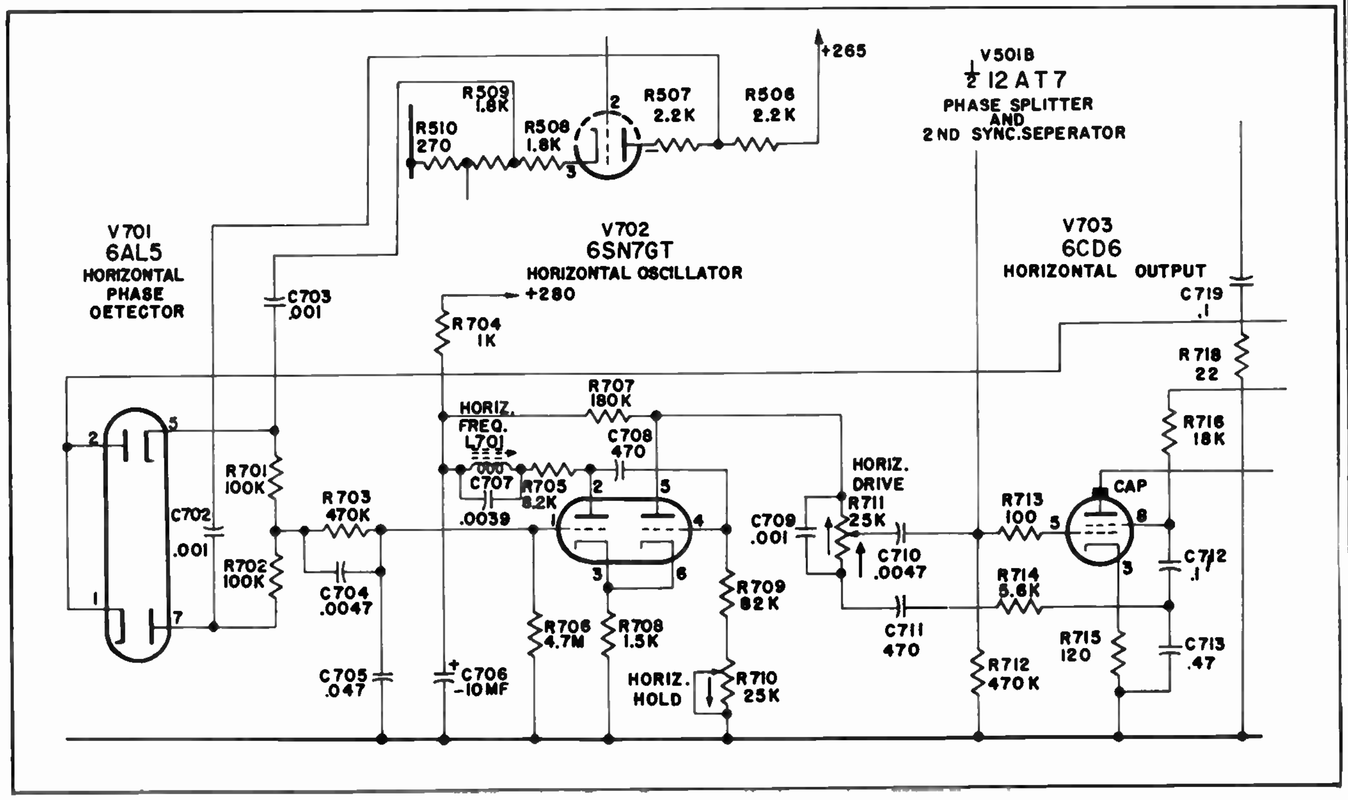

Figure 13. Horizontal Phase Detector

NOTE

To adjust VHF local oscillators, place tuner in VHF position, remove knobs, place fine tuner in middle of range so VHF local oscillators can be reached with proper alignment tool through UHF unit.

To adjust UHF local oscillator, place tuner in UHF position, remove knobs, place fine tuner in middle of range. Rotate units front knob. Adjust front screw head.

Horizontal Phase Detector

It has not been the general policy to include a discussion on circuit theory and operation in the service bulletins. A large number of text books and magazine articles have covered the field quite thoroughly. However, there have been a number of questions submitted by service personnel regarding the operation of the balanced horizontal phase detector.

Figure 13 shows the horizontal sweep section. Without a control voltage on the grid of the horizontal multivibrator, it operates at a free-running frequency which is determined by the inductance of L701 and the resistance of R710, all other factors remaining constant. These other factors are R and C component values, B+ supply voltage, and control voltage at grid No. 1, which at the moment is assumed to be zero. The nature of the frequency vs DC control voltage characteristic of

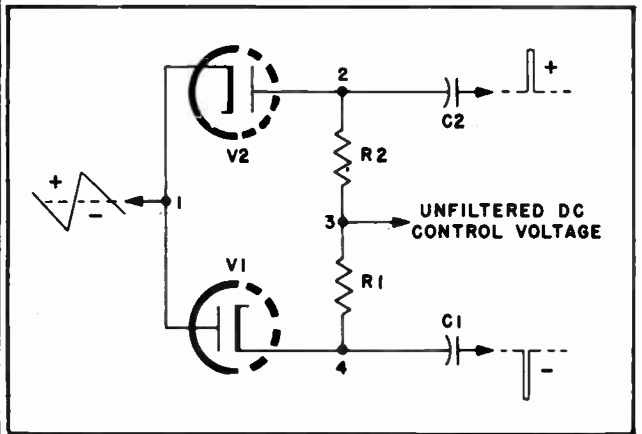

Figure 14. Basic Phase Detector

the common cathode type of multivibrator used in the 400 series chassis is such that a positive change in DC voltage on grid No. 1 produces a decrease in frequency and a negative change produces an increase in frequency, all other factors remaining constant. Since B+ supply voltage changes with line voltage variations and signal strength changes, and the R, L, and C component values change slightly with temperature and humidity, these frequency determining factors do not remain constant. It remains necessary to hold the multivibrator to a constant frequency by employing some factor which does remain constant for all practical purposes. This factor is the horizontal sync pulse frequency which originates at the transmitting source. This source is not used directly because of its poor immunity from random noise pulses, but it is used as a reference standard from which the correct value of DC control voltage is derived.

It remains to be shown how the DC control voltage is made to vary in such a manner as to counteract changes in the other factors so that the frequency will remain constant. Fundamentally, this is accomplished by comparing a sampling of the instantaneous frequency of the multivibrator output with the standard frequency source.

The difference between the two frequencies is made to generate a DC control voltage of such magnitude and polarity that the difference tends to remain zero for all practical purposes. Figure 14 is a simplified drawing of Figure 13 with all but the essential components deleted. V1 represents V701A, V2 represents V701B, R1 represents R701 and R2 represents R702. C719 and R718 complete the high deflection current path to ground, and the saw-tooth current produces a saw-tooth voltage across R718. The saw-tooth potential at 1, Figure 14 has an AC axis since DC is blocked by C712. The saw-tooth current frequency is the same as the horizontal multivibrator frequency so that the derived saw tooth is used as a sampling voltage. C1 and C2 represent C702 and C703 respectively. They serve to couple the sync pulses to the phase detector and to block DC as well as to serve as an active part of the phase detector circuit. R706 is used only as a grid leak for the horizontal multivibrator grid #1 Without this grid leak, a failure in the horizontal control tube would leave grid #1 with insufficient bias. Therefore plate and screen dissipation of the 6CD6 would exceed the rated values. R703, C704 and C705 form a low pass filter to the voltage at point 3, Figure 14. This filter offers a low impedance path to ground for the AC component of voltage that appears at point 3. In addition this filter performs the important function of making the DC control voltage at the multivibrator grid No. 1 relatively free from random noise pulses which "ride in" with the sync pulses. The time constant of the filter is very long compared to the change in circuit conditions that take place when several noise pulses get through, but the time constant is relatively short as far as DC change brought on by phase change is concerned.

The analysis is simplified by assuming an ideal saw-tooth voltage waveform (symmetrical about the AC axis) ideal diodes (equal conducting characteristics) and ideal sync pulses (equal shape and amplitude).

Each diode in conjunction with its respective coupling condenser forms a rectifier circuit. The condenser charges during the conduction period of the diode by an amount which is a function of the voltage applied between the diode electrodes.

Case I Multivibrator in Synchronization.

Consider the case when the multivibrator is in synchronization. Figure 15a shows graphically that the zero voltage point of the saw-tooth occurs at the same point in time that the middle of the sync pulses occur. When the system is in equilibrium, the sync pulses must occur sometime during the return line or

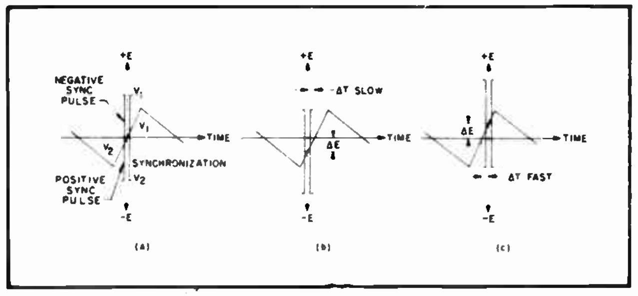

Figure 15. Waveform Analysis of Phase Detector

fly-back; that is, during the steep portion of the saw-tooth wave. This restriction is necessary for viewing of the picture in correct frame position. It is the positive half of the saw tooth at the plate of V1 and the negative sync pulse at the cathode of V1 that cause diode V1 to conduct current. It is the negative half of the saw tooth at the cathode of V2 and positive sync pulse at the plate of V2 that cause diode V2 to conduct current. This situation is shown graphically by flipping the sync pulses with respect to the zero potential axis. The waveforms are labeled in Figure 15a to indicate these facts. The two potentials acting at either diode are series aiding, and the amount of diode conduction depends on the sum of the two potentials applied across the diode at any instant. For the present case, the potential variation across each diode is the same over one cycle, so each condenser charges an equal amount. The instantaneous rate of charge is not the same for each condenser. This gives rise to pulsating output. A pulsating voltage is equivalent to an AC voltage component superimposed on a DC voltage component. The low-pass filter attenuates the AC component to a negligible value. Since each condenser charges by the same amount, points 2 and 4 are at potentials of equal amplitude and opposite polarity if C1 equals C2. The potential at point 3 is the algebraic sum of these two potentials, so it is zero.

Case II Multivibrator Too Slow.

Figure 15b shows that the saw-tooth zero potential point occurs ΔT seconds (a few millionths of a second in order of magnitude) later than the middle of the sync pulses. For this case V2 has a greater potential difference across its electrodes and V1 has a smaller potential difference across its electrodes during the time that the sync pulses are applied than for the same interval of time in Case I. The difference is represented by ΔE volts. This means that the C2 will charge more and C1 charge less, relative to Case I. The potentials at points 2 and 4 are no longer of equal magnitude. The charge on C2 tends to equalize the charge on C1 by transferring electrons through R2 and R1. The potential at point 3 is the algebraic or net potential between 2 and 4, relative to ground; and it is several volts negative with respect to ground. The decrease in potential causes the multivibrator to speed up, and as its phase difference with the sync pulses decreases, the corrective voltage decrease toward zero.

Case III Multivibrator Too Fast.

Figure 15c shows that the saw-tooth zero potential point occurs ΔT seconds (a few millionths of a second in order of magnitude) before the middle of the sync pulses. For this case the potential relationships acting on the two diodes are reversed. C1 charges more than C2, and there is a net positive potential at point 3. This positive potential causes the multivibrator to slow down. The phase difference between saw-tooth and sync voltages tends toward zero, causing the correcting voltage to do the same.

The most stable state of equilibrium and the one that produces the correct picture frame phase relative to the blanking bar is the zero voltage state. The multivibrator will operate in a state of equilibrium for which the DC output of the phase detector is either slightly positive or negative, but this state is less stable. The picture frame phase is wrong, and the multivibrator is likely to lose sync (equilibrium) when switching channels or interrupting the horizontal sync pulse in some other manner.

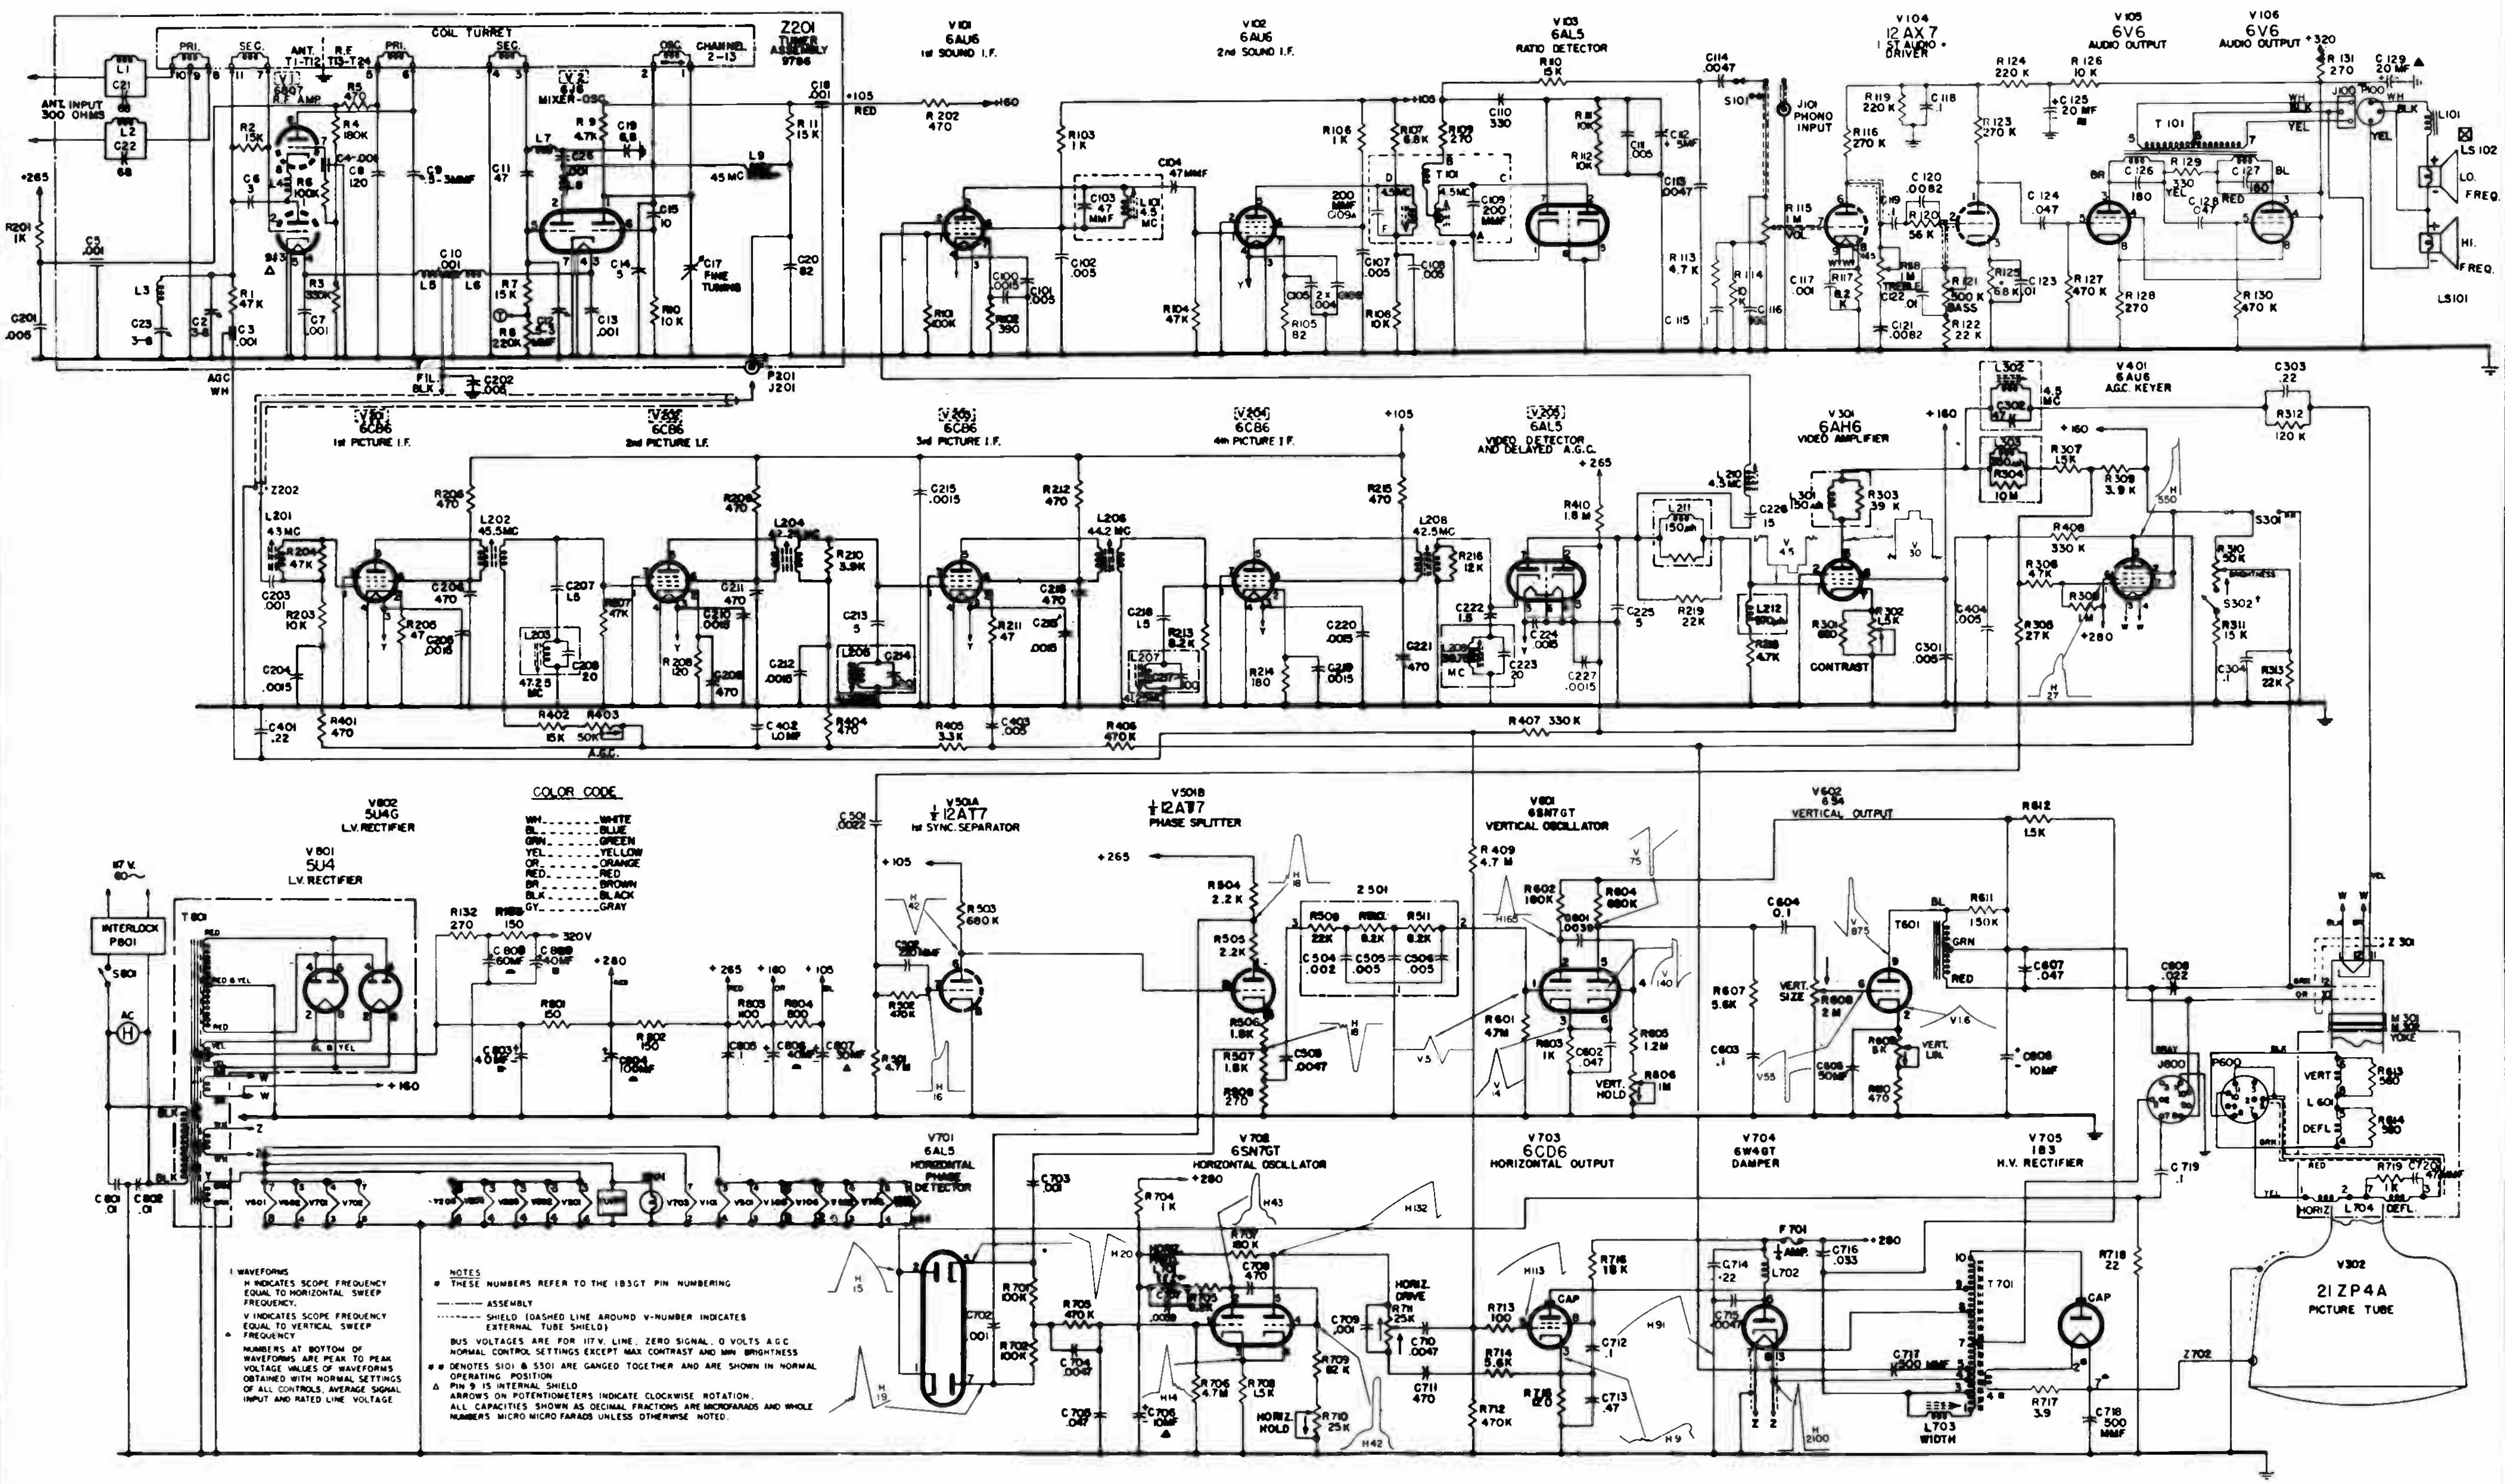

Figure 17. Schematic Diagram for Chassis 400

PARTS LIST

NOTE: Unless other wise noted all resistors are 1/2 watt composition type, ±10% tolerance with values given in ohms.

NOTE: Unless otherwise noted all condensers are 600 volt, molded phenolic type, ±20% tolerance with whole number values given in micromicrofarads and decimal fraction values given in microfarads. GMC - guaranteed minimum capacity.

		TRANSFORMERS
T101	5443	Transformer - Ratio Detector - 4.5 Mc
T102	5192	Transformer - Audio Output
T601	5157	Transformer - Vertical Output
T701	5184	Transformer - Horizontal Output
T801	5038	Transformer - Power
		CONTROL - SWITCHES
R114	4907	Control - Volume, 500K
R117	4890	Control - Tone, 1M
R302	4907	Control - Contrast Valve, 1.5K
R310	4867	Control - Brightness, 50K
R403	4853	Control - AGC, 50K
R606	4868	Control - Vertical Hold, 1M
R608	4864	Control - Vertical Size, 2M
R609	4865	Control - Vertical Linearity, 5K
R710	4859	Control - Horizontal Hold, 25K
R711	4859	Control - Horizontal Drive, 25K
		MISCELLANEOUS
F701	9782	Fuse - 1/4 Amp, Slo-Blo
I801	9505	Light - Pilot (#44 Mazda)
L601	9729	Yoke - Deflection 70°
L704	9729	Yoke - Deflection 70°
J101	6121	Receptacle - Phono Input
LS101	9091	Speaker - 5-1/4"
LS102	9074	Speaker - 11-1/2"
M301	9702	Ion Trap - 45 Gauss
M302	9789	Focuser
P801	6126	Receptacle - Power
Z201	9786 or 9795	Tuner - Cascode R-F - UHF-VHF, 40 Mc Standard Coil
Z301	6107-A	Socket - Kinescope with Leads
Z501	9695	Network - Vertical Integrator
Z702	6227	Plug - Anode Connector with Lead

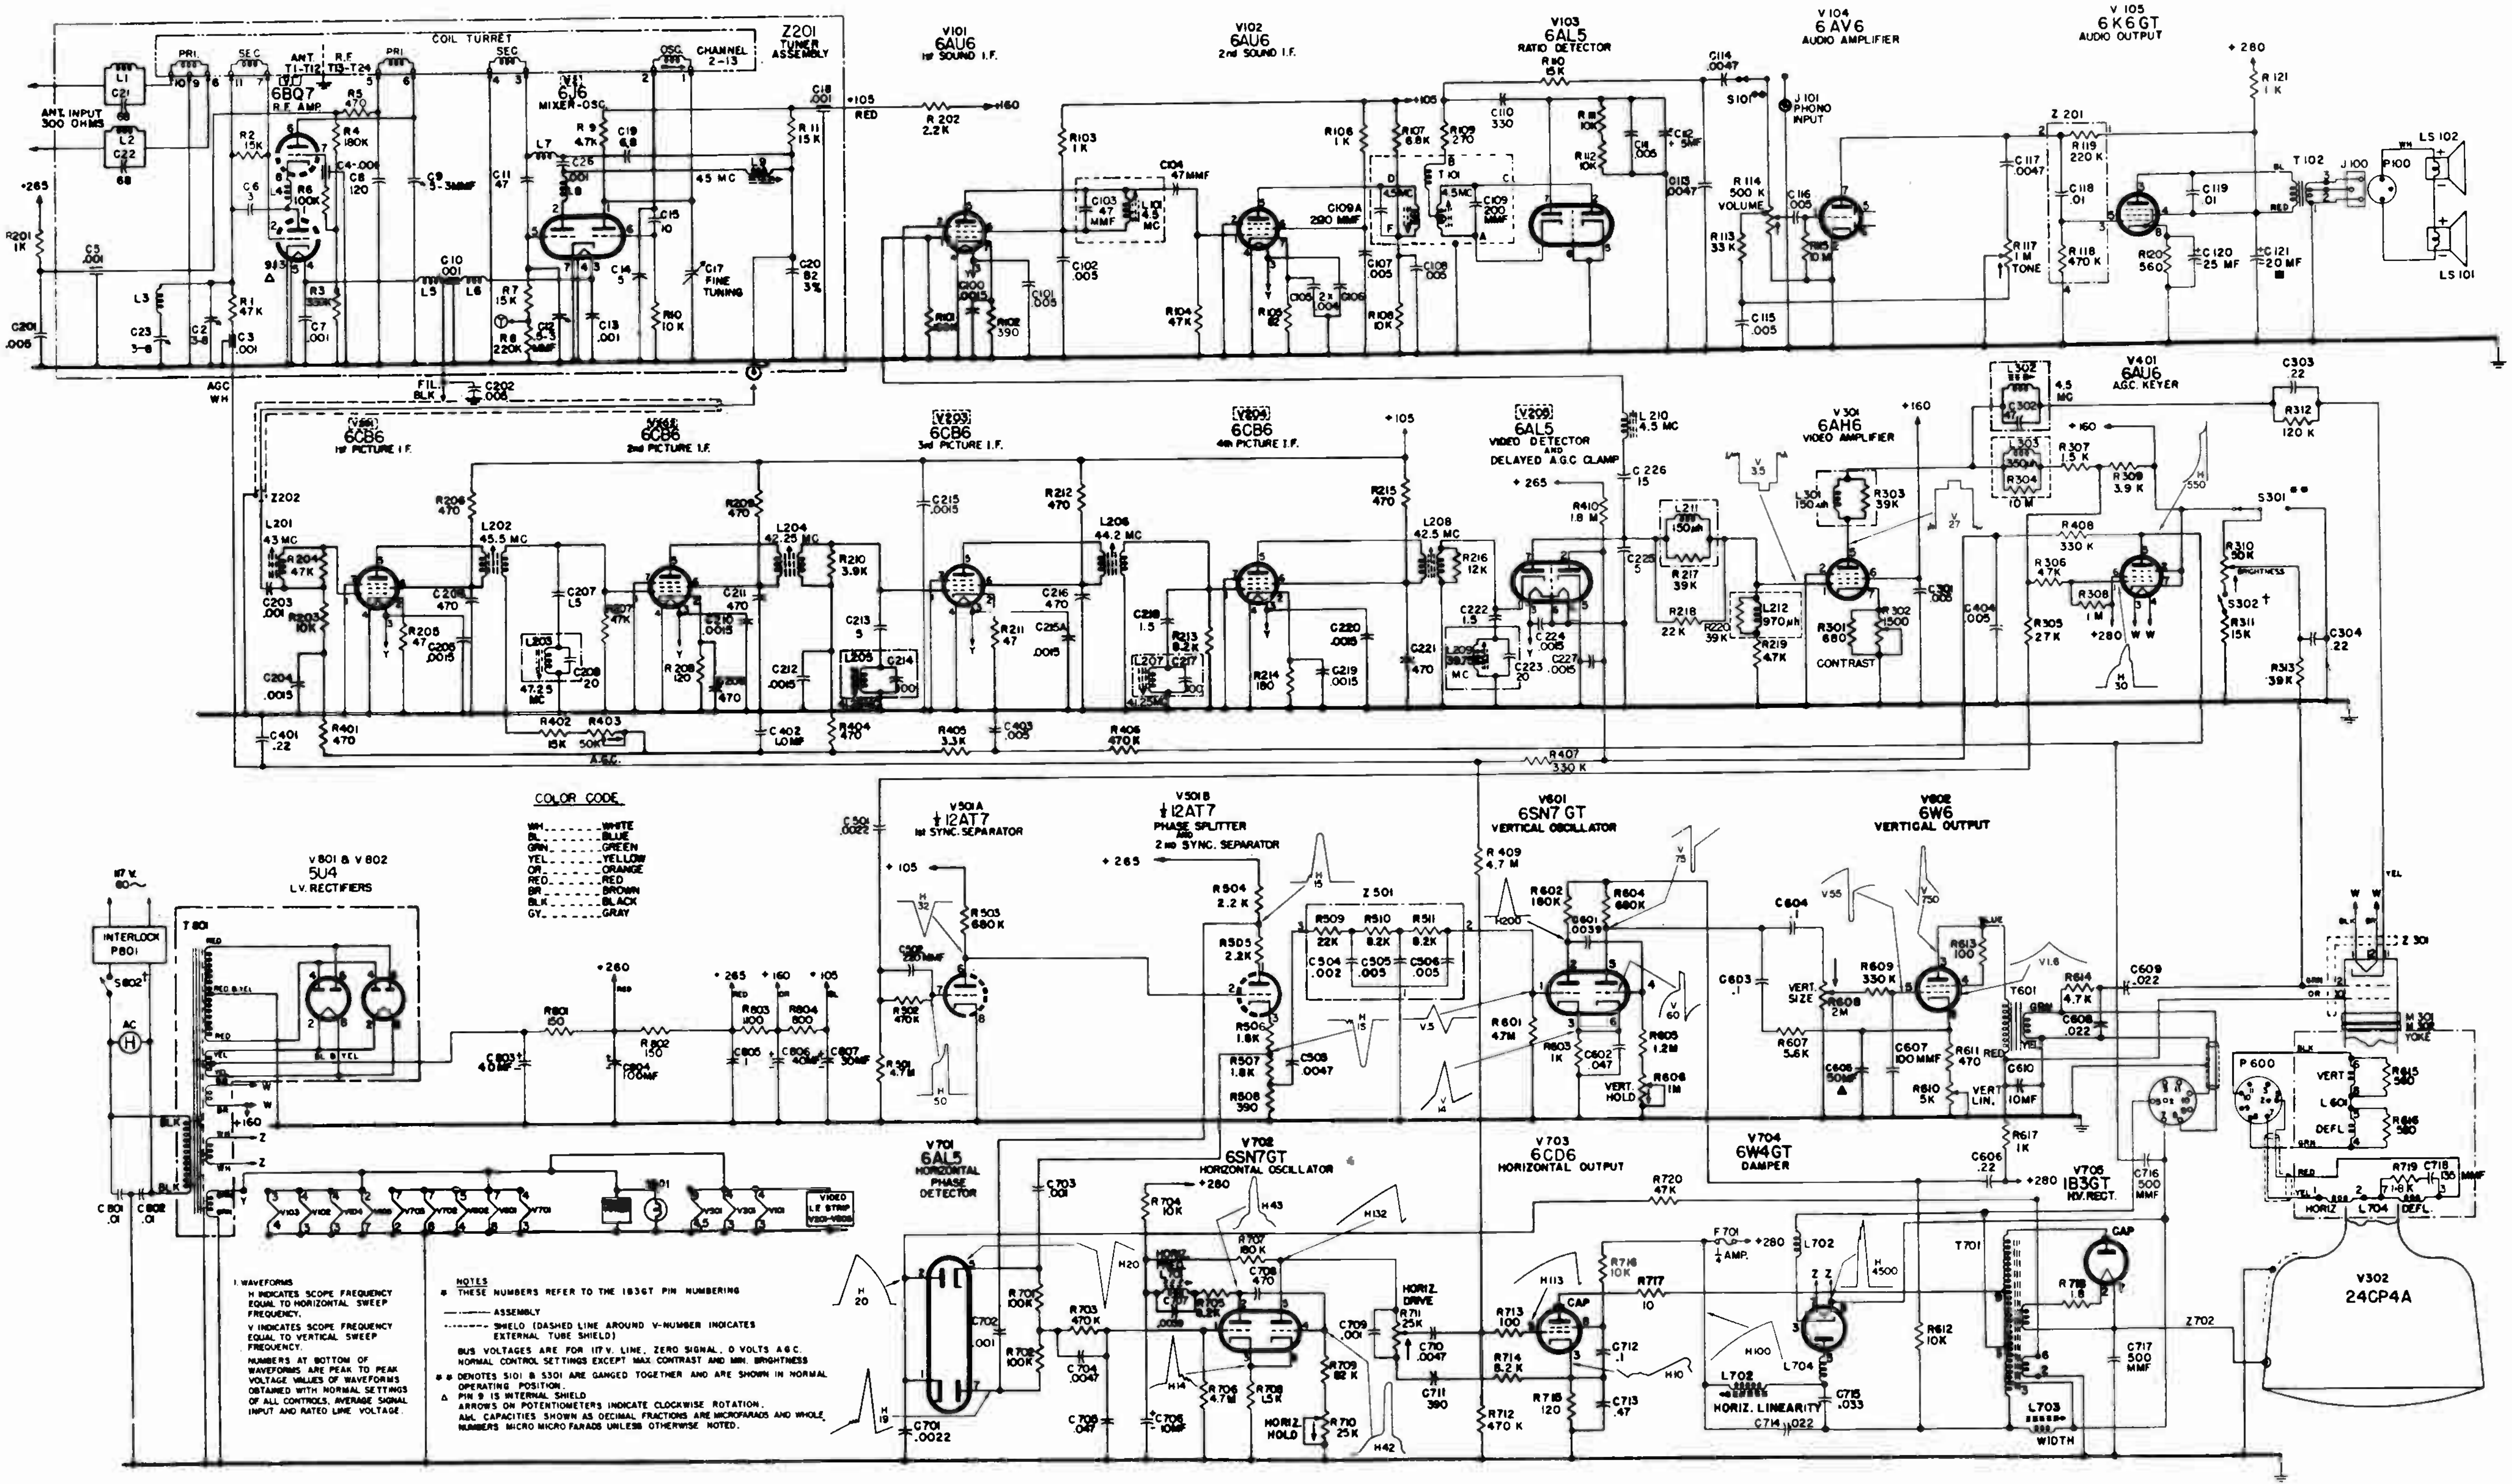

Figure 19. Schematic Diagram for Chassis 402

PARTS LIST

NOTE: Unless otherwise noted all resistors are 1/2 watt, composition type, ±10% tolerance with values given in ohms.

NOTE: Unless otherwise noted all condensers are 600 volt, molded phenolic type, ±20% tolerance with whole number values given in micromicrofarads and decimal fraction values given in microfarads. GMC - guaranteed minimum capacity.

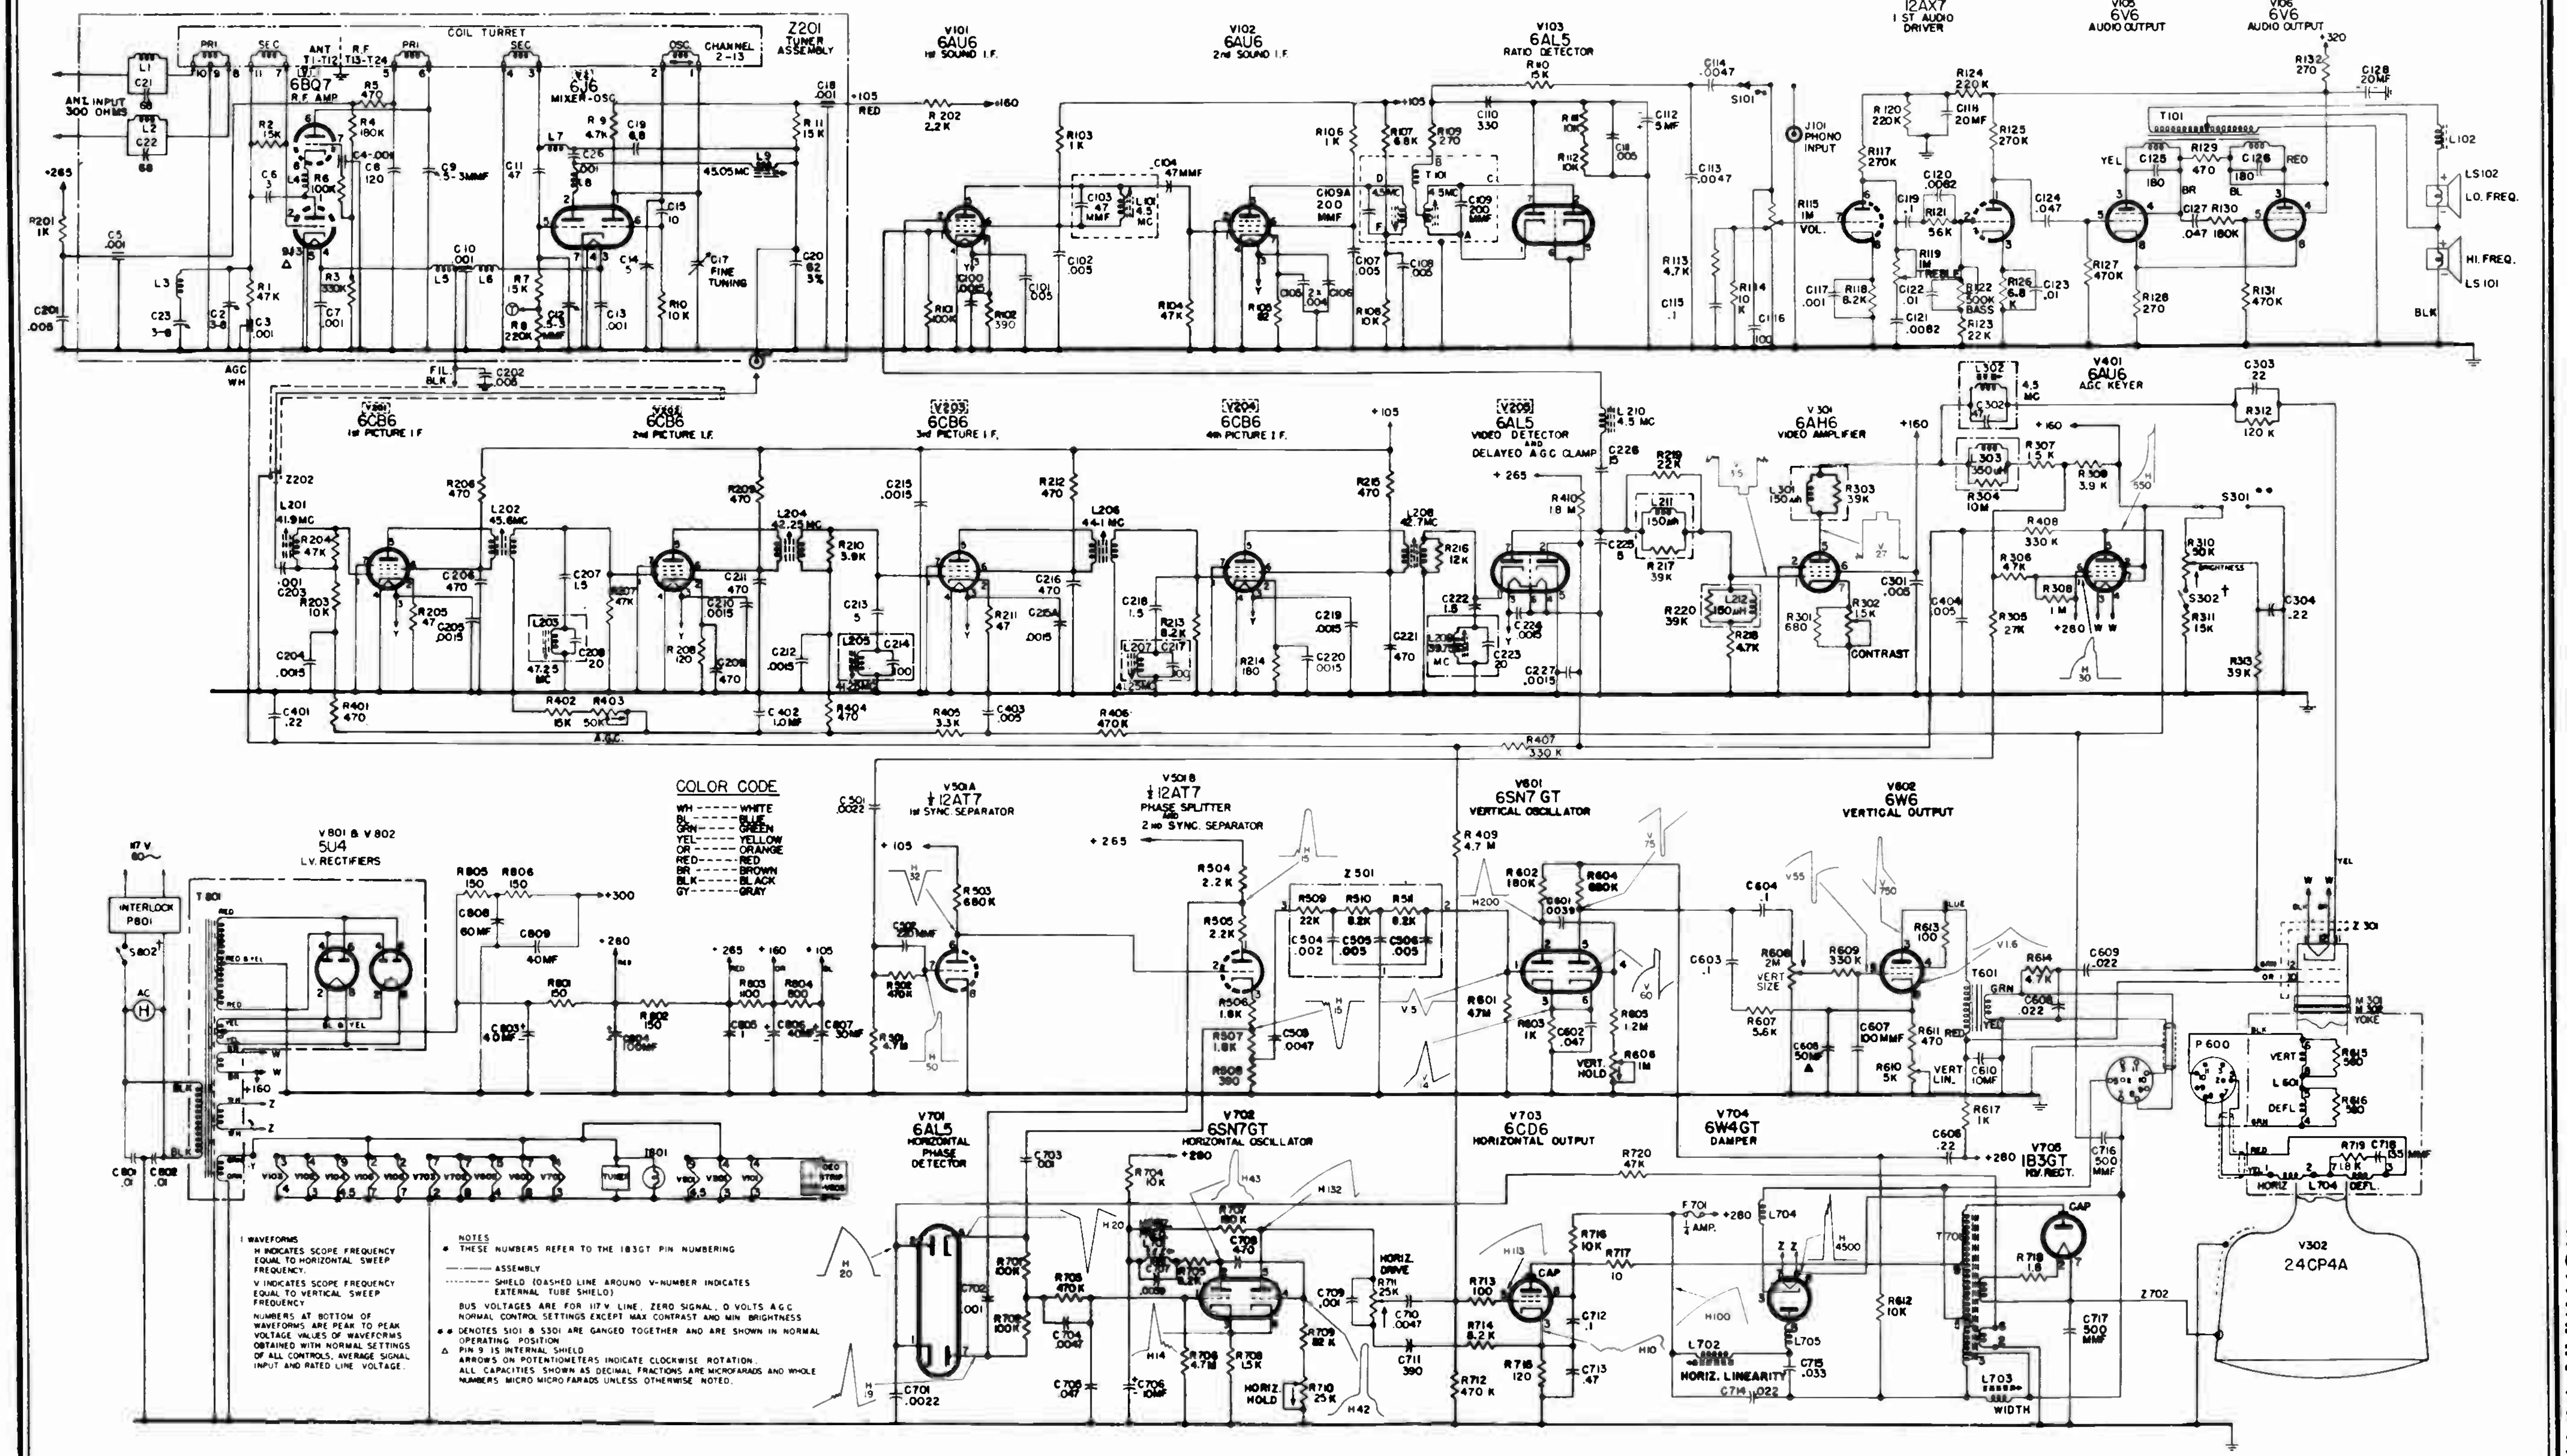

Figure 20. Schematic Diagram for Chassis 403

PARTS LIST

NOTE: Unless otherwise noted all resistors are 1/2 watt, composition type, ±10% tolerance with values given in ohms.

NOTE: Unless otherwise noted all condensers are 600 volt, molded phenolic type, ±20% tolerance with whole number values given in micromicrofarads and decimal fraction values given in microfarads. GMC - guaranteed minimum capacity.

Z402	6239	Plug - Anode Connector with Lead

DESCRIPTION

The Regency Model RC-600 UHF (Ultra High Frequency) Television Converter is designed to permit reception of UHF television signals on receivers designed for VHF channels 2 through 13.

The frequency coverage of the UHF television band is from 470 to 890 megacycles. Seventy UHF channels make up this band and are numbered 14 through 83. As adjusted at the factory, the RC-600 converts any of the UHF channels for reception on channel 10 on your VHF television receiver. If a signal on channel 10 makes this channel unusable, an easily performed adjustment will permit reception of the UHF signals on any channel from 8 to 13.

Two front panel control knobs are used on the Regency Model RC-600. (See figure 1.) The large control knob is used for tuning UHF stations with tuning indicated by the large slide rule type dial. The other front panel control actuates the selector switch. Switch positions are marked OFF-VHF-UHF. If the television receiver's AC plug is inserted into the receptacle on the back of the converter (see figure 2), the selector switch also controls power to the television receiver.

The action of the selector switch is as follows:

1. OFF POSITION—Power to both converter and receiver is turned off.
2. VHF POSITION—Power to the receiver and to the converter tube filaments is turned on, and the VHF antenna is connected through the switch to the receiver antenna input terminals. The receiver may now tune in any available VHF station from Channel 2 through 13.
3. UHF POSITION—Power to both receiver and converter is on. The VHF antenna is disconnected by the switch, and the converter output (channel 10 frequency) is fed to the antenna input terminals of the receiver. With the channel selector of the receiver in channel 10 position, the converter is tuned to an available UHF signal for best picture and sound.

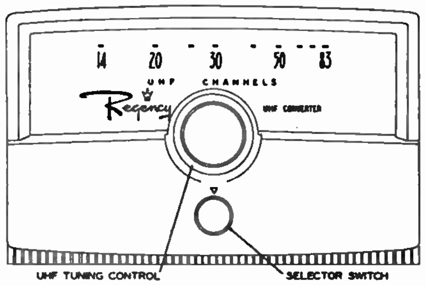

Figure 1.

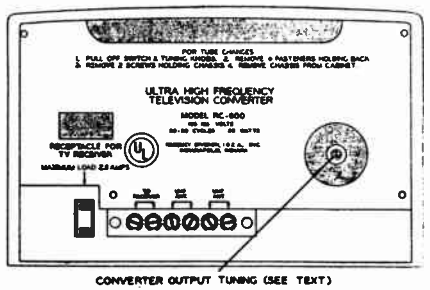

Figure 2.

INSTALLATION

1. Locate the converter as close to the television receiver as is convenient. Disconnect the VHF antenna lead from the receiver and connect it to the converter terminal strip marked VHF ANTENNA at the back of the unit.

2. Connect a short piece of 300 ohm twin lead from the receiver antenna input terminals to the converter terminals marked VHF SET.

3. Connect the UHF antenna lead-in to the converter terminals marked UHF ANTENNA. If a combination UHF and VHF antenna is employed, connect a short piece of 300 ohm twin lead from the converter terminals marked UHF ANTENNA to terminals marked VHF ANTENNA.

4. If it is desired to have the television receiver turned on and off by the converter selector switch, plug the receiver AC plug into the AC receptacle on the back of the converter.

5. Plug the converter power cord into a convenient outlet that provides 105-125 volts AC, 50 to 60 cycles. DO NOT CONNECT TO A DC SOURCE.

6. Select a clear VHF channel (8 to 13) for UHF reception, preferably channel 10, if available, and tune in a UHF station as described in OPERATION below. Adjust the converter output by means of the small fiber knob at the back of the converter (see figure 2) for best reception of the UHF television signal.

OPERATION

With the television receiver line cord plugged into the back of the converter, as previously described, the power switch of the television receiver should be left in "On" position at all times. The lower knob on the converter then turns the converter and receiver off and on simultaneously, thereby employing only one control for this operation.

To place your television receiver in operation, rotate the lower knob on the front of the converter cabinet to VHF position. In this position the television receiver may be used to tune in available VHF stations between channels 2 and 13 in the normal fashion. Since the filaments of the converter tubes are supplied with power in VHF position, a warm-up period is not required when switching to UHF position.

To receive UHF stations, turn the lower knob on the converter to the position marked UHF, and set the receiver channel selector knob to channel 10 position (or such other channel as may have been selected for UHF reception). The receiver is now set to receive signals from the UHF converter. Turn the large knob on the converter until the desired UHF channel is tuned as indicated by the pointer on the tuning dial. This setting of the tuning knob should always be adjusted for best picture and sound from the received UHF signal. Tuning may be touched up with the fine tuning control on the receiver.

In areas where only UHF stations are available, the converter is turned to UHF position and tuned to the desired channel. This requires a warm-up period to allow the tubes to reach their required operating temperature, thus insuring stable operation. Usually it is found that the normal warm-up period of the television receiver is sufficient. For some receivers it may be necessary to allow an additional minute or two of warm-up time to insure efficient operation.

SERVICING PROCEDURES

The Regency Model RC-600 converter employs a tuning drum unit consisting of a pre-selector circuit, crystal mixer, oscillator, and intermediate frequency amplifier. Both oscillator and converter tubes, type 6AF4 and 6BK7, are contained inside the tuning drum. A power transformer supplies filament voltages and provides voltage to the half wave selenium rectifier in the B plus circuit.

When servicing the converter, any components may be replaced with the exception of those contained in the tuning drum. Should difficulties occur in the tuning drum or if alignment is required, it is suggested that the entire converter unit be returned to the factory for service. To aid in locating the various converter components, the top and bottom chassis views are shown in figures 3 and 4.

TUBE REPLACEMENT—A tube puller is supplied with each tube in the tuning drum. If tube replacement is required, perform the following steps:

1. Remove knobs from front of cabinet.
2. Remove back cover.
3. Remove hex head screws holding chassis in.
4. Remove chassis.
5. Remove the 6BK7 tube (located at center of tuning drum, nearest the front of chassis).
6. Remove screw holding shield plate near top of tuning drum.
7. Remove the 6AF4 tube.
8. Remove tube pullers from old tubes and replace on new tubes.
9. Re-assemble the chassis into the cabinet.

Normally, a tube replacement will not necessitate converter alignment. However, if the unit does not track properly or if converter operation is not up to standard after tube replacement, it is suggested that a number of tubes (particularly the 6AF4 oscillator) be tried. In this way, it will be possible to select a tube whose characteristics more nearly approach those of the original tube.

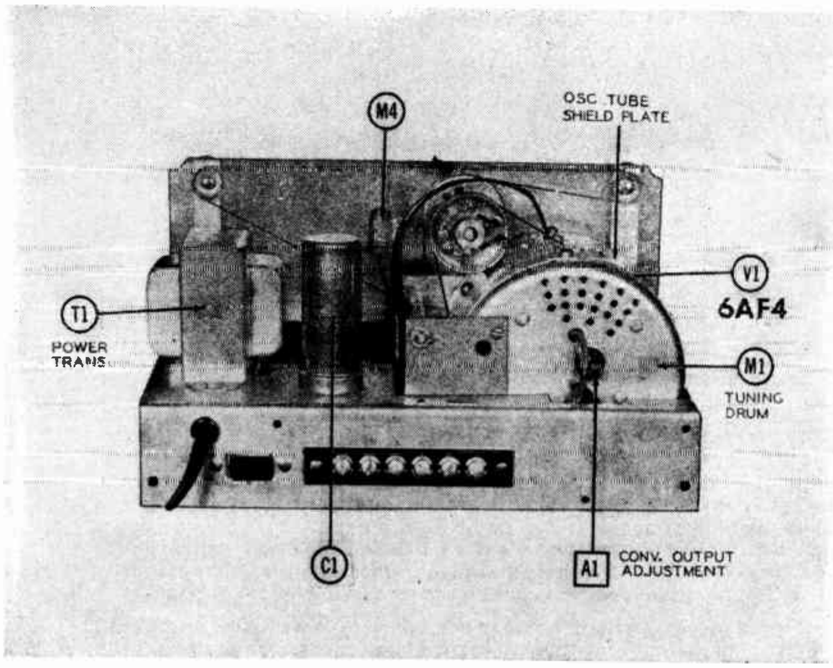

Figure 3. Chassis Rear View

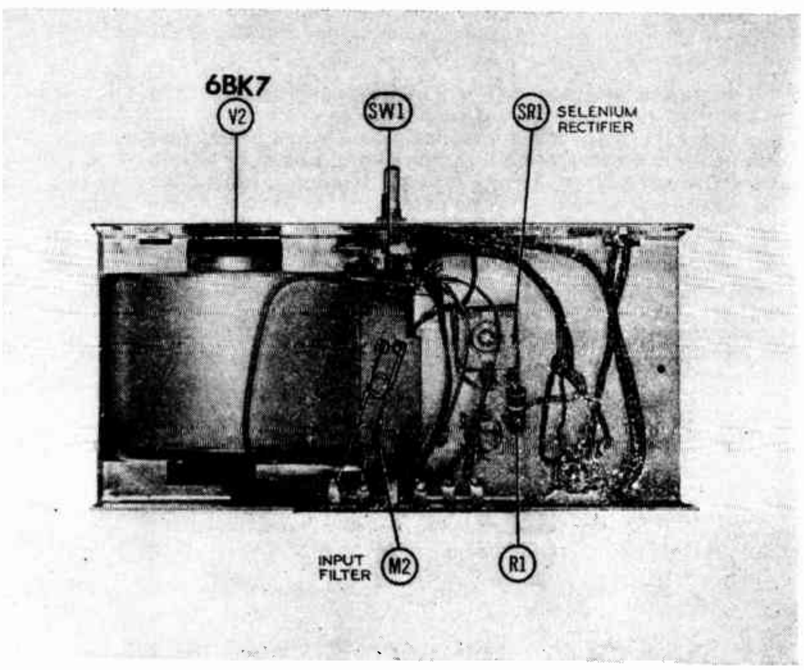

Figure 4. Chassis Bottom View

REPLACEMENT PARTS

In ordering replacement parts from the factory, always give part number (and number printed on the part, if different from number shown on parts list) and name or description of part.

All parts on which adjustments or replacements are desired must be returned to REGENCY DIVISION, I. D. E. A. INC., 7900 Pendleton Pike, Indianapolis 26, Indiana, with a letter specifying the reason for the return and giving the model and serial number of the converter in which the parts are to be used. This converter is manufactured according to standard specifications, and any competent serviceman should be able to correct faults locally with the information in this instruction manual.

The following list is for identification of parts and may be referred to figures 3 and 4 for locations of these parts. Most resistors, capacitors, etc. can be supplied by your parts dealer from the description or by comparison with old parts. If you are unable to locate parts, we will be glad to supply additional information if required.

I GENERAL DESCRIPTION

The following Series of Television Receivers are distinguished by related chassis types.

Models 5620, 5620-1: 26-tube receiver (including picture tube and two rectifiers). Features include: full 12 channel coverage; latest Standard Coil Cascode Circuit RF tuner, with high signal to noise ratio, UHF adaptable; limiter-discriminator FM sound system; high second anode potential for full picture brilliance and definition; automatic frequency control of the horizontal oscillator (Syncrolok); full 4 mc. bandwidth of the picture channel; noise saturation circuits; keyed A.G.C.; a connection is provided for adaptation to color reception; and a phonograph input connector by means of which the sound section may be used as an audio amplifier. Reference is made to the overall circuit diagram.

Models 2400, 2426, 2426B: These sets have a chassis especially adapted for use with a 24" picture size, and is otherwise the same as Model 5620.

V 122	6 SH7	Horiz. Oscillator Control	
V 123	6AL5	Horiz. Syne Discriminator	

RF amplifier, RF Oscillator-Mixer tubes are also supplied. These are 6J6 oscillator and Mixer, and 6 BK7 RF amplifier in the tuner.

IV CIRCUIT DESCRIPTION

1. VIDEO I.F.

The video I.F. section is composed of the 4 amplifier stages V-101, V-102, V-103, and V-104. This video I.F. section provides ample gain and gives very satisfactory pictures in all TV signal reception areas. The I.F. sound is taken off at the plate of the 2nd I.F. video amplifier(V-102) taking advantage of the extra gain afforded by the 1st two video I.F. stages. The video I.F. section is equipped with adjacent traps to eliminate interference from channels on either side of the station being received. The video I.F. picture carrier frequency is 26.25 megacycles. Also, a 4.5 mc trap (T114) is incorporated to eliminate sound "pebble" from the picture.

2. VIDEO DETECTOR AND AMPLIFIERS

All Models employ a 6AL5 half-wave detector (V-105A); and a 6AU6 first video amplifier (V-106). A 6K6 (V-107) is employed as the second Video amplifier. The gain of the video is controlled in the cathode of this stage by degeneration with high frequency compensation.

3. SOUND SECTION

The sound section consists of one 6AU6 (V-117) sound I.F. amplifier and one 6AU6 limiter (V-118) tuned to 21.75 megacycles; a phase discriminator using a 6AL5 duodiode (V-119); a 6AT6 (V-120) first audio amplifier and a 6K6 (V-121) audio output tube.

Provision has been made to allow the audio section to be used as a phonograph amplifier. Phono input is located on the rear of the chassis, the picture tube and video amplifier are inactivated by turning the brightness control to the extreme counter-clockwise position until phono-switch shape into position.

4. SYNCHRONIZING CIRCUITS

The vertical and horizontal synchronizing pulses are taken off in the plate circuit of the 1st video amplifier. They are then fed through two 6SN7 (V-108A, V-108B) triode stages for shaping and amplification. The vertical sync pulse is removed after the second stage of amplification and is applied to the grid of a 6J5 (V-110) triode functioning as the vertical blocking oscillator. The resulting saw-tooth wave form is fed through a 6K6 (V-111) vertical amplifier which drives the vertical deflection coils.

The horizontal sync pulse is clipped and amplified by the 6SN7 (V-108A, V-108B) and then fed to the horizontal discriminator described below. The horizontal sweep voltage is applied to the grid of a 6BQ6 (V-113) horizontal amplifier which drives the horizontal deflection coils.

5. HORIZONTAL OSCILLATOR AND FREQUENCY CONTROL CIRCUIT

The Horizontal oscillator and frequency control system is essentially a modified Syncrolok circuit. This system retains all the advantages of the Syncrolok circuit including noise immunity and phasing control.

The circuit uses three tubes, a horizontal oscillator (1/2 6SN7 - V-112B), a horizontal oscillator control tube (6SH7 - V-122), and a horizontal sync discriminator (6AL5 - V-123). The discriminator compares the frequency and phase of the sine wave output of the oscillator with that of the incoming horizontal sync pulses. If there is a difference between the two, the discriminator circuit acts through the oscillator control circuit to correct the oscillator frequency.

Since the control tube circuit is designed to react only to changes in the average level of discriminator output, noise pulses have little effect on the circuit, their duration usually being too short to affect the average output level.

6. COLOR ADAPTABILITY

All receivers are provided with a terminal on the rear apron of the chassis for ready connection to an adapter for color reception. This connection is indicated in Fig III as the center lug on the terminal connection; the same connection containing the phono connection. This color lug is directly connected to the 60-cycle color sync pulse, from the vertical circuit, within the chassis.

7. HIGH VOLTAGE CIRCUIT

The high voltage supply consists of a "flyback" high voltage system, a 6W4 (V-115) damper tube, and a single 1B3 (V-114) high voltage rectifier. By employing an extremely efficient high voltage transformer, 15 KV anode voltage is consistently obtained on the picture tube.

8. LOW VOLTAGE SUPPLY

The low voltage supply is of the conventional type and consists of a 115V, 60-cycle power transformer, a 5U4G (V-116) full wave rectifier, plus its associated filter components.

V INSTALLATION NOTES

When the set is ready for installation, subject it to a thorough visual inspection to be sure that no damage has occurred in shipment.

The set should be used in conjunction with a suitable 300 ohm antenna. When the antenna has been installed and connected to the chassis, connect the set to a 115V 60-cycle AC outlet.

1. In some cases, it may not be possible, as a result of shipping, to first off obtain a satisfactory picture by means of the front panel controls. If this happens, it will be necessary to readjust the rear panel controls. The names and locations of these controls are shown on the accompanying diagram, Fig. III.

2. If the picture or raster is off-center with respect to the mask, to the right or left, or too high or too low, it may readily be repositioned by adjustment of the FOCUS COIL. The FOCUS COIL is located on the neck of the picture tube. This adjustment is accomplished by simply loosening the wing nuts holding the FOCUS COIL, repositioning the FOCUS COIL so that the picture is properly centered in the mask with no neck shadow, and then re-tightening the wing nuts. This adjustment is done while viewing the picture with the aid of a mirror placed in front of the television set.

3. If the picture has a slightly blurred or fuzzy appearance, this may be cleared up by adjustment of the FOCUS control.

4. When the height of the picture is not sufficient to fill the mask, or if vertical non-linearity is present (evinced by unequal heights of the vertical wedges in the test pattern, or heads and bodies being out of proportion in a picture), the VERTICAL LINEARITY AND HEIGHT controls must be adjusted. These two controls affect each other, and when one is adjusted, it is usually necessary to readjust the other to obtain a satisfactory picture. The HEIGHT CONTROL has its greatest effect on the bottom half of the picture, while the LINEARITY CONTROL mostly affects the top half. If the picture width is not right, or if horizontal non-linearity is present, (i.e. one side of the picture expanded and the other side squeezed in), adjustment of the HORIZONTAL WIDTH, HORIZONTAL LINEARITY and/or HORIZONTAL DRIVE controls will be necessary (See Fig. III).

5. If the picture does not hold in sync throughout the range of the HORIZONTAL HOLD control, it may be possible to make it do so by adjusting the SYNCROLOK control on the rear panel. If this cannot be done, a detailed adjustment of the sync system, as described in the following: Service, Section VI, must made.

VI SERVICE INFORMATION

Each television set is pre-aligned and pre-adjusted before being shipped from the factory, and should give satisfactory performance upon installation. However, should it become necessary to re-align either the Sound or Video I.F. stages, or re-adjust the horizontal synchronizing circuits, it is suggested that the following procedures be used as guides.

HIGH VOLTAGE WARNING: OPERATION OF THE TELEVISION RECEIVER OUTSIDE THE CABINET, OR WITH COVERS REMOVED INVOLVES A SHOCK HAZARD FROM THE RECEIVER POWER SUPPLIES. WHEN WORKING ON THE CHASSIS, ALL PRECAUTIONS SHOULD BE TAKEN TO PREVENT CONTACT WITH HIGH VOLTAGE POINTS. DO NOT OPERATE THE CHASSIS WITH THE HIGH VOLTAGE COMPARTMENT SHIELD REMOVED.

1. ADJUSTMENT OF HORIZONTAL OSCILLATOR

Connect a suitable antenna to the receiver and tune to an operating television station. A picture or test pattern should appear on the screen. The picture should remain in horizontal sync with the HORIZONTAL HOLD control in both the extreme clockwise and extreme counter-clockwise positions. The picture should also pull into sync with the hold control in either of these positions when the signal is momentarily removed.

If the above check reveals a lack of sync in the set, make the following adjustments:

(a) Tune in a television station and adjust the fine tuning control for best sound quality.
(b) Turn the syncrolok frequency control (on the rear of the chassis) until the picture is synchronized.
(c) If the blanking bar appears in the picture turn the "phase adjustment" (rear slug of syncrolok transformer under the chassis) until the blanking bar moves to the right and off the raster.
(d) Turn horizontal hold to extreme counter-clockwise position and turn "syncrolok frequency adjustment" (located on rear apron of the chassis) clockwise until the picture falls out of sync. Then turn the adjustment slowly counter-clockwise to the point where the picture falls into sync again.
(e) Readjust the phase adjustment so that the left side of the picture is close to to the left side of the raster, but does not begin to fold over.

(f) Turn HORIZONTAL HOLD to its extreme clockwise position. The right side of the picture should be close to the right side of the raster, but should not begin to fold over. If it does, readjust the phase.
(g) Momentarily remove the signal by tuning station selector off channel and then re-tuning. When the signal is restored, the picture should fall into sync. If it doesn't turn the sync frequency adjustment counter-clockwise until it does.
(h) Turn horizontal hold to extreme counter-clockwise position. Remove the signal momentarily. When the signal is restored, the picture should fall into sync.

2A. VIDEO I.F. ALIGNMENT

The following procedures should be followed when aligning the Video I.F. sections:

Connect the focus coil and deflection yokes to the set. Speaker and picture tube connections need not be made for I.F. alignment.

(a) Plug set into 115V, 60 cycle line; turn set on.
(b) Disable AGC by shorting Pin #1 of 6AU6 (V-109) keying tube to ground.
(c) Connect -1.5 volt bias between chassis and AGC strip. (Junction of R128 and C131).
(d) Connect a calibrated signal generator to the tuner by connecting the "hot" lead to the tuner mixer tube shield, and the ground lead to the chassis. Shield must be disconnected from ground so that signals can be coupled into the mixer through the shield to tube capacity.
(e) Connect one lead of a vacum tube voltmeter to the plate side of the 3900 ohm video detector load resistor, the other lead to ground, using lowest voltage range on meter.

(f) Adjust traps first. Inject trap frequencies of 20.25 mc; 21.75 mc; 27.75 mc; and 4.5 mc into tuner and adjust the respective traps for minimum deflection on meter. When adjusting 4.5 mc trap, a voltmeter with crystal probe should be connected between R141 and ground.
(g) Inject video I.F. amplifier frequencies of 25.8 mc; 22.8 mc; 22.3 mc; 25.7 mc and 23.9 mc. into the tuner, adjust each stagger tuned stage at its respective frequency for maximum deflection on vacuum tube voltmeter.
(h) Repeat Step (f).

Note: In all alignment procedures, use as low a signal input as possible to prevent overload.

3. SOUND I.F. ALIGNMENT

The following procedures should be followed when aligning the Sound I.F. sections of all the 260 Models.

The Sound I.F. carrier frequency is 21.75 mc. Inject a 21.75 mc. signal on the grid of the first sound I.F. amplifier. Connect a d.c. voltmeter in series with a 1. meg. resistor between ground and the high side of the second I.F. amplifier grid lead resistor (R-103). Adjust I.F. transformer (T-101) to obtain a maximum reading on the voltmeter (the voltage should be between -1 and -3 volts).

Now connect the voltmeter and the 1 meg. resistor between ground and the junction of the discriminator load resistors. Adjust the discriminator transfer primary for maximum deflection on the meter.

Connect the voltmeter across the total discriminator load and adjust the discriminator secondary for zero reading on the meter. Make sure that the meter goes positive as the secondary is adjusted to one side of the balance point and negative as it is moved to the other side.

4. USE OF OSCILLOSCOPE TO CHECK ALIGNMENT

In all cases it is desirable to check the alignment of both the Sound and Video I.F. sections as outlined above by using an oscilloscope in conjunction with suitable sweep equipment. This procedure is outlined herewith:

To check both Video and Sound I.F. alignment, attach a sweep generator to the antenna terminal and inject I.F. markers from the crystal controlled source between the chassis and the ground side of the cathode resistor of the first Video I.F. amplifier.

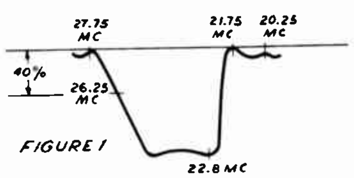

FIGURE 1

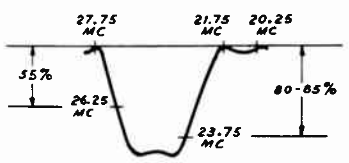

FIGURE 2

(a) Switch channel selector on set to Channel Six (6) and adjust the sweep generator to sweep Channel Six.
(b) Connect horizontal input of oscilloscope to "Scope" terminal of sweep generator.
(c) Connect vertical input of oscilloscope across the video detector load resistor (R-138).
(d) Slight adjustment of the video I.F. coils should bring the I.F. curve into proper shape. Check trap frequencies and half voltage point frequencies with crystal markers only.

The curves that should be obtained from a properly aligned I.F. are shown in Fig. I and II, depending on the set Model.

The sound I.F. curves can be observed by connecting the vertical input of the oscilloscope in series with a 50K resistor between the grid resistor of the 6AU6 limiter tube and ground series resistor. The discriminator curve can be observed by connecting the vertical input of the oscilloscope across the discriminator diode load resistors (Junction R-106 and R-108).

5. TUNER CHANNEL SLUG ADJUSTMENT

Individual channel tuner oscillator adjustments of the television receiver should be checked, upon its installation or servicing. If such adjustments are properly made, it is possible to on-tune from one station to another by merely turning the CHANNEL Selector and, if necessary, slightly readjusting the fine TUNING control. With correct oscillator channel adjustment, best picture and satisfactory sound will be located at the approximate center (half rotation) of the range of the FINE TUNING control.

Channel slug adjustment can be made without removing the chassis from the cabinet. Adjust as follows:

a. Turn the set on and allow 15 minutes to warm up.
b. Set the CHANNEL SELECTOR knob for a station; set other controls for normal picture and sound.
c. Set FINE TUNING control at center of its range by rotating it approximately half way.
d. Remove the CHANNEL Selector and FINE TUNING knobs.
e. Insert a 1/8" blade, non-metallic screwdriver in the 1/4" hole (to the right of the channel tuning shaft). For each channel in operation, carefully adjust its channel slug for best picture with clear detail and best sound. Be sure that the FINE TUNING control is set at the center of its range before adjusting each channel slug. Generally, only a slight rotation of the slug will be required; turning the slug in too far will cause it to fall into its coil. (If the slug falls into the coil, remove the coil strip from the tuner, move the retaining spring aside, lightly tap the open end of the coil until the slug slips out. Replace the slug and re-set retaining spring.)

6. TROUBLE SHOOTING DATA

Reference is made to "Resistance Measurement Chart", and "Voltage Measurement Chart" These charts are useful in detailing which section of the chassis may be inoperative. Any resistance or voltage measurements which do not correspond to these charts will point up the circuit breakdown as to resistor, condenser, etc.

*Do not measure these voltages with ordinary meters - DANGER - Extremely high potentials.

AC line voltage 115 volts.
Measurements in volts taken with reference to chassis ground.
All voltages D. C. unless otherwise specified.
All voltages positive unless otherwise specified.

All measurements taken with Senior Voltohmist with picture tube and antenna disconnected.
Permissible voltage variation ±20%.

VII TUNER DESCRIPTION

A new Cascode type Standard Coil tuner is used in all models It is a rugged, sensitive 12-position turret tuner. Each channel has its individual set of coils, connected into the television circuit, when selected. The cascode circuit of this tuner provides higher gain and greater signal-to-noise reception ratios than ever before practicable. The fine tuning control permits crisp, sharp pictures to be brought in individually for each channel, at the point of best and truest sound reception. Standard Coil Products, Inc., will make available UHF coil sets, for simple insertion in place of any unused VHF channel, for direct reception through this receiver of any ultra high frequency (UHF) channels that will be authorized by the F.C.C.

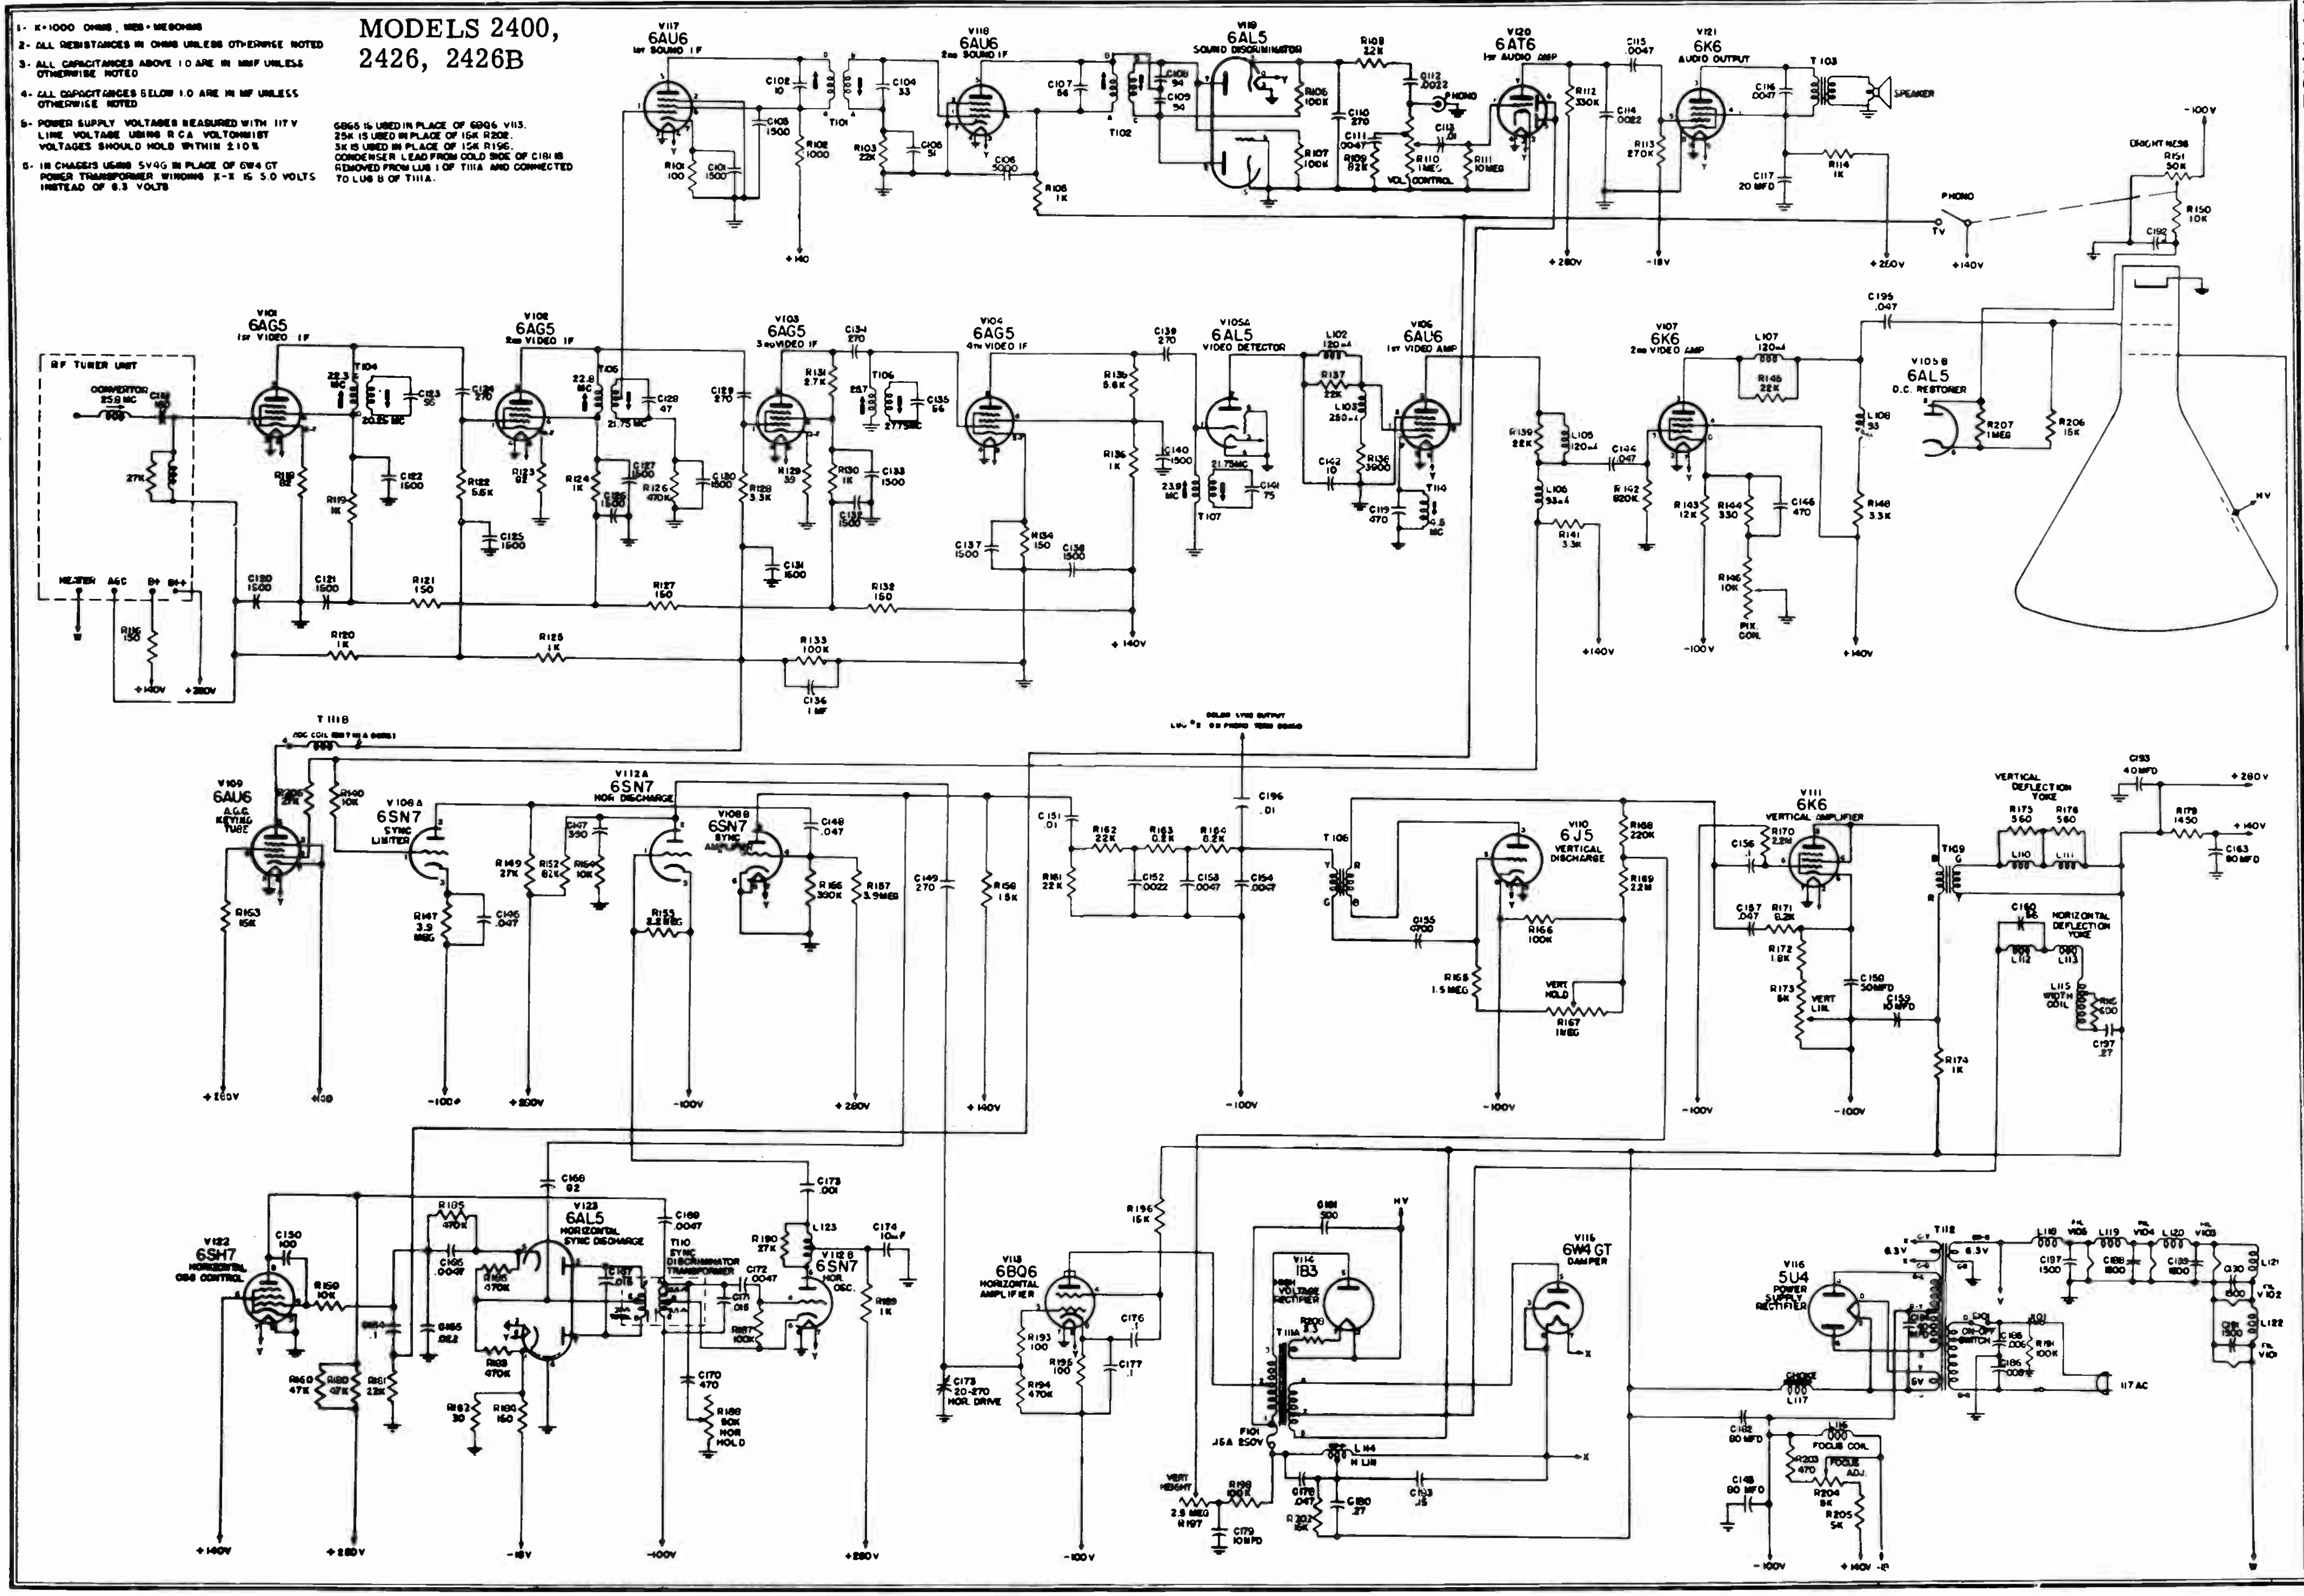
6- IN CHASSIS USING 5V4G IN PLACE OF 6W4 GT POWER TRANSFORMER WINDING X-X IS 5.0 VOLTS INSTEAD OF 6.3 VOLTS

6BG6 IS USED IN PLACE OF 6BQ6 V113.
25K IS USED IN PLACE OF 15K R202.
3K IS USED IN PLACE OF 15K R196.
CONDENSER LEAD FROM COLD SIDE OF C181 IS REMOVED FROM LUG 1 OF T111A AND CONNECTED TO LUG B OF T111A.



General Information

POWER SUPPLY—These receivers are designed to operate from a power source of 117 volts at 60 cycles A.C. It will, however, operate satisfactorily from a line whose voltage is no lower than 105 volts, or no greater than 125 volts at 60 cycles A.C. Always measure the voltage of the line with a dependable a-c voltmeter if it is suspected that the line voltage is beyond the above acceptable limits.

TUBES—In all receivers, all tubes, including the picture tube, are shipped properly mounted in their sockets. Check to see that all tubes are firmly seated since some may have worked loose during shipment. See Picture Tube Handling Precautions below.

ANTENNA—The installation and orientation of an antenna is one of the most important single factors in realizing optimum performance from a television receiver. An improperly oriented, or poorly matched, or unwisely chosen antenna can completely offset the good design engineered into these television receivers. For these reasons, choose, locate and install your antenna carefully, especially in poor signal areas. All receivers in these series are equipped with a built-in antenna which performs satisfactorily in locations where good signal strength is available, and where a minimum of noise is present.

When an outdoor antenna must be installed, use a standard, approved antenna, having a 300 ohm impedance, and match it with a balanced 300 ohm transmission line. Orient the antenna for maximum signal strength from the greatest number of stations, and for the minimum amount of interference and reflection. Where the receiver is to be installed beyond the range of good signal strength (about 30 miles) use a stacked array, being careful to match the impedance of the antenna, transmission line, and receiver (300 ohms). If additional gain is required, try a "booster" for improvement of signal-to-noise ratio.

In critical locations, where the receiver is surrounded by several stations, most of which are located beyond the 30 mile radius, a careful appraisal of the terrain and the measurement of field strength will usually yield acceptable television operation where a haphazard installation might have failed. To make full use of the directional and "gain" properties of a stacked array and booster, the following procedure is recommended:

1. Measure the field-strength of the transmitted signal from each of the desired stations on a calibrated field-strength meter.
2. Tabulate your results and conclude which stations are within reasonable quality distance. A field-strength of 300 microvolts-per-meter or higher will give acceptable results. A field-strength measurement of 100 microvolts-per-meter or lower may not be satisfactory without the use of a "booster."
3. Let the consumer decide which of the acceptable channels he desires, and orient the antenna to receive maximum signal from those desired stations.
4. Always twist the 300 ohm lead-in about once for every foot of length to minimize transmission line noise pick-up.

PICTURE TUBE HANDLING PRECAUTIONS

Extreme care should be used in handling the picture tube. The picture tube bulb encloses a high vacuum and, due to its large surface area is subjected to considerable air pressure. The front of the picture tube, particularly the rim of the viewing surface, must not be struck, scratched, or subjected to more than moderate pressure at any time. If the yoke sticks or fails to slip smoothly over the tube or its socket, check and remove the cause of the trouble. Do not under any circumstances force the yoke.

HIGH VOLTAGE WARNING

OPERATION OF THIS RECEIVER WITH INTERLOCKED BACK COVER REMOVED INVOLVES A SHOCK HAZARD FROM THE RECEIVER POWER SUPPLIES. WORK ON THIS RECEIVER SHOULD NOT BE ATTEMPTED BY ANYONE WHO IS NOT THOROUGHLY FAMILIAR WITH THE PRECAUTIONS NECESSARY WHEN WORKING ON HIGH VOLTAGE EQUIPMENT.

IMPORTANT—**With the exception of the next paragraph, all information in this folder pertains to 16", 17", 20" and 21"** screen receivers.

FOCUS AND YOKE ASSEMBLY INSTALLATION INSTRUCTIONS (FOR RECEIVERS WITH 20" AND 21" SCREEN ONLY)

1. Remove the slotted head P.K. screws retaining the back, and release the interlocked line cord.
2. Remove the Focus Coil from its shipping position against the side of the tube support bracket by removing the long machine screw and nut and retaining bracket. This bracket and hardware may be thrown away. Remove the 2 wingscrews located on the Focus Coil Mounting Bracket.
3. Remove the beam bender from the neck of the picture tube and carefully slide the Focus Coil, smooth side forward, over the neck of the C.R. tube until there is about $\frac{1}{4}$" separation between the Focus Coil and the rear of the Deflection Yoke.
4. Fasten the Focus Coil in place by means of the wingscrews removed in Step 2.
5. Slide the beam bender over the neck of the picture tube.
6. Connect the picture tube socket to the picture tube base.
7. The male octal plug from the Deflection Yoke and Focus Coil Assembly is already plugged into its female socket on the chassis.

BUILT-IN ANTENNA INSTALLATION

This receiver is shipped with the built-in antenna completely connected. A few precautions should be observed, upon installing this receiver, if optimum performance is to be obtained.

1. Try to locate the receiver in such a position so that:
   a) All requirements for good viewing position and ventilation are satisfied.
   b) It is near a 105-125 volt 60 cycle A.C. power outlet.
   c) The back of the receiver is parallel and close to a window which faces in the general direction of the transmitters.
   d) It is not adjacent to a street having heavy automobile traffic which may cause ignition interference.
2. After performing the Service Adjustments outlined on the following pages, try a few stations and observe if their signals are received with sufficiently good quality so that the receiver may be left in this position.
3. If signal strength and noise conditions are known to be good and operation is not satisfactory, it may be best to try a new receiver location, choosing one where the receiver will be rotated 90 degrees relative to its former position.

If, however, it is found that the receiver is not permitted to perform at its best because of limitations of the built-in antenna in a noisy or weak-signal area, an outdoor antenna should be installed.

To connect an outdoor antenna to this receiver:

1. Loosen the two screws on the antenna terminal strip.
2. Disconnect the existing built-in antenna wires.
3. Connect the 300 ohm lead-in from the external antenna to the terminals and tighten the screws.

SERVICE ADJUSTMENTS

Below is given a description of the steps required in adjustment of the Beam Bender and Deflection Yoke and the adjustment of the Focus, Vertical Size and Linearity and Horizontal Size, Linearity, Drive and A.F.C. controls. However, it should be remembered that these adjustments are to be made only when picture quality is such that service adjustment is warranted. Use this description as a check-list and if a particular phase of quality is good, leave it alone and go on to the next operation. Refer to figure 1 for location of front panel controls, and to figure 7 for location of rear panel controls.

IMPORTANT—The adjustment of the Beam Bender (Ion Trap magnet) must be performed immediately after the receiver warms up. If any length of time is permitted to elapse while the receiver is on, and while the Beam Bender is misadjusted, serious damage to the internal structure of the cathode-ray gun may result.

A. PREPARATION FOR SERVICE ADJUSTMENTS

1. Remove the three slotted-head P.K. screws on the back of the receiver (located one in each corner, and one closest to the center of the cabinet top), disengage the interlock, and remove the back with the line cord.
2. Drop hinged door on front panel for access to the auxiliary controls as illustrated in Fig. 1. The lower set of these controls is adjusted by means of a narrow shanked screwdriver.
3. Connect a substitute interlock line cord between receiver and suitable power outlet and turn on the receiver allowing about 30 seconds of warm-up period before proceeding.

B. BEAM BENDER (ION TRAP) ADJUSTMENT

1. Advance the BRIGHTNESS control almost fully clockwise.
2. Position the beam bender on the glass neck approximately $\frac{1}{2}$" from the picture tube base.
3. Starting from this position, adjust the Beam Bender by moving it forward or backward, and at the same time rotating it slightly around the neck of the tube until the brightest raster appears on the screen. If two maximum brightness positions are found, the one nearest the tube base is the correct setting. This adjustment should be done quickly to avoid damaging the gun structure.
4. Adjust the BRIGHTNESS control setting until the raster is slightly above average brilliance.
5. Re-adjust the Beam Bender carefully for maximum raster brilliance.

C. DEFLECTION YOKE ADJUSTMENT

1. Loosen the wing thumb screw located at the top of the deflection yoke frame.
2. Check to see that the deflection yoke mounting bracket rubber cushions press firmly against the flare of the tube.
3. Press the yoke firmly against the flare of the tube.
4. Rotate the yoke until the lines of the raster are horizontal and squared with the picture mask, and tighten the wing screw.

SERVICE ADJUSTMENTS *(Continued)*

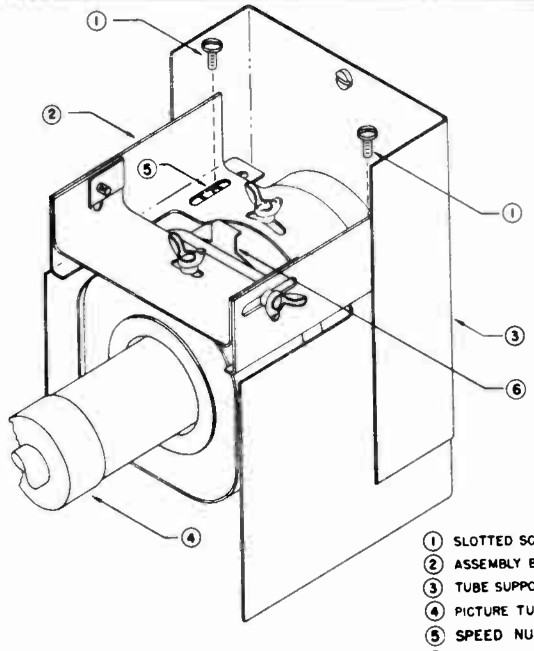
D. FOCUSING ADJUSTMENTS

1. Adjust BRIGHTNESS and CONTRAST controls so that the raster brilliance corresponds to that of an average picture.
2. If a corner of the raster is shadowed, it indicates that the electron beam is striking the neck of the tube. Loosen the Focus Coil Wing Screws and rotate the coil about its horizontal and vertical axis until the entire raster is visible, approximately centered, and with no shadowed corners. The Focus Coil should be kept close to, but not necessarily touching, the rear of the deflection coil for optimum range of the focus control. A slight readjustment of the Beam Bender may now be required.
3. Adjust the focus control (see Fig. 1) so that the lines of the raster are sharp and distinct over the greatest screen area.

E. HORIZONTAL A.F.C. ADJUSTMENT

In order to check this adjustment tune in a station, preferably one that is transmitting a test pattern. If difficulty is encountered in locking the picture horizontally or if it locks-in only when the Horizontal Hold Control is at either end of its rotation, adjust the Horizontal A.F.C. Control as follows:

1. Turn CONTRAST down about half way.
2. Turn HORIZONTAL HOLD CONTROL fully counterclockwise.
3. If the picture is not locked in, turn the HORIZONTAL A.F.C. control till it does lock-in. (See Fig. 7)
4. Momentarily interrupt the signal by switching the channel selecter off channel and then back. The picture should just fall out of sync. If it does not, turn the Horizontal A.F.C. adjustment screw slightly clockwise and again momentarily interrupt the signal. Continue this procedure until the picture just falls out of sync. only when the signal is interrupted.
5. Rotate the Horizontal Hold Control clockwise until the picture falls into sync. The picture should now stay in sync. throughout most of the range of the Horizontal Hold Control.
6. If the picture cannot be made to hold sync., carefully repeat the above procedure. If difficulty is still encountered, it may be necessary to make a complete alignment of the horizontal oscillator transformer using an oscilloscope, as described on page 3.



① SLOTTED SCREW
② ASSEMBLY BRACKET
③ TUBE SUPPORT BRACKET
④ PICTURE TUBE
⑤ SPEED NUT
⑥ CENTERING DISC

FIG. 2. DEFLECTION YOKE AND FOCUS COIL ASSEMBLY (20" and 21" RECEIVERS ONLY)

F. PICTURE CENTERING, SIZE AND LINEARITY

1. Horizontal or Vertical Centering is accomplished mechanically. To center the picture, loosen the Focus Coil Wing Nuts sufficiently to twist the Focus Coil slightly about its horizontal or vertical axis. Make sure the corners of the raster are not shadowed. See step D.2. Note: Some 20" receivers are equipped with a magnetic centering disc, located between the focus coil and the deflection yoke. To center the picture in the mask, rotate and slightly vary the position of the disc in its vertical plane. This adjustment should be made in conjunction with positioning of Focus Coil (described above).
2. Adjust the VERTICAL SIZE and VERTICAL LINEARITY controls until the test pattern is vertically linear and symmetrical from top to bottom, and fills the mask. Adjustment of either control may require readjustment of the other. If vertical synchronization "falls-out," readjust the VERTICAL HOLD control. (Refer to Fig. 1)
3. Adjust the HORIZONTAL SIZE control slotted screw, located at the rear of the High Voltage cage at the rear of the chassis, for correction of horizontal width. The large outer arcs of the test pattern should coincide with the edge of the picture mask. (Refer to fig 7)
4. Adjust the HORIZONTAL DRIVE control trimmer for horizontally symmetrical pattern, and elimination of any existing vertical bars in left center of picture. The final adjustment should have the control at least ½ turn counterclockwise from the maximum clockwise position. (See Fig. 7)
5. The readjustment of the HORIZONTAL A.F.C. control may now be necessary.
6. Adjust the HORIZONTAL LINEARITY control slotted screw, located at the rear of the High Voltage cage, for central alignment of the inner circles of the test pattern.

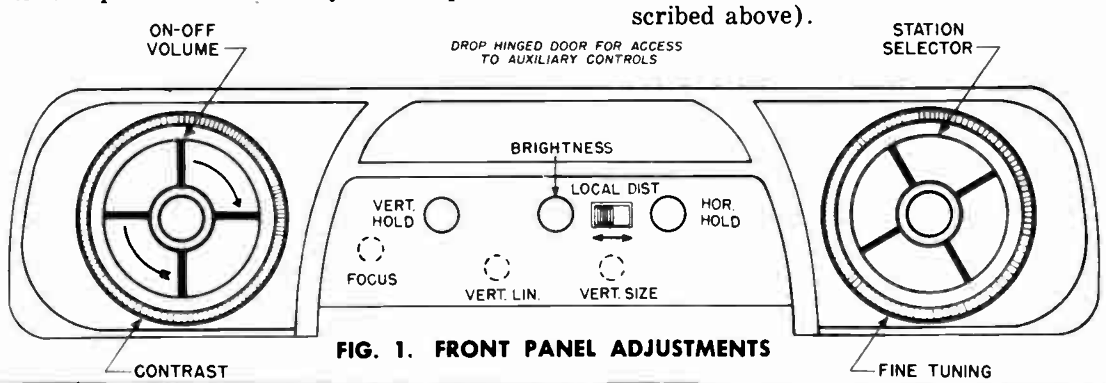


FIG. 1. FRONT PANEL ADJUSTMENTS

Alignment Instructions

Video I-F and Sound Alignment Procedure

TV I-F ALIGNMENT

1. Tune receiver to quiet portion of TV High Band.
2. Set contrast control fully counterclockwise.
3. Apply 3 v. negative bias between the A.G.C. bus (at C22A) and ground. (Use 2—1½ v. cells.)
4. Connect TV I-F Signal Generator through a 1500 MMF condenser to Test Point (A) of tuner unit; low side to ground. (See schematic diagram.)
5. Connect negative lead of V.T.V.M. (or meter of 20,000 ohms-per-volt, or better) to 4.7K diode load resistor TEST POINT (B); positive lead to ground. (See schematic diagram.)
6. Feed 23.2 MC [23.3]* (±.05 MC) from Signal Generator and adjust T4 for maximum deflection on meter. Maintain Signal Generator output so low that meter reads no more than 1.5 volts at peak.
7. Feed 21.8 MC [21.8]* (±.05 MC) from Signal Generator, and adjust T3 as above.
8. Feed 24.0 MC [23.9]* (±.05 MC) from Signal Generator, and adjust T2 as above.
9. Feed 24.7 MC [24.5]* (±.05 MC) from Signal Generator, and adjust T1 as above.
10. Replace the meter with the vertical input of an Oscilloscope through a 10K isolating resistor, low side to ground.
11. Remove Signal Generator. Feed a video I-F Sweep Generator (20 to 28MC) through loosely coupled shield of 6J6 converter tube, making sure shield is not grounded. (Refer to Fig. 3.)
12. Loosely couple high side of a TV I-F Marker Generator to the high Sweep Generator Lead; low side to ground.
13. Feed I-F Sweep, and observe response on 'scope. (See Fig. 5.) Use marker frequencies 20.25, 21.75 and 24.75 MC.
14. If response does not approximate that shown in Fig. 5, repeat steps 3 to 9, making sure that frequencies are precise, and that the Signal Generator output voltage is kept low. Continue with steps 10 to 13. A slight touch-up of individual slugs may be required to approximate the recommended curve of Fig. 5.

*NOTE: If 3v fixed bias is unavailable and zero fixed bias is used, set signal generator at [ ] bracketed frequencies values.

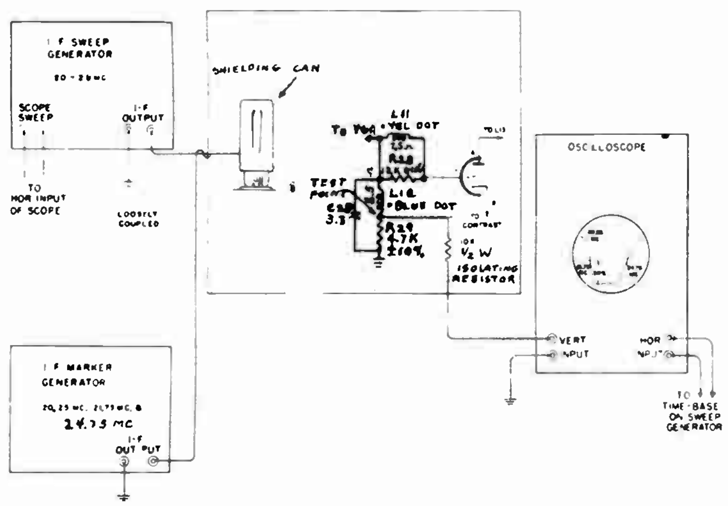

FIG. 3. IF ALIGNMENT BLOCK DIAGRAM

TV SOUND ALIGNMENT

NOTE: TV-phono switch must be in TV position.

1. Connect a 4.5 MC Signal Generator (±.01 MC) through a 1500 MMF condenser to the 4.7K video diode load resistor TESTPOINT (B); low side to ground. See schematic diagram.
2. Obtain two resistors of approximately 100,000 ohms each, whose resistances have been matched accurately with an ohmmeter. Connect them in series across the 18K resistor (R107) at the 6T8 tube socket (V9A).
3. Connect negative lead of V.T.V.M. to junction of matched resistors of step 2; positive lead to ground.
4. Feed 4.5MC (±.01 MC) from signal generator, and adjust L22, sound take-off coil, for maximum deflection on V.T.V.M. Two points of maximum deflection may be found when making this adjustment. Correct adjustment is attained when screw is at most outward maximum reading position.
5. Adjust the bottom slug of T10 for maximum deflection on V.T.V.M.
6. Connect positive lead of V.T.V.M. to junction of C96, and R106 TEST POINT (C), leaving negative lead of V.T.V.M. connected as in step 3. See schematic diagram.
7. Adjust top of T10 for zero output on V.T.V.M. between two opposite polarity peaks.

IMPORTANT: Keep the sweep generator and marker generator outputs at minimum to avoid curve distortion. Marker pips should be kept barely visible.

TABLE I RF ALIGNMENT FREQUENCIES

CHANNEL NUMBER	SWEEP GEN. CENTER FREQ. (10MC.SWEEP)	MARKER GENERATOR FREQUENCIES VIDEO CARRIER	SOUND CARRIER
2	57 MC.	55.25 MC.	59.75 MC.
3	63 MC.	61.25 MC.	65.75 MC.
4	69 MC.	67.25 MC.	71.75 MC.
5	79 MC.	77.25 MC.	81.75 MC.
6	85 MC.	83.25 MC.	87.75 MC.
7	177 MC.	175.25 MC.	179.75 MC.
8	183 MC.	181.25 MC.	185.75 MC.
9	189 MC.	187.25 MC.	191.75 MC.
10	195 MC.	193.25 MC.	197.75 MC.
11	201 MC.	199.25 MC.	203.75 MC.
12	207 MC.	205.25 MC.	209.75 MC.
13	213 MC.	211.25 MC.	215.75 MC.

R.F. and Oscillator Alignment

(STANDARD COIL TUNER)

R.F. ALIGNMENT

1. Connect TV Sweep Generator to Antenna Terminals.
2. Connect R.F. Marker Generator loosely to Antenna Terminals.
3. Connect vertical amplifier of Oscilloscope through a 10,000 ohm ½w. resistor to Test Point (A) fig 6.
4. Short A.G.C. Bus to ground on TV chassis (across C22A 5000 MMF Discap condenser).
5. Set Station Selector switch to Channel 12.
6. Feed 207 mc at 10 mc sweep from Sweep Generator, and 205.25 mc and 209.75 mc fixed frequencies from R.F. Marker Generator.
7. Observe response curve on Scope. If necessary adjust C2, C4, or C7 (See fig. 6) so that response curve corresponds approximately to that shown in fig. 5 and has maximum gain.
8. Check markers on response curve of all remaining channels, setting Sweep and Marker Generators at corresponding frequencies for each channel. See Table I for convenient tabulation of proper frequencies. If the R.F. Markers do not fall in automatically in their proper places on all channels, a compromise must be made by slight readjustment of C2, C4, or C7.

OSCILLATOR ALIGNMENT

1. Connect TV R.F. Sweep Generator to Antenna Terminals.
2. Couple R.F. Marker Generator loosely to Antenna Terminals.
3. Connect vertical amplifier of Oscilloscope across the video amplifier grid and ground (Pin 7 of 12BH7, V7A).
4. Couple 24.75 mc video I.F. Marker Generator loosely to first I.F. grid (Pin 1 of 6CB6, V3).
5. Rotate Fine Tuning control to center of range.
6. Set Station Selector switch to Channel 12.
7. Set Sweep Generator to 207 mc at 10 mc sweep and Marker Generator to 205.25 mc (video carrier).
8. Observe response curve and adjust C10 (fig. 6) for Zero-beat with 24.75 marker. Zero-beat is indicated by an unmistakable break-up of the observed response curve.

   NOTE: Quality of response curve does not affect accuracy of oscillator alignment, so long as a zero-beat is obtained.
9. Check for zero-beat on all channels in this manner, setting the Station Selector, Sweep Generator and Marker Generator at corresponding frequencies. (See Table I.) It is not usually necessary to make any further adjustments. However, if the individual oscillator coils must be touched-up, the following procedure should be employed:
   a) Rotate Fine Tuning control to center of range.
   b) Set Station Selector to desired channel, Sweep Generator to its center frequency with 10 mc sweep, R.F. Marker Generator to the corresponding video carrier frequency (See Table I), and I.F. Marker Generator at 24.75 mc.
   c) Place a non-metallic screwdriver through the opening marked 'Recessed Individual Osc. Adjustment', fig. 6, and adjust oscillator coil zero-beat with 24.75 mc marker on response curve.
   d) This adjustment can be repeated on any single channel, or, if necessary, on all channels.
   e) If difficulty is encountered in tuning any particular channel well within limits of Fine Tuning control after these adjustments are made, readjust C10 slightly (as in Step 8) shifting the whole range of frequencies in the desired direction.

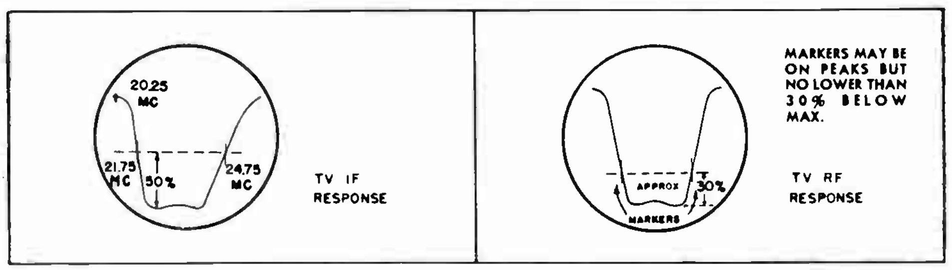

FIG. 5. RECOMMENDED RESPONSE CURVES.

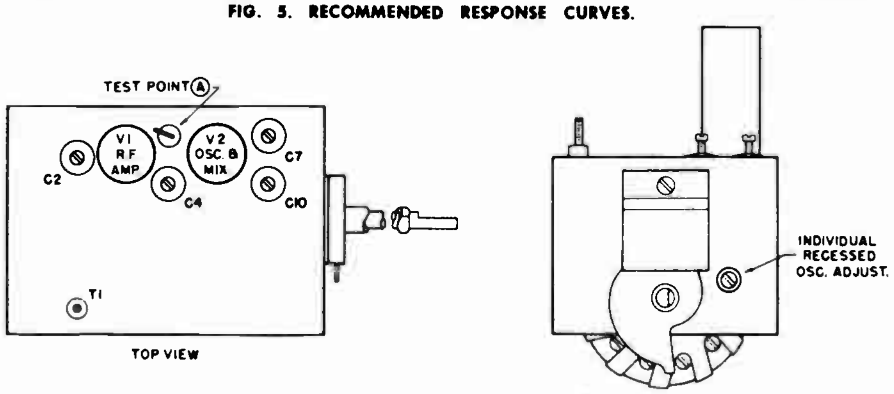

FIG. 6. R.F. TUNER ADJUSTMENT POINTS (STANDARD COIL TUNER)

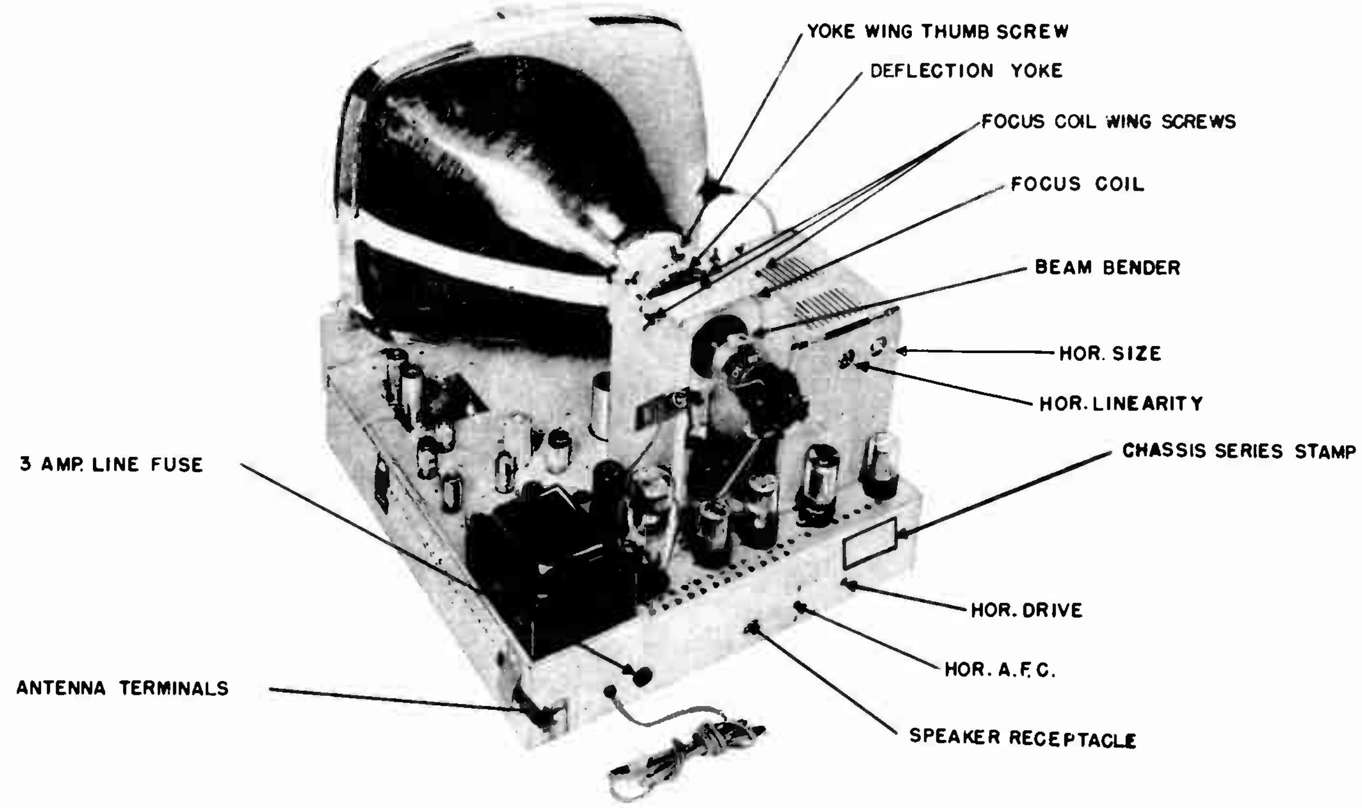

FIG. 7. PICTURE OF TV CHASSIS (REFER TO FIG. 2 FOR 20" & 21" YOKE & FOCUS ASSEMBLY)

HORIZONTAL OSCILLATOR TRANSFORMER ALIGNMENT

Refer to Service Adjustment "E" before proceeding with this alignment.

1. Tune in a TV station, preferably one that is transmitting a test pattern.
2. If after attempting the Horizontal A.F.C. Service Adjustment, described above, the picture cannot be made to sync. pre-set the Horizontal Stabilizing adjustment (inner slug of T8, beneath chassis) 5 turns in from its maximum out position.
3. Set the Horizontal Hold control to the center of its range and adjust the Horizontal A.F.C. adjustment until the picture is in sync.
4. Connect a low capacity probe of an oscilloscope to terminal "C" of the Horizontal oscillator transformer, T8; low side to ground. Set horizontal sweep to 7875 C.P.S. If a low capacity probe is unavailable, connect a 10K resistor in series with the vertical scope lead.
5. Adjust the Horizontal Stabilizing brass slotted screw until the broad and narrow peaks of the pattern on the oscilloscope are of equal height. (See illustration.) During Horizontal Stab. adjustment, picture must be kept in sync. by adjusting the Horizontal A.F.C. adjustment, if necessary.
6. Disconnect oscilloscope and follow Service Adjustment E above.

PART I

DESCRIPTION & SPECIFICATIONS

The Magnavox 105 Series TV Chassis are 21 tube receivers including a direct view picture tube. It is constructed on a single chassis and so designed as to accommodate 17″ rectangular, 20″ rectangular or 21″ rectangular picture tubes without any change in circuitry.

Features of this Series include:

- Capacity coupled video amplifier
- Intercarrier I-F Amplifiers for ease of alignment, increased stability and freedom from the effect of oscillator drift
- Keyed automatic gain control
- Magnalok type horizontal frequency control
- Cathode modulation of picture tube
- Vertical multivibrator circuit
- Noise inverter circuit for noise immunity

IMPEDANCE

300 ohm input..................Speaker Voice Coil 3.2 ohms

POWER REQUIREMENTS

TV with Audio..........205 watts, 117V, 60CPS
TV without Audio..........190 watts, 117V, 60CPS
TV with Audio & AM Tuner (Radio-TV Switch in Radio Position)..........170 watts, 117V, 60CPS

OPERATION AND INSTALLATION

1. Plug the receiver into the AC outlet.
2. Turn the receiver on by turning the PICTURE OFF-ON control to the right about ½ turn.
3. Adjust the BRIGHTNESS control for suitable picture brilliance. If no light appears, it may be limited by incorrect adjustment of the ion trap. Adjustment of this trap is as follows:

Turn the brightness control fully clockwise and adjust the ion trap until light appears on the screen. Reduce the brilliance to a point near extinction by turning the brightness control counter-clockwise. Readjust the ion trap for maximum brilliance.

It may be necessary to reduce the brilliance still further and readjust the ion trap for maximum brilliance.

The final adjustment should now be made for maximum brightness with the brightness control in full clockwise position.

4. Turn the CHANNEL SELECTOR to the desired channel number.
5. Adjust the FINE TUNING control for best picture quality. Do not tune for loudest sound as a distorted picture may result.
6. Adjust the PICTURE control for the proper degree of black, gray and white. With the brilliance at a point near extinction advance the control until sufficient picture detail appears without over-shading the light areas of the picture.
7. Adjust the VERTICAL HOLD control so the picture holds in vertical sync. If the picture rolls up or down, turn the control knob so the roll is downward, then turn it in the opposite direction until the picture locks in frame.
8. If the picture pulls out of horizontal sync, it can be brought back by adjustment of the HORIZONTAL HOLD control.
9. Adjust the FOCUS control so the lines making up the raster are clear and distinct.
10. Adjust the HEIGHT and VERTICAL LINEARITY controls so the picture just fills the mask and the linearity is uniform from top to bottom. Adjustment of either the vertical hold, vertical linearity or vertical height controls will slightly affect the other controls and readjustments may be necessary.
11. Adjust the HORIZONTAL DRIVE trimmer for the most drive consistent with good linearity. Turn it to the point where compression at the middle of the picture occurs, and then reduce it slightly.
12. Adjust the HORIZONTAL LINEARITY control for the most linear picture. Caution: There may be two positions of the slug which seem to provide horizontal linearity. Use the one which places the slug nearest all the way in.
13. Adjust the HORIZONTAL SIZE slug for proper width.
14. HORIZONTAL and VERTICAL CENTERING of the picture is accomplished by moving the centering lever on the front side of the focus magnet. Readjustment of the ion trap may be necessary after this plate has been adjusted. On receivers using electrostatic focus picture tubes, HORIZONTAL and VERTICAL CENTERING is accomplished by adjusting the CENTERING DEVICE located on the neck of the tube immediately behind the deflection coil. Properly adjusted, the ears of the CENTERING DEVICE will be to the right side when facing the back of the unit.
15. If it is necessary to make any large adjustments (greater than a fraction of a turn) of the horizontal drive trimmer, a check should be made of the range of the horizontal hold control. The following sequence should be used.
    a. Rotate the horizontal hold control fully clockwise and the picture should show a vertical blanking bar just emerging from the left side.
    b. Rotate the horizontal hold control full counter-clockwise. The picture should remain in sync.

c. Switch off channel and then back on channel. Picture may come in immediately or diagonal bars may appear.

d. If diagonal bars are present, turn the horizontal hold control clockwise slowly. The number of diagonal bars will reduce, and after three bars are reached a slight additional rotation of the control in a clockwise direction should result in the picture locking in sync. If the picture does not lock in until after two bars are reached, the horizontal lock trimmer needs to be adjusted. When less than two bars are present, adjust the trimmer slightly in a counter-clockwise direction. In the J and K versions, the LOCK trimmer was replaced with a fixed capacitor.

e. After making this adjustment check the pull in range again. With the horizontal hold control full counter-clockwise, switch off channel then back on. If diagonal bars appear, rotate the hold control clockwise slowly. The picture should lock in sync, with a slight rotation of the control, after three bars are reached. If necessary repeat the lock trimmer adjustment and then check until correct adjustment is attained. If this condition can not be obtained, check horizontal alignment, as outlined in alignment section.

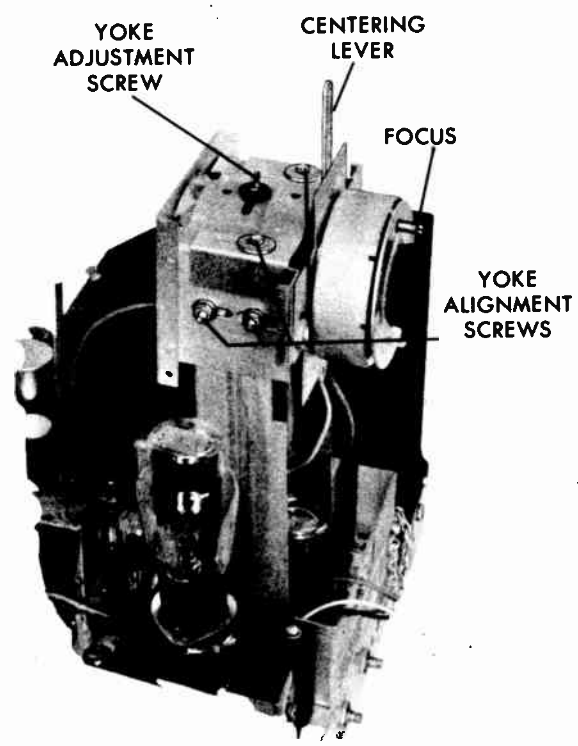

FIGURE 4

PICTURE TUBE ADJUSTMENTS

Note—On sets with electrostatic focus picture tubes, the focus coil is omitted. Focusing is accomplished by adjusting the focus control on rear apron of chassis and to the left of the high voltage compartment.

PART IV

CIRCUIT DESCRIPTION

R-F TUNER

The R-F tuner is a separate assembly and mounts at the right front of the receiver. It consists of an R-F amplifier V1 (6BC5) and mixer-oscillator V2 (12AT7). A 12-position channel selector rotary switch is used with a concentric shaft which operates the variable dielectric type fine tuner. For ease of alignment, inductances, adjustable by bending or spreading, are provided on every channel.

The antenna input transformer T1 is designed for optimum antenna coupling on all channels (2-13). An electrostatic shield is used between the primary and secondary to reduce the amount of man-made interference appearing on the R-F grid. As shown in the schematic, Fig. 10 the secondary of the antenna transformer T1 is tuned for each channel by shunting it with the proper value of inductance (S1, Section 4) to make it resonate with the R-F tube V1. (6BC5) input capacity.

Tuning of the R-F plate and mixer grid is accomplished by wafer sections 3 and 2, which are identical to the R-F grid wafer and have similar series strings of channel coils associated with them to resonate with the R-F plate capacity and mixer grid capacity, respectively. Coupling capacitors C7, C9, and C10 connected between appropriate points on the R-F plate and mixer grid coil strings provide the necessary coupling for the proper bandpass on all channels. Shields between the R-F grid, R-F plate, and mixer grid wafers reduce stray coupling.

The triode mixer V2A (½12AT7) is used because of its low noise characteristic. The triode mixer also has relatively low plate resistance compared to a pentode so that it furnishes a large portion of the damping needed for proper bandwidth in the mixer plate—I-F grid circuit. The mixer coil L4 is connected in series between the converter plate and 1st I-F grid to prevent the oscillator voltage appearing on the mixer plate from getting to the 1st I-F grid capacity in series. C22 (10 mmf.) eliminates the high channel mixer regeneration due to resonance of the lead from the mixer plate to the I-F coil L4 with the total stray and tube capacities. A test point is provided in the mixer grid circuit (junction of R14 and R6), to which a scope may be connected for observing the R-F band-pass curves. This is grounded when not in use in order to provide a short enough time constant to avoid white noise under very strong impulse noise conditions.

The local oscillator V2B (½12AT7) is of the Colpitts type. The circuit is conventional with the inductance (S1, Section 1) connected from grid to plate. Series coil switching is used for ease of alignment and wafer assembly. A variable dielectric type fine tuner (C19) is used. The tuning range obtained is about 4 mc on Channel 13 and 2 mc on Channel 2.

To reduce high band radiation from the main TV chassis, the choke L7 was added in the output lead to the 1st I-F tube grid and the tuner chassis was connected to the main chassis only at the tuner rear apron. To reduce high and low band radiation from the antenna, the tuner shield cover was shortened so that it extends only to the shield partition located between the R-F grid and plate switch wafers. To reduce all types of radiation, a metal shield to cover the fine tuning assembly, and an additional outside shield cover were added. This, in conjunction with the walls of the tuner well in the main TV chassis, provides a complete additional enclosure around the tuner. The shield is grounded at a number of points on the main TV chassis.

VIDEO I-F

The picture I-F amplifier consists of four single tuned circuits, stagger tuned to specific frequencies. Series tuning is used between the mixer plate and first I-F grid in order to reduce the amount of oscillator voltage appearing on the first I-F grid. Bifilar coils are used in the 1st and 2nd I-F stages, whereas a more conventional inter-stage coil is used to couple the 3rd I-F to the detector stage. The first and second I-F stages are stacked with AGC applied to the 1st I-F only. Because of the stacking arrangement the second I-F bias change will be proportional to the applied bias. The 3rd I-F and detector are also stacked. See power distribution block diagram, Figure 5.

The use of Bifilar coils provides the necessary low impedance in the grid and plate circuits of the three stages so that I-F bias is not developed by noise pulses that are of sufficient amplitude to draw grid current. L206 (36 microhenries), wound on the 18K converter circuit load resistor, provides a low impedance in the 1st I-F grid return.

In the 1st and 2nd I-F stages, V201 and V202, 6CB6 tubes are used to provide maximum stable gain. To compensate for variation in input capacity with change of gain, the cathode resistors R203 and R207 (47 ohms) are un-bypassed. A 6BC5 (V203) is used in the 3rd video I-F stage, and since this stage is not provided with gain control, the cathode is bypassed.

VIDEO DETECTOR AND 1ST SOUND I-F

Detection is accomplished by the diode action of the grid and cathode of V204. The 4.5 mc component is recovered from the plate of the tube after amplification. The video component is recovered at the detector load. The effect is identical to having a diode directly coupled to a pentode. However, since the grid and cathode of the pentode act as a detector and produce the same results, the diode is eliminated.

The video frequency voltage developed across the diode load resistor (R213) is of negative polarity. This signal is amplified by the direct coupled video amplifier V205, (6CB6), and coupled to the kinescope. In order to obtain the proper video response, the total stray and circuit capacity had to be kept to a minimum. It was for this reason that the 3rd video I-F coil had to be modified, since a standard Bifilar coil would contribute about 70 mmf. of capacity. L203, L201, and R213 provide the necessary peaking for the video amplifier, whereas C208 and L201 are so adjusted as to resonate at 4.5 mc, thus attenuating the 4.5 mc beat at the video amplifier and increasing the amplitude of the 4.5 mc carrier to the 1st Sound I-F amplifier. L202 (an R-F choke) and C207 attenuate the I-F carrier and its components.

The 4.5 mc FM modulated carrier generated in the diode action is amplified and transformer coupled through T-204 to the sound limiter V101, (6AU6). A double tuned circuit is used to provide good selectivity since a large portion of the demodulated video frequencies also exist in the plate circuit.

SOUND LIMITER AND DISCRIMINATOR

The sound limiter V101 (6AU6) is stacked with the sync amplifier V302A, sync clipper V302B, sync separator V301B and the R-F screen. This portion of the stacked arrangement is possible because of the relatively constant plate current characteristic of the sound limiter.

The limiter was designed on the basis of plate limiting and grid limiting. Plate limiting is accomplished by using a low screen potential and grid limiting is obtained by using grid leak bias. In this combination, the tube initially has zero bias with no signal at the grid. As soon as a signal is applied, the grid is driven slightly positive and charges C101 (56 mmf.). The capacitor attempts to discharge through R101 (220K), but due to the relatively long time constant, the discharge will occur slowly. Because of the current flow through R101, a voltage is developed, with the grid becoming negative. This bias varies with the amplitude of the incoming signal, in this way tending to keep the plate current constant within wide limits of input voltage.

Since substantially no AM rejection exists below the threshold of limiting, the circuit parameters were adjusted so that limiting occurs when the developed bias is approximately 1.2 V. across R101. Because of this action of the limiter, there is an F-M signal of constant amplitude applied to the discriminator transformer T101.

The 4.5 mc discriminator circuit uses the diodes (No. 1 and No. 2) section of V102A (½6T8) for detection. The discriminator is used because of the relative greater gain over the ratio detector. However, unlike the ratio detector, the discriminator is sensitive to both amplitude and frequency modulation. The AM output is zero at center frequency and is proportional to the frequency deviation from balance, but with limiter action, suppression of AM to either side of center frequency is accomplished.

The DC load for the discriminator is composed of R102 and R107. The audio output is modified by R108 and C106, the de-emphasis network; then coupled to the grid of the 1st audio amplifier V102B (½6T8).

AUDIO AMPLIFIER

The audio amplifier is a two-stage amplifier using ½6T8, (V102A) and 6V6, (V103). The triode in the 6T8 gives comparatively high gain. This makes it possible to use inverse feedback. The feedback is from the voice coil winding of the audio output transformer to the cathode of the 1st AF amplifier. By this method, the distortions introduced by V102, V103 and T102 can be greatly reduced. Such a connection also gives better speaker damping.

VIDEO AMPLIFIER

In addition to the notes on the detector, as given in the paragraph on the video detector and 1st sound I-F, the 4.5 mc trap serves to greatly reduce the amount of inter-carrier beat that may be present in the signal. As far as the video signal is concerned, the detector is compensated to approximately 4 mc. This is more than necessary, but is done for the reasons stated in the paragraph on the video detector and sound I-F.

The detector is DC coupled to the video amplifier V205, (6CB6). The DC level is retained for better picture quality, and AGC reference. The video amplifier is compensated for 3 mc response, this being the definition obtainable from the I-F. The video amplifier is AC coupled to the kinescope. The coupling time constant is long enough that vertical shading is minimized.

An external color converter connection is provided. It is connected to the cathode of the video amplifier and takes advantage of the cathode follower action when the contrast control is set to minimum.

NOISE INVERTER

The noise inverter, one half 12AX7 (V301A), is a grounded grid amplifier that forms a parallel signal path around the video amplifier tube. Since it is cathode driven, the noise inverter signal output is in phase with the detector signal while the video amplifier output is 180° out of phase.

The signals from these two sources are applied to common load resistors. For sync circuits, the gain through the noise inverter, due to its plate load (R215 and R218), is greater than that through the video amplifier plate load (R218), resulting in driving the noise into the white region and leaving the sync pulses free of noise bursts. This will result in a minor amount of low amplitude white noise in the picture. The noise inverter is biased beyond cutoff, enabling it to conduct only on noise signals which exceed the sync tips at the detector.

Bias for the noise inverter is obtained from the grid bias voltage of the horizontal output tube by means of a voltage divider in the output tube grid return. A filter network, R320 and C302, removes the horizontal sawtooth that exists in this circuit. Since bias on the horizontal output tube is determined by the signal amplitude on its grid, the horizontal drive control (C406) will affect the bias voltage of the noise inverter. The voltage divider has been set up to avoid any difficulty with the noise inverter when the horizontal drive is correctly adjusted.

AGC

The 105 chassis uses keyed AGC. Since peak type of AGC references on the sync tips only, it would be highly desirable to make the AGC system inoperative during the interval of time between sync pulses. This is accomplished by supplying a pulse from the horizontal output system to the plate of the AGC tube V206 (6AU6). The time constants used in this system are very short. This makes it very adaptable to reducing airplane flutter. A series fed pulse to the AGC amplifier was chosen because of the ease of filtering the derived AGC voltage. A more rapidly acting AGC is therefore possible.

The R-F AGC voltage is considerably delayed to reduce the medium signal noise content of the picture. The I-F gain is high enough that it is at the threshold of the noise level of the converter. If R-F and I-F bias were always equal, then the converter noise would appear in the picture at considerably higher signal level than necessary. To prevent this, the R-F bias is delayed until the I-F gain is reduced to where no converter noise appears in the picture. At this level the R-F bias starts increasing at a rate faster than the I-F bias. The result is that the R-F and I-F bias are equal at approximately —5.5 volts. This gives the set its best strong signal handling capabilities. At full sensitivity the noise at the R-F input masks out the converter noise.

The threshold of the R-F bias is adjusted so that when it has increased to —0.5V, the I-F bias is in the order of —2.7 to —3.0 volts. The crossover of R-F and I-F biases is approximately —5.5 volts. The R-F amplifier grid to cathode is used as a clamp for R-F bias delay in the AGC system.

The double time constant filtering, formed by C213, C214 and R212 at the AGC plate, is for eliminating a low frequency transient in the AGC bus following the vertical sync pulse.

SYNC SEPARATORS

The sync separators consist of three triode sections, one half 12AX7 (V301B) and a 6SN7 (V302A, V302B), which are, sync separator, sync amplifier, and sync clipper, respectively.

The grid of the sync separator has a double time constant (R304, C309, and R302, C303) that provides a faster recovery time under noise conditions. Having grid leak biasing, the sync separator will only accept a certain peak to peak portion of the positive peak of the signal. At low contrast levels this includes some of the video signal; therefore, another stage of separation is required. The first stage inverts the signal, making it necessary to cathode drive the sync amplifier, which operates in much the same manner as the sync separator. The sync tip amplitude, in particular the vertical serrated pulses, have become quite irregular due to successive stages of amplification, making it necessary to have another stage which will level off this side of the sync signal. A negative signal fed to the grid of the sync clipper accomplishes this purpose, and supplies a negative sync signal at the cathode for the vertical multivibrator and a positive sync signal at the plate for the horizontal AFC.

VERTICAL SWEEP OSCILLATOR

The vertical sweep oscillator V303 is a cross-coupled multivibrator. In the A and B versions a bridged T filter is used for feed back coupling to the grid of the first tube. This filter removes horizontal frequencies which would prevent proper interlace. Later versions have the bridged T network eliminated. The output is taken from the plate of the second triode. Trapezoidal wave shape is obtained by the peaking circuit composed of C307 and R315, and R316 in A and B versions. The resistance of the peaking circuit is divided to obtain retrace blanking for the kinescope. All other versions use C307 and R315 for peaking. The multivibrator circuit feeds the 6W6GT vertical output tube V304.

HORIZONTAL OSCILLATOR AND FREQUENCY CONTROL

The horizontal oscillator, discharge, and AFC circuits utilize a double triode tube 6SN7, (V401). The frequency of the blocking oscillator, V401B, can be adjusted by the top slug of T401. The frequency of oscillation is stabilized by a tuned circuit. The inductance for the tuned circuit is in T401 and the capacitor is C407. The generated sawtooth reaches the grid of the output tube V402 through the capacity divider C410-C406. The latter, marked horizontal drive, is variable and controls the amount of drive on the grid of V402 (6BQ6). This adjustment will affect the horizontal linearity, high voltage, and noise inverter tube bias.

Synchronization is accomplished by means of the AFC, V401A, as follows: A complex wave consisting of the sync pulse and a parabola is fed to the grid of this triode. The sync pulse rides at the peak of the complex wave. The tube is biased from the oscillator grid to such a value that plate current flows only during the positive peak portions of the complex wave. A portion of the cathode voltage is applied to the oscillator grid. Its magnitude affects the frequency of the oscillator in such a way as to automatically lock it in synchronism.

The plate voltage for the AFC as supplied through R412, R402, and R401, is obtained from the boost supply. This is to neutralize the horizontal oscillator frequency change due to the inherent regulation characteristics of the boost voltage at different brightness levels.

HORIZONTAL OUTPUT AND DAMPER

The function of the horizontal output tube V402 is to supply sufficient current of the proper waveform to the horizontal deflection coils to provide horizontal scanning for the kinescope. The function of the damper tube, V404, (6W4) is to stop oscillation of components at certain times and thus help provide a linear trace. Other functions of this circuit are to provide a high amplitude pulse for high voltage and to recover a good part of the energy in the system. The energy recovery appears in the form of a boost voltage at the damper cathode.

The inductance and distributed capacity of the system are controlled so that the self-resonant frequency will be in the order of 72 KC so that the retrace time will be sufficiently short.

THE RECTIFIED HIGH VOLTAGE SUPPLY

The high voltage is supplied by part of the energy stored in the horizontal system. When the 6BQ6 plate current is cut off by the horizontal sawtooth, a high positive pulse of voltage appears on the tertiary of T402 due to the rapidly collapsing field in the system. This high positive pulse is rectified by the high voltage rectifier V403 (1B3). This pulse charges the H. V. condenser C415. This condenser is returned to the plate of the damper tube so that the negative pulse that exists there simultaneously with the tertiary pulse will add to the available high voltage. This added high voltage is approximately 1500 V. The total high voltage applied to the picture tube is 14 KV.

The filament power is obtained from a one-turn coil around the horizontal output transformer core. Width is controlled by L401 and linearity is controlled mainly by L402; the drive control influences linearity to some extent.

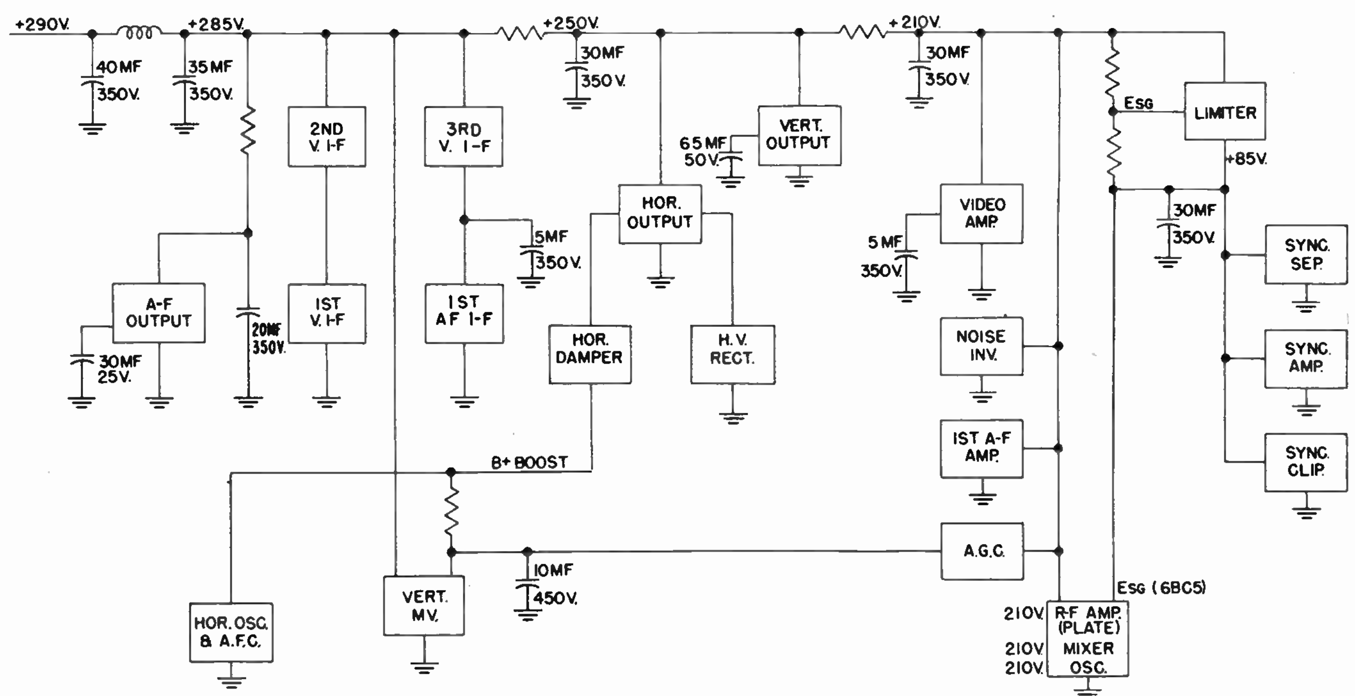
The capacitor and resistor in series across the upper half of the horizontal deflection coils cancel out the crosstalk transients. The resistor in series with the capacitor makes the value of the capacitor less critical. The resistors across the vertical windings damp out vertical transients.

LOW VOLTAGE SUPPLY

The low voltage power supply provides the filament and plate voltages for the receiver. A 5U4G (V501) rectifier tube is used to supply 290 volts DC input to the filter at approximately 230 ma. The power transformer has two 6.3 volt filament windings. One winding is grounded and supplies 11.4 amperes for all of the tubes except V202, V203, and V206. These three tubes are supplied by the second winding and draw 0.9 amperes. This winding is connected to the 140 volt bus so that the filament to cathode rating of the three tubes is not exceeded.

FOCUSING

Both permanent magnet and electrostatic focusing is employed in this series. On chassis having the permanent magnet focus unit, there is a centering plate on the front of the focus unit and a focus adjusting screw on the rear. Adjustment of the focus adjusting screw varies the flux density through which the electron beam passes. Ion trap and centering adjustments may be required after the beam is properly focused. The electrostatic focused units vary from the above in that the focus control is a potentiometer located on the rear apron of the chassis and centering is accomplished by means of a centering device located on the neck of the tube between the deflection coil and ion trap.



POWER DISTRIBUTION BLOCK DIAGRAM

FIGURE 5

PART V
ALIGNMENT

HORIZONTAL AFC

Horizontal frequency adjustment (T401 top slug).

1. Short out Terminals C-D of horizontal oscillator and AFC transformer. Set horizontal lock (if used) and horizontal drive trimmers 1½ turn from tight.
2. Turn horizontal hold control full clockwise, and adjust frequency slug (top of T401) until picture locks in.
3. Before further frequency adjustments are made, set up horizontal width and horizontal linearity, making any final adjustment necessary to horizontal drive trimmer. If the horizontal drive trimmer is changed at any time, the frequency adjustment will have to be checked.

Horizontal Oscillator waveform adjustment, (T401 bottom slug).

1. Remove short from terminals C-D of T401.
2. Connect oscilloscope, through series capacitor of approximately 15 mmf, to terminal C of T401. The pattern should be a sine wave, superimposed on a sawtooth. Adjust bottom slug of T109 for proper waveform, i.e. peak of sawtooth and sine waves should be nearly equal.
3. Remove the oscilloscope from T109. Turn the "horizontal hold" control full clockwise. Adjust frequency slug (top of T401) until picture is just out of sync. as indicated by blanking bar appearing at left of picture. Back off frequency slug slightly until picture again locks in sync. This adjustment is made with BRIGHTNESS control in full clockwise position.

VIDEO I-F ALIGNMENT

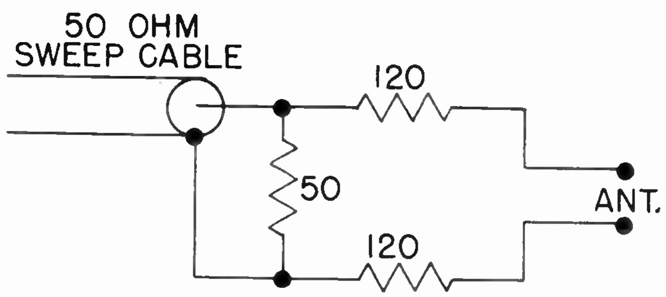
Test equipment needed:

A.M. Signal generator 21.25 to 25.75 MC
Sweep Generator
Cathode Ray Oscilloscope
Electronic Voltmeter

1. A low impedance voltage source, such as a tapped "C" battery must be used to apply fixed bias during alignment. Connect —1.5 volts to the R-F AGC bus and —4.5 volts to the I-F AGC bus. It is not necessary to remove the AGC tube during alignment.
2. Connect modulated signal generator to convertor grid wafer through hole in tuner shield.
3. Connect scope or VTVM across detector load resistor (R213). The scope is preferable as overload is more easily detected.
4. Tune the signal generator to the following frequencies and adjust the corresponding slugs for maximum indication.

Frequency	Adjust
23.1 MC	Converter Coil
25.3 MC	(T201) 1st I-F
23.4 MC	(T202) 2nd I-F
25.5 MC	(T203) 3rd I-F

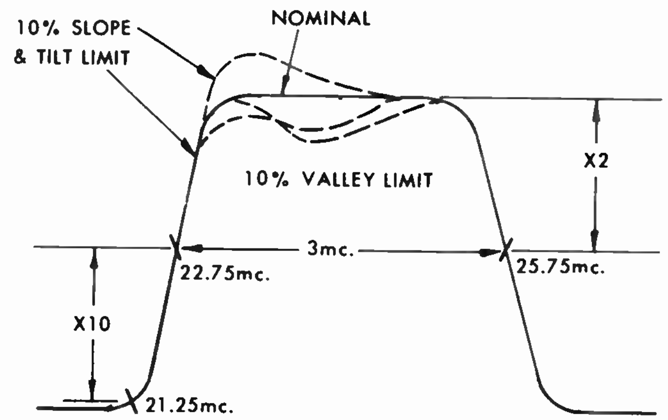
5. Remove signal generator and connect sweep generator to antenna terminals through proper impedance matching network, see Figure 6. Loosely couple marker generator to I-F chassis.



ANTENNA IMPEDANCE MATCHING NET

FIGURE 6

6. Tune sweep generator and television chassis to channel 6.
7. Retouch I-F coils if necessary for proper curve as shown on following page.



OVERALL I-F CURVE
FIGURE 7

NOTE: The converter (23.1 mc) will have most effect on the low frequency side of the curve, the 1st I-F transformer (25.3 mc) on the high frequency side. Tilt may be corrected by adjusting the 2nd or 3rd I-F transformer. Proper positioning of the markers is important, as no traps are used.

SOUND I-F ALIGNMENT

1. Connect VTVM through 1 meg. isolating resistor, across R101 (220K) limiter grid resistor. CAUTION: Case of VTVM will be at +85 volts.
2. Connect 4.5 MC signal to pin 1 (V204) and chassis ground.
3. Adjust primary (top slug) and secondary (bottom slug) of T204, for maximum reading. Keep output of signal generator low, so that this maximum reading does not exceed —5 volts.
4. Remove VTVM and connect from junction of R108 and C106 to ground.
5. Adjust primary (bottom slug) of T101 discriminator transformer for maximum output, and secondary (top slug) for zero reading.

NOTE: For accurate alignment do not change level of signal input after Step 3 above. Discriminator adjustments should be repeated until no improvement can be made.

OSCILLATOR ALIGNMENT

Oscillator alignment should be made only when the fine tuning control tunes in the extreme clockwise or counter-clockwise position, or if it will not tune at all within its tuning range.

TOUCH UP OSCILLATOR ALIGNMENT

If some channels do not tune at all, or not near enough to the center of the fine tuning range, adjust the oscillator trimmer for the best compromise tuning on all channels. If, for example all channels tune near one side of the control, adjustment of the trimmer will bring them all near the center. However if some channels tune near one end and others tune at the other end of the control, adjustment will move some to the center and move the others beyond the range of the control. In this case the oscillator coils will have to be adjusted individually as follows:

COMPLETE OSCILLATOR ALIGNMENT

Connect a sweep generator to the antenna terminals of the receiver. Connect an unmodulated signal generator to the antenna terminals and tune it to the channel 13 video carrier frequency. TV signals may be used.

Loosely couple an unmodulated signal generator to the first I-F grid and tune it to 25.75 MC. Connect an oscilloscope across the video detector load resistor through a 10K ohm resistor.

Turn on the receiver and set the vernier to the mid range position. When the receiver has warmed up, if there are two markers on the scope, determine which rotation of the vernier causes the markers to move closer together. If it is clockwise, reset the vernier to the midrange position and close the channel 13 oscillator coil. If it is counter-clockwise open the coil. Adjust for a zero beat. The channel 13 coil moves all high band channels. The channel 6 coil moves all low band channels.

Tune the sweep generator to channel 12. The signal generator to the channel 12 video carrier frequency. Set channel selector to 12. Adjust the channel 12 oscillator coil for a zero beat of the markers.

Repeat the procedure for channels 11 through 2. Recheck channels 13 through 7. The high channel coils are adjusted by moving them up or down and the low channel coils by spreading or pushing together.

TV CHANNEL FREQUENCIES

Channel No.	Band Width (MC)	Picture Carrier	Sound Carrier	Local Oscillator
2	54-60	52.25	59.75	81
3	60-66	61.25	66.75	87
4	66-72	67.25	71.75	93
5	76-82	77.25	81.75	103
6	82-88	83.25	87.75	109
7	174-180	175.25	179.75	201
8	180-186	181.25	185.75	207
9	186-192	187.25	191.75	213
10	192-198	193.25	197.75	219
11	198-204	199.25	203.75	225
12	204-210	205.25	209.75	231
13	210-216	211.25	215.75	237

ANTENNA, R-F AMPLIFIER AND CONVERTER ALIGNMENT

The desired pattern to be applied to the I-F amplifiers is the result of three variables. These three variables are the ANTENNA COIL (rear wafer), the R-F COIL (second wafer from rear) and the CONVERTER COIL (third wafer from rear).

These coils must be very carefully adjusted with only a slight movement. It is imperative that the following sequence of adjustment is followed to obtain the desired pattern. Antenna coils first, R-F coils second, and the converter coil last. The R-F wafer has B+ on it and should not be touched with the hand or a metal tool. Adjustment of the converter coil is critical. The oscillator coils (fourth wafer from rear) are properly adjusted and should not be touched.

The R-F tuner has been properly aligned at the factory and should not require any additional adjustment except when tubes are replaced in the tuner. Proper selection of the replacement tube will eliminate the necessity of making these coil adjustments. Try several tubes while observing their effects on the pattern. Use the one that gives the desired pattern. It is important that the tuner cover be in place when observing the pattern.

PART VI
SERVICE INFORMATION

HIGH VOLTAGE WARNING

The danger accompanying shock is always present when the receiver is operated outside the cabinet or when the rear cover is removed from the cabinet. Only a person familiar with the precautions to be observed when working with high-voltage equipment should service this receiver.

CATHODE RAY TUBE HANDLING

Shatterproof goggles and heavy gloves should be worn at all times when handling a cathode ray tube. The tube should not be handled in the vicinity of any person not so equipped. When handling the tube, always keep it away from the body.

Due to the large surface area of the tube and the high vacuum contained within, more than ordinary care is required to prevent shattering the tube. The large end of the bulb, particularly the rim of the viewing surface, must not be struck, scratched, or subjected to more than moderate pressure. If the tube binds during removal or replacement, determine the cause of the trouble. DO NOT FORCE THE TUBE.

PICTURE TUBE REPLACEMENT (HORIZONTAL CHASSIS)

If it becomes necessary to replace the picture tube, it should be done in the following manner.

1. Remove the tube socket from the rear of the picture tube, then remove the ion trap.
2. Remove the safety glass assembly by taking out the screws which hold the glass rail in position.
3. Loosen the nuts that secure the tube strap over the rim of the tube, and remove the strap.
4. Remove the high voltage anode connector and lift out the tube.
5. Install the replacement picture tube being careful not to force the neck when inserting thru the deflection coil.
6. Install the HV connector, replace the support strap, and fasten it down securely with the nuts removed in Step 3.
7. Loosen the thumbscrew on top of the deflection yoke, so the yoke moves freely. Loosen the two hex-head screws on each side of the deflection yoke mounting bracket, and push the top section forward until the rubber bumper fits against the bell of the tube, all the way around. Make sure tube face is vertical and neck of tube is parallel with chassis base. Then tighten the screws. Then press the deflection yoke forward as far as possible, and tighten the thumbscrew.
8. Loosen the two screws which secure the focus magnet, and move it so the neck of the tube is properly centered in it. Then tighten the screws and adjust the ion trap.
9. On chassis using "magnetic focus picture tubes" HORIZONTAL and VERTICAL CENTERING ¾ of the picture is accomplished by moving the "centering device" on the front side of the focus magnet. Readjustment of the ion trap may be necessary after this plate has been adjusted.

   On chassis using "electrostatic focus picture tubes", HORIZONTAL and VERTICAL CENTERING is accomplished by adjusting the "centering ring" located on the neck of the tube behind the deflection coil.

(VERTICAL CHASSIS)

In models where the chassis is mounted in a vertical position, the following procedure is recommended.

1. Remove the safety glass and mask assembly by taking out the screws which hold the glass rail in place.
2. Lay the cabinet on its side on a clean piece of felt or other soft material, with the chassis side down.
3. Remove the two metal wedges that brace the rim of the picture tube top and side. Two wood screws hold each in place.
4. Two ¼-20 screws secure each side of the chassis to the mounting rails of the cabinet. Remove these screws, and pull the chassis out of the cabinet. Proceed through steps 1 to 9 in the preceding section. Then replace the chassis.

REVISIONS

A comparison of the schematic diagrams for the A & B and the C chassis will show that a number of components were rearranged in the vertical multivibrator circuit. This was done to reduce the number of components requiring close tolerances, thereby simplifying service problems.

The vertical output stage was changed so that the 6W6 tube operates as a beam power tube rather than a triode as previously employed. This makes the selection of tubes less critical, as there are many 6W6's which will oscillate when triode connected, resulting in alternate light and dark horizontal bars on the screen. Two capacitors (C408 and C410) were changed in value, so that proper adjustment of the associated controls would be nearer the center of their range.

The "E" revision is similar to "C", with the following differences: R232 and R233 were added, and the value of C209 was changed to eliminate the possibility of intercarrier "buzz" and audio hum. R215 and R308 were changed to improve sync separation.

A focus control has been added in the "D" revision for use with electro-statically focused tubes. Otherwise, the circuit is the same as the "E".

A tone control has been added to some chassis. When the tone control is installed at the left of the control panel, the "D" becomes an "H" and the "E" becomes an "F"

On the J & K revisions, resistor R202 was changed to 8200 ohms. The horizontal lock trimmer C411 was changed from a variable to a fixed capacitor. R239 and C222 have been added to eliminate vertical sweep modulation at maximum settings of contrast and brilliance controls. R215 was changed in value to reduce twist at top of picture.

SERVICE HINTS ON THE 105 SERIES TV CHASSIS

Intercarrier Buzz

1. Check alignment of secondary (top slug) of discriminator transformer. Adjust for minimum buzz on transmitted signal.
2. Check 4.5 MC sound alignment as outlined in service manual.
3. Check response curve on video I-F. Align if necessary.
4. Buzz may be due to overmodulation at the transmitter. If more than one station is available, try all stations. Buzz on only one station will confirm this condition.
5. See revision "E", page 18.

White Raster, No Picture or Sound

1. Check AGC amplifier (6AU6).
2. Check keyer coil and width coil.
3. Check tuner and I-F tubes.
   Several tubes should be tried in the I-F amplifier. Because of the voltage stacking, these tubes must have nearly equal mutual conductances.
4. Check video amplifier tube.

Overall Focus

1. Make sure proper ion trap is installed.
   20″ and 21″ magnetic focus tubes use part number 360492-2 or 4 (yellow dot).
   20″ and 21″ electrostatic focus tubes use part number 360492-5 or 6 (green dot).
2. Check ion trap adjustment. Slight adjustment may be necessary to obtain maximum brightness at full clockwise position of brightness control.
3. Check focus adjustment. Adjust for best focus at normal brightness.
   A. On magnetic focus units the focus control is a screw-driver adjustment at the rear of the focus magnet. If good focus cannot be obtained, and picture changes position considerably with rotation of focus control, install a new focus magnet, part number 360504-1.
   B. On electrostatic focus units, the focus control is a potentiometer adjustment on the rear chassis apron.
4. On magnetic focus tubes make sure the focus magnet is placed ¼″ to ⅜″ in back of the deflection yoke.
5. If poor overall focus is noted replace deflection yoke. Use part number 360526-1 as replacement.
6. Try a picture tube which is known to give good focus in another instrument.

Picture Resolution and Contrast

1. Try known good tubes (6CB6) in I-F and video amplifiers. CAUTION: If it is necessary to change tubes in the I-F amplifier, check the alignment.
2. Check range of fine tuning control.
   The 4.5 mc. beat pattern should begin to appear in the picture at the left center of the fine tuning control range. If this cannot be accomplished, try adjusting the oscillator trimmer located on the front of the tuner. If further oscillator adjustment is necessary, proceed as outlined in the alignment instructions.
3. Check I-F alignment.

Background Noise

1. To reduce background noise in picture, change R223 from 4.7 megohm to 3.9 megohm.
2. Remove 10K ohm resistor, R231, in the 2nd I-F grid return.

NOTE: R231 not used in A and B models.

Vertical Sync

1. In weak signal areas, R215 in AGC grid circuit should be 27K ohm. In some chassis 10K ohms has been used.
2. If proper height and vertical linearity cannot be attained without "foldover" at bottom of raster, replace vertical output transformer, part number 320060-1.

Horizontal Sync

1. If horizontal circuit will not stay in adjustment, replace horizontal oscillator transformer, part number 360499-1.
2. If horizontal drive adjustment appears too critical, or if horizontal and vertical sync "motorboats," install noise inverter bias control as shown. This control can be installed in place of "color converter" jack.

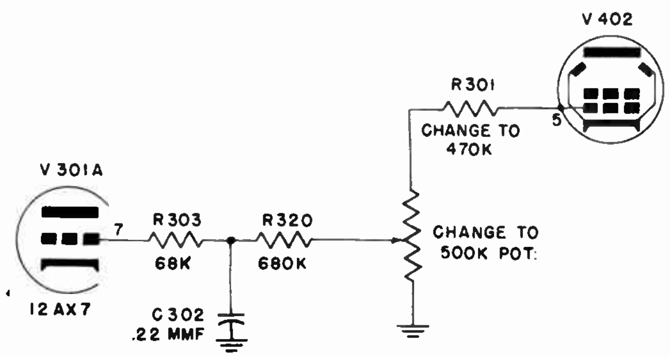


FIGURE 8

Adjust "noise bias" control for most stable sync.

3. Align horizontal oscillator and AFC.

Signal Blocking (Strong Signal Areas Only)

1. If signal blocks when tuning from weak to strong signal check noise inverter bias. This should be approximately—11V, and may be raised by adjustment of the horizontal drive control or "noise bias" control if used.
2. Replace V206, AGC amplifier tube.
3. Blocking may be due to excessive grid current in V203, the 3rd video I-F amplifier. This circuit may be modified as shown below.

†Varies with control settings.

WHY THE WAVEFORMS VARY

Assuming normal operation of the television receiver, voltage waveforms often do not appear as shown. This is a function of the type of oscilloscope used, and its input cable.

These waveforms are as reproduced on a Dumont 208B instrument but another, having greater or lesser frequency fidelity, may show a waveform quite different in shape and/or size. Therefore, the service technician must be familiar with his oscilloscope, must recognize its limitations and must make mental correction if waveforms do not appear to be "normal."

The same logic applies to the measure of D-C voltages. Measurements shown here are on an RCA Voltohymist, Jr. and the use of a 20,000 ohm per volt movement will indicate some D-C voltages to differ greatly from those shown. Again, logic and reasoning must be applied, realizing that in a high impedance circuit, the indicated voltage will be less than the actual operating voltage.

Allowances for scope waveforms and D-C meter readings may be computed if all pertinent factors are known, but the experienced technician makes mental correction and allowances to the end that high fidelity instruments are not required.

PARTS LIST FOR THE 105 SERIES

Ref. No.	DESCRIPTION	Part No.
T 101	Transformer, discriminator, 4.5 mc.	360512-1
T 102	Transformer, audio output, omit on "without audio"	320063-1
T 201	Transformer, 1st video I-F (J & K only)	360529-1
	Transformer, 1st video I-F, all others	360461-1
T 202	Transformer, 2nd video I-F	360461-1
T 203	Transformer, 3rd video I-F	360511-1
T 204	Transformer, sound, 4.5 mc.	360519-1
T 301	Transformer, V. O.	320060-1
T 401	Transformer, horizontal blocking oscillator	360499-1
T 402	Transformer, H. V.	320061-1
T 501	Transformer, power	300064-1
L 201	Coil, peaking, blue-blue	360443-17
L 202	Coil, peaking, black-black	360443-15
L 203	Coil, peaking, violet	360443-6
L 204	Coil, peaking, brown	360443-13
L 205	Coil, peaking, green-green	360443-14
L 206	Coil, peaking, white-white	360443-16
L 301	Coil, deflection	360515-2
L 301	Coil, deflection (side mounted chassis)	360516-1
L 301	Coil, deflection (electrostatic focus tube)	360526-1
L 401	Coil, keyer & horizontal size	360521-1
L 402	Coil, horizontal linearity	360517-1
L 501	Filter reactor	320058-1
	Focus magnet	360504-1
	Centering device (electrostatic focus tubes)	360525-1
C 101	Capacitor, mica, 56 mmf, 500 V.	250179-79
C 102	Capacitor, ceramic, dual, 4000 mmf, 450 V.	250195-2

POWER REQUIREMENTS

All chassis are rated 117 volts AC 60 cycles. Power consumptions listed are for 117 volt line.

TV with audio	205 Watts max.
TV without audio	190 watts max.

The addition of the UHF converter will increase the power consumption approximately 10 watts, the UHF tuner about 4 watts.

CIRCUIT DESCRIPTION

General

This receiver is basically designed to accommodate either a UHF tuner or a UHF converter. The converter can be added when the UHF transmissions start and the customer wishes it.

The TV receiver is constructed on a single chassis which may be used in conjunction with an AM tuner or a separate audio amplifier or record player. It is so designed that it will accommodate either 21-inch rectangular or 20-inch rectangular tubes without any changes in circuitry.

Cascode RF Tuner

The cascode RF tuner consists of an RF amplifier V1 (6BQ7) and mixer-oscillator V2 (6U8). A 12-position channel selector rotary switch is used with a concentric shaft which operates the variable type fine tuner. For ease of alignment, inductances adjustable by bending or spreading are provided on every channel.

As shown in the schematic diagram, the secondary of the antenna transformer T1 is tuned for each channel by shunting it with the proper value of inductance (S1, Section 4) to make it resonate with the RF tube V1 (6BQ7) input capacity. L1 and C1 form an IF trap, which is tuned to 44.5 MC for best average IF rejection on all channels. To further minimize IF interference an external IF trap assembly is available for those few areas where the overall IF interference is severe. These traps are series-connected in the receiver antenna lead-in and should be tuned to give maximum rejection at the undesired IF frequency.

Tuning of the RF plate and mixer grid is accomplished by wafer sections 2 and 3, which are identical to the RF grid wafer. Coupling capacitors C6, C9 and C10, connected between appropriate points, provide the necessary coupling for the proper bandpass on all channels. Shields between the RF grid, RF plate and mixer grid wafers reduce stray coupling. The 6BQ7 RF tube is used in a cascode circuit (triode 1 grounded cathode, triode 2 grounded grid) to minimize triode feedback so that the superior signal-to-noise ratio of a triode is realized with good stability.

The pentode mixer V2A (1/2 6U8) is used because of its low feedback characteristic with 41 MC IF.

To reduce high band radiation from the main TV chassis, common low side capacity coupling was used to the 1st IF tube grid circuit and the tuner chassis was connected to the main chassis only at the tuner rear apron.

Video IF

The video IF amplifier operates at a picture carrier frequency of 45.75 MC, with a 6 db design bandwidth of 3.0 MC and consists of a double-tuned circuit (low-side capacity coupled), followed by three stagger tuned I-F transformers. The double-tuned circuit consists of two similar coils that are physically separated, one in the tuner (converter plate coil), and one in the grid circuit of the 1st IF amplifier (T201).

The remainder of the IF amplifier consists of three stagger-tuned stages, using 6CB6's for maximum stable gain. A trap similar to that on the IF input coil is inductively coupled to the 1st IF plate coil (T202) and tuned to 47.25 MC adjacent channel sound carrier.

This chassis employs intercarrier sound IF (4.5 MC) produced by the beat between sound and picture carriers. The video detector is comprised of a crystal diode (IN64)located accessibly within shield can (T204), also containing the final IF bifilar coil, bypass capacitor and IF stabilizing filter choke.

The 4.5 MC intercarrier sound IF signal is applied to the single tuned 1st sound IF amplifier (V204) and in turn fed to the limiter stage (V101).

The limiter was designed on the basis of plate limiting and grid limiting. Plate limiting is accomplished by using a low screen potential and grid limiting is obtained by using grid leak bias.

The 4.5 MC discriminator circuit uses the diodes (#1 and #2) section of V102A (1/2 6T8) for detection. The AM output is zero at center frequency and is proportional to the frequency deviation from balance, and with limiter action, suppression of AM to either side of center frequency is accomplished.

Audio Amplifier

The audio amplifier is a two-stage amplifier using 1/2 6T8 (V102A) and 6V6 (V103). The triode in the 6T8 gives comparatively high gain. This makes it possible to use inverse feedback. The feedback is an overall feedback from the voice coil winding of the audio output transformer to the cathode of the 1st AF amplifier.

Video Detector, Video Amplifier

The detector is DC coupled to the video amplifier V205 (6CB6). The DC level is retained for better picture quality, and AGC reference. The video amplifier is compensated for 3 MC response, this being the definition obtainable from the IF. The video amplifier is AC coupled to the picture tube.

Noise Inverter

The noise inverter is for the purpose of removing noise bursts that exceed the sync pulse level from the signal that is fed to the AGC and the sync circuits. The noise inverter (one-half 12AX7 V301A) is a grounded grid amplifier that forms a parallel signal path around the video amplifier tube. Since it is cathode driven, the noise inverter signal output is in phase with the detector signal while the video amplifier out put is 180° out of phase.

The noise inverter is biased beyond cutoff, enabling it to conduct only on noise signals which exceed the sync tips at the detector.

Bias for the noise inverter is obtained from the grid bias voltage of the horizontal output by means of a voltage divider in the output tube grid return. Since bias on the horizontal output tube is determined by the signal amplitude on its grid, the horizontal drive control (C406) will affect the bias voltage of the noise inverter. A potentiometer (R304) provides for independent adjustment of noise inverter bias and horizontal drive. The voltage divider has been set up to avoid any difficulty with the noise inverter when the horizontal drive is correctly adjusted. The noise inverter bias usually is between -9V and -13V as measured with VTVM.

AGC

The 105-41 MC chassis uses keyed AGC for improved noise immunity and reduction of airplane flutter. A series-fed pulse to the AGC amplifier was chosen because of the ease of filtering the derived AGC voltage. A more rapidly acting AGC is therefore possible.

Sync Separators

The sync separators consist of three triode sections, one-half 12AX7 (V301B) and a 6SN7 (V302A, V302B), which are sync separator, sync amplifier and sync clipper, respectively.

Having grid leak bias, the sync separator will only accept a certain peak-to-peak portion of the positive peak of the signal. At low contrast levels this includes some of the video signal; therefore, another stage of separation is required. The first stage inverts the signal, making it necessary to cathode drive the sync amplifier, which operates in much the same manner as the sync separator. A negative signal fed to the grid of the sync clipper supplies a negative sync signal at the cathode for the vertical multivibrator and a positive sync signal at the plate for the horizontal AFC.

Vertical Sweep Oscillator

The vertical sweep oscillator is a plate-to-grid multivibrator using a 6SN7 dual triode. The integrated vertical sync is fed to the grid of the first triode section and the output wave is taken from the plate of the second triode. The pulse across the resistance R315 of the peaking circuit is also used for obtaining vertical retrace blanking of the picture tube.

The feedback circuit in the multivibrator is from the peaking resistor to the grid of the first triode. RC301 is a printed circuit integrating network for deriving the vertical synchronizing pulse.

Vertical Output Circuit

The vertical output amplifier is a type 6W6, pentode connected and transformer coupled to the yoke. Improvement in linearity is obtained by feedback from the transformer secondary to the grid.

Horizontal Oscillator and Frequency Control

The horizontal oscillator, discharge and AFC circuits utilize a double triode tube 6SN7 (V401). The frequency of the blocking oscillator (V401B) can be adjusted by the top slug of T401. The frequency of oscillation is stabilized by a tuned circuit. The inductance for the tuned circuit is in T401 and the capacitor is C407. The generated sawtooth reaches the grid of the output tube V402 through the capacity divider C410 - C406. The latter, marked HORIZONTAL DRIVE, is variable and controls the amount of drive on the grid of V402 (6BQ6). THIS ADJUSTMENT WILL AFFECT THE HORIZONTAL LINEARITY, HIGH VOLTAGE AND INVERTER TUBE BIAS.

Horizontal Output and Damper

The function of the output tube V402 is to supply sufficient current of the proper waveform to the horizontal deflection coils in order to provide horizontal scanning for the picture tube. The function of the damper tube, V404 (6W4) is to stop oscillation of the yoke current at retrace time and thus help provide a linear trace. Other functions of this circuit are to provide a high amplitude pulse for high voltage and to recover a good part of the energy in the system. Part of the energy recovered appears in the form of a boost voltage at the damper cathode, and part in actual deflection current in the yoke.

High Voltage Supply

The high voltage is supplied by part of the energy stored in the horizontal system. When the 6BQ6 plate current is cut-off by the horizontal sawtooth, a high positive pulse of voltage appears on the tertiary of T402 due to the rapidly collapsing field in the system. This high positive pulse is rectified by the H.V. rectifier V403 (1B3).

Anastigmatic Deflection Yoke

The anastigmatic deflection yoke has the windings spaced in a manner that gives very little deflection spot defocusing.

Low Voltage Supply

The low voltage power supply provides the filament and plate voltages for the receiver. A 5U4G (V501) rectifier tube is used to supply 290 volts DC input to the filter at approximately 230 MA. The power transformer has two 6.3 volt filament windings. One winding is grounded and supplies 11.4 amperes for all of the tubes except V202, V204 and V206. These three tubes are supplied by the second winding and draw 0.9 amperes. This winding is connected to the 140 volt bus so that the filament to cathode rating of the three tubes is not exceeded.

ALIGNMENT INSTRUCTIONS

HORIZONTAL OSC. AND AFC

1. Horizontal frequency adjustment (Top slug, T401).
   a. Short out terminals C and D of the horizontal oscillator and AFC transformer. Set HORIZONTAL DRIVE trimmer to 1½ turns from tight.
   b. Turn HORIZONTAL HOLD control to full clockwise position and adjust the top slug of T401 until picture locks in.
   c. Adjust HORIZONTAL DRIVE, LINEARITY, and WIDTH controls for proper size and linearity of picture. If it is necessary to change the HORIZONTAL DRIVE control, readjustment of the frequency slug will be necessary.

   NOTE: If proper frequency adjustment cannot be obtained
   1. Check the grid voltage on the noise invertor tube, Pin 7, V301 (12AX7). It should be between -9 and -13.5 V., (Measure with VTVM only).
   2. Recheck Horizontal Linearity adjustment.

   d. Repeat WIDTH, LINEARITY and FREQUENCY adjustments.

2. Horizontal Waveform adjustment (bottom slug T401).
   a. Remove short from terminals C and D of T401.
   b. Connect oscilloscope probe in series with 15 mmf. capacitor to terminal C. Set scope at horizontal frequency and adjust bottom slug of T401 so that the rounded and sharp peaks of the curve are of equal amplitude.
   c. Remove scope. With HORIZONTAL HOLD control in full clockwise position, adjust frequency slug (top of T401) until picture is just out of sync as indicated by blanking bar appearing at left of picture. Back off frequency slug slightly until picture again locks in sync. This adjustment is made with BRIGHTNESS control in full clockwise position.

VIDEO I-F ALIGNMENT

Test equipment needed:
A.M. Signal generator 41.25 to 47.25 MC
RF Sweep Generator
Cathode Ray Oscilloscope
Electronic Voltmeter
4.5 V "C" battery with tap at 1.5 volts

1. Connect positive (+) terminal of "C" battery to chassis ground. Connect -1.5 V Tap to RF grid return (junction R222 and R223). Connect -4.5 V Tap to IF grid return (junction R235 and C201).
2. Connect modulated signal generator to convertor grid wafer through hole in tuner shield.
3. Connect scope or VTVM across detector load resistor (R213).
4. Tune the signal generator to the following frequencies and adjust the corresponding slugs for as indicated in table below:

FREQUENCY	ADJUST	INDICATION
47.25MC	T203 (Top) 2nd IF	Minimum
47.25MC	T201 (Top) IF Input	Minimum
43.5 MC	T201 (Bottom) Input IF	Maximum
45.6 MC	Convertor Coil	Maximum
43.3 MC	T202 (Bottom) 1st, IF	Maximum
45.2 MC	T203 (Bottom) 2nd IF	Maximum
44.1 MC	T204 (Bottom) 3rd IF & Det	Maximum

NOTE: Do not readjust IF input coil after peaking converter coil.

5. Remove signal generator and connect sweep generator to antenna terminals through proper impedance matching network, see Fig. 1. (If generator output is unbalanced) loosely couple marker generator to IF chassis.

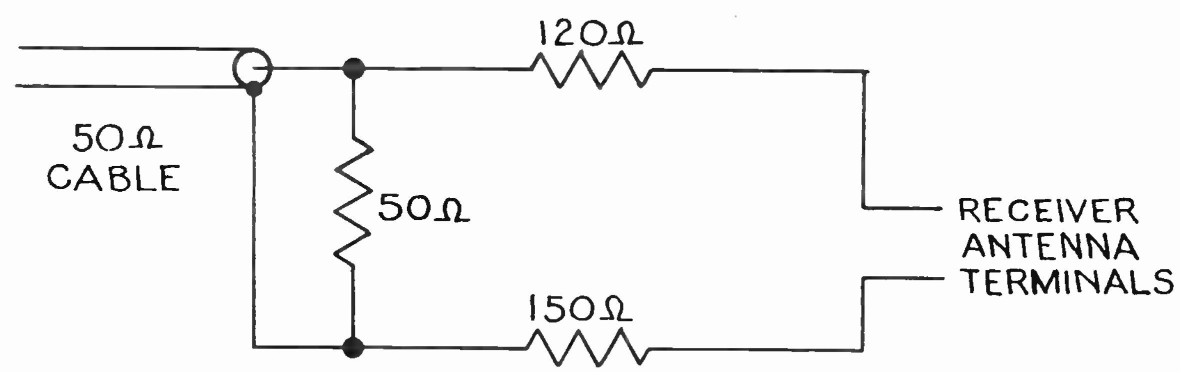

FIG. 1

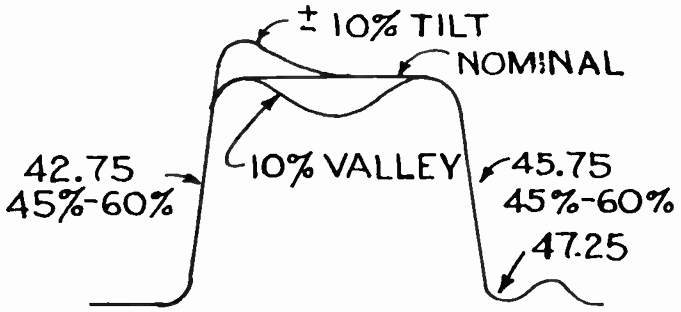
6. Tune sweep generator and television chassis to channel 4.
7. Retouch IF coils only if overall RF-IF curve does not fall within the limits shown. The RF oscillator must be on frequency when making this check.



OVERALL I-F CURVE

Note: To correct tilt, the 3rd IF (44.1MC should be adjusted. For correct marker-setting, the 1st IF (43.3MC) or 2nd IF (45.2MC) should be adjusted.

SOUND I-F ALIGNMENT

1. Connect VTVM through 1 mg. isolating resistor, across R101 (39K) limiter grid resistor. CAUTION: Case of VTVM will be at + 85 volts.
2. Connect 4.5 MC signal to terminal D (T204) and chassis ground.
3. Adjust L206 sound take-off coil and L101, sound IF coil for maximum reading. Keep output of signal generator low, so that this maximum reading does not exceed -2 volts.
4. Remove VTVM and connect from junction of R108 and C106 to ground.
5. Adjust primary (bottom slug) of T101 discriminator transformer for maximum output, and secondary (top slug) for zero reading.
   NOTE: For accurate alignment do not change level of signal input after Step 3 above. It may be necessary to detune secondary of T101 before peaking of the primary can be accomplished.

RF TUNER ALIGNMENT

Oscillator alignment should be made only when the fine tuning control tunes in the extreme clockwise or counter-clockwise position or if it will not tune at all within its tuning range.

TOUCH UP OSCILLATOR ALIGNMENT

If some channels do not tune at all, or not near enough to the center of the fine tuning range, adjust the oscillator trimmer for the best compromise tuning on all channels. If, for example all channels tune near one side of the control, adjustment of the trimmer will bring them all near the center. If the range of the trimmer is not sufficient to accomplish this, check the space between the "hot" plate of the fine tuner and the fine tuner cam. This space should not be greater than .015". If it is necessary to change the space it can be adjusted by carefully bending the "hot" plate. CAUTION: Do not decrease the space to the point of excessive rubbing. If some channels tune near one end and others tune at the other end of the control, adjustment will move some to the center and move the others beyond the range of the control. In this case the oscillator coils will have to be adjusted individually as follows:

COMPLETE OSCILLATOR ALIGNMENT

Connect a sweep generator to the antenna terminals of the receiver. Connect an unmodulated signal generator to the antenna terminals and tune it to the Channel 13 video carrier frequency. TV signals may be used.

Loosely couple an unmodulated signal generator to the first IF grid and tune it to 45.75MC. Connect an oscilloscope across the video detector load resistor.

Turn on the receiver and set the vernier to the mid range position. When the receiver has warmed up, if there are two markers on the scope, determine which rotation of the vernier causes the markers to coincide. If it is clockwise, reset the vernier to the midrange position and close the Channel 13 oscillator coil. If it is counter-clockwise, open the coil. Adjust for a zero beat. The Channel 13 coil moves all high band channels. The Channel 6 coil moves all low band channels.

CHANNEL NO.	BANDWIDTH (MC)	PICTURE CARRIER	SOUND CARRIER	LOCAL OSCILLATOR
2	54-60	55.25	59.75	101
3	60-66	61.25	65.75	107
4	66-72	67.25	71.75	113
5	76-82	77.25	81.75	123
6	82-88	83.25	87.75	129
7	174-180	175.25	179.75	221
8	180-186	181.25	185.75	227
9	186-192	187.25	191.75	233
10	192-198	193.25	197.75	239
11	198-204	199.25	203.75	245
12	204-210	205.25	209.75	251
13	210-216	211.25	215.75	257

Tune the sweep generator to Channel 12. The signal generator to the Channel 12 video carrier frequency. Set CHANNEL SELECTOR to 12. Adjust the Channel 12 oscillator coil for a zero beat of the markers.

Repeat the procedure for Channels 11 through 2. Recheck Channels 13 through 7. The high channel coils are adjusted by moving them up or down and the low channel coils by spreading or pushing together.

ANTENNA, RF AMPLIFIER AND CONVERTER ALIGNMENT

The desired pattern to be applied to the IF amplifiers is the result of three variables. These three variables are the ANTENNA COIL (rear wafer), the RF COIL (second wafer from rear) and the CONVERTER COIL (third wafer from rear).

These coils must be very carefully adjusted with only a slight movement. It is imperative that the following sequence of adjustment is followed to obtain the desired pattern. Antenna coils first, RF coils second, and the converter coil last. The RF wafer has B+ on it and should not be touched with the hand or a metal tool. Adjustment of the converter coil is critical. The oscillator coils (fourth wafer from rear) are properly adjusted and should not be touched.

The RF tuner has been properly aligned at the factory and should not require any additional adjustment except when tubes are replaced in the tuner. Proper selection of the replacement tube will eliminate the necessity of making these coil adjustments. Try several tubes while observing their effects on the pattern. Use the one that gives the desired pattern. It is important that the tuner cover be in place when observing the pattern.

PART I
DESCRIPTION AND SPECIFICATIONS

The Magnavox 103 series television chassis are all 24 tube receivers, including rectifiers and a direct view picture tube. All chassis of this series require an external audio amplifier either in an associated radio chassis in the combination models or the 127 amplifier for television only. Features of the 103 series include:

- R-F Tuner with tuned input to give improved signal to noise ratio, increased sensitivity, and improved image rejection.
- Four stages of stagger-tuned video I-F for reduced phase distortion, increased stability and ease of alignment.
- Three stages of sound I-F, plus the first video I-F, which amplifies both video and sound I-F frequencies.
- Direct coupled video amplifiers eliminating the necessity for a DC restorer.
- Separate audio amplifier chassis, to be omitted when the TV chassis is used with a radio in combination models. In models having TV only, the audio amplifier may be operated alone, for use with a record player.
- MAGNALOK horizontal AFC system, which controls the frequency by comparing the sine wave oscillator frequency with the frequency of the sync pulses. The result is applied to a reactance tube that controls the oscillator frequency.
- Amplified AGC affords maximum uniformity of performance when changing stations and reduces fading.
- De-energizing circuit eliminates bright spot on picture tube when the power is turned off.

RECEIVER OPERATING INSTRUCTIONS

1. Plug the receiver power cord into the power outlet.

2. Set the TV-PHONO switch on the rear of the TV chassis to TV.

3. Turn on the radio chassis and set the band selector switch to TV in combination models. On TV models only, turn the PICTURE OFF-ON control to the right about ½ turn.

4. Set the STATION SELECTOR switch to the desired channel number.

5. Adjust the FINE TUNING control for the best quality sound. Set the desired sound volume with the VOLUME control.

6. Advance the BRIGHTNESS control to slightly illuminate the picture tube screen. If no light appears, it may be due to incorrect ion trap adjustment. The proper procedure for adjusting the ion trap follows:

   With the brightness control full on, adjust the ion trap until light appears on the screen. Reduce the brightness to a point near extinction by turning the brightness control counterclockwise. Readjust the ion trap for maximum brightness. It may be necessary to reduce brightness still farthur and readjust the ion trap.

7. Adjust the PICTURE control for the desired contrast.

8. If the picture "rolls" up or down, turn the VERTICAL control knob so the "roll" is downward, then turn it in the opposite direction until the picture moves up to lock in frame. Switching from channel to channel will not cause the picture to lose sync if the control is properly set.

9. If the picture does not snap into horizontal sync immediately on being switched to a picture channel, but instead shows diagonal bars that slowly reduce in number until the picture snaps in, the following adjustments should be made. Remove the Horizontal Discriminator tube (V-116, 6AL5) and adjust the HORIZONTAL HOLD SCREW until the picture slowly moves back and forth with the blanking bar vertical. Replace the AFC discriminator tube. After allowing time for the tube to warm up, the picture should fall into sync immediately upon switching from channel to channel.

10. If horizontal linearity is unsatisfactory, adjust the Drive control for maximum width. This point may be determined by observing the height, as minimum height occurs simultaneously. Then adjust linearity control for linear pattern.

11. Adjust the HEIGHT control until the picture just fills the mask vertically. Adjust the VERTICAL LINEARITY until the test pattern is

symmetrical from top to bottom. These two controls are interacting and should be adjusted together.

12. The FOCUS MAGNET has an adjustable shunt ring that governs the amount of magnetic flux controlling the size of the electron stream. Set the FOCUS CONTROL at about mid-range, and adjust the shunt ring so proper focus appears at this point. This ring is adjusted by loosening the "Shunt Ring Adjusting Screw" shown in Figure 1, and moving the ring parallel to the neck of the tube. Any further focusing can be accomplished with the focus control.

It will probably be necessary to readjust the ion trap after the shunt ring has been moved.

13. To center the picture, loosen the screw on each side of the focus coil and move the coil about the neck of the tube until proper centering is accomplished. Tighten the screws with the coil in this position.

14. If shadows appear in the corners of the picture, adjust the spring loaded screws holding the focus magnet support plate to tilt the focus magnet in the direction to eliminate the shadows.

PART III
CIRCUIT DESCRIPTION

The tuner is a two tube unit with tuned input, providing good sensitivity, image rejection and signal to noise ratio. It consists of a 6BC5 pentode R-F amplifier and a 12AT7 twin-triode as oscillator-mixer. The antenna input transformer matches a 300-ohm balanced antenna to the tuner input, and has an electrostatic shield between primary and secondary. The channel selector is a positive acting, twelve position switch, connecting individual inductances for each channel. One oscillator adjustment suffices for all channels, and fine tuning is accomplished by a smooth operating, variable dielectric capacitor. The schematic diagram is shown in Fig. 12.

The video I-F amplifier is of the latest design incorporating adequate gain and band width. It consists of four 6CB6 tubes coupled by I-F transformers. I-F transformers are bi-filar wound, and coupling between stages is by the capacitive and inductive coupling between windings. The transformers are tuned by an adjustable iron core. The I-F passband is 3.75 Mc. wide, with a response of 50% at 22.0 Mc.

The converter coil and four transformers are stagger-tuned. The first stage includes a 19.75 Mc. adjacent channel picture trap. The second stage includes a 27.25 Mc. adjacent channel sound trap. A 21.25 Mc. sound trap is included in the third stage. These traps insure a minimum of interference from adjacent channels and the sound channel.

The first stage accommodates both the sound and video I-F signals. The sound portion is removed by the sound take-off transformer T105.

AGC bias is applied to the first three stages, and controls their gain inversely proportional to the applied signal strength. The last stage operates at cathode bias. The output of the I-F amplifier strip is essentially constant despite variations of input signal level.

The IN60 crystal detector conducts on negative cycles. Current flowing through its load resistor develops a voltage that varies with the modulation of the I-F carrier. The high frequency I-F component is bypassed to ground through a 10 mmf. capacitor and C137, .0015.

The first video amplifier is conventional and is direct coupled to the next stage, presenting a positive signal to the second video amplifier. The picture control governs the cathode degeneration of the second video amplifier.

The peaking network between the second video amplifier and the picture tube is conventional, except for the 4.5 Mc. trap, that is included to eliminate any beat between the sound and picture carriers.

The picture tube is grid modulated with a negative signal. Its brilliance is variable by means of the brightness control in the cathode circuit. The picture control has the AC switch on it, and also a switch that opens, putting −100 volts on the picture tube cathode thus decreasing the grid bias to zero when the power is turned off, quickly discharging the high voltage supply. This eliminates the bright spot noticeable on the picture tube of some receivers.

The sound I-F take-off transformer is tuned to 21.25 Mc. and removes the frequency modulated sound I-F signal from the video I-F strip. The three transformer coupled sound I-F amplifiers are all conventional. This highly efficient circuit applies an adequate signal to the FM discriminator. The resultant audio signal is applied to the amplifier section of the associated radio chassis when used in combination models.

Models featuring TV only use a high fidelity audio amplifier Amp. 127A. This amplifier chassis has its own power supply, a 6SJ7 audio amplifier and a 6V6 power output. It also contains the audio cable socket and speaker socket. Its line cord plugs into the AC socket on the TV chassis.

A Phono-TV switch and a phono jack are located on the rear apron of the TV chassis in models featuring TV only. For TV reception the switch must be turned to TV. When an external record player is used, its output is plugged into the phono jack and the switch must be in the Phono position. In the Phono position, 117V AC is applied to the Amp. 127 but not to the TV chassis. Thus the amplifier may be used independently.

The vertical and horizontal sync pulses appear on the video carrier, through the I-F amplifiers, detector and video amplifiers, between scanning lines of video modulation. Their appearance at the picture tube grid is always during retrace time, and cuts the beam to blanking level at those intervals.

The positive going signal, Fig. 4 (a), is sampled at the plate of the first video amplifier, and applied to the grid of the first sync amplifier V-112A. This tube is biased so the video portion of the signal falls below the knee of its characteristic curve, and receives but little amplification, and the sync pulses appear on the linear portion of the curve, and are amplified, as shown in Fig. 4 (b).

The negative signal that is fed to the second sync amplifier grid V-112B is again amplified. This tube is also biased so that any noise on the crest of the pulses is removed, and any noise between the sync pulses is reduced to their amplitude. The resulting wave form is shown in Fig. 4 (c).

The signal is in a positive direction at the sync clipper grid V-113A, and in that stage the lower half of the signal is removed, leaving only clean, square sync pulses, as shown in Fig. 4 (d).

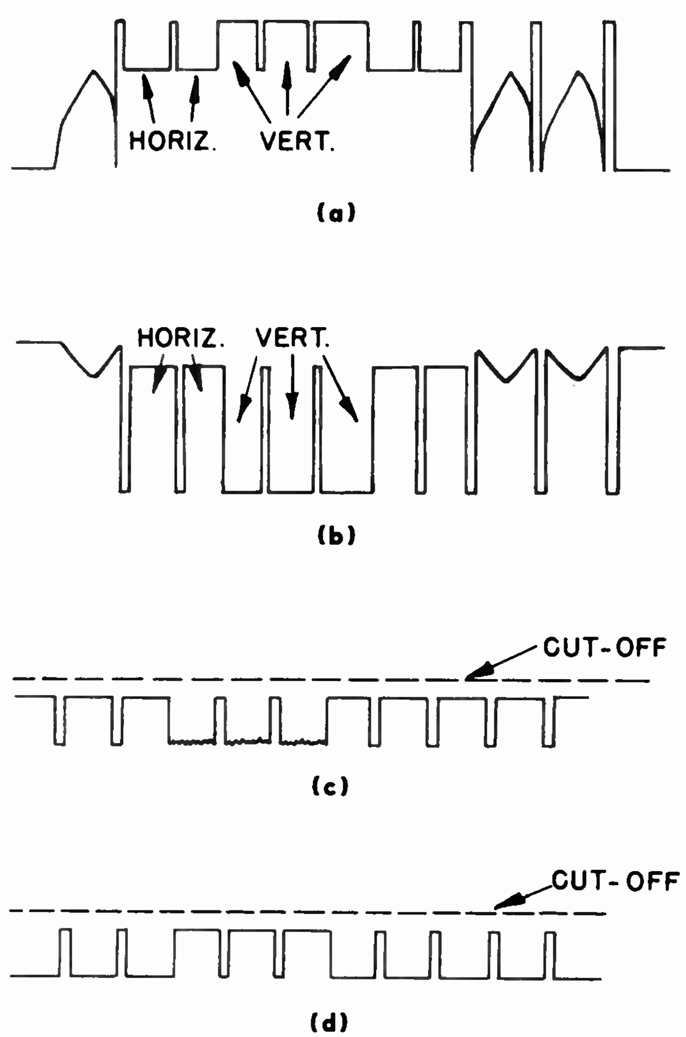

FIGURE 4

These are applied to the vertical oscillator stage V-113B, through RC-101, a filter network which passes only the low frequency vertical pulses. The vertical blocking oscillator and discharge stage, V-113B, is ½ of a 6SN7. During non-conduction, the grid voltage is negative with respect to the cathode. The plate draws current during discharge at a rate determined by the setting of the height control R-239. Due to the coupling of the oscillator transformer, there is a corresponding voltage rise on the grid, A to B in Fig. 5. When the grid becomes more positive than the cathode, it draws grid current. This quickly charges C-205, which drives the grid negative and cuts off the plate current, see B to C. Then the charge on C-205 is slowly discharged through the vertical speed control, R-218 and R-216, which allows the grid voltage to slowly rise to its normal bias, see C to A. Then plate current begins to flow again and the cycle is repeated at a frequency depending on the rate of C-205 discharge, which is controlled by the setting of R-218.

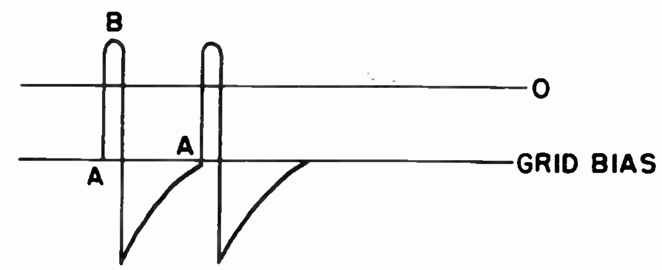

FIGURE 5

The frequency is adjusted at slightly slower than 60 cps. During the charging period of C-205 (C to A), the vertical sync pulse is applied just before it would "trip" in its free-running cycle. The magnitude of the sync pulse is sufficient to drive the tube into conduction, and therefore controls the frequency of the blocking oscillator.

The sync clipper output signal is also used to synchronize horizontal scanning. When free running, the Horizontal Oscillator V-117A operates at a frequency approximately correct for horizontal scanning. The resultant sine wave output is applied through T-112 to the plates of the Horizontal Discriminator V-116 *180° out of phase*. The horizontal sync pulses are applied to the center tap of the plate winding of the transformer, and appears at the plates of the Discriminator *in phase*. When the oscillator operates in synchronism with the transmitter, the pulses appear on the sine waves as one plate goes through zero voltage in a negative direction and as the other plate goes through zero voltage in a positive direction.

This may be seen in Fig. 6 (a).

Because the pulses appear when both plates are at zero voltage, there is no change in the operation of the circuit. However if the oscillator changes in frequency, the sync pulses at the detector plates do not appear when the oscillator voltage is zero, but at a point on each sine wave either before or after it goes through zero, as shown in Fig. 6 (b).

As the sine wave on one plate is of opposite polarity from the other, and as the sync pulse on one plate is of the same polarity as the other, the sync pulse will add to the sine wave that is positive, and subtract from the one that is negative. This condition will produce a voltage unbalance in the cathode circuit of the Discriminator.

This voltage difference, applied to the grid of V-115, the 6AU6 Horizontal Control stage, controls the variable reactance in shunt with the horizontal oscillator tank circuit, and causes the oscillator to change frequency in such a direction so as to come back into exact synchronism with the sync pulses.

Control for setting R-F bias. Use Plug Adaptor to plug into AGC tube socket, V105, AGC tube is removed.

FIGURE 8

PART IV
ALIGNMENT

DEFLECTION CIRCUIT ALIGNMENT

The horizontal AFC circuits are to be adjusted as follows:

1. Set station selector to a channel with a station.
2. Lock the picture in with the vertical control.
3. Remove the horizontal discriminator tube (V-116, 6AL5).
4. Adjust HORIZONTAL HOLD screw (rear of chassis) until diagonal bars disappear and the picture moves slowly across the screen with the blanking bar vertical.
5. Replace the 6AL5 tube and wait for it to warm up.
6. Adjust oscillator PHASING slug (inside chassis on oscillator transformer) to center the picture in the raster.
7. Adjust the HORIZONTAL DRIVE control counterclockwise until a bright vertical stripe is visible in the picture. Turn the control clockwise until the stripe disappears.
8. Adjust the HORIZONTAL LINEARITY screw for best linearity.
9. Adjust the WIDTH so the picture fills the mask.

VIDEO I-F ALIGNMENT

1. Adjust the bias on the tuner AGC lead to -2 volts by using the variable resistor and plug assembly (illustrated in Fig. 8) substituted for the AGC tube.
2. Connect the I-F signal generator to the converter grid wafer (through the hole provided in the bottom of the tuner shield) and chassis ground.
3. Connect the oscilloscope to the first video plate through a 10,000 ohm isolating resistor. The purpose of the oscilloscope is to observe the demodulated signal and make sure no overload develops. Overload is detected by no increase in output for an increase in input, and a distorted waveform.
4. Set the modulated signal generator to 19.75 Mc. and adjust the trap coil L-101 for minimum response.
5. Set the signal generator to 21.25 Mc. and adjust the trap coil L-103 and the sound pick-off coil T-105 for minimum response.
6. Set the signal generator to 27.25 Mc. and adjust trap coil L-102 for minimum response.
7. Set the signal generator to 25.5 Mc. Be sure the signal does not overload the receiver. Align the converter coil on the R-F tuner for maximum response.
8. Set the signal generator to 21.8 Mc. and adjust the first I-F transformer T-104 for maximum response.
9. Set the signal generator to 23.8 Mc. and adjust the second I-F transformer T-106 for maximum response.
10. Set the signal generator to 22.3 Mc. and adjust the third I-F transformer T-108 for maximum response.

To check the overall alignment, set the bias on the tuner AGC lead to −2 volts. Connect the sweep generator to the receiver antenna terminals. Connect the oscilloscope to the first video amplifier plate through a 10,000 ohm isolating resistor. Tune the receiver and the sweep generator to channel 13.

The video I-F can now be retouched if necessary to obtain the overall frequency response curve, Fig. 9, with the picture carrier at approximately 40% of maximum response as shown in the curve drawing. In making the final touch up adjustments, it should be remembered that the converter stage and the first video I-F stage are high Q circuits and tend to control the response at the high and low frequency ends of the pass band. The third and fourth video I-F's are relatively low Q circuits and they control the response over the center of the passband. The second video I-F controls the tilt. All twelve channels should be checked for alignment.

