22F2, 22M2

WAVEFORM DATA
(Waveforms given on schematic)

Waveforms taken with CONTRAST control set fully to the right, all other controls set for normal picture (in sync). Warning: Incorrect adjustment of the DX Range Finder control will cause waveform distortion.

Waveforms at video and sync stages obtained with transmitted signal input to receiver.

The oscilloscope sweep is adjusted for 30 cycles (which is one-half of the vertical frequency), or for 7875 cycles (which is one-half of the horizontal frequency) so that two pulses appear on the screen.

The peak-to-peak voltage readings shown are subject to some variations due to response of the oscilloscope and parts tolerances.

CAUTION

Pulsed high voltage is present on the caps of V406, V407 and pin 3 of V408. Do not make direct connection to these points with ordinary test equipment. Waveform and peak-to-peak voltage at pin 3 of V408 taken, using an oscilloscope with a capacitive voltage divider probe. Waveform at pin 3 of V408 can be taken by clipping or twisting the lead from the oscilloscope high side over the insulation on the cap lead. When taking the waveform this way, the shape of the waveform will be the same but the peak-to-peak voltage will be much lower, depending upon the degree of coupling.

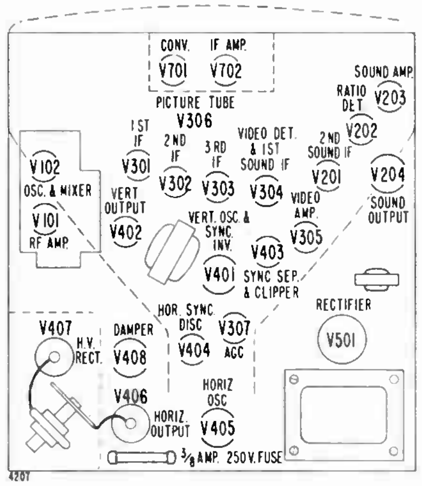
TV VOLTAGE DATA
(Voltages given on schematic)

- CONTRAST control turned fully clockwise. CHANNEL control set on an unused channel. Other front controls set at approximately half rotation. Vert. Lin. and Height set at approximately half rotation. DX Range Finder control set fully to the left (at "0" position).
- Antenna disconnected from set with terminals shorted.
- Voltages marked with an asterisk * will vary widely with control setting.
- Line voltage 117 volts AC.
- Voltages measured with a vacuum tube voltmeter between tube socket terminals and chassis, unless otherwise indicated.
- Voltages at V101 and V102 (TV Tuner) are measured with tube in socket. Use an adapter or lift tube out of socket just high enough to allow a needle point probe to contact tube pins.
- Voltages at V306 measured from top of socket with tube removed.

CAUTION

Pulsed high voltages are present on the cap of V406, pin 3 of V408, and on the filament terminals and cap of the 1B3GT tube. NO ATTEMPT SHOULD BE MADE TO TAKE MEASUREMENTS FROM THESE POINTS WITHOUT SUITABLE TEST EQUIPMENT.

Picture tube 2nd anode voltage can be measured from the 2nd anode connector and should be taken only with a high voltage instrument such as a kilovoltmeter or vacuum-tube voltmeter with a high voltage probe. 2nd anode voltage is approximately 17.5 KV. Proper filament voltage check of the 1B3GT tube may be made by observing filament brilliance as compared with that obtained with a 1.5 volt dry cell battery.



Top View of 22P2 Chassis. (V701 and V702 are accessible from underside of chassis).

22P2

WAVEFORM DATA
(Waveforms given on schematic)

Waveforms taken with CONTRAST control set fully to the right, all other controls set for normal picture (in sync). Warning: Incorrect adjustment of the DX Range Finder control will cause waveform distortion.

Waveforms at video and sync stages obtained with transmitted signal input to receiver.

The oscilloscope sweep is adjusted for 30 cycles (which is one-half of the vertical frequency), or for 7875 cycles (which is one-half of the horizontal frequency) so that two pulses appear on the screen.

The peak-to-peak voltage readings shown are subject to some variations due to response of the oscilloscope and parts tolerances.

Waveform at pin 3 of V408 can be taken by clipping or twisting the lead from the oscilloscope high side over the insulation on the cap lead. When taking the waveform this way, the shape of the waveform will be the same but the peak-to-peak voltage will be much lower, depending upon the degree of coupling.

VOLTAGE DATA
(Voltages given on schematic)

- TV voltage taken with function switch on "TV" position. CONTRAST control turned fully clockwise. CHANNEL control set on an unused channel. Other front controls set at approximately half rotation. Vert. Lin. and Height set at approximately half rotation. DX Range Finder control set fully to the left (at "0" position). TV antenna disconnected from set with terminals shorted.
- Radio voltages V701 and V702 taken with function switch on "Rad" position; voltages measured from underside of tube sockets. When measured from top of tube sockets (with tube removed), B plus voltage at pins 5 and 6 of V701 and V702 will be approximately 275 volts.
- B plus voltages at V203 and V204, will be slightly higher when set is switched to "Rad" position. Voltages marked with an asterisk * will vary widely with control setting.
- Line voltage 117 volts AC.
- Voltages measured with a vacuum tube voltmeter between tube socket terminals and chassis, unless otherwise indicated.
- Voltages at V306 measured from top of socket with tube removed.
- Voltages at V101 and V102 (TV Tuner) are measured with tube in socket. Use an adapter or lift tube out of socket just high enough to allow a needle point probe to contact tube pins.

CAUTION

Pulsed high voltages are present on the cap of V406, pin 3 of V408 and on the filament terminals and cap of the 1B3GT tube. NO ATTEMPT SHOULD BE MADE TO TAKE MEASUREMENTS FROM THESE POINTS WITHOUT SUITABLE TEST EQUIPMENT.

Picture tube 2nd anode voltage can be measured from the 2nd anode connector and should be taken only with a high voltage instrument such as a kilovoltmeter or VTVM with a high voltage probe. 2nd anode voltage is approximately 17.5 KV. Proper filament voltage check of the 1B3GT tube may be made by observing filament brilliance as compared with that obtained with a 1.5 volt dry cell battery.

DIAL STRINGING

Dial stringing for the radio tuning control is shown below.

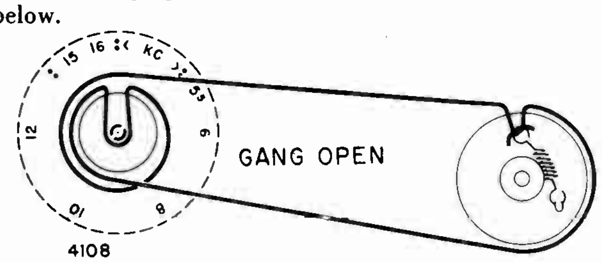

Figure 17. Dial Stringing for the 22P2 Chassis.

ALIGNMENT OF RADIO TUNER

The radio tuner in television and radio chassis should be aligned as instructed under "Radio Alignment Procedure" below.

The radio alignment trimmers are accessible without disassembly of the radio tuner from the TV chassis.

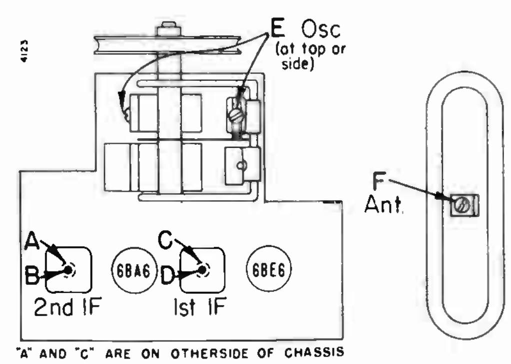

Figure 18. Trimmer Locations for AM Radio Tuner in 22P2 Chassis.

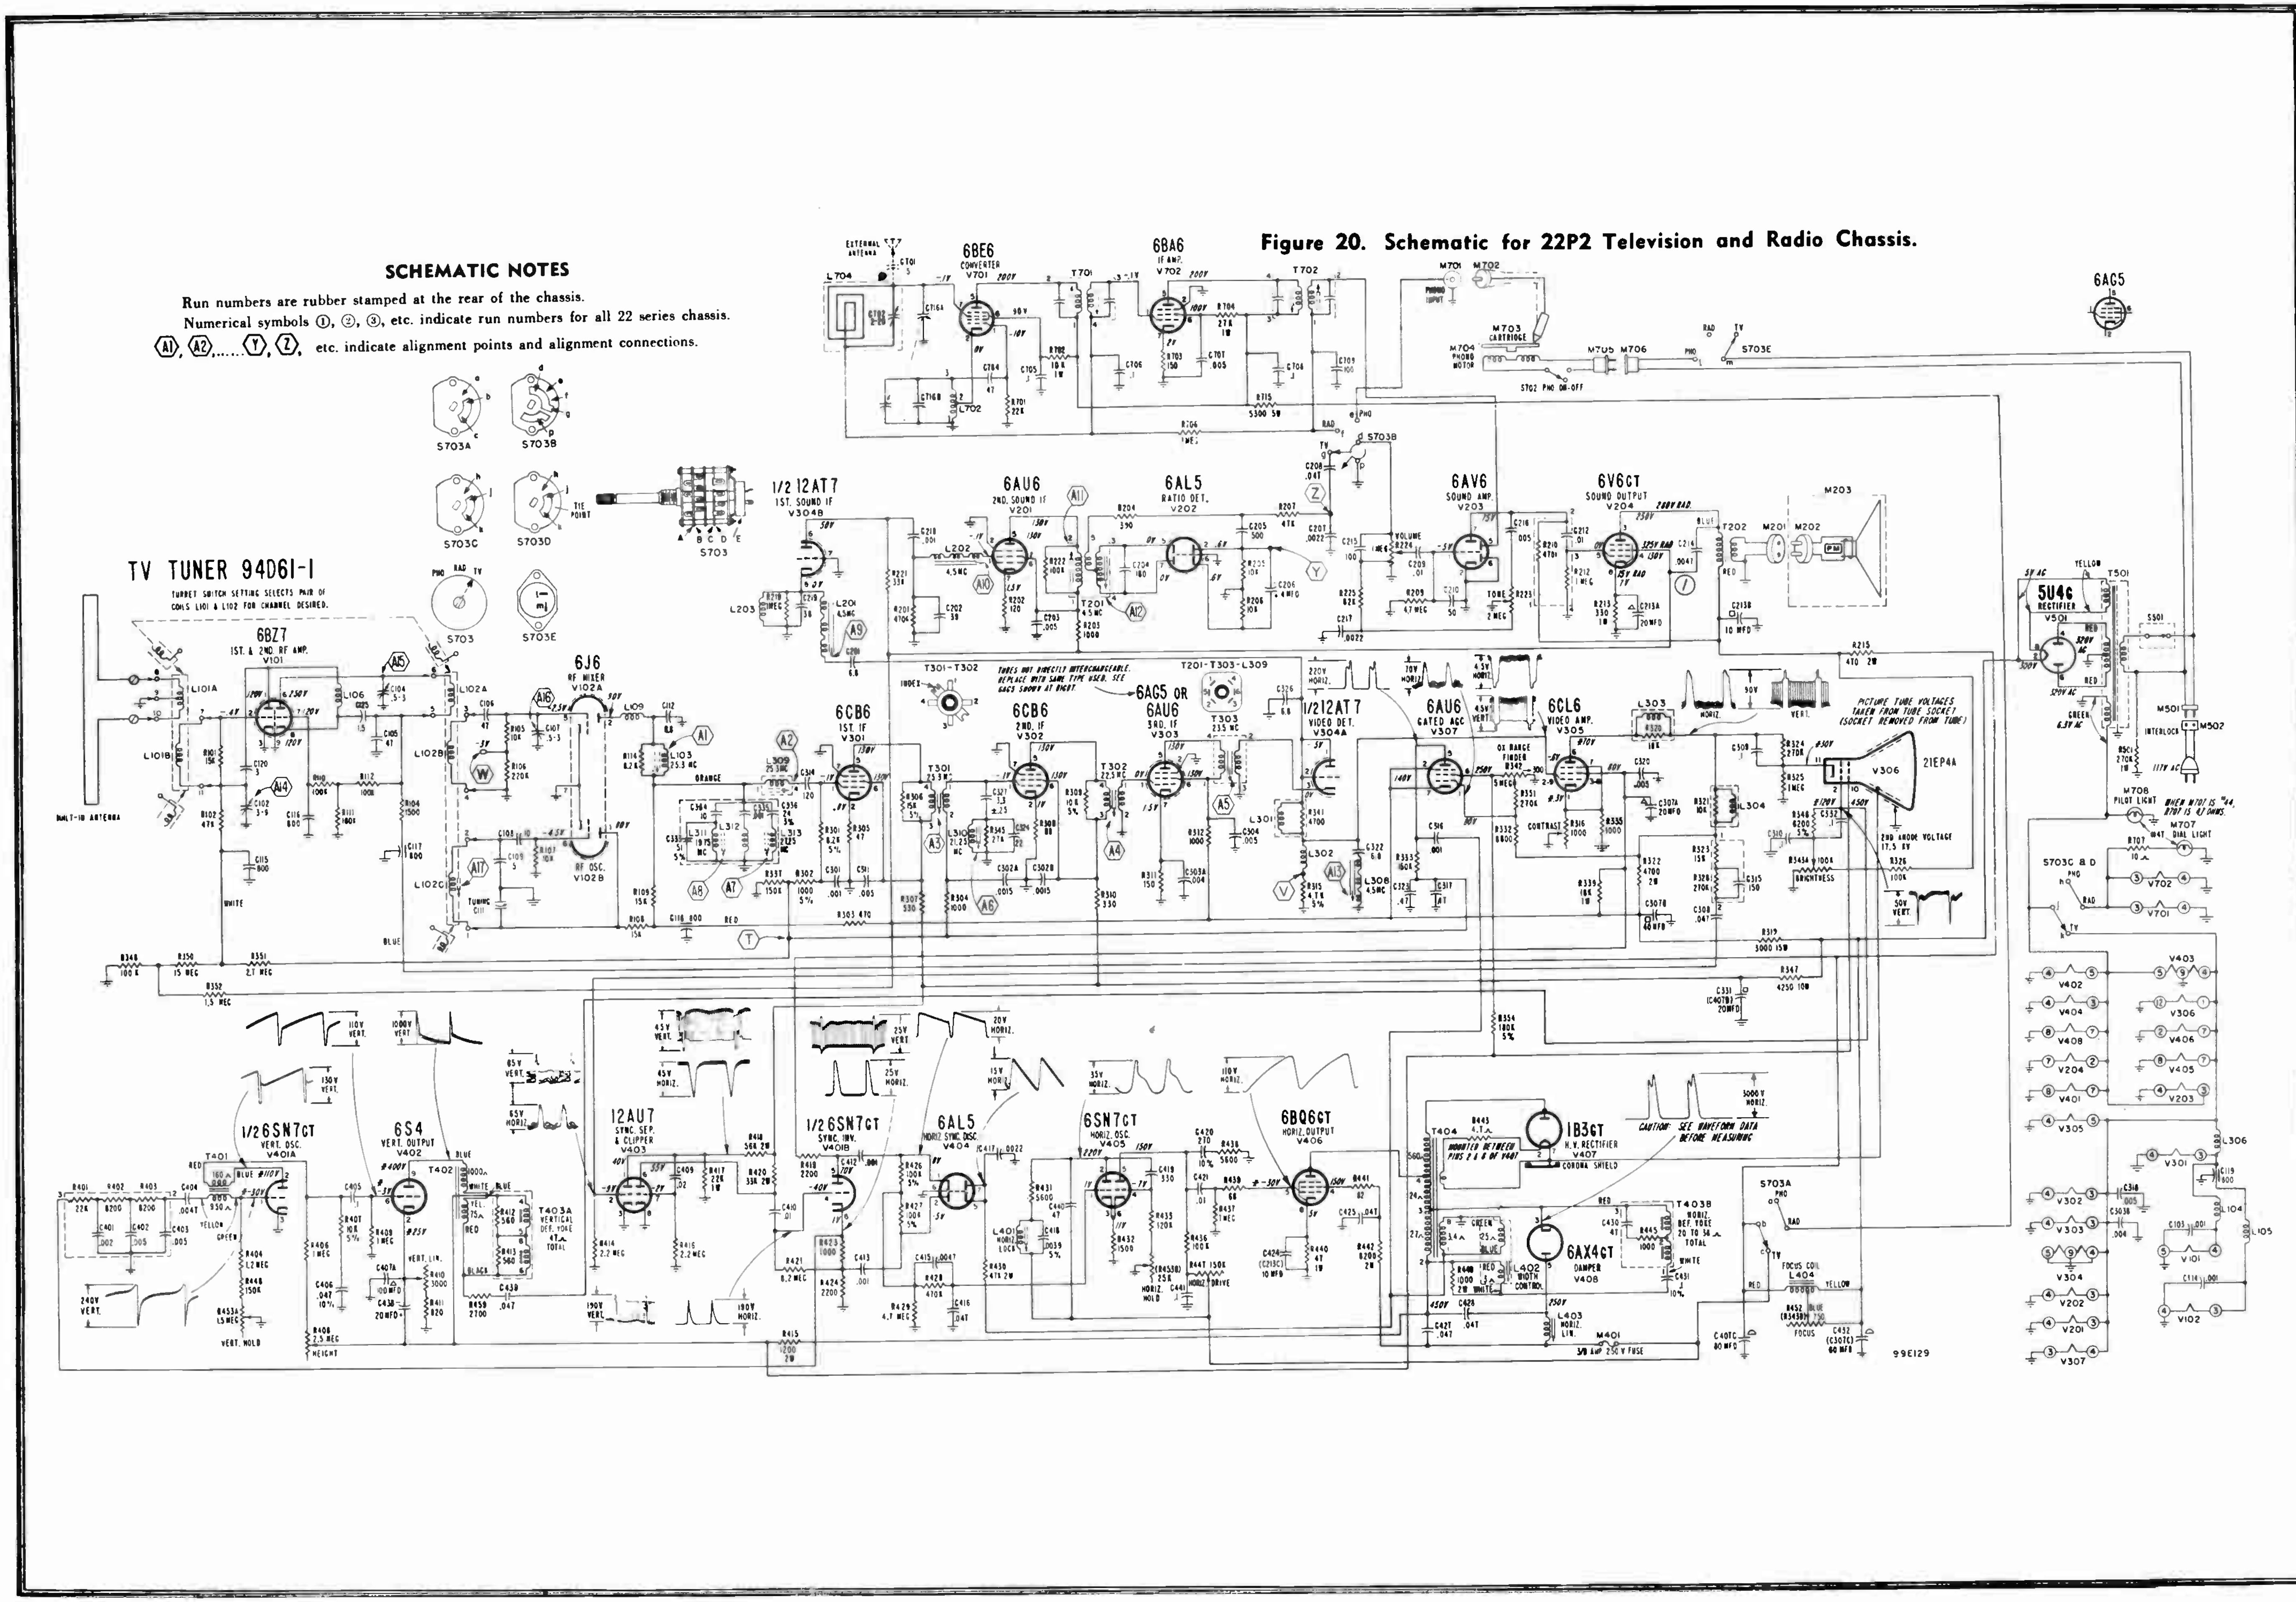

Figure 20. Schematic for 22P2 Television and Radio Chassis.

SCHEMATIC NOTES

Run numbers are rubber stamped at the rear of the chassis.

Numerical symbols ①, ②, ③, etc. indicate run numbers for all 22 series chassis.

Ⓐ1, Ⓐ2,......Ⓨ, Ⓩ, etc. indicate alignment points and alignment connections.

SCHEMATIC NOTES

Run numbers are rubber stamped at the rear of the chassis.

Numerical symbols ①, ②, ③, etc. indicate run numbers for all 22 series chassis.

(A1), (A2),.....(Y), (Z), etc. indicate alignment points and alignment connections.

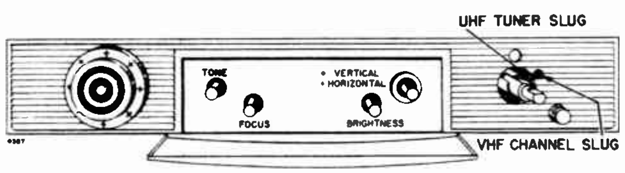

Figure 3. Control Panel for Models Using 23C1AZ and 23F1Z Chassis.

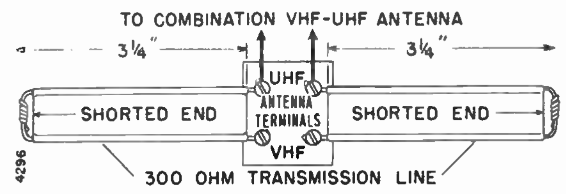

Figure 1. Antenna Connections When Combination VHF-UHF Antenna is Used.

Noise Gate Adjustment

The **Noise Gate** control, located at the rear of the set near the center, is used to improve sync stability in fringe areas and in noisy local areas.

Before making the **Noise Gate** adjustment, the **DX Range Finder**, located at the rear of the set, should be set at "0".

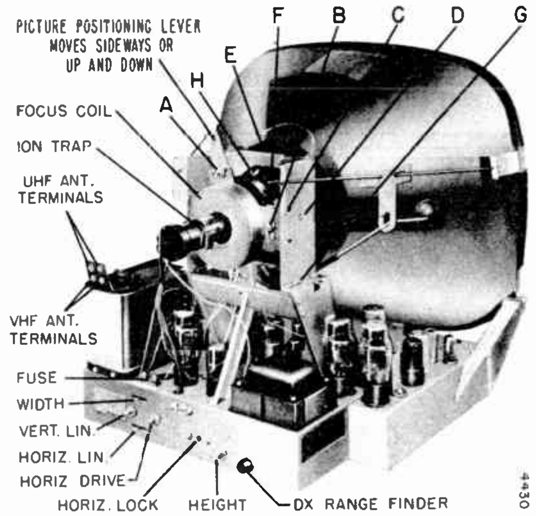

Figure 4. Rear View of 23E1Z and 23F1Z Chassis.

Set the **Noise Gate** fully to the left (counterclockwise). Set the **Channel Selector** for the strongest TV station and tune in a picture. Be sure that the **Vertical** and **Horizontal** controls on front panel are properly adjusted. If the picture is unstable (jitters or rolls), slowly turn the **Noise Gate** control to the right until picture just becomes stable. Check adjustment on other TV stations, and if necessary, readjust control.

Caution: If the **Noise Gate** control is turned too far to the right (clockwise) for a strong signal, the picture may become unstable (roll vertically or tear horizontally).

If the signal strength or noise level changes, it may be desirable to change the setting of the **Noise Gate**; however, it is generally possible to set it at a single compromise position which gives reasonable stability for the different signal conditions.

DX Range Finder Adjustment

The **DX Range Finder** control is at the extreme right when facing the rear of the chassis. This control is used to improve TV reception in fringe areas and in areas where there is interference.

The **DX Range Finder** should be set fully counterclockwise if good pictures can be obtained using the front panel controls of the receiver.

White flashes across the picture caused by extreme external noise can sometimes be minimized by careful adjustment of the **DX Range Finder**.

Where the TV signal strength is weak, the picture can often be improved by turning the **DX Range Finder** part

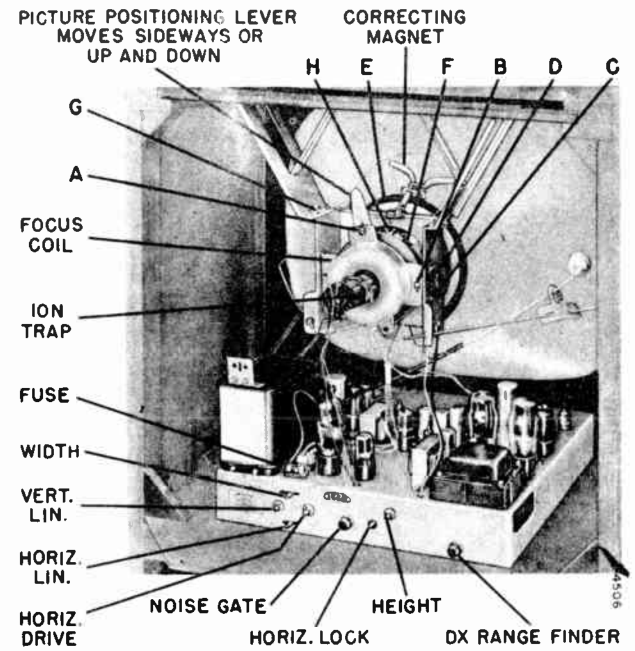

Figure 5. Rear View of 23B1AZ and 23C1AZ Chassis.

way to the right or, if necessary, fully clockwise. It may be necessary to make a slight readjustment of the **Noise Gate** control after adjusting the **DX Range Finder**.

If the signal strength changes, it may be desirable to change the setting of the **DX Range Finder**; however, it is generally possible to set it at a single compromise position which gives reasonable reception for the different signal strengths.

Caution: If the **DX Range Finder** is turned too far to the right for a strong signal, the picture may bend or disappear completely.

Horizontal Oscillator and Horizontal Drive Adjustment

When switching channels, the **Horizontal** control (on front panel) should keep the picture in horizontal sync through at least three fourths of its range. If the picture does not remain in horizontal sync, then adjust the rear panel controls as follows:

1. Allow the set to warm up. Tune in a station and adjust the **Brightness** and **Contrast** controls for average settings. Be sure that the **Noise Gate** and **DX Range Finder** controls are properly adjusted.
2. The **Horizontal Drive** control (at rear of set) is a potentiometer adjustment. Set the control to the approximate center of its rotation. If a white vertical line appears, turn the control to the left until the line just disappears.
3. Turn the **Horizontal** control (on front panel) fully to the left. While slowly rotating the **Horizontal** control to the right, switch the **Channel Selector** off and on a station several times. The picture should remain in horizontal sync for at least three fourths of the **Horizontal** control range. If not, set the **Horizontal** control to the position at which horizontal sync is lost.

Slowly turn the **Horizontal Lock** control to the right or left until the picture synchronizes. It may require one or more turns of the **Horizontal Lock** control to obtain the proper range for the **Horizontal** control on front panel.

THEORY OF OPERATION

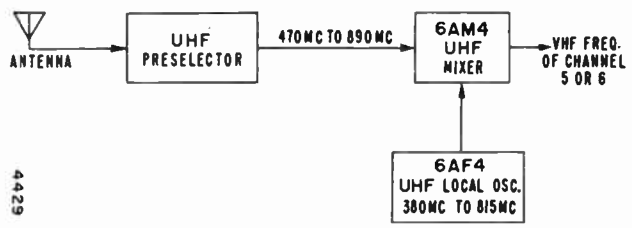

Figure 17. Block Diagram of UHF Tuner A4160.

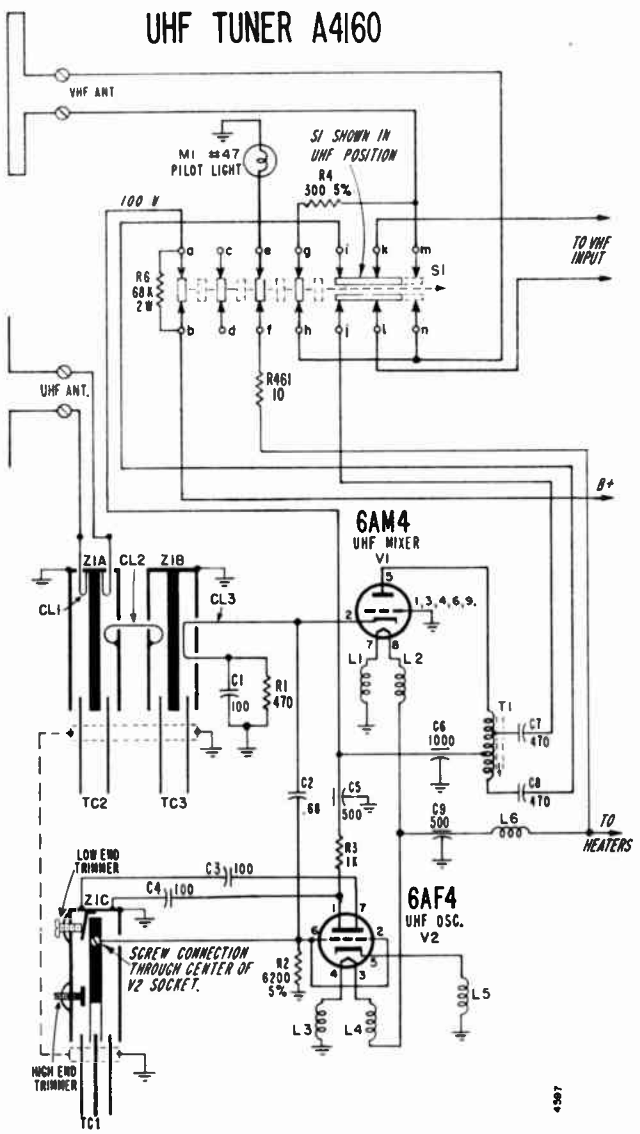

Figure 18. Schematic Diagram of UHF Tuner A4160.

TOUCH-UP OF RATIO DETECTOR SECONDARY USING A TELEVISION SIGNAL

This adjustment is accessible through the 1/4" hole (just below T201) in bottom of the cabinet or the chassis mounting shelf, located toward the right side facing the rear of the set. Removal of the chassis is therefore not required.

Adjustment need be made on one channel only. Proceed as follows:

1. Turn set on and allow about 15 minutes for warm up.
2. Tune set for normal picture and sound.
3. Carefully insert a non-metallic alignment tool through the top of T201. An alignment tool with a hexagonal end is required. When the alignment tool engages the bottom tuning slug A12, adjust the slug for best sound with minimum buzz level. Do this carefully as only slight rotation in either direction will generally be required. Correct adjustment point is located between the two maximum buzz peaks that will be noticed when turning the slug back and forth about 1/4 to 1/2 turn.
4. If necessary, repeat individual channel slug adjustment and conclude with retouching the ratio detector secondary. Note: If oscillator adjustment is required for other channels, it will *not* be necessary to repeat the ratio detector secondary adjustment after *once* correctly adjusting it.

ALIGNMENT OF 4.5 MC TRAP USING A TELEVISION SIGNAL

Beat interference (4.5 MC) appears in picture as very fine vertical or diagonal lines, very close together, having a "gauze-like" appearance, the pattern will vary with speech, forming a very fine herringbone pattern.

The trap can be tuned by watching the picture and adjusting the slug A13 for minimum 4.5 MC interference. If greater accuracy is required, the trap should be adjusted as instructed in step 3 under "4.5 MC Sound IF and Trap Alignment" procedure

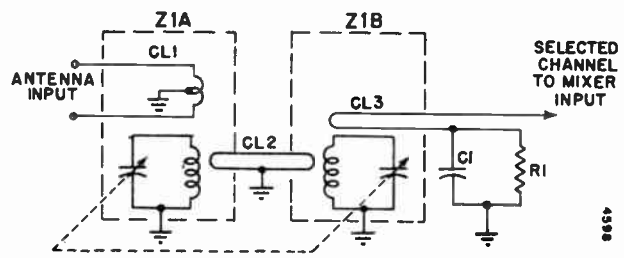

Figure 19. Equivalent Circuit of UHF Preselector.

SERVICE HINTS

UHF TUNER

The high frequencies at which the UHF tuner operates make it necessary that extreme care be exercised when servicing. The only field service recommended is minor repairs to the tuner such as replacement of tubes, switch S1 and resistors which are mounted on switch S1.

Alignment

The UHF tuner has been carefully aligned at the factory and generally should never require realignment in the field. Also, since alignment of the UHF tuner is quite involved, it is not recommended for field service. If it has been definitely determined that complete tuner alignment is required, it should be returned to your Admiral distributor for replacement.

Important: Do not under any circumstances attempt adjustment of the tracking screws or bend the capacitor tuning plates in any way.

The UHF tuner slug (mixer coupling network) may be adjusted to improve performance in weak signal areas or eliminate some forms of interference. This adjustment is located directly below the VHF channel slug adjustment. For information on "UHF Tuner Slug Adjustment"

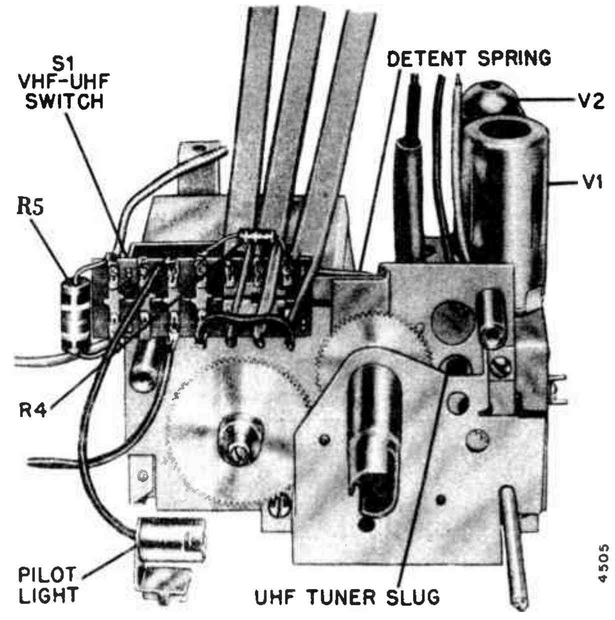

Figure 44. Front View of UHF Tuner.

Trouble Shooting

To isolate UHF trouble in a VHF-UHF receiver, it is suggested that VHF test equipment be used to check the VHF portion of the receiver in the same manner as checking for a defective VHF booster. If VHF operation is satisfactory, and it is known that a UHF signal of considerable strength exists, it can be assumed that the antenna or the UHF tuner is at fault. Carefully check the antenna and transmission line. If new tubes have been substituted in the UHF tuner and reception is still poor, the UHF tuner should be replaced. Be certain, however, that the VHF portion of the receiver is functioning normally. It is easy to be deceived where a strong VHF signal exists. Whenever possible, check VHF receiver sensitivity before replacing a UHF tuner. See "Fringe Area Television Reception" booklet, form number S346 Rev. 2, for instructions on checking sensitivity, expected sensitivity figures, and recommended equipment.

Faulty tubes will cause the majority of UHF tuner troubles. Listed below are some of the most common troubles generally due to faulty tubes.

1. Weak signal (excessive snow or no picture) can be caused by a faulty tube. Check V1 (6AM4) and V2 (6AF4).
2. Spurious responses. Spurious responses will show up as flashing on the screen while tuning in a picture. If flashing occurs at more than 6 points while tuning through the UHF band, check for a faulty oscillator tube V2 (6AF4).
3. Oscillator tube V2 (6AF4) gets excessively hot and B+ voltage at terminal "a" of VHF-UHF switch S1 is below 80 volts. Replace V2 (6AF4).

Note: Replacement of oscillator tube V2 (6AF4) may cause slight detuning of the oscillator circuit and thus affect tracking. If this occurs, a number of tubes should be tried, until the most satisfactory substitute for the original tube is found. Be sure that tubes and tube shields are pushed down and seated firmly.

Replacing Detent Spring on Switch S1

To replace the detent spring on switch S1, remove the mounting screw from the rear of the switch directly behind the spring. Lift the spring out with long nose pliers. Insert the replacement spring and mounting screw; do not tighten screw. Turn the High-Channel Selector shaft fully clockwise and position the detent spring until it engages the switch arm stud; then tighten screw. Check the operation of the switch to be sure that the switching action is positive.

Replacing Switch S1

To replace the VHF-UHF switch S1, carefully disconnect the leads and components from the switch. Remove switch mounting screws from the rear of the switch. Mount the replacement switch; do not tighten screws. Turn the High-Channel Selector shaft fully clockwise and position the detent spring until it engages the switch arm stud; then tighten screws. Check operation of the switch to be sure that the detent spring engages the switch and switching action is positive. Connect leads and components to the same terminals as on the original switch.

Servicing Tuning Drive

An all gear tuning drive assembly is used on UHF tuner A4160; see figure 45. The gear drive of these tuners should require very little attention. Rough tuning or play may be caused by insufficient clearance between gear M2 and idler pinion M3. The individual gears or the complete gear drive assembly are replaceable.

Lubrication: In general, the lubrication applied to the gears or bearing surfaces at time of manufacture should make lubrication seldom, if ever, necessary.

Lubricate gears or bearing surfaces with Admiral lubricant, part number 98A64-2, or light vaseline.

CAUTION: Use care so that lubricant does not come in contact with the UHF-VHF changeover switch. Do not use lubriplate or any similar lubricant containing zinc or cadmium.

Replacement of Gears: The complete gear train assembly or individual gears (M3, M4, M5, M6 and M7) are available for replacement (see figure 45). In general, it is recommended that the complete gear train and gear M2 be replaced, however, if difficulty is due to a specific gear or pinion, that particular part may be replaced individually.

When replacing the complete gear train, it will be necessary to remove the UHF tuner from the chassis

Gear M2 can be replaced without removing the UHF tuner from the chassis.

To replace gears M3, M4, M5, M6 and M7, proceed as follows:

1. Turn UHF fine tuning shaft (vernier) fully to the left (counterclockwise).
2. Remove the three screws which mount the gear cover plate to the tuner.
3. Remove and replace defective gear(s).
4. Set gears to original position. The UHF fine tuning shaft (vernier) must be rotated fully to the left (counterclockwise) and gear M2 must be about one tooth clockwise from full counterclockwise rotation.
5. Replace the three screws which mount the gear cover plate. **Important:** Before tightening screws, be sure gear M2 and idler pinion M3 have proper clearance to avoid binding or excessive backlash.

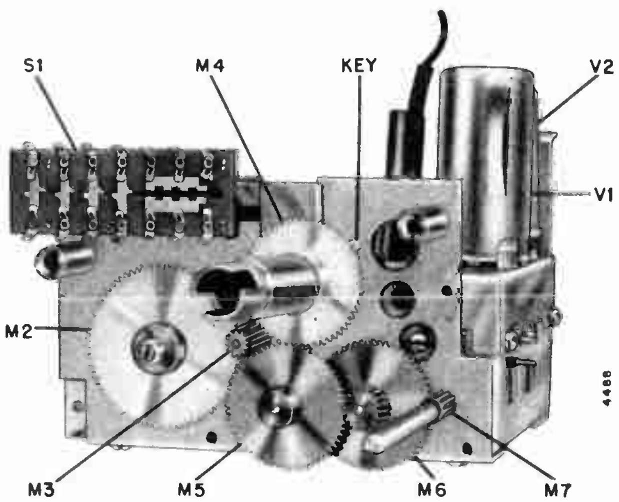

Figure 45. UHF Tuner Drive Assembly.

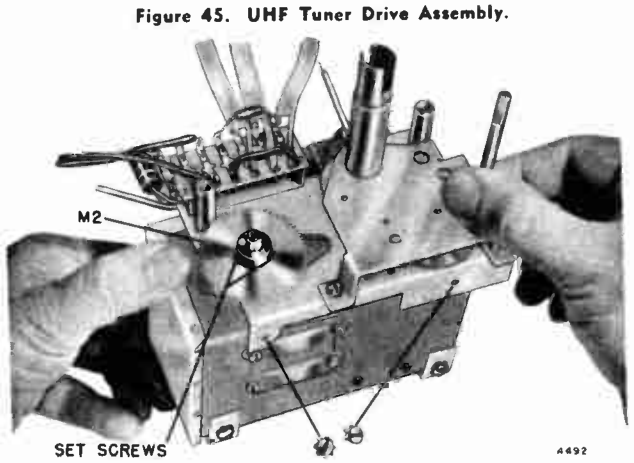

Figure 46. Front View of UHF Tuner A4160 Showing Removal of Gear Train.

To replace gear M2 without removing the UHF tuner from the chassis, it will be necessary to remove the screws which mount the VHF and UHF tuners to the chassis. Lower the tuners (without disconnecting wires) just far enough to allow access to gears. To replace gear M2, proceed as follows:

1. Turn UHF fine tuning shaft (vernier) fully to the left (counterclockwise).
2. Remove the two screws which mount the gear train assembly to the tuner; see figure 46.
3. Shift the gear train assembly to the right.
4. Using a #6 Allen wrench, loosen set screws on hub of gear M2; see figure 46.

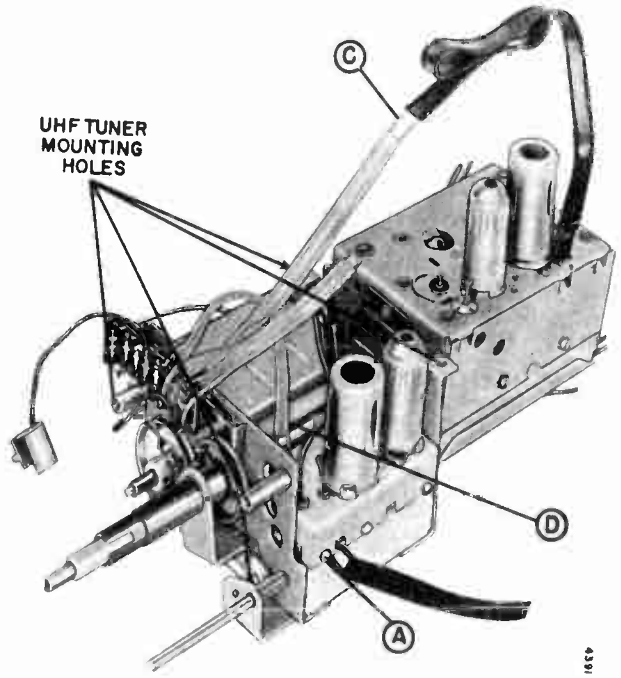

Figure 47. View of UHF and VHF Tuners With Connection Points for UHF Tuner Replacement.

5. Withdraw gear M2 from tuner shaft. **Caution:** Do not rotate M2 when removing, as tuner shaft may be marred.
6. Carefully insert the replacement gear. Space the gear 3/8 of an inch from the tuner and tighten each set screw equally.
7. Return the gear train assembly to its original position. The UHF fine tuning shaft must be rotated fully to the left (counterclockwise) and gear M2 must be about one tooth away from full counterclockwise rotation.
8. Replace the two screws which mount the gear train assembly to the tuner. **Important:** Before tightening screws, be sure that gears have proper clearance to avoid binding or excessive backlash.

Tuner Replacement

Replacement UHF tuners are supplied complete with connecting leads and components which are mounted to VHF-UHF switch S1. When soldering wires to switch S1, exercise care to prevent solder or rosin from running into the switch contacts. Switch contacts may also be damaged by application of excessive heat. Apply soldering iron to switch connection just long enough to melt solder.

A step-by-step procedure for removing the original UHF tuner and installing a replacement UHF tuner is given below. Carefully review the instructions and illustrations. Use figures 47, 48 and 49 for locations of connection points. See figure 22 for terminal location of VHF-UHF switch.

To remove the UHF tuner, proceed as follows:

1. Remove tube shields and tubes from the UHF tuner.

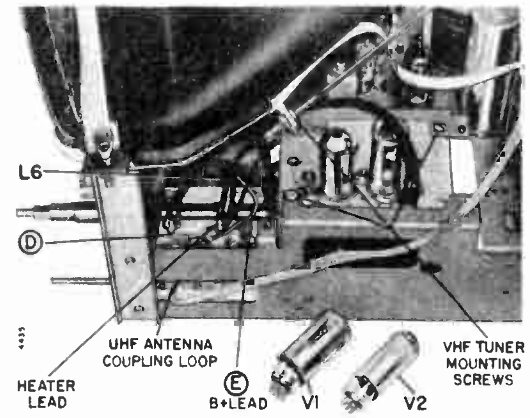

Figure 48. Side View of Chassis Showing UHF and VHF Tuners.

2. Unsolder the transmission line connected at point "A", terminals at the side of the UHF tuner.
3. Unsolder end of transmission line (23" length) connected to the lower terminals of the antenna terminal strip located at the top of the high voltage housing.
4. Unsolder the transmission line (7" length) at point "C", this runs from the VHF tuner to the VHF-UHF switch.
5. Unsolder the transmission line (6" length) at point "D", terminals of feed-thru insulators at top side of the UHF tuner. See figure 47.
6. Remove pilot light socket from mounting bracket.
7. Place the chassis on its side with the high voltage compartment away from the service bench.
8. Unsolder the lead connecting from terminal "b" of the VHF-UHF switch at point "F". Point "F" is the junction of C442 (20 mfd.) and R460 (12,000 ohms).

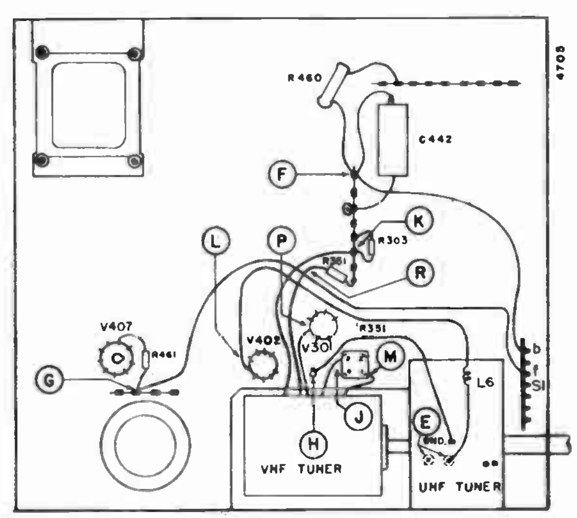

Figure 49. Bottom of TV Chassis With Connection Points for UHF and VHF Tuner Replacement.

V501 (tie-point), junction of capacitor C503. (.1 mfd.) and resistor R503 (9,000 ohms).

9. Unsolder the lead (usually brown) connecting from terminal "b" or "f" of VHF-UHF switch to point "G", terminal strip connection of resistor R461 (10 ohms).
10. Unsolder heater lead (wire with RF choke coil) at point "L", pin 5 of V402 (tie-point).
11. Unsolder the UHF tuner ground lead at point "H", ground lug in chassis.
12. Remove the tie bar at the front of the UHF tuner.
13. Remove the VHF tuner front mounting screws and only loosen the rear mounting screws. Use care so as not to break the short lead connecting from the VHF tuner to pin 1 of V301 (6CB6) tube.
14. Remove the UHF tuner front mounting screws and only loosen the rear mounting screws. Remove the rear mounting screws from the UHF tuner. Be careful so that the connections from the UHF tuner are not broken. To remove from chassis, lower the UHF tuner and slide it out while guiding the leads so that they do not catch on the chassis. See figure 50.

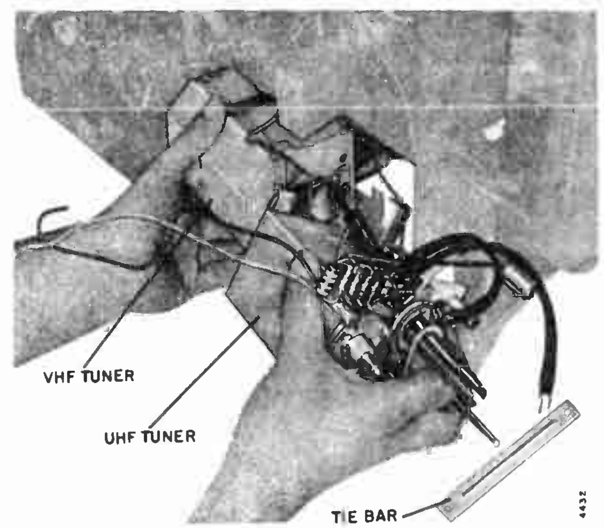

Figure 50. Bottom View of TV Chassis Showing Removal of UHF Tuner.

To install the replacement tuner, proceed as follows:

1. Remove the tube shields and tubes from the replacement UHF tuner. Insert the UHF tuner into the chassis so that the tuning shafts of the VHF tuner protrude through the center of the UHF tuning shaft. See figure 50.
2. Insert the pilot light socket through the rectangular cut-out and over the bar at the top front of the TV chassis. Insert the two lengths of transmission line through the rectangular cut-out in the chassis. Guide the heater lead (with choke coil), the ground lead (usually black) and leads from terminals "b" and "f" of VHF-UHF switch to the underside of the chassis through the rectangular cut-out in the chassis.

3. Replace the VHF and UHF tuner mounting screws. Before tightening screw, check tuner shafts to be sure that shafts operate freely, without binding. It may be necessary to shift tuners sideways or lower either tuner from the chassis, using washers as shims for proper clearance so that tuner shafts operate freely.
4. Solder transmission line from UHF antenna terminal to point "A", terminals at the side of the UHF tuner. **Important:** Do not twist wires. Lay wires parallel to each other, then solder.
5. Solder transmission line (23" length) connecting from terminals "m" and "n" of VHF-UHF switch to the lower terminals of the antenna terminal strip located at the top of the high voltage housing.
6. Solder transmission line (7" length) connecting from terminals "k" and "l" of VHF-UHF switch to point "C", junction of transmission line from VHF tuner.

   Important: Do not twist wires. Lay wires parallel to each other, then solder and tape.
7. Solder transmission line (6" length) connecting from terminals "i" and "j" of VHF-UHF switch to point "D", terminals of feed-thru insulators at top side of UHF tuner. See figures 47 and 48. **Important:** Do not twist wires. Lay wires parallel to each other, then solder.
8. Solder lead connecting from terminal "b" of VHF-UHF switch to point "F". Point "F" is the junction of C442 (20 mfd.) and R460 (12,000 ohms).
9. Solder pilot light lead (usually brown) connecting from terminal "f" of VHF-UHF switch to point "G", terminal strip connection of resistor R461 (10 ohms).
10. Solder heater lead (wire with RF choke coil) to point "L", pin 5 of V402 (tie-point).
11. Solder the UHF tuner ground lead to point "H", ground lug in chassis.
12. Replace tie bar at front of TV chassis.
13. Insert tubes and tube shields in tuner. **Important:** Be sure that tubes and tube shields are seated firmly.
14. Before operating set, check tuner to see that all mounting screws are tight and all soldered connections are secure. Refer to "Installation and Service Adjustments".

VHF TUNER

Servicing Channel Coils

The cabinets containing 23 series chassis have been provided with a rectangular cut-out in the chassis shelf just below the TV tuner. This access opening will permit servicing of the tuner channel coils or for installing UHF channel coils without removal of the chassis from the cabinet.

To gain access to the underside of the tuner, it is necessary to remove the screen covering from over the cut-out in the chassis shelf. Then remove the bottom shield from the bottom of the tuner. After servicing the channel coils, carefully replace the tuner shield. Replace the metal screen, using staples or thumb tacks to secure it to the cabinet.

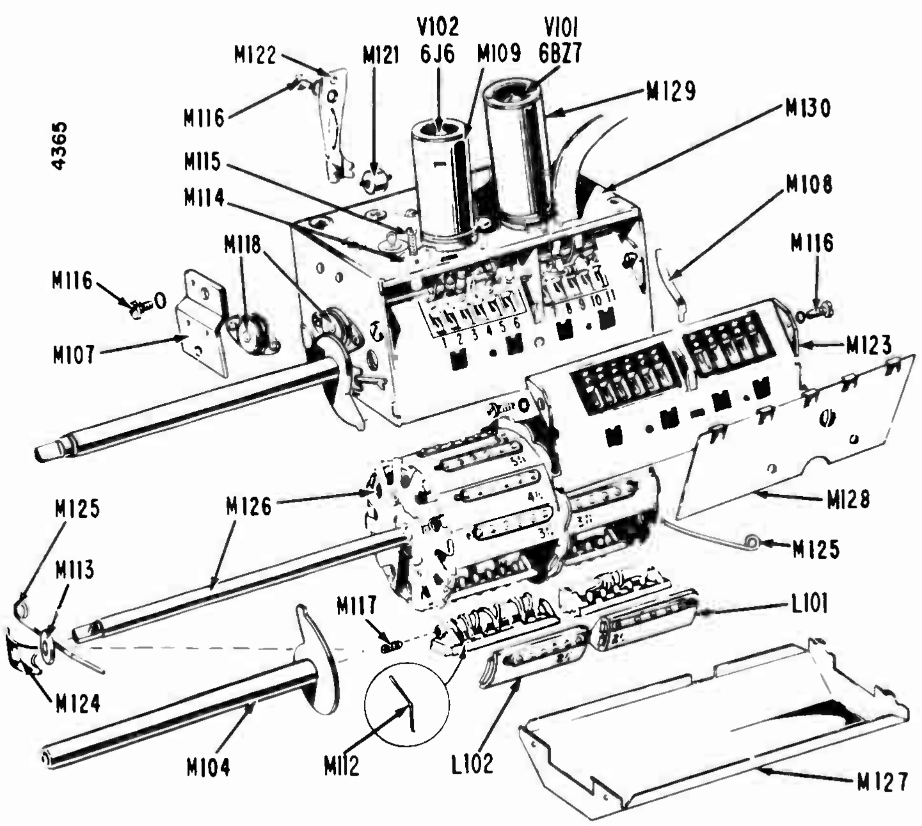

Figure 51. Exploded View of VHF Tuner.

Removing Channel Coils: Insert a screwdriver blade between the coil retainer spring and the turret end plate. Twist the blade away from the turret and lift the end of the coil upward.

Replacing Oscillator Slugs: If VHF oscillator slugs fall into the coil form, remove the channel coil, move the slug retaining spring M112 aside, and tap the coil assembly until the slug slips forward. Set the slug retaining spring into position; it should rest firmly against the slug.

Servicing Contacts of VHF Tuner

A rectangular opening is provided at the side of the chassis for convenience in servicing the stationary contacts of the TV tuner or for making voltage or resistance measurements.

To gain access to the stationary contacts of the TV tuner, it is necessary to remove the mounting screws from the side cover plate on the tuner and unsolder the soldered joint grounding the cover plate to the tuner. Reassemble the cover plate in the same manner.

Adjusting Contact Springs: Should the stationary contacts make poor connections due to insufficient tension, remove several sets of coils from the turret. Rotate the turret to position making the bottom of the contact strip accessible for observation. With a narrow blade screwdriver, adjust the contact spring tension by carefully bending the spring inward until the highest point on the spring extends about 9/64 of an inch above the plastic surface of the contact plate. With correct tension of the contact spring, the spring should clear the flat surface of the turret coil by about 1/64 of an inch.

Cleaning Contacts: Remove several sets of coils from turret and rotate turret to position making contact points of contact plate accessible for cleaning.

Using a small, stiff brush and carbon tetrachloride, clean contact surfaces of stationary contacts.

Remove accumulated dust or grease from stationary contacts and contact plate with a soft canvas cloth dampened with carbon tetrachloride. Accumulated rosin may be removed with a soft cloth dampened with alcohol.

Clean contact surfaces of rotating coils in same manner.

Removing Tuner Turret Assembly

1. Remove retaining bracket M107 in front of the tuner.
2. Remove rotor shaft assembly M104, rotor contact spring M124 and fiber washer M113. For reassembly, note order of parts removal.
3. Remove front and rear turret retaining springs M125 by pressing straight end away from tab on chassis.
4. Using a screwdriver blade at the side of the tuner, press the detent spring M122 and roller M121 away from the turret detent plate.
5. Grasp tuner shaft and slip out of end plate bearings.

Removing Contact Plate Assembly M123

1. Remove turret.
2. Remove the mounting screws at the front and rear of Contact Plate and Bracket Assembly M123.
3. Unsolder both ends of contact plate assembly. Press outward the front and rear tuner chassis end plates.
4. To free contact plate assembly, release the contact plate tabs by pushing them away from the slots in the end plates.
5. Unsolder all connections to contact plate. Unsolder the solder joint holding contact plate to the center partition of the tuner chassis.
6. Reassemble in the same manner.

Replacement of the Ungrounded Stator Plate of Tuning Control

Stator plate M118 (part number 94A45-86) is replaced with wiring lead and trimmer capacitor C110 attached, because it is difficult to solder the wire lead to the silver plated surface on the ceramic stator plate disc.

To replace the stator plate, remove the turret assembly. Remove mounting rivets from stator plate by drilling out or clipping them out with diagonal wire cutters. Remove trimmer screw M115 and locking nut M114 from trimmer capacitor C110. Unsolder wiring lead connecting trimmer to terminal on contact plate.

Assemble the replacement stator plate (M118) by placing the ceramic button over the ⅝" hole in the chassis with the wiring lead extending into the chassis. Place the mounting bracket over the ceramic button and mount securely using #4x3/16" round head machine screws with #4-40x3/16" hex nuts and #4 shake proof lock washers. Mount trimmer capacitor C110 in chassis and solder wire lead to its original terminal on the contact plate making this lead as short as possible. Dress wiring lead from ceramic stator plate to trimmer capacitor C110 so it does not come in contact with the turret drum. After replacement of the stator plate, adjust trimmer capacitor C110 (overall oscillator adjustment).

Tuner Lubrication

In general the lubrication applied to points of wear or friction at time of manufacture should make lubrication seldom, if ever, necessary. However, should tuner lubrication become necessary, it is important that the correct amount and type of lubricant be used.

Using a clean brush, apply a film of switch contact oil (Admiral part number 98A64-1 or Viscosity Oil Co. #7069) to the surfaces of the coil contacts and stationary contact points.

Lubricate bearing surfaces of all other moving parts with Admiral lubricant, part #98A64-2, Viscosity Oil Co. #8857 lubricant, or light vaseline.

Caution: Do not use lubriplate or any similar lubricant containing zinc or cadmium.

VHF Tuner Replacement in Sets Using UHF Tuner

The removal or installation of a replacement VHF tuner in VHF-UHF sets using the All-Channel UHF tuner requires the lowering of the UHF tuner and unsoldering of leads as shown in figure 52.

A step-by-step procedure is given below for removing and installing a replacement VHF tuner in sets using All-Channel UHF tuner A4160. Use figure 49 for location of connection points J, K, M, P and R, and figure 52 for illustration of VHF tuner removal.

To remove the VHF tuner, proceed as follows:

1. Remove all screws mounting the UHF tuner to the chassis. UHF tuner leads need not be disconnected, however, use care so as not to break wire connections or connector lugs on VHF-UHF switch.
2. Place the TV chassis on its side with VHF-UHF tuners nearest the workbench. Place a block under the side of the chassis to avoid damage to the antenna coupling terminals extending through the side of the chassis from the UHF tuner.

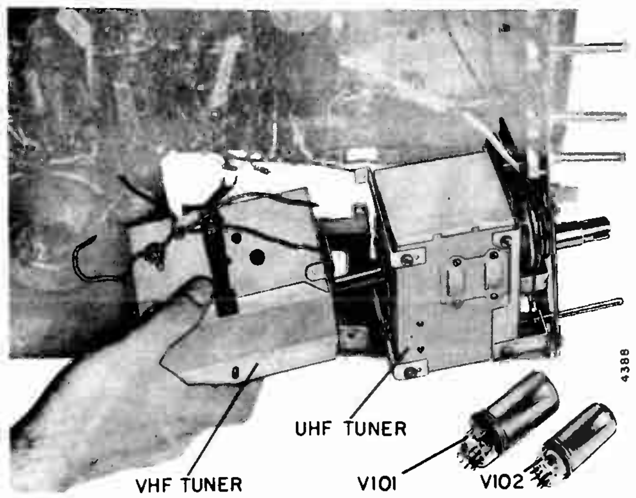

Figure 52. Bottom View of TV Chassis Showing Removal of VHF Tuner.

3. Unsolder VHF tuner leads at connection points J, K, M, P and R.
4. Remove tube shields and tubes from the VHF tuner.
5. Remove all screws mounting the VHF tuner to the chassis.
6. Remove the VHF tuner from the chassis by lowering the UHF tuner and sliding the VHF tuner to the rear of the chassis while lowering it at the same time.

To install a replacement VHF tuner, proceed as follows:

1. Remove tube shields and tubes from the replacement VHF tuner.
2. Apply a slight film of grease or vaseline to VHF tuner shaft.
3. Insert replacement VHF tuner in chassis by sliding the VHF tuner shaft through center of the UHF tuner shaft.
4. Replace VHF and UHF tuner mounting screws. Before tightening the mounting screws, check both tuner shafts to be sure that they operate freely, without binding. It may be necessary to shift tuners sideways or lower either tuner from the chassis by using washers as shims for proper clearance so that tuners operate freely.
5. Solder the VHF tuner leads to connection points J, K, M, P and R.
6. Insert the tubes and tube shields in the VHF tuner.
7. Before operating set, check VHF and UHF tuners to be sure that all mounting screws are tight and all soldered connections are secure. Refer to "Installation and Service Adjustments".

PRODUCTION CHANGES

Production changes coded RUN 2 and higher are given below. The run number is stamped on the rear of the chassis and indicates that the particular chassis has the change described under the run number, as well as all changes made prior to that time (i.e. all lower run numbers).

At the start of production the 23E1Z and 23B1AZ chassis were stamped RUN 1, however RUN 1 of the 23B1AZ chassis includes all the changes listed below through RUN 3. The 23C1AZ and 23F1Z were stamped RUN 4 at the start of production, and the 23E1AZ was stamped RUN 5.

RUN 2 (23E1Z Chassis)

Resistor Change to Improve Horizontal Linearity

See 23E1Z schematic for new circuit, see figure 53 below for original circuit.

R442 changed from 5,600 ohms, 2 watt to 18,000 ohms, 2 watt. R462, 5,600 ohms, 2 watt deleted. R462, 1,200 ohms, 2 watt added across horizontal linearity coil L403.

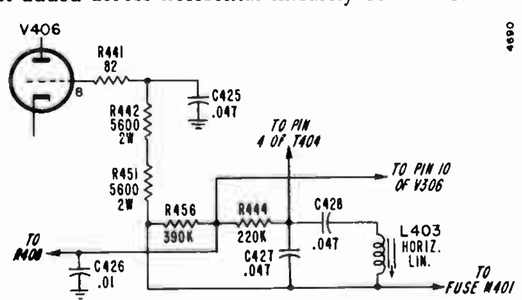

Figure 53. Original Screen Grid Circuit of V406 in 23E1Z Chassis.

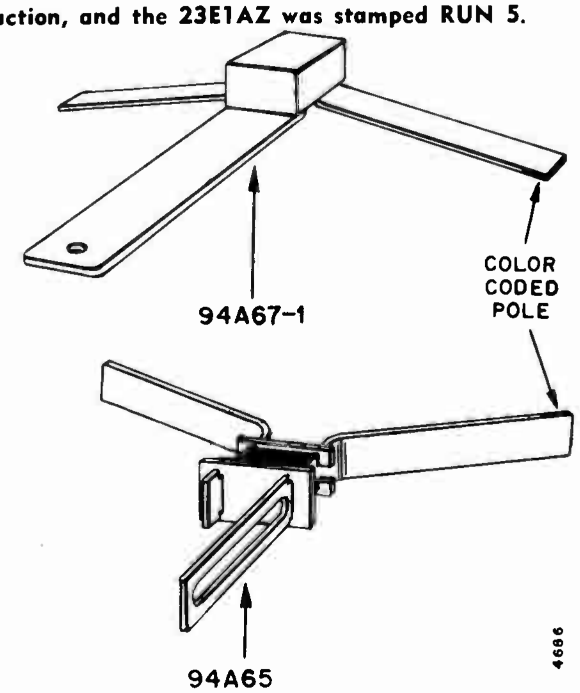

Figure 54. Different Types of Curvature Correcting Magnets.

RUN 3 (23E1Z Chassis, also RUN 1 23B1AZ Chassis)

Magnet Addition to Eliminate Pin-Cushion Effect

Curvature correcting magnets added to top and bottom of deflection yoke housing to eliminate pin-cushion effect at top and bottom of raster. Early production sets used part number 94A65 magnets while part number 94A67-1 magnets are currently being used. 94A67-1 magnets will be supplied as replacements (see figure 54 for illustration of different magnets).

RUN 4 (23B1AZ, 23C1AZ, 23E1Z and 23F1Z Chassis)

Capacitor Change to Improve Horizontal Oscillator Stability When Switching Channels

C419 changed from 470 mmfd. to 330 mmfd.

RUN 5 (23B1AZ, 23E1Z and 23E1AZ Chassis)

Resistor Change to Increase Width

R440 changed from 150 ohms, 2 watt to 120 ohms, 2 watt.

RUN 6 (23B1AZ and 23E1AZ Chassis)

Change to Increase Vertical Stability When Switching Channels

See 23B1AZ schematic on page 51 and 23E1AZ schematic on page 53 for new circuits. See figure 55 at right for original circuit.

R472 changed from 4,700 ohms to 3,300 ohms. R478 22,000 ohms, 2 watt and C445, 20 mfd, filter network added to plate circuit of V401B (½ 6SN7GT).

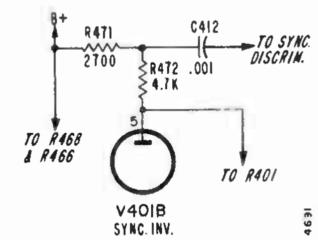

Figure 55. Original Plate Circuit of V401B in 23B1AZ and 23E1AZ Chassis.

RUN 7 (23B1AZ and 23E1AZ Chassis)

Resistor Change to Improve Horizontal Stability at Minimum Contrast

R335 changed from 1,000 ohms to 330 ohms, R331 changed from 180,000 ohms to 270,000 ohms.

ALIGNMENT

GENERAL

Complete alignment consists of the following individual procedures and should be performed in this sequence.

1. IF Amplifier and Trap Alignment.
2. IF Response Curve Check.
3. 4.5 MC Sound IF and Trap Alignment.
4. RF and Mixer Alignment.
5. Over-all RF and IF Response Curve Check.
6. VHF Oscillator Adjustment.

TEST EQUIPMENT

To properly service this receiver, it is recommended that the following test equipment be available.

Important: Many service instruments do not meet the requirements given below. A list of recommended equipment is available from your Admiral distributor.

Oscilloscope

Standard oscilloscope, preferably one with wide band vertical deflection, vertical sensitivity at least .5 volt (RMS) per inch.

Signal (Marker) Generator

4.5 MC frequency.

18 to 30 MC frequency range.

50 to 90 MC frequency range.

170 to 225 MC frequency range.

Must have a calibration crystal for checking dial accuracy.

Sweep Generator

The sweep generator must provide sweep frequencies from 18 to 30 MC, 50 to 90 MC and 170 to 225 MC. The sweep width must be at least 10 MC. The output must be adjustable with at least one-tenth of a volt maximum. The output impedance should be 300 ohms balanced to ground.

A sweep generator not having constant output voltage over the swept range and linear sweep, will produce curves which are widely different from the ideal curves shown in the following pages. If repeated difficulty is encountered in obtaining these curves, the sweep generator should be checked. A simple check is to observe the response curve for a set that is in alignment.

Before suspecting the generator, be sure the alignment instructions in this manual have been followed carefully.

Vacuum Tube Voltmeter

Preferably with low range (3 volt) DC zero center scale and a high voltage probe (30,000 volt range).

ALIGNMENT TOOLS

The following alignment tools are required. They are available from your Admiral distributor under the part numbers listed below:

Metal alignment screwdriver part number 98A30-9.

Non-metallic (fiber) alignment screwdriver (11½" long, ⅛" diameter) part number 98A30-10.

Non-metallic alignment wrench (9" long, for hexagon core IF slugs) part number 98A30-12.

ALIGNMENT HINTS

The following suggestions may be of assistance if difficulty is experienced during the alignment procedure.

Adjacent Channel Trap

If difficulty is experienced in aligning the 27.25 MC and 19.75 MC traps (A7 and A8), using the method outlined in the alignment procedure on page 38 make trap alignment as follows:

1. Connect an oscilloscope between plate of video amplifier V305 and chassis.
2. Make all connections and receiver control settings as instructed in steps 5 and 6 of the alignment procedure

3. Operate the signal generator with AM (audio) modulation turned on. Full generator output may be required. **Note:** If a termination resistor is used in the generator output cable, increased generator output can be obtained by disconnecting the terminating resistor. Connect a condenser (.002 mfd. or larger) in series with the generator high side.
4. Adjust A7 (27.25 MC trap) and A8 (19.75 MC trap) for minimum amplitude of the waveform on the oscilloscope.

IF Instability

When spot frequency aligning the IF amplifiers, the VTVM pointer may swing when the hand is placed too near the IF transformers. When viewing the IF response curve on an oscilloscope, the curve may change shape with hand capacity, especially when aligning A5 (3rd IF transformer T303). To correct either of these conditions, the following alignment hints should be tried:

1. Check the generator output leads to be certain that the unshielded portion (especially the grounded lead) be as short as practicable.
2. Be sure that a decoupling network is used at the video detector output and that the leads on the network are kept as short as possible. (See figure 60).
3. Insulate a tube shield as shown in figure 56.
4. The use of a non-metallic alignment tool, approximately eight inches long, will permit adjustment without coming too near to the IF transformers.

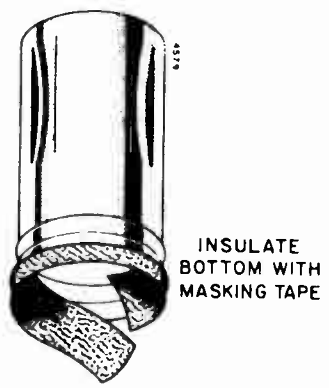

Figure 56. Special Tube Shield for IF Alignment and IF Response Curve Check.

Receiver Overloading When Checking Over-all Response Curve

Due to the inherent high sensitivity of these receivers, it is very easy to cause overloading in the third IF amplifier stage. In some cases, generator leakage alone is enough to produce a response curve on the oscilloscope. To prevent overloading do the following:

1. Be certain that the generator output attenuators are set at a minimum.
2. Some generators have a built-in pad in the output cable to be used when viewing the over-all response curve. Be sure that the pad in the cable is properly connected in the circuit. Refer to the generator instruction manual for details.
3. If a pad is not built in, the 12 db pad shown in figure 57 can be constructed and connected between the generator and the antenna terminals.

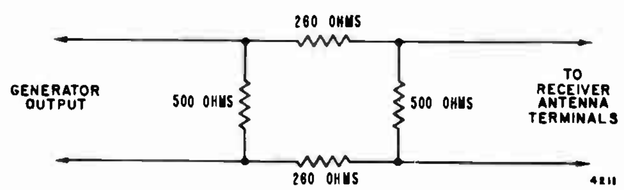

Figure 57. Illustration of 12 db Attenuation Pad for Viewing Over-all RF-IF Response Curve.

IF RESPONSE CURVE CHECK

Receiver Controls and Bias Battery	Sweep Generator	Marker Generator	Oscilloscope	Instructions
Set Channel Selector on channel 12 or an unassigned high channel. Contrast control fully to the left. Connect negative of 4½ volt bias battery to test point "T"; positive to chassis.	Connect high side to top of 6J6 mixer-osc. special tube shield. Connect low side to chassis, see figure 56. Set sweep frequency to 23MC, and sweep width approximately 7MC.	If an external marker generator is used, loosely couple high side to sweep generator lead on top of tube shield, low side to bottom of tube shield. Marker frequencies indicated an IF Response Curve.	Connect to test point "V" through a decoupling filter. See figures 60 and 61. Marker pips on scope will be more distinct if a condenser from 100 mmfd to 1000 mmfd is connected across the oscilloscope input.	Check curve obtained against ideal response curve in fig. 58. Note tolerances on curve. Keep marker and sweep outputs at very minimum to prevent overloading. A reduction in sweep output should reduce response curve amplitude without altering the shape of the response curve. If the curve is not within tolerance or the markers are not in the proper location on the curve, touch-up with IF slugs as instructed below. If curve changes shape with hand capacity, see "Alignment Hints"

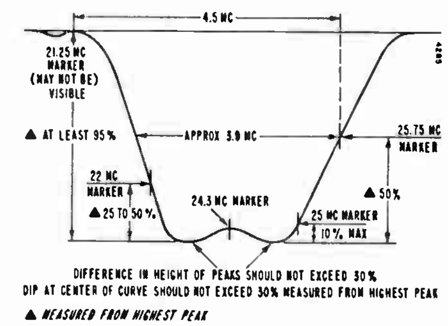

Figure 58. Ideal IF Response Curve.

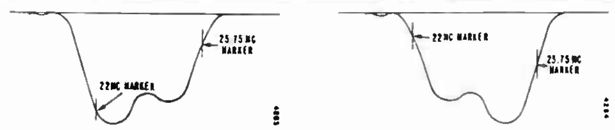

Figure 59. IF Response Curves, Incorrect Shape.

If it is necessary to adjust for approximate equal peaks, carefully adjust slug A5 (23.5 MC). It should not be necessary to turn slug more than one turn in either direction.

If the curve cannot be made to resemble the response curve shown at left, repeat all steps under "IF Amplifier and Trap Alignment" making sure that generator frequencies are accurate and adjustments are carefully made. If a satisfactory curve cannot be obtained after repeating these steps, it may be necessary to change IF amplifier tubes or check for a defective circuit component to be sure that each stage is operating properly.

* Before proceeding, be sure to check the signal generator used in alignment against a crystal calibrator or other frequency standard for absolute frequency calibration required for this operation. Also see "Adjacent Channel Trap"

IF AMPLIFIER AND TRAP ALIGNMENT

- Connect bias battery; negative to test point "T", see figure 61, positive to chassis. A 4½ volt battery is required for steps 1, 2, 3, 4, 7 and 8. A 1½ volt battery is required for steps 5 and 6.
- Disconnect antenna. Connect a jumper wire across the antenna terminals.
- Set Channel Selector to channel 12 or other unassigned high channel, to prevent interference during alignment.
- Set the Contrast control fully to the left (counterclockwise).
- Allow about 15 minutes for receiver and test equipment to warm up.
- Use lowest DC scale on VTVM.

Step	Signal Gen. Freq.	VTVM and Signal Generator Connections	Instructions	Adjust
1	25.3 MC	VTVM high side to test point "V" through a decoupling filter, common to chassis. See figures 60 and 61. Connect generator high side to top of special tube shield for 6J6 (V102); connect low side of generator to bottom part chassis. See figure 56.	Use 4½ volt bias battery. Use lowest DC scale on VTVM. When peaking, keep reducing generator output for VTVM reading of approx. 1 volt or less. Set channel switch to channel 12 or other unassigned high channel.	A1, A2 and A3 for maximum.
2	22.3 MC			A4 for maximum.
3	23.5 MC			A5 for maximum.
4	*21.25 MC			A6 for minimum.
5	*27.25 MC	Connect Generator and VTVM same as in step 1.	Use 1½ volt bias battery. Set channel switch between channels to break channel coil contact; VTVM reading will change when coil contact is broken.	A7 for minimum.
6	*19.75 MC			A8 for minimum.
7	25.3 MC	Connect Generator and VTVM same as in step 1.	Use 4½ volt bias battery. Set channel switch same as in step 1.	Readjust A1, A2 and A3 for maximum.
8	To insure correct IF alignment, make the "IF Response Curve Check" given below.			

4.5 MC SOUND IF AND TRAP ALIGNMENT

a. Connect signal generator high side to pin 1 or pin 2 of V304 (12AT7) through a .01 mfd. condenser, connect low side to chassis.

b. Allow about 15 minutes for receiver and test equipment to warm up.

c. Set Contrast control fully to the left (counterclockwise).

d. Use a ***non-metallic*** alignment tool. If Ratio Det. Transformer (T201) has hollow core slugs, bottom slug adjustment A11 can be made from top of chassis, if you use alignment tool #98A30-12 obtainable from Admiral distributor.

Step	Signal Gen. Freq. (MC)	VTVM Connections	Instructions	Adjust
	When using a signal generator, be sure to check it against a crystal calibrator or other frequency standard for accurate frequency calibration at 4.5 MC. Accuracy required is within one kilocycle. IMPORTANT: If a signal generator and frequency standard are not available, alignment can be made using a TV station signal. Tune in a station and follow steps 1, 2 and 3 below. If necessary use a higher scale on the VTVM.			
1	Set to exactly 4.5 MC.	High side to test point "Y"; common to chassis.	Use lowest DC scale on VTVM.	A9, A10 and A11 for maximum (keep reducing generator output to keep VTVM at approx. 1 volt).
2		High side to test point "Z"; common to chassis.	Use zero center scale on VTVM, if available.	A12 for zero on VTVM (the correct zero point is located between a positive and a negative maximum). If A12 was far off, repeat step 1.
3		High side to test point "Y"; common to chassis.	Connect a 10 mmfd. condenser from plate of V305 to pin 8 of V304 (12AT7). Use lowest DC scale on VTVM.	A13 for minimum.

SIMPLIFIED ALIGNMENT

After becoming familiar with alignment procedure, some servicemen simplify subsequent alignment of sets by merely using the essential alignment data given in figures 61 and 63.

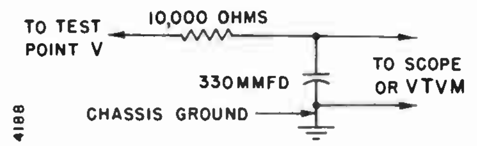

Figure 60. Decoupling Filter.

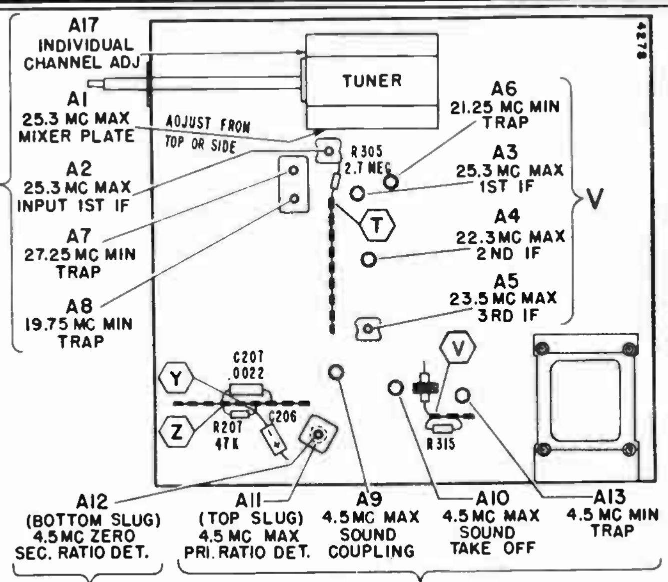

Figure 61. Bottom View of Chassis Showing Test Point Connections and IF Alignment Data.

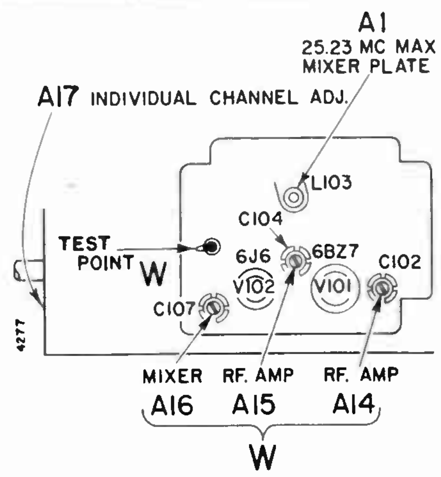

Figure 63. Top of TV Tuner, Showing Adjustment Locations.

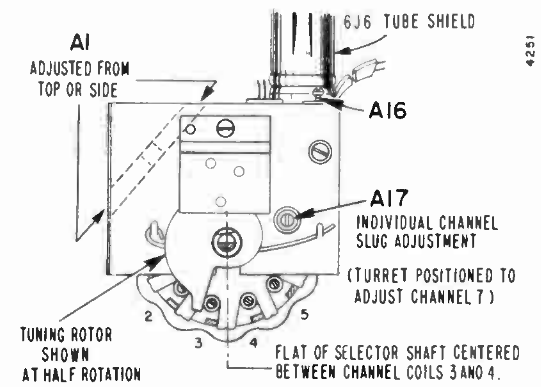

Figure 64. Front View of TV Tuner.

RF AND MIXER ALIGNMENT

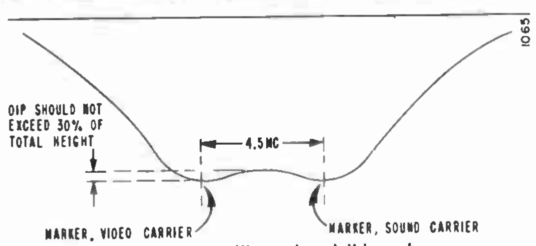
a. Connect negative of 4½ volt bias battery to AGC buss (test point "T"), positive to chassis. If it is difficult to obtain a curve of sufficient amplitude, remove battery and connect a wire jumper from test point "T" to chassis.

b. Connect sweep generator 300 ohm output to antenna terminals. If sweep generator does not have a built-in marker generator, loosely couple a marker generator to the antenna terminals. To avoid distortion of the response curve, keep sweep generator output at a minimum, marker pips just barely visible.

c. Connect oscilloscope through a 10,000 ohm resistor to test point "W" on tuner (figure 63). Keep scope leads away from chassis.

d. Allow about 15 minutes for receiver and test equipment to warm up.

Step	Marker Gen. Freq. (MC)	Sweep Gen. Frequency	Instructions
1	193.25 MC (Video Carrier) 197.75 MC (Sound Carrier)	Sweeping Channel 10. See frequency table below.	Check for RF response curve below. Alternately adjust A15 and A16 (figure 63) as required to obtain equal peak amplitudes and symmetry consistent with proper bandwidth and correct marker location.
2	83.25 MC (Video Carrier) 87.75 MC (Sound Carrier)	Sweeping Channel 6. See frequency table below.	Check for RF response curve below. Adjust A14 as required to obtain curve having maximum amplitude and flat top appearance consistent with proper bandwidth and correct marker location. After completing adjustment, recheck adjustment of step 1.
3	Set the sweep generator to sweep the channel to be checked. Set the marker generator to the corresponding video carrier frequency and sound carrier frequency.		Check each channel operating in the service area for curve shown below. In general, the adjustment performed in steps 1 and 2 are sufficient to give satisfactory response curves on all channels. However, if reasonable alignment is not obtained on a particular channel, (a) check to see that coils have not been intermixed, or (b) try replacing the pair of coils for that particular channel, or (c) repeat step 1 for a weak high channel as a compromise adjustment to favor the particular channel. Repeat step 2 for the weak low channel to favor the particular channel. If a compromise adjustment is made, other channels operating in the service area should be checked to make certain that they have not been appreciably affected.



Full skirt of curve will not be visible unless generator sweep swidth extends beyond 10 MC.

Figure 62. RF Response Curve.

FREQUENCY TABLE

Channel Number	Channel Freq., MC	Video Carrier, MC	Sound Carrier, MC	VHF Osc., MC
2	54-60	55.25	59.75	81
3	60-66	61.25	65.75	87
4	66-72	67.25	71.75	93
5	76-82	77.25	81.75	103
6	82-88	83.25	87.75	109
7	174-180	175.25	179.75	201
8	180-186	181.25	185.75	207
9	186-192	187.25	191.75	213
10	192-198	193.25	197.75	219
11	198-204	199.25	203.75	225
12	204-210	205.25	209.75	231
13	210-216	211.25	215.75	237

OVER-ALL RF AND IF RESPONSE CURVE CHECK

Receiver Controls and Bias Battery	Sweep Generator	Marker Generator	Oscilloscope	Instructions
Contrast control fully to the left. Channel Selector on channel 12 or other unassigned high channel. Connect negative of 4½ volt bias battery to test point "T", positive to chassis.	Connect to antenna terminals. Set generator to sweep channel selected. Keep generator output as low as possible to prevent overloading. See frequency table on previous page.	If an external marker generator is used, loosely couple high side to sweep generator lead. Marker frequencies are shown in frequency table on previous page.	Connect to point "V" through a decoupling filter. See figures 60 and 61.	Compare the response curve obtained against the ideal curve shown in figure 65. If the curve is not within tolerance, touch up the IF slug as instructed below. It should never be necessary to turn slugs more than one turn in either direction. If the curve is satisfactory on the channel checked, all other channels should also be satisfactory. IMPORTANT: When sweep output is reduced, response curve amplitude on scope should also decrease, but curve shape should remain the same. If curve shape changes, reduce sweep output and/or the scope gain until the shape does not change.

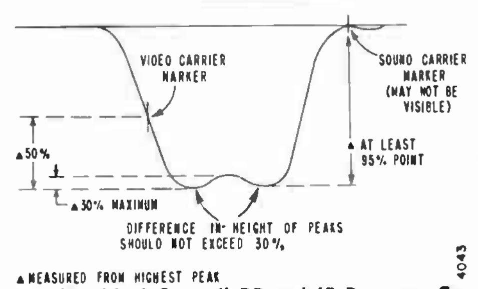


Figure 65. Ideal Over-all RF and IF Response Curve.

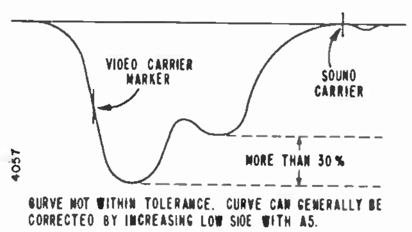
Note that video carrier (marker) on the "Over-all RF-IF Response Curve" will appear on the opposite side of the curve as compared to the "IF Response Curve" figure 8. This is due to action of the mixer tube.



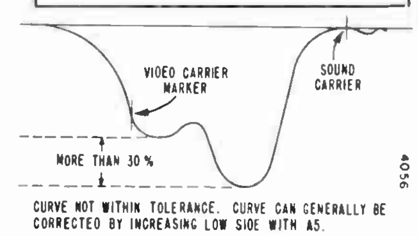


Figure 66. Over-all RF and IF Response Curves, Incorrect Shape.

VHF OSCILLATOR ADJUSTMENT USING SIGNAL GENERATOR

It is always advisable to make VHF oscillator adjustments using a Television Signal as instructed If a Television Signal is not available, VHF oscillator adjustment can be made using a crystal calibrated signal generator. Make adjustments as follows:

Receiver Control Settings	Signal Generator	Instructions
Set Channel Selector for each channel to be adjusted. Set "Tuning" control at half rotation. Turn volume control fully to the right (clockwise).	Connect to antenna terminals. Set generator to exact frequency of HF oscillator. See frequency table on previous page. **Set generator for maximum output.**	Connect a wire jumper from test point "W" on the tuner to test point "Z". See figure 61. Remove the ratio detector tube V202 (6AL5). Carefully adjust the individual oscillator slug A17 until a whistle (beat) is heard in the speaker of the receiver.

Schematic for 23B1AZ VHF Television Chassis.

SCHEMATIC NOTES

(A1), (A2),.....(Y), (Z), etc. indicate alignment points and alignment connections.
Numerical symbols ②, ③, ④, etc., on schematic indicate production changes covered by Run numbers. Run numbers are rubber stamped on the rear of the chassis.

TV VOLTAGE DATA
(Voltages given on schematic)

- **Contrast** control turned fully clockwise. **Channel Selector** set on an unused channel. Other front controls set at approximately half rotation. **Vert. Lin.** and **Height** set at approximately half rotation. **DX Range Finder** control set fully to the left (at "0" position). **Noise Gate** control set fully to the left.
- Antenna disconnected from set with terminals shorted.
- Line voltage 117 volts AC.
- Voltages measured with a vacuum-tube voltmeter between tube socket terminals and chassis, unless otherwise indicated.
  Voltages at V306 measured from top of socket with tube removed.
- Voltages at V101 and V102 (VHF tuner) are measured with tube in socket. Use an adapter or lift tube out of socket just high enough to allow a needle point probe to contact tube pins.
  Voltages at pins 1 and 8 of V101 (6BZ7) must be taken as described or no voltage reading will be obtained.
- Voltages marked with an asterisk (*) will vary widely with control setting.

CAUTION

Pulsed high voltages are present on the caps of V406 and V408 and on the filament terminals and cap of the 1B3GT tube. NO ATTEMPT SHOULD BE MADE TO TAKE MEASUREMENTS FROM THESE POINTS WITHOUT SUITABLE TEST EQUIPMENT.

Picture tube 2nd anode voltage can be measured from the 2nd anode connector and should be taken only with a high voltage instrument such as a kilovoltmeter or a vacuum-tube voltmeter with a high voltage probe. 2nd anode voltage is approximately 19 KV. Proper filament voltage check of the 1B3GT tube may be made by observing filament brilliancy as compared with that obtained with a 1.5 volt dry cell battery.

WAVEFORM DATA
(Waveforms given on schematic)

Waveform taken with **Contrast** control set fully to the right, all other controls set for normal picture (in sync). **DX Range Finder** control set fully to the left (at "0" position). **Warning:** Incorrect adjustment of the **DX Range Finder** control will cause waveform distortion. **Noise Gate** control set fully to the left.

Waveforms at video and sync stages obtained with transmitted signal input to receiver.

The oscilloscope sweep is adjusted for 30 cycles (which is one-half of the vertical frequency) or for 7875 cycles (which is one-half of the horizontal frequency) so that two pulses appear on the screen.

The peak-to-peak voltage readings shown are subject to some variations due to response of the oscilloscope and parts tolerances.

CAUTION

Pulsed high voltage is present on the caps of V406, V407 and V408. Do not make direct connection to these points with ordinary test equipment. Waveform and peak-to-peak voltage taken at cap of V408 using an oscilloscope with a capacitive voltage divider probe. Waveform at the cap of V408 can be taken by clipping or twisting the lead from the oscilloscope high side over the insulation on the cap lead. When taking the waveform this way, the shape of waveform will be the same but the peak-to-peak voltage will be much lower, depending upon the degree of coupling.

WAVEFORM DATA
(Waveforms given on schematic)

Waveform taken with **Contrast** control set fully to the right, all other controls set for normal picture (in sync). **DX Range Finder** control set fully to the left (at "0" position). **Warning:** incorrect adjustment of the **DX Range Finder** control will cause waveform distortion.

Waveforms at video and sync stages obtained with transmitted signal input to receiver.

The oscilloscope sweep is adjusted for 30 cycles (which is one-half of the vertical frequency), or for 7875 cycles (which is one-half of the horizontal frequency) so that two pulses appear on the screen.

The peak-to-peak voltage readings shown are subject to some variations due to response of the oscilloscope and parts tolerances.

CAUTION

Pulsed high voltage is present on the caps of V406, V407 and V408. Do not make direct connection to these points with ordinary test equipment. Waveform and peak-to-peak voltage taken at cap of V408 using an oscilloscope with a capacitive voltage divider probe. Waveform at the cap of V408 can be taken by clipping or twisting the lead from the oscilloscope high side over the insulation on the cap lead. When taking the waveform this way, the shape of waveform will be the same but the peak-to-peak voltage will be much lower, depending upon the degree of coupling.

TV VOLTAGE DATA
(Voltages given on schematic)

- **Contrast** control turned fully clockwise. **Channel Selector** set on an unused channel. Other front controls set at approximately half rotation. **Vert. Lin.** and **Height** set at approximately half rotation. **DX Range Finder** control set fully to the left (at "0" position).
- Antenna disconnected from set with terminals shorted.
- Line voltage 117 volts AC.
- Voltages measured with a vacuum-tube voltmeter between tube socket terminals and chassis, unless otherwise indicated.
  Voltages at V306 measured from top of socket with tube removed.
- Voltages at V101 and V102 (VHF tuner) are measured with tube in socket. Use an adapter or lift tube out of socket just high enough to allow a needle point probe to contact tube pins.
  In tuners using a 6BZ7 tube, voltages taken at pins 1 and 8 must be taken as described or no voltage reading will be obtained.
- Voltages marked with an asterisk (*) will vary widely with control setting.

CAUTION

Pulsed high voltages are present on the caps of V406 and V408 and on the filament terminals and cap of the 1B3GT tube. NO ATTEMPT SHOULD BE MADE TO TAKE MEASUREMENTS FROM THESE POINTS WITHOUT SUITABLE TEST EQUIPMENT.

Picture tube 2nd anode voltage can be measured from the 2nd anode connector and should be taken only with a high voltage instrument such as a kilovoltmeter or a vacuum-tube voltmeter with a high voltage probe. 2nd anode voltage is approximately 19 KV. Proper filament voltage check of the 1B3GT tube may be made b, observing filament brilliancy as compared with that obtained with a 1.5 volt dry cell battery.

Schematic for 23E1AZ VHF Television Chassis.

SCHEMATIC NOTES

Numerical symbols ②, ③, ④, etc., on schematic indicate production changes covered by Run numbers. Run numbers are rubber stamped on the rear of the chassis.

PARTS LIST

Electrical components are numbered in different series according to their location on the schematic. Numbers 1-99 indicate components in the UHF tuner; 101-199, VHF tuner; 201-299, sound circuits; 301-399, intercarrier IF and video circuits; 401-499, sync and deflection circuits; 501-599, power supply circuits. Order replacements from your Admiral distributor by part number and description.

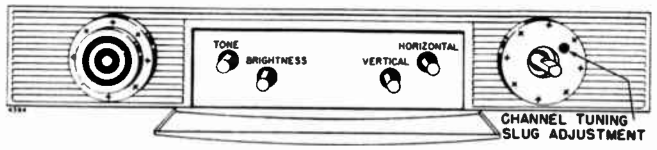

Figure 2. Control Panel in 20A2 and 20A2Z; CHANNEL Knob Removed.

SPECIFICATIONS

Picture Tube

Direct View Electromagnetic. See Model Identification Chart for different picture tubes used.

Operating Voltage

110-120 volts. 60 cycles, AC.

Wattage

195 watts for all models.

Input Impedance and Transmission Line

300-ohm balanced (between antenna terminals).

Note that 72 ohm coaxial cable may be used by connecting the outer conductor to the chassis and the inner conductor to either antenna terminal. In weak signal areas, the use of coaxial cable should be avoided.

Antenna

All models equipped with a built-in TV antenna. TV-Radio models equipped with a built-in radio antenna.

Intermediate Frequencies

Video 25.75 MC. Sound 21.25 MC.
Intercarrier Sound 4.5 MC.
Radio 455 KC. (TV-Radio models).

Fuse Location

The horizontal output circuit is fused with a 3/8 amp., 250 volt fuse, part number 84A4-3. The fuse is located at the rear of the high voltage compartment.

Record Changer

The model RC600 record changer is used in combination models. The changer model number is on the top rear of the changer pan and also on the changer model label on the underside of the changer.

For complete service data on the RC600 record changer, refer to Service Manual No. S454.

TUBE COMPLEMENT

V101	6BZ7	RF Amplifier
V102	6J6	Oscillator and Mixer

*V701	6BE6	Converter (AM Radio)
*V702	6BA6	IF Amplifier (AM Radio)

† 6Y6G tube used in combination sets. 6AS5 tube used in TV only sets.

§ See "Model Identification Chart" on front page for different picture tubes used.

* V701 and V702 used in combination sets only.

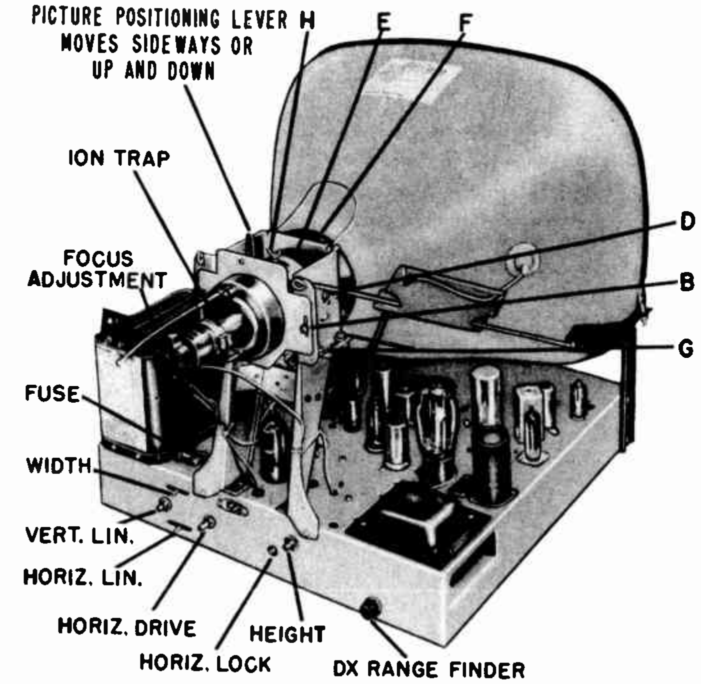

Figure 3. 20A2 and 20A2Z Chassis View Showing Rear Adjustment Locations.

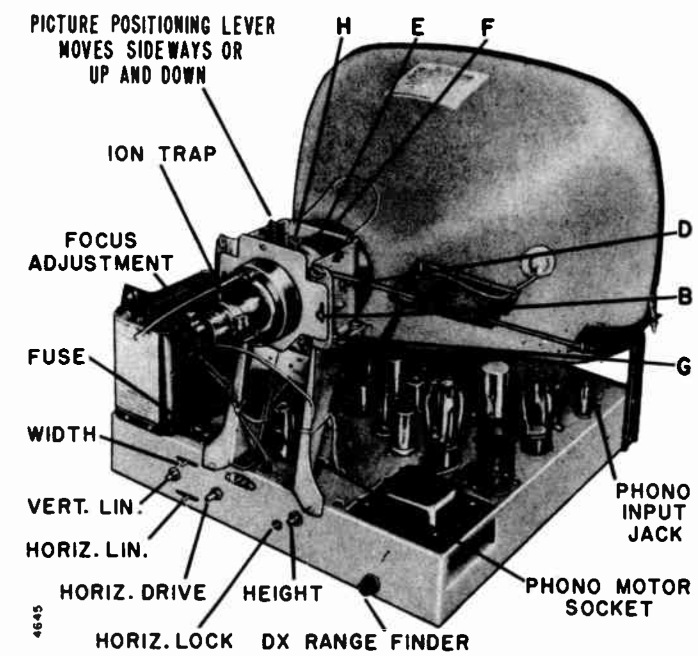

Figure 4. 20D2 Chassis View Showing Rear Adjustment Locations.

HORIZONTAL OSCILLATOR & DRIVE ADJ.

If the **Horizontal Drive** control (on rear of set) is not properly adjusted, it may be difficult to obtain sufficient picture width and brightness.

When switching channels, the **Horizontal** control (on front panel) should keep the picture in horizontal sync through at least three fourths of its range. If the picture does not remain in horizontal sync, then adjust the rear panel controls as follows:

a. Allow the receiver to warm up for a few minutes. Tune in a station, set the **Brightness** control at a lower than average setting. Turn **Contrast** control fully to the left. Important: Before proceeding, be sure that the **DX Range Finder** control (AGC) is adjusted according to the instructions given in this manual

b. Turn the **Horizontal** control (front panel) completely to the left. Turn the **Horiz. Drive** control fully to the right.

c. Turn the **Horiz. Lock** adjustment to the right until the picture falls out of sync. If the picture cannot be made to fall out of sync, momentarily interrupt the signal by switching the **Channel** control off channel and then back on.

d. With the picture out of sync, turn the **Horiz. Lock** adjustment slowly to the left until the picture just falls in sync.

e. Turn the **Channel** control to an unused channel. If a white vertical line(s) appears near the center of the screen, slowly turn the **Horiz. Drive** control to the left until the line(s) just disappears.

f. If, in step "e", the **Horiz. Drive** control required readjustment, tune in a station and repeat steps "c" and "d" to be sure of proper Horizontal Oscillator adjustment.

g. Adjustment should now be satisfactory. However, check adjustment by slowly rotating the **Horizontal** control in either direction while interrupting the television signal by switching the **Channel** control off channel and then back on. The picture should automatically fall in sync through at least half of the range of the **Horizontal** control. If necessary, repeat the above step.

h. Do not use the **Horiz. Drive** control to obtain correct width or linearity. If necessary, make Width and Horizontal Linearity adjustments.

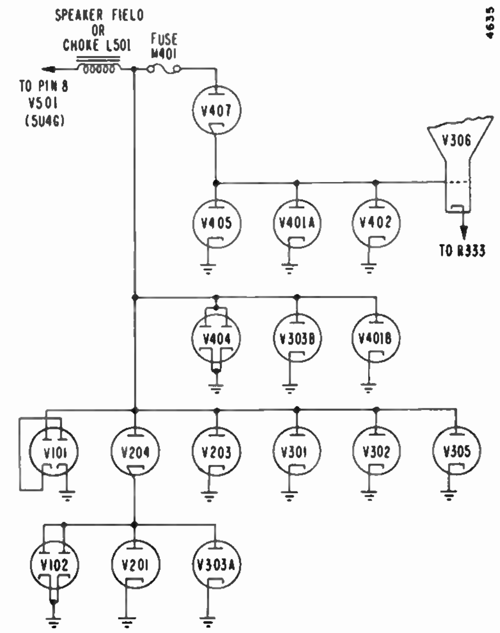

Figure 6. Simplified Diagram Showing B+ Distribution in 20A2 and 20A2Z Chassis.

TELEVISION ALIGNMENT PROCEDURE

GENERAL

Complete alignment consists of the following individual procedures and should be performed in this sequence.

a. IF Amplifier and Trap Alignment.
b. IF Response Curve Check.
c. 4.5 MC Sound IF and Trap Alignment.
d. RF and Mixer Alignment.
e. Over-all RF and IF Response Curve Check.
f. HF Oscillator Adjustment.

TEST EQUIPMENT

To properly service this receiver, it is recommended that the following test equipment be available.

IMPORTANT: Many service instruments do not meet the requirements given below. A list of recommended equipment is available from Admiral distributor.

Oscilloscope

Standard oscilloscope, preferably one with a wide band vertical deflection, vertical sensitivity at least .5 volt (RMS) per inch.

Signal (Marker) Generator

4.5 MC frequency.
18 to 30 MC frequency range.
50 to 90 MC frequency range.
170 to 225 MC frequency range.
Must have a built-in calibration crystal for checking dial accuracy.

Sweep Generator

Sweep generator must provide sweep frequencies from

18 to 30 MC range:	with at least 10 MC-sweep width.
50 to 90 MC range:	
170 to 225 MC range:	

Output: adjustable; at least one-tenth volt maximum.
Output impedance: 300 ohms balanced to ground.

A sweep generator not having constant output voltage over the swept range and linear sweep, will produce curves which are widely different from the ideal curves shown in the following pages. If repeated difficulty is encountered in obtaining these curves, the sweep generator should be checked. A simple check is to observe the response curve for a set that is in alignment.

Before suspecting the generator, be sure the alignment instructions in this manual have been followed carefully.

Vacuum-Tube Voltmeter

Preferably with low range (3 volt) DC zero center scale and a high voltage probe (30,000 volt range).

ALIGNMENT TOOLS

The following alignment tools are required. They can be obtained from the Admiral distributor under the part numbers listed below:

Metal alignment screwdriver, part number 98A30-9. ***Non-metallic*** (fiber) alignment screwdriver (11½" long, ⅛" diameter), part number 98A30-10.

Non-metallic alignment wrench (9" long, for hexagon core IF slugs), part number 98A30-12.

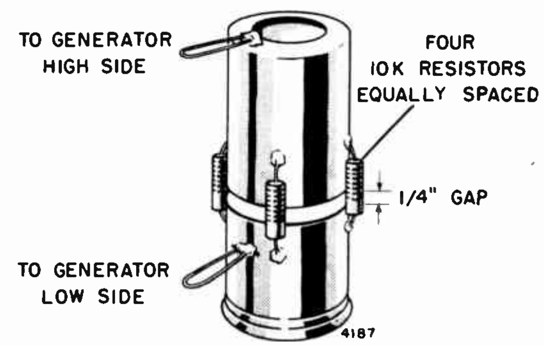

Figure 7. Special Tube Shield for IF Alignment and IF Response Curve Check.

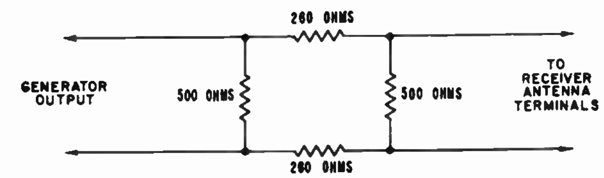

Figure 8. Illustration of 12 db Attenuation Pad for Viewing Over-all RF-IF Response Curve.

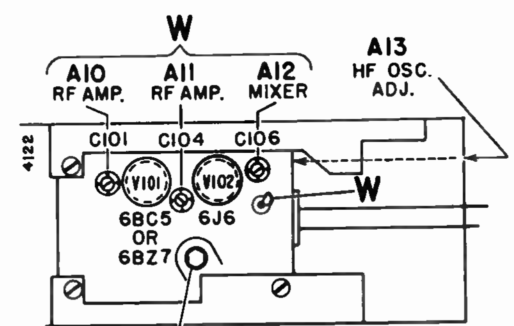

A5 23.1 MC MAX. MIXER PLATE

Figure 9. Top View of TV Tuner Showing Adjustment Locations.

IMPORTANT ALIGNMENT HINTS

The following suggestions should be performed if difficulty is experienced during the alignment procedure.

1. IF CIRCUIT INSTABILITY: When spot frequency aligning the IF amplifiers, the VTVM pointer may swing when the hand is placed too near the IF transformers. When viewing the IF response curve on an oscilloscope, the curve may change shape with hand capacity, especially when aligning A2 (3rd IF transformer T303). To correct either of these conditions, the following alignment hints should be tried:

(a) Check the generator output leads to be certain that the unshielded portion (especially the grounded lead) be as short as practicable.

(b) Be sure that a decoupling network is used at the video detector output and that the leads on the network are kept as short as possible (see figure 10).

(c) Construct a special tube shield as shown in figure 7. This is made from an ordinary tube shield and four 10,000 ohm resistors. Keep the spacing between the two halves of the shield at a minimum (1/8 inch).

(d) The use of a *non-metallic* alignment tool, approximately eight inches long (part number 98A30-12), will permit adjustment without coming too near to the transformers.

2. RECEIVER OVERLOADING WHEN CHECKING THE OVER-ALL RESPONSE CURVE: Due to the inherent high sensitivity of these receivers, it is very easy to cause overloading in the third IF amplifier stage. In some cases, generator leakage alone is enough to produce a response curve on the oscilloscope. To prevent overloading, do the following:

(a) Be certain that the generator output attenuators are set at a minimum.

(b) Some generators have a built-in pad in the output table to be used when viewing the over-all response curve. Be sure that the pad in the cable is properly connected in the circuit. Refer to the generator instruction manual for details.

(c) If a pad is not built in, the 12 db pad shown below in figure 8 can be constructed and connected between the generator and the antenna terminals.

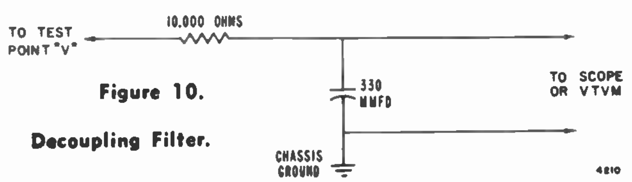

Figure 10.

Decoupling Filter.

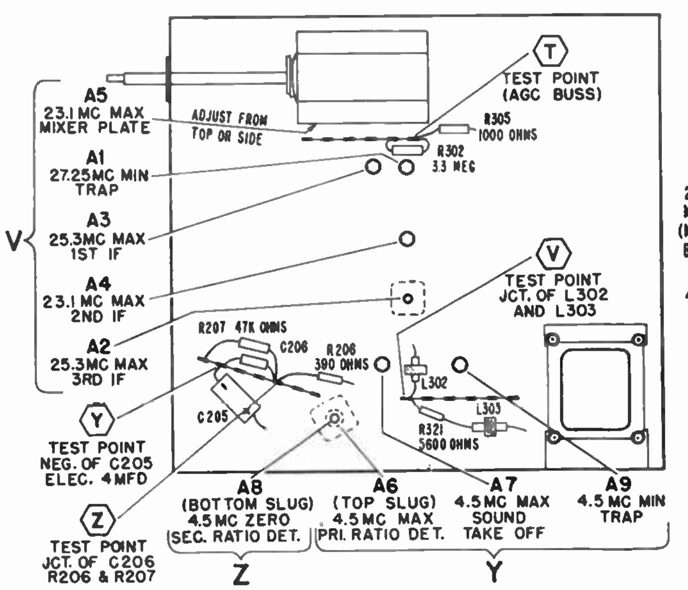

Figure 11. Bottom View of Chassis Showing Test Point Connections and IF Alignment Data.

IF AMPLIFIER AND TRAP ALIGNMENT

- Connect bias battery; negative to test point "T", see figure 11, positive to chassis. A 4½ volt battery is required for all steps below.
- Disconnect antenna. Connect a jumper wire across the antenna terminals.
- Set Channel Selector to channel 12 or other unassigned high channel, to prevent interference during alignment.
- Set the Contrast control fully to the left (counterclockwise).
- Allow about 15 minutes for receiver and test equipment to warm up.
- Use lowest DC scale on VTVM.

Step	Signal Gen. Freq.	VTVM and Signal Generator Connections	Instructions	Adjust
1	*27.25 MC	VTVM high side to test point "V" through a decoupling filter; see figs. 10 and 11, common to chassis. Generator high side to 6J6 (V102) special tube shield. Connect low side to bottom part of the tube shield, see figure 7.	Connect a 4½ volt bias battery to test point "T". Use lowest DC scale on VTVM. When peaking, keep reducing generator output for VTVM reading of approx. 1 volt or less. If unstable, refer to section 1 of the "Alignment Hints" on page 8.	A1 for minimum.
2	25.3 MC			A2 and A3 for maximum.
3	23.1 MC			A4 and A5 for maximum.
4	*27.25 MC			Repeat step 1 above.
5	To insure correct IF alignment, make the "IF Response Curve Check" given below.			

Before proceeding, be sure to check the signal generator used in alignment against a crystal calibrator or other frequency standard for absolute frequency calibration required for this operation.

IF RESPONSE CURVE CHECK

(Using sweep generator and oscilloscope)

Receiver Controls and Bias Battery	Sweep Generator	Marker Generator	Oscilloscope	Instructions
Set Channel Selector on channel 12 or an unassigned high channel. Contrast control fully to the left. Connect negative of 4½ volt bias battery to test point "T"; positive to chassis.	Connect high side to 6J6 mixer-osc. special tube shield, see fig. 7. Connect low side to bottom part of tube shield. Set sweep frequency to 23MC, and sweep width approximately 7MC.	If an external marker generator is used, loosely couple high side to sweep generator lead on tube shield, low side to chassis. Marker frequencies indicated on IF Response Curve.	Connect to test point "V" through a decoupling filter, see figs. 10 and 11. Marker pips on scope will be more distinct if a capacitor from 100 mmfd. to 1000 mmfd. is connected across the oscilloscope input.	Check curve obtained against ideal response curve in fig. 12. Note tolerances on curve. Keep marker and sweep outputs at very minimum to prevent overloading. A reduction in sweep output should reduce response curve amplitude without altering the shape of the response curve. If the curve is not within tolerance or the markers are not in the proper location on the curve, touchup with IF slugs as instructed below. **Important:** If curve changes shape with hand capacity, see section 1 of "Alignment Hints" on page 8.

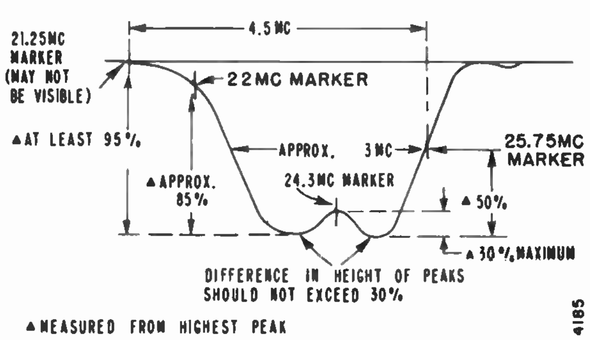

Figure 12. Ideal IF Response Curve.

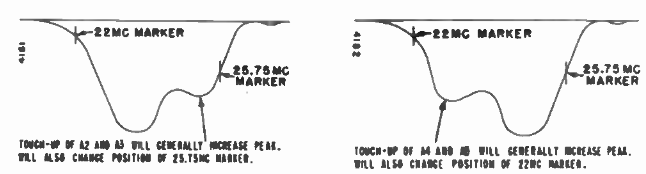

Figure 13. IF Response Curves, Incorrect Shape.

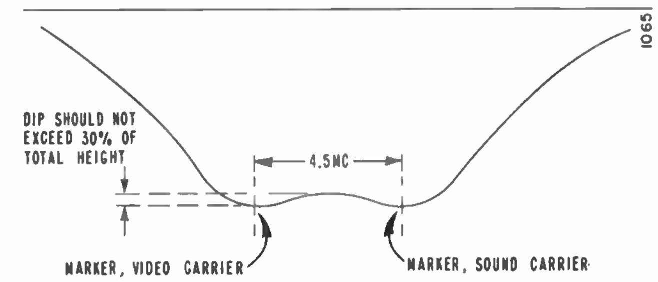
If it is necessary to adjust for approximate equal peaks and marker location, carefully adjust alignment slugs as instructed under the above figures. It should not be necessary to turn the slugs more than one turn in either direction.

If the curve cannot be made to resemble the response curve shown at left, repeat all steps under "IF Amplifier and Trap Alignment" making sure that generator frequencies are accurate and adjustments are carefully made. If a satisfactory curve cannot be obtained after repeating these steps, it may be necessary to change IF amplifier tubes or check for a defective circuit component to be sure that each stage is operating properly.



Full skirt of curve will not be visible unless generator sweep width extends beyond 10 MC.
Figure 14. RF Response Curve.

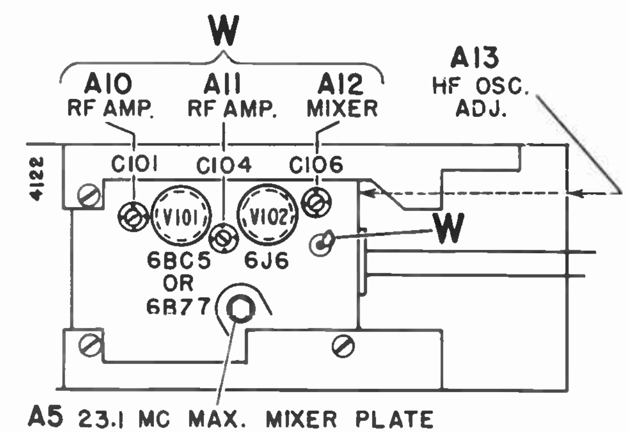


Figure 15. Top of TV Tuner, Showing Adjustment Location.

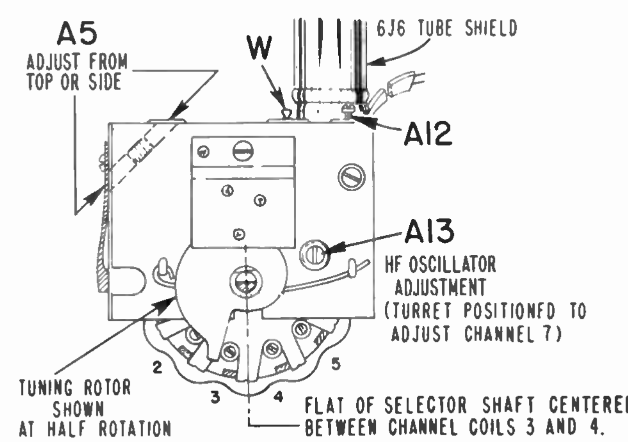

Figure 16. Front View of TV Tuner.

4.5 MC SOUND IF AND TRAP ALIGNMENT

See page 6 for touch-up of ratio detector using television signal without test equipment.

a. Connect signal generator high side to pin 2 of V304 (6AL5) through a .01 mfd. capacitor, connect low side to chassis.

b. Allow about 15 minutes for receiver and test equipment to warm up.

c. Set Contrast control fully to the left (counterclockwise).

d. Use a ***non-metallic*** alignment tool. If Ratio Det. Transformer (T201) has hollow core slugs, bottom slug adjustment A8 can be made from top of chassis, if you use alignment tool, part number 98A30-12 obtainable from Admiral distributor.

Step	Signal Gen. Freq. (MC)	VTVM Connections	Instructions	Adjust
	When using a signal generator, be sure to check it against a crystal calibrator or other frequency standard for accurate frequency calibration at 4.5 MC. Accuracy required is within one kilocycle. IMPORTANT: If a signal generator and frequency standard are not available, alignment can be made using a TV station signal. Tune in a station and follow steps 1, 2 and 3 below. If necessary use a higher scale on the VTVM.			
1	Set to exactly 4.5 MC	High side to test point "Y"; common to chassis.	Use lowest DC scale on VTVM.	A6 and A7 for maximum (keep reducing generator output to keep VTVM at approx. 1 volt).
2		High side to test point "Z"; common to chassis.	Use zero center scale on VTVM, if available.	A8 for zero on VTVM (the correct zero point is located between a positive and a negative maximum). If A6 was far off, repeat step 1.
3		High side to test point "Y"; common to chassis.	Connect a 10 mmfd. capacitor from pin 7 of V305 (12BY7) to pin 7 of V201 (6AU6). Use lowest DC scale on VTVM.	A9 for minimum.

RF AND MIXER ALIGNMENT

a. Connect negative of 4½ volt bias battery to AGC buss (test point "T"), positive to chassis. If it is difficult to obtain a curve of sufficient amplitude, remove battery and connect a wire jumper from test point "T" to chassis.

b. Connect sweep generator (with 300 ohm output) to antenna terminals. If sweep generator does not have a built-in marker generator, loosely couple a marker generator to the antenna terminals. To avoid distortion of the response curve, keep sweep generator output at a minimum, marker pips just barely visible.

c. Connect oscilloscope through a 10,000 ohm resistor to test point "W" on tuner (figure 15). Keep scope leads away from chassis.

d. Allow about 15 minutes for receiver and test equipment to warm up.

Step	Marker Gen. Freq. (MC)	Sweep Gen. Frequency	Instructions
1	193.25 MC (Video Carrier) 197.75 MC (Sound Carrier)	Sweeping channel 10. See frequency table.	Alternately adjust A11 and A12 (figure 15) as required to obtain equal peak amplitudes and symmetry, consistent with flat top appearance, proper band width and correct marker location, see figure 14.
2	83.25 MC (Video Carrier) 87.75 MC (Sound Carrier)	Sweeping channel 6. See frequency table.	Adjust A10 as required to obtain curve having maximum amplitude and flat top appearance consistent with proper band width and correct marker location, see figure 14. After completing adjustment, recheck adjustment of step 1.
3	Set the sweep generator to sweep the channel to be checked. Set the marker generator for the corresponding video carrier frequency and sound carrier frequency.		Check each channel operating in the service area for curve shown below. In general, the adjustment performed in steps 1 and 2 are sufficient to give satisfactory response curves on all channels. However, if reasonable alignment is not obtained on a particular channel, (a) check to see that coils have not been intermixed, or (b) try replacing the pair of coils for that particular channel, or (c) repeat step 1 for a weak high channel as a compromise adjustment to favor the particular channel. Repeat step 2 for the weak low channel to favor the particular low channel. If a compromise adjustment is made, other channels operating in the service area should be checked to make certain that they have not been appreciably affected.

OVER-ALL RF AND IF RESPONSE CURVE CHECK

(Using sweep generator and oscilloscope)

Receiver Controls and Bias Battery	Sweep Generator	Marker Generator	Oscilloscope	Instructions
Contrast control fully to the left. Channel Selector on channel 10 or other unassigned high channel. Connect negative of 4½ volt bias battery to test point "T", positive to chassis.	Connect to antenna terminals. Set generator to sweep channel selected. See frequency table on page 11. Keep generator output as low as possible, to prevent overloading. See section 2 of "Alignment Hints" on page 8.	If an external marker generator is used, loosely couple high side to sweep generator lead. Marker frequencies are shown in frequency table on page 11.	Connect to point "V" through a decoupling filter, see figs. 10 and 11.	Compare the response curve obtained against the ideal curve shown in figure 17. If the curve is not within tolerance, touch up the IF slug as instructed below. It should never be necessary to turn in slugs more than one turn in either direction. If the curve is satisfactory on the channel checked, all other channels should also be satisfactory. IMPORTANT: When sweep output is reduced, response curve amplitude on scope should also decrease, but curve shape should remain the same. If curve shape changes, reduce sweep output and/or the scope gain until the shape does not change. See section 2 of "Alignment Hints", on page 8.

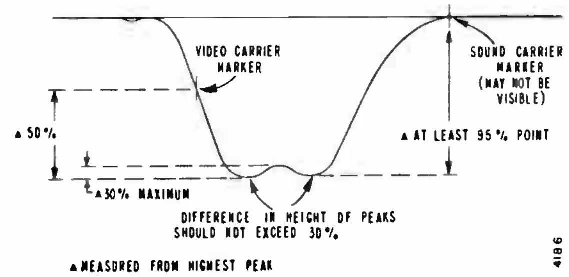

Figure 17. Ideal Over-all RF and IF Response Curve.

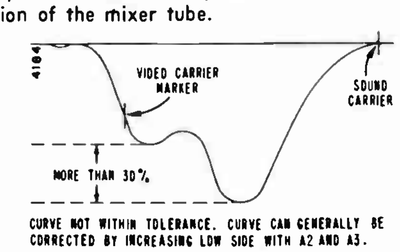
Note that video carrier (marker) on the "Over-all RF-IF Response Curve" will appear on the opposite side of the curve as compared to the "IF Response Curve" figure 12. This is due to action of the mixer tube.



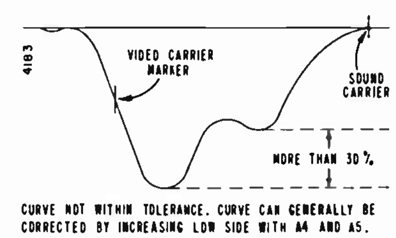


Figure 18. Over-all RF and IF Response Curves, Incorrect Shape.

HF OSCILLATOR ADJUSTMENT

(Using a signal generator)

It is always advisable to make HF oscillator adjustments using a Television Signal as instructed on page 3. If a Television Signal is not available, HF oscillator adjustment can be made using a crystal calibrated signal generator. Make adjustments as follows:

Receiver Control Settings	Signal Generator	Instructions
Set Channel selector for each channel to be adjusted. Set "Tuning" control at half rotation. Turn Volume control fully to the right (clockwise).	Connect to antenna terminals. Set generator to exact frequency of HF oscillator. See frequency table on page 11. **Set generator for maximum output.**	Connect a wire jumper from test point "W" on the tuner to test point "Z". See figure 11. Remove the ratio detector tube V202 (6AL5). Carefully adjust the oscillator slug A13 on each channel until a whistle (beat) is heard in the speaker of the receiver.

DIAL STRINGING

Dial stringing for the gang tuning control is shown below.

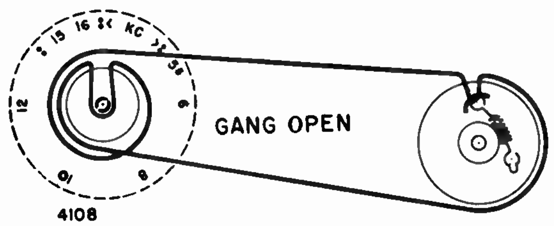

Figure 19. Dial Stringing for 20D2 Chassis.

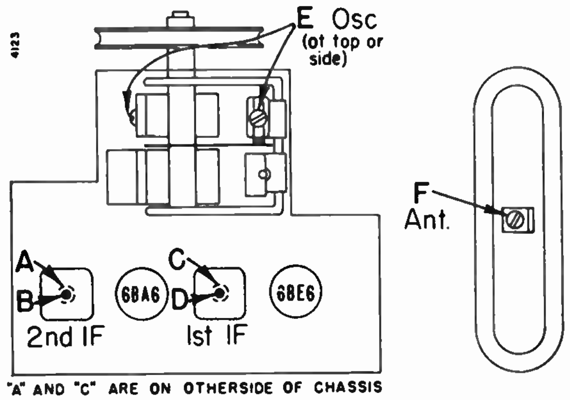

Figure 20. Radio Trimmer Locations.

WAVEFORM DATA

(Waveforms given on schematic)

Waveforms taken with **Contrast** control set fully to the right, all other controls set for normal picture (in sync). **DX Range Finder** control set fully to the left (at "0" position). Warning: Incorrect adjustment of the **DX Range Finder** control will cause waveform distortion.

Waveforms at video and sync stages obtained with transmitted signal input to receiver.

The oscilloscope sweep is adjusted for 30 cycles (which is one-half of the vertical frequency), or for 7875 cycles (which is one-half of the horizontal frequency) so that two pulses appear on the screen.

The peak-to-peak voltage readings shown are subject to some variations due to response of the oscilloscope and parts tolerances.

Waveform at V407 can also be taken by clipping or twisting the lead from the oscilloscope high side over the insulation on the lead connecting to pin 3. When taking the waveform this way, the shape of waveform will be the same but the peak-to-peak voltage will be much lower, depending upon the degree of coupling.

SCHEMATIC NOTES

Run numbers are rubber stamped at the rear of the chassis.

(A1), (A2),......(Y), (Z), etc. indicate alignment points and alignment connections.

IMPORTANT: Before making waveform and voltage measurements, see instructions on this page.

NOTE: To read schematic for 20A2 and 20A2Z chassis, use sections in heavy solid lines; to read schematic for 20D2 chassis, use sections in heavy dotted lines and connect appropriate points indicated by dots coded

B1 B2 etc.

RADIO ALIGNMENT PROCEDURE

- Connect output meter across speaker voice coil.
- Turn receiver Volume control fully on.
- Function switch in "Radio" position.
- Use lowest output setting of signal generator that gives a satisfactory reading on meter.
- Use a ***non-metallic*** alignment tool for IF adjustments.
- Repeat adjustments to insure good results.

Step	Connect Signal Generator	Dummy Antenna Between Radio and Signal Generator	Signal Generator Frequency	Receiver Dial Setting	Adj. Trimmers in Following Order to Max.
1	Gang capacitor antenna stator	.1 MFD	455 KC	Tuning gang wide open	*A-B (2nd IF) *C-D (1st IF)
2	"	"	1620 KC	"	E (oscillator)
3	Place generator lead close to loop of set to obtain adequate signal. No actual connection (signal by radiation).		1400 KC	Tune in signal	§F (antenna)

* Adjustments A and C made from underside of chassis. See figure 20 for trimmer locations.
§ AM antenna trimmer may not peak if antenna leads are not properly routed or separated.

TV VOLTAGE DATA

(Voltages given on schematic)

- **Contrast** control turned fully clockwise. **Channel Selector** set on an unused channel. Other front controls set at approximately half rotation. **Vert. Lin.** and **Height** set at approximately half rotation. **DX Range Finder** control set fully to the left (at "0" position).
- Antenna disconnected from set with terminals shorted.
- Line voltage 117 volts AC.
- Voltages measured with a vacuum-tube voltmeter between tube socket terminals and chassis, unless otherwise indicated.
- Voltages at V101 and V102 (VHF Tuner) are measured with tube in socket. Use an adapter or lift tube out of socket just high enough to allow a needle point probe to contact tube pins. Voltages at pins 1 and 8 of V101 (6BZ7) must be taken as described above or no voltage reading will be obtained.
- Voltages at V306 measured from top of socket with tube removed.
- Voltages marked with an asterisk (*) will vary widely with control setting. In combination models, B+ voltages in TV chassis will be slightly higher when set is switched to radio position. Alternate voltage readings for radio and TV are shown for sound output tube V204 (6Y6G) in 20D2 chassis.

CAUTION

Pulsed high voltages are present on the cap of V405, pin 3 of V407 and on the filament terminals and cap of the 1B3GT tube. NO ATTEMPT SHOULD BE MADE TO TAKE MEASUREMENTS FROM THESE POINTS WITHOUT SUITABLE TEST EQUIPMENT.

Picture tube 2nd anode voltage can be measured from the 2nd anode connector and should be taken only with a high voltage instrument such as a kilovoltmeter or a vacuum-tube voltmeter with a high voltage probe. 2nd anode voltage is approximately 16.5 KV. Proper filament voltage check of the 1B3GT tube may be made by observing filament brilliancy as compared with that obtained with a 1.5 volt dry cell battery.

SPECIFICATIONS

Picture Tube

Direct View Electromagnetic. See Model Identification Chart for different picture tubes used.

Operating Voltage

110-120 volts, 60 cycles, AC.

Wattage

205 watts for all VHF-UHF models.

Input Impedance and Transmission Line

300 ohm balanced (between antenna terminals).

Antenna

All models are equipped with built-in VHF-UHF antennas.

Intermediate Frequencies

Video 45.75 MC. Sound 41.25 MC.
Intercarrier Sound 4.5 MC.

Fuse Location

The horizontal output circuit is fused with a 3/8 amp., 250 volt fuse, part number 84A4-3. The fuse is located on the top side of the chassis. See tube location illustration

UHF TUNER ALIGNMENT

The UHF tuner has been carefully aligned at the factory and generally should never require realignment in the field. Also, since alignment of the UHF tuner is quite involved, for the present, it is not recommended for field service. If it has been definitely determined that complete tuner alignment is required, it should be returned to the Admiral distributor for replacement.

Important: Do not under any circumstances attempt adjustment of the tracking screws or bend the capacitor tuning plates in any way.

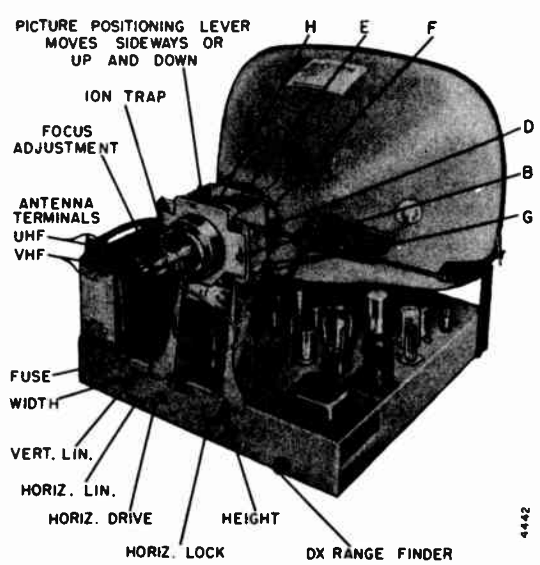

Figure 3. Rear View of 20L2 Chassis Showing Adjustment Locations.

HORIZONTAL OSCILLATOR AND DRIVE ADJUSTMENT

If the **Horizontal Drive** control (on rear of set) is not properly adjusted, it may be difficult to obtain sufficient picture width and brightness.

When switching channels, the **Horizontal** control (on front panel) should keep the picture in horizontal sync through at least three fourths of its range. If the picture does not remain in horizontal sync, then adjust the rear panel controls as follows:

a. Allow the set to warm up. Tune in a station and adjust the **Brightness** and **Contrast** controls for average settings. Be sure **DX Range Finder** control is adjusted as per instructions given previously.

b. The **Horizontal Drive** control (at rear of set) should be set to the approximate center of its rotation. If a white vertical line appears, turn the control to the left until the line disappears.

c. Turn the **Horizontal** control (on front panel) fully to the left. While slowly rotating the **Horizontal** control to the right, switch the **Channel Selector** off and on a station several times. The picture should remain in horizontal sync for at least three fourths of the **Horizontal** control range. If not, set the **Horizontal** control to the position at which horizonal sync is lost. As shown in the "Rear View of Chassis Showing Adjustment Location", slowly turn the **Horizontal Lock** control to the right or left until the picture synchronizes. It may require a few turns or more of the **Horizontal Lock** control to obtain the proper **Horizontal** control (on front panel) range.

SERVICE HINT

ALIGNMENT

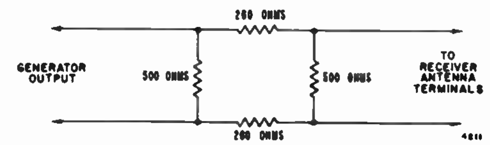

Figure 5. Illustration of 12 db Attenuation Pad for Viewing Over-all RF-IF Response Curve.

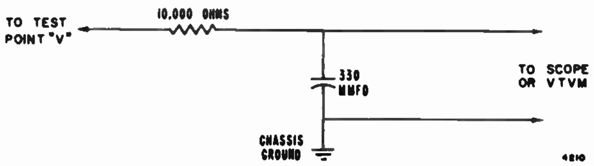

Figure 6. Decoupling Filter.

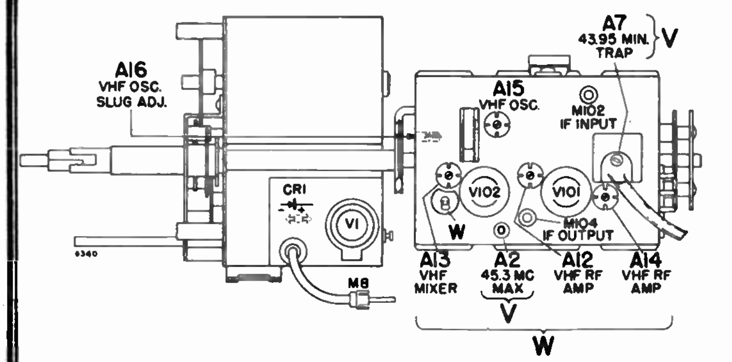

Figure 9. Top View of TV Tuner Showing Adjustment Locations.

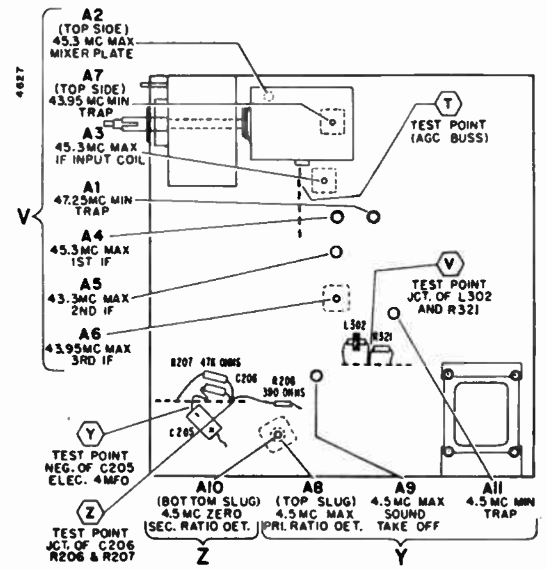

Figure 8. Bottom View of 20L2 Chassis Showing Test Point Connections and IF Alignment Data.

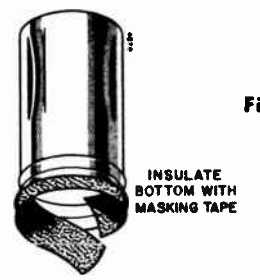

Figure 7. Tube Shield for IF Alignment and IF Response Curve Check.

IF RESPONSE CURVE CHECK

(Using sweep generator and oscilloscope)

Receiver Controls and Bias Battery	Sweep Generator	Marker Generator	Oscilloscope	Instructions
Set Channel Selector on channel 12 or an unassigned high channel. Contrast control fully to the left. Connect negative of 4½ volt bias battery to test point "T"; positive to chassis.	Connect high side to 6U8 mixer-osc. insulated tube shield, see fig. 7. Connect low side to chassis near tube shield. Set sweep frequency to 44.5 MC, and sweep width approximately 7 MC.	If an external marker generator is used, loosely couple high side to tube shield, low side to chassis. Marker frequencies indicated on IF Response Curve.	Connect to test point "V" through a decoupling filter, see figs. 6 and 8. Marker pips on scope will be more distinct if a capacitor from 100 mmfd. to 1000 mmfd. is connected across the oscilloscope input.	Check curve obtained against ideal response curve in fig. 10. Note tolerances on curve. Keep marker and sweep outputs at very minimum to prevent overloading. A reduction in sweep output should reduce response curve amplitude without altering the shape of the response curve. If the curve is not within tolerance or the markers are not in the proper location on the curve, touchup with IF slugs as instructed below. **Important:** If curve changes shape with hand capacity, see section 1 of "Alignment Hints."

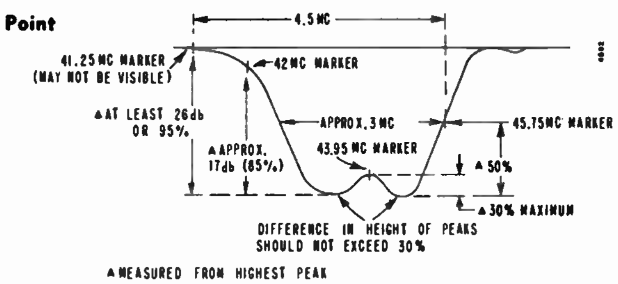

Figure 10. Ideal IF Response Curve.

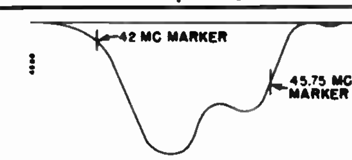

Figure 11. IF Response Curves, Incorrect Shape.

If it is necessary to adjust for approximate equal peaks and correct marker location, carefully adjust slug A2 and if necessary, adjust slug A3. It should not be necessary to turn the slugs more than one turn in either direction.

If the curve cannot be made to resemble the response curve shown at left, repeat all steps under "IF Amplifier and Trap Alignment" making sure that generator frequencies are accurate and adjustments are carefully made. If a satisfactory curve cannot be obtained after repeating these steps, it may be necessary to change IF amplifier tubes or check for a defective circuit component to be sure that each stage is operating properly.

IF AMPLIFIER AND TRAP ALIGNMENT

- Connect bias battery; negative to test point "T", see figure 8, positive to chassis. A 4½ volt battery is required for all steps below.
- Disconnect antenna. Connect a jumper wire across the antenna terminals.
- Set Channel Selector to channel 12 or other unassigned high channel, to prevent interference during alignment.
- Set the Contrast control fully to the left (counterclockwise).
- Allow about 15 minutes for receiver and test equipment to warm up.
- Use lowest DC scale on VTVM.

  Note: Since A2 and A3 are adjustments of an overcoupled double tuned circuit, adjustment of A3 is first made at 43.3 MC (step 3) and then at 45.3 MC (step 5), to obtain proper peak.

Step	Signal Gen. Freq.	VTVM and Signal Generator Connections	Instructions	Adjust
*1	*47.25 MC	VTVM high side to test point "V" through a decoupling filter; see figures 6 and 8, common to chassis.	Connect a 4½ volt bias battery to test point "T".	A1 for minimum.
2	45.3 MC		Use lowest DC scale on VTVM.	A2 for maximum.
3	45.3 MC	Generator high side to 6U8 (V102) special tube shield. Connect low side to chassis near the tube shield, see figure 7.	When peaking, keep reducing generator output for VTVM reading of approx. 1 volt or less. If unstable, refer to section 1 of the "Alignment Hints" on page 7.	A3 for maximum.
4	45.3 MC			Repeat step 2.
5	45.3 MC			**Readjust** A3 for maximum.
6	45.3 MC			A4 for maximum.
7	43.3 MC			A5 for maximum.
8	43.95 MC			A6 for maximum.
9	43.95 MC	Connect VTVM as above. Generator high side to antenna terminals; full output may be required.	Follow above instructions. Set Channel Selector to 2 or other low channel.	A7 for minimum.
10	To insure correct alignment, repeat steps 1 and 6. Make the "IF Response Curve Check" given on page 9.			

* Before proceeding with alignment, turn slugs A2 and A3 out fully (counterclockwise). Check the signal generator used in alignment against a crystal calibrator or other frequency standard for absolute frequency calibration required for this operation.

4.5 MC SOUND IF AND TRAP ALIGNMENT

See page 10 for touch-up of ratio detector using television signal without test equipment.

a. Connect signal generator high side to pin 2 of V304 (6AL5) through a .01 mfd. capacitor, connect low side to chassis.

b. Allow about 15 minutes for receiver and test equipment to warm up.

c. Set Contrast control fully to the left (counterclockwise).

d. Use a ***non-metallic*** alignment tool. If Ratio Det. Transformer (T201) has hollow core slugs, bottom slug adjustment A8 can be made from top of chassis, if you use alignment tool, part number 98A30-12 obtainable from Admiral distributor.

Step	Signal Gen. Freq. (MC)	VTVM Connections	Instructions	Adjust
	When using a signal generator, be sure to check it against a crystal calibrator or other frequency standard for accurate frequency calibration at 4.5 MC. Accuracy required is within one kilocycle. IMPORTANT: If a signal generator and frequency standard are not available, alignment can be made using a TV station signal. Tune in a station and follow steps 1, 2 and 3 below. If necessary use a higher scale on the VTVM.			
1	Set to exactly 4.5 MC.	High side to test point "Y"; common to chassis.	Use lowest DC scale on VTVM.	A8 and A9 for maximum (keep reducing generator output to keep VTVM at approximately 1 volt).
2		High side to test point "Z"; common to chassis.	Use zero center scale on VTVM if available.	A10 for zero on VTVM (the correct zero point is located between a positive and a negative maximum). If A8 was far off, repeat step 1.
3		High side to test point "Y"; common to chassis.	Connect a 10 mmfd. capacitor from pin 7 of V305 (12BY7) to pin 7 of V201 (6AU6). Use lowest DC scale on VTVM.	A11 for minimum.

TOUCH-UP OF RATIO DETECTOR SECONDARY USING TELEVISION SIGNAL (A10, BOTTOM SLUG OF T201)

Adjustment need be made on one channel only.

Proceed as follows:

a. Turn set on and allow about 15 minutes for warm up.

b. Tune set for normal picture and sound.

c. Carefully insert a non-metallic alignment tool in the bottom slug of T201. An alignment tool with a screw-driver blade or hexagonal end is required depending on the transformer used, see * note below. When the alignment tool engages the bottom tuning slug A10, adjust the slug for best sound with minimum buzz level. Do this carefully as only slight rotation in either direction will generally be required. Correct adjustment point is located between the two maximum buzz peaks that will be noticed when turning the slug back and forth about ¼ to ½ turn.

ALIGNMENT OF 4.5 MC TRAP A11, USING A TELEVISION SIGNAL

Beat interference (4.5 MC) appears in picture as very fine vertical or diagonal lines, very close together, having a "gauze-like" appearance, the pattern will vary with speech, forming a very fine herringbone pattern.

The trap can be tuned by watching the picture and adjusting slug A11 for minimum 4.5 MC interference. If greater accuracy is required, the trap should be adjusted as instructed in step 3 of the "4.5 MC Sound IF and Trap Alignment."

* If ratio detector transformer (T201) has hollow hexagonal core slugs, bottom slug adjustment (A10) can be made from top of chassis, if you use alignment tool (part number 98A30-12; available at Admiral Distributor). Bottom slug (A10) can be reached through the hole in the core of the upper slug (A8).

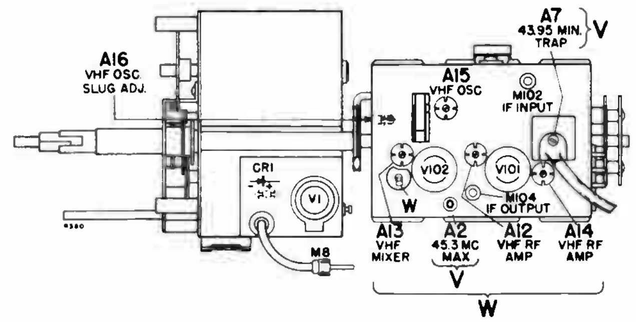

Figure 13. Top of Tuners, Showing VHF Adjustment Locations.

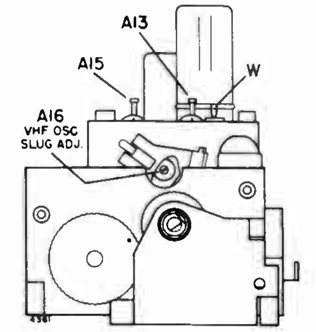

Figure 14. Front View of Tuners.

VHF OSCILLATOR ADJUSTMENT

(Using a signal generator)

It is always advisable to make VHF oscillator adjustments using a Television Signal as instructed on page 4. If a Television Signal is not available, HF oscillator adjustment can be made using a crystal calibrated signal generator. Note that adjustment "A15" (figure 10) is an overall oscillator adjustment and should only be made when the mixer-oscillator tube is replaced. Generally "A15" adjusts with about 3/16" of screw thread exposed. Make adjustments as follows:

Receiver Control Settings	Signal Generator	Instructions
Set Channel Selector for each channel to be adjusted. Set "Tuning" control at half rotation. Turn volume control fully to the right (clockwise).	Connect to antenna terminals. Set generator to exact frequency of VHF oscillator. See frequency table on page 10. **Set generator for maximum output.**	Connect a wire jumper from test point "W" on the tuner to test point "Z". See figure 8. Remove the ratio detector tube V202 (6AL5). Carefully adjust the oscillator slug A16 on each channel until a whistle (beat) is heard in the speaker of the receiver.

VHF TUNER RF AND MIXER ALIGNMENT

a. Connect negative of 4½ volt bias battery to AGC buss (test point "T"), positive to chassis. If it is difficult to obtain a curve of sufficient amplitude, remove battery and connect a wire jumper from test point "T" to chassis.

b. Connect sweep generator (with 300 ohm output) to antenna terminals. If sweep generator does not have a built-in marker generator, loosely couple a marker generator to the antenna terminals. To avoid distortion of the response curve, keep sweep generator output at a minimum, marker pips just barely visible.

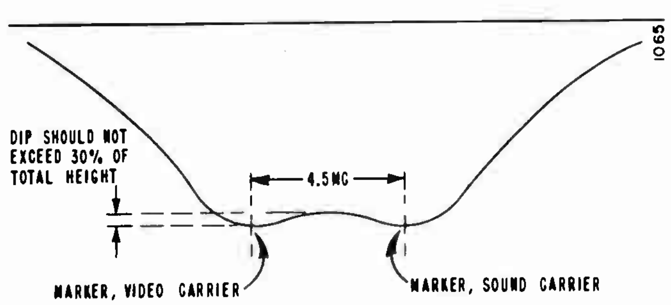
c. Connect oscilloscope through a 10,000 ohms resistor to test point "W" on tuner (figure 13). Keep scope leads away from chassis.

d. Allow about 15 minutes for receiver and test equipment to warm up.

Step	Marker Gen. Freq. (MC)	Sweep Gen. Frequency	Instructions
1	193.25 MC (Video Carrier) 197.75 MC (Sound Carrier)	Sweeping Channel 10. See frequency table below.	Alternately adjust A12 and A13 (figure 13) as required to obtain equal peak amplitudes and symmetry, consistent with flat top appearance, proper band width and correct marker location, see figure 12.
2	83.25 MC (Video Carrier) 87.75 MC (Sound Carrier)	Sweeping Channel 6. See frequency table below.	Adjust A14 as required to obtain curve having maximum amplitude and flat top appearance consistent with proper bandwidth and correct marker location, see figure 12. After completing adjustment, recheck adjustment of step 1.
3	Set the sweep generator to sweep the channel to be checked. Set the marker generator for the corresponding video carrier frequency and sound carrier frequency.		Check each channel operating in the service area for curve shown below. In general, the adjustment performed in steps 1 and 2 are sufficient to give satisfactory response curves on all channels. However, if reasonable alignment is not obtained on a particular channel, (a) check to see that coils have not been intermixed, or (b) try replacing the pair of coils for that particular channel, or (c) repeat step 1 for a weak high channel as a compromise adjustment to favor the particular channel. Repeat step 2 for the weak low channel to favor the particular low channel. If a compromise adjustment is made, other channels operating in the service area should be checked to make certain that they have not been appreciably affected.

OVER-ALL VHF AND IF RESPONSE CURVE CHECK

Receiver Controls and Bias Battery	Sweep Generator	Marker Generator	Oscilloscope	Instructions
Contrast control fully to the left. Channel Selector on channel 10 or other unassigned high channel. Connect negative of 4½ volt bias battery to test point "T", positive to chassis.	Connect to antenna terminals. Set generator to sweep VHF channel selected. See frequency table on page 10. Keep generator output as low as possible, to prevent overloading. See section 2 of "Alignment Hints."	If an external marker generator is used, loosely couple high side to sweep generator lead. VHF marker frequencies are shown in frequency table on page 10.	Connect to point "V" through a decoupling filter; see figs. 6 and 8.	Compare the response curve obtained against the ideal curve shown in figure 15. If the curve is not within tolerance, touch up the IF slug as instructed below. It should never be necessary to turn slugs more than one turn in either direction. If the curve is satisfactory on the channel checked, all other channels should also be satisfactory. IMPORTANT: When sweep output is reduced, response curve amplitude on scope should also decrease, but curve shape should remain the same. If curve shape changes, reduce sweep output and/or the scope gain until the shape does not change. See section 2 of "Alignment Hints."



Full skirt of curve will not be visible unless generator sweep width extends beyond 12 MC.

Figure 12. RF Response Curve.

VHF FREQUENCY TABLE

Channel Number	Channel Freq., MC	Video Carrier, MC	Sound Carrier, MC	HF Osc., MC
2	54-60	55.25	59.75	101
3	60-66	61.25	65.75	107
4	66-72	67.25	71.75	113
5	76-82	77.25	81.75	123
6	82-88	83.25	87.75	129
7	174-180	175.25	179.75	221
8	180-186	181.25	185.75	227
9	186-192	187.25	191.75	233
10	192-198	193.25	197.75	239
11	198-204	199.25	203.75	245
12	204-210	205.25	209.75	251
13	210-216	211.25	215.75	257

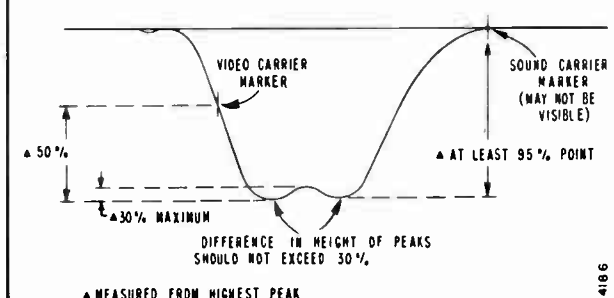


Figure 15. Ideal Over-all VHF and IF Response Curve.

Note that video carrier (marker) on the "Overall RF-IF Response Curve" will appear on the opposite side of the curve as compared to the "IF Response Curve" figure 10. This is due to action of the mixer tube.

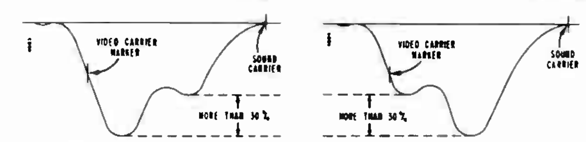

Figure 16. Over-all RF and IF Response Curves, Incorrect Shape.

Curves must have approximate equal peaks and correct marker location. If it is necessary to adjust for approximate equal peaks and marker location, carefully adjust slug A2 and if necessary slug A3. It should not be necessary to turn the slugs more than one turn in either direction.

IF PRE-AMPLIFIER RESPONSE CURVE CHECK AND ALIGNMENT

***Important:** This alignment is seldom required. It should be made only if UHF reception is poor and after usual causes of poor reception have been checked. This alignment should be made after completing preceding alignments.*

a. Set VHF Channel Selector at detent position midway between channels 5 and 6.

b. Connect negative of 4½ volt bias battery to AGC buss (test point "T"), positive to chassis.

c. Remove CR1 (mixer crystal) from holder. Connect sweep generator high side through 100 ohm resistor to negative clip of mixer crystal socket, see figure 13. If sweep generator does not have a built-in marker generator, loosely couple a marker generator to the high side of sweep generator. To avoid distortion of the response curve, keep sweep generator output at a minimum, marker pips just barely visible.

d. Connect oscilloscope through a 10,000 ohm resistor to test point "W" on tuner (figure 18). Keep scope leads away from chassis.

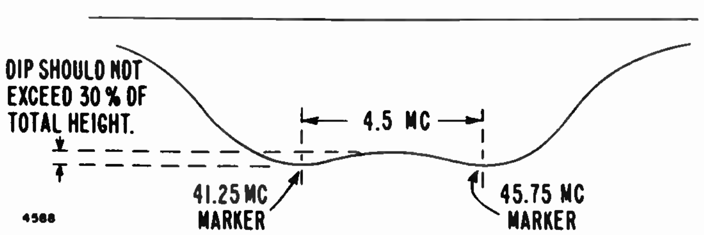
e. Allow about 15 minutes for receiver and test equipment to warm up.

f. Use a ***non-metallic*** alignment tool. If hollow core slugs are used, use alignment tool, part number 98A30-14.

Step	Marker Gen. Freq. (MC)	Sweep Gen. Frequency	Instructions
*1	45.75 MC (Video Carrier) 41.25 MC (Sound Carrier)	Set sweep at 43.5 MC, sweep width 12 MC.	Adjust A17 to obtain maximum amplitude at center of curve. Alternately adjust A18 and A19 (figure 18) as required to obtain equal peak amplitudes and symmetry, consistent with flat top appearance, proper band width and correct marker location; see figure 17.
2	If curve cannot be made to resemble response curve, figure 17, check to be sure all instructions have been followed. Check tubes V101 and V102 and repeat alignment. Important: After replacing tubes, it may be necessary to check "VHF Tuner RF And Mixer Alignment".		

* Before proceeding, detune slug A2 exactly 3 turns counter-clockwise. After completing this alignment, return slug A2 to its original setting by turning it exactly 3 turns clockwise.

Caution: Use extreme care to avoid damage to coils or slugs.



Full skirt of curve will not be visible unless generator sweep width extends beyond 12 MC.

Figure 17. IF Preamplifier Response Curve.

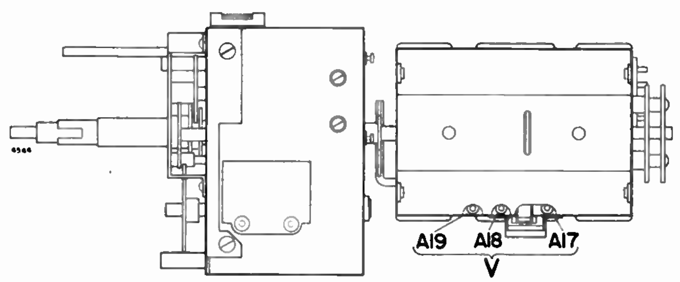


Figure 18. Bottom View of Tuners Showing IF Preamplifier Adjustments.

WAVEFORM DATA
(Waveforms given on schematic)

Waveforms taken with **Contrast** control set fully to the right, all other controls set for normal picture (in sync). **DX Range Finder** control set fully to the left (at "0" position). Warning: Incorrect adjustment of the **DX Range Finder** control will cause waveform distortion.

Waveforms at video and sync stages obtained with transmitted signal input to receiver.

The oscilloscope sweep is adjusted for 30 cycles (which is one-half of the vertical frequency), or for 7875 cycles (which is one-half of the horizontal frequency) so that two pulses appear on the screen.

The peak-to-peak voltage readings shown are subject to some variation due to response of the oscilloscope and parts tolerances.

Waveform at V407 can also be taken by clipping or twisting the lead from the oscilloscope high side over the insulation on the lead connecting to pin 3. When taking the waveform this way, the shape of waveform will be the same but the peak-to-peak voltage will be much lower depending upon the degree of coupling.

TV VOLTAGE DATA
(Voltages given on schematic)

- **Contrast** control turned fully clockwise. **Low-Channel Selector** set on an unused VHF channel. **High-Channel Selector** in the "VHF" position. Other front controls set at approximately half rotation. **Vert. Lin.** and **Height** set at approximately half rotation. **DX Range Finder** control set fully to the left (at "0" position).
- VHF Antenna disconnected from set with terminal shorted.
- Line voltage 117 volts AC.
- Voltages measured with a vacuum-tube voltmeter between tube socket terminals and chassis, unless otherwise indicated.
- Voltages at V101 and V102 (VHF Tuner) are measured with tube in socket. Use an adapter or lift tube out of socket just high enough to allow a needle point probe to contact tube pins. Voltages at pins 6 and 3 of V101 (6BZ7) must be taken as described above or no voltage reading will be obtained.
- Voltages at V306 measured from top of socket with tube removed.
- B+ voltage at terminal of VHF-UHF switch taken with tuner in UHF position.
- Voltages marked with an asterisk (*) will vary widely with control setting.

CAUTION

Pulsed high voltages are present on the cap of V405, pin 3 of V407 and on the filament terminals and cap of the 1B3GT tube. NO ATTEMPT SHOULD BE MADE TO TAKE MEASUREMENTS FROM THESE POINTS WITHOUT SUITABLE TEST EQUIPMENT.

Picture tube 2nd anode voltage can be measured from the 2nd anode connector and should be taken only with a high voltage instrument such as a kilovoltmeter or a vacuum-tube voltmeter with a high voltage probe. 2nd anode voltage is approximately 15 KV. Proper filament voltage check of the 1B3GT tube may be made by observing filament brilliancy as compared with that obtained with a 1.5 volt dry cell battery.

PRODUCTION CHANGES

Production changes are coded RUN 1, RUN 2, etc., as given in the headings below. Run number (stamped on chassis) indicates that this chassis has the change(s) incorporated which are explained under that particular run number heading below, as well as all changes (lower run numbers) made prior to that time. At the start of production chassis were stamped RUN 1; a few chassis were not stamped with a Run number.

CHANGE IN SYNC CIRCUITS

Run 2 and higher

In sets stamped Run 2 and higher, R330 was changed from 18,000 ohms to 27,000 ohms, R416 was changed from 2.7 megohms to 3.3 megohms, R417 was changed from 47,000 ohms to 27,000 ohms. The above changes were made to improve vertical sync and correct bending at top of picture.

SCHEMATIC NOTES

Run numbers are rubber stamped at the rear of the chassis.

A1, A2, ... Y, Z, etc. indicate alignment points and alignment connections.

IMPORTANT: Before making waveform and voltage measurements, see instructions on this page.

Figure 20. Schematic for 20L2 Chassis.

UHF TUNER ALIGNMENT

- Connect UHF Sweep Generator to UHF antenna terminals, sweep width 12 MC. If sweep generator does not have a built-in marker generator, loosely couple a UHF marker generator to the transmission line between antenna terminals and UHF tuner.
- Connect oscilloscope through a 10,000 ohm resistor to test point "W" on VHF tuner (figure 58).
- Connect negative terminal of 1½ volt bias battery to test point "T", positive to chassis.
- DX Range Finder (if used) set at "0".
- Allow about 15 minutes for receiver and test equipment to warm up.

Step	Marker Gen. Freq. (MC)	Sweep Gen. Center Frequency	Instructions
1	503.50 MC	503 MC	Tune UHF tuner to channel 19, or until RF response curve is observed on oscilloscope. Adjust A20 (figure 59) until marker is located in the center of the response curve. *See note 1 below.
2	869.50 MC	869 MC	Tune UHF tuner to channel 80, or until RF response curve is observed on oscilloscope. Adjust A21 (figure 59) until marker is located in the center of the response curve. *See note 1 below.
3	Set the sweep generator to sweep the channel to be checked. Alternately set the marker generator for the corresponding video carrier frequency and sound carrier frequency.		Check response curve for each channel operating in the service area. Marker locations should be as shown in figure 60. In general, the adjustments performed in steps 1 and 2 are sufficient to provide satisfactory curves and correct marker locations for all channels. However, if reasonable alignment is not obtained on a particular channel, see instructions given in steps 4 and 5 below.
4	885.25 (video carrier) 889.75 (sound carrier)	887 MC	Remove the snap fastened cover plate "B" from the bottom of the UHF tuner, see figure 59. Adjust both UHF preselector trimmer tabs (figure 61), by moving them up or down, to obtain maximum amplitude of response curve at test point "W". *See note 2 below.
5	Successively sweep channels 83 to 14, alternately inserting appropriate video and sound carrier marker.		Track both UHF preselector gangs to each other and to the oscillator gang from channel 83 to channel 14, by bending or knifing the preselector rotor blade segments (figure 61) adjacent to the stator line to obtain the desired response curve, see figure 60. Always knife the plates while tuning lower in frequency to avoid affecting the tracking above the point of knifing. Check which section requires knifing by touching the plates with the knifing tool while observing the response curve, then proceed with the knifing of the proper section or of both sections, if required. Use caution when knifing the preselector blades so as not to disturb the position of the polystyrene damping blocks located beneath the stator line.

*NOTE 1: If UHF tuner is far out of alignment, the response curve may be too low in amplitude to be readily observed, or it may be very distorted in shape. In this case, it will be necessary to roughly align the preselector before completing final oscillator adjustment. This is done by knifing the preselector rotor blade segments (figure 61) adjacent to the stator line at dial setting for the affected channel.

*NOTE 2: Adjustment of the trimmer tabs is made from the bottom side of the UHF tuner by means of a small hook shaped tool Do not remove the top-side cover of the UHF tuner during alignment.

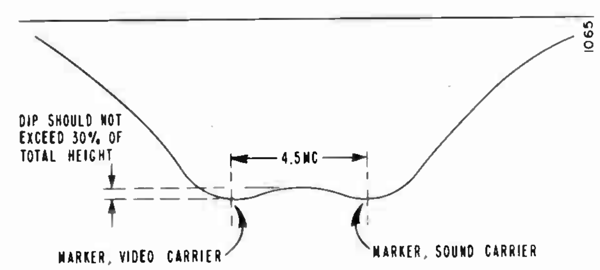

Figure 60. RF Response Curve Taken at Test Point "W".

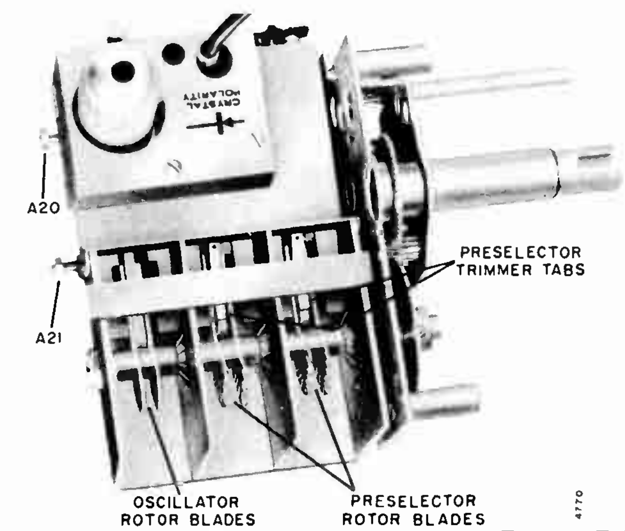

Figure 61. Top View of UHF Tuner Showing Trimmer Tab Locations (top-side cover removed for illustration only).

Make Horizontal Sync Adjustment as follows:

1. Set the **DX Range Finder** at "0" position (see chassis illustrations) and set the **Contrast** control (on front panel) for normal picture.
2. Important: Before making these adjustments, be sure that the picture can be made to sync vertically (remain stationary up and down) as lack of both vertical and horizontal sync is an indication of trouble in the sync circuits. If replacement of tubes V303, V401, V403 does not eliminate sync trouble, check for other trouble in the sync circuits.
3. With the picture in sync, rotate **Horizontal** control (A) on front panel from one end to the other. If picture does not hold sync as described in paragraphs "a" or "b" at left, set the **Horizontal** control (A) at the point where the picture just loses sync or becomes unstable, and slowly adjust the **Horizontal Frequency** (B) until the picture just falls back into sync. It may require several turns of adjustment (B). Repeat this procedure until the picture holds as described in paragraphs "a" or "b" at left. If the picture can be made to hold sync with adjustment of (B), adjustment is complete.

4. If horizontal sync is still unsatisfactory, carefully repeat entire procedure. Try replacing tube V403. It may be necessary to make Complete Horizontal Oscillator Alignment (using an oscilloscope)

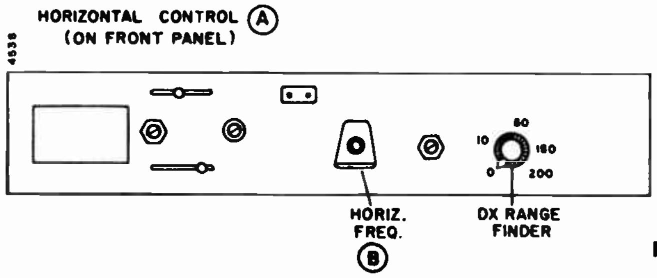

Figure 10. Rear View of Chassis Showing Horizontal Sync Adjustments.

COMPLETE HORIZONTAL OSCILLATOR ALIGNMENT

(Requires Oscilloscope)

1. IMPORTANT: Set the **DX Range Finder** at "0" position and set the **Contrast** control (on front panel) for normal picture.
2. Connect oscilloscope high side through a **10 mmfd. capacitor** to terminal marked "C" or "2" on the horizontal oscillator transformer T404 (see figure 11). It is important to use short leads and a very low capacity capacitor (at least 10 mmfd.) to avoid loading the circuit and thus distorting the waveform.

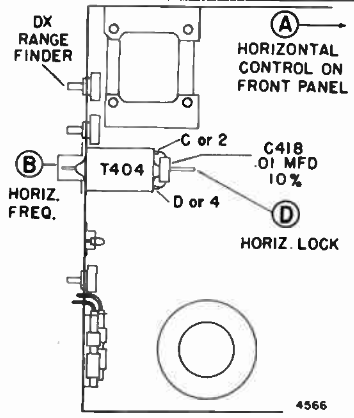

Figure 11. Bottom View of Chassis Showing Horizontal Sync Adjustments.

3. Set the oscilloscope sweep to 15.75 KC or a sub-multiple of it.
4. Adjust the **Horizontal Lock** slug (D) (see figure 11) until the oscilloscope waveform pattern appears as in figure 12. The rounded and pointed peaks of the waveform must have equal height. The picture must be kept in sync to obtain the proper oscilloscope waveform pattern. Keep the picture in sync by adjusting the **Hori-**

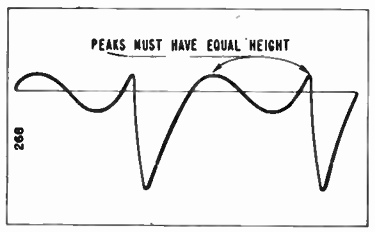

Figure 12. Horizontal Oscillator Waveform.

RADIO ALIGNMENT PROCEDURE

- Connect output meter across speaker voice coil.
- Turn receiver Volume control fully on.
- Function switch in "Radio" position.
- Connect ground wire from radio chassis to TV chassis.
- Use lowest output setting of signal generator that gives a satisfactory reading on meter.
- Use a ***non-metallic*** alignment tool for IF adjustments.
- Repeat adjustments to insure good results.

Step	Connect Signal Generator	Dummy Antenna Between Radio and Signal Generator	Signal Generator Frequency	Receiver Dial Setting	Adj. Trimmers in Following Order to Max.
1	Gang capacitor antenna stator	.1 MFD	455 KC	Tuning gang wide open	*A-B (2nd IF) *C-D (1st IF)
2	"	"	1620 KC	"	E (Oscillator)
3	Place generator lead close to loop of set to obtain adequate signal. No actual connection (signal by radiation).		1400 KC	Tune in signal	§F (antenna)

* Adjustments A and C made from underside of chassis. See figure 44 for alignment locations.
§ AM antenna trimmer may not peak if antenna leads are not properly routed or separated.

SERVICING RADIO TUNER IN 19M2 MODELS

SERVICING RADIO TUBES AND DIAL LIGHT

The radio tubes and radio dial light can be serviced without removing the TV chassis from the cabinet. The radio tubes can be reached through the opening cut in the underside of the chassis shelf.

The dial light can be serviced by removing the tuning knobs and plastic control panel. A number 47 dial light (part number 81A1-8) is used.

REMOVING RADIO TUNER

The radio tuner is mounted at the front apron of the chassis. Alignment, taking voltage readings or an inspection of the underside of the radio tuner can be performed without complete removal of the radio tuner from the TV chassis. To gain access to the underside of the radio tuner, remove the tuning drive drum and remove the four self-tappings screws at the front and rear of the radio tuner.

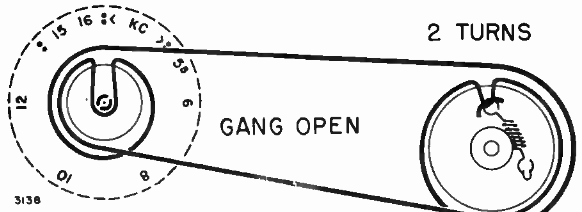

Figure 45. Drive Cord Stringing for Radio Tuner.

ALIGNMENT OF RADIO TUNER

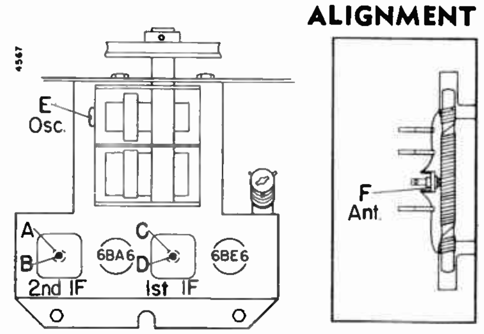

Figure 44. Location of Radio Alignment Adjustments.

The radio tuner in television and radio chassis should be aligned as instructed under "Radio Alignment Procedure" below.

Radio alignment adjustments B, C, D and F are accessible without disassembly of the radio tuner from the TV chassis. Adjustments A and C are made from underside of chassis, see paragraph above on "Removing Radio Tuner". The figure at left shows the locations of radio alignment adjustments.

SERVICING 3D1 RADIO CHASSIS

ALIGNMENT OF 3D1 RADIO CHASSIS

The 3D1 radio chassis should be aligned as instructed below.

Radio alignment adjustments are accessible without disassembly of the radio from the housing. Remove the radio escutcheon for aligning adjustments A and C. Adjustments A and C are accessible through holes in chassis housing. Location of alignment adjustments is shown in figure 47.

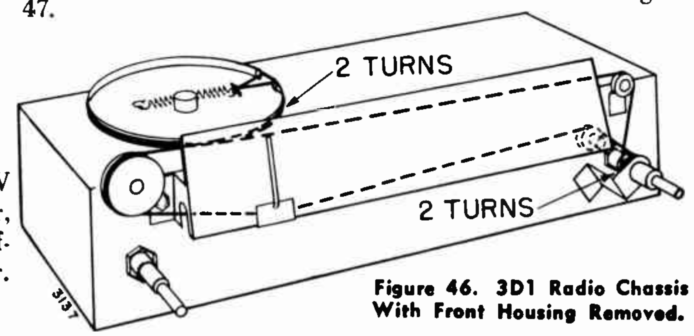

Figure 46. 3D1 Radio Chassis With Front Housing Removed.

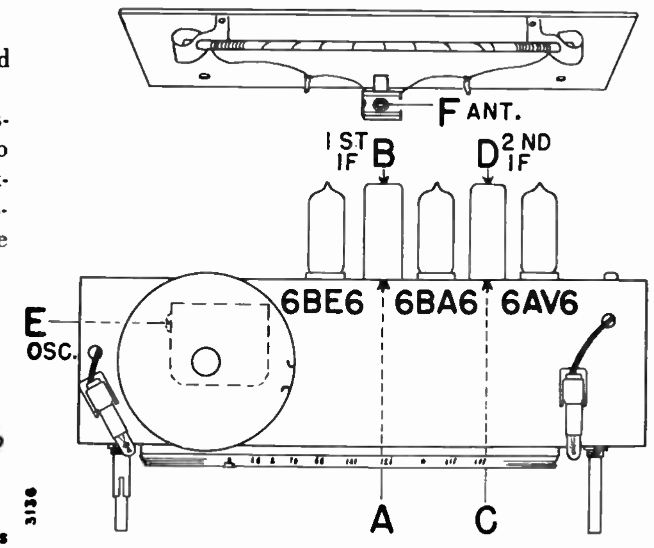

Figure 47. Trimmer Locations for 3D1 Radio.

3D1 RADIO ALIGNMENT PROCEDURE

- Connect output meter across speaker voice coil.
- Turn receiver Volume control fully on; Tone control fully clockwise.
- Band switch in AM position.
- AM antenna must be connected and placed in the same relative position to the chassis as when in the cabinet.
- Use lowest output setting of signal generator that gives a satisfactory reading on meter.
- Use a ***non-metallic*** alignment tool for IF adjustments.
- Repeat adjustments to insure good results.

Step	Connect Signal Generator	Dummy Antenna Between Radio and Signal Generator	Signal Generator Frequency	Receiver Dial Setting	Adj. Trimmers in Following Order to Max.
1	Gang capacitor antenna stator	.1 MFD	455 KC	Tuning Gang wide open	*A-B (2nd IF) *C-D (1st IF)
2	"	"	1620 KC	"	E (oscillator)
3	Place generator lead close to loop of set to obtain adequate signal. No actual connection (signal by radiation).		1400 KC	Tune in signal	§F (antenna)

* Adjustments A and C made from underside of chassis. See figure 47 above for alignment locations.
§ AM antenna trimmer adjustment "F" in step 3 should be repeated after set and antenna have been installed in cabinet. Important: AM antenna trimmer may not peak if antenna leads are not properly routed or separated.

TELEVISION ALIGNMENT PROCEDURE

GENERAL

Complete VHF and UHF IF Pre-amplifier alignment consists of the following individual procedures and should be performed in this sequence.

a. IF Amplifier and Trap Alignment.
b. IF Response Curve Check.
c. 4.5 MC Sound IF and Trap Alignment.
d. RF and Mixer Alignment.
e. Over-all RF and IF Response Curve Check.
f. VHF Oscillator Adjustment.
g. IF Pre-amplifier Response Curve Check and Alignment.

TEST EQUIPMENT

To properly service this receiver, it is recommended that the following test equipment be available.

IMPORTANT: Many service instruments do not meet the requirements given below. A list of recommended equipment is available from Admiral Distributor.

Oscilloscope

Standard oscilloscope, preferably one with a wide band vertical deflection, vertical sensitivity at least .05 volt (RMS) per inch.

Signal (Marker) Generator

4.5 MC frequency.
40 to 50 MC frequency range.
50 to 90 MC frequency range.
170 to 225 MC frequency range.

Must have a built-in calibration crystal for checking dial accuracy.

Sweep Generator

Sweep generator must provide sweep frequencies from
40 to 50 MC range:
50 to 90 MC range:
170 to 225 MC range:
} with at least 10 MC sweep width.

Output: adjustable; at least one-tenth volt maximum.
Output impedance: 300 ohms balanced to ground.

A sweep generator not having constant output voltage over the swept range and linear sweep, will produce curves which are widely different from the ideal curves shown in the following pages. If repeated difficulty is encountered in obtaining these curves, the sweep generator should be checked. A simple check is to observe the response curve for a set that is in alignment.

Before suspecting the generator, be sure the alignment instructions in this manual have been followed carefully.

Vacuum-Tube Voltmeter

Preferably with low range (3 volt) DC zero center scale and a high voltage probe (30,000 volt range).

ALIGNMENT TOOLS

The following alignment tools are required. They can be obtained from the Admiral Distributor under the part numbers listed below:

Metal alignment screwdriver part number 98A30-9.
Non-metallic (fiber) alignment screwdriver (11½" long, ⅛" diameter) part number 98A30-10.

Non-metallic alignment wrench (9" long, for large hexagon core IF slugs) part number 98A30-12.

Non-metallic alignment wrench (9" long, for small hexagon core IF slugs) part number 98A30-13.

IMPORTANT ALIGNMENT HINTS

The following suggestions should be performed if difficulty is experienced during the alignment procedure.

1. IF CIRCUIT INSTABILITY: When spot frequency aligning the IF amplifiers, the VTVM pointer may swing when the hand is placed too near the IF transformers. When viewing the IF response curve on an oscilloscope, the curve may change shape with hand capacity, especially when aligning A6 (3rd IF transformer T303). To correct either of these conditions, the following alignment hints should be tried:

(a) Check the generator output leads to be certain that the unshielded portion (especially the grounded lead) be as short as practicable.

(b) Be sure that a decoupling network is used at the video detector output and that the leads on the network are kept as short as possible (See figure 21).

(c) For injecting IF signal use an insulated tube shield over V102 (6U8) Oscillator-Mixer tube. Insulate bottom inside of tube shield with masking tape; see figure 16.

(d) The use of a non-metallic alignment tool, approximately eight inches long (part number 98A30-12), will permit adjustment without coming too near to the transformers.

2. RECEIVER OVERLOADING WHEN CHECKING THE OVER-ALL RESPONSE CURVE: Due to the inherent high sensitivity of these receivers, it is very easy to cause overloading in the third IF amplifier stage. In some cases, generator leakage alone is enough to produce a response curve on the oscilloscope. To prevent overloading, do the following:

(a) Be certain that the generator output attenuators are set at a minimum.

(b) Some generators have a built-in pad in the output table to be used when viewing the over-all response curve. Be sure that the pad in the cable is properly connected in the circuit. Refer to the generator instruction manual for details.

(c) If a pad is not built in, the 12 db pad shown below in figure 17 can be constructed and connected between the generator and the antenna terminals.

Figure 16. Tube Shield for IF Alignment and IF Response Curve Check.

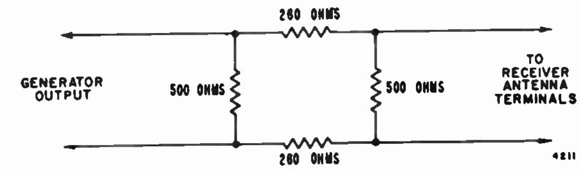

Figure 17. Illustration of 12 db Attenuation Pad for Viewing Over-all RF-IF Response Curve.

After becoming familiar with alignment procedure, some servicemen simplify subsequent alignment of sets by merely using the essential alignment data given in figures below.

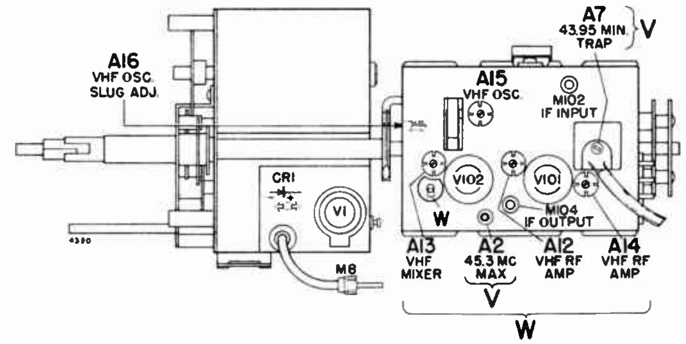

Figure 20. Top View of TV Tuner Showing Adjustment Locations.

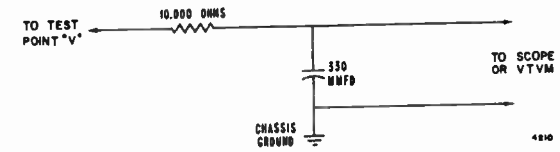

Figure 21. Decoupling Filter.

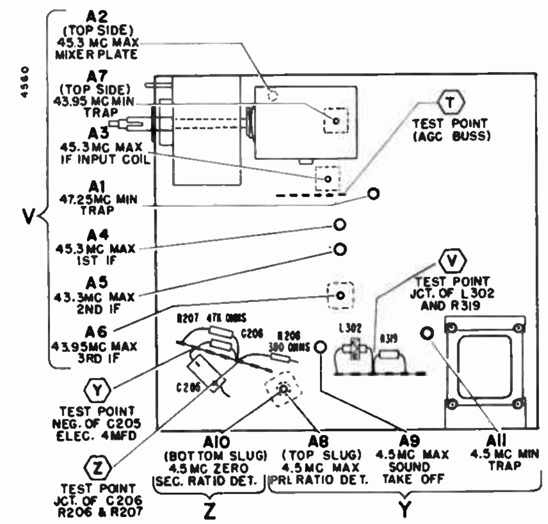

Figure 22. Bottom View of 19T1, 19W1 and 19W1A Chassis Showing Test Point Connections and IF Alignment Data.

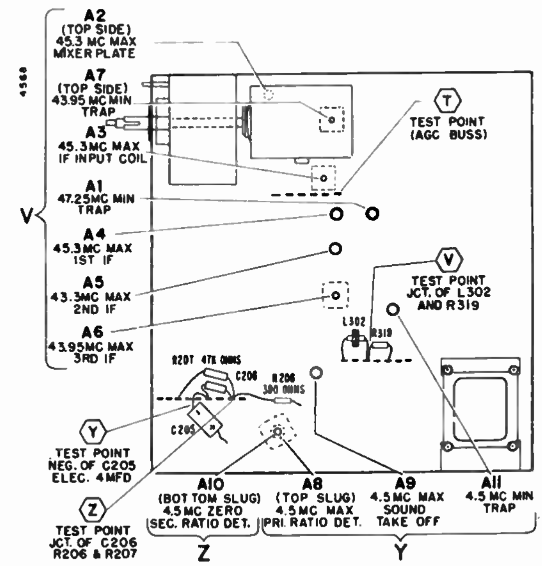

Figure 22A. Bottom View of 19L2, 19M2, 19N2Z and 19R2 Chassis Showing Test Point Connections and IF Alignment Data.

UHF TUNER ALIGNMENT

The UHF tuner has been carefully aligned at the factory and generally should never require realignment in the field. Also, since alignment of the UHF tuner is quite involved, for the present, it is not recommended for field service. If it has been definitely determined that complete tuner alignment is required, it should be returned to the Admiral distributor for replacement.

Important: Do not under any circumstances attempt adjustment of the tracking screws or bend the capacitor tuning plates in any way.

IF AMPLIFIER AND TRAP ALIGNMENT

- Connect bias battery; negative to test point "T", see figure 22, positive to chassis. A 4½ volt battery is required for all steps below.
- Disconnect antenna. Connect a jumper wire across the antenna terminals.
- Set Channel selector to Channel 12 or other unassigned high channel, to prevent interference during alignment.
- Set the Contrast control fully to the left (counterclockwise).
- Allow about 15 minutes for receiver and test equipment to warm up.
- Use lowest DC scale on VTVM.

*1	*47.25 MC	VTVM high side to test point "V" through a decoupling filter; see figs. 21 and 22, common to chassis. Generator high side to 6U8 (V102) special tube shield. Connect low side to chassis near the tube shield, see figure 16.	Connect a 4½ volt bias battery to test point "T". Use lowest DC scale on VTVM. When peaking, keep reducing generator output for VTVM reading of approx. 1 volt or less. If unstable, refer to section 1 of the "Alignment Hints" above.	A1 for minimum.
2	45.3 MC			A2 for maximum.
3	43.3 MC			A3 for maximum.
4	45.3 MC			Repeat step 2.
5	45.3 MC			Readjust A3 for maximum.
6	45.3 MC			A4 for maximum.
7	43.3 MC			A5 for maximum.
8	43.95 MC			A6 for maximum.
9	To insure correct alignment, repeat steps 1 and 4. Make the "IF Response Curve Check" given below.			

* Before proceeding with alignment, turn slugs A2 and A3 out fully (counter-clockwise). Check the signal generator used in alignment against a crystal calibrator or other frequency standard for absolute frequency calibration required for this operation.

IF RESPONSE CURVE CHECK

(Using sweep generator and oscilloscope)

Receiver Controls and Bias Battery	Sweep Generator	Marker Generator	Oscilloscope	Instructions
Set Channel selector on Channel 12 or an unassigned high channel. Picture control fully to the left. Connect negative of 4½ volt bias battery to test point "T"; positive to chassis.	Connect high side to 6U8 mixer-osc. insulated tube shield, see fig. 16. Connect low side to bottom part of tube shield. Set sweep frequency to 44.5 MC, and sweep width approximately 7 MC.	If an external marker generator is used, loosely couple high side to sweep generator lead on tube shield, low side to chassis. Marker frequencies indicated on IF Response Curve.	Connect to test point "V" through a decoupling filter, see figs. 21 and 22. Marker pips on scope will be more distinct if a condenser from 100 mmfd. to 1000 mmfd. is connected across the oscilloscope input.	Check curve obtained against ideal response curve in fig. 18. Note tolerances on curve. Keep marker and sweep outputs at very minimum to prevent overloading. A reduction in sweep output should reduce response curve amplitude without altering the shape of the response curve. If the curve is not within tolerance or the markers are not in the proper location on the curve, touchup with IF slugs as instructed below. *Important:* If curve changes shape with hand capacity, see section 1 of "Alignment Hints."

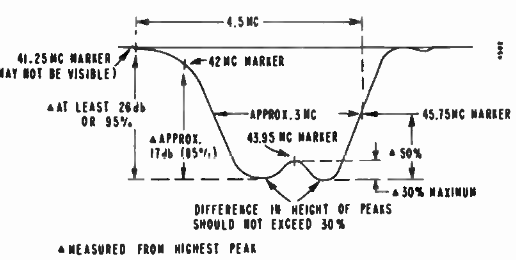

Figure 18. Ideal IF Response Curve.

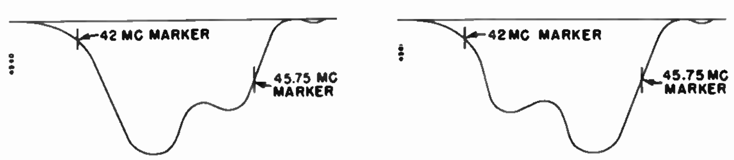

Figure 19. IF Response Curves, Incorrect Shape.

If it is necessary to adjust for approximate equal peaks and correct marker location, carefully adjust slug A2 and if necessary, adjust slug A3. It should not be necessary to turn the slugs more than one turn in either direction.

If the curve cannot be made to resemble the response curve shown at left, repeat all steps under "IF Amplifier and Trap Alignment" making sure that generator frequencies are accurate and adjustments are carefully made. If a satisfactory curve cannot be obtained after repeating these steps, it may be necessary to change IF amplifier tubes or check for a defective circuit component to be sure that each stage is operating properly.

4.5 MC SOUND IF AND TRAP ALIGNMENT

See below for touch-up of ratio detector using television signal without test equipment.

a. Connect signal generator high side to pin 2 of V304 (6AL5) through a .01 mfd. condenser, connect low side to chassis.

b. Allow about 15 minutes for receiver and test equipment to warm up.

c. Set Contrast control fully to the left (counterclockwise).

d. Use a NON-METALLIC alignment tool. If Ratio Det. Transformer (T201) has hollow core slugs, bottom slug adjustment A8 can be made from top of chassis, if you use alignment tool #98A30-12 obtainable from Admiral Distributor.

Step	Signal Gen. Freq. (MC)	VTVM Connections	Instructions	Adjust
	When using a signal generator, be sure to check it against a crystal calibrator or other frequency standard for accurate frequency calibration at 4.5 MC. Accuracy required is within one kilocycle. IMPORTANT: If a signal generator and frequency standard are not available, alignment can be made using a TV station signal. Tune in a station and follow steps 1, 2 and 3 below. If necessary use a higher scale on the VTVM.			
1	Set to exactly 4.5 MC	High side to test point "Y"; common to chassis.	Use lowest DC scale on VTVM.	A8 and A9 for maximum (keep reducing generator output to keep VTVM at approx. 1 volt).
2		High side to test point "Z"; common to chassis.	Use zero center scale on VTVM, if available.	A10 for zero on VTVM (the correct zero point is located between a positive and a negative maximum). If A8 was far off, repeat step 1.
3		High side to test point "Y"; common to chassis.	*Connect a 10 mmfd. capacitor from pin 5 of V305 (6CB6) to pin 7 of V201 (6AU6). Use lowest DC scale on VTVM.	A11 for minimum.

* In 19R2 chassis, connect 10 mmfd. capacitor from pin 7 of V305 (12BY7) to pin 7 of V201 (6AU6).

TOUCH-UP OF RATIO DETECTOR SECONDARY USING TELEVISION SIGNAL (A10, BOTTOM SLUG OF T201)

*Adjustment A10 is accessible through the ¼" hole (just below T201) in bottom of the cabinet or the chassis mounting shelf, located toward the left side facing the rear of the set. See figure 22. Removal of the chassis is therefore not required. ***Adjustment need be made on one channel only.*** Proceed as follows:

a. Turn set on and allow about 15 minutes for warm up.

b. Tune set for normal picture and sound.

c. Carefully insert a non-metallic alignment tool through the opening in cabinet bottom below T201. An alignment tool with a screwdriver blade or hexagonal end is required depending on the transformer used, see * note below. When the alignment tool engages the bottom tuning slug A10, adjust the slug for best sound with minimum buzz level. Do this carefully as only slight rotation in either direction will generally be required. Correct adjustment point is located between the two maximum buzz peaks that will be noticed when turning the slug back and forth about ¼ to ½ turn.

ALIGNMENT OF 4.5 MC TRAP A11, USING A TELEVISION SIGNAL

Beat interference (4.5 MC) appears in picture as very fine vertical or diagonal lines, very close together, having a "gauze-like" appearance, the pattern will vary with speech, forming a very fine herringbone pattern.

The trap can be tuned by watching the picture and adjusting slug A11 for minimum 4.5 MC interference. If greater accuracy is required, the trap should be adjusted as instructed in step 3 of the "4.5 MC Sound IF and Trap Alignment."

* If ratio detector transformer (T201) has hollow hexagonal core slugs, bottom slug adjustment A10 can be made from top of chassis, if you use alignment tool (part number 98A30-7; available at Admiral Distributor). Bottom slug (A10) can be reached through the hole in the core of the upper slug (A8)

VHF TUNER RF AND MIXER ALIGNMENT

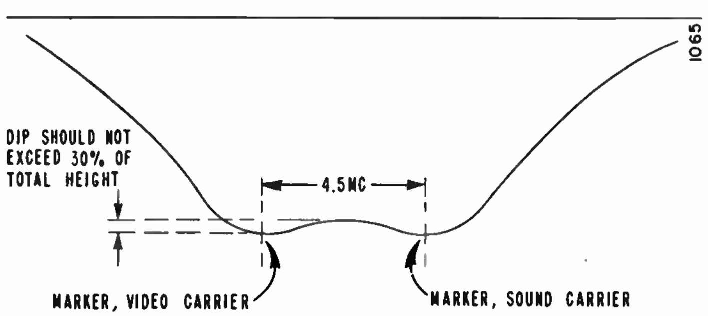
a. Connect negative of 4½ volt bias battery to AGC buss (test point "T"), positive to chassis. If it is difficult to obtain a curve of sufficient amplitude, remove battery and connect a wire jumper from test point "T" to chassis.

b. Connect sweep generator (with 300 ohm output) to antenna terminals. If sweep generator does not have a built-in marker generator, loosely couple a marker generator to the antenna terminals. To avoid distortion of the response curve, keep sweep generator output at a minimum, marker pips just barely visible.

c. Connect oscilloscope through a 10,000 ohm resistor to test point "W" on tuner (figure 21). Keep scope leads away from chassis.

d. Allow about 15 minutes for receiver and test equipment to warm up.

Step	Marker Gen. Freq. (MC)	Sweep Gen. Frequency	Instructions
1	193.25 MC (Video Carrier) 197.75 MC (Sound Carrier)	Sweeping Channel 10. See frequency table below.	Alternately adjust A12 and A13 (figure 24) as required to obtain equal peak amplitudes and symmetry, consistent with flat top appearance, proper band width and correct marker location; see figure 23.
2	83.25 MC (Video Carrier) 87.75 MC (Sound Carrier)	Sweeping Channel 6. See frequency table below.	Adjust A14 as required to obtain curve having maximum amplitude and flat top appearance consistent with proper band width and correct marker location; see figure 23. After completing adjustment, recheck adjustment of step 1.
3	Set the sweep generator to sweep the channel to be checked. Set the marker generator for the corresponding video carrier frequency and sound carrier frequency.		Check each channel operating in the service area for curve shown below. In general, the adjustment performed in steps 1 and 2 are sufficient to give satisfactory response curves on all channels. However, if reasonable alignment is not obtained on a particular channel, (a) check to see that coils have not been intermixed, or (b) try replacing the pair of coils for that particular channel, or (c) repeat step 1 for a weak high channel as a compromise adjustment to favor the particular channel. Repeat step 2 for the weak low channel to favor the particular low channel. If a compromise adjustment is made, other channels operating in the service area should be checked to make certain that they have not been appreciably affected.



Full skirt of curve will not be visible unless generator sweep width extends beyond 12 MC.
Figure 23. RF Response Curve.

VHF FREQUENCY TABLE

Channel Number	Channel Freq., MC	Video Carrier, MC	Sound Carrier, MC	HF Osc., MC
2	54- 60	55.25	59.75	101
3	60- 66	61.25	65.75	107
4	66- 72	67.25	71.75	113
5	76- 82	77.25	81.75	123
6	82- 88	83.25	87.75	129
7	174-180	175.25	179.75	221
8	180-186	181.25	185.75	227
9	186-192	187.25	191.75	233

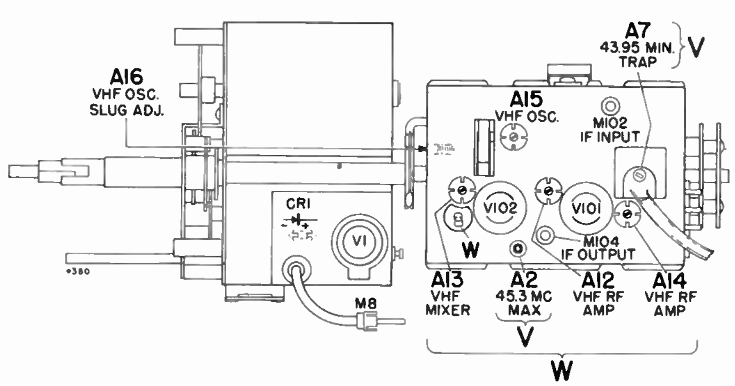

Figure 24. Top of Tuners, Showing VHF Adjustment Locations.

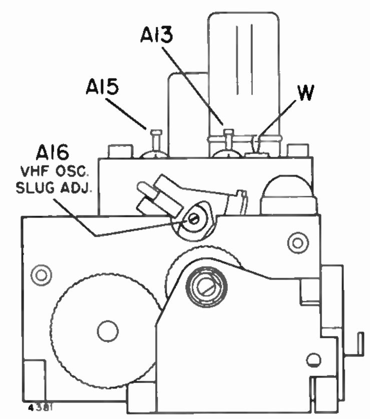

Figure 25. Front View of Tuners.

OVER-ALL VHF AND IF RESPONSE CURVE CHECK

Receiver Controls and Bias Battery	Sweep Generator	Marker Generator	Oscilloscope	Instructions
Contrast control fully to the left. Channel selector on nel selector on Channel 10 or other unassigned high channel. Connect negative of 4½ volt bias battery to test point "T", positive to chassis.	Connect to antenna terminals. Set generator to sweep VHF channel selected. See frequency table on page 23. Keep generator output as low as possible, to prevent overloading. See section 2 of "Alignment Hints."	If an external marker generator is used, loosely couple high side to sweep generator lead. VHF marker frequencies are shown in frequency table on page 23.	Connect to point "V" through a decoupling filter; see figs. 21 and 22.	Compare the response curve obtained against the ideal curve shown in figure 26. If the curve is not within tolerance, touch up the IF slug as instructed below. It should never be necessary to turn slugs more than one turn in either direction. If the curve is satisfactory on the channel checked, all other channels should also be satisfactory. IMPORTANT: When sweep output is reduced, response curve amplitude on scope should also decrease, but curve shape should remain the same. If curve shape changes, reduce sweep output and/or the scope gain until the shape does not change. See section 2 of "Alignment Hints."

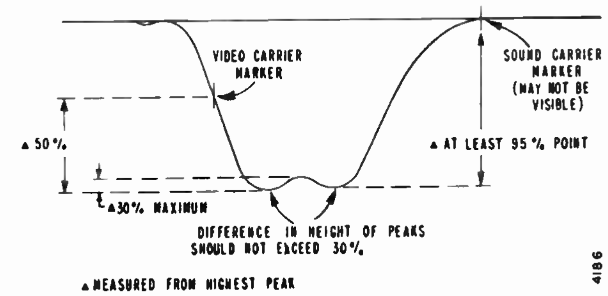

Figure 26. Ideal Over-all VHF and IF Response Curve.

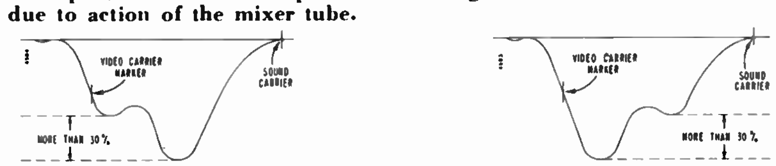
Note that video carrier (marker) on the "Over-all RF-IF Response Curve" will appear on the opposite side of the curve as compared to the "IF Response Curve" figure 18. This is due to action of the mixer tube.



Curves must have approximate equal peaks and correct marker location. If it is necessary to adjust for approximate equal peaks and marker location, carefully adjust slug A2 and if necessary adjust slug A3. It should not be necessary to turn the slugs more than one turn in either direction.
Figure 27. Over-all RF and IF Response Curves, Incorrect Shape.

VHF OSCILLATOR ADJUSTMENT

(Using a signal generator)

It is always advisable to make VHF oscillator adjustments using a Television Signal as instructed on page 8. If a Television Signal is not available, HF oscillator adjustment can be made using a crystal calibrated signal generator. Note that adjustment "A15" (figure 18) is an overall oscillator adjustment and should only be made when the mixer-oscillator tube is replaced. Generally "A15" adjusts with about 3/16" of screw thread exposed. Make adjustments as follows:

Receiver Control Settings	Signal Generator	Instructions
Set Channel selector for each channel to be adjusted. Set "Tuning" control at half rotation. Turn volume control fully to the right (clockwise).	Connect to antenna terminals. Set generator to exact frequency of VHF oscillator. See frequency table on page 23. *Set generator for maximum output.*	Connect a wire jumper from test point "W" on the tuner to test point "Z". See figure 22. Remove the ratio detector tube V202 (6AL5). Carefully adjust the oscillator slug A16 on each channel until a whistle (beat) is heard in the speaker of the receiver.

PARTS LIST

Electrical components have symbols in 100 series, 200 series, etc., according to location on schematic. Order parts by part number and description from Admiral Distributor.

IF PRE-AMPLIFIER RESPONSE CURVE CHECK AND ALIGNMENT

Important: This alignment is seldom required. It should be made only if UHF reception is poor and after usual causes of poor reception have been checked. This alignment should be made after completing preceding alignments.

a. Set VHF Channel selector at detent position midway between channels 5 and 6.

b. Connect negative of 4½ volt bias battery to AGC buss (test point "T"), positive to chassis.

c. Remove CR1 (mixer crystal) from holder. Connect sweep generator high side through 100 ohm resistor to negative clip of mixer crystal socket, see figure 24. If sweep generator does not have a built-in marker generator, loosely couple a marker generator to the high side of sweep generator. To avoid distortion of the response curve, keep sweep generator output at a minimum, marker pips just barely visible.

d. Connect oscilloscope through a 10,000 ohm resistor to test point "W" on tuner (figure 29). Keep scope leads away from chassis.

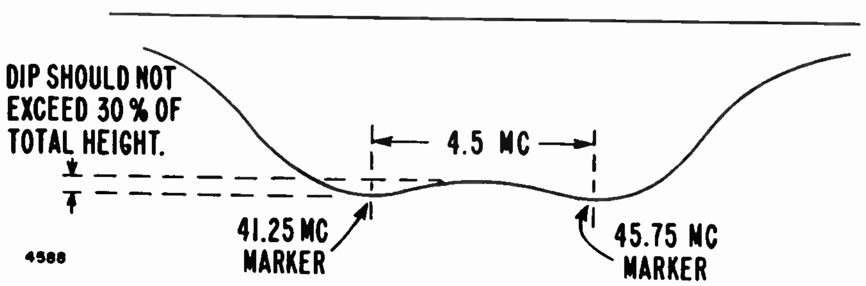
e. Allow about 15 minutes for receiver and test equipment to warm up.

f. Use a non-metallic alignment tool. If hollow core slugs are used, use alignment tool, part number 98A30-14.

Step	Marker Gen. Freq. (MC)	Sweep Gen. Frequency	Instructions
*1	45.75 MC (Video Carrier) 41.25 MC (Sound Carrier)	Set sweep at 43.5 MC, sweep width 12 MC.	Adjust A17 to obtain maximum amplitude at center of curve. Alternately adjust A18 and A19 (figure 29) as required to obtain equal peak amplitudes and symmetry, consistent with flat top appearance, proper band width and correct marker location; see figure 28.
2	If curve cannot be made to resemble response curve, figure 28, check to be sure all instructions have been followed. Check tubes V101 and V102 and repeat alignment. Important: After replacing tubes, it may be necessary to check "VHF Tuner RF And Mixer Alignment".		

* **Before proceeding, detune slug A2 exactly 3 turns counter-clockwise. After completing this alignment, return slug A2 to its original setting by turning it exactly 3 turns clockwise.**

Caution: Use extreme care to avoid damage to coils or slugs.



Full skirt of curve will not be visible unless generator sweep width extends beyond 12 MC.

Figure 28. IF Pre-amplifier Response Curve.

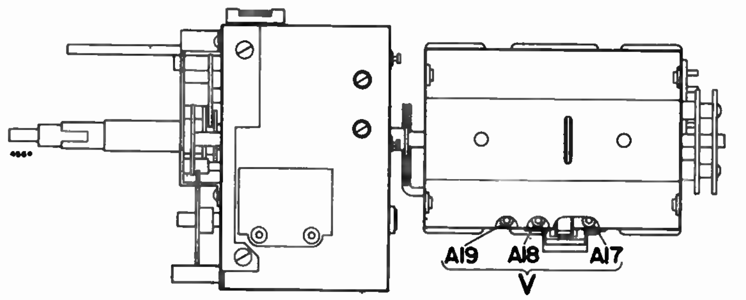


Figure 29. Bottom View of Tuners Showing IF Pre-amplifier Adjustments.

RESISTORS

§ May be part of couplate, part number 63C6-8. Replace with exact part or individual components.

Schematic for 19L2 and 19L2Z VHF-UHF Television Chassis.

TV VOLTAGE DATA
(Voltages given on schematic)

- CONTRAST control turned fully clockwise. LOW-CHANNEL selector set on an unused VHF channel. HIGH CHANNEL selector in the "VHF" position. Other front controls set at approximately half rotation. Vert. Lin. and Height set at approximately half rotation. DX Range Finder control set fully to the left (at "0" position).
- VHF antenna disconnected from set with terminal shorted.
- Line voltage 117 volts AC.
- Voltages measured with a vacuum-tube voltmeter between tube socket terminals and chassis, unless otherwise indicated.
- Voltages at V101 and V102 (VHF Tuner) are measured with tube in socket. Use an adapter or lift tube out of socket just high enough to allow a needle point probe to contact tube pins.
  Voltages at pins 1 and 8 of V101 (6BZ7) must be taken as described above or no voltage reading will be obtained.
- Voltages at V306 measured from top of socket with tube removed.
- B+ voltage at terminal of VHF-UHF switch taken with tuner in UHF position.
- Voltages marked with an asterisk (*) will vary widely with control setting.

SCHEMATIC NOTES

Run numbers are rubber stamped at the rear of the chassis.

(A1), (A2),......(Y), (Z), etc. indicate alignment points and alignment connections.

IMPORTANT: Before making waveform and voltage measurements, see instructions

WAVEFORM DATA
(Waveforms given on schematic)

Waveforms taken with CONTRAST control set fully to the right, all other controls set for normal picture (in sync). DX Range Finder control set fully to the left (at "0" position). Warning: Incorrect adjustment of the DX Range Finder control will cause waveform distortion.

Waveforms at video and sync stages obtained with transmitted signal input to receiver.

Waveform at pins 1 and 4 of V403 and terminal "C" (2) of T404 taken with a 10 mmfd. capacitor connected in series with the oscilloscope high side.

The oscilloscope sweep is adjusted for 30 cycles (which is one-half of the vertical frequency), or for 7875 cycles (which is one-half of the horizontal frequency) so that two pulses appear on the screen.

The peak-to-peak voltage readings shown are subject to some variations due to response of the oscilloscope and parts tolerances.

WAVEFORM DATA
(Waveforms given on schematic)

Waveforms taken with **Contrast** control set fully to the right, all other controls set for normal picture (in sync). **DX Range Finder** control set fully to the left (at "0" position). Warning: Incorrect adjustment of the **DX Range Finder** control will cause waveform distortion.

Waveforms at video and sync stages obtained with transmitted signal input to receiver.

Waveform at pins 1 and 4 of V403 and terminal "C" (2) of T404 taken with a 10 mmfd. capacitor connected in series with the oscilloscope high side.

The oscilloscope sweep is adjusted for 30 cycles (which is one-half of the vertical frequency), or for 7875 cycles (which is one-half of the horizontal frequency) so that two pulses appear on the screen.

The peak-to-peak voltage readings shown are subject to some variations due to response of the oscilloscope and parts tolerances.

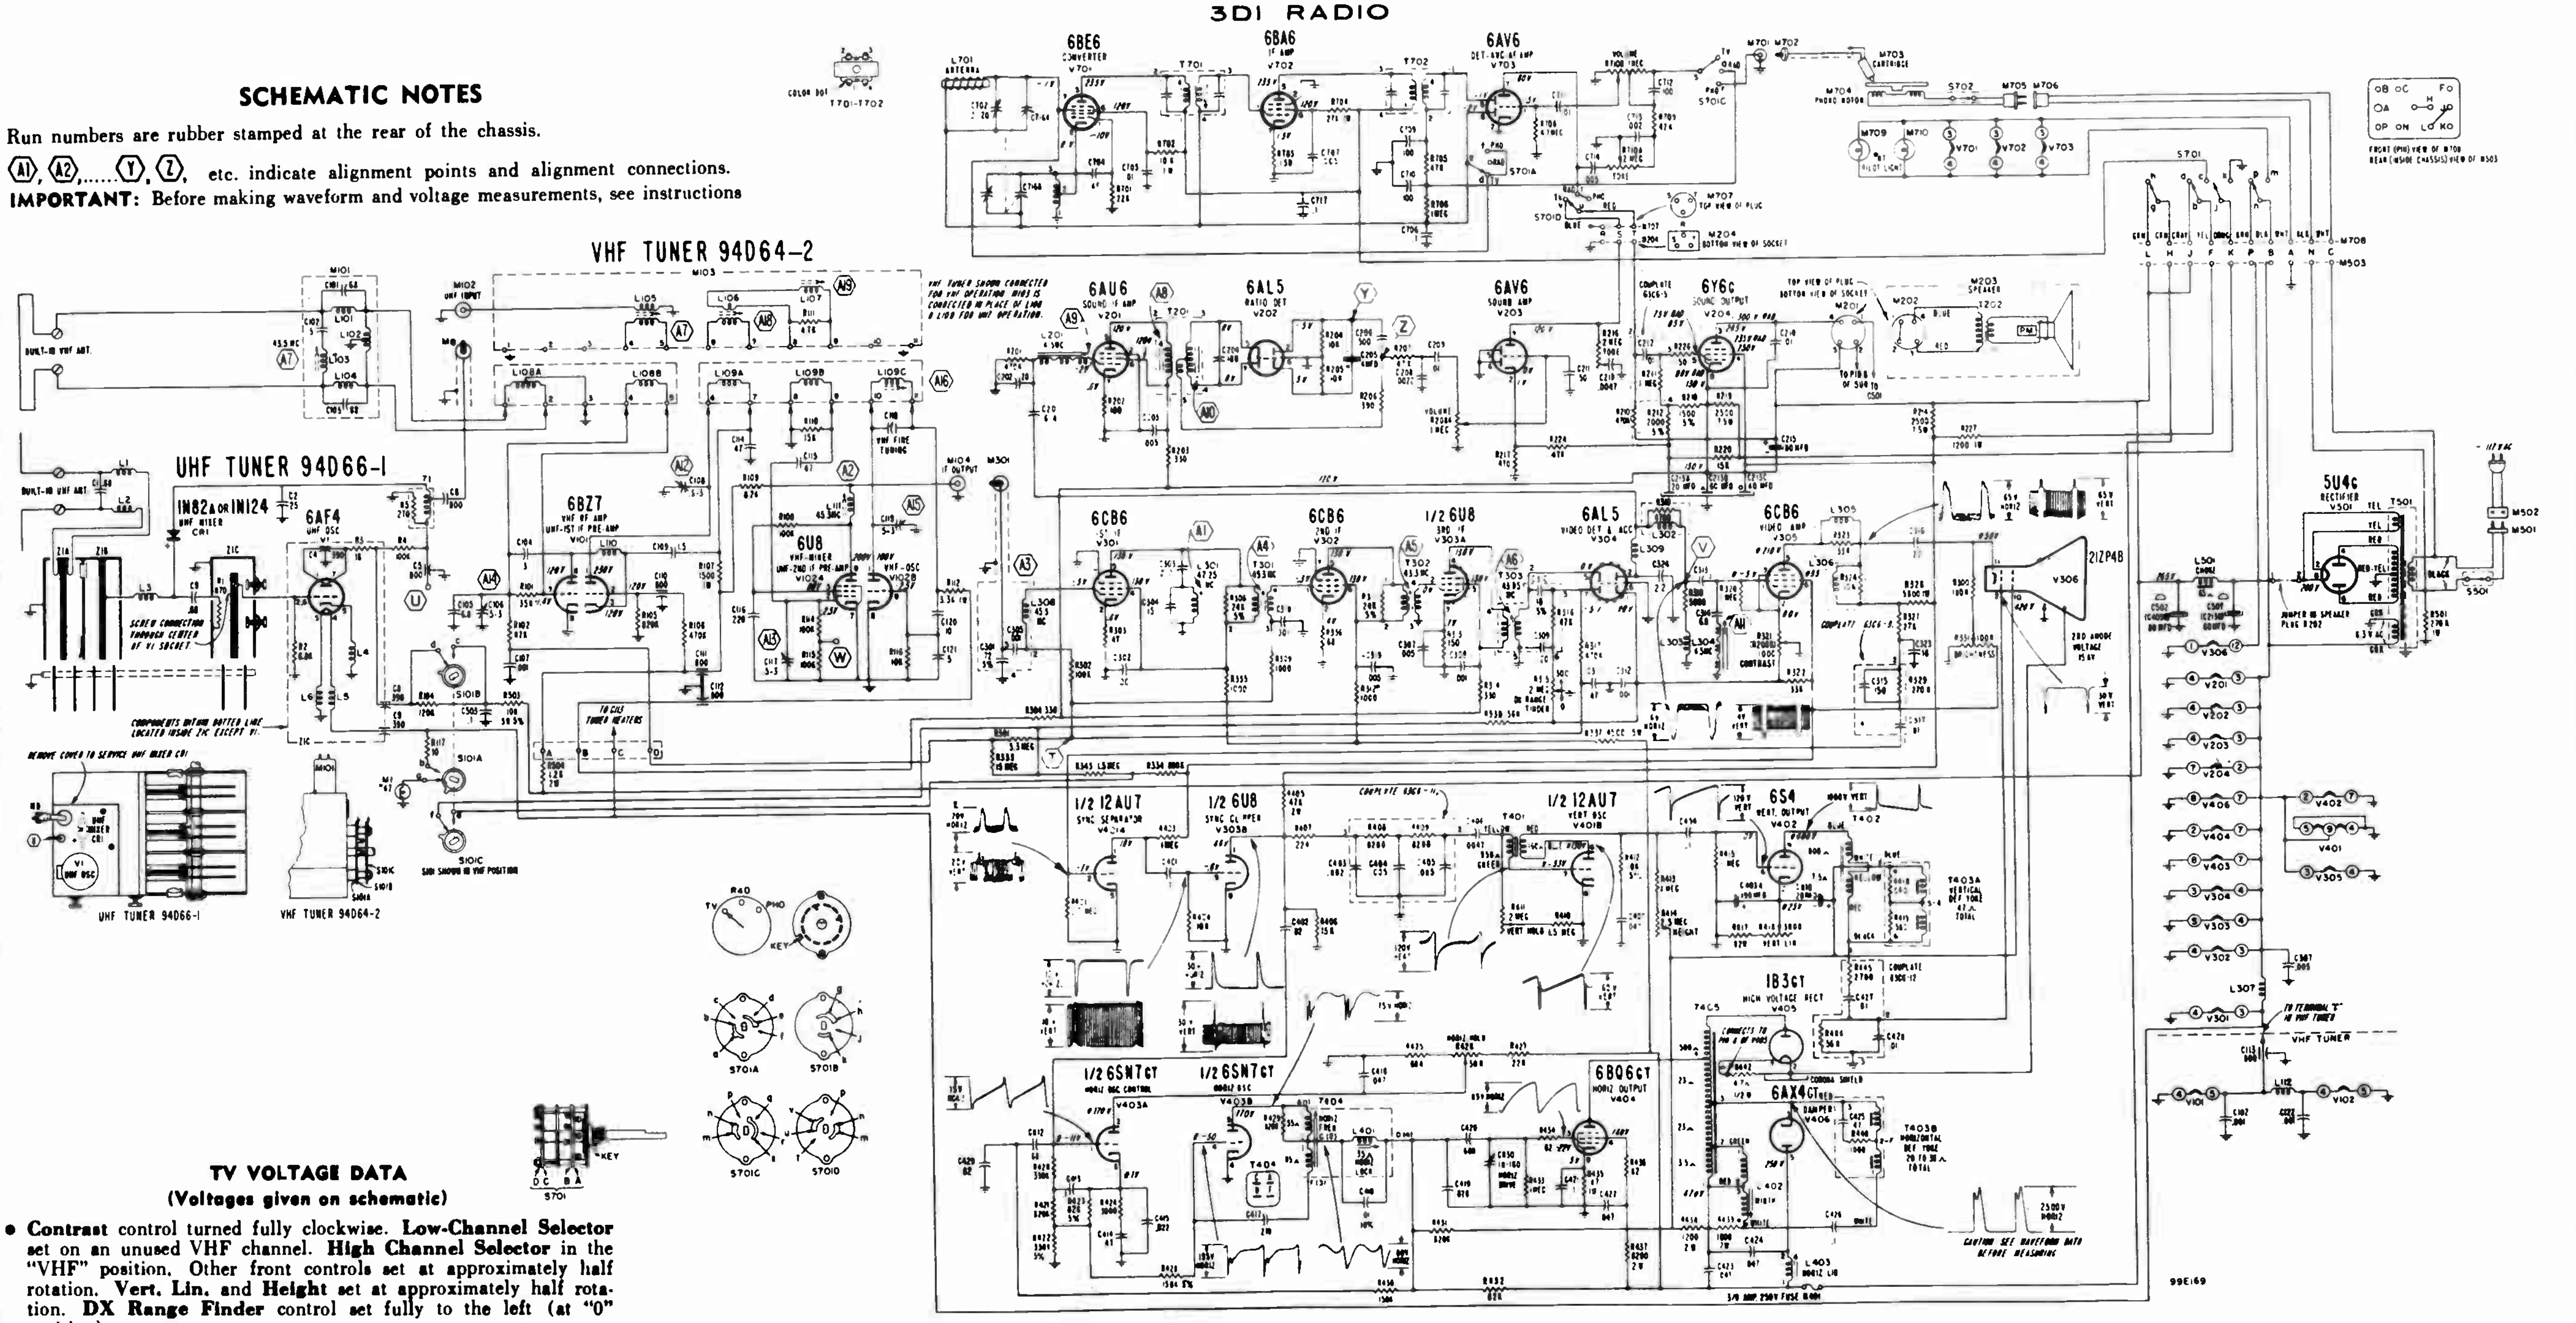
Schematic for 19N2Z VHF-UHF Television Chassis and 3D1 Radio.