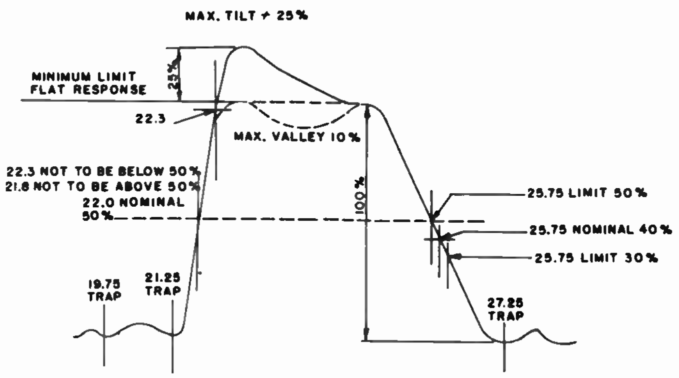

FIGURE 9

OSCILLATOR ADJUSTMENT

Set channel selector on channel 13. Apply a crystal controlled, amplitude modulated sound carrier to the receiver antenna terminals. Set the fine tuner to the mid-range position. Tune the oscillator trimmer for the null in the sound output. Each channel should be checked for proper tuning, the null should be more than 30 degrees rotation from either end of the fine tuner rotation.

NOTE: Complete alignment of the R-F Tuner is covered in other manuals and will not be repeated here. The schematic diagram of the tuner is shown in Fig. 12.

SOUND I-F ALIGNMENT

1. Adjust the bias on the tuner AGC lead to −2 volts by using the variable resistor and plug assembly. Set the modulated signal generator to 21.25 Mc. Connect the output cable of the generator to the grid of the first sound I-F (Pin 1 of V-101) and chassis ground. Connect an oscilloscope or VTVM to terminal 1 of T-102 through a 470,000 ohm isolating resistor. Align both slugs of T-101 and T-102 for maximum output.
2. Connect the oscilloscope to the junction of C-126 and R-116. Align the bottom slug of the discriminator transformer (T-103) for minimum output. Disconnect the signal generator.
3. Connect the sweep generator to Pin 1 of V-101 and chassis ground. Connect the oscilloscope to terminal 1 of T-102 through a 470,000 ohm isolating resistor. Check for symmetrical response about 21.25 Mc.
4. Connect the oscilloscope to junction of R-116 and C-126, and check the discriminator (T-103) for symmetrical output.

4.5 MC. TRAP ALIGNMENT

Connect the modulated signal generator to the first video amplifier grid. Tune the generator to 4.5 Mc. Connect a crystal detector to the picture tube grid lead. Turn the contrast control fully counterclockwise. Observe the signal at the crystal detector load resistor on an oscilloscope and adjust the 4.5 Mc. trap for minimum output at the scope.

I-F ALIGNMENT CHARTS

1. VIDEO I-F

This chart was prepared from the preceding detailed information, and is condensed in chart form for your convenience.
Caution: Set R-F bias to −2 volts as outlined in text before proceeding.

Connect Signal Gen.	Mod.	Connect Sweep Gen.	Freq. Mc.	Connect Scope	Adjust	For	Remarks
(1) Convertor Grid Wafer On Tuner	AM		19.75	Plate, Pin 2 Video Amp.	Trap L-101	Min.	Adjacent Channel Picture
(2)			21.25	V-110A Through	Trap L-103	Min.	Co-Channel Sound
(3)			21.25	10,000 ohm Isolating	T-105	Min.	Sound Takeoff Coil

PART V
SERVICE INFORMATION

PICTURE TUBE REPLACEMENT (HORIZONTAL CHASSIS)

If it becomes necessary to replace the picture tube, it should be done in the following manner.

1. Remove the tube socket from the rear of the picture tube, then remove the ion trap.
2. Remove the safety glass assembly by taking out the screws which hold the glass rail in position.
3. Loosen the nuts that secure the tube strap over the rim of the tube, and remove the strap.
4. Remove the high voltage anode connector and lift out the tube.
5. If metal tube, transfer the insulating ring to the replacement tube.
6. Install the HV connector, replace the support strap, and fasten it down securely with the nuts removed in step 3.
7. Loosen the thumbscrew on top of the deflection yoke, so the yoke moves freely. Loosen the two hex-head screws on each side of the deflection yoke mounting bracket, and push the top section forward until the rubber bumper fits against the bell of the tube, all the way around. Make sure tube face is vertical and neck of tube is parallel with chassis base. Then tighten the screws. If the screw heads on the left side are difficult to reach, use a right-angle spintite, an end wrench, or remove the HV compartment cover. Then press the deflection yoke forward as far as possible, and tighten the thumbscrew.
8. Tighten the three focus coil plate adjustment screws until the plate is near the deflection yoke, perpendicular to the neck of the tube.
9. Loosen the two screws which secure the focus coil, and move it so the neck of the tube is properly centered in it. Then tighten the screws and adjust the ion trap.
10. If centering is not satisfactory, move the focus coil around the neck of the tube until the picture is properly centered in the mask. It may be necessary to readjust the ion trap each time the focus coil is moved.

PICTURE TUBE REPLACEMENT (VERTICAL CHASSIS)

In models where the chassis is mounted in a vertical position, the following procedure is recommended.

1. Remove the safety glass and mask assembly by taking out the screws which hold the glass rail in place.
2. Lay the cabinet on its side on a clean piece of felt or other soft material, with the chassis side down.
3. Remove the two metal wedges that brace the rim of the picture tube top and side. Two wood screws hold each in place.
4. Two ¼-20 screws secure each side of the chassis to the mounting rails of the cabinet. Remove these screws, all connections to the amplifier, and pull the chassis out of the cabinet. Then proceed through steps 1 to 10 in the preceding section. Then replace the chassis.

NOTICE: In the event that proper centering cannot be accomplished, remove the ion trap, turn the front edge to the rear, install and readjust it. Then proceed with the centering adjustment. If proper centering still cannot be accomplished, remove the focus coil and rotate 180°.

MODIFICATIONS AND SERVICE SUGGESTIONS

SOUND DRIFT

The 103 series chassis is mounted vertically in some cabinets, and the heat rising to the tuner may cause some oscillator drift. The changes outlined below were made to compensate for this, and, if found necessary in early chassis, may be incorporated in the field.

Refer to Fig. 10 in making these modifications.

a. Replace C-21, 10 mmf. (black, brown, black, black, white) with 10 mmf. N-750 (violet, brown, black, black, white) Magnavox Part No. 250088G63. C-21 is the condenser connected from the oscillator socket to the front lug at the base of the front wafer.

b. Remove C-16, 3 mmf. N-750 (violet, black, orange, black) from oscillator socket.

c. Add 3 mmf. N-1800 (orange, orange, black, orange, black, green) Magnavox Part No. 250088G57 from rear lug at bottom of front wafer (connection point for C-17 oscillator trimmer) to chassis ground in front of oscillator socket (connection point for C-22). *Keep leads as short as possible.*

Check oscillator alignment on channel 13 (or on highest channel station) to see if oscillator tunes in with fine tuner not too close to either end of its rotation. If not, adjust oscillator trimmer C-17 (in front apron of tuner) with screwdriver.

Check oscillator alignment on all other channels (or on all available stations) to see if all other channels tune in with fine tuner not too close to either end of its rotation. If any channel does not tune in or tunes too close to either end of fine tuner rotation, adjust the inductance of the oscillator coil for that channel. Then check all lower channels, adjusting their coils also, if necessary. Re-check tuning of all channels after last coil is adjusted.

Although the above changes should correct this difficulty, in persistent cases change C-18, 100 mmf. condenser to part No. 250088-13, 100 mmf. N-750. It is also advisable to check the 22,000 ohm oscillator grid resistor R9, as this will sometimes change value with temperature increases. Changing C-18 and R-9 may also help in curing a similar complaint on the horizontally mounted chassis, but C-16 and C-21 should not be changed in this case.

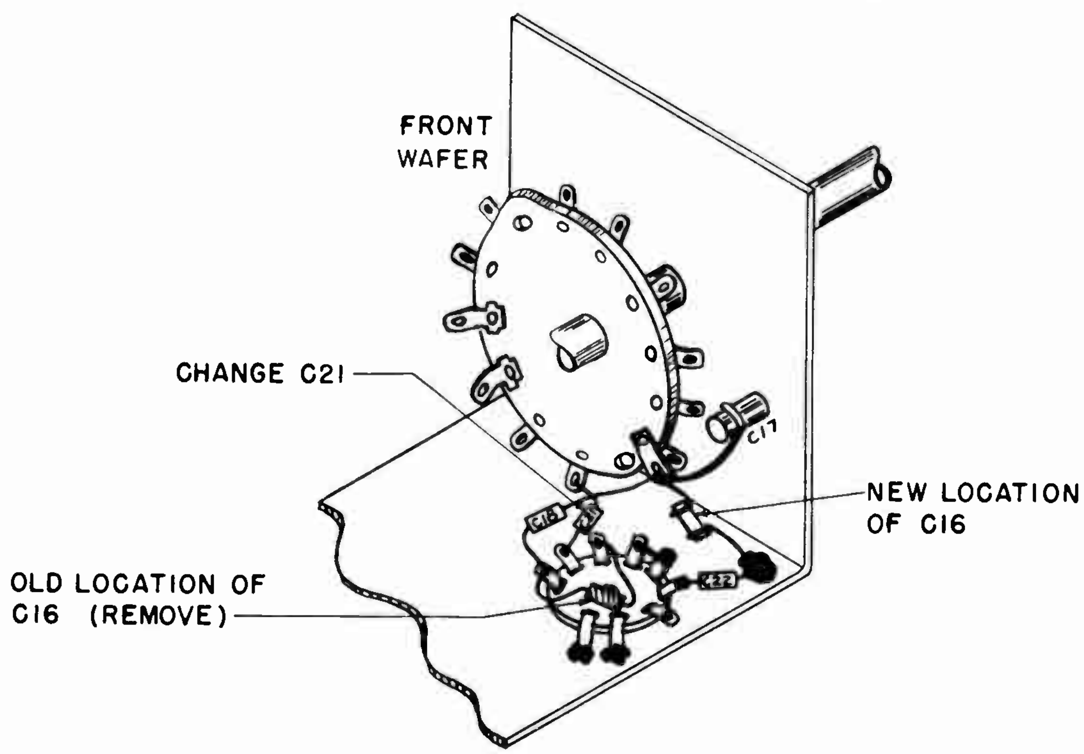

FIGURE 10

POOR RESOLUTION

Note that the overall video response curve shown in this manual differs from that of the preliminary manual. In cases of poor resolution, it is advisable to check the I-F alignment, making sure that the curve is within the limits shown in Fig. 9.

SIGNAL OVERLOAD

In very strong signal areas, some overload may be experienced on this chassis. This condition may be corrected by changing R-164 in the AGC clamp circuit to 2.7 megohms.

VOLTAGE CHART

Measurements made with receiver operating at 117 volts, 60 cycles AC, with a strong signal input. Measurements made with "Voltohmist" type VTVM, between indicated terminal and chassis ground, unless otherwise noted.

*AC voltage, measured from −100 volt tap.

‡Measured with electrostatic voltmeter.

Do not measure Horizontal Output plate or Damper plate with VTVM.

Pulses cause grid rectification in meter so reading is meaningless, and HV pulses may damage meter.

WHY THE WAVEFORMS VARY

Assuming normal operation of the television receiver, voltage waveforms often do not appear as shown. This is a function of the type of oscilloscope used, and its input cable.

These waveforms are as reproduced on a Dumont 208B instrument but another, having greater or lesser frequency fidelity, may show a waveform quite different in shape and/or size. Therefore, the service technician must be familiar with his oscilloscope, must recognize its limitations and must make mental correction if waveforms do not appear to be "normal."

The same logic applies to the measure of D-C voltages. Measurements shown here are on an RCA Voltohymist, Jr. and the use of a 20,000 ohm per volt movement will indicate some D-C voltages to differ greatly from those shown. Again, logic and reasoning must be applied, realizing that in a high impedance circuit, the indicated voltage will be less than the actual operating voltage.

Allowances for scope waveforms and D-C meter readings may be computed if all pertinent factors are known, but the experienced technician makes mental correction and allowances to the end that high fidelity instruments are not required.

PART VI

CIRCUIT DESCRIPTION

General

This chassis is designed to power a 27", 90 degree picture tube and supplies full sweep at a maximum high voltage consistent with the tube rating. Light output (using the aluminized tube) is comparable to or greater than that of the smaller screen chassis. A total of 27 tubes (including picture tube and rectifiers) plus a crystal detector is used.

The design features a cascode RF tuner, an increased sensitivity full bandwidth video IF amplifier, and wide band video amplifier to provide a high contrast, high definition picture. Other special features include a high gain intercarrier—sound IF amplifier with limiter and ratio detector, and a 10 watt push-pull audio amplifier. There are direct provisions for a UHF tuner, which can be added when needed.

The horizontal output system is of the new efficient auto transformer type, providing greater high voltage with full 90 degree deflection. The vertical deflection system provides full sweep with positive interlace.

Further features employed in the 107 design are, keyed AGC and noise inverter for optimum fringe area performance, and the "synchroguide" horizontal oscillator and AFC system.

The 107 design employs a single shallow-pan chassis for ease of service. The plug-in deflection yoke and 27" picture tube mount separately in the cabinet. The chassis is designed for any mounting position including side mounting.

The 107 chassis is rated for 117 volts 60 cycles AC line potential with power consumption of 315 watts. Sufficient additional power capacity for the UHF tuner has been included in the design of the power supply.

Cascode RF Tuner

The cascode RF tuner consists of an RF amplifier V1 (6BQ7) and mixer-oscillator V2 (6U8). A 12-position channel selector rotary switch is used with a concentric shaft which operates the variable fine tuner. For ease of alignment, inductances adjustable by bending or spreading are provided on every channel.

As shown in the schematic diagram, the secondary of the antenna transformer T1 is tuned for each channel by shunting it with the proper value of inductance (S1, Section 4) to make it resonate with the RF tube V1 (6BQ7) input capacity. L1 and C1 form an IF trap, which is tuned to 44.5 MC for best average IF rejection on all channels. To further minimize IF interference an external IF trap assembly is available for those few areas where the overall IF interference is severe. These traps are series-connected in the receiver antenna lead-in and should be tuned to give maximum rejection at the undesired IF frequency.

Tuning of the RF plate and mixer grid is accomplished by wafer sections 3 and 2, which are identical to the RF grid wafer. Coupling capacitors C6, C9 and C10, connected between appropriate points provide the necessary coupling for the proper bandpass on all channels. Shields between the RF grid, RF plate and mixer grid wafers reduce stray coupling. The 6BQ7 RF tube is used in a cascode circuit (triode 1 grounded cathode, triode 2 grounded grid) to minimize triode feedback so that the superior signal-to-noise ratio of a triode is realized with good stability.

The pentode mixer V2A (1/2 6U8) is used because of its low feedback characteristic with 41 MC IF.

To reduce high band radiation from the main TV chassis, common low side capacity coupling was used to the 1st IF tube grid circuit and the tuner chassis was connected to the main chassis only at the tuner rear apron.

Video IF

The video IF amplifier operates at a picture carrier frequency of 45.75 MC, with a design bandwidth of 4.0 MC at -6 db and consists of a double-tuned circuit (low-side capacity coupled), followed by a staggered quadruple. This double-tuned circuit consists of two similar coils that are physically separated, one in the tuner (converter plate coil,) and one in the grid circuit of the 1st IF amplifier (T201).

The remainder of the IF amplifier consists of four stagger-tuned stages, using 6CB6's for maximum stable gain. Inductively coupled to the 1st, 2nd and 3rd IF plate coils are three traps, similar to that on the IF input coil. Two of these traps are tuned to 47.25 MC (adjacent channel sound), and one to 39.75 MC (adjacent channel picture). An additional 41.25 MC trap is capacity-coupled to the plate of the 2nd IF tube to provide additional co-channel sound rejection.

The 1st and 2nd IF stages are in series, thus reducing the drain on the low voltage supply and at the same time providing a relatively "Stiff" effective "B" voltage for better AGC action. Similarly, the 4th IF tube is in series with the sound IF amplifier.

To provide stability, all IF coils and traps, with the exception of the capacity-coupled 41.25 MC trap, are completely shielded and the detector IN64 is enclosed in the 4th IF can. Two RF chokes (L201 and the RFC in 4th IF assembly) with a self-resonant frequency of 43 MC provide isolation of the IF amplifier and prevent stray coupling of the RF component.

Video Detector & Sound IF System

The 107 chassis employs intercarrier sound IF (4.5 MC) produced by the video detector. The latter comprises a crystal diode (IN64) located accessibly within shield can (T-205) also containing the final IF bifilar coil, bypass condenser and IF stabilizing filter choke.

The 4.5 MC intercarrier sound IF signal is amplified by the single tuned 1st sound IF amplifier (V101) and in turn fed to the limiter stage (V102). The limiter stage drives a conventional ratio detector circuit which provides additional AM rejection resulting in high quality FM sound performance in the recovered audio. It is to be noted that both grid and plate limiting occur in the limiter stage.

The audio amplifier comprises a resistance coupled voltage amplifier phase inverter stage (V104) driving a pair of 6V6GT push-pull output tubes giving 10 watts of high quality audio output. A phono switch and input jack is provided at the rear of the chassis for convenient use with an external phono. Provision is also made for connecting an external radio tuner to feed the TV audio amplifier.

Video Amplifier

The video amplifier employs two stages in order to provide full bandwidth with a good margin of drive voltage (up to 130 V.P-P) for the picture tube. The first stage is a 6CB6 (V205) direct coupled to the video detector for constant level noise clipping. Sync and AGC takeoff is from the plate side of V205, the AGC tube (V208) being DC coupled to this point.

The video signal is AC coupled to the grid of the video output tube (V206). By means of grid current DC restoration takes place at this point. The combined tube characteristics of the two stages are such that good contrast in the vicinity of "white" is achieved and DC restoration on the output tube grid maintains this condition with relative black/white content changes in the signal. Partial AC coupling from the output peaking circuit (L205 and R223) to the picture tube grid is employed in order to render less critical the variation in background (DC) component when switching between channels. THE LOAD RESISTOR (R223) IS WIRE WOUND AND HAS AN AMOUNT OF INDUCTANCE WHICH IS A PART OF THE COMPENSATION EMPLOYED AND SHOULD NOT BE REPLACED BY A NON-INDUCTIVE RESISTOR.

Noise Inverter

The noise inverter is for the purpose of removing noise bursts that exceed the sync pulse level, from the signal that is fed to the AGC and sync circuits. The noise inverter (one-half 12AX7, V301A) is a grounded grid amplifier that forms a parallel signal path around the video amplifier tube. Since it is cathode driven, the noise inverter signal output is in phase with the detector signal while the video amplifier output is 180° out of phase.

The noise inverter is biased beyond cutoff, enabling it to conduct only on noise signals which exceed the sync tips at the detector.

Bias for the noise inverter is obtained from the grid bias voltage of the horizontal output tube by means of a voltage divider in the output tube grid return. A potentiometer (R304) provides for independent adjustment of noise inverter bias and horizontal drive. The noise inverter bias usually is between -9V and -13V as measured with a VTVM.

This chassis uses keyed AGC for improved noise immunity and reduction of airplane flutter effects. A series fed pulse to the AGC amplifier was chosen because of the ease of filtering the derived AGC voltage. A more rapidly acting AGC is therefore possible.

The RF AGC voltage is considerably delayed to reduce the medium signal noise content of the picture. The RF amplifier grid to cathode conduction is used as a clamp for RF bias delay in the AGC system.

Sync Separators

The sync separator consists of three triode sections (V301B), V302A, V302B) which are, respectively, the sync separator, sync amplifier, and sync clipper.

The sync separator is direct coupled to the sync amplifier operating in its positive grid region. The sync clipper is AC coupled to the sync amplifier and levels off sync tips at a uniform level. The sync clipper also serves as a phase-splitter and supplies a negative sync signal at the cathode for the vertical system, and a positive sync signal at the plate for the horizontal system.

Vertical Sweep Oscillator

The vertical sweep oscillator is a plate to grid multivibrator using a 6SN7 dual triode. The integrated vertical sync is fed to the grid of the first triode section and the output wave is taken from the plate of the second triode (vertical discharge V303B).

The feedback circuit in the multivibrator is from the peaking resistor to the grid of the first triode. PC301 is a printed circuit integrating network and this together with an additional integrating section (R312 and C307) for improved interlace provides the vertical sync pulse.

Vertical Output

The vertical output amplifier is a type 6AU5GT (V304) pentode connected, and transformer coupled to the yoke.

The capacitor across the transformer secondary reduces horizontal pulses on the vertical yoke winding and improves interlace.

Retrace blanking is obtained by superimposing part of the vertical retrace pulse on the picture tube bias so that the picture tube is biased beyond cut-off during retrace.

Horizontal Oscillator and Frequency Control

The horizontal oscillator, discharge and AFC circuits utilize a double triode tube 6SN7, (V401). The frequency of the blocking oscillator, V401B, can be adjusted by the slug of L401 (accessible at rear of chassis). The frequency of oscillation is stabilized by a tuned circuit. The inductance for the tuned circuit is L401 and the capacity is composed of C410, C411 and C412. The generated sawtooth reaches the grid of the output tube V402 through the capacity divider C410 - C411. The latter, marked horizontal drive, is variable and controls the amount of drive on the grid of V402 (6CD6G). This adjustment will affect the horizontal linearity, high voltage and inverter tube bias and to a slight degree the frequency. Feedback capacitor (C408) affects the frequency slightly.

Synchronization is accomplished by means of the AFC, V401A, as follows: A complex wave consisting of the sync pulse and a parabola is fed to the grid of this triode. The sync pulse rides near the peak of the complex wave. The tube is biased from the oscillator grid to such a value that plate current flows only during the positive peak portions of the complex wave. A portion of the integrated cathode voltage is applied to the oscillator grid. Its magnitude controls the frequency of the oscillator in such a way as to automatically lock it in synchronism.

Horizontal Output and Damper

The function of the output tube V402 is to supply sufficient current of the proper waveform to the horizontal deflection coils for normal horizontal scanning of the picture tube. The function of the damper tubes (V404 and V405) is to damp oscillations of the yoke current following retrace time and thus help provide a linear trace. Two dampers are used due to the greater current requirement for 90° deflection. Because the output transformer is the auto transformer type, "inverted" damper tubes are required, and for this reason such tubes must withstand high heater-to-cathode potentials. Other functions of this circuit are to provide a high amplitude pulse for high voltage and to recover a substantial part of the energy in the system. Part of the energy recovered appears in the form of a boost voltage at the damper cathode and part in actual deflection current in the yoke.

The output transformer is a highly efficient auto transformer, and special insulation is used to protect it against H.V. breakdown. Normal retrace time in the system is 9 to 10 microseconds. Width is controlled by L402 and linearity is controlled mainly by L403; the drive control influences linearity to some extent.

High Voltage Supply

The high voltage is supplied by part of the energy stored in the horizontal system. When the 6CD6G plate current is cutoff by the horizontal oscillator pulse, a high positive pulse of voltage appears on the high voltage winding of T401 due to the rapidly collapsing field in the system. This high positive pulse is rectified by the H.V. rectifier V403 (1B3). The total high voltage applied to the picture tube is 20 KV.

Anastigmatic Deflection Yoke & Focusing

The anastigmatic deflection yoke has the windings distributed in a manner that gives very little deflection spot defocusing. This also produces a slight amount of raster distortion. Beam straighteners are used to correct this slight distortion. Otherwise the yoke is conventional in electrical characteristics.

The 90° deflection requires that the yoke be designed physically shorter than 70° systems in order to minimize neck shadows. This makes the yoke less sensitive, thus requiring greater deflection power and consequently more current.

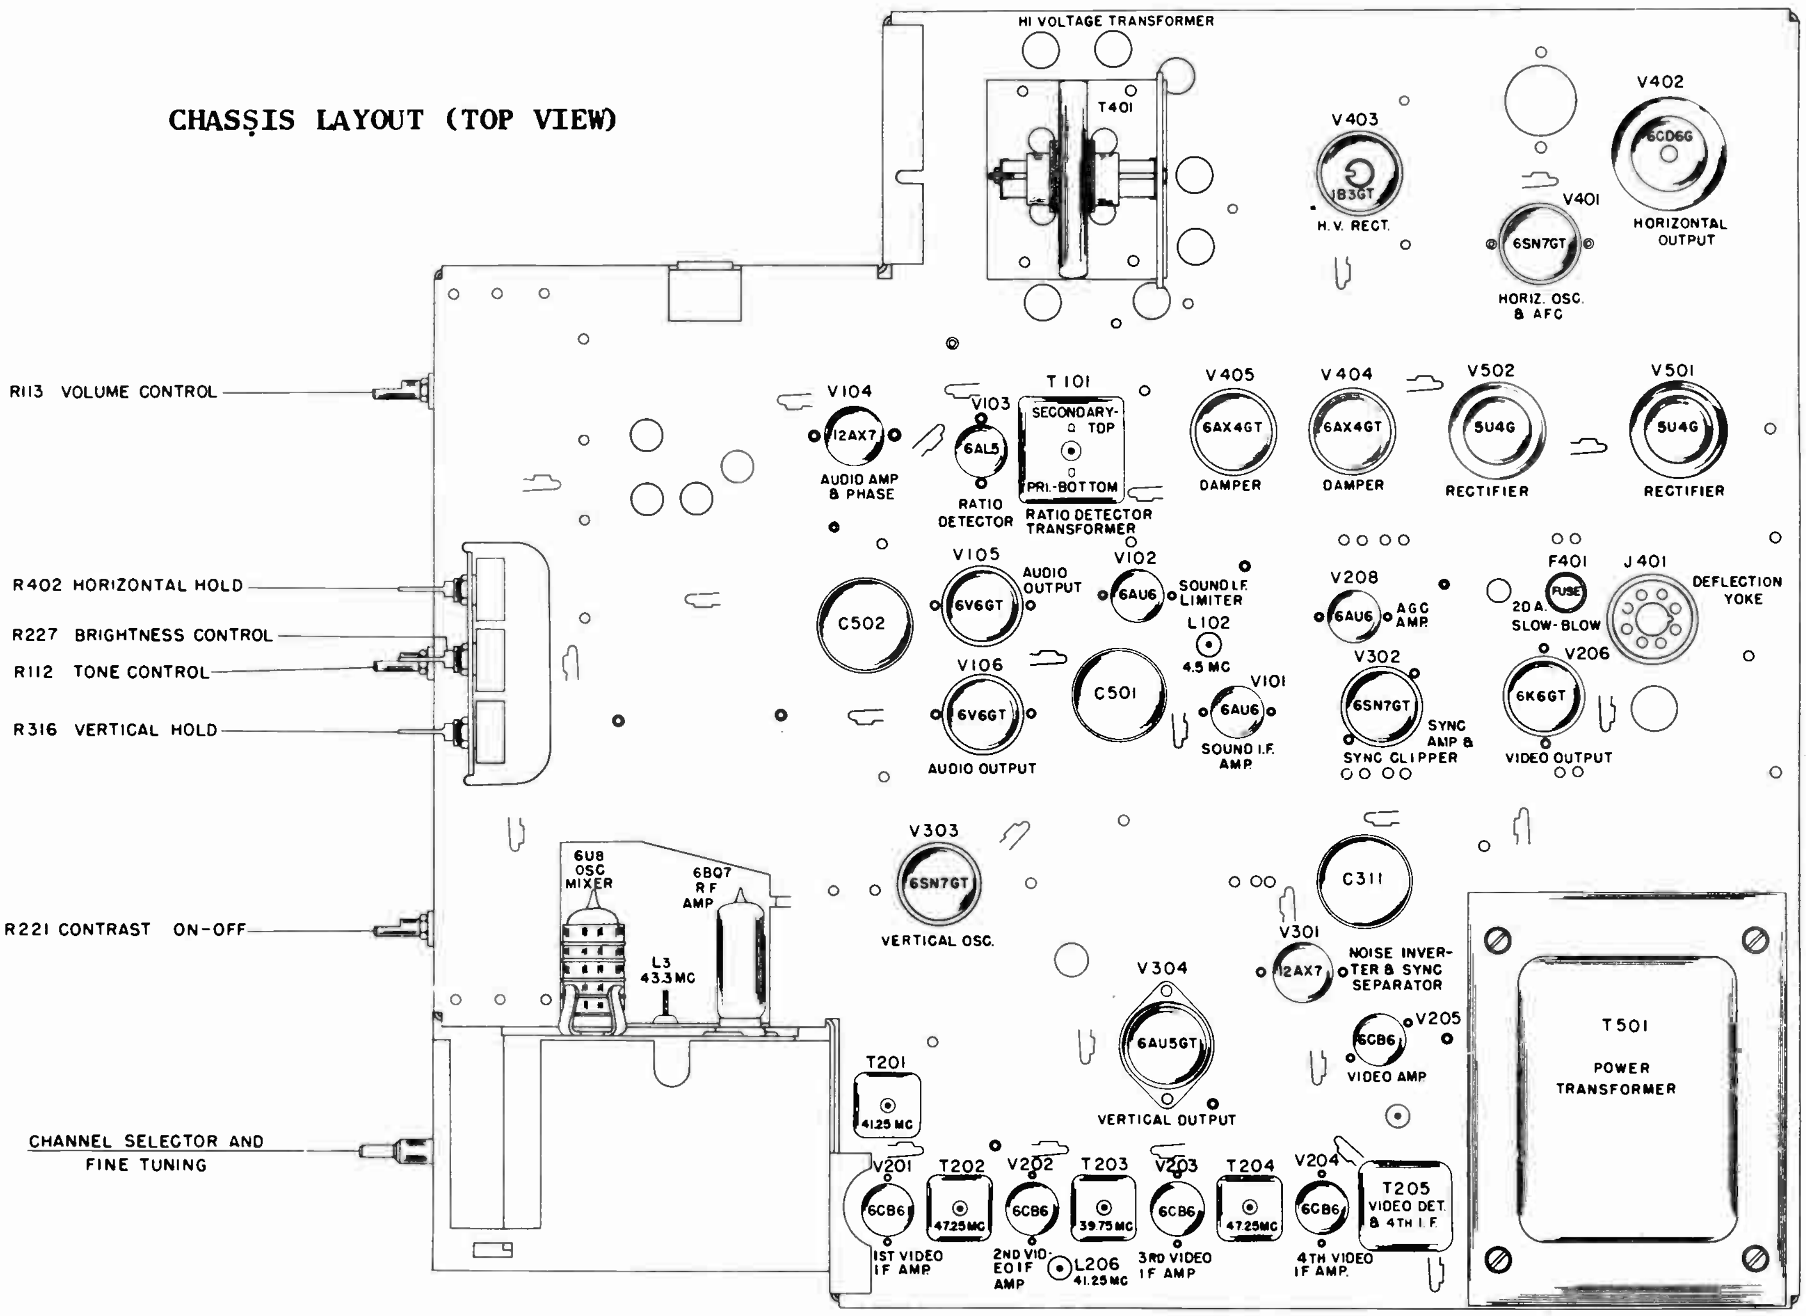
A permanent magnet focus unit which has a centering plate on the front and the focus adjusting screw at the rear of the assembly is used.

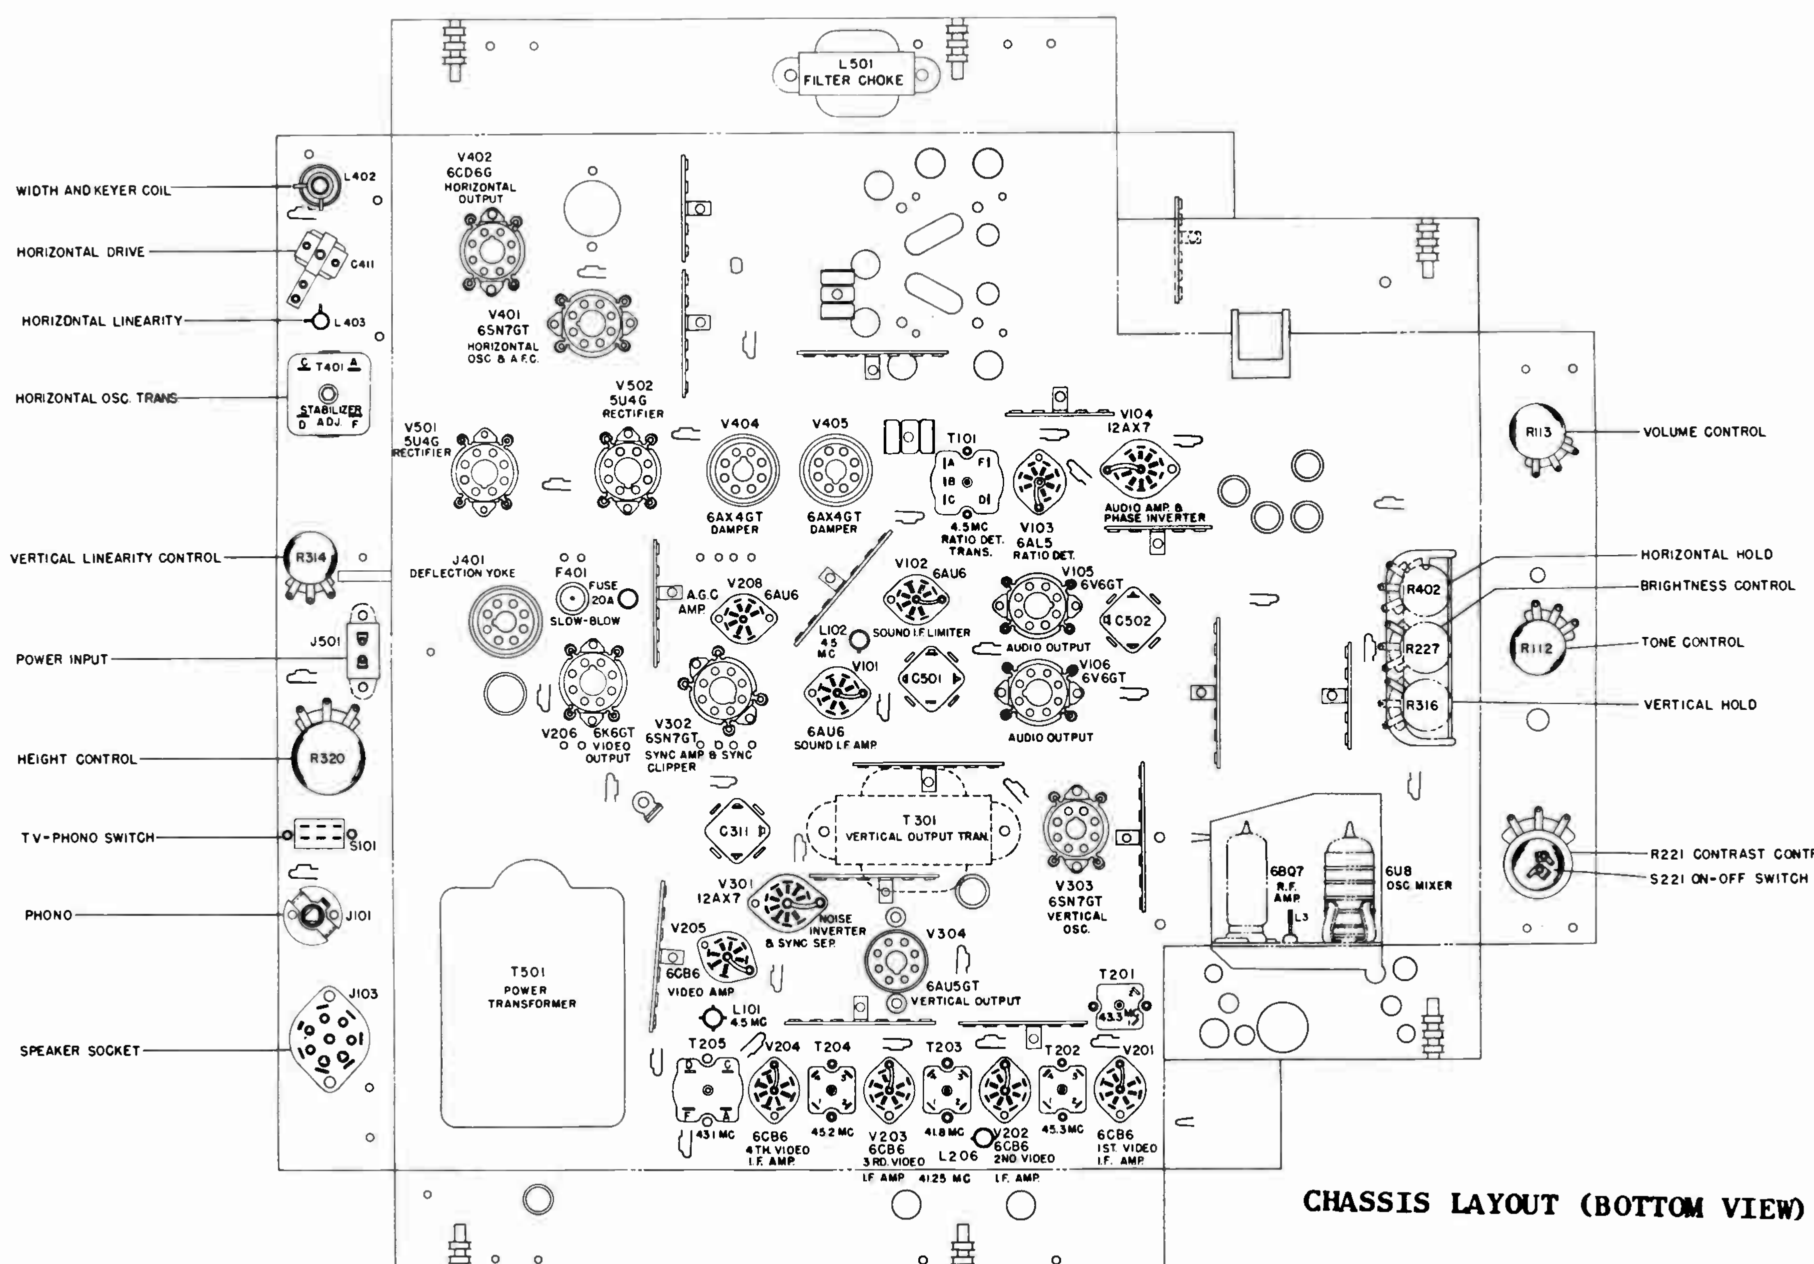
Low Voltage Supply

The low voltage power supply provides the filament and plate voltages for the receiver. Two 5U4G (V501 and V502) rectifier tubes are used to supply nominal 300 volts DC input to the filter at approximately 435 ma. The power transformer has one 6.3 volt and one 12.6 volt center tapped filament winding. The 12.6 volt winding is normally grounded at midpoint and supplies filament current for all of the tubes except V207, V101, V202, and V208. These four tubes are supplied by the second winding. This winding is connected to a 140 volt point so that the filament to cathode rating of the tubes is not exceeded.

MODEL MV 110M1, Ch. CT358, 107 Series, Prelim.

CHASSIS LAYOUT (TOP VIEW)





CHASSIS LAYOUT (BOTTOM VIEW)

ALIGNMENT INSTRUCTIONS

1. I-F ALIGNMENT

a. Using a 4.5 V "C" battery with a tap at 1.5 V, connect the positive terminal to ground. Connect the -1.5 V tap to the junction of R234 and R235, the R. F. grid return. Connect the -4.5 V terminal to the junction of R201 and C201, the I.F. grid return.

b. Connect oscilloscope and/or VTVM across R216, the video detector load resistor. The oscilloscope is preferable as overload is more easily detected.

c. Connect an AM signal generator to the convertor grid circuit. This connection can be made to convertor grid wafer of tuner through hole in bottom of tuner shield.

d. Align the following slugs for indicated output.

FREQUENCY	ADJUST	FOR
41.25 MC	T201 (Top)	Minimum Output
41.25 MC	L206 (Top)	Minimum Output
47.25 MC	T202 (Top)	Minimum Output
47.25 MC	T204 (Top)	Minimum Output
39.75 MC	T203 (Top)	Minimum Output
# * 43.3 MC	T201 (Bottom)	Maximum Output
* 43.3 MC	Convertor Coil (on tuner)	Maximum Output
# 45.3 MC	T202 (Bottom)	Maximum Output
# 41.8 MC	T203 (Bottom)	Maximum Output
# 45.2 MC	T204 (Bottom)	Maximum Output
43.1 MC	T205 (Bottom)	Maximum Output

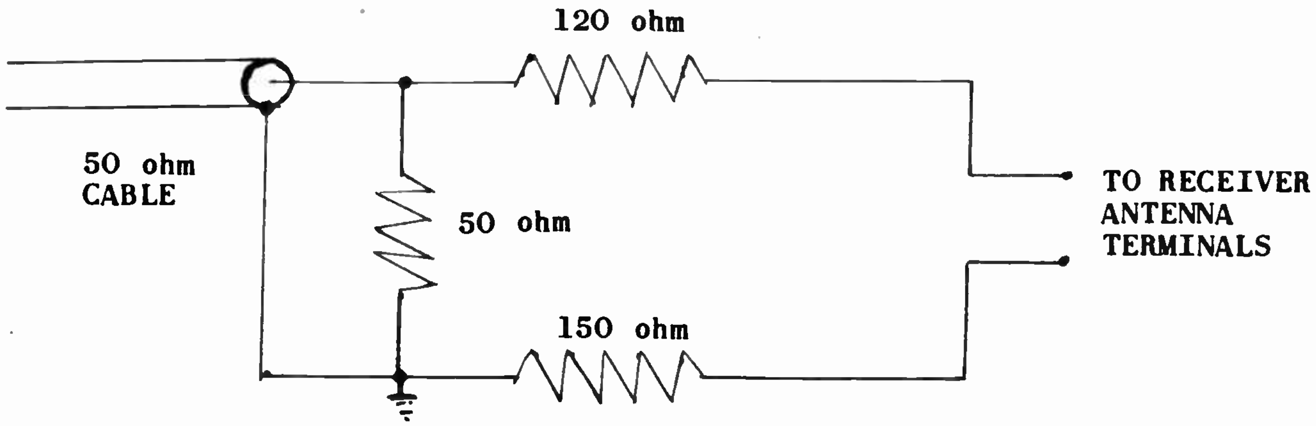
* The convertor coil and the bottom slug of T201 form a double tuned circuit and should be adjusted as follows:

(1) Detune convertor coil.
(2) Adjust T201 for maximum output.
(3) Adjust convertor coil for maximum output.
(4) Do not reset T201.

If any of these slugs require more than 3 turns readjust associated trap (top slug).

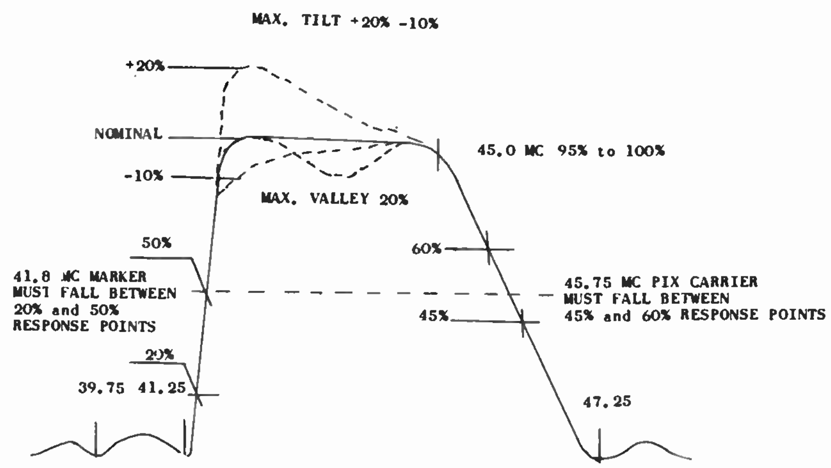
e. Remove signal from convertor grid and loosely couple signal generator for marker injection.

f. Set receiver and R-F sweep generator to channel 4 and connect R-F sweep generator to antenna terminals of receiver. Note: If balanced output cable for sweep generator is not available, the impedance matching network shown below should be used.



g. Retouch I-F slugs (bottom), if necessary, to obtain curve shown. If curve falls within prescribed limits do not readjust.

h. Check all channels for symmetry and bandwidth. If it is necessary to retouch any of the I-F adjustments, only the following should be adjusted.



To correct for excessive tilt, adjust 4th I-F (43.1 MC) coil. To adjust low frequency side of curve, adjust 2nd I-F (41.8 MC) coil. For high frequency correction, adjust the 1st & 3rd I-F coils (45.2 MC) and (45.3 MC).

2. 4.5 MC TRAP (L101) ADJUSTMENT

a. Remove V203, 3rd video I-F amplifier to prevent noise from masking output indication.

b. Connect 4.5 MC AM signal to terminal "D" of T205, video detector. Signal Input must not exceed 0.2 V. RMS.

c. Connect VTVM with crystal probe to grid lead of picture tube. (Pin 2, V207)

d. Turn contrast control to full clockwise position and adjust core of L101 for minimum output.

3. SOUND I-F ALIGNMENT

a. Connect 4.5 MC signal to terminal "D" of T205 as in 4.5 MC trap adjustment.

b. Connect VTVM from pin 7 of V103, 6AL5 to ground.

c. Adjust L102, Sound I-F coil, and primary of ratio detector transformer (bottom of T101) for maximum output. Reduce signal to maintain output below -5.0 volts to prevent overload.

d. Remove VTVM and connect negative lead to the junction of R109 and R110, and probe to junction of R108 and C112.

e. Adjust secondary (top) of ratio detector transformer for zero reading.
If secondary should require more than 3 or 4 turns for proper adjustment, repeat primary adjustment, as in (b) and (c).

4. HORIZONTAL OSCILLATOR AND AFC ALIGNMENT:

a. Tune set to weakest channel available.

b. Set noise bias control fully clockwise. Then set horizontal drive trimmer about 1/2 turn from full clockwise position as a preliminary setting.

c. Short terminals "C" and "D" of horizontal stabilizing coil (L401), and turn horizontal hold control to full clockwise position.

d. Adjust Horizontal Frequency coil (on rear chassis apron) until picture locks horizontally.

e. Adjust Horizontal Width, Drive and Linearity as follows:

1. Adjust Horizontal Drive trimmer for maximum sweep. Turn counterclockwise until compression appears at center (drive lines), then clockwise until compression is just eliminated.
2. Adjust Horizontal Linearity coil (L403) on rear chassis apron for proper linearity. Two positions may be found which appear correct. The proper adjustment is that with the core further out (counter-clockwise position).
3. Adjust Horizontal Width control (L402) on rear chassis apron for proper picture size.

f. Remove short from terminals "C" and "D" of stabilizing coil and connect oscilloscope through approximately 15 MMF capacitor to terminal "C" above.

g. Adjust stabilizing coil (L401) inside chassis so that sharp and rounded peaks of the pattern on the oscilloscope are of equal amplitude. If necessary, horizontal hold control may be adjusted to maintain sync.

h. Remove oscilloscope lead and turn horizontal hold to full clockwise position.

i. Turn Brightness Control to full clockwise position and adjust Horizontal Frequency control until blanking bar appears at left side of picture. Then back off until blanking bar and wiggle at top of picture is not present.

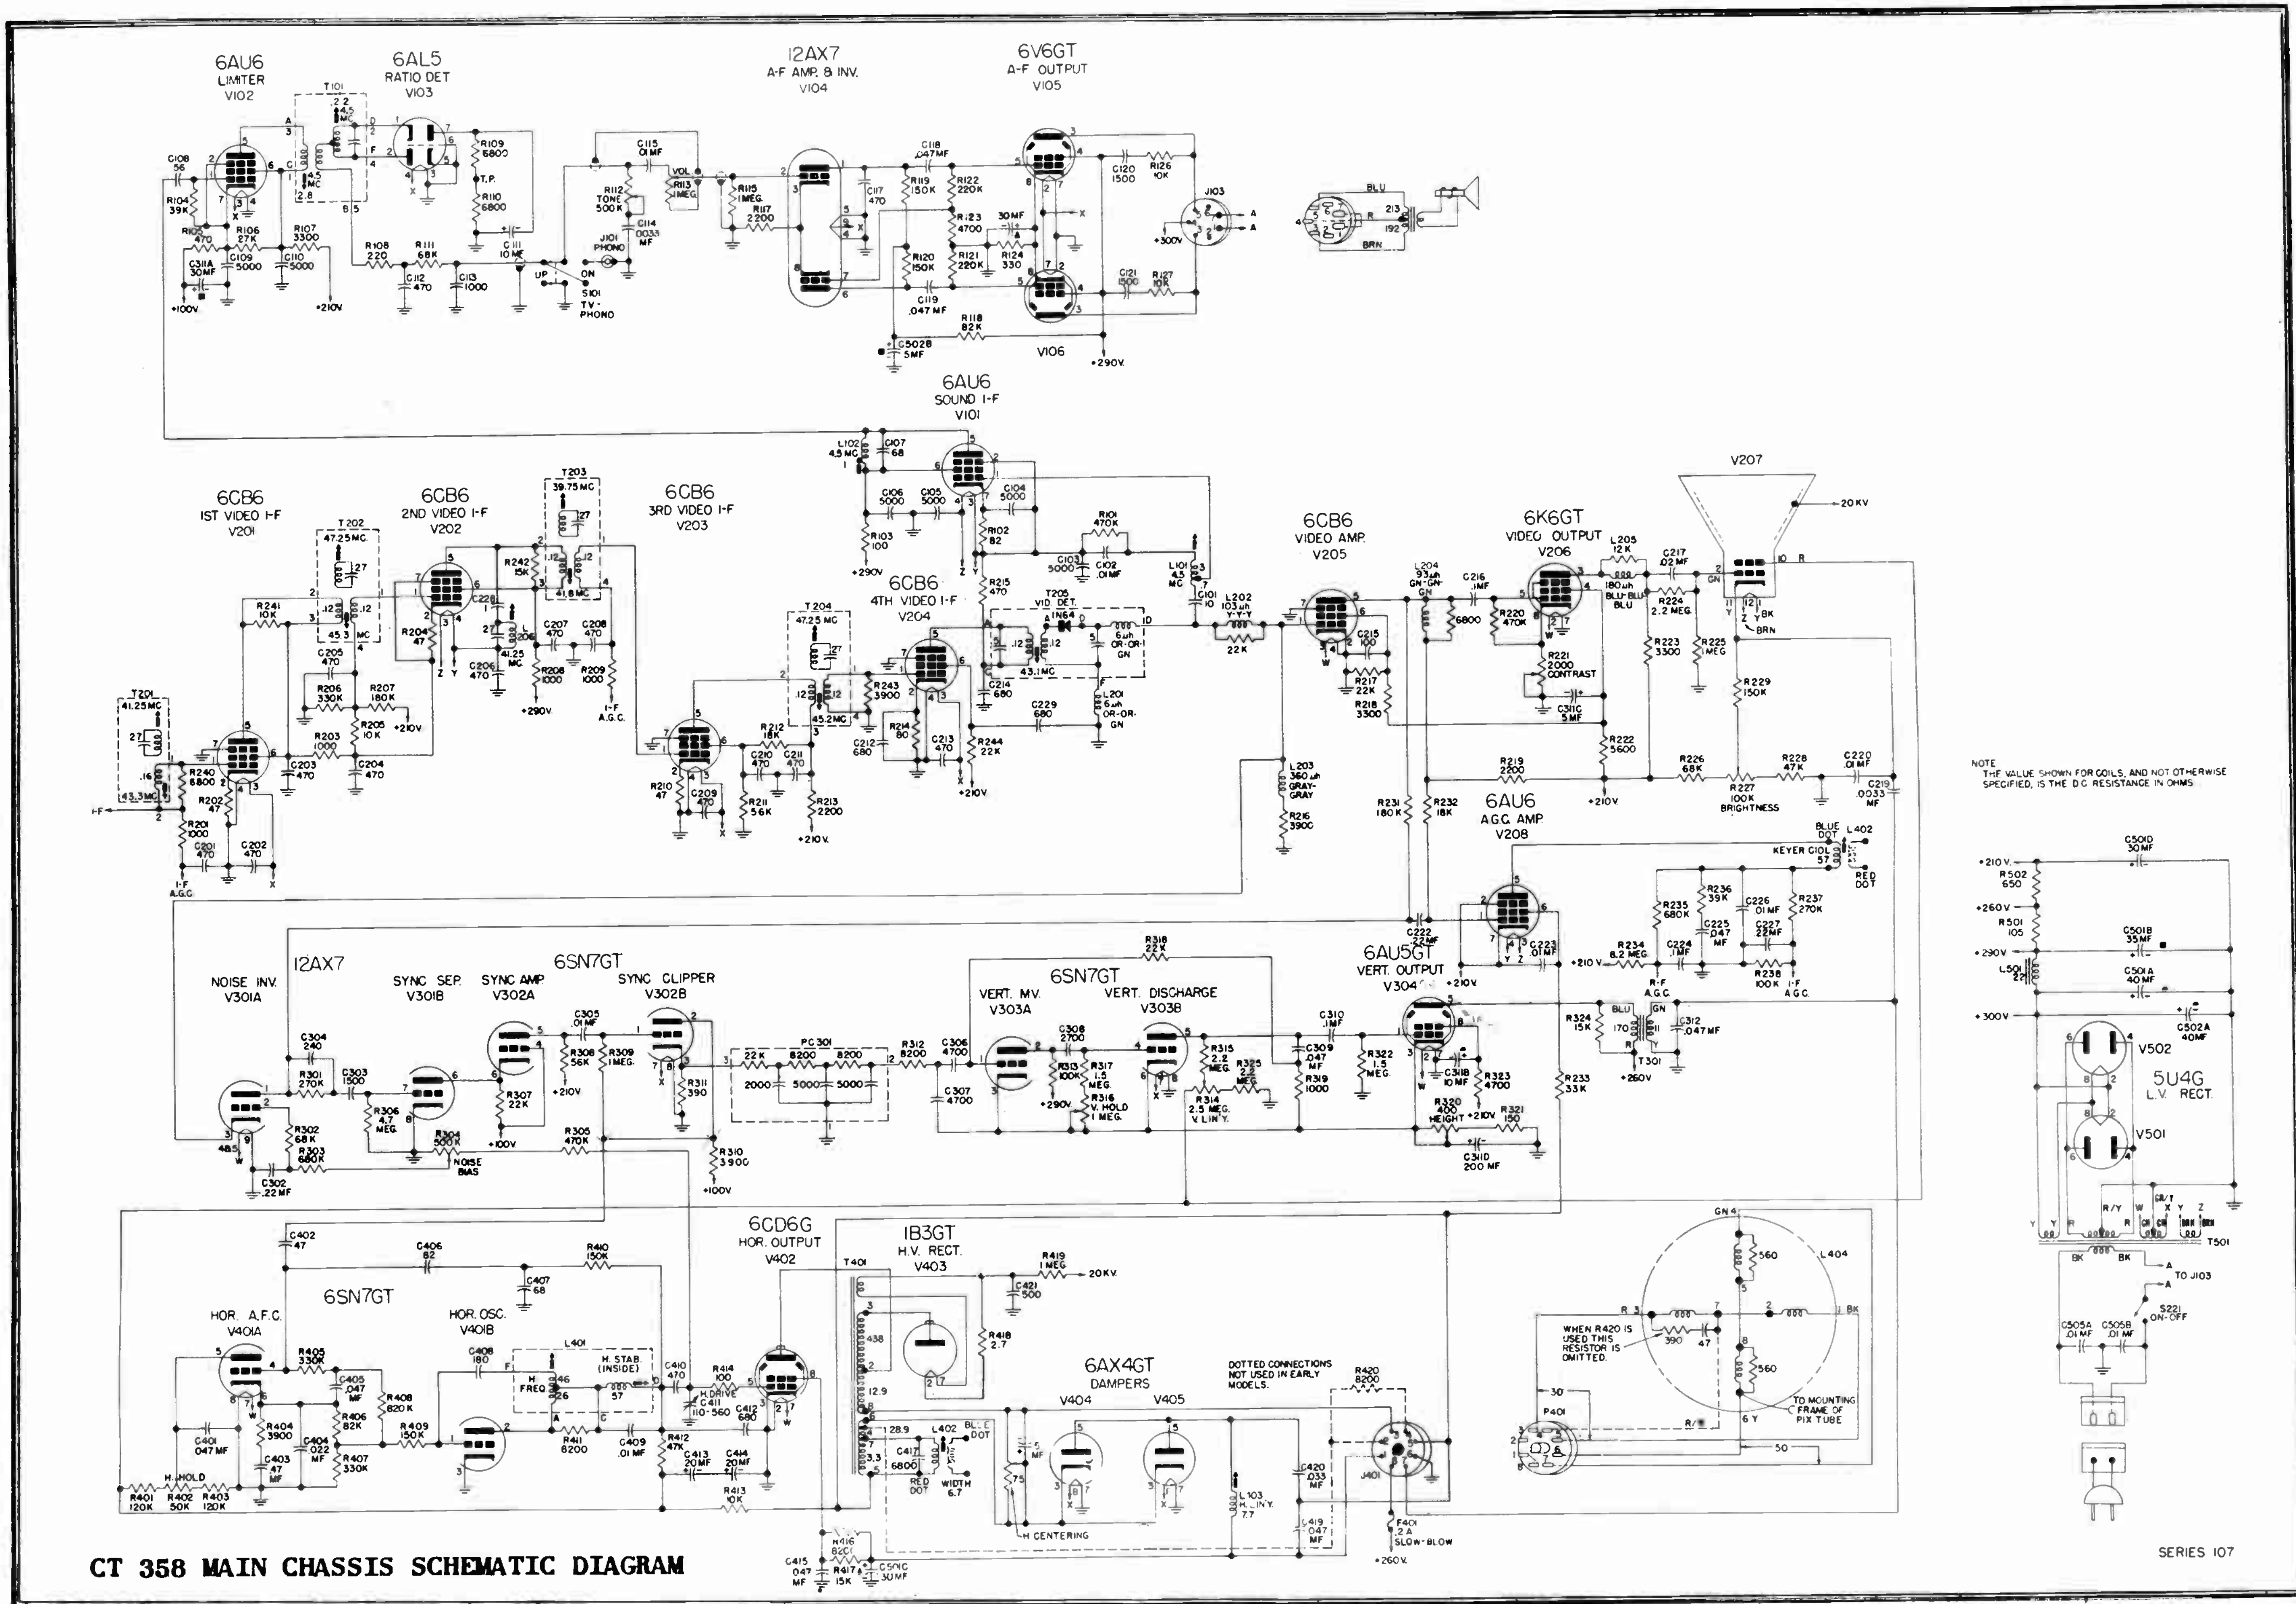
RF Tuner



CT 358 MAIN CHASSIS SCHEMATIC DIAGRAM

General Information

POWER SUPPLY—These receivers are designed to operate from a power source of 117 volts at 60 cycles A.C. It will, however, operate satisfactorily from a line whose voltage is no lower than 105 volts, or no greater than 125 volts at 60 cycles A.C. Always measure the voltage of the line with a dependable a-c voltmeter if it is suspected that the line voltage is beyond the above acceptable limits.

TUBES—In all receivers, all tubes, including the picture tube, are shipped properly mounted in their sockets. Check to see that all tubes are firmly seated since some may have worked loose during shipment. See Picture Tube Handling Precautions below.

ANTENNA—The installation and orientation of an antenna is one of the most important single factors in realizing optimum performance from a television receiver. An improperly oriented, or poorly matched, or unwisely chosen antenna can completely offset the good design engineered into these television receivers. For these reasons, choose, locate and install your antenna carefully, especially in poor signal areas. All receivers in these series are equipped with a built-in antenna which performs satisfactorily in locations where good signal strength is available, and where a minimum of noise is present.

When an outdoor antenna must be installed, use a standard, approved antenna, having a 300 ohm impedance, and match it with a balanced 300 ohm transmission line. Orient the antenna for maximum signal strength from the greatest number of stations, and for the minimum amount of interference and reflection. Where the receiver is tc be installed beyond the range of good signal strength (about 30 miles) use a stacked array, being careful to match the impedance of the antenna, transmission line, and receiver (300 ohms). If additional gain is required, try a "booster" for improvement of signal-to-noise ratio.

In critical locations, where the receiver is surrounded by several stations, most of which are located beyond the 30 mile radius, a careful appraisal of the terrain and the measurement of field strength will usually yield acceptable television operation where a haphazard installation might have failed. To make full use of the directional and "gain" properties of a stacked array and booster, the following procedure is recommended:

1. Measure the field-strength of the transmitted signal from each of the desired stations on a calibrated field-strength meter.
2. Tabulate your results and conclude which stations are within reasonable quality distance. A field-strength of 300 microvolts-per-meter or higher will give acceptable results. A field-strength measurement of 100 microvolts-per-meter or lower may not be satisfactory without the use of a "booster."
3. Let the consumer decide which of the acceptable channels he desires, and orient the antenna to receive maximum signal from those desired stations.
4. Always twist the 300 ohm lead-in about once for every foot of length to minimize transmission line noise pick-up.

PICTURE TUBE HANDLING PRECAUTIONS

Extreme care should be used in handling the picture tube. The picture tube bulb encloses a high vacuum and, due to its large surface area is subjected to considerable air pressure. The front of the picture tube, particularly the rim of the viewing surface, must not be struck, scratched, or subjected to more than moderate pressure at any time. If the yoke sticks or fails to slip smoothly over the tube or its socket, check and remove the cause of the trouble. Do not under any circumstances force the yoke.

HIGH VOLTAGE WARNING

OPERATION OF THIS RECEIVER WITH INTERLOCKED BACK COVER REMOVED INVOLVES A SHOCK HAZARD FROM THE RECEIVER POWER SUPPLIES. WORK ON THIS RECEIVER SHOULD NOT BE ATTEMPTED BY ANYONE WHO IS NOT THOROUGHLY FAMILIAR WITH THE PRECAUTIONS NECESSARY WHEN WORKING ON HIGH VOLTAGE EQUIPMENT.

IMPORTANT—With the exception of the next paragraph, all information pertains to 16", 17", 20" and 21" screen receivers.

IMPORTANT

The Series 112 and 113 Television Receivers are shipped with the ion trap (beam bender) and centering magnet taped to the neck of the electrostatic-focus picture tube. These components are very carefully adjusted and then taped to prevent accidental movement during shipment. The adjustment of the ion trap is especially critical in the electrostatic-focus type of picture tube. The electron gun of the picture tube can be damaged within seconds as a result of a misadjusted ion trap. **DO NOT READJUST THE ION TRAP UNLESS ABSOLUTELY NECESSARY.** If adjustment is required read the instructions in paragraph B of the Service Adjustments on page 3 before turning the receiver on.

BUILT-IN ANTENNA INSTALLATION

This receiver is shipped with the built-in antenna completely connected. A few precautions should be observed, upon installing this receiver, if optimum performance is to be obtained.

1. Try to locate the receiver in such a position so that:
   a) All requirements for good viewing position and ventilation are satisfied.
   b) It is near a 105-125 volt 60 cycle A.C. power outlet.
   c) The back of the receiver is parallel and close to a window which faces in the general direction of the transmitters.
   d) It is not adjacent to a street having heavy automobile traffic which may cause ignition interference.
2. After performing the Service Adjustments outlined on the following pages, try a few stations and observe if their signals are received with sufficiently good quality so that the receiver may be left in this position.
3. If signal strength and noise conditions are known to be good and operation is not satisfactory, it may be best to try a new receiver location, choosing one where the receiver will be rotated 90 degrees relative to its former position.

If, however, it is found that the receiver is not permitted to perform at its best because of limitations of the built-in antenna in a noisy or weak-signal area, an outdoor antenna should be installed.

To connect an outdoor antenna to this receiver:

1. Loosen the two screws on the antenna terminal strip.
2. Disconnect the existing built-in antenna wires.
3. Connect the 300 ohm lead-in from the external antenna to the terminals and tighten the screws.

SERVICE ADJUSTMENTS

Below is given a description of the steps required in adjustment of the Beam Bender and Deflection Yoke and the adjustment of the Focus, Vertical Size and Linearity and Horizontal Size, Linearity, Drive and A.F.C. controls. However, it should be remembered that these adjustments are to be made only when picture quality is such that service adjustment is warranted. Use this description as a check-list and if a particular phase of quality is good, leave it alone and go on to the next operation. Refer to figure 1 for location of front panel controls, and to figure 7 on the schematic diagram for location of rear panel controls.

IMPORTANT—The adjustment of the Beam Bender (Ion Trap magnet) must be performed immediately after the receiver warms up. If any length of time is permitted to elapse while the receiver is on, and while the Beam Bender is misadjusted, serious damage to the internal structure of the cathode-ray gun may result.

A. PREPARATION FOR SERVICE ADJUSTMENTS

1. Remove the eight slotted-head wood screws and the one hex-head P.K. screw adjacent the line cord bracket, disengage the interlock, and remove the back and the line cord.
2. Drop hinged door on front panel for access to the auxiliary controls as illustrated in Fig. 1. The lower set of these controls is adjusted by means of a narrow shanked screwdriver.
3. Connect a substitute interlock line cord between receiver and suitable power outlet and turn on the receiver allowing about 30 seconds of warm-up period before proceeding. Keep the BRIGHTNESS control turned fully counter-clockwise.

B. BEAM BENDER (ION TRAP) ADJUSTMENT

1. Position the beam bender on the glass neck approximately ½" from the picture tube base.
2. Advance the BRIGHTNESS control almost fully clockwise.
3. Starting from this position, adjust the Beam Bender by moving it forward or backward, and at the same time rotating it slightly around the neck of the tube until the brightest raster appears on the screen. If two maximum brightness positions are found, the one nearest the tube base is the correct setting. This adjustment should be done quickly to avoid damaging the gun structure.
4. Adjust the BRIGHTNESS control to maximum, fully clockwise.
5. Re-adjust the Beam Bender carefully for maximum raster brilliance.
6. The Beam Bender must be adjusted at all times for maximum brightness. A misadjusted Beam Bender can damage the picture tube in a matter of seconds and it is of utmost importance to make this the first adjustment when the set is turned on and the last adjustment before the cabinet back is reinstalled.

C. DEFLECTION YOKE AND PICTURE CENTERING ADJUSTMENT

1. Loosen the wing thumb screw located at the top of the deflection yoke frame.
2. Check to see that the deflection yoke mounting bracket rubber cushions press firmly against the flare of the tube.
3. Press the yoke firmly against the flare of the tube. An improperly positioned yoke will cause shadows on the corners of the raster. This indicates that the electron beam is striking the neck of the picture tube.
4. Rotate the yoke until the lines of the raster are horizontal and squared with the picture mask, and tighten the wing screw.
5. Position the centering magnet assembly approximately ½" to ¾" behind the yoke. Centering is accomplished by rotating the small horizontal shaft. When the shaft of the magnet is above the tube vertical centering results, if the entire magnet assembly is rotated on the picture tube neck. until the shaft is on either side of the neck, it will center horizontally. When both vertical and horizontal centering is necessary, rotate the magnet assembly while rotating the small magnet shaft. Improper adjustment may cause neck shadow. Check the yoke position as described in 3 above. Then readjust the centering magnet for proper centering without neckshadow. Readjust the Beam Bender for maximum brightness.

4. Adjust the focus control (see Fig. 1) so that the lines of the raster are sharp and distinct over the greatest screen area.

E. HORIZONTAL A.F.C. ADJUSTMENT

In order to check this adjustment tune in a station, preferably one that is transmitting a test pattern. If difficulty is encountered in locking the picture horizontally or if it locks-in only when the Horizontal Hold Control is at either end of its rotation, adjust the Horizontal A.F.C. Control as follows:

1. Turn CONTRAST down about half way.
2. Turn HORIZONTAL HOLD CONTROL fully counterclockwise.
3. If the picture is not locked in, turn the HORIZONTAL A.F.C. control till it does lock-in. (See Fig. 7)
4. Momentarily interrupt the signal by switching the channel selecter off channel and then back. The picture should just fall out of sync. If it does not, turn the Horizontal A.F.C. adjustment screw slightly clockwise and again momentarily interrupt the signal. Continue this procedure until the picture just falls out of sync. only when the signal is interrupted.
5. Rotate the Horizontal Hold Control clockwise until the picture falls into sync. The picture should now stay in sync. throughout most of the range of the Horizontal Hold Control.
6. If the picture cannot be made to hold sync., carefully repeat the above procedure. If difficulty is still encountered, it may be necessary to make a complete alignment of the horizontal oscillator transformer using an oscilloscope, as described on page .

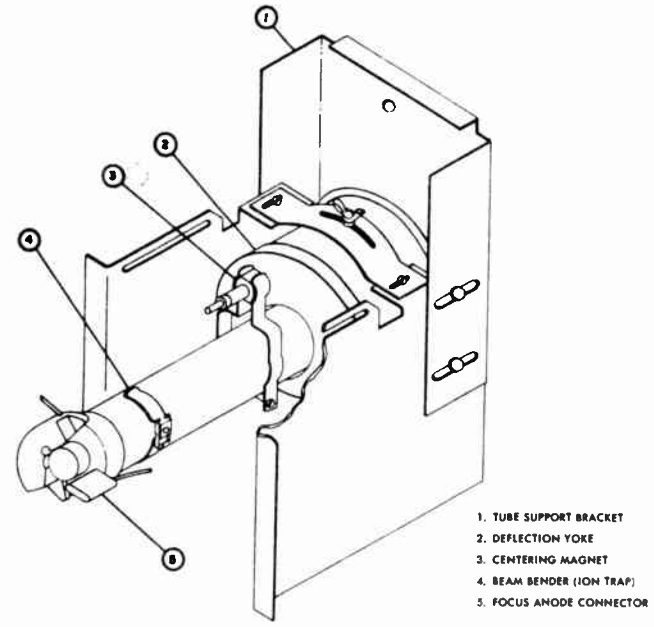


FIG. 2. DEFLECTION YOKE AND CENTERING MAGNET ASSEMBLY

F. PICTURE, SIZE AND LINEARITY

1. Adjust the VERTICAL SIZE and VERTICAL LINEARITY controls until the test pattern is vertically linear and symmetrical from top to bottom, and fills the mask. Adjustment of either control may require readjustment of the other. If vertical synchronization "falls-out," readjust the VERTICAL HOLD control. (Refer to Fig. 1)
2. Adjust the HORIZONTAL SIZE control slotted screw, located at the rear of the High Voltage cage at the rear of the chassis, for correction of horizontal width. The large outer arcs of the test pattern should coincide with the edge of the picture mask. (Refer to fig 7)
3. Adjust the HORIZONTAL DRIVE control trimmer for horizontally symmetrical pattern, and elimination of any existing vertical bars in left center of picture. The final adjustment should have the control at least ½ turn counterclockwise from the maximum clockwise position. (See Fig. 7)
4. The readjustment of the HORIZONTAL A.F.C. control may now be necessary.
5. Adjust the HORIZONTAL LINEARITY control slotted screw, located at the rear of the High Voltage cage, for central alignment of the inner circles of the test pattern.

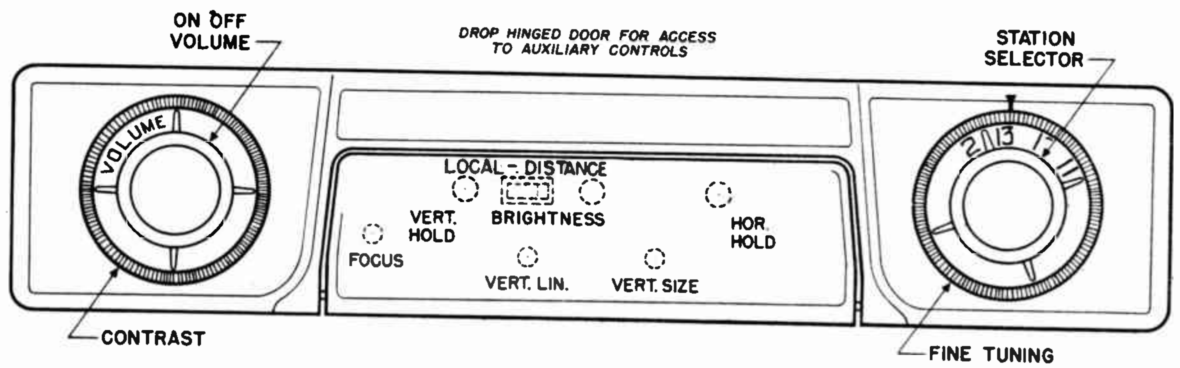

FIG. 1. FRONT PANEL ADJUSTMENTS

D. FOCUSING ADJUSTMENTS

1. Adjust BRIGHTNESS and CONTRAST controls so that the raster brilliance corresponds to that of an average picture.
2. Adjust focus control for best focus. Some electrostatic tubes will focus properly over the entire range of the focus control. This is no defect, it merely indicates an exceptionally well balanced gun structure.
3. Readjust the Beam Bender for maximum brightness.

Alignment Instructions

Video I-F and Sound Alignment Procedure

TV I-F ALIGNMENT

1. Tune receiver to quiet portion of TV High Band.
2. Set contrast control fully counterclockwise.
3. Apply 3 v. negative bias between the A.G.C. bus (at C22A) and ground. (Use 2—1½ v. cells.)
4. Connect TV I-F Signal Generator through a 1500 MMF condenser to Test Point (A) of tuner unit; low side to ground. (See schematic diagram.)
5. Connect negative lead of V.T.V.M. (or meter of 20,000 ohms-per-volt, or better) to 4.7K diode load resistor TEST POINT (B); positive lead to ground. (See schematic diagram.)
6. Feed 23.2 MC [23.3]* (±.05 MC) from Signal Generator and adjust T4 for maximum deflection on meter. Maintain Signal Generator output so low that meter reads no more than 1.5 volts at peak.
7. Feed 21.8 MC [21.8]* (±.05 MC) from Signal Generator, and adjust T3 as above.
8. Feed 24.0 MC [23.9]* (±.05 MC) from Signal Generator, and adjust T2 as above.
9. Feed 24.7 MC [24.5]* (±.05 MC) from Signal Generator, and adjust T1 as above.
10. Replace the meter with the vertical input of an Oscilloscope through a 10K isolating resistor, low side to ground.
11. Remove Signal Generator. Feed a video I-F Sweep Generator (20 to 28MC) through loosely coupled shield of 6J6 converter tube, making sure shield is not grounded. (Refer to Fig. 3.)
12. Loosely couple high side of a TV I-F Marker Generator to the high Sweep Generator Lead; low side to ground.
13. Feed I-F Sweep, and observe response on 'scope. (See Fig. 5.) Use marker frequencies 20.25, 21.75 and 24.75 MC.
14. If response does not approximate that shown in Fig. 5, repeat steps 3 to 9, making sure that frequencies are precise, and that the Signal Generator output voltage is kept low. Continue with steps 10 to 13. A slight touch-up of individual slugs may be required to approximate the recommended curve of Fig. 5.

*NOTE: If 3v fixed bias is unavailable and zero fixed bias is used, set signal generator at [ ] bracketed frequencies values.

TV SOUND ALIGNMENT

1. Connect a 4.5 MC Signal Generator (±.01 MC) through a 1500 MMF condenser to the 4.7K video diode load resistor TESTPOINT (B); low side to ground. See schematic diagram.

2. Obtain two resistors of approximately 100,000 ohms each, whose resistances have been matched accurately with an ohmmeter. Connect them in series across the 18K resistor (R107) at the 6T8 tube socket (V9A).

3. Connect negative lead of V.T.V.M. to junction of matched resistors of step 2; positive lead to ground.

4. Feed 4.5MC (±.01 MC) from signal generator, and adjust L22, sound take-off coil, for maximum deflection on V.T.V.M. Two points of maximum deflection may be found when making this adjustment. Correct adjustment is attained when screw is at most outward maximum reading position.

5. Adjust the bottom slug of T10 for maximum deflection on V.T.V.M.

6. Connect positive lead of V.T.V.M. to junction of C96, and R106 TEST POINT (C), leaving negative lead of V.T.V.M. connected as in step 3. See schematic diagram.

7. Adjust top of T10 for zero output on V.T.V.M. between two opposite polarity peaks.

IMPORTANT: Keep the sweep generator and marker generator outputs at minimum to avoid curve distortion. Marker pips should be kept barely visible.

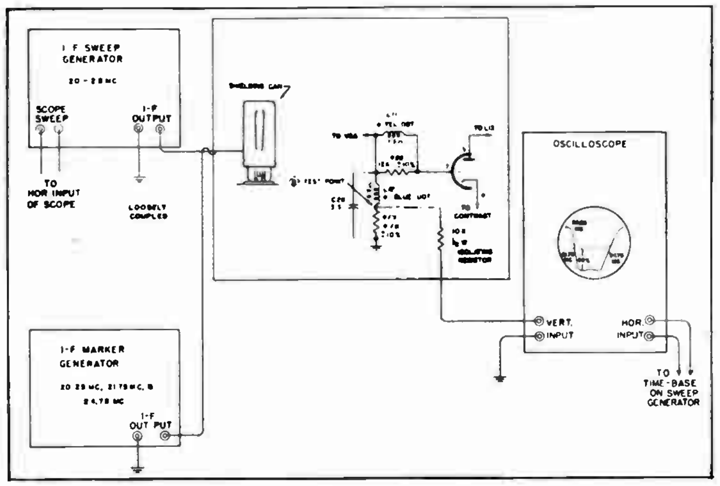

FIG. 3. IF ALIGNMENT BLOCK DIAGRAM

TABLE I RF ALIGNMENT FREQUENCIES			
CHANNEL NUMBER	SWEEP GEN. CENTER FREQ. (10MC.SWEEP)	MARKER GENERATOR FREQUENCIES	
		VIDEO CARRIER	SOUND CARRIER
2	57 MC.	55.25 MC.	59.75 MC.
3	63 MC.	61.25 MC.	65.75 MC.
4	69 MC.	67.25 MC.	71.75 MC.
5	79 MC.	77.25 MC.	81.75 MC.
6	85 MC.	83.25 MC	87.75 MC.
7	177 MC.	175.25 MC.	179.75 MC.
8	183 MC.	181·25 MC.	185.75 MC.
9	189 MC.	187.25 MC.	191.75 MC.
10	195 MC.	193·25 MC.	197.75 MC.
11	201 MC.	199·25 MC.	203.75 MC.
12	207 MC.	205.25 MC.	209.75 MC.
13	213 MC.	211,25 MC.	215.75 MC.

R.F. and Oscillator Alignment

(STANDARD COIL TUNER)

R.F. ALIGNMENT

1. Connect TV Sweep Generator to Antenna Terminals.
2. Connect R.F. Marker Generator loosely to Antenna Terminals.
3. Connect vertical amplifier of Oscilloscope through a 10,000 ohm ½w. resistor to Test Point (A) fig 6.
4. Short A.G.C. Bus to ground on TV chassis (across C22A 5000 MMF Discap condenser).
5. Set Station Selector switch to Channel 12.
6. Feed 207 mc at 10 mc sweep from Sweep Generator, and 205.25 mc and 209.75 mc fixed frequencies from R.F. Marker Generator.
7. Observe response curve on Scope. If necessary adjust C2, C4, or C7 (See fig. 6) so that response curve corresponds approximately to that shown in fig. 5 and has maximum gain.
8. Check markers on response curve of all remaining channels, setting Sweep and Marker Generators at corresponding frequencies for each channel. See Table I for convenient tabulation of proper frequencies. If the R.F. Markers do not fall in automatically in their proper places on all channels, a compromise must be made by slight readjustment of C2, C4, or C7.

OSCILLATOR ALIGNMENT

1. Connect TV R.F. Sweep Generator to Antenna Terminals.
2. Couple R.F. Marker Generator loosely to Antenna Terminals.
3. Connect vertical amplifier of Oscilloscope across the video amplifier grid and ground (Pin 7 of 12BH7, V7A).
4. Couple 24.75 mc video I.F. Marker Generator loosely to first I.F. grid (Pin 1 of 6CB6, V3).
5. Rotate Fine Tuning control to center of range.
6. Set Station Selector switch to Channel 12.
7. Set Sweep Generator to 207 mc at 10 mc sweep and Marker Generator to 205.25 mc (video carrier).
8. Observe response curve and adjust C10 (fig. 6) for Zero-beat with 24.75 marker. Zero-beat is indicated by an unmistakable break-up of the observed response curve.

   NOTE: Quality of response curve does not affect accuracy of oscillator alignment, so long as a zero-beat is obtained.

9. Check for zero-beat on all channels in this manner, setting the Station Selector, Sweep Generator and Marker Generator at corresponding frequencies. (See Table I.) It is not usually necessary to make any further adjustments. However, if the individual oscillator coils must be touched-up, the following procedure should be employed:
   a) Rotate Fine Tuning control to center of range.
   b) Set Station Selector to desired channel, Sweep Generator to its center frequency with 10 mc sweep, R.F. Marker Generator to the corresponding video carrier frequency (See Table I), and I.F. Marker Generator at 24.75 mc.
   c) Place a non-metallic screwdriver through the opening marked 'Recessed Individual Osc. Adjustment', fig. 6, and adjust oscillator coil zero-beat with 24.75 mc marker on response curve.
   d) This adjustment can be repeated on any single channel, or, if necessary, on all channels.
   e) If difficulty is encountered in tuning any particular channel well within limits of Fine Tuning control after these adjustments are made, readjust C10 slightly (as in Step 8) shifting the whole range of frequencies in the desired direction.

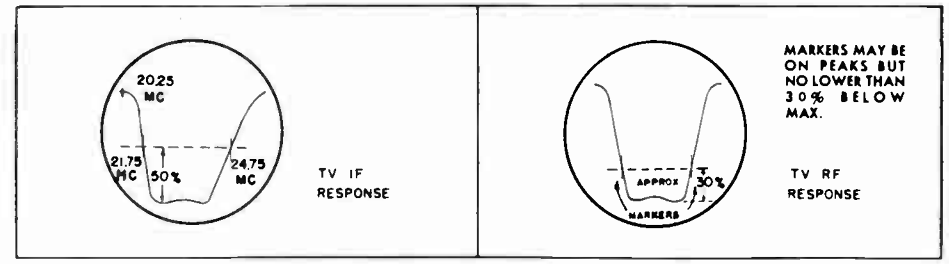

FIG. 5. RECOMMENDED RESPONSE CURVES.

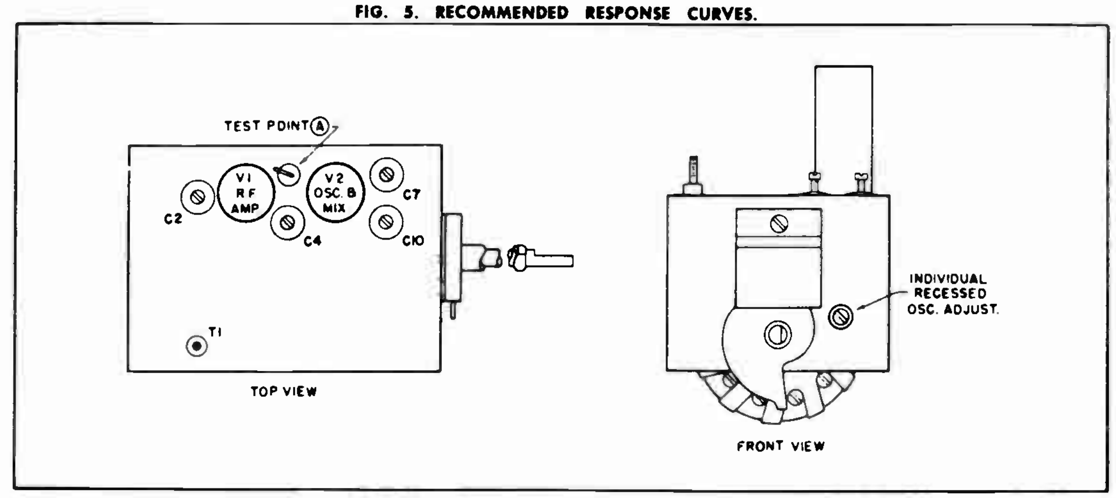

FIG. 6. R.F. TUNER ADJUSTMENT POINTS (STANDARD COIL TUNER)

HORIZONTAL OSCILLATOR TRANSFORMER ALIGNMENT

Refer to Service Adjustment "E" before proceeding with this alignment.

1. Tune in a TV station, preferably one that is transmitting a test pattern.
2. If after attempting the Horizontal A.F.C. Service Adjustment, described above, the picture cannot be made to sync. pre-set the Horizontal Stabilizing adjustment (inner slug of T8, beneath chassis) 5 turns in from its maximum out position.
3. Set the Horizontal Hold control to the center of its range and adjust the Horizontal A.F.C. adjustment until the picture is in sync.
4. Connect a low capacity probe of an oscilloscope to terminal "C" of the Horizontal oscillator transformer, T8; low side to ground. Set horizontal sweep to 7875 C.P.S. If a low capacity probe is unavailable, connect a 10K resistor in series with the vertical scope lead.
5. Adjust the Horizontal Stabilizing brass slotted screw until the broad and narrow peaks of the pattern on the oscilloscope are of equal height. (See illustration.) During Horizontal Stab. adjustment, picture must be kept in sync. by adjusting the Horizontal A.F.C. adjustment, if necessary.
6. Disconnect oscilloscope and follow Service Adjustment E above.

NOTES

1. Tune receiver to unused channel—no signal applied.
2. All front panel controls at maximum clockwise positions.
3. Screwdriver service adjustments, adjusted for normal raster.
4. All voltages measured with V.T.V.M. at 117 volts A.C. line.
5. Values shown are D.C. voltages measured from socket to ground unless otherwise specified.
6. N.C. designates no connection.
7. A dash designates the non existence of socket connections.

* Use high voltage insulated probe only.

† Top value is D.C. voltage to ground. Bottom value connect A.C. meter across socket connections 7 and 8.

** Top value is D.C. voltage to ground. Bottom value connect A.C. meter across socket connections 2 and 8.

CAUTION

The regular B+ voltages are dangerous, and precaution should be taken when the chassis is removed from the cabinet for service. Secondary human reactions to otherwise harmless shocks have been known to cause injury. Always discharge the picture anode to the receiver chassis before handling the tube. The picture tube is highly evacuated, and if broken, glass fragments will be violently expelled.

A.G.C. SYSTEM

This receiver utilizes a type of keyed A.G.C., the 6U8 tube performing dual functions of sound I.F. amplifier and A.G.C. Keyer.

This system requires a D.C. connection from the video detector through the video amplifier, to the A.G.C. Keyer (triode section 6U8). The A.G.C. Keyer is directly connected across a portion of the plate load resistance for the video amplifier. This establishes a bias voltage (-6 to -10 V.) across R-133, due to the current drain in the 12BY7 video amplifier, holding the 6U8 approximately at cutoff, depending on the contrast setting.

The plate circuit of the A.G.C. Keyer has no direct connection to B+, its plate supply voltage consisting entirely of pulses taken from a winding on the horizontal output transformer. This winding will normally supply a positive pulse of approximately 500 volts peak value to the keyer during the horizontal retrace time. This pulse will exceed the cathode voltage by approximately 150 volts, at the same time that the positive horizontal sync pulse will appear at the grid of the 6U8. The conduction of the 6U8 at this time will establish a small negative voltage across R-122, which is then filtered and applied to the controlled I.F. stages as the A.G.C. control voltage. This bias is cut in half by a simple voltage divider and only half is applied to the R.F. circuits (see schematic).

Due to the direct connection between the video amplifier and the A.G.C. Keyer, the A.G.C. voltage developed will depend to a large extent upon current through the video amplifier. Advancing the contrast control, as would be necessary on weak signals, has the effect of increasing the bias on the A.G.C. Keyer and consequently less A.G.C. voltage is developed. Conversely, retarding this control, as would be necessary on strong, local signals, will reduce the bias on the Keyer, and more A.G.C. voltage will be developed, in effect increasing the range of the contrast control.

Since the Keyer is conducting heavily not more than 5% of the time, random noise occuring during the active portion of the horizontal scan cannot charge up the A.G.C. filter system to any large degree, unless the noise is of sufficient amplitude to cause grid current in the controlled stages.

IMPORTANT NOTICE

In previous models, the filament winding on the power transformer which supplied heater voltage to the 6W4 was connected directly to the positive 140 volt supply. This was done to minimize the potential between heater and cathode of the 6W4 damper.

In these models, this heater winding is maintained at a positive 220 volts by means of a voltage divider connected between B+ and ground. The filament winding is bypassed by a .05 mfd 600 volt capacitor to ground.

*Readings taken from Pin Socket with +140 as common negative reference.

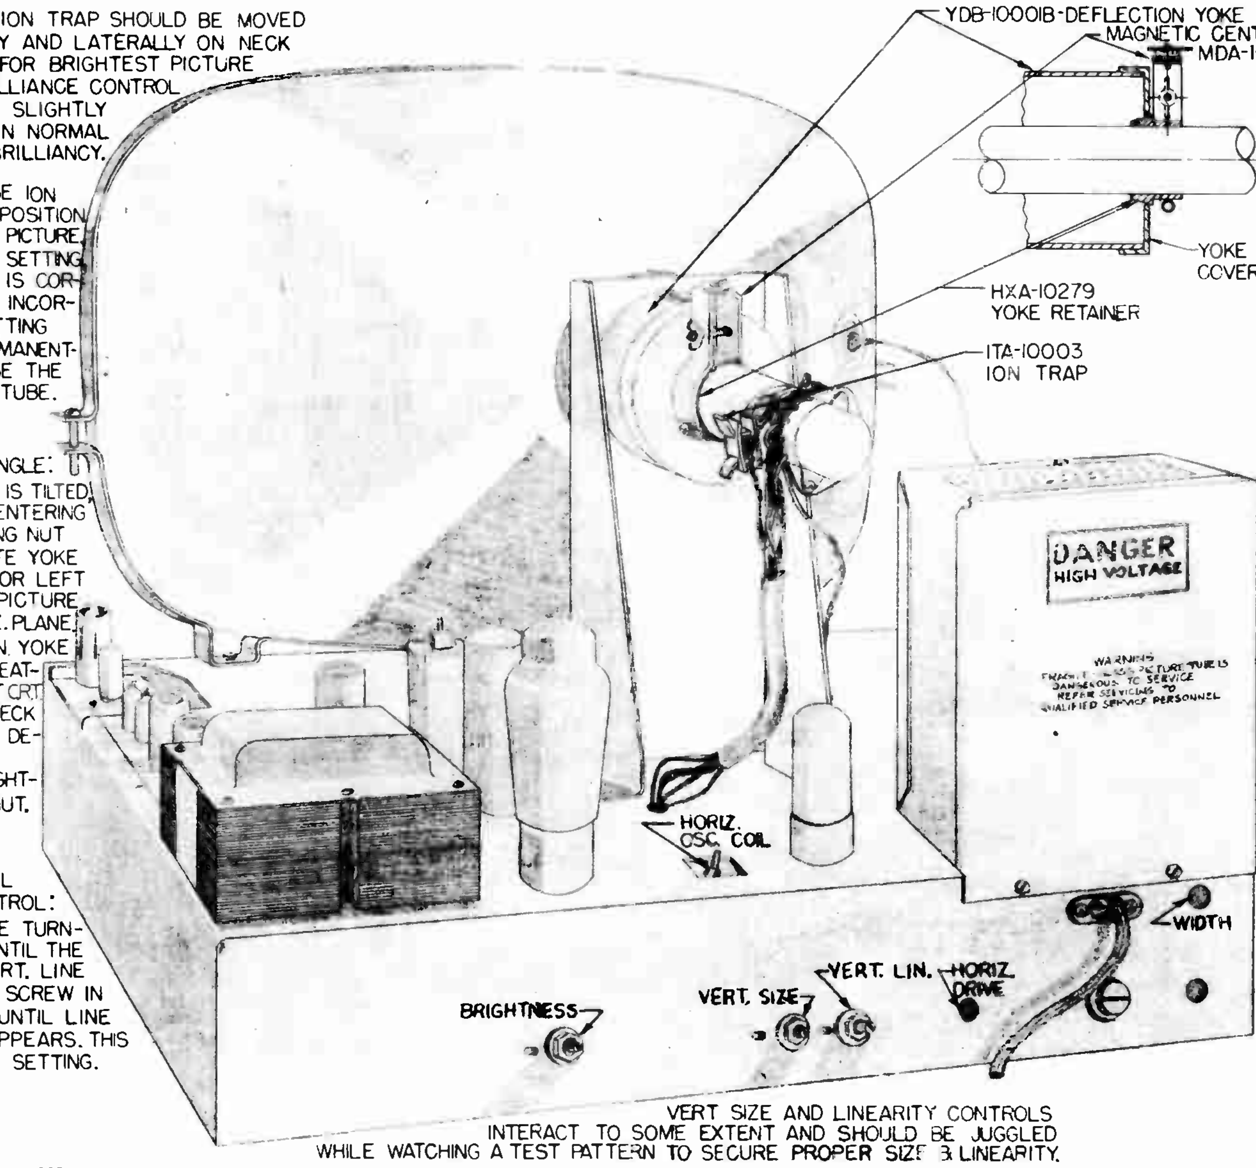
1. Where readings may vary according to control settings, min. & max. readings are given.
2. Measurements are from socket pin to chassis, unless otherwise stated.
3. All measurements taken with line voltage maintained at 117 A. C.

CAUTION: ION TRAP SHOULD BE MOVED CIRCULARLY AND LATERALLY ON NECK OF TUBE FOR BRIGHTEST PICTURE WHEN BRILLIANCE CONTROL IS SET AT SLIGHTLY MORE THAN NORMAL VIEWING BRILLIANCY.

NEVER USE ION TRAP TO POSITION OR FOCUS PICTURE. ONLY ONE SETTING OF TRAP IS CORRECT. AN INCORRECT SETTING WILL PERMANENTLY DAMAGE THE PICTURE TUBE.

PICTURE ANGLE: IF PICTURE IS TILTED LOOSEN CENTERING DEVICE WING NUT AND ROTATE YOKE TO RIGHT OR LEFT TO BRING PICTURE INTO HORIZ. PLANE. BE CERTAIN YOKE REMAINS SEATED AGAINST CRT BELL. RECHECK CENTERING DEVICE & ION TRAP & TIGHTEN WING NUT.

HORIZONTAL DRIVE CONTROL: SHOULD BE TURNED OUT UNTIL THE BRIGHT VERT. LINE APPEARS. SCREW IN CONTROL UNTIL LINE JUST DISAPPEARS. THIS IS PROPER SETTING.



TO PROPERLY ASSEMBLE THE YOKE, CENTERING DEVICE AND ION TRAP ON THE PICTURE TUBE REFER TO ILLUSTRATION.

THE PURPOSE OF THE YOKE RETAINER(RUBBER SLEEVE WITH CONE SHAPED END)IS TO CENTER THE BACK OF THE YOKE ON THE PICTURE TUBE NECK AND HOLD THE YOKE AGAINST THE PICTURE TUBE.

TO ASSEMBLE, HOLD THE YOKE IN POSITION AND SLIP THE PICTURE TUBE NECK THROUGH THE YOKE AND FIRMLY SEAT THE PICTURE TUBE IN ITS HARDWARE.

AFTER THE TUBE IS FASTENED SECURELY, CENTER THE YOKE ON TUBE NECK BY SLIDING THE YOKE RETAINER ON THE NECK WITH THE CONE PORTION TOWARD THE YOKE.

INSERT THE YOKE RETAINER IN THE REAR OF THE YOKE AND CENTER THE YOKE AT THE SAME TIME HOLDING THE YOKE AGAINST THE TUBE BELL. SLIP THE CENTERING DEVICE AROUND THE SLEEVE PORTION OF THE YOKE RETAINER WITH CLAMPING SCREW LOOSENED. INSTALL THE ION TRAP AND PICTURE TUBE SOCKET AND ADJUST THE ION TRAP. CENTER THE PICTURE BY BOTH ADJUSTING THE KNOB ON THE CENTERING DEVICE AND ROTATING THE CENTERING DEVICE AROUND THE SLEEVE PORTION OF THE YOKE RETAINER.

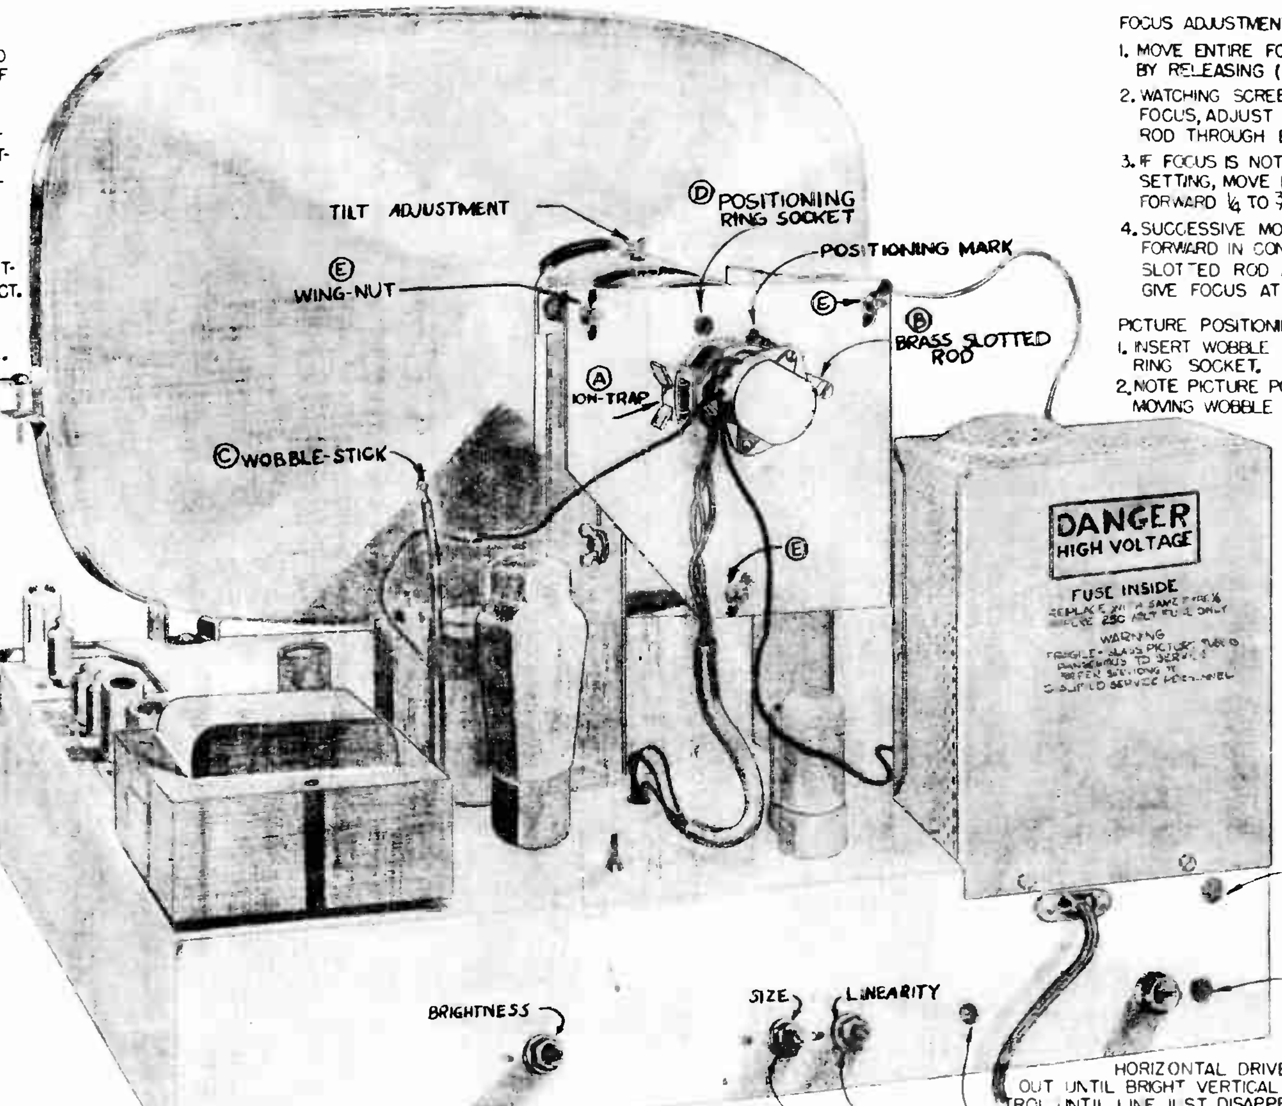
AFTER THE CENTERING HAS BEEN ACCOMPLISHED, TIGHTEN THE WING NUT ON THE CENTERING DEVICE TO HOLD THE YOKE IN PLACE. RECHECK THE ION TRAP ADJUSTMENT.

VERT SIZE AND LINEARITY CONTROLS INTERACT TO SOME EXTENT AND SHOULD BE JUGGLED WHILE WATCHING A TEST PATTERN TO SECURE PROPER SIZE & LINEARITY.

REAR VIEW OF CHASSIS
XXD-10707

CAUTION: ION TRAP SHOULD BE MOVED CIRCULARLY AND LATERALLY ON NECK OF PICTURE TUBE FOR BRIGHTEST PICTURE WHEN BRILLIANCE CONTROL IS SET AT SLIGHTLY MORE THAN NORMAL VIEWING BRILLIANCY.

NEVER USE ION TRAP TO POSITION OR FOCUS PICTURE. ONLY ONE SETTING OF TRAP IS CORRECT. AN INCORRECT SETTING WILL PERMANENTLY DAMAGE PICTURE TUBE.



FOCUS ADJUSTMENT:

1. MOVE ENTIRE FOCUS UNIT TO REAR BY RELEASING (3) WING NUTS.
2. WATCHING SCREEN FOR SHARPEST FOCUS, ADJUST BRASS SLOTTED ROD THROUGH ENTIRE RANGE.
3. IF FOCUS IS NOT REACHED WITH THIS SETTING, MOVE ENTIRE ASSEMBLY FORWARD 1/4 TO 3/8" AND REPEAT STEP 2.
4. SUCCESSIVE MOVING OF THE UNIT FORWARD IN CONJUNCTION WITH BRASS SLOTTED ROD ADJUSTMENT, WILL GIVE FOCUS AT SOME POINT.

PICTURE POSITIONING:

1. INSERT WOBBLE STICK IN POSITIONING RING SOCKET.
2. NOTE PICTURE POSITION IN MIRROR WHILE MOVING WOBBLE STICK FOR PICTURE CENTERING.

HORIZONTAL LINEARITY SHOULD BE ADJUSTED WHILE WATCHING A TEST PATTERN.

HORIZONTAL DRIVE CONTROL SHOULD BE TURNED OUT UNTIL BRIGHT VERTICAL LINE APPEARS. SCREW IN CONTROL UNTIL LINE JUST DISAPPEARS. THIS IS PROPER SETTING.

VERTICAL SIZE & LINEARITY CONTROLS INTERACT TO SOME EXTENT & SHOULD BE JUGGLED WHILE WATCHING A TEST PATTERN TO SECURE PROPER VERTICAL SIZE & LINEARITY.

REAR VIEW OF CHASSIS
XXD-10691

INSTALLATION AND ADJUSTMENT

BUILT-IN-ANTENNA

This receiver is equipped with a built-in antenna which should provide favorable reception of television signals within the primary service area, and where local interferences are not excessive. Do not locate the receiver near a large metal surface such as a radiator or metal partition, or a serious reduction of signal will result.

OUTSIDE ANTENNA

Where reception is weak due to less favorable receiving conditions with the built-in antenna, an outside antenna is recommended. When this external or outdoor antenna is connected to the receiver input terminals, the built-in antenna must be disconnected.

RECEIVER INSTALLATION

The receiver was shipped from the factory with all components preadjusted for normal operation. However, if in checking the receiver performance it becomes evident that one or more of the installation controls are out of adjustment, due to handling, it is necessary to re-adjust the affected controls. A complete adjustment of installation controls is outlined in the step by step procedure which follows. It will be noted that adjustment of some of the controls will interact on one or more of the others. These controls should be adjusted alternately, and in the given sequence of the procedure. Power should never be applied to the receiver for any great length of time, prior to the installation, without checking the ion trap adjustment for best screen illumination.

SEQUENCE OF ADJUSTMENTS

Ion Trap Adjustment

1. Remove the cabinet back cover. (In some cases, this will open circuit the A.C. interlock, and another line cord with appropriate fittings must be used temporarily until the necessary adjustments have been completed.) With power applied to the receiver and after allowing adequate warm-up time, set the brightness control in the center of its range and rotate the ion trap, or beam bender magnet, until light appears on the screen. After initial screen illumination is obtained, move the magnet forward or backward, and further rotate it to obtain the brightest raster. If two positions are noted which seem to give equal screen brightness, the setting closest to the picture tube base should be used. This is the only setting of the ion trap that is correct. NEVER ATTEMPT TO COMPENSATE FOR NECK SHADOWS OR FOCUS WITH THE ION TRAP OR BEAM BENDER ADJUSTMENT, IF BY SUCH ADJUSTMENT THE SCREEN BRIGHTNESS IS DECREASED.

Focus Adjustment

2. Adjust the brass screwdriver slotted rod to the right of the C.R.T. socket until best focus is obtained. The raster may be centered by movement of the positioning ring (inside the focusing ring) with the "Wobble Stick," which is supplied with every unit. This special nonmagnetic rod will be taped to an electrolytic capacitor on top of the chassis in every receiver employing a PM focus unit.

Yoke Positioning

3. Connect an antenna to the set and tune in a station, (test pattern if available). Check to make sure that the deflection yoke is positioned firmly against the "bell" of the picture tube. The yoke may be slightly tilted to the left or right in order to properly frame the picture within the mask.

Horizontal Drive Adjustment

4. Check the horizontal drive setting by turning the drive trimmer several turns counter-clockwise until one or more vertical white lines are observed on the left side of the screen. Then, turn the trimmer just far enough clockwise to eliminate these "drive lines." In the event that no drive lines are observed on the picture tube face, leave the trimmer set to the position of minimum capacity consistent with sufficient trimmer screw pressure and good horizontal linearity.

Vertical Sweep Adjustments

5. Adjust the vertical size and the vertical linearity controls on the rear of the chassis for correct height and best vertical linearity. Do not attempt this adjustment unless a test pattern is available.

Width Adjustment

6. Check the width coil for proper setting, and correct if necessary.

Caution

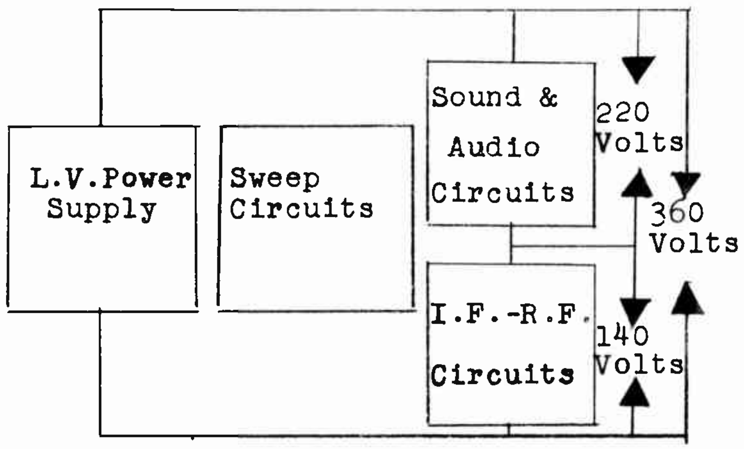
7. Re-Adjust the beam bender or ion trap if necessary.

*Some chassis will contain electrostatically focused picture tubes. These tubes will ordinarily have the focus electrode wired to the 140 volt B+ supply. Due to line voltage variations, however, it may become necessary to raise or lower the voltage on this electrode for best focus. Any well filtered voltage from zero, or ground, to a positive 400 volts is permissable on this electrode. If satisfactory focus is not obtained within this range of voltages, re-check the width and horizontal drive adjustments. If these adjustments are found to have been correctly made, check the second anode voltage on the picture tube. For this measurement, a voltmeter which will range to at least fifteen thousand volts is necessary. The picture tube second anode voltage should range between 11.5 and 13.5 K.V. positive. The picture is centered by means of a centering magnet, located just to the rear of the deflection yoke, in the position formerly occupied by the focus unit. This magnet may be rotated in any direction to correctly center the pattern. When this ring is in a vertical plane, the thumbscrew will adjust vertical centering. When the ring is in a horizontal plane, horizontal centering will be effected by adjustment of the thumbscrew. (See assembly instruction.)

General Circuit Description

The LOW VOLTAGE POWER SUPPLY is conventional, consisting of a center tapped power transformer used on conjunction with a 5U4 full wave rectifier.

This supply provides a filtered output of approximately 360 volts for application to the sweep or deflection circuits. It is interesting to note that the I.F.-R.F. portions and the sound-audio portions of the receiver are in series across the 360 volt supply. This arrangement provides 220 volts for application to the sound and audio circuits, and the remaining 140 volts is available for I.F.-R.F. supply potential. The audio power amplifier tube (6V6) is also used as a series voltage regulator. Its grid is returned to a high impedance voltage divider tapped at approximately 130 volts, while its cathode is wired directly to the 140 volt line. Any change in the 140 volt drain due to A.G.C. fluctuations thus changes the grid to cathode voltage of the 6V6 almost instantaneously, and the resulting cathode current change in this tube acts to maintain the 140 volt supply substantially constant. It should, therefore become apparent that if the 140 volt supply measures considerable higher than 140 volts, a short exists across the sound-audio circuits. If this voltage is considerably lower than the nominal 140 volts, and the 390 ohm resistor (R-80) in the plate supply circuit of the 6V6 is observed to overheat, a short exists across the 140 volt supply. If the 140 volt supply is measured considerably lower than its nominal value, and the 390 ohm resistor does not overheat, an open circuit is indicated in the 200 volt sound-audio portion of the receiver. (See Diagram Below.)



Alignment Procedure

Necessary Equipment:
- Television Sweep Generator
- Marker Frequency Generator
- Vacuum Tube Voltmeter
- 4.5MC Crystal Generator, or equivalent, Oscilloscope

Sound I.F. Alignment

1. Connect a 4.5 MC generator to the grid of the video amplifier tube. Low signal level is important here. Metering may be accomplished at the sound take-off point of the ratio detector (at the juncture of R-155 and C-160) with the meter ground connected to pin eight of the 6V6.

2. Adjust the slug of L-18 (sound take-off coil) for maximum negative meter indication. Attenuate the output of the generator so that not more than five volts is measured on the meter, as the alignment progresses.

3. Adjust the top slug of T-5 (ratio det. primary) for the maximum negative reading.

4. Move the meter ground to the juncture of R-156 and R-157 (6800 ohm resistors) in the sound detector circuit, and adjust the bottom slug of T-5 (Ratio Det.) for zero voltage. The other meter lead remains connected as in Step 1. N. 4.5MC trap adjustment is necessary. The trap consists of a coil L-17 which is self-resonant at 4.5MC.

Video I.F. Alignment

The I.F. amplifier contains five tuned circuits, no traps being necessary. The video carrier is passed through the I.F. at a freq. of 26.1MC, and the sound carrier at 21.6 MC. Extreme care must be taken in alignment to assure that the sound carrier is attenuated substantially below the level of the video carrier. This is necessary to assure that the slight AM modulation on the sound carrier due to picture modulation, will be sufficiently low to be removed by the detector, and not produce spurious phase modulation of the sound I.F. A band width of 3.4MC (6DB down) with a stage gain of from 12 to 15 times is attained. Earlier sets employed a staggered quintuple, which resulted in a different order of stagger of the I.F. coils. (See peaking frequencies below.) These sets may be identified by the values of the grid load resistors on the last two I.F. amplifier tubes, (R-109 and R-113) 6800 ohms. In the later sets, employing a staggered double, the third I.F. grid resistor, R-109, is 10,000 ohms, while the fourth, R-113, remains 6800. Another difference which will serve to help identify the quintuple stagger, lies in the wiring of the A.G.C. to the second I.F. amplifier. In the staggered quintuple alignment, the grid return of the tube is wired directly to the 1. mfd. A.G.C. filter capacitor (C-106). In the staggered triple-staggered double alignment, a 470 ohm resistor (R-106) and a .001 mfd capacitor (C-105) have been added as additional A.G.C. decoupling.

Peaking Frequencies

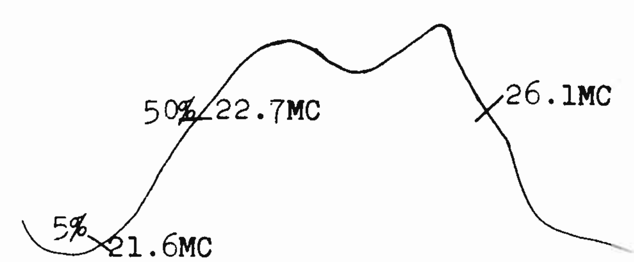
Adjust curve for band width of 3.4MC.

1st IF tuner slug to high side	25.9
2nd IF slug to middle of band	24.3
3rd IF slug to low side	23.1
4th IF slug to low side	22.9
5th IF slug to high side	25.7

Use only sufficient input to give pattern on scope with scope vertical control at maximum gain.

Should AGC be developed with this decreased input apply a D.C. battery of -3V to AGC line and align as before.

An I.F. alignment signal is best introduced to the chassis by means of a suitable cup, or tube shield floated over the mixer tube to capacity couple the signal to the plate circuit. It may be necessary to disable the local oscillator* to prevent R.F. harmonics from distorting the trace on the scope screen. The oscilloscope is connected to the grid of the video amplifier, through a 100,000 ohm isolating resistor. Metering is done on the AGC line, keeping the input attenuated to produce no more than a negative 1 volt reading. The resulting overall response should coincide with the curve shown below.



* A dummy 6J6 may be substituted for the mixer tube with the #1 pin removed, to facilitate alignment.

R.F. Alignment

The R.F. tuner in the receiver has to be pre-aligned by the manufacturer and adjustment in the field is not recommended. It may be necessary on occasional sets, however, to re-set the local oscillator tuning slug. This may be accomplished without test equipment, if it is possible to receive a signal of good quality, and if the I.F. and R.F. portions of the set are functioning correctly. Simply set the fine tuning in the center of its range and adjust the oscillator slug for best picture detail. The oscillator adjustment is recessed in a hole in the tuner front, directly to the right of the tuner shaft. This adjustment must be checked on each channel to be received. It is important that a non-metallic alignment screwdriver be used to prevent detuning when the adjustment is completed and the screwdriver withdrawn. On sets using a wooden front panel, a small hole is provided under the flanged tuner knob, which will accommodate this alignment tool, and make possible re-setting the osc. slug without removing the set from its cabinet. If a signal of sufficient strength is not available, oscillator adjustment may be made with the sweep generator connected as for I.F. alignment, and the video R.F. carrier frequency applied to the antenna terminals of the receiver from an accurately calibrated signal generator. With the hook-up outlined above, a pip, or marker indicating the video carrier for the particular channel being set will appear on the I.F. response curve. This pip will ride up and down on the curve when the fine tuning control is moved, and the oscillator is correctly set when the pip is passing through the point on the curve marked 26.1 in Fig. 5, with the fine tuning at the center of its rotation.

MODEL	DESCRIPTION
T212 - MZ	Mahogany 21" Consolette
T212 - BZ	Blonde 21" Consolette
T172 - MZ	Mahogany 17" Consolette
T172 - BZ	Blonde 17" Consolette

These models use 19 tubes (Including picture tube and rectifier) plus a crystal diode video detector and employ a intercarrier sound circuit. Picture tube has Electro Static focus which is automatic and permanent.

SAFETY PRECAUTIONS: The kinescope should be handled with extreme care. The person handling this tube should wear gloves and protective goggles as an added precaution.

When power is connected, care must be taken in servicing the HIGH VOLTAGE supply of these receivers. As a safety precaution the AC line is open when the cabinet back is removed. For servicing with chassis out of cabinet a separate line cord must be used.

VOLTAGE READINGS: The voltage readings to be obtained at various locations in the receiver have been indicated on the schematic diagram. These voltages will be very advantageous when "trouble shooting." Check voltages, tubes, fuse and inspect for damaged or burned parts before attempting to re-align receiver. A ¼ amp fuse is located in the low voltage power supply of the receiver.

All voltages were taken with a 117.5 V. 60 Cycle line and with no signal input. The contrast control set at the maximum clockwise position; the brightness control at 50% rotation and all other controls in normal operating position. All voltages are positive with respect to ground unless otherwise indicated.

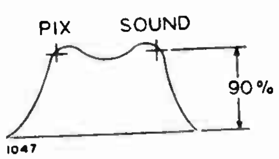
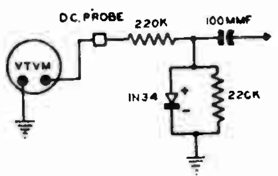
NOTE 4



PIX AND AUDIO MARKERS

NOTE 5



VTVM CONNECTIONS.
1045

CENTERING OF PICTURE: The picture may be centered in relation with the opening of the glass panel at the face of the receiver by shifting the centering magnet at the neck of the picture tube. The centering magnet should be rotated and the control adjusted until the picture is properly framed keeping in mind that the effect of the control is governed by the position of rotation. If the control is above or below the neck of the picture tube, the picture will be moved up or down. To the left or right of the neck of the picture tube, the picture will be moved either to the left or right.

CONTROL ADJUSTMENT

VERTICAL HEIGHT & VERTICAL LINEARITY CONTROLS: The vertical height and linearity controls should both be adjusted at the same time. For best results adjust while a test pattern is being transmitted. The linearity control affects the upper portion of the picture while the height control affects the overall size especially the lower portion of the picture. Adjust both controls simultaneously until the test pattern is symmetrical and fills the entire screen vertically.

WIDTH ADJUSTMENT: Adjust width by turning slug either clockwise or counter-clockwise. A clockwise rotation will decrease width. Proper width is obtained when raster covers entire screen of picture tube.

HORIZONTAL FREQ.: Tune in a station and adjust the horizontal hold control until the picture falls into sync. Momentarily remove the signal by switching off channel and then back. The picture should pull into sync. If in the above check the receiver fails to hold sync, reset horizontal hold slightly.

4.5 MC TRAP ALIGNMENT: 1. Connect the signal generator to the grid (pin 1) of the video amplifier tube v-6, through a 1000 MMF. Capacitor. 2. Connect the germanium crystal detector and voltmeter, between the cathode of the kinescope and chassis, as shown in note 5. 3. Set the signal generator at 4.5 MC and maximum output (setting of 4.5 MC must be accurate). Adjust 4.5 MC trap (L10) for minimum reading on the lowest voltage scale of the meter.

I. F. ALIGNMENT PROCEDURE

STEP NO.	CONNECT SIGNAL GENERATOR TO	SIGNAL GENERATOR FREQUENCY MC	CONNECT SWEEP GENERATOR TO	SWEEP GENERATOR FREQUENCY	CONNECT OSCILLOSCOPE TO	REMARKS	ADJUSTMENTS (Use peak obtained when screw is farthest out of can or coil.)
1. AUDIO IF ALIGNMENT	Grid of Video Amp. (6AH6) Pin No. 1. Contrast control at maximum.	4.5 MC. No Modulation. See Adjustments column.	NOT USED		NOT USED	Connect Vacuum Tube Voltmeter and zero center Microammeter as shown in Note 1 (50,000 ohm resistors shown in Note 1 must match within 5%).	Adjust L12 and T3 (Bottom) for maximum on Vacuum Tube Voltmeter. This adjustment should be made with Voltage on Vacuum Tube Voltmeter under 12 Volts. Adjust T3 (Top) for zero on Microammeter. If the receiver is receiving a signal, the above adjustment can be made off a weak station keeping the reading on the Vacuum Tube Voltmeter under 12 Volts.
2. PRELIMINARY VIDEO IF ALIGNMENT	Tube shield over 6J6. Disengage shield from clip to remove ground.	26.1 MC. No Modulation.	NOT USED		NOT USED	Connect —4.5 V. Battery to Junction of R20 and C24. Connect Vaccum Tube Voltmeter to A. G. C. point. Junction of R20 and R21.	Adjust 1st and 4th I. F. coils (L3 in Tuner and L7) for maximum on Vacuum Tube Voltmeter. Adjust at approximotely one volt.
3. PRELIMINARY VIDEO IF ALIGNMENT	Tube shield over 6J6. Disengage shield from clip to remove ground.	24.0 MC. No Modulation.	NOT USED		NOT USED	Connect —4.5 V. Battery to Junction of R20 and C24. Connect Vaccum Tube Voltmeter to A. G. C. point. Junction of R20 and R21.	Adjust 3rd I. F. coil (L6) for maximum on Vacuum Tube Voltmeter. Adjust at approximately one volt.
4.	Tube shield over 6J6. Disengage shield from clip to remove ground.	24.4 MC. No Modulation.	NOT USED		NOT USED	SAME AS ABOVE	Adjust 2nd I. F. coil (L5) for maximum on VTVM. Adjust at approximately one volt.
5. FINAL VIDEO IF ALIGNMENT	Signal Generator as shown in Note 2.	26.4 and 23.7 MC. No Modulation. See Note 3.	Tube shield over 6J6. Disengage shield from clip to remove ground.	24.3 Center Frequency and at least 6 MC wide.	Junction of R21 and L8.		With signal generator set at 26.4 MC adjust 1st and 4th I. F. coils to give correct marker position as shown in Note 3. Set signal generator at 23.7 MC and adjust 2nd and 3rd I. F. coils for pattern shown in Note 3. A slight readjustment of 1st and 2nd coils may be necessary.

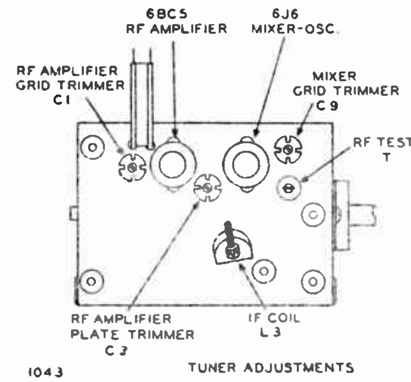
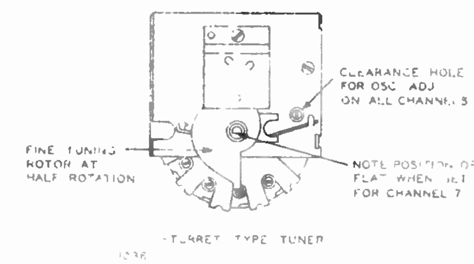
TUNER ALIGNMENT PROCEDURE



TUNER ADJUSTMENTS

NOTE 6



TURRET TYPE TUNER

NOTE 7

STEP NO.	CONNECT SIGNAL GENERATOR TO	SIGNAL GENERATOR FREQUENCY	CONNECT SWEEP GENERATOR TO	SWEEP GENERATOR FREQUENCY	CONNECT OSCILLOSCOPE TO	REMARKS	ADJUSTMENTS
1. RF & MIXER ALIGNMENT	Connect to piece of wire and wrap around 300 Ohm antenna lead.	205.25 MC (Picture Carrier). 209.75 MC (Sound Carrier.)	Antenna lead of receiver. (Generator must terminate in 300 ohms.)	TO SWEEP TV CHANNEL 12.	Through 10,000 Ohm resistor to test point (T) on tuner.	Connect negative of 1½ volt battery to junction of R10 and R12 and positive of battery to chassis ground.	With tuner set to channel 12, adjust Mixer Grid Trimmer (C9), RF Amplifier Plate Trimmer (C3), and RF Amplifier Grid Trimmer (C1) to obtain response curve shown in Note 4. Response curve should have maximum amplitude with proper band width.
2. RF & MIXER ALIGNMENT	SAME AS ABOVE	Correct sound and picture carrier for each channel. (See listing on first page of booklet.)	SAME AS ABOVE	TO SWEEP PROPER TV CHANNEL.	SAME AS ABOVE	Check response curve of each channel without disturbing trimmers.	If satisfactory response is not obtained for some particular channel try replacing coils for that channel or repeat step 1 of tuner alignment favoring weak channel without seriously affecting other channels.
3. OSCILLATOR ALIGNMENT FOR INDIVIDUAL CHANNEL	SAME AS ABOVE	Correct sound and picture carrier for each channel. (See listing on first page of booklet.)	SAME AS ABOVE	TO SWEEP PROPER TV CHANNEL.	JUNCTION OF C25 and [illegible]	All adjustments to oscillator coils (T9 [illegible]) must be made with [illegible] alignment [illegible] blade. If slug "falls in" during adjustment, remove [illegible] from tuner and raise slug retention spring. By tapping coil slightly, slug will return to a position retainable by spring.	For fine oscillator adjustment of channel, set tuner to channel and adjust slug of oscillator coil (T9) through hole in face plate of tuner (See Note 7) to position markers in the exact position on the response curve indicated in Note 3 under I. F. alignment. REPEAT OSC. ALIGNMENT FOR EACH CHANNEL AFTER SETTING TUNER TO PROPER CHANNEL.

V-21	17HP4	Picture Tube 17" Glass Rectangular (Electrostatic)

RECEIVER LOCATION — Advise the owner as to the proper location for the television receiver. The following may be used as a guide:

1. Choose an area in the home where sunlight or light from lamps does not strike the face of the picture tube and cause glare.
2. Remember the necessity of an electrical outlet and the location of the point at which the antenna leads enter the room.
3. The receiver should be placed a short distance from the wall to allow adequate ventilation.
4. The receiver should be placed to permit easy access for operation and comfortable viewing from all angles.

ANTENNA — This receiver has been designed to use an antenna with a 300 ohm balanced transmission line. This line must be as short as possible because the longer the line the greater the chances are for picking up electrical disturbances. Stand-off insulation should be used to keep the line away from the mast, metal or walls. Twist this line about one turn per foot throughout the line to cancel out direct signal and or noise pickup by the transmission line. It should also be securely anchored in place so that a change in weather will not affect its position.

HIGH VOLTAGE WARNING

This television receiver contains high voltages which are dangerous to life. Never operate or service the receiver outside of the cabinet or with the covers removed until all the safety precautions necessary for working with high voltage equipment have been observed.

PICTURE TUBE HANDLING PRECAUTIONS

Shatterproof goggles and heavy gloves must be worn by individuals while handling the picture tube or installing the picture tube into the receiver.

The picture tube encloses a high vacuum and due to the large surface area, is subjected to very high air pressure. Therefore, care should be taken not to bump or scratch the picture tube accidentally as it may cause the tube to implode resulting in damage to property or injury to an individual.

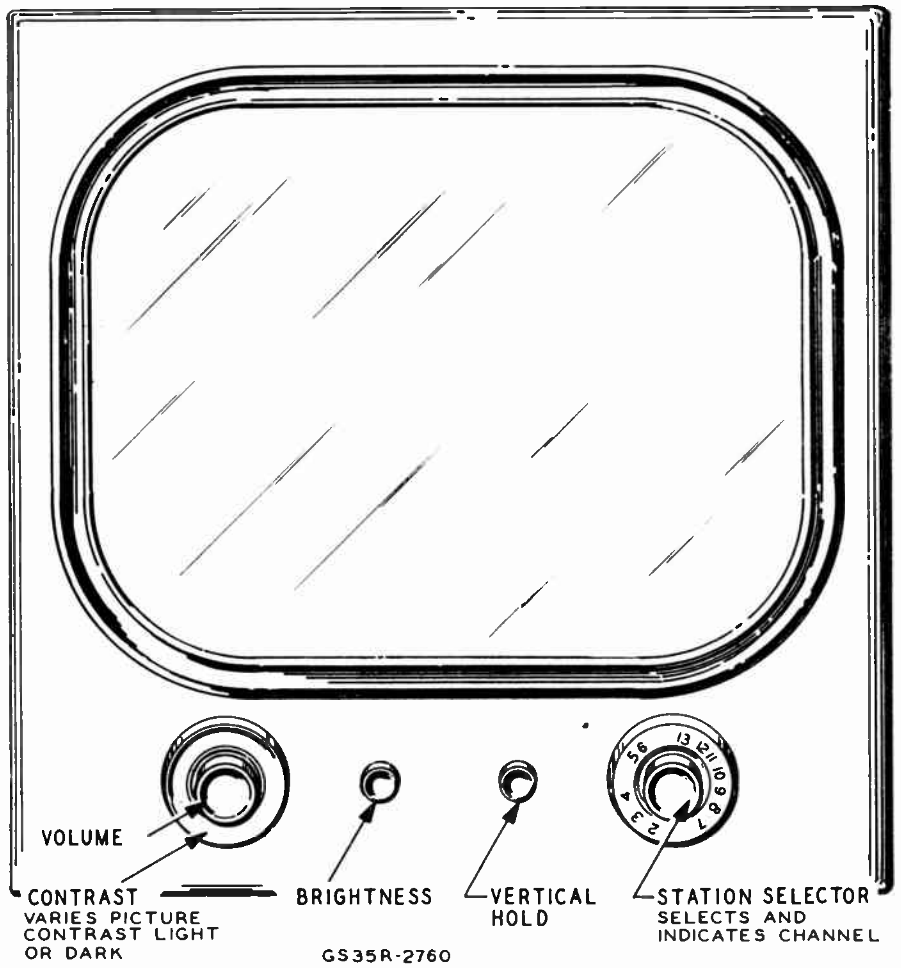

Fig. 2—Front Panel Controls

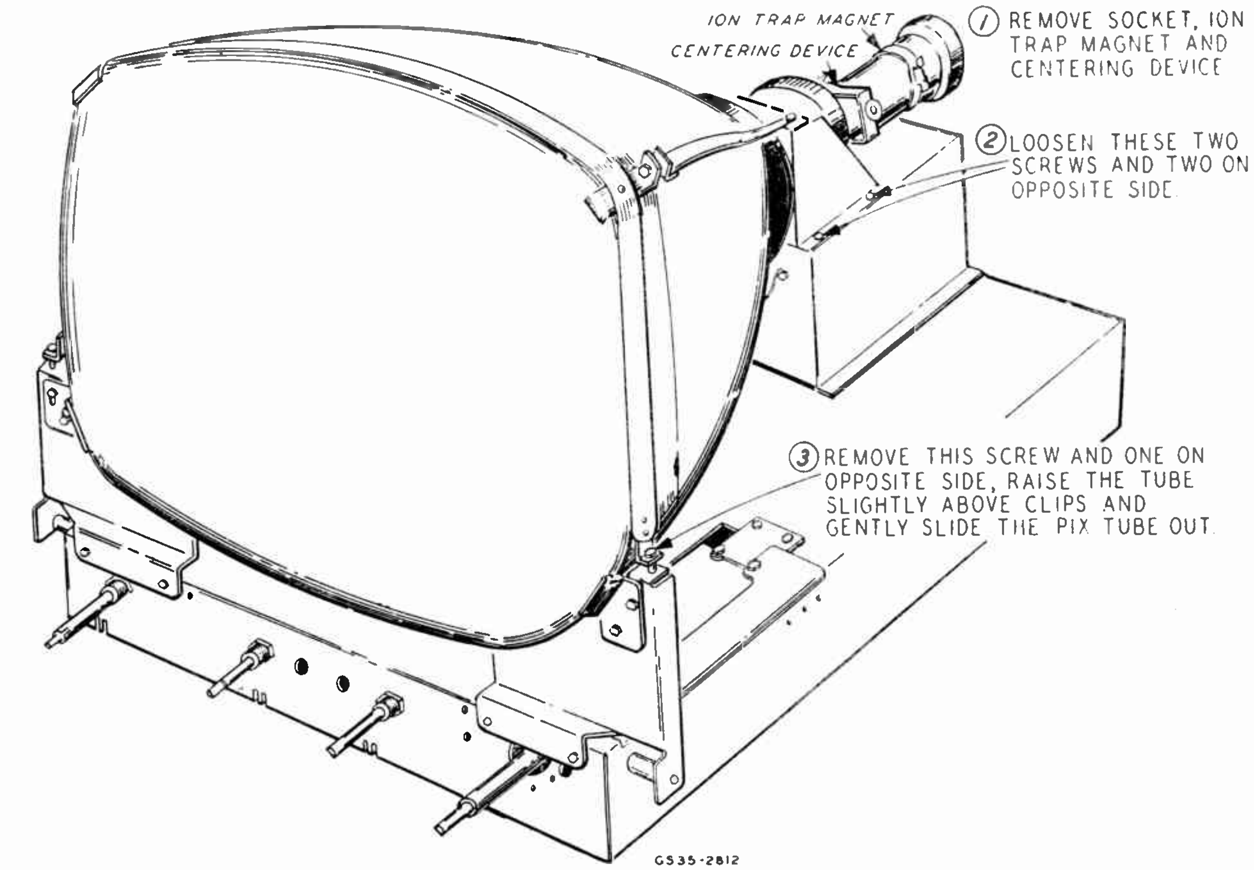

Fig. 3—Removal of Picture Tube.

TUNING PROCEDURE

1. To turn the television receiver on, turn the OFF-ON VOLUME control clockwise until a click is heard. Allow approximately 30 seconds for the tubes to warm up.
2. Turn the STATION SELECTOR control to the desired channel. This control may be turned in either direction.
3. Turn the CONTRAST control clockwise until activity or definite form is noted on the screen.
4. Adjust the STATION SELECTOR control for clearest picture and the VOLUME control for desired volume.
5. To turn off the receiver, turn the OFF-ON VOLUME control counterclockwise until a click is heard.

OCCASIONAL ADJUSTMENTS TO IMPROVE PICTURE RECEPTION

Brightness and Vertical Hold Controls are provided at the front of the receiver. These controls are pre-set at the factory and may occasionally need adjustment due to aging of the components in the receiver and the fluctuating line voltages in different areas. If any adjustments are necessary, follow the instructions under "Controls and Functions."

IMPORTANT — Be sure that the STATION SELECTOR Control has been set for the clearest picture before adjusting any control.

CONTROLS AND FUNCTIONS

HORIZONTAL HOLD—Stops horizontal movement (diagonal bars.) This control is located at the rear of the receiver.

BRIGHTNESS—Adjusts for desired picture brilliance.

VERTICAL HOLD—Stops upward or downward picture movement.

WARNING — Before handling the picture tube, it will be necessary to remove the static charge. In receivers with glass picture tubes, ground the anode lead to chassis, and insert an insulated wire from the well in the tube to chassis. In receivers with metal picture tubes, remove the static charge by grounding an insulated wire from the chassis to the metal portion of the tube.

PICTURE TUBE REPLACEMENT — To replace the picture tube it is necessary to remove the chassis from the cabinet. This may be accomplished in the following manner:

1. Remove the front control knobs by pulling them straight from their shafts.
2. Remove the cabinet back.
3. Disconnect the leads from the speaker, remove the antenna terminal board at the rear of the cabinet and then the five chassis mounting bolts. Pull chassis CAREFULLY out of the cabinet.
4. Remove the picture tube as shown and outlined in the illustration. To install a new picture tube, reverse the procedure making sure that the picture tube fits close against the picture tube cushion. If the picture tube sticks or fails to slip into place smoothly, investigate and remove the source of the trouble. Never force the tube. It is important that all the clips and shims used in mounting the tube be replaced, otherwise difficulty may be encountered when horizontal or vertical centering is required.

FRONT OF CHASSIS

Brightness	R-25

Deflection Yoke	Wing Screw
Width	L-15
Horizontal Drive	R-80
Horizontal Hold	L-14
Vertical Linearity	R-49
Height	R-54

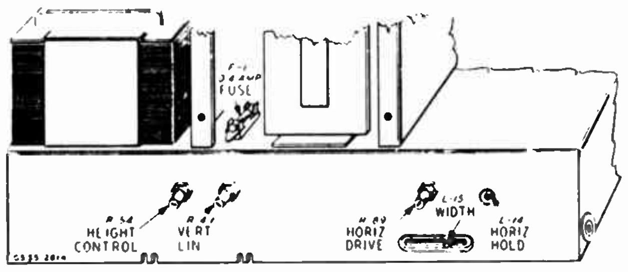

Fig. 4—Adjustments Rear of Chassis

ION TRAP MAGNET ADJUSTMENT—The ion trap magnet should be positioned close to the base of the tube. From this position adjust the magnet by moving it back and forth and at the same time rotating it slightly around the neck of the picture tube until the brightest raster is obtained on the picture screen. Reduce the brightness control setting until the raster is slightly above average brilliance. Readjust the ion trap magnet for maximum raster brilliance and best focus. MAXIMUM RASTER BRILLIANCE AND BEST FOCUS OCCUR AT THE SAME POINT. Do not sacrifice brilliance for best focus. The ion trap magnet adjustment is a very critical one especially with the electrostatic type zero focus picture tube. Consequently, great care should be taken to make sure that the ion trap magnet is correctly adjusted.

DEFLECTION YOKE ADJUSTMENT — If the lines of the raster are not horizontal or squared with the picture mask, rotate the deflection yoke until this condition is obtained. Tighten the yoke adjustment wing screw.

CENTERING ADJUSTMENT — If horizontal or vertical centering is required, adjust each ring in the centering device until proper centering is obtained.

PICTURE ADJUSTMENT — For further adjustments, obtain a test pattern on the receiver, Turn on receiver and follow tuning procedure on page 2. When a test pattern is obtained it may be necessary to slightly re-adjust the station selector control for clearest picture.

CHECK OF HORIZONTAL OSCILLATOR ALIGNMENT — Tune in a station and adjust the horizontal hold control until the picture falls into sync. Momentarily remove the signal by switching off channel and then back. The picture should pull into sync immediately. If in the above check the receiver fails to hold sync or pull-in to sync without hesitation it will be necessary to make a horizontal hold adjustment.

HEIGHT AND VERTICAL LINEARITY ADJUSTMENT — Adjust the height control (R-54) until the picture fills the mask vertically. Adjust the vertical linearity control (R-49 until the picture is symmetrical from top to bottom. Adjust the picture centering device to align picture with the mask. Adjustment of any control will require a re-adjustment of the other control.

WIDTH AND DRIVE ADJUSTMENTS —While receiving a signal from a station (with picture locked in sync) turn contrast control fully counter-clockwise, turn the brightness control (R-25) up so that the picture appears washed out. Adjust width control (L-15) until the picture fills the mask. Turn the horizontal drive control (R-89) clockwise until white bars appear in the left center portion of the raster, then turn counter-clockwise until the white bars just disappear. This adjustment will allow the horizontal system to operate at maximum efficiency. If adjustment of the horizontal drive (R-89) is required, it usually will be necessary to recheck the horizontal hold control. Adjust the picture centering device to align the picture with the mask.

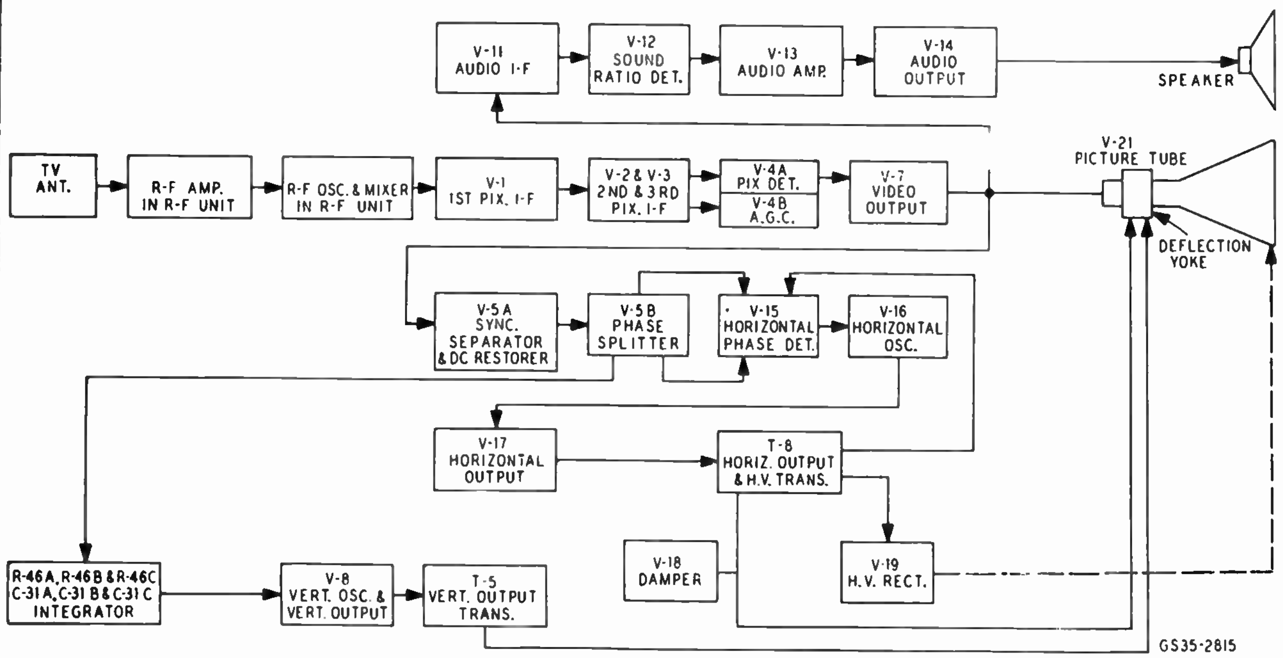

Fig. 5—Block Diagram.

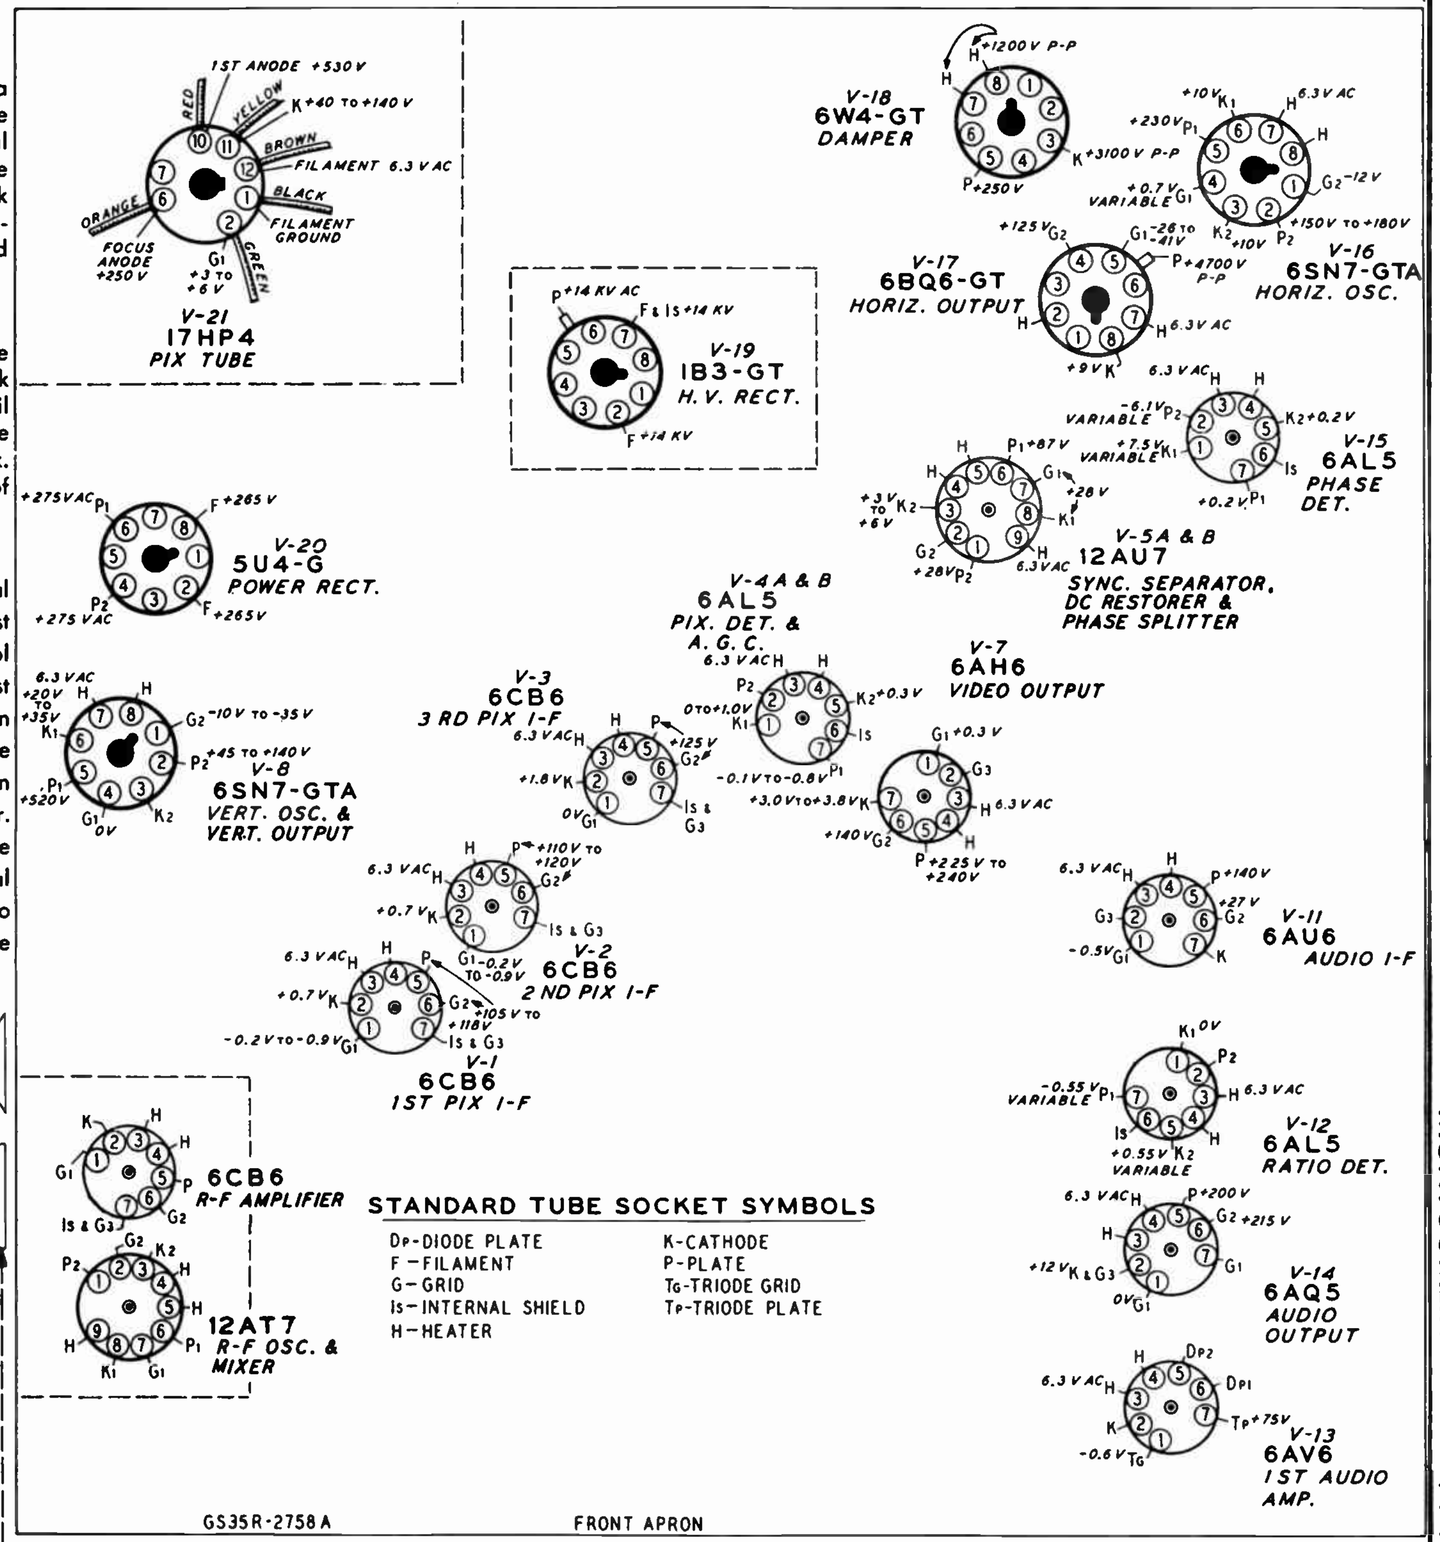

Fig. 6—Bottom Socket Voltages.

SERVICE SUGGESTIONS

NO RASTER ON PICTURE TUBE — If raster cannot be obtained check below for the possible causes.

1: Ion trap magnet adjustment is incorrect.
2: No +B voltage. Check 4 10 ampere fuse. Replace if defective. If fuse continually burns out, check
   (A) Horizontal output tube V-17 (6BQ6-GT)
   (B) Check damper tube V-18 (6W4-GT).
   (C) Check horizontal oscillator tube V-16 (6SN7-GTA) for proper operation.
   (D) With an ohm meter, check for a short between terminal 1 of the horizontal output transformer (T-8) and the chassis.
   (E) Check DC resistance of T-8.
3: No high voltage. Check V-17, V-18 and V-19 tubes and circuits. If the horizontal deflection circuits are operating as evidenced by the correct voltage (600V) measured on terminal No. 1 of T-8, the trouble can be isolated to the high voltage rectifier circuit. Either the high voltage winding to the 6BQ6-GT plate and 1B3 plate is open, tube V-19 is defective, its filament circuit is open, R-99 and C-78 defective or pix tube elements shorted internally.
4: Defective picture tube heater open or cathode return circuit open.

HORIZONTAL DEFLECTION ONLY — If only horizontal deflection is obtained as evidenced by a straight line across the face of the picture tube, it can be caused by the following:

1: Vertical oscillator and vertical output tube V-8 inoperative. Check socket voltages.
2: Vertical oscillator transformer (T-4) defective.
3: Vertical output transformer (T-5) open or shorted.
4: Yoke vertical coils open or shorted.
5: Vertical hold, height or linearity controls may be defective.

POOR VERTICAL LINEARITY — If adjustment of the height and linearity controls will not correct this condition, any of the following may be the cause.

1: Check variable resistors R-49 and R-54.
2: Vertical output transformer (T-5) defective.
3: Capacitors C-35A, or C-70 defective.
4: V-8 defective, check voltages.
5: Excess leakage or incorrect value of capacitor C-37, or open or incorrect value of resistors R-55 & R-56.
6: Low plate voltages. Check rectifier tube and capacitors in +B supply circuits.
7: Capacitor C-36 defective.
8: Vertical deflection coils (L-12) defective.

POOR HORIZONTAL LINEARITY — If adjustment of the Horizontal drive control does not correct this condition, check the following:

1: Check or replace horizontal output tube V-17.
2: Check or replace damper tube V-18 (6W4-GT).
3: Check capacitors C-74, C-76, for defects.
4: Horizontal deflection coils (L-17) defective.

TRAPEZOIDAL OR NONSYMMETRICAL RASTER

1: Defective yoke.

WRINKLES ON LEFT SIDE OF RASTER — This condition can be caused by:

1: Defective yoke due to C-75 or R-98 (internal in yoke assembly) being wrong value or open. These components are mounted in rear of yoke assembly.
2: V-18 (6W4-GT) defective.

SMALL RASTER — This condition can be caused by:

1: Low+B or line voltage. Check V-20 (5U4G).
2: Insufficient output from horizontal output tube V-17. Replace tube.
3: Insufficient output from vertical oscillator and vertical output tube V-8. Replace tube.
4: Incorrect setting of horizontal drive control R-89.
5: V-18 (6W4-GT) defective.
6: Incorrect setting of (L-15) width control.

RASTER; NO IMAGE, BUT ACCOMPANYING SOUND — This condition can be caused by:

1: No signal on picture tube grid. Check V-7 tube and associated circuits.
2: Bad contact to picture tube grid (lead to socket broken).

SIGNAL APPEARS ON PICTURE TUBE GRID BUT IMPOSSIBLE TO SYNCHRONIZE THE PICTURE VERTICALLY AND HORIZONTALLY — A condition of this nature can be caused by:

1: Defective V-5A sync separator or phase splitter V-5B.
2: If tube is O.K. check voltages, and associated circuits.
3: AGC system inoperative. Check V-4B (6AL5) AGC tube and associated circuit.

SIGNAL ON PICTURE TUBE GRID AND HORIZONTAL SYNC ONLY — If this condition is encountered, check:

1: Vertical integrating network capacitors C-31A, B & C, and resistors R-46 A, B & C.
2: Vertical hold control (R-51) defective.

SIGNAL ON PICTURE TUBE GRID AND VERTICAL SYNC ONLY

1: V-15 or V-16 defective.
2: Improper setting of (L-14) horizontal hold control.
3: Check setting of horizontal drive control.
4: Check V-15 and V-16 socket voltages.

PICTURE STABLE BUT WITH POOR RESOLUTION — If the picture resolution is not up to standard, it may be caused by any of the following:

1: Defective pix I-F tubes V-1, 2 & 3, (6CB6's).
2: Defective picture detector V-4A, (6AL5) or video output (V-7).
3: Defective picture tube.
4: Open video peaking coil. Check all peaking coils L-6, L-7, L-8, L-9 and L-10 for continuity. Note that L-6 and L-7 have shunting resistors.
5: Leakage in grid capacitor C-14. If the capacitor is not found to be defective, check the following:
   1: Check all potentials in video circuits.
   2: Check picture tube grid circuit for poor or dirty contact.
   3: Check and realign, if necessary, the picture I-F and R-F circuits.

PICTURE SMEAR:

1: A smear can be attributed to phase shift at the low or high frequency end of the video characteristic. This can be caused by improper values of resistors and capacitors in the video circuits. Check for grid current on video output tube V-7 (6AH6), open or shorted peaking coils, video amplifier load resistors are of improper value (high).
2: This trouble can also originate at the transmitter. Check reception from another station.
3: Check and realign, if necessary, the picture I-F and R-F circuits.

MAN MADE NOISE IN SOUND (Ignition, etc.)

1: Check sound I-F tubes V-11 & V-12 and associated circuits.
2: Check sound I-F alignment.

BENDING OR S-ING

1: Check capacitors C-35B and C-79B.
2: V-17 (6BQ6-GT) defective or V-16 (6SN7-GTA) defective.
3: Check sync separator tube V-5A (12AU7) and phase splitter V-5B (12AU7).
4: If contrast setting is too high it can cause this trouble.

PICTURE NORMAL—NO SOUND OR WEAK OR DISTORTED SOUND

1: Check sound I-F alignment.
2: Check V-11 (6AU6) V-12 (6AL5) V-13 (6AV6) V-14 (6AQ5) and associated circuits.

BUZZ IN SOUND:

1: Contrast setting too high.
2: Check sound I-F Alignment.

POOR FOCUS:

1: Improper setting of Ion Trap magnet.
2: Defective picture tube or picture tube socket.

PICTURE JITTER:

1: If regular sections at left of the picture are displaced, replace the horizontal oscillator tube V-16.
2: Vertical instability may be due to loose connections or noise received with the signal.
3: Horizontal instability may be due to unstable transmitted sync.
4: Check receiver AGC system for proper operation.
5: Check phase splitter V-5B, (12AU7) and sync separator V-5A.
6: Picture tube grid lead not held in position by support spring, ie: close proximity of grid lead to sync and horizontal tubes will cause picture to jitter at high contrast setting.
7: Contrast control setting either too high or too low.

ALIGNMENT PROCEDURE

TEST EQUIPMENT — To service this receiver properly, it is recommended that the following test equipment be available:

R-F SWEEP GENERATOR meeting the following requirements:

(a) Frequency ranges:
   18 to 30 mc, 10 mc sweep width
   40 to 90 mc, 10 mc sweep width
   170 to 225 mc, 10 mc sweep width
(b) Output adjustable with at least .1 volt maximum.
(c) Output constant on all ranges.
(d) Flat output in all attenuator positions.

CATHODE-RAY OSCILLOSCOPE preferably one with a wide band vertical deflection and an input calibrating source.

SIGNAL GENERATOR to provide the following frequencies: (Output on these ranges should be adjustable and at least .1 volt maximum.)

(a) Intermediate alignment frequencies.
   23.1 mc first picture I-F coil.
   24.1 mc third picture I-F coil.
   25.9 mc second picture I-F coil.
   21.7 mc sound trap.
   4.5 mc video trap & sound I-F.
   25.2 mc converter plate coil (Tuner).

HETERODYNE FREQUENCY METER with crystal calibrator if the signal generator is not crystal controlled.

ELECTRONIC VOLTMETER and a high voltage probe for use with this meter to permit measurements up to 20 kilovolts.

SERVICE PRECAUTIONS — To service the receiver remove the chassis from the cabinet. To do so, remove the knobs, the cabinet back, disconnect the leads from the speaker, remove the antenna terminal board at rear of cabinet, and then the 5 chassis mounting bolts. The chassis may be serviced with the picture tube in place provided the chassis is turned on its side with the power transformer on the bottom. The weight of the chassis will be supported against the power transformer and pix tube brackets.

CAUTION: Do not permit the kinescope second-anode lead to become shorted to the chassis. To do so will cause a considerable overload on the high voltage filter resistor R-99.

ALIGNMENT PROCEDURE

PIX I-F

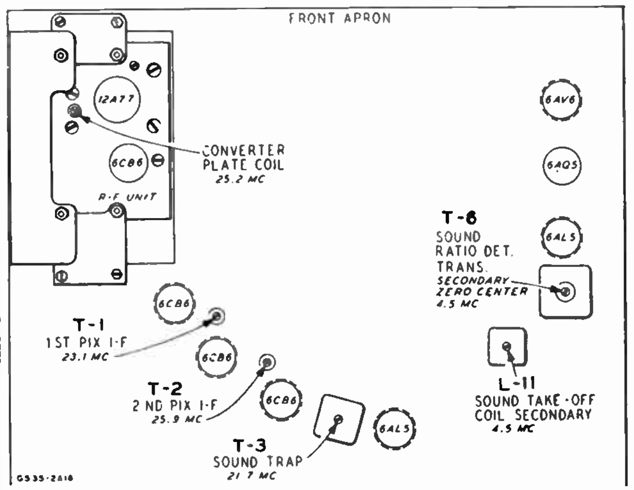

Fig. 7—Top Chassis Video and Audio I-F Adjustments

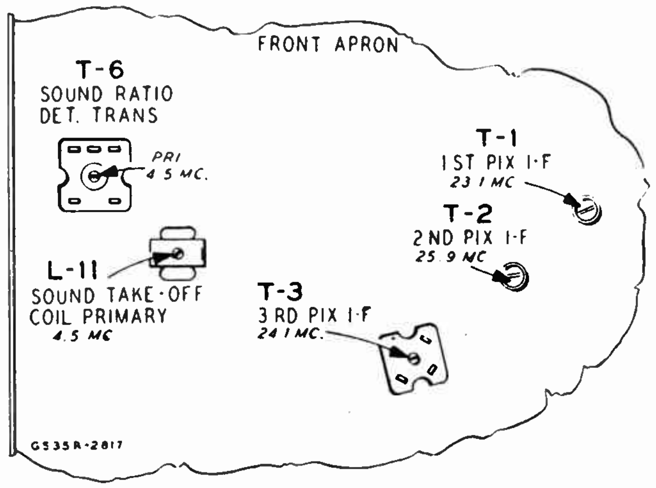

Fig. 8--Bottom Chassis Video and Audio I-F Adjustments

A. Unmodulated R-F signal into Converter Grid by means of tube shield insulated from base. VTVM with filter in lead of 22 K ohms and 5000 mmf connected to pic. det. load resistor, (R-14) 4700 ohms, in series with peaking coil (L-7) from Pin 5 of 6AL5. Input signal leval should be such that output is less than 2 volts D.C. Apply -4.5V battery bias on AGC line.

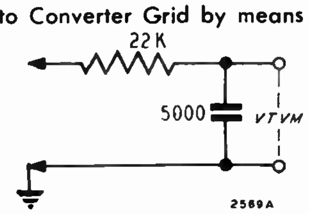

Fig. 9—VTVM Connections

	FREQUENCY	ADJUST
1.	25.2 MC	Converter plate coil (L-4) for maximum dc at picture detector
2.	23.1 MC	1st picture I-F coil (T-1) for maximum dc at picture detector.
3.	25.9 MC	2nd picture I-F coil (T-2) for maximum dc at picture detector.
4.	24.1 MC	3rd picture I-F coil (T-3 below chassis) for maximum dc at picture detector.
5.	21.7 MC	3rd picture I F trap (T-3 in can above chassis) for minimum dc at picture detector.

B. I-F Sweep Generator into converter grid by means of tube shield insulated from base.

Connect oscilloscope across R-14 (in place of VTVM). Apply -4.5V bias (DC) to AGC line (battery). Tuner should be turned to dead channel so as not to cause interference.

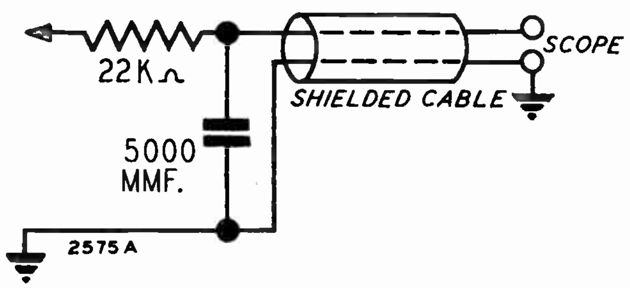

Fig. 10—Oscilloscope Connections.

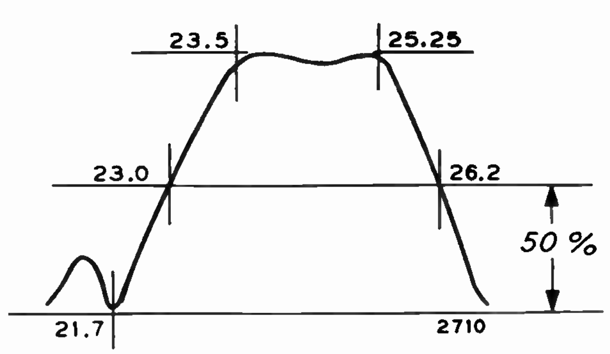

Fig. 11—Overall Response Curve

Observe overall I-F response, which should be as shown above. A slight touch-up may be required. At no time should the trap coil be re-adjusted, nor should it be necessary to turn any of the picture I-F coils more than 1/2 turn of the slug. The following comments are suggestions only:

1. The height of the 26.2 MC marker is controlled by the 25.2 MC (Converter Plate Coil on tuner) and the 25.9 MC (2nd P.I.F.) coils.
2. The uniformity of response (flatness across top and position of 23.5 MC) marker is controlled for the most part by the 24.1 MC third picture I-F coil.
3. The 23.0 MC marker position is controlled by the first picture I-F (23.1 MC coil). However, it is NOT advisable to change the setting of the coil, due to its effect on sound rejection. Its adjustment should be avoided unless believed to be absolutely necessary.

VIDEO

With 4.5 MC unmodulated signal from a high impedance source, (10,000 ohms in series with the generator) into cathode of the picture detector tube (Pin 5-6AL5) and VTVM on picture tube grid, tune sound take off coil primary (L-11 Bottom) for minimum response. VTVM on 0-10 V AC scale. This adjustment can also be made while observing a picture from a station. Tune trap for least 4.5 MC beat in picture.

AUDIO I-F

1: With signal generator set to 4.5 MC and dc VTVM connected to junction of R-17 and C-13, adjust sound take-off coil secondary (L-11 Top) for maximum.
2: With VTVM connected to pin 7 of V-12 (6AL5) adjust the ratio detector primary (T-6 Bottom) for maximum.
3: With VTVM connected to junction of R-66, R-69 and C-50, adjust ratio detector secondary (T-6 Top) for cross over (zero voltage) on lowest scale.
NOTE — If no signal generator is available, the procedure above may be followed by tuning in a station and using the 4.5 MC beat between picture and sound carrier.

CONTINUOUS TUNER ADJUSTMENTS

ALIGNMENT of tuner cannot be accomplished in the field, however, a pictorial of the tuner is shown below to be used ONLY for minor field adjustments. A replacement parts list and schematic diagram are shown on page 14.

NOTE—A FEW RECEIVERS WERE SHIPPED WITH A TURRET TYPE TUNER PART NUMBER 25A1080.

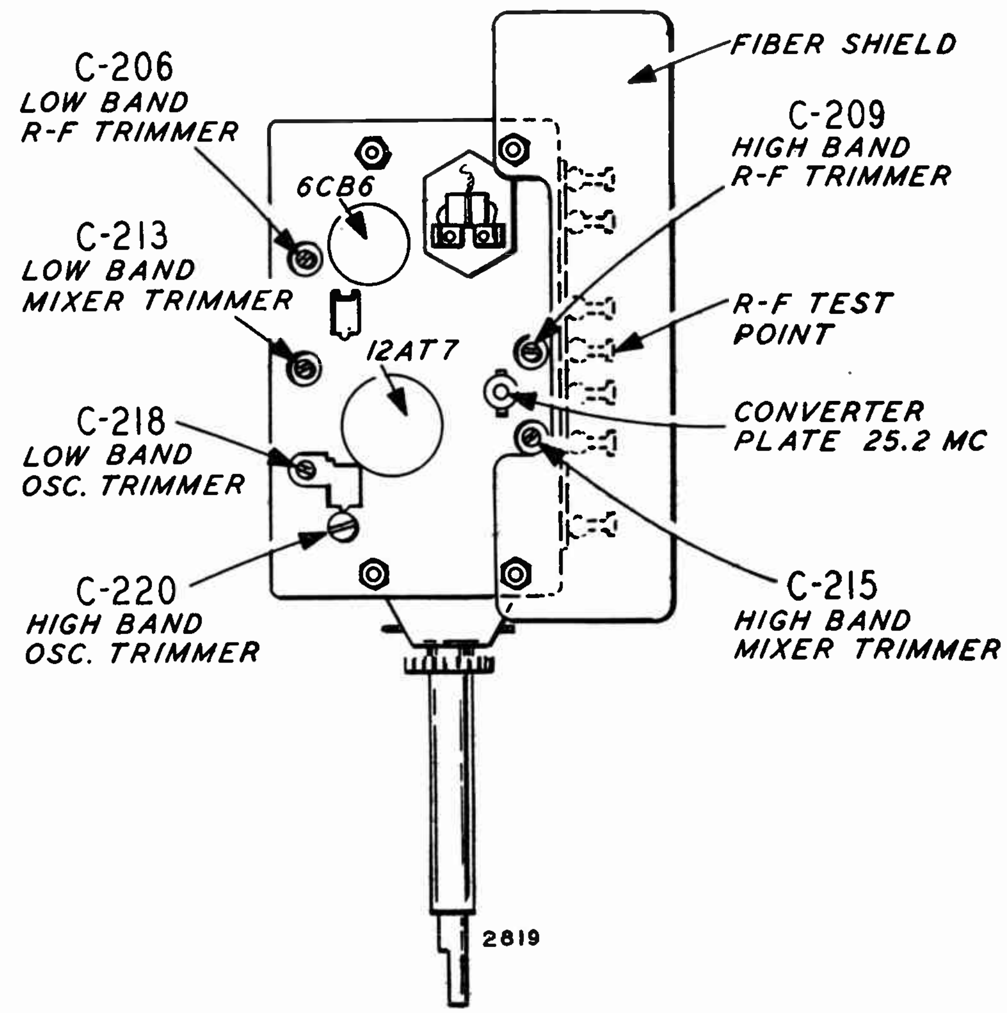

Fig. 12—Tuner Adjustments.

OSCILLOSCOPE WAVEFORM PATTERNS

The waveforms on this page were taken with the receiver tuned to a normal picture. The numbers on the waveforms correspond to the numbers on the schematic diagram which identifies each test point.
The voltages shown on each waveform are the approximate peak to peak amplitudes. The frequencies shown indicates the repetition rate of the waveform, not the sweep rate of the oscilloscope. If the waveforms are observed on the oscilloscope with a poor high frequency response, the corners of the pulses will tend to be more rounded than those shown below and the amplitudes of any high frequency pulse will tend to be less.

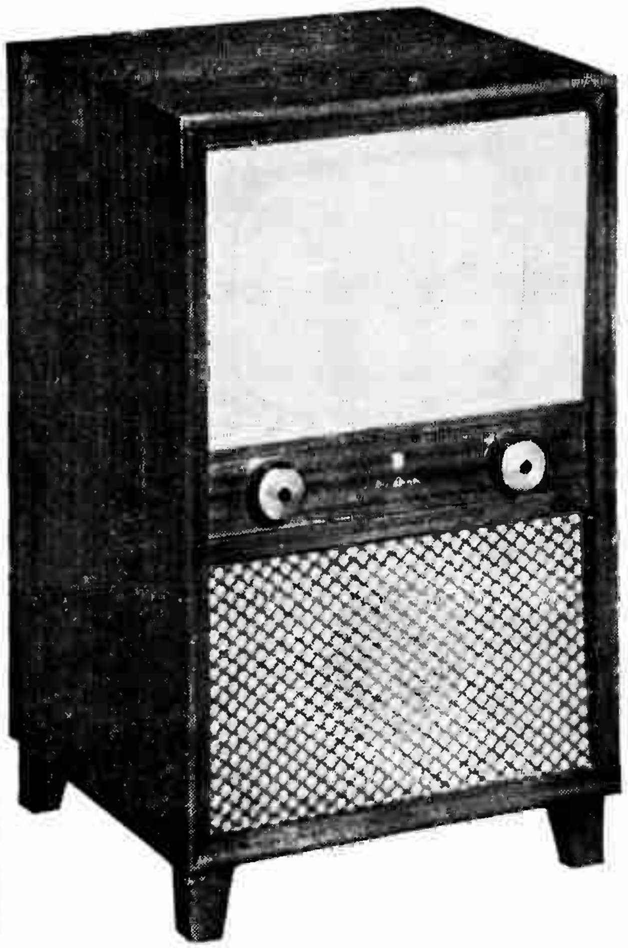

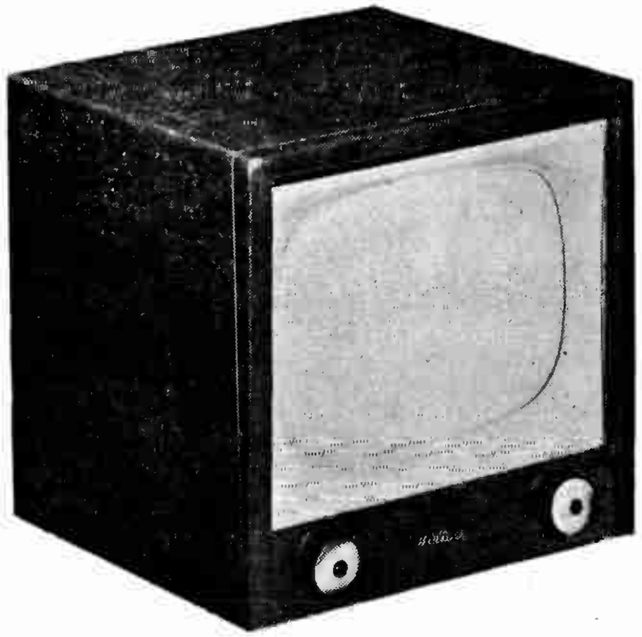

FIGURE 1 FRONT CONTROLS

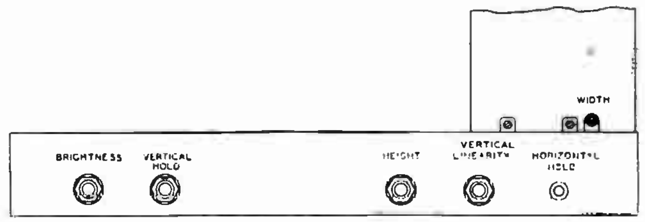

FIGURE 2 REAR CONTROLS

OFF-VOLUME: Turns set on or off and adjusts sound volume.

CONTRAST: Varies contrast between light and dark portions of the television picture.

STATION SELECTOR: Tunes the set to the desired station or channel. It may be turned in either direction.

FINE TUNING: Adjusts set so that both picture and sound are received with maximum clarity.

BRIGHTNESS: Controls brilliance of the picture.

VERTICAL HOLD: Stops picture from moving up or down.

HEIGHT: Changes size of picture vertically.

VERT. LINEARITY: Controls vertical distribution of picture.

HORZ. HOLD: Stops picture from moving.

WIDTH: Changes size of picture horizontally.

GENERAL DESCRIPTION

These models use 19 tubes, (including picture tube and rectifier) have a crystal diode video detector, employ a intercarrier sound circuit, have safety interlock and a fuse in the low voltage power supply. Picture tube has electrostatic focus, which is automatic and permanent.

ELECTRICAL SPECIFICATIONS

Power Supply	105-125 Volts AC 60 Cycles Only
Power Consumption	170 Watts
Power Output	2.7 Watts (Max.) 1.55 Watts (10% Distortion)
Tuning Range	12 Channel
Antenna Input Imp.	300 Ohms balanced
Intermediate Frequencies	Picture 26.4 MC Sound 21.9 MC
Intercarrier Sound System	4.5 MC
Loud Speaker	Electro-Magnetic
Voice Coil Imp.	3.2 Ohms 400 Cycles
Field Coil Resistance	90 Ohms

TUBE COMPLEMENT

Symbol	Type	Function
V1 Tuner	6BC5	R-F Amplifier
V2 Tuner	6J6	R-F Osc. & Mixer
V3	6CB6	1st Pix I-F Amplifier
V4	6CB6	2nd Pix I-F Amplifier
V5	6CB6	3rd Pix I-F Amplifier
V6	6AH6	Video Amp.
V7	6AU6	Sound Driver
V8	6AU6	Sync. Separator
V9	6AL5	Horizontal Phase Det.
V10 A&B	6SN7GT	Vert. Osc. & Phase Splitter
V11	6SN7GT	Horizontal Oscillator
V12 A&B	6T8	Audio Amp. & Ratio Detector
V13	6S4	Vertical Output
V14	6BQ6GT	Horizontal Output
V15	6W4-GT	Damper
V16	6Y6G	Audio Output
V17	1B3-GT	High Voltage Rectifier
V18	5U4-G	Low Voltage Rectifier
V19	17TP4	Pix Tube 17" Metal Rectangular

SERVICE ADJUSTMENTS

ION TRAP MAGNET ADJUSTMENT: The ION trap magnet should be positioned approximately over the diagonal slit in the electron gun. From this position adjust the magnet by moving it back and forth and at the same time rotating it slightly around the neck of the picture tube until the brightest raster is obtained on the picture screen. Reduce the brightness control setting until the raster is slightly above average brilliance.

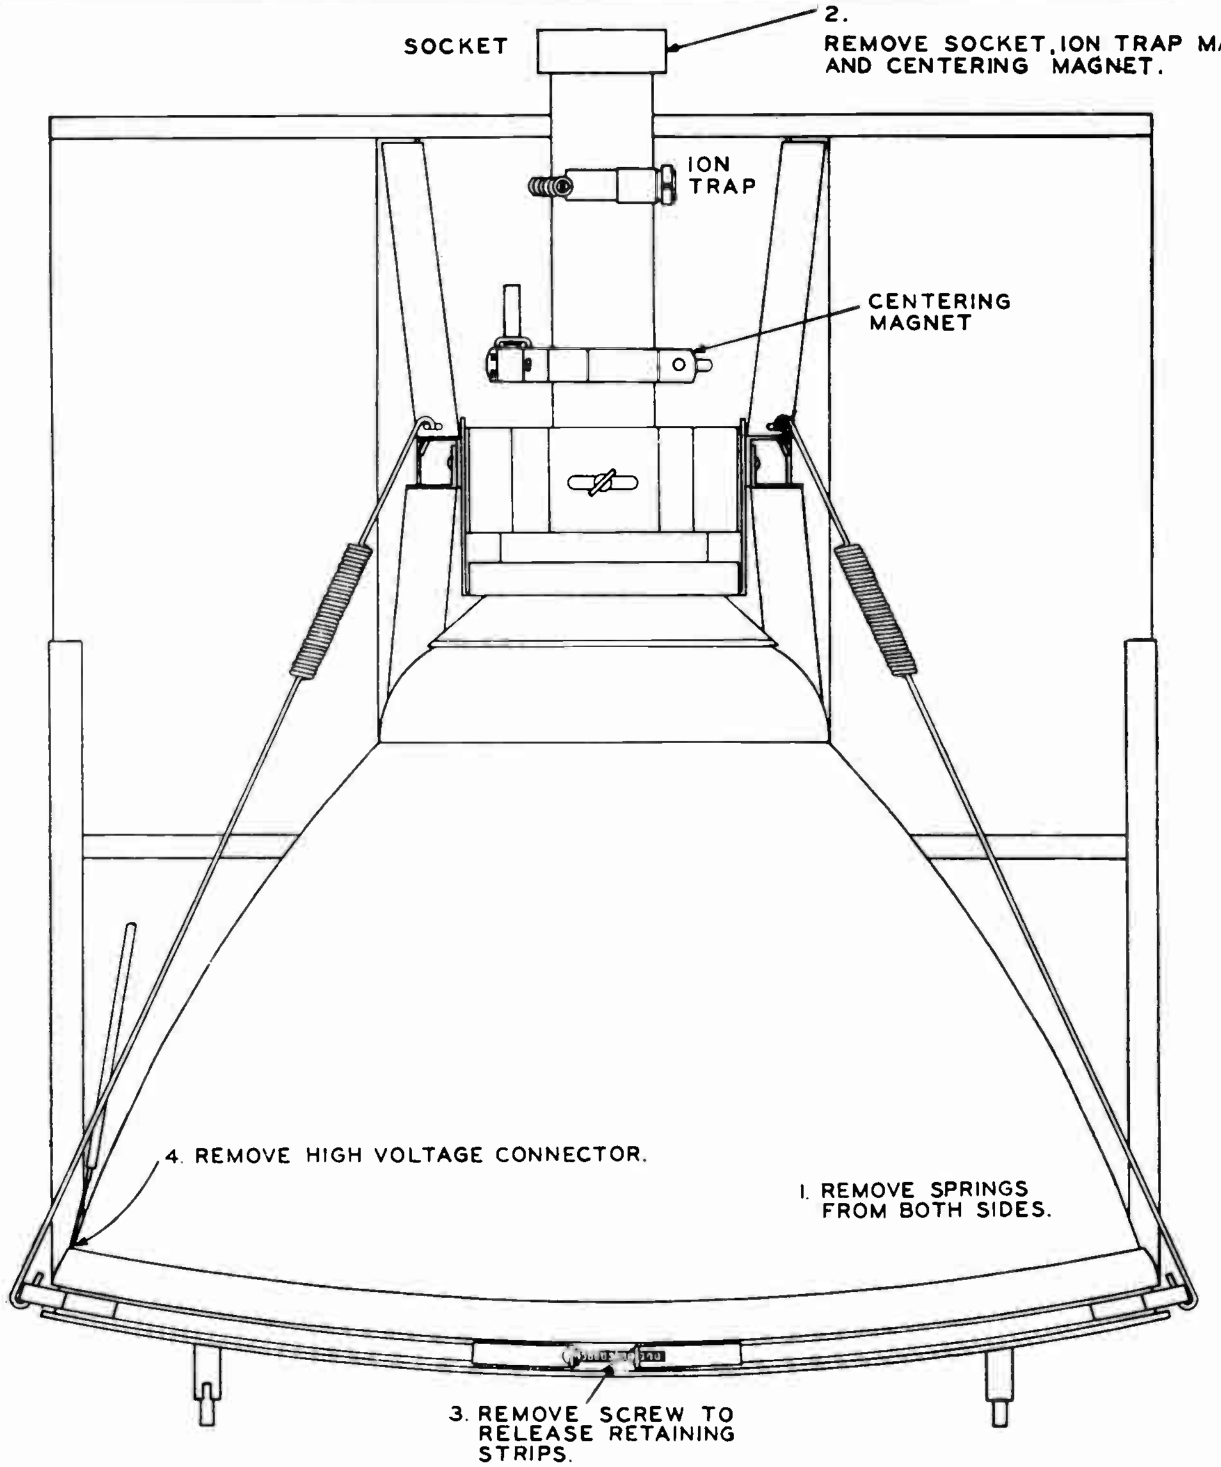
DEFLECTION YOKE ADJUSTMENT: If the lines of the raster are not horizontal or squared with the picture mask, rotate the deflection yoke until this condition is obtained. The correct position for the deflection yoke is as far forward on the neck of the picture tube as the shape of the tube will allow. Tighten the yoke adjustment wing screw.

CENTERING MAGNET: The centering magnet should be rotated and the control adjusted until the picture is properly framed keeping in mind that the effect of the control is governed by the position of rotation. If the control is above or below the neck of the picture tube, the picture will be moved up or down. To the left or right of the neck of the picture tube, the picture will be moved either to the left or right.

WIDTH ADJUSTMENTS: Adjust width by turning slug either clockwise or counter clockwise. A clockwise rotation will decrease width. Proper width is obtained when raster covers entire screen of picture tube.

CHECK OF HORIZONTAL OSC. ALIGNMENT: Tune in a station and adjust the horizontal hold control until the picture falls into sync. Momentarily remove the signal by switching off channel and then back. The picture should pull into sync. If in the above check the receiver fails to hold sync. re-set horizontal hold slightly.

HEIGHT AND VERTICAL LINEARITY ADJUSTMENTS: The vertical size and linearity controls should both be adjusted at the same time while a test pattern is being transmitted. The linearity control affects the upper portion of the picture while the size control affects the overall size especially the lower portion of the picture. Adjust both controls simultaneously until the test pattern is symmetrical and fills the entire screen vertically. Readjust the vertical hold control if necessary.



1037 FIG. 3 PICTURE TUBE ASSEMBLY

PICTURE TUBE REPLACEMENT: To replace the picture tube it is necessary to remove the chassis from the cabinet. This may be accomplished in the following manner:

1. Remove the front panel control knobs by pulling them straight from their shafts.
2. Remove the cabinet back. Remove antenna terminal board from cabinet back. You will not that the interlocked line cord disconnects the power when the cabinet back is removed.
3. Disconnect speaker plug from chassis, remove the five chassis mounting bolts. Pull chassis **CAREFULLY** out of the cabinet.
4. Remove the picture tube as shown and outlined in the illustration. To install a new picture tube, reverse the procedure making sure that the picture tube fits close against the picture tube cushion. If the picture tube sticks or fails to slip into place smoothly, investigate and remove the source of the trouble. Never force the tube. It is important that all the clips and shims used in mounting the tube be replaced, otherwise difficulty may be encountered when horizontal or vertical centering is required.

WARNING: Before handling the picture tube, it will be necessary to remove the static charge. In receivers with metal picture tubes, remove the static charge by grounding an insulated wire from the chassis to the metal portion of the tube.

SERVICE SUGGESTIONS

NO RASTER ON PICTURE TUBE: If raster cannot be obtained check below for the possible causes.

1. ION trap magnet adjustment is incorrect.
2. No B+ voltage. Check 1/4 ampere fuse. Replace if defective. If fuse continually burns out, check (A) for short of B+ circuit with ohmmeter, check (B) horizontal output tube V-14 (6BQ6-GT), check (C) damper tube V-15 (6W4-GT). (D) Check horizontal oscillator V-11 (6SN7-GT) for proper operation. (E) With an ohmmeter, check for a short between terminal 3 of the horizontal output transformer (T-6) and the chassis.
3. No high voltage. Check V-11, V-14, V-15 and V-17 tubes and circuits. If the horizontal deflection circuits are operating as evidenced by the correct voltage measured on pin 3 of the damper tube (V-15), the trouble can be isolated to the high voltage rectifier V-17 circuit. Either the high voltage winding to the 6BQ6GT plate and 1B3 plate is open, tube V-17 is defective, its filament circuit is open, or the high voltage filter capacitor C-70 is shorted.
4. Defective picture tube. Heater open or cathode return circuit open.

HORIZONTAL DEFLECTION ONLY: If only horizontal deflection is obtained as evidenced by a straight line across face of the picture tube, it can be caused by the following:

1. Vertical oscillator V-10A (6SN7-GT) or vertical output tube V-13 (6S4) inoperative. Check voltages on grid and plate.
2. Vertical oscillator transformer T-4 defective.
3. Vertical output transformer (T-5) open or shorted.
4. Yoke vertical coils open.
5. Vertical hold, height or linearity controls may be defective.

POOR VERTICAL LINEARITY: If adjustment of the height and linearity controls will not correct this condition, any of the following may be the cause.

1. Check variable resistors R-54 and R-59.
2. Vertical output transformer (T-5) defective.
3. Capacitors C-54A & B or C-53C & D defective.
4. V-10A (6SN7-GT) or V-13 (6S4) defective, check voltages.
5. Excess leakage or incorrect value of capacitor C-51, C-52, or open or incorrect value of resistors R-55, 56 & R-57.
6. Low plate voltages. Check rectifier tubes and capacitors in B+ supply circuits.
7. Vertical deflection coils defective (part of T-7 yoke).

POOR HORIZONTAL LINEARITY:

1. Check or replace horizontal output tube V-14 (6BQ6-GT).
2. Check or replace damper tube V-15 (6W4-GT).
3. Check capacitor C-67.
4. Horizontal deflection coils defective (part of T-7 yoke).

TRAPEZOIDAL OR NONSYMMETRICAL RASTER:

1. Improper adjustment of ION trap magnet.
2. Defective yoke.

SERVICE SUGGESTIONS (*Continued*)

BARS AND WRINKLES ON LEFT SIDE OF RASTER: This condition can be caused by:

1. Defective yoke due to C-69 or R-61, R-62 (Internal in yoke assembly) being wrong or open. These components are mounted in rear of yoke assembly.
2. V-15 (6W4) defective.

SMALL RASTER: This condition can bė caused by:

1. Low B+ or line voltage. Check V-18 (5U4G).
2. Insufficient output from horizontal output tube V-14. Replace tube.
3. Insufficient output from vertical oscillator tube V-10A or vertical output tube V-13. Replace tubes.
4. V-15 (6W4) defective.

RASTER: NO IMAGE, BUT ACCOMPANYING SOUND: This condition can be caused by:

1. No signal on picture tube grid. Check V-6 (6AH6) tube and associated circuits.

SIGNAL APPEARS ON PICTURE TUBE GRID BUT IMPOSSIBLE TO SYNCHRONIZE THE PICTURE VERTICALLY AND HORIZONTALLY:

A condition of this nature can be caused by:

1. Defective sync. Sep. V-8 or Horiz. splitter V-10B or Horiz. Phase Detector V-9.
2. If tubes are O.K. check voltages, and associated circuits.
3. AGC system inoperative.
4. Open video peaking coil. Check all coils, L-8, L-9, L-10, L-16 and L-11 for continuity. Note that L-9 and L-11 have shunting resistors.
5. Check all potentials in video circuits.
6. Check and realign, if necessary, the picture 1-F and R-F circuits.

POOR FOCUS:

1. Improper adjustment of ION trap.
2. Defective picture tube.

SNOWY PICTURE:

1. Insufficient signal input.
2. Defective antenna.
3. Weak V-1 (6BC5).
4. Defective Tuner.

PICTURE SMEAR:

1. Normally, smear can be attributed to shift at the low frequency end of the video characteristic. This can be caused by improper values of resistors and capacitors in the video circuits. Check for grid current on video output tube V-6 (6AH6).
2. This trouble can also originate at the transmitter. Check reception from another station.
3. Check and realign, if necessary, the picture I-F and R-F circuits.

PICTURE JITTER:

1. Replace the horizontal oscillator tube V-11.
2. Vertical instability may be due to loose connections or noise received with the signal.
3. Horizontal instability may be due to unstable transmitted sync. or to noise.
4. Check receiver AGC system for proper operation.
5. Check phase splitter V-10B (6SN7-GT).

LACK OF CONTRAST:

1. Defective V-3, V-4, V-5, V-6.
2. Defective crystal detector.
3. Defective Control R-28.

NO SOUND PICTURE NORMAL:

1. Defective V-7, V-12, V-16.
2. Speaker leads open.
3. T-2, T-3 defective.
4. Improper sound alignment.

CHECK OF R-F OSCILLATOR ADJUSTMENTS

The oscillator is preset at the factory and normally needs no adjustment. However, if adjustments are required, they can be made without removing the chassis from the cabinet. Remove the channel selector and fine tuning knobs from the tuning shaft.

TEST PROCEDURE:

1. Set channel selector to receive desired station.
2. Set fine tuning control in center of its range.
3. Adjust oscillator slug, with bakelite type screwdriver, for best picture resolution.
4. Repeat steps 1, 2 and 3 on all channels used.

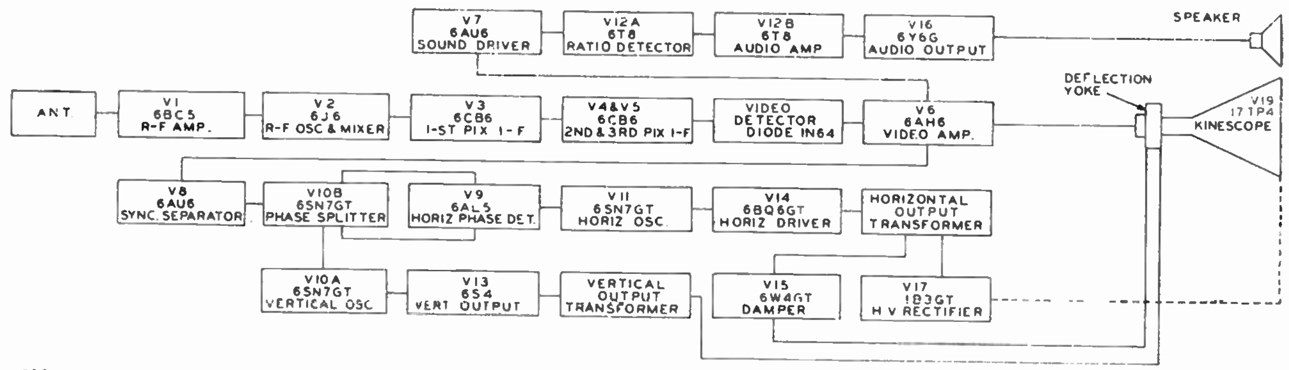
BOTTOM SOCKET VOLTAGES
FIG. 5

1044



1033

FIG 6 BLOCK DIAGRAM OF RECEIVER

ALIGNMENT PROCEDURE

TEST EQUIPMENT: To service this receiver properly, it is recommended that the following test equipment be available:

R-F SWEEP GENERATOR meeting the following requirements:

(a) Frequency ranges:

18 to 30 mc, 10 mc sweep width

40 to 90 mc, 10 mc sweep width

170 to 225 mc, 10 mc sweep width

(b) Output adjustable with at least .1 volt maximum.

(c) Output constant on all ranges.

(d) Flat output in all attenuator positions.

CATHODE-RAY OSCILLOSCOPE preferably one with a wide band vertical deflection and an input calibrating source.

Heterodyne Frequency Meter with crystal calibrator if the signal generator is not crystal controlled. Electronic Voltmeter and a high voltage probe for use with this meter to permit measurements up to 20 kilovolts.

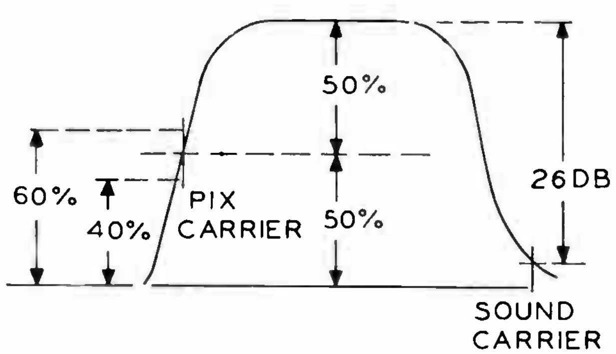


FIG.7 - OVERALL RESPONSE CURVE

1038

SIGNAL GENERATOR to provide the following frequencies; (Output on these ranges should be adjustable and at least .1 volt maximum.)

(a) Intermediate alignment frequencies.

26.1 Plate coil tuner

24.4 1st Pix I.F. Coil

24.0 2nd Pix I.F. Coil

4.5 mc video trap and sound I.F.

26.1 3rd Pix I.F. Coil

(b) Radio frequencies.

Channel No.	Picture Carrier Freq. Mc.	Sound Carrier Freq. Mc.
2	55.25	59.75
3	61.25	65.75
4	67.25	71.75
5	77.25	81.75
6	83.25	87.75
7	175.25	179.75
8	181.25	185.75
9	187.25	191.75
10	193.25	197.75
11	199.25	203.75
12	205.25	209.75
13	211.25	215.75

SERVICE PRECAUTIONS: To service the receiver remove the chassis from the cabinet. To do so, remove the knobs, the cabinet back, disconnect speaker plug from chassis, remove the antenna terminal board from cabinet back, and then the 5 chassis mounting bolts. The chassis may be serviced with the picture tube in place provided the chassis is turned on its side with the power transformer on the top. The weight of the chassis will be supported against the high voltage housing.

CAUTION: Do not permit the kinescope second-anode lead to become shorted to the chassis. To do so will cause a considerable overload on the high voltage filter resistor R-86.

LOCATION OF TUBES

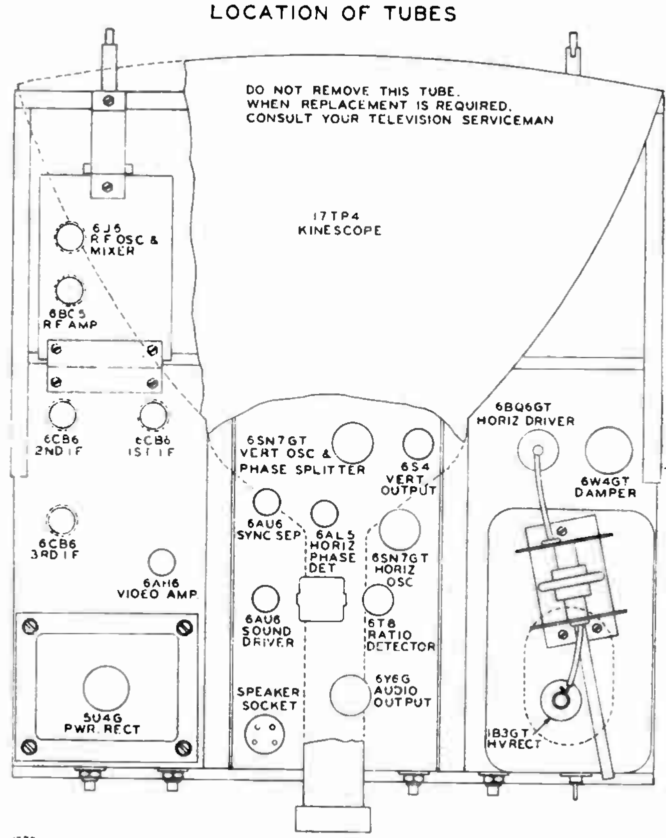

FIG 9

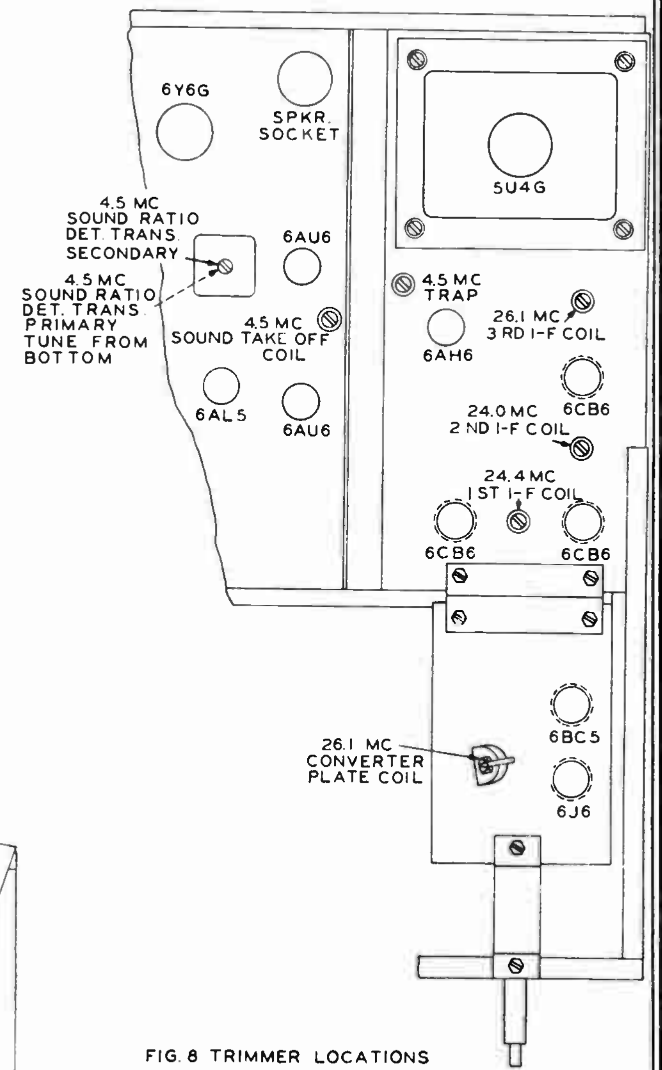

FIG. 8 TRIMMER LOCATIONS

A. Unmodulated R-F signal into Converter Grid by means of tube shield insulated from base. VTVM connected to junction picture detector load resistor, (R-21) 6800 ohms, and peaking coil (L-8). Input signal level should be such that output is less than 2 volts DC. apply — 4.5 V battery Bias on AGC line.

ALIGNMENT PROCEDURE (*Continued*)

Frequency	Adjust
1. 26.1 MC	Converter plate coil (on top of tuner) for maximum dc at picture detector.
2. 24.4 MC	1st picture I-F coil L-5 (above chassis) for maximum dc at picture detector.
3. 24.0 MC	2nd picture I-F coil L-6 (above chassis) for maximum dc at picture detector.
4. 26.1 MC	3rd picture I-F coil L-7 (above chassis) for maximum dc at picture detector.

B. I-F Sweep Generator into converter grid by means of tube shield insulated from base. Connect oscilloscope across R-21, 6800 Ohms (in place of VTVM). Apply — 4.5 bias (battery) to AGC line.

Tuner should be switched to a channel not being used so as not to cause interference.

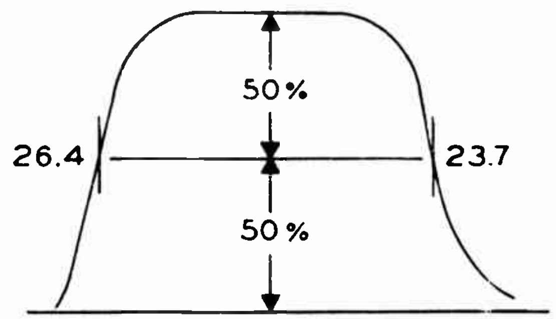

FIG. 10 OVERALL I.F. RESPONSE CURVE

1035

Observe overall I-F response, which should be as shown above: A slight touch-up may be required. At no time should it be necessary to turn any of the picture I-F coils more than ½ turn of the slug. The following comments are suggestions only:

1. The height of the 26.4 MC marker is controlled by the (26.1 MC) converter plate coil on tuner and the (26.1 MC) 3rd P.I.F. coils.
2. The 23.7 MC marker position is controlled by the 2nd picture I-F coil (24.0 MC) and the 1st picture I-F coil (24.4 MC).

4.5 MC TRAP ALIGNMENT:

1. Tune in a station.
2. Adjust fine tuning rotar until sound bars just appear in picture.
3. Turn L-10 slug all the way out (counter clockwise).
4. Turn the slug in (clockwise) until the horizontal scanning lines are smooth and continuous.

SOUND I-F ALIGNMENT: Connect signal generator to grid of video amp. (6AH6), adjust contrast control to maximum. Set signal generator to 4.5 MC (no modulation) (setting of 4.5 MC must be accurate). Connect (2) two 50,000 ohm resistors across C-39 (resistors must match within 5%). 1. VTVM is connected across C-39. **See Fig. 12.** Adjust L-12 and T-3 (Bottom) for maximum on VTVM. This adjustment should be made with voltage on VTVM under 12 volts. 2. Connect VTVM between junction of R-39, R-40 and junction of the (2) two 50,000 ohm resistors. **See Fig. 12.** Adjust T-3 (Top) for zero on VTVM. If VTVM reads below zero, reverse leads and again adjust T-3 (Top) for zero reading. Re-check step one.

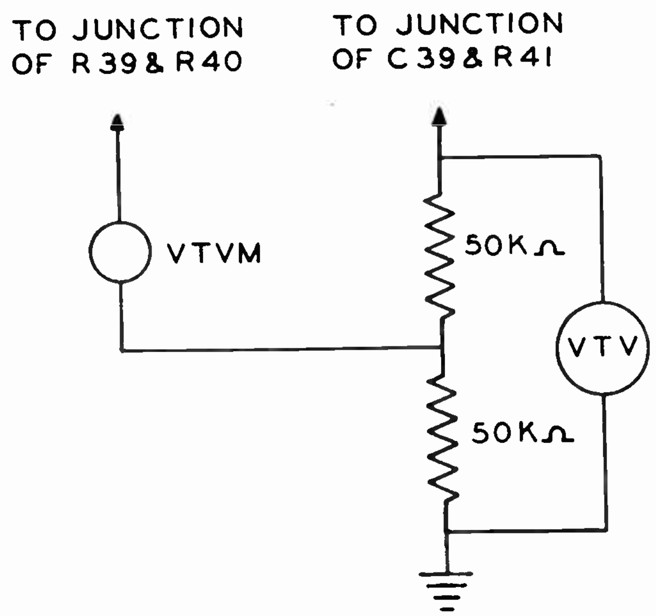

FIG. 12

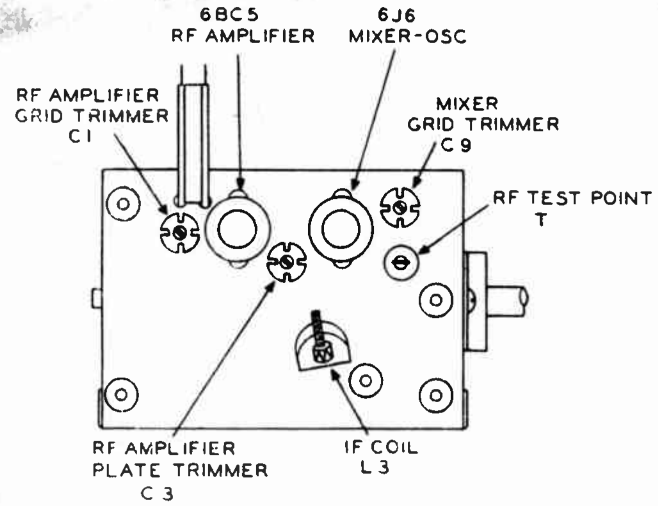
1039

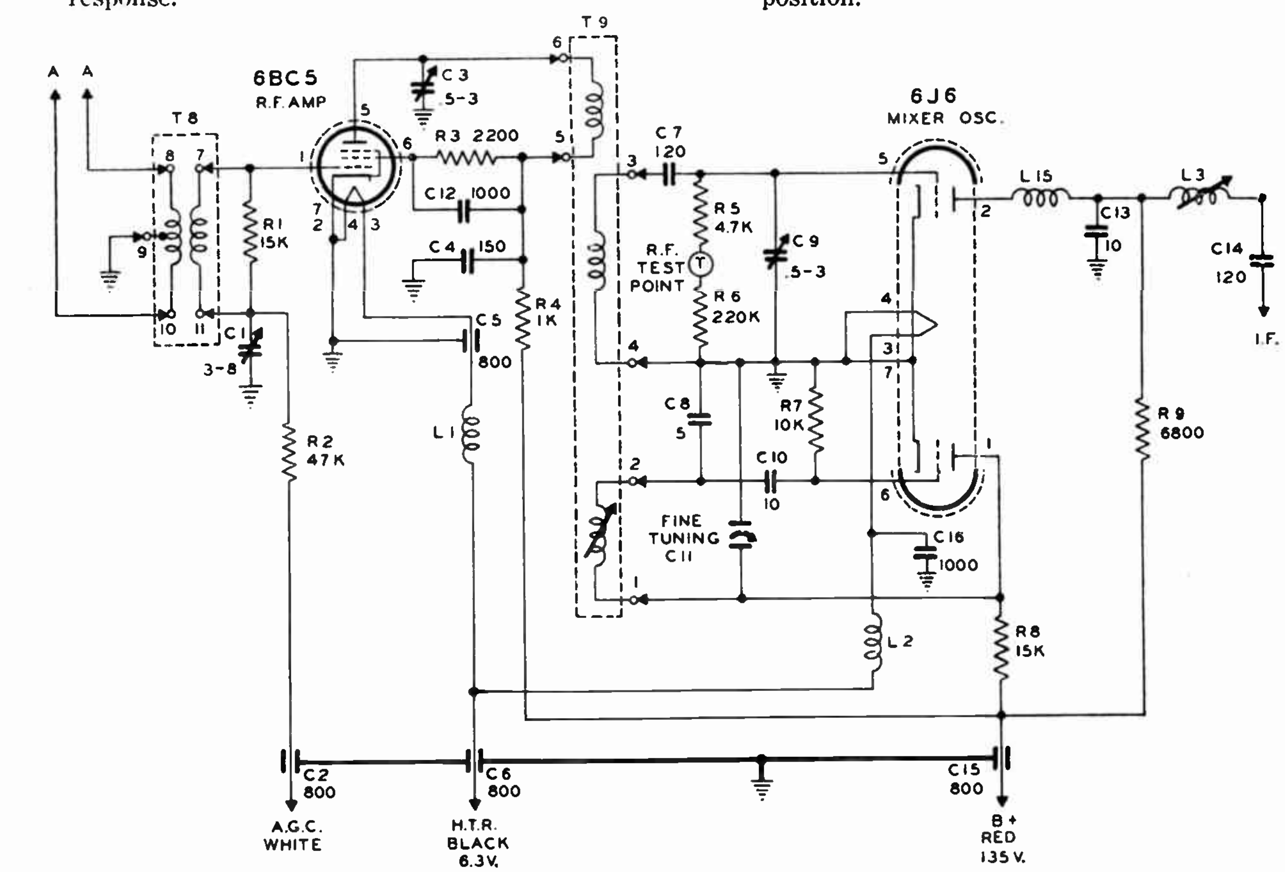
TUNER ALIGNMENT

A. Sweep generator with balanced 300 ohm output to antenna terminals. Marker generator output to antenna terminals. Oscilloscope to "Test Point" on tuner. Ground AGC line at junction of R-12 and C-17.



1043 FIG. 13 TUNER ADJUSTMENTS

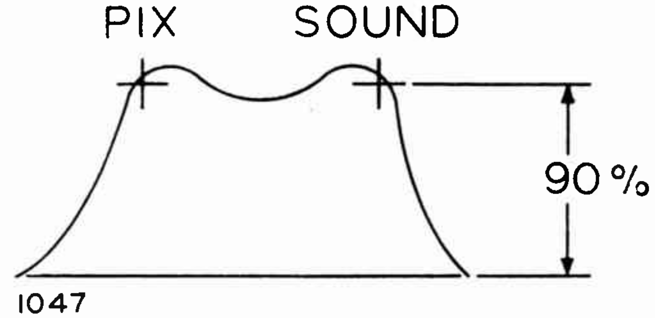
B. RF and converter adjustment:
1. With channel selector on channel 12, adjust C-1, C-9 and C-3 for response as in Figure 14. Picture and Sound markers at 90% maximum response.



I. ALL CAPACITANCE VALUES STATED IN MMF.

TUNER SCHEMATIC

2. Check response on all channels. If markers are below 70% on any channel, readjust C-1, C-9 and C-3. Re-check all channels.



1047

FIG. 14 – PIX AND AUDIO MARKERS

C. Oscillator adjustment:
1. Remove AGC ground. Apply — 4.5 Volts on I-F AGC line.
2. Connect oscilloscope to output of video detector. Place fine tuning in center of range. Check response on all channels. Picture marker should be at 50%. **See Fig. 7.**
3. If some channels are off, individual oscillator coil slugs will require adjustment. Adjust each channel slug, accessible through hole in front of chassis with a non-metallic screwdriver to bring Picture Marker to correct position.

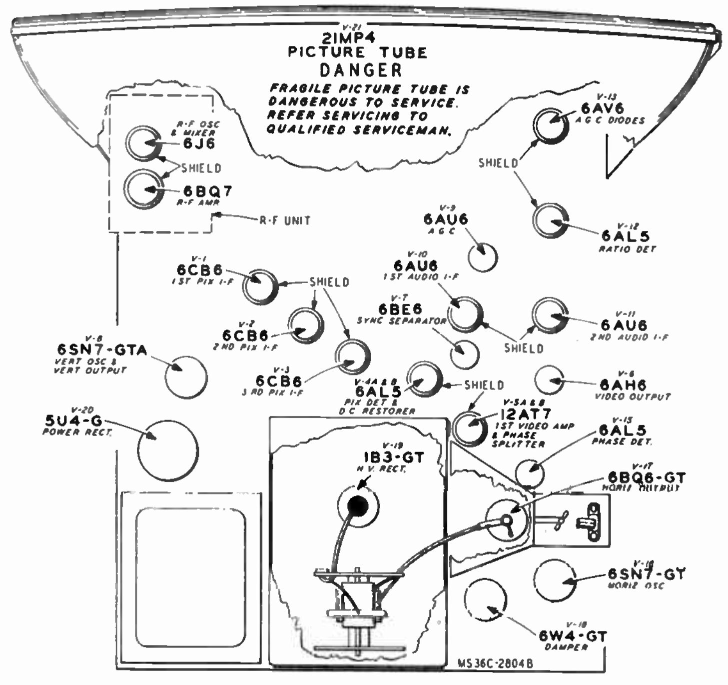

Fig. 1—Tube Layout.

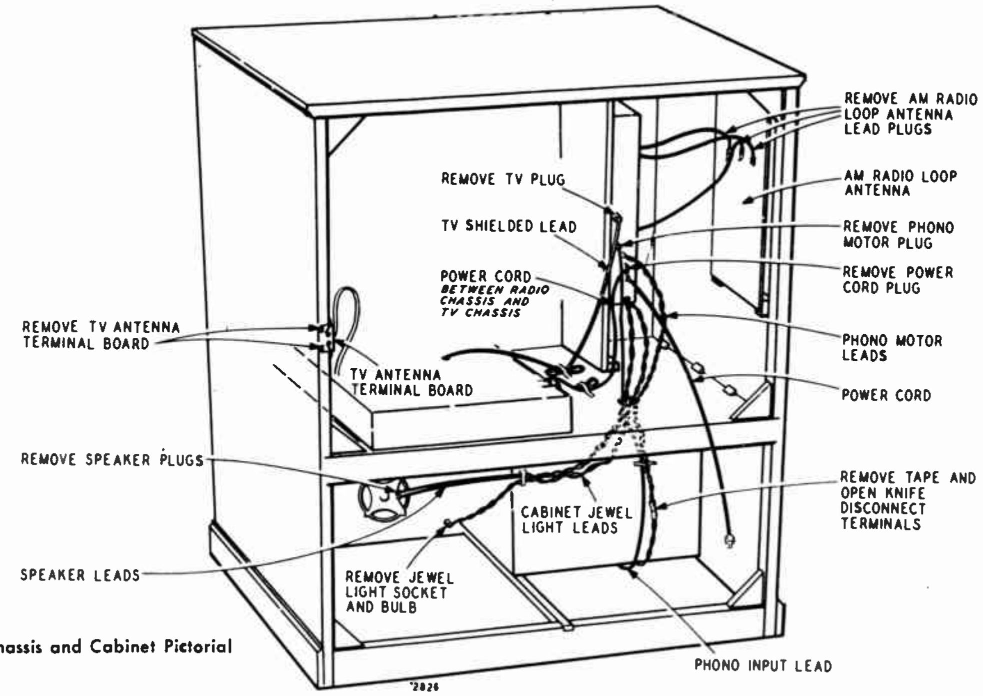

-Chassis and Cabinet Pictorial

PICTURE TUBE HANDLING PRECAUTIONS

Shatterproof goggles and heavy gloves must be worn by individuals while handling the picture tube or installing the picture tube into the receiver.

The picture tube encloses a high vacuum and due to the large surface area, is subjected to very high air pressure. Therefore, care should be taken not to bump or scratch the picture tube accidentally as it may cause the tube to implode resulting in damage to property or injury to an individual.

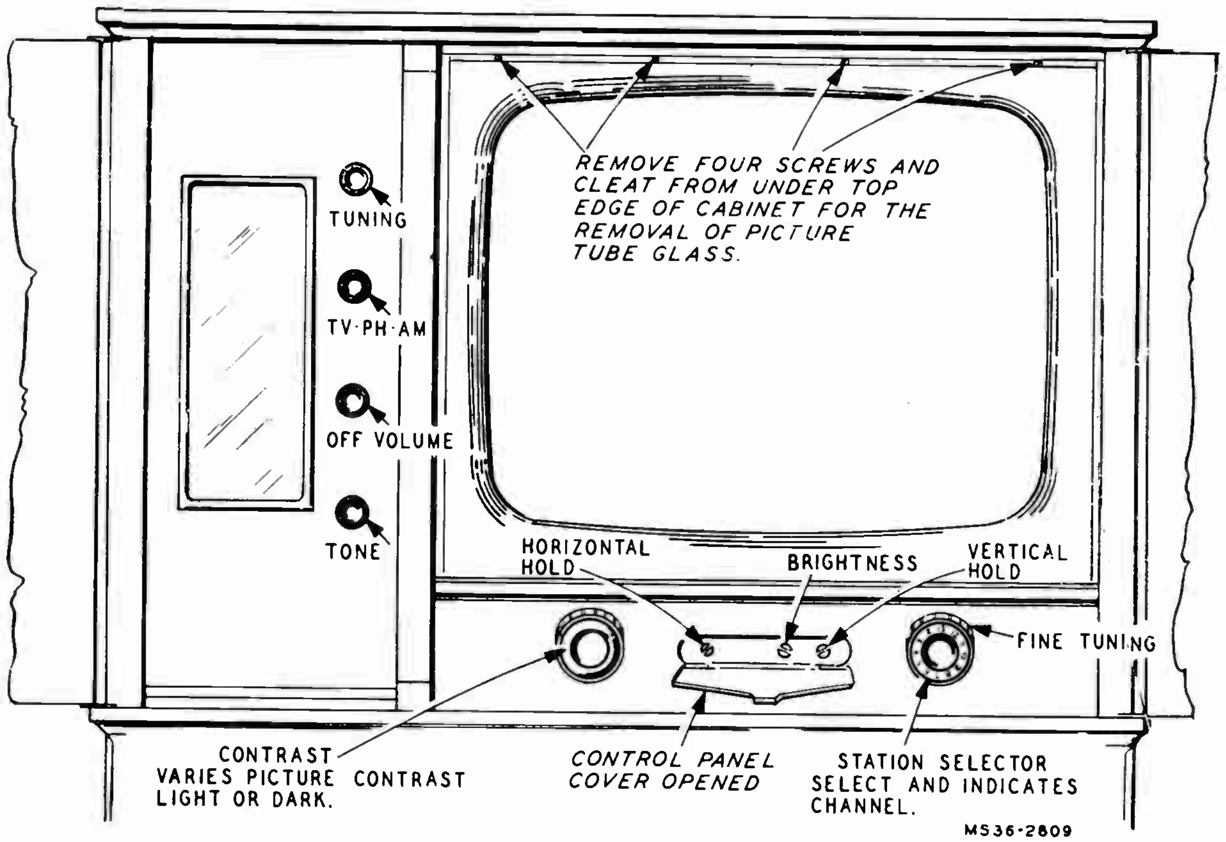

Fig. 2—Front Panel Controls

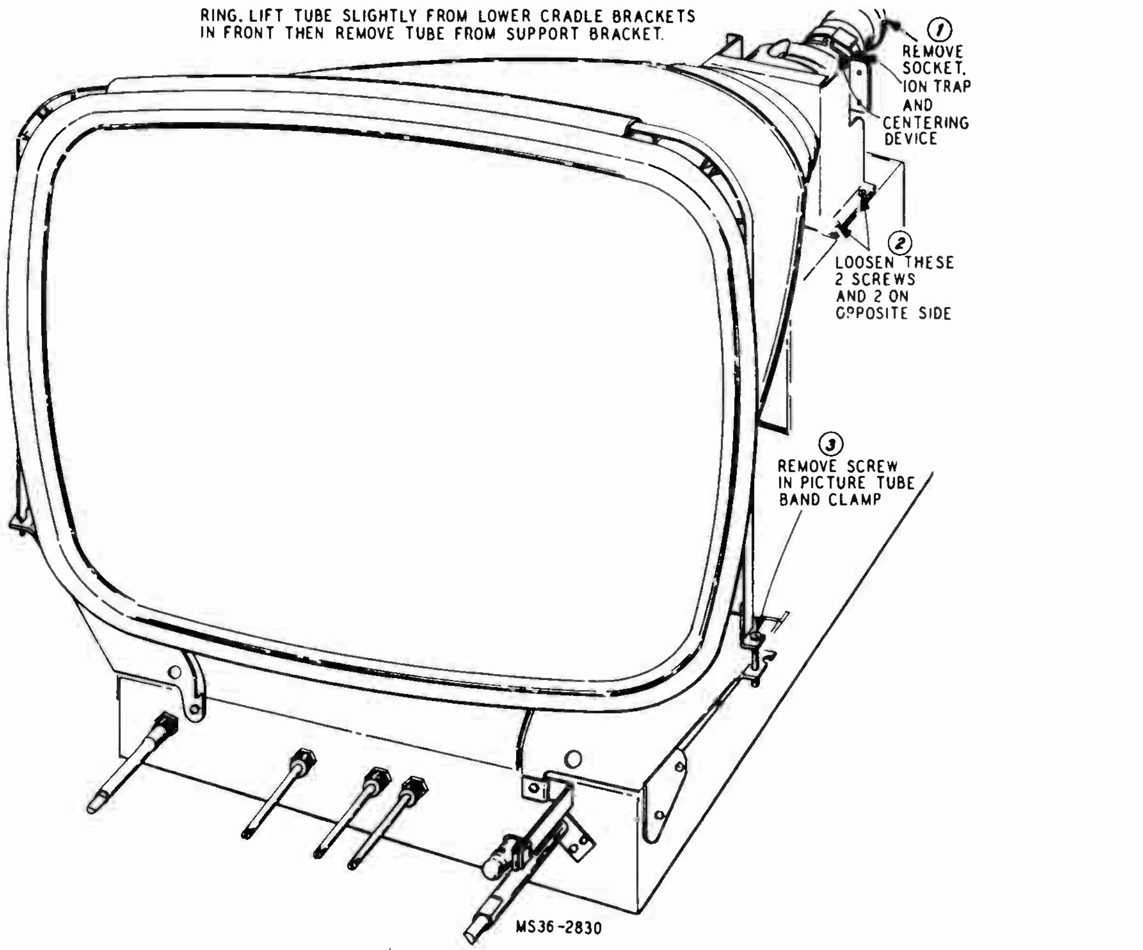

Fig. 3—Removal of Picture Tube

TUNING PROCEDURE

1. To turn the television receiver on, turn the OFF-ON VOLUME control on the radio panel clockwise until a click is heard. Allow approximately 30 seconds for the tubes to warm up.
2. Turn BAND SWITCH control on the radio panel to the TV position.
3. Turn the STATION SELECTOR control to the desired channel. This control may be turned in either direction.
4. Turn the CONTRAST control clockwise until activity or definite form is noted on the screen.
5. Adjust the FINE TUNING control for clearest picture and the VOLUME control for desired volume.
6. To turn off the receiver, turn only the OFF-ON VOLUME control counterclockwise until a click is heard.

OCCASIONAL ADJUSTMENTS TO IMPROVE PICTURE RECEPTION

There are three controls at the front of the chassis which are accessible when the hinged control panel is pulled downward. See illustration. (Figure 2.) These controls are pre-set at the factory and may occasionally need adjustment due to aging of the components in the receiver and the fluctuating line voltages in different areas.

If any adjustments are necessary follow the instructions under 'Controls and Functions."

IMPORTANT — Be sure that the FINE TUNING control has been set for the clearest picture before adjusting any controls.

CONTROLS AND FUNCTIONS

HORIZONTAL HOLD — Stops horizontal movement (diagonal bars.)

BRIGHTNESS—Adjusts for desired picture brilliance.

VERTICAL HOLD — Stops upward or downward picture movement.

PICTURE TUBE SAFETY GLASS

It will be necessary to clean this glass and the face of the picture tube occasionally. Remove the safety glass carefully as outlined in the illustration.

CAUTION—UPON REMOVAL OF THE LAST SCREW AND THE CLEAT THE GLASS WILL FALL FORWARD. SUPPORT THE GLASS WITH ONE HAND AS YOU LIFT IT GENTLY FROM THE CABINET. Clean the safety glass and the face of the picture tube with a soft lint-free cloth dampened with water or mild soapsuds.

WARNING — Before handling the picture tube, it will be necessary to remove the static charge. In receivers with glass picture tubes, ground the anode lead to chassis, and insert an insulated wire from the well in the tube to chassis. In receivers with metal picture tubes, remove the static charge by grounding an insulated wire from the chassis to the metal portion of the tube.

PICTURE TUBE REPLACEMENT — To replace the picture tube it is necessary to remove the chassis from the cabinet. This may be accomplished in the following manner:

1. Remove the front panel control knobs by pulling them straight from their shafts.
2. Remove the cabinet back.
3. Disconnect the leads from the speaker, the radio chassis, remove the antenna terminal board at the rear of the cabinet and then the five chassis mounting bolts. Pull chassis CAREFULLY out of the cabinet.
4. Remove the picture tube as shown and outlined in the illustration. To install a new picture tube, reverse the procedure making sure that the picture tube fits close against the picture tube cushion. If the picture tube sticks or fails to slip into place smoothly, investigate and remove the source of the trouble. Never force the tube. It is important that all the clips and shims used in mounting the tube be replaced, otherwise difficulty may be encountered when horizontal or vertical centering is required.

FRONT OF CHASSIS

(Accessible After Opening Front Panel Control Cover)

Horizontal Hold	R-94

Horizontal Linearity	L-16
Horizontal Drive	R-89
Horizontal Frequency	L-14
Vertical Linearity	R-49
Height	R-54
Sync Stability	R-39
AGC Threshold Control	R-108

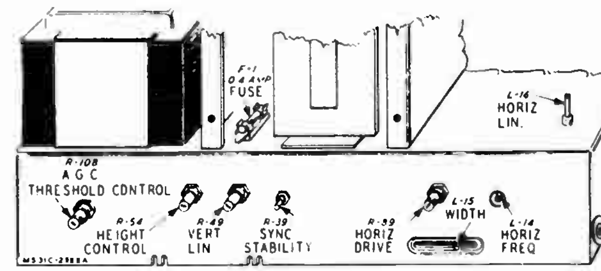

Fig. 4—Adjustments Rear of Chassis

ION TRAP MAGNET ADJUSTMENT—The ion trap magnet should be positioned close to the base of the tube with the magnet of the ion trap on the side where the electron gun is nearest the glass neck of the picture tube. From this position adjust the magnet by moving it back and forth and at the same time rotating it slightly around the neck of the picture tube until the brightest raster is obtained on the picture screen. Reduce the brightness control setting until the raster is slightly above average brilliance. Readjust the ion trap magnet for maximum raster brilliance and best focus. MAXIMUM RASTER BRILLIANCE AND BEST FOCUS OCCUR AT THE SAME POINT. Do not sacrifice brilliance for best focus. The ion trap magnet adjustment is a very critical one especially with the electrostatic type zero focus picture tube. Consequently, great care should be taken to make sure that the ion trap magnet is correctly adjusted.

DEFLECTION YOKE ADJUSTMENT — If the lines of the raster are not horizontal or squared with the picture mask, rotate the deflection yoke until this condition is obtained. Tighten the yoke adjustment wing screw.

CENTERING ADJUSTMENT — If horizontal or vertical centering is required, adjust each ring in the centering device until proper centering is obtained. If a clamp type centering device is used, rotate the device to the left or right and turn the knob located at the top of the device until the picture is centered correctly.

PICTURE ADJUSTMENT — For further adjustments, obtain a test pattern on the receiver. Turn on receiver and follow tuning procedure on page 18. When a test pattern is obtained it may be necessary to slightly re-adjust the fine tuning control for clearest picture.

ADJUSTMENT OF AGC THRESHOLD CONTROL — Tune the receiver to the strongest station in the area in which the receiver will be used. While observing the picture and listening to the sound, turn the control clockwise until signs of overloading (buzz in sound, washed-out picture) appear. Then turn the control a few degrees counter-clockwise from the point at which overloading occurs. (The stronger the signal input, the more counter-clockwise this setting will be.) In areas where the strongest signal does not exceed 10,000 uv the setting will usually be maximum clockwise. With the control set correctly, the AGC will automatically adjust the bias on the R.F. and I.F. amplifiers so that the best possible signal to noise ratio (Minimum snow) will be obtained for any signal input to the receiver.

ADJUSTMENT OF SYNC STABILITY CONTROL — When receiving strong (500 MV or more) signals, set hold controls so that the picture is locked in. Turn the sync control fully counter-clockwise, then, while observing the picture, turn the control slowly clockwise until a minimum amount of bending occurs. If the control is set incorrectly bending, tearing, etc., will be present and when switching from channel to channel the picture will not lock in quickly.

In weak signal areas the control should be set for maximum picture stability. In general the weaker the signal the more clockwise the control should be turned.
When the sync stability control is correctly adjusted the receiver will hold sync without tearing or rolling under even the most adverse noise conditions.

CHECK OF HORIZONTAL OSCILLATOR ALIGNMENT — Tune in a station and adjust the horizontal hold control until the picture falls into sync. Momentarily remove the signal by switching off channel and then back. The picture should pull into sync over a range of 90° rotation of the horizontal hold control. If in the above check the picture fails to hold sync or the pull-in range is at the extreme end of the control, it will be necessary to make the following adjustment.

HORIZONTAL FREQUENCY ADJUSTMENT — With the horizontal hold control set to the center of its range of rotation, adjust the horizontal frequency control (L-14) until the picture pulls into sync. Recheck the "Horizontal Oscillator Alignment."

HEIGHT AND VERTICAL LINEARITY ADJUSTMENT — Adjust the height control (R-54) until the picture fills the mask vertically. Adjust the vertical linearity control (R-49) until the picture is symmetrical from top to bottom. Adjust the picture centering device to align picture with the mask. Adjustment of any control will require a re-adjustment of the other control.

WIDTH, DRIVE AND LINEARITY ADJUSTMENTS— While receiving a signal from a station (with picture locked in sync) turn contrast control fully counter-clockwise, turn the brightness control (R-25) up so that the picture appears washed out. Adjust width control (L-15) until the picture fills the mask. Turn the horizontal drive control (R-89) clockwise until white bars appear in the left center portion of the raster, then turn counter-clockwise until the white bars just disappear. This adjustment will allow the horizontal system to operate at maximum efficiency. Adjust horizontal linearity control (L-16) for best linearity. If adjustment of the horizontal drive (R-89) or horizontal linearity (L-16) is required, it usually will be necessary to recheck the horizontal oscillator alignment. If adjustment of the horizontal linearity control (L-16) is required, readjustment of the horizontal drive control (R-89) will be necessary. Adjust the picture centering device to align the picture with the mask.

CHECK OF R-F OSCILLATOR ADJUSTMENTS

The oscillator is preset at the factory and normally needs no adjustment. However, if adjustments are required, they can be made without removing the chassis from the cabinet. Remove the channel selector and fine tuning knobs from the tuning shaft.

TEST PROCEDURE:

1. Set channel selector to receive desired station.
2. Set fine tuning control in center of its range.
3. Adjust oscillator slug, with bakelite type screwdriver, for best picture resolution.
4. Repeat steps 1, 2 and 3 on all channels used.

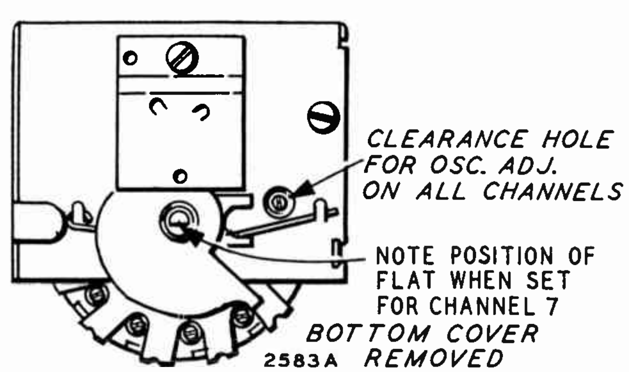

Fig. 5—Tuner Oscillator Adjustments

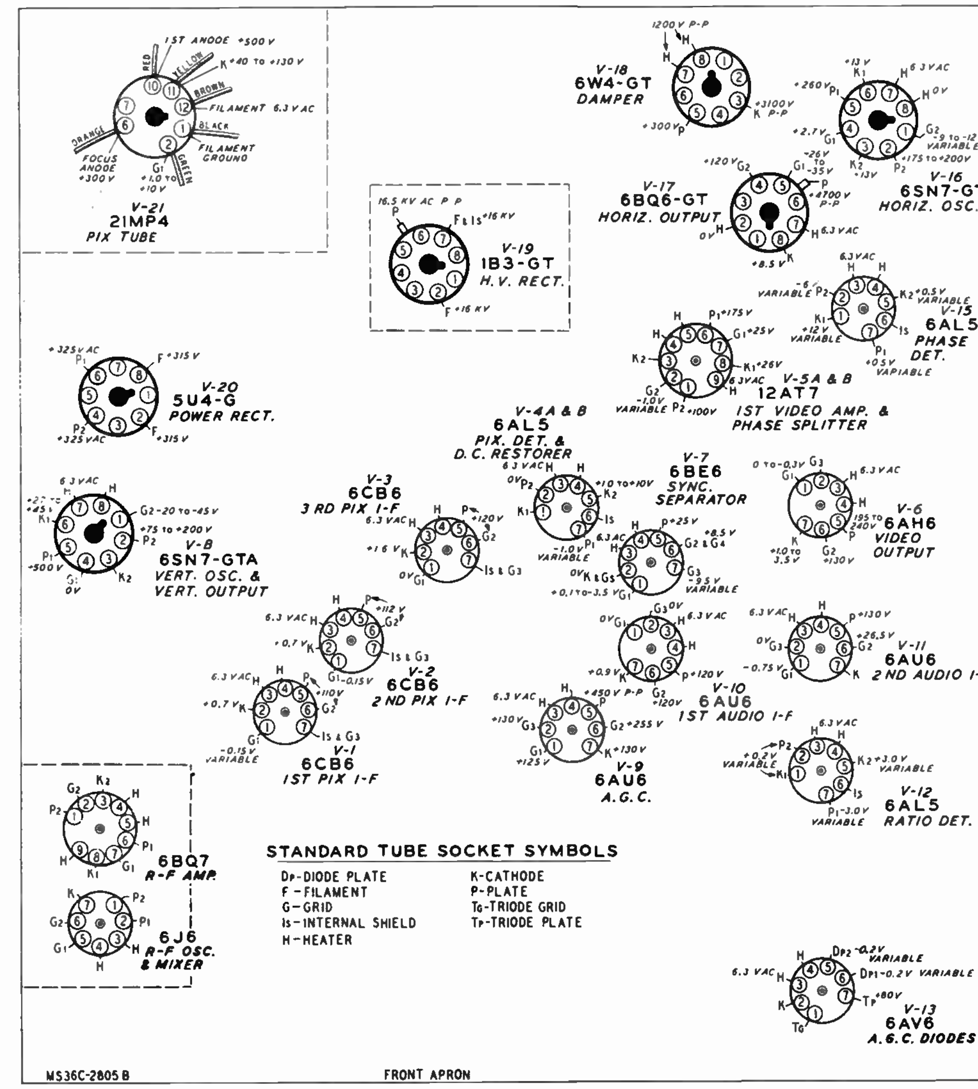

Fig. 6—Bottom Socket Voltages

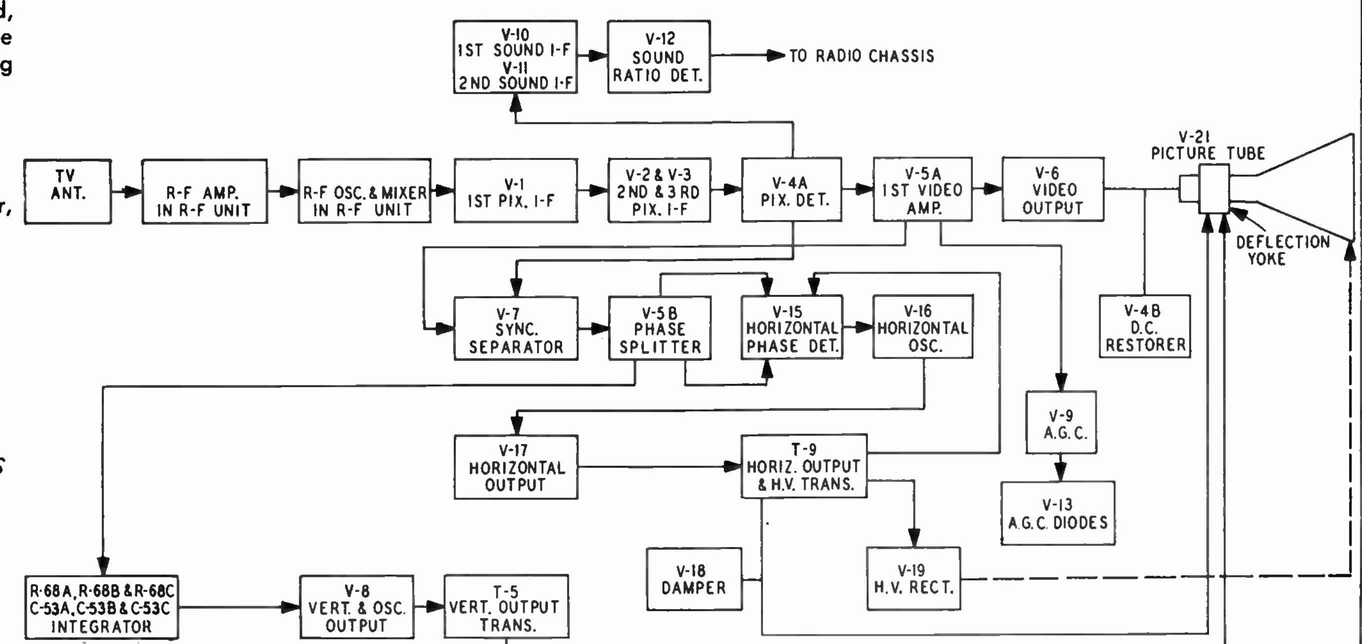

Fig. 7—Block Diagram

SERVICE SUGGESTIONS

NO RASTER ON PICTURE TUBE — If raster cannot be obtained check below for the possible causes.
1: Ion trap magnet adjustment is incorrect.
2: No +B voltage. Check 4/10 ampere fuse. Replace if defective. If fuse continually burns out, check
(A) Horizontal output tube V-17 (6BQ6-GT)
(B) Check damper tube V-18 (6W4-GT).
(C) Check horizontal oscillator tube V-16 (6SN7-GTA) for proper operation.
(D) With an ohm meter, check for a short between terminal 1 of the horizontal output transformer (T-9) and the chassis.
(E) Check DC resistance of T-9.
3: No high voltage. Check V-17, V-18 and V-19 tubes and circuits. If the horizontal deflection circuits are operating as evidenced by the correct voltage (600V) measured on terminal No. 1 of T-9, the trouble can be isolated to the high voltage rectifier circuit. Either the high voltage winding to the 6BQ6-GT plate and 1B3 plate is open, tube V-19 is defective, its filament circuit is open, R-105 and C-75 defective or pix tube elements shorted internally.
4: Defective picture tube heater open or cathode return circuit open.

HORIZONTAL DEFLECTION ONLY — If only horizontal deflection is obtained as evidenced by a straight line across the face of the picture tube, it can be caused by the following:
1: Vertical oscillator and vertical output tube V-8 inoperative. Check socket voltages.
2: Vertical oscillator transformer (T-4) defective.
3: Vertical output transformer (T-5) open or shorted.
4: Yoke vertical coils open or shorted.
5: Vertical hold, height or linearity controls may be defective.

POOR VERTICAL LINEARITY — If adjustment of the height and linearity controls will not correct this condition, any of the following may be the cause.
1: Check variable resistors R-49 and R-54.
2: Vertical output transformer (T-5) defective.
3: Capacitors C-47B, C-70 or C-71 defective.
4: V-8 defective, check voltages.
5: Excess leakage or incorrect value of capacitor C-68, or open or incorrect value of resistors R-90 & R-92.
6: Low plate voltages. Check rectifier tube and capacitors in +B supply circuits.
7: Capacitor C-67 defective.
8: Vertical deflection coils (L-12) defective.

POOR HORIZONTAL LINEARITY — If adjustment of the Horizontal drive and linearity controls does not correct this condition, check the following:
1: Check or replace horizontal output tube V-17.
2: Check or replace damper tube V-18 (6W4-GT).
3: Check capacitors C-77, C-78, C-79 and horizontal linearity control (L-16) for defects.
4: Horizontal deflection coils (L-17) defective.

TRAPEZOIDAL OR NONSYMMETRICAL RASTER
1: Defective yoke.

WRINKLES ON LEFT SIDE OF RASTER — This condition can be caused by:
1: Defective yoke due to C-76 or R-106 (internal in yoke assembly) being wrong value or open. These components are mounted in rear of yoke assembly.
2: V-18 (6W4-GT) defective.

SMALL RASTER — This condition can be caused by:
1: Low +B or line voltage. Check V-20 (5U4G).
2: Insufficient output from horizontal output tube V-17. Replace tube.
3: Insufficient output from vertical oscillator and vertical output tube V-8. Replace tube.
4: Incorrect setting of horizontal drive control R-89.
5: V-18 (6W4-GT) defective.
6: Incorrect setting of (L-15) width control.

RASTER; NO IMAGE, BUT ACCOMPANYING SOUND — This condition can be caused by:
1: No signal on picture tube grid. Check V-5A (12AT7) and V-6 (6AH6) tubes and associated circuits.
2: Bad contact to picture tube grid (lead to socket broken).
3: AGC tube (V-9) may be defective. Check tube and its associated circuit.

SIGNAL APPEARS ON PICTURE TUBE GRID BUT IMPOSSIBLE TO SYNCHRONIZE THE PICTURE VERTICALLY AND HORIZONTALLY — A condition of this nature can be caused by:
1: Defective sync separator V-7 or phase splitter V-5B.
2: If tubes are O.K. check voltages, and associated circuits.
3: AGC system inoperative. Check V-9 (6AU6) AGC tube and associated circuits.

SIGNAL ON PICTURE TUBE GRID AND HORIZONTAL SYNC ONLY — If this condition is encountered, check:
1: Vertical integrating network capacitors C-53A, B & C, and resistors R-68A, B & C.
2: Vertical hold control (R-51) defective.

SIGNAL ON PICTURE TUBE GRID AND VERTICAL SYNC ONLY
1: V-15 or V-16 defective.
2: Improper setting of (L-14) horizontal frequency control.
3: Check setting of horizontal drive control and horizontal linearity control.
4: Check V-15 and V-16 socket voltages.

PICTURE STABLE BUT WITH POOR RESOLUTION — If the picture resolution is not up to standard, it may be caused by any of the following:
1: Defective pix I-F tubes V-1, 2 & 3, (6CB6's).
2: Defective picture detector V-4A, (6AL5) or video amplifier V-5A or video output V-6 (6AH6).
3: Defective picture tube.
4: Open video peaking coil. Check all peaking coils L-5, L-6, L-8, L-9, L-10 and L-11 for continuity. Note that L-5, L-9 and L-10 have shunting resistors.
5: Leakage in V-6 (6AH6) grid capacitor C-36. If the capacitor is not found to be defective, check the following:
1: Check all potentials in video circuits.
2: Check picture tube grid circuit for poor or dirty contact.
3: Check and realign, if necessary, the picture I-F and R-F circuits.

PICTURE SMEAR:
1: A smear can be attributed to phase shift at the low or high frequency end of the video characteristic. This can be caused by improper values of resistors and capacitors in the video circuits. Check for grid current on video output tube V-6 (6AH6), open or shorted peaking coils, video amplifier load resistors are of improper value (high).
2: This trouble can also originate at the transmitter. Check reception from another station.
3: Check and realign, if necessary, the picture I-F and R-F circuits.

MAN MADE NOISE IN SOUND (Ignition, etc)
1: Check sound I-F tubes V-10, 11 & 12 and associated circuits.
2: Check sound I-F alignment.

BENDING OR S-ING
1: Check sync stability control adjustment.
2: Check capacitors C-47A and C-49A.
3: V-17 (6BQ6-GT) defective or V-16 (6SN7-GTA) defective.
4: Check sync separator tube V-7 (6BE6) and phase splitter V-5B (12AT7) and V-5A (12AT7) video amplifier.
5: Check AGC threshold control.

PICTURE NORMAL—NO SOUND OR WEAK OR DISTORTED SOUND
1: Check sound I-F alignment.
2: Check V-10 (6AU6) V-11 (6AU6) V-12 (6AL5) V-13 (6AV6) and associated circuits.

POOR FOCUS
1: Improper setting of Ion Trap magnet.
2: Defective picture tube or picture tube socket.

PICTURE JITTER:
1: If regular sections at left of the picture are displaced, replace the horizontal oscillator tube V-16.
2: Vertical instability may be due to loose connections or noise received with the signal.
3: Horizontal instability may be due to unstable transmitted sync.
4: Check receiver AGC system for proper operation.
5: Check phase splitter V-5B, (12AT7) and sync separator V-7 (6BE6).
6: Check for improper setting of sync stability control.
7: Picture tube grid lead not held in position by support spring, ie: close proximity of grid lead to sync and horizontal tubes will cause picture to jitter at high contrast setting.
8: Check AGC threshold control.

ALIGNMENT PROCEDURE

TEST EQUIPMENT — To service this receiver properly, it is recommended that the following test equipment be available:

R-F SWEEP GENERATOR meeting the following requirements:
(a) Frequency ranges:
18 to 30 mc, 10 mc sweep width
40 to 90 mc, 10 mc sweep width
170 to 225 mc, 10 mc sweep width
(b) Output adjustable with at least .1 volt maximum.
(c) Output constant on all ranges.
(d) Flat output in all attenuator positions.

CATHODE-RAY OSCILLOSCOPE preferably one with a wide band vertical deflection and an input calibrating source.

SIGNAL GENERATOR to provide the following frequencies: (Output on these ranges should be adjustable and at least .1 volt maximum.)
(a) Intermediate alignment frequencies.
23.1 mc first picture I-F coil.
24.1 mc third picture I-F coil.
25.9 mc second picture I-F coil.
21.7 mc sound trap.
4.5 mc video trap & sound I-F.
25.2 mc converter plate coil (Tuner).

HETERODYNE FREQUENCY METER with crystal calibrator if the signal generator is not crystal controlled.

ELECTRONIC VOLTMETER and a high voltage probe for use with this meter to permit measurements up to 20 kilovolts.

SERVICE PRECAUTIONS — To service the receiver remove the chassis from the cabinet. To do so, remove the knobs, the cabinet back, disconnect the leads from the speaker, the radio chassis, remove the antenna terminal board at rear of cabinet, and then the 5 chassis mounting bolts. The chassis may be serviced with the picture tube in place provided the chassis is turned on its side with the power transformer on the bottom. The weight of the chassis will be supported against the power transformer and pix tube brackets.

CAUTION: Do not permit the kinescope second-anode lead to become shorted to the chassis. To do so will cause a considerable overload on the high voltage filter resistor R-105.

ALIGNMENT PROCEDURE
PIX I-F

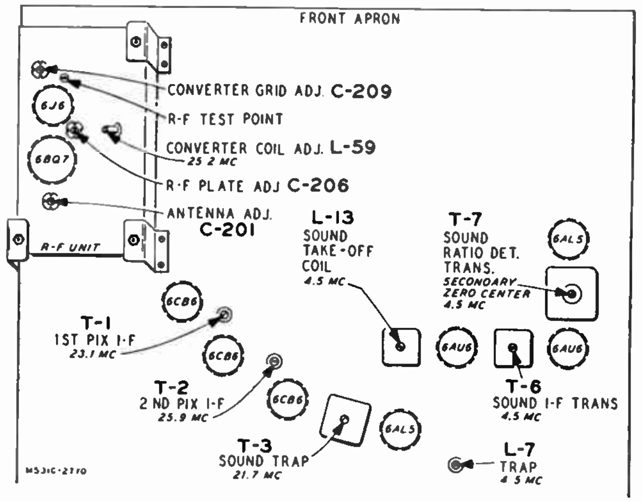

Fig. 8—Top Chassis Video and Audio I-F Adjustments

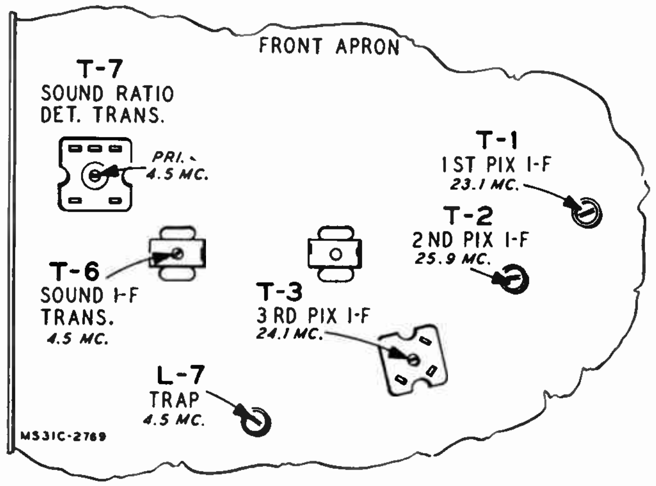

Fig. 9—Bottom Chassis Video and Audio I-F Adjustments.

A. Unmodulated R-F signal into Converter Grid by means of tube shield insulated from base. VTVM with filter in lead of 22 K ohms and 5000 mmf connected to pic. det. load resistor, (R-37) 4700 ohms, in series with peaking coil (L-6) from Pin 7 of 6AL5. Input signal level should be such that output is less than 2 volts DC. Apply -4.5V battery bias on AGC line.

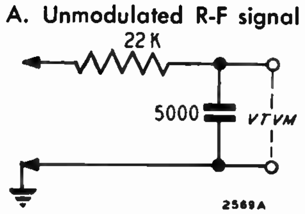

Fig. 10—VTVM Connections

	FREQUENCY	ADJUST
1.	25.2 MC	Converter plate coil on top of tuner for maximum dc at picture detector.
2.	23.1 MC	1st picture I-F coil (T-1) for maximum dc at picture detector.
3.	25.9 MC	2nd picture I-F coil (T-2) for maximum dc at picture detector.
4.	24.1 MC	3rd picture I-F coil (T-3 below chassis) for maximum dc at picture detector.
5.	21.7 MC	3rd picture I-F trap (T-3 in can above chassis) for minimum dc at picture detector.

B. I-F Sweep Generator into converter grid by means of tube shield insulated from base.

Connect oscilloscope across R-37 (in place of VTVM). Apply -4.5V bias (DC) to AGC line (battery).

Tuner should be switched to dead channel so as not to cause interference.

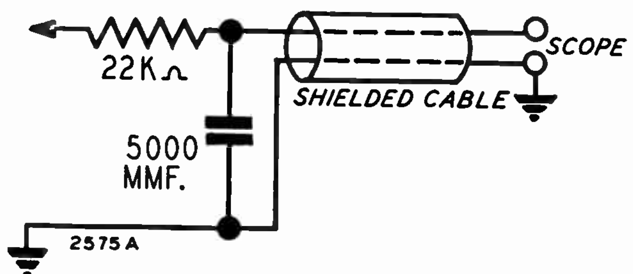

Fig. 11—Oscilloscope Connections

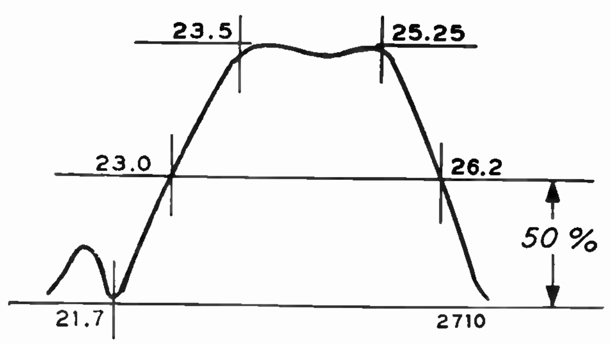

Fig. 12—Overall Response Curve

Observe overall I-F response, which should be as shown above: A slight touch-up may be required. At no time should the trap coil be re-adjusted, nor should it be necessary to turn any of the picture I-F coils more than 1/2 turn of the slug. The following comments are suggestions only:

ALIGNMENT PROCEDURE (Continued)

1. The height of the 26.2 MC marker is controlled by the 25.2 MC (Converter Plate Coil on tuner) and the 25.9 MC (2nd P.I.F.) coils.
2. The uniformity of response (flatness across top and position of 23.5 MC) marker is controlled for the most part by the 24.1 MC third picture I-F coil.
3. The 23.0 MC marker position is controlled by the first picture I-F (23.1 MC coil). However, it is NOT advisable to change the setting of the coil, due to its effect on sound rejection. Its adjustment should be avoided unless believed to be absolutely necessary.

VIDEO

With 4.5 MC unmodulated signal from a high impedance source, (10,000 ohms in series with the generator) into plate of the picture detector tube (Pin 7-6AL5) and VTVM on picture tube grid, tune 4.5 MC trap (L-7 Top) for minimum response. VTVM on 0-10 V AC scale. This adjustment can also be made while observing a picture from a station. Tune trap for least 4.5 MC beat in picture.

AUDIO I-F

1: With signal generator set to 4.5 MC and dc VTVM connected to junction of R-13 and C-14, adjust sound take-off coil (L-13 Top) and sound I-F transformer slugs (T-6 Top & Bottom) for maximum.

2: With VTVM connected to pin 7 of V-12 (6AL5) adjust the ratio detector primary (T-7 Bottom) for maximum.

3: With VTVM connected to junction of R-17, R-20 and C-18, adjust ratio detector secondary (T-7 Top) for cross over (zero voltage) on lowest scale.

NOTE — If no signal generator is available, the procedure above may be followed by tuning in a station and using the 4.5 MC beat between picture and sound carrier.

TUNER ALIGNMENT

A. Sweep generator with balanced 300 ohm output to antenna terminals. Marker generator output to antenna terminals. Oscilloscope to "test point" (Figure 13) on tuner. Connect 1½ V bias to AGC line at junction of R-34 and C-29 on the receiver.

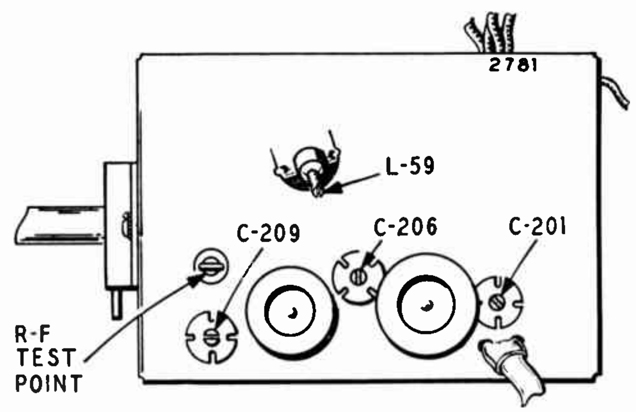

Fig. 13—Top Tuner Adjustments

B. RF AND CONVERTER ADJUSTMENT.

1. With channel selector on Channel 12, adjust C-201 slightly favoring the Pix carrier, then adjust C-206 and C-209 for response as in Figure 14. Picture and sound markers at 90% maximum response.

2. Check response on all channels. If markers are below 70% on any channels, readjust C-201, C-206, and C-209. Recheck all channels.

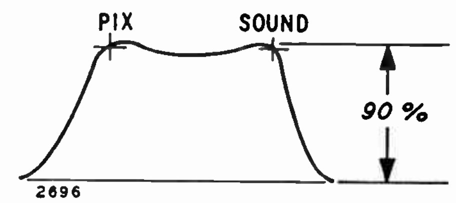

Fig. 14—Pix & Audio Markers

C. OSCILLATOR ADJUSTMENT.

1. Apply 4.5 volts on I-F AGC line at junction of R-1 and C-30A.

2. Connect oscilloscope to output of video detector. Place fine tuning in center of range. Check response on all channels. Sound marker should be in notch and picture marker at 50%. (See Figure 12).

3. If markers are off, individual oscillator coil slugs will require adjustment. Adjust each channel slug, accessible through hole in front of chassis with a non-metallic screwdriver to bring sound marker to correct position.

RADIO INFORMATION

ALIGNMENT PROCEDURE
RADIO

The following is required for aligning:
An All Wave Signal Generator Which Will Provide on Accurately Calibrated Signal at the Test Frequencies as Listed.
Output Indicating Meter, Non-Metallic Screwdriver, Dummy Antennas — .1 mf, and 50 mmf.

Volume Control Maximum all Adjustments.
Connect Chassis to Ground Post of Signal Generator with a Short Heavy Lead.
Allow Chassis and Signal Generator to "Heat Up" for Several Minutes.

SIGNAL GENERATOR						
FREQUENCY SETTING	CONNECT GENERATOR OUTPUT TO	THROUGH DUMMY ANTENNA	CONNECT GROUND TO	GANG CONDENSER SETTING	ADJUST	ADJUST FOR
455 KC	Control Grid I-F 6BA6 Pin No. 1	.1 mf	Chassis Base	Rotor Fully Open	2nd I.F. Pri. (1) and Sec. (2)	Maximum Output
455 KC	Control Grid 6BE6 Pin No. 7 1st Det.	.1 mf	Chassis Base	Rotor Fully Open	1st I.F. Pri. (4) and Sec. (3)	Maximum Output
455 KC	Control Grid 6BE6 Pin No. 7	.1 mf	Chassis Base	Rotor Fully Open	2nd I.F. Pri. (1) and Sec. (2)	Maximum Output
1620 KC	Control Grid R-F 6BA6 Pin No. 1	.1 mf	Chassis Base	Rotor Fully Open	Oscillator C-8	Maximum Output
1400 KC	Control Grid R-F 6BA6 Pin No. 1	.1 mf	Chassis Base	Turn Rotor to Max. Output. Set Pointer to 1400 KC See Note A	Interstage C-6 See Note B	Maximum Output
1400 KC	External Antenna Terminal	50 mmf	Chassis Base	Turn Rotor to Max. Output. Set Pointer to 1400 KC See Note A	Antenna C-2 See Note B	Maximum Output

NOTE A—If the pointer is not at 1400 KC on the dial, reset pointer to the 1400 KC mark on the dial scale.
NOTE B—Turn the rotor back and forth and adjust the trimmer until the peak of greatest intensity is obtained.

TUBE SOCKET VOLTAGES

Socket voltages are shown on the Bottom Socket diagram at the tube socket terminals. All voltages are between the socket terminals and chassis ground. Plate, screen and cathode voltages were taken with a 1000 ohm-per-volt meter with a 300 volt scale used for plate and screen voltages. Audio grid voltages were read with a vacuum tube volt-meter. Conditions of measurement are:

Line voltage ....117 Volts AC
Signal Input ....None
A Variation of ±10% is usually permissible.

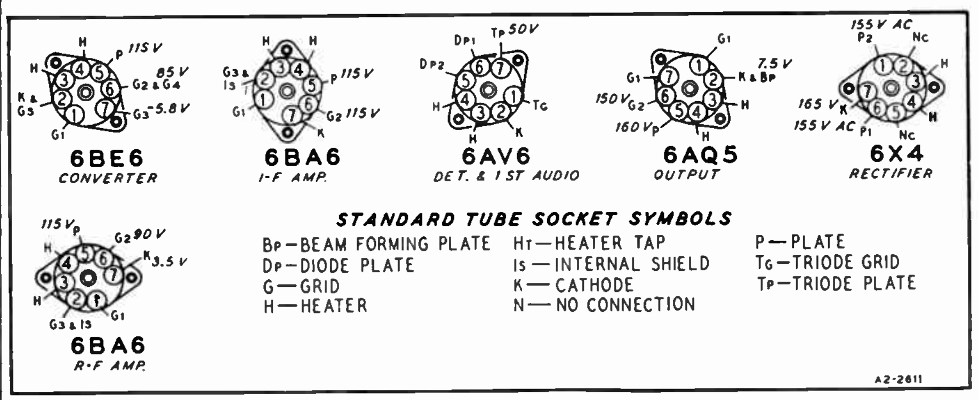

Fig. 21—Bottom Socket Voltages

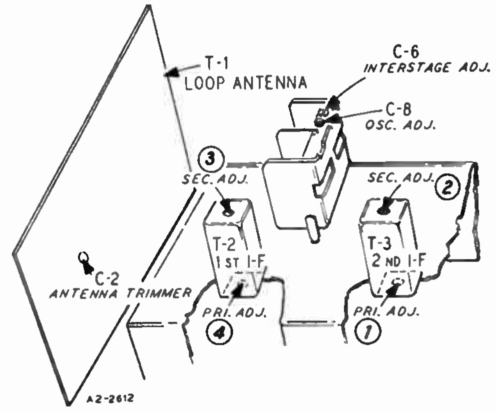

Fig. 17—Trimmer Adjustments

DRIVE CORD REPLACEMENT

DIAL POINTER CORD

Use a new S-10X77 drive cord assembly or a new length of cord 48 inches long for the installation. Install the cord as shown in the illustration, winding three turns counterclockwise around the drive shaft with the turns progressing away from the chassis. After completing the installation rotate the drive shaft a few turns to take up the slack in the cord.

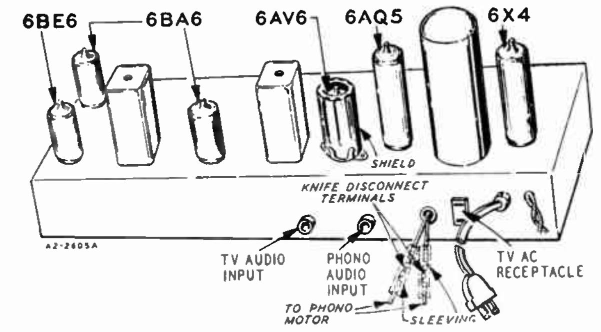

Fig. 18—Tube Layout

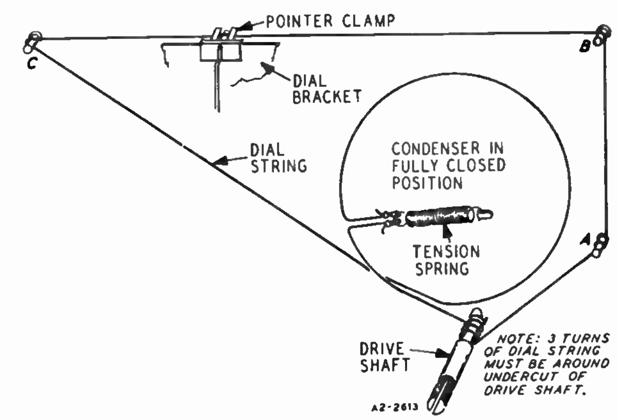

Fig. 19—Drive Cord Stringing.

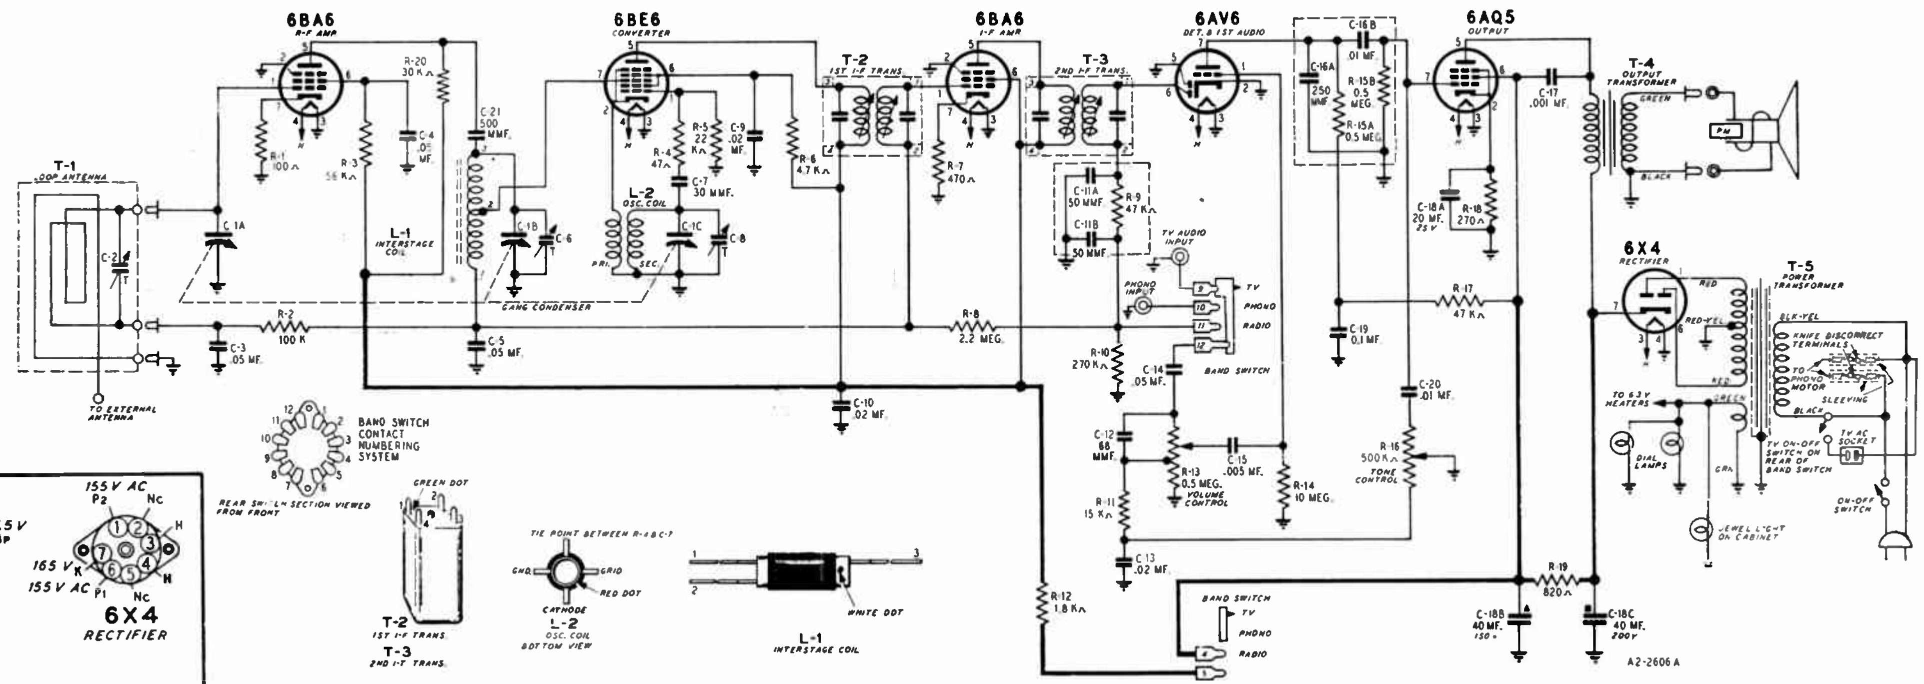

Fig. 20—Radio Schematic Diagram

OSCILLOSCOPE WAVEFORM PATTERNS

The waveforms on this page were taken with the receiver tuned to a normal picture. The numbers on the waveforms correspond to the numbers on the schematic diagram which identifies each test point.

The voltages shown on each waveform are the approximate peak to peak amplitudes. The frequencies shown indicates the repetition rate of the waveform, not the sweep rate of the oscilloscope. If the waveforms are observed on the oscilloscope with a poor high frequency response, the corners of the pulses will tend to be more rounded than those shown below and the amplitudes of any high frequency pulse will tend to be less.

MODEL
35WG-3060B (MAHOGANY)

MODEL
35WG-3070B (OAK)

SUPPLEMENTARY MANUAL

Models 35WG-3060B and 35WG-3070B are identical to models 25WG-3060A and 25WG-3070A except for a change in the V-18 damper tube from a 6W4-GT to a 6AX4-GT and a change in value of resistors R-82 and R-90 from 1.5 megohm and 1.2 megohm respectively to 1.8 megohm. The part number of the resistor is B84185.

SERVICE INFORMATION

UHF strips may be inserted into the tuner of this receiver without removing the chassis from the cabinet. Turn the cabinet upside down on top of a clean sheet of paper or cloth to avoid marring the finish of the cabinet. You will note an opening in the cabinet located directly below the tuner. Remove the protective cover from the opening and take off the tuner bottom cover. The tuner is now accessible for the removal of any VHF strip and the addition of any UHF strip. After the UHF strip has been inserted into the tuner, the bottom cover on the tuner and the protective cover on the cabinet have been replaced, turn the cabinet right side up.

Because of the addition of the UHF strip, an adjustment of the R-F oscillator will be necessary. Remove the channel selector and fine tuning knobs from the tuning shaft and proceed as follows:

1. Set channel selector to receive the desired UHF station.
2. Set fine tuning control in center of its range.
3. Through the clearance hole in the cabinet adjust the oscillator slug with a bakelite type screwdriver for best picture resolution.
4. Repeat steps 1, 2 and 3 on all channels used.

MODELS 3171A&B

MODELS 3173A&B

IMPORTANT

Issue "A" &"B" Series of Models 3171 & 3173 are identical except for a few minor changes in cabinet construction and design. For differences between the "A" & "B" models, see the parts list section.

ELECTRICAL SPECIFICATIONS

Power Supply	105-125 Volts AC 60 Cycles Only
Power Consumption	210 Watts
Power Output	2.4 Watts (Max.) 1.8 Watts (10% Distortion)
Tuning Ranges	VHF — Channels 2 thru 13 UHF — Channels 14 thru 83
Antenna Input Imp.	300 Ohms Balanced
Intermediate Frequencies	Picture 26.20 MC Sound 21.70 MC
I-F (UHF Position Only)	Picture 121.75 Sound 126.25
Intercarrier Sound System	4.5 MC
Loud Speaker	See Parts List
Voice Coil Imp.	3.2 Ohms 400 Cycles

TUBE COMPLEMENT

Symbol	Type	Function
VHF Tuner	6J6	R-F Osc. and Mixer
*VHF Tuner	6BQ7	R-F Amplifier
UHF Tuner	6AF4	R-F Osc.
UHF Tuner	1N72 or 1N82	Crystal Mixer

4115A

TUBE COMPLEMENT (Continued)

Symbol	Type	Function
V-1	6CB6	1st Pix I-F Amplifier
V-2	6CB6	2nd Pix I-F Amplifier
V-3	6CB6	3rd Pix I-F Amplifier
V-4 A & B	6AL5	Pix Det. and DC Restorer
V-5 A & B	12AT7	1st Video Amp. and Phase Splitter
V-6	6AH6	Video Output
V-7	6BE6	Sync. Separator
V-8	6SN7-GTA	Vertical Osc. & Vertical Output
V-9	6AU6	Automatic Gain Control
V-10	6AU6	1st Audio I-F

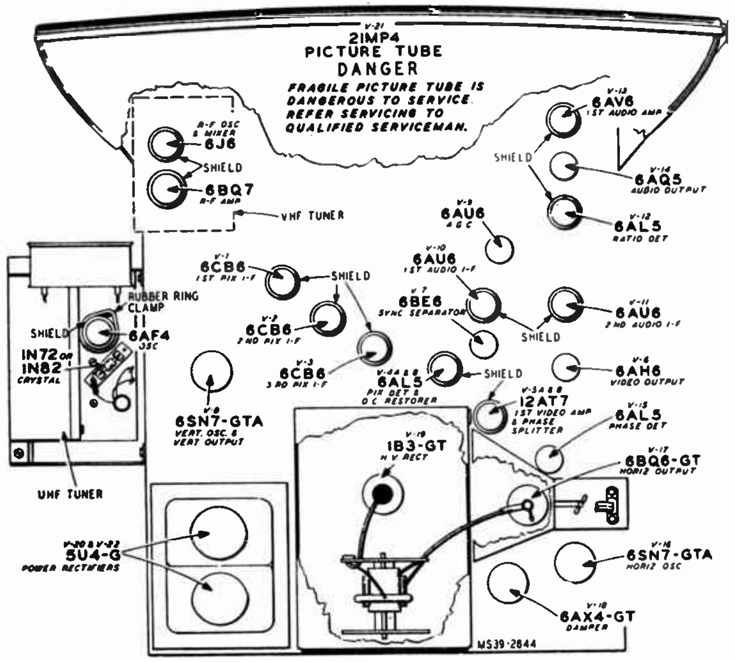

Fig. 1—Tube Layout.

RECEIVER LOCATION — Advise the owner as to the proper location for the television receiver. The following may be used as a guide:

1. Choose an area in the home where sunlight or light from lamps does not strike the face of the picture tube and cause glare.
2. Remember the necessity of an electrical outlet and the location of the point at which the antenna leads enter the room.
3. The receiver should be placed a short distance from the wall to allow adequate ventilation.
4. The receiver should be placed to permit easy access for operation and comfortable viewing from all angles.

ANTENNA — This receiver has been designed to use an antenna with a 300 ohm balanced transmission line. This line must be as short as possible because the longer the line the greater the chances are for picking up electrical disturbances. Stand-off insulation should be used to keep the line away from the mast, metal or walls. Twist this line about one turn per foot throughout the line to cancel out direct signal and/or noise pickup by the transmission line. It should also be securely anchored in place so that a change in weather will not affect its position.

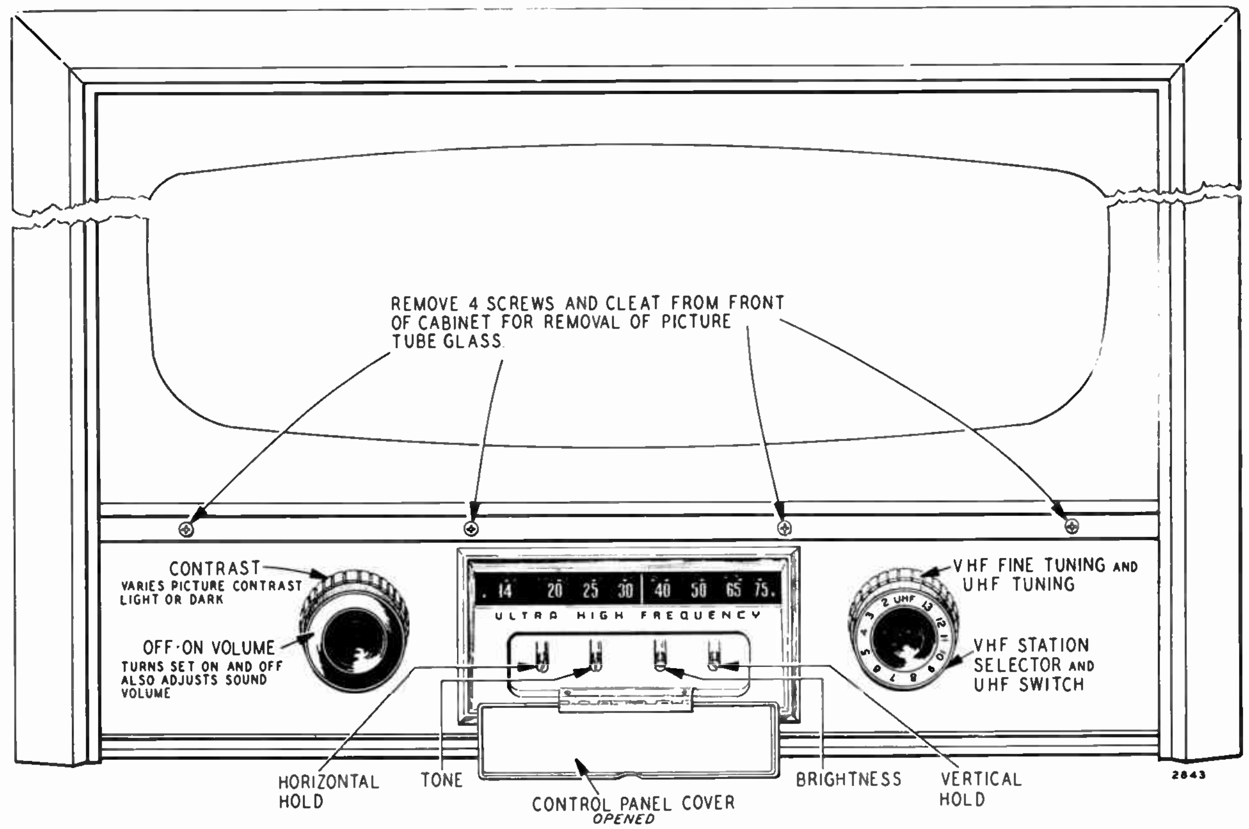
HIGH VOLTAGE WARNING

This television receiver contains high voltages which are dangerous to life. Never operate or service the receiver outside of the cabinet or with the covers removed until all the safety precautions necessary for working with high voltage equipment have been observed.

PICTURE TUBE HANDLING PRECAUTIONS

Shatterproof goggles and heavy gloves must be worn by individuals while handling the picture tube or installing the picture tube into the receiver.

The picture tube encloses a high vacuum and due to the large surface area, is subjected to very high air pressure. Therefore, care should be taken not to bump or scratch the picture tube accidentally as it may cause the tube to implode resulting in damage to property or injury to an individual.



NOTE — In some receivers it may be necessary to remove 5 screws and cleat from under top edge of cabinet for the removal of picture tube glass.

Fig. 2—Front Panel Controls

TUNING PROCEDURE

1. To turn the television receiver on, turn the OFF-ON VOLUME control clockwise until a click is heard. Allow approximately 30 seconds for the tubes to warm up.
2. Turn the STATION SELECTOR control to the desired channel. This control may be turned in either direction.
3. Turn the CONTRAST control clockwise until activity or definite form is noted on the screen.
4. Adjust the FINE TUNING control for clearest picture and the VOLUME control for desired volume.
5. To turn off the receiver, turn only the OFF-ON VOLUME control counterclockwise until a click is heard.
6. TONE CONTROL — When this Control is turned clockwise, the high notes will predominate and when turned counterclockwise, a deep bass effect will result.
7. In localities where UHF programs are available, turn the STATION SELECTOR control to the UHF position and tune in the desired station with the UHF Tuning Control. The dial scale is calibrated in channel numbers and covers the entire UHF range of channels 14 through 83.

OCCASIONAL ADJUSTMENTS TO IMPROVE PICTURE RECEPTION

There are four controls at the front of the chassis which are accessible when the hinged control panel is pulled downward. See illustration Figure 2. These controls are pre-set at the factory and may occasionally need adjustment due to aging of the components in the receiver and the fluctuating line voltages in different areas.

If any adjustments are necessary follow the instructions under "Controls and Functions."

IMPORTANT — Be sure that the FINE TUNING control has been set for the clearest picture before adjusting any controls.

CONTROLS AND FUNCTIONS

HORIZONTAL HOLD—Stops horizontal movement (diagonal bars.)

TONE—Adjusts for tonal quality bass or treble.

BRIGHTNESS—Adjusts for desired picture brilliance.

VERTICAL HOLD—Stops upward or downward picture movement.

PICTURE TUBE SAFETY GLASS

PICTURE TUBE SAFETY GLASS — It will be necessary to clean the picture tube safety glass and the face of the picture tube occasionally. Remove the screws and cleat as outlined in the illustration. Insert your fingers into the opening at the center of the frame and carefully lift up and pull out the safety glass. Clean the safety glass and the face of the picture tube with a soft lint-free cloth dampened with water or mild soapsuds.

For models that have the cleat and screws at the top of the cabinet the following caution must be observed.

CAUTION — UPON REMOVAL OF THE LAST SCREW AND THE CLEAT THE GLASS MAY FALL FORWARD. SUPPORT THE GLASS WITH ONE HAND AS YOU LIFT IT GENTLY FROM THE CABINET.

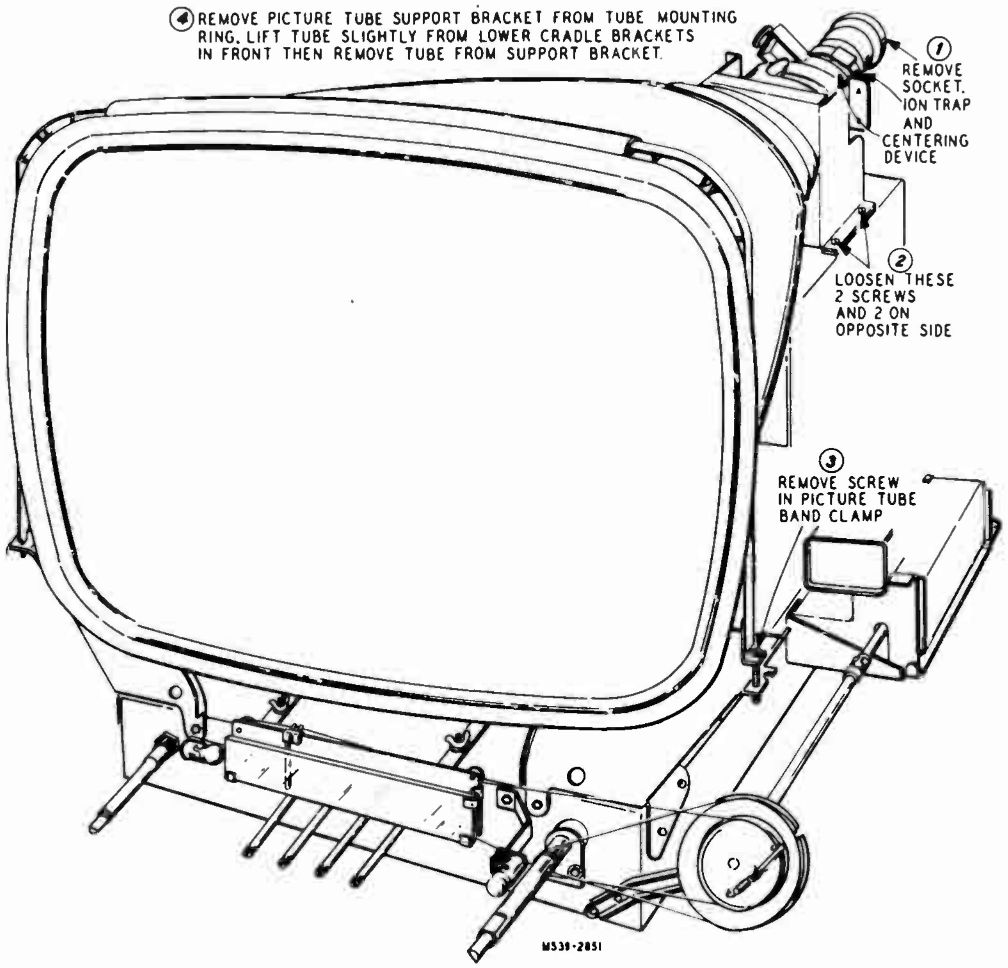


Fig. 3—Removal of Picture Tube

WARNING — Before handling the picture tube, it will be necessary to remove the static charge. In receivers with glass picture tubes, ground the anode lead to chassis, and insert an insulated wire from the well in the tube to chassis. In receivers with metal picture tubes, remove the static charge by grounding an insulated wire from the chassis to the metal portion of the tube.

PICTURE TUBE REPLACEMENT — To replace the picture tube it is necessary to remove the chassis from the cabinet. This may be accomplished in the following manner:

1. Remove the front panel control knobs by pulling them straight from their shafts.
2. Remove the cabinet back.
3. Disconnect the leads from the speaker, remove the antenna terminal boards at the rear of the cabinet and then the five chassis mounting bolts. Pull chassis CAREFULLY out of the cabinet.
4. Remove the picture tube as shown and outlined in the illustration. To install a new picture tube, reverse the procedure making sure that the picture tube fits close against the picture tube cushion. If the picture tube sticks or fails to slip into place smoothly, investigate and remove the source of the trouble. Never force the tube. It is important that all the clips and shims used in mounting the tube be replaced, otherwise difficulty may be encountered when horizontal or vertical centering is required.

Vertical Linearity R-49
Height R-54
Sync Stability R-39
AGC Threshold Control R-108

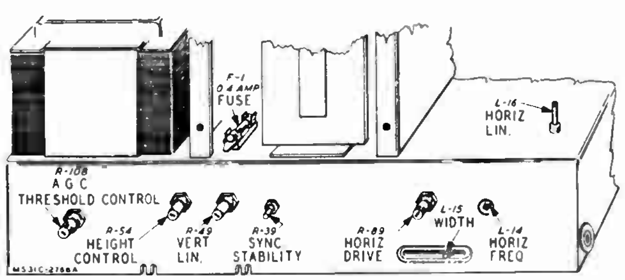

Fig. 4—Adjustments Rear of Chassis

ION TRAP MAGNET ADJUSTMENT—The ion trap magnet should be positioned close to the base of the tube with the magnet of the ion trap on the side where the electron gun is nearest the glass neck of the picture tube. From this position adjust the magnet by moving it back and forth and at the same time rotating it slightly around the neck of the picture tube until the brightest raster is obtained on the picture screen. Reduce the brightness control setting until the raster is slightly above average brilliance. Readjust the ion trap magnet for maximum raster brilliance and best focus. MAXIMUM RASTER BRILLIANCE AND BEST FOCUS OCCUR AT THE SAME POINT. Do not sacrifice brilliance for best focus. The ion trap magnet adjustment is a very critical one especially with the electrostatic type zero focus picture tube. Consequently, great care should be taken to make sure that the ion trap magnet is correctly adjusted.

DEFLECTION YOKE ADJUSTMENT — If the lines of the raster are not horizontal or squared with the picture mask, rotate the deflection yoke until this condition is obtained. Tighten the yoke adjustment wing screw.

CENTERING ADJUSTMENT — If horizontal or vertical centering is required, adjust each ring in the centering device until proper centering is obtained. If a clamp type centering device is used, rotate the device to the left or right and turn the knob located at the top of the device until the picture is centered correctly.

PICTURE ADJUSTMENT — For further adjustments, obtain a test pattern on the receiver. Turn on receiver and follow tuning procedure on page 28. When a test pattern is obtained it may be necessary to slightly re-adjust the fine tuning control for clearest picture.

ADJUSTMENT OF AGC THRESHOLD CONTROL — Tune the receiver to the strongest station in the area in which the receiver will be used. While observing the picture and listening to the sound, turn the control clockwise until signs of overloading (buzz in sound, washed-out picture) appear. Then turn the control a few degrees counter-clockwise from the point at which overloading occurs. (The stronger the signal input, the more counter-clockwise this setting will be.) In areas where the strongest signal does not exceed 10,000 uv the setting will usually be maximum clockwise. With the control set correctly, the AGC will automatically adjust the bias on the R.F. and I.F. amplifiers so that the best possible signal to noise ratio (Minimum snow) will be obtained for any signal input to the receiver.

ADJUSTMENT OF SYNC STABILITY CONTROL — When receiving strong (500 MV or more) signals, set hold controls so that the picture is locked in. Turn the sync control slowly clockwise until bending occurs at top of picture. Then turn the control a few degrees counter-clockwise until bending disappears. If the control is set incorrectly bending, tearing, etc., will be present and when switching from channel to channel the picture will not lock in quickly.

In weak signal areas the control should be set for maximum picture stability. In general the weaker the signal the more clockwise the control should be turned.

When the sync stability control is correctly adjusted the receiver will hold sync without tearing or rolling under even the most adverse noise conditions.

CHECK OF HORIZONTAL OSCILLATOR ALIGNMENT — Tune in a station and adjust the horizontal hold control until the picture falls into sync. Momentarily remove the signal by switching off channel and then back. The picture should pull into sync over a range of 90° rotation of the horizontal hold control. If in the above check the receiver fails to hold sync or the pull-in range is at the extreme end of the control, it will be necessary to make the following adjustment.

HORIZONTAL FREQUENCY ADJUSTMENT — With the horizontal hold control set to the center of its range of rotation, adjust the horizontal frequency control (L-14) until the picture pulls into sync. Recheck the "Horizontal Oscillator Alignment."

HEIGHT AND VERTICAL LINEARITY ADJUSTMENT — Adjust the height control (R-54) until the picture fills the mask vertically. Adjust the vertical linearity control (R-49) until the picture is symmetrical from top to bottom. Adjust the picture centering device to align picture with the mask. Adjustment of any control will require a re-adjustment of the other control.

WIDTH, DRIVE AND LINEARITY ADJUSTMENTS— While receiving a signal from a station (with picture locked in sync) turn contrast control fully counter-clockwise, turn the brightness control (R-25) up so that the picture appears washed out. Adjust width control (L-15) until the picture fills the mask. Turn the horizontal drive control (R-89) clockwise until white bars appear in the left center portion of the raster, then turn counter-clockwise until the white bars just disappear. This adjustment will allow the horizontal system to operate at maximum efficiency. Adjust horizontal linearity control (L-16) for best linearity. If adjustment of the horizontal drive (R-89) or horizontal linearity (L-16) is required, it usually will be necessary to recheck the horizontal oscillator alignment. If adjustment of the horizontal linearity control (L-16) is required, readjustment of the horizontal drive control (R-89) will be necessary. Adjust the picture centering device to align the picture with the mask.

CHECK OF R-F OSCILLATOR ADJUSTMENTS

The oscillator is preset at the factory and normally needs no adjustment. However, if adjustments are required, they can be made without removing the chassis from the cabinet. Remove the channel selector and fine tuning knobs from the tuning shaft.

TEST PROCEDURE:

1. Set channel selector to receive desired station.
2. Set fine tuning control in center of its range.
3. Adjust oscillator slug, with bakelite type screwdriver, for best picture resolution.
4. Repeat steps 1, 2 and 3 on all channels used.

Caution — These adjustments are intended only for VHF Channels. For information regarding UHF alignment, see paragraph "Tuner Alignment" on page 11.

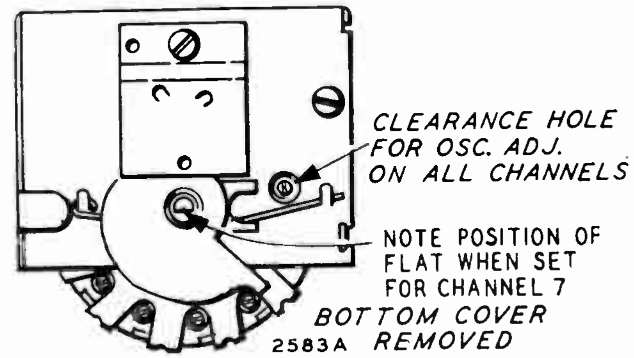

Fig. 5—Tuner Oscillator Adjustments

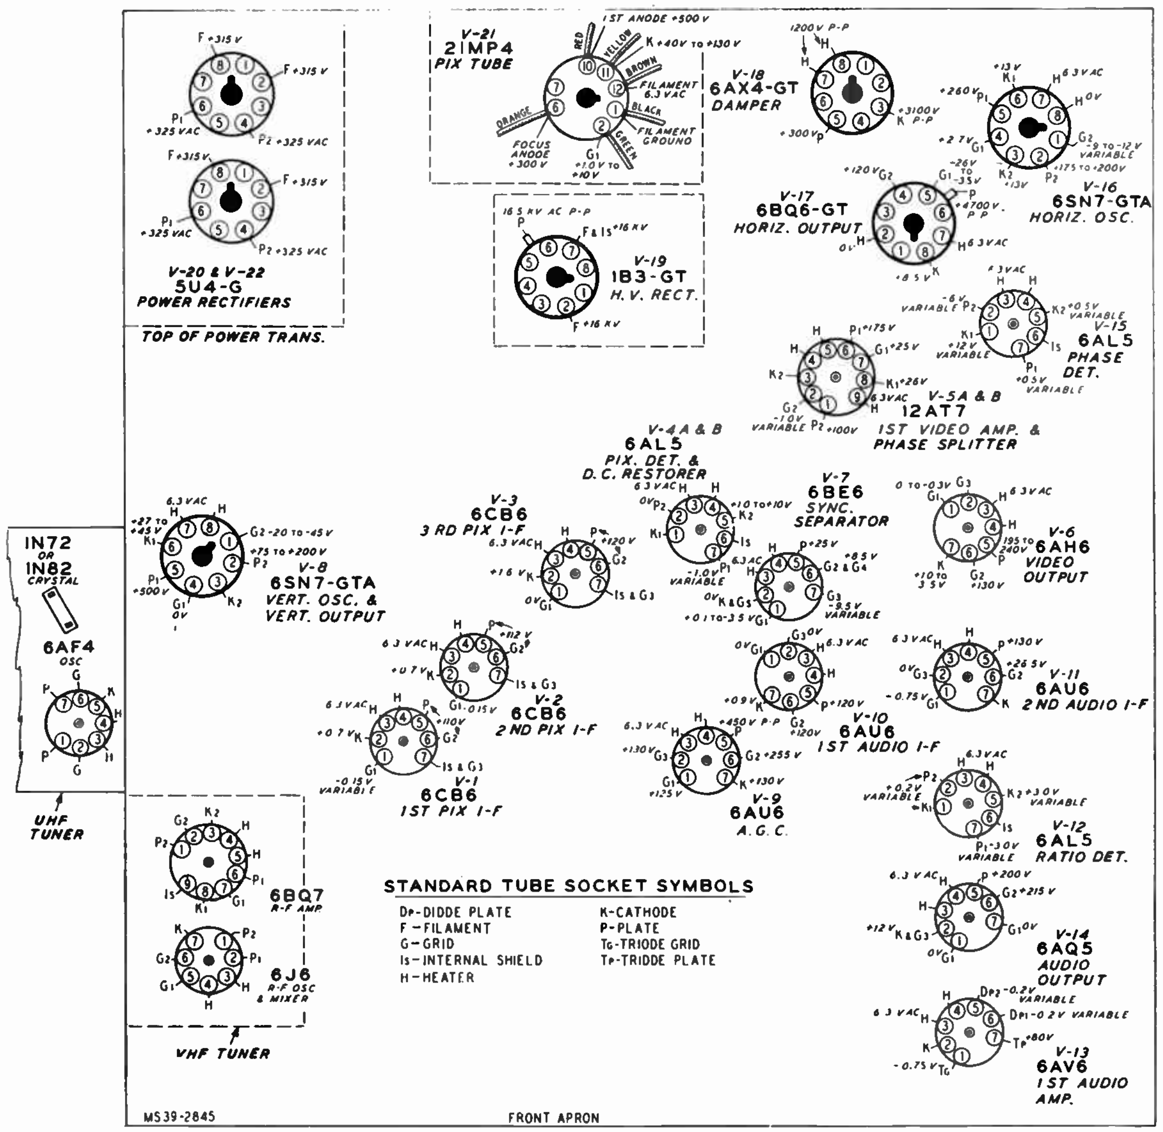

Fig 6—Bottom Socket Voltages

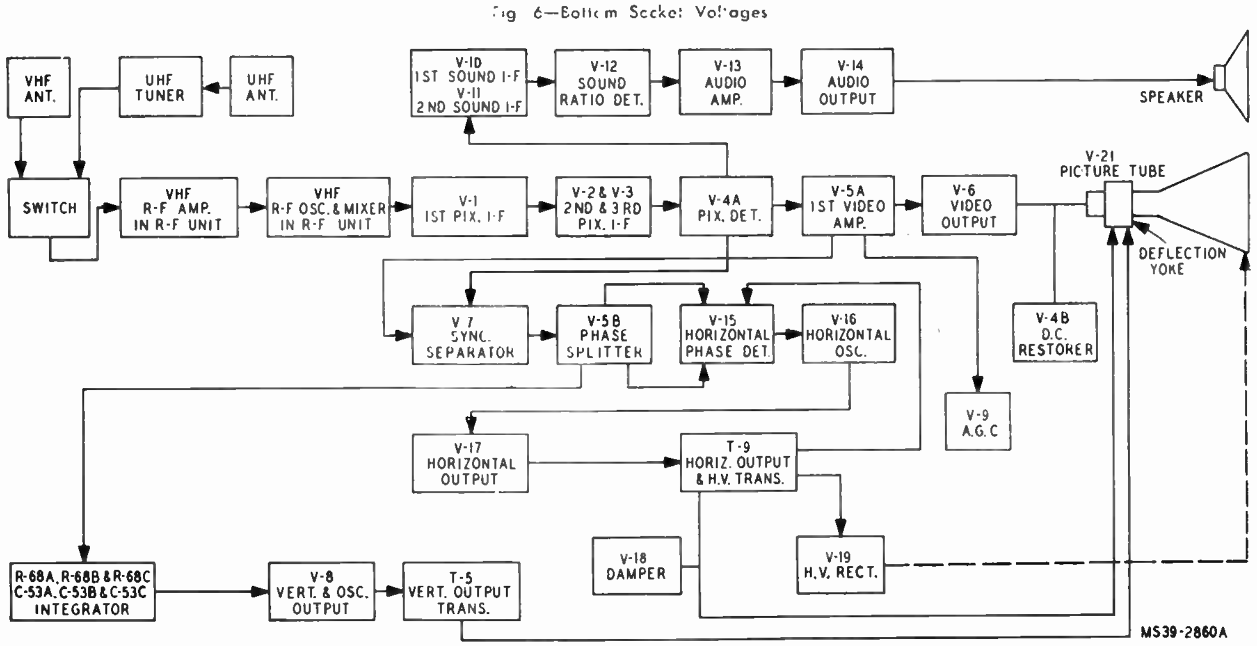

Fig. 7—Block Diagram

SERVICE SUGGESTIONS

NO RASTER ON PICTURE TUBE — If raster cannot be obtained check below for the possible causes.

1: Ion trap magnet adjustment is incorrect.
2: No +B voltage. Check 4/10 ampere fuse. Replace if defective. If fuse continually burns out, check
   (A) Horizontal output tube V-17 (6BQ6-GT)
   (B) Check damper tube V-18 (6AX4-GT).
   (C) Check horizontal oscillator tube V-16 (6SN7-GTA) for proper operation.
   (D) With an ohm meter, check for a short between terminal 1 of the horizontal output transformer (T-9) and the chassis.
   (E) Check DC resistance of T-9.
3: No high voltage. Check V-17, V-18 and V-19 tubes and circuits. If the horizontal deflection circuits are operating as evidenced by the correct voltage (600V) measured on terminal No. 1 of T-9, the trouble can be isolated to the high voltage rectifier circuit. Either the high voltage winding to the 6BQ6-GT plate and 1B3 plate is open, tube V-19 is defective, its filament circuit is open, R-105 and C-75 defective or pix tube elements shorted internally.
4: Defective picture tube heater open or cathode return circuit open.

HORIZONTAL DEFLECTION ONLY — If only horizontal deflection is obtained as evidenced by a straight line across the face of the picture tube, it can be caused by the following:

1: Vertical oscillator and vertical output tube V-8 inoperative. Check socket voltages.
2: Vertical oscillator transformer (T-4) defective.
3: Vertical output transformer (T-5) open or shorted.
4: Yoke vertical coils open or shorted.
5: Vertical hold, height or linearity controls may be defective.

POOR VERTICAL LINEARITY — If adjustment of the height and linearity controls will not correct this condition, any of the following may be the cause.

1: Check variable resistors R-49 and R-54.
2: Vertical output transformer (T-5) defective.
3: Capacitors C-47B, C-70 or C-71 defective.
4: V-8 defective, check voltages.
5: Excess leakage or incorrect value of capacitor C-68, or open or incorrect value of resistors R-90 & R-92.
6: Low plate voltages. Check rectifier tube and capacitors in +B supply circuits.
7: Capacitor C-67 defective.
8: Vertical deflection coils (L-12) defective.

POOR HORIZONTAL LINEARITY — If adjustment of the Horizontal drive and linearity controls does not correct this condition, check the following:

1: Check or replace horizontal output tube V-17.
2: Check or replace damper tube V-18 (6AX4-GT).
3: Check capacitors C-77, C-78, C-79 and horizontal linearity control (L-16) for defects.
4: Horizontal deflection coils (L-17) defective.

TRAPEZOIDAL OR NONSYMMETRICAL RASTER

1: Defective yoke.

WRINKLES ON LEFT SIDE OF RASTER — This condition can be caused by:

1: Defective yoke due to C-76 or R-106 (internal in yoke assembly) being wrong value or open. These components are mounted in rear of yoke assembly.
2: V-18 (6AX4-GT) defective.

SMALL RASTER — This condition can be caused by:

1: Low +B or line voltage. Check V-20 & V-22 (5U4G).
2: Insufficient output from horizontal output tube V-17. Replace tube.
3: Insufficient output from vertical oscillator and vertical output tube V-8. Replace tube.
4: Incorrect setting of horizontal drive control R-89.
5: V-18 (6AX4-GT) defective.
6: Incorrect setting of (L-15) width control.

RASTER; NO IMAGE, BUT ACCOMPANYING SOUND — This condition can be caused by:

1: No signal on picture tube grid. Check V-5A (12AT7) and V-6 (6AH6) tubes and associated circuits.
2: Bad contact to picture tube grid (lead to socket broken).
3: AGC tube (V-9) may be defective. Check tube and its associated circuit.

SIGNAL APPEARS ON PICTURE TUBE GRID BUT IMPOSSIBLE TO SYNCHRONIZE THE PICTURE VERTICALLY AND HORIZONTALLY — A condition of this nature can be caused by:

1: Defective sync separator V-7 or phase splitter V-5B.
2: If tubes are O.K. check voltages, and associated circuits.
3: AGC system inoperative. Check V-9 (6AU6) AGC tube and associated circuits.

SIGNAL ON PICTURE TUBE GRID AND HORIZONTAL SYNC ONLY — If this condition is encountered, check:

1: Vertical integrating network capacitors C-53A, B & C, and resistors R-68 A, B & C.
2: Vertical hold control (R-51) defective.

SIGNAL ON PICTURE TUBE GRID AND VERTICAL SYNC ONLY

1: V-15 or V-16 defective.
2: Improper setting of (L-14) horizontal frequency control.
3: Check setting of horizontal drive control and horizontal linearity control.
4: Check V-15 and V-16 socket voltages.

PICTURE STABLE BUT WITH POOR RESOLUTION — If the picture resolution is not up to standard, it may be caused by any of the following:

1: Defective pix I-F tubes V-1, 2 & 3, (6CB6's).
2: Defective picture detector V-4A, (6AL5) or video amplifier V-5A or video output V-6 (6AH6).
3: Defective picture tube.
4: Open video peaking coil. Check all peaking coils L-5, L-6, L-8, L-9, L-10 and L-11 for continuity. Note that L-5, L-9 and L-10 have shunting resistors.
5: Leakage in V-6 (6AH6) grid capacitor C-36. If the capacitor is not found to be defective, check the following:
   1: Check all potentials in video circuits.
   2: Check picture tube grid circuit for poor or dirty contact.
   3: Check and realign, if necessary, the picture I-F and R-F circuits.

PICTURE SMEAR:

1: A smear can be attributed to phase shift at the low or high frequency end of the video characteristic. This can be caused by improper values of resistors and capacitors in the video circuits. Check for grid current on video output tube V-6 (6AH6), open or shorted peaking coils, video amplifier load resistors are of improper value (high).
2: This trouble can also originate at the transmitter. Check reception from another station.
3: Check and realign, if necessary, the picture I-F and R-F circuits.

MAN MADE NOISE IN SOUND (Ignition, etc)

1: Check sound I-F tubes V-10, 11 & 12 and associated circuits.
2: Check sound I-F alignment.

BENDING OR S-ING

1: Check sync stability control adjustment.
2: Check capacitors C-47A and C-49A.
3: V-17 (6BQ6-GT) defective or V-16 (6SN7-GTA) defective.
4: Check sync separator tube V-7 (6BE6) and phase splitter V-5B (12AT7) and V-5A (12AT7) video amplifier.
5: Check AGC threshold control.

PICTURE NORMAL—NO SOUND OR WEAK OR DISTORTED SOUND

1: Check sound I-F alignment.
2: Check V-10 (6AU6) V-11 (6AU6) V-12 (6AL5) V-13 (6AV6) V-14 (6AQ5) and associated circuits.

RASTER ON TUBE BUT NO PICTURE OR SOUND

This condition can be caused by,
1: Defective pix I-F Amplifier tubes V-1, V-2 or V-3
2: Defective pix detector tube V-4A (6AL5). Check tube and its associated circuit.
3: Defective R-F Amplifier or oscillator mixer tubes in the tuner.
4: UHF-VHF switch defective.

POOR FOCUS

1: Improper setting of Ion Trap magnet.
2: Defective picture tube or picture tube socket.

PICTURE JITTER:

1: If regular sections at left of the picture are displaced, replace the horizontal oscillator tube V-16.
2: Vertical instability may be due to loose connections or noise received with the signal.
3: Horizontal instability may be due to unstable transmitted sync.
4: Check receiver AGC system for proper operation.
5: Check phase splitter V-5B, (12AT7) and sync separator V-7 (6BE6).
6: Check for improper setting of sync stability control.
7: Picture tube grid lead not held in position by support spring, ie: close proximity of grid lead to sync and horizontal tubes will cause picture to jitter at high contrast setting.
8: Check AGC threshold control.

NO PICTURE OR SOUND OR WEAK PICTURE OR SOUND IN UHF POSITION

If this condition is encountered
1: Check to see whether or not a UHF station is operating in the vicinity.
2: The 6AF4 oscillator tube or the IN72 (or IN82) crystal may be defective.
3: Pre-selector in UHF tuner defective.
4: Low pass filter defective.
5: The UHF antenna and oscillator strips in the VHF tuner defective.
6: Defective switch on UHF tuner.

ALIGNMENT PROCEDURE

TEST EQUIPMENT — To service this receiver properly, it is recommended that the following test equipment be available:

R-F SWEEP GENERATOR meeting the following requirements:
(a) Frequency ranges:
18 to 30 mc, 10 mc sweep width
40 to 90 mc, 10 mc sweep width
120 to 130 mc, 10 mc sweep width
170 to 225 mc, 10 mc sweep width
470 to 890 mc, 10 mc sweep width
(b) Output adjustable with at least .1 volt maximum.
(c) Output constant on all ranges.
(d) Flat output in all attenuator positions.

CATHODE-RAY OSCILLOSCOPE preferably one with a wide band vertical deflection and an input calibrating source.

SIGNAL GENERATOR to provide the following frequencies: (Output on these ranges should be adjustable and at least .1 volt maximum.)
(a) Intermediate alignment frequencies.
23.1 mc first picture I-F coil.
24.1 mc third picture I-F coil.
25.9 mc second picture I-F coil.
21.7 mc sound trap.
4.5 mc video trap & sound I-F.
25.2 mc converter plate coil (Tuner).

HETERODYNE FREQUENCY METER with crystal calibrator if the signal generator is not crystal controlled.

ELECTRONIC VOLTMETER and a high voltage probe for use with this meter to permit measurements up to 20 kilovolts.

SERVICE PRECAUTIONS — To service the receiver remove the chassis from the cabinet. To do so, remove the knobs, the cabinet back, disconnect the leads from the speaker, remove the antenna terminal boards at rear of cabinet, and then the 5 chassis mounting bolts. The chassis may be serviced with the picture tube in place provided the chassis is turned on its side with the power transformer on the bottom. The weight of the chassis will be supported against the power transformer and pix tube brackets.

CAUTION: Do not permit the kinescope second-anode lead to become shorted to the chassis. To do so will cause a considerable overload on the high voltage filter resistor R-105.

ALIGNMENT PROCEDURE
PIX I-F

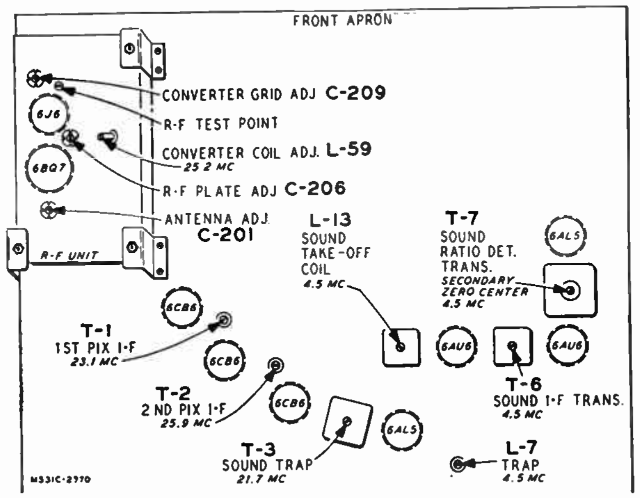

Fig. 8—Top Chassis Video and Audio I-F Adjustments

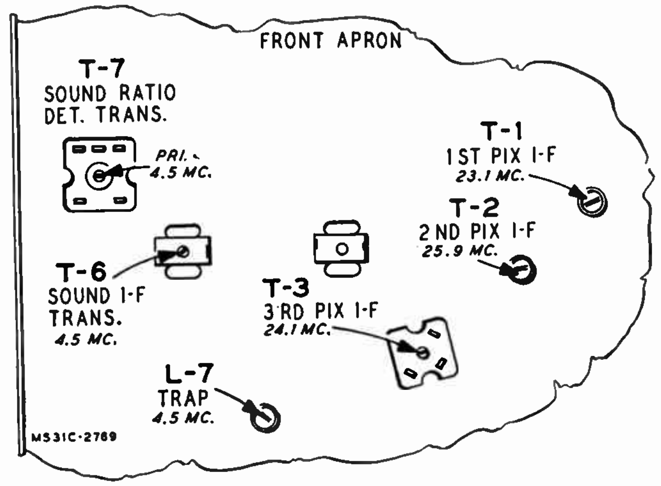

Fig. 9—Bottom Chassis Video and Audio I-F Adjustments.

A. Unmodulated R-F signal into Converter Grid by means of tube shield insulated from base. VTVM with filter in lead of 22 K ohms and 5000 mmf connected to pic. det. load resistor, (R-37) 4700 ohms, in series with peaking coil (L-6) from Pin 7 of 6AL5. Input signal level should be such that output is less than 2 volts DC. Apply -4.5V battery bias on AGC line.

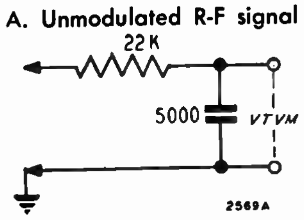

Fig. 10—VTVM Connections

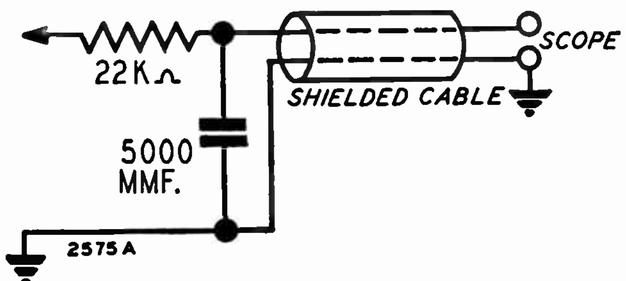

Fig. 11—Oscilloscope Connections

	FREQUENCY	ADJUST
1.	25.2 MC	Converter plate coil on top of tuner for maximum dc at picture detector.
2.	23.1 MC	1st picture I-F coil (T-1) for maximum dc at picture detector.
3.	25.9 MC	2nd picture I-F coil (T-2) for maximum dc at picture detector.
4.	24.1 MC	3rd picture I-F coil (T-3 below chassis) for maximum dc at picture detector.
5.	21.7 MC	3rd picture I-F trap (T-3 in can above chassis) for minimum dc at picture detector.

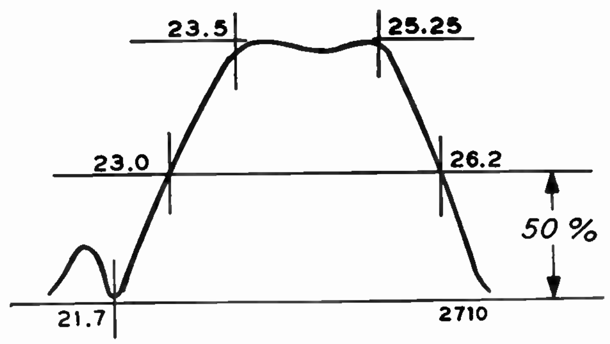

Fig. 12—Overall Response Curve

B. I-F Sweep Generator into converter grid by means of tube shield insulated from base.

Connect oscilloscope across R-37 (in place of VTVM). Apply -4.5V bias (DC) to AGC line (battery).

Tuner should be switched to dead channel so as not to cause interference.

Observe overall I-F response, which should be as shown above: A slight touch-up may be required. At no time should the trap coil be re-adjusted, nor should it be necessary to turn any of the picture I-F coils more than 1/2 turn of the slug. The following comments are suggestions only:

ALIGNMENT PROCEDURE (Continued)

1. The height of the 26.2 MC marker is controlled by the 25.2 MC (Converter Plate Coil on tuner) and the 25.9 MC (2nd P.I.F.) coils.
2. The uniformity of response (flatness across top and position of 23.5 MC) marker is controlled for the most part by the 24.1 MC third picture I-F coil.
3. The 23.0 MC marker position is controlled by the first picture I-F (23.1 MC coil). However, it is NOT advisable to change the setting of the coil, due to its effect on sound rejection. Its adjustment should be avoided unless believed to be absolutely necessary.

VIDEO

With 4.5 MC unmodulated signal from a high impedance source, (10,000 ohms in series with the generator) into plate of the picture detector tube (Pin 7-6AL5) and VTVM on picture tube grid, tune 4.5 MC trap (L-7 Top) for minimum response. VTVM on 0-10 V AC scale. This adjustment can also be made while observing a picture from a station. Tune trap for least 4.5 MC beat in picture.

AUDIO I-F

1: With signal generator set to 4.5 MC and dc VTVM connected to junction of R-13 and C-14, adjust sound take-off coil (L-13 Top) and sound I-F transformer slugs (T-6 Top & Bottom) for maximum.

2: With VTVM connected to pin 7 of V-12 (6AL5) adjust the ratio detector primary (T-7 Bottom) for maximum.

3: With VTVM connected to junction of R-17, R-20 and C-18, adjust ratio detector secondary (T-7 Top) for cross over (zero voltage) on lowest scale.

NOTE — If no signal generator is available, the procedure above may be followed by tuning in a station and using the 4.5 MC beat between picture and sound carrier.

TUNER ALIGNMENT

A. Sweep generator with balanced 300 ohm output to antenna terminals. Marker generator output to antenna terminals. Oscilloscope to "test point" (Figure 13) on tuner. Connect 1½ V bias to AGC line at junction of R-34 and C-29 on the receiver.

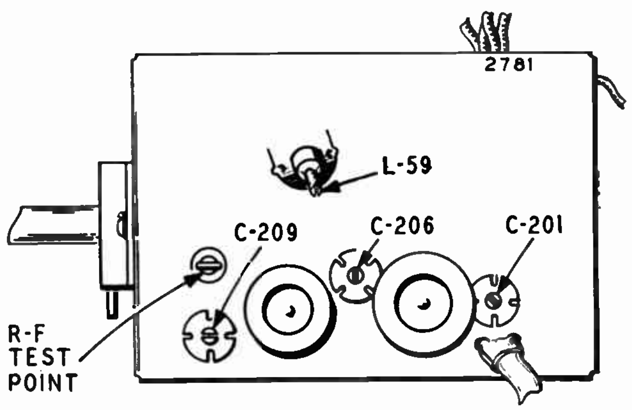

Fig. 13—Top Tuner Adjustments

B. RF AND CONVERTER ADJUSTMENT.

1. With channel selector on Channel 12, adjust C-201 slightly favoring the Pix carrier, then adjust C-206 and C-209 for response as in Figure 14. Picture and sound markers at 90% maximum response.
2. Check response on all channels. If markers are below 70% on any channels, readjust C-201, C-206, and C-209. Recheck all channels.

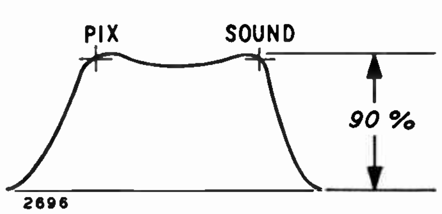

Fig. 14—Pix & Audio Markers

C. OSCILLATOR ADJUSTMENT.

1. Apply -4.5 volts on I-F AGC line at junction of R-1 and C-30A.
2. Connect oscilloscope to output of video detector. Place fine tuning in center of range. Check response on all channels. Sound marker should be in notch and picture marker at 50%. (See Figure 12).
3. If markers are off, individual oscillator coil slugs will require adjustment. Adjust each channel slug, accessible through hole in front of chassis with a non-metallic screwdriver to bring sound marker to correct position.
4. To adjust oscillator on UHF position, feed the sweep generator with center frequency of 124 MC and markers at 121.75 and 126.25 into the input of the low pass filter (output of UHF tuner). Adjust oscillator slug in the VHF tuner so that the 121.75 pix carrier marker is at 50% and that 126.25 marker is in the sound notch. If a sweep generator is not available, a single frequency generator set to 126.25 MC and VTVM may be used. Connect VTVM to the pix detector load resistor R-37. Feed generator into the low pass filter. Adjust oscillator slug in the VHF tuner so that the 126.25 marker is in the sound notch of the I-F curve.
5. If the 6AF4 oscillator tube in the UHF tuner is replaced, it may be necessary to adjust the oscillator trimmer C-309 on the UHF tuner located underneath the chassis. (See Figure 15). Adjust this trimmer until the tuner will cover a range of below 470 MC to above 890 MC.

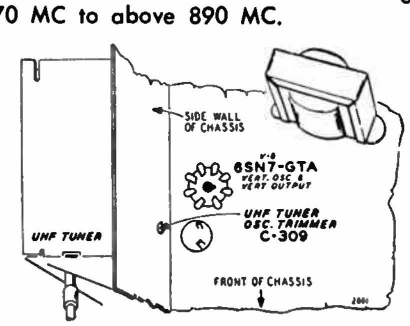

Fig. 15—UHF Tuner Adjustment.

VHF TUNER ASSEMBLY INFORMATION

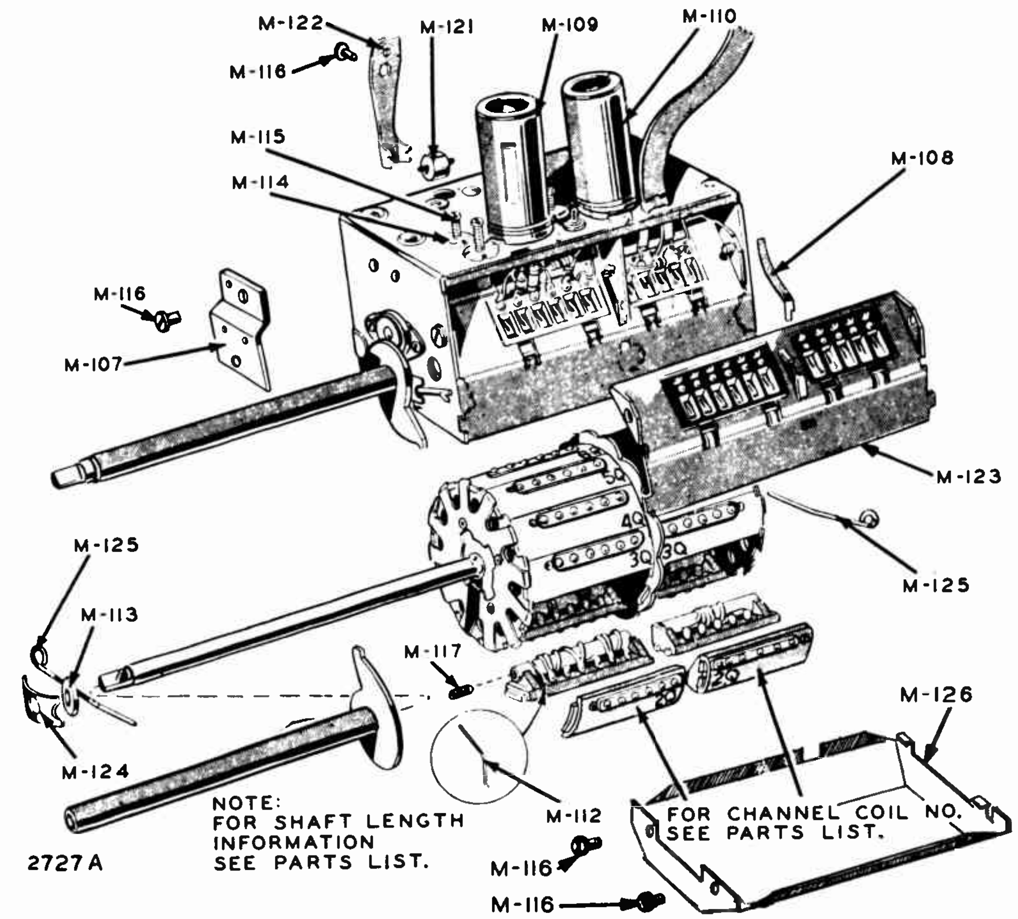

Fig. 16—"Q" Tuner Pictorial.

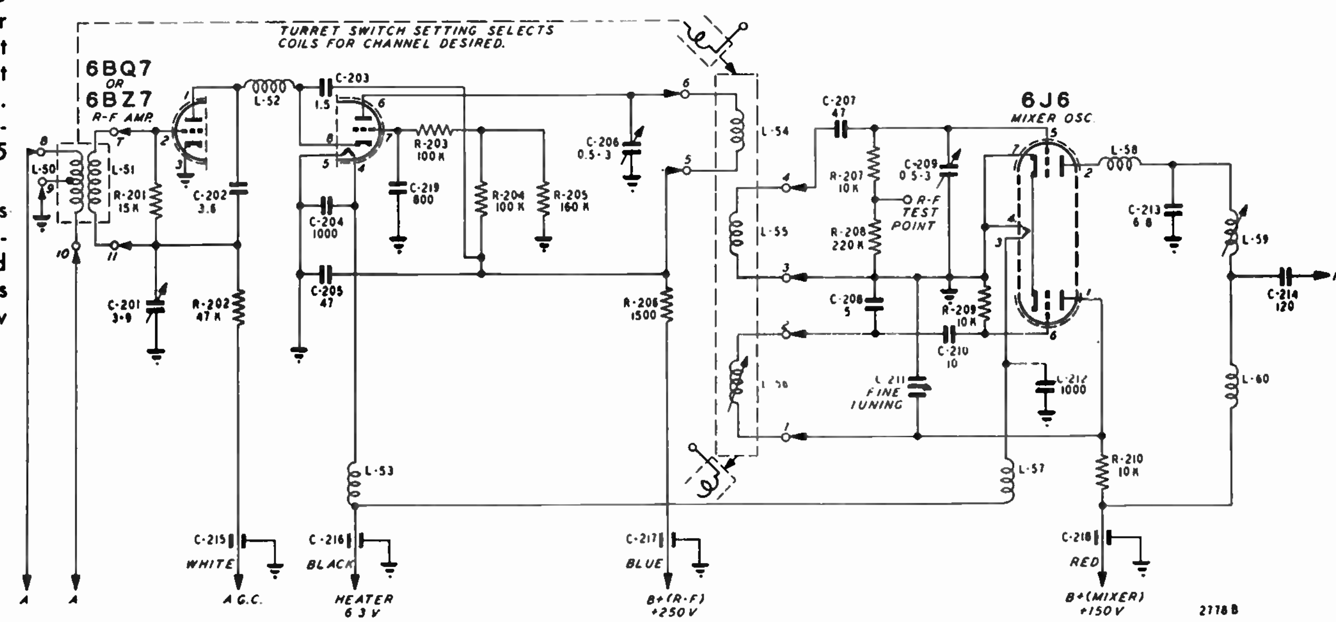

Fig. 17—"Q" Tuner Schematic Diagram.

UHF TUNER INFORMATION

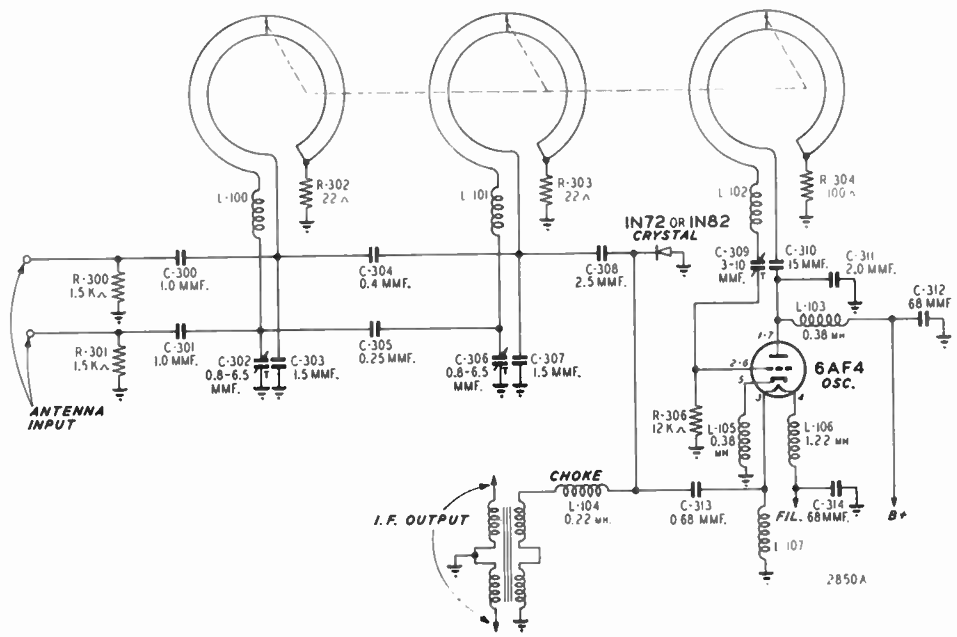

Fig. 18—UHF Tuner Schematic Diagram.

Due to the complexity of the UHF tuner, neither servicing nor aligning is encouraged in the field because replacement of any component within the R-F circuit may disturb the band-pass characteristics of the tuner. However, the 6AF4 tube or the 1N72 (or 1N82) crystal may be replaced in the field if found to be defective. A schematic diagram of this tuner is shown only for the purpose of outlining the circuit used.

If the UHF tuner does not operate satisfactorily after the tube or crystal replacement, disconnect the tuner and return it to the factory for repair.

DRIVE CORD REPLACEMENT

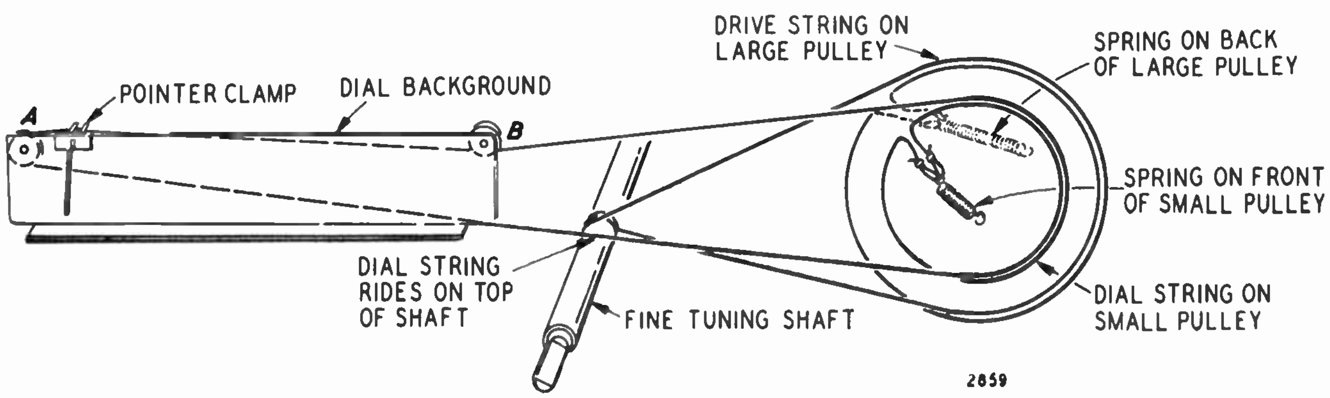

Fig. 19—Drive Cord Stringing.

You will note that there are two cords used for the pointer drive system on this receiver. Part number 10X88 Drive Cord assembly and part number 28X603 Spring are used on the tuning shaft and large pulley, while part number 10X89 Drive Cord and a part number 28X603 Spring are used on the small pulley system and the pointer. Install the cords as shown in the illustration. After completing the installation rotate the fine tuning shaft a few turns to take up the slack in the cord.

OSCILLOSCOPE WAVEFORM PATTERNS

The waveforms on this page were taken with the receiver tuned to a normal picture. The numbers on the waveforms correspond to the numbers on the schematic diagram which identifies each test point.
The voltages shown on each waveform are the approximate peak to peak amplitudes. The frequencies shown indicates the repetition rate of the waveform, not the sweep rate of the oscilloscope. If the waveforms are observed on the oscilloscope with a poor high frequency response, the corners of the pulses will tend to be more rounded than those shown below and the amplitudes of any high frequency pulse will tend to be less.

120V P-P 15,750 C.P.S.

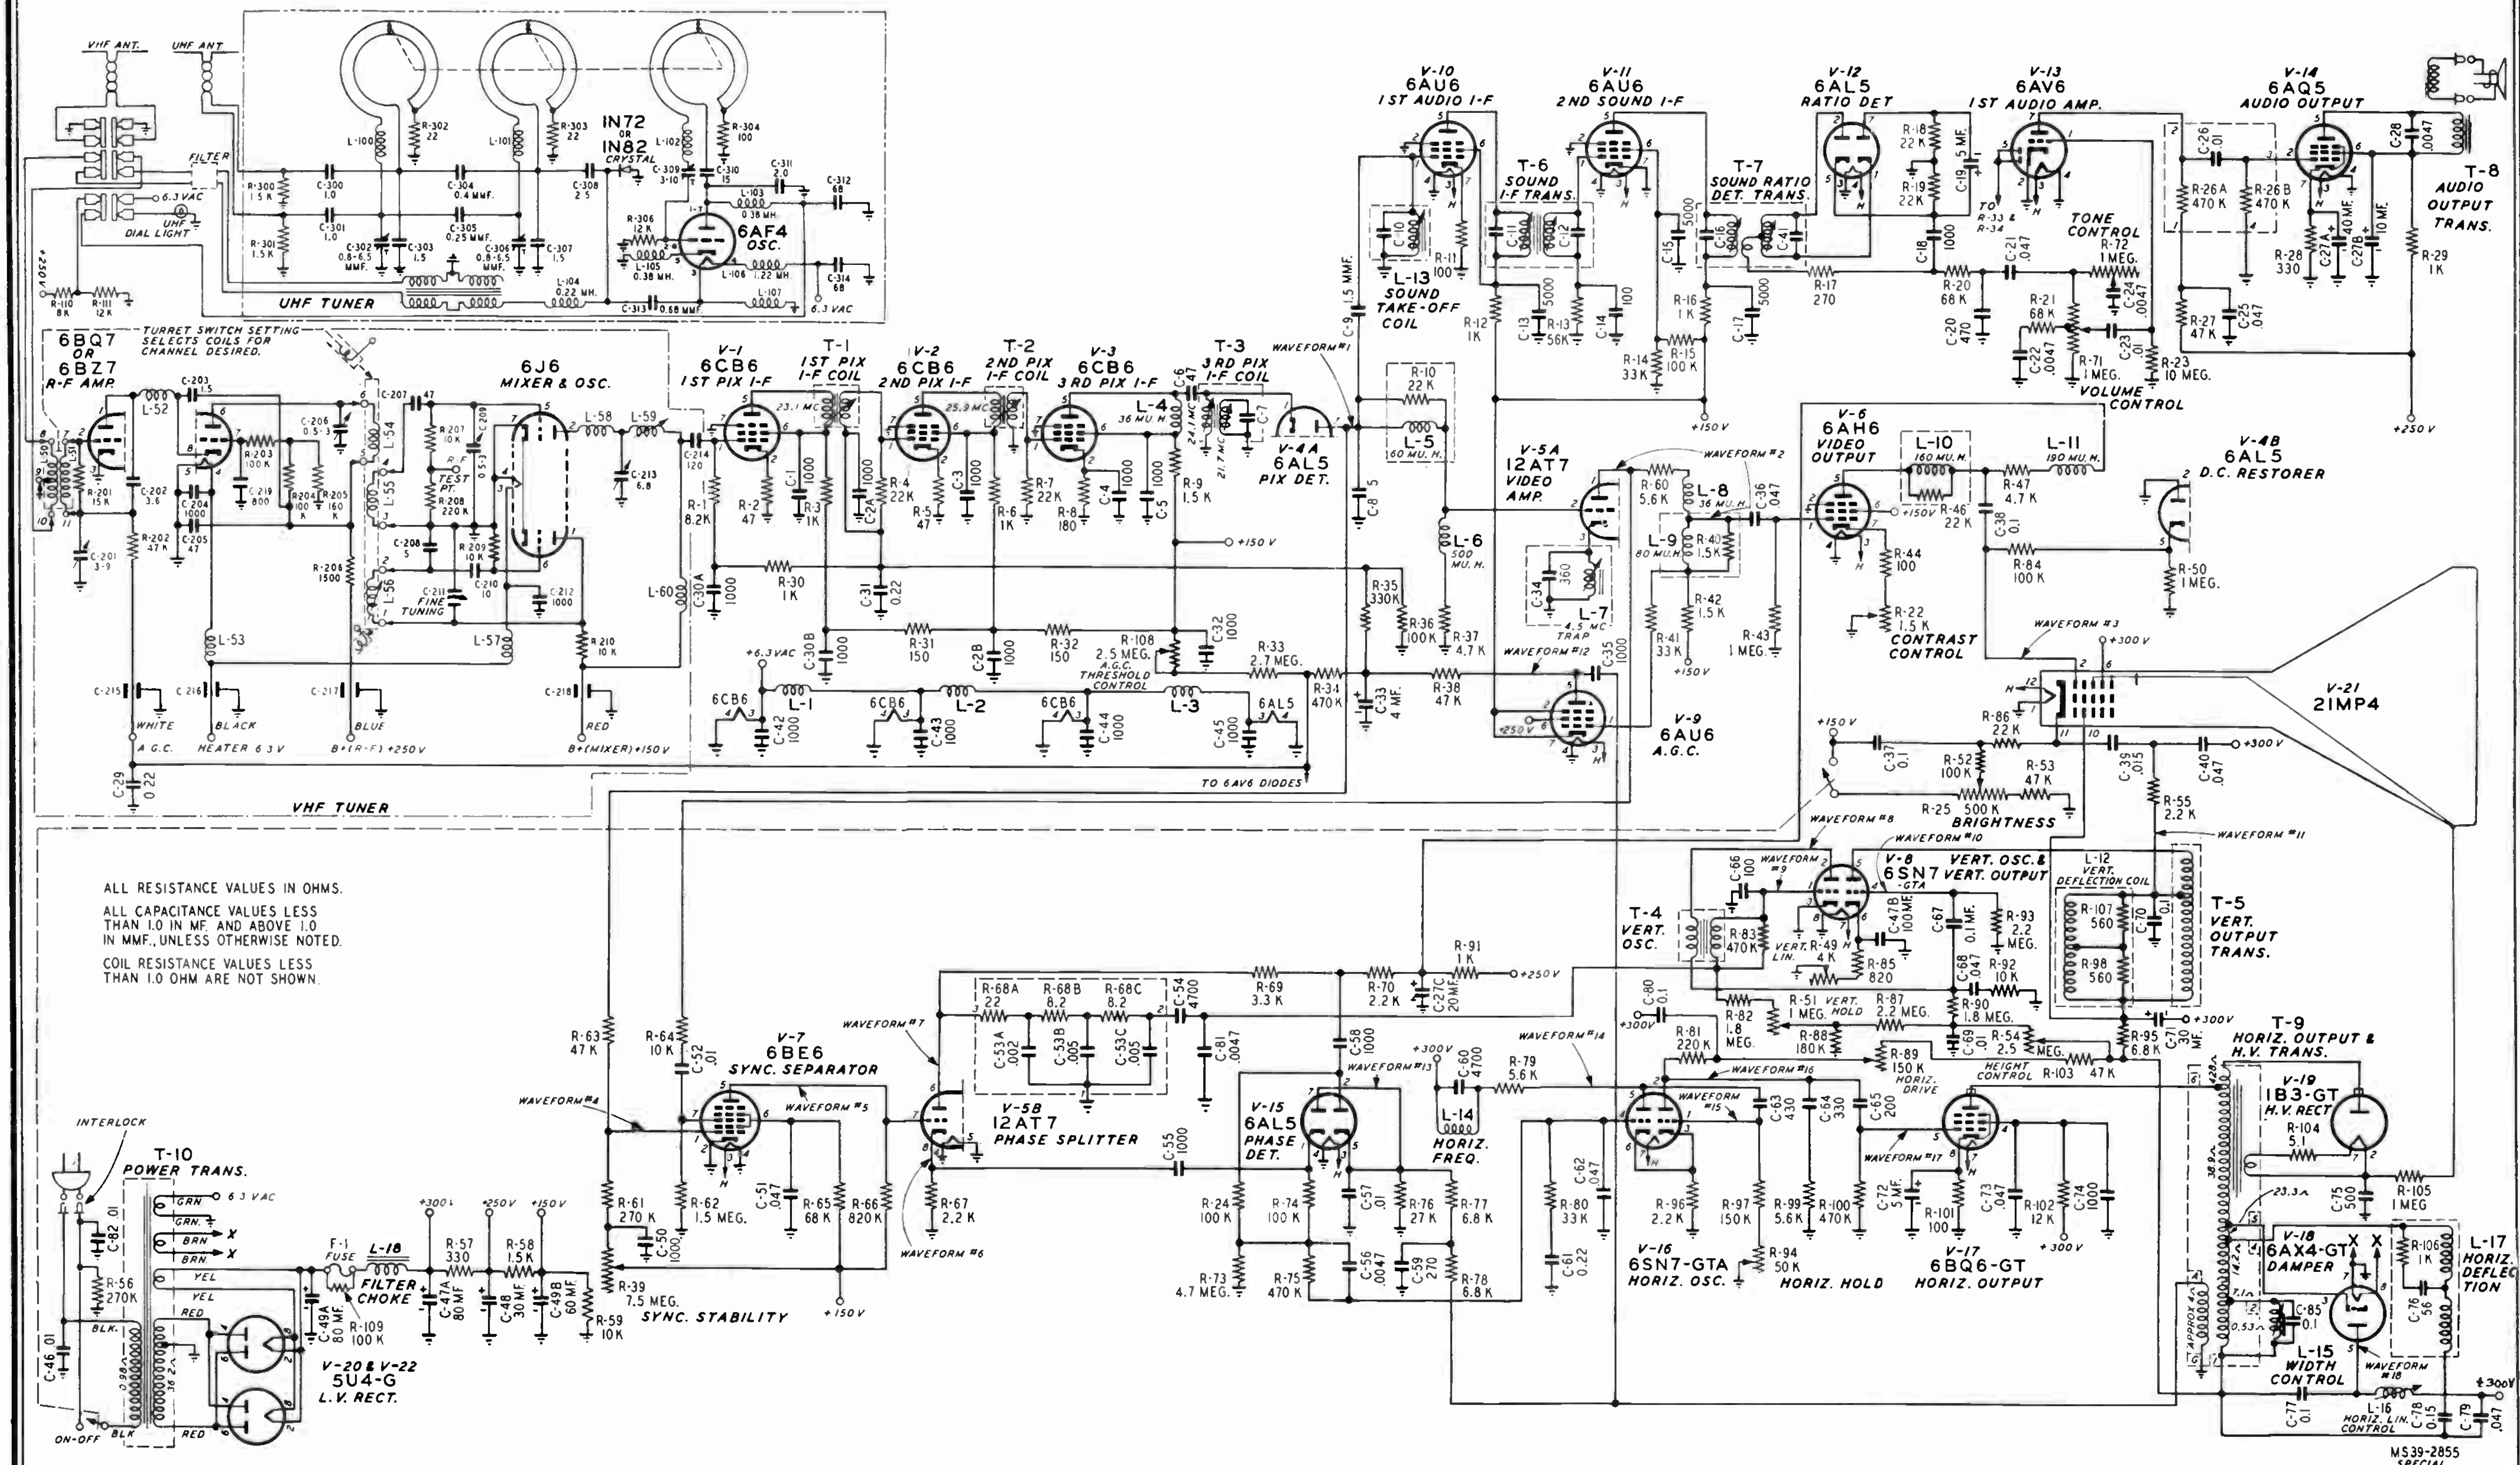
21" UHF-VHF TELEVISION RECEIVER



PRODUCTION CHANGES

There are two different ratio detector transformers (T-7) used in these receivers, Part Numbers 9A2269 and 9A2295. The T-7 circuit shown in this schematic diagram covers the 9A2269 ratio detector. Receivers using the 9A2295 ratio detector can be identified by the following changes:

C-18 becomes 47X570 330 mmf molded mica condenser

R-15 becomes B84333 33K ohm 0.5 W carbon resistor

R-18, R-19 become B83103 10K ohm 0.5 W carbon resistors

In addition, the 9A2295 ratio detector has terminals with numerical identification (1, 2, 3 etc.) whereas the 9A2269 ratio detector has terminals with alphabetical identification (A, B, C etc.)

VHF TUNER ASSEMBLY PARTS LIST

RESISTORS

GENERAL DESCRIPTION

The models covered in this manual are a 20 tube, including the picture tube, AC operated, direct view, 17 and 21-inch rectangular television receivers. The receivers are complete in one unit and feature full coverage of 12 V.H.F. and 70 U.H.F. channels, automatic gain control, automatic horizontal frequency control, intercarrier sound system, electrostatic focusing, magnetically deflected picture tube and a sync stabilizer switch and control to adjust the operational characteristics of the receiver for various signal areas.

At the rear of the receivers is a safety interlock to prevent dangerous electrical shock and as an added safety measure, a fusible resistor is located in the low voltage power supply to protect the receiver in case of overloading.

35BR-3167A (21-inch) Mahogany
35BR-3169A (21-inch) Blond

35BR-3158A (17-inch)
35BR-3168A (21-inch)

SPECIFICATIONS

Sensitivity at the Antenna
Video - 150 microvolts
Audio - 150 microvolts
(one volt above noise at detector)

Antenna Impedance Requirements
Balanced 300-ohm

Audio Power Output Rating
2 watts undistorted

Speaker
Permanent magnet type
3.2 ohm voice coil impedance

Power Supply Rating
115 volts 60 Cycles, AC
Power Consumption, 230 watts

Intermediate Frequencies
Video - 26.75 mc.
Audio - 22.25 mc.
Intercarrier Sound- 4.5 mc.

Dimensions
17" Chassis - 16"x 16½"x 2½"
21" Chassis - 19"x 17½"x 2½"

TUBE COMPLEMENT

Schematic Ref. No.	RTMA Type	Tube Function
1	6BQ7A	VHF, RF Amplifier
2	12AT7	VHF Oscillator-Converter
3-4-5	6CB6	IF Amplifiers
6	6AH6V	Video Amplifier
7	17HP4	Cathode-Ray Tube
7	21FP4A	Cathode-Ray Tube
8	6AU6	Audio IF Amplifier
9	6AL5	Audio Detector
10	6AV6	Audio Amplifier
11	25L6GT	Audio Output
12	6BE6	Sync Clipper
13	12SN7GT	Vert. Blocking Osc. and Output.
14	6AL5	A.F.C. Discriminator
15	6SN7GT	Horizontal Multivibrator
16	25BQ6GT	Horizontal Pulse Amplifier
17	6AX4GT	Damper
18	1X2A	High Voltage Rectifier
19	6AF4	UHF Oscillator
20	6BQ7A	UHF Pre-IF Amplifier

CONTROLS

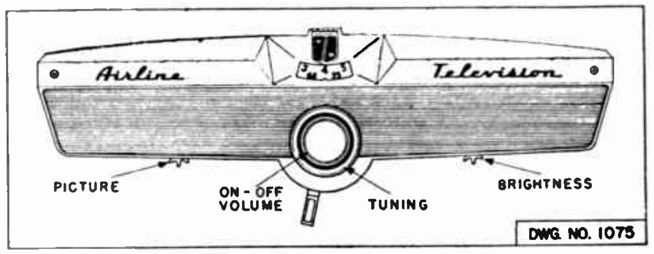

Figure 1. Front Controls

OPERATOR'S CONTROLS

On-Off Volume—Turns the receiver on or off and adjusts the sound volume level.

Contrast or Picture—Varies the contrast between the the light and dark portions of the picture.

Tuning—Tunes the receiver to the desired station or channel. May be turned in either direction.

Selector Switch—Selects the desired unit of the receiver for operation; either VHF or UHF.

Brightness—Controls the brilliance of the picture.

V. Hold—Controls synchronization of the picture vertically.

H. Hold—Controls synchronization of the picture horizontally.

SERVICEMAN'S CONTROLS

V. Size—Controls the size of the picture vertically.

V. Linearity—Controls vertical distribution of picture.

Fringe-Suburban-Local Switch—Three position switch for selection of the proper operational characteristics of the receiver for various signal level areas.

Sync Stabilizer Adjust—Changes the operational characteristics of the receiver for the area in which the receiver is located. Control has no effect in "local" switch position.

H. Size—Controls the size of the picture horizontally. To some extent, affects the vertical size control setting.

H. Linearity Magnet—Controls horizontal distribution of right side of picture.

Anti-Pin Cushion Magnet—(21" only)—Eliminates pin-cushioning and keystoning.

Centering Magnet—Controls positioning of the picture for proper framing.

Ion Trap Magnet—Controls focus and picture tube illumination.

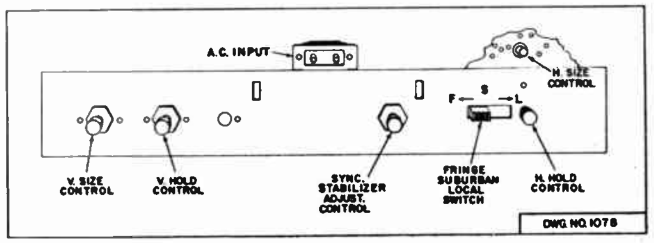

Figure 2. Rear Controls

NOTE: The V. Hold control on the rear flange (figure 2) has a rubber knob for easy identification. The position of all the controls are illustrated in figures 1, 2 and 3. Refer to figure 6 for the position of the vertical linearity control.

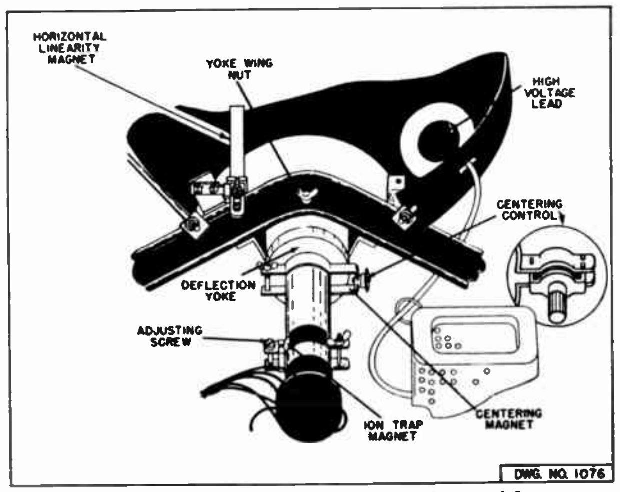

Figure 3A. 17-inch Tube Assembly

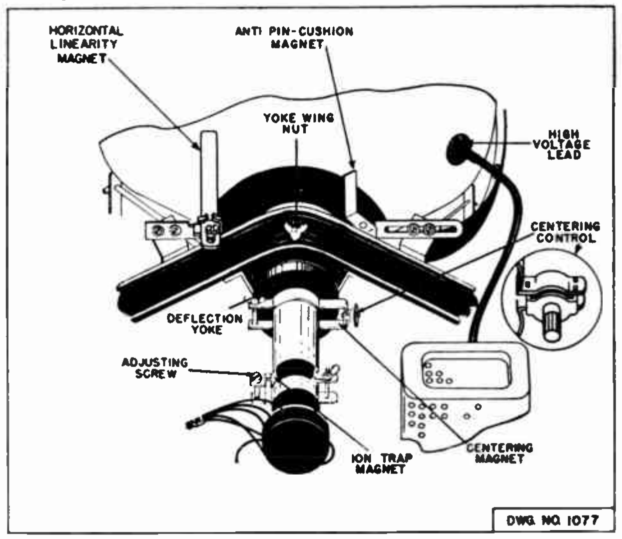

Figure 3B. 21-inch Tube Assembly

SERVICE ADJUSTMENTS

Vertical Size and Vertical Linearity Controls (R-73 and R-75):

The vertical size and linearity controls should both be adjusted at the same time while a test pattern is being transmitted. The linearity control affects the upper portion of the picture while the size control affects the overall size especially the lower portion of the picture. Adjust both controls simultaneously until the test pattern is symmetrical and fills the entire screen vertically. Readjust the vertical hold control if necessary.

CAUTION:

The vertical linearity control is on the top chassis plate, therefore, severe shock may result from contact. If an isolation transformer is unavailable, use an insulated screwdriver for the adjustment to reduce shock hazards. The adjustment can be made from either the top or bottom of the chassis.

Fringe-Suburban-Local Switch (Figure 2):

The three position switch selects the proper operational characteristics of the receiver for the signal strength area in which located. The position of the switch is governed by the signal strength available.

In the Fringe position the A.G.C. voltage is reduced to a bare minimum and the sync stabilizer adjust control affects the sync clipping level to reduce noise affects.

In the Suburban position full A.G.C. is applied and the sync stabilizer adjust control functions as in the fringe position.

In the Local position full A.G.C. is applied and the sync stabilizer adjust control is disabled.

Sync Stabilizer Adjust Control (R-61):

The control varies the operational characteristics of the sync clipper stage to obtain the optimum operation point for the least effect of noise interrupting synchronization. The control should be adjusted for a steady picture.

Ion Trap Magnet (Figure 3):

The position of the ion trap magnet MUST be over the grid of the picture tube (second cylinder from the base identified by a flared forward lip) If the adjustment is necessary, loosen the wing nut and rotate until the position which gives maximum illumination is found. Adjust the screw for maximum illumination. Repeat the above two steps. Rotate and slide magnet until the best focus position is found. Tighten wing nut. Adjustment should be made with brightness and picture controls set for normal viewing.

Horizontal Size Control (Figure 2):

The horizontal size control should be adjusted until the picture fills the entire screen horizontally. A clockwise rotation will decrease size. To some extent the vertical size control setting may be affected by a major horizontal size adjustment.

Horizontal Hold Control (L-30):

The horizontal hold control is located on the rear flange of the chassis and should be adjusted in the following manner.

Set the picture control to its normal operating position. Turn the thumb screw clockwise until it reaches its stop. Turn two complete turns counter-clockwise. The thumb screw is a vernier adjustment and will then be in the center of its range.

Turn the iron core with a small screwdriver or adjusting tool until the picture is steady (no horizontal movement). Set the core to the middle of its range.

After the iron core has been properly adjusted the thumb screw should then be used as a vernier adjustment to control synchronization when necessary.

Centering Magnet (Figure 3):

The centering magnet should be rotated and the control adjusted until the picture is properly framed keeping in mind that the effect of the control is governed by the position of rotation. If the control is above or below the neck of the picture tube, the picture will be moved up or down. To the left or right of the neck of the picture tube, the picture will be moved either to the left or right.

Deflection Yoke (Figure 3):

The correct position for the deflection yoke is as far forward on the neck of the picture tube as the shape of the tube will allow. Tube shadow or a tilted raster may result from an incorrectly positioned yoke. If a positioning adjustment is necessary, loosen the yoke wing nut located at the top of the picture tube assembly (fig 2).

Horizontal Linearity Magnet (Figure 3):

The horizontal linearity magnet affects the linearity of the right side of the picture only. The magnet pulls or stretches the right side and has a greater effect closer to the picture tube.

Anti-Pin Cushion Magnet - 21" only (Figure 3B):

Adjust centering until an edge of the raster is visible. Loosen the positioning screws and slide the magnet backward or forward until the edge of the raster is vertically straight. If keystoning is noticed adjust magnets in vertical plane.

NOTICE: Some receivers may incorporate a 6BK7 tube in place of the 6BQ7A R.F. Amplifier in the VHF tuner. Refer to page 26 for wiring differences.

Some receivers may also incorporate a 12BH7 in place of the 12SN7 Vertical Blocking Oscillator and Output tube. Refer to page 26 for wiring differences.

WARNING

At all times during operation the top chassis plate is at 125 volts DC potential above ground and it also may be at the line-voltage potential depending on how the line cord plug is inserted in the power receptacle.

Extreme caution must be observed when working with the chassis outside the cabinet and when power is applied to the receiver with the cabinet back removed. SEVERE SHOCK may result from contact with chassis.

Use an isolation transformer between the line cord plug and power receptacle when service is required. This removes all shock hazards and is the *ONLY* safeguard. Damage to the receiver and test equipment may result without the use of an isolation transformer.

SERVICE DATA

WARNING:

High voltage on the plate caps of the 1X2A high voltage rectifier and the 25BQ6 horizontal pulse amplifier. DO NOT MEASURE this voltage.

Schematic Diagram:

The schematic diagram located at the rear of this manual shows all the values of resistance and capacitance and gives all the proper voltages at the pins of the tube sockets. The voltage readings were taken with a 20,000 ohm/volt voltmeter with normal operation, no signal input, and line voltage at 115 volts A.C.

Replacing Tubes:

Before replacing the tubes the cabinet back must first be removed. Removing the cabinet back disengages the safety interlock and removes the power to the receiver. Do not tamper with or attempt to defeat the purpose of the safety interlock as severe shock may result.

Before replacing the High Voltage tubes first be sure the power is turned off and then short the corona ring of the 1X2A to the chassis.

WARNING:

Do not remove any tubes while the receiver is in operation as over-loading and component failures may result. Also contact with the top chassis plate during operation may produce a severe shock.

If the receiver has been in operation for some time, the tubes become hot and gloves should be used when replacing tubes to prevent finger burns.

Picture Tube Handling:

Due to the large surface and extreme high vacuum of the picture tube, care should be used when handling the chassis outside the cabinet. Do not subject the tube to excessive pressure of rough handling as an implosion may result causing serious personal injury.

High Voltage Power Supply:

In the process of inspection, repairs, changing of tubes or transformers, or for any other reason where it is necessary to work within the high voltage power supply, the following should be closely observed.

1. Terminals on the 1X2A socket must be dressed toward the inside of the corona ring and be free of sharp protrusions.
2. The corona ring must be dressed in such a way as to make its presence useful; that is, properly centered and about 1/8-inch below the socket terminals.
3. All leads must be dressed as far away as possible from the transformer winding. Excess lead length should be transferred to the top-side of the chassis.

When replacement of the H.V. deflection transformer is necessary, be sure to closely follow the precautions listed above. The transformer can easily be replaced with the chassis in the cabinet by the following procedure.

1. Remove two (2) hex head screws on either side of the H. Size control.
2. Disengage the H.V. lead holder ring. (back side of shield can)
3. Remove 25BQ6 plate cap
4. Remove shield can by pushing back side of shield can toward front and lifting up.

R. M. A. WIRE COLOR CODE

Listed below is a R.M.A. wire color code chart to aid in circuit tracing.

Wire Color	Where used
Black	B- or Ground leads
Brown	Filament leads
Red	B+ leads
Orange	Screen leads
Yellow	Cathode leads
Green	Grid or Control leads
Blue	Plate leads
Violet	Not used
Gray	A.C. leads
White	Bias leads

COIL DC RESISTANCE CHART

The DC resistance readings shown in the chart below have been taken with a ohmmeter directly across the coil being measured. The coils not listed in the chart have a DC resistance reading of less than one ohm. A tolerance of ±5% is permissible.

COILS	RESISTANCE IN OHMS	COILS	RESISTANCE IN OHMS
L17	1.5	T4 pri.	170
L20	1.5	T5 pri.	960
L22	2.2	sec.	160
L23	2	T6 pri.	1100
L24	2	sec.	6.6
L25	2	T7A	68
L27	8	B	12.5
L28	8	T8 25BQ6 plate to 1X2A plate	180
L29	1.5	25BQ6 plate to term 4	9.5

L34	2.3	T9 pri.	7
T3 pri.	4.7		

SERVICE DATA

REMOVABLE SAFETY GLASS

To clean the inside of the safety glass and the face of the picture tube follow the simple procedure below.

1. Remove the on-off volume and tuning knobs (pull straight out).
2. Remove two (2) phillips head screws at bottom of escutcheon.
3. Remove two (2) gold phillips head screws at top on either side of escutcheon.
4. Remove escutcheon.
5. Remove selector switch.
6. Carefully remove safety glass by pulling out and down from bottom.

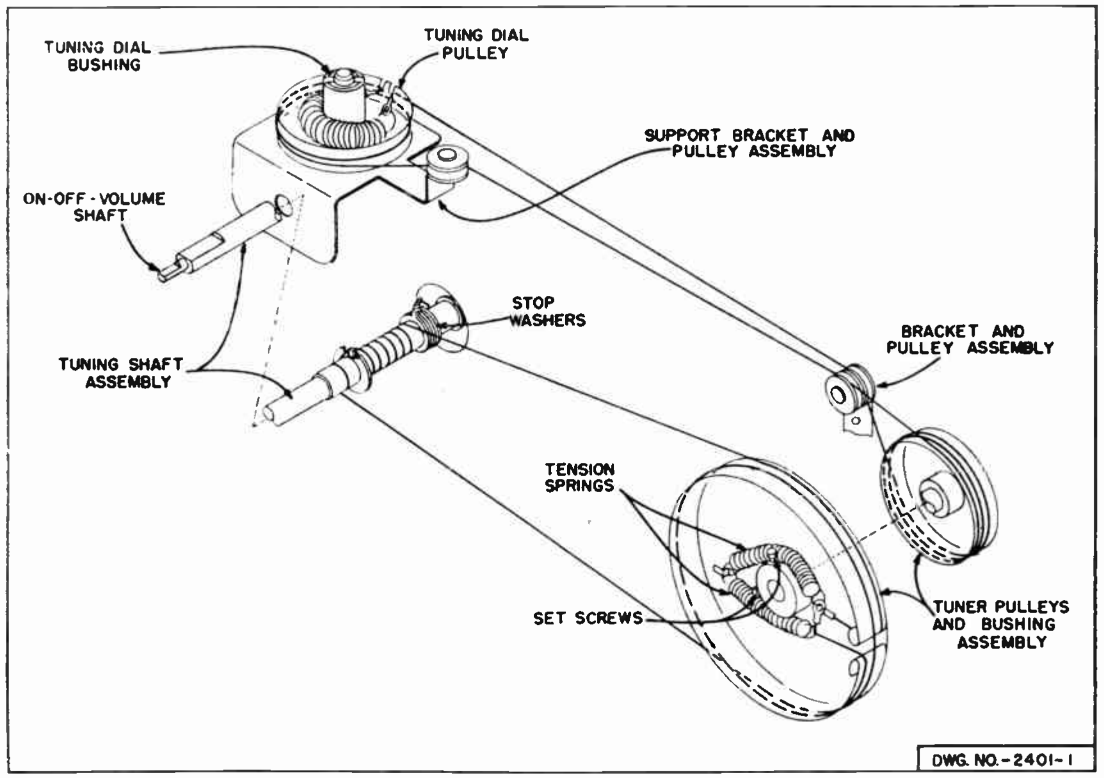

Figure 4. Dial Stringing

DIAL CORD REPLACEMENT

Dial Cord Stringing:
If dial cord replacement is necessary, turn the tuning shaft completely counter-clockwise. Two (2) separate dial cords are used and can be restrung separately.

Large Tuner Pulley Stringing:
Follow the diagram and start by attaching the dial cord to the top tension spring as shown on the large tuner pulley. Route the cord through the opening in the pulley and make a quarter counter-clockwise turn around the pulley and route to the tuning shaft assembly directly in front of the stop washers. Make six (6) counter-clockwise turns around the tuning shaft assembly and then one (1) counter-clockwise turn around the lug on the center washer and continue in the counter-clockwise direction and make one and one-half (1½) turns around the tuner shaft in front of the center washer. Route to the large pulley and make (1) complete turn around the pulley before routing through the opening and then attach to the tension spring. Add second tension spring as shown.

Small Tuner Pulley Stringing:
Follow the diagram and start by attaching the dial cord to the tension spring and route through the opening in the tuner dial pulley. Route over the bracket and pulley assembly (rear pulley) and make two and one-half (2½) counter-clockwise turns around the small tuner pulley and then route over the bracket and pulley assembly (front pulley) and over to the pulley on the support bracket and then make two (2) clockwise turns around the tuning dial pulley before routing through the opening and attaching to the other end of the tension spring.

Mechanical Tracking:

If for any reason the stop washers do not correspond to the stop position of the tuner, loosen the set screws on the tuner pulley and bushing assembly and re-position. Turn the tuning shaft to the extreme counter-clockwise position (stop washers in position shown in diagram) and tuner shaft also to the extreme counter-clockwise position. Retighten set screw.

Dial Calibration:

To correct any error in calibration, turn the tuning knob until the channel number appears in the opening. Press finger on the dial indicator and tune in the corresponding station.

VHF TROUBLE-SHOOTING

Trouble	Probable Location
No Raster No Sound	1. Defective tubes 11-13-16. 2. Defective selenium rectifier. 3. Defective resistors R52-82-101. 4. Defective capacitors C70-72-74-90-91. 5. Defective transformer T9 or choke L32. 6. Defective safety interlock or on-off switch.
No Raster Sound Normal	1. Insufficient or no high voltage, (refer to "No High Voltage" section). 2. Defective picture tube. 3. Second anode lead disconnected. 4. Ion trap magnet misadjusted. 5. Defective C.R.T. socket.
No High Voltage	1. Defective tubes 15-16-17-18. 2. Defective transformer T8, yoke T7 or coil L30-31-34. 3. Defective capacitor C105-106-107-108-110-111-112-113. 4. Defective resistor R92-96-97-98-99-100.
No Picture No Sound Raster Normal	1. Defective antenna or lead-in. 2. Defective tuner tube 1-2 or 19-20 3. Defective tuner (refer to page 43). 4. Defective tubes 3-4-5-6. 5. Improper voltages or resistances at sockets of tubes 3-4-5-6. 6. Improper alignment. 7. Defective crystal detector. 8. UHF power plug not in place.
No Sound Picture Normal	1. Defective tubes 8-9-10-11. 2. Improper voltages or resistances at socket of tube 8-9-10-11. 3. Defective speaker or leads broken or not in place. 4. Defective transformer T3-4 or coil L29. 5. Improper sound alignment.

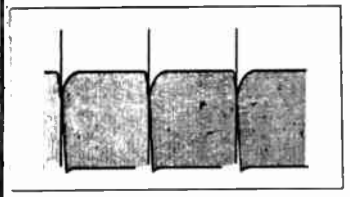
Trouble	Probable Location
No Sync	1. Defective tube 12. 2. Improper voltages or resistances at socket of tube 12. 3. Defective F-S-L switch or in wrong position. 4. Sync stabilizer adjust control misadjusted.
Insufficient or no Vertical Sweep	1. Defective tube 13. 2. Defective transformer T5-6 or yoke T7. 3. Defective capacitor C70-85-86-87. 4. Defective resistor R68-73-74-75-76-77.
Picture Cannot be Centered	1. Defective picture tube. 2. Defective centering magnet. 3. Defective ion trap magnet.
Poor Focus	1. Improper adjustment of Ion trap. 2. Defective picture tube.
Poor Horizontal Linearity	1. Improper adjustment of linearity magnet or anti-pin cushion magnet. 2. Defective tube 16-17. 3. Defective capacitor C105-106-111. 4. Defective transformer T8 or coil L31.
Snow or Poor Picture	1. Insufficient signal input. 2. Defective antenna or lead-in. 3. Improper alignment of C1-A-B. 4. Weak tubes 1-2-3-4-5-20. 5. Improper video IF alignment.
Lack of Contrast	1. Defective tube 6. 2. Defective crystal detector. 3. Improper video IF alignment.
Washed Out or Picture Smear	1. F-S-L switch in wrong position. 2. Defective crystal detector. 3. Gassy tube 1-3-4-20. 4. Improper video IF alignment.

WAVE FORM ANALYSIS

The drawings on this page illustrate the wave forms at various positions within the receiver. The wave forms are not theoretical but exact copies of that shown by an oscilloscope and were taken under normal operating conditions, with a transmitted signal and the picture in sync at all times.

When checking the wave forms, connect the ground lead from the oscilloscope to the top chassis plate and the hot lead to the position indicated. The wave shapes may vary somewhat depending on the strength of the signal, the picture information being transmitted and the adjustments of the various controls.

Under each wave form is the schematic reference, position taken at, peak-to-peak voltage and the type of wave form indicated (Vertical -60 cycles and Horizontal -15,750 cycles).



VERTICAL PULSE

VHF GENERAL DESCRIPTION

VHF Tuner:

The Tuner is composed of a separate sub-chassis consisting of a 6BQ7A (twin triode) cascode RF amplifier and a 12AT7 tube (twin triode) for the oscillator and converter. Separate high and low band coils and trimmers are used with an automatic switching device to change bands. The tuner selects and amplifies the stations signal and converts it to the carrier IF frequency of 26.75 MC for video and 22.25 MC for sound which in turn is then fed to the IF amplifiers for further amplification.

Video IF Amplifier:

The Video IF Amplifiers are mounted on a separate sub-chassis along with a crystal video detector and the A.G.C. network. The IF amplifier section consists of three (3) staggered tuned stages with an over coupled output IF transformer using 6CB6 (pentode) tubes with self resonant core tuned coils. Since the receiver is of the intercarrier type both the video and sound IF frequencies are amplified simultaneously and then detected by a Raytheon CK-706 crystal. The signal is then coupled to the video amplifier and the first grid of the sync clipper. The A.G.C. network of R-59 and C-78 develops a negative bias voltage proportional to the average composite video signal.

Video Amplifier:

The Video Amplifier section consists of a 6AH6V (pentode) tube with a degenerative picture (or contrast) control (R-33) to vary the signal to the cathode of the picture tube. The audio signal is also amplified in this stage and then separated by a 4.5 MC trap (L-29). This trap also serves to separate or keep the audio from appearing in the picture.

Sound Section:

The Sound Section consists of a 6AU6 (pentode) 4.5 MC audio IF amplifier, 6AL5 (twin diode) ratio detector, 6AV6 (triode) audio amplifier and a 25L6 (beam power amplifier) output tube. Due to the hetrodyne action between the video and sound IF frequencies at the video detector a 4.5 MC signal is obtained containing the audio information. After the video detector the audio information is amplified by the video amplifier, separated from the video by the trap (L-29), amplified, detected and further amplified before being coupled to the speaker.

Sync Clipper:

The Sync Clipper stage utilizes a 6BE6 (heptode) tube which functions as a sync separator and noise clipper. The signal from the output of the video amplifier is coupled to pin 7 through R-34 and C-77. With the positive going signal at pin 7 and the low plate voltage sync separation is accomplished. When noise bursts are present the negative going signal from the video detector, coupled through R-58 to pin 1, cuts the tube off and eliminates false sync information in the output. A sync stabilizer adjust control (R-61) is provided to adjust the cut-off or clipping level by varying the bias voltage to pin number 1. A three position F-S-L switch is also provided to change the operational characteristics of the receiver for various signal level areas. The switch disconnects the control (R-61) from the circuit and applies a fixed bias voltage only in the "local" position. In the "fringe" position the A.G.C. source is connected to 240 volt B plus through 20 megohms of resistance (R-56, R-60). No bias voltage to the RF and IF tubes is utilized in this position allowing maximum amplification. In the "suburban" and "local" positions, full A.G.C. is applied. The sync pulses are separated from the video signal without the noise effects and then coupled to the vertical blocking oscillator cathode and horizontal A.F.C.

Vertical Deflection:

The Vertical Deflection section consists of a 12SN7 (twin triode) tube, one-half being used as a blocking oscillator and the other half as an output amplifier. The signal from the plate of the sync clipper is coupled through R-67 and C-81 to the cathode of the blocking oscillator. The vertical hold control (R-69) in the grid circuit varies the oscillator operating frequency, thus providing adjustment for synchronization. The vertical size control (R-73) varies the amplitude of the pulse to the grid of the amplifier and controls the amount of vertical deflection. The vertical linearity control (R-75) varies the cathode resistance, thus adjusting the operating characteristics of the amplifier to provide the proper wave shape to obtain a linear picture vertically. The network of C-84, C-85 and R-70, R-71 is designed to eliminate vertical retrace lines at high brightness levels.

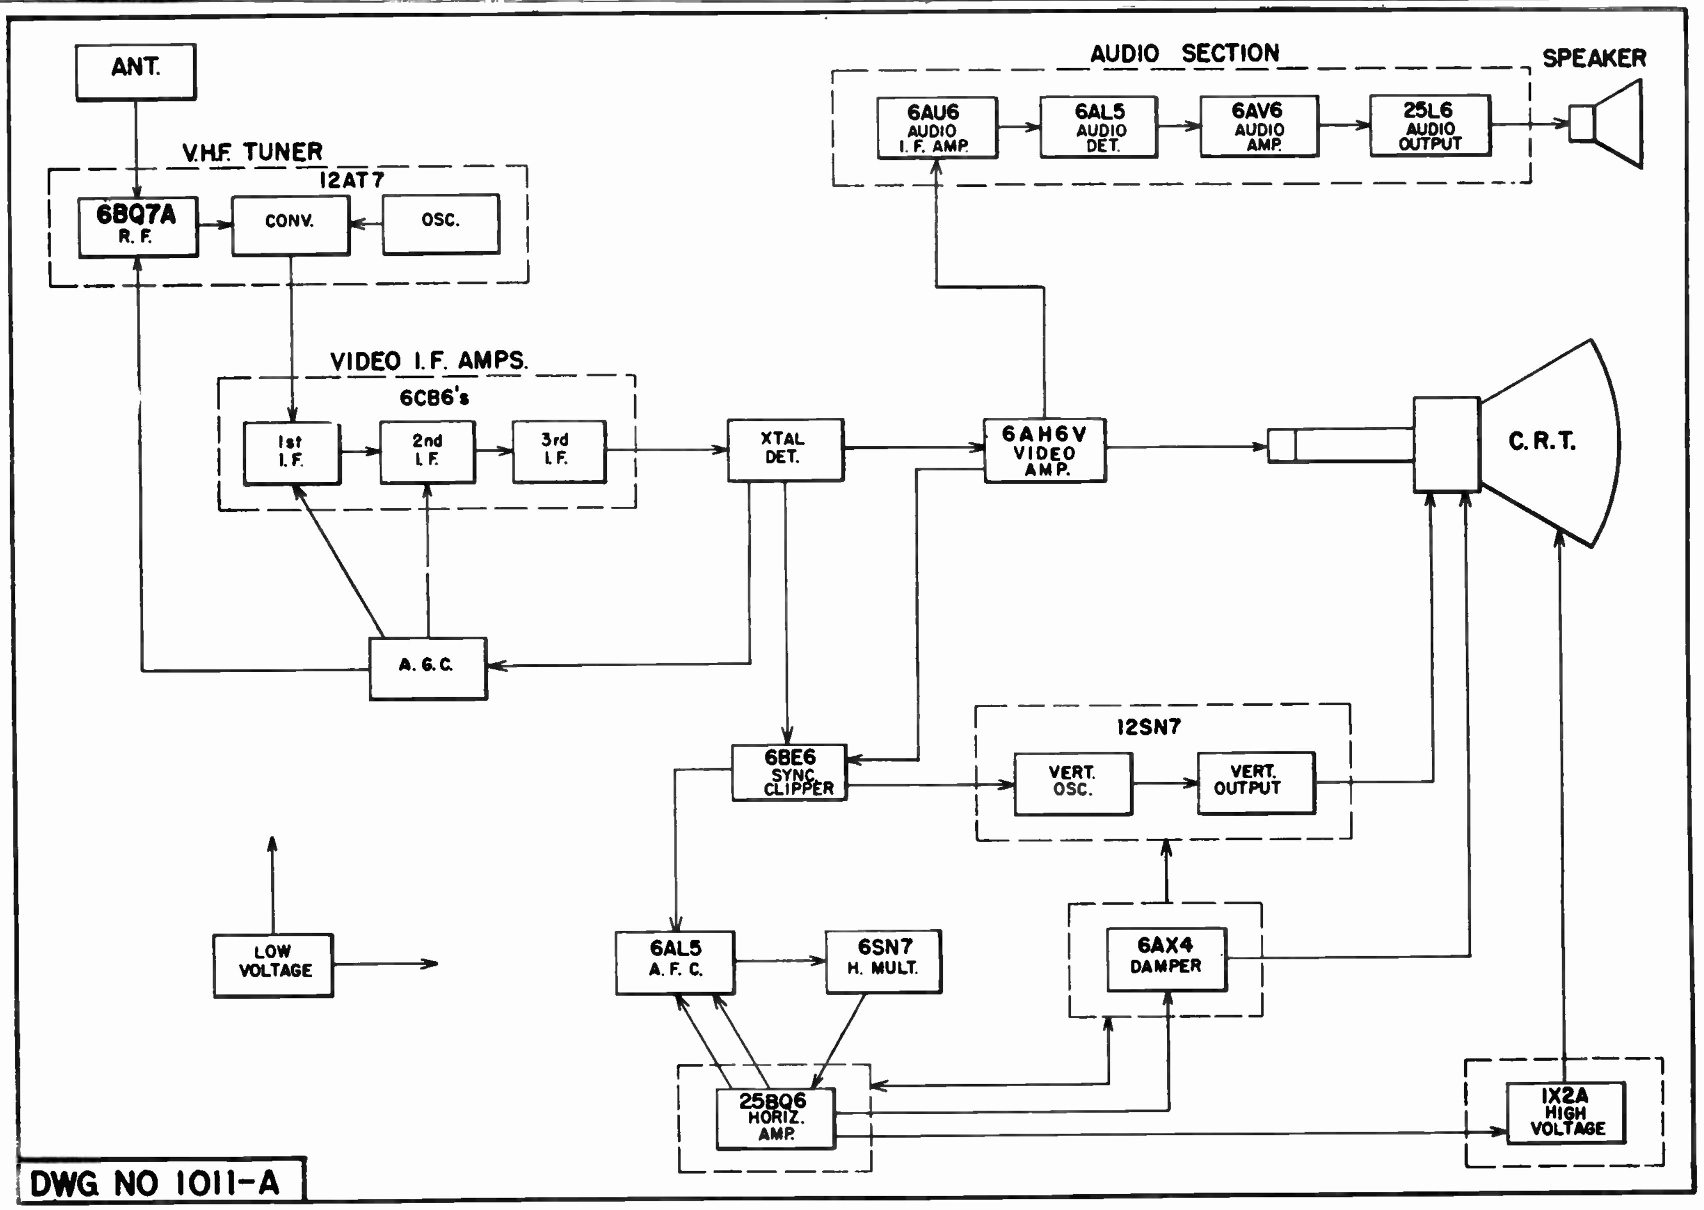

Figure 5. Block Diagram of VHF portion of Receiver

AFC Discriminator:

The Automatic Frequency Control section utilizes a 6AL5 (twin diode) tube which functions as a discriminator. The horizontal sync pulses from the output of the sync clipper are coupled to the AFC tube through capacitor C-79. At the same time two feed back voltages of opposite polarity are intergrated and applied to the plates of the AFC tube. The two feed back voltages are obtained from a separate winding (terminals 7 and 10) of the H V deflection transformer and are of the same frequency as the horizontal multivibrator. Any phase shift between the horizontal sync pulses and the horizontal multivibrator signal will cause one diode section to conduct more than that of the other. This will result in a DC bias voltage applied to the grid of the multivibrator and change the operating frequency. The output of the AFC discriminator thus synchronizes the horizontal multivibrator to the incoming horizontal sync pulse.

Horizontal Multivibrator:

The Horizontal Multivibrator uses a 6SN7 (twin triode) tube and is of the conventional cathode coupled type. The core tuned parallel resonant circuit (L-30 and C-97) is used as a hold adjustment to stabilize the frequency of oscillation. Because of the wide pull-in range of the automatic frequency control tube a fine hold control is not necessary. The output signal of the multivibrator is coupled to the horizontal pulse amplifier through capacitor C-106. Capacitor C-107 is a negative peaking device to aid in cutting off the pulse amplifier tube at the proper time.

Horizontal Pulse Amplifier:

The Horizontal Pulse Amplifier utilizes a 25BQ6 (beam pentode) tube to develop the necessary power for the fly back pulse and the horizontal winding of the deflection yoke.

VHF CIRCUIT DESCRIPTION

Damper:

The Damper tube (6AX4-diode) performs three functions: aids in horizontal scanning, suppresses oscillations which occur over part of the horizontal scanning cycle and gives an increase in plate supply voltage for the vertical blocking oscillator, vertical output amplifier and first anode of the picture tube.

Hi-Voltage Supply:

The High Voltage (second anode) is obtained from the auto-transfomer type primary winding of the H V deflection transformer (T-8). When the plate current of the H pulse amplifier tube is cut off, the field built-up in the primary winding collapses and induces a high voltage surge which is rectified by the 1X2A tube, filtered by the capacity of the aquadag coating of the picture tube and applied to the second anode. The 1X2A is a conventional half-wave high voltage rectifier and obtains its filament power from a separate secondary winding of the H V deflection transformer.

Low Voltage Supply:

The B plus voltage for the receiver is obtained from the voltage doubler arrangement of two selenium rectifiers and filter capacitors C-90 and C-91. The majority of the receivers tubes obtain its filament power from the filament transformer (T-9), however, three tubes are connected in series with resistor R-101 and placed across the 115 volt AC line. A safety interlock is provided to reduce shock hazards and a resistor type fuse is connected in series to protect the receiver in case of overloading.

VHF SERVICE HINTS

V.H.F. Tuner:

Before looking into the tuner for a particular trouble, first make the following observations. Since the receiver is of the intercarrier type both the sound and video information are amplified simultaneously by the tuner, I F and video amplifiers. Therefore, if the sound section is functioning normally it can be assumed that there are no defects in the tuner, I F or video amplifiers. If the receiver is "dead" (no sound or picture-raster normal) first determine whether a signal is being transmitted and then check the antenna, lead-in and connections to the receiver. Next, rotate the contrast or picture control completely to the left (counter-clockwise) and observe the face of the picture tube. Advance the control to the extreme clockwise position and again observe the face of the picture tube. If no "snow" appears check the video amplifier, detector and second and third I F amplifiers. If, however, an increase of "snow" appears check the first I F amplifier before looking into the tuner.

The tuner can easily be serviced by removing the three hex-head nuts on top and the one on the bottom which holds bottom cover in place. Removing the bottom cover makes all the tuner components within easy reach and all parts can be serviced. When working inside the tuner do not move any component a great distance as a change in the distributed capacity may result and offset the alignment. When replacing components be sure to obtain the same lead length and replace them in the same position.

A majority of tuner troubles are often open and high resistance ground or coil solder connections, defective trimmers or coils and defective switch contacts.

Open or high resistance connections can easily be repaired by placing a hot soldering iron at the solder connection.

Defective switch contacts may cause an intermittent condition or the loss of one or both bands. Contact replacement is easily accomplished by removing the two switch plate tension springs, the hex-head bolt and the switch plate bracket. Lift up the switch plate assembly and remove the switch contact holder and replace contacts.

A.G.C.

The A.G.C. is a negative bias voltage proportional to the average composite video signal, developed by the network of R-59 and C-78 and applied to the R F and first and second I F amplifiers. The magnitude of the A.G.C. voltage will vary according to the strength of the signal being received. However, it will closely correspond to the detector output voltage (across R-27). As a fast and simple check to determine whether the A.G.C. voltage is normal, measure both the A.G.C. and detector output voltage. Under normal operating conditions these two voltages will be approximately the same.

Sync Stability:

For optimum sync stability the following points should be considered. A three position F-S-L switch and a sync stabilizer adjust control are provided along with the two hold controls. The position of the switch is governed by the strength of the signal being received and the control should be adjusted for a steady picture. The position of the switch and the adjustment of the control are important for good sync stability (control will not function in "local" switch position).

For good horizontal sync stability both the horizontal hold thumb screw and coil core should be set to the center of their respective ranges. (Center position before going out of sync in either direction).

For good vertical sync stability the vertical hold control can be adjusted to reduce the effect of noise that may interrupt synchronization in reception areas where noise conditions exist. Rotate the vertical hold control until the picture is moving upward and just locks into place. At this control setting, the noise will have the least tendency to interrupt vertical synchronization.

Vertical Distribution:

A fast and simple method to check the vertical distribution of a TV picture, without a test pattern, rotate the vertical hold control until the picture is moving slowly downward. Observe the black horizontal bar. If the vertical size and linearity controls are properly adjusted, the bar will not change in thickness as it moves from top to bottom.

VIDEO I-F ALIGNMENT

Step No.	Signal Generator Freq. (mc.)	Sweep Generator Freq. (mc.)	Signal Input Point	Output Point	Remarks	Adjust	Response
1	23.5 26.2	25	Pin 1 of tube 5	Scope at junction of L25, R27, C53	Connect short between pin 5 and pin 6 of tube 4	T2 pri. T2 sec. Coupling rod	2	Calibrate scope for sensitivity of one volt per inch. 9	23.5 26.5	25	Converter grid *	Scope at junction of L25, R27, C58	Marker should be 50% down and response curve should be as shown — If not, repeat alignment.	Check point only	
Picture IF frequency 26.75 MC — Sound IF frequency 22.25 MC.

* NOTE: A very short lead from the generator must be used to prevent regeneration.

VIDEO TRAP COIL (L-29) ADJUSTMENT

1. Tune in a station.
2. Adjust the tuner until sound bars just appear.
3. Turn L-29 slug all the way out (counter-clockwise).
4. Turn the slug in (clockwise) until the horizontal scanning lines are smooth and continuous

SOUND I-F ALIGNMENT

Short antenna to ground.

Step No.	Signal Generator Freq. (mc.)	Sweep Generator Freq. (mc.)	Signal Input Point	Output Point	Remarks	Adjust	Response
1	4.5	——	Junction of L25, R27, C58	VTVM at junction of R44, C65, C67	——	T3 pri. (bottom of chassis)	Maximum Reading
2	——	4.5	Junction of L25, R27, C58	Scope at junction of R44, C65, C67	Sweep approximately ±100 kc—Adjust for maximum linearity	T3 sec. (bottom of chassis)	3	——	4.5	Junction of L25, R27, C58	Scope at junction of R44, C65, C67	Sweep approximately ±100 kc—Adjust for symmetry of peaks	T3 pri. (bottom of chassis)	
NOTE: L-29 coil should only be adjusted as prescribed. Do not adjust for maximum sound.

PRE-ALIGNMENT PRECAUTIONS

1. If sweep generator does not have a balanced output, connect a 150 ohm resistor in series with the ground lead and 150 ohms minus the internal resistance of the generator in series with the hot lead.
2. Connect a 1000 mmf capacitor across scope terminals and a 10K ohm resistor in series with hot scope lead as close to test point as possible.
3. Connect signal generator through a 1000 mmf capacitor.
4. Set F-S-L switch to "Fringe" position.
5. When aligning the IF Amplifier be sure tuner is turned to high band channel 13.

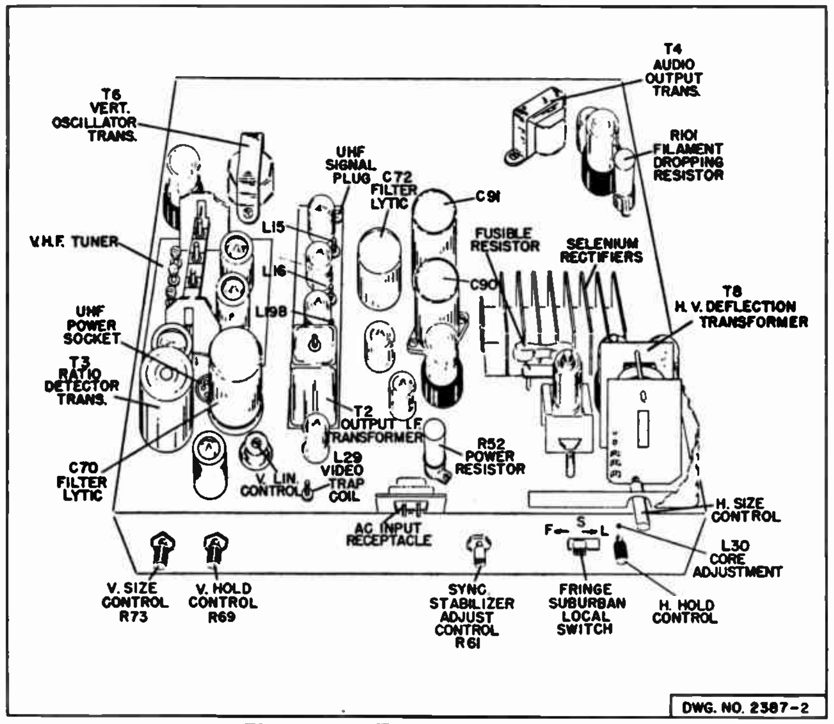

Figure 6. Top Chassis View (Shown with UHF tuner removed)

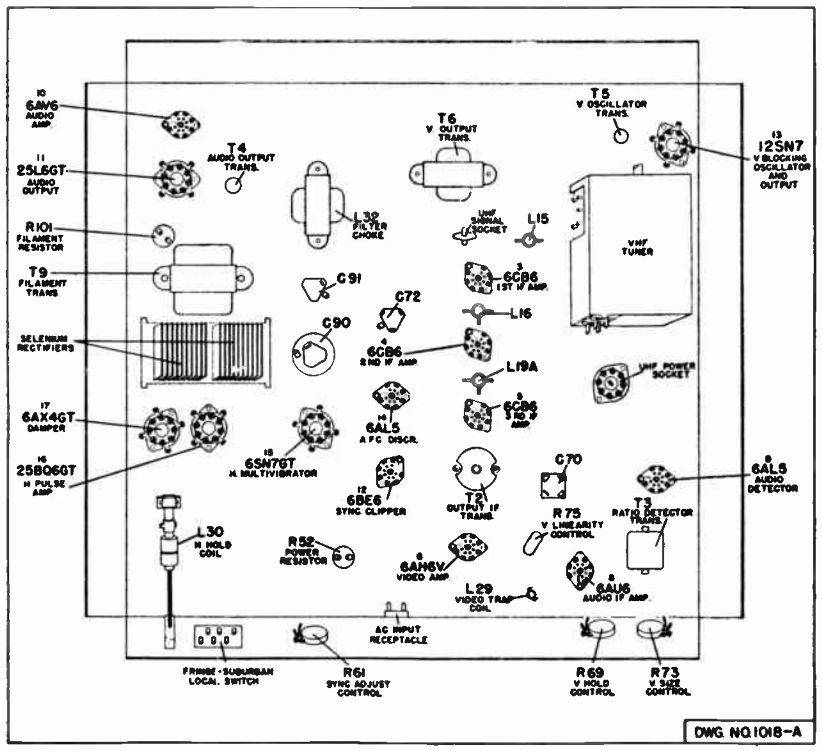

Figure 7. Bottom Chassis View

VHF TUNER ALIGNMENT

1. Preset trimmer screws C11-14-18-22-28-31- to dimensions shown on page 44.
2. Preset coil cores L3-5-7-8-10-11 in the following manner:
   - (a) In low band position, turn tuner to top of stroke (cores furthest out of coil).
   - (b) Switch will be in low band position.
   - (c) Adjust coil cores 1.6 inch from core to end of coil form (use core aligning tool if available).

VHF TUNER DIAGRAM

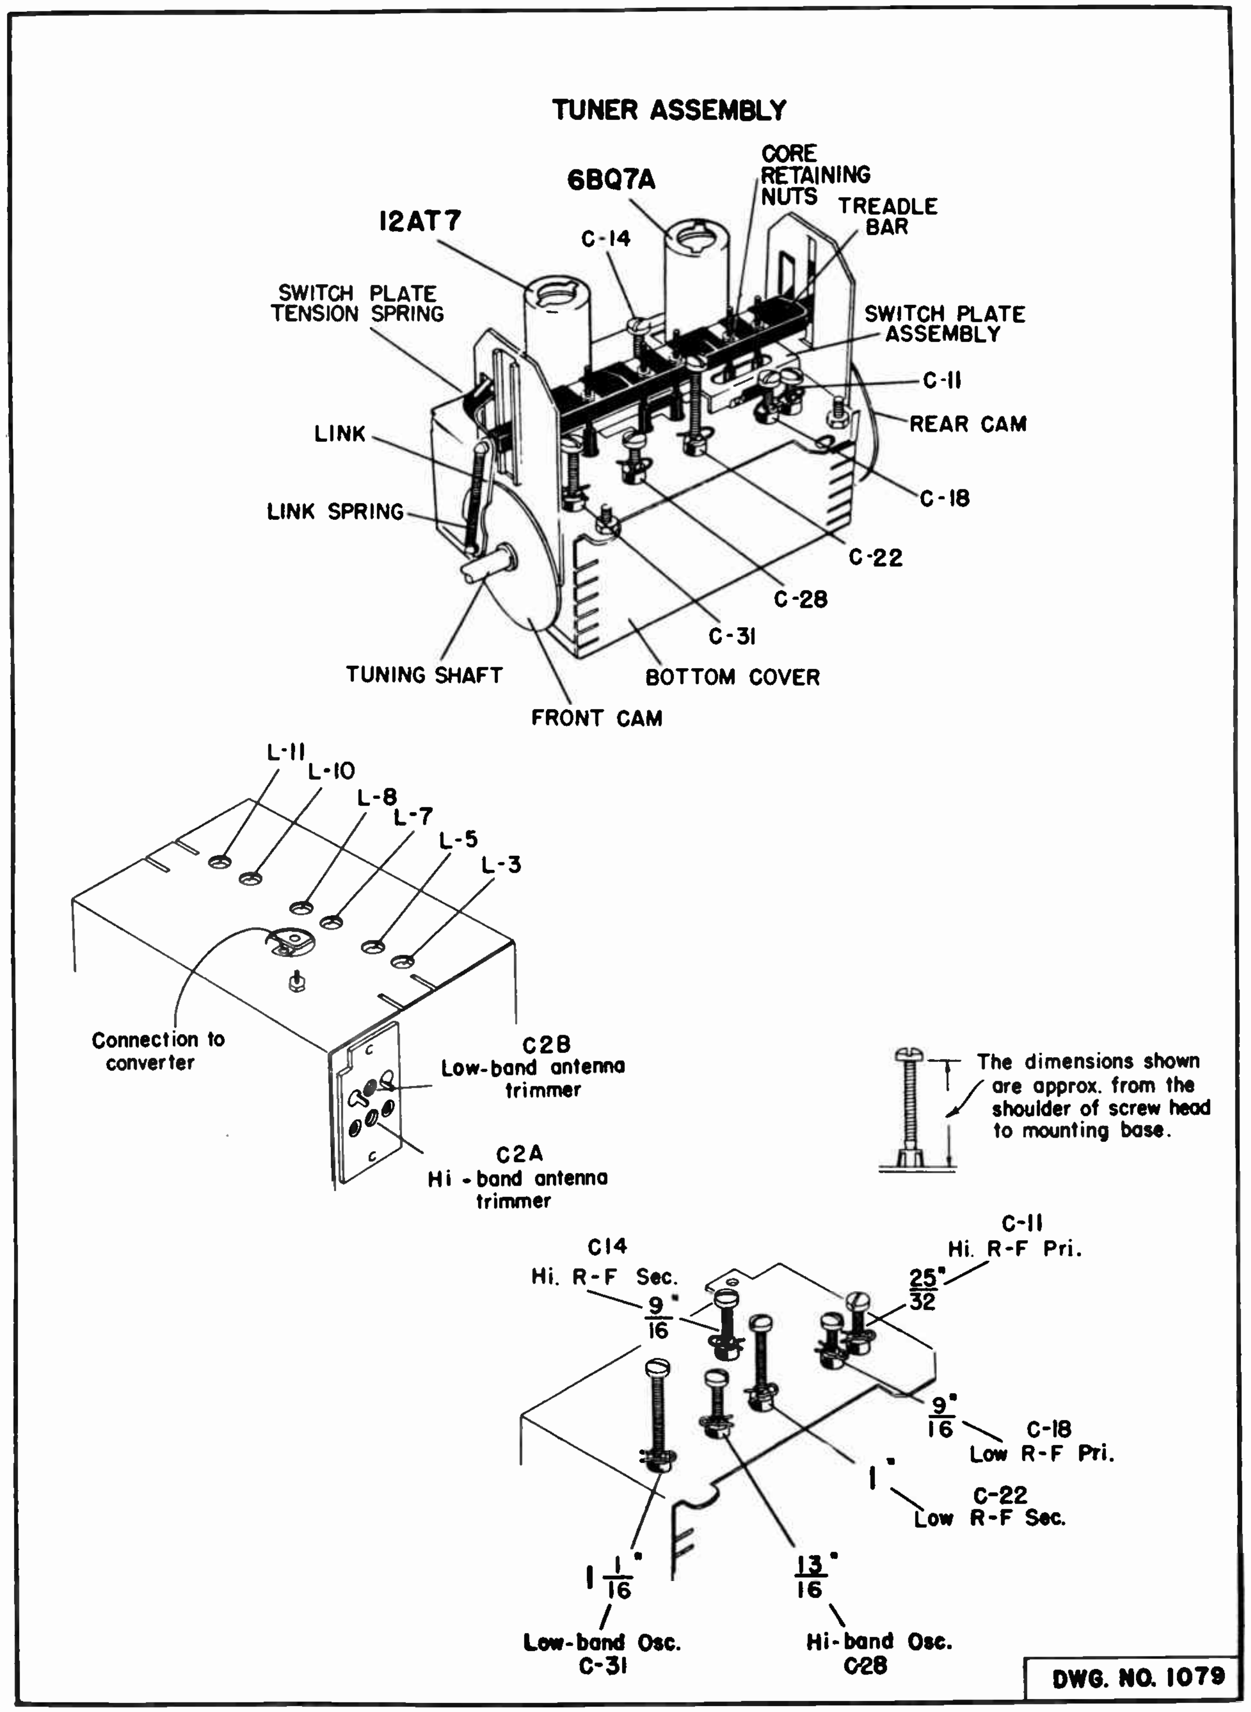

Figure 8. VHF Tuner Diagram

UHF GENERAL DESCRIPTION

The UHF Tuner is a single conversion, continuous tuning device which mechanically mounts directly over the VHF tuner in the receiver. The tuner is coupled to the VHF tuner by drive gears which thus provides tuning of both UHF and VHF by the same tuning knob. The tuner obtains its filament and plate supply voltages from the TV chassis and a switch is provided to select the desired tuner for operation.

The UHF Tuner selects the UHF stations video and sound carriers and converts them to the carrier IF frequency of 26.75 MC for video and 22.25 MC for sound which is coupled to the IF amplifiers in the receiver by 10 inches of RG-62U cable.

Some receivers may incorporate a 6BK7 tube in place of the 6BQ7A cascode pre-IF amplifier. Refer to figure 12 for wiring differences.

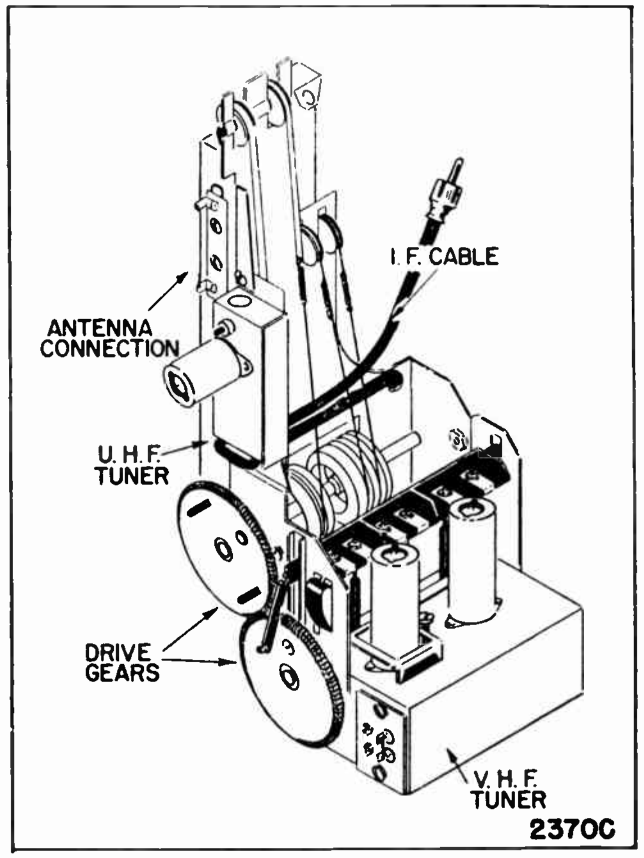

Figure 9

UHF CIRCUIT DESCRIPTION

The UHF Tuner employs a double coaxial line RF cavity pre-selector. The coaxial line arrangement has the advantages of high selectivity, low insertion losses, uniform band-width and good shielding against oscillator radiation. The coaxial cavity is basically a one-quarter wave shorted tuned stub. The electrical length of the cavities is varied by a ribbon which is attached to the dial cord and pulley arrangement. In this manner tuning is accomplished similar to varying the length of a tuned stub which would change the resonant length for various frequencies. The dial cord is of a special material which is not affected by temperature or moisture and is locked to the pulleys which eliminates the possibility of slippage. Tracking screws are provided in the cavities to obtain uniform band width and sensitivity. The tracking screws vary the capacity between the ribbon and the cavity wall and thus vary the electrical length of the ribbon.

The oscillator tube used is a 6AF4 which is similar to the 6F4. Oscillator tuning is accomplished by a one quarter wave shorted parallel wire transmission line arrangement. It differs from the RF cavities, in that a shorting bar is used to vary the electrical length of the lines. This method provides very stable operation.

Inductive or link coupling is employed to transfer the signal between stages. The arrangement of link coupling gives maximum selectivity and constant band-width over the entire UHF band. The signal from the output coupling link is mixed and detected by a CK-710 crystal detector and then applied to the tuned input of the cascode amplifier. A 6BQ7A tube is used as a cascode Pre-IF amplifier which is tuned to a center frequency of 25 MC and has the features of low noise and broad band-width. The signal is amplified by the cascode amplifier and then coupled to the IF amplifier section in the receiver through 10 inches of RG-62U coaxial cable.

UHF CIRCUIT DESCRIPTION

The UHF Tuner maintains a fairly constant antenna input impedance of 300 ohms, has an overall band-width of 6 to 8 megacycles and has an oscillator injection curent ratio of approximately 2 to 1. The only amplification of the signal takes place in the cascode amplifier. The signal is not amplified in the RF cavities, therefore, the sensitivity of the receiver on UHF will not quite equal that of VHF. A receiver equiped with a UHF tuner will have an overall UHF sensitivity of approximately 150 microvolts.

Service features of this tuner provides a convenient check point for measuring the oscillator grid current to determine whether the oscillator is functioning. Also provisions have been made for measuring the oscillator injection current to check both the crystal detector and the oscillator. An opening is also provided for coupling to the input grid coil when alignment of the cascode amplifier is necessary.

SERVICE HINTS

If the receiver is "dead" when attempting to view a UHF program, first check the position of the selector switch, then determine whether a signal is being transmitetd and then check the antenna and lead-in connections before suspecting the tuner for trouble.

Also as a fast check, view the face of the picture tube at minimum contrast or picture control setting and advance the control to maximum. Compare the difference. If there is little or no difference (no "snow") check the video detector and IF amplifiers. If an increase of "snow" appears at maximum control setting, check the first IF stage before looking to the tuner for a defect.

If the UHF tuner is not functioning properly, first substitute the oscillator (6AF4) and cascode amplifier (6BQ7A) tubes. Next check the voltages at the UHF power socket or cable connections in the receiver.

If soldering iron servicing, crystal detector or component parts replacement is necessary, the picture tube must be removed. Removing the picture tube makes the majority of the UHF Tuner components within easy reach and most of the parts can be serviced. The tuner should not be removed from the chassis when service is required, also caution must be observed not to lay the chassis on the tuner side. Damage to the UHF Tuner may result.