SCHEMATIC NOTES

Run numbers are rubber stamped at the rear of the chassis.

(A1), (A2),......(Y), (Z), etc. indicate alignment points and alignment connections.

IMPORTANT: Before making waveform and voltage measurements, see instructions



TV VOLTAGE DATA

(Voltages given on schematic)

- **Contrast** control turned fully clockwise. **Low-Channel Selector** set on an unused VHF channel. **High Channel Selector** in the "VHF" position. Other front controls set at approximately half rotation. **Vert. Lin.** and **Height** set at approximately half rotation. **DX Range Finder** control set fully to the left (at "0" position).
- VHF Antenna disconnected from set with terminal shorted.
- Line voltage 117 volts AC.
- Voltages measured with a vacuum-tube voltmeter between tube socket terminals and chassis, unless otherwise indicated.
- Voltages at V101 and V102 (VHF Tuner) are measured with tube in socket. Use an adapter or lift tube out of socket just high enough to allow a needle point probe to contact tube pins. Voltages at pins 1 and 8 of V101 (6BZ7) must be taken as described above or no voltage reading will be obtained.
- Voltages at V306 measured from top of socket with tube removed.
- B+ voltage at terminal of VHF-UHF switch taken with tuner in UHF position.
- Voltages marked with an asterisk (*) will vary widely with control setting. In combination models, B+ voltages in TV chassis will be slightly higher when set is switched to radio position. Alternate voltage readings for radio and TV are shown for sound output tube V204 (6Y6G).

CAUTION

Pulsed high voltages are present on the cap of V404, pin 3 of V406 and on the filament terminals and cap of the 1B3GT tube. NO ATTEMPT SHOULD BE MADE TO TAKE MEASUREMENTS FROM THESE POINTS WITHOUT SUITABLE TEST EQUIPMENT.

Picture tube 2nd anode voltage can be measured from the 2nd anode connector and should be taken only with a high voltage instrument such as a kilovoltmeter or a vacuum-tube voltmeter with a high voltage probe. 2nd anode voltage is approximately 15 KV. Proper filament voltage check of the 1B3GT tube may be made by observing filament brilliancy as compared with that obtained with a 1.5 volt dry cell battery.

WAVEFORM DATA

(Waveforms given on schematic)

Waveforms taken with **Contrast** control set fully to the right, all other controls set for normal picture (in sync). **DX Range Finder** control set fully to the left (at "0" position). Warning: Incorrect adjustment of the **DX Range Finder** control will cause waveform distortion.

Waveforms at video and sync stages obtained, with transmitted signal input to receiver.

Waveform at pins 1 and 4 of V403 and terminal "C" (2) of T404 taken with a 10 mmfd. capacitor connected in series with the oscilloscope high side.

The oscilloscope sweep is adjusted for 30 cycles (which is one-half of the vertical frequency), or for 7875 cycles (which is one-half of the horizontal frequency) so that two pulses appear on the screen.

The peak-to-peak voltage readings shown are subject to some variations due to response of the oscilloscope and parts tolerances.

Pulsed high voltages are present on the caps of V404, V405 and at pin 3 of V406. Do not make direct connection to these points with ordinary test equipment. Waveform and peak-to-peak voltage taken at pin 3 of V406, using an oscilloscope with a capacitive voltage divider probe. Waveform at V406 can also be taken by clipping or twisting the lead from the oscilloscope high side over the insulation on the lead connecting to pin 3. When taking the waveform this way, the shape of waveform will be the same but the peak-to-peak voltage will be much lower depending upon the degree of coupling.

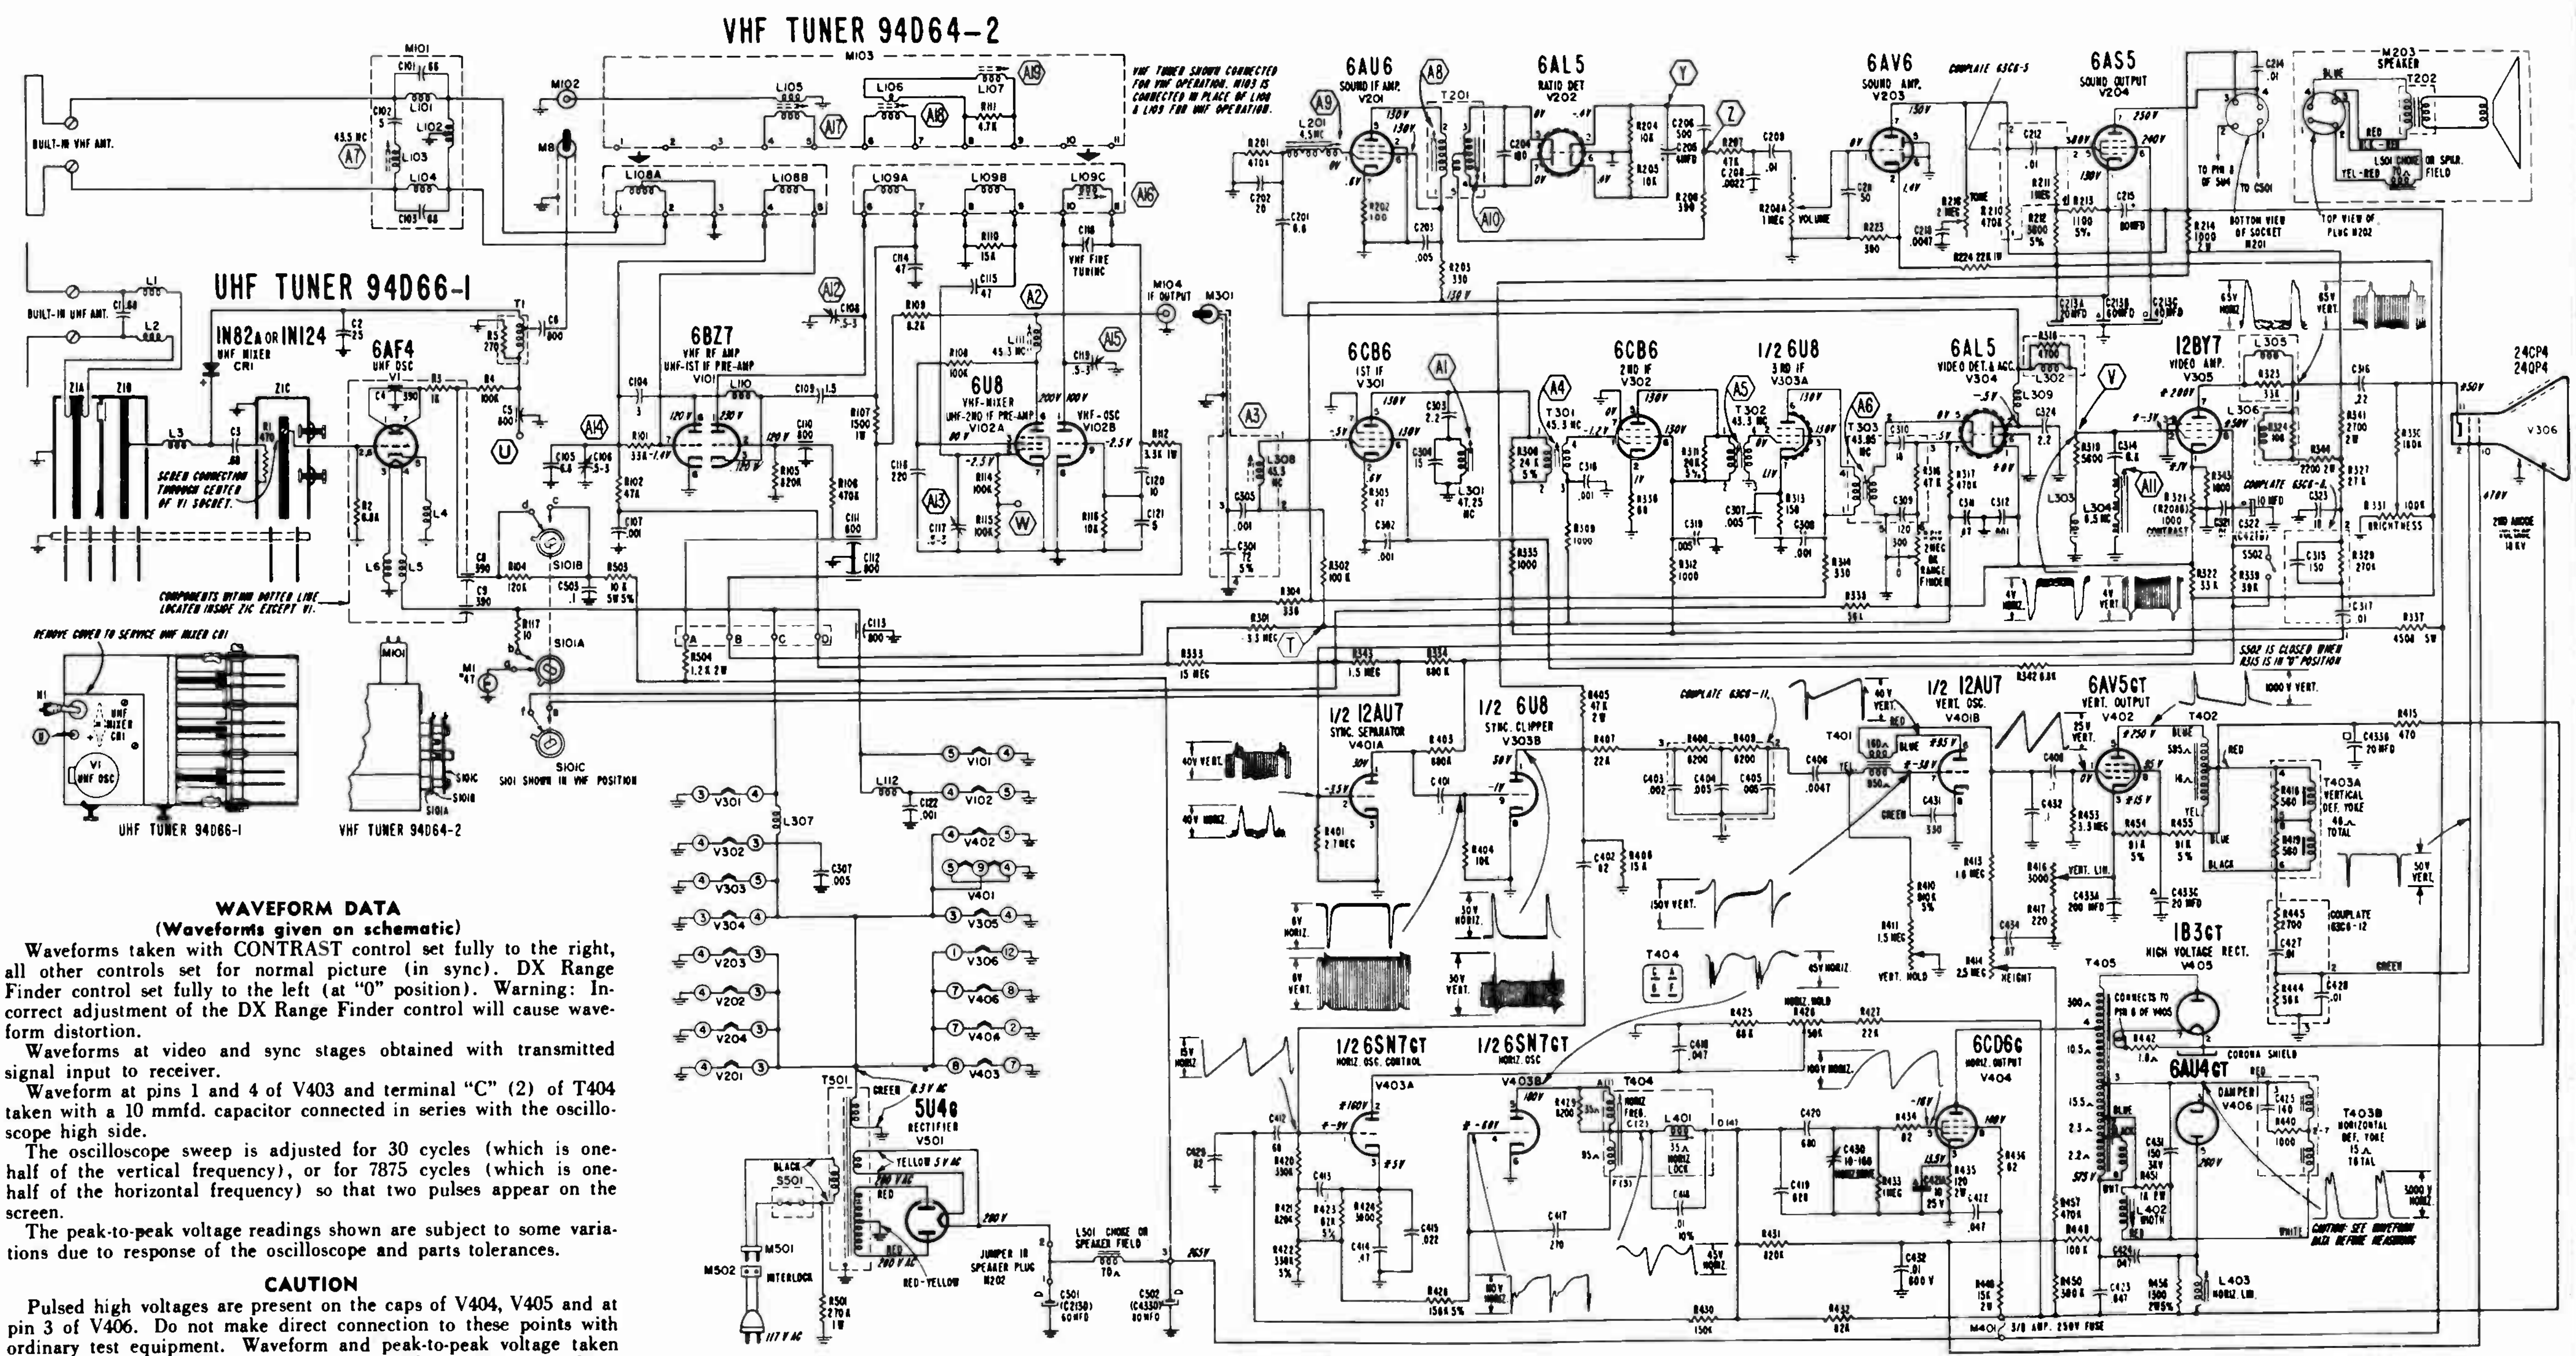
SCHEMATIC NOTES

Run numbers are rubber stamped at the rear of the chassis.

(A1), (A2),......(Y), (Z), etc. indicate alignment points and alignment connections.

IMPORTANT: Before making waveform and voltage measurements, see instructions

Schematic for 19R2 VHF-UHF Television Chassis.



WAVEFORM DATA
(Waveforms given on schematic)

Waveforms taken with CONTRAST control set fully to the right, all other controls set for normal picture (in sync). DX Range Finder control set fully to the left (at "0" position). Warning: Incorrect adjustment of the DX Range Finder control will cause waveform distortion.

Waveforms at video and sync stages obtained with transmitted signal input to receiver.

V10	6AU6	AGC Amp.	V20	6X8	Tuner Mixer Oscillator
V11	6BY6	Sync Separator	V21	6AF4	UHF Oscillator

WARNING

One side of the a-c line is connected to the chassis through C5 and L405. The other side of the a-c line is connected to the chassis through R420, SR 1, and C1A in series. Grounding the chassis will result in a short circuit across one or the other of these two branches in the voltage-doubler circuit. During servicing and alignment it is desirable that an a-c line isolation transformer capable of handling at least 300 watts be used. Failure to use an isolation transformer will greatly increase the shock hazard, and may result in damage to the test equipment or receiver, or both.

BUZZ CONTROL

This control (R104) is provided to adjust the AM rejection characteristics of the sound system (sync buzz, noise, or hiss). Since this control has been adjusted for an optimum setting at the factory, do not attempt to alter this adjustment unless sync buzz, noise, or hiss is present. Caution: Turn this control slowly from the present preset position---usually not more than 30 degrees rotation in either direction will be necessary.

YOKE ADJUSTMENT

The picture tube cone should fit snugly into the large front hole rimmed in rubber in the Yoke Mount Frame.
The Yoke Radial Adjustment (top wingscrew) allows the yoke to be rotated right or left--rotating the picture right or left.

The Yoke Vertical Adjustment (2 hex head screws each side) allows centering of the yoke coaxially with the tube neck. Proper positioning of the yoke is important so that picture corner-cutting and side-shadows can be readily removed by the centering control.

WIDTH AND HORIZONTAL LINEARITY

These controls (L404 and L403) are adjusted by clips which slide in vertical slots located on the right of the rear flange of the chassis. They should be adjusted simultaneously to provide good width and linearity with the picture extending approximately 1/4" beyond the edges of the mask.

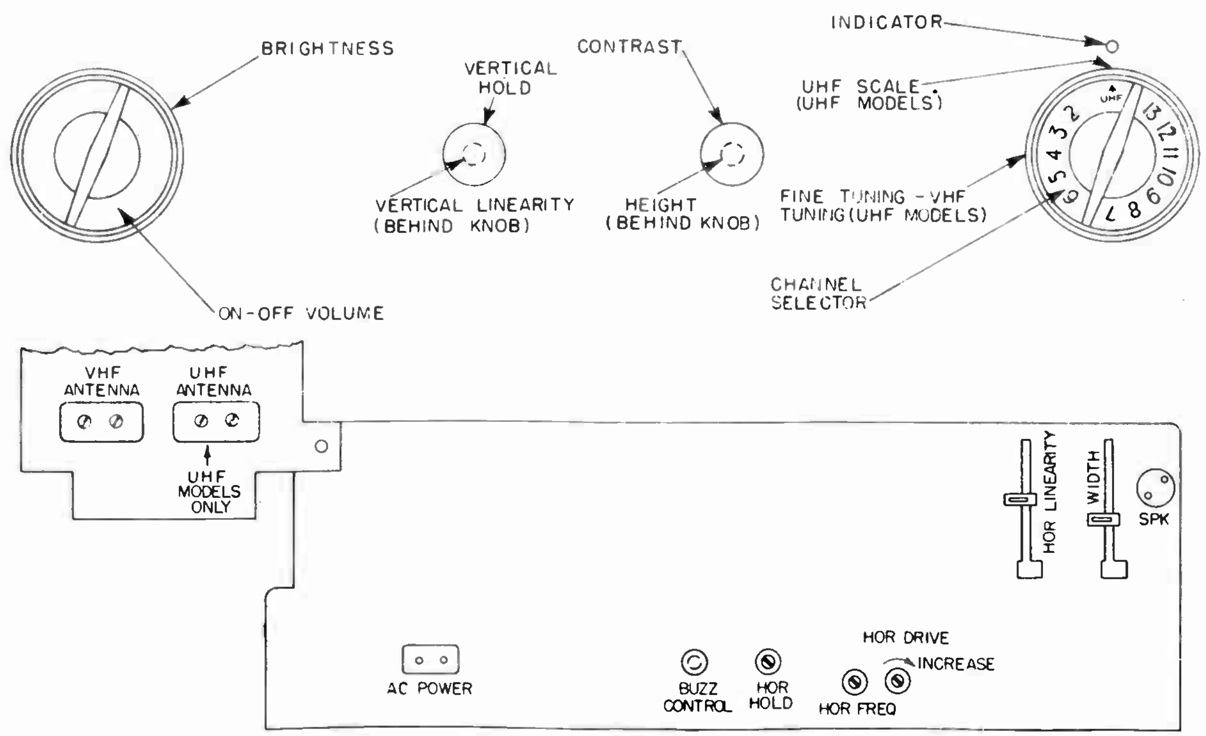
HORIZONTAL DRIVE

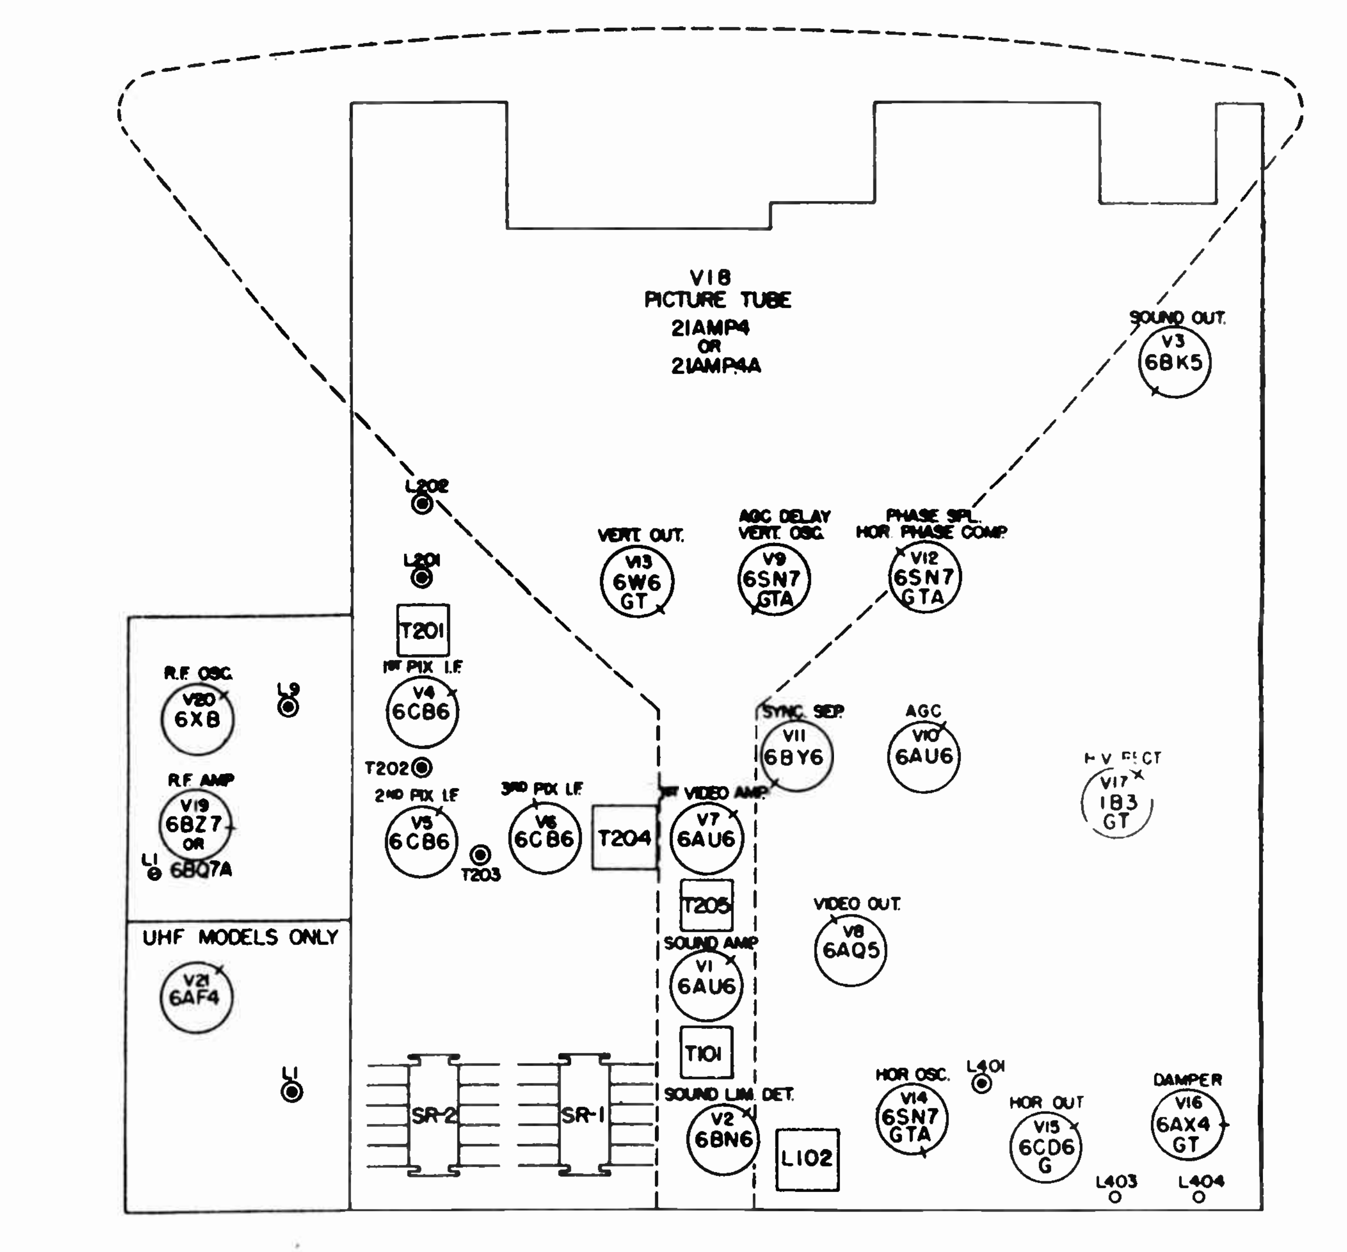
Adjust the Horizontal Drive Trimmer (C410B) to the point where "overdrive" lines (vertical white line near the center of the picture) just disappear. Turning this control to the right increases the Horizontal Drive.

HORIZONTAL FREQUENCY

Adjust the Horizontal Hold control to the center of its range. Adjust the Horizontal frequency trimmer (C410A) until picture will break sync at both ends of the Horizontal Hold range. When components are replaced the following procedure is to be used.

1. Short out horizontal lock lock coil (L401) and set the Horizontal hold control to the center of its range.
2. Adjust the horizontal frequency trimmer (C410A) for zero volts on the grid (pin 4 of V14) of the horizontal oscillator.
3. Remove the short from the Horizontal lock coil (L401) and adjust this coil for zero volts on the grid (pin 4 of V14) of the horizontal oscillator.





STAGGER-TUNED I.F. ALIGNMENT PROCEDURE

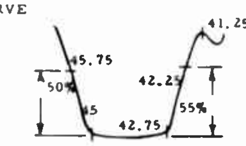
1. Set tuner to channel 9-10 or 11.
2. Pull AGC tube V10 out
3. Connect variable bias supply to junction R304 & R306. Adjust bias for -2 volts junction R202 & R205.
4. Connect VTVM across R212. Isolate VTVM with 18K resistor. Use -5V scale.
5. Connect RF signal generator to mixer tube shield (V20 6X8). Lift mixer tube shield until it is just ungrounded.
6. Good R.F. grounding between TV receiver on test and test equipment is necessary. A metal surface bench top should be used to insure proper RF grounding.

STEP	FREQUENCY	ADJUSTMENT	INSTRUCTIONS
1.	39.75 mc	Top L202 for min.	
2.	47.25 mc.	Top L201 for min.	Outer peak
3.	41.25mc.	Top T201 for min.	Outer peak
4.	42.9 mc.	Tuner coil for max.	
5.	45.2 mc.	Bottom T201 for max.	Outer peak--recheck steps 4 and 5.
6.	42.1 mc.	Top T202 for max.	Outer peak
7.	45.7 mc.	Top T203 for max.	Outer peak
8.	44.1 mc.	Bottom T204 for max.	Recheck steps 6, 7 and 8

OVERALL SWEEP CHECK

1. Connect RF signal generator to chassis near V4 for marker generator. Push shield down on mixer tube.
2. Connect oscilloscope across R212. Isolate oscilloscope lead with 300 μμf to ground and 18K resistor in series.
   To chassis ← 18K — To scope; 300 μμf to ground
3. Increase bias to -3.5 volts at junction R202 & R205.
4. Connect sweep generator to antenna terminals. Adjust sweep generator & tuner to channel 10.

CURVE



ADJUSTMENT	INSTRUCTIONS
T203	T203 positions 45.75 marker
T202	T202 positions 42.25
T204	T204 adjusts tilt of curve

Note: If desired curve cannot be obtained, slight adjustment of tu r coil and bottom T201 may be necessary.

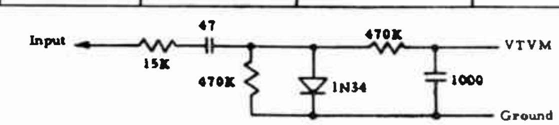
SOUND AND 4.5 MC TRAP ALIGNMENT

1. Tune in available TV station and reduce signal into set until hiss is heard with sound. This can be done by inserting an attenuator in the antenna lead-in or by removing antenna lead-in from the set and stray feeding in signal by placing lead-in in close proximity of the set.
2. Set buzz control in the middle of its range. Adjust take off coil (top T205), top and bottom T101, Quadrature coil (L102) and buzz control for cleanest sound and minimum buzz. If any adjustment cause hiss to disappear reduce signal into set until hiss reappears and continue with adjustments.

Note: If difficulty is encountered either in reducing signal sufficiently or adjustments being very broad. The following proceedu e may be used.

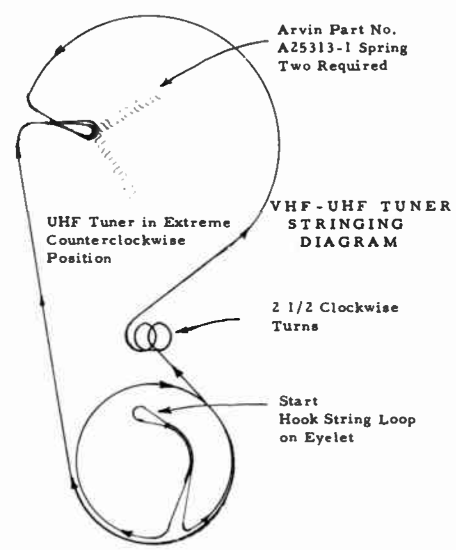
STEP	EQUIPMENT	CONNECTION	FREQUENCY	ADJUSTMENT	INSTRUCTIONS
1.	Det. jig *	Input of jig to pin 2 of V2			Keep lead between 15K resistor and pin 2 as short as possible
2.	VTVM	Output of jig	Tune in available channel	T205 Top (only), T101 (top and bottom) for max.	
3.		Remove jig	Same	Quadrature coil (L102) for max. sound	Set buzz control in middle of its range before adjusting L102
4.			Same	Buzz control for minimum buzz	Correct adjustment of buzz control is approx. middle of its range
5.	Det. jig *	Junction C321 and R333			Connect VTVM to output of jig
6.	RF signal generator	Pin 1 (V7)	4.5 mc	Tune 4.5 mc trap Bottom T205 for min.	

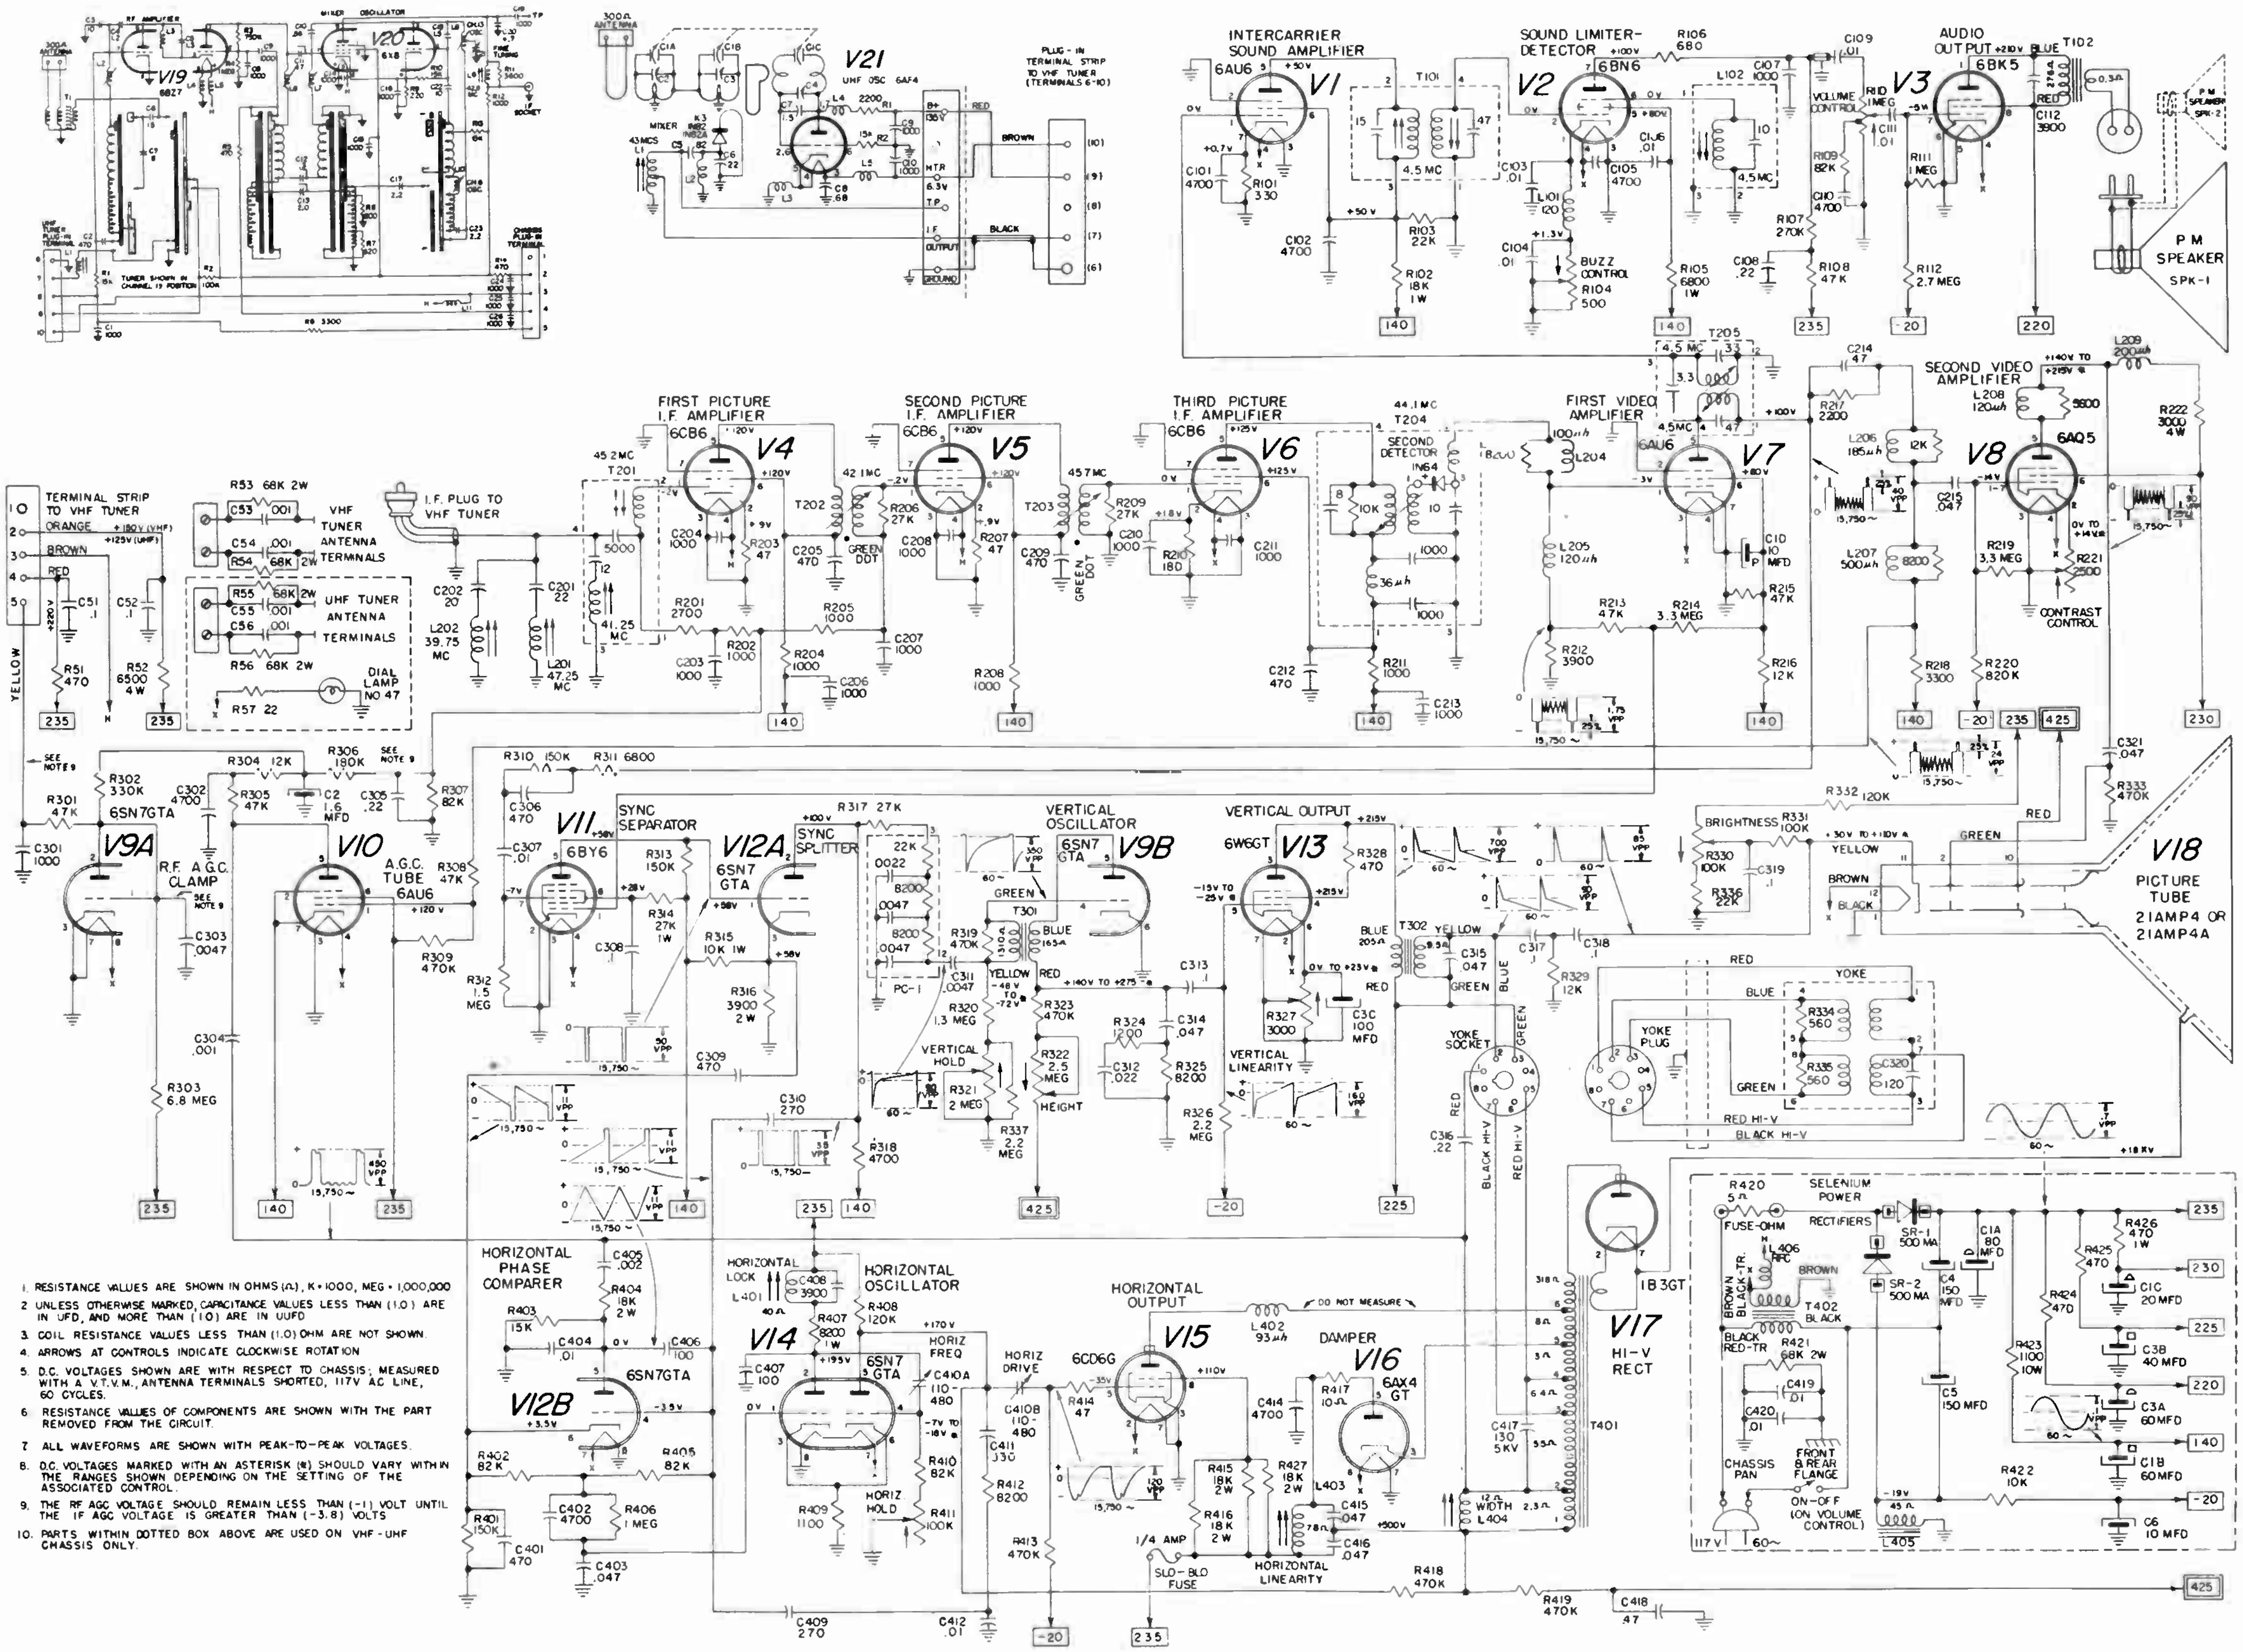
*Detector jig



TUBE FAILURE CHECK LIST

SYMPTOM	CHANGE TUBE
No picture--no sound--lighted screen	(UHF V21) V4, 5, 6, 7, 8, 19, 20
No sound--picture O.K.	V1, 2, 3
No picture--sound O.K. - no light on screen	V14, 15, 16, 17, 18
No picture--sound O.K.--one horizontal line on screen	V9, 13
No horizontal or vertical sychronization--sound O.K.	V11, 12
Picture weak, tears on strong signal	V10





1. RESISTANCE VALUES ARE SHOWN IN OHMS (Ω), K = 1000, MEG = 1,000,000
2. UNLESS OTHERWISE MARKED, CAPACITANCE VALUES LESS THAN (1.0) ARE IN UFD, AND MORE THAN (1.0) ARE IN UUFD
3. COIL RESISTANCE VALUES LESS THAN (1.0) OHM ARE NOT SHOWN.
4. ARROWS AT CONTROLS INDICATE CLOCKWISE ROTATION
5. D.C. VOLTAGES SHOWN ARE WITH RESPECT TO CHASSIS; MEASURED WITH A V.T.V.M., ANTENNA TERMINALS SHORTED, 117V AC LINE, 60 CYCLES.
6. RESISTANCE VALUES OF COMPONENTS ARE SHOWN WITH THE PART REMOVED FROM THE CIRCUIT.
7. ALL WAVEFORMS ARE SHOWN WITH PEAK-TO-PEAK VOLTAGES.
8. D.C. VOLTAGES MARKED WITH AN ASTERISK (*) SHOULD VARY WITHIN THE RANGES SHOWN DEPENDING ON THE SETTING OF THE ASSOCIATED CONTROL.
9. THE RF AGC VOLTAGE SHOULD REMAIN LESS THAN (-1) VOLT UNTIL THE IF AGC VOLTAGE IS GREATER THAN (-3.8) VOLTS
10. PARTS WITHIN DOTTED BOX ABOVE ARE USED ON VHF-UHF CHASSIS ONLY.

HOW TO ORDER PARTS

Replacement parts should be ordered by Arvin part number, description and model number of receiver from your Arvin Distributor. The Distributor will order direct from the factory. All prices subject to change with out notice. Parts shipments are F.O.B. Columbus, Indiana.

	41766-1	Tuner Assy. UHF
	42167	Tuner Assy. VHF
	42550-1	Focus Unit----PM Magnet
PC-1	24166	Printed Circuit (Vert. Int.)
	42158	Fuse .25 A Bussman MDV 1/4A, 250V.

SPECIFICATIONS

Power Supply	125 watts, 105-120 volts
Audio Power Rating	1.4 watts maximum 1.1 watts undistorted
Antenna Input Impedance	300 ohms
Video Response	3.3 MC
Focus	Electrostatic
Deflection	70 Magnetic
Picture Carrier	45.75 MC
Sound Carrier	41.25 MC

WARNING

One side of the AC line is connected directly to the metal chassis. During servicing and alignment an AC isolation transformer (150 watts or more) must be used to decrease the shock hazard and to prevent damage to the test equipment, receiver or both. The control mounting panel and the metal cabinet (Model 21-555) are isolated from the chassis by a 220K resistor and an .01 µf capacitor. A slight "shock" may be felt between earth ground an any of the screws at the rear of the cabinet. This "shock" is not dangerous as the current is limited by the isolation components. Care must be taken to prevent anything from shorting the control mounting panel or the cabinet to the chassis.

HEIGHT AND VERTICAL LINEARITY

These controls (R312 and R318) are a accessible only when the rear cover is removed. They should be adjusted simultaneously for proper height consistant with good vertical linearity. The picture should extend approximately 1/4" beyond the edges of the mask.

BUZZ CONTROL

This control (R103) is provided to adjust the AM rejection characteristics of the sound system (sync buzz, noise, or hiss). Since this control has been adjusted for an optimum setting at the factory, do not attempt to alter this adjustment unless sync buzz, noise, or hiss is present. Caution: Turn this control slowly from the present preset position---usually not more than 30 degrees rotation in either direction will be necessary.

YOKE ADJUSTMENT

The picture tube cone should fit snugly into the large front hole rimmed in rubber in the Yoke Mount Frame.

The Yoke Radial Adjustment (top wingscrew) allows the yoke to be rotated right or left--rotating the picture right or left.

The Yoke Vertical Adjustment (2 hex head screws each side) allows centering of the yoke coaxially with the tube neck. Proper positioning of the yoke is important so that picture corner-cutting and side -shadows can be readily removed by the centering control.

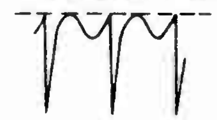
HORIZONTAL OSCILLATOR ADJUSTMENT

1. Adjust horizontal hold control (R404) maximum clockwise and connect a jumper from terminals C to D of Horizontal Oscillator transformer (T401).

2. Adjust top of T401 to get picture in Horizontal sync.

3. Remove jumper from terminals C to D and connect oscilloscope (lead isolated with 10K ohms) to terminal C of T401.

4. With picture in sync (it may be necessary to readjust top of T401) adjust bottom of T401 for curve with equal peaks as shown below.



(Make all adjustments at 117 volts AC line voltage)

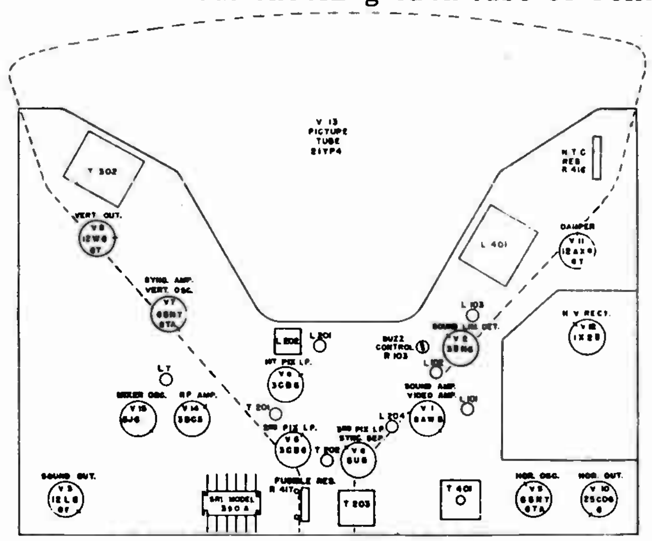
5. Remove oscilloscope. Readjust top of T401 so picture will break horizontal sync with 2 diagonal bars when hold control is turned to max. clockwise position.

TUBE FAULTS

It is possible to quickly locate a tube with a burned out filament by using a procedure such as this.

1. Remove the back and connect an ohm meter from one side of the fusing resistor to the chassis ground. An open circuit indicates a burned out filament.
2. Remove V1 (6AW8) and check continuity from pin 4 (counterclockwise from top of chassis) to fusing resistor. An open circuit here indicates an open filament V2, V7, V8, V9, V10, V11 or NTC resistor R418.
3. V3 can then be removed to find wheather the open filament is in the string consisting of V9, V10, V11 or NTC resistor R418 or in the string consisting of V3, V8, V7 or V2.

Thus the tube with an open filament can be singled out using a system such as this with out checking each tube or removing the complete chassis.



TUBE LAYOUT

DISASSEMBLY INSTRUCTIONS

1. Remove back which includes the AC line cord. Note: two screws must be removed from the bottom of each rear corner to release the back on model 21-555.
2. Unsolder red and green-white yoke leads from the terminal strip on the high voltage housing. Unsolder green and yellow vertical output transformer leads from the terminal strip on the left side of the yoke housing.

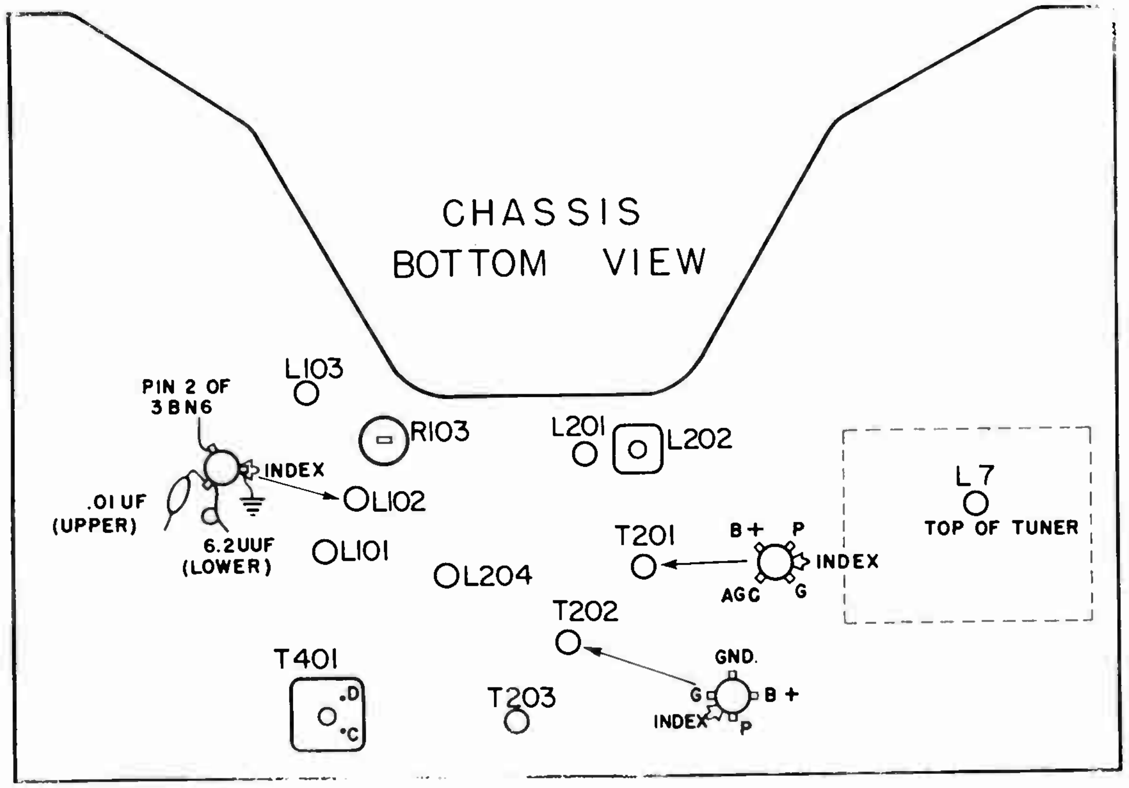
3. Remove screw holding ground strap from high voltage housing and unsolder speaker leads.

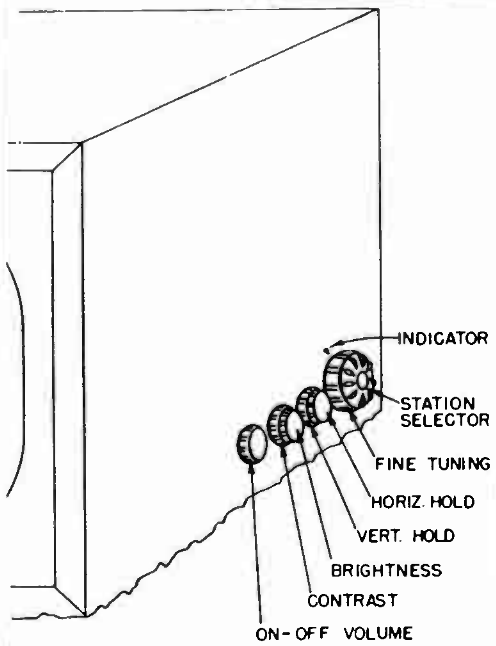
4. Pull off knobs. Loosen the three screws that hold the slotted tuner mounting bracket to the chassis and slide the tuner assembly to the right. This allows the shaft to clear the cabinet when the chassis is pulled to the rear.

5. Remove the five copper colored screws from the bottom. This allows the chassis to be removed.

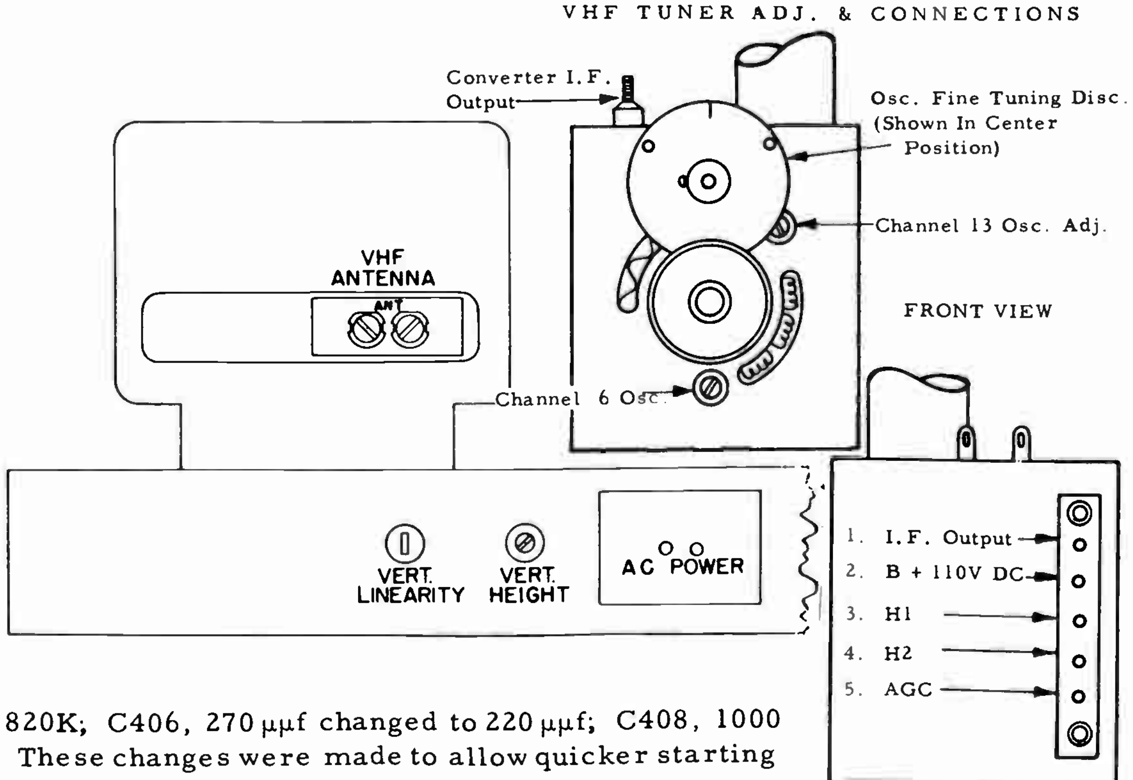
6. The cover on the high voltage housing may be removed by taking out two screws, sliding the cover to the rear and pulling the rear edge of the cover to the left. The high voltage housing may be removed by taking out four screws holding it to the chassis.

7. The second detector (1N64 part of T203) may be uncovered by removing two screws and lifting the transformer housing from the top of the chassis.





VHF TUNER ADJ. & CONNECTIONS



REAR VIEW

PRODUCTION CHANGES

1. R401, 1 meg changed to 820K; C406, 270 μμf changed to 220 μμf; C408, 1000 μμf changed to 1200 μμf. These changes were made to allow quicker starting of the horizontal oscillator.
2. C417, 4700 μμf; C418, 22 μμf, 3KV and L403, 10 μh added in damper circuit to improve the sync stability.
3. R330, 470K added above HEIGHT CONTROL.

NOTE: On early schematics horizontal deflection yoke connections were incorrectly numbered.

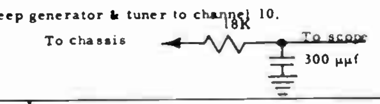
STAGGER-TUNED I.F. ALIGNMENT PROCEDURE

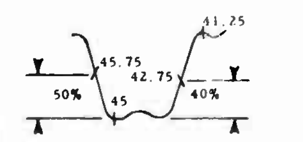
1. Set tuner to channel 9-10 or 11.
2. Connect variable bias supply to junction R211 & C207. Adjust bias for -2 volts.
3. Connect VTVM across R212. Isolate VTVM with 18K resistor. Use -5V scale.
4. Connect RF signal generator to mixer tube shield (V15 5J6). Lift mixer tube shield until it is just ungrounded.
5. Good R.F. grounding between TV receiver on test and test equipment is necessary. A metal surface bench top should be used to insure proper RF grounding. Use isolation transformer between chassis and AC line.

STEP	FREQUENCY	ADJUSTMENT	INSTRUCTIONS
1.	41.25 Mc	L201 for min.	
2.	42.9 Mc	Tuner coil for max.	L7 (top of tuner)
3.	45 Mc	L202 for max.	Recheck steps 2 and 3
4.	42.9 Mc	T201 for max.	
5.	45.3 Mc	T202 for max.	
6.	44 Mc	T203 for max.	
			Recheck steps 4, 5 and 6

OVERALL SWEEP CHECK

1. Connect RF signal generator to chassis near V4 for marker generator. Push shield down on mixer tube.
2. Connect oscilloscope across R212. Isolate oscilloscope lead with 300 μμf to ground and 18K resistor in series.
3. Increase bias to -2.5 volts
4. Connect sweep generator to antenna terminals. Adjust sweep generator & tuner to channel 10.





ADJUSTMENT	INSTRUCTIONS
T202	T202 positions 45.75 marker
T201	T201 positions 42.75
T203	T203 adjusts tilt of curve

Note: If desired curve cannot be obtained, slight adjustment of tuner coil and L202 may be necessary.

SOUND AND 4.5 MC TRAP ALIGNMENT

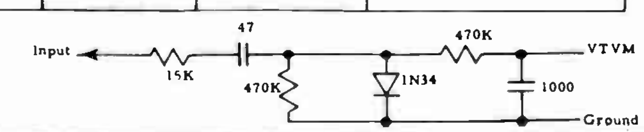
1. Tune in available TV station and reduce signal into set until hiss is heard with sound. This can be done by inserting an attenuator in the antenna lead-in or by removing antenna lead-in from the set and stray feeding in signal by placing lead-in in close proximity of the set.

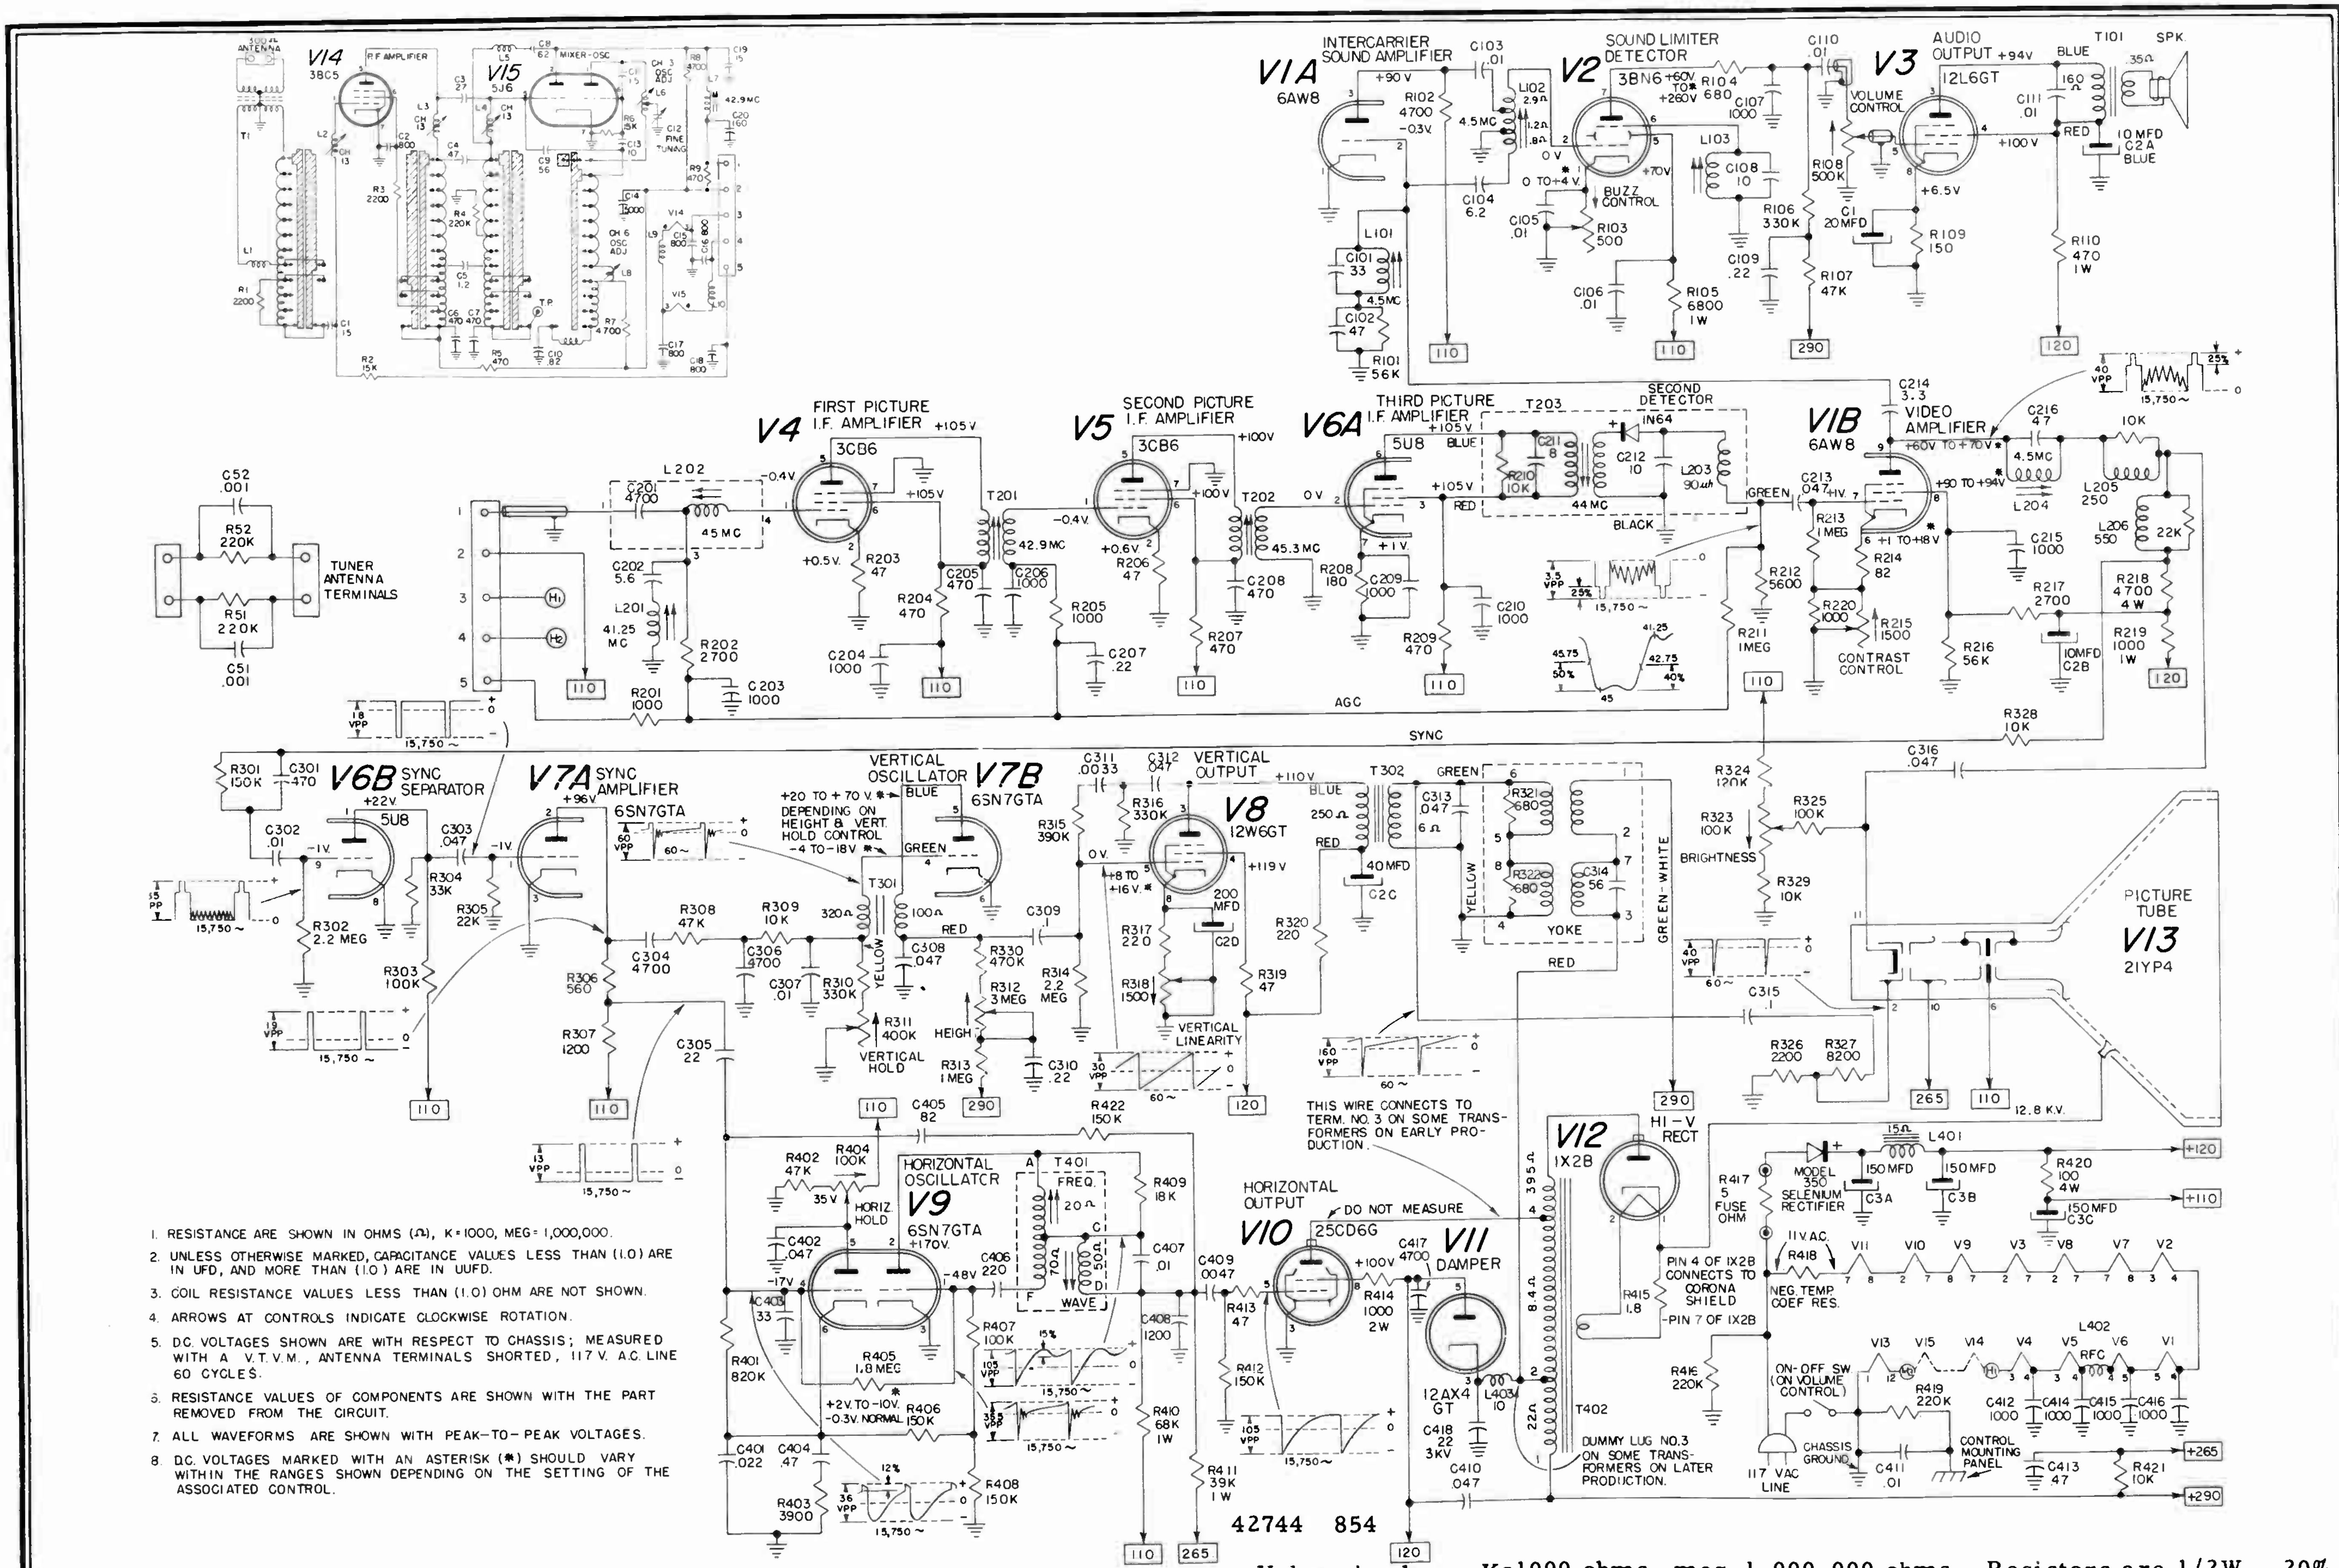
2. Set buzz control in the middle of its range. Adjust take off coil (top L101), L102, Quadrature coil (L103) and buzz control for cleanest sound and minimum buzz. If any adjustment cause hiss to disappear reduce signal into set until hiss reappears and continue with adjustments.

Note: If difficulty is encountered either in reducing signal sufficiently or adjustments being very broad. The following proceedure may be used.

STEP	EQUIPMENT	CONNECTION	FREQUENCY	ADJUSTMENT	INSTRUCTIONS
1.	Det. jig *	Input of jig to pin 2 of V2			Keep lead between 15K resistor and pin 2 as short as possible
2.	VTVM	Output of jig	Tune in available channel	L101 and L102 for max.	
3.		Remove jig	Same	Quadrature coil (L103) for max. sound	Set buzz control in middle of its range before adjusting L102
4.			Same	Buzz control for minimum buzz R103	Correct adjustment of buzz control is approx, middle of its range
5.	Det jig *	Junction C316 and R325			Connect VTVM to output of jig
6.	RF signal generator	Pin 7 (V1)	4.5 Mc	Tune 4.5 Mc trap L204 for min.	

* Detector jig





1. RESISTANCE ARE SHOWN IN OHMS (Ω), K=1000, MEG=1,000,000.
2. UNLESS OTHERWISE MARKED, CAPACITANCE VALUES LESS THAN (1.0) ARE IN UFD, AND MORE THAN (1.0) ARE IN UUFD.
3. COIL RESISTANCE VALUES LESS THAN (1.0) OHM ARE NOT SHOWN.
4. ARROWS AT CONTROLS INDICATE CLOCKWISE ROTATION.
5. D.C. VOLTAGES SHOWN ARE WITH RESPECT TO CHASSIS; MEASURED WITH A V.T.V.M., ANTENNA TERMINALS SHORTED, 117 V. A.C. LINE 60 CYCLES.
6. RESISTANCE VALUES OF COMPONENTS ARE SHOWN WITH THE PART REMOVED FROM THE CIRCUIT.
7. ALL WAVEFORMS ARE SHOWN WITH PEAK-TO-PEAK VOLTAGES.
8. D.C. VOLTAGES MARKED WITH AN ASTERISK (*) SHOULD VARY WITHIN THE RANGES SHOWN DEPENDING ON THE SETTING OF THE ASSOCIATED CONTROL.

Values of capacitors of 1 or less are in μf more than 1 in μμf unless otherwise indicated.

Values in ohms, K=1000 ohms, meg=1,000,000 ohms. Resistors are 1/2W., 20% unless otherwise indicated.

ALIGNMENT PROCEDURE

CAUTION

Always determine by suitable tests, the causes of unsatisfactory operation before attempting to align portions of the receiver. Necessity for realignment will, in all cases, be rare.

Note

Before attempting any alignment or adjustment procedures, always allow at least a ten minute warm-up period.

ALIGNMENT OF THE RF AND MIXER STAGES

1. Connect an RF sweep generator with at least a 10 MC sweep width to the antenna terminals through the pad shown in figure 2.

2. Remove the keyed AGC Amplifier tube V12. (This is necessary in order to eliminate AGC action which would interfere with RF alignment.)

3. Connect the positive terminal of a 3-volt dry cell supply to chassis ground and connect the negative terminal of the dry cell to the junction of resistors R11 and R9.

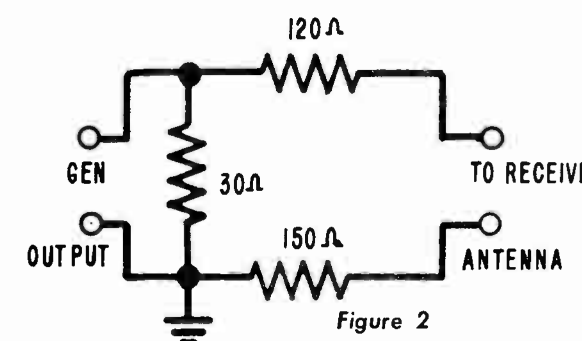

Figure 2

4. Attach the high side of the vertical input of an oscilloscope through a 10,000-ohm resistor to the test point located on the tuner. *(See figure 1, Tuner rear view.)* In order to synchronize the sweep of the oscilloscope with the RF sweep, connect the horizontal amplifier terminals of the oscilloscope to the terminals on the RF sweep generator labeled "oscillator sweep voltage".

5. Turn the station selector to channel 12 and adjust the sweep generator until it sweeps from 202 MC to 212 MC. (If the sweep generator does not supply marker signals at picture and sound carrier frequencies, an external source, such as a CW signal generator should be used to supply them. For method of marker injection, refer to instructions supplied by the manufacturer of the sweep generator being used.)

6. Adjust L1517 and L1518 located on tuner *(figure 1)* until the response curve is similar to that shown in figure 3. Check all other channels, readjusting L1517 and L1518 as required, to obtain optimum response on all twelve channels.

RF OSCILLATOR ALIGNMENT

1. Remove the Keyed AGC Amplifier Tube V12 from its socket and connect the negative terminal of a 3-volt dry cell bias supply to the RF and IF AGC test points. RF test point at junction of R11 and R9. IF test point at junction of R56 and R57. (This can best be accomplished by tying the two points together.)

2. Apply a CW signal to the antenna terminals through the pad shown in figure 2.

3. Connect the DC probe of a VTVM to V13, pin 1.

4. Turn the fine tuning control to approximately the center of its range and make the following adjustments:

a. LOW BAND ALIGNMENT

(1) Turn channel selector to channel No. 6.

(2) Tune signal generator to the sound carrier frequency of channel 6—87.75 MC.

(3) Adjust the low band oscillator slug L1545 *(figure 1)* until a sharp dip in the voltage on the VTVM is reached.

b. HIGH BAND ALIGNMENT

(1) Turn channel selector to channel No. 13.

(2) Tune signal generator to the sound carrier frequency of channel 13—215.75 MC.

(3) Adjust the high band oscillator slug L1551 *(figure 1)* until a sharp dip in the voltage reading on the VTVM is reached.

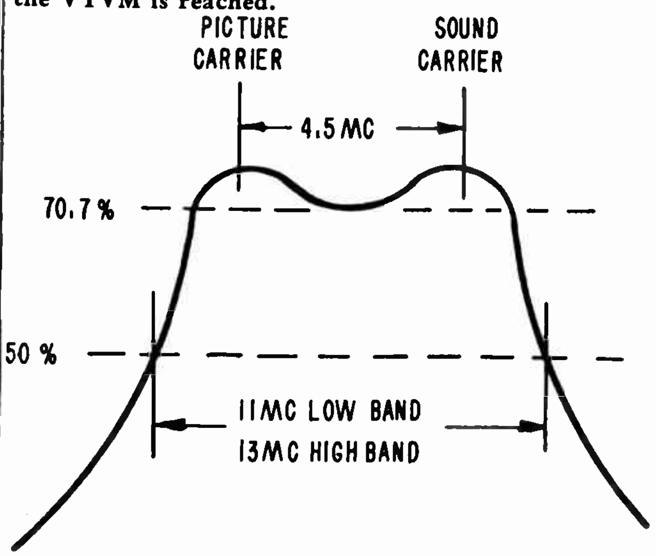

Figure 3

VISUAL CHECK OF IF ALIGNMENT

1. Lift the shield of the oscillator mixer tube V2 until it becomes ungrounded. Connect the high side of a sweep generator to the ungrounded tube shield and the ground lead to chassis ground. Connect a lead from the sweep synchronizing terminal on the sweep generator to the external sweep terminal on the oscilloscope.

2. Connect high side of oscilloscope to pin 7 of V13 video amplifier tube and ground lead to chassis ground. (Set contrast control at minimum.)

3. Remove the keyed AGC amplifier tube V12.

4. Connect the negative terminal of a 3-volt dry cell to the IF AGC test lead and the positive terminal to chassis ground.

5. Adjust sweep generator to sweep from 40 to 50 mc.

6. Connect a vacuum tube voltmeter between pin 1 of V13 and ground and adjust the sweep generator output until a reading of —2 volts is obtained.

7. Adjust the oscilloscope until the IF response curve is centered.

8. Place a lead from an AM signal generator near the IF strip and adjust it so that frequencies from 40 to 50 mc can be obtained.

9. Observe the response curve and the position of the markers *(see nominal response curve figure 4)*. A slight deviation from this response curve is permissible; however, complete realignment of the IF will be necessary if a great deviation is noted. Some improvement in the shape of the response curve may be accomplished by slightly readjusting L2 on the main chassis and L1558 on the tuner.

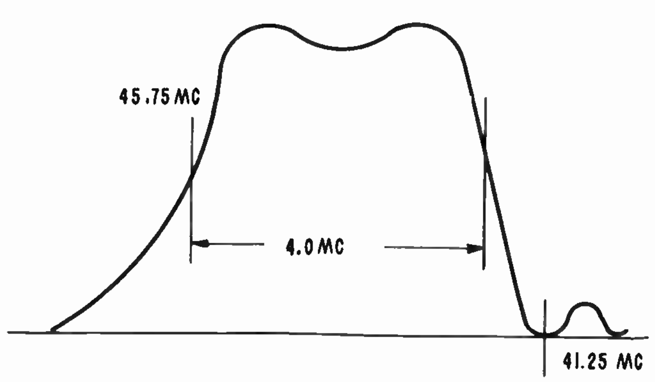

Figure 4

NOISE GATE ADJUSTMENT

NOTE: The noise gate control is adjusted at the factory to give optimum performance under varied conditions, therefore, only upon rare occasions would any adjustment be necessary.

If the receiver is to be operated in an extremely weak signal area where a high noise level is encountered, or this control becomes maladjusted by one means or another it can be satisfactorily SET by the following procedure:

Select and properly tune in the strongest station in the area.

Turn the contrast control to its maximum position (full clockwise).

With the noise gate control set at minimum, slowly turn it in the clockwise direction until a slight shifting of the picture in the horizontal plane is observed, then back off (counter-clockwise) ⅛ of a turn.

CAUTION: If this control is set too far in the clockwise direction poor sync operation may be obtained.

FOCALIZER ADJUSTMENT

Turn the plastic shaft, which extends through the back of the set near the picture tube base, for sharpest focus.

Move the arm which projects from the top of the focalizer assembly for proper picture centering. This arm can be adjusted in both the vertical and horizontal directions.

CAUTION: The ion trap magnet location should be re-checked upon completion of the above adjustments.

F. ALIGNMENT

Remove the AGC Amplifier (V12) from its socket. Connect the negative terminal of a 3 volt dry cell supply to the I.F. AGC test point and the positive terminal to chassis ground. Raise the tube shield of V2 so that it is not grounded and apply the signal to it.

Generator Freq.	VTVM Connections	Adjustment	Remarks
45 MC	To Test Point (C) and Ground	T3-T2-L1558*	Adjust for Max.
42 MC	To Test Point (C) and Ground	L5-T1-L2*	Adjust for Max.
41.25 MC	To Test Point (C) and Ground	L1-L3	Adjust for Min. with output of Signal Gen. at Max.
39.75 MC	To Test Point (C) and Ground	L4	Adjust for Min. with output of Signal Gen. at Max.

NOTE: It will be necessary to repeat the steps outlined above for optimum performance of the IF system.

* The designated frequencies for L1558 and L2 are to be used for preliminary alignment only. Since these two coils comprise a band pass circuit, final alignment should be made with a sweep generator.

SOUND ALIGNMENT

Connect the Negative Terminal of a 9 Volt dry cell supply to the I.F. AGC test point and the Positive Terminal to Chassis ground.

Signal Generator Coupling	Frequency	Connect	Adjust	Remarks
High side to Pin 1 of V13 (Video Amp)	4.5 MC	DC probe of VTVM to "Limiter grid test" Common lead to chassis.	L9 T10 (top & bottom)	Adjust for Max reading keeping output of Generator high enough to produce about 4V at "Lim. Grid Test."
SAME	4.5 MC	Parallel R38 with two 100K resistors which are within 1% of each other. DC probe of VTVM to "PT. A." Common lead to Chassis.	L11	Adjust for Max reading.
SAME	4.5 MC	DC probe of VTVM to "PT. B." Common lead to "PT. A."	L13	Adjust for Zero reading at cross over.

PRODUCTION CHANGE T14-15 & T14-16

Several reports from our factory field representatives indicates the vertical hold adjustment on the T14-15 and T14-16 chassis is rather critical in fringe operation. Improved "lock-in" may be had by slight reduction of the vertical height and linearity control settings.

The following production change has been incorporated at the factory and is suitable for field use where cases warrant:

1. The blue lead from R100, 2200 ohms, in the vertical plate return circuit, that formerly ran to the fuse, is now pulled down through the chassis and runs to the junction of R74A and R74B, the power supply filter resistors.

2. R73, the 47K plate resistor in the sync limiter and noise gate 6CS6 tube, V15, is disconnected from the + 150 volt supply and connected instead to Pin 6 of V12, the 6AU6 keyed A.G.C. amplifier.

SYMPTOM	CHASSIS TYPE	DEFECT	SUGGESTED REMEDY
Raster bouncing vertically at 60 cycle rate	T14	Open C42B	Replace electrolytic can C42A,B and C.
	T17	Open C31B	Replace electrolytic can C31A,B and C.
No vertical sync & critical horizontal sync.	T14	R85 burned open. Shorted 6SN7	Replace 6SN7 and R85
	T17	R69 burned open. Shorted 6SN7	Replace 6SN7 and R69

The charts attached have been compiled over the past year from information relayed to Bendix through our Field Service Engineers' Weekly Field Reports. The actual field defects, together with corrective measures taken, are listed.

These charts are not intended to imply that the defect associated with a particular symptom is necessarily the only possible defect causing an identical symptom. Rather, it should serve as a guide to indicate most probable cause, based on actuality.

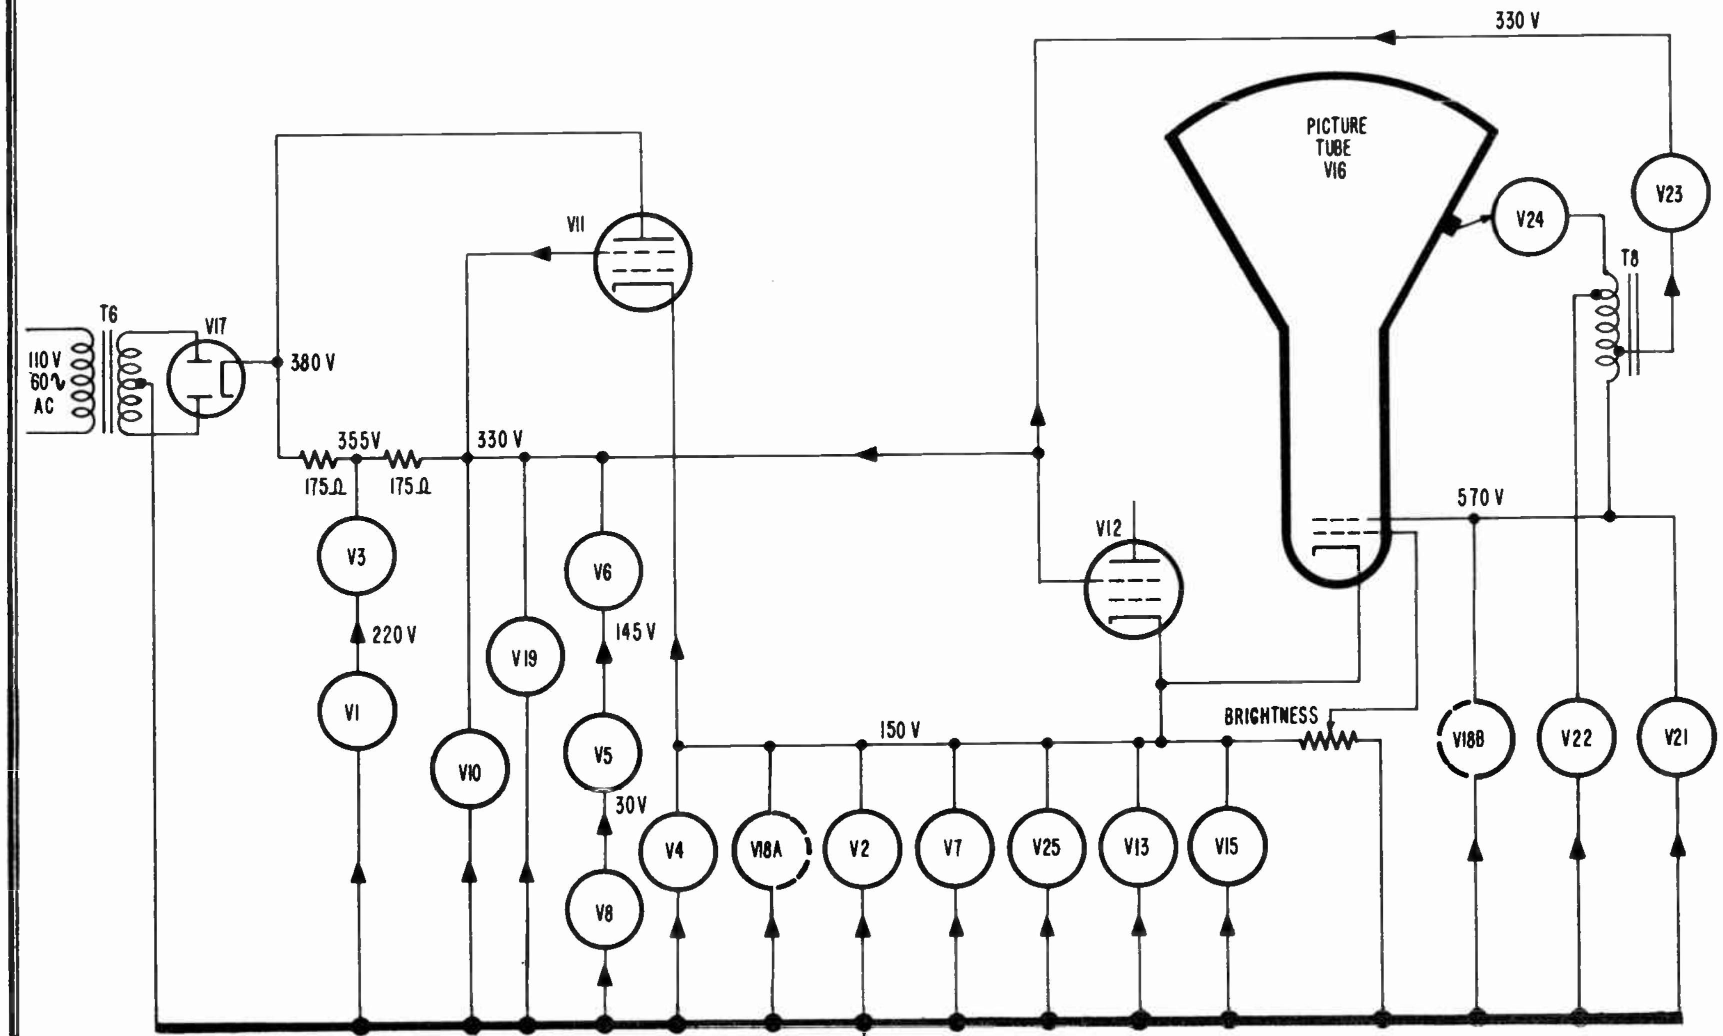

Figure 5—Voltage Distribution Chart T14-16

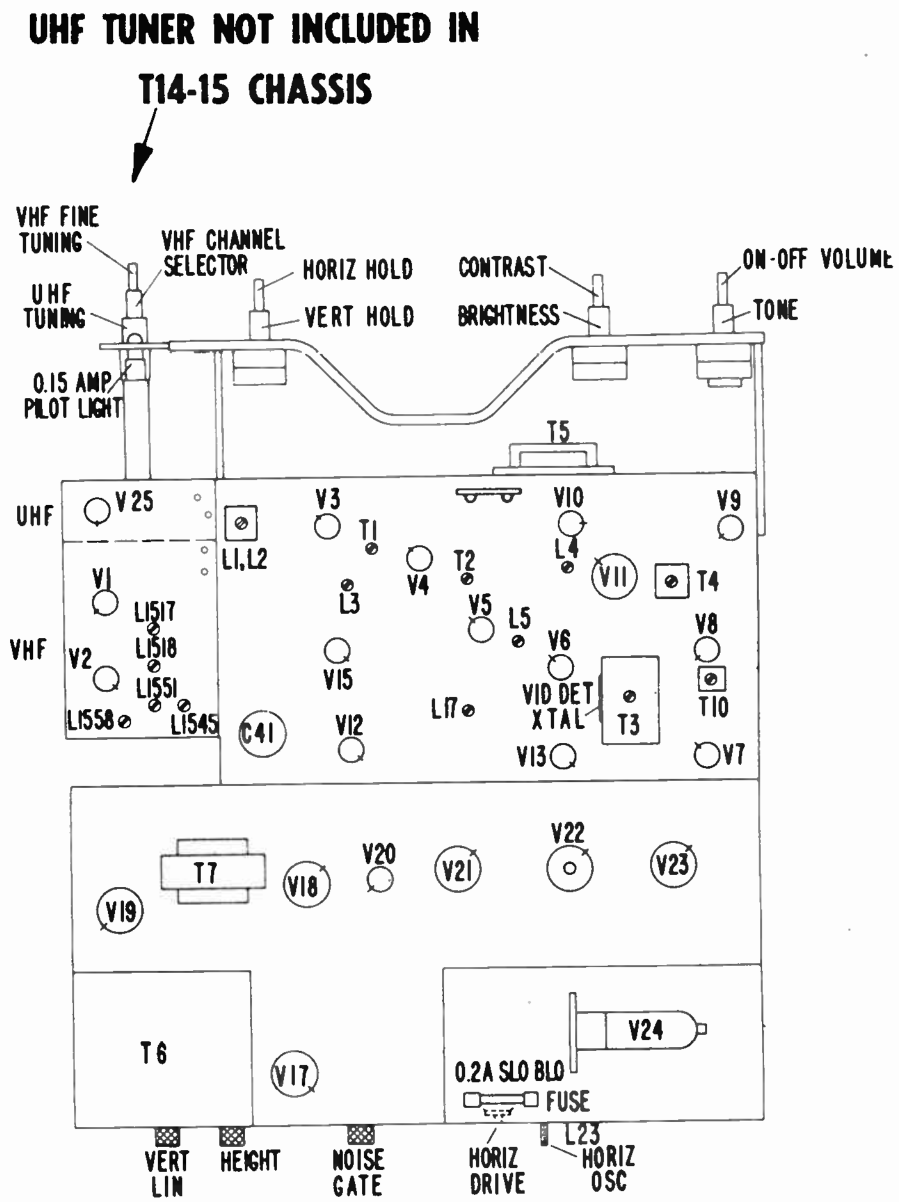

TOP VIEW

(Arrows Indicate Tube Keyways)

SYMPTOM	CHASSIS TYPE	DEFECT	SUGGESTED REMEDY
Intermittent and erratic horizontal oscillation.	T14	R117 changed value	Replace R117.
	T17	R105 changed value	Replace R105.
Low Sensitivity all channels, Standard Coil Tuner	T14	Check V2 for short & check value of R810	Replace V2 and/or R810 if necessary
	T17	Same	Same
Intermittent Audio	T14	Defective solder connection in ratio detector can.	Resolder all connections in can
	T17	Same	Same
Loss of picture and sound	T14	AGC line measures positive instead of negative due to shorted C86	Replace C86
	T17	Same trouble due to shorted C72	Replace C72
Loss of picture and sound.	T14	AGC line measures excessive negative voltage, R58 greatly increased in value.	Replace R58
	T17	Same trouble due to R42 greatly increased in value	Replace R42
Excessive vertical linearity	T14	Shorted C61 or R92 changed value	Replace C61 and/or R92
	T17	Shorted C47 or R80 changed value	Replace C47 and/or R80
Excessive loss of interlace. Scanning lines pairing.	T14	Leaky C57	Replace C57
	T17	Leaky C43	Replace C43
Audible sizzling or frying sound	T14 T17	Corona spray from 2nd anode of picture tube	Thoroughly clean surrounding area with lacquer thinner.
Picture shifted to left	T14	Faulty C93, .47 Mfd condenser	Replace C93
	T17	Faulty C-82 .47 Mfd	Replace C82
Insufficient height	T14	R99, 680K 1/2W increased in value	Replace R99 with 470K 1/2W
	T17	R87, 680K 1/2W increased in value	Replace R87 with 470K 1/2W
Set looses AGC when switching from weak to strong signal	T14 T17	IN60 crystal, video detector defective	Replace IN60 crystal
Short life 6BQ6 with possibly excess width	T14	C85, 10 Mfd 50V 6BQ6 cathode bypass shorted	Replace C85
	T17	C71, 10 Mfd 50V 6BQ6 cathode bypass shorted	Replace C71
Weak and erratic sync	T14	C50 2 Mfd 50V open	Replace C50
Weak and erratic horizontal sync	T14	Shorted turns in L23 horizontal oscillator coil or R83 changes value	Replace L23 or R83
	T17	Same trouble in L18 or R67 changes value	Replace L18 or R67
Erratic and distorted vertical sweep	T14	Leaky C59, .047 Mfd condenser	Replace C59
	T17	Leaky C45, .047 Mfd condenser	Replace C45
Vertical roll after warm up period	T14	R100, 2.2K, 2W resistor burnt or changed in value	Replace R100 with 2.2K, 4 watt.
	T17	Same trouble R88, 2.2K, 2W	Replace R88 with 2.2K, 4 watt
Set blows fuse when installed in cabinet	T14 T17	Chassis hold down bolt cutting B+ lead or leads	Tape lead & dress away from chassis basket lance
Poor brightness & blooming when brightness control is advanced.	T14	C67 shorted	Replace C67
	T17	C57 shorted	Replace C57
Raster pulls in considerably on both sides at max. brightness setting of brightness control	T14	C45 shorted	Replace C45
	T17	C35 shorted	Replace C35
Noise in sync, picture wanted to lock out the majority of the time. Noise inverter setting would not correct	T14 T17	Center tap on 300 ohm antenna winding of tuner not grounded	Connect center tap of tuner antenna coil to ground
No sound, no picture	T14	Shorted C4 & burnt R14, R74 or shorted C18 & burnt R25	Replace C4 and R14 & R74 or C18 and R25

TROUBLE SHOOTING THE BENDIX POWER MASTER CHASSIS (T-14 SERIES)*

I. RECEIVER DEAD - (No Sound or Raster)

1. Check AC power cord for good connection in AC outlet of known voltage source.
2. Check interlock on back of the chassis.
3. Check S1 on volume control R37R.
4. Check line cord for continuity to primary of power transformer T6.
5. Open primary on T6.
6. Check power transformer T6 secondary. For voltage and/or continuity each side of center tap.
7. Check for shorts in filament circuits and B+ shorts in low voltage filter circuits.
8. Gassy or open V17 (5U4G). Insure V17 is well seated in socket.

II. SOUND BUT NO RASTER

1. Check ion trap adjustment. (See Service Manual for procedure.) This check should be a "must" in initially setting up a new receiver.
2. Examine filament of V24 (1B3GT), high voltage rectifier; if lighted, this is good indication of second anode high voltage.
3. Examine connection to second anode, on picture tube.
4. Check to see if filament of picture tube (V14) is lighted. Possibility of bad socket connection.
5. Insure that plate cap for V22 (6BQ6GT or 6CU6) is making good connection.

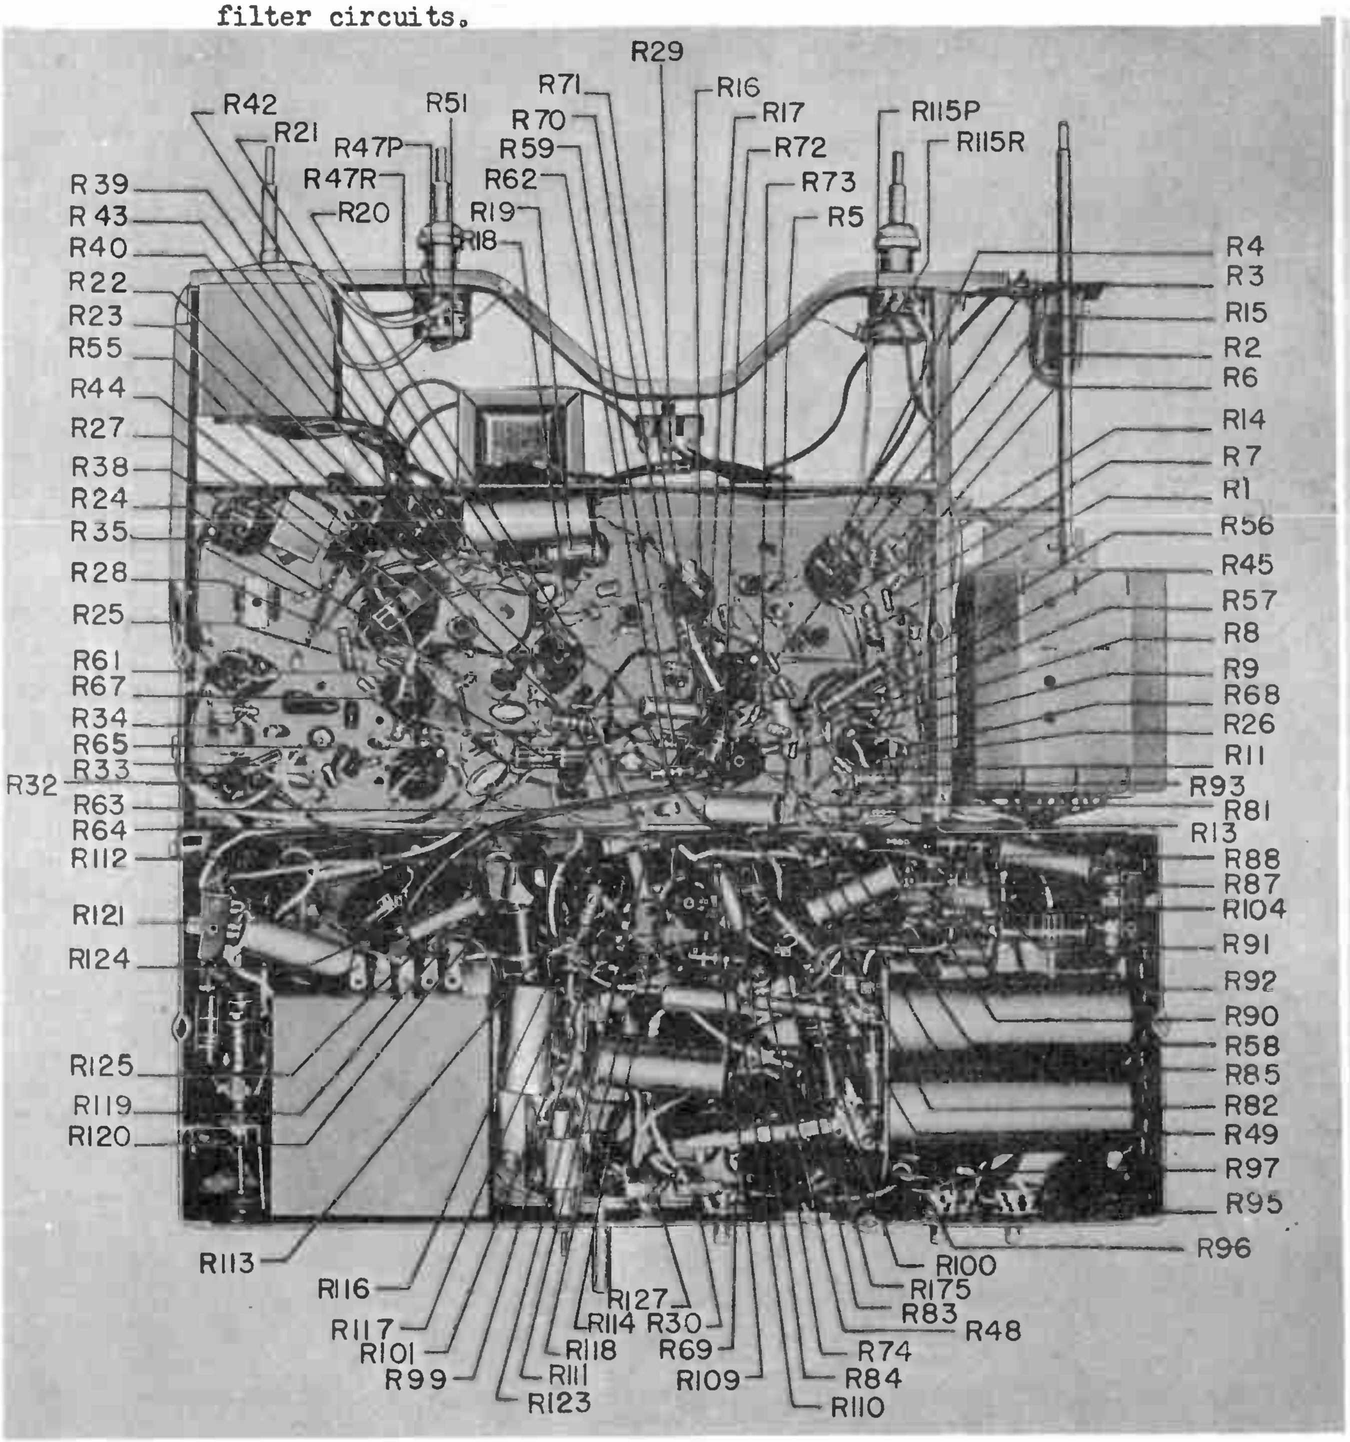

Figure 8a—Component Identification T14-15

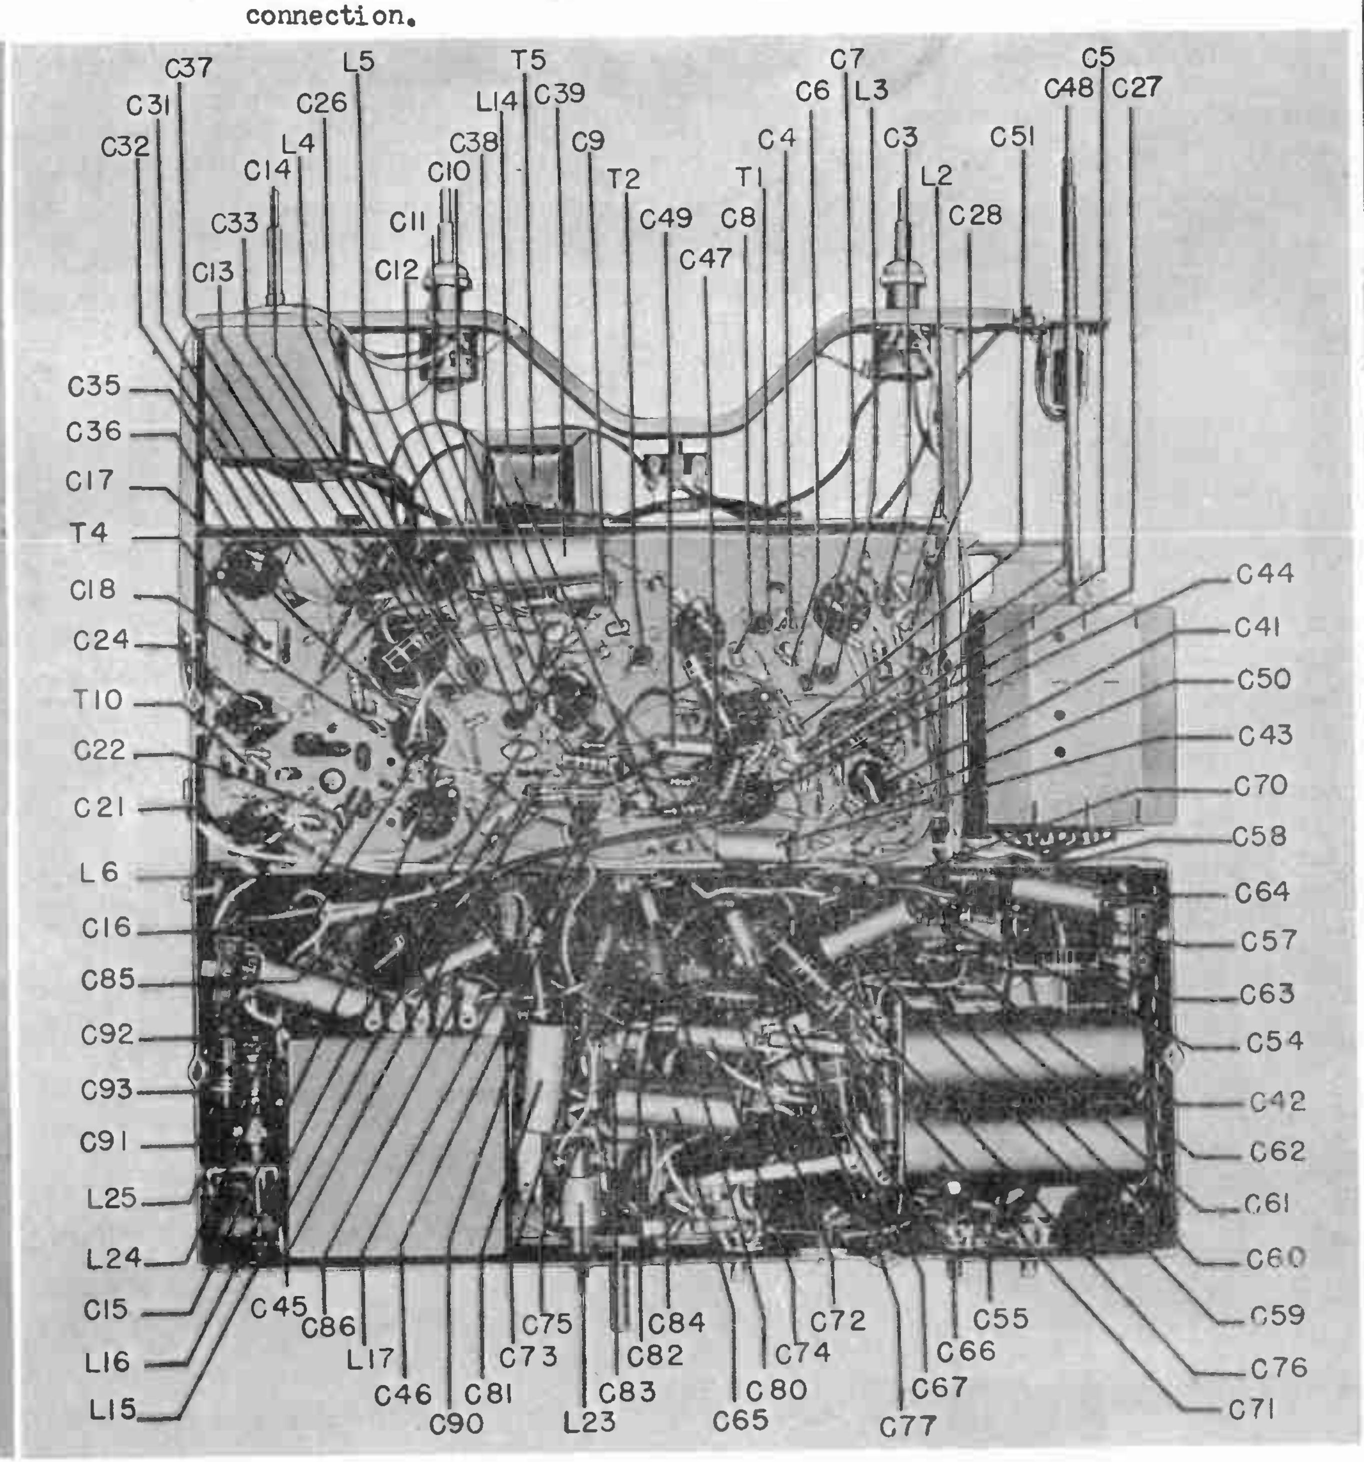

Figure 8b—Component Identification T14-15

6. Check for shorted or open V22 (6BQ6GT or 6CU6).
7. Check V23 (6W4GT or 6AX4) damper by replacement.
8. Check C94 (250 uuf) capacitor for leakage.
9. Check T8 horizontal output transformer for open primary and secondary. Do not overlook possibility of transformer breaking down under load.
10. Check V21 horizontal generator (6SN7GT) by replacement.
11. Check L23 horizontal oscillator coil.
12. Check C82, 330 uuf and C75, 3900 uuf for leakage.

III. PICTURE BUT NO SOUND

1. Check L9 for open.
2. Check connection to terminal #4 of T3.
3. Check V7, V8, V9 and V10.
4. Check for open voice coil or open secondary on T5.
5. Check connections to P2 and J2. (Speaker connections.)
6. Check for possible open connections or shorted turns in T4, ratio detector transformer.
7. Check R37R volume control for open circuit.
8. Insure correct voltages at tube socket connection in sound channel. If B/ voltage is low at any point, check for shorted by-pass condensers.

IV. WEAK SOUND, NORMAL PICTURE

1. Check V7, V8, V9 and V10.
2. Check for possible high resistance connections in T4 ratio detector transformer.
3. Check sound channel alignment. Do not overlook possibility of T4 secondary being misaligned at cross-over.

V. HUM IN SOUND

1. Check alignment of ratio detector transformer secondary (T4). Refer to Service Manual.
2. Check C35 for leakage.
3. Check V9, (6AL5), for cathode to filament leakage.
4. Insure that plate lead of vertical output transformer T7 is dressed as close to chassis as possible.
5. Keep AC switch lead dressed away from leads to volume control.

VI. HIGH VOLTAGE AND SOUND, BUT NO RASTER

1. Insure to see that picture tube V16 filament is lighted. Don't overlook possibility of a shorted picture tube.
2. Check to see that lead to second anode of picture tube is making good connection.

VII. NO HIGH VOLTAGE, BUT NORMAL SOUND

1. Check possibility of plate cap clip being disconnected from V22 (6BQ6GT or 6CU6) horizontal output tube.
2. Check V21, V22, V23 and V24.
3. Check L23 and C75.
4. Check C94, 250 uuf, capacitor.
5. Check T8 for open windings.

VIII. NO VERTICAL SWEEP APPEARING ON FACE OF PICTURE TUBE

1. Check for open primary of vertical output transformer T7.
2. Check V18 and V19.
3. Check C63 for short. (If shorted check value of R92.)

*Certain tubes are not found in the T14-15 & -16 chassis and should be disregarded.

IX. NO CONTROL OF VERTICAL SYNCHRONIZATION BY ADJUSTMENT OF THE VERTICAL HOLD

1. Check V18 and V19.
2. Check waveform with 'scope on both connections of C49, or its equivalent in T14-15 & -16 chassis.
3. Check for sync pulses on pin 1 and pin 3 of V18, (6SN7GT) sync clipper.
4. Check components in intergrating network C54, C57, R86, R87, R88, C58, C59.

X. EXCESSIVE VERTICAL SIZE

1. Check V18 and V19.
2. Check R97 for value change.
3. Check T7 vertical output transformer.

XI. INSUFFICIENT VERTICAL SIZE

1. Check V18 and V19.
2. Check T7 vertical output transformer.
3. Check C63 for leakage.

XII. NO CONTROL OF HORIZONTAL SYNC

1. Check V14, V15, V18, V20 and V21.
2. Check C70, C71, C73, C88 and C87.
3. Check C49 or its equivalent in T14-15, & -16 chassis.
4. Check L23 horizontal oscillator coil.

XIII. NO CONTROL OF HORIZONTAL OR VERTICAL SYNC

1. Check V13, V14, V15, and V18.

XIV. RECEIVER BLOWS FUSES

1. Check V21, V22 and V23.
2. Check for shorted winding in T8.
3. Check for short in yoke.
4. Check for short in vertical output transformer T7.
5. Shorted or gassy V19.
6. Check C63 for short or leakage.
7. Excessive leakage in C42B.

XV. SMEAR

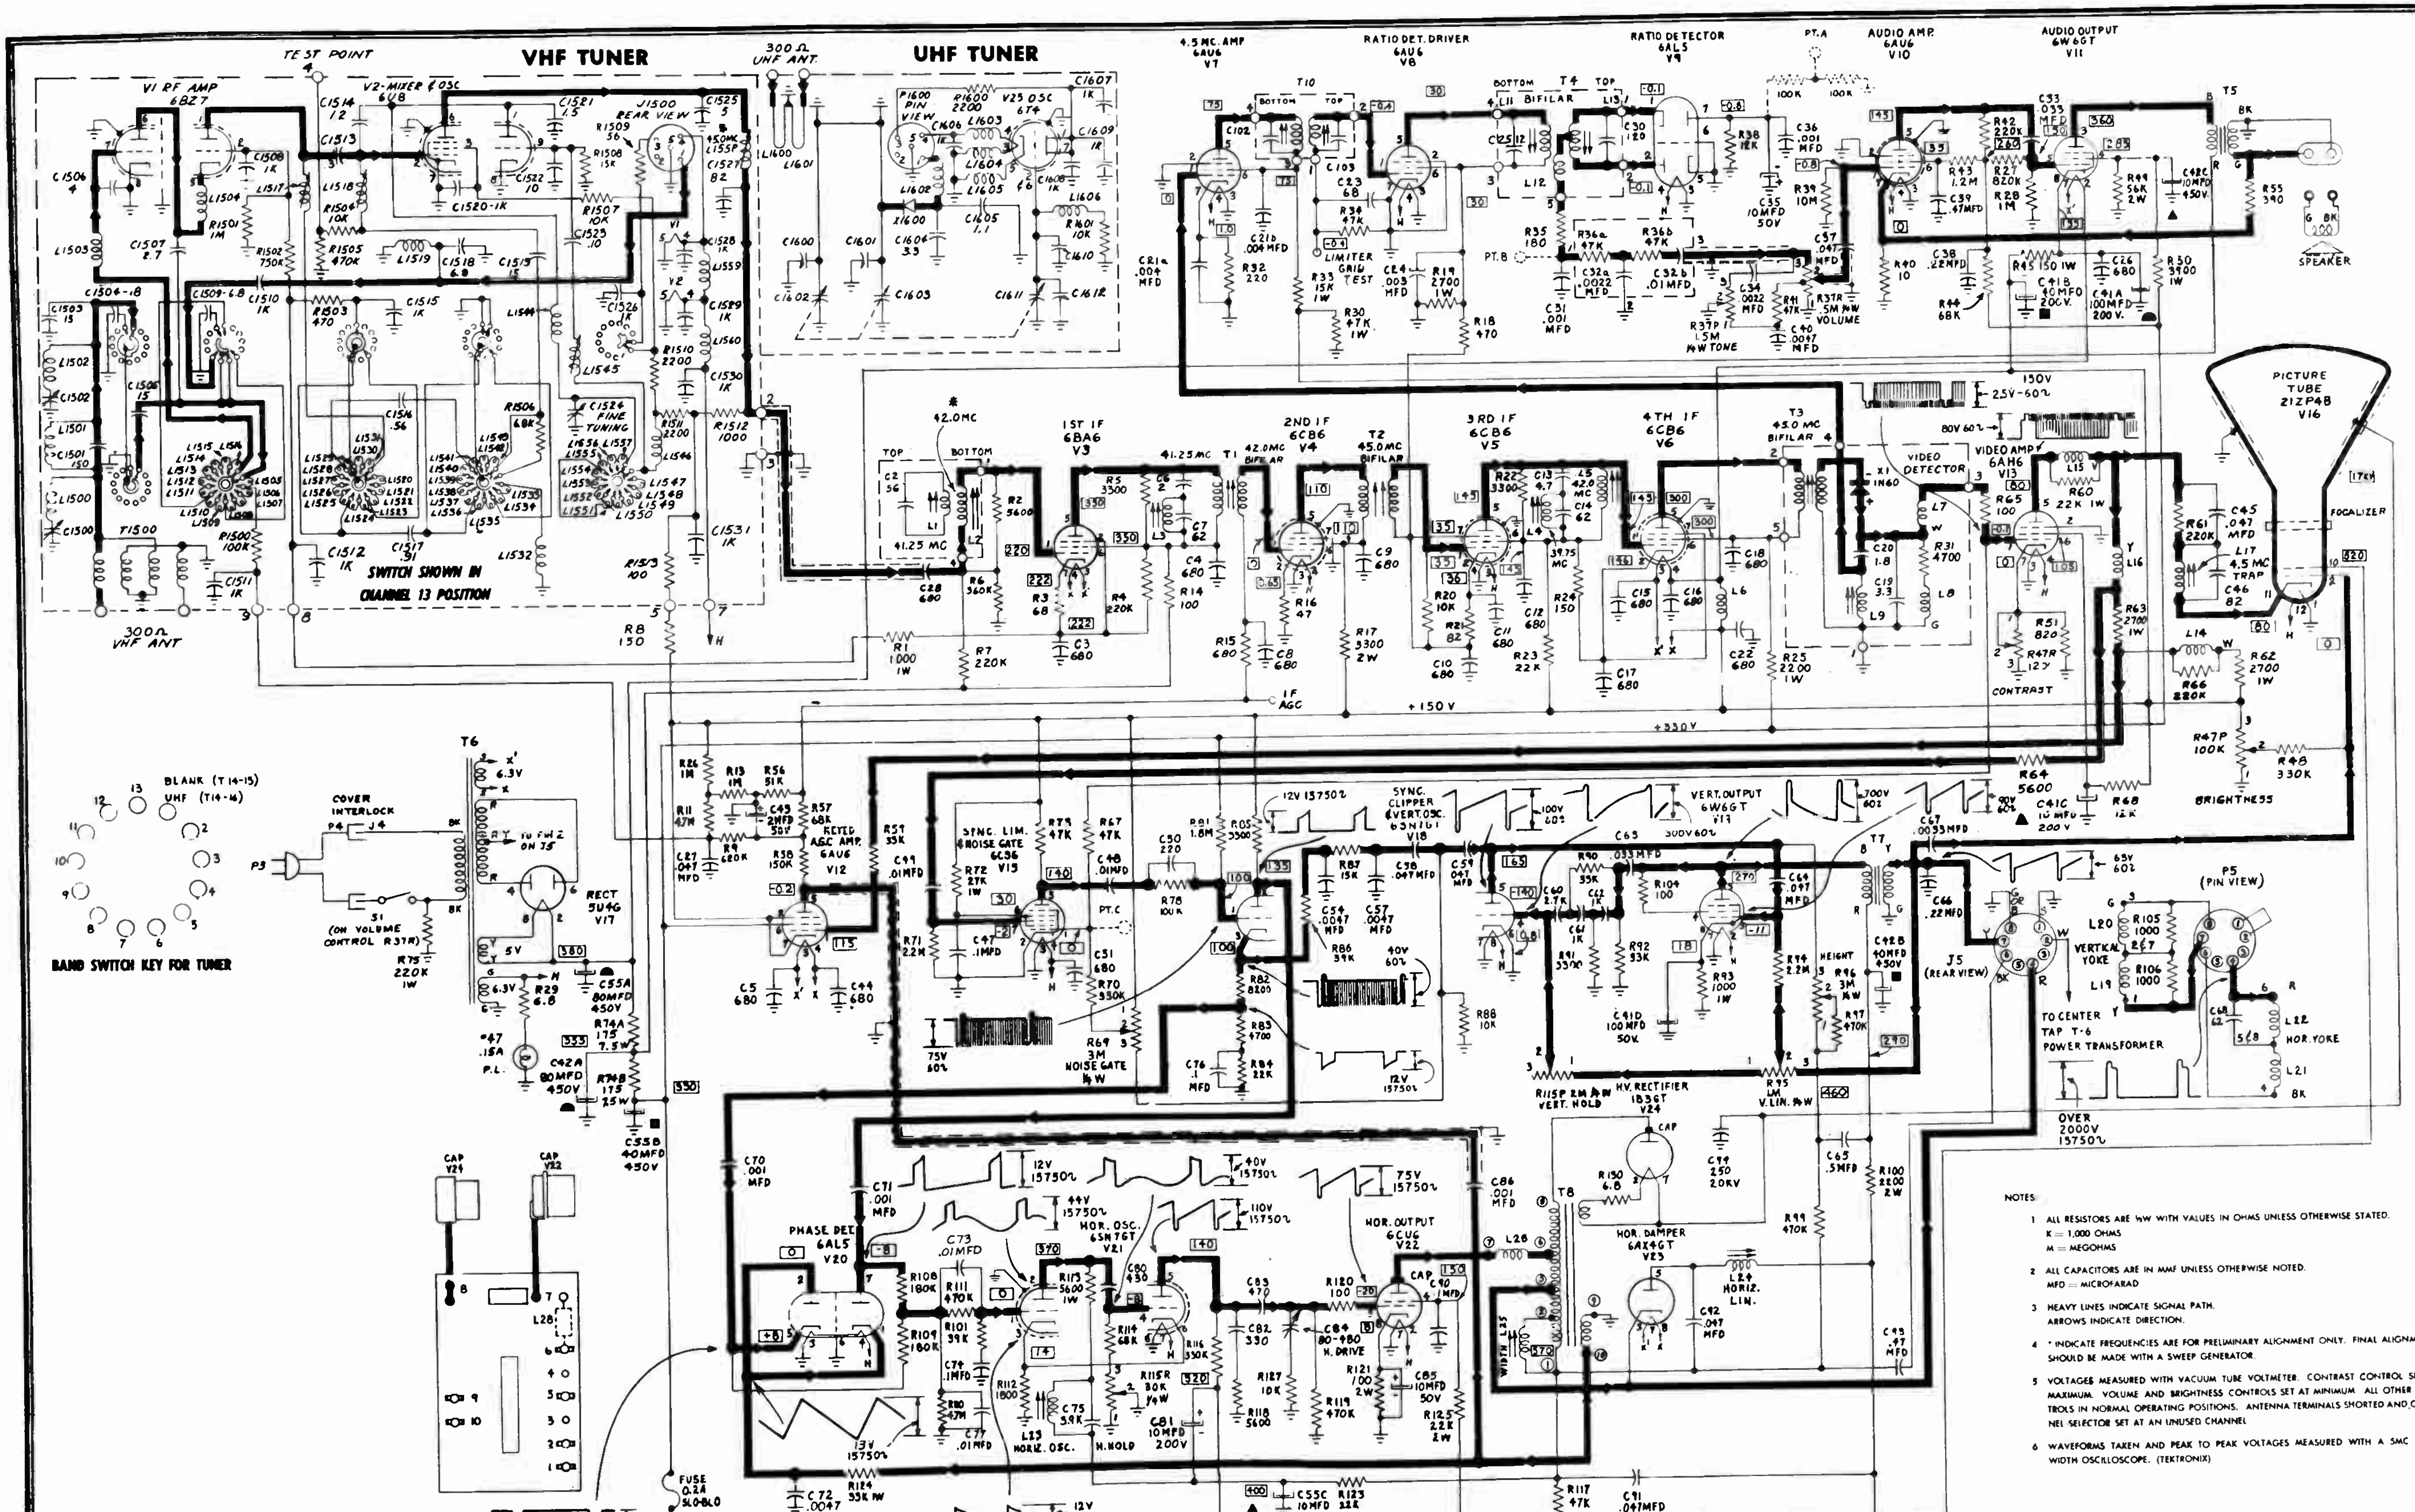
1. Check L2 for correct alignment at 42.0 mc.
2. Check C812 for leakage (Standard Coil) or its equivalent in the Sarkes Tarzian tuners.
3. Check L7, L8, L15 and L16 for open.
4. Check X1 video detector for poor front to back ratio.
5. Check by replacement V3, V4, V5, V6 and V13.

XVI. NOISE IN PICTURE

1. Arcing of high voltage or corona in the cage.
2. Intermittently open R131 (arcing). (Not present in T14-15 & -16 chassis)
3. Noisy contrast potentiometer R47R.

XVII. PICTURE BLOOMS

1. Possibility of picture tube being "gassy".
2. Gassy V19, V22 and V24.
3. Check value of R131. (Not present in T14-15 & -16 chassis)
4. Check horizontal damper tube V23, (6W4GT or 6AX4GT) by replacement.



NOTES.

1. ALL RESISTORS ARE ½W WITH VALUES IN OHMS UNLESS OTHERWISE STATED.
   K = 1,000 OHMS
   M = MEGOHMS
2. ALL CAPACITORS ARE IN MMF UNLESS OTHERWISE NOTED.
   MFD = MICROFARAD
3. HEAVY LINES INDICATE SIGNAL PATH.
   ARROWS INDICATE DIRECTION.
4. * INDICATE FREQUENCIES ARE FOR PRELIMINARY ALIGNMENT ONLY. FINAL ALIGNMENTS SHOULD BE MADE WITH A SWEEP GENERATOR.
5. VOLTAGES MEASURED WITH VACUUM TUBE VOLTMETER. CONTRAST CONTROL SET AT MAXIMUM. VOLUME AND BRIGHTNESS CONTROLS SET AT MINIMUM. ALL OTHER CONTROLS IN NORMAL OPERATING POSITIONS. ANTENNA TERMINALS SHORTED AND CHANNEL SELECTOR SET AT AN UNUSED CHANNEL
6. WAVEFORMS TAKEN AND PEAK TO PEAK VOLTAGES MEASURED WITH A 5MC BAND WIDTH OSCILLOSCOPE. (TEKTRONIX)

TELEVISION ALIGNMENT PROCEDURE

Aligning a television receiver is an exacting procedure and involves the use of bench space, test equipment and skilled personnel at the service shop, as well as the cost of making two trips to the customer's home. Before deciding that the chassis must be pulled and aligned at the shop, the serviceman should check these very common sources of trouble:

1 – The antenna and installation.

2 – Front panel and rear chassis controls, including picutre tube adjustments.

3 – Reception on all available channels.

4 – Tube failures. Substitute from your kit of known good replacements.

5 – Visual inspection of underside of chassis for obvious faults, such as loose connections, etc.

TEST EQUIPMENT REQUIRED FOR ALIGNMENT

The equipment specified below is desirable, but in cases where this equipment is not available, it is possible to align the receiver by use of a 20 to 30 mc. modulated r-f signal generator, using the picture and speaker as indication of alignment.

1 – Signal Generator with an output variable between 100 and 100,000 microvolts, and crystal controlled or crystal-calibrated at the following frequencies:

a– 4.5 megacycles

b– 22.8 megacycles

c– 25.4 megacycles

d– 21.25 megacycles

2 – DC Vacuum Tube Voltmeter with 5 volt and 10 volt scales.

3 – A pair of balanced (± 1%) 100K carbon resistors.

TEST EQUIPMENT REQUIRED FOR SWEEP ALIGNMENT CHECK

1 – R-F sweep generator with frequencies ranging from 40 to 220 megacycles, having sweep width of approximately 10 megacycles, and having adjustable output to approximately 0.1 volt.

2 – Crystal-controlled or crystal-calibrated markers for the picture and sound carriers of each channel.

3 – Cathode Ray Oscilloscope with good low frequency response.

CAUTION: THE SECOND ANODE LEAD TO THE PICTURE TUBE HAS A HIGH POTENTIAL. DURING THIS ALIGNMENT IT IS ADVISABLE TO REMOVE THE HORIZONTAL OUTPUT TUBE FROM ITS SOCKET, THUS ELIMINATING THIS HIGH VOLTAGE HAZARD.

I.F. ALIGNMENT PROCEDURE

1 – Connect "high" lead of signal generator to the test point located on the top of the RF tuner unit (Refer to the R-F tuner location diagram located on inside of cabinet). Connect ground to chassis.

2 – Connect DC VTVM lead (through 10K isolating resistor) to 4.7K diode load resistor (R113); ground to chassis. Set VTVM to 5 volt scale, negative polarity.

3 – Set I.F. generator to 25.4 megacycles with sufficient output to read approximately 3 volts on the VTVM.

4 – Carefully adjust L101 and L104 (see tube and tuner location) for maximum deflection on VTVM. Adjust sweep generator output to keep meter reading approximately 3 volts.

5 – Set I.F. signal generator to 22.8 megacycles with sufficient output to read approximately 3 volts on the VTVM.

6 – Carefully adjust L406, L103 (see tube and tuner location) for maximum deflection on VTVM. Adjust signal generator output to keep meter reading approximately 3 volts.

7 – Set I.F. signal generator to 21.25 megacycles, set VTVM to 10 volt scale (negative polarity), and adjust signal generator output for convenient deflection on VTVM.

8 – Adjust L114 for minimum deflection on VTVM.

SWEEP ALIGNMENT CHECK

Although not essential, a sweep alignment check is a desirable verification of good R-F and I.F. response. Proceed as follows:

1 – Connect R-F sweep generator to antenna terminals (antenna impedance 300 ohms.)

2 – Calibrate oscilloscope for convenient 5 volts peak-to-peak vertical deflection (5 volts peak-to-peak is approximately 1/4 of the peak-to-peak voltage of the 6.3V A.C. filament).

3 – Connect vertical input of oscilloscope (through 10K isolating resistor) to 4.7 diode load resistor (R113); ground to chassis. Connect horizontal input of oscilloscope to "scope" terminals of R-F generator; adjust for convenient horizontal sweep.

4 – Set R-F sweep generator to channel 3, television receiver to channel 3, and if necessary, adjust sweep generator output, sweep width, and scope horizontal setting for convenient band-pass display having 5 volts vertical deflection as previously calibrated. (If you must touch scope verticel settings during these adjustments recalibrate scope for 5 volts peak-to-peak as in step 2 above).

5 – Couple crystal-controlled R-F carrier markers very loosely to antenna terminals, adjust receiver FINE TUNING control till video carrier marker is 1/2 down on curve. Turn up marker output till R-f sound carrier is visible on bandpass and adjust sound trap (L114) to minimize effect of sound carrier marker.

6 – Check all channels as above.

SOUND ALIGNMENT

1 – Connect 4.5 megacycle signal generator to pin 2 of 12BH7 (V7) video amplifier.

2 – Connect DC V.T.V.M. lead to pin 7 of 6AL5 (V9) ratio detector, negative polarity.

3 – Adjust signal generator to precisely 4.5 megacycles; adjust output to read approximately 5 volts on V.T.V.M.

4 – Adjust L113 and bottom of T100 for maximum deflection on V.T.V.M. Keep V.T.V.M. reading below 10 volts at all times.

5 – Attach two series-connected 100K(± 1%) resistors across R126 (Ratio Detector Load Resistor). Connect DC V.T.V.M. to center-tap of 100K resistors, and connect ground wire of V.T.V.M. to junction of C119 and C120 (Audio Take-Off of T100).

6 – Adjust top of T100 for zero reading on V.T.V.M. between a plus and a minus peak.

VIDEO AMPLIFIER TRAP

When necessary, the video amplifier 4.5 mc trap (L110) should be adjusted as follows:

1 – Connect 4.5 mc signal generator "high" lead to picture tube grid; ground to chassis.

2 – Connect DC V.T.V.M. to pin 7 of 6AL5 (V9) ratio detector, 10 volt scale, negative polarity.

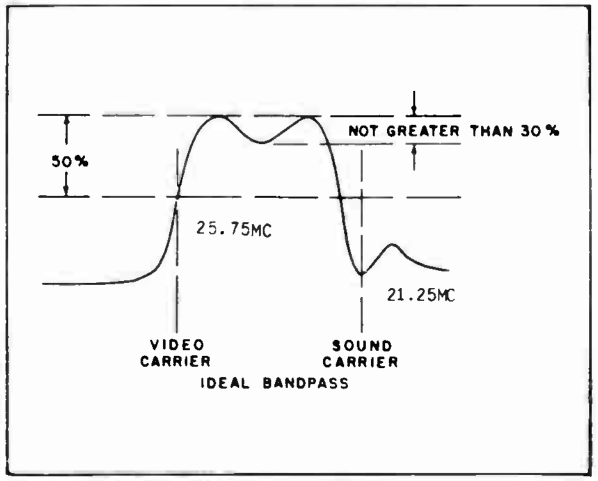
3 – Adjust L110 for minimum deflection on V.T.V.M.

R-F OSCILLATOR

If all channels are not within range of FINE TUNING control, adjust two screws located in <u>front</u> of r-f tuner unit for adjustment of either low or high band. <u>CAUTION:</u> Do not touch adjustments on <u>top</u> of r-f tuner unit, other than converter plate coil, <u>L404</u>, during IF Alignment.

HORIZONTAL OSCILLATOR ALIGNMENT

If the Horizontal Hold control fails to maintain sync, the horizontal oscillator should be reset. To reset this screwdriver adjustment, set the horizontal hold control in the center of its range and sync the picture with the horizontal A.F.C. adjustment screw. Check the hold control action on various channels and alter the screw adjustment as required to provide sync on all channels.



IDEAL BANDPASS

DEFLECTION YOKE, ION TRAP AND FOCUS ADJUSTMENT

Following is the proper procedure for adjusting the Deflection Yoke, Ion Trap and Focus.

The receiver should be turned on but not connected to an antenna. These steps should then be taken in the following order:

1 – The Deflection Yoke should be moved as far forward as possible on the neck of the CRT.

2 – The Brightness control should be turned to maximum (clockwise) and the Contrast control should be turned to minimum (counterclockwise).

3 – The Ion Trap should be rotated and at the same time moved forward and backward to find the position which produces the brightest raster on screen.

4 – The Deflection Yoke should be rotated so that the top and bottom edges of the raster are parallel to the top of the chassis.

5 – The Brightness control should now be reduced (ccw) to a point where the raster is slightly above normal brilliance.

6 – With Brightness and Contrast controls at normal positions, adjust the Focus control (rear of chassis) for well-defined scanning lines.

HEIGHT, WIDTH AND LINEARITY

To adjust the overall size and linearity of the picture it is almost mandatory that a test pattern transmitted from a local station be used. It should also be remembered that in areas where more than one station is being received, that pictures transmitted from different stations will vary slightly in size. The smallest transmitted picture should be made to fill the area outlined by the mask.

The Width control (rear of H.V. cage) should be adjusted to give a picture that will fill the mask horizontally.

The Height and Vertical Linearity controls (both rear of chassis) should then be adjusted for a linear picture that will fill the mask vertically.

PICTURE TUBE HANDLING PRECAUTIONS

The picture tube encloses a high vacuum and with the large surface area of glass involved, the stresses set up, particularly at the front rim of the tube, are considerable. An abnormal handling stress, accidental blow at a highly stressed surface, or even a scratch on the surface of the tube could cause it to implode or collapse with destructive violence.

HIGH VOLTAGE WARNING

Operation of this receiver outside the cabinet or with covers removed involves a shock hazard from the receiver power supplies. Work on the receiver should not be attempted by anyone who is not thoroughly familiar with the precautions necessary when working on high voltage equipment.

A541261-2	Rubber Cushion (CRT Front Support and Stop Bkt.)
A541102-6	Rubber Cushion (CRT Strap)

TELEVISION ALIGNMENT PROCEDURE

Aligning a television receiver is an exacting procedure and involves the use of bench space, test equipment and skilled personnel at the service shop, as well as the cost of making two trips to the customer's home. Before deciding that the chassis must be pulled and aligned at the shop, the serviceman should check these very common sources of trouble:

1 – The antenna and installation.

2 – Front panel and rear chassis controls, including picture tube adjustments.

3 – Reception on all available channels.

4 – Tube failures. Substitute from your kit of known good replacements.

5 – Visual inspection of underside of chassis for obvious faults, such as loose connections, etc.

TEST EQUIPMENT REQUIRED FOR ALIGNMENT

The equipment specified below is desirable, but in cases where this equipment is not available, it is possible to align the receiver by use of a 20 to 30 mc. modulated r-f signal generator, using the picture and speaker as indication of alignment.

1 – Signal Generator with an output variable between 100 and 100,000 microvolts, and crystal controlled or crystal-calibrated at the following frequencies:

a. 4.5 megacycles

b. 22.25 megacycles

c. 25.4 megacycles

d. 23.6 megacycles

e. 21.25 megacycles

2 – DC Vacuum Tube Voltmeter with 5 volt and 10 volt scales.

3 – A pair of balanced (±1%) 100K carbon resistors.

TEST EQUIPMENT REQUIRED FOR SWEEP ALIGNMENT CHECK

1 – R-F sweep generator with frequencies ranging from 40 to 220 megacycles, having sweep width of approximately 10 megacycles, and having adjustable output to approximately 0.1 volt.

2 – Crystal-controlled or crystal-calibrated markers for the picture and sound carriers of each channel, preferably 30% Amplitude-Modulated.

3 – Cathode Ray Oscilloscope with good low frequency response.

4 – 3 volt bias battery.

CAUTION: THE SECOND ANODE LEAD TO THE PICTURE TUBE HAS A HIGH POTENTIAL. DURING THIS ALIGNMENT IT IS ADVISABLE TO REMOVE THE COLOR PLUG FROM ITS SOCKET, THUS ELIMINATING THIS HIGH VOLTAGE HAZARD.

I.F. ALIGNMENT PROCEDURE

1 – Connect "high" lead of signal generator to the test point located on the top of the RF tuner unit (Refer to the R-F tuner location diagram located on the inside of cabinet). Connect ground to chassis.

2 – Connect DC VTVM lead (through 10K isolating resistor) to pin 1 of 6AU6 1st Video Amplifier (V12), ground to chassis. Set VTVM to 5 volt scale, negative polarity.

3 – Set I.F. generator to 25.4 megacycles with sufficient output to read approximately 3 volts on the VTVM.

4 – Carefully adjust L201 and L203 (see tube and tuner location) for maximum deflection on VTVM. Adjust sweep generator output to keep meter reading approximately 3 volts.

5 – Set I.F. signal generator to 22.25 megacycles with sufficient output to read approximately 3 volts on the VTVM.

6 – Carefully adjust L11, L202-top (see tube and trimmer location) for maximum deflection on VTVM. Adjust signal generator output to keep meter reading approximately 3 volts.

7 – Set i-f signal generator to 23.6 mc. with sufficient output to read approximately 3 volts on the VTVM.

8 – Carefully adjust L205 (see tube and trimmer location) for maximum deflection on VTVM. Adjust signal generator out-put to keep meter reading approximately 3 volts.

9 – Set I.F. signal generator to 21.25 megacycles, set VTVM to 10 volt scale (negative polarity), and adjust signal generator output for convenient deflection on VTVM.

10 – Adjust L202-bottom for minimum deflection on VTVM.

SWEEP ALIGNMENT CHECK

Although not essential, a sweep alignment check is a desirable verification of good R-F and I.F. response. Proceed as follows:

1 – Connect R-F sweep generator to antenna terminals (antenna impedance 300 Ohms).

2 – Calibrate oscilloscope for convenient 5 volts peak-to-peak vertical deflection (5 volts peak-to-peak is approximately 1/4 of the peak-to-peak voltage of the 6.3V A.C. Filament).

3 – Connect vertical input of oscilloscope (through 10K isolating resistor) to pin 1 of 6AU6 1st Vid. Amp. (V12) ground to chassis. Connect horizontal input of oscilloscope to "scope" terminals of R-F generator; adjust for convenient horizontal sweep.

4 – Connect 3 volt battery positive terminal to chassis negative terminal to AGC buss (see schematic diagram).

5 – Set R-F sweep generator to channel 3, television receiver to channel 3, and if necessary, adjust sweep generator output, sweep width, and scope horizontal setting for convenient band-pass display (see figure 1) having 5 volts vertical deflection as previously calibrated. (If you must touch scope vertical settings during these adjustments recalibrate scope for 5 volts peak-to-peak as in step 2 above).

6 – Adjust L205 slightly to even the height of peaks and to obtain an untilted bandpass.

7 – Couple crystal-controlled R-F carrier markers very loosely to antenna terminals, adjust receiver FINE TUNING control till video carrier marker is 1/2 down on curve. Turn up marker output till R-f sound carrier visible on bandpass and adjust sound trap (L114) to minimize effect to sound carrier marker.

NOTE: If the fine tuning control is at end of range or out of range so that video carrier cannot be set at 50%, follow R-F OSCILLATOR ALIGNMENT procedure outlined below.

8 – Check all channels.

R-F OSCILLATOR ALIGNMENT

If all channels are not within range of FINE TUNING control (as evidenced by inability to eliminate "sound bars" from picture or by poor picture quality), the individual oscillator slugs may require readjustment.

1 – Repeat the set-up as for SWEEP ALIGNMENT CHECK, steps 1 through 7.

2 – Set FINE TUNING CONTROL to center of range, and with long fiber screwdriver alignment tool, adjust the individual oscillator slugs of each channel. (Accessible through the front of the tuner) so that video carrier markers fall 50% down on curve. CAUTION: Do not touch adjustments on top of r-f tuner unit, other than the converter plate unit, L11, during I.F. alignment.

SOUND ALIGNMENT

1 – Connect 4.5 mc. signal generator to pin 1 of 6AU6 4.5 mc. amplifier (V13).

2 – Connect DC V.T.V.M. lead to pin 7 of 6AL5 (V15) ratio detector, negative polarity.

3 – Adjust signal generator to precisely 4.5 megacycles; adjust output to read approximately 5 volts on V.T.V.M.

4 – Adjust L206, L101, and bottom of T102 for maximum deflection on V.T.V.M. Keep V.T.V.M. reading below 10 volts at all times.

5 – Attach two series-connected 100K (± 1%) resistors across R106 (Ratio Detector Load Resistor). Connect DC V.T.V.M. to centertap of 100K resistors, and connect ground wire of V.T.V.M. to top of C109 (Audio take-Off of T102).

6 – Adjust top of T102 for zero reading on V.T.V.M. between a plus and a minus peak.

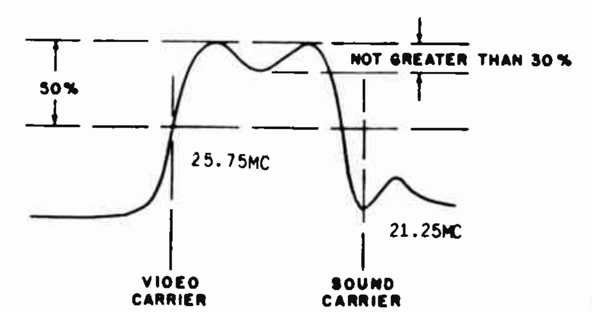
VIDEO AMPLIFIER 4.5 mc. TRAP

When necessary, the video amplifier 4.5 mc. trap (L104) should be adjusted as follows:

1 – Connect 4.5 mc. signal generator to pin 1 of 6AU6 1st video amplifier (V12).

2 – Adjust signal generator output till 4.5 mc. dot pattern is clearly visible on screen of picture tube.

3 – Adjust L104 to minimize the dot pattern.



IDEAL BANDPASS

X59908

HORIZONTAL OSCILLATOR ALIGNMENT

If the Horizontal Hold control fails to maintain sync, the horizontal oscillator should be reset. To reset this screwdriver adjustment, set the horizontal hold control in the center of its range and sync the picture with the horizontal A.F.C. adjustment screw. Check the hold control action on various channels and alter the screw adjustment as required to provide sync on all channels.

DEFLECTION YOKE, ION TRAP AND FOCUS ADJUSTMENT

Following is the proper procedure for adjusting the Deflection Yoke, Ion Trap and Focus.

The receiver should be turned on but not connected to an antenna. These steps should then be taken in the following order:

1 – The Deflection Yoke should be moved as far forward as possible on the neck of the CRT.

2 – The Brightness control should be turned to maximum (clockwise) and the Contrast control should be turned to minimum (counterclockwise).

3 – The Ion Trap should be rotated and at the same time moved forward and backward to find the position which produces the brightest raster on screen.

4 – The Deflection Yoke should be rotated so that the top and bottom edges of the raster are parallel to the top of the chassis.

5 – The Brightness control should now be reduced (ccw) to a point where the raster is slightly above normal brilliance.

HEIGHT, WIDTH, LINEARITY, AND HORIZONTAL DRIVE

To adjust the overall size and linearity of the picture it is almost mandatory that a test pattern transmitted from a local station be used. It should also be remembered that in areas where more than one station is being received, that pictures transmitted from different stations will vary slightly in size. The smallest transmitted picture should be made to fill the area outlined by the mask.

1 – Starting with the HORIZONTAL DRIVE control (rear of chassis) in extreme counterclockwise position, advance the control clockwise till the compression near the center of the picture (a vertical bright bar) is eliminated.

2 – The Width and Horizontal Linearity controls (rear of chassis) should be adjusted to give a picture that will fill the mask horizontally, with the minimum of stretching or compression.

3 – The Height and Vertical Linearity controls (both rear of chassis) should then be adjusted for a linear picture that will fill the mask vertically.

PICTURE TUBE HANDLING PRECAUTIONS

The picture tube encloses a high vacuum and with the large surface area of glass involved, the stresses set up, particularly at the front rim of the tube, are considerable. An abnormal handling stress, accidental blow at a highly stressed surface, or even a scratch on the surface of the tube could cause it to implode or collapse with destructive violence.

RADIO ALIGNMENT CHART

Step No.	Band Switch in Position	Dummy Antenna	Signal Generator Freq.	Signal Generator Connection	Dial Position	Output Meter	Adjust C or L	Adjust For	Remarks
1	AM	0.1 Mfd.	455 kc.	Pin #2 12AT7	1620 kc.	Across Speaker	T5 & T3	Maximum Reading

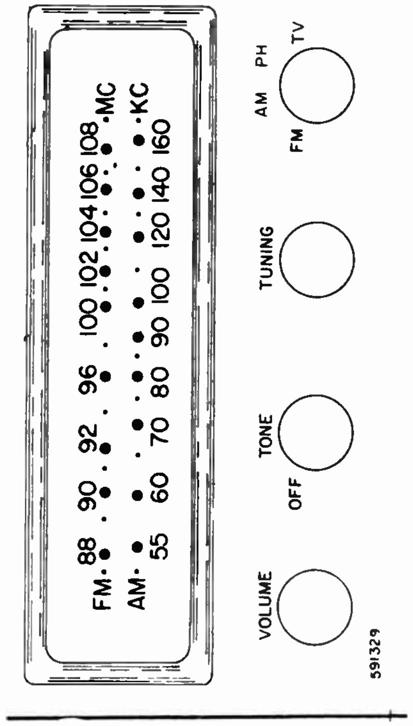
DIAL CALIBRATION AND KNOB LOCATION



ADJUSTMENT OF ANTI-PINCUSHION MAGNETS

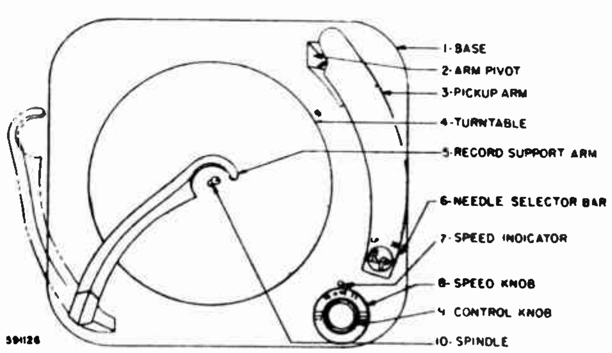
1-ADJUST THE HORIZONTAL CENTERING AND HORIZONTAL SIZE CONTROLS SO THAT ONE EDGE OF THE RASTER MAY BE SEEN.

2-IF EDGE OF RASTER IS BOWED, LOOSEN THE SCREW RETAINING THE ANTI-PINCUSHION MAGNET WHICH IS MOUNTED ON THE TIE-ROD BRACING THE PICTURE TUBE (ON THE SIDE WHICH SHOWS BOWING) SUFFICIENTLY TO ADJUST THE MAGNET BRACKET.

3-ADJUST THE MAGNET SPACING AND ROTATION, TO OBTAIN A STRAIGHT RASTER EDGE. TIGHTEN THE RETAINING SCREW.

4-REPEAT (1), (2), AND (3) FOR OPPOSITE EDGE OF RASTER.

OPERATION OF AUTOMATIC RECORD CHANGER



1. LOAD. Lift and turn Record Support Arm out of the way, place records on spindle, and place Record Support Arm back on top of records. (See figure 2).

2. SELECT SPEED. Set Speed Knob to proper speed for type of record to be played—33⅓—45, or 78 rpm.

3. SELECT NEEDLE. Observe carefully the red and white dots on the needle bar. Set this needle selector bar so that the red dot is showing when playing 33⅓—45 rpm records and the white dot showing when playing 78 rpm records.

4. START. Turn Control Knob on changer right hand front corner to "REJ" and release. The phonograph will then play the records on the spindle and automatically shut off the changer after the last record has been played.

5. MANUAL OPERATION

(a) With no records on the spindle shelf and record support over the spindle, turn "On-Off" Control Knob back to "REJ" and release. Changer will go through shut-off operation.

(b) Turn Control Knob to "On" position. (Do not turn past "On" position.)

(c) Lift pickup arm and place needle in the starting groove of the record.

6. VOLUME (first knob on left side of radio panel). The control marked "Volume" is actually a loudness control. The treble and bass are automatically balanced throughout the range of this control to give the best listening tone.

7. TONE (second knob on left side of radio panel). Turning to left on mid (Normal) position reduces the treble tone; turning clockwise emphasizes the treble tone.

8. REJECTING. To reject a record during playing, simply move the playing control knob (on the changer) forward and release as in starting.

IMPORTANT: Since the cabinet entirely closed is a fully engineered acoustic reproducer, the doors and drawer must be closed when playing. Playing this instrument with the drawer out will result in loss of the lower bass register.

The following equipment is necessary to properly align this receiver:

1. AM signal generator with frequency coverage from 455 kc. to 1700 kc.

2. FM or CW signal generator covering the FM band from 87 mc. to 109 mc. and 10.7 mc. for FM IF alignment.

3. Vacuum Tube Voltmeter (VTVM).

4. Output meter—to match 4 ohms, 5 watts maximum.

5. Insulated alignment screwdriver.

6. Dummy antenna—0.1 mfd. capacity, 300 ohm carbon resistor and inductive loop (fashioned from several turns of wire).

The safety glass of this receiver is removable so that the face of the picture tube may be cleaned. To accomplish this remove power cord from wall socket. Remove the upper strip that holds the safety glass in place by removing the five screws which secure the strip, supporting the safety glass so that it does not fall forward. Remove the safety glass by tilting it forward and lifting it out of the slot in the lower glass retaining strip. Be careful not to scratch or strike the surface of the picture tube with any object. Carefully clean face of picture tube and the inside surface of the safety glass with a soft, clean, dry cloth. DO NOT ATTEMPT TO REMOVE THE PICTURE TUBE MASK. Reassemble by inserting glass in slot of lower strip. Replace upper strip and tighten the screws securely.

Reference Notes to Alignment Chart

Before starting alignment, pointer must be set at 87.5 MC mark with gang fully closed.

Note A: Put two 100,000 ohm resistors in series across R–23 (30,000 ohms). Negative lead of V.T.V.M. is attached to the junction of these two resistors. Positive lead of V.T.V.M. is ground. V.T.V.M. on 3 volt scale.

Note B: Negative lead of V.T.V.M. same as in Note A, positive lead of V.T.V.M. at junction of R–22 (27K ohm) and shielded lead, on terminal strip at ratio detector.

Note C: The FM R.F. and OSC. coils are made of stiff wire. To adjust these coils for band coverage and tracking squeeze coils together or spread apart as required.

Note D: Tune F.M. antenna trimmer (C10b) and at the same time rock the signal generator frequency back and forth for maximum deflection on the meter.

I. F. ALIGNMENT PROCEDURE 40 mc IF

Before pulling a chassis for shop alignment, the serviceman should check these points:

1 – The antenna and installation:

2 – Front panel and rear chassis control settings, including picture tube adjustments.

3 – Reception on all available channels.

4 – Tubes: Substitute known good tubes for suspected defective ones.

5 – Wiring, connections and parts placement under the chassis, for loose joints, and accidental shorts.

TEST EQUIPMENT REQUIREMENTS

The equipment listed below is essential for the correct alignment of this receiver.

1 – Signal Generator with an output Variable between 10 and 100,000 microvolts, and crystal controlled or calibrated at the following frequencies:

a) 4.5 mc	d) 43.8 mc	g) 39.75 mc
b) 41.25 mc	e) 45.2 mc	h) 45.75 mc
c) 42.3 mc	f) 47.25 mc	i) 44.75 mc

2 – Signal Generator with an output Variable between from 30 to 230 mc, a sweep width of at least 10 mc and an output adjustable from 0 to .1 volt.

3 – Marker Generator, crystal controlled or calibrated for video and sound carrier frequencies of each channel. (Can be the same generator as in #1 if these frequencies are available.)

4 – Cathode Ray Oscilloscope with good low frequency response.

5 – D.C. Vacuum Tube Voltmeter with 5 volt and 10 volt ranges.

6 – Non metallic alignment tool, hexagonal bit, .095" across flats.

7 – One 3 volt battery.

8 – Two balanced (± 1%) 100K resistors.

I.F. ALIGNMENT

1 – Connect negative of 3V battery to AGC bus (Pin 7, test socket), positive to chassis.

2 – Remove mixer tube shield, connect Signal Generator, to it and replace over mixer tube so shield does not contact chassis.

3 – Connect VTVM negative lead to grid of first video amplifier (Pin 5, test socket) and positive lead to chassis.

4 – Plug line cord into receiver and electric outlet, turn receiver on and allow it to warm up a few minutes.

5 – Set VTVM on -5 volt range and signal generator to 44.75 mc unmodulated.

6 – Adjust 5th IF transformer L205 top slug for maximum output, setting signal generator attenuator to produce no more than a 3 volt reading on the VTVM.

7 – Set signal generator to 47.25 mc unmodulated and adjust L204 trap, bottom slug, for minimum reading on the VTVM.

8 – Set signal generator to 45.2 mc unmodulated and adjust top slug of 4th IF transformer L204 for maximum output as in (6).

9 – Set signal generator to 39.75 mc unmodulated and adjust trap L203, bottom slug for a minimum reading on VTVM.

10 – Set signal generator to 43.8 mc unmodulated and adjust top slug of L203 for a maximum VTVM reading as in (6).

11 – Set signal generator to 41.25 mc unmodulated and adjust trap L202, bottom slug, for a minimum VTVM reading.

12 – Set signal generator to 42.3 mc unmodulated and adjust the 2nd IF coil. L202, top slug, for a maximum VTVM reading as in (6).

13 – Set signal generator to 43.8 mc and adjust L201, 1st I.F. and and L14, tuner I.F. coil for an approximate maximum.

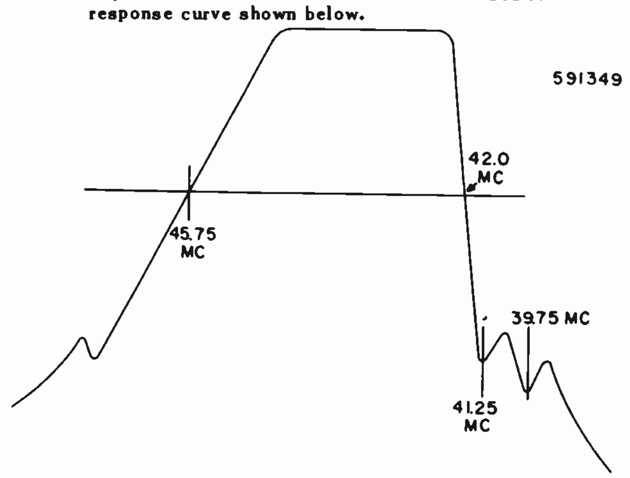
14 – Disconnect the signal generator from the tube shield.

15 – Connect Sweep Signal Generator to mixer tube shield and an oscilloscope, calibrated for 3 volts peak to peak as reference output level, in place of the VTVM.

16 – Loosely couple Marker Generator to input on the Sweep Signal Generator.

17 – Adjust Sweep Signal Generator dial and attenuator to show an IF response curve not over 3 volts peak to peak on the calibrated oscilloscope screen. (Exceeding this value will give a distorted response curve.)

18 – Adjust tuner IF coil and 1st IF coil L101 to obtain the response curve shown below.



RESPONSE CURVE 1100 SERIES

USUALLY: To set 45.75 marker at 50% point adjust tuner IF coil.

To compensate for tilt adjust 1st IF Coil L201. Bandwidth should be from 3.65 to 3.85 mc at the 50% point.

R-F OSCILLATOR (VHF TUNER PC541460)

If all channels are not within range of FINE TUNING control, adjust slug reached through front of r-f tuner unit for adjustment of each channel. CAUTION: Do not touch adjustments on top of r-f tuner unit, other than converter plate coil, L14, during IF Alignment.

SOUND ALIGNMENT

1 – Connect 4.5 megacycle signal generator pin 1 of 6AU6 (V12) video amplifier. (Test Socket pin 5).

2 – Connect DC V.T.V.M. lead to pin 7 of 6AL5 (V15) or to Test Socket pin 6, ratio detector, negative polarity.

3 – Adjust signal generator to precisely 4.5 megacycles; adjust output to read approximately 5 volts on V.T.V.M.

4 – Adjust sound take-off coil, L101 and bottom of T102 for maximum deflection on V.T.V.M. Keep V.T.V.M. reading below 10 volts at all times.

5 – Attach two series-connected 100K (±1%) resistors across R108 (Ratio Detector Load Resistor. (Test Socket pin 6 and Chassis). Connect DC V.T.V.M. to center-tap of 100K resistors, and connect ground wire of V.T.V.M. to test socket pin 3. (Audio Take-Off of T102).

6 – Adjust top of T102 for zero reading on V.T.V.M. between a plus and a minus peak.

VIDEO AMPLIFIER 4.5 mc. TRAP

When necessary, the video amplifier 4.5 mc. trap (L104) should be adjusted as follows:

1 – Connect 4.5 mc. signal generator to pin 1 of 6AU6 1st video amplifier (V12).

2 – Adjust signal generator output till 4.5 mc. dot pattern is clearly visible on screen of picture tube.

3 – Adjust L104 to minimize the dot pattern.

HORIZONTAL OSCILLATOR ALIGNMENT

If the Horizontal Hold control fails to maintain sync, the horizontal oscillator should be reset. To reset this screwdriver adjustment, set the horizontal hold control in the center of its range and sync the picture with the horizontal A.F.C. adjustment screw. Check the hold control action on various channels and alter the screw adjustment as required to provide sync on all channels.

DEFLECTION YOKE, ION TRAP AND FOCUS ADJUSTMENT

Following is the proper procedure for adjusting the Deflection Yoke, Ion Trap and Focus.

The receiver should be turned on but not connected to an antenna. These steps should then be taken in the following order:

1 – The Deflection Yoke should be moved as far forward as possible on the neck of the CRT.

2 – The Brightness control should be set halfway and the Contrast control should be turned to minimum (counterclockwise).

3 – The Ion Trap should be rotated and at the same time moved forward and backward to find the position which produces the brightest raster on screen. (Keep Brightness control low)

4 – The Deflection Yoke should be rotated so that the top and bottom edges of the raster are parallel to the top of the chassis.

5 – The Brightness control should now be reduced (ccw) to a point where the raster is slightly above normal brilliance.

6 – With Brightness and Contrast controls at normal positions, adjust the Focus control (rear of chassis) for well-defined scanning lines.

HEIGHT, WIDTH AND LINEARITY

To adjust the overall size and linearity of the picture it is almost mandatory that a test pattern transmitted from a local station be used. It should also be remembered that in areas where more than one station is being received, that pictures transmitted from different stations will vary slightly in size. The smallest transmitted picture should be made to fill the area outlined by the mask.

The Width control L402, should be adjusted to give a picture that will fill the mask horizontally.

The Height and Vertical Linearity controls should then be adjusted for a linear picture that will fill the mask vertically.

UHF TUNER ALIGNMENT

Tuner PC541459 41 mc. I.F. Coil Alignment.

Set the receiver channel selector for UHF.

1 – Connect the signal generator to the test point thru an isolating resistor of approximately 100K ohms.

2 – Connect VTVM to first video amplifier grid or to test socket pin 5.

3 – Set signal generator for 44.2 mc unmodulated. Turn receiver on and allow a short warm up period.

4 – Adjust T1 for maximum response as indicated on the VTVM.

ALIGNMENT PROCEDURE UHF TUNER PC541459

Alignment of the UHF Tuner is a simple procedure since its band-pass is essentially predetermined by the fixed characteristics of original component design, physical layout and associated circuitry. Except as stated otherwise in this procedure, band-pass is not subject to serious change during alignment, however, replacement of any component within the R-F or I-F circuits may disturb the band-pass characteristics. Accordingly, whenever parts within these circuits are replaced, electrical and physical specifications of the original components must be duplicated as closely as possible. Wires, parts and other accessories must be replaced in their former positions.

Complicated or specially designed test equipment is not required for practical alignment of the UHF Tuner. Instruments used for testing VHF sets are usually satisfactory. However, the following instruments are needed;

1 – VHF signal generator with AM output.

2 – Oscilloscope or vacuum tube volt-ohmmeter for measurement of the relative signal.

The oscilloscope or VTVM should be connected to the TV set first video amplifier grid or to test socket pin 5.

The procedure for alignment consists of the following steps.

1 – Positioning of the oscillator for proper band coverage.

2 – Alignment of R-F circuits for maximum effectiveness.

OSCILLATOR ADJUSTMENT

1 – Turn drum to extreme CCW position.

2 – Connect the signal generator to the UHF tuner antenna terminals and adjust generator for a signal between 459 and 466 megacycles. If no response is observed, carefully squeeze the short ends of the oscillator tuning condenser plates together or spread them apart until some frequency within the 459 to 466 mc range produces a response.

3 – Turn the tuning drum to extreme clockwise position.

4 – Swing the signal generator thru the frequency range 894 to 903 megacycles. If a response within this range is obtained, no adjustment is necessary. If a response below 894 mc occurs, carefully squeeze the long ends of the oscillator plates slightly together until a signal between 894 and 903 mc producea a response. If the output occurs above 903 mc carefully spread the oscillator plates slightly at the long end.

Only a very slight amount of bending should be required in any case of incomplete band coverage, as this unit is assembled in a precision jig.

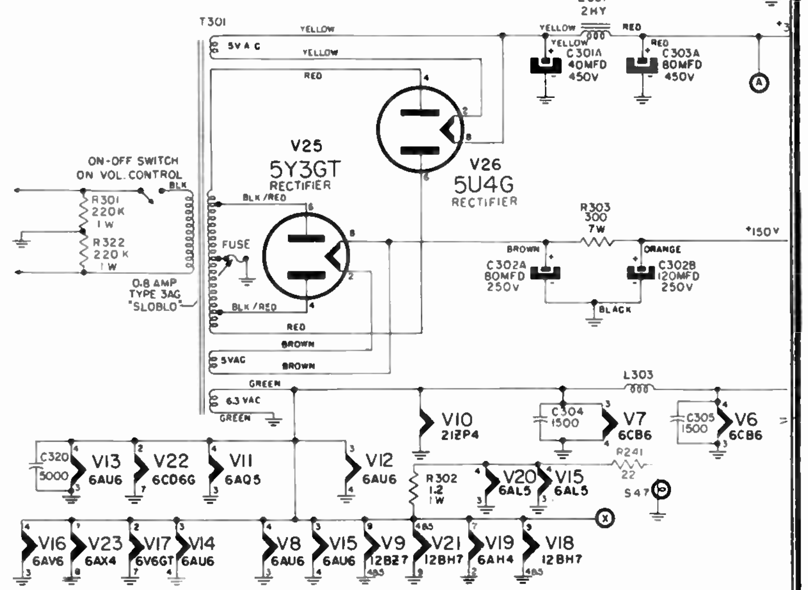
REAR CONTROLS



R. F. ALIGNMENT

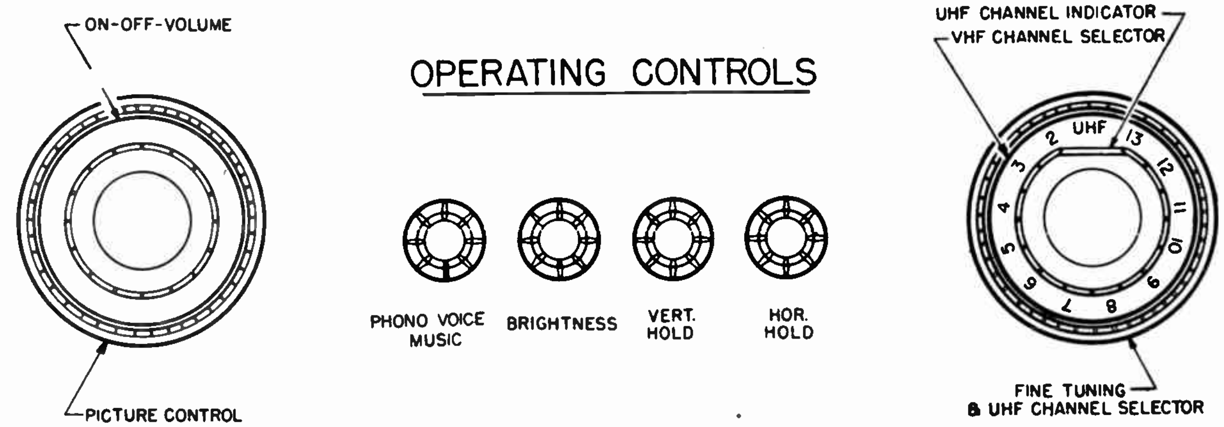
1 – With the signal generator and VTVM or oscilloscope connected as in the oscillator adjustment, adjust the signal generator to 470 mc and tune in this signal on the tuner. (near extreme counter clockwise position.)

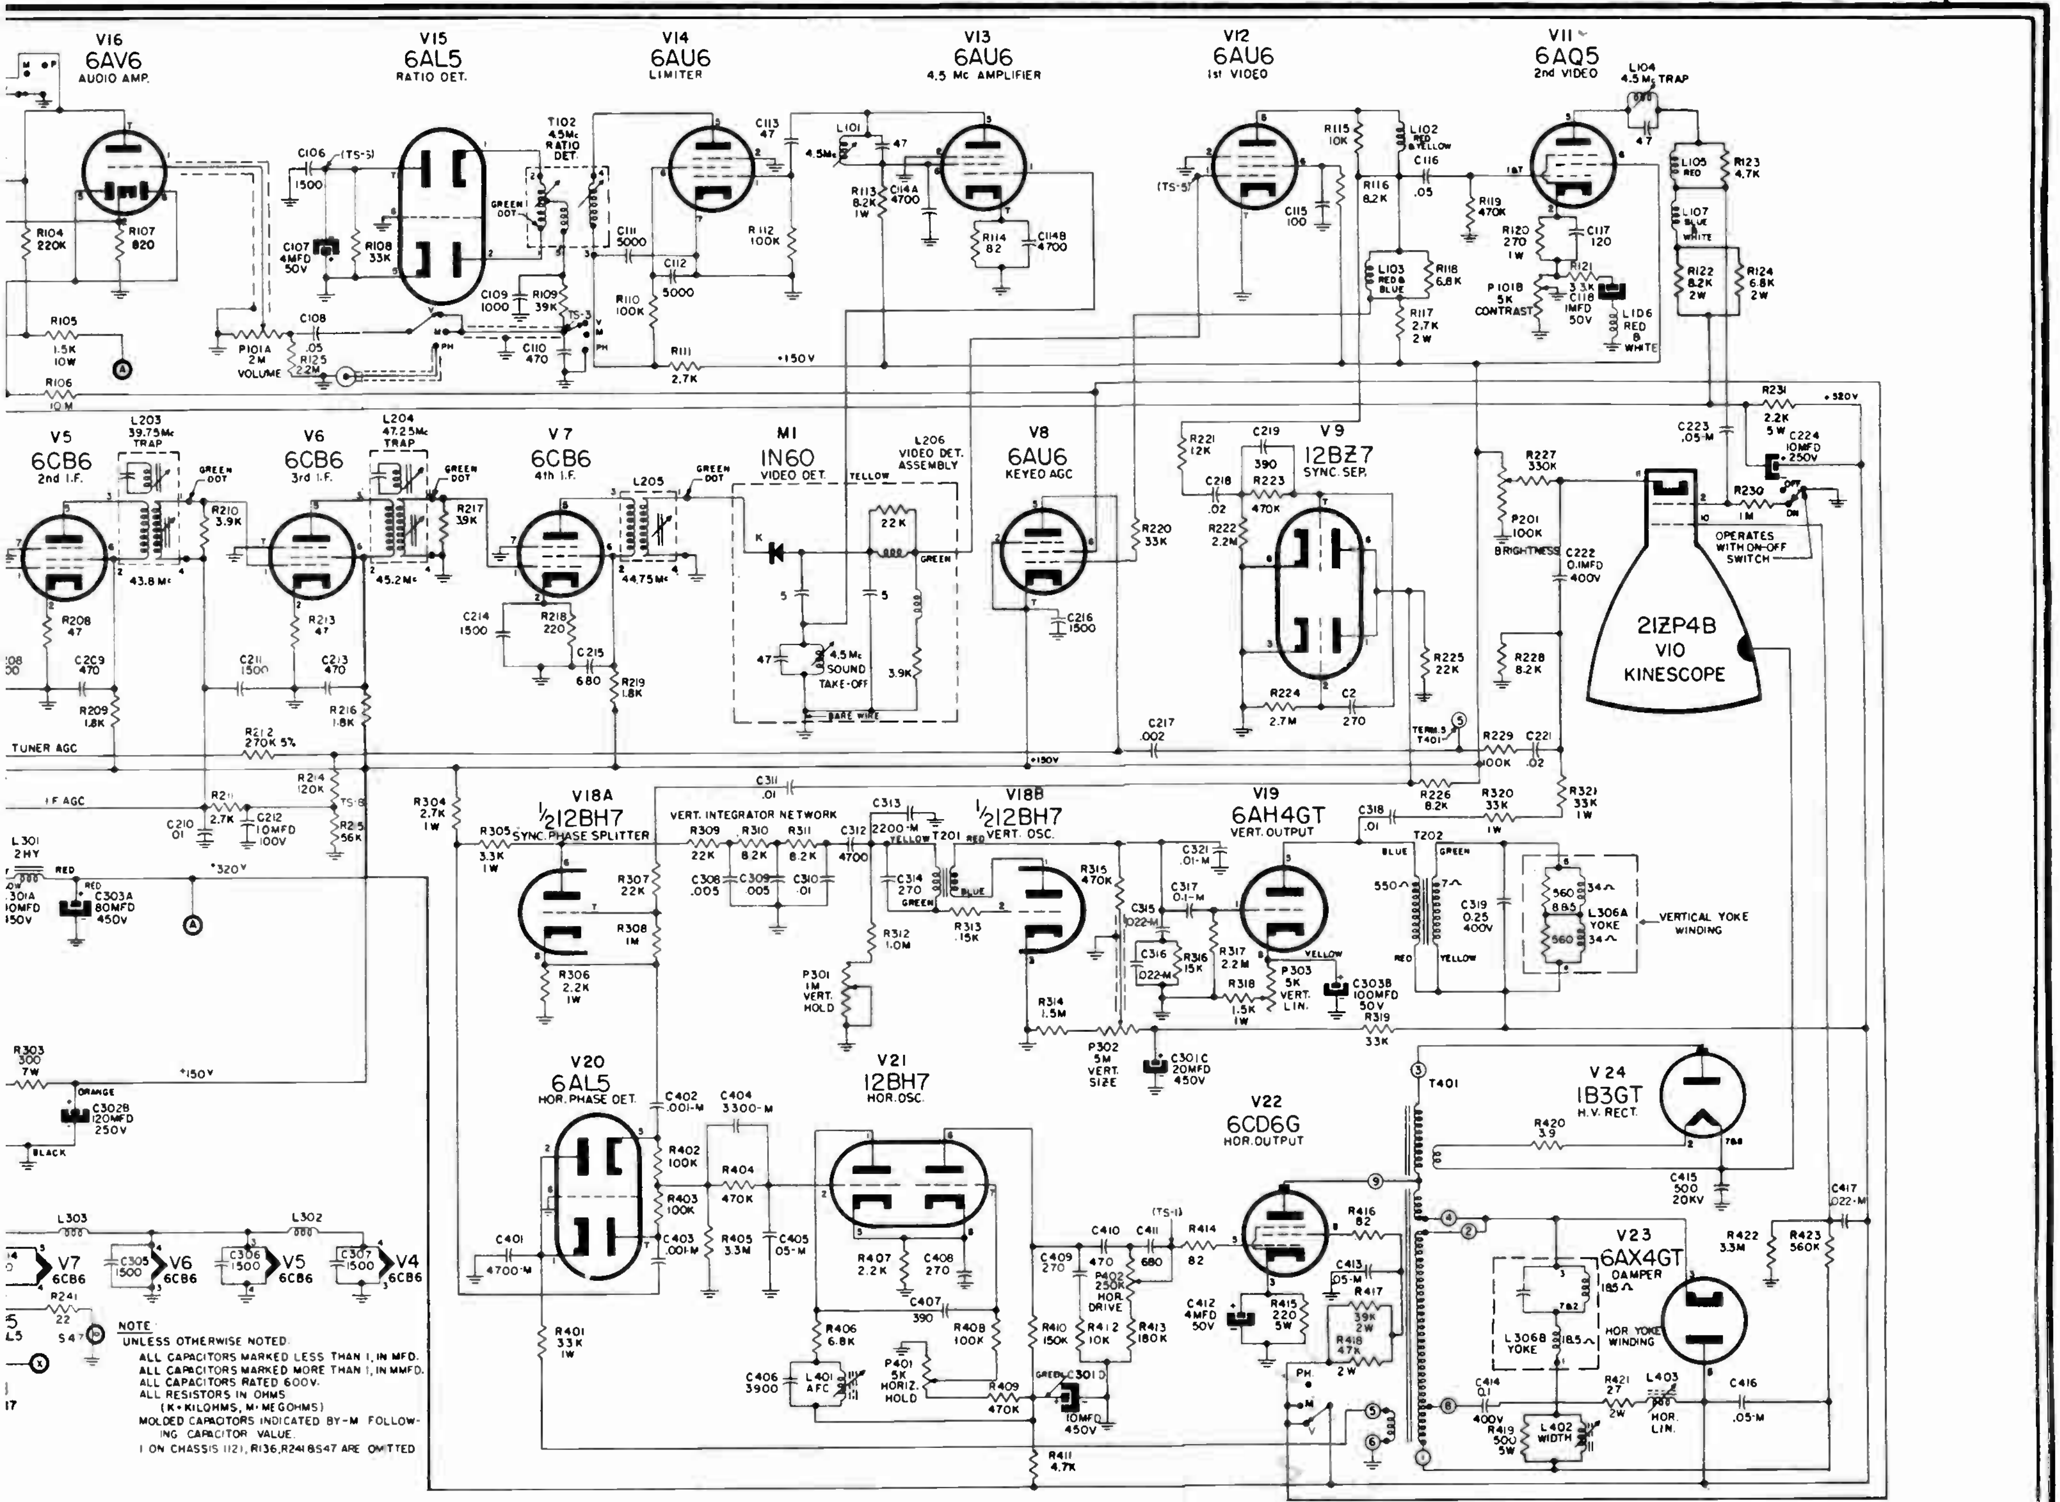
2 – Squeeze together or spread apart the short ends of the plates of the two R.F. tuning condenser sections until a maximum response is obtained.

3 – Set the signal generator to 890 mc and tune in this signal on the tuner (near extreme clockwise position).

4 – Squeeze together or spread apart the long ends of the RF tuning condenser plates until a maximum response is obtained.

These steps complete the UHF tuner alignment.





NOTE
UNLESS OTHERWISE NOTED:

PA541266	Tuner Shaft Grounding Spring
PA4584 or PA4588	Dial Cord Pulley
PP591116	Stringing Diagram

TELEVISION ALIGNMENT PROCEDURE

Aligning a television receiver is an exacting procedure and involves the use of bench space, test equipment and skilled personnel at the service shop, as well as the cost of making two trips to the customer's home. Before deciding that the chassis must be pulled and aligned at the shop, the serviceman should check these very common sources of trouble:

1 – The antenna and installation.

2 – Front panel and rear chassis controls, including picture tube adjustments.

3 – Reception on all available channels.

4 – Tube failures. Substitute from your kit of known good replacements.

5 – Visual inspection of underside of chassis for obvious faults, such as loose connections, etc.

TEST EQUIPMENT REQUIRED FOR ALIGNMENT

The equipment specified below is desirable, but in cases where this equipment is not available, it is possible to align the receiver by use of a 20 to 30 mc. modulated r-f signal generator, using the picture and speaker as indication of alignment.

1 – Signal Generator with an output variable between 100 and 100,000 microvolts, and crystal controlled or crystal-calibrated at the following frequencies:

a. 4.5 megacycles

b. 22.25 megacycles

c. 25.4 megacycles

d. 23.6 megacycles

e. 21.25 megacycles

2 – DC Vacuum Tube Voltmeter with 5 volt and 10 volt scales.

3 – A pair of balanced (∠1%) 100K carbon resistors.

TEST EQUIPMENT REQUIRED FOR SWEEP ALIGNMENT CHECK

1 – R-F sweep generator with frequencies ranging from 40 to 220 megacycles, having sweep width of approximately 10 megacycles, and having adjustable output to approximately 0.1 volt.

2 – Crystal-controlled or crystal-calibrated markers for the picture and sound carriers of each channel, preferably 30% Amplitude-Modulated.

3 – Cathode Ray Oscilloscope with good low frequency response.

4 – 3 volt bias battery.

CAUTION: THE SECOND ANODE LEAD TO THE PICTURE TUBE HAS A HIGH POTENTIAL. DURING THIS ALIGNMENT IT IS ADVISABLE TO REMOVE THE COLOR PLUG FROM ITS SOCKET, THUS ELIMINATING THIS HIGH VOLTAGE HAZARD.

I.F. ALIGNMENT PROCEDURE

1 – Connect "high" lead of signal generator to the test point located on the top of the RF tuner unit (Refer to the R-F tuner location diagram located on the inside of cabinet). Connect ground to chassis.

2 – Connect DC VTVM lead (through 10K isolating resistor) to pin 1 of 6AU6 1 st Video Amplifier (V12), ground to chassis. Set VTVM to 5 volt scale, negative polarity.

3 – Set I.F. generator to 25.4 megacycles with sufficient output to read approximately 3 volts on the VTVM.

4 – Carefully adjust L201 and L203 (see tube and tuner location) for maximum deflection on VTVM. Adjust sweep generator output to keep meter reading approximately 3 volts.

5 – Set I.F. signal generator to 22.25 megacycles with sufficient output to read approximately 3 volts on the VTVM.

6 – Carefully adjust L11, L202-top (see tube and tuner location) for maximum deflection on VTVM. Adjust signal generator output to keep meter reading approximately 3 volts.

7 – Set i-f signal generator to 23.6 mc. with sufficient output to read approximately 3 volts on the VTVM.

8 – Carefully adjust L205 (see tube and tuner location) for maximum deflection on VTVM. Adjust signal generator out-put to keep meter reading approximately 3 volts.

9 – Set I.F. signal generator to 21.25 megacycles, set VTVM to 10 volt scale (negative polarity), and adjust signal generator output for convenient deflection on VTVM.

10 – Adjust L202-bottom for minimum deflection on VTVM.

SWEEP ALIGNMENT CHECK

Although not essential, a sweep alignment check is a desirable verification of good R-F and I.F. response. Proceed as follows:

1 – Connect R-F sweep generator to antenna terminals (antenna impedance 300 Ohms).

2 – Calibrate oscilloscope for convenient 5 volts peak-to-peak vertical deflection (5 volts peak-to-peak is approximately 1/4 of the peak-to-peak voltage of the 6.3V A.C. Filament).

3 – Connect vertical input of oscilloscope (through 10K isolating resistor) to pin 1 of 6AU6 1st Vid. Amp. (V12) ground to chassis. Connect horizontal input of oscilloscope to "scope" terminals of R-F generator; adjust for convenient horizontal sweep.

4 – Connect 3 volt battery positive terminal to chassis negative terminal to AGC buss (see schematic diagram).

5 – Set R-F sweep generator to channel 3, television receiver to channel 3, and if necessary, adjust sweep generator output, sweep width, and scope horizontal setting for convenient band-pass display (see figure 1) having 5 volts vertical deflection as previously calibrated. (If you must touch scope vertical settings during these adjustments recalibrate scope for 5 volts peak-to-peak as in step 2 above).

6 – Adjust L205 slightly to even the height of peaks and to obtain an untilted bandpass.

7 – Couple crystal-controlled R-F carrier markers very loosely to antenna terminals, adjust receiver FINE TUNING control till video carrier marker is 1/2 down on curve. Turn up marker output till R-f sound carrier visible on bandpass and adjust sound trap (L114) to minimize effect to sound carrier marker.

NOTE: If the fine tuning control is at end of range or out of range so that video carrier cannot be set at 50%, follow R-F OSCILLATOR ALIGNMENT procedure outlined below.

8 – Check all channels.

R-F OSCILLATOR ALIGNMENT

If all channels are not within range of FINE TUNING control (as evidenced by inability to eliminate "sound bars" from picture or by poor picture quality), the individual oscillator slugs may require readjustment.

1 – Repeat the set-up as for SWEEP ALIGNMENT CHECK, steps 1 through 7.

2 – Set FINE TUNING CONTROL to center of range, and with long fiber screwdriver alignment tool, adjust the individual oscillator slugs of each channel. (Accessible through the front of the tuner) so that video carrier markers fall 50% down on curve. CAUTION: Do not touch adjustments on top of r-f tuner unit, other than the converter plate unit, L11, during I.F. alignment.

SOUND ALIGNMENT

1 – Connect 4.5 mc. signal generator to pin 1 of 6AU6 4.5 mc. amplifier (V13).

2 – Connect DC V.T.V.M. lead to pin 7 of 6AL5 (V15) ratio detector, negative polarity.

3 – Adjust signal generator to precisely 4.5 megacycles; adjust output to read approximately 5 volts on V.T.V.M.

4 – Adjust L206, L101, and bottom of T102 for maximum deflection on V.T.V.M. Keep V.T.V.M. reading below 10 volts at all times.

5 – Attach two series-connected 100K (∠1%) resistors across R106 (Ratio Detector Load Resistor). Connect DC V.T.V.M. to centertap of 100K resistors, and connect ground wire of V.T.V.M. to top of C109 (Audio take-Off of T102).

6 – Adjust top of T102 for zero reading on V.T.V.M. between a plus and a minus peak.

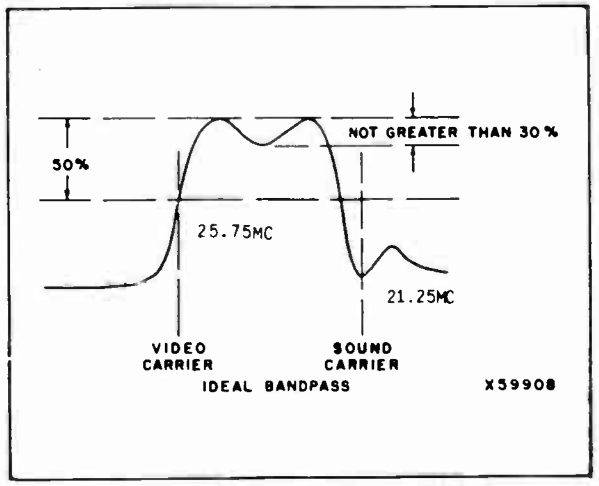
VIDEO AMPLIFIER 4.5 mc. TRAP

When necessary, the video amplifier 4.5 mc. trap (L104) should be adjusted as follows:

1 – Connect 4.5 mc. signal generator to pin 1 of 6AU6 1st video amplifier (V12).

2 – Adjust signal generator output till 4.5 mc. dot pattern is clearly visible on screen of picture tube.

3 – Adjust L104 to minimize the dot pattern.



HORIZONTAL OSCILLATOR ALIGNMENT

If the Horizontal Hold control fails to maintain sync, the horizontal oscillator should be reset. To reset this screwdriver adjustment, set the horizontal hold control in the center of its range and sync the picture with the horizontal A.F.C. adjustment screw. Check the hold control action on various channels and after the screw adjustment as required to provide sync on all channels.

DEFLECTION YOKE, ION TRAP AND FOCUS ADJUSTMENT

Following is the proper procedure for adjusting the Deflection Yoke, Ion Trap and Focus.

The receiver should be turned on but not connected to an antenna. These steps should then be taken in the following order:

1 – The Deflection Yoke should be moved as far forward as possible on the neck of the CRT.

2 – The Brightness control should be turned to maximum (clockwise) and the Contrast control should be turned to minimum (counterclockwise).

3 – The Ion Trap should be rotated and at the same time moved forward and backward to find the position which produces the brightest raster on screen.

4 – The Deflection Yoke should be rotated so that the top and bottom edges of the raster are parallel to the top of the chassis.

5 – The Brightness control should now be reduced (ccw) to a point where the raster is slightly above normal brilliance.

HEIGHT, WIDTH, LINEARITY, AND HORIZONTAL DRIVE

To adjust the overall size and linearity of the picture it is almost mandatory that a test pattern transmitted from a local station be used. It should also be remembered that in areas where more than one station is being received, that pictures transmitted from different stations will vary slightly in size. The smallest transmitted picture should be made to fill the area outlined by the mask.

1 – Starting with the HORIZONTAL DRIVE control (rear of chassis) in extreme counterclockwise position, advance the control clockwise till the compression near the center of the picture (a vertical bright bar) is eliminated.

2 – The Width and Horizontal Linearity controls (rear of chassis) should be adjusted to give a picture that will fill the mask horizontally, with the minimum of stretching or compression.

3 – The Height and Vertical Linearity controls (both rear of chassis) should then be adjusted for a linear picture that will fill the mask vertically.

PICTURE TUBE HANDLING PRECAUTIONS

The picture tube encloses a high vacuum and with the large surface area of glass involved, the stresses set up, particularly at the front rim of the tube, are considerable. An abnormal handling stress, accidental blow or a highly stressed surface, or even a scratch on the surface of the tube could cause it to implode or collapse with destructive violence.

HIGH VOLTAGE WARNING

Operation of this receiver outside the cabinet or with covers removed involves a shock hazard from the receiver power supplies. Work on the receiver should not be attempted by anyone who is not thoroughly familiar with the precautions necessary when working on high voltage equipment.

R-F OSCILLATOR

If all channels are not within range of FINE TUNING control, adjust two screws located in front of r-f tuner unit for adjustment of either low or high band. CAUTION: Do not touch adjustments on top of r-f tuner unit, other than converter plate coil, L405, during IF Alignment.

HORIZONTAL OSCILLATOR ALIGNMENT

If the Horizontal Hold control fails to maintain sync, the horizontal oscillator should be reset. To reset this screwdriver adjustment, set the horizontal hold control in the center of its range and sync the picture with the horizontal A.F.C. adjustment screw. Check the hold control action on various channels and alter the screw adjustment as required to provide sync on all channels.

DEFLECTION YOKE, ION TRAP AND FOCUS ADJUSTMENT

Following is the proper procedure for adjusting the Deflection Yoke, Ion Trap and Focus.

The Receiver should be turned on but not connected to an antenna. These steps should then be taken in the following order:

1 – The Deflection Yoke should be moved as far forward as possible on the neck of the CRT.

2 – The Brightness control should be turned to maximum (clockwise) and the Contrast control should be turned to minimum (counterclockwise).

3 – The Ion Trap should be rotated and at the same time moved forward and backward to find the position which produces the brightest raster on screen.

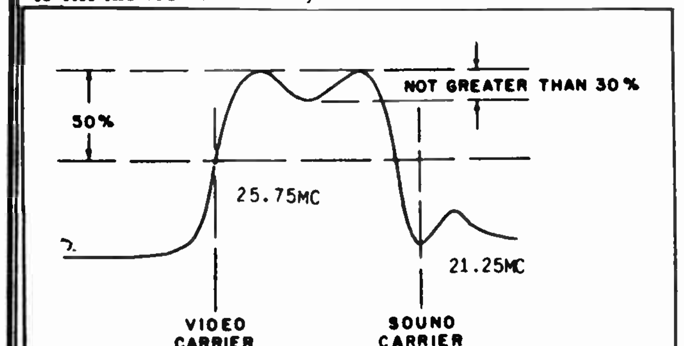
4 – The Deflection Yoke should be rotated so that the top and bottom edges of the raster are parallel to the top of the chassis.

5 – The Brightness control should now be reduced (ccw) to a point where the raster is slightly above normal brilliance.

6 – With Brightness and Contrast controls at normal positions, adjust the Focus control (rear of chassis) for well-defined scanning lines.

HEIGHT, WIDTH AND LINEARITY

To adjust the overall size and linearity of the picture it is almost mandatory that a test pattern transmitted from a local station be used. It should also be remembered that in areas where more than one station is being received, that pictures transmitted from different stations will vary slightly in size. The smallest transmitted picture should be made to fill the area outlined by the mask.



IDEAL BANDPASS

The Width control (rear of H.V. cage) should be adjusted to give a picture that will fill the mask horizontally.

The Height and Vertical Linearity controls (both rear of chassis) should then be adjusted for a linear picture that will fill the mask vertically.

TELEVISION ALIGNMENT PROCEDURE, UHF

Alignment of the UHF Tuner is a simple procedure since its bandpass is essentially predetermined by the fixed characteristics of original component design, physical layout and associated circuitry. Except as stated otherwise in this procedure, band-pass is not subject to serious change during alignment, however, replacement of any component within the R-F or I-F circuits may disturb the band-pass characteristics. Accordingly, whenever parts within these circuits are replaced, electrical and physical specifications of the original components must be duplicated as closely as possible. Wires, parts and other accessories must be replaced in their former positions.

Complicated or specially designed test equipment is not required for practical alignment of the UHF Tuner. Instruments used for testing VHF sets are usually satisfactory. However, the following instruments are needed;

1 – VHF signal generator with AM output and a sweep modulation of at least 12 megacycles.
2 – Oscilloscope or vacuum tube volt-ohmmeter for measurement of the relative signal.
3 – An operating VHF television set. (The latter is suggested as a practical amplifier for raising the output signal of the converter to a level which permits convenient observation.)

The UHF Tuner to be tested should be connected to the VHF television set in the usual manner. The oscilloscope or VTVM should then be connected to the TV set at a point which permits satisfactory observation of the relative intensity and character of the AM (or sweep-modulated) signal introduced into the tuner.

The procedure for alignment consists of the following steps in the suggested sequence given:

1 – Positioning of the oscillator for proper band coverage.
2 – Alignment of R-F-circuits for maximum effectiveness.

OSCILLATOR ADJUSTMENT

1 – Adjust UHF channel tuning control to extreme counter-clockwise position.
2 – Feed a 465-megacycle AM signal UHF Tuner antenna terminals through a resistive matching network. The input impedance of the tuner is 300 ohms balanced. Adjust oscillator trimmer (C3) for maximum signal. (Use non-metallic alignment tool.) (When using a VHF signal generator, a fundamental of 93 megacycles may be employed to produce the 5th harmonic energy of 465 megacycles.)
3 – Adjust VHF channel to extreme clockwise position.
4 – Set signal generator for a 900-megacycle output (5th harmonic of 180 megacycles). Carefully spread or pinch together the legs of the oscillator end-inductor (L3) for a maximum signal.
5 – Repeat above steps until no further improvement in signal is apparent. (The oscillator alignment figures of 465 and 900 megacycles are only approximate, and may not fall precisely at the maximum dial settings; however, in every case the oscillator must be aligned so that both frequencies can be tuned by normal manipulation of the dial.)

R.F. ALIGNMENT

1 – Adjust UHF channel tune control to extreme counter-clockwise position.
2 – Feed at 465-megacycle signal into the converter antenna terminals (as indicated above for oscillator alignment).
3 – Adjust R-F trimmers (C1 & C2) for maximum signal.
4 – Readjust tuning control to extreme clockwise position.
5 – Set signal generator for 900-megacycle output.
6 – Adjust end-inductors (L1 & L2) for maximum signal.
7 – Repeat above steps until no further improvement in signal is apparent.

PICTURE TUBE HANDLING PRECAUTIONS

The picture tube encloses a high vacuum and with the large surface area of glass involved, the stresses set up, particularly at the front rim of the tube, are considerable. An abnormal handling stress, accidental blow at a highly stressed surface, or even a scratch on the surface of the tube could cause it to implode or collapse with destructive violence.

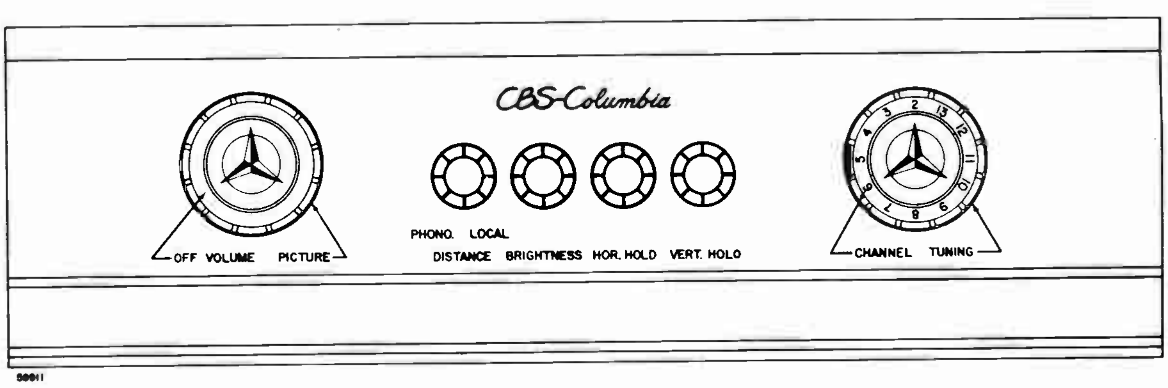
ADJUSTMENT OF ANTI-PINCUSHION MAGNETS

1-ADJUST THE HORIZONTAL CENTERING AND HORIZONTAL SIZE CONTROLS SO THAT THE ONE EDGE OF RASTER MAY BE SEEN.

2-IF EDGE OF RASTER IS BOWED, LOOSEN THE SCREW RETAINING THE ANTI-PINCUSHION MAGNET WHICH IS MOUNTED ON THE TIE-ROD BRACING THE PICTURE TUBE (ON THE SIDE WHICH SHOWS BOWING) SUFFICIENTLY TO ADJUST THE MAGNET BRACKET.

3-ADJUST THE MAGNET SPACING AND ROTATION, TO OBTAIN A STRAIGHT RASTER EDGE. TIGHTEN THE RETAINING SCREW.

4-REPEAT (1), (2), AND (3) FOR OPPOSITE EDGE OF RASTER.



The safety glass of this receiver is removable so that the face of the picture tube may be cleaned. To accomplish this remove power cord from wall socket. Remove the upper and side strips that hold the safety glass in place by removing the three screws which secure each of the strips, supporting the safety glass so that it does not fall forward. Remove the safety glass by tilting it forward and lifting it out of the slot found in the top edge of the control panel. Be careful not to scratch or strike the surface of the picture tube with any object. Carefully clean face of picture tube and the inside surface of the safety glass with a soft, clean, dry cloth. DO NOT ATTEMPT TO REMOVE THE PICTURE TUBE MASK. Reassemble by inserting lower edge of glass in slot. Replace upper and side strips and tighten the screws securely.

TELEVISION ALIGNMENT PROCEDURE

Aligning a television receiver is an exacting procedure and involves the use of bench space, test equipment and skilled personnel at the service shop, as well as the cost of making two trips to the customer's home. Before deciding that the chassis must be pulled and aligned at the shop, the serviceman should check these very common sources of trouble:

1 – The antenna and installation.

2 – Front panel and rear chassis controls, including picutre tube adjustments.

3 – Reception on all available channels.

4 – Tube failures. Substitute from your kit of known good replacements.

5 – Visual inspection of underside of chassis for obvious faults, such as loose connections, etc.

TEST EQUIPMENT REQUIRED FOR ALIGNMENT

The equipment specified below is desirable, but in cases where this equipment is not available, it is possible to align the receiver by use of a 20 to 30 mc. modulated r-f signal generator, using the picture and speaker as indication of alignment.

1 – Signal Generator with an output variable between 100 and 100,000 microvolts, and crystal controlled or crystal-calibrated at the following frequencies:

a– 4.5 megacycles

b– 22.8 megacycles

c– 25.4 megacycles

d– 21.25 megacycles

2 – DC Vacuum Tube Voltmeter with 5 volt and 10 volt scales.

3 – A pair of balanced (± 1%) 100K carbon resistors.

TEST EQUIPMENT REQUIRED FOR SWEEP ALIGNMENT CHECK

1 – R-F sweep generator with frequencies ranging from 40 to 220 megacycles, having sweep width of approximately 10 megacycles, and having adjustable output to approximately 0.1 volt.

2 – Crystal-controlled or crystal-calibrated markers for the picture and sound carriers of each channel.

3 – Cathode Ray Oscilloscope with good low frequency response.

CAUTION: THE SECOND ANODE LEAD TO THE PICTURE TUBE HAS A HIGH POTENTIAL. DURING THIS ALIGNMENT IT IS ADVISABLE TO REMOVE THE HORIZONTAL OUTPUT TUBE FROM ITS SOCKET, THUS ELIMINATING THIS HIGH VOLTAGE HAZARD.

I.F. ALIGNMENT PROCEDURE

1 – Connect "high" lead of signal generator to the test point located on the top of the RF tuner unit (Refer to the R-F tuner location diagram located on inside of cabinet). Connect ground to chassis.

2 – Connect DC VTVM lead (through 10K isolating resistor) to 4.7K diode load resistor (R113); ground to chassis. Set VTVM to 5 volt scale, negative polarity.

3 – Set I.F. generator to 25.4 megacycles with sufficient output to read approximately 3 volts on the VTVM.

4 – Carefully adjust L101 and L104 (see tube and tuner location) for maximum deflection on VTVM. Adjust sweep generator output to keep meter reading approximately 3 volts.

5 – Set I.F. signal generator to 22.8 megacycles with sufficient output to read approximately 3 volts on the VTVM.

6 – Carefully adjust L404, L103 (see tube and tuner location) for maximum deflection on VTVM. Adjust signal generator output to keep meter reading approximately 3 volts.

7 – Set I.F. signal generator to 21.25 megacycles, set VTVM to 10 volt scale (negative polarity), and adjust signal generator output for convenient deflection on VTVM.

8 – Adjust L114 for minimum deflection on VTVM.

SWEEP ALIGNMENT CHECK

Although not essential, a sweep alignment check is a desirable verification of good R-F and I.F. response. Proceed as follows:

1 – Connect R-F sweep generator to antenna terminals (antenna impedance 300 ohms.)

2 – Calibrate oscilloscope for convenient 5 volts peak-to-peak vertical deflection (5 volts peak-to-peak is approximately 1/4 of the peak-to-peak voltage of the 6.3V A.C. filament).

3 – Connect vertical input of oscilloscope (through 10K isolating resistor) to 4.7 diode load resistor (R113); ground to chassis. Connect horizontal input of oscilloscope to "scope" terminals of R-F generator; adjust for convenient horizontal sweep.

4 – Set R-F sweep generator to channel 3, television receiver to channel 3, and if necessary, adjust sweep generator output, sweep width, and scope horizontal setting for convenient band-pass display having 5 volts vertical deflection as previously calibrated. (If you must touch scope vertical settings during these adjustments recalibrate scope for 5 volts peak-to-peak as in step 2 above).

5 – Couple crystal-controlled R-F carrier markers very loosely to antenna terminals, adjust receiver FINE TUNING control till video carrier marker is 1/2 down on curve. Turn up marker output till R-f sound carrier is visible on bandpass and adjust sound trap (L114) to minimize effect of sound carrier marker.

6 – Check all channels as above.

SOUND ALIGNMENT

1 – Connect 4.5 megacycle signal generator to pin 2 of 12BH7 (V7) video amplifier.

2 – Connect DC V.T.V.M. lead to pin 7 of 6AL5 (V9) ratio detector, negative polarity.

3 – Adjust signal generator to precisely 4.5 megacycles; adjust output to read approximately 5 volts on V.T.V.M.

4 – Adjust L113 and bottom of T100 for maximum deflection on V.T.V.M. Keep V.T.V.M. reading below 10 volts at all times.

5 – Attach two series-connected 100K(± 1%) resistors across R126 (Ratio Detector Load Resistor). Connect DC V.T.V.M. to center-tap of 100K resistors, and connect ground wire of V.T.V.M. to junction of C119 and C120 (Audio Take-Off of T100).

6 – Adjust top of T100 for zero reading on V.T.V.M. between a plus and a minus peak.

VIDEO AMPLIFIER TRAP

When necessary, the video amplifier 4.5 mc trap (L110) should be adjusted as follows:

1 – Connect 4.5 mc signal generator "high" lead to picture tube grid; ground to chassis.

2 – Connect DC V.T.V.M. to pin 7 of 6AL5 (V9) ratio detector, 10 volt scale, negative polarity.

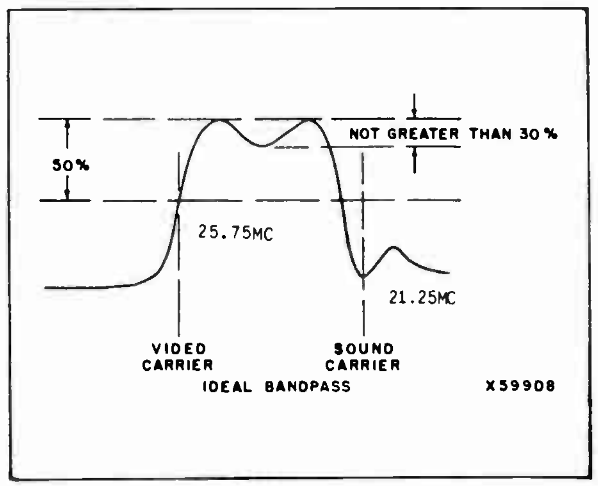
3 – Adjust L110 for minimum deflection on V.T.V.M.

R-F OSCILLATOR

If all channels are not within range of FINE TUNING control, adjust two screws located in front of r-f tuner unit for adjustment of either low or high band. CAUTION: Do not touch adjustments on top of r-f tuner unit, other than converter plate coil, L404, during IF Alignment.

HORIZONTAL OSCILLATOR ALIGNMENT

If the Horizontal Hold control fails to maintain sync, the horizontal oscillator should be reset. To reset this screwdriver adjustment, set the horizontal hold control in the center of its range and sync the picture with the horizontal A.F.C. adjustment screw. Check the hold control action on various channels and alter the screw adjustment as required to provide sync on all channels.



DEFLECTION YOKE, ION TRAP AND FOCUS ADJUSTMENT

Following is the proper procedure for adjusting the Deflection Yoke, Ion Trap and Focus.

The receiver should be turned on but not connected to an antenna. These steps should then be taken in the following order:

1 – The Deflection Yoke should be moved as far forward as possible on the neck of the CRT.

2 – The Brightness control should be turned to maximum (clockwise) and the Contrast control should be turned to minimum (counterclockwise).

3 – The Ion Trap should be rotated and at the same time moved forward and backward to find the position which produces the brightest raster on screen.

4 – The Deflection Yoke should be rotated so that the top and bottom edges of the raster are parallel to the top of the chassis.

5 – The Brightness control should now be reduced (ccw) to a point where the raster is slightly above normal brilliance.

6 – With Brightness and Contrast controls at normal positions, adjust the Focus control (rear of chassis) for well-defined scanning lines.

HEIGHT, WIDTH AND LINEARITY

To adjust the overall size and linearity of the picture it is almost mandatory that a test pattern transmitted from a local station be used. It should also be remembered that in areas where more than one station is being received, that pictures transmitted from different stations will vary slightly in size. The smallest transmitted picture should be made to fill the area outlined by the mask.

The Width control (rear of H.V. cage) should be adjusted to give a picture that will fill the mask horizontally.

The Height and Vertical Linearity controls (both rear of chassis) should then be adjusted for a linear picture that will fill the mask vertically.