CAUTION: When attempting to service the tuner, do not move or rearrange components or mechanical parts as a change in distributed capacity may result and off-set the alignment. When replacing a component, be sure to obtain the same lead lengths and replace in the same physical position.

SERVICE DATA

To determine whether the oscillator section is functioning, a convenient check point has been provided where the oscillator grid current can be measured. To measure the oscillator grid current, place a Simpson Model 260 Multimeter (or equivalent) on the 100 microamp scale across the 22 ohm resistor (R2). See figure 10. A reading of 10 to 30 microamperes should be obtained if the oscillator is functioning normally.

Both the oscillator and crystal detector can easily be checked by measuring the oscillator injection currrent. Place a Simpson Model 260 Multimeter (or equivalent) on the 100 microamp scale across the 22 ohm resistor (R10) at the terminal indicated in Figure 11. A reading of 5 to 40 microamperes should be obtained if both the oscillator and crystal are functioning normally.

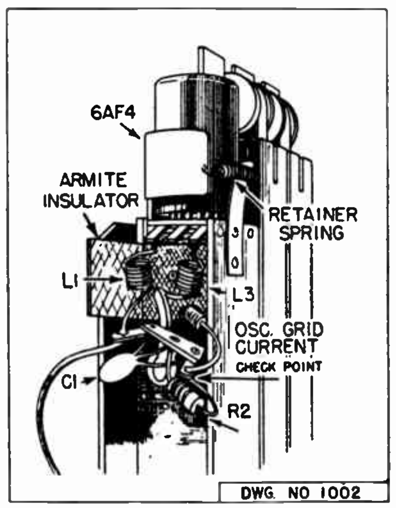

Figure 10

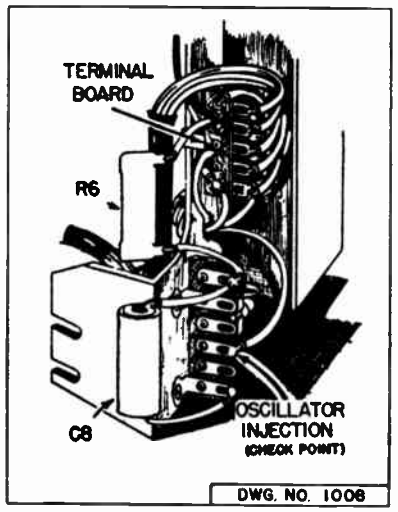

Figure 11

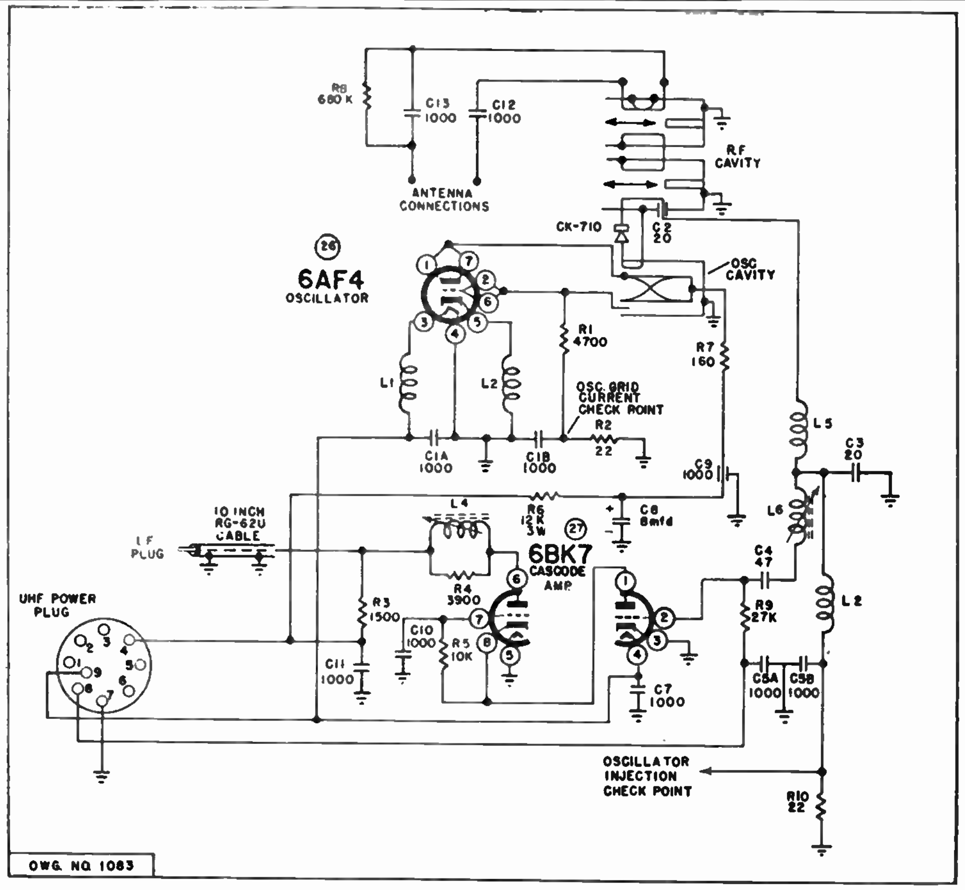

Figure 12 6BK7 UHF TUNER SCHEMATIC

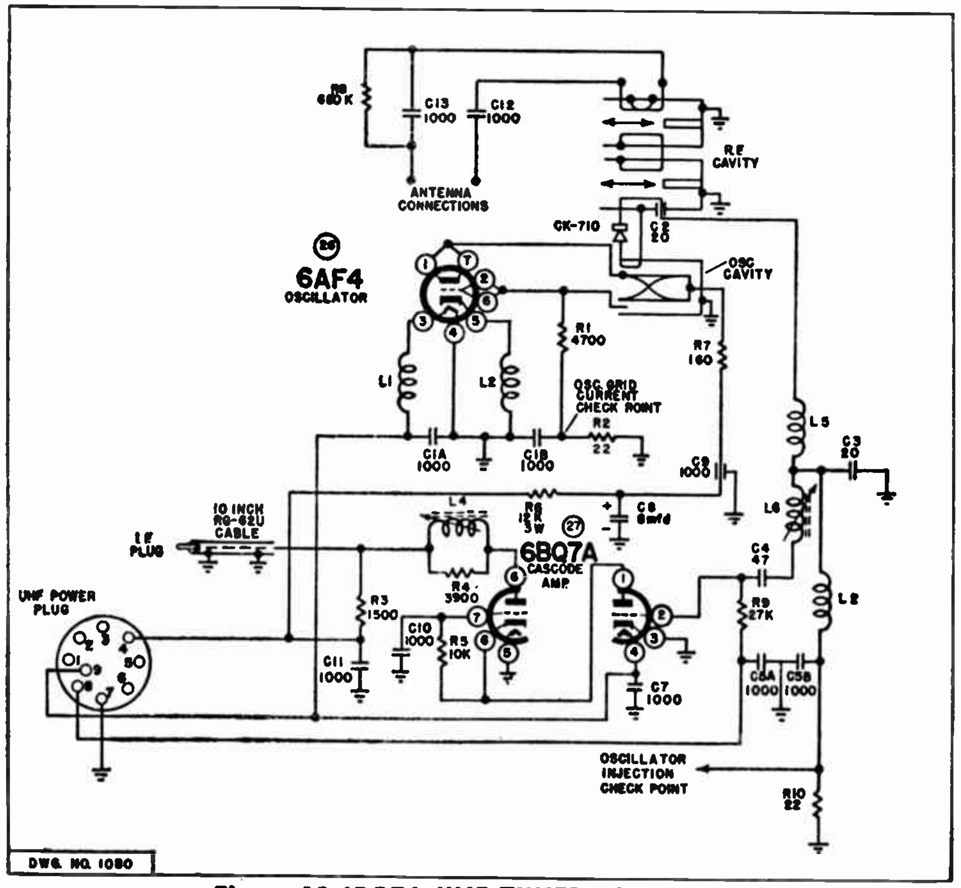

Figure 13 6BQ7A UHF TUNER SCHEMATIC

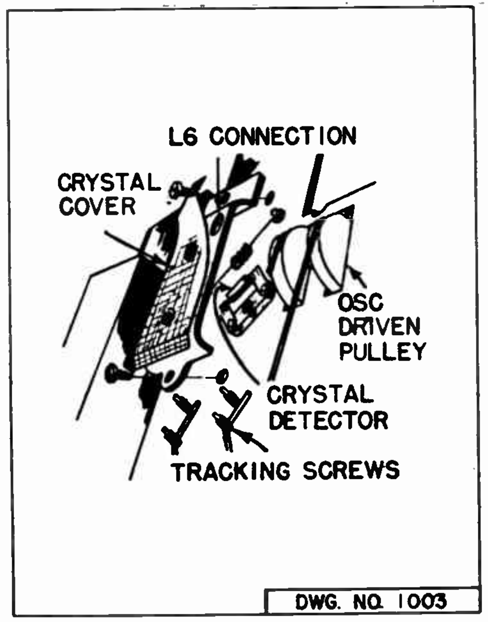

Figure 14

CRYSTAL DETECTOR: If replacement of the CK-710 Crystal Detector is necessary, the picture tube must be removed along with the cyrstal cover (refer to figure 14). The crystal is soldered into place and should be carefully resoldered after replacement. Overheating may damage the crystal. To dissipate the heat, grasp each crystal lead with a pliers when soldering into place.

ALIGNMENT

Since UHF is a relatively new field, test equipment necesary for RF and Oscillator Alignment is highly expensve and not readily available on the market at the present time. Therefore, a complete alignment procedure is not presented in this manual.

The cascode Pre-IF Amplifier can easily be realigned if necessary by connecting a 25 MC unmodulated signal to the junction of Coil L-5 and Capacitor C-2 (see figure 14), and a VTVM at the video IF Detector output of the receiver. Connect generator through a 1 mmf capacitor. Adjust both L4 and L6 for maximum VTVM reading.

If for any reason such as dial cord replacement, component replacement, etc., the RF cavities may be adjusted for peak performance. Before attempting adjustment, note position of ribbons and mark the UHF drive gear so that original positions can be relocated if necessary. Loosen the pulley positioning screw (refer to figure 15) and rotate the RF Drive Pulleys while viewing a UHF program. Rotate the pulleys for the sharpest and clearest picture.

CAUTION: Do not under any circumstances attempt adjustment of the tracking screws, oscillator trimmer screw or oscillator cavity. Precision test equipment is necessary for the adjustment.

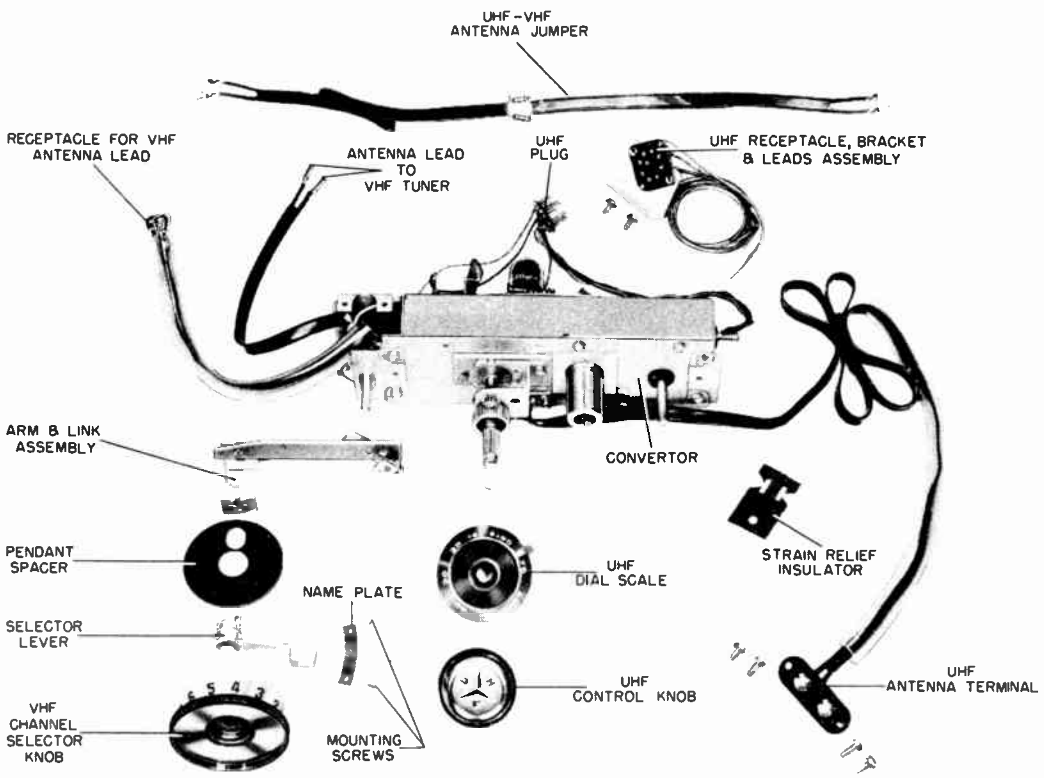
MODEL TC-101 SUPER-STRATA-TUNER



TYPICAL UHF CONVERTOR KIT (TK-19M SHOWN)

Part No. 68P730410

GENERAL INFORMATION

The Motorola Super Strata-Tuner is a two-tube UHF convertor which employs continuous tuning over all 70 of the UHF channels. This unit operates in conjunction with a VHF TV receiver as a double superheterodyne, using the RF stage of the VHF tuner as the 1st IF stage. The Super Strata-Tuner is available as a self-contained convertor, in kit form for installation in designated Motorola TV chassis, or factory-installed in Motorola receivers.

SELF-CONTAINED CONVERTOR

The self-contained UHF convertor has its own built-in power supply, and is housed in a wooden cabinet. It may be connected externally to any VHF TV receiver. The convertor models are:

Model	Cabinet Finish	Tuner
TC-101	Mahogany	TT-19
TC-101B	Limed oak	TT-19

CONVERTOR KITS

The UHF convertor kits are designed for installation in all Motorola TV receivers having UHF cut-out cover plates on the front panels of the cabinets. VHF chassis designed for installation of UHF convertor kits are listed in Chart I.

Note 1: Install receptacle if not in chassis.
Note 2: Gold dial with brown lettering and brown tuning knob. Early models—green dial and green tuning knob.
Note 3: Gold dial with black lettering and black tuning knob.
Note 4: Gold dial with brown lettering and green tuning knob.

The kits vary only by the addition of required hardware, knobs, and filament transformer. The transformer is included for installation of the convertor in series filament TV chassis. Kits TK-17M and VTK-17M, which are designed to cover early series and parallel filament chassis, include a filament transformer which is to be discarded when used in parallel filament TV chassis.

The UHF tuners used in the kits are basically the same and vary only in shaft lengths, mounting brackets, and the addition of a tone control. They receive their B+ and filament power from the VHF chassis.

If the VHF receiver contains a tone control, it is to be replaced, because of space limitations, with the tone control mounted on the appropriate UHF convertor tuner.

Late model TV chassis contain a receptacle for plugging in power connections to the UHF convertor, but early chassis require the convertor connections to be soldered.

Chart I lists convertor kits, the TV chassis with which they may be used, and differences between the convertors.

FACTORY-INSTALLED CONVERTORS

UHF tuners installed in the TV chassis at the factory are, in most cases, identical with the tuners listed in Chart I. The TV chassis containing factory-installed UHF tuners are designated with the suffix "Y". The "Y" version chassis is the same as the corresponding VHF TV chassis with the addition of UHF convertor. Use the VHF TV Service Manual for VHF parts and service information and this manual for UHF convertor information (i. e., TS-292Y UHF information would be found in this manual, while the VHF information would be found in the TS-292 Service Manual).

UHF tuners and the current TV chassis in which they are included from the factory are shown in Chart II.

TUNING RANGE - Channels 14 through 83 (470-890 mc)

TUBE COMPLEMENT

Ref. No.	Tube	Function
V-1	6AF4 or 6T4	UHF Oscillator (see Service Notes)
V-2	6BK7	Pre-amplifier
CR-1	CK-710 or equivalent	UHF Mixer Crystal

Discard the antenna jumper connection and connect each antenna to the proper input terminals when two outdoor antennas are being used.

In some areas where the VHF antenna and the jumper are used, it may be necessary to experiment with the length of the leads on the antenna jumper to get the best results.

The installation procedure for the outdoor UHF antenna will, in general, be the same as for the VHF antenna. The lead-in, however, should be the tubular, unshielded 300 ohm line instead of the ribbon type, as the latter attenuates UHF frequencies when damp. As the UHF antenna is more critical in setting up than the VHF, more care should be taken in properly positioning the antenna. Setting the UHF antenna toward the station will not necessarily give the best results, so check the area in order to deliver the maximum signal to the receiver.

When using the tubular lead, it is good practice to form a drainage loop before the lead enters the house, then punch a hole in the polyethylene at the low point. Unless this is done, the condensation formed inside the 300 ohm tubular line, may create a pool of water behind the television set.

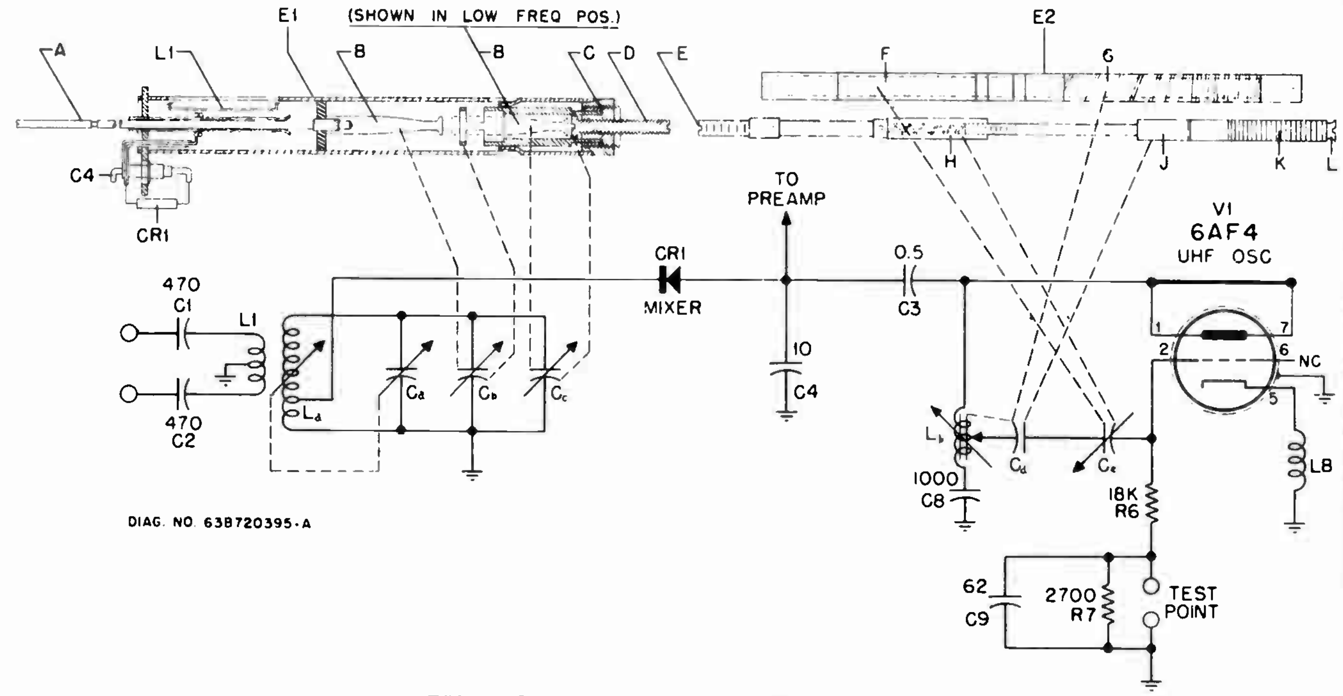

FIGURE 1. UHF TUNER FUNCTIONAL DIAGRAM

INSTALLATION & OPERATING INSTRUCTIONS

MODEL TC-101 SERIES - Refer to TC-101 Installation & Operating Instructions (Motorola Part No. 54P711714)

UHF CONVERTOR KITS - Refer to UHF convertor kit Installation & Operating Instructions (Motorola Part No. 68P720898)

ANTENNA

A separate, special antenna will normally be required for UHF reception.

The Motorola UHF "Bilt-In-Antenna" will give satisfactory UHF reception in "good signal" areas but, if you are located in a "fringe" or weak signal area, it is suggested that an outdoor antenna be used.

In some areas, an outdoor VHF antenna will be satisfactory for both UHF and VHF reception. If you are in such an area, a special jumper connection must be made between the VHF and UHF antenna terminals on the rear of your receiver. This jumper connection (furnished with the convertor) consists of a length of 300 ohm line, with a 150 ohm resistor in each lead.

If the outdoor antenna and antenna jumper connector are used for both VHF and UHF reception, the following precautions must be taken:

1. If the receiver is located in an area where there is a local UHF station and a fringe area VHF signal, connect the antenna to the VHF antenna terminals on the TV receiver (or TC-101 convertor).

2. If the receiver is located in an area where there is a local VHF station and a fringe area UHF signal, connect the antenna to the UHF antenna terminals on the TV receiver (or TC-101 convertor) instead of on the VHF side of the antenna jumper.

The above instructions will make it possible to use a single antenna for both UHF and VHF reception, but extreme caution must be taken when the antenna jumper is used, as this connector does result in a loss of signal. This signal loss cannot be tolerated if there is a very weak VHF signal as there might be too great a deterioration of the picture or, possibly, a complete loss of picture. In this case use separate outdoor antennas for UHF and VHF reception.

CIRCUIT DESCRIPTION

The UHF convertor was designed to operate as a double superheterodyne, in conjunction with a TV receiver, where the RF stage of the VHF tuner is used as the 1st IF. The UHF signal enters the convertor thru the antenna coupling RF coil, then it is loop-coupled to the transmission line, where a UHF mixer (losser type) crystal is tapped on. The incoming signal beats against the output of a series tuned Colpitts oscillator and the resultant frequency is either channel 5 or 6. The output of the crystal mixer is then amplified by a low-noise cascode amplifier and the amplified signal is coupled to the VHF receiver tuner.

The UHF signal enters a 300 ohm balanced input and is loop-coupled into the transmission line by L-1, which is inserted into a slot in the tubing.

Except for the power supply, all tuners are basically the same. The input is tuned by a capacity-loaded, shorted quarter-wave coaxial line. See £-1, Figures 1, 9 & 10. The tube wall, together with the rod & core assembly (A & B, Figure 1), form the inductance L_a. C_a is the distributed capacity between core (B) and the tube wall. As the core moves into the transmission line tube, the line is lengthened and its resonant frequency lowered. The line is capacity-loaded by C_b and C_c to keep the line from becoming too long. C_b, formed by the core (B) and the capacitor tuning, and C_c, formed by the core (B) and screw adjustment (D), are actually part of C_a but are adjusted to set C_a at a particular value at a particular frequency, i. e., C_c is the initial tracking adjustment at the low frequency end, while C_b is the initial mid-band adjustment. C_b is adjusted by threaded bushing (C).

A crystal mixer, CR-1, is tapped onto the transmission line, and the incoming signal beats against the output of a 6AF4 series-tuned, modified Colpitts oscillator. The difference frequency is either channel 5 or 6, depending upon which channel is unoccupied by a VHF station. The oscillator coil L_b consists of a glass coil form with a metallized covering (G, Figure 1) cut to form windings. In addition to the windings, there is also a solid metallized section (F) which, with core (H), form the tuning capacitor C_e. Core (J), in addition to tuning the inductance L_b, combines with the windings to form capacitor C_d. As its capacitance varies only slightly with the position of (J), C_d is effectively a fixed capacitor moving along the coil. Detuning slug (K), a series of copper rings, raises the resonant frequency of the unused portion of the inductance to keep its self-resonance higher than the operating frequency, thus preventing "suck-out" in the tuning range. (E) and (L) are high and low alignment adjustments, respectively.

The crystal, CR-1, is a losser type of mixer. Therefore, its output is fed to a 6BK7 cascode pre-amplifier which is used because of its good signal-to-noise ratio. It is a wide-band amplifier, passing both channel 5 and channel 6 carriers. The output of the pre-amp is 300 ohms balanced, and is coupled into the VHF receiver antenna terminals.

A two-position switch on the Built-In Supér Strata-Tuner allows the VHF antenna to be bypassed during UHF reception settings, while it bypasses the UHF antenna during VHF reception.

The two-position switch also controls the B+ supply. During UHF the B+ is approximately 260V, while during VHF the B+ supply is approximately 20V due to the 180,000 ohm dropping resistor (R-16). The low B+ is necessary to prevent deterioration of the UHF convertor tubes which would occur if no B+ were present while filament voltages were supplied to the tubes. The filaments are lit so that either UHF or VHF stations can be viewed without any "warm-up" period.

The switch on the TT-19 has a third position which acts as an on-off switch for both TV chassis and convertor when the TV receiver is plugged into an AC outlet on the back of the convertor.

Special Tools & Materials Required:

1. Antenna bushing adjusting tool - This adjusting tool can be made by filing off the edges of a 1/4" spintite so that the ridges fit into the slots on the antenna mid-frequency bushing.

2. Insulated screwdriver.

3. Hex alignment tool (3/32" hex - insulated) for iron cores (Motorola Part No. 66A891488).

4. Brass-iron tuning wand.

5. UHF plug and receptacle extension. Extension can be made up by soldering 28" lengths of wire between plug (Motorola Part No. 28K790063) and receptacle (Motorola Part No. 9K721371). See Figure 4.

ALIGNMENT

The built-in convertor chassis, as it is mounted in the TV chassis, does not have the adjustments readily accessible, therefore, the convertor must be removed from the main chassis.

The TT-19 (TC-101) must be removed from its cabinet for alignment.

Plug the convertors into the following sources of supply:

1. TT-19 into a 1:1 isolation transformer receiving 117V AC 60 cycle only.

2. Built-in convertors into a power supply having a B+ of 260V DC and a filament of 6.3V AC.

The B+ and filament voltages can be taken from the TV receiver by means of a plug and receptacle extension listed under "Special Tools Required for Alignment".

In convertors wired directly to the chassis (TT-27M, TT-28M, VTT-28M, and TT-31M), solder an extension to the B+, filament and ground leads.

As proper voltages are important for best alignment, use a variac if it is necessary to obtain 117 volt input.

On the TT-19, it is necessary to shunt a 330 ohm resistor across the "Dummy Load" input, as there is a possibility of standing waves appearing due to the long 300 ohm convertor output lead.

This alignment procedure will differ from those previously used in that it is necessary to adjust the high frequency oscillator and antenna adjustments before the IF can be aligned.

This alignment chart is laid out so that you can make a complete alignment by following all the steps in succession or you can align only one circuit by following the steps listed under the heading of the particular circuit you wish to align i.e., OSC steps #2 and #8.

Turn the selector switch to UHF (full clockwise position).

Connect the output of the UHF signal generator to the input of the UHF convertor (Figure 3).

Connect the output of the convertor to the input of the "Dummy Load". (Full details for construction of the dummy load can be found in Figure 5). Connect a sensitive microammeter to the output of the "Dummy Load" (Figure 3).

In order to properly align the UHF tuner, the following precautions should be taken:

1. Avoid turning the mid-frequency bushing and the low frequency slug in too far, as the high frequency plunger can strike it when the dial is fully counterclockwise.

2. The dial assembly must always stop due to the filled gear and not due to seating of the carriage or the slug on obstructions at either end of carriage travel.

3. Avoid spurious generator responses in the high frequency range. This can be detected by a marked difference in amplitude from the correct response.

4. Avoid making final adjustments with the UHF attenuator above 200K microvolts.

5. Use Figure 2 as a guide in aligning the set.

6. All electrical component references made in the alignment procedure refer to the UHF convertor.

Equipment Required:

1. UHF Signal Generator - Measurements Corp. Model M444, General Radio GR1021, or equivalent.

2. Microammeter - RCA-WV84, Simpson #374, or equivalent.

3. DC Meter - Low range electronic voltmeter (RCA voltohmyst junior or equivalent).

4. Power Supply

a. TC-101
117 volts 60 cycle only (thru isolation transformer)

b. Built-In Convertors

(1) B+ - 260 volts at 50 ma
(2) Fil - 6.3 volts at 0.675 amps

5. Dummy Load

6. Isolation Transformer

7. Variac

ALIGNMENT CHART

STEP	UHF GEN. FREQ.	TURN UHF CHANNEL SELECTOR	MISCELLANEOUS INSTRUCTIONS AND CAUTIONS	ADJUST			CHECKS
				OSC.	ANT.	IF	
1.			1) Remove IF core from output coil (L-11). 2) It is absolutely necessary to complete steps #2 & #3 before attempting the IF alignment.				
2.	900 Mc.	Fully Clockwise.	1) Generator output should be set at a point where an approximate midscale reading is obtained on the Microammeter. 2) Avoid spurious responses found in this frequency range.	Hi-freq slug for maximum reading on Micro-ammeter.			
3.	900 Mc.	Fully Clockwise.	1) Avoid spurious responses found in this frequency range. 2) Make final adjustment with the generator attenuator set on or below 200K microvolts.		Hi-freq slug for maximum reading on Micro-ammeter.		
4.	900 Mc.	Fully Clockwise.	1) Re-insert IF Core. 2) It is absolutely necessary to have completed steps #2 & #3 before attempting the IF alignment.			Output coil (L-11) for maximum reading on Micro-ammeter.	
5.	900 Mc.	Fully Clockwise.	1) Use brass-iron wanding tool and spread and compress coils as wand indicates. 2) CAUTION: Do not move or dress IF components after alignment.			Input coil (L-4) for maximum reading on Microammeter.	
6.	900 Mc.	Fully Clockwise.	1) Use brass-iron wanding tool and spread and compress coils as wand indicates. 2) CAUTION: Do not move or dress IF components after alignment.			Coupling coil (L-10) for maximum reading on Micro-ammeter.	
7.							RE-CHECK steps #3 & #4 for maximum response on Micro-ammeter.
8.	528 Mc.	Fully counter-clockwise and then return exactly two turns clockwise.	1) Hold Hi-freq slug while adjusting the Lo-freq slug. 2) The dial assembly must always stop due to the filled gear and not due to the seating of the carriage or the slugs on some obstructions.	Lo-freq slug for maximum reading on Micro-ammeter.			
9.	Adjust for maximum reading on meter.	Fully counter-clockwise.					Reading must be obtained between 457 and 470 Mc.
10.		Slowly from full counter-clockwise to fully clockwise position.	1) Clip VTVM across 2700 ohm res (R-7). 2) Set VTVM on lowest DC voltage range. 3) Be sure cover is on and screwed down.				Observe that meter reading does not go below .3 volt (variation may be 2:1).
11.	Set generator to approximately 900 Mc. Vary gen freq for maximum reading on Microammeter.		1) Disconnect VTVM. 2) If maximum readings do not meet limits, repeat steps #2, 8, 10 & 11.				Peak Microammeter reading must occur at 896 Mc ±5 Mc.
12.	600 Mc.	Turn exactly 7½ turns counter-clockwise from fully clockwise position.					Vary for maximum reading on Micro-ammeter which should occur between 580 to 620 Mc.
13.	600 Mc.	Turn exactly 7½ turns counter-clockwise from fully clockwise position.	1) Use special tool for this adjustment. 2) Avoid turning slug too far as the Hi-freq plunger can strike it when the dial is fully counter-clockwise. 3) Avoid making any adjustments when the UHF Gen. attenuator is above 200K microvolts.		Mid-freq bushing for maximum reading on Micro-ammeter.		
14.	460 Mc.	Fully counter-clockwise.	Make certain that the mid-freq bushing does not turn.		Low-freq slug for maximum reading on Microammeter		

ALTERNATE ALIGNMENT

The Alternate Alignment Procedure is for use only in the event that a UHF signal generator is not available.

This alignment procedure uses a Standard Measurements Corporation Model 80 AM signal generator (or equivalent) and a vacuum tube voltmeter (RCA Voltohmyst or equivalent) instead of the UHF signal generator and the micro-ammeter. The same special tools, as described in the regular alignment procedure, are required.

In this procedure, the signal generator is connected to the input of the UHF convertor (UHF antenna terminal) through a matching resistor network. The output of the convertor (spade lugs on TC-101; antenna terminal pins on all built-in convertors) goes to the VHF TV receiver, where the VTVM records the response at the video detector load resistor.

In this alternate alignment, the accuracy of the signal generator is of utmost importance as 2nd and 3rd harmonics are used throughout the alignment (i.e., a signal generator that is 5 mc "off frequency" would be 15 mc "off frequency" on the 3rd harmonic).

It is suggested that the convertor be aligned under the same conditions that would exist during normal operation, therefore:

1. Align convertor with the same TV chassis in which convertor is to be used.

2. Align convertor on the same VHF channel (5 or 6) that will be used for UHF reception.

3. Align convertor using the same antenna lead lengths that are furnished with the convertor. This might necessitate using a convertor mounting platform in order to connect the convertor output 300 ohm antenna leads to the VHF tuner.

The built-in convertor chassis, as it is mounted in the TV chassis, does not have the adjustments readily accessible, therefore, the convertor must be removed from the main chassis.

The TT-19 (TC-101) must be removed from its cabinet for alignment.

Plug the convertors into the following sources of supply:

1. TT-19 into a 1:1 isolation transformer receiving 117V AC 60 cycle only.

2. Built-in convertors into a power supply having a B+ of 260V DC and a filament of 6.3V AC.

The B+ and filament voltages can be taken from the TV receiver by means of a plug and receptacle extension listed under "Special Tools Required for Alignment".

In convertors wired directly to the chassis (TT-27M, TT-28M, VTT-28M and TT-31M), solder an extension to the B+, filament and ground leads.

As proper voltages are important for best alignment, use a variac, if necessary, to obtain 117 volt input.

This alignment procedure will differ from those previously used in that it is necessary to make the high frequency oscillator and antenna adjustments before the IF can be aligned.

This alignment chart is laid out so that you can make a complete alignment by following all the steps in succession or you can align only one circuit by following the steps listed under the heading of the particular circuit you wish to align (i.e., OSC steps #1 and #7).

Turn the switch to UHF (full clockwise position).

Connect the output of the signal generator to the input of the UHF convertor through a matching resistor network. In the case of the Standard Measurements Model 80, which has an output impedance of 50 ohms, insert a 100 ohm resistor in series with the output terminal, and a 150 ohm resistor in series with the ground terminal.

Connect the VTVM across the video (2nd) detector load resistor using the lowest possible DC range on the VTVM.

In order to properly align the UHF tuner, the following precautions should be taken:

1. Avoid turning the antenna mid-frequency bushing and the low frequency slug in too far, as the high frequency plunger can strike it when the dial is fully counterclockwise.

2. The dial assembly must always stop due to the stop on the dial scale actuating gear and not due to seating of the carriage or the slug on obstructions at either end of carriage travel.

3. Avoid spurious generator responses in the high frequency range. This can be detected by a marked difference in amplitude from the correct response.

4. Avoid making final adjustments when the VTVM reading is more than 2 volts above zero signal.

5. Use Figure 2 as a guide in aligning the set.

6. All electrical component references made in the Alternate Alignment Procedure refer to the UHF convertor.

ALTERNATE ALIGNMENT CHART

STEP	GEN. FREQ.	TURN UHF CHANNEL SELECTOR	MISCELLANEOUS INSTRUCTIONS AND CAUTIONS	ADJUST OSC.	ADJUST ANT.	ADJUST IF	CHECKS
1.	300 Mc. (3rd harmonic)	Fully Clockwise.	1) Generator output should be set at a point where an approximate 2 volt reading is obtained on the VTVM. 2) Avoid spurious responses found in this frequency range. 3) Check to see that the gearing is also at maximum.	Hi-freq slug for maximum reading on VTVM.			
2.	300 Mc. (3rd harmonic)	Fully Clockwise.	1) Avoid spurious responses found in this frequency range. 2) Make final adjustment with a 2 volt (above zero signal level) VTVM reading.		Hi-freq slug for maximum reading on VTVM.		
3.	300 Mc. (3rd harmonic)	Fully Clockwise.	It is absolutely necessary to have completed steps #2 & #3 before attempting the IF alignment.			Output coil (L-11) for maximum reading on VTVM.	
4.	300 Mc. (3rd harmonic)	Fully Clockwise.	1) Use brass-iron wanding tool and spread and compress coils as wand indicates. 2) CAUTION: Do not move or dress IF components after alignment.			Input coil (L-4) for maximum reading on VTVM.	
5.	300 Mc. (3rd harmonic)	Fully Clockwise.	1) Use brass-iron wanding tool and spread and compress coils as wand indicates. 2) CAUTION: Do not move components after alignment.			Coupling coil (L-10) for maximum reading on VTVM.	
6.							RE-CHECK steps #2 & #3 for maximum response on VTVM.
7.	264 Mc. (2nd harmonic)	Fully counter-clockwise and then return exactly two turns clockwise.	1) Hold Hi-freq slug while adjusting the Lo-freq slug. 2) The dial assembly must always stop due to the seating of the filled gear and not due to the seating of the carriage or the slugs on some obstructions. 3) If more than 2 turns were required, it will be necessary to repeat steps #1 & #7. 4) See Service Note regarding oscillator slug.	Lo-freq slug for maximum reading on VTVM.			
8.	Adjust for maximum reading on meter.	Fully counter-clockwise.					Reading must be obtained between 228 and 235 Mc.
9.		Slowly from full counter-clockwise to fully clockwise position.	1) Remove VTVM from video detector load and clip across 2700 ohm res (R-7). 2) Set VTVM on lowest DC voltage range. 3) Be sure cover is on and screwed down.				Observe that meter reading does not go below .3 volt.
10.	300 Mc. (2nd harmonic)	Turn exactly 7½ turns counter-clockwise from fully clockwise position.	1) Replace VTVM to video detector load.				Vary for maximum reading on VTVM which should occur between 290 to 310 Mc.
11.	300 Mc. (2nd harmonic)	Turn exactly 7½ turns counter-clockwise from fully clockwise position.	1) Use special tool for this adjustment. 2) Avoid turning slug too far as the Hi-freq plunger can strike it when the dial is fully counter-clockwise. 3) Avoid making any adjustments when VTVM reading is more than 2 volts above zero signal level.		Mid-freq bushing for maximum reading on VTVM.		
12.	230 Mc. (2nd harmonic)	Fully counter-clockwise.	Make certain that the mid-freq bushing does not turn.		Low-freq slug for maximum reading on VTVM.		

DUMMY LOAD INSTRUCTIONS

The dummy load, a necessity for proper UHF convertor alignment, can be constructed by the serviceman in a short time. All parts should be assembled onto a piece of plastic or bakelite. The schematic (Figure 5) gives a circuit description and lists all parts, electrical and mechanical, necessary for completion of the dummy load.

THE SUGGESTED CONSTRUCTION PROCEDURE IS LISTED BELOW:

1. Put sleeving over antenna impedance matching transformer and twist transformer leads as shown in schematic (Figure 5).

2. Wind 9 turns of #16 enameled wire on 1/4" diameter coil form approximately 1/2" from either end.

3. Remove enamel from both ends of wound coil and also from second turn on coil (Figure 5).

4. Insert core mounting nut and core into coil form so that iron core is capable of cutting across all 9 turns of wire.

5. Solder all connections, remembering to keep all leads, with the exception of the crystal leads, as short as possible. (Figure 5).

6. Add a length of wire to C so that a ground connection can be made to the convertor chassis.

DUMMY LOAD ALIGNMENT INSTRUCTIONS

1. Connect a Standard Measurements Corp. Model 80 signal generator (or equivalent) to dummy load input terminal strip, matching the generator to the receiver with a resistor network. In the case of a generator with a 50 ohm output impedance, insert a 100 ohm resistor in series with the output terminal, and a 150 ohm resistor in series with the ground terminal.

2. Connect sensitive microammeter (Simpson 374 or equivalent) to output terminals of dummy load.

3. Set signal generator to 84 mc.

4. Adjust L iron core for a maximum reading on the microammeter (on X-1 scale).

5. Reduce output of signal generator output as resonance is reached.

6. Check dummy load bandwidth as follows:

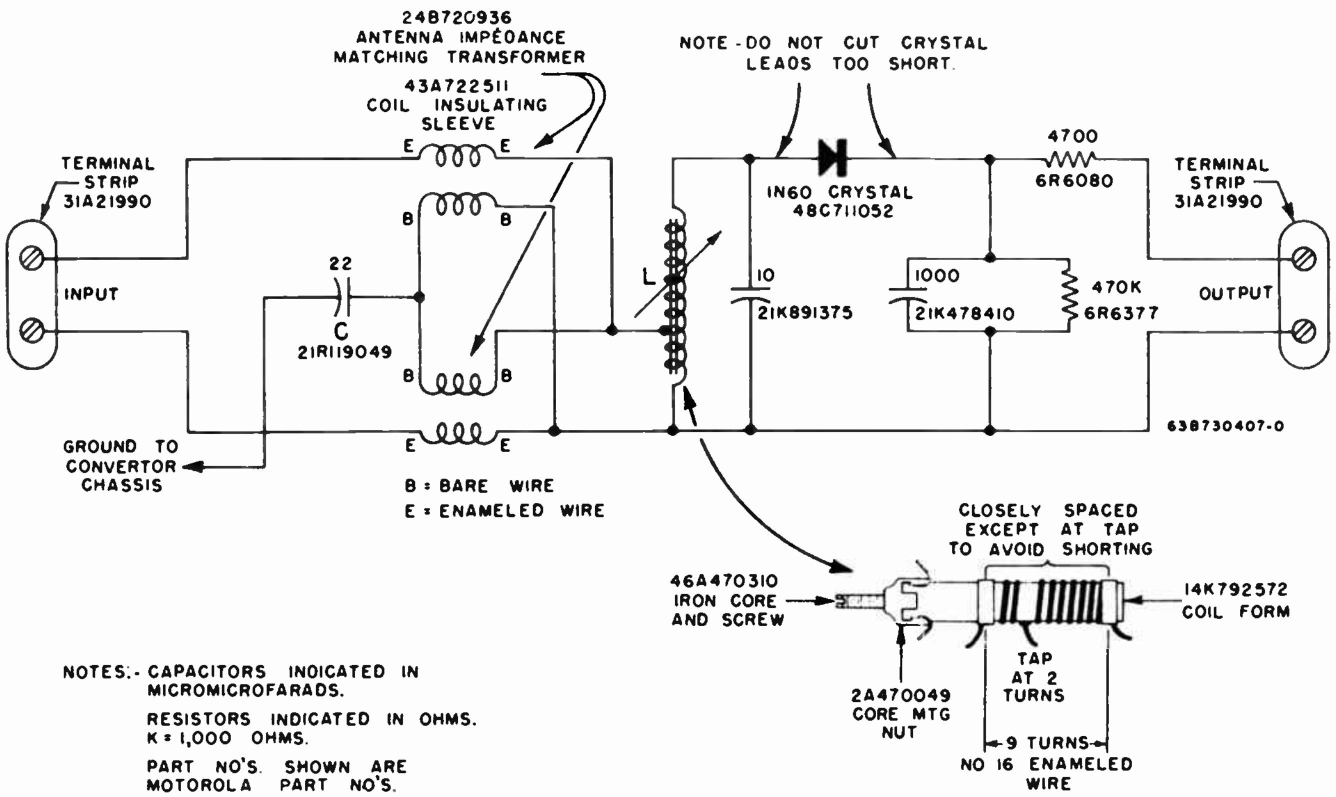
a. Set signal generator frequency to 84 mc.

b. Set output of signal generator to read 100 microamps on microammeter.

c. Lower frequency of signal generator until output reading drops to 70 microamps. Frequency should be in the range of 82 mc.

d. Raise frequency until the output reading drops to 70 microamps. Frequency should be in the range of 86 mc.

e. Relocate tap on coil L if frequency does not fall within the range in steps 3 or 4.



NOTES:- CAPACITORS INDICATED IN MICROMICROFARADS.
RESISTORS INDICATED IN OHMS.
K = 1,000 OHMS.

FIGURE 5. DUMMY LOAD SCHEMATIC DIAGRAM

SERVICE NOTES

Trouble	Remedy
Weak signal -snowy	Replace 6AF4 tube, L-1 shorted; replace crystal; replace C-13; check alignment.
Weak signal (low frequency end won't reach 470 mc)	Replace 6AF4 tube; ribbon broken on oscillator pipe; alignment
IF goes into oscillation at 600 mc	Change crystal
IF goes into oscillation across dial	Change shorted crystal
Oscillator not functioning on upper half	Check C-8 (realign after replacing)
Sudden dip in oscillator grid voltage on low end	Blue lead from C-3 to plates of V-1 dressed too close to oscillator pipe
Meter reading is less than .3 volt on injection check. (Step 10 Alignment Chart or step 9 Alternate Alignment Chart)	Check R-6 and R-7
Change in frequency during repairs	L-6 and L-7 are not parallel; blue lead from C-3 to plates of V-1 has been moved; C-8, L-6, L-7, L-8 and the blue lead from C-3 to plates of V-1 are very critical and should not be moved indiscriminately.
Set does not cover frequency range	Replace 6AF4; if actuating gear assembly has been removed or replaced, a careful check of the frequency range is absolutely necessary.
Difficulty in aligning oscillator on low frequency end	If oscillator is very badly out of alignment, on low frequency slug adjustment, remove oscillator core and adjust separation between slugs to 1-15/16" before attempting alignment operation.

USE OF 6T4 TUBE AS SUBSTITUTE FOR 6AF4

When using a 6T4 tube as a substitute for 6AF4 tube, proceed as follows:

1. Cut off pin #6 from 6T4 tube.
2. Place shorting strap (Motorola Part No. 42A730014) across pins #1 and #7.
3. Never place a used strap across pins #1 and #7.

MISCELLANEOUS MECHANICAL PARTS

The following parts are used with the kits indicated and also for receivers with factory built-in UHF convertors. Receivers with factory built-in UHF convertors are identified by a "Y" suffix following the model and chassis number. Knobs, and other parts directly connected with the UHF section of the "Y" version receiver are the same as listed in the appropriate convertor kit. Parts and service information for VHF section of "Y" version receivers will be found in the regular VHF service manual. (i.e., TS-292Y UHF information would be found in this manual, while the VHF information would be found in the TS-292 service manual).

* Differ from original VHF channel selector knob by shallower scale to allow clearance for UHF-VHF selector lever.

GENERAL INFORMATION

This service manual contains a record of production changes, a parts list supplement for the above UHF convertors, additional service notes, and schematic diagrams.

SCHEMATIC CHANGES

Revise TT-27M, VTT-28M etc., schematic diagram (Figure 10) in Service Manual Part No. 68P730410, to show pin numbers on PL-1 reading in clockwise instead of counterclockwise direction. All other PL-1 connections to remain as shown on diagram. The diagram note referring to pin 2 now refers to pin 7.

PRODUCTION CHANGES

Chassis Coding	Change
TT-19A TT-27MA TT-28MA VTT-28MA TT-31MA TT-35MA TT-50MA TT-52MA TT-57MA TT-58MA VTT-58MA TT-60MA	19 mmf capacitor added between pin 2 of the 6AF4 tube and the oscillator pipe to prevent oscillator drift with warm-up. A special type tube socket is used with this change. The crystal was moved under C-4 to prevent its shorting against plug button.

ADDITIONAL SERVICE NOTES

The position of the UHF mixer crystal in the UHF convertor is very important in determining the sensitivity of the unit. You will find that moving the crystal, within its lead length, may result in very good or very poor reception; in some instances, there may even be a complete loss of picture due to crystal dressing. There is no particular position into which the crystal can be placed for maximum sensitivity. If the crystal has to be moved for sensitivity peaking purposes, an insulated alignment tool should be inserted through the opening which is exposed by removing the plug button directly over the crystal location. Indiscriminate moving of the crystal should be avoided once the maximum response has been attained.

When the UHF mixer crystal is changed, the UHF convertor must be completely realigned.

Sometimes improved sensitivity can be realized by dressing the crystal take-off lead (buss wire between the crystal and the antenna transmission line assembly) for maximum performance.

If fluctuations are noticed in the picture, check to see if the white lead (C-4 to junction of L-3, C-5) is dressed close to and cemented to the chassis. The convertor sensitivity is also affected by the dressing of this lead.

Maximum oscillator efficiency can be obtained by keeping the following in mind:

a. The blue lead from the oscillator plate coil to R-11 should be dressed close to the chassis and away from the oscillator pipe.

b. The injector capacitor (C-3) leads should be kept as short and straight as possible.

c. The 18,000 ohm resistor (R-6) should be dressed about 3/8" away from and parallel to the oscillator pipe.

d. The clear space on the oscillator pipe (between grid and plate sections) should be kept free of rosin and other foreign matter. Rosin or foreign matter on this clear space will cause a leakage, especially in humid areas.

GENERAL INFORMATION

CHASSIS - Chassis TS-408A contains 17 tubes plus a 17" glass, rectangular, cylindrical face picture tube. The picture, sound, and scanning circuits, together with a selenium rectifier, full-wave doubler "B" supply, are contained on a single chassis. It employs the TT-44 cascode RF tuning unit and has a parallel heater circuit powered by means of a filament transformer. The channel selector knob is illuminated. Chassis TS-408A is similar to the TS-292A except for picture tube.

RADIO CHASSIS - Chassis HS-319 contains six tubes and receives AM broadcasts only. Except for a common speaker, it operates independently of the television receiver. Refer to HS-319 Service Manual for service data.

RECORD CHANGER - Three-speed Model RC-40. Refer to RC-40 Service Manual for service data.

TUNING RANGE - Channels 2 through 13 with provisions for UHF adaptation.

TV IF FREQUENCY - Sound - 21.9 mc
Picture - 26.4 mc

TV ANTENNA - "Bilt-In-Antenna" with provisions for connection of an external antenna.

TV ANTENNA INPUT IMPEDANCE - 300 ohms

POWER SUPPLY - 117 volts, 60 cycle AC only

TUBE COMPLEMENT

Ref. No.	Tube	Function
V-1	6BZ7	RF Amplifier
V-2	6U8	Mixer-Oscillator
V-3	6CB6	1st IF Amplifier
V-4	6CB6	2nd IF Amplifier
V-5	6CB6	3rd IF Amplifier
V-6	6AH6	Video Amplifier
V-7	6AU6	FM Driver
V-8	6AU6	FM Limiter
V-9	6AL5	Ratio Detector
V-10A	1/2 6SN7GT	1st Audio Amplifier
V-10B	1/2 6SN7GT	Phase Detector
V-11	6W6GT	Audio Output
V-12	6SN7GT	1st & 2nd Clippers
V-13A	1/2 12BH7	Vertical Blocking Oscillator
V-13B	1/2 12BH7	Vertical Output
V-14	6SN7GT	Horizontal Oscillator
V-15	6BQ6GT	Horizontal Output & High Voltage Generator
V-16	6AX4GT	Damping Diode
V-17	1B3GT	High Voltage Rectifier
V-18	17LP4	Picture Tube: rectangular; glass; electrostatic focus; cylindrical face

POWER CONSUMPTION - TV: 160 watts
RADIO & PHONO: 65 watts

HIGH VOLTAGE WARNING

Operation of this receiver outside its cabinet or with covers removed involves a shock hazard from the power supplies. No work should be attempted on this receiver by anyone not thoroughly familiar with the precautions necessary when working on high voltage equipment. Due to the full wave rectifier, there is always a potential difference between the chassis and earth and IT IS VERY IMPORTANT THAT AN ISOLATION TRANSFORMER BE USED WHEN SERVICING THE RECEIVER.

PICTURE TUBE HANDLING PRECAUTIONS

Extreme care must be used in handling the picture tube. This tube is highly evacuated and, due to its large size, is subjected to a considerable atmospheric pressure. The handler should wear safety goggles and gloves for protection. Avoid nicking or scratching the glass by rough contact with other objects. Before removing the coated glass picture tubes, discharge the capacitor formed by the inner and outer aquadag coatings on the tube by shorting the anode contact on the side of the tube to the outer surface with a well-insulated piece of wire.

INSTALLATION & OPERATING INSTRUCTIONS

ANTENNAS

These receivers are equipped with the Motorola "Bilt-In-Antenna", mounted inside the cabinet, for use in good signal areas.

The following precautions should be observed for best reception from the "Bilt-In-Antenna".

1. The signal should be relatively strong. As the signal strength will vary throughout the room in which the receiver is located, all possible locations should be tried, choosing the one in which the best pictures are received from all stations. Avoid large metallic objects such as radiators, metal panels, etc.

2. Lamps, vases and metallic objects, when placed on the receiver, may affect the efficiency of the "Bilt-In-Antenna".

If additional signal is necessary for good reception, an indoor or outdoor antenna may be required.

OPERATING CONTROLS

There is a dual control on the left and a triple control on the right of the receiver's front panel. See Figure 1 for control functions.

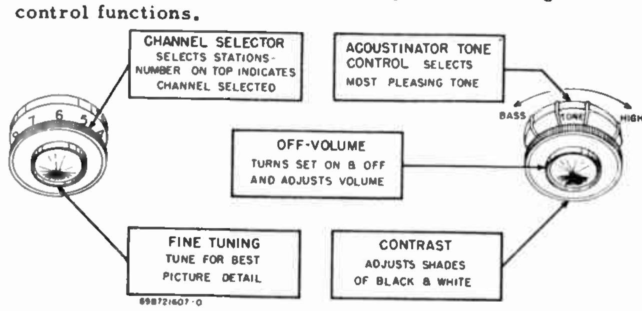

FIGURE 1. OPERATING CONTROLS

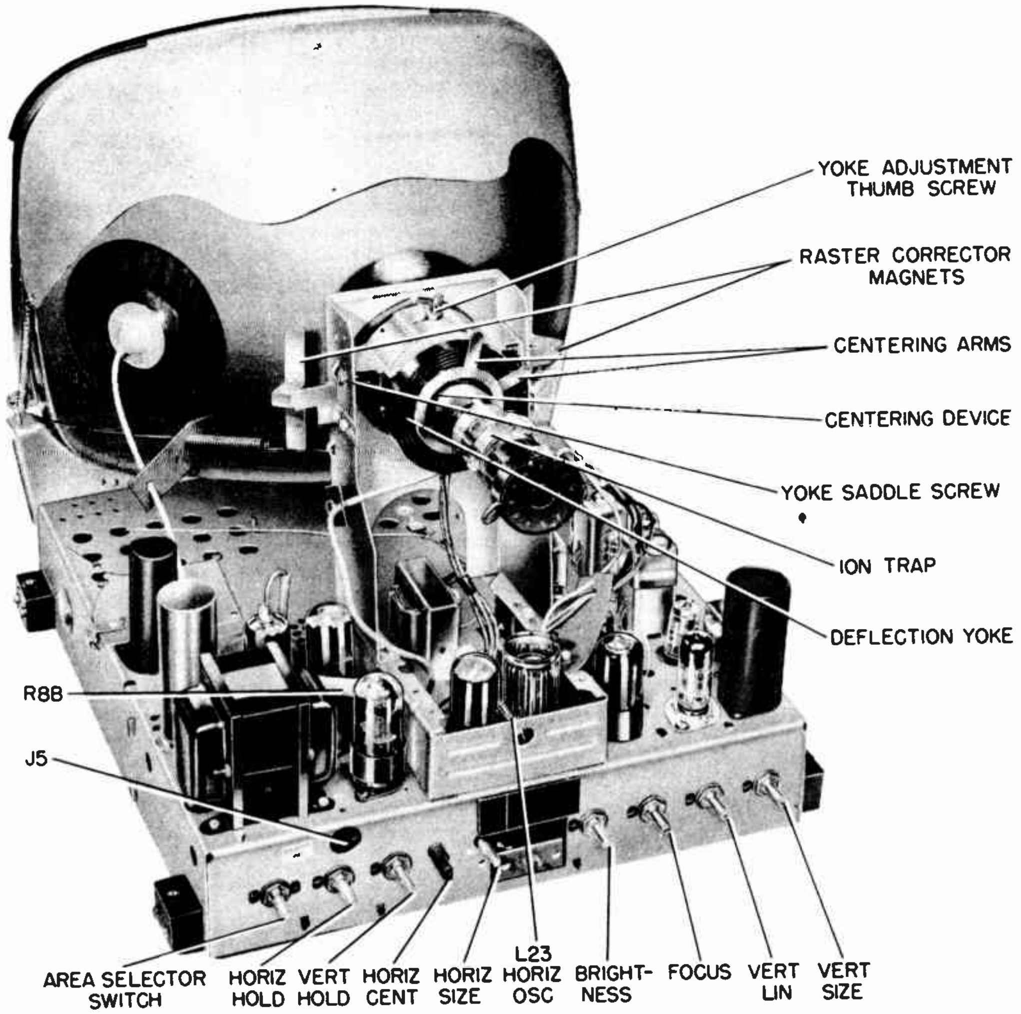

FIGURE 2. SERVICE ADJUSMENT CONTROLS

SERVICE ADJUSTMENTS

The receiver is completely adjusted at the factory, so normally none other than the front panel control operating instructions need be followed in putting the receiver in operation. However, to provide for misadjustment of the service controls due to handling, etc., the following instructions are in order. See Figure 2 for location of the service adjustment controls.

ADJUSTMENT OF THE ION TRAP

Under conditions of rough shipment, it is possible for the ion trap to become mis-adjusted. To prevent serious damage to the picture tube, the following method of adjustment should be used. See Figure 2.

Place the magnet on the neck of the tube so that it is positioned over the slash in the gun structure. (The slash is the separation between grids #1 and #2.) With the BRIGHTNESS control at low intensity, move the magnet a short distance forward and backward, at the same time rotating it, to obtain the brightest raster. If, in obtaining the brightest raster, the magnet has to be moved more than 1/2" forward from the slash, it is probably weak and should be replaced. Never correct for a shadowed raster with the ion trap magnet if such correction results in decreased brightness. The ion trap is always adjusted for maximum brightness and, if shadows occur at this setting, they should be eliminated by adjusting the magnetic centering device on the neck of the tube, or by changing the position of the yoke.

CAUTION: Keep the BRIGHTNESS control at low intensity until the ion trap is properly set.

CENTERING

NOTE: The ion trap should be properly adjusted before centering or focusing is attempted.

It is important, in achieving correct centering and good focus, that the magnetic centering device be properly adjusted. The centering device used with the electrostatically focused picture tube consists of two magnets arranged in such a way that the magnetic field intensity can be varied in angle or direction by means of the two projecting arms and by rotating the device about the tube neck. When the arms are superimposed, the fields of the two magnets cancel. Moving the arms progressively farther apart in a given direction, with respect to each other, will produce an increasing field intensity of a given polarity. If the arms are moved apart in the other direction, a field of opposite polarity will result. This controllable magnetic field, acting on the beam, normally provides a means of centering the picture vertically when the arms are initially at either side, and by rotation to a vertical arm position, it will also produce horizontal centering. Horizontal centering by means of the magnetic centering device should be held to a minimum because of the danger of defocusing and shadow.

To center the picture correctly, follow these steps:

1. Reduce the size of the picture so that all four edges are visible. Tune in a station; do not attempt centering with an uncontrolled raster.

2. Start with the magnetic centering device arms together and turned so they are horizontal. The device should be positioned as close to the yoke as possible without causing any part of it to slip inside the yoke opening.

3. Adjust the electrical horizontal centering control on the back of the chassis for best horizontal centering obtainable within the range of the control.

4. Separate the arms of the centering device in the proper direction to center the picture vertically.

5. If full horizontal centering was not obtained in step 3, complete the horizontal centering by slightly rotating the magnetic centering device as a unit one way or the other. It may then be necessary to readjust vertical centering by slightly changing the relative position of the arms.

6. Recheck adjustment of ion trap after centering is completed.

FOCUS

The zero focus type of electrostatically focused tube used in these chassis requires a fixed potential applied to the focusing anode which is supplied through the focus control potentiometer. This control, in effect, provides a means of compensating for differences in gun structure between tubes, but is far less critical in adjustment than was the focus control in the electromagnetically focused tubes. By carefully turning the control through its range, a point of adjustment will be found where optimum focus is obtained, but no misadjustment of the control will result in the extreme defocusing which resulted from the off-focus range in the control of electromagnetically focused tubes. In some tubes, the effect of the focus control is so slight as to lead the serviceman to believe that a fault exists in the circuit. The control should be adjusted to the point where the line structure is distinguishable over a 90% area of the screen.

Due to differences in gun structure between tubes mentioned above, it may be found that in some picture tubes better overall focus is obtained with the arms of the magnetic centering device pointing in a particular direction. If, after the magnetic centering device has been adjusted as in the paragraph on centering, good overall focus is not obtained, rotate the magnetic centering device 180° and repeat the centering procedure.

RASTER CORRECTOR MAGNETS

On chassis having a cylindrical face picture tube, there is a magnet on each side of the rear support bracket to straighten the raster sides, if necessary. They are correctly set at the factory but if moved in shipping or, if the yoke has been replaced, they may require readjustment. To do so:

1. Reduce raster size so that its sides are just visible.

2. Move corrector magnet forward or backward so that sides are straight.

VERTICAL HOLD

Adjust the VERTICAL HOLD control for the center of the vertical sync lock-in range.

VERTICAL SIZE AND VERTICAL LINEARITY

Adjust the VERTICAL SIZE control until the picture fills the mask vertically. Adjust the VERTICAL LINEARITY control for the best overall vertical linearity. Adjustment of the VERTICAL SIZE control may require a readjustment of the VERTICAL LINEARITY control and possibly of the VERTICAL HOLD control.

HORIZONTAL HOLD ADJUSTMENT

The HORIZONTAL HOLD control should have a sync range of approximately 50°. If the control is too critical, adjust as follows:

1. Shunt the HORIZONTAL OSCILLATOR coil L-23 to ground with a .25 mf 400V capacitor. This may be done with the chassis in the cabinet by placing the capacitor across the two-pin receptacle (J-5) located as shown in Figure 2.

2. With the HORIZONTAL CENTERING control, move the picture to the left so that the right edge of the raster can be seen, as viewed from the front of the set. Adjust the HORIZONTAL HOLD control for about 1/16" of sync pulse. (The sync pulse appears as a darker gray bar at the right edge of the blanking pulse. The blanking pulse is the gray bar at the right edge of the raster.)

3. Remove the .25 mf capacitor from across the HORIZONTAL OSCILLATOR coil.

4. Adjust the HORIZONTAL OSCILLATOR coil until the same amount of sync pulse can be seen as was noted in step 2.

HORIZONTAL SIZE

Adjust the HORIZONTAL SIZE control until the picture fills the mask horizontally. As this control also affects vertical size, it may be found necessary to readjust the VERTICAL SIZE control.

BRIGHTNESS

Adjust the BRIGHTNESS control, in combination with the CONTRAST control, for the most pleasing picture. Keep the brilliance as low as possible, to protect the fluorescent picture tube screen and to prevent poor picture detail.

DEFLECTION YOKE ADJUSTMENT

If the deflection yoke shifts, the picture will be tilted. To correct, loosen the thumbscrew on top of the deflection yoke and rotate yoke until the picture is straight. Before tightening the thumbscrew, make certain that the deflection yoke is as far forward as possible to prevent shadow.

If the yoke support and the picture tube have shifted in transit or, if for any reason, these parts have been removed and replaced, it is best to do a complete job of repositioning. See Figure 2. The picture tube should be mounted so that the front of the tube rests against the brackets on the front of the chassis. The clamp around the front of the tube should then be tightened. (NOTE: This applies only to the glass tubes. The position of the metal picture tubes is fixed by the front brackets.) The picture tube rear support bracket mounting screws should be loose enough to permit sliding the bracket forward until it fits snugly up against the flare of the tube. Loosen the yoke adjustment thumbscrew and yoke saddle screws and push the yoke up against the flare of the tube. CAUTION: Do not use force in sliding the bracket. If too much force is applied, a strain will be placed on the neck of the tube when the support bracket mounting screws are tightened, or the yoke may be forced out of position. The opening in the yoke should be concentric with the neck of the tube.

TEST RECEPTACLE

A three-pin receptacle, accessible from the side of the chassis (see J-4, Figures 4 & 11) is provided for checking sensitivity and AGC voltage. The video detector load resistor is connected to pin 3, the AGC line is brought out to pin 1, and pin 2 is grounded.

AREA SELECTOR SWITCH

A three-position AREA SELECTOR switch, located on the back of these chassis, permits them to be adapted to varying receiving conditions found in different localities. See Figure 2.

The LOCAL, SUBURBAN, and FRINGE positions correspond approximately with the settings required for strong, medium, or weak signals, respectively.

In the LOCAL position, AGC is applied to the RF amplifier, mixer, and the first two IF stages. In the SUBURBAN position, AGC is removed from the RF and mixer stages. In the FRINGE position, the AGC applied to the IF stages is reduced 50% and the video amp grid resistor is returned to ground to improve noise limiting.

Since the AREA SELECTOR switch allows the receiver to operate under best conditions for the signal strength at your location, an incorrect setting may give poor picture quality, instability, or a buzzing sound in the speaker. Set this switch in the position which gives the clearest and most stable picture.

TONE CONTROL LINKAGE SETTING

If, for any reason, it becomes necessary to replace the tone control linkage, the following procedure should be followed:

1. Set the tone control potentiometer at zero ohms (maximum counterclockwise).

2. Place the linkage over the TONE and CONTRAST-VOLUME shafts in such a manner that the arms and link are below the shafts.

3. Move the arms counterclockwise as far as possible and tighten the setscrew on the TONE control shaft.

4. After chassis has been replaced in cabinet, place the TONE control knob over the CONTRAST-VOLUME shaft so that the lettering is toward the top.

CHANGING OF TUBES

1. The power should be turned off when changing tubes.

2. Indiscriminate changing or interchanging of tubes should be avoided for the following reasons:

a. A change of IF or RF tubes or crystal detector can cause loss of sensitivity or poor picture quality. Check alignment and sensitivity.

b. A change of limiter or ratio detector tubes can cause distorted audio, buzz, or loss of audio sensitivity. Check audio alignment and sensitivity.

c. Changing horizontal oscillator tube can result in poor noise rejection or cause the horizontal hold control to be out of range. This may necessitate readjustment of the horizontal oscillator coil.

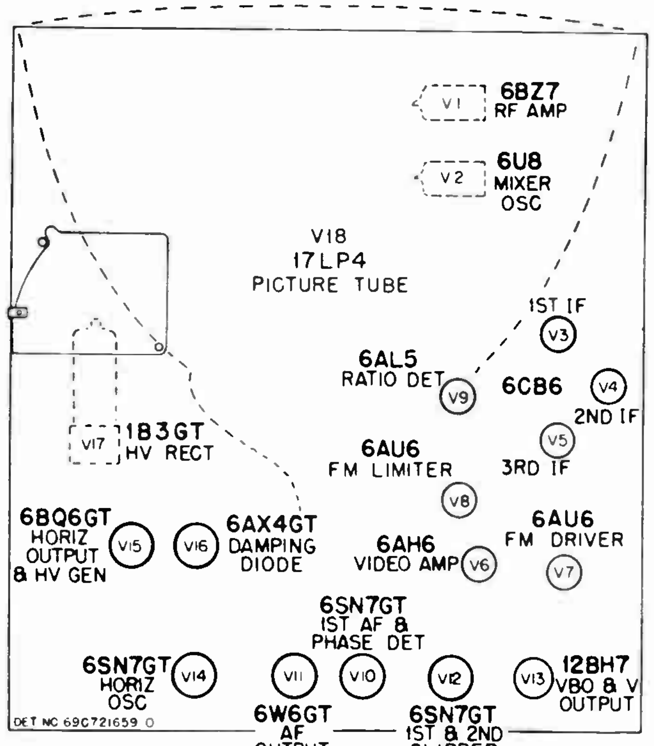

FIGURE 3. TUBE LOCATIONS

ORDER OF ALIGNMENT

A complete receiver alignment can be most conveniently performed in the following order:

1. IF & Mixer Transformers

2. Oscillator & RF Sections

3. 4.5 Mc Trap

4. Audio Take-Off, Interstage Coil, & Ratio Detector

IF AMPLIFIER ALIGNMENT

Equipment Required:

IF Sweep Generator meeting the following requirements:

1. 18 to 30 mc, approximately 12 mc sweep width.

2. Output constant and adjustable to at least 0.1 volt maximum.

3. Accurately calibrated, adjustable markers

Cathode Ray Oscilloscope - Preferably one with a calibrated attenuator.

AM Signal Generator - Adjustable Output

NOTE: If there is no built-in marker in the sweep generator, loosely couple the output of an accurately calibrated AM signal generator to the IF strip. At all times, keep the marker output low enough to prevent the marker from distorting the response curve.

If a wide band scope is used, the marker will be more distinct if a capacitor of 100 to 1000 mmf is placed across the scope input. Use the smallest size possible, since too large a value will affect the shape of the curve.

If necessary, use a variac to obtain input of 117 volts.

Procedure:

1. Remove the horizontal output tube, V-15, to eliminate RF interference in the oscilloscope.

2. By means of an external battery, apply a negative 3 volt bias, through a decoupling resistor of 47K ohms, to the AGC line, which is connected to pin 1 of the test receptacle (J-4). See Figure 4 for receptacle location.

3. Through a 47K ohm decoupling resistor, connect the oscilloscope across the video detector load resistor R-27 (4700) which may be reached from pin 3 of test receptacle (J-4). If a stronger output is required, connect the scope between picture tube cathode (yellow lead) and chassis. The curve seen at this position will be the reverse of the polarity shown in Figures 5 & 6.

4. Turn Area Selector Switch (S-2, Figure 2) to LOCAL position.

5. Using leads as short as possible, connect the sweep generator, through a 1000 mmf capacitor, to jack J-3, feeding into the grid of 1st IF tube V-3. See Figure 4. (Do not use the loose or "spraying" method of coupling.) Set the generator center frequency to 24.6 mc, with a sweep deviation of 10 mc.

6. Detune the oscillator by placing a shunt wire across the oscillator inductance (from position 2 to position 13 on the bandswitch).

7. Tune the 1st IF transformer, T-4, to place a 26.6 mc marker on the high side of the response curve 50% down from maximum response. At the same time, adjust T-6 to provide a flat top or symmetrical response curve. Tuning

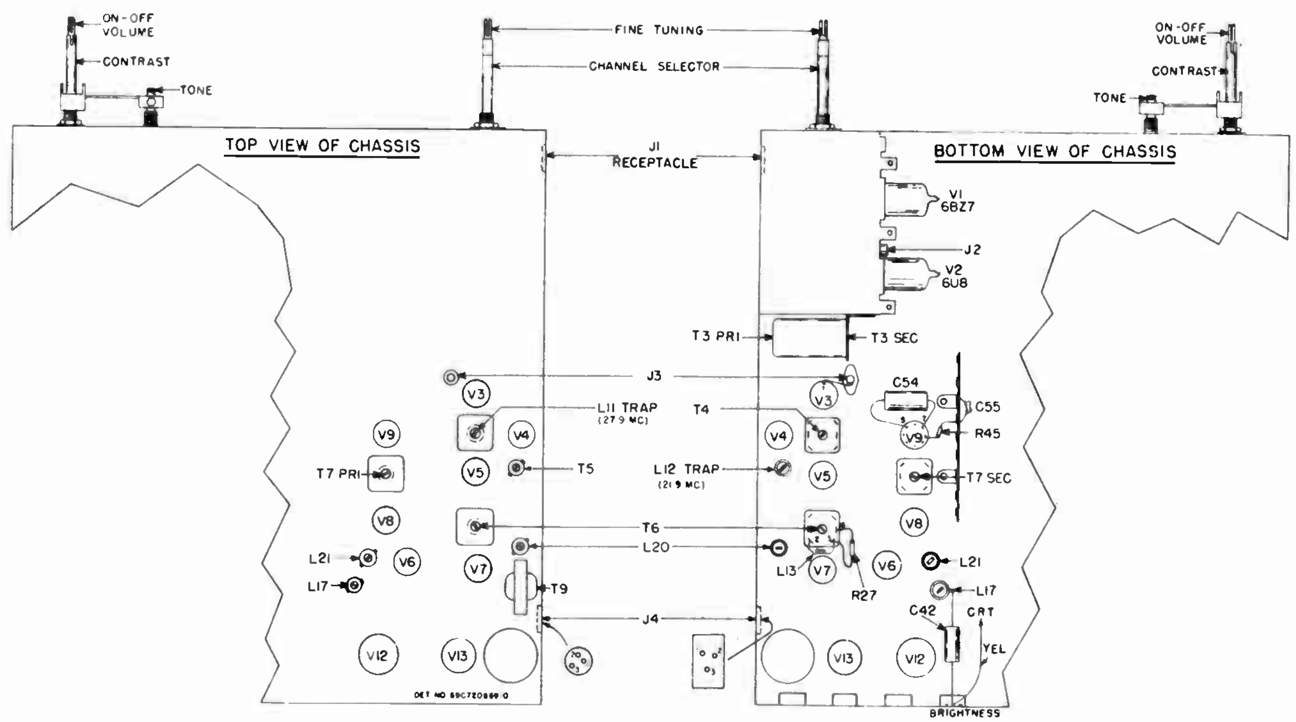

FIGURE 4. ALIGNMENT ADJUSTMENT LOCATIONS

ALIGNMENT

GENERAL

The chassis should be mounted on angle iron brackets so that all connections and adjustments may be made easily.

Since the power cord circuit is broken by the interlock when the cabinet back is removed, it will be necessary to obtain an extra power cord with the female interlock receptacle on it in order to make a power connection to the receiver. Order Motorola Part No. 30B470756.

It is important that an isolation transformer be used between the receiver and the line when any test equipment is attached to the chassis. Due to the full wave rectifier, there is always a potential difference between the chassis and earth, and it is very important that an isolation transformer be used when servicing the receiver. This precaution is especially important if grounded test equipment is used. NEVER GROUND THE RECEIVER CHASSIS DURING TESTING OPERATIONS OR INSTALLATION UNLESS AN ISOLATION TRANSFORMER IS USED.

As proper voltages are important for best alignment, use a variac if necessary to obtain 117 volt input.

the two transformers together will make for proper marker placement and "jacking" action of T-6. See Figure 5.

CAUTION: A. Keep the signal input low, to prevent flattening the top of the curve, due to limiting in the video or scope amplifiers.

B. The dressing of plate and grid components in the IF circuit affects tuning. Do not move indiscriminately.

C. The resonance point of the IF coils and the trap will be found at two settings of the core. The correct setting is the one with the core at the outer end of the winding.

8. Tune the 2nd IF transformer, T-5, to place a 22.8 mc marker on the low side of the response curve 50% down from maximum response. At the same time, adjust T-6 to provide a flat top or symmetrical response curve as in step 6. See Figure 5.

9. Tune trap L-12 for maximum attenuation on the curve at 21.9 mc, as in Figure 5. Make sure the core is toward the outside of the trap winding (toward the top).

10. Tune trap L-11 for maximum attenuation on the curve at 27.9 mc, as in Figure 5. Make sure the core is toward the outside of the trap winding (toward the top).

11. Move the generator and capacitor to jack J-2. See Figure 7. Short out R-11 (4700) located between the jack and the mixer grid.

12. Turn the primary and secondary of the mixer IF transformer, T-3 so that the bandpass appears as in Figure 6.

NOTE: This is a double-tuned circuit. Make sure the slugs are tuned away from the center of the coil.

NOTE: It is important that the 21.9 mc and 27.9 carriers are attenuated as much as shown in Figure 6. To calculate, connect an AM generator to the mixer grid and a VTVM across the detector load resistor. Take voltage readings at 21.9 mc, 24.6 mc, and 27.9 mc and divide per following formula: With proper attenuation -

$$\frac{\text{voltage reading at 24.6}}{\text{voltage reading at 21.9}} = \text{between 50 and 80}$$

and

$$\frac{\text{voltage reading at 24.6}}{\text{voltage reading at 27.9}} = \text{at least 100}$$

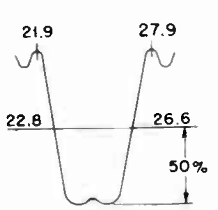

FIGURE 5.
IF RESPONSE CURVE

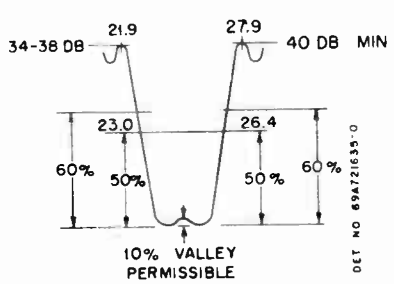

FIGURE 6.
MIXER RESPONSE CURVE

BANDWIDTH

The IF bandwidth may be checked with an AM signal generator, if desired. Connect the generator, through a 1000 mmf capacitor, to jack J-2 in the grid circuit of the mixer tube, V-2B, and an electronic voltmeter across the video detector load resistor R-27 (4700). Short out R-11 (4700), set the generator frequency to 24.6 mc, and adjust its output for a 1 volt reading on the meter. Double the output of the generator. Tune to both sides of 24.6 mc and note the frequencies at which the meter again reads 1 volt. These frequencies indicate the 6 db bandwidth points and should be 22.9 mc and 26.4 mc. By watching the meter while tuning slowly through the band, any serious peaks or holes in the response curve can be detected.

REGENERATION

After the mixer and IF stages have been aligned, a check for regeneration in the IF strip should be made as follows:

1. Remove the battery bias and observe the response curve on the scope as taken between the picture tube cathode (yellow lead) and chassis. The bandwidth may change with the bias removed, but should not change more than 0.2 mc. If the bandwidth does change more than 0.2 mc, check the cathode resistors or change tubes.

2. Set the contrast control at maximum gain (fully clockwise).

3. Decrease the generator input until the output signal shows a marked decrease.

4. Any regeneration present will be indicated by sharp peaks on the overall response curve.

NOTE: The oscillator should be detuned, as described above, during this procedure

CAUTION: Do not inject too much marker signal.

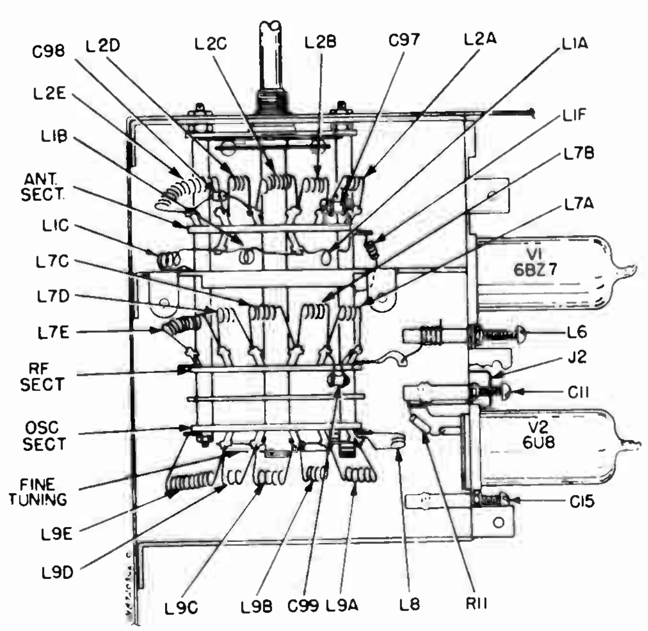

FIGURE 7. ANTENNA, RF & OSC LOCATIONS

MIXER SENSITIVITY MEASUREMENTS

1. Connect an AM signal generator, set at 24.6 mc, modulated 30% with 400 cycles, to jack J-2 through a capacitor of 1000 mmf. Short out R-11 (4700).

2. Remove the battery bias from the AGC line.

3. Remove shunt wire from oscillator.

4. Connect the oscilloscope to the cathode of the picture tube. Turn contrast control to maximum.

5. Turn the station selector switch to the low channel position which gives the lowest noise reading on the meter.

6. The signal required to produce 20 volts peak-to-peak on the scope should be less than 100 microvolts.

NOTE: To calibrate scope, connect it across the 6.3 volt filament supply. The peak-to-peak amplitude on the screen will then be approximately 18V (6.3 x 2.8).

IF SENSITIVITY MEASUREMENT

1. Move generator to jack J-3 feeding into the grid of the 1st IF tube (V-3, 6CB6).

2. Connect the electronic voltmeter, through a 100K decoupling resistor, across the video detector load resistor R-27 (4700).

3. The signal required to produce 1 volt on the voltmeter should be less than 750 microvolts.

ANTENNA, RF & OSCILLATOR ALIGNMENT

NOTE: The IF circuits must be aligned before the oscillator section can be properly phased.

Equipment Required:

Sweep generator having:

1. Frequency range 40-220 mc
2. 10 mc sweep width
3. Output constant and adjustable
4. Adjustable markers (markers should be calibrated occasionally by checking against an accurate signal generator).

AM Signal Generator having:

1. Frequency range 40-220 mc
2. Accurate frequency and attenuator calibration
3. 400 cycle, AM modulation

Oscilloscope: Preferably one with a calibrated input attenuator.

FREQUENCY CHART

Chan	Frequency	Picture	Sound	Oscillator
2	54-60	55.25	59.75	81.65
3	60-66	61.25	65.75	87.65
4	66-72	67.25	71.75	93.65
5	76-82	77.25	81.75	103.65
6	82-88	83.25	87.75	109.65
7	174-180	175.25	179.75	201.65
8	180-186	181.25	185.75	207.65
9	186-192	187.25	191.75	213.65
10	192-198	193.25	197.75	219.65
11	198-204	199.25	203.75	225.65
12	204-210	205.25	209.75	231.65
13	210-216	211.25	215.75	237.65

ANTENNA & RF ALIGNMENT PROCEDURE

1. Remove the horizontal output tube V-15, to eliminate RF interference in the oscilloscope. Connect a 5000 ohm 10 watt resistor between the red B+ bus and chassis to normalize the bus voltages.

2. Detune the oscillator by placing a shunt wire across the oscillator inductance (from position 2 to position 13 on the bandswitch).

3. Remove the antenna lead-in from the chassis, and connect the sweep generator to the antenna receptacle. Keep the leads from the generator to the socket short. Use internal markers or an accurately calibrated external signal generator for markers.

4. Connect the oscilloscope, through a decoupling resistor of 47K ohms to jack J-2 in the grid circuit of the mixer tube V-2B. See Figure 7.

5. Ground the AGC lead to the mixer and RF stages by moving the area selector switch to the suburban or fringe position.

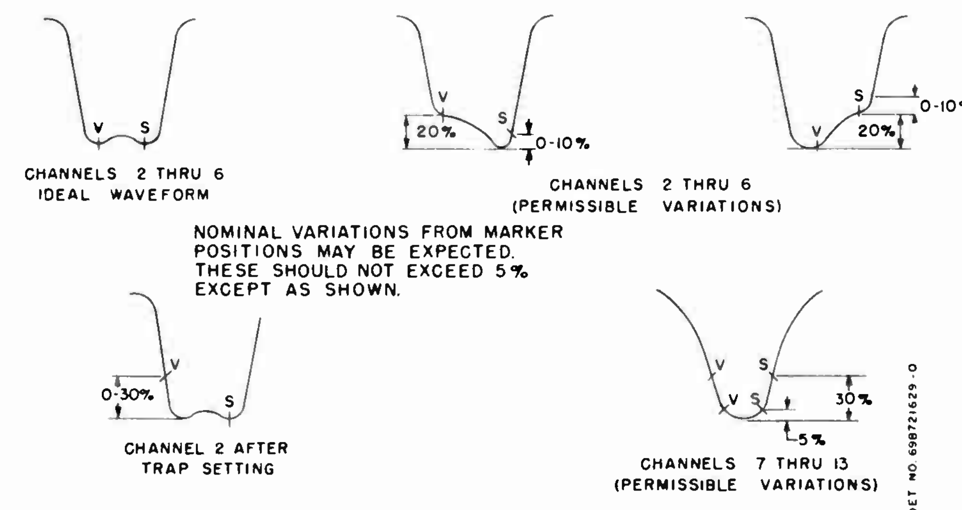

FIGURE 8. RF RESPONSE CURVE

6. Refer to Figure 7 for the location of the trimmers and coils. The chart listed above gives the picture and sound carrier frequencies.

7. The antenna coils are tuned to the video carrier side and the RF coils are tuned to the sound carrier side. Figure 8 shows the shape of the curve which should appear on the oscilloscope.

8. Set the screw in channel 13 RF coil, L-6, midway in the coil.

9. Turn the station selector switch to channel 8. Set the center frequency of the sweep generator to the center frequency of channel 8 (183 mc).

10. Adjust ceramic trimmer, C-11, so that the video and sound markers appear on the response curve within the limits shown in Figure 8.

NOTE: The two impedance matching transformers, T-1 and T-2 must be a minimum of 1/4" apart or a "suck-out" will be noted on channel 12 or 13.

11. Move the station selector switch to channel 13, and set the generator to the center frequency of the channel (213 mc). Adjust the screw in coil L-6 for the proper response on channel 13 (see Figure 8).

12. Recheck channel 8 for proper response. Readjust trimmer C-11, if necessary.

13. Check channels 13 through 7 and compare the curves in Figure 8. It is important that the antenna primary coil (L-1F) is not changed. The wave shapes may be narrowed by reducing the inductance in the coil but the signal-to-noise ratio will be seriously affected.

NOTE: If the response is checked with the cover on the tuner, the picture marker will move up the left side of the curve a short distance, but the markers should be within tolerance.

14. Move the station selector switch to channel 6 and set the generator to the center frequency of the channel (85 mc).

15. Compress or spread the channel 6 antenna coil, L-2E, and RF coil, L-7E, to obtain the proper response. See Figure 7 for coil locations and Figure 8 for response curve. The antenna coil affects the video carrier and the RF coil affects the sound carrier.

NOTE: The tilt on the low channels, particularly channels 5 and 6, can be controlled by adjusting the antenna matching coil, L-1C.

16. Align channels 5 through 2, in that order, in the same manner as channel 6. As the coils are in series, the proper phasing of channel 6 will simplify the alignment of the lower channels. On one of the lower channels, check that the same waveform is obtained with the sweeper head reversed. Waveform deviations indicate a faulty coil.

CAUTION: Make certain the bandswitch is on the correct channel before checking bandpass.

17. With channel selector on channel 2, adjust the two traps formed by C-97 & C-99 across L-2A and L-7A, respectively. Proceed as follows:

a. Move the oscilloscope to the picture tube cathode (yellow lead), and connect an AM generator, set at 104.7 mc and modulated 30%, to the antenna input.

b. With the contrast control at maximum gain (fully clockwise), adjust the fine tuning control for maximum amplitude on scope.

c. Adjust coils L-2A and L-7A (by spreading or compressing) for minimum amplitude on scope. These coils can be reached with the tuner cover on through two holes in the cover.

d. To check rejection of 104.7 mc, set the generator output high enough so that a 20 volt peak-to-peak wave appears on the scope. Note the generator output reading.

e. Tune the generator to 57 mc, tune fine tuning trimmer for maximum amplitude on scope, and adjust the generator output to give a 20 volt peak-to-peak wave on the scope. Again note the generator output reading.

f. Using figures noted in steps (d) and (e), divide using formula shown in step (g).

g. For proper rejection,

$$\frac{\text{generator output at 104.7 mc}}{\text{generator output at 57 mc}} = \text{at least 6000}$$

h. If voltage ratio in (g) is less than 6000, repeat steps (a) through (g).

OSCILLATOR ADJUSTMENT

NOTE: The IF and mixer circuit must be aligned before the oscillator is adjusted.

1. Remove shunt wire from oscillator inductance.

2. Connect the oscilloscope, through a 47K ohm resistor, across the video detector load resistor R-27 (4700). Restore AGC to the mixer and RF tubes by placing the Area Selector Switch into LOCAL position.

3. Refer to Figure 7 for the locations of the trimmers and coils. The sound carrier frequencies may be obtained from the preceding chart.

4. Set fine tuning trimmer for mid-capacity.

5. Turn station selector switch to channel 10.

6. Set the sweep generator to channel 10, with a center frequency of 195 mc. Keep the output low enough to show no evidence of limiting in the overall response curve.
NOTE: The curve should be substantially that of the mixer as in Figure 6. Any consistent tilting of the response curve indicates that the mixer and IF stages are not properly aligned.

7. Introduce a marker corresponding to the sound carrier of channel 10 (197.75 mc). Keep marker signal as low as possible.

8. Adjust the oscillator trimmer C-15 to place the sound marker slightly higher in frequency than the 21.9 mc trap dip. This allowance must be made for the shift caused by the bottom shield being off. When the shield is replaced, the sound marker will move down into the trap dip. The picture marker will then be approximately one-half down from the base line on the opposite side of the curve.

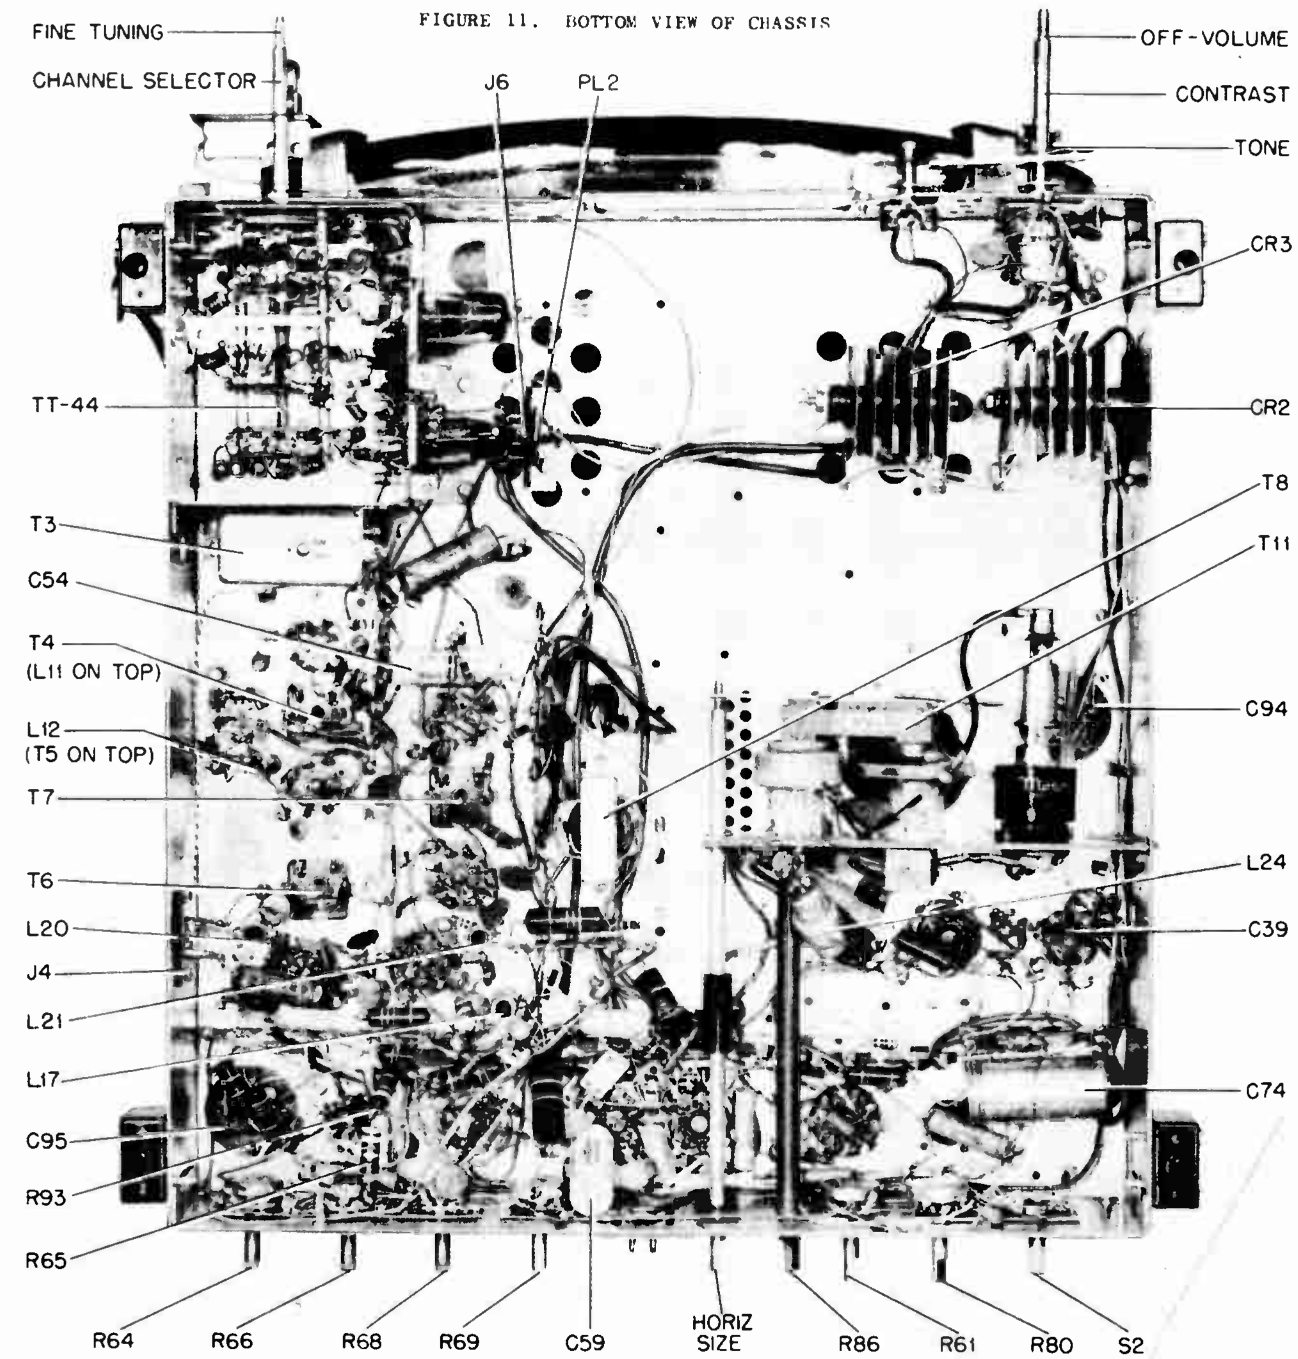
9. Check channels 7 through 13, noting whether the sound marker falls just above the trap dip, with the fine tuning trimmer at approximately mid-capacity.

10. If more than a 30 degree change in the fine tuning trimmer was needed in step 9, adjust the channel 13 oscillator coil L-8 by spreading or compressing the turns. If L-8 is adjusted, it may be necessary to readjust trimmer C-15 on channel 10. Coil L-8 has more effect on channels 10 to 13 than on channels 7 to 9.

11. Turn the station selector switch to channel 6, and set the sweep generator center frequency to 85 mc.

12. Set the fine tuning trimmer to 15° off mid-capacity (toward less capacity) as in Figure 9.

FIGURE 11. BOTTOM VIEW OF CHASSIS



NOTE: It is important that the rotor be set as nearly as possible to the drawing. Otherwise, the fine tuning trimmer may not have sufficient range to suitably tune a weak signal.

13. Introduce a marker corresponding to the sound carrier of channel 6 (87.75 mc).

14. Compress or spread the channel 6 oscillator coil L-9E until the sound marker is placed just above the dip in the 21.9 mc trap.

15. Align channels 5 through 2, in that order, in the same manner as channel 6, so that the sound marker falls just above the trap dip, with the fine tuning trimmer within 15 degrees of initial setting in step 12.

NOTE: Since the oscillator coils are in series, it is necessary to adjust the high channel coils first, before proceeding to a lower channel.

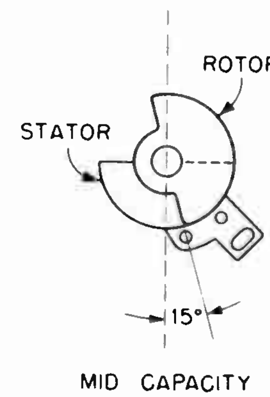


FIGURE 9. FINE TUNING TRIMMER SETTING

OVERALL SENSITIVITY MEASUREMENTS

An overall measurement of sensitivity is made as follows:

1. Connect an AM signal generator to the antenna receptacle on the receiver chassis, matching the generator to the receiver with a resistor network. In the case of a generator with a 50 ohm output impedance, insert a 100 ohm resistor in series with the output terminal, and a 150 ohm resistor in series with the ground terminal.

2. From the cathode of the picture tube (yellow lead) to chassis, connect a calibrated oscilloscope. NOTE: To calibrate scope, connect it across the 6.3 volt filament supply. The peak-to-peak amplitude on the screen will then be approximately 18V (6.3 x 2.8).

3. Set the contrast control for maximum sensitivity (fully clockwise).

4. Set the signal generator for 30% modulation at 400 cycles, tune it to the mid-carrier frequency of the channel being checked, and rotate the fine tuning trimmer for maximum output.

5. The generator signal necessary to produce 20 volts peak-to-peak on the scope should be less than:

a) 20 microvolts for channels 2 through 6
b) 30 microvolts for channels 7 through 13

4.5 MC TRAP ALIGNMENT

Equipment Required:

AM Signal Generator: Accurately calibrated at 4.5 mc Adjustable output
DC Meter: Low range electronic voltmeter

Procedure:

1. Connect the signal generator to pin 3 of test receptacle, J-4.

2. Set CONTRAST control for maximum gain (fully clockwise).

3. Connect the voltmeter and a germanium crystal detector, as shown in Figure 10, between the cathode of the picture tube (yellow lead) and chassis.

4. With the signal generator accurately set at 4.5 mc and maximum output, adjust trap L-17 for minimum reading on the lowest voltage scale of the meter.

AUDIO TAKE-OFF, INTERSTAGE COIL, & RATIO DETECTOR

Refer to Figure 4 for location of adjustments.

1. If possible, it is desirable to align the audio section from an actual station signal, since the 4.5 mc alignment frequency will be exact. To permit operation below the limiting level of the audio driver tube, for sharp alignment, the fine tuning trimmer should be turned off the station slightly so that there is between 6 and 8V as measured from one side of C-54 and chassis.

2. If a signal generator is used, tune it accurately to 4.5 mc, and adjust the output to approximately 5,000 microvolts. Connect the high side of the signal generator to pin 3 of the test receptacle and the low side to chassis. The following steps apply whether the station signal or signal generator is used.

3. From either side of electrolytic capacitor C-54 (10 mf) through a 10K ohm decoupling resistor, connect an electronic voltmeter to chassis.

4. Tune audio take-off coil L-20 for maximum reading on meter.

5. Tune interstage coil L-21 for maximum reading on meter.

NOTE: As adjustments are brought to resonance, it is advisable to reduce the signal generator output to prevent overloading.

6. Tune ratio detector (T-7) primary (top core) for maximum reading on meter.

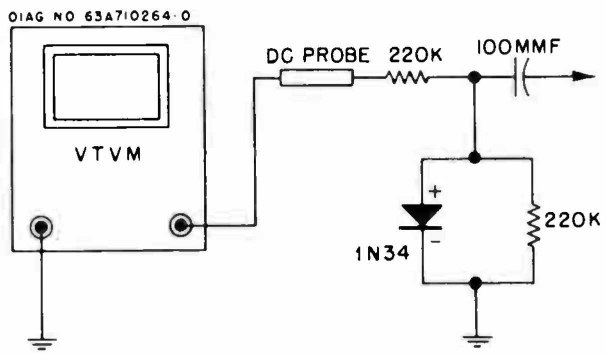

FIGURE 10. ELECTRONIC VOLTMETER CONNECTIONS

NOTE: Both the primary and secondary of the ratio detector transformer have two tuning points. Only one, with the cores at the outer end of the windings, is the proper point.

7. Move the meter and decoupling resistor to the junction of R-45 (33K) and C-55 (1000 mmf).

8. Adjust T-7 secondary (bottom core) for zero response on the lowest scale of the meter. Be sure the slug is tuned to the outside of the winding (toward the top). This corresponds to the cross-over point of the FM detector curve. If desired, the symmetry of the curve may be checked by tuning the signal generator 25 kc above and below 4.5 mc and noting the plus and minus voltage produced, reversing the meter connections, as necessary. For proper balance of the ratio detector system, the voltages in each direction should be approximately equal. If not, check the tuning of L-20, L-21, and both the primary and secondary of T-7, the ratio detector transformer. If necessary, replace the ratio detector tube V-9.

9. Repeat steps 4 through 8 for maximum accuracy.

AUDIO SENSITIVITY MEASUREMENT

1. Connect the signal generator to pin 3 of the test receptacle.

2. Connect the electronic voltmeter from either side of electrolytic capacitor C-54, through a 10K ohm decoupling resistor, to chassis.

3. Set the generator at 4.5 mc.

4. With a 5,000 microvolt signal, the AVC voltage read on the meter should be greater than 5 volts.

CHASSIS
HS-319

1. Connect a low range output meter across the speaker voice coil.

2. Connect an AM signal generator as in chart below.

3. Set the signal generator for 400 cycle, 30% modulation.

4. Rotate the PHONO-RADIO switch to the "RADIO" position.

5. Turn the receiver volume control to maximum.

6. Use a small fibre screwdriver for aligning the IF and diode transformers.

7. Adjust the signal generator output to produce 1.27 volts (.5 watts) across the voice coil. As stages are aligned, to avoid overloading the receiver, reduce the generator output to maintain the 1.27 volt level.

8. See Figure 2 for adjustment locations, and the following chart for procedure.

ALIGNMENT CHART

STEP	DUMMY ANTENNA	GENERATOR CONNECTION	GENERATOR FREQUENCY	GANG SETTING	ADJUST	REMARKS
IF ALIGNMENT						
1.	.1 mf	Grid of conv. V-2 (pin 7, 6BE6)	455 Kc	Fully opened	1, 2, 3 & 4 (IF cores)	Adjust for maximum.
RF ALIGNMENT						
2.	.1 mf	Grid of conv. V-2 (pin 7, 6BE6)	1620 Kc	Fully opened	5 (Osc)	Adjust for maximum.*
3.	-	-	-	-	-	Connect BC loop to chassis.
4.	-	Across radiation loop**	1400 Kc	Tune in signal	8 (Ant)	Adjust for maximum.

5. If, after the receiver has been aligned as above, it is found to be badly off calibration, it will be necessary to adjust oscillator core (7) as follows: connect the generator to the grid of the converter tube and, with the gang fully closed, adjust core (7) at 535 Kc. It is advisable to repeat the oscillator adjustments at 1620 Kc and 535 Kc several times until the tuning range is correct. Core (7) has been pre-set at the factory and normally should require no retuning.

* If difficulty is encountered in tuning trimmer (5), adjust trimmer (6) to 1/2 turn from tight.

** Connect generator output across 5" diameter, 5 turn loop and couple inductively to receiver loop. Keep loops at least 12" apart.

T-3	24C485553	IF Transformer: 455 Kc; complete with capacitors, cores & shield.............	.95
T-4	24K485555	Diode Transformer: 455 Kc; complete with capacitors, cores & shield.............	1.20
T-5	25B502142	Audio Output Transformer....	1.60

CHASSIS HS-319 MECHANICAL PARTS

Part Number	Description	List Price
43K890398	Bushing, line cord retainer (use with 43A890397).................	.05
43A890397	Bushing, line cord strain relief (use with 43K890398)............	.05
42A485548	Clip, coil can mtg (IF transformers)......................doz	.20
30K21859	Cord, line: with plug; 9 ft lg....	1.00
1X600490	Dial Plate Assembly: less dial scale & pointer.................	1.95
34C611148	Dial scale: glass................	.65
2S7051	Nut, hex palnut: 3/8-32 x 9/16; cad pl (control mtg).........doz	.15
28K22183	Plug, phono pick-up..............	.05
52B481704	Pointer, dial.....................	.25
1A691015	Pulley, gang drive: 3-1/2" diameter; with double D washer......	.15
9A600040	Receptacle, phono motor: 3-prong; less shell & insulator..........	.15
9A791031	Receptacle, TV power: 2-prong; less shell & insulator..........	.05
1X600489	Shaft, tuning: includes pulley....	.20
15A690616	Shell, receptacle: with insulator (for phono motor receptacle).....	.05
15K74443	Shell, receptacle: with insulator (for TV power receptacle)........	.05
9K600685	Socket, pilot light: includes mtg bracket.........................	.25
9K484167	Socket, tube: miniature; 7-prong..	.20
9A76209	Socket, tube: octal..............	.15
41A14244	Spring, tension (pointer & drive cord)........................doz	.55
37K21114	Strip, channel: rubber (dial scale mtg)...................doz	.15
29A76280	Terminal, pin (on speaker leads)doz	.45
4A70015	Washer, "C" (tuning shaft retainer)....................per/c	.50

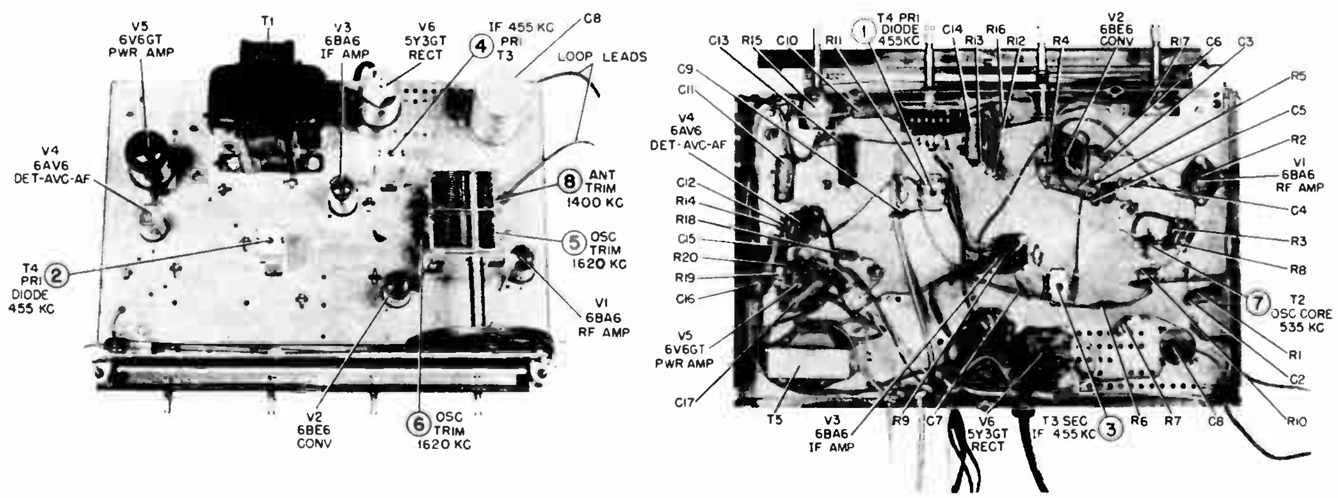

FIGURE 2. ALIGNMENT ADJUSTMENTS & PARTS LOCATIONS

SUPPLEMENT NO. 1

PRODUCTION CHANGES

Chassis Coding	Change
TS-408A-00	Original production incorporated the changes of the TS-292A-03.
TS-408A-01	Revised 3rd IF transformer. Differs from the original only in that L-13 is mounted inside the transformer shield and becomes a part of the T-6 assembly. Transformer has new part number.
TS-408A-02	C-74 changed from 20 mf to 10 mf to eliminate vertical flutter due to line voltage variations.

REPLACEMENT PARTS LIST SUPPLEMENT

NOTE: When ordering parts, specify model number of set in addition to part number and description of part. The following parts are revisions of, or additions to, the original items listed in the TS-408A Service Manual.

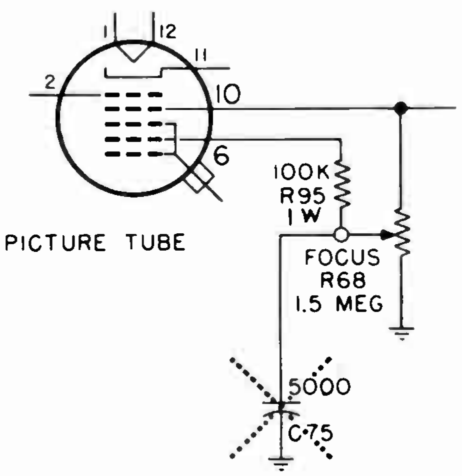
Ref. No.	Part Number	Description	List Price
C-74	23A702450	Capacitor, electrolytic: 10 mf 450V.................	1.35
T-6	24K720421	Transformer, 3rd IF: with CR-1, C-31, L-13, core & mtg base (this is electrically the same as the former transformer 24B720980 except L-13 has been added inside assembly. Use 24K720421 as replacement for 24B720980 in early chassis. The new transformer is wired the same as the old except that L-13 is inside the shield)....................	4.15

PRICES SUBJECT TO CHANGE WITHOUT NOTICE

SUPPLEMENT NO. 2

PRODUCTION CHANGE

Chassis Coding	Change
TS-408A-03	C-75 (5000 mmf) omitted and a 100K 1-watt resistor added between the focus control arm and the blue lead to the picture tube focusing anode. This adds protection to the focus control potentiometer.



Ref. No.	Part Number	Description	List Price
R-95	6R118214	Resistor, carbon: 100,000 20% 1W..................... NOTE: The value of this resistor is not critical. Substitute values of 120K and 150K may be found in some chassis. Substitutes should have at least a one-watt rating, however.	.20

REPLACEMENT PARTS LIST SUPPLEMENT

NOTE: When ordering parts, specify model number of set in addition to part number and description of part. The following part is an addition to the original items in the TS-408 Series

PARTS LIST

NOTE: When ordering parts, specify model number of set in addition to part number and description of part.

E-4	48K720969	Magnet, raster corrector: left-hand.................	.75
Pilot Light			
I-1	65X11854	Bulb: 6-8V; type 47; bayonet base......................	.15
Receptacles			
J-1 & J-2		See Tuner Parts List........	-
J-3	9A702469	Receptacle, one-pin (for alignment generator).......	.15

Ref. No.	Part Number	Description	List Price
J-4	9A702778	Receptacle, three-pin (test receptacles)	.15
J-5	9A720006	Receptacle, two-pin (for L-23 adjustment)	.20
J-6	1V720408	Receptacle, UHF; with mtg brkt	.40
J-7	9A22367	Receptacle, speaker: 5-prong; less contacts	.15
Coils			
L-1 thru L-9		See Tuner Parts List	-
L-10	24A721274	Filament choke	.10
L-11		27.9 mc trap (part of T-4)	
L-12		21.9 mc trap (part of T-5)	
L-13	24B711413	RF choke: yellow dot	.35
L-14	24K721272	Compensating coil: purple dot (wound on R-29)	.35
L-15	24K710140	Compensating coil: red dot	.35
L-16	24K721116	Compensating coil: green dot (wound on R-34)	.45
L-17	1V792736	4.5 mc trap: with core & mtg nut	.75
L-18	24K710140	Compensating coil: red dot	.35
L-19	24K721271	Compensating coil: black dot (wound on R-36)	.45
L-20	1V790341	Sound take-off: with core & mtg nut	.90
L-21	1V790341	Interstage coil: with core & mtg nut	.90
L-22	24K720622	Deflection yoke: 70°; complete less cover & centering device	11.65
L-23	24K701558	Horizontal oscillator: with core & clip	2.50
L-24	24A710751	Horizontal linearity (wound on C-92)	.85
L-25	24B711413	RF choke: yellow dot	.35
L-26	25B701075	Filter choke (mounted on PM spkr frame in combination models)	1.80
Speakers			
LS-1	50C711976		
or	50C711061		
or	50C701615		
or	50C489002	Electrodynamic: 6"; 85 ohm field coil (cold); 3.2 ohm voice coil (table models)	5.50*
		exch	4.15
	50C721467	Electrodynamic: oval; 6" x 9"; 85 ohm field coil (cold); 3.2 ohm voice coil (17K16C)	7.95*
		exch	5.95
	50K700850		
or	50C703098		
or	50C720156		
or	50C703337		
or	50C721294	Electrodynamic: 8"; 85 ohm field coil (cold); 3.2 ohm voice coil (17K14C & 17K15C)	7.25*
		exch	5.45
	50C701328		
or	50C701634		
or	50C703099		
or	50C702057		
or	50C702550	PM: 10"; 3.2 ohm voice coil; with 25B701075 filter choke mounted on spkr (combination models)	12.80*
		exch	9.60

R-83	6R2096	330,000 10% 1/2W doz	1.20
R-85	6R6080	4700 10% 1/2W doz	1.20
R-86	1V721286	Horizontal centering control: 75 ohm; with insulator & lugs	.80
R-88	1K711027	7.5 10% 5W; wire wound; with strip & eyelets	.70
R-89	6R2034	15 10% 1/2W doz	1.20
R-93	6R476012	3900 10% 2W	.25
R-94	17K721772	0.47 20% 1/2W; wire wound.	.15
Switches			
S-1		Switch, channel selector (part of tuner)	-
S-2	40A720172	Switch, Area Selector	.80
Transformers			
T-1 thru T-3		See Tuner Parts List	-
T-4	24B720977	1st IF: with L-11, C-24, core, mtg base, & shield	1.75
T-5	24B721273	2nd IF: with L-12, C-30, cores, & mtg nut	1.35
T-6	24B720980	3rd IF: with CR-1, C-31, core, mtg base & shield	3.85
T-7	24B702543	Ratio detector: with C-49, C-50, cores, mtg base & shield	3.20
T-8	25K720128	Audio output	1.80
T-9	25K702429	Vertical blocking oscillator	1.60
T-10	25K721027	Vertical output	3.40
T-11	24K721290-C	High voltage transformer: includes V-17 & horizontal centering control (specify issue "C" -early issues are not coded)	9.70
T-12	25B720749	Filament transformer	10.25

CHASSIS TS-408A - MECHANICAL PARTS

Part Number	Description	List Price
1V712011	Arms & Link Assembly, tone control: consists of two control arms, link, & anti-backlash clip.	.25
7A720122	Bracket, high-voltage (for mtg HV shield)	.05
1V720642	Bracket, picture tube support & positioning: right-hand (on front of chassis)	.80
1V720644	Bracket, picture tube support & positioning: left-hand (on front of chassis)	.75
7A710947	Bracket, selenium rectifier mtg (for 48B720081 rectifier)	.05
7B792568	Bracket, yoke mtg (across top of yoke)	.30
35K700532	Bumper, rubber (circular bumper on rear support bracket)	.15
75A721374	Bumper, rubber (on front of support & positioning brkts) doz	.25
35A700603	Bumper, rubber (for yoke)	.05
75A720718	Bumper, rubber: round (on picture tube support brkts)	.35
42A720007	Cap, plate (V-15)	.30
42A720008	Cap, plate: with lead (V-17)	.20
42K720285	Clip, retainer (for dial light)	.10
42A76244	Clip, coil retainer (L-23) doz	.25
42K721773	Clip, speed (movable clip holding rotating cover) doz	.35
42K721774	Clip, speed (stationary clip holding rotating cover) doz	.35
42A703226	Clip, tube shield (V-5)	.05
42A72609	Clip, tube shield (V-10)	.05
42K720059	Connector, 2nd anode	.50
39K711407	Contact, pin terminal (in speaker receptacle) doz	.25
46A702436	Core, iron (L-11, T-4 & T-6)	.10
46K702437	Core, iron (T-7)	.10
46A470310	Core, iron, & screw (L-12, L-17, L-20 & T-5)	.15
46A780344	Core, iron, & screw (L-23)	.45
58A702714	Coupling, shaft (couples horizontal size shaft and extension)	.10
15K721532	Cover, tuner housing (tuner bottom cover)	.40
5A790684	Grommet, rubber (V-13 & V-14 socket cushion) doz	.35
14A720238	Insulator, chassis mtg (on sides of chassis)	.20
14K712339	Insulator, control (insulates controls from chassis)	.05
14A703329	Insulator, horizontal size shaft (insulates shaft from chassis) doz	.15
14A703228	Insulator, interlock (insulates power input plug)	.05
36B712294	Knob, control: with spring insert (area selector switch)	.25
36A720197	Knob, control: push-on type (for hold controls)	.15
2A470049	Nut, coil & core mtg (L-12, L-17, L-20, & T-5) doz	.50
2S7051	Nut, hex: palnut; 3/8-32 x 3/16 (control mtg) doz	.15
35K711648	Pad, cushion (large pads on tube retaining strap)	.15
35K790169	Pad, cushion (small pad on tube retaining strap) doz	.40
9K471267	Plate, electrolytic mtg: 3-lug; wax impregnated (C-94)	.05
9A484098	Plate, electrolytic mtg: 4-lug; wax impregnated (C-95)	.05
1V703212	Plate, socket adaptor: with grommets (V-13)	.20
28K712319	Plug, line cord	.15
5A720193	Rivet, shoulder: nkl pl (V-13 & V-14 socket mtg) doz	.20

Part Number	Description	List Price
47A720282	Rod, light conducting (conducts light from bulb to dial)	.20
3K711490	Screw, thumb: cad pl (yoke adjustment)	.05
3K712076	Screw, special: slotted round head; cad pl (48B700555 selenium rectifier mtg)	.05
1A710608	Shaft & Key Assembly (horizontal centering control)	.65
47A702711	Shaft, extension (horizontal size control)	.25
47A702704	Shaft, horizontal size control (attached to core arm of T-11)	.15
1V721881	Shield, high voltage compartment: with tape	2.00
26A720284	Shield, light (for dial light)	.05
1V711012	Shield, radiation: complete (mounts with coil springs over picture tube)	.40
26A703225	Shield, tube (V-5)	.10
26A26283	Shield, tube (V-10)	.10
9K720629	Socket, picture tube: 12-pin; with leads	1.00
1V720294	Socket, dial light: with bracket & light rod clip	.45
9K702049	Socket, tube: miniature; 7-prong; 1" mc; wafer type	.20
9K702361	Socket, tube: miniature; 7-prong; with dummy lug & center shield; 1-5/16" mc; wafer type	.20
9K702360	Socket, tube: noval; molded type (V-13)	.35
9A701065	Socket, tube: octal	.20
9A480274	Socket, tube: octal (V-17)	.20
1V790307	Socket, tube: octal; cushioned type (V-14)	.40
41A70955	Spring, compression (on horizontal centering control shaft)....per/c	.50
41A721373	Spring, tension (for rotating cover)	.05
41K700032	Spring, tension (picture tube support)	.20
1V720646	Strap, picture tube retaining: with pads (around picture tube)	.60
31A700082	Strip, contact (receptacle for R-88)	.25
31A21990	Strip, terminal: two-screw (antenna terminal)	.15
4A21941	Washer, "C" (horizontal centering control shaft mtg)....doz	.15
4K73809	Washer, "C": 7/32" (on horizontal size shaft)....per/c	.50
4K24124	Washer, "C": 7/16" (on horizontal size shaft & extension)....doz	.15
4A711501	Washer, shoulder: fibre (tuner shaft mtg)....doz	.30
4K690571	Washer, shoulder: fibre (control mtg)....doz	.20
61A720692	Window, light (for dial light).doz	.20

Insulating Compounds

Part Number	Description	List Price
11M490423	Coating, high-voltage insulating: red-brn	-
11M490387	Wax, biwax	-

TUNER MODEL TT-44 - ELECTRICAL PARTS

Part Number	Description	List Price
1U720970	TT-44 Cascode Tuning Unit: complete	39.45
	exch	29.60

Capacitors

Ref. No.	Part Number	Description	List Price
C-1	21R115905	Ceramic tubular: 220 mmf 500V	.25
C-2	21R115905	Ceramic tubular: 220 mmf 500V	.25
C-3	21K720975	Ceramic disc: ribbon lead; 220 mmf 500V	.30
C-4	21R400932	Ceramic tubular:150 mmf 500V	.25
C-5	21A701029	Ceramic disc: 1500 mmf 500V.	.25
C-6	21A701029	Ceramic disc: 1500 mmf 500V.	.25
C-7	21R114554	Ceramic disc: 470 mmf 500V..	.20
C-8	21A701029	Ceramic disc: 1500 mmf 500V.	.25
C-9	21R114554	Ceramic disc: 470 mmf 500V..	.20
C-10	21A701029	Ceramic disc: 1500 mmf 500V.	.25
C-11	1V710954	Trimmer, ceramic: .5-3 mmf; with screw & mtg nut	.60
C-12	21R119049	Ceramic tubular: 22 mmf 500V (temperature compensated)..	
C-13	21A701029	Ceramic disc: 1500 mmf 500V.	.25
C-14	21R115640	Ceramic tubular: 18 mmf 500V (temperature compensated)..	.25
C-15	1V710954	Trimmer, ceramic: .5-3 mmf; with screw & mtg nut	.60
C-16	21R114071	Ceramic tubular: 1 mmf 500V (temperature compensated)..	.30
C-17		Trimmer, fine tuning (part of switch)	-
C-18	21A701029	Ceramic disc: 1500 mmf 500V.	.25
C-20	21R400936	Ceramic disc: 1000 mmf 500V.	.25
C-21	21R115312	Ceramic disc: 5000 mmf 450V.	.25
C-22	21A701029	Ceramic disc: 1500 mmf 500V.	.25
C-97	21C119295	Ceramic tubular: 27 mmf 500V (temperature compensated)..	.25
C-98	21R115959	Molded phenolic: 1.5 mmf 500V	.10
C-99	21R114153	Ceramic tubular: 47 mmf 500V (temperature compensated)..	.10

Receptacles

Ref. No.	Part Number	Description	List Price
J-1	9K703309	Receptacle, two-pin (antenna receptacle)	.15
J-2	9A702469	Receptacle, one-pin (for alignment generator)	.15

Coils

Ref. No.	Part Number	Description	List Price
L-1A,B	24K721337	Antenna primary: low frequency; channels 2-5	.20
L-1C	24K721489	Antenna primary: low frequency; channel 6	.20
L-1D, E & F	24K721338	Antenna primary: high frequency; channels 7-13	.15
L-2	24K721210	Antenna coil: channels 2 thru 6; includes L-2A thru L-2E (high channel coils are part of switch)	.25
L-3	24K721257	Neutralization coil	.10
L-4	24B721256	Neutralization coil	.05
L-5	24A721274	Filament choke	.10
L-6	24A721394	RF coil: channel 13	.15
L-7	24K721209	RF coil: channels 2 thru 6; includes L-7A thru L-7E (high channel coils are part of switch)	.25
L-8	24K703077	Oscillator coil: channel 13.	.10
L-9	24C721208	Oscillator coil: channels 2 thru 6; includes L-9A thru L-9E (high channel coils are part of switch)	.10

Resistors

Note: All resistors are insulated carbon type

Ref. No.	Part Number	Description	List Price
R-1	6R6397	22,000 10% 1/2W....doz	1.20
R-2	6R6032	470,000 20% 1/2W....doz	1.20
R-3	6R5550	47 10% 1/2W....doz	1.20
R-4	6R6377	470,000 10% 1/2W....doz	1.20
R-5	6R5700	1500 10% 1W	.20

R-13	6R6014	330,000 20% 1/2W....doz	1.20
R-14	6R6301	1000 20% 1/2W....doz	1.20
R-15	6R6117	5600 10% 1/2W....doz	1.20

Transformers

Ref. No.	Part Number	Description	List Price
T-1	24B720936	Antenna impedance matching transformer	.75
T-2	24B720936	Antenna impedance matching transformer	.75
T-3	24B720937	Mixer IF: complete with shield, cores, & mtg base..	1.55

TUNER MODEL TT-44 - MECHANICAL PARTS

Part Number	Description	List Price
42K703087	Clip, spring: phosphor bronze (around collar on fine tuning shaft)	.10
46A702436	Core, iron (T-3)	.10
14K721396	Insulator, tuning core (L-6)	.05
2S400482	Nut: palnut (C-11, C-15 & L-6 mtg)....doz	.15
1K702822	Rotor plate, fine tuning: with bushing	.25
3S118702	Screw, machine: 5-40 x 1; slotted round head (L-6 adj)....doz	.15
3S9650	Screw, machine: 6-32 x 3/4 slotted round head (C-11 & C-15 adj)..doz	.15
47K720256	Shaft, fine tuning	1.25
9K720941	Socket, tube: noval (V-1)	.20
9K712224	Socket, tube: noval (V-2)	.20

MODEL 17F13C CABINET PARTS

Part Number	Description	List Price
24C690896	Antenna, loop, & panel (radio)	1.40
15C721218	Back cover (radio)	1.75
1V721216	Back cover (TV): complete with picture tube rear cover & line cord.	3.45
13K720279	Bezel, picture tube (window frame)	9.05
7A720704	Bracket, bezel retaining	.10
16F720722	Cabinet, combination: red-brn mahogany; less window, mask, & bezel	**
55K712372	Castor: includes 55K712373 gripneck	.85
55K72307	Catch, bullet: statuary bronze finish (door latch-on cabinet)	.10
42A720717	Clip, speed (bezel & window assembly mtg)	.05
35K720727	Cloth, grille: brown & gold;11-1/2 x 16-1/8	4.40
1V790756	Cord, line: with plug & receptacle (TV back cover)	1.35
15D721138	Cover, cabinet bottom (under TV chassis)	1.30
15B710068	Cover, picture tube rear (on back cover)	.65
13C791478	Escutcheon, radio dial: brass	3.75
55K790731	Hinge, stop: LH (at top of lower door)	.30
55K790733	Hinge, stop: LH (at LH top and RH bottom of upper doors)	.25
55K712289	Hinge, stop: RH (at bottom of lower door)	.25
55K712169	Hinge, stop: RH (at RH top and LH bottom of upper doors)	.25
36B720253	Knob, control: channel selector; includes front & rear knobs	1.50
36C720252	Knob, control: contrast	.65
36B720250	Knob, control: fine tuning & off-volume	.50
36C701150	Knob, control: radio	.45
36C720251	Knob, control: tone (TV)	.50
1V720754	Mask, picture tube: with gasket	3.05
1V721114	Medallion, UHF: with insert	1.30
2S490840	Nut: speednut; 1/16" (medallion mtg)....doz	.15
2S118784	Nut: speednut; 5/16" (med plate mtg)....doz	.15
64A720785	Plate, medallion mtg....doz	.40
55K720092	Pull, door (lower door)....pr	1.55
55K720728	Pull, door (upper door)....pr	3.60
5K791856	Rivet, shoulder (TV line cord mtg)	.05
3S114993	Screw, machine: 1/4-20 x 1-3/4 plain hex head; cad pl (TV chassis mtg)....doz	.50
3S7534	Screw, sheet metal: #8 x 1-3/8 plain hex head; cad pl (radio chassis mtg)....doz	.15
55K72308	Strike, bullet: statuary bronze finish; with 1/2" steel nail (door latch - on door)	.15
64K791029	Tracks, record changer....pr	5.90
61D720245	Window, picture tube	7.00

MODEL 17F13BC CABINET PARTS - Same as 17F13C except:

Part Number	Description	List Price
16K720723	Cabinet, combination: limed oak; less window, mask, & bezel	**
55K482792	Catch, bullet: brs (door latch - on cabinet)	.10
35K720726	Cloth, grille: eggshell & gold; 11-1/2 x 16-1/8	4.40
55K712168	Hinge, stop: semi-invisible; brs; LH (at LH top & RH bottom of upper doors)....pr	.55
55K790734	Hinge, stop: semi-invisible; brs; RH (at RH top & LH bottom of upper doors)....pr	.55
55K790732	Hinge, stop: semi-invisible; brs; LH (top of lower door)	.45
55K712288	Hinge, stop: semi-invisible; brs; RH (at bottom of lower door)	.20
55K482793	Strike, bullet: brass; with 1/2" steel nail (door latch - on door)	.10

MODEL 17K14C CABINET PARTS

Part Number	Description	List Price
1V720799	Back cover: with picture tube rear cover & line cord	4.00
13K720279	Bezel, picture tube (window frame)	9.05

Part Number	Description	List Price
7A720704	Bracket, bezel retaining	.10
16F720232	Cabinet, console: red-brn mahogany; less window, mask, & bezel	**
55K712372	Castor: includes 55K712373 gripneck	.85
42A720717	Clip, speed (window & bezel assembly mtg)	.05
35K720235	Cloth, grille: mahogany and gold; 19-15/16 x 14	3.70
30K712361	Cord, line: with plug & receptacle	1.25
15D721142	Cover, cabinet bottom	1.30
15B710068	Cover, picture tube rear (on back cover)	.65
36B720253	Knob, control: channel selector; includes front & rear knobs	1.50
36C720252	Knob, control: contrast	.65
36B720250	Knob, control: fine tuning & off-volume	.50
36C720251	Knob, control: tone	.50
1V720754	Mask, picture tube: with gasket	3.05
1V721114	Medallion, UHF: with insert	1.30
2S490840	Nut: speednut; 1/16" (medallion mtg) doz	.15
2S118784	Nut: speednut; 5/16" (medallion plate mtg) doz	.15
64A720785	Plate, medallion mtg doz	.40
5K791856	Rivet, shoulder (line cord mtg)	.05
3S114993	Screw, machine: 1/4-20 x 1-3/4 plain hex head; cad pl (chassis mtg) doz	.50
61D720245	Window, picture tube	7.00

MODEL 17K14BC CABINET PARTS - Same as 17K14C except:

Part Number	Description	List Price
16K720233	Cabinet, console: limed oak; less window, mask, & bezel	**
35K720236	Cloth, grille: eggshell & gold; 19-15/16 x 14	3.70

MODEL 17K14WC CABINET PARTS - Same as 17K14C except:

Part Number	Description	List Price
16K720234	Cabinet, console: walnut; less window, mask, & bezel	**
35K720237	Cloth, grille: walnut & gold; 19-15/16 x 14	3.70

MODEL 17K15C CABINET PARTS

Part Number	Description	List Price
1V720799	Back cover: complete with picture tube rear cover & line cord	4.00
13K720279	Bezel, picture tube (window frame)	9.05
7A720704	Bracket, bezel retaining	.10
16F720763	Cabinet, console: red-brn mahogany; less window, mask, & bezel	**
55K712372	Castor: includes 55K712373 gripneck	.85
55B72307	Catch, bullet: statuary bronze (door latch - on cabinet)	.10
35K720768	Cloth, grille: mahogany & gold; 12-5/8 x 19-3/4	3.15
42A720717	Clip, speed (window & bezel assembly mtg)	.05
15D721138	Cover, cabinet bottom	1.30
30K712361	Cord, line: with plug & receptacle	1.25
15B710068	Cover, picture tube rear (on back cover)	.65
55K790733	Hinge, stop: semi-invisible; statuary bronze finish; LH (at LH top & RH bottom) pr	.50
55K712169	Hinge, stop: semi-invisible; statuary bronze finish; RH (at RH top & LH bottom) pr	.50
36B720253	Knob, control: channel selector; includes front & rear knobs	1.50
36C720252	Knob, control: contrast	.65
36B720250	Knob, control: fine tuning & off-volume	.50
36C720251	Knob, control: tone	.50
1V720754	Mask, picture tube: with gasket	3.05
1V721114	Medallion, UHF: with insert	1.30
2S490840	Nut: speednut; 1/16" (med mtg) doz	.15
2S118784	Nut: speednut; 5/16" (medallion plate mtg) doz	.15

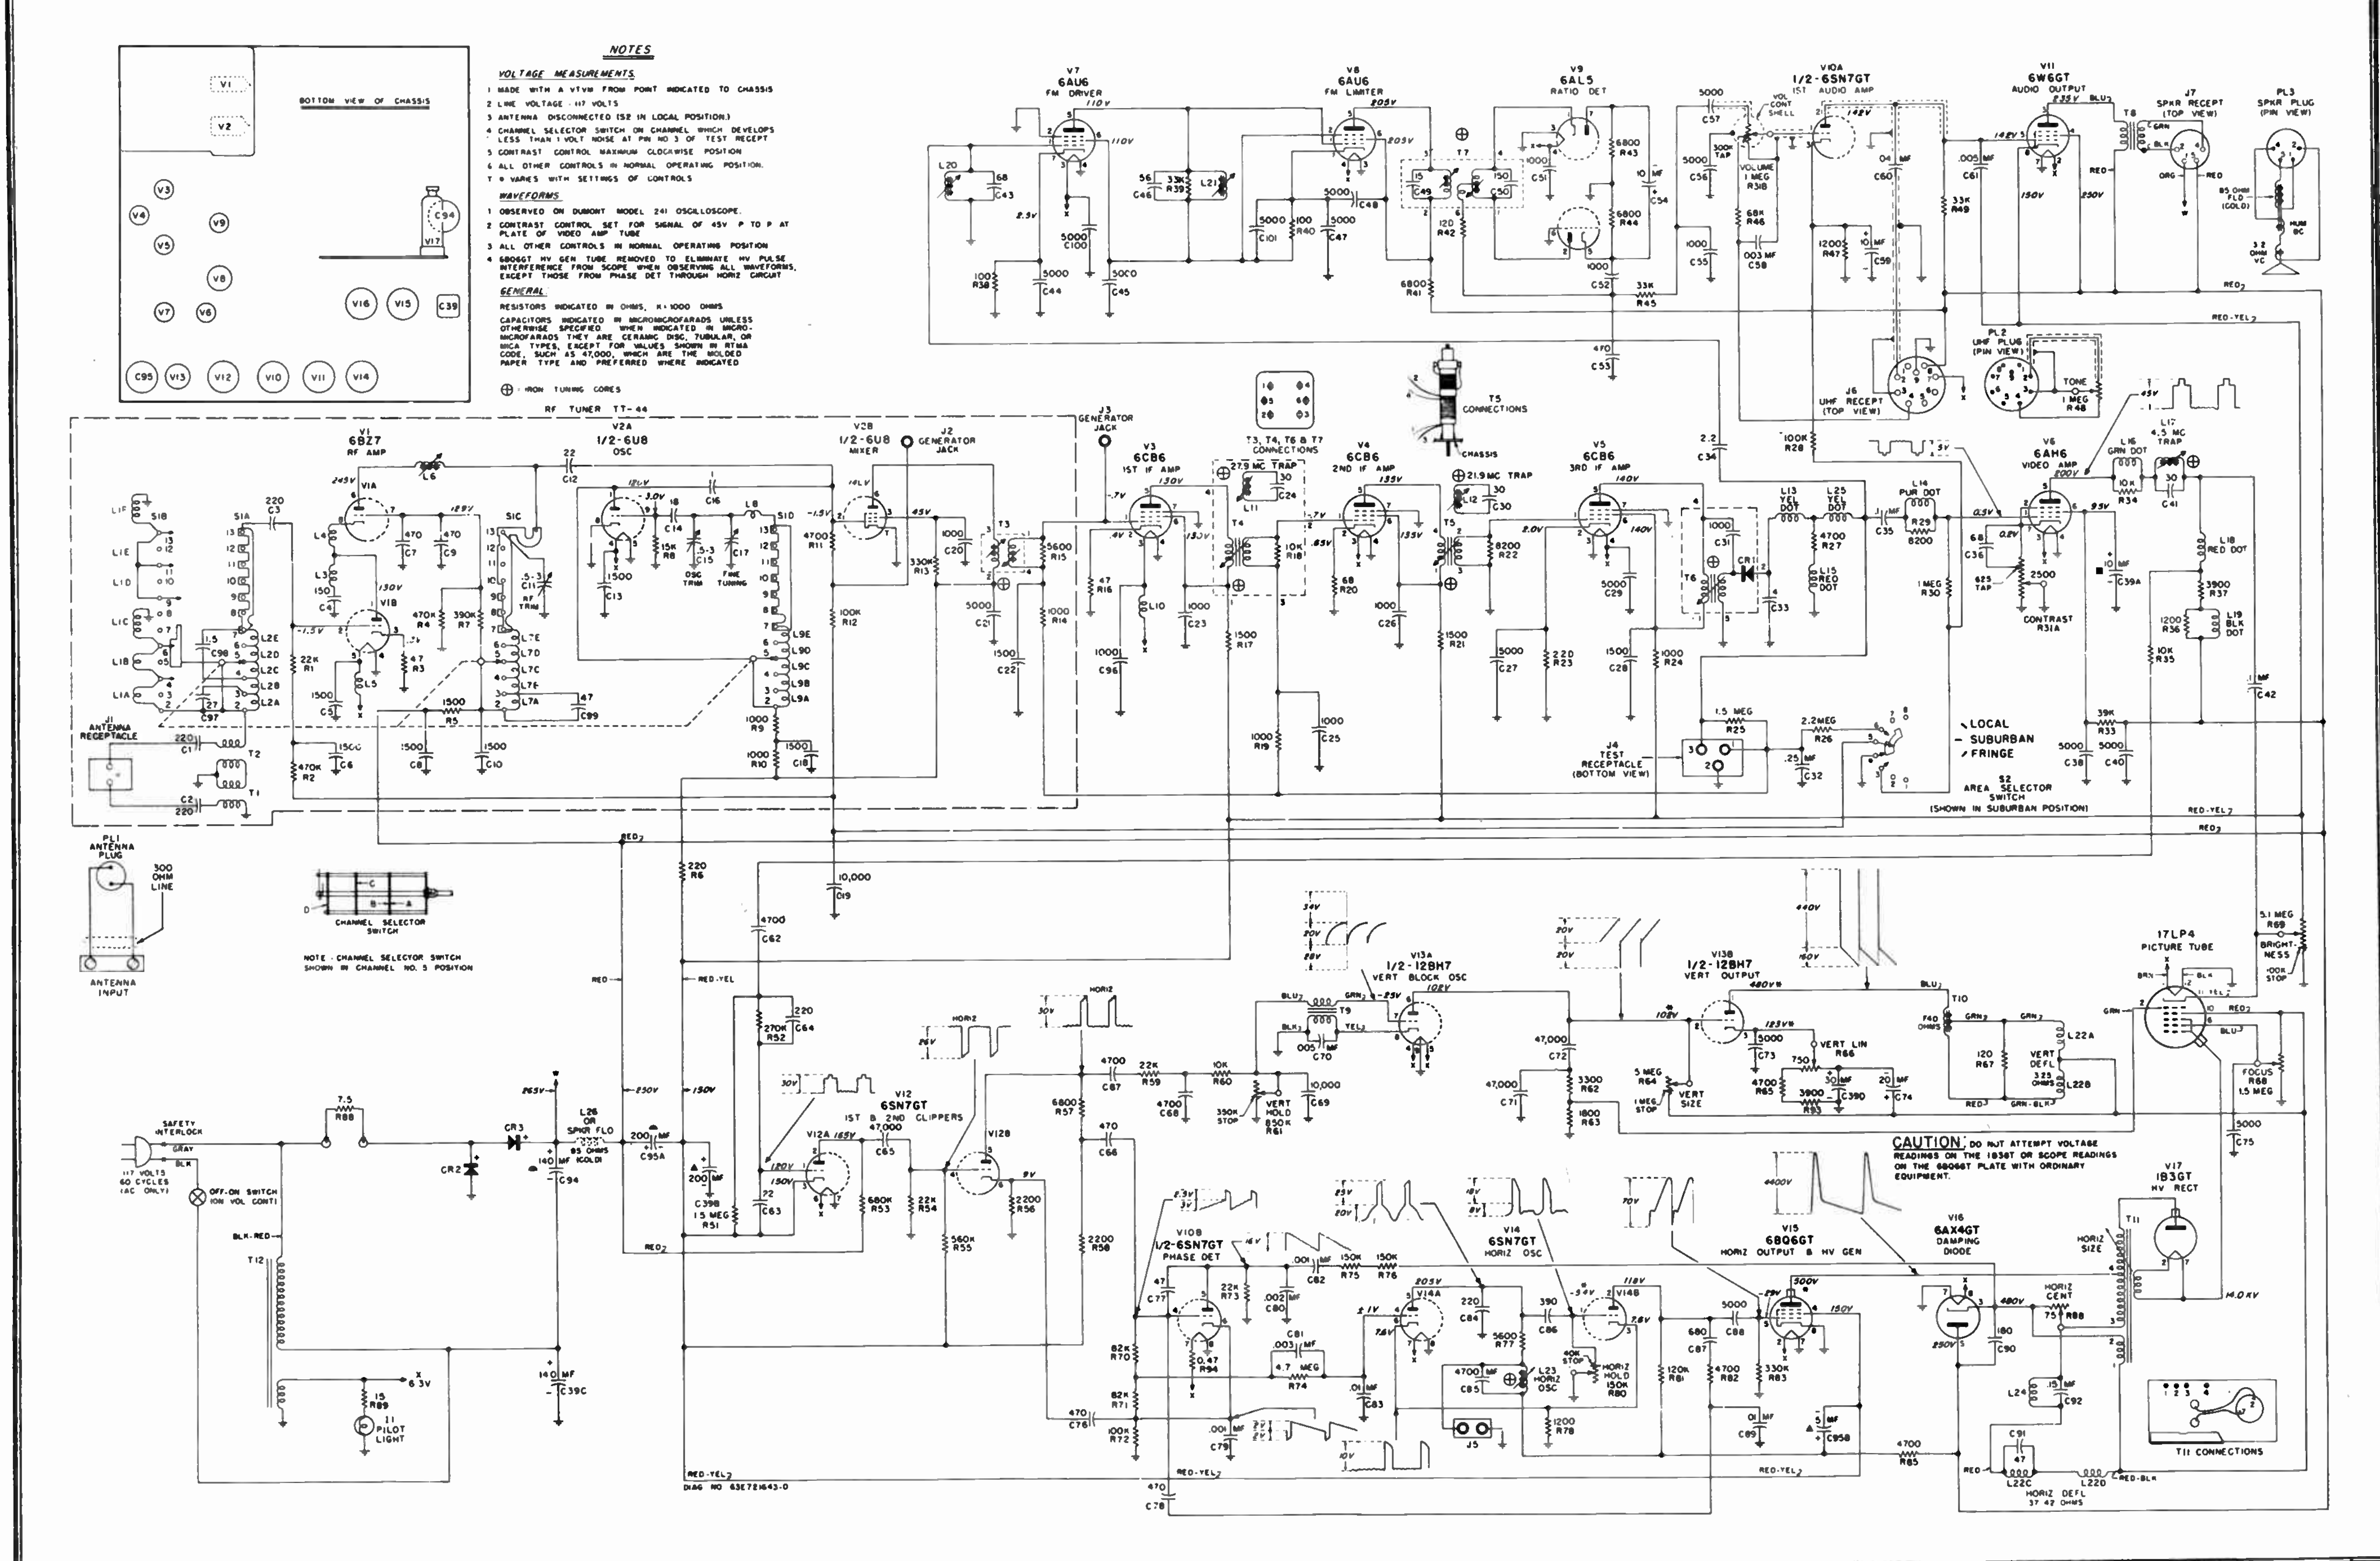
TELEVISION CHASSIS TS-408A-00



NOTES

VOLTAGE MEASUREMENTS.

1 MADE WITH A VTVM FROM POINT INDICATED TO CHASSIS
2 LINE VOLTAGE - 117 VOLTS
3 ANTENNA DISCONNECTED (S2 IN LOCAL POSITION.)
4 CHANNEL SELECTOR SWITCH ON CHANNEL WHICH DEVELOPS LESS THAN 1 VOLT NOISE AT PIN NO 3 OF TEST RECEPT
5 CONTRAST CONTROL MAXIMUM CLOCKWISE POSITION
6 ALL OTHER CONTROLS IN NORMAL OPERATING POSITION.
7 • VARIES WITH SETTINGS OF CONTROLS

WAVEFORMS

1 OBSERVED ON DUMONT MODEL 241 OSCILLOSCOPE.
2 CONTRAST CONTROL SET FOR SIGNAL OF 45V P TO P AT PLATE OF VIDEO AMP TUBE
3 ALL OTHER CONTROLS IN NORMAL OPERATING POSITION
4 6BQ6GT HV GEN TUBE REMOVED TO ELIMINATE HV PULSE INTERFERENCE FROM SCOPE WHEN OBSERVING ALL WAVEFORMS, EXCEPT THOSE FROM PHASE DET THROUGH HORIZ CIRCUIT

GENERAL

RESISTORS INDICATED IN OHMS, K=1000 OHMS

CAPACITORS INDICATED IN MICROMICROFARADS UNLESS OTHERWISE SPECIFIED. WHEN INDICATED IN MICRO-MICROFARADS THEY ARE CERAMIC DISC, TUBULAR, OR MICA TYPES, EXCEPT FOR VALUES SHOWN IN RTMA CODE, SUCH AS 47,000, WHICH ARE THE MOLDED PAPER TYPE AND PREFERRED WHERE INDICATED

⊕ = IRON TUNING CORES

SUPPLEMENT NO. 3

GENERAL INFORMATION

This service manual supplement contains a supplementary parts list and a record of production changes for the TS-408 series chassis (from TS-408A-04 thru TS-408B-03), a listing of receivers not included in previous service manuals or supplements, and replacement parts for chassis and receivers containing factory-installed UHF tuners.

CHASSIS DESCRIPTION

The basic chassis is TS-408. Suffixes (A-04, B-01 etc.) to this basic number indicate production changes. A "Y" suffix designates a chassis containing a factory-installed UHF tuner.

CHASSIS TS-408 SERIES

Refer to TS-408A Service Manual and Supplements No. 1 and No. 2 for service information on chassis TS-408A through TS-408A-03. This manual contains supplementary data on chassis TS-408A-04 through TS-408B-03.

CHASSIS TS-408Y SERIES

Chassis model numbers with a "Y" suffix (TS-408AY-04) indicate that the chassis contains factory-installed UHF tuners. The TS-408Y series chassis uses the TT-52M UHF tuning unit. Refer to the TT-52M for service data and UHF tuning unit replacement parts.

RECEIVER MODEL CHART

Model	Type of Set	TV Chassis Used	Radio Chassis Used	Record Changer Used
17F13BCY	Combination, limed oak	TS-408Y	HS-319	RC-40
17F13CY	Combination, red-brn mahogany	TS-408Y	HS-319	RC-40
17F13F	Combination, red-brn mahogany	TS-408	HS-319	C3RC
17F13FB	Combination, limed oak	TS-408	HS-319	C3RC
17F13FBY	Combination, limed oak	TS-408Y	HS-319	C3RC
17F13FY	Combination, red-brn mahogany	TS-408Y	HS-319	C3RC
17K14BCY	Console, limed oak	TS-408Y		
17K14CY	Console, red-brn mahogany	TS-408Y		
17K14WCY	Console, walnut	TS-408Y		
17K15CY	Console, red-brn mahogany	TS-408Y		
17K16CY	Console, white birch (with detachable legs)	TS-408Y		
17T11CY	Table, walnut plastic	TS-408Y		
17T11ECY	Table, ebony plastic	TS-408Y		
17T12CY	Table, red-brn mahogany	TS-408Y		
17T12BCY	Table, limed oak	TS-408Y		
17T12WCY	Table, walnut	TS-408Y		

PRODUCTION CHANGES

Chassis Coding	Changes
TS-408A-04	Fusing wire (F-1) added to filament circuit.
TS-408A-05	R-82 (4700) changed to 6800 ohms. R-85 (4700) changed to 6800 ohms. C-80 (.002) changed to 4700 mmf, to reduce horizontal overdrive and fold-over.
TS-408A-06	R-62 (3300) changed to 1800 ohms and R-63 (1800) changed to 3300 ohms, to increase blanking pulse at the grid of the picture tube. (This change does not occur in some chassis until "B-01".)
TS-408A-07	The On-Off switch moved to the high side of the AC line.
TS-408B-00	NOTE: Chassis marked "B-00" do not incorporate the change listed under "A-06". Compensating coil L-16 and L-17 (4.5 mc trap) interchanged, to improve video response.
	"Framelock" circuit added, as listed below, to improve vertical sync under noise conditions: C-103 (33), C-104 (22), R-96 (1000) and L-27 added to 3rd IF stage. C-28 (1500) changed to 1000 mmf. C-105 (470) and R-97 (15K) added to video amplifier stage. C-63 (22) removed from 1st clipper.
TS-408B-01	These chassis incorporated all changes listed under "A-06" and "B-00".
TS-408B-02	R-53 (680K) changed to 1 meg, to improve interlace.
TS-408B-03	C-75 (5000 mmf, 2000V) added from picture tube focusing anode (blue lead) to chassis and C-73 (5000 mmf) changed to capacitor with 2000V rating, to prevent high voltage flash-over within the picture tube and the vertical output tube, respectively.

SERVICE NOTES

CAUTION: If the 6BQ6GT horizontal output tube is removed during alignment, be sure to insulate the plate cap to prevent its shorting to the chassis and ruining the high voltage transformer.

REPLACEMENT PARTS LIST SUPPLEMENT

NOTE: When ordering parts, specify model number of set in addition to part number and description of part. The following parts are additions to the original items in the TS-408 Service Manuals.

TS-408B ELECTRICAL PARTS - Same as TS-408A except:

Ref. No.	Part Number	Description	List Price
Capacitors			
C-28	21R115386	Ceramic disc: 1000 mmf 500V.	.25

SS-0039

SPECIFICATIONS

OPERATING LINE VOLTAGE — 108 to 125 Volts 60 Cycle A.C.

CHANNEL COVERAGE—VHF Channels 2 to 13 inclusive; UHF Channels 14 to 83 with "Snap-in" adapter strips.

I.F. VIDEO CARRIER 25.1 MC — I.F. SOUND CARRIER 20.6 MC.

POWER CONSUMPTION — 235 Watts.

AUDIO POWER OUTPUT — 1.5 Watts Undistorted — measured with standard load.

LOUD SPEAKER — 10" P.M. Type using Alnico 5.

VOICE COIL IMPEDANCE — 3.2 Ohms at 400 Cycles.

PROTECTIVE FUSE.

HIGH VOLTAGE — 18,000 Volts at 2nd Anode.

OTHER ADVANTAGES ARE: ONE KNOB picture control — HIGH GAIN channel selector — R.F. STAGE on ALL channels — SNAP-IN COILS in tuner gives selection of VHF and UHF stations. — BALANCED 300 Ohm impedance input to tuner or 72 Ohm unbalanced line — SYNCHROGUIDE A.F.C. reduces noise interference in picture — DARK FLUORESCENT EYE SAVER picture tube — INTERCARRIER SOUND limits the drift to a minimum amount while locking the sound to the picture. — IMPROVED high voltage flyback circuit for BRIGHTER pictures and BETTER contrast — HIGH FIDELITY F.M. SOUND — INVERSE FEEDBACK for improved audio response — FOUR I.F. transformers for better SELECTIVITY and RESOLUTION — PLATE VOLTAGE REGULATION for smoother over-all performance — MODERATE TEMPERATURE RISE — CONVENIENT SERVICE ADJUSTMENTS — ANTI-GLARE picture mask — SAFETY GLASS protection — HAND-RUBBED WOOD cabinets of many styles. APPROVED BY NATIONAL BOARD OF UNDERWRITERS.

HIGH VOLTAGE WARNING

Operation of this receiver with interlocked back cover removed involves a shock hazard from the receiver power supplies. Work on this receiver should not be attempted by anyone who is not thoroughly familiar with the precautions necessary when working on high voltage equipment.

CATHODE RAY TUBE HANDLING PRECAUTIONS

Shatterproof goggles and heavy gloves should be worn at all times when handling the cathode ray tube. The tube should not be handled in the vicinity of any person not so equipped. When handling the cathode ray tube, always keep it away from the body. It is fitting and proper to request the customer and his children to leave the room during a Picture tube exchange.

The cathode ray tube bulb, due to its large surface area and high vacuum contained within, is subjected to high air pressure. More than ordinary care is required to prevent shattering the tube. The large end of the bulb, particularly the rim of the viewing surface, must not be struck, scratched, or subjected to more than moderate pressure at any time. If the tube sticks or fails to slip smoothly into place during replacement, remove the tube and determine the cause of the trouble.

DO NOT FORCE THE TUBE

FRONT PANEL SERVICE CONTROLS

(located under Muntz nameplate)

HORIZONTAL HOLD: The horizontal hold control locks the horizontal oscillator to the frequency of the transmitted sync. pulse. Rotating the control clockwise the picture should fall out of sync. showing one vertical blanking bar. The picture should remain in horizontal sync. when rotating the H. hold control counter clockwise. (See horizontal A.F.C. Alignment, Page 4.)

VERTICAL HOLD: The vertical hold control locks the vertical sweep with the transmitted sync. pulse. Set the vertical hold where the picture snaps into vertical lock.

BRILLIANCE: Adjust the brilliance control in combination with the picture control for the most pleasing picture. Set the brilliance to a point where the picture control will give a dark black, a brilliant white, and varying degrees of grey.

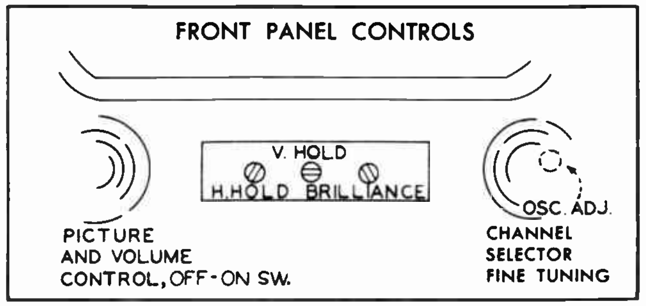

Figure No. 1

REAR CHASSIS SERVICE CONTROLS

VERTICAL LINEARITY AND VERTICAL SIZE: The Vertical linearity and Vertical size controls should be adjusted simultaneously to fill the picture mask vertically and in the proper proportions. The Vertical Size controls picture heights and the Vertical linearity picture proportion.

HORIZONTAL DRIVE: This control affects picture width and horizontal linearity, particularly the left side of the picture. This control somewhat affects the horizontal A.F.C. alignment. See Page 4. The correct setting of the Drive trimmer is at the point where the drive line is eliminated.

HORIZONTAL RANGE: See Horizontal A.F.C. Alignment (Page 4).

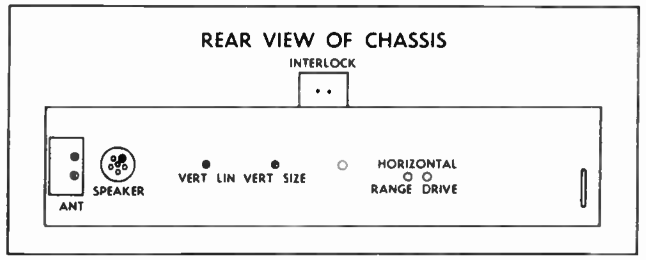

Figure No. 2

DEFLECTION YOKE ADJUSTMENT

If picture is tilted, loosen the wing nut on the deflection yoke coil and slightly rotate the yoke coil until picture is straight. Before tightening the wing nut, make sure that the deflection yoke is moved as far forward as possible, otherwise corners of the raster may be shaded. See Centering Adjustment.

PICTURE TUBE ADJUSTMENTS

ADJUSTMENT OF ION TRAP

To prevent serious damage to the picture tube the following method of adjustment should be used: Place the Ion Trap so that it is near the picture tube base socket, and adjust the Brilliance control 80° counter-clockwise before turning set on.

Turn set on and allow for normal warm-up time. Move the Ion Trap a short distance forward or backward at the same time rotating it until the point of optimum raster brightness is found. Reduce brilliance and reset ion trap for maximum screen brilliance.

CAUTION: Keep brilliance control at low intensity until the ion trap is properly set.

DO NOT at any time adjust the ion trap to correct for centering or a shadowed raster. (See focalizer adjustment).

If the focus adjustment, centering lever, focalizer or deflection yoke are in any way readjusted or changed, the ion trap should again be readjusted for maximum brilliance.

ALWAYS MAKE THE ION TRAP THE FIRST AND LAST ADJUSTMENT.

FOCALIZER ADJUSTMENT

The focalizer is used to center the picture with the best possible line detail. Adjustments are provided as shown in Fig. 3 or Fig. 4.

The focalizer should be positioned as close to the deflection yoke as is consistent with good line detail and correct picture centering.

CENTERING ADJUSTMENT

Push deflection yoke forward on neck of tube against the flare (See deflection yoke adjustment). Centering Lever — Vertical movement of the lever shifts the picture horizontally; horizontal movement of the lever controls the vertical positioning. If picture is difficult to center or neck shadow is present, loosen and reposition focalizer.

FOCUS ADJUSTMENT

Focus is made by rotating the Focus Adjustment located on the focalizer assembly. Set the picture control to a normal picture and the Brilliance control to a slighty above average brightness. Rotate the focus adjustment until the picture is in sharp focus with the clearest line detail throughout the picture.

INDIVIDUAL CHANNEL ADJUSTMENT

The tuner is completely and accurately aligned at the factory, however, for best performance it is necessary to touch up the oscillator coil tuning slug on each of the operating channels.

The oscillator coil tuning slugs may be reached by removing the channel selector knob and the fine tuning knob. See Fig. 1.

A. Turn the TV set on and allow a 10 minute warm-up period.

B. Turn channel selector to an operating channel. Remove channel selector and fine tuning knobs.

C. Set fine tuning control shaft to center of its range.

D. Turn up volume control and picture control to a normal setting.

E. Use a non-metallic screwdriver and adjust slug for most efficient compromise of both sound and picture. Repeat procedure for each operating channel.

CAUTION: Do not screw slug past its thread limitations as it will drop into coil form. Always start by turning the adjusting slug in a counter-clockwise direction.

ADJUSTING THE HORIZONTAL A. F. C. IN THE HOME

A receiver which requires horizontal sync. adjustment may be corrected by following the procedure given below.

Check to see if adjustment is necessary by rotating the H. hold control located under the MUNTZ nameplate. The picture should hold as follows:

A. Fully counter-clockwise, the picture should remain in horizontal sync.

B. Rotate the H. hold control fully clockwise and the picture should fall out of sync. showing one vertical bar (on weak signals up to 3½ bars are acceptable).

If the horizontal A.F.C. does not fill the above requirements the circuit needs readjusting. Before making these adjustments, try replacing the following tubes V-14 HOR. AFC. & OSC. (6SN7), V-11 Sync. Separator (12AT7).

A. Reset the horizontal range trimmer (Fig. 2) ¼ turn out from full "in" position.

B. Tune in station and set picture control below a normal-contrast condition.

C. Turn H. Hold control to a full clockwise position and adjust top slug of horizontal A.F.C. can (T6) (See Fig. 20) until picture snaps into horizontal sync. with one bar. Rotating control counter-clockwise picture should remain in sync. the H. Hold should normally be set 20 degrees counter-clockwise from where the picture pulls into horizontal sync.

If the above conditions can not be met, the horizontal A.F.C. circuit needs complete alignment. Follow instructions "Complete alignment of A.F.C."

2nd Anode Voltage 18 KV. Use a KV meter or V.T.V.M. with special High Voltage Probe. Set Contrast to maximum and Brightness to minimum and adjust Horz. Drive Trimmer to where the drive line just disappears.

ALIGNMENT INSTRUCTIONS

When observing the television receiver band pass characteristics on the scope, it is important to avoid distortion of the response curve which would occur when using an abnormal signal input from the sweep and marker generators.

Always set the generator attenuator below the point where its output voltage starts to alter the shape of the response curve shown on the scope. This applies to both sweep and marker generators.

Figure No. 6

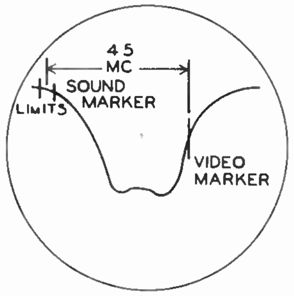

Figure No. 7

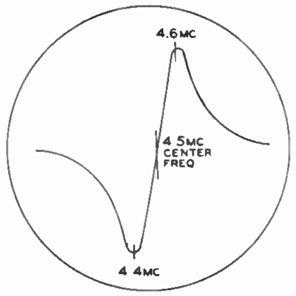

Figure No. 11

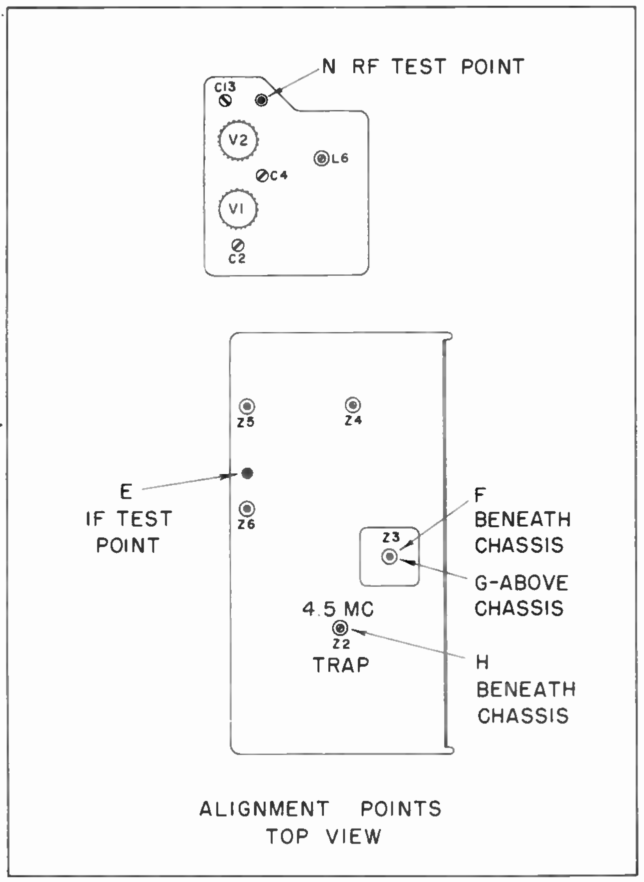

Figure No. 8

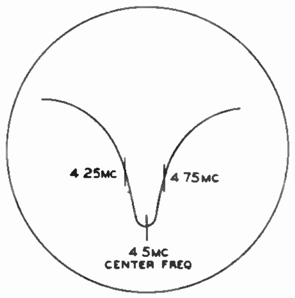

Figure No. 9

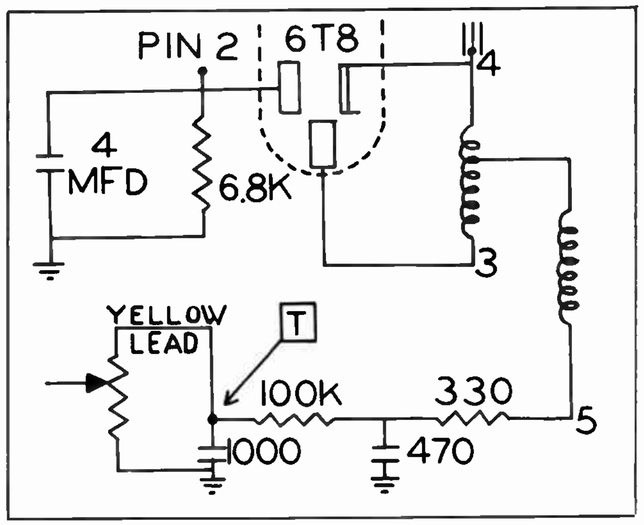

Figure No. 10

COMPLETE ALIGNMENT OF HORIZONTAL OSCILLATOR A. F. C.

1. Tune in a known good signal (test pattern where possible) and adjust the contrast control well below an over-contrast condition.
2. Turn both Horz. Osc. slugs out of coil can No. LO-0039 (T-6) as far as possible. Caution: For manufacturing convenience both of the oscillator adjustments are within the can No. LO-0039. If the Horz. Osc. slugs are turned too far in, a coupled condition is reached which is undesirable.
3. Place jumper wire between terminals C and D of T-6.

BENEATH CHASSIS

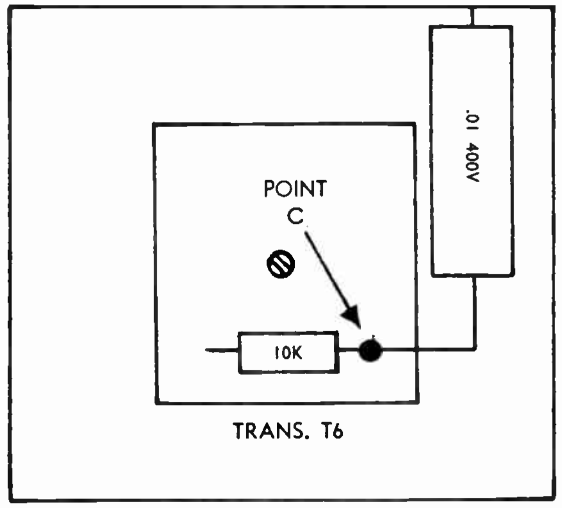

Figure No. 12

4. Preset Horz. Range Trimmer ¼ turn out from full "in" position. Turn Horz. Hold control fully clockwise. Through adjustment of top slug of T-6 cause the picture to sync. If necessary, re-adjust Horz. Range Trimmer slightly in order to sync picture.
5. With picture in sync., check picture width and linearity, adjusting Horz. Drive until a normal picture is obtained.
6. Remove jumper between terminals C and D of T-6. Picture should remain in sync. If it does not, re-adjust Horz. Range Trimmer or top slug of T-6. *IMPORTANT:* The Oscilloscope used in the following adjustment must have a flat vertical amplifier response up to 500 K. C. or better or a false waveform will result. A scope with poor vertical response will show a perfect waveform as shown in Figure 12A but when checked against a good wide band oscilloscope, the waveform will be found to have considerable tilt. This is highly undesirable because the bottom core is not adjusted properly, although we are led to believe it is. We stress the importance of a good Wide Band Scope such as the Sylvania Model 400 T.V. Oscilloscope or equivalent. Fig. 12 and 12A.
7. Connect scope having a 5 mmf. condenser in series with the vertical lead to point C Fig. 12. Adjust bottom slug of T-6 until the broad and sharp peaks are of equal height (Fig. 12A) keeping picture in sync at all times. If picture goes

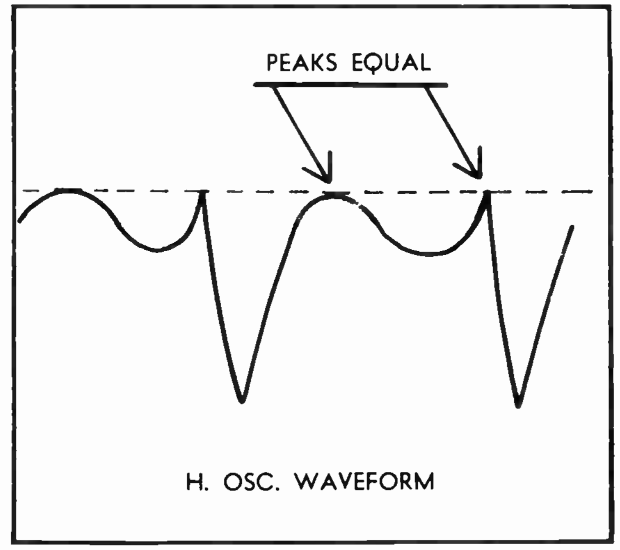

Figure No. 12A

out of sync. at any time repeat procedure under step 6. If the picture still goes out of sync., there is a defect in the Horz. control and A.F.C. circuit. Try a new 6SN7 tube before checking further.
The above adjustment is very important to correct circuit operation. If the broad peak is lower than the sharp peak the noise immunity becomes poor, hence the osc. is not stabilized as well resulting in greater drift. If the broad peak is higher than the sharp peak, the oscillator becomes over-stabilized and double triggering can occur when the hold control approaches full clockwise position. REMOVE SCOPE.
8. Set the Horz. Hold control to extreme clockwise position and adjust top slug of T-6 for one vertical blanking bar. Rotate Horz. Hold control fully counter-clockwise. Picture should remain in sync.

Y_1	Crystal IN60 CK706	CX-0028 CX-0030	Use only Simpson Model 260 Meter or equivalent. These tests are not effective with a V.T.V.M. Forward Resistance (Use RX1 Scale.) Reject if below 30 ohms and above 250 ohms. Backward Resistance (Use RX10,000 Scale.) Reject if below 200 K ohms and above 2.5 megohms. The front to back ratio should be from approximately 1,000 to 1,500 times in a good crystal. The resistance values of the crystal detector are approximately correct, but not in every instance. The best method of checking this component is by substitution during I.F. alignment. Establish an amplitude reference on the scope, disconnect one end of the crystal in question and place a new crystal in the circuit. By comparison in amplitude, determine the efficiency of the crystal in question.		

TUNER MAINTENANCE

The entire turret drum, with coils in place, may be removed from the tuner chassis by removing the springs at each end of the unit. This gives access to the components and tube sockets which are not accessible from the side of the tuner.

CAUTION: The high frequencies used in television make it necessary that extreme care be exercised in handling or servicing tuners. Location and lead dress of components and wiring are very critical. At high frequencies, wiring leads tend to act as small inductances and stray capacities; consequently, any change made may appreciably alter the electrical characteristics of critical circuits. Parts location and ground connections should be maintained as originally made. When replacing components, it is important that they be replaced with parts of identical characteristics and physical size.

If the oscillator slug is turned too far in a clockwise direction, control of the slug will be lost, as the slug will fall into the coil form. To recover the slug remove the coil from the drum assembly, move the slug retaining spring aside, tap the coil board in a way to move the slug forward. Reset the slug retaining spring. For alignment information see Page 4, paragraph "Oscillator Alignment."

TUBE REPLACEMENT

Replacement of tubes (especially the 6J6 oscillator tube) may cause excessive change in frequency of tuner circuits. This is due to differences of inter-electrode capacitances, unavoidable in the manufacture of tubes. When replacing a 6J6 tube, it is recommended that several tubes be tried in order to select a tube which will cause the least oscillator frequency shift. Doing so, will in most cases eliminate the need for realignment of the tuner circuits.

CLEANING AND LUBRICATION

Dirty switch contacts prevent the passage of R.F. and detune the circuits. At certain high frequencies they even act as small rectifiers causing very unwanted conditions. It is VERY IMPORTANT that the switch contacts in the tuner be PERIODICALLY CLEANED AND LUBRICATED. Properly doing so reduces wear and gives lasting service to the second most costly part in the TV chassis.

Remove the bottom cover plate. Remove the drum retaining springs at either end of the tuner. The complete drum may now be removed from the chassis.

Clean the coil board contacts and stator contacts with a lint free cloth. Lubricate with a pure sulphur-free, mineral oil. Many wholesale TV stores merchandise special contact lubricants that are sulphur-free and easily stored in a repairman's kit.

CAUTION: Switch contacts are brass, silver plated, and every care is exercised to preserve the silver plating. No abrasive should be used in cleaning contacts as some of the abrasive material may become imbedded in the silver and wear it away.

MECHANICAL TROUBLES

If mechanical parts are broken, it must be determined whether to repair or replace the unit. Removal of the drum assembly was described in the paragraph "Tuner Maintenance."

Erratic operation on any one channel requires checking the coil boards of that channel. To remove a coil board, insert a screwdriver between the coil retainer spring and the turret end plate. Press the blade away from the turret and lift the end of the coil upward and remove. Parts mounted on the reverse side of the coil board can then be examined and tested. Should excessive rosin from the soldering connections be found on the coil board, clean away with care. Rosin causes high resistance leakage. A coil board may be returned to the drum assembly in the reverse manner in which it was removed.

There are eleven contact springs located in the side of the tuner wall. A side view of a spring looks like a lobe or tear drop. With continued use the contact springs may become fatigued. If this is the case, adjust the lobe of the spring as required. Clean and lubricate with an approved contact fluid. Reassemble and check all channels.

Noisy channel switching may be due to the detent spring roller not rotating on the detent plate. Lubricate both surfaces with high vacuum grease.

For microphonism produced by tapping the tubes or tuner chassis, or in case of intermittent video and sound, first replace the tubes. If trouble persists, look for loose connections; clean contact surfaces and lubricate as explained above.

CIRCUIT OPERATION

The R.F. Circuit employs a dual triode which is connected in cascode. The cascode amplifier circuit is a grounded-cathode stage followed by a grounded-grid stage. These two stages employ a new nine-pin miniature dual triode developed for use in VHF cascode circuits (6BQ7 or 6BZ7). Each triode section has a separate cathode, and the two units are electrically independent. To minimize interstage coupling, an internal shield is located between the two triode sections. This shield is connected to Pin 9, and consequently Pin 9 is connected directly to the ground. This cascode circuit design delivers several times the R.F. gain in comparison with the pentode circuit. Also the noise developed by the shielded triodes in the 6BQ7 tube is much less than in the pentode tube. Therefore the signal-to-noise ratio is also much improved for the cascode circuit.

A higher B+ voltage is used with the R.F. amplifier circuit than is used in the mixer-oscillator circuits. For this reason independent B+ feed leads are extended from the tuner, Fig. 14.

TROUBLE SHOOTING

Tube substitution is the first step. This is discussed in the paragraph on tube replacement on Page 5. The presence of oscillator grid voltage is very important. Lack of it indicates that the oscillator is not operating. Lack of voltage at test point N, when the oscillator is working, indicates trouble in the mixer circuit.

The following RESISTANCE and VOLTAGE CHARTS will be helpful. Improper voltage or resistance readings are indications of problems involved.

U. H. F.

(ULTRA HIGH FREQUENCY

No modification is necessary to the MUNTZ TV 17B8 chassis to receive U.H.F. signals. The insertion of the U.H.F. channel strip in an unused V.H.F. position in R.F. Tuner Turret is all that is needed. The U.H.F. strip is in two sections (as is the V.H.F. strip) which contains all the required components to complete the conversion to U.H.F. reception; no other tubes, parts or external connections are required.

The short strip (Antenna) includes the antenna input circuit and a 1st I.F. grid coil. The long strip (Osc) consists of the coils for the 1st I.F. plate, converter grid and the Oscillator plus a crystal harmonic generator and its bias network.

In operation, the U.H.F. signal is fed into the antenna input coil and is coupled to the mixer circuit where it is mixed with an oscillator frequency (Harmonic of the fundamental oscillator frequency) to produce an I.F. frequency which falls in the spectrum between the two present V.H.F. television bands. This I.F. frequency is then coupled into the grid of the R.F. amplifier which in this case acts as a 1st I.F. amplifier. The amplified I.F. signal is then coupled into the mixer circuit where the fundamental oscillator frequency mixes with it to produce the regular I.F. frequency of the receiver. The functions of the receiver from this point on then are the same as for V.H.F. reception.

K—Crystal (Harmonic Generator)
L—RF Coupling
M—Converter Grid Coil
N—Oscillator Coil
O—Oscillator Slug

INSTALLING U.H.F. STRIPS

Before installing U.H.F. channel coils, be sure that the letters stamped on the U.H.F. coils are the same as the letter stamped on the V.H.F. coils in the tuner. Each coil has the number of the channel it will receive and a letter following (ie..10Q) Channel 10 Q type coil.

Therefore this tuner will use Q type coils. If the letter is an F, it will use F type U.H.F. or V.H.F. coils. (See Figure 13A.)

Be sure the U.H.F. channel coil is stamped with the correct channel number for the U.H.F. station in operation in your area.

Handle U.H.F. coils very carefully so the spacing between wires and components is not disturbed. Do not adjust screws adjacent to contacts on the 5 contact antenna coil section. They are preset at the factory.

1. Remove the unused V.H.F. channel strips.
2. Insert long (Osc) strip in front section of tuner drum.
3. Insert short (Antenna) strip in rear section of tuner drum. Be sure that pin in long strip makes secure contact.
4. Turn on your MUNTZ TV set and rotate channel selector so that U.H.F. channel strip is in operating position.
5. Rotate fine tuning control. If the best picture is not received at the center of fine tuning range, adjust oscillator slug. (See oscillator adj. section).
6. Do not attempt to adjust individual coils in antenna section, they are factory adjusted to give correct performance.

VHF-UHF FREQUENCY ALLOCATIONS

Chan. No.	Frequency Band (Mc)	Video Carrier	Audio Carrier	Chan. No.	Frequency Band (Mc)	Video Carrier	Audio Carrier

PRODUCTION CHANGES

The following tabulation furnishes complete details on changes which occurred during receiver production. The receivers incorporating these changes are identified by a RUN NUMBER stamped on rear surface of chassis, immediately following the chassis serial number. INITIAL PRODUCTION CARRIED NO RUN NUMBER. Run No. 1 was not used.

RUN NUMBERS	DESCRIPTION OF CHANGE
NO RUN NUMBER	Vertical Oscillator and Vertical Output Circuit used in Initial Production.

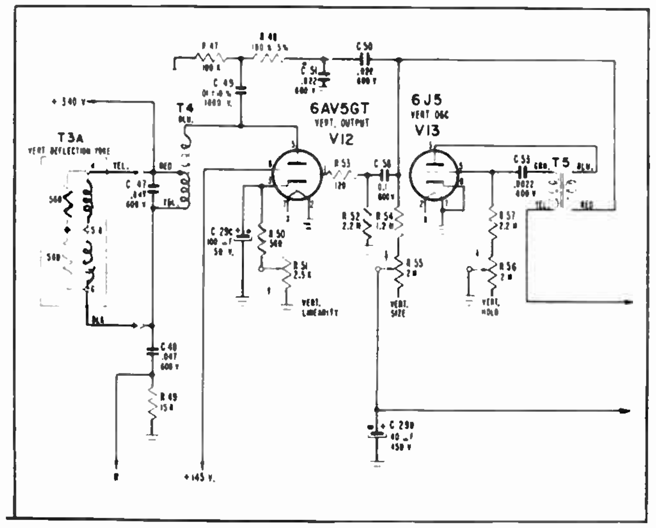

Figure No. 17

NO RUN NUMBER The Following Change was incorporated to meet a U.L. requirement.

1. The 5. ampere 250 volt fuse in the primary of the power transformer was deleted.
2. The ½ ampere 250 volt fuse was placed in series with the 340 volt buss, to the plate of the 6V3 damper tube and the screen grid of the 6CD6 Horizontal Output Tube.

NO RUN NUMBER The following change was made to allow for the use of various makes of 6CD6 tubes. The two replacements must be made simultaneously.

1. Capacitor C68 was changed from .01 mf. ± 20% 600 volts, to .022 mf. ± 20% 600 volts.
2. Resistors R66 and R71 were changed from 100K ± 10% ½ watt and 82K ± 10% 1 watt to 82K ± 10% 1 watt and 68K ± 10% 1 watt respectively, as shown on schematic.

RUN NUMBERS	DESCRIPTION OF CHANGE

NO RUN NUMBER The following changes were made to minimize component failure.

1. Capacitor C60 was changed from a Mica 68 mmf. ± 10% 500 volts to a Mica 68 mmf. ± 10% 1000 volts.
2. Capacitor C64 was changed from a tubular ceramic Durez insulated 1000 mmf. ± 20% 500 volts to a tubular ceramic 1000 mmf. ± 20% 1000 volts.
3. Capacitor C62 was changed from a tubular ceramic 180 mmf. ± 10% 500 volts negative temperature co-efficient 330 to a tubular ceramic Durez insulated 180 mmf. ± 10% 500 volts negative temperature co-efficient 330.

NO RUN NUMBER Anti Pin Cushion Magnets. In initial production, two anti pin cushion magnets were used to compensate for bowing of the raster, due to the cosine deflection yoke being used. The magnets were mounted on flanges attached to the deflection yoke collar. Engineering advancement in yoke design has eliminated the need for such magnets.

NO RUN NUMBER Vertical Pulse In Audio Output. In initial production "buzz" may be heard in the audio output due to pulse radiation of the vertical output Circuit. Placing a metal shield (Muntz Part No. MP-0487) between the 6AV5GT Vertical Output tube and the 6W6GT Audio Output Tube will reduce the pulse pick-up and the buzz will be inaudible.

RUN NUMBER 2 Relocation of the Vertical Circuits to eliminate the possibility of vertical pulses being found in the audio output. Models previous to Run Number 2 used the tube layout on following page.

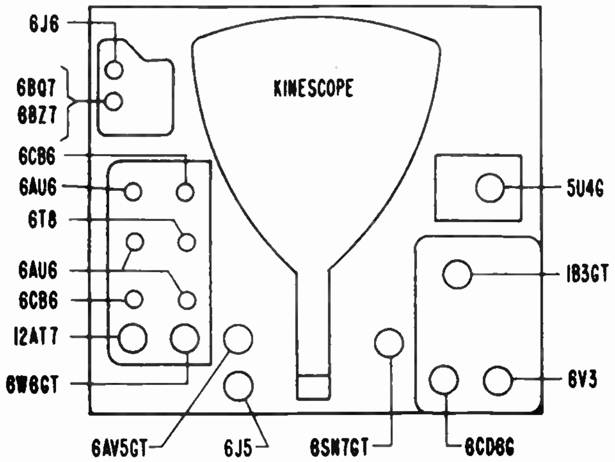

Figure No. 18

RUN NUMBERS	DESCRIPTION OF CHANGE

RUN NUMBER 3 The ½ Amp. 250 Volt Fuse (FU-0002-2) has been deleted from the 17B8 chassis and a 5 Amp. "Slo-Blo" Fuse (FU-0005-2) has been inserted in the primary circuit of the power transformer.

RUN NUMBER 4
1. To reduce the effect of the contrast control on the sound I.F. circuit; condenser C71 has been added from the cathode of the Video Amplifier to ground. C71 Capacitor, Tub. Cer. Durez 270 mmf. 20% 500 volt.
2. In addition to the above, a wiring change has been made. The wiring of electrolytic condensers C26A and C29A has been transposed. Doing so has reduced the coupling effect between sections of the condensers.

RUN NUMBER 5 To reduce the possibility of corona and arcing, of the 1B3GT high voltage rectifier tube socket assembly, the following parts have been changed.

Old Part No.	Description	New Part No.
SO-0047	H.V. Socket and Corona Ring Assembly	JC-0030
None used	Cover, H. V. Tube Socket	IN-0098
IN-0102	Insulator, H.V. Socket Mounting	SO-0042
WF-0030	Washer, Corona Shield Insulator	WF-0030-1

Note: The above new parts comprising the 1B3GT Tube Socket assembly are not interchangeable with those used in the 17B8 chassis below Run #5.

RUN NUMBER 6
1. To improve the stability of the Horizontal A.F.C. circuit, Condenser, C-63 has been changed to a moulded paper condenser.

RUN NUMBERS	DESCRIPTION OF CHANGE

C-63 Capacitor Tubular Paper Moulded —.01 Mfd.—20% 600V—CPM-0101.

2. For better isolation of the Tuner from the I.F. Circuits, a 4700 ohm Resistor (R-10) has been added in series with the (white) AGC lead to the tuner. This resistor is located on the I.F. Panel Assembly.

R-10 Resistor—4700 ohms—10% ½W RC-4701-18.

RUN NUMBER 7 To comply with an underwriter Labratory request, the interlock wiring assembly has been changed. Previous to RUN 7 a dual capacitor (2 x .01mf G.M.V. 500V.) Part No. CC-0096 was used across the A.C. input of the inter lock socket.

INTERESTING NOTES

ALL CHASSIS 17B8 The value of R54 will vary in early production models in accordance with the scan of the yoke used. A ½ watt resistor varying from 1.2 meg. to 2.2 meg., dependent upon the vertical size, may be used. The deflection yoke has now been standardized, and for that reason, a 1.8 meg. ± 10% ½ watt carbon resistor is now used at R54, see schematic diagram.

ALL CHASSIS 17B8 To minimize neck shadow at the left side of the picture and to correct centering of the picture, the 27 ohm, 2 watt resistor (R81) connected to terminals #5 and #6 of the horizontal output transformer (TO-0036) should be lowered in value. A 120 ohm ½ watt resistor connected in parallel with the 27 ohm resistor is recommended as this reduces the value of the resistance to approximately 22 ohms. However, the value of the resistor may be varied in accordance with the centering and shadow problem.

CAUTION: Before varying the resistance value of the 27 ohm resistor, check to see that all adjustments are properly completed along the neck of the CRT.

OSCILLOGRAMS

To obtain a close approximation of the wave forms and peak to peak voltages as shown, the receiver should be connected to 117 volt AC line and the contrast control set for 40 volts peak to peak at the cathode of the picture tube. Any scope may be calibrated to read peak to peak voltages by applying a 60 cycle voltage (of known RMS value) to the vertical input. The peak to peak amplitude of the sine wave seen on the scope is equal to 2.83 times its RMS value. The 6.3 volt AC filament can be used for this purpose. 6.3 times 2.82 = 17.8. This voltage may be used as a reference voltage to calibrate the scope.

The wave forms and voltages are subject to variations due to the response of the scope used and parts tolerances.

Caution: No reading should be attempted with the scope at pin #5 of the 6AV5 Vertical Output tube due to the high pulse voltage present. Wave form #10 is indicative of the vertical output.

All wave forms were taken with a Model No. 400 Sylvania Oscilloscope and peak to peak voltages calibrated as detailed above.

TUBE LAYOUT AND SIGNAL PATH CHART

The signal path chart provided is to assist the Serviceman in isolating a particular trouble in the easiest and fastest way possible. As an example; the receiver under test has picture and no audio. A quick look at the audio signal will tell you immediately that the trouble lies somewhere between V-4 and the speaker.

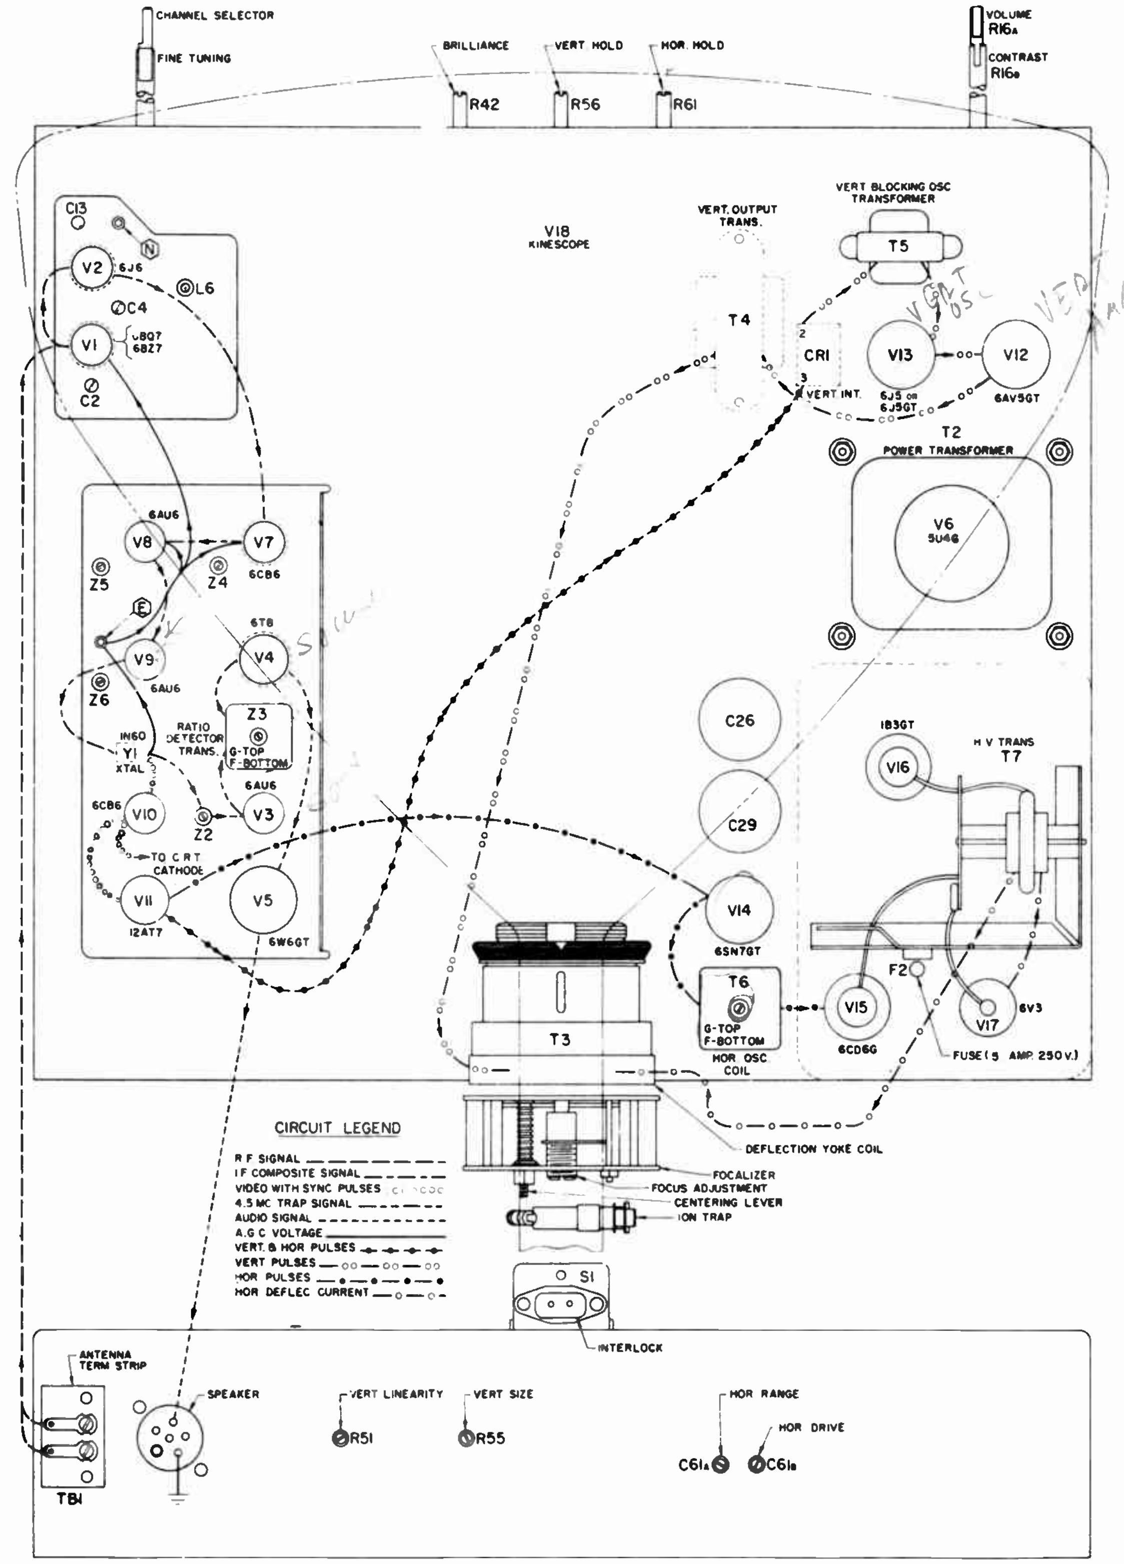

Figure No. 20

OPERATION AND SERVICE DATA

RADIO CHASSIS—8FM34

ANTENNA

(A) Broadcast Band: A highly selective loop antenna is provided for broadcast reception. The loop antenna will give excellent results in most locations. In unfavorable locations where distant reception is required a well constructed outdoor antenna about fifty feet long may be used. The antenna should be connected to the antenna terminal strip at the rear of the chassis marked "A."

(B) F-M Band: A built-in antenna is provided at the rear of the cabinet, and connected to the antenna strip F-M terminal posts for F-M reception.

Although the receiver will operate without a ground connection in most locations, a good ground will often reduce noise pickup on the broadcast band in noisy locations. A good ground connection can be made by connecting to a pipe driven into the ground. The ground wire from the clamp should be connected to the antenna strip terminal post marked "G" at the rear of the chassis.

CONTROLS

(A) On-Off switch and Volume Control: This control knob marked "VOLUME" combines the line on-off switch and volume control.

(B) Tone Control: This control knob marked "TONE" when turned to the right (clockwise) produces a deep bass effect, while rotation to the left (counter-clockwise) produces a more brilliant treble tone. Various shading between the extremes may be obtained at intermediate settings of the control.

(C) Band Selector Switch: This three position control knob is provided with a dot marker for designating the proper position in selecting the frequency band desired, and also connects the "Phono" pickup into the circuit for use of the record changer. The extreme left hand position marked "F-M" designates the "F-M" band. The second position marked "A-M" selects the "Broadcast" band. The third position marked "Phono" selects the "Phonograph" position.

(D) Tuning Control. This control marked "Tuning" selects the desired F-M or Broadcast station, the frequency of which is indicated by the dial pointer.

OPERATION

F-M Band—Set the Selector Switch to "F-M" Position. Turn the Volume control knob to the right; a click will be heard indicating that power is being delivered to your receiver. Allow about 30 seconds for the tubes to warm up. Advance the volume by turning the Volume control knob to the right. Turn the Tuning control knob slowly so that the dial pointer indicates the frequency in megacycles of the desired F-M station on the upper scale of the dial marked FREQUENCY MODULATION. The F-M band is ultra-high frequency and necessitates slow precision tuning. Rotate the Tuning knob back and forth in tuning in the desired F-M station. Tune for best sound quality and minimum hiss. When stations are properly tuned, reception on this band should be clear and free from hiss or disturbing noise. If this is not the case check your antenna installation or cabinet antenna connections. Adjust the volume by turning the Volume control knob to the left or right to suit the listener. NEVER REDUCE THE VOLUME BY DETUNING—ALWAYS USE THE VOLUME CONTROL KNOB. The tone control knob may be used to adjust the quality of reproduction to suit individual preferences, or to compensate for defects in room acoustics.

BROADCAST BAND — TURN THE BAND SELECTOR SWITCH TO THE "BC" POSITION. Turn the Tuning control knob slowly so that the dial pointer indicates the frequency of the desired station on the lower portion of the dial scale marked STANDARD BROADCAST. Then tune carefully for best and clearest reception. Adjust the Volume and Tone control knobs to suit the listener. High pitched noises such as those caused by electrical interference will be reduced when the tone control knob is turned to the right or bass position.

PHONOGRAPH—SET THE SELECTOR SWITCH TO THE "PHONO" POSITION. Open the automatic record changer compartment and follow the instructions on Page 12. Adjust the Volume and Tone control knobs to suit the listener.

LINE VOLTAGE

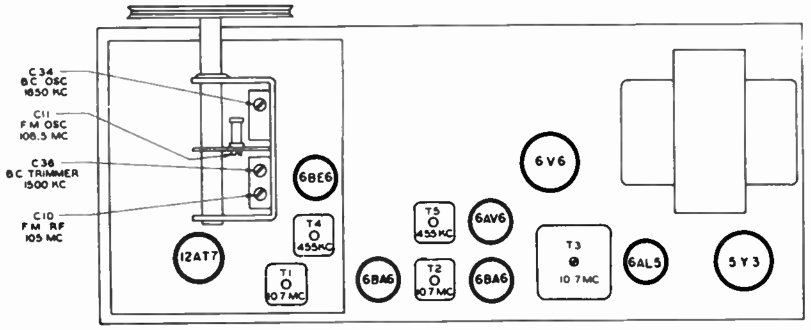
This receiver is designed for operation on 105-125 Volts; 60 Cycles, Alternating Current (AC) only. POWER CONSUMPTION INCLUDING RECORD CHANGER: 115 Watts.

TUBES

The Tubes used, and their functions, are as follows:

12AT7	R-F Amplifier and Mixer (F-M)
6BE6	A-M Converter and F-M Oscillator
6BA6	1st I-F Amplifier (A-M & F-M)
6BA6	2nd I-F Amplifier (F-M)
6AL5	F-M Detector
6AV6	A-M Detector, A.V.C. and Audio Amp.
6V6GT	Beam Power Amplifier
5Y3GT	Rectifier

For the placement of these tubes, refer to the diagram.



TUBE AND ADJUSTMENT LOCATION DIAGRAM

ALIGNMENT CHART

STEP	CIRCUIT ALIGNED	RECEIVER DIAL AT	SIGNAL GENERATOR TYPE	SIGNAL GENERATOR FREQ.	SIGNAL GENERATOR CONNECTIONS	METER TYPE	METER CONNECTIONS	ADJUST	METER INDICATION
1	B.C.I.F.	B.C. Band Max. Freq.	A.M.	455 KC 30% Mod.	Rear B.C. Section Of Variable Condenser	Output	Across Voice Coil	Top & Bot. Of T4 & T5	Max. Output
Preferred Method 2	F.M.	F.M. Band	F.M.	10.7 MC. 30% Mod.	High Side Through .005 MF. (Approx.) Cap To Pin 7 Of 12AT7	Output	Across Voice Coil	Top & Bot. Of T1 & T2; Bot. of T3	Max. Output
Alternate Method 2	I.F.	Max. Freq.	R.F. or A.M.	10.7 MC. Unmod.		D.C. V.T.V.M.	Negative To Pin 7 Of 6AL5; Positive To Ground		Max. Deflection
Preferred Method 3	F.M.	F.M. Band	F.M.	10.7 MC. 30% Mod.		Output	Across Voice Coil	Top Of T3	Max. Output
Alternate Method 3	Det.	Max. Freq.	R.F. or A.M.	10.7 MC. Unmod.		D.C. V.T.V.M.	Neg. To Junction Of 8.2K Resistor At 6AL5; Pos. To Junction Of R15 & C17.		Zero Between Two Opposite Polarity Peaks
Preferred Method 4	F.M.	F.M. Band	F.M.	108.5 MC. 30% Mod.	Each Side Of Gen. Output Through 150 OHM Resistor To F.M. Ant. Terminals	Output	Across Voice Coil	Trimmer On Top Center Of Var. Cond. (C11)	Max. Output
Alternate Method 4	OSC.	Max. Freq.	R.F. or A.M.	108.5 MC. Unmod.		D.C. V.T.V.M.	Negative To Pin 7 Of 6AL5; Positive To Ground		Max. Deflection
Preferred Method 5	F.M.	F.M. Band	F.M.	105 MC. 30% Mod.		Output	Across Voice Coil	Trimmer At Rear Of Var. Cond. (C10)	Max. Output
Alternate Method 5	R.F.	105 MC.	R.F. or A.M.	105 MC. Unmod.		D.C. V.T.V.M.	Negative To Pin 7 Of 6AL5; Positive To Ground		Max. Deflection
6	B.C. OSC.	B.C. Band Max. Freq.	A.M.	1650 KC. 30% Mod.	Rear B.C. Section Of Variable Condenser	Output	Across Voice Coil	Trimmer At Front Of Var. Cond. (C34).	Max.
7	B.C. R.F.	B.C. Band 1500 KC.	A.M.	1500 KC. 30% Mod.	Each Side Of Gen. Output To 2 Or 3-Turn Loop (1 Foot Dia.) Several Feet From Ant.	Output	Across Voice Coil	B.C. Trim. At Rear Of Var. Cond. (C36).	Output

Notes:
1—Turn Volume Control Fully Clockwise.
2—Maintain Signal Input Low Enough To Have Less Than 2 Volts Across Meters.
3—Unless Otherwise Noted, Connect Low Side Of Signal Generator to Chassis.
4—Unless Otherwise Noted, Set Variable Condenser To Minimum Capacity (Max. Freq.)
5—Use Proper Tool For Small I.F. Trans. Adjustments — I.E., .150 Dia. Bakelite With Blade .075 Thick.
6—Maintain 60 Cycle Line Voltage At Approx. 117 Volts.

PARTS LIST

Muntz TV Part Number	Description	Garod Number
(1) LI -9001	AM - I.F. Transformer	(C-1.445-3)
(2) LO -9001	BC - Oscillator Coil	(C-1.436-2)
(3) LI -9002	FM - I.F. Transformer	(C-1.446-2)
(4) LI -9003	FM - I.F. Transformer	(C-1.446-3)
(5) LI -9004	Ratio Detector Transformer Can Height 2½"	(C-1.524)
LI -9004	Ratio Detector Transformer Can Height 1 15/16"	(C-1.542-1)
(6) LC -9001	Filament Choke	(B-1.501)
(7) LC -9002	RF Choke - RF Plate	(B-1.512)
(8) LC -9003	RF Choke - Osc. Cathode	(B-1.535-1)
(9) LC -9004	RF Choke - RF Cathode	(B-1.535-2)
(10) LO -9002	FM Oscillator Coil	(B-1.538)
(11) LR -9001	FM - RF Grid Coil	(B-1.539)
(12) AN -9001	BC Loop Antenna	(D-1.540)
(13) LC -9005	Modulator Plate Choke	(B-1.536-1)
(14) LC -9006	Parasitic Suppressor	(B-1.536-2)
(15) CV -9001	Variable Condenser	(C-2.222)
(16) VC -9001	Volume Control & Switch	(C-8.201-11)
(16)(A) VC -9002	Tone Control	(C-8.201-12)
(17) TO -9001	Output Transformer	(C-9.241-3)
(18) TP -9001	Power Transformer	(D-9.248)
(19) LC -9007	Filter Choke	(C-9.255)
(20) SW-9001	Band-Switch	(C-8.228)
(21) SK -0014	10" Speaker	
(22) CC -9001	Dual Shielded Ceramic Capacitor	(B-4.125-1)
(23) CE -9001	Dry Electrolytic Capacitor Unit	(C-5.421-7)
(24) CE -9002	Electrolytic Capacitor	(C-5.430)
(25) CT -9001	Ceramic Trimmer .7 to 3.5 mmf	(B-4.118)
(26) AN -9002	Cabinet Antenna for FM	

MISCELLANEOUS PARTS

DG -0025	Dial Glass (AM - FM)	
ES -0029	Escutcheon - Radio	
KB -0034	Knob Tuning, Tone & Volume	
KB -0035	Knob, Band Switch	
FB -0009	Background - Dial Scale	
PL -0005	Plug - Phono	
PL -0025	Plug - Min. Connector	
PL -0026	Plug - Speaker Connector	
RB -0040	Strip - Dial Glass	

Radio Chassis—8FM34

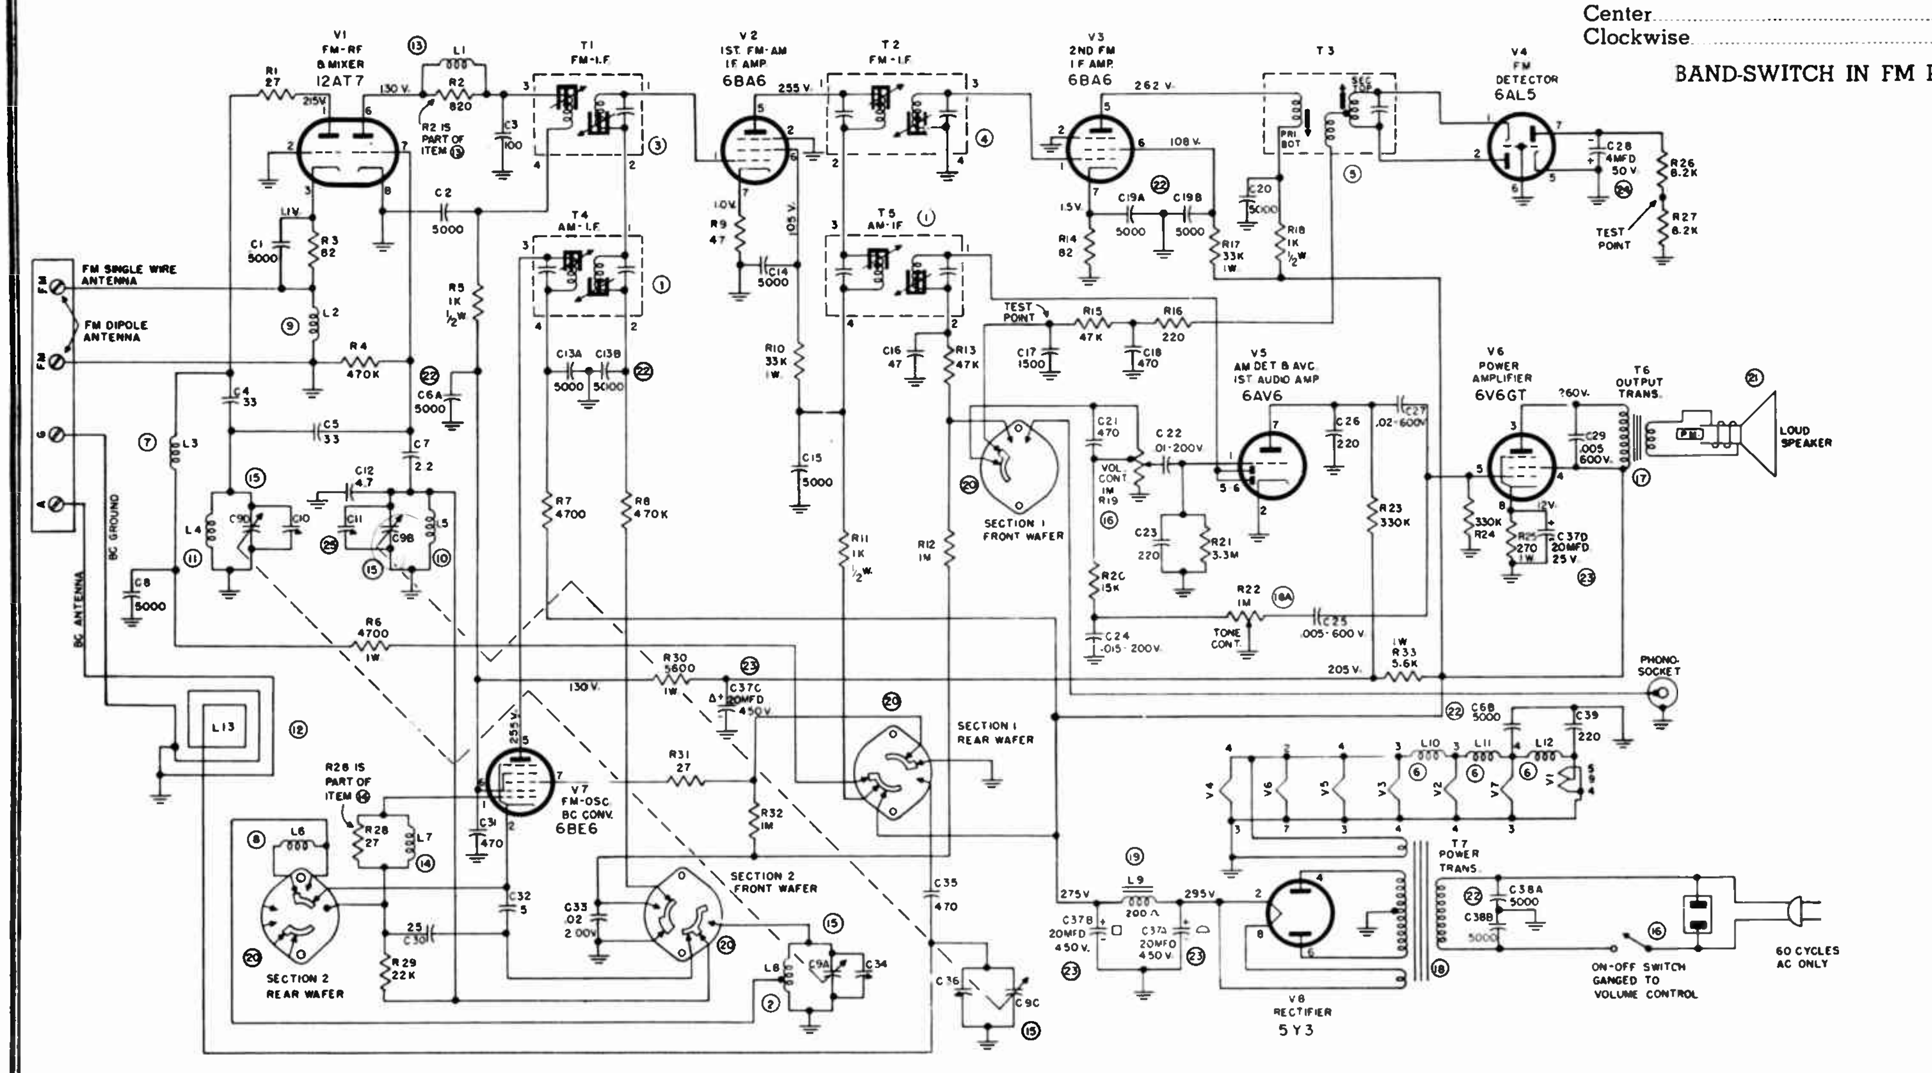
BAND-SWITCH POSITIONS

Counter Clockwise .... FM (87.5-108.5MC)
Center .... AM (540 -1650KC)
Clockwise .... Phono.

BAND-SWITCH IN FM POSITION.

K=Kilohms FM-I.F.=10.7MC
M=Megohms AM-I.F=455KC

All Condensers Shown In MMF.
All Condensers 500V. Except As Shown.
All Resistors ½ Watt Except As Shown.



OPERATION AND SERVICE DATA

AUTOMATIC RECORD CHANGER

VM MODEL 950

PREPARING FOR OPERATION

SHIPPING BOLTS: Before placing in operation, the player must be floated freely on the mounting springs. During shipment, the mechanism is secured by means of two shipping bolts. To float the changer, remove the turntable by lifting it straight up the spindle. Turn the two shipping bolts in a clockwise direction as far as they will go and replace the turntable. Before the turntable can be fully seated, the idler wheel must be gently pushed back out of the way to prevent damage to the rubber tire.

LEVELING RECORD CHANGER: It is essential to have the record changer absolutely level. Use a torpedo or similar type level on the record changer baseplate. Use adequate shims to level the record changer pan or radio combination cabinet to achieve perfect level.

OPERATION

Loading—

1. Pull straight upon record support knob until record support clears spindle. Swing record support to the left until pin in shaft drops into locating groove.

2. Changer will automatically play ten - 12" either standard or long-play records, twelve - 10" either standard or long-play records, any assortment

1. Pull straight up on record support knob until of ten—12" and 10" records intermixed, or twelve - 7" long-play or fine-groove records.

NOTE: Standard, fine-groove, and long-play records cannot be intermixed. Motor speed control knob must be reset for each type of recording.

3. Place records on spindle and lower to off-set shelf. Hold records level and replace record support over spindle.

To Play Standard Recordings—

1. Motor speed control knob must be in the "78" position.

2. To start, turn changer control knob to "Rej." and release. Changer will operate automatically until the last record has been played. Pickup arm returns to rest and the changer control knob to the "Off" position. Changer automatically stops.

To Play Long-Play (33⅓ RPM) Records—

1. Motor speed control knob must be in the "33" position.

To Play Fine-Groove (45 RPM) Records—

1. Motor speed control knob must be in the "45" position.

2. These records are manufactured with a 1½" spindle hole. It is essential that a record adapter be inserted into each 45 RPM record to be played. This is necessary to reduce the spindle hole to conventional size.

REJECTING: To reject a record at any time while changer is operating, turn changer control knob to 'Rej." and release.

STOPPING: To turn off changer before automatic shut-off, turn changer control knob to 'Off." Lift pickup arm and place on rest.

UNLOADING: Lift the record support and swing to the left until pin on shaft drops into locating groove. Lift stack of records straight up and off spindle.

MANUAL OPERATION: To play single records or home recordings, allow the changer to go through its complete shut-off cycle. Lift the record support arm and move it to the left clear of the turntable. Place record on spindle and lower to spindle shelf. Tilt record down toward the rear of pickup arm and lower record to turntable. Turn changer control knob to "On" position only. Raise pickup arm and place in lead-in groove of record.

REPEATING OF 7", 10", OR 12" RECORDS: To repeat records, swing record support clear of spindle, place record on the turntable, and start changer. Record repeats until control is turned "Off." If a 12" record is repeated, wait for the changer to finish cycling and reposition the pickup arm manually to the 12" position.

SUGGESTIONS: When loading and unloading the changer, use care to prevent bending of the spindle. Records should not be left on the spindle except during operation of changer. Records will warp. When machine is not in use, it is suggested that the speed control knob be left in the "78" position. For best reproduction, keep needle and records clean. Store records flat, in folders or in albums. Do not lay record on record.

CHANGE CYCLE

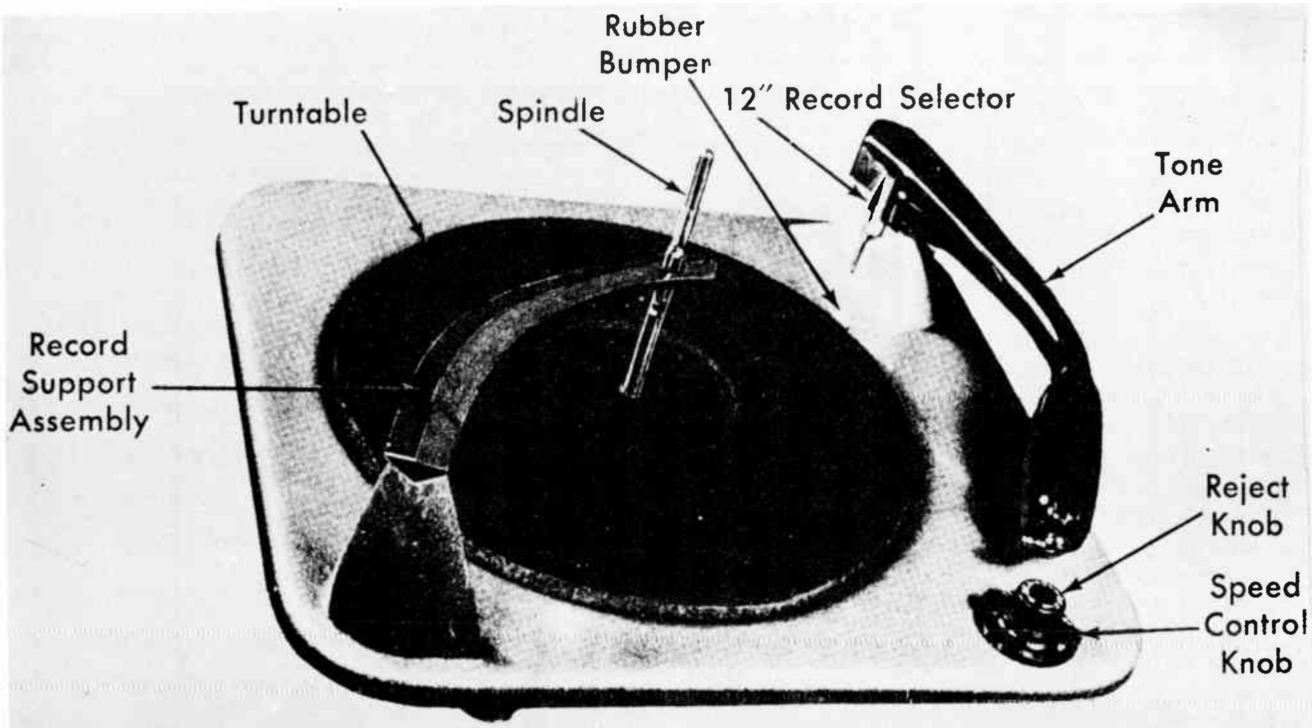
This changer is provided with what is known as a velocity trip mechanism. The change cycle is started by the faster inward motion of the pickup arm when the needle enters the trip grooves at the end of the record. Only records having fast-finishing grooves before the eccentric cycling groove will operate this velocity trip.

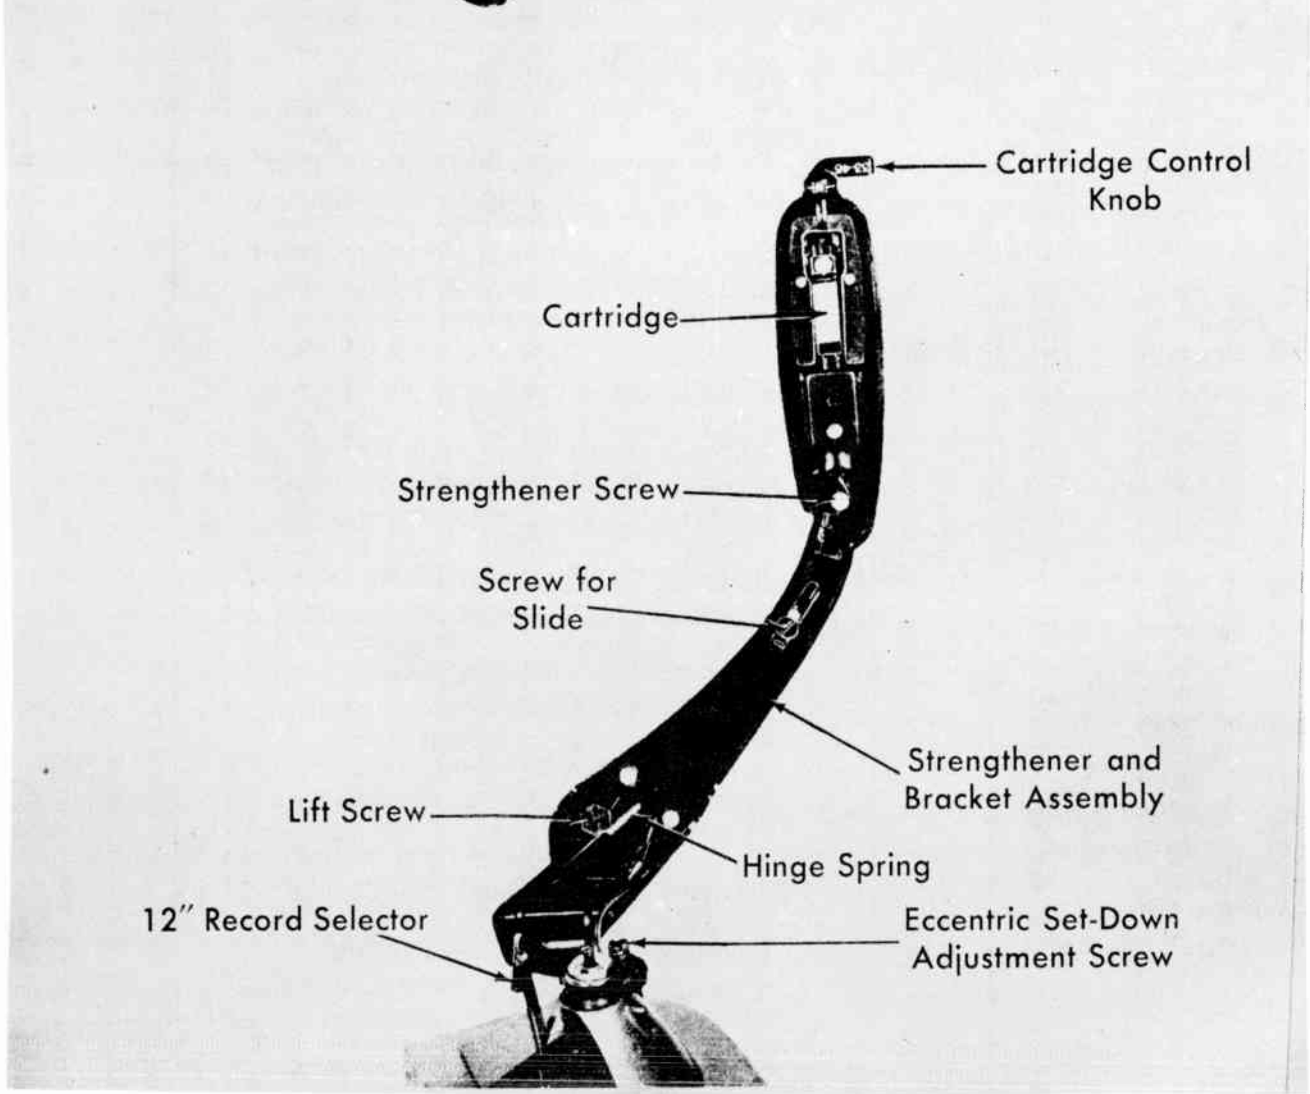
ADJUSTMENTS

NEEDLE SET-DOWN: The set-down position of the needle is adjusted by means of the set-down adjustment screw mounted on the hinge arm assembly. Turn this screw adjusting pickup arm for correct set-down on 10" record. When the correct set-down is obtained for the 10" position, the 12" and the 7" needle set-down will also be correct.

PICKUP ARM HEIGHT: The pickup arm height is adjusted by the lift screw located at the rear of the strengthener. To raise the height of the pickup arm, turn this screw counter-clockwise. To lower the pickup arm, turn clockwise. The pickup arm height should be adjusted so that with a 1⅛" stack of records the pickup arm lifts ¼" straight up as the change cycle starts.

NEEDLE PRESSURE: The needle pressure should be between 10 and 12 grams. Adjustment may be made by loosening the screw on the slide which moves in a slot in the tone arm strengthener. Move the slide back and forth until the correct needle pressure is obtained.





CABINETS—CABINET PARTS

CABINETS

Part No.	Description	Model Number

SPECIFICATIONS

Direct View Electromagnetic Picture Tube
- 14" Rectangular
- 17" Rectangular
- 20" Rectangular

Operating Voltage
- 110-120 60 Cycles

Wattage
- 175 Watts

Input Impedance and Transmission Line
- 300 ohm balanced (between antenna terminals)
- 75 ohm coaxial cable may be used by connecting shield to chassis and inner conductor to either antenna terminal

Intermediate Frequencies
- Video - 25.75 Mc.
- Sound - 21.25 Mc.
- Intercarrier Sound - 4.5 Mc.

Fuse Location
- Horizontal output fuse, F_1, is located inside the high voltage enclosure.
- The line fuse, F_2, is located in a fuse holder on the rear apron of the chassis.

INSTALLATION AND SERVICE ADJUSTMENTS

When installing, each set should be checked for picture centering, picture tilt, shaded corners, proper size, linearity, etc., to insure best performance. It is especially important that the Ion Trap be checked, and that the Channel Slugs be adjusted upon installation or servicing of every set to insure ease of tuning. Any adjustments required should be made as described here.

For best results, all checks or adjustments should be made using a transmitted television test pattern. A mirror placed in front of the picture tube screen will be of help in observing the picture while adjusting rear chassis controls.

HIGH VOLTAGE WARNING

Operation of this receiver outside of its cabinet involves a shock hazard from the power supplies. No work should be attempted on this receiver by anyone who is not thoroughly familiar with the precautions necessary when working on the high voltage equipment.

EXTERNAL ANTENNA

When an external indoor or an outdoor antenna is required, be sure to disconnect the built-in antenna leads from the antenna terminal board, tape them and place them away from the chassis.

OPERATING THE TELEVISION RECEIVER

The controls of this receiver are operated conventionally. When tuning, carefully adjust the TUNING control for the best picture.

INDIVIDUAL CHANNEL SLUG ADJUSTMENT "A3" USING TELEVISION SIGNAL

Individual channel oscillator adjustment of every receiver should be checked upon installation or servicing. If this adjustment is properly made, it is possible to tune from one station to another by merely turning the CHANNEL control. With correct oscillator channel adjustment, best picture will be located at the approximate center of the range of the Tuning control.

Channel slug adjustment can be made without removing the chassis from the cabinet. Adjust as follows:

a. Turn the set on and allow 15 minutes to warm up.
b. Set the CHANNEL knob for a station in operation. Set all other controls for a normal picture.
c. Set TUNING control at center of its range by rotating it approximately half-way.
d. Remove the CHANNEL and TUNING knobs.

e. Insert a 1/8" blade, NON-METALLIC screwdriver in the 1/4" hole adjacent to the channel tuning shaft. For each channel in operation, carefully adjust the channel slug for the best picture with clear detail. Be sure that the Tuning control is set at the center of its range before adjusting each channel slug. Only slight rotation of the slug will be required; turning the slug in too far will cause it to fall into the coil. (If the slug falls into the coil, remove the coil, move the retaining spring aside, lightly tap the open end of the coil until the slug slips out. Replace slug and re-set retaining spring;)

If a number of slugs are found to tune all the way in or all the way out, or if the 6J6 oscillator-mixer tube has been replaced, it may be necessary to make the "Overall Oscillator Adjustment" as discussed below.

OVER-ALL OSCILLATOR ADJUSTMENT "A1" USING TELEVISION SIGNAL

Over-all oscillator adjustment should only be necessary when replacing the oscillator-mixer tube (6J6), or when all channel slugs are off in the same direction. When replacing the oscillator-mixer tube (6J6), it is recommended that several tubes be tried to select one which will cause least oscillator frequency shift.

A1 is generally adjusted so that approximately 3/16" of screw thread is exposed.

Adjust as follows:

a. Follow steps "a", "b", and "c" above.
b. Carefully adjust trimmer C6 (figure 8) for best picture with clear detail.
c. Check and, if necessary, make individual channel adjustments as indicated above.

ION TRAP ADJUSTMENT

To properly adjust the Ion Trap, Focusing Device and the Deflection Yoke the following procedure should be followed.

The Deflection Yoke should be placed in position closest to the "bell" of the Cathode Ray Tube as far forward on the neck of the tube as is possible. The Focus Device is next in line and Ion Trap last. See Figure 1.

The antenna should be connected to the receiver, the set should be turned on, the brilliance control turned to MAXIMUM and the contrast control at MAXIMUM.

The Ion Trap should be moved forward and backward and at the same time rotated to achieve the brightest raster on the face of the CRT.

Reduce the brilliance control to a point slightly over normal brightness and adjust the Focus Control on the rear of the Focus Device with a non-magnetic screwdriver for clearest and sharpest horizontal sweep lines. The Ion Trap should then be readjusted slightly for the brightest response on the face of the tube.

The Focus Device aperture should be moved to secure a complete raster centered and with no corners cut off.

Finally the Deflection Yoke should be rotated to "square" the raster with the chassis as a reference. The screws on the yoke brackets should then be set.

HEIGHT, WIDTH AND LINEARITY

To adjust the overall size and linearity of the picture it is almost mandatory that a pattern transmitted from a local station be used. Linearity adjustments, particularly, cannot be accurately made on moving transmissions. It should also be remembered that in areas where more than one station is being received, that pictures transmitted from different stations will vary slightly in size. The smallest transmitted picture should be made to fill the area delineated by the mask.

The first step in linearity and size adjustment is to turn the Width Control (rear of chassis) all the way in. (clockwise)

The Horizontal Drive trimmer should then be adjusted for the best compromise between maximum brightness and good horizontal linearity. Misadjustment of the Horizontal drive condenser will show as bright vertical bars on the left hand side of the picture. The Width Control should then be backed out until the picture is the correct width.

Vertical Linearity and height adjustment are made in the conventional manner. It will be noted that there is some interaction between these controls.

HORIZONTAL OSCILLATOR ADJUSTMENT

The set should hold horizontal sync over approximately one turn of the horizontal hold control. This will vary with signal strength of the received station. The control will bind at the extreme ends of its rotation. Do not attempt to force it to turn after binding is encountered or serious damage will result. If the set does not hold at a point in the center of the control range it indicates trouble in the horizontal oscillator or sync phase detector.

PICTURE TUBE REPLACEMENT

Important: After replacing any picture tube, be sure to make all deflection adjustments -- Picture Centering, Deflection Yoke, and Ion Trap - Especially note comments on picture centering.

WARNING: Because of the high 2nd anode voltage used (approximately 12KV) and the possibility of danger of implosion due to high vacuum, the following precautions should be noted when removing or replacing picture tubes:

a. Before handling a picture tube, remove the 2nd anode static charge from both the picture tube and the 2nd anode connector by shorting them to chassis.
b. Shatterproof goggles and heavy gloves should be worn while handling or installing a picture tube.
c. Always handle the picture tube very carefully. DO NOT pick the tube up by the neck.

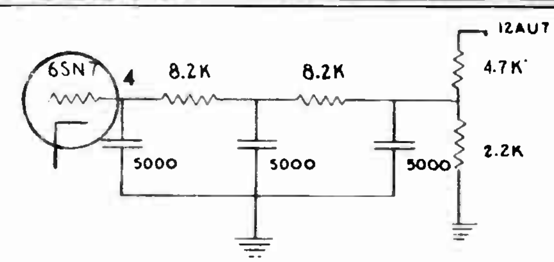
INCREASING SENSITIVITY FOR OPERATION IN FRINGE AREAS

The following hints may be helpful for improving sensitivity in fringe areas. These hints should be followed in the sequence given. The balance of the procedure can be omitted if satisfactory results are obtained at any point in the procedure.

a. Make sure that the proper antenna is used and correctly installed. Information on various types of high gain antennas is available from the Distributor.
b. Check the rectifier tube (5U4G) by substitution as the voltage output of some tubes may be slightly higher. An increase in B-voltage will increase sensitivity.
c. Check the video amplifier tube (6AC7) by substitution. Increased contrast is sometimes obtained with tube replacement.
d. Check the power line voltage. If the voltage is known to vary greatly, it is recommended that the set be operated from a constant voltage transformer with a power rating of at least 300 watts.
e. Carefully realign the receiver following the instructions given in this manual. Checking tubes (by substitution) in the RF amplifier, oscillator-mixer, IF stages, and video detector while aligning will often give considerable increase in gain. The increase in gain may be observed by an increase in amplitude, on the response curve. Realignment of the particular stage should always be made after each tube replacement, in order to realize the maximum gain possible.

Change to Improve Vertical Sync Stability in Weak Signal Area

1. Remove vertical integrator plate.
2. Make up vertical integrating circuit shown below:



PRODUCTION VARIATIONS

1. One or two 100 ohm 10 watt resistors were added between the center tap of some power transformers and chassis to reduce the B plus voltage to approximately 360 volts.

2. In sets of serial 51,200 and below the audio de-emphasis network was 33K and 2200 MMF.

3. Vertical hold control may be 750K, when this is used, a 390K resistor is connected in series with it.

4. In some sets coupling condenser between vertical multivibrator and vertical output tube may be .25 MFD - 600 V.

5. In sets of serial 50,000 and below, 1000 MMF condensers coupling sync to phase detector may be 1500 MMF $\pm$ 10%.

TELEVISION ALIGNMENT PROCEDURE

GENERAL

Complete alignment consists of the following individual procedures. Complete alignment should be performed in this sequence.

a. IF Amplifier Alignment.
b. 4.5 MC Sound IF Alignment.
c. RF and Mixer Alignment.
d. Overall RF and IF Response Curve Check and High Frequency Oscillator Alignment.

TEST EQUIPMENT

To properly service this receiver, it is recommended that the following test equipment be available. Note: Equipment below may be available as a single unit, except for the vacuum tube voltmeter.

SWEEP GENERATOR

Sweep generator must provide sweep frequencies from
18 to 30 MC range: 10 MC sweep width.
50 to 90 MC range: 10 MC sweep width.
170 to 225 MC range: 10 MC sweep width.
Output: adjustable; at least one-tenth volt maximum.
Output impedance: 300 ohms balanced to ground.
Sweep generator should preferably have a built-in marker generator with calibration crystal for checking dial accuracy.

SIGNAL GENERATOR with crystal calibrator which can also be used as a marker generator.
4.5 MC frequency.
18 to 30 MC frequency range.
50 to 90 MC frequency range.
170 to 225 MC frequency range.
Must have a built-in calibration crystal for checking dial accuracy.

OSCILLOSCOPE

Standard oscilloscope, preferably one with a wide band vertical deflection, vertical sensitivity at least .5 volt peak-to-peak per inch.

VACUUM-TUBE VOLTMETER

Standard Vacuum-tube Voltmeter with high resistance input and low voltage DC Range (3 volts or less). In addition, a zero center low voltage range will be found useful.

ALIGNMENT TOOLS

An alignment tool kit consisting of one metallic and one non-metallic screwdriver is necessary.

SWEEP GENERATOR NOTE

A sweep generator which does not have constant output voltage and reasonably linear sweep frequency distribution, will produce curves which are widely different from the "IF" Response Curve" or Overall RF and IF Response Curve" Shown in the following pages. If repeated difficulty is encountered in obtaining these curves, the sweep generator should be checked. A simple check is to observe the response curve for a set that is known to be in alignment.

Before suspecting the generator, be sure the alignment instructions have been followed carefully.

IF AMPLIFIER ALIGNMENT

a. Disconnect antenna; connect jumper wire across terminals.

b. Set receiver to channel 13 or other unassigned high channel to prevent signal interference during IF alignment. Set Picture control fully to right (clockwise).

c. Allow about 15 minutes for receiver and test equipment to warm up.

Step	Signal Gen. Freq. (MC)	VTVM and Signal Generator Connections	Instructions	Adjust
1	21.25	VTVM high side to test point "T", low to chassis. R.F. gen. high side to floating tube shield on 6J6 low to chassis.	Use VTVM 3 volt DC scale. Adjust signal generator to maintain approximately 1 volt output.	L5 for min.
2	23.2			L 3 & 4 for max.
3	25.2			L 1 & 2 for max.
4	To insure correct I.F. alignment, make the "I.F. Response Curve Check" given below.			

IF RESPONSE CURVE CHECK

(Using sweep generator and oscilloscope with sweep input to RF Mixer V2).

Differences in tube gain and component values affect IF response. These differences are not apparent in alignment of IFs when using a signal generator and VTVM (single frequency alignment); hence it is preferable that an IF response curve check be made after completion of the IF amplifier alignment.

The IF response curve check can be made as indicated directly below. However, also note that a better check can be made by feeding the sweep signal through the entire RF and IF system as given under "Overall RF and IF Response Curve Check (Step 1)". The overall check should be made after making all other alignments.

a. Make all control settings and connections as given in "a" through "c" the IF amplifier alignment chart above.

b. Connect oscilloscope* between point "T" and chassis ground, see fig. 4. Keep leads away from receiver.

c. Connect sweep generator high side to tube shield of 6J6 (V2) osc-mixer tube. Be sure to insulate tube shield from chassis. Connect sweet generator low side to chassis close to 6J6 tube base. Set sweep generator to sweep the IF band pass (19 to 29 MC).

d. If sweep generator does not have a built-in marker generator, loosely couple marker generator high side to the sweep generator lead connected to tube shield on tuner; low side to chassis ground.

To avoid distortion of the response curve, keep the sweep generator and marker generator outputs at a very minimum.

Marker pips should be just kept barely visible. To minimize distortion, set sweep generator output for VTVM reading of approximately .6 volt DC, measured between test point "T" and chassis. Connecting a 1-1/2 volt battery (negative to AGC Line, positive to chassis) will allow greater signal input without distorting the response curve.

e. Check curve obtained against the ideal IF response curve shown in figure 3. Since it is not always possible to get ideal curves, it should be noted that the height of opposite peaks should be within 30% of each other. The dip or valley in the center of the curve should not be greater than 30% down from the highest peak of the curve. Check video and sound IF carrier points by means of marker generator. It is important that marker pips be in the proper location on the response curve. The 25.75 MC marker, should be 50% below the highest peak on the high frequency side of the curve. The 22 MC marker should be at the opposite side of the response curve, located approximately 85% below the highest peak. The 21.25 MC marker should be located at least 95% below the highest peak, and may or may not be visible.

Consistent with proper band width and correct location of markers, the response curve should preferably have maximum amplitude, symmetry, and flat top appearance.

If the procedure given has been carefully followed and the response curve obtained differs greatly from the curve shown, repeat the IF Amplifier Alignment, making sure generator frequencies are precise and adjustments are accurately made.

***OSCILLOSCOPE NOTE**

*** In dealing with RF and IF response curves, it is well to remember that an inverted or mirror image may result, depending on the sweep generator and oscilloscope used. The general waveform should still be identical.**

When using a wide band oscilloscope for alignment, marker pips will be more distinct if condenser from 100 to 1,000 mmfd. is connected across the oscilloscope input. Caution: Use the smallest condenser possible, since too high a capacity will affect the shape of the response curve.

ALIGNMENT HINT

After becoming familiar with alignment procedure, some servicemen simplify subsequent alignment of sets by merely using the essential alignment data given in figures below.

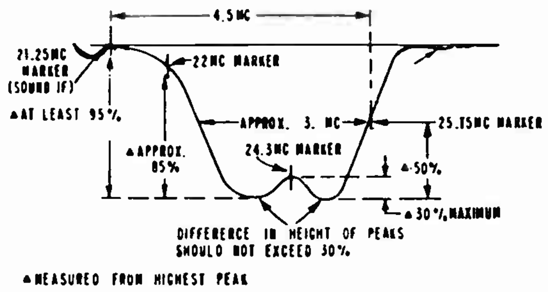


Figure 3 IF Response Curve.

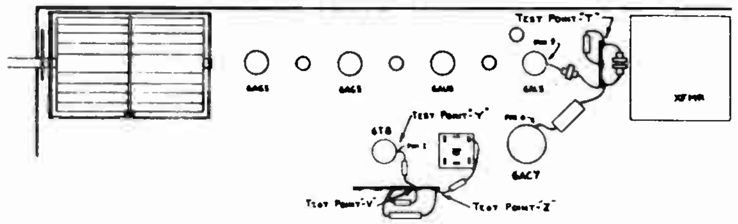

Figure 4 Bottom View Showing Test Point Connections.

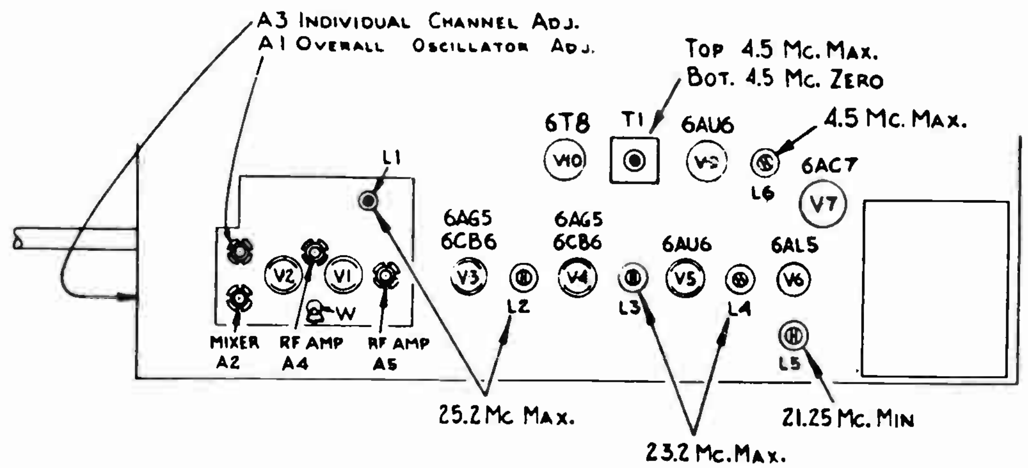

Figure 5 Top View of Chassis Showing Alignment Data.

4.5 MC SOUND IF ALIGNMENT

a. Disconnect antenna. Connect jumper wire across terminals.

b. Connect signal generator high side to Pin 4 V7, connect low side to chassis.

c. Allow about 15 minutes for receiver and test equipment to warm up.

d. Set Picture control fully to the right (clockwise).

Step	Signal Gen. Freq. (MC)	VTVM Connections	Instructions	Adjust
1	Since the transmitted video and sound carriers have an accurate 4.5 MC frequency difference, it is advisable to use a TV station signal instead of a signal generator for accurate alignment of steps below. When using a television signal, it may be necessary to use a higher scale on the VTVM. (30V) IMPORTANT: When using a signal generator, be sure to check it against a crystal calibrator or other frequency standard for accurate frequency calibration at 4.5 MC. Accuracy required is within one kilocycle.			
2	4.5 unmodulated or AM modulated. See step 1 for use of station signal.	High side to test point "Y"; common to chassis.	Use 3 volt DC scale on VTVM. Keep VTVM leads well separated from signal generator (if used) and chassis wiring.	L 6 and top of T1 for maximum (keep reducing generator output to keep VTVM at approx. 1 volt).
3		High side to test point "Z" common to test point "V"	Use 3 volt zero center scale on VTVM, if available. Keep VTVM leads well separated from signal generator (if used) and chassis wiring.	Bottom of T1 for zero on VTVM (the correct zero point is located between a positive and a negative maximum).

(See Page 4 for MC Chart, Fig. 6. RF Response Curve, Fig. 7. Front view of T V Tuner and Fig. 8. Top of TV Tuner, Showing Adjustment Location) Fig. 4 For Test Point Location.

RF AND MIXER ALIGNMENT

a. If used earlier, disconnect 1-1/2 volt battery.

b. Disconnect antenna from receiver.

c. Connect sweep generator to antenna terminals. If sweep generator does not have a built-in marker generator, loosely couple a marker generator to the antenna terminals. To avoid distortion of the response curve, keep sweep generator output at a minimum, marker pips just barely visible.

d. Connect oscilloscope through a 10,000 ohm resistor to test point "W" on tuner (Fig. 8). Keep scope leads away from chassis.

e. Allow about 15 minutes for receiver and test equipment to warm up.

Step	Marker Gen. Freq. (MC)	Sweep Gen. Frequency	Instructions
1	205.25 (Video Carrier) 209.75 (Sound Carrier)	Sweeping Channel 12	Check for curve resembling RF Response Curve shown below. If necessary, adjust A8, A9 and A10 (figure 9) as required. Note that adjusting A9 will shift the center of the response curve in relation to the video and sound carrier markers. A8 and A10 should be alternately adjusted for best gain with flat top appearance. Consistent with proper band width and correct marker location, response curve should have maximum amplitude and flat top appearance.
2	See frequency table below. Set the sweep generator to sweep the channel to be checked. Set the marker generator for the corresponding video carrier frequency and sound carrier frequency.		Check each channel operating in the service area for curve resembling RF Response Curve shown below. In general, the adjustment performed in step 1 is sufficient to give satisfactory response curves on all channels. However, if reasonable alignment is not obtained on a particular channel, (a) check to see that coils have not been intermixed, or (b) try replacing the pair of coils for that particular channel, or (c) repeat step 1 for the weak channel as a compromise adjustment to favor this particular channel. If a compromise adjustment is made, other channels operating in the service area should be checked to make certain that they have not been appreciably affected.

OVERALL RF and IF RESPONSE CURVE CHECK (Step 1) and HF OSCILLATOR ALIGNMENT (Step 2)

(Using sweep generator and oscilloscope.)

IMPORTANT

Since HF Oscillator alignment requires absolute frequency accuracy, a station signal is generally best suited for alignment of the individual channel oscillator slugs A3. The procedure for using a station signal (and without removal of chassis) is given in "Individual Channel Slug Adjustment Using Television Signal" on page 1.

The procedure for HF Oscillator alignment with an oscilloscope and a sweep generator is given below.

a. Disconnect antenna.

b. Disconnect signal generator and VTVM (if used earlier).

c. Set the Tuning control at half rotation by rotating it approximately 150° as shown in Figure 7.

d. Connect sweep generator to antenna terminals. If sweep generator does not have a built-in marker generator, loosely couple a marker generator to the antenna terminals. To avoid distortion of the response curve, keep sweep generator output at a minimum, marker pips just barely visible. Connecting a 1-1/2 volt battery (negative to AGC Line; positive to chassis) will allow greater signal input without distorting response curve.

e. Connect oscilloscope between point "T" and chassis ground (see Figure 4). Keep oscilloscope leads away from chassis.

f. Allow about 15 minutes for receiver and test equipment to warm up.

g. When adjusting A3, use a NON-METALLIC alignment screwdriver with a 1/8 inch blade.

Step	Marker Gen. Freq. (MC)	Sweep Gen. Frequency	Instructions
1			Sweep the RF band pass (channel 13 or other unassigned high channel) and check the shape of the overall response curve obtained against the ideal curve shown below. If shape of curve is not within limits shown, it will be necessary to repeat the IF Amplifier Alignment. The IFs must be accurately aligned before correct oscillator adjustment can be made.
2	See frequency table on page 11. Set the sweep generator to sweep the channel to be checked. Set the marker generator for the corresponding video carrier frequency and sound carrier frequency. Marker generator must have, or be used with, a calibrating source providing an accuracy of at least .05%.		Set the Tuning control at half rotation (see figure 7). Check to see whether oscillator alignment is required by comparing the location of the video and sound carrier markers (sound carrier marker may or may not be visible) on the response curve obtained for each channel with the "Overall RF and IF Response Curve" shown below. Note whether mis-alignment is evident on a major number of channels or on only a few channels. *If the markers for a major number of channels* are far off in the same direction, adjust the overall oscillator adjustment A1 (on channel 13 or other unassigned high channel) so that the video carrier marker is located as shown in the response curve given below. (If the video carrier marker is at the proper point on the curve, the sound carrier marker should locate at the proper point on the curve.) Be sure the Tuning control is at half rotation while making this adjustment. Recheck all channels individually for proper marker location. *If only individual channel adjustment is required,* adjust the particular individual channel slug A3, (using a NON-METALLIC alignment tool with a 1/8" blade) so that the video carrier marker is located as shown in the response curve given below. Only slight rotation of the slug will be required; turning the slug in too far will cause the slug to fall into the coil.* (If the video carrier marker is at the proper point on the curve, the sound carrier marker should locate at the proper point on the curve.) Be sure the Tuning control is at half rotation while making this adjustment.
3			To insure best reception and ease of tuning, a "touchup" adjustment of the individual channel slugs A3, using the station signal from each of the stations in the service area, must be made, preferably in the customer's home. See "Individual Channel Slug Adjustment Using Television Signal" on page 1.

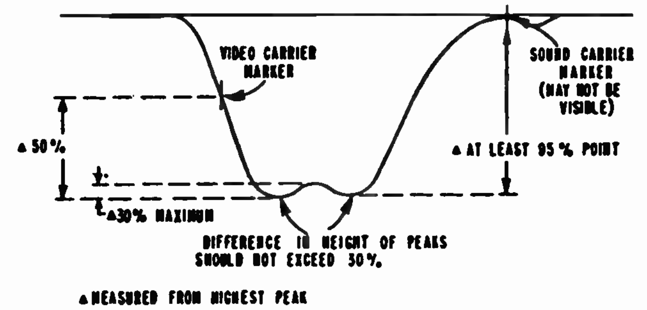

Fig. 9 Overall RF and IF Response Curve.

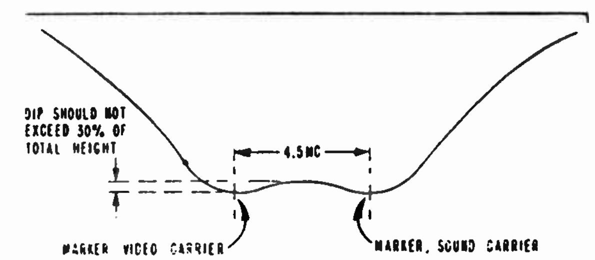
* If an oscillator slug should fall into a coil, remove the coil, move the slug retaining spring aside, lightly tap the open end of the coil against a solid object until the slug slips out. Replace slug and set the retaining spring into its cut-out slot.

Channel Number	Channel Freq. MC	Video Carrier, MC	Sound Carrier, MC
2	54- 60	55.25	59.75
3	60- 66	61.25	65.75
4	66- 72	67.25	71.75
5	76- 82	77.25	81.75
6	82- 88	83.25	87.75
7	174-180	175.25	179.75
8	180-186	181.25	185.75
9	186-192	187.25	191.75
10	192-198	193.25	197.75
11	198-204	199.25	203.75
12	204-210	205.25	209.75
13	210-216	211.25	215.75



Full skirt of curve will not be visible unless generator sweep width extends beyond 10 MC.

Figure 6. RF Response Curve.

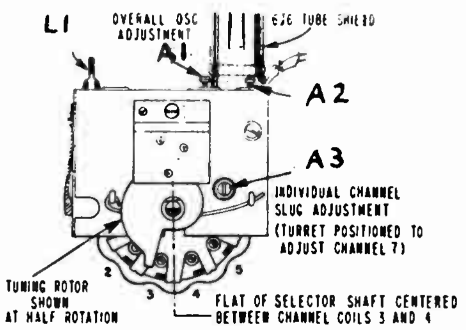


Fig. 7. Front View of TV Tuner.

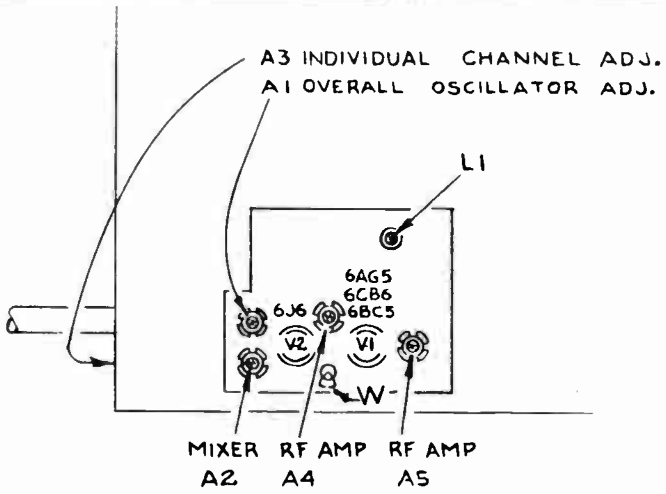

Figure 8. Top of TV Tuner, Showing Adjustment Location.

TELEVISION TUNER SERVICE

GENERAL

The TV tuner is a sub-chassis consisting of an RF amplifier stage and a mixer-oscillator stage.

Three different RF amplifier tubes, either 6AG5, 6BC5, or 6CB6, are used in this tuner. Although these tubes have similar characteristics and are generally interchangeable, it is advisable to check the RF amplifier curve with a sweep generator and oscilloscope after replacement. A dual triode 6J6 tube is used in the mixer-oscillator stage.

Channel selection is accomplished by rotation of the tuner turret assembly, which has a separate set of two coils for each of the 12 television channels. Each set consists of an antenna coil in one assembly, and a mixer-oscillator coil in another. Coils are the snap-in type. Coils can be identified as to channel by the number stamped on the outside of the coil assembly. A Tuning control permits fine adjustment of oscillator frequency.

The high frequencies used in television make it necessary that extreme care be exercised in servicing tuners.

Location and lead dress of components and wiring are usually very critical. Wiring leads, acting as small inductances or capacities, may appreciably alter electrical characteristics of critical circuits at high frequencies.

Parts location and ground connections should be as originally made. When replacing components, *it is important that they be replaced with parts of identical electrical characteristics and physical size.*

TUNING CONTROL

The Tuning control is a variable dielectric type condenser. The normal tuning range of the Tuning control for high channels is plus or minus 3 MC, for low channels plus or minus 1.5 MC.

Slight rubbing of the dielectric rotor of M104 against the grounded stator plate M107 is intentional, in order to avoid vibration with resulting microphonics. However the dielectric rotor should not be allowed to contact the circular disc riveted to the body of the tuner.

The Tuning control is permanently set at the factory and cannot be readjusted for frequency tuning range.

Refer to parts list for temperature coefficients, tolerances, and other essential description.

Note resemblance between some ceramic condensers and resistors. If in doubt, check Schematic.

Also note that replacement of tubes (especially 6J6 oscillator-mixer tube) may cause some slight detuning of tuner circuits. This is due to the inherent differences of inter-electrode capacitances. When replacing 6J6 tube, it is recommended that several tubes be tried in order to select a tube which will cause least oscillator frequency shift. This is easily checked by noting the amount of rotation of the Tuning control required to tune in the television signal. It is recommended that this check be made on the high channels. Make individual channel slug adjustments as instructed on page

Channel snap-in coils must be handled with care. Do not disturb coil windings. Also be sure the coils are properly paired for the indicated channel number, and that coils follow proper sequence when reassembled in the turret drum. For proper reference of tuner shaft in relation to coil position refer to figure 7.

TUNER REPLACEMENT

Replacement of the complete tuner should generally never become necessary since electrical and mechanical parts are easily replaceable. At time of publication, the manufacturer can supply a replacement tuner on an exchange basis, if you are unable to make repairs.

REMOVING CHANNEL COILS

Insert a screwdriver blade between the coil retainer spring and the turret end plate. Twist the blade away from the turret and lift the end of the coil upward.

CLEANING CONTACTS

Remove several sets of coils from turret and rotate turret to position making contact points of contact plate accessible for cleaning.

Using a small, stiff brush and carbon tetrachloride, clean contact surfaces of stationary contacts.

Remove accumulated dust or grease from stationary contacts and contact plate with a soft canvas cloth dampened with carbon tetrachloride. Accumulated rosin may be removed with a soft cloth dampened with alcohol.

Clean contact surfaces of rotating coils in same manner.

TUNER LUBRICATION

In general the lubrication applied to points of wear or friction at time of manufacture should make lubrication seldom, if ever necessary. However, should tuner lubrication become necessary, it is important that the correct amount and type of lubricant be used.

Using a clean brush, apply a film of switch contact oil, Viscosity Oil Co. #7069) to the surfaces of the coil contacts and stationary contact points.

Lubricate bearing surfaces of all other moving parts with light vaseline or preferably Viscosity Oil Co. #8857 lubricant.

CAUTION: Do not use lubriplate or any similar lubricant containing zinc or cadmium.

ADJUSTING CONTACT SPRINGS

Should the stationary contact springs make poor contact due to insufficient tension, remove several sets of coils from the turret. Rotate the turret to position making the bottom of the contact strip accessible for observation. With a narrow blade screwdriver, adjust the contact spring tension by carefully bending the spring inward until highest point on the spring extends about 9/64 of an inch above the plastic surface of the contact plate. With correct tension of the contact spring, the spring should clear the flat surface of the turret coil by about 1/64 of an inch.

OSCILLATOR SLUGS IN TOO FAR

If HF oscillator slugs "fall into" coil form, remove the channel coil, move the slug retaining spring M112 aside, and tap the coil assembly until the slug slips forward. Set the slug retaining spring into position; it should rest firmly against the slug.

REMOVING TUNER TURRET ASSEMBLY

a. Remove retaining bracket M107 in front of the tuner.
b. Remove rotor shaft assembly M104, rotor contact spring M124 and fibre washer M113. For reassembly, note order of parts removal.
c. Remove front and rear turret retaining springs M125 by pressing straight end away from tab on chassis.
d. Using a screwdriver blade at the side of the tuner, press the detent spring M122 and roller M121 away from the turret detent plate.
e. Grasp tuner shaft and slip out of end plate bearings.

REPLACEMENT OF THE UNGROUNDED STATOR PLATE OF TUNING CONTROL

Stator plate M118 is replaced with wiring lead and trimmer condenser C5 attached, because it is difficult to solder the wire lead to the silver plated surface on the ceramic stator plate disc.

To replace the stator plate, remove the turret assembly. Remove mounting rivets from stator plate by drilling out or clipping them out with diagonal wire cutters. Remove trimmer screw M115 and locking nut M114 from trimmer condenser C5. Unsolder wiring lead connecting trimmer to terminal on contact plate.

Assemble the replacement stator plate (M118) by placing the ceramic button over the 5/8" hole in the chassis with the wiring lead extending into the chassis. Place the mounting bracket over the ceramic button and mount securely using #4x3/16 round head machine screws with #4-40x3/16 hex nuts and #4 shake proof lock washers. Mount trimmer condenser C5 in chassis and solder wire lead to its original terminal on the contact plate making this lead as short as possible. Dress wiring lead from ceramic stator plate to trimmer condenser C5 so it does not come in contact with the turret drum. After replacement of the stator plate, adjust trimmer condenser C5 (overall oscillator adjustment).

REMOVING CONTACT PLATE ASSEMBLY M123

a. Remove turret.
b. Remove the mounting screws at the front and rear of Contact Plate and Bracket Assembly M123.
c. Unsolder both ends of contact plate assembly. Press outward the front and rear tuner chassis end plates.
d. To free contact plate assembly, release the contact plate tabs by pushing them away from the slots in the end plates.
e. Unsolder all connections to contact plate. Unsolder the solder joint holding contact plate to the center partition of the tuner chassis.
f. Reassemble in the same manner.

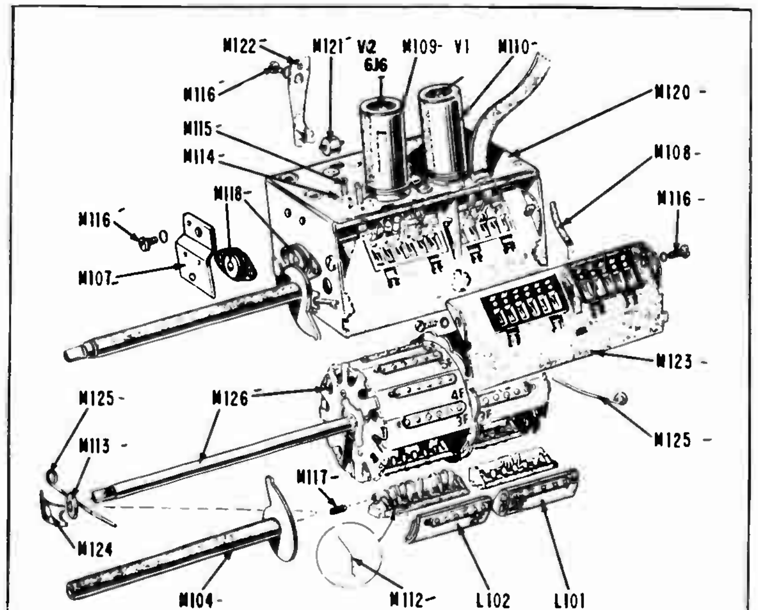

Figure 10. Exploded View, TV Tuner.

INTERMITTENT PICTURE AND SOUND

This trouble is most commonly due to an intermittent tube, loose tube socket contacts, dirty or loose coil contacts, loose or cold (rosin) soldered joints, or loose or vibrating parts in the underside of the tuner chassis.

When replacing tubes, see tube note under "General"

Loose tube socket contacts may sometimes be tightened by compressing contacts with an ice pick or a large needle. Defective tube socket contacts can sometimes be replaced individually.

For cleaning and adjusting coil contacts, see "Cleaning Contacts" and "Adjusting Contact Springs".

Loose or intermittent connections can be found by tapping components or rotating the channel selector and watching the pattern on an oscilloscope. A visual inspection or a continuity check will also be helpful.

Apply a hot soldering iron to soldered joints which appear doubtful. Caution: Do not change lead lengths or move components other than to slightly separate parts or leads which have caused trouble by contact with the chassis or other parts. See discussion under "General".

SOUND BARS IN PICTURE (DUE TO MICROPHONICS)

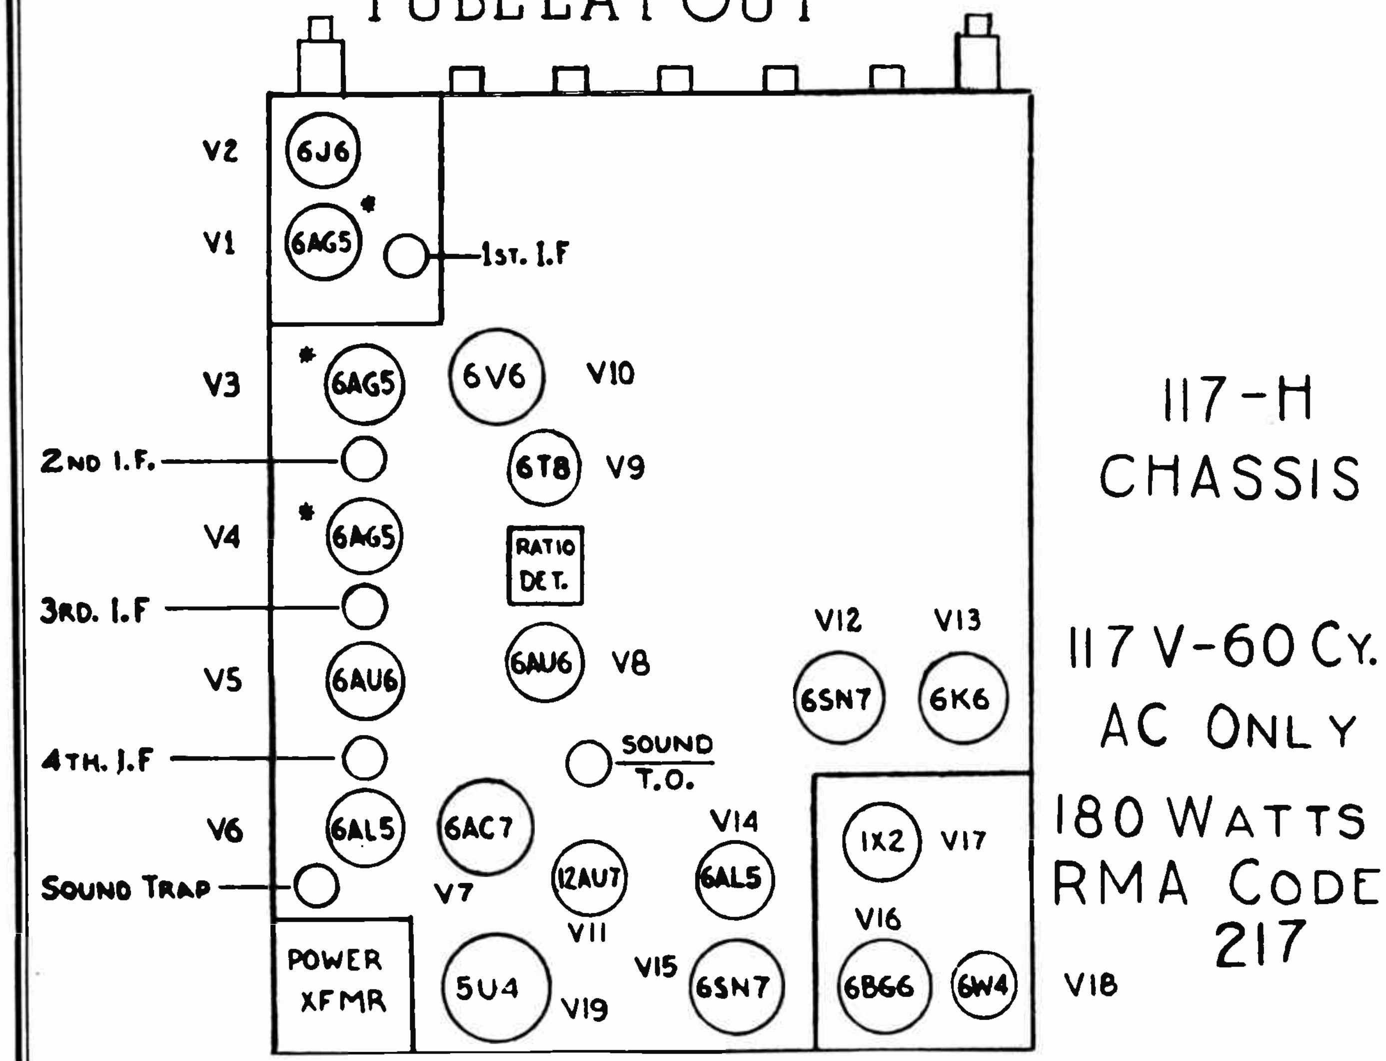
Microphonics in the TV Tuner will generally produce sound bars in the picture or a ringing sound as the volume is turned up or as the cabinet is tapped lightly.

Check for microphonic oscillator mixer tube, V2 (6J6). It is recommended that several tubes be tried, in order to select a tube which will be least microphonic and at the same time, causes a minimum of oscillator frequency shift, as noted with rotation of Tuning control. In some cases, replacement of the oscillator mixer tube, may necessitate readjustment of trimmer condenser A1 (C5) (overall oscillator adjustment).

Microphonics can also be due to vibration of loose wires or loose components. In some instances, the ceramic stator plate M118 (tuning stator) has been a source of microphonics since the rivets which fasten this part to the tuner chassis may be loose. This can be remedied by soldering the plate mounting bracket to the tuner chassis. To solder the plate mounting bracket to the tuner chassis, remove the grounded Tuning stator plate M107, and move the tuner shaft M104 forward.

Also, check for any mechanical "rub" such as loose screws which hold the tuner sub-chassis to the main chassis, loose solder connection from tube shield base to chassis, or extremely dry tuner shaft.

TUBELAYOUT



* Alternate Tubes: 6BC5-6CB6

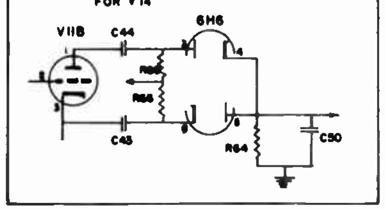
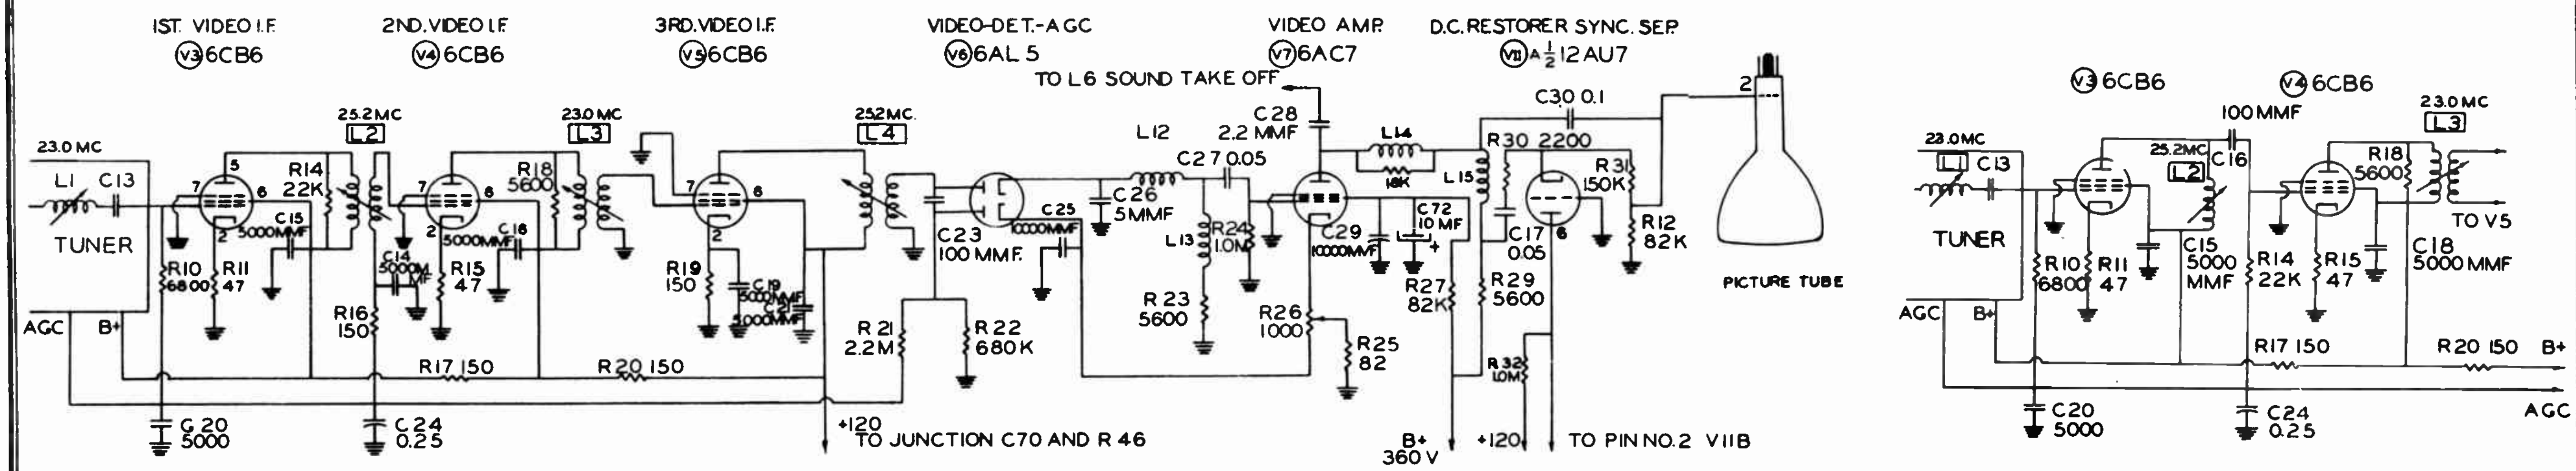
ALTERNATE CIRCUIT FOR V14



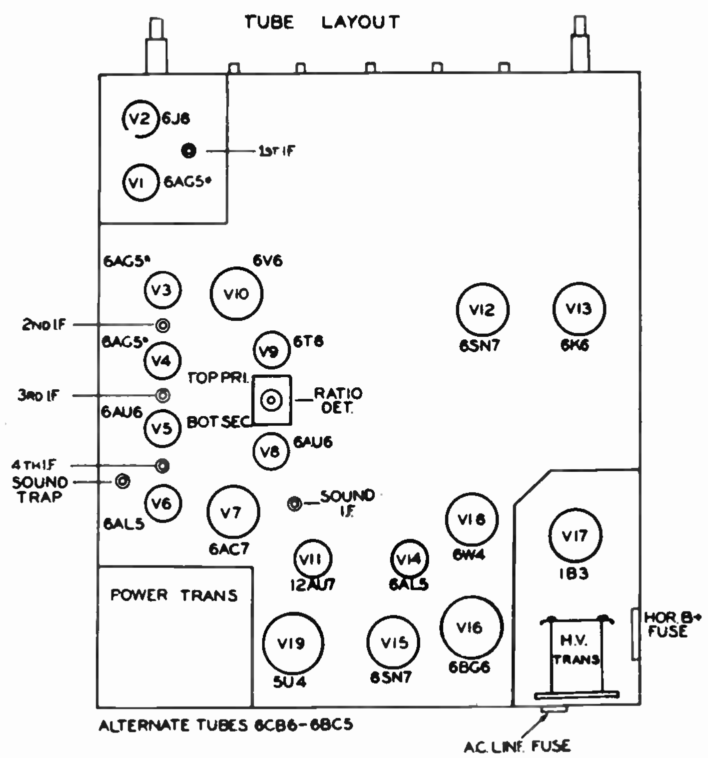


SCHEMATIC SUPPLEMENT

NOTE:
WHEN 6AG5 OR 6BC5 TUBES ARE USED FOR V3, V4, AND V5, PIN NO. 7 IS UNCONNECTED.

CHANGES IN MODEL 217 CHASSIS

The supplement to the schematic shows the changes in the video IF amplifier made. The changes in the sync separator and DC restorer were also incorporated into some chassis.
The changes in the IF amplifier were made to improve sensitivity and stability.
The changes in the DC restorer and sync separator improve the operation of the sync circuit and also improve the operation of the DC restorer so that the brightness control requires a minimum of adjustment when the contrast control is changes.
The following table should be substituted for the table labeled "IF AMPLIFIER ALIGNMENT".



ALTERNATE TUBES 6CB6-6BC5

117V-60~AC ONLY
180 WATTS
RMA CODE 217

IF AMPLIFIER ALIGNMENT

a. Disconnect antenna; connect jumper wire across terminals.

b. Set receiver to channel 13 or other unassigned high channel to prevent interference during IF alignment.

Set Picture control fully to right.

c. Allow about 15 minutes for receiver and test equipment to warm up.

STEP	SIGNAL GEN. FREQUENCY (MC)	VTVM AND SIGNAL GENERATOR CONNECTIONS	INSTRUCTIONS	ADJUST
1	25.2	VTVM high side to test point "T", low to chassis. R.F. gen. high side to floating tube shield on 6J6. Low to chassis.	Use VTVM 3 volt DC scale. Adjust signal generator to maintain approximately 1 volt output.	L4 & L2 for Max.
2	23.0			L1 & L3 for Max.
3	To insure correct I.F. alignment, make the "I.F. Response Curve Check" given below			

When ordering replacements, be sure to give complete description of part, chassis number, model number, and any other pertinent information in addition to part number if available.

SPECIFICATIONS

Direct View Electromagnetic Picture Tube
14" Rectangular — 21" Rectangular
17" Rectangular — 24" Round
20" Rectangular

Operating Voltage
110-120 60 Cycles

Wattage
175 Watts

Input Impedance and Transmission Line
300 ohm balanced (between antenna terminals)
75 ohm coaxial cable may be used by connecting shield to chassis and inner conductor to either antenna terminal

Intermediate Frequencies
Video - 25.75 Mc.
Sound - 21.25 Mc.
Intercarrier Sound - 4.5 Mc.

Fuse Location
Horizontal output fuse, F_1, is located inside the high voltage enclosure.
The line fuse, F_2, is located in a fuse holder on the rear apron of the chassis.

INSTALLATION AND SERVICE ADJUSTMENTS

When installing, each set should be checked for picture centering, picture tilt, shaded corners, proper size, linearity, etc., to insure best performance. It is especially important that the Ion Trap be checked, and that the Channel Slugs be adjusted upon installation or servicing of every set to insure ease of tuning. Any adjustments required should be made as described here.

For best results, all checks or adjustments should be made using a transmitted television test pattern. A mirror placed in front of the picture tube screen will be of help in observing the picture while adjusting rear chassis controls.

HIGH VOLTAGE WARNING

Operation of this receiver outside of its cabinet involves a shock hazard from the power supplies. No work should be attempted on this receiver by anyone who is not thoroughly familiar with the precautions necessary when working on the high voltage equipment.

EXTERNAL ANTENNA

When an external indoor or an outdoor antenna is required, be sure to disconnect the built-in antenna leads from the antenna terminal board, tape them and place them away from the chassis.

OPERATING THE TELEVISION RECEIVER

The controls of this receiver are operated conventionally. When tuning, carefully adjust the TUNING control for the best picture.

INDIVIDUAL CHANNEL SLUG ADJUSTMENT "A3" USING TELEVISION SIGNAL

Individual channel oscillator adjustment of every receiver should be checked upon installation or servicing. If this adjustment is properly made, it is possible to tune from one station to another by merely turning the CHANNEL control. With correct oscillator channel adjustment, best picture will be located at the approximate center of the range of the Tuning control.

Channel slug adjustment can be made without removing the chassis from the cabinet. Adjust as follows:

a. Turn the set on and allow 15 minutes to warm up.
b. Set the CHANNEL knob for a station in operation. Set all other controls for a normal picture.
c. Set TUNING control at center of its range by rotating it approximately half-way.
d. Remove the CHANNEL and TUNING knobs.
e. Insert a 1/8" blade, NON-METALLIC screwdriver in the 1/4" hole adjacent to the channel tuning shaft. For each channel in operation, carefully adjust the channel slug for the best picture with clear detail. Be sure that the Tuning control is set at the center of its range before adjusting each channel slug. Only slight rotation of the slug will be required; turning the slug in too far will cause it to fall into the coil. (If the slug falls into the coil, remove the coil, move the retaining spring aside, lightly tap the open end of the coil until the slug slips out. Replace slug and re-set retaining spring;)

If a number of slugs are found to tune all the way in or all the way out, or if the 6J6 oscillator-mixer tube has been replaced, it may be necessary to make the "Overall Oscillator Adjustment" as discussed below.

OVER-ALL OSCILLATOR ADJUSTMENT "A1" USING TELEVISION SIGNAL

Over-all oscillator adjustment should only be necessary when replacing the oscillator-mixer tube (6J6), or when all channel slugs are off in the same direction. When replacing the oscillator-mixer tube (6J6), it is recommended that several tubes be tried to select one which will cause least oscillator frequency shift.

A1 is generally adjusted so that approximately 3/16" of screw thread is exposed.

Adjust as follows:

a. Follow steps "a", "b", and "c" above.
b. Carefully adjust trimmer C6 (figure 8) for best picture with clear detail.
c. Check and, if necessary, make individual channel adjustments as indicated above.

ION TRAP ADJUSTMENT

To properly adjust the Ion Trap, Focusing Device and the Deflection Yoke the following procedure should be followed.

The Deflection Yoke should be placed in position closest to the "bell" of the Cathode Ray Tube as far forward on the neck of the tube as is possible. The Focus Device is next in line and Ion Trap last. See Figure 1.

The antenna should be connected to the receiver, the set should be turned on, the brilliance control turned to MAXIMUM and the contrast control at MAXIMUM.

The Ion Trap should be moved forward and backward and at the same time rotated to achieve the brightest raster on the face of the CRT.

Reduce the brilliance control to a point slightly over normal brightness and adjust the Focus Control on the rear of the Focus Device with a non-magnetic screwdriver for clearest and sharpest horizontal sweep lines. The Ion Trap should then be readjusted slightly for the brightest response on the face of the tube.

The Focus Device aperture should be moved to secure a complete raster centered and with no corners cut off.

Finally the Deflection Yoke should be rotated to "square" the raster with the chassis as a reference. The screws on the yoke brackets should then be set.

HEIGHT, WIDTH AND LINEARITY

To adjust the overall size and linearity of the picture it is almost mandatory that a pattern transmitted from a local station be used. Linearity adjustments, particularly, cannot be accurately made on moving transmissions. It should also be remembered that in areas where more than one station is being received, that pictures transmitted from different stations will vary slightly in size. The smallest transmitted picture should be made to fill the area delineated by the mask.

The first step in linearity and size adjustment is to turn the Width Control (rear of chassis) all the way in. (clockwise)

The Horizontal Drive trimmer should then be adjusted for the best compromise between maximum brightness and good horizontal linearity. Misadjustment of the Horizontal drive condenser will show as bright vertical bars on the left hand side of the picture. The Width Control should then be backed out until the picture is the correct width.

Vertical Linearity and height adjustment are made in the conventional manner. It will be noted that there is some interaction between these controls.

HORIZONTAL OSCILLATOR ADJUSTMENT

The set should hold horizontal sync over approximately one turn of the horizontal hold control. This will vary with signal strength of the received station. The control will bind at the extreme ends of its rotation. Do not attempt to force it to turn after binding is encountered or serious damage will result. If the set does not hold at a point in the center of the control range it indicates trouble in the horizontal oscillator or sync phase detector.

PICTURE TUBE REPLACEMENT

Important: After replacing any picture tube, be sure to make all deflection adjustments -- Picture Centering, Deflection Yoke, and Ion Trap -- as given on page 3. Especially note comments on picture centering.

WARNING: Because of the high 2nd anode voltage used (approximately 12KV) and the possibility of danger of implosion due to high vacuum, the following precautions should be noted when removing or replacing picture tubes:

a. Before handling a picture tube, remove the 2nd anode static charge from both the picture tube and the 2nd anode connector by shorting them to chassis.
b. Shatterproof goggles and heavy gloves should be worn while handling or installing a picture tube.
c. Always handle the picture tube very carefully. DO NOT pick the tube up by the neck.

TELEVISION ALIGNMENT PROCEDURE

GENERAL

Complete alignment consists of the following individual procedures. Complete alignment should be performed in this sequence.

a. IF Amplifier Alignment.
b. 4.5 MC Sound IF Alignment.
c. RF and Mixer Alignment.
d. Overall RF and IF Response Curve Check and High Frequency Oscillator Alignment.

TEST EQUIPMENT

To properly service this receiver, it is recommended that the following test equipment be available. Note: Equipment below may be available as a single unit, except for the vacuum tube voltmeter.

SWEEP GENERATOR

Sweep generator must provide sweep frequencies from
18 to 30 MC range: 10 MC sweep width.
50 to 90 MC range: 10 MC sweep width.
170 to 225 MC range: 10 MC sweep width.
Output: adjustable; at least one-tenth volt maximum.
Output impedance: 300 ohms balanced to ground.
Sweep generator should preferably have a built-in marker generator with calibration crystal for checking dial accuracy.

SIGNAL GENERATOR with crystal calibrator which can also be used as a marker generator.
4.5 MC frequency.
18 to 30 MC frequency range.
50 to 90 MC frequency range.
170 to 225 MC frequency range.
Must have a built-in calibration crystal for checking dial accuracy.

OSCILLOSCOPE

Standard oscilloscope, preferably one with a wide band vertical deflection, vertical sensitivity at least .5 volt peak-to-peak per inch.

VACUUM-TUBE VOLTMETER

Standard Vacuum-tube Voltmeter with high resistance input and low voltage DC Range (3 volts or less). In addition, a zero center low voltage range will be found useful.

ALIGNMENT TOOLS

An alignment tool kit consisting of one metallic and one non-metallic screwdriver is necessary.

SWEEP GENERATOR NOTE

A sweep generator which does not have constant output voltage and reasonably linear sweep frequency distribution, will produce curves which are widely different from the "IF" Response Curve" or Overall RF and IF Response Curve" Shown in the following pages. If repeated difficulty is encountered in obtaining these curves, the sweep generator should be checked. A simple check is to observe the response curve for a set that is known to be in alignment.

Before suspecting the generator, be sure the alignment instructions in this manual have been followed carefully.

IF AMPLIFIER ALIGNMENT

a. Disconnect antenna; connect jumper wire across terminals.
b. Set receiver to channel 13 or other unassigned high channel to prevent interference during IF alignment. Set Picture control fully to right.
c. Allow about 15 minutes for receiver and test equipment to warm up.

Step	Signal Gen. Frequency (MC)	VTVM and Signal Generator Connections	Instructions	Adjust
1	25.2	VTVM high side to test point "T", low to chassis. R.F. gen. high side to floating tube shield on 6J6. Low to chassis.	Use VTVM 3 volt DC scale. Adjust signal generator to maintain approximately 1 volt output.	L4 & L2 for Max.
2	23.0			L1 & L3 for Max.
3	To insure correct I.F. alignment, make the "I.F. Response Curve Check" given below.			

IF RESPONSE CURVE CHECK

(Using sweep generator and oscilloscope with sweep input to RF Mixer V2).

Differences in tube gain and component values affect IF response. These differences are not apparent in alignment of IFs when using a signal generator and VTVM (single frequency alignment); hence it is preferable that an IF response curve check be made after completion of the IF amplifier alignment.

The IF response curve check can be made as indicated directly below. However, also note that a better check can be made by feeding the sweep signal through the entire RF and IF system as given under "Overall RF and IF Response Curve Check (Step 1)". The overall check should be made after making all other alignments.

a. Make all control settings and connections as given in "a" through "c" the IF amplifier alignment chart above.
b. Connect oscilloscope* between point "T" and chassis ground, see fig. 4. Keep leads away from receiver.
c. Connect sweep generator high side to tube shield of 6J6 (V2) osc-mixer tube. Be sure to insulate tube shield from chassis. Connect sweet generator low side to chassis close to 6J6 tube base. Set sweep generator to sweep the IF band pass (19 to 29 MC).
d. If sweep generator does not have a built-in marker generator, loosely couple marker generator high side to the sweep generator lead connected to tube shield on tuner; low side to chassis ground.

To avoid distortion of the response curve, keep the sweep generator and marker generator outputs at a very minimum.

Marker pips should be just kept barely visible. To minimize distortion, set sweep generator output for VTVM reading of approximately .6 volt DC, measured between test point "T" and chassis. Connecting a 1-1/2 volt battery (negative to AGC Line, positive to chassis) will allow greater signal input without distorting the response curve.

e. Check curve obtained against the ideal IF response curve shown in figure 3. Since it is not always possible to get ideal curves, it should be noted that the height of opposite peaks should be within 30% of each other. The dip or valley in the center of the curve should not be greater than 30% down from the highest peak of the curve. Check video and sound IF carrier points by means of marker generator. It is important that marker pips be in the proper location on the response curve. The 25.75 MC marker, should be 50% below the highest peak on the high frequency side of the curve. The 22 MC marker should be at the opposite side of the response curve, located approximately 85% below the highest peak. The 21.25 MC marker should be located at least 95% below the highest peak, and may or may not be visible.

Consistent with proper band width and correct location of markers, the response curve should preferably have maximum amplitude; symmetry, and flat top appearance.

If the procedure given has been carefully followed and the response curve obtained differs greatly from the curve shown, repeat the IF Amplifier Alignment, making sure generator frequencies are precise and adjustments are accurately made.

***OSCILLOSCOPE NOTE**

*** In dealing with RF and IF response curves, it is well to remember that an inverted or mirror image may result, depending on the sweep generator and oscilloscope used. The general waveform should still be identical.**
When using a wide band oscilloscope for alignment, marker pips will be more distinct if condenser from 100 to 1,000 mmfd. is connected across the oscilloscope input. Caution: Use the smallest condenser possible, since too high a capacity will affect the shape of the response curve.

ALIGNMENT HINT

After becoming familiar with alignment procedure, some servicemen simplify subsequent alignment of sets by merely using the essential alignment data given in figures below.

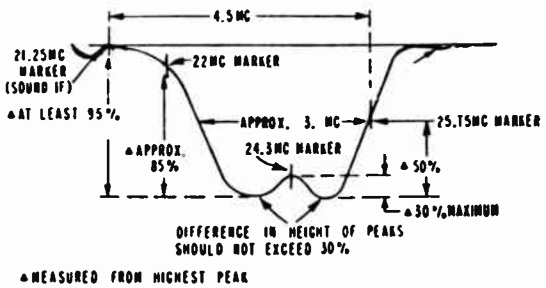

Figure 3 IF Response Curve.

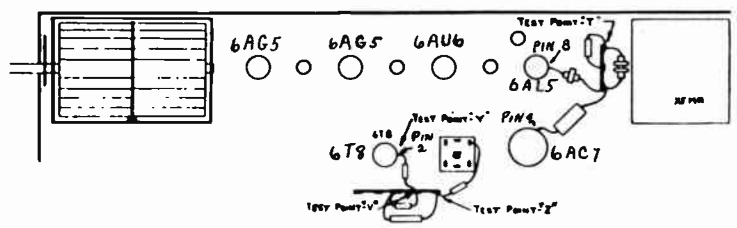

Figure 4 Bottom View Showing Test Point Connections.

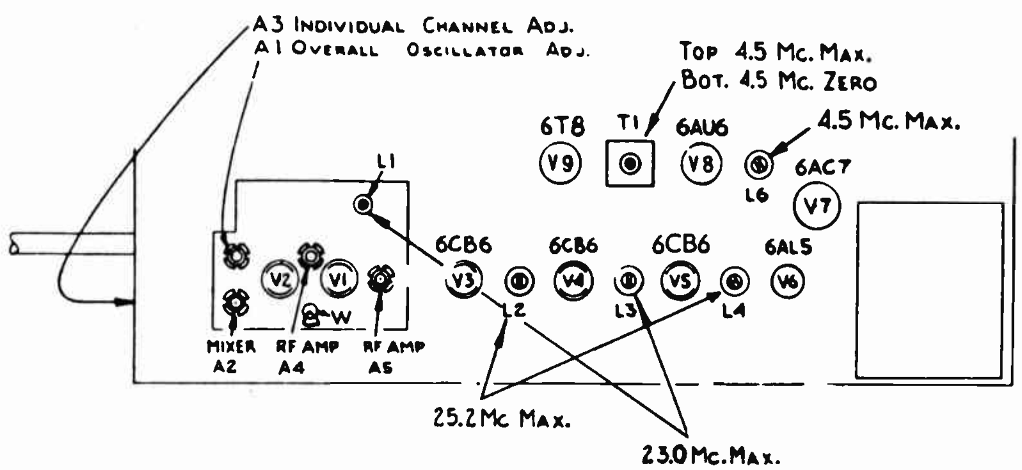

Figure 5 Top View of Chassis Showing Alignment Data.

4.5 MC SOUND IF ALIGNMENT

a. Disconnect antenna. Connect jumper wire across terminals.
b. Connect signal generator high side to Pin 4 V7, connect low side to chassis.
c. Allow about 15 minutes for receiver and test equipment to warm up.
d. Set Picture control fully to the right (clockwise).

Step	Signal Gen. Freq. (MC)	VTVM Connections	Instructions	Adjust
1	Since the transmitted video and sound carriers have an accurate 4.5 MC frequency difference, it is advisable to use a TV station signal instead of a signal generator for accurate alignment of steps below. When using a television signal, it may be necessary to use a higher scale on the VTVM. (30V) IMPORTANT: When using a signal generator, be sure to check it against a crystal calibrator or other frequency standard for accurate frequency calibration at 4.5 MC. Accuracy required is within one kilocycle.			
2	4.5 uumodulated or AM modulated. See step 1 for use of station signal.	High side to test point "Y"; common to chassis.	Use 3 volt DC scale on VTVM. Keep VTVM leads well separated from signal generator (if used) and chassis wiring.	L6 and top of T1 for maximum (keep reducing generator output to keep VTVM at approx. 1 volt).
3		High side to test point "Z" common to test point "V"	Use 3 volt zero center scale on VTVM, if available. Keep VTVM leads well separated from signal generator (if used) and chassis wiring.	Bottom of T1 for zero on VTVM (the correct zero point is located between a positive and a negative maximum).

(See Page 11 for MC Chart, Fig. 6. RF Response Curve, Fig. 7. Front view of T V Tuner and Fig. 8. Top of TV Tuner, Showing Adjustment Location) Fig. 4 For Test Point Location.

RF AND MIXER ALIGNMENT

a. If used earlier, disconnect 1-1/2 volt battery.
b. Disconnect antenna from receiver.
c. Connect sweep generator to antenna terminals. If sweep generator does not have a built-in marker generator, loosely couple a marker generator to the antenna terminals. To avoid distortion of the response curve, keep sweep generator output at a minimum, marker pips just barely visible.
d. Connect oscilloscope through a 10,000 ohm resistor to test point "W" on tuner (Fig. 8). Keep scope leads away from chassis.
e. Allow about 15 minutes for receiver and test equipment to warm up.

Step	Marker Gen. Freq. (MC)	Sweep Gen. Frequency	Instructions
1	205.25 (Video Carrier) 209.75 (Sound Carrier)	Sweeping Channel 12	Check for curve resembling RF Response Curve shown below. If necessary, adjust A8, A9 and A10 (figure 9) as required. Note that adjusting A9 will shift the center of the response curve in relation to the video and sound carrier markers. A8 and A10 should be alternately adjusted for best gain with flat top appearance. Consistent with proper band width and correct marker location, response curve should have maximum amplitude and flat top appearance.
2	See frequency table below. Set the sweep generator to sweep the channel to be checked. Set the marker generator for the corresponding video carrier frequency and sound carrier frequency.		Check each channel operating in the service area for curve resembling RF Response Curve shown below. In general, the adjustment performed in step 1 is sufficient to give satisfactory response curves on all channels. However, if reasonable alignment is not obtained on a particular channel, (a) check to see that coils have not been intermixed, or (b) try replacing the pair of coils for that particular channel, or (c) repeat step 1 for the weak channel as a compromise adjustment to favor this particular channel. If a compromise adjustment is made, other channels operating in the service area should be checked to make certain that they have not been appreciably affected.

OVERALL RF and IF RESPONSE CURVE CHECK (Step 1) and HF OSCILLATOR ALIGNMENT (Step 2)

(Using sweep generator and oscilloscope.)

IMPORTANT

Since HF Oscillator alignment requires absolute frequency accuracy, a station signal is generally best suited for alignment of the individual channel oscillator slugs A3. The procedure for using a station signal (and without removal of chassis) is given in "Individual Channel Slug Adjustment Using Television Signal" on page 11.

The procedure for HF Oscillator alignment with an oscilloscope and a sweep generator is given below.

a. Disconnect antenna.
b. Disconnect signal generator and VTVM (if used earlier).
c. Set the Tuning control at half rotation by rotating it approximately 150° as shown in Figure 7.
d. Connect sweep generator to antenna terminals. If sweep generator does not have a built-in marker generator, loosely couple a marker generator to the antenna terminals. To avoid distortion of the response curve, keep sweep generator output at a minimum, marker pips just barely visible. Connecting a 1-1/2 volt battery (negative to AGC Line; positive to chassis) will allow greater signal input without distorting response curve.
e. Connect oscilloscope between point "T" and chassis ground (see Figure 4). Keep oscilloscope leads away from chassis.
f. Allow about 15 minutes for receiver and test equipment to warm up.
g. When adjusting A3, use a NON-METALLIC alignment screwdriver with a 1/8 inch blade.

Step	Marker Gen. Freq. (MC)	Sweep Gen. Frequency	Instructions
1	Sweep the RF band pass (channel 13 or other unassigned high channel) and check the shape of the overall response curve obtained against the ideal curve shown below. If shape of curve is not within limits shown, it will be necessary to repeat the IF Amplifier Alignment. The IFs must be accurately aligned before correct oscillator adjustment can be made.		
2	See frequency table Set the sweep generator to sweep the channel to be checked. Set the marker generator for the corresponding video carrier frequency and sound carrier frequency. Marker generator must have, or be used with, a calibrating source providing an accuracy of at least .05%.		Set the Tuning control at half rotation (see figure 7). Check to see whether oscillator alignment is required by comparing the location of the video and sound carrier markers (sound carrier marker may or may not be visible) on the response curve obtained for each channel with the "Overall RF and IF Response Curve" shown below. Note whether mis-alignment is evident on a major number of channels or on only a few channels. *If the markers for a major number of channels* are far off in the same direction, adjust the overall oscillator adjustment A1 (on channel 13 or other unassigned high channel) so that the video carrier marker is located as shown in the response curve given below. (If the video carrier marker is at the proper point on the curve, the sound carrier marker should locate at the proper point on the curve.) Be sure the Tuning control is at half rotation while making this adjustment. Recheck all channels individually for proper marker location. *If only individual channel adjustment is required,* adjust the particular individual channel slug A3, (using a NON-METALLIC alignment tool with a 1/8" blade) so that the video carrier marker is located as shown in the response curve given below. Only slight rotation of the slug will be required; turning the slug in too far will cause the slug to fall into the coil.* (If the video carrier marker is at the proper point on the curve, the sound carrier marker should locate at the proper point on the curve.) Be sure the Tuning control is at half rotation while making this adjustment.
3	To insure best reception and ease of tuning, a "touchup" adjustment of the individual channel slugs A3, using the station signal from each of the stations in the service area, must be made, preferably in the customer's home. See "Individual Channel Slug Adjustment Using Television Signal" on page 11.		

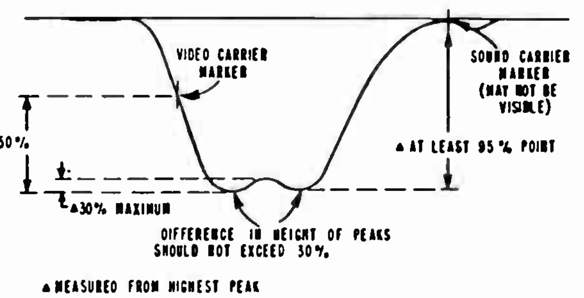

Fig. 9 Overall RF and IF Response Curve.

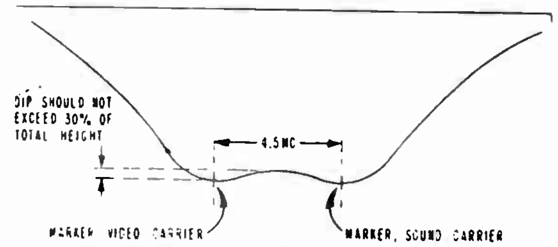
* If an oscillator slug should fall into a coil, remove the coil, move the slug retaining spring aside, lightly tap the open end of the coil against a solid object until the slug slips out. Replace slug and set the retaining spring into its cut-out slot.

Channel Number	Channel Freq. MC	Video Carrier, MC	Sound Carrier, MC
2	54- 60	55.25	59.75
3	60- 66	61.25	65.75
4	66- 72	67.25	71.75
5	76- 82	77.25	81.75
6	82- 88	83.25	87.75
7	174-180	175.25	179.75
8	180-186	181.25	185.75
9	186-192	187.25	191.75
10	192-198	193.25	197.75
11	198-204	199.25	203.75
12	204-210	205.25	209.75
13	210-216	211.25	215.75



Full skirt of curve will not be visible unless generator sweep width extends beyond 10 MC.
Figure 6. RF Response Curve.

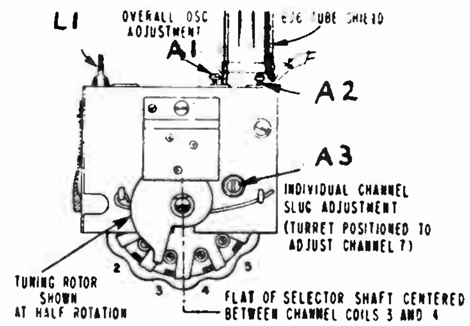


Fig. 7. Front View of TV Tuner.

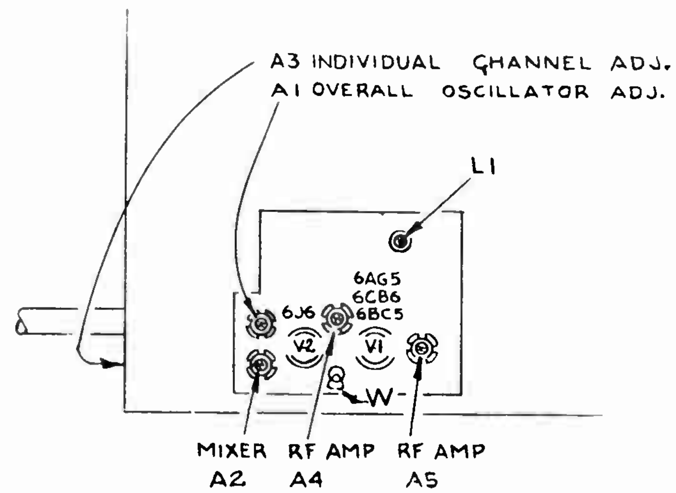

Figure 8. Top of TV Tuner, Showing Adjustment Location.

TELEVISION TUNER SERVICE

GENERAL

The TV tuner is a sub-chassis consisting of an RF amplifier stage and a mixer-oscillator stage.

Three different RF amplifier tubes, either 6AG5, 6BC5, or 6CB6, are used in this tuner. Although these tubes have similar characteristics and are generally interchangeable, it is advisable to check the RF amplifier curve with a sweep generator and oscilloscope after replacement. A dual triode 6J6 tube is used in the mixer-oscillator stage.

Channel selection is accomplished by rotation of the tuner turret assembly, which has a separate set of two coils for each of the 12 television channels. Each set consists of an antenna coil in one assembly, and a mixer-oscillator coil in another. Coils are the snap-in type. Coils can be identified as to channel by the number stamped on the outside of the coil assembly. A Tuning control permits fine adjustment of oscillator frequency.

The high frequencies used in television make it necessary that extreme care be exercised in servicing tuners.

Location and lead dress of components and wiring are usually very critical. Wiring leads, acting as small inductances or capacities, may appreciably alter electrical characteristics of critical circuits at high frequencies.

Parts location and ground connections should be as originally made. When replacing components, *it is important that they be replaced with parts of identical electrical characteristics and physical size.*

Refer to parts list for temperature coefficients, tolerances, and other essential description.

Note resemblance between some ceramic condensers and resistors. If in doubt, check Schematic.

Also note that replacement of tubes (especially 6J6 oscillator-mixer tube) may cause some slight detuning of tuner circuits. This is due to the inherent differences of interelectrode capacitances. When replacing 6J6 tube, it is recommended that several tubes be tried in order to select a tube which will cause least oscillator frequency shift. This is easily checked by noting the amount of rotation of the Tuning control required to tune in the television signal. It is recommended that this check be made on the high channels. Make individual channel slug adjustments as instructed on page 11.

Channel snap-in coils must be handled with care. Do not disturb coil windings. Also be sure the coils are properly paired for the indicated channel number, and that coils follow proper sequence when reassembled in the turret drum. For proper reference of tuner shaft in relation to coil position refer to figure 7.

TUNER REPLACEMENT

Replacement of the complete tuner should generally never become necessary since electrical and mechanical parts are easily replaceable. At time of publication, the manufacturer can supply a replacement tuner on an exchange basis, if you are unable to make repairs.

TUNING CONTROL

The Tuning control is a variable dielectric type condenser. The normal tuning range of the Tuning control for high channels is plus or minus 3 MC, for low channels plus or minus 1.5 MC.

Slight rubbing of the dielectric rotor of M104 against the grounded stator plate M107 is intentional, in order to avoid vibration with resulting microphonics. However the dielectric rotor should not be allowed to contact the circular disc riveted to the body of the tuner.

The Tuning control is permanently set at the factory and cannot be readjusted for frequency tuning range.

REMOVING CHANNEL COILS

Insert a screwdriver blade between the coil retainer spring and the turret end plate. Twist the blade away from the turret and lift the end of the coil upward.

CLEANING CONTACTS

Remove several sets of coils from turret and rotate turret to position making contact points of contact plate accessible for cleaning.

Using a small, stiff brush and carbon tetrachloride, clean contact surfaces of stationary contacts.

Remove accumulated dust or grease from stationary contacts and contact plate with a soft canvas cloth dampened with carbon tetrachloride. Accumulated rosin may be removed with a soft cloth dampened with alcohol.

Clean contact surfaces of rotating coils in same manner.

TUNER LUBRICATION

In general the lubrication applied to points of wear or friction at time of manufacture should make lubrication seldom, if ever necessary. However, should tuner lubrication become necessary, it is important that the correct amount and type of lubricant be used.

Using a clean brush, apply a film of switch contact oil, Viscosity Oil Co. #7069) to the surfaces of the coil contacts and stationary contact points.

Lubricate bearing surfaces of all other moving parts with light vaseline or preferably Viscosity Oil Co. #8857 lubricant.

CAUTION: Do not use lubriplate or any similar lubricant containing zinc or cadmium.

ADJUSTING CONTACT SPRINGS

Should the stationary contact springs make poor contact due to insufficient tension, remove several sets of coils from the turret. Rotate the turret to position making the bottom of the contact strip accessible for observation. With a narrow blade screwdriver, adjust the contact spring tension by carefully bending the spring inward until highest point on the spring extends about 9/64 of an inch above the plastic surface of the contact plate. With correct tension of the contact spring, the spring should clear the flat surface of the turret coil by about 1/64 of an inch.

OSCILLATOR SLUGS IN TOO FAR

If HF oscillator slugs "fall into" coil form, remove the channel coil, move the slug retaining spring M112 aside, and tap the coil assembly until the slug slips forward. Set the slug retaining spring into position; it should rest firmly against the slug.

REMOVING TUNER TURRET ASSEMBLY

a. Remove retaining bracket M107 in front of the tuner.
b. Remove rotor shaft assembly M104, rotor contact spring M124 and fibre washer M113. For reassembly, note order of parts removal.
c. Remove front and rear turret retaining springs M125 by pressing straight end away from tab on chassis.
d. Using a screwdriver blade at the side of the tuner, press the detent spring M122 and roller M121 away from the turret detent plate.
e. Grasp tuner shaft and slip out of end plate bearings.

REPLACEMENT OF THE UNGROUNDED STATOR PLATE OF TUNING CONTROL

Stator plate M118 is replaced with wiring lead and trimmer condenser C5 attached, because it is difficult to solder the wire lead to the silver plated surface on the ceramic stator plate disc.

To replace the stator plate, remove the turret assembly. Remove mounting rivets from stator plate by drilling out or clipping them out with diagonal wire cutters. Remove trimmer screw M115 and locking nut M114 from trimmer condenser C5. Unsolder wiring lead connecting trimmer to terminal on contact plate.

Assemble the replacement stator plate (M118) by placing the ceramic button over the 5/8" hole in the chassis with the wiring lead extending into the chassis. Place the mounting bracket over the ceramic button and mount securely using #4x3/16 round head machine screws with #4-40x3/16 hex nuts and #4 shake proof lock washers. Mount trimmer condenser C5 in chassis and solder wire lead to its original terminal on the contact plate making this lead as short as possible. Dress wiring lead from ceramic stator plate to trimmer condenser C5 so it does not come in contact with the turret drum. After replacement of the stator plate, adjust trimmer condenser C5 (overall oscillator adjustment).

REMOVING CONTACT PLATE ASSEMBLY M123

a. Remove turret.
b. Remove the mounting screws at the front and rear of Contact Plate and Bracket Assembly M123.
c. Unsolder both ends of contact plate assembly. Press outward the front and rear tuner chassis end plates.
d. To free contact plate assembly, release the contact plate tabs by pushing them away from the slots in the end plates.
e. Unsolder all connections to contact plate. Unsolder the solder joint holding contact plate to the center partition of the tuner chassis.
f. Reassemble in the same manner.

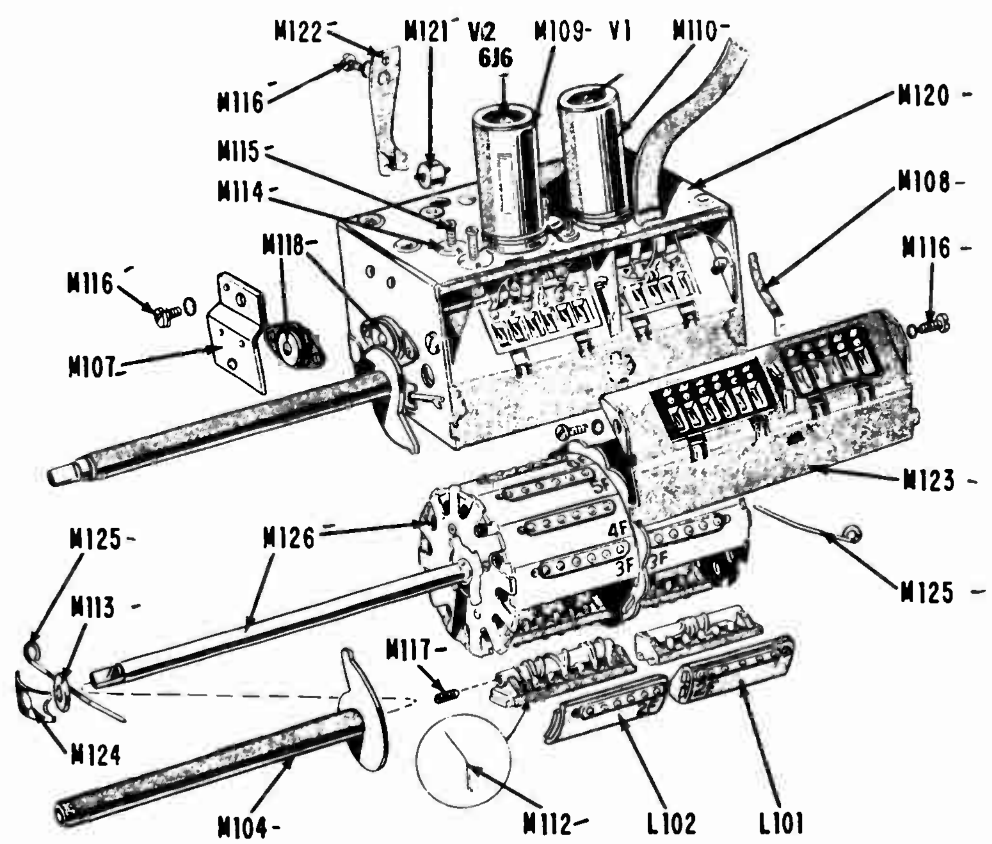

Figure 10. Exploded View, TV Tuner.

INTERMITTENT PICTURE AND SOUND

This trouble is most commonly due to an intermittent tube, loose tube socket contacts, dirty or loose coil contacts, loose or cold (rosin) soldered joints, or loose or vibrating parts in the underside of the tuner chassis.

When replacing tubes, see tube note under "General"

Loose tube socket contacts may sometimes be tightened by compressing contacts with an ice pick or a large needle. Defective tube socket contacts can sometimes be replaced individually.

For cleaning and adjusting coil contacts, see "Cleaning Contacts" and "Adjusting Contact Springs".

Loose or intermittent connections can be found by tapping components or rotating the channel selector and watching the pattern on an oscilloscope. A visual inspection or a continuity check will also be helpful.

Apply a hot soldering iron to soldered joints which appear doubtful. Caution: Do not change lead lengths or move components other than to slightly separate parts or leads which have caused trouble by contact with the chassis or other parts. See discussion under "General".

SOUND BARS IN PICTURE (DUE TO MICROPHONICS)

Microphonics in the TV Tuner will generally produce sound bars in the picture or a ringing sound as the volume is turned up or as the cabinet is tapped lightly.

Check for microphonic oscillator mixer tube, V2 (6J6). It is recommended that several tubes be tried, in order to select a tube which will be least microphonic and at the same time, causes a minimum of oscillator frequency shift, as noted with rotation of Tuning control. In some cases, replacement of the oscillator mixer tube, may necessitate readjustment of trimmer condenser A1 (C5) (overall oscillator adjustment).

Microphonics can also be due to vibration of loose wires or loose components. In some instances, the ceramic stator plate M118 (tuning stator) has been a source of microphonics since the rivets which fasten this part to the tuner chassis may be loose. This can be remedied by soldering the plate mounting bracket to the tuner chassis. To solder the plate mounting bracket to the tuner chassis, remove the grounded Tuning stator plate M107, and move the tuner shaft M104 forward.

Also, check for any mechanical "rub" such as loose screws which hold the tuner sub-chassis to the main chassis, loose solder connection from tube shield base to chassis, or extremely dry tuner shaft.

ADDITIONAL SERVICE INFORMATION

These chassis use a keyed AGC system and unless certain precautions are observed some difficulties may be encountered when IF or RF alignment adjustments are made. First be sure to read carefully the "Television Alignment Procedure"

A $1\frac{1}{2}$ volt bias battery should be connected across the AGC line (negative to junction of C24 and R52, positive to chassis), when making all alignment adjustments. This will prevent the amplifiers from overloading in the event that it is not possible to attenuate the signal generator sufficiently. Also, when the RF or IF amplifiers are sweep aligned the response curves will be distorted if a fixed bias is not applied to the AGC line due to the fact that the time constant of the keyed AGC circuit is short compared to the sweep frequency of the sweep generator. Therefore, the gain of the IF and RF amplifiers will not remain constant while the signal is sweeping through the response curve. When a sweep generator which does not have blanking is used, it will be impossible to make the forward and reverse response curves coincide unless a fixed bias is used.

In order to check the keyed AGC circuit for proper operation, the following simple test will be useful. When the grid of the AGC key tube (pin 1 V13) is shorted to the cathode (pin 7) the voltage on the AGC bus (across C24) should be approximately 40 to 70 volts **negative** as measured with a VTVM. In the event that this voltage is not obtained the trouble will probably be in the key tube V13, the horizontal output transformer T5, in one of the coupling or bypass condensers in the AGC line, or R52.

It may be found that in some cases there are minor deviations in the receivers in part values from those specified in the schematic. For example a .047 mfd condenser may be used in place of a .05 mfd condenser or a .22 mfd condenser in place of a .25 mfd condenser. In decoupling circuits in the AGC and B+ lines 100 ohm or 200 ohm resistors may be used in place of the 150 ohm resistors specified with negligible effect on the performance. When such substitutions are made they are always made in locations where the value of the part is not critical for it to effectively perform its function. There are many locations where tolerances of 100% or more are permissible. However, when replacements are made, if there is any doubt as to the suitability of the replacement part, the value as specified in the manual should be used.

Occasionally 6AG5 tubes are used in place of the 6CB6 tubes specified in the manual for the IF amplifiers V3, V4, and V5. It should be noted that these tubes are not directly interchangeable due to the different internal wiring of the tubes. Therefore, when replacing these tubes, be sure to use the same type that was originally supplied in the receiver. If 6AG5 tubes were originally used this type number will appear on the chassis near the tubes.

When requesting technical advice concerning service problems please give as complete detailed information as possible as regards to the remedies tried and the specific effects caused by the troubles. This will better enable us to suggest possible remedies for the trouble. Be sure to mention the model number, serial number, and chassis number when requesting information.

RADIO SPECIFICATIONS

Power Supply	105-125 volts 60 cycle AC only.
Power Consumption	65 Watts.
Frequency Range FM	88 to 108 MC.
Frequency Range AM	540 to 1600 KC.
I.F. Frequency FM	10.7 MC.
I.F. Frequency AM	455 KC.
Band width, FM, Ratio Detector	330 KC.
Band width, FM, 1st I.F.	280 KC.
Band width, FM, Converter	220 KC.

The tubes used are as follows:

12AT7	FM RF Amplifier, Converter
6BE6	FM Osc, Am Osc, Converter
6BA6	FM-AM, 1st I.F. Amplifier
6BA6	FM, 2nd I.F. Amplifier
6AL5	FM Detector
6AT6	AM Detector, AVC, Audio
6AQ5	Power Output
6X4	Power Rectifier
No. 44	Pilot Lights (2)

SERVICE NOTES

GENERAL

CAUTION: If realignment is necessary be sure the proper test equipment is available, as listed below, before proceeding with the alignment procedure as given.

Due to the high frequencies at which FM signals are received the service man must use great care when servicing thes sets. Extreme caution must be used regarding the moving of component parts in the R.F. and oscillator circuits of the receiver as those circuits can be detuned in this manner.

If it becomes necessary to replace components such as resistors and condensers they must be replaced with parts of the same size, type, voltage rating and tolerance as called for in the parts list.

When installing new parts they should be placed in the same position as the original, and the leads should be cut to the same length.

ALIGNMENT NOTES

This receiver has been thoroughly inspected and tested at the factory, using the most modern test equipment available, such as FM sweep generators and oscilloscopes. All R.F. and I.F. circuits have been accurately adjusted at the factory and no attempt should be made to realign these circuits unless it is absolutely necessary.

EQUIPMENT USED FOR ALIGNMENT

- Vacuum tube voltmeter.
- AM Signal generator
- FM Sweep generator.
- Oscilloscope.
- Insulated screw driver.
- Dummy antenna:
  - .1 MFD condenser
  - .00025 MFD mica condenser
  - 150 ohm resistor (2)
- Output meter.

NOTE A: When aligning the FM I.F. circuits, keep the out put from the signal generator as low as possible.

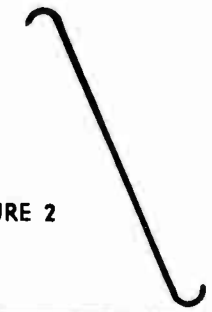

FIGURE 2

Band Switch on AM position. Dial 1600 KC. No Signal.

All voltage readings are taken from tube pin to chassis.

All measurements are made with no signal, using a 20,000 ohm per volt meter.

AC input voltage must be maintained at 117 volts for accurate readings.

AC voltages shown are at 1000 ohms per volt.

All voltages shown are approximate.

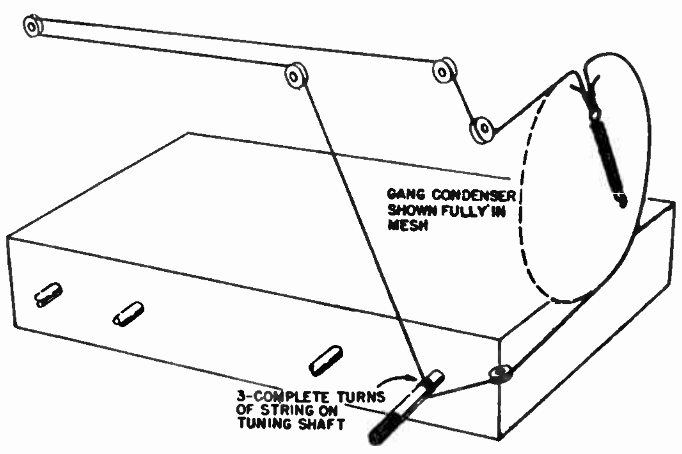

FIG. 4 DIAL CORD STRINGING

HOW TO ORDER REPAIR PARTS

Always give the part No. (No. printed on the part if different from that shown on this list), and the name of the part. When No. is not available, give complete description of part. Be sure to always give the Model No. and Catalog No. The Model No. will be found on a printed label which will be found at the back of the cabinet.

OLYMPIC TELEVISION RECEIVERS, CHASSIS TYPES TM AND TN

These models are twenty tube direct viewing television receivers differing only in type of cabinet, size of speaker and their use in conjunction with a radio receiver and automatic record changer in the combination models. A 17" electrostatically focused rectangular tube (17HP4) is used in the 17" models and a 21" magnetically focused rectangular tube (21ZP4A) is used in the 21" models. Replacement, in all cases, must be of the identical size and type.

Service information for radio chassis in combination models will be found in the Operating and Service Instructions (IB-3020), which is furnished with each set along with operating instructions for the automatic record changer.

Centering .... Centering Magnet on Neck of Pix Tube
Focus .... Single Control — Screwdriver Adjustment (Concealed) Front Panel — TN Only

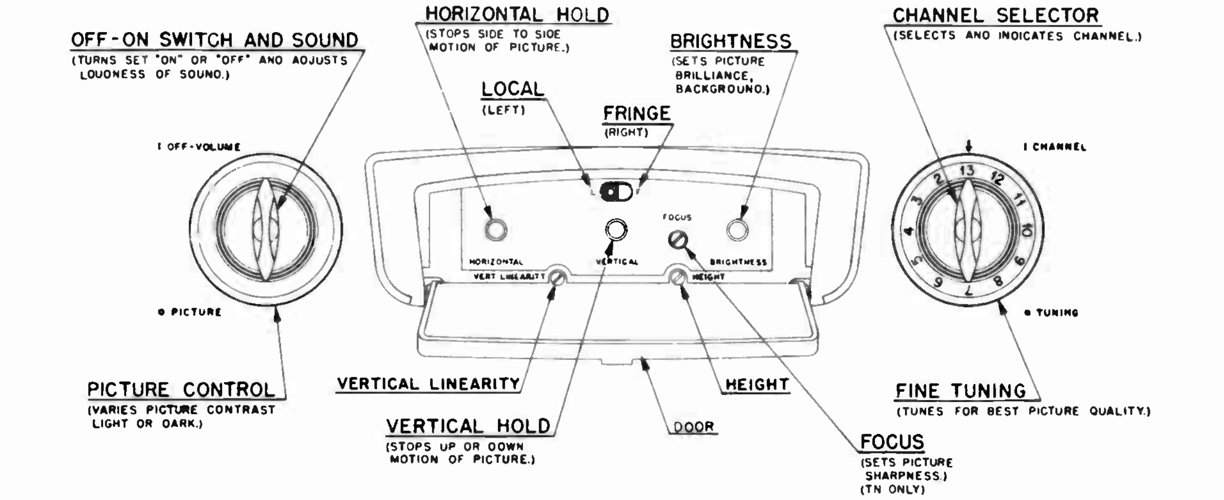

FIG. 1

CIRCUIT DESCRIPTION

GENERAL

The Olympic receivers covered by this manual use the Intercarrier type of Video and Sound IF System. Both Picture and Sound signals are received by the tuner, converted to an IF frequency and then fed, together, through three stages of video IF amplification. At the Video detector stage the two signals are separated. The sound signal is fed into a Sound IF Amplifier and then through a Ratio Detector, an Audio amplifier, an Audio Output stage and ultimately to the speaker. The Video signal with its accompanying Sync pulses are fed through a Video Amplifier after which the Sync pulses are diverted into four Sync Separating and Clipping Stages and from there to the Vertical and Horizontal Sweep Oscillators. The Video information is fed from the Video amplifier to the Cathode of the Cathode Ray (Picture) Tube.

TUNER

These receivers include the Olympic "Rocket" Tuner which is of the new cascode type. The principal advantages of the Rocket tuner are; greater sensitivity, improved Signal-to-noise ratio, and low radiation. Most of these properties are accomplished through the use of a dual triode (6BQ7 or 6BK7 — V1) in which the two sections of the tube are separated by a grounded shield. The first triode is used as grounded cathode amplifier and the AGC voltage, generated later in the Video Detector and AGC Stage, is applied to the grid. The second Triode section of the tube is a Grounded Grid Amplifier and is directly coupled to the first section. The first section is neutralized by a factory adjusted coil to resonate with the grid-cathode capacity of the second section. The overall gain of the two stages is only slightly higher than that of a single pentode but through the use of triodes, which have a smaller amount of tube noise, the signal to noise ratio is greatly improved.

The Oscillator and Mixer stages are essentially the same as earlier Olympic turret type tuners with the addition of a complete shield covering the entire underside of the tuner, internal shielding, and added decoupling, all to minimize radiation.

PICTURE IF SYSTEM

These receivers have three stages of Video IF Amplification. 6CB6's are used in all three positions (V7, 8 and 9). The first IF coil (L301) is located on the tuner and functions as the output coupling of the tuner. The second IF coil (L-5) is followed by the Adjacent Sound Trap (L-6). The adjacent sound trap eliminates interference in the picture which might be caused by the sound signal of the next lowest channel when the lower channel is used in the same area. The third Picture IF transformer (L-7) has no trap but the Fourth Picture IF (L-8) is followed by an Accompanying Sound Trap (L-9). All coils and traps are adjusted from the top of the chassis. The IF coils are "stagger-tuned" to four frequencies described later in this manual under "RF-IF Alignment Procedure."

VIDEO DETECTOR AND AGC

Both video detection and the development of the AGC voltage are accomplished in the triode section of a 6U8 (triode-pentode) V10. Video detection occurs between cathode (Input) and grid (output) while the AGC voltage is generated from cathode (input) to plate (output) of this triode (V10A). The AGC voltage is fed to the tuner and to the IF stages in the "local" position of the "Local-Distance" switch. In the fringe position "Average" AGC from the Detector load resistor is fed to the IF stages and half the AGC voltage to the tuner.

The sound portion of the composite signal is picked off the output of the Video detector by the 1st Sound IF Amplifier. This stage utilizes the pentode section of the 6U8 (V10B).

VIDEO AMPLIFIER

The signal that is fed into the grid (Pin 4) of the 6AC7 Video Amplifier (V11) has already had the sound information removed. (See "Video Detector and AGC" above). The Video information and the Sync and Blanking pulses are amplified in this stage. The Sync is picked off through an "RC" network consisting of R42 and C37 in the Plate circuit and fed to the Sync Separator and Clipper stages (V 12). The Video information goes to the cathode of the Kinescope (V 19 — Pin 11) after passing through a 4.5 Mc trap (L10) to eliminate any sound interference in the picture.

SYNC SEPARATOR AND CLIPPERS

The sync system of these receivers employs four stages. Two dual triodes, both 12AU7's, (V12 & V13). The first triode of the first tube (V12) is the sync separator stage. This in turn feeds into the first triode of the second tube (V13), the sync amplifier. The sync amplifier supplies pulses to the Horizontal AFC and oscillator (V15) and simultaneously to the Vertical Blocking oscillator (V14) (through the vertical integrating network). The second half of the first tube (V12) is the sync clipper and the second half of the second tube (V13) is the noise clipper.

SWEEP SYSTEM — VERTICAL

The second triode of the 12BH7, Vertical Oscillator and Output tube (V 14) serves as a vertical oscillator and discharge tube. The sync pulses from the Sync Separator and Clipper (V 12), after being shaped by the Vertical Integrating Network, are used to control the frequency of this section. The output of the oscillator stage is amplified in the first section of the same tube (V 14) and then fed through the Vertical Output Transformer to the vertical windings of the Deflection Yoke.

SWEEP SYSTEM — HORIZONTAL

The Horizontal Oscillator is essentially of the blocking oscillator type. The operation of the A.F.C. system depends upon a correcting voltage developed in the control section of the Horizontal Oscillator and AFC tube (V 15) where the oscillator output and the incoming pulses differ in either phase or frequency. The control tube, (first section V 15) is maintained at cut-off until such time as the sync pulse is either ahead or behind the Oscillator sawtooth peak. When either case occurs the control tube develops a voltage which is applied as a bias to the oscillator grid and alters the oscillator frequency to coincide with the frequency of the incoming pulses. The Horizontal Oscillator transformer (L16) has an adjustable core which is a coarse adjustment of the oscillator frequency and the front panel Horizontal Hold Control is a fine adjustment in the same sense.

Note: Many of the components in the horizontal circuits are of critical value and therefore should only be replaced by the exact replacement part. Care should also be taken in dressing leads and locating parts when replacing. This can be accomplished by carefully noting positions of parts and leads before removal.

SOUND SYSTEM

The sound carrier is taken off the plate (Pin 1) of the Video detector and AGC tube (V10A) and fed into the grid of the 1st Sound IF Amplifier (V10B — Pin 2) and from there through the Ratio Detector (V4), the Audio Amplifier (V5), the Audio Output tube (V6) and then to the speaker.

HIGH VOLTAGE POWER SUPPLY

The Energy stored in the horizontal windings of the deflection yoke during the forward sweep produces high voltage surges during retrace. This is multiplied by the "Auto Transformer" (primary) winding of the Horizontal Output Transformer (TR 2771) and is then rectified by a 1B3/G (V17) to provide approximately 15 Kilovolts for the picture tube anode (V20).

"B" VOLTAGE POWER SUPPLY

The "B" voltage in these chassis is provided by a standard transformer-rectifier circuit. The secondary of the Power Transformer provides, in addition to a center-tapped "B" voltage winding, a five-volt filament winding for the 5U4G Power Rectifier (V19), and two six-volt windings. One six-volt source is used for the filaments of the Damper Tube (V18) only, and the other for the filaments of all other tubes. A "B" voltage of +145 volts is derived from the cathode of the 6W6/GT Audio Output Tube (V 6). This voltage is utilized primarily in the IF circuits and removal of the 6W6 from its socket will therefore make the entire IF strip inoperative.

ADJUSTMENTS

ION TRAP MAGNET ADJUSTMENT

Turn the brightness control fully clockwise and the contrast control fully counterclockwise. Adjust the ion trap magnet by moving it forward or backward and at the same time rotating it slightly around the neck of the kinescope until the raster on the screen is brightest. Of two possible positions, use the one nearest the tube base. Reduce the brightness control setting until the raster is slightly above average brilliance. Adjust focus control until the line structure of the raster is clearly visible (sharp). Readjust the ion trap magnet again for maximum raster brilliance. The final touches on this adjustment should be made with the brightness control at the maximum position with which good line focus can be maintained. Never correct for a shadowed raster with the ion trap.

DEFLECTION YOKE ADJUSTMENT

If the lines of the raster are not horizontal or squared with the picture mask. Loosen the deflection yoke adjustment screw and rotate the deflection yoke until this condition is obtained, and retighten the yoke adjustment screw. If neck shadow is evident or the corners of the raster are dark, the deflection yoke must be moved forward as far as possible and the wing screw retightened.

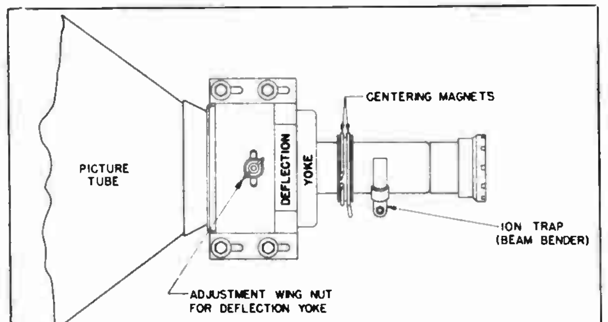

FIG. 2 - TM ONLY

CENTERING MAGNET ADJUSTMENT (17"—"TM" ONLY)

The centering magnet consists of two magnetic rings located on the neck of the picture tube. Each ring has a small tab and adjustment is accomplished by rotating these tabs around the neck of the tube. The tab which extends horizontally will affect the vertical position of the picture and the tab which extends vertically will affect the horizontal position of the picture. The two magnetic rings have their maximum affect when they are farthest apart but should never be more than 45° apart to avoid neck shadow.

CENTERING ADJUSTMENT (21" — "TN" — ONLY)

The 21" receivers are electromagnetically focused and centering is accomplished by adjusting an arm which extends vertically from the front of the focus coil. This arm may be rotated, for a limited distance, around the neck of the tube and may also be moved up and down. The physical setting of the focus coil itself in relation to the neck of the tube will also affect picture position. Before the adjustment arm is used, it should be ascertained that (1) the focus coil is at right angles to the neck of the tube (by setting the two nuts which tighten the tube support rods) and (2) that the neck of the tube is directly centered in the focus coil (by loosening the two mounting screws on either side of the focus coil and sliding up or down).

Note: Remove corrugated shipping clip from around neck of pix tube before attempting any adjustments.

ADJUSTMENT OF HORIZONTAL OSCILLATOR

(1) Allow set to warm up to operating temperature. Select station operating normally.

(2) Short out horizontal Phasing Coil (L 17) Terminals C and D.

(3) Set horizontal hold control at maximum clock-wise rotation.

(4) Adjust horizontal frequency screw (L 16) until picture falls into sync. Turning the horizontal frequency screw (L 16) clockwise lowers the frequency, (bars sloping downward to left). Turning the screw counter-clockwise increases frequency (bars sloping downward to right).

(5) Connect vertical input lead of oscilloscope with 5 MMF isolating condenser in series to terminal "C" of horizontal oscillator transformer and ground oscilloscope to chassis. Set frequency of scope to approximately 5 KC.

(6) Remove short from terminals of the horizontal phasing coil (L 17) and adjust screw (L 17) until wave shape as observed on scope is like that shown in sketch. (See Fig. 3.)

(7) Some further adjustment of horizontal frequency screw (L 16) may be necessary to keep picture in sync after adjusting L 17 for proper wave shape.

(8) Remove scope from terminal "C" and retouch L 16, as per "9" below.

(9) Turn horizontal hold control through entire range. Picture should fall out of sync at either end of rotation. At full clockwise rotation blanking bar or jitter should be evident. At full counter-clockwise position picture should fall out to $4\frac{1}{2}$ to 5 bars sloping downward to the left. (If picture stays in sync the tuner switch should be rotated to interrupt signal momentarily)

Caution: It is important that the picture be centered in the mask properly with the horizontal hold control in the mid-position, otherwise the set user may attempt to center the picture by means of the hold control. Under this condition the control may be on "edge" and impulse noise or change of camera will cause the picture to fall out of synchronization. It should also be noted that some manufacturers types of 6SN7GT may perform better than others in the horizontal oscillator socket and excessive drift of the horizontal oscillator circuit may be caused by a weak or defective 6SN7GT tube.

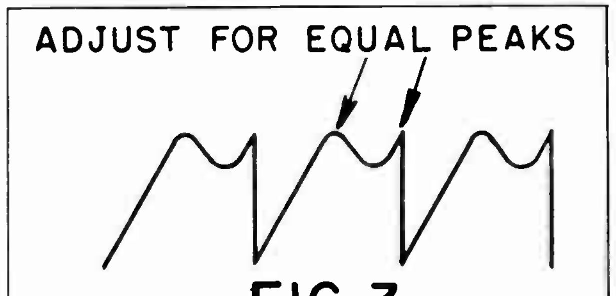

FIG. 3

HEIGHT AND VERTICAL LINEARITY ADJUSTMENTS

For best results it is preferable that these adjustments be made on a transmitted test pattern; although satisfactory results can be obtained from an active picture.

Both controls will affect the height **AND** linearity of the picture and therefore must be adjusted simultaneously. It will be found that the Height Control has a tendency to affect the bottom of the picture more than the top and the linearity control just the reverse.

Note: It is advisable that both height and width of the picture be adjusted to a size slightly larger than the mask opening, so that during periods of low line voltage adequate picture size is maintained.

HORIZONTAL WIDTH & DRIVE ADJUSTMENT

The Horizontal Width Control Coil (L19) and the Horizontal Drive Trimmer (C67) should be adjusted simultaneously. The Horizontal Drive Trimmer should be screwed tight (clockwise) and then backed off (counter-clockwise) until Horizontal Drive bars appear. Then turn Drive Trimmer in again (clockwise) until drive bars, just disappear. (Note: In some sets no horizontal drive bars will appear regardless of Drive Trimmer adjustment. In these sets the trimmer should be set at 2 turns out (counter-clockwise) from tight.) After the drive trimmer has been set, the width coil should be adjusted for proper picture width to fill the mask aperture.

Important: The horizontal oscillator frequency must be checked for proper range of horizontal control after any adjustment of horizontal drive (C67). Any adjustment of C67 will usually require resetting of the horizontal frequency adjustment coil (L-16).

BUILT-IN ANTENNA

All models are equipped with a built-in antenna which provide satisfactory reception in many locations. In areas of weak reception an outside antenna will substantially improve the performance of the receiver. Antenna binding posts are provided at the rear of chassis and are accessible through the opening in the masonite back to permit the connection of an outside aerial. The built-in antenna is normally connected to the antenna posts and must be disconnected when attaching the outside aerial. To prevent the lead-in wires of the built-in antenna from contacting chassis parts and tubes, it is recommended that the lead-in wire be folded and held in place by tape or a rubber band. In some cases reception can be improved by changing the location of the receiver in the room when set is operating with built-in antenna.

RF-IF ALIGNMENT PROCEDURE

EQUIPMENT REQUIRED

(1) RF signal generator to provide the following accurate frequencies:

(a) 4.5 Mc (Video Amplifier Trap, Sound IF and Ratio Detector)

(b) IF Frequencies

21.75	MC	Accompanying Sound Trap (L9)
27.75	MC	Adjacent Sound Trap (L6)
25.5	MC	First Pix IF Transformer (L301)
23.25	MC	Second Pix IF Transformer (L5)
25.25	MC	Third Pix IF Transformer (L7)
23.25	MC	Fourth Pix IF Coil (L8)
21.75	MC	Sound Carrier Marker
26.25	MC	Picture Carrier Marker
23.5	MC	Shoulder Marker

(c) **RF Frequencies**

CHANNEL NUMBER	PICTURE CARRIER FREQ. MC	SOUND CARRIER FREQ. MC
2	55.25	59.75
3	61.25	65.75
4	67.25	71.75
5	77.25	81.75
6	83.25	87.75
7	175.25	179.75
8	181.25	185.75
9	187.25	191.75
10	193.25	197.75
11	199.25	203.75
12	205.25	209.75
13	211.25	215.75

(d) Output on these ranges should be adjustable and capable of providing at least .1 volt.

If the accuracy of the generator frequencies is not known, some type of crystal calibrator should be utilized to check the correct settings of the RF generator for each particular frequency.

(2) Electronic Voltmeter

(3) Cathode Ray Oscilloscope, 3" minimum screen.

(4) RF Sweep Generator, meeting the following requirements:

(a) Frequency Ranges:

18 to 30 MC
40 to 90 MC } 10 MC sweep width
170 to 225 MC

(b) Output adjustable to .1 volt.

TO REMOVE CHASSIS FROM CABINET

Remove: (1) Line cord from power outlet
(2) Masonite back.
(3) Antenna Lead-in from terminal posts.
(4) Speaker plug from rear of chassis.
(5) Knobs from front of cabinet.
(6) Four mounting screws and washers from bottom of cabinet.

In sliding chassis out of cabinet, be careful that the kinescope tube does not strike against speaker or any other obstruction.

Before proceding it will be necessary to use an extra line (or "cheater") cord to supply AC current to the chassis as the set's line cord is attached to the masonite back of the cabinet.

ORDER OF ALIGNMENT

When complete receiver alignment is necessary, it should be performed in the following sequence:

(1) Accompanying Sound Trap
(2) Adjacent Sound Trap
(3) Pix IF Coils
(4) 4.5 MC Trap
(5) 4.5 MC Sound IF and Ratio Detector
(6) Tuner

After removing chassis from cabinet re-connect power and speaker plugs.

If a local station is not operating on Channel 9 set the tuner to this channel, turn on power switch and proceed as follows: (If 9 is a local station, use Channel 8 or 10.)

ACCOMPANYING AND ADJACENT SOUND TRAPS

Insert a 100,000 ohm $1/2$ watt resistor in series with the "Hot Lead" of the electronic voltmeter and connect to the junction of L12 and C33. Meter switch should be set to the lowest negative scale. Ground lead of meter should be connected to chassis.

Remove the shield of the RF Oscillator and Mixer tube (V2) from ground clips leaving shield resting on tube and connect hot lead of the RF Signal Generator to it. This will couple generator output to mixer plate.

Set the generator frequency accurately to 21.75 MC, and adjust (L9) sound trap (See Fig. 6 Tube and Trimmer Layout) for **minimum** reading on voltmeter.

Set the generator frequency accurately to 27.75 MC and adjust (L6) Adjacent Sound Trap for **minimum** reading on voltmeter.

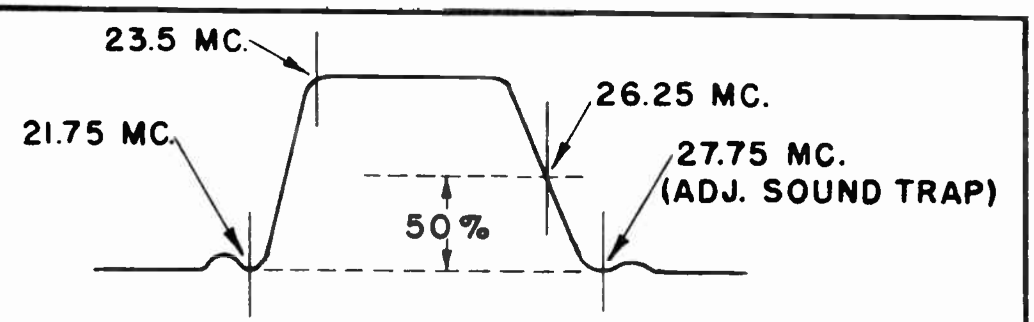

FIG. 4 STANDARD RESPONSE CURVE

PIX IF COIL ADJUSTMENT

Adjust the following slugs for maximum output at frequencies and sequence indicated with meter and generator connected as above: (See Sound Traps.)

L301	25.5 MC
L5	23.25 MC
L7	26.00 MC
L8	23.00 MC

Note: After setting L301 **DO NOT** readjust to improve wave shape.

If oscillation occurs during alignment, temporarily raise frequency of L5 by turning screw counter-clockwise until screw projects approximately 3/4". Oscillation is evidenced by high reading on voltmeter (—5V to —20V) with signal generator OFF and no signal coming in through the antenna terminals. After properly adjusting L301, L7 and L8 reset L5 to proper frequency, if it had been necessary to detune.

Connect hot lead of sweep generator through a 330 uuf condenser to test point on tuner and connect ground lead to chassis.

Connect vertical input terminal of oscilloscope to junction of peaking coil L12 and C33 and connect ground lead of scope to chassis.

Connect 1.5 V flashlight battery with positive terminal to chassis and negative terminal to junction of R32 and R33. Place the Local Distance Switch in the Local position. This point is origin of AGC bias voltage. Set tuner to Channel 9 unless local station is operating on this frequency, in which case an adjacent channel should be used.

Set Sweep Generator frequency to IF sweep on the 20 to 30 MC range.

Adjust sweep generator output to produce a curve on the scope which is approximately 2/3 of the screen diameter.

Loosely couple output of RF signal generator by using shield on V2 and set frequency of RF signal generator to 26.25 MC (marker).

Curve shown on scope should be similar to the response curve shown in Figure 4. For proper setting of the pix carrier the 26.25 MC marker should appear on the curve at a point approximately 50% of the vertical height of the curve.

To obtain this setting retouch L7.

Reset RF signal generator frequency to 23.5 MC and retouch L525 and L8 for correct positioning of marker on shoulder of curve.

Recheck setting of 26.25 MC marker to make sure that position has not shifted on curve.

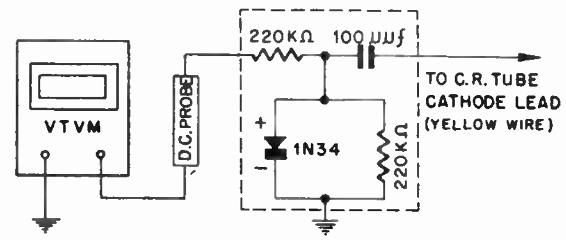
Disconnect bias battery.

Note: If the curve cannot be made to appear as above due to a local station or other interference, or if multiple markers appear, remove (V1-6BK7 or 6BQ7) RF tube from tuner.

4.5 MC TRAP ALIGNMENT

Connect voltmeter lead to Diode crystal rectifier as shown in Fig. 5. Connect Diode crystal rectifier between C.R. Tube Cathode lead (yellow wire) and chassis ground. Signal generator is connected at junction of L12 and C33. Set contrast control at maximum and voltmeter to 3 volt scale (negative). Remove 6CB6 (V9) from socket. Use maximum output of generator at 4.5 MC. Adjust L14 trap for **minimum** reading on meter.

When it is necessary to retouch this trap in the field, proper adjustment can be made by using the local station signal and turning the Fine Tuning Control to bring fine herringbone sound beat into the picture. The 4.5 MC trap (L14) should then be adjusted to minimize this beat interference.



VOLTMETER AND CRYSTAL DIODE CONNECTIONS

FIG. 5

SOUND IF TRANSFORMER, (4.5 MC) AND RATIO DETECTOR ADJUSTMENT

In view of the fact that the transmitted sound signal from a TV station is probably the most accurate available, as far as frequency is concerned, it is recommended that a working signal be used for sound alignment. The set should be connected to an antenna, turned on, allowed to warm up for about 5 to 10 minutes and then tuned for the best picture. A vacuum tube voltmeter should be connected to Pin 2-V4 and the meter set to the minus 30 volt scale. The 4.5 MC Sound IF Transformer (L1 & L2) and the primary of the Ratio Detector (L3 — bottom of chassis) should be tuned for maximum deflection of the meter. The vacuum tube voltmeter should then be connected to the junction of R10 and C9 and one side of the volume control and the secondary of the Ratio Detector (L4 — top adjustment) should be adjusted for a zero reading with the meter set to the 3 volt scale. The secondary can also be adjusted by ear by tuning L4 for the elimination of buzz in the sound.

TUNER ALIGNMENT FOR MODELS USING TUNER PART CL-2755-1

Note: Before making a complete tuner adjustment it is essential that all the IF, Trap, Sound and Discriminator circuits be aligned to their proper frequencies as described above. WHEN CHANGING THE CONVERTER TUBE IT IS NECESSARY TO REALIGN THE OSCILLATOR ADJUSTMENT ON ALL CHANNELS WITH THE V2 TUBE SHIELD IN PLACE.

A. RF and Converter Alignment

(1) Set Channel Selector switch to #12.

(2) Connect oscilloscope through 10,000 ohms to test point on tuner (bare tinned copper loop wire located between V1 and V2).

(3) Set fine tuning control at approximately midpoint of its tuning range. Temporarily connect jumper wire from Test Point "D" to chassis.

(4) Feed sweep generator into antenna terminals, sweeping channel 12.

(5) Adjust C301, C302 and C304 for flat top response curve. Check picture and sound carrier markers corresponding to frequencies shown in Service Data Section.

(6) Remove jumper from Test Point "D" to chassis.

B. Oscillator Alignment

Note: Oscillator adjustments (which are accessible through the hole in the front of the tuner) are provided for each channel. See "Tube and Trimmer Layout". Any oscillator coil slug can be adjusted without interaction on any other channel since individual coils are used for each of the 12 channels. This adjustment may be made on the station or with sweep generator and signal generator as follows:

(1) Set fine tuning control to midpoint of range. Do not touch during alignment.

(2) Connect sweep generator and marker (signal) generator to antenna terminals.

(3) Connect vertical input lead of scope with 50K resistor in series to test point A.

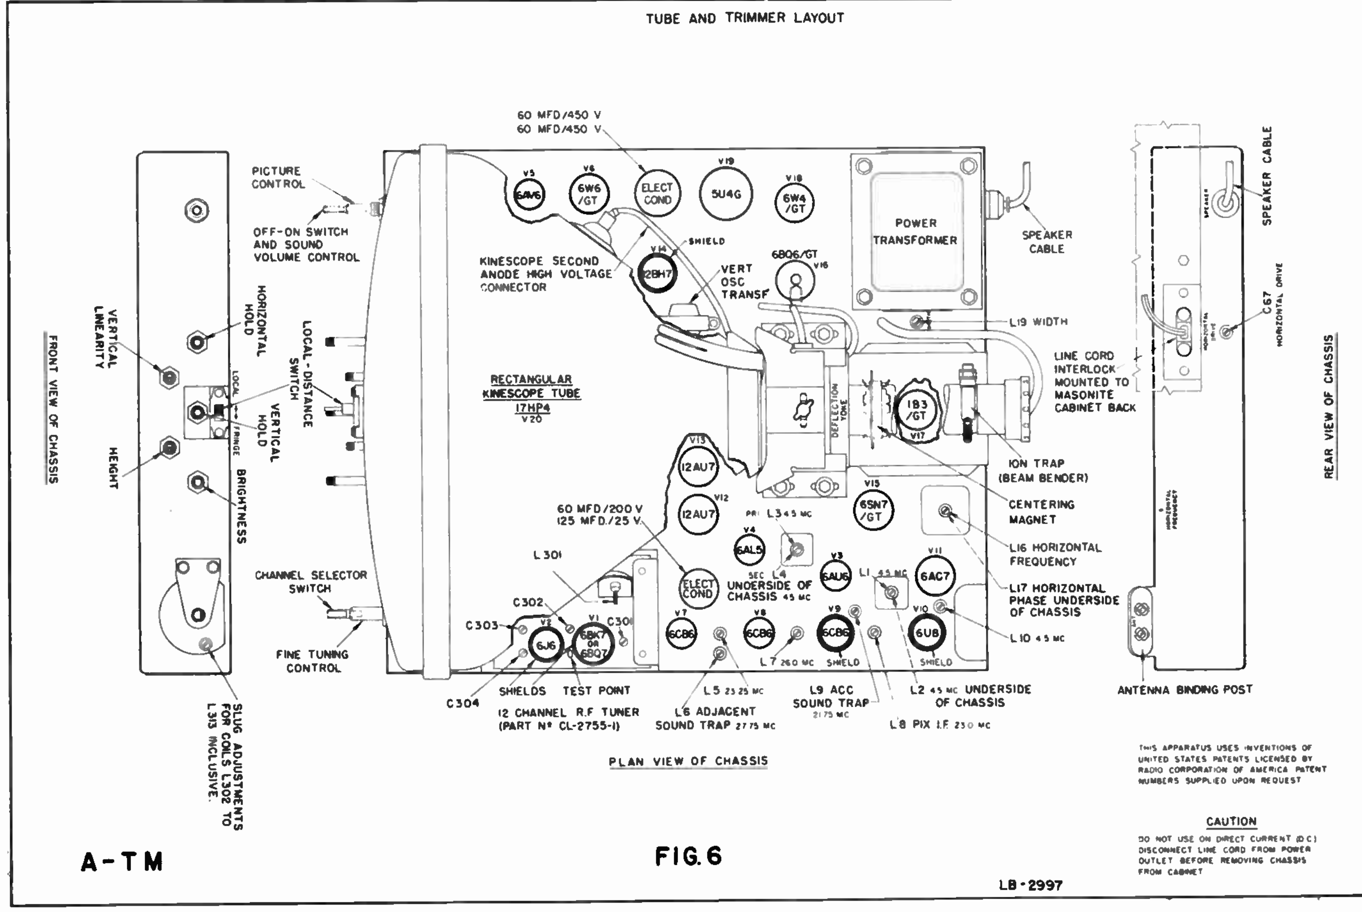
(4) Refer to following table for frequencies and adjustments.

Couple marker and Sweep Generator as in Section "B", Step 2

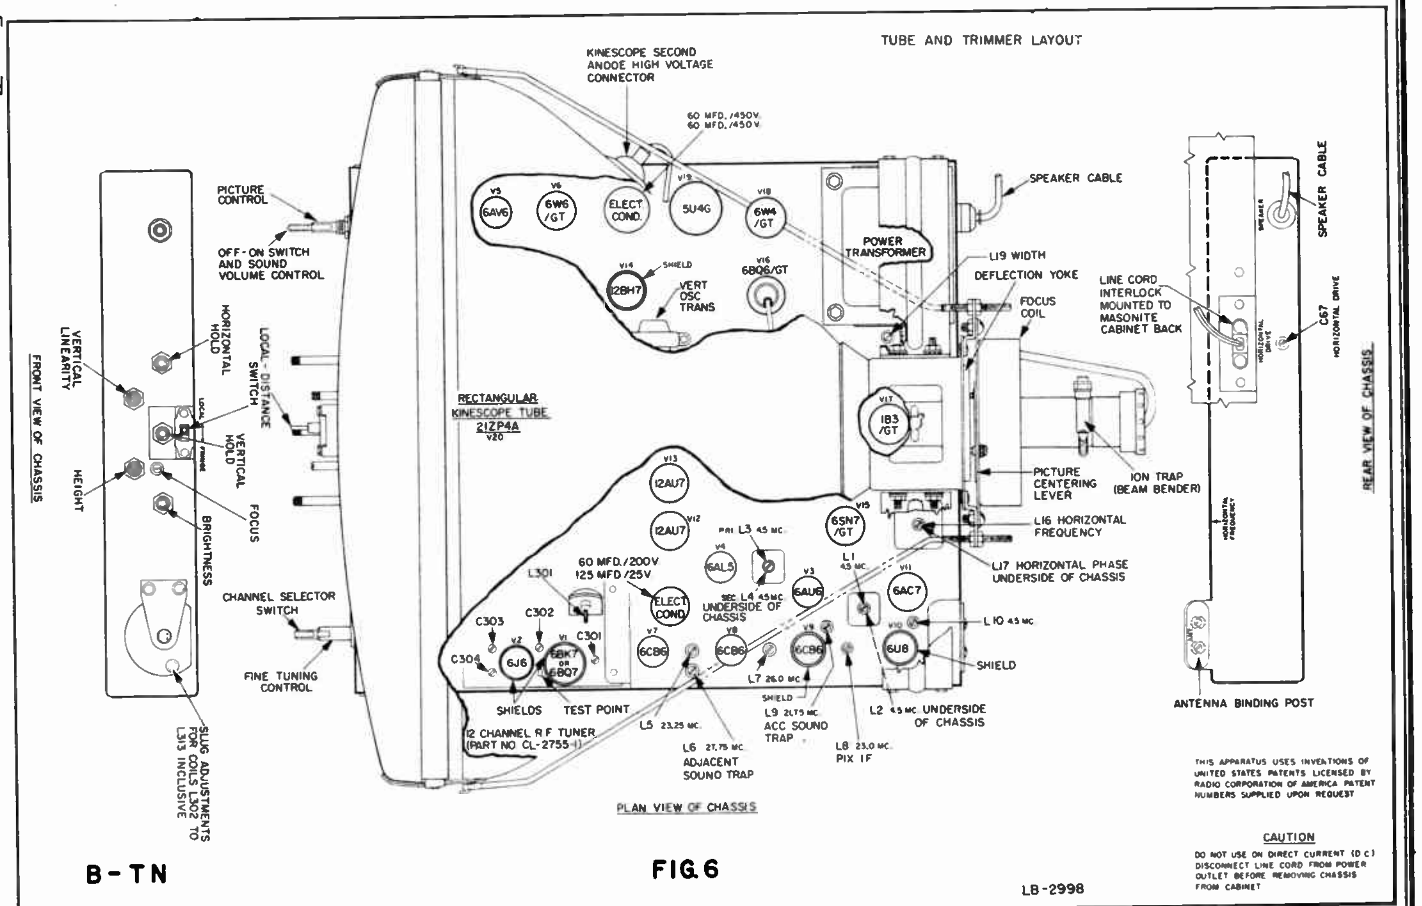
Connect Scope Through 10K Isolating Resistor to Test Point "A" and Low Side to Chassis

SIGNAL GENERATOR INPUT

Step	Sweep Gen.	Marker Gen.	Channel	Adjust	Procedure
1	207.0 MC.	209.75 MC.	12	L-312	Adjust for placement of 21.25 MC. marker as per response curve Fig. 4.
2	207.0 MC.	209.75 MC.	12	C-301 C-302 C-304	Adjust shape of response curve Fig. 4 for maximum amplitude and bandwidth.
3	213.0 MC.	215.75 MC.	13	L-313	Adjust as in Step 1.
4	201.0 MC.	203.75 MC.	11	L-311	Adjust as in Step 1.
5	195.0 MC.	197.75 MC.	10	L-310	Adjust as in Step 1.
6	189.0 MC.	191.75 MC.	9	L-309	Adjust as in Step 1.
7	183.0 MC.	185.75 MC.	8	L-308	Adjust as in Step 1.
8	177.0 MC.	179.75 MC.	7	L-307	Adjust as in Step 1.
9	85.0 MC.	87.75 MC.	6	L-306	Adjust as in Step 1.
10	79.0 MC.	81.75 MC.	5	L-305	Adjust as in Step 1.
11	69.0 MC.	71.75 MC.	4	L-304	Adjust as in Step 1.
12	63.0 MC.	65.75 MC.	3	L-303	Adjust as in Step 1.
13	57.0 MC.	59.75 MC.	2	L-302	Adjust as in Step 1.



A-TM FIG.6



B-TN FIG.6

OPERATING AND SERVICE INSTRUCTIONS

for

OLYMPIC AM-PHONO-TV 3-SPEED CHANGER COMBINATION

Frequency Range: A.M. 540-1620 kc.

Power Requirement: 105-120 Volts a-c 60 cycles.

Power Consumption: Receiver: 30 watts. Receiver with Record Changer: 50 watts.

IMPORTANT NOTICE:

This AM-PHONO-TV receiver and automatic 3-speed record changer console is for use on alternating current ONLY and should never be used on direct current.

Before operating the record changer it will be necessary to loosen the two record changer mounting screws completely as described in separate accompanying Record Changer Instruction Sheet.

This instrument is equipped with two separate chassis; one a 5 tube (including rectifier) AM chassis and a 20 tube (including rectifiers) television chassis. Built-in antennas are provided for both AM and TV sections of the receiver which will provide satisfactory reception under normal operating conditions. For AM reception an outside antenna will seldom be required whereas on TV the use of an outside antenna will generally improve the quality of reception.

AM RECEIVER CONTROLS: (see separate folder for television controls and operation)
The AM receiver has four control knobs marked according to their function, and reading from left to right as follows:

1. VOLUME   2. OFF-ON-TONE   3. AM-PH-TV   4. TUNING

NOTE: The power switches for operating the television and radio sections of this instrument are interconnected and therefore it is necessary that the power switch of the unit which is not in operation be turned to the "OFF" position.

TUNING:

To place receiver in operation turn the OFF-ON knob clockwise until a click is heard. The tubes require a warm-up period of about one-half minute before the set is ready to function.

A.M.

For AM reception turn AM-PH-TV knob to the position where AM faces the indicator dot. The tuning knob should now be turned until the dial pointer is at the frequency of the desired station. Dial numbers are converted to kilocycles by adding one zero. For example, 70 on the dial is 700 kilocycles. With volume control set to LOW volume level turn the station selector knob until the desired station is received loudest. Now adjust volume to the desired level and the tone control to the desired tone. DO NOT USE TUNING KNOB TO ADJUST VOLUME BY TUNING OFF STATION AS THIS WILL RESULT IN POOR TONE QUALITY.

NOTE: When operating this console as a Radio Receiver be sure that the motor switch on the record changer is in the OFF position.

TR 2690-1	Output Transformer

RECORD CHANGER OPERATION:

To operate the record changer, turn the AM-PH-TV knob so that PH faces indicator dot. Leave the "OFF-ON' 'knob in the "ON" position and adjust volume and tone with the same knobs as used in receiver operation. FOR DETAILED INSTRUCTIONS CONCERNING RECORD CHANGER SEE SEPARATE FOLDER ACCOMPANYING THIS INSTRUMENT.

TELEVISION RECEPTION:

To use the television receiver in this instrument it is IMPORTANT that the AM-PH-TV knob be set in the position where TV faces indicator dot. If this is not observed the sound section of the television receiver will be inoperative. For instructions how to use television receiver read the separate instructions accompanying this instrument.

SERVICE AND ALIGNMENT INSTRUCTIONS

To remove the chassis from the console, it is first necessary to disconnect all plugs and sockets between the rear of the receiver chassis, the speaker, the television set and the record changer, respectively. Then remove the four knobs and the three screws holding the chassis to its mounting panel.

CAUTION: WHEN REMOVING THE CHANGER BE SURE TO PLACE IT IN A POSITION IN WHICH THE CHANGER MECHANISM WILL NOT BE DAMAGED.

ALIGNMENT:

Equipment Required: Modulated R.F. signal generator; output meter; insulated screw-driver; two .1 mfd 400 volt condensers.

To insure proper alignment a radiated signal will be required during part of the alignment procedure. To radiate a signal connect a loop of about 6" to 8" diameter (one turn of #14 or #12 wire) across the output of the signal generator and place this loop parallel to the loop of the receiver to be aligned at a distance of about 8" or 10".

To align the receiver it is necessary to remove the chassis from the cabinet, check that the pointer coincides with the left vertical side of the gold rectangle surrounding the calibration points (below 550 kc.). In this position the condenser should be completely closed. Connect the output meter and signal generator as follows:

Output meter — Connect across voice coil and turn volume control to maximum.

Signal generator — Connect the low side of the signal generator to the common B minus bus thru a .1 mfd condenser and keep the output as low as possible, then proceed in the sequence shown on the alignment chart.

ALIGNMENT PROCEDURE CHART

STEP	CONNECT HIGH SIDE OF SIGNAL GENERATOR TO-	SET SIGNAL GENERATOR TO-	TURN RECEIVER DIAL TO-	ADJUST THE FOLLOWING FOR MAXIMUM OUTPUT. (KEEP SIGNAL FROM SIGNAL GENERATOR AS LOW AS POSSIBLE.)
1	ANTENNA SECTION TUNING CONDENSER IN SERIES WITH .1 MFD COND.	455 KC.	FULL CLOCKWISE POSITION. (CONDENSER PLATES FULLY OPEN)	L4, L3, L2, L1 AND REPEAT IN SAME ORDER (1ST. AND 2ND I.F. TRANSFORMERS)
2	USE RADIATED SIGNAL	1500 KC.	1500 KC. (150 ON DIAL)	C2 (OSCILLATOR)
3		1500 KC	MAXIMUM SIGNAL (APPROX. 150 ON DIAL)	C1 (ANTENNA)

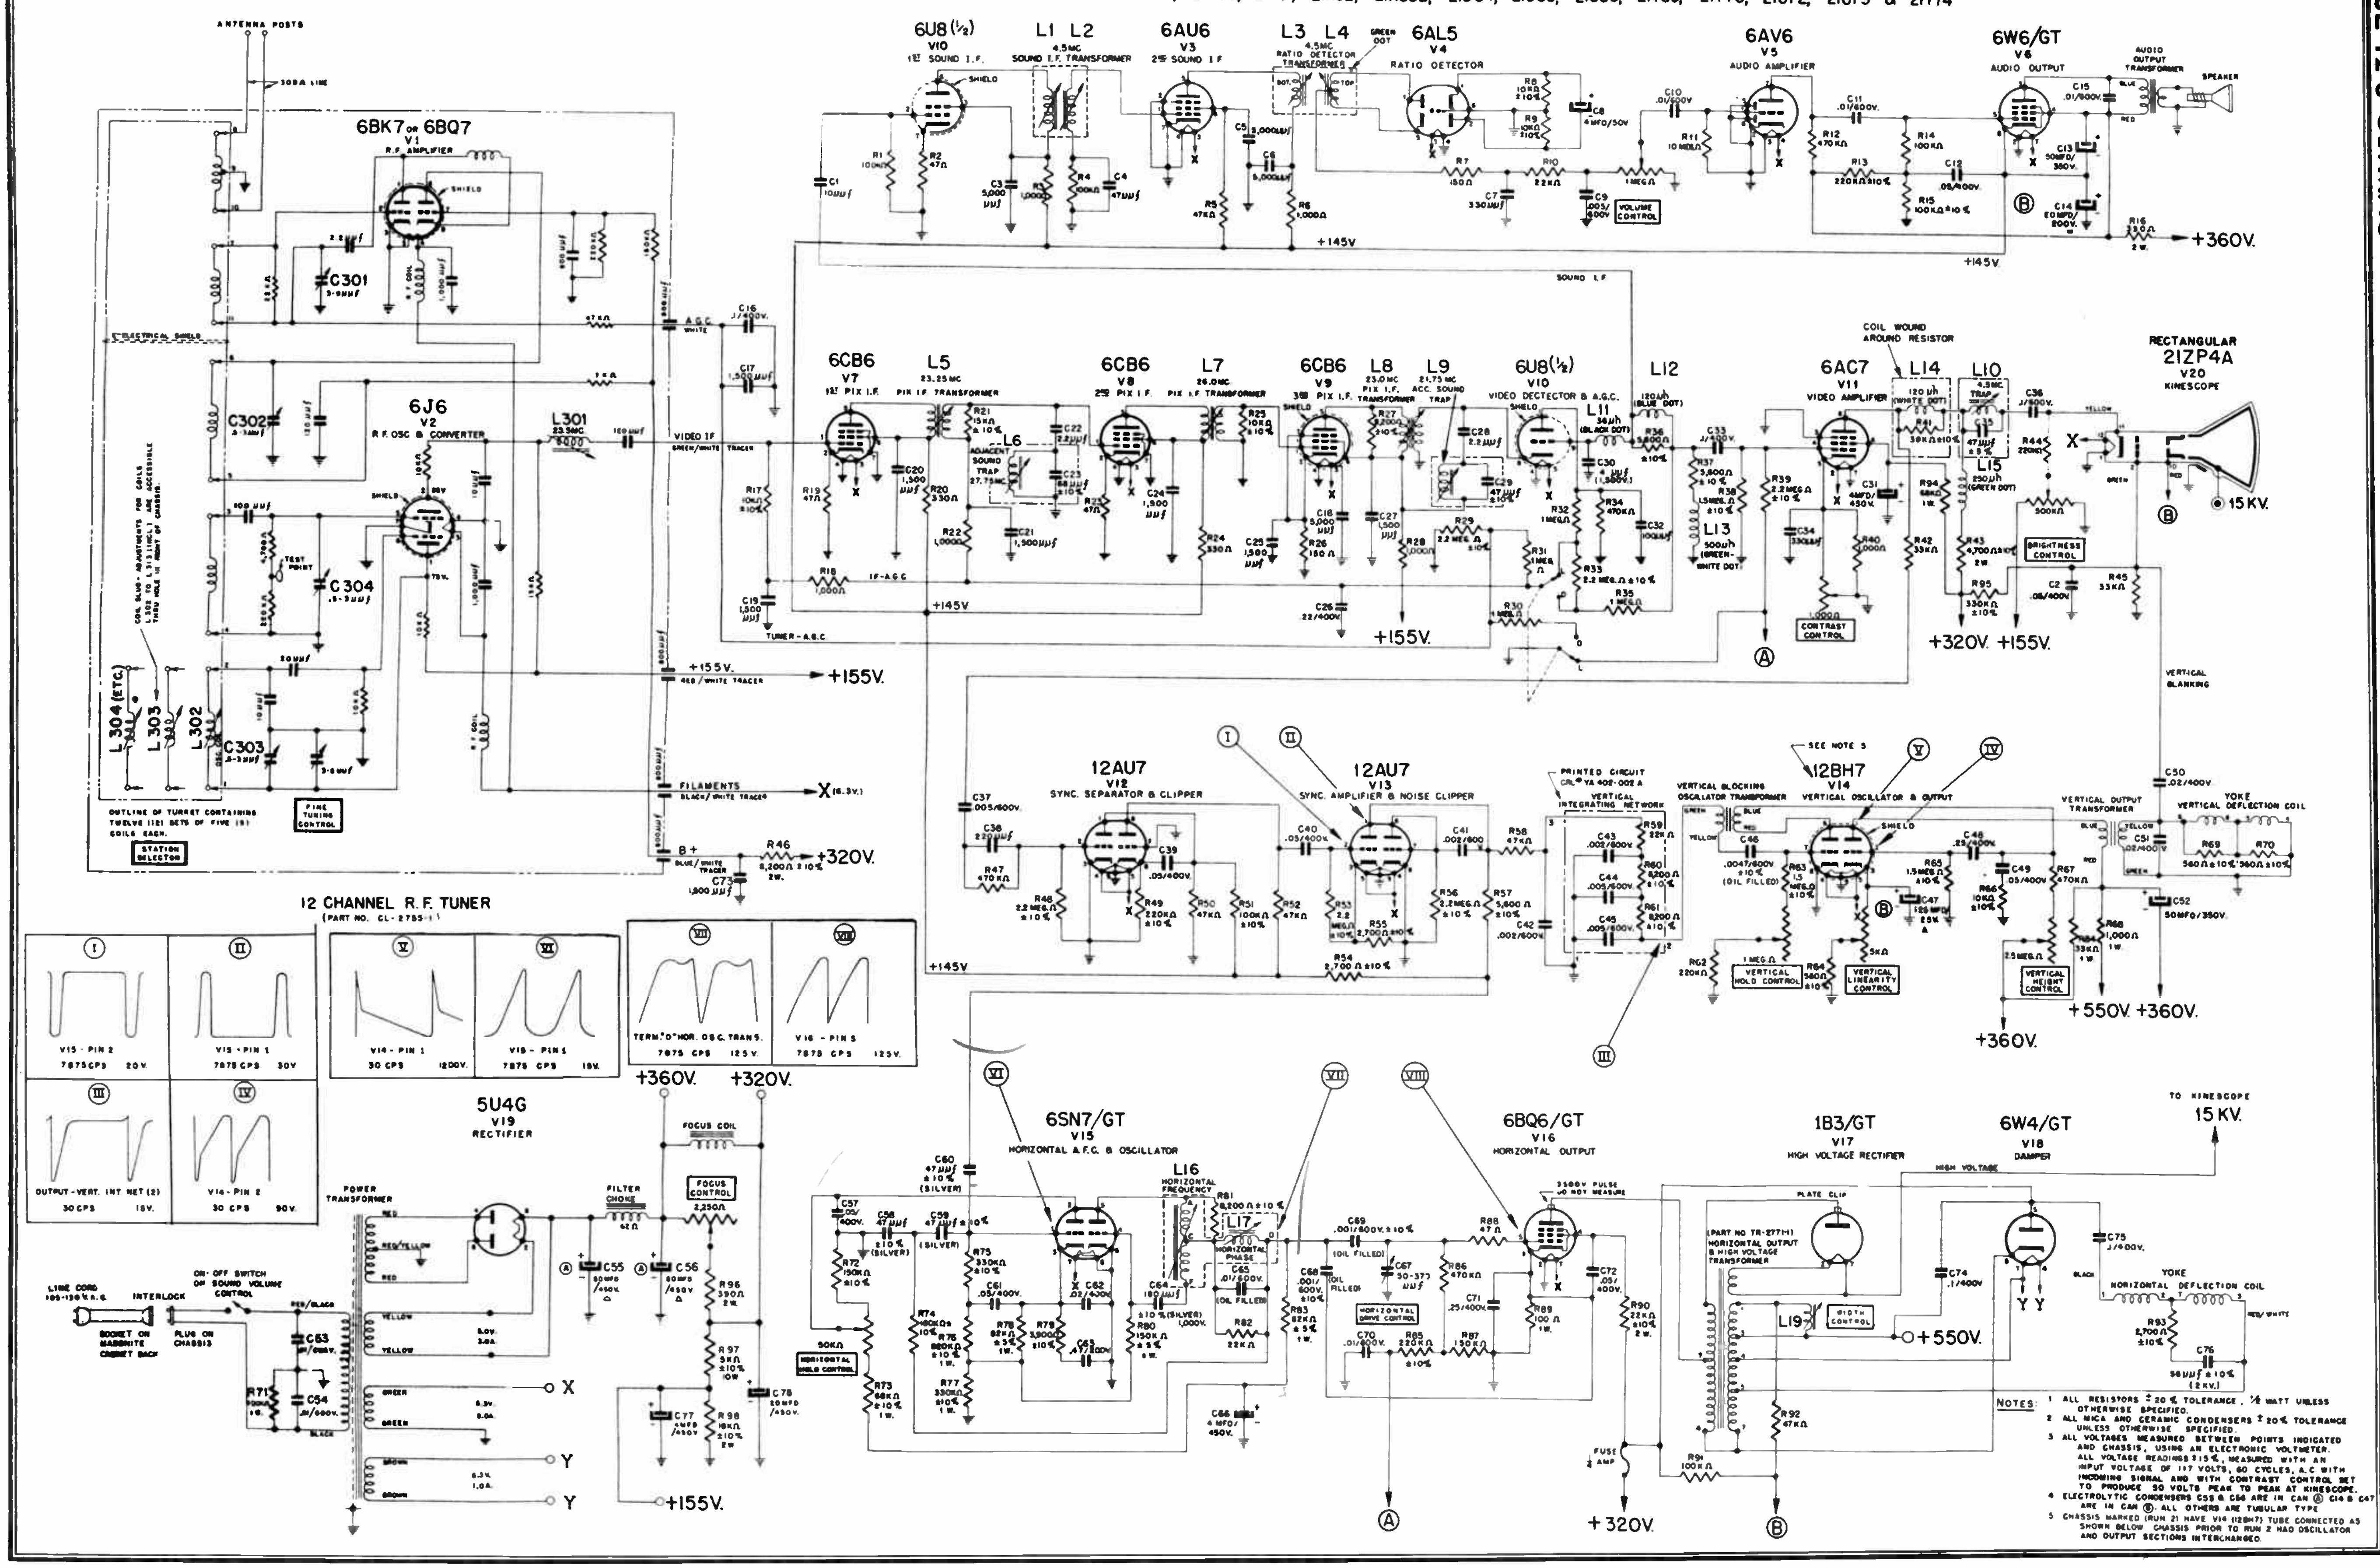
OLYMPIC TN-21 CHASSIS

21" TN MODELS: 21T58, 21D60, 21K61, 21K62, 21K63B, 21D64, 21C65, 21C68, 21T69, 21T70, 21C72, 21C73 & 21T74

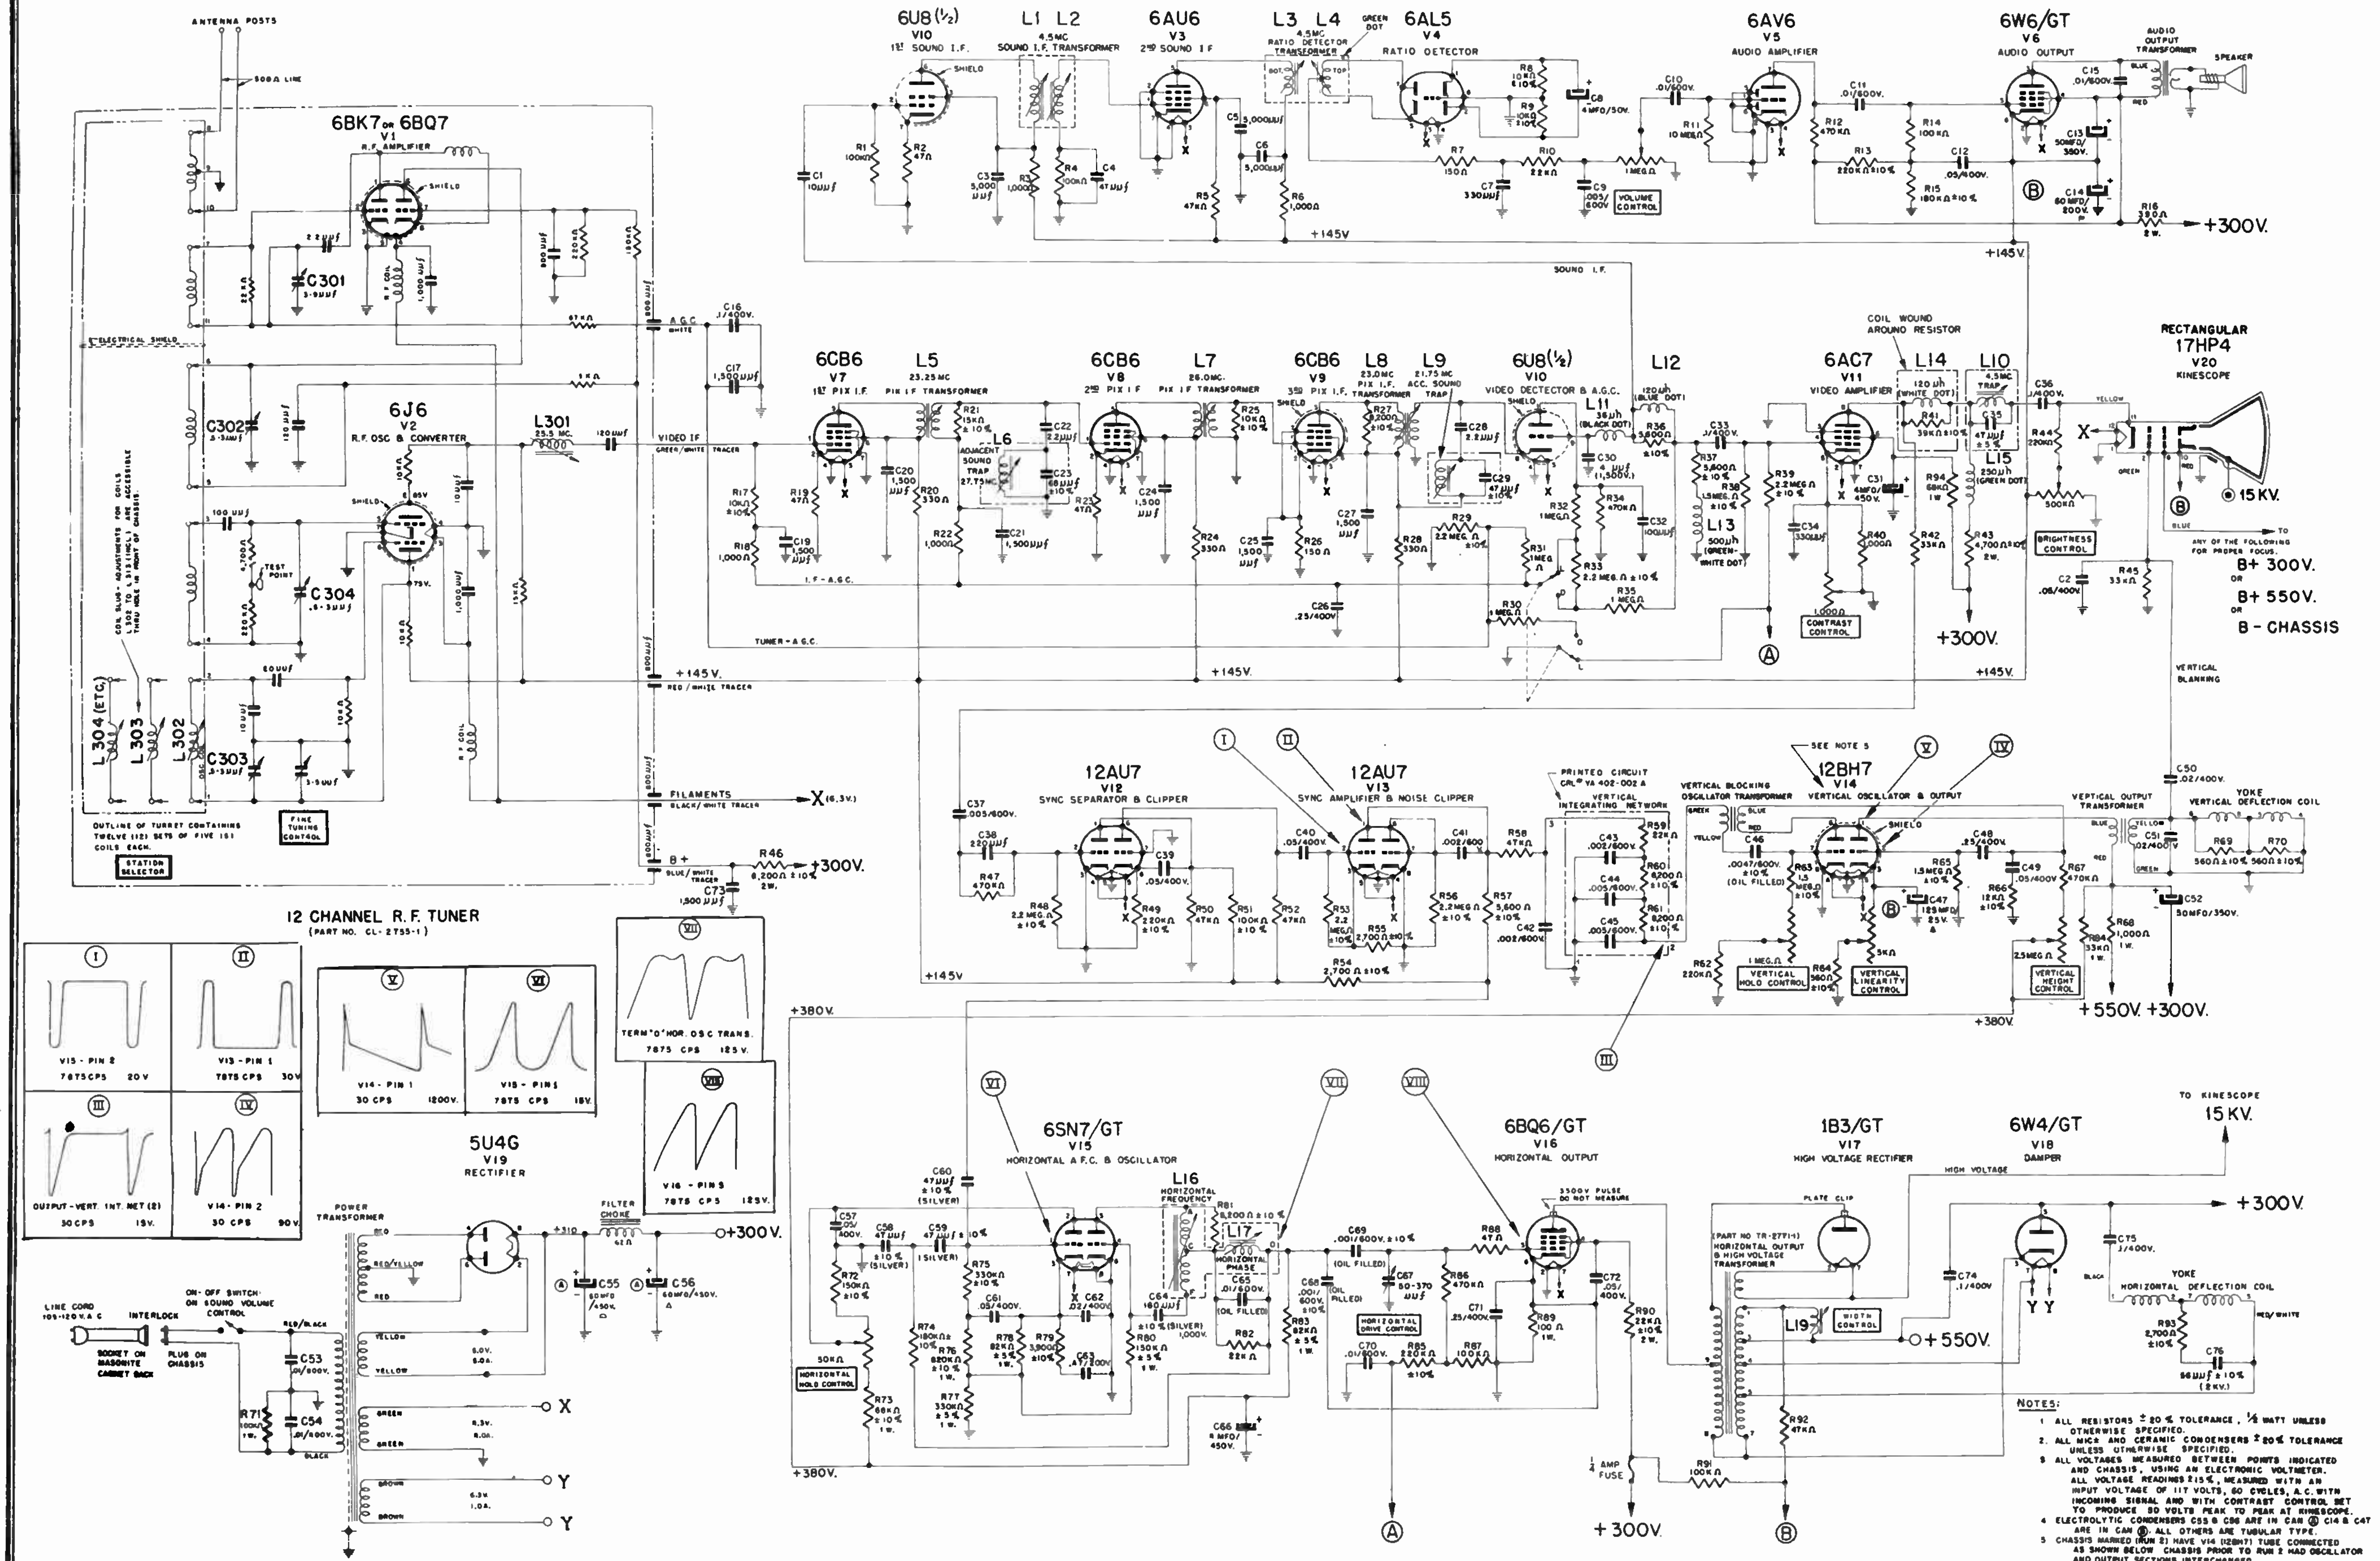


NOTES:

1. ALL RESISTORS ± 20% TOLERANCE, ½ WATT UNLESS OTHERWISE SPECIFIED.
2. ALL MICA AND CERAMIC CONDENSERS ± 20% TOLERANCE UNLESS OTHERWISE SPECIFIED.
3. ALL VOLTAGES MEASURED BETWEEN POINTS INDICATED AND CHASSIS, USING AN ELECTRONIC VOLTMETER. ALL VOLTAGE READINGS ±15%, MEASURED WITH AN INPUT VOLTAGE OF 117 VOLTS, 60 CYCLES, A.C WITH INCOMING SIGNAL AND WITH CONTRAST CONTROL SET TO PRODUCE 50 VOLTS PEAK TO PEAK AT KINESCOPE.
4. ELECTROLYTIC CONDENSERS C55 & C56 ARE IN CAN (A) C14 & C47 ARE IN CAN (B). ALL OTHERS ARE TUBULAR TYPE
5. CHASSIS MARKED (RUN 2) HAVE V14 (12BH7) TUBE CONNECTED AS SHOWN BELOW. CHASSIS PRIOR TO RUN 2 HAD OSCILLATOR AND OUTPUT SECTIONS INTERCHANGED.

OLYMPIC TM-17 CHASSIS

17" TM MODELS: 17K55, 17T56 & 17C57



NOTES:

1. ALL RESISTORS ± 20 % TOLERANCE, 1/2 WATT UNLESS OTHERWISE SPECIFIED.
2. ALL MICA AND CERAMIC CONDENSERS ± 20 % TOLERANCE UNLESS OTHERWISE SPECIFIED.
3. ALL VOLTAGES MEASURED BETWEEN POINTS INDICATED AND CHASSIS, USING AN ELECTRONIC VOLTMETER. ALL VOLTAGE READINGS ± 15 %, MEASURED WITH AN INPUT VOLTAGE OF 117 VOLTS, 60 CYCLES, A.C. WITH INCOMING SIGNAL AND WITH CONTRAST CONTROL SET TO PRODUCE 50 VOLTS PEAK TO PEAK AT KINESCOPE.
4. ELECTROLYTIC CONDENSERS C55 & C56 ARE IN CAN (A) C14 & C47 ARE IN CAN (B). ALL OTHERS ARE TUBULAR TYPE.
5. CHASSIS MARKED (RUN 2) HAVE V14 (12BH7) TUBE CONNECTED AS SHOWN BELOW. CHASSIS PRIOR TO RUN 2 HAD OSCILLATOR AND OUTPUT SECTIONS INTERCHANGED.

MODEL 180 UHF TUNER
(ALSO USED IN MODEL 2152)

ALIGNMENT PROCEDURE

PRELIMINARY NOTES:

VHF tuner and TV I-F strip must be in proper alignment before attempting alignment of UHF tuner.

Connect oscilloscope or VTVM across the 4.7K ohms video detector load, R-12, TV schematic.

EQUIPMENT REQUIRED—AM VHF signal generator with 12 Mc sweep; oscilloscope or VTVM; insulated screwdriver.

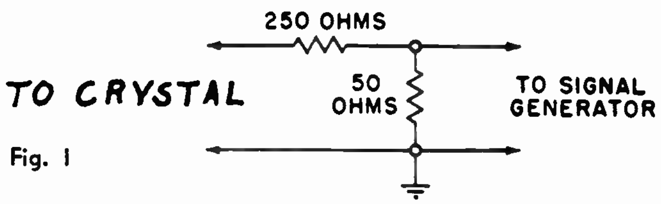


Fig. 1

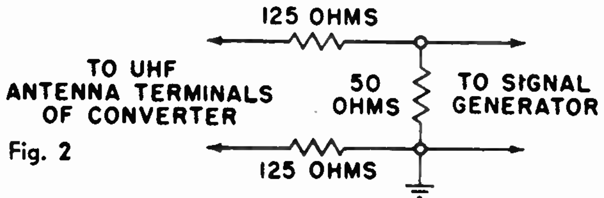

Fig. 2

SIG. GEN. CONNECTION	SIG GEN. FREQ.	ADJUST	REMARKS
I-F ALIGNMENT			
1—To crystal at junction of items 21, 29, 45, 51, UHF schematic, thru matching net. Fig. 1.	82 Mc	I-F transformers. Items 5 & 6, Figs. 3 & 4.	Adjust for maximum signal.
2—Same as 1.	82 Mc with 12 Mc sweep.	Item 6, Figs. 3 & 4.	Adjust for equal signal response at VHF channels 5 & 6. Maximum gain for minimum band-width of 12 Mc.
OSCILLATOR ALIGNMENT			
3—UHF antenna terminals thru matching net. See Fig. 2.	465 Mc (5th harmonic of 93 Mc)	Oscillator trimmer, item 48, Fig. 3.	Set pointer at extreme left of dial. Adjust for maximum.
4—Same as 3.	900 Mc (5th harmonic of 180 Mc)	Carefully spread or pinch legs of oscillator end-inductor, see Fig. 3.	Set pointer at extreme right of dial. Adjust for maximum.
5—Repeat steps 3 and 4 until no further improvement in signal is apparent. 465 Mc and 900 Mc are approximations and may not fall precisely at extreme left and right dial positions. However, oscillator alignment must be made so that both frequencies may be tuned within dial limits.			
6—Same as 3.	465 Mc	R-F trimmers, Item 72, Fig. 4.	Set pointer at extreme left of dial. Adjust for maximum.
7—Same as 3.	900 Mc	R-F end-inductors, Fig. 3.	Set pointer at extreme right of dial. Adjust for maximum.
8—Repeat steps 6 and 7 until no further improvement in signal is apparent.			
9—Same as 3.	465 Mc	Coupling trimmer, item 74, Fig. 4.	Set pointer at extreme left of dial. Adjust for maximum.

GENERAL SPECIFICATIONS

Antenna	Built-in with Provisions for External 300 Ohms Antenna
Intercarrier Sound System .	4.5 Megacycles
Picture Carrier I-F . . .	45.75 Megacycles
Sound Carrier I-F . . .	41.25 Megacycles
Power Supply	110-120 Volts, 60 Cycle, AC.
Power Consumption . .	215 Watts
Speaker	PM Type 3.2 Ohms Voice Coil

ADJUSTMENTS

WARNING — OPERATION OF THE RECEIVER CHASSIS OUTSIDE OF THE CABINET INVOLVES THE DANGER OF WORKING WITH HIGH VOLTAGES. EXTREME CAUTION SHOULD BE EXERCISED AT ALL TIMES.

Occasional minor adjustments will be needed if any circuit work or tube replacement is required. A test pattern, generated locally or from a broadcast station, is recommended for best results. The operating and auxiliary controls, located on the front panel and rear apron, should be set for as good a pattern as possible before making the following adjustments:

CENTERING

Rotate each of the Centering Rings separately until the picture is properly centered.

HEIGHT AND WIDTH

Adjust the Height and Width Controls so that the picture fills out the dimensions of the screen. A slight re-adjustment of the centering control may be necessary.

HORIZONTAL DRIVE CONTROL

The Horizontal Drive Control (C51B) is adjustetd by backing off the control until a vertical white bar appears in the middle of the picture, and then going in one full turn from this point. This adjustment may be reached from the underside of the chassis mounting board. See below for detailed description of Horizontal Oscillator Sync Adjustment.

VERTICAL LINEARITY CONTROL

Set the Vertical Linearity Adjustments for a symmetrical pattern. A slight re-adjustment of the Height and Width Controls may then be necessary.

Note: The sequence of adjustments outlined above is suggested as a convenient method of approach and not an arbitrary procedure. The procedure used to obtain the final results may be varied to fit the circumstances.

NOISE BALANCE CONTROL

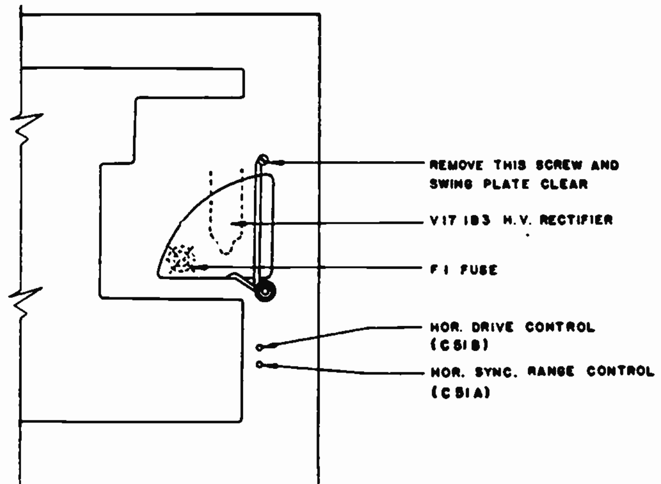
Turn the Channel Selector to the strongest station signal on the air. Slowly turn the Noise Balance Control from full clockwise position counterclockwise until the picture just starts to show a distorted shape. Then turn the control slightly in the opposite direction so that the picture shape is normal. Check all channels. If the picture shape is distorted on any channel, advance the control slightly clockwise to restore normal shape. (NOTE: WHENEVER THE PICTURE IS DISTORTED, OR SLANTING BARS ARE ENCOUNTERED WHICH CANNOT BE ADJUSTED CORRECTLY WITH THE HORIZONTAL LOCK OR FINE TUNING CONTROLS, ALWAYS SET THE NOISE BALANCE CONTROL FULLY CLOCKWISE BEFORE MAKING ANY OTHER ADJUSTMENT.)

PICTURE TUBE ADJUSTMENTS

WARNING: THE PICTURE TUBE ENVELOPE ENCLOSES A HIGH VACUUM. ANY ACCIDENTAL BLOW OR ROUGH HANDLING MAY CAUSE THE TUBE TO IMPLODE WITH DANGEROUS AND DESTRUCTIVE FORCE. THE WEARING OF HEAVY GLOVES AND SHATTER-PROOF GOGGLES IS ADVISED WHEN HANDLING THE PICTURE TUBE.

1. Turn the Brightness Control to maximum (clockwise) and the Picture Control to minimum (Counterclockwise).
2. Rotate the Ion Trap Magnet and at the same time move it backward and forward to obtain the brightest raster.
3. Reduce the Brightness Control so that the raster is slightly over normal brilliance and re-adjust the Ion Trap Magnet for maximum brightness.
4. Loosen the Deflection Yoke adjusting screws and rotate the Deflection Yoke so that the top and bottom edges of the raster are parallel to the top of the chassis. When this adjustment is made, tighten screws.
5. Adjust the Centering Control until the entire raster is visible, centered within the opening of the mask, with no shadowed corners.
6. Move the Ion Trap Magnet as in step 2 for final adjustment.

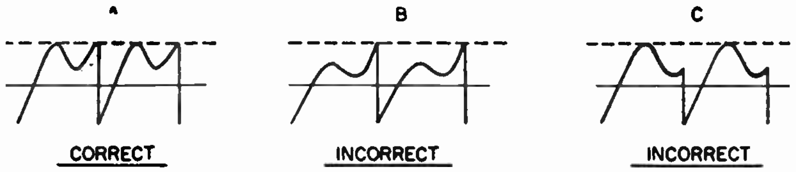
HORIZONTAL OSCILLATOR SYNC ADJUSTMENT



CHASSIS SHELF BOTTOM

1. Set the Noise Balance control to maximum clockwise.
2. Connect an oscilloscope to terminal "C" on the Synchroguide transformer (T-8) through a small capacitor, from 10 to 50 UUF.
3. Connect a DC VTMV from the grid of the type 6AU5 Horizontal Output tube (V-15) to the chassis. Use a high impedance probe.
4. Set the trimming capacitor adjustment screws in tight for the Horizontal Locking Range (C-51a) and the Horizontal Drive (C-51b).
5. Back off the trimmer for the Horizontal Locking Range 1/4 turn.
6. Back of the trimmer for the Horizontal Drive until the VTVM registers —9 volts (approximately one full turn).
7. Adjust front screw of Synchroguide to lock-in picture horizontally.

8. Adjust inside core of Synchroguide to give correct wave form. Re-adjust front screw simultaneously to keep in sync. Use non-metallic screw driver on inside core.



9. Trim front screw to get approximately three bars break-out when switching channels, with Horizontal Lock control in maximum clockwise position.

THE HORIZONTAL LOCK CONTROL SHOULD PRODUCE THE FOLLOWING CONDITIONS:

A. Sync should hold with control in maximum counterclockwise position.

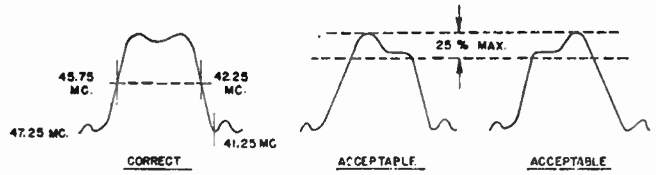
B. Sync should pull in when switching channels over at least half of the rotation range of the control.

C. Picture should not jitter at any position of the control.
   a. If sync does not hold in maximum counterclockwise position, back off front screw of Synchroguide. Retain correct wave form by adjustment of inside core.
   b. If sync does not pull in when switching channels over half of rotation range, back off C-51a, 1/4 turn at a time, until correct lock-in range is established.
   c. If the picture jitters at any position of the Horizontal Lock control, advance the control in a clockwise direction to the position that produces the greatest amount of jitter and adjust the front screw of the Synchroguide in a clockwise direction until the jitter stops. If jitter is not eliminated, advance C-51a trimmer adjustment. If jitter persists, shunt a 100 UUF capacitor across C-51a. Re-check break-out on clockwise end when switching channels. Back off C-51a if sync does not pull in over at least half of rotation range of Horizontal Lock control.

ALIGNMENT

NOTE: ALWAYS SET NOISE BALANCE CONTROL FULLY CLOCKWISE BEFORE MAKING ANY ALIGNMENT TESTS OR ADJUSTMENTS.

I-F ALIGNMENT



Lift the top section of the shield on the R-F oscillator-mixer tube so that it does not make electrical contact with its base. Connect one side of the output of an A-M signal generator to the shield, the other side to the chassis.

Connect a VTVM across the 4.7K video detector load. Use the lowest scale reading on the meter. Always attenuate the signal generator output for a reading below the limits of the meter, approximately —1 to —1.5 volts.

Set the Volume and Contrast controls to minimum. Set the Channel Selector to channel 7 or 13, depending on local conditions or interference.

PROCEDURE

SIG. GEN FREQUENCY	ADJUST	METER READING	REMARKS
1. 43.90 Mc	T-11	Maximum	
2. 44 Mc	I-F Adjustment on Tuner	Maximum	Connect a 1K resistor from grid of V-1 to AGC line for this step only.
3. 44.0 Mc	Bottom of T-1	Maximum	
4. 42.50 Mc	Bottom of T2	Maximum	
5. 45.35 Mc	Bottom of T-10	Maximum	
6. 41.25 Mc	top of T-1	Minimum	
7. 41.25 Mc	Top of T-2	Minimum	
8. 47.25 Mc	Top of T-10	Minimum	
9. Repeat steps 3, 4, and 5			
10. Repeat step 1.			

The I-F passband may be observed by substituting a sweep generator for the A-M signal generator and substituting an oscilloscope for the VTVM. Connect a 3 volt battery so that its positive terminal is connected to the chassis and the negative terminal is connected to the AGC lead. The sweep generator should be set to approximately 44 Mc and then adjusted to center the wave form on the scope face. To avoid overload and to assure a true view of the wave shape, the output of the sweep generator should be attenuated until further attenuation has a minimum effect on the wave shape. If necessary, a slight adjustment of the I-F transformers may be made to obtain a close approximation to the ideal curve. Adjustment of T-2 or T-10 affects the band width. Adjustment of T-1 or T-11 affects the slope of the top. However, T-1 should be preferred for slope adjustment.

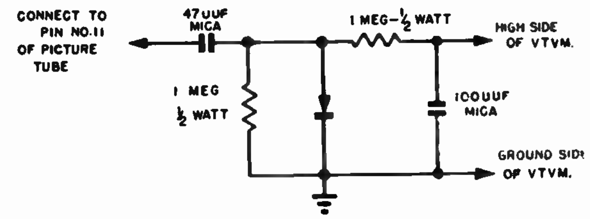
F-107

SOUND ALIGNMENT

1. Connect an A-M signal generator tuned to 4.5 Mc between the grid of V5 and ground. Connect the alignment test circuit shown below and tune L8 for a minimum reading on a VTVM.

2. Disconnect the alignment test circuit and connect the VTVM to ground and Pin 5 of V7. Adjust L9 and primary of T3 (Bottom) for maximum indication.

3. Remove the VTVM and re-connect it to ground and junction of R27 and R28. Adjust secondary of T3 (Top) for zero. (Note: When tuning through the proper setting, the meter should swing negative on one side and positive on the other side.)