AM RADIO ALIGNMENT PROCEDURE

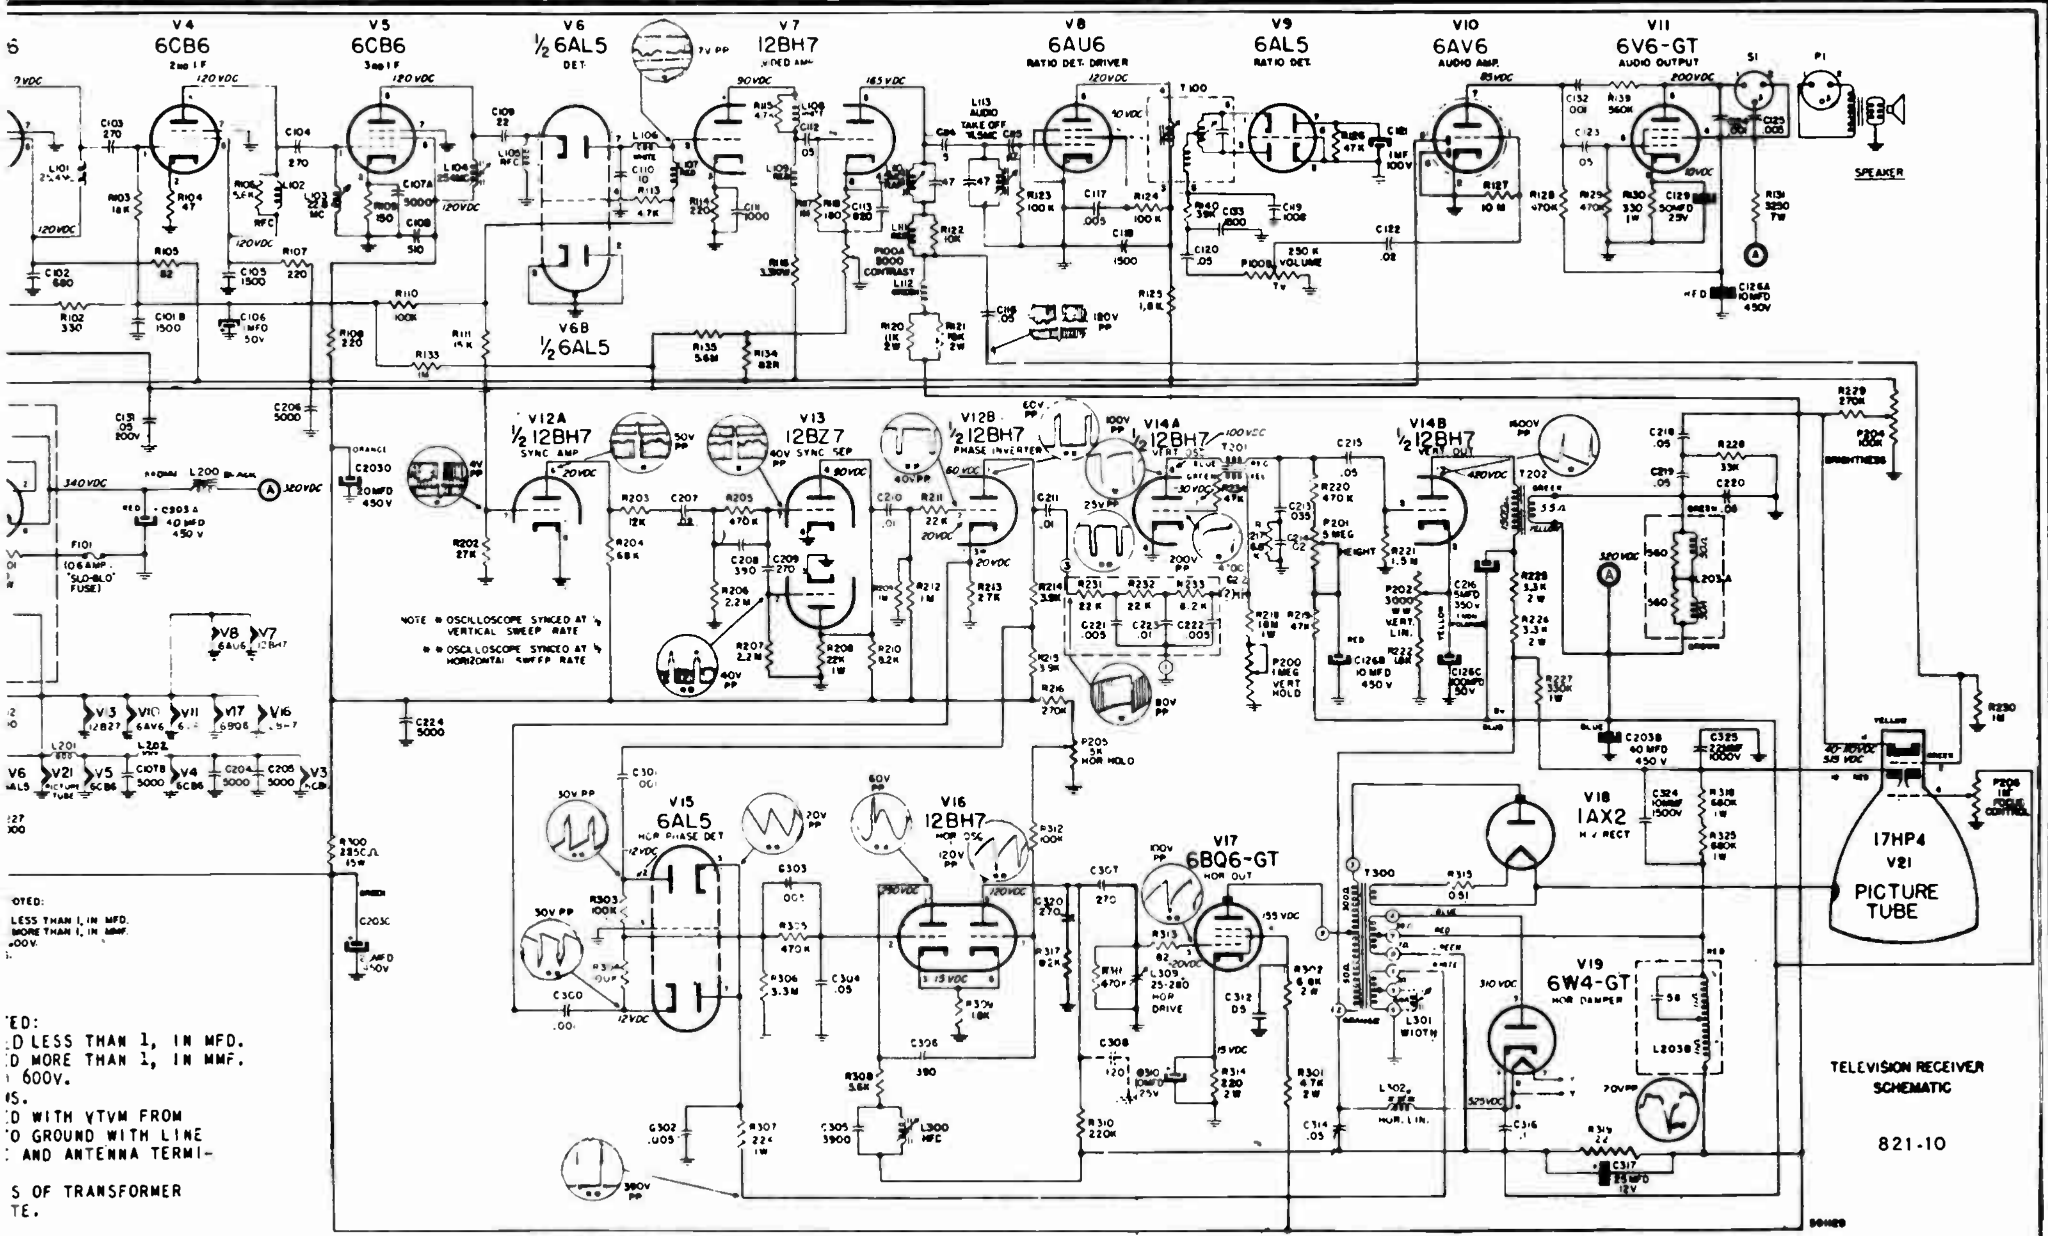
Signal Generator	Alignment Frequency	Adjust	Read Max. Output Across Voice Coil
Connected to Antenna Section of Gang and Gnd. thru 0.1 mfd Capacitor.	455 KC	Top & Bottom T502 & T501	Gang Open
	1620 KC	Trimmer C501B	
Connected to Radiating Loop.	1400 KC	Trimmer C501A	Gang Tuned To 1400 KC

PICTURE TUBE HANDLING PRECAUTIONS

The picture tube encloses a high vacuum and with the large surface area of glass involved, the stresses set up, particularly at the front rim of the tube, are considerable. An abnormal handling stress, accidental blow at a highly stressed surface, or even a scratch on the surface of the tube could cause it to implode or collapse with destructive violence.

HIGH VOLTAGE WARNING

Operation of this receiver outside the cabinet or with covers removed involves a shock hazard from the receiver power supplies. Work on the receiver should not be attempted by anyone who is not thoroughly familiar with the precautions necessary when working on high voltage equipment.



TELEVISION RECEIVER SCHEMATIC

821-10

SWEEP ALIGNMENT CHECK

though not essential, a sweep alignment check is a desirable verification of l-F and I.F. response. Proceed as follows:

– Connect R-F sweep generator to antenna terminals (antenna impedance 300 ohms.)
– Calibrate oscilloscope for convenient 5 volts peak-to-peak vertical deflection (5 volts peak-to-peak is approximately 1/4 of the peak-to-peak voltage of the 6.3V A.C. filament).
– Connect vertical input of oscilloscope (through 10K isolating resistor) to 4.7 diode load resistor (R113); ground to chassis. Connect horizontal input of oscilloscope to "scope" terminals of R-F generator; adjust for convenient horizontal sweep.
– Set R-F sweep generator to channel 3, television receiver to channel 3, and if necessary, adjust sweep generator output, sweep width, and scope horizontal setting for convenient band-pass display having 5 volts vertical deflection as previously calibrated. (If you must touch scope vertical settings during these adjustments recalibrate scope for 5 volts peak-to-peak as in step 2 above).
– Couple crystal-controlled R-F carrier markers very loosely to antenna terminals, adjust receiver FINE TUNING control till video carrier marker is 1/2 down on curve. Turn up marker output till R-f sound carrier is visible on bandpass and adjust sound trap (L114) to minimize effect of sound carrier marker.
– Check all channels as above.

SOUND ALIGNMENT

- Connect 4.5 megacycle signal generator to pin 2 of 12BH6 (V7) video amplifier.
- Connect DC V.T.V.M. lead to pin 7 of 6AL6 (V9) ratio detector, negative polarity.
- Adjust signal generator to precisely 4.5 megacycles; adjust output to read approximately 5 volts on V.T.V.M.
- Adjust L113 and bottom of T100 for maximum deflection on V.T.V.M. Keep V.T.V.M. reading below 10 volts at all times.
- Attach two series-connected 100K (± 1%) resistors across R126 (Ratio Detector Load Resistor). Connected DC V.T.V.M. to center-tap of 100K resistors, and connect ground wire of V.T.V.M. to junction of C119 and C120 (Audio Take-Off of T100).
- Adjust top of T100 for zero reading on V.T.V.M. between a plus and a minus peak.

VIDEO AMPLIFIER TRAP

ıen necessary, the video amplifier 4.5 mc trap (L110) should be adjusted as ı:

- Connect 4.5 mc signal generator "high" lead to picture tube grid; ground to chassis.
- Connect DC V.T.V.M. to pin 7 to 6AL5 (V9) ratio detector, 10 volt scale, negative polarity.
- Adjust L110 for minimum deflection on V.T.V.M.

REAR VIEW

TELEVISION ALIGNMENT PROCEDURE VHF

Aligning a television receiver is an exacting procedure and involves the use of bench space, test equipment and skilled personnel at the service shop, as well as the cost of making two trips to the customer's home. Before deciding that the chassis must be pulled and aligned at the shop, the serviceman should check these very common sources of trouble:

1 – The antenna and installation.
2 – Front panel and rear chassis controls, including picture tube adjustments.
3 – Reception on all available channels.
4 – Tube failures. Substitnte from your kit of known good replacements.
5 – Visnal inspection of underside of chassis for obvious faults, such as loose connections, etc.

TEST EQUIPMENT REQUIRED FOR ALIGNMENT

The equipment specified below is desirable, but in cases where this equipment is not available, it is possible to align the receiver by use of a 20 to 30 mc. modulated r-f signal generator, using the picture and speaker as indication of alignment.

1 – Signal Generator with an output variable between 100 and 100,000 microvolts, and crystal controlled or crystal-calibrated at the following frequencies:
  a– 4.5 megacycles
  b– 22.8 megacycles
  c– 25.4 megacycles
  d– 21.25 megacycles
2 – DC Vacuum Tube Voltmeter with 5 volt and 10 volt scales.
3 – A pair of balanced (± 1%) 100K carbon resistors.

TEST EQUIPMENT REQUIRED FOR SWEEP ALIGNMENT CHECK

1 – R-F sweep generator with frequencies ranging from 40 to 220 megacycles, having sweep width of approximately 10 megacycles, and having adjustable output to approximately 0.1 volt.
2 – Crystal-controlled or crystal-calibrated markers for the picture and sound carriers of each channel.
3 – Cathode Ray Oscilloscope with good low frequency response.

CAUTION: THE SECOND ANODE LEAD TO THE PICTURE TUBE HAS A HIGH POTENTIAL. DURING THIS ALIGNMENT IT IS ADVISABLE TO REMOVE THE HORIZONTAL OUTPUT SOCKET FROM ITS SOCKET, THUS ELIMINATING THIS HIGH VOLTAGE HAZARD.

I.F. ALIGNMENT PROCEDURE

1 – Connect "high" lead of signal Generator to the VHF antenna. (Test point cannot be used for IF alignment because low generator impedance detunes IF circuits in plate circuits of 6x8 mixer oscillator.)
2 – Connect DC VTVM lead (through 10K isolating resistor) to 4.7K diode load resistor (R113); ground to chassis. Set VTVM to 5 volt scale, negative polarity.
3 – Set I.F. generator to 25.4 megacycles with sufficient output to read approximately 3 volts on the VTVM.
4 – Carefully adjust L101 and L104 (see tube and tuner location) for maximum deflection on VTVM. Adjust sweep generator output to keep meter reading approximately 3 volts.
5 – Set I.F. signal generator to 22.8 megacycles with sufficient output to read approximately 3 volts on the VTVM.
6 – Carefully adjust L405, L103 (see tube and tuner location) for maximum deflection on VTVM. Adjust signal generator output to keep meter reading approximately 3 volts.
7 – Set I.F. signal generator to 21.25 megacycles, set VTVM to 10 volt scale (negative polarity), and adjust signal generator output for convenient deflection on VTVM.
8 – Adjust L114 for minimum deflection on VTVM.

SAFETY GLASS REMOVAL INSTRUCTION

The safety glass of this receiver is removable so that the face of the Picture Tube may be cleaned. Before proceeding, carefully observe the following precautions:

1 – REMOVE THE POWER CORD FROM THE WALL SOCKET.

2 – DO NOT ATTEMPT TO REMOVE THE PIX TUBE MASK UNDER ANY CIRCUMSTANCES.

3 – BE CAREFUL NOT TO SCRATCH OR STRIKE THE SURFACE OF THE PICTURE TUBE WITH ANY OBJECT.

4 – CLEAN THE FACE OF THE PICTURE TUBE AND THE INSIDE SURFACE OF THE SAFETY GLASS WITH A SOFT, CLEAN, DRY CLOTH.

Remove upper strip secured by (5) screws. Tilt glass forward and lift out of slot of lower glass retaining strip. Observing the above precautions, carefully clean Pix Tube and Safety Glass. Reassemble by inserting glass in slot of lower strip, replacing upper strip and tightening screws securely.

CABINET REPAIR PARTS LIST

PART NAME	MODEL 22K38	PART NAME	MODEL 22K38
Cabinet	PE60194	Speaker	PC58121 10" PM
Trapdoor	PD4497	Knob, TV/AM/Phono Switch	PA39266

TELEVISION RECEIVER SCHEMATIC 821-20

59990A

TELEVISION ALIGNMENT PROCEDURE

Aligning a television receiver is an exacting procedure and involves the use of bench space, test equipment and skilled personnel at the service shop, as well as the cost of making two trips to the customer's home. Before deciding that the chassis must be pulled and aligned at the shop, the serviceman should check these very common sources of trouble:

1 – The antenna and installation.

2 – Front panel and rear chassis controls, including picture tube adjustments.

3 – Reception on all available channels.

4 – Tube failures. Substitute from your kit of known good replacements.

5 – Visual inspection of underside of chassis for obvious faults, such as loose connections, etc.

TEST EQUIPMENT REQUIRED FOR ALIGNMENT

The equipment specified below is desirable, but in cases where this equipment is not available, it is possible to align the receiver by use of a 20 to 30 mc. modulated r-f signal generator, using the picture and speaker as indication of alignment.

1 – Signal Generator with an output variable between 100 and 100,000 microvolts, and crystal controlled or crystal-calibrated at the following frequencies:

a. 4.5 megacycles

b. 22.25 megacycles

c. 25.4 megacycles

d. 23.6 megacycles

e. 21.25 megacycles

2 – DC Vacuum Tube Voltmeter with 5 volt and 10 volt scales.

3 – A pair of balanced (⁄1%) 100K carbon resistors.

TEST EQUIPMENT REQUIRED FOR SWEEP ALIGNMENT CHECK

1 – R-F sweep generator with frequencies ranging from 40 to 220 megacycles, having sweep width of approximately 10 megacycles, and having adjustable output to approximately 0.1 volt.

2 – Crystal-controlled or crystal-calibrated markers for the picture and sound carriers of each channel, preferably 30% Amplitude-Modulated.

3 – Cathode Ray Oscilloscope with good low frequency response.

4 – 3 volt bias battery.

CAUTION: THE SECOND ANODE LEAD TO THE PICTURE TUBE HAS A HIGH POTENTIAL. DURING THIS ALIGNMENT IT IS ADVISABLE TO REMOVE THE COLOR PLUG FROM ITS SOCKET, THUS ELIMINATING THIS HIGH VOLTAGE HAZARD.

I.F. ALIGNMENT PROCEDURE

1 – Connect "high" lead of signal generator to the test point located on the top of the RF tuner unit (Refer to the R-F tuner location diagram located on the inside of cabinet). Connect ground to chassis.

2 – Connect DC VTVM lead (through 10K isolating resistor) to pin 1 of 6AU6 1 st Video Amplifier (V12), ground to chassis. Set VTVM to 5 volt scale, negative polarity.

3 – Set I.F. generator to 25.4 megacycles with sufficient output to read approximately 3 volts on the VTVM.

4 – Carefully adjust L201 and L203 (see tube and tuner location) for maximum deflection on VTVM. Adjust sweep generator output to keep meter reading approximately 3 volts.

5 – Set I.F. signal generator to 22.25 megacycles with sufficient output to read approximately 3 volts on the VTVM.

6 – Carefully adjust L11, L202-top (see tube and tuner location) for maximum deflection on VTVM. Adjust signal generator output to keep meter reading approximately 3 volts.

7 – Set i-f signal generator to 23.6 mc. with sufficient output to read approximately 3 volts on the VTVM.

8 – Carefully adjust L205 (see tube and tuner location) for maximum deflection on VTVM. Adjust signal generator out-put to keep meter reading approximately 3 volts.

9 – Set I.F. signal generator to 21.25 megacycles, set VTVM to 10 volt scale (negative polarity), and adjust signal generator output for convenient defection on VTVM.

10 – Adjust L202-bottom for minimum deflection on VTVM.

SWEEP ALIGNMENT CHECK

Although not essential, a sweep alignment check is a desirable verification of good R-F and I.F. response. Proceed as follows:

1 – Connect R-F sweep generator to antenna terminals (antenna impedance 300 Ohms).

2 – Calibrate oscilloscope for convenient 5 volts peak-to-peak vertical deflection (5 volts peak-to-peak is approximately 1/4 of the peak-to-peak voltage of the 6.3V A.C. Filament).

3 – Connect vertical input of oscilloscope (through 10K isolating resistor) to pin 1 of 6AU6 1st Vid. Amp. (V12) ground to chassis. Connect horizontal input of oscilloscope to "scope" terminals of R-F generator; adjust for convenient horizontal sweep.

4 – Connect 3 volt battery positive terminal to chassis negative terminal to AGC buss (see schematic diagram).

5 – Set R-F sweep generator to channel 3, television receiver to channel 3, and if necessary, adjust sweep generator output, sweep width, and scope horizontal setting for convenient band-pass display (see figure 1) having 5 volts vertical defection as previously calibrated. (If you must touch scope vertical settings during these adjustments recalibrate scope for 5 volts peak-to-peak as in step 2 above).

6 – Adjust L205 slightly to even the height of peaks and to obtain an untilted bandpass.

7 – Couple crystal-controlled R-F carrier markers very loosely to antenna terminals, adjust receiver FINE TUNING control till video carrier marker is 1/2 down on curve. Turn up marker output till R-f sound carrier visible on bandpass and adjust sound trap (L114) to minimize effect to sound carrier marker.

NOTE: If the fine tuning control is at end of range or out of range so that video carrier cannot be set at 50%, follow R-F OSCILLATOR ALIGNMENT procedure outlined below.

8 – Check all channels.

R-F OSCILLATOR ALIGNMENT

If all channels are not within range of FINE TUNING control (as evidenced by inability to eliminate "sound bars" from picture or by poor picture quality), the individual oscillator slugs may require readjustment.

1 – Repeat the set-up as for SWEEP ALIGNMENT CHECK, steps 1 through 7.

2 – Set FINE TUNING CONTROL to center of range, and with long fiber screwdriver alignment tool, adjust the individual oscillator slugs of each channel. (Accessible through the front of the tuner) so that video carrier markers fall 50% down on curve. CAUTION: Do not touch adjustments on top of r-f tuner unit, other than the converter plate unit, L11, during I.F. alignment.

SOUND ALIGNMENT

1 – Connect 4.5 mc. signal generator to pin 1 of 6AU6 4.5 mc. amplifier (V13).

2 – Connect DC V.T.V.M. lead to pin 7 of 6AL5 (V15) ratio detector, negative polarity.

3 – Adjust signal generator to precisely 4.5 megacycles; adjust output to read approximately 5 volts on V.T.V.M.

4 – Adjust L206, L101, and bottom of T102 for maximum deflection on V.T.V.M. Keep V.T.V.M. reading below 10 volts at all times.

5 – Attach two series-connected 100K (⁄1%) resistors across R106 (Ratio Detector Load Resistor). Connect DC V.T.V.M. to centertap of 100K resistors, and connect ground wire of V.T.V.M. to top of C109 (Audio take-Off of T102).

6 – Adjust top of T102 for zero reading on V.T.V.M. between a plus and a minus peak.

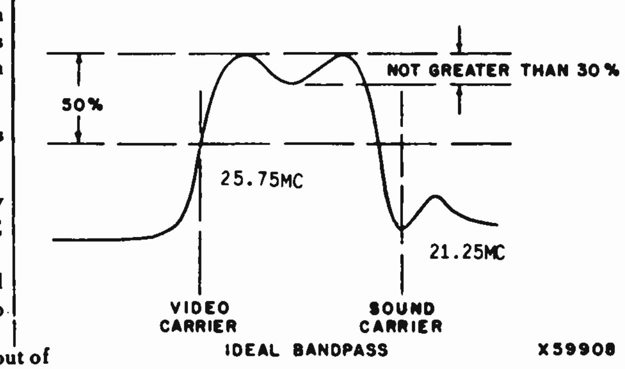
VIDEO AMPLIFIER 4.5 mc. TRAP

When necessary, the video amplifier 4.5 mc. trap (L104) should be adjusted as follows:

1 – Connect 4.5 mc. signal generator to pin 1 of 6AU6 1st video amplifier (V12).

2 – Adjust signal generator output till 4.5 mc. dot pattern is clearly visible on screen of picture tube.

3 – Adjust L104 to minimize the dot pattern.



HORIZONTAL OSCILLATOR ALIGNMENT

If the Horizontal Hold control fails to maintain sync, the horizontal oscillator should be reset. To reset this screwdriver adjustment, set the horizontal hold control in the center of its range and sync the picture with the horizontal A.F.C. adjustment screw. Check the hold control action on various channels and alter the screw adjustment as required to provide sync on all channels.

DEFLECTION YOKE, ION TRAP AND FOCUS ADJUSTMENT

Following is the proper procedure for adjusting the Deflection Yoke, Ion Trap and Focus.

The receiver should be turned on but not connected to an antenna. These steps should then be taken in the following order:

1 – The Deflection Yoke should be moved as far forward as possible on the neck of the CRT.

2 – The Brightness control should be turned to maximum (clockwise) and the Contrast control should be turned to minimum (counterclockwise).

3 – The Ion Trap should be rotated and at the same time moved forward and backward to find the position which produces the brightest raster on screen.

4 – The Deflection Yoke should be rotated so that the top and bottom edges of the raster are parallel to the top of the chassis.

5 – The Brightness control should now be reduced (ccw) to a point where the raster is slightly above normal brilliance.

HEIGHT, WIDTH, LINEARITY, AND HORIZONTAL DRIVE

To adjust the overall size and linearity of the picture it is almost mandatory that a test pattern transmitted from a local station be used. It should also be remembered that in areas where more than one station is being received, that pictures transmitted from different stations will vary slightly in size. The smallest transmitted picture should be made to fill the area outlined by the mask.

1 – Starting with the HORIZONTAL DRIVE control (rear of chassis) in extreme counterclockwise position, advance the control clockwise till the compression near the center of the picture (a vertical bright bar) is eliminated.

2 – The Width and Horizontal Linearity controls (rear of chassis) should be adjusted to give a picture that will fill the mask horizontally, with the minimum of stretching or compression.

3 – The Height and Vertical Linearity controls (both rear of chassis) should then be adjusted for a linear picture that will fill the mask vertically.

PICTURE TUBE HANDLING PRECAUTIONS

The picture tube encloses a high vacuum and with the large surface area of glass involved, the stresses set up, particularly at the front rim of the tube, are considerable. An abnormal handling stress, accidental blow at a highly stressed surface, or even a scratch on the surface of the tube could cause it to implode or collapse with destructive violence.

HIGH VOLTAGE WARNING

Operation of this receiver outside the cabinet or with covers removed involves a shock hazard from the receiver power supplies. Work on the receiver should not be attempted by anyone not thoroughly familiar with the precautions necessary when working on high voltage equipment.

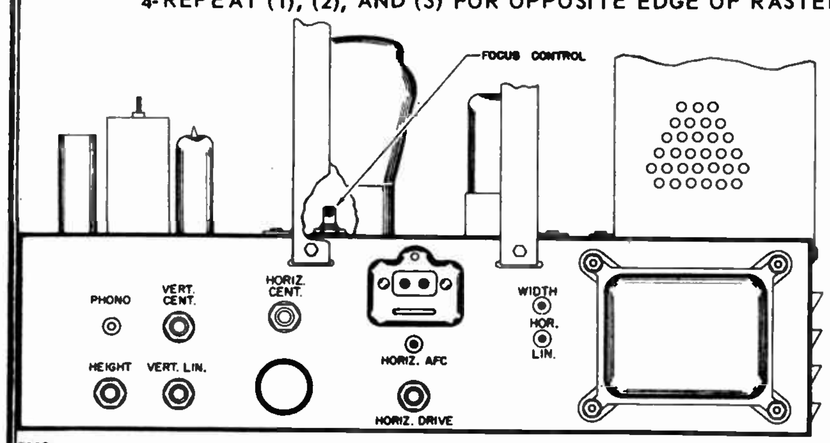
ADJUSTMENT OF ANTI-PINCUSHION MAGNETS

1-ADJUST THE HORIZONTAL CENTERING AND HORIZONTAL SIZE CONTROLS SO THAT THE ONE EDGE OF RASTER MAY BE SEEN.

2-IF EDGE OF RASTER IS BOWED, LOOSEN THE SCREW RETAINING THE ANTI-PINCUSHION MAGNET WHICH IS MOUNTED ON THE TIE-ROD BRACING THE PICTURE TUBE (ON THE SIDE WHICH SHOWS BOWING) SUFFICIENTLY TO ADJUST THE MAGNET BRACKET.

3-ADJUST THE MAGNET SPACING AND ROTATION, TO OBTAIN A STRAIGHT RASTER EDGE. TIGHTEN THE RETAINING SCREW.

4-REPEAT (1), (2), AND (3) FOR OPPOSITE EDGE OF RASTER.



REAR CONTROLS
1021 CHASSIS

The safety glass of this receiver is removable so that the face of the picture tube may be cleaned. To accomplish this remove power cord from wall socket. Remove the upper strip that holds the safety glass in place by removing the five screws which secure the strip, supporting the safety glass so that it does not fall forward. Remove the safety glass by tilting it forward and lifting it out of the slot in the lower glass retaining strip. Be careful not to scratch or strike the surface of the picture tube with any object. Carefully clean face of picture tube and the inside surface of the safety glass with a soft, clean, dry cloth. DO NOT ATTEMPT TO REMOVE THE PICTURE TUBE MASK. Reassemble by inserting glass in slot of lower strip. Replace upper strip and tighten the screws securely.

*Used on all chassis unless otherwise specified in this column. If specified, the part is used only on the chassis indicated.

TELEVISION ALIGNMENT PROCEDURE VHF

Aligning a television receiver is an exacting procedure and involves the use of bench space, test equipment and skilled personnel at the service shop, as well as the cost of making two trips to the customer's home. Before deciding that the chassis must be pulled and aligned at the shop, the serviceman should check these very common sources of trouble:

1 – The antenna and installation.
2 – Front panel and rear chassis controls, including picture tube adjustments.
3 – Reception on all available channels.
4 – Tube failures. Substitute from your kit of known good replacements.
5 – Visual inspection of underside of chassis for obvious faults, such as loose connections, etc.

TEST EQUIPMENT REQUIRED FOR ALIGNMENT

The equipment specified below is desirable, but in cases where this equipment is not available, it is possible to align the receiver by use of a 20 to 30 mc. modulated r-f signal generator, using the picture and speaker as indication of alignment.

1 – Signal Generator with an output variable between 100 and 100,000 micro-volts, and crystal controlled or crystal-calibrated at the following frequencies:
a–4.5 megacycles c–25.4 megacycles
b–22.8 megacycles d–21.25 megacycles
2 – DC Vacuum Tube Voltmeter with 5 volt and 10 volt scales.
3 – A pair of balanced (± 1%) 100K carbon resistors.

TEST EQUIPMENT REQUIRED FOR SWEEP ALIGNMENT CHECK

1 – R-F sweep generator with frequencies ranging from 40 to 220 megacycles, having sweep width of approximately 10 megacycles, and having adjustable output to approximately 0.1 volt.
2 – Crystal-controlled or crystal-calibrated markers for the picture and sound carriers of each channel.
3 – Cathode Ray Oscilloscope with good low frequency response.

CAUTION: THE SECOND ANODE LEAD TO THE PICTURE TUBE HAS A HIGH POTENTIAL. DURING THIS ALIGNMENT IT IS ADVISABLE TO REMOVE THE HORIZONTAL OUTPUT TUBE FROM ITS SOCKET, THUS ELIMINATING THIS HIGH VOLTAGE HAZARD.

I.F. ALIGNMENT PROCEDURE

1 – Connect "high" lead of signal Generator to the VHF antenna. (Test point cannot be used for IF alignment because low generator impedance detunes IF circuits in plate circuits of 6x8 mixer oscillator.)
2 – Connect DC VTVM lead (through 10K isolating resistor) to 4.7K diode load resistor (R113); ground to chassis. Set VTVM to 5 volt scale, negative polarity.
3 – Set I.F. generator to 25.4 megacycles with sufficient output to read approximately 3 volts on the VTVM.
4 – Carefully adjust L101 and L104 (see tube and tuner location) for maximum deflection on VTVM. Adjust sweep generator output to keep meter reading approximately 3 volts.
5 – Set I.F. signal generator to 22.8 megacycles with sufficient output to read approximately 3 volts on the VTVM.
6 – Carefully adjust L2, L103 (see tube and tuner location) for maximum deflection on VTVM. Adjust signal generator output to keep meter reading approximately 3 volts.
7 – Set I.F. signal generator to 21.25 megacycles, set VTVM to 10 volt scale (negative polarity), and adjust signal generator output for convenient deflection on VTVM.
8 – Adjust L114 for minimum deflection on VTVM.

SWEEP ALIGNMENT CHECK

Although not essential, a sweep alignment check is a desirable verification of good R-F and I.F. response. Proceed as follows:

1 – Connect R-F sweep generator to antenna terminals (antenna impedance 300 ohms.)
2 – Calibrate oscilloscope for convenient 5 volts peak-to-peak vertical deflection (5 volts peak-to-peak is approximately 1/4 of the peak-to-peak voltage of the 6.3V A.C. filament).
3 – Connect vertical input of oscilloscope (through 10K isolating resistor) to 4.7K diode load resistor (R113); ground to chassis. Connect horizontal input of oscilloscope to "scope" terminals of R-F generator; adjust for convenient horizontal sweep.
4 – Set R-F sweep generator to channel 3, television receiver to channel 3, and if necessary, adjust sweep generator output, sweep width, and scope horizontal setting for convenient band-pass display having 5 volts vertical deflection as previously calibrated. (If you must touch scope vertical settings during these adjustments recalibrate scope for 5 volts peak-to-peak as in step 2 above).
5 – Couple crystal-controlled R-F carrier markers very loosely to antenna terminals, adjust receiver FINE TUNING control till video carrier marker is 1/2 down on curve. Turn up marker output till R-f sound carrier is visible on bandpass and adjust sound trap (L114) to minimize effect of sound carrier marker.
6 – Check all channels as above.

SOUND ALIGNMENT

1 – Connect 4.5 megacycle signal generator to pin 2 of 12BH6 (V7) video amplifier.
2 – Connect DC V.T.V.M. lead to pin 7 of 6AL6 (V9) ratio detector, negative polarity.
3 – Adjust signal generator to precisely 4.5 megacycles; adjust output to read approximately 5 volts on V.T.V.M.
4 – Adjust L113 and bottom of T100 for maximum deflection on V.T.V.M. Keep V.T.V.M. reading below 10 volts at all times.
5 – Attach two series-connected 100K (± 1%) resistors across R126 (Ratio Detector Load Resistor). Connected DC V.T.V.M. to center-tap of 100K resistors, and connect ground wire of V.T.V.M. to junction of C119 and C120 (Audio Take-Off of T100).
6 – Adjust top of T100 for zero reading on V.T.V.M. between a plus and a minus peak.

VIDEO AMPLIFIER TRAP

When necessary, the video amplifier 4.5 mc trap (110) should be adjusted as follows:

1 – Connect 4.5 mc signal generator "high" lead to picture tube grid; ground to chassis.
2 – Connect DC V.T.V.M. to pin 7 to 6AL5 (V9) ratio detector, 10 volt scale, negative polarity.
3 – Adjust L110 for minimum deflection on V.T.V.M.

R-F OSCILLATOR

If all channels are not within range of FINE TUNING control, adjust two screws located in front of r-f tuner unit for adjustment of either low or high band. CAUTION: Do not touch adjustments on top of r-f tuner unit, other than converter plate coil, L2. during IF Alignment.

HORIZONTAL OSCILLATOR ALIGNMENT

If the Horizontal Hold control fails to maintain sync, the horizontal oscillator should be reset. To reset this screwdriver adjustment, set the horizontal hold control in the center of its range and sync the picture with the horizontal A.F.C. adjustment screw. Check the hold control action on various channels and alter the screw adjustment as required to provide sync on all channels.

DEFLECTION YOKE, ION TRAP AND FOCUS ADJUSTMENT

Following is the proper procedure for adjusting the Deflection Yoke, Ion Trap and Focus.

The Receiver should be turned on but not connected to an antenna. These steps should then be taken in the following order:

* L406 in chassis 105-3-81706, 105-3-82104 & 105-3-82106

1 – The Deflection Yoke should be moved as far forward as possible on the neck of the CRT.
2 – The Brightness control should be turned to maximum (clockwise) and the Contrast control should be turned to minimum (counterclockwise).
3 – The Ion Trap should be rotated and at the same time moved forward and backward to find the position which produces the brightest raster on screen.
4 – The Deflection Yoke should be rotated so that the top and bottom edges of the raster are parallel to the top of the chassis.
5 – The Brightness control should now be reduced (ccw) to a point where the raster is slightly above normal brilliance.
6 – With Brightness and Contrast controls at normal positions, adjust the Focus control (rear of chassis) for well-defined scanning lines.

HEIGHT, WIDTH AND LINEARITY

To adjust the overall size and linearity of the picture it is almost mandatory that a test pattern transmitted from a local station be used. It should also be remembered that in areas where more than one station is being received, that pictures transmitted from different stations will vary slightly in size. The smallest transmitted picture should be made to fill the area outlined by the mask.

The Width control (rear of H.V. cage) should be adjusted to give a picture that will fill the mask horizontally.

The Height and Vertical Linearity controls (both rear of chassis) should then be adjusted for a linear picture that will fill the mask vertically.

TELEVISION ALIGNMENT PROCEDURE, UHF

Alignment of the UHF Tuner is a simple procedure since its bandpass is essentially predetermined by the fixed characteristics of original component design, physical layout and associated circuitry. Except as stated otherwise in this procedure, band-pass is not subject to serious change during alignment, however, replacement of any component within the R-F or I-F circuits may disturb the band-pass characteristics. Accordingly, whenever parts within these circuits are replaced, electrical and physical specifications of the original components must be duplicated as closely as possible. Wires, parts and other accessories must be replaced in their former positions.

Complicated or specially designed test equipment is not required for practical alignment of the UHF Tuner. Instruments used for testing VHF sets are usually satisfactory. However, the following instruments are needed;

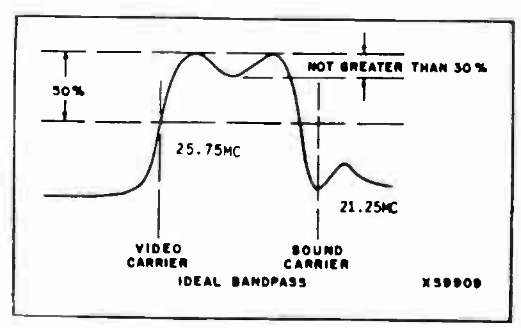
1 – VHF signal generator with AM output and a sweep modulation of at least 12 megacycles.
2 – Oscilloscope or vacuum tube volt-ohmmeter for measurement of the relative signal.
3 – An operating VHF television set. (The latter is suggested as a practical amplifier for raising the output signal of the converter to a level which permits convenient observation.)

PICTURE TUBE HANDLING PRECAUTIONS

The picture tube encloses a high vacuum and with the large surface area of glass involved, the stresses set up, particularly at the front rim of the tube, are considerable. An abnormal handling stress, accidental blow or a highly stressed surface, or even a scratch on the surface of the tube could cause it to implode or collapse with destructive violence.

HIGH VOLTAGE WARNING

Operation of this receiver outside the cabinet or with covers removed involves a shock hazard from the receiver power supplies. Work on the receiver should not be attempted by anyone who is not thoroughly familiar with the precautions necessary when working on high voltage equipment.



ALIGNMENT PROCEDURE UHF TUNER PC541452

Alignment of the UHF Tuner is a simple procedure since its bandpass is essentially predetermined by the fixed characteristics of original component design, physical layout and associated circuitry. Except as stated otherwise in this procedure, band-pass is not subject to serious change during alignment, however, replacement of any component within the R-F or I-F circuits may disturb the band-pass characteristics. Accordingly, whenever parts within these circuits are replaced, electrical and physical specifications of the original components must be duplicated as closely as possible. Wires, parts and other accessories must be replaced in their former positions.

Complicated or specially designed test equipment is not required for practicsl alignment of the UHF Tuner. Instruments used for testing VHF sets are usually satisfactory. However, the following instruments are needed;

1 – VHF signal generator with AM output.
2 – Oscilloscope or vacuum tube volt-ohmmeter for measurement of the relative signal.

The oscilloscope or VTVM should be connected across the TV set video detector load resistor, R113.

The procedure for alignment consists of the following steps in the suggested sequence given;

1 – Positioning of the oscillator for proper band coverage.
2 – Alignment of R-F circuits for maximum effectiveness.

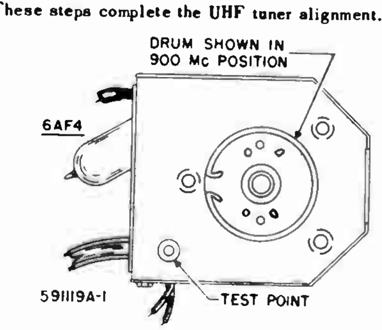
OSCILLATOR ADJUSTMENT

1 – Turn drum to extreme CCW position.
2 – Correct the signal generator to the UHF tuner antenna terminals and adjust generator for a signal between 459 and 466 megacycles. If no response is observed, carefully squeeze the short ends of the oscillator tuning condenser plates together or spread them apart until some frequency within the 459 to 466 mc range produces a response.
3 – Turn the tuning drum to extreme clockwise position.
4 – Swing the signal generator thru the frequency range 894 to 903 megacycles. If a response within this range is obtained, no adjustment is necessary. If a response below 894 mc occurs, carefully squeeze the long ends of the oscillator plates slightly together until a signal between 894 and 903 mc produces a response. If the output occurs above 903 mc carefully spread the oscillator plates slightly at the long end.

NOTE: Only a very slight amount of bending should be required in any case of incomplete band coverage, as this unit is assembled in a precision jig.

1 – With the signal generator and VTVM or oscilloscope connected as in the oscillator adjustment, adjust the signal generator to 470 mc and tune in this signal on the tuner. (near extreme counter clockwise position.)
2 – Squeeze together or spread apart the short ends of the plates of the two R.F. tuning condenser sections until a maximum response is obtained.
3 – Set the signal generator to 890 mc and tune in this signal on the tuner (near extreme clockwise position).
4 – Squeeze together or spread apart the long ends of the RF tuning condenser plates until a maximum response is obtained.

These steps complete the UHF tuner alignment.



125.25 Mc UHF TUNER PC 541452

SAFETY GLASS REMOVAL INSTRUCTIONS

The safety glass of some receivers is removable so that the face of the Picture Tube may be cleaned. Before proceeding, carefully observe the following precautions:

1. REMOVE THE POWER CORD FROM THE WALL SOCKET.
2. DO NOT ATTEMPT TO REMOVE THE PIX TUBE MASK UNDER ANY CIRCUMSTANCES.
3. BE CAREFUL NOT TO SCRATCH OR STRIKE THE SURFACE OF THE PICTURE TUBE WITH ANY OBJECT.
4. CLEAN THE FACE OF THE PICTURE TUBE AND THE INSIDE SURFACE OF THE SAFETY GLASS WITH A SOFT, CLEAN, DRY CLOTH.

WOOD TABLE MODELS WITH 17 INCH PICTURE TUBE

Remove wood strip along upper edge of glass, secured by (4) screws. Tilt glass forward and lift out of slot over control panel. Observing the above precautions, carefully clean Pix Tube and Safety Glass. Reassemble by inserting glass in slot, replace upper strip and tightening screws securely.

METAL TABLE MODELS WITH 17 INCH PICTURE TUBE

Remove (2) ornamental clips which retain safety glass at corners of lower edge of glass. Raise glass slightly and bring forward, observing the above precautions. Carefully clean Pix Tube and Safety Glass.

Reassemble by inserting glass in slot, replacing clips, and tightening screws securely.

METAL TABLE MODELS WITH 21 INCH PICTURE TUBE

Proceed as for 17" Metal Table Models, except that lower edge of glass is retained by metal strip, secured by (4) screws.

MODELS WITH 21 INCH PICTURE TUBE

Remove upper strip secured by (5) screws. Tilt glass forward and lift out of slot of lower glass retaining strip. Observing the above precautions, carefully clean Pix Tube and Safety Glass. Reassemble by inserting glass in slot of lower strip, replacing upper strip and tightening screws securely.

*Used on all chassis unless otherwise specified in this column. If specified, the part is used only on the chassis indicated.

DESCRIPTION OF CHASSIS

CHASSIS NO.	DESCRIPTION
700	19 Tube Television Receiver chassis (including rectifiers), for 12½" round picture tube.
700-1	19 Tube Television Receiver chassis, including rectifiers, for 16" rectangular picture tube.
700-10	20 Tube Television Receiver chassis, including rectifiers, for 16" rectangular picture tube.
700-2	19 Tube Television Receiver chassis, including rectifiers, for 16" rectangular tube with provision for connecting 507 AM/FM chassis and record changer.
700-20	20 Tube Television Receiver chassis including rectifiers, for 16" rectangular tube with provision for connecting 507 AM/FM chassis and record changer.
700-30	20 Tube Television Receiver chassis, including rectifiers, for 14" rectangular picture tube.
700-40	20 Tube Television Receiver chassis, including rectifiers, for 19" round tube.
700-50	20 Tube Television Receiver chassis, including rectifiers, for 16" Rectangular tube with provision for connecting 703 AM/FM chassis and record changer.
700-90	20 Tube Television Receiver chassis, including rectifiers, for 16" rectangular tube, with socket for color adapter connection.
700-91	20 Tube Television Receiver chassis, including rectifiers, for 19" round tube, with socket for color adapter connection.
700-92	20 Tube Television Receiver chassis, including rectifiers, for 16" rectangular tube, with provision for connecting 703 AM/FM chassis and record changer, and socket for color adapter.
700-93	20 Tube Television Receiver chassis, including rectifiers, for 20" rectangular tube, with socket for color picture connection.
700-95	20 Tube Television Receiver chassis, including rectifiers, for 20" rectangular tube, with provision for connecting 703 AM/FM record changer and socket for color adapter.
700-96	20 Tube Television Receiver chassis, including rectifiers, for 17" rectangular tube, with socket for color adapter connection.

PARTS REMOVAL

TO REMOVE THE CHASSIS FROM THE CABINET:

1 — Remove the screws holding the back to the cabinet.
2 — Remove the screws holding the antenna terminal strip to the cabinet.
3 — Remove the screws holding the interlock bracket to the cabinet.
4 — Reach into the cabinet from the rear and remove the speaker plug from the speaker socket.
5 — Remove all the knobs from the front of the cabinet by pulling them straight out.
6 — Remove the mounting screws from the base of the chassis. These screws will be found under the cabinet in the table models and under the chassis mounting board in the console models.
7 — Slide the chassis straight out being careful not to hit the picture tube.
8 — To replace the chassis reverse the operations listed above.

CAUTION:

THE PICTURE TUBE ENCLOSES A HIGH VACUUM AND, DUE TO ITS LARGE AREA, IS SUBJECTED TO CONSIDERABLE AIR PRESSURE. THEREFORE, PICTURE TUBES MUST BE HANDLED WITH EXTREME CARE.

DO NOT OPEN THE PICTURE TUBE SHIPPING CARTON, INSTALL, REMOVE OR HANDLE THE PICTURE TUBE IN ANY MANNER UNLESS SHATTERPROOF GOGGLES AND HEAVY GLOVES ARE WORN. PEOPLE NOT SO EQUIPPED SHOULD BE KEPT AT A DISTANCE WHILE PICTURE TUBES ARE BEING HANDLED.

THE LARGE END OF THE PICTURE TUBE, PARTICULARLY THAT PART AT THE RIM OF THE VIEWING SURFACE, MUST NOT BE SUBJECTED TO ANY IMPACT, SCRATCH, OR MORE THAN MODERATE PRESSURE AT ANY TIME.

IN INSTALLATION OR REMOVING, IF THE TUBE STICKS OR FAILS TO SLIP SMOOTHLY INTO ITS SOCKET OR DEFLECTION YOKE, INVESTIGATE AND REMOVE THE CAUSE OF THE TROUBLE. DO NOT FORCE THE TUBE.

ANTENNA SYSTEM

All models covered in this manual, with the exception of the 16M1, 17M1 and 20M1 feature a built-in antenna which is shipped connected to the receiver input. In those installations where an external antenna is desired, it will be necessary to disconnect the built-in antenna from terminals 1 and 3, (shown below) and hook up the external antenna lead-in as follows:—

1 — Where the external antenna lead-in is 300 ohm ribbon, make connection to Terminals 1 and 3 on the antenna terminal strip, leaving the resistor and lug assembly from terminal 2 hanging free.

2 — Where the external antenna lead-in is 75 ohm coaxial line, connect the center conductor to terminal 1, the shield to terminal 2, and strap the Resistor supplied with terminal 2 between terminal 2 and 3.

TELEVISION ALIGNMENT PROCEDURE

Aligning a television receiver is an exacting procedure and involves tying up bench space, test equipment and skilled personnel at the service shop, as well as the cost of making two trips to the user's home. Before deciding that the chassis must be pulled and aligned at the shop, the serviceman should check these very common sources of trouble;

1 — The antenna and installation.

2 — Front panel and rear chassis controls, including Picture Tube adjustments.

3 — Reception on all available channels.

4 — Tube failures. Substitute from your kit of known good replacements.

5 — Visual inspection of under side of chassis for obvious faults, such as loose connections, etc.

TEST INSTRUMENTS REQUIRED FOR ALIGNMENT:

The equipment specified below is desirable but in cases where the service shop does not have it, it is possible to align the receiver by use of a 30mc. generator, using the picture and speaker as indication of alignment.

1 — Signal Generator with an output variable between 100 and 100,000 microvolts, and crystal-controlled or crystal-calibrated at the following frequencies;
(a) 4.5 megacycles
(b) 23.0 megacycles — See note below
(c) 25.4 megacycles — See note below

NOTE: On some of the models covered in this manual, the I.F. frequencies were 22.8 and 25.2 megacycles. In order to eliminate interference at certain locations, these frequencies were changed to 23.0 and 25.4 megacycles. Except for areas where interference prevents use of 22.8 and 25.2 megacycles, either set of frequencies can be used.

2 — R.F. Sweep Generator having a frequency range from 40 to 220 megacycles with a sweep width of 10 megacycles, and an adjustable output of at least 0.1 volt, maximum.

3 — Crystal-controlled or crystal-calibrated markers for the sound carrier cf each television channel 2 through 13. Picture carrier markers are desirable but not necessary.

4 — Cathode Ray Oscilloscope.

5 — Vacuum Tube Voltmeter-VTVM.

CAUTION: THE SECOND ANODE LEAD TO THE PICTURE TUBE HAS A POTENTIAL OF APPROXIMATELY 12,000 VOLTS. DURING THIS ALIGNMENT IT IS ADVISABLE TO REMOVE THE 6BQ6 TUBE FROM ITS SOCKET, THUS ELIMINATING THIS HIGH VOLTAGE HAZARD.

SEQUENCE OF ALIGNMENT:

It is recommended that the ratio detector driver be aligned first, followed by the ratio detector, I.F., and tuner alignments in that order unless the location of the misalignment is known.

AIDS IN SERVICING:

In addition to step-by-step alignment procedures following, see the instrument connection figures, and voltages and waveshapes charts.

V.T.V.M. CONNECTION FOR RATIO DETECTOR ALIGNMENT

RATIO DETECTOR DRIVER AND RATIO DETECTOR ALIGNMENT

In aligning this section of the television receiver, the sound trap must be resonated at 4.5 mc. to separate the sound from the picture information, and the ratio detector transformer must be adjusted to complete balance in the secondary winding for maximum AM rejection. The sound trap is T1, located between the video amplifier (V8B) and the detector driver (V9). The discriminator transformer is T2, located between the detector driver (V9) and the ratio detector (V10A). A 4.5 mc. signal is fed into the final video amplifier, and the sound trap and ratio detector are adjusted in proper sequence to obtain VTVM readings across the detector plate load resistor R23, as specified in the step-by-step procedure below;

1 — Connect the VTVM across R23, with the positive lead from the meter to the chassis and the negative lead to the other side of R23. On those chassis utilizing a 6T8 tube as the detector V10, this latter connection will be at pin 2 of the 6T8. On those chassis utilizing a 6AL5 as the detector, this connection will be at pin 7 of the 6AL5. See figure 10B showing these connections.

2 — Connect the signal generator output through a .001 mfd mica capacitor to the junction of L5 and L6 in the input to the first video amplifier, V8A. Ground the other side of the generator to the chassis. See figure 10A for this connection.

3 — Set the signal generator to 4.5 mc. and adjust its output to provide about 10 volts reading on the VTVM.

4 — Adjust sound trap T1 for maximum reading on the VTVM. Two types of sound traps were used in the production of the models covered herein, i.e., a single-ended coil, and a double-ended coil. The single-ended coil is adjusted from the top, and the double-ended coil, from the bottom, since the top half of this coil is not used. Both of these coils can be peaked at two points, and the peak point selected should be the one closest to the full counter-clockwise position of the slug. This setting minimizes the possibility of intercarrier buzz.

5 — Adjust the top slug on the discriminator transformer T2 for maximum reading on the VTVM.

6 — Connect two 100k resistors across R23 as shown in figure 10C.

7 — Reconnect the VTVM, running one lead to the junction point of these two 100k resistors, and the other lead to the tertiary winding lug (pin 6) of the discriminator transformer T2. See figure 10C for these connections. Adjust VTVM for zero center at 5 volts.

8 — Adjust bottom slug on T2. Note that during this adjustment, a point will be found where the VTVM will swing rather sharply from positive to negative, or vice versa. The correct setting of this adjustment is obtained when the VTVM pointer reads zero, setting as per (7) above, as the slug is passed through this point.

9 — Repeat steps 4, 5, 6, 7, and 8. This completes the ratio detector alignment.

I.F. ALIGNMENT:

The I.F. alignment of the models covered in this manual is based on peaking one set of I.F. coils at 23.0 mc. and the other set of I.F. coils at 25.4 mc. A signal generator feeds these frequencies to the I.F. strip, and a VTVM connected across the video detector load resistor R16 in proper polarity, serves as a measuring device for this peaking operation. The pair of 23.0 mc. coils are L401 on the tuner sub-chassis, and L2, located between the second and third I.F. stages. The 25.4 mc. coils are L1, located between the first and second I.F. stages, and L4, located between the third I.F. and the video detector. A recommended step-by-step procedure is given below;

1 — Set front panel "CONTRAST" control 1/4 turn clockwise.

2 — Connect the VTVM in proper polarity across the video detector (V7A) load resistor R16. One connection should be to the chassis, and the other to the junction of shunt peaking coil L6 and R16. See Figure 9B.

3 — Connect the signal generator through a .001 mfd capacitor to the test loop located between the two tubes on top of the tuner sub-chassis. See Figure 9A.

4 — Inject minus 3 volt bias to A.G.C. terminal on tuner, Figure 13C.

5 — Set the signal generator to 23.0 mc. and adjust its output so that the VTVM shows a reading of 2.5 volts maximum.

6 — Adjust L2 and L401 for maximum reading on the VTVM.

7 — Reset the signal generator to 25.4 mc. and adjust its output so that the VTVM shows a reading of 2.5 volts maximum.

8 — Adjust L1 and L4 for maximum VTVM reading.

9 — Repeat steps 4, 5, 6 and 7 in sequence to achieve further peak readings on the VTVM. If the VTVM pointer goes off scale, lower the signal generator output accordingly.

R.F. TUNER ALIGNMENT

The alignment of the R.F. bandpass was made at the factory and it is not desirable to readjust it in the field inasmuch as all adjustments must be made by moving and spreading coils. It any adjustment of the tuner must be made, it is recommended that the entire sub-chassis be replaced, and the defective unit returned to the source for repair.

NOTE: BEFORE ATTEMPTING TO ALIGN THE TUNER, IT IS NECESSARY THAT THE I.F. AMPLIFIER BE CORRECTLY ALIGNED. Sweep I.F. to make sure that it is the tuner and not the I.F. that needs alignment.

PROCEDURE — LOCAL OSCILLATOR ALIGNMENT:

1 — Connect the R.F. sweep generator to the antenna terminals. See Figure 11A. Put 3 volt bias between ground and an AGC terminal.

2 — If the sweep generator is not provided with internal crystal-controlled or crystal-calibrated markers, connect a marker generator to the antenna terminals also. See Figure 11A.

3 — Connect the cathode ray oscilloscope across the video detector load resistor R16. See Figure 11B.

4 — Adjust the R.F. sweep generator for 10 mc. sweep width, with center frequency at approximately 213 mc.

5 — Adjust the marker generator for the picture carrier of channel 13 (211.25 mc.).

6 — Set the Channel Selector switch to channel 13, with the fine tuning control at the middle of its rotation range.

7 — Turn on the receiver and allow about 15 minutes for it to warm up and stabilize.

8 — Set the oscilloscope gain control for a convenient size picture on the oscilloscope.

9 — Adjust the slug in channel 13 oscillator coil until the oscillator pip is at the middle of the picture side of the response curve on the oscilloscope, per Figure 12B.

10 — Set the Channel Selector switch to channel 12 and using the frequencies shown in Figure 14 below, adjust by displacing the channel 12 increment loop until the oscillator pip is at the middle of the picture side of the response curve on the oscilloscope, per Figure 12B.

11 — Repeat operation 10 above using the appropriate frequencies and increment loops for Channel Selector switch settings of 11, 10, 9, 8 and 7 in that order. This completes the high band oscillator alignment.

12 — Set Channel Selector switch to 6, and proceed as in 9 above, using the proper slug and frequencies. See Figures 13 and 14.

Channel Switch Setting	2	3	4	5	6	7	8	9	10	11	12	13
Sweep Gen.	57	63	69	79	85	177	183	189	195	201	207	213
Marker Gen. Settings (Pix carrier)	55.25	61.25	67.25	77.25	83.25	175.25	181.25	187.25	193.25	199.25	205.25	211.25

PROCEDURE — R.F. TUNER BANDPASS ALIGNMENT

Do not attempt to align the RF bandpass unless you find it necessary. The procedure is as follows;

1 — Connect the R.F. Sweep Generator, Marker Generator, and Oscilloscope as in 1, 2, and 3, under R.F. Tuner Alignment. Refer to table below for instrument settings for each channel alignment. Put 3 volt bias between ground and AGC.

2 — Set the R.F. sweep generator for 10 mc. sweep width, and its center frequency at 213 mc.

3 — Set the CHANNEL SELECTOR switch to channel 13, and the fine tuning control at the middle of its rotation range.

4 — Turn on the television receiver and allow about 15 minutes for the set to warm up and stabilize.

5 — Set the oscilloscope gain control for a convenient size picture on the oscilloscope.

6 — See permissable response curves, Figure 12. If the response curve on the oscilloscope does not fall within these limits, the picture on the oscilloscope can be made to approach the desirable form by either spreading or compressing the particular coils in the tuner circuit at channel 13 setting. Referring to the 5 decks on the master switch in the tuner, note that the deck nearest the front (shaft) end of the tuner contains those coils regulating the local oscillator, and these should NOT be touched during any bandpass adjustments. On the second, third and fourth decks of the master switch are the coils for the mixer grid, the R.F. amplifier plate, and the antenna coupling transformer, respectively, and the particular coils connected in the circuit for channel 13, on these three rear decks are the ones that should be compressed or expanded to achieve the desired bandpass characteristic. Note that too broad a curve results in loss of sensitivity, and rejection.

7 — Proceed with Channel Selector switch at 12, and with Sweep and marker generators set per Figure 15 below, repeat 6 above to achieve proper curve. Repeat for channel 11, then 10, 9, etc. When completion of channel 2 is reached, the bandpass alignment is finished.

Channel Selector Switch	2	3	4	5	6	7	8	9	10	11	12	13
R.F. Sweep Generator Setting	57	63	69	79	85	177	183	189	195	201	207	213
Marker Generator Setting (Sound)	59.75	65.75	71.75	81.75	87.75	179.75	185.75	191.75	197.75	203.75	209.75	215.75
Marker Generator Setting (Picture)	55.25	61.25	67.25	77.25	83.25	175.25	181.25	187.25	193.25	199.25	205.25	211.25

MODEL 703 AM—FM TUNER

Used with Model 16K1, 17K1 AND 20K1 Television Receiver

ELECTRICAL AND MECHANICAL DATA

Frequency Range........(AM) 535 KC to 1620 KC
(FM) 87 MC to 109 MC
Intermediate Frequency..............(AM) 455 KC (FM) 10.7 MC

Power Supply.........117 volts AC, 60 cycles
Speaker ....PM

TUBE COMPLEMENT

1	12AT7	Oscillator-Converter
1	6AU6	1st IF Amplifier
1	6AU6	2nd IF Amplifier*
1	6SQ7	AM Detector—1st Audio (AM-FM)
1	6AL5	FM Detector

* Not in Circuit in AM Position

SOCKET VOLTAGES

TUBE	POSITION	1	2	3	4	5	6	7	8
12AT7	Oscillator-Converter	245	0	4.2 AC	6.3 AC	6.3 AC	245	−4.5	0
6AU6	1st IF. Amplifier	−0.5	0	0	6.3 AC	250	155	1.1	....

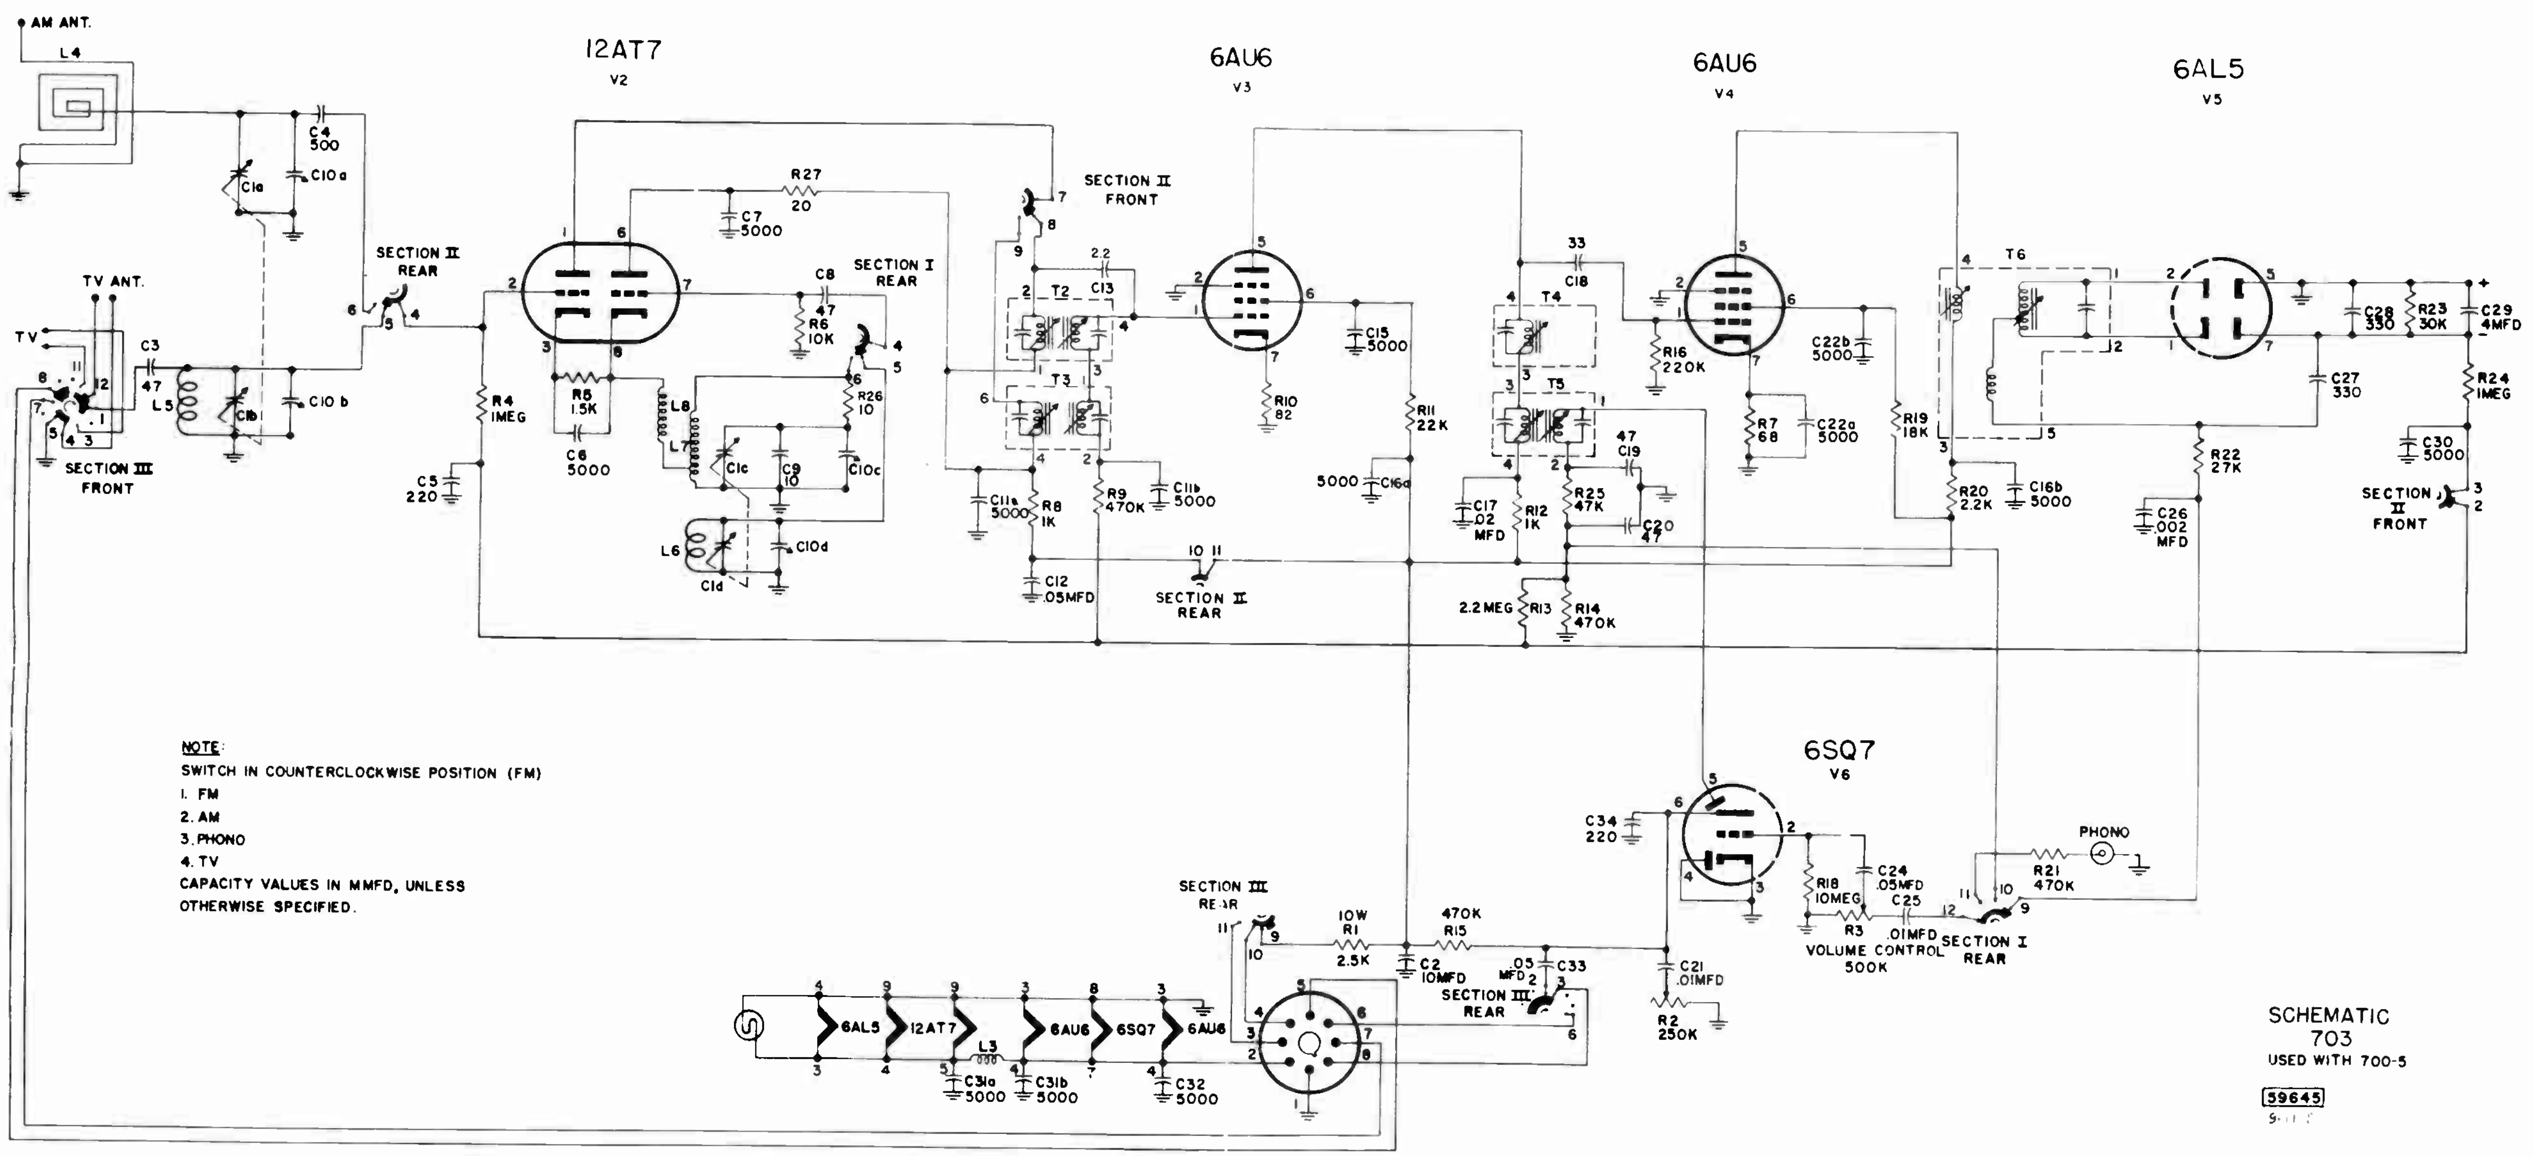
6SQ7	AM Detector 1st Audio (AM-FM)	0	0.8	0	0	−0.5	92	6.3 AC	0
6AL5	FM Detector	−1.6	−1.4	6.3 AC	0	0	0	−2.5	....

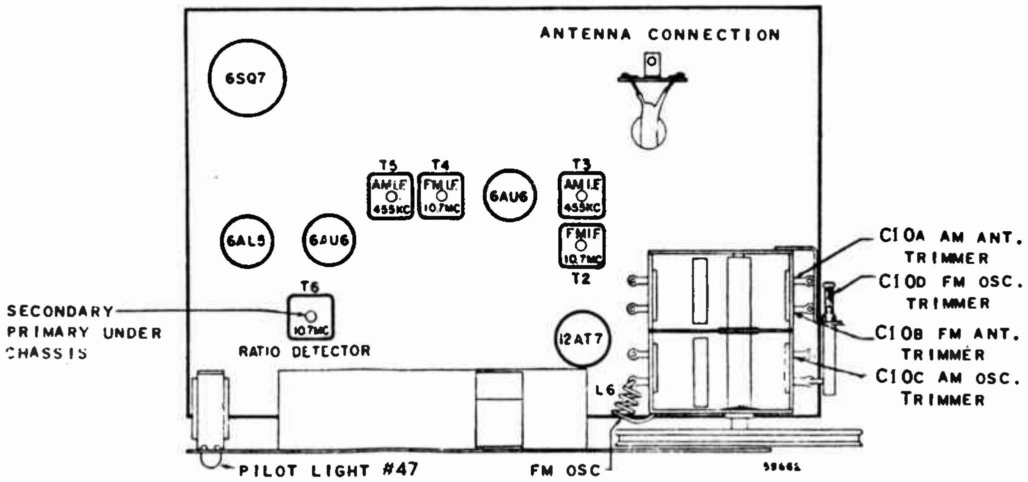
NOTE: All DC voltages measured with V.T.V.M. from Chassis to socket contact indicated. All voltages are positive DC unless otherwise marked.
Volume control full on. Zero signal input.

Tone control in counter-clockwise position.
Band switch in "AM" position.
Variable condenser set at minimum.
Line voltage 117 volts, 60 cycle AC.



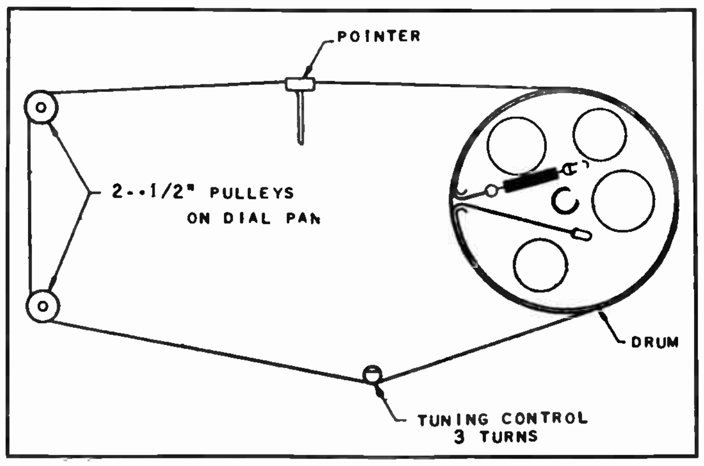
SCHEMATIC 703
USED WITH 700-5
59645

ALIGNMENT PROCEDURE



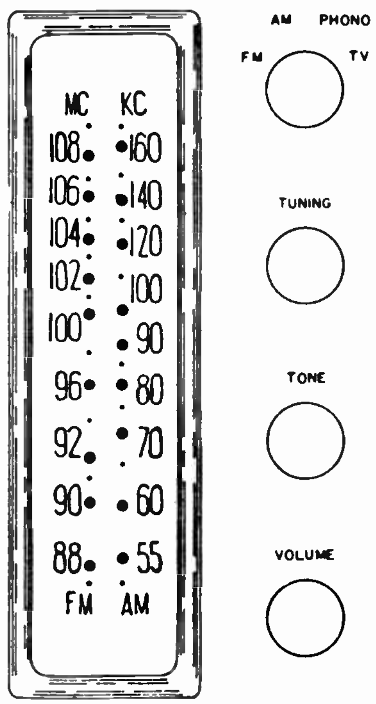
The following equipment is necessary to properly align this receiver:

1. AM signal generator with frequency coverage from 455 kc. to 1700 kc.
2. FM or CW signal generator covering the FM band from 87 mc. to 109 mc. and the 10.7 mc. for FM IF alignment.
3. Vacuum Tube Voltmeter (VTVM).
4. Output meter—to match 4 ohms, 5 watts maximum.
5. Insulated alignment screwdriver.
6. Dummy antenna—0.1 mfd. capacitor, 300 ohm carbon resistor and inductive loop (fashioned from several turns of wire).



DIAL STRINGING

DIAL CALIBRATION AND KNOB LOCATION



Reference Notes to Alignment Chart Below.

Before starting alignment, pointer must be set 87.5 MC. mark with gang fully closed

Note A: Put two 100,000 ohm resistors in series across R-23 (30,000 ohms). Negative lead of V.T.V.M. is attached to the junction of these two resistors. Positive lead of V.T.V.M. is ground. V.T.V.M. on 3 volt scale.

Note B: Negative lead of V.T.V.M. same as in Note A, positive lead of V.T.V.M. at junction of R-22 (27K ohm) and shielded lead, on terminal strip at ratio detector.

Note C: The FM R.F. and OSC. coils are made of stiff wire. To adjust these coils for bandwidth and tracking move coils together or apart as required.

Note D: Tune F.M. antenna trimmer (ClOb) and at the same time rock the signal generator frequency back and forth for maximum deflection on the meter.

ALIGNMENT CHART

See circuit diagram for 703 chassis at rear of book

Step No.	Band Switch in Position	Dummy Antenna	Signal Generator		Dial Position	Output Meter	See Fig. 34 Adjust		Remarks
			Freq.	Connection			C or L	For

CIRCUIT CHANGES IN PRODUCTION ON CHASSIS 700-10, 20, 30, 40, 50

The following changes were made on the above chassis as production progressed, in order to make certain improvements. They are not retroactive. If you have an early production chassis which does not incorporate the changes below, do not make the change except to correct an actual complaint.

1—TO REDUCE RESISTOR FAILURE ON ALL 110.700 SERIES CHASSIS:—
R48 was changed from a 1W to a 2W Resistor, 3.3K ±10%.

2—TO IMPROVE AGC STABILITY:—
C6 was changed from .1 mfd 200v Capacitor to .25 mfd. 200v.
C9 was changed from .005 mfd. 600v to a Ceramic 22 mmf, 600v. ±20%.
R77 — a Resistor (270K, 1/2W ±10%) was added between the Cathode of the Picture Tube and the arm of the brightness control.

3—TO IMPROVE VERTICAL SWEEP LINEARITY AND OPERATING POINT OF THE VERTICAL SWEEP OUTPUT TUBE:—
R49 was changed from 330 ohms to 1,000 ohms.
R43 was changed from 3.3 meg ohms to 1.5 meg ohms.
R86 was added (3300 ohms 2W.) in series with the low end of the vertical output transformer primary.
C35 was changed from .01 mfd to .02 mfd. 600v.

4—TO INCREASE AUDIO SENSITIVITY:—
R20 was removed.
C16 connection to junction of R69 and L11 was changed to Pin 1 of 12BH7 video amplifier.

5—TO IMPROVE IMMUNITY OF VERTICAL TRIGGERING TO NOISE:—
C16 was changed from .01 mfd to .05 mfd, 600v on all 16" and 19" chassis.
R26 was added (3900 ohms 1/2W ±10%) between ground and junction of R38 — R39.

6—TO INCREASE RANGE OF CONTRAST CONTROL ON ALL 16" CHASSIS:—
R10 was changed from 2.2 meg ohms to 1 meg.
R76 was changed from 1 meg ohm to 3.3 meg ohms.

7—TO IMPROVE HORIZONTAL LINEARITY ON ALL CHASSIS:—
C62 was changed from .1 mfd 600v to .05 mfd, 600v.
C50 was changed from .25 mfd. to 25 mfd 12v., Electrolytic.

8—TO IMPROVE SYNC STABILITY:—
On all 16" Chassis:
R32 was changed from 3.9k to 1.8k.
R34 was changed from 3.3 megs to 1 meg.
R52 was changed from 6.8k to 2.7k.
R83 was added (1,000 ohms 1/2W ±20%) between side of C14 and ground.
R17 was changed from 560 ohm to 330 ohm.

CIRCUIT CHANGES IN PRODUCTION ON CHASSIS 700-90, 91, 92, 93, 95, 96

The following changes were made on the above 16", 17" and 20" Chassis as production progressed, in order to make certain improvements. They are not retroactive. If you have a previous production chassis which does not incorporate the changes below do not make the change except to correct an actual complaint.

1—R66—was removed in Picture Tube high voltage lead: This resistor was removed in accordance with revision of Underwriters' specifications.

2—R81—was removed in the Filament Supply of V-14: Design changes in the 12BH7 Tube eliminated the need for a dropping resistor in the Filament Supply.

3—Correction of Schematic:
The filament supply for the Tuner Tubes comes directly from the 6.3 winding of the Power Transformer, and no dropping resistor (shown on the print as R81) is in series filament supply of the Tuner Tubes.

4—Additional Capacitor required because of change in Vertical Blocking Osc. Transformer T5:
In some sets T5 Blocking Osc. Transformer A10125 was used instead of A10106. The use of Blocking Osc. Transformer A10125 required an additional capacitor C72-.001 mfd) between the red lead of this transformer and ground.

5—Changes required to improve Sync. Stability:
(a) R33 — changed from 270K to 180K.
(b) R36 — changed from 2700 Ohm to 3300 Ohm.
(c) R82 — An additional Resistor (27K) connected between pins 1 and 3 of V13.
(d) C69 — An additional Capacitor (.002 mfd) inserted betwen R38 and pin 1 of V13.

6—Changes in Contrast Control:
Some sets were manufactured with the Contrast Control (PL-a) as a 10K potentiometer, requiring a 1.8K fixed resistor R14 in parallel between the center arm and ungrounded terminal of PL-a. If a 1.5K potentiometer was used as PL-a in the chassis, this shunting resistor (R14) was omitted.

7—To Eliminate Horizontal Fold Over:
C 61 was changed from .005 mfd 600 Volts to .01 mfd 600 Volts.

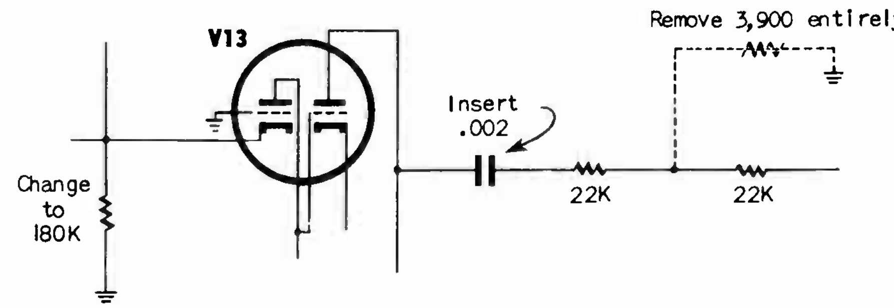
8—To minimize feed-back from Antenna on AM/FM TV Combination sets:
C12 (.1 mfd 600v) A Capacitor, was added to the Circuit, connected between ground and the junction of R5 and C4-a.

SERVICE NOTES

1—We are now substituting the contrast and volume control, old part number A24109 (10,000 ohms), with a similar control part number A24124 (1500 ohms). When using the new control A24124 the 1800 ohm resistor from the center arm to the high side of the old control should be removed.
The substitution of the control A24124 in place of A24109 (10,000 ohms) is only applicable to our models #700-90-91-92-93 and 95. These models can easily be identified in the fied by the fact that the contrast control is in the cathode of the 1st video amplifier (V8A). This change is not applicable in the other 700 series chassis due to the fact that the contrast control #24109 is used in an entirely different manner.

2—To increase vertical sync stability a .002 capacitor should be inserted between the 22,000 ohm resistor and plate (pin #1) of the sync amplifier and phase splitting tube (V-13) as shown in the drawing below. In conjunction with this change the 3,900 ohm resistor from the junction of the 22,000 ohm resistor to ground should be removed.

3—To further improve vertical sync stability in strong signal areas, change the 270,000 ohm cathode resistor of V-13 to 180,000 ohms. These changes are now being incorporated in our current production.



4—Field complaints have been received of an audio buzz or hum in some chassis of the 700 series due to poor contact of the aquadag coating of the Hytron 16RP4 tubes with the grounding strap. It has been found that under certain conditions of humidity, the binder used in the aquadag will form a chalky coating which prevents proper contact between the aquadag and the grounding strap.
This can be corrected by carefully washing the area around and under the contact spring, using a cloth moistened with water. After the area around the grounding spring has been washed and dried, it should be blackened by the application of graphite from a very soft pencil.
CAUTION: The set must be shut off and the high voltage supply discharged when this is done. NO OTHER TYPE PICTURE TUBE SHOULD BE WASHED IN THIS MANNER BECAUSE MOST STANDARD AQUADAG COATINGS ARE WATER SOLUBLE AND WOULD BE REMOVED IF WASHED.

5—Hum in the model 16K1 (6 way combination) can be corrected by shielding the following 2 leads:
a. There is an orange colored wire running from the switch on chassis #703 to pin #7 on the plug. Change this to a shielded wire and ground the shield close to the switch.
b. There is a wire, usually yellow, running from pin #7 of the socket on the side of the chassis to the junction of the 60 ohm and 220 ohm resistors (R29 and R82) in the upper right hand corner of the chassis. This lead must be shielded and the shield grounded at the end closest to the junction of the two resistors.
Shielding of these two leads will eliminate or reduce the hum to an extremely low level.

6—Referring to the 700-90 schematic in our service manual, the following changes will further improve the vertical sync stability:
a. Add a 27 K ohm resistor from pin #1 to pin #3 of V13.
b. Change R36 from 2.7 K to 3.3 K ohms.
c. Change R37 from 3.9 K to 8.2 K ohms.

Horizontal Foldover

7—When the AFC control is correctly adjusted in the Air King chassis 700-10 or later series, the picture will fall into horizontal sync instantly when changing from station to station and it should be stable. Sometimes this cannot be done without causing a foldover on either the right or the left side of the picture. When this condition is present, it is an indication of unstable horizontal hold due to incorrect phasing from the transmitter. At certain adjustments of the AFC control the picture will jitter violently. To correct this condition, the 2.7K phasing resistor (R52) will have to be increased to approximately 5K if the foldover is on the left side of the picture or decreased to about 1K if the foldover is on the right side of the picture.

8—Buzzing — A small number of 700-93 chassis have been shipped which were found to have a considerable amount of hum or buzz. This can be corrected by putting a shield over the glass 6SQ7 tube, providing the 6SQ7 is of the metal ring base type. (substitution of a metal 6SQ7 will have the same effect).

	PICTURE CARRIER	SOUND CARRIER
2	55.25	59.75
3	61.25	65.75

* Used on all chassis (700,-2,-20,-40,-50,-30,-90,-91,-92,-93,-95) unless specified in this column. If specified, the part is used only on chassis shown.

RESISTORS FOR 17" & 20" CHASSIS

SCHEM. LOCATION	PART NO.	DESCRIPTION
R 1	PE 231-1167	Resistor 5.6K 1/2 W ± 10%
R 2	PE 231-1115	Resistor 39 Ohm 1/2 W ± 10%
R 3	PE 231-1181	Resistor 22,000 Ohm 1/2 W ± 10%
R 4-5	PE 231-1123	Resistor 82 Ohm 1/2 W ± 10%
R 6	PE 232-1171	Resistor 8,200 Ohm 1 W ± 10%
R 7-8	PE 231-1123	Resistor 82 Ohm 1/2 W ± 10%
R 9	PE 231-1137	Resistor 330 Ohm 1/2 W ± 10%
R 10	PE 231-1221	Resistor 1 Megohm 1/2 W ± 10%
R 11-12	PE 231-1123	Resistor 82 Ohm 1/2 W ± 10%
R 13-16	PE 231-1165	Resistor 4.7K 1/2 W ± 10%
R 16	PE 233-1165	Resistor 4.7K 2 W ± 10%
R 19	PE 231-1197	Resistor 100,000 Ohm 1/2 W ± 10%
R 20	PE 231-1127	Resistor 120 Ohm 1/2 W ± 10%
R 21	PE 231-1197	Resistor 100,000 Ohm 1/2 W ± 10%
R 23	PE 231-1189	Resistor 47,000 Ohm 1/2 W ± 10%
R 24	PE 231-1237	Resistor 4.7 Megohm 1/2 W
R 25-26	PE 231-1213	Resistor 470,000 Ohm 1/2 W ± 10%
R 27	PE 232-1137	Resistor 330 Ohm 1 W ± 10%
R 28	PE 231-1123	Resistor 82 Ohm 1/2 W ± 10%
R 29	PP 21107	Resistor 60 Ohm 10 W wirewound
R 30	PE 23151	Resistor 1.2 Ohm 1 W ± 10%
R 31	PA 21110	Resistor Wirewound 2,500 Ohm 15 W
R 32	PE 231-1155	Resistor 1,800 Ohm 1/2 W ± 10%
R 33	PE 231-1203	Resistor 180K Ohm 1/2 W ± 10%
R 34	PE 231-1221	Resistor 1 Megohm 1/2 W ± 10%
R 35	PE 231-1163	Resistor 3,900 Ohm 1/2 W ± 10%
R 36	PA 231-1161	Resistor 3.3K Ohm 1/2 W ± 10%
R 37	PE 231-1171	Resistor 8.2K Ohm 1/2 W ± 10%
R 38-39	PE 231-1181	Resistor 22,000 Ohm 1/2 W
R 40	PE 231-1171	Resistor 8,200 Ohm 1/2 W ± 10%
R 41	PE 231-1225	Resistor 1.5 Meg 1/2 W ± 10%
R 42	PE 231-1213	Resistor 470,000 Ohm 1/2 W ± 10%
R 43	PE 231-1225	Resistor 1.5 Meg 1/2 W ± 10%

SCHEM. LOCATION	PART NO.	DESCRIPTION
R 44	PE 231-1171	Resistor 8,200 Ohm 1/2 W ± 10%
R 45	PE 231-1163	Resistor 3,900 Ohm 1/2 W ± 10%
R 48	PE 233-1161	Resistor 3.3K 2W ± 10%
R 49	PE 231-2249	Resistor 1,000 Ohm 1/2 W ± 20%
R 50	PA 21111	Resistor Wirewound 3,250 Ohm 7W ± 10%
R 51	PE 231-1159	Resistor 2.7K 1/2 W ± 10%
R 52	PE 231-1165	Resistor 4.7K 1/2 W ± 10%
R 53	PE 231-1233	Resistor 3.3 Megohm 1/2 W ± 10%
R 54-55	PE 231-1197	Resistor 100,000 Ohm 1/2 W ± 10%
R 56	PE 231-1213	Resistor 470,000 Ohm 1/2 W ± 10%
R 57	PE 231-1163	Resistor 3,900 Ohm 1/2 W ± 10%
R 58	PE 231-1159	Resistor 2,700 Ohm 1/2 W ± 10%
R 59	PE 231-1197	Resistor 100,000 Ohm 1/2 W ± 10%
R 60	PE 231-1207	Resistor 270,000 Ohm 1/2 W ± 10%
R 61	PE 233-1129	Resistor 150 Ohm 2W ± 10%
R 62	PE 231-1213	Resistor 470,000 Ohm 1/2 W ± 10%
R 63	PE 231-1123	Resistor 82 Ohm 1/2 W
R 67	PE 231-1155	Resistor 1,800 Ohm 1/2 W ± 10%
R 68	PE 233-1165	Resistor 4,700 Ohm 2 W ± 10%
R 69	PE 232-1157	Resistor 2.2K 1 W ± 10%
R 70	PE 233-1165	Resistor 4,700 Ohm 2 W ± 10%
R 71	PE 231-1137	Resistor 330 Ohm 1/2 W ± 10%
R 72	PE 231-1143	Resistor 560 Ohm 1/2 W ± 10%
R 73	PE 231-1221	Resistor 1 Megohm 1/2 W ± 10%
R 74	PE 232-1189	Resistor 47,000 1 W ± 10%
R 75	PE 232-1201	Resistor 150,000 1 W ± 10%
R 77	PE ?31-1207	Resistor 270,000 Ohm 1/2 W ± 10%
R 78	PE 231-1189	Resistor 47,000 Ohm 1/2 W ± 10%
R 81	PE 23151	Resistor 1.2 Ohm 1 W ± 10%
R 82	PE 231-1183	Resistor 27K Ohm 1/2 W ± 10%
R 86	PE ?33-1161	Resistor 3.3K Ohm 2 W ± 10%
R 100	PE 231-1233	Resistor 3.3 Megohm 1/2 W ± 10%

*Some sets use ?-60 Ohm resistors in series; others use a 75 Ohm 15 W resistor

Specifications

Picture Tube
Type	CBS Hytron 19VP22
Dimensions	19-inch round, all glass. Viewing area 205 square inches

Operating Controls
Station Selector, Fine and UHF Tuning, Vertical and Horizontal Hold, Contrast, Volume, Tone, Chroma and Hue

Power Rating
Source	105—120 volts 60-cycle AC
Consumption	500 Watts

Number of Tubes
41 tubes plus 3 rectifiers, 2 selenium rectifiers and 3 crystal diodes

Ant. Input Impedance
VHF	300 ohms balanced
UHF	300 ohms balanced

Frequency Range
Channels 2 through 82

Intermediate Frequencies
Video IF	45.75 mc
Sound IF	41.25 mc
Sound Intercarrier Freq.	4.5 mc
Color Subcarrier Freq.	42.17 mc
Adjacent Channel Sound Trap Freq.	39.75 mc
Adjacent Channel Video Trap Freq.	47.25 mc
Accompanying Channel Sound for less than 10% distortion	41.25 mc

Crt High Voltage
26 kv adjusted

Loudspeakers
Size	Two, 6½ in x 9¼ in. speakers
Voice Coil	3.2 ohms at 400 cycles

Focus
Electrostatic

Deflection
Electromagnetic

Convergence
Static	PM Magnetic
Dynamic	Electromagnetic

Cabinet Dimensions
Model	Width	Height	Depth
205C1 Console	34¼	42-11/16	26-1/16
205C2 Console w/Doors	34¼	42-11/16	26-15/16

Warning – High Voltage
POTENTIALS AS HIGH AS 26,000 VOLTS ARE PRESENT WHEN THIS RECEIVER IS OPERATING. OPERATION OF THE RECEIVER OUTSIDE THE CABINET OR WITH COVERS REMOVED INVOLVES A SHOCK HAZARD FROM THE RECEIVER POWER SUPPLIES. WORK ON THE RECEIVER SHOULD NOT BE ATTEMPTED BY ANYONE WHO IS NOT THOROUGHLY FAMILIAR WITH THE PRECAUTIONS NECESSARY WHEN WORKING ON HIGH-VOLTAGE EQUIPMENT.

General

The CBS-Columbia Model 205 is an 82 channel VHF-UHF color television receiver employing a CBS-Hytron 19-inch round, direct-viewing Colortron. The receiver utilizes 44 tubes, 2 selenium rectifiers and 3 crystal diodes.

Features of the receiver include: 205 square-inch picture, CBS-Columbia "360" Full-Fidelity sound system, wide-band color reproduction, regulated high-voltage supply, five-stage picture i-f amplification, stabilized horizontal and vertical sweep circuits, 3.58-mc crystal oscillator with afc, slide-out color tube mount, dual-chassis construction, and conveniently located service controls.

Installation

Antenna
The antenna requirements for color reception are somewhat more critical than for black-and-white reception. In general, outdoor antennas are preferred. The antenna used must have a flat response over the frequency range of the color channel being received, and tbe transmission line must be properly matched to the antenna and the receiver input (300 ohms).

Antenna orientation is more critical. Some antenna positions may provide black-and-white reception but no color reception. The antenna should be oriented for best color reception while receiving a color program. Where several stations are received from different directions an antenna rotator may be required.

Multiple antenna installations, particularly those employing distribution amplifier systems, may not provide satisfactory color reception. If such an installation is to be used, modification of the system may be required.

Many TV boosters do not have sufficient bandwidth for color reception. If a booster is to be used it should be checked to insure adequate results.

An antenna specially designed for color reception is available from your CBS-Columbia Distributor.

Unpacking
The receiver and the color picture tube assembly are shipped in separate cartons. All controls are adjusted and the components on the neck of the picture tube are properly positioned at the factory. To avoid the need for complete adjustment of the receiver, the controls and the CRT components should not be disturbed during the unpacking and installation of the receiver.

The following procedure should be used to prepare the receiver for operation:

1. Remove the receiver and picture tube assembly from their cartons.
2. Remove the cabinet back cover.
3. Remove the staples fastening the CRT cup to the cabinet shelf.
4. Insert the rear end of the cup into the large hole in the back cover, from the front side of the cover. Tap the front edge of the cup with a mallet until it snaps into place.
5. Remove the four bolts fastening the picture-tube assembly to its shipping pallet and discard the pallet.
6. Slide the picture tube assembly carefully into place on the cabinet shelf and position it so that the picture-tube screen is properly centered and flush against the mask.
7. Insert the four bolts removed in step 5 through the slots in the picture-tube mounting board into the holes in the cabinet shelf, and tighten.
8. Insert the Field Neutralizing, Yoke, and Convergence Assembly plugs into their sockets on the deflection chassis. Connect the CRT high-voltage Connector to the deflection chassis high-voltage lead, insert the Video Output plug into its socket on the signal chassis, and fasten the CRT socket to the base of the picture tube.

Initial Adjustment
After the receiver has been unpacked and installed, an initial check of performance should be made to determine whether or not the receiver requires adjustment. The room lighting should be subdued during the performance check.

The following procedure should be used:

1. Connect an antenna to the receiver and apply power.

2. Turn the set on and tune to the channel which provides the strongest signal available.

3. If overload occurs, adjust the AGC control. The customer control panel must be removed to provide access to the AGC control. Removal of the panel is described in steps 4 and 5 of the paragraph on Service Controls.

4. Check the action of the HORIZONTAL HOLD control and adjust the AFC (front of deflection chassis, Fig. 2) if required.

5. Check the size, linearity, and centering, and adjust if necessary.

6. If a drive line (bright vertical line near center of picture) is observed, turn the HORIZONTAL DRIVE control fully clockwise, then counterclockwise until the line just disappears.

7. Adjust the BRIGHTNESS and CONTRAST controls for a normal picture, then rotate the BRIGHTNESS control throughout its range. If variation in picture size is noted at *normal* brightness settings, perform the High-Voltage Adjustment procedure.

Note: The picture size should remain constant over most of the BRIGHTNESS control range. Loss of regulation, (indicated by a sudden increase in picture size) near maximum brightness setting, is normal. The BRIGHTNESS should always be operated within the range of regulation.

8. Adjust the BRIGHTNESS and CONTRAST controls for a normal picture. If two or three severely misregistered color images are observed, adjust the Static Convergence Magnets as described in steps 1 and 2 of the Convergence procedure.

9. Turn the CONTRAST control fully counterclockwise and the BRIGHTNESS control fully clockwise. The raster should be a a uniform dim neutral gray without signs of color contamination.

10. If the entire screen shows a uniform coloring, other than neutral gray, adjust the SCREEN controls (Fig. 2) as described in steps 2, 3 and 4 of the paragraph on White Adjustment.

11. If only portions of the screen show coloring in step 9, turn the CONTRAST, BLUE SCREEN and GREEN SCREEN controls fully counterclockwise and the BRIGHTNESS control fully clockwise. Set the RED SCREEN control for a barely visible red raster and adjust the FIELD NEUTRALIZING control for a pure red raster without signs of color impurity. If a pure red raster cannot be obtained, perform the Purity Adjustment Procedure.

12. Perform the White Adjustment procedure.

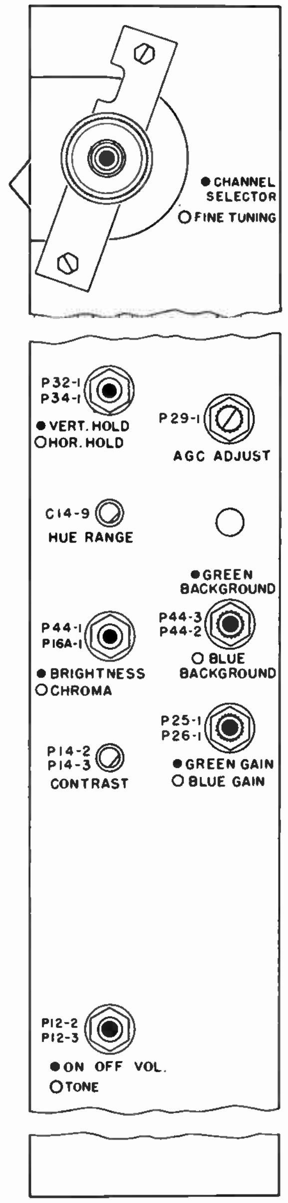

Fig. 1—Signal chassis front controls.

13. Adjust the BRIGHTNESS and CONTRAST controls for a normal picture. If severe misregistration is observed near the edges of the picture, perform the complete Convergence procedure.

14. Tune to a station transmitting a color signal, or a black-and-white signal with a color stripe. The color stripe is a narrow vertical bar (yellowish-green in color) appearing at the left and right edges of the picture. To synchronize the color circuits when receiving the stripe adjust the AFC control (Fig. 2) so that the picture moves to the left, placing the left-hand stripe in the horizontal blanking internal.

15. Adjust the HUE and CHROMA controls for proper hue and saturation.

Service Controls

Access to the service controls and adjustments may be obtained as follows:

1. Remove the cabinet rear cover.

2. Remove the two large bolts located at the upper right and left hand corners of the cabinet back.

3. Pull the cabinet top back about two inches, toward the rear of the cabinet, and lift it off the cabinet.

Note: The receiver is provided with a Top Interlock, located directly above the customer controls. To operate the receiver with the top off, remove the a-c plug from the deflection chassis and apply power directly to the chassis using a space line cord.

4. Remove all front panel knobs.

5. Using a thin screwdriver, unfasten the two clips holding the customer control panel in place and pull the panel away from the cabinet. The clips are located at the bottoms of the holes through which the Channel Selector and Off-On Volume control shafts project.

6. Locate the recessed finger grips on the bottom of the board running across the lower edge of the cabinet front. If the board is held in place by a screw, remove the screw.

7. Grasp the board with both hands and pull it firmly away from the cabinet.

Color Tube Adjustment Procedure

Equipment Required

1. High-Voltage Meter with a full-scale range of at least 50 KV.

2. White Dot Generator. The generator should supply round dots approximately 1/8" in diameter on a 19-inch coolr CRT. The Hickock 650C is a suitable instrument.

3. Off-the-air test pattern, or a linearity bar or cross hatch generator. Most dot generators supply a suitable crosshatch pattern.

4. T-Connector for insertion in the high-voltage lead when making measurements.

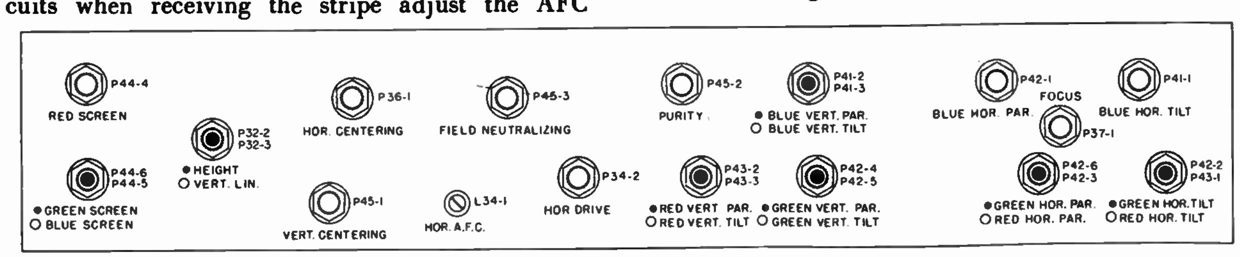

Fig. 2—Deflection chassis front controls.

High-Voltage Adjustment

1. Turn the set off, open the CRT High-Voltage Connector, ("L" in Fig. 3) and insert a T-Connector in the lead.

Caution: To avoid an electrical shock ground the high voltage before touching the lead.

2. Connect a High-Voltage Meter (50 kv range) to the T-Connector.

3. Turn the BRIGHTNESS and CONTRAST controls fully counterclockwise and turn the set on.

4. After allowing sufficient time for the set to warm-up, adjust the HIGH-VOLTAGE REGULATOR control (rear of deflection chassis) for a meter reading of 26 kv.

5. Turn the BRIGHTNESS control up to a high level and note the variation in high-voltage. The voltage should not drop more than 500 volts up to the point where loss of regulation occurs. If the BRIGHTNESS is advanced excessively loss of regulation, indicated by marked picture blooming, will occur. The brightness should always be operated within the range of regulation.

6. Turn the set off and disconnect the High-Voltage Meter.

Color Purity Adjustment

1. Connect a Dot Generator to the receiver antenna terminals.

2. Turn the set on and adjust the FINE TUNING, BRIGHTNESS, CONTRAST and FOCUS controls for a clearly visible dot display.

Note: The room lighting should be subdued during the balance of the procedure. Set the BRIGHTNESS and CONTRAST controls at the lowest levels that give a clearly visible dot pattern.

3. Adjust the RED, GREEN and BLUE SCREEN controls to make the red, green and blue dots on the CRT screen approximately the same size.

4. Check the physical positioning of the Yoke, Convergence Coil Assembly, Purity Magnet (or coil) and the Blue Beam Corrector. The correct positioning of these components is shown in Fig. 3.

Note: If the above components are not properly positioned it may be impossible to set up the CRT correctly.

5. Adjust the Red, Green and Blue Static Convergence Magnets (Fig. 3) and the Blue Beam Corrector ("S" in Fig. 3) to converge (superimpose) the group of dots, (a red, a green and a blue dot) located nearest the center of the screen. See Fig. 4B for adjustment procedure.

6. Turn the CONTRAST control and the GREEN and BLUE SCREEN controls fully counterclockwise,

and turn the BRIGHTNESS and RED SCREEN controls fully clockwise.

7. Set the FIELD NEUTRALIZING control at mid-position.

8. Loosen the Yoke Positioning Screws ("N" in Fig. 3) and slide the Deflection Yoke back toward the base of the CRT as far as possible without touching the Convergence Coil Assembly.

9. Rotate the Purity Magnet (or coil) around the neck of the tube, increasing the field strength in steps, until a large pure red area is obtained in the center of the screen. Disregard the size of the area —adjust for the purest possible red in the *center* of the screen.

Note: If the receiver uses a Purity *Magnet*, the field strength is increased by separating the tabs (H in Fig. 3) on the magnet. If a Purity *Coil* is used the field strength is increased by turning the Purity control clockwise. Use the weakest field that provides satisfactory results.

10. Slide the Deflection Yoke slowly forward on the neck of the tube until the largest uniform red field is obtained on the CRT screen. Lock the Yoke in position.

Note: The rear surface of the Yoke should be perpendicular to the neck of the CRT, and the space between the inner surface of the Yoke and the tube neck should be uniform at all points.

11. If a completely uniform red field is not obtained in the previous step, readjust the Purity Magnet (or coil) slightly. If color contamination still exists at the edges of the screen, adjust the FIELD NEUTRALIZING control to minimize it.

Note: If satisfactory purity cannot be obtained the yoke may be moved slightly out of alignment with the CRT neck to minimize contamination. This should be done only when good purity cannot be obtained as previously described.

12. Turn the RED SCREEN control fully counterclockwise and the GREEN SCREEN control fully clockwise. A uniform green field should be obtained over the entire face of the CRT.

13. Turn the GREEN SCREEN control fully counterclockwise and the BLUE SCREEN control fully clockwise. A uniform blue field should be obtained over the entire face of the CRT.

Note: If neck shadow, due to improper Yoke positioning, or serious color contamination is noted in steps, 13, 14 or 15, repeat the purity adjustment from step 9.

14. Turn the BLUE SCREEN control fully counterclockwise and the RED SCREEN control clockwise until a barely visible red raster is obtained.

15. Turn up the GREEN SCREEN control until the raster turns yellow.

16. Turn up the BLUE SCREEN control until the raster turns a neutral gray (low-brightness white).

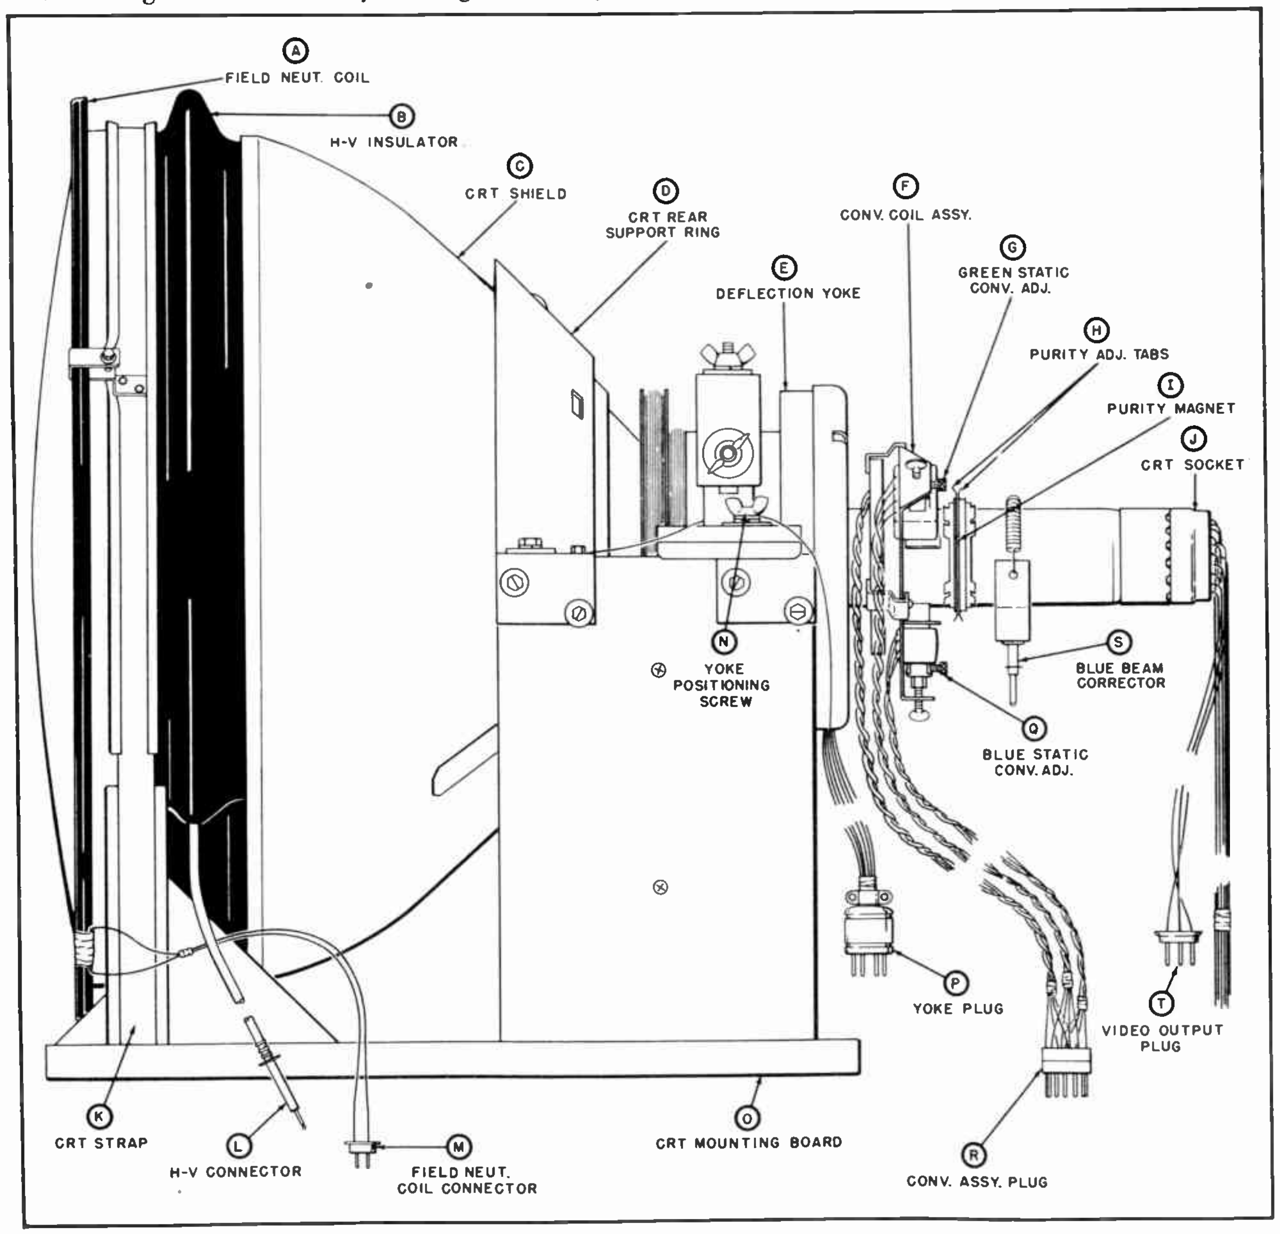

Fig. 3—Picture tube assembly.

Size and Linearity

1. Connect an antenna to the receiver and tune in a station transmitting a test pattern. If a test pattern is not available a suitable bar or crosshatch generator is required for the steps that follow.

2. Adjust the CONTRAST and BRIGHTNESS controls in the normal manner for a black-and-white picture. Disregard any color fringing or contamination in the picture.

3. Adjust the HEIGHT, VERTICAL LINEARITY, and VERTICAL CENTERING controls to provide a linear picture that extends no more than 1/4 inch above and below the mask opening.

4. Adjust the WIDTH, HORIZONTAL CENTERING and HORIZONTAL LINEARITY controls to provide a linear picture that extends no more than 1/4 inch beyond the left and right hand edges of the mask opening.

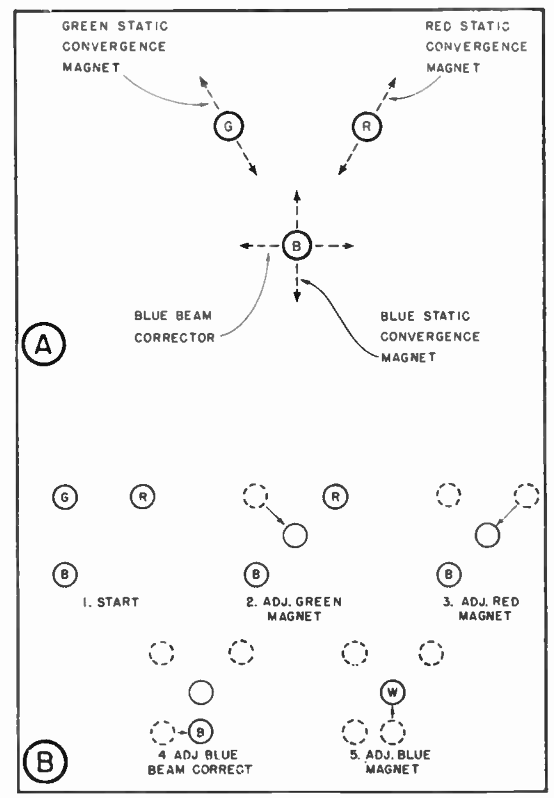

Fig. 4—(A) Motions of the color dots produced by adjustment of the Red, Green, and Blue Static Convergence Magnets. (B) Procedure for converging group of dots using the Static Convergence Magnets and Blue Beam Corrector.

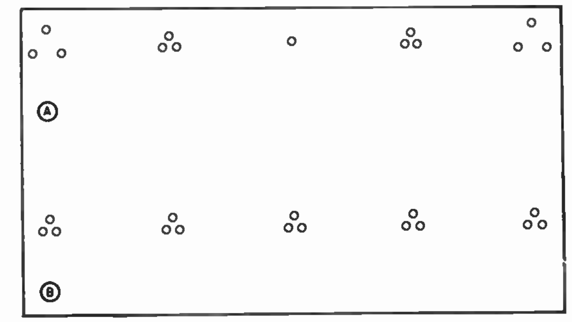

Fig. 5—Dots along horizontal through center of screen, (A) before adjustment of HORIZONTAL PARABOLA and TILT controls and, (B) after proper adjustment of HORIZONTAL PARABOLA and TILT controls.

Convergence Adjustments

1. Connect a Dot Generator to the receiver and adjust the BRIGHTNESS and CONTRAST CONTROLS for a low brightness dot display.

2. Adjust the Red, Green, and Blue Static Convergence Magnets and the Blue Beam Corrector (neck of CRT, Fig. 3) until the group of dots nearest the center of the screen is converged (see Fig. 4B) and forms a single white dot.

Note: The objective in this step and those that follow is to position all of the dots on the screen in the form of small equilateral triangles of uniform size, each consisting of a red, a green and a blue dot, as shown in Figs. 5 and 6.

3. Adjust the RED, GREEN and BLUE HORIZONTAL PARABOLA controls until all of the triangles along a horizontal line through the center of the screen are as uniform in size and shape as possible (see Fig. 5). Adjustment of the HORIZONTAL PARABOLA controls causes the triangles at the left and right edges of the screen to decrease in size and those in the center to increase in size.

Note: The movement of the dots produced by adjustment of each of the PARABOLA and TILT controls is shown in Fig. 7.

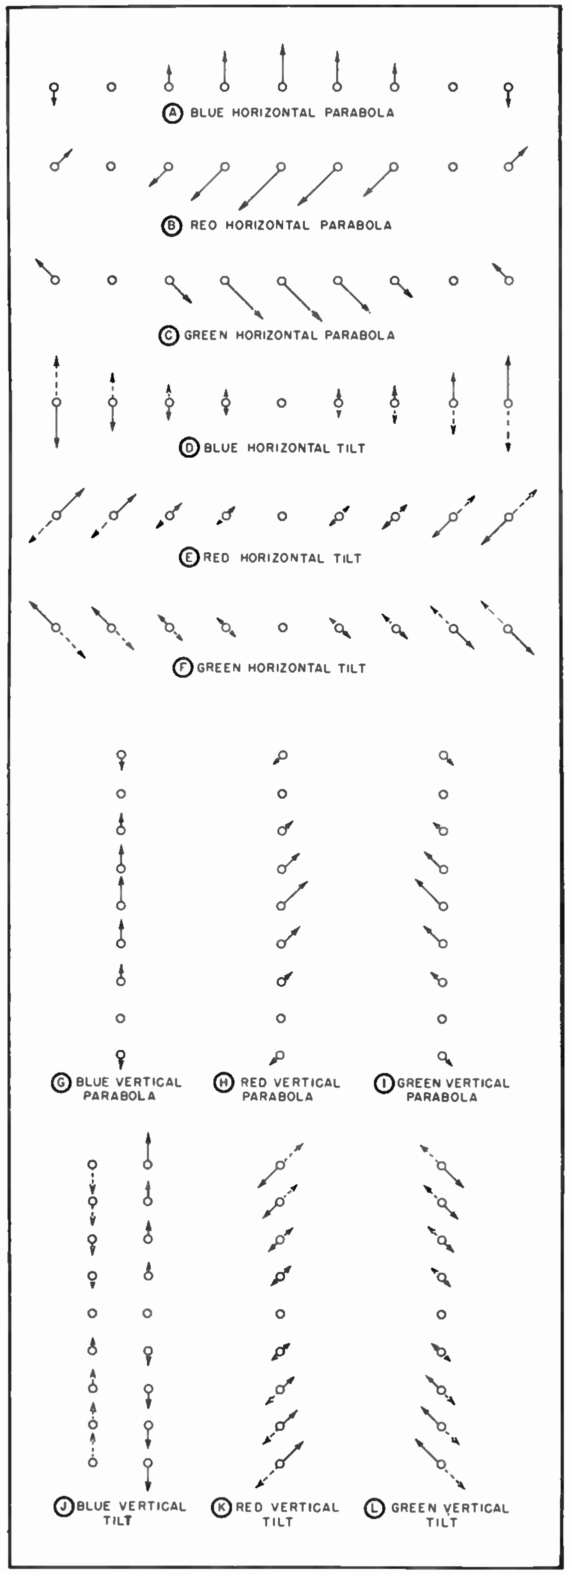

Fig. 7—Motions of colored dots caused by adjustment of PARABOLA and TILT controls. Dotted lines indicate effect of counterclockwise rotation, solid lines indicate effect of clockwise rotation. Effects of PARABOLA controls are shown for rotation from full counterclockwise to full clockwise positions.

4. Adjust the RED, GREEN and BLUE HORIZONTAL TILT controls to eliminate any nonuniformity in the triangles along the horizontal line through the center of the screen. Adjustment of the HORIZONTAL TILT controls increases or decreases the sizes of the triangles at either side of the raster. They have little effect at the center of the screen. After completion of this step, adjust the Red, Green and Blue Static Convergence Magnets to provide approximately 1/16 inch spacing between the dots in each triangular group along the horizontal line.

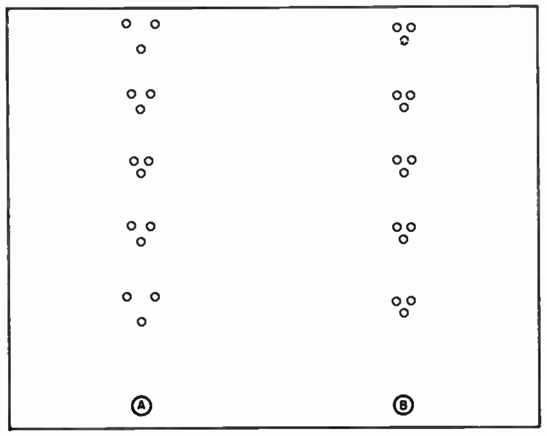

Fig. 6—Dots along vertical line through center of screen, (A) before adjustment of VERTICAL PARABOLA and TILT controls and, (B) after proper adjustment of VERTICAL PARABOLA and TILT controls.

5. Adjust the RED, GREEN and BLUE VERTICAL PARABOLA controls until all of the triangles along a vertical line through the center of the picture are as uniform as possible (see Fig. 6). Adjustment of the VERTICAL PARABOLA controls causes the triangles at the top and bottom of the screen to decrease in size and those in the center to increase in size.

6. Adjust the RED, GREEN and BLUE VERTICAL TILT controls to eliminate any nonuniformity in the triangles along the vertical line through the center of the screen. Adjustment of the VERTICAL TILT controls causes the triangles at the top and bottom of the screen to increase or decrease in size. They have little effect at the center of the screen.

7. The PARABOLA and TILT controls may interact to some extent. As a result, minor readjustment of these controls may be necessary to obtain small, uniform equilateral triangles over as large an area of the screen as possible.

8. Adjust the Red, Green and Blue Static Convergence Magnets, and the Blue Beam Corrector to converge (superimpose) the three dots in the group nearest the center of the screen. Refer to Fig. 4B for adjustment procedure. With this final adjustment all of the groups of three colored dots should converge simultaneously to form white dots.

White Adjustment

1. Connect an antenna to the receiver and tune in a station transmitting a black-and-white program.
2. Turn the CONTRAST, BLUE SCREEN and GREEN SCREEN controls fully counterclockwise.

3. Turn the BRIGHTNESS control fully clockwise and adjust the RED SCREEN control for a barely visible red raster.

4. Turn the GREEN SCREEN control clockwise until the raster turns a greenish-yellow.

5. Turn the BLUE SCREEN control clockwise until the raster turns a neutral gray (low-brightness white).

6. Advance the CONTRAST control to obtain a normal picture.

7. Adjust the BLUE and GREEN GAIN controls until the picture is black-and-white.

8. Turn the BRIGHTNESS control counterclockwise until the picture is just visible and adjust the BLUE and GREEN BACKGROUND controls for neutral gray picture.

9. Run the BRIGHTNESS and CONTRAST controls through their range. If tinting is observed in the picture repeat steps 7 and 8 until it is eliminated.

F-27COMU (Mahogany)
F-27COBU (Blond)

SOUND ALIGNMENT

1. Connect crystal controlled 4.5 mc. 400 cycle amplitude modulated signal, modulated 30% or greater, between grid of video amplifier and chassis.

2. Connect high side of scope through detector probe to the junction of R132 and C121 (picture tube cathode, pin 11). Connect low side of scope to chassis. Adjust 4.5 mc. trap, L111, for minimum 400 cycle deflection on scope.

3. Connect electronic voltmeter to lug 2 of ratio detector, V105, and adjust 4.5 mc. sound take-off (L115) and bottom of ratio detector transformer (T102) for peak reading on voltmeter. Adjust the input to make this peak reading 4 volts.

4. Adjust input to obtain 12 volts output. Transfer electronic voltmeter to junction of R135 and R136 (refer to Schematic Wiring Diagram). Adjust top of T102 for zero balance on electronic voltmeter.

5. Recheck steps 2, 3 and 4 above.

6. Remove input signal, scope and electronic voltmeter.

I. F. ALIGNMENT

All lead connections from the signal marker generator and sweep generator must be shielded. Keep exposed ends and ground leads as short as possible (about one inch). Always locate the ground lead connections as close as possible to their respective "hot" leads in the television receiver chassis. The sweep generator output, signal generator output, and contrast control must be kept low enough to prevent overloading the television receiver circuits.

CAUTION: One side of the chassis is connected to the power line. Therefore, test equipment should not be connected to the receiver unless an isolation transformer is used between the power line and the receiver. DO NOT GROUND THE RECEIVER CHASSIS UNLESS AN ISOLATION TRANSFORMER IS USED.

To Check I.F. Alignment (on Oscilloscope)

Equipment: Sweep Generator, Marker Frequency Generator, Oscilloscope, VTVM (electronic voltmeter), Variable Bias Control Assembly with 4 1/2 volt battery.

a. Set up vertical gain control on scope to read approximately 8.8 volts peak to peak between arbitrary reference lines. This can readily be done as follows:

   1. Draw two horizontal lines spaced approximately 3" apart (depending on size of tube).

   2. Connect low side of scope lead to chassis and the high side of lead to the 6.3 volt filament circuit. This will provide a signal with a peak to peak voltage of 17.6 volts.

   3. Adjust scope vertical gain control until the distance between the two horizontal lines equals one-half the peak to peak amplitude of the 60 cycle sine wave. Leave the vertical gain in this position until the sweep generator attenuator has been set in step "h."

b. Set channel selector knob to unused channel. Set fine tuning control and contrast control to maximum counter-clockwise position. Set noise gate to maximum counter-clockwise position. Set Local-Distance switch to "Local" position.

c. Remove RF amplifier tube (V1) from socket on VHF tuner.

d. Lift the shield of the Oscillator-Mixer tube V2 sufficiently to clear the socket ground clips. Connect the high side of lead from sweep signal generator to the ungrounded tube shield and the ground side of generator lead to the tuner chassis. Keep leads as short as possible (about 1 inch).

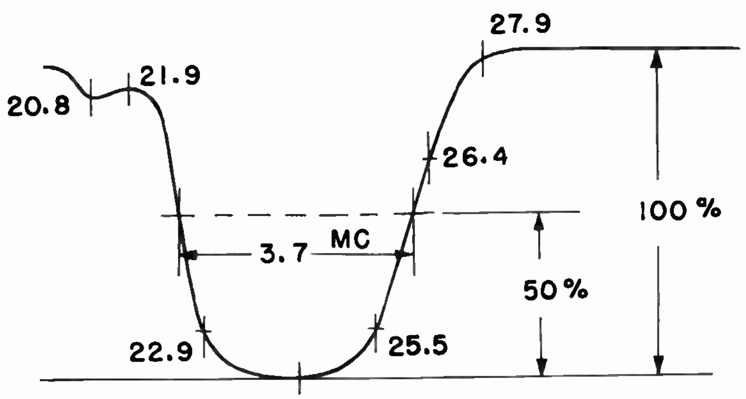
e. Connect center tap of -4.5 volt variable bias supply to pin #1 of AGC amplifier (refer to sketch of "Variable Bias Control Assembly"). Connect high side lead of VTVM to the junction of C115, R107 and R110. Connect the common lead to the chassis. Adjust bias control to obtain -3v. DC reading on the meter.

f. Set generator to sweep from 20 mc. to 32 mc.

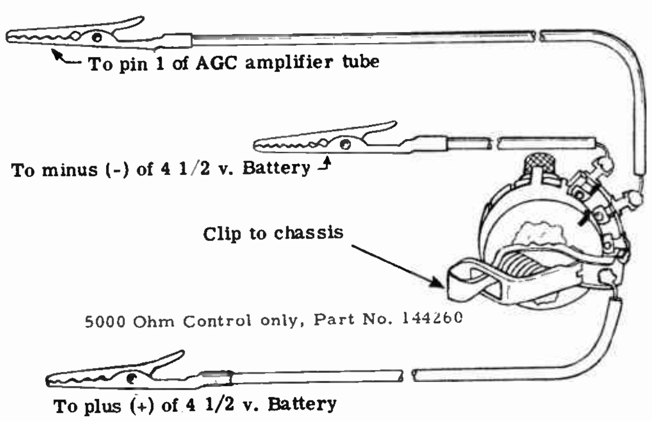
g. Transfer high side of scope lead to top of R116. Adjust the output of the sweep generator to obtain curve on scope of approximately 10 volts peak to peak. (Excessive input will overload the circuit and cause distortion in the wave form. Check for possible overload by temporarily increasing and decreasing the signal input level and noting any change in the wave form. Be sure to keep the input level below the overload point, indicated by a flattening of the peak).

h. Set the marker generator to the various frequencies given (20.8 mc, 21.9 mc, etc.) and compare their relative position with those shown on the Nominal Response Curve. (Be sure to keep the marker at the minimum usable amplitude. Excessive signal will distort wave shape.) Slight deviation in shape from the nominal response curve is permissable, but if any great deviation is noted, it will be necessary to re-align the IF amplifier as in section 2. (NOTE: The response curve may vary with the type of sweep equipment used. Such variations due to equipment can be checked by comparing the resultant curve with that observed on a known good chassis.)

I. F. ALIGNMENT (Cont'd)



NOMINAL OVERALL I.F. RESPONSE CURVE
NOTE: Response as Seen by Means of Sweep Generator



VARIABLE BIAS CONTROL ASSEMBLY

I.F. Alignment Procedure (Using Signal Generator and VTVM)

Equipment: Signal (Marker) Generator, VTVM (electronic voltmeter, 1000 mmf. capacitor, Swamping Network (see step "o"), Variable Bias Control Assembly with 4 1/2 volt battery.

a. Set channel selector switch to an unoccupied channel and the fine tuning control to the maximum counter-clockwise position. A channel in the upper band (channels 7 to 13) will allow easier adjustment of L10 in step "o".

b. Set contrast control to the maximum counter-clockwise position. Set noise gate to the maximum counter-clockwise position. Set Local Distance switch to "Local" position.

c. Remove RF amplifier tube (V1) from socket on VHF tuner.

d. Connect center tap of -4.5 volt Variable Bias Supply to pin #1 of AGC amplifier (see sketch of "Variable Bias Control Assembly"). Connect high side lead of VTVM to the junction of C115, R107 and R110; connect the common lead to the chassis. Adjust the bias control for meter reading of -3.5 volt DC.

e. Connect high side of lead from signal (marker) generator through a 1000 mmf. capacitor to TP-2 (wire protruding from top of tuner through the insulating grommet next to L10). Connect the ground lead to the RF tuner case.

f. Transfer high side lead of VTVM to top of detector load resistor, R116.

g. Set signal (Marker) generator to 24.4 mc and set attenuator of signal generator to produce a meter deflection of approximately -2 volts DC. Adjust top of T101 for maximum DC meter reading. (Be sure sweep generator is off.) Readjust output from signal generator if necessary to keep meter deflection at -2 volts DC maximum.

h. Set signal generator to 22.9 mc and adjust top of L103 for maximum DC meter indication. Limit meter deflection to approximately -2 volts DC maximum by adjusting output attenuator on generator.

i. Set signal generator to 21.9 mc and adjust bottom of L103 for minimum DC meter deflection. Input should be high enough to permit a definite null to be observed on meter. (If necessary, IF bias may be reduced for this step.)

j. Repeat steps "h" and "i". Reset bias to -3.5 volts if necessary.

k. Reset IF bias at -3.5v. Set generator to 25.5 mc and adjust top of L102 for maximum meter deflection. Limit meter reading to approximately -2 volts DC maximum by adjusting output attenuator on generator.

l. Reset signal generator to 24.4 mc. Adjust top of L101 for maximum meter deflection. Limit meter reading to approximately -2 volts DC maximum by adjusting output attenuator on generator.

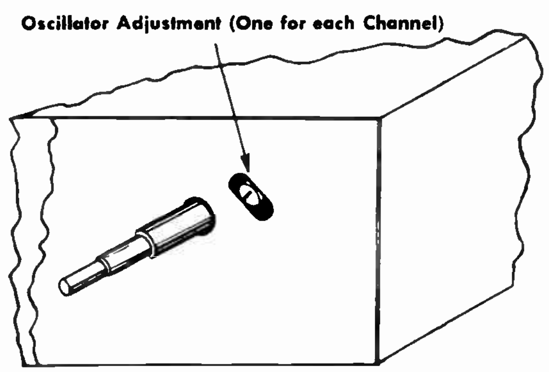
m. Reset signal generator to 27.9 mc and adjust the bottom of L101 for minimum DC meter deflection. Signal generator output must be sufficient to produce a definite null. (If necessary IF bias may be reduced for this step).

n. Repeat steps "l" and "m". If bias has been reduced below -3.5 volts, reset to -3.5 volts for step "l".

o. Transfer high side of signal generator lead to TP-1. Set signal generator to 25.5 mc. Set IF bias to -3.5 volts. Connect the Swamping Network (a 1000 ohm resistor in series with a 1000 mmf capacitor) across L101 making connections to the two lugs on the coil form closest to the chassis. Adjust L10 for a maximum meter reading. I-F bias may be reduced if necessary to obtain a usable deflection. Remove Swamping Network.

p. Disconnect alignment equipment.

VHF TUNER OSCILLATOR ADJUSTMENT



CHASSIS FRONT VIEW

A turret type VHF tuner is used on this receiver, and there is an oscillator adjustment for each channel. When the receiver is installed, the oscillator should be adjusted for each channel on which a station is operating in the area. Set the Channel Switch to the channel that is to be adjusted. Turn the Fine Tuning control to the center of its range. The oscillator trimmer screw is directly to the right of the tuner shaft, and is accessible through a hole in the front of the chassis after the two VHF tuning knobs have been removed. Use a non-metallic screw driver and adjust the oscillator trimmer screw until the proper tuning point is in the center of the Fine Tuning range.

UHF ALIGNMENT

ALIGNMENT NOTES:

CAUTION: This UHF converter unit is used with a VHF receiver that has one side of the chassis connected to the power line. DO NOT CONNECT TEST EQUIPMENT TO ANY PART OF THE RECEIVER OR GROUND THE CHASSIS UNLESS AN ISOLATION TRANSFORMER IS USED BETWEEN THE POWER LINE AND RECEIVER.

1. Remove the UHF Converter from the VHF receiver chassis.

2. In order that the converter will operate with the tuning shaft in maximum CCW* position, it will be necessary to disengage the function switch shaft from the linkage which operates it and manually set the switch to the UHF position. To accomplish this, loosen the two set-screws which secure the arm and hub assembly to the shaft. Turn the switch clockwise to the UHF position and leave it in this position while aligning.

3. Connect the output leads of the UHF converter to the R.F. input terminals of the VHF Tuner.

4. Reconnect the B+ and filament leads of the tuner to the same points on the VHF receiver from which they were disconnected. Connect UHF Converter chassis to B- (VHF receiver chassis).

5. Keep all leads as short as possible. One suggested way of doing this is to mount the UHF converter at right angles to the TV chassis with one mounting screw. Most of the leads on the UHF converter will then be of sufficient length that no additional length will need to be added.

6. Set VHF Tuner to Channel 6.

7. Alignment should be followed in the order shown.

IF ALIGNMENT

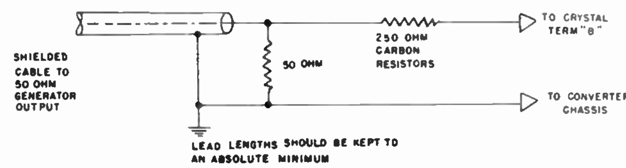
1. Connect an electronic voltmeter or an oscilloscope across the second detector load resistor.

2. Turn on the power.

3. Apply an 82 mc. signal (amplitude modulated if a scope is used) to the crystal terminal (B) at the junction of C13 and L9 through the resistor network shown in Sketch A.

* CW = Clockwise
CCW = Counter-clockwise

Resistor Matching Network for I.F. Alignment



SKETCH A-12

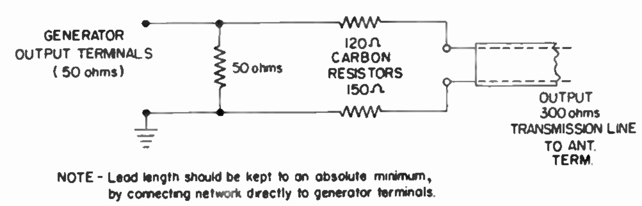
4. Adjust plate coil (T1) and grid coil (T2) for maximum indication on the electronic voltmeter or scope.

5. Disconnect the resistor network from the crystal terminal.

OSCILLATOR ALIGNMENT:

1. With the electronic voltmeter or scope connected across the second detector load resistor, apply a 460 mc. signal (amplitude modulated if a scope is used) to the UHF antenna terminals through the resistor network shown in Sketch B.

Resistor Matching Network for Osc. & R.F. Alignment



SKETCH B-12

2. With the tuner shaft at maximum CCW* position, adjust the oscillator trimmer C6 for peak reading on the electronic voltmeter or maximum indication on the scope (oscillator frequency is set to 84 mc. below the carrier frequency).

3. Set the signal generator to 904 mc.

4. Rotate the tuner shaft to the maximum CW position and adjust the oscillator end inductor L4 up or down for maximum reading on the voltmeter.

5. Open the ground connection on L10 and connect an 0-10 ma. D.C. meter between the open end of the crystal return choke L10 and ground.

UHF ALIGNMENT (Cont'd)

6. Adjust the oscillator coupling coil L11 for maximum crystal current when the tuner shaft is rotated to the maximum CW position. When operating at normal line voltage (117 volts, 60 cycles), the maximum current should not exceed 5 ma. at any setting of the tuner shaft. When operating at low line voltage (105 volts, 60 cycles), the minimum crystal current must not be less than 0.3 ma. at any setting of the tuner shaft.

7. Repeat steps 1 through 4 until maximum reading is obtained.

R-F CIRCUIT ALIGNMENT

1. With the electronic voltmeter or scope connected across the second detector load resistor of the VHF receiver, apply a 460 mc. signal (amplitude modulated if a scope is used) to the UHF antenna terminals through the resistor network shown in Sketch B.

2. With the tuner shaft at the maximum CCW position, adjust the antenna trimmer C4 for maximum meter reading or for maximum scope indication.

3. Reset signal generator to 904 mc.

4. Rotate the tuner shaft to maximum CW position. Adjust the antenna end inductor L3 by forming larger or smaller loop until maximum reading on the meter (or scope) is obtained.

5. Repeat steps 1 through 4 until maximum reading is obtained.

6. Turn the power switch to the "OFF" position.

7. Disconnect the generator, the electronic voltmeter or scope, and the resistor network. Disconnect the 0-10 ma. meter, and solder the open lead of L10 to the chassis.

8. Re-engage the toggle coupling in the pin on the arm and hub assembly and tighten the set-screws that secure the collar to the switch shaft.

9. The Function Switch should be checked for proper operation under conditions of customer use. At full CCW rotation of the tuner shaft, all VHF position contacts must be fully and firmly made and all UHF position contacts must be fully broken. All UHF position contacts must be fully and firmly made and all VHF position contacts must be fully broken, when the tuner shaft is 7 1/2° or more from full CCW, as tuner shaft is rotated in a clockwise direction.

10. Replace the UHF Converter on the VHF receiver chassis.

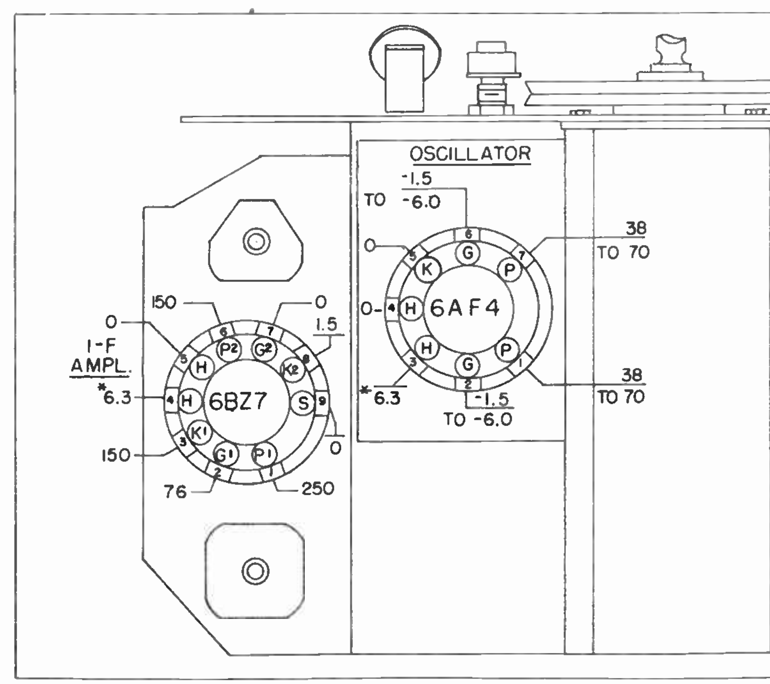
UHF SOCKET VOLTAGE CHART

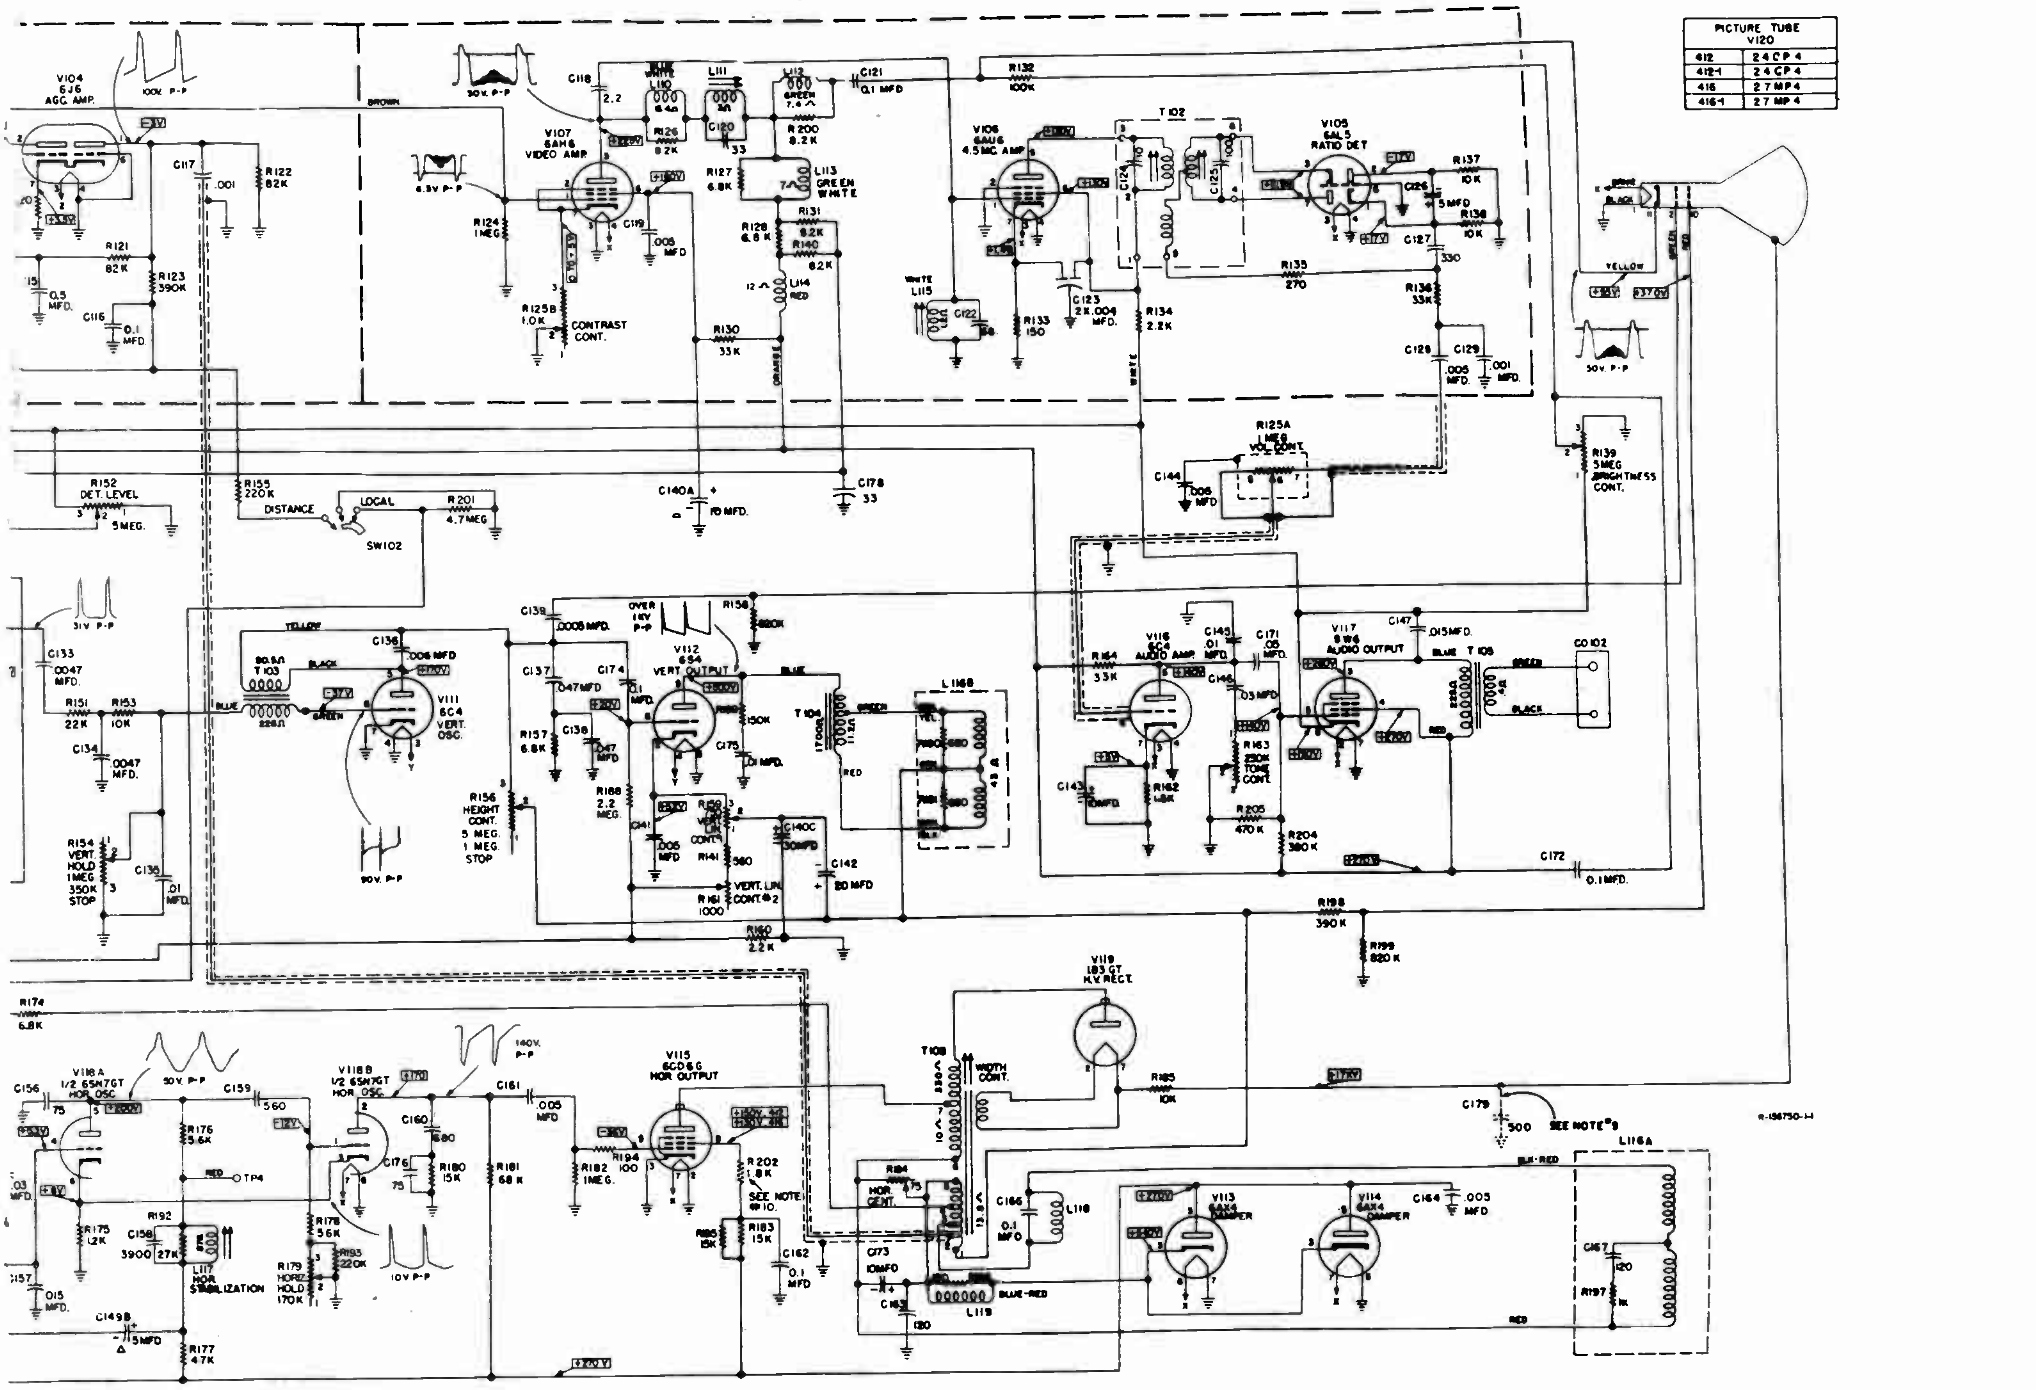


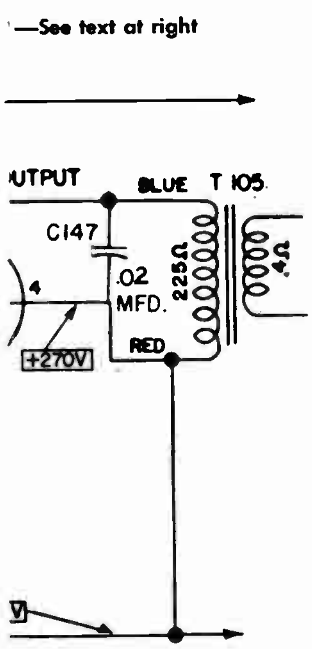
NOTES:

1. BOTTOM VIEW OF TUBE SOCKETS.
2. VOLTAGES MEASURED WITH AN ELECTRONIC VOLTMETER CONNECTED FROM SOCKET LUG TO CHASSIS WITH THE FUNCTION SWITCH IN "UHF" POSITION.
3. * = AC. VOLTAGES.
   NC = NO CONNECTION.
4. OSCILLATOR SOCKET VOLTAGE VARIES WITH FREQUENCY, OTHER VOLTAGES ± 10%.
5. LINE VOLTAGES, 117V, 60 ∿ AC.
6. MINIMUM CRYSTAL CURRENT FOR PROPER OPERATION OF THE OSCILLATOR, 300 μa.

412, 412-1, 416 & 416-1 (See note*)

PICTURE TUBE V120	
412	24CP4
412-1	24CP4
416	27MP4
416-1	27MP4



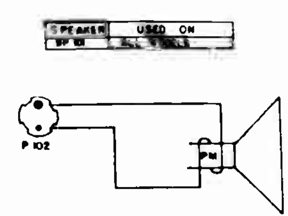


A), capacitor C146 is connected as shown in Figure 2. The ...hematic is made in later production sets to eliminate the possibility of oscillation in the Audio Amplifier. Figures 3 and 4 also show circuits used on chassis 412 (Code A & B), 412-1 (Code A), and 416 (Code A). In later production sets the .01 mfd. capacitor (see Fig. 3) is omitted to reduce horizontal distortion at high brightness levels. At the same time a 4.7 megohm resistor (see full chassis schematic) was added to improve sync stability with action of the AGC switch.

On chassis 412 (Codes A, B, & C), 412-1 (Code A), and 416 (Code A & B), the coupling between the Audio Amplifier and Audio Output stages is direct coupling, as shown in Fig. 2. The circuit which appears in later production sets (shown on the complete schematic) is a production change only, not a design improvement.

*Note: Chassis schematic printed here is for chassis coded as follows: 412 (Code D)
412-1 (Code B)
416 (Code C)
416-1 (Code A)

For circuit variations found in chassis with earlier code letters, see page 20.



NOTES:

1. ALL VOLTAGES MEASURED WITH AN ELECTRONIC VOLTMETER CONNECTED FROM SOCKET LUG TO CHASSIS.

CODE LETTER CHANGES

CHASSIS 412, 412-1, 416 & 416-1

IMPORTANT

Chassis 412 (Code A) and 412-1 (Code A) are furnished with a double cathode 6CD6G tube. In all later models a single cathode type 6CD6G is used. It has since been found that some manufacturers' single cathode types will not perform as satisfactorily as those tubes used in factory production. Therefore, when replacing the 6CD6G in these chassis, use only the double cathode type. Crosley Service Parts Department will stock only 6CD6G's with double cathodes.

Chassis 412 (Codes A & B), 412-1 (Code A)

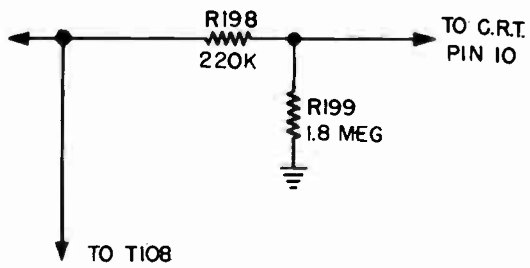

Fig. 1

The circuit shown in Fig. 1 appears in the chassis listed above the figure. To improve the contrast ratio, all later production chassis use the resistor values shown in the full chassis schematic.

Chassis 412 (Codes A & B), 412-1 (Code A)

In these chassis, R202 is omitted in the screen circuit of the 6CD6G. It is added in later production chassis to reduce excessive high voltage.

VHF TUNER SCHEMATIC

Model F-24PDMU
(Mahogany)
Model F-24PDBU
(Blond)

POWER SUPPLY: . . . . .117 volts, 60 cycle, a.c.

POWER CONSUMPTION:
VHF Television Position . . . . 175 watts
UHF Television Position . . . . 180 watts
AM-FM Radio Position . . . . 65 watts
Phonograph Position . . . . 85 watts

AUDIO POWER OUTPUT:
Television . . . . 1.4 watts maximum
Radio or Phonograph . . . . .2 watts undistorted

ANTENNA INPUT IMPEDANCE:
Television . . . . 300 ohms balanced
FM Radio . . . . 75 ohms balanced

INTERMEDIATE FREQUENCY (AM-FM CHASSIS):
AM - 455 kc.
FM - 10.7 mc.

INTERMEDIATE FREQUENCY (TV CHASSIS):

Video Carrier—26.4 mc.
Sound Carrier—21.9 mc.
Intercarrier Sound—4.5 mc.
U.H.F. Output—Channels 5 or 6.

DEFLECTION: Electromagnetic.

FOCUS: Magnetic (P.M.)

ION TRAP: Single Permanent Magnet.

HORIZONTAL SCANNING FREQ: 15,750 c.p.s.

VERTICAL SCANNING FREQ: 60 c.p.s.

FRAME FREQUENCY: 30 c.p.s.

SCANNING: Interlaced, 525 lines.

SPEAKER: 12" Permanent Magnet.

VOICE COIL IMPEDANCE: 3.2 ohms at 400 cycles.

I. F. ALIGNMENT

All lead connections from the signal marker generator and sweep generator must be shielded. Keep exposed ends and ground leads as short as possible (about one inch). Always locate the ground lead connections as close as possible to their respective "hot" leads in the television receiver chassis. The sweep generator output, signal generator output, and contrast control must be kept low enough to prevent overloading the television receiver circuits.

CAUTION: One side of the chassis is connected to the power line. Therefore, test equipment should not be connected to the receiver unless an isolation transformer is used between the power line and the receiver. DO NOT GROUND THE RECEIVER CHASSIS UNLESS AN ISOLATION TRANSFORMER IS USED.

To Check I. F. Alignment (on Oscilloscope):

Equipment: Sweep Generator, Marker Frequency Generator, Oscilloscope, VTVM (electronic voltmeter), Variable Bias Control Assembly with 4 1/2 volt battery.

a. Set up vertical gain control on scope to read approximately 8.8 volts peak to peak between arbitrary reference lines. This can readily be done as follows:

1. Draw two horizontal lines spaced approximately 3" apart (depending on size of tube).

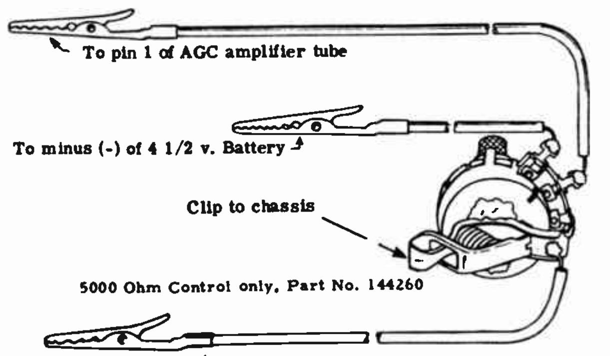
2. Connect low side of scope lead to chassis and the high side of lead to the 6.3 volt filament circuit. This will provide a signal with a peak to peak voltage of 17.6 volts.

3. Adjust scope vertical gain control until the distance between the two horizontal lines equals one-half the peak to peak amplitude of the 60 cycle sine wave. Leave the vertical gain in this position until the sweep generator attenuator has been set in step "h".

b. Set channel selector knob to unused channel. Set fine tuning control and contrast control to maximum counter-clockwise position. Set noise gate to maximum counter-clockwise position. Set Local-Distance switch to "Local" position.

c. Remove RF amplifier tube (V1) from socket on VHF tuner.

d. Lift the shield of the Oscillator-Mixer tube V2 sufficiently to clear the socket ground clips. Connect the high side of lead from sweep signal generator to the ungrounded tube shield and the ground side of generator lead to the tuner chassis. Keep leads as short as possible (about 1 inch).



VARIABLE BIAS CONTROL ASSEMBLY

e. Connect center tap of -4.5 volt variable bias supply to pin #1 of AGC amplifier (refer to sketch of "Variable Bias Control Assembly"). Connect high side lead of VTVM to the junction of C115, R107 and R110. Connect the common lead to the chassis. Adjust bias control to obtain -3v. DC reading on the meter.

f. Set generator to sweep from 20 mc. to 32 mc.

g. Transfer high side of scope lead to top of R116. Adjust the output of the sweep generator to obtain curve on scope of approximately 10 volts peak to peak. (Excessive input will overload the circuit and cause distortion in the wave form. Check for possible overload by temporarily increasing and decreasing the signal input level and noting any change in the wave form. Be sure to keep the input level below the overload point, indicated by a flattening of the peak).

h. Set the marker generator to the various frequencies given (20.8 mc, 21.9 mc, etc.) and compare their relative position with those shown on the Nominal Response Curve. (Be sure to keep the marker at the minimum usable amplitude. Excessive signal will distort wave shape.) Slight deviation in shape from the nominal response curve is permissible, but if any great deviation is noted, it will be necessary to re-align the IF amplifier as in section 2. (NOTE: The response curve may vary with the type of sweep equipment used. Such variations due to equipment can be checked by comparing the resultant curve with that observed on a known good chassis.)

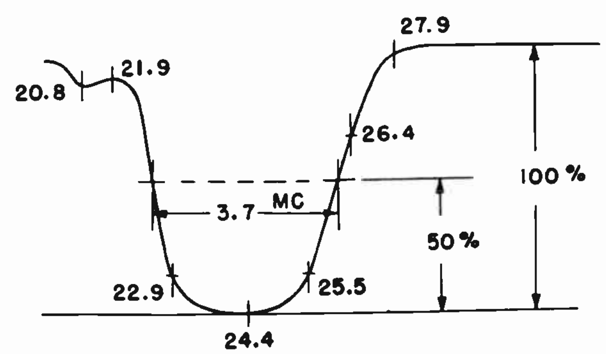
I. F. Alignment Procedure
(Using Signol Generator and VTVM):

Equipment: Signal (Marker) Generator, VTVM (electronic voltmeter), 1000 mmf. capacitor, Swamping Network (see step "o"), Variable Bias Control Assembly with 4 1/2 volt battery.

a. Set channel selector switch to an unoccupied channel and the fine tuning control to the maximum counter-clockwise position. A channel in the upper band (channels 7 to 13) will allow easier adjustment of L10 in step "o".

b. Set contrast control to the maximum counter-clockwise position. Set noise gate to the maximum counter-clockwise position. Set Local Distance switch to "Local" position.

c. Remove RF amplifier tube (V1) from socket on VHF tuner.



NOMINAL OVERALL I. F. RESPONSE CURVE
NOTE: Response as Seen by Means of Sweep Generator

d. Connect center tap of -4.5 volt Variable Bias Supply to pin #1 of AGC amplifier (see sketch of "Variable Bias Control Assembly"). Connect high side lead of VTVM to the junction of C115, R107 and R110; connect the common lead to the chassis. Adjust the bias control for meter reading of -3.5 volt DC.

e. Connect high side of lead from signal (marker) generator through a 1000 mmf. capacitor to TP-2 (wire protruding from top of tuner through the insulating grommet next to L10). Connect the ground lead to the RF tuner case.

f. Transfer high side lead of VTVM to top of detector load resistor, R116.

g. Set signal (marker) generator to 24.4 mc. and set attenuator of signal generator to produce a meter deflection of approximately -2 volts DC. Adjust top of T101 for maximum DC meter reading. (Be sure sweep generator is off.) Readjust output from signal generator if necessary to keep meter deflection at -2 volts DC maximum.

h. Set signal generator to 22.9 mc. and adjust top of L103 for maximum DC meter indication. Limit meter deflection to approximately -2 volts DC maximum by adjusting output attenuator on generator.

i. Set signal generator to 21.9 mc. and adjust bottom of L103 for minimum DC meter deflection. Input should be high enough to permit a definite null to be observed on meter. (If necessary, IF bias may be reduced for this step.)

j. Repeat steps "h" and "i". Reset bias to -3.5 volts if necessary.

k. Reset IF bias at -3.5v. Set generator to 25.5 mc. and adjust top of L102 for maximum meter deflection. Limit meter reading to approximately -2 volts DC maximum by adjusting output attenuator on generator.

l. Reset signal generator to 24.4 mc. Adjust top of L101 for maximum meter deflection. Limit meter reading to approximately -2 volts DC maximum by adjusting output attenuator on generator.

I. F. ALIGNMENT (continued)

m. Reset signal generator to 27.9 mc. and adjust the bottom of L101 for minimum DC meter deflection. Signal generator output must be sufficient to produce a definite null. (If necessary IF bias may be reduced for this step).

n. Repeat steps "l" and "m". If bias has been reduced below -3.5 volts, reset to -3.5 volts for step "l".

o. Transfer high side of signal generator lead to TP-1. Set signal generator to 25.5 mc. Set IF bias to -3.5 volts. Connect the Swamping Network (a 1000 ohm resistor in series with a 1000 mmf. capacitor) across L101 making connections to the two lugs on the coil form closest to the chassis. Adjust L10 for a maximum meter reading. IF bias may be reduced if necessary to obtain a usable deflection. Remove Swamping Network.

p. Disconnect alignment equipment.

SOUND ALIGNMENT

1. Connect crystal controlled 4.5 mc. 400 cycle amplitude modulated signal, modulated 30% or greater, between grid of video amplifier (pin 1, V109) and chassis.

2. Connect high side of scope through detector probe to the junction of R132 & C121 (picture tube cathode). Connect low side of scope to chassis. Adjust 4.5 mc. trap, L111, for minimum 400 cycle deflection on scope.

3. Connect electronic voltmeter to pin 2 of ratio detector tube, V107, and adjust 4.5 mc. sound take-off (L115) and bottom of ratio transformer (T102) for peak reading on voltmeter. Adjust input to make this peak reading 4 volts.

4. Adjust input to obtain 12 volts output. Transfer high side of voltmeter to junction of R135 and R136 (refer to Schematic Wiring Diagram). Adjust top of T102 for zero balance on electronic voltmeter.

5. Recheck steps 2, 3 and 4 above.

6. Remove input signal, scope and electronic voltmeter.

UHF ALIGNMENT

ALIGNMENT NOTES:

CAUTION: This UHF converter unit is used with a VHF receiver that has one side of the chassis connected to the power line. DO NOT CONNECT TEST EQUIPMENT TO ANY PART OF THE RECEIVER OR GROUND THE CHASSIS UNLESS AN ISOLATION TRANSFORMER IS USED BETWEEN THE POWER LINE AND RECEIVER.

1. Remove the UHF Converter from the VHF receiver chassis.

2. In order that the converter will operate with the tuning shaft in maximum CCW* position, it will be necessary to disengage the function switch shaft from the linkage which operates it and manually set the switch to the UHF position. To accomplish this, loosen the two set-screws which secure the arm and hub assembly to the shaft. Turn the switch clockwise to the UHF position and leave it in this position while aligning.

3. Connect the output leads of the UHF converter to the R. F. input terminals of the VHF Tuner.

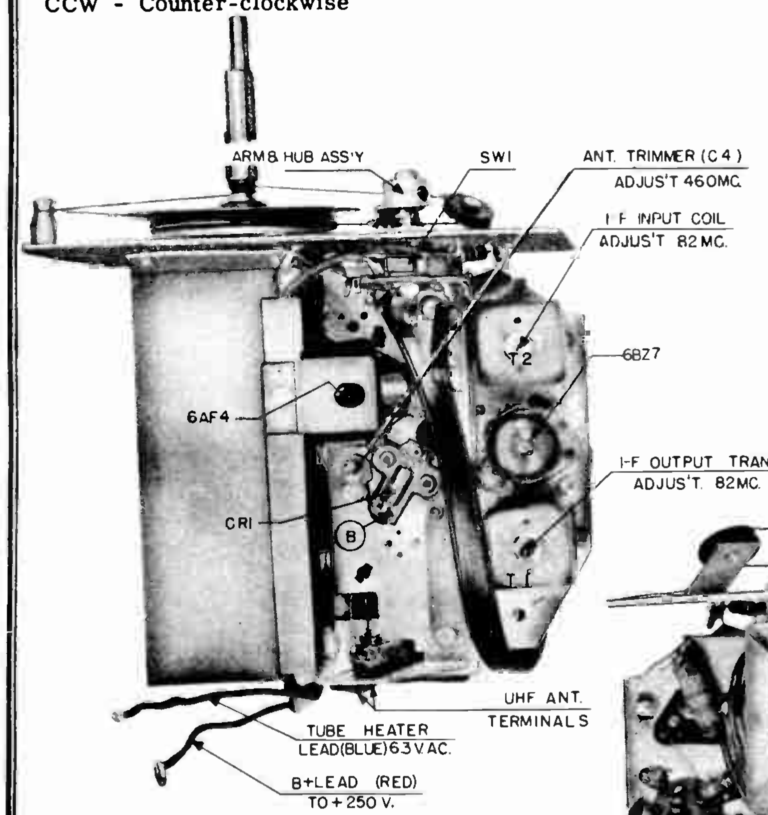
4. Reconnect the B+ and filament leads of the tuner to the same points on the VHF receiver from which they were disconnected. Connect UHF Converter chassis to B- (VHF receiver chassis).

5. Keep all leads as short as possible. One suggested way of doing this is to mound the UHF converter at right angles to the TV chassis with one mounting screw. Most of the leads on the UHF converter will then be of sufficient length that no additional length will need to be added.

6. Set VHF Tuner to Channel 6.

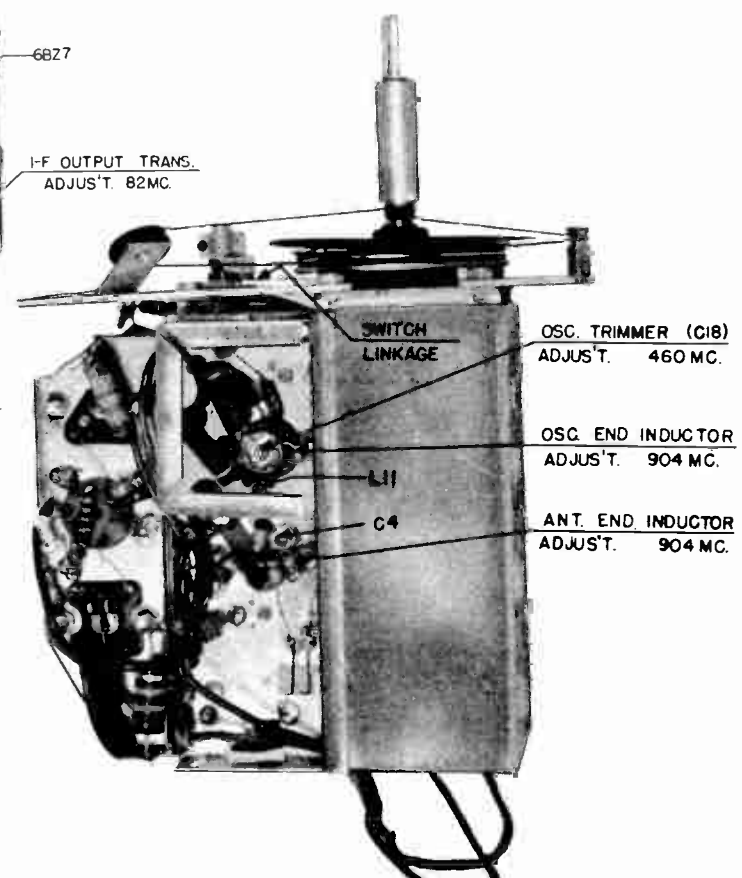
7. Alignment should be followed in the order shown.

*CW - Clockwise
CCW - Counter-clockwise



TOP VIEW - UHF Converter

BOTTOM VIEW - UHF Converter



UHF ALIGNMENT (continued)

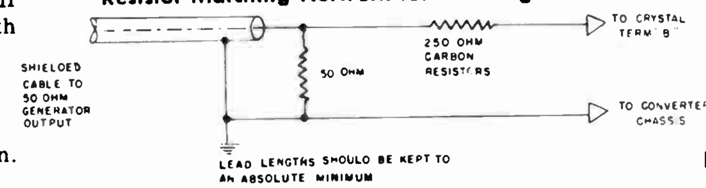
I. F. ALIGNMENT

1. Connect an electronic voltmeter or an oscilloscope across the second detector load resistor.

2. Turn on the power.

3. Apply an 82 mc. signal (amplitude modulated if a scope is used) to the crystal terminal (B) at the junction of C13 and L9 through the resistor network shown in Sketch A.

Resistor Matching Network for I. F. Alignment



SKETCH A

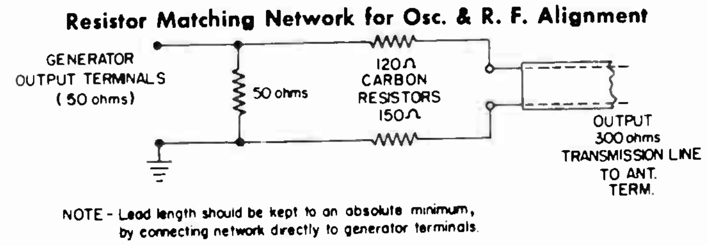
4. Adjust plate coil (T1) and grid coil (T2) for maximum indication on the electronic voltmeter or scope.

5. Disconnect the resistor network from the crystal terminal.

OSCILLATOR ALIGNMENT:

1. With the electronic voltmeter or scope connected across the second detector load resistor, apply a 460 mc. signal (amplitude modulated if a scope is used) to the UHF antenna terminals through the resistor network shown in Sketch B.

Resistor Matching Network for Osc. & R. F. Alignment



SKETCH B

2. With the tuner shaft at maximum CCW* position, adjust the oscillator trimmer C6 for peak reading on the electronic voltmeter or maximum indication on the scope (oscillator frequency is set to 84 mc. below the carrier frequency).

3. Set the signal generator to 904 mc.

4. Rotate the tuner shaft to the maximum CW position and adjust the oscillator end inductor L4 up or down for maximum reading on the voltmeter.

*CW - Clockwise
CCW - Counter-clockwise

5. Open the ground connection on L10 and connect an 0-10 ma. D.C. meter between the open end of the crystal return choke L10 and ground.

6. Adjust the oscillator coupling coil L11 for maximum crystal current when the tuner shaft is rotated to the maximum CW position. When operating at normal line voltage (117 volts, 60 cycles), the maximum current should not exceed 5 ma. at any setting of the tuner shaft. When operating at low line voltage (105 volts, 60 cycles), the minimum crystal current must not be less than 0.3 ma. at any setting of the tuner shaft.

7. Repeat steps 1 through 4 until maximum reading is obtained.

R. F. CIRCUIT ALIGNMENT

1. With the electronic voltmeter or scope connected across the second detector load resistor of the VHF receiver, apply a 460 mc. signal (amplitude modulated if a scope is used) to the UHF antenna terminals through the resistor network shown in Sketch B.

2. With the tuner shaft at the maximum CCW position, adjust the antenna trimmer C4 for maximum meter reading or for maximum scope indication.

3. Reset signal generator to 904 mc.

4. Rotate the tuner shaft to maximum CW position. Adjust the antenna end inductor L3 by forming larger or smaller loop until maximum reading on the meter (or scope) is obtained.

5. Repeat steps 1 through 4 until maximum reading is obtained.

6. Turn the power switch to the "OFF" position.

7. Disconnect the generator, the electronic voltmeter or scope, and the resistor network. Disconnect the 0-10 ma. meter, and solder the open lead of L10 to the chassis.

8. Re-engage the toggle coupling in the pin on the arm and hub assembly and tighten the set-screws that secure the collar to the switch shaft.

9. The Function Switch should be checked for proper operation under conditions of customer use. At full CCW rotation of the tuner shaft, all VHF position contacts must be fully and firmly made and all UHF position contacts must be fully broken. All UHF position contacts must be fully and firmly made and all VHF position contacts must be fully broken, when the tuner shaft is 7 1/2° or more from full CCW, as tuner shaft is rotated in a clockwise direction.

10. Replace the UHF Converter on the VHF receiver chassis.

ALIGNMENT CHART

For alignment locations see photograph on page 14 and chart on page 19.

ALIGNMENT SEQUENCE	SIGNAL GENERATOR OUTPUT			POSITION OF		ADJUST	TYPE OF SELECTIVITY CURVE	REMARKS

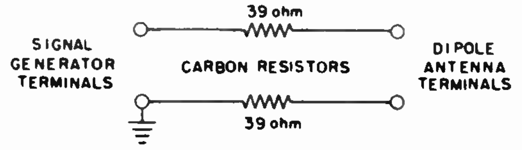
13	1400 KC	200 mmf.	Ext. Ant. Term.	AM	1400 KC	S	----------	Note 9

ALIGNMENT CHART NOTES

1. Use an unmodulated signal with generator output of approximately 100,000 microvolts output.
2. Connect an electronic voltmeter across the 27,000 ohm diode load resistor, R309.
3. Connect two 100,000 ohm carbon resistors, matched within 2%, in series. Connect resistors across the 4 mfd. stabilizing capacitor, C320 in the diode circuit. Connect the electronic voltmeter between the output of the I. F. bypass network, C316 and the midpoint of the two 100,000 ohm resistors. Align secondary core (F) of T303 for zero volts, first using a high scale on the voltmeter and then switching to the lowest scale for balance.
4. Use an unmodulated signal. Connect electronic voltmeter across the 27,000 ohm load resistor R309. Limit output of signal generator so that the DC. reading on the voltmeter does not exceed 5 volts. Reduce signal generator output when necessary to hold the 5 volt alignment level. Shift gang capacity slightly to remove interfering spurious FM oscillator signal during FM I. F. alignment.
5. Remove the two 100,000 ohm resistors and the electronic voltmeter after alignment.
6. Adjust turn spacing on FM oscillator coil by spreading or squeezing slightly so that the 98 megacycle signal falls on the 98 megacycle mark on the dial background.
7. Rock gang while adjusting the FM R. F. trimmer until maximum output meter reading is obtained or align for maximum noise level at zero signal.
8. Adjust turn spacing on FM R. F. coil until maximum output meter reading is obtained, using tuning wand to determine "off frequency" setting.
9. Receiver and loop antenna should be in place in the cabinet when aligning the antenna trimmer "S" on the loop support. Align for maximum output.

F. M. DUMMY ANTENNA



AM-FM TUNER ALIGNMENT PROCEDURE

NOTE: As the radio dial is mounted in the cabinet, it will be necessary to mark oscillator alignment points on the dial background when the chassis is removed from the cabinet, before proceeding with alignment. It will be noted that the dial background has an indentation near the left-hand end. With the tuning gang in full mesh, set the dial pointed to center over this indentation. Using the indentation as a reference point, measure off 2 29/32" to the right and make a pencil mark on the dial background close to the bottom. This mark will correspond to the "98" (98 MC.) calibration on the upper portion of the radio dial. Make another mark 5 1/16" from the indentation to locate the "140" (1400 KC) position on the dial background.

1. Connect an isolation transformer between the power line and the power cord of the television receiver.
2. With the radio tuner power and heater cables and the speaker connected to the television receiver, set the function switch to the position indicated on the ALIGNMENT CHART.
3. Connect output meter across the secondary of the output transformer or voice coil leads to speaker (3.2 ohms).
4. All Amplitude Modulated Input signals are modulated 30% at 400 c.p.s. with the high side of signal generator connected to the receiver as indicated in the ALIGNMENT CHART and the low side of the generator connected to the receiver chassis.
5. All Frequency Modulated signals are modulated 30% at 400 c.p.s.; 30% modulation being equivalent to a deviation of 22.5 kilocycles.
6. Turn the volume control knob to maximum clockwise position and adjust signal generator output to produce a noticeable output meter reading. Keep signal generator output as low as possible to prevent AVC action in the receiver.
7. Alignment sequence must be followed.

VHF OSCILLATOR ADJUSTMENT - A turret type VHF tuner is used on this receiver, and there is an oscillator adjustment for each channel. When the receiver is installed, the oscillator should be adjusted for each channel on which a station is operating in the area. Set the Channel Switch to the channel that is to be adjusted. Turn the Fine Tuning control to the center of its range. The oscillator trimmer screw is directly to the right of the tuner shaft, and is accessible through a hole in the front of the chassis after the two VHF tuning knobs have been removed. Use a non-metallic screwdriver and adjust the oscillator trimmer screw until the proper tuning point is in the center of the Fine Tuning range.

bol No. L10 refer to corresponding numbers on Exploded View of the VHF Tuner

NOTES:

1. ALL VOLTAGES MEASURED WITH AN ELECTRONIC VOLTMETER CONNECTED FROM SOCKET LUG TO CHASSIS.
2. SUPPLY VOLTAGE 117 VOLTS 60 CYCLE AC.
3. K = 1000
4. ALL CAPACITANCE VALUES IN MMF. AND ALL RESISTANCE VALUES IN OHMS UNLESS OTHERWISE NOTED.
5. R166 IS USED ON 414 CHASSIS.
6. I104 IS USED ON 414 CHASSIS.
7. R165 IS USED ON 414-1 CHASSIS.
8. I101, I102, I103 IS USED ON 414-1 CHASSIS.
9. WHEN SERVICING THE TELEVISION CHASSIS WITH THE RADIO TUNER DISCONNECTED, A DUMMY PLUG MUST BE INSERTED IN THE 9 PIN SOCKET ON THE REAR APRON OF THE TV. CHASSIS, AND A WIRE STRAP MUST BE CONNECTED ACROSS THE OUTSIDE TERMINALS OF CO103 AND A GROUND STRAP FROM CENTER TERMINAL TO CHASSIS TO COMPLETE THE TUBE HEATER CIRCUIT.
10. EARLY PRODUCTION CHASSIS USED A CONTRAST CONTROL WITH A RESISTANCE ELEMENT OF 1500 OHMS. A 3300 OHM, 10%, 1/2 WATT FIXED RESISTOR (PART NUMBER 39374-31) WAS CONNECTED BETWEEN TERMINAL LUG 1 AND LUG 3 OF THE CONTROL. THE 1500 OHM CONTROL HAS THE SAME PART NUMBER (155580-1) AS THE 1000 OHM CONTROL. THE SERVICE DEPT. WILL FURNISH ONLY THE 1000 OHM CONTROL. WHEN USING THIS CONTROL, DO NOT USE THE 3300 OHM RESISTOR SHUNT. (NO CODE LETTER IS USED TO DESIGNATE THIS CHANGE).

R308	39374-45	Resistor, 47,000 ohm, 10%, 1/2 w.
R309	39374-42	Resistor, 27,000 ohm, 10%, 1/2 w.
R310	39374-61	Resistor, 1 megohm, 10%, 1/2 w.
R311	39374-41	Resistor, 22,000 ohm, 10%, 1/2 w.
R312	39374-35	Resistor, 6800 ohm, 10%, 1/2 w.

Symbol No.	Part No.	Description
R313	39374-124	Resistor, 8200 ohm, 10%, 1 w.
R315	39374-73	Resistor, 3.3 megohm, 10%, 1/2 w.
R316	39374-215	Resistor, 15,000 ohm, 10%, 2 w.
R317	39374-57	Resistor, 470,000 ohm, 10%, 1/2 w.
R318	39374-33	Resistor, 4700 ohm, 10%, 1/2 w.
R319	39374-53	Resistor, 220,000 ohm, 10%, 1/2 w.
R320	39374-41	Resistor, 22,000 ohm, 10%, 1/2 w.
R321	39374-85	Resistor, 10 megohm, 10%, 1/2 w.
R322	39374-58	Resistor, 560,000, 10%, 1/2 w.
R323	39374-49	Resistor, 100,000 ohm, 10%, 1/2 w.
R324	152338-4	Resistor, 2500 ohm, 5%, 10 w.
R325	155936-1	Resistor, 1200 ohm, 5%, 7 w.
R326	39374-215	Resistor, 15,000 ohm, 10%, 2 w.
R327	39374-57	Resistor, 470,000 ohm, 10%, 1/2 w.
R328	39374-57	Resistor, 470,000 ohm, 10%, 1/2 w.
R329	39374-57	Resistor, 470,000 ohm, 10%, 1/2 w.
R330	39303-8	Resistor, 1 ohm, 10%, 1/2 w.
CA301		Cable, 75 ohm Transmission Line
CA302	156640-1	Cable & Switch Assy. (R312, R318, CA302, C330, C347, C349, SW301, SW302, CA303)
CA303	Part of CA302	Cable, Heater Cable & Lugs
CO301	150208-1	Assembly, Terminal Board
I301	138437-1	Dial Bulb, Type 47, 6.3 v., .15 amp.
I302	138437-1	Dial Bulb, Type 47, 6.3 v., .15 amp.
J301	155717-1	Connector, Phonograph
L301	143322-1	Coil, F. M. Antenna Primary
L302	145724-1	Coil, F. M. Antenna Secondary
L303	143837-1	Coil, Choke
L304	151747-1	Coil, R. F. (F. M.)
L305	151746-1	Coil, Oscillator (F. M.)
L306	152345-1	Loop Antenna (A. M.)
L308	152448-1	Coil, Oscillator (A. M.)
L309	143837-1	Choke
L310	149187-1	Choke
L311	149187-1	Choke
P301	152203	Connector, Cable
SW301A	156120	Switch, Range & Power (Assembly)
SW301B		
SW302A		
SW302B		
T301	139919-3	Transformer, 1st I. F. (455 Kc.)
T302	145025-1	Transformer, 2nd I. F. (10.7 Mc.)
T303	145193-1	Transformer, Ratio Detector
T304	145025-3	Transformer, 1st I. F. (10.7 Mc.)
T305	139919-3	Transformer, 2nd I. F. (455 Kc.)
	152125-3	Background Assembly, Dial
	131154-1	Cotter (External), Drive Shaft
	145697	Insulation & Bushing Assembly
	138853	Insulator, Control Mtg.
	155952	Insulator, Dial Background (2 used)
	155517	Link
	155721	Link and Connecting Arms
	139040	Mounting (Shock), Sub Chassis
	152195	Pointer, Dial
	137939-1	Pulley, Drive Cord Idler
	132028	Rivet, Drive Cord
	137940-1	Rivet, Idler Pulley
	39311-60	Set Screw
	155518	Shaft, Dial Drive
	152651	Shield Assembly
	145205	Socket, Contact (AM Antenna Leads)
	136565-25	Socket, Dial Light
	139727-10	Socket and Cable, Phono Motor
	142761	Socket, Tube (V301, V302)
	39462-2	Socket, Tube (V303, V304)
	144732	Socket, Tube (V305)
	145607	Socket, Tube (V306)
	145757	Spring, Drive Cord
	138568	Strip (Paper), Dial Pointer
	139121	Stud, Insulating
	134916	Washer (Spring), Drive Shaft
	138976	Washer (Extruded), Control Mtg.

* These Two Capacitors Replace a Two Section .004 Capacitor Used in Early Production.

SCHEMATIC REPLACEMENT PARTS LIST

Symbol No.	Part No.	Description
C101	156201-1	Capacitor, 470 mmf., 2 kv., disc ceramic
C102	156201-1	Capacitor, 470 mmf., 2 kv., disc ceramic
C103	137499-37	Capacitor, 110 mmf., 10%, 500 v., mica (Part of L101)
C104	156201-3	Capacitor, 470 mmf., 500 v., disc ceramic
C105	144675-28	Capacitor, .001 mfd., 500 v., disc ceramic
C106	144675-28	Capacitor, .001 mfd., 500 v., disc ceramic
C107	144675-28	Capacitor, .001 mfd., 500 v., disc ceramic
C108	137499-33	Capacitor, 68 mmf., 10%, 500 v., mica (Part of L104)
C109	144675-2	Capacitor, .005 mfd., 500 v., disc ceramic
C110	39001-19	Capacitor, .1 mfd., 600 v., paper
C111	156201-4	Capacitor, .0012 mfd., 600 v., disc ceramic
C112	137727-135	Capacitor, 10 mmf., 500 v., ceramic
C113	137727-103	Capacitor, 5 mmf., 500 v., ceramic
C114	39001-19	Capacitor, .1 mfd., 600 v., paper
C115	154157-1	Capacitor, .5 mfd., -10% + 40%, 25 v., paper
C116	39001-19	Capacitor, .1 mfd., 600 v., paper
C117	156201-2	Capacitor, .001 mfd., 2 kv., disc ceramic
C118	154100-4	Capacitor, 2.2 mmf., 500 v., ceramic
C119	144675-2	Capacitor, .005 mfd., 500 v., disc ceramic
C120	137727-126	Capacitor, 33 mmf., 500 v., ceramic
C121	39001-19	Capacitor, .1 mfd., 600 v., paper
C122	137737-133	Capacitor, 68 mmf., 10%, 500 v., ceramic
C123	144675-6	Capacitor, .004 mfd., 500 v. Two Section
		Capacitor, .004 mfd., 500 v. Disc Ceramic
C124	Part of T102	Capacitor, 10 mmf.
C125	Part of T102	Capacitor, 100 mmf.
C126	154103-1	Capacitor, 5 mfd., 50 v., electrolytic
C127	137727-129	Capacitor, 330 mmf., 500 v., ceramic
C128	144675-2	Capacitor, .005 mfd., 500 v., disc ceramic
C129	144675-28	Capacitor, .001 mfd., 500 v., disc ceramic
C130	39001-19	Capacitor, .1 mfd., 600 v., paper
C131	39477-7	Capacitor, .01 mfd., 600 v., molded paper
C132	39001-17	Capacitor, .05 mfd., 600 v., paper
C133	39477-5	Capacitor, .0047 mfd., 600 v., molded paper
C134	39477-5	Capacitor, .0047 mfd., 600 v., molded paper
C135	39478-7	Capacitor, .01 mfd., 10%, 600 v., molded paper
C136	39001-78	Capacitor, .006 mfd., 600 v., paper
C137	39477-11	Capacitor, .047 mfd., 600 v., molded paper
C138	39477-11	Capacitor, .047 mfd., 600 v., molded paper
C139	39001-5	Capacitor, ,0005 mfd., 600 v., paper
C140A	155910-1	Capacitor, 10 mfd., 10%, 300 v.
C140B		Capacitor, 200 mfd., 10%, 150 v. Electrolytic
C140C		Capacitor, 30 mfd., 10%, 150 v.
C140D		Capacitor, 200 mfd., 10% 150 v.
C141	144675-2	Capacitor, .005 mfd., 500 v., disc ceramic
C142	156021-1	Capacitor, 20 mfd., 10%, 600 v., electrolytic
C143	154104-1	Capacitor, 10 mfd., 50 v., electrolytic
C144	144675-2	Capacitor, .005 mfd., 500 v., disc ceramic
C145	39001-7	Capacitor, .001 mfd., 600 v., paper
C146	39001-82	Capacitor, .03 mfd., 600 v., paper
C147	39001-13	Capacitor, .01 mfd., 600 v., paper
C148	155911-1	Capacitor, 200 mfd., 10%, 150 v., electrolytic
C149A	155436-1	Capacitor, 200 mfd., 300 v. Electrolytic
C149B		Capacitor, 5 mfd., 300 v.
C150	137727-132	Capacitor, 1000 mmf., 500 v., ceramic
C151	137727-132	Capacitor, 1000 mmf., 500 v., ceramic
C152	39478-114	Capacitor, .0033 mfd., 10%, 1000v., molded paper
C153	146434-16	Capacitor, .006 mfd., 10%, 600 v., paper
C154	39001-82	Capacitor, .03 mfd., 600 v., paper
C155	39001-76	Capacitor, .003 mfd., 600 v., paper
C156	137737-134	Capacitor, 75 mmf., 10%, 500 v., ceramic
C158	137499-30	Capacitor, 3900 mmf., 10%, 500 v., mica
C159	137499-34	Capacitor, 560 mmf., 10%, 500 v., mica
C160	137499-32	Capacitor, 680 mmf., 10%, 500 v., mica
C161	144675-2	Capacitor, .005 mfd., 500 v., disc ceramic
C162	39001-19	Capacitor, .1 mfd., 600 v., paper
C163	156569-1	Capacitor, 120 mmf., 10%, 5 kv., disc ceramic
C164	144675-2	Capacitor, .005 mfd., 500 v., disc ceramic
C165	39001-14	Capacitor, .015 mfd., 600 v., paper
C166	Part of L118	Capacitor, .1 mfd., 5%, 200 v., paper
C167	154988	Capacitor, 120 mmf., 10%, 3 kv., disc ceramic
C168	39001-11	Capacitor, .005 mfd., 600 v., paper
C169	137727-126	Capacitor, 33 mmf., 500 v., ceramic
C170	39001-19	Capacitor, .1 mfd., 600 v., paper
C171	39001-13	Capacitor, .01 mfd., 600 v., paper

Symbol No.	Part No.	Description

R101	39374-57	Resistor, 470,000 ohm, 10%, 1/2 w.
R102	39374-57	Resistor, 470,000 ohm, 10%, 1/2 w.
R103	39374-17	Resistor, 220 ohm, 10%, 1/2 w.
R104	39374-15	Resistor, 150 ohm, 10%, 1/2 w.
R105	Part of L104	Resistor, 3900 ohm, 5%, 1/2 w.
R106	39374-9	Resistor, 47 ohm, 10%, 1/2 w.
R107	39374-36	Resistor, 8200 ohm, 10%, 1/2 w.
R108	39375-73	Resistor, 10,000 ohm, 5%, 1/2 w.
R109	39374-25	Resistor, 1000 ohm, 10%, 1/2 w.
R110	39374-25	Resistor, 1000 ohm, 10%, 1/2 w.
R111	39374-11	Resistor, 68 ohm, 10%, 1/2 w.
R112	39374-25	Resistor, 1000 ohm, 10%, 1/2 w.
R113	39375-75	Resistor, 12,000 ohm, 5%, 1/2 w.
R114	39374-15	Resistor, 150 ohm, 10%, 1/2 w.
R115	39374-25	Resistor, 1000 ohm, 10%, 1/2 w.
R116	39375-67	Resistor, 5600 ohm, 5%, 1/2 w.
R117	39374-45	Resistor, 47,000 ohm, 10%, 1/2 w.
R118	39374-41	Resistor, 22,000 ohm, 10%, 1/2 w.
R119	39374-61	Resistor, 1 megohm, 10%, 1/2 w.
R120	39374-25	Resistor, 1000 ohm, 10%, 1/2 w.
R121	39374-48	Resistor, 82,000 ohm, 10%, 1/2 w.
R122	39374-48	Resistor, 82,000 ohm, 10%, 1/2 w.
R123	39374-56	Resistor, 390,000 ohm, 10%, 1/2 w.
R124	39374-61	Resistor, 1 megohm, 10%, 1/2 w.
R125A	155580-1	Control, Volume (1 megohm) Assembly
R125B		Control, Contrast (1000 ohm)
R126	Part of L110	Resistor, 8200 ohm, 10%, 1/2 w.
R127	Part of L113	Resistor, 6800 ohm, 10%, 1/2 w.
R128	39375-365	Resistor, 6800 ohm, 5%, 2 w.
R129	39374-13	Resistor, 100 ohm, 10%, 1/2 w.
R130	39374-131	Resistor, 33,000 ohm, 10%, 1 w.
R131	39374-36	Resistor, 8200 ohm, 10%, 1/2 w.
R132	39374-49	Resistor, 100,000 ohm, 10%, 1/2 w.
R133	39374-15	Resistor, 150 ohm, 10%, 1/2 w.
R134	39374-29	Resistor, 2200 ohm, 10%, 1/2 w.
R135	39374-18	Resistor, 270,000 ohm, 10%, 1/2 w.
R136	39374-43	Resistor, 33,000 ohm, 10%, 1/2 w.
R137	39375-73	Resistor, 10,000 ohm, 5%, 1/2 w.
R138	39375-73	Resistor, 10,000 ohm, 5%, 1/2 w.
R139	155352-1	Control, Brightness (5 megohm)
R140	39374-36	Resistor, 8200 ohm, 10%, 1/2 w.
R141	39374-22	Resistor, 560 ohm, 10%, 1/2 w.
R142	156332-1	Control, Noise Gate (10 megohm)
R143	39374-56	Resistor, 390,000 ohm, 10%, 1/2 w.
R144	39374-56	Resistor, 390,000 ohm, 10%, 1/2 w.
R145	39374-67	Resistor, 1.8 megohm, 10%, 1/2 w.
R146	39374-63	Resistor, 1.2 megohm, 10%, 1/2 w.
R147	39374-49	Resistor, 100,000 ohm, 10%, 1/2 w.
R148	39374-31	Resistor, 3300 ohm, 10%, 1/2 w.
R149	39374-31	Resistor, 3300 ohm, 10%, 1/2 w.
R150	39374-30	Resistor, 2700 ohm, 10%, 1/2 w.
R151	39374-41	Resistor, 22,000 ohm, 10% 1/2 w.
R152	156334-1	Control, Dectector Level (5 megohm)
R153	39374-37	Resistor, 10,000 ohm, 10%, 1/2 w.
R154	155610-1	Control, Vertical Hold (1 megohm)
R155	39374-53	Resistor, 220,000 ohm, 10%, 1/2 w.
R156	154086-1	Control, Height (5 megohm)
R157	39374-35	Resistor, 6800 ohm, 10%, 1/2 w.
R158	39374-60	Resistor, 820,000 ohm, 10%, 1/2 w.
R159	155519-1	Control, Vertical Linearity (750 ohm)
R160	39374-117	Resistor, 2200 ohm, 10%, 1 w.
R161	148861-1	Control, Vertical Linearity (1000 ohm)
R162	39374-27	Resistor, 1500 ohm, 10%, 1/2 w.
R163	155956-1	Control, Tone (1.5 megohm)
R164	39374-43	Resistor, 33,000 ohm, 10%, 1/2 w.
R165	39303-9	Resistor, 1.2 ohm, 10%, 1/2 w. (On 414-1 Chassis)
R166	39303-9	Resistor, 1.2 ohm, 10%, 1/2 w. (On 414 Chassis)
R167	156540	Resistor, 7.5 ohm, 10%, 7.5 w., wire wound
R168	39374-49	Resistor, 100,000 ohm, 10%, 1/2 w.
R169	39374-49	Resistor, 100,000 ohm, 10%, 1/2 w.

SCHEMATIC REPLACEMENT PARTS LIST

Chassis 414 & 414-1

Symbol No.	Part No.	Description	Symbol No.	Part No.	Description
R170	39374-41	Resistor, 22,000 ohm, 10%, 1/2 w.	L105	156362	Coil, R. F. Choke (5 microhenries)
R171	39374-135	Resistor, 68,000 ohm, 10%, 1w.	L106	154376	Coil, Diode Choke (15.5 microhenries)
R172	39374-77	Resistor, 4.7 megohm, 10%, 1/2 w.	L107	156714	Coil, Video Peaking (90 microhenries)
R173	39374-77	Resistor, 4.7 megohm, 10%, 1/2 w.	L108	154184	Coil, Video Peaking (335 microhenries)
R174	39374-135	Resistor, 68,000 ohm, 10%, 1 w.	L109	155256	Coil, Choke R.F. Filament (.576 microhenries)
R175	39374-26	Resistor, 1200 ohm, 10%, 1/2 w.			
R176	39374-34	Resistor, 5600 ohm, 10%, 1/2 w.	L110	154194	Coil, Video Peaking (414 microhenries)
R177	39374-33	Resistor, 4700 ohm, 10%, 1/2 w.	L111	155446	Coil, 4.5 Mc. Trap (27-57 microhenries)
R178	39374-46	Resistor, 56,000 ohm, 10%, 1/2 w.	L112	156618	Coil, Video Peaking (117 microhenries)
R179	155511-1	Control, Horizontal Hold (170,000 ohm)	L113	154206	Coil, Video Peaking (106 microhenries)
R180	39374-39	Resistor, 15,000 ohm, 10%, 1/2 w.	L114	156619	Coil, Video Peaking (240 microhenries)
R181	39374-47	Resistor, 68,000 ohm, 10%, 1/2 w.	L115	155442	Coil, Sound Take-Off (12-23 microhenries)
R182	39374-61	Resistor, 1 megohm, 10%, 1/2 w.	L116A	156839-1	Deflection Yoke Assembly
R183	39374-215	Resistor, 15,000 ohm, 10%, 2 w.	L116B		Deflection Yoke Assembly

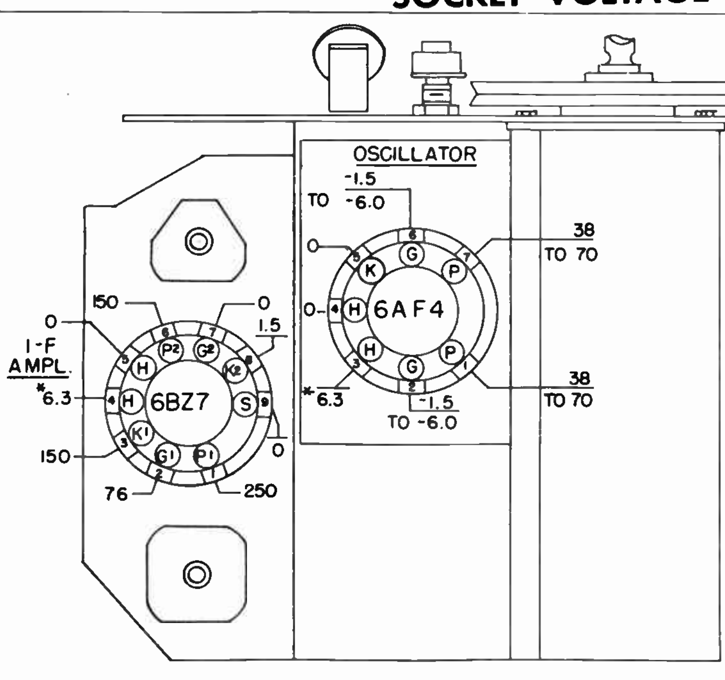
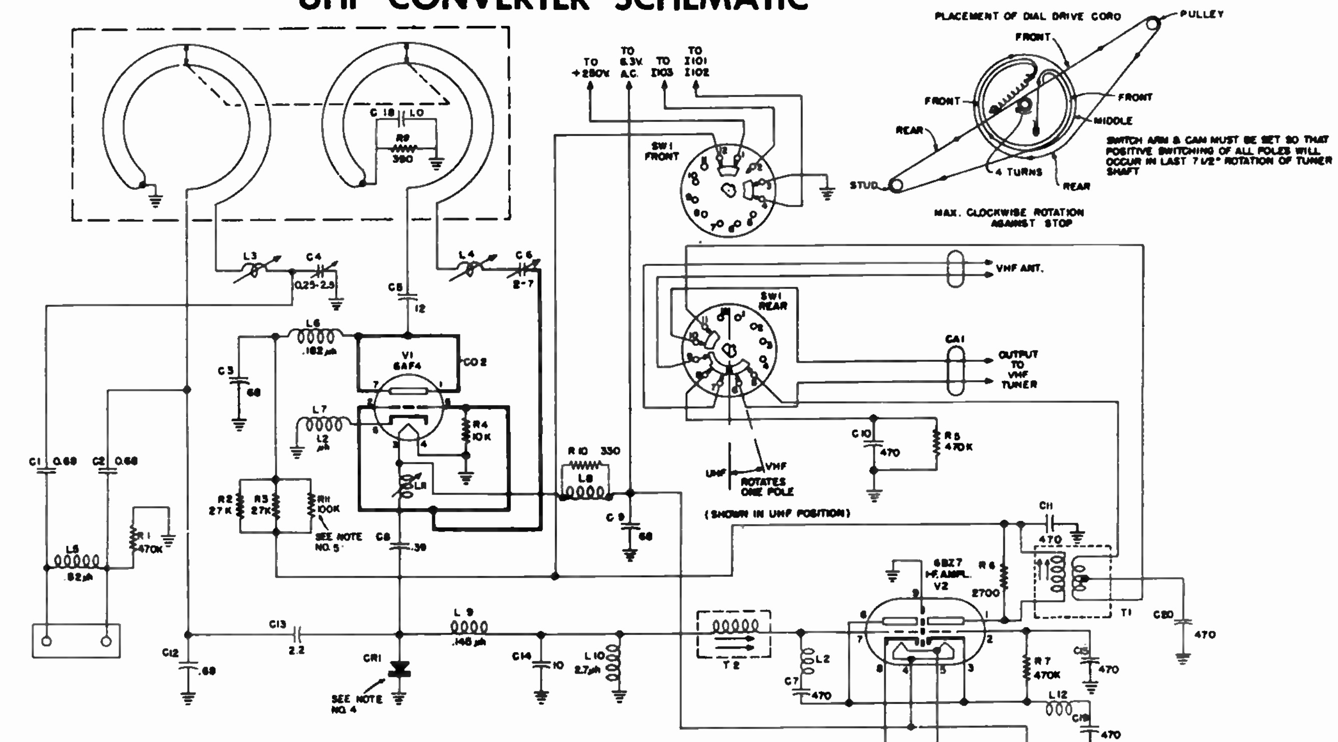
UHF CONVERTER SOCKET VOLTAGE CHART



NOTES:

1. BOTTOM VIEW OF TUBE SOCKETS.
2. VOLTAGES MEASURED WITH AN ELECTRONIC VOLTMETER CONNECTED FROM SOCKET LUG TO CHASSIS WITH THE FUNCTION SWITCH IN "UHF" POSITION.
3. * = AC. VOLTAGES.
   NC = NO CONNECTION.
4. OSCILLATOR SOCKET VOLTAGE VARIES WITH FREQUENCY, OTHER VOLTAGES ± 10%.
5. LINE VOLTAGES, 117V, 60∿AC.
6. MINIMUM CRYSTAL CURRENT FOR PROPER OPERATION OF THE OSCILLATOR, 300 μa.

UHF CONVERTER SCHEMATIC



NOTES:

1. K = 1000
2. All Capacitance Values In MMF. And All Resistance In Ohms Unless Otherwise Noted.
3. All Sections Of Switch SW1 Are Viewed From The Shaft End.
4. When Possible, Replace The Crystal Mixer With One Of The Same Type. When The Same Type Is Not Available One Of The Other Types Can Ordinarily Be Used As A Substitute. However, Because Of Individual Crystal Characteristics The Substitution Of The 1N72 (Part No. 151871) For The 1N82 (Part No. 155459) Or K3D May Be Less Satisfactory.
5. In Some Early Production UHF Tuners, R11 Was Not Used. In Some Later UHF Tuners, R11 Is 87,000 Ohm, 10%, 1/2 Watt.

REPLACEMENT PARTS LIST

I. F. ALIGNMENT

All lead connections from the signal marker generator and sweep generator must be shielded. Keep exposed ends and ground leads as short as possible (about one inch). Always locate the ground lead connections as close as possible to their respective "hot" leads in the television receiver chassis. The sweep generator output, signal generator output, and contrast control must be kept low enough to prevent overloading the television receiver circuits.

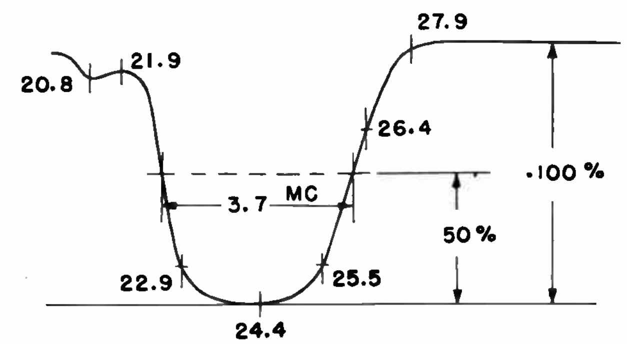
CAUTION: One side of the chassis is connected to the power line. Therefore, test equipment should not be connected to the receiver unless an isolation transformer is used between the power line and the receiver. DO NOT GROUND THE RECEIVER CHASSIS UNLESS AN ISOLATION TRANSFORMER IS USED.

To Check I. F. Alignment (on Oscilloscope):

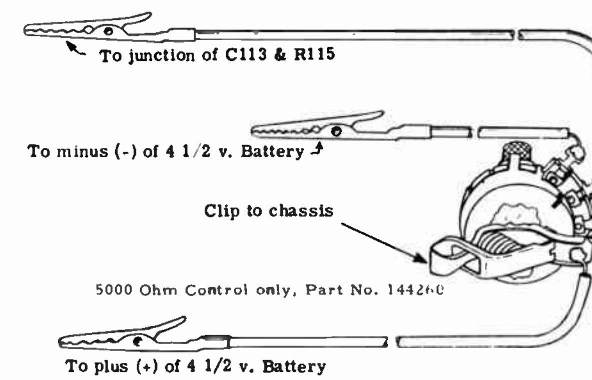
Equipment: Sweep Generator, Marker Frequency Generator, Oscilloscope, VTVM (electronic voltmeter), Variable Bias Control Assembly with 4 1/2 volt battery.

a. Set up vertical gain control on scope to read approximately 8.8 volts peak to peak between arbitrary reference lines. This can readily be done as follows:

1. Draw two horizontal lines spaced approximately 3" apart (depending on size of tube).
2. Connect low side of scope lead to chassis and the high side of lead to the 6.3 volt filament circuit. This will provide a signal with a peak to peak voltage of 17.6 volts.
3. Adjust scope vertical gain control until the distance between the two horizontal lines equals one-half the peak to peak amplitude of the 60 cycle sine wave. Leave the vertical gain in this position until the sweep generator attenuator has been set in step "h".



VARIABLE BIAS CONTROL ASSEMBLY



NORMAL OVERALL I. F. RESPONSE CURVE
NOTE: Response as Seen by Means of Sweep Generator

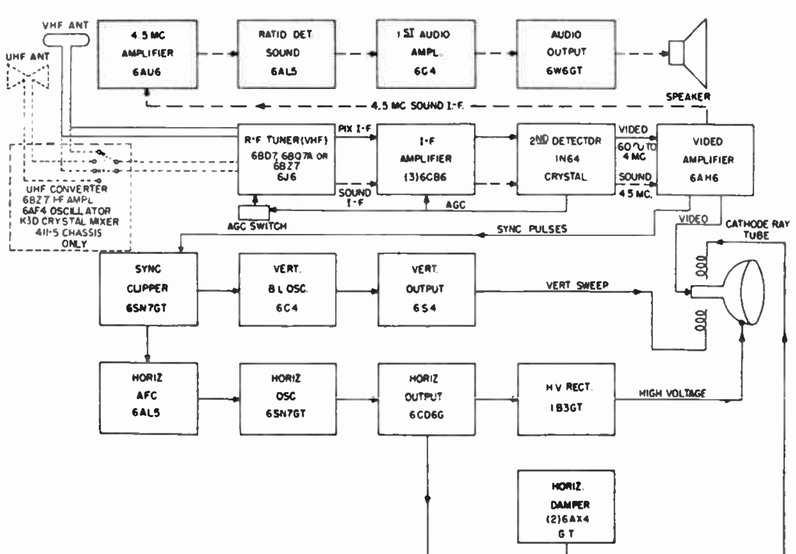
POWER SUPPLY: 117 volts, 60 cycle, a.c.

POWER CONSUMPTION: 160 watts VHF.
165 watts UHF.

AUDIO POWER OUTPUT: 1.4 watts maximum.

ANTENNA INPUT IMPEDANCE: 300 ohms balanced.

BLOCK DIAGRAM:



INTERMEDIATE FREQUENCY:

Video Carrier—26.4 mc.
Sound Carrier—21.9 mc.
Intercarrier Sound—4.5 mc.
U.H.F. Output—Channels 5 or 6.

DEFLECTION: Electromagnetic.

FOCUS: Magnetic (P.M.)

ION TRAP: Single Permanent Magnet.

HORIZONTAL SCANNING FREQ: 15,750 c.p.s.

VERTICAL SCANNING FREQ: 60 c.p.s.

FRAME FREQUENCY: 30 c.p.s.

SCANNING: Interlaced, 525 lines.

SPEAKER: 12" Permanent Magnet.

VOICE COIL IMPEDANCE: 3.2 ohms at 400 cycles.

b. Set channel selector knob to unused channel. Set fine tuning control and contrast control to maximum counter-clockwise position. Set noise gate to maximum counter-clockwise position. Set Local-Distance switch to "Local" position.

c. Remove RF amplifier tube (V1) from socket on VHF tuner.

d. Lift the shield of the Oscillator-Mixer tube V2 sufficiently to clear the socket ground clips. Connect the high side of lead from sweep signal generator to the ungrounded tube shield and the ground side of generator lead to the tuner chassis. Keep leads as short as possible (about 1 inch).

e. Apply -3.0 volts D.C. bias to I-F Bias line, junction of C113 and R115 (see "Variable Bias Control Assembly").

f. Set generator to sweep from 20 mc. to 32 mc.

g. Transfer high side of scope lead to top of R116. Adjust the output of the sweep generator to obtain curve on scope of approximately 10 volts peak to peak. (Excessive input will overload the circuit and cause distortion in the wave form. Check for possible overload by temporarily increasing and decreasing the signal input level and noting any change in the wave form. Be sure to keep the input level below the overload point, indicated by a flattening of the peak).

I. F. ALIGNMENT (continued)

h. Set the marker generator to the various frequencies given (20.8 mc., 21.9 mc., etc.) and compare their relative position with those shown on the Nominal Response Curve. (Be sure to keep the marker at the minimum usable amplitude. Excessive signal will distort wave shape.) Slight deviation in shape from the nominal response curve is permissible, but if any great deviation is noted, it will be necessary to re-align the IF amplifier as in section 2. (NOTE: The response curve may vary with the type of sweep equipment used. Such variations due to equipment can be checked by comparing the resultant curve with that observed on a known good chassis.)

I. F. Alignment Procedure
(Using Signal Generator and VTVM):

Equipment: Signal (Marker) Generator, VTVM (electronic voltmeter), 1000 mmf. capacitor, Swamping Network (See step "o"), Variable Bias Control Assembly with 4 1/2 volt battery.

a. Set channel selector switch to an unoccupied channel and the fine tuning control to the maximum counter-clockwise position. A channel in the upper band (channels 7 to 13) will allow easier adjustment of L10 in step "o".

b. Set contrast control to the maximum counter-clockwise position. Set noise gate to the maximum counter-clockwise position. Set Local Distance switch to "Local" position.

c. Remove RF amplifier tube (V1) from socket on VHF tuner.

d. Apply -3.0 volts D.C. bias to I-F Bias line, junction of C113 and R115 (see "Variable Bias Control Assembly").

e. Connect high side of lead from signal (marker) generator through a 1000 mmf. capacitor to TP-2 (wire protruding from top of tuner through the insulating grommet next to L10). Connect the ground lead to the RF tuner case.

f. Transfer high side lead of VTVM to top of detector load resistor, R116.

g. Set signal (Marker) generator to 24.4 mc. and set attenuator of signal generator to produce a meter deflection of approximately -2 volts DC. Adjust top of T101 for maximum DC meter reading. (Be sure sweep generator is off.) Readjust output from signal generator if necessary to keep meter deflection at -2 volts DC maximum.

h. Set signal generator to 22.9 mc. and adjust top of L103 for maximum DC meter indication. Limit meter deflection to approximately -2 volts DC maximum by adjusting output attenuator on generator.

i. Set signal generator to 21.9 mc. and adjust bottom of L103 for minimum DC meter deflection. Input should be high enough to permit a definite null to be observed on meter. (If necessary, IF bias may be reduced for this step.)

j. Repeat steps "h" and "i". Reset bias to -3.5 volts if necessary.

k. Reset IF bias at -3.5 v. Set generator to 25.5 mc. and adjust top of L102 for maximum meter deflection. Limit meter reading to approximately -2 volts DC maximum by adjusting output attenuator on generator.

l. Reset signal generator to 24.4 mc. Adjust top of L101 for maximum meter deflection. Limit meter reading to approximately -2 volts DC maximum by adjusting output attenuator on generator.

m. Reset signal generator to 27.9 mc. and adjust the bottom of L101 for minimum DC meter deflection. Signal generator output must be sufficient to produce a definite null. (If necessary IF bias may be reduced for this step).

n. Repeat steps "l" and "m". If bias has been reduced below -3.5 volts, reset to -3.5 volts for step "l".

o. Transfer high side of signal generator lead to TP-1. Set signal generator to 25.5 mc. Set IF bias to -3.5 volts. Connect the Swamping Network (a 1000 ohm resistor in series with a 1000 mmf. capacitor) across L101 making connections to the two lugs on the coil form closest to the chassis. Adjust L10 for a maximum meter reading. I-F bias may be reduced if necessary to obtain a usable deflection. Remove Swamping Network.

p. Disconnect alignment equipment.