USE IN34 CRYSTAL
SOUND ALIGNMENT TEST CIRCUIT

DESCRIPTION

COMBINATION RECEIVERS USING CHASSIS 155 & 155-1 A-M RADIO TUNER TV CHASSS 150-4, 150-31, & 150-61

Chassis model 155 is a two tube A-M radio tuner with built-in loop antenna, a type 6BE6 converter tube, a type 6BA6, 455 Kc, I-F amplifier, tube, and a crystal diode detector, type 1N65. This A-M radio tuner has a control panel separate from the television controls. The audio amplifying and audio output circuits of the television receiver provide these functions for radio reception. A three position function switch on the radio control panel (S1a, 1b, 1c radio schematic) permits changing the source of the audio signal voltage across the volume control potentiometer (R-13a, TV schematic) from TV to radio or phonograph, as desired. The 155 A-M radio tuner is connected to the television circuit through an adapter socket on the back of the TV chassis. The phono motor is also plugged into the back of the TV chassis, but the phono pick-up lead is plugged into the A-M radio tuner.

Chassis 155-1 is the same as 155 except for length of control shafts.

COMBINATION RECEIVERS USING CHASSIS 160 AM RADIO TUNER TV CHASSIS 150-10

Chassis model 160 is also a two tube A-M radio tuner with the same type of converter, I-F amplifier, and detector as chassis 155. The function of the two tuners is also the same. However, a single set of controls is used to provide both television and radio reception on receivers with the 160 chassis. The radio dial is attached to the TV Fine Tuning control, which gives this control a dual capacity, depending on the position of the TV-RADIO-PHONO function switch. The 160 chassis is mounted on the underside of the TV chassis directly behind the front panel auxiliary controls. Its tuning gang is driven off the fine tune shaft with a pulley and string-ing arrangement. The function switch (S-1a, 1b, 1c radio schematic) is connected directly into the TV audio circuit between the high frequency de-emphasis net, R-28 - C27, and the coupling capacitor C-28, to the volume control potentiometer, R-13a (TV schematic).

The phono motor and phono pick-up leads are plugged into the back of the TV chassis.

COMBINATION RECEIVERS USING CHASSIS 113 RADIO, TV CHASSIS 150-2, MODEL 2080

Chassis model 113 is a 5 tube superheterodyne A-M radio receiver with built-in loop antenna. The radio and TV chassis are complete within themselves, with separate power supplies and control panels. One speaker is used, with the secondaries of the two voice coils wired to the speaker in parallel through the PHONO-RADIO-TV function switch on the radio panel. On some sets the audio output transformer of the TV is mounted on the radio chassis.

RECORD CHANGERS

There are three types of record changers used in Pacific Mercury combination receivers.

Pacific Mercury model 90023 is a V-M, model 950, record changer. Pacific Mercury model 90025 is a Webster-Chicago, model 114 record changer.

Pacific Mercury model 90026 is a General Instrument & Appliance Corp., model 700F-33/45, record changer.

All three record changers operate on 117 volts AC, 60 cycle power.

CHASSIS 150-9 & 150-16

Chassis 150-9 and 150-16 use a 17HP4 type picture tube. The 17HP4 has electrostatic focus with 450 volts on Pin No. 6, and 290 volts on Pin No. 10. See installation and adjustment instructions of electrostatic focus picture tubes.

CHASSIS 150-7 & 150-12

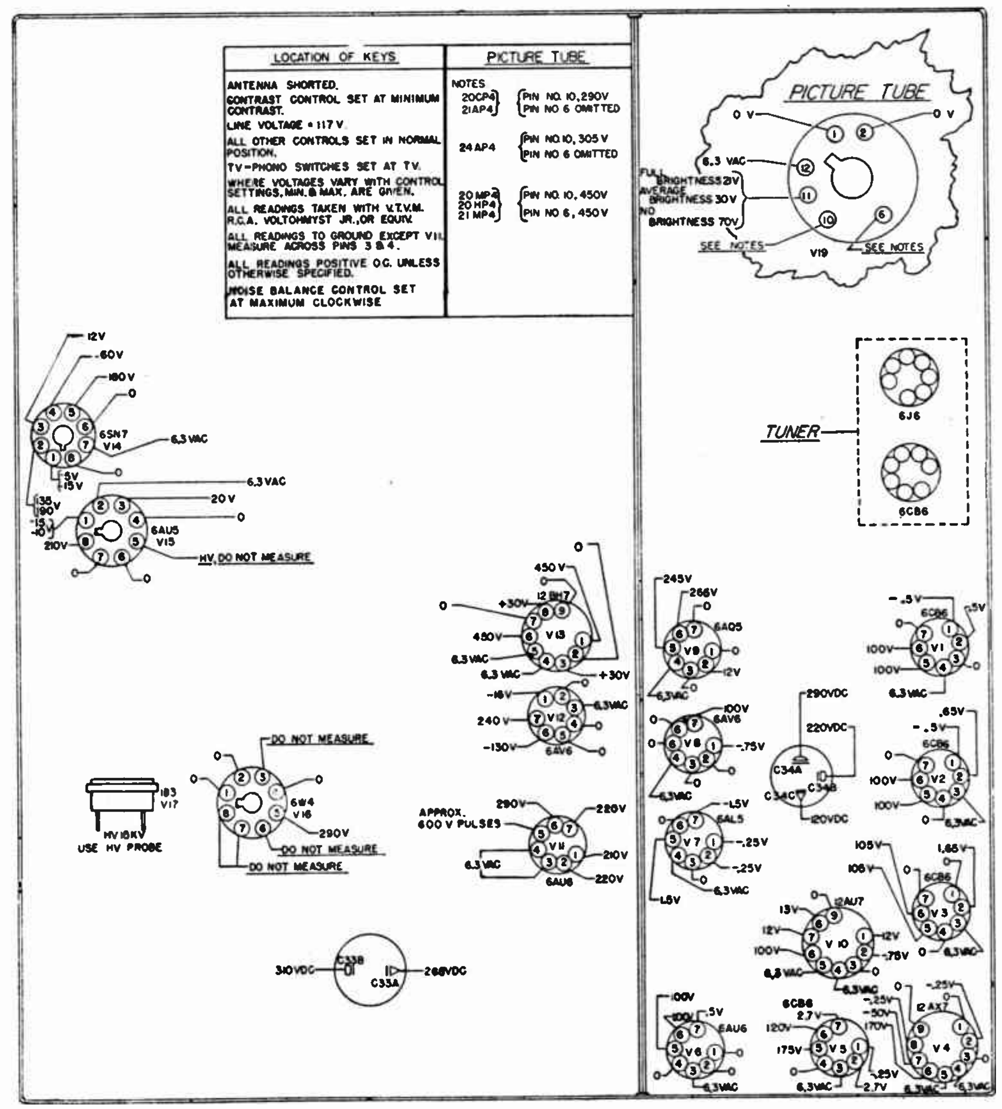
Chassis 150-7 and 150-12 also use a type 17HP4 picture tube. These two models are 20 tube chassis, similar to the basic chassis 150-Series except for the omission of the Noise Balance circuit.

The second half of V-4 (Type 12AX7), which formerly functioned as the Noise Balance Control, is used as the audio amplifier in these models, and V-8, the type 6AV6 tube, which was formerly used for audio amplification, is omitted.

There is no coupling between the two halves of the twin triode V-4, in the twenty tube receivers even though they are in the same envelope. The output from the first half, the video detector, is coupled to the video amplifier (V-5) only. The signal input to the second half of V-4 is taken off the pontentiometer, R-13A (Volume Control), across which is developed the audio signal voltage from the 4.5 Mc ratio detector, V-7. There is no phono jack on the twenty tube chassis. The voltage readings on the pins of V-4 are as follows:

VIDEO DETECTOR PIN NO.	VOLTAGE	FUNCTION	AUDIO AMPLIFIER PIN NO.	VOLTAGE
1	0	Plate	6	100
2	—.25	Control Grid	7	—.75
3	0	Cathode	8	0
4	6.3 AC	Filament	5	6.3 AC

Pin No. 9 is a common ground for both halves of the filament. The voltage readings on the pins of the other tubes in the twenty tube chassis are the same as for the twenty-one tube chassis, 150-Series.



150-SERIES CHASSIS.

ROTARY SWITCH TUNER—PMB-57003

Chassis 150-7 only, uses a rotary switch R-F tuner. This R-F selector is electrically equivalent to a tapped coil whose inductance is reduced from its maximum value by means of a rotary switch. The switch progressively shorts additional taps to ground as the selector knob is rotated and the oscillator coils are switched in and out of the circuit from channel 2 to channel 13.

The R-F amplifier tube is a type 6AG5, 6BC5, or 6CB6.

A twin triode, type 6J6, is used for the combination mixer and oscillator.

CHASSIS 150-5 & 150-51

Chassis models 150-5 and 150-51 use a 24 inch, magnetic focus, metal picture tube, type 24AP4. The use of this tube requires changing the circuit of the basic 150-Series chassis as follows:

Resistor R-36 in the low voltage rectifier filter circuit has been replaced by a choke coil, L-13. A filter network (R-89, C-43, and R-90, C-73) is used to increase stability of the vertical sweep circuit with line voltage variations.

The capacity of C-66 has been reduced from .25 mfd. to .1 mfd. to provide the additional linearity and width control necessary for the larger raster.

ADJUSTMENTS

The chassis listed in this supplement require the same type of adjustments as described in the 150-Series Service Manual.

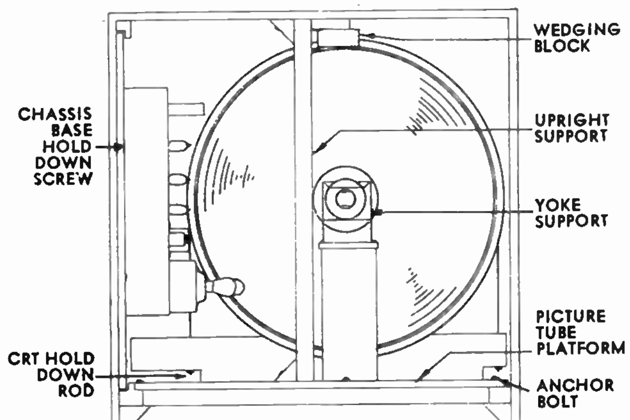
INSTALLING AND ADJUSTING PICTURE TUBES

17HP4

Rotate each of the Centering Rings separately until the picture is properly centered.

24AP4

The 24 inch picture tube is mounted on a triangular wooden platform, and this platform is bolted to the cabinet at each of its three corners. The chassis is mounted separately on a flat wooden base which in turn is fastened to the side of the cabinet with four wood screws.



MODEL 2401—REAR VIEW

REMOVING THE PICTURE TUBE

To remove the picture tube, it is first necessary, to remove the chassis.

WARNING: OBSERVE ALL HIGH VOLTAGE AND PICTURE TUBE HANDLING PRECAUTIONS

1. Remove the push-on type control knobs on the front panel and remove the back of the cabinet.
2. Remove the upright support (Held in place by two wood screws) located in the rear of the cabinet to the left of the neck of the picture tube.
3. Disconnect:
   a. Speaker plug.
   b. Antenna.
   c. Anode lead of picture tube.
   d. Picture tube socket.
   e. Ion trap.
   f. Deflection yoke (Some models have plug-in yoke leads).
   g. Focusing assembly.
   h. Wire or spring that is used to ground the deflection yoke support and tube mounting strap to the chassis.
4. Remove the four screws on the side of the cabinet that hold the wooden base of the chassis in place and slide the chassis and base out of the cabinet.

Note: The chassis may be operated for servicing without removing the picture tube from the cabinet by taking the chassis off its base and placing it next to the cabinet in such a position that all necessary connections can be made.

5. Remove the wooden block that acts as a wedge support for the top of the rim of the picture tube.
6. Remove the three anchor bolts that fasten the platform support to the cabinet and slide the platform and picture tube out of the cabinet.
7. Unfasten the mounting strap from the rim of the tube.

INSTALLING THE PICTURE TUBE

1. Set the picture tube on its supporting platform, with its rim resting in the cradle, and attach the mounting strap. Position the tube so that the key-way for the tube socket will be toward the chassis. Place the rubber collar and deflection yoke support as far forward on the neck of the tube as possible.
2. Slide the supporting platform inside the cabinet and bolt it in the proper position. The supporting platform has elongated holes for the three bolts that anchor it to the cabinet. This allows adjustment of the platform's position so that the face of the tube can be made to fit properly against the mask, regardless of variations in dimensions or shapes of new tubes.
3. Replace the wooden block that acts as a wedge support for the top of the rim of the picture tube.
4. Slide the chassis, mounted on its base, into the grooved track on the side of the cabinet and fasten it in place with the four wood screws. The holes through which the chassis is bolted to its base are large enough to shift the chassis to the position that will allow the control shafts to fit properly.
5. Connect:
   a. Focusing assembly.
   b. Deflection yoke (or plug).
   c. Ion trap.
   d. Picture tube socket.
   e. Anode lead.
   f. Wire or spring that is used to ground the deflection yoke support and tube mounting strap to the chassis.
   g. Speaker plug.
   h. Antenna.
6. If the picture is not properly centered, move the Centering Control Lever on the rear of the receiver a short distance in any direction necessary for correction. Do not use force in making this adjustment as excessive strain may be exerted on the neck of the picture tube. If proper centering cannot be restored in this manner, a slight adjustment of the deflection yoke or focus magnet mountings may be necessary.
7. Replace the upright support.
8. Replace the back of the cabinet and the push-on control knobs.

ALIGNMENT

NOTE: ALWAYS SET NOISE BALANCE CONTROL FULLY CLOCKWISE BEFORE MAKING ANY ALIGNMENT TESTS OR ADJUSTMENTS.

I-F SWEEP PATTERNS AND ALIGNMENT CHART

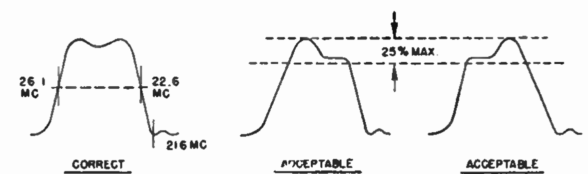


FIG. 8

SIGNAL GENERATOR FREQUENCY	ADJUSTMENT	VTVM INDICATION
24.35 Mc	T2, 1st I-F coil on tuner, and L1	Maximum
23.2 Mc	L3	Maximum
25.2 Mc	T1	Maximum
21.6 Mc	L2	Minimum

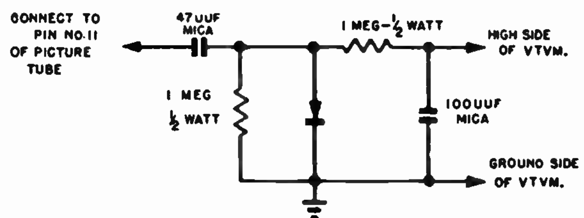
I-F ALIGNMENT

1. Lift the top section of the shield on the 6J6 mixer so that the shield does not make electrical contact with its base. Connect the output of an A-M signal generator to the shield and ground to the chassis.
2. Connect a VTVM across R12, the 4,700 ohm video detector load.
3. Set the Volume and Contrast Controls to minimum.
4. Tune the signal generator to 24.35 Mc and attenuate the signal generator output for a reading of —1 to —1.5 volts to avoid overload and consequent inaccurate alignment.
5. Peak the fourth I-F transformer (T2) to 24.35 Mc keeping the VTVM reading at —1 to —1.5 volts by adjustment of the attenuator on the signal generator.
6. Connect a 1,000 ohm resistor from the grid of V1 to the junction of R2 and R4. Adjust the first I-F coil located on the tuner for a maximum reading on the VTVM of between —1 and —1.5 volts (L9, Fig. 10). Remove the 1,000 ohm resistor.
7. Place the tuner turret so that it is between any two channels and adjust L1 for maximum indication on the VTVM. (Note: on sets below serial number 10525, L1 is fixed and step 7 should be disregarded.)
8. Peak the third I-F coil (L3) to 23.2 Mc keeping the VTVM reading at —1 to —1.5 volts.

9. Tune the signal generator to 25.2 Mc and adjust the second I-F transformer (T1) for maximum, keeping the VTVM reading at —1 to —1.5 volts.
10. Adjust the signal generator to 21.6 Mc and tune the trap L2 for a minimum reading.
11. The I-F passband may be observed by connecting a sweep generator across the terminals of the A-M signal generator and substituting an oscilloscope for the VTVM. Place a 3 volt battery so that its positive terminal is connected to the chassis and its negative terminal is connected to the junction of R2 and R4. The sweep generator should be set to approximately 24.35 Mc and then adjusted to center the waveform on the scope face. To avoid overload, and to assure a true view of the wave shape, the output of the sweep generator should be attenuated until further attenuation has a minimum effect on the wave shape. If necessary, a slight adjustment of the I-F transformers may be made to obtain a close approximation to the ideal curve. Adjustment of L3 or T1 affects the bandwidth. Adjustment of T2 affects the slope of the top.

SOUND ALIGNMENT

1. Connect an A-M signal generator tuned to 4.5 Mc between the grid of V5 and ground. Connect the alignment test circuit shown below and tune L8 for a minimum reading on a VTVM.
2. Disconnect the alignment test circuit and connect the VTVM to ground and Pin 5 of V7. Adjust L9 and primary of T3 (Bottom) for maximum indication.
3. Remove the VTVM and re-connect it to ground and junction of R27 and R28. Adjust secondary of T3 (Top) for zero. (Note: When tuning through the proper setting, the meter should swing negative on one side and positive on the other side.)

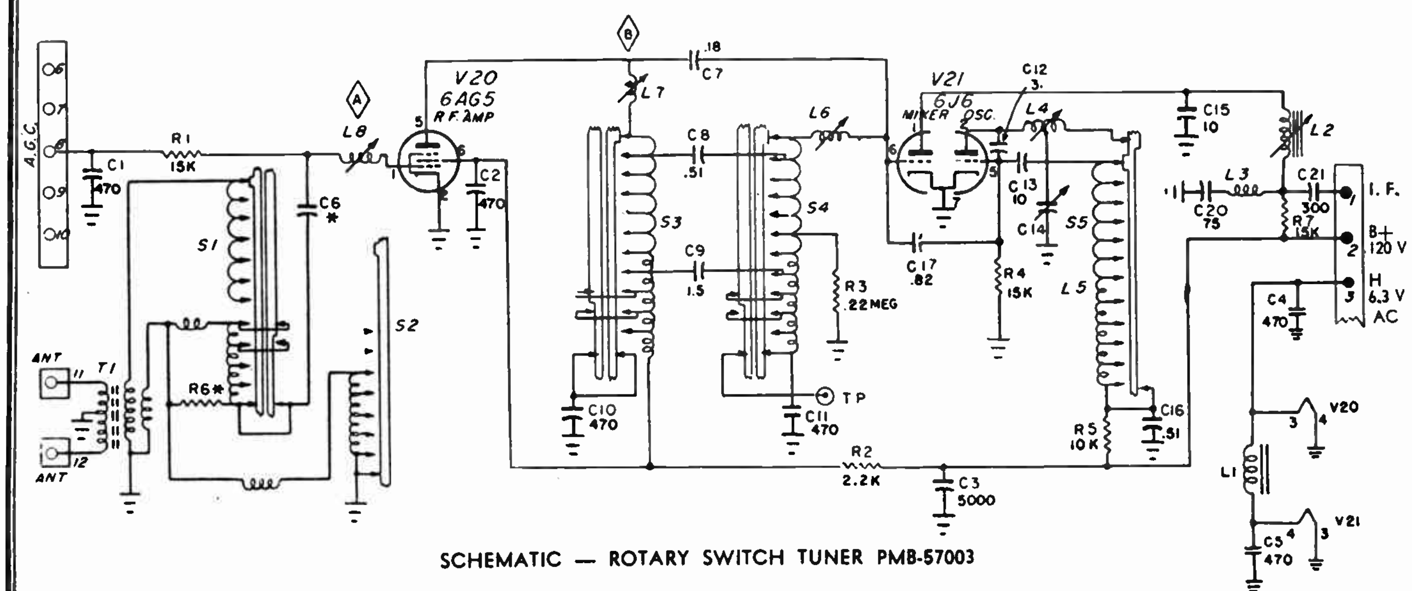


USE IN34 CRYSTAL

FIG. 9—SOUND ALIGNMENT TEST CIRCUIT

ALIGNMENT OF THE ROTARY SWITCH TUNER PMB-57003

Note: This tuner has been carefully checked and aligned at the factory to give the best possible performance. Alignment should not be necessary in the field unless tubes or other components are replaced.



SCHEMATIC — ROTARY SWITCH TUNER PMB-57003

OSCILLATOR ADJUSTMENT

1. Turn station selector to channel 13.
2. Connect signal generator, adjusted to correct channel 13 oscillator frequency, to the antenna.
3. Connect oscilloscope to test point through 10,000 ohms.
4. Set fine tuning in center of range. Check channel 13 and 6 for zero beat on scope.

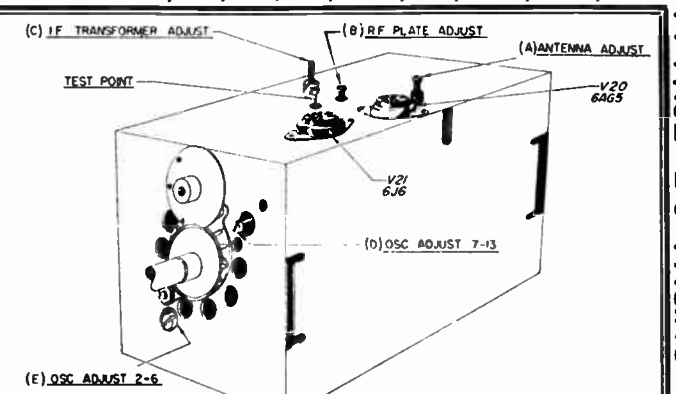
If it is necessary to make adjustments to the oscillator, the following steps should be followed:

A. Align high channels for correct frequency with channel 13 oscillator screw (See illustration, Adjustment D). A non-metallic screwdriver is advisable.
B. Align low channels for correct frequency with channel 6 oscillator screw (Adjustment E).
C. Adjustment of channel 13 and channel 6 oscillator brings all other channels in adjustment. Do not back up the screws more than 8 turns from tight. At that point the electrical effect has ceased. Further backing up will cause the screw to drop out.

Notes: Cover and tube shields to be on. Have rated supply voltages fed to tuner. Allow at least 3 minutes warm up. When replacing oscillator tube, select one which requires minimum touch-up. Clockwise rotation of screws increases frequency.

BAND PASS ALIGNMENT

1. Use R-F sweep to antenna and oscilloscope to the test point through 10,000 ohms.
2. The oscillator must be operating for each channel at nearly the correct frequency.
3. Align channel 13 R-F plate (Adjustment B) and R-F grid (Adjustment A) end inductances. Align channel 13 mixer grid end inductances by spreading or pushing together the turns. The band pass should include both carriers, have steep sides, and maximum gain.
4. Align the incremental loops of the R-F plate, R-F grid, and mixer grid from 12 to 7, in that order. Pushing the loops inwards increases the frequency.
5. Align channel 6 R-F plate, R-F grid, and mixer grid to obtain a flat response with maximum gain. Spreading the coils increases the frequency. Band pass should include both carriers and have steep sides.
6. Align incremental coils of R-F plate, R-F grid, and mixer grid from 5 to 2 in that order. Spreading coils increases the frequency. A tuning wand may be used to determine what change is necessary.



ROTARY SWITCH TUNER PMB-57003 ADJUSTMENTS

CAUTION: Band pass alignment is carefully made at the factory. Attempt this alignment only with proper equipment and set-up.

CONDITIONS OF MEASUREMENT:

"B" Supply .... 120 Volts
Heater Supply .... 6.3 Volts AC
Grid Bias .... —.5 Volts

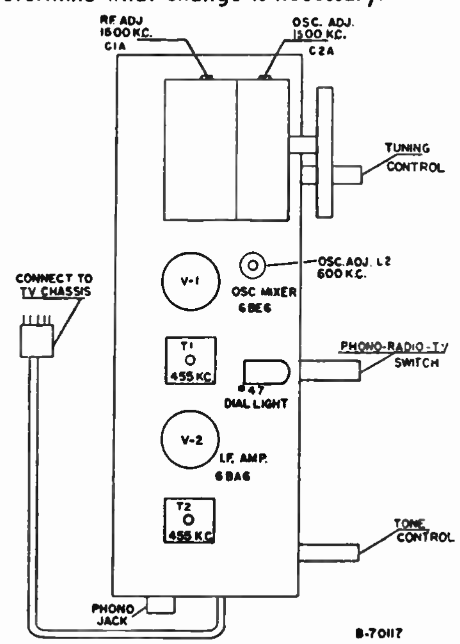
ALIGNMENT OF THE A-M RADIO TUNER, CHASSIS 155

Set RADIO-PHONO-TV function switch to RADIO position.

Set Volume and Tone controls at full clockwise position. With tuning gang fully closed, align dial pointer exactly ⅝" from left edge of dial panel background.

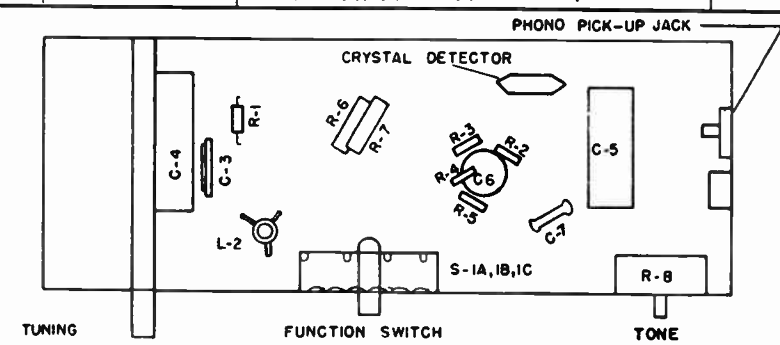
Connect output meter across voice coil.

Notes: Use an insulated alignment screwdriver. Use signal generator having 30% modulation at 400 cycles. Attenuate signal generator to keep output meter reading below 1.25 volts.



CHASSIS 155—TOP VIEW

DUMMY ANTENNA	SIG. GEN. COUPLING	SIG. GEN. FREQUENCY	DIAL SETTING	ADJUST	REMARKS
1.) .1 mfd.	High side to Pin No. 7, V-1 Radio, through .05 mfd. Low side to ground.	455 Kc	Tuning gang fully open.	Top & Bottom T1. 1st I-F Top & Bottom T2 2nd I-F	Adjust for max.
2.) None	To loop (form from a few turns of wire). Place in proximity of built-in antenna.	1500 Kc	Adjust gang to bring pointer 4⅛" from left edge of dial panel background.	C-2a Osc. trimmer.	Adjust for max.
3.) None	Same as (2).	600 Kc	1½" from left edge.	L-2 Osc. Slug Rock Gang.	Adjust for max.
4.) None	Same as (2).	1500 Kc	4⅛" from left edge.	C-1a R-F.	Adjust for max.
		Repeat (2), (3) and (4) if necessary.			

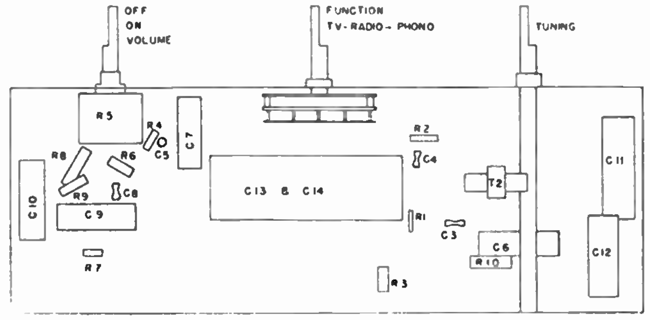


CHASSIS 155—BOTTOM VIEW

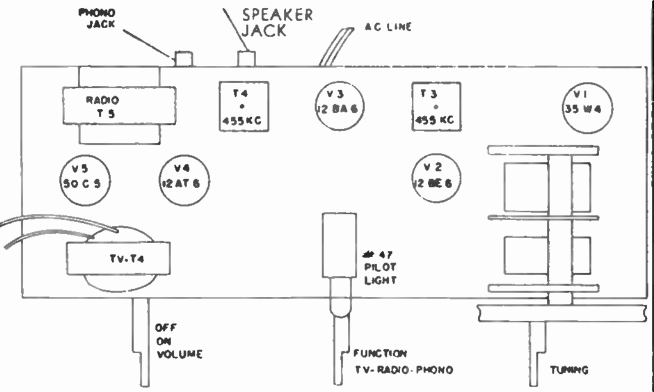
ALIGNMENT OF THE A-M RADIO TUNER, CHASSIS 160

The alignment procedure for this tuner is basically the same as for chassis 155, except for dial setting. The radio dial is fastened to the TV Fine Tuning dial in such a manner that the low end mark on the dial is opposite the radio Index with the gang fully closed. (The radio Index is either to the right, or above the dial. When ordering dial replacement give position of Index.) Before removing the chassis from the cabinet, mark the TV Channel Selector Knob with a grease pencil or bit of plastic tape opposite the radio Index. Remove and replace the knobs when removing the chassis, without changing the position of the TV Channel Selector or Fine Tuning controls. This will provide a reference point for the radio dial settings under the alignment procedure. Dial settings will correspond to signal generator frequencies except for 455 Kc. For this frequency open tuning gang fully.

It is necessary to retain the connections between the radio tuner and the radio built-in antenna fastened to the cabinet, during alignment.



CHASSIS 113—BOTTOM VIEW



CHASSIS 113—TOP VIEW

SECTION I

GENERAL INFORMATION

DESCRIPTION OF MODELS:

MODEL 2721, Fig. 1, is a console television receiver with full length doors. Chassis 2720 is used. The 21 inch rectangular picture tube is mounted in the cabinet on a removable shelf. Cabinet finishes are Mahogany, American Colonial, French Provincial, and Blonde Oak.

MODEL 2722, Fig. 2, is a console television receiver with full length doors. Chassis 2720 is used. The 24 inch round, metal picture tube is mounted in the cabinet on a removable shelf. Cabinet finishes are Mahogany, American Colonial, French Provincial, and Blonde Oak.

MODEL 2723 STANDARD, Fig. 3, is an open face console television receiver using chassis 2710. The 21 inch rectangular picture tube is mounted on the chassis. Cabinet finishes are Mahogany, Maple, and Blonde Oak.

MODEL 2723 DE LUXE, (not shown) has full length doors. Otherwise it looks exactly like the 2723 standard shown in Fig. 3.

MODEL 2724, Fig. 4, is a table model television receiver using chassis 2710. The 21 inch rectangular picture tube is mounted on the chassis. Cabinet finishes are Mahogany and Blonde.

CHASSIS 2710, Figs. 8 and 9, is designed for horizontal mounting in the cabinet and mounts a 21 inch rectangular picture tube. It is used in models 2723 Standard and De Luxe and in Model 2724 (table model).

CHASSIS 2720, Figs. 10 and 11, is smaller than the 2710 chassis since it does not mount the picture tube. It is designed for vertical mounting in the cabinet and is used in Models 2721 and 2722.

SPECIFICATIONS:

OVERALL DIMENSIONS:

	2721	2722	2723 std	2723 dlx	2724
Height	37 in.	39 in.	37 in.	37 in.	23 in.
Width	31 in.	35 in.	25 in.	26 in.	24 in.
Depth	24 in.	25 in.	23 in.	24 in.	22 in.
Ship. Wt.	180 lbs.	210 lbs.	150 lbs.	165 lbs.	115 lbs.

TELEVISION TUNING FREQUENCY RANGE:

All 12 VHF television channels currently allocated in the United States, consisting of channels 2 thru 13, and covering frequencies from 54 to 88 Mc. and 174 to 216 Mc.

Coil strips are available for UHF channels 14 thru 83.

INTERMEDIATE FREQUENCIES:

Picture Carrier: 25.0 Mc.
Sound Carrier: 20.5 Mc.
Intercarrier Sound: 4.5 Mc.

ELECTRICAL RATINGS:

Line voltage (all models), 110-120 volts AC, 60 cycles per second.

Power consumprion (all models), 190 watts.

LOUDSPEAKER DATA:

Type (all models): Permanent Magnet.

Voice coil impedance (all models): 3.2 ohms at 400 cycles per second.

Cone diameter, 2721, 2722 and 2723 de luxe: 10 in. with 3.16 oz. Alnico V.

Cone diameter, 2723 standard and 2724: 6 in. with 2.15 oz. Alnico V.

FOCUS:

Electrostatic.

SWEEP DEFLECTION:

Electromagnetic, 70 degree.

SCANNING:

525 lines interlaced.

HORIZONTAL SCANNING FREQUENCY:

15,750 cycles per second.

VERTICAL SCANNING FREQUENCY:

60 fields per second.

PICTURE REPETITION RATE:

30 frames per second.

TUBE COMPLEMENT:

No.	Tube	Function
V-1	6AU6	Sound I-F
V-2	6CB6	Driver
V-3	6AL5	Ratio Detector
V-4	6AV6	1st Audio Amplifier
V-5	6V6-GT	Audio Output
V-6	6CB6	1st Pix I-F
V-7	6CB6	2nd Pix I-F
V-8	6CB6	3rd Pix I-F
V-9	6CB6	4th Pix I-F
V-10A	½6AL5	Pix Detector
V-10B	½6AL5	D. C. Restorer
V-11	6CB6	1st Video Amplifier
V-12	6K6-GT	2nd Video Amplifier
V-13	12AU7	Sync Pulse Separator and Amplifier
V-14	6AL5	Automatic Frequency Control and Discriminator
V-15	6SN7-GT	Horizontal Oscillator
V-16	6J5 or 6J5-GT	Horizontal Discharge
V-17	6AV5-GT or 6AU5-GT	Horizontal Output
V-18	6AX4-GT	Damper
V-19	1B3-GT	High Voltage Rectifier
V-20	6AV6	Automatic Noise Inverter
V-21	6AU6	Keyed Automatic Gain Control
V-22	6J5 or 6J5-GT	Vertical Oscillator
V-23	6S4	Vertical Output
V-24	5U4-G	Low Voltage Rectifier
V-25	21FP4A	Pix Tube for models 2721, 2723 (both standard and deluxe), and 2724.
	24BP4	Pix Tube for model 2722.
V-26	6BQ7	R-F Amplifier Note: Early models using R-F Tuner 10531 may use either a 6BQ7 or a 6BK7. Tube must be replaced with type removed.
V-27	6J6	Oscillator and Mixer

PHONO RECEPTACLE AND SWITCH

There is a receptacle on the rear of the chassis to accommodate a record player. There is also a TV-PHONO switch that connects either the set or the record player.

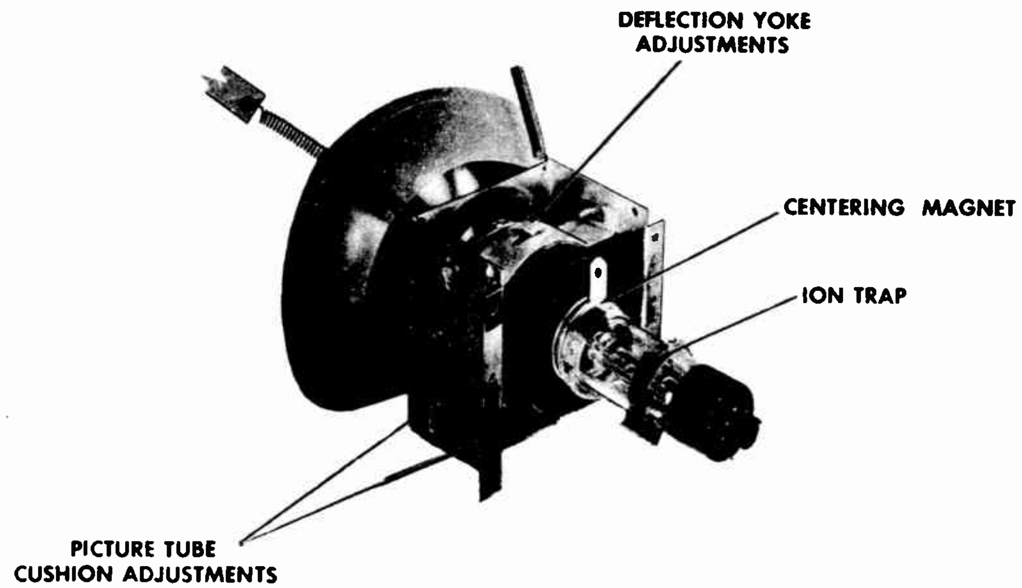

Fig. 5. Picture Tube Yoke Assembly

SECTION II

INSTALLATION INSTRUCTIONS

PICTURE TUBE ADJUSTMENTS:

The following picture tube adjustments are to be checked upon installation or whenever the receiver is serviced. (See Fig. 5, Picture Tube Yoke Assembly.)

1. Deflection Yoke. Loosen deflection yoke adjustment screw and rotate yoke so that raster is square with picture tube frame. Make certain yoke is positioned firmly against cone of tube.
2. Ion Trap. Turn contrast control to minimum. Set brightness control at approximately 90% clockwise and slowly slide ion trap backward and forward, at the same time rotating around neck of tube, until maximum brightness is obtained.
   Reset brightness control to just light tube. Turn contrast control clockwise to 90% of maximum and readjust ion trap for peak brightness.
3. Centering. The centering magnet is a dual ring magnet. The centering is dependent upon the relation of the rings to each other and the relation of both to the tube. The centering magnet is positioned almost against the deflection yoke, then the two sections rotated in relation to each other, and as a whole, until proper centering is obtained. This adjustment is quite stable and will need little attention unless its position is disturbed.

NOTE: If centering magnet requires adjustment, repeat step 2 above.

REMOVING AND REPLACING PICTURE TUBE:

CAUTION

WEAR GOGGLES OR A MASK AND USE GLOVES TO HANDLE TUBE. DO NOT STRIKE OR SCRATCH TUBE OR SUBJECT IT TO MORE THAN MODERATE PRESSURE.

NOTE: It is not necessary to remove the picture tube to clean the tube face. Simply remove three screws in front rail and remove safety glass. Clean glass and face of tube with window cleaning fluid on a soft cloth.

In all models it is necessary to remove the chassis before removing the picture tube.

The procedure on models 2721 and 2722 is as follows:

1. Disconnect power plug.
2. Remove back.
3. Remove picture tube socket, yoke plug, anode lead clip, and speaker plug.
4. Remove chassis by removing the four mounting bolts, removing knobs from control panel, and sliding chassis out.
5. Remove four bolts holding tube support platform.
6. Slide picture tube and tube support platform out of the cabinet.
7. Slide ion trap and centering magnet off neck of picture tube.
8. Remove tube securing band, rubber band and mounting ring. This step applies to model 2722 only.
9. Replace the tube by reversing the above procedure. Shell should be flush against deflection yoke rubber cushions.

The procedure on models 2723 and 2724 is as follows:

1. Disconnect power plug.
2. Remove back.
3. Remove chassis by removing control knobs on panel and four bolts on bottom of shelf.
4. Remove picture tube socket.
5. Remove ion trap and centering magnet.
6. Disconnect high voltage lead from picture tube.
7. Remove spring harness and unfasten band over top of picture tube.
8. Pull tube forward and out of yoke.

OPERATING INSTRUCTIONS, ALL MODELS:

1. Turn receiver on by turning VOLUME CONTROL clockwise.
2. Allow for normal tube warm up.
3. Turn SELECTOR to desired television channel.
4. Adjust FINE TUNING CONTROL for maximum picture quality.
5. Adjust CONTRAST CONTROL for most pleasing picture.
6. Adjust VOLUME CONTROL to desired level.

NON-OPERATING CONTROLS:

GENERAL:

The non-operating controls are located similarly on all models. Six of them are under the nameplate escutcheon on the front of the set. They are:

ANI (automatic noise inverter)
Vertical hold
Brightness
Vertical linearity
Height
Focus

To reach these controls open the spring doors on the escutcheon.

There are four non-operating controls at the rear of the chassis. They are:

Horizontal hold
Horizontal drive
Horizontal linearity
Width

All controls are marked. Read the following instructions before making any adjustments.

ADJUSTMENT OF NON-OPERATING CONTROLS:

The following adjustments should be made while observing a station test pattern. Allow receiver to warm up for ten minutes.

Adjustment of FOCUS control and BRIGHTNESS control is self explanatory.

Set HORIZONTAL HOLD to synchronize picture horizontally.

Set VERTICAL HOLD so that picture does not move up or down.

Adjust HEIGHT and WIDTH controls in conjunction with VERTICAL LINEARITY and HORIZONTAL LINEARITY controls to obtain symmetrical pattern of correct size.

The automatic noise inverter (ANI) control MUST be adjusted at the location where the receiver is to be used. Moreover, it must be adjusted using the weakest signal that will be received. The procedure is as follows:

1. Rotate the ANI control to its extreme counterclockwise position.
2. Advance the control clockwise until the picture begins to distort.
3. Return the control counterclockwise slightly beyond where the distortion disappears.
4. Check all channels for picture stability. If adjustment has not been made on the weakest signal, synchronization may be lost on another channel.

The HORIZONTAL DRIVE control is adjusted by rotating it clockwise until a bright vertical bar appears, causing picture compression. Then the control is rotated counterclockwise until the compression just disappears.

SECTION III

ALIGNMENT PROCEDURE

GENERAL:

It is important that the service technician read and adhere to the alignment instructions in this section. This point cannot be stressed too strongly, especially in the case of the picture I-F alignment.

Many service technicians have been accustomed to aligning the picture I-F response curve on the oscilloscope alone. This procedure is not recommended because it is actually quite possible to get what appears to be an acceptable curve and still be lacking in horizontal resolution.

Instead, the spot frequency alignment outlined below should be followed.

It will be noted that in the following procedure the sweep generator is fed in through the antenna terminals. This being the case, the output impedance of the generator must match the 300 ohm input impedance of the set. A matching network may be devised to accomplish this. At the factory a Sylvania type 500 sweep generator was used. This generator has an output impedance of 75 ohms. The network used to match this particular impedance to the set is shown in Fig. 6. For a generator with 50 ohms impedance, use 56 ohms for the shunt resistor, and 130 ohms for each of the series resistors.

Also in step 12 it is directed that the generator be loosely coupled to the converter tube. This is done by disconnecting the tube shield from ground and connecting the generator between the shield and ground.

Test point locations are shown on the schematic diagram, Fig. 20, and on the chassis illustrations, Figs. 8, 9, 10, and 11.

Allow the set to warm up for 10 minutes before alignment.

PICTURE I-F ALIGNMENT:

1. Remove ANI tube, 6AV6 (V-20).
2. Connect a 3 volt battery between point "A" and ground, with the negative lead to point "A."
3. Connect a vacuum tube voltmeter between points "B" and "C."
4. Connect signal generator between ground and first I-F grid (V-6, pin 1), through a .001 mfd capacitor. Set output at maximum.

NOTE: Early models have traps on 1st and 2nd I-F's only. These are tuned to 26.5 Mc. and 20.5 Mc. respectively. Alignment procedure is as described in steps 6 and 7 below, using 26.5 Mc. instead of 26.25 Mc.

Steps 5 through 12 are listed in tabular form.

Step	Signal Generator Frequency	Adjust.	For
5.	18.75 Mc.	S-22B	Minimum
6.	26.25 Mc.	S-21B and S-19B	Minimum
7.	20.50 Mc.	S-20B	Minimum
8.	22.15 Mc.	S-22A	Maximum
	(Adjust generator output for 2.5 to 3 volt VTVM reading for steps 8 thru 12.)		
9.	23.70 Mc.	S-21A	Maximum
10.	21.25 Mc.	S-20A	Maximum
11.	24.80 Mc.	S-19A	Maximum

REPEAT STEPS 5 THROUGH 11

Disconnect signal generator from I-F grid and loosely couple it to converter tube, V-27. See general instructions, this section.

Step	Signal Generator Frequency	Adjust.	For
12.	21.05 Mc.	S-6A (on R-F tuner)	Maximum

13. Disconnect VTVM and 3 volt battery.
14. Connect oscilloscope to point "B," using a 22,000 ohm isolating resistor in series with the scope probe. Connect an electrolytic capacitor, 5 mfd., 50 volt, between point "J" and ground, the negative lead going to point "J." The capacitor should previously have been checked for leakage. There should be no drop in A.G.C. voltage when the capacitor is connected.

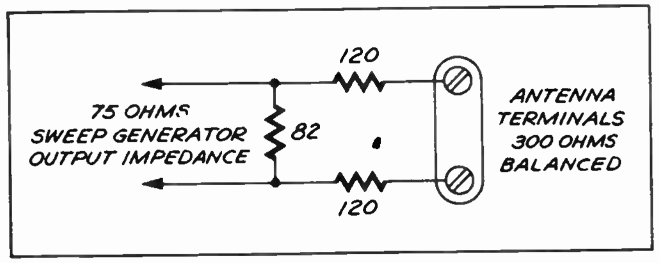

Fig. 6. Matching Network

15. Connect sweep generator to antenna terminals through an impedance matching network. (See preceding general instructions.)
16. Rotate tuner to a low frequency channel, say channel 3, and set sweep generator to center frequency of channel used (63 Mc. for channel 3). With a sweep width of 10 Mc., adjust generator output to develop approximately 4 volts of A.G.C.
17. With signal generator loosely coupled to converter tube, adjust output to provide the markers shown on the response curve, Fig. 7. Check the position of the markers one at a time.
18. Observe the waveform obtained on the oscilloscope, and compare it with the waveform shown in Fig. 7. If the spot frequency alignment has been carefully done, the comparison will be favorable. However, slight retouching of the I-F adjustments may be required. It should not be necessary to change any adjustment appreciably. The markers should be located as follows:
    The 20.5 Mc., the 26.25 Mc. and the 18.75 Mc. markers at minimum response.
    The 25.0 Mc. marker at 50% response.
    The 21.55 Mc. marker at 100% response.

ALIGNMENT OF 4.5 Mc. TRAP:

1. Remove Pix Detector-D.C. Restorer tube, 6AL5 (V-10).
2. Connect signal generator between point "B" and ground thru a .001 mfd isolating capacitor.
3. Turn contrast control to maximum.
4. Connect a R-F VTVM to point "D." If an R-F vacuum tube voltmeter is not available, connect a germanium diode crystal in series with the positive probe of a conventional VTVM.
5. Set signal generator to 4.5 Mc., exactly, with the output at one volt or more.
6. Adjust trap, S-23, for minimum VTVM reading.

Note: If signal generator is not capable of one volt output, it will be necessary to adjust the trap by visual means. To do this, observe the picture and adjust the trap to eliminate the 4.5 Mc. beat.

SOUND I-F AND RATIO DETECTOR ALIGNMENT:

1. Connect signal generator between point "B" and ground.
2. Connect VTVM between points "E" and "F."
3. With generator frequency at 4.5 Mc., adjust S-1, S-2, and S-3 for maximum output.
4. Connect VTVM between point "G" and ground.
5. With generator at 4.5 Mc., adjust Ratio Detector primary, S-4, for maximum output. A positive voltage will be noted.
6. Connect VTVM between points "G" and "H."
7. Adjust Ratio Detector secondary, S-5, for zero between positive and negative peaks.

RADIO FREQUENCY TUNER:

The radio frequency tuner used is the "Standard Cascode Tuner" manufactured by Standard Coil Products Inc. for Packard-Bell Co. Most models use tuner 10532 (Packard-Bell part number), but early models incorporated tuner 10531. Schematics of both are shown, Figs. 17 and 18.

The 10531 tuner uses a 6BK7 or a 6BQ7 tube as an R-F amplifier, but these tubes are not interchangeable. A tube must be replaced by the type that is removed.

The 10532 tuner has an improved circuit designed for use with the 6BQ7 tube only as the R-F amplifier.

Special Note: Some 10532 tuners are supplied with a 6BQ7A or a 6BZ7. These tubes are interchangeable with the usual 6BQ7.

Alignment of the tuner, other than channel slugs and converter I-F, is not recommended.

UHF OPERATION:

UHF coil strips for the radio frequency tuner will be available through Packard-Bell Factory Service Departments for channels 14 through 83. When requesting strips specify the tuner part number. Tuner 10531 uses "K" strips and tuner 10532 uses "Q" strips. These strips are not interchangeable.

No tuner adjustment is needed after strip installation except normal oscillator slug adjustment.

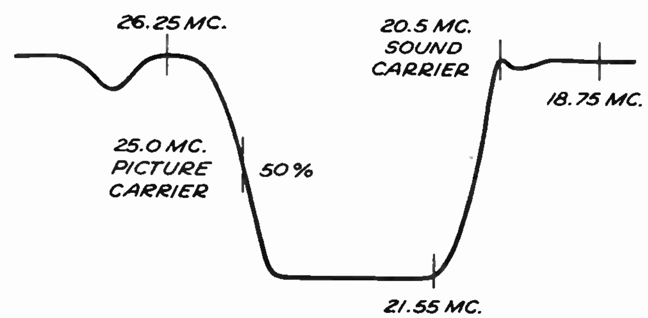

Fig. 7. I-F Response Curve

CHASSIS 2710 IS USED ON MODELS 2723 AND 2724.

LIST OF ADUSTMENTS:

Reference Symbol	Description
S-1	Intercarrier sound, 4.5 Mc.
S-2	Sound I-F, primary, 4.5 Mc.
S-3	Sound I-F, secondary, 4.5 Mc.
S-4	Ratio detector, primary
S-5	Ratio detector, secondary
S-6A	Converter I-F, in R-F tuner
S-6B	Mixer, in R-F tuner
S-6C	R-F, in R-F tuner
S-6D	Antenna, in R-F tuner
S-6E	Oscillator trimmer, in 10531 tuner only
S-7 thru S-18	Oscillator slugs for the 12 channels

Reference Symbol	Description
S-19A	1st picture I-F, 24.8 Mc.
S-19B	Trap, 26.25 Mc.
S-20A	2nd picture I-F, 21.25 Mc.
S-20B	Trap, 20.5 Mc.
S-21A	3rd picture I-F, 23.7 Mc.
S-21B	Trap, 26.25 Mc.
S-22A	4th picture I-F, 22.15 Mc.
S-22B	Trap, 18.75 Mc.
S-23	Trap, 4.5 Mc.
S-24	Horizontal hold
S-25	Horizontal linearity
S-26	Width

SECTION IV

SPECIAL SERVICING INFORMATION

BLOCK CIRCUIT DIAGRAM:

The block circuit diagram shown in Fig. 12 will enable service personnel to trace the signal through the receiver in a logical manner.

PRODUCTION MODIFICATIONS:

The following production modifications were made since the publication of "Preliminary Service Data" concerning these models. They are mentioned here in order to explain any variation between the schematic diagram and the receiver being serviced. THE REASON FOR THE CHANGE IS SHOWN IN CAPITAL LETTERS.

1. EASE IN ASSEMBLY. Capacitor C-3, 100 mmf, and R-4, 22,000 ohms are now combined into one unit called a "capristor." The Packard-Bell part number of the capristor is 23970.
2. IMPROVED PERFORMANCE. The front end tuner, Packard-Bell number 10531, has been replaced with tuner 10532.
3. IMPROVED OVERALL AUDIO RESPONSE. Capacitor C-13, .005 mfd. has been changed to .01 mfd., and resistor R-97, 1.5 megohms, has been added between plates of V-4 and V-5.
4. SUPPRESSION OF ADJACENT-CHANNEL INTERFERENCE. All four picture I-F transformers have been changed to a new type embodying adjacent-channel traps on each. In making this change, R-26 was changed from 8200 ohms to 10,000 ohms and resistor R-34 from 5600 ohms to 4700 ohms.

RASTER BUT NO SOUND OR PICTURE

1. Tuner defective.
2. V-21 defective, check A.G.C. voltage.
3. V-5 defective.

SOUND AND RASTER BUT NO PICTURE

1. V-11 or V-12 may be defective; change V-11, check voltages; if trouble does not disappear, change V-12 and check voltages.
2. Check video wave-forms.

PICTURE STABLE BUT POOR RESOLUTION OR DEFINITION

1. V-11 or V-12 may be defective. Change tubes successively, then check voltages and associated components.
2. Check centering magnet and ion trap for proper adjustment.
3. R-F or I-F circuit may be improperly aligned.
4. Video peaking coils may be open or shorted.

WEAK RASTER

1. Low B plus or line voltage.
2. V-24 may be defective; change tube then check voltages.
3. V-16, V-18, V-19 defective; change tubes, then check voltages and associated components.
4. Power transformer T-4 may be defective. Check plate winding.
5. Filter capacitors may be defective. Check C-11B, C-11C, C-60B and C-60C.

LOCATING TROUBLE BY PICTURE TUBE OBSERVATION:

A large proportion of circuit failures may be isolated by observing certain characteristics present in the picture. Listed below are a number of possible picture faults and their probable cause.

NO RASTER ON PICTURE TUBE

1. Incorrect adjustment of ion trap magnet.
2. V-16, V-18, V-19, V-24 defective; check voltages and associated components.
3. V-15 defective (no horizontal drive); change tube, then check voltages and associated components.
4. Check horizontal sweep wave-forms.
5. No high voltage; check transformer T-2 for defects.
6. Blown fuse; if fuse continues to blow out, check for short in B boost voltage.
7. Defective picture tube or picture tube socket.

PICTURE NOT STABLE

1. If regular sections of the left picture are displaced, V-16 may be defective; check voltages.
2. Check for loose connections or noise.

PICTURE WILL NOT HOLD HORIZONTAL SYNC.

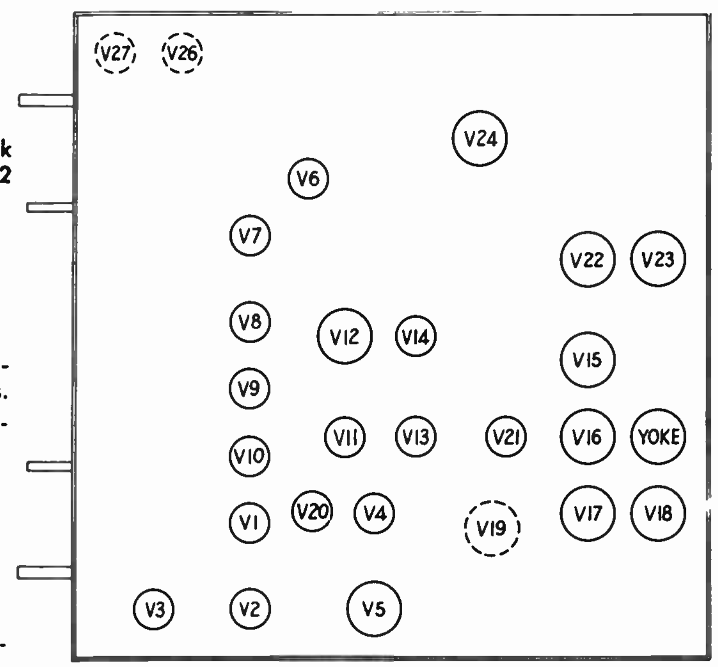
1. Horizontal hold control out of adjustment. See NON-OPERATING CONTROLS.
2. V-15 defective; change tube then check voltages and associated components.
3. Check horizontal sweep circuit wave-forms.

POOR VERTICAL LINEARITY

1. Incorrect adjustment of vertical linearity control. See NON-OPERATING CONTROLS.
2. Vertical output transformer defective, (T-3).

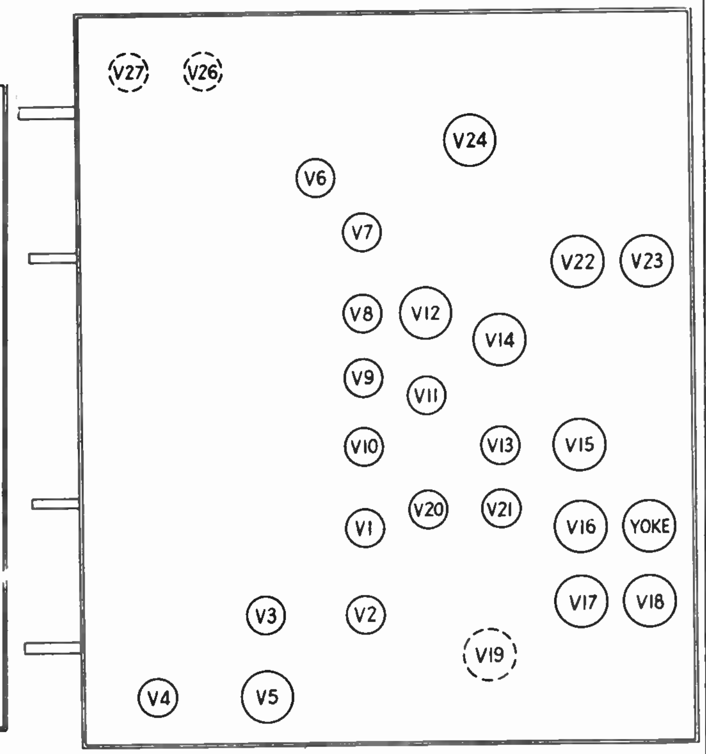
HIGH VOLTAGE WARNING

The picture tube second anode voltage is approximately 15,500 volts. Only personnel familiar with high voltage handling procedure should undertake servicing the chassis after it has been removed from the cabinet. DO NOT, AT ANY TIME, WORK ON THE CHASSIS WITH THE HIGH VOLTAGE CAGE COVER REMOVED AND THE RECEIVER CURRENT ON.



Bottom View

Fig. 14. Tube Location Chart, Chassis 2720



Bottom View

Fig. 13. Tube Location Chart, Chassis 2710

NO HORIZONTAL DEFLECTION

1. Horizontal deflection coil L-19B open.

NO VERTICAL DEFLECTION

1. V-23 defective; change tube then check voltages and associated components.
2. Vertical deflection coil L-19A open.

INSUFFICIENT WIDTH

1. V-24 defective; change tube, then check for adequate B plus voltage.
2. Power transformer T-4 may be defective; check plate winding.
3. V-16, V-19 defective; change tubes then check voltages.
4. Defective horizontal output transformer T-2.
5. Check horizontal sweep wave-forms.

NON-SYMMETRICAL RASTER

1. Check centering magnet and ion trap adjustments.
2. Yoke assembly may be defective.
3. Check vertical linearity and height adjustments.

PICTURE BUT NO SOUND

1. V-1, V-2, V-3, V-4, or V-5 defective; change tubes, then check voltages and associated components.
2. Audio output transformer T-1 open.
3. Speaker voice coil open.

CRITICAL LEAD DRESS:

In the event parts are replaced, refer to the appropriate chassis illustration, Fig. 8, 9, 10, or 11 for proper placement and lead dress. Particular attention should be given the following:

1. Do not displace components in the picture I-F circuit. If it is necessary to replace components in this section, the alignment should be checked following the changes.
2. Dress high voltage leads up and away from the chassis.
3. If parts are replaced in the high voltage section, solder joints must be rounded and free from sharp corners.
4. The lead from the ANI control, R-68, should be dressed away from the 4.5 Mc. trap S-23.

SOCKET VOLTAGES:

The socket voltages shown were measured on a typical chassis, under the following conditions:

1. No signal.
2. Line voltage, 117 volts.
3. Volume and contrast controls set at minimum, other controls at normal operating position.
4. D.C. voltages measured with a vacuum tube voltmeter.
5. A.C. voltages measured with a 1000 ohms per volt meter.
6. Voltages measured with respect to ground with the exception of those on V-1, V-2, V-5, and V-21. Voltages on these tubes were measured with respect to the cathode of V-5, which itself is 117 volts above ground.

NOTE: Some voltage readings are subject to a variation depending upon the setting of related controls. Thus the voltages on the vertical oscillator tube V-22 depend on the setting of the vertical hold control and the height control. Likewise the voltages on V-23 are varied by R-91.

All figures given below show the approximate magnitude of the reading to be expected, rather than the exact voltage.

Tube location is shown on Figs. 13 and 14, which are diagrams of the bottom view of each chassis.

TABLE OF REPLACEABLE PARTS

To be assured of genuine Packard-Bell replacement parts, order by the Packard-Bell part number from your nearest Packard-Bell Service Department. Their addresses are listed below.

City	Address
Los Angeles (home office)	1101 So. Hope St.
Alhambra	2221 West Valley Blvd.
Burbank	3007 Magnolia Blvd.
Compton	14912 So. Atlantic Blvd.
Culver City	2405 So. La Cienega Blvd.
Denver	1441 Ogden St.
El Paso	1515 Wyoming St.
Fresno	531 "P" St.
Honolulu	1923 Kalakaua Ave.
Oakland	1009 Cypress St.
Phoenix	228 E. Roosevelt St.
Portland	326 N. W. 21st Ave.
Riverside	247 La Cadena Dr.
Salt Lake City	624 So. State St.
San Diego	3069 El Cajon Blvd.
San Francisco	1157 Post St.
San Mateo	1037 No. Bayshore Blvd.
Santa Ana	1324 W. First St.
Seattle	2310 4th Ave.
Spokane	South 125 Stevens St.
Tacoma	2327 So. Tacoma Ave.

CAPACITORS

Notes: (1) "GMV" means "capacities listed are Guaranteed Minimum Values over a range of from plus 10 degrees C. to plus 65 degrees C."

(2) Unless otherwise specified, tolerances are:
Electrolytic capacitors, +50%, —10%
Paper capacitors, +30%, —10%

(3) "NPO" denotes zero temperature coefficient.

REFERENCE SYMBOL	DESCRIPTION		PACKARD-BELL PART NO.

GENERAL INFORMATION

DESCRIPTION OF MODELS:

MODEL 2921, Fig. 1, is a console television-radio-phonograph with full length doors. A 21 inch rectangular picture tube is employed, and the record changer is a three speed V-M, model 950. Cabinet finishes are Mahogany, French Provincial, American Colonial, and Blonde Oak.

MODEL 2922, Fig. 2, is a console television-radio-phonograph with full length doors. A 24 inch round metal picture tube is employed, and the record changer is a three speed Webster, model 114. Cabinet finishes are Mahogany, French Provincial, American Colonial, and Blonde Oak.

DESCRIPTION OF CHASSIS:

CHASSIS 2921, Figs. 8 and 9, is designed for horizontal mounting in the cabinet and mounts a 21 inch rectangular picture tube. The tuner is mounted in such a manner that it need not be removed for servicing. Tube replacement in the tuner, however, will necessitate removal of the chassis from the cabinet. Chassis 2921 is used in Model 2921.

CHASSIS 2922, Figs. 10 and 11, is the same electrically as the 2921 chassis, but is designed for vertical mounting in the cabinet. It is used in Model 2922.

SPECIFICATIONS:

OVERALL DIMENSIONS:

	Model 2921	Model 2922
Height	37 in.	39 in.
Width	38 in.	43 in.
Depth	25 in.	25 in.
Shipping Weight	220 lbs.	260 lbs.

TELEVISION TUNING FREQUENCY RANGE:

All 12 VHF television channels currently allocated in the United States, consisting of channels 2 thru 13, and covering frequencies from 54 to 88 Mc. and 174 to 216 Mc.

Coil strips are available for UHF channels 14 thru 83.

INTERMEDIATE FREQUENCIES:

AM Radio: 455 Kc.
Picture Carrier: 25.0 Mc.
Sound Carrier: 20.5 Mc.
Intercarrier Sound: 4.5 Mc.

ELECTRICAL RATINGS:

Line voltage, both models: 110-120 volts AC, 60 cycles per second.

Power consumption, both models:

TV	190 watts
Radio	80 watts
Phono	80 watts

TUBE COMPLEMENT:

	24BP4 Model 2922	Pix Tube
V-28	6BQ7	R-F Amplifier Note: Early models using R-F Tuner 10531 may use either a 6BQ7 or a 6BK7. Tube must be replaced with type removed.
V-29	6J6	Oscillator and Mixer

LOUDSPEAKER DATA:

	Model 2921	Model 2922
Type . . .	Permanent Magnet	Permanent Magnet
Voice coil impedance at 400 cycles	3.2 ohms	6.0 ohms (two speakers used, 3 ohm voice coils connected in series).
Size	10 in.	6 in. by 9 in. elliptical
Magnet . .	3.16 oz. Alnico V	2.15 oz. Alnico V

FOCUS:

Electrostatic.

SWEEP DEFLECTION:

Electromagnetic, 70 degree.

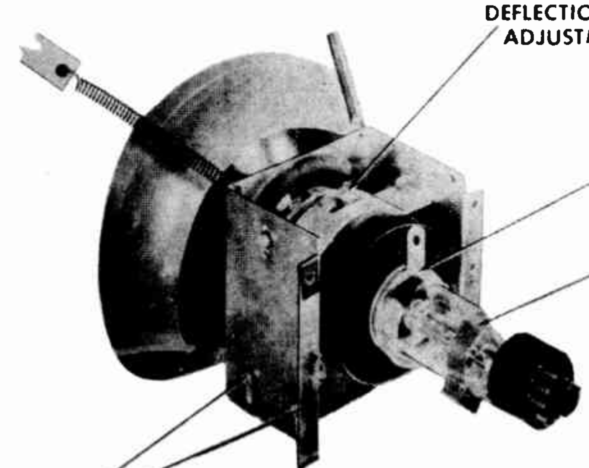

Fig. 3. Picture Tube Yoke Assembly

SECTION II

INSTALLATION INSTRUCTIONS

PICTURE TUBE ADJUSTMENTS:

The following picture tube adjustments are to be checked upon installation or whenever the receiver is serviced. (See Fig. 3. Picture Tube Yoke Assembly.)

1. Deflection Yoke. Loosen deflection yoke adjustment screw and rotate yoke so that raster is square with picture tube frame. Make certain yoke is positioned firmly against cone of tube.
2. Ion Trap. Turn contrast control to minimum. Set brightness control at approximately 90% clockwise and slowly slide ion trap backward and forward, at the same time rotating around neck of tube, until maximum brightness is obtained.
   Reset brightness control to just light tube. Turn contrast control clockwise to 90% of maximum and readjust ion trap for peak brightness.
3. Centering. The centering magnet is a dual ring magnet. The centering is dependent upon the relation of the rings to each other and the relation of both to the tube. The centering magnet is positioned almost against the deflection yoke, then the two sections rotated in relation to each other, and as a whole, until proper centering is obtained. This adjustment is quite stable and will need little attention unless its position is disturbed.

NOTE: If centering magnet requires adjustment, repeat step 2 above.

REMOVING AND REPLACING PICTURE TUBE:

CAUTION

WEAR GOGGLES OR A MASK AND USE GLOVES TO HANDLE TUBE. DO NOT STRIKE OR SCRATCH TUBE OR SUBJECT IT TO MORE THAN MODERATE PRESSURE.

NOTE: It is not necessary to remove the picture tube to clean the tube face. Simply remove three screws in front rail and remove safety glass. Clean glass and face of tube with window cleaning fluid on a soft cloth.

In both models it is necessary to remove the chassis before removing the picture tube.

The procedure on model 2921 is as follows:

1. Disconnect power plug.
2. Remove back.
3. Remove chassis by removing control knobs on panel and four bolts on bottom of shelf.
4. Remove picture tube socket.
5. Remove ion trap and centering magnet.
6. Disconnect high voltage lead from picture tube.
7. Remove spring harness and unfasten band over top of picture tube.
8. Pull tube forward and out of yoke.

The procedure on model 2922 is as follows:

1. Disconnect power plug.
2. Remove back.
3. Remove picture tube socket, yoke plug, anode lead clip, and speaker plug.
4. Remove chassis by removing the four mounting bolts, removing knobs from control panel, and sliding chassis out.
5. Remove four bolts holding tube support platform.
6. Slide picture tube and tube support platform out of the cabinet.
7. Slide ion trap and centering magnet off neck of picture tube.
8. Remove tube securing band, rubber band and mounting ring.
9. Replace the tube by reversing the above procedure. Shell should be flush against deflection yoke rubber cushions.

OPERATING INSTRUCTIONS:

TELEVISION OPERATION, BOTH MODELS:

1. Turn receiver on and set SELECTOR to TV position.
2. Allow for normal tube warm up.
3. Rotate CHANNEL SELECTOR to desired television channel.
4. Adjust FINE TUNING CONTROL for maximum picture quality.
5. Adjust CONTRAST CONTROL for most pleasing picture.
6. Adjust VOLUME CONTROL to desired level.

WHEN SWITCHING FROM TELEVISION TO RADIO OR VICE VERSA, ALLOW FOR TUBE WARM UP PERIOD.

RADIO OPERATION, BOTH MODELS:

1. Turn receiver on and set SELECTOR to AM position.
2. Allow for normal tube warm up.
3. Adjust TUNING CONTROL to desired station.
4. Adjust VOLUME and TONE CONTROLS to desired level.

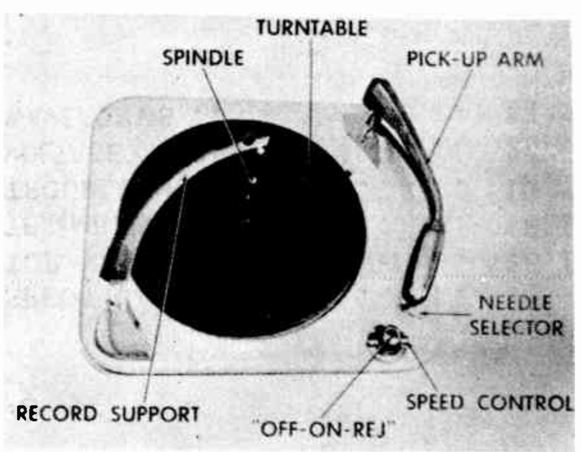

Fig. 4. V-M Record Changer

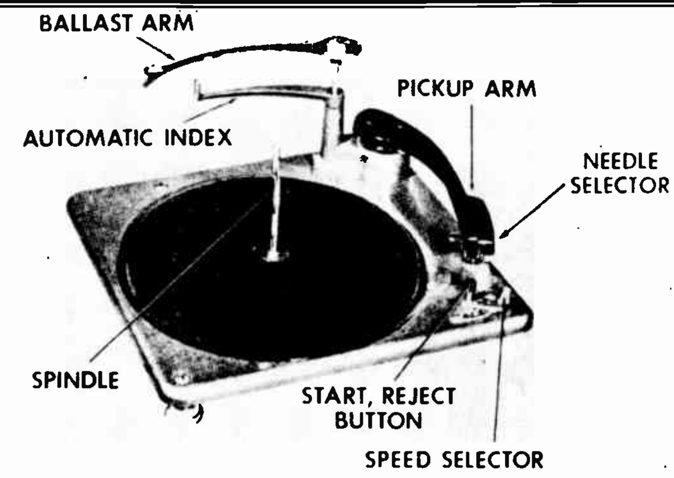

Fig. 5. Webster Record Changer

PHONOGRAPH OPERATION, MODEL 2921:

(Model 2921 uses the V-M Model 950 three speed automatic record changer, Fig. 4.)

1. Turn receiver on and set SELECTOR to Phono position.
2. Pull record support straight up and swing it to side until small pin on shaft drops into locating groove.
3. Place records on spindle and lower to offset shelf. Hold records level and replace record support over spindle. Changer will play ten 12 inch records, twelve 10 inch records, (standard or long playing), or twelve 7 inch records. The 10 inch and 12 inch may be intermixed if they are to be played at the same speed.
4. Set speed control and needle selector to correspond with type of record being played.
5. Turn on-off-reject button to "REJ." to start turntable and drop first record. Operation is now automatic; the changer will shut off after the last record has been played.
6. To reject any record while playing, turn on-off-reject button to "REJ."

REMOVING RECORDS, (model 2921):

1. Lift record support and swing it to side until small pin on shaft drops into locating groove.
2. Lift stack straight up off spindle.

MANUAL OPERATION, (model 2921):

1. With no records on turntable and record support in position on spindle, turn on-off-reject button and allow changer to go thru shut off cycle.
2. Lift record support and swing it to side. Place record on turntable and return record support to position on spindle.
3. Set speed control and needle selector to correspond with the type record being played.
4. Start turntable and place needle on record.

PHONOGRAPH OPERATION, MODEL 2922:

(Model 2922 uses the Webster Model 114 three speed automatic record changer, Fig. 5.)

1. Turn receiver on and set SELECTOR to Phono position.
2. Lift the record ballast arm and swing it away from the spindle and exert a slight downward pressure until it latches.
3. Place up to a one inch stack of any one size of records on the spindle and swing the record ballast arm back to the spindle, allowing it to drop in position with the spindle in the hole. The automatic index finger will remain away from the record until the change cycle starts. It will then move in to feel the diameter of the record and automatically index the pickup arm to the proper playing position.
4. Rotate needle selector to correspond with the type of the records to be played, "33-45" for 33⅓ or 45 R. P. M. records, "78" for 78 R. P. M. records.
5. Move the speed selector lever to correspond with the speed of the records to be played. Push the START-REJECT button to drop the first record. Hold button down until pickup arm moves.
6. To reject any record while playing automatically, push the START-REJECT button.
7. After the last record has been played, the turntable will shut off automatically and pickup arm will return to rest position.

REMOVING RECORDS, (model 2922):

1. Set the speed selector to off.
2. Lift and swing ballast arm away from spindle until it latches.
3. Place the fingers of both hands under opposite sides of the bottom record. Do not apply pressure to the top, but keep thumbs free, lifting the entire stack of records up following the contour of the spindle.

MANUAL OPERATION, (model 2922):

1. Lift the record ballast arm and swing it away from the spindle and exert a slight downward pressure until it latches.
2. Place a record on the turntable and move the speed control lever to correspond with the record being played.
3. Rotate needle selector to correspond with record being played.
4. Place pickup arm on record, turntable will start automatically.
5. When record has been played, remove pickup arm to rest position, turntable will shut off automatically.

IMPORTANT: ALWAYS MOVE SPEED SELECTOR TO "N" (NEUTRAL) POSITION WHEN RECORD PLAYER IS NOT IN USE.

NON-OPERATING CONTROLS:

GENERAL:

The non-operating controls are located similarly on both models. Six of them are under the nameplate escutcheon on the front of the set. They are:

ANI (automatic noise inverter)
Vertical hold
Brightness
Vertical linearity
Height
Focus

To reach these controls open the spring doors on the escutcheon.

There are four non-operating controls at the rear of the chassis. They are:

Horizontal hold
Horizontal drive
Horizontal linearity
Width

All controls are marked. Read the following instructions before making any adjustments.

ADJUSTMENT OF NON-OPERATING CONTROLS:

The following adjustments should be made while observing a station test pattern. Allow receiver to warm up for ten minutes.

Adjustment of FOCUS control and BRIGHTNESS control is self explanatory.

Set HORIZONTAL HOLD to synchronize picture horizontally.

Set VERTICAL HOLD so that picture does not move up or down.

Adjust HEIGHT and WIDTH controls in conjunction with VERTICAL LINEARITY and HORIZONTAL LINEARITY controls to obtain symmetrical pattern of correct size.

The automatic noise inverter (ANI) control MUST be adjusted at the location where the receiver is to be used. Moreover, it must be adjusted using the weakest signal that will be received. The procedure is as follows:

1. Rotate the ANI control to its extreme counterclockwise position.
2. Advance the control clockwise until the picture begins to distort.
3. Return the control counterclockwise slightly beyond where the distortion disappears.
4. Check all channels for picture stability. If adjustment has not been made on the weakest signal, synchronization may be lost on another channel.

The HORIZONTAL DRIVE control is adjusted by rotating it clockwise until a bright vertical bar appears, causing picture compression. Then the control is rotated counterclockwise until the compression just disappears.

SECTION III

ALIGNMENT PROCEDURE

GENERAL:

It is important that the service technician read and adhere to the alignment instructions in this section. This point cannot be stressed too strongly, especially in the case of the picture I-F alignment.

Many service technicians have been accustomed to aligning the picture I-F response curve on the oscilloscope alone. This procedure is not recommended because it is actually quite possible to get what appears to be an acceptable curve and still be lacking in horizontal resolution.

Instead, the spot frequency alignment outlined below should be followed.

It will be noted that in the following procedure the sweep generator is fed in through the antenna terminals. This being the case, the output impedance of the generator must match the 300 ohm input impedance of the set. A matching network may be devised to accomplish this. At the factory a Sylvania type 500 sweep generator was used. This generator has an output impedance of 75 ohms. The network used to match this particular impedance to the set is shown in Fig. 6. For a generator with 50 ohms impedance, use 56 ohms for the shunt resistor, and 130 ohms for each of the series resistors.

Also in step 12 it is directed that the generator be loosely coupled to the converter tube. This is done by disconnecting the tube shield from ground and connecting the generator between the shield and ground.

Test point locations are shown on the schematic diagram, Fig. 20, and on the chassis illustrations, Figs. 8, 9, 10, and 11.

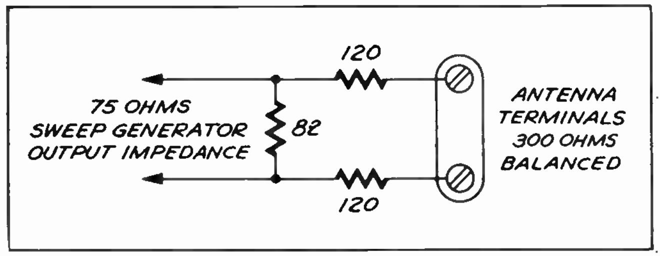

Fig. 6. Impedance Matching Network

Allow the set to warm up for 10 minutes before alignment.

PICTURE I-F ALIGNMENT:

1. Remove ANI tube, 6AV6 (V-22).
2. Connect a 3 volt battery between point "A" and ground, with the negative lead to point "A."
3. Connect a vacuum tube voltmeter between points "B" and "C."
4. Connect signal generator between ground and first I-F grid, (V-8, pin 1), through a .001 mfd capacitor. Set output at maximum.

NOTE: Early models have traps on 1st and 2nd I-F's only. These are tuned to 26.5 Mc. and 20.5 Mc. respectively. Alignment procedure is as described in steps 6 and 7 below, using 26.5 Mc. instead of 26.25 Mc. Steps 5 through 12 are listed in tabular form.

Step	Signal Generator Frequency	Adjust	For
5.	18.75 Mc.	S-32B	Minimum
6.	26.25 Mc.	S-31B and S-29B	Minimum
7.	20.50 Mc.	S-30B	Minimum
8.	22.15 Mc. (Adjust generator output for 2.5 to 3 volt VTVM reading for steps 8 thru 12.)	S-32A	Maximum
9.	23.70 Mc.	S-31A	Maximum
10.	21.25 Mc.	S-30A	Maximum
11.	24.80 Mc.	S-29A	Maximum

REPEAT STEPS 5 THROUGH 11

Disconnect signal generator from I-F grid and loosely couple it to converter tube, V-29. See general instructions, this section.

Step	Signal Generator Frequency	Adjust	For
12.	21.05 Mc.	S-12 (on R-F tuner)	Maximum

13. Disconnect VTVM and 3 volt battery.
14. Connect oscilloscope to point "B," using a 22,000 ohm isolating resistor in series with the scope probe. Connect an electrolytic capacitor, 5 mfd., 50 volt, between point "J" and ground, the negative lead going to point "J." The capacitor should previously have been checked for leakage. There should be no drop in A.G.C. voltage when the capacitor is connected.
15. Connect sweep generator to antenna terminals through an impedance matching network. (See preceding general instructions.)
16. Rotate tuner to a low frequency channel, say channel 3, and set sweep generator to center frequency of channel used (63 Mc. for channel 3). With a sweep width of 10 Mc., adjust generator output to develop approximately 4 volts of A.G.C.
17. With signal generator loosely coupled to converter tube, adjust output to provide the markers shown on the response curve, Fig. 7. Check the position of the markers one at a time.
18. Observe the waveform obtained on the oscilloscope, and compare it with the waveform shown in Fig. 7. If the spot frequency alignment has been carefully done, the comparison will be favorable. However, slight retouching of the I-F adjustments may be required. It should not be necessary to change any adjustment appreciably. The markers should be located as follows:

The 20.5 Mc., the 26.25 Mc. and the 18.75 Mc. markers at minimum response.

The 25.0 Mc. marker at 50% response.

The 21.55 Mc. marker at 100% response.

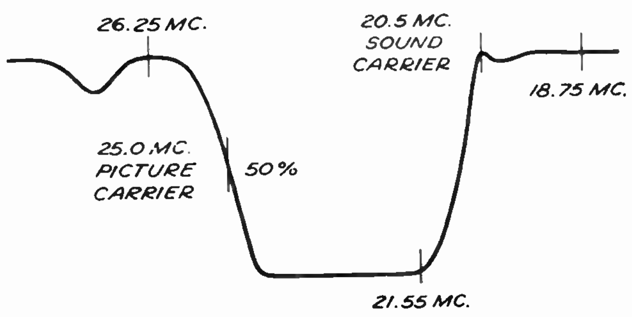

Fig. 7. I-F Response Curve

ALIGNMENT OF 4.5 Mc. TRAP:

1. Remove Pix Detector-D.C. Restorer tube, 6AL5 (V-12).
2. Connect signal generator between point "B" and ground thru a .001 mfd. isolating capacitor.
3. Turn contrast control to maximum.
4. Connect a R-F VTVM to point "D." If an R-F vacuum tube voltmeter is not available, connect a germanium diode crystal in series with the positive probe of a conventional VTVM.
5. Set signal generator to 4.5 Mc., exactly, with the output at one volt or more.
6. Adjust trap, S-33, for minimum VTVM reading.

Note: If signal generator is not capable of one volt output, it will be necessary to adjust the trap by visual means. To do this, observe the picture and adjust the trap to eliminate the 4.5 Mc. beat.

SOUND I-F AND RATIO DETECTOR ALIGNMENT:

1. Connect signal generator between point "B" and ground.
2. Connect VTVM between points "E" and "F."
3. With generator frequency at 4.5 Mc., adjust S-7, S-8, and S-9 for maximum output.
4. Connect VTVM between point "G" and ground.
5. With generator at 4.5 Mc., adjust Ratio Detector primary, S-10, for maximum output. A positive voltage will be noted.
6. Connect VTVM between points "G" and "H."
7. Adjust Ratio Detector secondary, S-11, for zero between positive and negative peaks.

THIS CHASSIS IS USED ON MODEL 2921

LIST OF ADJUSTMENTS:

Reference Symbol	Description
S-1	Antenna Trimmer, AM Tuner

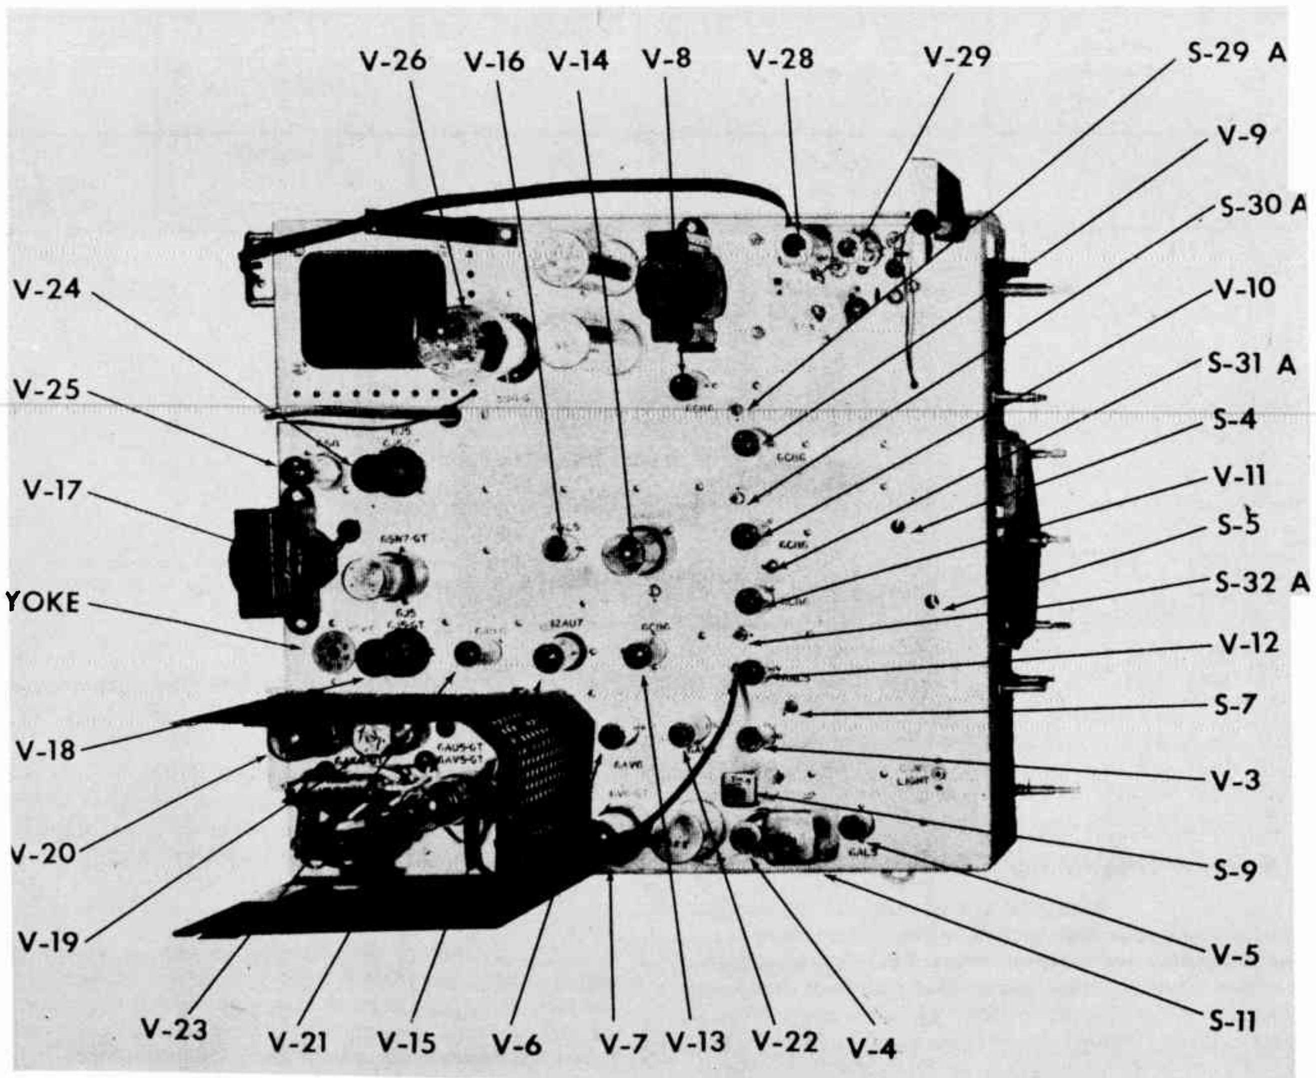

Fig. 10. Chassis 2922, Top View

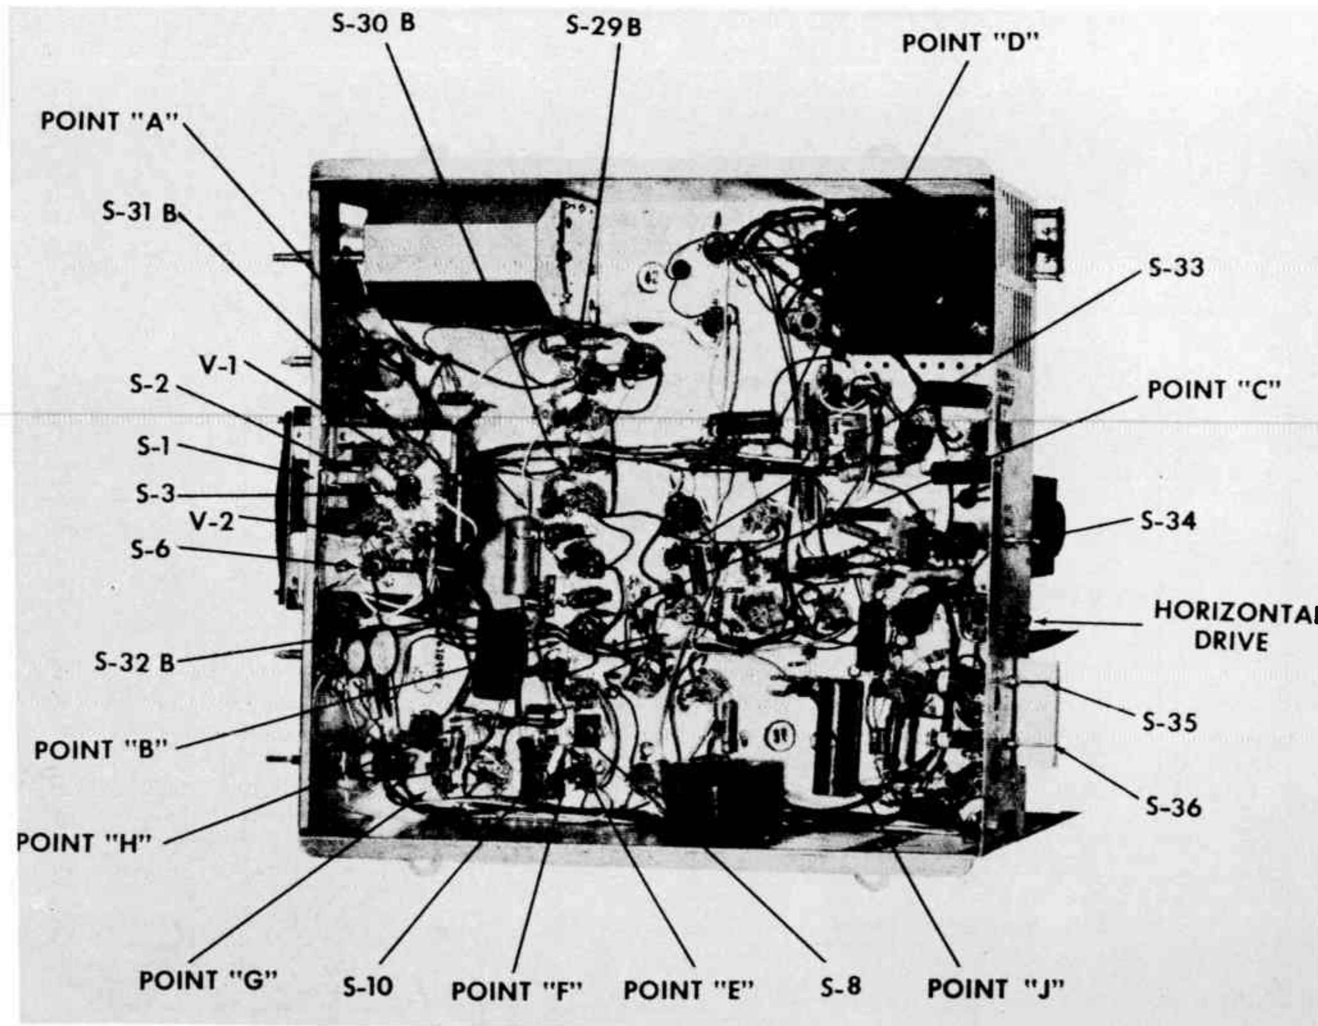

Fig. 11. Chassis 2922, Bottom View

RADIO FREQUENCY TUNER:

The radio frequency tuner used is the "Standard Cascode Tuner" manufactured by Standard Coil Products Inc. for Packard-Bell Co. Most models use tuner 10532 (Packard-Bell part number), but early models incorporated tuner 10531. Schematics of both are shown, Figs. 17 and 18.

The 10531 tuner uses a 6BK7 or a 6BQ7 tube as an R-F amplifier, but these tubes are not interchangeable. A tube must be replaced by the type that is removed.

The 10532 tuner has an improved circuit designed for use with the 6BQ7 tube only as the R-F amplifier.

Special Note: Some 10532 tuners are supplied with a 6BQ7A or a 6BZ7. These tubes are interchangeable with the usual 6BQ7.

UHF OPERATION:

UHF coil strips for the radio frequency tuner will be available through Packard-Bell Factory Service Departments for channels 14 through 83. When requesting strips specify the tuner part number. Tuner 10531 uses "K" strips and tuner 10532 uses "Q" strips. These strips are not interchangeable.

No tuner adjustment is needed after strip installation except normal oscillator slug adjustment.

D. C. RESISTANCE MEASUREMENTS, AM RADIO:

1st I-F Transformer, AM Radio	
Primary (terminals 2 & 3)	14.9 ohms
Secondary (terminals 1 & 4)	14.9 ohms
2nd I-F Transformer, AM Radio	
Primary (terminals 2 & 3)	16.5 ohms
Secondary (terminals 1 & 4)	11.5 ohms
Oscillator Coil, AM Radio	
Start to ground	5.5 ohms
Tap to ground	.65 ohms

ALIGNMENT OF AM RADIO:

The alignment of the AM radio consists of the steps shown in the following chart. Use the smallest possible input signal in each case. Connect the output meter to the speaker voice coil.

Refer to Figs. 8, 9, 10, and 11 for location of adjustments and test points.

Step	Connect Oscillator thru a .01 mfd. capacitor to:	Oscillator Setting	Pointer Setting	Adjust
1.	V-1 grid (pin 7) and ground	455 Kc.	540 Kc.	S-3, S-4, S-5 and S-6 for max. output
2.	Test loop*	1620 Kc.	1620 Kc.	S-2 for max. output
3.	Test loop*	1500 Kc.	1500 Kc.	S-1 for max. output
4.	Test loop* *Two or three turns of wire approximately 10 inches in diameter placed about two feet from receiver.	600 Kc.	600 Kc.	Move sleeve on which ferroloop is wound for maximum output. On some models a segment of the coil is movable.
Repeat step 3 and 4 several times to insure perfect tracking.				

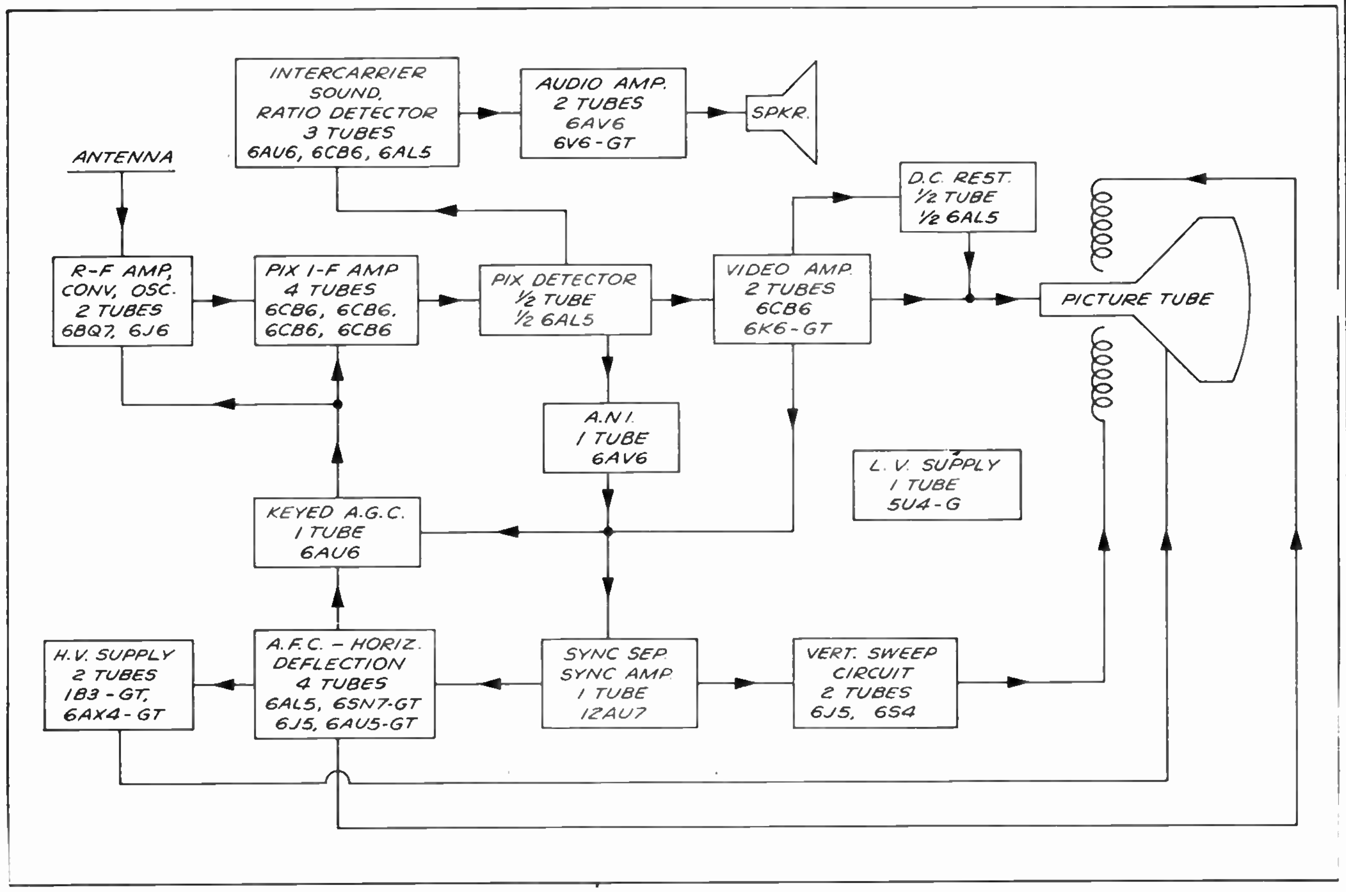

Fig. 12. Block Circuit Diagram, TV Section

HIGH VOLTAGE WARNING

The picture tube second anode voltage is approximately 15,500 volts. Only personnel familiar with high voltage handling procedure should undertake servicing the chassis after it has been removed from the cabinet. DO NOT, AT ANY TIME, WORK ON THE CHASSIS WITH THE HIGH VOLTAGE CAGE COVER REMOVED AND THE RECEIVER CURRENT ON.

SECTION IV

SPECIAL SERVICING INFORMATION

BLOCK CIRCUIT DIAGRAM:

The block circuit diagram shown in Fig. 12 will enable service personnel to trace the signal through the receiver in a logical manner.

PRODUCTION MODIFICATIONS:

The following production modifications were made since the publication of "Preliminary Service Data" concerning these models. They are mentioned here in order to explain any variation between the schematic diagram and the receiver being serviced. THE REASON FOR THE CHANGE IS SHOWN IN CAPITAL LETTERS.

1. EASE IN ASSEMBLY. Capacitor C-10, 100 mmf, and R-11, 22,000 ohms, are now combined into one unit called a "capristor". The Packard-Bell part number of the capristor is 23970.
2. IMPROVED PERFORMANCE. The front end tuner, Packard-Bell number 10531, has been replaced with tuner 10532.
3. SUPPRESSION OF ADJACENT-CHANNEL INTERFERENCE. All four picture I-F transformers have been changed to a new type embodying adjacent-channel traps on each. In making this change, R-35 was changed from 8200 ohms to 10,000 ohms and resistor R-43 from 5600 ohms to 4700 ohms.

LOCATING TROUBLE BY PICTURE TUBE OBSERVATION:

A large proportion of circuit failures may be isolated by observing certain characteristics present in the picture. Listed below are a number of possible picture faults and their probable cause.

NO RASTER ON PICTURE TUBE

1. Incorrect adjustment of ion trap magnet.
2. V-18, V-20, V-21, V-26 defective; check voltages and associated components.
3. V-17 defective, (no horizontal drive); change tube, then check voltages and associated components.
4. Check horizontal sweep wave-forms.
5. No high voltage; check transformer T-2 for defects.
6. Blown fuse; if fuse continues to blow out, check for short in B boost voltage.
7. Defective picture tube or picture tube socket.

RASTER BUT NO SOUND OR PICTURE

1. Tuner defective.
2. V-23 defective, check A. G. C. voltage.
3. V-7 defective.

SOUND AND RASTER BUT NO PICTURE

1. V-13 or V-14 may be defective; change V-13, check voltages; if trouble does not disappear, change V-14 and check voltages.
2. Check video wave-forms.

PICTURE STABLE BUT POOR RESOLUTION OR DEFINITION

1. V-13 or V-14 may be defective. Change tubes successively, then check voltages and associated components.
2. Check centering magnet and ion trap for proper adjustment.
3. R-F or I-F circuit may be improperly aligned.
4. Video peaking coils may be open or shorted.

WEAK RASTER

1. Low B plus or line voltage.
2. V-26 may be defective; change tube then check voltages.
3. V-18, V-20, V-21 defective; change tubes, then check voltages and associated components.
4. Power transformer T-4 may be defective. Check plate winding.
5. Filter capacitors may be defective. Check C-20B, C-20C, C-69B, and C-69C.

PICTURE NOT STABLE

1. If regular sections of the left picture are displaced, V-18 may be defective; check voltages.
2. Check for loose connections or noise.

PICTURE WILL NOT HOLD HORIZONTAL SYNC.

1. Horizontal hold control out of adjustment. See non-operating controls on page 14.
2. V-17 defective; change tube, then check voltages and associated components.
3. Check horizontal sweep circuit wave-forms.

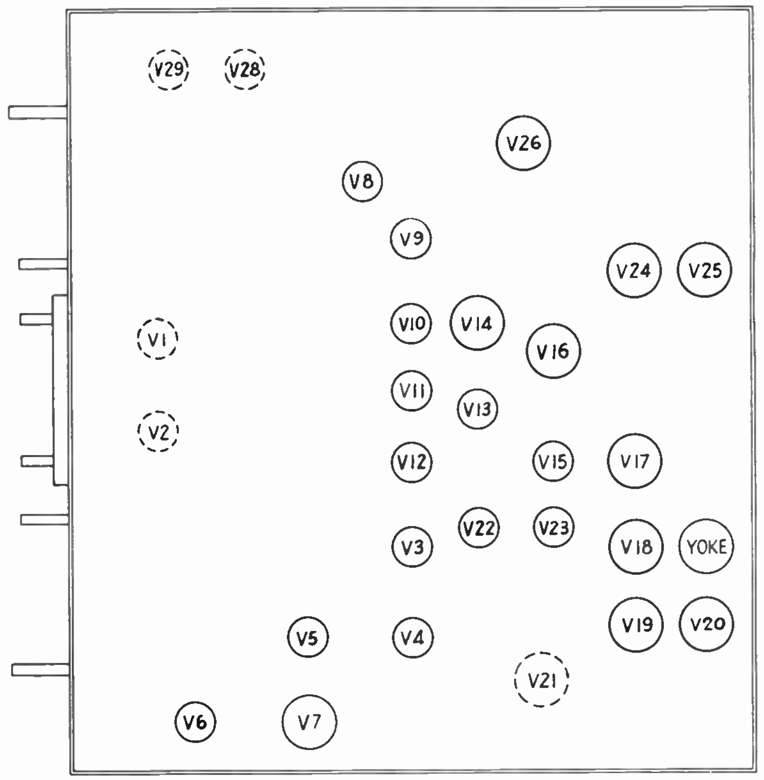

Fig. 13. Tube Location Chart, Chassis 2921, Bottom View

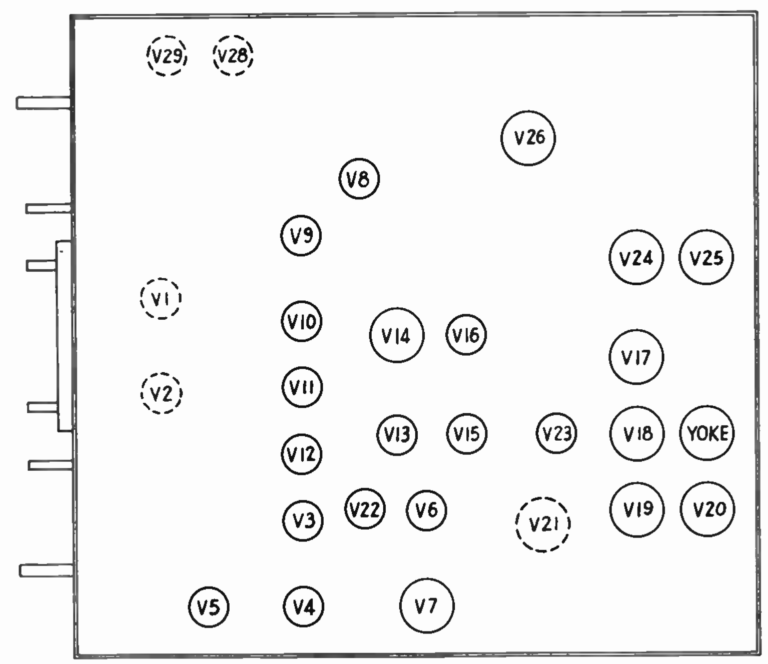

Fig. 14. Tube Location Chart, Chassis 2922, Bottom View

POOR VERTICAL LINEARITY

1. Incorrect adjustment of vertical linearity control. See non-operating controls on page 7.
2. Vertical output transformer defective, (T-3).

NO HORIZONTAL DEFLECTION

1. Horizontal deflection coil L-22B open.

NO VERTICAL DEFLECTION

1. V-25 defective; change tube, then check voltages and associated components.
2. Vertical deflection coil L-22A open.

INSUFFICIENT WIDTH

1. V-26 defective; change tube, then check for adequate B plus voltage.
2. Power transformer T-4 may be defective; check plate winding.
3. V-18, V-21 defective; change tubes, then check voltages.
4. Defective horizontal output transformer T-2.
5. Check horizontal sweep wave-forms.

NON-SYMMETRICAL RASTER

1. Check centering magnet and ion trap adjustments.
2. Yoke assembly may be defective.
3. Check vertical linearity and height adjustments.

PICTURE BUT NO SOUND

1. V-3, V-4, V-5, V-6, or V-7 defective; change tubes, then check voltages and associated components.
2. Audio output transformer T-1 open.
3. Speaker voice coil open.

CRITICAL LEAD DRESS:

In the event parts are replaced, refer to the appropriate chassis illustration, Fig. 8, 9, 10, or 11, for proper placement and lead dress. Particular attention should be given the following:

1. Do not displace components in the picture I-F circuit. If it is necessary to replace components in this section, the alignment should be checked following the changes.
2. Dress high voltage leads up and away from the chassis.
3. If parts are replaced in the high voltage section, solder joints must be rounded and free from sharp corners.
4. The lead from the ANI control, R-77, should be dressed away from the 4.5 Mc. trap, S-33.
5. The lead from the center tap of the height control, R-57B, should be dressed away from the tone control, R-20.

SOCKET VOLTAGES:

The socket voltages shown were measured on a typical chassis, under the following conditions:

1. No signal.
2. Line voltage, 117 volts.
3. Volume and contrast controls set at minimum, other controls at normal operating position.
4. D.C. voltages measured with a vacuum tube voltmeter.
5. A.C. voltages measured with a 1000 ohms per volt meter.
6. Voltages measured with respect to ground with the exception of those on V-3, V-4, V-7, and V-23. Voltages on these tubes were measured with respect to the cathode of V-7, which itself is 117 volts above ground.

NOTE: Some voltage readings are subject to a variation depending upon the setting of related controls. Thus the voltages on the vertical oscillator tube V-24 depend on the setting of the vertical hold control and the height control. Likewise the voltages on V-25 are varied by R-100.

All figures given below show the approximate magnitude of the reading to be expected, rather than the exact voltage.

Tube location is shown on Figs. 13 and 14, which are diagrams of the bottom view of each chassis.

SOCKET VOLTAGES, SWITCH IN "TV" POSITION

V-1, 6BE6, A.M. Converter
Not used in TV reception

V-2, 6BA6, A.M. I-F Amp.
Not used in TV reception

V-3, 6AU6, Sound I-F*

Pin	Element	Voltage
1	Grid 1	0
2	Grid 3	0
3	Heater	0
4	Heater	6.3 AC
5	Plate	135
6	Grid 2	135
7	Cathode	1 4

V-4, 6CB6, Driver*

Pin	Element	Voltage
1	Grid 1	2.9
2	Cathode	3.6
3	Heater	0
4	Heater	6.3 AC
5	Plate	52
6	Grid 2	52
7	Grid 3	3.2

V-5, 6AL5, Ratio Detector

Pin	Element	Voltage
1	Cathode 1	9.5
2	Plate 2	0
3	Heater	0
4	Heater	6.3 AC
5	Cathode 2	6.2
6	Shield	0
7	Plate 1	4.3

V-6, 6AV6, 1st Audio

Pin	Element	Voltage
1	Grid	–.56
2	Cathode	0
3	Heater	6.3 AC
4	Heater	0
5	Diode Plate	0
6	Diode Plate, not used	
7	Plate	110

V-7, 6V6-GT, Audio Output*

Pin	Element	Voltage
1	No connection	
2	Heater	6.3 AC
3	Plate	160
4	Grid 2	177
5	Grid 1	–5.5
6	No connection	
7	Heater	0
8	Cathode	0

V-8, 6CB6, 1st Pix I-F

Pin	Element	Voltage
1	Grid 1	–.3
2	Cathode	1.05
3	Heater	0
4	Heater	6.3 AC
5	Plate	109
6	Grid 2	109
7	Grid 3	0

V-9, 6CB6, 2nd Pix I-F

Pin	Element	Voltage
1	Grid 1	–.3
2	Cathode	1.25
3	Heater	0
4	Heater	6.3 AC
5	Plate	110
6	Grid 2	110
7	Grid 3	0

V-10, 6CB6, 3rd Pix I-F

Pin	Element	Voltage
1	Grid 1	–.3
2	Cathode	1.05
3	Heater	0
4	Heater	6.3 AC
5	Plate	113
6	Grid 2	113
7	Grid 3	0

V-11, 6CB6, 4th Pix I-F

Pin	Element	Voltage
1	Grid 1	0
2	Cathode	2.0
3	Heater	0
4	Heater	6.3 AC
5	Plate	117
6	Grid 2	117
7	Grid 3	0

V-12, (A & B), 6AL5 Pix Detector and D. C. Restorer

Pin	Element	Voltage
1	Cathode 1	11
2	Plate 2	0
3	Heater	0
4	Heater	6.3 AC
5	Cathode 2	5.6
6	Shield	0
7	Plate 1	9.8

V-13, 6CB6, 1st Video

Pin	Element	Voltage
1	Grid 1	9.8
2	Cathode	12.0
3	Heater	0
4	Heater	6.3 AC
5	Plate	95
6	Grid 2	117
7	Grid 3	0

V-14, 6K6-GT, 2nd Video

Pin	Element	Voltage
1	No connection	
2	Heater	0
3	Plate	320
4	Grid 2	117
5	Grid 1	0
6	No connection	
7	Heater	6.3 AC
8	Cathode	14

*Voltages taken with respect to cathode of V-7; see paragraph 6 at beginning of this section.

V-15, 12AU7, Sync. Amplifier

Pin	Element	Voltage
1	Plate 2	13.5
2	Grid 2	–3.5
3	Cathode 2	0
4	Heater	0
5	Heater	0
6	Plate 1	76
7	Grid 1	13.5
8	Cathode 1	13.5
9	Heater Tap	6.3 AC

V-16, 6AL5, A. F. C., Discriminator

Pin	Element	Voltage
1	Cathode 1	0
2	Plate 2	0
3	Heater	0
4	Heater	6.3 AC
5	Cathode 2	6
6	Shield	0
7	Plate 1	–4.2

V-17, 6SN7-GT, Horiz. Osc.

Pin	Element	Voltage
1	Grid 2	–1
2	Plate 2	110
3	Cathode 2	13
4	Grid 1	1
5	Plate 1	300
6	Cathode 1	13
7	Heater	0
8	Heater	6.3 AC

V-18, 6J5 or 6J5-GT, Horiz. Discharge

Pin	Element	Voltage
1	Shell in 6J5 No connection in 6J5-GT	0
2	Heater	0
3	Plate	165
4	No connection	
5	Grid	–21
6	No connection	
7	Heater	6.3 AC
8	Cathode	0

V-19, 6AV5-GT or 6AU5-GT, Horiz. Output

Pin	Element	Voltage
1	Grid 1	4.8
2	Heater	0
3	Cathode, Grid 3	62
4	No connection	
5	Plate	5 Kv. pulse
6	No connection	
7	Heater	6.3 AC
8	Grid 2	240

V-20, 6AX4-GT, Damper

Pin	Element	Voltage
1	No connection	
2	No connection	
3	Cathode	580
4	No connection	
5	Plate	330
6	No connection	
7	Heater	0
8	Heater	6.3 AC

V-21, 1B3-GT, H.V. Rectifier

15,500 volts between pin 2 and ground

V-22, 6AV6, Automatic Noise Inverter

Pin	Element	Voltage
1	Grid	–.3
2	Cathode	9.8
3	Heater	0
4	Heater	6.3 AC
5	Diode Plate, not used	
6	Diode Plate, not used	
7	Plate	116

V-23, 6AU6, Keyed Automatic Gain Control*

Pin	Element	Voltage
1	Grid 1	–22
2	Grid 3	0
3	Heater	0
4	Heater	6.3 AC
5	Plate	–115
6	Grid 2	210
7	Cathode	0

*Voltages taken with respect to cathode of V-7; see paragraph 6 at beginning of this section.

V-24, 6J5 or 6J5-GT, Vertical Oscillator

Pin	Element	Voltage
1	Shell in 6J5 No connection in 6J5-GT	0
2	Heater	0
3	Plate	150
4	No connection	
5	Grid	–8
6	No connection	
7	Heater	6.3 AC
8	Cathode	13.5

V-25, 6S4, Vertical Output

Pin	Element	Voltage
1	Internal connection	
2	Cathode	29
3	Grid	0
4	Heater	0
5	Heater	6.3 AC
6	Grid (same as 3)	0
7	Internal connection	
8	Internal connection	
9	Plate	500

V-26, 5U4-G, L. V. Rectifier

Pin	Element	Voltage
1	No connection	
2	Filament	5 AC, 340 DC
3	No connection	
4	Plate	350 AC
5	No connection	
6	Plate	350 AC
7	No connection	
8	Filament	5 AC, 340 DC

SOCKET VOLTAGES, SWITCH IN "RADIO" OR "PHONO" POSITION:

V-1, 6BE6, A.M. Converter

Pin	Element	Voltage (radio or phono)
1	Grid 1	–3.5
2	Cathode, Grid 5	0
3	Heater	0
4	Heater	6.3 AC
5	Plate	90
6	Grids 2 & 4	90
7	Grid 3	–.8

V-2, 6BA6, A.M. I-F Amplifier

Pin	Element	Voltage (radio or phono)
1	Grid 1	–.8
2	Grid 3	0
3	Heater	0
4	Heater	6.3 AC
5	Plate	95
6	Grid 2	95
7	Cathode	1

V-6, 6AV6, A. M. Detector and Amplifier

Pin	Element	Voltage (radio or phono)
1	Grid	–.56
2	Cathode	0
3	Heater	0
4	Heater	6.3 AC
5	Diode plate	0
6	Diode plate, not used	
7	Plate	110

V-7, 6V6-GT, Audio Output*

Pin	Element	Voltage (Radio)	Voltage (Phono)
1	No connection		
2	Heater	0	0
3	Plate	220	225
4	Grid 2	240	245
5	Grid 1	–14.5	–16
6	No connection		
7	Heater	6.3 AC	6.3 AC
8	Cathode	0	0

*Voltages taken with respect to cathode of V-7; see paragraph 6 at beginning of this section.

TABLE OF REPLACEABLE PARTS

To be assured of genuine Packard-Bell replacement parts, order by the Packard-Bell part number from your nearest Packard-Bell Service Department. Their addresses are listed below.

City	Address	Phone
Los Angeles (home office)	1101 So. Hope St.	RIchmond 7-6411
Alhambra	2221 West Valley Blvd.	ATlantic 2-3195
Burbank	3007 Magnolia Blvd.	CHarleston 0-4877
Compton	14912 So. Atlantic Blvd.	NEwmark 5-8148
Culver City	2405 So. La Cienega Blvd.	VErmont 9-8953
Denver	1441 Ogden St.	Keystone 6365
El Paso	1515 Wyoming St.	2-1608
Fresno	531 "P" St.	
Honolulu	1923 Kalakaua Ave.	99-8420
Oakland	1009 Cypress St.	TEmplebar 6-1662
Phoenix	228 E. Roosevelt St.	ALpine 4-5514
Portland	326 N. W. 21st Ave.	Capital 9716
Riverside	247 La Cadena Dr.	1338
Salt Lake City	624 So. State St.	9-3748
San Diego	3536 Adams	TAlbot 1-8163
San Francisco	1157 Post St.	PRospect 6-1880
San Mateo	1037 No. Bayshore Blvd.	DIamond 4-6882
Santa Ana	1324 W. First St.	KImberly 3-6571
Seattle	2310 4th Ave.	Mutual 2400
Spokane	South 125 Stevens St.	Riverside 6153
Tacoma	2327 So. Tacoma Ave.	Broadway 2175
Tucson	745 No. 4th Ave.	4-2408

CAPACITORS

Notes: (1) "GMV" means "capacities listed are Guaranteed Minimum Values over a range of from plus 10 degrees C. to plus 65 degrees C."

(2) Unless otherwise specified, tolerances are:
Electrolytic capacitors, +50%, —10%
Paper capacitors, +30%, —10%

(3) "NPO" denotes zero temperature coefficient.

REFERENCE SYMBOL	DESCRIPTION	PACKARD-BELL PART NO.
C-1	See "CONTROLS"	
C-2	Ceramic, 220 mmf, 20%, 350 volt	23915
C-3	Paper, .05 mfd, 200 volts	23017
C-4	Ceramic, 220 mmf, 20%, 350 volt	23915
C-5	Ceramic, 10,000 mmf GMV, 500 volt, disc	23939
C-6	Ceramic, 10,000 mmf GMV, 500 volt, disc	23939
C-7	Tweet filter network, consisting of two 100 mmf capacitors and a 47,000 ohm resistor	23930
C-8	Ceramic, 2.2 mmf ±.25 mmf, 500 volt, NPO	23969
C-9A	Ceramic, 4000 mmf GMV, 500 volts } dual, disc	23955
C-9B	Ceramic, 4000 mmf GMV, 500 volts } dual, disc	
C-10	Capristor (consists of a 100 mmf capacitor in parallel with a 22,000 ohm resistor)	23970
C-11A	Ceramic, 4000 mmf GMV, 500 volt } dual, disc	23955
C-11B	Ceramic, 4000 mmf GMV, 500 volt } dual, disc	
C-12	Ceramic, 10,000 mmf GMV, 500 volt, disc	23939
C-13A	Electrolytic, 5 mfd 75 volt } quadruple	24069
C-13B	Electrolytic, 100 mfd 15 volt } quadruple	
C-13C	Electrolytic, 25 mfd 25 volt } quadruple	
C-13D	Electrolytic, 5 mfd 75 volt } quadruple	
C-14	Ceramic, 470 mmf, 20%, 500 volt	23916
C-15	Paper, .003 mfd 600 volt	23016
C-16	Ceramic, 10,000 mmf GMV, 500 volt, disc	23939
C-17	Ceramic, 10,000 mmf GMV, 500 volt, disc	23939
C-18	Paper, .02 mfd 600 volt	23007

PHILCO UHF TUNER-ADAPTER UT-21, PART No. 43-6475

Philco UHF Tuner-Adapter Part No. 43-6475 provides for reception of UHF signals on television channels 14 through 83. It is designed for installation in Philco Television Receivers using r-f chassis 41, 42, 44, or 71. The Tuner-Adapter consists of a UHF converter and preamplifier unit, a change-over switch, adapter cables and plugs, a tuner driving assembly, and mounting hardware.

CIRCUIT DESCRIPTION

The UHF Tuner-Adapter functions as a converter, and converts the signals of the UHF band to a frequency selected within the VHF band. The frequency selected is that of either Channel 2 or Channel 3, depending upon the locality in which the receiver is used.

The incoming UHF signals are coupled through the antenna input line, and through two 680-μμf. condensers and a 150-ohm transmission line to the antenna tank of the tuner. See figure 1. The antenna tank is coupled to the mixer tank by means of the mutual coupling of L2 and L3 and the stray capacitance, C5. The desired UHF signal is selected by tuning the antenna tank and the mixer tank to the proper frequency, and the signal is then coupled to the crystal mixer circuit by means of the mutual coupling of L4 and L5. The local-oscillator signal is generated by a 6AF4 tube, V1, and the associated circuit. The local-oscillator signal is coupled to the crystal mixer circuit by means of a 300-ohm, miniature transmission line and the mutual coupling of L7 to L5 and L8 to L6. The UHF r-f signal and the oscillator signal are mixed in the crystal mixer circuit to produce a radio-frequency signal that is within the range of the VHF tuner when the tuner is set to either Channel 2 or Channel 3. This signal is fed into a preamplifier, and the amplified signal is then fed into the VHF tuner through a twin-wire lead. In the VHF tuner, the signal is reconverted to the intermediate frequency of the television receiver.

On VHF operation, a 150,000-ohm resistor is placed in series with the UHF oscillator plate, thus making the oscillator inoperative.

The purpose of using two r-f tanks in the UHF tuner is to readily admit the r-f signals, and, at the same time, to prevent the i-f and oscillator signals from feeding back into the antenna and causing interference with other receivers.

CHANGE-OVER SWITCH

The change-over switch supplied with the Tuner-Adapter is used to switch from VHF to UHF, and vice versa. It is operated either by pulling the UHF tuning knob forward or pushing it back toward the control panel. When the knob is pulled forward, the switch is thrown to the UHF position; when the knob is pushed back, the switch is thrown to the VHF position. When thrown to the UHF position, the switch connects the antenna to the UHF tuner, turns on the UHF pilot light, and connects the output of the UHF tuner to the antenna input of the VHF tuner. When thrown to the VHF position, the switch connects the antenna to the VHF tuner input, turns off the UHF pilot light, and places a 150,000-ohm resistor in series with the UHF oscillator plate, as explained above.

TUNER AND POINTER DRIVE

The shaft of the tuning-condenser gang is connected to the tuning shaft by means of a drive cord and pulley assembly. Another drive cord connects the tuning-gang shaft to the pointer and pointer shaft assembly. A switch washer, which is fastened to the tuning shaft, operates the change-over switch when the shaft is pulled forward or pushed back.

ALIGNMENT AND REPAIRS

The frequencies at which the tuner operates are extremely high; therefore, it is important that the utmost care be taken to safeguard against upsetting the delicate adjustments of the tuner. It is recommended that the serviceman make only minor repairs on the tuner, such as replacement of a tube or crystal and the wiring of external leads. The tuner should be returned to the factory for alignment and major repairs, unless the serviceman is properly equipped to perform this work. In general, a good rule to follow is not to remove the cover of the tuner.

Replacing a tube with a new one may detune the tuner. If this occurs, try a number of tubes until the best substitute for the original tube is found.

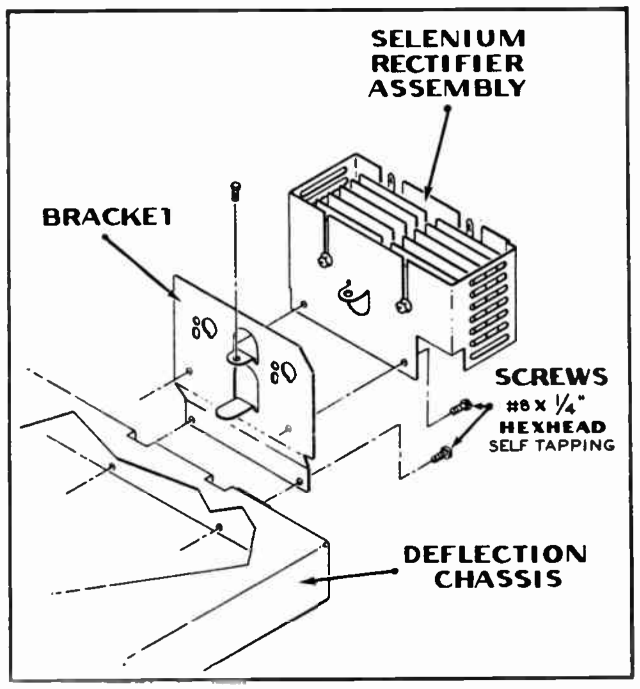
INSTALLATION INSTRUCTIONS

To install the Tuner-Adapter, proceed as follows:

1. Remove the cabinet back from the cabinet.

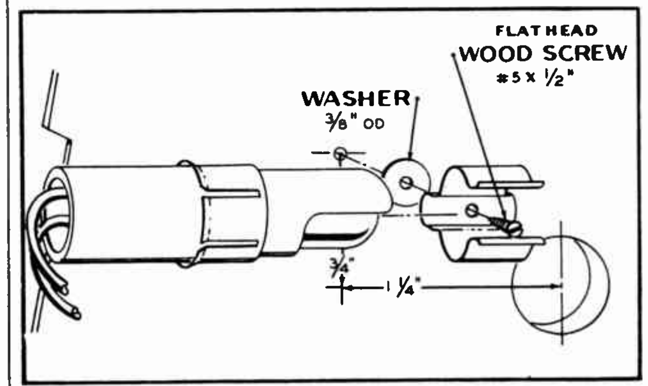
2. Remove the medallion on the control panel by pushing it out from the back. If the set does not have a medallion on the panel, drill a 9/16-inch hole in line with the shafts, and centered between the two inner shafts.

3. If the selenium rectifiers do not leave sufficient clearance for the UHF tuner assembly, remove the deflection chassis from the cabinet. Then remove the three mounting screws that hold the selenium-rectifier assembly to the chassis. Mount the selenium-rectifier bracket (supplied) on the chassis, using the same mounting screws and holes that were used to hold the rectifier assembly. Then mount the rectifier assembly on the bracket. See figure 6.



TP2-2665

Figure 6. Selenium Rectifier Mounting Details



P2-2581

Figure 7. Pilot-Light-Clip Installation Details

4. Mount the pilot-light clip near the UHF tuner shaft hole, as shown in figure 7.

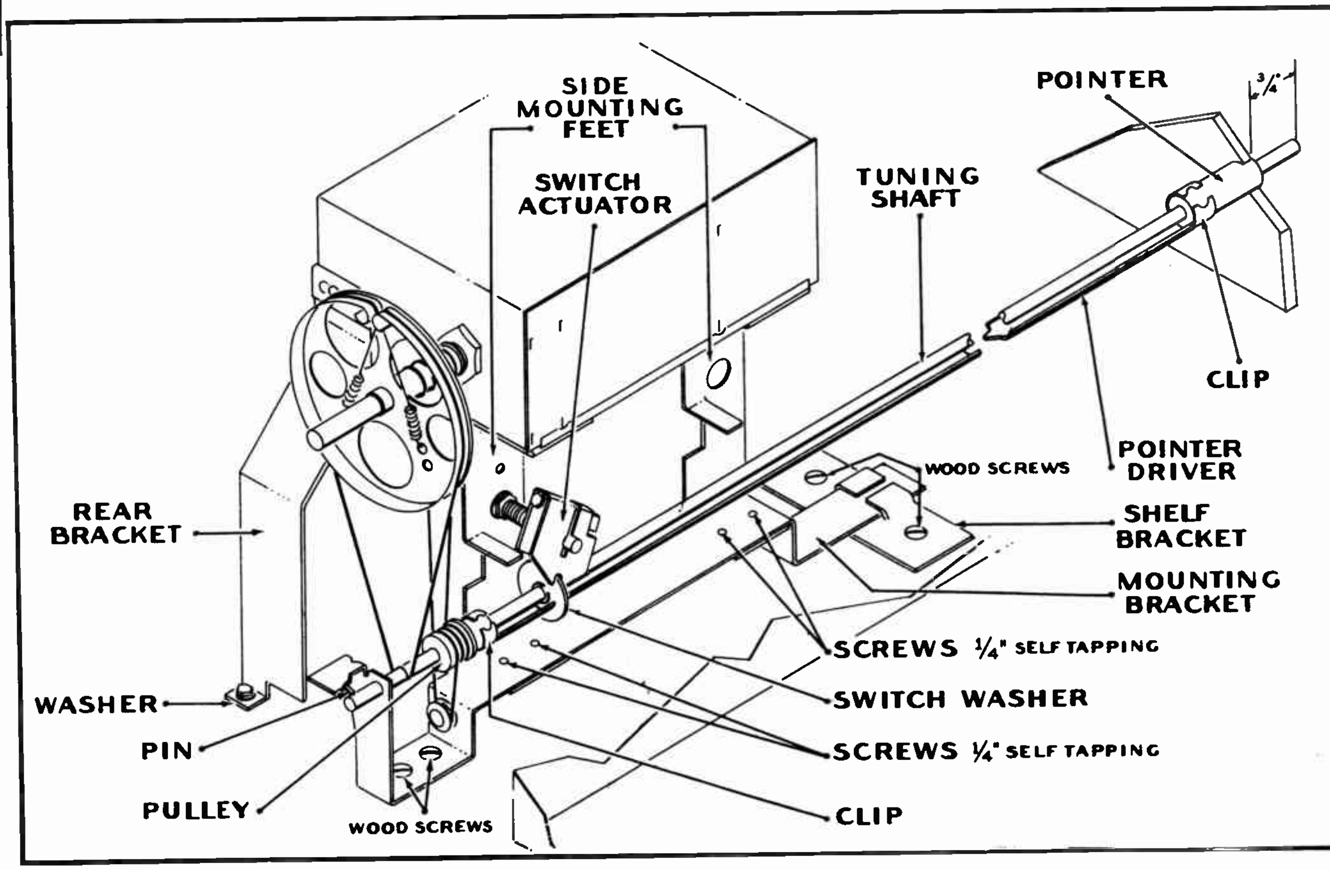
5. Attach the tuner assembly side mounting feet to the mounting bracket, using the four 1/4-inch self-tapping screws provided. See figure 8.

6. Draw a line on the chassis shelf, in line with the center of the middle shaft hole in the cabinet, and extend this line to the rear of the shelf. This line is to be used as a reference line for mounting the UHF tuner assembly.

7. Insert the switch washer on the tuning shaft, and then insert the "E" washers into the grooves on the tuning shaft—one on each side of the switch washer. See figure 9. For 17-inch models with metal cabinets, use grooves "A". For all other models, use grooves "B".

8. Slide the clip onto the pulley, and then slide the pulley and clip onto the tuning shaft, between the switch washer and the rear of the shaft. Insert the shaft through the rear bearing hole of the mounting bracket, with the switch washer in the slot of the switch actuator. See figure 8. Set the switch in the VHF position (tuning shaft to the rear).

9. Place the shelf bracket on the chassis shelf, with the screw holes 8 inches back from the front edge of the r-f chassis, and the scored line on the bracket over the reference line on the cabinet shelf. (See step 6.)



TP2-2608-B

Figure 8. Tuner Mounting Details

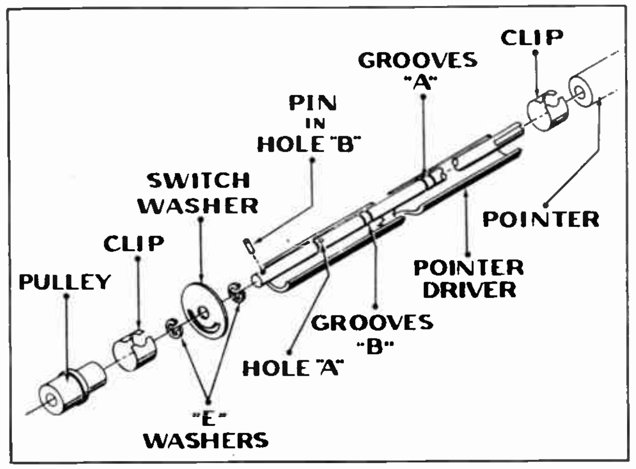


Figure 9. Tuning Shaft and Switch Washer Details

The score line on the bracket should be placed to the rear of the shelf. Fasten the bracket with the two ⅜-inch wood screws provided. (See figure 8.)

10. Reinstall the deflection chassis if the chassis was removed in step 3.

NOTE: The chassis must be installed before mounting the UHF tuner, so that the UHF tuner will not interfere with the installation of the chassis.

11. Insert the adapter plug into the interconnecting power socket on the deflection chassis, and then insert the plug of the interconnecting power cable into the socket on the adapter.

12. Insert the pilot-light socket into the clip, near the UHF tuning shaft.

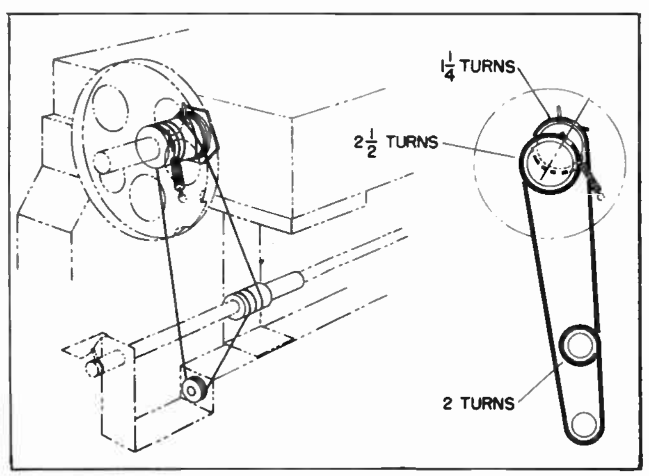

Figure 10. Pointer-Drive-Cord Installation Details

13. Position the assembly inside the cabinet by inserting the front foot of the mounting bracket into the slot of the shelf bracket. Slide the tuner assembly forward until the front end of the tuning shaft extends through the center hole ¾-inch beyond the front of the control panel. See figure 8. Use one of the two mounting holes in the rear foot of the mounting bracket, and fasten the bracket in place with the #5 x ⅜-inch wood screw provided. In some models the rear foot of the mounting bracket will locate over the vent hole in the chassis shelf. In these models, use the remaining shelf bracket to straddle the vent hole, and fasten the shelf bracket under the side mounting foot, with the extruded section facing downward. Fasten the shelf bracket and rear bracket to the chassis mounting board. When the rear side mounting foot is mounted on top of the shelf bracket, use one washer under the rear bracket.

14. Using a pair of pliers, push the pin provided into hole "A" or hole "B" in the tuning shaft. See figure 9. For 17-inch models with metal cabinets, use hole "A"; for these models, remove the excess length by cutting the shaft at the slot behind the pin. For all other models, use hole "B".

15. Fasten the pointer to the pointer driver with the clip provided. See figure 9. Place a felt washer on the pointer, and feed the pointer through the hole in the dial backing plate so that the backing plate of the color which matches the cabinet faces the front of the pointer. Insert the pointer driver through the center hole in the cabinet, and feed the pointer, felt washer, and backing plate over the tuning shaft.

16. Feed the pointer driver through the switch washer, and join the pointer driver to the pulley on the tuning shaft, using the clip provided.

17. String the pointer drive assembly cord as shown in figure 10, using the long dial cord supplied.

18. String the main drive-shaft cord as shown in figure 11, using the short dial cord supplied.

19. Put the knob on the tuning shaft, and turn the shaft to the extreme counterclockwise position. Place the template (figure 12) behind the pointer, and line up the pointer with the index mark on the template. Remove the knob and template, place the dial over the tuning shaft and pointer, center the dial on the control panel, and fasten in place.

20. Cut the antenna lead from the VHF tuner to about 4 inches in length, and remove about one-half inch of insulation from the end. Insert the bare ends of the wires into the twin-lead connector, and fasten them with the screws in the side of the connector.

21. Replace the fishpaper antenna-lead holder with the new holder provided. Fasten the new holder with the two nails provided, and then pass the twin-wire leads through the holes, as shown in figure 13.

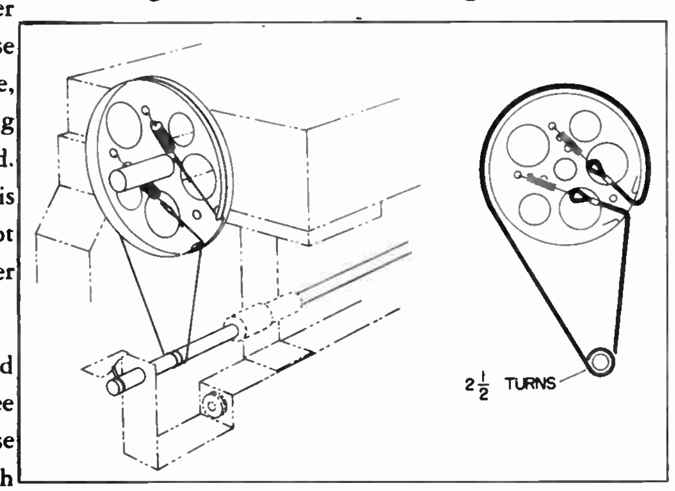

Figure 11. Drive-Shaft Drive-Cord Installation Details

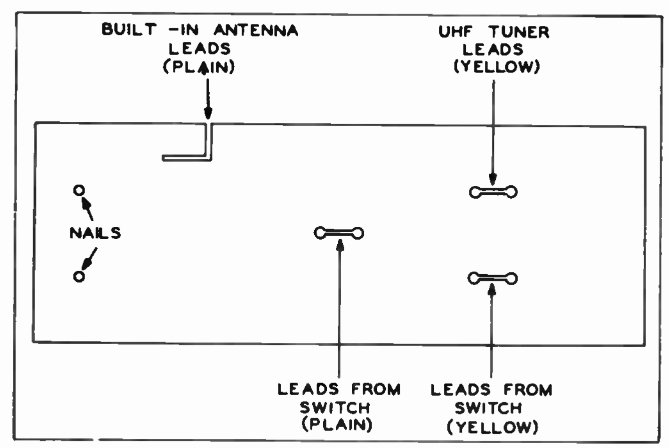

Figure 13. Lead Dress and Lead Holder Details

22. Cut holes in the cabinet back, and fasten the antenna terminal board provided, as shown in figures 14 through 18. Replace the cabinet back and make connections as illustrated, according to the type of antenna installation being used.

23. Paste the label provided over the outside-antenna instructions on the cabinet back.

CIRCUIT DESCRIPTION

Philco "B line", Code 130 Television Receivers use two chassis—r-f chassis R-181, containing the r-f, video, audio, and sync circuits, and deflection chassis D-181, containing the power and deflection circuits. Since these chassis are not isolated from the 60-cycle power line, all protruding shafts and mounting feet are insulated from the chassis.

CAUTION: See A-C LINE ISOLATION.

A separate subchassis contains the r-f amplifier, the oscillator, and the mixer. The r-f amplifier uses a 6BZ7 tube, V1. The oscillator and mixer each use one half of a 12AZ7 tube, V2. The output of the mixer is fed to a three-stage, stagger-tuned, i-f amplifier system employing three 6CB6 tubes. A type 1N64 crystal diode is used for the video detector, the output of which is amplified by a single-stage video amplifier utilizing a type 12BY7 tube, V6. The connections at the detector are such as to produce a composite video signal with negative-going sync pulses. The signal, which is subjected to a 180-degree phase shift through the video amplifier, is applied to the cathode of the picture tube; therefore, the sync pulses at this point are positive-going. The grid of the picture tube is returned to ground through a resistor (R309). A blanking pulse, taken from the vertical output stage, is applied across R309, for suppression of the vertical retrace.

Sound i.f. (intercarrier) is obtained by utilizing the beat frequency produced when the 26.6-mc. video carrier and the 22.1-mc. sound carrier are mixed in the video detector. The 4.5-mc. beat frequency is the difference between 26.6 mc. and 22.1 mc., and contains the FM sound signal. This 4.5-mc. signal contains only a negligible amount of video amplitude modulation, provided that the amplitude of the 22.1-mc. signal is considerably lower than that of the 26.6-mc. signal. The proper relationship between the two carriers is established during the alignment of the receiver. There is sound output only when both the video and sound carriers are present.

The oscillator is tuned primarily to obtain the best picture, since the 4.5-mc. relationship always exists between the two carriers. The 4.5-mc. sound i.f. (intercarrier), which is taken from the plate circuit of the video amplifier, is passed through a 4.5-mc. sound i-f stage using a 6AU6 tube, V7, and is then applied to the FM detector, which utilizes two diode sections of a 6T8 tube, V8A. The triode section of the 6T8, V8B, is used as the first audio amplifier. The power amplifier uses a 6K6GT tube, V9.

A portion of the video signal appearing at the grid of the video amplifier is applied to the pentode section of a 6U8 tube which operates as a sync amplifier V10A. The output of this stage is composite video with positive-going sync, and is applied to grid 3 (pin 7) of the 6BE6 sync separator, V11. Since grid-leak bias is used on grid 3, the tips of the sync pulses are clamped to zero, and the video components swing in a negative direction from zero. Because of the cut-off characteristics of grid 3, the video components are eliminated, and only negative-going sync pulses appear in the plate circuit of the sync separator. At the same time, however, a signal is taken from the video detector and applied to grid 1 (pin 1) of the 6BE6 tube. This grid is returned to B plus, and the bias is maintained close to zero, because of a small grid-current flow. Since the signal applied to grid 1 is composite video with negative-going sync, any noise modulation present in the signal appears in the form of sharp spikes, driving in a negative direction. The circuit constants are chosen to allow grid 1 to cut off plate current whenever the signal goes more negative than the sync pulses. A series grid-limiting resistor (R614) is also incorporated, to prevent the video components from appearing in the plate circuit of the sync separator. A-G-C voltage is also developed in the sync separator circuit in the following manner: On tips of the sync pulses, grid 3 (pin 7) of the 6BE6 tube draws current, which flows downward through the network composed of R609, R610, R611, L214, and R211, causing capacitors C604, C602, and C603 to assume negative charges that are proportional to the amount of peak signal applied to grid 3. The tuner a-g-c voltage is delayed by means of a resistor divider network, which applies a small positive voltage to the tuner a-g-c circuit. This positive voltage prevents a-g-c action from lowering the tuner gain on weak signals. To prevent the delay voltage from driving the tuner a-g-c voltage positive on weak signals, a diode clamp (part of V8B) is connected across C602.

The negative-going sync pulses appearing in the plate circuit of the sync separator are fed to the sync inverter stage, V10B (triode section of the 6U8 tube). This stage acts as a phase-splitter circuit; positive sync pulses appear in the plate circuit, and negative sync pulses are taken from the cathode. Both positive and negative sync pulses are fed through the interchassis cable into the deflection chassis.

Proper triggering of the vertical oscillator requires negative synchronizing pulses. The vertical sync signal is separated from the horizontal sync signal by the integrator circuit, and is fed to the grid of the vertical oscilator (V12), a cathode-coupled multivibrator. The output of the vertical oscillator is amplified by a type 12B4 tube, V13, which is employed as the vertical output amplifier. The output of the amplifier is applied to the vertical-deflection coils through the vertical-output transformer.

The horizontal sweep circuits require both positive and negative sync pulses. The phase-comparer circuit uses a 6AL5 tube, V14. Positive sync pulses are applied to the plate of V14A, and negative sync pulses are applied to the cathode of V14B. A saw-tooth voltage is fed to the plate of V14B and to the cathode of V14A, for comparison of the sync and horizontal sweep voltages. When the saw-tooth and sync signals are exactly in phase, no voltage is developed across R800, but when the two signals are out of phase, either a positive or a negative voltage is developed, depending upon whether the horizontal-oscillator frequency is lower or higher than the sync-pulse frequency. The grid circuit of the horizontal oscillator, a 12AU7 (V15) cathode-coupled multivibrator, is connected to R800 through a filter network; when the voltage at this point goes in a positive direction, the frequency of the horizontal oscillator is increased, and when the voltage swings negative, the frequency of the oscillator is decreased. In this manner the frequency of the horizontal oscillator is controlled over the lock-in range of the circuit. The horizontal-oscillator hold control (R812) adjusts the horizontal-oscillator frequency so that it is within the control range of the phase comparer. The output of the horizontal oscillator is fed to the horizontal output amplifier, which makes use of a 6BQ6GT tube, V16. The screen voltage for the horizontal amplifier is supplied from a voltage-divider network. R816, R817, (the WIDTH control), R818, R307 (the BRIGHTNESS control), and R311 are parts of this divider. R817 varies the voltage applied to the screen, thus adjusting for proper picture width. Adjusting R307 for brightness varies the bias on the picture tube. The change in bias causes a change in beam current, and would tend to result in a change in picture width and variation in the second-anode voltage. However, when the control arm of the BRIGHTNESS control, R307, is moved toward ground, less of the control is shunted by the 22K resistor, R311, and the total resistance of the voltage divider is increased. This increase in resistance results in a decrease in the current through the divider, and the screen voltage on the horizontal amplifier is increased proportionally, thus compensating automatically for the increase in beam current in the picture tube. The horizontal amplifier feeds the deflection coils through the horizontal output transformer. A 6AX4GT tube, V17, is used as the horizontal damper.

The second-anode voltage for the picture tube is supplied by one 1B3GT high-voltage rectifier tube, V18. The B plus voltage for the receiver is supplied by two selenium rectifiers, CR100 and CR101, in a full-wave, voltage-doubler circuit, operating directly from the power line. Bias voltage is obtained from across a filter choke, L405, which is in series with the negative side of the B plus supply. The B plus boost voltage, derived from the horizontal damper circuit, supplies higher B plus voltage to the vertical oscillator and the first anode of the picture tube. Filament voltage for all the tubes except the high-voltage rectifier is supplied by a step-down transformer. Filament voltage for the high-voltage rectifier is supplied by a winding on the horizontal output transformer.

IMPORTANT
A-C LINE ISOLATION

CAUTION: One side of the a-c line is connected to the chassis through C101 and L405. The other side of the a-c line is connected to the chassis through R100, F100, CR100, and C103, in series. Grounding the chassis will result in a short circuit across one or the other of these two branches in the voltage-doubler circuit. During servicing and alignment it is desirable that an a-c line isolation transformer capable of handling at least 225 watts (Philco Part No. 45-9600) be used. Failure to use an isolation transformer will greatly increase the shock hazard, and may result in damage to the test equipment or receiver, or both.

SPECIFICATIONS

VHF TUNING .... Twelve channel, 12-position incremental tuner, covering VHF Television Channels 2 through 13; fine tuning of local oscillator

UHF TUNING .... Continuous tuning, covering UHF Television Channels 14 through 83; fine and coarse tuning

INTERMEDIATE FREQUENCIES
- Video Carrier .... 26.6 mc.
- Sound (intercarrier) .... 4.5 mc.

TRANSMISSION LINE .... 300-ohm, twin-wire lead

OPERATING VOLTAGE .... 110 to 120 volts, 60 cycles, a.c.

POWER CONSUMPTION .... Without UHF, 175 watts; with UHF, 180 watts

TUBE COMPLEMENT
R-F CHASSIS R-181

Reference Symbol	Tube Type	Function
V1	6BZ7 miniature	R-F Amplifier
V2	12AZ7 miniature	Oscillator-Mixer

V17	6AX4GT octal	Horizontal Damper
V18	1B3GT octal	High-Voltage Rectifier

B SUPPLY FUSE REPLACEMENT

The B supply protective fuse, F100, is wired into the low-voltage section, and is in series with the selenium rectifiers. For replacement, use a 1.6-ampere, delayed-action-type fuse, Philco Part No. 45-2656-23.

CAUTION: Discharge the circuit before replacing the fuse.

HORIZONTAL-OSCILLATOR ADJUSTMENT

To adjust the horizontal-oscillator circuit, tune in a station and proceed as follows:

1. Reduce the width of the picture until approximately 1 inch of blank screen appears at the right-hand and left-hand sides of the picture.
2. Increase the BRIGHTNESS control setting until the blanking becomes visible. This will appear as a dark vertical bar on each side of the picture.
3. Connect a .1-μf. condenser from the test point, adjacent to TC800, to ground. (The plate side of the horizontal ringing coil, L800, is connected to the test point.)
4. Set the HORIZONTAL HOLD control to the approximate center of its mechanical rotation.
5. Adjust the HORIZ. HOLD CENTERING control until equal portions of the blanking bar appear on both sides of the picture.
6. Remove the .1-μf. condenser from the test point.
7. Adjust the horizontal ringing coil, L800, until equal portions of the blanking bar again appear on both sides of the picture.
8. Rotate the HORIZONTAL HOLD control through its range. The picture should fall out of sync on both sides of the center of its rotation. If the picture does not fall out of sync on both sides, re-adjust the HORIZ. HOLD CENTERING control.
9. Rotate the HORIZONTAL HOLD control through its range, and observe the number of diagonal blanking bars that appear just before the picture pulls into sync. The pull-in should occur with from 1 to 2 diagonal bars when the sync position is approached from either direction. If proper pull-in is not obtained, repeat the above procedure.

VIDEO-DETECTOR PEAKING-COIL ADJUSTMENT

The video-detector peaking coil, L214, is adjusted at the factory for proper transient response of the video circuit. Ordinarily, this coil will require no further adjustment by the serviceman. On any station where excessive overshoot or excessive smear is present, a slight adjustment of L214 may improve the picture quality on that station; however, this adjustment may sacrifice the quality on other channels. If L214 is replaced in servicing, adjustment will be required.

Before adjusting L214, check the tuner alignment and i-f alignment. (Never adjust L214 until the alignment of the receiver is correct.) Then tune in a station and adjust L214 until there are no trailing whites or smear in the picture. Turning TC206 clockwise reduces trailing whites and overshoot; turning TC206 counterclockwise reduces picture smear and increases trailing whites. The proper position is the point where no smear or trailing whites appear in the picture.

The above procedure for adjustment of TC206 applies to a particular station exhibiting smear or overshoot. After TC206 is adjusted, reception on all the other stations should be checked, to make certain that the adjustment has not impaired the picture quality.

TELEVISION ALIGNMENT

GENERAL

The alignment consists of tuning each i-f coil to a given frequency, using an AM signal, and then feeding in a sweep signal at the antenna terminals and touching up the adjustments to obtain the desired pass band.

The over-all response curve (r-f, i-f) of the circuits from the antenna terminals to the video detector, after the i-f stages have been aligned, should appear essentially the same, regardless of the channel under test. If not, the tuner should be aligned.

The video-carrier intermediate frequency is 26.6 mc., and the sound intermediate (intercarrier) frequency is 4.5 mc. Alignment of these circuits requires careful workmanship and good equipment. The following precautions must be observed:

1. There must be a good bond between the receiver chassis and the test equipment. This is most easily obtained by having the top of the workbench metallic. The receiver chasis should be placed tuner-side down on the bench. If the bench has no metallic top, the test equipment and chassis can be bonded by a strip of copper about 2 inches wide. The section of the chassis nearest the tuner should rest on the strip.
2. Do not disconnect the picture tube, picture-tube yoke, or speaker while the receiver is turned on.
3. Allow the receiver and test equipment to warm up for 15 minutes before starting the alignment.
4. The marker (AM) signal generator should be calibrated accurately to the frequencies used and to the sound and video r-f carriers of each channel used during alignment. If Model 7008 is used, the built-in crystal calibrator provides an excellent means of calibration. An alternate method for calibrating the signal generator to the sound and video r-f carrier frequencies is to zero-beat the signal generator with the received signals.

For further information regarding calibration, refer to Philco Lesson PR-1745 (J), entitled "Television Service in the Home."

TEST EQUIPMENT REQUIRED

The following test equipment is recommended for aligning the receiver:

1. Philco Precision Visual Alignment Generator for Television and FM, Model 7008, or equivalent.
2. Vacuum-tube voltmeter, or 20,000-ohms-per-volt voltmeter.
3. R-F Probe, Philco Part No. 76-3595 (for use with Model 7008 generator).

JIGS AND ADAPTERS REQUIRED

Mixer Jig

Connections to the grid of the mixer tube may be made through the alignment jack provided for that purpose. To connect the generator to this point, a mixer jig, Philco Part No. 45-1739, and a connecting cable, Philco Part No. 45-1635, may be used. As an alternate, a Philco alligator-clip adapter, Part No. 45-1636, with as short a ground lead as possible, may be used to connect the alignment jack. The ground lead should be connected as close as possible to the mixer tube. It is essential that the signal-generator output lead be terminated with a 68-ohm resistor (carbon), so that regeneration, caused by connection of the lead to the mixer, is held to a minimum.

Antenna-Input Matching Network

Figure 1 shows an impedance-matching network for coupling the signal generator to the antenna-input terminals of the receiver. This network, which is designed to have an input impedance of 75 ohms and an output impedance of 300 ohms, is used to match a 75-ohm generator to a 300-ohm antenna-input circuit. The resistors used in this network should be of carbon-composition construction, and should be chosen from a group to obtain values within 10% of those indicated. The resistors should be placed in a shield can, to prevent variable effects. An antenna matching jig, Philco Part No. 45-1736, which consists of a matching transformer and connecting box, may be used in place of the resistor network.

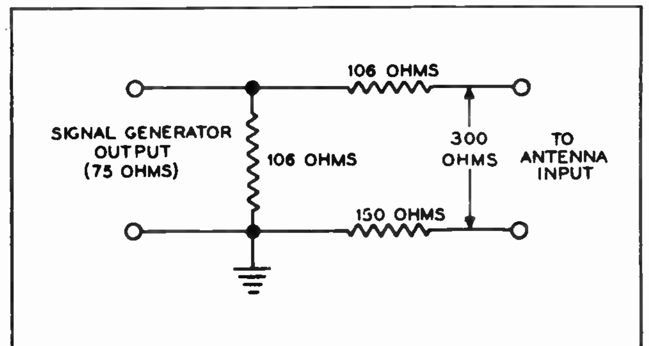

Figure 1. Antenna-Input Matching Network

Video I-F Alignment Jig
(Video Test Jack Adapter)

The alignment jig shown in figure 2 should be used during the i-f alignment, to apply the proper bias to the a-g-c bus, and to provide a convenient oscilloscope connection. This jig consists of a 5-prong plug, a 10,000-ohm potentiometer, a 2200-ohm isolating resistor, and a 7½-volt battery. A suggested method of fabricating the jig is also shown. It is suggested that the bias battery and potentiometer be mounted in a metal box of convenient size.

The potentiometer and switch are connected across the 7½-volt battery. The switch is used to disconnect the potentiometer, to prevent the discharge of the battery while not in use. The 1000-ohm resistor in series with the arm of the control will prevent rapid discharge of the battery if the leads are accidentally shorted.

Sound I-F Alignment Jig

Figure 3 shows the jig that should be used to connect the voltmeter and oscilloscope to the VOLUME CONTROL socket, J400. A suggested method of fabricating the jig is also shown.

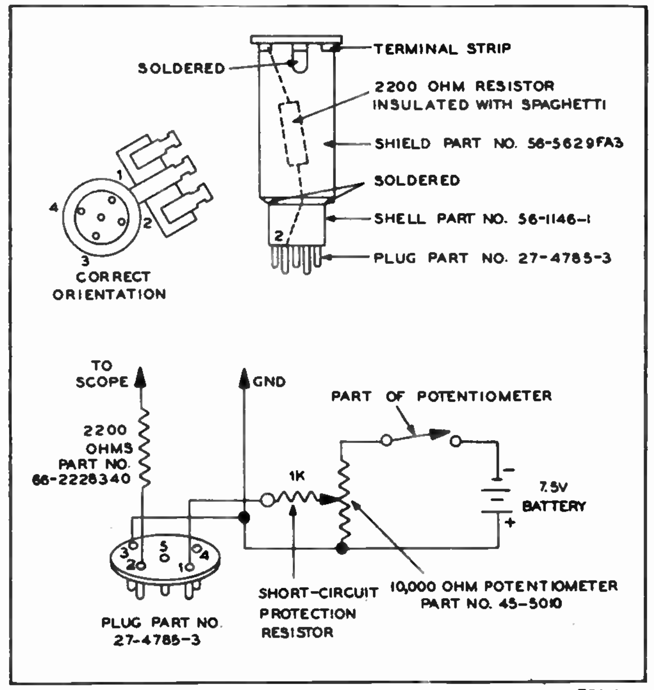

Figure 2. Video I-F Alignment Jig

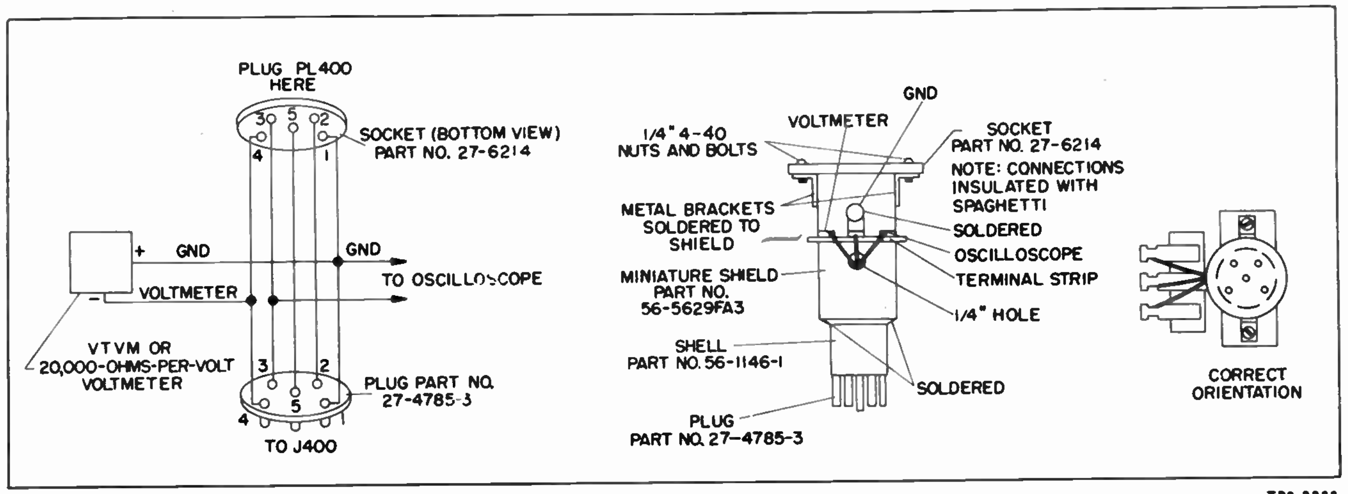

Figure 3. Sound I-F Alignment Jig TP2-2200

TELEVISION TUNER ALIGNMENT

After the tuner is serviced, or if an i-f alignment is required, the tuner alignment should be checked by observing the tuner response curve, as given under Bandpass Alignment. If the response curve does not fall within the limits shown in figure 5, the tuner should be realigned. If realignment is necessary, use the procedure given below.

Since the frequency of the local oscillator affects the tuner response, the local-oscillator alignment should be made first.

Oscillator Alignment

General

Tuning cores are provided in the oscillator coils at channels 13, 11, 9, 7, 6, and 4. By adjusting these tuning cores, all channels may be placed on frequency. This procedure should be carried out with the highest-frequency channel first, since the alignment of each channel affects the alignment of all the channels below it in frequency. The channel adjustments are so arranged that, with one exception, each adjustment corrects the tuning of more than one channel. The coverage of the various adjustments is as follows:

Channel Adjustment	Channels Corrected By Adjustment
13	13 and 12
11	11 and 10
9	9 and 8
7	7 only
6	6 and 5
4	4, 3, and 2

The FINE TUNING cam should be preset for all adjustments by placing the stop on the FINE TUNING cam between the Channel 7 and 8 holes on the front plate of the tuner. See figure 4.

Procedure Using Signal Generator

An r-f signal (unmodulated), at the oscillator frequency, is fed into the antenna input from an AM signal generator, and the oscillator tuning cores are adjusted for zero beat. The r-f signal frequency should be accurately determined. It is preferable that the signal be taken from a crystal-controlled source; if this is not available, the signal generator may be calibrated against the television station.

1. Connect the hot lead of the oscilloscope to the mixer plate test point, G2, through a 1000-ohm resistor, and connect the ground lead of the oscilloscope to the chassis, near the test point. (High oscilloscope gain may be necessary to obtain a visual beat. In this instance, base-line hum may be ignored.)

2. Connect the AM (marker) generator to the 300-ohm antenna-input terminals. For this purpose the antenna-input matching network is not required.

3. Disconnect the white (a-g-c) lead from the tuner, and connect it to the negative terminal of a 1½-volt battery. Ground the positive terminal. If regeneration is observed, the bias may be increased to 4 or 5 volts, to reduce the regeneration.

4. Mechanically preset the fine-tuning cam as shown in figure 4.

5. Feed in an r-f signal (unmodulated), at the oscillator frequency for Channel 13, with the CHANNEL SELECTOR set for Channel 13.

6. Adjust the Channel 13 tuning core (see figure 4).

7. Reset the signal-generator frequency and the CHANNEL SELECTOR, and adjust the tuning cores for Channels 11 and 9, respectively.

8. Repeat steps 5, 6 and 7 until Channels 13, 11, and 9 are within plus or minus 500 kc. of the correct frequency.

9. Feed in r-f (unmodulated) signals, at the oscillator frequencies for Channels 7, 6, and 4, consecutively (see NOTE below), and adjust the respective tuning cores (see figure 4).

NOTE: The exact position of the FINE TUNING cam should be marked when Channel 4 is correctly aligned. This position is to be used in step 4 of the i-f alignment procedure.

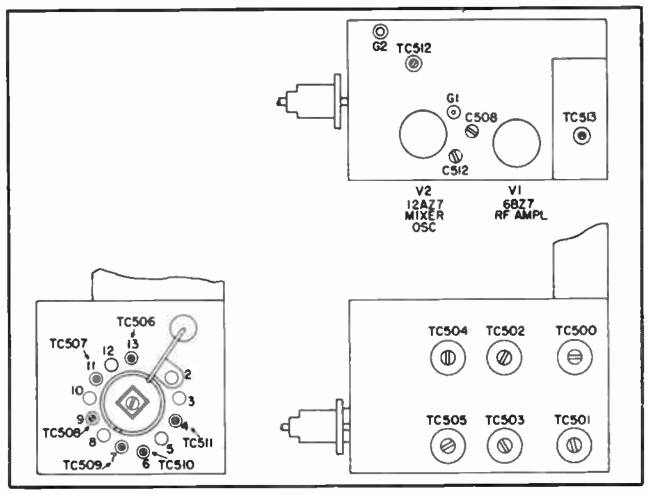

Figure 4. Television Tuner, Showing Locations of Adjustments TP2-2201

Procedure Using Station Signal

The following simplified procedure may be used to align the oscillator when the television i-f alignment is satisfactory and a station signal is available:

1. Mechanically preset the FINE TUNING cam to the center of its range (see figure 4).

2. Tune in the highest frequency channel to be received.

3. Adjust the tuning core for that channel, or the next highest channel, for the best picture; that is, starting with sound in the picture, turn the tuning core until the sound disappears. Repeat for each channel received in the area.

Bandpass Alignment

General

The bandpass alignment consists of aligning the tuner at Channels 13 and 6, and then making it track down to Channels 7 and 2, respectively.

During the alignment, a fixed bias of 1½ volts is applied to the r-f amplifier tube.

An FM (sweep) signal is applied to the antenna-input circuit, and an oscilloscope is connected to the mixer plate circuit. The oscilloscope gain should be as high as possible, consistent with hum level and "bounce" conditions. Hum conditions will cause distortion of the time base and response. Bounce conditions, which are caused by poor line regulation, will cause the response and time base to jump up and down. The use of too high an oscilloscope gain aggravates these conditions, whereas the use of too low a gain necessitates increasing the generator output to a point where the tuner may be overloaded. Overload may be checked by changing the generator output while observing the shape of the response curve; any change in the shape of the curve indicates overload, in which case a lower generator output and higher oscilloscope gain must be used. The tuner coupling link should be disconnected from the i-f section and a 40- to 70-ohm resistor connected across the open end of the link, to eliminate the absorption effect of this coil on the response curve.

1. Disconnect the white (a-g-c) lead from the tuner, and connect it to the negative terminal of a 1½-volt battery. Ground the positive terminal.

2. Disconnect the tuner link at terminal board B11-5 and B11-7 (see figure 36), and connect a 40- to 70-ohm carbon resistor to the two leads of the link.

3. Connect a 1000-ohm resistor in series with the hot lead of the oscilloscope. Connect the other end of the resistor to the mixer plate test point, G2, and connect the ground lead of the oscilloscope to the chassis, near the test point.

4. Connect the FM (sweep) generator to the 300-ohm antenna-input terminals through an antenna-input matching network. See figure 1.

Procedure

1. Set the CHANNEL SELECTOR and FM (sweep) generator to Channel 13 (213 mc.): Adjust the generator for sufficient sweep to show the complete response curve.

2. Establish the channel limits (see figure 5) by using the marker (AM r-f) signal generator to produce marker pips on the response curve. (Set the marker generator first to 210 mc., then to 216 mc.)

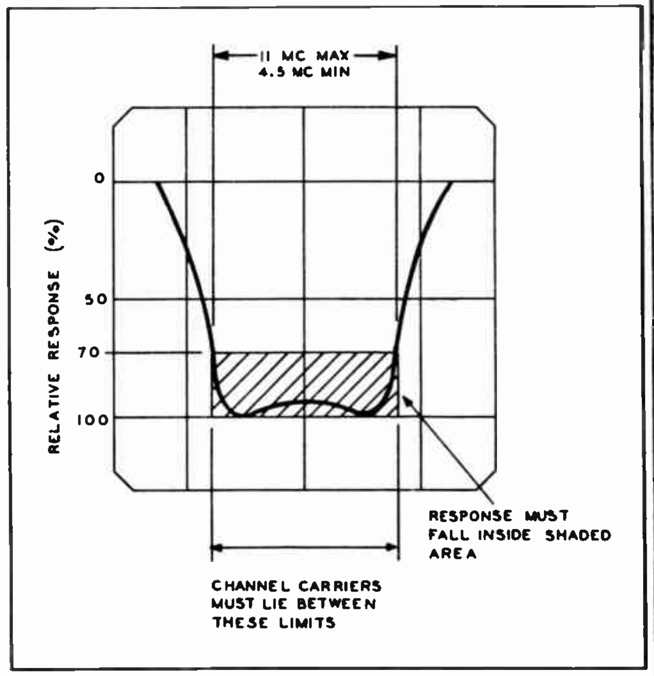

Figure 5. Television Tuner Response Curve, Showing Bandpass Limits TP9-5128-1

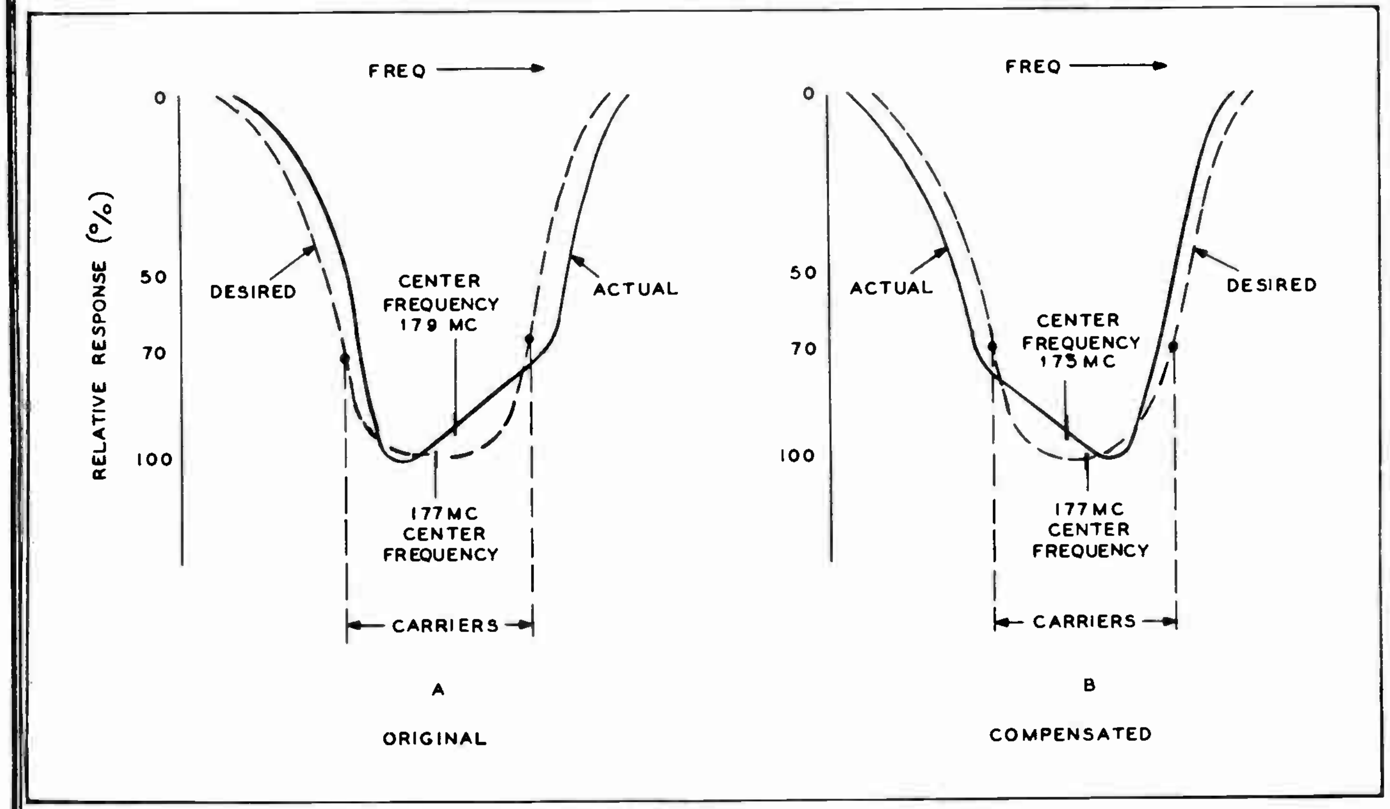

Figure 6. Television Tuner Response Curve, Showing Tracking Compensation

The curve should be reasonably flat between the limits shown in figure 5.

3. Adjust TC502 and TC504 (figure 4) for a symmetrical, approximately centered pass band. Set the marker generator to 213 mc. Detune TC504 counterclockwise until a single peak appears. Adjust TC502 until the peak falls on the 213-mc. marker. It may be necessary to increase the output of the generator during this adjustment. Then adjust TC500 for maximum curve height and symmetry of the single peak. The antenna circuit is now tuned for the high-frequency channels.

4. Readjust TC502 and TC504 for a symmetrical response, centered about 213 mc., and falling within the limits shown in figure 5.

5. Set the CHANNEL SELECTOR and FM generator to Channel 7 (177 mc.).

6. Establish the channel limits by using the marker generator to produce marker pips on the response curve. (Set the generator first to 174 mc., then to 180 mc.). The curve should be reasonably flat between the limits.

7. On Channel 7, note the response curve, with respect to tilt and center frequency. The curve should be centered in the pass band, and should be symmetrical.

8. If the curve is not symmetrical, and appears unbalanced, as shown in figure 6, leave the generator and tuner set to Channel 7, and adjust C508 and C512 (see figure 4) to obtain a response curve which is the mirror image (tilt in the opposite direction) of the original. This is a form of overcompensation, to allow for the effect of Channel 13 adjustment on Channel 7. For example, if the Channel 7 response appears as in figure 6A, then the trimmer should be adjusted to obtain the response shown in figure 6B.

9. Reset the CHANNEL SELECTOR and generators to Channel 13. Readjust TC502 and TC504 for a symmetrical and centered pass band. See step 4.

10. Set the CHANNEL SELECTOR and generators to Channel 7, and check the response for center frequency and symmetry. Repeat steps 8 and 9 as many times as necessary to obtain the most symmetrical and centered response curves on Channels 13 and 7. Channels 7 through 13 are now correctly aligned.

11. Set the CHANNEL SELECTOR and sweep generator to Channel 6 (85 mc.).

12. Establish the channel limits, using the marker generator to produce marker pips on the response curve. (Set the generator first to 82 mc., then to 88 mc.)

13. Adjust TC503 and TC505 for a symmetrical, approximately centered pass band. Set the marker generator to 85 mc. Detune TC505 counterclockwise until a single peak appears.

> CAUTION: Do not turn TC505 excessively, or it will fall out of the coil.

Adjust TC503 until the peak falls on the 85-mc. marker. It may be necessary to increase the output of the generator during this adjustment. Then adjust TC501 for maximum curve height and symmetry of the single peak. The antenna circuit is now tuned for Channels 2 through 6. To prevent overloading, the output of the generator should be reduced after this adjustment is completed.

14. Readjust TC503 and TC505 for a symmetrical response, centered about 85 mc.

VIDEO I-F ALIGNMENT

Preliminary

Before proceeding with the alignment or making an alignment check, observe the following preliminary instructions:

1. Preset the CONTRAST and BRIGHTNESS controls to the maximum counterclockwise position.
2. Preset the CHANNEL SELECTOR to Channel 4.
3. Insert the video i-f alignment jig into J200.
4. Connect the oscilloscope to the 2200-ohm resistor from the video i-f alignment jig. Connect the ground lead of the oscilloscope to the ground lead of the jig.
5. Connect a 3-volt bias battery to the video i-f alignment jig, with the negative terminal of the battery to the bias lead of the jig, and the positive terminal to the ground lead.
6. Connect the AM generator to the mixer test point, G-1, through a mixer jig, and adjust the generator for approximately 30 percent modulation at 400 cycles. Adjust the output of the generator during alignment, to keep the output at the second detector below .6 volt, peak to peak.

> NOTE: If the i-f shield has been removed for repairs, it must be replaced before proceeding with the alignment.

Procedure

1. Tune the AM generator to 28.1 mc., and adjust TC200 (see figure 7) for minimum output, as observed on the oscilloscope.
2. Tune the AM generator to 22.1 mc., and adjust TC203 for minimum output, as observed on the oscilloscope.

> NOTE: In steps 1 and 2 it is necessary to keep the generator output sufficiently high that a null indication may be observed on the oscilloscope; however, avoid overloading of the receiver by excessive signal.

3. Tune the AM generator to the frequencies indicated below, and adjust the tuning cores for maximum output.
   - a. 24.0 mc., adjust TC512.
   - b. 25.7 mc., adjust TC201.
   - c. 23.6 mc., adjust TC202.
   - d. 26.4 mc., adjust TC204.
   - e. 24.5 mc., adjust TC205.

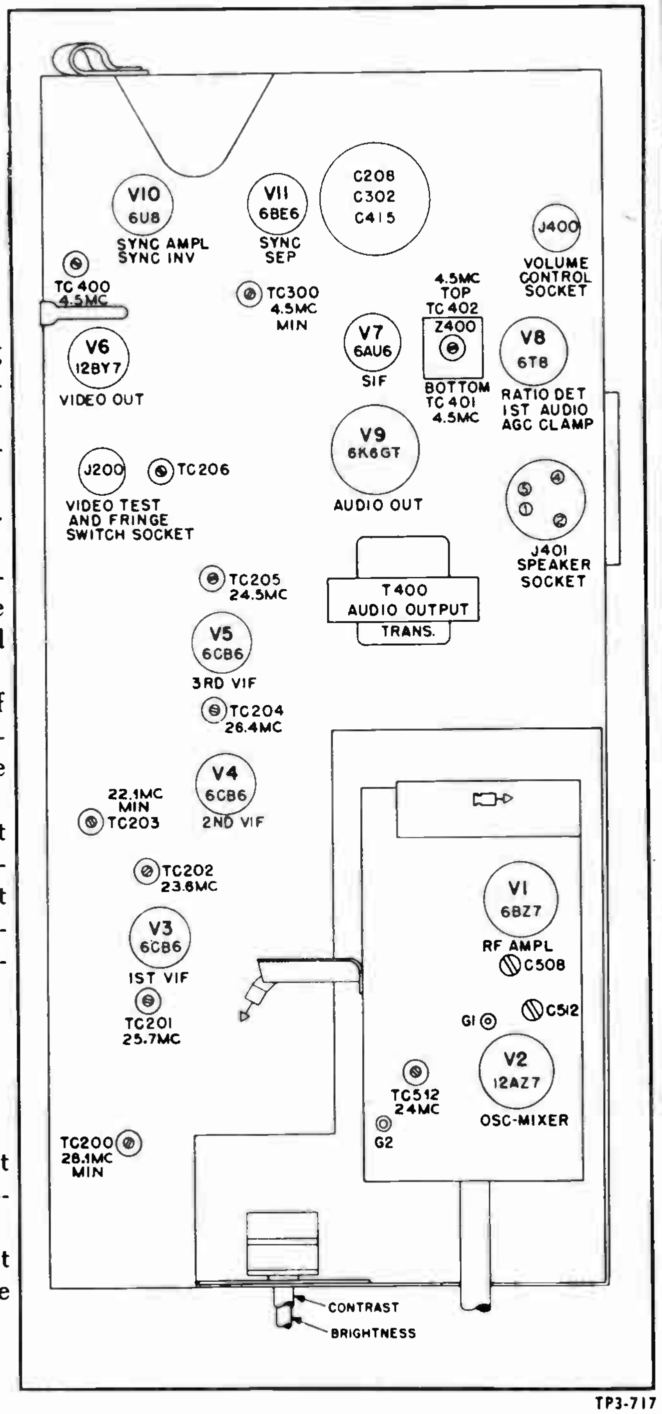

Figure 7. R-F Chassis R-181, Top View, Showing Locations of Adjustments

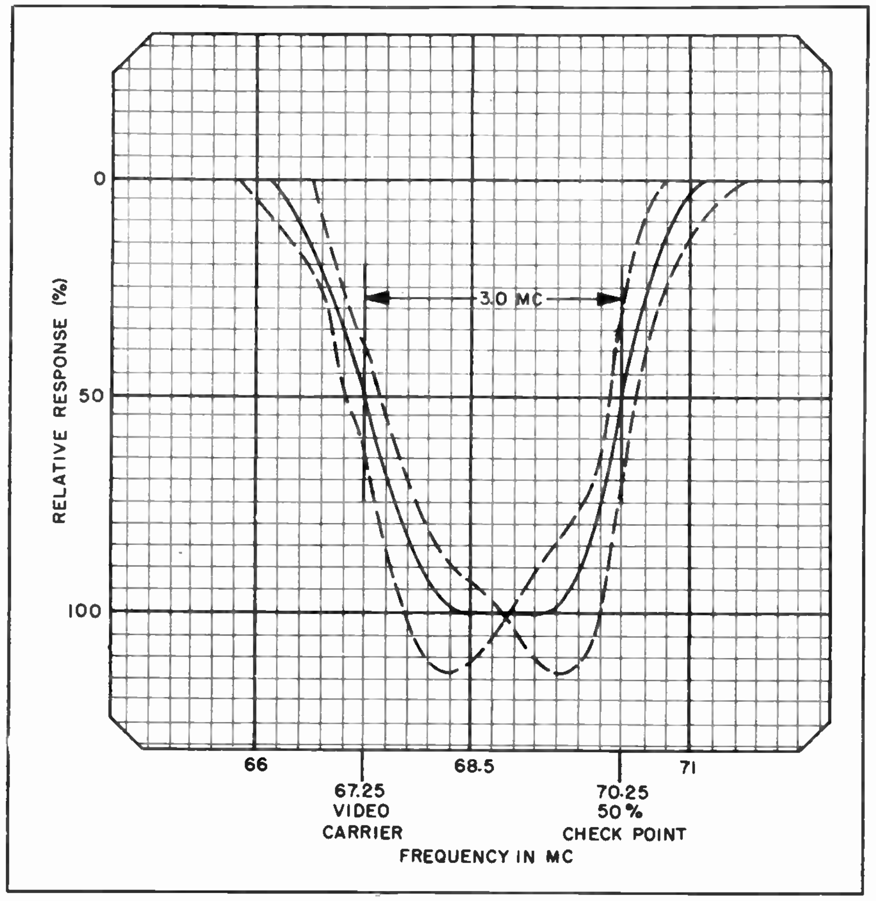
4. Connect the sweep generator and r-f marker generator to the antenna terminals through a matching jig. (If a separate oscilloscope is used, connect the sweep output of the generator to the horizontal input of the oscilloscope.) Set the CHANNEL SELECTOR to Channel 4, and tune the sweep generator for output on Channel 4. After the equipment is properly connected, adjust the FINE TUN-



TP2-2202

Figure 8. Over-all R-F, I-F Response Curve, Showing Tolerance Limits

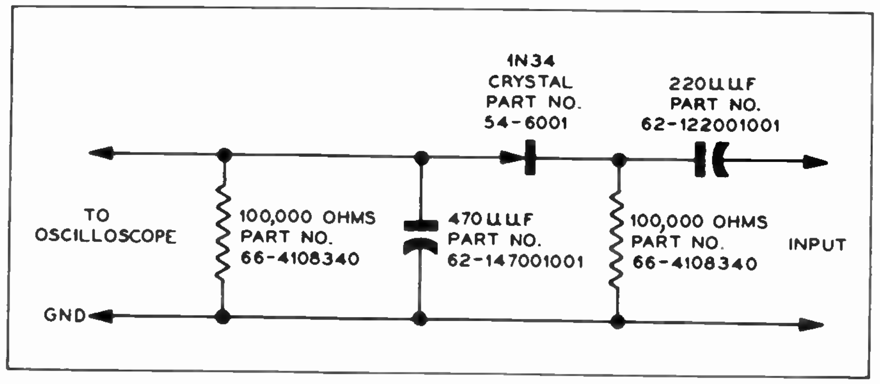
ING control to the mark previously made (see NOTE under Oscillator Alignment).

5. If the response curve does not fall within the limits shown in figure 8, the adjustment of the tuning cores may be touched up slightly while observing the response curve with the sweep generator. Do not touch the setting of TC200 and TC203. To adjust the curve, adjust TC201 and TC204 for proper video carrier level. The top of the curve may be leveled by adjusting TC205, and the low-frequency side of the curve may be adjusted by adjusting TC202. By means of these adjustments the response curve should be brought within the limits shown in figure 8.

> CAUTION: Do not turn any of the tuning cores excessively. To retouch, only turn the tuning cores slightly. This caution applies particularly to TC202.

SOUND I-F ALIGNMENT

1. Remove the 1st v-i-f tube, and connect a v.t.v.m. or a 20,000-ohms-per-volt voltmeter to the sound i-f alignment jig. Adjust the VOLUME control for moderate speaker output.



TP0-1150

Figure 9. Wiring Diagram of Crystal Detector

2. Feed in an accurately calibrated 4.5-mc. AM signal through the 2200-ohm resistor in the video i-f alignment jig, to pin 2 of J200.

3. Tune TC400, TC401, and TC402 for maximum indications on the meter. The point of maximum meter indication for TC402 should also be the point of minimum speaker output.

4. Tune TC402 for minimum speaker output.

5. Connect an r-f probe or crystal detector to the cathode (pin 11) of the picture tube. See NOTE below.

6. Tune TC300 for minimum indication on oscilloscope. (If a crystal detector is not available, TC300 may be adjusted for minimum beat pattern, as observed on the picture tube, with a station picture present.)

7. Replace the 1st v-i-f tube. Tune in a station and use the speaker output as an indication.

8. Turn the FINE TUNING control clockwise to obtain a slightly fuzzy picture.

9. Tune TC402 for minimum AM (noise) output.

> NOTE: The R-F Probe, Part No. 76-3595, is used as a detector of the 4.5-mc. signal, and the oscilloscope is used as an indicating device. An alternate crystal detector may be made up as shown in figure 9.

OSCILLOSCOPE WAVEFORM PATTERNS

These waveforms were taken with the receiver adjusted for an approximate peak-to-peak output of 3 volts at the video detector. The voltage given with the waveforms are approximate peak-to-peak values. The frequencies shown are those of the waveforms—not the sweep rate of the oscilloscope. The waveforms were taken with an oscilloscope having good high-frequency response. With oscilloscopes having poor high-frequency response, the sharp peaks of the horizontal waveforms are more rounded than those shown, and the peak voltages differ from those shown.

Figure 31. Horizontal-Deflection Yoke,
***Pin 7 of J800**
3000 volts, 15,750 c.p.s.
***See CAUTION note**

*CAUTION: High-voltage pulses are present in the horizontal-output circuit. The waveform in figure 31 was taken with the alligator clip of the oscilloscope lead clipped over the insulation of the lead connected to pin 7 of J800. (To prevent puncture of the insulation of the lead, file off the teeth of the alligator clip, and wrap friction tape around the clip.) Connection to other points in the horizontal-output circuit is dangerous, because of the high voltages present. The peak-to-peak voltage shown for figure 31 is the actual voltage present; however, the amplitude of the scope presentation depends upon the degree of coupling.

VOLTAGE MEASUREMENTS

The voltages given here and on the schematics were taken with a 20,000-ohms-per-volt voltmeter, with a line voltage of 117 volts, and no signal input to the receiver.

UHF TUNER-ADAPTER UT21D, PART NO. 43-6778 FOR RECEIVERS USING R-F CHASSIS R-181

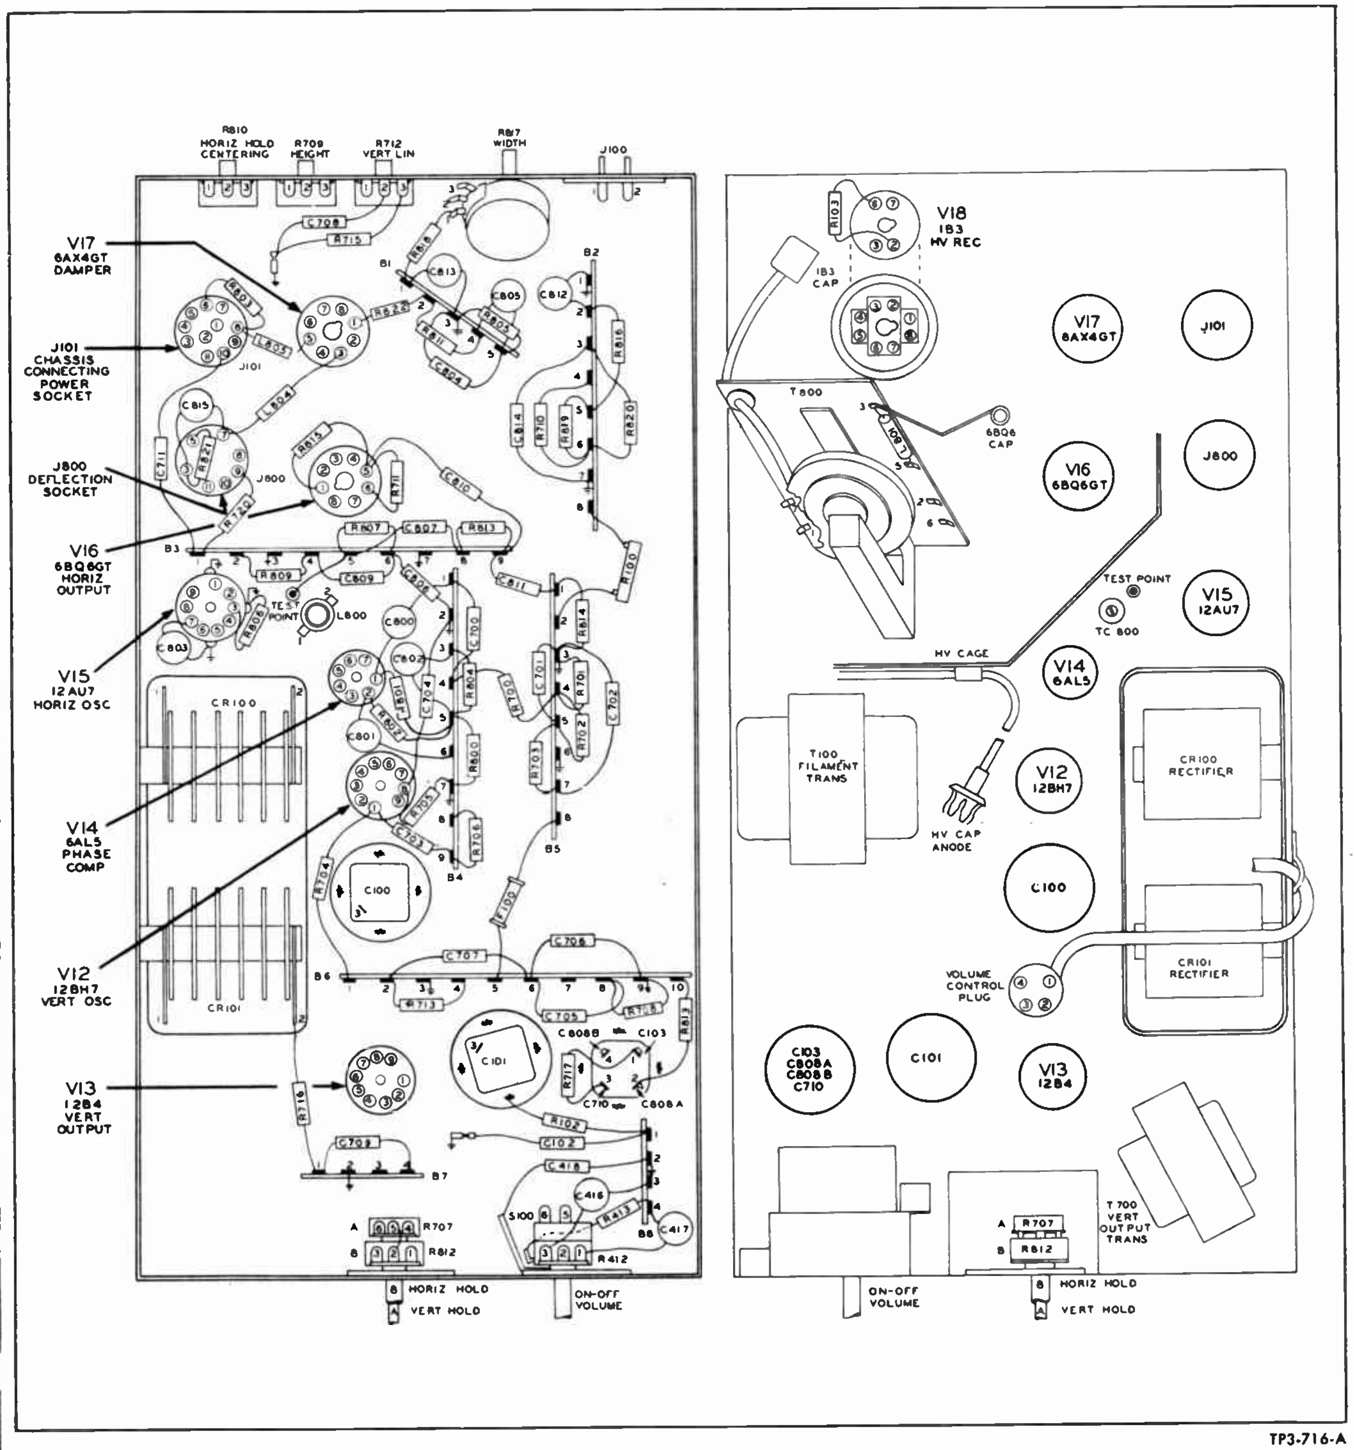

Figure 39. Deflection Chassis D-181, Run 4 (First Production), Base Layout

UHF Tuner-Adapter UT21D, Part No. 43-6778, provides for the reception of UHF signals on television channels 14 through 83. It is designed for installation in Philco Television Receiver models that have a model number beginning with "B," and use r-f chassis R181. The adapter consists of a UHF converter and preamplifier unit, a change-over switch, adapter cables and plugs, a planetary drive tuning-assembly, and mounting hardware.

CIRCUIT DESCRIPTION

The UHF Tuner-Adapter functions as a converter, and converts the signals of the UHF band to a frequency selected within the VFH band. The frequency selected is that of either Channel 2 or Channel 3, depending upon the locality in which the receiver is used.

The incoming UHF signal is coupled through the antenna input line, and through two 680-$\mu\mu$f. condensers and a 150-ohm transmission line to the antenna tank of the tuner. See figure 42. The antenna tank is coupled to the mixer tank by means of the mutual coupling of L2 and L3 and the stray capacitance, C5. The desired signal is selected by tuning the antenna tank and the mixer tank to the proper frequency, and the signal is then coupled to the crystal mixer circuit by means of the mutual coupling of L4 and L5. The local-oscillator signal is generated by a 6AF4 tube, and the associated circuit. The local-oscillator signal is coupled to the crystal mixer circuit by means of a 300-ohm, miniature transmission line and the mutual coupling of L7 to L5 and L8 to L6. The UHF r-f signal and the oscillator signal are mixed in the crystal mixer circuit, producing a radio-frequency signal within range of the VHF tuner when the tuner is set to either Channel 2 or Channel 3. This signal is fed into a preamplifier, which amplies it, and it is then fed into the VHF tuner through a twin-wire lead. In the VHF tuner, the signal is converted to the intermediate frequency of the television receiver. In VHF operation, a 150,000-ohm resistor is placed in series with the UHF oscillator plate, which makes this oscillator inoperative.

The purpose of using two r-f tanks in the UHF tuner is to readily admit the r-f signals, and, at the same time, prevent the UHF i-f and oscillator signals from feeding back into the antenna and causing interference with other receivers.

CHANGE-OVER SWITCH

The change-over switch supplied with the Tuner-Adapter is used to switch from VHF to UHF, and vice versa. It is installed on the back of the VHF tuner, and is operated by an actuator mounted on the VHF tuner shaft. When the VHF Channel Selector is turned to the position for UHF operation, the switch connects the antenna to the UHF tuner, turns off the VHF pilot light, turns on the UHF pilot light, and connects the output of the UHF tuner to the antenna input of the VHF tuner. When the VHF Channel Selector is turned to any VHF position, the switch connects the antenna to the VHF tuner, turns off the UHF pilot light, turns on the VHF pilot light, and places a 150,000-ohm resistor in series with the UHF oscillator plate, as explained above.

PLANETARY DRIVE

The UHF tuner is tuned by means of a 3-gang tuning condenser, which is driven through a specially designed planetary drive. The planetary drive is so constructed that fine tuning and coarse tuning can be accomplished with a single control knob. The tuning shaft is coupled to the driving shaft through three balls, which form a planetary drive that produces slow rotation for fine tuning. See figure 40. After rotating 180 degrees with the tuning shaft, a pin engages the driving shaft, and the two shafts are direct-coupled, for coarse tuning. To re-engage the planetary drive for fine tuning, it is only necessary to reverse the direction of the rotation. The dial pointer is connected to the tuning gang through a cord drive, and indicates the channel number to which the tuner is tuned.

ALIGNMENT AND REPAIRS

The frequencies at which the Tuner-Adapter operates are extremely high; therefore, it is necessary that the utmost care be taken to safeguard against upsetting the delicate adjustments of the tuner. It is recommended that the serviceman make only minor repairs to the tuner, such as replacement of the tube or crystal and the wiring of external leads. The Tuner-Adapter should be returned to the factory for alignment and major repairs, unless the serviceman is properly equipped to perform these jobs. In general, a good rule to follow is not to remove the cover of the Tuner-Adapter unless so equipped.

NOTE: Replacing the tube with a new one may detune the tuner. If this occurs, a number of tubes should be tried, until the most satisfactory substitute for the original is found.

INSTALLATION INSTRUCTIONS

This tuner will provide reception of UHF Channels 14 through 83 by converting the UHF signal to the VHF frequency of Channel 2 or Channel 3. When the VHF CHANNEL SELECTOR of the Receiver is rotated in the counterclockwise direction, either the Channel 2 or Channel 3 position may be used for the reception of the converted UHF signal; when the VHF CHANNEL SELECTOR is rotated in the clockwise direction, both Channel 2 and Channel 3 may be received. To install the tuner, proceed as follows:

1. Remove the cabinet back and the r-f chassis from the cabinet. Then remove the nameplate from the control panel.

2. Insert the dial scale and bezel assembly into the hole provided in the cabinet. The four studs should be passed through the four holes provided. Fasten the assembly in place with the washers and small pal-nuts supplied.

3. Remove the tuner assembly from the mounting board with which it was shipped. Keep the screws for mounting the tuner in the cabinet.

4. Place the spacers on the mounting studs, and use the studs to attach the bracket and socket assembly to the rear of the VHF tuner on the r-f chassis, as shown in figure 47.

5. Place the switch-actuator assembly on the shaft that extends from the rear of the VHF tuner; position the assembly so that the switch-actuator studs point away from the tuner. See figure 47.

6. Place the switch assembly on the mounting studs, push the switch toward the top of the tuner, and fasten it in place with the washers, lock washers, and nuts provided. See figure 47.

7. Set the VHF CHANNEL SELECTOR to Channel 3, and rotate the switch actuator on the tuner shaft in the counterclockwise direction (as viewed from the rear of the VHF tuner) until the switch-actuator studs are positioned as shown in figure 48. Exert slight pressure against the actuator in the clockwise direction, and fasten the actuator securely on the shaft in this position. Then check to make certain that the operation of the UHF-VHF change-over switch and actuator is as follows: When the change-over switch is thrown to UHF in the Channel 3 position, the switch actuator should throw to the position shown in figure 49. The change-over switch should throw to UHF on Channels 2 and 3 when the VHF CHANNEL SELECTOR is switched from Channel 4 to Channel 3 and then to Channel 2. The change-over switch should not throw when the VHF CHANNEL SELECTOR is switched from Channel 13 to Channel

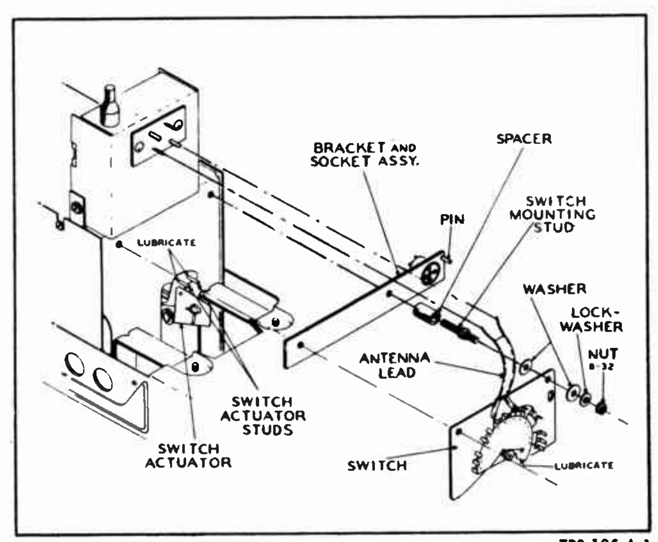

Figure 47. UHF-VHF Change-over Switch, Showing Mounting Details

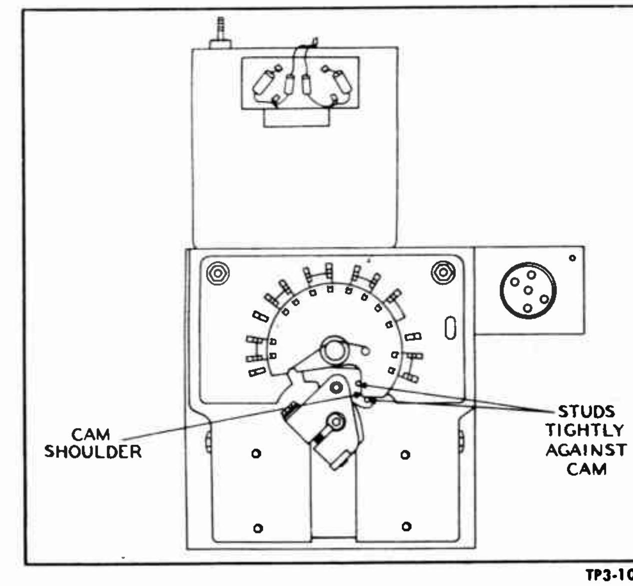

Figure 48. Switch Actuator Stud Position with Change-over Switch in VHF Position and VHF CHANNEL SELECTOR on Channel 3

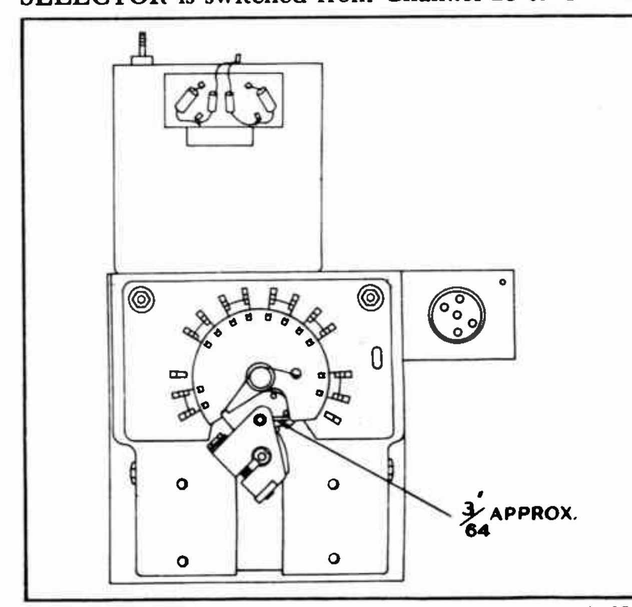

Figure 49. Switch Actuator Stud Position with Change-over Switch in UHF Position and VHF CHANNEL SELECTOR on Channel 3

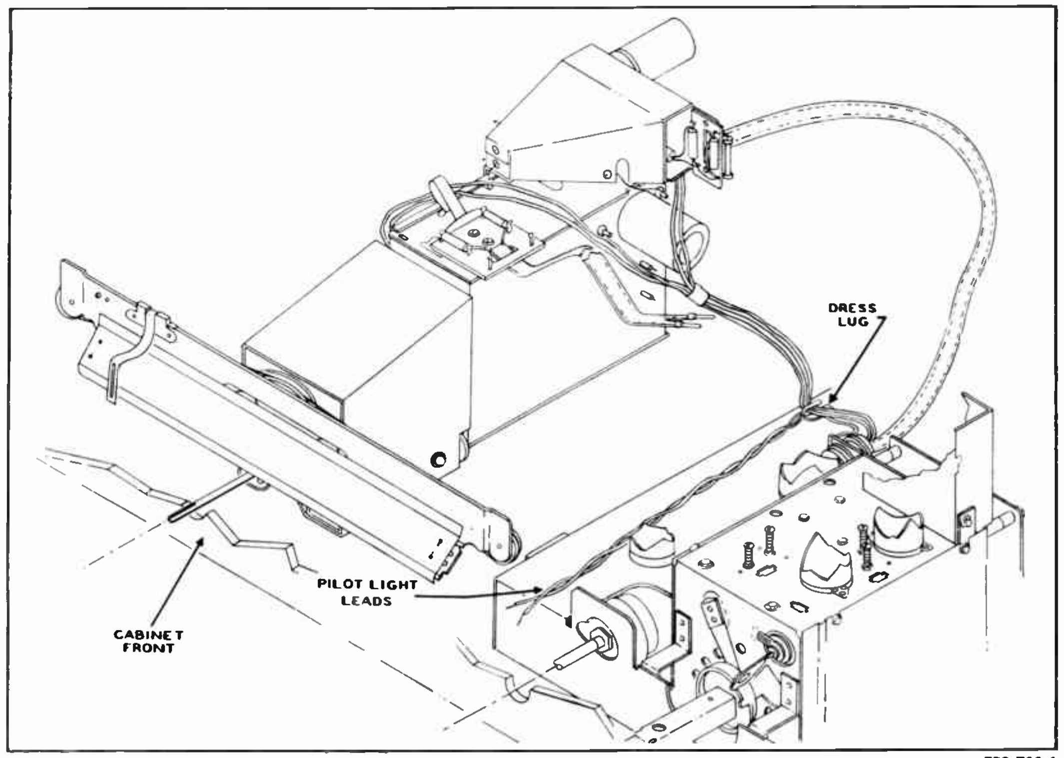

Figure 50. Lead Dress and UHF Tuner Mounting Details

2 and then to Channel 3. Make certain that the actuator clears the cam shoulder when the CHANNEL SELECTOR is switched from Channel 3 to Channel 4. If the switch does not throw properly, reposition the switch on the mounting studs and the switch actuator on the VHF tuner shaft until the switch operates as described above. Lubricate the switch cam and switch actuator studs with cup grease.

8. Remove the bulb and shield from the pilot-light assembly on the r-f chassis, place the bulb in the empty socket of the UHF tuner assembly, and place the shield over the bulb. Cut the pilot-light leads about one inch from the chassis, and tape up each end separately.

9. Remove the audio output tube, plug the octal adapter into the tube socket, and place the tube in the adapter socket. The octal adapter is wired to the switch.

CAUTION: MAKE SURE THAT THE LEADS DO NOT TOUCH THE TUBES.

10. Remove the antenna lead from the VHF tuner, and solder the short lead from the UHF-VHF change-over switch to the VHF tuner antenna terminals from which the antenna lead was removed. See figure 47. Insert the two twin-wire leads from the change-over switch through the paper lead holder, and then slide the lead holder over the tapered-line assembly on the VHF tuner.

11. Fasten the dress lug to the chassis with the screw provided (sec figuro 50).

12. Place the UHF tuner in the cabinet, in the center of the chassis shelf, and position it so that the UHF knob shaft protrudes 9/16 inch from the front of the cabinet. Fasten the UHF tuner to the chassis shelf with the three screws removed in step 3. It is important that these screws be tightened securely to hold the UHF tuner firmly in place on the chassis shelf. Turn the UHF tuning shaft to its extreme counterclockwise position, and check the pointer position on the scale. If the pointer is not properly positioned, loosen the three mounting bolts, move the UHF tuner to properly position the pointer, and fasten the assembly with the three mounting screws.

13. Install the r-f chassis in the cabinet, and insert the pilot-light socket into the pilot-light clip. Fasten the r-f chassis with the original bolts, and place the original knobs on their shafts.

14. Connect the 5-pin plug of the UHF tuner to the 5-pin socket in the bracket and socket assembly installed in step 4. Connect the remaining single-wire lead from the UHF tuner to the single pin located near the 5-pin socket. Dress the leads under the dress lug as shown in figure 50.

15. Replace the fishpaper antenna-lead holder with the new holder provided. Fasten the new holder with the two nails supplied, and then pass the twin-wire leads through the holes as shown in figure 51. Wrap tape around the yellow-marked twin-wire leads with the lug ends, to prevent the leads from passing back through the twin holder.

16. Fasten the antenna terminal board on the cabinet back. Replace the cabinet back on the cabinet, and dress the leads through the back. Connect the antennas to their respective terminal boards as shown in figures 52 through 56.

17. Paste the label provided over the outside-antenna instructions on the cabinet back.

PARTS LIST

IMPORTANT

General replacement items commonly stocked by the serviceman are omitted from this parts list. All condensers are molded-bakelite Philco condensers, with a 600-volt rating, and all resistors are ½ watt, unless otherwise indicated. Parts are listed according to chassis type, and should be ordered in this way rather than by model number. A list of miscellaneous parts is given at the end of the parts list for each chassis type. All parts are symbolized in the schematic diagram and base layout, for identification purposes.

NOTE: Part numbers identified by an asterisk (*) are general replacement items. These numbers may not be identical with those on factory parts. Also, the electrical values of some replacement items may differ from the values indicated in the schematic diagram and parts list. The values substituted in any case are so chosen that the operation will be unchanged. When ordering replacements, use only the "Service Part No."

L211	Coil, series peaking, 40 µh.	32-4143-1
L212	Coil, series peaking, 4 µh.	32-4112-24
L213	Coil, series peaking, 125 µh.	32-4480-8
L214	Coil, variable, video peaking, 200—400 µh.	32-4467-17
R202	Resistor, filter, 330 ohms, 1 watt	66-1334340*
R207	Resistor, voltage dropping, 2500 ohms, 6.2 watts	33-3446-5
T200	Transformer, video i-f input	32-4486-32
T201	Transformer, 2nd video i-f	32-4486-29
T202	Transformer, 3rd video i-f	32-4486-33

SECTION 3—VIDEO

Reference Symbol	Description	Service Part No.
C301	Condenser, 4.5-mc. trap, 68 µµf.	62-068409011
C302	Condenser, filter, 10 µf., 300v	Part of C208
L300	Coil, 4.5-mc. trap	32-4463-2
L301	Coil, series peaking, 180 µh.	32-4480-9
L302	Coil, variable, video peaking, 60—200 µh.	32-4467-18
R301	Potentiometer, CONTRAST control, 1000 ohms	Part of R307
R305	Resistor, plate load, 3900 ohms, 7 watts	33-1335-116
R307	Potentiometer, BRIGHTNESS control, 100,000 ohms	33-5563-63

SECTION 4—SOUND

Reference Symbol	Description	Service Part No.
C400	Condenser, coupling, 2.2 µµf.	30-1221-6
C401	Condenser, fixed trimmer, 18 µµf.	62-018400021
C404	Condenser, fixed trimmer	Part of Z400
C405	Condenser, fixed trimmer	Part of Z400
C406	Condenser, detector balancing, 150 µµf.	62-115001011
C409	Condenser, r-f by-pass, 330 µµf.	62-133001001
C410	Condenser, filter, 2 µf.	30-2417-7
C414	Condenser, plate by-pass, 6800 µµf., 1000v	30-4650-91
C415	Condenser, filter, 20 µf., 300v	Part of C208
J400	Socket, volume control	27-6273
J401	Socket, speaker	27-4785-22
L400	Coil, audio take-off	32-4463-10
L401, L402 and L403	Coils, ratio detector	Part of Z400
L404	Coil, filament choke	32-4112-15
L405	Choke, filter, 1 hy., 60 ohms	32-8617
PL400	Plug, volume control	Part of cable and plug ass'y. (see Misc. "A")
PL401	Plug, speaker	Part of speaker cable ass'y. (see cabinet parts)
R401	Resistor, screen dropping, 12,000 ohms, 1 watt	66-3124340*
R409	Resistor, cathode bias, 270 ohms, 1 watt	66-1274340*
R410	Resistor, screen dropping, 4700 ohms, 1 watt	66-2474340*
R412	Potentiometer, VOLUME control, 2 megohms	33-5564-14
T400	Transformer, audio output	32-8578
Z400	Transformer, ratio detector	32-4450-6A

SECTION 6—SYNC

Reference Symbol	Description	Service Part No.
C600	Condenser, by-pass, 330 µµf.	62-133001001
R603	Resistor, plate load, 18,000 ohms, 2 watts	66-3185340*
R609	Resistor, voltage divider, 1 megohm, ½ watt, 5%	66-5108240
R618	Resistor, voltage divider, 8200 ohms, 1 watt	66-2824340*
R619	Resistor, voltage divider, 10 megohms, ½ watt, 5%	66-6108240
R620	Resistor, decoupling, 18,000 ohms, 2 watts	66-3185340*

MISCELLANEOUS "B"

Description	Service Part No.
Cable and plug ass'y., chassis connecting	41-4146-10°
Cable and socket ass'y., picture tube	41-4147
Cable and socket ass'y., pilot light	27-6233-103°
Shield, tube, 6T8	56-5629-5
Shield, tube, 6CB6	56-5629FA3
Shield, pilot light	56-9074-2FA3

CIRCUIT DESCRIPTION

The Philco "B" line, Code 150 television receivers use two chassis, the r-f chassis, R-204, containing the r-f, video, audio, and sync circuits, and the deflection chassis, D-204, containing the power and deflection circuits.

Since these chassis are not isolated from the 60-cycle power line, all protruding shafts and mounting feet are insulated from the chassis.

CAUTION: See A-C Line Isolation.

The r-f amplifier, oscillator, and mixer section is built on a separate subchassis. The r-f amplifier uses a 6BZ7 tube, V1. The oscillator and mixer each use one half of a 12AZ7 tube, V2. The output of the mixer is fed to a four-stage, stagger-tuned, i-f amplifier system employing four 6CB6 tubes, V3, V4, V5, and V6. A 1N64 crystal diode is used for the video detector. One half of a 6U8 tube, V7A, is used as the first video amplifier, which drives a 6AQ5 video output amplifier, V8.

Sound i.f. (intercarrier) is obtained by utilizing the beat frequency produced when the 45.75-mc. video carrier and the 41.25-mc. sound carrier are mixed in the video detector. The beat frequency, 4.5 mc., is the difference between 45.75 mc., and 41.25 mc., and contains the FM sound signal. This 4.5-mc. signal contains only a negligible amount of the video amplitude modulation, provided that the amplitude of the 41.25-mc. signal is considerably lower than that of the 45.75-mc. signal. The proper relative amplitudes of the two carriers are established in the alignment of the receiver. There is sound output only when both the video and sound carriers are present.

The oscillator is tuned primarily to obtain the best picture, since the 4.5-mc. relationship always exists between the two carriers. The 4.5-mc. sound i.f. (intercarrier), which is taken from the video detector, is amplified by a 6BA6 tube, V9, and a 6AU6 tube, V10, and is fed to the FM detector, which utilizes two diode sections of a 6T8 tube, V11A. The triode section of the 6T8 tube, V11B, is used as the first audio amplifier. The power amplifier uses a type 6L6GA tube, V12.

A-G-C voltage for the video i-f system and the r-f amplifier is obtained from a keyed a-g-c system which uses a 6AU6 tube, V13, as the a-g-c gate. Composite video from the video-amplifier plate circuit, V7A, is fed to the grid of the a-g-c gate tube, while a gating or keying pulse, obtained from a winding on the horizontal-output transformer, located on the deflection chassis, is applied to the plate. The sync-pulse polarity applied to the grid of V13 is positive; therefore, the a-g-c gate can conduct in proportion to the amplitude of the sync-pulse tips if the gating or keying pulse occurs at the same time as the sync. Because the keying or gate pulse is of constant amplitude, approximately 500 volts peak, the amplitude of the sync pulse determines the amount of conduction in the gate tube. The plate current of the keyed a-g-c gate tube flows through R220, R219, and R218, developing a voltage which is negative with respect to the chassis and whose amplitude is proportional to the plate current. This negative voltage is used to control the gain of the receiver. Since conduction cannot occur in the a-g-c gate tube unless the sync pulse and gating pulse occur at the same time, noise disturbances that occur during the intervals between sync pulses cannot affect the a-g-c voltage.

Composite video for the sync circuits is taken from the plate circuit of the video amplifier, V7A. The full output of the amplifier is fed to the grid of the noise inverter, one half of a 12AU7 tube, V14B, and to the grid of the sync separator, one half of a 6U8 tube, V7B. The noise inverter is operated with a low value of plate voltage and high bias (applied to the cathode by a voltage-divider network), which keeps the tube beyond cutoff. When the composite video signal is applied to the grid of the noise inverter through C601, the sync appears as positive pulses; noise which could affect the sweep circuits also appears as positive pulses. Harmful noise pulses usually have amplitudes far greater than the sync pulses, and, therefore, drive the grid of the noise inverter positive sufficiently to allow conduction in the noise-inverter plate circuit. To prevent the noise inverter from conducting during the sync-pulse interval, the gated leveler, using one half of a 12AU7 tube, V14A, is employed to clamp the sync pulses below the conduction level of the noise inverter. The gated leveler conducts only when the sync pulses and gating pulse occur at the same time, thus leveling the noise-inverter input to the sync-pulse level.

The output of the noise inverter consists of negative-going noise pulses. It should be noted that the noise pulses which exceed the sync level have been passed and their polarity reversed by the noise inverter. The output of the noise inverter is now mixed with the composite video and fed to the grid of the sync separator. Since the composite video fed to the grid of the sync separator has positive sync polarity, the positive noise pulses carried with the composite video would be passed by the sync separator; however, the output of the noise inverter consists of these same noise pulses, but they are of opposite polarity; thus, the noise pulses are cancelled. The output of the sync separator contains only the sync pulses which are fed to the deflection chassis through the connecting cable.

The phase splitter, using one half of a 12AU7 tube, V15A, inverts the sync polarity for proper triggering of the vertical oscillator. The vertical sync is separated from the horizontal sync by the integrator circuit, and is fed to the grid of the vertical blocking oscillator, using one half of a 12AU7 tube, V15B. The output of the vertical oscillator is amplified by the vertical-output amplifier, a 12B4 tube, V16. The output of the amplifier is applied to the vertical-deflection coils through the vertical-output transformer.

The phase splitter also supplies horizontal sync to the phase-comparer diodes, a 6AL5 tube, V17. The horizontal sync outputs are taken from the phase splitter, one from the cathode, the other from the plate circuit. These two outputs are of opposite polarity, and are fed to the two diodes of the phase comparer, the negative pulses to the cathode of V17B, and the positive pulses to the plate of V17A. A saw-tooth voltage is fed to the plate of V17B and the cathode of V17A for comparison of the sync and horizontal-sweep voltages. When the sweep and sync are in phase, no voltage is developed across R800, but when the two signals are out of phase, a voltage is developed. This voltage controls the frequency of the horizontal oscillator, a 12AU7 tube, V18. When this control voltage is positive, it increases the frequency of the oscillator; when the voltage is negative, it reduces the frequency of the oscillator. Thus the control voltage acts to hold the horizontal oscillator in phase with the sync signal. The HORIZ. HOLD control, R811, adjusts the horizontal oscillator to the proper frequency, so that it may be controlled by the phase comparer. The output of the horizontal oscillator is fed to the horizontal-output amplifier, which uses a 6BQ6GT tube, V19.

The screen voltage for the horizontal amplifier is supplied from a voltage-divider network. R816, R815 (the WIDTH control), R822, R313 (the BRIGHTNESS control), and R314 are parts of this divider. R815 varies the voltage applied to the screen, thus adjusting for proper picture width. Adjusting R313 for brightness varies the bias on the picture tube. The change in bias causes a change in beam current, and would tend to result in a change in picture width and variation in the second-anode voltage. However, when the control arm of the BRIGHTNESS control, R313, is moved toward ground, a smaller part of the control is shunted by the 22,000-ohm resistor, R314, and the total resistance of the voltage divider is increased. This increase in resistance results in a decrease in the current through the divider, and the screen voltage on the horizontal amplifier is increased proportionately, thus compensating automatically for the increase in beam current in the picture tube. The horizontal amplifier feeds the deflection coils through the horizontal-output transformer. A 6AX4GT tube, V20, is used as the horizontal damper.

The second-anode voltage for the picture tube is furnished by a high-voltage winding of the horizontal-output transformer, T800, and is rectified by a 1B3GT high-voltage rectifier tube, V21. The B-plus voltage for the receiver is supplied by two selenium rectifiers, CR100 and CR101, in a full-wave voltage-doubler circuit, operating directly from the power line. Bias voltage is obtained from across a filter choke, mounted on the speaker, which is in series with the negative side of the B-plus supply. The B-plus boost voltage, derived from the horizontal-damper circuit, supplies higher B-plus voltage to the vertical amplifier, the vertical oscillator, and the first anode of the picture tube. Filament current for all the tubes except the high-voltage rectifier is supplied by a 110-volt, 60-cycle filament transformer. Filament current for the high-voltage rectifier is supplied by a winding on the horizontal-output transformer.

IMPORTANT

A-C LINE ISOLATION

CAUTION: One side of the a-c line is connected to the chassis through C101 and L406. The other side of the a-c line is connected to the chassis through F100, R100, CR100, and C103, in series. Grounding the chassis will result in a short circuit across one or the other of these two branches in the voltage-doubler circuit. During servicing and alignment, it is desirable that an a-c line isolation transformer capable of handling at least 225 watts (Philco Part No. 45-9600) be used. Failure to use an isolation transformer will greatly increase the shock hazard, and may result in damage to the equipment.

SPECIFICATIONS

VHF TUNING ....Twelve channel, 13-position incremental tuner, covering VHF Television Channels 2 through 13 and UHF position; fine tuning of local oscillator

UHF TUNING (if provided) ....Continuous tuning, covering UHF Television Channels 14 through 83; fine and coarse tuning

INTERMEDIATE FREQUENCIES
Video carrier ....45.75 mc.
Sound (intercarrier) ....4.5 mc.

TRANSMISSION LINE ....300-ohm, twin-wire lead

OPERATING VOLTAGE ....110 to 120 volts, 60 cycles, a. c.

POWER CONSUMPTION..without UHF, 215 watts; with UHF, 220 watts

B SUPPLY FUSE REPLACEMENT

The B supply protective fuse, F100, is wired into the low-voltage section, and is in series with the selenium rectifiers. For replacement, use a 1.6-ampere delayed-action-type fuse, Philco Part No. 45-2656-23.

CAUTION: Discharge the circuit before replacing the fuse.

HORIZONTAL-OSCILLATOR ADJUSTMENT

To adjust the horizontal-oscillator circuit, tune in a station and proceed as follows:

1. Reduce the width of the picture so that approximately one inch of blank screen appears on the right-hand and left-hand sides of the picture.

2. Increase the BRIGHTNESS control setting so that the blanking time becomes visible. This appears as a dark bar along the right-hand and left-hand sides of the picture.

3. Connect a .1-µf. condenser from pin 2 of the gate-pulse socket, J801, to ground.

4. Set the HORIZ. HOLD control to the center of its mechanical rotation.

5. Adjust the HORIZ. HOLD CENTERING control to bring the picture into the center of the blanking bars. When the picture is centered in the blanking bars, the bars on the right-hand and left-hand sides of the picture will be of equal width.

6. Remove the .1-µf. condenser previously connected to pin 2 of the gate-pulse socket.

7. Adjust the horizontal ringing coil, L800, until the picture is again centered in the blanking bar.

8. Rotate the HORIZ. HOLD control through its range. The picture should fall out of sync on both sides of the center of its rotation. If the picture does not fall out of sync to both sides, readjust the HORIZ. HOLD CENTERING control to obtain fall-out to either side of sync.

9. Rotate the HORIZ. HOLD control through its range and observe the number of diagonal blanking bars just before the picture pulls into sync. The pull-in should occur with from 1 to 2 diagonal bars when the sync position is approached from either direction. If proper pull-in is not obtained, repeat the above procedure.

VIDEO PEAKING-COIL ADJUSTMENT

The video peaking coils, L305 and L307, are adjusted at the factory for proper transient response of the video amplifiers. Ordinarily, these coils will require no further adjustment by the serviceman except in cases where they have been tampered with, or where replacement becomes necessary. Under normal circumstances, when alignment of the tuner or i-f stages is undertaken, the video peaking coils should not require adjustment.

Before adjusting L305 and L307, check both the tuner and i-f alignment. (Never adjust L305 and L307 until the alignment of the receiver is correct.) Then tune in a station and adjust the receiver to give a picture of the best obtainable quality, with medium contrast. Turn the fine tuning control clockwise until a very slight beat pattern appears in the picture. Carefully observe the appearance of the picture regarding smear or overshoot (trailing whites). A small amount of overshoot may be desirable, to produce a sharper picture. Conversely, in weak-signal areas, a small amount of smear may be desirable, to reduce the harsh appearance of snow. The adjustments of L305 and L307, and their effects on the picture are as follows:

1. The amount of overshoot may be reduced by turning both TC302 and TC303 counterclockwise.

2. The amount of smear may be reduced by turning both TC302 and TC303 clockwise.

Normally, the point of proper adjustment is where minimum smear and trailing whites appear in the picture; however, a compromise adjustment may be made to suit prevailing conditions. As a rule, when properly adjusted, the adjustment screws (TC302 and TC303) should protrude from the chassis by approximately ½ to ¾ inch.

TELEVISION ALIGNMENT

GENERAL

The alignment consists of tuning each i-f coil to a given frequency, using an AM signal, and then feeding in a sweep signal at the antenna terminals and touching up the adjustments to obtain the desired pass band.

The over-all response curve (r-f, i-f) of the circuits from the antenna terminals to the video detector, after the i-f stages have been aligned, should appear essentially the same, regardless of the channel under test. If not, the tuner should be aligned. Before aligning the tuner, refer to the CAUTION given under Procedure, in Tuner Bandpass Alignment.

The video-carrier intermediate frequency is 45.75 mc., and the sound intermediate (intercarrier) frequency is 4.5 mc. Alignment of these circuits requires careful workmanship and good equipment. The following precautions must be observed:

1. There must be a good bond between the receiver chassis and the test equipment. This is most easily obtained if the top of the workbench is metallic. The receiver chassis should be placed tuner-side-down on the bench. If the bench has no metallic top, the test equipment and chassis can be bonded by a strip of copper about two inches wide. The section of the chassis nearest the tuner should rest on the strip.

2. Do not disconnect the picture tube, picture-tube yoke, or speaker while the receiver is turned on.

3. Allow the receiver and test equipment to warm up for 15 minutes before starting the alignment.

4. The marker (AM) signal generator should be calibrated accurately to the frequencies used and to the sound and video r-f carriers of each channel used during alignment. If the Philco Model 7008 is used, the built-in crystal calibrator provides an excellent means of calibration. An alternate method of calibrating the signal generator to the sound and video r-f carrier frequencies is to zero-beat the signal generator with the received signals.

For further information regarding calibration, refer to Philco Lesson PR-1745(J), entitled "Television Service in the Home."

TEST EQUIPMENT REQUIRED

The following test equipment is recommended for aligning the receiver:

1. Philco Precision Visual Alignment Generator for Television and FM, Model 7008, or equivalent.

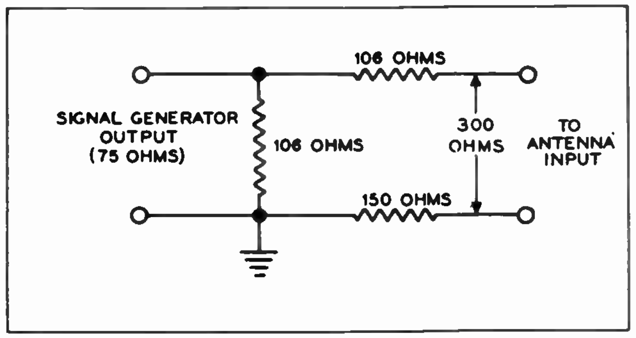
2. Vacuum-tube voltmeter, or 20,000-ohms-per-volt voltmeter.

3. R-F Probe, Philco Part No. 76-3595 (for use with Model 7008 generator).

JIGS AND ADAPTERS REQUIRED

Mixer Jig

Connections to the grid of the mixer tube may be made through the alignment jack provided for this purpose. To connect the generator to this point, a mixer-grid jig, Philco Part No. 45-1739, and a connecting cable, Philco Part No. 45-1635, may be used. As an alternate, a Philco alligator-clip adapter, Part No. 45-1636, with as short a ground lead as possible, may be used to connect the alignment jack. The ground lead should be connected as close as possible to the mixer tube. It is essential that the signal-generator output lead be terminated with a 68-ohm resistor (carbon), so that regeneration, caused by connection of the lead to the mixer, is held to a minimum.



TP0-1179

Figure 1. Antenna-Input Matching Network

Antenna-Input Matching Network

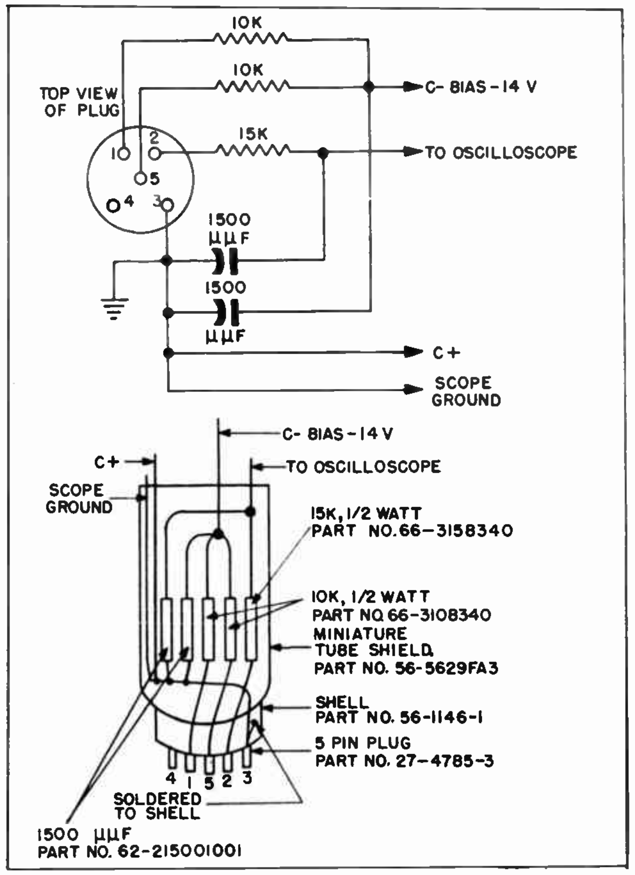
An impedance-matching network for coupling the signal generator to the antenna input terminals of the receiver is shown in figure 1. This network, which is designed to have an input impedance of 75 ohms and an output impedance of 300 ohms, is used to match a 75-ohm generator to a 300-ohm antenna-input circuit. The resistors used in this network should be of carbon-composition construction, and should be chosen from a group, to obtain values within ten percent of those indicated. The resistors should be placed in a shield can, to prevent variable effects. An antenna-matching jig, Philco Part No. 45-1736, which consists of a matching transformer and connecting box, may be used in place of the resistor network.

Video I-F Alignment Jig *(Video Test Jack Adapter No. 1)*

This alignment jig designed for use at J200, and shown in figure 2, should be used during the i-f alignment, to apply the proper bias to the a-g-c bus, and to provide a convenient oscilloscope connection. The adapter consists of a five-pin plug, two 10,000-ohm resistors, and a 1500-μμf. condenser for isolation of the bias supply. To isolate the oscilloscope from the receiver circuits, a 15,000-ohm resistor, by-passed by a 1500-μμf. condenser, is used. A suggested method of fabricating the jig is also shown in figure 2. This jig should not be used to observe the composite video from the video detector output.

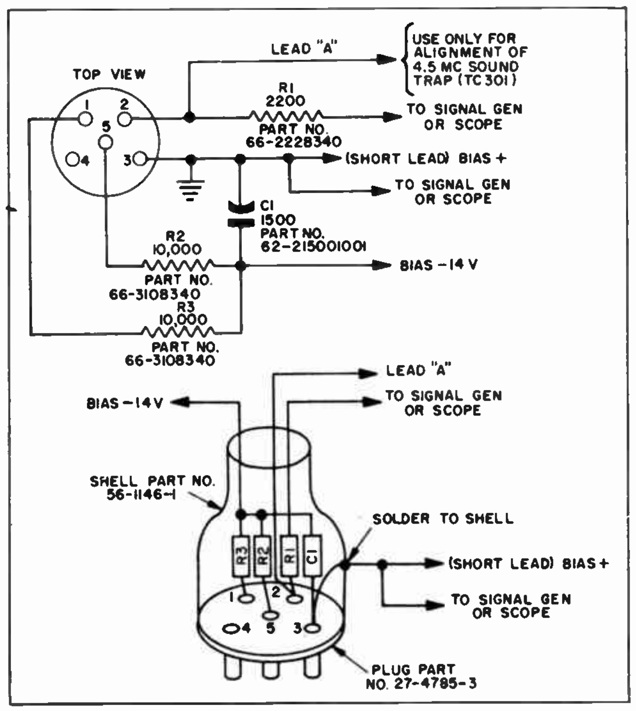
Sound I-F Input Alignment Jig *(Video Test Jack Adapter No. 2)*

To observe the composite video at J200, a jig may be made with a five-pin plug and a 2200-ohm resistor. (See figure 3.) The 2200-ohm resistor should be connected to pin 2 of the plug. A ground lead should be connected to pin 3. To observe the composite video, connect the oscilloscope to the 2200-ohm resistor and the ground lead. This jig is also used for injection of the 4.5-mc. signal during sound i-f alignment.



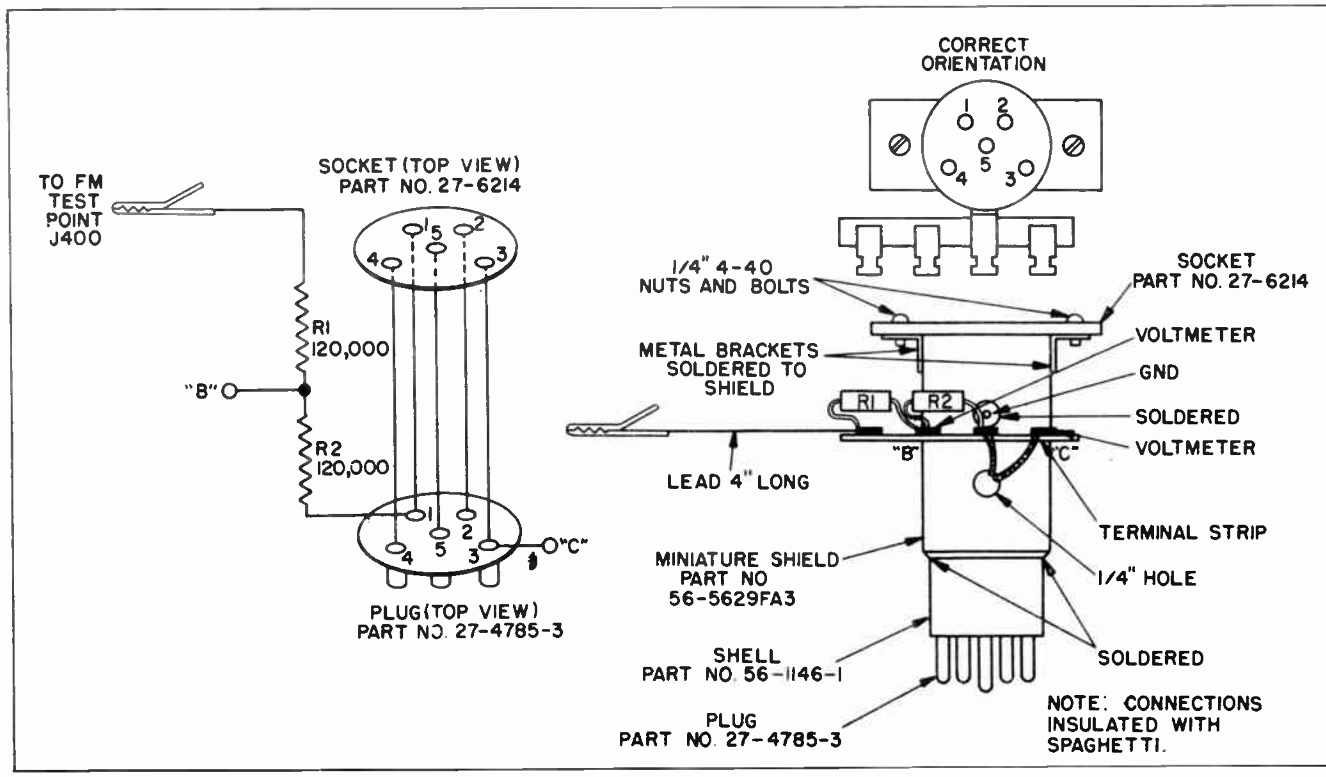
TP2-1507-B

Figure 2. Video I-F Alignment Jig (Video Test Jack Adapter No. 1)



TP2-3265-A

Figure 3. Sound I-F Input Alignment Jig (Video Test Jack Adapter No. 2)



TP2-3263-A

Figure 4. Sound I-F Output Alignment Jig (FM Test Point and Volume Control Jack Adapter)

Sound I-F Output Alignment Jig *(FM Test Point and Volume Control Socket Adapter)*

Figure 4 shows the adapter that should be used to connect the voltmeter to the FM detector through the volume control socket, J400, and FM test point (G400). The adapter should be inserted into the volume control socket, and the clip lead from the adapter connected to the FM test point. The volume control cable and plug, PL400, is inserted into the socket on top of the adapter.

TELEVISION TUNER ALIGNMENT

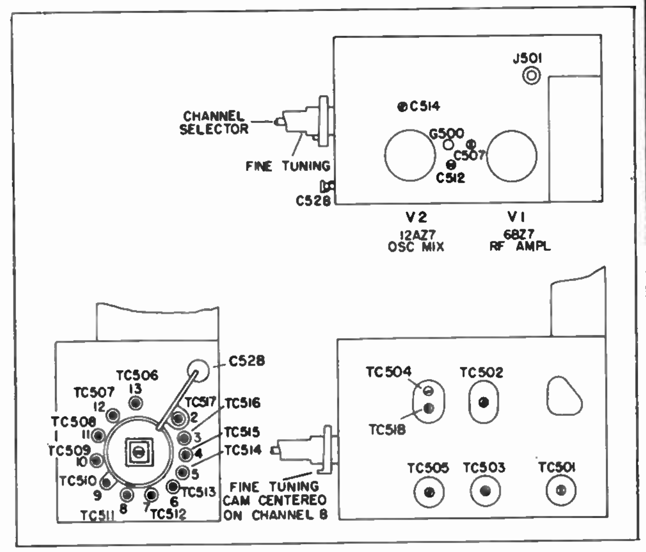
After the tuner is serviced, or if an i-f alignment is required, the tuner alignment should be checked. If realignment is necessary, use the procedure given below.

Since the frequency of the local oscillator affects the tuner response, the local-oscillator alignment should be made first.

Oscillator Alignment

General

It is possible to place each channel exactly on frequency by adjusting the tuning core of each coil, the adjustment procedure should be carried out with the highest channel (13) first, since the alignment of each channel will affect the alignment of the channels below it in frequency. The FINE TUNING control should be preset for all adjustments by placing the stop on the fine-tuning cam at Channel 8 oscillator tuning core. See figure 5.



TP3-942-A

Figure 5. Television Tuner, Showing Locations of Adjustments

Procedure Using Signal Generators

An r-f signal (unmodulated), at the video carrier frequency of the channel, is fed into the antenna input, and an i-f signal, at the i-f carrier frequency, is fed to the first i-f amplifier. Two AM signal generators are used to supply these signals. An oscilloscope is connected to the video detector output. The oscillator core is then adjusted for zero beat on each channel. The two generators should be accurately calibrated as described in Philco Lesson Series PR-1745(J).

To align the oscillator, proceed as follows:

1. To observe the zero beat, connect the oscilloscope to the video-detector output through the video i-f alignment jig. See figure 2. Bias the tuner and i-f a-g-c circuits with $1\frac{1}{2}$ volts, and remove the gate-pulse plug, PL801, from the socket, J801. To apply the bias to the tuner, connect the battery to the white lead which comes from the feed-through condenser at the top of the tuner. To make certain that good connection is made to the tuner a-g-c circuit, remove the glyptol coating on this condenser terminal.

2. To feed in the i-f comparison signal, remove the shield from the first v-i-f tube and wrap several turns of insulated copper wire around the tube. Connect the output leads of the v-i-f signal generator to the two ends of the wire loop, and set the generator for unmodulated output at 45.75 mc.

3. To feed in the signal representing the channel frequency, set the r-f signal generator at the video carrier frequency of Channel 13, and connect the output to the antenna-input terminals of the receiver, through the proper matching jig.

4. Mechanically preset the fine-tuning cam, as shown in figure 5, and set the CHANNEL SELECTOR to Channel 13.

5. Adjust the Channel 13 tuning core for zero beat, as indicated by the oscilloscope.

6. Retune the r-f signal generator and reset the CHANNEL SELECTOR for Channel 12, then 11, etc., each time adjusting the respective tuning core for zero beat. The tuning cores should be adjusted progressively from the highest-frequency channel to the lowest, because the higher channel adjustments will affect the lower channels.

Procedure Using Station Signal

The following simplified procedure may be used to align the oscillator when the television i-f alignment is satisfactory and a station signal is available. If this procedure is used in the service shop, signals from all stations which the customer can receive must be available in the service shop.

1. Mechanically preset the fine-tuning cam as shown in figure 5.

2. Tune in the highest-frequency channel to be received, and adjust the tuning core for that channel for the best picture; that is, starting with sound in the picture, turn the tuning core until the sound in the picture just disappears.

3. Repeat step 2 for each channel received in the area, starting with the highest-frequency channel and finishing with the lowest channel.

Tuner Bandpass Alignment

General

The bandpass alignment consists of aligning the tuner at Channels 13 and 6, and then making it track properly.

During the alignment, a fixed bias of $1\frac{1}{2}$ volts is applied to the r-f amplifier tube through the white a-g-c lead.

An FM (sweep) signal is applied to the antenna-input circuit through the proper matching jig, and an oscilloscope is connected to the junction of R518 and the tuner red lead. The oscilloscope gain should be as high as possible, consistent with "hum" level and "bounce" conditions. Hum conditions will cause distortion of the time base and response. Bounce conditions will cause the response and the time base to jump up and down, and this effect is caused by poor line regulation. The use of too high an oscilloscope gain aggravates these conditions, whereas the use of too low a gain necessitates increasing the generator output to a point where the tuner may be overloaded. The scope controls should be adjusted so that the width of the presentation is double the height. Overload may then be checked by changing the generator output while observing the shape of the response curve. When the generator output is changed, the vertical gain of the oscilloscope should be readjusted to keep the scope presentation amplitude the same. Do not readjust the horizontal gain control. Any change in the shape of the curve indicates overload, in which case a lower generator output and higher oscilloscope gain must be used.

The signal-generator output must be properly matched to the antenna-input circuit of the tuner. The antenna-input matching network shown in figure 1, or a Philco Antenna Matching Jig, Part No. 45-1637, may be used for this purpose. If a matching jig is not used, the result obtained will be extremely unreliable.

Regeneration or a mismatch in the test setup will also cause poor and unreliable results. To check for regeneration or mismatch move the hand along the generator cable after all equipment is connected, and observe the response curve on the oscilloscope screen. If the response curve on the oscilloscope changes as the hand is moved along the cable, regeneration or mismatch is indicated. Another check may also be made with the volume control advanced until noise can be heard from the speaker. If the level of the noise changes as the hand is moved along the generator cable, regeneration or mismatch is indicated. The symptoms which indicate these conditions may also be caused by failure to use the proper matching jig, as described above.

Procedure

CAUTION: When comparing the response curves from channel to channel, maintain the 2-to-1 width-to-height relationship in the oscilloscope presentation, as described above.

1. Connect the FM (sweep) and AM marker generators to the 300-ohm antenna input terminals through an antenna-input matching jig.

2. Connect the oscilloscope to the junction of R518 (15k, 1w) and the tuner red lead.

3. Apply $1\frac{1}{2}$ volts of bias to the white tuner a-g-c lead.

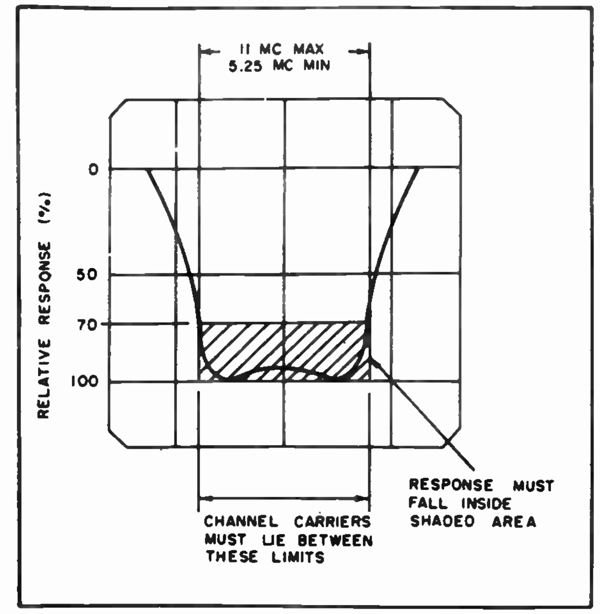
4. Disconnect the tuner coupling link at wiring panel B-14, terminals 1 and 4, and solder a 68-ohm, one-half watt carbon resistor to the open link coming from the tuner. See figure 8. Remove the first i-f tube from its socket.

5. Set the CHANNEL SELECTOR and FM (sweep) generator to Channel 13 (213 mc.). Adjust the generator for sufficient sweep width to show the complete response curve.

6. Establish channel limits (see figure 6) by using the marker (AM r-f) signal generator to produce marker pips on the response curve. (Set the marker generator first to 210 mc., then 216 mc.) The response curve should be reasonably flat between the limits.

7. Readjust TC502 and TC504 for a symmetrical response, centered about 213 mc. and falling within the specifications, as shown in figure 6.

8. Set the CHANNEL SELECTOR and FM (sweep) generator to Channel 7 (177 mc.). Establish the channel limits by using the marker-signal generator to produce marker pips on the response curve. (Set the marker generator first to 174 mc., and then to 180 mc.) The curve should be reasonably flat between the limits.



TP3-1213

Figure 6. Television Tuner Response Curve, Showing Bandpass Limits

9. On Channel 7, observe the tilt and center frequency of the response curve. The curve should be centered on the pass band and should be symmetrical. If it is not symmetrical, and appears unbalanced, as in figure 7, adjust C507 and C512 (figure 5) to obtain a response curve which is the mirror image (tilt in the opposite direction) of the original; for example, if Channel 7 response curve appears as in figure 7A, adjust C507 and C512 until the curve appears as in figure 7B. This adjustment overcompensates to make allowance for the effect of Channel 13 adjustments (to be made in step 10) upon Channel 7 response.

10. Reset the CHANNEL SELECTOR and generators to Channel 13, and repeat steps 8 through 10 as many times as is necessary, to obtain the most symmetrical and centered response curves on Channels 13 and 7. Channels 7 through 13 are now correctly aligned.

11. Set the CHANNEL SELECTOR and sweep generator to Channel 6 (85 mc.).

12. Establish the channel limits, using the marker generator to produce marker pips on the response curve. (Set the marker generator first to 82 mc., then to 88 mc.).

13. Adjust TC503 and TC505 for a symmetrical, approximately centered pass band. Set the marker generator to 85 mc. Detune TC505 counterclockwise until a single peak appears. Adjust TC503 until the peak falls on the 85-mc. marker. It may be necessary

to increase the output of the generator during this adjustment. Then adjust TC501 for maximum curve height and symmetry of the single peak. The antenna circuit is now tuned for Channels 2 through 6.

14. Readjust TC503 and TC506 for a symmetrical response, centered about 85 mc. and falling within the specifications, as shown in figure 6. Channels 2 through 6 are now correctly aligned.

VIDEO I-F ALIGNMENT

Preliminary

Before proceeding with the i-f alignment or making an alignment check, observe the following preliminary instructions:

1. Preset the CONTRAST and BRIGHTNESS controls to the maximum counterclockwise position.

2. Preset the CHANNEL SELECTOR to Channel 4.

3. Insert the video i-f alignment jig into J200.

4. Connect the oscilloscope to the 15,000-ohm resistor from the video i-f alignment jig. Connect the ground lead of the oscilloscope to the ground lead from the adapter.

5. With a voltmeter connected across the points shown in figure 2, set the potentiometer to furnish –14 volts of bias.

6. Connect the AM generator to the mixer test point, G500, through a mixer jig, and adjust the generator for approximately 30 percent modulation at 400 cycles. Adjust the output of the generator during the alignment to keep the output at the second detector below .6 volt, peak to peak.

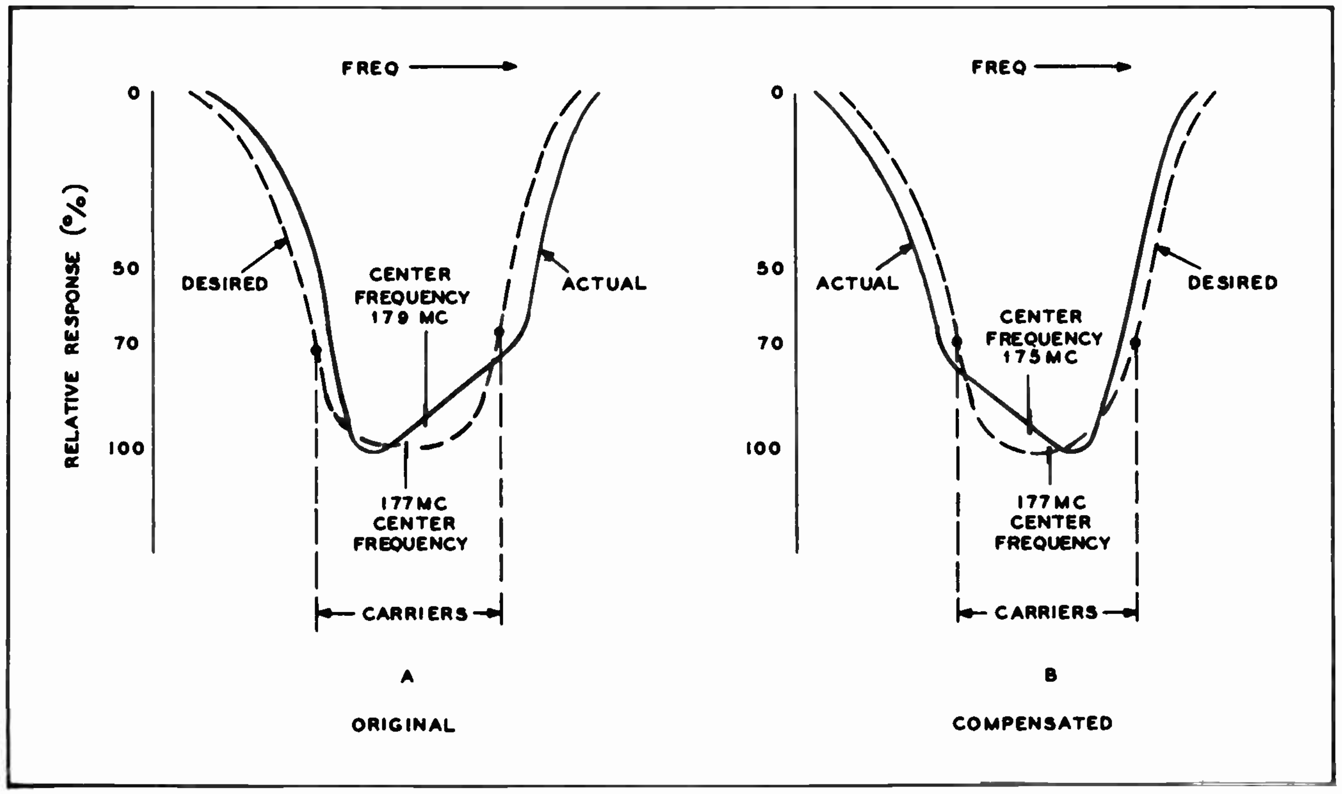
NOTE: If the i-f shield has been removed for repairs, it must be replaced before proceeding with the alignment.

Procedure

1. Tune the AM generator to 47.25 mc., and adjust C201 for minimum output, as observed on the oscilloscope.

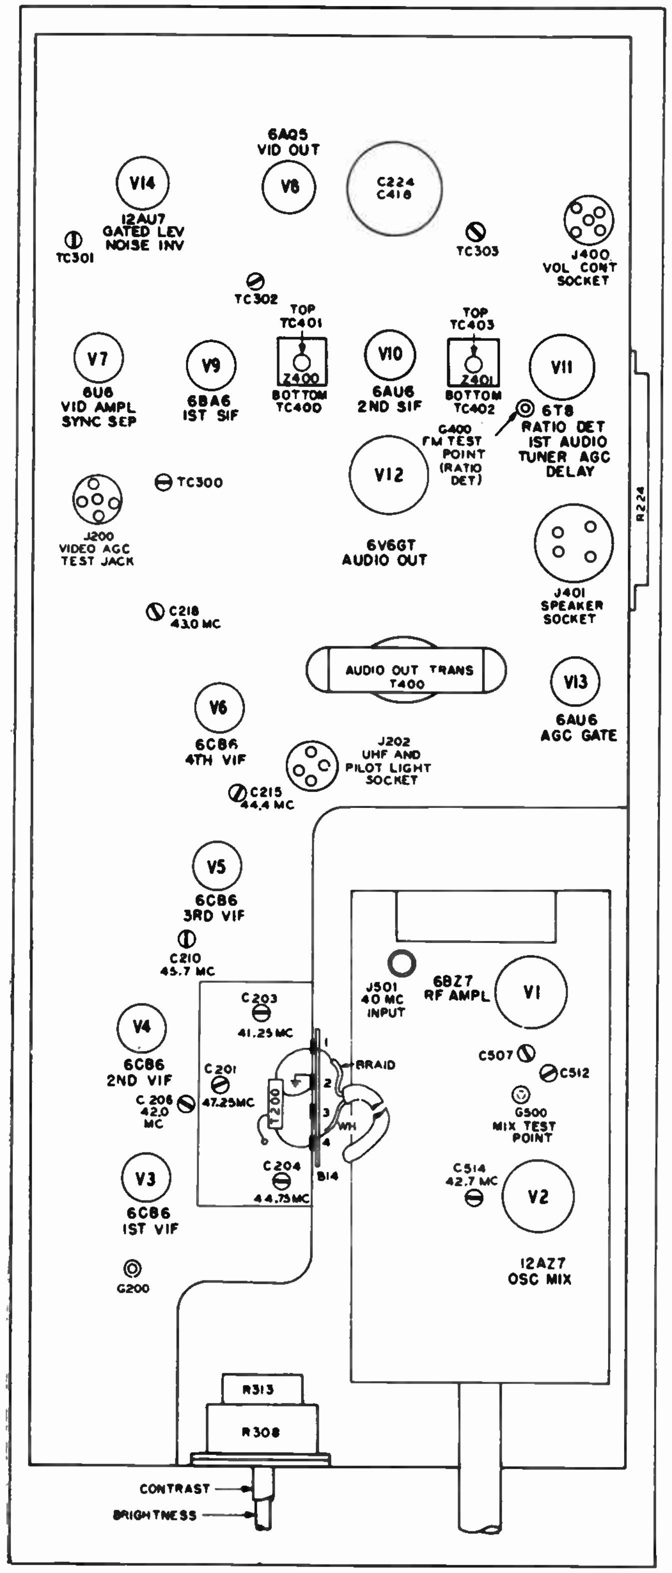
2. Tune the AM generator to 41.25 mc., and adjust C203 for minimum output, as observed on the oscilloscope.

NOTE: In steps 1 and 2, it is necessary to keep the generator output sufficiently high that a null indication may be observed on the oscilloscope; however, avoid overloading of the receiver by excessive signal.



TP0-1174

Figure 7. Television Tuner Response Curve, Showing Tracking Compensation



TP3-943-A

Figure 8. R-F Chassis R-204, Top View, Showing Locations of Adjustments

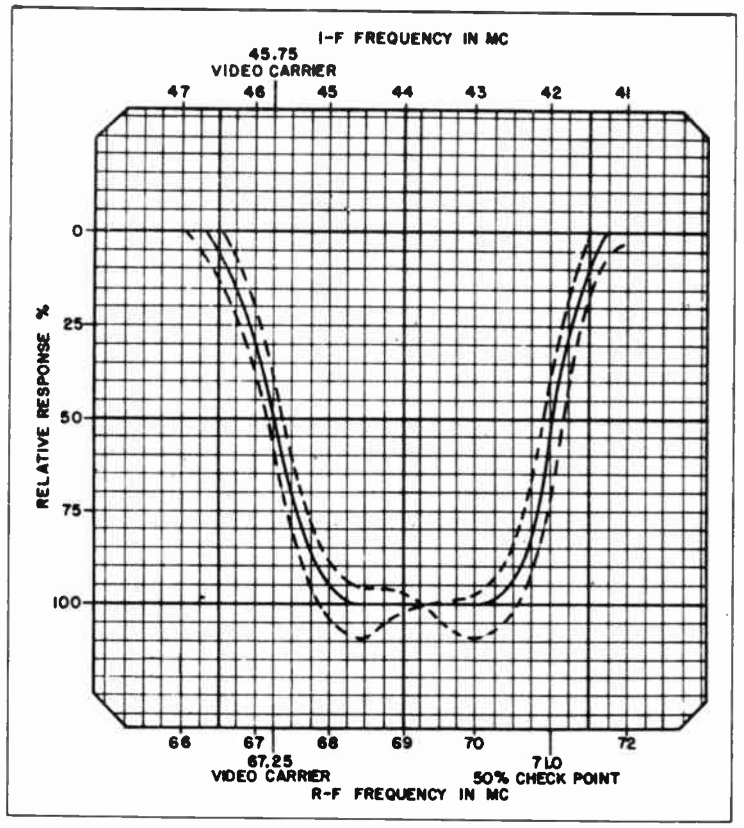
3. Tune the AM generator to the frequencies indicated below, and adjust the trimmers (see figure 8) for maximum output.

a. 42.7 mc.—adjust C514
b. 44.75 mc.—adjust C204
c. 45.7 mc.—adjust C210
d. 44.4 mc.—adjust C215
e. 43.0 mc.—adjust C218
f. 42.0 mc.—adjust C206

4. Increase the bias (by means of the potentiometer) until the scope presentation of step f, above, is reduced to 50 percent of its previous amplitude, and retouch C206 for maximum indication on the oscilloscope.

5. Connect the sweep generator and r-f marker generator to the antenna terminals through a matching jig. (If a separate oscilloscope is used, connect the sweep output of the generator to the horizontal input of the oscilloscope.) Set the CHANNEL SELECTOR to Channel 4, and tune the sweep generator for output on Channel 4. Tune the r-f marker generator for the video carrier frequency of Channel 4 (67.25 mc.), and tune the i-f marker generator (connected through jig to mixer grid) to 45.75 mc. Note that two marker generators are used for this procedure. The r-f marker generator is connected to the antenna terminals, while the i-f marker generator is connected capacitively to the mixer grid test point, G500. A jig constructed from a piece of fiber tubing, with $\frac{3}{16}$ inch inside diameter, and a brass machine screw which fits tightly into the tubing, is used to connect the generator capacitively to the test point. The screw is adjusted so that it clears the test point by approximately $\frac{1}{64}$ inch. The output cable of the marker generator is connected to the head of the brass screw in the jig and to chassis near the mixer tube. Both marker generators should be adjusted for the minimum output required to make the markers barely visible. Failure to observe this precaution, or the use of excessive output from the sweep generator, will cause misleading results. After the equipment is properly connected, adjust the FINE TUNING control for zero-beat of the two markers, as observed on the oscilloscope. When zero beat is obtained, remove the i-f marker.

6. If the response curve does not fall within the limits, as shown in figure 9, the adjustment of the trimmers may be touched up slightly, while observing the response curve. Do not retouch the setting of C201, C203, or C206. To adjust the curve, first adjust C215 and C218 alternately until maximum improvement is obtained. C215 affects the tilt of the



TP3-944

Figure 9. Over-all R-F, I-F Response Curve

curve, and C218 affects the dip of the curve. After C215 and C218 have been adjusted, adjust C514 for proper slope at the 42.25-mc. side of the curve, and then adjust C204 and C210 for proper level at the video carrier frequency (45.75 mc.).

CAUTION: Do not turn any of the trimmers excessively. To retouch, only turn the trimmers slightly.

SOUND I-F ALIGNMENT

The sound i-f system may be aligned by the use of a station signal or an accurately calibrated signal generator, for the signal source. If the station signal is used, tune the FINE TUNING control for the best picture, regardless of sound. It will be necessary to reduce the signal input to the receiver, so that the d-c output at the sound detector, as measured with the aid of the sound i-f output alignment jig (between point "B" and ground), is kept below 5 volts, maximum, and preferably below 3 volts. To establish this level in strong-signal areas, it may be necessary to short the antenna terminals and to apply bias to the a-g-c circuit. The signal input to the receiver may be adjusted by varying the length of the shorting lead. The bias may be applied to the a-g-c circuit by means of the jig shown in figure 3. The sound i-f output alignment jig shown in figure 4 should be used for convenient connection of the meter to the sound-detector output.

When a signal generator is used, bias should be applied to the a-g-c circuit, to avoid any possibility of regeneration, using the sound i-f input alignment jig (figure 3). In addition, the first video i-f tube should be removed, to aid in the reduction of circuit noises from the i-f system.

NOTE: To perform the sound i-f alignment it will be necessary to plug the radio-tuner plug, PL402, into socket J402 and set the function switch to the TV position.

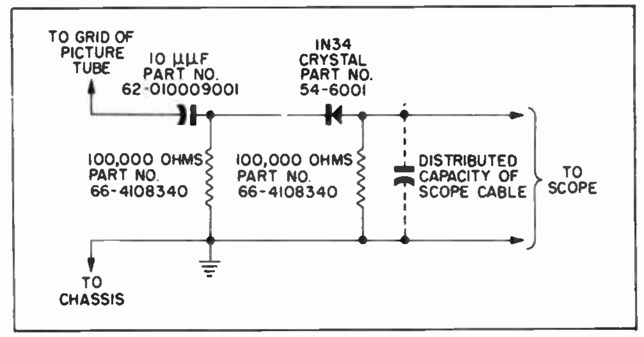
1. Connect the generator through the 2200-ohm resistor, in the sound i-f input alignment jig, to pin 2 of J200. The generator should be adjusted for unmodulated output at 4.5 mc.

2. Insert the sound i-f output alignment jig into the volume-control socket, J400, and insert the volume-control plug, PL400, in the top of the jig. Connect the clip lead to the FM test point, G400; connect a 20,000-ohms-per-volt voltmeter between point "B" and the ground lug of the jig, with the negative lead of the meter going to point "B."

3. Adjust TC300, TC400, TC401, and TC402 for maximum output, as indicated on the meter. If the output exceeds 5 volts, reduce the signal input to the receiver.

4. Shift the positive lead of the meter to point "C" on the sound i-f output alignment jig, and adjust TC403 for zero crossover. Zero crossover is indicated by a zero indication on the meter. When TC403 is turned in one direction from this zero point, the meter will swing positive; turning TC403 in the opposite direction will cause a negative swing. (To aid in reading a positive and negative swing on the meter, set the pointer, by means of its zero-adjustment screw, to a convenient calibration mark on the scale, before connecting the meter to the circuit.)

5. Replace the first video i-f tube, and tune in a station on the receiver. Turn the FINE TUNING control to obtain a slightly fuzzy picture, and retouch TC403 for minimum AM (noise or buzz), using the speaker output as an indication.



TP2-2670

Figure 10. R-F Probe for Sound-Trap Adjustment

ADJUSTMENT OF 4.5-MC. TRAP

To adjust the 4.5-mc. trap in the plate circuit of the first video amplifier, proceed as follows:

1. Connect the output of the signal generator to the lead from pin 2 of the sound i-f alignment jig (see figure 2). Adjust the generator for 4.5 mc., 400-cycle modulated output. Set the output attenuator for maximum output from the generator.

2. Connect the input of the r-f probe, shown in figure 10, to the grid of the picture tube, and connect the output of the probe to the vertical input of the oscilloscope. Adjust the vertical gain of the oscilloscope to maximum.

3. Adjust TC301 for minimum indication on the oscilloscope. (The normal setting for TC301 is with the screw approximately ⅝ inch out from the chassis.)

An alternate method for adjustment of TC301 may be used if a 4.5-mc. generator is not available. To adjust TC301 without the generator, proceed as follows:

1. Tune in a strong station signal.

2. Turn the FINE TUNING control in a clockwise direction until a fine beat pattern appears in the picture.

3. Adjust TC301 until the beat disappears or is at a minimum. When correctly adjusted, the screw will be out from the chassis approximately ⅝ inch.

4. If more than one station is available, check the setting of TC301 on all stations.

OSCILLOSCOPE WAVEFORM PATTERNS

The waveforms illustrated were taken with the receiver adjusted for an approximate peak-to-peak output of 2 volts at the video detector. The voltages given with the waveforms are approximate peak-to-peak values. The frequencies shown are those of the waveforms—not the sweep rate of the oscilloscope.

The waveforms were taken with an oscilloscope having good high-frequency response. With oscilloscopes having poor high-frequency response, the sharp peaks of the horizontal waveforms are more rounded than those shown, and the peak voltages differ from those shown.

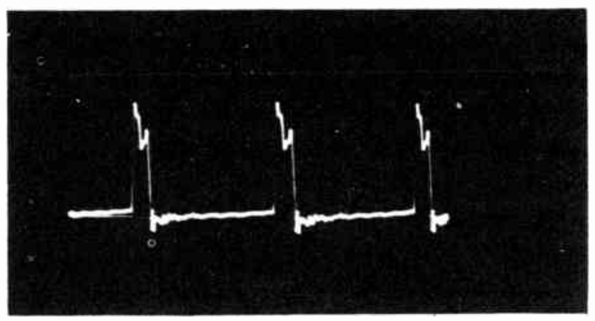
***See CAUTION.**



TP2-654

Figure 34. Gate-Pulse Socket, Pin 4 of J801
500 volts, 15,750 c.p.s.

* CAUTION: High-voltage pulses are present in the horizontal-output circuit. The waveform shown in figure 33 was taken with the alligator clip of the oscilloscope lead clipped over the insulation of the lead connected to pin 7 of J800. (To prevent puncture of the insulation of the lead, file off the teeth of the alligator clip, and wrap friction tape around the clip.) Connection to other points in the horizontal-output circuit is dangerous, because of the high voltages present. The peak-to-peak voltage shown for figure 33 is the actual voltage present; however, the amplitude of the scope presentation depends upon the degree of coupling.

VOLTAGE MEASUREMENTS

The voltages given below and on the schematics were taken with a 20,000-ohms-per-volt voltmeter, with a line voltage of 117 volts, and no signal input to the receiver. Since voltage readings taken in the video i-f stages vary widely with different test equipment setups, voltage measurements for these stages are omitted from the diagrams.

UHF TUNER-ADAPTER UT20B, PART NO. 43-6701

UHF Tuner-Adapter UT20B, Part No. 43-6701, provides for reception of UHF signals on television Channels 14 through 83. UHF Tuner-Adapter UT20B is designed for installation in Philco B line television receivers and is installed on BU models. These receivers use r-f chassis R-204.

The Tuner-Adapter consists of a UHF Tuner, a VHF-UHF change-over switch, adapter cables and plugs, a planetary tuner driving assembly and mounting hardware.

CIRCUIT DESCRIPTION

The UHF tuner converts the UHF signals to the intermediate frequency of the r-f chassis.

The incoming UHF signal is coupled through the antenna input line, and through two i-f traps, two 680-$\mu\mu$f. condensers, and a 150-ohm transmission line to the antenna tank of the tuner. See figure 45. The antenna tank is coupled to the mixer tank by means of the mutual coupling of L2 and L3 and the stray capacitance, C5. The desired signal is and the stray capacitance, C5. The desired signal is selected by tuning the antenna tank and the mixer tank to the correct frequency, and the signal is then coupled to the crystal mixer circuit by means of the mutual coupling of L4 and L5. The local-oscillator signal is generated by a 6AF4 tube, V1, and the associated circuit. The oscillator circuit is coupled to the crystal mixer circuit by a 300-ohm, miniature transmission line and the mutual coupling of L7 to L5 and L8 to L6. The r-f signal and the oscillator signal are mixed in the crystal mixer circuit to produce a 45.75-mc. video carrier intermediate-frequency signal. This signal is coupled to the VHF tuner through L18, a coaxial cable, and J500 on the VHF tuner. In UHF operation, the local oscillator of the VHF tuner is inoperative, and the r-f amplifier and mixer tubes of the VHF tuner operate as i-f amplifiers.

The two tanks of the UHF tuner, the antenna tank and the mixer tank, are used to prevent the i-f and oscillator signals from feeding back to the antenna and interfering with other receivers. The two tanks pass incoming signals readily, but do not pass the i-f or oscillator signal.

CHANGE-OVER SWITCH

The change-over switch supplied with the Tuner-Adapter is used to switch from VHF to UHF, and vice versa. It is installed on the back of the VHF tuner, and is operated by an actuator mounted on the VHF tuner shaft. When the Channel Selector of the VHF tuner is turned to the UHF position, the change-over switch makes proper connections for UHF operation. In this position, the switch places a 150,000-ohm resistor in series with the VHF mixer plate, which drops the voltage on the plate of the tube. (In the UHF position, the VHF Channel Selector places extra inductances in the VHF r-f and mixer circuits, permitting them to operate as i-f amplifiers, and it also shunts the VHF oscillator grid circuit with a 10-ohm resistor, putting the oscillator out of operation.) The change-over switch also turns off the VHF pilot light, turns on the UHF dial pilot lights, and connects the antenna to the UHF tuner.

When the VHF Channel Selector is turned to any VHF position, the change-over switch places a 150,000-ohm resistor in series with the UHF local oscillator plate circuit, which drops the voltage applied to the plate, and puts the oscillator out of operation. The switch also turns on the VHF pilot light, turns off the UHF dial pilot lights, and connects the antenna to the VHF tuner.

PLANETARY DRIVE

The UHF tuner is tuned by means of a 3-gang tuning condenser, which is driven through a specially designed planetary drive. The planetary drive is so constructed that fine tuning and course tuning can be accomplished with a single control knob. The tuning shaft is coupled to the driving shaft through three balls, which form a planetary drive that produces slow rotation for fine tuning. See figure 43. After rotating 180 degrees with the tuning shaft, a pin engages the driving shaft, and the two shafts are direct-coupled, for coarse tuning. To re-engage the planetary drive for fine tuning, it is only necessary to reverse the direction of rotation. The dial pointer is connected to the tuning gang through a cord drive, and indicates the channel number to which the tuner is tuned.

ALIGNMENT AND REPAIRS

The frequencies at which the Tuner-Adapter operates are extremely high; therefore, it is necessary that the utmost care be taken to safeguard against upsetting the delicate adjustments of the tuner. It is recommended that the serviceman make only minor repairs to the tuner, such as replacement of the tube or crystal and the wiring of external leads. The

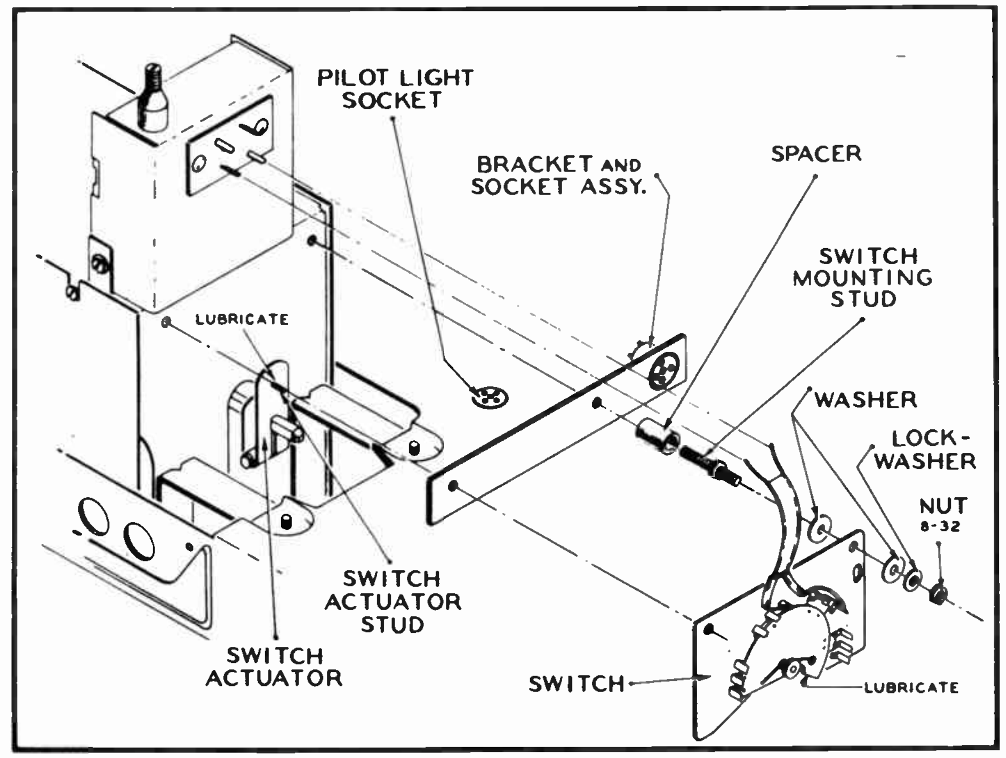
Figure 47. Top View and Base View of UHF Tuner-Adapter UT20B, Without Board Assemblies



TP3-480-A

Figure 49. VHF-UHF Change-Over Switch, Mounting Details

Tuner-Adapter should be returned to the factory for alignment and major repairs, unless the serviceman is properly equipped to perform these jobs. In general, a good rule to follow is not to remove the cover of the Tuner-Adapter.

NOTE: Replacing the tube with a new one may detune the tuner. If this occurs, a number of tubes should be tried, until the most satisfactory performance is obtained.

INSTALLATION INSTRUCTIONS

To install the UHF tuner-adapter, proceed as follows:

1. Remove the cabinet back and r-f chassis from the cabinet; then remove the nameplate on the control panel by pushing it out from inside the cabinet.

2. Insert the dial scale and bezel assembly into the hole provided in the cabinet. Fasten the assembly in place with the two 10-32 nuts provided.

3. Remove the tuner assembly from the mounting board with which it was shipped. Keep the three screws for mounting the tuner in the cabinet.

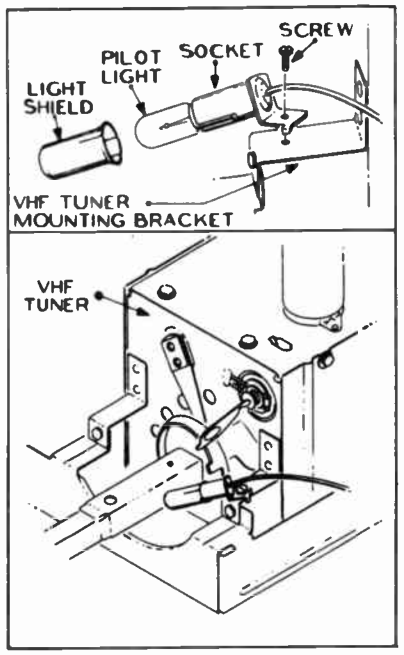
4. Place the spacers on the mounting studs and attach the bracket and socket assembly to the rear of the VHF tuner on the r-f chassis. See figure 49.

5. Place the switch-actuator assembly on the shaft extending from the rear of the VHF tuner with the switch-actuator stud pointing away from the tuner. See figure 49.

6. Place the switch assembly on the two mounting studs, and fasten it in place with the flat washers, lock washers, and nuts provided. See figure 49.

7. Put the VHF Channel Selector in the Channel 2 position. Rotate the switch actuator clockwise on the tuner shaft until the actuator touches the fiber cam on the change-over switch, and fasten the switch actuator in this position. Rotate the VHF Channel Selector to the UHF position. Check the switch operation, to make sure that the switch is thrown properly. Rotate the VHF Channel Selector to Channel 13 position, and check the switch operation, to make sure that the switch is not thrown in this position. Lubricate the switch-actuator stud and switch cam with cup grease.

8. Remove the pilot lamp from the r-f chassis pilot-light socket. Remove and discard the pilot-light socket and cable assembly from the r-f chassis. Insert the plug from the change-over switch into the socket on the r-f chassis from which the pilot-light cable was removed. Mount the new pilot-light socket from the change-over switch as shown in figure 50. Insert the pilot light in the socket, and install the shield provided over it.



TP3-755

Figure 50. Pilot-Light Socket, Mounting Details

9. Remove the antenna lead from the VHF tuner, and solder the short lead from the UHF-VHF change-over switch to the VHF tuner terminals from which the antenna lead was removed. Slide the folded fiber lead holder over the tapered-line coil assembly on the VHF tuner, and dress the twin-wire antenna leads through the holder. See figure 51. The fiber holder will prevent the twin-wire leads from touching the tubes on the r-f chassis.

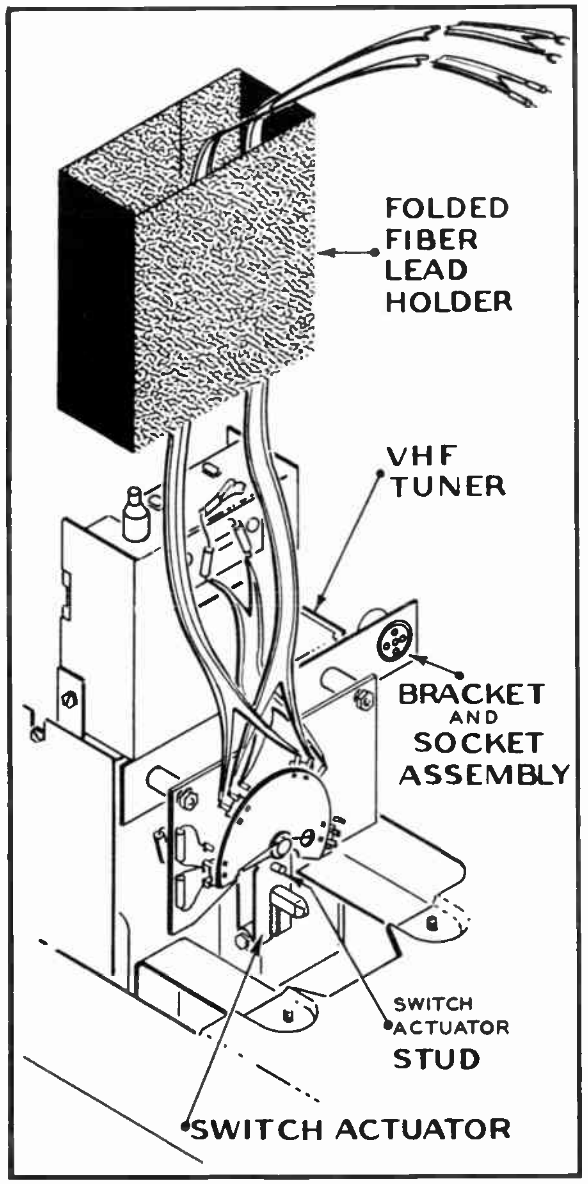
10. Place the UHF tuner in the cabinet between the r-f and deflection chassis, and fasten the UHF tuner to the chassis shelf with the three screws removed in step 3. It is important that these screws be tightened securely, so as to hold the UHF tuner in place on the chassis shelf.

11. Fasten one end of the ground lead to the r-f chassis with the drive screw. See figure 52. Install the chassis in the cabinet, and fasten the other end of the ground lead to the UHF tuner with the 8-32 x 1/4 inch hex-head machine screw. Fasten the r-f chassis with the original mounting bolts. Place the original knobs on their shafts, and the knob provided on the UHF tuning shaft.

12. Insert the plug from the UHF tuner into the socket on the bracket installed in step 4.

13. Insert the coaxial cable into the jack on the VHF tuner. See figure 52.

14. Replace the fiber antenna-lead holder with the new holder provided. Fasten the new holder with the



TP3-756

Figure 51. Folded Fiber Lead Holder and VHF-UHF Change-over Switch, Mounting Details

nails provided, and then pass the twin-wire leads through the holes as shown in figure 53. Pull the leads through the holder until they are tight, making certain that the leads do not contact the tubes or the chassis. Wrap tape around the yellow-marked twin-wire leads with the spade lug ends, to prevent the leads from passing back through the fiber holder.

15. Fasten the antenna terminal board provided as shown in figures 54 through 58. Replace the cabinet back and make the connections illustrated for the type of antenna installation being used.

16. Paste the label provided over the outside-antenna instructions on the cabinet back.

PARTS LIST

IMPORTANT

General replacement items commonly stocked by the serviceman are omitted from this parts list. All condensers are molded-bakelite Philco condensers, with a 600-volt rating, and all resistors are ½ watt, unless otherwise indicated. Parts are listed according to chassis type, and should be ordered in this way rather than by model number; in addition, a miscellaneous listing will be found at the end of the parts list for each chassis type. All parts are symbolized in the schematic diagrams and base layouts, for identification purposes.

NOTE: Part numbers identified by an asterisk (*) are general replacement items. These numbers may not be identical with those on factory parts. Also, the electrical values of some replacement items may differ from the values indicated in the schematic diagrams and parts list. The values substituted in any case are so chosen that the operation will be unchanged. When ordering replacements, use only the "Service Part No."

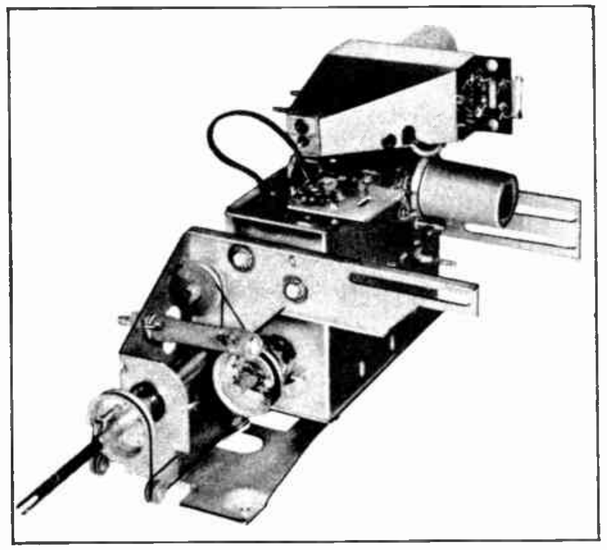
UHF Tuner-Adapter (Chassis Only) for R-F Chassis 91, 91R, 94, and 94R TP2-2869



UHF Tuner-Adapter (Chassis Only) for R-F Chassis 81 and 84 TP2-2870

UHF TUNER-ADAPTER PART No. 43-6474, FOR RECEIVERS USING R-F CHASSIS 81 OR 84

UHF Tuner-Adapter Part No. 43-6474 provides for the reception of UHF signals on television channels 14 through 83. It is designed for installation in Philco Television Receivers using r-f chassis 81 or 84. The adapter consists of a UHF converter and preamplifier unit, a change-over switch, adapter cables and plugs, a planetary tuner driving assembly, and mounting hardware.

CIRCUIT DESCRIPTION

The UHF Tuner-Adapter functions as a converter, and converts the signals of the UHF band to a frequency selected within the VHF band. The frequency selected is that of either Channel 2 or Channel 3, depending upon the locality in which the receiver is used.

The incoming UHF signal is coupled through the antenna input line, and through two 680-$\mu\mu f$. condensers and a 150-ohm transmission line to the antenna tank of the tuner. See figure 1. The antenna tank is coupled to the mixer tank by means of the mutual coupling of L2 and L3 and the stray capacitance, C5. The desired signal is selected by tuning the antenna tank and the mixer tank to the proper frequency, and the signal is then coupled to the crystal mixer circuit by means of the mutual coupling of L4 and L5. The local-oscillator signal is generated by a 6AF4 tube, V1, and the associated circuit. The local-oscillator signal is coupled to the crystal mixer circuit by means of a 300-ohm, miniature transmission line and the mutual coupling of L7 to L5 and L8 to L6. The UHF r-f signal and the oscillator signal are mixed in the crystal mixer circuit, producing a radio-frequency signal within range of the VHF tuner when the tuner is set to either Channel 2 or Channel 3. This signal is fed into a preamplifier, which amplifies it, and it is then fed into the VHF tuner through a twin-wire lead. In the VHF tuner, the signal is converted to the intermediate frequency of the television receiver. On VHF operation, a 150,000-ohm resistor is placed in series with the UHF oscillator plate, which makes this oscillator inoperative.

The purpose of using two r-f tanks in the UHF tuner is to readily admit the r-f signals, and, at the same time, prevent the UHF i-f signal from feeding back into the antenna and causing interference with other receivers.

CHANGE-OVER SWITCH

The change-over switch supplied with the Tuner-Adapter is used to switch from VHF to UHF, and vice versa. It is installed on the back of the VHF tuner, and is operated by an actuator mounted on the VHF tuner shaft. When the VHF Channel Selector is turned to the position for UHF operation, the switch connects the antenna to the UHF tuner, turns off the VHF pilot light, turns on the UHF pilot light, and connects the output of the UHF tuner to the antenna input of the VHF tuner. When the VHF Channel Selector is turned to any VHF position, the switch connects the antenna to the VHF tuner, turns off the UHF pilot light, turns on the VHF pilot light, and places a 150,000-ohm resistor in series with the UHF oscillator plate, as explained above.

ADAPTER CABLES AND PLUGS

The adapter plugs shown in the schematic diagram are not used in factory-installed units; the cables are wired directly into the chassis at the proper places. The plugs are used only in field-installed units. (Refer

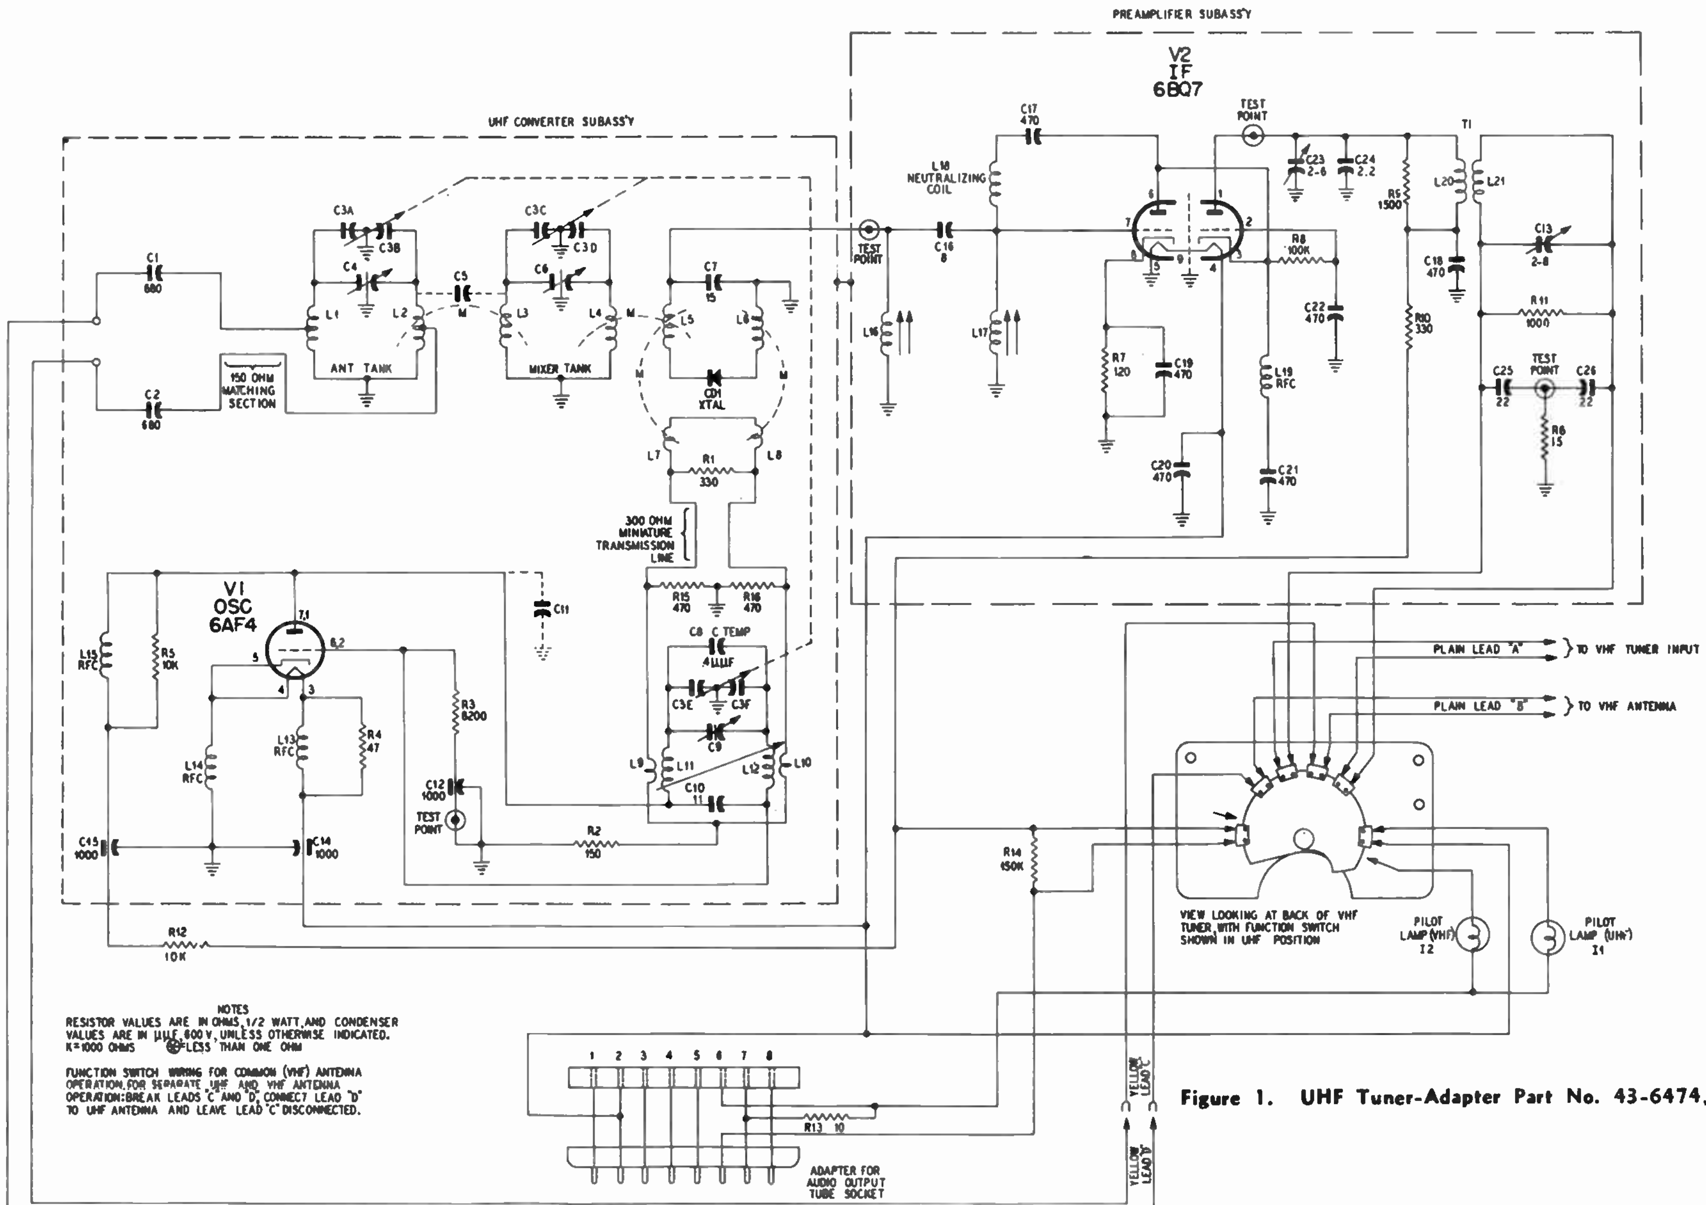


Figure 1. UHF Tuner-Adapter Part No. 43-6474, Schematic Diagram

to steps 10 and 11 of the installation instructions given below.)

PLANETARY DRIVE

The UHF tuner is tuned by means of a 3-gang tuning condenser, which is driven through a specially designed planetary drive. The planetary drive is constructed so that fine tuning and coarse tuning can be accomplished with a single control knob. The tuning shaft is coupled to the driving shaft through three balls, which form a planetary drive that produce slow rotation for fine tuning. See figure 2. After rotating 180 degrees with the tuning shaft, a pin engages the driving shaft, and the two shafts are direct-coupled, for coarse tuning. To re-engage the planetary drive for fine tuning, it is only necessary to reverse the direction of the rotation. The dial pointer is connected to the tuning gang through a cord drive, and indicates the channel number to which the tuner is tuned.

ALIGNMENT AND REPAIRS

The frequencies at which the Tuner-Adapter operates are extremely high; therefore it is necessary that the utmost care be taken to safeguard against upsetting the delicate adjustments of the tuner. It is recommended that the serviceman make only minor repairs to the tuner, such as replacement of the tube or crystal and the wiring of external leads. The Tuner-Adapter should be returned to the factory for alignment and major repairs, unless the serviceman is properly equipped to perform these jobs. In general, a good rule to follow is not to remove the cover of the Tuner-Adapter.

NOTE: Replacing the tube with a new one may detune the tuner. If this occurs, try a number of tubes until one is found that will most nearly replace the original.

INSTALLATION INSTRUCTIONS

To install the UHF Tuner-Adapter on the r-f chassis, proceed as follows:

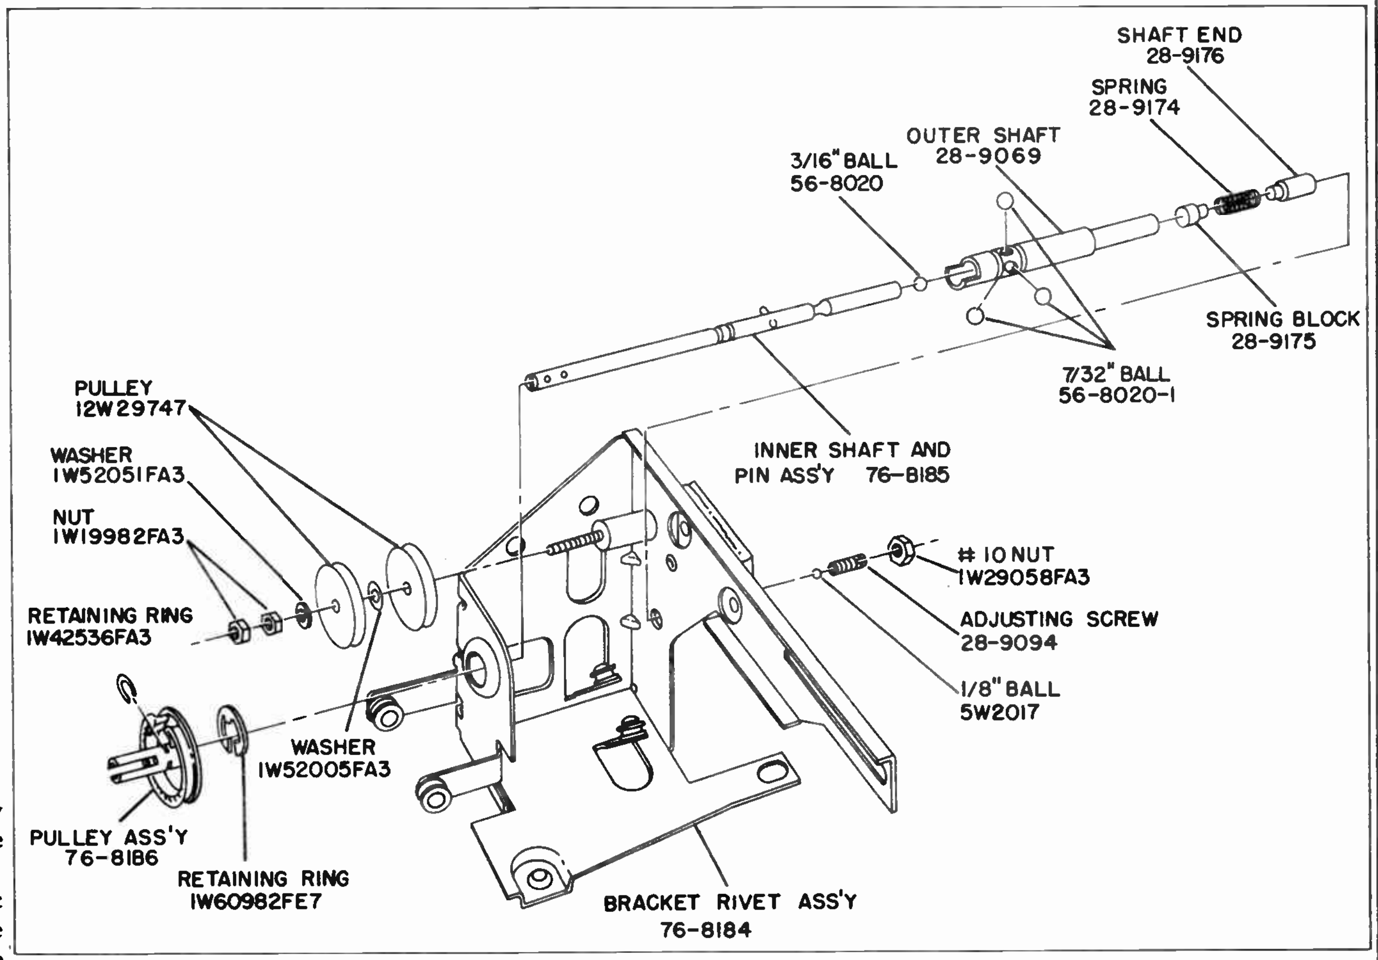
1. Remove the cabinet back and r-f chassis from the cabinet. Then remove the nameplate on the control panel by pushing it out from inside the cabinet.
2. Attach the front chassis bracket to the r-f chassis with the two screws provided with the tuner. See figure 4.
3. Attach the rear support angle to the r-f chassis with the two screws provided. See figure 4.
4. Measure the distance between the centers of the shaft hole for the contrast-brightness control and the center hole (previously covered by the nameplate) on the control panel. Mount the UHF tuner assembly loosely on the r-f chassis with the screws, nut, and washers provided; then slide the UHF tuner so that the distance between the centers of the UHF shaft and contrast-brightness shaft is equal to the distance between the centers of the two holes in the control panel. Make certain that the fish paper insulator is in place over the mounting arm of the tuner assembly. See figure 5. Fasten the UHF tuner securely in place.
5. Put the spacers on the mounting studs, and attach the mounting studs to the rear of the VHF tuner, on the r-f chassis. See figure 6.
6. Place the switch-actuator assembly on the shaft extending from the rear of the VHF tuner, with the switch-actuator stud pointing away from the tuner. See figure 6.
7. Place the switch assembly on the mounting studs, and fasten it in place with the fiber washers, lock washers, and nuts provided. See figure 6.

   NOTE: In some cases the switch mounting hardware provided may be as shown in figure 7. If so, disregard steps 5 and 7, and mount the switch as shown in figure 7.

8. Put the VHF Channel Selector on the channel position to be used for UHF operation (Channel 2 or Channel 3). Rotate the switch actuator on the tuner shaft until the actuator stud throws the switch. Fasten the switch actuator in this position. Rotate the Channel Selector on either side of the UHF position, and check the switch operation, to make sure that the switch is thrown in the UHF position but not on either side of the UHF position. Lubricate the switch-actuator stud and the switch cam with cup grease.

   On factory-installed units, the switch actuator may have two studs, as shown in figure 8. If so, remove the one stud, as indicated in the drawing.

9. Remove the bulb and shield from the pilot-light assembly on the r-f chassis, and place them in the empty socket from the UHF tuner assembly. Tape up the old socket from the r-f chassis.
10. Remove the audio output tube (6K6GT in r-f chassis 81, or 6L6GA in r-f chassis 84), plug the octal adapter into the tube socket, and place the tube in the adapter socket. The octal adapter is wired to the switch.
11. Cut the antenna lead from the VHF tuner to about 3 inches in length, and remove about ½ inch of insulation from the end. Insert the bare ends of the wires into the twin-lead connector, and fasten them with the screws in the sides of the connector.
12. Install the UHF pilot-light clip inside the cabinet near the UHF tuner shaft hole, as shown in figure 9.
13. Fasten the dress lug to the chassis with the screw provided (see figure 5); then dress the leads except the 300-ohm twin leads, under the lug.
14. Install the chassis in the cabinet, and insert the pilot-light sockets into the pilot-light clips. The socket with the red leads must be installed in the UHF clip, and the socket with the brown leads, in the VHF clip.
15. Put the knob on the UHF shaft, and set the shaft in the extreme counterclockwise position. Then remove the knob.
16. Install the background plate and pointer over the UHF tuning shaft. The background plate has the two sides colored differently, so that the proper color may be chosen to harmonize with the cabinet color.



TP2-3182

Figure 2. Planetary Assembly, Exploded View, Showing Mechanical Layout (Both Tuner-Adapters)

17. Place the dial scale over the tuner shaft, and line up the holes in the dial background plate with the holes in the dial scale. Line up the dial scale with the front panel, and fasten the scale with the screws provided. Place the knob on the UHF tuner shaft. Replace the control knobs on the r-f chassis control shaft.
18. Replace the fish paper antenna-lead holder with the new holder provided. Fasten the new holder with the two nails provided, and then pass the twin-wire leads through the holes, as shown in figure 10.
19. Cut holes in the cabinet back, and fasten the antenna terminal board provided, as shown in the illustrations above (figures 11 through 15). Replace the cabinet back, and make the connections as illustrated, according to the type of antenna installation being used.
20. Paste the label provided over the outside-antenna instructions on the cabinet back.

UHF TUNER-ADAPTER PART No. 43-6473, FOR RECEIVERS USING R-F CHASSIS 91, 91R, 94 OR 94R

UHF Tuner-Adapter Part No. 43-6473 provides for the reception of UHF signals on television channels 14 through 83. It is designed for installation in Philco High-Fidelity Television Receivers using r-f chassis 91 or 94. The Tuner-Adapter may also be used in remote-control sets using r-f chassis 91R or 94R, if it is used in conjunction with Shaft Extension Adapter, Part No. 43-6476.

The Tuner-Adapter consists of a UHF tuner, a change-over switch, adapter cables and plugs, a planetary tuner driving assembly, and mounting hardware.

CIRCUIT DESCRIPTION

The UHF tuner converts the UHF signals to the intermediate frequency of the r-f chassis.

The incoming UHF signal is coupled through the antenna input line, and through two i-f traps, two 680-$\mu\mu$f. condensers, and a 150-ohm transmission line to the antenna tank of the tuner. See figure 19. The antenna tank is coupled to the mixer tank by means of the mutual coupling of L2 and L3 and the stray capacitance, C5. The desired signal is selected by tuning the antenna tank and the mixer tank to the correct frequency, and the signal is then coupled to the crystal mixer circuit by means of the mutual coupling of L4 and L5. The local-oscillator signal is generated by a 6AF4 tube, V1, and the associated circuit. The oscillator signal is coupled to the crystal mixer circuit by a 300-ohm, miniature transmission line and the mutual coupling of L7 to L5 and L8 to L6. The r-f signal and the oscillator signal are mixed in the crystal mixer circuit to produce a 45.75-mc. video carrier intermediate frequency signal. This signal is coupled to the VHF tuner through L18, a coaxial cable, and J500 on the VHF tuner. In UHF operation, the local oscillator of the VHF tuner is inoperative, and the r-f amplifier and mixer tubes of the VHF tuner operate as i-f amplifiers.

The two tanks of the UHF tuner, the antenna tank and the mixer tank, are used to prevent the i-f signal from feeding back to the antenna and interfering with other receivers. The two tanks pass incoming signals very readily, but do not pass the i-f signal.

CHANGE-OVER SWITCH

The change-over switch supplied with the Tuner-Adapter is used to switch from VHF to UHF, and vice versa. It is installed on the back of the VHF tuner, and is operated by an actuator mounted on the VHF tuner shaft. When the Channel Selector of the VHF tuner is turned to the UHF position, the change-over switch makes proper connections for UHF operation. In this position, the switch places a 150,000-ohm resistor in series with the VHF mixer plate, which drops the voltage on the plate of the tube.

(In the UHF position, the VHF Channel Selector places extra inductances in the VHF r-f and mixer circuits, permitting them to operate as i-f amplifiers, and it also removes the inductances from the VHF oscillator circuit, putting it out of operation.) The change-over switch also tuns off the VHF pilot light, turns on the UHF pilot light, and connects the antenna to the UHF tuner. When the VHF Channel Selector is turned to any VHF position, the change-over switch places a 150,000-ohm resistor in series with the UHF local-oscillator plate circuit, which drops the voltage applied to the plate, and puts the oscillator out of operation. The switch also turns on the VHF pilot light, turns off the UHF pilot light, and connects the antenna to the VHF tuner.

ADAPTER PLUGS

The adapter plugs shown in the schematic diagram are not used in factory-installed units; the cables are wired directly into the chassis at the proper places. The plugs are used only in field-installed units. (Refer to steps 9 and 11 of the installation procedure given below.)

The octal adapter is inserted into the audio output tube socket, and the tube is then inserted into the adapter socket. This adapter supplies B+ and filament voltages to the UHF tuner.

The B+ disconnect assembly of the r-f chassis is in series with the VHF mixer plate.

When the UHF tuner is installed, this socket and plug are separated, and the plug, which is connected to the VHF mixer plate, is plugged into the socket of the UHF tuner, so that, in UHF operation, the change-over switch can place a 150,000-ohm resistor in series with the VHF mixer plate. (The original socket of the B+ disconnect assembly is left disconnected, since it has no further function after the UHF tuner is installed.)

The antenna disconnect assembly is used to connect the VHF tuner antenna input to the change-over switch.

PLANETARY DRIVE

The UHF tuner is tuned by means of a 3-gang tuning condenser, which is driven through a specially designed planetary drive. The planetary drive is constructed so that fine tuning and coarse tuning can be accomplished with a single control knob. The tuning shaft is coupled to the driving shaft through three balls, which form a planetary drive that produces slow rotation for fine tuning. See figure 2. After rotating 180 degrees with the tuning shaft, a pin engages the driving shaft, and the two shafts are direct-coupled, for coarse tuning. To re-engage the planetary drive for fine tuning, it is only necessary to reverse the direc-

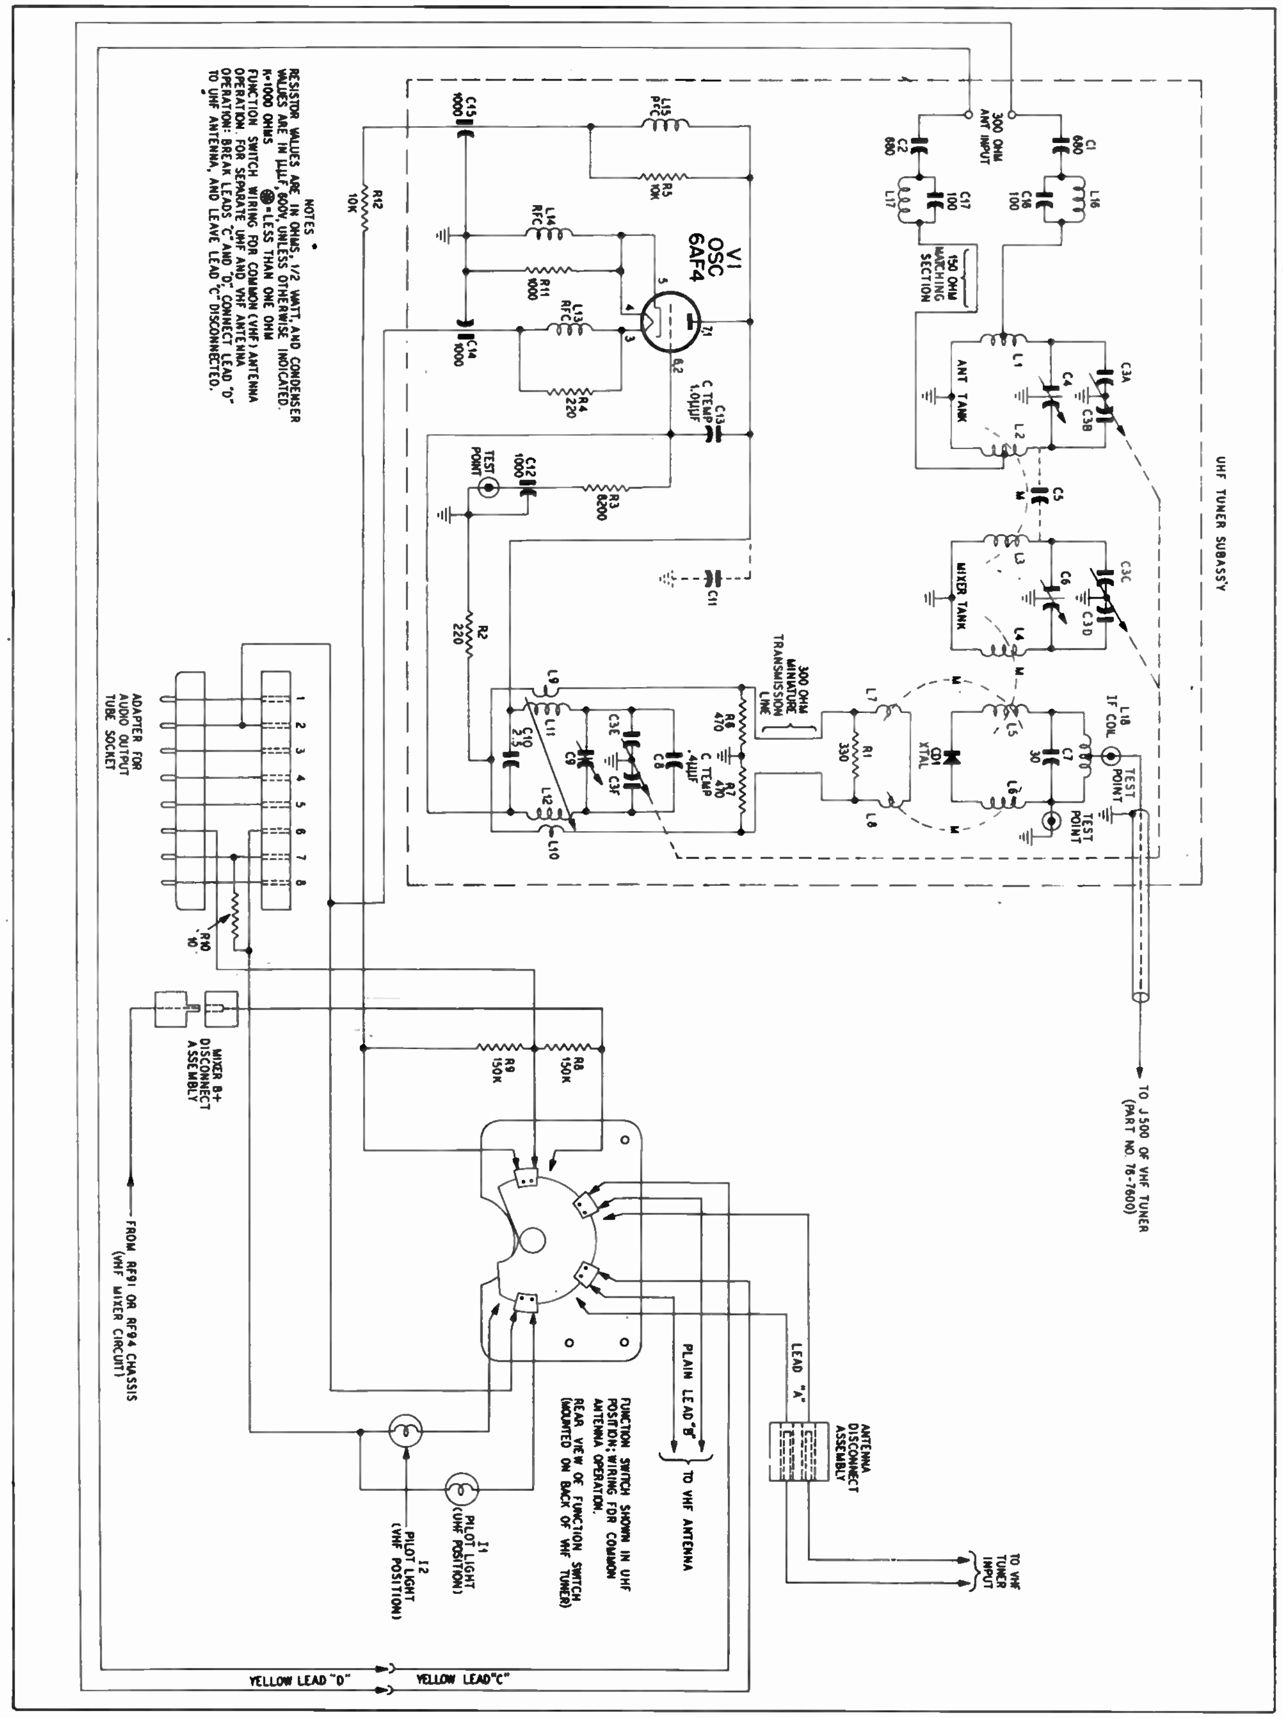

Figure 19. Philco UHF Tuner-Adapter Part No. 43-6473, Schematic Diagram

TP2-2669

tion of rotation. The dial pointer is connected to the tuning gang through a cord drive, and indicates the channel number to which the tuner is tuned.

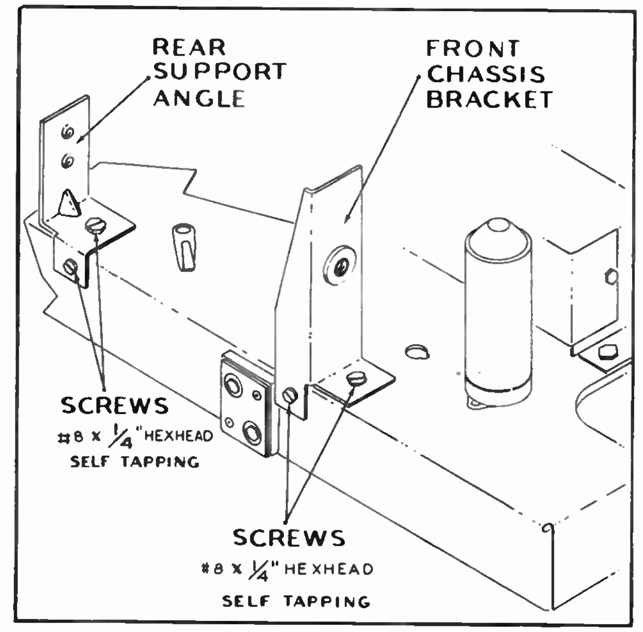
ALIGNMENT AND REPAIRS

The frequencies at which the Tuner-Adapter operates are extremely high; therefore, it is necessary that the utmost care be taken to safeguard against upsetting the delicate adjustments of the tuner. It is recommended that the serviceman make only minor repairs to the tuner, such as replacement of the tube or crystal and the wiring of external leads. The Tuner-Adapter should be returned to the factory for alignment and major repairs, unless the serviceman is properly equipped to perform these jobs. In general, a good rule to follow is, not to remove the cover of the Tuner-Adapter.

NOTE: Replacing the tube with a new one may detune the tuner. If this occurs, try a number of tubes until one is found that will most nearly replace the original.

INSTALLATION INSTRUCTIONS

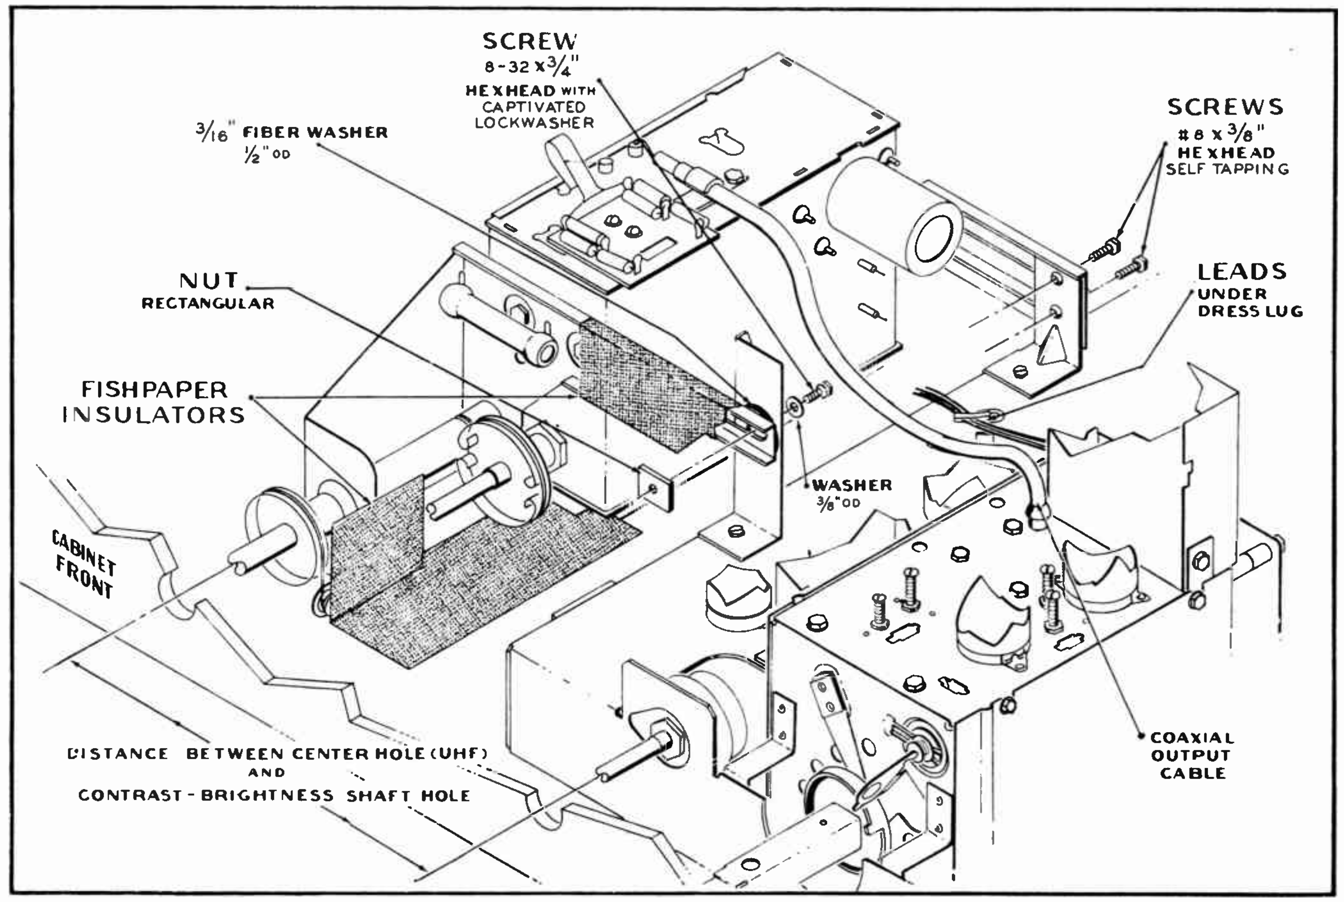
To install the UHF Tuner-Adapter on the r-f chassis, proceed as follows:



TP2-2578A

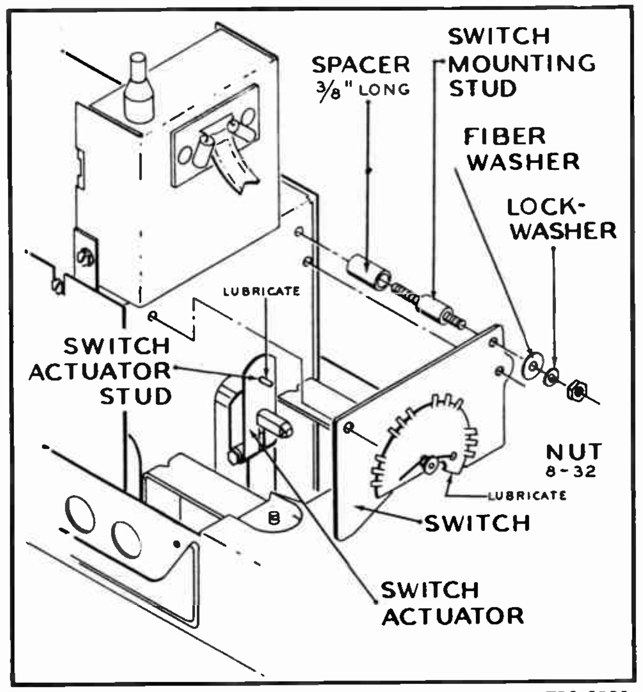
Figure 20. Placement of Mounting Brackets on R-F Chassis (Tuner-Adapter Part No. 43-6473)

1. Remove the cabinet back and r-f chassis from the cabinet; then remove the nameplate on the control panel by pushing it out from inside the cabinet.



TP2-2579A

Figure 21. UHF Tuner-Adapter Part No. 43-6473, Mounted on R-F Chassis



TP2-2580

Figure 22. Change-Over Switch Mounting Details (Tuner-Adapter Part No. 6473)

2. Attach the front chassis bracket to the r-f chassis with the two screws provided. See figure 20.

3. Attach the rear support angle to the r-f chassis with the two screws provided. See figure 20.

4. Measure the distance between the centers of the shaft hole for the contrast-brightness control and the center hole (previously covered by the nameplate) on the control panel. Mount the UHF tuner assembly loosely on the r-f chassis with the screws, nuts, and washers provided (see figure 21); then slide the UHF tuner so that the distance between the centers of the UHF tuner shaft and contrast-brightness shaft is equal to the distance between the centers of the two holes in the control panel. Make certain that the fish paper insulator is in place over the mounting arm of the tuner assembly. Fasten the UHF tuner securely in place.

5. Put the spacers on the mounting studs, and attach the mounting studs to the rear of the VHF tuner on the r-f chassis. See figure 22.

6. Place the switch-actuator assembly on the shaft extending from the rear of the VHF tuner with the switch-actuator stud pointing away from the tuner.

7. Place the switch assembly on the two mounting studs, and fasten it in place with the fiber washers, lock washers, and nuts provided. See figure 22.

NOTE: In some cases the switch mounting hardware provided may be as shown in figure 7. If so, disregard the procedure given in steps 5 and 7, and attach the switch as illustrated in figure 7.

8. Put the VHF Channel Selector in the Channel 2 position. Rotate the switch actuator on the tuner shaft (clockwise, as viewed from the rear of the chassis) until it just touches the edge of the movable portion of the switch. Secure the actuator in this position. Turn the VHF Channel Selector to the UHF position, and then to the Channel 13 position. Make sure that the switch contacts make proper contact in each position. If not, loosen the switch mounting screws and adjust the switch so that it functions properly. Recheck the switch on the Channel 2, UHF, and Channel 13 positions. Lubricate the switch-actuator stud and the switch cam with cup grease.

9. Open the B+ disconnect assembly (small plug and socket on r-f chassis, near rear of tuner), and plug the male connector from the r-f chassis into the socket from the switch. Tape up the old socket from the r-f chassis.

10. Remove the bulb and shield from the pilot-light assembly on the r-f chassis, and place them in the empty socket from the UHF tuner assembly. Tape up the old socket from the r-f chassis.

11. Remove the audio output tube (6V6GT in r-f chassis 91, or 6L6GA in r-f chassis 94), plug the octal adapter into the tube socket, and place the tube in the adapter socket. The octal adapter is wired to the switch.

12. Plug the UHF tuner coaxial output cable into the jack on the VHF tuner. See figure 21.

13. Cut the antenna lead from the VHF tuner to about 3 inches in length, and remove about ½ inch of insulation from the end. Insert the bare ends of the wires into the twin-lead connector, and fasten them with screws in the sides of the connector.

14. Dress all leads except the 300-ohm twin leads under the dress lugs, as shown in figure 21.

15. Install the UHF pilot-light clip inside the cabinet, near the UHF tuner shaft hole, as shown in figure 9.

16. Install the chassis in the cabinet, and insert the pilot-light sockets into the pilot-light clips. The socket with the red leads must be installed in the UHF clip, and the socket with the brown leads, in the VHF clip.

17. Put the knob on the UHF shaft, and turn the shaft until the pointer pulley shaft is in the extreme counterclockwise position; then remove the knob.

18. Install the background plate and pointer on the UHF tuner shaft. The background plate has the two sides colored differently, so that the proper color may be chosen to harmonize with the cabinet color.

19. Place the dial scale over the tuner shaft, and line up the holes in the dial background plate with the holes in the dial scale. Line up the dial scale with the front panel, and fasten the scale with the screws provided. Place the knob on the UHF tuner shaft, and replace the control knobs on the r-f chassis shafts.

20. Replace the fish paper antenna-lead holder with the new holder provided. Fasten the new holder with the two nails provided, and then pass the twin-wire leads through the holes, as shown in figure 10.

21. Cut the holes in the cabinet back, and fasten the antenna terminal board provided as shown in the illustrations above (figures 11 through 15). Replace the cabinet back, and make the connections as illustrated, according to the type of antenna installation being used.

22. Paste the label provided over the outside-antenna instructions on the cabinet back.

CIRCUIT DESCRIPTION

Philco 1953, Code 127, Television Receivers use two chassis—the r-f chassis 97, containing the r-f, video, audio, and sync circuits, and the deflection chassis J-7, containing the power and deflection circuits.

Since these chassis are not isolated from the 60-cycle power line, all protruding shafts and mounting feet are insulated from the chassis.

CAUTION: See A-C Line Isolation.

The r-f amplifier, oscillator, and mixer section is built on a separate subchassis. The r-f amplifier uses a 6BZ7 or 6BQ7 tube, V1. The oscillator and mixer each use one half of a 12AZ7 tube, V2. The output of the mixer is fed to a four-stage i-f amplifier system employing four 6CB6 tubes, V3, V4, V5, and V6. A 1N64 crystal diode is used for the video detector. One half of a 6U8 tube, V7A, is used as the first video amplifier, which feeds into a 6AQ5 video output amplifier, V8.

Sound i-f (intercarrier) is obtained by utilizing the beat frequency produced when the 45.75-mc. video carrier and the 41.25-mc. sound carrier are mixed in the video detector. The beat frequency, 4.5 mc., is the difference between 45.75 mc. and 41.25 mc., and contains the FM sound signal. This 4.5-mc. signal contains only a negligible amount of the video amplitude modulation, provided that the amplitude of the 41.25-mc. signal is considerably lower than that of the 45.75-mc. signal. The proper relative amplitude of the two carriers is established in the alignment of the receiver. There is sound output only when both the video and sound carriers are present.

The oscillator is tuned primarily to obtain the best picture, since the 4.5-mc. relationship always exists between the two carriers. The 4.5-mc. sound i.f. (intercarrier), which is taken from the video detector, is amplified by a 6BA6 tube, V9, and a 6AU6 tube, V10, and is fed to the FM detector, which utilizes two diode sections of a 6T8 tube, V11A. The triode section of the 6T8 tube, V11B, is used as the first audio amplifier. The power amplifier uses a 6L6GA tube, V12.

A-G-C voltage for the video i-f system and the r-f amplifier is obtained from a keyed a-g-c system which uses a 6AU6 tube, V13, as the a-g-c gate. Composite video from the video amplifier plate circuit, V7A, is fed to the grid of the a-g-c gate tube, while a gating or keying pulse, obtained from a winding on the horizontal-output transformer located on the deflection chassis, is applied to the plate. The sync-pulse polarity applied to the grid of V13 is positive; therefore, the a-g-c gate can conduct in proportion to the amplitude of the sync-pulse tips if the gating or keying pulse occurs at the same time as the sync. Because the keying, or gate pulse, is of constant amplitude (approximately 500 volts peak), the amplitude of the sync pulse determines the amount of conduction in the gate tube. The plate current of the keyed a-g-c gate tube flows through R220, R219, and R218, developing a voltage which is negative with respect to the chassis, and is proportional to the plate current. This negative voltage is used to control the gain of the receiver. Since conduction cannot occur in the a-g-c gate tube unless the sync pulse and gating pulse occur at the same time, noise disturbances that occur during the intervals between sync pulses cannot affect the a-g-c voltage.

Composite video for the sync circuits is taken from the plate circuit of the video amplifier, V7A. The plate load of the video amplifier consists of two sections, R304 and R305. The full output of the amplifier is fed to the grid of the noise inverter, one half of a 12AU7 tube, V14B, and to the grid of the sync separator, one half of a 6U8 tube, V7B. The output developed across R305 only is fed to the grid of the a-g-c gate, a 6AU6 tube, V13. The noise inverter is operated with a low value of plate voltage and with high bias (applied to the cathode by a voltage-divider network), which keeps the tube beyond cutoff. When the composite video signal is applied to the grid of the noise inverter through C601, the sync appears as positive pulses, and noise which could affect the sweep circuits also appears as positive pulses. Harmful noise pulses usually have amplitudes far greater than that of the sync pulses and, therefore, drive the grid of the noise inverter positive sufficiently to allow conduction in the noise inverter plate circuit. To prevent the noise inverter from conducting during the sync pulse interval, the gated leveler, using one half of a 12AU7 tube, V14A, is used to clamp the sync pulses below the conduction level of the noise inverter. The gated leveler conducts only when the sync pulses and gating pulse occur at the same time, thus leveling the noise inverter input to the sync-pulse level.

The output of the noise inverter consists of negative-going noise pulses. It should be noted that the noise pulses which exceed the sync level have been passed and their polarity reversed by the noise inverter. The output of the noise inverter is now mixed with the composite video and fed to the grid of the sync separator. Since the composite video fed to the grid of the sync separator has positive sync polarity, the positive noise pulses carried with the composite video would be passed by the sync separator; however, the output of the noise inverter consists of these same noise pulses, but of opposite polarity. Thus, cancellation of the noise pulses is effected. The output of the sync separator contains only the sync pulses, which are fed to the deflection chassis through the connecting cable.

The phase splitter, using one half of a 12AU7 tube, V15A, inverts the sync polarity for proper triggering of the vertical oscillator. The vertical sync is separated from the horizontal sync by the integrator circuits, and is fed to the grid of the vertical blocking oscillator, which uses one half of a 12AU7 tube, V13B. The output of the vertical oscillator is amplified by the vertical-output amplifier, which uses a 6BQ6GT tube, V16. The output of this amplifier is applied to the vertical-deflection coils through the vertical-output transformer.

In addition to the vertical-sync output, two horizontal-sync outputs are taken from the phase splitter, one from the cathode, and the other from the plate circuit. These two outputs are of opposite polarity, and are fed to the two diodes of the phase comparer, a 6AL5 tube, V17; the negative pulses are fed to the cathode of V17B, and the positive pulses, to the plate of V17A. A portion of the horizontal sweep output voltage is taken from the horizontal-output transformer, and is fed to the plate of V17B and the cathode of V17A, for comparison of the horizontal-sync and horizontal-sweep voltages. When the sweep and sync are in phase, no voltage is developed across R800, but when the two signals are out of phase, a voltage is developed across R800. When this voltage is positive, it increases the frequency of the horizontal oscillator (a 12AU7 tube, V18); when the voltage is negative, it reduces the frequency of the oscillator. This action holds the horizontal oscillator in phase with the sync signal. The horizontal hold control, R811, adjusts the horizontal-oscillator frequency so that it may be controlled by the phase comparer. The output of the horizontal oscillator is fed to the horizontal-output amplifier, which uses a 6CD6G tube, V19. The horizontal-output tube feeds the deflection coils through the horizontal-output transformer. A 6V3 tube, V20, is used as the horizontal damper.

The second-anode voltage for the picture tube is supplied by two 1B3GT high-voltage-rectifier tubes, V21 and V22, connected in a voltage-doubler circuit. The B-plus voltage for the receiver is supplied by two selenium rectifiers, CR100 and CR101, in a full-wave voltage-doubler circuit, operating directly from the power line. Bias voltage is obtained across the filter choke which is in series with the negative side of the B-plus supply. The B-plus-boost voltage derived from the horizontal-damper circuit supplies higher B-plus voltage to the first anode of the picture tube. Filament current for all the tubes except the high-voltage rectifiers is supplied by a 117-volt, 60-cycle step-down transformer. Filament current for the high-voltage rectifiers is supplied by two windings on the horizontal-output transformer.

NOTE: The J-7 Chassis incorporates a protective high-voltage shorting switch (located on the rear of the high-voltage cage), which shorts the output of the 1B3GT high-voltage doubler-rectifier (V22) to ground when the cabinet back is removed. Do not attempt to operate the receiver with the cabinet back removed without first disabling this shorting switch. The switch can be disabled temporarily for service work by removing the two self-tapping screws at the bottom edge of the rear cover of the high-voltage cage, and propping up the rear cover.

IMPORTANT

A-C LINE ISOLATION

CAUTION: One side of the a-c line is connected to the chassis through C101, L100, and R104, in series. The other side of the a-c line is connected to the chassis through R100, F100, CR100, and C103, in series. Grounding the chassis will result in a short circuit across one or the other of these two branches in the voltage-doubler circuit. During servicing and alignment, it is desirable that an a-c line isolation transformer capable of handling at least 250 watts (Philco Part No. 45-9600) be used. Failure to use an isolation transformer will greatly increase the shock hazard, and may result in damage to the test equipment, or receiver, or both.

SPECIFICATIONS

CHANNEL TUNING — Twelve-channel, 13-position, wafer-switch incremental tuner; fine tuning of local oscillator

FREQUENCY RANGE — Television Channels 2 through 13 and U-H-F position

INTERMEDIATE FREQUENCIES
- Video carrier — 45.75 mc.
- Sound (intercarrier) — 4.5 mc.

TRANSMISSION LINE — 300-ohm, twin-wire lead

OPERATING VOLTAGE — 110 to 120 volts, 60 cycles, a.c.

POWER CONSUMPTION — 250 watts

TUBE COMPLEMENT

R-F 97 CHASSIS

Reference Symbol	*Tube Type*	*Function*

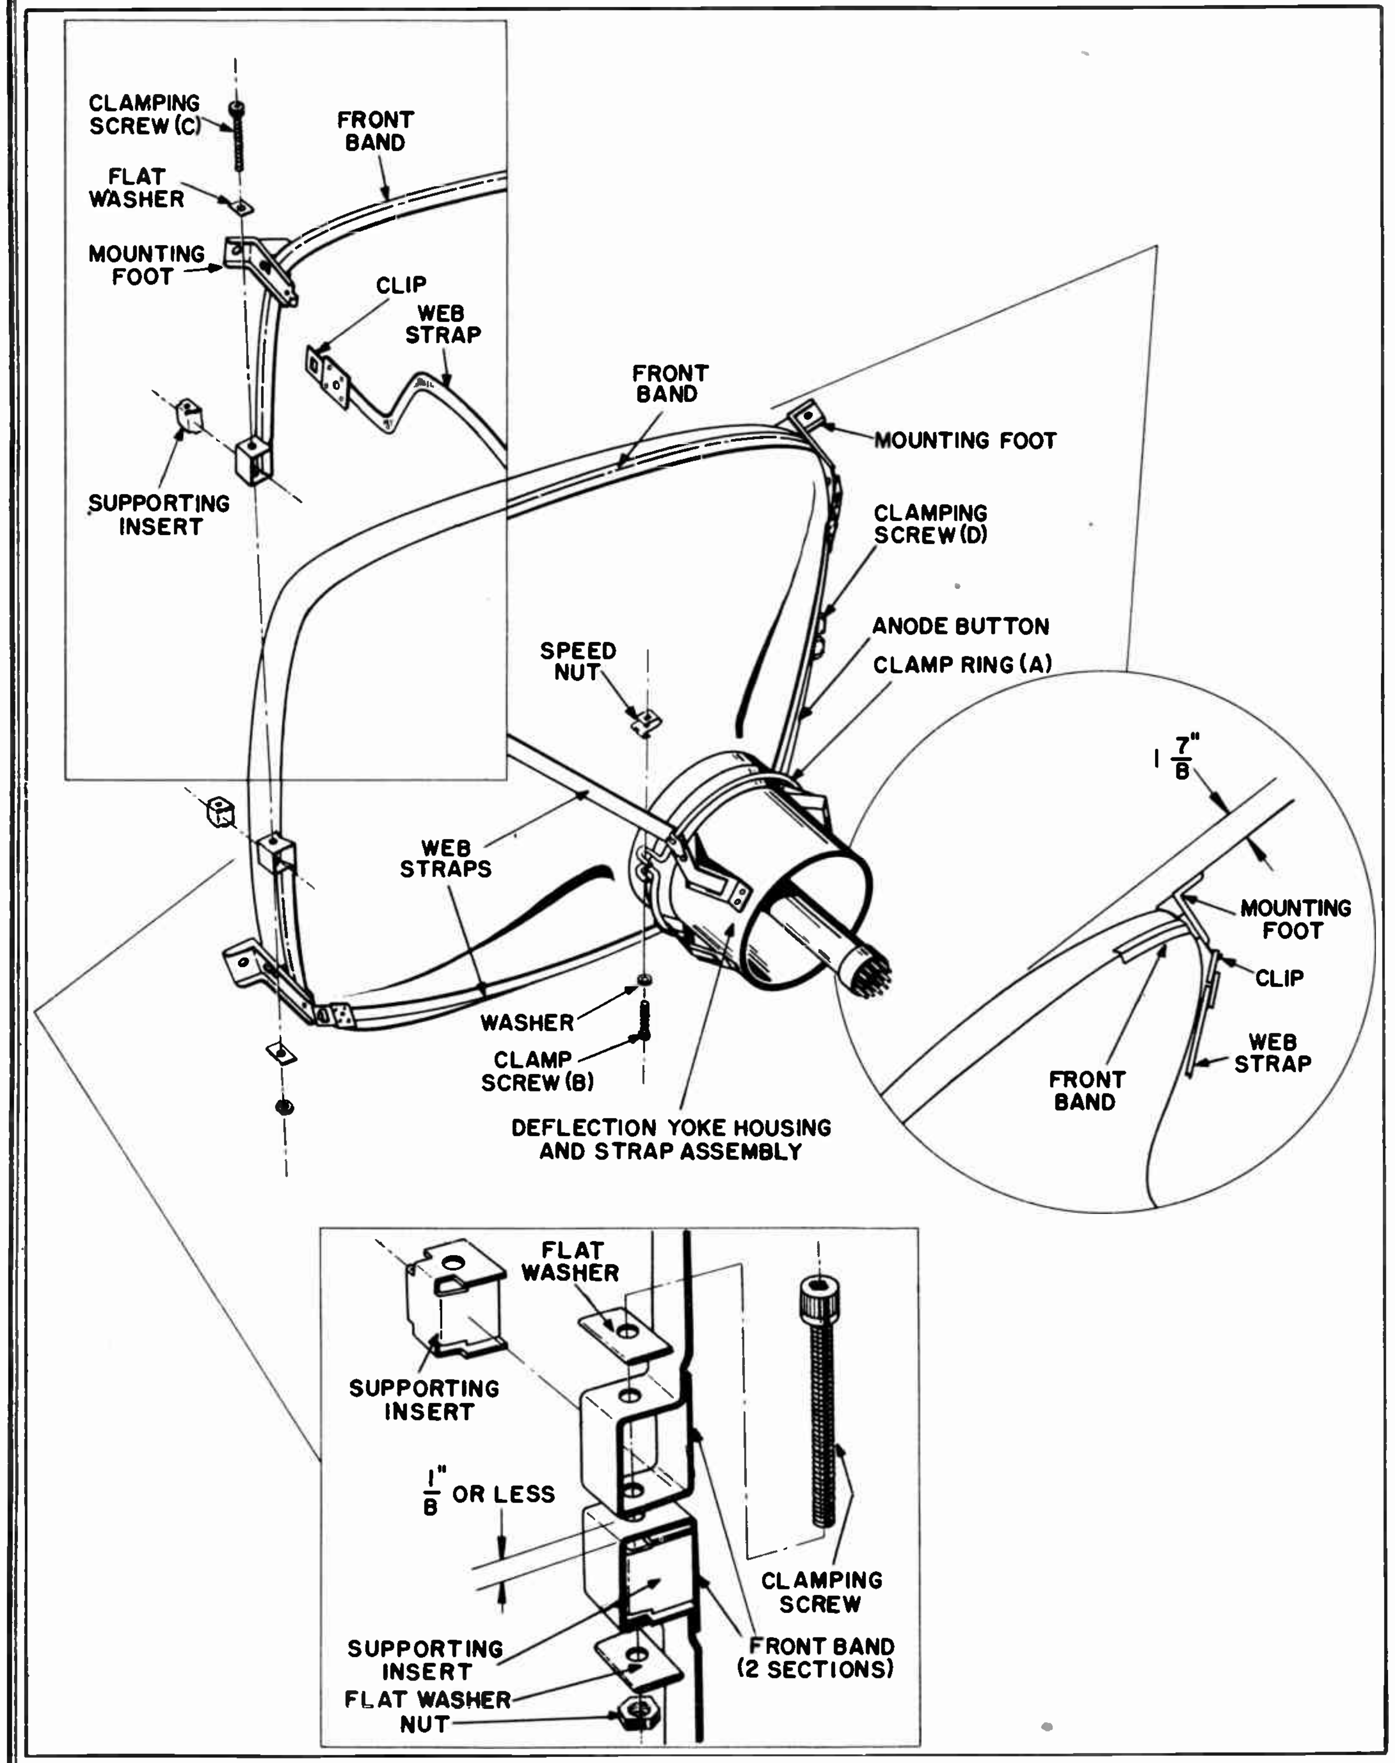

Figure 1. 27LP4 Picture-Tube Assembly

TP2-3264

REMOVING AND REPLACING 27LP4 PICTURE TUBE

GENERAL

The Philco 27LP4 picture tube is designed for a maximum of safety. Moreover, when properly mounted in the frame assembly, the picture tube is supported in such a manner as to provide a maximum of protection against breakage. Therefore, it is important that the tube be properly installed in its supporting frame. It is suggested that the service technician protect his eyes and the exposed parts of his body when handling all picture tubes. The removal and installation of the 27LP4 picture tube is quite safe if the procedure given below is followed.

> CAUTION: Because of the bulkiness and increased weight of the 27LP4 tube, as compared with that of the smaller picture tubes, replacement of the 27LP4 requires two men. These tubes are not delicate when handled in the proper manner; however, care must be taken not to mar the glass in any way, as surface scratches and chips weaken a glass structure considerably. Also, because of its weight, do not attempt to handle this tube by the neck.

PROCEDURE FOR REMOVING 27LP4 TUBE

1. Remove both the deflection chassis and the r-f chassis from the cabinet.

2. Lay the cabinet face-down on the floor, taking precautions against marring the cabinet.

3. Remove the four nuts and washers that secure the mounting feet of the assembly to the front of the cabinet.

4. Remove the two wood screws that secure the rear supporting struts of the tube assembly to the cabinet.

5. Remove the tube assembly (one man on each side of the cabinet).

6. Place the tube assembly face-down on a soft, protective cloth or mat, and slip the beam-bender magnet off the rear end of the tube. Referring to figure 1, loosen clamp ring (A) by means of clamp screw (B), unhook the four clips securing the web straps to the mounting feet, and lift the deflection-yoke housing and strap assembly (containing the deflection yoke and focus assembly) off the neck of the tube.

7. Mark the positions of the four mounting feet on the front band with a pencil or scriber (this is necessary because the mounting feet are free to slide, once the front band is loosened).

8. Loosen the two Allen head clamping screws (C) and (D) with a 5/16-inch Allen wrench, and remove the front band assembly.

PROCEDURE FOR INSTALLING 27LP4 TUBE

1. Place the picture tube face-down on a soft, protective cloth or mat, and position the front band assembly over the tube so that the lateral indentation in the band coincides with the welded seam around the outer edge of the tube's face plate.

Take up slack in the band, tightening both clamping screws (C) and (D) by hand.

> NOTE: If the front band is positioned correctly, the distance from the bottom edge of each mounting foot to the surface on which the tube is resting will be 1⅞ inches, as shown in figure 1.

2. Position the mounting feet, on the front band, to coincide with the marks previously made on the front band.

3. Tighten both clamping screws (C) and (D) alternately, using a 5/16-inch Allen wrench.

> NOTE: Take up on clamping screws (C) and (D) as tightly as possible. As can be seen from figure 1, the separation between the ends of the bands must be less than ⅛ inch, when tightened.

4. Slip the deflection-yoke housing and strap assembly (containing the deflection yoke and focus assembly) over the neck of the tube, and position it so that clamp screw (B) on clamp ring (A) is on the side of the tube opposite the anode button.

5. Place the clips (on the web straps) over the hooks on the four mounting feet, and tighten clamp ring (A) by means of clamp screw (B).

6. With the cabinet face-down on the floor, place the tube assembly in the cabinet (one man on each side of cabinet), and replace the four nuts and washers that secure the mounting feet to the front of the cabinet.

7. Replace the two wood screws that secure the rear supporting struts of the tube assembly to the cabinet.

8. Stand the cabinet upright, and install the r-f chassis, deflection chassis, and beam-bender magnet.

ADJUSTING 27LP4 PICTURE-TUBE ASSEMBLY

1. Mechanically center the focus assembly, over the neck of the tube, by adjusting the centering plate. It is important that the focus assembly and yoke be concentric with the tube neck for best focus and shadow clearance.

2. Set the HORIZ. CENTERING control (R824) to its extreme counterclockwise position, and set the BRIGHTNESS control for maximum brightness of the picture.

3. Adjust the beam bender for maximum brightness of the picture.

4. If necessary, loosen the wing nuts and rotate the deflection yoke, to correct for picture tilt. Make certain that the deflection yoke is as far forward as possible, and tighten the wing nuts.

5. Adjust the centering plate so that neck shadow is just eliminated on the right-hand side of the screen, at the same time keeping the picture centered vertically. Do not attempt to center the picture horizontally by means of the centering plate.

6. Adjust the FOCUS control (on focus assembly). Set the CONTRAST control for the proper level, and readjust the FOCUS control for the best over-all focus.

7. Repeat steps 3 and 5, if necessary.

8. Adjust the HORIZ. CENTERING control (R824) for proper horizontal centering of the picture.

9. Turn the BRIGHTNESS control slowly toward the minimum position, checking that shadow does not appear at any brightness level. If shadow does appear, repeat steps 5 and 8, and recheck.

B SUPPLY FUSE REPLACEMENT

The B supply protective fuse, F100, is wired into the low-voltage section, and is in series with the selenium rectifiers. For replacement, use a 1.6-ampere delayed-action-type fuse, Philco Part No. 45-2656-23.

CAUTION: Discharge the circuit before replacing the fuse.

HORIZONTAL-OSCILLATOR ADJUSTMENT

To adjust the horizontal-oscillator circuit, tune in a station and proceed as follows:

1. Reduce the width of the picture so that approximately one inch of blank screen appears at the right-hand and left-hand sides of the picture.

2. Increase the BRIGHTNESS control setting so that the blanking time becomes visible. This appears as a dark vertical bar at the right-hand and left-hand sides of the picture.

3. Connect a .1-μf. condenser from Test Point J802 to ground.

4. Set the HORIZ. HOLD control to the center of its mechanical rotation.

5. Adjust the HORIZ. HOLD CENTERING control to bring the picture into the center of the blanking bars. When the picture is centered in the blanking bars, the bars at the left-hand and right-hand sides of the picture will be of equal width.

6. Remove the .1-μf. condenser from the Test Point. (See step 3.)

7. Adjust the horizontal ringing coil, L800, until the picture is again centered in the blanking bar.

8. Rotate the HORIZ. HOLD control through its range. The picture should fall out of sync to both sides of the center of rotation. If the picture does not fall out of sync to both sides, readjust the HORIZ. HOLD CENTERING control to obtain fall-out to either side of sync.

9. Rotate the HORIZ. HOLD control through its range, and observe the number of diagonal blanking bars that are visible just before the picture pulls into sync. The pull-in should occur with from 1 to 2 diagonal bars when the sync position is approached from either direction. If proper pull-in is not obtained, repeat the above procedure.

VIDEO PEAKING COIL ADJUSTMENT

The video peaking coils, L305 and L307, are adjusted at the factory for proper transient response of the video amplifiers. Ordinarily, these coils will require no further adjustment by the serviceman except in cases where they have been tampered with, or where replacement becomes necessary. Under normal circumstances, when alignment of the tuner or i-f stages is undertaken, the video peaking coils should not require adjustment.

Before adjusting L305 and L307, check both the tuner and i-f alignment. (Never adjust L305 and L307 until the alignment of the receiver is correct.) Then tune in a station and adjust the receiver to give a picture of the best obtainable quality, with medium contrast. Turn the fine tuning control clockwise until a very slight beat pattern appears in the picture. Carefully observe the appearance of the picture regarding smear or overshoot (trailing whites). A small amount of overshoot may be desirable, to produce a sharper picture. Conversely, in weak-signal areas, a small amount of smear may be desirable, to reduce the harsh appearance of "snow". The adjustments of L305 and L307, and their effects on the picture, are as follows:

1. The amount of overshoot may be reduced by turning both TC302 and TC303 counterclockwise.

2. The amount of smear may be reduced by turning both TC302 and TC303 clockwise.

Normally the point of proper adjustment is where minimum smear and trailing whites appear in the picture; however, a compromise adjustment may be made to suit prevailing conditions. As a rule, when properly adjusted, the adjustment screws (TC302 and TC303) should protrude from the chassis by approximately ½ inch to ¾ inch.

TELEVISION ALIGNMENT PROCEDURE

General

The alignment consists of tuning each i-f coil to a given frequency, using an AM signal, then feeding in a sweep signal at the antenna terminals and touching up the adjustments to obtain the desired pass band.

The over-all response curve (r-f, i-f) of the circuits from the antenna terminals to the video detector, after the i-f stages have been aligned, should appear essentially the same, regardless of the channel under test. If not, the tuner should be aligned. Before aligning the tuner, refer to the CAUTION given under TUNER BANDPASS ALIGNMENT.

The video-carrier intermediate frequency is 45.75 mc., and the sound intermediate (intercarrier) frequency is 4.5 mc. Alignment of these circuits requires careful workmanship and good equipment. The following precautions must be observed:

1. There must be a good bond between the receiver chassis and the test equipment. This is most easily obtained by providing the workbench with a metallic top. The receiver chassis should be placed tuner-side-down on the bench. If the bench has no metallic top, the test equipment and chassis can be bonded by a strip of copper about 2 inches wide. The section of the chassis nearest the tuner should rest on the strip.

2. Do not disconnect the picture tube, picture-tube yoke, or speaker while the receiver is turned on.

3. Allow the receiver and test equipment to warm up for 15 minutes before starting the alignment.

4. The marker (AM) signal generator should be calibrated accurately to the sound and video r-f carriers of each channel used during alignment. If Model 7008 is used, the built-in crystal calibrator provides an excellent means of calibration. An alternate method of calibrating the signal generator to the sound and video r-f carrier frequencies is to zero-beat the signal generator with the received signals.

For further information concerning calibration, refer to Philco Lesson PR-1745 (J), entitled "Television Service in the Home."

Test Equipment Required

The following test equipment is recommended for aligning the receiver:

1. Philco Precision Visual Alignment Generator for Television and FM, Model 7008, or equivalent.

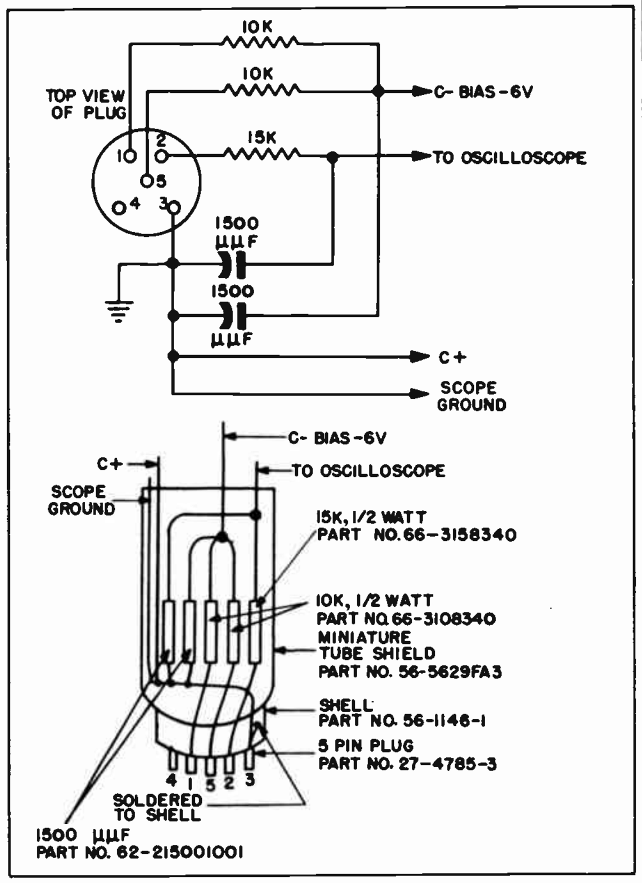
2. Vacuum-tube voltmeter, or 20,000-ohms-per-volt voltmeter.

3. R-F Probe, Philco Part No. 76-3595 (for use with Model 7008 generator).

Jigs and Adapters Required

Mixer Jig

Connections to the grid of the mixer tube may be made through the alignment jack provided for this purpose. To connect the generator to this point, a mixer-grid jig, Philco Part No. 45-1739, and a connecting cable, Philco Part No. 45-1635, may be used. As an alternate, a Philco alligator-clip adapter, Part No. 45-1636, with as short a ground lead as possible, may be used to connect the alignment jack. The ground lead should be connected as close as possible to the mixer tube. It is essential that the signal-generator output lead be terminated with a 68-ohm carbon resistor (used with alligator-clip adapter only), so that any regeneration caused by connection of the lead to the mixer is held to a minimum.



TP2-1507-A

Figure 2. Video I-F Alignment Jig (VIDEO TEST Jack Adapter No. 1)

Antenna-Input Matching Network

An impedance-matching network for coupling the signal generator to the antenna-input terminals of the receiver is shown in figure 2 on page 5 of Service Manual PR-2170. This network, which is designed to have an input impedance of 75 ohms and an output impedance of 300 ohms, is used to match a 75-ohm generator to a 300-ohm antenna-input circuit. The resistors used in this network should be of carbon-composition construction, and should be chosen from a group, to obtain values within 10% of those indicated. The resistors should be placed in a shield can, to prevent variable effects. An antenna-matching jig, Philco Part No. 45-1736, which consists of a matching transformer and connecting box, may be used in place of the resistor network.

Video I-F Alignment Jig (VIDEO TEST Jack Adapter No. 1)

The alignment jig shown in figure 2 should be used during the i-f alignment, to apply the proper bias to the a-g-c bus, and to provide a convenient oscilloscope connection. This adapter consists of a 5-prong plug, two 10,000-ohm resistors, and a 1500-$\mu\mu$f. condenser for isolation of the bias supply. To isolate the oscillo-

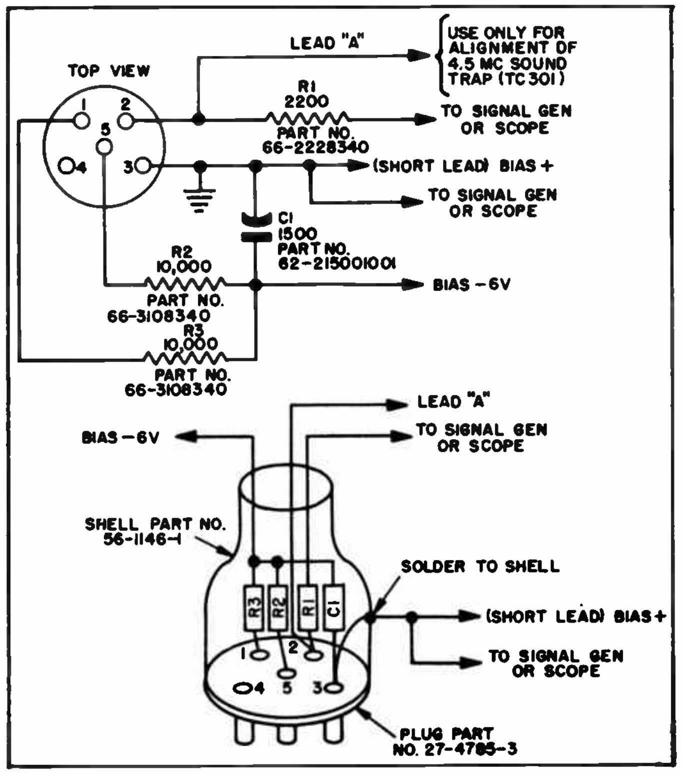


Figure 3. Sound I-F Input Alignment Jig (VIDEO TEST Jack Adapter No. 2

scope from the receiver circuits, a 15,000-ohm resistor, by-passed by a 1500-$\mu\mu$f. condenser, is used. A suggested method of fabricating the jig is also shown in figure 2. This jig should not be used to observe the composite video from the video-detector output.

Sound I-F Input Alignment Jig (VIDEO TEST Jack Adapter No. 2)

To observe the composite video, a jig may be made with a 5-pin plug and a 2200-ohm resistor. See figure 3. The 2200-ohm resistor should be connected to pin 2 of the plug. A ground lead should be connected to pin 3. For convenience in applying bias to the a-g-c circuits, a lead should be connected to pin 5. To observe the composite video, connect the oscilloscope to the 2200-ohm resistor and the ground lead. This jig is also used for injection of the 4.5-mc. signal during sound i-f alignment.

Sound I-F Output Alignment Jig (FM Test Point and Volume Control Socket Adapter)

Figure 4 shows the adapter that should be used to connect the voltmeter to the FM detector through the Volume Control socket (J401) and FM Test Point (J403). The adapter should be inserted into the Volume Control socket, and the clip lead from the adapter connected to the FM Test Point. The Volume Control cable and plug (PL401) is inserted into the socket on top of the adapter.

TELEVISION TUNER ALIGNMENT

After the tuner is serviced, or if an i-f alignment is required, the tuner alignment should be checked. If realignment is necessary, use the procedure given below.

Since the frequency of the local oscillator affects the tuner response, the local-oscillator alignment should be made first.

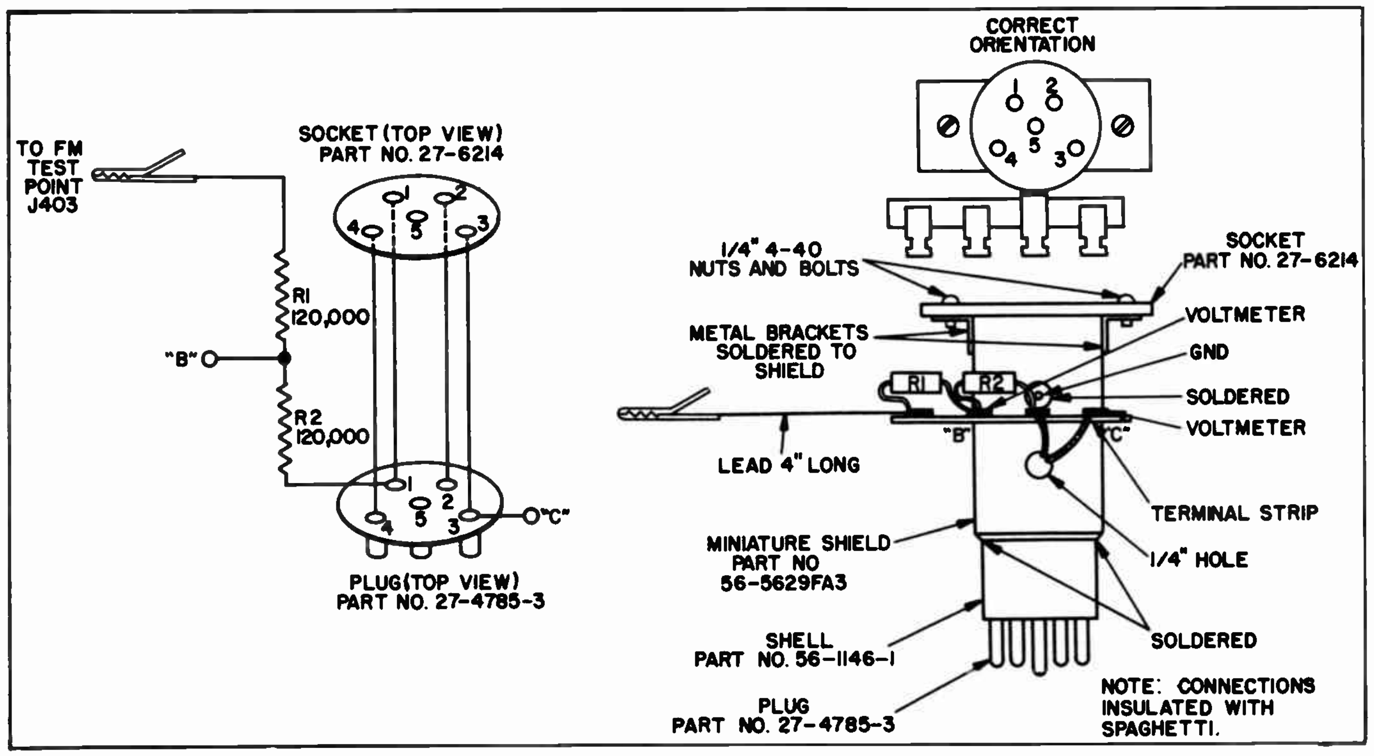

Figure 4. Sound I-F Output Alignment Jig (FM Test Point and Volume Control Socket Adapter)

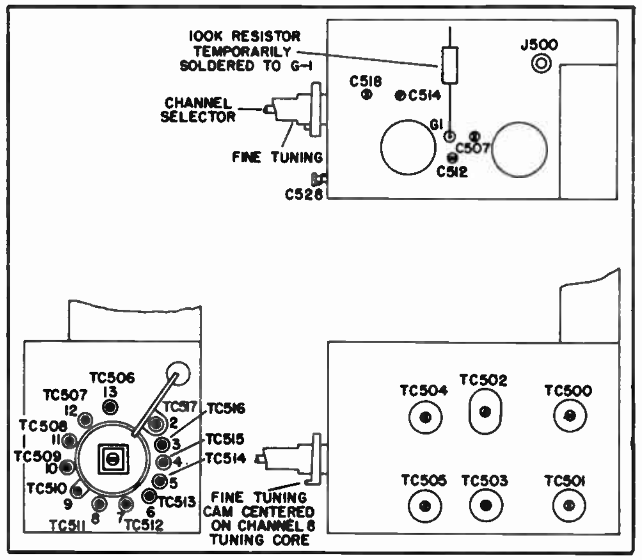

Figure 5. Television Tuner, Showing Location of Adjustments

OSCILLATOR ALIGNMENT

General

It is possible to place each channel exactly on frequency by adjusting the tuning core of each coil. The adjustment procedure should be carried out with the highest-frequency channel (13) first, since the alignment of each channel will affect the alignment of the channels below it in frequency. The FINE TUNING control should be preset for all adjustments by placing the stop on the fine-tuning cam at the Channel 8 oscillator tuning core. See figure 5.

Procedure Using Signal Generators

An r-f signal (unmodulated), at the video carrier frequency of the channel, is fed into the antenna input, and an i-f signal, at the i-f carrier frequency is fed to the first i-f amplifier. Two AM signal generators are used to supply the above signals. An oscilloscope is connected to the video detector output. The oscillator core is then adjusted for zero beat on each channel. The two generators should be accurately calibrated, as described in Philco Lesson PR-1745(J).

To align the oscillator, proceed as follows:

1. To observe the zero beat, connect the oscilloscope to the video-detector output through the video i-f alignment jig. See figure 2. Bias the tuner and the i-f a-g-c circuits with 1.5 volts, and remove the Gate Pulse Plug, PL801, from the socket, J801. To apply bias to the tuner, connect the battery to the white lead which comes out of the top of the tuner. On later runs of this tuner, the white a-g-c lead connects to a feed-through condenser on top of the tuner. To make certain that good connection is made to the tuner a-g-c circuit, remove the glyptol coating on this condenser terminal before connecting the bias battery.

2. To feed in the i-f comparison signal, remove the shield from the first v-i-f tube and wrap several turns of insulated copper wire around the tube. Connect the output leads of the v-i-f signal generator to the two ends of the wire loop, and set the generator for unmodulated output at 45.75 mc.

3. To feed in the signal representing the channel frequency, set the r-f signal generator to the video carrier frequency of Channel 13, and connect the output to the antenna terminals of the receiver, through the proper matching jig.

4. Mechanically preset the fine-tuning cam, as shown in figure 5, and set the CHANNEL SELECTOR to Channel 13.

5. Adjust the Channel 13 tuning core for zero beat, as indicated by the oscilloscope.

6. Retune the r-f signal generator and the CHANNEL SELECTOR for Channels 13, then 11, etc., each time adjusting the respective tuning core for zero beat. The tuning cores should be adjusted progressively from the highest-frequency channel to the lowest, because the higher channel adjustments will affect the lower channels.

Procedure Using Station Signal

The following simplified procedure may be used to align the oscillator when the television i-f alignment is satisfactory and a station signal is available. If this procedure is used in the service shop, signals from all stations which the customer can receive must be available in the service shop.

1. Mechanically preset the fine-tuning cam to the center of its range. See figure 5.

2. Tune in the highest-frequency channel to be received, and adjust the tuning core for that channel for the best picture; that is, starting with sound in the picture, turn the tuning core until the sound in the picture just disappears.

3. Repeat step 2 for each channel received in the area, starting with the highest-frequency channel and finishing with the lowest.

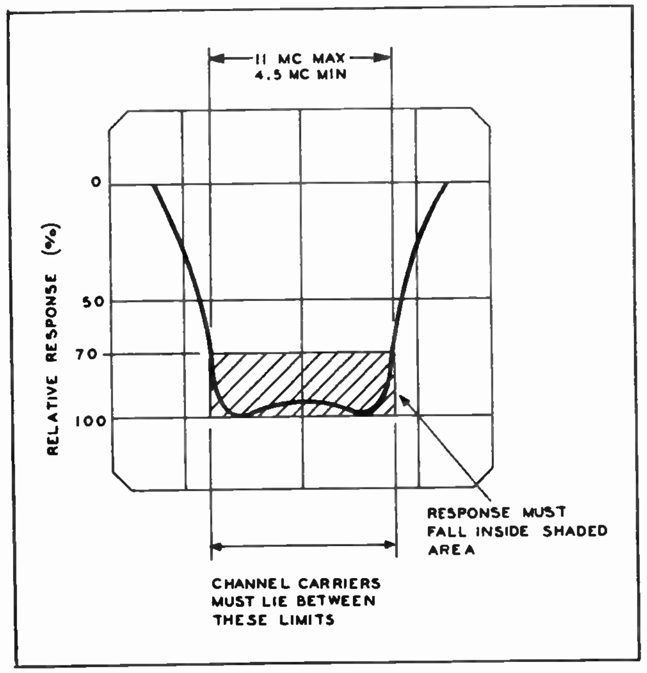
TUNER BANDPASS ALIGNMENT

General

The bandpass alignment consists of aligning the tuner at Channels 13 and 6, and then making it track properly.

During the alignment, a fixed bias of 1.5 volts is applied to the r-f amplifier tube through the white a-g-c lead.

An FM (sweep) signal is applied to the antenna-input circuit through the proper matching jig, and an oscilloscope is connected through a 100,000-ohm resistor to the mixer-grid test point. The oscilloscope gain should be as high as possible, consistent with hum level and "bounce" condition. Hum conditions will cause distortion of the time base and response. Bounce conditions will cause the response and the time base to jump up and down, and is caused by poor line regulation. The use of too high an oscilloscope gain aggravates these conditions, whereas the use of too low a



TP9-512B-1

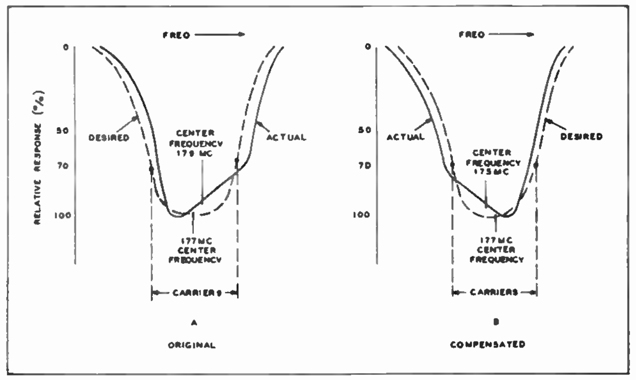
Figure 6. Television Tuner Response Curve, Showing Bandpass Limits

gain necessitates increasing the generator output to a point where the tuner may be overloaded. The scope controls should be adjusted so that the width of the presentation is 2 times the height. Overload may then be checked by changing the generator output while observing the shape of the response curve. When the generator output is changed, the vertical gain of the oscilloscope should be readjusted, to keep the scope presentation amplitude the same. Do not readjust the horizontal gain control. Any flattening of the curve indicates overload, in which case a lower generator output and higher oscilloscope gain must be used.

The signal-generator output must be properly matched to the antenna input of the tuner.

Correct alignment cannot be obtained without the use of a suitable matching jig.

Regeneration or a mismatch in the test setup will also make it impossible to obtain correct alignment. To check for these conditions, move the hand along the generator cable, after all equipment is connected, and observe the response curve on the oscilloscope screen. If the response curve changes as the hand is moved along the cable, regeneration or mismatch is indicated. Another check may also be made with the volume control advanced until noise can be heard from the speaker. If the level of the noise changes as the hand is moved along the generator cable, regeneration or mismatch is indicated. The symptoms which indicate these conditions may also be caused by failure to use the proper matching jig, as described above.



TP0-1174

Figure 7. Television Tuner Response Curve, Showing Tracking Compensation

CAUTION: When comparing the response curves from channel to channel, maintain the 2-to-1 width-to-height relationship in the oscilloscope presentation, as described above.

Procedure

1. Connect the FM (sweep) and AM marker generators to the 300-ohm antenna input through an antenna-input matching jig.

2. Connect the oscilloscope to the mixer-grid test point through a 100,000-ohm, one-half watt resistor, as shown in figure 5. Connect the ground lead of the oscilloscope as close to the mixer tube as possible.

3. Apply 1.5 volts bias to the white tuner a-g-c lead.

4. Disconnect the tuner coupling link at wiring panel B-13, terminals 1 and 4, and solder a 68-ohm, one-half watt carbon resistor to the open link coming from the tuner. See figure 7. Remove the first i-f tube from the socket.

5. Set the CHANNEL SELECTOR and FM (sweep) generator to Channel 13 (213 mc.). Adjust the generator for sufficient sweep width to show the complete response curve.

6. Establish the channel limits (see figure 6) by using the marker (AM r-f) signal generator to produce marker pips on the response curve. (Set the marker generator first to 210 mc., then to 216 mc.) The response curve should be reasonably flat between the limits.

7. Adjust TC502 and TC504 (figure 5) for a symmetrical, approximately centered pass band. Set the marker generator to 213 mc. Detune TC504 counterclockwise until a single peak appears. Adjust TC502 until the peak falls on the 213-mc. marker. (It may be necessary to increase the output of the generator during this adjustment.) Then adjust TC500 for maximum curve height and symmetry of the single peak. The antenna circuit is now tuned for the high-band channels.

NOTE: On later runs of the tuner, L506 is not tunable and TC500 is omitted; therefore, the adjustments in step 7 should be confined to TC502 and TC504 when later run tuners are encountered.

8. Readjust TC502 and TC504 for a symmetrical response, centered about 213 mc., and falling within the specifications, as shown in figure 6.

9. Set the CHANNEL SELECTOR and FM generator to Channel 7 (177 mc.). Establish the channel limits by using the marker signal generator to produce marker pips on the response curve. (Set the marker generator first to 174 mc., then to 180 mc.) The curve should be reasonably flat between the limits.

10. On Channel 7, observe the tilt and center frequency of the response curve. The curve should be centered on the pass band, and should be symmetrical. If it is not symmetrical, and appears unbalanced, as in figure 7, adjust C507 and C512 (figure 5) to obtain a response curve which is the mirror image (tilt in the opposite direction) of the original; for example, if Channel 7 response curve appears as in figure 7A, adjust C506 and C514 until the curve appears as in figure 7B. This adjustment overcompensates, to make allowance for the effect of Channel 13 adjustments (to be made in step 11) upon Channel 7 response.

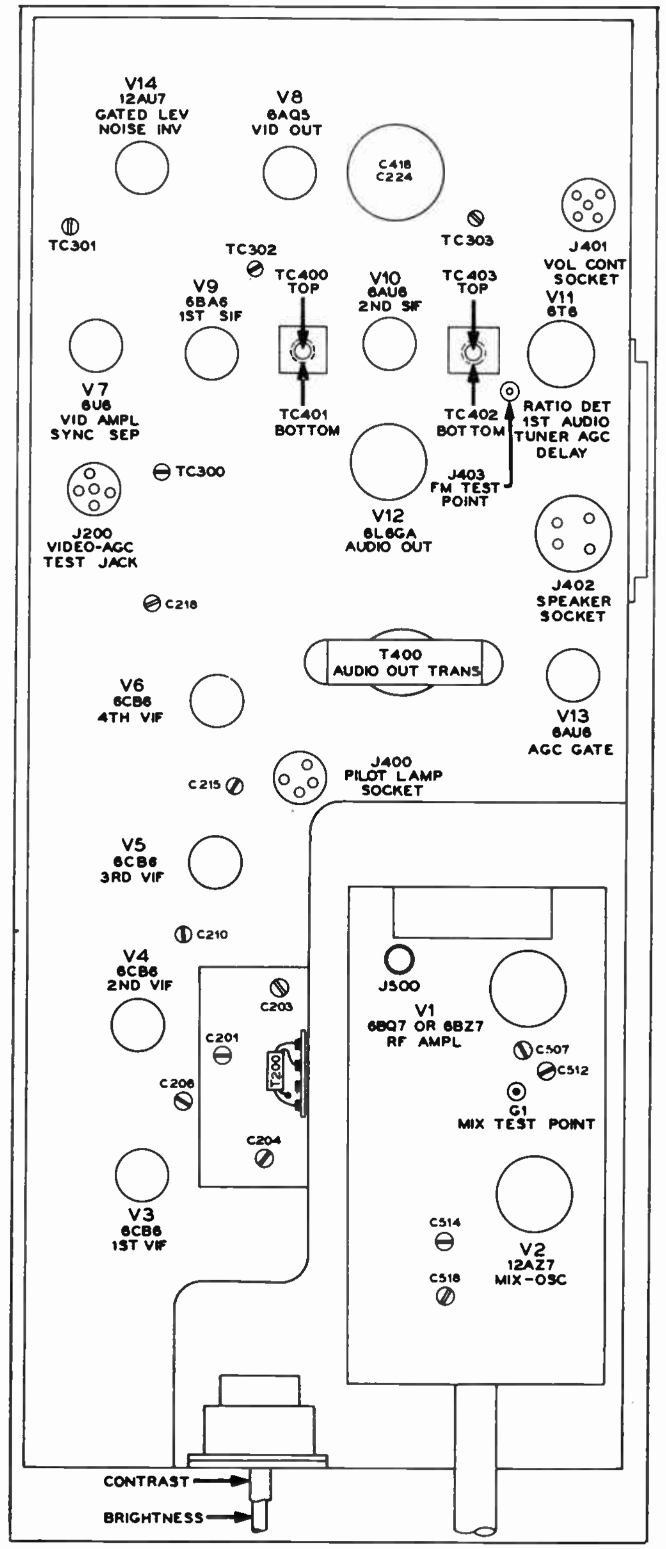
11. Reset the CHANNEL SELECTOR and generators to Channel 13, and repeat steps 8 through 10 as many times as necessary to obtain the most symmetrical and centered response curves on Channels 13 and 7. Channels 7 through 13 are now correctly aligned.

12. Set the CHANNEL SELECTOR and sweep generator to Channel 6 (85 mc.).

13. Establish the channel limits, using the marker generator to produce marker pips on the response curve. (Set the marker generator first to 82 mc., then to 88 mc.)

14. Adjust TC503 and TC505 for a symmetrical, approximately centered pass band. Set the marker generator to 85 mc. Detune TC505 counterclockwise until a single peak appears. Adjust TC503 until the peak falls on the 85-mc. marker. It may be necessary to increase the output of the generator during this adjustment. Then adjust TC501 for maximum curve height and symmetry of the single peak. The antenna circuit is now tuned for Channels 2 through 6.

15. Readjust TC503 and TC506 for a symmetrical response, centered about 85 mc., and falling within the specifications, as shown in figure 6. Channels 2 through 6 are now correctly aligned.



TP2-3191

Figure 8. R-F Chassis 97, Top View, Showing Location of Adjustments

VIDEO I-F ALIGNMENT

PRELIMINARY

Before proceeding with the i-f alignment or making an alignment check, observe the following preliminary instructions:

1. Preset the CONTRAST and BRIGHTNESS controls to the maximum counterclockwise position.
2. Preset the CHANNEL SELECTOR to Channel 4.
3. Insert the video i-f alignment jig into J200.
4. Connect the oscilloscope to the 15,000-ohm resistor from the video i-f alignment jig. Connect the ground lead of the oscilloscope to the ground lead from the adapter.
5. Connect a 6-volt battery to the a-g-c test jack, with the negative terminal to the bias lead and the positive terminal to the ground lead.
6. Connect the AM generator to the mixer-grid

test point, G1, through a mixer jig, and adjust the generator for approximately 30 percent modulation at 400 cycles.

NOTE: If the i-f shield has been removed for repairs, it must be replaced before proceeding with the alignment.

PROCEDURE

1. Tune the AM generator to 39.75 mc., and adjust C518 (see figure 8) for minimum output, as observed on the oscilloscope.
2. Tune the AM generator to 47.25 mc., and adjust C201 for minimum output, as observed on the oscilloscope.
3. Tune the AM generator to 41.25 mc., and adjust C203 for minimum output, as observed on the oscilloscope.

NOTE: In steps 1, 2, and 3, it is necessary to keep the generator output sufficiently high that a null indication may be observed on the oscilloscope. However, avoid overloading of the receiver by excessive signal.

4. Tune the AM generator to the frequencies indicated below, and adjust the trimmers for maximum output.
   a. 42.7 mc.—adjust C514
   b. 45.4 mc.—adjust C204
   c. 42.0 mc.—adjust C206
   d. 45.0 mc.—adjust C210
   e. 44.4 mc.—adjust C215
   f. 43.0 mc.—adjust C218
5. Connect the sweep generator and r-f marker generator to the antenna terminals through a matching jig. (If a separate oscilloscope is used, connect the sweep output of the generator to the horizontal input of the oscilloscope.) Connect a 7.5-volt battery to the a-g-c test jack, with the negative terminal to the bias lead and the positive terminal to the ground lead. Set the CHANNEL SELECTOR to Channel 4, and tune the sweep generator for output on Channel 4. Tune the r-f marker generator for the video carrier frequency of Channel 4 (67.25 mc.), and tune the i-f marker generator (connected to mixer grid) to 45.75 mc. Note that two marker generators are used for this procedure. The r-f marker generator is connected to the antenna terminals, while the i-f marker generator is connected to the mixer-grid test point, G1. A jig constructed from a piece of fiber tubing, with 3/16 inch inside diameter, and a brass machine screw which fits tightly into the tubing, is used to connect the generator to the test point. The screw is adjusted so that it clears the test point by approximately 1/64 inch. The output cable of the marker generator is connected to the head of the brass screw in the jig and to the chassis near the mixer tube. Both marker generators should be adjusted for the minimum output required to make the markers barely visible. Failure to observe this precaution, or the use of excessive output from the sweep generator, will cause misleading results. After the equipment is properly connected, adjust the FINE TUNING control for zero beat of the two markers, as observed on the oscilloscope. When zero beat is obtained, remove the i-f marker.
6. If the response curve does not fall within the limits, as shown in figure 9, the adjustment of the trimmers may be touched up slightly. Do not retouch the setting of C518, C201, C203, or C206. To adjust the curve, first adjust C215 and C218 alternately, until maximum improvement has been obtained. C215 affects the tilt of the curve, and C218 affects the dip of the curve. After C215 and C218 have been adjusted, adjust C514 for the proper slope at the 42.25-mc. side of the curve, then adjust C204 and C210 for the proper level at the video carrier frequency (45.75 mc.).

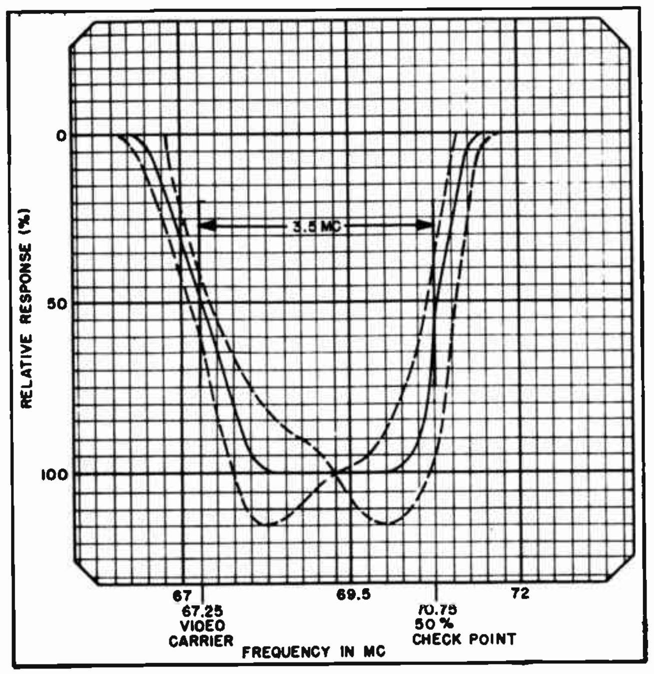


Figure 9. Over-all R-F, I-F Response Curve

CAUTION: Do not turn any of the trimmers excessively. To retouch, make only a slight adjustment.

SOUND I-F ALIGNMENT

The sound i-f system may be aligned by the use of a station signal or an accurately calibrated signal generator, for the signal source. If the station signal is used, tune the FINE TUNING control for the best picture, regardless of sound. It will be necessary to reduce the signal input to the receiver, so that the d-c output at the sound detector, as measured with the aid of the sound i-f output alignment jig (between point "B" and ground), is kept below 5 volts maximum, and preferably below 3 volts. To establish this level in strong signal areas, it may be necessary to short the antenna terminals and to apply bias to the a-g-c circuit. The signal input to the receiver may be adjusted by varying the length of the shorting lead. The bias may be applied to the a-g-c circuit by means of the jig shown in figure 3. The sound i-f output alignment jig shown in figure 4 should be used for convenient connection of the meter to the sound-detector output.

When signal generator (accurately calibrated) is used, bias should be applied to the a-g-c circuit, to avoid any possibility of regeneration, using the sound i-f input alignment jig (figure 3). In addition, the first video i-f tube should be removed, to aid in the reduction of circuit noises from the i-f system.

1. Connect the generator through the 2200-ohm resistor, in the sound i-f input alignment jig, to pin 2 of J200. The generator should be adjusted for unmodulated output at 4.5 mc.
2. Insert the sound i-f output alignment jig in the volume-control socket (J401), and insert the volume-control plug (PL401) in the top of the jig. Connect the clip lead to the FM Test Point (J403); connect a 20,000-ohms-per-volt voltmeter between point "B" and the ground lug of the jig, the negative lead of the meter going to point "B."
3. Adjust TC300, TC400, TC401, and TC402 for maximum output, as indicated on the meter. If the output exceeds 5 volts, reduce the signal input to the receiver.
4. Shift the positive lead of the meter to point "C" on the sound i-f output alignment jig, and adjust TC403 for zero crossover. Zero crossover is indicated by a zero indication on the meter. When TC403 is turned in one direction from this zero point, the meter will swing positive; turning TC403 in the opposite direction will cause a negative swing. (To aid in reading a positive and negative swing on the meter, set the pointer, by means of its zero-adjustment screw, to a convenient calibration mark on the scale, before connecting the meter to the circuit.)
5. Replace the first video i-f tube, and tune in a station on the receiver. Turn the FINE TUNING control to obtain a slightly fuzzy picture, and tune TC403 for minimum AM noise, using the speaker output as an indication.

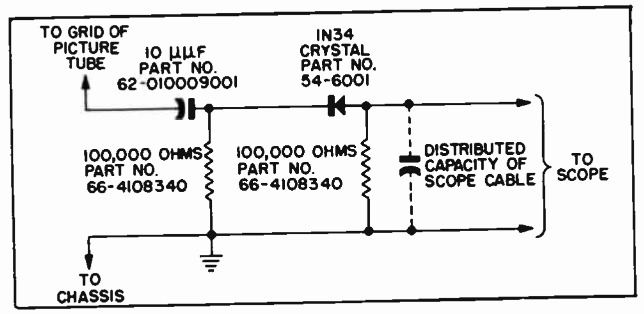

Figure 10. R-F Probe for Sound-Trap Adjustment

ADJUSTMENT OF 4.5-MC. TRAP

To adjust the 4.5 mc. trap in the plate circuit of the first video amplifier, proceed as follows:

1. Connect the output of the signal generator to lead "A" from pin 2 of the sound i-f input alignment jig (see figure 3). Adjust the generator for 4.5 mc., 400-cycle modulated output. Set the output attenuator for maximum output from the generator.
2. Connect the input of the r-f probe, shown in figure 10, to the grid of the picture tube, and connect the output of the probe to the vertical input of the oscilloscope. Adjust the vertical gain of the oscilloscope to maximum. Adjust the horizontal sweep of the oscilloscope for 400 cycles.
3. Adjust TC301 for minimum indication on the oscilloscope. (The normal setting for TC301 is with the screw approximately 3/8 inch out from the chassis.)

An alternate method for adjustment of TC301 may be used if a 4.5-mc. generator is not available. To adjust TC301 without the generator, proceed as follows:

1. Tune in a strong station signal.
2. Turn the FINE TUNING control in the clockwise direction until a fine beat pattern appears in the picture.
3. Adjust TC301 until the beat disappears or is at a minimum. When correctly adjusted, the screw will be out from the chassis by approximately 3/8 inch.
4. If more than one station is available, check the setting of TC301 on all stations.

OSCILLOSCOPE WAVEFORM PATTERNS

The waveforms shown below were taken with the receiver adjusted for an approximate peak-to-peak output of 2 volts at the video detector. The voltages given with the waveforms are approximate peak-to-peak values. The frequencies shown are those of the waveforms—not the sweep rate of the oscilloscope. The waveforms were taken with an oscilloscope having good high-frequency response. With oscilloscopes having poor high-frequency response, the sharp peaks of the horizontal waveforms will be more rounded than those shown, and the peak voltages will differ from those shown.

*CAUTION: High-voltage pulses are present in the horizontal-output circuit. The waveform in figure 33 was taken with the alligator clip of the oscilloscope lead clipped over the insulation of the lead connected to pin 7 of J800. (To prevent puncture of the insulation of the lead, file off the teeth of the alligator clip and wrap friction tape around the clip.) Connection to other points in the horizontal-output circuit is dangerous, due to the high voltages present. The peak-to-peak voltage shown for figure 33 is the actual voltage present; however, the amplitude of the scope presentation depends upon the degree of coupling.

PARTS LIST

IMPORTANT

General replacement items commonly stocked by the serviceman are omitted from this parts list. All condensers are molded-bakelite Philco condensers, with a 600-volt rating, and all resistors are ½ watt, unless otherwise indicated. Parts are listed according to chassis type and should be ordered in this way rather than by model number; in addition, a miscellaneous listing will be found at the end of the parts list for each chassis type. All parts are symbolized in the schematic diagrams and base layouts, for identification purposes.

NOTE: Part numbers identified by an asterisk (*) are general replacement items. These numbers may not be identical with those on factory parts. Also, the electrical values of some replacement items may differ from the values indicated in the schematic diagram and parts list. The values substituted in any case are so chosen that the operation will either be unchanged or improved. When ordering replacements, use only the "Service Part No."

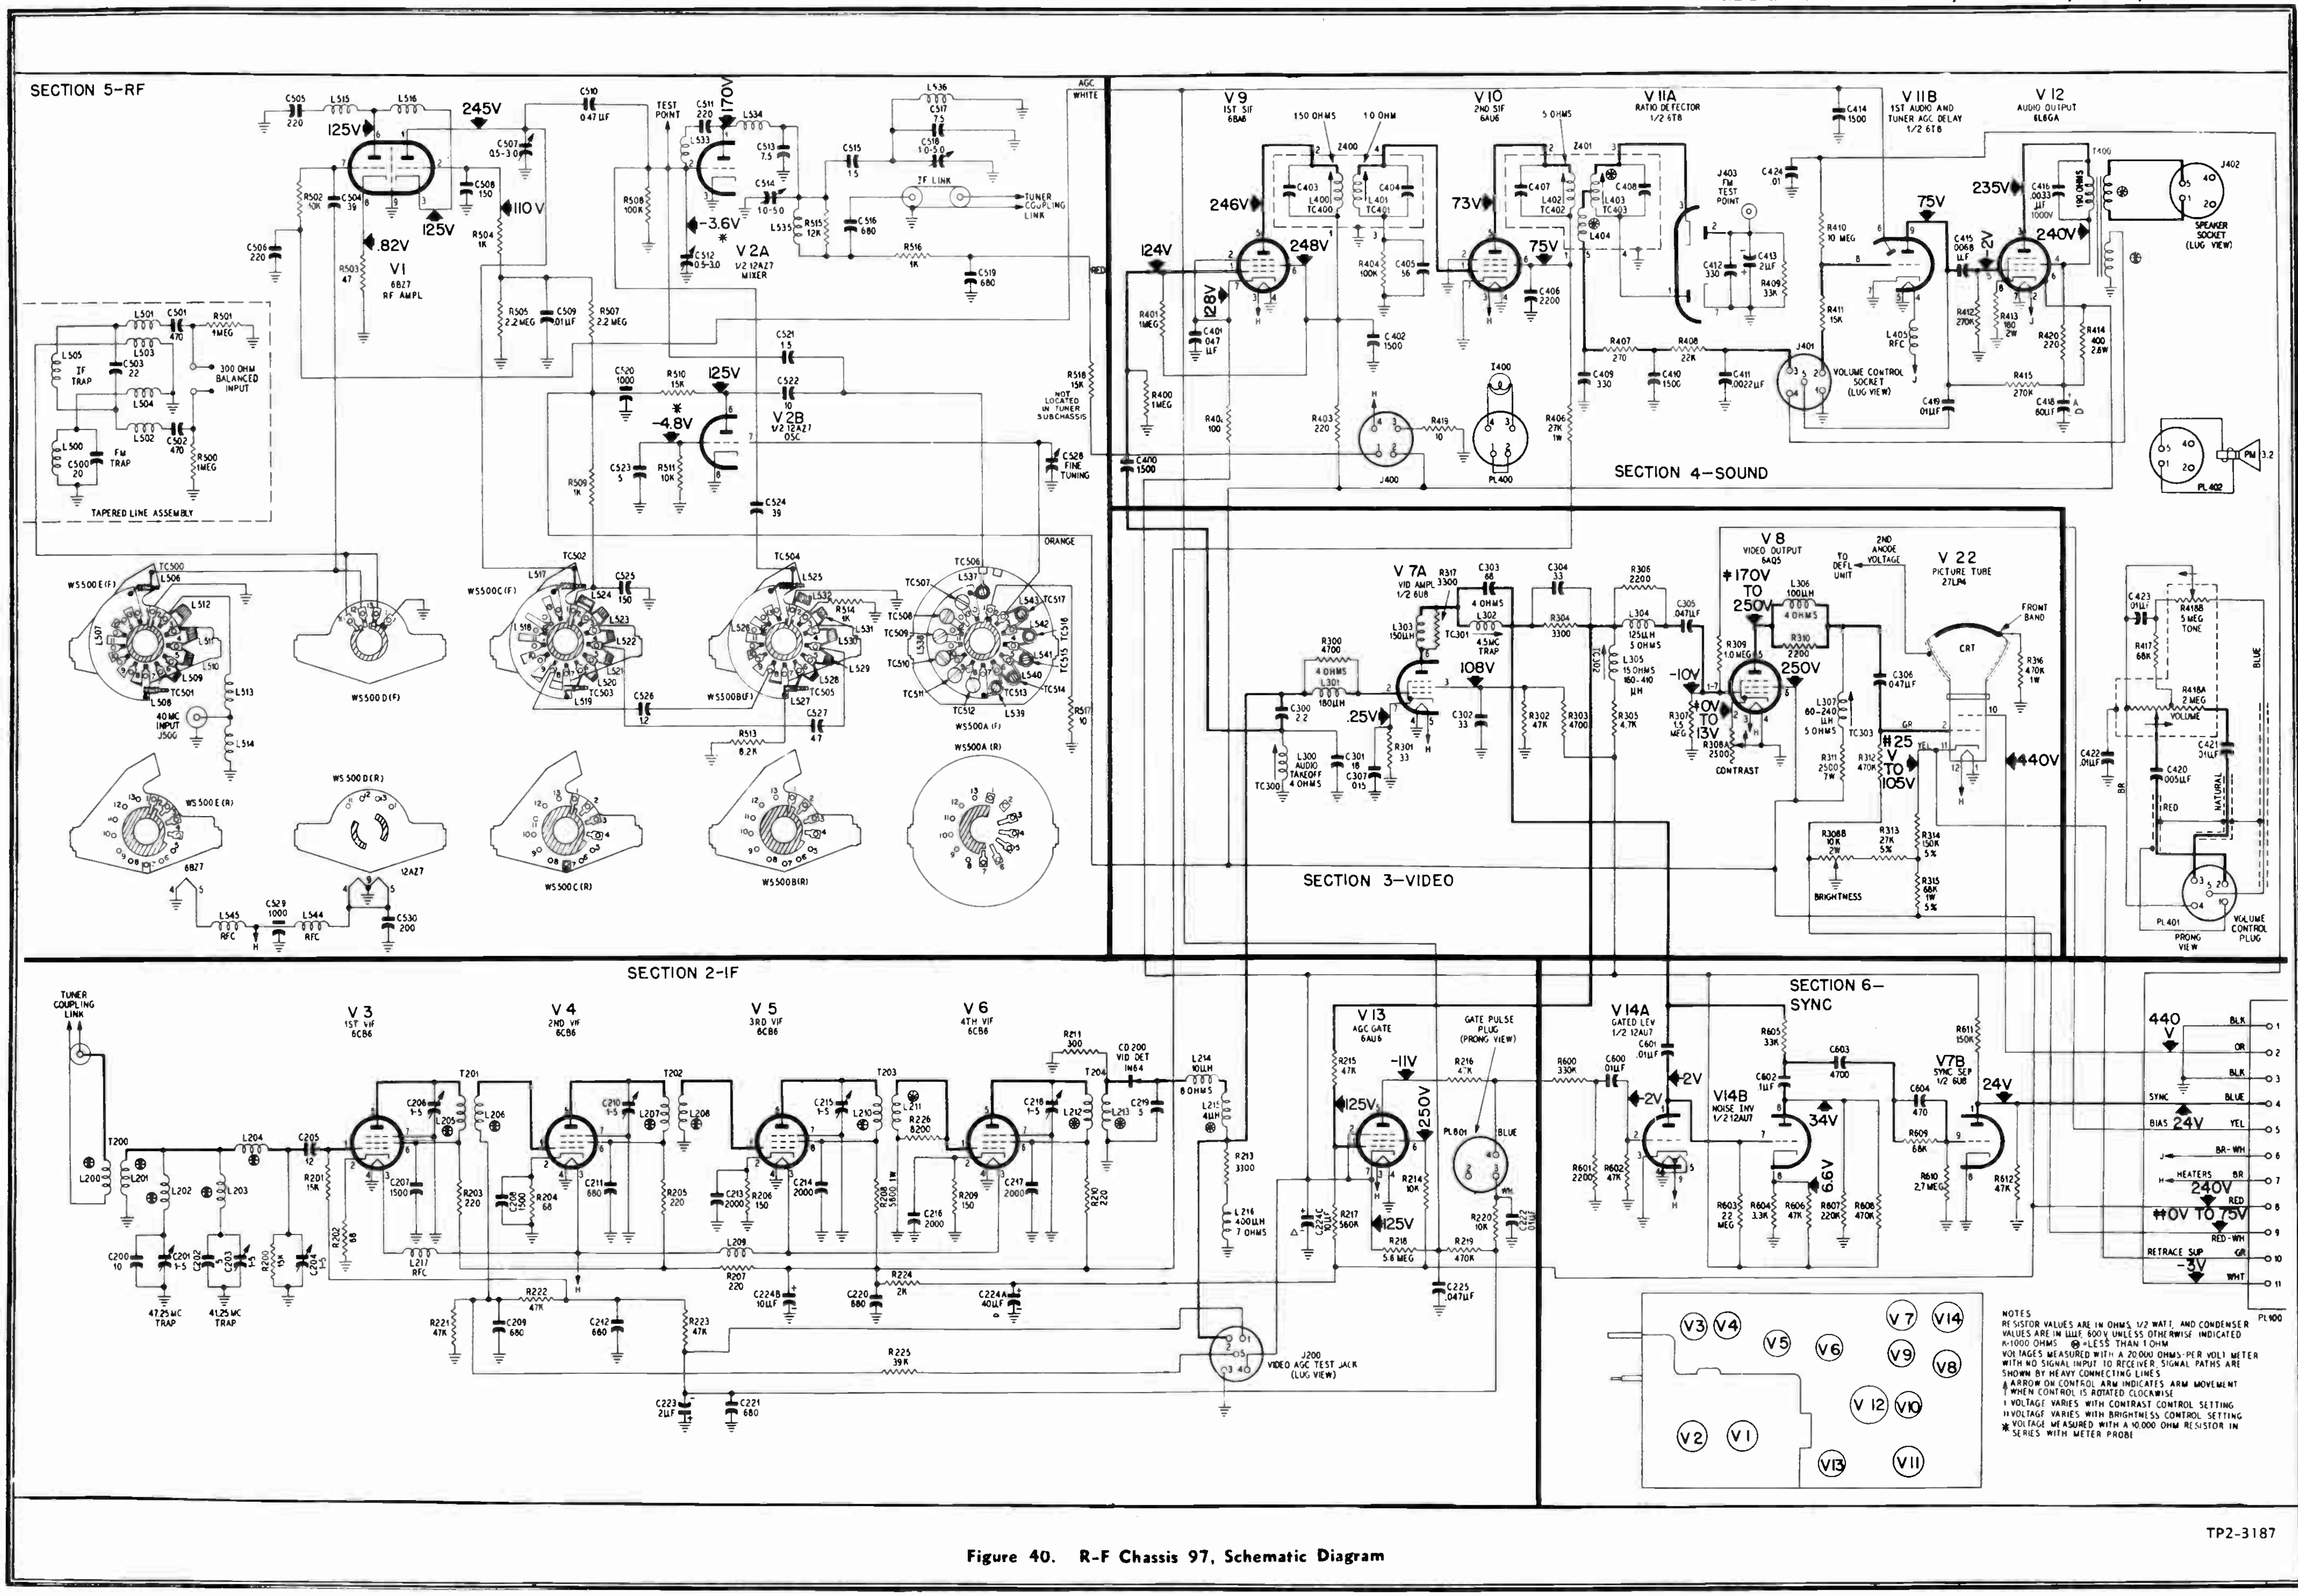

Figure 40. R-F Chassis 97, Schematic Diagram

CIRCUIT DESCRIPTION

Philco "B" line, Code 140, Television Receivers use two chassis—the r-f chassis R-191, containing the r-f, video, audio, and sync circuits, and deflection chassis D-191, containing the power and deflection circuits. Since these chassis are not isolated from the 60-cycle power line, all protruding shafts and mounting feet are insulated from the chassis.