SOUND ALIGNMENT

1. Connect crystal controlled 4.5 mc. 400 cycle amplitude modulated signal, modulated 30% or greater, between grid of video amplifier and chassis.
2. Connect high side of scope through detector probe to the picture tube cathode (pin 11). Connect low side of scope to chassis. Adjust 4.5 mc. trap, L109, for minimum 400 cycle deflection on scope.
3. Connect electronic voltmeter to pin 2 of ratio detector tube, V104, and adjust 4.5 mc. sound take-off (L112) and bottom of ratio transformer (T102) for peak reading on voltmeter. Adjust input to make this peak reading 4 volts.
4. Adjust input to obtain 12 volts output. Transfer electronic voltmeter to junction of R129 and C128 (refer to Schematic Wiring Diagram). Adjust top of T102 for zero balance on electronic voltmeter.
5. Recheck steps 2, 3 and 4 above.
6. Remove input signal, scope and electronic voltmeter.

VHF CHASSIS (411-4) BOTTOM VIEW
(Tube Socket and Alignment Locations)

UHF ALIGNMENT

ALIGNMENT NOTES:

CAUTION: This UHF converter unit is used with a VHF receiver that has one side of the chassis connected to the power line. DO NOT CONNECT TEST EQUIPMENT TO ANY PART OF THE RECEIVER OR GROUND THE CHASSIS UNLESS AN ISOLATION TRANSFORMER IS USED BETWEEN THE POWER LINE AND RECEIVER.

1. Remove the UHF Converter from the VHF receiver chassis.
2. In order that the converter will operate with the tuning shaft in maximum CCW* position, it will be necessary to disengage the function switch shaft from the linkage which operates it and manually set the switch to the UHF position. To accomplish this, loosen the two set-screws which secure the arm and hub assembly to the shaft. Turn the switch clockwise to the UHF position and leave it in this position while aligning.
3. Connect the output leads of the UHF converter to the R. F. input terminals of the VHF Tuner.
4. Reconnect the B+ and filament leads of the tuner to the same points on the VHF receiver from which they were disconnected. Connect UHF Converter chassis to B- (VHF receiver chassis).

* CW - Clockwise
CCW - Counter-clockwise

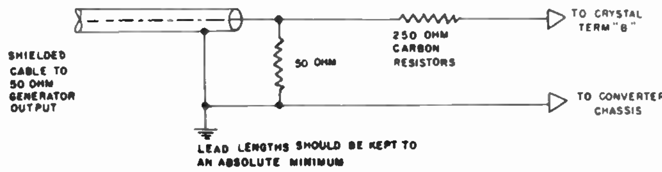
5. Keep all leads as short as possible. One suggested way of doing this is to mount the UHF converter at right angles to the TV chassis with one mounting screw. Most of the leads on the UHF converter will then be of sufficient length that no additional length will need to be added.
6. Set VHF Tuner to Channel 6.
7. Alignment should be followed in the order shown.

I. F. ALIGNMENT

1. Connect an electronic voltmeter or an oscilloscope across the second detector load resistor.
2. Turn on the power.
3. Apply an 82 mc. signal (amplitude modulated if a scope is used) to the crystal terminal (B) at the junction of C13 and L9 through the resistor network shown in Sketch A.

UHF ALIGNMENT (continued)

Resistor Matching Network for I. F. Alignment



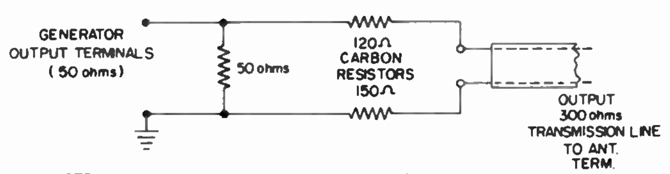
SKETCH A

4. Adjust plate coil (T1) and grid coil (T2) for maximum indication on the electronic voltmeter or scope.
5. Disconnect the resistor network from the crystal terminal.

OSCILLATOR ALIGNMENT:

1. With the electronic voltmeter or scope connected across the second detector load resistor, apply a 460 mc. signal (amplitude modulated if a scope is used) to the UHF antenna terminals through the resistor network shown in Sketch B.

Resistor Matching Network for Osc. & R. F. Alignment



NOTE - Lead length should be kept to an absolute minimum, by connecting network directly to generator terminals.

SKETCH B

2. With the tuner shaft at maximum CCW* position, adjust the oscillator trimmer C6 for peak reading on the electronic voltmeter or maximum indication on the scope (oscillator frequency is set to 84 mc. below the carrier frequency).
3. Set the signal generator to 904 mc.
4. Rotate the tuner shaft to the maximum CW position and adjust the oscillator end inductor L4 up or down for maximum reading on the voltmeter.
5. Open the ground connection on L10 and connect an 0-10 ma. D.C. meter between the open end of the crystal return choke L10 and ground.

*CW - Clockwise
CCW - Counter-clockwise

6. Adjust the oscillator coupling coil L11 for maximum crystal current when the tuner shaft is rotated to the maximum CW position. When operating at normal line voltage (117 volts, 60 cycles), the maximum current should not exceed 5 ma. at any setting of the tuner shaft. When operating at low line voltage (105 volts, 60 cycles), the minimum crystal current must not be less than 0.3 ma. at any setting of the tuner shaft.
7. Repeat steps 1 through 4 until maximum reading is obtained.

R. F. CIRCUIT ALIGNMENT

1. With the electronic voltmeter or scope connected across the second detector load resistor of the VHF receiver, apply a 460 mc. signal (Amplitude modulated if a scope is used) to the UHF antenna terminals through the resistor network shown in Sketch B.
2. With the tuner shaft at the maximum CCW position, adjust the antenna trimmer C4 for maximum meter reading or for maximum scope indication.
3. Reset signal generator to 904 mc.
4. Rotate the tuner shaft to maximum CW position. Adjust the antenna end inductor L3 by forming larger or smaller loop until maximum reading on the meter (or scope) is obtained.
5. Repeat steps 1 through 4 until maximum reading is obtained.
6. Turn the power switch to the "OFF" position.
7. Disconnect the generator, the electronic voltmeter or scope, and the resistor network. Disconnect the 0-10 ma. meter, and solder the open lead of L10 to the chassis.
8. Re-engage the toggle coupling in the pin on the arm and hub assembly and tighten the set-screws that secure the collar to the switch shaft.
9. The Function Switch should be checked for proper operation under conditions of customer use. At full CCW rotation of the tuner shaft, all VHF position contacts must be fully and firmly made and all UHF position contacts must be fully broken. All UHF position contacts must be fully and firmly made and all VHF position contacts must be fully broken, when the tuner shaft is 7 1/2° or more from full CCW, as tuner shaft is rotated in a clockwise direction.
10. Replace the UHF Converter on the VHF receiver chassis.

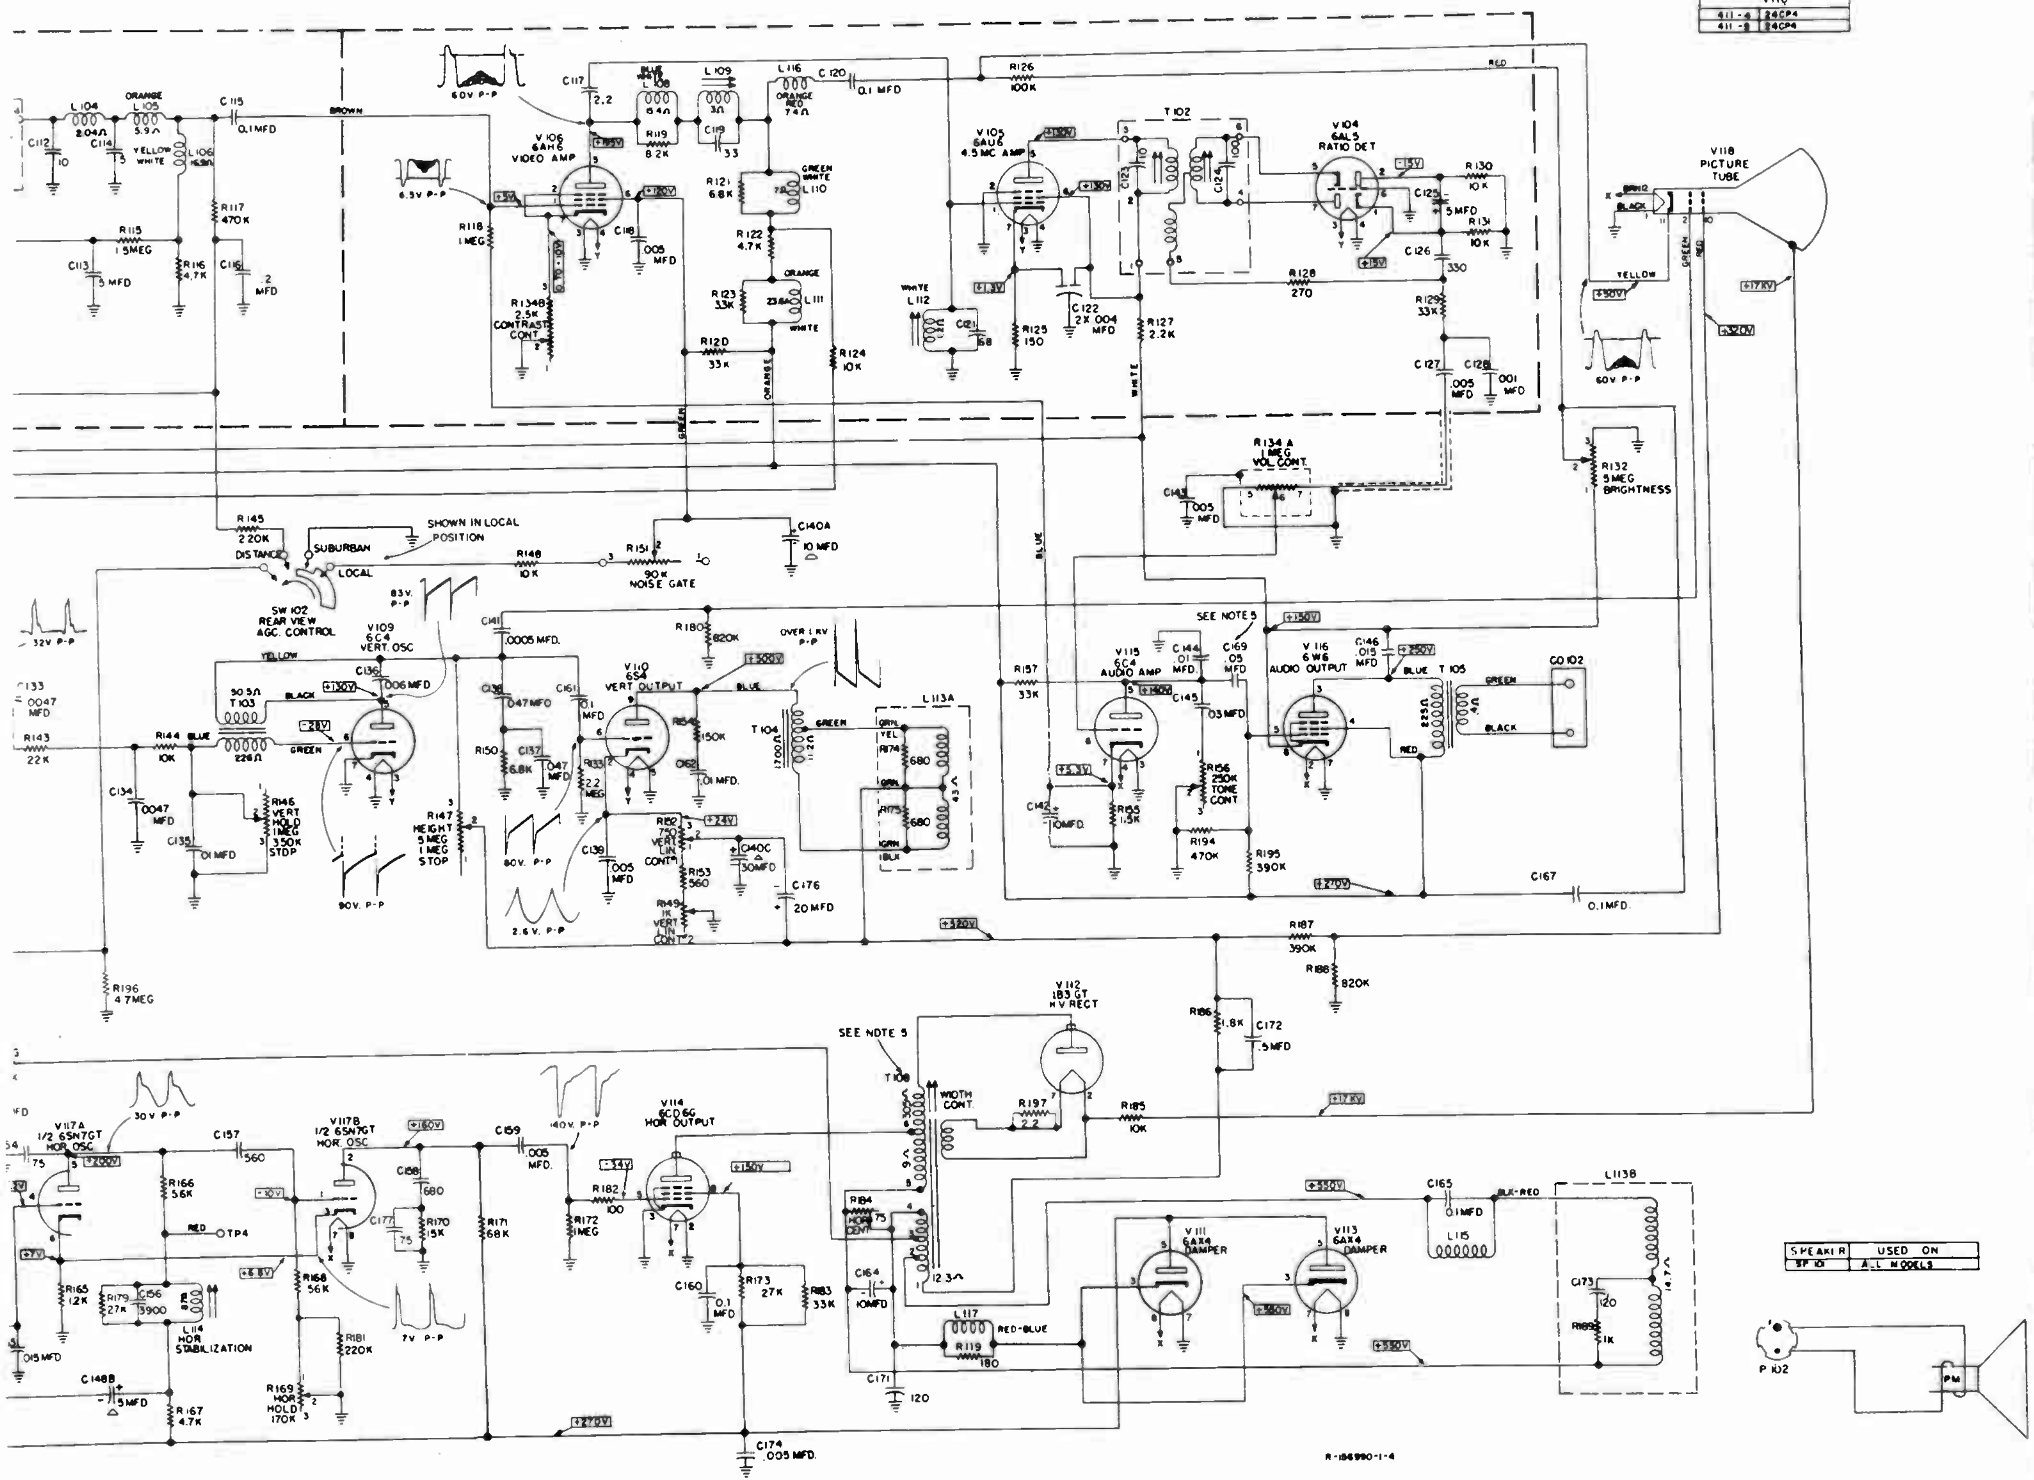
R147	154086	Control, Height (5 megohm)
R148	39374-125	Resistor, 10,000 ohm, 10%, 1 w.
R149	148861	Control, Vertical Linearity (1000 ohm)
R150	39374-35	Resistor, 6800 ohm, 10%, 1/2 w.
R151	155576	Control, Noise Gate (90,000 ohm)
R152	155519	Control, Vertical Linearity (750 ohm)
R153	39374-22	Resistor, 560 ohm, 10%, 1/2 w.
R154	39374-139	Resistor, 150,000 ohm, 10%, 1 w.
R155	39374-27	Resistor, 1500 ohm, 10%, 1/2 w.
R156	155389	Control, Tone (250,000 ohm)
R157	39374-43	Resistor, 33,000 ohm, 10%, 1/2 w.
R158	156540	Resistor, 7.5 ohm, 10%, 5 w. wire wound
R159	39374-49	Resistor, 100,000 ohm, 10%, 1/2 w.
R160	39374-49	Resistor, 100,000 ohm, 10%, 1/2 w.
R161	39374-41	Resistor, 22,000 ohm, 10%, 1/2 w.
R162	39374-135	Resistor, 68,000 ohm, 10%, 1 w.
R163	39374-77	Resistor, 4.7 megohm, 10%, 1/2 w.
R164	39374-77	Resistor, 4.7 megohm, 10%, 1/2 w.
R165	39374-26	Resistor, 1200 ohm, 10%, 1/2 w.
R166	39374-34	Resistor, 5600 ohm, 10%, 1/2 w.
R167	39374-33	Resistor, 4700 ohm, 10%, 1/2 w.
R168	39374-46	Resistor, 56,000 ohm, 10%, 1/2 w.
R169	155511	Control, Horizontal Hold
R170	39374-39	Resistor, 15,000 ohm, 10%, 1/2 w.
R171	39374-47	Resistor, 68,000 ohm, 10%, 1/2 w.
R172	39374-61	Resistor, 1 megohm, 10%, 1/2 w.
R173	39374-218	Resistor, 27,000 ohm, 10%, 2 w.
R174	39374-23	Resistor, 680 ohm, 10%, 1/2 w. (Part of L113)
R175	39374-23	Resistor, 680 ohm, 10%, 1/2 w. (Part of L113)
R176	39374-135	Resistor, 68,000 ohm, 10%, 1 w.
R177	39374-25	Resistor, 1000 ohm, 10%, 1/2 w.
R179	39374-42	Resistor, 27,000 ohm, 10%, 1/2 w.
R180	39374-60	Resistor, 820,000 ohm, 10%, 1/2 w.
R181	39374-53	Resistor, 220,000 ohm, 10%, 1/2 w.
R182	39374-13	Resistor, 100 ohm, 10%, 1/2 w.
R183	39374-219	Resistor, 33,000 ohm, 10%, 2 w.
R184	155844	Control, Horizontal Centering (75 ohm)
R185	39374-37	Resistor, 10,000 ohm, 10%, 1/2 w. (Part of T108)
R186	39374-204	Resistor, 1800 ohm, 10%, 2 w.
R187	39374-56	Resistor, 390,000 ohm, 10%, 1/2 w.
R188	39374-60	Resistor, 820,000 ohm, 10%, 1/2 w.
R189	39374-25	Resistor, 100 ohm, 10%, 1/2 w.
R190	39374-57	Resistor, 470,000 ohm, 10%, 1/2 w.
R191	Part of L117	Resistor, 180 ohm, 10%, 1/2 w.
R193	39374-13	Resistor, 1000 ohm, 10%, 1/2 w.
R194	39374-57	Resistor, 470,000 ohm, 10%, 1/2 w.
R195	39374-56	Resistor, 390,000 ohm, 10%, 1/2 w.
R196	39374-77	Resistor, 4.7 megohm, 10%, 1/2 w.
L101	155304	Coil, Converter IF (1.98-4.5 microhenries)
L102	155319	Coil, 1st IF (1.95-4 microhenries)
L103	155348	Coil, 2nd IF (2.4-4.5 microhenries)
L104	154376	Coil, Choke Diode (15.5 microhenries)
L105	156714	Coil, Video Peaking (90 microhenries)
L106	154184	Coil, Video Peaking (335 microhenries)
L107	155256	Choke, RF Filament (.576 microhenries)
L108	154194	Coil, Video Peaking (412 microhenries)
L109	155446	Coil, 4.5 MC. Trap (27-57 microhenries)
L110	154206	Coil, Video Peaking (106 microhenries)
L111	154176	Coil, Video Peaking (840 microhenries)
L112	155442	Coil, Sound Take Off (12-35 microhenries)
L113A	156839-1	Deflection Yoke } Assembly
L113B		Deflection Yoke
L114	154220	Coil, Horizontal Oscillator (18-37 microhenries)
L115	155944	Network, Yoke Coupling (10 millihenries)
L116	156035	Coil, Video Peaking (117 microhenries)
L117	156575	Coil, RF Choke (16 microhenries)
T101	155594	Transformer, Diode IF
T102	154108	Transformer, Ratio Detector
T103	155255-1	Transformer, Vertical Oscillator
T104	155966	Transformer, Vertical Output
T105	154109-3	Transformer, Audio Output
T106	155532	Transformer, Filament
T107	156005-1	Choke, Filter
T108	155445-5	Transformer, Horizontal Deflection
CO102	138352	Socket, Speaker
CO103	154114	Socket, Terminal Strip
SW101	Part of R134	Switch, ON-OFF
SW102	155554	Switch, Rotary
CR101	154111	Crystal, 1N64 (Part of T101)
SR101	155575-1	Selenium Rectifier
SR102	155575-1	Selenium Rectifier
SP101	138762-6	Speaker, P.M. (12")
CA101	132300-6	Cable & Plug, AC Power
P101	154125	Receptacle, Interlock
P102	131983	Plug, 2 Prong Male

VIRING DIAGRAM CHASSIS 411-4 & 411-5



CODE LETTER CHANGES

CHASSIS 411-4 & 411-5

(Important)

-4 (Code A) the coupling between the Audio Amplifier and Audio Output stages is direct coupling, as shown in circuit which appears in the complete schematic applys to chassis 411-4 (Code B and later) and to all 411-5 is a production change only.

Chassis 411-4 (Code A)

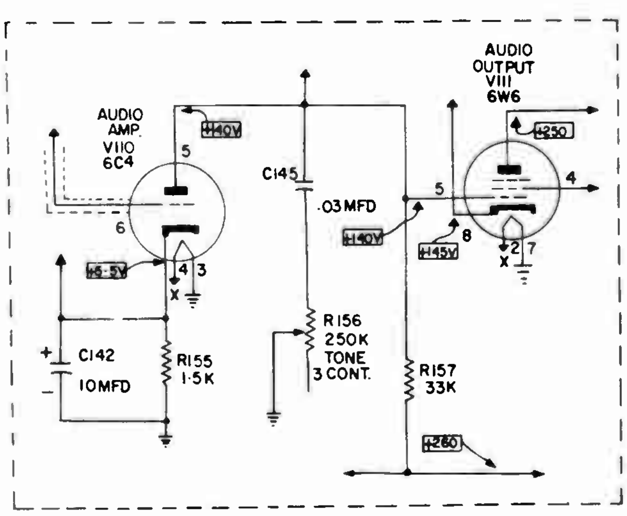


Figure 1

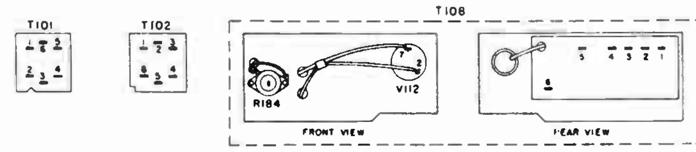
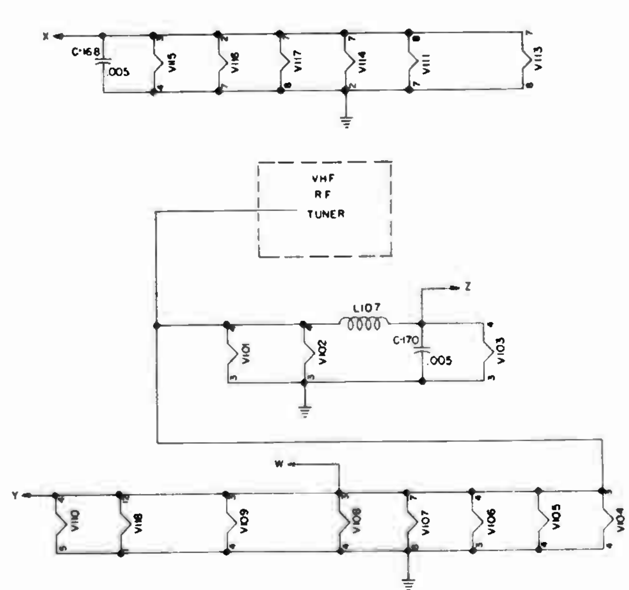
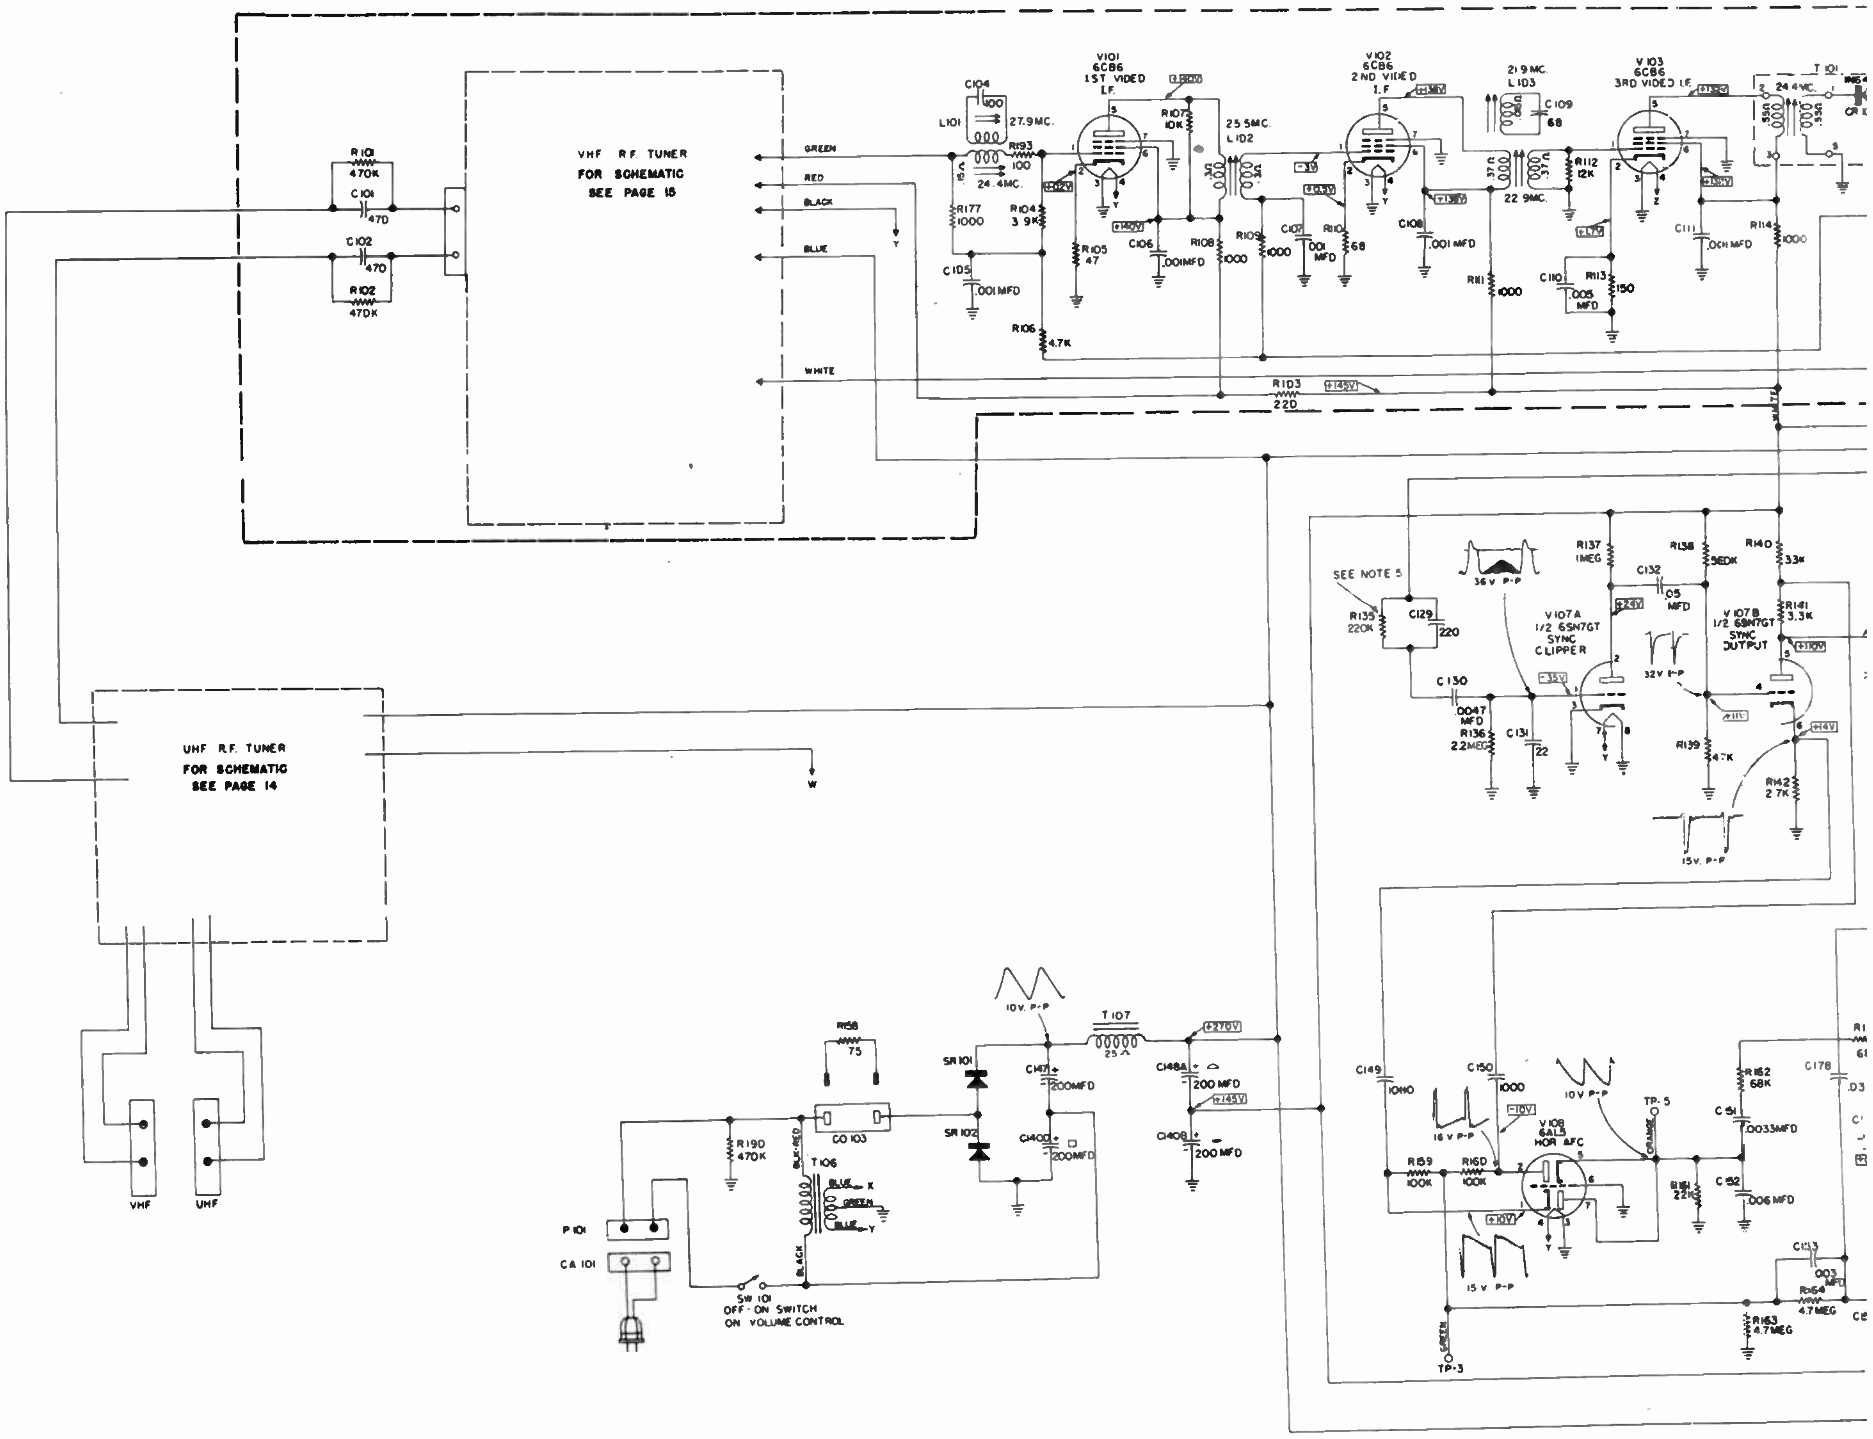
Chassis 411-4 (Code A or B) 411-5 (Code A)

NOTES:
1. ALL VOLTAGES MEASURED WITH AN ELECTRONIC VOLTMETER CONNECTED FROM SOCKET LUG TO CHASSIS.
2. SUPPLY VOLTAGE 117 VOLTS 60 CYCLE AC.
3. K=1000
4. ALL CAPACITANCE VALUES IN MMF. AND ALL RESISTANCE VALUES IN OHMS UNLESS OTHERWISE NOTED.
5. IMPORTANT - SEE CODE CHANGES







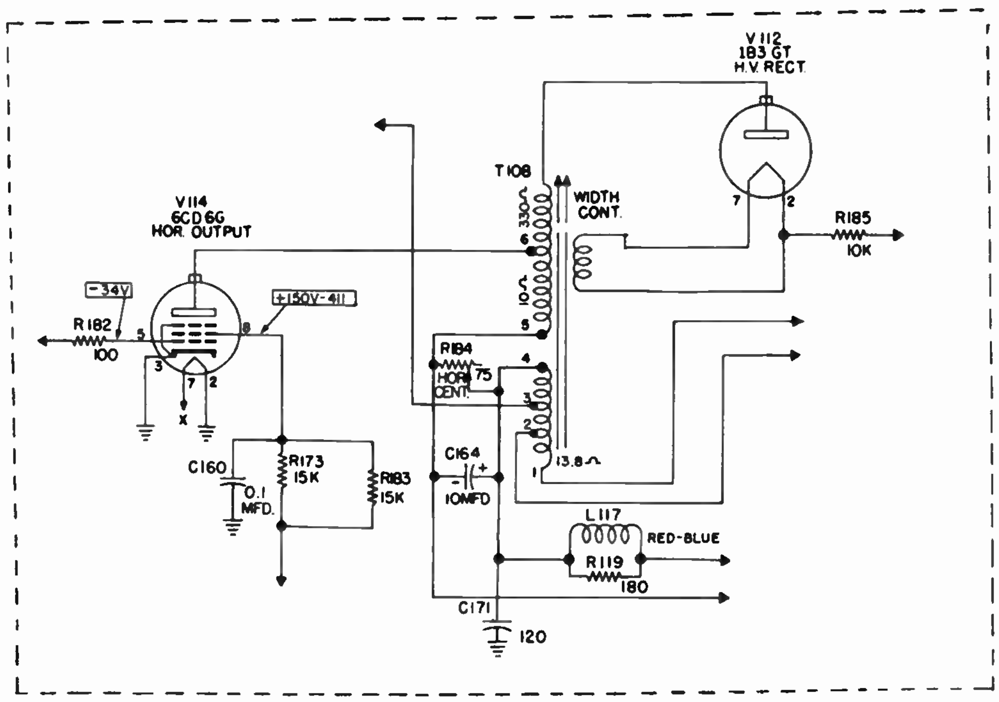


Figure 2

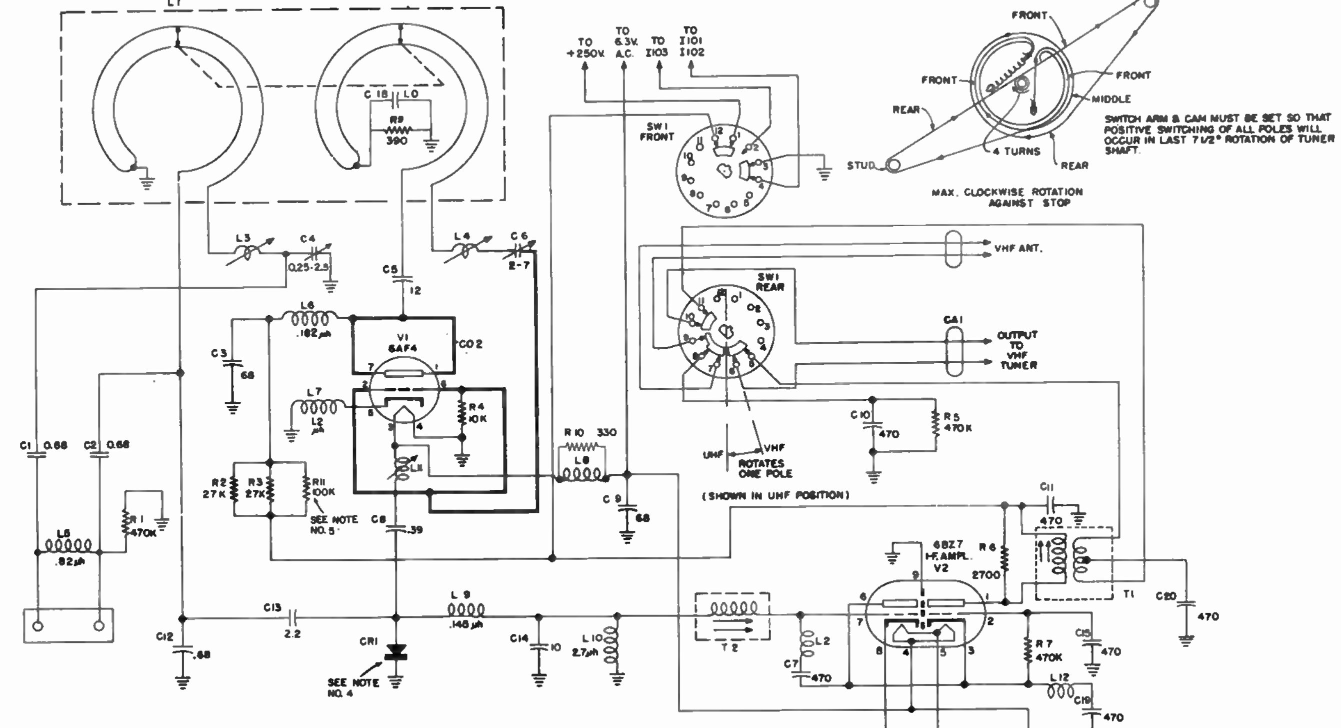
On chassis 411
Figure 1. The
chassis. This

On chassis 411-4 (Code A or B), 411-5 (Code A), T108 Horizontal Deflection Transformer, Part No. 155455-1 is used. Resistors R173 and R183 are 15,000 ohm, 2 w., 10%, as shown in Figure 2. The Transformer T108 and Resistors R173 and R183 which appear in the complete schematic apply to chassis 411-4 (Code C or later) and to chassis 411-5 (Code B or later).

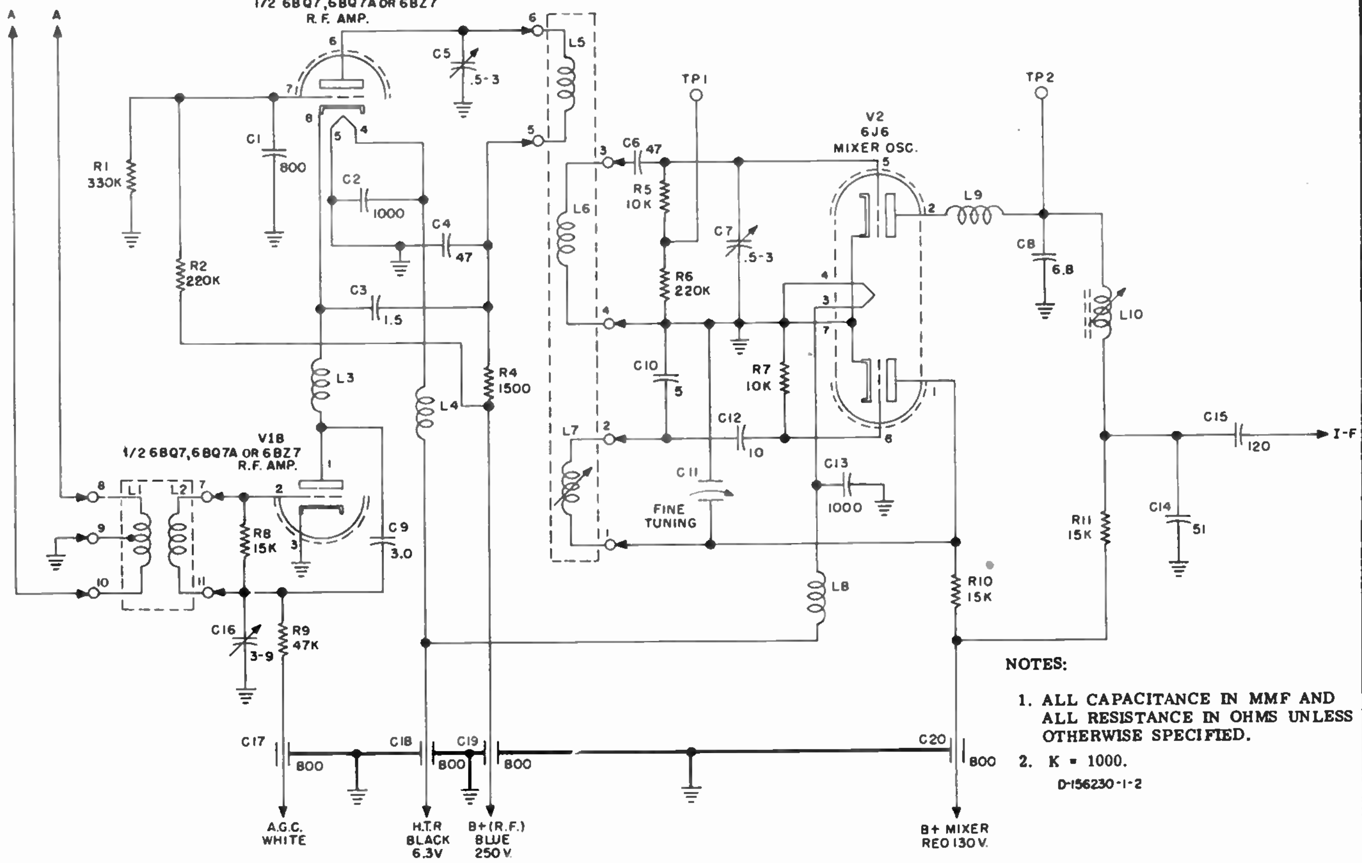
On chassis 411-4 (Code A or B), 411-5 (Code A) Resistor, R135 is 470,000 ohm. On chassis 411-4 (Code C or later), 411-5 (Code B or later) Resistor, R135 is 220,000 ohm. This resistor was changed to improve the Vertical Sync stability.

UHF CONVERTER SCHEMATIC



NOTES:
1. K = 1000
2. All Capacitance Values In MMF. And All Resistance In Ohms Unless Otherwise Noted.
3. All Sections Of Switch SW1 Are Viewed From The Shaft End.
4. When Possible, Replace The Crystal Mixer With One Of The Same Type. When The Same Type Is Not Available One Of The Other Types Can Ordinarily Be Used As A Substitute. However, Because Of Individual Crystal Characteristics The Substitution Of The 1N72 (Part No. 151871) For The 1N82 (Part No. 155459) Or K3D May Be Less Satisfactory.
5. In Some Early Production UHF Tuners, R11 Was Not Used. In Some Later UHF Tuners, R11 Is 87,000 Ohm, 10%, 1/2 Watt.

VHF TUNER SCHEMATIC



NOTES:
1. ALL CAPACITANCE IN MMF AND ALL RESISTANCE IN OHMS UNLESS OTHERWISE SPECIFIED.
2. K = 1000.

*One Antenna Coil Assembly and one R. F. & Oscillator Coil Assembly are necessary for each channel to be received. The dash number following the basic part number indicates the channel for which the assembly is designed. Example: 156907-2, Antenna Coil Assembly for Channel 2; 156908-13, R. F. & Oscillator Coil Assembly for Channel 13.

NOTE: Reference numbers (1, 2, 3, etc.) that follow Symbol No. L10 refer to corresponding numbers on Exploded View of the VHF Tuner

POWER SUPPLY: . . . . . . 117 volts, 60 cycle, a.c.

POWER CONSUMPTION:

VHF Position . . . . 150 watts
UHF Position . . . . 155 watts

AUDIO POWER OUTPUT: . . . . 1.4 watts maximum

ANTENNA INPUT IMPEDANCE: . 300 ohms balanced

INTERMEDIATE FREQUENCY:

Video Carrier—26.4 mc.
Sound Carrier—21.9 mc.
Intercarrier Sound—4.5 mc.
U. H. F. Output—Channels 5 or 6.

DEFLECTION: Electromagnetic.

FOCUS: Magnetic (P.M.) on 404-4 & 404-5 chassis
Electrostatic on 402-4 & 404-5 chassis

ION TRAP: Single Permanent Magnet.

HORIZONTAL SCANNING FREQ: 15,750 c.p.s.

VERTICAL SCANNING FREQ: 60 c.p.s.

FRAME FREQUENCY: 30 c.p.s.

SCANNING: Interlaced, 525 lines.

SPEAKER: 10" Permanent Magnet console models.
5 1/4" Permanent Magnet table models.

VOICE COIL IMPEDANCE: 3.2 ohms at 400 cycles.

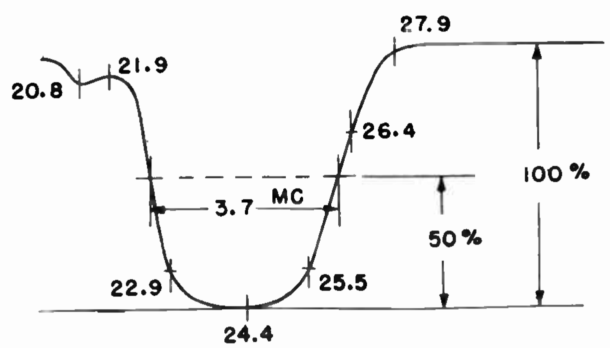
I. F. ALIGNMENT

All lead connections from the signal marker generator and sweep generator must be shielded. Keep exposed ends and ground leads as short as possible (about one inch). Always locate the ground lead connections as close as possible to their respective "hot" leads in the television receiver chassis. The sweep generator output, signal generator output, and contrast control must be kept low enough to prevent overloading the television receiver circuits.

CAUTION: One side of the chassis is connected to the power line. Therefore, test equipment should not be connected to the receiver unless an isolation transformer is used between the power line and the receiver. DO NOT GROUND THE RECEIVER CHASSIS UNLESS AN ISOLATION TRANSFORMER IS USED.

To Check I. F. Alignment (on Oscilloscope):

Equipment: Sweep Generator, Marker Frequency Generator, Oscilloscope, VTVM (electronic voltmeter), Variable Bias Control Assembly with 4 1/2 volt battery.



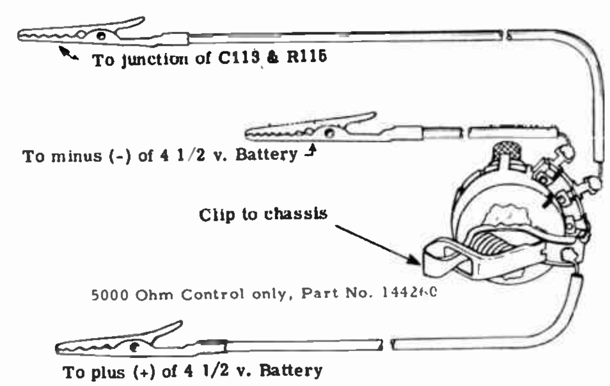
NORMAL OVERALL I. F. RESPONSE CURVE
NOTE: Response as Seen by Means of Sweep Generator

a. Set up vertical gain control on scope to read approximately 8.8 volts peak to peak between arbitrary reference lines. This can readily be done as follows:

1. Draw two horizontal lines spaced approximately 3" apart (depending on size of tube).

2. Connect low side of scope lead to chassis and the high side of lead to the 6.3 volt filament circuit. This will provide a signal with a peak to peak voltage of 17.6 volts.

3. Adjust scope vertical gain control until the distance between the two horizontal lines equals one-half the peak to peak amplitude of the 60 cycle sine wave. Leave the vertical gain in this position until the sweep generator attenuator has been set in step "h".



VARIABLE BIAS CONTROL ASSEMBLY

I. F. ALIGNMENT (continued)

b. Set channel selector knob to unused channel. Set fine tuning control and contrast control to maximum counter-clockwise position. Set noise gate to maximum counter-clockwise position. Set Local-Distance switch to "Local" position.

c. Remove RF amplifier tube (V1) from socket on VHF tuner.

d. Lift the shield of the Oscillator-Mixer tube V2 sufficiently to clear the socket ground clips. Connect the high side of lead from sweep signal generator to the ungrounded tube shield and the ground side of generator lead to the tuner chassis. Keep leads as short as possible (about 1 inch).

e. Apply -3.0 volts D.C. bias to I-F Bias line, junction of C113 and R115 (see "Variable Bias Control Assembly").

f. Set generator to sweep from 20 mc. to 32 mc.

g. Transfer high side of scope lead to top of R116. Adjust the output of the sweep generator to obtain curve on scope of approximately 10 volts peak to peak. (Excessive input will overload the circuit and cause distortion in the wave form. Check for possible overload by temporarily increasing and decreasing the signal input level and noting any change in the wave form. Be sure to keep the input level below the overload point, indicated by a flattening of the peak).

h. Set the marker generator to the various frequencies given (20.8 mc., 21.9 mc., etc.) and compare their relative position with those shown on the Nominal Response Curve. (Be sure to keep the marker at the minimum usable amplitude. Excessive signal will distort wave shape.) Slight deviation in shape from the nominal response curve is permissible, but if any great deviation is noted, it will be necessary to realign the IF amplifier as in section 2. (NOTE: The response curve may vary with the type of sweep equipment used. Such variations due to equipment can be checked by comparing the resultant curve with that observed on a known good chassis.)

I. F. Alignment Procedure
(Using Signal Generator and VTVM):

Equipment: Signal (Marker) Generator, VTVM (electronic voltmeter), 1000 mmf. capacitor, Swamping Network (See step "o"), Variable Bias Control Assembly with 4 1/2 volt battery.

a. Set channel selector switch to an unoccupied channel and the fine tuning control to the maximum counter-clockwise position. A channel in the upper band (channels 7 to 13) will allow easier adjustment of L10 in step "o".

b. Set contrast control to the maximum counter-clockwise position. Set noise gate to the maximum counter-clockwise position. Set Local Distance switch to "Local" position.

c. Remove RF amplifier tube (V1) from socket on VHF tuner.

d. Apply -3.0 volts D.C. bias to I-F Bias line, junction of C113 and R115 (see "Variable Bias Control Assembly").

e. Connect high side of lead from signal (marker) generator through a 1000 mmf. capacitor to TP-2 (wire protruding from top of tuner through the insulating grommet next to L10). Connect the ground lead to the RF tuner case.

f. Transfer high side lead of VTVM to top of detector load resistor, R116.

g. Set signal (Marker) generator to 24.4 mc. and set attenuator of signal generator to produce a meter deflection of approximately -2 volts DC. Adjust top of T101 for maximum DC meter reading. (Be sure sweep generator is off.) Readjust output from signal generator if necessary to keep meter deflection at -2 volts DC maximum.

h. Set signal generator to 22.9 mc. and adjust top of L103 for maximum DC meter indication. Limit meter deflection to approximately -2 volts DC maximum by adjusting output attenuator on generator.

i. Set signal generator to 21.9 mc. and adjust bottom of L103 for minimum DC meter deflection. Input should be high enough to permit a definite null to be observed on meter. (If necessary, IF bias may be reduced for this step.)

j. Repeat steps "h" and "i". Reset bias to -3.5 volts if necessary.

k. Reset IF bias at -3.5 v. Set generator to 25.5 mc. and adjust top of L102 for maximum meter deflection. Limit meter reading to approximately -2 volts DC maximum by adjusting output attenuator on generator.

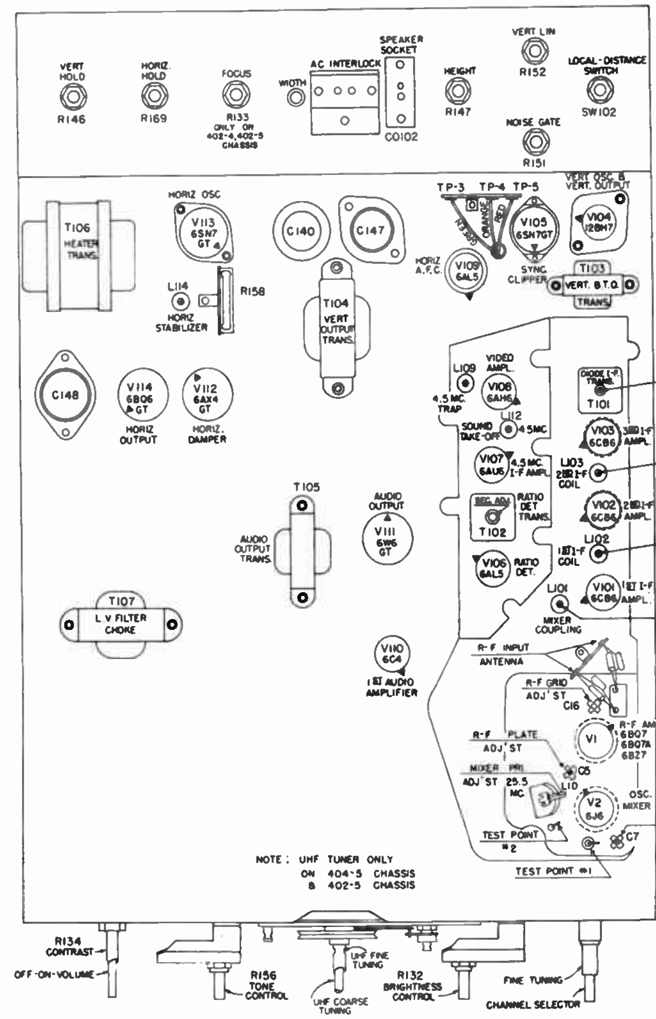
l. Reset signal generator to 24.4 mc. Adjust top of L101 for maximum meter deflection. Limit meter reading to approximately -2 volts DC maximum by adjusting output attenuator on generator.

m. Reset signal generator to 27.9 mc. and adjust the bottom of L101 for minimum DC meter deflection. Signal generator output must be sufficient to produce a definite null. (If necessary IF bias may be reduced for this step).

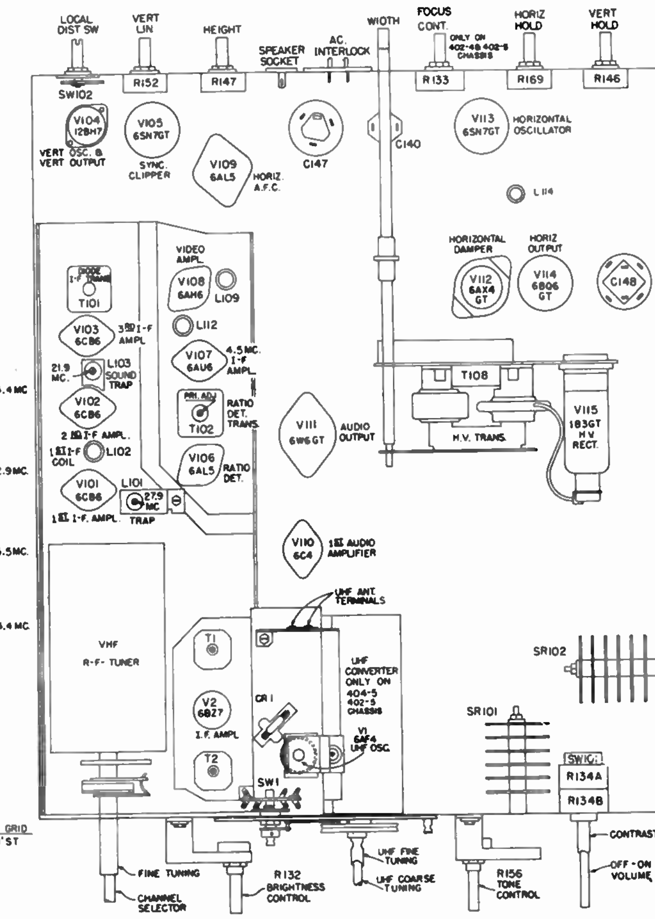
n. Repeat steps "l" and "m". If bias has been reduced below -3.5 volts, reset to -3.5 volts for step "l".

o. Transfer high side of signal generator lead to TP-1. Set signal generator to 25.5 mc. Set IF bias to -3.5 volts. Connect the Swamping Network (a 1000 ohm resistor in series with a 1000 mmf. capacitor) across L101 making connections to the two lugs on the coil form closest to the chassis. Adjust L10 for a maximum meter reading. I-F bias may be reduced if necessary to obtain a usable deflection. Remove Swamping Network.

p. Disconnect alignment equipment.



VHF CHASSIS (404-5 & 402-5) TOP VIEW
(Tube and Alignment Locations)



VHF CHASSIS (404-5 & 402-5) BOTTOM VIEW
(Tube Socket and Alignment Locations)

SOUND ALIGNMENT

1. Connect crystal controlled 4.5 mc. 400 cycle amplitude modulated signal, modulated 30% or greater, between grid of video amplifier and chassis.

2. Connect high side of scope through detector probe to the picture tube cathode (pin 11). Connect low side of scope to chassis. Adjust 4.5 mc. trap, L109, for minimum 400 cycle deflection on scope.

3. Connect electronic voltmeter to pin 2 of ratio detector tube, V104, and adjust 4.5 mc. sound take-off (L112) and bottom of ratio transformer (T102) for peak reading on voltmeter. Adjust input to make this peak reading 4 volts.

4. Adjust input to obtain 12 volts output. Transfer electronic voltmeter to junction of R129 and C128 (refer to Schematic Wiring Diagram). Adjust top of T102 for zero balance on electronic voltmeter.

5. Recheck steps 2, 3 and 4 above.

6. Remove input signal, scope and electronic voltmeter.

UHF ALIGNMENT (continued)

ALIGNMENT NOTES:

CAUTION: This UHF converter unit is used with a VHF receiver that has one side of the chassis connected to the power line. DO NOT CONNECT TEST EQUIPMENT TO ANY PART OF THE RECEIVER OR GROUND THE CHASSIS UNLESS AN ISOLATION TRANSFORMER IS USED BETWEEN THE POWER LINE AND RECEIVER.

1. Remove the UHF Converter from the VHF receiver chassis.
2. In order that the converter will operate with the tuning shaft in maximum CCW* position, it will be necessary to disengage the function switch shaft from the linkage which operates it and manually set the switch to the UHF position. To accomplish this, loosen the two set-screws which secure the arm and hub assembly to the shaft. Turn the switch clockwise to the UHF position and leave it in this position while aligning.
3. Connect the output leads of the UHF converter to the R. F. input terminals of the VHF Tuner.
4. Reconnect the B+ and filament leads of the tuner to the same points on the VHF receiver from which they were disconnected. Connect UHF Converter chassis to B- (VHF receiver chassis).

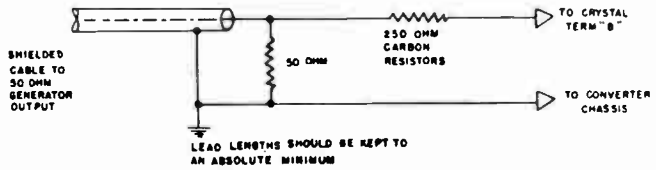
* CW - Clockwise
CCW - Counter-clockwise

5. Keep all leads as short as possible. One suggested way of doing this is to mount the UHF converter at right angles to the TV chassis with one mounting screw. Most of the leads on the UHF converter will then be of sufficient length that no additional length will need to be added.
6. Set VHF Tuner to Channel 6.
7. Alignment should be followed in the order shown.

I. F. ALIGNMENT

1. Connect an electronic voltmeter or an oscilloscope across the second detector load resistor.
2. Turn on the power.
3. Apply an 82 mc. signal (amplitude modulated if a scope is used) to the crystal terminal (B) at the junction of C13 and L9 through the resistor network shown in Sketch A.

Resistor Matching Network for I. F. Alignment



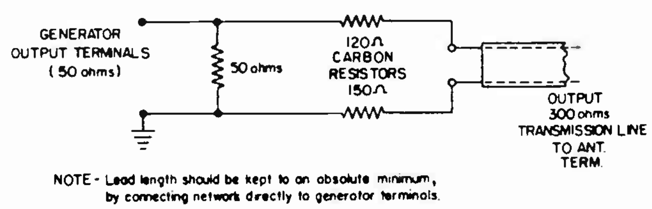
SKETCH A

4. Adjust plate coil (T1) and grid coil (T2) for maximum indication on the electronic voltmeter or scope.
5. Disconnect the resistor network from the crystal terminal.

OSCILLATOR ALIGNMENT:

1. With the electronic voltmeter or scope connected across the second detector load resistor, apply a 460 mc. signal (amplitude modulated if a scope is used) to the UHF antenna terminals through the resistor network shown in Sketch B.

Resistor Matching Network for Osc. & R. F. Alignment



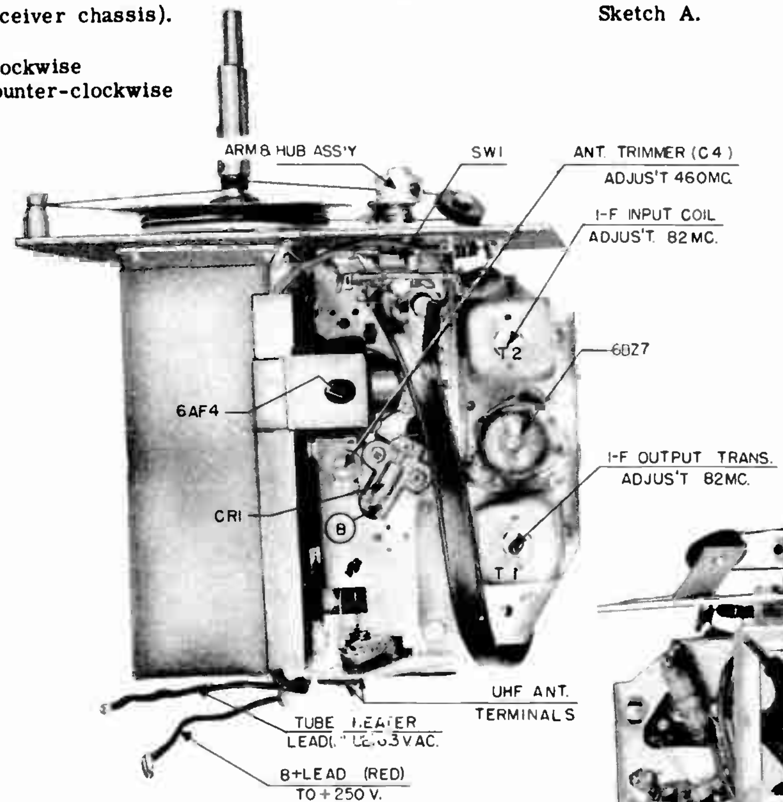
SKETCH B

2. With the tuner shaft at maximum CCW* position, adjust the oscillator trimmer C6 for peak reading on the electronic voltmeter or maximum indication on the scope (oscillator frequency is set to 84 mc. below the carrier frequency).
3. Set the signal generator to 904 mc.
4. Rotate the tuner shaft to the maximum CW position and adjust the oscillator end inductor L4 up or down for maximum reading on the voltmeter.
5. Open the ground connection on L10 and connect an 0-10 ma. D.C. meter between the open end of the crystal return choke L10 and ground.
6. Adjust the oscillator coupling coil L11 for maximum crystal current when the tuner shaft is rotated to the maximum CW position. When operating at normal line voltage (117 volts, 60 cycles), the maximum current should not exceed 5 ma. at any setting of the tuner shaft. When operating at low line voltage (105 volts, 60 cycles), the minimum crystal current must not be less than 0.3 ma. at any setting of the tuner shaft.
7. Repeat steps 1 through 4 until maximum reading is obtained.

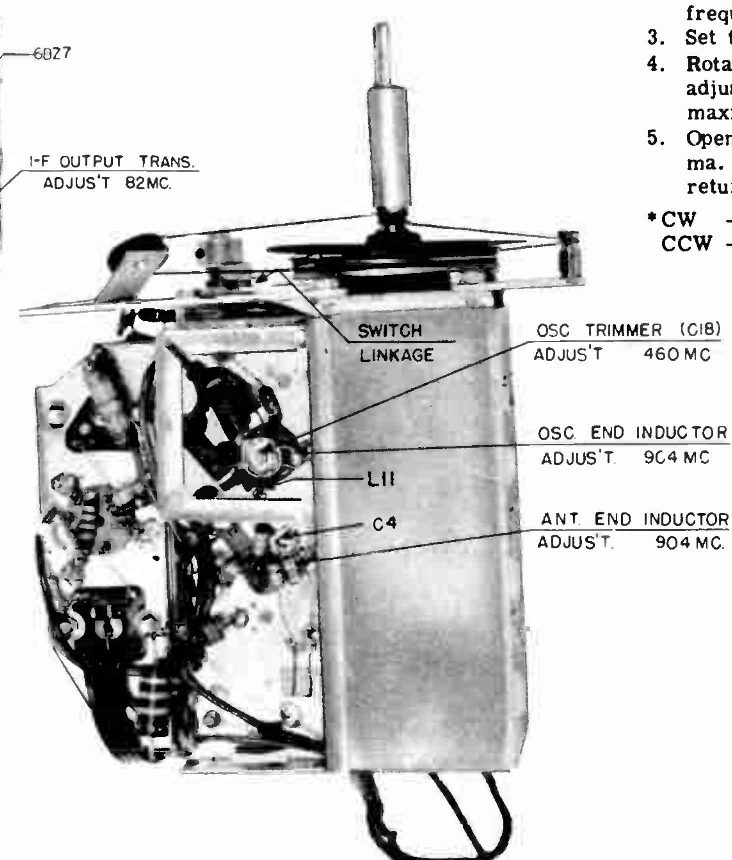
*CW - Clockwise
CCW - Counter-clockwise

R. F. CIRCUIT ALIGNMENT

1. With the electronic voltmeter or scope connected across the second detector load resistor of the VHF receiver, apply a 460 mc. signal (Amplitude modulated if a scope is used) to the UHF antenna terminals through the resistor network shown in Sketch B.
2. With the tuner shaft at the maximum CCW position, adjust the antenna trimmer C4 for maximum meter reading or for maximum scope indication.
3. Reset signal generator to 904 mc.
4. Rotate the tuner shaft to maximum CW position. Adjust the antenna end inductor L3 by forming larger or smaller loop until maximum reading on the meter (or scope) is obtained.
5. Repeat steps 1 through 4 until maximum reading is obtained.
6. Turn the power switch to the "OFF" position.
7. Disconnect the generator, the electronic voltmeter or scope, and the resistor network. Disconnect the 0-10 ma. meter, and solder the open lead of L10 to the chassis.
8. Re-engage the toggle coupling in the pin on the arm and hub assembly and tighten the set-screws that secure the collar to the switch shaft.
9. The Function Switch should be checked for proper operation under conditions of customer use. At full CCW rotation of the tuner shaft, all VHF position contacts must be fully and firmly made and all UHF position contacts must be fully broken. All UHF position contacts must be fully and firmly made and all VHF position contacts must be fully broken, when the tuner shaft is 7 1/2° or more from full CCW, as tuner shaft is rotated in a clockwise direction.
10. Replace the UHF Converter on the VHF receiver chassis.

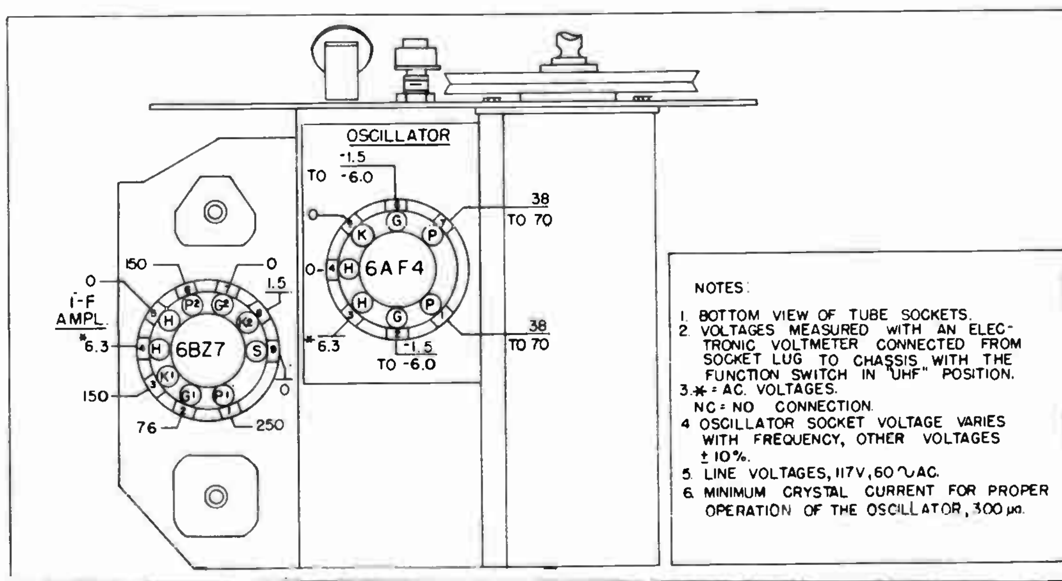


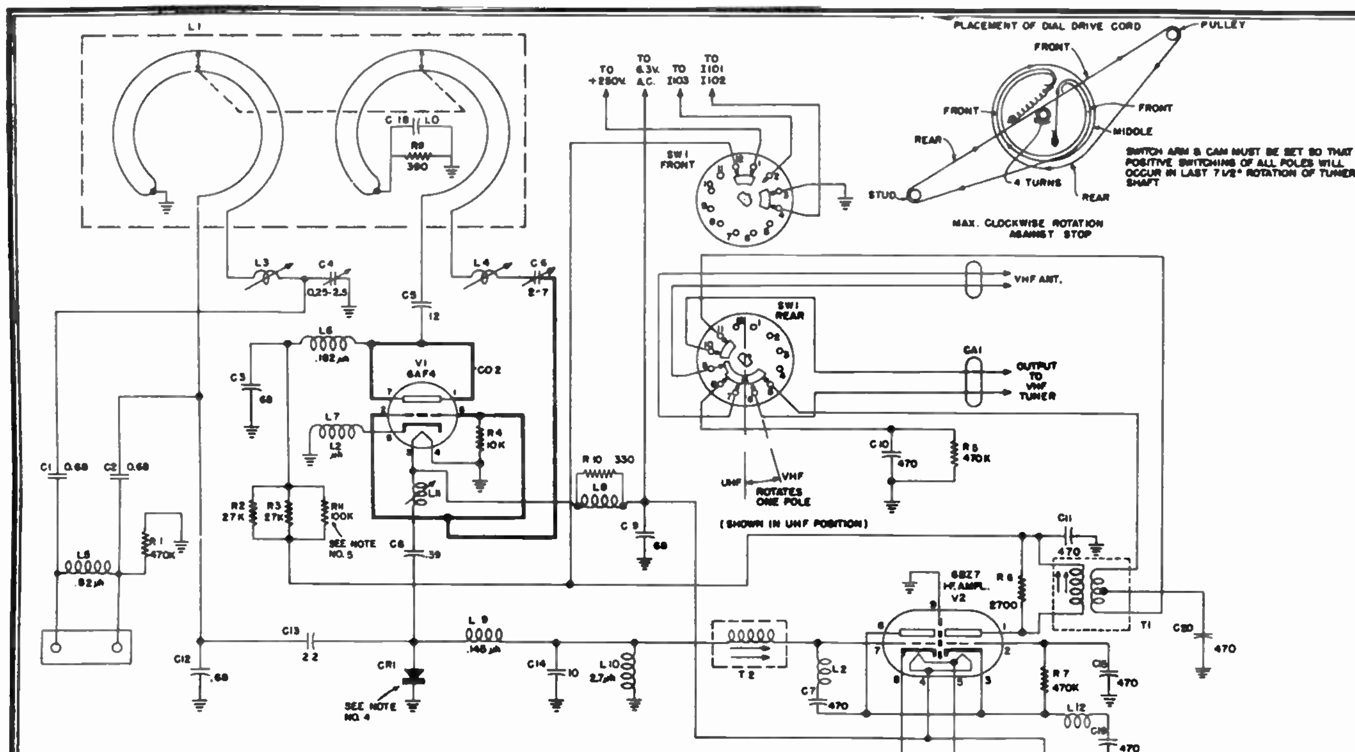
TOP VIEW - UHF Converter



BOTTOM VIEW - UHF Converter

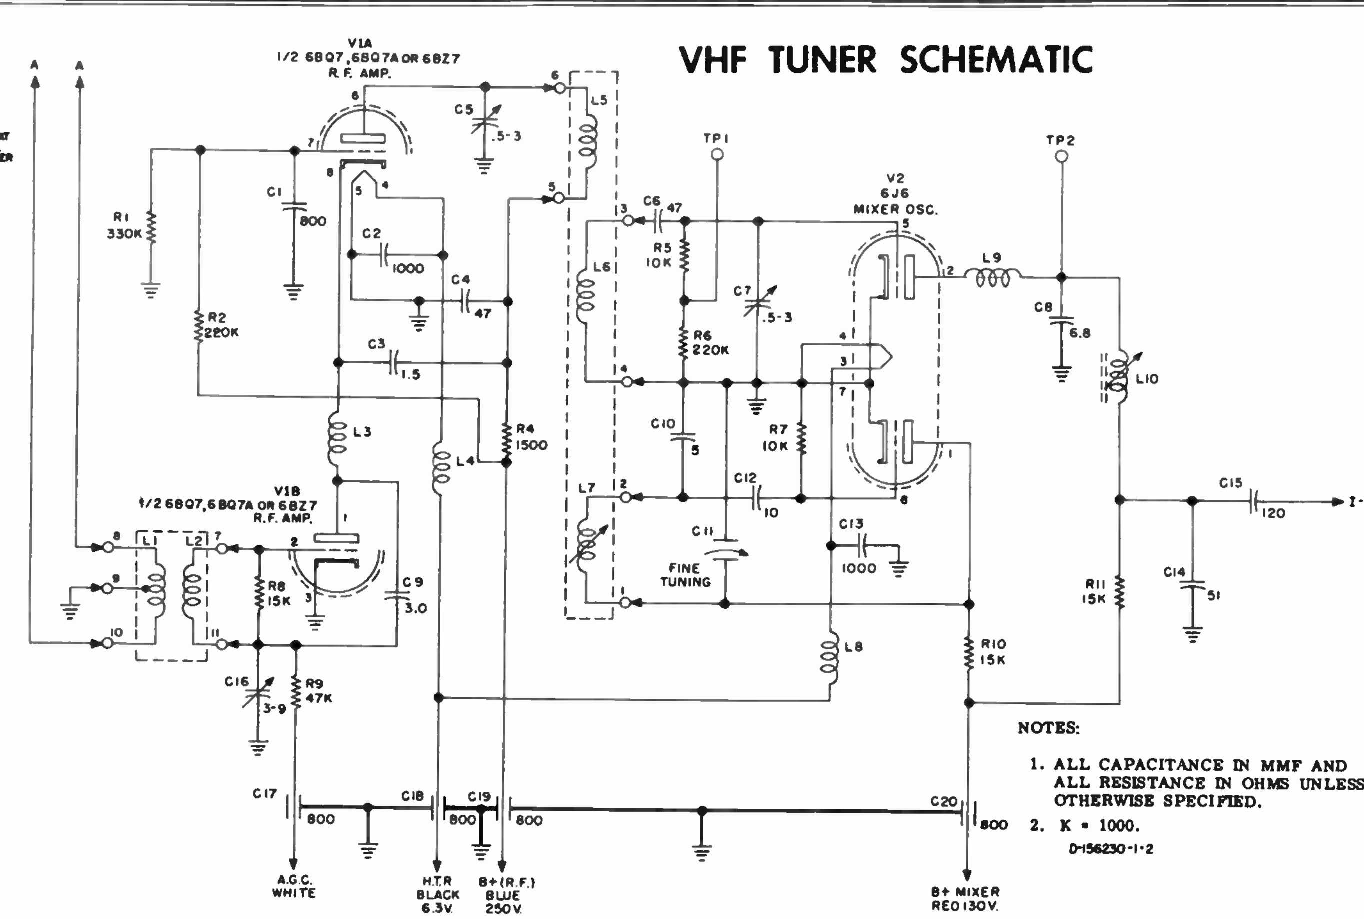
SOCKET VOLTAGE CHART





NOTES:
1. K = 1000
2. All Capacitance Values In MMF. And All Resistance In Ohms Unless Otherwise Noted.
3. All Sections Of Switch SW1 Are Viewed From The Shaft End.
4. When Possible, Replace The Crystal Mixer With One Of The Same Type. When The Same Type Is Not Available One Of The Other Types Can Ordinarily Be Used As A Substitute. However, Because Of Individual Crystal Characteristics The Substitution Of The 1N72 (Part No. 151871) For The 1N82 (Part No. 155459) Or K3D May Be Less Satisfactory.
5. In Some Early Production UHF Tuners, R11 Was Not Used. In Some Later UHF Tuners, R11 Is 87,000 Ohm, 10%, 1/2 Watt.

UHF CONVERTER SCHEMATIC



NOTES:
1. ALL CAPACITANCE IN MMF AND ALL RESISTANCE IN OHMS UNLESS OTHERWISE SPECIFIED.
2. K = 1000.

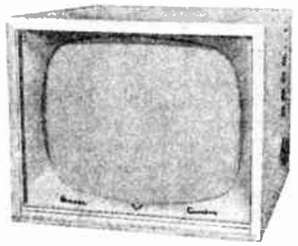
53 thru 64	See L5, L6, & L7	R. F. & Oscillator Coil Assembly
	156189	VHF Tuner Complete

* One Antenna Coil Assembly and one R. F. & Oscillator Coil Assembly are necessary for each channel to be received. The dash number following the basic part number indicates the channel for which the assembly is designed. Example: 156907-2, Antenna Coil Assembly for Channel 2; 156908-13, R. F. & Oscillator Coil Assembly for Channel 13.

NOTE: Reference numbers (1, 2, 3, etc.) that follow Symbol No. L10 refer to corresponding numbers on Exploded View of the VHF Tuner



MODEL G-21TOBH
(Blond)

SPECIFICATIONS

POWER SUPPLY: 117 volts, 60 cycle, a.c.
POWER CONSUMPTION 130 watts.
AUDIO POWER OUTPUT: 1.0 watts maximum.
ANTENNA INPUT IMPEDANCE: 300 ohms balanced
FREQUENCY RANGE: 54 to 88 mc. & 174 to 216 mc. (Channels 2 thru 13)

INTERMEDIATE FREQUENCY:
Video Carrier—26.4 mc.
Sound Carrier—21.9 mc.
Intercarrier Sound—4.5 mc.

DEFLECTION: Electromagnetic.
FOCUS: Electrostatic.
ION TRAP: Single Permanent Magnet.
HORIZONTAL SCANNING FREQ: 15,750 c.p.s.
VERTICAL SCANNING FREQ: 60 c.p.s.
FRAME FREQUENCY: 30 c.p.s.
SCANNING: Interlaced, 525 lines.
SPEAKER: 4" Permanent Magnet.
VOICE COIL IMPEDANCE: 3.2 ohms @ 400 cycles.

ION TRAP MAGNET ADJUSTMENT

The proper adjustment of the Ion Trap Magnet cannot be overemphasized, for it is not only important to obtain maximum brightness and a good quality picture, but also to the life expectancy of the picture tube. (See Service Instruction No. 4-03).

Place the Ion Trap on the neck of the picture tube close to the tube base and over the internal pole pieces that are mounted on the gun structure. If there is a code dot or arrow on the magnet, this side should be toward the tube face. There are two possible positions on the tube neck where the Ion Trap will produce maximum brightness. ALWAYS SET THE ION TRAP IN THE POSITION CLOSEST TO THE BASE OF THE TUBE.

If the picture tube has been installed or if the receiver has been moved, it is imperative that the Brightness control be kept at a low setting until after the initial adjustment of the Ion Trap and also that the adjustment be made immediately after the receiver is turned on. It is important that the intensity of the beam be low when the receiver starts operating, if the magnet has not yet been adjusted. By keeping the intensity low, the beam current is low enough that the electron beam is not likely to damage the anode top disc before the magnet is adjusted.

TO ADJUST THE ION TRAP MAGNET- Set the Brightness control completely counter-clockwise, then advance slightly clockwise (less than 1/4 turn). Slide the trap forward or backward on the neck of the tube and at the same time rotate trap clockwise or counter-clockwise until a raster appears, then adjust for maximum brightness. If no raster is obtained with this setting of the Brightness control, advance the control slightly clockwise and repeat adjustment of the trap until a raster appears. The final setting of the trap should be made with the Brightness control set to the maximum position with which good line focus can be obtained. If neck shadow is encountered, or if the picture is off center, correction should be made with the centering magnet on the back cover of the deflection yoke. Never use the Ion Trap to correct neck shadow. Always set the trap to the position where maximum brightness is obtained. After any adjustment of the deflection yoke or centering magnet the Ion Trap should always be checked and readjusted for maximum brightness.

DISASSEMBLY

IMPORTANT: When it is necessary to remove the cabinet from the cabinet base, or to remove the picture tube or chassis from the cabinet base, care should be exercised to be sure that the correct screws are being loosened. It is advisable, when loosening the screws on the underneath side of the base, to keep the base in its normal position but extended slightly over the edge of the work-bench.

Removing The Cabinet From The Cabinet Base

1. Remove the control knobs, the cabinet back, the antenna terminal plate, and the wires from the speaker (or the speaker from the cabinet).
2. Remove the two wood screws on the inside rear corners that hold the cabinet base to the wood supports on the bottom of each side and the two screws that hold the chassis to the wood strip on the inside of the cabinet above the chassis.
3. Remove the six hex head screws and the lockwashers on the underside of the base (along the sides of the cabinet) and also one wood screw that is through the base at the center front on the bottom.
4. Lift the cabinet up and off the base.
5. To replace the cabinet, reverse the removal procedure.

Removing The Chassis From The Cabinet Base

Should it be necessary to trouble shoot or to replace parts in the IF strip, the following procedures may be useful in servicing the chassis.

1. Remove the cabinet back and cabinet as outlined above.
2. Remove the CRT socket and Ion Trap.
3. Disconnect the CRT high voltage lead.
4. Remove the two hex head screws holding the interlock receptacle tothe base.
5. Remove the two nuts below the vertical controls (On the screws holding the chassis to the CRT rear support).
6. Remove the bolts that hold the chassis to the base and carefully slide the chassis from around the CRT neck. DO NOT ALLOW PRESSURE TO BE EXERTED ON THE NECK OF THE PICTURE TUBE.

Should it be necessary to use the CRT during service, proceed as follows:

1. Remove the yoke wing nut and turn the yoke around.
2. Turn the chassis around and carefully slide the yoke and chassis over the neck of the tube.
3. Use a short piece of tape and tape the yoke to the bell of the CRT.
4. Use a short jumper between the high voltage lead and the CRT.
5. Replace Ion Trap and CRT socket.

Removing The Picture Tube

HANDLING PRECAUTIONS - Do not remove or handle the picture tube in any manner unless heavy gloves and protective goggles are worn. KEEP TUBE AWAY FROM THE BODY WHILE HANDLING.

1. Remove cabinet from the chassis and cabinet base as outlined above.
2. Disconnect the tube socket and remove the ion trap magnet from the neck of the tube. Loosen the wing screw on the deflection yoke bracket.
3. Disconnect the second anode lead from the bell of the tube.
4. Remove the nuts on both tie rods that extend from the tube support bracket to the tube rests. Unhook the tie rods.
5. Remove the two nuts that are on the screws that hold the top of the tube support bracket to the chassis.
6. Remove both hex head machine screws that hold the tube strap to the base on either side of the two tube rests, and lift off the strap.
7. Raise tube slightly at the front so that it will clear the stops on the tube rests, and pull the tube forward to remove.

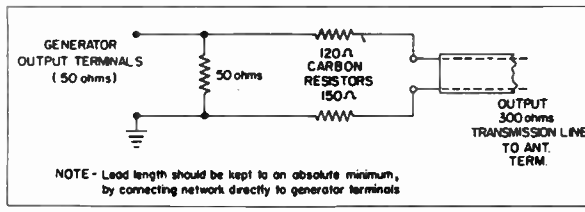
DO NOT ALLOW PRESSURE TO BE EXERTED ON THE NECK OF THE TUBE.

Replacing The Picture Tube

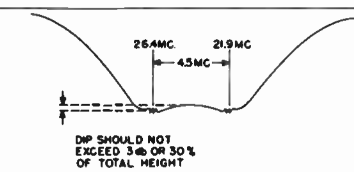
1. Guide neck of tube through opening in the tube support bracket and deflection yoke, and place bottom of face plate against stops on tube rests. Be sure the pads are in position between the tube and tube rests.
2. Place pad and strap over tube and insert the two hex head screws through the base and screw into the strap brackets but do not tighten.
3. Replace and tighten the two nuts on the screws that hold the tube support to the chassis.
4. Replace the tie rods, apply the nuts and tighten. Bell of tube should rest against insulating ring on the tube support bracket.
5. Tighten the two screws that hold the strap to the base.
6. Connect second anode to the tube.
7. Push deflection yoke forward against flare of tube, and tighten wing screw.
8. Replace ion trap on neck of tube and connect tube socket.
9. Make necessary adjustments on the ion trap and deflection yoke. See "ADJUSTMENTS" on page 5.
10. Replace the cabinet over the chassis and base, then follow instructions for "Removing The Chassis From The Cabinet", steps 1 to 3 in reverse order.

R.F. AND MIXER ALIGNMENT

Step No.	Station Selector	Oscilloscope	Bias	Signal Generator To	Adjust
1.	Chan. #10	High side through a 10,000 ohm resistor to TP1 on Tuner. Ground lead to Tuner Case.	-1.5 volts to white lead on tuner.	Signal Generator set to 195.5 MC., 400 cycle 30% AM modulated. Through Dummy Antenna to the Antenna lead-in.	C-3 for maximum 400 cycle response on scope. Remove signal Generator.
2.	"	"	"	Sweep Generator to Antenna lead-in through dummy antenna. Set Generator to sweep Channel 10 freq. Loosely couple Marker Generator to sweep output cable. Set marker to either 21.9 or 26.4 mc.	Adjust C5 & C9, to produce a response curve similar to R.F. and Mixer Response Curve.



DUMMY ANTENNA



R. F. & MIXER RESPONSE CURVE

Without disturbing the R.F. grid, R.F. plate, and mixer-grid trimmer, check the response on the other VHF TV channels by setting the station selector to the desired channel and changing the frequency of the sweep generator to correspond to the channel being checked. The response curve should be essentially the same on all channels and the markers should fall in similar positions on the response curve. A slight amount of tilt can be tolerated. The amount of tilt indicated by the relative amplitudes of the response curves where the picture and sound I.F. Markers rest should not exceed 30% of the over-all response curve amplitude.

R125	39374-15	Resistor, 150 ohm, 10%, 1/2 w.
R126	39374-49	Resistor, 100,000 ohm, 10%, 1/2 w.
R127	39374-29	Resistor, 2200 ohm, 10%, 1/2 w.
R128	39374-18	Resistor, 270 ohm, 10%, 1/2 w.
R129	39374-43	Resistor, 33,000 ohm, 10%, 1/2 w.
R130	39375-73	Resistor, 10,000 ohm, 5%, 1/2 w.
R131	39375-73	Resistor, 10,000 ohm, 5%, 1/2 w.
R132	155352	Control, Brightness (5 megohm)
R133	154094	Control, Focus (1.5 megohm, used on 402-4 and 402-5 chassis only)
R134A	154085	Control, Volume (1 megohm) } Assembly
R134B		Control, Contrast (2500 ohm) } Assembly
R135	39374-53	Resistor, 220,000 ohm, 10%, 1/2 w.
R136	39374-69	Resistor, 2.2 megohm, 10%, 1/2 w.
R137	39374-61	Resistor, 1 megohm, 10%, 1/2 w.
R138	39374-146	Resistor, 560,000 ohm, 10%, 1 w.
R139	39374-41	Resistor, 22,000 ohm, 10%, 1/2 w.
R140	39374-31	Resistor, 3300 ohm, 10%, 1/2 w.
R141	39374-35	Resistor, 6800 ohm, 10%, 1/2 w.
R142	39374-29	Resistor, 2200 ohm, 10%, 1/2 w.
R143	39374-41	Resistor, 22,000 ohm, 10%, 1/2 w.
R144	39374-37	Resistor, 10,000 ohm, 10%, 1/2 w.
R145	39374-53	Resistor, 220,000 ohm, 10%, 1/2 w.
R146	155610	Control, Vertical Hold
R147	154086	Control, Height
R148	39374-125	Resistor, 10,000 ohm, 10%, 1 w.
R149	39374-60	Resistor, 820,000 ohm, 10%, 1/2 w.
R150	39374-33	Resistor, 4700 ohm, 10%, 1/2 w.
R151	155576	Control, Noise Gate (90,000 ohm)
R152	155519	Control, Vertical Linearity
R153	39374-215	Resistor, 15,000 ohm, 10%, 2 w.
R154	39374-14	Resistor, 120 ohm, 10%, 1/2 w.
R155	39374-27	Resistor, 1500 ohm, 10%, 1/2 w.
R156	155389	Control, Tone (250,000 ohm)
R157	39374-43	Resistor, 33,000 ohm, 10%, 1/2 w.
R158	154089	Resistor, 7.5 ohm, 10%, 5 w. Wire Wound
R159	39374-49	Resistor, 100,000 ohm, 10%, 1/2 w.
R160	39374-49	Resistor, 100,000 ohm, 10%, 1/2 w.
R161	39374-41	Resistor, 22,000 ohm, 10%, 1/2 w.
R162	39374-139	Resistor, 150,000 ohm, 10%, 1 w.
R163	39374-77	Resistor, 4.7 megohm, 10%, 1/2 w.
R164	39374-77	Resistor, 4.7 megohm, 10%, 1/2 w.
R165	39374-26	Resistor, 1200 ohm, 10%, 1/2 w.
R166	39374-34	Resistor, 5600 ohm, 10%, 1/2 w.
R167	39374-33	Resistor, 4700 ohm, 10%, 1/2 w.
R168	39374-45	Resistor, 47,000 ohm, 10%, 1/2 w.
R169	155511	Control, Horizontal Hold
R170	39374-36	Resistor, 8200 ohm, 10%, 1/2 w.
R171	39374-50	Resistor, 120 ohm, 10%, 1/2 w.
R172	39374-57	Resistor, 470,000 ohm, 10%, 1/2 w.
R173	156911-1	Resistor, 10,000 ohm, 10%, 2 w.
R174	39374-6	Resistor, 27 ohm, 10%, 1/2 w. (Used on 404-4 & 404-5 Chassis only)
R175	39303-12	Resistor, 2.2 ohm, (Part of T108)
R176	39374-139	Resistor, 150,000 ohm, 10%, 1 w.
R177	39374-25	Resistor, 1000 ohm, 10%, 1/2 w.

R105	39374-9	Resistor, 47 ohm, 10%, 1/2 w.
R106	39374-33	Resistor, 4700 ohm, 10%, 1/2 w.
R107	39375-73	Resistor, 10,000 ohm, 5%, 1/2 w.
R108	39374-25	Resistor, 1000 ohm, 10%, 1/2 w.
R109	39374-25	Resistor, 1000 ohm, 10%, 1/2 w.
R110	39374-11	Resistor, 68 ohm, 10%, 1/2 w.
R111	39374-25	Resistor, 1000 ohm, 10%, 1/2 w.
R112	39375-75	Resistor, 12,000 ohm, 5%, 1/2 w.
R113	39374-15	Resistor, 150 ohm, 10%, 1/2 w.
R114	39374-25	Resistor, 1000 ohm, 10%, 1/2 w.
R115	39374-65	Resistor, 1.5 megohm, 10%, 1/2 w.
R116	39375-65	Resistor, 4700 ohm, 5% 1/2 w.
R117	39374-57	Resistor, 470,000 ohm, 10%, 1/2 w.
R118	39374-61	Resistor, 1 megohm, 10%, 1/2 w.
R119	Part of L108	Resistor, 8200 ohm, 10%, 1/2 w.

REPLACEM

(

Chassis 402-4,

Symbol No.	Part No.	Description
T102	154108	Transformer, Ratio Detector
T103	155255-1	Transformer, Vertical Oscillator
T104	155572	Transformer, Vertical Output
T105	154109-2	Transformer, Audio Output
T106	155390	Transformer, Filament
T107	155529-1	Choke, Filter
T108	157045-1	Transformer, Horizontal Deflection
CO102	138352	Socket, Speaker
CO103	154114	Socket, Terminal Strip
SW101	Part of R134 A & B	Switch, ON-OFF Power

I.F. ALIGNMENT

All lead connections from the signal marker generator and sweep generator must be shielded. Keep exposed ends and ground leads as short as possible (about one inch). Always locate the ground lead connections as close as possible to their respective "hot" leads in the television receiver chassis. The sweep generator output, signal generator output, and contrast control must be kept low enough to prevent overloading the television receiver circuits.

CAUTION: One side of the chassis is connected to the power line. Therefore, test equipment should not be connected to the receiver unless an isolation transformer is used between the power line and the receiver. DO NOT GROUND THE RECEIVER CHASSIS UNLESS AN ISOLATION TRANSFORMER IS USED.

The front side of the chassis as referred to below means the side opposite the tubes.
The rear side of the chassis means the side on which the tubes are mounted.

VIDEO I. F. ALIGNMENT (with VTVM)

In the I.F. Alignment, limit input of signal generator so that reading on VTVM does not exceed -2 volts.

Step No.	Connect Signal Generator Through a .01 Capacitor	Signal Gen. Freq. MC.	Connect VTVM	Miscellaneous Connections and Instructions	Adjust
1.	Test Point No. 2 on Tuner (closest to L9 slug adjustment).	24.4 mc.	Junction of R118 and C113 and chassis.	Connect 3 volt bias battery negative lead to white lead from tuner, positive lead to chassis	T101 for maximum indication on meter, limit input to make peak less than -2 volts D.C. on VTVM.
2.	"	22.9 mc.	"	"	L103 (rear slug) for maximum. Use first peak from tinnerman clip end of coil.
3.	"	21.9 mc.	"	"	L103 (front slug) for minimum. Input level should be high enough to produce at least .5 volts at null on VTVM. Use first null obtained from end of coil form opposite tinnerman clip.
4.	Repeat steps 2 and 3.				
5.	"	25.5 mc.	"	"	L102 for maximum.
6.	"	25.1 mc.	"	"	L101 (front slug) for maximum. Use first peak from tinnerman clip end of coil.
7.	"	27.9 mc.	"	"	See Note 1. L101 (rear slug) for minimum deflection on VTVM. Use first null obtained from end of coil form opposite tinnerman clip.
8.	Repeat step 6 (and 7, if adjacent channel trap is used).				
9.	Test Point No. 1 on Tuner (closest to C21 trimmer screw).	25.1 mc.	"	Connect a 100 ohm resistor in series with a 1000 mmf. cap. across L101.	L9 (brass screw) on the Tuner for maximum.

Note 1. This adjustment can be made only on receivers where the Adjacent Channel Trap has been added. For installation of this trap in areas where adjacent channel interference is prevalent

TO CHECK I. F. ALIGNMENT (with scope)

Excessive sweep input will overload the circuit and cause distortion in the wave form. Check for possible overload by temporarily increasing and decreasing the signal input level and noting any change in the wave form.

Excessive signal from the marker generator will also distort the wave form. Be sure to keep the marker at the minimum usable amplitude.

Sweep Gen. Connected to	Scope Connected to	Bias	Sweep Gen. Set to	Remarks
Ungrounded shield of V2 and chassis.	High side of contrast control R120 and chassis. Contrast control at minimum contrast.	Connect 3 volt bias battery negative lead to white lead from tuner, positive lead to chassis.	Sweep from 20 to 30 megacycles.	Provide markers as shown on curve.  Nominal Overall I.F. Response Curve A slight deviation in response curve is tolerable, but if any great deviation is noted, the I. F. stages will have to be realigned.

SOUND ALIGNMENT

The 4.5 mc. trap (front of L109) must be aligned first, regardless of which procedure is used for the remainder of the alignment (Procedure A or B).

Step No.	Channel Set To	Adjust	Remarks
1.	Any unused channel	Connect a crystal controlled 4.5 mc., 400 cycle amplitude modulated signal (30% or greater) between pin 8 of V104 and chassis. Connect high side of scope through a detector probe to cathode of picture tube, low side to chassis. Adjust L109 (rear slug) for minimum 400 cycle indication on scope.	Remove signal generator and scope from the receiver.

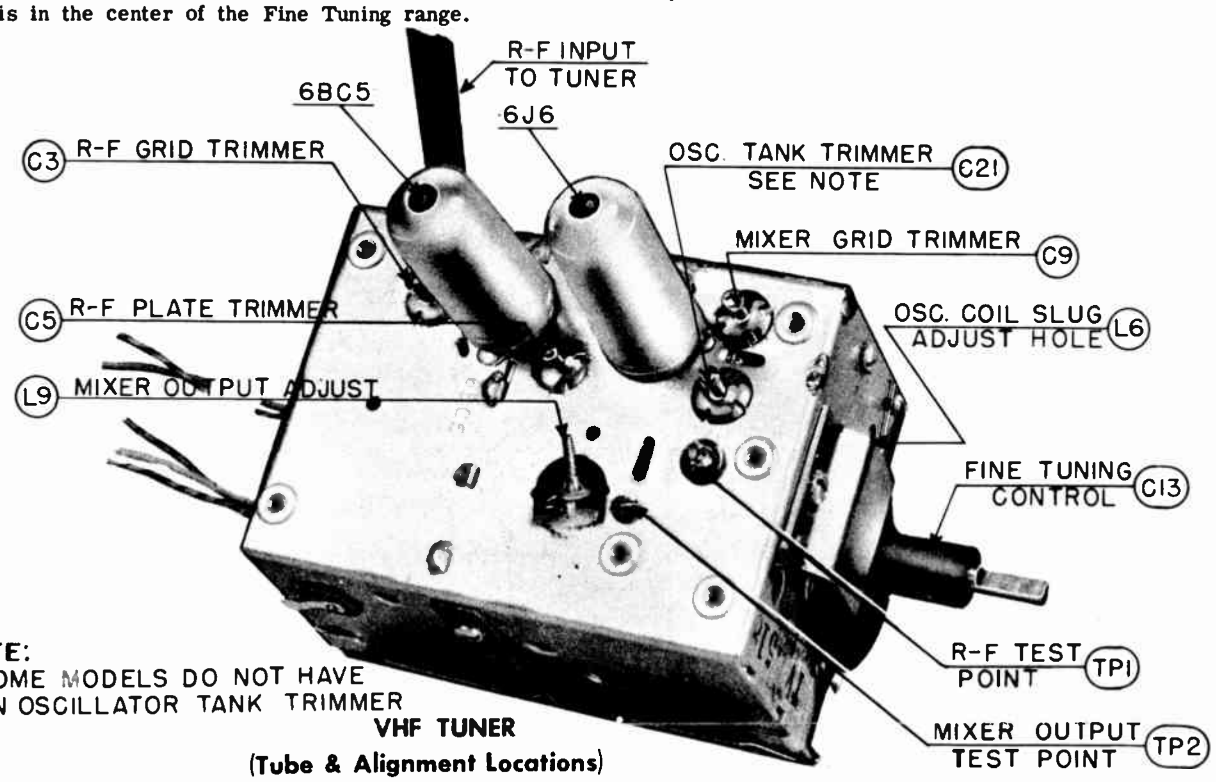
Proceed with the remainder of the Sound Alignment, using either a signal from a TV station as in Procedure A, or alignment equipment as in Procedure B.

PROCEDURE A (with signal from station)

Step No.	Channel Set To	Adjust	Remarks
1.	Strong signal	L106 for maximum sound output.	Set Buzz Control (R132) approximately 90° from clockwise stop.
2.	Weak signal	L111 and L109 (front slug) for maximum sound output.	If the signal in the area is too strong to obtain these peaks, remove the antenna from the receiver.
3.	Weak signal	Buzz Control (R132) for minimum noise (hash).	This signal should be weak enough to allow noise (hash) to come through along with the sound.
4.	Strong signal	L106 again for maximum sound output.	Limit the volume control setting so that this peak can be heard.

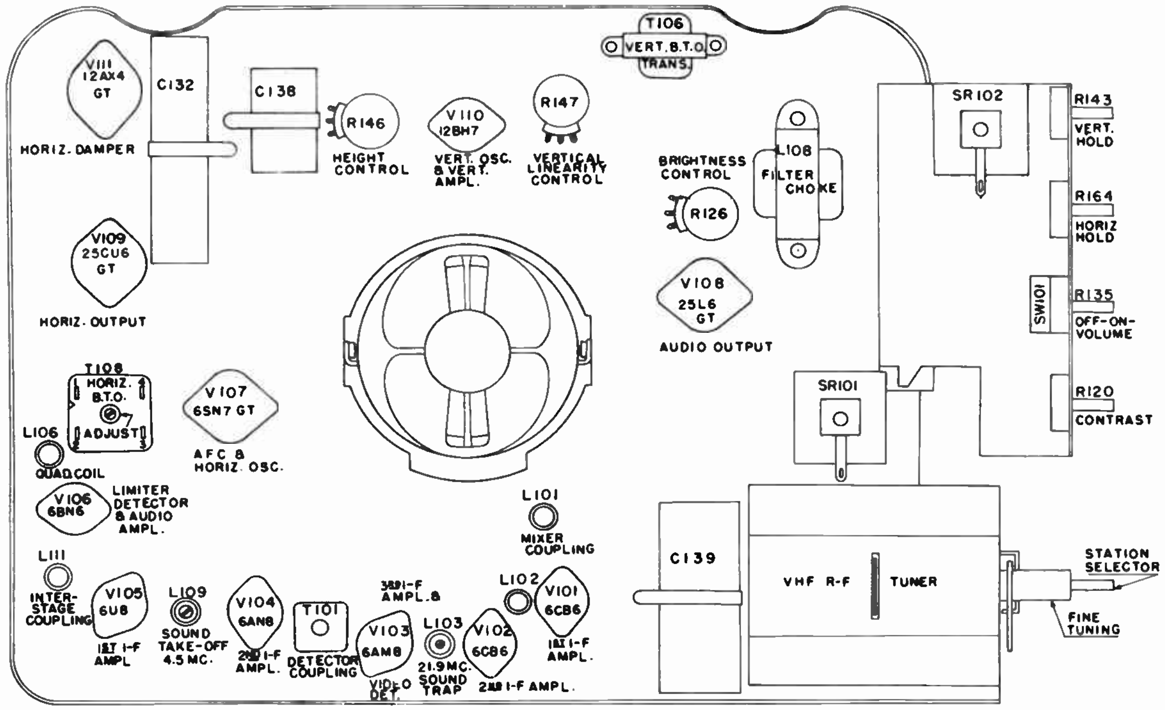
ALTERNATE OSCILLATOR ALIGNMENT

A turret type VHF tuner is used on this receiver, and there is an oscillator adjustment for each channel. When the receiver is installed, the oscillator should be adjusted for each channel on which a station is operating in the area. Set the Channel Switch to the channel that is to be adjusted. Turn the Fine Tuning control to the center of its range. The oscillator trimmer screw is directly below the tuner shaft, and is accessible through a hole in the front of the chassis after the two VHF tuning knobs have been removed. Use a non-metallic screw driver and adjust the oscillator trimmer screw until the proper tuning point is in the center of the Fine Tuning range.



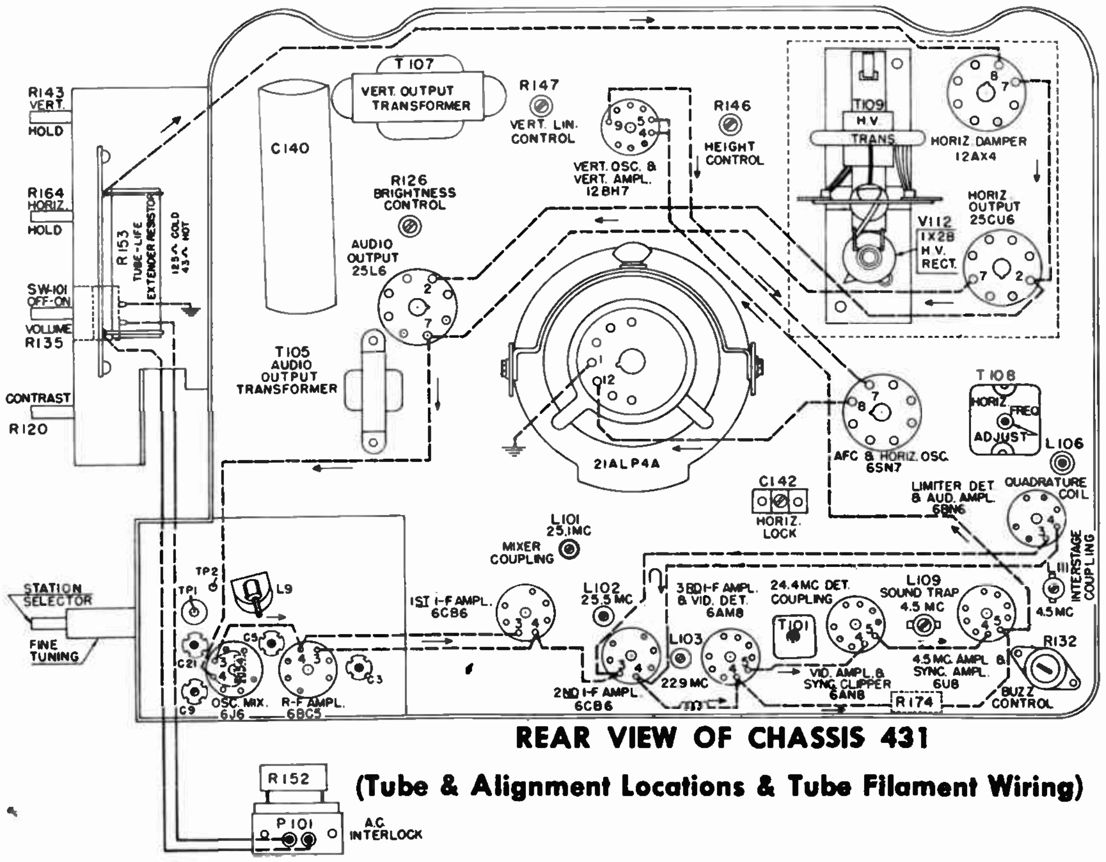
NOTE:
SOME MODELS DO NOT HAVE
AN OSCILLATOR TANK TRIMMER

VHF TUNER
(Tube & Alignment Locations)



FRONT VIEW OF CHASSIS 431

(Tube & Alignment Locations)



REAR VIEW OF CHASSIS 431

(Tube & Alignment Locations & Tube Filament Wiring)

VHF OSCILLATOR ALIGNMENT

OSCILLATOR ALIGNMENT (using scope)

Step No.	Oscilloscope	Channel Selector	Sweep Generator	Marker Generator	Adjust
1.	High side of scope to high side of R120 contrast control. Low side to chassis. See Note.	Chan. #2	To sweep Channel 2 frequencies. Connect Gen. output in series with dummy antenna to antenna lead-in. (See sketch of dummy antenna, page 6.)	59.75 Sound I. F. Carrier.	Channel 2 oscillator slug so that marker falls into bottom of valley on curve (the point corresponding to the 21.9 mc. marker as shown on Nominal Overall I. F. Response Curve sketch.) Be sure that the Fine Tuning Control is set to the center of its range.
2.	Repeat the above procedure for each of the remaining channels, by resetting the sweep generator and the marker generator to the correct frequencies for each channel that is to be adjusted.				

Note: Apply a -3.0 volts negative bias to Junction of C111 and R117 or to white lead from VHF R. F. Tuner. Use whichever is the most convenient point.

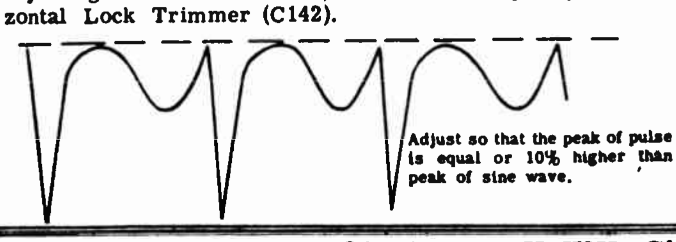
PROCEDURE B (with alignment equipment)

Step No.	Connect Signal Gen.	Signal Gen. Freq. MC.	Connect Scope	Miscellaneous Instructions	Adjust
1.	Pin 8 of V104.	4.5 mc. FM modulated 400 c.p.s., 25 kc. deviation.	Across secondary of output trans. T105.	Set Buzz Control (R132) to approximately 90° from clockwise. stop. Set the Volume Control (R135) at a low level.	L106 for maximum 400 cycle indication on scope.
2.	"	"	"	"	L111 for maximum response keeping input signal at a low level (below limiting).
3.	"	"	"	"	L109 (front slug) for maximum response keeping input signal at a low level.
4.	"	4.5 MC. AM modulated 400 c.p.s.	"	Use a high input level on signal generator.	Buzz Control (R132) for null (minimum 400 c.p.s. amplitude on scope).
5.	"	4.5 MC. FM modulated 400 c.p.s., 25KC. deviation.	" "	Set the Volume Control (R135) at a low level.	Re-peak L106 for maximum 400 cycle indication on scope.

HORIZONTAL BLOCKING OSCILLATOR ALIGNMENT

Tune Receiver to TV signal, adjust contrast control for normal picture below limiting in the Video Amplifier, and proceed as follows:

Step No.	Contrast Control Set For	Miscellaneous	Adjust
1.	Normal Picture	----------------------	Horizontal Hold Control (R164) and Horizontal Frequency Adjustment (rear slug of T108) until picture is in sync.
2.	"	Connect scope in series with 10 mmf. to lug 4 of T108.	Adjust Horizontal BTO Trap (front slug of T108) to obtain the waveform shown below. Keep the picture in sync at all times by re-adjusting the Horizontal Hold, Horizontal Frequency and/or Horizontal Lock Trimmer (C142).



3.	"	Horizontal Hold set fully clockwise.	Adjust Horizontal Frequency (rear slug of T108) by turning out until the picture is just out of sync. Then turn the control slowly in until the picture is just ready to fall into sync (indicated by a wide black vertical or diagonal horizontal blanking bar).
4.	"	Horizontal Hold set fully counter-clockwise.	Picture should normally be in sync. Remove the signal by tuning off and then re-tuning to the station. If more than seven bars are present, adjust the Horizontal Lock Trimmer slightly counter-clockwise until three or four bars appear when the receiver is tuned off and then re-tuned to the station (Horizontal Hold Control still set fully counter-clockwise). If less than three bars are present, adjust the Horizontal Lock Trimmer clockwise to obtain the three or four bars as described above. Since the Horizontal Lock Trimmer adjustment affects the horizontal frequency, the adjustments of both the Horizontal Frequency Adjustment and the Horizontal Lock Trimmer must be repeated until the conditions outlined in steps 3 and 4 exist simultaneously at the extreme positions of the Horizontal Hold control. Check pull-in range, which should be normally 60^{o} to 120^{o}.
5.	Weak Picture	----------------------	Set the Horizontal Hold Control so that when the receiver is tuned off and then re-tuned to the station, the picture returns completely in sync.

TABLE OF SOCKET VOLTAGES

The following voltages were measured with an electronic voltmeter while the set was operating on 117 volts, 60 cycle a.c. with no signal input, antenna terminals shorted, Station Selector set to channel 3, and the Brightness and Contrast Controls at minimum setting. Electronic voltmeter connected between socket lug and chassis. * = AC. voltages. Voltages may vary depending upon the setting of other controls.
D. C. current at junction of L108 and C132B, with contrast control in the maximum counter-clockwise position, 190 ma. With contrast set at maximum clockwise position, D. C. current at this point is 200 ma.

			R7	158106-10	Resistor, 4700 ohm, 10%, 1/2 w., (IRC Type BTS)
C14	158106-16	Capacitor, 43 mmf.	R8	39374-53	Resistor, 220,000 ohm, 10%, 1/2 w
C15	158106-3	Capacitor, 120 mmf., 10%, N750, Disc Ceramic	R9	39374-37	Resistor, 10,000 ohm, 10%, 1/2 w.

NOTES

VHF TUNER

1. All capacitance in mmf. and all resistance in ohms unless otherwise specified.
2. K = 1000.
3. TUNER STRIPS. One Antenna Coil Assembly and one R.F. and Oscillator Coil Assembly are necessary for each channel to be received (VHF or UHF). The dash number following the part number indicates the channel for which the assembly is designed.

   Examples for VHF: 158021-2 is the Antenna Coil Assembly for Channel 2.
   158022-13 is the R.F. and Oscillator Coil Assembly for Channel 13.

   UHF coils are not furnished as part of the tuner. The two coil assemblies required for and UHF channel may be ordered as one part under part numbers 158023-14 (for channel 14) through 158023-83 (for channel 83). The coil assemblies listed above are stamped with the channel number and the letter "H". The letter "H" indicates that the coils are designed for use with the tuner in this chassis.

1. All D.C. voltages measured with an electronic voltmeter connected from socket lug to chassis. Some voltages are variable depending upon signal input. Voltages shown were measured with a signal voltage of 850,000 microvolts and with a normal picture on the picture tube and the contrast and brightness controls set for 50 volts peak to peak on the cathode (pin 11) of the picture tube. Socket voltage tolerance 10%. For table of socket voltages under no-signal conditions
2. Supply voltage, 117 volts, 60 cycle AC.
3. K = 1000.
4. On all capacitance values in mmf. and all resistance values in ohms unless otherwise noted.
5. Better focus may be obtained with replacement picture tubes if the electronic focus anode is connected to a point other than +150 volts. Suggested points to try are: chassis ground, +260 volts, +285 (picture tube, pin 10) and +480 volts.
6. The Horizontal Hold control R164 used in chassis 431 has an overall resistance of 145,000 ohms, with a 70,000 ohm stop. This control is marked with Part No. B-157802-1-2 or B-157802-1-3. It is directly interchangeable with an earlier control marked B-157802-1-1, which has an overall resistance of 170,000 ohms, with a 70,000 ohm stop. It will be noticed, however, that the control with the lower overall resistance gives a somewhat wider hold range.
7. On the Vertical Integrating Network C131, leads 2 and 3 are closely spaced, and lead 2 is the middle lead. On the Sync Take-Off Network C129, leads 1 and 2 are closely spaced, and lead 2 is the middle one. When replacing either of these units, the leads must be connected as shown in the schematic in order to obtain satisfactory operation.
8. In some early production chassis 431, certain circuits may be found to differ from those shown on the schematic.
   a. In some chassis, R108 is a 3900 ohm, 10%, 1/2 watt resistor (Part No. 39374-32) in place of the 4700 ohm, 10%, 1/2 watt resistor (Part No. 39374-33) shown in the schematic and parts list.
   b. In some chassis, a 47,000 ohm, 10%, 1/2 watt resistor (Part No. 39374-45) is added between lead #2 of Sync Take-Off Network (Part No. 157813-1) and ground. Where this resistor is added, there is also a 3900 ohm, 10%, 1/2 watt resistor (Part No. 39374-32) added in parallel with L105 and R123. When a replacement Network is installed, these two resistors are not required and should be removed. The network should then be connected as shown in the schematic.
   c. To reduce horizontal overdrive, a 22 mmf., 10%, 1/2 watt resistor (Part No. 39374-5) was added in some chassis between the cathode of V109 (25CU6) and chassis ground. This resistor was no longer used in production when the Code B change went into effect, as described below.
9. Code Change B: On chassis 431, Code B, the values of two capacitors were changed to reduce horizontal overdrive. C150 was changed to a 560 mmf., 10%, 500 v., disc ceramic capacitor (Part No. 144675-32). C152 was changed to an 82 mmf., 10%, N750, 3000 v., disc ceramic capacitor (Part No. 158215-32).

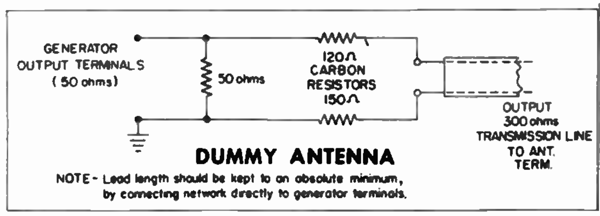
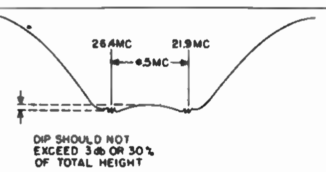
V1	6T4	Oscillator
V2	6BK7A	I. F. Amplifier
CR1	1N82 1N82A or 4JB2C-9	Crystal Mixer

R.F. AND MIXER ALIGNMENT

Step No.	Station Selector	Oscilloscope	Bias	Signal Generator To	Adjust
1.	Chan. #10	High side through a 10,000 ohm resistor to TP1 on Tuner. Ground lead to Tuner Case.	-1.5 volts to white lead on tuner.	Signal Generator set to 195.5 MC., 400 cycle 30% AM modulated. Through Dummy Antenna to the Antenna lead-in.	C-3 for maximum 400 cycle response on scope. Remove signal Generator.
2.	"	"	"	Sweep Generator to Antenna lead-in through dummy antenna. Set Generator to sweep Channel 10 freq. Loosely couple Marker Generator to sweep output cable. Set marker to either 21.9 or 26.4 mc.	Adjust C5 & C9, to produce a response curve similar to R.F. and Mixer Response Curve.



R. F. & MIXER RESPONSE CURVE



Without disturbing the R.F. grid, R.F. plate, and mixer-grid trimmer, check the response on the other VHF TV channels by setting the station selector to the desired channel and changing the frequency of the sweep generator to correspond to the channel being checked. The response curve should be essentially the same on all channels and the markers should fall in similar positions on the response curve. A slight amount of tilt can be tolerated. The amount of tilt indicated by the relative amplitudes of the response curves where the picture and sound I.F. Markers rest should not exceed 30% of the over-all response curve amplitude.

I.F. ALIGNMENT

All lead connections from the signal marker generator and sweep generator must be shielded. Keep exposed ends and ground leads as short as possible (about one inch). Always locate the ground lead connections as close as possible to their respective "hot" leads in the television receiver chassis. The sweep generator output, signal generator output, and contrast control must be kept low enough to prevent overloading the television receiver circuits.

CAUTION: One side of the chassis is connected to the power line. Therefore, test equipment should not be connected to the receiver unless an isolation transformer is used between the power line and the receiver. DO NOT GROUND THE RECEIVER CHASSIS UNLESS AN ISOLATION TRANSFORMER IS USED.

The front side of the chassis as referred to below means the side opposite the tubes.
The rear side of the chassis means the side on which the tubes are mounted.

VIDEO I. F. ALIGNMENT (with VTVM)

In the I.F. Alignment, limit input of signal generator so that reading on VTVM does not exceed -2 volts.

Step No.	Connect Signal Generator Through a .01 Capacitor	Signal Gen. Freq. MC.	Connect VTVM	Miscellaneous Connections and Instructions	Adjust
1.	Test Point No. 2 on Tuner (closest to L9 slug adjust-ment).	24.4 mc.	Junction of R118 and C113 and chassis.	Connect 3 volt bias battery negative lead to white lead from tuner, positive lead to chassis	T101 for maximum indication on meter, limit input to make peak less than -2 volts D.C. on VTVM.
2.	"	22.9 mc.	"	"	L103 (rear slug) for maximum. Use first peak from tinnerman clip end of coil.
3.	"	21.9 mc.	"	"	L103 (front slug) for minimum. Input level should be high enough to produce at least .5 volts at null on VTVM. Use first null obtained from end of coil form opposite tinnerman clip.
4.	Repeat steps 2 and 3.				
5.	"	25.5 mc.	"	"	L102 for maximum.
6.	"	25.1 mc.	"	"	L101 (front slug) for maximum. Use first peak from tinnerman clip end of coil.
7.	"	27.9 mc.	"	"	See Note 1. L101 (rear slug) for minimum deflection on VTVM. Use first null obtained from end of coil form opposite tinnerman clip.
8.	Repeat step 6 (and 7, if adjacent channel trap is used).				
9.	Test Point No. 1 on Tuner (closest to C21 trimmer screw).	25.1 mc.	"	Connect a 100 ohm resistor in series with a 1000 mmf. cap. across L101.	L9 (brass screw) on the Tuner for maximum.

Note 1. This adjustment can be made only on receivers where the Adjacent Channel Trap has been added. For installation of this trap in areas where adjacent channel interference is prevalent, see page 4.

TO CHECK I. F. ALIGNMENT (with scope)

Excessive sweep input will overload the circuit and cause distortion in the wave form. Check for possible overload by temporarily increasing and decreasing the signal input level and noting any change in the wave form.

Excessive signal from the marker generator will also distort the wave form. Be sure to keep the marker at the minimum usable amplitude.

Sweep Gen. Connected to	Scope Connected to	Bias	Sweep Gen. Set to	Remarks
Ungrounded shield of V2 and chassis.	High side of contrast control R120 and chassis. Contrast control at minimum contrast.	Connect 3 volt bias battery negative lead to white lead from tuner, positive lead to chassis.	Sweep from 20 to 30 megacycles.	Provide markers as shown on curve.  Nominal Overall I.F. Response Curve. A slight deviation in response curve is tolerable, but if any great deviation is noted, the I. F. stages will have to be realigned.

VHF OSCILLATOR ALIGNMENT

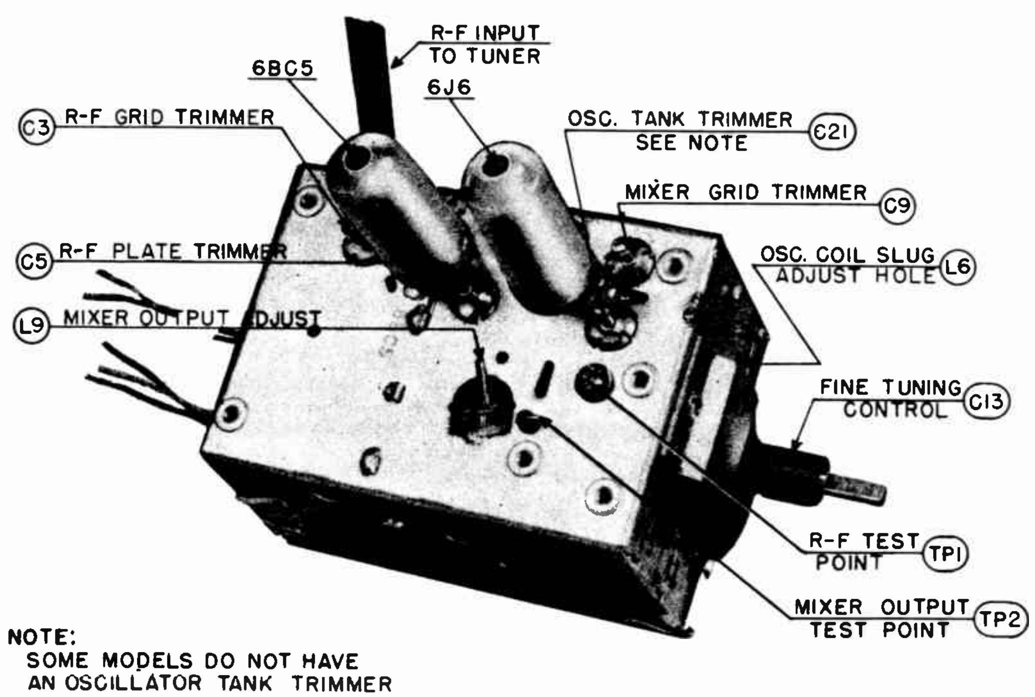
OSCILLATOR ALIGNMENT (using scope)

Step No.	Oscilloscope	Channel Selector	Sweep Generator	Marker Generator	Adjust
1.	High side of scope to high side of R120 contrast control. Low side to chassis. See Note:	Chan. #2	To sweep Channel 2 Freq. Connect Gen. output in series with dummy antenna to antenna lead-in.	59.75 Sound I.F. Carrier.	Channel 2 oscillator slug so that marker falls into bottom of valley on curve (the point corresponding to the 21.9 mc. marker as shown on Nominal Overall I.F. Response Curve sketch.) Be sure that the Fine Tuning Control is set to the center of its range.
2.	Repeat the above procedure for each of the remaining channels, by resetting the sweep generator and the marker generator to the correct frequencies for each channel that is to be adjusted.				

Note: Apply a -3.0 volts negative bias to Junction of C111 and R117 or to white lead from VHF R.F. Tuner. Use whichever is the most convenient point.

ALTERNATE OSCILLATOR ALIGNMENT

A turret type VHF tuner is used on this receiver, and there is an oscillator adjustment for each channel. When the receiver is installed, the oscillator should be adjusted for each channel on which a station is operating in the area. Set the Channel Switch to the channel that is to be adjusted. Turn the Fine Tuning control to the center of its range. The oscillator trimmer screw is directly to the right of the tuner shaft, and is accessible through a hole in the front of the chassis after the two VHF tuning knobs have been removed. Use a non-metallic screw driver and adjust the oscillator trimmer screw until the proper tuning point is in the center of the Fine Tuning range.



NOTE:
SOME MODELS DO NOT HAVE
AN OSCILLATOR TANK TRIMMER

VHF TUNER
(Tube & Alignment Locations)

HORIZONTAL BLOCKING OSCILLATOR ALIGNMENT

Tune Receiver to TV signal, adjust contrast control for normal picture below limiting in the Video Amplifier, and proceed as follows:

Step No.	Contrast Control Set For	Miscellaneous	Adjust
1.	Normal Picture	---------------------	Horizontal Hold Control (R164) and Horizontal Frequency Adjustment (rear slug of T108) until picture is in sync.
2.	"	Connect scope in series with 10 mmf. to lug 4 of T108.	Adjust Horizontal BTO Trap (front slug of T108) to obtain the waveform shown below. Keep the picture in sync at all times by re-adjusting the Horizontal Hold, Horizontal Frequency and/or Horizontal Lock Trimmer (C142). 3.	"	Horizontal Hold set fully clock-wise.	Adjust Horizontal Frequency (rear slug of T108) by turning out until the picture is just out of sync. Then turn the control slowly in until the picture is just ready to fall into sync (indicated by a wide black vertical or diagonal horizontal blanking bar).
4.	"	Horizontal Hold set fully counter-clockwise.	Picture should normally be in sync. Remove the signal by tuning off and then re-tuning to the station. If more than seven bars are present, adjust the Horizontal Lock Trimmer slightly counter-clockwise until three or four bars appear when the receiver is tuned off and then re-tuned to the station (Horizontal Hold Control still set fully counter-clockwise). If less than three bars are present, adjust the Horizontal Lock Trimmer clockwise to obtain the three or four bars as described above. Since the Horizontal Lock Trimmer adjustment affects the horizontal frequency, the adjustments of both the Horizontal Frequency Adjustment and the Horizontal Lock Trimmer must be repeated until the conditions outlined in steps 3 and 4 exist simultaneously at the extreme positions of the Horizontal Hold control. Check pull-in range, which should be normally 60° to 120°.
5.	Weak Picture	---------------------	Set the Horizontal Hold Control so that when the receiver is tuned off and then re-tuned to the station, the picture returns completely in sync.

TABLE OF SOCKET VOLTAGES

The following voltages were measured with an electronic voltmeter while the set was operating on 117 volts, 60 cycle a.c. with no signal input, antenna terminals shorted, Station Selector set to channel 3, and the Brightness and Contrast Controls at minimum setting. Electronic voltmeter connected between socket lug and chassis. * = AC. voltages. Voltages may vary depending upon the setting of other controls.

D. C. current at junction of L108 and C132B, with contrast control in the minimum counter-clockwise position, 190 ma. With contrast set at maximum clockwise position, D. C. current at this point is 200 ma.

● Do not measure. High voltage pulse over 2 kv. on cathode of Damper Tube and over 1 kv. on pin 6 of V110.

SOUND ALIGNMENT

The 4.5 mc. trap (front of L109) must be aligned first, regardless of which procedure is used for the remainder of the alignment (Procedure A or B).

Step No.	Channel Set To	Adjust	Remarks
1.	Any unused channel	Connect a crystal controlled 4.5 mc., 400 cycle amplitude modulated signal (30% or greater) between pin 8 of V104 and chassis. Connect high side of scope through a detector probe to cathode of picture tube, low side to chassis. Adjust L109 (rear slug) for minimum 400 cycle indication on scope.	Remove signal generator and scope from the receiver.

Proceed with the remainder of the Sound Alignment, using either a signal from a TV station as in Procedure A, or alignment equipment as in Procedure B.

PROCEDURE A (with signal from station)

Step No.	Channel Set To	Adjust	Remarks
1.	Strong signal	L106 for maximum sound output.	Set Buzz Control (R132) approximately 90° from clockwise stop.
2.	Weak signal	L111 and L109 (front slug) for maximum sound output.	If the signal in the area is too strong to obtain these peaks, remove the antenna from the receiver.
3.	Weak signal	Buzz Control (R132) for minimum noise (hash).	This signal should be weak enough to allow noise (hash) to come through along with the sound.
4.	Strong signal	L106 again for maximum sound output.	Limit the volume control setting so that this peak can be heard.

PROCEDURE B (with alignment equipment)

Step No.	Connect Signal Gen.	Signal Gen. Freq. MC.	Connect Scope	Miscellaneous Instructions	Adjust
1.	Pin 8 of V104.	4.5 mc. FM modulated 400 c.p.s., 25 kc. deviation.	Across secondary of output trans. T105.	Set Buzz Control (R132) to approximately 90° from clockwise. stop. Set the Volume Control (R135) at a low level.	L106 for maximum 400 cycle indication on scope.
2.	"	"	"	"	L111 for maximum response keeping input signal at a low level (below limiting).
3.	"	"	"	"	L109 (front slug) for maximum response keeping input signal at a low level.
4.	"	4.5 MC. AM modulated 400 c.p.s.	"	Use a high input level on signal generator.	Buzz Control (R132) for null (minimum 400 c.p.s. amplitude on scope).
5.	"	4.5 MC. FM modulated 400 c.p.s., 25KC. deviation.	" "	Set the Volume Control (R135) at a low level.	Re-peak L106 for maximum 400 cycle indication on scope.

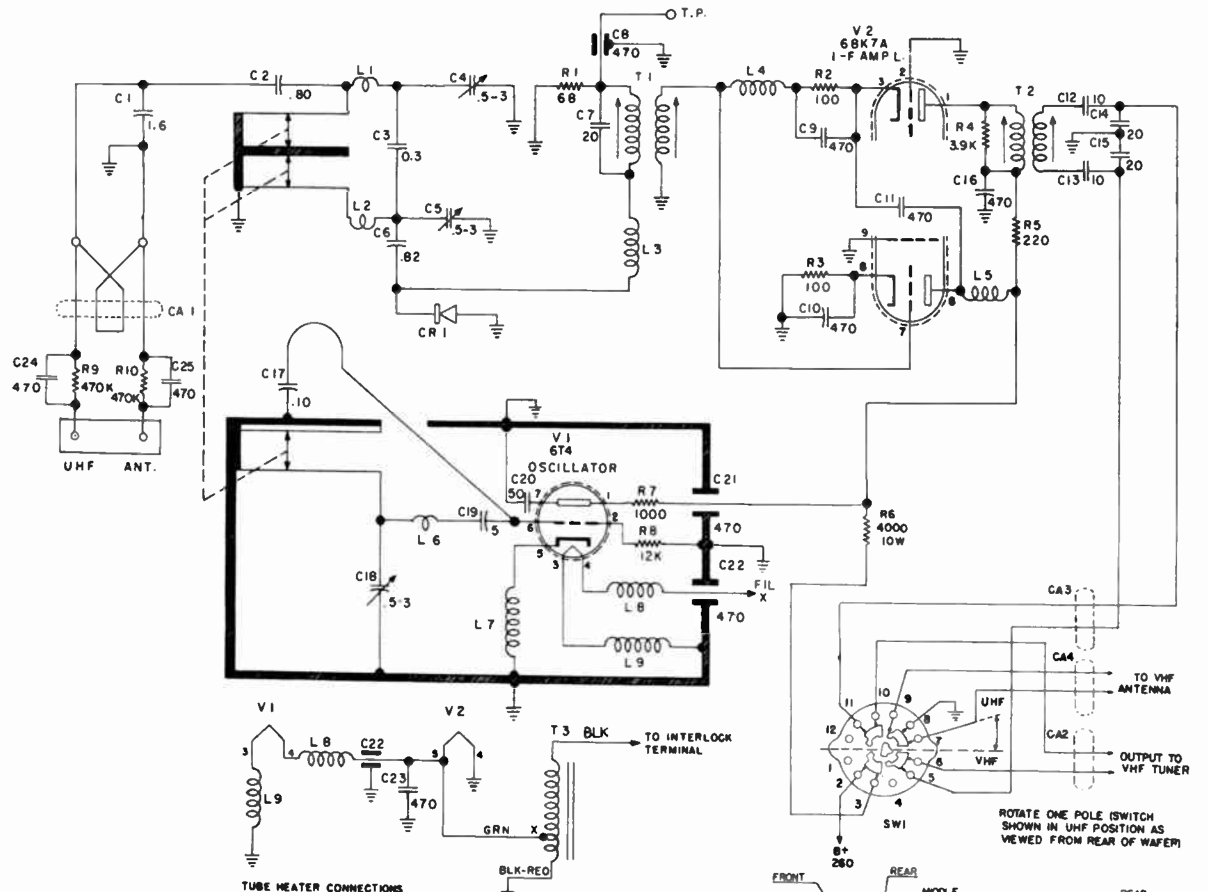
SCHEMATIC UHF CONVERTER

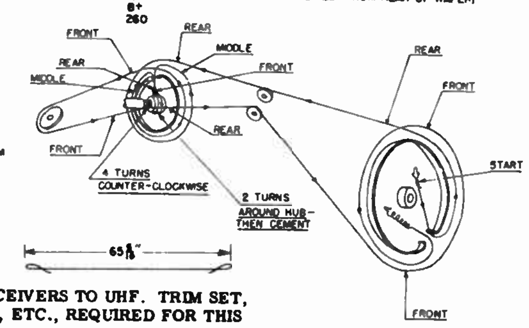
(Part No. 158116)



NOTES:

ALL CAPACITANCE VALUES IN MMF. & ALL RESISTANCE VALUES IN OHMS UNLESS OTHERWISE NOTED.
ALL RESISTORS 1/2 WATT, EXCEPT AS NOTED.
K = 1000.

PLACEMENT OF DIAL DRIVE CORD SHOWN WITH PULLEYS IN MAXIMUM COUNTER-CLOCKWISE ROTATION AGAINST STOP.



THIS CONVERTER, PART NO. 158116, MAY ALSO BE USED TO CONVERT NON-UHF RECEIVERS TO UHF. TRIM SET, PART NO. 158156-1, CONTAINS THE NECESSARY KNOBS, HARDWARE & INSTRUCTIONS, ETC., REQUIRED FOR THIS CONVERSION.

Symbol No.	Part No.	Description
R6	158186-12	Resistor, 4000 ohm, 10 w., Wirewound
SW1	157867-1	Switch, VHF-UHF
T3	157915-1	Transformer, Filament
CA1	157982	Transmission Line, (125 ohm) order in feet only
*CR1	158186-21	Crystal Mixer, 1N82A
	158186-22	Crystal Mixer, 1N82
	158186-23	Crystal Mixer, 4JB2C-9
	157884-1	Bracket, Tuner and Resistor Mounting
	157896-1	Bracket, Tuner and Transformer Mounting
	157783-1	Grommet (Nylon), 3 used
	158038-1	Insulator (Plastic sleeve), Pulley Hub
	157940-1	Standoff (Fibre), Antenna

*When replacing the crystal, it is best to make the replacement with the same type crystal as the one originally used in the converter. Because of slight variations between crystals of the same part number, it is generally considered good practice to try several different crystals of a particular type to select the one that gives the best performance in that particular converter.

*See Note #10

NOTES

VHF TUNER

1. All capacitance in mmf. and all resistance in ohms unless otherwise specified.
2. K = 1000.
3. TUNER STRIPS. One Antenna Coil Assembly and one R.F. and Oscillator Coil Assembly are necessary for each channel to be received (VHF or UHF). The dash number following the part number indicates the channel for which the assembly is designed.

   Examples for VHF: 158021-2 is the Antenna Coil Assembly for Channel 2.
   158022-13 is the R.F. and Oscillator Coil Assembly for Channel 13.

   UHF coils are not furnished as part of the tuner. The two coil assemblies required for any UHF channel may be ordered as one part under part numbers 158023-14 (for channel 14) through 158023-83 (for channel 83). The coil assemblies listed above are stamped with the channel number and the letter "H". The letter "H" indicates that the coils are designed for use with the tuner in this chassis.

NOTES

CHASSIS 432

1. All D.C. voltages measured with an electronic voltmeter connected from socket lug to chassis. Some voltages are variable depending upon signal input. Voltages shown were measured with a signal voltage of 850,000 microvolts and with a normal picture on the picture tube and the contrast and brightness controls set for 50 volts peak to peak on the cathode (pin 11) of the picture tube. Socket voltage tolerance 10%. For table of socket voltages under no-signal conditions, see page 11.
2. Supply voltage, 117 volts, 60 cycle AC.
3. K = 1000.
4. All capacitance values in mmf. and all resistance values in ohms unless otherwise noted.
5. Lug 3 connected to boost voltage and Lug 3, 8 and 5 connected internally.
6. Better focus may be obtained with replacement picture tubes if the electronic focus anode is connected to a point other than +150 volts. Suggested points to try are: chassis ground, +260 volts, +285 (picture tube, pin 10) and +480 volts.
7. The Horizontal Hold control R164 used in chassis 432 has an overall resistance of 145,000 ohms, with a 70,000 ohm stop. This control is marked with Part No. B-157802-1-2 or B-157802-1-3. It is directly interchangeable with an earlier control marked B-157802-1-1, which has an overall resistance of 170,000 ohms, with a 70,000 ohm stop. It will be noticed, however, that the control with the lower overall resistance gives a somewhat wider hold range.
8. On the Vertical Integrating Network C131, leads 2 and 3 are closely spaced, and lead 2 is the middle lead. On the Sync Take-Off Network C129, leads 1 and 2 are closely spaced, and lead 2 is the middle one. When replacing either of these units, the leads must be connected as shown in the schematic in order to obtain satisfactory operation.
9. The yellow lead wire from pin 11 CRT is taped to the rest of CRT lead wires in late models. This was done to reduce the possibilities of regeneration due to the yellow wire getting too close to the I.F. input coil.

   If regeneration occurs in early model sets, the taping of the yellow lead wire will help to reduce it.
10. In some early production chassis 432 (not designated by a code letter), C139 is a 140 mfd., 300 v., electrolytic capacitor, Part No. 157837-1. For replacement purposes, use either Part No. 157837-1 or 158557-1, whichever may be available.
11. The inset at the lower left of the complete schematic wiring diagram shows a slight variation in circuitry which was used on some early production chassis 432. The code letter following the chassis number was not changed to designate this change in circuitry, because of the relatively small number of chassis on which it was used.

VIDEO IF ALIGNMENT RA-312/313

Place STATION SELECTOR between channels to disable oscillator. Remove fuse, F201. Connect a short length of wire to grid of mixer tube (see figure 1). Use the lowest VTVM range for all steps.

Step	Signal Generator Frequency	Signal Generator Connect To	Output Indicator	Connect to	Adjust
1	43.5 MC Center Freq. 10 MC deviation.	Grid of Mixer 1	Oscillograph through XTAL	Pin 5, V201 1XTAL	L201 (top) for 41.25 MC trap. L201 (bottom) for 47.25 MC trap. Z201 (bottom) for 42.25 MC marker. Mixer plate coil (T101) and Z201 (top) for 45.75 MC marker. Note: Repeat adjustments until markers are positioned as specified. (42.25 MC, 45.75 MC, 55%, 70%, 41.25 MC, 47.25 MC)
2	44.0 MC (Marker) No Sweep	As Above 2	VTVM	Pin 7, V205 2VTVM	Z204 for maximum negative reading. Set signal generator output to maintain reading on lowest range of VTVM.
3	42.35 MC (Marker) No Sweep	As Above 3	VTVM	As Above 3VTVM	Z203 for maximum negative reading.
4	44.85 MC (Marker) No Sweep	As Above 4	VTVM	As Above 4VTVM	Z202 for maximum negative reading.
5	4.5 MC 400 CPS AM	Pin 7, V205 5	Oscillograph through XTAL	Junction of C220 and R226 5XTAL	L207 for minimum reading.

SOUND IF ALIGNMENT

Step	Signal Generator Frequency	Signal Generator Connect To	Output Indicator	Connect to	Adjust
6	4.5 MC 1 MC Sweep	Pin 7, V205 6	Oscillograph through XTAL	Pin 7, V207 6XTAL	L211 and Z206 (bottom) for waveform (4.5MC)
7	As Above	As Above 7	Oscillograph DIRECT	Junction of C236 & R242 7DIR	Z206 (top) for waveform. (4.5MC)

ALTERNATE SOUND IF ALIGNMENT — USING TV SIGNAL

Step	Signal	Output Indicator	Connect to	Adjust
6	TV Signal. Teleset must be tuned for best picture	VTVM	Pin 7, V207 6VTVM	L211 and Z206 (bottom) for maximum reading.
7	As Above	VTVM	Junction of C236 & R242 7VTVM	Z206 (top) for null point.

ALIGNMENT TEST POINTS

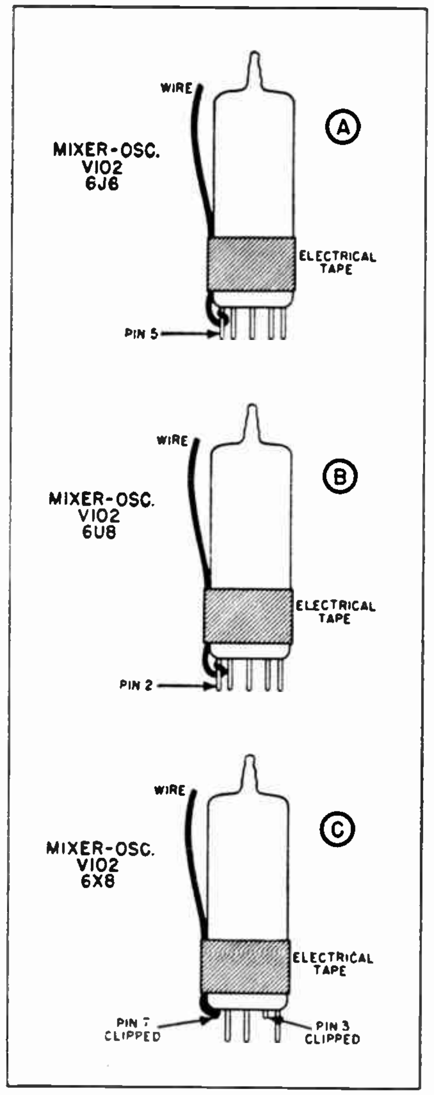

Figure 1. Adapter tubes for use in connecting alignment equipment to the grid of the mixer stage. A—6J6 adapter for chassis with tuner 89 012 912. B—6U8 adapter for chassis with tuner 89 013 461. C—6X8 adapter for chassis with tuner 89 013 561.

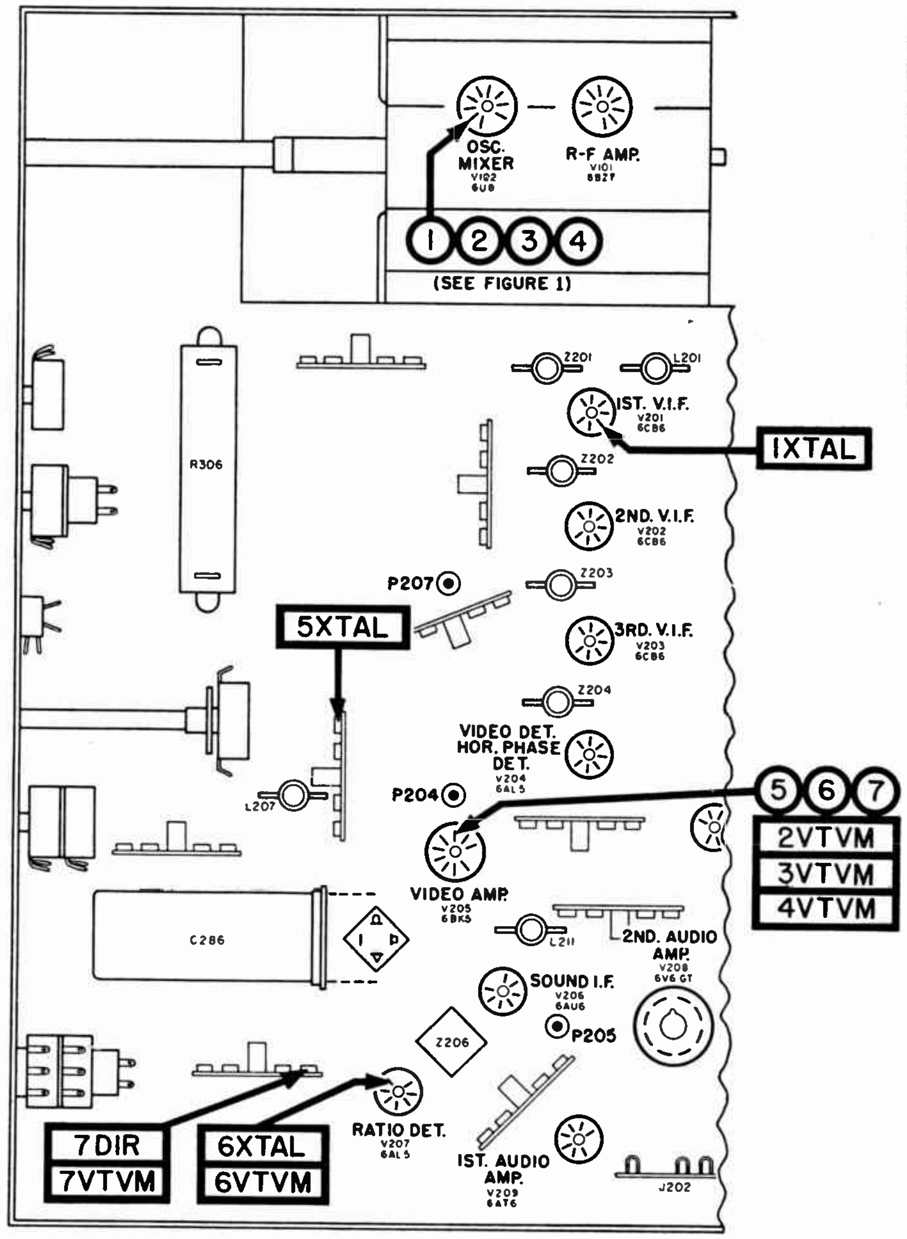

NOTES

When the alignment procedure has been completed the setting of the tuner oscillator slugs should be checked on each available channel and corrected if necessary.

For tuners 89 012 912 and 89 013 461 proceed as follows:

1. Tune the receiver to each available channel.
2. Place the flat of the Fine Tuning control face downward and adjust the oscillator slug for best picture and sound.

For Tuner 89 013 561 use the following procedure:

1. Turn the station selector to the highest frequency channel that does not tune in properly.
2. Place the flat of the Fine Tuning Control face upward.
3. On Channels 7 through 13 adjust the oscillator slug over the tuner shafts for best picture and sound. On channels 2 through 6 adjust the oscillator slug below the tuner shafts for best picture and sound.

Note: The oscillator slug above the tuner shafts affects the tuning of all channels from 7 through 13 while the lower oscillator slug affects the tuning of all channels from 2 through 6.

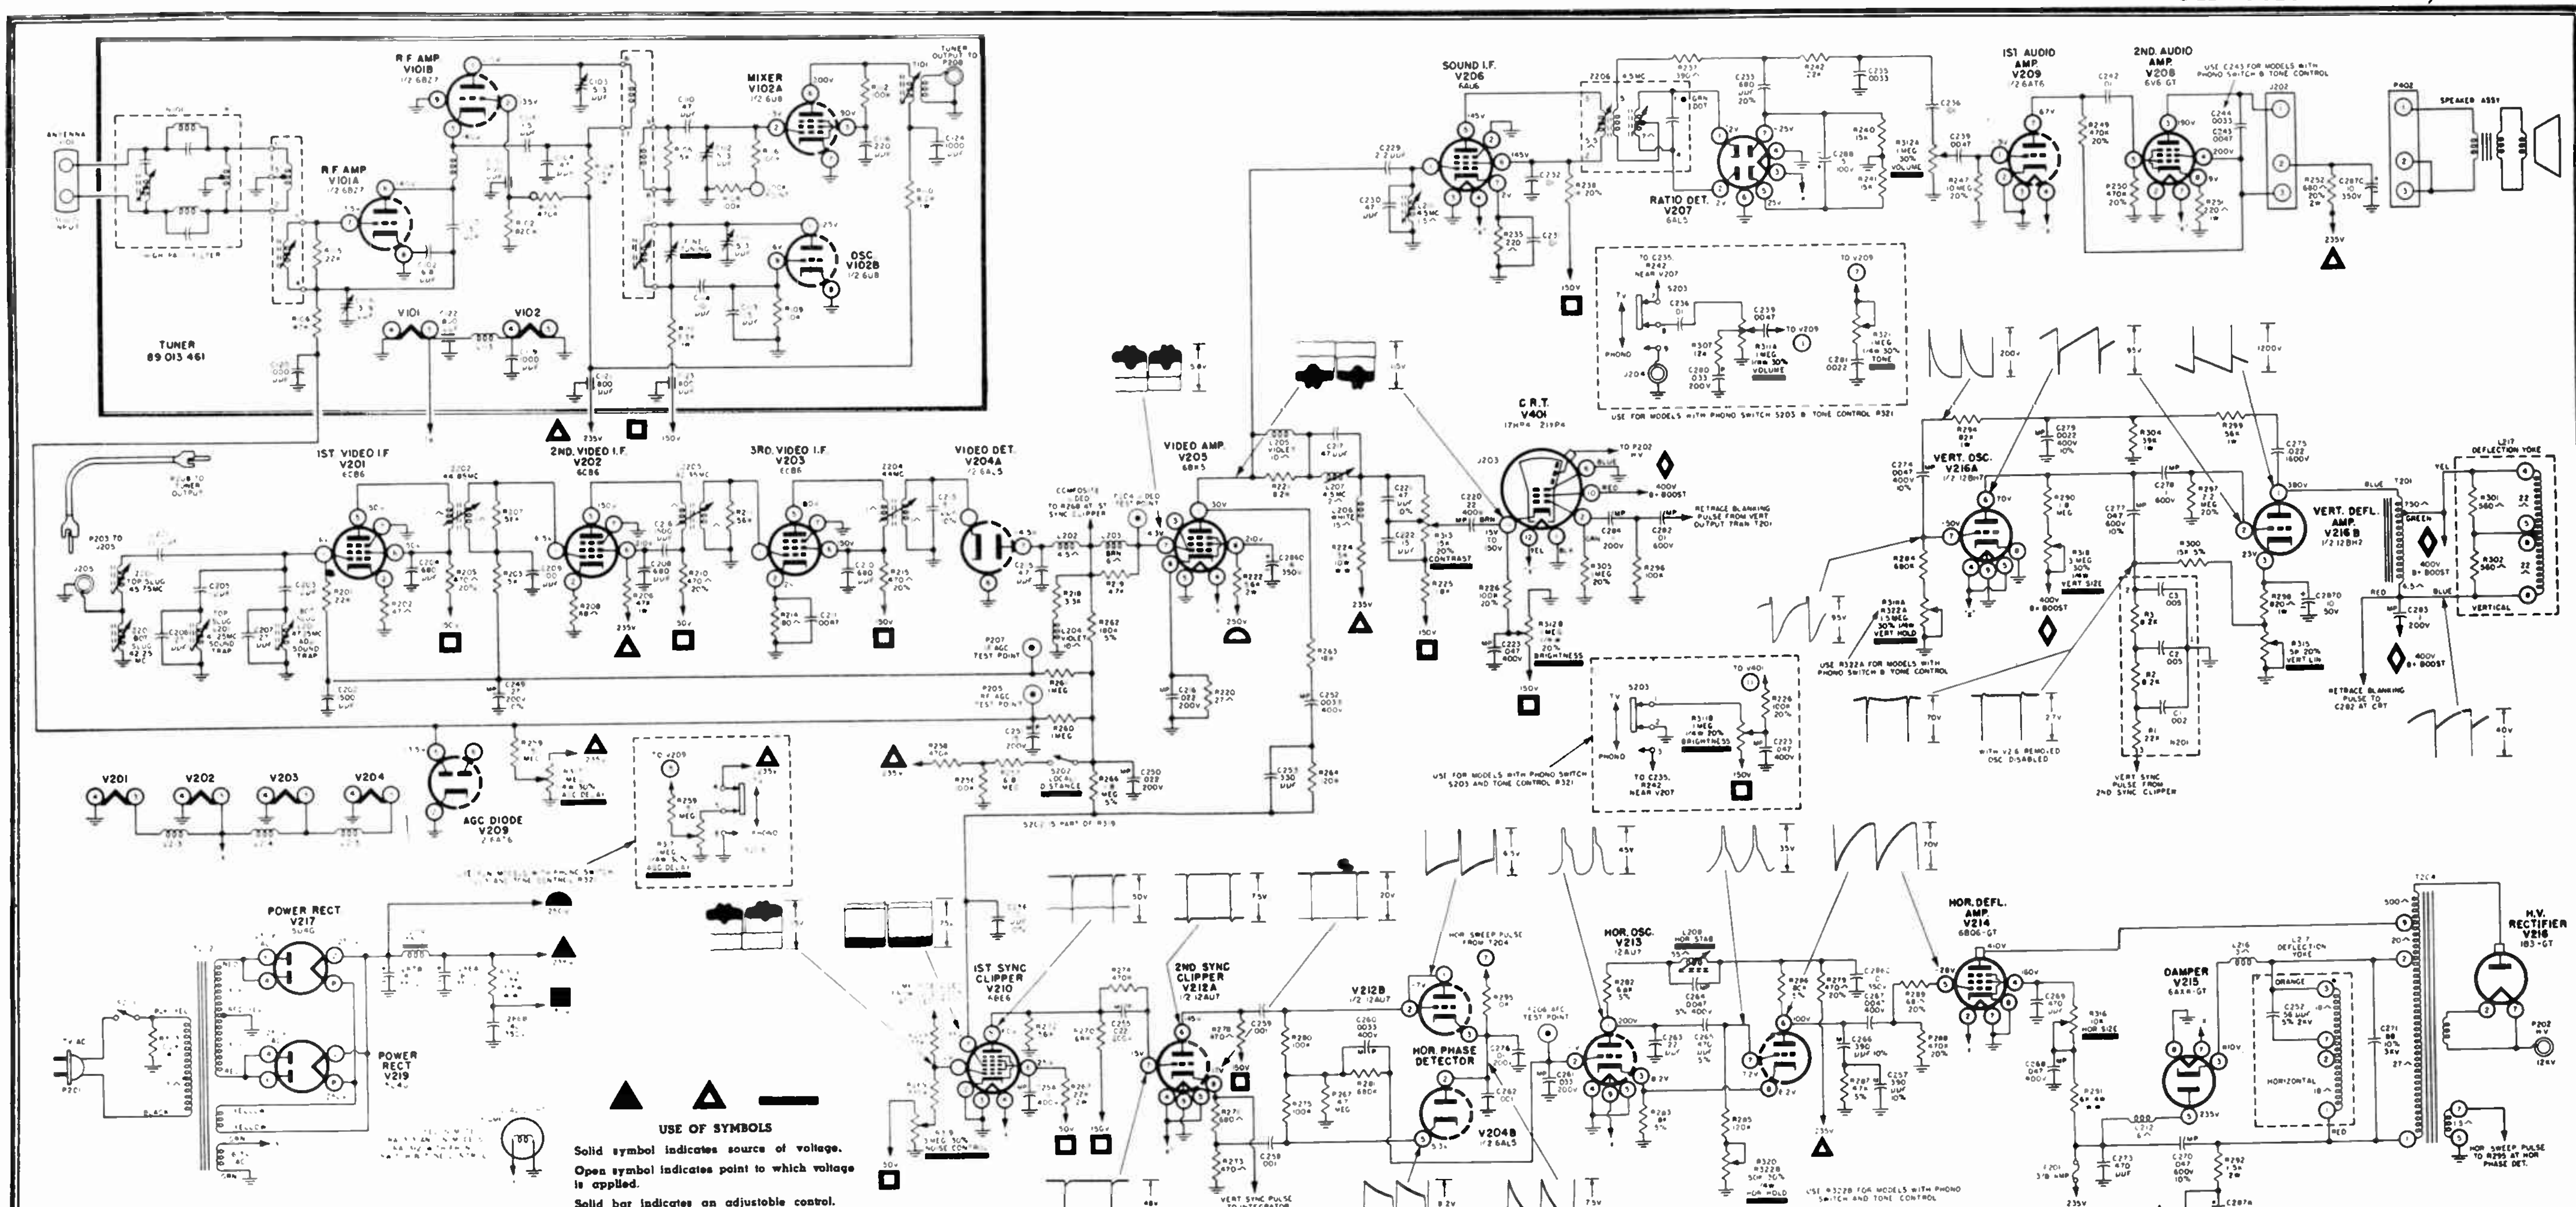
31 021 962	Door Control
45 005 964	Knob Fine Tuning RA-312
45 005 974	Knob Brightness RA-312
45 006 013	Knob Selector 13 Pos. Bld. RA-313
45 006 013	Knob Selector 13 Pos. Wal. RA-313
45 006 014	Knob Selector 13 Pos. Mahog. RA-312
45 006 015	Knob Selector 13 Pos. Bld. RA-312
45 006 015	Knob Selector 13 Pos. Wal. RA-312
45 006 022	Knob Volume Mahog.
45 006 023	Knob Volume Blonde
45 006 023	Knob Volume Walnut

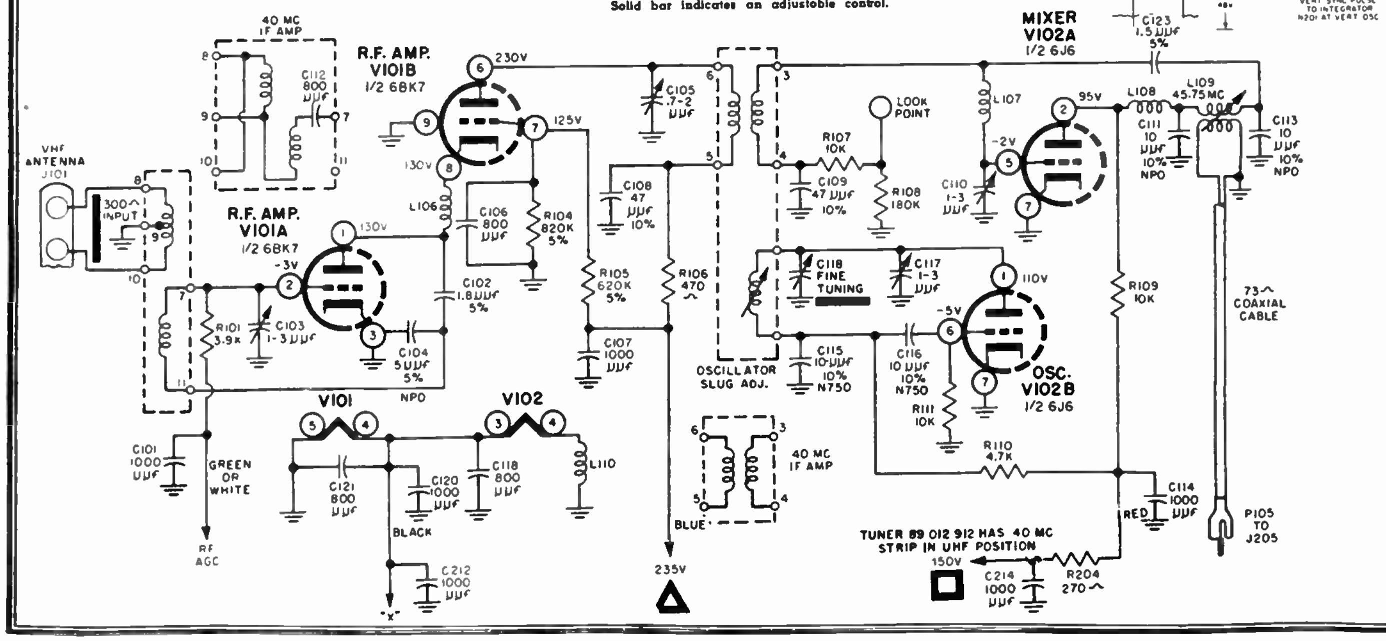
Winsted, Bradley

Part No.	Description
32 004 442	Front Panel, Winsted
38 015 512	Cushion Glass Top
38 015 542	Mask and GI Side Support

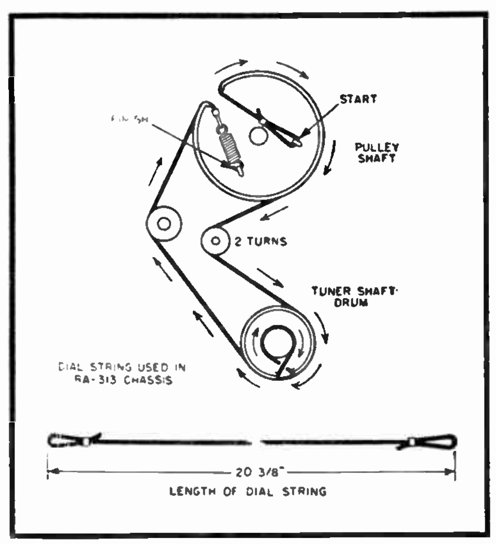
Bradley

Part No.	Description
32 004 431	Panel Front, Mahog.
32 004 432	Panel Front, Blonde
32 004 433	Panel Front, Walnut





DIAL STRINGING



NOTES

1. All waveforms and voltages were taken under operating conditions. The receiver was tuned to an average strength TV signal, the Contrast control rotated fully clockwise and the Noise control was rotated fully counter-clockwise.
2. The Noise control and Local-Distance switch consists of a potentiometer, R319, and a snap switch, S202. When R319 is rotated fully counter-clockwise S202 opens (Local position as shown in the schematic).
3. Voltages ± 20% of those shown are normal.
4. All resistors are 10%, one-half watt, unless otherwise indicated. W. W. indicates wire wound resistor.
5. All capacitors are 20%, 500V, unless otherwise indicated. All capacitors are ceramic, unless indicated as follows: M-mica, P-paper, ± -electrolytic, MP-Molded Paper.
6. Tuner 89 013 461 is used in RA-312 chassis with Phono switch and Tone control. Tuner 89 013 561 is used in RA-312 chassis without Phono switch and Tone control. Tuner 89 012 912 and filter N202 are used with UHF tuner 89 013 293 in RA-313 chassis.
7. In some of the earlier chassis the circuit is as follows: Pin 6 of the 6CB6 2nd video i-f is connected to the junction of R210 and Z203. C218, R206 are not used. R222 is a 4.7K 10% 2W resistor connecting to the + 235 volt line. R262 is a 120K 10% 1/2W resistor, R258 is a 220K 10% 1/2W resistor and R266 is a 1.8 Meg. 10% 1/2W resistor. A 180K 10% 1/2W resistor is connected between the junction of R261, R262 and the junction of R260 and R266. R300 is connected to pin 3 of the 12BH7 Vertical Deflection Amplifier.

RECEIVER CHARACTERISTICS

ITEM	DESCRIPTION
Voltage Rating	115 V. - 60 Cycles A. C.
Power Consumption	205 Watts
Frequency Range VHF	54 - 88 mc.; 174 - 216 mc.
Frequency Range UHF	470 - 890 mc.
Intermediate Frequencies	Video - 45.75 mc. Audio - (intercarrier) 4.5 mc.
Antenna Input Impedance	300 ohms, Balanced
Channel Selection VHF	Twelve Position Rotary Turret
Channel Selection UHF	Continuous Tuning Channels 14 to 83

CHASSIS 120179-B & 120203-B

CHASSIS DIFFERENCES

UHF-VHF Chassis 120179-B and 120203-B are electrically similar. Different chassis numbers have been assigned due to the slightly different placement of the 5U4GT rectifier tubes.

VHF Chassis 120204-B and 120205-B are also electrically similar, but have been assigned different chassis numbers for the same reason as above.

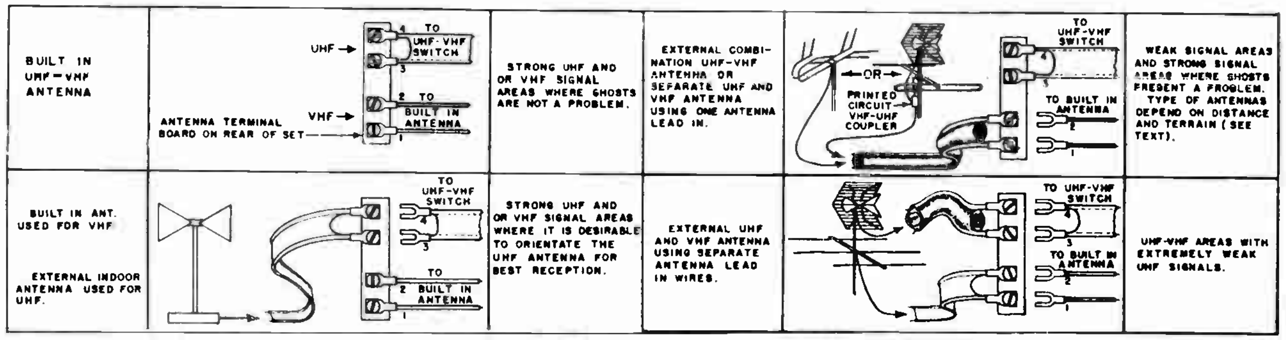

Figure 4. ANTENNA CONNECTIONS

ALIGNMENT V.H.F.

ALIGNMENT

a. Equipment Required - A sweep generator, (10 MC. sweep with center frequency of 44 MC. plus all necessary R.F. sweep frequencies as listed in R.F. Table), accurate marker generator, oscilloscope and V.T.V.M. are required for alignment. The marker generator must supply frequencies of 4.5 MC., 40 to 48 MC. and 50 to 216 MC.

b. Alignment Points - The location of all I.F. transformers, Tuned Circuits, and trimmers shown in Figure 9.

TV R.F. & MIXER ALIGNMENT (V.H.F.)

Connect 3 volt bias battery to both I.F. and R.F. AGC. circuits, positive terminal to chassis, negative terminal to junction of R-19, C-19, C-18. Add a jumper wire from this junction to junction of R-10, R-16, C-8 so that the bias battery is also applied to I.F. AGC.

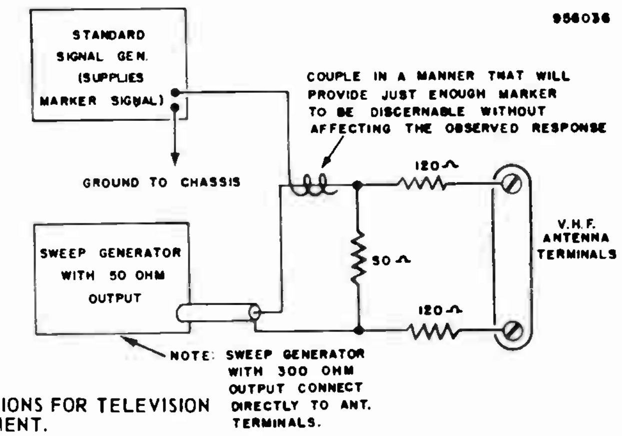

Figure 5. GENERATOR CONNECTIONS FOR TELEVISION R.F. CHANNEL ALIGNMENT.

ALIGNMENT OF MIRACLE PICTURE LOCK (Horizontal A.F.C. & Osc.)

Before proceeding be sure the Fringe Compensator Switch has been turned "OFF" (fully counter clockwise past click).

1. Tune set to a good channel.
2. Short phase coil (L-13) with a jumper wire, leads have been brought to top of chassis on terminal strip near V-13 horizontal oscillator (see tube location diagram Figure 11).
3. Short horizontal control grid to chassis. This point has also been brought to top of chassis on same strip as mentioned in Step 2.
4. Rotate horizontal hold control (R-73) to center of its mechanical range.
5. Adjust horizontal balance control (R-71) (rear of chassis) until picture pulls into synchronism (in most cases picture will sway from side to side).
6. Remove short from horizontal phase coil (L-13) and adjust L-13 for same synchronous condition as Step 5 above.
7. Remove short from horizontal control grid. Horizontal frequency circuits are now properly aligned.
8. When properly adjusted (Steps 1 to 7) the horizontal hold control can be moved slowly over most of its range without throwing the picture out of sync.
9. Readjust horizontal hold control (R-73) so that the picture remains in sync when switching channels (near center of range).

ADJUSTMENT OF NOISE INVERTER (Fringe Compensator)

1) Be sure the miracle picture lock has been properly adjusted (horizontal hold circuits). See above.

2) Tune in a weak station. Turn fringe compensator switch to the "ON" position and adjust the fringe compensator control for best picture stability.

3) Try all channels and readjust fringe compensator if necessary for best overall picture stability.

NOTE: In most locations this added protection will not be necessary and the fringe compensator should remain in the "OFF" position. If this is not done, picture wiggle and or vertical roll might result in strong signal areas.

SWEEP & MARKER GENERATOR CONNECTIONS	SWEEP & MARKER GENERATOR FREQ. RANGE	MARKER GEN. FREQ.	OSCILLOSCOPE CONNECTIONS	MISCELLANEOUS INSTRUCTIONS	TRIMMER OR SLUG	TYPE OF ADJUSTMENT AND OUTPUT INDICATION
Connect as shown in Fig. 5 and adjust sweep controls for width so that complete channel response may be observed as shown in Fig. 6	Channel #12 207 MC. Center Freq.	209.75 MC. Sound Carrier 205.25 MC. Pix Carrier	Vert. input of scope through 10K resistor to test point on tuner Fig. 9 Low side to chassis	Set Channel Selector to #12 NOTE Keep output of R.F. Marker Generator at a level that provides a readable marker but does not distort the curve that is being observed on the scope.	C-2 R.F. Amp. Input Trimmer C-5 R.F. Plate Trimmer C-6 Mixer Grid Trimmer	Adjust Trimmers C-2, C-5 and C-6 to obtain response shown in Fig. 6 IMPORTANT: When adjusting trimmers C-2, C-5 and C-6 it will be noted that the band pass characteristic can be broadened by sacrificing amplitude. It is undesirable to overly broaden the curve as that would result in a loss of sensitivity.
Same as Above	#13 213 MC.	*215.75 MC. **211.25 MC.	Same as Above	Set Channel Selector to #13 (See Note Above)		The r-f band pass characteristic of the other television channels should now be checked without disturbing the settings of trimmers C-2, C-5 and C-6. Adjust the r-f sweep generator and marker generator for operation on the other television channels, observing position of both the sound carrier and picture carrier markers.
	#11 201 MC.	*203.75 MC. **199.25 MC.		Set Channel Selector to #11 (See Note Above)		
	#10 195 MC.	*197.75 MC. **193.25 MC.		Set Channel Selector to #10 (See Note Above)		
	#9 189 MC.	*191.75 MC. **187.25 MC.		Set Channel Selector to #9 (See Note Above)		
	#8 183 MC.	*185.75 MC. **181.25 MC.		Set Channel Selector to #8 (See Note Above)		
	#7 177 MC.	*179.75 MC. **175.25 MC.		Set Channel Selector to #7 (See Note Above)		
	#6 85 MC.	* 87.75 MC. ** 83.25 MC.		Set Channel Selector to #6 (See Note Above)		
	#5 79 MC.	* 81.75 MC. ** 77.25 MC.		Set Channel Selector to #5 (See Note Above)		
	#4 69 MC.	* 71.75 MC. ** 67.25 MC.		Set Channel Selector to #4 (See Note Above)		
	#3 63 MC.	* 65.75 MC. ** 61.25 MC.		Set Channel Selector to #3 (See Note Above)		
	#2 57 MC.	* 59.75 MC. ** 55.25 MC.		Set Channel Selector to #2 (See Note Above)		

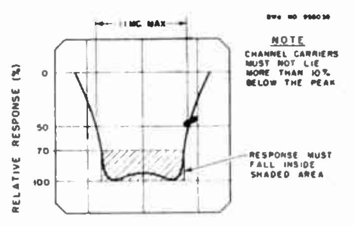

Figure 6 -- TUNER RESPONSE CURVE SHOWING BAND-PASS LIMITS.

The response for all channels should meet with the requirements of Fig. 6. To do so it may be necessary to compromise by slightly changing the initial channel #12 adjustments of C-2, C-5 and C-6 while switched to channel which does not conform.

I.F. ALIGNMENT

1) Tune receiver to unused Channel 10 or 12.

2) Connect 3 volt bias battery with negative terminal to I.F. AGC. (Junction R-10, C-8, R-16) positive terminal to chassis.

3) Connect D.C. V.T.V.M. to video test point, low side to chassis.

4) Connect terminated marker generator to floating shield of converted tube V-23 6J6. (Shield raised slightly so that it does not make contact with chassis). Use unmodulated marker. See Fig. 8.

NOTE: WE HAVE RECENTLY STANDARDIZED ON THE USE OF HEX. HEAD SLUGS. THESE CAN BE ADJUSTED FROM TOP OR BOTTOM. BEFORE ADJUSTING SLUGS MAKE CERTAIN THE CORRECT TYPE OF FIBRE ALIGNMENT TOOL IS USED (SEE FIG. 8A) ALTERNATE PART NUMBERS SHOWN ON PARTS LIST HAVE SLOTTED SLUGS.

MARKER GENERATOR	ADJUST	PROCEDURE
45.75 MC. Unmodulated	T-4	Peak for maximum response. Adjust output of signal generator so that maximum response does not produce more than -2V. D.C. on V.T.V.M.
43.2 MC. Unmodulated	T-3	
42.0 MC. Unmodulated	T-2	
45.0 MC. Unmodulated	L-3 T-1	
41.25 MC. Unmodulated	L-2	Adjust trap for minimum response. Increase output from signal generator so that a true minimum position can be found.

5) Connect vertical input of an oscilloscope instead of V.T.V.M. to video test point with vertical scope gain set at, or near, maximum. (Horizontal scope sweep set at 400 cycles).

MARKER GENERATOR	ADJUST	PROCEDURE
47.25 MC. 400 Cycles Amp. Mod.	L-1	With signal generator set at maximum output, adjust L-1 for minimum vertical response on scope.

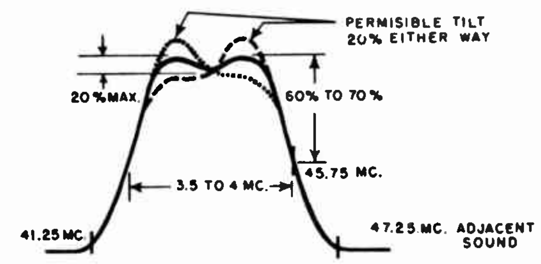
*Sound Carrier Marker
**Picture Carrier Marker

6) Now that all the I.F. coils and transformers have been set, the overall response can be observed and adjusted if necessary.

SIGNAL GENERATOR INPUT CONNECTION	FREQUENCY SWEEP	FREQUENCY MARKER	MEASURING INSTRUMENT	ADJUST	PROCEDURE
Connect terminated sweep and marker as shown in Fig. 8	Center frequency 44 MC. 10 MC. Sweep	45.75 MC.	Scope connected to Video Test Point low side to chassis	T-4	If 45.75 MC. doesn't lie from 60 to 70% down adjust T-4 (see fig. 7) for tolerances. *

Providing overall curve is within tolerances as shown below, no further adjustments are needed. If band width or tilt is not as specified, repeat entire alignment procedure. If still out then a slight retouching is permissible. TRAPS L-1 and L-2 MUST BE ADJUSTED AS INDICATED ABOVE. DO NOT RE-ADJUST WHILE OBSERVING OVERALL I.F. RESPONSE CURVE.

*KEEP OUTPUT OF SIGNAL GENERATOR AS LOW AS POSSIBLE WHEN OBSERVING THE OVERALL I.F. SHAPE SINCE TUBE OVERLOAD MIGHT RESULT AND THE RESPONSE WILL APPEAR INCORRECTLY FLAT AND WIDE.



NOTE: It may be impossible to observe the 47.25 MC. marker with the average service equipment due to the high attenuation of trap L-1 (adjacent sound).

Figure 7. OVERALL I.F. RESPONSE CURVE

All instrument leads should be dressed as shown and kept as short as possible to prevent interaction between input and output leads. Failure to do this may result in an unstable response indication.

NOTE: It is important that the output cable of the sweep and marker generator be properly terminated in their characteristic impedance which is usually from 50 to 75 ohms. If this termination has not been built into the end of the cable by the instrument manufacturer * then a resistor of the proper value (characteristic impedance) should be connected across the output of each generator cable as shown above.

*If in doubt check your instruction book which is issued by the test equipment manufacturer.

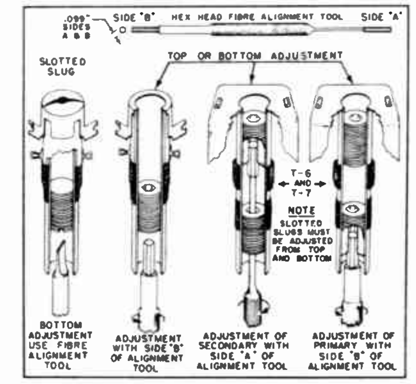


FIGURE 8A

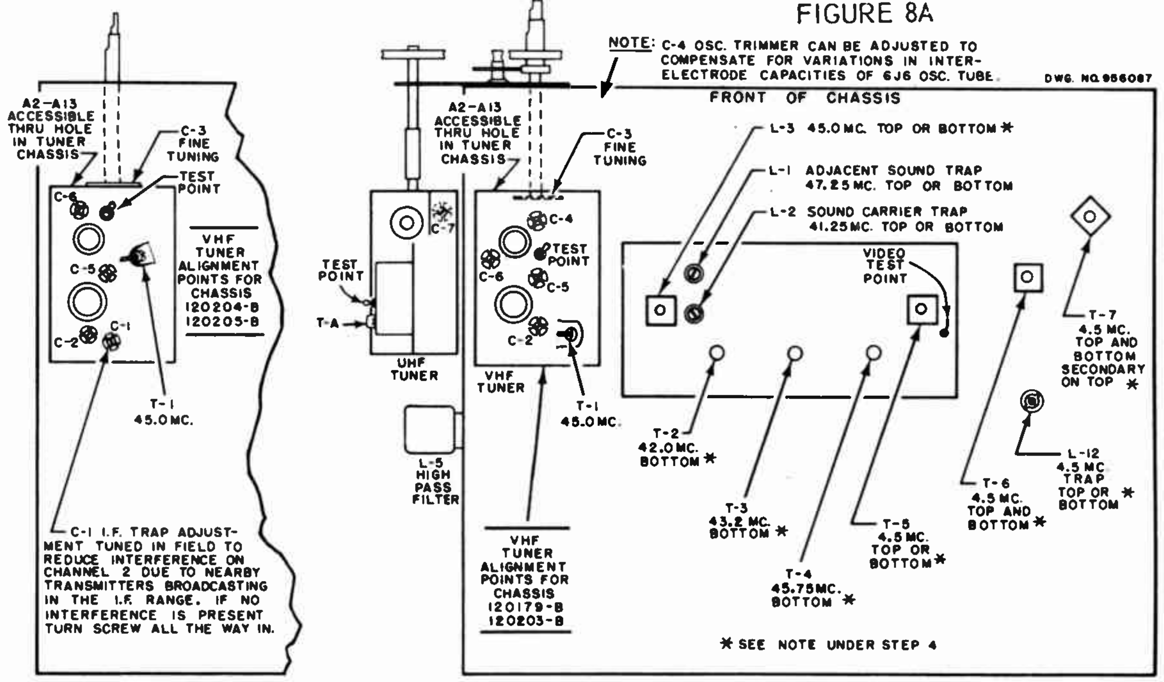

Figure 9. LOCATION OF ALIGNMENT POINTS (TOP VIEW)

R.F. OSCILLATOR ALIGNMENT (V.H.F.)

1. Connect maker and sweep generator as shown in Figure 5, low side to chassis.
2. Connect scope to junction L-8, R-22, low side to chassis or video test point.
3. Connect 3 volt bias battery as described under R.F. alignment
4. Before undertaking oscillator alignment be sure I.F. circuits are correctly aligned for band pass characteristic and trap settings.
5. During oscillator alignment, it is necessary to set the fine tuning control so that the tooth on the fine tuning cam points downward. On the 470712 tuner the flat of the fine tuning shaft should point downward with respect to the bottom of the chassis.

MARKER SIGNAL GENERATOR FREQUENCY	SWEEP GENERATOR FREQUENCY	MISCELLANEOUS INSTRUCTIONS	TRIMMER OR SLUG	TYPE OF ADJUSTMENT AND OUTPUT INDICATION
*209.75 MC. **205.25 MC.	Channel #12 Center Frequency 207 MC. 10 MC. Sweep	Be sure that fine tuning control has been properly positioned (tooth on the cam pointing down) NOTE During this step and thru-out all succeeding steps it is necessary to: 1. Keep output of sweep generator at a level that does not allow the reading on a VTVM to exceed minus 1 volt when connected across video detector load at minimum sweep width. 2. Keep output of standard signal generator at a level that provides a readable marker but does not distort the curve that is being observed on the scope.	Adjust Slug A-12	NOTE: Before making the following adjustment, advance the vertical gain control on the scope in order to magnify the sound trap portion of the response curve. Then, use a non-metallic screwdriver to adjust channel #12 oscillator slug (accessible thru hole on front of r-f tuner unit) and shift response curve so that sound carrier marker is located at the position indicated below. Now reduce gain control setting of scope to restore pattern to normal amplitude and observe position of picture carrier marker. This marker should appear on the high frequency side of the characteristic curve. The amplitude of the picture carrier should be between 60 and 70% down from peak response.
*215.75 MC. **211.25 MC.	Channel #13 213 MC.	Set Channel Selector to #13 (See note above)	Adjust the r-f sweep generator and marker generator for operation on other television channels; set marker generator to sound carrier frequency. After setting Channel Selector to corresponding channel, adjust oscillator slug thru hole on front of r-f tuner unit. (A-2 to A-13) This permits response curve to be shifted so that sound carrier marker will appear at the position indicated below.	
*203.75 MC. **199.25 MC.	Channel #11 201 MC.	Set Channel Selector to #11 (See note above)		
*197.75 MC. **193.25 MC.	Channel #10 195 MC.	Set Channel Selector to #10 (See note above)		
*191.75 MC. **187.25 MC.	Channel #9 189 MC.	Set Channel Selector to #9 (See note above)		
*185.75 MC. **181.25 MC.	Channel #8 183 MC.	Set Channel Selector to #8 (See note above)	 TYPICAL OVERALL RESPONSE CURVE	
*179.75 MC. **175.25 MC.	Channel #7 177 MC.	Set Channel Selector to #7 (See note above)		
* 87.75 MC. ** 83.25 MC.	Channel #6 85 MC.	Set Channel Selector to #6 (See note above)		
* 81.75 MC. ** 77.25 MC.	Channel #5 79 MC.	Set Channel Selector to #5 (See note above)		
* 71.75 MC. ** 67.25 MC.	Channel #4 69 MC.	Set Channel Selector to #4 (See note above)		
* 65.75 MC. ** 61.25 MC.	Channel #3 63 MC.	Set Channel Selector to #3 (See note above)		
* 59.75 MC. ** 55.25 MC.	Channel #2 57 MC.	Set Channel Selector to #2 (See note above)	NOTE: Make sure that cam on fine tuning control shaft remains properly positioned during this step (tooth on the cam pointing downward).	

NOTE: If an unsatisfactory overall response is obtained for a particular channel, observe R-F amp. and Mixer response curve for that channel (as described in R-F Amp. and Mixer Alignment Table). If characteristic curve does not conform reasonably well within the typical curve shown in Figure 6, then do the following things:

1. Check method of connecting scope, voltmeter and generator leads to eliminate possible distortion of observed response, or:
2. Attempt to obtain a better compromise for R.F. response on all channels by realigning R-F Amp. and Mixer circuits, or:
3. Try replacing Antenna, R-F and Oscillator coils for the particular channel.

*Sound Carrier Marker
**Picture Carrier Marker

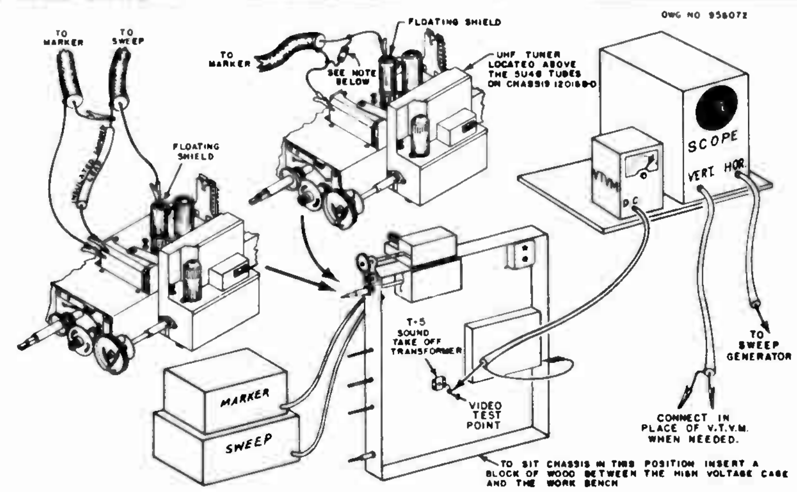

Figure 8. CONNECTIONS FOR I.F. ALIGNMENT

SOUND ALIGNMENT

(A) USING 4.5 mc UNMODULATED SIGNAL GENERATOR

1) Short pin #1 of V-3 Chassis with short jumper wire.
2) Keep output of signal generator low so as to provide a sharp meter indication with adjustment of transformers.

(B) USING TRANSMITTED TV AIR SIGNAL

1) Connect antenna and tune to a good on the air TV station.
2) Adjust fine tuning control for best picture.
3) Adjust antenna coupling for moderate signal so as to provide a sharp meter indication with adjustment of transformers.
4) Meter reading may pulsate due to changes in signal strength; do not confuse with a peak adjustment.

STEP	SIGNAL GENERATOR INPUT		MEASURING INSTRUMENT	ADJUST	PROCEDURE
	CONNECTION	FREQUENCY			
1	Marker Gen. through .01 MF to Pin 7 of V-4 low side to chassis. - or - Connect antenna and tune in a good transmitted TV. signal (any channel)	4.5 MC (Unmodulated) - or - A good on the air TV. channel	Conntec D.C. V.T.V.M. (negative scale) through 10K Resistor to Junction of C-30, R-35, R-36 – low side to chassis.	T-5 Top or Bottom T-6 Top and Bottom	Peak for maximum voltage. Adjust output of signal generator to produce about a one volt D.C. rise on meter (1 volt above noise* voltage) If T.V. signal is used adjust ant. coupling to receiver to produce about the same voltage rise.
2	Same as above.	Same as above.	Connect V.T.V.M. through 10K Resistor to Junction of R-44, C-34 – low side to chassis.	T-7 Top and Bottom (Discriminator on top)	A) Detune Discriminator secondary T-7 for maximum negative meter reading. B) Adjust primary T-7 for maximum negative meter reading. C) Readjust Discriminator secondary (towards original setting) for zero D.C. reading on V.T.V.M. D) Check Audio, if distorted repeat steps A – C.

* The noise voltage is measured under no signal conditions (antenna terminals shorted directly at tuner by means of a short jumper wire; or disconnect 4.5 MC. generator if procedure (A) above is followed.)

4.5 MC VIDEO TRAP ALIGNMENT (L-12)

1. Connect crystal controlled 4.5 mc. signal generator through a .01 mf. condenser to the grid of the video amplifier tube (Pin 1 of V-5, 6CB6) low side to chassis.
2. Set contrast control for maximum contrast (fully clockwise).
3. Connect a V.T.V.M. (D.C. scale) through an R.F. probe to the cathode of the picture tube (Pin 11, yellow lead) low side to chassis.
4. Adjust the 4.5 mc. trap L-12 for minimum reading on the V.T.V.M.

If a crystal controlled generator is not available the video trap can be adjusted in the field by setting the fine tuning control for maximum 4.5 mc. in picture and adjusting the 4.5 mc. trap (L-12) until this 4.5 mc. beat note is reduced. Be sure that video ringing is not introduced from this adjustment since this indicates the trap was aligned at too low a frequency.

ALIGNMENT (UHF TUNER)

The alignment of the tuner is factory set and will actually not require any additional adjustments other than to compensate for differences in 6J6 oscillator tubes. Because of this fact, the only adjustment to be made in the field is trimmer C-7 which is located next to the 6J6 oscillator tube.

This trimmer is normally set at the factory to track the highest U.H.F. channel (83). This must be done with a U.H.F. sweep and marker generator. In the field however, this equipment is not readily available and C-7 should therefore be used to track the highest U.H.F. channel received in the area. It is usually best to try a few 6J6 tubes until one is found which more nearly resembles the original, thus requiring only a slight adjustment of C-7.

In the event T-A has been tampered with or replaced, it should be adjusted for best results on all U.H.F. channels received in the area. This I.F. sometimes normally has only a slight effect on the picture or sound.

Before doing any work on this U.H.F. tuner, whether in the field or shop, be sure that the V.H.F. I.F. and R.F. circuits have been properly set up, (this can be checked by viewing an on the air V.H.F. channel or by instruments).

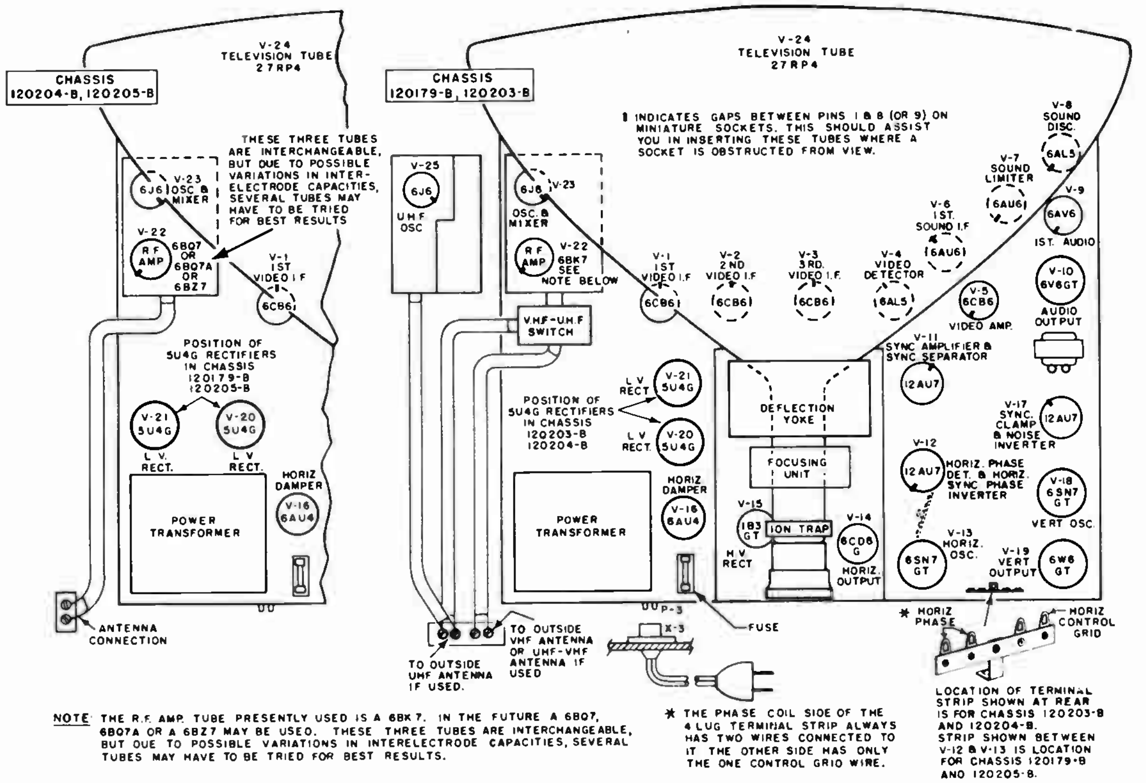

Figure 11. TUBE LOCATIONS DIAGRAM FOR CHASSIS 120179-B, 120203-B, 120204-B, 120205-B

TUBE TROUBLE ANALYSIS CHART FOR CHASSIS 120179-B 120203-B, 120204-B, 120205-B

Insufficient vertical size, or white horizontal bar in picture, horizontal size OK - - - - - - - - - - UHF and or VHF	V-19
No sound, no raster - tubes lit - - - - - - - - - - - - UHF and or VHF	Fuse, V-20, V-21
No sound, no raster - tubes not lit - - - - - - - - - - UHF and or VHF	Plug connection in wall socket, ON-OFF switch, line cord.

By raster we mean the illuminated scanning lines.

* Another very common fault is a shorted or open circuit antenna connection to set.

** Some 120179-B chassis used two 6AX4GT tubes (V-16, V-26) instead of one 6AU4G (V-16).

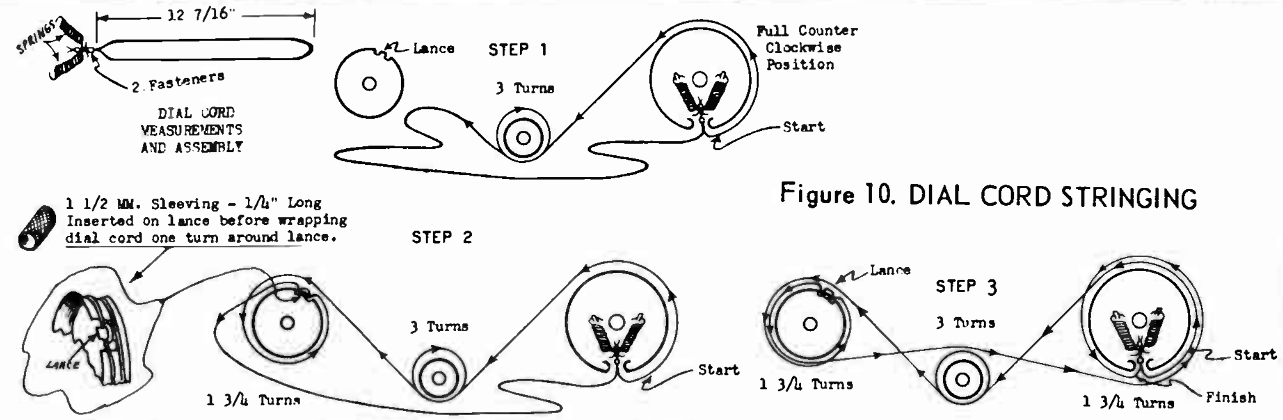

Figure 10. DIAL CORD STRINGING

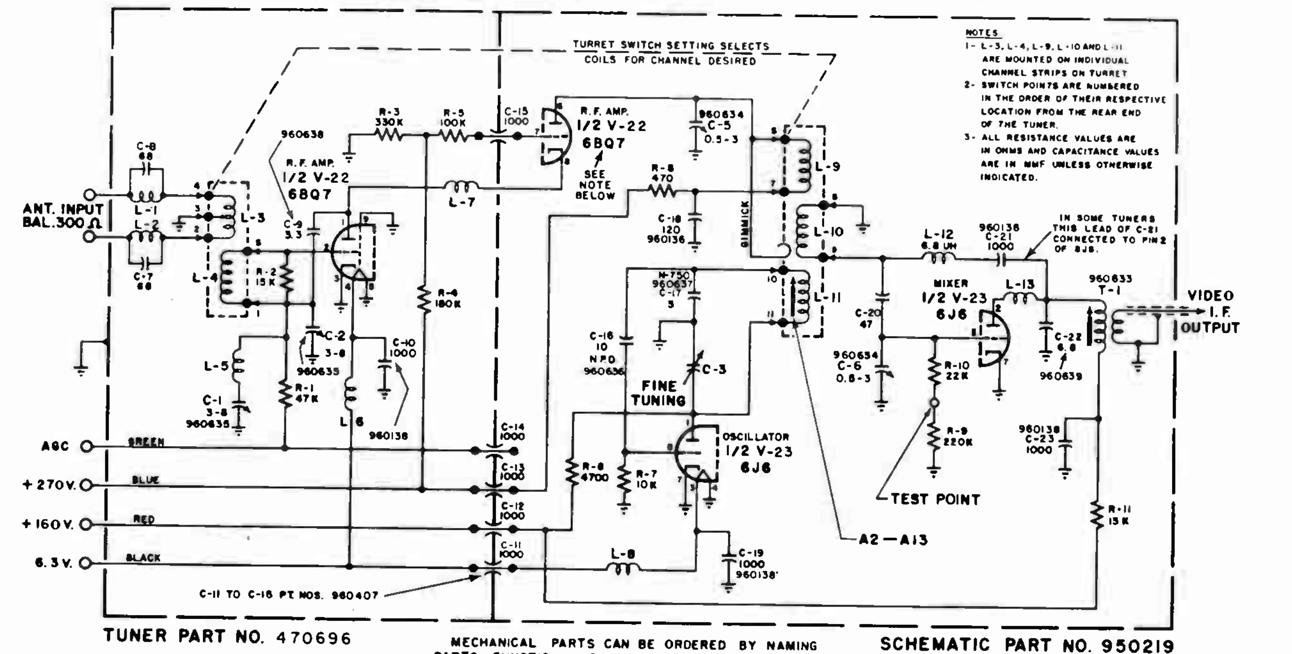

NOTE: THE R.F. AMP. TUBE PRESENTLY USED IS A 6BQ7. IN THE FUTURE A 6BQ7, 6BQ7A OR A 6BZ7 MAY BE USED. THESE THREE TUBES ARE INTERCHANGEABLE, BUT DUE TO POSSIBLE VARIATIONS IN INTERELECTRODE CAPACITIES, SEVERAL TUBES MAY HAVE TO BE TRIED FOR BEST RESULTS.

Figure 12. SCHEMATIC DIAGRAM OF TURRET TYPE TUNER USED ON VHF CHASSIS 120204-B, 120205-B

REPAIR OF VHF TUNER

The majority of tuner troubles which are not due to defective tubes can usually be detected by a physical examination of the tuner (turret removed), such as burnt resistors, broken parts, bent or dirty contact fingers, cold solder joints, broken socket pins, etc.

If the tuner checks out physically it should then be checked according to the following trouble shooting chart.

It should always be borne in mind that a burnt resistor is usually the result of a shorted condenser or tube.

The part numbers of items which are not generally commercially available are given on the tuner schematic. When replacing parts, leads should be kept as short as possible and components replaced in the same position as the original parts.

More detailed general information on turret tuner repairs can be found in Service Note titled "Emerson Turret Type Tuner #470651" released April 1, 1951.

TUNER TROUBLE SHOOTING CHART

Measurements taken under same conditions as listed   To take measurements from 6BQ7 socket, remove 6BQ7 tube but leave 6J6 tube in its socket, likewise when taking measurements from the 6J6 socket leave 6BQ7 tube in its socket.

V-22	PIN NO.	NORMAL READINGS		POSSIBLE TROUBLES IF READINGS NOT NORMAL
		VOLTAGE	RESISTANCE

	Pin 7	OV.	0 ^	Cold solder joint
	Test Point	−1 V. to −4 V.	210K	Oscillator injection voltage varies between channels (low frequency channels have higher injection voltage about −4 v.)

GENERAL TROUBLE SHOOTING INFORMATION (UHF TUNER)

Since the operation of this tuner is dependent almost entirely on its mechanical configuration, all component parts whether lumped constants or transmission line sections, have been manufactured and mounted as rigid as possible. If it is necessary to replace a component, the exact replacement part should be used. Be sure it is mounted in the same position using the same lead lengths as the original. This is very important since at UHF frequencies a small piece of wire has an appreciable inductance. Stray capacitances between components and chassis also tend to effect the circuit's operation to a marked degree.

Due to the simplicity of design and manufacture of this tuner, little trouble is to be expected. In the event that this tuner becomes defective in any way, the trouble shooting chart in this note can be used to good advantage.

If the crystal D-2 is open or shorted, or the oscillator is inoperative, there will be no bias developed across R-2. If replacing D-2 does not rectify this condition, then it can be assumed that the oscillator is not functioning.

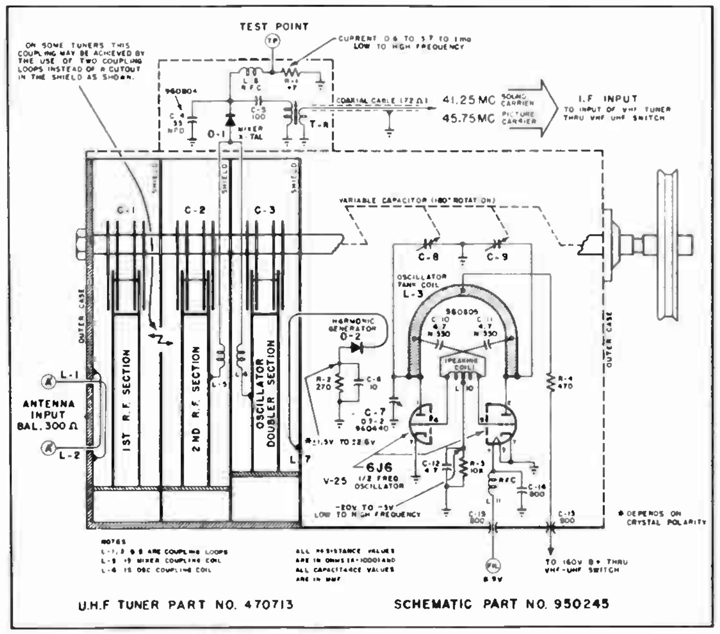

Figure 13 – SCHEMATIC DIAGRAM UHF TUNER 470713

Be sure that the harmonic generator coupling loop (L-7) is not touching the shield. A voltage and resistance check of the 6J6 oscillator circuit should soon locate the trouble.

If the correct bias is measured across the resistor R-2 and the set still operates poorly on UHF, then it can be assumed that the mixer crystal D-1 is defective in some way. This can easily be determined by lifting R-1 off chassis and inserting a D.C. milliameter between it and chassis. In the event that the current readings are abnormally low or high, a new crystal known to be good should be inserted (see trouble shooting chart). If it is desired to localize the difficulty further, C-4 and, or C-5 can be disconnected. When soldering near crystals, be sure to use a small tipped, low wattage iron, placing the pliers between the crystal and the connection so as to absorb the heat thus protecting the crystal. This is important, since excessive heat can easily damage it.

Do not attempt to repair or adjust this tuner by adjusting any of the coupling loops or by moving various components. The only adjustment that can be made in the field is C-7 to compensate for a change in interelectrode capacities when a new 6J6 is used. The proper procedure for this is shown under alignment

Components which are not a part of the R.F. or oscillator tuned circuits such as feed thru condensers, B plus resistors, T-A, etc., can usually be replaced with little difficulty providing the above precautions are observed.

NOTE: In the event that this tuner needs an overall alignment or service of parts, the defective tuner should be returned for repairs through your Emerson distributor.

REPLACEMENT OF TUNERS (UHF - VHF CHASSIS)

If it becomes necessary to return a UHF tuner to your distributor for repair or replacement, remove and retain the extension shaft and pulley. When returning the VHF tuner, remove and retain the VHF-UHF switch and the front plate which consists of a pulley and gear combination. This is important since replacement tuners will not come equipped with the above devices.

Under no conditions are both the VHF and UHF tuners to be returned as a unit. Before returning for replacement or repair, an honest effort should be made to repair the unit since all special and major parts will be available through your Emerson distributor.

TROUBLE SHOOTING CHART (UHF TUNER)

Component		Variations Low to High Frequency	POSSIBLE TROUBLE (If voltage readings not normal)
6J6	B+ Filament R-3	+160V. 6.3V. A.C -20V. to -3V.	C-10, C-15, C-11 shorted, the V.H.F.-U.H.F. switch L-11 open, C-14, C-13 shorted R-3 open, C-12 shorted, L-10 open or shorted
D-2 Harmonic Gen. Crystal	R-2	-1.5V. to -2.6V.	Crystal defective, C-6 shorted Voltage polarity depends upon crystal polarity
D-1 Mixer Crystal	Current thru R-1 Insert Milliameter	0.6 thru 3.7 to 1.00 ma. (current)	D-1 defective, C-4 shorted, L-8 open

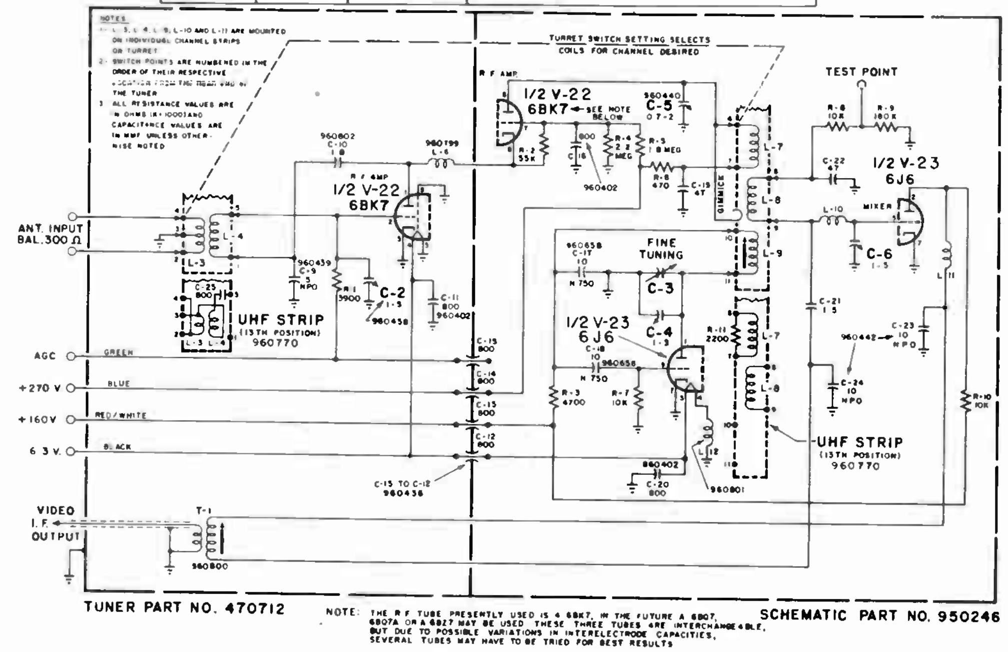

Figure 14. SCHEMATIC DIAGRAM OF VHF TUNER 470712 USED ON UHF-VHF CHASSIS 120179-B, 120203-B

REPAIR OF TUNER

The majority of tuner troubles which are not due to defective tubes can usually be detected by a physical examination of the tuner (turret removed), such as burnt resistors, broken parts, bent or dirty contact fingers, cold solder joints, broken socket pins, etc.

If the tuner checks out physically it should then be checked according to the following trouble shooting chart.

It should always be borne in mind that a burnt tuner resistor is usually the result of a shorted condenser or tube.

The part numbers of items which are not generally commercially available are given on the tuner schematic. When replacing parts, leads should be kept as short as possible and components replaced in the same position as the original parts.

TUNER TROUBLE SHOOTING CHART

Measurements taken under same conditions as listed To take measurements from 6BK7 socket, remove 6BK7 tube but leave 6J6 tube in its socket. likewise when taking measurements from the 6J6 socket leave 6BK7 tube in its socket. VHF tuner switched to any channel except UHF position.

		VOLTAGE	RESISTANCE	
6BK7 or 6BQ7 or 6BQ7A or 6BZ7	Pin 1	105V	2 meg.	(C-9, 3.3 mmf) shorted
	Pin 2	−.4V.	1.6 meg.	(R-2, 15K) or (R-1, 47K) open or shorted
	Pin 3	OV.	0 ^	Cold solder joint
	Pin 6	+270V.	24K	(C-5) trimmer shorted, (C-18, C-13) shorted, (L-9)open, (R-8, 470 ohm) open or shorted
	Pin 7	+142V.	1.6 meg.	(R-3, 330 K),(R-4, 180 K) or (R-5, 100 K) open or shorted, (C-15, 1000 mmf) shorted
	Pin 8	+142V..	1.6 meg.	(C-9, 3.3 mmf) shorted
	Pin 9	OV.	0 ^	Cold solder joint

V-23	PIN NO.	NORMAL READINGS		POSSIBLE TROUBLES IF READINGS NOT NORMAL
		VOLTAGE	RESISTANCE	
6J6	Pin 1	+160V.	17K	(R-6, 4700 ohm) open or shorted, (C-12, 1000 mmf), (C-16, 10 mmf) or (C-17, 5 mmf) shorted
	Pin 2	+160V.	25K	(L-13) open, (C-21, 1000 mmf), (C-22, 6.8 mmf) or (C-23, 1000 mmf) shorted, (R-11, 15 K) open or shorted
	Pin 5	OV.	200 K	
	Pin 6	OV.	10 K	(C-16, 10 MMF) shorted
	Pin 7	OV.	0 ^	Cold solder joint
	Test Point	−.5V. to −3.5V.	180 K	Oscillator injection voltage varies between channels (low frequency channels have higher injection voltage about −4 v.)