CAUTION: See A-C LINE ISOLATION

A separate subchassis contains the r-f amplifier, the oscillator, and the mixer. The r-f amplifier uses a type 6BZ7 tube, V1. The oscillator and the mixer use a type 6X8 tube, V2, the pentode section of the tube being used for the mixer, and the triode section for the oscillator. The output of the mixer is fed to a three-stage, stagger-tuned, i-f amplifier system employing three type 6CB6 tubes, V3, V4, and V5. A type 1N64 crystal diode, CD200, is used for the video detector, the output of which is amplified by a two-stage video amplifier utilizing a type 6AU6 tube, V6, and a type 6AQ5 output tube, V7. The connections at the detector are such as to produce a composite video signal with negative-going sync pulses. The signal, which is subjected to a 360-degree phase shift through the video amplifier, is applied to the grid of the picture tube, V19; therefore the sync pulses at this point are negative-going. A positive-going blanking pulse, taken from the vertical-output stage, is applied to the cathode of the picture tube for suppression of the vertical retrace.

Sound i.f. (intercarrier) is obtained by utilizing the beat frequency produced when the 45.75-mc. video carrier and the 41.25-mc. sound carrier are mixed in the video detector. The 4.5-mc. beat frequency is the difference between 45.75 mc. and 41.25 mc., and contains the FM sound signal. This 4.5-mc. signal contains only a negligible amount of video amplitude modulation, provided that the amplitude of the 41.25-mc. signal is considerably lower than that of the 45.75-mc. signal. The proper relationship between the two carriers is established during the alignment of the receiver. There is sound output only when both the video and sound carriers are present.

The oscillator is tuned primarily to obtain the best picture, since the 4.5-mc. relationship always exists between the two carriers. The 4.5-mc. sound i.f. (intercarrier), which is taken from the plate circuit of the video amplifier, is passed through a 4.5-mc. sound i-f stage using a 6AU6 tube, V8, and is then applied to the FM detector, which utilizes two diode sections of a 6T8 tube, V9A. The triode section of the 6T8, V9B, is used as the first audio amplifier. The power amplifier uses a type 6V6GT tube, V10.

A portion of the video signal appearing at the output of the first video amplifier is applied to grid 3 (pin 7) of the 6CS6 sync separator, V11. Since grid-leak bias is used on grid 3, the tips of the sync pulses are clamped to zero, and the video components swing in a negative direction from zero. Because of the cut-off characteristics of grid 3, the video components are eliminated, and only negative-going sync pulses appear in the plate circuit of the sync separator. At the same time, however, a signal is taken from the video detector and applied to grid 1 (pin 1) of the 6CS6 tube. This grid is returned to B plus, and the bias is maintained close to zero, because of a small grid-current flow. Since the signal applied to grid 1 is composite video with negative-going sync, any noise modulation present in the signal appears in the form of sharp spikes, driving in a negative direction. The circuit constants are chosen to allow grid 1 to cut off plate current whenever the signal goes more negative than the sync pulses. A series grid-limiting resistor, R608, is also incorporated to prevent the video components from appearing in the plate circuit of the sync separator. A-G-C voltage is also developed in the sync separator circuit in the following manner: On tips of the sync pulses, grid 3 (pin 7) of the 6CS6 tube draws current which flows downward through the network R602, R603, R604, R211, and L214, causing capacitors C605, C602, and C603, to assume negative charges proportional to the amount of peak signal applied to grid 3. The tuner a-g-c voltage is delayed by means of a resistor divider network which applies a small positive voltage to the tuner a-g-c circuit. This positive voltage prevents a-g-c action from lowering the tuner gain on weak signals. To prevent the delay voltage from driving the tuner a-g-c voltage positive on weak signals, a diode clamp (part of V9B) is connected across C602.

The negative-going sync pulses appearing in the plate circuit of the sync separator are fed to one half of a 12AU7 tube, V12A, connected as a phase-splitter circuit; positive sync pulses appear in the plate circuit, and negative sync pulses are taken from the cathode.

Proper triggering of the vertical oscillator requires positive synchronizing pulses. The vertical sync signal is separated from the horizontal sync signal by the vertical integrator circuit, and is fed to the grid circuit of the vertical blocking oscillator, one half of a 12AU7 tube (V12B). The output of the vertical oscillator is amplified by a type 12B4 tube, V13, which is employed as the vertical-output amplifier. The output of the amplifier is applied to the vertical-deflection coils through the vertical-output transformer.

The horizontal-sweep circuits require both positive and negative sync pulses. The phase-comparer circuit uses a 6AL5 tube, V14. Positive sync pulses are applied to the plate of V14A, and negative sync pulses are applied to the cathode of V14B. A saw-tooth voltage, taken from the horizontal-output circuit, is fed to the plate of V14B and to the cathode of V14A, for comparison of the sync and horizontal sweep voltages. When the saw-tooth and sync signals are exactly in phase, no voltage is developed across R800, but when the two signals are out of phase, either a positive or a negative voltage is developed, depending upon whether the horizontal-oscillator frequency is lower or higher than the sync-pulse frequency. The grid circuit of the horizontal oscillator, a type 12AU7 tube, V15, operating as a cathode-coupled multivibrator, is connected to R800 through a filter network. When the voltage at this point goes in a positive direction, the frequency of the horizontal oscillator is increased; when the voltage swings negative, the frequency of the oscillator is decreased. In this manner the frequency of the horizontal oscillator is controlled over the lock-in range of the circuit. The horizontal hold control, R811, adjusts the horizontal-oscillator frequency so that it is within the control range of the phase comparer. The output of the horizontal oscillator is fed to the horizontal output amplifier, which makes use of a type 6BQ6GT tube, V16. The screen voltage for the horizontal amplifier is supplied from a voltage-divider network. The network includes R818, R816 (the WIDTH control), R817, R315 (the BRIGHTNESS control), and R316. R816 varies the voltage applied to the screen, thus adjusting for proper picture width. Adjusting R315 for brightness varies the bias on the picture tube. The change in bias causes a change in beam current, and would tend to result in a change in picture width and a variation in the second-anode voltage. However, when the control arm of the BRIGHTNESS control, R315, is moved toward ground, a smaller part of the control is shunted by the 22,000-ohm resistor, R316, and the total resistance of the voltage divider is increased. This increase in resistance results in a decrease in the current through the divider, and the screen voltage on the horizontal amplifier is increased proportionally, thus compensating automatically for the increase in beam current in the picture tube. The horizontal amplifier feeds the deflection coils through the horizontal-output transformer. A 6AX4GT tube, V17, is used as the horizontal damper.

The second-anode voltage for the picture tube is supplied by one 1B3GT high-voltage rectifier tube, V18. The B plus voltage for the receiver is supplied by two selenium rectifiers, CR100 and CR101 in a full-wave, voltage-doubler circuit, operating directly from the power line. Bias voltage is obtained from across a filter choke, which is in series with the negative side of the B plus supply. The B plus boost voltage, derived from the horizontal damper circuit, supplies higher B plus voltage to the vertical oscillator, first audio stage, and the first anode of the picture tube. Filament voltage for all the tubes except the high-voltage rectifier is supplied by a step-down transformer. Filament voltage for the high-voltage rectifier is supplied by a winding of the horizontal-output transformer.

IMPORTANT

A-C LINE ISOLATION

CAUTION: One side of the a-c line is connected to the chassis through C101 and L405. The other side of the a-c line is connected to the chassis through F100, R100, CR100, and C103, in series. Grounding the chassis will result in a short circuit across one or the other of these two branches in the voltage-doubler circuit. During servicing and alignment it is desirable that an a-c line isolation transformer capable of handling at least 225 watts (Philco Part No. 45-9600) be used. Failure to use an isolation transformer will greatly increase the shock hazard, and may result in damage to the test equipment or receiver, or both.

SPECIFICATIONS

VHF TUNING ....Twelve channel, 12-position incremental tuner, covering VHF Television Channels 2 through 13; fine tuning of local oscillator

UHF TUNING (if provided).......Continuous tuning, covering UHF Television Channels 14 through 83; fine and coarse tuning

INTERMEDIATE FREQUENCIES
Video Carrier ....45.75 mc.
Sound (intercarrier) ....4.75 mc.

TRANSMISSION LINE ....300-ohm, twin-wire lead

OPERATING VOLTAGE ....110 to 120 volts, 60 cycles, a. c.

POWER CONSUMPTION..without UHF, 175 watts; with UHF, 180 watts

B SUPPLY FUSE REPLACEMENT

The B supply protective fuse, F100, is wired into the low-voltage section, and is in series with the selenium rectifiers. For replacement, use a 1.6-ampere delayed-action-type fuse, Philco Part No. 45-2656-23.

CAUTION: Discharge the circuit before replacing the fuse.

HORIZONTAL-OSCILLATOR ADJUSTMENT

To adjust the horizontal-oscillator circuit, tune in a station and proceed as follows:

1. Reduce the width of the picture until approximately 1 inch of blank screen appears at the right-hand and left-hand sides of the picture.

2. Increase the BRIGHTNESS control setting until the blanking becomes visible. This will appear as a dark vertical bar on each side of the picture.

3. Connect a .1 μf. condenser from the test point, adjacent to TC800, to ground. (The plate side of the horizontal ringing coil, L800, is connected to the test point.)

4. Set the HORIZONTAL HOLD control to the approximate center of its mechanical rotation.

5. Adjust the HORIZ HOLD CENTERING control until equal portions of the blanking bar appear on both sides of the picture.

6. Remove the .1-μf. condenser from the test point.

7. Adjust the horizontal ringing coil, L800, until equal portions of the blanking bar again appear on both sides of the picture.

8. Rotate the HORIZONTAL HOLD control through its range. The picture should fall out of sync on both sides of the center of its rotation. If the picture does not fall out of sync on both sides, readjust the HORIZ HOLD CENTERING control.

9. Rotate the HORIZONTAL HOLD control through its range, and observe the number of diagonal blanking bars that appear just before the picture pulls into sync. The pull-in should occur with from 1 to 2 diagonal bars when the sync position is approached from either direction. If proper pull-in is not obtained, repeat the above procedure.

VIDEO PEAKING-COIL ADJUSTMENT

The video peaking coil, L303, is adjusted at the factory for proper transient response of the video circuits. Ordinarily, this coil will require no further adjustment by the serviceman. On any station where excessive overshoot or excessive smear is present, a slight adjustment of L303 may improve the picture quality on that station; however, this adjustment may sacrifice the quality on other channels. If L303 is replaced in servicing, adjustment will be required.

Before adjusting L303, check the tuner alignment and i-f alignment. (Never adjust L303 until the alignment of the receiver is correct.) Then tune in a station and adjust L303 until there are no trailing whites or smear in the picture. Turning TC301 clockwise reduces trailing whites and overshoot; turning TC301 counterclockwise reduces picture smear and increases trailing whites. The proper position is the point where no smear or trailing whites appear in the picture.

The above procedure for adjustment of TC301 applies to a particular station exhibiting smear or overshoot. After TC301 is adjusted, reception on all the other stations should be checked, to make certain that the adjustment has not impaired the picture quality.

TELEVISION ALIGNMENT

GENERAL

The alignment procedure follows the general pattern of first checking the tuner response with an FM sweep generator and oscilloscope, comparing the response curve with that given in the manual, and aligning the tuner if necessary. After it is established that the tuner is in correct alignment, the video i-f channel is aligned by tuning each coil to its assigned pole frequency, using an AM signal, and then feeding in a sweep signal at the antenna terminals and retouching the i-f adjustments to obtain the desired pass band. Finally, the sound channel is aligned, using an AM signal, by tuning the sound take-off coil and the i-f and ratio-detector transformers.

The over-all response curve (r-f, i-f) of the circuits from the antenna terminals to the video detector, after the i-f stages have been aligned, should appear essentially the same, regardless of the channel under test. If not, the tuner should be aligned.

The video-carrier intermediate frequency is 45.75 mc., and the sound intermediate (intercarrier) frequency is 4.5 mc. Alignment of these circuits requires careful workmanship and good equipment. The following precautions must be observed:

1. There must be a good bond between the receiver chassis and the test equipment. This is most easily obtained by having the top of the workbench metallic. The receiver chassis should be placed tuner-side down on the bench. If the bench has no metallic top, the test equipment and chassis can be bonded by a strip of copper about 2 inches wide. The section of the chassis nearest the tuner should rest on the strip.

2. Do not disconnect the picture tube, picture-tube yoke, or speaker while the receiver is turned on.

3. Allow the receiver and test equipment to warm up for 15 minutes before starting the alignment.

4. The marker (AM) signal generator should be calibrated accurately to the frequencies used and to the sound and video r-f carriers of each channel used during alignment. If Model 7008 is used, the built-in crystal calibrator provides an excellent means of calibration. An alternate method for calibrating the signal generator to the sound and video r-f carrier frequencies is to zero-beat the signal generator with the received signals.

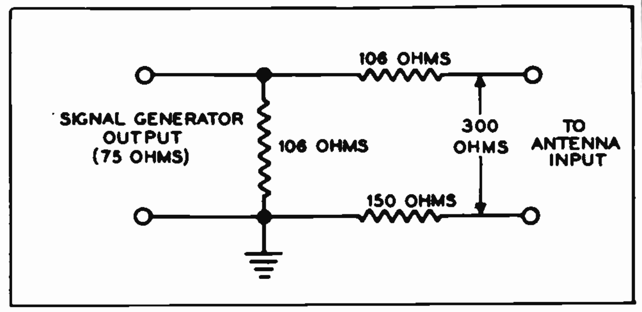
For further information regarding calibration, refer to Philco Lesson PR-1745 (J) entitled "Television Service in the Home."

TEST EQUIPMENT REQUIRED

The following test equipment is recommended for aligning the receiver:

1. Philco Precision Visual Alignment Generator for Television and FM, Model 7008, or equivalent.

2. Vacuum-tube voltmeter, or 20,000-ohms-per-volt voltmeter.



TPO-1179

Figure 1. Antenna-Input Matching Network

3. R-F Probe, Philco Part No. 76-3595 (for use with Model 7008 generator).

JIGS AND ADAPTERS REQUIRED

Mixer Jig

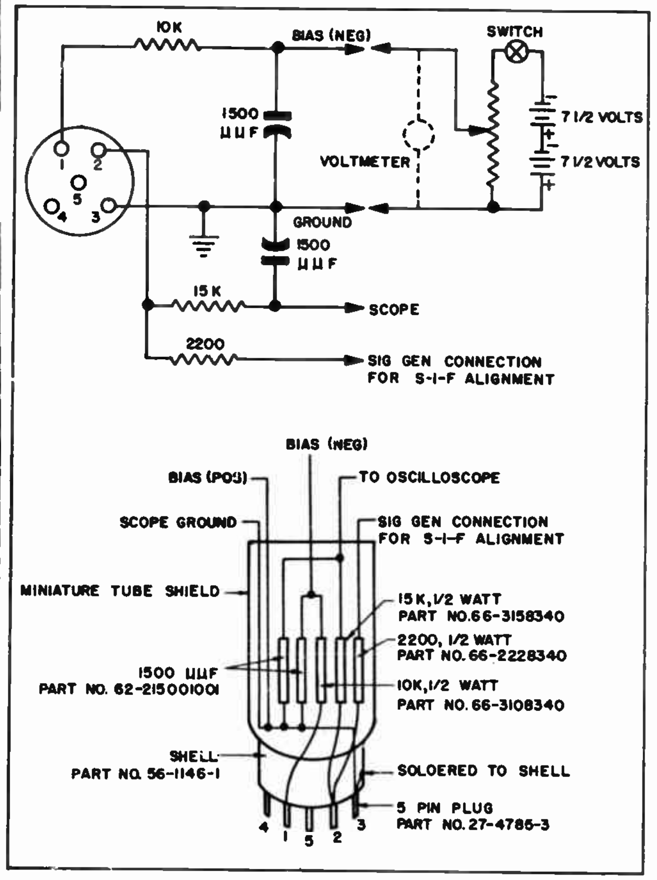
Connections to the grid of the mixer tube may be made through the alignment jack provided for that purpose. To connect the generator to this point, a mixer jig, Philco Part No. 45-1739, and a connecting cable, Philco Part No. 45-1635, may be used. As an alternate, a Philco alligator-clip adapter, Part No. 45-1636, with as short a ground lead as possible, may be used to connect the alignment jack. The ground lead should be connected as close as possible to the mixer tube. It is essential that the signal-generator output lead be terminated with a 68-ohm resistor (carbon), so that regeneration, caused by connection of the lead to the mixer, is held to a minimum.

Antenna-Input Matching Network

Figure 1 shows an impedance-matching network for coupling the signal generator to the antenna-input terminals of the receiver. This network, which is designed to have an input impedance of 75 ohms and an output impedance of 300 ohms, is used to match a 75-ohm generator to a 300-ohm antenna-input circuit. The resistors used in this network should be of carbon-composition construction, and should be chosen from a group to obtain values within 10% of those indicated. The resistors should be placed in a shield can, to prevent variable effects. An antenna matching jig, Philco Part No. 45-1736, which consists of a matching transformer and connecting box, may be used in place of the resistor network.

Video I-F Alignment Jig
(Video Test Jack Adapter)

The alignment jig shown in figure 2 should be used during the i-f alignment, to apply the proper bias to the a-g-c bus, and to provide a convenient oscilloscope connection. This jig consists of a 5-prong plug, a 10,000-ohm potentiometer, two isolating resistors (one 10,000-ohm and one 15,000-ohm), two 1500-



TP3-988

Figure 2. Video I-F Alignment Jig

micromicrofarad capacitors, two 7½-volt batteries and switch. A suggested method of fabricating the jig is also shown. It is suggested that the bias batteries and potentiometer be mounted in a metal box of convenient size.

The potentiometer and switch are connected across the two 7½-volt batteries. The switch is used to disconnect the potentiometer, to prevent the discharge of the battery while not in use.

Sound I-F Alignment Jig

Figure 3 shows the jig that should be used to connect the voltmeter and oscilloscope to the VOLUME CONTROL socket, J400.

TELEVISION TUNER ALIGNMENT

After the tuner is serviced, or if an i-f alignment is required, the tuner alignment should be checked by observing the tuner response curve, as given under Bandpass Alignment. If the response curve does not fall within the limits shown in figure 5, the tuner should be realigned. If realignment is necessary, use the procedure given below.

Since the frequency of the local oscillator affects the tuner response, the local-oscillator alignment should be made first.

Oscillator Alignment

General

Tuning cores are provided in the oscillator coils at channels 13, 11, 9, 7, 6, and 4. By adjusting these tuning cores, all channels may be placed on frequency. This procedure should be carried out with the highest-frequency channel first, since the alignment of each channel affects the alignment of all the channels below it in frequency. The channel adjustments are so arranged that, with one exception, each adjustment corrects the tuning of more than one channel. The coverage of the various adjustments is as follows:

CHANNEL ADJUSTMENT	CHANNELS CORRECTED BY ADJUSTMENT
13	13 and 12
11	11 and 10
9	9 and 8
7	7 only
6	6 and 5
4	4, 3, and 2

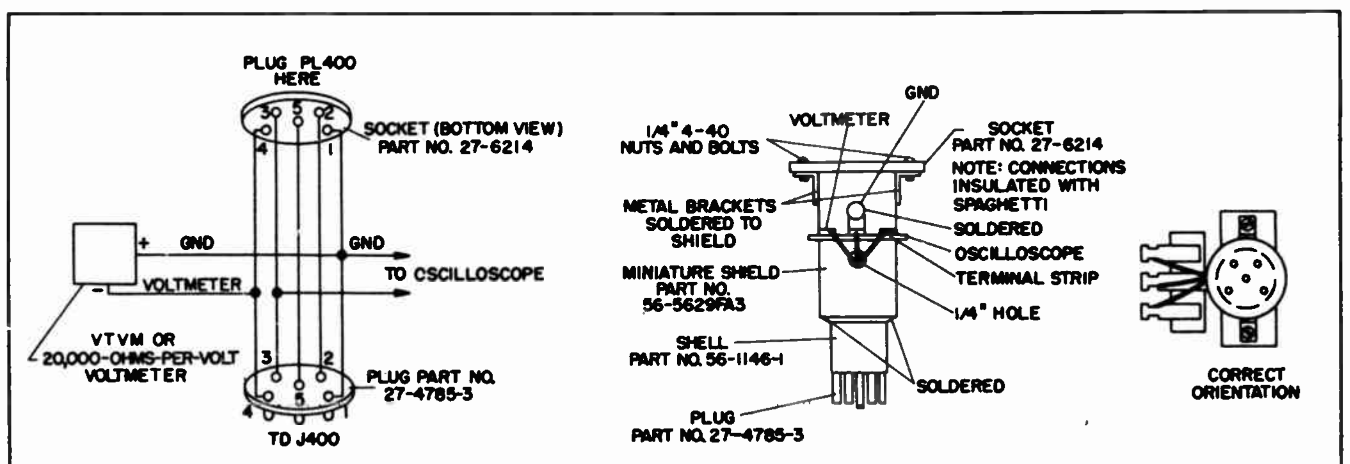


Figure 3. Sound I-F Alignment Jig TP2-2200

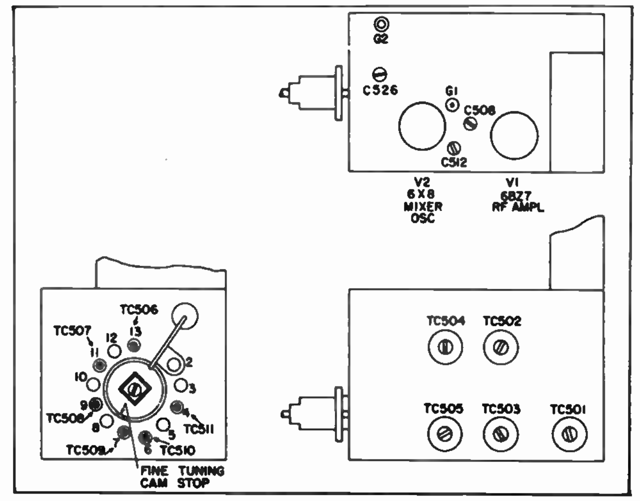

TP2-2201-1

Figure 4. Television Tuner, Showing Locations of Adjustments

The FINE TUNING cam should be preset for all adjustments by placing the stop on the FINE TUNING cam between the Channel 7 and 8 holes on the front plate of the tuner. See figure 4.

Procedure Using Signal Generator

An r-f signal (unmodulated), at the oscillator frequency, is fed into the antenna input from an AM signal generator, and the oscillator tuning cores are adjusted for zero beat. The r-f signal frequency should be accurately determined. It is preferable that the signal be taken from a crystal-controlled source; if this is not available, the signal generator may be calibrated against the television station.

1. Connect the hot lead of the oscilloscope to the mixer plate test point, G2, through a 1000-ohm resistor, and connect the ground lead of the oscilloscope to the chassis, near the test point. (High oscilloscope gain may be necessary to obtain a visual beat. In this instance, base-line hum may be ignored.)
2. Connect the AM (marker) generator to the 300-ohm antenna-input terminals. For this purpose the antenna-input matching network is not required.
3. Disconnect the white lead from the tuner, and connect it to the negative terminal of a 1½-volt battery. Ground the positive terminal. If regeneration is observed, the bias may be increased to 4 or 5 volts, to reduce the regeneration.
4. Mechanically preset the fine-tuning cam stop as shown in figure 4.
5. Feed in an r-f signal (unmodulated), at the oscillator frequency for Channel 13, with the CHANNEL SELECTOR set for Channel 13.
6. Adjust the tuning core for Channel 13 (see figure 4).
7. Reset the signal-generator frequency and the CHANNEL SELECTOR, and adjust the tuning cores for Channels 11 and 9, respectively.
8. Repeat steps 5, 6, and 7 until Channels 13, 11, and 9 are within plus or minus 500 kc. of the correct frequency.
9. Feed in r-f (unmodulated) signals, at the oscillator frequencies for Channels 7, 6, and 4, consecutively (see NOTE below), and adjust the respective tuning cores (see figure 4).

NOTE: The exact position of the FINE TUNING cam should be marked when Channel 4 is correctly aligned. This position is to be used in step 4 of the i-f alignment procedure.

Procedure Using Station Signal

The following simplified procedure may be used to align the oscillator when the television i-f alignment is satisfactory and a station signal is available:

1. Mechanically preset the FINE TUNING cam to the center of its range (see figure 4).
2. Tune in the highest-frequency channel to be received.
3. Adjust the tuning core for that channel, or the next higher channel, for the best picture; that is, starting with sound in the picture, turn the tuning core until the sound disappears. Repeat for each channel received in the area.

Bandpass Alignment

General

The bandpass alignment consists of aligning the tuner at Channels 13 and 6, and then making it track down to Channels 7 and 2, respectively.

During the alignment, a fixed bias of 1½ volts is applied to the r-f amplifier tube.

An FM (sweep) signal is applied to the antenna-input circuit, and an oscilloscope is connected to the mixer plate circuit. The oscilloscope gain should be as high as possible, consistent with hum level and "bounce" conditions. Hum conditions will cause distortion of the time base and response. Bounce conditions, which are caused by poor line regulation, will cause the response and time base to jump up and down. The use of too high an oscilloscope gain aggravates these conditions, whereas the use of too low a gain necessitates increasing the generator output to a point where the tuner may be overloaded. Overload may be checked by changing the generator output while observing the shape of the response curve; any change in the shape of the curve indicates overload, in which case a lower generator output and higher oscilloscope gain must be used. The tuner coupling link should be disconnected from the

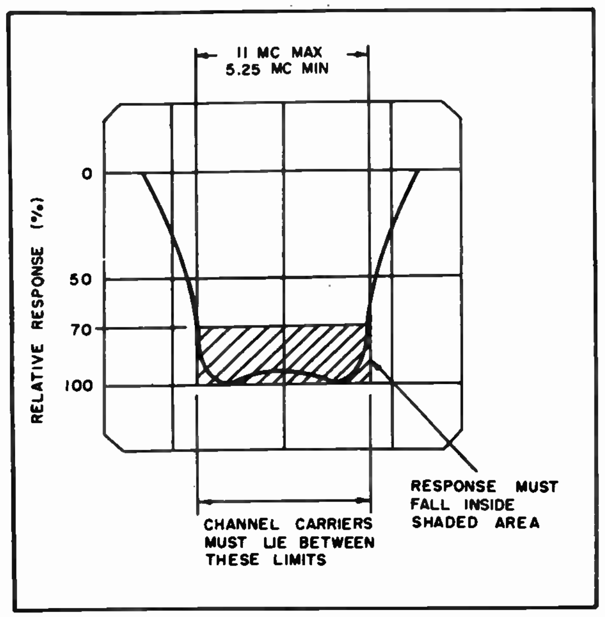

Figure 5. Television Tuner Response Curve, Showing Bandpass

i-f section by removing the plug, PL500, and a 40- to 70-ohm carbon resistor should be connected across the open end of the plug. This is done to eliminate the absorption effect of the tuner link coil, L200, on the response curve.

Procedure

1. Disconnect the white (a-g-c) lead, from the tuner, and connect it to the negative terminal of a $1\frac{1}{2}$-volt battery. Ground the positive terminal.
2. Disconnect the tuner plug, PL500, at terminal board B13 (see figure 33), and connect a 40- to 70-ohm carbon resistor across the plug.
3. Connect a 1000-ohm resistor in series with the hot lead of the oscilloscope. Connect the other end of the resistor to the mixer plate test point, G2, and connect the ground lead of the oscilloscope to the chassis, near the test point.
4. Connect the FM (sweep) generator to the 300-ohm antenna-input terminals through an antenna-input matching network. See figure 1.
5. Set the CHANNEL SELECTOR and FM (sweep) generator to Channel 13 (213 mc.). Adjust the generator for sufficient sweep to show the complete response curve.
6. Establish the channel limits (see figure 5) by using the marker (AM r-f) signal generator to produce marker pips on the response curve. (Set the marker generator first to 210 mc., then to 216 mc.) The curve should be reasonably flat between the limits shown in figure 5.
7. Adjust TC502 and TC504 (figure 4) for a symmetrical, approximately centered pass band.
8. Set the CHANNEL SELECTOR and FM generator to Channel 7 (177 mc.).
9. Establish the channel limits by using the marker generator to produce marker pips on the response curve. (Set the generator first to 174 mc., then to 180 mc.) The curve should be reasonably flat between the limits.
10. On Channel 7, note the response curve, with respect to tilt and center frequency. The curve should be centered in the pass band, and should be symmetrical.
11. If the curve is not symmetrical, and appears unbalanced, as shown in figure 6, leave the generator and tuner set to Channel 7, and adjust C508 and C512 (see figure 4) to obtain a response curve which is the mirror image (tilt in the opposite direction) of the original. This is a form of overcompensation, to allow for the effect of Channel 13 adjustment on Channel 7. For example, if the Channel 7 response appears as in figure 6A, then the trimmer should be adjusted to obtain the response shown in figure 6B.
12. Reset the CHANNEL SELECTOR and generators to Channel 13. Readjust TC502 and TC504 for a symmetrical and centered band pass. See step 4.
13. Set the CHANNEL SELECTOR and generators to Channel 7, and check the response for center frequency and symmetry. Repeat steps 8 and 9 as many times as is necessary to obtain the most symmetrical, centered response curves on Channels 13 and 7. Channels 7 through 13 are now correctly aligned.
14. Set the CHANNEL SELECTOR and sweep generator to Channel 6 (85 mc.).
15. Establish the channel limits, using the marker generator to produce marker pips on the response curve. (Set the generator first to 82 mc., then to 88 mc.)
16. Adjust TC503 and TC505 for a symmetrical, approximately centered pass band. Set the marker generator to 85 mc. Detune TC505 counterclockwise until a single peak appears.

    CAUTION: Do not turn the core of TC505 excessively, or it will fall out of the coil.

    Adjust TC503 until the peak falls on the 85-mc. marker. It may be necessary to increase the output of the generator during this adjustment. Then adjust TC501 for maximum curve height and symmetry of the single peak. The antenna circuit is now tuned for Channels 2 through 6. To prevent overloading, the output of the generator should be reduced after this adjustment is completed.
17. Readjust TC503 and TC505 for a symmetrical response, centered about 85 mc.

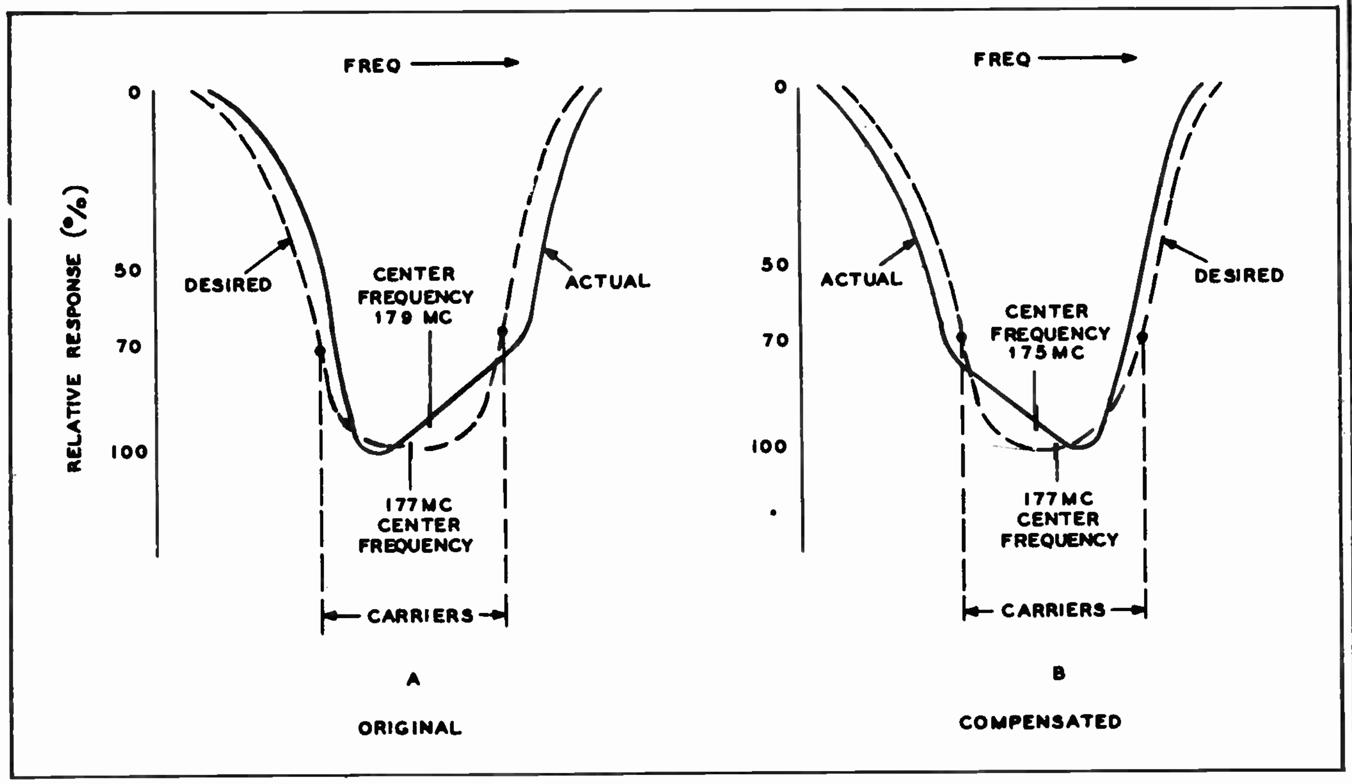

Figure 6. Television Tuner Response Curve, Showing Tracking Compensation

VIDEO I-F ALIGNMENT

Preliminary

Before proceeding with the i-f alignment or making an alignment check, observe the following preliminary instructions:

1. Preset the CONTRAST and BRIGHTNESS controls to the maximum counterclockwise position.
2. Preset the CHANNEL SELECTOR to Channel 4.
3. Insert the video i-f alignment jig (figure 2) into J200.
4. Connect the oscilloscope to the 15,000-ohm resistor from the video i-f alignment jig. Connect the ground lead of the oscilloscope to the ground lead from the adapter.
5. With a voltmeter connected across the points shown in figure 2, set the potentiometer to furnish –6 volts of bias.
6. Connect the AM generator to the mixer test point, G1, through a mixer jig (described in step 4 of procedure given below), and adjust the generator for approximately 30 percent modulation with 400 cycles. Adjust the output of the generator during the alignment to keep the output at the second detector below .6 volt, peak to peak.

    NOTE: If the i-f shield has been removed for repairs, it must be replaced before proceeding with the alignment.

Procedure

1. Preset condenser C526 for minimum capacitance (turn screw counterclockwise).
2. Tune the AM generator to 47.25 mc., and adjust C200 for minimum output, as observed on the oscilloscope. See figure 7.

    NOTE: It is necessary to keep the generator output sufficiently high that a null indication may be observed on the oscilloscope; however, avoid overloading of the receiver by excessive signal.
3. Tune the AM generator to the frequencies indicated below, and adjust the trimmers for maximum output, as observed on the oscilloscope.
    a. 45.7 mc.—adjust C526
    b. 42.6 mc.—adjust C202
    c. 45.0 mc.—adjust C206
    d. 43.2 mc.—adjust C210
    e. 44.3 mc.—adjust C212
4. Connect the sweep generator and r-f marker generator to the antenna terminals through a matching jig. (If a separate oscilloscope is used, connect the sweep output of the generator to the horizontal input of the oscilloscope.) Set the CHANNEL SELECTOR to Channel 4, and tune the sweep generator for output on Channel 4. Tune the r-f marker generator to the video carrier frequency of Channel 4 (67.25 mc.),

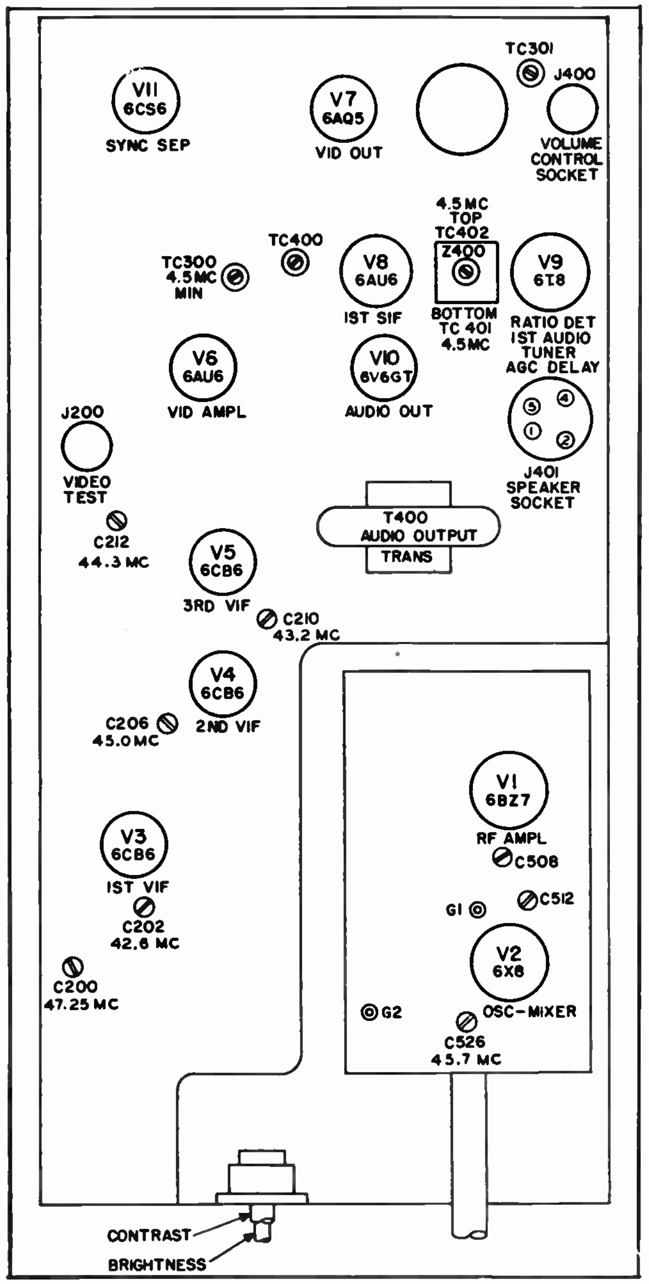

Figure 7. R-F Chassis R-191, Top View, Showing Locations of Adjustments

and tune the i-f marker generator (capacitively coupled to the mixer grid) to 45.75 mc. Note two marker generators are used for this procedure. The r-f marker generator is connected to the antenna terminals, while the i-f marker generator is coupled capacitively to the mixer grid test point, G1. A jig constructed from a piece of fiber tubing, with $\frac{3}{16}$-inch inside diameter, and a brass machine screw which fits tightly into the tubing, is used to couple the generator capacitively to the test point. The screw is adjusted so that its tip clears the test point by approximately $\frac{1}{64}$ inch. The output cable of the marker generator is connected to the head of the brass screw in the jig and to the chassis near the mixer tube. Both marker generators should be adjusted for the minimum output required to make the markers barely visible. Failure to observe this precaution, or the use of excessive output from the sweep generator, will cause misleading results. After the equipment is properly connected, adjust the FINE TUNING control for zero beat of the two markers, as observed on the oscilloscope. When zero beat is obtained, remove the i-f marker.

5. If the response curve does not fall within the limits shown in figure 8, the adjustment of the trimmers may be touched up slightly, while observing the response curve. Do not retouch the setting of C202 at this point. To adjust the curve, first adjust C206 and C212, alternately, until maximum improvement has been obtained. C212 affects the tilt of the curve, and C206 affects the dip of the curve. After C212 and C206 have been adjusted, adjust C210 for proper slope at the 42.5-mc. side of the curve, then adjust C526 for proper level at the video carrier frequency (45.75 mc.). After these adjustments have been made, if the response curve still does not fall within the limits shown in figure 8, a slight readjustment of C202 is permissible.

CAUTION: Do not turn any of the trimmers excessively. To retouch, turn the trimmers only slightly.

SOUND I-F ALIGNMENT

1. Remove the 1st v-i-f tube, and connect a v.t.v.m. or a 20,000-ohms-per-volt voltmeter to the sound i-f alignment jig (figure 3). Adjust the VOLUME control for moderate speaker output.

2. Feed in an accurately calibrated 4.5-mc. AM signal, through the 2200-ohm resistor in the video i-f alignment jig, to pin 2 of J200.

3. Tune TC400, TC401, and TC402 for maximum indications on the meter. The point of maximum meter indication for TC402 should also be the point of minimum speaker output.

4. Tune TC402 for minimum speaker output.

5. Connect an r-f probe or crystal detector to the grid (pin 2) of the picture tube. See NOTE below.

6. Tune TC300 for minimum indication on oscilloscope. (If a crystal detector is not available, TC300 may be adjusted for minimum beat pattern, as observed on the picture tube, with a station picture present.)

7. Replace the 1st v-i-f tube. Tune in a station, using the speaker output as an indication of correct tuning.

8. Turn the FINE TUNING control clockwise to obtain a slightly fuzzy picture.

9. Tune TC402 for minimum AM (noise) output.

NOTE: The R-F Probe, Part No. 76-3595, is used as a detector of the 4.5-mc. signal, and the oscilloscope is used as an indicating device. An alternate crystal detector may be made up as shown in figure 9.

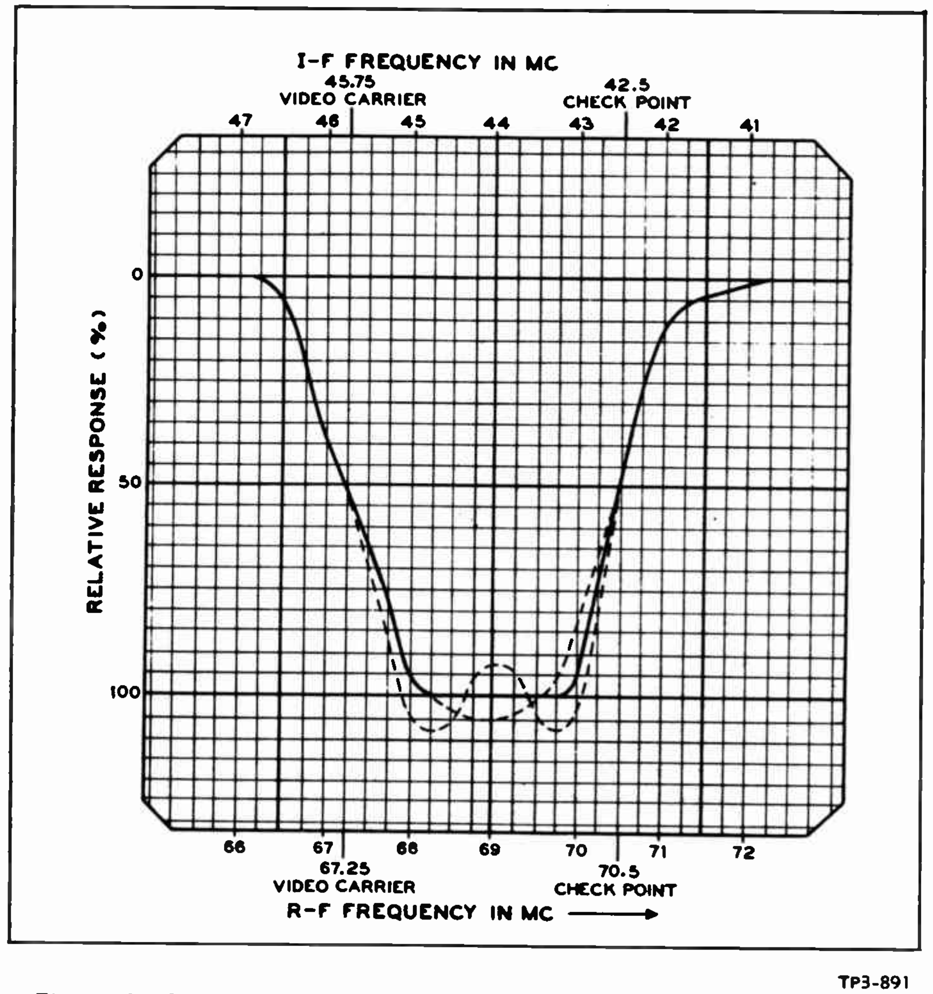

Figure 8. Over-All, R-F, I-F Response Curve, Showing Tolerance Limits

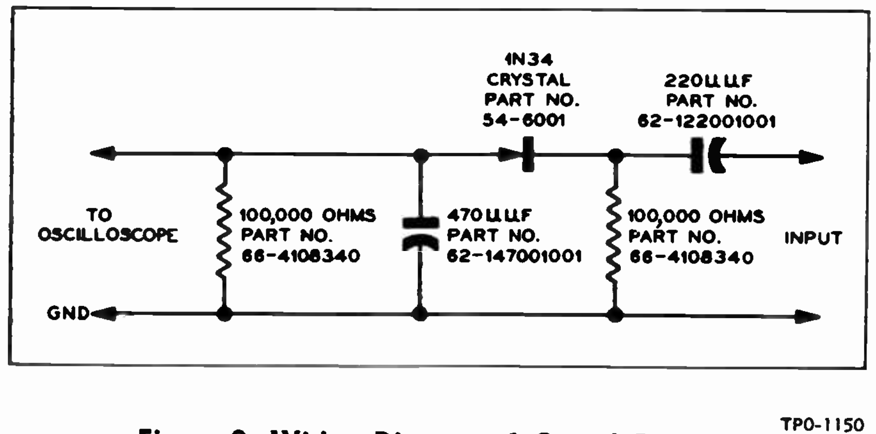

Figure 9. Wiring Diagram of Crystal Detector

OSCILLOSCOPE WAVEFORM PATTERNS

These waveforms were taken with the receiver adjusted for an approximate peak-to-peak output of 2 volts at the video detector. The voltages given with the waveforms are approximate peak-to-peak values. The frequencies shown are those of the waveforms—not the sweep rate of the oscilloscope. The waveforms were taken with an oscilloscope having good high-frequency response. With oscilloscopes having poor high-frequency response, the sharp peaks of the horizontal waveforms will be more rounded than those shown, and the peak-to-peak voltages will differ from those shown.

VOLTAGE MEASUREMENTS

The voltages given here and on the schematics were taken with a 20,000-ohms-per-volt voltmeter, with a line voltage of 117 volts, and no signal input to the receiver. Since voltage readings taken in the video i-f stages vary widely with different test equipment setups, voltage measurements for these stages are omitted from the diagrams.

*** See CAUTION.**

* CAUTION: High-voltage pulses are present in the horizontal-output circuit. The waveform in figure 28 was taken with the alligator clip of the oscilloscope lead clipped over the insulation of the lead connected to pin 7 of J800. (To prevent puncture of the insulation of the lead, file off the teeth of the alligator clip, and wrap friction tape around the clip.) Connection to other points in the horizontal-output circuit is dangerous, because of the high voltages present. The peak-to-peak voltage shown for figure 28 is the actual voltage present; however, the amplitude of the scope presentation depends upon the degree of coupling.

UHF TUNER-ADAPTER UT22, PART NO. 43-6703, FOR RECEIVERS USING R-F CHASSIS R-191

UHF Tuner-Adapter UT22, Part No. 43-6703, will provide for the reception of UHF Channels 14 through 83. It is designed for installation in Philco B line television receivers, and is installed on all BU models. These receivers use r-f chassis R-191.

The Tuner-Adapter consists of a UHF tuner, a change-over switch, adapter cables and plugs, a planetary tuner driving assembly, and mounting hardware.

CIRCUIT DESCRIPTION

The incoming UHF signal is coupled through the antenna input line to blocking condensers C1 and C2, leakage resistors R8 and R9, an i-f trap, C5-L1, C6-L2, and a 150-ohm transmission line, to the antenna tank of the tuner. See figure 37. The antenna tank is coupled to the mixer tank by means of the mutual coupling of L2 and L3 and the stray capacitance, C5. The desired signal is selected by tuning the antenna tank and the mixer tank to the correct frequency; this is accomplished by tuning condensers C3A, C3B, C3C, and C3D. These condensers, plus C3E and C3F, located in the oscillator tank circuit, form the manual tuning gang.

The signal is then fed to the crystal mixer circuit by means of the mutual coupling of L4 and L5. The local-oscillator signal is generated by a 6AF4 tube, V1, and its associated circuit. The frequency of oscillation is maintained at 45.75 mc. above the signal frequency in the antenna and mixer tank, in order to effect a 45.75-mc. video carrier intermediate frequency when the two signals are subsequently mixed in the crystal mixer tank.

The output signal from this local oscillator is introduced into the crystal mixer circuit through a 300-ohm, miniature transmission line and the mutual coupling of L7 to L5 and L8 to L6. These four printed inductances, in addition to C7, form the mixer board assembly. The signal is fed into a 6BQ7 preamplifier stage, then to the video i-f circuits, and through the UHF change-over switch, by means of a coaxial connection. On VHF operation, a 150,000-ohm resistor is placed in series with the UHF oscillator plate, rendering this oscillator inoperative.

The two tanks of the UHF tuner, the antenna tank and the mixer tank, are used to prevent the i-f signal from feeding back to the antenna and interfering with other receivers. These two tanks pass incoming signals very readily, but do not pass the i-f signal.

CHANGE-OVER SWITCH

The change-over switch supplied with the Tuner-Adapter is used to switch from VHF to UHF, and vice versa. It is installed on the back of the VHF tuner, and is operated by an actuator mounted on the VHF tuner shaft. When the Channel Selector of the VHF tuner is turned to the UHF position, the change-over switch makes proper connection for UHF operation. In this position, the switch places a 150,000-ohm resistor in series with the VHF B-plus lead, which drops the B-plus voltage applied to the VHF tuner. The antenna is connected to the UHF tuner, the VHF pilot light is turned off, and the UHF pilot lights are turned on; the output of the UHF tuner is connected to the video i-f input circuit.

When the VHF Channel Selector is turned to any VHF position, the change-over switch places a 150,000-ohm resistor in series with the UHF local-oscillator plate circuit, which drops the voltage applied to the plate, and disables the oscillator. The switch also connects the antenna to the VHF tuner, turns off the UHF pilot lights, and turns on the VHF pilot light.

ADAPTER CABLES AND PLUGS

The adapter plugs shown in the schematic diagram are not used in factory-installed units; the cables are wired directly into the chassis at the proper places. The plugs are used only in field-installed units. (Refer to the installation instructions for the proper method of inserting and connecting all plugs and cables.)

PLANETARY DRIVE

The UHF tuner is tuned by means of a 3-gang tuning condenser, which is driven through a specially designed planetary drive. The planetary drive is constructed so that fine tuning and coarse tuning can be accomplished with a single control knob. The tuning shaft is coupled to the driving shaft through three steel balls, which form a planetary drive that produces a slow rotation for fine tuning. See figure 38. After rotating 180 degrees with the tuning shaft, a pin engages the driving shaft, and the two shafts are direct-coupled, for coarse tuning. To re-engage the planetary drive for fine tuning, it is only necessary to reverse the direction of the rotation. The dial pointer

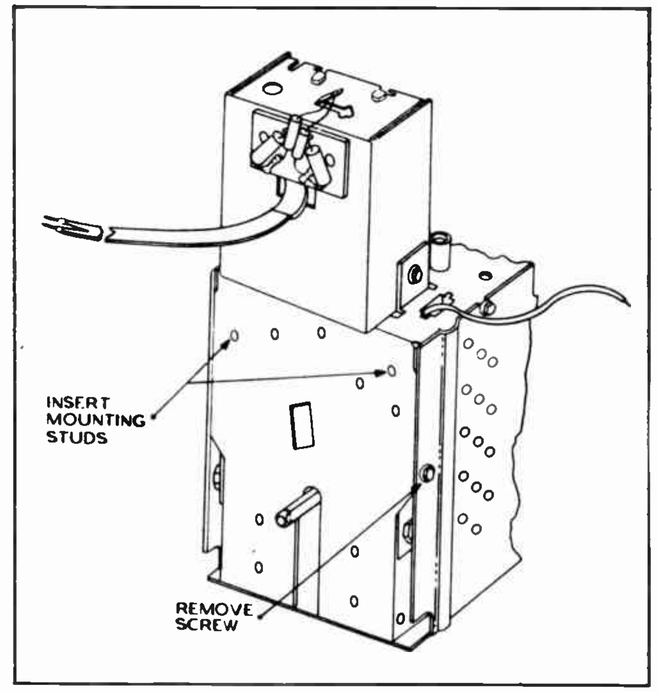
is connected to the tuning gang through a cord drive, and indicates the channel number to which the tuner is tuned.

ALIGNMENT AND REPAIRS

The frequencies at which the Tuner-Adapter operates are extremely high; therefore, it is necessary that the utmost care be taken to safeguard against upsetting the delicate adjustments of the tuner. It is recommended that the serviceman make only minor repairs to the tuner, such as replacement of the tube or crystal and the wiring of external leads. The



TP3-793
Figure 45. Rear View of VHF Tuner

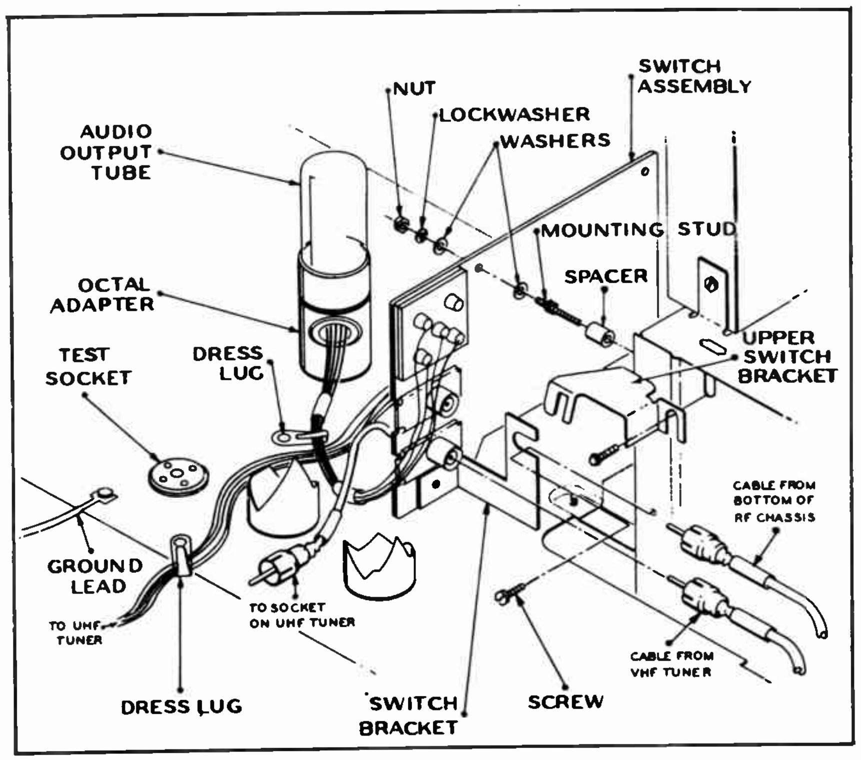
Tuner-Adapter should be returned to the factory for alignment or major repairs, unless the serviceman is properly equipped to perform these jobs. In general, a good rule to follow is not to remove the cover of the Tuner-Adapter, unless so equipped.

NOTE: Replacing the tube with a new one may detune the tuner. If this occurs, try a number of tubes until one is found that will provide the most satisfactory performance.

INSTALLATION INSTRUCTIONS

To install the UHF Tuner-Adapter on the r-f chassis, proceed as follows:

1. Remove the cabinet back and r-f chassis from the cabinet; then remove the nameplate on the control panel by pushing it out from inside the cabinet.
2. Insert the dial scale and bezel assembly into the hole provided in the cabinet. Fasten the assembly in place with the two nuts provided.
3. Remove the UHF tuner assembly from the mounting board with which it was shipped. Keep the three screws for mounting the tuner in the cabinet.
4. Remove the coaxial cables from the two sockets at the side of the VHF tuner. Remove the bracket and socket assembly (J500 and J201) from the back of the VHF tuner, and discard them.
5. Place the switch-actuator assembly on the shaft extending from the rear of the VHF tuner so that the switch-actuator stud points away from the tuner. See figure 44. Place the spacers on the mounting studs



TP3-795

Figure 46. Change-Over Switch Mounting Details and Lead-Dress Details

and attach to the rear of the VHF tuner on the r-f chassis. See figure 45.

6. Remove the screw on the side of the VHF tuner, as shown in figure 41. Place the switch assembly on the two mounting studs, and fasten it in place with the flat washers, lock washers, and nuts provided. See figure 46. Fasten the upper switch bracket in place as shown in figure 46.

7. Put the VHF Channel Selector in the Channel 2 position. Rotate the switch actuator clockwise (as viewed from the rear of the VHF tuner) on the tuner shaft until the actuator touches the fiber cam on the change-over switch. Fasten the switch actuator in this position. Rotate the Channel Selector to the UHF position. Check the switch operation to make sure that the switch is thrown properly. Rotate the Channel Selector to Channel 13 position and check the switch operation to make sure that the switch is not thrown in this position. Fasten the lower switch bracket to the side of the VHF tuner with the screw removed in step 6. Lubricate the switch-actuator stud and switch cam with cup grease.

8. Remove the audio-output tube from its socket, and insert the adapter plug into the socket. Insert the tube into the adapter. See figure 46.

9. Insert the coaxial cable from the VHF tuner into the bottom socket on the change-over switch. Insert the coaxial cable from the r-f chassis into the top socket on the switch. See figure 46.

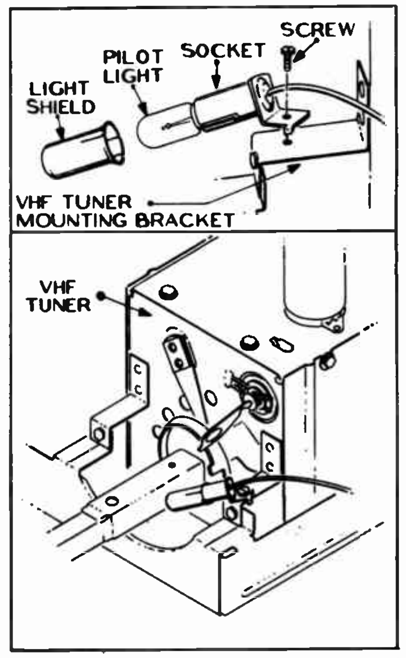
10. Pull the orange lead from the VHF tuner up out of the r-f chassis, and cut it off at the point where it comes through the chassis. Skin the orange lead attached to the VHF tuner, and solder it to the lug on the change-over switch, as shown in figure 44.

CAUTION: The orange lead supplies B plus to the VHF tuner. Tape the loose end to prevent shorting to the chassis.

11. Remove the pilot lamp from the r-f chassis pilot-light socket. Cut the pilot-light lead from the r-f chassis where it passes through the chassis, and discard the socket and lead. Tape up the lead to prevent the possibility of a short circuit. Mount the new pilot-light socket from the change-over switch with the drive screw provided, as shown in figure 47. Insert the pilot light in the socket, and install the shield provided over it.

12. Remove the antenna lead from the VHF tuner, and solder the short lead from the UHF-VHF change-over switch to the VHF tuner terminals from which the antenna lead was removed. Slide the folded fiber lead holder over the tapered-line coil assembly on the VHF tuner, and dress the twin-wire antenna leads through the holder. See figure 44. The fiber holder will prevent the twin-wire leads from touching the tubes on the r-f chassis.

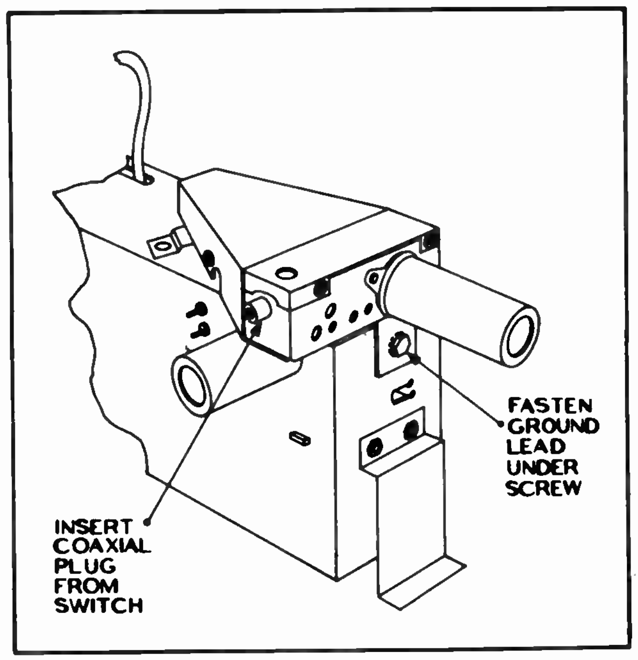
13. Place the UHF tuner in the cabinet between the r-f and deflection chassis, and fasten the UHF



TP3-755

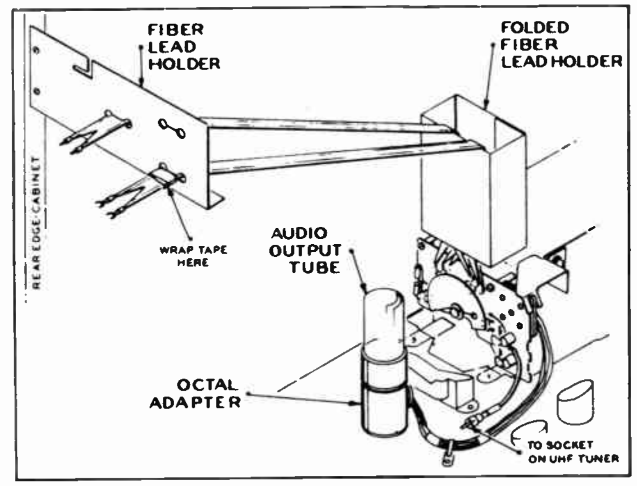
Figure 47. Pilot Light Mounting Details

tuner to the chassis shelf with the three screws removed in step 3. It is important that these screws be tightened securely, so as to hold the UHF tuner in place on the chassis shelf. Turn the UHF tuning shaft to its extreme counterclockwise position, and check the pointer position on the scale. The pointer should be positioned just below the Channel 14 mark on the scale. If the pointer is not properly positioned, loosen the three mounting bolts and move the UHF tuner



TP3-792

Figure 48. UHF Tuner, Showing Location of Ground Lead and Coaxial Socket



TP3-794

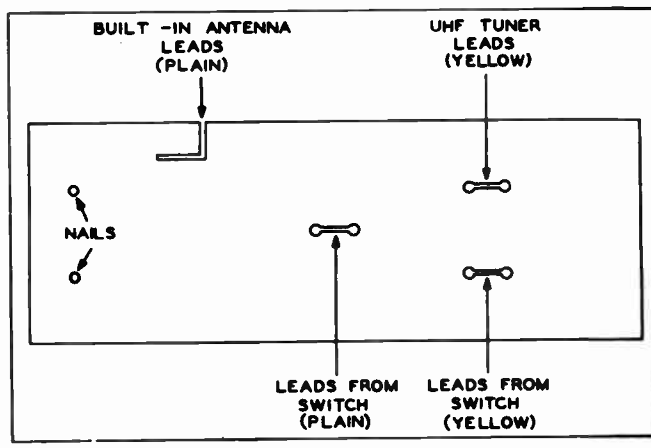
Figure 49. Rear View of VHF Tuner, Showing Lead Dress

assembly to properly position the pointer; then fasten the assembly with the three mounting screws.

14. Fasten the ground lead and the dress lugs to the r-f chassis with drive screws. See figure 46. Install the chassis in the cabinet, and fasten the ground strap under the screw on the UHF tuner as shown in figure 48. Fasten the r-f chassis with the original mounting bolts. Place the original knobs on their shafts, and the felt washer and knob supplied on the UHF tuning shaft.

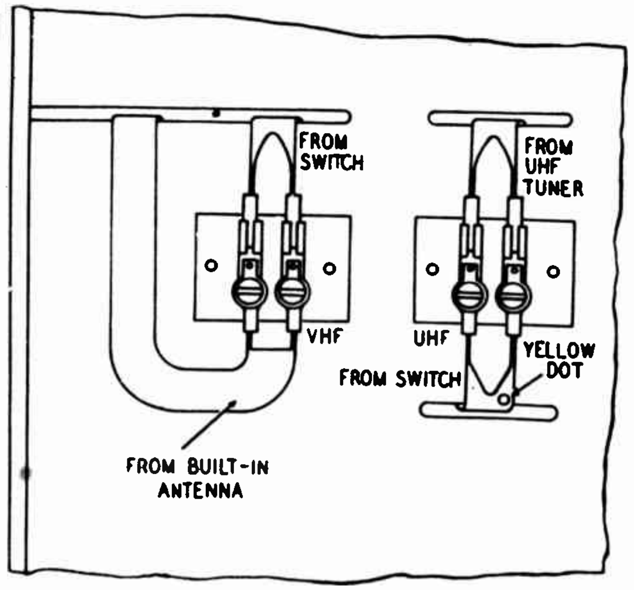
15. Insert the coaxial plug from the change-over switch into the socket on the UHF tuner. See figure 48. Insert the 5-pin plug from the UHF tuner into the socket on the bracket at the rear of the VHF tuner. Dress the leads under the dress lug as shown in figure 46.

16. Replace the fiber antenna-lead holder with the new holder provided. Fasten the new holder with the nails provided (or screws for metal cabinets), and then pass the twin-wire leads through the holes as shown in figures 49 and 50. Pull the leads through



TP2-3169

Figure 50. Antenna-Lead Holder



TP2-3170-1

the holder until they are tight, making certain that the leads do not contact the tubes or the chassis. Wrap tape around the yellow-marked twin-wire leads with the spade-lug ends, to prevent the leads from passing back through the fiber holder..

17. Fasten the antenna terminal board provided as shown in the illustrations above (figures 51 to 55). Replace the cabinet back, and make the connections as illustrated, according to the type of antenna installation being used.

18. Paste the label provided over the outside-antenna instructions on the cabinet back.

PARTS LIST

IMPORTANT

General replacement items commonly stocked by the serviceman are omitted from this parts list. All condensers are molded-bakelite Philco condensers, with a 600-volt rating, and all resistors are ½ watt, unless otherwise indicated. Parts are listed according to chassis type, and should be ordered in this way rather than by model number. A list of miscellaneous parts is given at the end of the parts list for each chassis type. All parts are symbolized in the schematic diagram and base layout, for identification purposes.

NOTE: Part numbers identified by an asterisk (*) are general replacement items. These numbers may not be identical with those on factory parts. Also, the electrical values of some replacement items may differ from the values indicated in the schematic diagram and parts list. The values substituted in any case are so chosen that the operation will be unchanged. When ordering replacements, use only the "Service Part No."

C502	Condenser, FM trap, 20 $\mu\mu$f.	30-1251-4
C503	Condenser, grid coupling, 39 $\mu\mu$f.	62-039403011
C505	Condenser, a-g-c by-pass, 220 $\mu\mu$f.	62-122001011
C506	Condenser, grid by-pass, 680 $\mu\mu$f.	62-168001011
C507	Condenser, decoupling, .01 μf.	30-1238-6
C508	Condenser, trimmer, r-f plate, .5—3 $\mu\mu$f.	31-6520-3
C509	Condenser, by-pass, 150 $\mu\mu$f.	62-115001011
C510	Condenser, coupling, .68 $\mu\mu$f.	30-1221-11
C511	Condenser, coupling, 15 $\mu\mu$f.	62-015409011
C512	Condenser, trimmer, mixer grid, .5—3 $\mu\mu$f.	31-6520-7
C513	Condenser, oscillator coupling, 2.2 $\mu\mu$f.	30-1221-6
C514	Condenser, grid blocking, 15 $\mu\mu$f.	30-1224-113
C515	Condenser, fixed trimmer, 3.3 $\mu\mu$f.	30-1224-114
C516	Condenser, FINE TUNING, plastic tube	76-6935-1
C517	Condenser, by-pass, 3.3 $\mu\mu$f.	30-1224-58
C518	Condenser, output coupling, 680 $\mu\mu$f.	62-168001021
C519	Condenser, screen by-pass, 680 $\mu\mu$f.	62-168001011
C520	Condenser, filament by-pass, 220 $\mu\mu$f.	62-122001011
C521	Condenser, filament by-pass, 800 $\mu\mu$f.	30-1238-7
C522	Condenser, coupling, 3.9 $\mu\mu$f.	30-1221-14
C523	Condenser, coupling, .82 $\mu\mu$f.	30-1221-10
C524	Condenser, filament by-pass, 220 $\mu\mu$f.	62-122001011
C525	Condenser, by-pass, 800 $\mu\mu$f.	30-1238-7
C527	Condenser, i-f trap, 22 $\mu\mu$f.	Part of L527

R-F CHASSIS R-191 (Cont.)

TV TUNER, PART No. 76-8400 (Cont.)

Reference Symbol	Description	Service Part No.
J500	Socket, tuner link	Part of Connector ass'y., tuner to i-f (see Misc. "C")
L500, L501, L502, and L503	Coils, tapered line	32-4432-3
L504	Coil, FM trap	32-4550-3
L505 to L511 incl.	Coils, antenna tuning	Part of WS500A
L512	Coil, r-f coupling	312-5145-22
L513 to L519 incl.	Coils, r-f plate tuning	Part of WS500B
L520 to L526 incl.	Coils, mixer grid tuning	Part of WS500C
L527	Coil, i-f trap	32-4552-1
L528	Coil, mixer plate	312-5151-10
L530	Coil, filament choke	32-4550-1
L531	Coil, filament choke	32-4550-11
L532 to L538 incl.	Coils, oscillator tuning	Part of WS500D
PL500	Plug, tuner link	Part of Cable and Plug ass'y. (see Misc. "C")
R508	Resistor, oscillator feed, 33,000 ohms	66-3334340
R510	Resistor, mixer plate feed, 10,000 ohms, 1 watt	66-3104540
WS500A(F) and WS500A(R)	Switch, wafer, antenna	76-8410
WS500B(F) and WS500B(R)	Switch, wafer, r-f plate	76-8409
WS500C(F) and WS500C(R)	Switch, wafer, mixer grid	76-8408
WS500D(F) and WS500D(R)	Switch, wafer, oscillator	76-8407
Z500	Tapered line ass'y.	76-8417

UHF TUNER-ADAPTER UT21B, PART NO. 43-6592 FOR RECEIVERS USING R-F CHASSIS 81 OR 84

UHF Tuner-Adapter UT21B, Part No. 43-6592, provides for the reception of UHF signals on television channels 14 through 83. It is designed for installation in Philco Television Receiver models that have a model number beginning with "A-T," and use r-f chassis 81 or 84. The adapter consists of a UHF converter and preamplifier unit, a change-over switch, adapter cables and plugs, a planetary tuner driving assembly, and mounting hardware.

CIRCUIT DESCRIPTION

The UHF Tuner-Adapter functions as a converter, and converts the signals of the UHF band to a frequency selected within the VHF band. The frequency selected is that of either Channel 2 or Channel 3, depending upon the locality in which the receiver is used.

The incoming UHF signal is coupled through the antenna input line, and through two 680-$\mu\mu$f. condensers and a 150-ohm transmission line to the antenna tank of the tuner. See figure 1. The antenna tank is coupled to the mixer tank by means of the mutual coupling of L2 and L3 and the stray capacitance, C5. The desired signal is selected by tuning the antenna tank and the mixer tank to the proper frequency, and the signal is then coupled to the crystal mixer circuit by means of the mutual coupling of L4 and L5. The local-oscillator signal is generated by a 6AF4 tube, V1, and the associated circuit. The local-oscillator signal is coupled to the crystal mixer circuit by means of a 300-ohm, miniature transmission line and the mutual coupling of L7 to L5 and L8 to L6. The UHF r-f signal and the oscillator signal are mixed in the crystal mixer circuit, producing a radio-frequency signal within range of the VHF tuner when the tuner is set to either Channel 2 or Channel 3. This signal is fed into a preamplifier, which amplifies it, and it is then fed into the VHF tuner through a twin-wire lead. In the VHF tuner, the signal is converted to the intermediate frequency of the television receiver. In VHF operation, a 150,000-ohm resistor is placed in series with the UHF oscillator plate, which makes this oscillator inoperative.

The purpose of using two r-f tanks in the UHF tuner is to readily admit the r-f signals, and, at the same time, prevent the UHF i-f and oscillator signals from feeding back into the antenna and causing interference with other receivers.

CHANGE-OVER SWITCH

The change-over switch supplied with the Tuner-Adapter is used to switch from VHF to UHF, and vice versa. It is installed on the back of the VHF tuner, and is operated by an actuator mounted on the VHF tuner shaft. When the VHF Channel Selector is turned to the position fo- UHF operation, the switch connects the antenna to the UHF tuner, turns off the VHF pilot light, turns on the UHF pointer pilot light, and connects the output of the UHF tuner to the antenna input of the VHF tuner. When the VHF Channel Selector is turned to any VHF position, the switch connects the antenna to the VHF tuner, turns off the UHF pointer pilot light, turns on the VHF pilot light, and places a 150,000-ohm resistor in series with the UHF oscillator plate, as explained above.

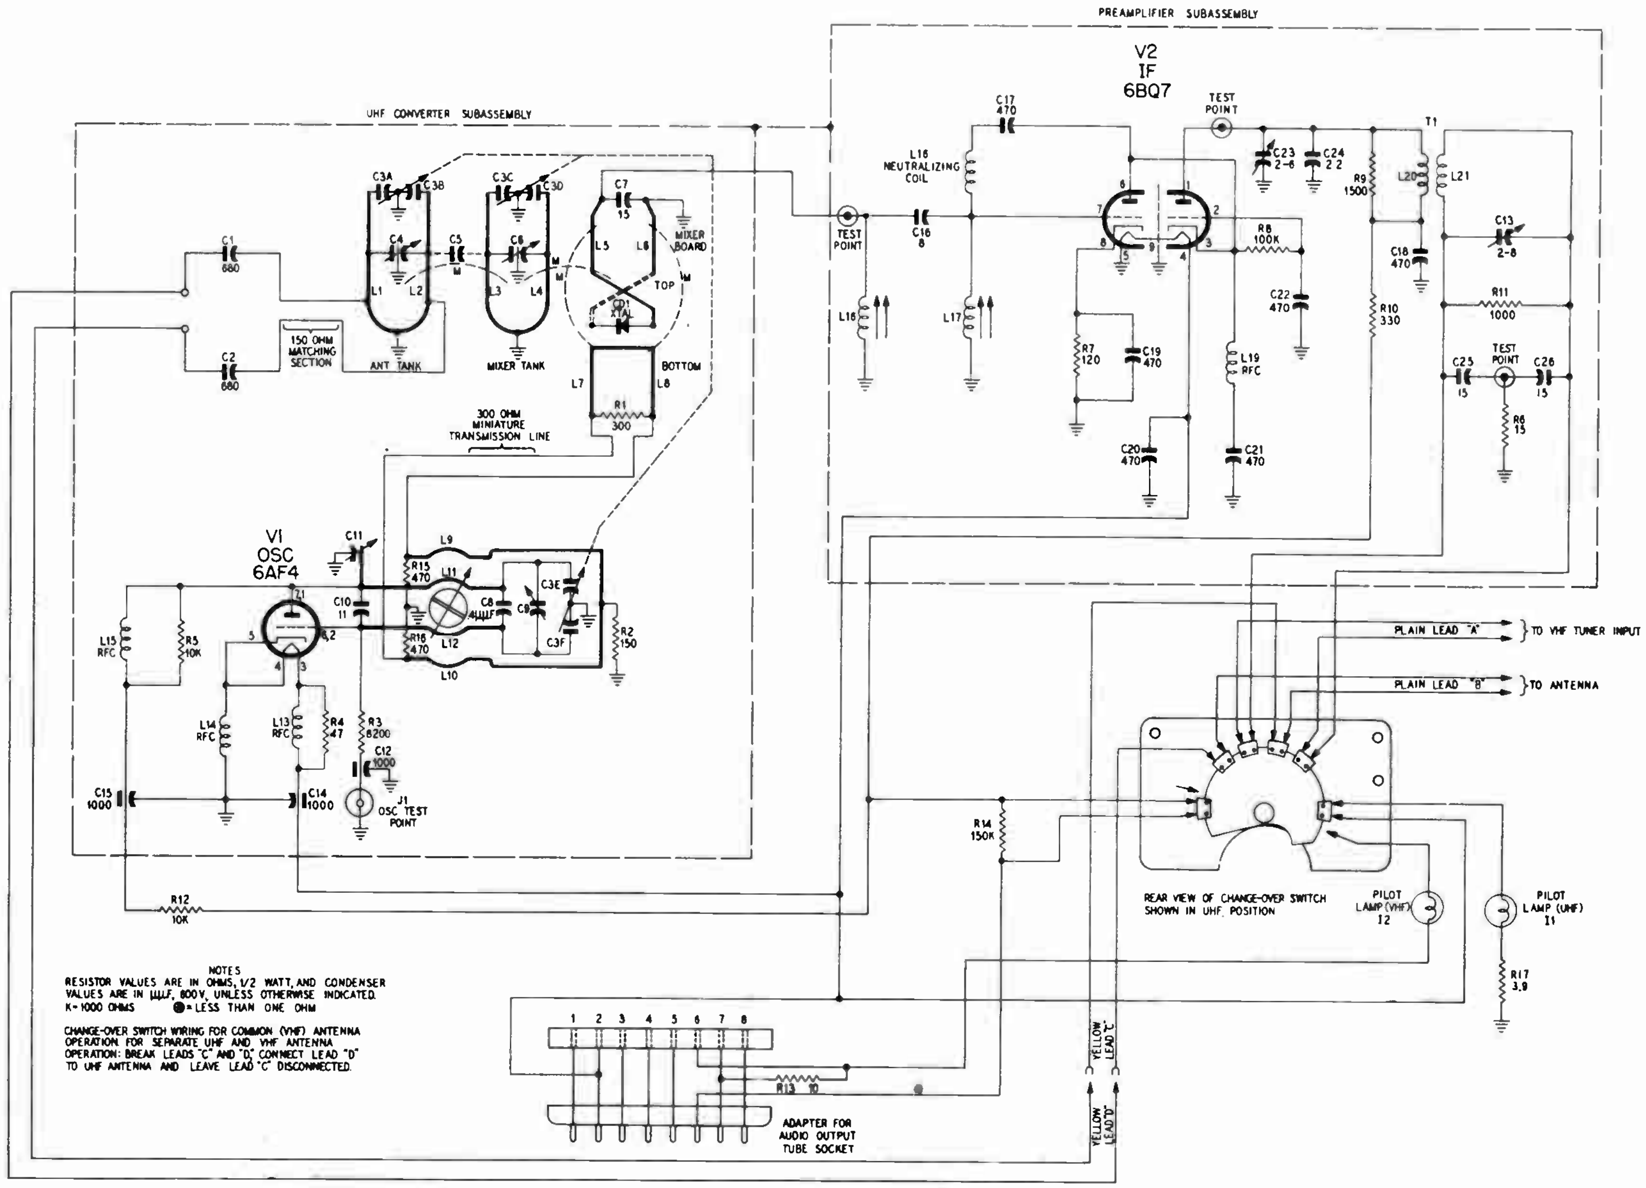

Figure 1. UHF Tuner-Adapter UT21B, Part No. 43-6592, Schematic Diagram

PLANETARY DRIVE

The UHF tuner is tuned by means of a 3-gang tuning condenser, which is driven through a specially designed planetary drive. The planetary drive is so constructed that fine tuning and coarse tuning can be accomplished with a single control knob. The tuning shaft is coupled to the driving shaft through three balls, which form a planetary drive that produces slow rotation for fine tuning. See figure 2. After rotating 180 degrees with the tuning shaft, a pin engages the driving shaft, and the two shafts are direct-coupled, for coarse tuning. To re-engage the planetary drive for fine tuning, it is only necessary to reverse the direction of the rotation. The dial pointer is connected to the tuning gang through a cord drive, and indicates the channel number to which the tuner is tuned.

BEAM-OF-LIGHT POINTER

The beam-of-light pointer consists of a pilot-light-socket assembly, a small light box, a focusing lens, and a mechanical assembly which moves the unit as the tuning shaft is rotated. The lamp, light box, and lens project a beam of light on the dial scale, and the mechanical assembly moves this beam across the scale. The pointer drive cord connects the pointer assembly to the tuning shaft.

ALIGNMENT AND REPAIRS

The frequencies at which the Tuner-Adapter operates are extremely high; therefore, it is necessary that the utmost care be taken to safeguard against upsetting the delicate adjustments of the tuner. It is recommended that the serviceman make only minor repairs to the tuner, such as replacement of the tube or crystal and the wiring of external leads. The Tuner-Adapter should be returned to the factory for alignment and major repairs, unless the serviceman is properly equipped to perform these jobs. In general, a good rule to follow is not to remove the cover of the Tuner-Adapter.

NOTE: Replacing the tube with a new one may detune the tuner. If this occurs, a number of tubes should be tried, until the most satisfactory substitute for the original is found.

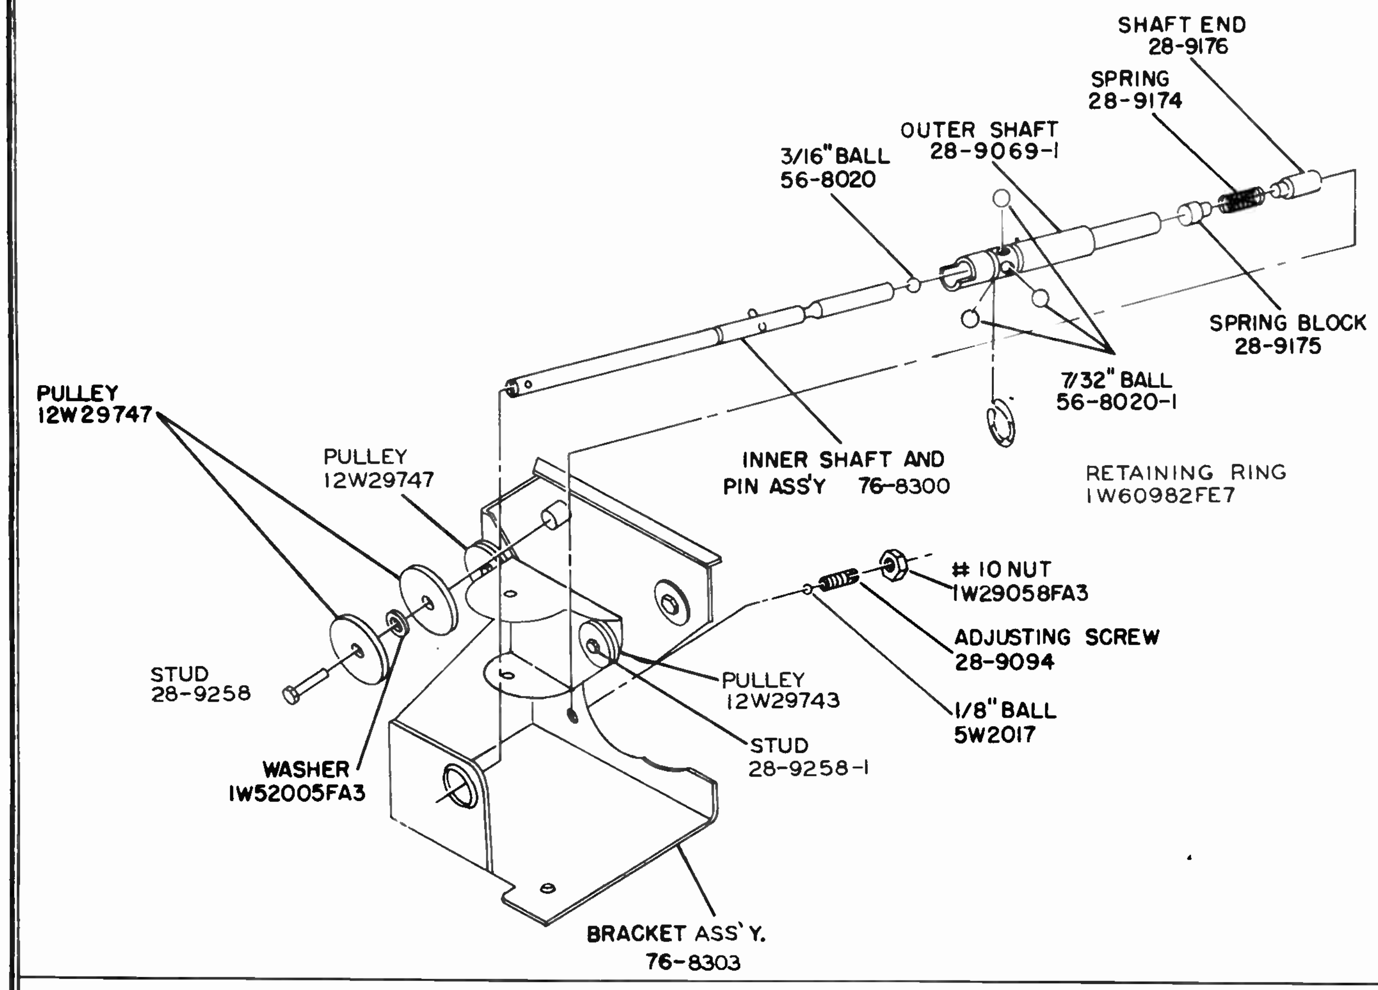

Figure 2. Planetary Drive Assembly, Exploded View, Showing Mechanical Construction (Both Tuner-Adapters)

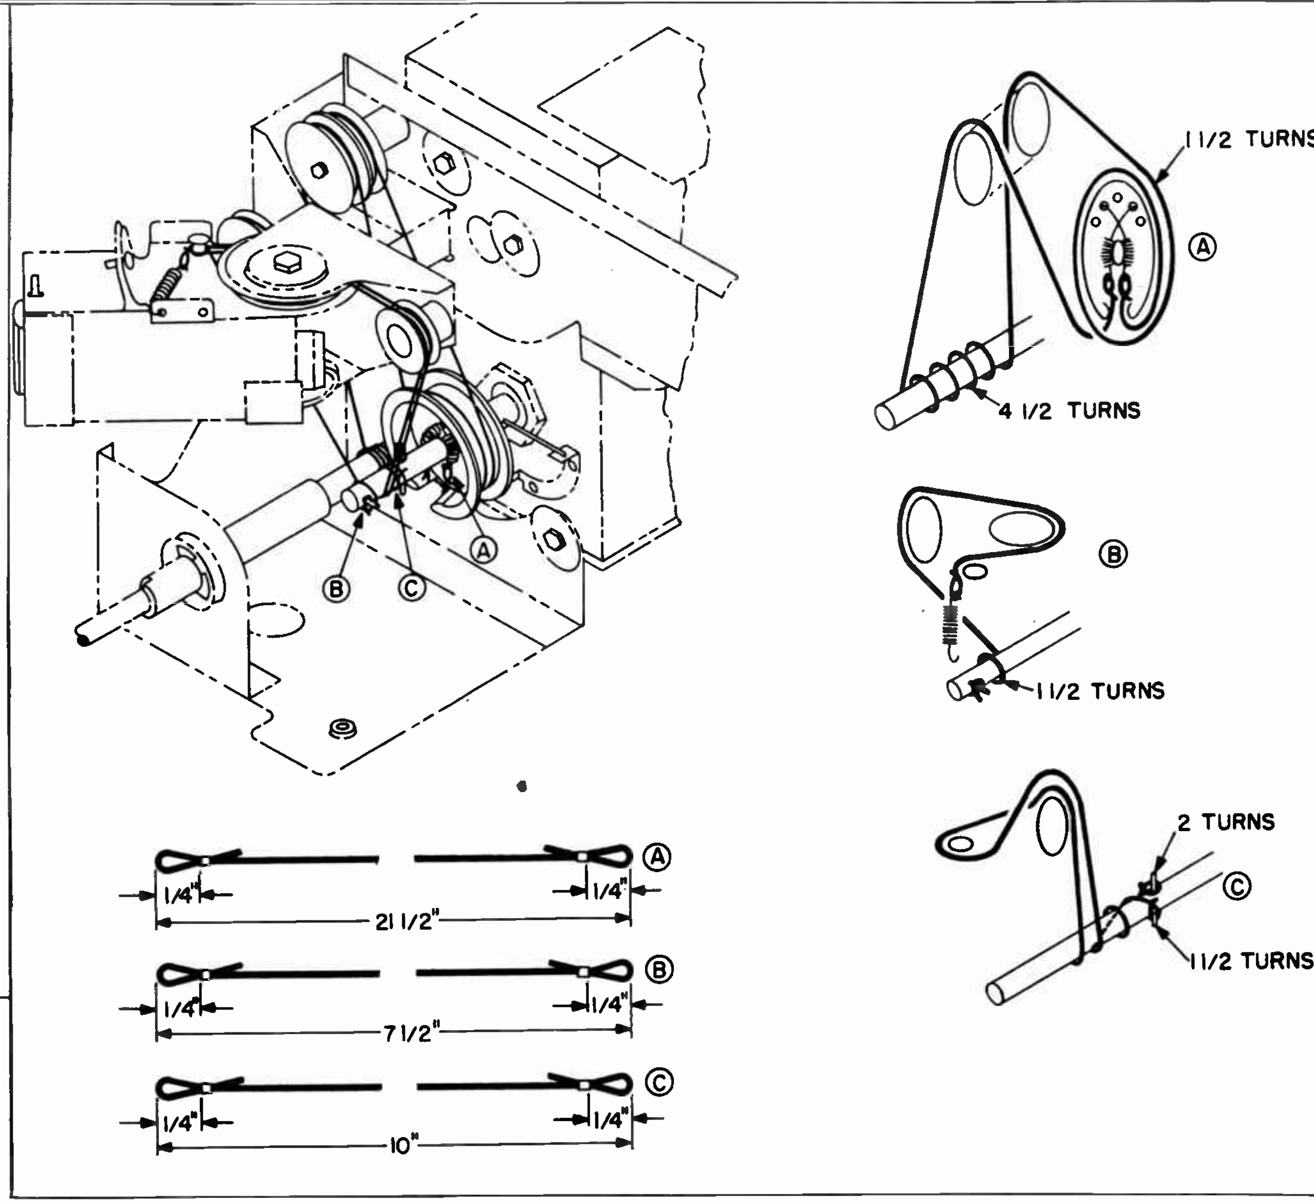

Figure 3. Drive-Cord Stringing Arrangement (Both Tuner-Adapters)

INSTALLATION INSTRUCTIONS

To install the Tuner-Adapter on the r-f chassis, proceed as follows:

1. Remove the cabinet back and r-f chassis from the cabinet. Then remove the nameplate on the control panel by pushing it out from inside the cabinet.

2. Insert the dial scale and bezel assembly into the hole provided in the cabinet. The four studs should be passed through the four holes provided. Fasten the assembly in place with the washers and small palnuts provided.

3. Remove the tuner assembly from the mounting board with which it is was shipped. Keep the screws for mounting the tuner in the cabinet.

4. Place the spacers on the mounting studs, and use the studs to attach the bracket and socket assembly to the rear of the VHF tuner on the r-f chassis, as shown in figure 4.

5. Place the switch-actuator assembly on the shaft extending from the rear of the VHF tuner so that the switch-actuator stud points away from the tuner. See figure 4.

6. Place the switch assembly on the mounting studs, and fasten it in place with the fiber washers, lock washers, and nuts provided. See figure 4.

7. The UHF tuner is designed to convert the UHF signals to the frequency of Channel 2 or Channel 3. If a VHF station is available on Channel 2 in the area where the receiver is to be used, set the switch actuator to operate the switch on Channel 3. If a station is available on Channel 3, set the actuator to throw the switch on Channel 2. Fasten the actuator in place, and check the operation of the actuator stud and the switch, to see that the switch is thrown properly.

8. Remove the bulb and shield from the pilot-light assembly on the r-f chassis, and place them in the empty socket of the UHF tuner assembly. Tape up the old socket of the r-f chassis with the tape provided.

9. Remove the audio output tube (6K6GT in r-f chassis 81, or 6L6GA in r-f chassis 84), plug the octal adapter into the tube socket, and place the tube in the adapter socket. The octal adapter is wired to the switch.

10. Remove the antenna lead from the VHF tuner, and solder the short lead from the UHF-VHF change-over switch to the VHF tuner antenna terminals from which the antenna lead was removed. See figure 4.

11. Fasten the dress lug to the chassis with the screw provided (see figure 5); then dress the leads under the lug.

12. Install the r-f chassis in the cabir t, and insert the pilot-light socket into the pilot-light clip. Fasten the r-f chassis with the original bolts. Place the original knobs on their shafts.

13. Place the UHF tuner in the cabinet, between the r-f and deflection chassis, and fasten the UHF tuner to the chassis shelf with the three screws removed in step 3. It is important that these screws be tightened securely, to hold the UHF tuner in place on the chassis shelf.

14. Plug the 5-pin plug of the UHF tuner into the 5-pin socket on the bracket installed in step 4. Fasten the lead with the clip over the pin located near the 5-pin socket. Dress the leads as shown in figure 5.

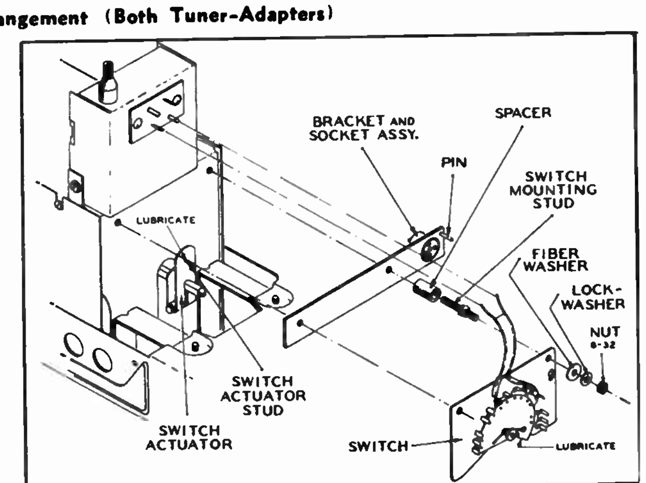

Figure 4. Change-Over Switch Mounting Details (Tuner-Adapter Part No. 43-6592)

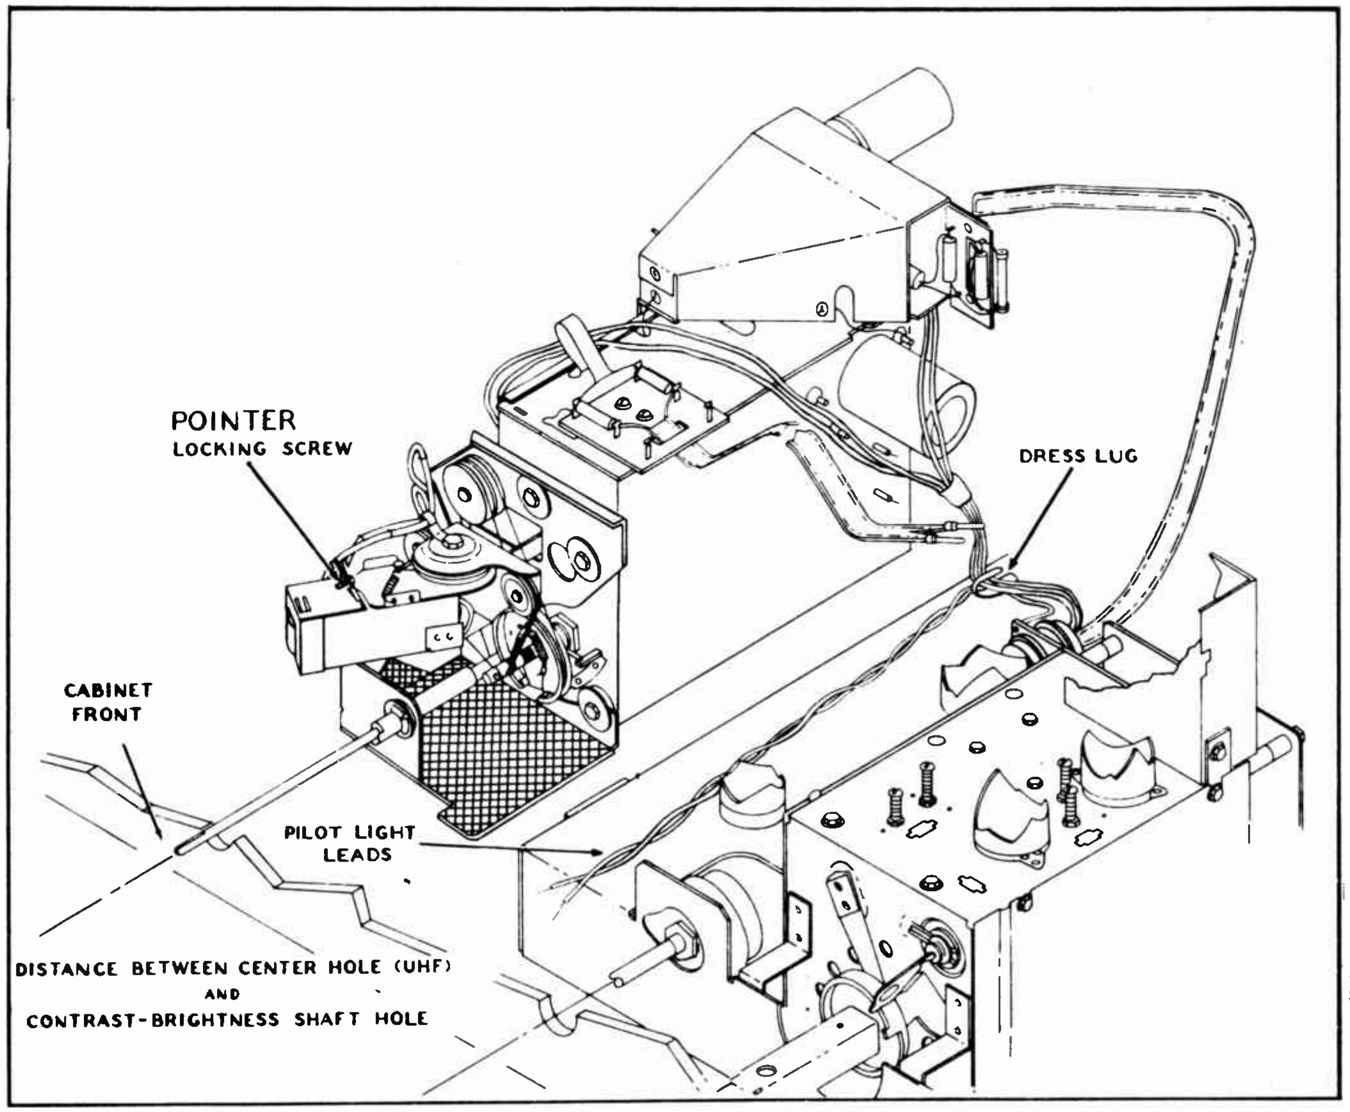
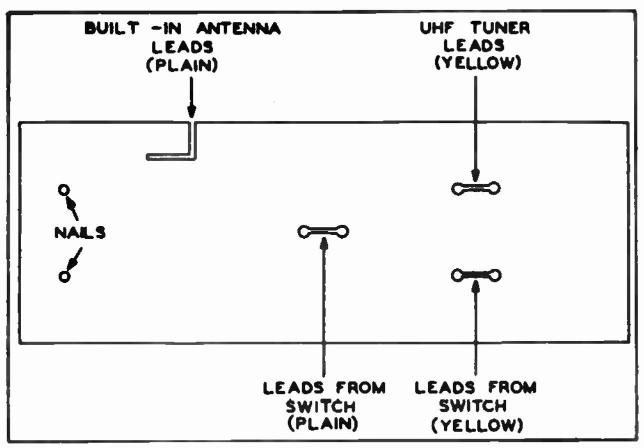


TP2-3282

Figure 5. Lead Dress and Tuner Mounting Details (Tuner-Adapter Part No. 43-6592)

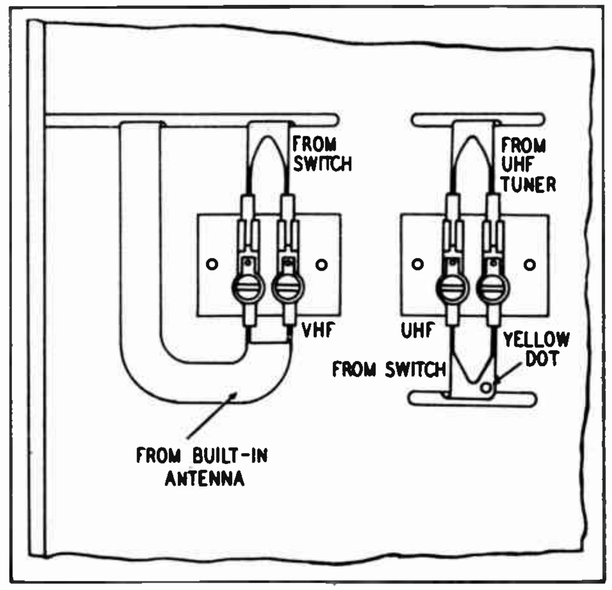


TP2-3169

Figure 6. Antenna-Lead Holder (Both Tuner-Adapters)

15. Place the knob provided on the UHF tuner shaft, and set the tuning shaft in the extreme counter-clockwise position. Turn the receiver on, and set the VHF Channel Selector to UHF. From the back of the cabinet, observe the position of the beam-of-light pointer on the back of the scale. If the light beam does not fall on the index mark, turn the receiver off and loosen the locking screw on the pointer. See figure 5. Move the pointer assembly slightly in the required direction. Again turn the receiver on and observe the position of the light-beam pointer. If necessary, repeat the adjustment until the pointer falls on the index mark; then fasten the locking screw.

16. Replace the fishpaper antenna-lead holder with the new holder provided. Fasten the new holder with the two nails provided, and then pass the twin-wire leads through the holes as indicated in figure 6.



TP2-3170

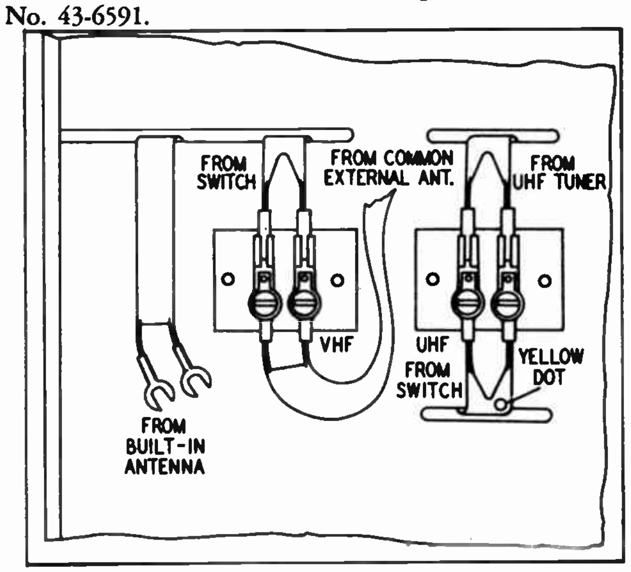
Figure 7. Antenna-Lead Connections, Common Built-in Antenna (Both Tuner-Adapters)

17. Fasten the antenna terminal board provided as shown in figures 7 through 11. Replace the cabinet back, and make the connections illustrated for the type of antenna installation being used.

18. Paste the label provided over the outside-antenna instructions on the cabinet back.

REPLACING AND ADJUSTING BEAM-OF-LIGHT POINTER PILOT LAMP

When the beam-of-light pointer pilot lamp is replaced, or if the assembly is disturbed, the pointer assembly must be refocused. To refocus the assembly, follow the procedure given under the above heading in the section on UHF Tuner-Adapter UT20A, Part No. 43-6591.



TP2-3172

UHF TUNER-ADAPTER UT20A, PART NO. 43-6591, FOR RECEIVERS USING R-F CHASSIS 91A, 94A, OR 97

UHF Tuner-Adapter UT20A, Part No. 43-6591, provides for the reception of UHF signals on television channels 14 through 83. It is designed for installation in Philco High-Fidelity Television Receivers using r-f chassis 91A or 94A. The Tuner-Adapter may also be used in receivers using r-f chassis 97, if it is used in conjunction with Extension Kit, Part No. 43-6593.

The Tuner-Adapter consists of a UHF tuner, a change-over switch, adapter cables and plugs, a planetary tuner driving assembly, and mounting hardware.

CIRCUIT DESCRIPTION

The UHF tuner converts the UHF signals to the intermediate frequency of the r-f chassis.

The incoming UHF signal is coupled through the antenna input line, and through two i-f traps, two 680-$\mu\mu$f. condensers, and a 150-ohm transmission line to the antenna tank of the tuner. See figure 16. The antenna tank is coupled to the mixer tank by means of the mutual coupling of L2 and L3 and the stray capacitance, C5. The desired signal is selected by tuning the antenna tank and the mixer tank to the correct frequency, and the signal is then coupled to the crystal mixer circuit by means of the mutual coupling of L4 and L5. The local-oscillator signal is generated by a 6AF4 tube, V1, and the associated circuit. The oscillator signal is coupled to the crystal mixer circuit by a 300-ohm, miniature transmission line and the mutual coupling of L7 to L5 and L8 to L6. The r-f signal and the oscillator signal are mixed in the crystal mixer circuit to produce a 45.75-mc. video-carrier intermediate-frequency signal. This signal is coupled to the VHF tuner through L18, a coaxial cable, and J500 on the VHF tuner. In UHF operation, the local oscillator of the VHF tuner is inoperative, and the r-f amplifier and mixer tubes of the VHF tuner operate as i-f amplifiers.

The two tanks of the UHF tuner, the antenna tank and the mixer tank, are used to prevent the i-f and oscillator signals from feeding back to the antenna and interfering with other receivers. The two tanks pass incoming signals readily, but do not pass the i-f or oscillator signal.

CHANGE-OVER SWITCH

The change-over switch supplied with the Tuner-Adapter is used to switch from VHF to UHF, and vice versa. It is installed on the back of the VHF tuner, and is operated by an actuator mounted on the VHF tuner shaft. When the Channel Selector of the VHF tuner is turned to the UHF position, the change-over switch makes proper connections for UHF operation. In this position, the switch places a 150,000-ohm resistor in series with the VHF mixer plate, which drops the voltage on the plate of the tube. (In the UHF position, the VHF Channel Selector places extra inductances in the VHF r-f and mixer circuits, permitting them to operate as i-f amplifiers, and it also shunts the VHF oscillator grid circuit with a 10-ohm resistor, putting the oscillator out of operation.) The change-over switch also turns off the VHF pilot light, turns on the UHF pointer pilot light, and connects the antenna to the UHF tuner.

When the VHF Channel Selector is turned to any VHF position, the change-over switch places a 150,000-ohm resistor in series with the UHF local-oscillator plate circuit, which drops the voltage applied to the plate, and puts the oscillator out of operation. The switch also turns on the VHF pilot light, turns off the UHF pointer pilot light, and connects the antenna to the VHF tuner.

PLANETARY DRIVE

The UHF tuner is tuned by means of a 3-gang tuning condenser, which is driven through a specially designed planetary drive. The planetary drive is so constructed that fine tuning and coarse tuning can be accomplished with a single control knob. The tuning shaft is coupled to the driving shaft through three balls, which form a planetary drive that produces slow rotation for fine tuning. See figure 2. After rotating 180 degrees with the tuning shaft, a pin engages the driving shaft, and the two shafts are direct-coupled, for coarse tuning. To re-engage the planetary drive for fine tuning, it is only necessary to reverse the direction of rotation. The dial pointer is connected to the tuning gang through a cord drive, and indicates the channel number to which the tuner is tuned.

BEAM-OF-LIGHT POINTER

The beam-of-light pointer consists of a pilot light and socket assembly, a small light box, a focusing lens, and a mechanical assembly which moves the unit as the tuning shaft is rotated. The lamp, light box, and lens project a beam of light on the dial scale, and the mechanical assembly moves this beam across the scale. The pointer drive cord connects the pointer assembly to the tuning shaft.

ALIGNMENT AND REPAIRS

The frequencies at which the Tuner-Adapter operates are extremely high; therefore, it is necessary that the utmost care be taken to safeguard against upsetting the delicate adjustments of the tuner. It is recommended that the serviceman make only minor repairs to the tuner, such as replacement of the tube or crystal and the wiring of external leads. The Tuner-Adapter should be returned to the factory for alignment and major repairs, unless the serviceman is properly equipped to perform these jobs. In general, a good

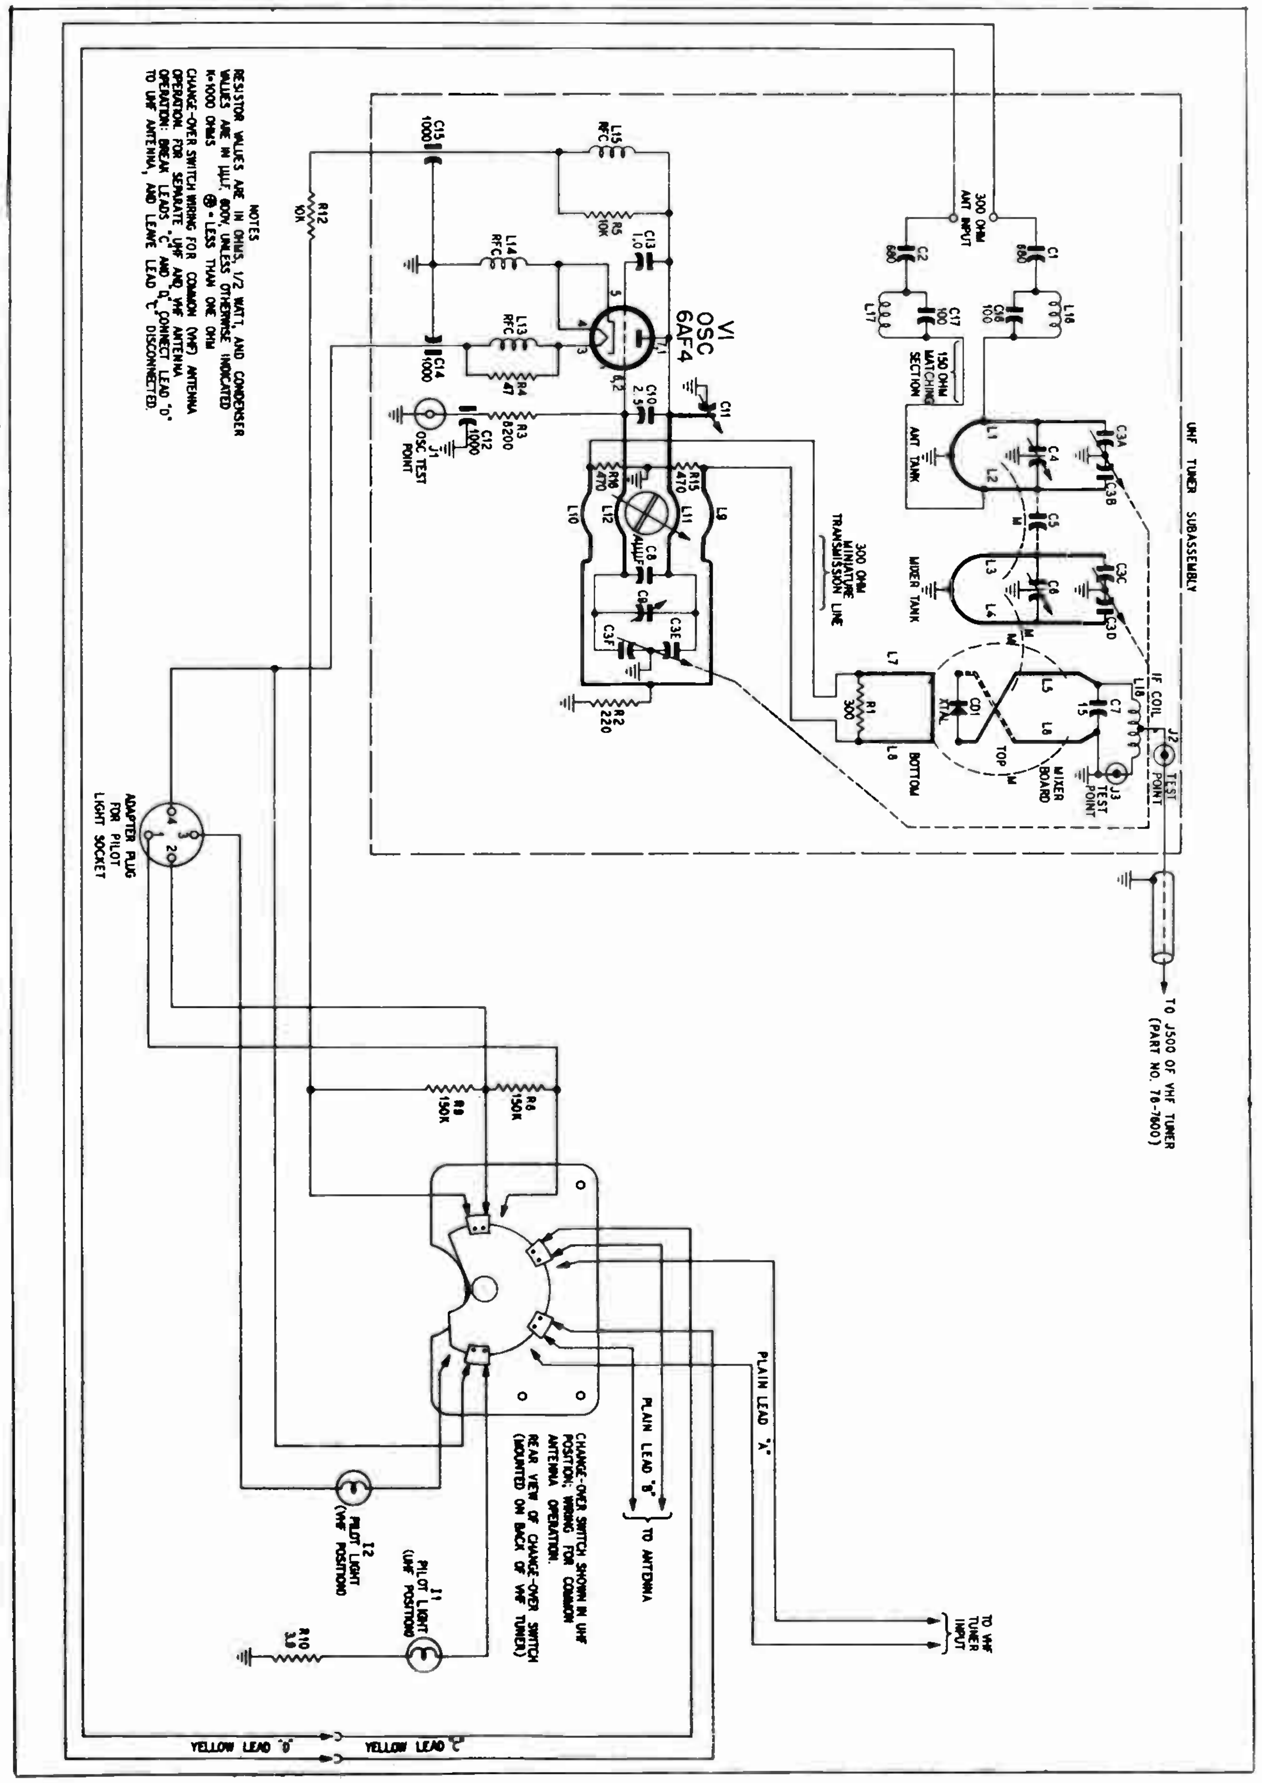

Figure 16. UHF Tuner Adapter UT20A, Part No. 43-6591, Schematic Diagram

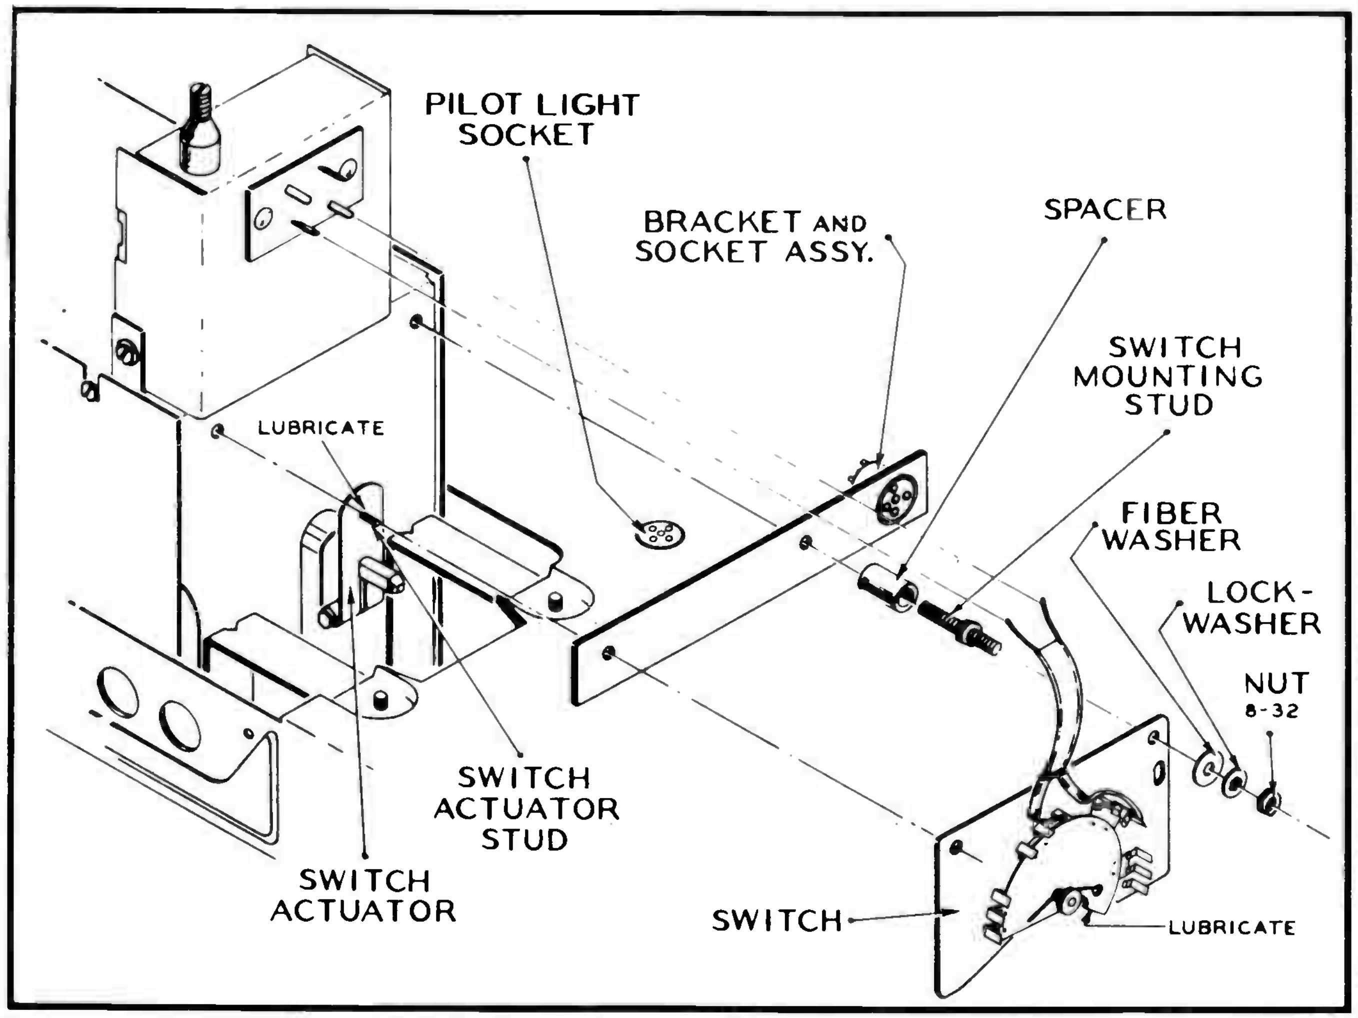

Figure 17. Change-Over Switch Mounting Details (Tuner-Adapter Part No. 43-6591)

rule to follow is not to remove the cover of the Tuner-Adapter.

NOTE: Replacing the tube with a new one may detune the tuner. If this occurs, a number of tubes should be tried, until the most satisfactory substitute for the original is found.

INSTALLATION INSTRUCTIONS

UHF Tuner-Adapter UT20A, Part No. 43-6591, is designed for installation in Philco High Fidelity TV-90 Television Receivers using r-f chassis 91A or 94A; with Extension Kit, Part No. 43-6593, this Tuner-Adapter may also be used in Television Receivers using r-f chassis 97. To install the UHF Tuner-Adapter on the r-f chassis, proceed as follows:

1. Remove the cabinet back and r-f chassis from the cabinet; then remove the nameplate on the control panel by pushing it out from inside the cabinet.

2. Insert the dial scale and bezel assembly into the hole provided in the cabinet. The four studs should be passed through the four holes provided. Fasten the assembly in place with the clips provided.

3. Remove the tuner assembly from the mounting board with which it was shipped. Keep the three screws for mounting the tuner in the cabinet.

4. Place the spacers on the mounting studs, and use the studs to attach the bracket and socket assembly to the rear of the VHF tuner on the r-f chassis. See figure 17.

5. Place the switch-actuator assembly on the shaft extending from the rear of the VHF tuner so that the switch-actuator stud points away from the tuner. See figure 17.

6. Place the switch assembly on the two mounting studs, and fasten it in place with the fiber washers, lock washers, and nuts provided. See figure 17.

7. Put the VHF Channel Selector in the Channel 2 position. Rotate the switch actuator on the tuner shaft until the actuater touches the fiber cam on the changeover switch. Fasten the switch actuator in this position. Rotate the Channel Selector to the UHF position. Check the switch operation, to make sure that the switch is thrown properly. Rotate the Chan-

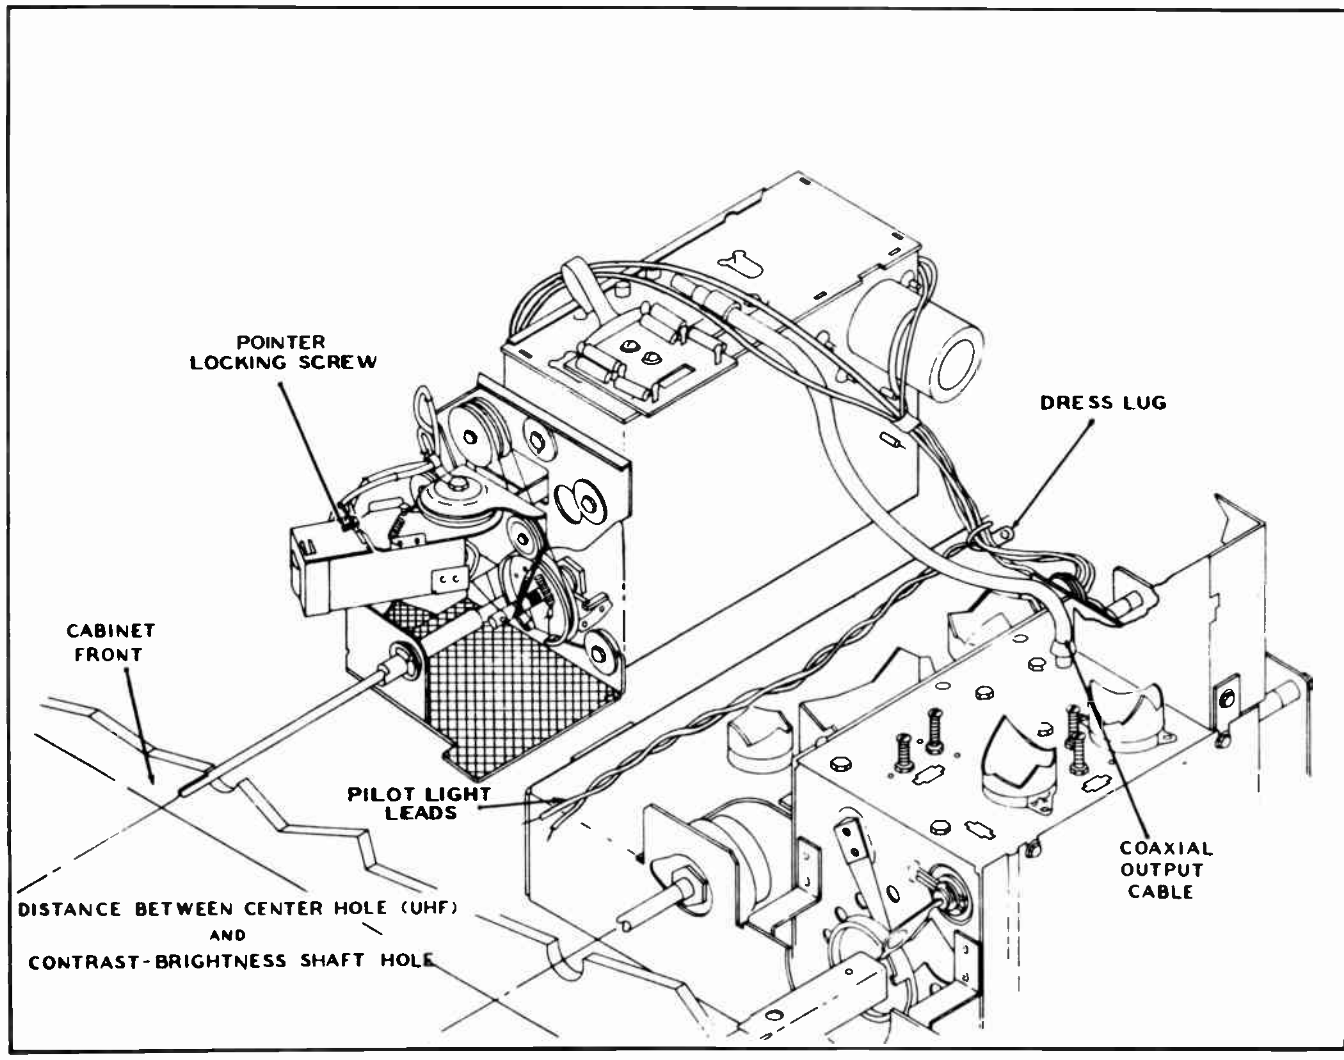

Figure 18. Lead Dress and Tuner Mounting Details (Tuner-Adapter Part No. 43-6591)

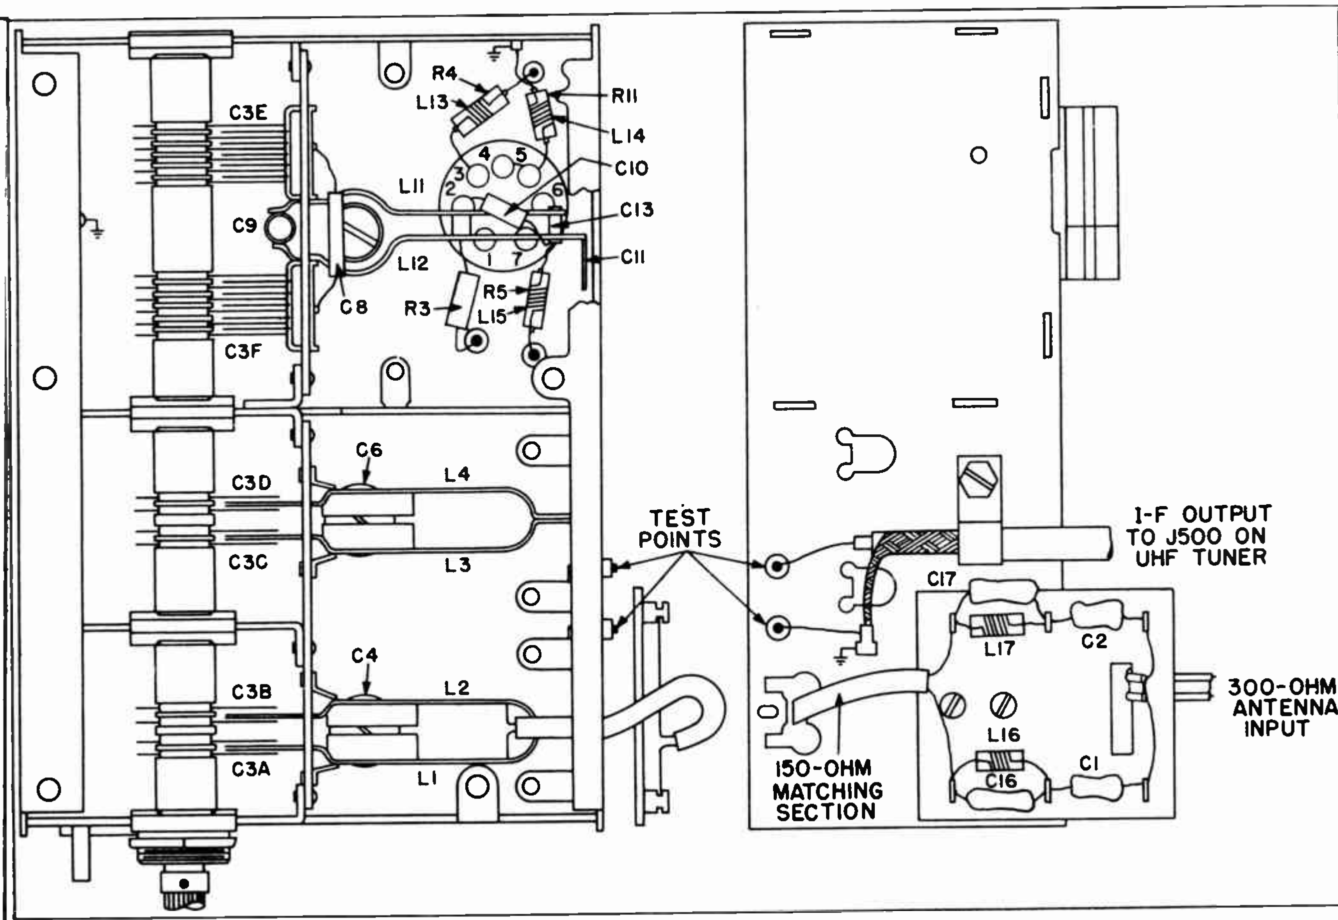

Figure 19. Side View and Base View of Tuner-Adapter UT20A, Part No. 43-6591, Without Board Assemblies

nel Selector to Channel 13 position, and check the switch operation, to make sure that the switch is not thrown in this position. Lubricate the switch-actuator stud and switch cam with cup grease.

8. Remove the bulb and shield from the pilot-light assembly on the r-f chassis, and place them in the pilot-light socket of the UHF tuner assembly. Remove the pilot-light socket and cable assembly from the r-f chassis. (The socket and cable assembly may be discarded, as it is no longer required.) Insert the 4-pin plug from the switch into the 4-pin pilot-light socket on the r-f chassis. See figure 17.

9. Remove the antenna lead from the VHF tuner, and solder the short lead from the UHF-VHF change-over switch to the VHF tuner terminals from which the antenna lead was removed.

10. Install the chassis in the cabinet, and insert the pilot-light socket into the pilot-light clip. Fasten the r-f chassis with the original mounting bolts. Place the original knobs on their shafts.

11. Place the UHF tuner in the cabinet, between the r-f and deflection chassis, and fasten the UHF tuner to the chassis shelf with the three screws removed in step 3. It is important that these screws be tightened securely, to hold the UHF tuner in place on the chassis shelf.

12. Insert the coaxial cable into the jack on the VHF tuner. See figure 18.

13. Insert the 4-pin plug of the UHF tuner into the 4-pin socket on the bracket installed in step 4. Dress the leads as shown in figure 18.

14. Place the knob provided on the UHF tuner shaft, and set the tuning shaft in the counterclockwise position. Turn the receiver on, and, from the back of the cabinet, observe the position of the beam-of-light pointer on the dial scale. If the light beam does not fall on the scale index mark on the back of the scale, turn the receiver off and loosen the locking screw on the pointer. See figure 18. Move the pointer assembly slightly in the required direction. Again turn on the receiver and observe the position of the light-beam pointer. If necessary, repeat the adjustment until the pointer falls on the index mark; then fasten the locking screw.

15. Replace the fishpaper antenna-lead holder with the new holder provided. Fasten the new holder with the two nails provided, and then pass the twin-wire leads through the holes as shown in figure 6.

16. Fasten the antenna terminal board provided as shown in figures 7 through 11. Replace the cabinet back, and make the connections illustrated for the type of antenna installation being used.

17. Paste the label provided over the outside-antenna instructions on the cabinet back.

INSTALLATION INSTRUCTIONS FOR EXTENSION CABLE PART NO. 43-6593

Extension Cable Part No. 43-6593 is designed to provide for installation of UHF Tuner-Adapter UT20A, Part No. 43-6591, in Philco Television Receivers using r-f chassis 97. To install the extension cable with the Tuner-Adapter, follow the instructions supplied with the Tuner-Adapter, except for step 12. Change step 12 to read as follows:

Insert the coaxial cable from the UHF tuner into the jack on the end of the extension cable. Insert the extension cable into the jack on the VHF tuner.

REPLACING AND ADJUSTING BEAM-OF-LIGHT POINTER PILOT LAMP

When the beam-of-light pointer pilot lamp is replaced, or if the assembly is disturbed, the pointer assembly must be refocused. To refocus the assembly, proceed as follows:

1. Remove the pointer locking screw, and remove the pilot light and lens assembly from the tuner by sliding the assembly forward.

2. Disconnect the two wires of the pilot-light socket at the terminal board on the side of the tuner.

3. Remove the cement that holds the pilot-light socket in position; then place the assembly in a focusing jig such as that shown in figure 21. This jig may be constructed from heavy-gauge sheet metal. Connect the two leads from the socket to a 6.3-volt source.

NOTE: If the pilot lamp requires replacement, it must be replaced with one having a straight-wire type of filament. If the filament is of coiled wire, proper focus cannot be obtained.

GENERAL DESCRIPTION

Models 17T250DE and 17T261DE are deluxe "17 inch" television receivers. The receivers are identical except for cabinets, and speakers.

Features of the television unit are: full twelve channel coverage; "totem" r-f amplifier; intercarrier FM sound system; ratio detector; 40 mc picture i-f; improved picture brilliance; pulsed picture A-G-C; A-F-C horizontal hold; stabilized vertical hold; compensated video gain control; noise saturation circuits; improved sync separator and clipper; four mc. band width for picture channel and reduced hazard high voltage supply. An auxiliary audio input jack is provided to permit the use of an external record playing attachment.

ELECTRICAL AND MECHANICAL SPECIFICATIONS

PICTURE SIZE......146 square inches on a 17QP4 Kinescope

TELEVISION R-F FREQUENCY RANGE
All 12 television channels, 54 mc. to 88 mc., 174 mc. to 216 mc.
Picture I-F Carrier Frequency....................45.75 mc.
Sound I-F Carrier Frequency...........41.25 mc. and 4.5 mc.

VIDEO RESPONSE...............................To 4 mc.

SWEEP DEFLECTION...........................Magnetic

FOCUS...Magnetic

POWER SUPPLY RATING
KCS74......................115 volts, 60 cycles, 190 watts

AUDIO POWER OUTPUT RATING
KCS74....................................5.0 watts max.

CHASSIS DESIGNATIONS
KCS74 or KCS74M1.......In Models 17T250DE and 17T261DE
*KCS74 (V110-6CL6)-KCS74M1 (V110-6AG7)

LOUDSPEAKERS
Model 17T250DE........(971490-3) 8" PM Dynamic, 3.2 ohms
Model 17T261DE........(92569-12) 12" PM Dynamic, 3.2 ohms

WEIGHT

Model		Shipping Weight	Width Inches	Height Inches	Depth Inches
17T250DE	88 lbs.	105 lbs.	21⅝	22⅝	22¾
17T261DE	102 lbs.	126 lbs.	24	37¼	23¼

RECEIVER ANTENNA INPUT IMPEDANCE
Choice: 300 ohms balanced or 72 ohms unbalanced.

RCA TUBE COMPLEMENT

Tube Used	Function
(1) RCA 6BQ7	R-F Amplifier
(2) RCA 6X8	R-F Oscillator and Mixer
(3) RCA 6AU6	1st Picture I-F Amplifier
(4) RCA 6CB6	2nd Picture I-F Amplifier
(5) RCA 6CB6	3rd Picture I-F Amplifier
(6) RCA 6CB6	4th Picture I-F Amplifier
(7) RCA 6CL6 (6AG7)	* Video Amplifier
(8) RCA 6AU6	1st Sound I-F Amplifier
(9) RCA 6AU6	2nd Sound I-F Amplifier
(10) RCA 6AL5	Ratio Detector
(11) RCA 6AV6	1st Audio Amplifier
(12) RCA 6AQ5	Audio Output
(13) RCA 6CB6	AGC Amplifier
(14) RCA 6SN7GT	Sync Separator
(15) RCA 6SN7GT	Vert. Sync Amplifier and Vert. Sweep Osc.
(16) RCA 6AQ5	Vertical Sweep Output
(17) RCA 6SN7GT	Horizontal Sync Amplifier
(18) RCA 6SN7GT	Horizontal Sweep Oscillator and Control
(19) RCA 6BQ6GT	Horizontal Sweep Output
(20) RCA 6W4GT	Damper
(21) RCA 1B3-GT/8016	High Voltage Rectifier
(22) RCA 17QP4	Kinescope

*(Refer to Figure 79)

ELECTRICAL AND MECHANICAL SPECIFICATIONS

(Continued)

PICTURE INTERMEDIATE FREQUENCIES
Picture Carrier Frequency........................45.75 mc.
Adjacent Channel Sound Trap...................47.25 mc.
Accompanying Sound Traps.......................41.25 mc.
Adjacent Channel Picture Carrier Trap............39.25 mc.

SOUND INTERMEDIATE FREQUENCIES
Sound Carrier Frequency............41.25 mc. and 4.5 mc.

VIDEO RESPONSE...............................To 4 mc.

FOCUS...Magnetic

SWEEP DEFLECTION............................Magnetic

SCANNING............................Interlaced, 525 line

HORIZONTAL SWEEP FREQUENCY...............15,750 cps

VERTICAL SWEEP FREQUENCY....................60 cps

FRAME FREQUENCY (Picture Repetition Rate).........30 cps

OPERATING CONTROLS (Front Panel)
Channel Selector / Fine Tuning ....Dual Control Knobs
Picture / Brightness ....Dual Control Knobs
Picture Horizontal Hold / Picture Vertical Hold ....Dual Control Knobs
Sound Volume and On-Off Switch / Tone Control and Phono Switch ....Dual Control Knobs

NON-OPERATING CONTROLS (not including r-f and i-f adjustments)
Picture Centering....................top chassis adjustment
Width..............................rear chassis adjustment
Height..............................rear chassis adjustment
Horizontal Linearity......rear chassis screwdriver adjustment
Vertical Linearity...................rear chassis adjustment
Horizontal Drive..........rear chassis screwdriver adjustment
Horizontal Oscillator Frequency.......rear chassis adjustment
Horizontal Oscillator Waveform.....bottom chassis adjustment
Horizontal Locking Range............rear chassis adjustment
Focus..............................top chassis adjustment
Ion Trap Magnet.....................top chassis adjustment
Deflection Coil.............top chassis wing nut adjustment
AGC Control........................rear chassis adjustment

HIGH VOLTAGE WARNING

OPERATION OF THIS RECEIVER OUTSIDE THE CABINET OR WITH THE COVERS REMOVED, INVOLVES A SHOCK HAZARD FROM THE RECEIVER POWER SUPPLIES. WORK ON THE RECEIVER SHOULD NOT BE ATTEMPTED BY ANYONE WHO IS NOT THOROUGHLY FAMILIAR WITH THE PRECAUTIONS NECESSARY WHEN WORKING ON HIGH VOLTAGE EQUIPMENT. DO NOT OPERATE THE RECEIVER WITH THE HIGH VOLTAGE COMPARTMENT SHIELD REMOVED.

KINESCOPE HANDLING PRECAUTIONS

DO NOT REMOVE THE RECEIVER CHASSIS, INSTALL, REMOVE OR HANDLE THE KINESCOPE IN ANY MANNER UNLESS SHATTERPROOF GOGGLES ARE WORN. PEOPLE NOT SO EQUIPPED SHOULD BE KEPT AWAY WHILE HANDLING KINESCOPES. KEEP THE KINESCOPE AWAY FROM THE BODY WHILE HANDLING.

The kinescope bulb encloses a high vacuum and, due to its large surface area, is subjected to considerable air pressure. For this reason, the kinescope must be handled with more care than ordinary receiving tubes.

The large end of the kinescope bulb—particularly that part at the rim of the viewing surface—must not be struck, scratched or subjected to more than moderate pressure at any time. During service if the tube sticks or fails to slip smoothly into its socket, or deflecting yoke, investigate and remove the cause of the trouble. Do not force the tube. Refer to the Receiver Installation section for detailed instructions on kinescope installation. All RCA replacement kinescopes are shipped in special cartons and should be left in the cartons until ready for installation in the receiver.

OPERATING INSTRUCTIONS

The following adjustments are necessary when turning the receiver on for the first time.

1. See that the TV-PH tone switch is in a "TV" position.

2. Turn the receiver "ON" and advance the SOUND VOLUME control to approximately mid-position.

3. Set the STATION SELECTOR to the desired channel.

4. Adjust the FINE TUNING control for best pix and the SOUND VOLUME control for suitable volume.

5. Turn the BRIGHTNESS control fully counter-clockwise, then clockwise until a light pattern appears on the screen.

6. Adjust the VERTICAL hold control until the pattern stops vertical movement.

7. Adjust the HORIZONTAL hold control until a picture is obtained and centered.

8. Adjust the PICTURE and BRIGHTNESS controls for suitable picture contrast and brightness.

9. In switching from one channel to another, it may be necessary to repeat steps 4 and 8.

10. When the set is turned on again after an idle period it should not be necessary to repeat the adjustment if the positions of the controls have not been changed. If any adjustment is necessary, step number 4 is generally sufficient.

11. If the positions of the controls have been changed, it may be necessary to repeat steps 2 through 8.

12. To use a record player, plug the record-player output cable into the PHONO jack on the rear apron, and set the TV-PH tone switch to a "PH" position.

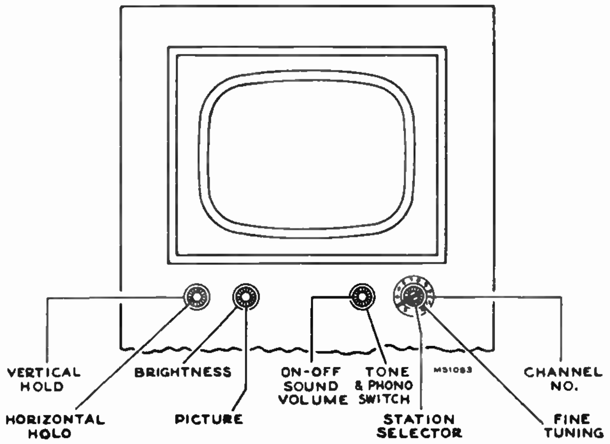

Figure 1—Receiver Operating Controls

INSTALLATION INSTRUCTIONS

UNPACKING.—These receivers are shipped complete in cardboard cartons. The kinescope is shipped in place in the receiver.

Take the receiver out of the carton and remove all packing material.

Make sure that all tubes are in place and are firmly seated in their sockets.

Check to see that the kinescope high voltage lead clip is in place.

Plug a power cord into the 115 volt a-c power source and into the receiver interlock receptacle. Turn the receiver power switch to the "on" position, the brightness control fully clockwise, and the picture control counter-clockwise.

ION TRAP MAGNET ADJUSTMENT. — Set the ion trap magnet approximately in the position shown in Figure 2. Starting from this position immediately adjust the magnet by moving it forward or backward at the same time rotating it slightly around the neck of the kinescope for the brightest raster on the screen. Reduce the brightness control setting until the raster is slightly above average brilliance. Turn the focus control (shown in Figure 2) until the line structure of the raster is clearly visible. Readjust the ion trap magnet for maximum raster brilliance. The final touches of this adjustment should be made with the brightness control at the maximum clockwise position with which good line focus can be maintained.

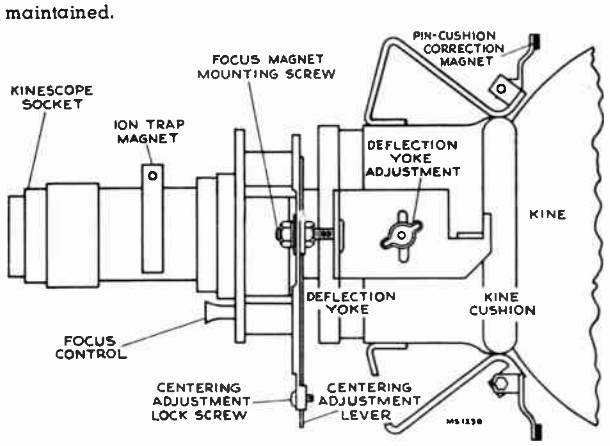

Figure 2—Yoke and Focus Magnet Adjustments

DEFLECTION YOKE ADJUSTMENT. — If the lines of the raster are not horizontal or squared with the picture mask, rotate the deflection yoke until this condition is obtained. Tighten the yoke adjustment wing screw.

PICTURE ADJUSTMENTS. — It will now be necessary to obtain a test pattern picture in order to make further adjustments. Connect the antenna transmission line to the receiver.

If the Horizontal Oscillator and AGC System are operating properly, it should be possible to sync the picture at this point. However, if the AGC control is misadjusted, and the receiver is overloading, it may be impossible to sync the picture.

If the receiver is overloading, turn R181 on the rear apron (see Figure 3) counter-clockwise until the set operates normally and the picture can be synced.

CHECK OF HORIZONTAL OSCILLATOR ALIGNMENT. — Turn the horizontal hold control to the extreme counter-clockwise position. The picture should remain in horizontal sync. Momentarily remove the signal by switching off channel then back. Normally the picture will be out of sync. Turn the control clockwise slowly. The number of diagonal black bars will be gradually reduced and when only 2 or 3 bars sloping downward to the left are obtained, the picture will pull into sync upon slight additional clockwise rotation of the control. Pull-in should occur before the control has been turned 120 degrees from the extreme counter-clockwise position. The picture should remain in sync for approximately 90 degrees of additional clockwise rotation of the control. At the extreme clockwise position, the picture should remain in sync and should not show a black bar in the picture.

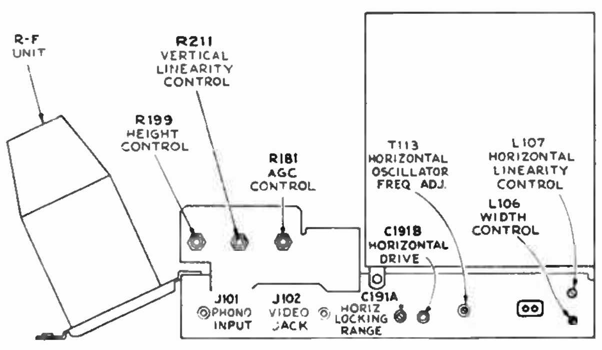

Figure 3—Rear Chassis Adjustments

INSTALLATION INSTRUCTIONS

If the receiver passes the above checks and the picture is normal and stable, the horizontal oscillator is properly aligned. Skip "Alignment of Horizontal Oscillator" and proceed with "Focus Magnet Adjustment."

ALIGNMENT OF HORIZONTAL OSCILLATOR. — If in the above check the receiver failed to hold sync with the hold control at the extreme counter-clockwise position or failed to hold sync over 90 degrees of clockwise rotation of the control from the pull-in point, it will be necessary to make the following adjustments.

Horizontal Frequency Adjustment. — Turn the horizontal hold control to the extreme clockwise position. Tune in a television station and adjust the T113 horizontal frequency adjustment at the rear of the chassis until the picture is just out of sync and the horizontal blanking appears as a vertical or diagonal black bar in the raster. Then turn the T113 core until the bar moves out of the picture leaving it in sync.

Horizontal Locking Range Adjustment. — Set the horizontal hold control to the full counter-clockwise position. Momentarily remove the signal by switching off channel then back. The picture may remain in sync. If so turn the T113 rear core slightly and momentarily switch off channel. Repeat until the picture falls out of sync with the diagonal lines sloping down to the left. Slowly turn the horizontal hold control clockwise and note the least number of diagonal bars obtained just before the picture pulls into sync.

If more than 3 bars are present just before the picture pulls into sync, adjust the horizontal locking range trimmer C191A slightly clockwise. If less than 2 bars are present, adjust C191A slightly counter-clockwise. Turn the horizontal hold control counter-clockwise, momentarily remove the signal and recheck the number of bars present at the pull-in point. Repeat this procedure until 2 or 3 bars are present.

Repeat the adjustments under "Horizontal Frequency Adjustment" and "Horizontal Locking Range Adjustment" until the conditions specified under each are fulfilled. When the horizontal hold operates as outlined under "Check of Horizontal Oscillator Alignment" the oscillator is properly adjusted.

If it is impossible to sync the picture at this point and the AGC system is in proper adjustment it will be necessary to adjust the Horizontal Oscillator by the method outlined in the alignment procedure on page 11. For field purposes paragraph "B" under Horizontal Oscillator Waveform Adjustment may be omitted.

FOCUS MAGNET ADJUSTMENT. — The focus magnet should be adjusted so that there is approximately three-eighths inch of space between the rear cardboard shell of the yoke and the flat of the front face of the focus magnet. This spacing gives best average focus over the face of the tube.

The axis of the hole through the magnet should be parallel with the axis of the kinescope neck with the kinescope neck through the center of the opening.

PIN-CUSHION CORRECTION. — Two pin-cushion correction magnets are employed to correct a small amount of pin-cushion of the raster due to the lens effect of the face of the kinescope. These magnets are mounted on small arms, one on each side of the kinescope as shown in Figure 2. The arms hinge in one plane on self tapping screws which act both as a hinge and an adjustment locking screw. When the magnets are swung towards the tube, maximum correction is obtained. Minimum correction is obtained when the arms are swung away from the tube. To adjust the magnets, loosen the two self tapping screws and position the magnets until the sides of the raster appear straight. Tighten the screws without shifting the position of the magnets. In some cases it may be necessary to twist or bend the magnet support arms to obtain the appearance of straight raster edges.

CENTERING ADJUSTMENT. — No electrical centering controls are provided. Centering is accomplished by means of a separate plate on the focus magnet. The centering plates include a locking screw which must be loosened before centering. Up and down adjustment of the plate moves the picture side to side and sidewise adjustment moves the picture up and down.

If a corner of the raster is shadowed, check the position of the ion trap magnet. Reposition the magnet within the range of maximum raster brightness to eliminate the shadow and recenter the picture by adjustment of the focus magnet plate. In no case should the magnet be adjusted to cause any loss of brightness since such operation may cause immediate or eventual damage to the tube. In some cases it may be necessary to shift the position of the focus magnet in order to eliminate a corner shadow.

WIDTH, DRIVE AND HORIZONTAL LINEARITY ADJUSTMENTS. — Adjustment of the horizontal drive control affects the high voltage applied to the kinescope. In order to obtain the highest possible voltage hence the brightest and best focused picture, adjust horizontal drive trimmer C191B counter-clockwise until the picture begins to "wrinkle" in the middle then clockwise until the "wrinkle" disappears.

Turn the horizontal linearity control L107 clockwise until the picture begins to "wrinkle" on the right and then counter-clockwise until the "wrinkle" disappears and best linearity is obtained.

Adjust the width control L106 to obtain correct picture width.

A slight readjustment of these three controls may be necessary to obtain the best linearity.

Adjustments of the horizontal drive control affect horizontal oscillator hold and locking range. If the drive control was adjusted, recheck the oscillator alignment.

HEIGHT AND VERTICAL LINEARITY ADJUSTMENTS. — Adjust the height control (R199 on chassis rear apron) until the picture fills the mask vertically. Adjust vertical linearity (R211 on rear apron), until the test pattern is symmetrical from top to bottom. Adjustment of either control will require a readjustment of the other. Adjust centering to align the picture with the mask.

FOCUS. — Adjust the focus magnet for maximum definition in the test pattern vertical "wedge" and best focus in the white areas of the pattern.

Recheck the position of the ion trap magnet to make sure that maximum brightness is obtained.

Check to see that the yoke thumbscrew and the focus magnet mounting screws are tight.

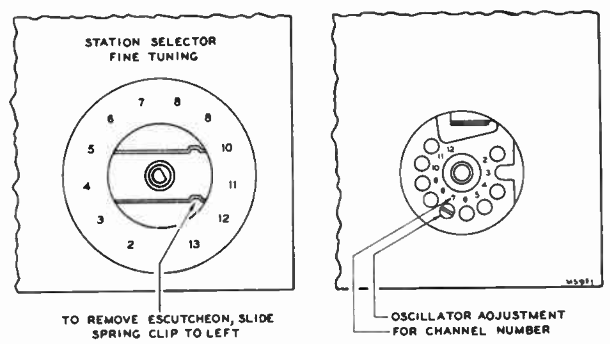

Figure 4—R-F Oscillator Adjustments

CHECK OF R-F OSCILLATOR ADJUSTMENTS. — Tune in all available stations to see if the receiver r-f oscillator is adjusted to the proper frequency on all channels. If adjustments are required, these should be made by the method outlined in the alignment procedure on page 9. The adjustments for channels 2 through 12 are available from the front of the cabinet by removing the station selector escutcheon as shown in Figure 4. Adjustment for channel 13 is on top of the chassis.

AGC THRESHOLD CONTROL. — The AGC threshold control R181 is adjusted at the factory and normally should not require readjustment in the field.

To check the adjustment of the AGC Threshold Control, tune in a strong signal and sync the picture. Momentarily remove the signal by switching off channel and then back. If the picture reappears immediately, the receiver is not overloading due to improper setting of R181. If the picture requires an appreciable portion of a second to reappear, or bends excessively, R181 should be readjusted.

INSTALLATION INSTRUCTIONS

Turn R181 fully counter-clockwise. The raster may be bent slightly. This should be disregarded. Turn R181 clockwise until there is a very, very slight bend or change of bend in the picture. Then turn R181 counter-clockwise just sufficiently to remove this bend or change of bend.

If the signal is weak, the above method may not work as it may be impossible to get the picture to bend. In this case, turn R181 clockwise until the snow in the picture becomes more pronounced, then counter-clockwise until the best signal to noise ratio is obtained.

The AGC control adjustment should be made on a strong signal if possible. If the control is set too far clockwise on a weak signal, then the receiver may overload when a strong signal is received.

FM TRAP ADJUSTMENT. — In some instances interference may be encountered from a strong FM station signal. A trap is provided to eliminate this type of interference. To adjust the trap tune in the station on which the interference is observed and adjust the L58 core on top of the antenna matching transformer for minimum interference in the picture.

CAUTION. — In some receivers, the FM trap L58 will tune down into channel 6 or even into channel 5. Needless to say, such an adjustment will cause greatly reduced sensitivity on these channels. If channels 5 or 6 are to be received, check L58 to make sure that it does not affect sensitivity on these two channels.

Replace the cabinet back and connect the receiver antenna leads to the cabinet back. Make sure that the screws holding it are up tight, otherwise it may rattle or buzz when the receiver is operated at high volume.

KINESCOPE SCREEN CLEANING. — The kinescope safety glass is held in place by four spring clips which may be removed from the back of the front panel. This permits removing the safety glass for cleaning without the necessity of removing the chassis and kinescope.

CHASSIS REMOVAL. — To remove the chassis from the cabinet for repair or installation of a new kinescope, remove the control knobs, the cabinet back, unplug the speaker cable, the kinescope socket, the antenna cable, the yoke and high voltage cable. Take out the chassis bolts under the cabinet. Withdraw the chassis from the back of the cabinet.

KINESCOPE HANDLING PRECAUTION. — Do not install, remove, or handle the kinescope in any manner, unless shatter-proof goggles and heavy gloves are worn. People not so equipped should be kept away while handling the kinescope. Keep the kinescope away from the body while handling.

REMOVAL OF KINESCOPE.—To remove the kinescope from the cabinet, loosen the two nuts and disengage the rods alongside the kinescope. Remove the wing screw which holds the yoke frame to the cabinet. Remove the kinescope, the yoke frame with yoke and focus magnet as an assembly.

Handle this tube by the portion at the edge of the screen. Do not cover the glass bell of the tube with fingermarks as it will produce leakage paths which may interfere with reception. If this portion of the tube has inadvertently been handled, wipe it clean with a soft cloth moistened with "dry" carbon tetrachloride.

INSTALLATION OF KINESCOPE. — Wipe the kinescope screen surface and front panel safety glass clean of all dust and fingermarks with a soft cloth moistened with "Windex" or similar cleaning agent.

Replace the kinescope and chassis by reversal of the removing process. The kinescope should be installed so that the high voltage contact is to the right when looking at it from the rear of the cabinet. The magnet of the ion trap magnet should be to the left.

CABINET ANTENNA.—A cabinet antenna is provided in these receivers and the leads are brought out near the antenna terminal board. The cabinet antenna may be employed in place of the outdoor antenna in areas where the signals are strong and no reflections are experienced.

ANTENNAS.—The finest television receiver built may be said to be only as good as the antenna design and installation. It is therefore important to select the proper antenna to suit the particular local conditions, to install it properly and orient it correctly.

If two or more stations are available and the two stations are in different directions, it may be possible to make a compromise orientation which will provide a satisfactory signal on all such channels.

If it is impossible to obtain satisfactory results on one or more channels, it may become necessary either to provide means for turning the antenna when switching channels or to install a separate antenna for one or more channels and to switch antennas when switching channels.

In some cases, the antenna should not be installed permanently until the quality of the picture reception has been observed on a television receiver. A temporary transmission line can be run between receiver and the antenna, allowing sufficient slack to permit moving the antenna. Then, with a telephone system connecting an observer at the receiver and an assistant at the antenna, the antenna can be positioned to give the most satisfactory results on the received signal. A shift of direction or a few feet in antenna position may effect a tremendous difference in picture reception.

REFLECTIONS. — Multiple images sometimes known as echoes or ghosts, are caused by the signal arriving at the antenna by two or more routes. The second or subsequent image occurs when a signal arrives at the antenna after being reflected off a building, a hill or other object. In severe cases of reflections, even the sound may be distorted. In less severe cases, reflections may occur that are not noticeable as reflections but that will instead cause a loss of definition in the picture.

Under certain extremely unusual conditions, it may be possible to rotate or position the antenna so that it receives the cleanest picture over a reflected path. If such is the case, the antenna should be so positioned. However, such a position may give variable results as the nature of reflecting surfaces may vary with weather conditions. Wet surfaces have been known to have different reflecting characteristics than dry surfaces.

Depending upon the circumstances, it may be possible to eliminate the reflections by rotating the antenna or by moving it to a new location. In extreme cases, it may be impossible to eliminate the reflection.

INTERFERENCE.—Auto ignition, street cars, electrical machinery and diathermy apparatus may cause interference which spoils the picture. Whenever possible, the antenna location should be removed as far as possible from highways, hospitals, doctors' offices and similar sources of interference. In mounting the antenna, care must be taken to keep the antenna rods at least ¼ wave length (at least 6 feet) away from other antennas, metal roofs, gutters or other metal objects.

Short-wave radio transmitting and receiving equipment may cause interference in the picture in the form of moving ripples. In some instances it may be possible to eliminate the interference by the use of a trap in the antenna transmission line. However, if the interfering signal is on the same frequency as the television station, a trap will provide no improvement.

WEAK PICTURE.—When the installation is near the limit of the area served by the transmitting station, the picture may be speckled, having a "snow" effect, and may not hold steady on the screen. This condition is due to lack of signal strength from the transmitter.

RECEIVER LOCATION.—The owner should be advised of the importance of placing the receiver in the proper location in the room.

The location should be chosen—

—Away from bright windows and so that no bright light will fall directly on the screen. (Some illumination in the room is desirable, however.)

—To give easy access for operation and comfortable viewing.

—To permit convenient connection to the antenna.

—Convenient to an electrical outlet.

—To allow adequate ventilation.

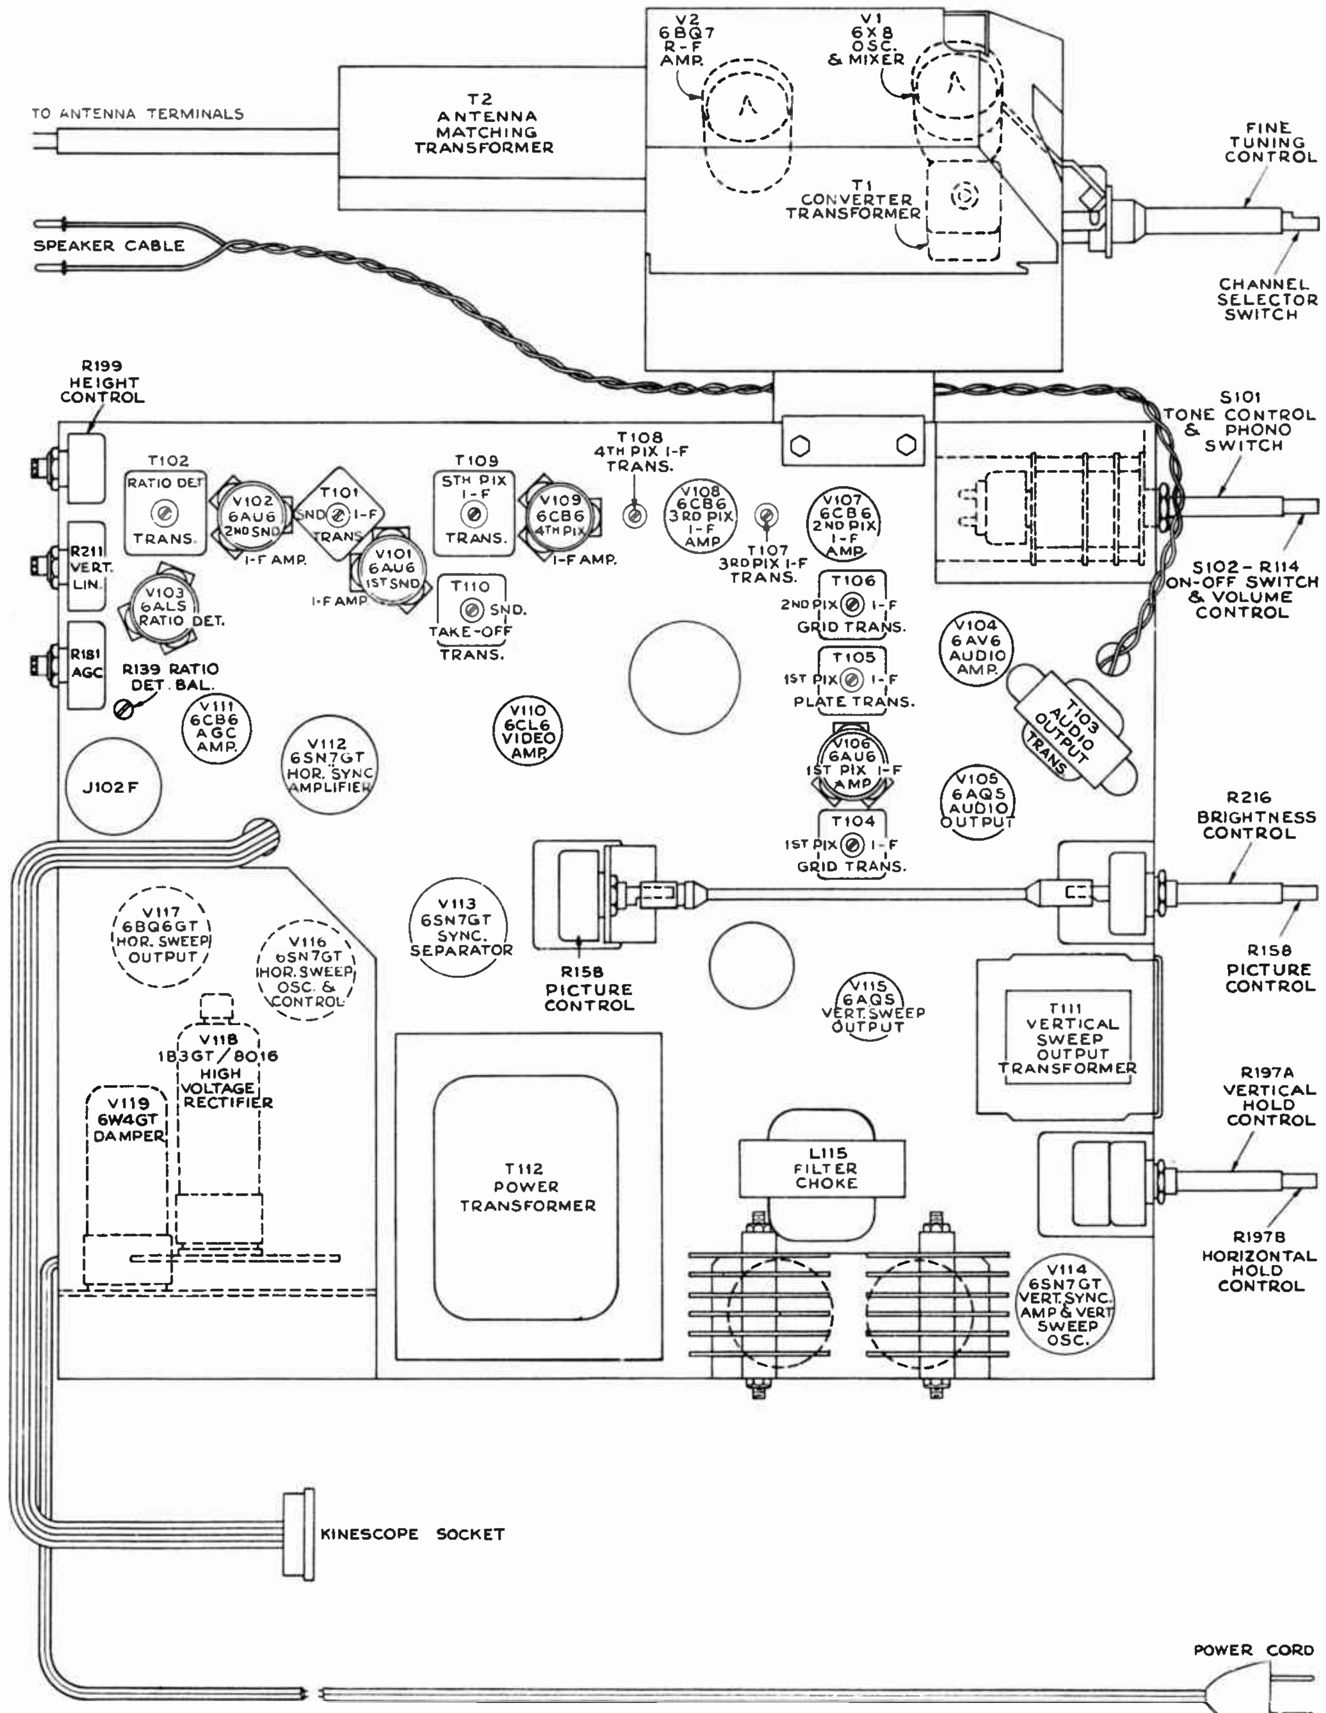

Figure 5—Chassis Top View

CHASSIS BOTTOM VIEW

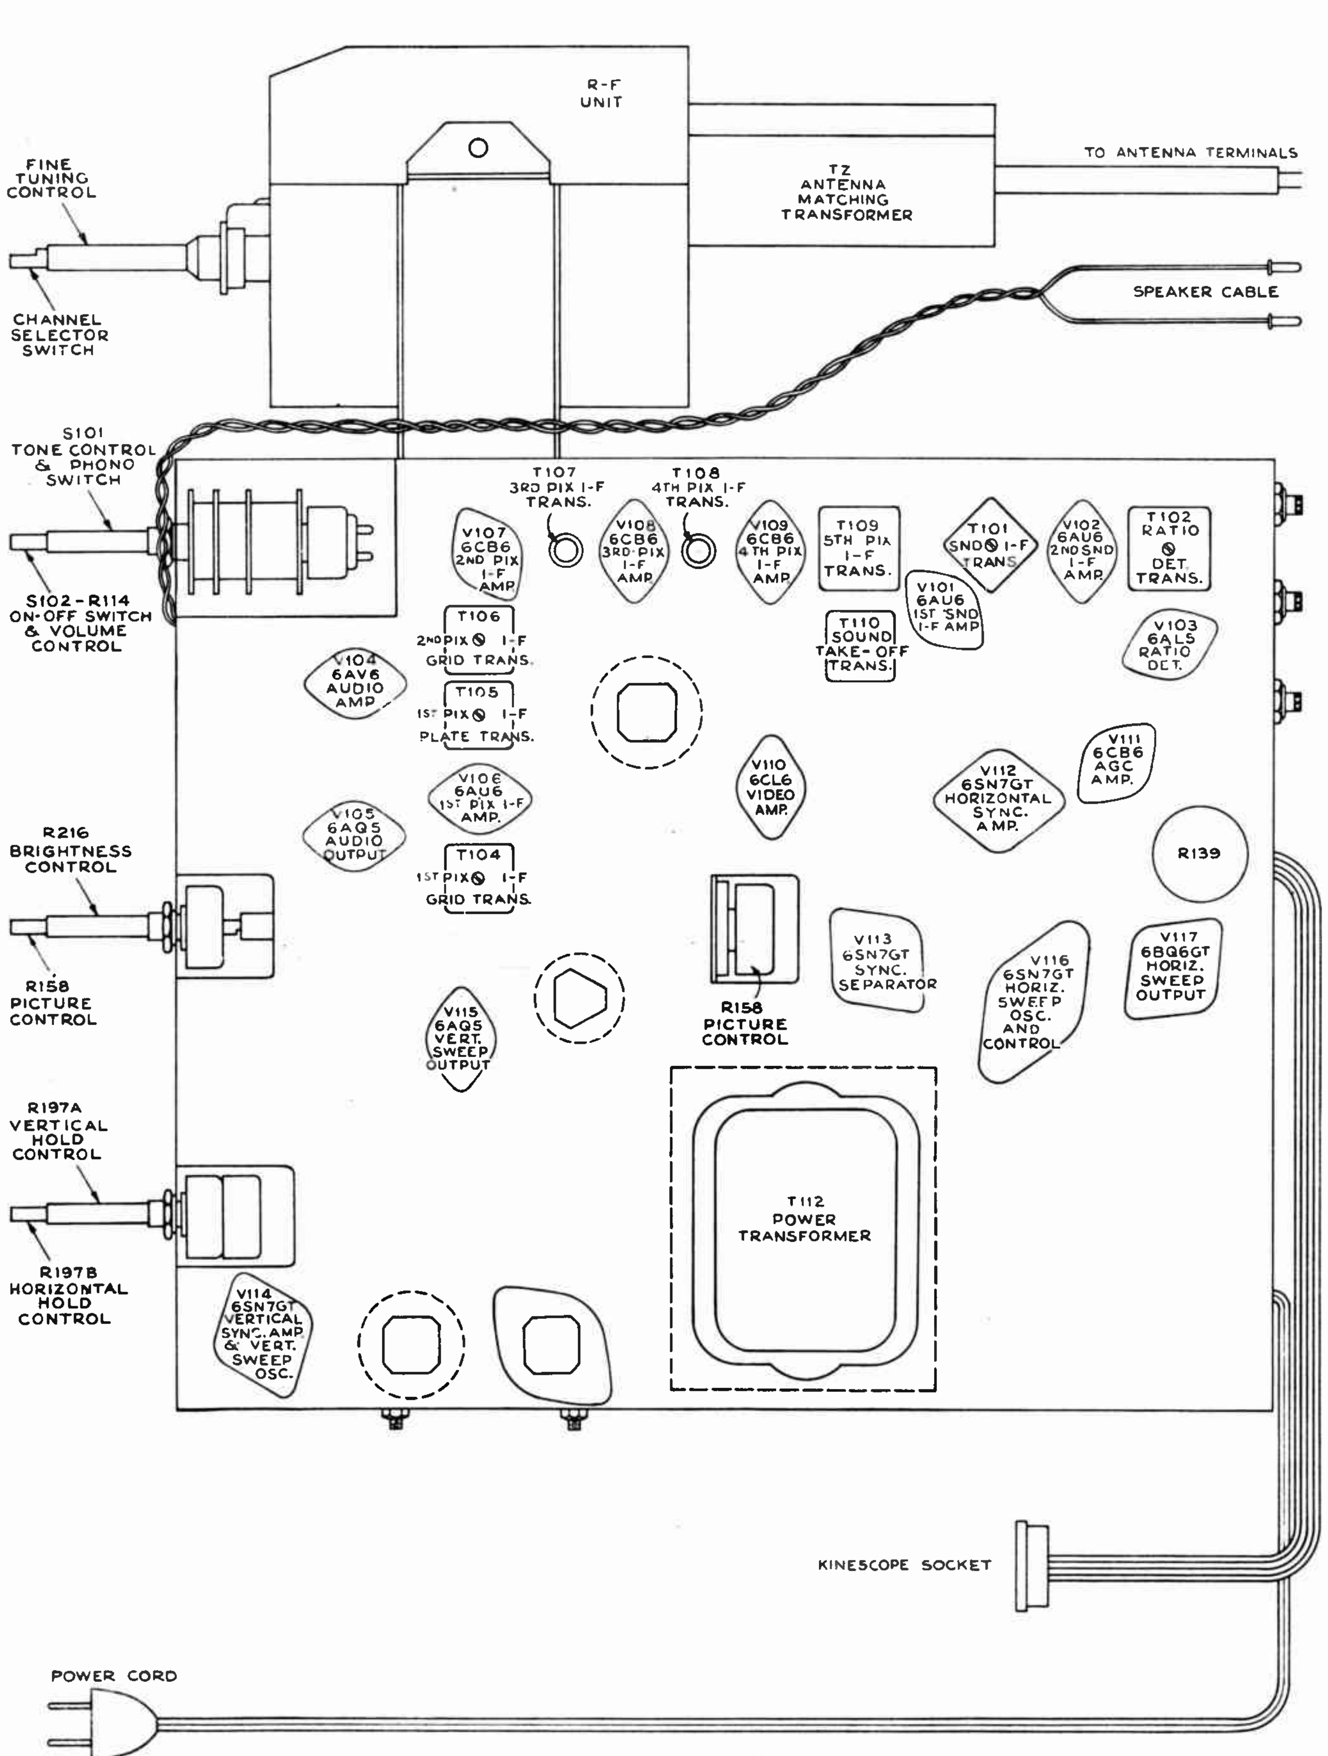

Figure 6—Chassis Bottom View

ALIGNMENT PROCEDURE

TEST EQUIPMENT. — To properly service the television chassis of this receiver, it is recommended that the following test equipment be available:

R-F Sweep Generator meeting the following requirements:

(a) Frequency Ranges

35 to 90 mc., 1 mc. to 12 mc. sweep width
170 to 225 mc., 12 mc. sweep width

(b) Output adjustable with at least .1 volt maximum.

(c) Output constant on all ranges.

(d) "Flat" output on all attenuator positions.

Cathode-Ray Oscilloscope. — For alignment purposes, the oscilloscope employed must have excellent low frequency and phase response, and should be capable of passing a 60-cycle square wave without appreciable distortion.

For video and sync waveform observations, the oscilloscope must have excellent frequency and phase response from 10 cycles to at least two megacycles in all positions of the gain control.

Signal Generator to provide the following frequencies with crystal accuracy.

(a) Intermediate frequencies

4.5 mc., 39.25 mc., 41.25 mc., 45.75 mc., 47.25 mc.

(b) Radio frequencies

Channel Number	Picture Carrier Freq. Mc.	Sound Carrier Freq. Mc.	Receiver R-F Osc. Freq. Mc.
2	55.25	59.75	101
3	61.25	65.75	107
4	67.25	71.75	113
5	77.25	81.75	123
6	83.25	87.75	129
7	175.25	179.75	221
8	181.25	185.75	227
9	187.25	191.75	233
10	193.25	197.75	239
11	199.25	203.75	245
12	205.25	209.75	251
13	211.25	215.75	257

(c) Output of these ranges should be adjustable and at least .1 volt maximum.

Heterodyne Frequency Meter with crystal calibrator if the signal generator is not crystal controlled.

Electronic Voltmeter of Junior or Senior "VoltOhmyst" type and a high voltage multiplier probe for use with this meter to permit measurements up to 20 kv.

ORDER OF ALIGNMENT. — When a complete receiver alignment is necessary, it can be most conveniently performed in the following order:

(1) Ant. Matching Unit
(2) R-F Unit
(3) Ratio Detector
(4) Sound I-F Trans.
(5) Sound Take-Off Trans.
(6) Picture I-F Traps
(7) Picture I-F Trans.
(8) Sweep Alignment of I-F
(9) Horizontal Oscillator
(10) Sensitivity Check

ANTENNA MATCHING UNIT ALIGNMENT. — The antenna matching unit is accurately aligned at the factory. Adjustment of this unit should not be attempted in the customer's home since even slight misalignment may cause serious attenuation of the signal especially on channel 2. The r-f unit is aligned with a particular antenna matching transformer in place. If for any reason, a new antenna matching transformer is installed, the r-f unit should be realigned.

The F-M Trap which is mounted in the antenna matching unit may be adjusted without adversely affecting the alignment of the unit.

To align the antenna matching unit disconnect the lead from the F-M Trap L58 to the channel selector switch S5.

With a short jumper, connect the output of the matching unit through a 1000 mmf capacitor to the grid of the second pix i-f amplifier, pin 1 of V107.

Replace the cover on the matching unit while making all adjustments.

Remove the first pix i-f amplifier tube V106.

Connect the positive terminal of a bias box to the chassis and the potentiometer arm to the junction of R193 and R194. Set the potentiometer to produce approximately −6.0 volts of bias at the junction of R193 and R194.

Connect an oscilloscope to pin 2 of V110 (pin 4 if 6AG7 used) and set the oscilloscope gain to maximum.

Connect a signal generator to the antenna input terminals. Modulate the signal generator 30% with an audio signal.

Tune the signal generator to 45.75 mc. and adjust the generator output to give an indication on the oscilloscope. Adjust L59 in the antenna matching unit for minimum audio indication on the oscilloscope.

Tune the signal generator to 41.25 mc. and adjust L60 for minimum audio indication on the oscilloscope.

Remove the jumper from the output of the matching unit.

Connect a 300 ohm ½ watt composition resistor from L58 to ground, keeping the leads as short as possible.

Connect an oscilloscope low capacity crystal probe from L58 to ground. The sensitivity of the oscilloscope should be approximately 0.03 volts per inch. Set the oscilloscope gain to maximum.

Connect the r-f sweep generator to the matching unit antenna input terminals. In order to prevent coupling reactance from the sweep generator into the matching unit, it is advisable to employ a resistance pad at the matching unit terminals. Figure 11 shows three different resistance pads for use with sweep generators with 50 ohm co-ax output, 72 ohm co-ax output or 300 ohm balanced output. Choose the pad to match the output impedance of the particular sweep employed.

Connect the signal generator loosely to the matching unit antenna terminals.

Set the sweep generator to sweep from 45 mc. to 54 mc. With RCA type WR59A sweep generators, this may be accomplished by retuning channel number 1 to cover this range. With WR59B sweep generators this may be accomplished by retuning channel number 2 to cover the range. In making these adjustments on the generator, be sure not to turn the core too far clockwise so that it becomes lost beyond the core retaining spring.

Adjust L61 and L62 to obtain the response shown in Figure 12. L61 is most effective in locating the position of the shoulder of the curve at 52 mc. and L62 should be adjusted to give maximum amplitude at 53 mc. and above consistent with the specified shape of the response curve. The adjustments in the matching unit interact to some extent. Repeat the above procedure until no further adjustments are necessary.

Remove the 300 ohm resistor and crystal probe connections. Restore the connection between L58 and S5. Replace V106.

R-F UNIT ALIGNMENT. — An r-f unit which is operative and requires only touch up adjustments, requires no presetting of adjustments. For such units, skip the remainder of this paragraph. For units which are completely out of adjustment, preset all adjustments to the approximate center of their range with the following exceptions: Set C18 so that the screw head is approximately three-eighths of an inch above chassis. Set C11 near maximum capacity (one-quarter turn from tight). Do not change any of the adjustments in the antenna matching unit.

Disconnect the link from terminals "A" and "B" of T104 and terminate the link with a 39 ohm composition resistor.

The r-f unit is aligned with zero AGC bias. To insure that the bias will remain constant, take a clip lead and short circuit the r-f unit power terminal board terminal 3 to ground.

Connect the oscilloscope to the test point TP1 on top of the r-f unit. Set the oscilloscope gain to maximum.

Turn the receiver channel selector switch to channel 2.

Connect the output of the signal generator to the grid of the r-f amplifier, V2. To do this, remove the tube from the socket and fashion a clip by twisting one end of a small piece of wire around pin number 7. Replace the tube in the socket leaving the end of the wire protruding from under the tube. Connect the signal generator to this wire through a 1,500 mmf. capacitor.

Tune the signal generator to 43.5 mc. and modulate it 30% with a 400 cycle sine wave. Adjust the signal generator for maximum output.

ALIGNMENT PROCEDURE

Adjust L65 on top of the r-f unit for minimum 400 cycle indication on the oscilloscope. If necessary, this adjustment can be retouched in the field to provide additional rejection to one specific frequency in the i-f band pass. However, in such cases, care should be taken not to adjust it so as to reduce sensitivity on channel 2.

Remove the wire clip from pin 7 of V2 and replace the tube and tube shield.

Set the channel selector switch to channel 8.

Turn the fine tuning control 30 degrees clockwise from the center of its mechanical range now and at all times when adjusting the oscillator frequency.

Adjust C2 for proper oscillator frequency, 227 mc. This may be done in several ways. The easiest way and the way which will be recommended in this procedure will be to use the signal generator as a heterodyne frequency meter and beat the oscillator against the signal generator. To do this, tune the signal generator to 227 mc. with crystal accuracy. Insert one end of a piece of insulated wire into the r-f unit through the hole provided for the adjustment for C11. Be careful that the wire does not touch any of the tuned circuits as it may cause the frequency of the r-f unit oscillator to shift. Connect the other end of the wire to the "r-f in" terminal of the signal generator. Adjust C2 to obtain an audio beat with the signal generator.

Note.—If on some units, it is not possible to reach the proper channel 8 oscillator frequency by adjustment of C2, switch to channel 13 and adjust L46 to obtain proper channel 13 oscillator frequency as indicated in the table on page 8. Then, switch to channel 12 and adjust L11 to obtain proper channel 12 oscillator frequency. Continue down to channel 8 adjusting the appropriate oscillator trimmer to obtain the proper frequency on each channel. Then again on channel 8, adjust C2 to obtain proper channel 8 oscillator frequency. Switch back to channel 13 and adjust L46 and back to channel 8 and adjust C2.

Set the T1 core for maximum inductance (core turned counter-clockwise.)

Connect the sweep generator through a suitable attenuator as shown in Figure 11 to the input terminals of the antenna matching unit.

Connect the signal generator loosely to the antenna terminals.

Set the sweep generator to cover channel 8.

Set the oscilloscope to maximum gain and use the minimum input signal which will produce a useable pattern on the oscilloscope. Excessive input can change oscillator injection during alignment and produce consequent misalignment even though the response as seen on the oscilloscope may look normal.

Insert markers of channel 8 picture carrier and sound carrier, 181.25 mc. and 185.75 mc.

Adjust C9, C11, C15 and C18 for approximately correct curve shape, frequency, and band width as shown in Figure 13.

The correct adjustment of C18 is indicated by maximum amplitude of the curve midway between the markers. C15 tunes the r-f amplifier plate circuit and affects the frequency of the pass band most noticeably. C9 tunes the mixer grid circuit and affects the tilt of the curve most noticeably (assuming that C18 has been properly adjusted). C11 is the coupling adjustment and hence primarily affects the response band width.

Set the receiver channel switch to channel 6.

Adjust the signal generator to the channel 6 oscillator frequency 129 mc.

Turn the fine tuning control 30 degrees clockwise from the center of its mechanical range.

Adjust L5 for an audible beat with the signal generator as before.

Set the sweep generator to channel 6.

From the signal generator, insert channel 6 sound and picture carrier markers, 83.25 mc. and 87.75 mc.

Adjust L48, L50 and L53 for proper response as shown in Figure 13.

L50 tunes the r-f amplifier plate circuit and primarily affects the frequency of the pass band. L53 tunes the r-f amplifier grid and is adjusted to give maximum amplitude of the curve between the markers. L48 affects the tilt of the curve but not quite the same as C9 adjustment. When the circuits are correctly adjusted and L48 is rocked on either side of its proper setting, the high frequency (sound carrier) end of the curve appears to remain nearly fixed in amplitude while the picture carrier end tilts above or below this point.

Turn off the sweep and signal generators.

Connect the "VoltOhmyst" to the r-f unit test point TP1.

Adjust the oscillator injection trimmer C8 for −3.5 volts or at maximum if −3.5 volts cannot be reached. This voltage should fall between −2.5 and −5.5 volts on all channels when the alignment of all circuits is completed.

Turn the sweep generator and signal generator back on and recheck channel 6 response. Readjust L48, L50 and L53 if necessary.

Set the receiver channel selector switch to channel 8 and readjust C2 for proper oscillator frequency, 227 mc.

Set the sweep generator and signal generator to channel 8.

Readjust C9, C11, C15 and C18 for correct curve shape, frequency and band width.

Turn off the sweep and signal generators, switch back to channel 6 and check the oscillator injection voltage at TP1 if C9 was adjusted in the recheck of channel 8 response.

If the initial setting of oscillator injection trimmer C8 was far off, it may be necessary to adjust the oscillator frequency and response on channel 8, adjust the oscillator injection on channel 6 and repeat the procedure several times before the proper setting is obtained.

Turn off the sweep generator and switch the receiver to channel 13.

Adjust the signal generator to the channel 13 oscillator frequency 257 mc.

Set the fine tuning control 30 degrees clockwise from the center of its mechanical range.

Adjust L46 to obtain an audible beat. Slightly overshoot the adjustment of L46 by turning the slug a little more in the same direction from the original setting, then reset the oscillator to proper frequency by adjusting C2 to again obtain the beat.

Check the response of channels 7 through 13 by switching the receiver channel switch, sweep generator and marker oscillator to each of these channels and observing the response and oscillator injection obtained. See Figure 13 for typical response curves. It should be found that all these channels have the proper shaped response with the markers above 80% response.

If the markers do not fall within this requirement, switch to channel 8 and readjust C9, C11, C15 and C18 as necessary.

Turn off the sweep generator and check the channel 8 oscillator frequency. If C2 has to be readjusted for channel 8, the principle of overshooting the adjustment and then correcting by adjusting L46 should be followed in order to establish the L/C ratio for the desired oscillator tracking.

Turn the receiver channel selector switch to channel 6. Adjust L5 for correct oscillator frequency, 129 mc.

Turn the sweep generator on and to channel 6 and observe the response curve. If necessary readjust L48, L50 and L53.

Switch the receiver, the sweep and signal generators to channel 2 and adjust T1 clockwise to a point where there is no change in the channel 2 response as T1 is turned.

Switch the receiver through channel 6 down through channel 2 and check for normal response curve shapes and oscillator injection voltage.

If excessive tilt in the same direction occurs on channels 2, 3 and 4, adjust C18 on channel 2 to overshoot the correction of this tilt, then switch to channel 6 and adjust L53 for maximum amplitude of curve between markers. This adjustment should produce "flat" response on the low channels if the other adjustments especially L48 are correct.

Likewise check channels 7 through 13, stopping on 13 for the next step.

With the receiver on channel 13, check the receiver oscillator frequency. Correct by adjustment of C2 if necessary.

Adjust the oscillator to frequency on all channels by switching the receiver and the frequency standard to each channel and adjusting the appropriate oscillator trimmer to obtain the audible beat. It should be possible to adjust the oscillator to the correct frequency on all channels with the fine tuning control in the middle third of its range. When employing WR39 calibrators to adjust the receiver oscillator, tune the calibrator to one-half the receiver oscillator frequency on channels 4, 5 and 6 and to one-fourth the receiver oscillator frequency on channels 11, 12 and 13.

ALIGNMENT PROCEDURE

Channel Number	Picture Carrier Freq. Mc.	Sound Carrier Freq. Mc.	Receiver R-F Osc. Freq. Mc.	Channel Oscillator Adjustment
2	55.25	59.75	101	L1
3	61.25	65.75	107	L2
4	67.25	71.75	113	L3
5	77.25	81.75	123	L4
6	83.25	87.75	129	L5
7	175.25	179.75	221	L6
8	181.25	185.75	227	L7
9	187.25	191.75	233	L8
10	193.25	197.75	239	L9
11	199.25	203.75	245	L10
12	205.25	209.75	251	L11
13	211.25	215.75	257	C1

Remove the 39 ohm resistor from the link and reconnect the link to terminals "A" and "B" of T104.

RATIO DETECTOR ALIGNMENT. — Set the signal generator at 4.5 mc. and connect it to the second sound i-f grid, pin 1 of V102. Set the generator for 30% 400 cycle modulation.

As an alternate source of signal, the RCA WR39B or WR39C calibrator may be employed. If used, connect its output cable to the grid of the 4th pix i-f amplifier, pin 1 of V109. Set the frequency of the calibrator to 45.75 (pix carrier) and modulate with 4.5 mc. crystal. Also turn on the internal AM audio modulation. The 4.5 mc. signal will be picked off at T110A and amplified through the sound i-f amplifier.

Connect the "VoltOhmyst" to the junction of R110 and R150.

Connect the oscilloscope to the junction of R111 and C113.

Tune the ratio detector primary, T102 top core for maximum DC output on the "VoltOhmyst." Adjust the signal level from the signal generator for 10 volts on the "VoltOhmyst" when finally peaked. This is approximately the operating level of the ratio detector for average signals.

Connect the "VoltOhmyst" to the junction of R111 and C113.

Tune the ratio detector secondary T102 bottom core for zero d-c on the "VoltOhmyst."

Adjust R139 for minimum AM indication on the oscilloscope.

Retune the T102 bottom core to obtain zero d-c on the "VoltOhmyst."

Repeat the adjustment of T102 bottom core for zero d-c on the "VoltOhmyst" and R139 for minimum AM indication on the oscilloscope until both conditions are satisfied at the same settings of the adjustments. Final touches on these adjustments must be made with the input signal adjusted to produce 10 volts d-c on the "VoltOhmyst" at the junction of R110 and R150.

SOUND I-F ALIGNMENT. - Connect the sweep generator to the first sound i-f amplifier grid, pin 1 of V101. Adjust the generator for a sweep width of 1 mc. at a center frequency of 4.5 mc.

Insert a 4.5 mc. marker signal from the signal generator into the first sound i-f grid.

Connect the oscilloscope in series with a 10,000 ohm resistor to terminal A of T101.

Adjust T101 top and bottom cores for maximum gain and symmetry about the 4.5 mc. marker on the i-f response. The pattern obtained should be similar to that shown in Figure 14.

The output level from the sweep should be set to produce approximately 2.0 volt peak-to-peak at terminal A of T101 when the final touches on the above adjustment are made. It is necessary that the sweep output voltage should not exceed the specified values otherwise the response curve will be broadened, permitting slight misadjustment to pass unnoticed and possibly causing distortion on weak signals.

Connect the oscilloscope to the junction of R111 and C113 and check the linearity of the response. The pattern obtained should be similar to that shown in Figure 15.

SOUND TAKE-OFF ALIGNMENT. — Connect the 4.5 mc. generator in series with a 1,000 ohm resistor to terminal "C" of T110. The input signal should be approximately 0.5 volts.

Short the fourth pix i-f grid to ground, pin 1 V109, to prevent noise from masking the output indication.

As an alternate source of signal the RCA WR39B or WR39C calibrator may be used. In such a case, disregard the above two paragraphs. Connect calibrator across link circuit, T104 A, B, and modulate 45.75 carrier with 4.5 mc. crystal.

Connect the crystal diode probe of a "VoltOhmyst" to the plate of the video amplifier, pin 6 of V110 (pin 8 if 6AG7 used).

Adjust the core of T110 for minimum output on the meter.

Remove the short from pin 1 V109 to ground, if used.

PICTURE I-F TRAP ADJUSTMENT. — Connect the i-f signal generator across the link circuit on terminals A and B of T104.

Connect the "VoltOhmyst" to the junction of R193 and R194.

Obtain a 7.5 volt battery capable of withstanding appreciable current drain and connect the ends of a 1,000 ohm potentiometer across it. Connect the battery positive terminal to chassis and the potentiometer arm to the junction of R193 and R194.

Set the bias pot to produce approximately −1.0 volt of bias at the junction of R193 and R194.

Connect the "VoltOhmyst" to pin 2 of V110 (pin 4 of 6AG7).

Set the signal generator to each of the following frequencies and adjust the corresponding circuit for minimum d-c output at pin 2 of V110. Use sufficient signal input to produce 1.0 volt of d-c on the meter when the final adjustment is made.

39.25 mc.	T104 top core
41.25 mc.	T105 bottom core
47.25 mc.	T106 bottom core

PICTURE I-F TRANSFORMER ADJUSTMENTS. — Set the signal generator to each of the following frequencies and peak the specified adjustment for maximum indication on the "VoltOhmyst." During alignment, reduce the input signal if necessary in order to produce 1.0 volt of d-c at pin 2 of V110 with −1.0 volt of i-f bias at the junction of R193 and R194.

43.7 mc.	T109
45.5 mc.	T108
41.8 mc.	T107

To align T105 and T106, connect the sweep generator to the first picture i-f grid, pin 1 of V106 through a 1,000 mmf ceramic capacitor. Shunt R136, R143 and terminals "A" and "F" of T109 with 330 ohm composition resistors. Set the i-f bias to −1.0 volt at the junction of R193 and R194.

Connect the oscilloscope to pin 2 of V110 (pin 4 of 6AG7).

Adjust T105 and T106 top cores for maximum gain and curve shape as shown in Figure 16. For final adjustments set the output of the sweep generator to produce 0.5 volts peak-to-peak at the oscilloscope terminals.

To align T1 and T104, connect the sweep generator to the mixer grid test point TP2. Use the shortest leads possible, with not more than one inch of unshielded lead at the end of the sweep cable.

Set the channel selector switch to channel 4.

Connect a 180 ohm composition resistor from terminal B of T105 to the junction of R131 and C131. Connect the oscilloscope diode probe to terminal B of T105 and to ground.

Couple the signal generator loosely to the diode probe in order to obtain markers.

C122 is variable and is provided as a band width adjustment. Preset C122 to minimum capacity.

Adjust T1 top and T104 bottom for maximum gain at 43.5 mc. and with 45.75 mc. at 70% of maximum response.

Adjust C122 until 41.25 mc. is at 85% response with respect to the low frequency shoulder at approximately 41.9 mc. as shown in Figure 17.

Disconnect the diode probe, the 180 ohm and three 330 ohm resistors.

SWEEP ALIGNMENT OF PIX I-F. — Connect the oscilloscope to pin 2 of V110 (pin 4 where V110 is a 6AG7).

Adjust the bias potentiometer to obtain −6.0 volts of bias as measured by a "VoltOhmyst" at the junction of R193 and R194.

ALIGNMENT PROCEDURE

Leave the sweep generator connected to the mixer grid test point TP2 with the shortest leads possible and with not more than one inch of unshielded lead at the end of the sweep cable. If these precautions are not observed, the receiver may be unstable and the response curves obtained may be unreliable.

Adjust the output of the sweep generator to obtain 3.0 volts peak-to-peak on the oscilloscope.

Couple the signal generator loosely to the grid of the first pix i-f amplifier. Adjust the output of the signal generator to produce small markers on the response curve.

Retouch T108 and T109 to obtain the response shown in Figure 18. Do not adjust T107 unless absolutely necessary. If T107 is adjusted too low in frequency it will raise the level of the 41.25 mc. sound i-f carrier and may create interference in the picture. It will also cause poor adjacent channel picture rejection. If T107 is tuned too high in frequency, the level of the 41.25 mc. sound i-f carrier will be too low and may produce noisy sound in weak signal areas.

Remove the oscilloscope, sweep and signal generator connections.

Remove the bias box employed to provide bias for alignment.

HORIZONTAL OSCILLATOR ADJUSTMENT.—Normally the adjustment of the horizontal oscillator is not considered to be a part of the alignment procedure, but since the oscillator waveform adjustment may require the use of an oscilloscope, it can not be done conveniently in the field. The waveform adjustment is made at the factory and normally should not require readjustment in the field. However, the waveform adjustment should be checked whenever the receiver is aligned or whenever the horizontal oscillator operation is improper.

Horizontal Frequency Adjustment.—Tune in a station and sync the picture. If the picture cannot be synchronized with the horizontal hold control R197B, then adjust the T113 frequency core on the rear apron until the picture will synchronize. If the picture still will not sync, turn the T113 waveform adjustment core (under the chassis) out of the coil several turns from its original position and readjust the T113 frequency core until the picture is synchronized.

Examine the width and linearity of the picture. If picture width or linearity is incorrect, adjust the horizontal drive control C191B, the width control L106 and the linearity control L107 until the picture is correct.

Horizontal Oscillator Waveform Adjustment.—The horizontal oscillator waveform may be adjusted by either of two methods. The method outlined in paragraph A below may be employed in the field when an oscilloscope is not available. The service shop method outlined in paragraph B below requires the use of an oscilloscope.