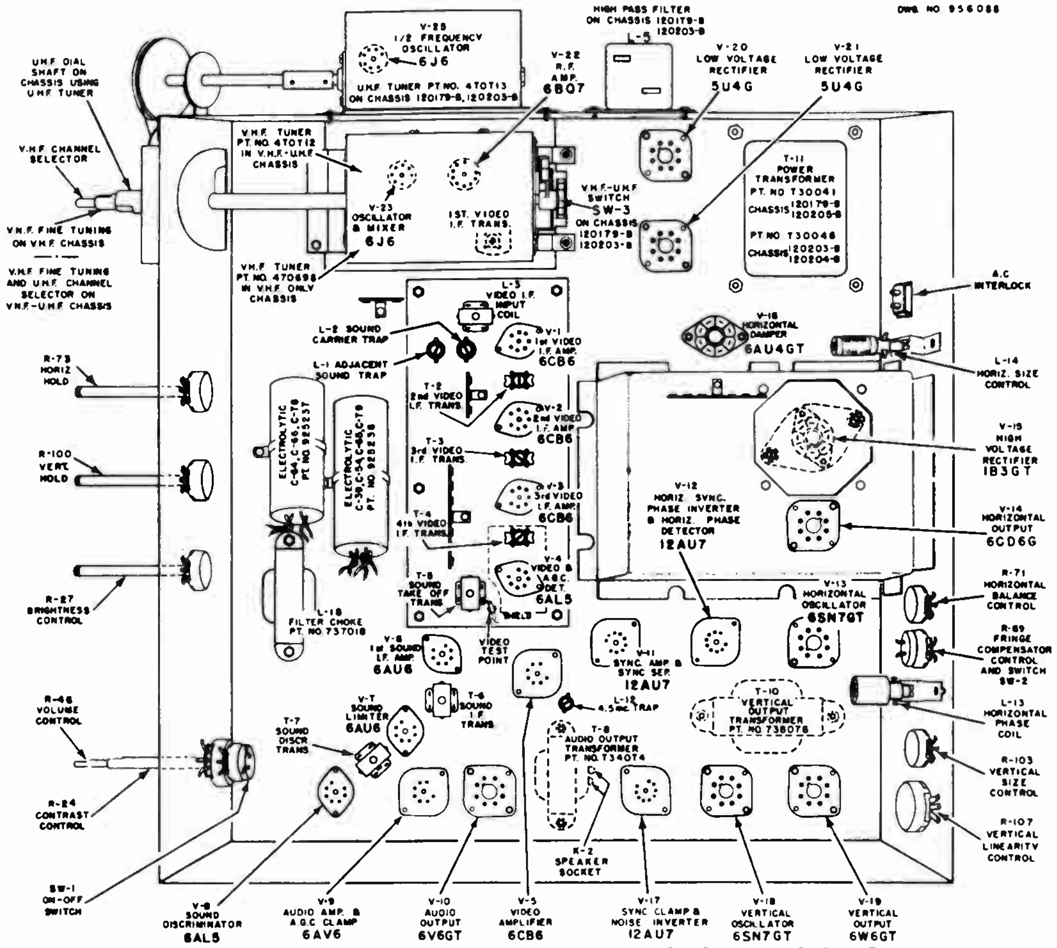

Figure 16. UNDERSIDE VIEW OF CHASSIS. 120179-B & 120205-B

NOTE: UNDERSIDE VIEW OF CHASSIS 120203-B & 120204-B THE SAME AS ABOVE EXCEPT FOR LOCATIONS OF 5U4G RECTIFIER TUBES

PRODUCTION CHANGES

In the course of production various changes were incorporated in the order shown below. Changes as listed under a particular letter also include changes as listed under all previous letters unless otherwise noted. All changes released after this note is printed will be sent out to our distributors in the form of field service bulletins. These should be kept together with the service note for future reference. By utilizing this information the schematic can be easily modified to correspond to a chassis of any triangle code.

1. The wattage of resistors R-108 (470 ohms) and R-110 (33,000 ohm) have increased from 1/2 watt to 1 watt to prevent these resistors from overloading at extreme settings of the vertical size and linearity controls. Chassis incorporating this change are coded as follows.
   120179-B △A 120203-B, 120204-B, 120205-B – Initial Production

2. For standardization purposes the two 6AX4GT damper tubes (V-16, V-26) have been replaced with a single 6AU4GT damper tube (V-16). Chassis incorporating this change are coded as follows.
   120179-B △B 120203-B, 120204-B, 120205-B – Initial Production

3. Due to component variations it was found necessary to change R-74 from 330K to 390K 1/2 watt in order to eliminate an overdrive bar that has developed (white vertical line in raster).
   At the same time a 100mmf 4kv. condenser (pt. No. 928114) was added between terminals 4 and 8 of the horizontal output transformer to increase width for low line voltage operation. Chassis incorporating these changes are coded as follows.
   120179-B △C 120203-B, 120204-B – Initial Production 120205-B △B

NOTE: Triangle △A on the 120205-B chassis signifies the use of a 27RP4 picture tube instead of a 27EP4. Since the 27RP4 has an acquadag coating it forms it's own Hi-voltage filter condenser and as a result C-61 (500 mmf, 30kv.) and R-84 (100K, 1 watt) are omitted. The 27RP4 is used on the 120203-B and 120204-B chassis.

4. C-38 .0047 mf condenser has been increased from 400 to 600 volts to reduce the possibility of failure in the event the set is operated with the speaker disconnected. Chassis incorporating this change are coded as follows.
   120203-B △A 120204-B △A

5. R-105 has been changed from 1 meg to 1.5 meg to center the range of the vertical size control. Chassis incorporating this change are coded as follows.
   120203-B △B 120204-B △B

CONDITIONS FOR TAKING VOLTAGE AND RESISTANCE READINGS

The voltage and resistance measurements listed were taken on chassis 120205-B, coded with a triangle. △A

Due to component variations, voltage and resistance readings may vary slightly from those given here. Slight variations may also be noticed if chassis is not coded as mentioned above. Slight variations may be noticed on chassis 120179-B, 120203-B & 120204-B due to difference in coding for same triangle change.

The deflection yoke and high voltage circuits were connected to take the following readings and waveshapes.

1. Antenna disconnected and antenna terminals shorted on tuner and connected to chassis (use short leads).
2. Line voltage 117 volts (Disconnect power for resistance readings).
3. 3 volt bias battery connected to A.G.C. circuit, positive terminal to chassis, negative terminal to junction of R-10, C-8, R-16 BIAS BATTERY USED FOR VOLTAGE READINGS ONLY.
4. All controls in position for normal picture. (Varied when it directly effects reading).
5. All measurements taken with a vacuum tube voltmeter and ohmmeter.
6. All readings listed in tables were taken between points shown and chassis.
7. Resistance readings are given in ohms unless otherwise noted.
8. N.C. denotes no connection.

WAVE SHAPE ANALYSIS CHART

The waveshapes shown were taken on chassis 120205-B coded triangle. △A

Slight peak to peak voltage differences may be noticed on chassis of later triangle codes.

When taking waveshapes on chassis 120179-B, 120203-B and 120204-B bear in mind that a slight peak to peak variations are possible due to differences in chassis coding for the same change. See Production changes for further information.

The peak to peak voltage given may also vary slightly depending on signal strength and component variations.

To accurately observe the wave shapes, the relatively high input capacity of an oscilloscope must be reduced so as not to change the operating characteristics of the television set. Failure to do this will result in wrong wave shape readings. This is accomplished by using an Emerson low capacity probe as outlined previously in the service note for models 686L, 687L, and 696L using chassis 120142-B which was issued at an earlier date.

1. Connect antenna and tune receiver to channel where best reception has been obtained in the past.
2. Low end of the probe is connected to CHASSIS and the contrast control is set at MAXIMUM CONTRAST.
3. The 30 and 7875 C.P.S. oscilloscope sweep settings are used so as to permit the serviceman to observe two cycles of the wave shape.

NOTE: A wave shape seen in your oscilloscope may be upside down from same wave shape shown here. This will depend on the number of stages of amplification in the oscilloscope used.

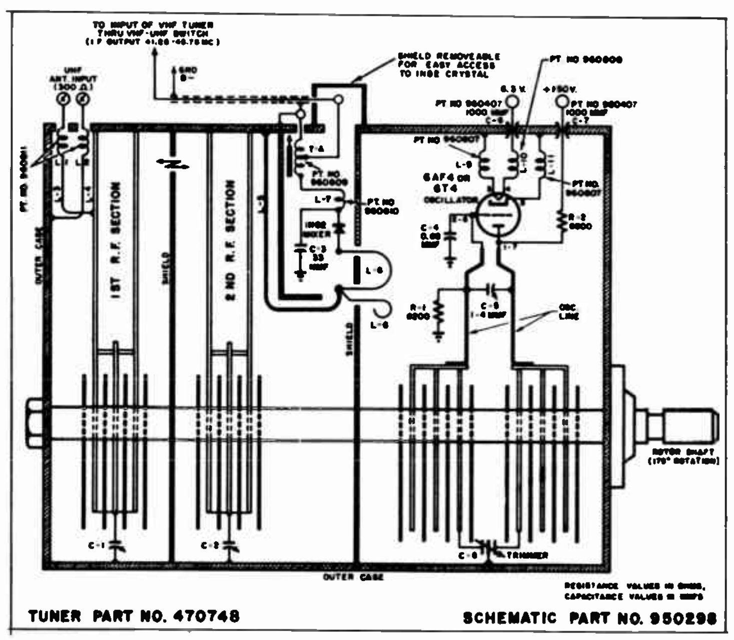
ALL CHANNEL TURRET TYPE
DETENT TUNER
PT. NO. 470738

GENERAL DESCRIPTION

The all-channel tuner is the combination of a VHF tuner and a UHF tuner in a single assembly. Three concentric shafts are brought out to a group of three knobs for simplified tuning. (See Fig. #4)

The rear section of the assembly contains a conventional VHF cascode turret tuner having twelve detent positions. This turret connects to the inner shaft (A) which passes through the UHF tuner section to the front and is controlled by the VHF and UHF unit channel selector knob. The VHF tuner contains an I. F. strip which is actuated by a cam on the rear of the UHF turret. This strip is automatically inserted for UHF reception and converts the VHF tuner into a two stage low noise cascode I. F. amplifier for additional amplification. Fine tuning, controlled by the fine tuning knob (C) is obtained by varying the amount of dielectric between capacitor plates of the VHF oscillator.

The UHF tuner located in front of the VHF section consists of a turret with nine detent positions. It is connected to the middle shaft (B) and controlled by the UHF channel selector knob. One position (VHF) disengages the I. F. strip within the VHF tuner to allow for normal reception of VHF channels 2 to 13. The other eight positions cover all UHF channels in eight major groups by means of a separate coil strip for each group. Each coil strip is further tuned for individual channels within the group by variable dielectric type condensers which are part of each tuned circuit. This inter-group tuning is accomplished in detented steps by turning the inner shaft. (See Fig. #5) Fine tuning controlled by the fine tuning knob is obtained by varying the amount of dielectric between capacitor plates of the UHF oscillator.



SCHEMATIC DIAGRAM OF TUNER #470748
USED IN CHASSIS 120211-F

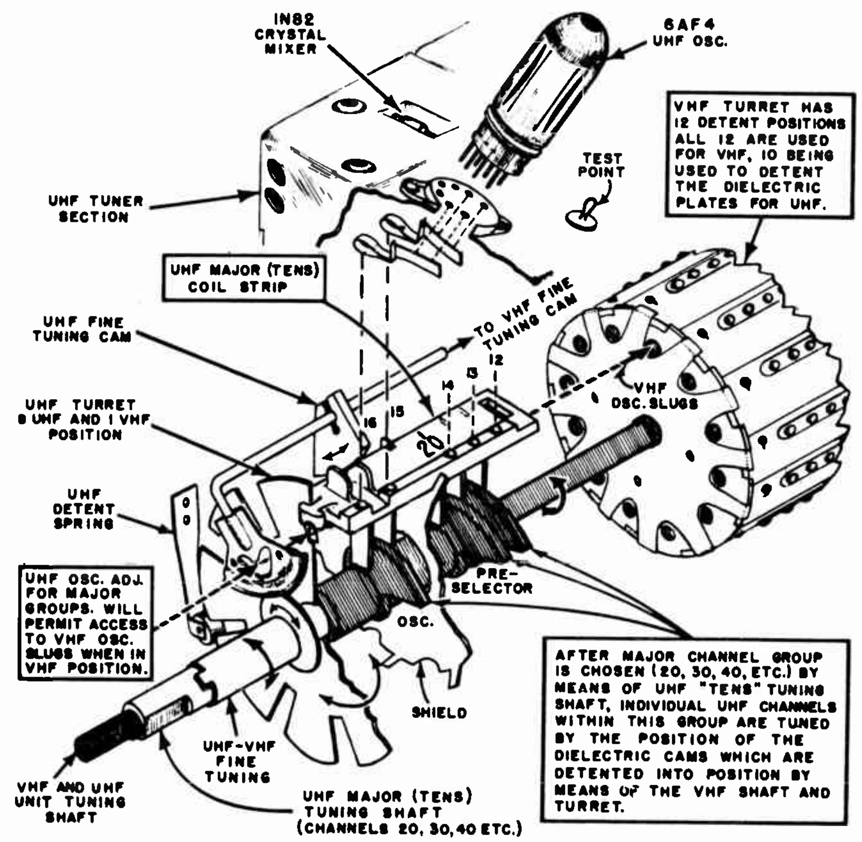

FIGURE 5

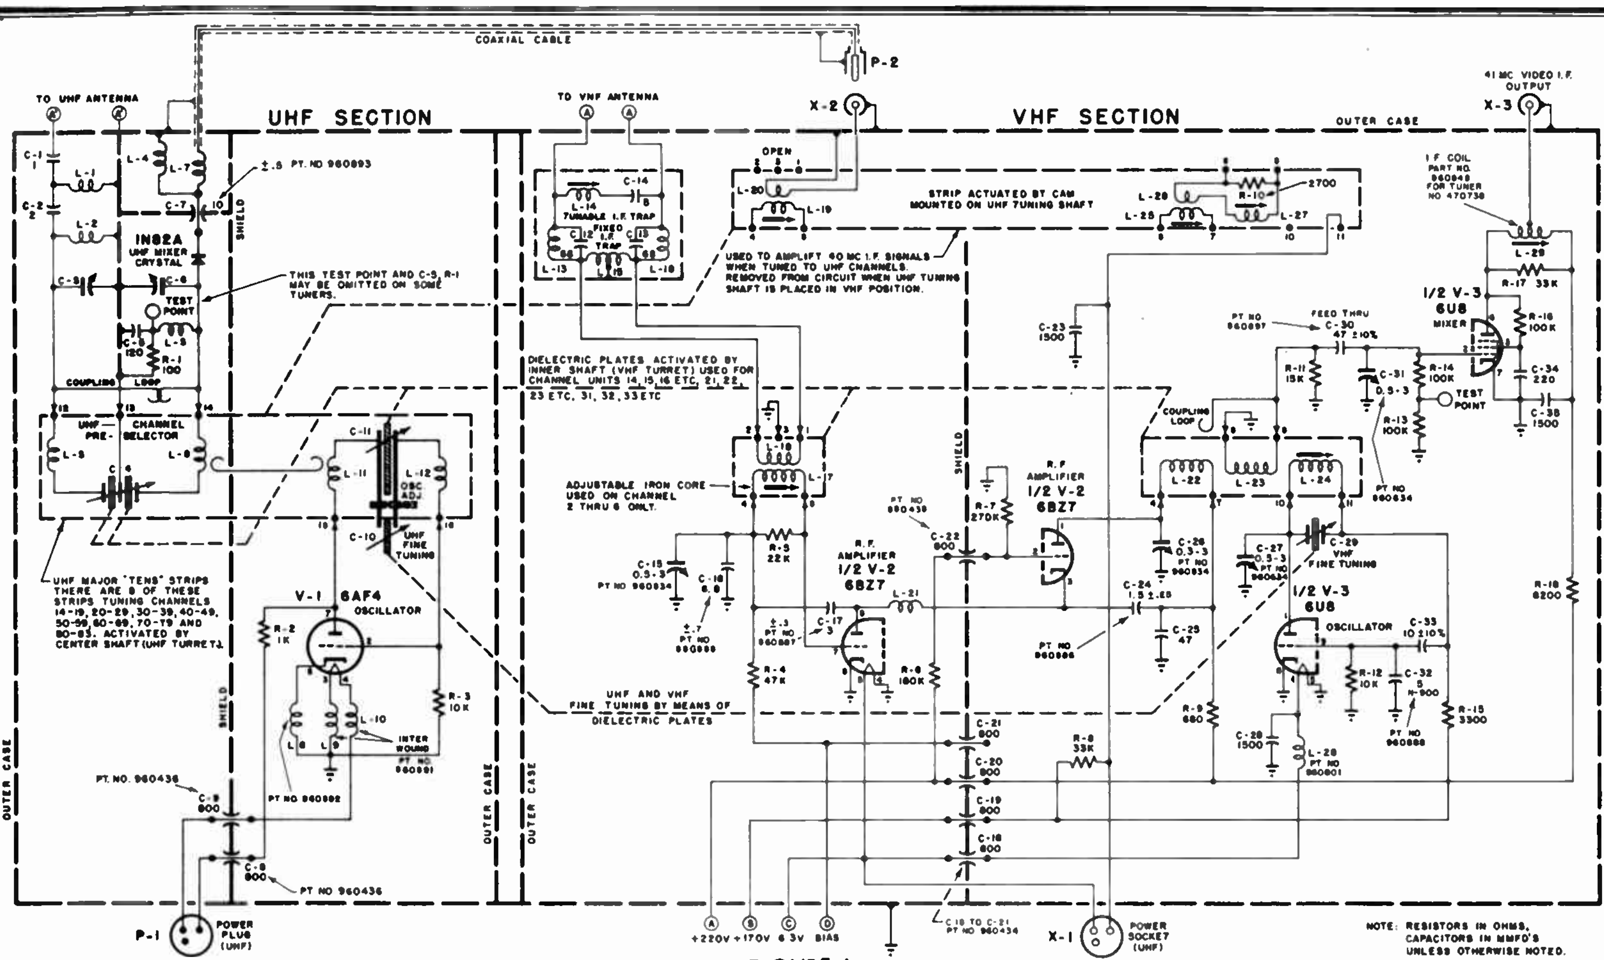
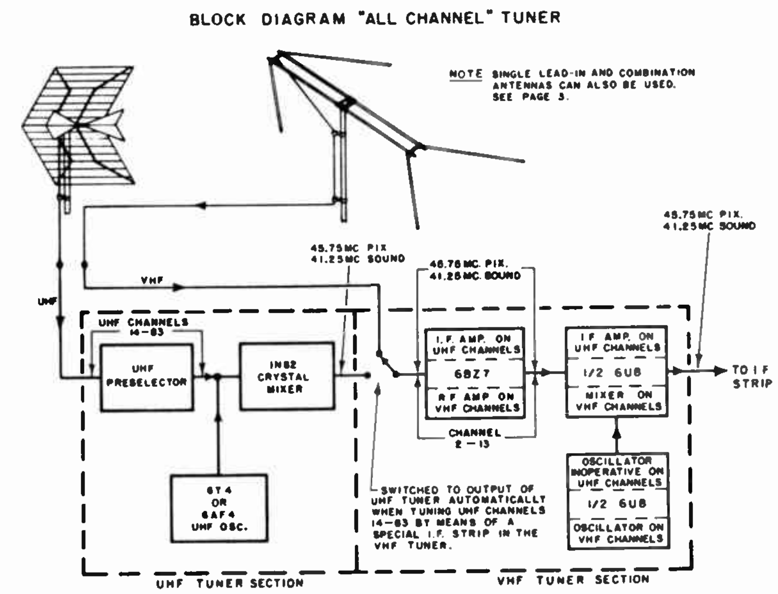


TUNER PART NO. 470738 FIGURE 6 SCHEMATIC PART NO. 950269



TUNER TROUBLE SHOOTING CHART

The voltages listed were taken with B+ inputs of 220 volts, 170 volts and a 3 volt AGC battery connected directly to the AGC input of the tuner. A 6.3 volt AC filament source was also provided. Antenna terminals were shorted directly to the tuner chassis using short leads. A VTVM has been used for all voltage and resistance readings. In the event slightly different input voltages are applied to the tuner a proportionate voltage change will occur at the various pin numbers.

Resistance readings are taken with respect to the tuner itself, therefore, disconnect the 220 volt, 170 volt, and AGC input leads from the receiver chassis to the tuner power input board. To assist you in easily localizing a defective component, the resistance has been measured from the pin numbers with respect to three different points (place low side of ohmmeter to proper points). Note: Since readings are taken from the top side of the tube socket, remove only the required tube.

FIELD ALIGNMENT

Field alignment should be restricted primarily to the proper setting up of the VHF and UHF oscillators. We are assuming that the R.F. and I.F. alignment is correct and has not been tampered with. If you know the immediate area is capable of good pictures and the following adjustments do not improve reception, then a more complete shop alignment will probably be necessary (shown on pages 5, 6 and 7).

The adjustment of the VHF oscillator is conventional in that the VHF portion of the 82 channel UHF-VHF tuner is almost identical to our regular cascode VHF turret tuners. To align the VHF oscillator in the field, use an "on the air" channel and with a 9" fibre alignment tool, adjust the VHF oscillator slug through the hole provided in the fine tuning plate and UHF turret for best picture. This should be done for all VHF channels received in the area. Keep fine tuning in center of mechanical range during these adjustments. Note: There is a tunable I.F. trap (L-14) on this tuner which can be adjusted in the field if necessary to reduce interference due to nearby transmitters which may be operating in the I.F. range.

The UHF oscillator can be adjusted in the field on an "on the air" station as follows:

(a) Set proper knobs to desired channel.
(b) Place fine tuning knob to the middle of its range.
(c) With a fibre alignment tool adjust oscillator slug through fine tuning plate and hole in tuner chassis for best picutre.
(d) Repeat steps a, b and c for all other UHF channels. Note: If you receive two UHF channels which use the same UHF major (tens) coil strips (20-29, 30-39, etc.) set the oscillator for the channel closest to the center of the group (14, 24, 34, etc.).

In the event the UHF preselector trimmers (C-3, C-6) have been misadjusted, they can be reset in the field on the weakest UHF channel. This should only be attempted in areas which have a maximum of about 3 UHF channels. Adjust trimmers (C-3, C-6) for maximum contrast with minimum noise (snow). The antenna coupling should be varied if necessary so that there is always a slight amount of snow in the picture during this preselector alignment. These two preselector trimmers are located between the UHF input terminals and the 6AF4 UHF oscillator tube.

If more than one UHF channel is weak or more than 3 are received, field adjustment of these trimmers are not recommended.

SHOP ALIGNMENT INFORMATION

This tuner can be aligned and repaired in the receiver chassis or in a special jig. If a jig is made, it should supply the necessary B+ and filament voltages which are shown on the schematic. If step 2D is performed (alternate procedure to 2B) a regular chassis will have to be used or a jig which has at least one stage of I.F. and a sound trap.

1 - Equipment Needed

(A) Oscilloscope with a vertical sensitivity of at least .05 volts per inch of deflection, (.01 preferred).
(B) UHF sweep (fundamental preferred) with a sweep width of approximately 40 mc. (± 20 mc). Good linearity and flat output necessary. Generator should have at least .1 volts output, (.5 volts preferred).
(C) VHF sweep should have same characteristics as above except that only a 10 mc sweep width is required. This unit should have a 40 mc sweep position available.
(D) I.F. UHF and VHF marker generator. This could be two separate units or a combination. Fundamental operation preferred but not necessary. An output of at least .05 volts is desirable. Accuracy of marker should be at least 0.5%.

2 - Alignment of UHF Tuner Section

(A) UHF R.F. Alignment (preselectors). Turn the set off during this alignment.

1- Remove the plug (P-2) from the VHF tuner. This is the plug which feeds the I.F. output from the UHF tuner into the VHF tuner. Insert a 100 ohm resistor between center conductor and ground of shielded lead (see figure #8). Connect scope across 100 ohm resistor. Note: If a test point is provided on UHF section (see figure #8) merely connect scope across this point.

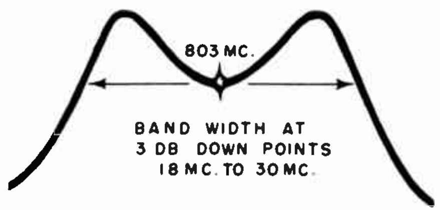
2- Connect unbalanced 300 ohm UHF sweep generator to UHF antenna connections. If 300 ohm generator is not available, match output impedance similar to that shown in figure #8.

3- Turn tuner selector knob to channel 69.

4- Set UHF sweep generator to approximately 803 mc (center of channel 69) with a total sweep width of approximately 40 mc. In the event channel 69 is occupied in your area, use channel 59 for 2A and 2B.

5- Inject market at 803 mc (center of channel 69), as shown in figure #8.

6- Adjust capacitor C-3 and C-6 to obtain an over-coupled pattern with channel 69 marker in the center of the bandpass.



7- Turn the set back on.

(B) Tuner I.F. strip alignment (Rocking Horse). Using separate I.F. and UHF marker generators.

In the event you use a combination marker the alternate procedure (d) should be followed. Note: The complete UHF RF alignment (step 2A) should be attempted first. This insures the proper frequency setting of the UHF sweep generator on channel 69 (or 59) which should not be changed during the following alignment.

1- Remove 100 ohm resistor added in step 2A-1 above, and reconnect shielded lead to VHF tuner.

2- (a) Connect a 3 volt bias battery to tuner AGC and I.F. AGC if tuner is in a regular chassis instead of a jig.

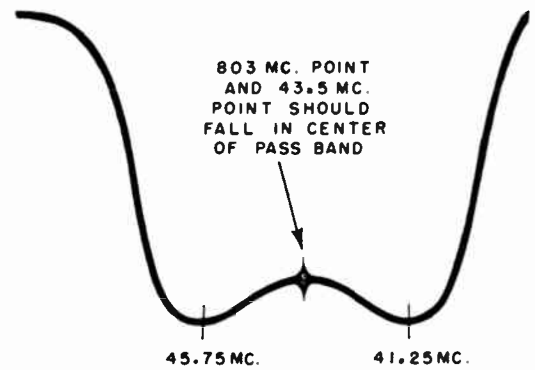
(b) Connect the negative terminal of a 6 volt bias battery to the grid of the horizontal output tube to cut it off (positive terminal to chassis). This will allow for a clear sweep indication.

3- With sweep and UHF market input and setting as in RF alignment above, connect oscilloscope through 10 K resistor to test point on VHF tuner.

4- Inject IF marker 43.5 mc (center of IF band) to the insulation of the shielded lead going from the UHF to VHF section (see figure #9).

5- With the fine tuning at center of its mechanical range adjust oscillator slug (see C-3 below) for zero beat on oscilloscope (set marker and scope gain at or near maximum). Note: In the event the tuner IF strip is completely out of alignment, it might be difficult to get a beat pattern. If this is the case, adjust L-25 a half turn at a time trying then to secure a beat pattern by adjusting the UHF oscillator slug. This beat pattern comes and goes very quickly so adjust slug very slowly keeping scope and marker gains at maximum. It is sometimes easier to observe the two markers on the response curve merely adjusting the UHF oscillator slug so the two markers coincide.

6- Now that the oscillator and sweep generator have been properly set, adjust L-19, L-25 and L-27 in the tuner I.F. strip (rocking horse) to obtain a symmetrical and flat IF bandpass. With I.F. marker connected as shown in Fig. 9, check positions of 41.25 and 45.75 mc markers as indicated in diagram. These coils should be adjusted with a fibre alignment tool. Note: To be sure that the oscillator frequency has been set above and not below the UHF signal the image sweep frequency should be approximately 88 mc higher (803 + 88 = 891 mc). This sweep frequency should cause some response on the oscilloscope providing the UHF sweep generator has sufficient output.



(C) UHF Oscillator Alignment

1- Repeat steps 1, 2 and 3 of section 2B above using channel #14. (Turn knobs to channel 14).

2- Set UHF sweep generator to approximately center of channel #14 (473 mc) and marker generator to 473 mc (sweep and marker connected to UHF input as in RF alignment figure #8).

3- With the fine tuning at center of its mechanical range adjust the oscillator slug from front end of tuner with a fibre alignment tool until an IF pattern is observed with the marker positioned in the center of the IF bandpass.

4- Leaving the fine tuning and generator connections as is, repeat steps 1, 2 and 3 on channels 24, 34, 44, 54, 64, 74 and 80 (frequencies shown in figure #10). Note: As long as channel 69 had a flat response disregard relative tilts of other channels providing it does not exceed about 40%. In the event you want optimum response on a particular weak channel, the UHF preselectors can be set up on that channel.

(D) Alternate Tuner IF Strip Alignment (Rocking Horse)

If only a combination IF, VHF and UHF marker is available, we can make use of the sound trap alignment frequency (41.25 mc) as a reference point. The complete UHF-RF alignment (step A) should be done first. This insures the proper setting of the sweep generator which should not be changed during this tuner IF strip alignment (rocking horse).

1- Make sure the chassis IF circuits have been properly aligned especially with regard to the 41.25 mc sound trap which will be used as a reference.

2- Sweep and marker connected as in UHF RF alignment. Leave sweep frequency unchanged but change marker frequency to sound carrier of channel 69 (805.75 mc) or 59 (745.75 mc).

3- Connect oscilloscope through 10 K resistor to output of video detector. Adjust sweep output and gain of scope for regular IF response curve (do not touch sweep frequency setting).

4- With fine tuning in center of mechanical range, adjust UHF oscillator slug to position 805.75 mc marker in dip of 41.25 mc sound trap.

5- Now that the oscillator is properly set connect scope through 10 K resistor to VHF test point and proceed with step #6 under IF strip alignment (2B).

(B) Connect sweep generator to VHF antenna terminals and connect oscilloscope through 10 K decoupling resistor to VHF test point.

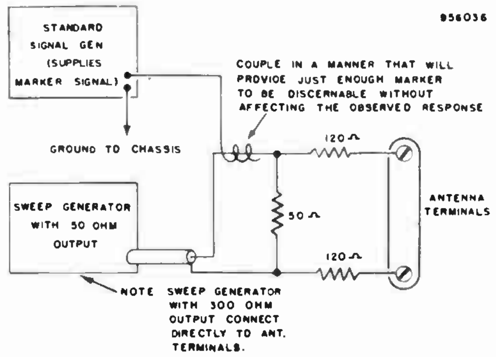
(C) Turn the tuner selector knob to channel 10 or 12 (VHF) whichever is not occupied in area.

(D) Set VHF sweep and marker to center of channel 10 band (195 mc) or 12 band (207 mc).

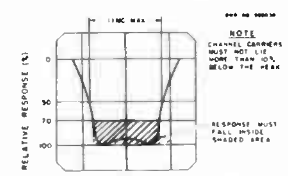
(E) Adjust C-26, C-31 dnd C-15 for response shown. It will be noted that the bandpass characteristics can be broadened by sacrificing amplitude. It is undesirable to overly broaden the curve as this results in a loss of sensitivity.

(F) Adjust oscillator slug from front end of tuner with a long insulated alignment tool to correct frequency. A clearance hole is provided through the UHF unit when the UHF drum is rotated to VHF position.

The individual oscillator slugs can be set up using an "on the air" TV station or by using a marker generator as indicated in any of our current service notes (models 740 - 792). In the event the 6U8 oscillator tube is replaced, the oscillator trimmer C-27 can be readjusted to compensate for any variations in the tubes interelectrode capacities.



GENERATOR CONNECTIONS FOR VHF R.F. CHANNEL ALIGNMENT.



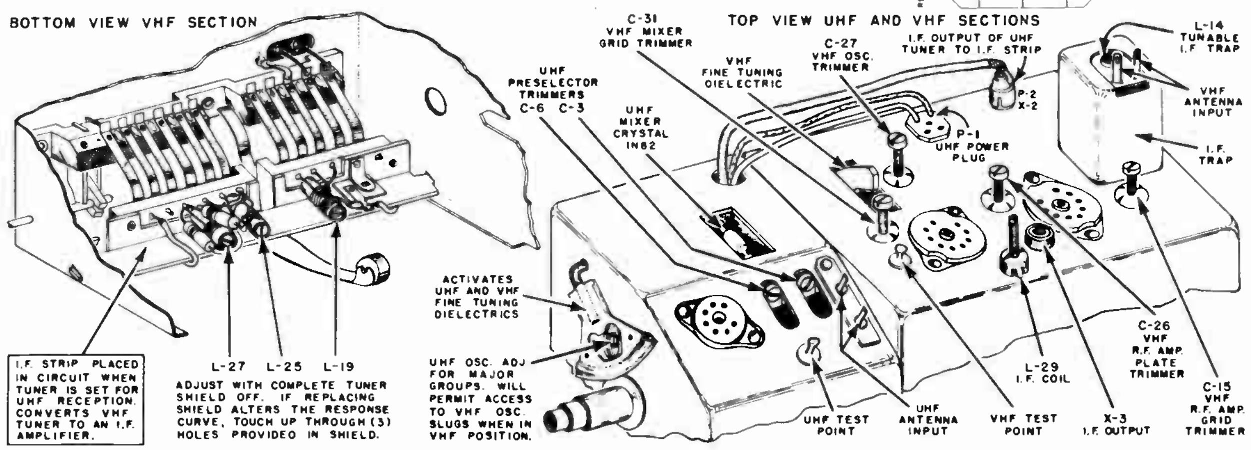


FIGURE 7

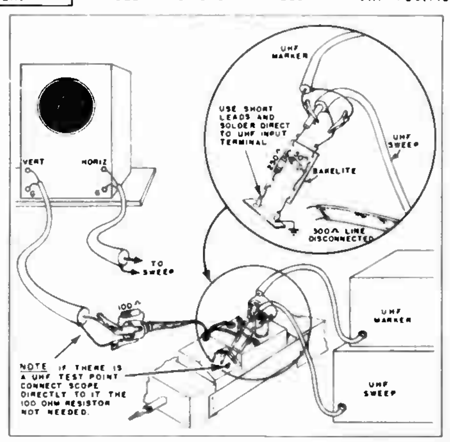

FIGURE 8

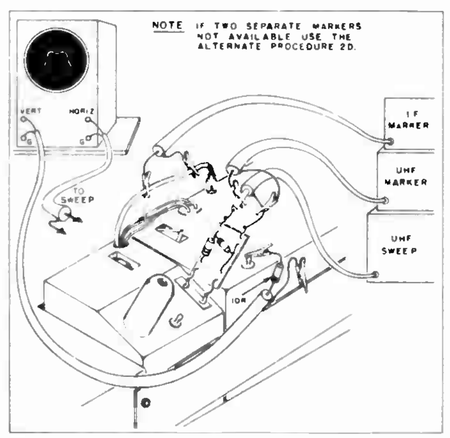

FIGURE 9

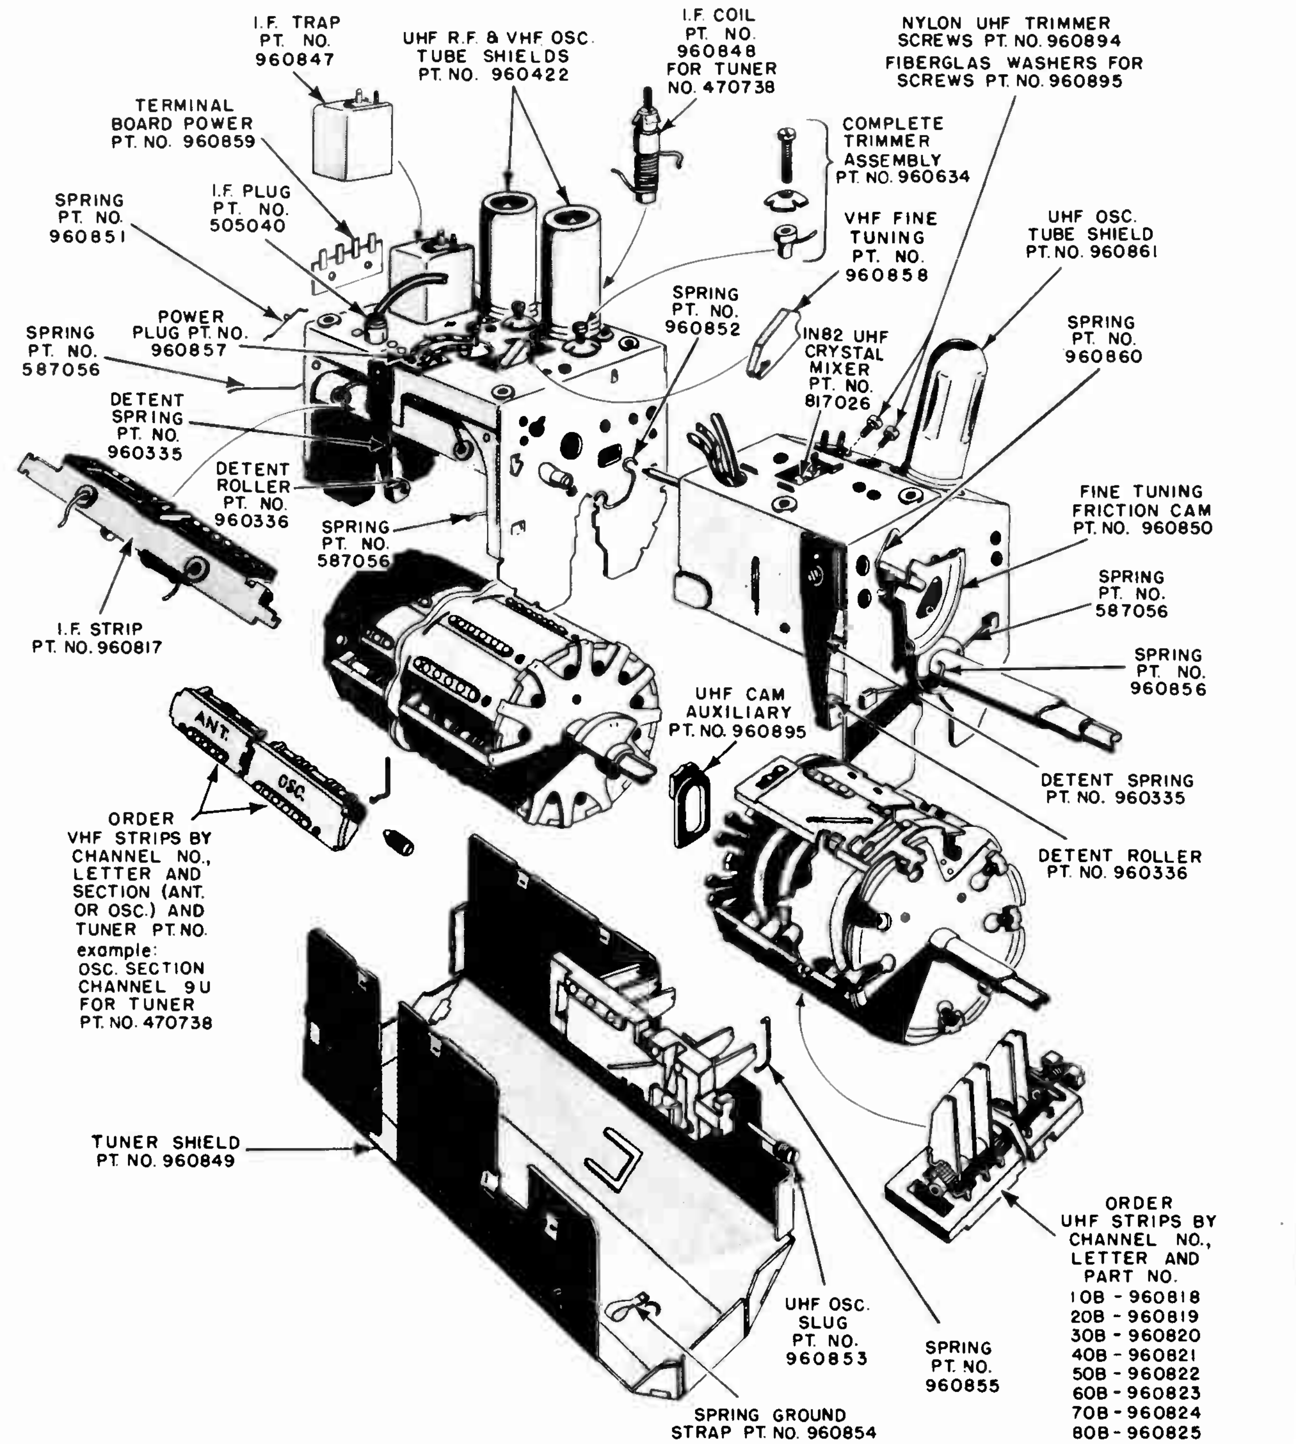
All instrument leads should be dressed as shown and kept as short as possible to prevent interaction between input and output leads.

To minimize standing waves it is important that the sweep generator and tuner be properly matched. This can be done with the type of pad shown in figure #8. Use short leads and make direct solder connections to sweep and tuner to obtain a good match. Non-inductive high frequency resistors should be used.

In the event the sweep pattern is unstable when touching sweep cable (standing waves) try moving equipment leads and ground connections for best stability.



EXPLODED DRAWING OF TUNER

The above drawing shows the part numbers and locations of those mechanical parts which may at some time require replacement. When needed, these parts should be ordered through your local Emerson distributor making reference to the tuner part number as well as the part numbers of the parts desired.

In the event a part is needed for which we have not assigned a part number, order by mechanical description, purpose and tuner part number.

MODEL 784A

ALL CHANNEL UHF-VHF RECEIVERS

The Emerson models listed above are direct view television receivers, designed to receive both VHF channels 2 to 13 and UHF channels 14 to 83. These models incorporate such features as, noise inverter circuit with fringe compensator for superior stability in noisy fringe areas; built in UHF-VHF antenna and provisions for connecting separate external VHF and UHF antennas or a combination UHF-VHF antenna using a common lead in wire; simplimatic UHF-VHF tuning (with illuminated channel selector dial); removable front glass for ease in cleaning picture tube face and mask; black magic contrast; miracle picture lock (automatic horizontal frequency control); multiplex automatic gain control; vertical retrace blanking circuit; electrostatic focusing; minimum operating controls and many other features.

MODEL 753F

RECEIVER CHARACTERISTICS

ITEM	DESCRIPTION
Voltage Rating	115 V. - 600 Cycles A.C.
Power Consumption	190 Watts
Frequency Range VHF	54 - 88 mc.; 174 - 216 mc.
Frequency Range UHF	470 - 890 mc.
Intermediate Frequencies	Video - 45.75 mc. Audio - (intercarrier) 4.5 mc.
Antenna Input Impedance	300 ohms, Balanced
Channel Selection VHF	Twelve Position Rotary Turret
Channel Selection UHF	Continuous Tuning Channels 14 to 83

TUNERS

Combination V.H.F. and U.H.F. tuning is achieved through the use of two tuners which are connected to the same tuning knobs making V.H.F. or U.H.F. channel tuning very simple. The V.H.F. cascode turret tuner has 13 positions (one more than the conventional type), 12 being used for V.H.F. reception, (channels 2 to 13), while the 13th or U.H.F. position is used to activate the proper U.H.F. circuits and provides additional amplification for the converted 40 mc U.H.F. signals. In this position, a window is provided to observe the continuous tuning of the U.H.F. channels

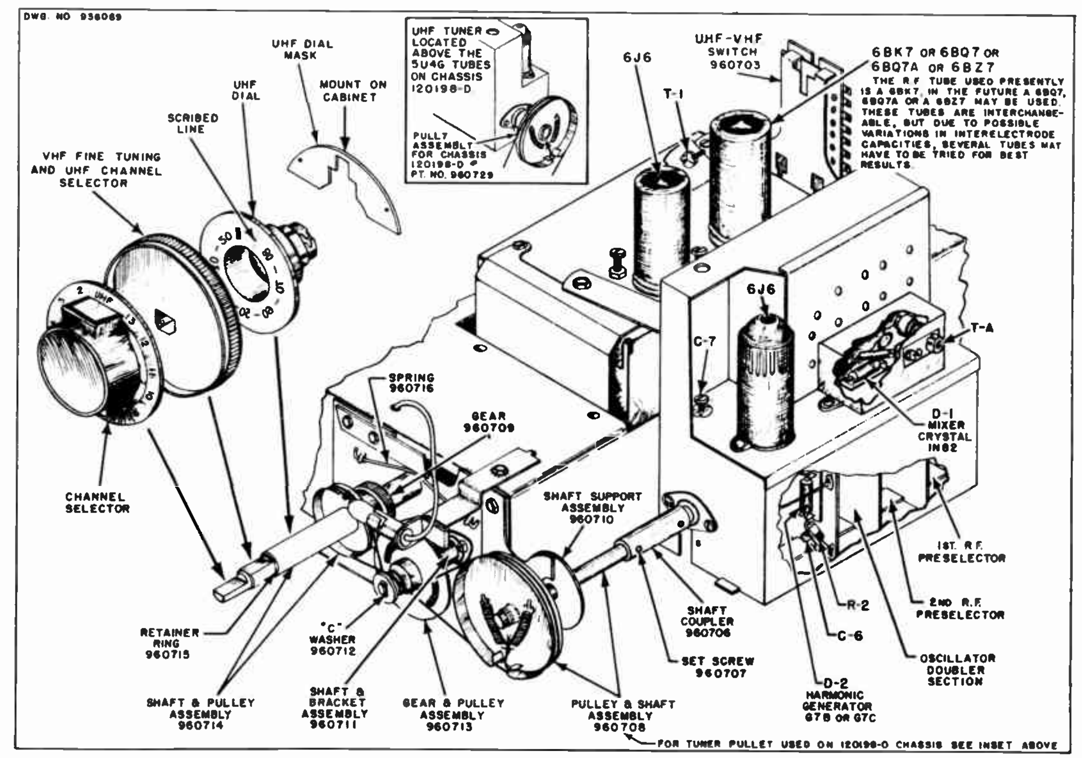

FIGURE 2 - UHF-VHF TUNER ASSEMBLY DRAWING

V.H.F TUNER

The V H.F tuner in this set is a low radiation tuner, having an improved noise factor. The low radiation characteristics greatly reduce local oscillator radiation The improved noise factor becomes apparent in fringe areas where it is of prime importance. From the customer point of view this means a viewable picture with less hash or snow.

The new design features of this tuner are confined to the R.F. amplifier stage (V-22, 6BK7 or 6BQ7 or 6BZ7). The oscillator and mixer section (V-23, 6J6) remain substantially identical to the earlier turret type tuners except that now a metal shield completely encases the turret and additional decoupling and internal shielding have been provided. A 13th or UHF position has also been added to this tuner.

The improved noise factor of this tuner is the result of the development of a circuit permitting the use of a dual triode as an R.F. amplifier which has much less tube noise than pentodes. Previously triodes with useful gain were not used as R.F. amplifiers because of their higher grid to plate capacitance which resulted in excessive oscillator radiation, and overall instability. The dual triode 6BK7 consists of two triodes in a single envelope completely separated by a ground shield. One triode section is used as a grounded cathode amplifier the gain of which is controlled by the A.G.C. applied to the grid. The second triode section is used as a grounded grid amplifier and is directly coupled to the first section. Neutralization of the first section is accomplished by the use of C-10 and C-9.

The combined operation of both triode sections of V-22 (6BK7 or 6BQ7, 6BQ7A or 6BZ7) yield an overall gain which is superior to that of a single well designed pentode stage, (6AG5, 6BC5, 6CB6) and yet the noise generated (snow) is equivalent to that of a triode stage. Due to the use of a 40 mc. I.F., it is necessary to neutralize the mixer tube (1/2 V-23, 6J6). This is accomplished by means of a bridge circuit composed of C-23, T-1 and C-21. The R.F. voltage fed to the grid of the mixer through C-21 cancels any R.F. voltage fed back to the grid through the tube plate to grid capacitance thus neutralizing this stage. In the 13th or U.H.F. position the V.H.F. turret tuner is designed to act as a 40 mc. amplifier for the converted 40 mc. U.H.F. signal.

The V.H.F. antenna input circuit incorporates a high pass filter circuit (L-5) to reduce any interference from nearby transmitters which are operating in the 40 mc. I.F. band. The output of this high pass filter then feeds into the tuner's balanced 300 ohm input circuit. For circuit diagram see Pages 4 and 21.

DESCRIPTION OF UHF TUNER

The tuned elements in this tuner are of the modified coaxial transmission line type. As you can see from the schematic on Page 20, the incoming U.H.F. signal is tuned by means of two R.F. preselectors.

These preselectors are quarter wave end tuned coaxial lines. Capacitive tuning is employed at the open ends to electrically adjust the line to 1/4 wave length and, therefore, effect a resonant condition at any frequency within the U.H.F. band. Two identical preselector circuits are coupled together to provide the proper band pass characteristic. The ganged variable capacitors adjust the two preselector lines and are similar to those used in conventional low frequency circuits. Each line is tuned by four rotor plates. Capacitor trimmers are located behind the coaxial line to preset the high frequency end of the R.F. preselectors. The antenna input in this tuner is coupled to the 1st preselector circuit and is designed to match a balanced 300 ohm transmission line. The output from the preselector stages is fed through an R.F. choke (L-5) to the mixer crystal D-1.

The U.H.F. local oscillator uses a 6J6 (V-25) in a conventional push pull circuit using lumped circuit constants. This oscillator operates at 1/2 the deisred frequency which greatly stabilizes the circuit and permits the use of a thoroughly field tested and debugged tube (6J6). The two outer oscillator capacitor plates are slotted to allow for factory corrections of pass band characteristics.

The output from this oscillator is loop coupled to the oscillator doubler section through L-7. A crystal diode (D-2) is employed in series with this coupling loop to provide rectification of the oscillator signal and thus effect more efficient doubling action. The output from this doubler is fed through L-6 to the mixer crystal D-1 where it beats with the preselected incoming U.H.F. signal. A picture I.F. of 45.75 mc. and a sound I.F. of 41.25 mc. are generated in this fashion. When the receiver is tuned to any V.H.F. channel a 100K ohm resistor (R-6) is inserted in series with the B plus to the U.H.F. tuner as shown in the switch diagram on Page 4 of this note. This is done to prevent weak operation of the U.H.F. oscillator after long periods of inoperation (set used on V.H.F.).

C-7 is used to set the high end of the oscillator and can be used in the field to compensate for slight variations in 6J6s. The range of this trimmer has been limited so as not to effect tuner tracking. Because of this, several 6J6s may have to be tried if adjustment of C-7 does not produce the desired results. Complete tuner shielding is provided to reduce oscillator radiation and stray pickup to a minimum.

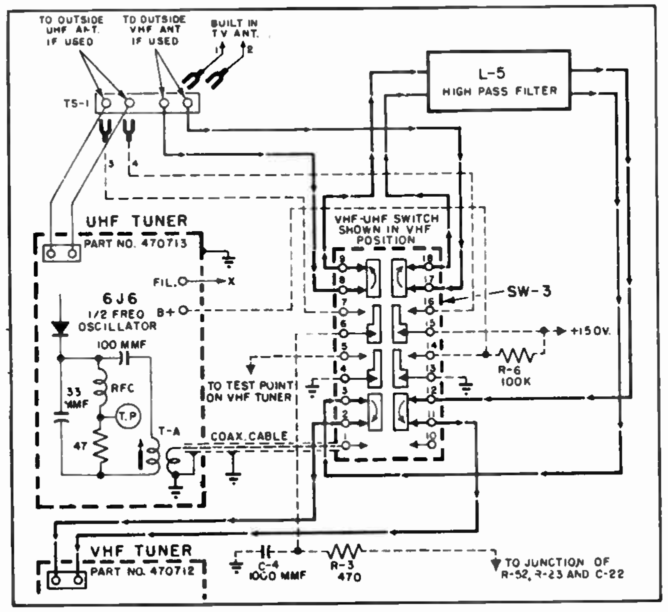
The advantage of using a crystal mixer is its simplicity of design. Since a crystal generally has a higher conversion loss than V.H.F. mixer tubes, it becomes desirable to insert additional I.F. amplification so that the sensitivity of V.H.F. and U.H.F. will be of similar magnitudes.

This is accomplished by feeding the I.F. output from the U.H.F. tuner (T-A) to the input of the V.H.F. tuner. In the 13th or U.H.F. position, the V.H.F. tuner becomes a two stage low noise cascode I.F. amplifier. The tuner input changes from 300 ohm balanced to a 72 ohm unbalanced line to match the I.F. output of the U.H.F. tuner. Since this U.H.F. strip (13th position) does not have any coil section for the V.H.F. oscillator, plate voltage is removed from this section of the 6J6 tube causing it to be inoperative.

OPERATION OF VHF-UHF SWITCH

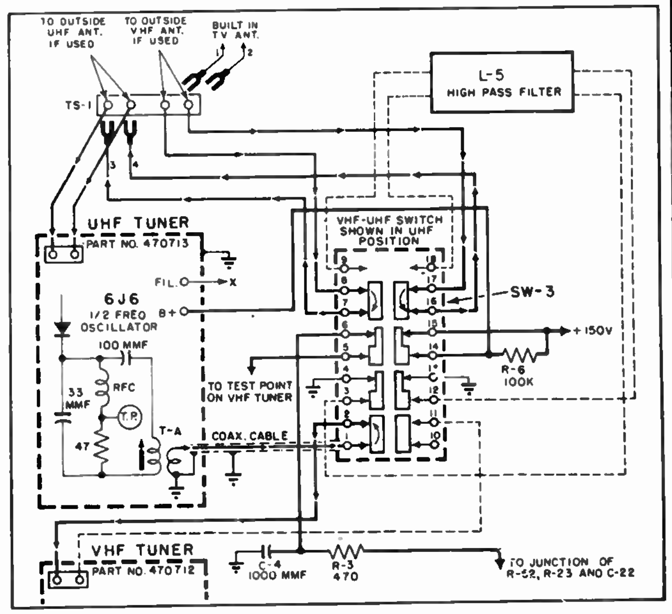
This switch is automatically operated by a cam located on the V.H.F. tuner shaft. This cam changes the switch from its V.H.F. position to U.H.F. whenever the V.H.F. tuner is set for U.H.F. operation.

The following diagram and description should make the operation of this switch clear.



VHF POSITION

The V.H.F. antenna is connected through the switch to the input of the high pass filter L-5. The output of this filter is connected to the input of the V.H.F. tuner through this same switch. B+ is supplied to the U.H.F. tuner through a 100K ohm resistor (R-6) preventing it from oscillating but allowing some current to flow through the 6J6 so that its cathode will not be poisoned during long periods of inoperation (V.H.F. reception.)



UHF POSITION

The VHF antenna or combination VHF-UHF antenna is disconnected from the VHF tuner and connected to the input of the UHF tuner through the switch and terminals 3 & 4 (providing they are connected, see installation instructions for more information). If a separate lead is is used for UHF, then terminals 3 & 4 should not be connected to the UHF antenna terminals.

The single ended output of the UHF tuner is fed through the switch to the input of the VHF tuner.

The 100K resistor R-6 is shorted out by the switch so that full B+ is applied to the UHF tuner.

Since the VHF mixer tube functions as a 40 mc amplifier when tuned to UHF, fixed grid bias is applied to it (test point VHF tuner) through the switch (SW-3).

V.H.F. TUNER OUTPUT - I.F. INPUT, I.F. CIRCUITS & TRAPS

The output of the 6J6 mixer tube which contains the video and audio I.F. carriers (45.75 mc and 41.25 mc) are fed to the first I.F. tube through a low impedance link coupled circuit T-1 and L-3 (T-1 is mounted on tuner while L-3 is mounted on chassis). R-4 which is a 15 ohm resistor determines the coupling between T-1, and L-3 so that they act like a single tuned circuit and, therefore, both input I.F.'s can be peaked to the same frequency without a sweep generator. Because of the low impedance coupling (R-4, 15 ohms) dressing and lead length in this input circuit, which would ordinarily be very critical, have very little effect upon the response curve.

The I.F. signals are then further amplified through V-1, V-2, and V-3 which are all stagger tuned by the use of Bi-Filar transformers.

Both the adjacent sound and sound carrier traps (L-1 and L-2 respectively) are connected across the 15 ohm (R-4) coupling resistor in the low impedance link circuit feeding the first I.F. tube.

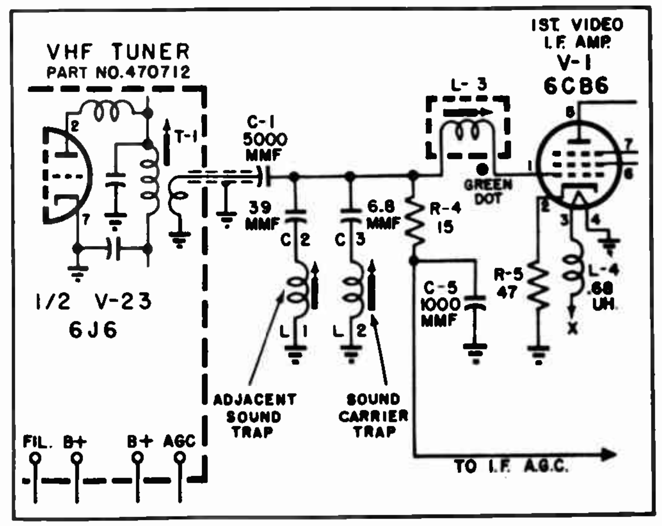


FIGURE 3 - TUNER OUTPUT AND I.F. INPUT CIRCUIT

At each of these sound frequencies (adjacent and carrier) one of the traps (L-1 or L-2) will be in series resonance, thus effectively shorting out the 15 ohm coupling resistor (R-4) and the signal. The adjacent channel sound trap in this chassis is extremely efficient, and as a result appreciably less adjacent channel sound interference should be noticed in those few areas where this type of interference presents a problem.

When using a 40 mc I.F. tube neutralization is necessary. This is accomplished by not fully by-passing the R.F. voltage from the screen grid of the video I.F. tubes. This voltage tends to cancel the R.F. signal which is fed back to the grid, through the grid to plate capacity, thus preventing the tube from oscillating. When replacing components in this circuit make sure they are of the same values, types and placed in their original positions with leads cut as short as possible.

A.G.C. is applied to the grids of V-1 and V-2 so that picture contrast will remain fairly constant over wide variations in received signal strength.

The sound carrier level is maintained just below the point of interference with the video I.F. but is not completely rejected as the audio I.F. must hetrodyne with the video I.F. in the detector (V-4, 6AL5) to produce the 4.5 mc inter-carrier audio I.F. The 4.5 mc beat is obtained across the tuned 4.5 mc trap T-5 and is fed to the first I.F. amplifier (V-6, 6AU6).

A.G.C. WITH TUNER DELAY

This A.G.C. system is designed to give superior performance of the receiver in very weak and strong signal areas. It is accomplished by separate A.G.C. control of the R.F. tube, namely keeping this tube at optimum gain at weak signals and very low gain at strong signals. The I.F. is controlled by simple A.G.C. resulting in an extended control range.

For best operation, a larger variation of R.F. A.G.C. voltage than I.F. A.G.C. voltage is required. This can be obtained by using the D.C. output of the video detector for I.F. A.G.C. and using a circuit which rectifies the peak carrier with a suitable delay for R.F. A.G.C.

This is accomplished by an A.G.C. detector (V-4, Pins 2 and 5), which is used to rectify the positive half of the modulation envelope and is keyed with the negative sync pulses above the average D.C. The D.C. voltage thus obtained across R-18 is equal to the approximate peak to peak carrier voltage less the average of 1/2 the negative modulation envelope. This voltage is superimposed on the negative average D.C. voltage developed by the video detector (V-4 Pins 1 and 7) across R-22 which results in a D.C. voltage approximately equal to the peak to peak carrier.

To operate the R.F. amplifier at maximum gain at low signal level, a positive delay voltage is applied to the A.G.C. buss by means of R-43. A clamping diode (V-9, Pins 2, 5 and 6) is used to keep the A.G.C. voltage on the buss equal to the tube contact potential (approximately minus - 0.7 volts) until the incoming signal is strong enough to develop sufficient bias to overcome the positive delay voltage.

VIDEO DETECTOR

One half of a type 6AL5, (V-4, Pins 1 and 7) is used as the video detector. The demodulated composite video signal is fed to the video amplifier (V-5, 6CB6) through the primary of the transformer (T-5) tuned to 4.5 mc (which minimizes the effect of 4.5 mc in the picture and serves as a sound takeoff). The frequency response of the video detector is extended to the amount necessary for good picture definition by using a low value of load resistor (R-22, 4700 ohms) and series-shunt peaking (primary T-5, R-20, L-8). An R.F. choke L-9 (20 uh) is used to further isolate the I.F. from the video signals.

VIDEO AMPLIFIER

The output of the video detector (V-4) is coupled through T-5, L-9 and C-21 to the grid of the video amplifier which consists of a single high gain stage (V-5, 6CB6). Since only one tube is used, the output of the video amplifier is connected to the cathode of the kinescope so that correct picture phase is realized. Fixed bias, developed across R-51 is applied to the grid of this stage, (V-5, 6CB6). The contrast control varies the tube operating bias and the amount of degeneration thus changing its gain. Series-shunt peaking and a low load resistance (R-26, 6800 ohms) is used in the plate circuit to extend the frequency response of this tube to that necessary for good picture response.

SYNC AMPLIFIER AND SEPARATOR

The composite negatively phased video signal is fed to the grid of the sync amplifier V-11A (Pin #2, 12AU7) where it is amplified and fed to the grid of the sync separator (V-11B, 12AU7).

The sync separator is operated in such a manner (low B+, high grid leak bias) that the picture and blanking information are kept below tube cutoff while the sync pulses which are of greater amplitude will cause the tube to conduct. This effectively separates the vertical and horizontal sync pulses from the picture information.

The horizontal and vertical sync pulses are fed to the vertical cascaded integrating network (R-95, C-71, R-96, C-72). This network due to its relatively long time constant with regard to horizontal pulses effectively filters out horizontal pulses while allowing the vertical sync pulses to trigger the vertical oscillator (V-18, 6SN7) keeping it in synchronism.

SYNC AMPLIFIER AND SEPARATOR (Continued)

Due to the relatively short time constant of C-42 (82 mmf) R-60 (330 K) only the horizontal sync pulses develop a pulse voltage across R-60 which operates the horizontal phase inverter. Since the vertical sync pulses are serrated at a horizontal rate these serrations also cause a pulse to be developed across R-60. This maintains horizontal synchronization even during vertical retrace improving the overall stability of the circuit.

These pulses do not actually trigger the horizontal oscillator as in the case of the vertical pulses but are used as a frequency and phase reference by means of the phase inverter (V-12A) and phase detector (V-12B) for "Horizontal Automatic Frequency Control." This is explained in further detail under "Horizontal Automatic Frequency Control."

NOISE INVERTER, SYNC CLAMP AND FRINGE COMPENSATOR

In electrically noisy fringe areas it is quite possible that the amplitude of the externally caused electrical noise pulses are greater than that of the video sync pulses. It is these relatively high amplitude noise pulses, which are of the same polarity as the sync, that cause picture instability since they upset the operation of the sync separator (V-11B, 12AU7) by charging its grid circuit up to an abnormally high negative value as a result of heavy grid conduction. This condition can cause the loss of a few sync pulses (horizontal or vertical) until the sync separator grid circuit has discharged through R-56 to its normal negative value which is determined by the peak sync amplitude. If these troublesome noise pulses could be eliminated or reduced to a point below the sync level, stability would be greatly improved.

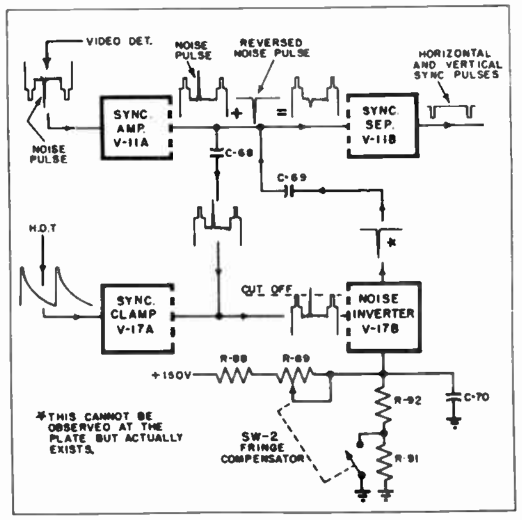

FIGURE 4 - BLOCK DIAGRAM OF NOISE INVERTER CIRCUIT

This reduction in the amplitude of the noise pulse is accomplished by the noise inverter (V-17B, 12AU7), as explained below.

In extremely strong signal areas the noise inverter circuit should be made inoperative. This is accomplished by means of the switch mounted to the "Fringe Compensator Control." This switch when "OFF" effectively increases the bias (inserts an additional 10K resistor R-91 in the cathode circuit) on the noise inverter keeping it well below cut off at all times thus effectively eliminating it from the circuit.

Failure to keep this circuit beyond cut off in strong signal areas may result in vertical roll and or wiggle. The operation of the noise inverter is as follows.

NOISE INVERTER

A composite video signal of positive polarity is taken from the sync amplifier plate (junction R-53 and R-54) and fed to the grid circuit of the noise inverter tube through C-68. The grid bias on this tube is set by adjusting R-89 (fringe compensator) which effectively varies the positive voltage on the cathode of the tube (Pin 3, V-17B) so that the tube does not conduct (is just below the cut off) on sync or video information.

However all positive noise pulses of greater amplitude than the sync pulses will cause this tube to conduct. The peaks of the sync pulses are clamped just below the cut off point of the noise inverter tube by the clamper (V-17A) to prevent their causing conduction of the noise inverter, over wide variations in signal amplitude. The operation of the clamp tube is explained below.

Since positive going noise pulses of greater amplitude than the sync pulses undergo an additional stage of amplification through the noise inverter (V-12B, 12AU7) they are greatly amplified and reversed in polarity so that when they are fed back to the composite video signal (junction R-55, C-40) through C-69 they completely cancel out the noise pulse. As you can see by the block diagram the amplified negative going noise pulse is of greater amplitude than the original thus causing a slight dip on the composite video signal.

This system eliminates those noise pulses which would have otherwise adversely affected the operation of the sync separator.

SYNC CLAMP

In order to keep the tips of the sync pulses below the cut off point of the noise inverter tube over wide variations in input signal level, the peaks of the horizontal sync pulses are clamped to approximately zero volts by automatically varying the bias across R-90 (2.2 meg. noise inverter grid resistor) in accordance with the strength of the horizontal sync pulse. (See Figures 5 and 6).

This is accomplished by the sync clamp tube (V-17A, 12AU7) in the following manner: The first horizontal sync pulse (Figure 5, Item A) will cause plate current to flow (Ip) charging C-68 (.01 mf.) to the peak of the sync pulse.

Due to the relatively long time constant of C-68 and R-90 (2.2 meg.) the voltage developed across R-90 as a result of the discharge of C-68 (.01 mf.) will be equal to the peak of the sync. pulse, (Figure 5, Item B). Stronger signals will cause more plate conduction thereby increasing the bias across R-90 while weak signals will cause less plate conduction thereby decreasing the bias across R-90. (See Figure 6).

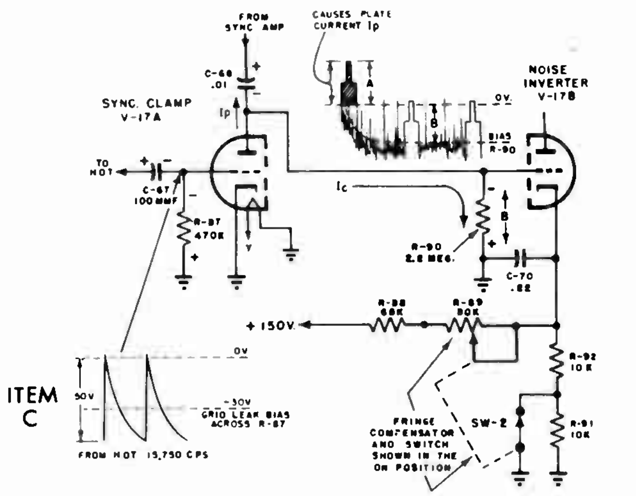

FIGURE 5

As you can see the clamp tube (V-17A) in conjunction with C-68 automatically adjusts the bias across R-90 so that the tips of the sync pulses will be clamped at approximately zero volts over wide variations in signal strength.

The grid to cathode bias of the noise inverter (V-17B) is then set by the "Fringe Compensator" so that the tips of the sync pulses (approximately zero volts to chassis) will be below the cut off point of the noise inverter.

As mentioned above this point is always maintained by the sync clamp tube (V-17A).

In order for the bias across R-90 to be dependent only on the sync amplitude and not noise pulses the sync clamp tube is kept at cut off at all times except during the horizontal sync pulses (15,750 times per second). This is accomplished by triggering the grid of the sync clamp tube at a horizontal rate with a positive pulse from the H.O.T. (See Figure 5, Item C). This pulse (about 50V. P. to P.) drives the grid of the sync clamp tube positive, causing grid conduction.

This conduction charges the grid capacitor (C-67, 100 mmf.) up to the peak value of the positive pulse (approx. -30V).

Due to the relatively long time constant of C-67 (100 mmf.) and R-87 (470K) the voltage across R-87 due to the discharge of C-67 remains at about -30V. until the next horizontal pulse comes along at which time the grid again draws current charging C-67 back to -30V. at which time the above process is repeated (See Figure 6, Item A).

This causes the tube to remain well below cut off except when the grid is driven positive 15,750 times per second (horizontal rate) see Figure 6.

Since the transmitted horizontal sync pulses of the composite video signal which are fed to the plate of the sync clamp tube through C-68 (.01 mf.) occur at the same instant the grid of this tube is driven positive, plate conduction can only occur at this time. Noise pulses which occur between sync pulses cannot possibly cause this tube to conduct since the grid of the sync clamp tube is well below cut off at that time (See Figure 6). BECAUSE OF THIS FACT, THE NEGATIVE VOLTAGE DEVELOPED ACROSS THE NOISE INVERTER GRID RESISTOR (R-90) WILL BE DEPENDENT ONLY ON THE AMPLITUDE OF THE HORIZONTAL SYNC PULSES.

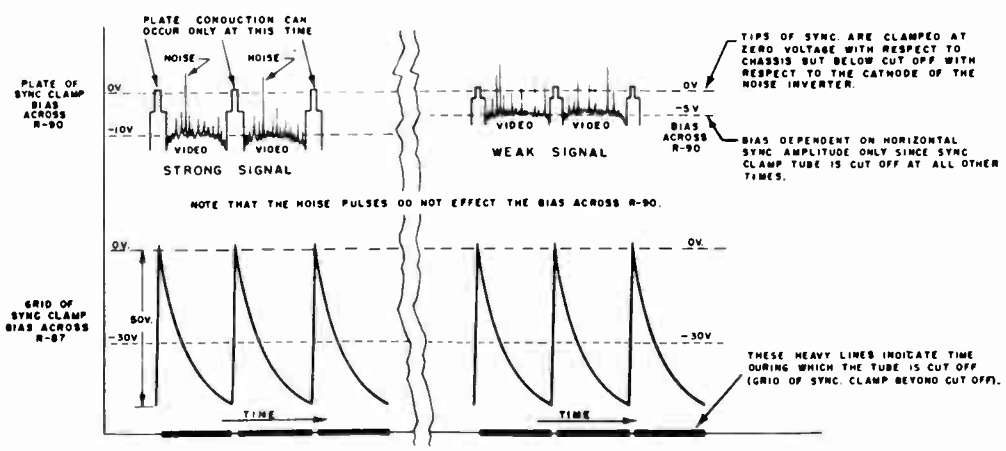

FIGURE 6

HORIZONTAL AUTOMATIC FREQUENCY CONTROL (MIRACLE PICTURE LOCK)

In modern day receivers it is necessary to use some form of automatic frequency control so that the horizontal sync pulses do not directly trigger the horizontal oscillator. This is necessary since occasional noise bursts may prematurely trigger the oscillator, causing the picture to either spear or tear out.

By using A.F.C. the average of a group of sync pulses are used to control the frequency of the oscillator, therefore, if a sync is distorted or masked by noise little effect will be observed on the screen.

HORIZONTAL AUTOMATIC FREQUENCY CONTROL (Continued)

This type of system is especially useful in the fringe areas where the signal to electrical noise interference is very poor.

This particular chassis uses a comparison of phase between the sync signal and the generated sawtooth as a basis for automatic frequency control (A.F.C.). Such a system is little influenced by changes in sync amplitude or occasional noise and, therefore, operates extremely well.

A Phase Detector V-12B compares the difference in phase between the transmitted horizontal sync pulse and the horizontal sawtooth voltage which is generated in the receiver. Whenever the phase of the horizontal multivibrator (V-13) changes, the phase of the sawtooth generated by this tube also changes. This effect changes the phase between the sync and sawtooth voltages causing the sync pulse to ride higher or lower on the sawtooth retrace portion changing the peak amplitude of this composite wave. (See Figure 7). This change in amplitude is detected by the phase detector (V-12B) by means of the grid leak voltage developed across R-65, R-64 and R-63 which is proportional to the peak positive amplitude of this composite wave (sawtooth plus horizontal sync pulse). (See Figure 7).

When the frequency and phase of the sync and sawtooth is correct the negative grid leak voltage developed across R-64 is equal to the positive cathode voltage developed across R-63 (100 K), therefore, the net control voltage applied to the grid of the horizontal oscillator (V-13) is zero. With zero voltage on the grid the oscillator is set to have the proper frequency and phase by means of the horizontal hold control, horizontal balance control and phase coil.

Just as soon as a phase difference develops between the horizontal sync and the sawtooth, a negative or positive control voltage is generated, which immediately corrects the phase of the oscillator, returning the control voltage back to approximately zero (will be slightly positive or negative depending upon the setting of the horizontal hold control R-73).

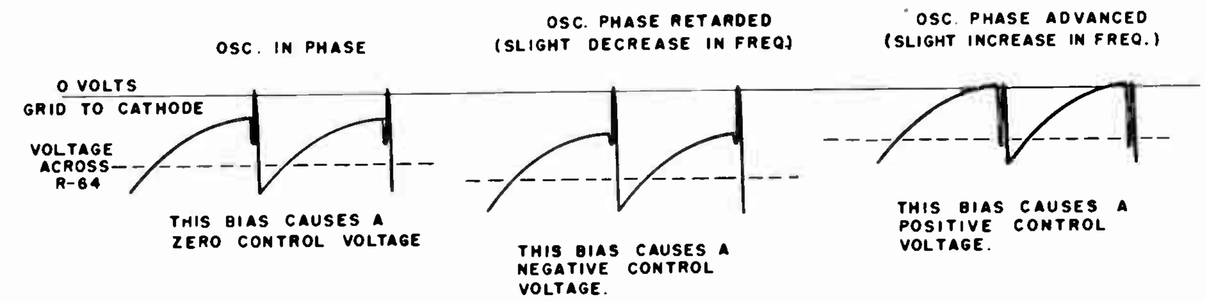

FIGURE 7

The purpose of the phase inverter is to provide a positive and negative going sync pulse of equal amplitude so that noise and sync pulses cancel themselves out at the control voltage take off point (Junction R-65, R-64) making the control voltage proportional only to phase differences.

R-75, R-68, C-47, R-66 and C-46 are used to couple and shape the positive pulse from the horizontal output transformer to a negatively phased sawtooth.

C-56 and C-55 reduce the amplitude of the generated horizontal sawtooth before it is fed to the grid of the phase detector by C-48.

The network of R-67 (2.2 meg.) in parallel with C-49 (.001) used in conjunction with C-50 (.015) tends to filter unwanted high frequency pulses, while permitting the low frequency control voltage to pass.

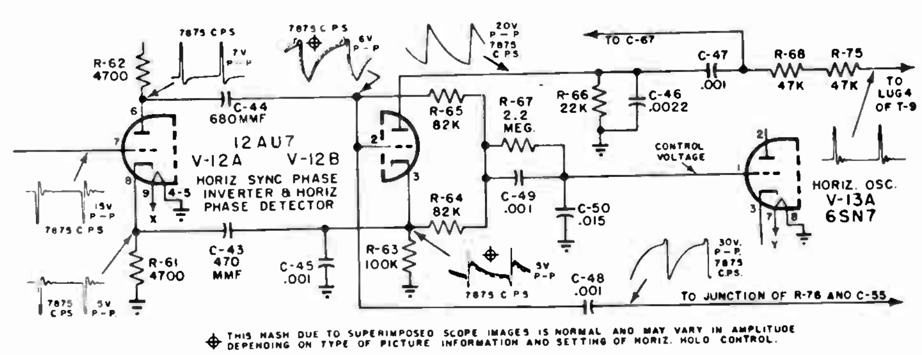

FIGURE 8 - HORIZONTAL AUTOMATIC FREQUENCY CONTROL NETWORK

HORIZONTAL OSCILLATOR, SWEEP, AND OUTPUT

V-13, 6SN7 is a cathode coupled multivibrator whose free running frequency and phase depends upon such factors as setting of R-71 (Horizontal Balance), R-73 (Horizontal Hold), adjustment of L-13 (Horizontal Phase Coil) and the applied plate and grid voltages. Since automatic frequency control is to be used in this circuit, one of the above factors will have to be automatically varied. Since the grid of V-13A offers a convenient control point its voltage will be varied automatically to control the oscillation frequency and phase of V-13. The method of control is outlined under "Horizontal Automatic Frequency Control."

The horizontal phase coil (L-13) is adjusted so that its natural resonant frequency is the same as the horizontal sync rate (15,750 CPS). The abrupt voltage changes in the plate circuit of V-13A shock this circuit into oscillation. Since the frequency of L-13 and C-53 is not effected by voltage changes or other component changes, it greatly stabilizes the operation of the circuit by modulating the plate voltage of V-13A with a 15,750 sine wave. The polarity and phase of this sine wave is such that it maintains the free running frequency at 15,750 C.P.S.

The sweep voltage which is developed across C-56, C-55 as a result of the charge through R-74 (47K) and discharge through the horizontal oscillator tube (V-13B) is coupled to the grid of the 6BQ6GT horizontal output tube. The 6BQ6GT (V-14) is used as a power amplifier so as to supply the necessary horizontal deflection current to the deflection yoke. The horizontal output transformer (T-9) matches the relatively low impedance of the horizontal deflection yoke winding (L-16) to the plate circuit of the 6BQ6GT (V-14) for maximum efficiency. The damper tube V-16 (6W4GT) is effectively connected across the horizontal deflection yoke to damp out oscillations which occur over part of the horizontal scanning cycle. The resultant energy from these damped oscillations provides the boosted B+ voltage.

VERTICAL OSCILLATOR SWEEP AND OUTPUT

A cathode coupled multivibrator is used as the vertical oscillator (V-18, 6SN7). The vertical hold control (R-100) controls the free running frequency of V-18. The intergrated vertical sync pulse causes V-18 to lock in at the proper frequency. The amplitude of the sweep voltage is controlled by the vertical size control (R-103). Since R-103 changes the plate voltage of V-18, its adjustment may require resetting of R-100 (vertical hold control) as well.

The sweep voltage developed across C-76 in series with R-104 is coupled through C-77 to the vertical output tube V-19. The vertical output transformer (T-10) matches the low impedance of the vertical deflection yoke L-17, to the relatively high output impedance of V-19 for maximum efficiency. R-107 (vertical linearity control) changes the operating characteristics of the vertical output tube V-18, thus changing the vertical linearity of the picture.

DEFLECTION

Spot deflection is achieved by means of a deflection yoke (L-16 horizontal deflection coil and L-17 vertical deflection coil), mounted around the neck of the picture tube. Vertical and horizontal deflection currents flowing through these coils set up a magnetic field within the tube which causes the spot to be scanned both vertically and horizontally. R-111 and R-112 damp out the vertical coils to prevent spurious oscillations. C-81 connected across one half of the horizontal yoke winding is used to make both halfs of this winding electrically identical. This in conjunction with R-83 (8200 ohm) connected between the horizontal output transformer and the yoke help to eliminate yoke ringing (rippling of raster lines).

HIGH VOLTAGE SUPPLY

A voltage pulse in the plate circuit of the horizontal output amplifier (V-14, 6BQ6GT) which is developed during horizontal retrace is stepped up by the auto-transformer type primary of the horizontal output transformer T-9. Approximately 15,000 volts are generated in this manner due to the high efficiency of this circuit. A 1B3 (V-15) rectifies this pulse which is then filtered by C-61, (500 mmf.) and R-84, (100K). Filament power for this tube is obtained from a tap on the horizontal output transformer.

LOW VOLTAGE SUPPLY

Two dual rectifiers (V-20, 5U4G, V-21, 5U4G) are used to supply the proper D.C. voltages and currents to the receiver from the applied A.C. power.

Although each tube is connected as a half wave rectifier, together they form a full wave rectifier circuit.

Filtering is accomplished by a condenser input filter (C-64, 80 mf.; L-18, filter choke and C-66, 40 mf.). Voltages of plus 245, 225 and 150 are available from this supply. The B plus 150 volts is further filtered through R-86, (1250 ohm) and C-65, 40 mf. Since the center tap of the power transformer T-11 is above chassis by 8.5 ohms (R-51) a small negative voltage is developed which supplies a fixed bias to the video amplifier tube (V-5, 6CB6). A .6 amp. slow blowing type fuse is placed in series with the center tap of the power transformer (T-11) to protect the receiver in the event a short in the Hi B plus circuit (+245V. and +225V.) should occur.

FOCUS AND CENTERING

The 21MP4 (V-24) is pre-focused electrostatically by means of a focus electrode in the gun assembly operating at a nominal voltage of 150 volts. The voltage on this electrode may be varied between 0 and the boosted B+ voltage of 430 volts by means of the potentiometer marked "Focus" (R-31) at the rear of the chassis in order to secure the best possible focus.

Centering is accomplished by means of a centering unit placed on the neck of the picture tube slightly behind the yoke.

This device consists of two magnetized rings which when rotated together cause the electron beam to shift thus centering the picture. If the centering range is not sufficient a slight rotation of one of the rings with respect to the other will vary the amount of range until the right point is reached. For further information on the use of this centering unit see note on centering procedure.

BEAM BENDER (ION TRAP)

A single magnet type of beam bender is used and should always be adjusted by sliding and rotating the unit for maximum brightness. Do not adjust the trap for removing corner shadows or improving focus if in so doing the brightness is reduced.

If two positions of maximum brightness are found use the one closer to the picture tube socket.

ADJUSTMENT OF NOISE INVERTER (Fringe Compensator)

1) Be sure the miracle picture lock has been properly adjusted (horizontal hold circuits). See Page 15.

2) Tune in a weak station. Turn fringe compensator switch to the "ON" position and adjust the fringe compensator control for best picture stability.

3) Try all channels and readjust fringe compensator if necessary for best overall picture stability.

NOTE: In most locations this added protection will not be necessary and the fringe compensator should remain in the "OFF" position. If this is not done, picture wiggle and or vertical roll might result in strong signal areas.

CENTERING PROCEDURE

1. Set the unit, magnets forward, on the tube so that the magnets are about 1/4" behind the yoke. Adjust the clamp so that the unit is a sliding fit on the tube.
2. Set the magnets so that the adjusting arms are approximately 120° apart (Figure 9).
3. Adjust the ion trap magnet for maximum brightness.
4. Rotate the whole unit, this will cause the picture to move around a circle. Stop where the picture is most nearly centered.
5. Rotate the magnets separately, in equal distances but in opposite directions to complete the centering.
6. Repeat steps 3, 4 and 5 if necessary.
7. Tighten clamp.
8. Readjust the ion trap magnet to give maximum brightness.

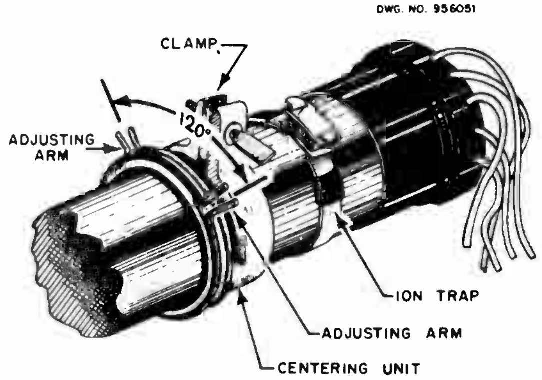

FIGURE 9 - CENTERING UNIT LOCATION DRAWING

CAUTION: It is important that the centering magnets not be operated too close to the yoke as the A-C field from the yoke may cause the centering magnets to become demagnetized.

SETTING OF TUNING KNOBS

1) Make sure chassis has been adjusted in the cabinet so that the tuning shafts are perfectly centered through the cabinet hole.
2) Insert fine tuning knob on shaft and rotate fully counter clockwise (no further rotation of outer U.H.F. dial shaft).
3) Remove fine tuning knob and insert the U.H.F. dial (contains U.H.F. channel Nos.) on U.H.F. dial shaft. Set the scribed line at 12 o'clock before placing on shaft. Do not twist or turn when inserting U.H.F. dial. The scribe line is a hair thickness and is located about 3/16" to the right of the heavy black line near 0 of channel 20.
4) Place fine tuning and selector knobs on their respective shafts.

NOTE: Leave enough space between knobs so that there will not be any binding.

ALIGNMENT V.H.F.

ALIGNMENT

a. Equipment Required - A sweep generator, (10 MC. sweep with center frequency of 44 MC. plus all necessary R.F. sweep frequencies as listed in R.F. Table), accurate marker generator, oscilloscope and V.T.V.M. are required for alignment. The marker generator must supply frequencies of 4.5 MC., 40 to 48 MC. and 50 to 216 MC.

b. Alignment Points - The location of all I.F. transformers, Tuned Circuits, and trimmers shown in Figure 14.

TV R.F. & MIXER ALIGNMENT (V. H. F.)

Connect 3 volt bias battery to both I.F. and R.F. AGC. circuits, positive terminal to chassis, negative terminal to junction of R-19, C-19, C-18. Add a jumper wire from this junction to junction of R-10, R-16, C-8 so that the bias battery is also applied to I.F. AGC.

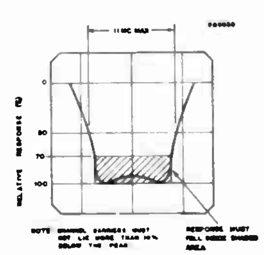

Figure 11 -- TUNER RESPONSE CURVE SHOWING BAND-PASS LIMITS.

The response for all channels should meet with the requirements of Fig. 11. To do so it may be necessary to compromise by slightly changing the initial channel #12 adjustments of C-2, C-5 and C-6 while switched to channel which does not conform.

*Sound Carrier Marker
**Picture Carrier Marker

I.F. ALIGNMENT

1) Tune receiver to unused Channel 10 or 12.

2) Connect 3 volt bias battery with negative terminal to I.F. AGC. (Junction R-10, C-8, R-16) positive terminal to chassis.

3) Connect D.C. V.T.V.M. to video test point (see location in Fig. 13 and 14).

4) Connect terminated marker generator to floating shield of converter tube V-23 6J6. (Shield raised slightly so that it does not make contact with chassis). Use unmodulated marker. See Fig. 13.

MARKER GENERATOR	ADJUST	PROCEDURE
45.75 MC. Unmodulated	T-4	Peak for maximum response. Adjust output of signal generator so that maximum response does not produce more than -2V. D.C. on V.T.V.M.
43.2 MC. Unmodulated	T-3	
42.0 MC. Unmodulated	T-2	
45.0 MC. Unmodulated	L-3 T-1	
41.25 MC. Unmodulated	L-2	Adjust trap for minimum response. Increase output from signal generator so that a true minimum position can be found.

5) Connect vertical input of an oscilloscope instead of V.T.V.M. to video test point with vertical scope gain set at, or near, maximum. (Horizontal scope sweep set at 400 cycles).

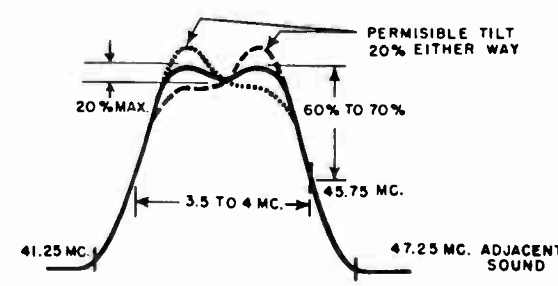
MARKER GENERATOR	ADJUST	PROCEDURE
47.25 MC. 400 Cycles Amp. Mod.	L-1	With signal generator set at maximum output, adjust L-1 for minimum vertical response on scope.

6) Now that all the I.F. coils and transformers have been set, the overall response can be observed and adjusted if necessary.

SIGNAL GENERATOR INPUT CONNECTION	FREQUENCY SWEEP	FREQUENCY MARKER	MEASURING INSTRUMENT	ADJUST	PROCEDURE
Connect terminated sweep and marker as shown in Fig. 13.	Center frequency 44 MC. 10 MC. Sweep	45.75 MC.	Scope connected to Video Test Point	T-4	If 45.75 MC. doesn't lie from 60 to 70% down adjust T-4 (see fig 12) for tolerances. *

Providing overall curve is within tolerances as shown below, no further adjustments are needed. If band width or tilt is not as specified, repeat entire alignment procedure. If still out then a slight retouching is permissible. TRAPS L-1 and L-2 MUST BE ADJUSTED AS INDICATED ABOVE. DO NOT RE-ADJUST WHILE OBSERVING OVERALL I.F. RESPONSE CURVE.

***KEEP OUTPUT OF SIGNAL GENERATOR AS LOW AS POSSIBLE WHEN OBSERVING THE OVERALL I.F. SHAPE SINCE TUBE OVERLOAD MIGHT RESULT AND THE RESPONSE WILL APPEAR INCORRECTLY FLAT AND WIDE.**



NOTE: It may be impossible to observe the 47.25 MC. marker with the average service equipment due to the high attenuation of trap L-1 (adjacent sound).

Figure 12. OVERALL I.F. RESPONSE CURVE

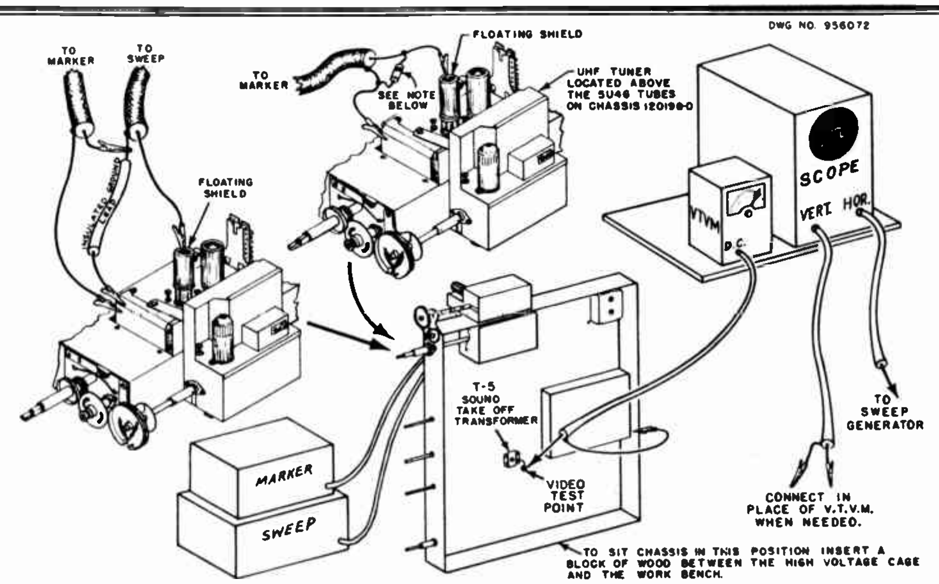


Figure 13. CONNECTIONS FOR I.F. ALIGNMENT.

All instrument leads should be dressed as directed and as short as possible to prevent interaction between input and output leads. Failure to do this may result in an unstable response indication.

NOTE: It is important that the output cable of the sweep and marker generator be properly terminated in their characteristic impedance which is usually from 50 to 75 ohms. If this termination has not been built into the end of the cable by the instrument manufacturer* then a resistor of the proper value (characteristic impedance) should be connected across the output of each generator cable as shown above.

* If in doubt check your instruction book which is issued by the test equipment manufacturer.

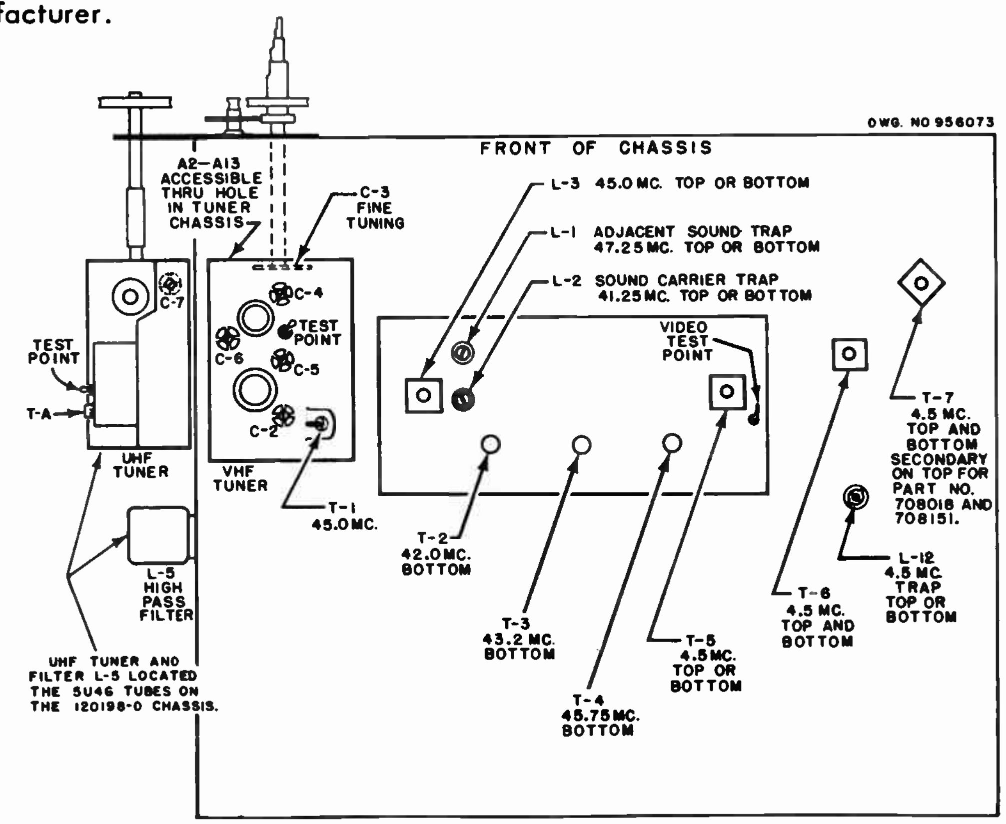

Figure 14 - LOCATION OF ALIGNMENT POINTS (TOP VIEW)

R.F. OSCILLATOR ALIGNMENT (V.H.F.)

1. Connect marker and sweep generator as shown in Figure 10, low side to chassis.
2. Connect scope to video test point (see location Fig. 13 and 14).
3. Connect 3 volt bias battery as described under R.F. Alignment Page 11.
4. Before undertaking oscillator alignment be sure I.F. circuits are correctly aligned for band pass characteristic and trap settings.
5. During oscillator alignment, it is necessary to set the fine tuning control so that the tooth on the fine turning cam points downward.

MARKER SIGNAL GENERATOR FREQUENCY	SWEEP GENERATOR FREQUENCY	MISCELLANEOUS INSTRUCTIONS	TRIMMER OR SLUG	TYPE OF ADJUSTMENT AND OUTPUT INDICATION
*209.75 MC. **205.25 MC.	Channel #12 Center Frequency 207 MC. 10 MC. Sweep	Be sure that fine tuning control has been properly positioned (tooth on the cam pointing down) NOTE During this step and thru-out all succeeding steps it is necessary to: 1. Keep output of sweep generator at a level that does not allow the reading on a VTVM to exceed minus 1 volt when connected across video detector load at minimum sweep width. 2. Keep output of standard signal generator at a level that provides a readable marker but does not distort the curve that is being observed on the scope.	Adjust Slug A-12	NOTE: Before making the following adjustment, advance the vertical gain control on the scope in order to magnify the sound trap portion of the response curve. Then, use a non-metallic screwdriver to adjust channel #12 oscillator slug (accessible thru hole on front of r-f tuner unit) and shift response curve so that sound carrier marker is located at the position indicated below. Now reduce gain control setting of scope to restore pattern to normal amplitude and observe position of picture carrier marker. This marker should appear on the high frequency side of the characteristic curve. The amplitude of the picture carrier should be between 60 and 70% down from peak response.
*215.75 MC. **211.25 MC.	Channel #13 213 MC.	Set Channel Selector to #13 (See note above)	Adjust the r-f sweep generator and marker generator for operation on other television channels; set marker generator to sound carrier frequency. After setting Channel Selector to corresponding channel, adjust oscillator slug thru hole on front of r-f tuner unit. (A-2 to A-13) This permits response curve to be shifted so that sound carrier marker will appear at the position indicated below.

TYPICAL OVERALL RESPONSE CURVE

NOTE: Make sure that cam on fine tuning control shaft remains properly positioned during this step (tooth on the cam pointing downward).

NOTE: If an unsatisfactory overall response is obtained for a particular channel, observe R-F amp. and Mixer response curve for that channel (as described in R-F Amp. and Mixer Alignment Table). If characteristic curve does not conform reasonably well within the typical curve shown in Figure 11, then do the following things:

1. Check method of connecting scope, voltmeter and generator leads to eliminate possible distortion of observed response, or:
2. Attempt to obtain a better compromise for R.F. response on all channels by realigning R-F Amp. and Mixer circuits, or:
3. Try replacing Antenna, R-F and Oscillator coils for the particular channel.

*Sound Carrier Marker
**Picture Carrier Marker

R.F. OSCILLATOR ALIGNMENT PROCEDURE

SOUND ALIGNMENT

(A) USING 4.5 mc UNMODULATED SIGNAL GENERATOR

1) Short pin #1 of V-3 to Chassis with short jumper wire.
2) Keep output of signal generator low so as to provide a sharp meter indication with adjustment of transformers.

(B) USING TRANSMITTED TV AIR SIGNAL

1) Connect antenna and tune to a good on the air TV station.
2) Adjust fine tuning control for best picture.
3) Adjust antenna coupling for moderate signal so as to provide a sharp meter indication with adjustment of transformers.
4) Meter reading may pulsate due to changes in signal strength; do not confuse with a peak adjustment.

STEP	SIGNAL GENERATOR INPUT		MEASURING INSTRUMENT	ADJUST	PROCEDURE
	CONNECTION	FREQUENCY			
1	Marker Gen. through .01 MF to Pin 7 of V-4 low side to chassis. - or - Connect antenna and tune in a good transmitted TV. signal (any channel)	4.5 MC (Unmodulated) - or - A good on the air TV. channel	Connect D.C. V.T.V.M. (negative scale) through 10K Resistor to Junction of C-30, R-35, R-36 - low side to chassis.	T-5 Top or Bottom T-6 Top and Bottom	Peak for maximum voltage. Adjust output of signal generator to produce about a one volt D.C. rise on meter (1 volt above noise* voltage) If T.V. signal is used adjust ant. coupling to receiver to produce about the same voltage rise.
2	Same as above.	Same as above.	Connect V.T.V.M. through 10K Resistor to Junction of R-44, C-34 - low side to chassis.	T-7 Top and Bottom (Discriminator)	A) Detune Discriminator secondary T-7 (Top Pt. #708018, 708151; Bottom Pt. #708017) for maximum negative meter reading. B) Adjust primary T-7 for maximum negative meter reading. C) Readjust Discriminator secondary (towards original setting) for zero D.C. reading on V.T.V.M. D) Check Audio, if distorted repeat steps A - C.

* The noise voltage is measured under no signal conditions (antenna terminals shorted directly at tuner by means of a short jumper wire; or disconnect 4.5 MC. generator if procedure (A) above is followed.)

4.5 MC VIDEO TRAP ALIGNMENT (L-12)

1. Connect crystal controlled 4.5 mc. signal generator through a .01 mf. condenser to the grid of the video amplifier tube (Pin 1 of V-5, 6CB6) low side to chassis.
2. Set contrast control for maximum contrast (fully clockwise).
3. Connect a V.T.V.M. (D.C. scale) through an R.F. probe to the cathode of the picture tube (Pin 11, yellow lead) low side to chassis.
4. Adjust the 4.5 mc. trap L-12 for minimum reading on the V.T.V.M.

If a crystal controlled generator is not available the video trap can be adjusted in the field by setting the fine tuning control for maximum 4.5 mc. in picture and adjusting the 4.5 mc. trap (L-12) until this 4.5 mc. beat note is reduced. Be sure that video ringing is not introduced from this adjustment since this indicates the trap was aligned at too low a frequency.

ALIGNMENT OF MIRACLE PICTURE LOCK (Horizontal A.F.C. & Osc.)

Before proceeding be sure the Fringe Compensator Switch has been turned "OFF" (fully counter clockwise past click).

1. Tune set to a good channel.
2. Short phase coil (L-13) with a jumper wire, leads have been brought to top of chassis on terminal strip near V-13 horizontal oscillator (see tube location diagram Figure 19 Page 19).
3. Short horizontal control grid to chassis. This point has also been brought to top of chassis on same strip as mentioned in Step 2.
4. Rotate horizontal hold control (R-73) to center of its mechanical range.
5. Adjust horizontal balance control (R-71) (rear of chassis) until picture pulls into synchronism (in most cases picture will sway from side to side).
6. Remove short from horizontal phase coil (L-13) and adjust L-13 for same synchronous condition as Step 5 above.
7. Remove short from horizontal control grid. Horizontal frequency circuits are now properly aligned.
8. When properly adjusted (Steps 1 to 7) the horizontal hold control can be moved slowly over most of its range without throwing the picture out of sync.
9. Readjust horizontal hold control (R-73) so that the picture remains in sync when switching channels (near center of range).

ALIGNMENT (UHF TUNER)

The alignment of the tuner is factory set and will actually not require any additional adjustments other than to compensate for differences in 6J6 oscillator tubes. Because of this fact, the only adjustment to be made in the field is trimmer C-7 which is located next to the 6J6 oscillator tube. (See Figure 2, Page 2)

This trimmer is normally set at the factory to track the highest U.H.F. channel (83). This must be done with a U.H.F. sweep and marker generator. In the field however, this equipment is not readily available and C-7 should therefore be used to track the highest U.H.F. channel received in the area. It is usually best to try a few 6J6 tubes until one is found which more nearly resembles the original, thus requiring only a slight adjustment of C-7.

In the event T-A has been tampered with or replaced, it should be adjusted for best results on all U.H.F. channels received in the area. This I.F. sometimes normally has only a slight effect on the picture or sound.

Before doing any work on this U.H.F. tuner, whether in the field or shop, be sure that the V.H.F. I.F. and R.F. circuits have been properly set up, (this can be checked by viewing an on the air V.H.F. channel or by instruments). Information pertaining to the use of instruments can be found on Pages 11, 12 and 13.

GENERAL INSTALLATION INSTRUCTIONS

ANTENNA

This chassis is designed to operate from either its built in UHF-VHF antenna, an external combination UHF-VHF antenna or separate UHF and VHF antennas using one or two sets of antenna lead in wires.

This set as delivered is ready to operate from its built in UHF-VHF antenna. In most strong UHF-VHF signal areas this will suffice.

If it is necessary to install an external antenna, disconnect the built in antenna by removing the spade lugs (1 and 2) from the VHF antenna terminals.

If one antenna lead in is used for both UHF and VHF reception, it should be connected to the VHF input terminals. When the receiver is set for UHF reception, the UHF-VHF switch automatically transfers the single antenna lead in to the input of the UHF tuner removing it from the VHF tuner. This transfer will only take place providing the jumper twin lead connected to terminals 7 and 16 of the UHF-VHF switch is also connected to the UHF input antenna terminal strip by means of spade lugs 3 and 4.

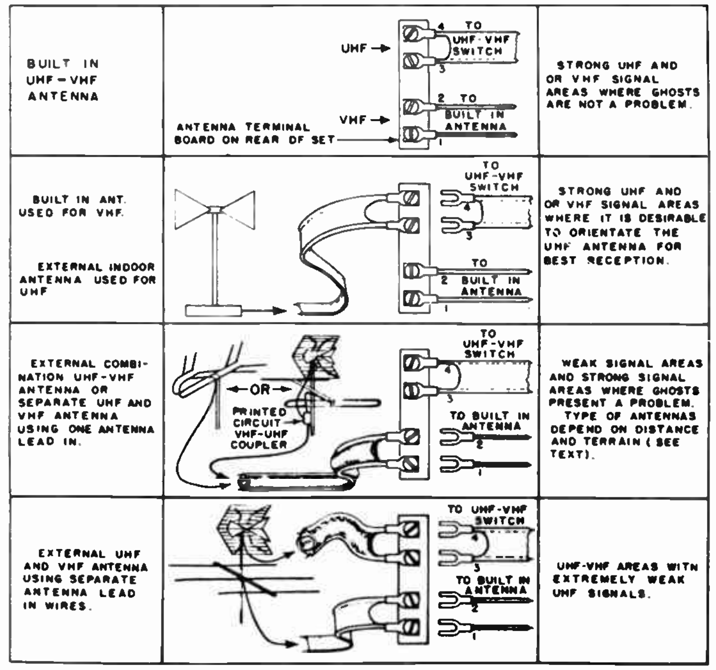

Figure 15. ANTENNA CONNECTIONS

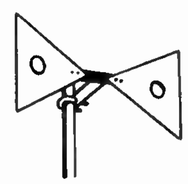
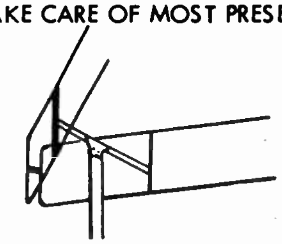
If separate UHF and, or VHF antenna lead in wires are used, they should be connected to their respective antenna input terminals. Under these conditions, spade lugs 3 and 4 must be removed from the UHF input antenna terminals.

For new installations, it would be desirable and economical to install a combination UHF-VHF antenna providing of course that a VHF station has been allocated to that area. In the event that the terrain is hilly or in a metropolitan area, ghosts may present quite a problem and it may be better to install separate UHF and VHF antennas. This may be necessary since combination antennas usually have poor directivity at UHF. Separate UHF and VHF antennas can be connected to one lead in if desired through a printed circuit filter, which is commercially available.

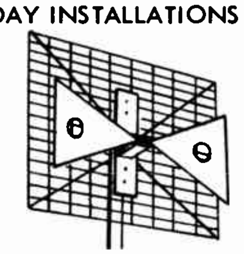
U H F ANTENNAS WHICH WILL TAKE CARE OF MOST PRESENT DAY INSTALLATIONS



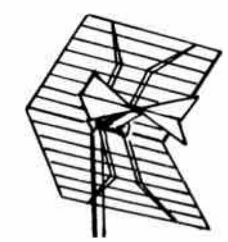
SINGLE BOW TIE
For use in strong signal areas where ghosts do not present a problem.



STACKED V
For use in weak signal areas where ghosts do not present much of a problem. Can also be used for strong VHF signals.



BOW TIE SCREEN RELFECTOR
For use in strong or weak signal areas where ghosts present a problem.



FOLDED BOW TIE CORNER REFLECTOR
For use in strong or fringe areas where ghosts present a problem.

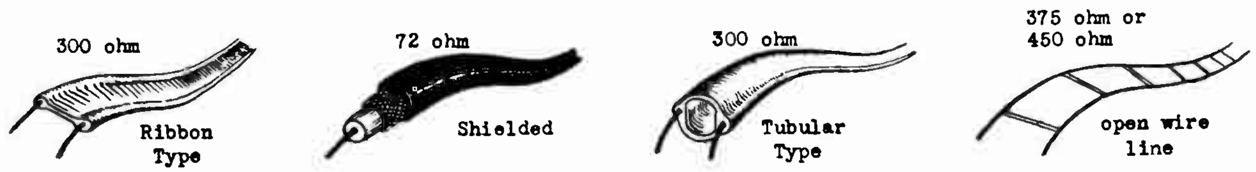
NOTE: All of the above four antennas will operate over all 70 UHF channels.

In UHF the use of free space terminals and rigid construction is an important detail. By free space terminals we mean air insulation between the terminals of each antenna section instead of bakelite or poly. The use of an insulation other than air, tends to collect moisture which creates a signal leakage path thus reducing the signal.

Since UHF frequencies have relatively short wave lengths, rigid elements are very important. The slightest movement could easily become an appreciable part of a wave length which may effect signal pickup.

ANTENNA WIRE

The common type 300 ohm ribbon line will work out satisfactorily only in strong signal areas, since when wet line losses increase by almost 8 times at the high end of the UHF band. The tubular 300 ohm line is much better in this respect as the leakage path is not as readily effected by moisture and it can therefore be used in most signal areas. When wet, tubular line losses increase slightly more than two times at the high end of the UHF band. In the extreme fringe areas the use of open wire line may be best, but it is more difficult to work with. Shielded 72 ohm or 300 ohm transmission line is not at all effected by weather conditions but these lines generally have a higher loss to start with and are comparatively expensive.



Transmission lines other than the shielded type should be mounted away (6 to 7 inches) from all nearby metal objects by use of stand offs, as the closer these lines are to metal, the greater will be the losses. In the event that it is impractical to use stand offs, shielded lines such as RG-59U or RG-11U should be used. Never rest unshielded lines next to metal objects over any appreciable distance as losses will be exceptionally high and will vary to a great extent depending on weather conditions.

If tubular line is used, be sure that the ends are sealed to prevent moisture from entering the line. This is easily done by heating the ends and pressing them together to form a good seal. It is also a good idea to use a small drain hole in the tubular line just before it enters the house so that condensed moisture may leak out.

HEIGHT AND ORIENTATION OF ANTENNAS AT U.H.F.

Since the wave lengths at UHF are much shorter than at VHF, objects which did not appreciably reflect the VHF wave will now reflect UHF waves. Because of this, orientation and the use of directive antennas is much more important to minimize the pickup of reflected or ghost signals.

Another effect of these shorter wave lengths is to cause a more rapid variation of signal pickup with antinna height. Because of this fact, it is important that antenna height be probed for maximum signal pickup. A foot higher or lower may yield a marked increase in the signal pickup.

U.H.F. CHANNELS AND THEIR CORRESPONDING FREQUENCIES

Channel	Freq.	Video	Audio	Half Wave (Inches)

By raster we mean the illuminated scanning lines.

* Another very common fault is a shorted or open circuit antenna connection to set.

GENERAL TROUBLE SHOOTING INFORMATION (UHF TUNER)

Since the operation of this tuner is dependent almost entirely on its mechanical configuration, all component parts whether lumped constants or transmission line sections, have been manufactured and mounted as rigid as possible. If it is necessary to replace a component, the exact replacement part should be used. Be sure it is mounted in the same position using the same lead lengths as the original. This is very important since at UHF frequencies a small piece of wire has an appreciable inductance. Stray capacitances between components and chassis also tend to effect the circuit's operation to a marked degree.

Due to the simplicity of design and manufacture of this tuner, little trouble is to be expected. In the event that this tuner becomes defective in any way, the trouble shooting chart in this note can be used to good advantage.

If the crystal D-2 is open or shorted, or the oscillator is inoperative, there will be no bias developed across R-2. If replacing D-2 does not rectify this condition, then it can be assumed that the oscillator is not functioning.

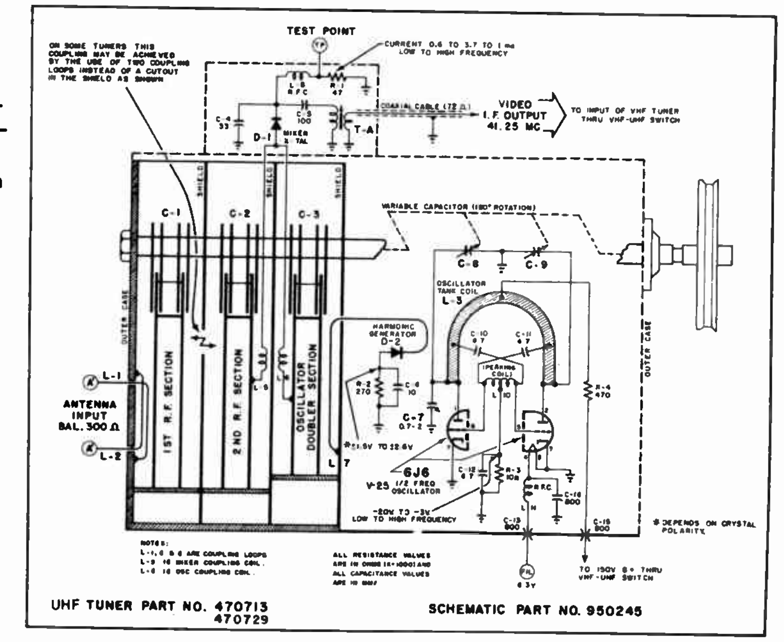

Figure 20 - SCHEMATIC DIAGRAM UHF TUNER 470713 470729

Be sure that the harmonic generator coupling loop (L-7) is not touching the shield. A voltage and resistance check of the 6J6 oscillator circuit should soon locate the trouble.

If the correct bias is measured across the resistor R-2 and the set still operates poorly on UHF, then it can be assumed that the mixer crystal D-1 is defective in some way. This can easily be determined by lifting R-1 off chassis and inserting a D.C. milliameter between it and chassis. In the event that the current readings are abnormally low or high, a new crystal known to be good should be inserted (see trouble shooting chart). If it is desired to localize the difficulty further, C-4 and, or C-5 can be disconnected. When soldering near crystals, be sure to use a small tipped, low wattage iron, placing the pliers between the crystal and the connection so as to absorb the heat thus protecting the crystal. This is important, since excessive heat can easily damage it.

Do not attempt to repair or adjust this tuner by adjusting any of the coupling loops or by moving various components. The only adjustment that can be made in the field is C-7 to compensate for a change in interelectrode capacities when a new 6J6 is used. The proper procedure for this is shown under alignment, Page 16.

Components which are not a part of the R.F. or oscillator tuned circuits such as feed thru condensers, B plus resistors, T-A, etc., can usually be replaced with little difficulty providing the above precautions are observed.

NOTE: In the event that this tuner needs an overall alignment or service of parts, the defective tuner should be returned for repairs through your Emerson distributor.

REPLACEMENT OF TUNERS

If it becomes necessary to return a UHF tuner to your distributor for repair or replacement, remove and retain the extension shaft and pulley. When returning the VHF tuner, remove and retain the VHF-UHF switch and the front plate which consists of a pulley and gear combination. This is important since replacement tuners will not come equipped with the above devices.

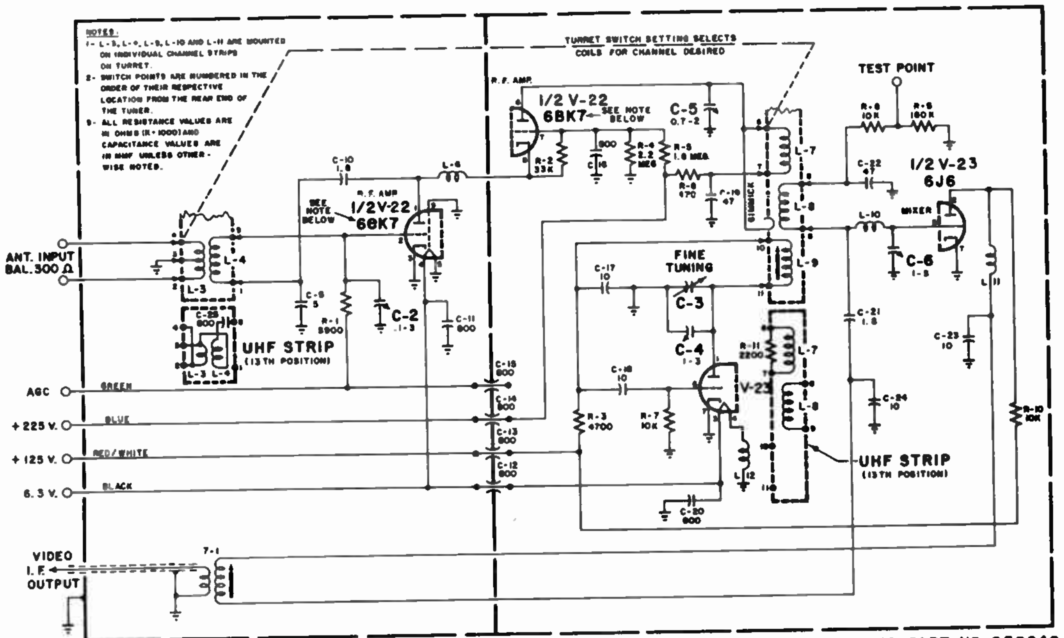
Under no conditions are both the VHF and UHF tuners to be returned as a unit. Before returning for replacement or repair, an honest effort should be made to repair the unit since all special and major parts will be available through your Emerson distributor.

TROUBLE SHOORING CHART (UHF TUNER) -

Component		Variations Low to High Frequency	POSSIBLE TROUBLE (If voltage readings not normal)
6J6	B+ Filament R-3	+150V. 6.3V. A.C. -20V. to -3V.	C-10, C-15, C-11 shorted, the V.H.F.-U.H.F. switch L-11 open, C-14, C-13 shorted R-3 open, C-12 shorted, L-10 open or shorted
0-2 Harmonic Gen. Crystal	R-2	±1.5V. to ±2.6V.	Crystal defective, L-7 shorted to chassis, C-7 shorted Voltage polarity depends upon crystal polarity
D-1 Mixer Crystal	Current thru R-1 Insert Milliameter	0.6 thru 3.7 to 1.00 ma. (current)	0-1 defective, C-4 shorted, L-8 open

NOTE: Voltages taken with receiver in UHF position under same conditions as listed on top of Page 22.

GENERAL TROUBLE SHOOTING INFORMATION (VHF TUNER)



VHF TUNER PART NO. 470712 NOTE: THE R.F. TUBE PRESENTLY USED IS A 6BK7, IN THE FUTURE A 6BQ7,6BQ7A OR A 6BZ7 MAY BE USED. THESE THREE TUBES ARE INTERCHANGEABLE, BUT DUE TO POSSIBLE VARIATIONS IN INTERELECTRODE CAPACITIES, SEVERAL TUBES MAY HAVE TO BE TRIED FOR BEST RESULTS. SCHEMATIC PART NO. 950246

Figure 21 - SCHEMATIC DIAGRAM OF VHF TUNER 470712

REPAIR OF VHF TUNER

The majority of tuner troubles which are not due to defective tubes can usually be detected by a physical examination of the tuner (turret removed), such as burnt resistors, broken parts, bent or dirty contact fingers, cold solder joints, broken socket pins, etc.

If the tuner checks out physically it should then be checked according to the following trouble shooting chart.

It should always be borne in mind that a burnt tuner resistor is usually the result of a shorted condenser or tube.

The part numbers of items which are not generally commercially available are given on the tuner schematic. When replacing parts, leads should be kept as short as possible and components replaced in the same position as the original parts.

More detailed general information on turret tuner repairs can be found in Service Note titled "Emerson Turret Type Tuner #470651" released April 1, 1951.

TUNER TROUBLE SHOOTING CHART VHF TUNER

Measurements taken under same conditions as listed on top of Page 22. To take measurements from 6BK7 socket, remove 6BK7 tube but leave 6J6 tube in its socket, likewise when taking measurements from the 6J6 socket leave 6BK7 tube in its socket.

V-22	PIN NO.	NORMAL READINGS		POSSIBLE TROUBLES IF READINGS NOT NORMAL
		VOLTAGE	RESISTANCE	
6BK7 or 6BQ7 or 6BQ7A or 6BZ7	Pin 1	130V.	1 meg.	(C-9, 3.3 mmf) shorted
	Pin 2	-2.5 V.	1.8 meg.	(R-2, 15K) or (R-1, 47K) open or shorted
	Pin 3	OV.	0 ^	Cold solder joint
	Pin 6	+215V.	16 K	(C-5) trimmer shorted, (C-18, C-13) shorted, (L-9) open, (R-8, 470 ohm) open or shorted
	Pin 7	+130 V.	1 meg.	(R-3, 330 K),(R-4, 180 K) or (R-5, 100 K) open or shorted, (C-15, 1000 mmf) shorted
	Pin 8	+130 V.	1 meg.	(C-9, 3.3 mmf) shorted
	Pin 9	OV.	0 ^	Cold solder joint

V-23	PIN NO.	NORMAL READINGS		POSSIBLE TROUBLES IF READINGS NOT NORMAL
		VOLTAGE	RESISTANCE	
6J6	Pin 1	150 V.	16 K	(R-6, 4700 ohm) open or shorted, (C-12, 1000 mmf), (C-16, 10 mmf) or (C-17, 5 mmf) shorted
	Pin 2	150 V.	20 K	(L-13) open, (C-21, 1000 mmf), (C-22, 6.8 mmf) or (C-23, 1000 mmf) shorted, (R-11, 15 K) open or shorted
	Pin 5	OV.	190 K	
	Pin 6	OV.	8.5 K	(C-16, 10 MMF) shorted
	Pin 7	OV.	0 ^	Cold solder joint
	Test Point	-1 V. to -3 V.	200 K	Oscillator injection voltage varies between channels (low frequency channels have higher injection voltage about -4 v.)

CONDITIONS FOR TAKING VOLTAGE AND RESISTANCE READINGS

The resistance measurements listed below are for chassis 120174B and 120198D with no triangle code markings.

Due to component variations, voltage and resistance readings may vary slightly from those given here. Slight variations may also be noticed if chassis is not coded as mentioned above.

The picture tube, deflection yoke and high voltage circuits were connected to take the following readings and waveshapes.

1. Antenna disconnected and antenna terminals shorted on tuner and connected to chassis (use short leads).
2. Line voltage 117 volts (Disconnect power for resistance readings).
3. 3 volt bias battery connected to both I.F. and R.F. A.G.C. circuits, positive terminal to chassis, negative terminal to junction of R-19, C-19, C-18. Add a jumper wire from this junction to junction of R-16, C-8, R-10 so that bias battery is also applied to I.F. A.G.C. BIAS BATTERY USED FOR VOLTAGE READINGS ONLY.
4. All controls in position for normal picture. (Varied when it directly effects reading).
5. All measurements taken with a vacuum tube voltmeter and ohmmeter.
6. All readings listed in tables were taken between points shown and chassis.
7. Resistance readings are given in ohms unless otherwise noted.
8. N.C. denotes no connection.

WAVE SHAPE ANALYSIS CHART FOR CHASSIS 120174B AND 120198D

The information listed below was taken from a chassis with no triangle code markings.

Slight peak to peak voltage differences may be noticed if chassis is not triangle code marked as mentioned above.

The wave shapes shown here are arranged so as to give the serviceman an easy method of signal tracing. The peak to peak voltage given may vary slightly depending on signal strength and component variations.

To accurately observe the wave shapes, the relatively high input capacity of an oscilloscope must be reduced so as not to change the operating characteristics of the television set. Failure to do this will result in wrong wave shape readings. This is accomplished by using an Emerson low capacity probe as outlined previously in the service note for models 686L, 687L, and 696L using chassis 120142-B which was issued at an earlier date.

Connect antenna and tune receiver to channel where best reception has been obtained in the past.

Low end of the probe is connected to CHASSIS and the contrast control is set at MAXIMUM CONTRAST.

The 30 and 7875 C.P.S. oscilloscope sweep settings are used so as to permit the serviceman to observe two cycles of the wave shape.

NOTE: A wave shape seen in your oscilloscope may be upside down from same wave shape shown here. This will depend on the number of stages of amplification in the oscilloscope used.

PRODUCTION CHANGES

In the course of production various changes were incorporated in the order shown below. Changes as listed under a particular letter also include changes as listed under all previous letters unless otherwise noted. All changes released after this note is printed will be sent out to our distributors in the form of field service bulletins. These should be kept together with the service note and entered in the following table for a quick reference. By utilizing this information the schematic can be easily modified to correspond to a chassis of any triangle code.

Triangle Code Letter	F.S.B. No.	Supp. No.	Purpose
A (in triangle)	Service Note	O	See Schematic Page 23.

ADDENDUM SERVICE NOTE

This information should be considered as part of the Service Note for Models 752A, 755A, 784A, 753F, 785C and 785E using chassis 120174-B, 120198-D

Model Numbers	TV Chassis	Tube Size	TV Tuner
753D, 761C	120180-D	17LP4 (Glass-Rect.)	470712 - VHF 470729 - UHF

MODELS 753D, 761C
BUILT IN ALL CHANNEL UHF-VHF RECEIVERS

The above models incorporate Chassis 120180-D which is electrically identical to Chassis 120198-D. The differences between the two chassis are in the physical placement of the 5U4G tubes and the use of a different chassis base.

With the exception of the Cabinet Parts List (below) and the Tube Location Diagram (other side), all technical information pertaining to the models listed above will be found in the Service Note covering Models 752A, 755A, 784A, 753F, 785C and 785E using chassis 120174-B, 120198-D

NOTE: THE R.F. AMP. TUBE PRESENTLY USED IS A 6BK7. IN THE FUTURE A 6BQ7, 6BQ7A OR A 6BZ7 MAY BE USED. THESE THREE TUBES ARE INTERCHANGEABLE, BUT DUE TO POSSIBLE VARIATIONS IN INTER-ELECTRODE CAPACITIES, SEVERAL TUBES MAY HAVE TO BE TRIED FOR BEST RESULTS.

TUBE LOCATION DIAGRAM CHASSIS 120180-D

ADDENDUM SERVICE NOTE

This information should be considered as part of the Service Note for Models 752A, 755A, 784A, 753F, 785C and 785E using chassis 120174-B, 120198-D

Model 768A

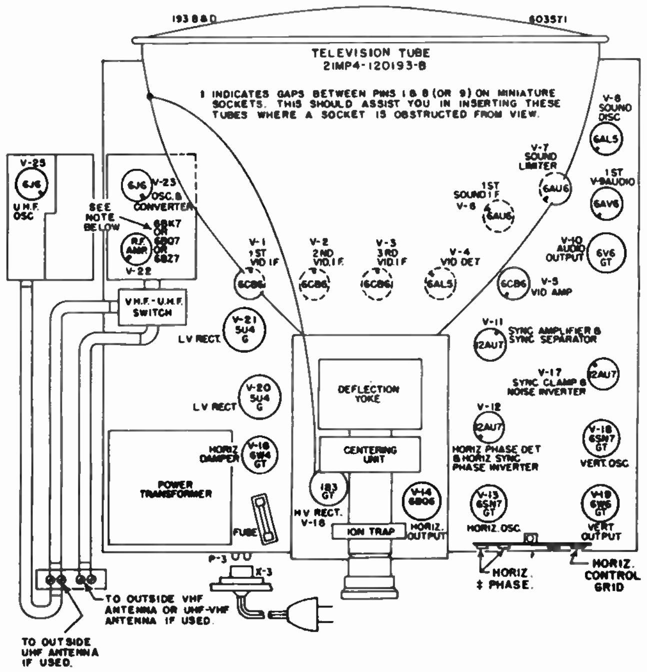
Models 772A

Model 774A

BUILT IN ALL CHANNEL UHF - VHF RECEIVERS

Chassis 120193-B are "ALL CHANNEL UHF - VHF RECEIVERS". Combination UHF and VHF tuning is achieved through the use of two tuners which are connected to the same tuning knobs making VHF or UHF channel tuning very simple. The VHF cascode turret tuner has 13 positions (one more than the conventional type), 12 being used for VHF reception, (channels 2 to 13), while the 13th or UHF position is used to activate the proper UHF circuits and provides additional amplification for the converted 40 mc. UHF signals. In this position, a window is provided to observe the continuous tuning of the UHF channels.

The 120193-B Chassis is electrically identical to the 120174-B Chassis of which this is an Addendum. Dual chassis numbers (120174, 120193) have been assigned since these chassis differ physically in the type of chassis base used and the placement of the 5U4G rectifier tubes.



NOTE: THE R.F. AMP. TUBE PRESENTLY USED IS A 6BK7. IN THE FUTURE A 6BQ7, 6BQ7A OR A 6BZ7 MAY BE USED. THESE THREE TUBES ARE INTERCHANGEABLE, BUT DUE TO POSSIBLE VARIATIONS IN INTERELECTRODE CAPACITIES, SEVERAL TUBES MAY HAVE TO BE TRIED FOR BEST RESULTS.

TUBE LOCATION DIAGRAM CHASSIS 120193-B

‡ The Phase Coil side of the 4 lug terminal strip always has two wires connected to it. The other side has only the one Control Grid wire.

Corrections to the 120174-B & 120198-B Chassis Service Note

The following corrections should be noted directly on the schematic diagram Pages 23 and 24 of the Service Note:

1) C-34 should read .0022 mf instead of .0022 mmf.
2) R-23 in cathode circuit of V-6 should be changed to R-33.
3) The wave shape shown going to the junction of R-76 and C-55 should be altered to look like wave shape shown here.

ADDENDUM SERVICE NOTE

This information should be considered as part of the Service Note for Models 752A, 755A, 784A, 753F, 785C and 785E using chassis 120174-B, 120198-D

Chassis 120209-D and 120209-F are "ALL CHANNEL UHF - VHF RECEIVERS." Combination UHF and VHF channel tuning is achieved through the use of two tuners which are connected to the same tuning knobs making VHF or UHF channel tuning very simple. The VHF cascode turret tuner has 13 positions (one more than the conventional type), 12 being used for VHF reception, (channels 2 to 13), while the 13th or UHF position is used to activate the proper UHF circuits and provides additional amplification for the converted 40 mc. UHF signals. In this position, a window is provided to observe the continuous tuning of the UHF channels.

The 120209-D chassis is electrically identical to the 120193-B chassis except that a chassis mounted 21YP4 picture tube is used instead of a cabinet mounted 21MP4. Information on the 120193-B chassis was previously released as supplement #2.

The 120209-F chassis is electrically identical to the 120209-D except for the use of a different UHF tuner (pt. #470748). A diagram and brief description of this tuner is given in this addendum service note.

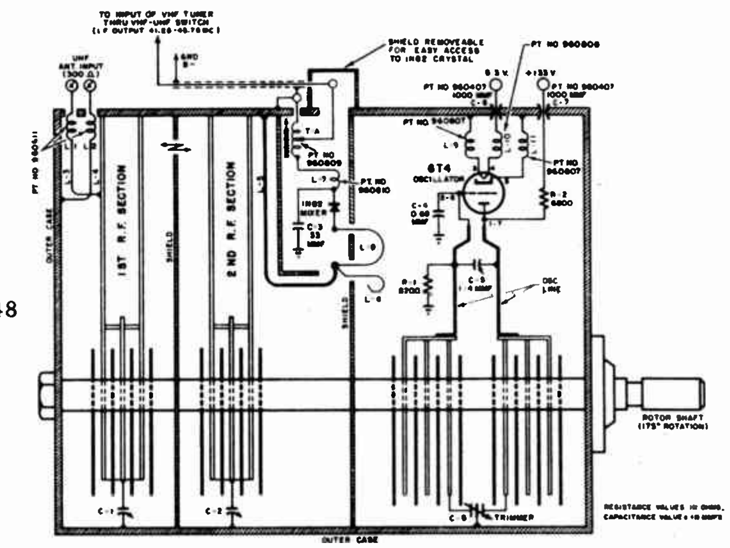
DESCRIPTION OF UHF TUNER PT. NO. 470748

The tuned elements in this tuner are of the modified coaxial transmission line type. As you can see from the schematic, the incoming UHF signal is tuned by means of two R.F. preselectors. These preselectors are quarter wave end tuned coaxial lines. Capacitive tuning is employed at the open ends to electrically adjust the line to 1/4 wave length and, therefore, effect a resonant condition at any frequency within the UHF band. Two identical preselector circuits are coupled together to provide the proper band pass characteristic. The ganged variable capacitors adjust the two preselector lines and are similar to those used in conventional low frequency circuits. Each line is tuned by four rotor plates. Capacitor trimmers (C-1, C-2) are located behind the coaxial lines to preset the high frequency end of the R.F. preselectors.

UHF TUNER PT. NO. 470748



TUNER PART NO. 470748 SCHEMATIC PART NO. 950298

The antenna input in this tuner is coupled to the 1st preselector circuit and is designed to match a balanced 300 ohm transmission line.

The output from the 2nd R.F. preselector (desired UHF channel) is fed by means of L-5 to the mixer crystal D-1 (1N82) through the oscillator coupling loop L-7 where it beats with the oscillator to form the desired I.F. frequencies (45.75 mc picture, 41.25 mc sound). T-A is tuned to pass these frequencies. An oscillator (6AF4) whose resonant frequency is determined by an end tuned coaxial line connected between its plate and grid is used in this UHF tuner. Capacity tuning is employed at the open end of this coaxial line to adjust it to 1/4 wave at the desired frequency of operation (45.75 mc above the R.F. video carrier). Trimmer C-8 is used to set the high frequency end of the oscillator whereas C-5 is used to set the low end for best overall tuner tracking. C-8 can be adjusted in the field to compensate for slight variations between replacement 6AF4 tubes. Several 6AF4 tubes should be tried picking the one which requires the least adjustment of C-8 so that tuner tracking will not be effected.

Complete tuner shielding is provided to reduce oscillator radiation and stray pickup to a minimum.

GENERAL TROUBLE SHOOTING INFORMATION (UHF TUNER)

Since the operation of this tuner is dependent almost entirely on its mechanical configuration, all component parts whether lumped constants or transmission line sections, have been manufactured and mounted as rigid as possible. If it is necessary to replace a component, the exact replacement part should be used. Be sure it is mounted in the same position using the same lead lengths as the original. This is very important since at UHF frequencies a small piece of wire has an appreciable inductance. Stray capacitances between components and chassis also tend to effect the circuit's operation to a marked degree.

Due to the simplicity of design and manufacture of this tuner, little trouble is to be expected.

If the oscillator is working correctly, the injection current (measured with a D.C. milliameter between the tap of T-A and tuner chassis) should be within the range of .5 ma to 4.5 ma.

If the measured reading is not within these limits check the following in the order shown. 6AF4 oscillator, 1N82 crystal, supply voltages to tuner, T-A, C-3, C-68. Make certain that the coupling loop (L-8 and L-6) are not touching the shield between the oscillator and R.F. compartments.

Components which are not a part of the R.F. or oscillator tuned circuits such as feed through condensers, B+ resistors, T-A, etc., can usually be replaced with little difficulty providing the above precautions are observed.

Do not attempt to repair or align this tuner by adjusting any of the coupling loops or by moving various components. The only adjustment that can be made in the field is C-8 to compensate for a slight change in inter-electrode capacities when a new 6AF4 tube is used.

REPLACEMENT OF TUNERS

If it becomes necessary to return a UHF tuner to your distributor for repair or replacement, remove and retain the extension shaft and pulley. When returning the VHF tuner, remove and retain the VHF-UHF switch and the front plate which consists of a pulley and gear combination. This is important since replacement tuners will not come equipped with the above devices.

Under no conditions are both the VHF and UHF tuners to be returned as a unit. Before returning for replacement or repair, an honest effort should be made to repair the unit since all special and major parts will be available through your Emerson distributor.

TUNING RANGE: Channels 2 through 13.
SOUND RATIO DETECTOR FREQUENCY: 4.5MC.
SOUND IF FREQUENCY: 4.5MC.
PICTURE IF FREQUENCY: 26.1MC.
POWER CONSUMPTION: 250 watts.
AUDIO OUTPUT: 3.2 watts.

ANTENNA: "Built-in-Antenna" with provisions for connection of external antenna where necessary.
EXTERNAL ANTENNA IMPEDANCE: Balanced 300 ohms.
POWER SUPPLY: 117 volts, 60 cycles A.C.

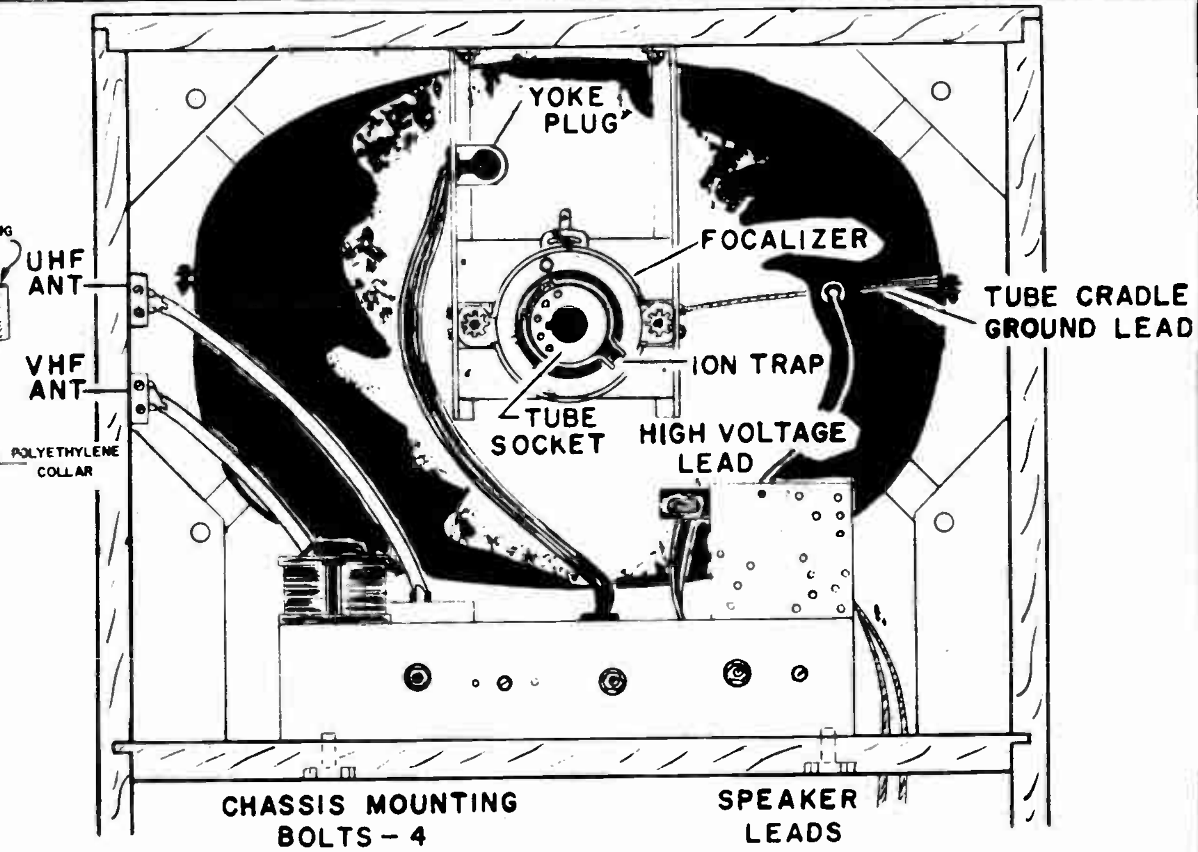

FIG. 1B

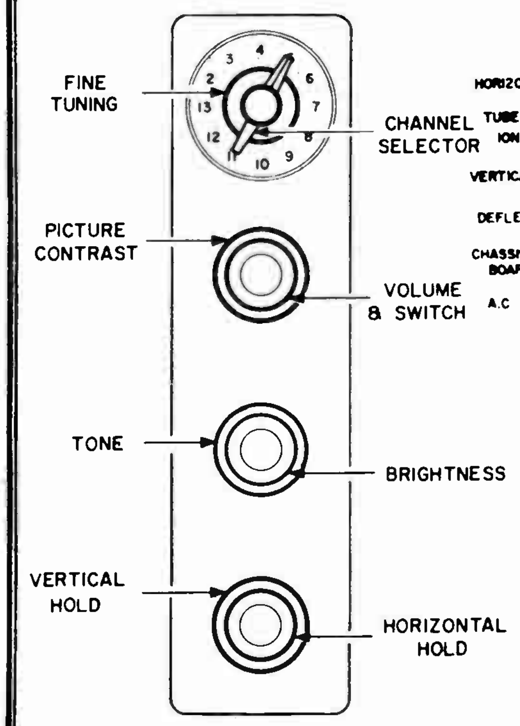
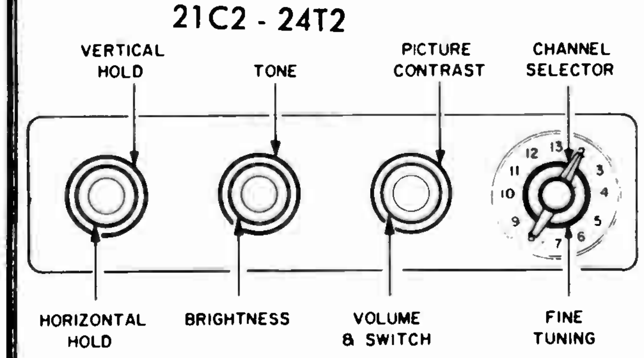
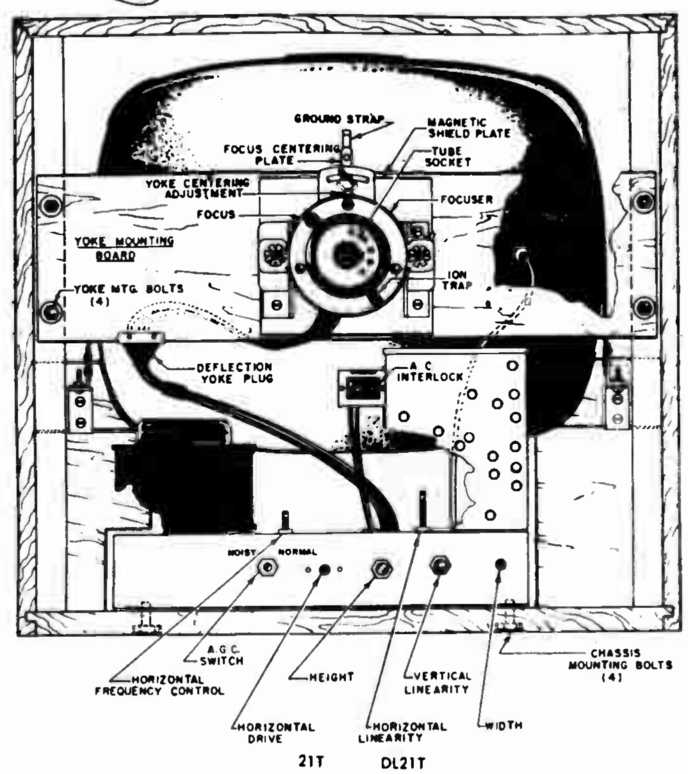


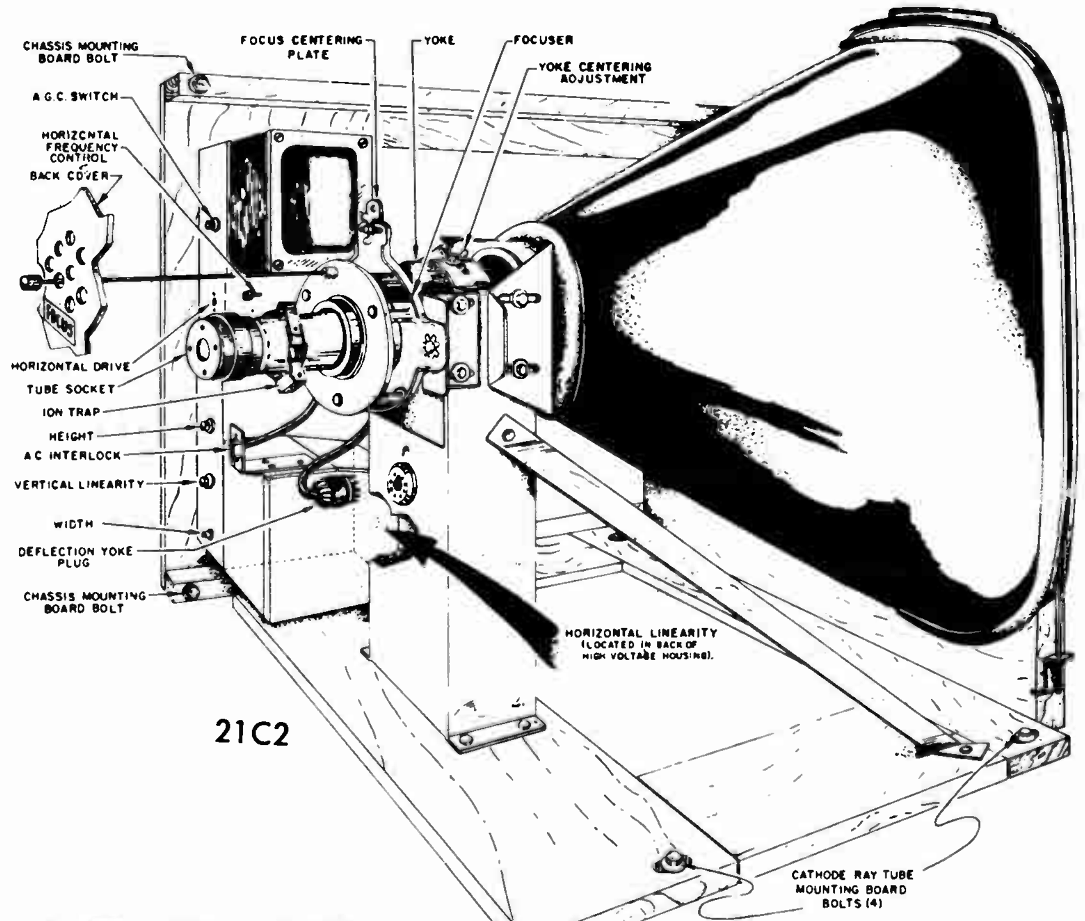
21C2 - 24T2



21T - DL21T

FIG. 1. OPERATING CONTROLS





21C2

FIG. 2. SERVICE ADJUSTMENT AND CONTROLS

SOUND RATIO DETECTOR AND IF ALIGNMENT

1. Connect probe of the VTVM to the diode plate of the ratio detector tube V20B (6T8, pin 2). Common to ground. See Figure 11.

2. Connect high side of the signal generator to the grid of the ratio detector driver. V21 (6AU6, pin 1). Common to ground. See Figure 11.

3. Tune the signal generator to exactly 4.5mc and attenuate the generator so it does not exceed 8 volts on the VTVM.

4. Peak L16 bottom core (FIG. 11) for maximum.

5. Peak L17 top core (FIG. 12) for maximum.

6. Adjust attenuator of signal generator to give exactly eight volts on the VTVM.

7. Move probe of VTVM to junction of R28, C31 and C29. (FIG. 11).

8. Adjust L17 top core (FIG. 12) for exactly 4 volts on the VTVM.

9. Move signal generator to video output tube V8 (6AG7, pin 4) (FIG. 11) and repeat steps number 1 and 3.

10. Peak L12 bottom (FIG. 11) and L13 top (FIG. 12) for maximum.

11. Repeat with care steps 1-3-4-5-6-7-8.

ALTERNATIVE PROCEDURE FOR STEPS 6-7-8:

1. Connect common lead of VTVM to junction of R29 and R30 (FIG. 11).

2. Connect probe of VTVM to junction of R28, C31, and C29. (FIG. 11).

3. Adjust L17 top (FIG. 12) for zero reading on the VTVM.

12. Connect detector probe shown in figure 6 between kinescope cathode (junction of R37 and R38) and ground.

13. Rotate the contrast control to its maximum clockwise position. Connect probe of VTVM to detector.

14. Adjust L12 (bottom slug) for minimum output on VTVM.

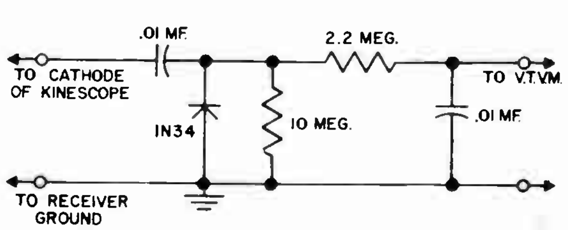


FIG. 6. DETECTOR PROBE

PICTURE I.F. (ROUGH ALIGNMENT)

1. Connect the bias battery as shown in fig. 11. The negative side of the bias battery to the junction of R8, R5, and C81, and the positive side to ground. Disconnect the white wire, that goes to the center terminal of the AGC switch (S2), from the junction of R8, R5, and C81. Connect the output of the signal generator between the test point on the R.F. unit (see fig. 12) and ground.

2. Connect the probe of the VTVM to the junction of L11 and R16 (fig. 11). Common to ground.

3. Set the signal generator to 21.6 mc. and adjust L25, co-channel sound trap, (fig. 12) for minimum output on VTVM.

4. Reset the signal generator to 23.25 mc. Adjust the output of the signal generator for approximately 2.5 volts on the VTVM.

5. Peak first Picture I.F. coil (located on R.F. Unit) and the third Picture I.F. coil L6 (fig. 12) for maximum. Maintain approximately 2.5 volts on the VTVM by adjusting the generator output.

6. Reset signal generator to 25.7 mc.

7. Peak second Picture I.F. coil L3 and the fourth Picture I.F. coil L9 (fig. 12) for maximum.

PICTURE I.F. (FLAT-TOPPING)

1. Remove signal generator and VTVM.

2. Connect the sweep generator between the R.F. test point and ground.

3. Connect the oscilloscope probe to the junction of L11 and R16.

4. Connect the hot side of the signal generator to the chassis side apron nearest the first I.F. stage. Leave the ground side disconnected.

5. With most sweep generators, there is enough output to give an I.F. response curve of sufficient height on the oscilloscope. If there is insufficient output use 3 volts bias instead of 4.5 volts. In adjusting the output of the sweep generator, make sure you do not overload the I.F.'s. This can be ascertained by noticing that the relative shape of the I.F. response does not change with small variations in sweep generator output.

6. Set the signal generator to 26.1 mc. and advance the output until a marker pip is visible on the Picture I.F. curve on the oscilloscope. Be careful not to distort the I.F. curve by advancing the generator output too far. Adjust L3 and L9 so that the marker pip is at the 50% point. See Fig. 7 Picture I.F. curves and Markers.

7. Set the signal generator to 22.7 mc. Adjust the first Picture I.F. coil (located on the R.F. Tuner) and L6 so that the marker pip is at the 50% point. See Fig. 7.

8. Repeat steps 6 and 7 until an acceptable curve is achieved.

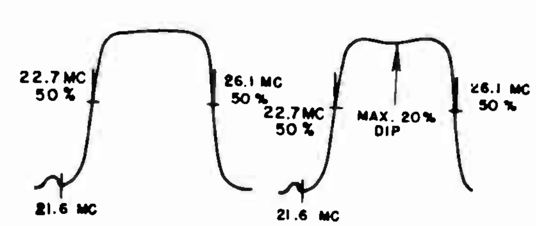

FIG. 7. TYPICAL PICTURE I.F. CURVES AND MARKERS

OSCILLATOR AND R.F. ALIGNMENT

The R.F. Unit is a turret type tuner with separate coil segments for each channel. Normal channel sequence is progressive in a clockwise direction covering channels 2 to 13. The R.F. amplifier is of the cascode type utilizing a 6BQ7 or 6BK7. The converter stage utilizes a 6J6.

OSCILLATOR ALIGNMENT

It should be possible to tune in all channels with the fine tuning control C212 (see figs. 11 and 12) in the middle third of its range. When V3 ages, the oscillator may shift slightly in frequency requiring adjustment. If V3 is defective and must be replaced, several tubes should be tried to find one that requires the least oscillator adjustment.

If an accurately calibrated signal generator that covers all the R.F. frequencies is available then continue with step 1. If not go on to step 10.

1. Remove tube shield on 6J6, V3.

2. Modify a tube shield which will fit snugly over the 6J6 and still remain ungrounded.

3. Remove shorting wire from channel 11 oscillator coil and replace segment and R.F. unit bottom shield.

4. Turn channel selector to channel 12.

5. Set generator to the oscillator frequency which is 231.35 mc. for channel 12.

6. With reference to figure 8 connect the generator to one of the 10 mmf capacitors and connect the other 10 mmf capacitor to the ungrounded tube shield over the 6J6. Connect remaining terminal on probe to vertical input on oscilloscope.

7. Set fine tuning control C212 (fig. 12) to center of its range. Adjust C211 for zero beat pattern on the oscilloscope screen. (The oscillator coil slug which is accessible from the chassis front apron should be in its mechanical mid-position. If the slug should fall in during adjustment, the oscillator coil segment will have to be removed from the turret housing, the little wire spring which normally fits into the slug threads lifted up, and the slug brought forward to its mean position.)

8. Reset the generator for the oscillator frequency of channel 11. Adjust the oscillator coil slug for zero beat on the oscilloscope screen. Use a non-metallic screw-driver in adjusting the oscillator coil slug.

9. Repeat step 8 for the remaining channels, making sure the signal generator is set for the proper frequency on each channel.

When an accurately calibrated generator is not available, then oscillator alignment can only be accomplished when the local T.V. transmitters are on the air.

10. Remove bias battery and replace AGC lead to junction of R8, R5, and C81 (fig. 11).

11. Set fine tuning control C212 (fig. 12) to center of its range.

12. Rotate channel selector control to one of the local T.V. stations and adjust the oscillator coil slug, which is accessible from the front chassis apron (fig. 12), for best picture.

13. Check remaining local stations by rotating the channel selector switch to, each channel in turn and adjusting the oscillator slug for best picture.

14. If on one or two of the channels you do not have enough oscillator range, readjust C211 and repeat steps 12 and 13.

It is possible to adjust the oscillator channel slugs without removing the chassis from the cabinet. The slugs are made accessible by removing the channel selector and fine tuning knobs and by moving the escutcheon plate to one side. Use a long thin fibre or bakelite screwdriver for making adjustments.

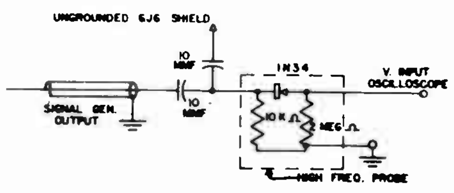

FIG. 8.

R.F. ALIGNMENT

1. Reconnect bias battery as in step 1. Picture I.F. (Rough alignment). Disconnect white AGC wire. Set bias for 3 volts.

2. Connect oscilloscope through 10,000 ohms to test point on R.F. Unit. Connect sweep generator to antenna terminals. If the sweep generator is not terminated for balanced 300 ohms, insert the network shown in fig. 9 below.

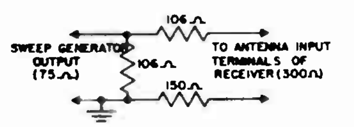

FIG. 9.

3. Set fine tuning control at approximately the midpoint of its tuning range and rotate channel selector to channel 12.

4. Adjust sweep generator to channel 12 and loosely couple signal generator to sweep generator in order to obtain picture carrier and sound carrier markers.

5. Adjust C206, C203, and C213 for flat top response curve. See figure 10 for acceptable R.F. passbands.

6. Check remaining channels. If the response curves obtained on any channel is not acceptable, it might be necessary to return to channel 12 and make a compromise of its response. If one channel is extremely out, that coil section should be repaired or replaced. It is not necessary to remove the tuner from the chassis in order to repair or replace a coil section.

ALL VOLTAGES MEASURED WITH RESPECT TO CHASSIS WITH A VACUUM TUBE VOLTMETER ADJUST PICTURE TO NORMAL HEIGHT AND WIDTH. TUNE IN AN UNUSED CHANNEL AND DISCONNECT ANTENNA SET CONTRAST AND BRIGHTNESS CONTROLS AT MAXIMUM COUNTER-CLOCKWISE POSITION. WITH 117 V A.C. INPUT, VOLTAGES SHOULD HOLD WITHIN 20%.
DIRECTION OF ARROWS AT CONTROLS INDICATES CLOCKWISE ROTATION.
K= 1000
ALL CONDENSERS IN MMF UNLESS OTHERWISE SPECIFIED.
CONNECT TO ANTENNA TERMINAL FOR OPERATION ON INDOOR ANTENNA
BUILT-IN CABINET ANTENNA

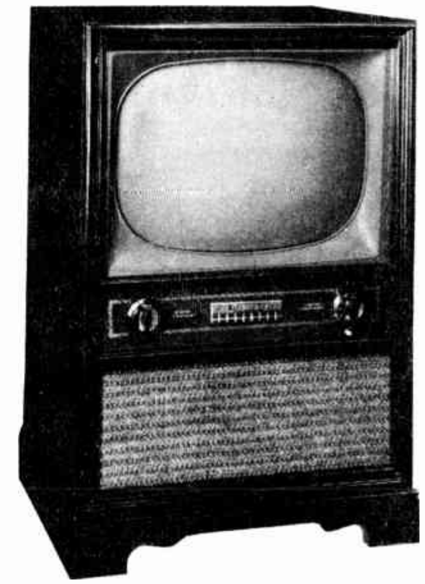
ELECTRICAL SPECIFICATIONS

Power Supply	117 Volts AC 60 cycles only
Power Consumption	250 Watts
Tuning Ranges	VHF — Channels 2 thru 13 UHF — Channels 14 thru 83
Power Output	2.5 Watts (Max.) 1.5 Watts 10% Distortion
Intermediate Frequencies	Picture — 45.75 MC Sound — 41.25 MC
Intercarrier Sound System	4.5 MC
Antenna Input Imp.	300 Ohms Balanced
Focus	Magnetic
Sweep Deflection	Magnetic
Loud Speaker	10" PM Dynamic
Voice Coil Imp.	3.2 Ohms 400 Cycles



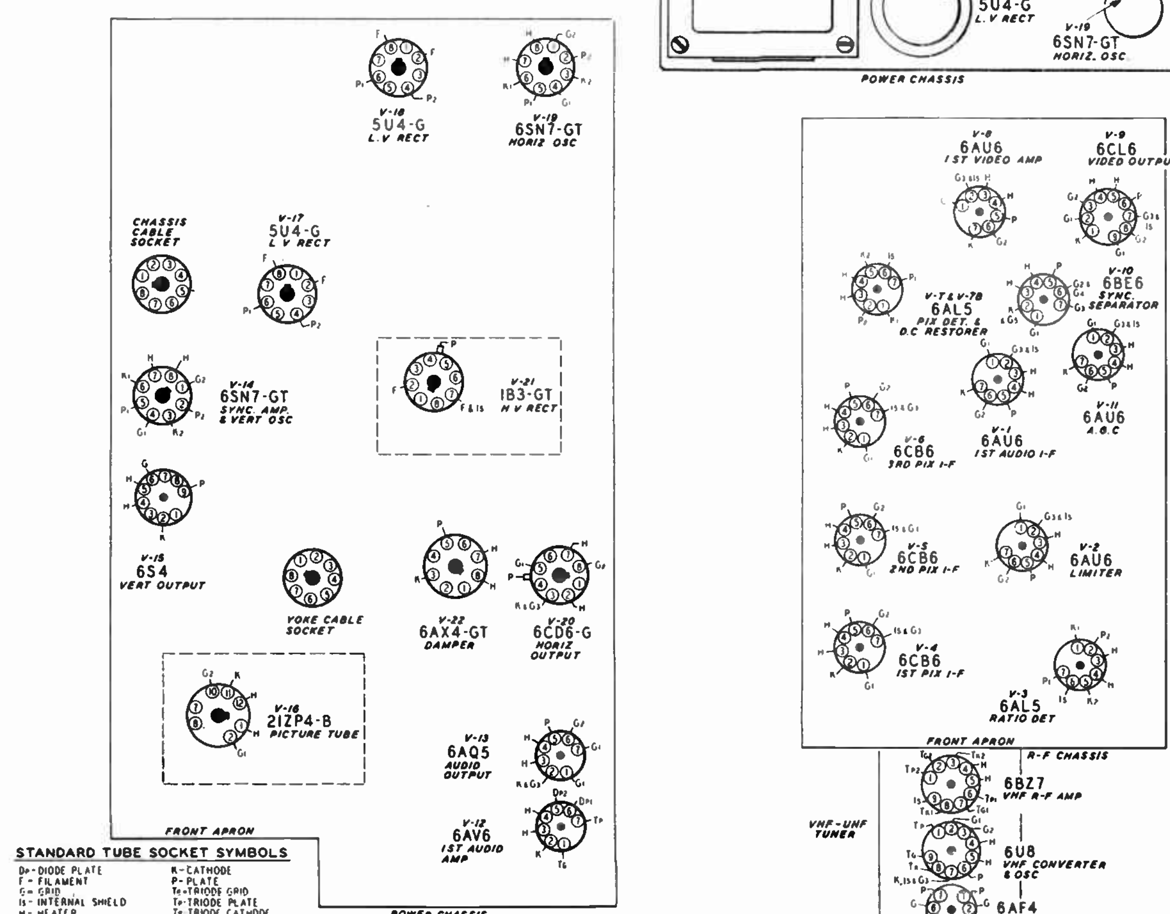


Fig. 2 — Bottom Socket.

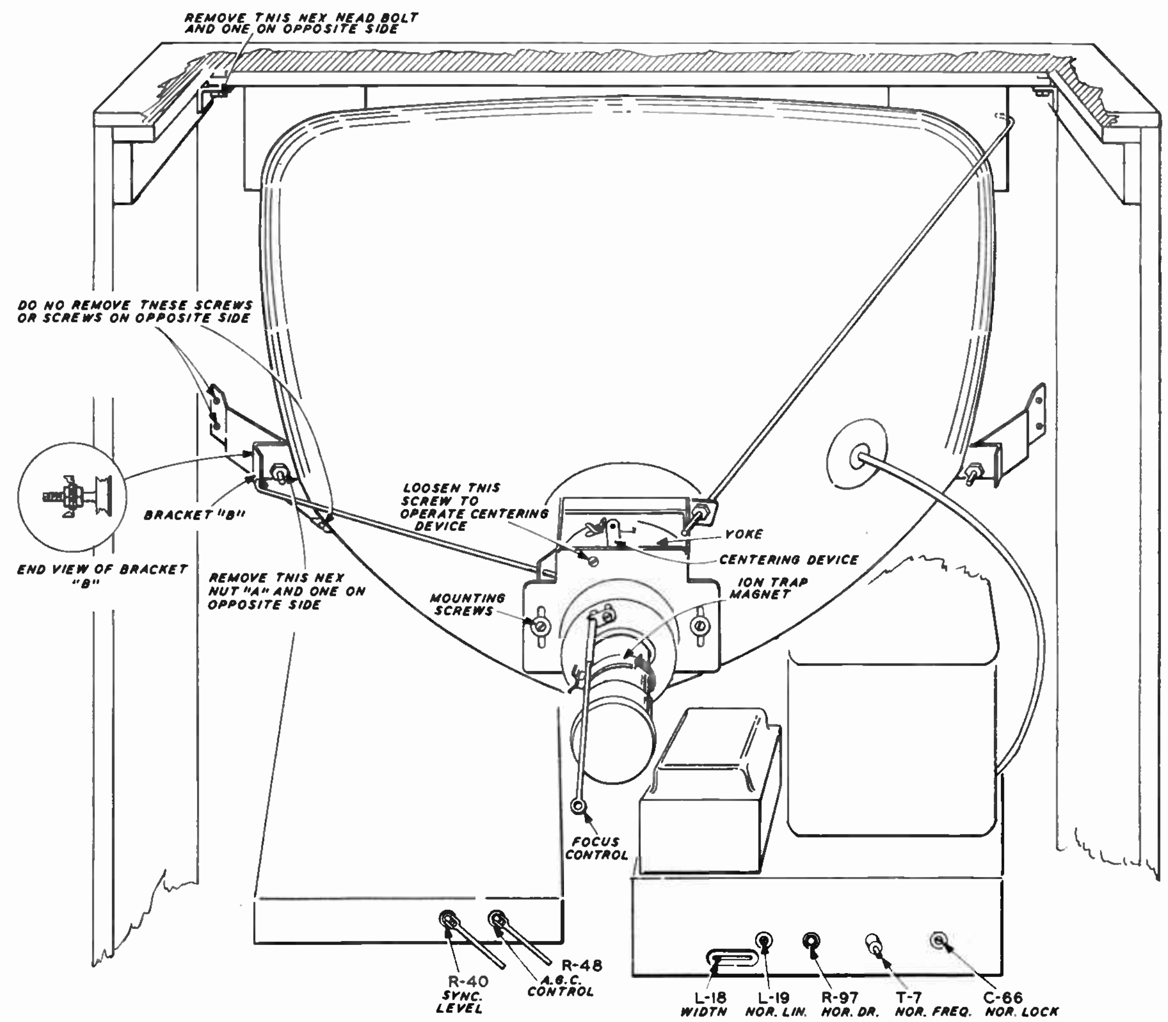

Fig. 4 — Tube Removal and Rear Chassis Controls.

HORIZONTAL WAVE FORM ADJUSTMENT — This is a factory adjustment and it should not be necessary to re-adjust unless the setting has been disturbed. However, if it is found that re-adjustment is required, follow this procedure: With the picture in sync. connect an oscilloscope through about a 10 mmf isolation condenser to Terminal C of T-7. Adjust the horizontal wave form (T-7 inside chassis) until the two peaks of the wave form shown in Fig. 6 are equal. NOTE· Picture must be in sync. during this adjustment.

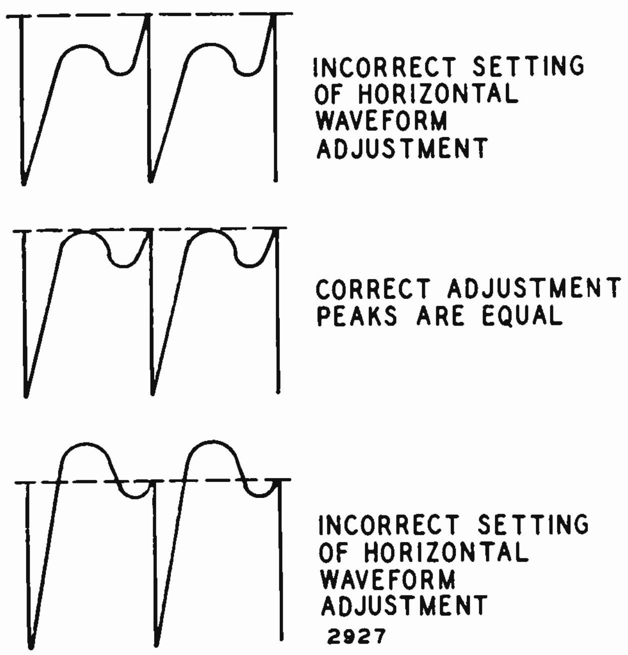

Fig. 6 — Settings of Waveform Adj.

HORIZONTAL LOCKING RANGE ADJUSTMENT — Set the horizontal hold control to the extreme counter-clockwise position. Momentarily remove the signal by switching off channel and then back. Slowly turn the horizontal hold control clockwise and note the least number of diagonal bars obtained just before the picture pulls into sync. If more than 3 bars are present just before the picture pulls into sync. adjust the horizontal locking range trimmer (C-66) slightly clockwise. If less than 2 bars are present, adjust the trimmer slightly counter-clockwise. Turn the horizontal hold counter-clockwise, momentarily remove the signal and recheck the number of bars present at the pull-in point. Repeat this procedure until 2 to 3 bars are present. Repeat the adjustments under "Horizontal Frequency Adjustment" and "Horizontal Locking Range Adjustment" until the condition specified under each are fulfilled. When the horizontal hold operates as outlined under "Check of Horizontal Oscillator Alignment" the oscillator is properly adjusted.

WIDTH, DRIVE AND LINEARITY ADJUSTMENT — While receiving a signal from a station (with picture locked in sync) turn contrast control fully counter-clockwise, turn the brightness control (R-65) up so that the picture appears washed out. Adjust width control (L-18) until the picture fills the mask. Turn the horizontal drive control (R-97) clockwise until white bars appear in the left center portion of the raster, then turn counter-clockwise until the white bars just disappear. This adjustment will allow the horizontal system to operate at maximum efficiency. Adjust horizontal linearity control (L-19) for best linearity. If adjustment of the horizontal linearity control (L-19) is required, readjustment of the horizontal drive control (R-97) will be necessary. Adjust the picture centering device to align the picture with the mask.

CHECK OF R-F OSCILLATOR ADJUSTMENTS

The oscillator is preset at the factory and normally needs no adjustment. However, if adjustments are required, they can be made without removing the chassis from the cabinet.

TEST PROCEDURE

1. Turn the large Channel Selector control knob until the letters VHF appear centered at top of the knob.
2. Turn the small Channel Selector to receive desired channel.
3. Remove the two Channel Selector knobs.
4. Set Fine Tuning control in center of its range.
5. With a 10" or longer bakelite type screwdriver adjust oscillator slug for best picture resolution.
6. Repeat steps 2, 4 and 5 on all Channels used.

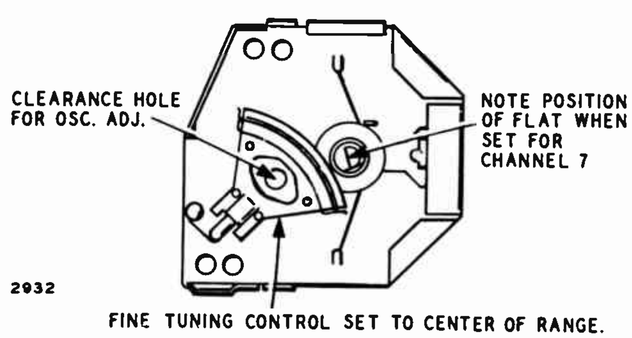

Fig. 7 — VHF Osc. Adj.

SERVICE SUGGESTIONS

NO RASTER ON PICTURE TUBE — If raster cannot be obtained check below for the possible causes.
1: Ion trap magnet adjustment is incorrect.
2: No +B voltage. Check 4/10 ampere fuse. Replace if defective.
If fuse continually burns out, check
(A) Horizontal output tube V-20 (6CD6-G)
(B) Check damper tube V-22 (6AX4-GT)
(C) Check horizontal oscillator tube V-19 (6SN7-GTA) for proper operation.
(D) With an ohm meter, check for a short between terminal 3 of the horizontal output transformer (T-8) and the chassis.
(E) Check DC resistance of T 8.
3: No high voltage. Check V-20, V-21 and V-22 tubes and circuits. If the horizontal deflection circuits are operating as evidenced by the correct voltage (600V) measured on terminal No. 3 of T-8, the trouble can be isolated to the high voltage rectifier circuit. Either the high voltage winding to the 6CD6-G plate and 1B3 plate is open, tube V-21 is defective, its filament circuit is open, R-105 and C-86 defective or pix tube elements shorted internally.
4: Defective picture tube heater open or cathode return circuit open.

HORIZONTAL DEFLECTION ONLY — If only horizontal deflection is obtained as evidenced by a straight line across the face of the picture tube, it can be caused by the following:
1: Vertical oscillator tube V-14B and vertical output tube V-15 inoperative. Check socket voltages.
2: Vertical oscillator transformer (T-4) defective.
3: Vertical output transformer (T-5) open or shorted.
4: Yoke vertical coils open or shorted.
5: Vertical hold, height or linearity controls may be defective.

POOR VERTICAL LINEARITY — If adjustment of the height and linearity controls will not correct this condition, any of the following may be the cause.
1: Check variable resistors R-59 and R-60.
2: Vertical output transformer (T-5) defective.
3: Capacitors C-44, C-45, C-48 or C-73C and Resistors R-56-57-61-64-62 defective.
4: V-8 defective, check voltages.
5: Low plate voltages. Check rectifier tube and capacitors in +B supply circuits.
6: Vertical deflection coils (L-23) defective.

POOR HORIZONTAL LINEARITY — If adjustment of the Horizontal drive and linearity controls does not correct this condition, check the following:
1: Check or replace horizontal output tube V-20.
2: Check or replace damper tube V-22 (6AX4-GT).
3: Check capacitors C-84, C-85, C-81 and horizontal linearity control (L-19) for defects.
4: Horizontal deflection coils (L-22) defective.

TRAPEZOIDAL OR NONSYMMETRICAL RASTER
1: Defective yoke.

WRINKLES ON LEFT SIDE OF RASTER — This condition can be caused by:
1: Defective yoke, transformer T-8, or R-111.
2: V-22 (6AX4-GT) defective.

SMALL RASTER — This condition can be caused by:
1: Low +B or line voltage. Check V-17 & V-18 (5U4G).
2: Insufficient output from horizontal output tube V-20. Replace tube.
3: Insufficient output from vertical oscillator (V-14B) and vertical output tube V-15. Replace tubes.
4: Incorrect setting of horizontal drive control R-97.
5: V-22 (6AX4-GT) defective.
6: Incorrect setting of (L-18) width control and height and linearity controls.

RASTER; NO IMAGE, BUT ACCOMPANYING SOUND — This condition can be caused by:
1: No signal on picture tube grid. Check V-8 (6AU6) and V-9 (6CL6) tubes and associated circuits.
2: Bad contact to picture tube grid (lead to socket broken).
3: AGC tube (V-11) may be defective. Check tube and its associated circuit.

SIGNAL APPEARS ON PICTURE TUBE GRID BUT IMPOSSIBLE TO SYNCHRONIZE THE PICTURE VERTICALLY AND HORIZONTALLY — A condition of this nature can be caused by:
1: Defective sync separator V-10 or sync amplifier V-14A.
2: If tubes are O.K. check voltages, and associated circuits.
3: AGC system inoperative. Check V-11 (6AU6) AGC tube and associated circuits.

SIGNAL ON PICTURE TUBE GRID AND HORIZONTAL SYNC ONLY — If this condition is encountered, check:
1: Vertical integrating network defective.
2: Vertical hold control (R-53) defective.

SIGNAL ON PICTURE TUBE GRID AND VERTICAL SYNC ONLY
1: V-19 defective.
2: Improper setting of (T-7) horizontal frequency control.
3: Check V-19 socket voltages.

PICTURE STABLE BUT WITH POOR RESOLUTION — If the picture resolution is not up to standard, it may be caused by any of the following:
1: Defective pix I-F tubes V-4, 5 & 6, (6CB6's).
2: Defective picture detector V-7A, (6AL5) or video amplifier V-8 or video output V-9 (6LC6) and associated circuits.
3: Defective picture tube.
4: Open video peaking coil. Check all peaking coils L-9, L-10, L-13, L-14, L-15 and L-16 for continuity. Note that L-9, L-14 and L-16 have shunting resistors.
5: Leakage in V-9 (6CL6) grid capacitor C-29. If the capacitor is not found to be defective, check the following:
1: Check all potentials in video circuits.
2: Check picture tube grid circuit for poor or dirty contact.
3: Check and realign, if necessary, the picture I-F and R-F circuits.

PICTURE SMEAR:
1: A smear can be attributed to phase shift at the low or high frequency end of the video characteristic. This can be caused by improper values of resistors and capacitors in the video circuits. Check for grid current on video output tube V-9 (6CL6), open or shorted peaking coils, video amplifier load resistors are of improper value (high).
2: This trouble can also originate at the transmitter. Check reception from another station.

SERVICE SUGGESTIONS—(continued)

3: Check and realign, if necessary, the picture I-F and R-F circuits.

MAN MADE NOISE IN SOUND (Ignition, etc.):
1: Check sound I-F tubes V-1, V-2 or V-3 and associated circuits.
2: Check sound I-F alignment.

BENDING OR S—ING
1: Check sync level control adjustment.
2: V-20 (6CD6-GT) defective or V-19 (6SN7-GTA) defective.
3: Check sync separator tube V-10 (6BE6) and V-8 (6AU6) video amplifier.
4: Check AGC threshold control.
5: Check wave form adjustment (T-7 inside chassis).

PICTURE NORMAL — NO SOUND OR WEAK OR DISTORTED SOUND
1: Check sound I-F alignment.
2: Check V-1 (6AU6) V-2 (6AU6) V-3 (6AL5) V-13 (6AQ5) V-12 (6AV6) and associated circuits.
3: Check pix I-F alignment.

RASTER ON TUBE BUT NO PICTURE OR SOUND
This condition can be caused by:
1: Defective pix I-F Amplifier tubes V-4, V-5 or V-6.
2: Defective pix detector tube V-7A (6AL5). Check tube and its associated circuit.
3: Defective R-F Amplifier or oscillator mixer tubes in the tuner.
4: UHF-VHF switch defective.

POOR FOCUS
1: Improper setting of focus control or defective pix tube.

PICTURE JITTER:
1: Horizontal instability may be due to unstable transmitted sync.
2: Check receiver AGC system for proper operation.
3: Check sync separator V-10 (6BE6) or sync amp V-14A and associated circuits.
4: Check for improper setting of sync level control.
5: Check AGC threshold control.
6: Check antenna for loose connections.

NO PICTURE OR SOUND OR WEAK PICTURE OR SOUND IN UHF POSITION
If this condition is encountered
1: Check to see whether or not a UHF station is operating in the vicinity.
2: The 6AF4 oscillator tube or the IN82 crystal may be defective.
3: Pre-selector in UHF section of tuner defective.
4: Defective switch on UHF section of tuner.

ALIGNMENT PROCEDURE

TEST EQUIPMENT — To service this receiver properly, it is recommended that the following test equipment be available:

R-F SWEEP GENERATOR meeting the following requirements:
(a) Frequency ranges:
38 to 90 mc, 10 mc sweep width
170 to 225 mc, 10 mc sweep width
470 to 890 mc, 10 mc sweep width
(b) Output adjustable with at least .1 volt maximum.
(c) Output constant on all ranges.
(d) Flat ouput in all attenuator positions.
(e) A source of the following Markers:

41.25 Mc	Cathode Trap
42.25 Mc	
42.50 Mc	1st Pix I-F Coil (Bottom)
43.9 Mc	3rd Pix I-F Coil
44.5 Mc	
45.3 Mc	2nd Pix I-F Coil
45.75 Mc	
47.25 Mc	1st Pix I-F Coil (Top)

CATHODE-RAY OSCILLOSCOPE with good low frequency response in vertical amplification and an input calibrating source.
BIAS BATTERY —1.5V & —4.5V
VTVM
DIODE DETECTOR

40 Mc I.F. ALIGNMENT

Connect sweep output to ungrounded shield of converter tube in tuner (6U8). With short leads connect crystal diode detector (Fig. 8) to plate of 1st I-F tube. Connect —1.5 V to A.G.C. line (Junction of R-1, R-3 & C-3A). Connect oscilloscope to detector output. Adjust sweep output to give adequate deflection.

A.	FREQUENCY	ADJUST
1.	47.25 Mc	1st Pix I-F Coil (L-1 Top) to center notch over 47.25 Mc marker.
2.		Converter Plate Coil (L-210 Top of Tuner) 1st I-F Grid Coil (L-4) and Input Coupling Coil (L-5) to give the response shown in figure 9.

The converter plate and 1st I-F grid coils control the shape of the top. The input coupling coil controls the position of the 41.25 marker. This adjustment must be made accurately or the sound rejection will not be correct (41.25 Mc 31 to 36 db down from top of overall P.I.F. response). 45.75 Mc marker must be set exactly on peak or the position of the 44.50 Mc marker in the overall response curve will not be correct.

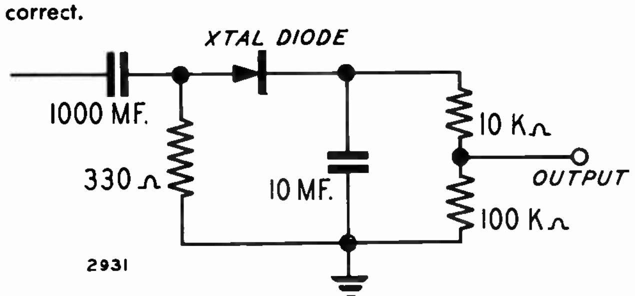

Fig. 8 — Crystal Diode Detector.

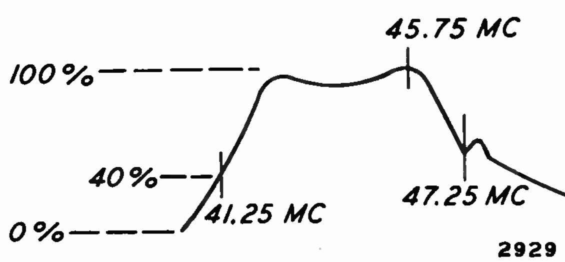

Fig. 9 — Input Circuit Response.

ALIGNMENT PROCEDURE—(continued)

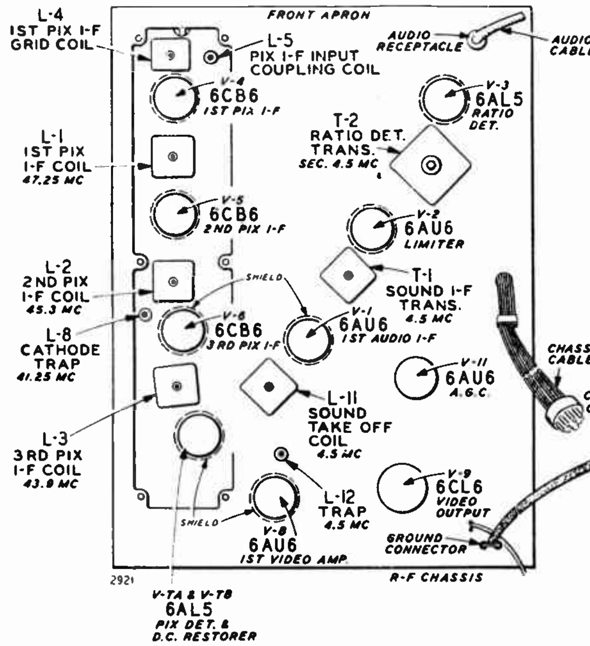

Fig. 10 — Top Chassis Adj.

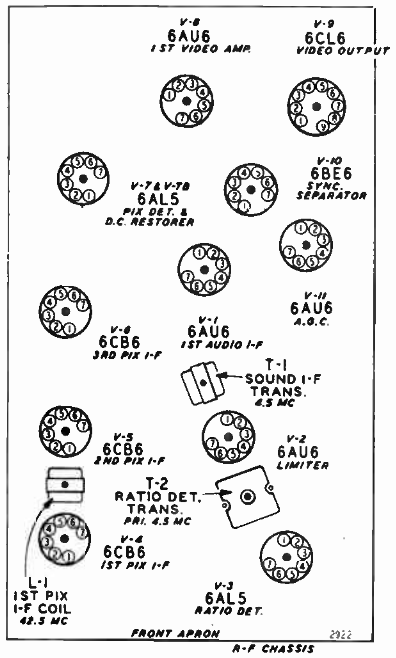

Fig. 11 — Bottom Chassis Adj.

B. When the input circuit is aligned place —4.5 V bias on the A.G.C. line. Remove the crystal detector and connect oscilloscope and VTVM to the 2nd Pix detector load resistor R-25. Adjust sweep output to give 1.0 VDC at detector.

	FREQUENCY	ADJUST
1.	42.5 Mc	1st Pix I-F Coil (L-1 Bottom) for maximum height of 42.5 Mc marker.
2.	45.3 Mc	2nd Pix I-F Coil (L-2 Top) for maximum height of 45.3 Mc marker.
3.	43.9 Mc	3rd Pix I-F Coil (L-3 Top) for maximum height of 43.9 Mc marker.
4.	41.25 Mc	Cathode Trap (L-8 Top) for minimum height of 41.25 Mc marker.

These adjustments may be made with a single frequency generator if it is more convenient to do so.

C. After these adjustments have been made recheck the peak to peak output on the oscilloscope. If the shape of the curve is not as shown in figure 12, it will be necessary to retouch the adjustments. A small fraction of a turn is all that is necessary if the strip is operating correctly. The position of the 44.5 Mc marker is critical (98%). The 43.9 Mc transformer (3rd I-F) controls the symmetry of the top. The 45.3 Mc transformer (2nd I-F) controls the height of the 45.75 Mc marker. The 43.5 Mc transformer (1st I-F) controls the height of the 42.25 Mc marker. This adjustment will very seldom need retouching.

DO NOT RETOUCH the converter plate coil or the input grid coil. These coils MUST be adjusted correctly with the diode detector. Recheck position of 41.25 Mc and 47.25 Mc markers. Reset if necessary.

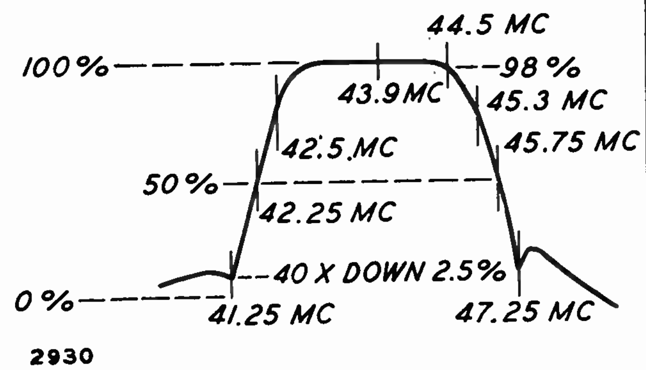

Fig. 12 — Overall Response Curve.

VIDEO

With 4.5 MC unmodulated signal from a high impedance source, (10,000 ohms in series with the generator) into plate of the picture detector tube (Pin 2-6AL5) and VTVM on picture tube grid, tune 4.5 MC trap (L-12 Top) for minimum response. VTVM on 0-10 V AC scale. This adjustment can also be made while observing a picture from a station. Tune trap for least 4.5 MC beat in picture.

AUDIO I-F

1: With signal generator set to 4.5 MC and dc VTVM connected to junction of R-17 and C-23, adjust sound take-off coil (L-11 Top) and sound I-F transformer slugs (T-1 Top & Bottom) for maximum.

2: With VTVM connected to pin 7 of V-3 (6AL5) adjust the ratio detector primary (T-2 Bottom) for maximum. In the above adjustment to avoid limiting or overloading of the amplifiers, use as little output from signal generator as possible.

3: With VTVM connected to junction of R-21, R-24 and C-27, adjust ratio detector secondary (T-2 Top) for cross over (zero voltage) on lowest scale.
NOTE — If desired, the procedure above may be followed by tuning in a station and using the 4.5 MC beat between picture and sound carrier.

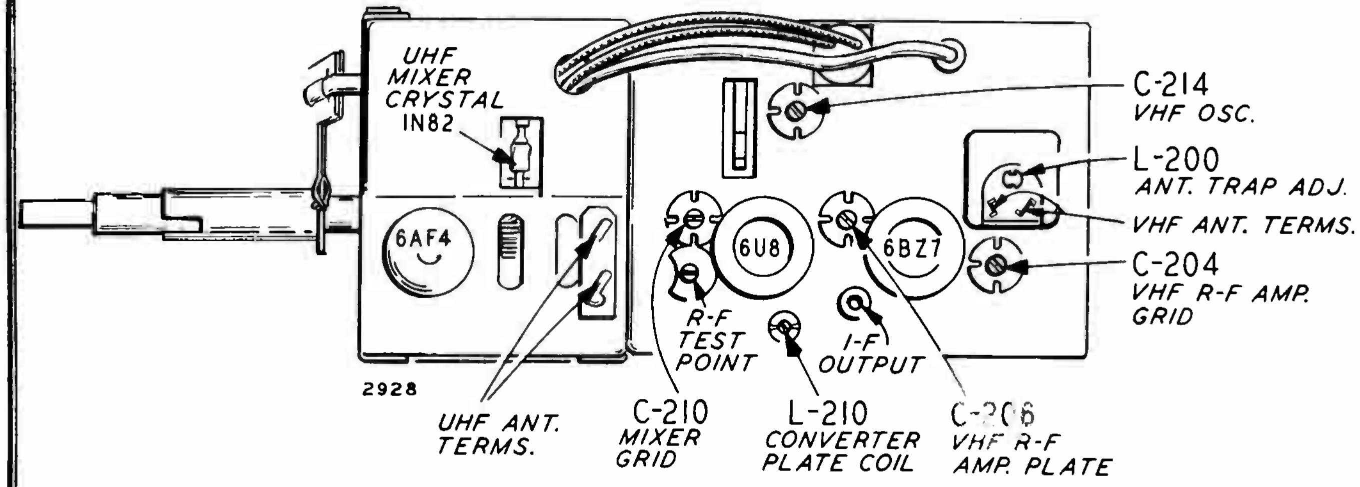

Fig. 13 — Top Tuner Adjustment.

VHF TUNER ALIGNMENT

A. Sweep generator with balanced 300 ohm output to antenna terminals. Marker generator output to antenna terminals. Oscilloscope to "test point" (Figure 13) on tuner. Connect —3V bias to AGC line at junction of R-45, R-47 and C-36 on the receiver.

B. RF AND CONVERTER ADJUSTMENT.

1. With channel selector on Channel 12, adjust C-204 slightly favoring the Pix carrier, then adjust C-206 and C-210 for response as in Figure 14. Picture and sound markers at 90% maximum response.
2. Check response on all channels. If markers are below 70% on any channels, readjust C-204, C-206, and C-210. Recheck all channels.

C. OSCILLATOR ADJUSTMENT.

1. Apply -4.5 volts on I-F AGC line at junction of R-3 and C-3A.

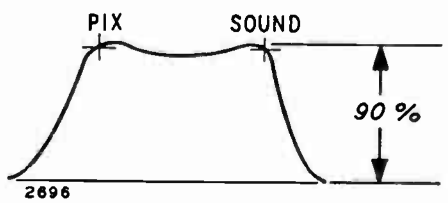

Fig. 14 — Pix & Audio Markers.

2. Connect oscilloscope to output of video detector. Place fine tuning in center of range. Check response on all channels. Sound marker should be in notch and picture marker at 50%. (See Figure 12).
3. If markers are off, individual oscillator coil slugs will require adjustment. Adjust each channel slug, accessible through hole in front of chassis with a non-metallic screwdriver to bring sound marker to correct position.

UHF TUNER ALIGNMENT

Aligning or servicing the UHF section of the 82 position tuner is not recommended in the field because replacement of any component within the R-F circuit may disturb the band pass characteristics of the tuner. However the tubes and the IN82 crystal may be replaced in the tuner if found to be defective.

Antenna trap L-200 is a trap to reduce interference caused by signals which fall within the pix I-F pass band (40-48 Mc). It is best tuned by observing the interference in the picture and tuning the slug for minimum interference. This trap is located in the shield can to which the VHF antenna lead is connected.

Do not adjust the UHF oscillator slugs unless the fine tuning control cannot be tuned through the point of best picture resolution. Before attempting to adjust any of the slugs, check to see if the UHF oscillator tube (6AF4) is firmly seated and straight in the socket. Each coil strip in the UHF section tunes 10 channels. For example, strip 20B covers channels 20 through 29 etc. If there are two UHF channels in the vicinity, perhaps channels 20 and 26, the oscillator slug should be adjusted so that the fine tuning control will tune both channels through the point of best picture quality. The position of the fine tuning control will not necessarily be the same for all channels. Always use a bakelite type screwdriver for the oscillator slug adjustments.

IMPORTANT
HORIZONTAL OUTPUT TRANSFORMERS

In early production the 53X337 horizontal output transformer did not have a center tap on the winding coupling the deflection yoke. All service orders for the 53X337 transformer will be filled with a 53X338 transformer which will necessitate removing two 83 mmf ceramic condensers from the deflection yoke socket. These condensers will no longer be required because the 53X338 transformer has a center tap at terminal number six (6) which should be connected to pin 5 on the deflection yoke socket. The schematic diagram shows the circuitry of the 53X338 transformer together with all the latest circuit changes listed below.

Various changes were made during production in the Power Supply and R-F Chassis. Each change can be identified by a color code mark on the back of the chassis.

CHANGE NO. I

TO INCREASE SYNC STABILITY
RED PAINT MARK ON BACK OF R-F CHASSIS

1. The sync separator tube (V-10) was changed from a type 6BE6 to a type 6CS6.
2. The sync separator grid condenser (C-31) was changed in value from .01 mf 400V to .047 mf 400V.
3. Condensers C-91, C-92, C-93, C-94 and resistor R-112 were added to the circuit.

CHANGE NO. II

TO IMPROVE NOISE IMMUNITY
ORANGE PAINT MARK ON BACK OF R-F CHASSIS

1. The AGC filter (C-34) 4 mf dry electrolytic was changed to a 1000 mmf ceramic condenser.
2. A .47 mf condenser (C-95) was added to the I-F AGC circuit.

CHANGE NO. III

TO REDUCE JITTERS AND BENDING IN PICTURE
ORANGE PAINT MARK ON BACK OF POWER SUPPLY CHASSIS

1. R-80 (Sync Amp plate resistor) was changed in value from 4.7K ohms to 10K ohms.
2. R-51 formerly a 3.9K ohm sync plate resistor was changed to a 820K ohm sync amp cathode resistor.
3. C-68 (sync coupling condenser) was changed in value from 36 mmf to 18 mmf.
4. C-90 a 220 mmf condenser was added to the circuit.

CHANGE NO. IV

SO THAT ANY MANUFACTURERS 6AU6 TUBES
CAN BE USED FOR REPLACEMENT PURPOSES
YELLOW PAINT MARK ON BACK OF R-F CHASSIS

1. R-15 (1st Sound I-F cathode resistor) was changed in value from 68 ohms to 100 ohms.

Vertical Centering	Part of Focus Mag. Assy.
Focus Control	Part of Focus Mag. Assy.
Ion Trap Magnet	See paragraph, page 6
Deflection Yoke	Wing Screw
Width	L-18
Horizontal Locking Range	C-66
Horizontal Linearity	L-19
Horizontal Drive	R-97
Horizontal Frequency (Outside Chassis)	T-7
Wave Form (Inside Chassis)	T-7
Sync Level	R-40
AGC Threshold Control	R-48

CENTERING ADJUSTMENT — If horizontal or vertical centering is required, loosen the screw holding centering device in place (Figure 4. and adjust the lever for proper centering. Moving the lever up and down moves the picture side to side and moving the lever side to side moves the picture up and down.

PICTURE ADJUSTMENT — For further adjustments, obtain a test pattern on the receiver. When a test pattern is obtained it may be necessary to slightly re-adjust the fine tuning control for clearest picture.

CHECK OF HORIZONTAL OSCILLATOR ALIGNMENT — Turn the horizontal hold control to the extreme counter-clockwise position. The picture should remain in horizontal sync. Momentarily remove the signal by switching off channel and then back. Normally the picture may be out of sync. Turn the control slowly clockwise. The number of diagonal bars will be gradually reduced and when only 2 to 3 bars sloping downward to the left are obtained, the picture will pull into sync upon slight additional clockwise rotation of the control.
At the extreme clockwise position the picture should be just starting to pull out of sync.
If the receiver passes the above checks and the picture is normal and stable, the horizontal oscillator is properly aligned.

ION TRAP MAGNET ADJUSTMENT — The ion trap magnet should be positioned close to the base of the tube with the magnet of the ion trap on the side where the electron gun is nearest the glass neck of the picture tube. From this position adjust the magnet by moving it back and forth and at the same time rotating it slightly around the neck of the picture tube until the brightest raster is obtained on the picture screen. Reduce the brightness control setting until the raster is slightly above average brilliance. Readjust the ion trap magnet for maximum raster brilliance.

DEFLECTION YOKE ADJUSTMENT — The deflection yoke should be positioned as far forward on the neck of the tube as the bell will allow. Then, if the lines of the raster are not horizontal or squared with the picture mask, rotate the deflection yoke until this condition is obtained. Upon completion of this adjustment, tighten the yoke adjustment wing screw.

TUBE COMPLEMENT

Symbol	Type	Function

OSCILLOSCOPE WAVEFORM PATTERNS

The waveforms shown on the schematic diagrams were taken with the receiver tuned to a normal picture. The voltages shown on each waveform are the approximate peak to peak amplitudes. The frequency accompanying each waveform indicates the repetition rate of the waveform not the sweep rate of the oscilloscope. If the waveforms are observed on the oscilloscope with a poor high frequency response, the corners of the pulses will tend to be more rounded than those shown on the schematic diagram and the amplitude of any high frequency pulse will tend to be less.

TELEVISION ALIGNMENT PROCEDURE

Aligning a television receiver is an exacting procedure and involves the use of bench space, test equipment and skilled personnel at the service shop, as well as the cost of making two trips to the customer's home. Before deciding that the chassis must be pulled and aligned at the shop, the serviceman should check these very common sources of trouble:

1 – The antenna and installation.

2 – Front panel and rear chassis controls, including picture tube adjustments.

3 – Reception on all available channels.

4 – Tube failures. Substitute from your kit of known good replacements.

5 – Visual inspection of underside of chassis for obvious faults, such as loose connections, etc.

TEST EQUIPMENT REQUIRED FOR ALIGNMENT

The equipment specified below is desirable, but in cases where this equipment is not available, it is possible to align the receiver by use of a 20 to 30 mc. modulated r-f signal generator, using the picture and speaker as indication of alignment.

1 – Signal Generator with an output variable between 100 and 100,000 microvolts, and crystal controlled or crystal-calibrated at the following frequencies:

a. 4.5 megacycles

b. 22.25 megacycles

c. 25.4 megacycles

d. 23.6 megacycles

e. 21.25 megacycles

2 – DC Vacuum Tube Voltmeter with 5 volt and 10 volt scales.

3 – A pair of balanced (⁄1%) 100K carbon resistors.

TEST EQUIPMENT REQUIRED FOR SWEEP ALIGNMENT CHECK

1 – R-F sweep generator with frequencies ranging from 40 to 220 megacycles, having sweep width of approximately 10 megacycles, and having adjustable output to approximately 0.1 volt.

2 – Crystal-controlled or crystal-calibrated markers for the picture and sound carriers of each channel, preferably 30% Amplitude-Modulated.

3 – Cathode Ray Oscilloscope with good low frequency response.

4 – 3 volt bias battery.

CAUTION: THE SECOND ANODE LEAD TO THE PICTURE TUBE HAS A HIGH POTENTIAL. DURING THIS ALIGNMENT IT IS ADVISABLE TO REMOVE THE COLOR PLUG FROM ITS SOCKET, THUS ELIMINATING THIS HIGH VOLTAGE HAZARD.

I.F. ALIGNMENT PROCEDURE

1 – Connect "high" lead of signal generator to the test point located on the top of the RF tuner unit (Refer to the R-F tuner location diagram located on the inside of cabinet). Connect ground to chassis.

2 – Connect DC VTVM lead (through 10K isolating resistor) to pin 1 of 6AU6 1st Video Amplifier (V12), ground to chassis. Set VTVM to 5 volt scale, negative polarity.

3 – Set I.F. generator to 25.4 megacycles with sufficient output to read approximately 3 volts on the VTVM.

4 – Carefully adjust L201 and L203 (see tube and tuner location) for maximum deflection on VTVM. Adjust sweep generator output to keep meter reading approximately 3 volts.

5 – Set I.F. signal generator to 22.25 megacycles with sufficient output to read approximately 3 volts on the VTVM.

6 – Carefully adjust L11, L202-top (see tube and tuner location) for maximum deflection on VTVM. Adjust signal generator output to keep meter reading approximately 3 volts.

7 – Set i-f signal generator to 23.6 mc. with sufficient output to read approximately 3 volts on the VTVM.

8 – Carefully adjust L205 (see tube and tuner location) for maximum deflection on VTVM. Adjust signal generator out-put to keep meter reading approximately 3 volts.

9 – Set I.F. signal generator to 21.25 megacycles, set VTVM to 10 volt scale (negative polarity), and adjust signal generator output for convenient defection on VTVM.

10 – Adjust L202-bottom for minimum deflection on VTVM.

SWEEP ALIGNMENT CHECK

Although not essential, a sweep alignment check is a desirable verification of good R-F and I.F. response. Proceed as follows:

1 – Connect R-F sweep generator to antenna terminals (antenna impedance 300 Ohms).

2 – Calibrate oscilloscope for convenient 5 volts peak-to-peak vertical deflection (5 volts peak-to-peak is approximately 1/4 of the peak-to-peak voltage of the 6.3V A.C. Filament).

3 – Connect vertical input of oscilloscope (through 10K isolating resistor) to pin 1 of 6AU6 1st Vid. Amp. (V12) ground to chassis. Connect horizontal input of oscilloscope to "scope" terminals of R-F generator; adjust for convenient horizontal sweep.

4 – Connect 3 volt battery positive terminal to chassis negative terminal to AGC buss (see schematic diagram).

5 – Set R-F sweep generator to channel 3, television receiver to channel 3, and if necessary, adjust sweep generator output, sweep width, and scope horizontal setting for convenient band-pass display (see figure 1) having 5 volts vertical defection as previously calibrated. (If you must touch scope vertical settings during these adjustments recalibrate scope for 5 volts peak-to-peak as in step 2 above).

6 – Adjust L205 slightly to even the height of peaks and to obtain an untilted bandpass.

7 – Couple crystal-controlled R-F carrier markers very loosely to antenna terminals, adjust receiver FINE TUNING control till video carrier marker is 1/2 down on curve. Turn up marker output till R-f sound carrier visible on bandpass and adjust sound trap (L114) to minimize effect to sound carrier marker.

NOTE: If the fine tuning control is at end of range or out of range so that video carrier cannot be set at 50%, follow R-F OSCILLATOR ALIGNMENT procedure outlined below.

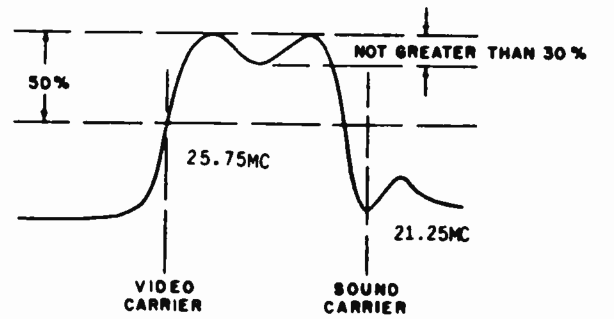
8 – Check all channels.

R-F OSCILLATOR ALIGNMENT

If all channels are not within range of FINE TUNING control (as evidenced by inability to eliminate "sound bars" from picture or by poor picture quality), the individual oscillator slugs may require readjustment.

1 – Repeat the set-up as for SWEEP ALIGNMENT CHECK, steps 1 through 7.

2 – Set FINE TUNING CONTROL to center of range, and with long fiber screwdriver alignment tool, adjust the individual oscillator slugs of each channel. (Accessible through the front of the tuner) so that video carrier markers fall 50% down on curve. CAUTION: Do not touch adjustments on top of r-f tuner unit, other than the converter plate unit, L11, during I.F. alignment.



IDEAL BANDPASS X59908

SOUND ALIGNMENT

1 – Connect 4.5 mc. signal generator to pin 1 of 6AU6 4.5 mc. amplifier (V13).

2 – Connect DC V.T.V.M. lead to pin 7 of 6AL5 (V15) ratio detector, negative polarity.

3 – Adjust signal generator to precisely 4.5 megacycles; adjust output to read approximately 5 volts on V.T.V.M.

4 – Adjust L206, L101, and bottom of T102 for maximum deflection on V.T.V.M. Keep V.T.V.M. reading below 10 volts at all times.

5 – Attach two series-connected 100K (⁄1%) resistors across R106 (Ratio Detector Load Resistor). Connect DC V.T.V.M. to centertap of 100K resistors, and connect ground wire of V.T.V.M. to top of C109 (Audio take-Off of T102).

6 – Adjust top of T102 for zero reading on V.T.V.M. between a plus and a minus peak.

VIDEO AMPLIFIER 4.5 mc. TRAP

When necessary, the video amplifier 4.5 mc. trap (L104) should be adjusted as follows:

1 – Connect 4.5 mc. signal generator to pin 1 of 6AU6 1st video amplifier (V12).

2 – Adjust signal generator output till 4.5 mc. dot pattern is clearly visible on screen of picture tube.

3 – Adjust L104 to minimize the dot pattern.

HORIZONTAL OSCILLATOR ALIGNMENT

If the Horizontal Hold control fails to maintain sync, the horizontal oscillator should be reset. To reset this screwdriver adjustment, set the horizontal hold control in the center of its range and sync the picture with the horizontal A.F.C. adjustment screw. Check the hold control action on various channels and alter the screw adjustment as required to provide sync on all channels.

PICTURE TUBE HANDLING PRECAUTIONS

The picture tube encloses a high vacuum and with the large surface area of glass involved, the stresses set up, particularly at the front rim of the tube, are considerable. An abnormal handling stress, accidental blow at a highly stressed surface, or even a scratch on the surface of the tube could cause it to implode or collapse with destructive violence.

HIGH VOLTAGE WARNING

Operation of this receiver outside the cabinet or with covers removed involves a shock hazard from the receiver power supplies. Work on the receiver should not be attempted by anyone who is not thoroughly familiar with the precautions necessary when working on high voltage equipment.

ELECTRICAL SPECIFICATIONS

Power Supply	117 Volts AC 60 Cycles Only
Power Consumption	200 Watts
Power Output	2.4 Watts (Max.) 1.8 Watts (10% Distortion)
Tuning Range	VHF—Channels 2 thru 13
Intermediate Freq. (Tel.)	Picture—45.75 MC Sound—41.25 MC
Tel. Antenna Input Imp.	300 Ohms Balanced
Intercarrier Sound System	4.5 MC
Loud Speaker	See Parts List
Voice Coil Impedance	3.2 Ohms 400 Cycles
Focus	Magnetic
Sweep Deflection	Magnetic

DEFLECTION YOKE ADJUSTMENT — The deflection yoke should be positioned as far forward on the neck of the tube as the bell will allow. Then, if the lines of the raster are not horizontal or squared with the picture mask, rotate the deflection yoke until this condition is obtained. Upon completion of this adjustment, tighten the yoke adjustment wing screw.

ADJUSTMENT OF SYNC STABILITY CONTROL — When receiving strong (500 MV or more) signals, set hold controls so that the picture is locked in. Turn the sync control slowly clockwise until bending occurs at top of picture. Then turn the control a few degrees counter-clockwise until bending disappears. If the control is set incorrectly bending, tearing, etc., will be present and when switching from channel to channel the picture will not lock in quickly.

In weak signal areas the control should be set for maximum picture stability. In general the weaker the signal the more clockwise the control should be turned.

When the sync stability control is correctly adjusted the receiver will hold sync without tearing or rolling under even the most adverse noise conditions.

CHECK OF HORIZONTAL OSCILLATOR ALIGNMENT — Tune in a station and adjust the horizontal hold control until the picture falls into sync. Momentarily remove the signal by switching off channel and then back. The picture should pull into sync over a range of 90° rotation of the horizontal hold control. If in the above check the receiver fails to hold sync or the pull-in range is at the extreme end of the control, it will be necessary to make the following adjustment.

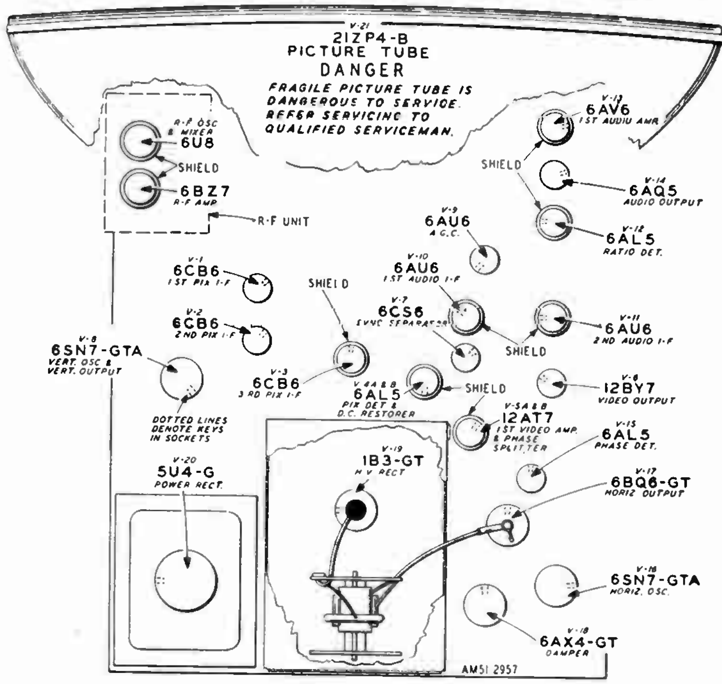

Fig. 1—Tube Layout.

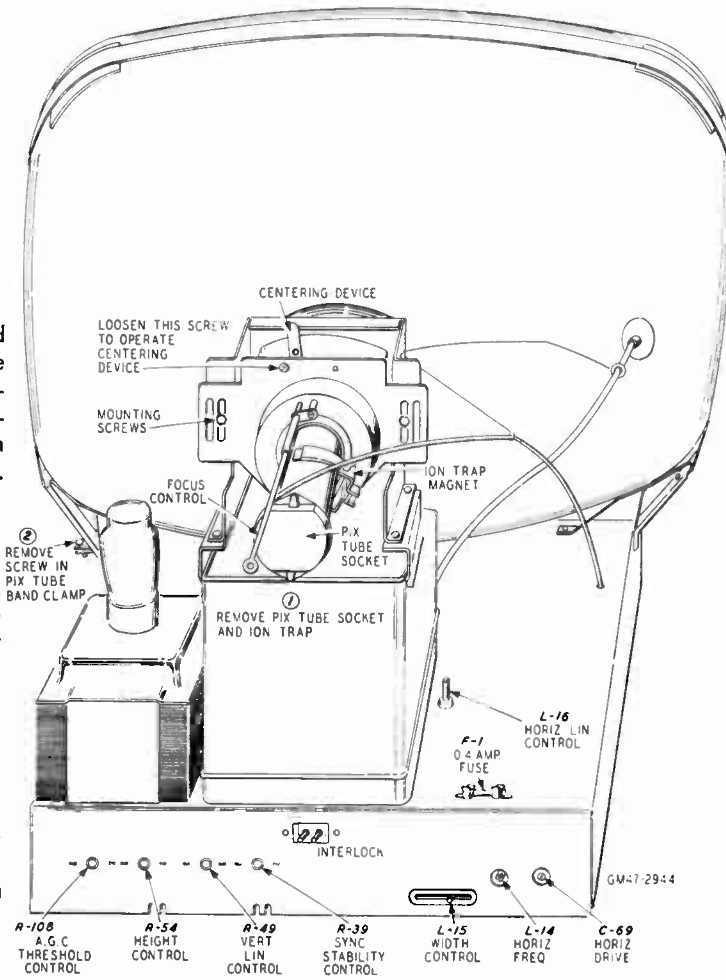

Fig. 2—Removal of Picture Tube and Rear Chassis Controls

*For replacement purposes a 6BQ7 tube may be used in place of a 6BZ7 tube.

HORIZONTAL FREQUENCY ADJUSTMENT — With the horizontal hold control set to the center of its range of rotation, adjust the horizontal frequency control (L-14) until the picture pulls into sync. Recheck the "Horizontal Oscillator Alignment."

HEIGHT AND VERTICAL LINEARITY ADJUSTMENT — Adjust the height control (R-54) until the picture fills the mask vertically. Adjust the vertical linearity control (R-49) until the picture is symmetrical from top to bottom. Adjust the picture centering device to align picture with the mask. Adjustment of any control will require a re-adjustment of the other control.

WIDTH, DRIVE AND LINEARITY ADJUSTMENTS— While receiving a signal from a station (with picture locked in sync) turn contrast control fully counter-clockwise, turn the brightness control (R-25) up so that the picture appears washed out. Adjust width control (L-15) until the picture fills the mask. Turn the horizontal drive control (C-69) clockwise until the picture appears cramped near the center then turn the control counter-clockwise until the cramping disappears. This adjustment will allow the horizontal system to operate at maximum efficiency. Adjust horizontal linearity control (L-16) for best linearity. If adjustment of the horizontal drive (C-69) or horizontal linearity (L-16) is required, it usually will be necessary to recheck the horizontal oscillator alignment. If adjustment of the horizontal linearity control (L-16) is required, readjustment of the horizontal drive control (C-69) will be necessary. Adjust the picture centering device to align the picture with the mask.

ANTENNA TRAP ADJUSTMENT—Antenna trap L-50 is a trap to reduce interference caused by signals which fall within the pix I-F pass band (40-48 Mc.) It is best tuned by observing the interference in the picture and tuning the slug for minimum interference. This trap is located in the shield can to which the VHF antenna lead is connected.

CHECK OF R-F OSCILLATOR ADJUSTMENTS

The oscillator is preset at the factory and normally needs no adjustment. However, if adjustments are required, they can be made without removing the chassis from the cabinet. Remove the channel selector and fine tuning knobs from the tuning shaft and slide the pilot light socket off the bracket.

TEST PROCEDURE:

1. Set channel selector to receive desired station.
2. Set fine tuning control in center of its range.
3. Adjust oscillator slug, with bakelite type screwdriver, for best picture resolution.
4. Repeat steps 1, 2 and 3 on all channels used.

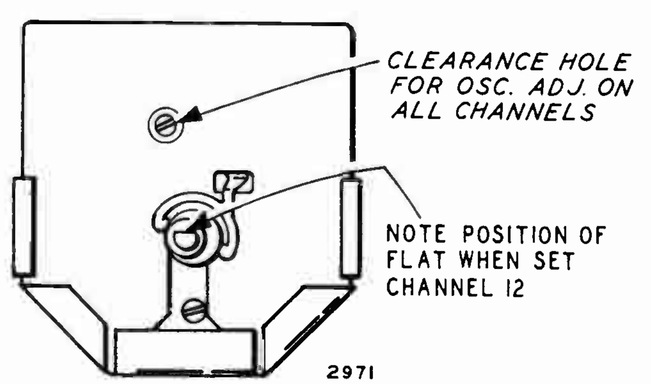

Fig. 3—Tuner Oscillator Adjustments

SERVICE SUGGESTIONS

NO RASTER ON PICTURE TUBE — If raster cannot be obtained check below for the possible causes.

1: Ion trap magnet adjustment is incorrect.
2: No +B voltage. Check 4/10 ampere fuse. Replace if defective. If fuse continually burns out, check
   (A) Horizontal output tube V-17 (6BQ6-GT)
   (B) Check damper tube V-18 (6AX4-GT).
   (C) Check horizontal oscillator tube V-16 (6SN7-GTA) for proper operation.
   (D) With an ohm meter, check for a short between terminal 1 of the horizontal output transformer (T-9) and the chassis.
   (E) Check DC resistance of T-9.
3: No high voltage. Check V-17, V-18 and V-19 tubes and circuits. If the horizontal deflection circuits are operating as evidenced by the correct voltage (600V) measured on terminal No. 1 of T-9, the trouble can be isolated to the high voltage rectifier circuit. Either the high voltage winding to the 6BQ6-GT plate and 1B3 plate is open, tube V-19 is defective, its filament circuit is open, R-99 and C-78 defective, or pix tube elements shorted internally.
4: Defective picture tube heater open or cathode return circuit open.

HORIZONTAL DEFLECTION ONLY — If only horizontal deflection is obtained as evidenced by a straight line across the face of the picture tube, it can be caused by the following:

1: Vertical oscillator and vertical output tube V-8 inoperative. Check socket voltages.
2: Vertical oscillator transformer (T-4) defective.
3: Vertical output transformer (T-5) open or shorted.
4: Yoke vertical coils open or shorted.
5: Vertical hold, height or linearity controls may be defective.

POOR VERTICAL LINEARITY — If adjustment of the height and linearity controls will not correct this condition, any of the following may be the cause.

1: Check variable resistors R-49 and R-54.
2: Vertical output transformer (T-5) defective.
3: Capacitors C-35A or C-70 defective.
4: V-8 defective, check voltages.
5: Excess leakage or incorrect value of capacitors C-37 & C-38 or open or incorrect value of resistors R-55 & R-56.
6: Low plate voltages. Check rectifier tube and capacitors in +B supply circuits.
7: Capacitor C-36 defective.
8: Vertical deflection coils (L-12) defective.

POOR HORIZONTAL LINEARITY — If adjustment of the Horizontal drive and linearity controls does not correct this condition, check the following:

1: Check or replace horizontal output tube V-17.
2: Check or replace damper tube V-18 (6AX4-GT).
3: Check capacitors C-74, C-76, C-77 and horizontal linearity control (L-16) for defects.
4: Horizontal deflection coils (L-17) defective.

TRAPEZOIDAL OR NONSYMMETRICAL RASTER

1: Defective yoke.

WRINKLES ON LEFT SIDE OF RASTER — This condition can be caused by:

1: Defective yoke.
2: V-18 (6AX4-GT) defective.

SMALL RASTER — This condition can be caused by:

1: Low +B or line voltage. Check V-20 (5U4G).
2: Insufficient output from horizontal output tube V-17. Replace tube.
3: Insufficient output from vertical oscillator and vertical output tube V-8. Replace tube.
4: Incorrect setting of horizontal drive control C-69.
5: V-18 (6AX4-GT) defective.
6: Incorrect setting of (L-15) width control.

SIGNAL ON PICTURE TUBE GRID AND VERTICAL SYNC ONLY

1: V-15 or V-16 defective.
2: Improper setting of (L-14) horizontal frequency control.
3: Check setting of horizontal drive control and horizontal linearity control.
4: Check V-15 and V-16 socket voltages.

PICTURE STABLE BUT WITH POOR RESOLUTION — If the picture resolution is not up to standard, it may be caused by any of the following:

1: Defective pix I-F tubes V-1, 2 & 3, (6CB6's).
2: Defective picture detector V-4A, (6AL5) or video amplifier V-5A or video output V-6 (12BY7).
3: Defective picture tube.
4: Open video peaking coil. Check all peaking coils L-5, L-6, L-8, L-9, L-10 and L-11 for continuity. Note that L-5, L-9 and L-10 have shunting resistors.
5: Leakage in V-6 (12BY7) grid capacitor C-11. If the capacitor is not found to be defective, check the following:
   1: Check all potentials in video circuits.
   2: Check picture tube grid circuit for poor or dirty contact.
   3: Check and realign, if necessary, the picture I-F and R-F circuits.

PICTURE SMEAR:

1: A smear can be attributed to phase shift at the low or high frequency end of the video characteristic. This can be caused by improper values of resistors and capacitors in the video circuits. Check for grid current on video output tube V-6 (12BY7), open or shorted peaking coils, video amplifier load resistors are of improper value (high).
2: This trouble can also originate at the transmitter. Check reception from another station.
3: Check and realign, if necessary, the picture I-F and R-F circuits.

MAN MADE NOISE IN SOUND (Ignition, etc)

1: Check sound I-F tubes V-10, 11 & 12 and associated circuits.
2: Check sound I-F alignment.

RASTER ON TUBE BUT NO PICTURE OR SOUND

This condition can be caused by,

1: Defective pix I-F Amplifier tubes V-1, V-2 or V-3
2: Defective pix detector tube V-4A (6AL5). Check tube and its associated circuit.
3: Defective R-F Amplifier or oscillator mixer tubes in the tuner.

PICTURE NORMAL—NO SOUND OR WEAK OR DISTORTED SOUND

1: Check sound I-F alignment.
2: Check V-10 (6AU6) V-11 (6AU6) V-12 (6AL5) V-13 (6AV6) V-14 (6AQ5) and associated circuits.

BENDING OR S-ING

1: Check sync stability control adjustment.
2: Check capacitors C-35B and C-79B.
3: V-17 (6BQ6-GT) defective or V-16 (6SN7-GTA) defective.
4: Check sync separator tube V-7 (6CS6) and phase splitter V-5B (12AT7) and V-5A (12AT7) video amplifier.
5: Check AGC threshold control.

POOR FOCUS

1: Improper setting or defective focus magnet.
2: Defective picture tube.

PICTURE JITTER:

1: If regular sections at left of the picture are displaced, replace the horizontal oscillator tube V-16.
2: Vertical instability may be due to loose connections or noise received with the signal.
3: Horizontal instability may be due to unstable transmitted sync.
4: Check receiver AGC system for proper operation.
5: Check phase splitter V-5B, (12AT7) and sync separator V-7 (6CS6).
6: Check for improper setting of sync stability control.
7: Picture tube grid lead not held in position by support spring, ie: close proximity of grid lead to sync and horizontal tubes will cause picture to jitter at high contrast setting.
8: Check AGC threshold control.

ALIGNMENT PROCEDURE

TEST EQUIPMENT — To service this receiver properly, it is recommended that the following test equipment be available:

R-F SWEEP GENERATOR meeting the following requirements:

(a) Frequency ranges:
    38 to 90 mc, 10 mc sweep width
    170 to 225 mc, 10 mc sweep width
(b) Output adjustable with at least .1 volt maximum.
(c) Output constant on all ranges.
(d) Flat ouput in all attenuator positions.
(e) A source of the following Markers:

41.25 Mc	Cathode Trap
42.25 Mc	
42.50 Mc	1st Pix I-F Coil (Bottom)
43.9 Mc	3rd Pix I-F Coil
44.5 Mc	
45.3 Mc	2nd Pix I-F Coil
45.75 Mc	
47.25 Mc	1st Pix I-F Coil (Top)

CATHODE-RAY OSCILLOSCOPE with good low frequency response in vertical amplification and an input calibrating source.

BIAS BATTERY —1.5V & —4.5V

VTVM

DIODE DETECTOR

40 Mc I.F. ALIGNMENT

Connect sweep output to ungrounded shield of converter tube in tuner (6U8). With short leads connect crystal diode detector (Fig. 6) to plate of 1st I-F tube. Connect —1.5 V to A.G.C. line (Junction of R-1, R-4 & C-21A). Connect oscilloscope to detector output. Adjust sweep output to give adequate deflection.

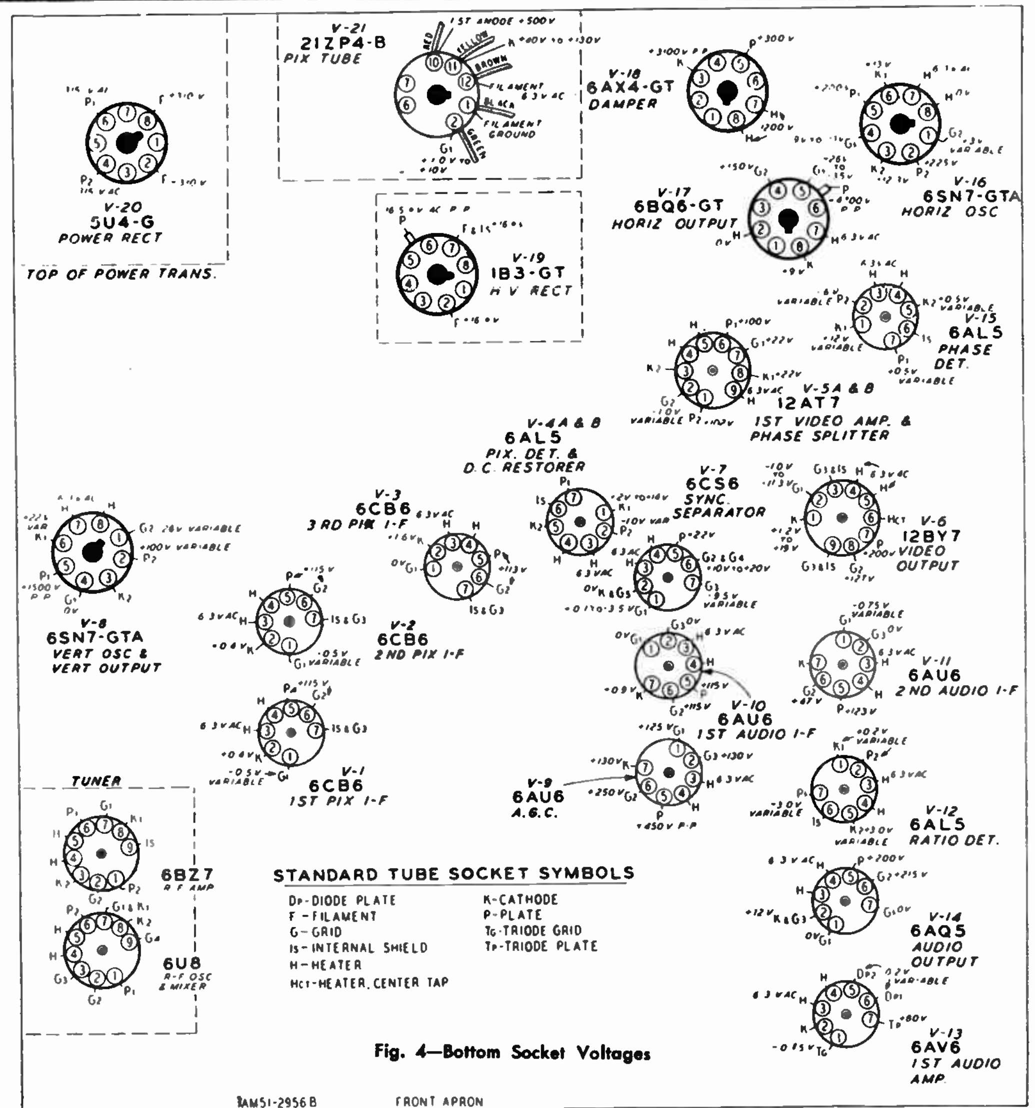

Fig. 4—Bottom Socket Voltages

A. FREQUENCY	ADJUST
1. 47.25 Mc	1st Pix I-F Coil (T-1 Top) to center notch over 47.25 Mc marker.
2.	Converter Plate Coil (L-61 Top of Tuner) 1st I-F Grid Coil (L-1) and Input Coupling Coil (L-2) to give the response shown in figure 7.

The converter plate and 1st I-F grid coils control the shape of the top. The input coupling coil controls the position of the 41.25 marker. This adjustment must be made accurately or the sound rejection will not be correct (41.25 Mc 31 to 36 db down from top of overall P.I.F. response). 45.75 Mc marker must be set exactly on peak or the position of the 44.50 Mc marker in the overall response curve will not be correct.

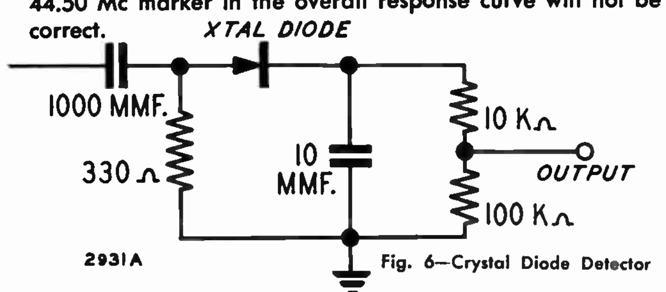

Fig. 6—Crystal Diode Detector

B. When the input circuit is aligned place —4.5 V bias on the A.G.C. line. Remove the crystal detector and connect oscilloscope and VTVM to the 2nd Pix detector load resistor R-100. Adjust sweep output to give 1.0 VDC at detector.

FREQUENCY	ADJUST
1. 42.5 Mc	1st Pix I-F Coil (T-1 Bottom) for maximum height of 42.5 Mc marker.
2. 45.3 Mc	2nd Pix I-F Coil (T-2 Top) for maximum height of 45.3 Mc marker.
3. 43.9 Mc	3rd Pix I-F Coil (T-3 Top) for maximum height of 43.9 Mc marker.
4. 41.25 Mc	Cathode Trap (L-4 Top) for minimum height of 41.25 Mc marker.

These adjustments may be made with a single frequency generator if it is more convenient to do so.

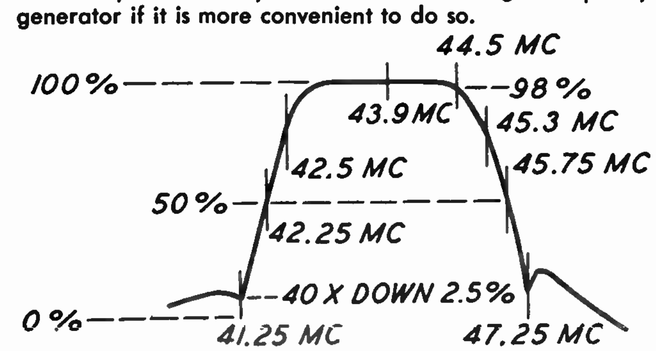

Fig. 8—Overall Response Curve.

C. After these adjustments have been made recheck the peak to peak output on the oscilloscope. If the shape of the curve is not as shown in figure 8, it will be necessary to retouch the adjustments. A small fraction of a turn is all that is necessary if the strip is operating correctly. The position of the 44.5 Mc marker is critical (98%). The 43.9 Mc transformer (3rd I-F) controls the symmetry of the top. The 45.3 Mc transformer (2nd I-F) controls the height of the 45.75 Mc marker. The 43.5 Mc transformer (1st I-F) controls the height of the 42.25 Mc marker. This adjustment will very seldom need retouching.

DO NOT RETOUCH the converter plate coil or the input grid coil. These coils MUST be adjusted correctly with the diode detector. Recheck position of 41.25 Mc and 47.25 Mc markers. Reset if necessary.

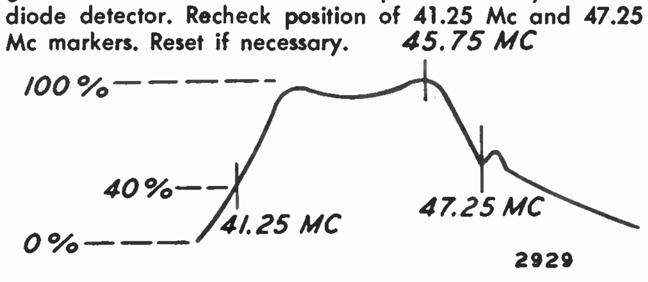

Fig. 7—Input Circuit Response

VIDEO

With 4.5 MC unmodulated signal from a high impedance source, (10,000 ohms in series with the generator) into plate of the picture detector tube (Pin 2-6AL5) and VTVM on picture tube grid, tune 4.5 MC trap (L-7 Top) for minimum response. VTVM on 0-10 V AC scale. This adjustment can also be made while observing a picture from a station. Tune trap for least 4.5 MC beat in picture.

AUDIO I-F

1: With signal generator set to 4.5 MC and dc VTVM connected to junction of R-62 and C-46, adjust sound take-off coil (L-13 Top) and sound I-F transformer slugs (T-6 Top & Bottom) for maximum.

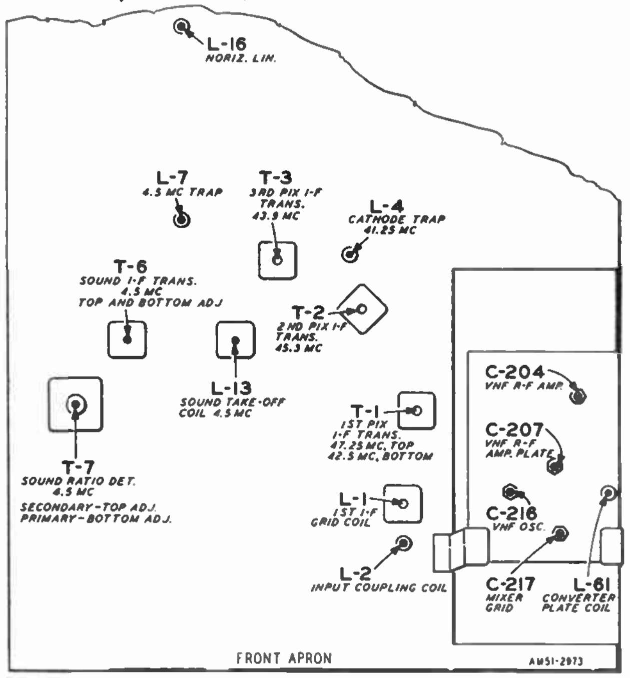

Fig. 9—Video & Audio I-F Adjustments

2: With VTVM connected to pin 7 of V-12 (6AL5) adjust the ratio detector primary (T-7 Bottom) for maximum.

3: With VTVM connected to junction of R-66, R-69 and C-50, adjust ratio detector secondary (T-7 Top) for cross over (zero voltage) on lowest scale.

NOTE — If no signal generator is available, the procedure above may be followed by tuning in a station and using the 4.5 MC beat between picture and sound carrier.

TUNER ALIGNMENT

A. Sweep generator with balanced 300 ohm output to antenna terminals. Marker generator output to antenna terminals. Oscilloscope to "test point" Figure 10 on tuner. Connect —3 V bias to AGC line at junction of R-33 and C-20 on the receiver.

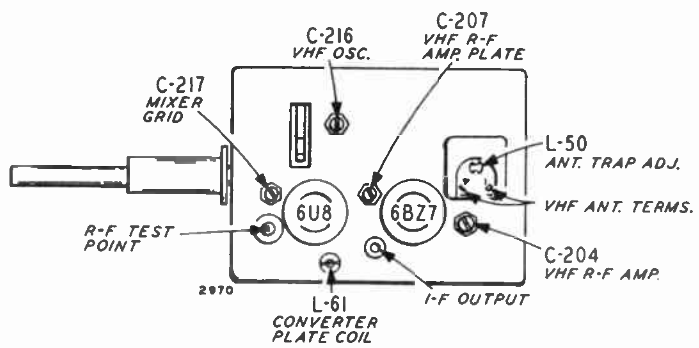

Fig. 10—Top Tuner Adjustments

B. RF AND CONVERTER ADJUSTMENT.

1. With channel selector on Channel 12, adjust C-204 slightly favoring the Pix carrier, then adjust C-207 and C-217 for response as in Figure 11. Picture and sound markers at 90% maximum response.
2. Check response on all channels. If markers are below 70% on any channels, readjust C-204, C-207, and C-217. Recheck all channels.

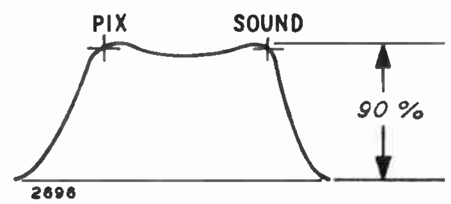

Fig. 11—Pix & Audio Markers

C. OSCILLATOR ADJUSTMENT.

1. Apply -4.5 volts on I-F AGC line at junction of R-1 and C-21A.
2. Connect oscilloscope to output of video detector. Place fine tuning in center of range. Check response on all channels. Sound marker should be in notch and picture marker at 50%. (See Figure 8).
3. If markers are off, individual oscillator coil slugs will require adjustment. Adjust each channel slug, accessible through hole in front of chassis with a non-metallic screwdriver to bring sound marker to correct position.
4. If fine tuning on all channels is off in the same direction, adjust the oscillator trimmer C-216.

OSCILLOSCOPE WAVEFORM PATTERNS

The waveforms on this page were taken with the receiver tuned to a normal picture. The numbers on the waveforms correspond to the numbers on the schematic diagram which identifies each test point.
The voltages shown on each waveform are the approximate peak to peak amplitudes. The frequencies shown indicate the repetition rate of the waveform, not the sweep rate of the oscilloscope. If the waveforms are observed on the oscilloscope with a poor high frequency response, the corners of the pulses will tend to be more rounded than those shown below and the amplitudes of any high frequency pulse will tend to be less.

ALIGNMENT PROCEDURE

SOUND CHANNEL ALIGNMENT PROCEDURE

1. Short antenna terminals together with a jumper wire.
2. Set receiver Channel Selector to any inactive television channel and Contrast control to its maximum counter-clockwise position; other controls may be left at any desired setting.
3. A small screwdriver (preferably non-metallic) can be used for alignment of Sound IF. The blade of this tool will fit the slot in the core of the transformer.

STANDARD SIGNAL GENERATOR		VTVM CONNECTIONS	MISCELLANEOUS INSTRUCTIONS	TRIMMER OR SLUG	TYPE OF ADJUSTMENT AND OUTPUT INDICATION
CONNEC-TIONS	FREQUENCY				
Connect as shown in Fig. 1.	**4.5 MC.** unmodulated IMPORTANT This signal must be accurate within ¼ of 1% of 4.5 Mc. Check generator calibration against a crystal controlled signal source by "zero beating" (heterodyning) with harmonics of the crystal frequency.	Connect as shown in Fig. 2.	1. Set Contrast control to its maximum counter-clockwise position. 2. A special detector must be utilized when aligning the 4.5 Mc. Sound Trap Coil. This unit can be constructed in accordance with the information contained in Fig. 3. If a VTVM containing a high frequency A.C. probe is available, this probe can be utilized in place of the crystal detector shown in Fig. 2 3. During this adjustment only, remove one of the three 6CB6 IF amplifier tubes (V1, V2 or V3). This will prevent noise in the RF stages from affecting the voltage reading while adjusting the sound trap.	**#1** 4.5 MC Sound Trap (See Fig. 10)	Adjust for minimum reading on VTVM.
Same as above	Same as above.	Connect as shown in Fig. 4.	A "swishing" sound may be heard in the speaker during Sound Channel Alignment. This spurious oscillation is caused by horizontal sweep voltage being picked up in the audio system thru stray coupling of instrument leads; it should be disregarded as it will have no effect on alignment of the sound channel.	**#2** Discriminator Secondary (See Fig. 10)	Adjust for maximum reading on VTVM.
				#3 Discriminator Primary (See Fig. 8)	Adjust for maximum reading on VTVM.
				#4 Sound IF Transformer (See Fig. 10)	Adjust for maximum reading on VTVM.
Same as above.	Same as above.	Connect as shown in Fig. 5.	To obtain zero balance of the discriminator circuit, two 68,000 ohm resistors will be required. These resistors must be matched so that their respective resistances do not differ by more than 1%—the accuracy of the total resistance is not critical. Connect the two resistors in series from pin 2 of the 6T8 tube to chassis ground as shown in Fig. 5.	**#2** Discriminator Secondary (See Fig. 10)	Note that as slug #2 is rotated, a point will be found where the voltmeter will swing rather sharply from a positive to a negative reading or vice versa. The correct setting of slug #2 is obtained when the meter reads zero as the slug is moved thru this point.

Replace the type 6CB6 tube previously removed in the above procedure and turn set on. Tune in to a local channel and should there be an unusual amount of "Intercarrier Buzz" refer to procedure on adjoining page to remove this aforementioned fault.

REDUCTION OF INTERCARRIER BUZZ

Under actual reception conditions slight "dynamic" unbalance of the discriminator secondary can emphasize intercarrier buzz due to incomplete amplitude modulation rejection. Therefore it is vitally important to obtain an accurate setting of the discriminator secondary slug under these conditions.

Disconnect all instruments (be sure that I.F. tube removed for the adjustment of Sound Trap has been replaced) and then connect an antenna to the receiver to obtain program reception from a local station. If intercarrier buzz is prominent, a slight readjustment of the discriminator secondary slug (#2) should be made to obtain the "dip" point for the buzzing sound. Note that program sound will be clear and free from distortion at this point. Buzz should now be at an acceptable minimum if station transmission is not at fault.

 	**STANDARD SIGNAL GENERATOR** **42 Mc., 43.5 Mc. & 44.9 Mc.** **SWEEP GENERATOR** **45 Mc.** Sweep Width 10 Mc.	Remove detuning clip discussed in previous step. Connect a 3 volt battery to receiver AGC system as explained in instruction 7 at the head of this chart.	**# 7 and # 8** 2nd IF Trans. FIG. 9
View of IF Strip

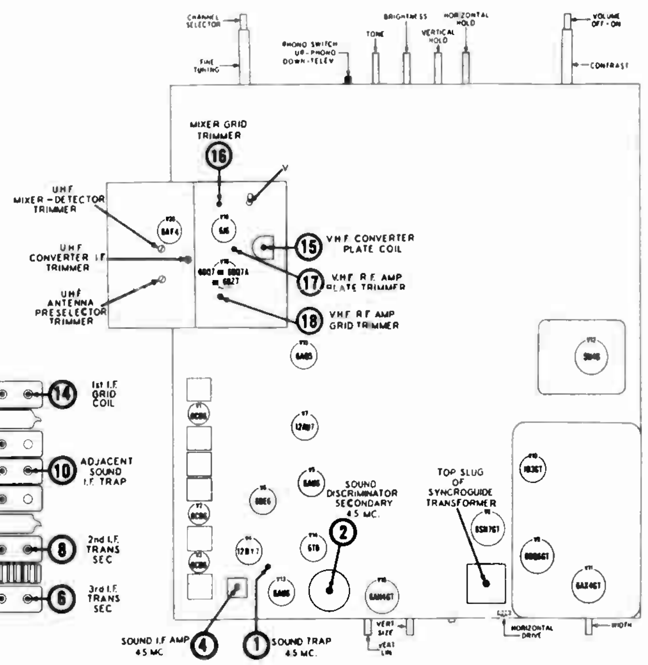

FIG. 10
Top View of Chassis

GENERATOR CONNECTIONS	GENERATOR FREQUENCIES	MISCELLANEOUS INSTRUCTIONS	TRIMMER OR SLUG	TYPE OF ADJUSTMENT AND OUTPUT INDICATION
 	**STANDARD SIGNAL GENERATOR** **42.5 Mc. & 44.5 Mc.** **SWEEP GENERATOR** **45 Mc.** Sweep Width 10 Mc.	Connect a 3 volt battery to receiver AGC system as explained in instruction 7 at the head of this chart.	**# 14** 1st IF Grid Coil (See Fig. 9) **#15** Converter Plate Coil (See Fig. 10)	Adjust trimmers for maximum amplitude, bandwidth and correct positioning of markers as shown. 	STANDARD SIGNAL GENERATOR **39.75 Mc., 41.25 Mc., 45.75 Mc. & 47.25 Mc.** **SWEEP GENERATOR** **45 Mc.** Sweep Width 10 Mc.	Same as above.	The general shape of the overall IF response curve and position of markers should compare with that shown. The picture carrier marker (45.75 Mc.) should appear at approximately the 50% amplitude position. Should this observation fail to meet the above requirement, it will be necessary to make a small change in the setting of one or a combination of the following trimmers until the desired results are achieved. Trimmers, # 5, 6, 7, 8, 11, 12, 14 and slug 15. The sound carrier marker (41.25 Mc.) should appear at the position shown on the curve. If the position of this marker is not correct, then it will be necessary to readjust the setting of trimmer # 9 as explained previously in this procedure. To properly observe the position of the adjacent channel picture carrier (39.75 Mc.) and the adjacent channel sound carrier (47.25 Mc.), it will be necessary to increase the vertical gain control on the 'scope and the output of the sweep and standard signal generators. Also, be sure to disconnect the 3 volt AGC battery from receiver. If these markers do not compare favorably with that shown, repeat the adjustment of trimmers # 10 and 13 as explained previously in this procedure, exercising greater care in obtaining a minimum reading on the VTVM.

VHF RF CHANNEL ALIGNMENT PROCEDURE

STANDARD SIGNAL GENERATOR CONNECTIONS	STANDARD SIGNAL GENERATOR FREQUENCY	SWEEP GENERATOR CONNECTIONS	SWEEP GENERATOR FREQ.	VTVM CONNECTIONS	SCOPE CONNECTIONS	MISCELLANEOUS INSTRUCTIONS	TRIMMER OR SLUG	TYPE OF ADJUSTMENT AND OUTPUT INDICATION
RF AMPLIFIER AND MIXER ALIGNMENT								
Connect as shown in Fig. 11.	209.75 MC. Sound Carrier 205.25 MC. Picture Carrier Marker.	Connect as shown in Fig. 11 and set controls for sweep width of 10 Mc. on television channel specified in the next column.	CHANNEL #12	Not used.	Connect as shown in Fig. 12.	Set Channel Selector to #12. IMPORTANT: Keep output of standard signal generator at a level that provides a readable marker but does not distort the curve that is being observed on the scope.	#16 Mixer Grid. (See Fig. 18) #17 RF Amp. Plate. (See Fig. 18) #18 RF Amp. Grid. (See Fig. 18)	Adjust these trimmers to obtain properly shaped RF band pass characteristic as shown in Fig. 15. Use Mixer Grid trimmer #16; and RF Amplifier Plate trimmer #17 to obtain correct amplitude of characteristic in vicinity of picture and sound carrier markers. Then adjust RF Amp. Grid trimmer #18 to equalize overall amplitude. Repeat adjustment of trimmers to be sure correct response has been obtained. IMPORTANT: When adjusting trimmers #16, 17 and 18 it will be noted that the bond pass characteristic can be broadened by sacrificing amplitude. It is undesirable to overly broaden the curve as that would result in a loss of sensitivity.
Same as above.	The bandpass characteristic for each of the successive channels should now be observed individually. For frequency setting of marker signals see table in Fig. 14.	Same as above.	Set sweep generator to channel frequencies being observed.	Not used.	Same as above.	Set channel selector to channel being observed.		The RF bond pass characteristic of the other television channels should now be checked without disturbing the settings of trimmers #16, 17 and 18. Adjust the RF sweep generator and marker generator for operation on the other television channels, observing position of both the sound carrier and picture carrier markers. Band pass characteristic of these channels should conform close to the RF response curve in Fig. 15. If necessary, a compromise may be obtained to compensate for large variations in channel response by returning to channel #12 and making slight changes in the settings of trimmers #16, 17 and 18.

OSCILLATOR ALIGNMENT

1. **IMPORTANT:** Before undertaking oscillator alignment be sure IF circuits are correctly aligned for band pass characteristic illustrated in IF alignment procedure.
2. During oscillator alignment, it is necessary to set the Fine Tuning control so that the tooth on the fiber fine tuning cam points downward (correct position for this control is shown in Fig. 17).
3. During this step and thru-out all succeeding steps it is necessary to: keep output of sweep generator at a level that does not allow reading on VTVM to exceed one volt.
4. Keep output of standard signal generator at a level that provides a readable marker but does not distort the curve that is being observed on the 'scope.

STANDARD SIGNAL GENERATOR CONNECTIONS	STANDARD SIGNAL GENERATOR FREQUENCY	SWEEP GENERATOR CONNECTIONS	SWEEP GENERATOR FREQ.	VTVM CONNECTIONS	SCOPE CONNECTIONS	MISCELLANEOUS INSTRUCTIONS	TYPE OF ADJUSTMENT AND OUTPUT INDICATION
Connect as shown in Fig. 11.	209.75 MC. Sound Carrier Marker. 205.25 MC. Picture Carrier Marker.	Connect as shown in Fig. 11 and set controls for sweep width of 10 Mc. on television channel specified in the next column.	CHANNEL #12	Connect as shown in Fig. 13.	Connect as shown in Fig. 13.	Set Channel Selector to #12. Be sure that generator's output does not exceed voltage specified in instructions #3 and 4 above.	Using a non-metallic screwdriver to adjust channel #12 oscillator slug (accessible thru hole on front of RF Tuner Unit—see Fig. 17) shift response curve so that picture carrier marker is located at the position indicated in Fig. 16. Position of sound carrier marker should appear as indicated in Fig. 16.
Same as above.	The bandpass characteristic for each of the successive channels should now be observed individually. For frequency setting of marker signals see table in Fig. 14.	Same as above.	Set sweep generator to channel frequencies being observed.	Same as above.	Same as above.	Set channel selector to channel being observed.	Adjust the RF sweep generator and marker generator for operation on the other television channels. After setting Channel Selector to corresponding channel, adjust oscillator slug thru hole on front of RF Tuner Unit (see Fig. 17). This permits response curve to be shifted so that picture and sound carriers markers will appear at the position indicated in Fig. 16. NOTE: Make sure that cam on fine tuning control shaft remains properly positioned during this step (tooth on the cam pointing downward—see Fig. 17).

If an oscillator slug "falls into" its coil form during adjustment, remove the Channel Coil from the turret assembly and lift the Slug Retaining Spring aside. By tapping the coil form it should be possible to make the slug move toward the end so that its threads will be engaged by the Slug Retaining Spring when that spring is returned to its normal position.

If an unsatisfactory overall response is obtained for a particular channel, observe RF Amp. and Mixer response curve for that channel. If characteristic does not conform reasonably well within the typical curve shown in Fig. 15, then, (1) attempt to obtain a better compromise for RF response on all channels by realigning RF Amp. and Mixer circuits, or (2) try replacing Antenna, RF and Oscillator coils for the particular channels.

CHANNEL NUMBER	PICTURE CARRIER MARKER FREQ.	SOUND CARRIER MARKER FREQ.
13	211.25 MC.	215.75 MC.
12	205.25 MC.	209.75 MC.

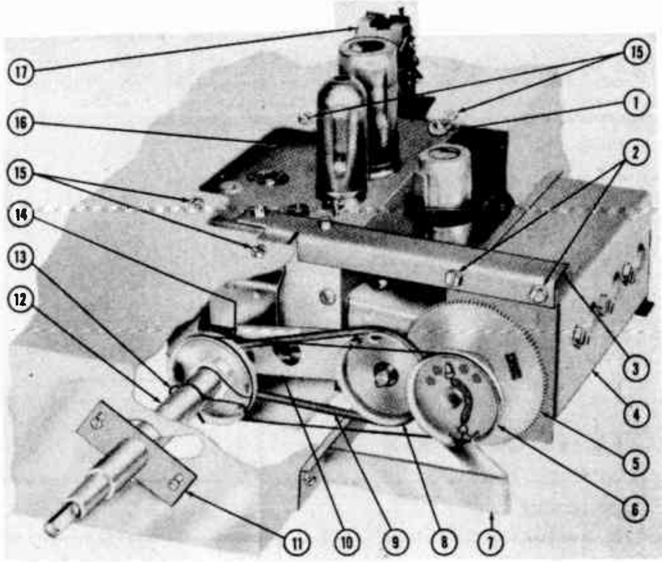
V.H.F.–U.H.F. TUNER SERVICING PROCEDURE



The tuning mechanism of this receiver comprises two R.F. tuning units—a 13-position V.H.F. tuner which covers the 12 V.H.F. channels and a continuous type U.H.F. tuner which covers all of the U.H.F. television channels.

When it is necessary to remove the tuning units for service, it can be accomplished by following the procedure given in the following paragraphs. For simplicity, there is a separate removal procedure for each of the tuners.

Instructions for replacing the U.H.F. tuning belt and the dial drive cord are also given below.

REMOVING U.H.F. TUNER

(Numbers which appear after parts mentioned in text refer to parts shown in illustration above.)

1. Disconnect leads marked S, R and T on "Bottom View of Chassis Showing Connections of R.F. Tuners." Also disconnect 300-ohm twin-lead to U.H.F. Tuner (4) at V.H.F. Selector Switch (17); terminals S3 and S12.
2. Remove Bracket and Triangular Shaped Guard (7) shielding U.H.F. Tuning Gear (5).
3. Turn fine tuning knob until U.H.F. tuner shaft is fully counter-clockwise, then loosen two set screws and slide U.H.F. Dial Drive Pulley (6) off of shaft. (To avoid the necessity of restringing U.H.F. dial drive cord, hold Drive Pulley (6) so that cord does not slip off and clamp cord tightly around pulley by wrapping "scotch" tape around the two strands of cord as near as possible to the pulley. Also clamp cord around Dial Pulley and Shaft (12) in this manner.)
4. Remove the two U.H.F. Tuner Mounting Screws (2) and a third screw (not shown in illustration) located underneath chassis on Mounting Bracket (1).
5. Loosen the two set screws on U.H.F. Tuning Gear (5) and free tuner from mounting by pulling away from bottom of chassis. Tuner may now be completely removed by sliding it toward rear of chassis, thus disengaging unit from Gear (5) and Pulley Brackets (10).

If tuner is returned to factory for repair it must be shipped with all parts removed as indicated above.

REMOVING V.H.F. TUNER

(Numbers which appear after parts mentioned in text refer to parts shown in illustration above.)

1. Remove U.H.F. tuner as described above.
2. Disconnect leads marked M, N, P, Q and U on "Bottom View of Chassis Showing Connections of R.F. Tuners." Also disconnect the two white and yellow leads from the tuner to the V.H.F. Selector Switch (17); at terminals S8 and S17.
3. Rotate Channel Selector knob until V.H.F. Selector Switch Actuator Cam is completely disengaged from Switch (17) and remove the two switch mounting screws.
4. Remove channel Selector knob, Fine Tuning knob and U.H.F. Dial from their shafts by pulling them forward.
5. Remove Fiber Bracket (11) which supports tuner operating shafts. Also remove fiber dial lite shield which is fastened by one of the fiber bracket mounting screws.
6. Remove the four Tuner Mounting Screws (15) and lift V.H.F. tuner (16) from chassis.
7. Remove Clip (13) which retains U.H.F. Dial Shaft and Pulley (12) and slide shaft and pulley off of inner shaft.
8. Remove U.H.F. Tuning Belt (9) from pulleys.
9. Loosen two set screws and remove U.H.F. Tuning Pulley (14).
10. Remove U.H.F. Tuning Pulley and Bracket Assembly (10).
11. Remove Front Mounting Bracket (3) and Rear Mounting Bracket (1).
12. Loosen set screw and remove V.H.F. Selector Switch Actuator Cam mounted on rear of turret shaft.

If tuner is returned to factory for repair it must be shipped with all parts removed as indicated above.

REINSTALLING TUNERS

The reinstallation of the tuner can be made in the reverse order given in the removal procedure, observing the following precautions.

1. Remount V.H.F. Tuner (16) in mounting holes that place tuner as far back on chassis as possible.
2. Position coaxial cable lead so that it completely clears the V.H.F. Selector Switch Actuator Cam.
3. When reinstalling U.H.F. Dial Drive Pulley (6), turn U.H.F. tuning shaft to its extreme counter-clockwise position and turn Drive Pulley (6) until the opening in its rim is as shown in **lower** illustration before tightening pulley set screws.
4. When removing "scotch" tape from U.H.F. dial drive card, hold drive pulleys so that cord is sufficiently taut to prevent it from sliding off of pulleys.
5. Before replacing U.H.F. dial, be sure that **"Fine Tuning" shaft** is in a fully counter-clockwise position or until U.H.F. dial shaft is fully **clockwise.** Place U.H.F. dial on its shaft so that the number 83 is in top center position.

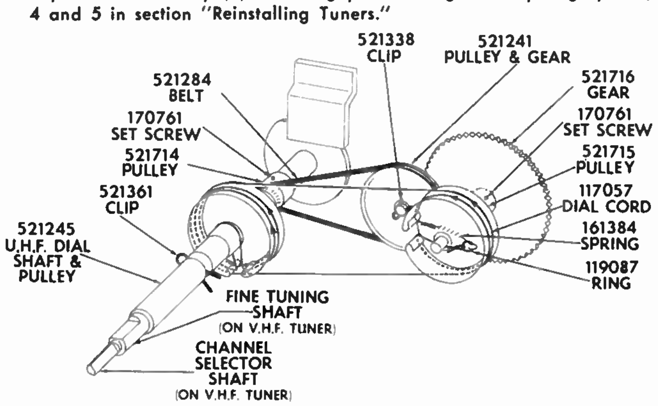
REPLACING U.H.F. DIAL DRIVE CORD

As it is necessary to remove drive cord when replacing U.H.F. Tuning Belt (9), the belt should be replaced at this time if it is worn. The method of accomplishing this is given in a separate procedure outlined below.

1. Remove Bracket and Triangular Shaped Guard (7).
2. Turn U.H.F. tuner shaft fully counter-clockwise and if necessary loosen set screws and turn Drive Pulleys (6) and (12) until opening in their rims are located as shown in **lower** illustration.
3. String drive cord by placing ring at end of cord over tongue of Drive Pulley (6) and winding cord around pulleys as shown in **lower** illustration.
4. Replace U.H.F. dial by following procedure given in paragraph 5 in section entitled "Reinstalling Tuners."

REPLACING U.H.F. TUNING BELT

1. Follow steps 2 and 3 in procedure entitled "Removing U.H.F. Tuner" and step 4 in procedure entitled "Removing V.H.F. Tuner."
2. Remove old Tuning Belt (9) by pulling it over Drive Pulleys (6) and (12) and through shaft opening on front of chassis.
3. Install new belt by using reverse of procedure given in step 2 above.
4. Replace Drive Pulley (6) following procedure given in paragraphs 3, 4 and 5 in section "Reinstalling Tuners."



DIAL DRIVE CORD ARRANGEMENT

SYNCROGUIDE TRANSFORMER ALIGNMENT

(Chassis that do not include series "E" change)

Alignment of the Syncroguide transformer, circuit diagram #128, which is used in the Horizontal Oscillator circuit on those receivers that **do not** include the letter "E" in the series designation at the rear of the chassis, can be accomplished by utilizing the procedure outlined below. To perform this alignment, it will be necessary to use an oscilloscope, preferably one that has a 2 megacycle response and a low input capacity probe—under 100 mmfd. to ground.

1. Set the "Top Slug" and "Bottom Slug" of the Syncroguide transformer to their maximum counter-clockwise positions.
2. Short together terminals C and D of the Syncroguide transformer.
3. Set "Horizontal Range" control, located on rear of chassis pan, to its maximum clockwise position.
4. Set "Horizontal Hold" control, located at front of chassis to its maximum counter-clockwise position.
5. Turn on receiver and tune in any local TV channel.
6. Adjust "Top Slug" clockwise until picture just locks in horizontally.
7. Remove short from terminals C and D. If picture does not hold sync when short is removed, adjust "Bottom Slug" clockwise until picture locks in.
8. Connect 'scope to terminal C of Syncroguide transformer and adjust sweep rate of 'scope until two cycles of oscillogram remain stationary. Turn "Bottom Slug" clockwise until wave form peaks are equal in height as shown in Fig. 1.

IMPORTANT: The first peak of the wave form should never be higher than the second peak nor should the first peak be lower than the second peak by more than 3%. Also when adjusting the "Bottom Slug," the picture must be in sync, therefore it may be necessary to turn the "Horizontal Hold" control clockwise when performing this step. After this adjustment has been completed, disconnect 'scope from receiver.

9. Set "Horizontal Hold" control counter-clockwise and adjust "Top Slug" until picture is locked in and does not lose sync when switching "Channel Selector" knob. Then, turn "Top Slug" slowly counter-clockwise until picture is just ready to lose sync as shown in Fig. 4.
10. Horizontal holding action of receiver should now be as follows:
    a. When "Horizontal Hold" control is at its maximum counter-clockwise position and "Channel Selector" knob is switched, picture may appear as shown in Fig. 4 or be out of sync.
    b. When "Horizontal Hold" control is at its maximum clockwise position, picture may lose sync when switching "Channel Selector" knob.
    c. When "Horizontal Hold" control is in the center or near the center of its range, picture remains stable when switching "Channel Selector" knob.
11. If the foregoing steps fail to correct for loss of horizontal holding action under normal receiver operation, be sure that condenser 130 (.01 mfd.) connected across terminals C and D of the Syncroguide transformer is part 512311, tubular, .01 mfd., 400 V. Do not use a substitute part.

SYNCROGUIDE TRANSFORMER ALIGNMENT

(Series "E" type chassis)

Alignment of the Syncroguide transformer, circuit diagram #128, which is used in the Horizontal Oscillator circuit can be accomplished by utilizing the procedure outlined below. To perform this alignment, it will be necessary to use an oscilloscope, preferably one that has a 2 megacycle response and a low input capacity probe—under 100 mmfd. to ground.

1. Set the "Top Slug" and "Bottom Slug" of the Syncroguide transformer to their maximum counter-clockwise positions.
2. Short together terminals C and D of the Syncroguide transformer.
3. Adjust "Horizontal Drive" control, located on rear of chassis pan one-half turn out from its maximum clockwise position.
4. Set "Horizontal Hold" control, located at front of chassis, to its maximum clockwise position.
5. Turn on receiver and tune in any local TV channel.
6. Adjust "Top Slug" clockwise until picture just locks in horizontally.
7. Remove short from terminals C and D. If picture does not hold sync when short is removed, adjust "Bottom Slug" clockwise until picture locks in.
8. Connect 'scope to terminal C of Syncroguide transformer and adjust sweep rate of 'scope until two cycles of oscillogram remain stationary. Turn "Bottom Slug" clockwise until wave form peaks are equal in height as shown in Fig. 1.

IMPORTANT: The first peak of the wave form should never be higher than the second peak nor should the first peak be lower than the second peak by more than 3%. Also, when adjusting the "Bottom Slug," the picture must be in sync, therefore, it may be necessary to turn the "Horizontal Hold" control counter-clockwise when performing this step. After this adjustment has been completed, disconnect 'scope from receiver.

9. Set "Horizontal Hold" control counter-clockwise and adjust "Top Slug" until picture is locked in and does not lose sync when switching "Channel Selector" knob. Then, turn "Top Slug" slowly counter-clockwise until picture is just ready to lose sync as shown in Fig. 4.
10. Horizontal Holding action of receiver should now be as follows:
    a. When "Horizontal Hold" control is at its maximum counter-clockwise position and "Channel Selector" knob is switched, picture may appear as shown in Fig. 4 or be out of sync.
    b. When "Horizontal Hold" control is at its maximum clockwise position, picture may lose sync when switching "Channel Selector" knob.
    c. When "Horizontal Hold" control is in the center or near the center of its range, picture remains stable when switching "Channel Selector" knob.

PRODUCTION CHANGES

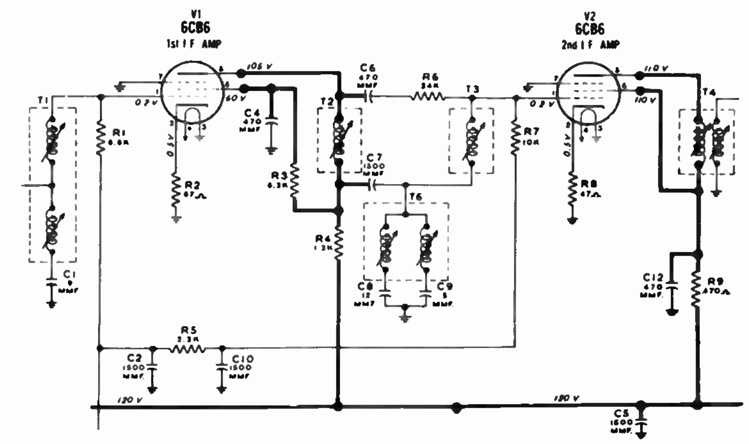
The following tabulation furnishes complete details on changes which occurred during receiver production. The receivers incorporating these changes are identified by coding stamped on rear surface of chassis. The coding consists of one or more letters following the word SERIES, as SERIES B, SERIES AC, etc., and corresponds to similarly lettered changes shown below. Chassis incorporate only that change indicated by letter designation; i.e., chassis stamped "SERIES 8E" does not include changes "A" or "C" or "D".

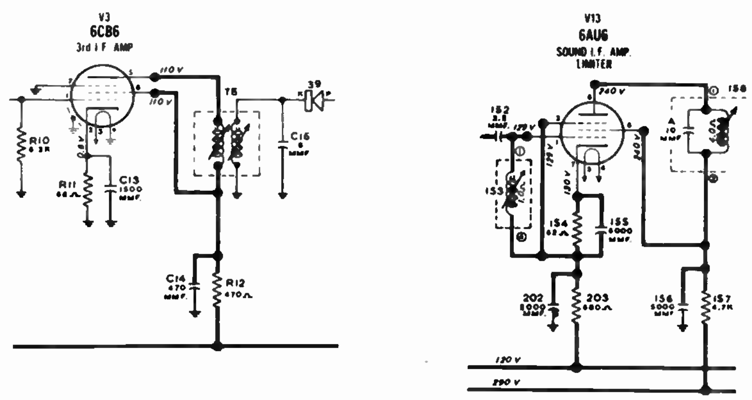
The circuit shown on this page applies to "SERIES ABCDEFGHJK" chassis

A letter following the component circuit diagram number thus—201^A, indicates that this particular item was affected by a circuit change. The letter corresponds to the series code letter listed in the production change column, from which complete change information can be obtained.

LETTER DESIGNATION	DESCRIPTION OF CHANGE
UNCODED	**INITIAL PRODUCTION**

"A" The following changes were incorporated to provide for the use of an alternate type of I. F. system.
1. The voltage supply of the various elements of tube V1 (1st I.F. Amp.) and V2 (2nd I.F. Amp.) and V13 (Sound I.F. Amp-Limiter) as well as components to these elements were changed. The circuit, for tubes V1, V2, V3, and V13 for chassis that do not incorporate the letter "A" is shown below:





"B" The following changes were incorporated to improve interlace and vertical hold action.
1. Change condenser 71 in plate circuit of tube V7B (Vert. Blocking Osc.) from 5000 Mmfd. to .03 Mfd.
2. Change resistor 186 in grid circuit of tube V78 (Vert. Blocking Osc.) from 1.5 Meg. to 1.2 Meg.

"C" The following change was incorporated to reduce current drain.
1. Omit resistor 208 (7500 Ohms) connected between the 120 volt supply and the 270 volt supply.

This change should only be undertaken when the letter "A" is incorporated in series designation at rear of chassis.

"D" The following change was incorporated to prevent regeneration in I.F. system.
1. Add trap coil 241 (Part 522020) between the grid of tube V4 (Video Amp.) and perking coil 41.

"E" The following changes were incorporated to extend the useful range of the Horizontal Hold control.
1. Change Horizontal Range 108-A control in the grid circuit of V8A (Horizontal A.F.C.) from a variable condenser (10-160 Mmfd.) to a fixed condenser 218 (47 Mmfd.).
2. Change resistor 113 in grid circuit of tube V8A (Horizontal A.F.C.) from 150,000 Ohms to 220,000 Ohms.
3. Change resistor 114 in grid circuit of tube V8A (Horizontal A.F.C.) from 330,000 Ohms to 1 Meg.
4. Add resistor 212 (150,000 Ohms) from the junction of condenser 109 (47 Mmfd.) and resistor 114 (1 Meg.) to chassis ground.
5. Remove resistor 133 (10,000 Ohms) in grid circuit of tube V9 (Horizontal Scanning Output) and replace with condenser 133 (270 Mmfd.).
6. Change resistor 97 in grid circuit of tube V6 (Gated Sync. Separator) from 820,000 Ohms to 1.5 Meg.
7. Change resistor 106 from 10,000 Ohms to 4700 Ohms and add resistor 105 (4700 Ohms) in series with resistor 106 and plate of tube V7A. Resistor 182 (18,000 Ohms) remains connected to the plate of tube V7A—12AU7 while condenser 107 (100 Mmfd.) is reconnected to the junction of resistors 105 and 106.

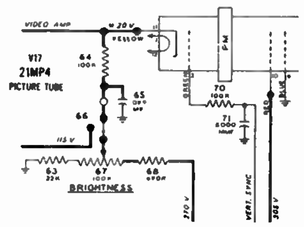
In addition to the above changes the Syncroguide transformer must be re-adjusted in accordance with the procedure (for a Series "E" chassis) given in the service data section of the manual.

The following changes were incorporated to improve the blanking during horizontal retrace interval.
1. Add resistor 213 (150,000 Ohms) between cathode of tube V9 (Horizontal Scanning Output) and the grid circuit of tube V17 (Picture Tube).
2. Add resistor 214 (1 Meg.) between pin 1 of the horizontal output transformer and grid circuit of tube V17 (Picture Tube).
3. Add resistor 215 (56,000 Ohms) from the junction of resistors 213 and 214 to chassis ground.
4. Add condenser 216 (100 Mmfd.) from the junction of resistors 213 and 214 to the grid of tube V17 (Picture Tube).

The following change was incorporated to reduce illumination of picture tube with minimum setting of the Brightness Control.
1. Change resistor 68 in the brightness circuit from 470,000 Ohms to 330,000 Ohms.

"F" The following change was incorporated to minimize frequency drift in the syncroguide circuit.
1. Change condenser 130 from a .01 Mfd. to a .01 Mfd. (Special characteristic) part 512311 only.

"G" The following changes were incorporated to improve the useful range of the Contrast control.
1. Change connection of Brightness control 67A associated circuit from cathode of tube V17 (Picture tube) to grid of the same tube. The Brightness circuit for chassis that do not incorporate the letter "G" is shown at the right:



2. Add resistor 219 (470,000 Ohms) in parallel with condenser 62 (.1 Mfd.) located in cathode circuit of tube V17 (Picture tube).
3. Change resistor 70 in plate circuit of tube V7B (Vert. Blocking Osc.) from 100,000 Ohms to 47,000 Ohms and add condenser 210 (.1 Mfd.) in series with resistor 70. Connect other end of condenser 210 to the junction of condenser 190 (.047 Mfd.) and resistor 191 (8200 Ohms).

"H" The following changes were incorporated to improve the video response.
1. Change peaking coil 51 in plate circuit of tube V4 (Video Amp.) from part 520984 to 520689.
2. Change resistor 52 in parallel with peaking coil 51 from 15,000 Ohms to 12,000 Ohms.
3. Change peaking coil 53 in plate circuit of tube V4 (Video Amp.) from part 520986 to part 509342.
4. Change resistor 54 in plate circuit of tube V4 (Video Amp.) from 3900 Ohms to 2200 Ohms.
5. Change resistor 55 in plate circuit of tube V4 (Video Amp.) from 1500 Ohms to 1800 Ohms.

"J" The following change was incorporated to maintain proper focus for the normal range of the brightness control.
1. Change resistor 68 in brightness circuit from 100,000 Ohms to 220,000 Ohms.

"K" The following change was incorporated to permit the use of the I.F. system in various type chassis.
1. Add condenser 240 (680 Mmfd.) between the grid of tube V1 (1st I.F. Amp.) and I.F. transformer 9.

RESISTORS

SCHEMATIC LOCATION	PART NO.	DESCRIPTION
R 1	510151	Resistor—carbon 6800 Ohms ±10% ½ watt
R 2	510112	Resistor—carbon 47 Ohms ±10% ½ watt
R 3	510153	Resistor—carbon 8200 Ohms ±10% ½ watt
R 4	510138	Resistor—carbon 1200 Ohms ±10% ½ watt
R 5	510142	Resistor—carbon 2200 Ohms ±10% ½ watt
R 6	510783	Resistor—carbon 24,000 Ohms ±5% ½ watt
R 7	510154	Resistor—carbon 10,000 Ohms ±10% ½ watt
R 8	510112	Resistor—carbon 47 Ohms ±10% ½ watt
R 9	510130	Resistor—carbon 470 Ohms ±10% ½ watt
R 10	510153	Resistor—carbon 8200 Ohms ±10% ½ watt
R 11	510114	Resistor—carbon 56 Ohms ±10% ½ watt
R 12	510130	Resistor—carbon 470 Ohms ±10% ½ watt (The above resistors were used when letter "A" is not included in series designation at rear of chassis.)
7	510118	Resistor—carbon 100 Ohms ±10% ½ watt
8	510348	Resistor—carbon 4700 Ohms ±10% 2 watt
12	510151	Resistor—carbon 6800 Ohms ±10% ½ watt
13	510112	Resistor—carbon 47 Ohms ±10% ½ watt
15	510151	Resistor—carbon 6800 Ohms ±10% ½ watt
17	510138	Resistor—carbon 1200 Ohms ±10% ½ watt
21	510783	Resistor—carbon 24,000 Ohms ±5% ½ watt
23	510172	Resistor—carbon 100,000 Ohms ±10% ½ w.
26	510151	Resistor—carbon 6800 Ohms ±10% ½ watt
27	510174	Resistor—carbon 120,000 Ohms ±10% ½ w.
29	510112	Resistor—carbon 47 Ohms ±10% ½ watt
32	510153	Resistor—carbon 8200 Ohms ±10% ½ watt
33	510117	Resistor—carbon 82 Ohms ±10% ½ watt
36	510130	Resistor—carbon 470 Ohms ±10% ½ watt (The above resistors were used when letter "A" is included in series designation at rear of chassis.)
43	510150	Resistor—carbon 5600 Ohms ±10% ½ watt
44	510166	Resistor—carbon 47,000 Ohms ±10% ½ w.
48	510153	Resistor—carbon 8200 Ohms ±10% ½ watt
52	510723	Resistor—carbon 12,000 Ohms ±5% ½ watt (used when letter "H" is included in series designation at rear of chassis)
	510744	Resistor—carbon 15,000 Ohms ±5% ½ watt (used when letter "H" is not included in series designation at rear of chassis)
54	510242	Resistor—carbon 2200 Ohms ±10% 1 watt (used when letter "H" is included in series designation at rear of chassis)
	510247	Resistor—carbon 3900 Ohms ±10% 1 watt (used when letter "H" is not included in series designation at rear of chassis)
55	510141	Resistor—carbon 1800 Ohms ±10% ½ watt (used when letter "H" is included in series designation at rear of chassis)
	510139	Resistor—carbon 1500 Ohms ±10% ½ watt (used when letter "H" is not included in series designation at rear of chassis)
56	510163	Resistor—carbon 33,000 Ohms ±10% ½ w.
57	510701	Resistor—carbon 3.3 Meg. ±10% ½ watt
59	510172	Resistor—carbon 100,000 Ohms ±10% ½ w.
60	510172	Resistor—carbon 100,000 Ohms ±10% ½ w.
63	510157	Resistor—carbon 15,000 Ohms ±10% ½ w. (used when letter "G" is not included in series designation at rear of chassis)
64	510186	Resistor—carbon 560,000 Ohms ±10% ½ w. (used when letter "G" is included in series designation at rear of chassis)
	510172	Resistor—carbon 100,000 Ohms ±10% ½ w. (used when letter "G" is not included in series designation at rear of chassis)

RESISTORS—Continued

SCHEMATIC LOCATION	PART NO.	DESCRIPTION
68	510178	Resistor—carbon 220,000 Ohms ±10% ½ w. (used when letter "J" is included in series designation at rear of chassis)
	510172	Resistor—carbon 100,000 Ohms ±10% ½ w. (used when letter "G" is included in series designation at rear of chassis)
	510181	Resistor—carbon 330,000 Ohms ±10% ½ w. (used when letter "E" is included in series designation at rear of chassis)
	510184	Resistor—carbon 470,000 Ohms ±10% ½ w. (used when letters "E," "G" and "J" are not included in series designation at rear of chassis)
70	510167	Resistor—carbon 47,000 Ohms ±10% ½ w. (used when letter "G" is included in series designation at rear of chassis)
	510172	Resistor—carbon 100,000 Ohms ±10% ½ w. (used when letter "G" is not included in series designation at rear of chassis)
77	510101	Resistor—carbon 10 Ohms ±10% ½ w.
83	510172	Resistor—carbon 100,000 Ohms ±10% ½ w.
84	510782	Resistor—wire wound 50 Ohms ±10% 5 w.
87	510741	Resistor—wire wound 600 Ohms ±10% 10 w.
88	510779	Resistor—wire wound 400 Ohms ±10% 10 w.
92	510139	Resistor—carbon 1500 Ohms ±10% ½ watt
93	510357	Resistor—carbon 15,000 Ohms ±10% 2 w.
94	510159	Resistor—carbon 18,000 Ohms ±10% ½ w.
96	510193	Resistor—carbon 2.2 Meg. ½ watt
97	510752	Resistor—carbon 1.5 Meg. ±10% ½ watt (used when letter "E" is included in series designation at rear of chassis)
	510777	Resistor—carbon 1.2 Meg. ±5% ½ watt (used when letter "E" is not included in series designation at rear of chassis)
99	510171	Resistor—carbon 82,000 Ohms ±10% ½ w.
100	510178	Resistor—carbon 220,000 Ohms ±10% ½ w.
102	510160	Resistor—carbon 22,000 Ohms ±10% ½ w.
104	510197	Resistor—carbon 10 Meg. ½ watt
105	510148	Resistor—carbon 4700 Ohms ±10% ½ w. (used when letter "E" is included in series designation at rear of chassis)
	510145	Resistor—carbon 3300 Ohms ±10% ½ w. (used when letter "E" is not included in series designation at rear of chassis)
106	510148	Resistor—carbon 4700 Ohms ±10% ½ w. (used when letter "E" is included in series designation at rear of chassis)
	510254	Resistor—carbon 10,000 Ohms ±10% 1 w. (used when letter "E" is not included in series designation at rear of chassis)
111	510181	Resistor—carbon 330,000 Ohms ±10% ½ w.
112	510189	Resistor—carbon 820,000 Ohms ±10% ½ w.
113	510178	Resistor—carbon 220,000 Ohms ±10% ½ w. (used when letter "Q" is included in series designation at rear of chassis)
	510175	Resistor—carbon 150,000 Ohms ±10% ½ w. (used when letter "Q" is not included in series designation at rear of chassis)
114	510190	Resistor—carbon 1 Meg. ±10% ½ w. (used when letter "Q" is included in series designation at rear of chassis)
	510181	Resistor—carbon 330,000 Ohms ±10% ½ w. (used when letter "Q" is not included in series designation at rear of chassis)
116	510172	Resistor—carbon 100,000 Ohms ±10% ½ w.
117	510281	Resistor—carbon 330,000 Ohms ±10% 1 w.
118	510148	Resistor—carbon 4700 Ohms ±10% ½ watt
120	510169	Resistor—carbon 68,000 Ohms ±10% ½ w.
124	510174	Resistor—carbon 120,000 Ohms ±10% ½ w.
125	510175	Resistor—carbon 150,000 Ohms ±10% ½ w.
126	510154	Resistor—carbon 10,000 Ohms ±10% ½ w.
129	510269	Resistor—carbon 68,000 Ohms ±10% 1 w.
133	510154	Resistor—carbon 10,000 Ohms ±10% ½ w. (used when letter "E" is not included in series designation at rear of chassis)
134	510184	Resistor—carbon 470,000 Ohms ±10% ½ w.
136	510318	Resistor—carbon 100 Ohms ±10% 2 watt
138	510166	Resistor—carbon 47,000 Ohms ±10% ½ w.
139	510356	Resistor—carbon 12,000 Ohms ±10% 2 watt
143	510725	Resistor—carbon 3.3 Ohms ±10% ½ watt
145	510190	Resistor—carbon 1 Meg. ±10% ½ watt
146	510134	Resistor—carbon 680 Ohms ½ watt
154	510117	Resistor—carbon 82 Ohms ±10% ½ watt
157	510249	Resistor—carbon 4700 Ohms 1 watt
159	510124	Resistor—carbon 220 Ohms ±10% ½ watt
161	510159	Resistor—carbon 18,000 Ohms ±10% ½ w.
163	510124	Resistor—carbon 220 Ohms ±10% ½ watt
164	510169	Resistor—carbon 68,000 Ohms ±10% ½ w.
168	510197	Resistor—carbon 10 Meg. ½ watt
169	510160	Resistor—carbon 22,000 Ohms ±10% ½ w.
172	510184	Resistor—carbon 470,000 Ohms ±10% ½ w.
177	510778	Resistor—carbon 560,000 Ohms ±5% ½ w.
178	510747	Resistor—carbon 820,000 Ohms ±5% ½ w.
182	510159	Resistor—carbon 18,000 Ohms ±10% ½ w.
183-B	508062	Resistor—carbon 22,000 Ohms ⅕ watt (part of Integrator Unit)
183-D	508062	Resistor—carbon 8200 Ohms ⅕ watt (part of Integrator Unit)
183-F	508062	Resistor—carbon 8200 Ohms ⅕ watt (part of Integrator Unit)

COILS AND TRANSFORMERS

T 1	521782	Coil—1st I.F. Grid and Adjacent Picture I.F. Trap
T 2	521783	Coil—1st I.F. Plate
T 3	521784	Coil—2nd I.F. Grid
T 4	521786	Transformer—2nd I.F.
T 5	521787	Transformer—3rd I.F.
T 6	521785	Trap—Sound I.F. and Adjacent Sound I.F. (The above coils and transformers were used when letter "A" is not included in series designation at rear of chassis)
9	521782	Coil—1st I.F. grid and Adjacent Picture I.F. Trap (used when letter "A" is included but letter "J" is not included in series designation at rear of chassis)
	522087	Coil—1st I.F. grid and Adjacent Picture I.F. Trap (used when letters "A" and "J" are included in series designation at rear of chassis)
16	521783	Coil—1st I.F. plate
22	521785	Trap—sound I.F. and Adjacent Sound I.F.
25	521906	Coil—2nd I.F. Grid
31	521786	Transformer—2nd I.F.
37	521907	Transformer—3rd I.F. (The above coils and transformers were used when letter "A" is included in series designation at rear of chassis)
41	520620	Coil—peaking
42	520985	Coil—peaking
49	509603	Coil—4.5. Mc. trap (includes slug and condenser #50)
	507357	Slug core for 4.5 Mc. trap coil
51	520689	Coil—peaking (used when letter "H" is included in series designation at rear of chassis)
	520984	Coil—peaking (used when letter "H" is not included in series designation at rear of chassis)

COILS AND TRANSFORMERS—Continued

53	509342	Coil—peaking (used when letter "H" is included in series designation at rear of chassis)
	520986	Coil—peaking (used when letter "H" is not included in series designation at rear of chassis)
76	520951	Transformer—power
86	508341	Choke—filter
128	520943	Transformer—syncroguide
	521064	Slug core for syncroguide transformer
140	521066	Transformer—horizontal output
151-A,B	520942	Yoke—picture tube deflection (includes leads, connectors and resistors #199 and #200)
153	509378	Transformer—audio take-off
158	509706	Transformer—TV sound discriminator (includes condensers 158A and 158B)
180	509376	Transformer—audio output
184	520980	Transformer—vertical blocking oscillator
198	520975	Transformer—vertical output (includes connectors for deflection yoke leads)
241	522020	Coil—43 Mc. trap (used when letter "D" is included in series designation at rear of chassis)
401	521821	Coil—U.H.F. I.F. Coupling (Coded "•1Q•") (includes resistors 414, 416 and condenser 415)
402	521822	Coil—antenna; channel #2 (Coded "•2Q•")
	521823	Coil—antenna; channel #3 (Coded "•3Q•")
	521824	Coil—antenna; channel #4 (Coded "•4Q•")
	521825	Coil—antenna; channel #5 (Coded "•5Q•")
	521826	Coil—antenna; channel #6 (Coded "•6Q•")
	521827	Coil—antenna; channel #7 (Coded "•7Q•")
	521828	Coil—antenna; channel #8 (Coded "•8Q•")
	521829	Coil—antenna; channel #9 (Coded "•9Q•")
	521830	Coil—antenna; chan. #10 (Coded "•10Q•")
	521831	Coil—antenna; chan. #11 (Coded "•11Q•")
	521832	Coil—antenna; chan. #12 (Coded "•12Q•")
	521833	Coil—antenna; chan. #13 (Coded "•13Q•")
407	520701	Coil—cathode coupling
412	521841	Coil—U.H.F. I.F. Coupling (Coded "•1R•")
413	521842	Coil—R.F. & osc.; chan. #2 (Coded "•2R•")
	521843	Coil—R.F. & osc.; chan. #3 (Coded "•3R•")
	521844	Coil—R.F. & osc.; chan. #4 (Coded "•4R•")
	521845	Coil—R.F. & osc.; chan. #5 (Coded "•5R•")
	521846	Coil—R.F. & osc.; chan. #6 (Coded "•6R•")
	521847	Coil—R.F. & osc.; chan. #7 (Coded "•7R•")
	521848	Coil—R.F. & osc.; chan. #8 (Coded "•8R•")
	521849	Coil—R.F. & osc.; chan. #9 (Coded "•9R•")
	521850	Coil—R.F. & osc.; ch. #10 (Coded "•10R•")
	521851	Coil—R.F. & osc.; ch. #11 (Coded "•11R•")
	521852	Coil—R.F. & osc.; ch. #12 (Coded "•12R•")
	521853	Coil—R.F. & osc.; ch. #13 (Coded "•13R•")
	507786	Slug for osc. coil; auxiliary fine tuning adj.
429	521834	Coil—neutralizing
431	521835	Choke—mixer plate
433	521836	Coil
441	520518	Coil—choke
444	520520	Coil—choke
505	‡	Industor—Ant. End
507A	‡	Inductor—Antenna Preselector tuning
507B	‡	Inductor—Mixer-Detector tuning
507C	‡	Inductor—Oscillator tuning
514	‡	Transformer—U.H.F. converter I.F.
515	‡	Inductor—Mixer End
517	‡	Coil—choke
523	‡	Inductor—Oscillator End
526	‡	Coil—choke
527	‡	Coil—choke
528	‡	Coil—choke
531	‡	Cail—choke

CONTROLS

46-A,B,C	521288	Contrast and Volume potentiometers (includes On-Off switch) A—Contrast (300 Ohms ½ watt) B—On-Off Switch C—Volume (1 Meg. ¼ watt)
66-A, B	520563	Switch, "PHONO-TELEV."
67	509893	Brightness potentiometer (100,000 Ohms ¼ watt)
108	508071	Horizontal Drive Condenser (10-160 Mmfd.) (used when letter "E" is included in series designation at rear of chassis)
	520991	Horizontal Range and Horizontal Drive trimmer condenser assembly A—Horizontal Range (10-160 Mmfd.) B—Horizontal Drive (10-160 Mmfd.) (used when letter "E" is not included in series designation at rear of chassis)
123	521059	Horizontal Hold potentiometer (50,000 Ohms ¼ watt)
148	520996	Width potentiometer (400 Ohms ±10% 4 w.)
176	520746	Tone potentiometer (500,000 Ohms ¼ watt)
187	521058	Vertical Hold potentiometer (1 Meg. ¼ w.)
189	520944	Vertical Size potentiometer (2.5 Meg. ¼ w.)
196	520945	Vertical Linearity potentiometer (5000 Ohms ½ watt)
422	*	Fine Tuning condenser (3-5 Mmfd.)

*—This part is not supplied as a Service replacement item.
‡—This part is not supplied as a Service replacement item. Tuner to be returned to factory for repair.

OTHER ELECTRICAL PARTS

39	509386	Crystal detector
69	521183	Ion trap
72	521267	Centering magnets (included with back cover of yoke)
75	521803	Fuse; 4 amp. 125 volt "Slow Blow"
78	118921	Channel lite (Mazda #47) 6-8V. 150 Ma.
149	508713	Fuse for horizontal sweep circuit; ¼ Amp. 250 volt

MECHANICAL PARTS OF 521187 V.H.F. R.F. TUNER

(for electrical parts see preceding classified listings of condensers, resistors and coils)

521187	R.F. Tuner; 12 channels V.H.F., 1 position U.H.F. (includes tubes and tuning coils, LESS: U.H.F. dial shaft, pulleys, brackets, selector switch, and actuating cam)
521324	Bracket, pulley support
521321	Bracket, supports U.H.F. and V.H.F. tuners (front)
521322	Bracket, supports U.H.F. and V.H.F. tuners (rear)
521713	Cam, switch actuator (includes set screws)
507339	Clip for mounting converter plate coil
521361	Clip, retains U.H.F. dial shaft and pulley
521837	Fine tuning cam and shaft
521714	Pulley, U.H.F. tuning (includes set screws)
508708	Roller—detent
170761	Screw, set; #6-32 x ⅛" "Allen type"; retains tuning pulley
13392	Screw, set; #8-32 x 3/16" "Allen type"; retains cam
521245	Shaft and pulley far U.H.F. dial
520535	Shield, bottom cover
520536	Shield, side cover
520519	Shield, tube; miniature for 6BQ7, 6BQ7A or 6BZ7 tube
520534	Shield—tube; miniature for 6J6 tube
507987	Socket—miniature (7 pin) for 6J6 (includes base for mounting shield)
520521	Socket—miniature (9 pin) for 6BQ7, 6BQ7A or 6BZ7 (includes base for mounting shield)
507986	Slug for osc. coil fine tuning adjustment
509062	Slug core for converter plate coil
508709	Spring—detent
507967	Spring—turret shaft retaining
507966	Spring contactar washer (on front turret shaft)
507990	Spring—retains osc. fine tuning slug
520517	Stator contact assembly (includes 11 contacts and metal frame)
521838	Tuner turret and shaft assembly (less coils)
507965	Washer, fiber spacer (on turret shaft)

MECHANICAL PARTS OF 521170 U.H.F. R.F. TUNER

(for electrical parts see preceding classified listings of condensers, resistors and coils)

521170	R.F. Tuner; U.H.F. tuner, channels 14-83; (includes tubes, tuning segments and coils, LESS: pulleys, gears and brackets)
522018	Belt, U.H.F. tuning
521324	Bracket, pulley support
521321	Bracket, supports U.H.F. and V.H.F. tuners (front)
521322	Bracket, supports U.H.F. and' V.H.F. tuners (rear)
521338	Clip, retains U.H.F. tuning pulley and gear
117057	Cord—dial drive (3 ft. required)........per ft.
521282	Dial, U.H.F.
521716	Gear, U.H.F. tuning (includes set screws)
521715	Pulley, U.H.F. dial drive (includes set screws)
521241	Pulley and gear for U.H.F. tuning
170761	Screw, set; #6-32 x ⅛" "Allen type"; retains gear
111766	Spring, anti-backlash
161384	Spring—dial cord tension

CABINET PARTS

521106	Back for cabinet (less cup and power cord)
521971	Cabinet for Model 9038A
521969	Cabinet for Model 9081A
520492	Caster far console cabinet
520135	Cup for cabinet back

CABINET PARTS—Continued

521282	Dial, U.H.F.
520937	Glass window for picture tube
521278	Knob, Channel Selector
521281	Knob, Contrast
521280	Knob, V.H.F. Fine Tuning and U.H.F. Tuning
521279	Knob, "OFF-VOLUME-ON"
521102-A	Mask for picture tube
521757	Nameplate (includes spring and hinge)
520927	Screw—#6x1" oval head; mounts glass retaining strip
18807	Screw—#14x1"; mounts TV chassis
521455	Strip, wood; retains glass window
507351	Terminal strip for antenna connection

MISCELLANEOUS PARTS

521120	Base for mounting tube shield (9 pin)
522018	Belt, U.H.F. Tuning
520950	Bracket, bridge, supports rear of picture tube
521855	Bracket, chassis support at U.H.F. Tuner
520312	Bracket for mounting picture tube (front left hand)
520311	Bracket for mounting picture tube (front right hand)
521652	Bracket mounts antenna terminal strip
520952	Bracket; mounts rubber ring and supports flared neck of picture tube
509673	Bracket, mounts yoke
521324	Bracket; pulley support
521321	Bracket; supports U.H.F. and V.H.F. tuners (front)
521322	Bracket supports U.H.F. and V.H.F. tuners (rear)
521713	Cam; switch actuator (includes set screw)
521054	Clamp (plastic), for antenna lead
521267	Centering magnet (included with back cover of yoke)
508149	Clip for mounting antenna terminal strip
505101	Clip for mounting sound take-off transformer
507339	Clip for mounting V.H.F. video converter plate and trap coil
521065	Clip—retains horizontal output transformer
521361	Clip; retains U.H.F. dial shaft and pulley
521338	Clip; retains U.H.F. tuning pulley and gear
117057	Cord; dial drive (3 ft. required)...........Per ft.
521184	Connector for filament lead of 1B3GT tube (includes cap and lead)
521282	Dial; U.H.F.
520989	Fuse holder
521716	Gear; U.H.F. tuning (includes set screws)
521122	H.V. connector with Insulated lead
521123	H.V. connector with braided lead
521183	Ion trap
507699	Power cord assembly includes plugs at both ends
500966	Plug (1 pin) for Phono, input socket
521382	Plug (5 pin) for interconnection of chassis
521241	Pulley and gear for U.H.F. tuning
521715	Pulley; U.H.F. dial drive (includes set screws)
521714	Pulley; U.H.F. tuning (includes set screws)
520313	Ring, insulating; for mounting picture tube
115327	Rod, anchor; lower (insulated)
520971	Rod, picture tube retaining
520966	Rubber ring; supports flared neck of picture tube
170761	Screw—set; #6x32 x ⅛" "Allen type"; retains tuning pulleys and gear
13392	Screw—set; #8x32 x 3/16" "Allen type"; retains cam
18807	Screw—#14 x 1"; mounts chassis
512245	Shaft and pulley for U.H.F. dial
521052	Shield for 1B3GT socket
521614	Shield for crystal detector
115284	Shield—H.V. compartment
521121	Shield—tube (9 pin)
507357	Slug core for 4.5 Mc. trao coil
521064	Slug for syncroguide transformer
521620	Socket and cable assembly for picture tube
521269	Socket and mounting bracket for TV dial lite
522146	Socket assembly—octal; for 1B3GT (includes resistors 143 and 144, filament lead, high voltage lead, and soldering lug)
115267	Socket male, power cord interlock (includes mounting bracket)
160039	Socket (1 pin) for phono. pick-up cable
521383	Socket (5 pin) for interconnection of chassis
507364	Socket—tube (7 pin)
506220	Socket—tube (octal)
521053	Socket—(octal) for 1B3GT tube
508044	Socket—tube (9 pin)
111766	Spring, anti-backlash
161384	Spring, dial cord tension
115326	Strap, anchor; upper (insulated)
521063	Strip, retains H.V. lead
520981	Support for tuner shaft (plastic)
521095	Terminal strip for deflection yoke connections (fits on vertical output transformer)
507351	Terminal strip for TV antenna connection
170741	Wing screw—#8-32; for mounting or forward adj. af yoke

*—This part is not supplied as a Service replacement item.
‡—This part is not supplied as a Service replacement item. Tuner to be returned ta factory for repair.

CHARACTERISTICS

Intermediate frequencies (i.f.)
- Video – 25.1 Mc
- Sound – 20.6 Mc
- Audio strip – 4.5 Mc

Receiver input impedance
- 300 – ohms

Speaker voice – coil impedance
- 3.2 ohms at 400 cps

Power supply input
- 117 volts, 60 cps, a.c.

Power consumption
- 170 watts

Tube complement
- 18 tubes – 2 selenium rectifiers and 1 crystal diode as follows:
  - R-F amplifier – 6BK7A or 6BZ7
  - Mixer-oscillator – 6J6
  - 1st video i-f amplifier – 6CB6
  - 2nd video i-f amplifier – 6CB6

Tube complement – *con't*
- 3rd video i-f amplifier – 6CB6
- Crystal video detector – 1N64
- Video amplifier – 6CB6
- Sound driver-amplifier – 6AU6
- Sound detector-amplifier – 6BN6
- Audio output – 25L6
- Sync clipper and sync splitter – 12AU7
- Vertical sweep oscillator and d-c restorer – 12AU7
- Vertical output amplifier – 25L6
- Horizontal afc phase detector – 6AL5
- Horizontal sweep oscillator – 6SN7
- Horizontal sweep output amplifier – 25BQ6
- Horizontal damper – 25W4
- High voltage rectifier – 1B3G
- Picture tube – 17BP4, 21EP4, or 21ZP4
- Low voltage rectifiers (selenium) – SR-300

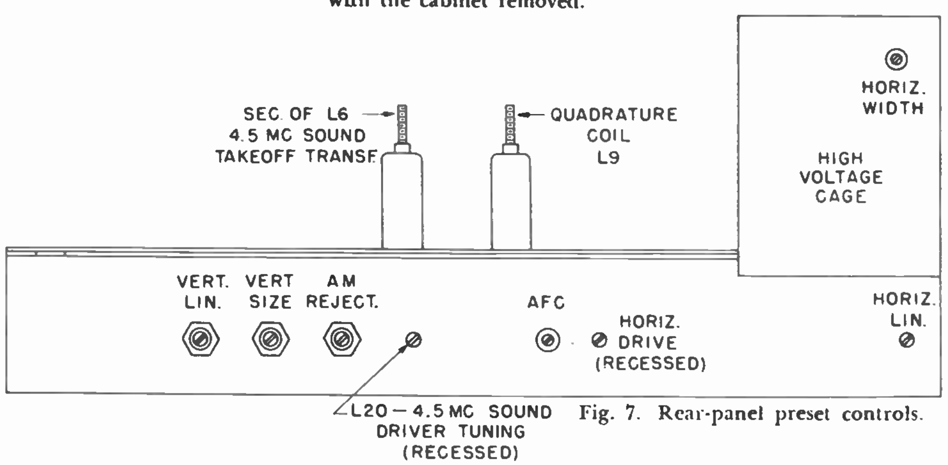

Fig. 7. Rear-panel preset controls.

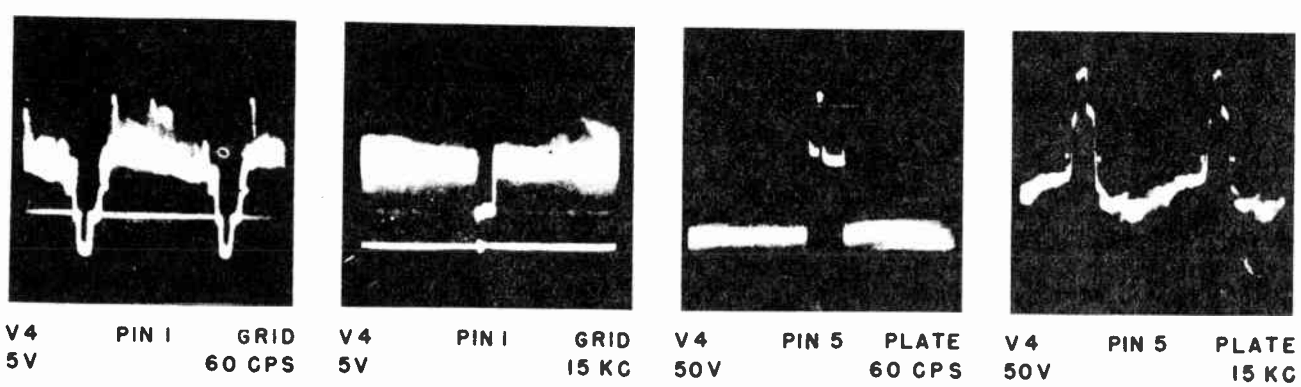

Fig. 8. Video, sync, and sweep waveforms chart indicating the tube pin number where each waveform exists and the peak-to-peak voltages.

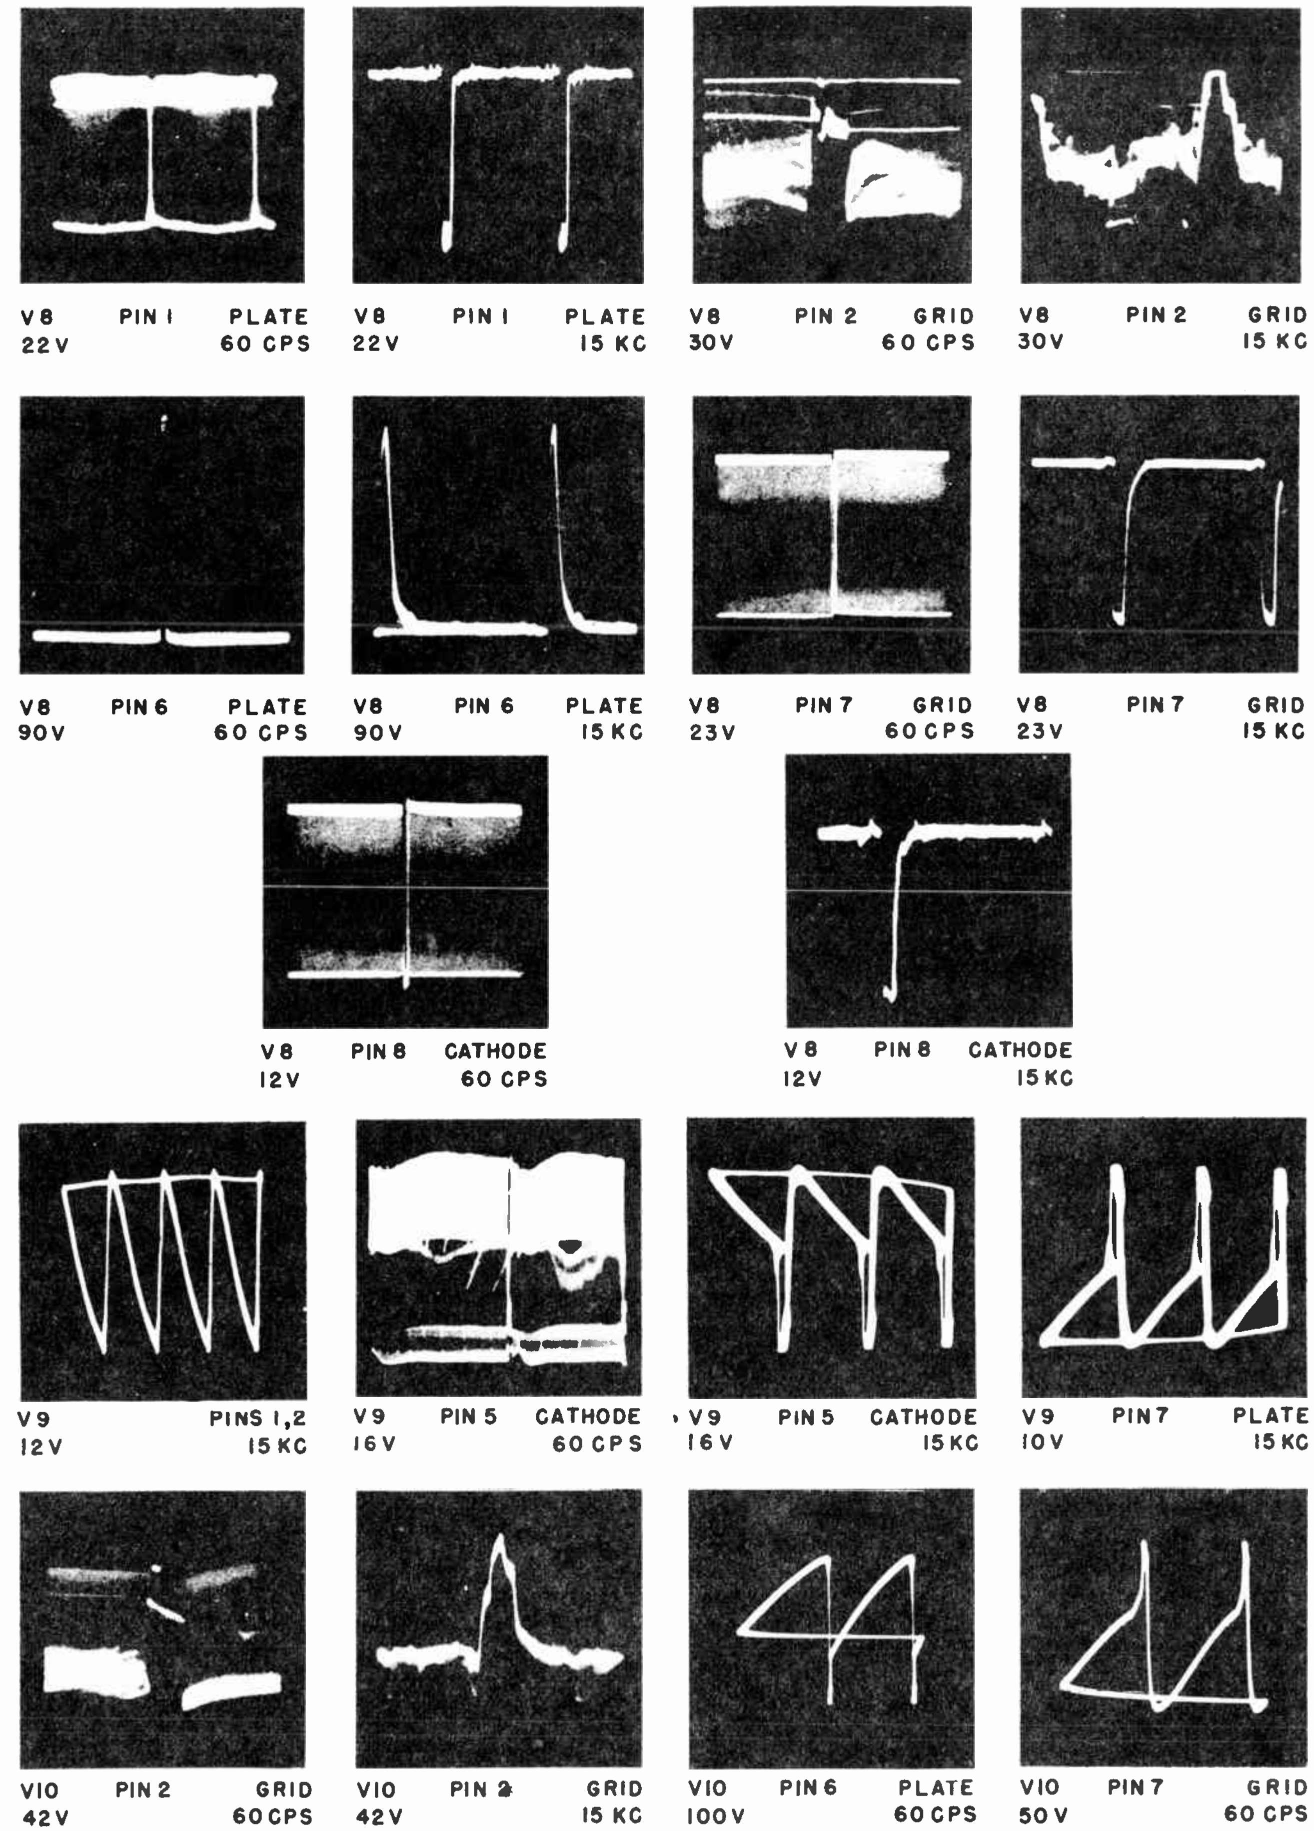


RAM FOR CORONADO TELEVISION
3-43-9038A & 45TV13-43-9081A

OSCILLOGRAMS

All oscillograms taken with ground lead of 'Scope connected to receiver chassis and controls set for normal reception. Contrast control adjusted to give 50 volts peak to peak at cathode of picture tube. Oscilloscope vertical amplifier response was flat to within 20% at 2 MC.

Number appearing to the left of oscillogram specifies setting of horizontal sweep frequency control on 'Scope.

VOLTAGE MEASUREMENTS

All voltages measured with a 20,000 Ohm per volt meter with the receiver connected to a 117 volt 60 cycle power supply.

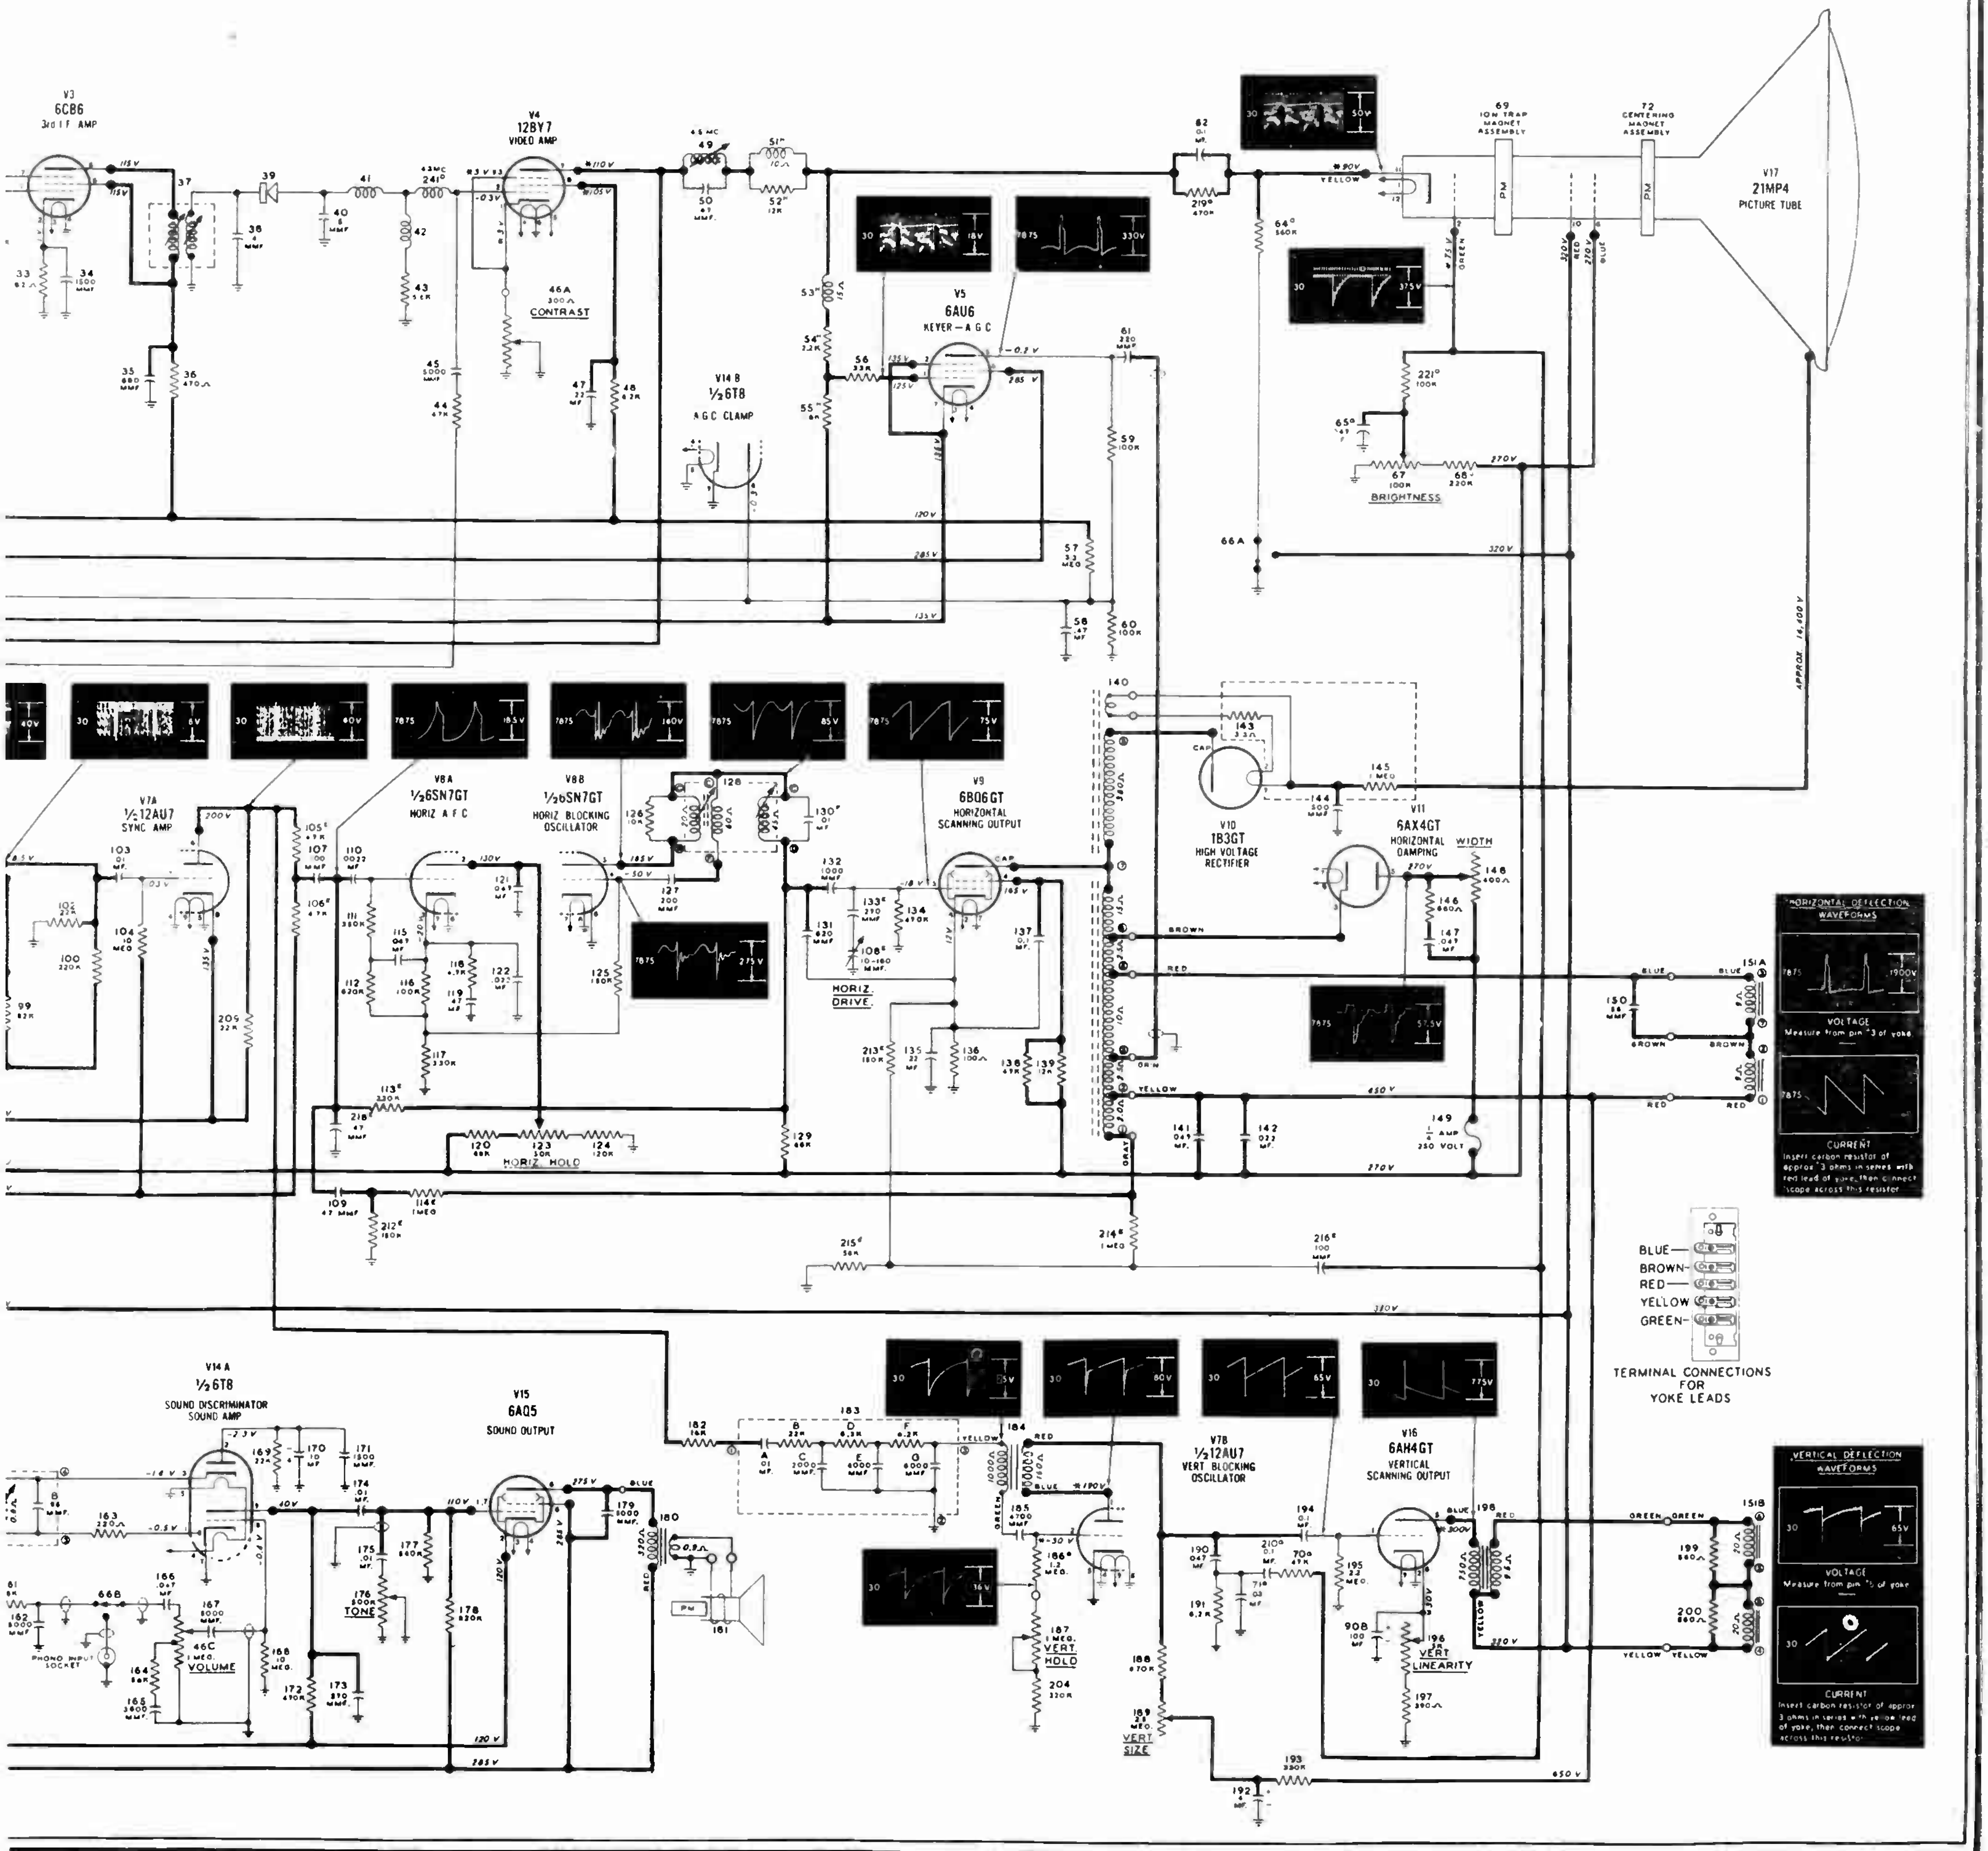
Tuner set to an inactive channel with antenna terminals shorted and connected to ground.

Controls set for normal reception—Contrast control completely counterclockwise.

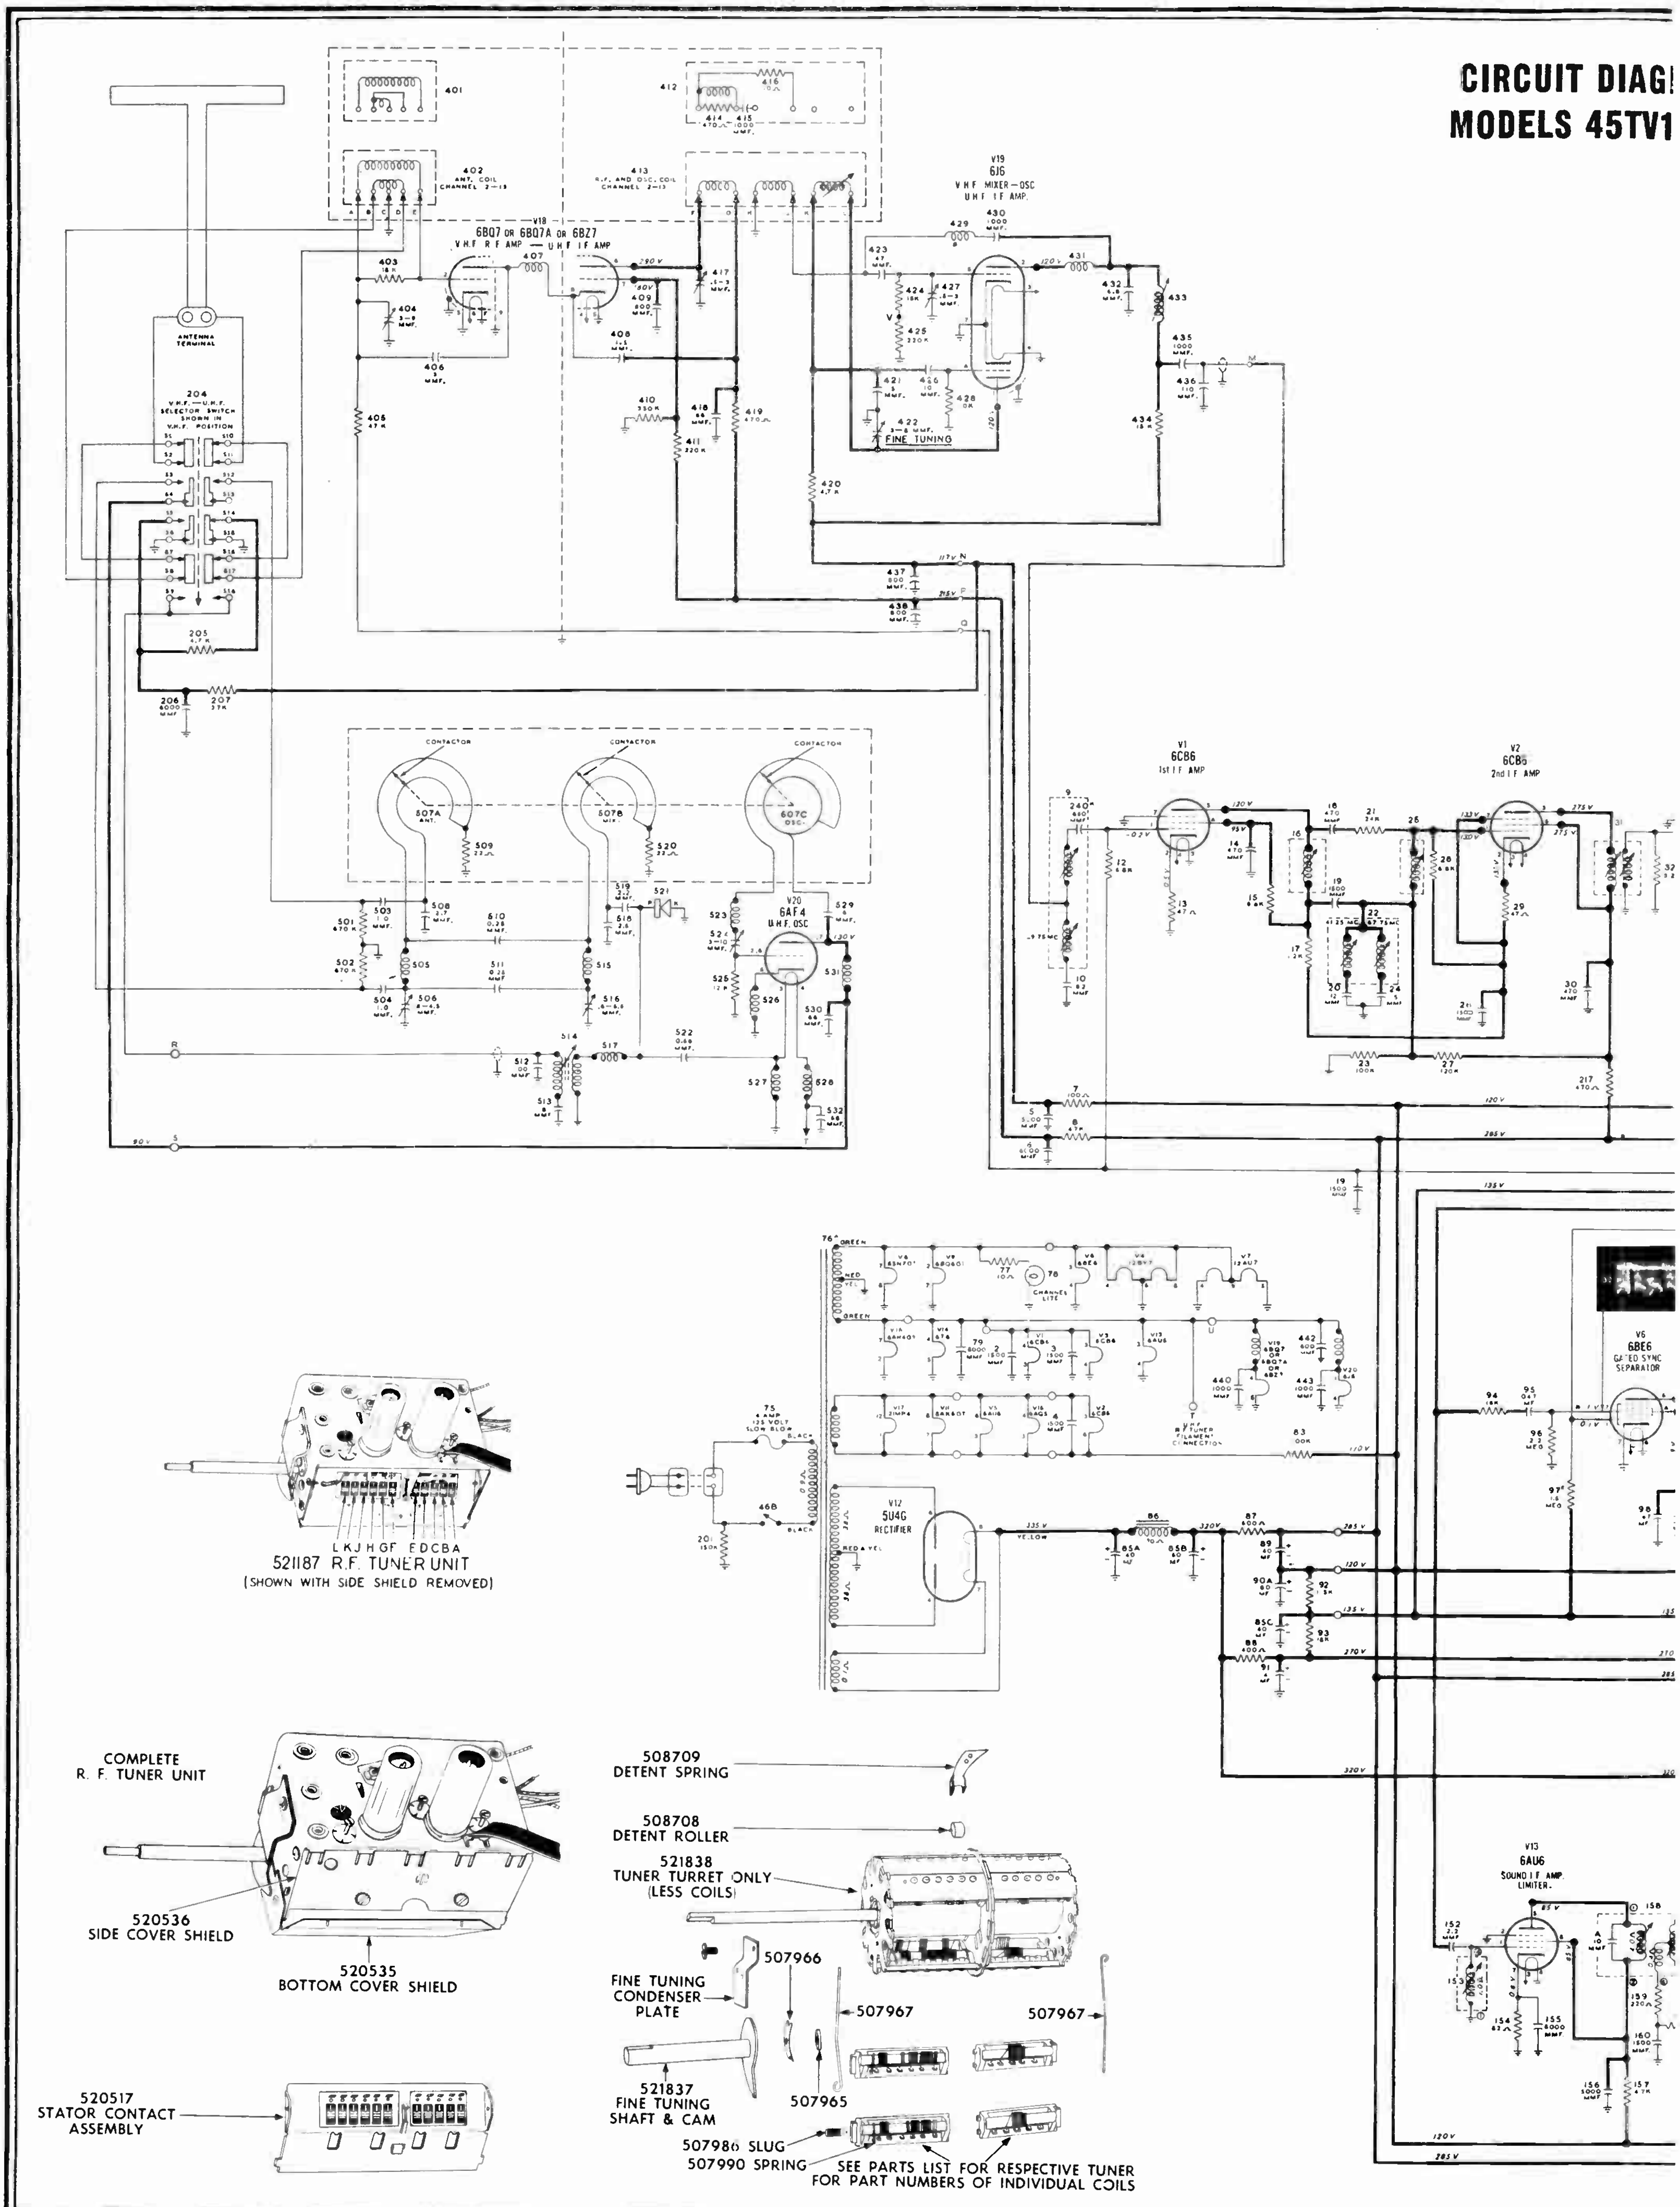
Voltages marked with an asterisk (*) will vary widely with control settings.

R.F. tuner voltages were measured with tubes removed from socket.

No voltage reading at a tube element indicate zero voltage or voltage which cannot be accurately measured with a 20,000 Ohm per volt meter.



CIRCUIT DIAG
MODELS 45TV1



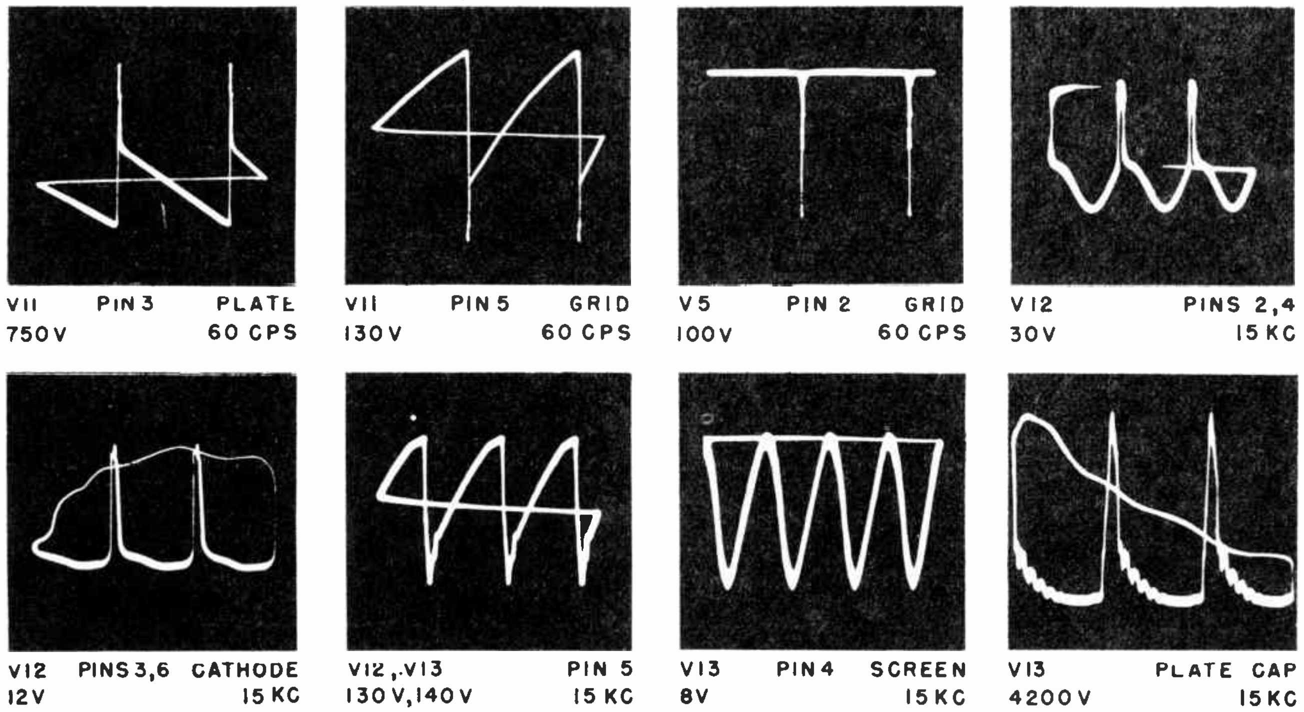


Fig. 8. *Continued.*

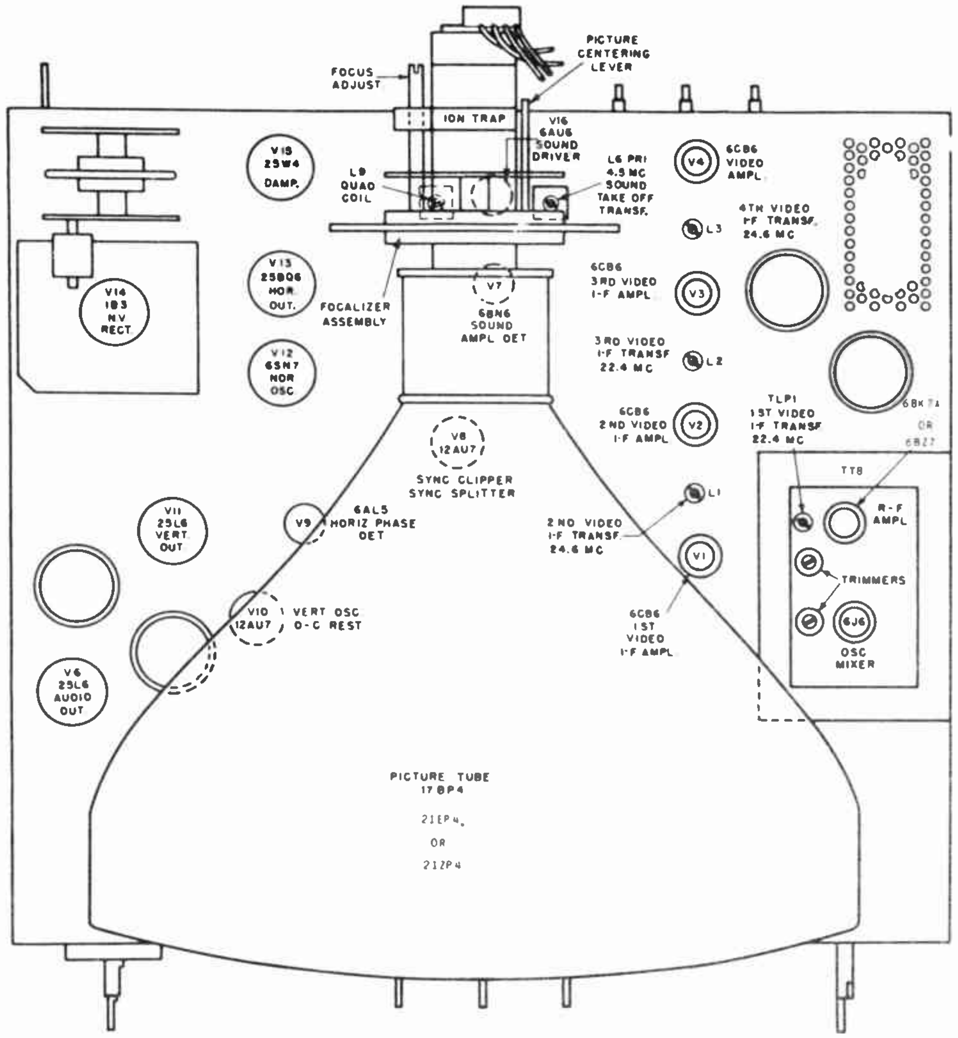

Fig. 9. Top chassis view showing the layout and alignment points.

ALIGNMENT PROCEDURE

Test Equipment

The test equipment required for the alignment of this receiver is as follows:

Marker Generator	(RCA WR39B or equivalent)
Sweep Generator	(RCA WR59B or equivalent)
Oscilloscope	(RCA WO55B or equivalent)
VTVM	(RCA WV97A or equivalent)

The marker generator is an r-f signal generator used for peaking the i-f coils and also to supply marker pips on the response pattern. The required frequency range of this generator should be approximately from 20 to 30 Mc. The accuracy of the frequency calibration of this generator is very important.

The sweep generator should have its output continually variable in frequency. In this alignment, only one output sweep signal is needed, that sweeping between 20 to 30 Mc. The oscilloscope used should be a high-gain, general-purpose type employed for test purposes. The frequency response and size of the screen is unimportant. The VTVM is of the standard type with a high input impedance. It should have provision for a-c and d-c measurements. The use of test equipment for sound and oscillator alignment is not required. For all adjustments use a good insulated screwdriver alignment tool.

Alignment

For the alignment points of the different sections of the receiver refer to the figure indicated in the discussion. Aside from the oscillator adjustments most of the other alignment points are located on top of the chassis as indicated in the top chassis view of Fig. 9. It is recommended that the order of alignment in the following procedure be adhered to if alignment is found necessary. The ground leads of the test instruments should be connected to the top chassis plate (B minus) of the receiver.

Video I-F Alignment

Connect the oscilloscope or the VTVM to the junction of *R118* and *L5*. Adjust the contrast control to its minimum setting. Feed the output signal of the marker generator through a tube shield placed over the mixer tube. *Be certain that this shield is not grounded.*

Set the marker generator at 22.4 Mc, amplitude modulated 30 per cent at 400 cycles. Adjust *TLP1*, the first video i-f coil, which is located on top of the tuner, for maximum deflection on the oscilloscope or VTVM. Repeat this process with the third video i-f coil *L2*. Leaving the generator connected as is, reset its frequency to 24.6 Mc and tune the second and fourth video i-f coils, *L1* and *L3* respectively, for maximum response on either indicating device. The screwdriver adjustments for all the above i-f coils are located on the top of the chassis as shown in Fig. 9.

Over-all Picture Response

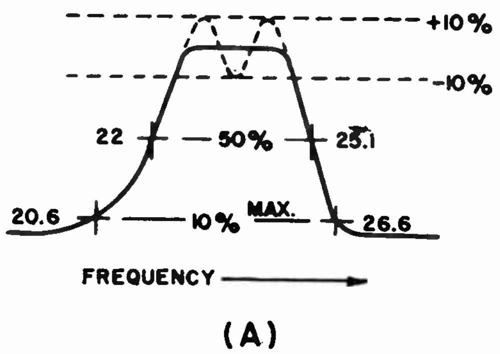
With the sweep generator adjusted for a 10-Mc sweep with a center frequency of about 25 Mc (i.e., sweeping 20-30 Mc) connect the sweep output cable to the mixer tube similar to the method in the video i-f alignment. *Loosely couple* the marker generator to the same mixer tube. Inject individual markers of 25.1 Mc, 22 Mc, 20.6 Mc, and 26.6 Mc in the order indicated and note the position of the marker pips on the response curve for each case. If necessary, readjust the four video i-f coils for an over-all picture response as indicated in Fig. 10 (A). The solid line at the top of the curve is the ideal straight line response. The dotted portions of this part of the curve indicate the possible limitations and variations that usually exist and which are permissible for correct alignment. In part (B) of Fig. 10 is an actual over-all video i-f alignment curve taken on a "XT-100" chassis

NOTE: The 25.1-Mc and 22-Mc markers should fall approximately halfway down the slope on either side of the curve. The 20.6-Mc marker should be well down on the base of the low side of the curve. (This is the frequency of the sound i-f output from the mixer tube.) Coil *TLP1* will effectively peak the low side, while coils *L1* and *L3* affect the high side of the curve. Coil *L2* should be used as the final adjustment for a symmetrical pass-band.

Sound Alignment

This is the alignment of the 4.5-Mc section of the receiver. For the quickest method of aligning this section, an actual station transmission is used as the basic signal instead of any meter or visual method of alignment. No measuring or indicating devices are needed for this method of alignment.

In order to correctly align coils *L6* and *L20*, an input television signal must be used that is *below* the



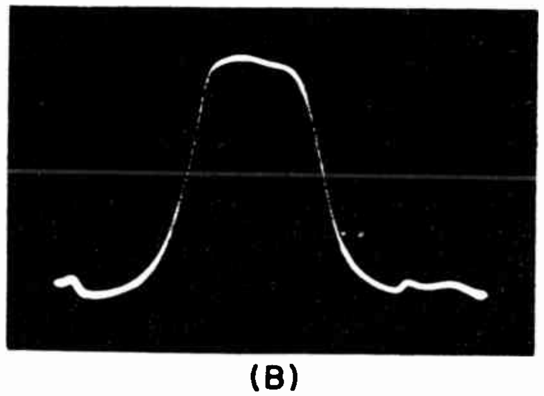


Fig. 10. Over-all video i-f response; (A) drawing showing marker points, and allowable variations in shape, (B) an actual response curve.

limiting level of the 6BN6 gated-beam tube. This level can easily be identified by the "hiss" which appears in the sound output. Some method of attenuation must be employed to reduce this signal. Although various methods are possible some sort of attenuator between the antenna and input terminals is preferred. A simple resistance pad similar to that indicated in Fig. 11 will suffice. If not enough attenuation is secured with one pad, add another or more until there is sufficient attenuation. Conversely, in order to properly align the quadrature coil *L9* and the a-m rejection control, *P12*, a signal above the limiting value is necessary.

The sound alignment is as follows:

1. Tune in a station that has a steady signal with no fading. A station with a tone signal (test pattern) on the air is preferred, otherwise any available signal will do.

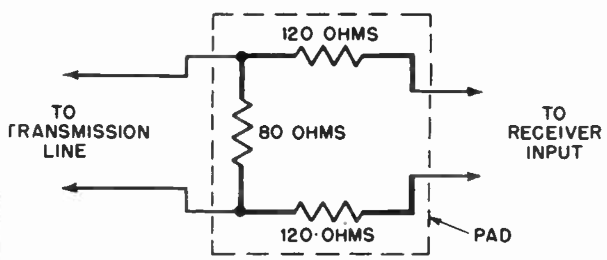

Fig. 11. A typical attenuation pad.

2. Adjust the attenuator until the signal coming in is reduced to the level where a "hiss" is heard with the sound output. Next adjust the primary and secondary of the 4.5-Mc sound take-off coil *L6*. The secondary adjustment of *L6* is made from the underside of the chassis as indicated in Fig. 12; the primary adjustment is made from the top of the chassis. The 4.5-Mc sound driver coil *L20* is adjusted next for maximum sound output regardless of any hiss or buzz. If any of these sound adjustments may cause the "hiss" to disappear, the attenuator should be readjusted so that the "hiss" reappears.

3. When the maximum sound output is attained, adjust the attenuator in the opposite direction so that the "hiss" disappears. This raises the signal above the limiting level of the 6BN6 gated-beam tube.

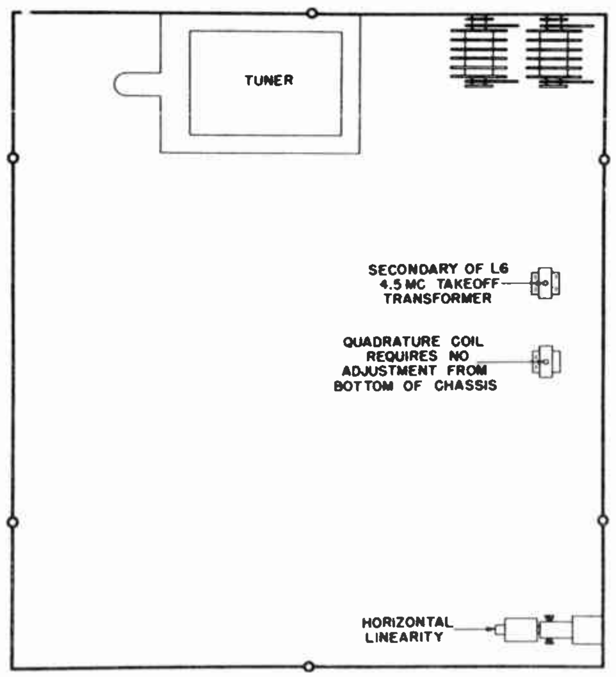

Fig. 12. Underside of chassis indicating location of L6 primary.

4. Next adjust the quadrature coil, *L9*, for maximum sound output. For this, it is recommended that a station of average signal strength in your area be used. The a-m rejection control *P12* is then adjusted until the intercarrier buzz is eliminated. Then repeat the *L9* and *P12* adjustment.

Proper alignment of the sound system can be checked easily at any time by turning the a-m rejection control first to the right and then to the left of the final setting. Whatever happens in one direction, such as the appearance of buzz or decrease of the f-m output, should also occur in the opposite direction. If this does not happen, then realign once again in the same manner as set forth above.

Alternate Method. An a-m or marker generator may also be used to align the takeoff transformer *L6*, and the sound driver coil *L20*.

Set the generator to 4.5 Mc, amplitude modulated 30% at 400 cycles. Connect the output cable of the generator to the junction of the .05 mf capacitor (*C118*) and the two peaking coils *L4* and *L5* in the grid circuit of the 6CB6 video amplifier. Place the vertical input terminals of an oscilloscope or VTVM across the voice coil or the volume control *PD10*. Set the volume and contrast controls at maximum.

Adjust the a-m rejection control for the first maximum response on the oscilloscope or VTVM as the control is turned in a clockwise direction. Lower the generator output until a "hiss" is heard from the speaker. Next peak the primary and then the secondary of the takeoff transformer *L6* for maximum response on the oscilloscope or VTVM. If the "hiss" disappears, lower the generator output until it reappears. Then adjust the sound driver coil *L20* in the same fashion.

The quadrature coil *L9* can then be aligned either by ear as in the first method, or by use of a tone modulated pattern transmission from an actual station. If the latter is available, the input is set above the limiting level of the 6BN6 (no hiss in the output) and the quadrature coil is peaked for maximum response on the oscilloscope or VTVM.

Oscillator Alignment

As far as the r-f tuner is concerned only the oscillator alignment is discussed here. Alignment of the r-f section is not included because it is felt that very seldom will it require alignment. If any trouble is suspected in the r-f section it is suggested that the receiver or tuner be returned to the manufacturer or an authorized service agency.

This tuner employs the principle of incremental inductances as you move from channel 13 down to channel 2. Oscillator adjustments, therefore, are made sequentially from channel 13 through channel 2. No instruments are needed for this alignment, station transmissions on each channel are the only signal sources. The alignment procedure is as follows:

The fine tuning control is first set to the midrange of its adjustment. Set the channel selector switch to channel 13. Adjust the oscillator slug for this channel (see Fig. 13) until the best picture and sound is received. Bear in mind that the a-m rejection control must be properly adjusted beforehand for the clearest sound as discussed in alignment of the sound section. Next, repeat this procedure for channel 12, then channel 11 and so on down the line.

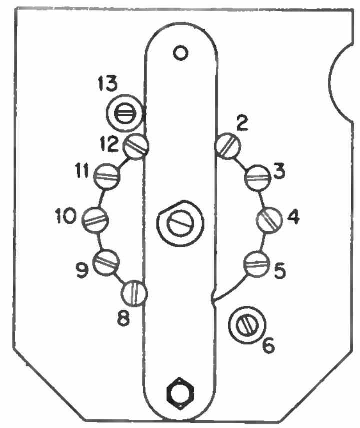

Fig. 13. Oscillator alignment points.

There is no oscillator adjustment for channel 7, alignment of the channel 8 oscillator automatically assures proper alignment of the channel 7 oscillator. After the high-frequency channels are aligned (13 through 7), although each low frequency can be aligned individually, the oscillator slug for channel 6 can be used to shift the complete low-frequency band if desired. Position of all the oscillator slugs for both bands are indicated in Fig. 13.

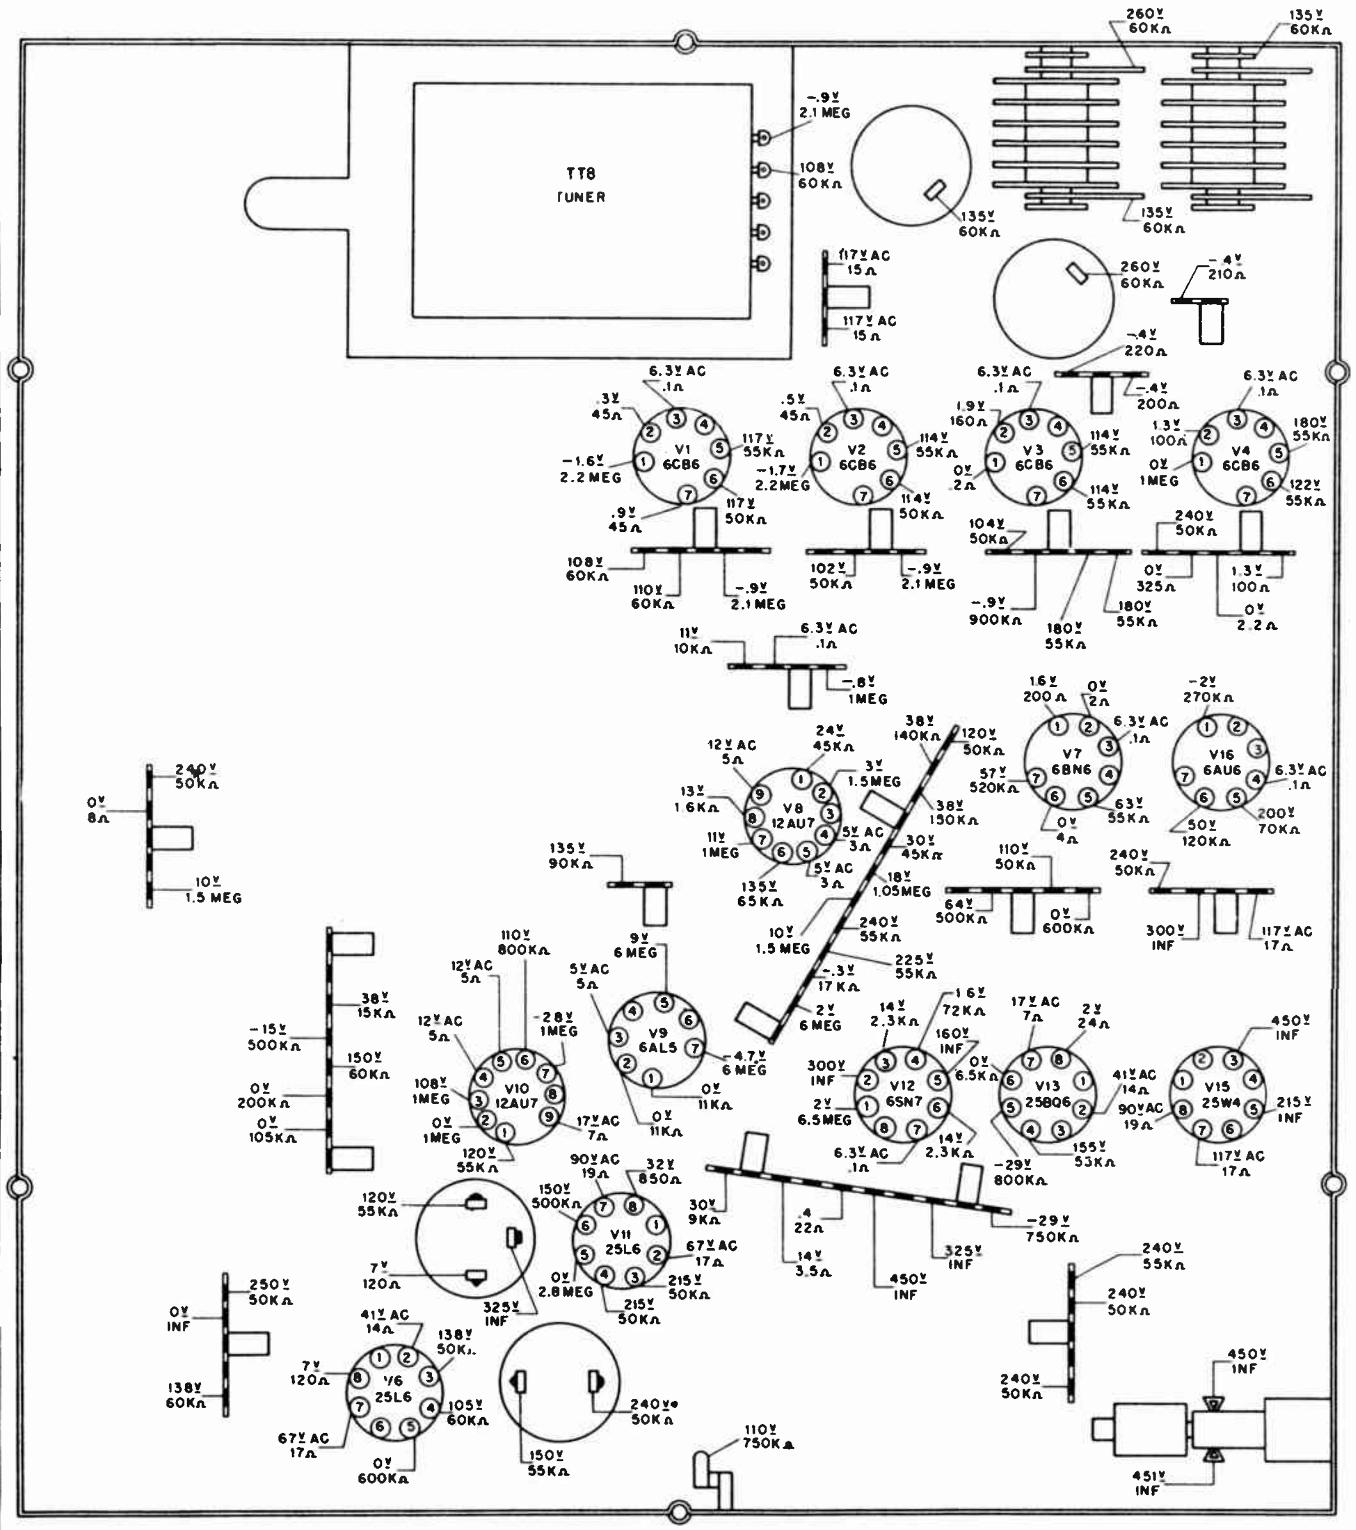

Fig. 17. Bottom view of receiver showing voltage and resistance values.

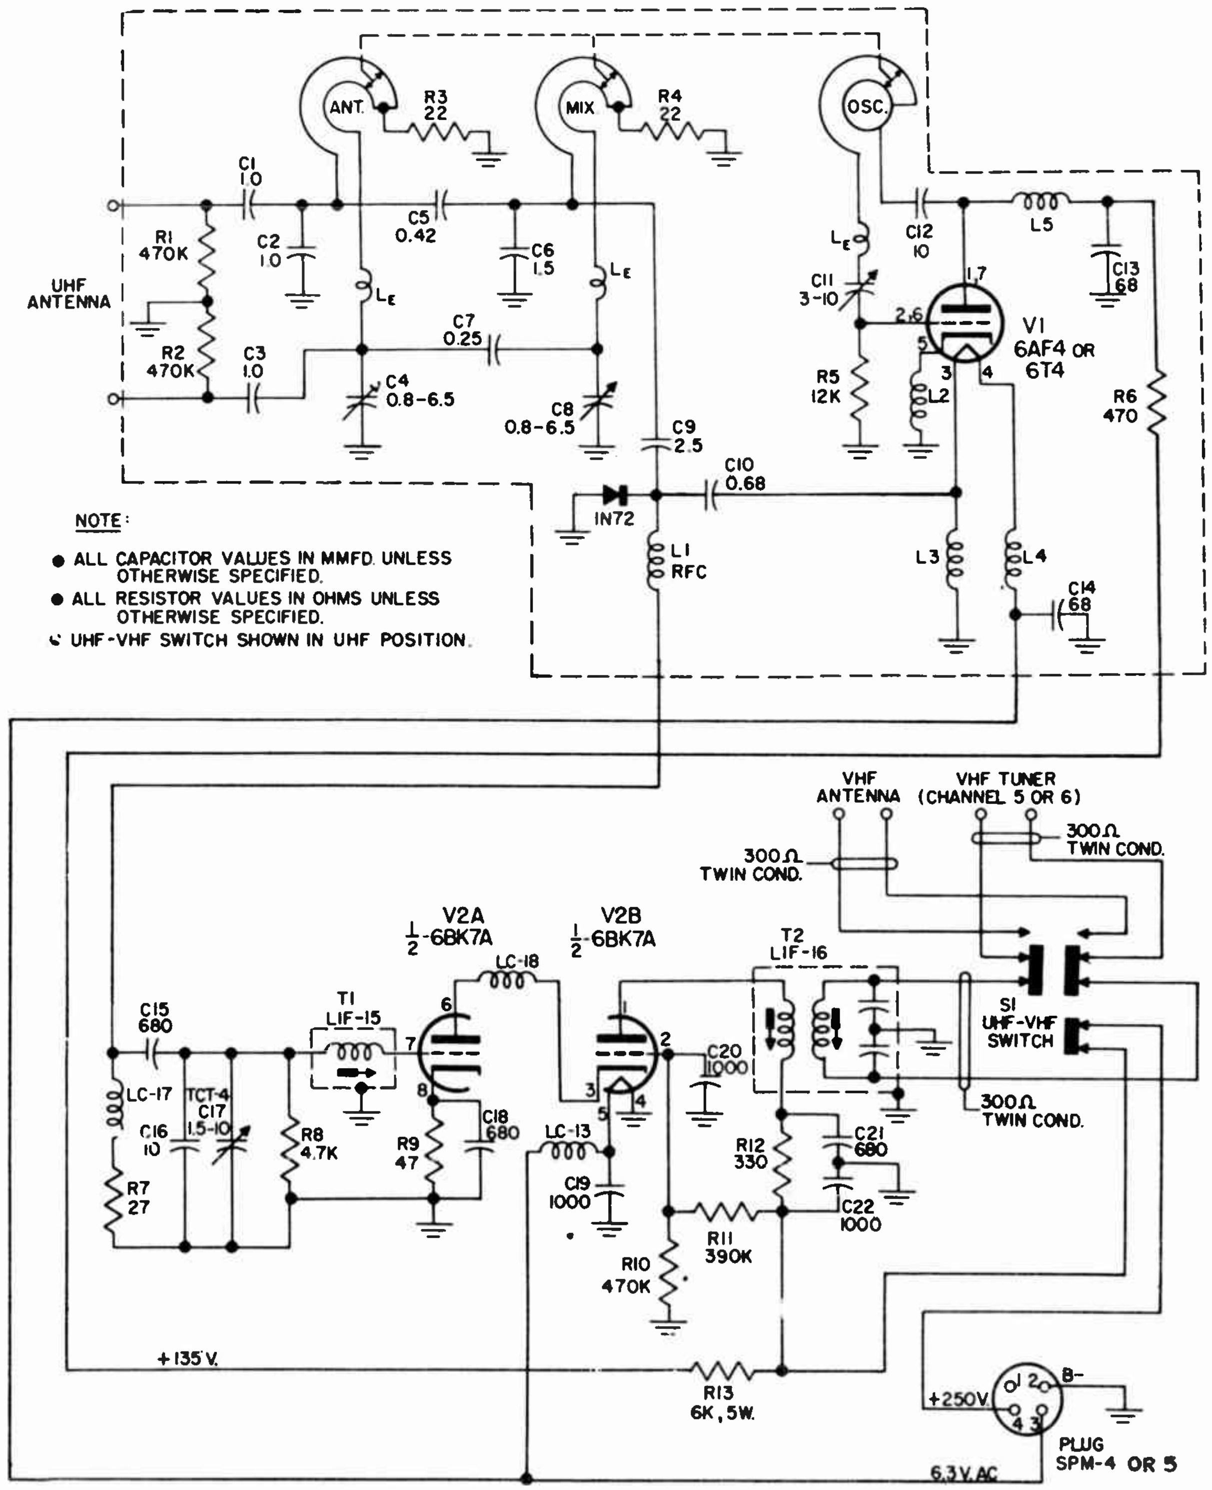
UHF TUNERS

The UHF Tuner found in the XT-100 series receivers may be either a Mallory Inductuner of a Radio Receptor UHF Tuner.

Because of the critical nature of the UHF Tuners, field servicing other than replacement of tubes or crystal mixer is not recommended. If major trouble that cannot be corrected by tube or crystal replacement occurs, remove the UHF Tuner unit only and return to the factory for repair.

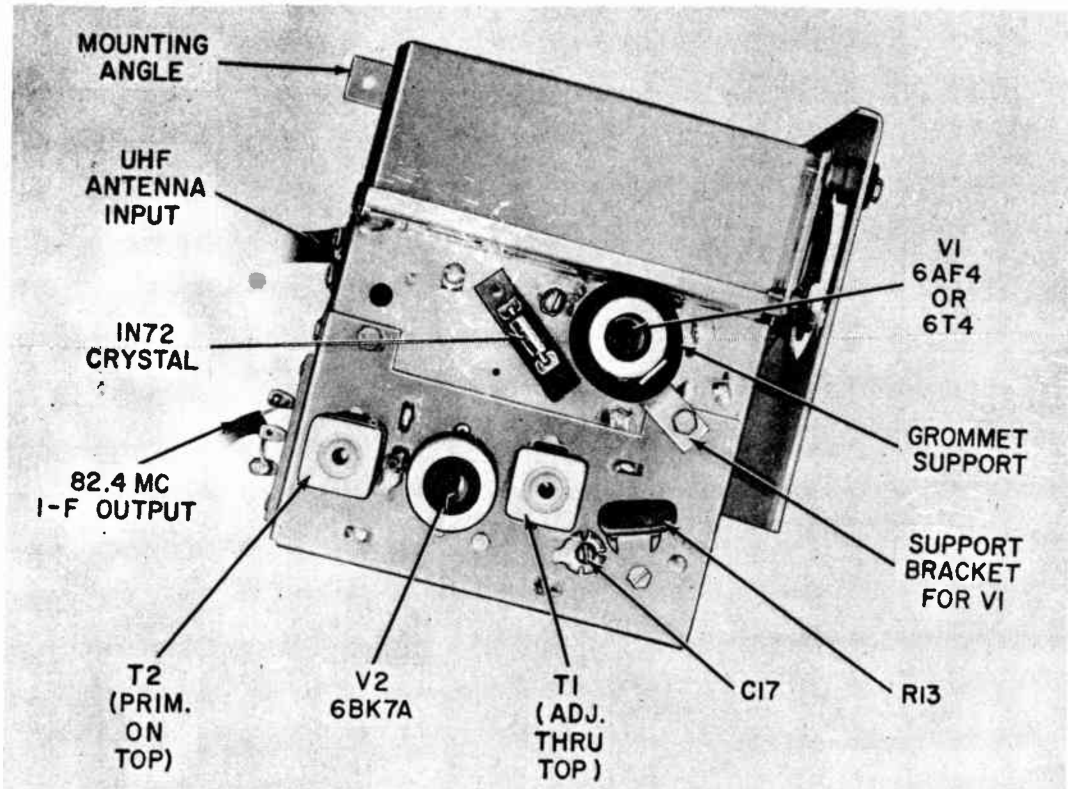
To identify the two types of UHF Tuners and understand the functions of each, refer to the following photos and schematics.

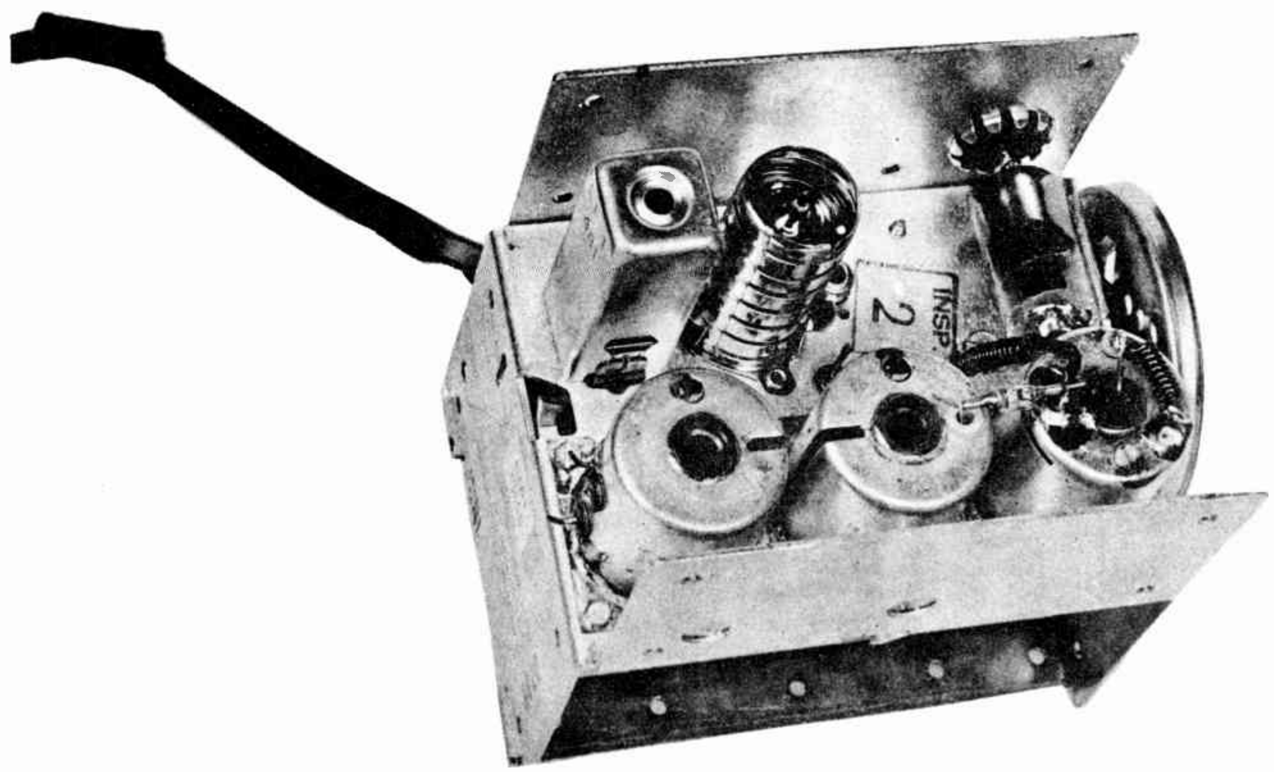
MALLORY INDUCTUNER



NOTE:

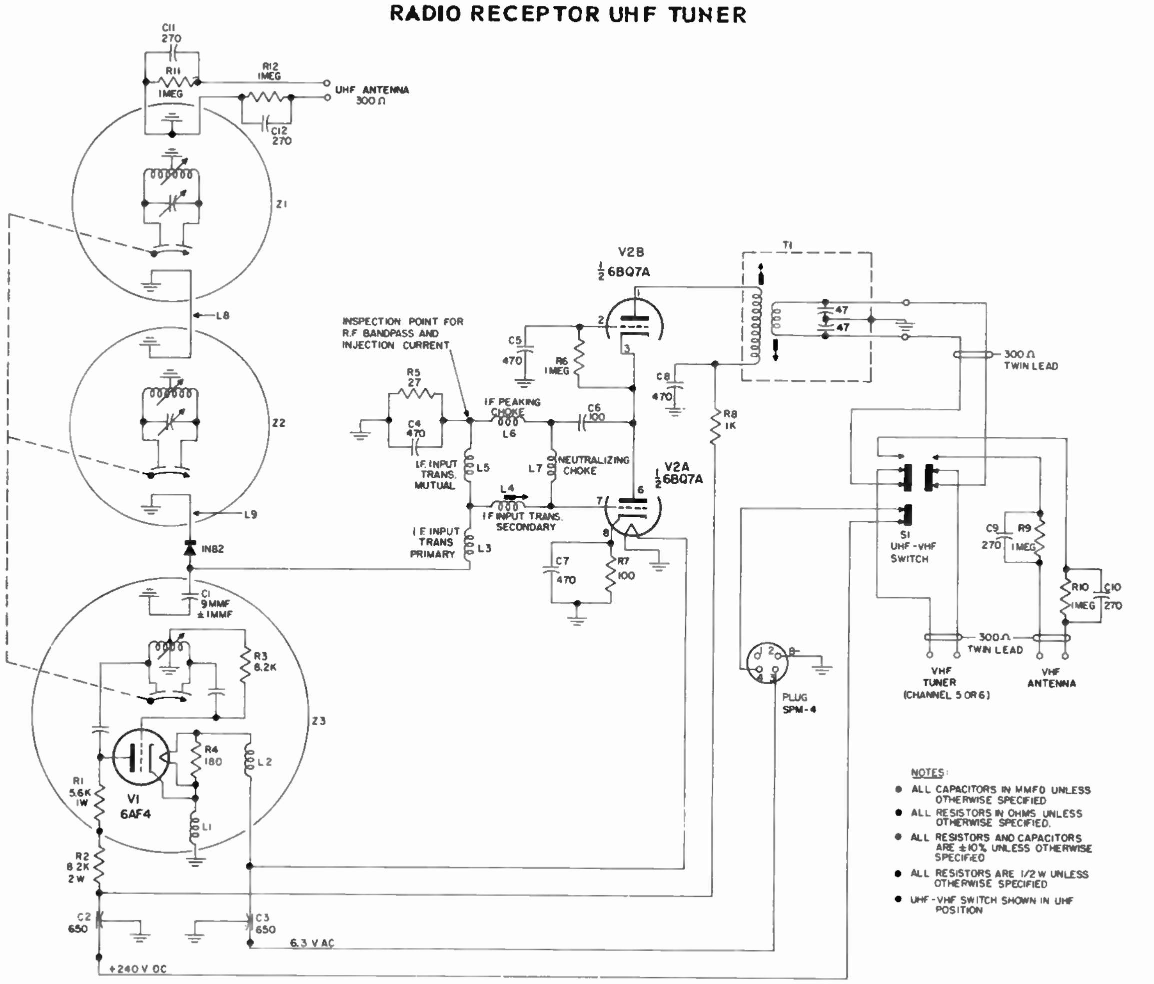
- ALL CAPACITOR VALUES IN MMFD UNLESS OTHERWISE SPECIFIED.
- ALL RESISTOR VALUES IN OHMS UNLESS OTHERWISE SPECIFIED.
- UHF-VHF SWITCH SHOWN IN UHF POSITION.





Dial cord stringing data.

RADIO RECEPTOR UHF TUNER



Since the tuning section of the converter is continuous, a dial cord drive and pulley system is required. Figure 1, illustrates two different types of dial cord stringing diagrams. Part (A) shows arrangement which may be found on some converters, and Part (B) is the arrangement which will be found on most converter units. On the latter type, the dial-cord arrangement varies slightly (shown by the dotted lines) for 21-inch picture tube receivers.

* Part No. 8-1010 (Blue or Black dial bezel) used with Mallory UHF Tuner and Part No. 8-1014 (Green dial bezel) used with Radio Receptor UHF Tuner.

** Uses EU7A - Channel Selector Escutcheon and EU12A - On, Off, Volume, Contrast Escutcheon.

Used EU7A and EU12A Escutcheons. Also used 8-1009 (Blue or Black) dial bezel for Mallory UHF Tuner and 8-1013 (Green) dial bezel for Radio Receptor UHF Tuner.

PHONOGRAPH REFERENCE

Models 45TV11-43-9130A and 45TV11-43-9131A, Television-Radio-Phonograph Combinations, may be equipped with either a VM Model 950 record changer or a Webster-Chicago Model 114 record changer

Both changers are orginally equipped with an Astatic type ACD-M cartridge and an Astiatic type A-1 (J)

AUDIO POWER OUTPUT:	Undistorted ... 1.5 watts Maximum ... 2.5 watts

PICTURE TUBE:	Type ... 21EP4-A or -B Size ... 21 inches Construction ... Glass, rectangular Deflection Angle ... 70 degrees Mask ... Rectangular, elliptical sides Picture size ... 13½ inches high x 18¾ inches wide

FOCUS UNIT: Loosen the focus unit securing nuts and laterally adjust the focus unit for the dimension shown in Fig. 2. Make sure the circular focus magnet remains concentric about and perpendicular to the tube neck. Tighten the focus unit securing nuts. Adjust the focus control screw for best focus. Some receivers use a slightly different focus unit as illustrated in Fig. 3.

PICTURE CENTERING: The wobble plate lever which is located on the forward end of the focus unit is the centering control. Loosen its two securing screws and move the lever in a restricted circular path until the picture is centered. Readjust the focus control if the picture centering process disturbed the focus adjustment. Refer to Fig. 3 for a different type of lever on top of unit.

PICTURE STRAIGHTENERS: These are the two anti-pincushioning magnets mounted near the bell of the picture tube. Adjust these magnets as follows:

(a) Reduce the picture size so that the raster edges are visible.

(b) Adjust the straightening magnets so that the raster edges are perfectly straight. These magnets will have an effect upon the width, but their important function is to keep the raster edges from being "bowed" in or out.

(c) Return picture to normal size with the size controls.

A. TO REMOVE PICTURE TUBE

1. Disconnect all cables and leads. Remove chassis.
2. Lay cabinet face down on a soft, nonscratching surface.
3. Remove ion trap.
4. Loosen and remove nuts and washers which secure the mounting rods to the picture tube strap assembly.
5. Remove entire picture tube mount assembly.
6. Remove picture tube assembly and picture tube.
7. Remove picture tube strap and remove tube from mask.

B. TO REPLACE PICTURE TUBE

1. Replace picture tube in mask and replace strap and tighten it.
2. Replace, in reverse order, all yoke and focus assembly parts removed in "A" above.
3. The nuts on each side of the flux shield (large disk) should be set for proper distance between the disk and the flange as shown in Fig. 2 and 3. Next, tighten the nut behind the forward plate of the focus unit thus maintaining it in its maximum forward position.
4. Replace ion trap.
5. Replace chassis and connect all leads and cables.

R-F TUNER UNIT

GENERAL DESCRIPTION

The r-f amplifier, converter and local oscillator are constructed as a complete subassembly unit which can be easily dismounted from the main chassis. This unit is designed and shielded to reduce oscillator radiation to a minimum.

The r-f tuner unit uses two r-f amplifiers, a converter and an oscillator. The intermediate output frequencies are: 45.75 megacycles for picture and 41.25 megacycles for sound.

The circuits are tuned by series coils and their distributed capacity, the tube capacity, and the capacity of three trimmers. As the channel selector is switched to lower channels, coils are added in series to lower the frequency. The oscillator section has a tuning adjustment for each channel so that the oscillator frequency may be correctly adjusted for every channel with one setting of the fine tuning control at the center of its range:

The antenna is coupled to the cathode of the first r-f amplifier by a balanced input transformer to reduce noise pick-up.

The r-f tuner unit includes an intermediate frequency trap in the cathode circuit of the first r-f amplifier to remove interfering frequencies, in the intermediate frequency pass-band, which may be picked by the antenna system. The trap is connected into the circuit when the receiver is tuned to the critical Channels, 2 through 6. Late production tuners incorporate a tunable cathode coil, L100.

Two major versions of tuners were used during the production run of these receivers. The 1st production receivers incorporate an "EE" version which uses a 6AB4 tube as 1st r-f tube, while the 2nd and 3rd production receivers incorporate a "BK" version using a 6BK7 tube as a 1st r-f amplifier. Refer to pages 14 and 25B for further details.

Delayed automatic gain control bias is applied to the second r-f amplifier. The i-f output of the converter is applied to the first i-f amplifier through a low-impedance coupling line to the i-f input coil. A test point "I" is added at the converter grid which is isolated from the grid by a resistor.

SERVICE ON R-F TUNER UNIT

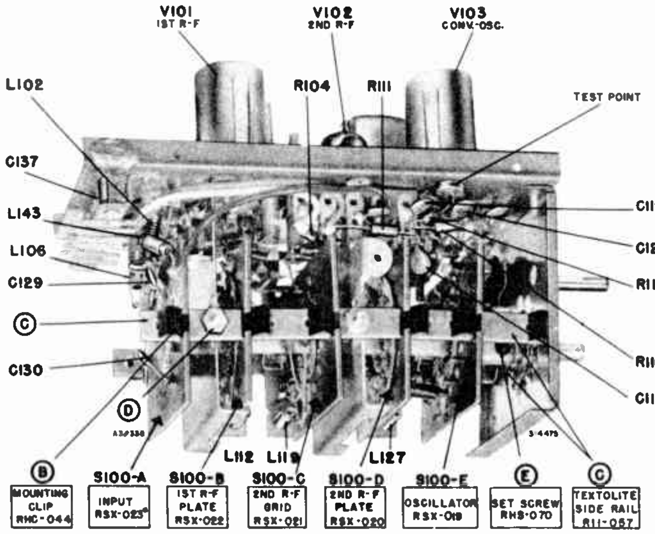
The r-f tuner unit has been carefully designed for trouble-free operation and ease in servicing. All parts including the switch wafers with the coils mounted are readily replaceable.

It is recommended that any trouble be definitely located before removing the r-f tuner unit. Make the following checks to help ascertain whether or not the trouble is in the r-f tuner.

1. If video or sound is present this usually eliminates the r-f tuner unit as a source of trouble. If both video and sound are absent, but the raster is normal, the trouble may be in the video i-f stages as well as in the r-f tuner unit.
2. If a noise pattern is evident on the screen, it usually indicates that the r-f tuner unit, the video i-f and the video amplifier circuits are operating normally. Check for a short or an open circuit in the antenna or antenna input circuits or first r-f stage.
3. Replace r-f tuner tubes with known good tubes. Note: When a new tube is used, slight differences in interelectrode capacities between tubes may cause a slight detuning of r-f circuits. If an oscillator tube is replaced, the fine tuning range should be checked.
4. Check for proper AGC bias voltage at test point No. X. A normal signal should produce approximately −3 volts VTVM reading.
5. The oscillator may be checked by measuring the voltage at test point No. I. If the oscillator is functioning it should develop approximately −3 volts as by a vacuum tube voltmeter. If the oscillator is inoperative the voltage at test point No. I will drop below 1 volt.
6. Check the i-f output coupling for open or short circuit.
7. Couple a 44-megacycle 400-cycle amplitude modulated signal to test point No. I. If the 400-cycle modulation is present at the output of the video amplifier plate as seen on an oscilloscope or observed on the screen of the picture tube in the form of horizontal bars, it is highly probable that the trouble lies somewhere in the r-f tuner unit ahead of the converter, V103B, grid (pin 7). However, should this 400-cycle information fail to appear in the receiver output, a check should be made of the video i-f amplifier stages, the crystal diode and the video amplifiers.
8. Check r-f tuner socket voltages shown in Fig. 27, page 24.

REMOVAL OF TUNER UNIT FROM CHASSIS—

1. Disconnect the antenna transmission line and the tuner output i-f coupling at the i-f assembly.
2. Remove self-tapping screws holding the tuner to the mounting brackets at the front and rear of the tuner.
3. Disconnect the following leads from the r-f tuner terminals: AGC, 6.3-volt heater, high B+ and low B+, see Fig. 19.



*Late production RSW-101

Fig. 12. R-F Tuner, Side View

4. Disconnect the black phenolic coupling from the r-f tuner switch shaft. The tuner assembly is now free for removal.

REPLACEMENT OF SWITCH WAFERS—See Fig. 12 and 13.

1. Remove the r-f tuner unit from the chassis and remove its shield.
2. Loosen setscrew (E) which holds Textolite switch shaft into the brass coupling RMK-007 and slide shaft out of the rear of the switch.
3. Remove the spring clips (B) which secure the switch wafer to the Textolite side rails (C). There are six of these springs on each side. These may be removed by lifting the tab out of the hole in the Textolite side rails.
4. Unscrew the four hex nuts (D) which secure the side rails (C) to the shields. The side rails may be lifted out of the switch wafers.
5. Unsolder the connections to the wafer to be removed and replace with the new wafer.

TO REMOVE THE OSCILLATOR WAFER ONLY—See Fig. 12 and 13.

1. Remove the r-f tuner from the chassis and remove the r-f tuner unit shield.
2. Loosen the Allen setscrew (E) which holds the Textolite switch shaft to the coupling and pull the shaft out of the oscillator wafer.
3. Remove the four spring clips (B) which secure the Textolite side rails (C) to the r-f tuner unit front apron and the oscillator wafer.
4. Remove the two self-tapping screws (A) which hold the r-f tuner unit front apron to the chassis, and pull the front apron forward so that the oscillator wafer may be removed. Use care not to break the connection to the tuning capacitor, C118.
5. Unsolder the connections to the oscillator wafer and remove it by springing up the Textolite side rails (C).

When reassembling the r-f tuner unit and replacing switch wafers, use care not to damage or distort any of the coils mounted on the switch wafers. Reassemble the r-f tuner unit in the reverse order that it was disassembled.

REMOVAL OF TUNING CAPACITOR OR DETENT ASSEMBLY—See Fig. 12 and 13.

1. Remove the r-f tuner unit from the chassis as outlined.
2. Remove the r-f tuner unit shield.
3. Remove the two spring clips (B) which hold the Textolite side rails.
4. Loosen the rear setscrew which holds the Textolite shaft into the brass coupling (RMK-007) and slide the Textolite shaft out of the coupling.
5. Remove the two self-tapping screws which secure the front apron to the r-f tuner unit chassis.
6. Spring up the Textolite side rails (C) to release the front apron for access to the tuning capacitor.
7. Unsolder the tuning capacitor lead at the 12AT7 socket.
8. To remove the detent assembly, remove the "C" washer on brass shaft.

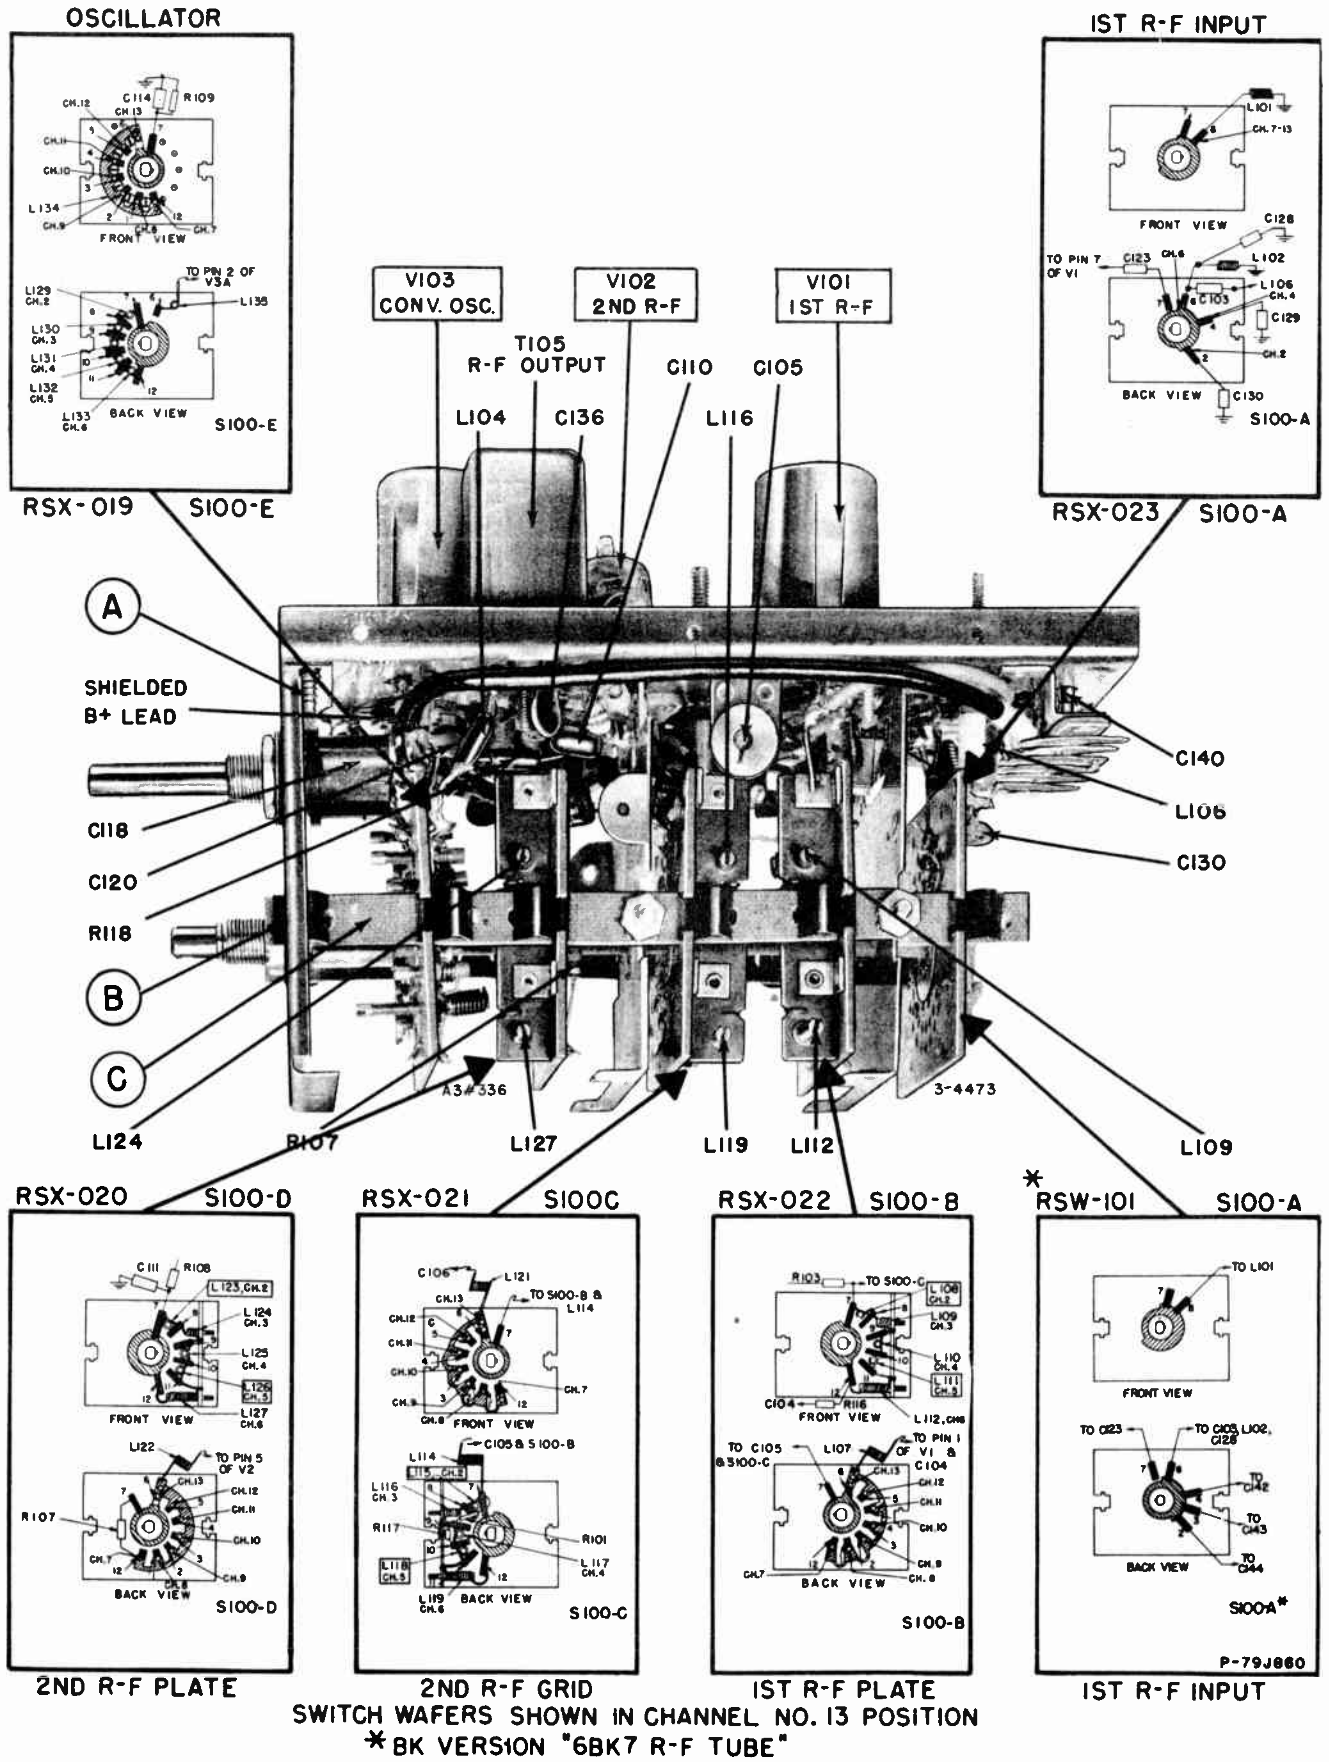


Fig. 13. R-F Tuner and Switch, Wafer Wiring

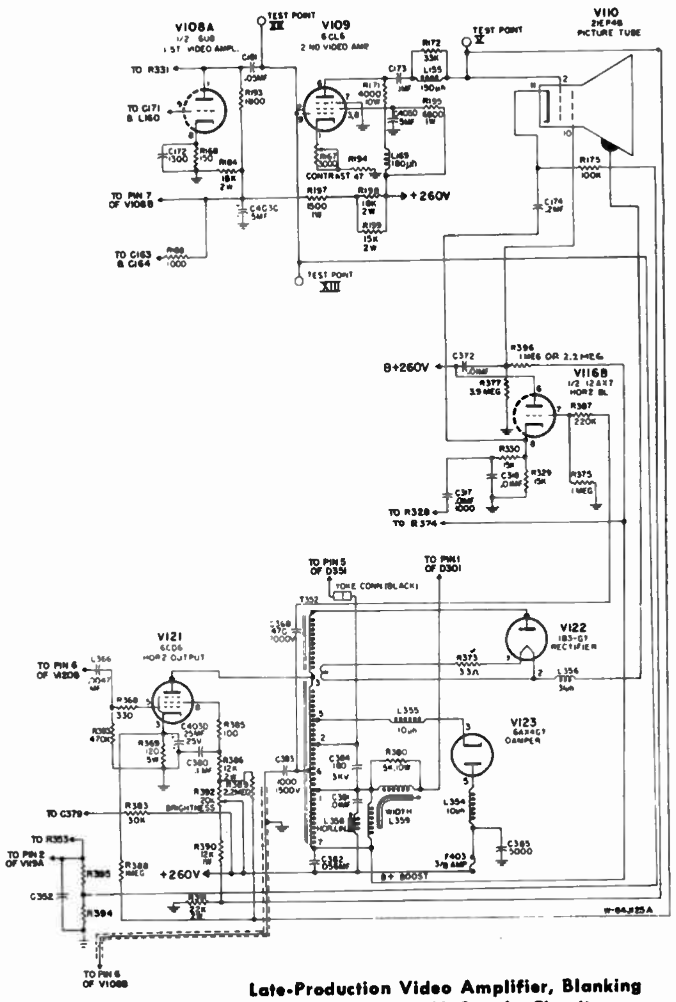

Late-Production Video Amplifier, Blanking Circuit and H. V. Supply Circuit

R-F Alignment

NOTES:

1. The r-f tuner may be aligned without removing it from the main chassis. Disconnect the 300-ohm transmission line from the antenna input transformer, T100 and disconnect the B+ to the oscillator, see Fig. 19. To remove B+ from the oscillator, clip the jumper between the center terminal lugs and transpose 250-volt lead from top feed through capacitor to lug No. 3 (reading left to right, looking down at top of tuner). Be sure to replace jumper and properly connect 250-volt lead after alignment.
2. Connect the sweep generator to the r-f tuner antenna input transformer using the G-E ST-8A balanced adapter to obtain 300 ohms output, see Fig. 14. The adapter should be connected to the r-f tuner through approximately three feet of 300-ohm transmission line and a resistor pad, as shown in Fig. 16A. When using other test equipment of the unbalanced output type, a pad as shown in Fig. 16B should be used instead.
3. Connect a 3-volt battery to the AGC terminal of the r-f tuner, see Fig. 19, with the positive lead of the battery connected to the tuner chassis.
4. Should it become difficult to obtain proper tracking on Channels 7–13 with the indicated adjustments, proper tracking may be achieved by dressing the coil L122. This coil is available through the opening of the tuner shield as shown in Fig. 17. This coil should be dressed with an insulated tool to prevent a B+ short.
5. It is possible to obtain two different settings of C105, Fig. 17, that will give the proper r-f bandwidth. The correct setting may be determined by switching from Channel 13 to Channel 12 and observing the change in bandwidth. The correct setting will result in a slightly greater bandwidth on Channel 12.
6. When proper tracking on the low channels cannot be achieved with the provided screw adjustments, the inductance of the coils L110, L111, L117, L118, L125 and L126 (Fig. 13) may be varied by inserting a knife blade between the windings. This method of adjustment requires the removal of the tuner shield, a procedure which will detune the circuits. However, in most cases the provided screw-type adjustments will suffice to achieve proper tracking through all channels after the shield has been replaced.
7. The picture and sound carrier marker should not be less than 75% of the peak of the r-f response curve. Refer to the "limits" curves shown in the accompanying alignment chart.
8. Seal trimmer screw of C105 and the brass cores in the coils L114, L112, L109, L119, L116, L127 and L124, Fig. 17, with wax to prevent detuning. Seal the tuning screws in trimmers C104, C106 and C108, Fig. 18, with glue. Reconnect the B+ oscillator lead on the r-f tuner terminal board and connect the transmission line to r-f tuner input transformer.
9. For receiver over-all alignment check, see page 19 (Step 3 and 4 of I-F Alignment Chart).

R-F Alignment Chart

(a) Set generator sweep width to 10–15 mc.
(b) Signal input point at r-f tuner input transformer, T100.
(c) Observe response curve at test point I, Fig. 18, through 10,000-ohm resistor. Connect test equipment ground lead to r-f tuner chassis.
(d) Adhere to following order when performing a complete alignment.
(e) When following the procedure below, an attempt should be made to obtain the indicated ideal response curves. Minor deviations from the ideal curves may occur, the maximum limits of "tilt" and/or bandwidth being shown in the "Remarks" column.

STEP	RECEIVER AND SWEEP GENERATOR CHANNEL	MARKER GENERATOR FREQUENCY MC	ADJUST	REMARKS
1	No. 13	211.25 215.75	C104, C105 and C108 (Fig. 17 and 18) for maximum gain and proper bandwidth of 4.5 mc to obtain curve "A" below. Limits are shown in last column.	Retune C108 and/or redress L122 (Fig. 17) for proper tracking; see note 4; C105 controls bandwidth, C104, C106 and C108 bring circuits into resonance.
2	No. 12	205.25 209.75	Adjust L100 on Channel 12 for maximum amplitude of *center* of response curve. Do not adjust beyond this point even if peaks tend to increase in amplitude. ("BK" version only)

Oscillator Alignment

GENERAL. Two methods of oscillator frequency adjustment are given below. The first method uses a transmitting station for the adjustment while the second method requires a sweep generator to align the oscillator coils.

A. *"ON Station Signal" Alignment*

R-F and video i-f alignment must be correct before attempting oscillator alignment. A transmitted station signal is needed for each one of the coils being adjusted. Tune in the stations starting with the highest frequency channels and adjust the tuning screws for all available stations so that with the fine tuning control in the full-clockwise position, audio is just visible in the picture. Then, check to see that best picture response on all channels takes place approximately in the center of the oscillator fine tuning range.

B. *Sweep Alignment*

1. R-F and video i-f must be properly aligned before aligning the oscillator.
2. Connect a 3-volt battery to the AGC terminal of the r-f tuner, see Fig. 19, with the positive lead of the battery connected to the tuner chassis.
3. Disconnect the 300-ohm transmission line from the antenna terminals to the r-f terminals and connect the sweep generator to the r-f tuner terminals as described in note 2 on page 14.
4. Set the fine tuning knob 180° (½ turn) from the counter-clockwise limit of its rotation, i.e. rotate the fine tuning knob counterclockwise to the end of its travel, then turn the fine tuning control knob 180° (½ turn) clockwise. This setting of the fine tuning control should be maintained for all oscillator adjustments.
5. Make the indicated adjustments so that the picture carrier marker for the channel falls at 50% on the high frequency side of the response curve.

AUDIO I-F ALIGNMENT

NOTES:

1. Tune in a television signal. This will provide a 4.5 mc signal source for audio alignment. Keep the Volume control turned down unless the speaker is connected.

2. Figure 21 shows a simple resistor network needed for the alignment of T202 secondary. These two 100,000-ohm resistors should be chosen as accurately as possible, for equal resistance. Be sure to remove these resistors after completing the alignment. Align as follows:

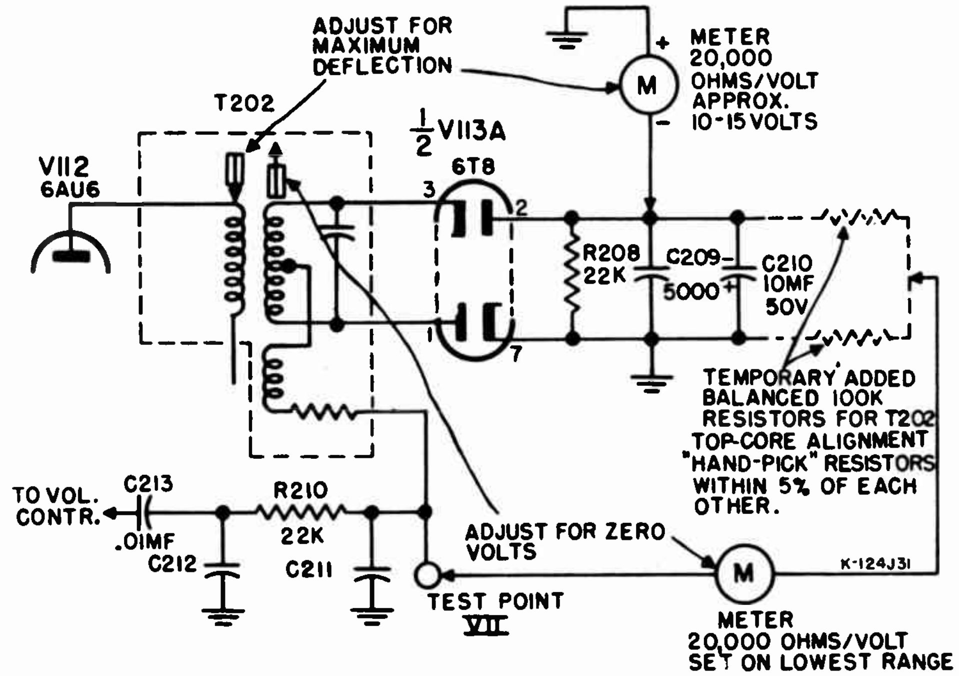

Fig. 21. Audio I-F Meter Connections

AUDIO I-F ALIGNMENT CHART

STEP	CONNECT VTVM OR 20,000 OHMS/VOLTMETER	ADJUST	METER INDICATION	REMARKS
1	To test point VI and chassis.	L157 and T201 (top and bottom cores).	Adjust for maximum deflection.	Voltage to be read is negative with respect to chassis.
2	V113A, pin 2 and chassis.	T202 primary (bottom core).		
3	Test Point VII and center of two 100K ohms resistors. See Fig. 21.	T202 secondary (top core).	Adjust for zero volts d-c output.	Repeat steps 1, 2 and 3 to assure proper final adjustment.

L106 TRAP ADJUSTMENT

ALIGNMENT OF L106 I-F TRAP

The trap, L106 (Fig. 18) is incorporated in the r-f tuner to remove or attenuate any interfering frequency in the i-f range. The trap should be aligned by tuning for minimum i-f channel interference pattern on the screen. If the interference is intermittent and the interfering frequency is known, L106 may also be aligned by the use of a calibrated signal generator.

NOTES:

1. Connect 3 volts bias from the AGC line on the r-f tuner (see Fig. 19) to chassis with the positive terminal of the battery connected to chassis.

2. Use an accurate marker generator to furnish a signal of the same frequency as the interfering frequency and a sweep generator with its center frequency set approximately at the interference frequency. Connect the scope to view the response curve at the output of the video detector.

3. Use the GEST-8A balanced adapter and a 3-foot piece of 300-ohm transmission line to couple the r-f sweep to the antenna terminals of the receiver.

4. Be sure, in tuning the trap, that it does not attenuate Channel No. 2.

L106 ALIGNMENT CHART

MARKER FREQUENCY	SWEEP FREQUENCIES AND INPUT POINT	OBSERVE RESPONSE CURVE AT	CHANNEL SWITCH SETTING	ADJUST
Interference frequency	40 to 50 mc to antenna terminals	Test Point IV	2	Core of L106 for minimum amplitude of curve at marker

RECEIVER ALIGNMENT

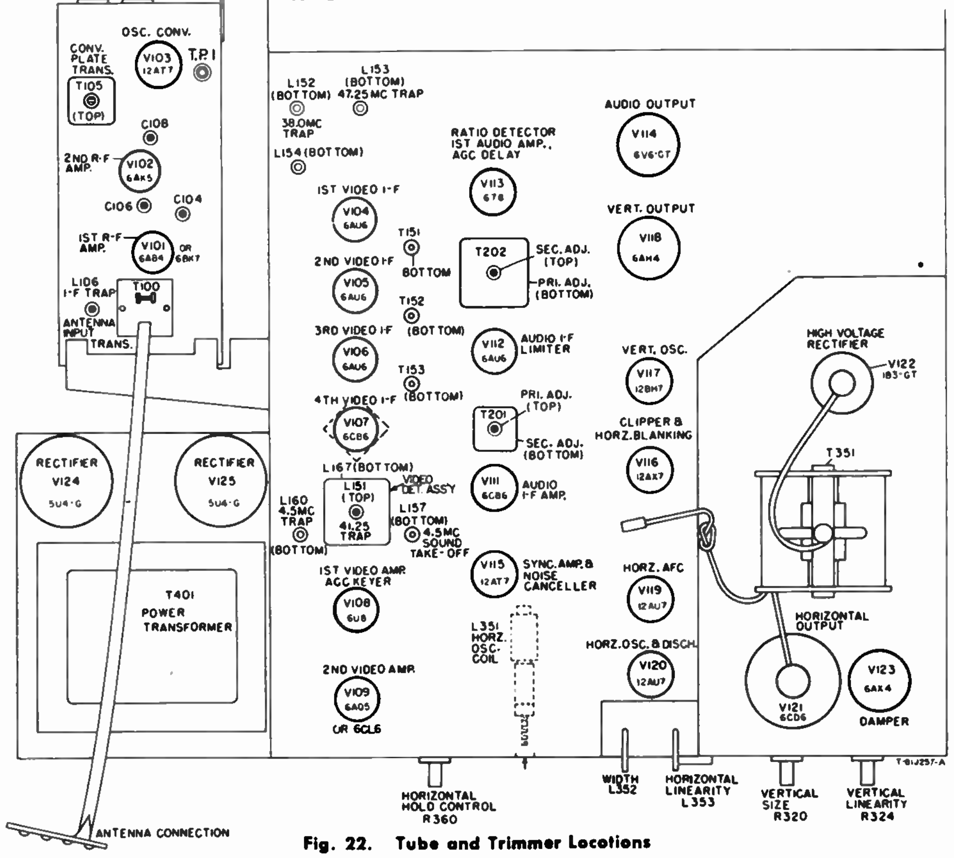

Fig. 22. Tube and Trimmer Locations

VIDEO I-F ALIGNMENT

Introduction:

The following alignment data is divided into two separate procedures. Because of the extremely high adjacent channel trap attenuation, the conventional method of sweep observation of these traps becomes difficult. Hence all traps shall be pretuned by applying an amplitude-modulated signal and adjusted for minimum signal output.

The second portion of this procedure involves the shaping of the i-f response curve in the conventional manner by the application of a sweep generator signal. During this procedure, observe the usual precautions regarding warm-up time, equipment cable lead dress and generator output cable termination, see Fig. 15.

TRAP ALIGNMENT

GENERAL:

As noted above, an AM signal is required for trap alignment. In many cases, the technician will have a suitable AM signal generator available. It should cover the range of 37 to 48 megacycles at fundamental frequency, with available internal 400-cycle modulation. When this type of signal is used, the traps should be adjusted for minimum 400-cycle signal as observed on the oscilloscope.

Owners of General Electric sweep alignment equipment may obtain the required amplitude-modulated carrier frequencies by a simple manipulation of the equipment controls as noted below.

Those technicians who do not have either of the above equipment available are advised to omit the trap alignment procedure. With the exception of the video amplifier 4.5 mc trap L160, the traps will not become seriously misaligned due to tube changes. The above-mentioned 4.5 mc trap may be sweep-aligned, if desired, in which case a 4.5 mc sweep signal should be used in step 3, of trap alignment chart. The trap may then be tuned to minimum response at 4.5 mc which should be crystal marker calibrated.

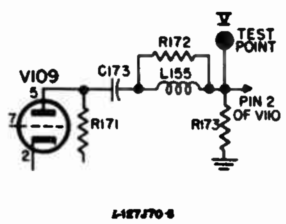
OBTAINING AM OUTPUT FROM G-E SWEEP EQUIPMENT

The General Electric ST-4A Sweep Generator will provide 60-cycle square-wave amplitude-modulated signal. To obtain this signal proceed as follows:

1. Turn the sweep generator sweep width control fully counter-clockwise. This will provide a steady (zero sweep) carrier.
2. Turn the sweep generator blanking switch "on." This will square-wave-modulate the carrier at a 60-cycle rate.
3. The next step is to calibrate the frequency of this AM carrier.
   a. Turn the marker generator "on" and set the dial to the desired frequency (4.5 mc, 38.0 mc, 41.25 mc or 47.25 mc).
   b. Slowly tune the sweep generator through the desired frequency. As the desired frequency is approached, a strong beat signal will be observed on the oscilloscope. At *exact* resonance, a zero beat condition will be noticed, on each side of which will appear a beat pattern. Minor sweep generator back-and-forth frequency drift may be noted. However, this drift is insignificant and may be disregarded.
   c. Turn off the marker output.
4. Apply this AM signal according to the instructions in the chart on page 19.
5. The signal observed on the oscilloscope appears as two parallel lines. When the traps are properly tuned the distance between these lines will be at a minimum. NOTE: It may be necessary to use full output of the sweep generator and near maximum oscilloscope gain to observe proper trap tuning.

ALIGNMENT NOTES:

1. Remove V121 plate cap. Temporarily connect a 2500-ohm, 25-watt resistor from B+ 260 V to Chassis.
2. Remove tube V115 from its socket.
3. Turn the Volume control to minimum and the Picture Contrast control to maximum. Turn the Brightness control fully counterclockwise.
4. Set Channel Selector to Channel 11 position. Set the fine tuning control to its maximum counterclockwise position.
5. Connect oscilloscope to test point V (picture tube grid).
6. Allow receiver and test equipment to warm up for 15 minutes. Refer to Fig. 22 for alignment adjustments location.



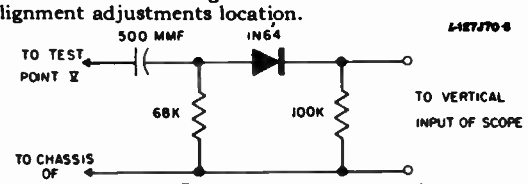


Fig. 23. Detector Network

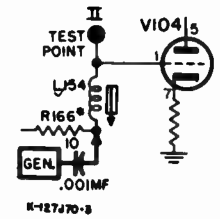
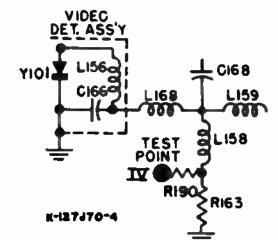
TRAP ALIGNMENT CHART

STEP	AM—GENERATOR INPUT POINT	AM—GENERATOR FREQUENCY	ADJUST FOR MINIMUM OUTPUT	REMARKS
1	Through .001 mf capacitor to junction of R178 and L154; connect generator cable shield to receiver chassis (see figure below)	41.25 mc	L151	May require maximum oscilloscope vertical gain.
		47.25 mc	L153	
		38.0 mc	L152	
2	Test Point IV (Diode Load) (see figure below)	4.5 mc	L160	Connect detector network between oscilloscope input and receiver test point V as shown in Fig. 23. Remove V107 during this step.



* R178 (Mid and Late Prod.)



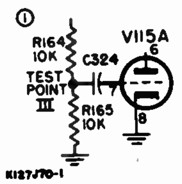
I-F SYSTEM SWEEP ALIGNMENT

GENERAL:—

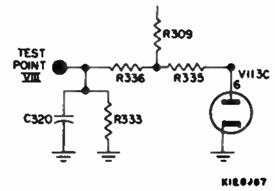
Now that the traps have been set at their proper frequencies the i-f curve may be shaped.

NOTES:—

1. Turn Picture Contrast control to minimum.
2. Connect oscilloscope to test point III (junction of R164 and R165).
3. Apply a negative 4½-volt battery bias voltage to test point



VIII. Connect positive lead of battery to chassis.



4. Calibrate the vertical gain of the oscilloscope to provide a 2-inch deflection with applied signal, 1¾ volts peak-to-peak.
5. Note that the following procedure uses 45.0 mc as the 100% reference point. Maintain the sweep generator output so that the baseline-to-45.0 mc marker amplitude equals 2 inches. Align as indicated in the alignment chart below.

I-F ALIGNMENT CHART

STEP	CONNECT SWEEP GENERATOR	ADJUST	DESIRED RESPONSE	REMARKS
1	Into Test Point II and chassis through .001 mf capacitor. Center sweep frequency approx. 44.0 mc. Sweep width approx. 10 mc.	T151 for proper 42.0 mc response. T153 for proper 45.75 mc response. T152 & L167 for zero "tilt" and maximum gain without "saddle-back."		Make indicated adjustments to obtain maximum gain consistent with proper curve. Corners of curve peak must show slight rounding. Peak of curve may extend 10% (max.) beyond 45.0 mc marker.
2	Into Test Point I and chassis through .001 mf capacitor. Center sweep frequency approx. 44.0 mc. Sweep width approx. 10 mc.	L154 and T105 (R-F Tuner) for maximum gain and proper marker position.		Obtain maximum gain and proper marker positions. Peak of curve should extend 15% beyond 45.0 mc marker, with slight rounding.
3	Into R-F Tuner input through balanced adapter and 300-ohm pad and line. Sweep Channels 2–13. Sweep width approx. 10 mc.	C108 (R-F Tuner)	Align for zero "tilt" on ch. 10. Check chs. 7–13 and make further compromise adjustment so that each channel will have no more than ±20% "tilt" with the Fine Tuning adjusted to provide the proper sound and picture i-f markers.	
4		L124 & L127 (R-F Tuner)	Align for zero "tilt" on Channels 3 and 5. Check chs. 2–6 and make further compromise adjustment, so that each channel will have no more than ±20% "tilt" with the Fine Tuning adjusted to provide the proper sound and picture i-f markers.	

TROUBLE SHOOTING

In many cases a circuit difficulty may be localized by observing the picture or test pattern and by noting the presence or absence of sound. In general, the tubes in defective circuits should be checked first since this check does not take much time and the probability of failure is higher in tubes than in components. When substituting tubes in r-f or video i-f circuits, the original tube should be replaced in the socket if it is found to be satisfactory.

Always make sure that all tubes are making good socket contact. In some cases it may be necessary to clean the tube pins to eliminate intermittances.

To facilitate trouble shooting, the waveforms of Fig. 31 should be consulted. Alignment equipment may be used to isolate defective r-f or video i-f stages by checking for the response curves given in the alignment procedure.

General Service Information

1. CRITICAL LEAD DRESS

To prevent the effects of undesired 4.5 mc harmonic radiation, it is essential that all audio and video i-f components be replaced in exactly the same position they occupied when they were wired in at the factory. All r-f, video and sync carrying leads should be made as short as possible. Check lead dress of picture tube anode lead to prevent high-voltage arc-over.

2. NOISE INVERTER CHECK

A simple oscillographic check may be performed which will display the operation of the noise inverter. The procedure is based upon noise pulse inversion in the absence of signal.

1. Turn on receiver. Set channel selector switch to an unoccupied channel.
2. Connect oscilloscope to Junction of C303 and C304.
3. Bias off the noise inverter (V115B) by connecting a 100,000-ohm resistor between its pin No. 3 and +250 volts.
4. Supply a moderate-amplitude noise signal to the antenna input terminals. A suitable noise source would be an electric shaver or similar "spark" type noise generator.
5. Observe positive polarity of noise pulses on oscilloscope. Removal of the temporarily added 100,000-ohm resistor should cause the noise signal to reverse itself and hence become negative in polarity.

3. KEYER TUBE CHECK

The proper operation of the AGC Keyer tube V108B may be checked by shorting pins 2 and 7 and observing the AGC voltage. This voltage should reach a value of approximately 40 volts as measured at the AGC terminal of the r-f tuner (see Fig. 19).

SYMPTOM	CHECK FOR
DEFECTS OF THE R-F AND I-F CIRCUITS	
A. No sound, no picture	1. Inoperative local oscillator, V103A 2. Open video i-f coupling capacitor, C167 3. Improper or no screen or plate voltage at r-f or i-f tubes due to shorted screen by-pass capacitor or open resistor 4. Open video detector crystal, Y151
B. No picture, sound possibly weak, raster satisfactory	1. Shorted capacitor, C168 2. Open coupling capacitor, C167 3. Defective crystal diode, Y151
C. Noisy picture (Low signal strength)	1. Open input circuit and components of antenna input circuit, such as open capacitors, C183, C184, or open transformer, T100 2. Defective antenna, or antenna transmission line 3. Antenna orientation 4. Open filament, V101
D. Wiggles in picture background, trailing whites, sound normal	1. Alignment of i-f amplifier and associated traps 2. Low value resistor, R163
E. "Motorboat" or flutter in picture and/or audio	1. Open by-pass C319 2. Open AGC filter capacitor C320 3. Alignment of r-f and video i-f amplifiers
F. Lack of picture detail (Focus satisfactory)	1. Misalignment of video i-f amplifier 2. Misalignment of r-f amplifier 3. Mismatch of input impedances at antenna input terminals of receiver 4. Overloading of r-f stages
G. Sound bars in picture	1. Microphonic tubes: V101, V102, V103, V104, V105, V106, V107, V108, V109 and V110 2. Misalignment of adjacent channel sound trap L153 or misalignment of accompanying sound trap L151
DEFECTS OF THE VIDEO AMPLIFIER	
A. No picture, sound satisfactory	1. Open compensating choke L162 2. Shorted capacitor, C403C in cathode circuit V108B 3. Open coupling capacitor, C181 to tube V109 4. Open plate resistors at tube V108A or V109. Check plate voltages 5. Short of grid to cathode in picture tube
B. Lack of picture detail (focus satisfactory)	1. Shorted peaking coils 2. Open peaking coils (only those coils shunted by resistors) 3. Increase in value of diode load and video amplifier plate resistors
C. Trailing Whites	1. Decrease in value of diode load and/or video amplifier plate resistors

SYMPTOM	CHECK FOR
DEFECTS OF THE SYNC SECTION	
A. Weak or no horizontal sync; vertical sync, picture and sound satisfactory	1. Sync amplitude at input to discriminator tube, V119A 2. Bias and plate voltage on control tube, V119B 3. Sine-wave oscillator components, L351, C361, C357, R358 and R359 4. Leaky or shorted capacitors, C354 and C355 5. Waveform feedback components, C364, R365, R366 and C365
B. Weak or no composite sync, otherwise picture and sound normal	1. Defective coupling capacitor C303 or C304 to clipper tube 2. Incorrect value of plate resistor, R312 of clipper tube, V116A 3. Insufficient amplitude of composite signal applied to sync amplifier from video detector; check video detector circuit
C. No vertical sync, horizontal sync satisfactory	1. Sync pulse at input of vert. oscillator, check integrator plate P301 2. Vert. oscillator frequency, if far off from 60 cps, check vert. oscillator components such as C311 and R317 3. Leakage in feedback capacitor, C315
D. Picture displaced to left, right edge wavy	1. Open or low value of capacitor, C304
E. Horizontal sync out, bright bar or bars in picture	1. Shorted, open or leaky capacitor, C360 2. Improper value resistor, R361
F. "Gear Tooth" effect	1. Open or low value capacity of C356 2. Open or high resistance of R357
G. Noise "tearing" picture (noise inverter failure)	1. Low value, R340 2. Open C302 3. Open or high value, R305
H. Poor composite sync (attributable to noise inverter failure)	1. Open or high value of R340 2. Low value R305 3. Leaky or shorted C302
DEFECTS OF THE VERTICAL DEFLECTION CIRCUIT	
A. Poor vertical linearity, inadequate height	1. Low emission of sweep output tube, V118 2. Improper grid input "drive" voltage at V118 3. Defective sweep output transformer T301 4. Low B+ voltage to sweep output tube V118 5. Low value of cathode capacitor, C402C
B. Inadequate picture height	1. Rise in resistance value of vert. oscillator plate resistor, R319 or R374 2. Leakage in capacitor C312 3. Incorrect value of plate, or grid voltages on putout tube, V118 4. Low value capacitor in cathode of vert. output tube, C402C (This usually results in poor linearity) 5. Weak vertical deflection tube, V117 or V118
C. No vertical deflection	1. Open vertical deflection coils, D301 2. Defective sweep output transformer, T301 3. Shorted capacitor C312, C314 4. Poor contacts in yoke plug
D. Poor vertical linearity, height satisfactory	1. Defective linearity control components such as cathode capacitor, C402C, or improper value of R323 2. Open capacitor, C314 3. Leaky capacitor, C316 4. Vertical output tube, V118
E. Excessive height	1. Too low value of resistor R319 or R374 or defective height control, R320
F. Poor vertical linearity, fold-over at bottom of picture, picture height excessive	1. Low resistance leakage of capacitor, C313, C316
G. Vertical keystoning	1. External short across vertical deflection coils 2. Defective vertical deflection coil, D301
DEFECTS OF THE HORIZONTAL DEFLECTION CIRCUITS	
A. Too great sweep width, reception normal otherwise	1. Open width control coil 2. Open winding between width coil taps on horizontal output transformer
B. Inadequate sweep width	1. Correct waveshape and amplitude of input "drive" voltage at grid of V121 2. Shorted width control or defective deflection coil, D351 3. Defective horizontal output transformer shorted turns or arc-over 4. Low emission of tube, V121, V123 5. Low B+ voltage to tubes V120A, V120B, V121
C. Single vertical line in center, sound normal	1. Open horizontal deflection coils, D351 2. Open yoke plug connection

TROUBLE SHOOTING

DEFECTS OF THE HORIZONTAL DEFLECTION CIRCUITS (Cont'd)

SYMPTOM	CHECK FOR
D. Poor horizontal linearity	1. Shorted linearity control 2. Defective yoke, D351 3. Defective capacitors, C376, C367 or C382
E. Poor horizontal linearity, bright vertical bars, inadequate width	1. Open or low value of capacitor, C367 or C382 2. Defective damper tube, V123
F. Black "beady" vertical line or lines, receiver normal otherwise	1. Defective output tube, V121 2. Defective horizontal sweep output transformer 3. Defective deflection yoke, D351
G. No raster—sound satisfactory	1. Defective sweep output tube, V121 or damper tube, V123 2. Defective tubes, V120B, V120A 3. Shorted capacitor C367 or C382 4. No screen voltage on V121 5. Adequate drive at grid of V121 6. Open linearity control 7. Defective horizontal sweep output transformer 8. Open fuse, F402

DEFECTS OF THE POWER SUPPLY

SYMPTOM	CHECK FOR
A. No raster, no sound	1. Power supply interlocks and/or fuses open 2. Power cord plug and cable 3. Rectifier components 4. Open filter choke 5. Defective power transformer 6. Yoke plug not connected
B. Picture size small, brilliance low, sound normal	1. Open or low value of input filter capacitor, C402 of power supply 2. Defective rectifier, V124 or V125
C. Picture blooms	1. Defective H.V. rectifier, V122 2. Defective picture tube
D. Hum bar in picture, waviness in edges of raster ("Mae West" movement)	1. Open or low value of filter capacitor, C401B
E. Low picture brilliance, sound satisfactory	1. Low voltage at H.V. anode of picture tube, caused by defective rectifier V122 2. Improper adjustment of ion trap 3. Defective brightness control circuit 4. Low voltage at 1st anode of picture tube (pin 10) 5. Defective picture tube

MISCELLANEOUS DEFECTS

SYMPTOM	CHECK FOR
A. No raster—sound satisfactory	1. Open or shorted picture tube heater 2. No voltage at 1st anode of picture tube (pin 10) 3. Excessively high bias voltage at cathode of picture tube 4. Defective picture tube, check by substitution
B. Receiver overloads on moderate to strong signals	1. Shorted C305 2. V108B inoperative
C. Brightness control partially or completely inoperative	1. Defective brightness control, R176 or circuit components 2. Defective (short or leaky) capacitor, C173 3. Defective capacitor C174
D. Picture pulled out of shape on one side or corner	1. Proper orientation of the Picture Straighteners
E. Poor focus	1. Proper focus unit adjustment and position 2. Defective picture tube
F. Vertical retrace lines visible	1. Open input capacitor to blanking circuit, C317 2. Check for shorted capacitor in blanking circuit, C318 3. Open coupling capacitor C174 to picture tube cathode
G. Horizontal blanking inoperative	1. Defective horizontal blanking tube, V116B 2. Open capacitor, C368 or C369 3. Shorted capacitor, C371

PRODUCTION CHANGES

1. VIDEO I-F AMPLIFIER

During early production capacitor C151 in 38.0 mc trap circuit was changed from 75 to 8 mmf, capacitor C161 in 47.25 mc trap circuit was changed from 8 to 22 mmf. Together with this change capacitor R182, 47 mmf and R166, 10 ohms at the bottom end of the i-f grid coil, L154, were removed and the coil directly connected to the coaxial link from the r-f tuner.

In receivers bearing these changes, capacitor C141, 39 mmf, at the output of the r-f tuner is omitted. For early production receivers use replacement r-f tuner RJX-056.

2. R-F TUNERS

During the 1st production of these receivers two different types of the "EE" version tuner were used. Both types incorporate a 6AB4 tube as 1st r-f amplifier. The early version incorporates the capacitor C141, see Fig. 27A; this type is used together with the early type traps L152 and L153 using R166 and C182 in the video input i-f circuit, see Fig. 35. Receivers using the later type traps without R166 and C181 in the input circuit use a "EE" tuner without the capacitor C141.

During the 2nd and 3rd production the "BK" version tuner was incorporated in the receiver, using a 6BK7 tube as 1st r-f amplifier. Receivers with this tuner are stamped with the number "453" or higher. The tuner is easily identifiable by the tunable cathode choke coil, L100, mounted at the input transformer T100, see Fig. 18.

Early type tuners incorporate capacitor C141, so that they may be used with the early type traps L152 and L153. This capacitor is connected between the coaxial link and ground.

3. HORIZONTAL SWEEP OUTPUT CIRCUIT

The linearity of the horizontal sweep was improved by incorporating a new circuit which used the following new items:

RLD-056 Horizontal Linearity Coil
RLD-058 Horizontal Width Coil
RTO-146 Horizontal Output Transformer

These items should not be used as replacement in earlier production chassis.

Chassis incorporating this production change bear a rubber stamp "548" and in most cases also bear a label on the high-voltage cage which calls attention to the above listed electrical items.

4. REDUCTION OF I-F INTERFERENCE

To assist in the reduction of i-f interference chassis bottom plate, RHS-119 and adjacent channel trap shield can, RHS-112 was added during the production run.

5. VIDEO AMPLIFIER

The video output tube 6AQ5 was changed to 6CL6 and the circuitry has been slightly modified as illustrated in Fig. 35. Receivers incorporating this circuit may be identified by noting the 6CL6 tube type on the tube layout label affixed to the cabinet back.

6. BRIGHTNESS CONTROL CIRCUIT

To provide greater consistancy of raster size with respect to changes in the brightness level a new brightness control circuit was used in late production receivers. Refer to Fig. 33 for complete diagram of this circuit. The new brightness control Cat. No. is RRC-245.

ULTRA HIGH FREQUENCY TUNERS

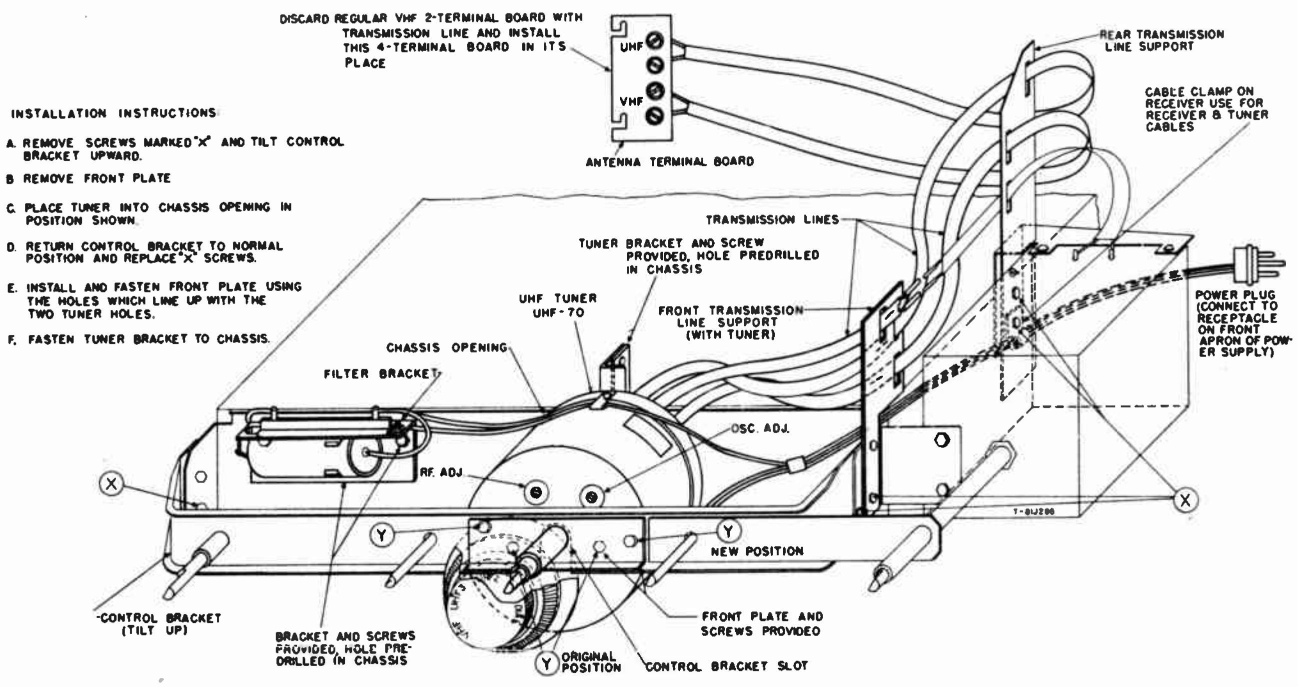

Fig. 37. UHF-70 Tuner Assembly & Wiring Diagram

Two types of UHF tuners were used in these receivers; one type, the Model UHF-70 has two fixed UHF- positions and one position for continuous tuning. Refer to Fig. 37 for tuner assembly and lead connections. The other type, Model UHF-90 is a continuous tuner mostly used in late production receivers. Refer to Fig. 45 for tuner assembly and lead connections. The label affixed to the back of the television receiver indicates which of the two tuners is used in a particular model.

ALIGNMENT CHART

Oscillator Alignment

STEP	RF GEN. SETTING	UHF MARKER & SWEEP	TUNE	DESIRED RESPONSE	REMARKS
1.	82 mc	460 mc	C521	82 MC & 460MC MARKERS COINCIDE	Set UHF tuner drum shaft fully counter clockwise.
2.	82 mc	910 mc	"L_e" oscillator	82MC & 910MC MARKERS COINCIDE (K-135J38)	Set UHF tuner drum fully clockwise; also see note 2.
3.			Repeat steps 1 and 2		Tune across band & check for note 3.

R. F. Alignment

STEP	RF GEN. SETTING	UHF MARKER & SWEEP	TUNE	DESIRED RESPONSE	REMARKS
1.		550 mc	C503 & C506	550MC	Tune for maximum symmetrical response
2.		850 mc	"L_e" R.F. "L_e" Mixer	850 MC	Tune for max. symmetrical response. See Note 2.
3.			Repeat steps 1 and 2		Produce as near ideal curve as possible.
4.		910 mc	L502	Check crystal current.	Connect meter between test point & chassis. See Note 4. Disconnect R-F generator during current test.

I-F Alignment

STEP	RF GEN. SETTING	UHF MARKER & SWEEP	TUNE	DESIRED RESPONSE	REMARKS
1.	82 mc	550 mc	See "Remarks"	82MC 550MC	Adjust tuner shaft so that 550 mc marker coincides with 82 mc marker.
2.	76.5 mc & 88.5 mc	550 mc	T501 T502	550MC 76.5MC 88.5MC (K-135J39)	Tune for max. response & 12 mc bandwidth between peaks.
3.		Check at 460 mc thru 910 mc	Check converter tracking from 460 mc to 910 mc.		Neither marker should fall below 30% at any point thruout tuning range. If 30% "tilt" tolerance cannot be met, recheck steps 1 & 2.

NOTES:
1. Crystal polarity is important to r-f tracking. Crystal must be inserted with cathode to front of chassis as shown in Fig. 43.
2. "L_e" is a short variable inductance between the tuned line and the tube socket and is varied by bending with a polystyrene rod through holes in bottom of converter chassis.
3. In cases where the output falls off severely, or pattern shape varies extremely, change oscillator tube and recheck steps 1 and 2.
4. As converter is tuned through complete range, crystal current should not fall below .5 ma or be greater than 4 ma.

UHF TUNER UHF-90

The Model UHF-90 Tuner unit is a continuous-tuning type UHF tuner and covers the entire band between 470 to 890 megacycles. Reception of UHF television signals with this unit is accomplished by double-conversion to either VHF Channel 5 or 6. The choice of either of these channels will depend essentially upon local VHF interference considerations.

If the UHF tuner is operating in an area with VHF stations operation on Channel 5 or 6, switch the television receiver to the channel of least interference. It is quite obvious that if the VHF station on Channel 5 is fairly strong, it will be picked up by the television receiver even when the UHF tuner is operating, and therefore affect the picture quality. The i-f circuits of the UHF tuner are designed to give good reception for both channels, so that no additional adjustments of the i-f are necessary.

VIDEO IF ALIGNMENT

Connect positive terminal of a tapped 4½ volt "C" battery to chassis, -1½ volt tap to junction of C213 and R224, and -3 volt tap to junction of C212 and R223. Set "Fringe-Local" switch to local position and Contrast control fully counter-clockwise (min. contrast).

SWEEP GEN. COUPLING	SWEEP GEN. FREQUENCY	MARKER GEN. COUPLING	MARKER GEN. FREQUENCY	CONNECT SCOPE	ADJUSTMENTS
1st IF grid (test point TP1 on main chassis)	43mc. Adjust gain so trap suckout is visible.	Converter grid. (Use test point lead wire thru top of VHF Tuner)	47.25mc modulated. Adjust gain so pip is just visible.	Across vid. det. load R211. Place 10K res. in series with probe.	Adjust trap (top of T202) to center pip in suckout. See Fig. 1. Max. attenuation is at two core positions, use one with slug furthest out.
"	43 mc. Set gen. output for approx. 2V P/P output at scope.	"	Unmodulated 42.75 mc. 45.0 mc. 45.75 mc.	"	Check for response curve similar to Fig. 2. Tune T203 for max. gain between 42.75 mc and 45.75 mc. Tune T202 (bottom slug) to place 45.75 mc marker at 60% response. Tune T201 to place 42.75 mc marker at 60% of response. Recheck 47.25 mc trap.
Converter grid (use wire test point lead fed thru top of VHF Tuner)	"	Loosely couple	Same as above	"	Set VHF Tuner to clear channel (6-13). Tune converter plate coil L3 for max. gain with 45.75 mc marker at 50% response. (See Fig. 2.) Tune 1st IF grid coil T201 for max. gain and proper tilt. Interaction might require repeating these two adjustments until Fig. 2 is duplicated.
VHF ant. terms. Use network in Fig. 4 if cable is not balanced.	Channels 2 thru 13 R.F.	"	Same as above	"	Check all channels for bandwidth, slope and position of carrier. Use oscillator trimmer to set osc. at high VHF channel for middle of fine tuner range. Refer to Magnavox Manual 5250 for complete VHF Tuner alignment.
UHF crystal term. nearest UHF osc. tube use 1K isolation resistor.	43 mc. same gain	"	Same as above	"	Set VHF Tuner to UHF position. Adjust R.F. amp. grid coil A41 for min. tilt (slug of A41 is at top rear of VHF Tuner). Response should conform to Fig. 2.

R613	Carbon, 220 ohms, ½ W.	230104-54
	Crystal	530035-1
	PARTS LIST FOR THE 700426 UHF TUNER	
	COILS - TRANSFORMERS	
L604	RF coupling	360415-44
L607	Input IF	360571-1
L608	IF coupling choke	360522-6
L609	Crystal return choke	360522-5
L611	Osc. plate choke	360522-7
L612	Osc. fil. choke	360574-8
L613	Osc. fil. choke	360574-8
L614	Osc. cathode choke	360574-8
L615	Fil. choke	360574-8
L616	Fil. choke	360574-10
L617	Output IF	360572-1
	CAPACITORS	
C601	Molded, .82 mmf.	250221-113
C602	Molded, .82 mmf.	250221-113
C603	Trimmer	250188-8
C604	Molded, 2.7 mmf.	250221-119
C605	Molded, 2.7 mmf.	250221-119
C606	Trimmer	250188-7
C607	Molded, 1.2 mmf.	250221-115
C608	Ceramic, 10 mmf.	250207-3
C609	Ceramic disc, 8 mmf.	250175-11
C610	Trimmer	250188-8
C611	Fine tuning trimmer	260120-1
C612	Trimmer	250220-2
C613	Molded, .1 mmf.	250221-101
C614	Ceramic disc, 470 mmf.	250175-8
C615	Ceramic disc, 470 mmf.	250175-8
C616	Ceramic disc, 470 mmf.	250175-8
C617	Ceramic disc, 470 mmf.	250175-8
C618	Ceramic disc, 470 mmf.	250175-8
C619	Ceramic, 470 mmf.	250207-50
C620	Ceramic disc, 470 mmf.	250175-8
C621	Ceramic, 56 mmf.	250207-81
C622	Ceramic disc, 470 mmf.	250175-8
C623	Ceramic disc, 470 mmf.	250175-8
C624	Molded, .68 mmf.	250221-112
C625	Molded, 6.8 mmf.	250221-125
C626	Ceramic disc, 470 mmf.	250175-8
	RESISTORS	
R601	100,000 ohms, ½ W.	230104-86
R602	100,000 ohms, ½ W.	230104-86
R603	22,000 ohms, ½ W.	230104-78
R604	1200 ohms, 1 W.	230105-63
R605	100,000 ohms, ½ W.	230104-86
R606	100,000 ohms, ½ W.	230104-86
R607	100 ohms, ½ W.	230104-50
R608	470,000 ohms, ½ W.	230104-94
R609	470,000 ohms, ½ W.	230104-94
R610	1000 ohms, ½ W.	230104-62
R611	100 ohms, ½ W.	230104-50
R612	10,000 ohms, 1 W.	230105-74
R613	10,000 ohms, 1 W.	230105-74
R614	10,000 ohms, 1 W.	230105-74
R615	220 ohms, ½ W.	230104-54
R616	150,000 ohms, ½ W.	230104-88
	CRYSTAL	
X601	1N124	530036-1
	TRANSFORMERS	
T101	Ratio Detector	360482-1
T201	IF Input and Trap	360545-1
T202	1st IF and Trap	360546-1
T203	2nd IF and Trap	360546-1
T204	3rd IF and Trap	360546-1
T205	4th IF and Video Detector	360549-1
T301	Vertical Output (106 & 400 Series)	330034-1
	Vertical Output (358AA, BA only)	330035-1
	Vertical Output (All Other 107 & 500 Series)	330035-2
T401	H.V. Transformer (106 Series)	360561-1
	H.V. Transformer (400 Series)	360594-1
	H.V. Transformer (107 & 500 Series)	360593-2
T402	AFC Sawtooth	360590-1
T501	Power, (106 & 400 Series, Audio Version)	300067-4
	Power, (106 & 400 Series, No Audio Version)	300069-2
	Power, (107 & 500 Series)	300068-4
	COILS	
L101	4.5 MC Sound Takeoff	360535-1
L102	4.5 MC Sound IF	360481-1
L201	Peaking, Orange, Orange, Green	360443-23
L202	Peaking, Yellow, Yellow, Yellow	360443-24
L203	Peaking, Gray, Gray	360443-19
L204	Peaking, Orange, Orange, Red, 1000 ohm (400 Series)	360443-33
	Peaking, Green, Green, Green, (All Others)	360443-25
L205	Peaking, Blue, Blue, Blue	360443-26
L206	Trap Coil Assembly	360554-1
L207	4.5 MC Trap	360481-2
L301	Choke, .47 uh	360372-1
L401	Horizontal Oscillator (106 & 107 Series)	360499-4
	Horizontal Oscillator (400 Series)	360579-1
	Horizontal Oscillator (500 Series)	360591-1
L402	Keyer and Horizontal Width	360570-1
L403	Horizontal Linearity	360533-1
L404	Deflection Yoke (106 Series)	360566-2
	Deflection Yoke (400 Series)	360566-3
	Deflection Yoke (107 Series)	360556-5
	Deflection Yoke (500 Series)	360556-4
L501	Filter Reactor (106 & 400 Series)	320065-1
	Filter Reactor (107 & 500 Series)	320064-1
	CAPACITORS	
C101	Ceramic, 10 mmf. 500 V.	250207-3
C102	Ceramic, 10,000 mmf. 500 V.	250175-2
C103	Ceramic, 5000 mmf, 500 V.	250175-1
C104	Ceramic, 5000 mmf, 500 V.	250175-1
C105	Ceramic, 5000 mmf, 500 V.	250175-1
C106	Ceramic, 5000 mmf, 500 V.	250175-1
C107	Mica, 68 mmf, 500 V.	250159-80
C108	Mica, 56 mmf, 500 V.	250159-79
C109	Ceramic, 5000 mmf, 500 V.	250175-1
C110	Ceramic, 5000 mmf, 500 V.	250175-1
C111	Electrolytic, 10 mfd, 350 V.	270027-4
C112	Mica, 470 mmf. 500 V.	250159-90
C113	Ceramic, 1000 mmf, 350 V.	250088-46
C114	Paper, .0033 mfd, 600 V.	250201-4
C115	Paper, .0033 mfd, 600 V. (106 & 400 Series)	250201-4
C115	Paper, .01 mfd, 600 V. (107 & 500 Series)	250201-7
C117	Mica, 680 mmf, 500 V. (106 & 400 Series)	250160-62
	Mica, 470 mmf, 500 V. (107 & 500 Series)	250159-90
C118	Paper, .047 mfd, 600 V.	250201-11
C119	Paper, .047 mfd, 600 V.	250201-11
C120	Paper, .0015 mfd, 600 V.	250201-2
C121	Paper, .0015 mfd, 600 V.	250201-2
C122	Ceramic, 150 mmf, 500 V.	250207-17
C201	Ceramic, 470 mmf, 450 V.	250175-9
C202	Ceramic, 470 mmf, 450 V.	250175-9
C203	Ceramic, 470 mmf, 450 V.	250175-9
C204	Ceramic, 470 mmf, 450 V.	250175-9
C205	Ceramic, 470 mmf, 450 V.	250175-9
C206	Ceramic, 470 mmf. 450 V.	250175-9
C207	Ceramic, 470 mmf. 450 V.	250175-9
C208	Ceramic, 470 mmf, 450 V.	250175-9
C209	Ceramic. 470 mmf, 450 V.	250175-9
C210	Ceramic, 470 mmf, 450 V.	250175-9
C211	Ceramic, 470 mmf, 450 V.	250175-9
C212	Ceramic, 680 mmf, 450 V.	250218-4
C213	Ceramic, 470 mmf, 450 V.	250175-9
C214	Ceramic, 680 mmf, 450 V.	250218-4
C215	Ceramic, 100 mmf, 500 V. (106 & 107 Series)	250207-46
	Electrolytic, 5 mfd, 350 V. (400 & 500 Series)	270027-24
C216	Paper, .1 mfd, 400 V.	250211-13
C217	Ceramic, 20,000 mmf, 450 V.	250175-7
C218	Mica, 150 mmf. 500 V.	250159-2051
C219	Paper, .0033 mfd, 600 V.	250201-4
C220	Paper, .01 mfd, 600 V.	250201-7
C222	Paper, .22 mfd, 200 V.	250202-15
C223	Paper, .01 mfd, 600 V.	250201-7
C224	Paper, .1 mfd, 200 V.	250202-13
C225	Paper, .047 mfd, 200 V.	250202-11
C226	Paper, .01 mfd, 600 V.	250201-7
C227	Paper, .22 mfd, 200 V.	250202-15
C228	Ceramic, 1 mmf, 500 V.	250209-114
C229	Ceramic, 680 mmf, 450 V.	250218-4
C302	Paper, .22 mfd. 200 V.	250202-15
C303	Ceramic, 1500 mmf, 500 V.	250175-3
C304	Mica, 240 mmf, 500 V.	250159-56
C305	Ceramic. 10,000 mmf, 500 V.	250175-2
C306	Paper, .0047 mfd, 600 V.	250201-5
C307	Paper. .0047 mfd, 600 V.	250201-5
C308	Mica, 2700 mmf, 500 V.	250160-48
C309	Paper. .047 mfd. 600 V.	250201-11
C310	Paper, .1 mfd, 600 V. (106A Series only)	250201-13
	Paper, .22 mfd. 600 V. (All Other 106 Series)	250211-15
C311	Electrolytic. 10-30-5/350 V, 200/25 V.	270021-46
C312	Paper, .047 mfd, 600 V.	250201-11
C401	Paper, .001 mfd, 400 V. (500 Series)	250211-1
	Paper, .047 mfd. 600 V. (All Others)	250201-11
C402	Mica. 47 mmf, 500 V. (106 & 107 Series)	250159-78
	Paper, .001 mfd. 400 V. (400 & 500 Series)	250211-1
C403	Paper. .0047 mfd, 400 V. (500 Series)	250211-5
	Paper, .47 mfd, 200 V. (All Others)	250202-17
C404	Paper, .022 mfd, 200 V. (106 & 107 Series)	250202-9
	Paper. .0047 mfd. 400 V. (400 & 500 Series)	250211-5
C405	Paper. .047 mfd, 200 V.	250202-11
C406	Mica, 82 mmf, 500 V. (106 & 107 Series)	250159-81
	Mica, 390 mmf. 500 V. (400 & 500 Series)	250159-5061
C407	Silver Mica, 3900 mmf. 500 V. (400 & 500 Series)	250161-5041
	Mica, 68 mmf, 500 V. (106 & 107 Series)	250159-80
C408	Mica. 180 mmf, 500 V. (106 & 107 Series)	250159-53
	Mica, 510 mmf. 500 V. (400 & 500 Series)	250159-64
C409	Mica. 10,000 mmf, 300 V. (106 & 107 Series)	250161-47
	Mica, 330 mmf, 500 V. (400 & 500 Series)	250159-5059
C410	Mica, 560 mmf, 500 V. (106 Series)	250160-61
	Mica, 470 mmf, 500 V. (107 Series)	250159-90
	Paper, .0047 mfd, 400 V. (400 Series)	250211-5
	Paper, .001 mfd, 400 V. (500 Series)	250211-1
C411	Electrolytic, 10 mfd, 350 V. (500 Series)	270027-23
	Variable, Mica Dialectric (All Others)	260116-1
C412	Mica, 680 mmf, 500 V. (107 Series)	250159-131
	Mica, 680 mmf, 500 V. (106 & 400 Series)	250160-62
C413	Electrolytic, 10 mfd, 500 V. (106 & 400 Series)	270027-19
	Electrolytic, 20 mfd, 350 V. (107 Series)	270027-20
C414	Electrolytic, 20 mfd, 350 V.	270027-20
C415	Paper, .047 mfd, 600 V.	250201-11
C417	Paper, .0022 mfd, 600 V.	250201-3
C419	Paper, .033 mfd, 600 V. (106 & 400 Series)	250201-10
	Paper, .047 mfd, 600 V. (107 & 500 Series)	250201-11
C420	Paper, .033 mfd, 600 V. (107 Series)	250201-10
	Paper, .047 mfd, 600 V. (All Others)	250201-11
C421	High Voltage (106 & 400 Series)	250189-1
	High Voltage (107 & 500 Series)	250189-2
C501	Electrolytic, 40-30-30-30/350 V.	270021-43
C502	Electrolytic, 40-5/350 V, 30/25 V. (106 & 107 Series)	270021-49
	Electrolytic, 40-20-5/350 V, 30/25 V. (400 & 500 Series)	270021-53
C503	Ceramic, .01 mfd, 1000 V.	250219-2
C504	Electrolytic, 30 mfd/350 V. (106 Series)	270021-50
	Electrolytic, 30-20/350 V. (400 Series)	270021-54
C505	Ceramic, 2 x .01 mfd, 1000 V.	250219-3
	RESISTORS	
R101	470,000 ohms, ½ W.	230104-94
R102	82 ohm, ½ W.	230104-49
R103	100 ohm, ½ W.	230104-50
R104	39,000 ohm, ½ W.	230104-81
R105	470 ohm, ½ W.	230104-50

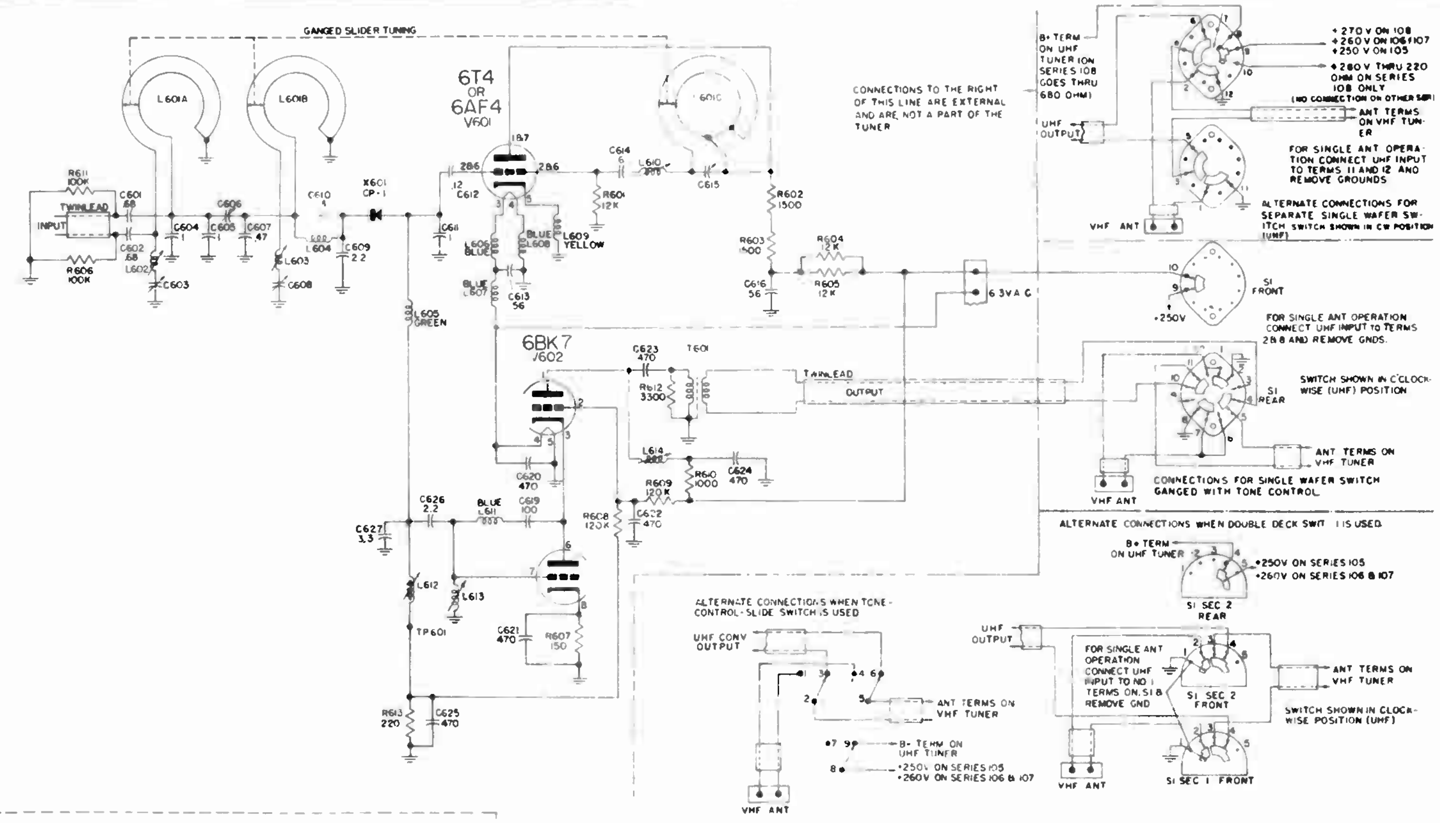

FIGURE 8

SCHEMATIC DIAGRAM, 700359 UHF CONVERTER

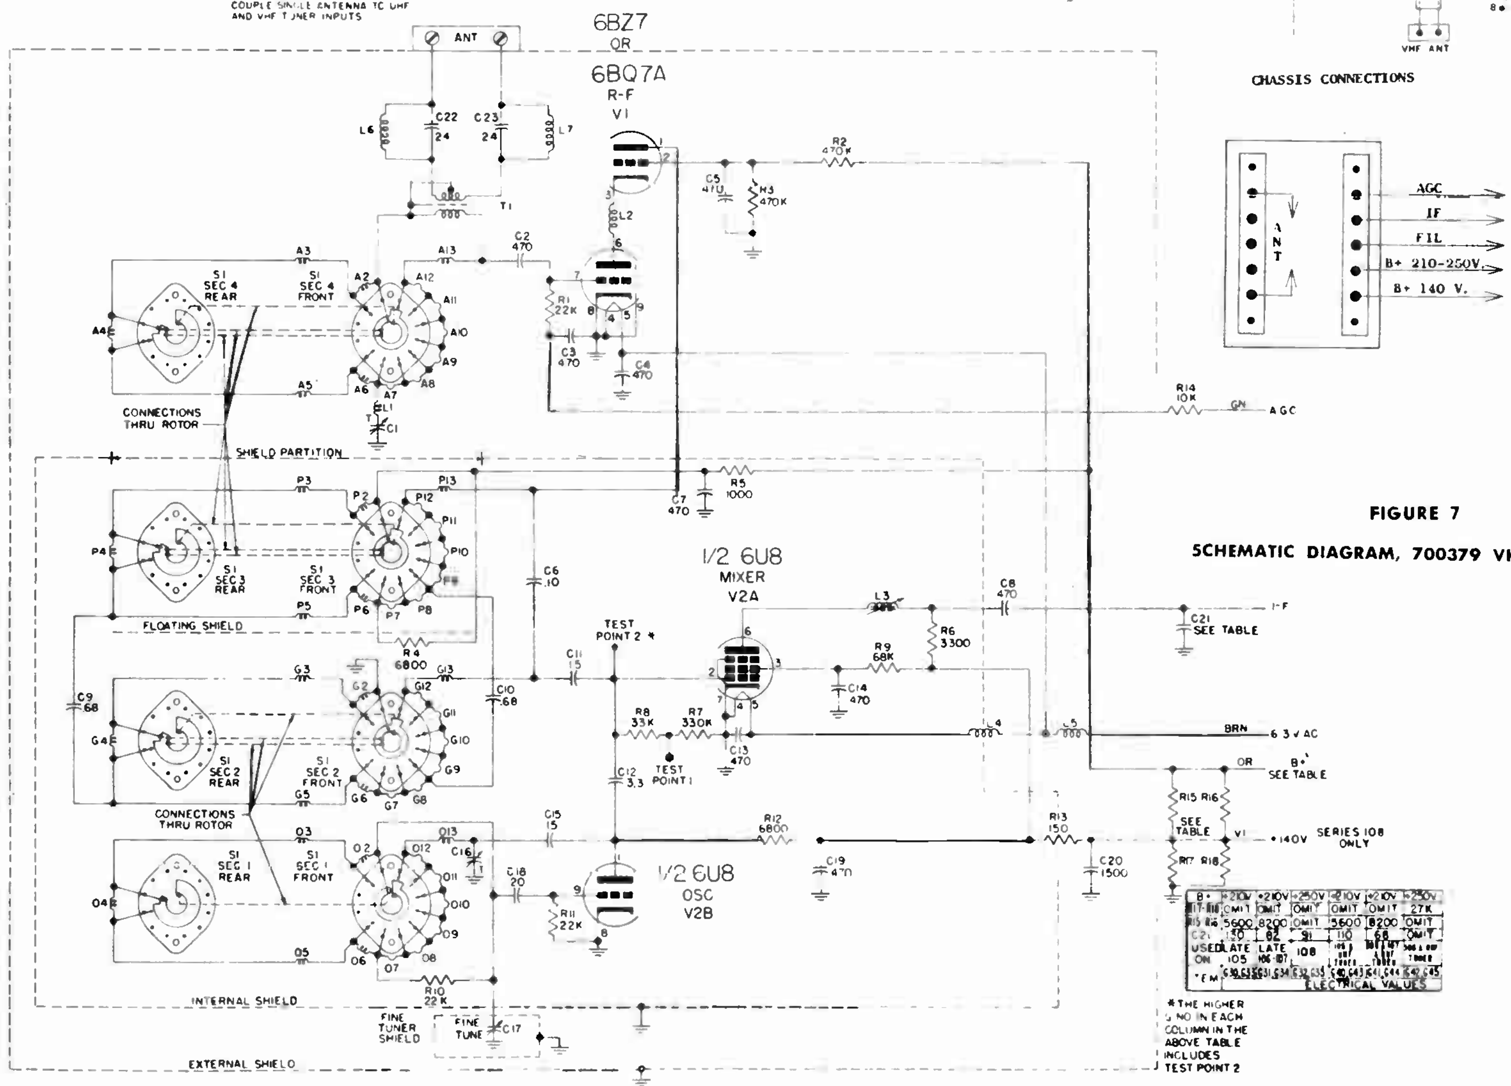

FIGURE 7

SCHEMATIC DIAGRAM, 700379 VHF TUNER

markers on the scope, determine which rotation of the vernier causes the markers to move closer together. If it is clockwise, reset the vernier to the midrange position and close the channel 13 oscillator coil. If it is counter-clockwise open the coil. Adjust for a zero beat. The channel 13 coil moves all high band channels. The channel 6 coil moves all low band channels.

Tune the sweep generator to channel 12. The signal generator to the channel 12 video carrier frequency. Set channel selector to 12. Adjust the channel 12 oscillator coil for a zero beat of the markers.

Repeat the procedure for channels 11 through 2. Recheck channels 13 through 7. The high channel coils are adjusted by moving them up or down and the low channel coils by spreading or pushing together.

ANTENNA, R-F AMPLIFIER AND CONVERTER ALIGNMENT

The desired pattern to be applied to the IF amplifiers is the result of three variables. These three variables are the ANTENNA COIL (rear wafer), the RF COIL (second wafer from rear) and the CONVERTER COIL (third wafer from rear).

These coils must be very carefully adjusted with only a slight movement. It is imperative that the following sequence of adjustment is followed to obtain the desired pattern. Antenna coils first, RF coils second, and the converter coil last. The RF wafer has B+ on it and should not be touched with the hand or a metal tool. The oscillator coils (fourth wafer from rear) are properly adjusted and should not be touched.

The RF tuner has been properly aligned at the factory and should not require any additional adjustment except when tubes are replaced in the tuner. Proper selection of the replacement tube will eliminate the necessity of making these coil adjustments. Try several tubes while observing their effects on the pattern. It is important that the tuner cover be in place when observing the pattern.

UHF TUNER

OSCILLATOR ALIGNMENT

Turn on the receiver and turn UHF-VHF switch to UHF. Connect oscilloscope to TP601, 300 ohm sweep cable to UHF antenna terminals and loosely couple signal generator to the preselector as in R. F. alignment.

Set the sweep generator center frequency to 553 mc. Turn channel selector to channel 20. Set marker signal to 565 mc, turn fine tuner fully clockwise and adjust C612 to place oscillator marker at 565 mc. Set marker signal to 541 mc., turn fine tuner fully counter-clockwise and bend the fine tuner stop to place oscillator marker at 541 mc.

Set the sweep generator to 895 mc., turn channel selector to channel 77 and fine tuner fully clockwise. Set marker signal to 907 mc., and adjust L610 inductance lead on oscillator grid by bending lead to center the oscillator marker at 907 mc. Set marker signal to 883 mc., turn fine tuner fully counter-clockwise and carefully adjust L605, inductance lead on the glass fine tuner, to center the marker at 883 mc.

Because of interaction between high end and low end oscillator adjustments, recheck the low frequency setting.

Set the channel selector to channel 50 and sweep generator frequency to 733 mc. Set marker signal to 743 mc. and turn fine tuner fully clockwise. Oscillator marker must be at 743 mc. or above. Set marker signal to 723 mc. then turn fine tuner fully counter-clockwise. Oscillator marker must be at 723 mc. or below.

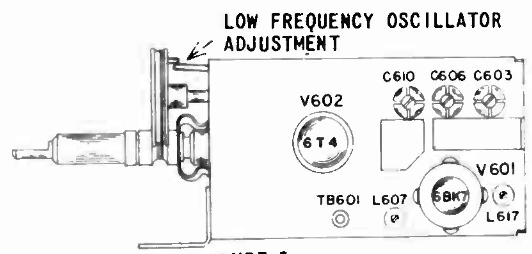

FIGURE 5
TOP VIEW OF TUNER

UHF CONVERTER

OSCILLATOR ALIGNMENT

A. Remove the shield and 6BK7 tube from its socket.

B. Connect the UHF marker generator, through a .5 mmf. capacitor, to the junction of X601, L605, C611 and C612.

C. Connect the oscilloscope to test point 602, through a 10,000 ohm isolating resistor.

D. Tune the converter to its lowest frequency (extreme counter-clockwise) position.

E. Set the marker generator frequency on 378 mc. and adjust the oscillator trimmer C615 for a beat on the scope.

F. Tune the converter to its highest frequency (extreme clockwise) position.

G. Set the marker generator frequency to 828 mc. and adjust the end inductor L610 for a beat on the scope.

H. Recheck both high and low frequency positions so the beats appear without further adjustment.

SERVICE INFORMATION

HIGH VOLTAGE WARNING

The danger accompanying shocks is always present when the receiver is operated outside the cabinet or when the rear cover is removed from the cabinet. Only a person familiar with the precautions to be observed when working with high-voltage equipment should service this receiver.

PICTURE TUBE HANDLING

Shatterproof goggles and heavy gloves should be worn at all times when handling a picture tube. The tube should not be handled in the vicinity of any person not so equipped. When handling the tube, always keep it away from the body.

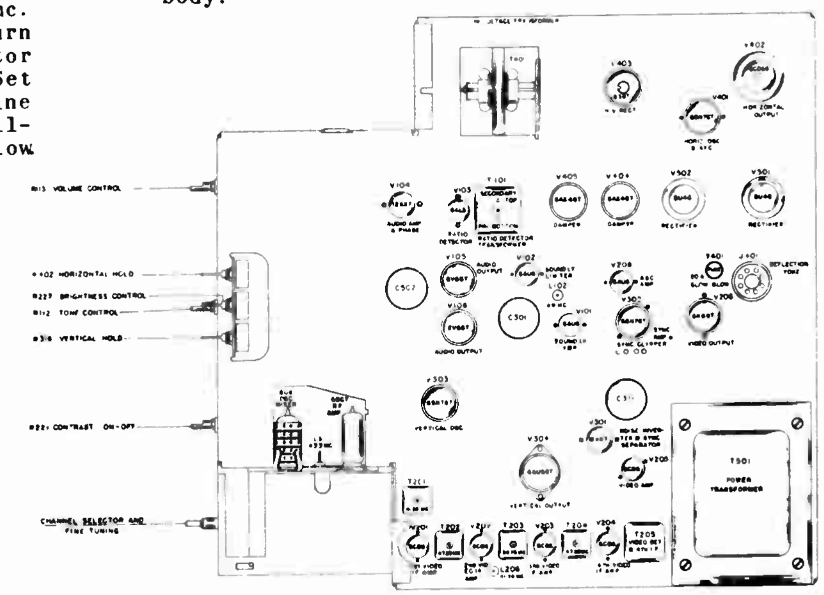

FIGURE 6
TOP VIEW OF CHASSIS

Due to the large surface area of the tube and the high vacuum contained within, more than ordinary care is required to prevent shattering the tube. The large end of the bulb, particularly the rim of the viewing surface, must not be struck, scratched, or subjected to more than moderate pressure. If the tube binds during removal or replacement, determine the cause of the trouble. DO NOT FORCE THE TUBE.

PICTURE TUBE REPLACEMENT

If it becomes necessary to replace the picture tube, it should be done in the following manner:

1. Remove the tube socket from the rear of the picture tube, then remove the ion trap.

2. Remove the safety glass assembly by taking out the screws which hold the glass rail in position.

3. Loosen the nuts that secure the tube strap over the rim of the tube, and remove the strap.

4. Remove the high voltage anode connector and lift out the tube.

5. Install the replacement picture tube being careful not to force the neck when inserting through the deflection coil.

6. Install the HV connector, replace the support strap, and fasten it down securely with the nuts removed in Step 3.

7. Loosen the thumbscrew on top of the deflection yoke, so the yoke moves freely. Loosen the two hex-head screws on each side of the deflection yoke mounting bracket, and push the top section forward until the rubber bumper fits against the bell of the tube, all the way around. Then tighten the screws. Then press the deflection yoke forward as far as possible, and tighten the thumbscrew.

8. Loosen the two screws which secure the focus magnet, and move it so the neck of the tube is properly centered in it. Then tighten the screws and adjust the ion trap.

9. HORIZONTAL and VERTICAL CENTERING of the picture is accomplished by moving the "centering device" on the front side of the focus magnet. Readjustment of the ion trap may be necessary after this plate has been adjusted.

SERVICE HINTS

IMPROVED HIGH VOLTAGE TRANSFORMERS. 107 & 500 SERIES CHASSIS

Always use #360593-2 HV transformer when replacement becomes necessary. This has been used in late production with favorable results.

TROUBLE SHOOTING SYNC CIRCUITS

A separate DC bias supply consisting of a 15 volt battery across an approximately 50.000 ohm potentiometer is helpful in trouble shooting. Remove the AGC amplifier tube and connect the bias supply from the plate circuit of the AGC amplifier to chassis. Try various values of bias and trace the sync pulse throughout the circuits with a scope. This will eliminate the effects of AGC malfunction and facilitate locating the trouble should it not be in the AGC system.

INTERCARRIER BUZZ

1. Check alignment of secondary (top slug) of discriminator transformer. Adjust for minimum buzz on transmitted signal.

2. Check 4.5 mc. sound alignment as outlined in service manual.

3. Check response curve on video IF. Align if necessary.

4. Buzz may be due to overmodulation at the transmitter. If more than one station is available, try all stations. Buzz on only one station will confirm this condition.

F. Remove the short between terminals "C" and "D" of the stabilizing coil and connect oscilloscope through a 15 mmf. capacitor to terminal "C".

G. Adjust stabilizing coil (L401 inside chassis) so the sharp and the rounded peaks of the pattern obtained are of equal amplitude. If necessary, adjust horizontal hold control to maintain sync.

Remove oscilloscope lead and turn horizontal hold to full clockwise. Turn brightness control fully clockwise and adjust horizontal frequency coil until blanking bar appears at left side of picture. Then back off until blanking bar and wiggle at top of picture is no longer present.

H. Adjust noise bias control for best noise immunity.

HORIZONTAL AFC, 400 & 500 CHASSIS

Tune receiver to an acceptable channel. Set noise bias control fully clockwise.

A. Turn horizontal hold control to the center of its range.

B. Adjust horizontal frequency coil (L401, on rear chassis apron) until picture locks horizontally. The vertical lines near the top should not "hook" to the right or left.

C. Adjust horizontal drive control (in models that use one) for maximum sweep until compression appears at center (drive lines), then back off control until compression is just eliminated.

D. Adjust horizontal linearity coil (L403) on rear chassis apron, for proper linearity. If two positions seem to be correct, use the one with the core farthest out.

E. Adjust width control (L402) on rear chassis apron for proper size.

F. Turn horizontal hold control fully clockwise and switch off channel. Turn the control fully counter-clockwise and switch off channel. The picture should hold in sync over the entire range of the horizontal hold control or should have the same number of blanking bars at each end of its range.

G. Adjust noise bias control for best noise immunity.

4.5 MC. TRAP ALIGNMENT

A. Remove V203 (6CB6) 3rd video IF amplifier or short 4th video IF grid (V204-1, 6CB6) to ground, to prevent noise from masking the output indication.

B. Connect the 4.5 mc. signal to Terminal "D" of T205 video detector. The input signal should not exceed 0.2 V. RMS.

C. Connect the crystal probe of the oscilloscope or VTVM to Pin 2 of V207 picture tube grid lead.

D. Turn contrast control fully clockwise.

E. Adjust the core of L207 for minimum output.

SOUND I-F ALIGNMENT

A. Connect the 4.5 mc. signal to Terminal "D" of T205 video detector.

B. Connect probe of VTVM to high side of diode load resistor R109, 15 K ohm (V103-7) and negative lead to chassis ground. Adjust VTVM for zero center.

C. Adjust L102 Sound IF and primary of T101, ratio detector (bottom core) for maximum reading. This reading must not exceed -5.0 V. at any time, to prevent possibility of overload.

D. Remove 4.5 mc. signal from Terminal D of T205 and connect it to junction of R216 (3.9 K) and L203 (360 uh) with negative lead to chassis ground.

E. Adjust L101, sound takeoff coil, for maximum reading. This reading must not exceed -5.0 volts at any time to prevent possibility of overload.

F. Remove VTVM from high side of R109 and chassis ground. Connect two 100 K ohms 5% resistors in series across R109: Connect negative lead of VTVM to junction of these two resistors and the probe to junction of R108 (220 ohms) and C112 (470 mmf). Adjust secondary of ratio detector (top core) for zero reading.

VIDEO I-F ALIGNMENT

A. Connect external bias to 1st IF grid return (junction R201, 1 K and C201, 470 mmf.) and RF grid return (junction R234, 8.2 meg. and R235, 680 K). Adjust IF bias to minus 4.5 V. and RF bias to minus 1.5 V. DC. A battery with 1.5 V. and 4.5 V. taps or an equivalent low impedance source may be used.

B. Connect oscilloscope and VTVM to junction of R216 (3.9 K) and L203 (360 uh) and chassis ground.

C. Connect the IF signal to converter grid wafer lug (cut-out in VHF tuner cover) and adjust the corresponding circuits for the DC output indicated below. During alignment, reduce the signal input if necessary so the detector output does not exceed -1.5 V.

41.25 mc.	T201 & L206 (top)	Minimum
47.25 mc.	T202 & T204 (top)	Minimum
39.75 mc.	T203 (top)	Minimum
43.3 mc.	T201 (bottom and L3 (on tuner)	Maximum
45.3 mc.	T202 (bottom)	Maximum
41.8 mc.	T203 (bottom)	Maximum
45.2 mc.	T204 (bottom)	Maximum
43.1 mc.	T205 (bottom)	Maximum

Note: T201 and L3 comprise a double-tuned circuit and must be aligned as follows:

a. Detune Primary (L3) by backing slug all the way out.

b. Adjust secondary (T201) for maximum output.

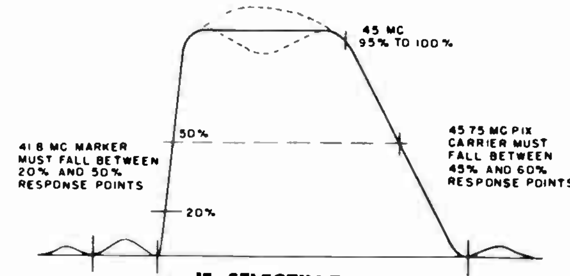
c. Adjust primary (L3) for maximum output.

d. Do not re-set secondary (T201).

Recheck the 41.25 mc., 47.25 mc. and 39.75 mc. trap adjustments after completing peaking.

D. Remove signal from converter grid wafer lug. Connect IF sweep to converter grid (test point #2 on tuner). Loosely couple in IF markers.

E. Check response for symmetry and bandwidth as shown in the following curve.



IF SELECTIVITY CURVE

FIGURE 2

If necessary, readjust slugs in T202 and T205 to set overall IF response to nominal limit (no tilt). Do not readjust T201 for any reason.

F. If receiver has a UHF Tuner, remove IF sweep from converter grid and connect to UHF Tuner at the high side (front end) of the UHF crystal holder. Use a 1000 ohm isolation resistor in the very end of the hot side of the IF sweep cable, the low side of the cable going to ground. Turn UHF-VHF switch to UHF position.

Note: If balanced output cable for sweep generator is not available, the impedance matching network shown below should be used.

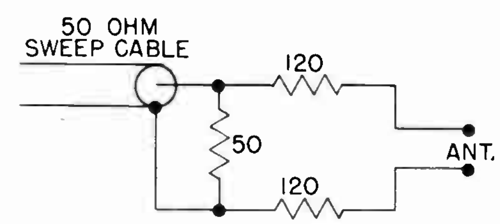


FIGURE 3

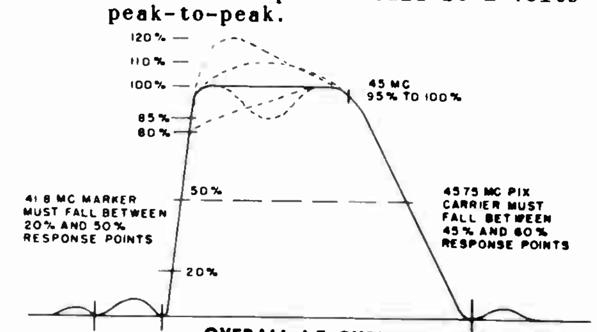
ANTENNA IMPEDANCE MATCHING NETWORK

G. Remove UHF tuner shield cover and adjust IF amplifier plate coil (L617) with insulated screw driver (using slot in bottom of iron core) for maximum gain while setting the 45.75 mc. marker at 50%. Adjust IF amplifier grid coil (L607) with short aligning tool for maximum gain and proper tilt. Check to see that the response curve is within limits. Do not readjust T201 for any reason.

H. Remove IF sweep from UHF Tuner. Switch UHF-VHF switch to VHF if receiver has UHF. Connect RF sweep to VHF antenna terminals. Switch the sweep generator and the receiver to channel 13.

I. With RF oscillator on frequency, check overall RF-IF response for symmetry and bandwidth as shown below.

Note: Oscilloscope must be calibrated to provide accurate marker setting. Detector output should be 2 volts peak-to-peak.



OVERALL I-F CURVE

FIGURE 4

J. Switch RF sweep and receiver channels and check to make sure overall response is within limits of overall selectivity curve on all channels when the RF oscillator is on frequency. Do not readjust any IF coils after step (E) above.

VHF TUNER
TOUCH-UP OSCILLATOR ALIGNMENT

Oscillator alignment should be made only when the fine tuning control tunes in the extreme clockwise or counter-clockwise position, or if it will not tune at all within its tuning range.

If some channels do not tune at all, or not near enough to the center of the fine tuning range, adjust the oscillator trimmer for the best compromise tuning on all channels. If, for example all channels tune near one side of the control, adjustments of the trimmer will bring them all near the center. However, if some channels tune near one end and others tune at the other end of the control, adjustment will move some to the center and move the others beyond the range of the control. In this case the oscillator coils will have to be adjusted individually as follows.

COMPLETE OSCILLATOR ALIGNMENT

Connect a sweep generator to the antenna terminals of the receiver. Connect an unmodulated signal generator to the antenna terminals and tune it to the channel 13 video carrier frequency. TV signals may be used.

Loosely couple an unmodulated signal generator to the first IF grid and tune it to 45.75 mc. Connect an oscilloscope across the video detector load resistor through a 10 K ohm resistor.

Turn on the receiver and set the vernier to the midrange position. When the receiver has warmed up, if there are two

DESCRIPTION & SPECIFICATIONS

The Magnavox 106, 107, 400 and 500 Series Television Chassis are direct view receivers, each constructed on a single chassis. The 106 and 400 series are designed to accommodate a 21" rectangular picture tube. The 107 and 500 series will allow the use of either a 24" or 27" picture tube without any change in circuitry.

Features of these Chassis include:

- A low-noise VHF Tuner, with a cascode RF Amplifier for extreme fringe area performance.
- A choice of VHF only, UHF Converter or UHF Tuner. Each of the latter covers all UHF channels without the need of adaptors or other accessories.
- A four-stage, stagger-tuned Inter-carrier IF section for good resolution, ease of alignment and freedom from the effect of oscillator drift.
- Push-pull Audio Amplifier.
- Fast acting keyed Automatic Gain Control for instantaneous control of receiver gain.
- Noise suppressor stage.
- Vertical retrace blanking to eliminate retrace lines regardless of control settings.
- Three basic versions. For TV only, TV in conjunction with a radio chassis, and TV with power provisions for a radio tuner.

IMPEDANCE

300 ohm input.....Speaker Voice Coil 3.2 ohms

POWER REQUIREMENTS

106 & 400 Series, TV with Audio............................280 watts, 117v, 60cps
106 & 400 Series, TV without Audio.........................230 watts, 117v, 60cps
106 & 400 Series, TV with Audio & Radio Tuner..............280 watts, 117v, 60cps
(Radio-TV Switch in TV Position)

107 & 500 Series, TV with Audio............................320 watts, 117v, 60cps
107 & 500 Series TV with Audio & Radio Tuner...............320 watts, 117v, 60cps
(Radio-TV Switch in TV Position)

CHASSIS DIFFERENCES

Maintenance information on the 106, 107, 400 and 500 Series Chassis is so similar that it has been included in one service manual.

Prefix letters CT indicate the use of 700379 VHF Tuner only; CU uses the VHF Tuner and a 700359 UHF Converter; while CMU uses the VHF Tuner and a 700426 UHF Tuner.

The basic chassis differences are as follows:

106 SERIES

BASIC CHASSIS NO.	PIX TUBE	CHASSIS DIFFERENCES
CT,CU or CMU381AA,AB,AC,AD,BC & BD	21"	Audio on chassis
CT,CU or CMU382AA,AB,AC,AD,BC & BD	21"	No audio
CT,CU or CMU383AA,AB,AC,AD,BC & BD	21"	Audio and radio input

107 SERIES

CT,CU or CMU358AA,AB,BA,BB & CB	27"	Audio on chassis
CT,CU or CMU359AA,AB,BA,BB & CB	27"	Audio and radio input
CT,CU or CMU385AA,AB,BA,BB & CB	24"	Aluminized Picture Tube
CT,CU or CMU386AA,AB,BA,BB & CB	24"	Non-aluminized Picture Tube

400 SERIES

CT,CU or CMU381CE & CF	21"	Audio on chassis
CT,CU or CMU382CE & CF	21"	No audio
CT,CU or CMU383CE & CF	21"	Audio and radio input

Additional prefix letter added: A indicates audio on chassis; B indicates no audio; C indicates audio and radio input.

CTA,CUA or CMUA381CJ & CK	21"	Audio on chassis
CTB,CUB or CMUB382CJ & CK	21"	No audio
CTC,CUC or CMUC383CJ & CK	21"	Audio and radio input

500 SERIES

CTA,CUA or CMUA358DC & DD	27"	Audio on chassis
CTA,CUA or CMUA359DC & DD	27"	Audio and radio input
CTA,CUA or CMUA385DC & DD	24"	Aluminized Picture Tube
CTA,CUA or CMUA386DC & DD	24"	Non-aluminized Picture Tube

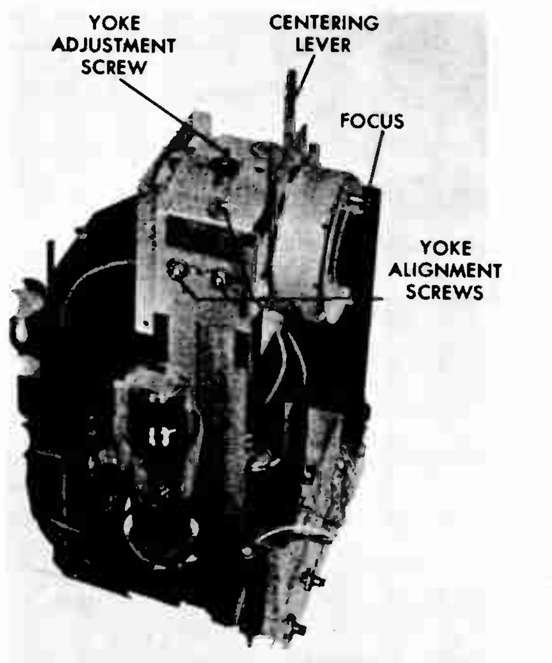

FIGURE 1
PICTURE TUBE ADJUSTMENTS

ALIGNMENT

HORIZONTAL AFC, 106 & 107 CHASSIS

Tune receiver to weakest channel available. Set noise bias control fully clockwise. Set horizontal drive trimmer about 1/2 turn from full clockwise position.

A. Short out terminals "C" and "D" of horizontal stabilizing coil (L401), and turn horizontal hold control fully clockwise.

B. Adjust horizontal frequency coil (L401, on rear chassis apron) until picture locks horizontally.

C. Adjust horizontal drive trimmer for maximum sweep. Turn counter-clockwise until compression appears at center (drive lines), then clockwise until compression is just eliminated.

D. Adjust horizontal linearity coil (L403) on rear chassis apron for proper linearity. If two positions seem to be correct, use the one with the core farthest out.

E. Adjust width control (L402) on rear chassis apron for proper size.

I. F. Alignment Procedure, IT-76R Chassis
Models 776, 1176, and 1376

REFERENCE:

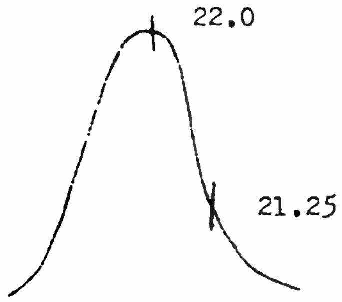
Circuit Diagram E-734

EQUIPMENT:

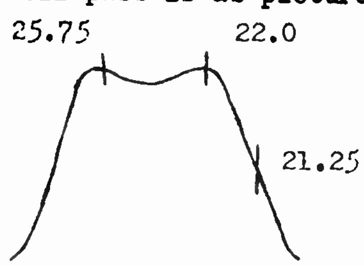
1. Sweep generator, 23.5 mc. center frequency, 10 mc. sweep width.
2. Marker generator, 21.25 mc., 22.0 mc., and 25.75 mc.
3. Crystal oscillator, variable output, 4.5 mc. unmodulated.
4. Oscilloscope.
5. 20,000 ohm per volt meter.

PROCEDURE, VIDEO I.F.:

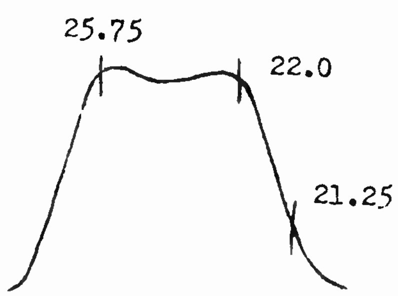
1. Connect oscilloscope to J1 test point.
2. Move tuner between channels to disconnect coils.
3. Connect sweep generator, decoupled with 1000 uuf., to pin 1 of V5. Turn the slug on L17 until it is centered in the coil. (This narrows the band pass of this stage.) Adjust L12 and L16 until the pass appears as below:



Now adjust L17 until pass is as pictured:

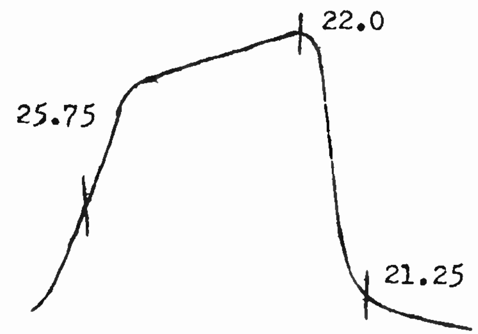


5. Move sweep generator to pin 1 of V4. Adjust L15 until pass balances, adjust L13 until pass balances. When properly adjusted, pass will look as pictured below:



6. Move sweep generator to pin 1 of V3. Adjust L11 and L9 as in above step. Pass will now be as pictured:

7. Move sweep generator to test point on tuner (can be located as a loop of wire between V1 and V2 on top of tuner chassis); adjust L8 (square can on tuner) until the pass rocks through a tilt and leave adjusted with a 10% tilt in the pass, as pictured below:



The video I.F. is now correctly aligned.

INTERCARRIER SOUND SYSTEM:

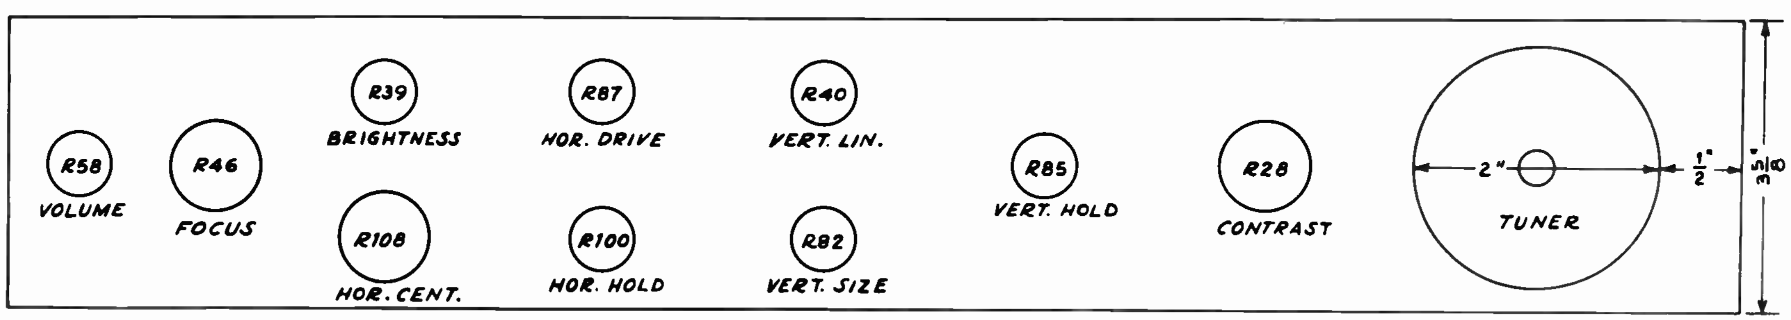
1. Connect voltmeter, set on 10 volt scale across C46, observing polarity.
2. Insert 4.5 mc. generator, capacity decoupled, in J1.
3. Reduce signal so that voltmeter reads a maximum of 3.0 volts, and continue to reduce as adjustments are made so as not to exceed this value.

Adjust in the order given, the following transformer slugs for maximum output:

a. Bottom slug, T3.
b. L23.
c. Top slug, T3.

Repeat to insure accurate setting.

Intercarrier sound system is now properly aligned.



FRONT VIEW

PARTS LIST

NOTE: Unless otherwise noted all condensers are 600 volt, molded phenolic type, ± 20% tolerance with whole number values given in micromicrofarads and decimal fraction values given in microfarads. GMC - guaranteed minimum capacity.

NOTE: Unless otherwise noted all resistors are 1/2 watt, composition type, ± 10% tolerance with values given in ohms.

6. BUS VOLTAGES ARE FOR 117 V. LINE, ZERO SIGNAL, 0 VOLTS A G C.
7. Z2 TUNER OUTPUT CABLE SHOULD HAVE A NOMINAL CAPACITY OF 22 ± 10 % MMF WHICH IS EQUIVALENT TO 9 1/2 INCH OF CABLE NO. 3195
Ŧ V204 AND V205 OCCUPY THE SAME ENVELOPE.
* V401 AND V502 OCCUPY THE SAME ENVELOPE

TABLE III - TV ALIGNMENT PROCEDURE

STEP NO.	SIGNAL GENERATOR FREQUENCY, MC	CONNECT SIGNAL TO	OUTPUT INDICATOR	ADJUST	INSTRUCTIONS	SPECIAL CONNECTIONS AND SETTINGS
			SOUND I. F. AND RATIO DETECTOR			
1	4.5 CW	Pin 2 of V301	Meter across pin 7 of V102 and ground.	T101 Pri. (bottom) L101	Tune for maximum reading on meter.	Signal level should be low enough to obtain approximately 4 to 7 volts on meter. Use isolation networks shown in Figures 2 and 3.
2	4.5 CW	"	Meter across ground and junction of R105 and C108.	T101 Sec. (top)	Tune for zero meter reading; use same signal level as in step 1.	Repeat tuning of T101 primary and secondary until adjustments do not change.
			TRAPS AND PICTURE I. F.			
3	4.5 CW	Pin 2 of V301	Meter connected through detector network to picture tube cathode lead.	L302	Tune for minimum reading on meter.	Detector and isolating networks shown in Figures 2 and 4.
4	41.25 CW	Mixer Grid	Voltmeter across R217.	Z201	Tune for minimum reading on meter.	Apply -4V bias to AGC buss. See text for connection to mixer grid. Keep generator output low. Set contrast control for maximum contrast. Adjust signal level throughout I. F. alignment so that a 1 volt DC output is maintained across R217.
5	43 CW	"	"	T204	Tune for maximum.	
	44.00CW	"	"	T203	"	
	42.5CW	"	"	T202	"	
	45.3CW	"	"	T201	Tune for maximum reading on meter.	
6	45 CW	"	"	L9	Tune for minimum reading on meter.	
7	45 CW	"	"	L203	Tune for maximum.	
8	39.75 CW	"	"	L201	Tune for minimum.	
9	47.25 CW	"	"	L202	Tune for minimum.	
10	REPEAT STEP NUMBER 7					
11	45 CW	"	"	L9	Tune for maximum.	
12	Approximately 43.5 with 10 mc sweep. Marker required.	Mixer Grid	High gain scope across R217	Adjust T201, T202, T203, T204 if necessary.	Set 45.75 mc marker at 50% point.	See Figure 5 for isolation network. Use markers to determine bandpass between picture carrier and 50% point on opposite skirt. Bandpass should be between 3.65mc and 3.85mc.

* Do not measure with meter. Spikes of voltage may damage meter. D. C. value of voltage will be approximately 460 volts.

Boost voltage may be measured at width coil and will be about 550 volts on 410-24 chassis and approximately 460 volts on 407-21 and 408-21 chassis.

Voltages indicated in voltage chart were taken with Simpson Model 260 meter. Receiver was operating on 117 volt AC with all controls set for normal operation of channel received. Detected signal at plate of video detector developed negative 1 1/2 volts. All voltages read to chassis ground. These voltages are intended as a reference to be used in service and repair of this chassis and are not to be considered as maximum or minimum limits for operation. The normal allowable variations in component values, as well as line voltage and signal variation, will cause slight differences in voltages read on chassis of the same model.

IDENTIFICATION

The 407-21, 408-21 and 410-24 chassis are variations of the super deluxe chassis used in the above named models of Hoffman television receivers. The All-Wave models are identified by a "U" following the model number. Chassis 407-21 is a Super Deluxe chassis with single ended audio section. Chassis 408-21 and 410-24 have a push-pull hi-fi audio circuit. Chassis 410-24 is the same as 408-21, except the sweep circuits which are designed to accommodate a 24" picture tube. All three chassis have a four stage 40mc I. F. strip and cascode tuner with negative bias supplied by a keyed AGC system. The low voltage power supply uses selenium rectifiers connected as a voltage doubler.

An unusual feature of the chassis is the addition of a secondary control for operation in noisy signal areas. This control is located under the plastic escutcheon plate on front control panel. Its use is explained under Operating Instructions.

Earphone jacks with speaker switch are used on above listed models. Reference to the schematics will show that the earphone jack is operative at all times, and that speakers can be either on or off depending upon the position of the speaker switch.

Some models using above chassis will have three speakers. Reference to the schematic will show that the two low frequency speakers are in parallel with each other. A single high frequency or tweeter speaker is used. A frequency divider network feeds the audio to the proper speaker for reproduction.

TABLE I ELECTRICAL & MECHANICAL DATA

Operating Voltage	115 Volts AC, 60CPS
Power Consumption	407-21 170 Watts 408-21 180 Watts 410-24 215 Watts
VHF Tuner Range	2 through 13
All-Wave Tuner Range	2 through 83
Intermediate Frequencies	Picture Carrier 45.75mc Audio Carrier 41.25mc
Intercarrier Sound I. F. Freq.	4.5mc
Audio Output Impedance	407-21 3.2 ohms 408-21 6.4 ohms center tapped 410-24 6.4 ohms center tapped
Maximum Undistorted Audio Output	407-21 3 Watts 408-21 10 Watts 410-24 10 Watts
Antenna Input Impedance	3.2 ohms balanced
Picture Tube Size	21" Rectangular 407-21, 408-21 24" Rectangular 410-24
Focus	Electrostatic Focus 407-21 and 408-21 Magnetic Focus 410-24
Video Response	to 3.75mc

ALIGNMENT

The following discussion describes recommended methods and equipment to be used and precautions to be observed during the alignment procedure. Table III offers a ready reference alignment guide to be followed after the more detailed procedure has been studied.

For best results it is important that alignment be performed on a metal topped bench with all instruments and equipment securely bonded together and to ground. All leads should be as short as is practicable, particularly in the input grid circuits. Allow about fifteen minutes for the test equipment and receiver to warm before beginning the alignment. Isolation circuits will be required for both the input and output connections. It is important that composition resistors, preferably the half-watt size, and disc type ceramic condensers be used in making up these isolation networks so that a minimum amount of external inductance is added to the tuned circuits being adjusted.

The following equipment will be required in order to align the picture and sound I. F. stages of the receiver properly.

1. Accurate CW signal generator covering the following frequencies:

4.5 mc	39.75 mc
41.25 mc	44.00 mc
42.00 mc marker freq.	45 mc
43 mc	45.3 mc
42.5 mc	45.75 marker freq.
	47.25 mc

The generator must have an attenuation control which can be used to vary its output signal level.

2. Sweep frequency generator with a sweep center frequency of approximately 43.5 mc and a 10 mc sweep width.
3. Cathode ray oscilloscope with at least a moderately high vertical gain. Must have external sweep input or internal sweep frequency equal to the sweep generator sweep frequency and capable of phase control.
4. DC voltmeter with sensitivity of 20,000 ohms per volt or higher and voltage scale ranges which include approximately 10 volts and 3 volts (full scale deflection). VTVM with zero center scale adjustment is an ideal type.
5. -4 volt bias source such as a battery.
6. Detector network shown in Figure 4.
7. .005 uf isolating condenser.
8. 10K ohm, 1/2 watt composition resistor.
9. .001 uf condenser for shunting oscilloscope input.

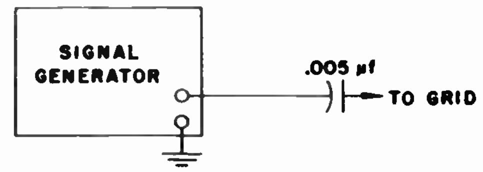

Figure 2. Signal Generator Isolation

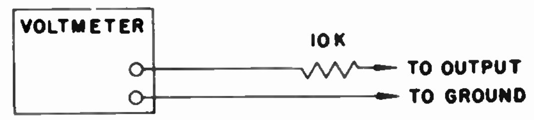

Figure 3. Voltmeter Isolation

TUNING PICTURE I. F. COILS

Equipment: Instruments and setup remain the same as for trap alignment during the first part of the procedure. For final adjustment the sweep frequency generator is also used and the voltmeter should be replaced by the oscilloscope. See Figure 5 for oscilloscope isolation details.

Procedure: Tune the I. F. coils by setting the coil frequency on the CW generator and adjusting the coil for maximum voltmeter reading. The CW generator output must be attenuated so that the DC output voltage of the video detector (indicated on the voltmeter), remains at 1 volt as the I. F. coils are tuned. The order of tuning is from the last I. F. stage toward the tuner. Repeat the trap and I. F. alignment procedure until no additional change in adjustments is necessary.

OSCILLATOR ALIGNMENT

The procedure given below makes use of the picture I. F. stages common to the sound stages, the sound I. F. stages and the ratio detector. Therefore, the accuracy of the oscillator setting is dependent upon the accuracy of the alignment of the aforementioned stages.

EQUIPMENT:

Connect the "hot" lead of the marker generator (CW source) to one antenna terminal and connect the generator ground lead to ground. Set the generator for unmodulated output. Connect the voltmeter to measure the ratio detector balance voltage at sound I. F. Use center scale of the voltmeter if available.

PROCEDURE:

Set the fine tuning control at the center of its tuning range. Set the tuner to Channel 12 and the signal generator to the sound carrier frequency of Channel 12 (209.75 mc). Using a non-metallic alignment screwdriver, adjust C12 for zero reading on the voltmeter. With C12 correctly adjusted, tune the brass slug through the hole in the front of the chassis and tuner for zero voltmeter reading on each of the other eleven channels, using a non-metallic screwdriver. Switch the signal generator to the correct sound carrier frequency for each channel. C12 is an all-channel adjustment and should not be altered after adjusting it for Channel 12. If difficulty is encountered in obtaining a zero voltmeter reading on a particular channel, check the coil board containing the oscillator winding.

* Do not measure - High amplitude spikes of D. C. may damage meter. D. C. value will be about same as boost voltage. Boost voltage at pin #1 of horizontal output transformer about 400 volts.

Voltages taken with Simpson #260 meter on 303-21 chassis operating as follows: AC line voltage 115 volts, receiver tuned to station with normal setting of all controls, negative 2.5 volts developed at plate of video detector by signal received. All voltages are positive D. C. unless otherwise indicated.

These readings are prepared as a service reference and should not be considered as minimum or maximum specifications for the operation of this chassis. Variations within limits will be noted, due to operating conditions and the normal allowable tolerances in component values.

Fine tuning is accomplished by a shaft concentric with the channel selector shaft. Slight rubbing of the dielectric rotor against the grounded stator plate is intentional, in order to avoid vibration with resulting interference. However, the dielectric rotor should not be allowed to rub or contact the silvered ceramic disc riveted to the chassis. If the fine tuning shaft binds, it should be removed and cleaned with carbon tetrachloride (using a light canvas cloth) and both the dielectric blade and the drum shaft should be lubricated with switch grease or vaseline.

Erratic operation on any one channel requires checking of the coil boards for that channel. Both contact points and windings should be checked. Clean the contact points with a light canvas cloth dampened with carbon tetrachloride. If the operation is still unsatisfactory, press the contact springs lightly with an insulated screwdriver. If the tuner cannot be made to operate, more contact spring pressure is required. Contact rise should be approximately 1/32 inch. To adjust contact rise, several sets of coil boards should be removed from the tuner. To remove a coil board insert a screwdriver between the coil retainer spring and the turret end plate. Twist the blade away from the turret and lift the end of the coil upward and remove. Rotate the drum so that no coil board is under the contact springs. Press the contact springs down slightly to give increased pressure. With the coil boards removed, clean the contact surfaces of the contact springs with carbon tetrachloride (using a small stiff brush) and lubricate with a pure mineral oil. Replace the coil boards, and check all channels.

If oscillator slugs fall into the coil form, remove the coil board, move the slug retaining spring aside, and tap the coil board until the slug slips forward. Reset the slug retaining spring.

Noisy channel switching may be due to the detent spring roller not rotating on the detent plate. Lubricate both surfaces with switch grease or vaseline.

For microphonism produced by tapping the tubes or tuner chassis, or in case of intermittent video and sound, first replace the tubes. If the trouble persists, clean contact surfaces and lubricate surfaces as explained above.

TROUBLE SHOOTING

Tube substitution is recommended first for localizing the trouble. The presence of oscillator grid voltage is very important. Lack of it indicates that the oscillator is not operating. This voltage may be checked from pin 6 of the 6J6 tube to ground by using an isolating resistor of 25,000 ohms on the voltmeter test probe. The isolating resistor is required to prevent excessive loading of the oscillator circuit. Lack of voltage at test point, when the oscillator is operating, indicates trouble in the mixer grid circuit. This voltage should be at least 2 volts on the high channels and 3 volts on the low channels, measured with VTVM or 20,000 ohms per voltmeter between test point and chassis. Resistance checks should reveal the source of trouble when incorrect voltage or abnormal operation is noted.

ALIGNMENT

The tuned circuits are very stable and normally do not require adjustment unless a tube or component part has been replaced or the adjustment of the trimmer condensers have been indiscriminantly changed by an inexperienced individual.

The following alignment procedure describes alignment of the R-F, mixer and oscillator stages of the tuner with the exception of the converter output coil, L9. The latter adjustment is described in the IF alignment procedure section of the individual chassis data bulletins. Table IV offers a ready reference guide to be followed after the detailed procedure has been studied.

The following equipment will be necessary in order to align the tuner. DO NOT ATTEMPT ANY ALIGNMENT BEYOND THE "FIELD ADJUSTMENTS OF OSCILLATOR" UNLESS THE EQUIPMENT IS AVAILABLE.

1. Accurate AM signal generator covering the television picture and sound carrier frequencies listed in Table IV, with low impedance output and calibrated attenuator.

2. R-F sweep generator covering the frequency band of the twelve television channels, preferably with 300 ohm balanced output to match its output to antenna input. Sweep width at least 12 mc wide.

3. D.C. voltmeter with at least 20,000 ohms per volt sensitivity and low range.

4. An oscilloscope with at least a moderate sensitivity.

5. A 3 volt bias battery.

Most sweep generators have an output impedance less than 300 ohms. In order to match the generator to its load (tuner input), a matching network is used. A suggested network can be made up from several inches of 300 ohm twin lead and three composition type, 1/2 watt resistors of suitable value. Figure 5 shows the details. The length of lead l_g should be as short as is practicable so as not to provide a 300 ohm line between network and generator. Lead l_a should be just long enough to keep network and generator leads from shorting against TV chassis or tuner chassis. The network can be taped to further eliminate possible shorts. The values given for R1, R2 and R3 are the result of a compromise between making the network a universal one for all generators with output impedances of approximately 50 to 75 ohms, and availability of resistors of a desired value. More exact values for a particular generator are usually given in the instruction manual supplied with the generator.

The AM signal generator is used as a marker generator for the video and sound carrier frequencies, and it is also used as a CW source in adjusting the oscillator frequencies. Therefore, it is most desirable, from the standpoint of accuracy and alignment time, that the generator provide pairs of controlled or crystal calibrated channel picture and sound carrier frequencies. However, if pairs of frequencies are not available, the signal marker frequency can be shifted from the picture to sound carrier frequency for each step in the alignment procedure. A VTVM is recommended for the D.C. voltmeter because the sensitivity is very high and a zero-center scale is available on most models. Shielded leads should be used for all connections. All ground leads and equipment should be well bonded together. Composition resistors must be used in the matching and isolating networks. Before beginning the alignment procedure, allow about 15 minutes for receiver and test equipment to warm up to operating temperature.

R.F. AND MIXER ALIGNMENT

EQUIPMENT:

Disconnect antenna from the receiver if one is being used, and connect the sweep generator to the antenna terminals. Use matching network if necessary. Loosely couple marker generator to antenna terminal, using unmodulated signal to obtain marker pips of video and sound R.F. carriers. This may be done by clipping the marker generator "hot" lead to an insulated part of the sweep generator lead, or by coupling with a small capacitor (2 or 3 uuf). Avoid distortion of response curve by keeping the marker generator output at a minimum, marker pips being just barely visible. Temporarily disconnect the tuner AGC lead from the AGC buss and connect it to the negative terminal of the bias source. Connect positive terminal of bias source to chassis ground. Connect synchronized sweep voltage from the sweep generator to the horizontal input of the oscilloscope for horizontal deflection or set the scope to internal 60 cycle sweep if the sweep frequency of the generator is 60 cycles. Connect the vertical input lead of the scope through a 10K ohm resistor to point T, the wire loop on top of the tuner. Tuner alignment adjustments are located as follows:

1. C12 is near front side of oscillator mixer tube socket.
2. C9 is between the two tuner tube sockets.
3. C2 is near back side of R.F. amplifier tube socket.
4. C23 is beside C2 adjustment.

PROCEDURE:

Set the channel selector to Channel 12 (at this setting the coil boards marked "8" are at the bottom center position). Channel 12 is the reference channel for trimmer alignment. Set the fine tuning control at the center of its tuning range. Set the sweep generator to approximately 207 mc. Insert the picture and sound markers. Remember that the sound marker is higher in frequency than the picture marker before conversion to the I.F. Adjust C2, C9 and C23 for an approximately flat top response curve which should be located symmetrically between the markers and be of maximum amplitude. See Figure 6 for appearance of curve. Normally this curve appears somewhat overcoupled (double humped) with a 10% or 15% peak to valley excursion, and the markers occur at approximately maximum response. In general the adjustment performed for Channel 12 is sufficient to give satisfactory response curves on all channels. Check the response of Channels 2 through 11 and Channel 13 by switching the receiver channel selector, sweep generator and marker generator to each of these channels and observe the response obtained. Curves obtained should approximate those shown in Figure 6, although variation is to be expected between different units. However, in general, the peak to valley excursion should never exceed 30%, and the markers should never occur at points below 70% of the maximum amplitude of the curve. If reasonable alignment is not obtained on a particular channel, (a) check to see that coil boards have not been intermixed; (b) adjust C2, C9 and C23 as a compromise adjustment, favoring this particular channel and recheck all channels to see that they have not been seriously affected; (c) try replacing the coil board for the weak channel.

ALIGNMENT

TABLE III - TV ALIGNMENT PROCEDURE

STEP NO.	SIGNAL GENERATOR FREQUENCY MC	CONNECT SIGNAL TO	OUTPUT INDICATOR	ADJUST	INSTRUCTIONS	SPECIAL CONNECTIONS AND SETTINGS
			SOUND I. F. AND RATIO DETECTOR			
1	4.5 CW	Pin 1 of V301	Meter across pin 7 of V102 and ground.	L102 Pri. (bottom) L101	Tune for maximum reading on meter.	Signal level should be low enough to obtain approximately 4 to 6 volts on meter. Use isolation networks shown in Figures 2 and 3.
2	4.5 CW	"	Meter across ground and junction of R105 and C108.	L102 Sec. (top)	Tune for zero meter reading; use same signal level as in step 1.	Repeat tuning of L102 primary and secondary until adjustments do not change.
			TRAPS AND PICTURE I. F.			
3	4.5 CW	Pin 1 of V301	Meter connected through detector network to picture tube cathode lead.	L302	Tune for minimum reading on meter.	Detector and isolating networks shown in Figures 2 and 4.
4	41.25 CW	Mixer grid	Voltmeter across Pin #6 of V203	Top of L202	Tune for minimum reading on meter.	Apply -3V bias to AGC buss. See text for connection to mixer grid. Keep generator output low. Set contrast control for maximum contrast. Adjust signal level throughout I. F. alignment so that a -1 volt DC output is maintained across video detector load.
5	47.25 CW	"	"	Top of L203	"	
6	44. CW	"	"	L204	Tune for maximum.	
7	45.4 CW	"	"	L203	"	
8	43.25 CW	Mixer Grid	"	L202	Tune for maximum reading on meter.	
9	43 CW	"	"	L9	Tune for minimum reading on meter.	
10	43 CW	"	"	L201	Tune for maximum.	
11	45 CW	"	"	L9	Tune for maximum.	
			Repeat steps 4 through 10 until adjustments do not change.			
12	Approximately 43.5 with 10- mc sweep. Marker required.	Mixer grid	High gain scope across Pin 1 of V301 and ground.	Adjust L202, L203 and L204 if necessary.	Set 45.75 mc marker at 50% point with L202. Eliminate tilt with L204.	See Figure 5 for isolation network. Use markers to determine bandpass between picture carrier and 50% point on opposite skirt. Bandpass should be between 3.15 mc and 3.35 mc.

VHF TUNER

FIELD ADJUSTMENT OF RF OSCILLATOR

The following alignment procedure is intended only as a field operation, using television transmitter signals to correct minor misalignment of the oscillator on a few channels. This is generally evidenced by inability to peak the picture at or near the mid-point of the fine tuning control range.

The coils for each channel are independent of all other coils, and are switched in and out of the tuned circuits by rotating the turret. Access to the oscillator coil adjustment slugs is obtained through the hole above and to the right of the channel selector shaft with the fine tuning control in mid-range position.

To trim the oscillator on an individual channel, turn the selector switch to that channel and, using an insulated alignment tool, adjust the slug available through the access hole until the picture reception is peaked. This process may be repeated on all channels as required.

If these adjustments do not correct the condition, or if either sound or picture reception on all channels is below normal, it may be necessary to perform the complete bench alignment procedure as outlined in the alignment section.

TUNER MAINTENANCE

The entire turret drum, with coils in place, may be removed from the tuner chassis by removing the retaining springs at each end of the unit. This gives access to the components and tube sockets which are not accessible from the side of the tuner.

The high frequencies used in television make it necessary that extreme care be exercised in handling or servicing tuners. Location and lead dress of components and wiring are very critical. At high frequencies, wiring leads tend to act as small inductances and stray capacities; consequently any change made may appreciably alter the electrical characteristics of critical circuits. Parts location and ground connections should be maintained as originally made. When replacing components, it is important that they be replaced with parts of identical electrical characteristics and physical size.

TUBE REPLACEMENT

Replacement of tubes (especially 6J6 oscillator-mixer tubes) may cause excessive change in frequency of tuner circuits. This is due to differences of inter-electrode capacitances, unavoidable in the manufacture of tubes. When replacing a 6J6 tube, it is recommended that several tubes be tried in order to select a tube which will cause the least oscillator frequency shift. This practice will in most cases eliminate the need for realignment of the tuner.

CLEANING AND LUBRICATION

1. Remove the ground plate of the fine tuning assembly and slide the fine tuning shaft and blade off the drum shaft. Remove bottom cover plate. Remove the drum retaining springs at either end of the chassis. The complete drum may now be removed from the chassis.

2. Clean the coil board contacts and stator contacts with carbon tetrachloride applied with a light canvas cloth and lubricate with a pure, sulphur-free, mineral oil, such as "Nujol". Clean all bearing surfaces and lubricate these with switch grease or white "Vaseline". CAUTION: No abrasive should be used in cleaning contacts as some of the abrasive material may become imbedded in the silver contact causing excessive wear and noisy contacts.

MECHANICAL TROUBLES

Apart from tube failures, most troubles are likely to be mechanical. Firstly, if mechanical parts are broken, it must be determined whether to repair or replace the unit.

The turret drum, including coil boards may be removed from the tuner chassis by removing the turret retaining springs at each end.

IDENTIFICATION

The 303 chassis series includes all deluxe chassis used in the above indicated models of Hoffman television receivers. This service data applies to both VHF and All-Wave model receivers. Models using the All-Wave tuner are identified by a U following the Model number. If the All-Wave tuner is used, refer to Service Data #500 for service information. VHF tuner data is provided in this bulletin.

The 303 chassis has a power transformer with an additional 130 volt tap in the primary. This feature may be utilized in areas where power supply varies from the normal 117 volt AC. If the receiver is operated with line voltage around 130 volts, this connection may be used to provide correct operating voltage and assure added protection for all components in the chassis. Another feature added to improve set operation in extreme fringe areas is a removable jumper across R711. This jumper is easily reached by removal of bottom cover and may be clipped loose at one end to provide a negative 2 volt bias to grid of the video amplifier. (See General Circuit Description)

TABLE I
ELECTRICAL AND MECHANICAL DATA

Operating Voltage	115 volts AC 60 cps
Power Consumption	125 watts
VHF Tuner Range	Channels 2 through 13

* All Wave Tuner Only + VHF Tuner Only

The following equipment will be required in order to align the picture and sound I.F. stages of the receiver properly.

1. Accurate CW signal generator covering the following frequencies:

4.5 mc	43.25 mc
41.25 mc	45 mc
42.5 mc marker freq	45.4 mc
45.75 mc marker freq	47.25 mc
43 mc	44 mc

The generator must have an attenuation control which can be used to vary its output signal level.

2. Sweep frequency generator with a sweep center frequency of approximately 43.5 mc and a 10 mc sweep width.
3. Cathode ray oscilloscope with at least a moderately high vertical gain. Must have external sweep input or internal sweep frequency equal to the sweep generator sweep frequency and capable of phase control.
4. D. C. voltmeter with sensitivity of 20,000 ohms per volt or higher and voltage scale ranges which include approximately 10 volts and 3 volts (full scale deflection). VTVM with zero center scale adjustment is an ideal type.
5. 3 volt bias source such as a battery.
6. Detector network shown in Figure 1.
7. .005 uf isolating condenser.
8. 10K ohm, 1/2 watt composition resistor.
9. .001 uf condenser to shunt oscilloscope input.

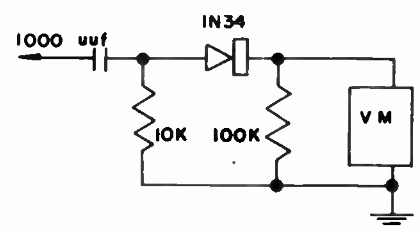

Figure 1. **Detector Network**

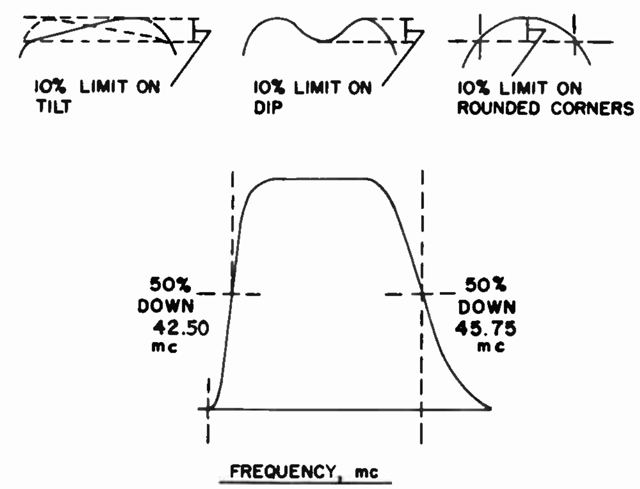

Figure 2. **Picture I-F Response Curve**

Before alignment is begun, tune the tuner off-channel by turning the tuner channel selector shaft so that the detent roller rests on one of the high points of the drum disc. In all steps of video I.F. alignment, the input signal should be maintained to a level of approximately one (1) volt D.C. output across video detector load. This is to insure against false tuning due to overloading.

It is important that the alignment be performed in order listed, with the exception of items 1 and 2, because there is some interaction within the various stages.

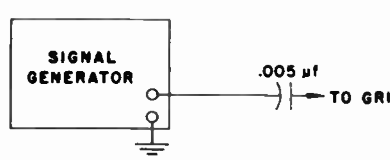

Figure 3. Signal Generator Isolation

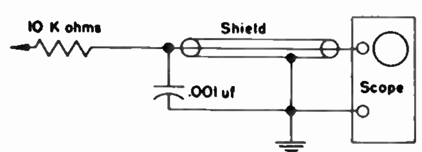

Figure 4. Oscilloscope Isolation

F-M SOUND CHANNEL ALIGNMENT

1. Connect 4.5 MC generator, 400 cycle 30% AM, to video amplifier grid (Pin 8).
2. Connect detector and oscilloscope (See Fig. 5 for circuit) to picture tube cathode.
3. Set contrast control to max. clockwise rotation, and volume control to one-half max. clockwise rotation.
4. Turn slug in primary (video amplifier plate winding) of ((L-109) sound take-off transformer completely out of coil winding in direction of chassis.
5. Turn slug in secondary (4.5 MC amplifier grid winding) of L-109 completely out of coil winding in direction away from chassis.
6. Turn slug in primary of L-109 into coil until a minimum oscilloscope deflection is obtained.
7. Remove detector and oscilloscope from picture tube cathode.
8. Connect oscilloscope input directly across secondary of audio output transformer.
9. Change 4.5 MC generator modulation from 400 cycles 30% AM to 400 cycles 7.5 KC FM.
10. Set buzz control approximately 90° from clockwise stop.
11. Reduce generator input below level where output limiting occurs.
12. Starting with slug completely out of coil winding on chassis side, adjust quadrature coil (L-106) for maximum oscilloscope indication. Turn volume control down as required to maintain pattern size on scope.
13. Adjust secondary of L-109 for maximum output indication on oscilloscope. Reduce generator output as required to keep signal level below output limiting.
14. Adjust L-111, sound coupling transformer between 4.5 MC amplifier plate and sound detector grid for maximum output indication on oscilloscope. Reduce generator output as required to keep signal level below output limiting.
15. Increase signal generator output to level above output limiting.
16. Change 4.5 MC generator modulation from 400 cycles 7.5 KC FM to 400 cycles 30% AM.
17. Adjust buzz control R-132 for minimum indication on oscilloscope.
18. Change 4.5 MC generator modulation from 400 cycles 30% AM to 400 cycles 7.5 KC FM.
19. Readjust quadrature coil L-106 for maximum output indication.
20. Reduce generator output below level of output limiting and recheck steps 13 and 14.

HORIZONTAL OSCILLATOR ALIGNMENT

1. Preset horizontal lock trimmer to one-half turn from full tight.
2. Connect receiver antenna terminals to source of test pattern signal of approximately 10,000 microvolts.
3. Adjust R-164 (horizontal hold) and/or T-108, horizontal frequency control to bring pattern into horizontal synchronization. Adjust all other controls for normal picture.
4. Connect oscilloscope, with 10 mmf in series, to terminal 4 of horizontal oscillator transformer. Adjust horizontal oscillator trap coil slug for waveform of Fig. 6. Readjust horizontal hold and/or horizontal frequency control as required to keep pattern in sync during this trap coil adjustment.
5. Disconnect scope lead.
6. Turn horizontal hold control fully counterclockwise.
7. Turn horizontal frequency adjustment out (counterclockwise) until picture is out of horizontal sync with diagonal bars sloping downward from left to right.
8. Turn horizontal frequency adjustment in (clockwise) until picture is just ready to fall in sync, as indicated by a wide balck vertical or diagonal bar.
9. Turn horizontal hold control clockwise until pattern falls out of sync. If pattern is still in sync at clockwise end of control, interrupt signal momentarily to knock picture out of sync.
10. Turn horizontal hold control slowly counterclockwise until picture just falls into sync. Observe number of diagonal bars present just before picture falls in sync.
11. If number of bars in step 10 is more than three, adjust horizontal lock control slightly clockwise. If number of bars in step 10 is less than two, adjust horizontal lock control slightly counter-clockwise.
12. Repeat steps 6 through 11 as required until number of bars in step 10 is two or three.
13. Check point on rotation of horizontal hold control at which picture just pulls in sync in step 10. Must be at least 60 degrees from maximum counterclockwise rotation.

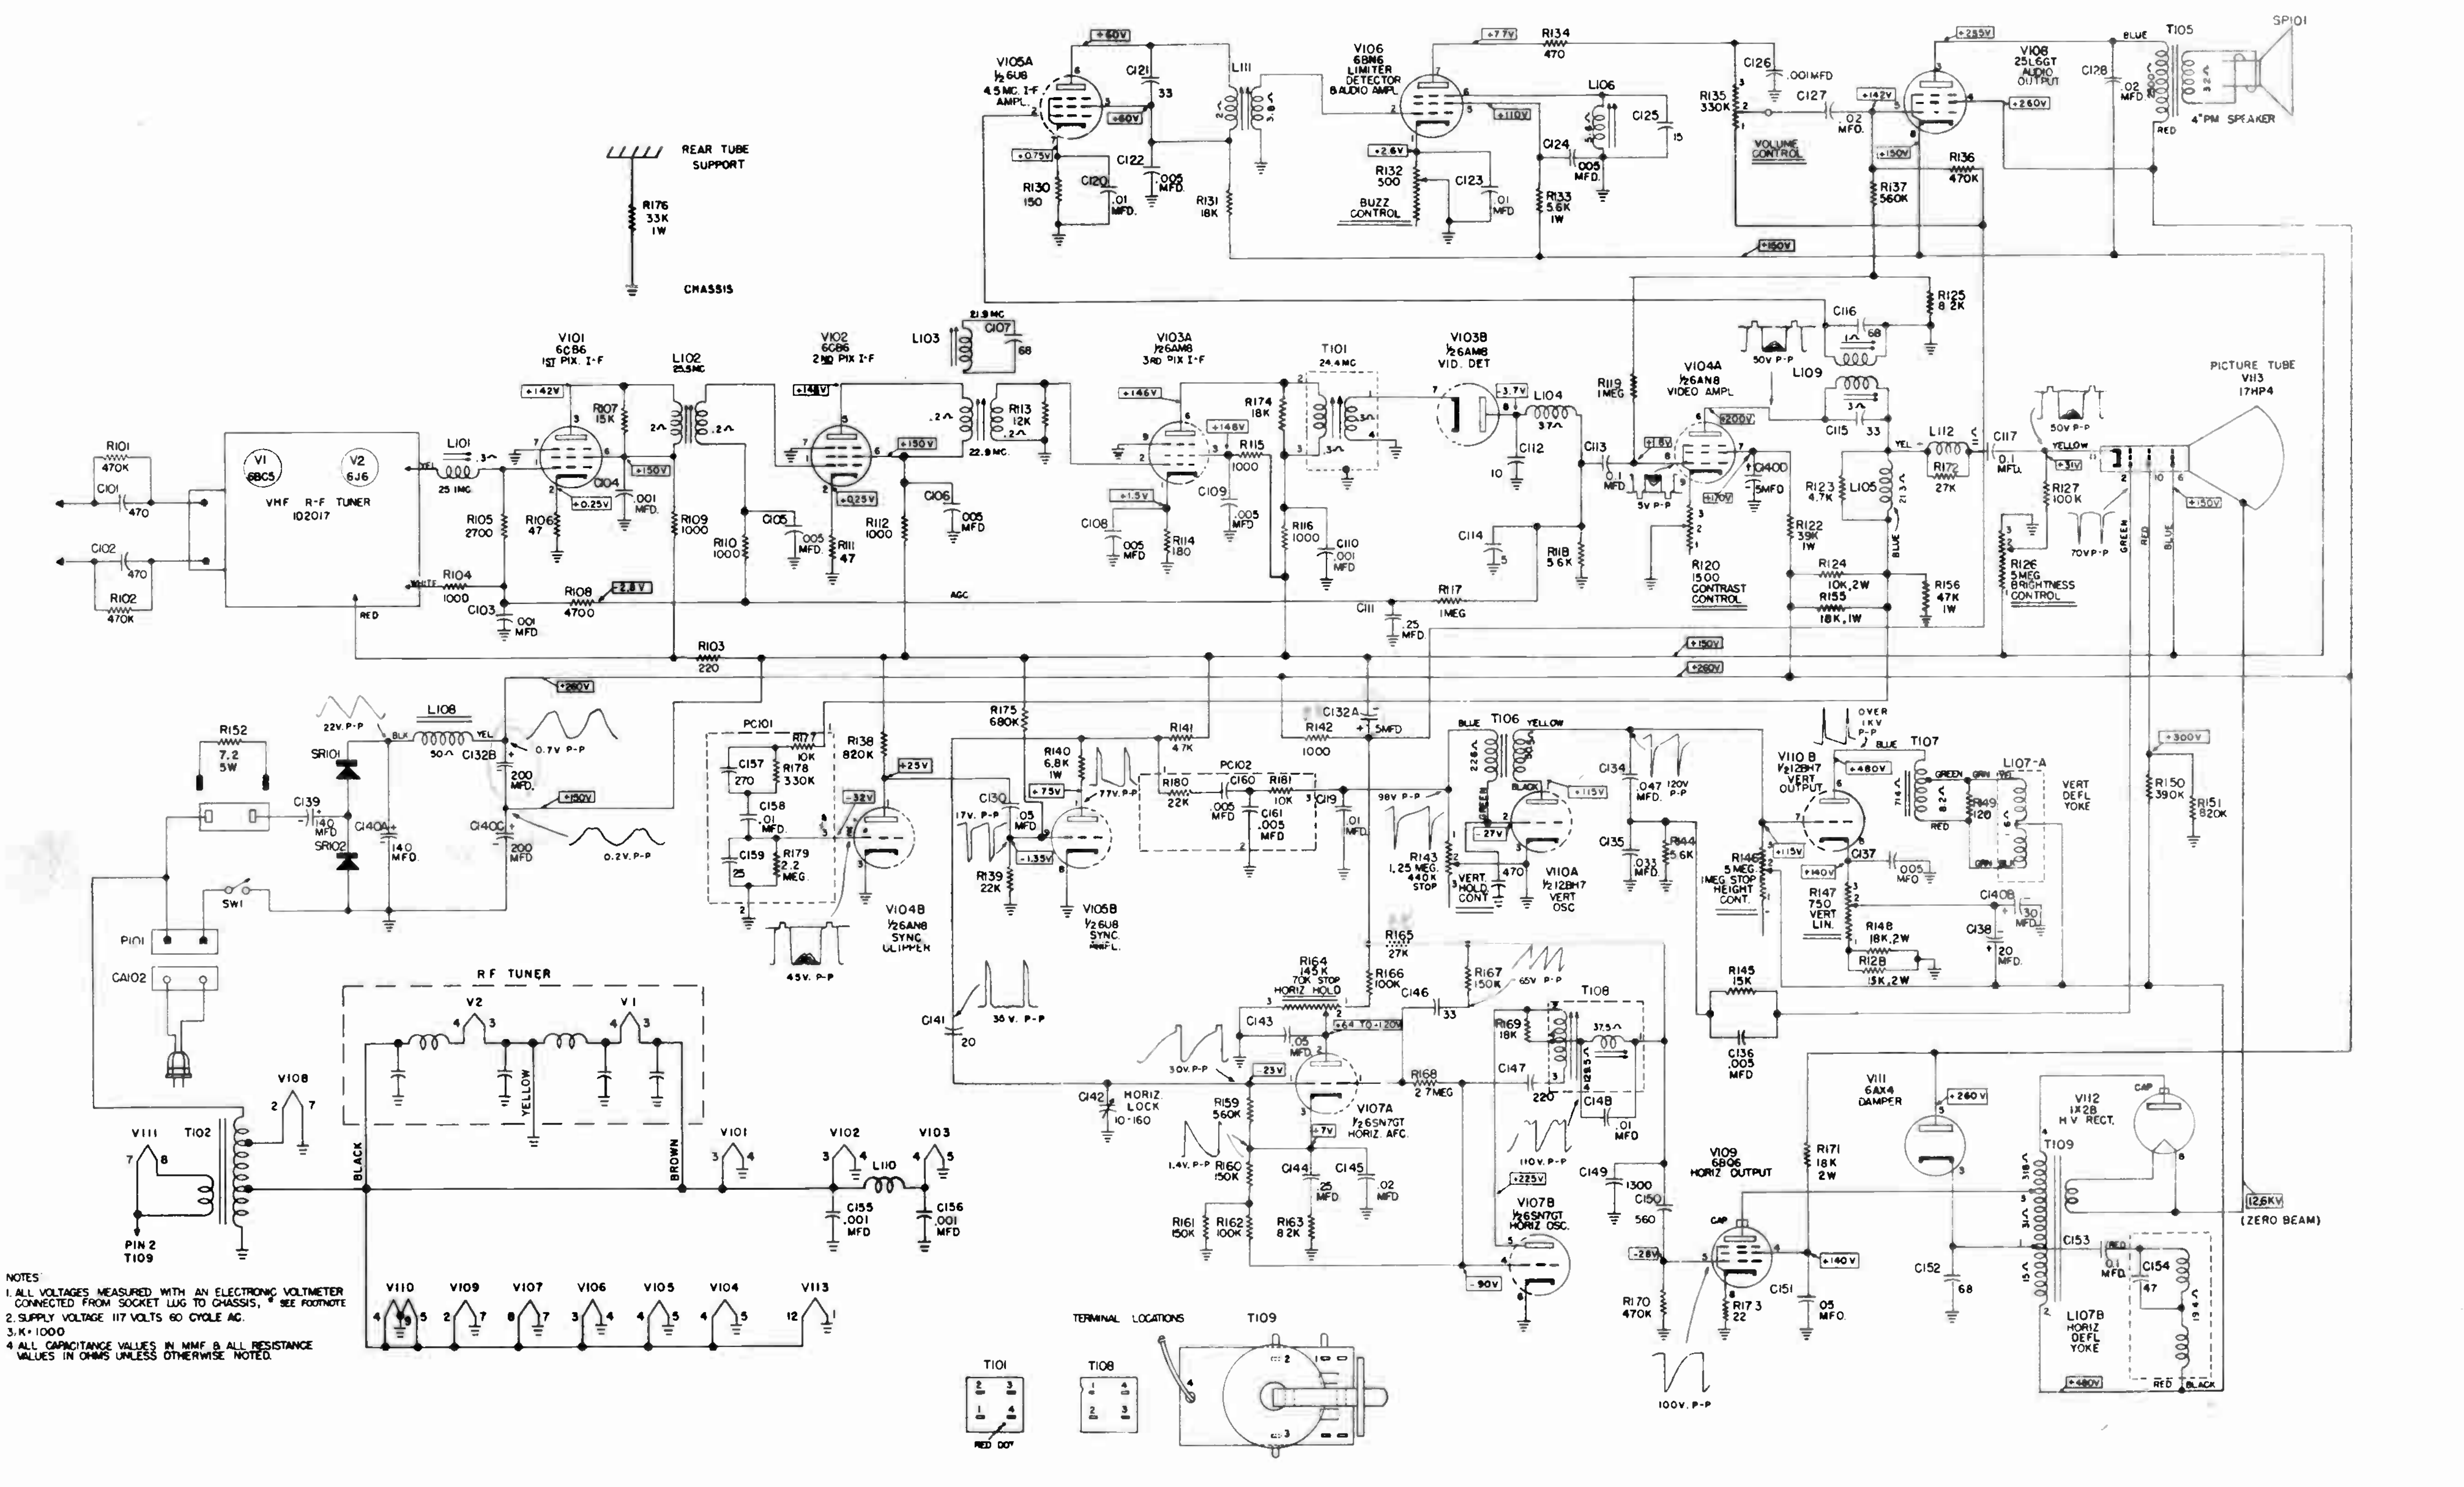
Cabinet back assembly; less snap-in pix tube shield	41A25599
Glass retainer clip	76A1260
Glass, safety	22C423
Knob, fine tuning	15D762
Knob, channel selector	15D761
Knob, control	15A775
Line cord and plugs	87B1668-1
Mask, picture tube	7C574
Shield picture tube	69C668
Speaker, 4" P.M. dynamic	35C175



NOTES:

1. ALL VOLTAGES MEASURED WITH AN ELECTRONIC VOLTMETER CONNECTED FROM SOCKET LUG TO CHASSIS, * SEE FOOTNOTE
2. SUPPLY VOLTAGE 117 VOLTS 60 CYCLE AC.
3. K=1000
4. ALL CAPACITANCE VALUES IN MMF & ALL RESISTANCE VALUES IN OHMS UNLESS OTHERWISE NOTED.

* SOME VOLTAGES ARE VARIABLE, & VOLTAGES SHOWN WERE MEASURED WITH A NORMAL PICTURE ON THE PICTURE TUBE AND THE CONTRAST AND BRIGHTNESS CONTROL SET FOR 50 VOLTS PEAK TO PEAK ON THE CATHODE (PIN 11) OF THE PICTURE TUBE. SOCKET VOLTAGE TOLERANCE ± 10%.

VALUES AND TOLERANCES SHOWN ARE NOMINAL AND VARIATIONS MAY BE FOUND. IT IS RECOMMENDED THAT THE VALUE OF ANY REPLACEMENT CORRESPOND TO THE NOMINAL VALUE OF THE PART BEING REPLACED.

GENERAL SPECIFICATIONS

TUBES	15 plus 2 Selinium Rect.
ANTENNA	Built-in or External
ANTENNA INPUT	300 Ohms
TUNING	12 Channels 2-13
PICTURE TUBE	17HP4
PICTURE CARRIER I-F	26.25 MC
SOUND CARRIER I-F	21.75 MC
SOUND I-F	4.5 MC
POWER SUPPLY	110-120 volts 60 cycles
POWER CONSUMPTION	150 watts

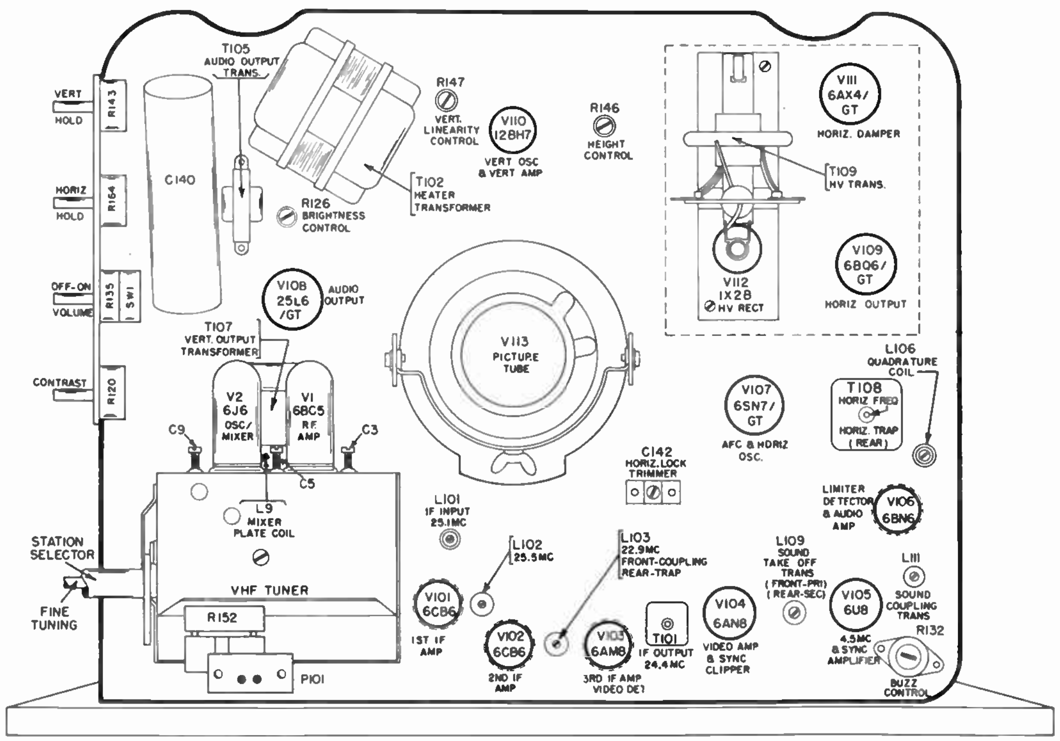

Fig. 2. Tube and Alignment Locations 1600D Chassis

GENERAL ALIGNMENT INSTRUCTIONS

1. Maintain AC supply voltage at 117 volts.
2. Disable horizontal output amplifier. (Example: by removing 6AX4 damper tube from socket.)
3. Use suitable resistance load (2250 ohms - 30 watts) to simulate DC current drain of horizontal output amplifier.

I-F ALIGNMENT

1. Turn tuner channel selector to Channel 13.
2. Connect sweep generator output to mixer grid through access hole provided for this purpose in side of tuner case. Use the shortest and most direct leads possible to make this connection.
3. Apply - 3 volts bias to IF AGC circuit.
4. Connect a detector and oscilloscope (See Fig. 4 for circuit) to plate (Pin 5) of 1st IF amplifier.
5. Adjust mixer plate coil and 1st IF amplifier grid coil as required to obtain the response curve shown in Fig. 7.
6. Remove detector and oscilloscope from plate of 1st IF amplifier tube.
7. Connect oscilloscope input across video detector load resistor, using 3300 ohm isolation resistor in series with "high" side.
8. Adjust remaining three IF coils as required to obtain a response curve within the specifications of Fig. 8. In order to accomplish this, it is necessary to:
   - a) tune the 1st IF amplifier plate coil (L102) toward the high frequency end of the desired pass band.
   - b) tune the 2nd IF amplifier plate coil (L103) toward the low frequency end of the desired pass band, keeping the trap coil on this coil form adjusted for a response minimum at 21.9 mc.
   - c) tune the third IF amplifier plate coil (T101) approximately to the center of the desired pass band.

NOTES

(1) The construction of some picture IF coils on the chassis proper is such that each has two positions of the tuning slug which may appear as proper tuning points. The sound trap on the 2nd IF amplifier plate coil (L103) should be tuned with the slug entering the coil from the end away from the chassis pan. All others should be tuned with the slug entering the coil from the end nearest the chassis pan.

(2) Care should be taken during all steps of the picture IF alignment to use a combination of oscilloscope gain and sweep generator signal level which will result in a response curve display of adequate size without overload.

SERVICE PARTS LIST

TRANSFORMERS AND COILS

Schematic Symbol	Description	Hallicrafters Part Number
T-101	Transformer, 1st I-F	50B573
T-102	Transformer, 2nd I-F	50B574
T-103	Transformer, 3rd I-F	50B575
T-104	Transformer, vertical blocking oscillator	55B190
T-105	Transformer, vertical output	55C192
T-106	Transformer, heater	52D290
T-106-1	Transformer, heater	52C258
*T-107	Transformer, horizontal output	55D223 or 55D235
T-107-1	Transformer, horizontal output	55D197
T-108	Transformer, ratio detector	50B473
T-109	Transformer, audio output	55C191

*T-107 (55D223) may be used with either 51B1788 or 51B1835 Width Coil
T-107 (55D235) may be used only with 51B1788 Width Coil

Schematic Symbol	Description	Hallicrafters Part Number
L-101	Coil, tuner I-F coupling	51B1643
L-101-1	Coil, tuner I-F coupling	51A1841
L-102	Coil, tweet filter	53A307
L-103	Coil, video peaking	51B1709 or 51B1838
L-104	Coil, video peaking	51B1710
L-105	Coil, A.G.C. network	53A304
L-106	Coil, video peaking; wound on R-125	51B1711
L-107	Coil, 4.5 mc. trap	51B1541
L-108	Coil, video peaking	51B1712
L-109	Coil, video peaking; wound on R-129	51B1713
L-110	Choke, heater	53A282
L-111	Choke, heater	53A282
L-113	Coil, horizontal stabilizer (includes C-147 & R-159)	51B1642
L-114	Coil, 4.5 mc. amplifier grid adj.	51B1542
L-115	Voice coil,; part of speaker	-----
L-116	Hum bucking coil; part of speaker	-----
L-117	Field coil; part of speaker	-----
L-118	Deflection coils	53C303
L-118-1	Deflection coils	53A271
L-118-2	Deflection coils	53C320
L-119	Coil, yoke coupling; wound on C-172	-----
L-120	Coil, width control	[redacted] 51B1835
L-121	Choke, damper tube	53A307
L-401	Coil, coupling; input cascode amplifier	51A1754
L-402	Coil, neutralizing; cascode I-F amplifier	51A1755

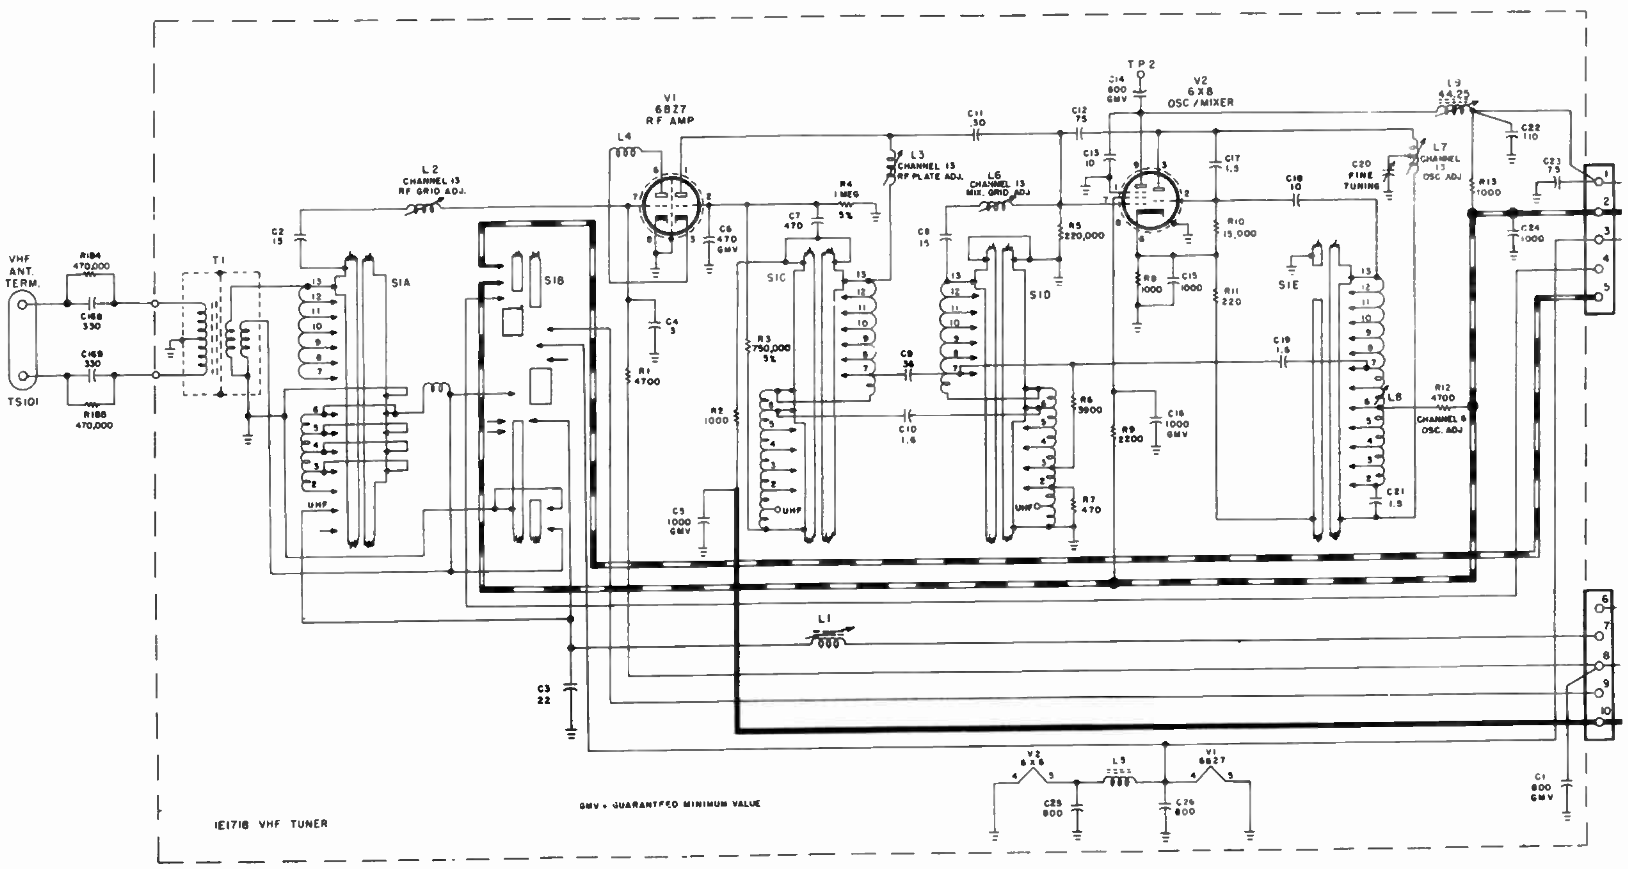
1E1855 UHF Tuner

PICTURE TUBE REMOVAL

1. Remove the chassis from the cabinet. Note that on chassis with the horizontal and vertical hold controls on the rear apron the knobs on the control shafts and the A.G.C. control switch must be removed before the cabinet back may be removed. These are push-on type knobs.
2. Insure the discharge of the high voltage power supply by disconnecting the anode plug and shorting it to the chassis. Also short the anode socket or metal cone of the picture tube to the chassis.
3. Remove the picture tube socket from the base of the tube.
4. Slip the ion trap and the centering device from the neck of the tube. On some chassis, the centering device is an integral part of the deflection yoke assembly.
5. Carefully remove the rear support tension spring on each side of the picture tube. If a glass cone picture tube is involved, remove the metalized paper picture tube shield and ground by unhooking the springs on each side and the hook on the top center of the picture tube mounting strap.
6. Remove the mounting strap from the front rim of the picture tube.
7. Lift the front of the picture tube just far enough to clear the front mounting brackets and slip the tube forward until the neck is clear of the deflection yoke and the rubber collar. Use a slight twisting pull to break the cone of the tube from the rubber collar if the two are stuck together. Loosen the deflection yoke adjustment screw if required for clearance when raising the front of the picture tube over the front mounting brackets.

CAUTION - IF THE TUBE FAILS TO SLIP OUT EASILY, INVESTIGATE AND REMOVE THE CAUSE OF TROUBLE. DO NOT USE FORCE AS THE NECK OF THE PICTURE TUBE IS EASILY BROKEN.



SERVICE ADJUSTMENTS

VERTICAL AND HORIZONTAL HOLD CONTROLS - These two controls should be adjusted until a single steady picture is obtained. With average signal strength it should be possible to switch from one active channel to another without losing sync when these two controls are properly adjusted. These two controls will be found on the front apron of some chassis.

CENTERING — (C1300D & D1300D Chassis only)

Place the horizontal centering control, located on the rear apron of the chassis, in the approximate center of its range. Rotate the two ring magnets by the ears around the neck of the picture tube until the picture is properly centered. Slight readjustment of the ion trap may then be necessary. The horizontal centering control may now be used for fine adjustment.

(A1300D, B1300D, H1300D, & J1300D Chassis only)

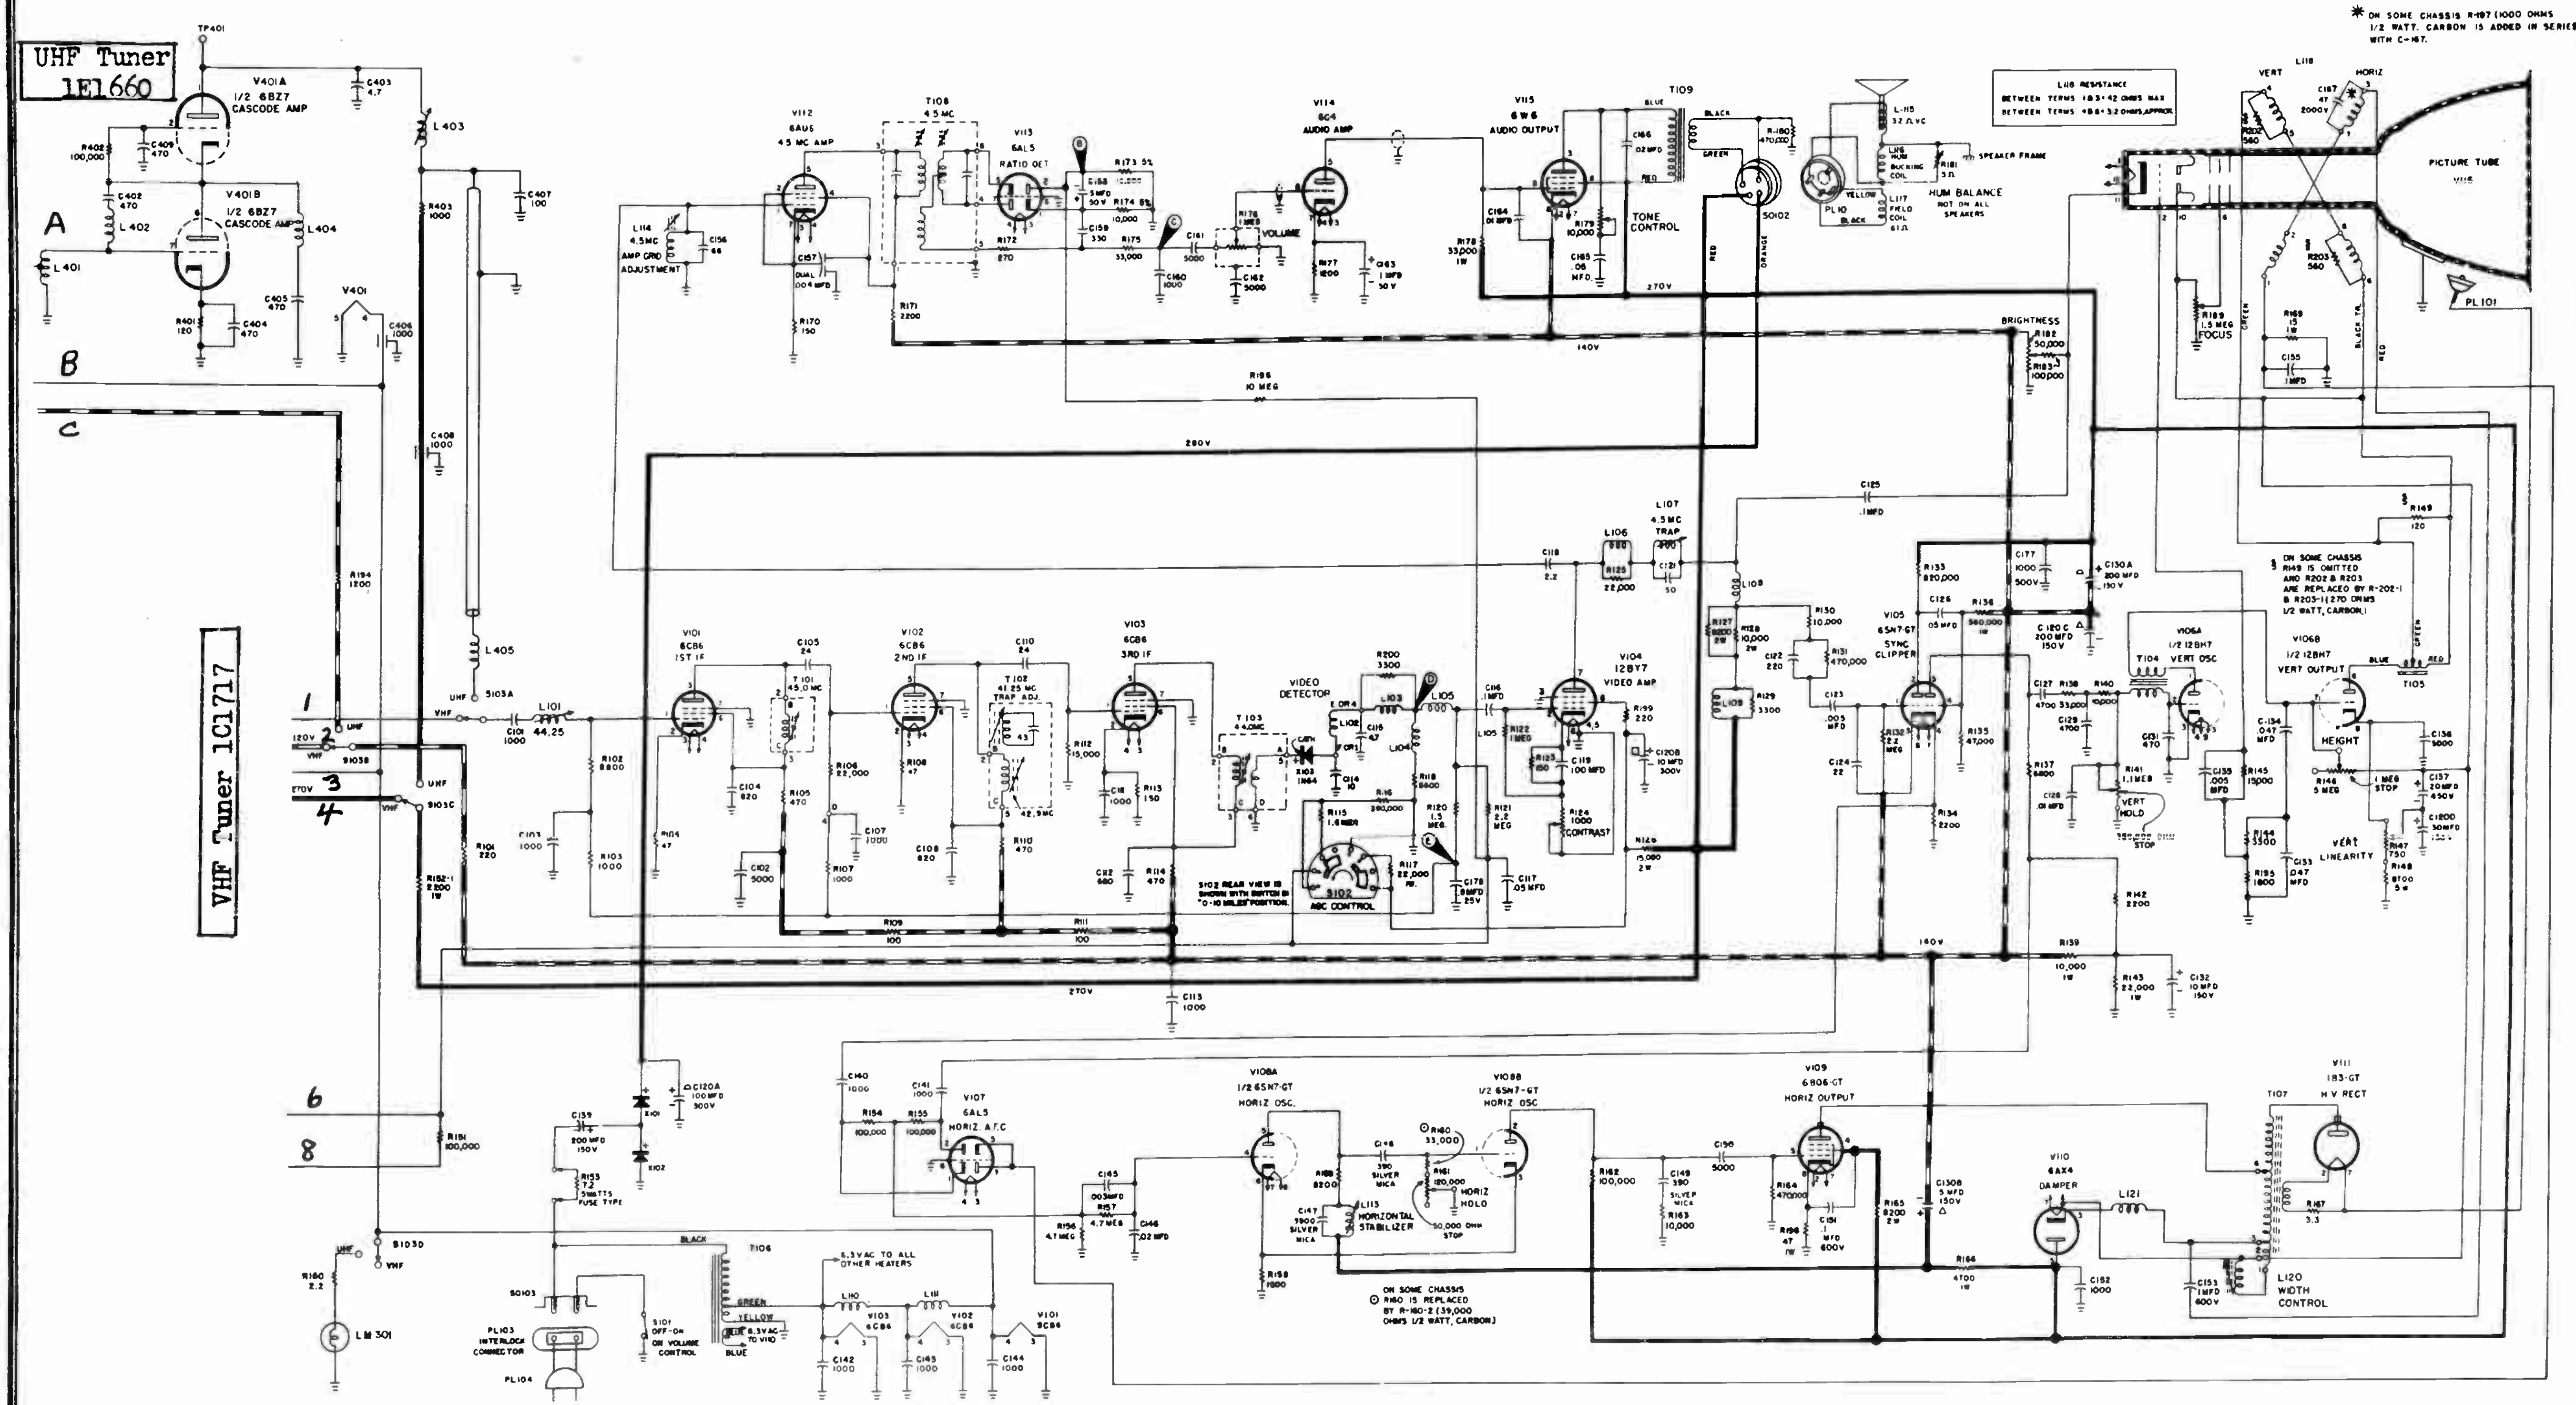
Same as above except horizontal control on rear apron omitted.

(E1300D & F1300D Chassis only)

Move the centering lever a short distance in any direction, up or down, or to either side. Slight readjustment of the ion trap setting may then be necessary.

HEIGHT CONTROL AND VERTICAL LINEARITY ADJUSTMENT - A test pattern will be required for the proper adjustment of these two controls. The height control has a pronounced effect on the overall picture height and at the same time the adjustment of this control will expand or contract the top of the picture more than the bottom. The vertical linearity control will affect the height somewhat but will have a more pronounced effect on the bottom portion of the picture. The interaction between these two controls makes it necessary to adjust both for proper picture height and vertical linearity.

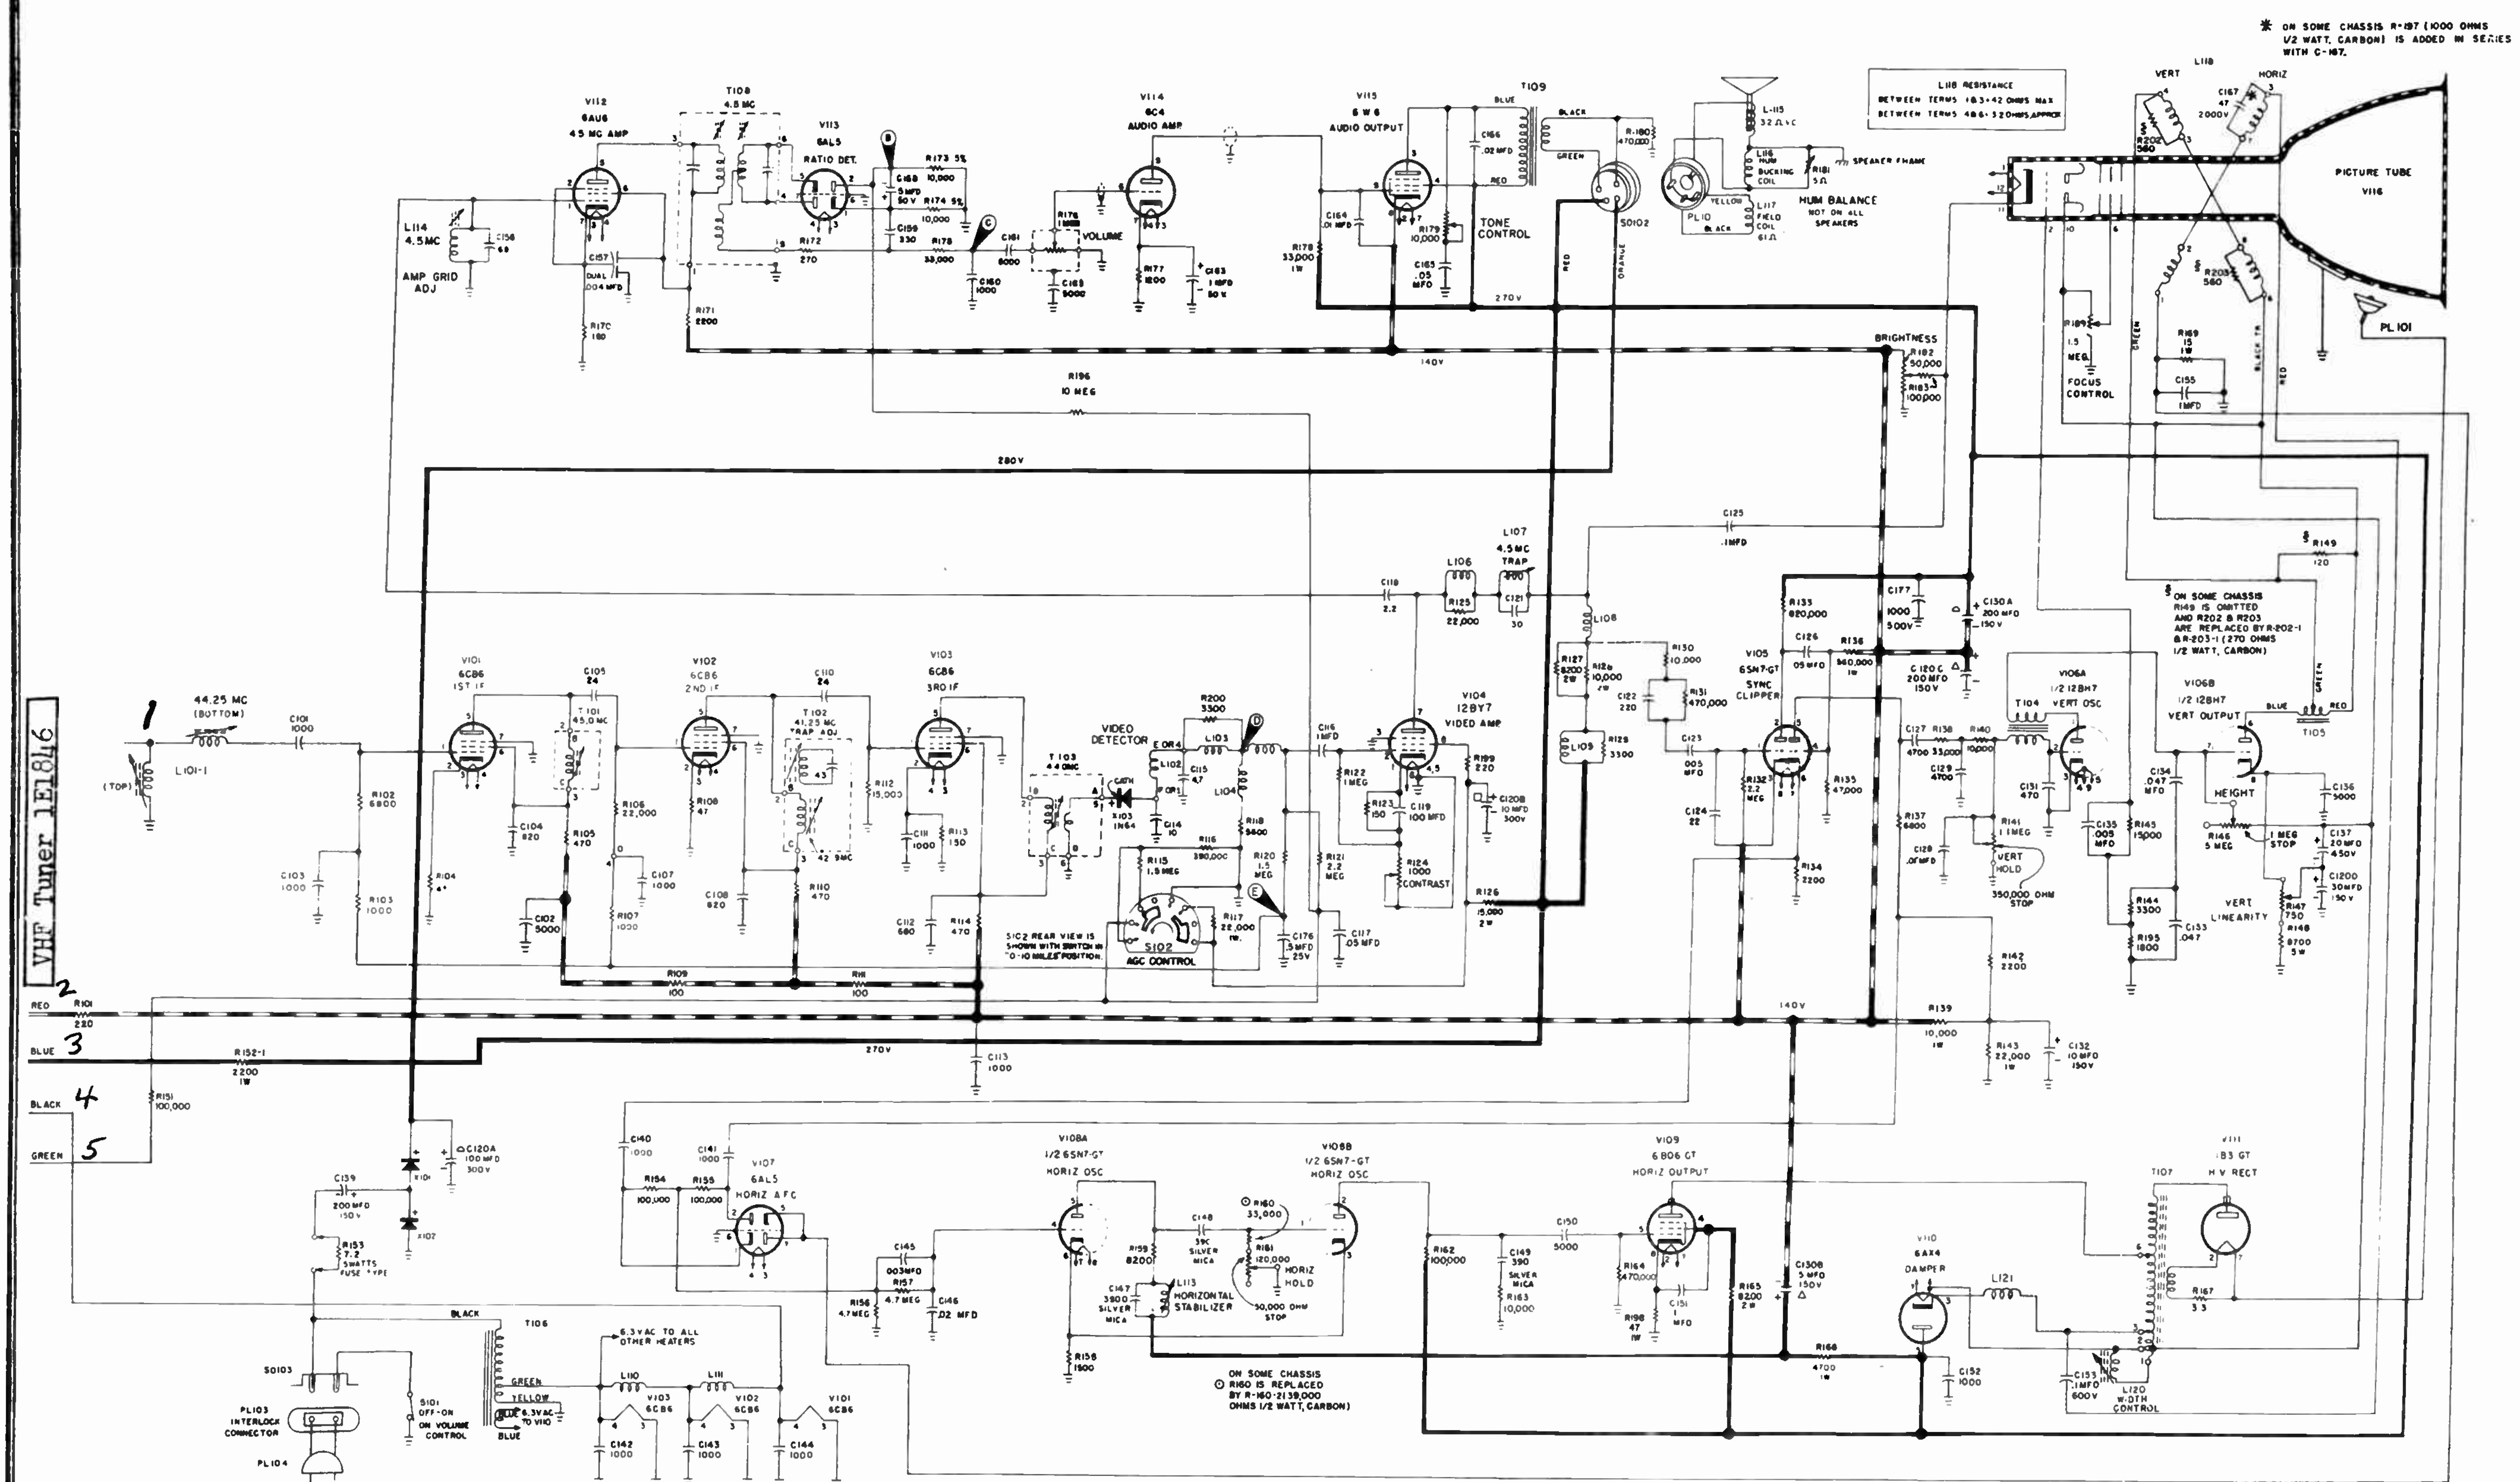
1. CAPACITOR VALUES ARE IN MMF UNLESS OTHERWISE SPECIFIED.
2. RESISTOR VALUES ARE IN OHMS & HAVE 1/2 WATT RATING UNLESS OTHERWISE SPECIFIED.
3. 270 VOLT B+ LEADS SHOWN IN HEAVY SOLID LINES
4. 140 VOLT B+ LEADS SHOWN IN HEAVY BROKEN LINES
5. DO NOT MEASURE VOLTAGES ON PLATE OF V109. PEAK VOLTAGES PRESENT MAY DAMAGE TEST EQUIPMENT.



VALUES AND TOLERANCES SHOWN ARE NOMINAL AND VARIATIONS MAY BE FOUND. IT IS RECOMMENDED THAT THE VALUE OF ANY REPLACEMENT CORRESPOND TO THE NOMINAL VALUE OF THE PART BEING REPLACED.

VHF-UHF
17" CHASSIS

B1300D
RUN 1



ON ALL (-2) RUNS OF ALL CHASSIS THE FOLLOWING CHANGES ARE MADE:

A. T-106 IS REPLACED BY T-106-1 (52C258) WHICH INCLUDES 12V. LEAD.
B. V-105 IS REPLACED BY V-105-1 (12SN7GT).
C. R-198 (47 OHMS 1 WATT, CARBON) DELETED.

ON J1300D CHASSIS THE FOLLOWING CHANGES HAVE BEEN MADE:

A. C-150 IS REPLACED BY C-150-2 (1000 MMF. 500 V., CERAMIC DISC.)
B. C-151 IS REPLACED BY C-151-1 (.047 MFD. 400 V., PAPER TUBULAR.)
C. R-160 IS REPLACED BY R-160-3 (56,000 OHMS 1/2 WATT, CARBON.)
D. R-161 IS REPLACED BY R-161-1 WHICH IS IDENTICAL TO R-161 EXCEPT FOR DELETION OF 50,000 OHM STOP.
E. L-118 DEFLECTION YOKE IS REPLACED BY L-118-2 (53C320)

BAND PASS ALIGNMENT OF 1C1717 TV TUNERS

CAUTION: Band pass alignment is carefully made at the factory. Attempt this alignment only with proper equipment and set-up. The tube shields and the bottom cover for the tuner must be in place. The oscillator adjustment given on page 1954-29 must be completed before the band pass alignment is started.

1. Complete the set-up procedure given on page 1954-29.
2. Connect the leads from the sweep and marker generators to the tuner antenna terminals.
3. Turn the channel selector to channel 13. Adjust the generators to the correct frequencies for channel 13 as shown in the chart on page 1954-25.
4. Adjust L-3 (channel 13 rf plate), and L-6 (channel 13 mixer grid) adjusting screws (see Fig. 29B) for a band pass characteristic containing both carriers with steep sides and maximum gain.

If the factory adjustment of the incremental loops and coils has not been disturbed, alignment on the rf plate, rf grid, and mixer grid should be complete after the completion of step 4 unless extensive repairs have been made on the tuner. Check the other channels for a similar band pass characteristic as shown in Fig. 30A. If they have the correct characteristics further alignment is not necessary. If they do not, repeat step 4 and adjust L-2 by spreading or compressing the turns of the coil before continuing with steps 5 and 6.

5. Adjust the coils of the rf plate, rf grid, and mixer grid for channels 12 through 7 starting with channel 12. Adjust the signal generators for each channel to the frequencies given in the chart on page 1954-25. Pushing the half turn coil loops towards the center of the switch so that they are closer to the switch wafer will increase the frequency while pulling them out and away from the switch wafer will decrease the frequency. Adjust for a band pass characteristic containing both carriers with steep sides and maximum gain.
6. Adjust the coils of the rf plate, rf grid, and mixer grid for channels 6 through 2 starting with channel 6. Adjust the signal generators for each channel to the frequencies given in the chart on page 1954-25. Spreading the turns of the coils will increase the frequency while squeezing the turns together will decrease the frequency. Adjust for a band pass characteristic containing both carriers with steep sides and maximum gain. A tuning wand may be used to determine what change is necessary.

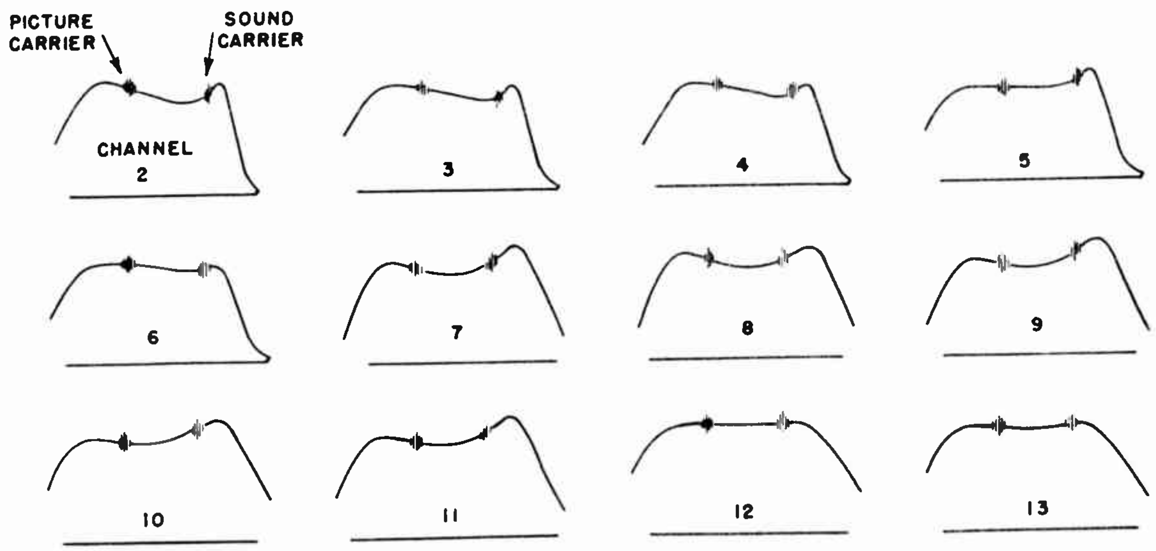

Fig. 30A. Typical Channel Response Curves for TV Tuners

ALIGNMENT OF THE 1E1660 AND 1E1855 UHF TUNERS

These tuners have been carefully aligned at the factory by personnel using precision equipment. Minor adjustments of the tuner may be necessary after making tube or part replacement. When replacing tubes in a tuner use the same tube type as the original tube which was removed. It is advisable to try several tubes and select the one that gives the best performance. Realignment of the tuner will probably not be required if a selected tube is used for replacement. For those service engineers who are properly equipped as specified, the following alignment procedure is included. DO NOT ATTEMPT THIS PROCEDURE UNTIL THE TV RECEIVER IS KNOWN TO BE FUNCTIONING PROPERLY AND THE I-F ALIGNMENT IS CORRECT.

THE HALLICRAFTERS SERVICE DEPARTMENT PROVIDES A TUNER EXCHANGE SERVICE FOR A NOMINAL FEE. THE SERVICE TECHNICIAN IS URGED TO AVAIL HIMSELF OF THAT SERVICE RATHER THAN TO ATTEMPT FIELD ALIGNMENT OF THESE TUNERS.

OSCILLATOR ALIGNMENT

Step	Signal Generator Connection	Frequency	Output Connection	Adjust	Comments
1	Through circuit of Fig. 31A to junction of L304 & L305 (1E1660) or diode clip nearest oscillator section (1E1885)	945.0 mc. or 475.5 mc. (2nd. harmonic) or 236.25 mc. (4th harmonic)	Detector network of Fig. 31B to T.P. 401 on Cascode amplifier. Output of detector to Vertical Input of Score.	C-309 for zero beat on scope, signal tracer, or hi gain audio amp.	With VHF/UHF switch in UHF position set UHF Tuner rotor to full clockwise position (maximum freq.). Use a long screwdriver through hole in Tuner cradle. Use only sufficient output from Signal Generator to give zero beat. Large Signal Generator output may cause UHF oscillator to "pull" and mixer crystal to burn out.
2	Through circuit of Fig. 31A to junction of L304 & L305 (1E1660) or diode clip nearest oscillator section (1E1855)	504.0 mc. or 252.0 mc. (2nd. harmonic) or 126.0 mc. (4th harmonic)	Detector network of Fig. 31B to T.P. 401 on Cascode amplifier. Output of detector to Vertical Input of Scope.	See comments.	With VHF/UHF switch in UHF position set UHF Tuner rotor to full counterclockwise position (minimum freq.) **1E1660** Zero beat must occur at 504.0 mc. ± 3 MC. If it does not, repeat step 1 with new 6J6 tube. **1E1855** Adjust C305 for zero beat at 504.0 mc. Repeat steps 1 and 2 until satisfactory. After completing alignment, replace crystal shield.

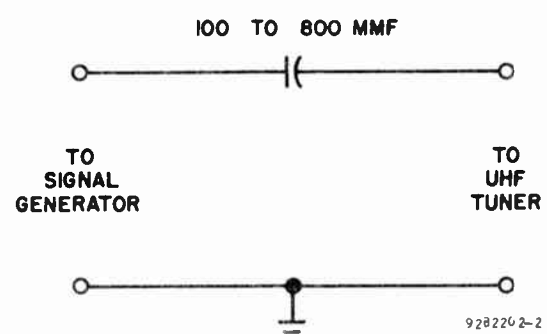

Fig. 31A. Sweep Generator Coupling

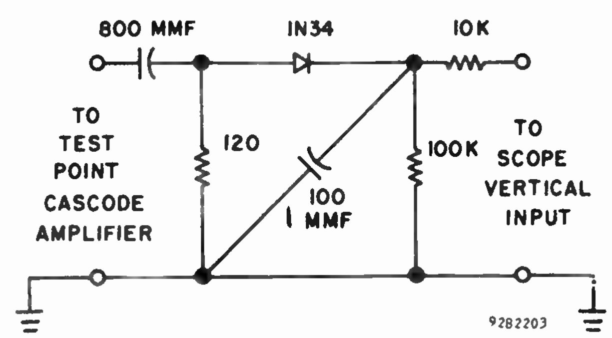

Fig.31 B. Detector Circuit

BAND-PASS ALIGNMENT FOR 16 POSITION VHF TUNERS 1E1483, 1E1670, & 1E1718

DO NOT ATTEMPT THIS ALIGNMENT UNTIL THE I-F ALIGNMENT OF THE RECEIVER HAS BEEN CHECKED AND IS KNOWN TO BE CORRECT. THE OSCILLATOR ADJUSTMENT PROCEDURE GIVEN ON PAGE 1954-26 MUST ALSO BE COMPLETED BEFORE STARTING THIS ALIGNMENT.

1. Connect the balanced sweep output from a signal generator to the VHF tuner antenna terminals through the 300 ohm pad shown in Fig. 26A. Set the sweep generator for 20 MC or maximum sweep.

2. Connect the negative side of the $1\frac{1}{2}$ volt bias supply through a 1000 ohm resistor to terminal 8 of the VHF tuner. Connect the positive side of the bias supply to the chassis.

3. Connect the oscilloscope and band-pass detector circuit shown in Fig. 18A to Test Point TP-2 shown in Fig. 27B.

4. Set the VHF tuner channel selector to channel 13.

5. Loosely couple the high side of the marker generator to the band-pass detector circuit by clipping the lead over the germanium diode in the detector circuit. Connect the ground side of the generator to the chassis of the VHF tuner.

6. Set the sweep generator for channel 13 and turn the VHF tuner channel selector to channel 13.

7. Adjust L-2 (channel 13 r-f grid), L-3 (channel 13 r-f plate), and L-6 (channel 13 mixer grid) adjusting screws (see Fig. 27B) for a band pass characteristic containing both carriers with steep sides and maximum gain. See curves shown on page 1953-26. The r-f grid adjustment (L-2) must be adjusted for maximum mid-band gain regardless of the shape of the skirts. The slope and position of the skirts are primarily controlled by the r-f plate adjustment (L-3) while the mixer grid adjustment (L-6) controls the slope of the flat topped portion of the curve. Always adjust to place the picture carrier marker on a peak of the curve.

If the factory adjustment of the incremental loops and coils has not been disturbed, alignment of the r-f plate, r-f grid and mixer grid should be complete after the completion of step 7, unless extensive repairs have been made on the tuner. Check the other channels for a similar band-pass characteristic as shown in Fig. 27A. If they have the correct characteristics further alignment is not necessary. If they do not, proceed with the following steps.

8. Adjust the coils of the r-f plate, r-f grid and mixer grid for channels 12 through 7 starting with channel 12. Adjust the signal generators for each channel to the frequencies given in the chart on page 1954-25. Pushing the half turn incremental loops toward the center of the switch so that they are closer to the switch wafer will increase the frequency while pulling them out and away from the switch wafer will decrease the frequency. Always adjust the r-f grid coils for maximum mid-band gain and the r-f plate and mixer grid coil loops as outlined in step 7.

9. Adjust the coils of the r-f plate, r-f grid and mixer grid for channels 6 through 2 starting with channel 6. Adjust the signal generators for each channel to the frequencies given in the chart on page 1954-25. Spreading the turns of the coils will increase the frequency while squeezing the turns together will decrease the frequency. Always adjust the r-f grid coils for maximum mid-band gain and the r-f plate and mixer grid coil loops as outlined in step 7.

10. Repeat step 7 as final adjustment for channel 13.

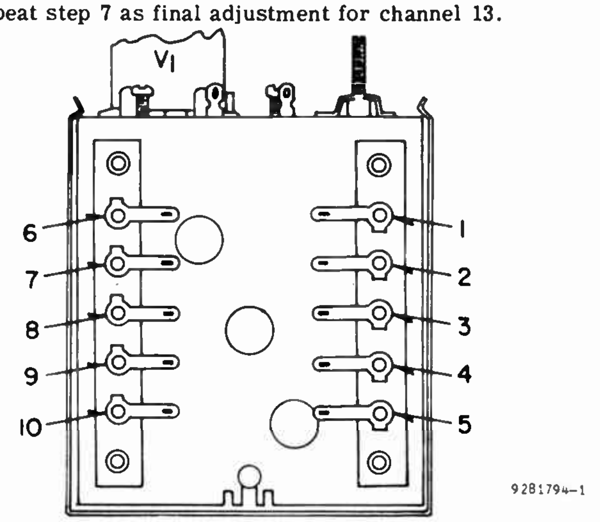

Fig. 28A. Numbering of Tuner Terminals

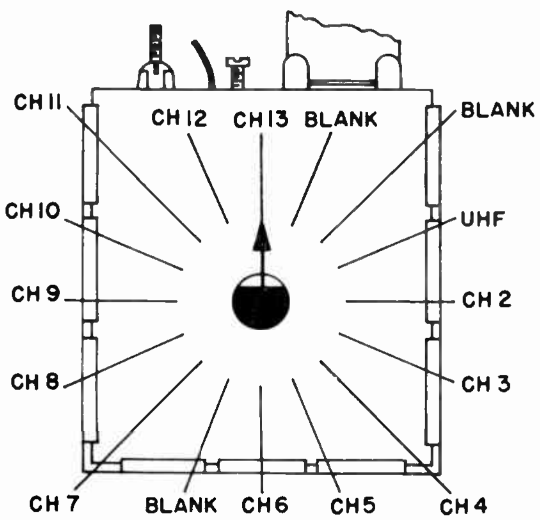

Fig. 28B. Channel Selector Switch Positions

ALIGNMENT FOR 1C1717 12 POSITION VHF CASCODE TUNERS

These tuners have been carefully aligned at the factory by personnel using precision equipment. Minor alignment adjustments of the tuner may be necessary after making tube or part replacements. When replacing tubes in a tuner use the same tube type as the original tube which was removed from the tuner and also try several different tubes and select the one which gives best performance. Realignment of the tuner probably will not be required if a selected tube is used for replacement. Use of an alternate tube may require a complete realignment of the TV tuner. For those service engineers who are properly equipped as specified, the following alignment procedure is included. Balance of TV receiver must be functioning properly before aligning tuner.

EQUIPMENT REQUIRED FOR TV TUNER ALIGNMENT

1. Sweep generator .... RCA type WR-59B or equiv.
2. Marker Generator .... RCA type WR-39C Television Calibrator or equivalent.
3. Oscilloscope .... RCA type WO-56A or equiv.
4. Bias Source .... 1.5 volt battery.
5. Isolation Transformer .... 150 watt rating or higher

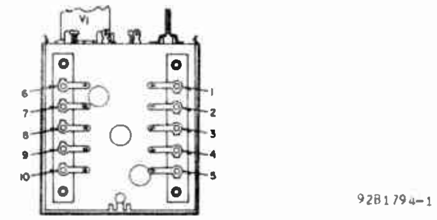

Fig. 29A. Numbering of Tuner Terminals

SET-UP PROCEDURE FOR TUNER ALIGNMENT

1. Check to be sure that the tube shields and the bottom cover for the tuner are in place.
2. Connect all test equipment and the television chassis to a common ground. Be sure to use an isolation transformer for the receiver chassis. Allow at least a 5 minute warm-up period for the receiver chassis.
3. Connect the negative terminal of a 1.5 volt bias source through a 1.000 ohm resistor to terminal 8 of the TV tuner. See Fig. 29A for terminal numbering. Connect the positive side of the bias source to any convenient ground point on the chassis.
4. Connect the hot lead from the oscilloscope through a 10,000 ohm carbon resistor to test point T.P.-1. See figure 29B. Connect the ground lead from the oscilloscope to any convenient ground point on the TV tuner chassis. Set the scope sweep oscillator to roughly 120 cycles.

OSCILLATOR ADJUSTMENT

1. Turn the channel selector to channel 13
2. Set the marker generator to 257 mc. and connect generator leads to the antenna terminals.
3. Rotate the fine tuning control until a zero beat is indicated on the scope. When the fine tuning control is rotated a band will appear across the face of the scope. As the point of zero beat is approached this band will increase in amplitude and then decrease sharply until a minimum is reached which is the point of zero beat. If the fine tuning control is rotated farther in the same direction the amplitude of the band will increase sharply and then decrease. The point of zero beat should fall in the approximate center of the range over which the fine tuning control may be rotated. If it does not, set the fine tuning control at the approximate center of its range and adjust L-7 (Channel 13 Oscillator Adjustment) for the zero beat. Do not disturb the setting of the fine tuning control after this adjustment.
4. Set the channel selector to channel 6.
5. Set the marker generator to 129 mc.
6. Adjust L-8 (Channel 6 Oscillator Adjustment) for the zero beat indication on the scope.

NOTE: Adjustment of the channel 13 and channel 6 oscillator coils automatically brings all other channel into adjustment. The adjustment screws cover their entire electrical range within eight full revolutions counterclockwise from the tight position. Any further rotation of these screws may cause them to fall out. Counterclockwise rotation of the screws will decrease the oscillator frequency. Best results will be obtained if a non-metallic screwdriver is used.

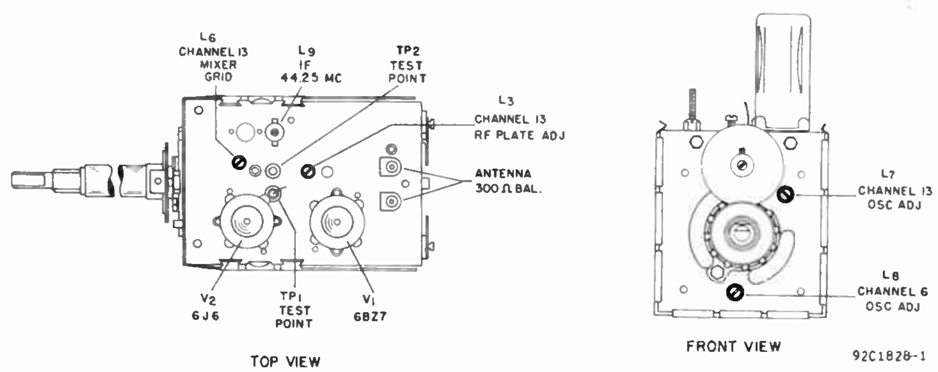

Fig. 29B. 1C1717 Cascode TV Tuner Alignment Adjustments

ALIGNMENT FOR 1E1483, 1E1670, & 1E1718 VHF 16 POSITION CASCODE TUNERS

These tuners have been carefully aligned at the factory by personnel using precision equipment. Minor adjustments of the tuner may be necessary after making tube or part replacements. When replacing tubes in a tuner use the same tube type as the original tube which was removed from the tuner and also try several different tubes and select the one which gives best performance. Realignment of the tuner probably will not be required if a selected tube is used for replacement. For those service engineers who are properly equipped as specified, the following alignment procedure is included. DO NOT ATTEMPT TUNER ALIGNMENT UNTIL THE TV RECEIVER IS KNOWN TO BE FUNCTIONING PROPERLY AND THE I-F ALIGNMENT OF THE RECEIVER IS CORRECT.

EQUIPMENT REQUIRED FOR VHF TUNER ALIGNMENT

Sweep Generator	RCA type WR-59B or equiv.
Marker Generator	RCA type WR-39C or equiv.
Oscilloscope	RCA type WO-56A or equiv.
Bias Source	$1\frac{1}{2}$ volt battery or equiv.
Detector Circuit	See Fig. 18A.
Isolation Transformer	150 watt rating or higher

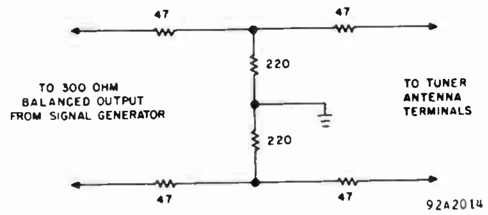

Fig. 26A. Sweep Generator 300 Ohm Pad

OSCILLATOR ADJUSTMENT FOR 16 POSITION TUNERS

1. Connect the balanced sweep output from a signal generator to the VHF tuner antenna terminals through the 300 ohm pad shown in Fig. 26A. Set sweep generator for 20 MC or maximum sweep.

2. Connect the negative side of $1\frac{1}{2}$ volt bias supply through a 1000 ohm resistor to terminal 8 of the VHF tuner. Connect the positive side of the bias supply to the chassis.

3. Connect the oscilloscope and band-pass detector circuit shown in Fig. 18A to Test Point TP-2 shown in Fig. 27B.

4. Set the VHF tuner channel selector to channel 13.

5. Loosely couple the high side of the marker generator to the antenna input terminals by clipping the lead over the insulation of one sweep generator lead. Connect the ground side of the generator to the chassis of the VHF tuner. Set the marker generator to the channel 13 picture carrier frequency of 211.25 MC.

6. Carefully note the position of the marker pip on the response curve. Use a grease pencil if necessary to mark the position on the face of the cathode ray tube.

7. Loosely couple the high side of the marker generator to the band-pass detector circuit by clipping the lead over the germanium diode in the detector circuit. Connect the ground side of the generator to the chassis of the VHF tuner. Set the marker generator to 45.75 MC.

8. Rotate the fine tuning control of the VHF tuner until the 45.75 MC marker is in the same spot as the marker in steps 5 and 6. If this cannot be accomplished by adjustment of the fine tuning control, adjust the channel 13 oscillator adjustment (L-7) to position the 45.75 MC marker. DO NOT DISTURB THE SETTING OF THE FINE TUNING CONTROL AFTER THIS ADJUSTMENT.

9. Switch the VHF tuner channel selector and sweep generator to channel 12.

10. Repeat steps 5 and 6 except use the picture carrier frequency for channel 12 (205.25 MC) in step 5.

11. Repeat step 7 using the same marker frequency of 45.75 MC.

12. Adjust the incremental oscillator coil for the channel until the 45.75 MC marker pip is in the same position on the curve as the marker pip for the picture carrier was in step 10.

13. Repeat steps 9, 5, 6, 7 and 12 for channels 11, 10, 9, 8 and 7 in that order. In each case switch the channel selector and sweep generator to the channel being aligned. The marker generator frequency for step 5 will be the picture carrier frequency for the channel being aligned. See the chart on page 1954-25 for the picture carrier frequency of each channel:

14. Switch the channel selector and sweep generator to channel 6 and repeat steps 5 and 6 except use the picture carrier frequency for channel 6 (83.25 MC) in step 5.

15. Repeat step 7 using the same marker frequency of 45.75 MC.

16. Adjust the channel 6 oscillator adjustment until the 45.75 MC marker pip is in the same position on the curve as the marker pip in step 14. See Fig. 27B.

17. Repeat step 9, 5, 6, 7 and 12 for channels 5, 4, 3 and 2 in that order. In each case switch the channel selector and sweep generator to the channel being aligned. The marker generator frequency for step 10 will be the picture carrier frequency for the channel being aligned. See the chart on page 1954-25 for the picture carrier frequency of each channel.

NOTE: If two marker generators are available the alignment can be greatly simplified by using one generator for the picture carrier marker and the other for the 45.75 MC marker. Both generators are connected to the receiver at all times as directed in the above instructions. The use of two generators will produce two pips on the pattern. The adjustments outlined above will make these two pips coincide on the oscilloscope pattern.

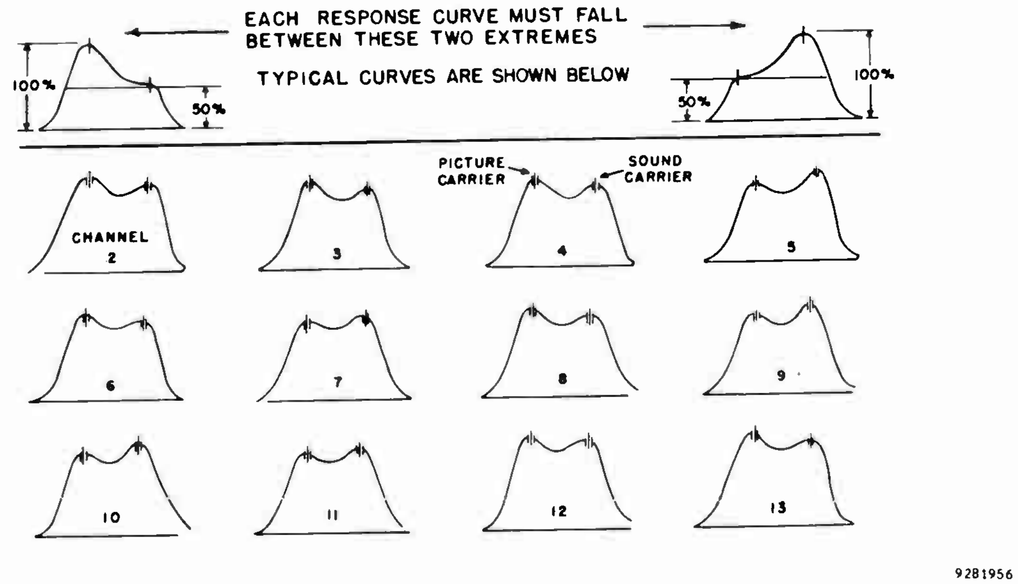

Fig. 27A. 16 Position VHF Tuner Typical Channel Response Curves

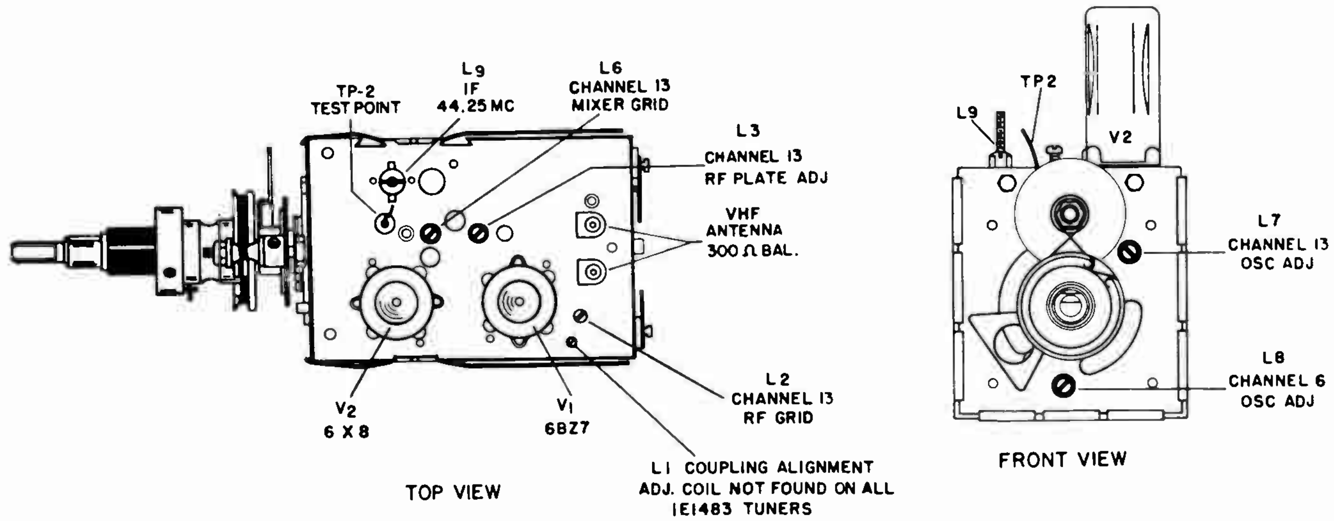

Fig. 27B. Alignment Adjustments for 1E1483, 1E1670, or 1E1718 Tuners

ALIGNMENT OF 1E1846 & 1B1969 CASCODE VHF TUNERS

SET-UP PROCEDURE FOR TUNER ALIGNMENT

1. Set the channel selector switch to channel 13.
2. Connect the oscilloscope through a 10,000 ohm carbon resistor to the test point on the top of the tuner chassis.
3. Connect the negative side of the bias source through a 1000 ohm isolation resistor to the terminal where the AGC (green wire) lead from the tuner is connected. Connect the positive side of the bias source to the receiver chassis.
4. Set the fine tuning control at the approximate midpoint of its tuning range.
5. Connect the sweep generator to the antenna terminals through the balanced pad shown in Fig. 19B and adjust the output to sweep channel 13.
6. Couple the output from the marker generator to the antenna circuit by connecting the hot lead from the generator to the junction of the four 220 ohm resistors of the pad shown in Fig. 19B. Connect the ground lead to the r-f tube shield in the VHF tuner. Use the minimum amount of signal from the marker generator required to give a good marker or pip on the oscilloscope pattern.

NORMAL ANTENNA AND R-F CIRCUIT ADJUSTMENT

1. Complete the set-up procedure.
2. Adjust C-3, C-5, and C-10 for a flat-top response curve and maximum gain.
3. Check the position of the markers on all channels. They should fall in place automatically. Correct marker frequencies for each channel are given in the Picture Carrier and Sound Carrier columns of the chart on page 1954-25. The response curves in Fig. 20A are ideal curves and the adjustments should be made to approach these curves as nearly as possible.
4. If the proper response curves can not be obtained repeat steps 1, 2, and 3 with a different set of selected tubes in the tuner.

COMPLETE ANTENNA AND R-F CIRCUIT ADJUSTMENT

If the "Normal" adjustment described above does not give the desired response curves a complete realignment of the tuner will be required. Before this alignment can be completed it will be necessary to remove the tuner from the chassis without disconnecting the electrical connections to the tuner. It may be necessary to insert extention leads on the red, blue, black, and green wires from the tuner. Do not disturb the shielded output cable or attempt to insert an extention in this cable. The side shield plate must also be removed from the tuner in order to get at the internal adjustments.

To prevent the possibility of the tuner circuits in the antenna input circuit from effecting the response curves obtained in the steps 1-10 a 330 ohm, $\frac{1}{2}$ watt resistor may be connected across L-2 while making these adjustments. However, this will introduce loss and the output of the signal generators or the gain of the oscilloscope used may not be high enough to obtain a useable oscilloscope indication. With this resistor in place the valleys of the response curves will appear deeper and the band width will be wider than shown in the tuner response curves.

1. Set the channel selector switch to channel 5.
2. Connect the oscilloscope through a 10,000 ohm carbon resistor to the test point on the top of the tuner chassis.
3. Complete steps 3 and 4 as given under SET-UP PROCEDURE.
4. Connect the sweep generator as given in step 5 of the SET-UP PROCEDURE and adjust the output to sweep channel 5.
5. Connect the marker generator as given in step 6 of the SET-UP PROCEDURE and adjust the output for channel 5 sound and picture carrier frequencies. See chart on page 1954-25.

ALIGNMENT OF 1E1846 & 1B1969 CASCODE VHF TUNERS

COMPLETE ANTENNA AND R-F CIRCUIT ADJUSTMENT (Cont.)

6. Adjust C-22 (wire gimmick) to change the bandwidth over a narrow range. Push the free end of C-22 towards the contact terminals to increase the band width or pull it away to decrease band width. CAUTION -- THIS GIMMICK MUST NOT TOUCH THE CHASSIS OF THE TUNER OR THE SIDE SHIELD PLATE. IF IT DOES, R-6 WILL BE BURNED OUT.
7. Switch the channel selector and the test equipment to channel 13.
8. Adjust L-7 to control the tilt of the response curve and Capacitors C-8 and C-9 for the desired bandwidth. To reduce the picture carrier side of the response curve it is necessary to increase the inductance of L-7 by spreading or unwinding the turns. To increase the amplitude of the picture carrier side of the response curve it is necessary to decrease the inductance of L-7 by compressing or winding up the turns. Capacitors C-8 and C-9 are fixed disc ceramic units and they themselves are not adjustable. However, the physical distance between these two capacitors will effect band width on the higher channels. Moving the two capacitors together will narrow the band width while moving them apart will widen the band width.
9. Adjust C-5 and C-10 for a flat-top response curve and maximum gain.
10. Repeat steps 1 through 9.
11. Check channels 7 to 13 for the depth of the valley in the center of the response curve and adjust L-8 for optimum results on these channels. Decreasing the inductance of L-8 by spreading the turns will decrease the depth of the valley.
12. Remove the 330 ohm resistor if it has been used for the previous steps.
13. Set channel selector and test equipment to channel 13.
14. Adjust C-3 for maximum gain and a flat top response curve.
15. Disconnect all alignment equipment and replace the shield on the side of the tuner and air check the receiver on all active channels.
16. Remount the tuner in the chassis and check the alignment of the tuned circuits in the output circuit of the tuner and the grid circuit of the first i-f amplifier stage. Instructions for this alignment are given under the i-f alignment procedure.

OSCILLATOR CIRCUIT ADJUSTMENT

1. Set the fine tuning control at the approximate midpoint of its tuning range.
2. Place a non-metallic screwdriver through the openings provided in the front of the chassis and tuner assembly and adjust the oscillator coil slug for each active VHF channel to give the best possible picture.

NOTE -- If the slug in the oscillator coil does not have enough range on any channel, place the slug in the approximate center of its range and adjust C-17 for the best possible picture. It will then be necessary to adjust all of the oscillator coils as directed in steps 1 and 2. When replacing 6J6 tubes, C-17 may be adjusted for the best possible picture on any one active channel and thereby eliminate the necessity of adjusting each individual oscillator core.

ALIGNMENT FOR THE 1E1852 TV TUNER

OSCILLATOR CIRCUIT ADJUSTMENT

1. Set the fine tuning control at the approximate midpoint of its tuning range.

2. Place a non-metallic screwdriver through the openings provided in the front of the chassis and the tuner assembly and adjust the oscillator coil slug for each active VHF channel to give best possible picture.

NOTE- Adjustment of the oscillator slugs may be accomplished on some models while the chassis is in the cabinet by removing the front knob escutcheon. An access hole for this adjustment is provided in the cabinets with removable front safety glass, but not in the knob escutcheons.

40 to 54 MC TRAP - The antenna input circuit of the VHF tuner contains a trap that may be adjusted to attenuate or eliminate interference within the range of 40 to 54 MC. If interference is encountered adjust C-23 on the top of the VHF tuner for minimum picture interference. Improper adjustment of this trap may affect the frequency response of channel 2. Care must be exercised that this does not happen.

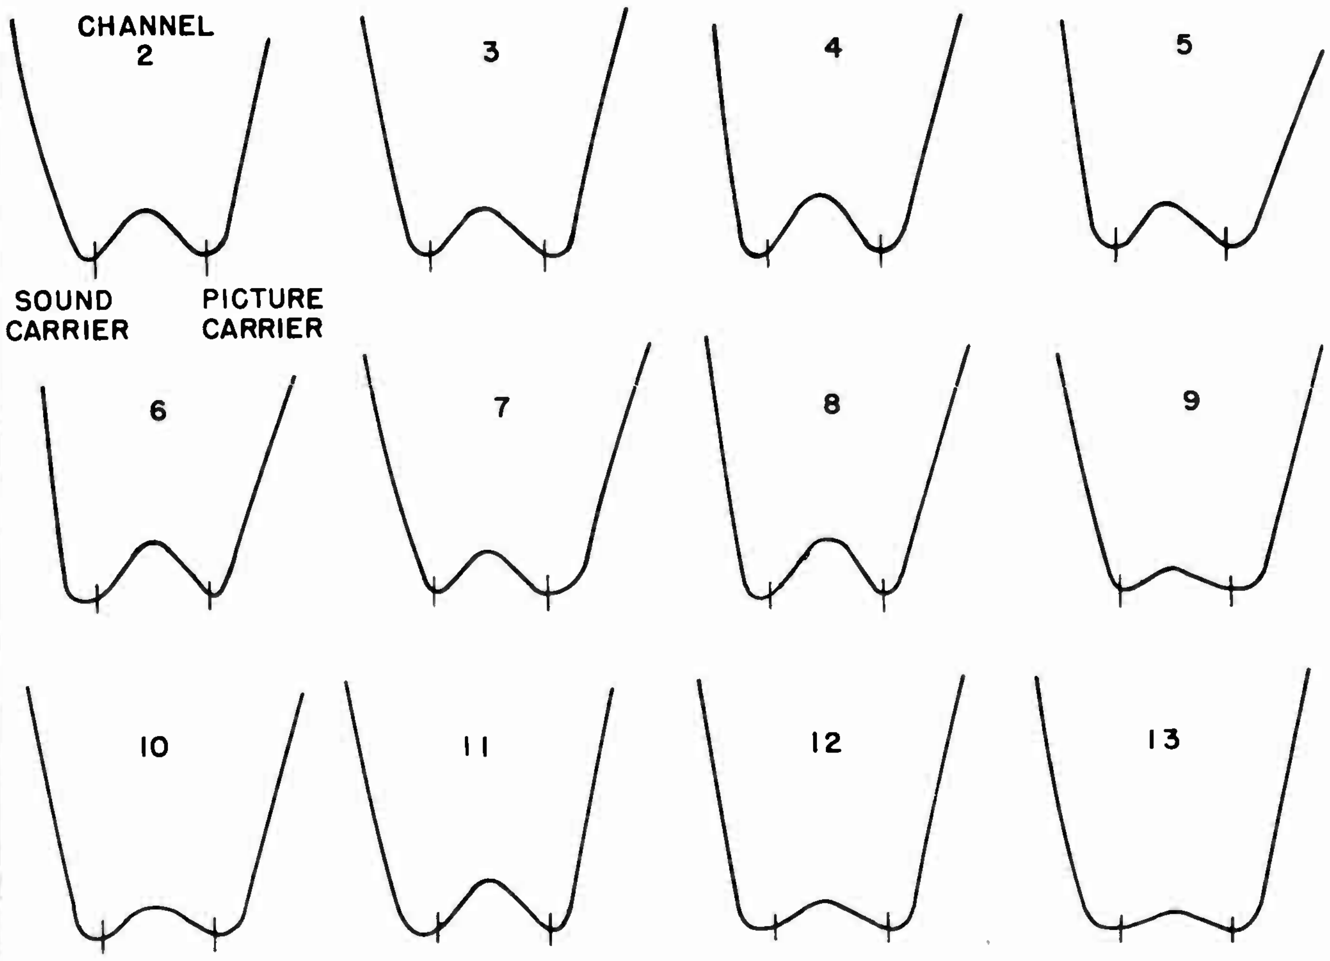

Fig. 20A. Typical Response Curves for VHF Channels

SERVICING AND ALIGNING THE 1E1846 & 1B1969 VHF CASCODE TUNERS

NO ATTEMPT TO REALIGN THE TUNER SHOULD BE MADE UNTIL THE BALANCE OF THE TV RECEIVER IS KNOWN TO BE IN PROPER OPERATING CONDITIONS AND IS PROPERLY ALIGNED.

This tuner was carefully aligned at the factory and should not require complete realignment under normal operating conditions. When replacing tubes it is of utmost importance that several different tubes are tried and the one giving the best performance selected for use. The use of selected tubes will, in the majority of cases, eliminate the necessity of tuner alignment when tubes are replaced. When replacing tubes use the same type as those found in the tuner. When selecting tubes tune the receiver to the highest active channel as slight differences in the tube will show up more clearly on the high channels.

When the oscillator tube has been replaced it may be necessary to adjust the individual oscillator coil slugs even though a selected tube has been used. However, before adjusting the individual oscillator coil slugs try adjusting C-17 for the desired results. This capacitor is in parallel with the fine tuning capacitor and determines the tuning range of the fine tuning capacitor. If C-17 is adjusted to obtain the desired picture on one active channel, all other active channels should automatically give proper reception.

Whenever it is necessary to replace components within the tuner the following precautions must be observed to prevent the necessity of tuner realignment after the service work has been completed. The physical location of all components and wires must not be changed. If a new component is installed it must have the same lead length as the old part and be placed in the same location. The position and settings of the various air core coils must not be changed. Note that the series coil (L-6) in the r-f plate/cathode circuit requires special test equipment for adjustment and, every precaution should be used to prevent disturbing the setting of this coil.

In order to adjust L-6 a grid dip oscillator capable of tuning from 230 to 235 MC will be required. This coil must be resonated at a frequency between 230 and 235 MC in order to provide increased gain on the higher VHF channels. It is resonated by the plate to ground capacitance of the first triode section and the cathode to ground capacitance of the second triode section. With the plate voltage (blue wire) removed and the heater voltage applied to the cascode amplifier the turns of L-6 may be compressed or expanded until it resonates at a frequency between 230 and 235 MC. This adjustment may be made at any time and will require a grid dip oscillator as an indicator.

If the service work on the tuner is confined to components in the oscillator/mixer stage it is necessary to align only the oscillator/mixer stage. It will not be necessary to adjust C-3 in the grid circuit of the first triode section of the cascode amplifier. In the great majority of cases, if care is used when servicing the tuner, it will only be necessary to adjust C-5, C-10 & C-17 after working on the oscillator/mixer section.

Similarly, if the service work has been done in the first triode section of the cascode amplifier an adjustment of C-3 only should restore the tuner to normal provided L-6 has been adjusted as outlined above.

EQUIPMENT REQUIRED FOR TUNER ALIGNMENT

VHF Sweep Generator - - -	RCA type WR-59B or equiv.
VHF Marker Generator - - -	RCA type WR-39C or equiv.
Oscilloscope - - - - - - - -	RCA type WO-56A or equiv.
Bias Source - - - - - - - - -	3 volt battery or equiv.
Input Pad - - - - - - - - - -	See Fig. 19B.

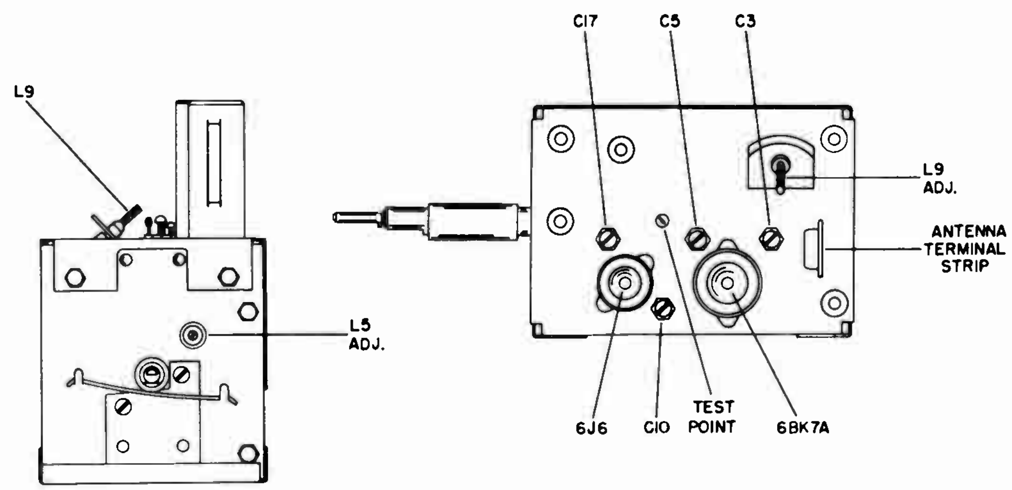

Fig. 24A. Alignment Adjustments for 1E1846 & 1B1969 VHF Tuner

ALIGNMENT OF THE CASCODE I-F AMPLIFIER IN UHF/VHF CHASSIS

NO ATTEMPT SHOULD BE MADE TO PERFORM THE FOLLOWING PROCEDURE UNTIL THE BALANCE OF THE TV RECEIVER IS KNOWN TO BE IN PROPER OPERATING CONDITION AND THE REGULAR I-F ALIGNMENT HAS BEEN COMPLETED. (See Fig. 33A or 33B for location of adjustments and Fig. 18B for response curve.)

EQUIPMENT REQUIRED

Sweep Generator	RCA type WR-59B or equiv.
Marker Generator	RCA type WR-39C or equiv.
Oscilloscope	RCA type WO-56A or equiv.
Detector Circuit	Shown 12 Fig. 18A.
Isolation Transformer	150 watt rating or higher.

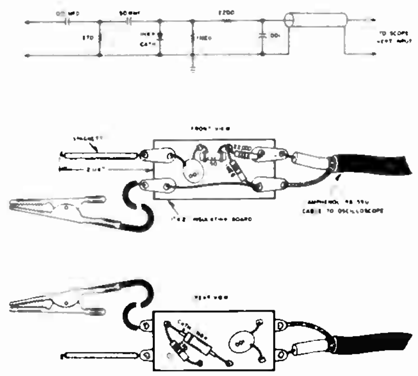

Fig. 18A. Detector Circuit for Cascode I-F Alignment

PROCEDURE

1. Set the UHF/VHF switch to UHF position. Select an inactive channel between 35 and 45.
2. Connect all test equipment and the television chassis to a common ground. Be sure to use an isolation transformer for the receiver chassis. Allow at least a 5 minute warm-up in this position.
3. Connect the hot lead of the sweep generator to pin 7 of V-401 (Cascode I-F amplifier). Set the generator to sweep from 40 to 48 mcs.
4. Connect the oscilloscope to the plate circuit of V-101 through the detector circuit of Fig. 18A.
5. Loosely couple the hot lead of the marker generator to the hot side of the sweep generator through a 22 mmf. capacitor. This coupling may also be accomplished by clipping the hot lead from the marker generator over the crystal diode in the detector circuit in Fig. 18A.
6. Adjust L-403 to place the 45.75 marker on one peak of the response curve on the oscilloscope. Note the position of the 42.75 marker.
7. Adjust L-405 by compressing or spreading its turns to equalize the two peaks on the response curve on the scope.

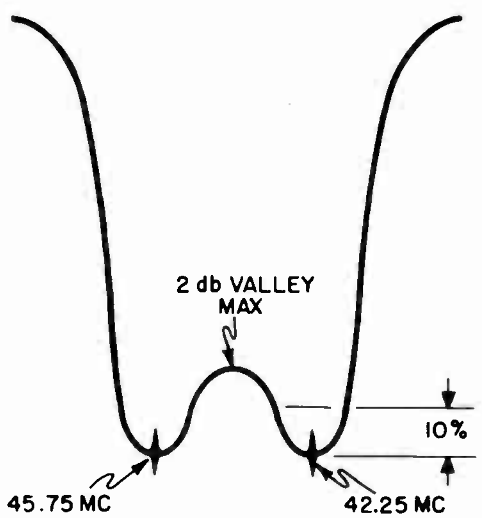

Fig. 18B. Response Curve for Cascode I-F Alignment

ALIGNMENT FOR THE 1E1852 TV TUNER

The tuner was carefully aligned at the factory and should not require complete realignment under normal operating conditions. A slight readjustment of the individual oscillator slugs may be required as the tubes in the tuner age or are replaced. Use of selected tubes is recommended to obtain the best possible results without aligning the tuner. NO ATTEMPT TO REALIGN THE TUNER SHOULD BE MADE UNTIL THE BALANCE OF THE TV RECEIVER IS KNOWN TO BE IN PROPER OPERATING CONDITION AND IS PROPERLY ALIGNED.

EQUIPMENT REQUIRED

VHF Sweep Generator	RCA type WR-59B or equiv.
VHF Marker Generator	RCA type WR-39C or equiv.
Oscilloscope	RCA type WO-56A or equiv.
Bias source	3 volt battery or equiv.

SET-UP PROCEDURE

1. Set the channel selector switch to Channel 10.
2. Connect the oscilloscope through a 10,000 ohm resistor to TP-9 shown in Fig. 19A.
3. Connect the negative side of the bias source through a 1000 ohm isolation resistor to the terminal where the AGC lead (white wire) from the tuner is connected. Connect the positive side of the bias source to the receiver chassis.
4. Set the fine tuning control by placing widest point on cam on left side of shaft.
5. Connect the sweep generator to the antenna terminals through the pad shown in Fig. 19B. and adjust the output to sweep channel 10.
6. Couple the output from the marker generator to the antenna circuit by connecting the hot lead from the generator to the junction of the four 220 ohms resistors in the pad shown in Fig. 19B. Connect the ground lead to the r-f tube shield in the VHF tuner. Use minimum amount of signal from generator necessary to obtain good pip in scope pattern.

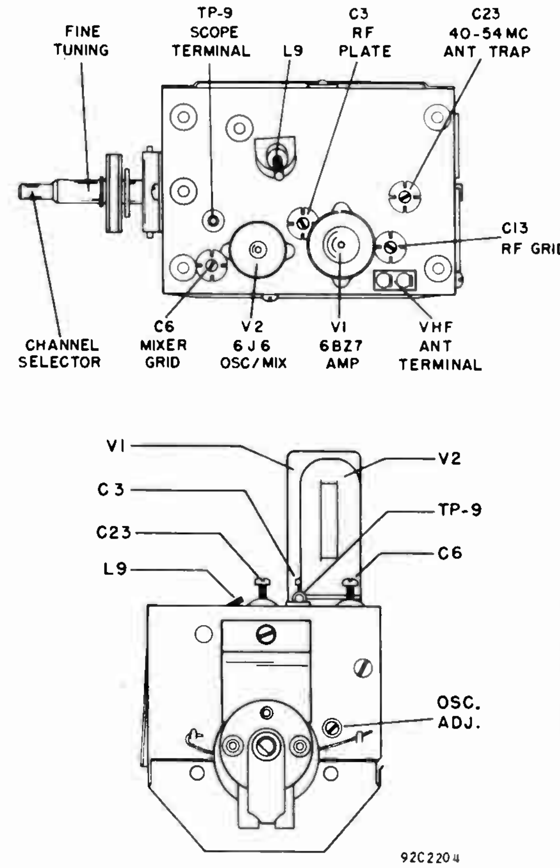

Fig. 19A. Alignment Adjustments for 1E1852 TV Tuner

ANTENNA AND R-F CIRCUIT ADJUSTMENT

7. Adjust C-13, C-3, and C-6 for a flat-top response curve and maximum gain. Check the position of the markers on all channels. They should fall in place automatically on all channels. Correct marker frequencies for each channel are given in the Picture Carrier and Sound Carrier columns of the chart on page 1954-25. The response curves shown in Fig. 20A. should be used as a guide to show the various shapes that the response curves may have and still be satisfactory. If necessary adjust C-25 (gimmick) to change bandwidth over a narrow range (approx. 2 mc.) on Channel 10. To increase bandwidth, push the gimmick closer to the contact terminals. CAUTION: This gimmick must not touch the tuner chassis as it is connected to the plate of the r-f stage.
8. Disconnect the bias source and test equipment.
9. Air check the receiver on all active VHF channels. If it is possible to receive a normal picture on all active channels by adjusting the fine tuning control, further alignment is not absolutely necessary.

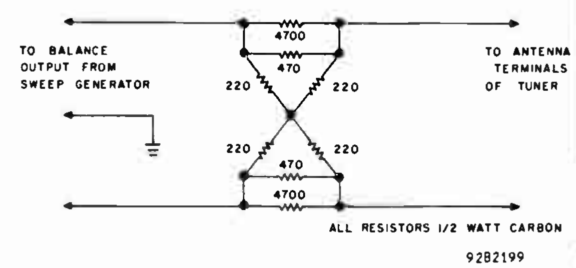

Fig. 19B. Sweep Generator Pad

I-F AMPLIFIER ALIGNMENT FOR 1300D CHASSIS

EQUIPMENT REQUIRED

SWEEP GENERATOR	RCA type WR-59B or equivalent.
MARKER GENERATOR	RCA type WR-39C Television Calibrator or equivalent.
OSCILLOSCOPE	RCA type WO-56A or equivalent.
VACUUM TUBE VOLTMETER (VTVM)	RCA type WV-97A or equivalent.
BIAS SOURCE	Three volt battery.
TEST CIRCUIT	Shown in Fig. 16A.
ISOLATION TRANSFORMER	150 watt rating or higher.

PROCEDURE

1. Set the UHF/VHF switch to the VHF position. Set the channel selector to channel 3 or 4, whichever is vacant.

2. Connect all test equipment to a common ground. Connect the TV chassis to this same ground after installing an isolation transformer between the power line and the TV chassis. One side of the line cord connects directly to the TV chassis and an isolation transformer must be used for safety. Allow a 15 minute warm up period.

3. Set the AVC switch on the rear chassis apron to the 0-10 MILE (counterclockwise) position.

4. Connect the negative side of a 3 volt battery supply to test point Ⓔ through a 1,000 Ω resistor. Connect the positive side of the supply to the TV chassis. See schematic diagram.

5. Connect a VTVM to test point Ⓓ through a 47,000 ohm carbon resistor Connect the ground side of the meter to the TV chassis. See Fig. 13A or 14A.

6. Connect the high side of a marker generator to the shield of the osc./mixer tube. This connection will capacitively couple the generator output to the tube. Make sure the shield is ungrounded by raising it above the grounded clips that hold it in place.

7. Set the marker generator output (unmodulated) for a two volt negative dc reading on the VTVM and adjust the three i-f transformers, L-9, and L-101 according to the I-F AMPLIFIER ALIGNMENT CHART shown below. Readjust the signal generator output as required to maintain the two volt VTVM reading.

I-F AMPLIFIER ALIGNMENT CHART

Signal Generator Frequency (No Modulation)	Adjustment	Transformer or Coil Location	VTVM Indication
45.0 MC	T-101	See Fig. 13A or 14A	Maximum
42.8 MC	T-102 (bottom)		Maximum
44.0 MC	T-103		Maximum
41.25 MC	T-102 (top)		Minimum
42.8 MC	T-102 (bottom)		Maximum
44.25 MC	§*L-101 (top) or L-101-1 (bottom)		Maximum
44.25 MC	#L-9		Maximum

IMPORTANT — The wax in the end of the coil forms holding the iron core in position may be softened for adjustment of the core by means of a heated screwdriver or a small pencil type soldering iron inserted into the wax. Remelt wax after adjustment.

* NOTE: Temporarily connect the series resistor-capacitor combination shown in Fig. 16A to the tuner test point TP-2 when making this adjustment on all tuners except the 1E1852 or 1E1846. With the 1E1852, 1E1846, or 1B1969 tuner hold the channel selector between channels when making this adjustment.

§ NOTE: Top adjustment of L-101-1 may be used in conjunction with L-9 of 1E1846 or 1B1969 tuner to give proper band width response.

\# NOTE: Temporarily connect the series resistor-capacitor combination shown in Fig. 16A to the grid (pin 1) of V-101 the 6CB6 first i-f amplifier when making this adjustment.

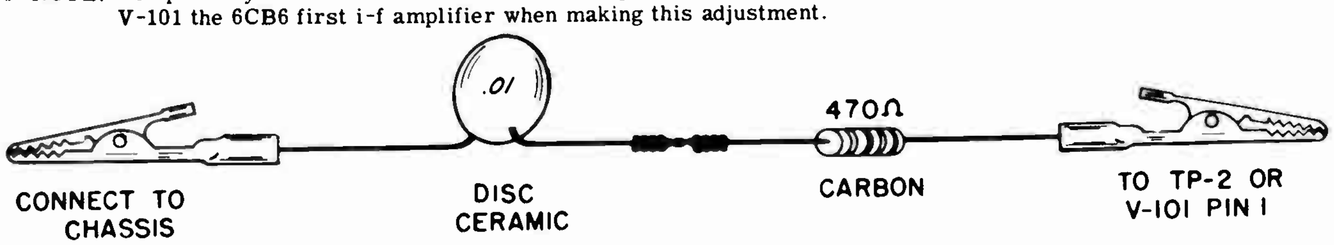

Fig. 16A. Test Circuit for I-F Amplifier Alignment

8. Disconnect the VTVM and marker generator connected in steps 4 and 5. The balance of the set-up should be as directed in steps 1, 2, 3 and 6.

9. Capacitively couple the high side of the sweep generator r-f output to the osc./mixer tube by connecting to the tube shield which has been raised above its grounding clips. The ground side of the sweep generator should be connected to the receiver chassis. Adjust the generator to sweep from 40.5 to 46.5 MC.

10. Loosely couple the high side of the marker generator to the high side of the sweep generator by clipping the marker generator r-f lead over the insulation of the sweep generator r-f lead. The ground side of the marker generator should be connected to the receiver chassis.

IMPORTANT — To prevent overloading of the i-f amplifier keep the output of the sweep and marker generators as low as possible. The marker generator output should be just high enough to produce visible pips on the pattern. In some cases the 41.25 MC pip will not be visible unless the r-f output of the marker generator is increased to overcome the attenuation of the 41.25 MC signal by the trap in the top of T-102.

11. Connect the sweep output terminals on the sweep generator to the input of the horizontal amplifier in the oscilloscope.

12. Connect one side of a 47,000 ohm 1/2 watt resistor to test point Ⓓ shown in the schematic diagrams. Connect the other end of the resistor to the high side of the input terminals for the vertical amplifier in the oscilloscope. The scope ground terminal connects to the receiver chassis. Keep the scope leads away from the internal chassis wiring, particularly the horizontal output section.

13. Reduce the r-f output of the sweep generator and increase the gain of the vertical amplifier in the oscilloscope as much as possible without introducing an excessive amount of noise on the test pattern. This will prevent overloading of the i-f system.

14. Check the position of the markers shown in Fig. 17A. Adjust only the bottom cores of T-101, T-102 and T-103 for a response curve of maximum amplitude with a slightly tilted flat topped appearance as shown in Fig. 17A. This tilt is required to compensate for the capacitive coupling used for the signal generators. The actual response obtained will be flat when the pattern viewed on the oscilloscope has this tilt. The bottom core of T-103 will primarily control the tilt of this central portion of the curve.

The bottom core of T-101 should be adjusted to position the 45.75 MC marker in the 50% position shown in Fig. 517A.

The bottom core of T-101 should be adjusted to determine the slope of the curve between 41.25 MC and 42.8 MC with the 42.25 MC marker down 50% on the curve as shown in Fig. 17A.

Under no circumstances should an attempt be made to adjust L-9, L-101 and the 41.25 MC trap in the top of T-102 by means of an oscilloscope and sweep generator. Maladjustment of these coils does not give a noticeable indication on the oscilloscope. Align these coils by following the procedure given in steps 1 through 7 only.

I-F AMPLIFIER SENSITIVITY MEASUREMENT

To determine the i-f amplifier sensitivity, disconnect the r-f output lead from the tuner where it connects to L-101. Temporarily connect one side of a .005 mfd. mica or ceramic capacitor to grid pin 1 of the first 6CB6 i-f amplifier tube V-101. Connect the unmodulated r-f output of a marker generator to the other side of the capacitor and the ground side of the generator to the TV chassis. Set the marker generator to 43.75 MC. Connect a VTVM as directed in step 5 of the alignment procedure. The 3 volt battery must be removed. If a generator output of 200 to 400 microvolts produces a 1 volt reading on the VTVM, the i-f amplifier sensitivity is normal.

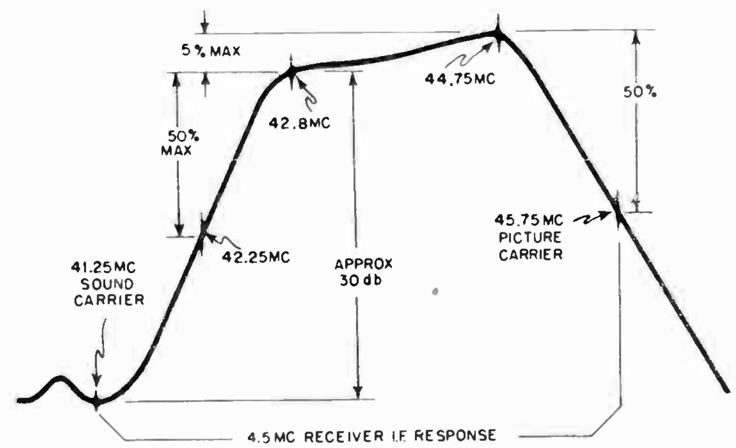

Fig. 17A. Typical Response for 41.25 to 45.75 MC I-F Amplifiers

FM SOUND CHANNEL ALIGNMENT FOR 1300D SERIES CHASSIS

EQUIPMENT REQUIRED

Signal generator covering 4 to 30 mc. unmodulated.

Vacuum tube voltmeter (VTVM).

Sound alignment test circuit shown in Fig. 12A.

Power line isolation transformer.

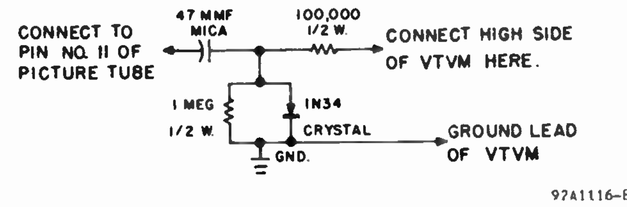

Fig. 12A. Sound Alignment Test Circuit

PROCEDURE

1. Connect all test equipment to a common ground. Connect the TV chassis to this same ground after installing an isolation transformer between the power line and the TV chassis. One side of the line cord connects directly to the TV chassis and an isolation transformer must be used for safety.

2. Set the channel selector to any vacant channel and the contrast control at minimum.

3. Connect the signal generator output through a .005 mfd. capacitor to test point (D) shown in schematic diagram. Ground the shield of the generator output cable to the chassis.

4. Connect the sound alignment detector circuit and VTVM as shown in Fig. 12A. Adjust the 4.5 mc. generator output (unmodulated) to give a 1 volt reading on the VTVM.

5. Adjust the 4.5 mc. trap adjustment (L-107) at 4.5 mc. for a minimum VTVM reading.

6. Disconnect the test circuit and connect the VTVM to test terminal (B) (Pin 2 of FM detector, V-113). See schematic diagram.

7. Adjust the 4.5 mc. amplifier grid adjustment (L-114) and the primary of T-108 (bottom core) at 4.5 mc. for a maximum VTVM reading.

8. Connect the VTVM to test terminal (C), shown in the schematic diagram. Adjust the secondary of T-108 (top core) at 4.5 mc. for the zero reading which occurs between the positive and negative peaks. If the zero reading occurs at more than one setting, use the position nearest the top limit of the core.

9. Shift the signal generator an equal amount on either side of 4.5 mc. and touch up the primary of T-108 (bottom core) for approximately equal peaks. Use just enough signal output to obtain one volt peaks for best results.

HORIZONTAL OSCILLATOR ADJUSTMENT

If the horizontal hold control fails to restore synchronization, the horizontal stabilizer coil (L-113) should be adjusted. Procedure for this adjustment is as follows:

1. Set the horizontal hold control in the approximate center of the range over which it may be rotated.

2. Set the channel selector to an active channel and adjust the horizontal stabilizer for a single steady picture. See Fig. 12B.

3. Rotate the horizontal hold control full clockwise. The picture may or may not remain in sync. If it does, momentarily switch the channel selector to another channel and return it to the original channel. The picture should now be slightly out of sync.

4. Rotate the horizontal hold control full counterclockwise. The picture may or may not remain in sync. If it does, momentarily switch the channel selector to another channel and return it to the original channel. The picture should now be slightly out of sync.

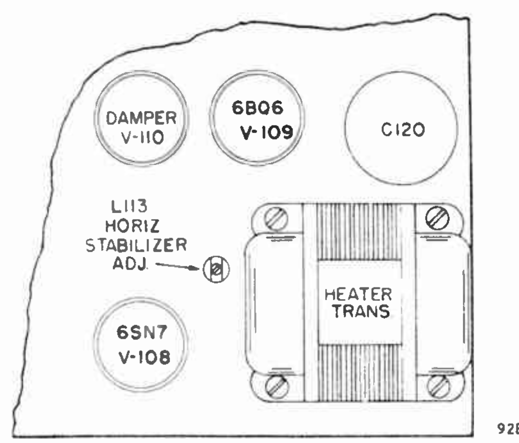

Fig. 12B. Horizontal Oscillator Adjustment Point

When the horizontal stabilizer coil is properly adjusted the results outlined in steps 3 and 4 will be obtained. If the correct results are not obtained, repeat steps 2, 3 and 4 until they are.

SERVICE PARTS LIST

TRANSFORMERS AND COILS

Schematic Symbol	Description	Hallicrafters Part Number
T-101	Transformer, 1st - 2nd I.F.	50B561
T-102	Transformer, 2nd - 3rd I.F.	50B568
T-103	Transformer, 3rd. I.F. - diode detector	50B562
T-104	Transformer, vertical blocking oscillator	55B190
T-105	Transformer, vertical output	55C192
* T-106	Transformer, horizontal output	55D193
T-107	Transformer, ratio detector	50C473
T-108	Transformer, audio output	55C191
* T-109	Transformer, horizontal output	55D197
* T-110	Transformer, heater	52C258
* T-111	Transformer, heater	52C290
T-201	Transformer, 1st - 2nd I.F.	50B573
T-202	Transformer, 2nd - 3rd I.F.	50B574
T-203	Transformer, 3rd. I.F. - diode detector	50B575
L-101	Coil, converter i-f	51B1301
L-102	Coil, video peaking	51A1578
L-103	Coil, video peaking	51A1579
L-104	Coil, video peaking (wound on R-119)	51A1580
L-105	Coil, 4.5 MC trap	51B1541
L-106	Coil, video peaking (wound on R-122)	51A1581
L-107	Coil, video peaking (wound on R-123)	51A1582
L-108	Coil, horizontal stabalizer	51B1642
L-109	Coil, yoke coupling (wound on C-148)	53B264
L-110	Coil, 4.5 MC amplifier grid adjustment	51B1542
L-111	Coil, speaker field (part of speaker)	--------
L-112	Deflection yoke	53A271
L-113	Choke heater	53B294
L-114	Choke, r-f (channel 5 tweet filter)	53B008
L-201	Coil, converter - I.F.	51-1643
L-202	Filament choke	53A282
L-203	Filament choke	53A282
L-204	Filament choke	53A282

ALIGNMENT FOR 1E1483 VHF 16-POSITION CASCODE TUNER

These tuners have been carefully aligned at the factory by personnel using precision equipment. Minor adjustments of the tuner may be necessary after making tube or part replacements. When replacing tubes in a tuner use the same tube type as the original tube which was removed from the tuner and also try several different tubes and select the one which gives best performance. Realignment of the tuner probably will not be required if a selected tube is used for replacement. For those service engineers who are properly equipped as specified, the following alignment procedure is included. DO NOT ATTEMPT TUNER ALIGNMENT UNTIL THE TV RECEIVER IS KNOWN TO BE FUNCTIONING PROPERLY AND THE I-F ALIGNMENT OF THE RECEIVER IS CORRECT.

EQUIPMENT REQUIRED FOR VHF TUNER ALIGNMENT

Sweep Generator	RCA type WR-59B or equiv.
Marker Generator	RCA type WR-39C or equiv.
Oscilloscope	RCA type WO-56A or equiv.
Bias Source	1½ volt battery or equiv.
Detector Circuit	See Fig. 20CA.
Isolation Transformer	150 watt rating or higher.

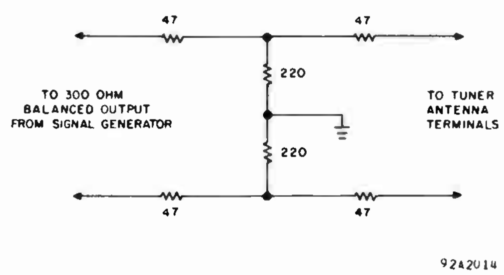

Fig. 20BA. Sweep Generator 300 Ohm Pad

OSCILLATOR ADJUSTMENT FOR 16 POSITION TUNERS

1. Connect the balanced sweep output from a signal generator to the VHF tuner antenna terminal through the 300 ohm pad shown in Fig. 20BA. Set sweep generator for 10 MC sweep.

2. Connect the negative side of 1½ volt bias supply to terminal 8 of the VHF tuner. Connect the positive side of the bias supply to the chassis.

3. Connect the oscilloscope and band-pass detector circuit shown in Fig. 20CA to Test Point TP-2 shown in Fig. 20CB.

4. Set the VHF tuner channel selector to channel 13.

5. Loosely couple the high side of the marker generator to the antenna input terminals by clipping the lead over the insulation of one sweep generator lead. Connect the ground side of the generator to the chassis of the VHF tuner. Set the marker generator to the channel 13 picture carrier frequency of 211.25 MC.

6. Carefully note the position of the marker pip on the response curve. Use a grease pencil if necessary to mark the position on the face of the cathode ray tube.

7. Loosely couple the high side of the marker generator to the band-pass detector circuit by clipping the lead over the germanium diode in the detector circuit. Connect the ground side of the generator to the chassis of the VHF tuner. Set the marker generator to 45.75 MC.

8. Rotate the fine tuning control of the VHF tuner until the 45.75 MC marker is in the same spot as the marker in steps 5 and 6. If this cannot be accomplished by adjustment of the fine tuning control, adjust the channel 13 oscillator adjustment (L-7) to position the 45.75 MC marker. DO NOT DISTURB THE SETTING OF THE FINE TUNING CONTROL AFTER THIS ADJUSTMENT.

9. Switch the VHF tuner channel selector and sweep generator to channel 12.

10. Repeat steps 5 and 6 except the picture carrier frequency for channel 12 (205.25 MC) in step 5.

11. Repeat step 7 using the same marker frequency of 45.75 MC.

12. Adjust the incremental oscillator coil for the channel until the 45.75 MC marker pip is in the same position on the curve as the marker pip for the picture carrier was in step 10.

13. Repeat steps 9, 5, 6, 7 and 12 for channels 11, 10, 9, 8 and 7 in that order. In each case switch the channel selector and sweep generator to the channel being aligned. The marker generator frequency for step 5 will be the picture carrier frequency for the channel being aligned. See the chart on page 1953-14 for the picture carrier frequency of each channel.

14. Switch the channel selector and sweep generator to channel 6 and repeat steps 5 and 6 except use the picture carrier frequency for channel 6 (83.25 MC) in step 5.

15. Repeat step 7 using the same marker frequency of 45.75 MC.

16. Adjust the channel 6 oscillator adjustment until the 45.75 MC marker pip is in the same position on the curve as the marker pip in step 14. See Fig. 20CB.

17. Repeat steps 9, 5, 6, 7 and 12 for channels 5, 4, 3 and 2 in that order. In each case switch the channel selector and sweep generator to the channel being aligned. The marker generator frequency for step 10 will be the picture carrier frequency for the channel being aligned. See the chart on page 1953-14 for the picture carrier frequency of each channel.

NOTE: If two marker generators are available the alignment can be greatly simplified by using one generator for the picture carrier marker and the other for the 45.75 MC marker. Both generators are connected to the receiver at all times as directed in the above instructions. The use of two generators will produce two pips on the pattern. The adjustments outlined above will make these two pips coincide on the oscilloscope pattern.

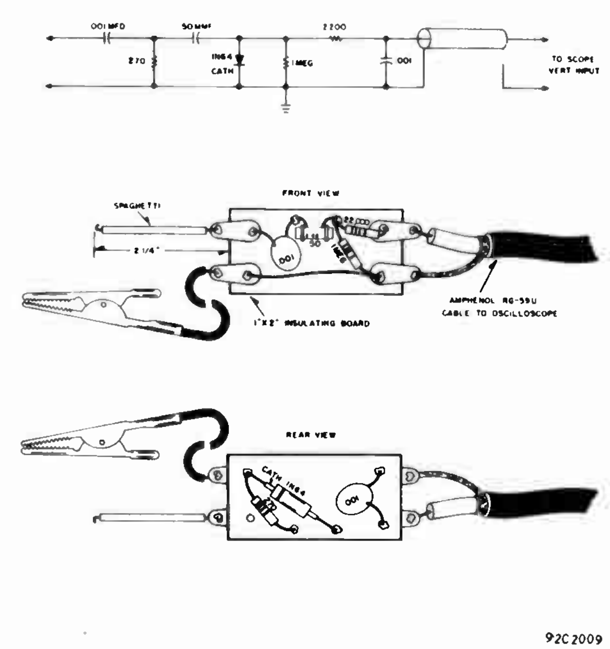

Fig. 20CA. Detector Circuit For Tuner Alignment

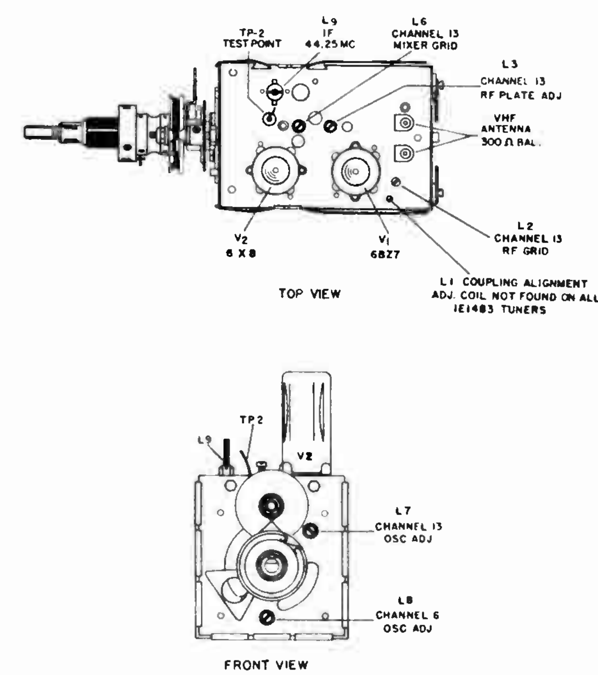

Fig. 20CB. Alignment Adjustments For 1E1483 Tuner

1E1380 CASCODE TV TUNER ALIGNMENT (ANT. & RF CIRCUITS)

The tuner was carefully aligned at the factory and should not require complete realignment under normal operating conditions. A slight readjustment of the individual oscillator slugs may be required as the tubes in the tuner age or are replaced. In some rate cases it will be necessary to realign the tuner after replacing either of the two tubes. If any service work is performed on the tuner, realignment may or may not be required. NO ATTEMPT TO REALIGN THE TUNER SHOULD BE MADE UNTIL THE BALANCE OF THE TV RECEIVER IS KNOWN TO BE IN PROPER OPERATING CONDITION AND IS PROPERLY ALIGNED.

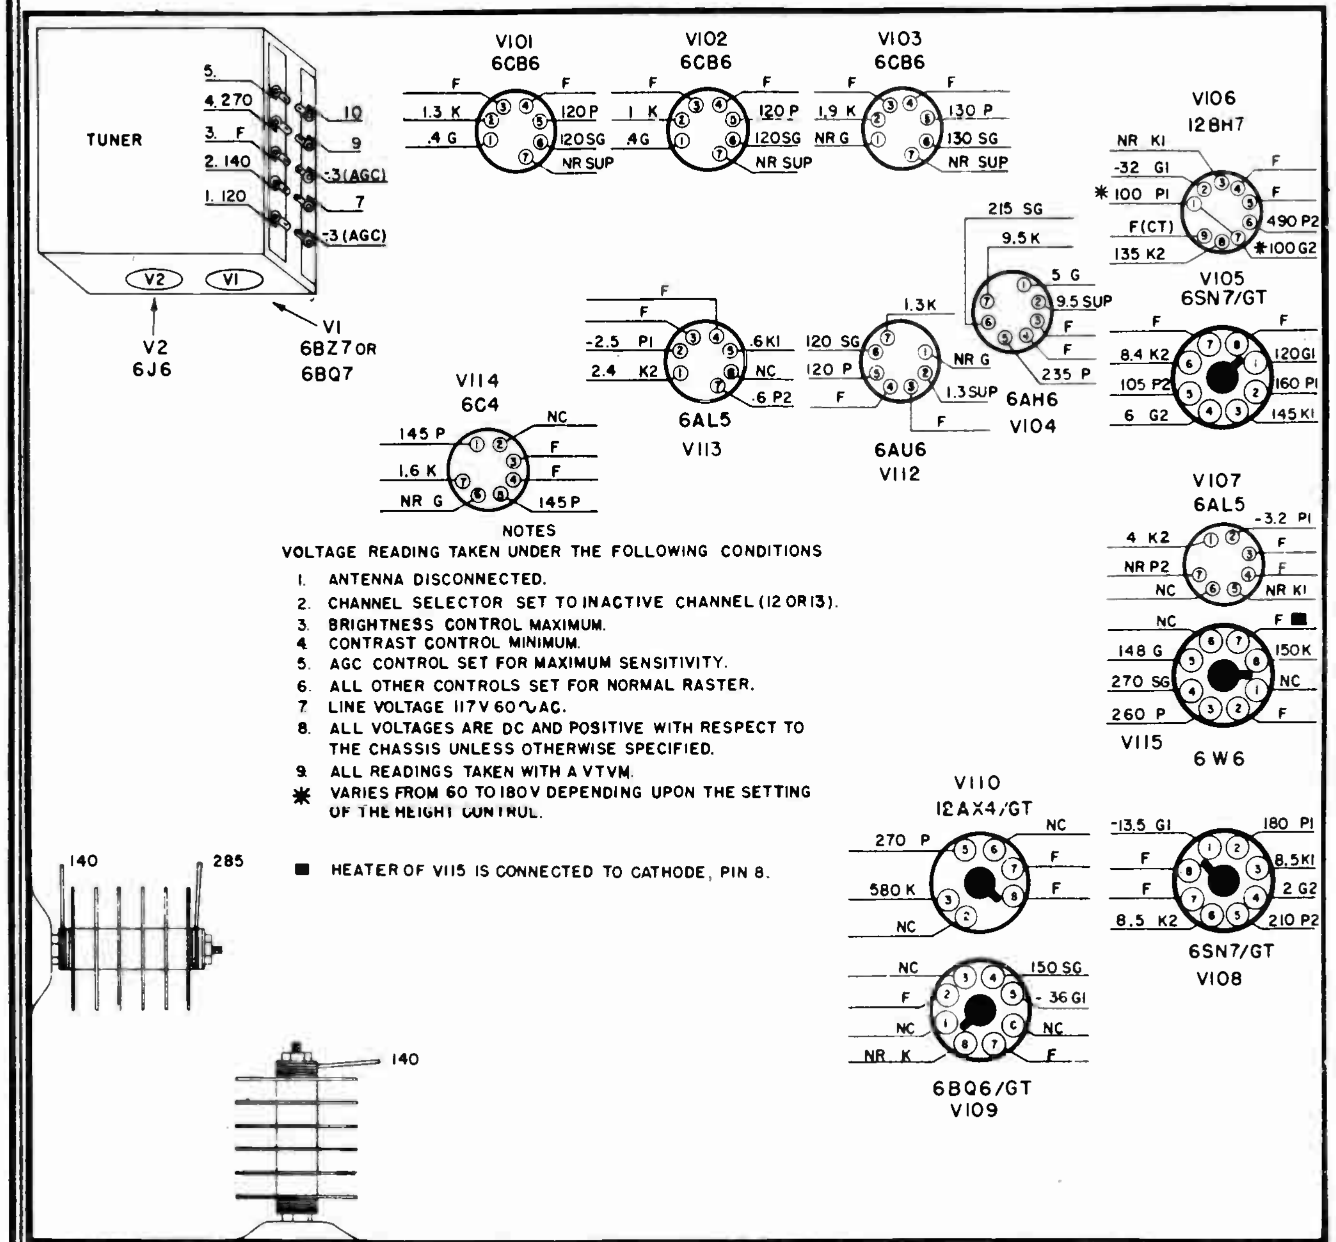

Fig. 20A. Voltage Chart for AJ1200D Chassis with 1C1376 Cascode Tuner AL1200D Run 2 and AY1200D Chassis with 1E1677 Cascode Tuner, and AZ1200D Chassis with 1E1380 Cascode Tuner

EQUIPMENT REQUIRED

1. Sweep generator covering all 12 television channels.
2. Marker generator covering the same range as the sweep generator.
3. Oscilloscope.
4. Vacuum tube voltmeter (VTVM).

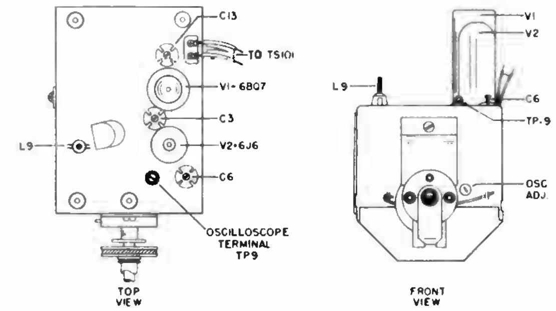

Fig. 20AA. 1E1380 Cascode Tuner Alignment Adjustments

SET-UP PROCEDURE

1. Set the CHANNEL SELECTOR switch to channel 12.
2. Connect the vertical amplifier input of the oscilloscope through a 10,000 ohm resistor to test point TP-9 on the tuner. (See Schematic Diagram and Fig. 20AA). The horizontal amplifier in the oscilloscope should be connected to the oscilloscope sweep voltage output from the sweep generator.
3. Connect the negative pole of a 1.5 volt dry cell to the terminal where the AGC lead (white wire) from the tuner is connected. (Connect the positive pole of the dry cell to the receiver chassis. (See Schematic Diagram).
4. Set the FINE TUNING control at the approximate midpoint of its tuning range.
5. Connect the sweep generator to the antenna terminals and adjust to sweep channel 12. Keep the output of the sweep generator as low as possible to prevent overloading the r-f stage.
6. Loosely couple the r-f output from the marker generator to the antenna terminals. Use the minimum amount of coupling and signal from the marker generator required to give a good marker on pipe on the oscilloscope pattern.

ANTENNA AND RF CIRCUIT ALIGNMENT

7. Adjust C-13, C-3 and C-6 for a flat-top response curve and maximum gain. Check markers on all channels. They should fall in automatically on each channel. Correct marker frequencies for each channel are given in the Picture Carrier and Sound Carrier columns of the chart on page 1953-14. Refer to Fig. 20AB.
8. Disconnect the battery used to obtain negative bias.
9. Disconnect the test equipment and air check the receiver on all active channels. If it is possible to receive a normal picture on all active channels by adjusting the FINE TUNING control, further alignment will not be necessary.

1E1380 CASCODE TV TUNER ALIGNMENT (OSC. CIRCUIT)

1. Set the FINE TUNING control at the approximate midpoint of its tuning range.
2. Place a non-metallic screwdriver through the openings provided in the front of the chassis and the tuner assembly and adjust the oscillator coil slug for each active channel to give the best possible picture.

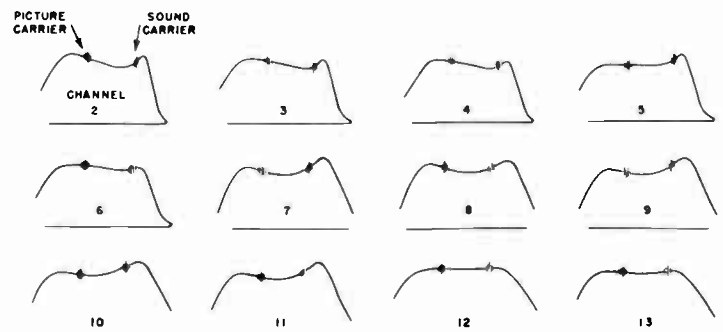

Fig. 20AB. Typical Channel Response Curves for TV Tuners

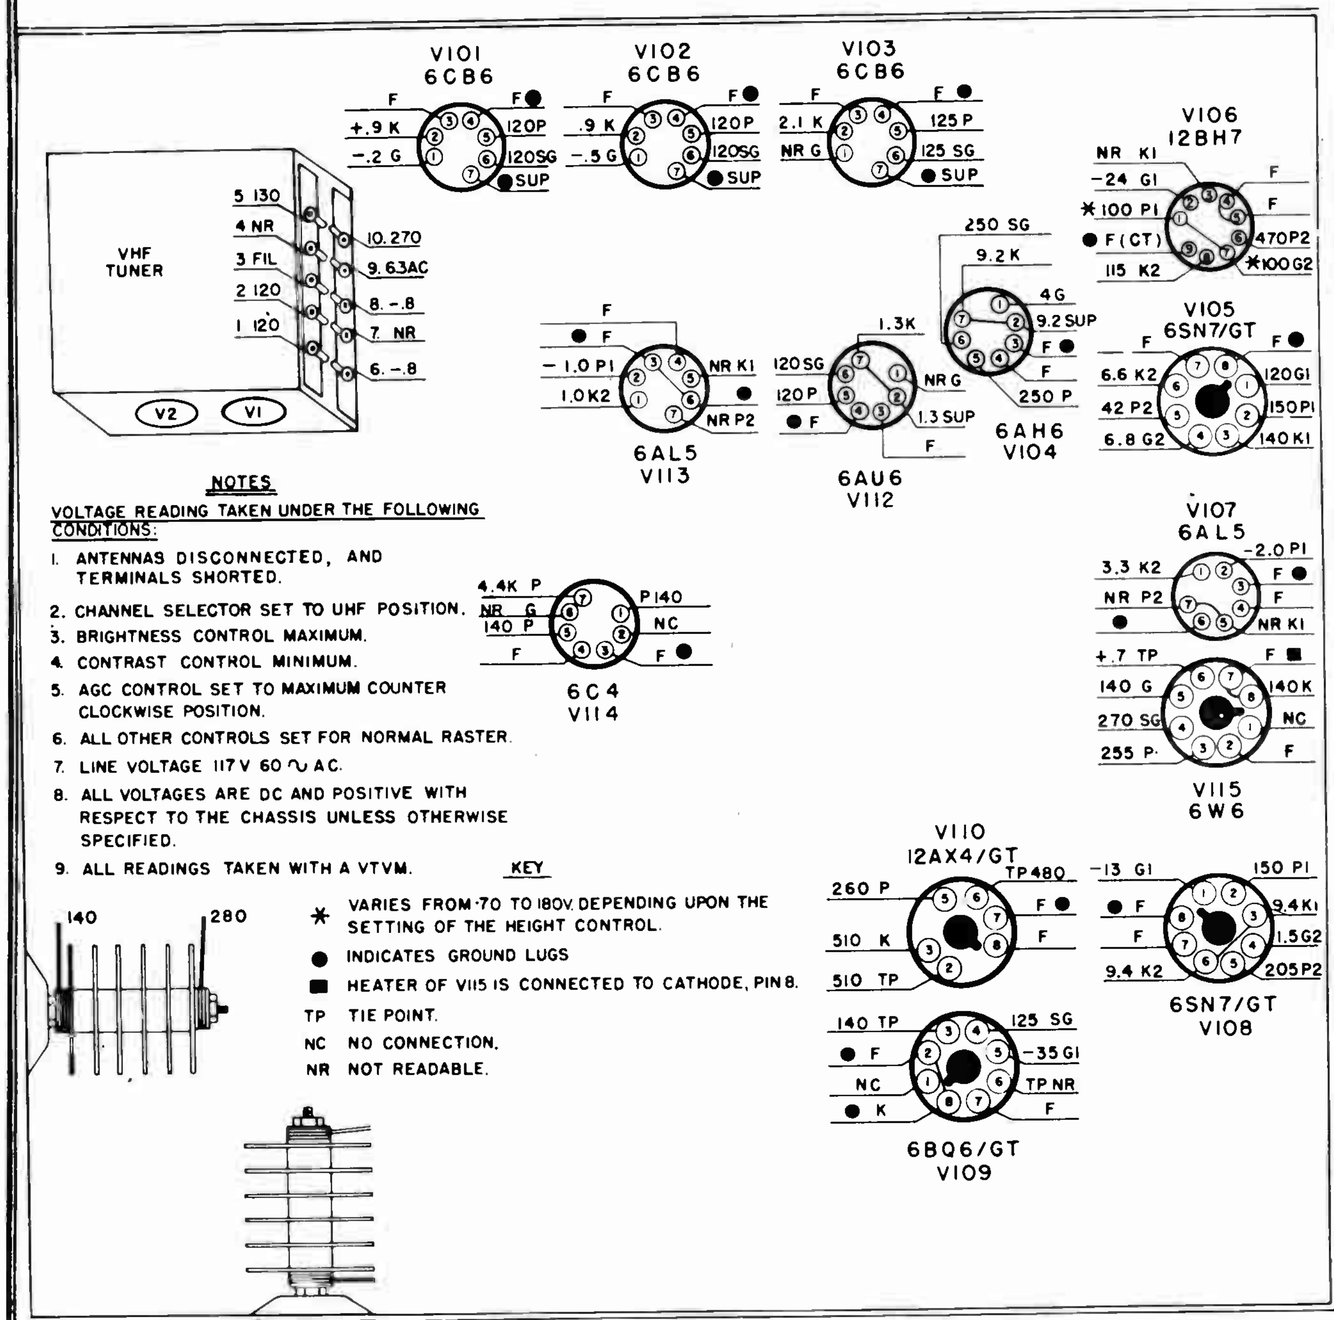

Fig. 18BA. Voltage Chart for BA1200D Chassis with 1E1483 Cascode Tuner

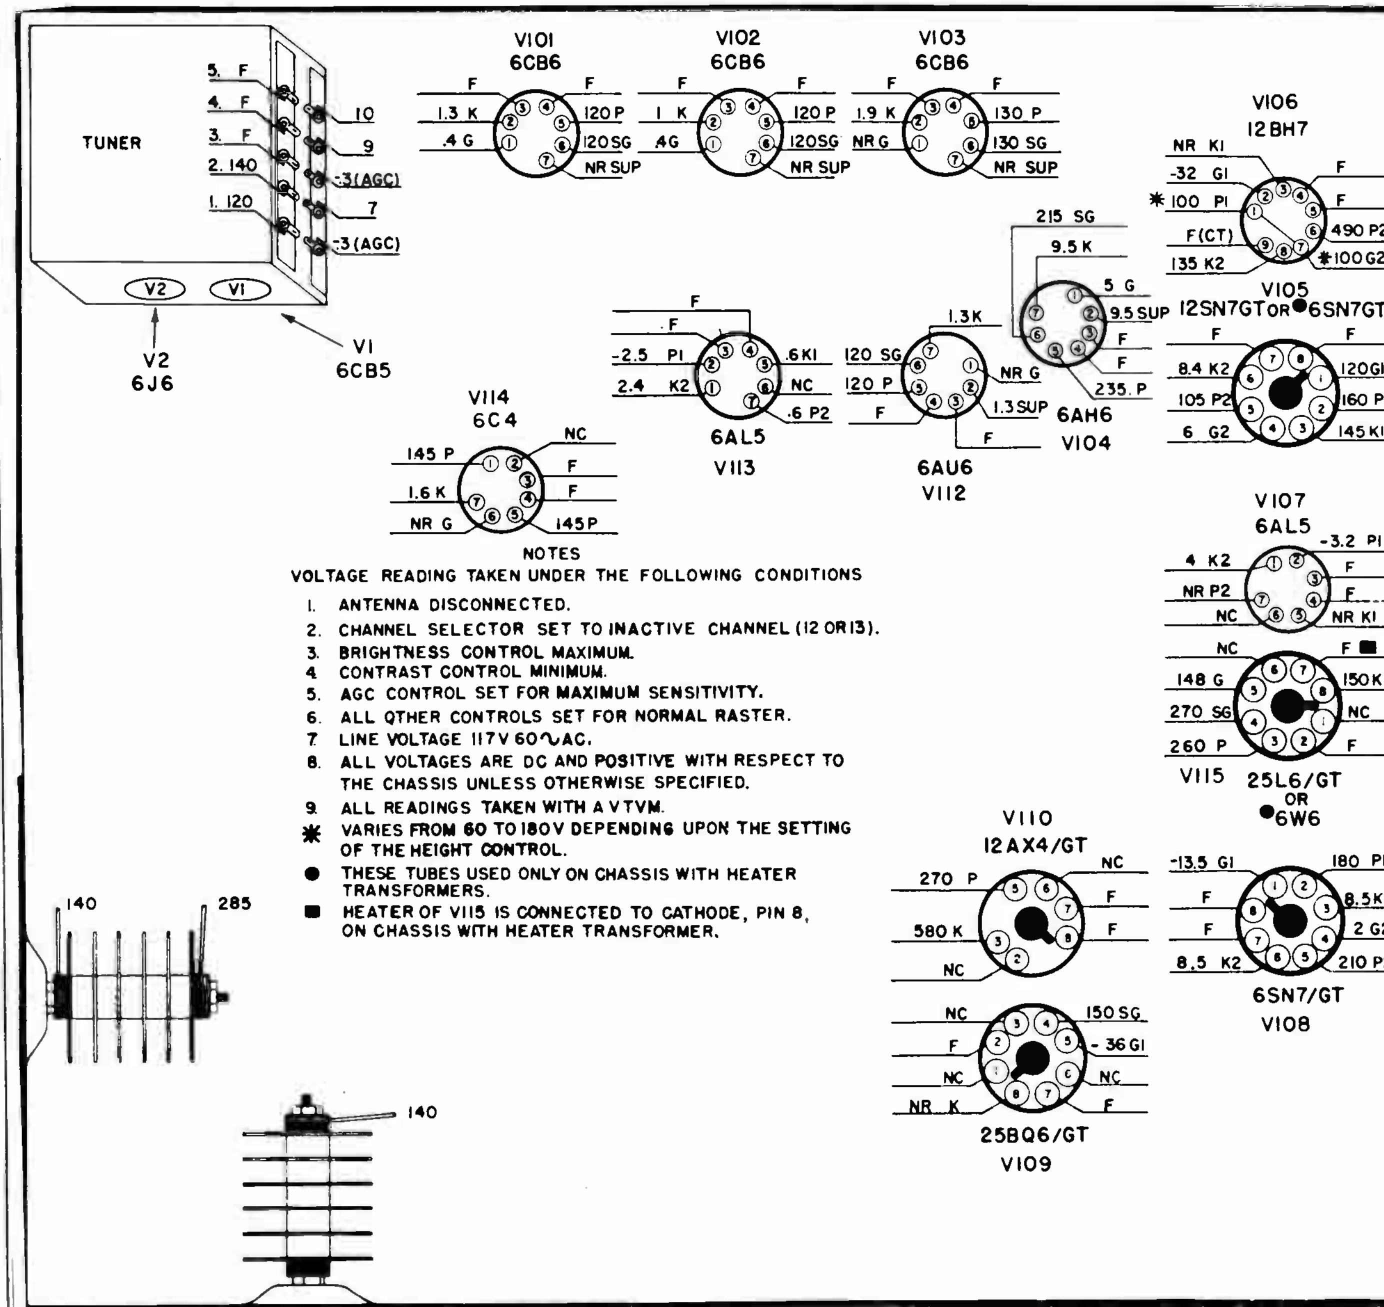

Fig. 19A. Voltage Chart for AG1200D, AH1200D, or AR1200D Chassis with 1E1492 Pentode Tuner and AL1200D (Runs 3 & 4) or AX1200D Chassis with 1C1345 Pentode Tuner

BAND PASS ALIGNMENT OF 1C1345, 1C1376, 1E1492, & 1E1677 TV TUNERS

CAUTION: Band pass alignment is carefully made at the factory. Attempt this alignment only with proper equipment and set-up. The tube shields and the bottom cover for the tuner must be in place. The oscillator adjustment given on page 1953-15 must be completed before the band pass alignment is started.

1. Complete the set-up procedure given on page 1953-15.
2. Connect the leads from the sweep and marker generators to the tuner antenna terminals.
3. Turn the channel selector to channel 13. Adjust the generators to the correct frequencies for channel 13 as shown in the chart on page 1953-14.
4. Adjust L-3 (channel 13 rf plate), L-2 (channel 13 rf grid), and L-6 (channel 13 mixer grid) adjusting screws (see Fig. 16A or 16B) for a band pass characteristic containing both carriers with steep sides and maximum gain. The 1C1376 cascode tuners do not require adjustment of the channel 13 rf grid coil (L-2) and hence a screw for this adjustment will not be found on the top of these tuners.

If the factory adjustment of the incremental loops and coils has not been disturbed, alignment of the rf plate, rf grid, and mixer grid should be complete after the completion of step 4 unless extensive repairs have been made on the tuner. Check the other channels for a similar band pass characteristic as shown in Fig. 17A. If they have the correct characteristics further alignment is not necessary. If they do not, procede with step 5. When aligning the 1C1376 cascode tuners it will first be necessary to repeat step 4 and adjust L-2 by spreading or compressing the turns of the coil before continuing with steps 5 and 6.

5. Adjust the coils of the rf plate, rf grid, and mixer grid for channels 12 through 7 starting with channel 12. Adjust the signal generators for each channel to the frequencies given in the chart on page 1953-14. Pushing the half turn coil loops towards the center of the switch so that they are closer to the switch wafer will increase the frequency while pulling them out and away from the switch wafer will decrease the frequency. Adjust for a band pass characteristic containing both carriers with steep sides and maximum gain.
6. Adjust the coils of the rf plate, rf grid, and mixer grid for channels 6 through 2 starting with channel 6. Adjust the signal generators for each channel to the frequencies given in the chart on page 1953-14. Spreading the turns of the coils will increase the frequency while squeezing the turns together will decrease the frequency. Adjust for a band pass characteristic containing both carriers with steep sides and maximum gain. A tuning wand may be used to determine what change is necessary.

ALIGNMENT FOR 1C1345 OR 1E1492 PENTODE- & 1C1376 OR 1E1677 CASCODE TUNERS

These tuners have been carefully aligned at the factory by personnel using precision equipment. Minor alignment adjustments of the tuner may be necessary after making tube or part replacements. When replacing tubes in a tuner use the same tube type as the original tube which was removed from the tuner and also try several different tubes and select the one which gives best performance. Realignment of the tuner probably will not be required if a selected tube is used for replacement. Use of an alternate tube may require a complete realignment of the TV tuner. For those service engineers who are properly equipped as specified, the following alignment procedure is included. Balance of TV receiver must be functioning properly before aligning tuner.

EQUIPMENT REQUIRED FOR TV TUNER ALIGNMENT

1. Sweep generator ____________ RCA type WR-59B or equiv.
2. Marker Generator ____________ RCA type WR-39C Television Calibrator or equivalent.
3. Oscilloscope ____________ RCA type WO-56A or equiv.
4. Bias Source ____________ 1.5 volt battery.
5. Isolation Transformer ________ 150 watt rating or higher

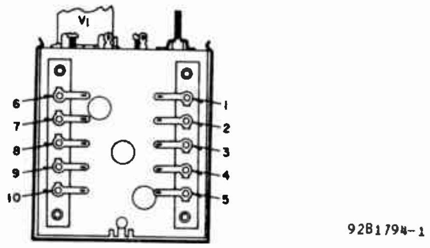

Fig. 15A. Numbering of Tuner Terminals

SET-UP PROCEDURE FOR TUNER ALIGNMENT

1. Check to be sure that the tube shields and the bottom cover for the tuner are in place.
2. Connect all test equipment and the television chassis to a common ground. Be sure to use an isolation transformer for the receiver chassis. Allow at least a 5 minute warm-up period for the receiver chassis.
3. Connect the negative terminal of a 1.5 volt bias source to terminal 8 of the TV tuner. See Fig. 15A for terminal numbering. Connect the positive side of the bias source to any convenient ground point on the chassis.
4. Connect the hot lead from the oscilloscope through a 10,000 ohm carbon resistor to test point T.P.-1 (See page 1953-16). Connect the ground lead from the oscilloscope to any convenient ground point on the TV tuner chassis. Set the scope sweep oscillator to roughly 120 cycles.

OSCILLATOR ADJUSTMENT

1. Turn the channel selector to channel 13.
2. Set the marker generator to 237.5 mc. and connect generator leads to the antenna terminals.
3. Rotate the fine tuning control until a zero beat is indicated on the scope. When the fine tuning control is rotated a band will appear across the face of the scope. As the point of zero beat is approached this band will increase in amplitude and then decrease sharply until a minimum is reached which is the point of zero beat. If the fine tuning control is rotated farther in the same direction the amplitude of the band will increase sharply and then decrease. The point of zero beat should fall in the approximate center of the range over which the fine tuning control may be rotated. If it does not, set the fine tuning control at the approximate center of its range and adjust L-7 (Channel 13 Oscillator Adjustment) for the zero beat. Do not disturb the setting of the fine tuning control after this adjustment.
4. Set the channel selector to channel 6.
5. Set the marker generator to 109.5 mc.
6. Adjust L-8 (Channel 6 Oscillator Adjustment) for the zero beat indication on the scope.

NOTE: Adjustment of the channel 13 and channel 6 oscillator coils automatically brings all other channel into adjustment. The adjustment screws cover their entire electrical range within eight full revolutions counterclockwise from the tight position. Any further rotation of these screws may cause them to fall out. Counterclockwise rotation of the screws will decrease the oscillator frequency. Best results will be obtained if a non-metallic screwdriver is used.

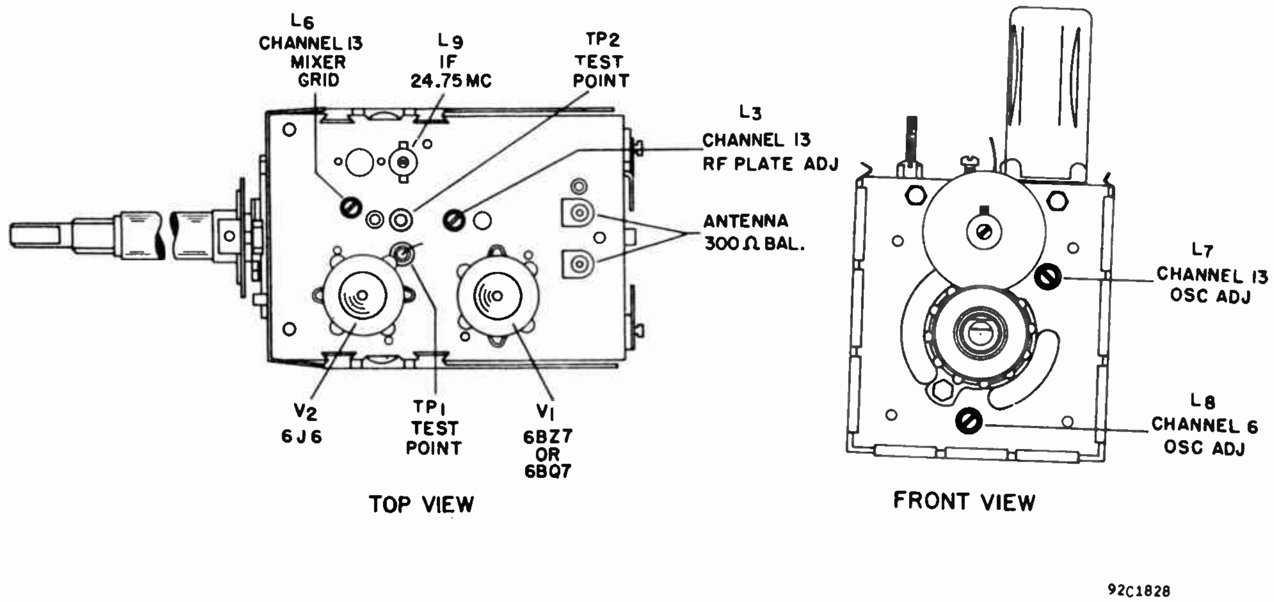

Fig. 16B. 1C1376 or 1E1677 Cascode TV Tuner Alignment Adjustments

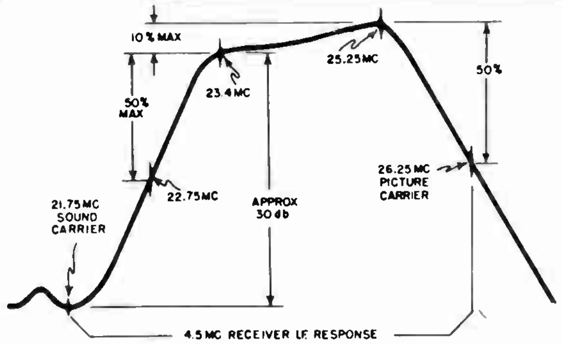

Fig. 14A. Typical Response for 21.75 to 26.25 MC I-F Amplifier

I-F AMPLIFIER ALIGNMENT FOR BA1200D CHASSIS

PROCEDURE

1. Connect all test equipment to a common ground. Connect the TV chassis to this same ground after installing an isolation transformer between the power line and the TV chassis. One side of the line cord connects directly to the TV chassis and an isolation transformer must be used for safety. Allow a 15 minute warm up period.

2. Set the AVC switch on the rear chassis apron to the 0-10 MILE (counterclockwise) position.

3. Connect the negative side of a 3 volt battery supply to test point Ⓔ. Connect the positive side of the supply to the TV chassis. See schematic diagram.

4. Connect a VTVM to test point Ⓓ through a 47,000 ohm carbon resistor. Connect the ground side of the meter to the TV chassis. See Fig. 11C.

5. Connect the high side of a marker generator to the shield of the osc./mixer tube. This connection will capacitively couple the generator output to the tube. Make sure the shield is ungrounded by raising it above the grounded clips that hold it in place.

6. Set the channel selector to channel 3 or 4, whichever is vacant.

7. Set the marker generator output (unmodulated) for a two volt negative dc reading on the VTVM and adjust the three i-f transformers, L-9, and L-201 according to the I-F AMPLIFIER ALIGNMENT CHART shown below. Readjust the signal generator output as required to maintain the two volt VTVM reading.

I-F AMPLIFIER ALIGNMENT CHART

Signal Generator Frequency (No Modulation)	Adjustment	Transformer or Coil Location	VTVM Indication
45.0 MC	T-201 (bottom)	See Fig. 11C	Maximum
42.8 MC	T-202 (bottom)	Under Chassis	Maximum
44.0 MC	T-203 (bottom)	See Fig. 11C	Maximum
41.25 MC	T-202 (top)	See Fig. 11C	Maximum
42.8 MC	T-202 (bottom)	See Fig. 11C	Maximum
44.25 MC	*L-201	See Fig. 11C	Maximum
44.25 MC	#L-9	See Fig. 11C	Maximum

IMPORTANT - The wax in the end of the coil forms holding the iron core in position may be softened for adjustment of the core by means of a heated screwdriver or a small pencil type soldering iron inserted into the wax. Remelt wax after adjustment.

* NOTE: Temporarily connect the series resistor-capacitor combination shown in Fig. 12A to the tuner test point TP-2 when making this adjustment.

NOTE: Temporarily connect the series resistor-capacitor combination shown in Fig. 12A to the grid (pin 1) of V-101 the 6CB6 first i-f amplifier when making this adjustment.

8. Disconnect the VTVM and marker generator connected in steps 4 and 5. The balance of the set-up should be as directed in steps 1, 2, 3 and 6.

9. Capacitively couple the high side of the sweep generator r-f output to the osc./mixer tube by connecting to the tube shield which has been raised above its grounding clips. The ground side of the sweep generator should be connected to the receiver chassis. Adjust the generator to sweep from 40.5 to 46.5 MC.

10. Loosely couple the high side of the marker generator to the high side of the sweep generator by clipping the marker generator r-f lead over the insulation of the sweep generator r-f lead. The ground side of the marker generator should be connected to the receiver chassis.

IMPORTANT — To prevent overloading of the i-f amplifier keep the output of the sweep and marker generators as low as possible. The marker generator output should be just high enough to produce visible pips on the pattern. In some cases the 41.25 MC pip will not be visible unless the r-f output of the marker generator is increased to overcome the attenuation of the 41.25 MC signal by the trap in the top of T-202.

11. Connect the sweep output terminals on the sweep generator to the input of the horizontal amplifier in the oscilloscope.

12. Connect one side of a 47,000 ohm 1/2 watt resistor to test point Ⓓ shown in the schematic diagrams. Connect the other end of the resistor to the high side of the input terminals for the vertical amplifier in the oscilloscope. The scope ground terminal connects to the receiver chassis. Keep the scope leads away from the internal chassis wiring, particularly the horizontal output section.

13. Reduce the r-f output of the sweep generator and increase the gain of the vertical amplifier in the oscilloscope as much as possible without introducing an excessive amount of noise on the test pattern. This will prevent overloading of the i-f system.

14. Check the position of the markers shown in Fig. 14BA. Adjust only the bottom cores of T-201, T-202 and T-203 for a response curve of maximum amplitude with a slightly tilted flat topped appearance as shown in Fig. 14BA. This tilt is required to compensate for the capacitive coupling used for the signal generators. The actual response obtained will be flat when the pattern viewed on the oscilloscope has this tilt. The bottom core of T-203 will primarily control the tilt of this central portion of the curve.

    The bottom core of T-201 should be adjusted to position the 45.75 MC marker in the 50% position shown in Fig. 14BA.

    The bottom core of T-202 should be adjusted to determine the slope of the curve between 41.25 MC and 42.8 MC with the 42.25 MC marker down 50% on the curve as shown in Fig. 14BA.

    Under no circumstances should an attempt be made to adjust L-9, L-201 and the 41.25 MC trap in the top of T-202 by means of an oscilloscope and sweep generator. Maladjustment of these coils does not give a noticeable indication on the oscilloscope. Align these coils by following the procedure given in steps 1 through 7 only.

I-F AMPLIFIER SENSITIVITY MEASUREMENT

To determine the i-f amplifier sensitivity, disconnect the r-f output lead from the tuner where it connects to L-201. Temporarily connect one side of a .005 mfd. mica or ceramic capacitor to grid pin 1 of the first 6CB6 i-f amplifier tube V-101. Connect the unmodulated r-f output of a marker generator to the other side of the capacitor and the ground side of the generator to the TV chassis. Set the marker generator to 43.75 MC. Connect a VTVM as directed in step 4 of the alignment procedure. The 3 volt battery must be removed. If a generator output of 200 to 400 microvolts produces a 1 volt reading on the VTVM, the i-f amplifier sensitivity is normal.

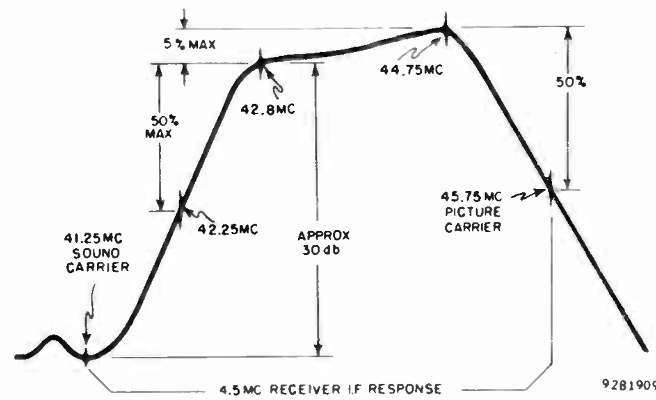

Fig. 14BA. Typical Response for 41.25 to 45.75 MC I-F Amplifiers

I-F AMPLIFIER ALIGNMENT

EQUIPMENT REQUIRED

SWEEP GENERATOR	RCA type WR-59B or equivalent.
MARKER GENERATOR	RCA type WR-39C Television Calibrator or equivalent.
OSCILLOSCOPE	RCA type WO-56A or equivalent.
VACUUM TUBE VOLTMETER (VTVM)	RCA type WV-97A or equivalent.
BIAS SOURCE	Three volt battery.
TEST CIRCUIT	Shown in Fig. 12A.
ISOLATION TRANSFORMER	150 watt rating or higher.

PROCEDURE

1. Connect all test equipment to a common ground. Connect the TV chassis to this same ground after installing an isolation transformer between the power line and the TV chassis. One side of the line cord connects directly to the TV chassis and an isolation transformer must be used for safety. Allow a 15 minute warm up period.

2. Set the AVC switch on the rear chassis apron to the 0-10 MILE (counterclockwise) position.

3. Connect the negative side of a 3 volt battery supply to test point Ⓔ Connect the positive side of the supply to the TV chassis.

4. Connect a VTVM to test point Ⓓ through a 47,000 ohm carbon resistor. Connect the ground side of the meter to the TV chassis.

5. Connect the high side of a marker generator to the shield of the osc./mixer tube. This connection will capacitively couple the generator output to the tube. Make sure the shield is ungrounded by raising it above the grounded clips that hold it in place.

6. Set the channel selector to any vacant channel.

7. Set the marker generator output (unmodulated) for a two volt negative dc reading on the VTVM and adjust the three i-f transformers, L-9, and L-101 according to the I-F AMPLIFIER ALIGNMENT CHART shown below. Readjust the signal generator output as required to maintain the two volt VTVM reading.

I-F AMPLIFIER ALIGNMENT CHART

Signal Generator Frequency (No Modulation)	Adjustment	Location	VTVM Indication
25.4 MC	T-101 (bottom)	See Fig. 11Aor B	Maximum
23.4 MC	T-102 (bottom)	Under Chassis	Maximum
24.5 MC	T-103 (bottom)	See Fig. 11A or B	Maximum
21.75 MC	T-102 (top)	See Fig. 11A or B	Minimum
23.4 MC	T-102 (bottom)	See Fig. 11A or B	Maximum
24.75 MC	*L-101	See Fig. 11A or B	Maximum
24.75 MC	#L-9	See Fig. 11A or B	Maximum

IMPORTANT — The wax in the end of the coil forms holding the iron core in position may be softened for adjustment of the core by means of a heated screwdriver or a small pencil type soldering iron inserted into the wax. Remelt wax after adjustment.

*NOTE: On chassis with the 1C1345 or 1E1492 Pentode and 1E1376 or 1E1677 Cascode tuners, temporarily connect the series resistor-capacitor combination shown in Fig. 12A to the tuner test point TP-2 when making this adjustment. On chassis with the 1E1380 Cascode tuner, hold the channel selector between channels when making this adjustment.

#NOTE: Temporarily connect the series resistor-capacitor combination shown in Fig. 12A to the grid (pin 1) of V-101 the 6CB6 first i-f amplifier when making this adjustment.

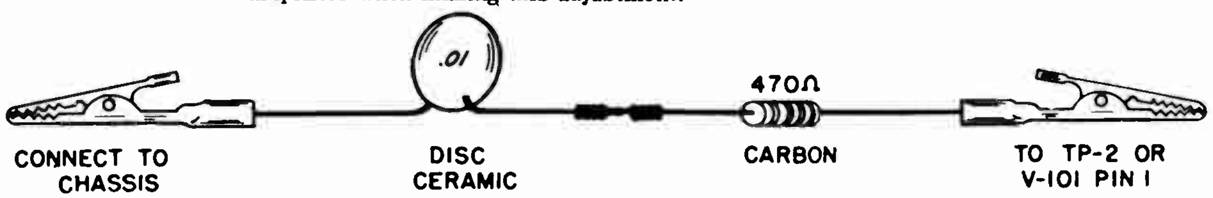

Fig. 12A. Test Circuit for I-F Amplifier Alignment

9281771

8. Disconnect the VTVM and marker generator connected in steps 4 and 5. The balance of the set-up should be as directed in steps 1, 2, 3 and 6.

9. Capacitively couple the high side of the sweep generator r-f output to the osc./mixer tube by connecting to the tube shield which has been raised above its grounding clips. The ground side of the sweep generator should be connected to the receiver chassis. Adjust the generator to sweep from 19 to 29 MC.

10. Loosely couple the high side of the marker generator to the high side of the sweep generator by clipping the marker generator r-f lead over the insulation of the sweep generator r-f lead. The ground side of the marker generator should be connected to the receiver chassis.

IMPORTANT - To prevent overloading of the i-f amplifier keep the output of the sweep and marker generators as low as possible. The marker generator output should be just high enough to produce visible pips on the pattern. In some cases the 21.75 MC pip will not be visible unless the r-f, output of the marker generator is increased to overcome the attenuation of the 21.75 MC signal by the trap in the top of T-102.

11. Connect the sweep output terminals on the sweep generator to the input of the horizontal amplifier in the oscilloscope.

12. Connect one side of a 47,000 ohm 1/2 watt resistor to test point Ⓓ shown in the schematic diagrams. Connect the other end of the resistor to the high side of the input terminals for the vertical amplifier in the oscilloscope. The scope ground terminal connects to the receiver chassis. Keep the scope leads away from the internal chassis wiring, particularly the horizontal output section.

13. Reduce the r-f output of the sweep generator and increase the gain of the vertical amplifier in the oscilloscope as much as possible without introducing an excessive amount of noise on the test pattern. This will prevent overloading of the i-f systems.

14. Check the position of the markers shown in Fig. 14A. Adjust only the bottom cores of T-101, T-102 and T-103 for a response curve of maximum amplitude with a slightly tilted flat topped appearance as shown in Fig. 14A. This tilt is required to compensate for the capacitive coupling used for the signal generators. The actual response obtained will be flat when the pattern viewed on the oscilloscope has this tilt. The bottom core of T-103 will primarily control the tilt of this central portion of the curve.

The bottom core of T-101 should be adjusted to position the 26.25MC marker in the 50% position shown in Fig. 14A.

The bottom core of T-102 should be adjusted to determine the slope of the curve between 21.75 MC and 23.4 MC with the 22.75 MC marker down 50% on the curve as shown in Fig. 14A.

Under no circumstances should an attempt be made to adjust L-9, L-101 and the 21.75 MC trap in the top of T-102 by means of an oscilloscope and sweep generator. Maladjustment of these coils does not give a noticeable indication on the oscilloscope. Align these coils by following the procedure given in steps 1 through 7 only.

MEASUREMENT OF I-F AMPLIFIER SENSITIVITY

To determine the i-f amplifier sensitivity, disconnect the r-f output lead from the tuner where it connects to L-101. Temporarily connect one side of a .005 mfd. ceramic or mica capacitor to grid pin 1 of the 6CB6 first i-f amplifier tube V-101. Connect the unmodulated r-f output of a marker generator to the other side of the capacitor and the ground side of the generator to the TV chassis. Set the marker generator to 24.75 MC. Connect a VTVM as directed in step 4 of the alignment procedure. The three volt battery must be removed. If a generator output of 200 to 400 microvolts produces a 1 volt reading on the VTVM, the i-f amplifier sensitivity is normal.

FM SOUND CHANNEL ALIGNMENT FOR 1200 SERIES CHASSIS

EQUIPMENT REQUIRED

Signal generator covering 4 to 30 mc unmodulated.

Vacuum tube voltmeter (VTVM).

Sound alignment test circuit shown in Fig. 10A.

Power line isolation transformer.

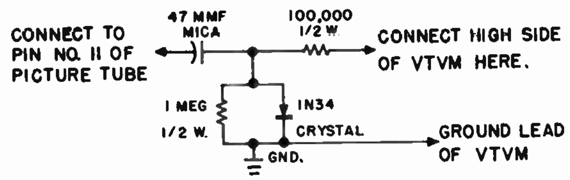

Fig. 10A. Sound Alignment Test Circuit

PROCEDURE

1. Connect all test equipment to a common ground. Connect the TV chassis to this same ground after installing an isolation transformer between the power line and the TV chassis. One side of the line cord connects directly to the TV chassis and an isolation transformer must be used for safety.

2. Set the channel selector to any vacant channel and the contrast control at minimum.

3. Connect the signal generator output through a .005 mfd. capacitor to test point Ⓓ shown in schematic diagram. Ground the shield of the generator output cable to the chassis.

4. Connect the sound alignment detector circuit and VTVM as shown in Fig. 10A. Adjust the 4.5 mc. generator output (unmodulated) to give a 1 volt reading on the VTVM.

5. Adjust the 4.5 mc. trap adjustment (L-105) at 4.5 mc. for a minimum VTVM reading.

6. Disconnect the test circuit and connect the VTVM to test terminal Ⓑ (Pin 2 of FM detector, V-113). See schematic diagram.

7. Adjust the 4.5 mc. amplifier grid adjustment (L-110) and the primary of T-107 (bottom core) at 4.5 mc. for a maximum VTVM reading.

8. Connect the VTVM to test terminal Ⓒ, shown in the schematic diagram. Adjust the secondary of T-107 (top core) at 4.5 mc. for the zero reading which occurs between the positive and negative peaks. If the zero reading occurs at more than one setting, use the position nearest the top limit of the core.

9. Shift the signal generator an equal amount on either side of 4.5 mc. and touch up the primary of T-107 (bottom core) for approximately equal peaks. Use just enough signal output to obtain one volt peaks for best results.

YOUR INTRODUCTION TO ULTRA HIGH FREQUENCIES

The Federal Communication Commission, recognizing the need for many additional television stations, has set aside the ultra high frequency band (470 to 890 megacycles) for commercial television use. This action makes room for thousands of new stations throughout the nation, which will transmit on channels 14 through 83. Reception of these channels is beyond the normal range of your standard VHF television receiver which tunes only channels 2 through 13. In order to receive these higher channels, a UHF converter must be added to your receiver.

The Granco Coaxial Tuned UHF Converter Model MTU, has been specifically designed to permit reception of all UHF stations, present and future, on any standard VHF television receiver. It does this by electronically converting the higher channels to channels 5 or 6 which your set can receive. The conversion takes place simply and efficiently without effecting your normal VHF reception. Installation and operation is as simple as a radio set, as explained in the following instructions.

FIG. 1

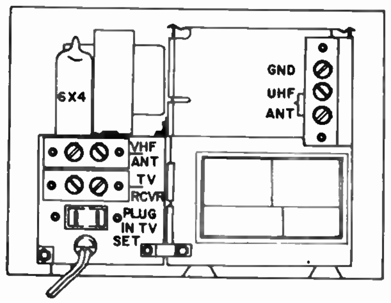

FIG. 2

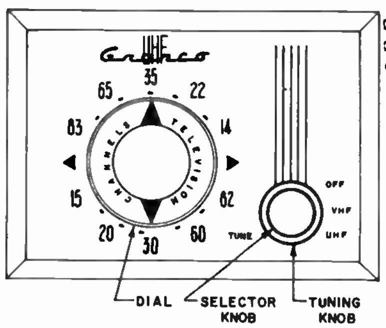


INSTALLATION

The converter should be located as closely as possible to your television set. The most satisfactory location would be either on top or to the right side of your set because these are closest to the set antenna terminals. All connections are made to the rear of the converter as shown in Figure 1. A label attached to the chassis rear clearly identifies each of the terminal connections, which are further defined as follows:

VHF ANT — Connects to the VHF antenna wire now used with your television set.

TV RCVR — Connects to your television set antenna terminals.

PLUG IN TV SET — Your television set power line cord plugs in here.

UHF ANT — Connect your UHF antenna twin lead here. If coaxial cable is used, connect shield braid to *GND* terminal and insulated inner conductor wire to *ANT* terminal directly below GND terminal.

To insure proper installation the following procedure should be used, however, before starting make sure that the power cord of the converter is not connected to an electrical outlet.

Installation Procedure

1. Connect UHF antenna twin lead to terminals marked *UHF ANT*. If coaxial lead-in is used connect to terminal marked *GND* and adjacent *ANT* terminal.
2. Disconnect wires from TV set antenna terminals and connect to *VHF ANT* terminals on converter.
3. Connect a short piece of twin lead cable between the TV set antenna terminals and converter *TV RCVR* terminals.

   NOTE: In areas of strong local reception on channels 5 or 6, it is advisable to use shielded 300 ohm twin lead to avoid interference with UHF reception.
4. Remove TV set power cord plug from wall outlet and plug into converter receptacle marked *PLUG IN TV SET*. Turn TV set power switch on and leave in this position at all times.
5. Check all connections to be sure that they are tight, and no loose strands are shorting across the terminals.
6. Turn the *SELECTOR* knob (see Figure 2) to *OFF* position and plug the converter power line cord into 117 volt 60 cycle wall receptacle.

OPERATION

Your set has now been converted into a modern 82 channel television receiver, capable of receiving any television transmission in your vicinity. Proper operation requires control of both the converter and television set knobs. The two converter knobs (see Figure 2) control UHF tuning, and OFF — VHF — UHF switching.

The Selector knob position functions are further explained as follows:

OFF — Power to both converter and TV is turned off.

VHF — The TV set and the converter tube filaments are turned on. The VHF antenna is connected to TV by the internal switch. Channels 2 through 13 may now be selected in the normal way.

UHF — Power to both converter and set is on. The VHF antenna is disconnected, shorted, and grounded, to prevent interference. The converter output is connected to the receiver antenna input terminals by the internal switch. With the TV channel selector in channels 5 or 6 position any UHF channel may be selected by turning the UHF tuning knob.

To insure proper operation the following procedure should be used. Be sure TV power switch is on and left on at all times.

Operating Procedure

1. Turn "Selector" knob to *VHF*. Allow a few minutes for warm-up and then operate TV set in normal way if programs on any of channels 2 through 13 are desired.
2. To receive programs on channels 14 through 83 turn "Selector" knob to *UHF* and set TV channel selector to either 5 or 6. *NOTE*: Always select the channel which is *not* being used by a local VHF television station. This will eliminate the possibility of interference with UHF reception.
3. Tune in the desired UHF channel by turning the "Tuning" knob on the converter and adjusting for best picture and sound. Tuning may be further improved by using the TV set fine tuning control.
4. To turn the converter and receiver off, rotate "Selector" knob on converter to *OFF*. *Do not* turn receiver power switch off. Leave on at all times.

HOW TO GET THE MOST FROM YOUR GRANCO UHF CONVERTER

Antenna

One of the most important accessories required for satisfactory reception is a properly installed UHF antenna. Your local service man or television dealer is equipped to select and install an antenna best suited to your requirements.

Service Notes

The Granco Model MTU, UHF Converter has been carefully designed and assembled to give long trouble-free performance. However, occasions may arise when tube changes or minor service adjustments are required. On such occasions it is recommended that you call in your local service man or television dealer, who is trained to make these adjustments most efficiently. The following notes are intended for his guidance.

Tube Replacement

The 6X4 rectifier tube is readily accessible by removing back cabinet cover. The 6AF4 oscillator, 6BQ7A I-F amplifier, and 1N82 detector, are contained within the tuner compartment. For replacement of any of these proceed as follows:

1. Remove knobs and back cover.
2. Remove 4 bottom mounting screws.
3. Remove chassis.
4. Remove top tuner shield by compressing front and back flaps inward using thumb and fore-finger, simultaneously pulling straight up. This action will release friction catches which retain top shield.
5. Replace tubes and reassemble chassis into cabinet, after replacing shield.

NOTE: A plug button opposite the 6AF4 tube may be removed as an aid in replacing this tube. Reinsert button after tube has been changed.

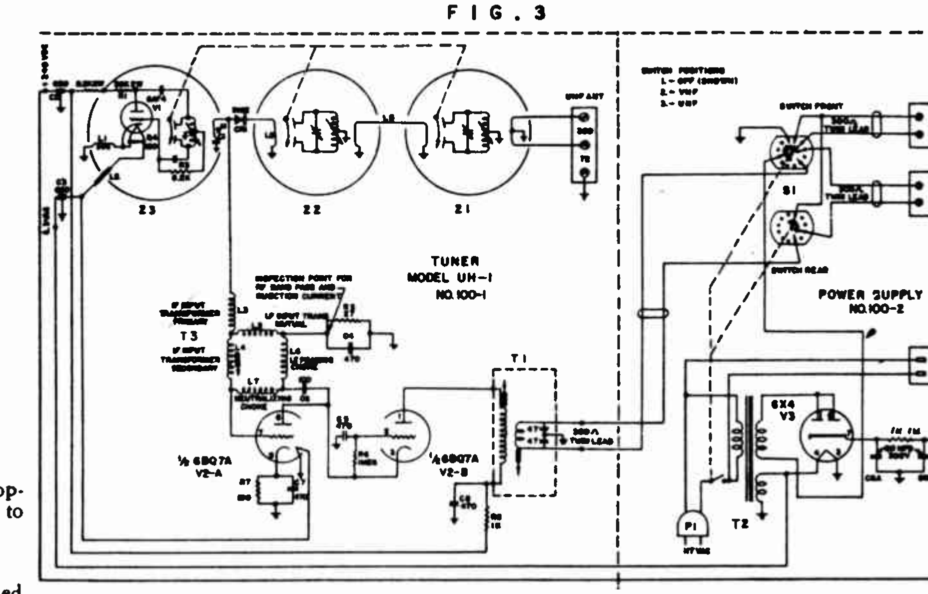
A tube change normally will not require realignment. However, be sure that all tubes are firmly seated in their sockets. This is especially true of the 6AF4 tube.

Component Replacement

All components, including those contained in the tuner compartment may be readily replaced. It is recommended, however, that where trouble is suspected in the tuner, either the entire converter or the tuner section be returned to the factory for retest.

Replacement parts may be ordered from the factory by using the symbol numbers given in Schematic, Figure 3, as well as the chassis serial number printed on rear tube label.

FIG. 3



REPLACEMENT PARTS

STOCK No.	DESCRIPTION
	RF UNIT ASSEMBLIES
	KRK29
77853	Capacitor—Ceramic, variable, for fine tuning capacitor—plunger type (C27)
	Capacitor—Adjustable, mica:
77616	4-40 mmf. (C33)
	Capacitor—Adjustable, steatite:
77151	0.8—3.0 mmf. (C11, C21, C25)
77913	0.8—3.0 mmf. (C22)
76532	1-4 mmf. (C7)
	Capacitor—Ceramic:
77084	Feed-thru, 1000 mmf. (C5, C15, C17, C18, C19)
	Capacitor—Fixed, ceramic, non-insulated, Temp. coef. = 0
77865	10 mmf., ±1 mmf., 500 volts (C26, C37)
	Capacitor—Fixed, ceramic, High "K" disc:
77293	470 mmf., +100%, 0%, 500 volts (C29, C34, C35)
77252	1000 mmf., +100%, 0%, 500 volts (C8, C9, C14, C20)
73960	10,000 mmf., +100%, 0%, 500 volts (C28)
	Capacitor—Fixed, ceramic, insulated, High "K":
75437	100 mmf., ±20%, 500 volts (C36)
78276	150 mmf., ±10%, 500 volts (C12)
75199	270 mmf., ±20%, 500 volts (C6, C10, C13)
	Capacitor—Fixed, ceramic, non-insulated, Temp. coef. = 0
93056	5 mmf., ±0.5 mmf., 500 volts (C2)
54207	18 mmf., ±10%, 500 volts (C1)
70935	27 mmf., ±10%, 500 volts (C3)
76739	33 mmf., ±10%, 500 volts (C4)
	Capacitor—Fixed, ceramic, non-insulated, Temp. coef = -750
78247	10 mmf., ±10%, 500 volts (C24)
	Capacitor—Fixed, headed-lead:
71504	0.68 mmf., ±20%, 500 volts (C23)
71502	2.2 mmf., ±20%, 500 volts (C31)
71503	3.3 mmf., ±20%, 500 volts (C32)
	Capacitor—Mica trimmer:
78397	80-150 mmf. (C16)
77854	Clip—Fine tuning clip for fine tuning core
73591	Coil—Antenna matching coil (Part of T1)
73874	Coil—Channel #6 mixer coil (L48)
73460	Coil—Channel #6 r.f. plate coil (L32)
78401	Coil—Channel #6 antenna coil (L61)
77915	Coil—Channel #13 oscillator coil (L49)
77919	Coil—Channel #13 mixer coil (L36)
77921	Coil—Channel #13 r.f. plate coil (L20)
78224	Coil—Choke coil (.47 muh) (L27)
77206	Coil—Filament choke coil (L33)
76763	Coil—Heater choke coil (L34, L35)
78271	Coil—I.F. input coil complete with adjustable core (L9)
76562	Coil—R.F. amplifier coupling coil (L7)
76537	Coil—Shunt coil complete with adjustable core (L3).
76538	Coil—Shunt coil complete with adjustable core (L2)
	Resistor—Fixed, composition:
503015	15 ohms, ±10%, ½ watt (R19)
503039	39 ohms, ±10%, ½ watt (R18)
503112	120 ohms, ±10%, ½ watt (R2)
503147	470 ohms, ±10%, ½ watt (R14)
503210	1000 ohms, ±10%, ½ watt (R6, R20)
503233	3300 ohms, ±10%, ½ watt (R9)

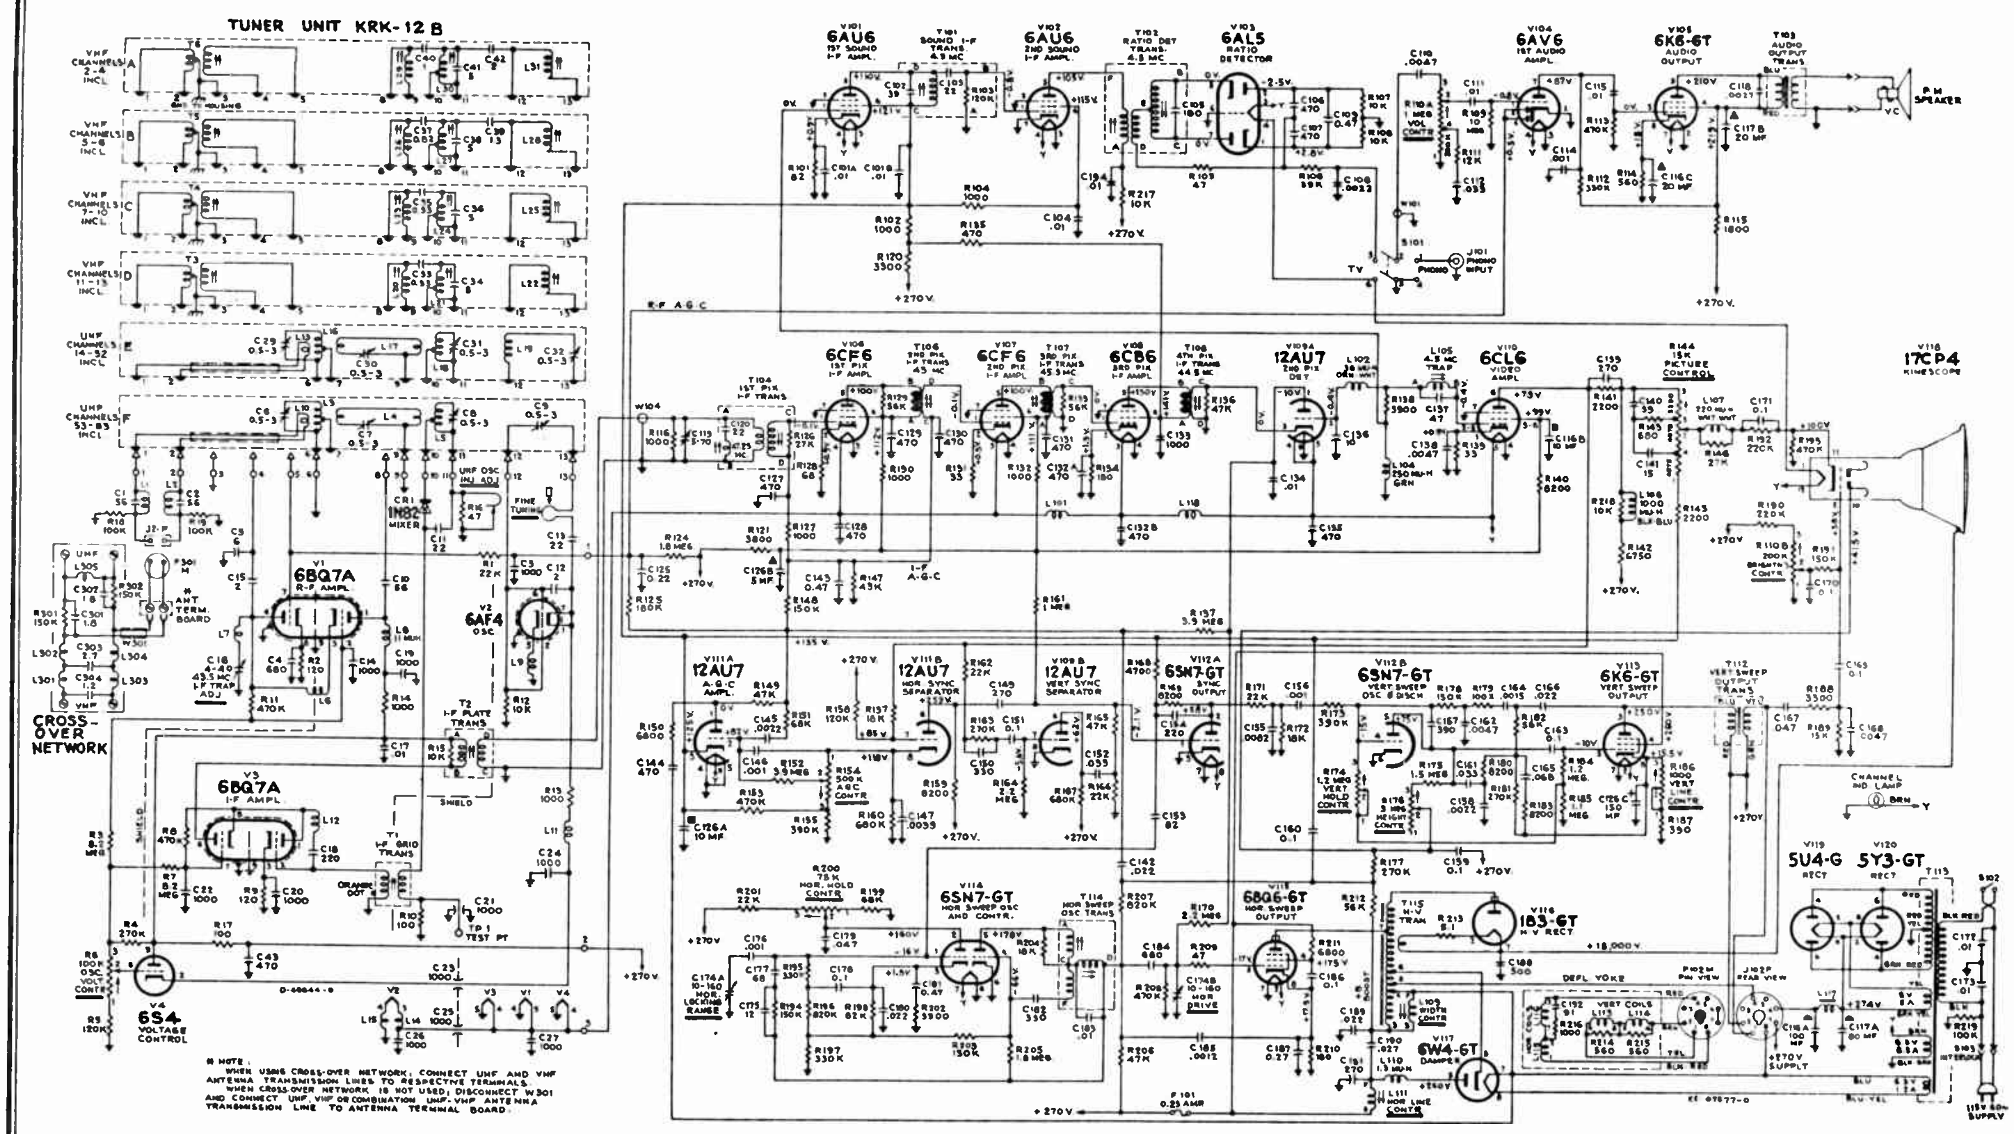
CIRCUIT SCHEMATIC DIAGRAM KCS78J



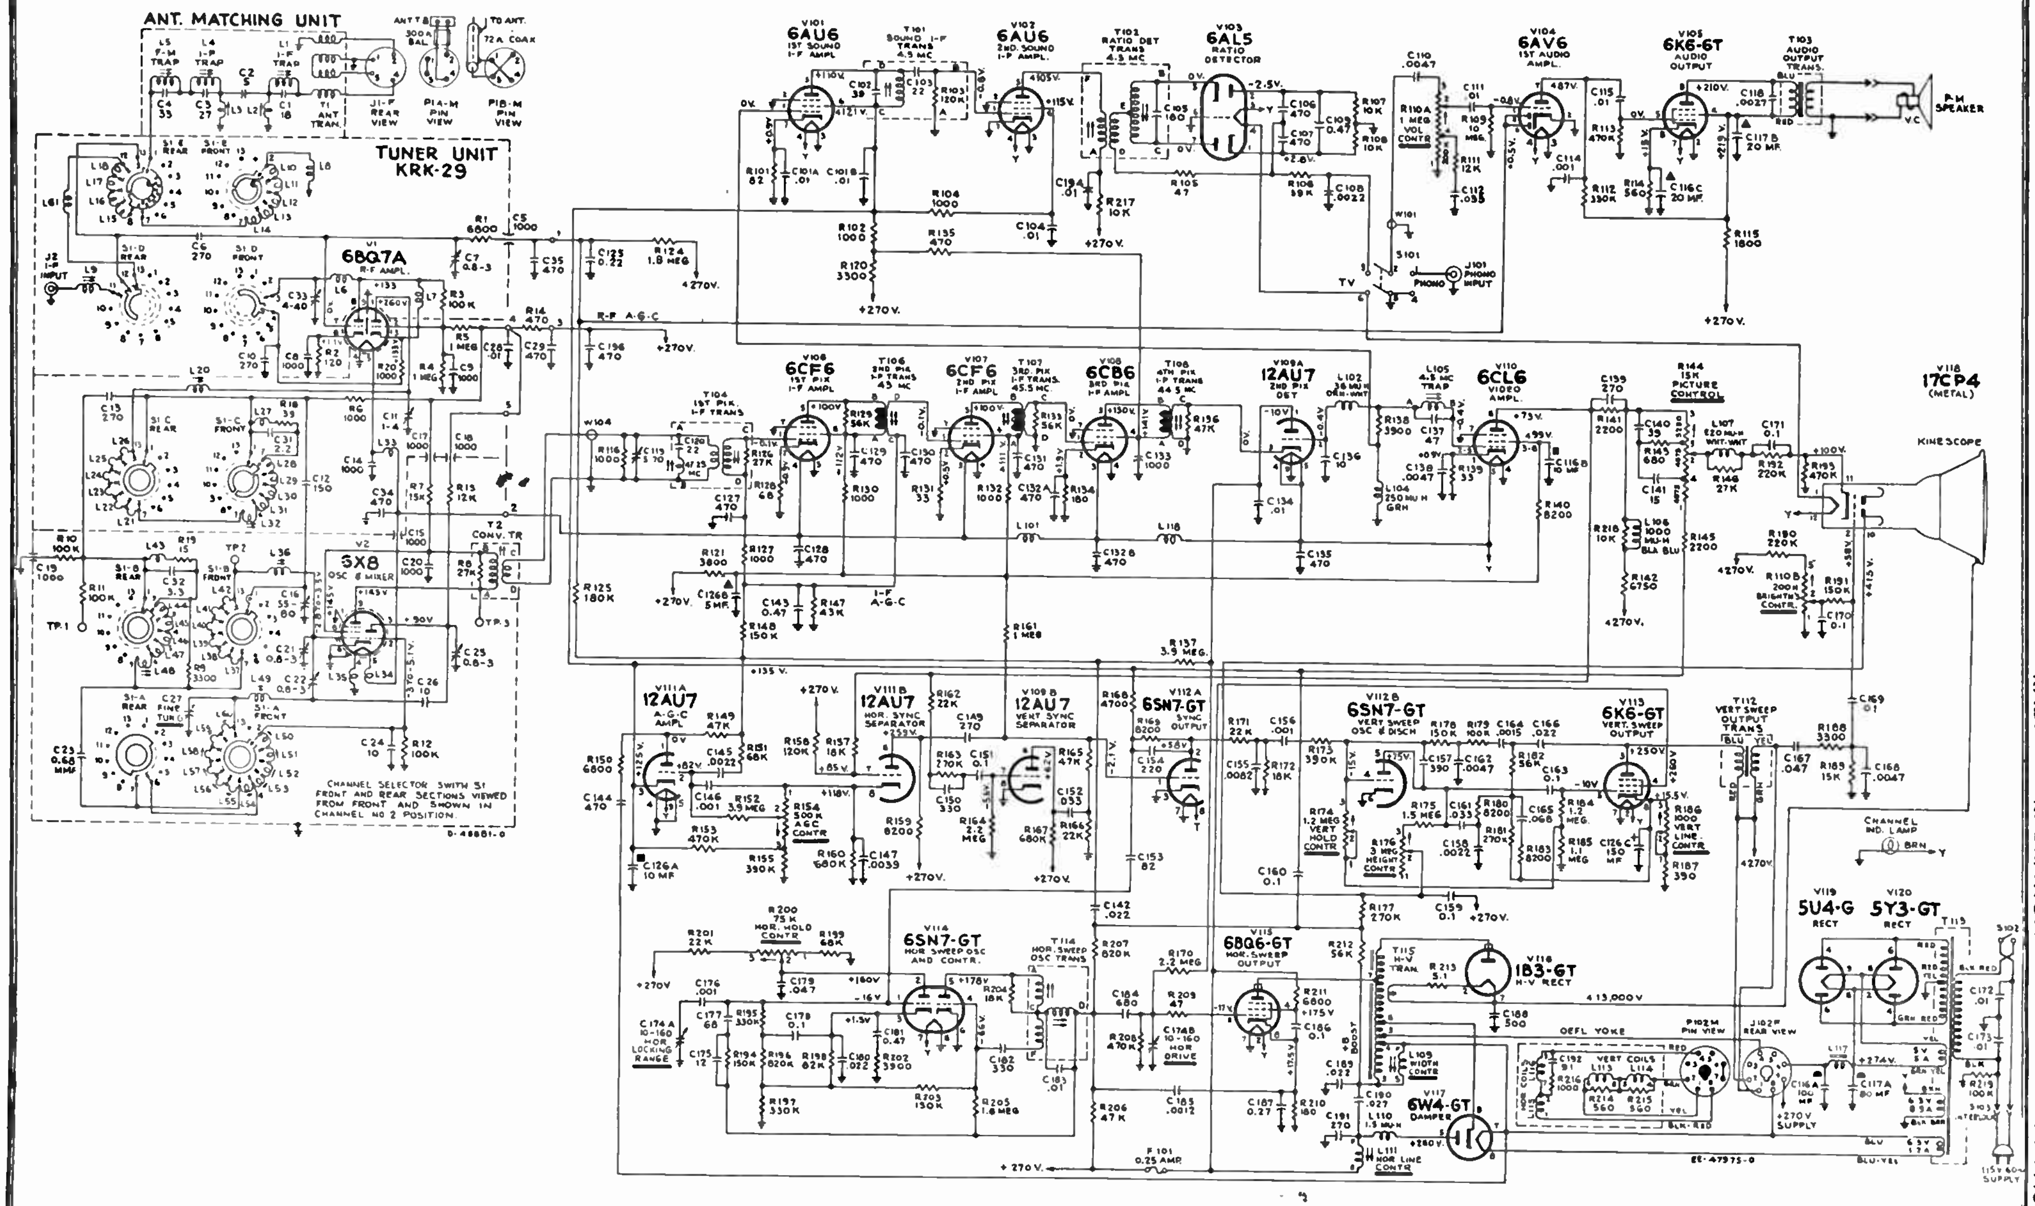
All resistance values in ohms. K = 1000.

All capacitance values less than 1 in MF and above 1 in MMF unless otherwise noted.

Direction of arrows at controls indicates clockwise rotation.

All voltages measured with "VoltOhmyst" and with no signal input. Voltages should hold within ±20% with 117 v. a-c supply.

Figure 28—Circuit Schematic Diagram, KCS78J



All resistance values in ohms. K = 1000.

All capacitance values less than 1 in MF and above 1 in MMF unless otherwise noted.

Direction of arrows at controls indicates clockwise rotation.

All voltages measured with "VoltOhmyst" and with no signal input. Voltages should hold within ±20% with 117 v. a-c supply.

Figure 27—Circuit Schematic Diagram KCS78F

VOLTAGE CHART

The following measurements represent two sets of conditions. In the first condition, a 15000 microvolt test pattern signal was fed into the receiver, the picture synced and the AGC control properly adjusted. The second condition was obtained by removing the antenna leads and short circuiting the receiver antenna terminals. Voltages shown are read with a type WV97A senior "VoltOhmyst" between the indicated terminal and chassis ground and with the receiver operating on 117 Volts, 60 cycles, a-c. The symbol < means less than.

ALIGNMENT PROCEDURE

Connect the potentiometer arm of the second bias supply to the junction of R147 and R148, and ground the positive battery terminal. Adjust the bias potentiometer to produce − 5 volts of i-f bias as indicated on the "VoltOhmyst" at the junction point.

Connect the oscilloscope to the junction of R138 and L105. Use 3 to 5 volts peak-to-peak output on the oscilloscope.

Turn the adapter switch on to apply plate voltage to the oscillator.

Turn the channel selector to the lowest UHF channel to be used.

Set the fine tuning control to the center of its range.

Adjust the oscillator core to proper frequency. To do this, connect the VHF signal generator to test point TP1 with the shortest leads possible. Insert a 45.75 mc. marker from the VHF generator.

Set the UHF sweep generator to sweep the desired channel, and observe the output on the oscilloscope. If the sweep generator is not sweeping the correct frequency range, it may be necessary to readjust the sweep in order to place the 45.75 marker on the response curve as in Fig. 14.

Set the UHF marker gen. to the picture carrier of the channel insert being adjusted and connect to test point TP1.

Adjust the oscillator core until the markers for 45.75 mc. and the picture carrier coincide on the sweep pattern on the oscilloscope.

Adjust mixer core for maximum gain with proper wave shape.

Connect the "VoltOhmyst" to test point TP1, using 1.5 volt D.C. scale.

Set oscillator injection adjustment to read .1 volts on the "VoltOhmyst."

Repeat the above steps for all UHF inserts adjusting the oscillator injection control only if the reading on the "VoltOhmyst" exceeds .3 volts. Adjust as necessary to read .3 volts or less at TP1.

AGC CONTROL ADJUSTMENT.—Disconnect all test equipment except the oscilloscope which should be connected to pin 6 of V110.

Connect an antenna to the receiver antenna terminals.

Turn the AGC control fully counter-clockwise.

Tune in a strong signal and adjust the oscilloscope to see the video waveform.

Turn the AGC control clockwise until the tips of sync begin to be compressed, then counter-clockwise until no compression is obtained.

HORIZONTAL OSCILLATOR ADJUSTMENT. — Normally the adjustment of the horizontal oscillator is not considered to be a part of the alignment procedure, but since the oscillator waveform adjustment may require the use of an oscilloscope, it cannot be done conveniently in the field. The waveform adjustment is made at the factory and normally should not require readjustment in the field. However, the waveform adjustment should be checked whenever the receiver is aligned or whenever the horizontal oscillator operation is improper.

Horizontal Frequency Adjustment.—Tune in a station and sync the picture. If the picture cannot be synchronized with the horizontal hold control R200, then adjust the T114 frequency core on the rear apron until the picture will synchronize. If the picture still will not sync, turn the T114 waveform adjustment core (under the chassis) out of the coil several turns from its original position and readjust the T114 frequency core until the picture is synchronized.

Examine the width and linearity of the picture. If picture width or linearity is incorrect, adjust the horizontal drive control C174B, the width control L109 and the linearity control L111 until the picture is correct.

Horizontal Oscillator Waveform Adjustment.—The horizontal oscillator waveform may be adjusted by either of two methods. The method outlined in paragraph A below may be employed in the field when an oscilloscope is not available. The service shop method outlined in paragraph B below requires the use of an oscilloscope.

A.—Turn the horizontal hold control completely clockwise. Place adjustment tools on both cores of T114 and be prepared to make simultaneous adjustments while watching the picture on the screen. First, turn the T114 frequency core (on the rear apron) until the picture falls out of sync and three or four diagonal black bars sloping down to the right appear on the screen. Then, turn the waveform adjustment core (under the chassis) into the coil while at the same time adjusting the frequency core so as to maintain three or four diagonal black bars on the screen. Continue this procedure until the oscillator begins to motorboat, then turn the waveform adjustment core out until the motorboating just stops. As a check, turn the T114 frequency core until the picture is synchronized then reverse the direction of rotation of the core until the picture falls out of sync with the diagonal bars sloping down to the right. Continue to turn the frequency core in the same direction. No more than three or four bars should appear on the screen. Instead, the horizontal oscillator should begin to motorboat. Retouch the adjustment of the T114 waveform adjustment core if necessary until this condition is obtained.

B.—Connect the low capacity probe of an oscilloscope to terminal C of T114. Turn the horizontal hold control one-quarter turn from the clockwise position so that the picture is in sync. The pattern on the oscilloscope should be as shown in Figure 24. Adjust the waveform adjustment core of T114 until the two peaks are at the same height. During this adjustment, the picture must be kept in sync by readjusting the hold control if necessary.

This adjustment is very important for correct operation of the circuit. If the broad peak of the wave on the oscilloscope is lower than the sharp peak, the noise immunity becomes poorer, the stabilizing effect of the tuned circuit is reduced and drift of the oscillator becomes more serious. On the other hand, if the broad peak is higher than the sharp peak, the oscillator is overstabilized, the pull-in range becomes inadequate and the broad peak can cause double triggering of the oscillator when the hold control approaches the clockwise position.

Remove the oscilloscope upon completion of this adjustment.

Horizontal Locking Range Adjustment.—Set the horizontal hold control to the full counterclockwise position. Momentarily remove the signal by switching off channel then back. The picture may remain in sync. If so turn the T114 frequency core slightly and momentarily switch off channel. Repeat until the picture falls out of sync with the diagonal lines sloping down to the left. Slowly turn the horizontal hold control clockwise and note the least number of diagonal bars obtained just before the picture pulls into sync.

If more than 3 bars are present just before the picture pulls into sync, adjust the horizontal locking range trimmer C174A slightly clockwise. If less than 2 bars are present, adjust C174A slightly counter-clockwise. Turn the horizontal hold control counter-clockwise, momentarily remove the signal and recheck the number of bars present at the pull-in point. Repeat this procedure until 2 or 3 bars are present.

Turn the horizontal hold control to the maximum clockwise position. Adjust the T114 frequency core so that the diagonal bar sloping down to the right appears on the screen and then reverse the direction of adjustment so that bar just moves to the left side of the screen leaving the picture in synchronization.

ALIGNMENT DATA

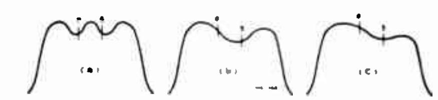

Figure 12—KRK12B UHF Insert Responses

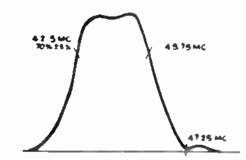

Figure 13 KRK12B T2 and T104 Response

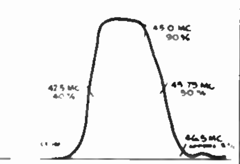

Figure 14 Over-all I-F Response with KRK12B

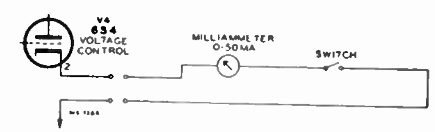

Figure 15—KRK12B Voltage Control Adapter

Connect the oscilloscope to the test point TP2 on top of the tuner unit. Set the oscilloscope to maximum gain.

Connect the output of the VHF signal generator to the output of the antenna matching unit at the junction of L5 and C4 at the bottom of the FM trap L5.

Tune the signal generator to 43.5 mc. and modulate it 30% with a 400 cycle sine wave. Adjust the signal generator for maximum output.

Adjust C33 on top of the tuner, for minimum 400 cycle indication on the oscilloscope. If necessary, this adjustment can be retouched in the field to provide additional rejection to one specific frequency in the i-f band pass. However, in such cases, care should be taken not to tune C33 into channel 2, thereby reducing sensitivity on channel 2.

Connect the potentiometer arm of one of the bias supplies to the AGC terminal on the tuner and ground the battery positive terminal to the tuner case. Adjust the bias potentiometer to produce —3.0 volts of bias, as measured by the "VoltOhmyst" at the AGC terminal on the tuner.

Set the channel selector switch to channel 8.

Preset C22 to read —3.0 volts at the test point TP1, as read on the "VoltOhmyst." The limits for oscillator injection voltage are 2 volts minimum and not exceeding a maximum of 5.5 volts.

Turn the fine tuning control fully clockwise.

Adjust C25 for proper oscillator frequency, 227 mc. This may be done in several ways. The easiest way and the way which will be recommended in this procedure will be to use the signal generator as a heterodyne frequency meter and beat the oscillator against the signal generator. To do this, tune the signal generator to 227 mc. with crystal accuracy. Insert one end of a piece of insulated wire into the tuner unit through the hole provided for the adjustment of C16. Be careful that the wire does not touch any of the tuned circuits as it may cause the frequency of the tuner oscillator to shift. Connect the other end of the wire to the "r-f in" terminal of the signal generator. Adjust C25 to obtain an audible beat with the signal generator.

Turn C27 clockwise until the beat note just begins to change, then turn one full turn in the same clockwise direction.

Return the fine tuning control to the mechanical center of its range.

NOTE:—If on some units, it is not possible to reach the proper channel 8 oscillator frequency by adjustment of C25, switch to channel 13 and adjust L49 to obtain proper channel 13 oscillator frequency as indicated in the table on page 8. Then, switch to channel 12 and adjust L60 to obtain proper channel 12 oscillator frequency. Continue down to channel 8, adjusting the appropriate oscillator trimmer to obtain the proper frequency on each channel. Then again on channel 8, adjust C25 to obtain proper channel 8 oscillator frequency. Switch back to channel 13 and readjust L49 and back to channel 8 and adjust C25.

Set the T2 core for maximum inductance (core turned counter-clockwise).

Connect the sweep generator through a suitable attenuator, as shown in figure 10 to the input terminals of the antenna matching unit.

Connect the signal generator loosely to the antenna terminals.

Set the sweep generator to cover channel 8.

Set the oscilloscope to maximum gain and use the minimum input signal which will produce a usable pattern on the oscilloscope. Excessive input can change oscillator injection during alignment and produce consequent misalignment even though the response as seen on the oscilloscope may look normal.

Insert markers of channel 8 picture carrier and sound carrier, 181.25 mc. and 185.75 mc.

Adjust C21, C16, C11 and C7 for approximately correct curve shape, frequency, and band width as shown in figure 18.

The correct adjustment of C7 is indicated by maximum amplitude of the curve midway between the markers. C11 tunes the r-f amplifier plate circuit and affects the frequency of the pass band most noticeably. C21 tunes the mixer grid circuit and affects the tilt of the curve most noticeably (assuming that C7 has been properly adjusted). C16 is the coupling adjustment and hence primarily affects the response band width.

Connect the "VoltOhmyst" to test point TP1. Adjust C22 to read —3.0 volts dc on the "VoltOhmyst" at TP1. Readjust C27, C21, C16 and C11 for proper response. Adjust C7 for maximum gain at midpoint of the curve. Repeat if necessary until the proper response is obtained.

Set the receiver channel switch to channel 13.

Adjust the signal generator to the channel 13 oscillator frequency 257 mc.

Turn the fine tuning control fully clockwise.

Adjust L49 to obtain an audible beat. Slightly overshoot the adjustment of L49 by turning the slug an additional turn in the same direction from the original setting, then reset the oscillator to proper frequency by adjusting C27 to again obtain the beat.

Set the sweep generator to channel 13.

From the signal generator, insert channel 13 sound and picture carrier markers, 211.25 mc. and 215.75 mc.

Adjust L36 and L20 for proper response as shown in figure 18.

Turn off the sweep and signal generators.

Connect the "VoltOhmyst" to the tuner test point TP1.

Check the oscillator injection voltage to be within limits as previously specified. Adjust if necessary to bring within range.

If it was necessary to readjust C22, turn the sweep and signal generators back on and recheck the channel 13 response. Readjust L36 and L20 if necessary.

Set the receiver channel selector switch to channel 8 and readjust C27 for proper oscillator frequency, 227 mc.

Set the sweep generator and signal generator to channel 8.

Readjust C21, C16, C11 and C7 for correct curve shape, frequency and band width.

Turn off the sweep and signal generators, switch back to channel 13 and check the oscillator injection voltage at TP1 if C21 was adjusted in the recheck of channel 8 response.

If the initial setting of the oscillator injection trimmer was far off, it may be necessary to adjust the oscillator frequency and response on channel 8, adjust the oscillator injection on channel 13 and repeat the tracking procedure several times before the proper setting is obtained.

Turn off the sweep generator and switch the receiver to channel 6.

Adjust the signal generator to the channel 6 oscillator frequency 129 mc.

Set the fine tuning control to the center of its mechanical range.

Adjust L54 for an audible beat. Adjust L48 and L32 for proper curve shape as shown in figure 18. Recheck the oscillator injection voltage at TP1, to insure that it is within the limits specified. Readjust C22 if necessary.

If C22 required adjustment, switch the receiver and the signal generator to channel 8. Readjust C21 for correct curve shape and recheck C27 and C25 for proper oscillator frequency.

Check the response of channels 2 through 6 by switching the receiver channel switch, sweep generator and marker generator to each of these channels and observing the response and oscillator injection voltage obtained. See figure 18 for typical response curves. It should be found that all these channels have the proper response with the markers above 80% response.

If the markers fail to fall within this requirement readjust L48 and L32 in order to obtain curves within the proper limits.

Switch the channel selector, signal generator and marker generator through channels 7 to 13 and observe the response curves, referring to figure 18 for proper wave shape. Check the injection voltage at each channel to be within limits. If necessary readjust C11, C21 or C16 to obtain the proper response.

With the receiver and signal generator on channel 13 adjust L49 for an audible beat with the signal generator.

Adjust the oscillator to frequency on all channels by switching the receiver and the frequency standard to each channel and adjusting the appropriate oscillator slug to obtain the audible beat. It should be possible to adjust the oscillator to obtain the audible beat on each channel. Recheck the oscillator injection voltage on each channel to verify that the voltage is within the specified limits.

KRK12B TUNER ALIGNMENT

Models 17-T-352U & 17-T-361U

TUNER VHF ALIGNMENT.—Remove the 6S4 voltage control tube from its socket and insert the adapter. Insert the 6S4 in the adapter.

Connect the 0-50 milliampere meter to the adapter socket leads and turn the adapter switch on.

Remove the tuner cover shield.

Rotate the channel selector to a point midway between channels, disengaging the insert contacts, and observe the non-oscillating plate current. Some tubes may oscillate even with the tuned circuits disengaged. To be sure the oscillator is in a non-oscillatory state, short circuit the spring contacts 12 and 13, the two contacts nearest the tuner front.

(NOTE: The contacts are at zero d-c potential.) Should the plate current rise, keep the contacts shorted while adjusting the oscillator plate current. Adjust R6, oscillator voltage control, for a 28 milliampere reading on the meter.

Replace the tuner cover shield.

Connect the VHF sweep generator to the antenna terminals.

Connect the VHF signal generator loosely to the antenna terminals.

Connect the oscilloscope, through the preamplifier, if needed with oscilloscope used, to test point TP1.

Ground the AGC bias at the tuner terminal board using a clip lead to insure that the bias will remain constant.

Turn off the adapter switch, removing plate voltage from the oscillator. This is required because of RF-IF interaction when a crystal is used as a mixer.

Set the channel selector and the sweep generator to channel 2.

Insert markers of channel 2 picture carrier and sound carrier, 55.25 mc. and 59.75 mc.

Adjust antenna T6, r-f amplifier plate L29 and mixer L130 adjustments for a symmetrical curve with maximum gain at the center of the pass band. The curves will have a deep valley because of no crystal loading and nonlinear detector characteristics. The limits for the 100% response points are shown in Figure 11. The proper curve shape is shown in Figure 11(b). (See note on page 13 for detailed explanation of adjustments.) If the bandwidth is out of tolerance, it can usually be corrected by redressing the coupling capacitor of the double tuned circuit, C40 on insert A. Maximum bandwidth occurs when the capacitor is centered in the insert chamber.

Repeat the above steps for all VHF channels adjusting the appropriate antenna, r-f amplifier plate and mixer slugs for a symmetrical curve with maximum gain at the center of the pass band.

Turn off the sweep generator.

Remove the oscilloscope and preamplifier if used, from test point TP1.

Turn the AGC control fully clockwise.

Remove the clip lead grounding the AGC bias on the tuner terminal board.

Connect the potentiometer arm of one of the bias supplies to the AGC terminal on the tuner and ground the battery positive terminal to the tuner case. Adjust the bias potentiometer to produce —3.5 volts of bias, as measured by the "VoltOhmyst" at the AGC terminal on the tuner.

Connect the potentiometer arm of the second bias supply to the junction R147 and R148, and ground the positive battery terminal. Adjust the bias potentiometer to produce —5 volts of i-f bias as indicated on the "VoltOhmyst" at the junction point.

Connect the oscilloscope to the junction of R138 and L105. Use 3 to 5 volts peak-to-peak output on the oscilloscope.

Turn the adapter switch on to apply plate voltage to the oscillator.

Turn the channel selector to channel 13.

Set the fine tuning control to the center of its range.

Adjust the oscillator slug L22 to proper frequency, 257 mc. This may be done in several ways. The easiest way and the way which will be recommended in this procedure will be to use the signal generator as a heterodyne frequency meter and beat the oscillator against the signal generator. To do this, tune the signal generator to 257 mc. with crystal accuracy. Insert one end of a piece of insulated wire into the tuner through either of the two holes next to the oscillator tube on the right front top corner of the tuner. Be careful that the wire does not touch any of the tuned circuits as it may cause the frequency of the oscillator to shift. Connect the other end of the wire to the "r-f in" terminal of the signal generator. Adjust L22 oscillator slug to obtain an audio beat with the signal generator.

Turn on the sweep generator and set to Channel 13. Adjust T1 for maximum gain on the oscilloscope. Adjust mixer tank circuit L21 for maximum gain and flat-topped curve. Recheck T1 for maximum gain at center of band with the proper response. Maximum gain and flat-topped response should be obtained simultaneously.

Adjust the oscillator to frequency on all VHF channels by switching the receiver and signal generator to each VHF channel and adjusting the appropriate oscillator slug to obtain a beat with the signal generator. Adjust the appropriate mixer slug where necessary to obtain maximum gain and proper curve shape as explained above.

Adjust the tunable I-F Trap C16-L7. To do this connect the signal generator to the fixed I-F Trap C2-L2 at the end opposite the antenna terminal plug. Set the signal generator to 43.5 mc. and adjust the output of the signal generator to obtain sufficient indication on the oscilloscope. Tune the I-F Trap C16-L7 for minimum indication on the oscilloscope.

Remove the signal generator and the oscilloscope.

TUNER UHF ALIGNMENT—To align the UHF inserts:

Turn off the adapter switch, removing plate voltage from the oscillator.

Ground the AGC bias at the tuner terminal board using a clip lead to insure that the bias will remain constant.

Connect the oscilloscope, through the preamplifier if needed with oscilloscope used, to test point TP1.

Connect the UHF sweep generator to the antenna terminals. Use a 10 DB attenuator pad to assure proper alignment.

Connect the UHF signal generator loosely to the antenna terminals.

Set the channel selector to the desired position and the sweep generator to sweep the frequency of the insert being used.

Insert markers of the picture carrier and sound carrier for desired channel.

Adjust UHF antenna link coupling and mixer adjustments for a symmetrical curve, with maximum gain, centered about the pass band.

The responses are shown in Figure 12. The curve shape will usually vary from Fig. 12 (a) to Fig. 12 (c) going higher in frequency, however any of these responses are acceptable.

Repeat the above steps for all UHF inserts used adjusting the appropriate antenna, link coupling and mixer slugs for a symmetrical curve, with maximum gain, centered about the pass band.

Remove the oscilloscope and preamplifier if used, from test point TP1.

Remove the clip lead grounding the AGC bias on the tuner terminal board.

Connect the potentiometer arm of one of the bias supplies to the AGC terminal on the tuner and ground the battery positive terminal to the tuner case. Adjust the bias potentiometer to produce —3.5 volts of bias, as measured by the "VoltOhmyst" at the AGC terminal.

ALIGNMENT PROCEDURE

NOTE ON KRK12B TUNER ALIGNMENT.—**The use of a crystal mixer makes it necessary to observe the insert responses with the oscillator disabled. This is due to undesirable r-f/i-f interaction if the oscillator was allowed to operate during alignment. Therefore, the responses shown in Figure 11 are not a strictly true representation of the insert band pass during actual operation. When an insert is aligned, using an oscilloscope to observe the response, the curve shown in Figure 11 (b) will be the correct response for reference. In actual operation, the band pass will be such that the sound and picture carriers will be at the tips of the curve. The adjacent channel picture and sound carriers will be in the valleys at each side. Care should be taken not to exceed the limits shown in Figure 11(a) and 11(c).**

The valley, in the center of the response curve, may vary from 0 to 50% above the base line for VHF inserts. Adjust the output level of the sweep generator to prevent excessive signal input to the tuner. Excessive signal input will be indicated by the valley rising above the 50% level, particularly on the higher VHF channels.

Oscillator injection voltage is not adjusted on VHF inserts. A check may indicate variations from .08 to .3 volts at TP1, but such readings should not be interpreted as an indication of trouble. On UHF channels, however, the injection voltage should be adjusted to fall within the specified limits.

TEST EQUIPMENT.—To properly service the television chassis of these receivers, it is recommended that the following test equipment be available:

VHF Sweep Generator meeting the following requirements:

(a) Frequency Ranges
35 to 90 mc., 1 mc. to 12 mc. sweep width
170 to 225 mc., 12 mc. sweep width
(b) Output adjustable with at least .1 volt maximum.
(c) Output constant on all ranges.
(d) "Flat" output on all attenuator positions.

VHF Signal Generator to provide the following frequencies with crystal accuracy:

(a) Intermediate frequencies
4.5 mc., 39.25 mc., 41.25 mc., 43.5 mc., 45.75 mc., 47.25 mc.
(b) Radio frequencies

(c) Output of these ranges should be adjustable and at least .1 volt maximum.

VHF Heterodyne Frequency Meter with crystal calibrator if the signal generator is not crystal controlled.

UHF Sweep Generator with a frequency range of 470 mc. to 890 mc. RCA Types 40A or 41A or their equivalent.

UHF Signal Generator to provide the following frequencies with crystal accuracy if RCA Type 41A is used.

Cathode Ray Oscilloscope.—An oscilloscope with a sensitivity of 1 millivolt per inch is required. A suitable pre-amplifier may be employed with oscilloscopes of lesser sensitivity.

Electronic Voltmeter.—A voltmeter with a 1.5 volt DC scale is required. RCA Senior "VoltOhmyst" or equivalent.

DC Milliammeter.—A milliammeter with a range of 0-50 milliamperes full scale.

Adapter Socket.—An adapter socket is required to meter the cathode current of the 6S4 voltage control tube of the KRK12B Tuner. Wiring of adapter is shown in Figure 15.

KRK29 ANTENNA MATCHING UNIT ALIGNMENT.—The antenna matching unit is accurately aligned at the factory. Adjustment of this unit should not be attempted in the customer's home since even slight misalignment may cause serious attenuation of the signal especially on channel 2. The r-f unit is aligned with a particular antenna matching transformer in place. If for any reason, a new antenna matching transformer is installed, the r-f unit should be realigned.

The F-M Trap which is mounted in the antenna matching unit may be adjusted without adversely affecting the alignment of the unit.

To align the antenna matching unit disconnect the lead from the F-M trap L5 to the channel selector switch S1-E.

With a short jumper, connect the output of the matching unit through a 1000 mmf. capacitor to the grid of the second pix i-f amplifier, pin 1 of V107.

Replace the cover on the matching unit while making all adjustments.

Remove the first pix i-f amplifier tube V106.

Connect the positive terminal of a bias box to the chassis and the potentiometer arm to the junction of R127 and R148. Set the potentiometer to produce approximately –5.0 volts of bias at the junction of R127 and R148.

Connect an oscilloscope to pin 2, V110 and set the oscilloscope gain to maximum.

Connect a VHF signal generator to the antenna input terminals. Modulate the signal generator 30% with an audio signal.

Tune the signal generator to 45.75 mc. and adjust the generator output to give an indication on the oscilloscope. Adjust L4 in the antenna matching unit for minimum audio indication on the oscilloscope.

Tune the signal generator to 41.25 mc. and adjust L1 for minimum audio indication on the oscilloscope.

Remove the jumper from the output of the matching unit.

Connect a 300 ohm ½ watt composition resistor from L5 to ground, keeping the leads as short as possible.

Connect an oscilloscope low capacity crystal probe from L5 to ground. The sensitivity of the oscilloscope should be approximately 0.03 volts per inch. Set the oscilloscope gain to maximum.

Connect the VHF sweep generator to the matching unit antenna input terminals. In order to prevent coupling reactance from the sweep generator into the matching unit, it is advisable to employ a resistance pad at the matching unit terminals. Figure 10 shows three different resistance pads for use with sweep generators with 50 ohm co-ax output, 72 ohm co-ax output or 300 ohm balanced output. Choose the pad to match the output impedance of the particular sweep employed.

Connect the signal generator loosely to the matching unit antenna terminals.

Set the sweep generator to sweep from 45 mc. to 54 mc. With RCA Type WR59A sweep generators, this may be accomplished by returning channel number 1 to cover this range. With WR59B sweep generators this may be accomplished by retuning channel number 2 to cover the range. In making these adjustments on the generator, be sure not to turn the core too far clockwise so that it becomes lost beyond the core retaining spring.

Adjust L2 and L3 to obtain the response shown in figure 19. L3 is most effective in locating the position of the shoulder of the curve at 52 mc. and L2 should be adjusted to give maximum amplitude at 53 mc. and above consistent with the specified shape of the response curve. The adjustments in the matching unit interact to some extent. Repeat the above procedure until no further adjustments are necessary.

Remove the 300 ohm resistor and crystal probe connections. Restore the connection between L5 and S1-E. Replace V106.

PICTURE I-F TRANSFORMER ADJUSTMENTS.—

Model 17-T-361

Connect the i-f signal generator across the link circuit on terminals A and B of T104.

Connect the "VoltOhmyst" to the junction of R147 and R148 and to ground.

Obtain a 7.5 volt battery capable of withstanding appreciable current drain and connect the ends of a 1,000 ohm potentiometer across it. Connect the battery positive terminal to chassis and the potentiometer arm to the junction of R147 and R148.

Set the bias to produce approximately —5.0 volt of bias at the junction of R147 and R148.

Connect the "VoltOhmyst" to the juncture of R138 and L105 and to ground.

Set the VHF signal generator to each of the following frequencies and peak the specified adjustment for maximum indication on the "VoltOhmyst". During alignment, reduce the input signal if necessary in order to produce 3.0 volts of d-c at R138, L105 with minus 5.0 volts of i-f bias at the junction of R147 and R148.

44.5 mc.	T108
45.5 mc.	T107
43.0 mc.	T106

Set the VHF signal generator to the following frequency and adjust the picture i-f trap for minimum d-c output at R138, L105. Use sufficient signal input to produce 3.0 volts of d-c on the meter when the adjustment is made.

47.25 mc.	T104 top core

Models 17-T-352U & 17-T-361U

Connect the "VoltOhmyst" to the junction of R147 and R148 and to ground.

Turn the AGC control fully clockwise.

Obtain a 7.5 volt battery capable of withstanding appreciable current drain and connect the ends of a 1,000 ohm potentiometer across it. Connect the battery positive terminal to chassis and the potentiometer arm to the junction R147 and R148. Adjust the potentiometer for —5.0 volts indication on the "VoltOhmyst".

Connect the "VoltOhmyst" to the junction of R138 and L105 and to ground.

Connect the output of the signal generator to the front terminal of the crystal mixer in series with a 1500 mmf ceramic capacitor.

Set the VHF generator to each of the following frequencies and with a thin fiber screwdriver tune the specified adjustment for maximum indication on the "VoltOhmyst". In each instance the generator should be checked against a crystal calibrator to insure that the generator is on frequency.

During alignment, reduce the input signal if necessary in order to produce 3.0 volts of d-c at R138, L105 with —5.0 volts of i-f bias at the junction of R147 and R148.

44.5 mc.	T108
45.5 mc.	T107
43.0 mc.	T106

Set the signal generator to the following frequency and adjust the picture i-f trap for minimum d-c output at R138, L105. Use sufficient signal input to produce 3.0 volts of d-c on the meter when the adjustment is made.

47.25 mc.	T104 top core

SWEEP ALIGNMENT OF PIX I-F.—

Model 17-T-361

To align T2 and T104, connect the sweep generator to the mixer grid test point TP2, in series with a 1500 mmf ceramic capacitor. Use the shortest leads possible, with not more than one inch of unshielded lead at the end of the sweep cable. Connect the sweep ground lead to the r-f unit outer shield.

Set the channel selector switch to channel 4.

Clip 330 ohm resistors across terminals A and B of T107 and T108.

Preset C119 to minimum capacity.

Adjust the bias box potentiometer to obtain —5.0 volts of bias as measured by a "VoltOhmyst" at the junction of R147 and R148. Set the AGC control fully clockwise.

Connect a 180 ohm composition resistor from pin 5 of V106 to terminal A of T106. Connect the oscilloscope diode probe to pin 5 of V106 and to ground.

Couple the signal generator loosely to the diode probe in order to obtain markers.

Adjust T2 (top) and T104 (bottom) for maximum gain and with 45.75 mc. at 70% of maximum response.

Set the sweep output to give 0.3 volt peak-to-peak on the oscilloscope when making the final touch on the above adjustment.

Adjust C119 until 42.5 mc. is at 70% response with respect to the low frequency shoulder of the curve as shown in Figure 22.

Disconnect the diode probe, the 180 ohm and two 330 ohm resistors.

Connect the oscilloscope to the junction of R138 and L105.

Leave the sweep generator connected to the mixer grid test point TP2 with the shortest leads possible

Adjust the output of the sweep generator to obtain 3.0 volts peak-to-peak on the oscilloscope.

Couple the signal generator loosely to the grid of the first pix i-f amplifier. Adjust the output of the signal generator to produce small markers on the response curve.

Retouch T106, T107 and T108 to obtain the response shown in figure 23.

Models 17-T-352U & 17-T-361U

To align the crystal mixer plate circuit, T2 and T104 connect the VHF sweep generator to the front terminal of the 1N82 crystal holder in series with a 1500 mmf ceramic capacitor. Use the shortest leads possible, grounding the sweep generator to the tuner case.

Clip 330 ohm resistors across terminals A and B of T107 and T108.

Set the channel selector to channel 5.

Connect a 180 ohm composition resistor from pin 5 of V106 to terminal A of T106. Connect the oscilloscope diode probe to pin 5 of V106 and to ground.

Couple the signal generator loosely to the diode probe in order to obtain markers.

The shunt trimmer C119 across terminals A and B of T104 is variable and is provided as a bandwidth adjustment. Preset the shunt trimmer to minimum capacity. Adjust T2 (top) and T104 (bottom) for maximum gain at 43.5 mc. and with 45.75 mc. at 70% of maximum response.

Adjust T1 for maximum gain. Readjust T2 and T104 if necessary to obtain proper wave shape, see Fig. 13.

Disconnect the diode probe, the 180 ohm and the two 330 ohm resistors.

Connect the oscilloscope to the junction of R138 and L105.

Adjust the bias potentiometer to obtain —5.0 volts of bias as measured by a "VoltOhmyst" at the junction of R147 and R148.

Leave the sweep generator connected to the front terminal of the 1N82 crystal holder with the shortest leads possible and with not more than one inch of unshielded lead at the end of the sweep cable. If these precautions are not observed, the receiver may be unstable and the response curves obtained may be unreliable.

Adjust the output of the sweep generator to obtain 3.0 to 5.0 volts peak-to-peak on the oscilloscope.

Couple the signal generator loosely to the grid of the first pix i-f amplifier. Adjust the output of the signal generator to produce small markers on the response curve.

Retouch T106, T107 and T108 to obtain the response shown in Figure 14.

Remove the oscilloscope, sweep and signal generator connections.

Remove the bias box employed to provide bias for alignment.

KRK29 TUNER ALIGNMENT

Model 17-T-361

A tuner unit which is operative and requires only touch up adjustments, requires no presetting of adjustments. For such units, skip the remainder of this paragraph. For units which are completely out of adjustment, preset C27 all the way out. Set channel 7 to 13 oscillator slugs one turn from tight. Turn T2 slug all the way out. Do not change any of the adjustments in the antenna matching unit.

Disconnect the link from terminals "A" and "B" of T104 and terminate the link with a 39 ohm composition resistor.

Turn the receiver chânnel selector switch to channel 2.

The 43.5 mc. trap is adjusted with zero bias. To insure that the bias will remain constant, take a clip lead and short circuit the AGC terminal of the tuner at the terminal board to ground.

GENERAL DESCRIPTION

Models 17-T-352U, 17-T-361 and 17-T-361U are "17 inch" television receivers. Models 17-T-352U and 17-T-361U are identical except for cabinets, and speakers. Model 17-T-361 has full 12 channel VHF coverage. Models 17-T-352U and 17-T-361U feature full 12 channel VHF coverage plus any 4 UHF channels desired.

All models include intercarrier FM system; ratio detector; improved picture brilliance; pulsed picture A-G-C; A-F-C horizontal hold; stabilized vertical hold; improved sync separator (3.5 mc. band width for picture channel); and reduced hazard high voltage supply. An auxiliary audio input jack is provided to permit the use of an external record playing attachment.

ELECTRICAL AND MECHANICAL SPECIFICATIONS

PICTURE SIZE 146 square inches on a 17CP4 Kinescope

TELEVISION R-F FREQUENCY RANGE

Model 17-T-361

All 12 television channels, 54 mc. to 88 mc., 174 mc. to 216 mc.

Models 17-T-352U & 17-T-361U

Any of 70 UHF channels .... 470 mc. to 890 mc.
Any of 12 VHF channels, 54 mc. to 88 mc., 174 mc. to 216 mc.
(Any desired combination of 16 UHF and/or VHF channels may be used.)

INTERMEDIATE FREQUENCIES

Picture I-F Carrier Frequency .... 45.75 mc.
Sound I-F Carrier Frequency .... 41.25 mc.

POWER RATING .... 17-T-361-215 watts
17-T-352U & 17-T-361U-230 watts

AUDIO POWER OUTPUT RATING .... 4 watts max.

VIDEO RESPONSE .... To 3.5 mc.

SWEEP DEFLECTION .... Magnetic

FOCUS .... Magnetic

ANTENNA INPUT IMPEDANCE

Model 17-T-361

Choice: 300 ohms balanced or 72 ohms unbalanced.

Models 17-T-352U & 17-T-361U

UHF—300 ohms balanced.
VHF—300 ohms balanced.

RCA TUBE COMPLEMENT

Tube Used	Function
Tuner KRK29 (17-T-361)	
(1) RCA 6BQ7A	R-F Amplifier
(2) RCA 6X8	R-F Oscillator and Mixer

RCA TUBE COMPLEMENT

Tube Used	Function
Tuner KRK12B (17-T-352U & 17-T-361U)	
(1) RCA 6BQ7A	R-F Amplifier (VHF only)
(2) RCA 6AF4	R-F Oscillator
(3) RCA 6BQ7A	I-F Amplifier
(4) RCA 6S4	Voltage Control

A 1N82 crystal is used as a mixer.

Tube Used	Function
All Models	
(1) RCA 6CF6	1st Picture I-F Amplifier
(2) RCA 6CF6	2nd Picture I-F Amplifier
(3) RCA 6CB6	3rd Picture I-F Amplifier
(4) RCA 12AU7	Picture 2nd Detector and Vert. Sync. Sep.
(5) RCA 6CL6	Video Amplifier
(6) RCA 6AU6	1st Sound I-F Amplifier
(7) RCA 6AU6	2nd Sound I-F Amplifier
(8) RCA 6AL5	Ratio Detector
(9) RCA 6AV6	1st Audio Amplifier
(10) RCA 6K6GT	Audio Output
(11) RCA 12AU7	Horiz. Sync. Sep. & AGC
(12) RCA 6SN7GT	Vertical Osc. & Sync. Output
(13) RCA 6K6GT	Vertical Sweep Output
(14) RCA 6SN7GT	Horizontal Sweep Oscillator and Control
(15) RCA 6BQ6GT	Horizontal Sweep Output
(16) RCA 6W4GT	Damper
(17) RCA 1B3-GT/8016	High Voltage Rectifier
(18) RCA 17CP4	Kinescope
(19) RCA 5U4G	Rectifier
(20) RCA 5Y3GT	Rectifier

ALIGNMENT PROCEDURE

NOTE ON KRK12B TUNER ALIGNMENT.—The use of a crystal mixer makes it necessary to observe the insert responses with the oscillator disabled. This is due to undesirable r-f/i-f interaction if the oscillator was allowed to operate during alignment. Therefore, the responses shown in Figure 11 are not a strictly true representation of the insert band pass during actual operation. When an insert is aligned, using an oscilloscope to observe the response, the curve shown in Figure 11 (b) will be the correct response for reference. In actual operation, the band pass will be such that the sound and picture carriers will be at the tips of the curve. The adjacent channel picture and sound carriers will be in the valleys at each side. Care should be taken not to exceed the limits shown in Figure 11(a) and 11(c).

The valley, in the center of the response curve, may vary from 0 to 50% above the base line for VHF inserts. Adjust the output level of the sweep generator to prevent excessive signal input to the tuner. Excessive signal input will be indicated by the valley rising above the 50% level, particularly on the higher VHF channels.

Oscillator injection voltage is not adjusted on VHF inserts. A check may indicate variations from .08 to .3 volts at TP1, but such readings should not be interpreted as an indication of trouble. On UHF channels, however, the injection voltage should be adjusted to fall within the specified limits.

TEST EQUIPMENT.—To properly service the television chassis of these receivers, it is recommended that the following test equipment be available:

VHF Sweep Generator meeting the following requirements:

(a) Frequency Ranges
 35 to 90 mc., 1 mc. to 12 mc. sweep width
 170 to 225 mc., 12 mc. sweep width
(b) Output adjustable with at least .1 volt maximum.
(c) Output constant on all ranges.
(d) "Flat" output on all attenuator positions.

VHF Signal Generator to provide the following frequencies with crystal accuracy:

(a) Intermediate frequencies
 4.5 mc., 39.25 mc., 41.25 mc., 43.5 mc., 45.75 mc., 47.25 mc.
(b) Radio frequencies

(c) Output of these ranges should be adjustable and at least .1 volt maximum.

VHF Heterodyne Frequency Meter with crystal calibrator if the signal generator is not crystal controlled.

UHF Sweep Generator with a frequency range of 470 mc. to 890 mc. RCA Types 40A or 41A or their equivalent.

UHF Signal Generator to provide the following frequencies with crystal accuracy if RCA Type 41A is used.

Cathode Ray Oscilloscope.—An oscilloscope with a sensitivity of 1 millivolt per inch is required. A suitable pre-amplifier may be employed with oscilloscopes of lesser sensitivity.

Electronic Voltmeter.—A voltmeter with a 1.5 volt DC scale is required. RCA Senior "VoltOhmyst" or equivalent.

DC Milliammeter.—A milliammeter with a range of 0-50 milliamperes full scale.

Adapter Socket.—An adapter socket is required to meter the cathode current of the 6S4 voltage control tube of the KRK12B Tuner. Wiring of adapter is shown in Figure 15.

KRK29 ANTENNA MATCHING UNIT ALIGNMENT.—The antenna matching unit is accurately aligned at the factory. Adjustment of this unit should not be attempted in the customer's home since even slight misalignment may cause serious attenuation of the signal especially on channel 2. The r-f unit is aligned with a particular antenna matching transformer in place. If for any reason, a new antenna matching transformer is installed, the r-f unit should be realigned.

The F-M Trap which is mounted in the antenna matching unit may be adjusted without adversely affecting the alignment of the unit.

To align the antenna matching unit disconnect the lead from the F-M trap L5 to the channel selector switch S1-E.

With a short jumper, connect the output of the matching unit through a 1000 mmf. capacitor to the grid of the second pix i-f amplifier, pin 1 of V107.

Replace the cover on the matching unit while making all adjustments.

Remove the first pix i-f amplifier tube V106.

Connect the positive terminal of a bias box to the chassis and the potentiometer arm to the junction of R127 and R148. Set the potentiometer to produce approximately –5.0 volts of bias at the junction of R127 and R148.

Connect an oscilloscope to pin 2, V110 and set the oscilloscope gain to maximum.

Connect a VHF signal generator to the antenna input terminals. Modulate the signal generator 30% with an audio signal.

Tune the signal generator to 45.75 mc. and adjust the generator output to give an indication on the oscilloscope. Adjust L4 in the antenna matching unit for minimum audio indication on the oscilloscope.

Tune the signal generator to 41.25 mc. and adjust L1 for minimum audio indication on the oscilloscope.

Remove the jumper from the output of the matching unit.

Connect a 300 ohm ½ watt composition resistor from L5 to ground, keeping the leads as short as possible.

Connect an oscilloscope low capacity crystal probe from L5 to ground. The sensitivity of the oscilloscope should be approximately 0.03 volts per inch. Set the oscilloscope gain to maximum.

Connect the VHF sweep generator to the matching unit antenna input terminals. In order to prevent coupling reactance from the sweep generator into the matching unit, it is advisable to employ a resistance pad at the matching unit terminals. Figure 10 shows three different resistance pads for use with sweep generators with 50 ohm co-ax output, 72 ohm co-ax output or 300 ohm balanced output. Choose the pad to match the output impedance of the particular sweep employed.

Connect the signal generator loosely to the matching unit antenna terminals.

Set the sweep generator to sweep from 45 mc. to 54 mc. With RCA Type WR59A sweep generators, this may be accomplished by returning channel number 1 to cover this range. With WR59B sweep generators this may be accomplished by retuning channel number 2 to cover the range. In making these adjustments on the generator, be sure not to turn the core too far clockwise so that it becomes lost beyond the core retaining spring.

Adjust L2 and L3 to obtain the response shown in figure 19. L3 is most effective in locating the position of the shoulder of the curve at 52 mc. and L2 should be adjusted to give maximum amplitude at 53 mc. and above consistent with the specified shape of the response curve. The adjustments in the matching unit interact to some extent. Repeat the above procedure until no further adjustments are necessary.

Remove the 300 ohm resistor and crystal probe connections. Restore the connection between L5 and S1-E. Replace V106.

PICTURE I-F TRANSFORMER ADJUSTMENTS.—

Model 17-T-361

Connect the i-f signal generator across the link circuit on terminals A and B of T104.

Connect the "VoltOhmyst" to the junction of R147 and R148 and to ground.

Obtain a 7.5 volt battery capable of withstanding appreciable current drain and connect the ends of a 1,000 ohm potentiometer across it. Connect the battery positive terminal to chassis and the potentiometer arm to the junction of R147 and R148.

Set the bias to produce approximately —5.0 volt of bias at the junction of R147 and R148.

Connect the "VoltOhmyst" to the juncture of R138 and L105 and to ground.

Set the VHF signal generator to each of the following frequencies and peak the specified adjustment for maximum indication on the "VoltOhmyst". During alignment, reduce the input signal if necessary in order to produce 3.0 volts of d-c at R138, L105 with minus 5.0 volts of i-f bias at the junction of R147 and R148.

44.5 mc.	T108
45.5 mc.	T107
43.0 mc.	T106

Set the VHF signal generator to the following frequency and adjust the picture i-f trap for minimum d-c output at R138, L105. Use sufficient signal input to produce 3.0 volts of d-c on the meter when the adjustment is made.

47.25 mc. .... T104 top core

Models 17-T-352U & 17-T-361U

Connect the "VoltOhmyst" to the junction of R147 and R148 and to ground.

Turn the AGC control fully clockwise.

Obtain a 7.5 volt battery capable of withstanding appreciable current drain and connect the ends of a 1,000 ohm potentiometer across it. Connect the battery positive terminal to chassis and the potentiometer arm to the junction R147 and R148. Adjust the potentiometer for —5.0 volts indication on the "VoltOhmyst".

Connect the "VoltOhmyst" to the junction of R138 and L105 and to ground.

Connect the output of the signal generator to the front terminal of the crystal mixer in series with a 1500 mmf ceramic capacitor.

Set the VHF generator to each of the following frequencies and with a thin fiber screwdriver tune the specified adjustment for maximum indication on the "VoltOhmyst". In each instance the generator should be checked against a crystal calibrator to insure that the generator is on frequency.

During alignment, reduce the input signal if necessary in order to produce 3.0 volts of d-c at R138, L105 with —5.0 volts of i-f bias at the junction of R147 and R148.

44.5 mc.	T108
45.5 mc.	T107
43.0 mc.	T106

Set the signal generator to the following frequency and adjust the picture i-f trap for minimum d-c output at R138, L105. Use sufficient signal input to produce 3.0 volts of d-c on the meter when the adjustment is made.

47.25 mc. .... T104 top core

SWEEP ALIGNMENT OF PIX I-F.—

Model 17-T-361

To align T2 and T104, connect the sweep generator to the mixer grid test point TP2, in series with a 1500 mmf ceramic capacitor. Use the shortest leads possible, with not more than one inch of unshielded lead at the end of the sweep cable. Connect the sweep ground lead to the r-f unit outer shield.

Set the channel selector switch to channel 4.

Clip 330 ohm resistors across terminals A and B of T107 and T108.

Preset C119 to minimum capacity.

Adjust the bias box potentiometer to obtain —5.0 volts of bias as measured by a "VoltOhmyst" at the junction of R147 and R148. Set the AGC control fully clockwise.

Connect a 180 ohm composition resistor from pin 5 of V106 to terminal A of T106. Connect the oscilloscope diode probe to pin 5 of V106 and to ground.

Couple the signal generator loosely to the diode probe in order to obtain markers.

Adjust T2 (top) and T104 (bottom) for maximum gain and with 45.75 mc. at 70% of maximum response.

Set the sweep output to give 0.3 volt peak-to-peak on the oscilloscope when making the final touch on the above adjustment.

Adjust C119 until 42.5 mc. is at 70% response with respect to the low frequency shoulder of the curve as shown in Figure 22.

Disconnect the diode probe, the 180 ohm and two 330 ohm resistors.

Connect the oscilloscope to the junction of R138 and L105.

Leave the sweep generator connected to the mixer grid test point TP2 with the shortest leads possible.

Adjust the output of the sweep generator to obtain 3.0 volts peak-to-peak on the oscilloscope.

Couple the signal generator loosely to the grid of the first pix i-f amplifier. Adjust the output of the signal generator to produce small markers on the response curve.

Retouch T106, T107 and T108 to obtain the response shown in figure 23.

Models 17-T-352U & 17-T-361U

To align the crystal mixer plate circuit, T2 and T104 connect the VHF sweep generator to the front terminal of the 1N82 crystal holder in series with a 1500 mmf ceramic capacitor. Use the shortest leads possible, grounding the sweep generator to the tuner case.

Clip 330 ohm resistors across terminals A and B of T107 and T108.

Set the channel selector to channel 5.

Connect a 180 ohm composition resistor from pin 5 of V106 to terminal A of T106. Connect the oscilloscope diode probe to pin 5 of V106 and to ground.

Couple the signal generator loosely to the diode probe in order to obtain markers.

The shunt trimmer C119 across terminals A and B of T104 is variable and is provided as a bandwidth adjustment. Preset the shunt trimmer to minimum capacity. Adjust T2 (top) and T104 (bottom) for maximum gain at 43.5 mc. and with 45.75 mc. at 70% of maximum response.

Adjust T1 for maximum gain. Readjust T2 and T104 if necessary to obtain proper wave shape, see Fig. 13.

Disconnect the diode probe, the 180 ohm and the two 330 ohm resistors.

Connect the oscilloscope to the junction of R138 and L105.

Adjust the bias potentiometer to obtain —5.0 volts of bias as measured by a "VoltOhmyst" at the junction of R147 and R148.

Leave the sweep generator connected to the front terminal of the 1N82 crystal holder with the shortest leads possible and with not more than one inch of unshielded lead at the end of the sweep cable. If these precautions are not observed, the receiver may be unstable and the response curves obtained may be unreliable.

Adjust the output of the sweep generator to obtain 3.0 to 5.0 volts peak-to-peak on the oscilloscope.

Couple the signal generator loosely to the grid of the first pix i-f amplifier. Adjust the output of the signal generator to produce small markers on the response curve.

Retouch T106, T107 and T108 to obtain the response shown in Figure 14.

Remove the oscilloscope, sweep and signal generator connections.

Remove the bias box employed to provide bias for alignment.

KRK29 TUNER ALIGNMENT

Model 17-T-361

A tuner unit which is operative and requires only touch up adjustments, requires no presetting of adjustments. For such units, skip the remainder of this paragraph. For units which are completely out of adjustment, preset C27 all the way out. Set channel 7 to 13 oscillator slugs one turn from tight. Turn T2 slug all the way out. Do not change any of the adjustments in the antenna matching unit.

Disconnect the link from terminals "A" and "B" of T104 and terminate the link with a 39 ohm composition resistor.

Turn the receiver channel selector switch to channel 2.

The 43.5 mc. trap is adjusted with zero bias. To insure that the bias will remain constant, take a clip lead and short circuit the AGC terminal of the tuner at the terminal board to ground.

Connect the oscilloscope to the test point TP2 on top of the tuner unit. Set the oscilloscope to maximum gain.

Connect the output of the VHF signal generator to the output of the antenna matching unit at the junction of L5 and C4 at the bottom of the FM trap L5.

Tune the signal generator to 43.5 mc. and modulate it 30% with a 400 cycle sine wave. Adjust the signal generator for maximum output.

Adjust C33 on top of the tuner, for minimum 400 cycle indication on the oscilloscope. If necessary, this adjustment can be retouched in the field to provide additional rejection to one specific frequency in the i-f band pass. However, in such cases, care should be taken not to tune C33 into channel 2, thereby reducing sensitivity on channel 2.

Connect the potentiometer arm of one of the bias supplies to the AGC terminal on the tuner and ground the battery positive terminal to the tuner case. Adjust the bias potentiometer to produce —3.0 volts of bias, as measured by the "VoltOhmyst" at the AGC terminal on the tuner.

Set the channel selector switch to channel 8.

Preset C22 to read —3.0 volts at the test point TP1, as read on the "VoltOhmyst." The limits for oscillator injection voltage are 2 volts minimum and not exceeding a maximum of 5.5 volts.

Turn the fine tuning control fully clockwise.

Adjust C25 for proper oscillator frequency, 227 mc. This may be done in several ways. The easiest way and the way which will be recommended in this procedure will be to use the signal generator as a heterodyne frequency meter and beat the oscillator against the signal generator. To do this, tune the signal generator to 227 mc. with crystal accuracy. Insert one end of a piece of insulated wire into the tuner unit through the hole provided for the adjustment of C16. Be careful that the wire does not touch any of the tuned circuits as it may cause the frequency of the tuner oscillator to shift. Connect the other end of the wire to the "r-f in" terminal of the signal generator. Adjust C25 to obtain an audible beat with the signal generator.

Turn C27 clockwise until the beat note just begins to change, then turn one full turn in the same clockwise direction.

Return the fine tuning control to the mechanical center of its range.

NOTE:—If on some units, it is not possible to reach the proper channel 8 oscillator frequency by adjustment of C25, switch to channel 13 and adjust L49 to obtain proper channel 13 oscillator frequency as indicated in the table on page 8. Then, switch to channel 12 and adjust L60 to obtain proper channel 12 oscillator frequency. Continue down to channel 8, adjusting the appropriate oscillator trimmer to obtain the proper frequency on each channel. Then again on channel 8, adjust C25 to obtain proper channel 8 oscillator frequency. Switch back to channel 13 and readjust L49 and back to channel 8 and adjust C25.

Set the T2 core for maximum inductance (core turned counter-clockwise).

Connect the sweep generator through a suitable attenuator, as shown in figure 10 to the input terminals of the antenna matching unit.

Connect the signal generator loosely to the antenna terminals.

Set the sweep generator to cover channel 8.

Set the oscilloscope to maximum gain and use the minimum input signal which will produce a usable pattern on the oscilloscope. Excessive input can change oscillator injection during alignment and produce consequent misalignment even though the response as seen on the oscilloscope may look normal.

Insert markers of channel 8 picture carrier and sound carrier, 181.25 mc. and 185.75 mc.

Adjust C21, C16, C11 and C7 for approximately correct curve shape, frequency, and band width as shown in figure 18.

The correct adjustment of C7 is indicated by maximum amplitude of the curve midway between the markers. C11 tunes the r-f amplifier plate circuit and affects the frequency of the pass band most noticeably. C21 tunes the mixer grid circuit and affects the tilt of the curve most noticeably (assuming that C7 has been properly adjusted). C16 is the coupling adjustment and hence primarily affects the response band width.

Connect the "VoltOhmyst" to test point TP1. Adjust C22 to read —3.0 volts dc on the "VoltOhmyst" at TP1. Readjust C27, C21, C16 and C11 for proper response. Adjust C7 for maximum gain at midpoint of the curve. Repeat if necessary until the proper response is obtained.

Set the receiver channel switch to channel 13.

Adjust the signal generator to the channel 13 oscillator frequency 257 mc.

Turn the fine tuning control fully clockwise.

Adjust L49 to obtain an audible beat. Slightly overshoot the adjustment of L49 by turning the slug an additional turn in the same direction from the original setting, then reset the oscillator to proper frequency by adjusting C27 to again obtain the beat.

Set the sweep generator to channel 13.

From the signal generator, insert channel 13 sound and picture carrier markers, 211.25 mc. and 215.75 mc.

Adjust L36 and L20 for proper response as shown in figure 18.

Turn off the sweep and signal generators.

Connect the "VoltOhmyst" to the tuner test point TP1.

Check the oscillator injection voltage to be within limits as previously specified. Adjust if necessary to bring within range.

If it was necessary to readjust C22, turn the sweep and signal generators back on and recheck the channel 13 response. Readjust L36 and L20 if necessary.

Set the receiver channel selector switch to channel 8 and readjust C27 for proper oscillator frequency, 227 mc.

Set the sweep generator and signal generator to channel 8.

Readjust C21, C16, C11 and C7 for correct curve shape, frequency and band width.

Turn off the sweep and signal generators, switch back to channel 13 and check the oscillator injection voltage at TP1 if C21 was adjusted in the recheck of channel 8 response.

If the initial setting of the oscillator injection trimmer was far off, it may be necessary to adjust the oscillator frequency and response on channel 8, adjust the oscillator injection on channel 13 and repeat the tracking procedure several times before the proper setting is obtained.

Turn off the sweep generator and switch the receiver to channel 6.

Adjust the signal generator to the channel 6 oscillator frequency 129 mc.

Set the fine tuning control to the center of its mechanical range.

Adjust L54 for an audible beat. Adjust L48 and L32 for proper curve shape as shown in figure 18. Recheck the oscillator injection voltage at TP1, to insure that it is within the limits specified. Readjust C22 if necessary.

If C22 required adjustment, switch the receiver and the signal generator to channel 8. Readjust C21 for correct curve shape and recheck C27 and C25 for proper oscillator frequency.

Check the response of channels 2 through 6 by switching the receiver channel switch, sweep generator and marker generator to each of these channels and observing the response and oscillator injection voltage obtained. See figure 18 for typical response curves. It should be found that all these channels have the proper response with the markers above 80% response.

If the markers fail to fall within this requirement readjust L48 and L32 in order to obtain curves within the proper limits.

Switch the channel selector, signal generator and marker generator through channels 7 to 13 and observe the response curves, referring to figure 18 for proper wave shape. Check the injection voltage at each channel to be within limits. If necessary readjust C11, C21 or C16 to obtain the proper response.

With the receiver and signal generator on channel 13 adjust L49 for an audible beat with the signal generator.

Adjust the oscillator to frequency on all channels by switching the receiver and the frequency standard to each channel and adjusting the appropriate oscillator slug to obtain the audible beat. It should be possible to adjust the oscillator to obtain the audible beat on each channel. Recheck the oscillator injection voltage on each channel to verify that the voltage is within the specified limits.

KRK12B TUNER ALIGNMENT

Models 17-T-352U & 17-T-361U

TUNER VHF ALIGNMENT.—Remove the 6S4 voltage control tube from its socket and insert the adapter. Insert the 6S4 in the adapter.

Connect the 0-50 milliampere meter to the adapter socket leads and turn the adapter switch on.

Remove the tuner cover shield.

Rotate the channel selector to a point midway between channels, disengaging the insert contacts, and observe the non-oscillating plate current. Some tubes may oscillate even with the tuned circuits disengaged. To be sure the oscillator is in a non-oscillatory state, short circuit the spring contacts 12 and 13, the two contacts nearest the tuner front.

(NOTE: The contacts are at zero d-c potential.) Should the plate current rise, keep the contacts shorted while adjusting the oscillator plate current. Adjust R6, oscillator voltage control, for a 28 milliampere reading on the meter.

Replace the tuner cover shield.

Connect the VHF sweep generator to the antenna terminals.

Connect the VHF signal generator loosely to the antenna terminals.

Connect the oscilloscope, through the preamplifier, if needed with oscilloscope used, to test point TP1.

Ground the AGC bias at the tuner terminal board using a clip lead to insure that the bias will remain constant.

Turn off the adapter switch, removing plate voltage from the oscillator. This is required because of RF-IF interaction when a crystal is used as a mixer.

Set the channel selector and the sweep generator to channel 2.

Insert markers of channel 2 picture carrier and sound carrier, 55.25 mc. and 59.75 mc.

Adjust antenna T6, r-f amplifier plate L29 and mixer L130 adjustments for a symmetrical curve with maximum gain at the center of the pass band. The curves will have a deep valley because of no crystal loading and nonlinear detector characteristics. The limits for the 100% response points are shown in Figure 11. The proper curve shape is shown in Figure 11(b). (See note on page 13 for detailed explanation of adjustments.) If the bandwidth is out of tolerance, it can usually be corrected by redressing the coupling capacitor of the double tuned circuit, C40 on insert A. Maximum bandwidth occurs when the capacitor is centered in the insert chamber.

Repeat the above steps for all VHF channels adjusting the appropriate antenna, r-f amplifier plate and mixer slugs for a symmetrical curve with maximum gain at the center of the pass band.

Turn off the sweep generator.

Remove the oscilloscope and preamplifier if used, from test point TP1.

Turn the AGC control fully clockwise.

Remove the clip lead grounding the AGC bias on the tuner terminal board.

Connect the potentiometer arm of one of the bias supplies to the AGC terminal on the tuner and ground the battery positive terminal to the tuner case. Adjust the bias potentiometer to produce —3.5 volts of bias, as measured by the "VoltOhmyst" at the AGC terminal on the tuner.

Connect the potentiometer arm of the second bias supply to the junction R147 and R148, and ground the positive battery terminal. Adjust the bias potentiometer to produce —5 volts of i-f bias as indicated on the "VoltOhmyst" at the junction point.

Connect the oscilloscope to the junction of R138 and L105. Use 3 to 5 volts peak-to-peak output on the oscilloscope.

Turn the adapter switch on to apply plate voltage to the oscillator.

Turn the channel selector to channel 13.

Set the fine tuning control to the center of its range.

Adjust the oscillator slug L22 to proper frequency, 257 mc. This may be done in several ways. The easiest way and the way which will be recommended in this procedure will be to use the signal generator as a heterodyne frequency meter and beat the oscillator against the signal generator. To do this, tune the signal generator to 257 mc. with crystal accuracy. Insert one end of a piece of insulated wire into the tuner through either of the two holes next to the oscillator tube on the right front top corner of the tuner. Be careful that the wire does not touch any of the tuned circuits as it may cause the frequency of the oscillator to shift. Connect the other end of the wire to the "r-f in" terminal of the signal generator. Adjust L22 oscillator slug to obtain an audio beat with the signal generator.

Turn on the sweep generator and set to Channel 13. Adjust T1 for maximum gain on the oscilloscope. Adjust mixer tank circuit L21 for maximum gain and flat-topped curve. Recheck T1 for maximum gain at center of band with the proper response. Maximum gain and flat-topped response should be obtained simultaneously.

Adjust the oscillator to frequency on all VHF channels by switching the receiver and signal generator to each VHF channel and adjusting the appropriate oscillator slug to obtain a beat with the signal generator. Adjust the appropriate mixer slug where necessary to obtain maximum gain and proper curve shape as explained above.

Adjust the tunable I-F Trap C16-L7. To do this connect the signal generator to the fixed I-F Trap C2-L2 at the end opposite the antenna terminal plug. Set the signal generator to 43.5 mc. and adjust the output of the signal generator to obtain sufficient indication on the oscilloscope. Tune the I-F Trap C16-L7 for minimum indication on the oscilloscope.

Remove the signal generator and the oscilloscope.

TUNER UHF ALIGNMENT—To align the UHF inserts:

Turn off the adapter switch, removing plate voltage from the oscillator.

Ground the AGC bias at the tuner terminal board using a clip lead to insure that the bias will remain constant.

Connect the oscilloscope, through the preamplifier if needed with oscilloscope used, to test point TP1.

Connect the UHF sweep generator to the antenna terminals. Use a 10 DB attenuator pad to assure proper alignment.

Connect the UHF signal generator loosely to the antenna terminals.

Set the channel selector to the desired position and the sweep generator to sweep the frequency of the insert being used.

Insert markers of the picture carrier and sound carrier for desired channel.

Adjust UHF antenna link coupling and mixer adjustments for a symmetrical curve, with maximum gain, centered about the pass band.

The responses are shown in Figure 12. The curve shape will usually vary from Fig. 12 (a) to Fig. 12 (c) going higher in frequency, however any of these responses are acceptable.

Repeat the above steps for all UHF inserts used adjusting the appropriate antenna, link coupling and mixer slugs for a symmetrical curve, with maximum gain, centered about the pass band.

Remove the oscilloscope and preamplifier if used, from test point TP1.

Remove the clip lead grounding the AGC bias on the tuner terminal board.

Connect the potentiometer arm of one of the bias supplies to the AGC terminal on the tuner and ground the battery positive terminal to the tuner case. Adjust the bias potentiometer to produce —3.5 volts of bias, as measured by the "VoltOhmyst" at the AGC terminal.

ALIGNMENT PROCEDURE

Connect the potentiometer arm of the second bias supply to the junction of R147 and R148, and ground the positive battery terminal. Adjust the bias potentiometer to produce —5 volts of i-f bias as indicated on the "VoltOhmyst" at the junction point.

Connect the oscilloscope to the junction of R138 and L105. Use 3 to 5 volts peak-to-peak output on the oscilloscope.

Turn the adapter switch on to apply plate voltage to the oscillator.

Turn the channel selector to the lowest UHF channel to be used.

Set the fine tuning control to the center of its range.

Adjust the oscillator core to proper frequency. To do this, connect the VHF signal generator to test point TP1 with the shortest leads possible. Insert a 45.75 mc. marker from the VHF generator.

Set the UHF sweep generator to sweep the desired channel, and observe the output on the oscilloscope. If the sweep generator is not sweeping the correct frequency range, it may be necessary to readjust the sweep in order to place the 45.75 marker on the response curve as in Fig. 14.

Set the UHF marker gen. to the picture carrier of the channel insert being adjusted and connect to test point TP1.

Adjust the oscillator core until the markers for 45.75 mc. and the picture carrier coincide on the sweep pattern on the oscilloscope.

Adjust mixer core for maximum gain with proper wave shape.

Connect the "VoltOhmyst" to test point TP1, using 1.5 volt D.C. scale.

Set oscillator injection adjustment to read .1 volts on the "VoltOhmyst."

Repeat the above steps for all UHF inserts adjusting the oscillator injection control only if the reading on the "VoltOhmyst" exceeds .3 volts. Adjust as necessary to read .3 volts or less at TP1.

AGC CONTROL ADJUSTMENT.—Disconnect all test equipment except the oscilloscope which should be connected to pin 6 of V110.

Connect an antenna to the receiver antenna terminals.

Turn the AGC control fully counter-clockwise.

Tune in a strong signal and adjust the oscilloscope to see the video waveform.

Turn the AGC control clockwise until the tips of sync begin to be compressed, then counter-clockwise until no compression is obtained.

HORIZONTAL OSCILLATOR ADJUSTMENT. — Normally the adjustment of the horizontal oscillator is not considered to be a part of the alignment procedure, but since the oscillator waveform adjustment may require the use of an oscilloscope, it cannot be done conveniently in the field. The waveform adjustment is made at the factory and normally should not require readjustment in the field. However, the waveform adjustment should be checked whenever the receiver is aligned or whenever the horizontal oscillator operation is improper.

Horizontal Frequency Adjustment.—Tune in a station and sync the picture. If the picture cannot be synchronized with the horizontal hold control R200, then adjust the T114 frequency core on the rear apron until the picture will synchronize. If the picture still will not sync, turn the T114 waveform adjustment core (under the chassis) out of the coil several turns from its original position and readjust the T114 frequency core until the picture is synchronized.

Examine the width and linearity of the picture. If picture width or linearity is incorrect, adjust the horizontal drive control C174B, the width control L109 and the linearity control L111 until the picture is correct.

Horizontal Oscillator Waveform Adjustment.—The horizontal oscillator waveform may be adjusted by either of two methods. The method outlined in paragraph A below may be employed in the field when an oscilloscope is not available. The service shop method outlined in paragraph B below requires the use of an oscilloscope.

A.—Turn the horizontal hold control completely clockwise. Place adjustment tools on both cores of T114 and be prepared to make simultaneous adjustments while watching the picture on the screen. First, turn the T114 frequency core (on the rear apron) until the picture falls out of sync and three or four diagonal black bars sloping down to the right appear on the screen. Then, turn the waveform adjustment core (under the chassis) into the coil while at the same time adjusting the frequency core so as to maintain three or four diagonal black bars on the screen. Continue this procedure until the oscillator begins to motorboat, then turn the waveform adjustment core out until the motorboating just stops. As a check, turn the T114 frequency core until the picture is synchronized then reverse the direction of rotation of the core until the picture falls out of sync with the diagonal bars sloping down to the right. Continue to turn the frequency core in the same direction. No more than three or four bars should appear on the screen. Instead, the horizontal oscillator should begin to motorboat. Retouch the adjustment of the T114 waveform adjustment core if necessary until this condition is obtained.

B.—Connect the low capacity probe of an oscilloscope to terminal C of T114. Turn the horizontal hold control one-quarter turn from the clockwise position so that the picture is in sync. The pattern on the oscilloscope should be as shown in Figure 24. Adjust the waveform adjustment core of T114 until the two peaks are at the same height. During this adjustment, the picture must be kept in sync by readjusting the hold control if necessary.

This adjustment is very important for correct operation of the circuit. If the broad peak of the wave on the oscilloscope is lower than the sharp peak, the noise immunity becomes poorer, the stabilizing effect of the tuned circuit is reduced and drift of the oscillator becomes more serious. On the other hand, if the broad peak is higher than the sharp peak, the oscillator is overstabilized, the pull-in range becomes inadequate and the broad peak can cause double triggering of the oscillator when the hold control approaches the clockwise position.

Remove the oscilloscope upon completion of this adjustment.

Horizontal Locking Range Adjustment.—Set the horizontal hold control to the full counterclockwise position. Momentarily remove the signal by switching off channel then back. The picture may remain in sync. If so turn the T114 frequency core slightly and momentarily switch off channel. Repeat until the picture falls out of sync with the diagonal lines sloping down to the left. Slowly turn the horizontal hold control clockwise and note the least number of diagonal bars obtained just before the picture pulls into sync.

If more than 3 bars are present just before the picture pulls into sync, adjust the horizontal locking range trimmer C174A slightly clockwise. If less than 2 bars are present, adjust C174A slightly counter-clockwise. Turn the horizontal hold control counter-clockwise, momentarily remove the signal and recheck the number of bars present at the pull-in point. Repeat this procedure until 2 or 3 bars are present.

Turn the horizontal hold control to the maximum clockwise position. Adjust the T114 frequency core so that the diagonal bar sloping down to the right appears on the screen and then reverse the direction of adjustment so that bar just moves to the left side of the screen leaving the picture in synchronization.

VOLTAGE CHART

The following measurements represent two sets of conditions. In the first condition, a 15000 microvolt test pattern signal was fed into the receiver, the picture synced and the AGC control properly adjusted. The second condition was obtained by removing the antenna leads and short circuiting the receiver antenna terminals. Voltages shown are read with a type WV97A senior "VoltOhmyst" between the indicated terminal and chassis ground and with the receiver operating on 117 Volts, 60 cycles, a-c. The symbol < means less than.

76476	330 mmf., 1000 volts (C182)
73094	390 mmf., 1000 volts DC (C157)
39644	470 mmf., 500 volts DC (C106, C107)
	Capacitor—Ceramic:
76461	500 mmf., 20,000 volts (C188)
	Capacitor—fixed, ceramic, High "K" disc:
7 293	470 mmf., +100%, -0%, 500 volts DC (C127, C128, C129, C130, C131, C135, C196 for KCS78F)
77672	Dual 470 mmf., +100%, -0%, 500 volts DC (C132A, C132B)
77252	1000 mmf., +100%, -0%, 500 volts DC (C133)
73960	10,000 mmf., +100%, -0%, 500 volts DC (C104, C134, C194)
76991	Dual 10,000 mmf., +100%, -0%, 500 volts DC (C101A, C101B)
	Capacitor—Fixed, ceramic, insulated:
77673	470 mmf., ±10%, 1500 volts DC (C144)
	Capacitor—Fixed, ceramic, non-insulated, Temp. coef. = -750
	CHASSIS ASSEMBLIES KCS 78F—VHF Chassis KCS 78J—UHF/VHF chassis
77609	Transformer—Mixer I.F. transformer complete with adjustable cores (T1)
77610	Transformer—Primary I.F. link transformer complete with adjustable cores (T2, R15)
77636	Trap—I.F. trap (L1, C1, L2, C2)
77489	Rectifier—Germanium rectifier IN82 (CR1)
	Resistor—Fixed, composition:
503047	47 ohms, ±10%, ½ watt (R16)
503110	100 ohms, ±10%, ½ watt (R10, R17)
503112	120 ohms, ±10%, ½ watt (R2, R9)
503210	1000 ohms, ±10%, ½ watt (R14)
503310	10,000 ohms, ±10%, ½ watt (R12)
503322	22,000 ohms, ±10%, ½ watt (R1)
503410	100,000 ohms, ±10%, ½ watt (R18, R19)
503412	120,000 ohms, ±10%, ½ watt (R5)
503427	270,000 ohms, ±10%, ½ watt (R4)
503447	470,000 ohms, ±10%, ½ watt (R8)
503582	8.2 megohm, ±10%, ½ watt (R3, R7)
77614	Control—Oscillator voltage control (R6)
77617	Control—UHF oscillator injection adjustment control
78047	2 mmf., ±10%, 500 volts DC (C42)
77628	Coil—IF trap (L7)
77634	Coil—IF neutralizing coil (L12)
77629	Coil—Oscillator cathode coil (L9)
77632	Coil—Oscillator heater coil (L15)
77631	Coil—Oscillator heater coil (L14)
78224	Coil—Oscillator plate coil (L11)
77627	Coil—Peaking coil (L6, R11)
77695	Coil—RF plate coil (L8)
	Capacitor—Fixed, ceramic, High "K" disc:
77625	220 mmf., +100%, -0%, 500 volts DC (C18)
77293	470 mmf., +100%, -0%, 500 volts DC (C43)
77624	680 mmf., +100%, -0%, 500 volts DC (C4)
77252	1000 mmf., +100%, -0%, 500 volts DC (C14, C20, C22, C27)
73960	10,000 mmf., +100%, -0%, 500 volts DC (C17)
	Capacitor—Fixed, ceramic, insulated:
77667	Comprising: 1 section of 2 mmf., and 1 section of 22 mmf. (C12, C13)
	Capacitor—Fixed, ceramic, non-insulated, Temp. coef. -0
77210	2 mmf., ±0.25 mmf., 500 volts DC (C15)
77688	5 mmf., ±.5 mmf., 500 volts DC (C34, C36, C38, C41)
74182	6 mmf., ±0.5 mmf., 500 volts DC (C5)
	Capacitor—Fixed, ceramic, non-insulated, Temp. coef. = -750
71924	56 mmf., ±10%, 500 volts DC (C10)
	Capacitor—Fixed, headed-lead type:
77691	.33 mmf., ±10%, 500 volts DC (C33, C35)
77689	.82 mmf., ±10%, 500 volts DC (C37)
77690	1.0 mmf., ±10%, 500 volts DC (C40)
71500	1.5 mmf., ±10%, 500 volts DC (C39)

STOCK No.	DESCRIPTION
	Capacitor—Mica trimmer:
71496	5-70 mmf. (C119)
75217	Dual 10-160 mmf. (C174A, C174B)
	Capacitor—Electrolytic:
75218	Comprising: 1 section of 10 mfd., 350 volts, 1 section of 5 mfd., 350 volts and 1 section of 150 mfd., 50 volts (C126A, C126B, C126C)
77644	Comprising: 1 section of 80 mfd., 400 volts and 1 section of 20 mfd., 400 volts (C117A, C117B)
76970	Comprising: 1 section of 100 mfd., 400 volts, 1 section of 10 mfd., 350 volts and 1 section of 20 mfd., 50 volts (C116A, C116B, C116C)
	Capacitor—Fixed, tubular, paper, oil impregnated:
75643	.001 mfd., 1000 volts (C114, C146, C156, C176)
73595	.0022 mfd., 600 volts (C108, C145, C158)
73818	.0027 mfd., 1600 volts (C118)
73796	.0039 mfd., 600 volts (C147)
73920	.0047 mfd., 600 volts (C110, C138, C162, C158)
73808	.0082 mfd., 1000 volts (C155)
73561	.01 mfd., 400 volts (C111, C115)
73562	.022 mfd., 400 volts (C180)
73798	.022 mfd., 600 volts (C166)
73810	.022 mfd., 1000 volts (C142, C189)
73811	.027 mfd., 1000 volts (C190)
73552	.033 mfd., 400 volts (C112, C152)
73596	.033 mfd., 1000 volts (C161)
73553	.047 mfd., 400 volts (C179)
73592	.047 mfd., 600 volts (C167)
73792	.068 mfd., 400 volts (C165)
73784	0.1 mfd., 200 volts (C171)
73551	0.1 mfd., 400 volts (C151, C159, C169, C170, C178)
73557	0.1 mfd., 600 volts (C160, C163, C186)
73794	0.22 mfd., 400 volts (C125)
73786	0.27 mfd, 200 volts (C187)
73787	0.47 mfd., 200 volts (C109, C143, C181)
	Capacitor—Fixed, tubular, moulded, oil impregnated:
76479	.00068 mfd., 600 volts (C184)
76995	.0012 mfd., 600 volts (C185)
77123	.0015 mfd., 1000 volts (C164)
73594	.01 mfd., 600 volts (C172, C173, C183)
77676	Choke—Filter choke (L117)
73477	Coil—Choke coil (L101, L118)
76442	Coil—Horizontal linearity coil complete with adjustable core (L111)
76011	Coil—Peaking coil (36 muh) (L102)
77925	Coil—Peaking coil (220 muh) (L107, R146)
71526	Coil—Peaking coil (250 muh) (L104)
77124	Coil—Peaking coil (1000 muh) (L106, R218)
76640	Coil—RF choke coil (1.5 muh) (L110)
76441	Coil—Width coil complete with adjustable core (L109)
76975	Control—AGC control (R154)
77641	Control—Brightness control, volume control and power switch (R110A, R110B, S102)
77924	Control—Height control (R176)
77639	Control—Horizontal hold control (R200)
76445	Control—Picture control (R144)
77642	Control—Vertical hold control (R174)
77643	Control—Vertical linearity control (R186)
	Resistor—Wire wound:
76796	5.1 ohms, 1/3 watt (R213)
76639	180 ohms, 2 watts (R210)
77670	3300 ohms, 7 watts (R120)
77671	3800 ohms, 7 watts (R121)
76642	6750 ohms, 10 watts (R142)
	Resistor—Fixed, composition:
30789	33 ohms, ±5%, ½ watt (R131)
503033	33 ohms, ±10%, ½ watt (R139)
503047	47 ohms, ±10%, ± watt (R105, R209)
34763	68 ohms, ±5%, ½ watt (R128)
503082	82 ohms, ±10%, ½ watt (R101)
502118	180 ohms, ±5%, ½ watt (R134)
503139	390 ohms, ±10%, ½ watt (R187)
503147	470 ohms, ±10%, ½ watt (R135)
513156	560 ohms, ±10%, 1 watt (R114)
503168	680 ohms, ±10%, ½ watt (R143)
503210	1000 ohms, ±10%, ½ watt (R104, R116, R127, R130, R132)
513210	1000 ohms, ±10%, 1 watt (R02)
523218	1800 ohms, ±10%, 2 watts (R115)
503222	2200 ohms, ±10%, ½ watt (R145)
523222	2200 ohms, ±10%, 2 watts (R141)
503233	3300 ohms, ±10%, ½ watt (R188)
502239	3900 ohms, ±5%, ½ watt (R138)
503239	3900 ohms, ±10%, ½ watt (R202)

STOCK No.	DESCRIPTION
502247	4700 ohms, ±5%, ½ watt (R168)
513268	6800 ohms, ±10%, 1 watt (R150)
523268	6800 ohms, ±10%, 2 watts (R211)
503282	8200 ohms, ±10% ½ watt (R159, R169, R180, R183)
523282	8200 ohms, ±10%, 2 watts (R140)
502310	10,000 ohms, ±5%, ½ watt (R107, R108)
513310	10,000 ohms, ±10%, 1 watt (R217)
503312	12,000 ohms, ±10%, ½ watt (R111)
503315	15,000 ohms, ±10%, ½ watt (R189)
503318	18,000 ohms, ±10%, ½ watt (R157, R172, R204)
503322	22,000 ohms, ±10%, ½ watt (R162, R166, R171, R201)
503339	39,000 ohms, ±10%, ½ watt (R106)
70351	43,000 ohms, ±5%, ½ watt (R147)
503347	47,000 ohms, ±10%, ½ watt (R136, R149, R165)
512347	47,000 ohms, ±5%, 1 watt (R206)
502356	56,000 ohms, ±5%, ½ watt (R129, R133)
503356	56,000 ohms, ±10%, ½ watt (R212)
512356	56,000 ohms, ±5%, 1 watt (R182)
503368	68,000 ohms, ±10%, ½ watt (R151, R199)
503382	82,000 ohms, ±10%, ½ watt (R198)
513410	100,000 ohms, ±10%, 1 watt (R179, R219)
503412	120,000 ohms, ±10%, ½ watt (R158)
502415	150,000 ohms, ±5%, ½ watt (R148)
503415	150,000 ohms, ±10%, ½ watt (R178, R191, R194)
512415	150,000 ohms, ±5%, 1 watt (R203)
502418	180,000 ohms, ±5%, ½ watt (R125)
503422	220,000 ohms, ±10%, ½ watt (R190, R192)
502427	270,000 ohms, ±5%, ½ watt (R181)
503427	270,000 ohms, ±10%, ½ watt (R163, R177)
503433	330,000 ohms, ±10%, ½ watt (R112, R195, R197)
503439	390,000 ohms, ±10%, ½ watt (R155, R173)
503447	470,000 ohms, ±10%, ½ watt (R113, R153, R193, R208)
503468	680,000 ohms, ±10%, ½ watt (R160, R167)
503482	820,000 ohms, ±10%, ½ watt (R196, R207)
503510	1 megohm, ±10%, ½ watt (R161)
502511	1.1 megohm, ±5%, ½ watt (R185)
503512	1.2 megohms, ±10%, ½ watt (R184)
503515	1.5 megohm, ±10%, ½ watt (R175)
11769	1.8 megohm, ±5%, ½ watt (R124, R205)
503522	2.2 megohm, ±10%, ½ watt (R164, R170)
503539	3.9 megohm, ±10%, ½ watt (R137, R152)
503610	10 megohm, ±10%, ½ watt (R109)
76795	Transformer—Hi-voltage transformer (T115)
76440	Transformer—Horizontal oscillator transformer complete with adjustable core (T114)
76982	Transformer—Output transformer (T103)
77635	Transformer—Power transformer, 117 volts, 60 cycle (T113)
77112	Transformer—Ratio detector transformer (T102, C105)
76981	Transformer—Sound I.F. transformer complete with adjustable cores (T101, C102, C103, R103)
77636	Transformer—Vertical output transformer (T112)
77637	Transformer—1st pix I.F. transformer complete with adjustable cores (T104, C120, R126)
77638	Transformer—2nd pix I.F. transformer complete with adjustable core (T106)
76433	Transformer—3rd or 4th pix I.F. transformer (T107, T108)
76983	Trap—4.5 MC trap (L105, C137)
77585	Washer—"C" washer for picture control extension shaft (2 req'd)
	SPEAKER ASSEMBLIES 971636-1W RL101C5 RMA-274 (For Model 17T352U)
77000	Speaker—5" P.M. speaker complete with cone and voice coil (3.2 ohms)
	SPEAKER ASSEMBLIES 971490-3W 971490-3R RL105E6 RMA-274 RMA-285 (For Models 17T361, 17T361U)
75024	Cone—Cone and voice coil (3.2 ohms) for speaker stamped 971490-3W
77129	Cone—Cone and voice coil (3.2 ohms) for speaker stamped 971490-3R
75022	Speaker—8" P.M. speaker complete with cone and voice coil (3.2 ohms)

ELECTRICAL AND MECHANICAL SPECIFICATIONS

PICTURE SIZE.......227 square inches on a 21AP4 Kinescope

TELEVISION R-F FREQUENCY RANGE

Models 21-D-358 to 21-D-380 Incl.

All 12 VHF channels......54 mc. to 88 mc., 174 mc. to 216 mc.

Models 21-D-358U to 21-D-380U Incl.

Any of 70 UHF channels..................470 mc. to 890 mc.

Any of 12 VHF channels..54 mc. to 88 mc., 174 mc. to 216 mc.

(Any desired combination of 16 UHF and/or VHF channels may be used.)

INTERMEDIATE FREQUENCIES

Picture I-F Carrier Frequency......................45.75 mc.

Sound I-F Carrier Frequency......................41.25 mc.

POWER RATING.............21-D-358 to 21-D-380 295 watts
21-D-358U to 21-D-380U 305 watts

AUDIO POWER OUTPUT RATING...............4 watts max.

RCA TUBE COMPLEMENT

Tube Used	Function
Tuner KRK29 (21-D-358 to 21-D-380 Incl.)	
(1) RCA 6BQ7A	R-F Amplifier
(2) RCA 6X8	R-F Oscillator and Mixer

ANTENNA INPUT IMPEDANCE

Models 21-D-358 to 21-D-380 Incl.

Choice: 300 ohms balanced or 72 ohms unbalanced.

Models 21-D-358U to 21-D-380U Incl.

UHF—300 ohms balanced.

VHF—300 ohms balanced.

CHASSIS DESIGNATIONS

KCS81F...............In Models 21-D-358, 21-D-368, 21-D-376, 21-D-377, 21-D-378, 21-D-379, 21-D-380

KCS81J............In Models 21-D-358U, 21-D-368U, 21-D-376U, 21-D-377U, 21-D-378U, 21-D-379U, 21-D-380U

VIDEO RESPONSE...............................To 4 mc.

FOCUS...Magnetic

SWEEP DEFLECTION.............................Magnetic

SCANNING............................Interlaced, 525 line

HORIZONTAL SCANNING FREQUENCY............15,750 cps

VERTICAL SCANNING FREQUENCY..................60 cps

FRAME FREQUENCY (Picture Repetition Rate)..........30 cps

RCA TUBE COMPLEMENT

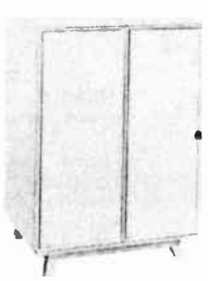
Tube Used	Function
Tuner KRK12B (21-D-358U to 21-D-380U Incl.)	
(1) RCA 6BQ7A	R-F Amplifier (VHF only)
(2) RCA 6AF4	R-F Oscillator
(3) RCA 6BQ7A	I-F Amplifier
(4) RCA 6S4	Voltage Control
A 1N82 crystal is used as a mixer.	
All Models	
(1) RCA 6AU6	1st Picture I-F Amplifier
(2) RCA 6CB6	2nd Picture I-F Amplifier
(3) RCA 6CB6	3rd Picture I-F Amplifier
(4) RCA 6CB6	4th Picture I-F Amplifier
(5) RCA 6CL6	Video Amplifier
(6) RCA 6AU6	1st Sound I-F Amplifier
(7) RCA 6AU6	2nd Sound I-F Amplifier
(8) RCA 6AL5	Ratio Detector
(9) RCA 6AV6	1st Audio Amplifier
(10) RCA 6AQ5	Audio Output
(11) RCA 12AU7	Vertical Sync Separator and AGC
(12) RCA 12AU7	Horiz. Sync Separator and Sync Amplifier
(13) RCA 6SN7GT	Vert. Sync Amplifier and Vert. Sweep Osc.
(14) RCA 6AQ5	Vertical Sweep Output
(15) RCA 6SN7GT	Horizontal Sweep Oscillator and Control
(16) RCA 6CD6G	Horizontal Sweep Output
(17) RCA 6W4GT (2 tubes)	Dampers
(18) RCA 1B3GT/8016	High Voltage Rectifier
(19) RCA 5U4G (2 tubes)	Rectifiers
(20) RCA 21AP4	Kinescope

OPERATING CONTROLS (front panel)

Channel Selector / Fine Tuning	Dual Control Knobs
Brightness / Sound Volume and On-Off Switch	Dual Control Knobs
Picture Horizontal Hold	Single Control (Knurled)
Picture Vertical Hold	Single Control (Knurled)
Picture	Single Control Knob
Tone Switch	Single Control Knob

NON-OPERATING CONTROLS

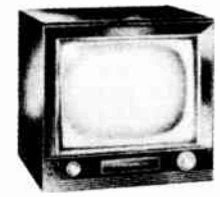
Horizontal Centering	top chassis adjustment
Vertical Centering	top chassis adjustment
AGC	rear chassis adjustment
Height	front panel screwdriver adjustment
Horizontal Linearity	rear chassis adjustment
Horizontal Locking	rear chassis screwdriver adjustment
Vertical Linearity	front panel screwdriver adjustment
Horizontal Drive	rear chassis screwdriver adjustment
Horizontal Oscillator Frequency	rear chassis adjustment
Horizontal Oscillator Waveform	bottom chassis adjustment
Width Link	H.V. compartment adjustment
Focus	top chassis adjustment
Ion Trap Magnet	top chassis adjustment
Deflection Coil	top chassis adjustment
Focus Magnet	top chassis adjustment



Models 21-D-378, 21-D-378U "Newport" Oak, Natural Walnut

Models 21-D-379, 21-D-379U "Bradbury" Mahogany, Walnut

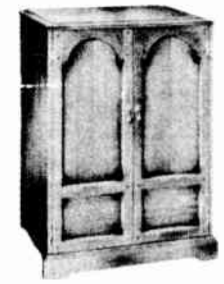
Models 21-D-380, 21-D-380U "Beaumont" Maple, Red Cherry



Models 21-D-358, 21-D-358U "Dunbar" Mahogany, Oak

Models 21-D-368, 21-D-368U "Talmadge" Mahogany, Oak

Models 21-D-376, 21-D-376U "Caldwell" Mahogany, Oak



Models 21-D-377, 21-D-377U "Vincennes" Red Cherry, Natural Cherry

GENERAL DESCRIPTION

All models are "21 inch" television receivers. Models 21-D-358, 21-D-368, 21-D-376, 21-D-377, 21-D-378, 21-D-379 and 21-D-380 are identical except for cabinets and speakers. These models feature full 12 channel VHF coverage. Models 21-D-358U, 21-D-368U, 21-D-376U, 21-D-377U, 21-D-378U, 21-D-379U and 21-D-380U are identical except for cabinets and speakers. These models feature full 12 channel VHF coverage plus any 4 UHF channels desired. All models have an auxiliary audio input jack to permit the use of an external record playing attachment.

ALIGNMENT PROCEDURE

Connect a 300 ohm ½ watt composition resistor from L5 to ground, keeping the leads as short as possible.

Connect an oscilloscope low capacity crystal probe from L5 to ground. The sensitivity of the oscilloscope should be approximately 0.03 volts per inch. Set the oscilloscope gain to maximum.

Connect the VHF sweep generator to the matching unit antenna input terminals. In order to prevent coupling reactance from the sweep generator into the matching unit, it is advisable to employ a resistance pad at the matching unit terminals. Figure 10 shows three different resistance pads for use with sweep generators with 50 ohm co-ax output, 72 ohm co-ax output or 300 ohm balanced output. Choose the pad to match the output impedance of the particular sweep employed.

Connect the signal generator loosely to the matching unit antenna terminals.

Set the sweep generator to sweep from 45 mc. to 54 mc. With RCA Type WR59A sweep generators, this may be accomplished by retuning channel number 1 to cover this range. With WR59B sweep generators this may be accomplished by retuning channel number 2 to cover the range. In making these adjustments on the generator, be sure not to turn the core too far clockwise so that it becomes lost beyond the core retaining spring.

Adjust L2 and L3 to obtain the response shown in Figure 19. L3 is most effective in locating the position of the shoulder of the curve at 52 mc. and L2 should be adjusted to give maximum amplitude at 53 mc. and above consistent with the specified shape of the response curve. The adjustments in the matching unit interact to some extent. Repeat the above procedure until no further adjustments are necessary.

Remove the 300 ohm resistor and crystal probe connections. Restore the connection between L5 and S1-E. Replace V106.

PICTURE I-F TRAP ADJUSTMENT.—Connect the i-f signal generator across the link circuit on terminals A and B of T104.

Connect the "VoltOhmyst" to the junction of R133 and C133B.

Obtain two 7.5 volt batteries capable of withstanding appreciable current drain and connect the ends of a 1,000 ohm potentiometer across each. Connect the positive terminal of one battery to chassis and the potentiometer arm to the junction of R133 and C133B.

Set the bias to produce approximately −1.0 volt of bias at the junction of R133 and C133B.

Connect the "VoltOhmyst" to pin 9 of V110, the 6CL6 video amplifier.

Set the signal generator to each of the following frequencies and adjust the corresponding circuit for minimum d-c output at pin 9 of V110. Use sufficient signal input to produce 1.0 volt of d-c on the meter when the final adjustment is made.

39.25 mc.	T104 top core
41.25 mc.	T105 bottom core
47.25 mc.	T106 bottom core

PICTURE I-F TRANSFORMER ADJUSTMENTS.—
Models 21-D-358 to 21-D-380 Incl.

Set the signal generator to each of the following frequencies and peak the specified adjustment for maximum indication on the "VoltOhmyst." During alignment, reduce the input signal if necessary in order to produce 1.0 volt of d-c at pin 9 of V110 with −1.0 volt of i-f bias at the junction of R133 and C133B.

43.7 mc.	T109
45.5 mc.	T108
41.8 mc.	T107

To align T105 and T106, connect the sweep generator to the first picture i-f grid, pin 1 of V106 through a 1,000 mmf. ceramic capacitor. Shunt R137, R141 and terminals "A" and "F" of T109 with 330 ohm composition resistors. Set the i-f bias to −1.0 volt at the junction of R133 and C133B.

Connect the oscilloscope to pin 9 of V110.

Adjust T105 and T106 top cores for maximum gain and curve shape as shown in Figure 22. For final adjustment set the output of the sweep generator to produce 0.5 volt peak-to-peak at the oscilloscope terminals.

To align T2 and T104, connect the sweep generator to the mixer grid test point TP2. Use the shortest leads possible, with not more than one inch of unshielded lead at the end of the sweep cable.

Adjust C121 until 41.25 mc. is at 85% response with respect to the low frequency shoulder at approximately 41.9 mc. as shown in Figure 23.

Disconnect the diode probe, the 180 ohm and three 330 ohm resistors.

Models 21-D-358U to 21-D-380U incl.

Set the signal generator to each of the following frequencies and peak the specified adjustment for maximum indication on the "VoltOhmyst." During alignment, reduce the input signal if necessary in order to produce 1.0 volt of d-c at pin 9 of V110 with −1.0 volt of i-f bias at the junction of R133 and C133B.

43.7 mc.	T109
45.5 mc.	T108
41.8 mc.	T107

To align T105 and T106, connect the sweep generator to the first picture i-f grid, pin 1 of V106 through a 1,000 mmf. ceramic capacitor. Shunt R137, R141 and terminals "A" and "F" of T109 with 330 ohm composition resistors. Set the i-f bias to −1.0 volt at the junction of R133 and C133B.

Connect the oscilloscope to pin 9 of V110, the 6CL6 video amplifier.

Adjust T105 and T106 top cores for maximum gain and curve shape as shown in Figure 22. For final adjustment set the output of the VHF sweep generator to produce 0.5 volt peak-to-peak at the oscilloscope terminals.

To align the crystal mixer and T2 and T104, connect the VHF sweep generator to the front terminal of the 1N82 crystal holder in series with a 1,500 mmf. ceramic capacitor. Use the shortest leads possible, grounding the sweep generator to the tuner case.

Set the channel selector to channel 5.

Connect a 180 ohm composition resistor between terminal "B" of T105 and the junction of R131 and C133A.

Connect the oscilloscope diode probe to terminal "B" of T105 and ground. Couple the signal generator loosely to the diode probe in order to obtain markers.

The shunt trimmer C121 across terminals "A" and "B" of T104 is variable and is provided as a bandwidth adjustment. Preset the shunt trimmer to minimum capacity. Adjust T2 (top) and T104 (bottom) for maximum gain at 43.5 mc. and with 45.75 mc. at 70% of maximum response.

Adjust the shunt trimmer C121 until 41.25 mc. is at 85% response with respect to the low frequency shoulder at approximately 41.9 mc. as shown in Figure 13. Adjust T1 for maximum gain. Readjust T2 and T104 if necessary to obtain proper wave shape, see Figure 13.

Disconnect the diode probe, the 180 ohm and the three 330 ohm resistors.

SWEEP ALIGNMENT OF PICTURE I-F.—
Connect the oscilloscope to pin 9 of V110.

Adjust the bias potentiometer to obtain −6.0 volts of bias as measured by a "VoltOhmyst" at the junction of R133 and C133B.

Leave the sweep generator connected to the mixer grid test point TP2 on KRK29 Tuner or to the front terminal of the 1N82 crystal holder on KRK12B Tuner. Use the shortest leads possible with not more than one inch of unshielded lead at the end of the sweep cable. If these precautions are not observed, the receiver may be unstable and the response curves obtained may be unreliable.

Adjust the output of the sweep generator to obtain 3.0 volts peak-to-peak on the oscilloscope.

Couple the signal generator loosely to the grid of the first pix i-f amplifier. Adjust the output of the signal generator to produce small markers on the response curve.

Retouch T108 and T109 to obtain the response shown in Figure 14. Do not adjust T107 unless absolutely necessary. If T107 is adjusted too low in frequency it will raise the level of the 41.25 mc. sound i-f carrier and may create interference in the picture. It will also cause poor adjacent channel picture rejection. If T107 is tuned too high in frequency, the level of the 41.25 mc. sound i-f carrier will be too low and may produce noisy sound in weak signal areas.

Remove the oscilloscope, sweep and signal generator connections.

Remove the bias box employed to provide bias for alignment.

KRK29 TUNER ALIGNMENT
Models 21-D-358 to 21-D-380 incl.

A tuner unit which is operative and requires only touch up adjustments, requires no presetting of adjustments. For such units, skip the remainder of this paragraph. For units which are completely out of adjustment, preset C27 all the way out. Set channel 7 to 13 oscillator slugs one turn from tight. Turn T2 slug all the way out. Do not change any of the adjustments in the antenna matching unit.

Disconnect the link from terminals "A" and "B" of T104 and terminate the link with a 39 ohm composition resistor.

Turn the receiver channel selector switch to channel 2.

The 43.5 mc. trap is adjusted with zero bias. To insure that the bias will remain constant, take a clip lead and short circuit the AGC terminal of the tuner at the terminal board to ground.

Connect the oscilloscope to the test point TP1 on the side of the tuner unit. Set the oscilloscope to maximum gain.

Connect the output of the VHF signal generator to the output of the antenna matching unit at the junction of L5 and C4 at the bottom of the FM trap L5.

Tune the signal generator to 43.5 mc. and modulate it 30% with a 400 cycle sine wave. Adjust the signal generator for maximum output.

Adjust C33 on top of the tuner, for minimum 400 cycle indication on the oscilloscope. If necessary, this adjustment can be retouched in the field to provide additional rejection to one specific frequency in the i-f band pass. However, in such cases, care should be taken not to tune C33 into channel 2, thereby reducing sensitivity on channel 2.

Connect the potentiometer arm of one of the bias supplies to the AGC terminal on the tuner and ground the battery positive terminal to the tuner case. Adjust the bias potentiometer to produce −3.0 volts of bias, as measured by the "VoltOhmyst" at the AGC terminal on the tuner.

Set the channel selector switch to channel 8.

Preset C22 to read −3.0 volts at the test point TP1, as read on the "VoltOhmyst." The limits for oscillator injection voltage are 2 volts minimum and not exceeding a maximum of 5.5 volts.

Turn the fine tuning control fully clockwise.

Adjust C25 for proper oscillator frequency, 227 mc. This may be done in several ways. The easiest way and the way which will be recommended in this procedure will be to use the signal generator as a heterodyne frequency meter and beat the oscillator against the signal generator. To do this, tune the signal generator to 227 mc. with crystal accuracy. Insert one end of a piece of insulated wire into the tuner unit through the hole provided for the adjustment of C16. Be careful that the wire does not touch any of the tuned circuits as it may cause the frequency of the tuner oscillator to shift. Connect the other end of the wire to the "r-f in" terminal of the signal generator. Adjust C25 to obtain an audible beat with the signal generator.

Turn C27 clockwise until the beat note just begins to change, then turn one full turn in the same clockwise direction.

Return the fine tuning control to the mechanical center of its range.

NOTE.—If on some units, it is not possible to reach the proper channel 8 oscillator frequency by adjustment of C25, switch to channel 13 and adjust L49 to obtain proper channel 13 oscillator frequency as indicated in the table on page 8. Then, switch to channel 12 and adjust L60 to obtain proper channel 12 oscillator frequency. Continue down to channel 8, adjusting the appropriate oscillator trimmer to obtain the proper frequency on each channel. Then again on channel 8, adjust C25 to obtain proper channel 8 oscillator frequency. Switch back to channel 13 and readjust L49 and back to channel 8 and adjust C25.

Set the T2 core for maximum inductance (core turned counterclockwise).

Connect the sweep generator through a suitable attenuator, as shown in Figure 10 to the input terminals of the antenna matching unit.

Connect the signal generator loosely to the antenna terminals.

Set the sweep generator to cover channel 8.

Set the oscilloscope to maximum gain and use the minimum input signal which will produce a usable pattern on the oscilloscope. Excessive input can change oscillator injection during alignment and produce consequent misalignment even though the response as seen on the oscilloscope may look normal.

Insert markers of channel 8 picture carrier and sound carrier, 181.25 mc. and 185.75 mc.

Adjust C21, C16, C11 and C7 for approximately correct curve shape, frequency, and bandwidth as shown in Figure 18.

The correct adjustment of C7 is indicated by maximum amplitude of the curve midway between the markers. C11 tunes the r-f amplifier plate circuit and affects the frequency of the pass band most noticeably. C21 tunes the mixer grid circuit and affects the tilt of the curve most noticeably (assuming that C7 has been properly adjusted). C16 is the coupling adjustment and hence primarily affects the response bandwidth.

Connect the "VoltOhmyst" to test point TP1. Adjust C22 to read −3.0 volts dc on the "VoltOhmyst" at TP1. Readjust C27, C21, C16 and C11 for proper response. Adjust C7 for maximum gain at midpoint of the curve. Repeat if necessary until the proper response is obtained.

Set the receiver channel switch to channel 13.

Adjust the signal generator to the channel 13 oscillator frequency 257 mc.

Turn the fine tuning control fully clockwise.

Adjust L49 to obtain an audible beat. Slightly overshoot the adjustment of L49 by turning the slug an additional turn in the same direction from the original setting, then reset the oscillator to proper frequency by adjusting C27 to again obtain the beat.

Set the sweep generator to channel 13.

From the signal generator, insert channel 13 sound and picture carrier markers, 211.25 mc. and 215.75 mc.

Adjust L36 and L20 for proper response as shown in Figure 18.

Turn off the sweep and signal generators.

Connect the "VoltOhmyst" to the tuner test point TP1.

Check the oscillator injection voltage to be within limits as previously specified. Adjust if necessary to bring within range.

If it was necessary to readjust C22, turn the sweep and signal generators back on and recheck the channel 13 response. Readjust L36 and L20 if necessary.

Set the receiver channel selector switch to channel 8 and readjust C27 for proper oscillator frequency, 227 mc.

Set the sweep generator and signal generator to channel 8.

Readjust C21, C16, C11 and C7 for correct curve shape, frequency and bandwidth.

Turn off the sweep and signal generators, switch back to channel 13 and check the oscillator injection voltage at TP1 if C21 was adjusted in the recheck of channel 8 response.

If the initial setting of the oscillator injection trimmer was far off, it may be necessary to adjust the oscillator frequency and response on channel 8 adjust the oscillator injection on channel 13 and repeat the tracking procedure several times before the proper setting is obtained.

Turn off the sweep generator and switch the receiver to channel 6.

Adjust the signal generator to the channel 6 oscillator frequency, 129 mc.

Set the fine tuning control to the center of its mechanical range.

Adjust L54 for an audible beat. Adjust L48 and L32 for proper curve shape as shown in Figure 18. Recheck the oscillator injection voltage at TP1, to insure that it is within the limits specified. Readjust C22 if necessary.

If C22 required adjustment, switch the receiver and the signal generator to channel 8. Readjust C21 for correct curve shape and recheck C27 and C25 for proper oscillator frequency.

Check the response of channels 2 through 6 by switching the receiver channel switch, sweep generator and marker generator to each of these channels and observing the response and oscillator injection voltage obtained. See Figure 18 for typical response curves. It should be found that all these channels have the proper response with the markers above 80% response.

If the markers fail to fall within this requirement readjust L48 and L32 in order to obtain curves within the proper limits.

Switch the channel selector, signal generator and marker generator through channels 7 to 13 and observe the response curves, referring to Figure 18 for proper wave shape. Check the injection voltage at each channel to be within limits. If necessary readjust C11, C21 or C16 to obtain the proper response.

With the receiver and signal generator on channel 13 adjust L49 for an audible beat with the signal generator.

Adjust the oscillator to frequency on all channels by switching the receiver and the frequency standard to each channel and adjusting the appropriate oscillator slug to obtain the audible beat. It should be possible to adjust the oscillator to obtain the audible beat on each channel. Recheck the oscillator injection voltage on each channel to verify that the voltage is within the specified limits.

KRK12B TUNER ALIGNMENT

Models 21-D-358U to 21-D-380U incl.

TUNER VHF ALIGNMENT. — Remove the 6S4 voltage control tube from its socket and insert the adapter. Insert the 6S4 in the adapter.

Connect the 0-50 milliampere meter to the adapter socket leads and turn the adapter switch on.

Remove the tuner cover shield.

Rotate the channel selector to a point midway between channels, disengaging the insert contacts, and observe the non-oscillating plate current. Some tubes may oscillate even with the tuned circuits disengaged. To be sure the oscillator is in a non-oscillatory state, short circuit the spring contacts 12 and 13, the two contacts nearest the tuner front.

(NOTE: The contacts are at zero d-c potential.) Should the plate current rise, keep the contacts shorted while adjusting the oscillator plate current. Adjust R6, oscillator voltage control, for a 28 milliampere reading on the meter.

Replace the tuner cover shield.

Connect the VHF sweep generator to the antenna terminals.

Connect the VHF signal generator loosely to the antenna terminals.

Connect the oscilloscope through the preamplifier, if needed with oscilloscope used, to test point TP1.

Ground the AGC bias at the tuner terminal board using a clip lead to insure that the bias will remain constant.

Turn off the adapter switch, removing plate voltage from the oscillator. This is required because of RF-IF interaction when a crystal is used as a mixer.

Set the channel selector and the sweep generator to channel 2.

Insert markers of channel 2 picture carrier and sound carrier, 55.25 mc. and 59.75 mc.

Adjust antenna T6, r-f amplifier plate L29 and mixer L30 adjustments for a symmetrical curve with maximum gain at the center of the pass band. The curves will have a deep valley because of no crystal loading and nonlinear detector characteristics. The limits for the 100% response points are shown in Figure 11. The proper curve shape is shown in Figure 11(b). (Refer to note on page 13 for detailed explanation of adjustments.) If the bandwidth is out of tolerance, it can usually be corrected by redressing the coupling capacitor of the double tuned circuit, C40 on insert A. Maximum bandwidth occurs when the capacitor is centered in the insert chamber.

Repeat the above steps for all VHF channels adjusting the appropriate antenna, r-f amplifier plate and mixer slugs for a symmetrical curve with maximum gain at the center of the pass band.

Turn off the sweep generator.

Remove the oscilloscope and preamplifier if used, from test point TP1.

Turn the AGC control fully clockwise and remove the clip lead grounding the AGC bias on the tuner terminal board.

Connect the potentiometer arm of one of the bias supplies to the AGC terminal on the tuner and ground the battery positive terminal to the tuner case. Adjust the bias potentiometer to produce –3.5 volts of bias, as measured by the "VoltOhmyst" at the AGC terminal on the tuner.

Connect the potentiometer arm of the second bias supply to the junction R133 and C133B, and ground the positive battery terminal. Adjust the bias potentiometer to produce –5 volts of i-f bias as indicated on the "VoltOhmyst" at the junction point.

Connect the oscilloscope to pin 9 of V110. Use 3 to 5 volts peak-to-peak output on the oscilloscope.

Turn the adapter switch on to apply plate voltage to the oscillator.

Turn the channel selector to channel 13.

Set the fine tuning control to the center of its range.

Adjust the oscillator slug L22 to proper frequency, 257 mc. This may be done in several ways. The easiest way and the way which will be recommended in this procedure will be to use the signal generator as a heterodyne frequency meter and beat the oscillator against the signal generator. To do this, tune the signal generator to 257 mc. with crystal accuracy. Insert one end of a piece of insulated wire into the tuner through either of the two holes next to the oscillator tube on the right front top corner of the tuner. Be careful that the wire does not touch any of the tuned circuits as it may cause the frequency of the oscillator to shift. Connect the other end of the wire to the "r-f in" terminal of the signal generator. Adjust L22 oscillator slug to obtain an audio beat with the signal generator.

Turn on the sweep generator and set to channel 13. Adjust T1 for maximum gain on the oscilloscope. Adjust mixer tank circuit L21 for maximum gain and flat-topped curve. Recheck T1 for maximum gain at center of band with the proper response. Maximum gain and flat-topped response should be obtained simultaneously.

Adjust the oscillator to frequency on all VHF channels by switching the receiver and signal generator to each VHF channel and adjusting the appropriate oscillator slug to obtain a beat with the signal generator. Adjust the appropriate mixer slug where necessary to obtain maximum gain and proper curve shape as explained above.

Adjust the tunable I-F Trap C16-L7. To do this connect the signal generator to the fixed I-F Trap C2-L2 at the end opposite the antenna terminal plug. Set the signal generator to 43.5 mc. and adjust the output of the signal generator to obtain sufficient indication on the oscilloscope. Tune the I-F Trap C16-L7 for minimum marker indication on the oscilloscope.

Remove the signal generator and the oscilloscope.

TUNER UHF ALIGNMENT. — To align the UHF inserts:

Turn off the adapter switch, removing plate voltage from the oscillator.

Ground the AGC bias at the tuner terminal board using a clip lead to insure that the bias will remain constant.

Connect the oscilloscope, through the preamplifier if needed with oscilloscope used, to test point TP1.

Connect the UHF sweep generator to the antenna terminals. Use a 10 DB attenuator pad to assure proper alignment.

Connect the UHF signal generator loosely to the antenna terminals.

Set the channel selector to the desired position and the sweep generator to sweep the frequency of the insert being used.

Insert markers of the picture carrier and sound carrier for desired channel.

Adjust the UHF antenna, link coupling and mixer adjustments for a symmetrical curve, with maximum gain, centered about the pass band.

The responses are shown in Figure 12. The curve shape will usually vary from Figure 12 (a) to Figure 12 (c) going higher in frequency; however, any of these responses are acceptable.

Repeat the above steps for all UHF inserts used, adjusting the appropriate antenna, link coupling and mixer slugs for a symmetrical curve, with maximum gain, centered about the pass band.

Remove the oscilloscope and preamplifier, if used, from test point TP1.

Remove the clip lead grounding the AGC bias on the tuner terminal board.

Connect the potentiometer arm of one of the bias supplies to the AGC terminal on the tuner and ground the battery positive terminal to the tuner case. Adjust the bias potentiometer to produce –3.5 volts of bias, as measured by the "VoltOhmyst" at the AGC terminal.

Connect the potentiometer arm of the second bias supply to the junction of R133 and C133B, and ground the positive battery terminal. Adjust the bias potentiometer to produce –5 volts of i-f bias as indicated on the "VoltOhmyst" at the junction point.

Connect the oscilloscope to pin 9 of V110. Use 3 to 5 volts peak-to-peak output on the oscilloscope.

Turn the adapter switch on to apply plate voltage to the oscillator.

Turn the channel selector to the lowest UHF channel to be used, and set the fine tuning control to the center of its range.

Adjust the oscillator core to proper frequency. To do this, connect the VHF signal generator to test point TP1 with the shortest leads possible. Insert a 45.75 mc. marker from the VHF generator.

Set the UHF sweep generator to sweep the desired channel, and observe the output on the oscilloscope. If the sweep generator is not sweeping the correct frequency range, it may be necessary to readjust the sweep in order to place the 45.75 marker on the response curve as in Figure 14.

Set the UHF marker generator to the picture carrier of the channel insert being adjusted and connect to test point TP1.

Adjust the oscillator core until the markers for 45.75 mc. and the picture carrier coincide on the sweep pattern on the oscilloscope.

Adjust the mixer core for maximum gain with proper wave shape.

Connect the "VoltOhmyst" to test point TP1, using 1.5 volt DC scale.

Set oscillator injection adjustment to read .1 volt on the "VoltOhmyst."

Repeat the above steps for all UHF inserts adjusting the oscillator injection control only if the reading on the "VoltOhmyst" exceeds .3 volt. Adjust as necessary to read .3 volt or less at TP1.

RATIO DETECTOR ALIGNMENT. — In order to obtain good ratio detector alignment an AM modulated signal generator that is exceptionally free from FM modulation must be employed. Set the signal generator at 4.5 mc. and connect it to the second sound i-f grid, pin 1 of V102. Set the generator for 30% 400 cycle modulation.

As an alternate source of signal, the RCA WR39B or WR39C calibrator may be employed. If used, connect it to the grid of the 4th pix i-f amplifier, pin 1, V109. Set the frequency of the calibrator to 45.75 (pix carrier) and modulate with 4.5 mc. crystal. Also turn on the internal AM audio modulation. The 4.5 mc. signal will be picked off at T110A and amplified through the sound i-f amplifier.

Connect the "VoltOhmyst" to the junction of R111 and C111.

Connect the oscilloscope across the speaker voice coil and turn the volume control for maximum output.

Tune the ratio detector primary, T102 top core for maximum DC output on the "VoltOhmyst." Adjust the signal level from the signal generator for –10 volts on the "VoltOhmyst" when finally peaked. This is approximately the operating level of the ratio detector for average signals.

Connect the "VoltOhmyst" to the junction of R110 and C110.

Adjust the T102 bottom core for zero d-c on the meter. Then, turn the core to the nearest minimum AM output on the oscilloscope.

Repeat adjustments of T102 top for maximum DC and T102 bottom for minimum output on the oscilloscope making final adjustment with the 4.5 mc. input level adjusted to produce 10 volts d-c on the "VoltOhmyst" at the junction of R111 and C111.

Connect the "VoltOhmyst" to the junction of R110 and C110 and note the amount of d-c present. If this voltage exceeds ±1.5 volts, adjust R108 by turning it in until zero d-c is obtained. Readjust the T102 bottom core for minimum output on the oscilloscope. Repeat adjustments of R108 and T102 bottom core until the voltage at R110 and C110 is less than ±1.5 volts when T102 bottom core is set for minimum output on the oscilloscope.

Connect the "VoltOhmyst" to the junction of R111 and C111 and repeak T102 top core for maximum d-c on the meter and again reset the generator so as to have –10 volts on the meter.

Repeat the adjustments in the above two paragraphs until the voltage at R110 and C110 is less than ±1.5 volts when the T102 top core is set for maximum d-c at the junction of R111 and C111 and the T102 bottom core is set for minimum indication on the oscilloscope.

SOUND I-F ALIGNMENT. — Connect the sweep generator to the first sound i-f amplifier grid, pin 1 of V101. Adjust the generator for a sweep width of 1 mc. at a center frequency of 4.5 mc.

Insert a 4.5 mc. marker signal from the signal generator into the first sound i-f grid. With the WR39B or WR39C calibrators the 4.5 mc. crystal signal may be obtained at the R-F out terminal by turning the variable osc. switch off, the calibrate switch to 4.5 mc. and the volume control with mod. off.

Connect the oscilloscope in series with a 10,000 ohm resistor to terminal A of T101.

Adjust T101 top and bottom cores for maximum gain and symmetry about the 4.5 mc. marker on the i-f response. The pattern obtained should be similar to that shown in Figure 20.

The output level from the sweep should be set to produce approximately 2.0 volt peak-to-peak at terminal A of T101 when the final touches on the above adjustment are made. It is necessary that the sweep output voltage should not exceed the specified values otherwise the response curve will be broadened, permitting slight misadjustment to pass unnoticed and possibly causing distortion on weak signals.

Connect the oscilloscope to the junction of R110 and C110 and check the linearity of the response. The pattern obtained should be similar to that shown in Figure 21.

ALIGNMENT PROCEDURE

SOUND TAKE-OFF ALIGNMENT. — Connect the 4.5 mc. generator in series with a 1,000 ohm resistor to terminal "C" of T110. The input signal should be approximately 0.5 volt.

Short the fourth pix i-f grid to ground, pin 1, V109, to prevent noise from masking the output indication.

As an alternate source of signal the RCA WR39B or WR39C calibrator may be used. In such a case, disregard the above two paragraphs. Connect calibrator across link circuit, T104 A, B, and modulate 45.75 with 4.5 mc. crystal.

Connect the crystal diode probe of a "VoltOhmyst" to the plate of the video amplifier, pin 6 of V110.

Adjust the core of T110 for minimum output on the meter.

Remove the short from pin 1 V109 to ground, if used.

HORIZONTAL OSCILLATOR ADJUSTMENT. — Normally the adjustment of the horizontal oscillator is not considered to be a part of the alignment procedure, but since the oscillator waveform adjustment may require the use of an oscilloscope, it can not be done conveniently in the field. The waveform adjustment is made at the factory and normally should not require readjustment in the field. However, the waveform adjustment should be checked whenever the receiver is aligned or whenever the horizontal oscillator operation is improper.

Horizontal Frequency Adjustment. — Tune in a station and sync the picture. If the picture cannot be synchronized with the horizontal hold control R210, then adjust the T114 frequency core on the rear apron until the picture will synchronize. If the picture still will not sync, turn the T114 waveform adjustment core (under the chassis) out of the coil several turns from its original position and readjust the T114 frequency core until the picture is synchronized.

Examine the width and linearity of the picture. If picture width or linearity is incorrect, adjust the horizontal drive control C186B, the width control L109 and the linearity control L111 until the picture is correct.

Horizontal Oscillator Waveform Adjustment. — The horizontal oscillator waveform may be adjusted by either of two methods. The method outlined in paragraph A below may be employed in the field when an oscilloscope is not available. The service shop method outlined in paragraph B below requires the use of an oscilloscope.

A.—Turn the horizontal hold control completely clockwise. Place adjustment tools on both cores of T114 and be prepared to make simultaneous adjustments while watching the picture on the screen. First, turn the T114 frequency core (on the rear apron) until the picture falls out of sync and one diagonal black bar sloping down to the right appears on the screen. Then, turn the waveform adjustment core (under the chassis) into the coil while at the same time adjusting the frequency core so as to maintain one diagonal black bar on the screen. Continue this procedure until the oscillator begins to motorboat, then turn the waveform adjustment core out until the motorboating just stops. As a check, turn the T114 frequency core until the picture is synchronized then reverse the direction of rotation of the core until the picture begins to fall out of sync with the diagonal bar sloping down to the right. Continue to turn the frequency core in the same direction. Additional bars should not appear on the screen. Instead, the horizontal oscillator should begin to motorboat. Retouch the adjustment of the T114 waveform adjustment core if necessary until this condition is obtained.

B.—Connect the low capacity probe of an oscilloscope to terminal C of T114. Turn the horizontal hold control one-quarter turn from the clockwise position so that the picture is in sync. The pattern on the oscilloscope should be as shown in Figure 25. Adjust the waveform adjustment core of T114 until the two peaks are at the same height. During this adjustment, the picture must be kept in sync by readjusting the hold control if necessary.

This adjustment is very important for correct operation of the circuit. If the broad peak of the wave on the oscilloscope is lower than the sharp peak, the noise immunity becomes poorer, the stabilizing effect of the tuned circuit is reduced and drift of the oscillator becomes more serious. On the other hand, if the broad peak is higher than the sharp peak, the oscillator is overstabilized, the pull-in range becomes inadequate and the broad peak can cause double triggering of the oscillator when the hold control approaches the clockwise position.

Remove the oscilloscope upon completion of this adjustment.

Horizontal Locking Range Adjustment. — Set the horizontal hold control to the full counter-clockwise position. Momentarily remove the signal by switching off channel then back. The picture may remain in sync. If so turn the T114 frequency core slightly and momentarily switch off channel. Repeat until the picture falls out of sync with the diagonal lines sloping down to the left. Slowly turn the horizontal hold control clockwise and note the least number of diagonal bars obtained just before the picture pulls into sync.

If more than 3 bars are present just before the picture pulls into sync, adjust the horizontal locking range trimmer C186A slightly clockwise. If less than 2 bars are present, adjust C186A slightly counter-clockwise. Turn the horizontal hold control counter-clockwise, momentarily remove the signal and recheck the number of bars present at the pull-in point. Repeat this procedure until 2 or 3 bars are present.

Turn the horizontal hold control to the maximum clockwise position. Adjust the T114 frequency core so that the diagonal bar sloping down to the right appears on the screen and then reverse the direction of adjustment so that bar just moves off the screen leaving the picture in synchronization.

SENSITIVITY CHECK. — A comparative sensitivity check can be made by operating the receiver on a weak signal from a television station and comparing the picture and sound obtained to that obtained on other receivers under the same conditions.

RESPONSE CURVES. — The response curves shown on pages 14 and 15 and referred to throughout the alignment procedure were taken from a production set. Although these curves are typical, some variations can be expected.

The response curves are shown in the classical manner of presentation, that is with "response up" and low frequency to the left. The manner in which they will be seen in a given test set-up will depend upon the characteristics of the oscilloscope and the sweep generator. The curves may be seen inverted and/or switched from left to right depending on the deflection polarity of the oscilloscope and the phasing of the sweep generator.

NOTE ON KRK12B TUNER ALIGNMENT. — The use of a crystal mixer in the KRK12B Tuner makes it necessary to observe the insert responses with the oscillator disabled. This is due to undesirable r-f/i-f interaction if the oscillator was allowed to operate during alignment. Therefore, the responses shown in Figure 11 are not a strictly true representation of the insert band pass during actual operation. When an insert is aligned, using an oscilloscope to observe the response, the curve shown in Figure 11(b) will be the correct response for reference. In actual operation, the band pass will be such that the sound and picture carriers will be at the tips of the curve. The adjacent channel picture and sound carriers will be in the valleys at each side. Care should be taken not to exceed the limits shown in Figures 11(a) and 11(c).

The valley, in the center of the response curve, may vary from 0 to 50% above the base line for VHF inserts. Adjust the output level of the sweep generator to prevent excessive signal input to the tuner. Excessive signal input will be indicated by the valley rising above the 50% level, particularly on the higher VHF channels.

Oscillator injection voltage is not adjusted on VHF inserts. A check may indicate variations from .08 to .3 volts at TP1 but such readings should not be interpreted as an indication of trouble. On UHF channels, however, the injection voltage should be adjusted to fall within the specified limits.

VOLTAGE CHART

The following measurements represent two sets of conditions. In the first condition, a 5000 microvolt test pattern signal was fed into the receiver, the picture synchronized and the AGC control properly adjusted. The second condition was obtained by removing the antenna leads and short circuiting the receiver antenna terminals. Voltages shown are read with a type WV97A senior "VoltOhmyst" between the indicated terminal and chassis ground and with the receiver operating on 117 volts, 60 cycles, a-c.

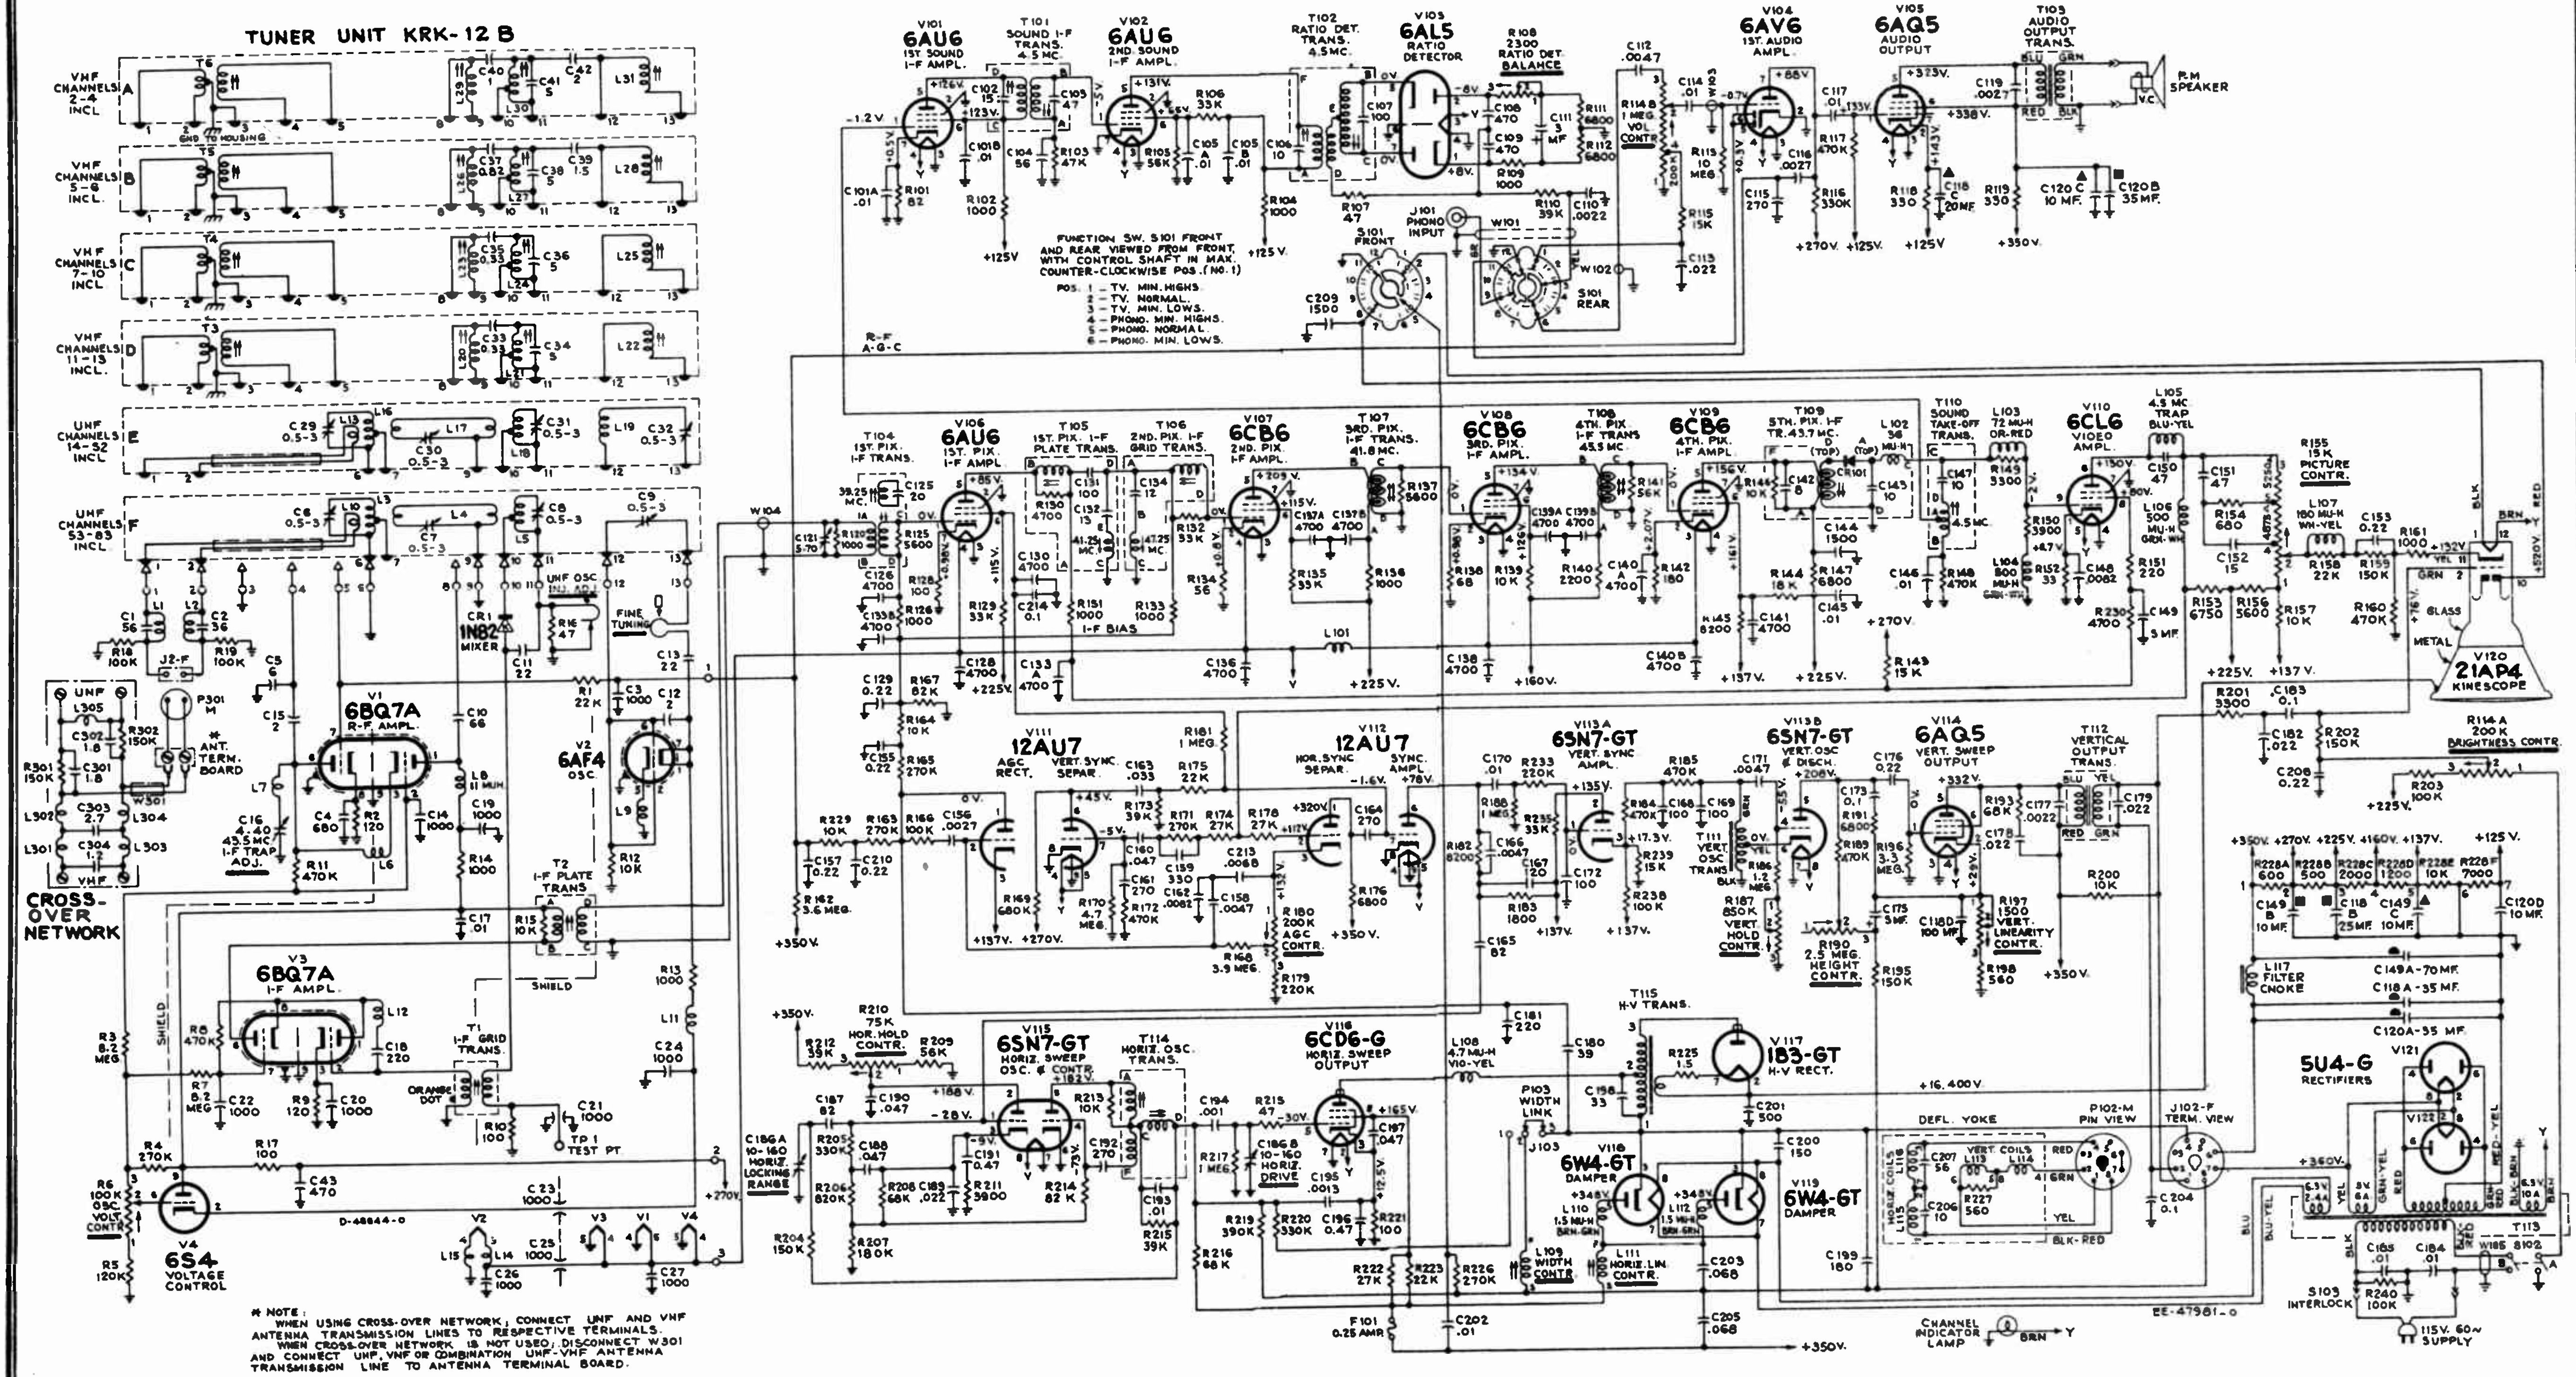
KCS81J CIRCUIT SCHEMATIC DIAGRAM



* NOTE: WHEN USING CROSS-OVER NETWORK, CONNECT UHF AND VHF ANTENNA TRANSMISSION LINES TO RESPECTIVE TERMINALS. WHEN CROSS-OVER NETWORK IS NOT USED, DISCONNECT W301 AND CONNECT UHF, VHF OR COMBINATION UHF-VHF ANTENNA TRANSMISSION LINE TO ANTENNA TERMINAL BOARD.

The schematic is shown in the latest condition at the time of printing. All resistance values in ohms. K = 1000.

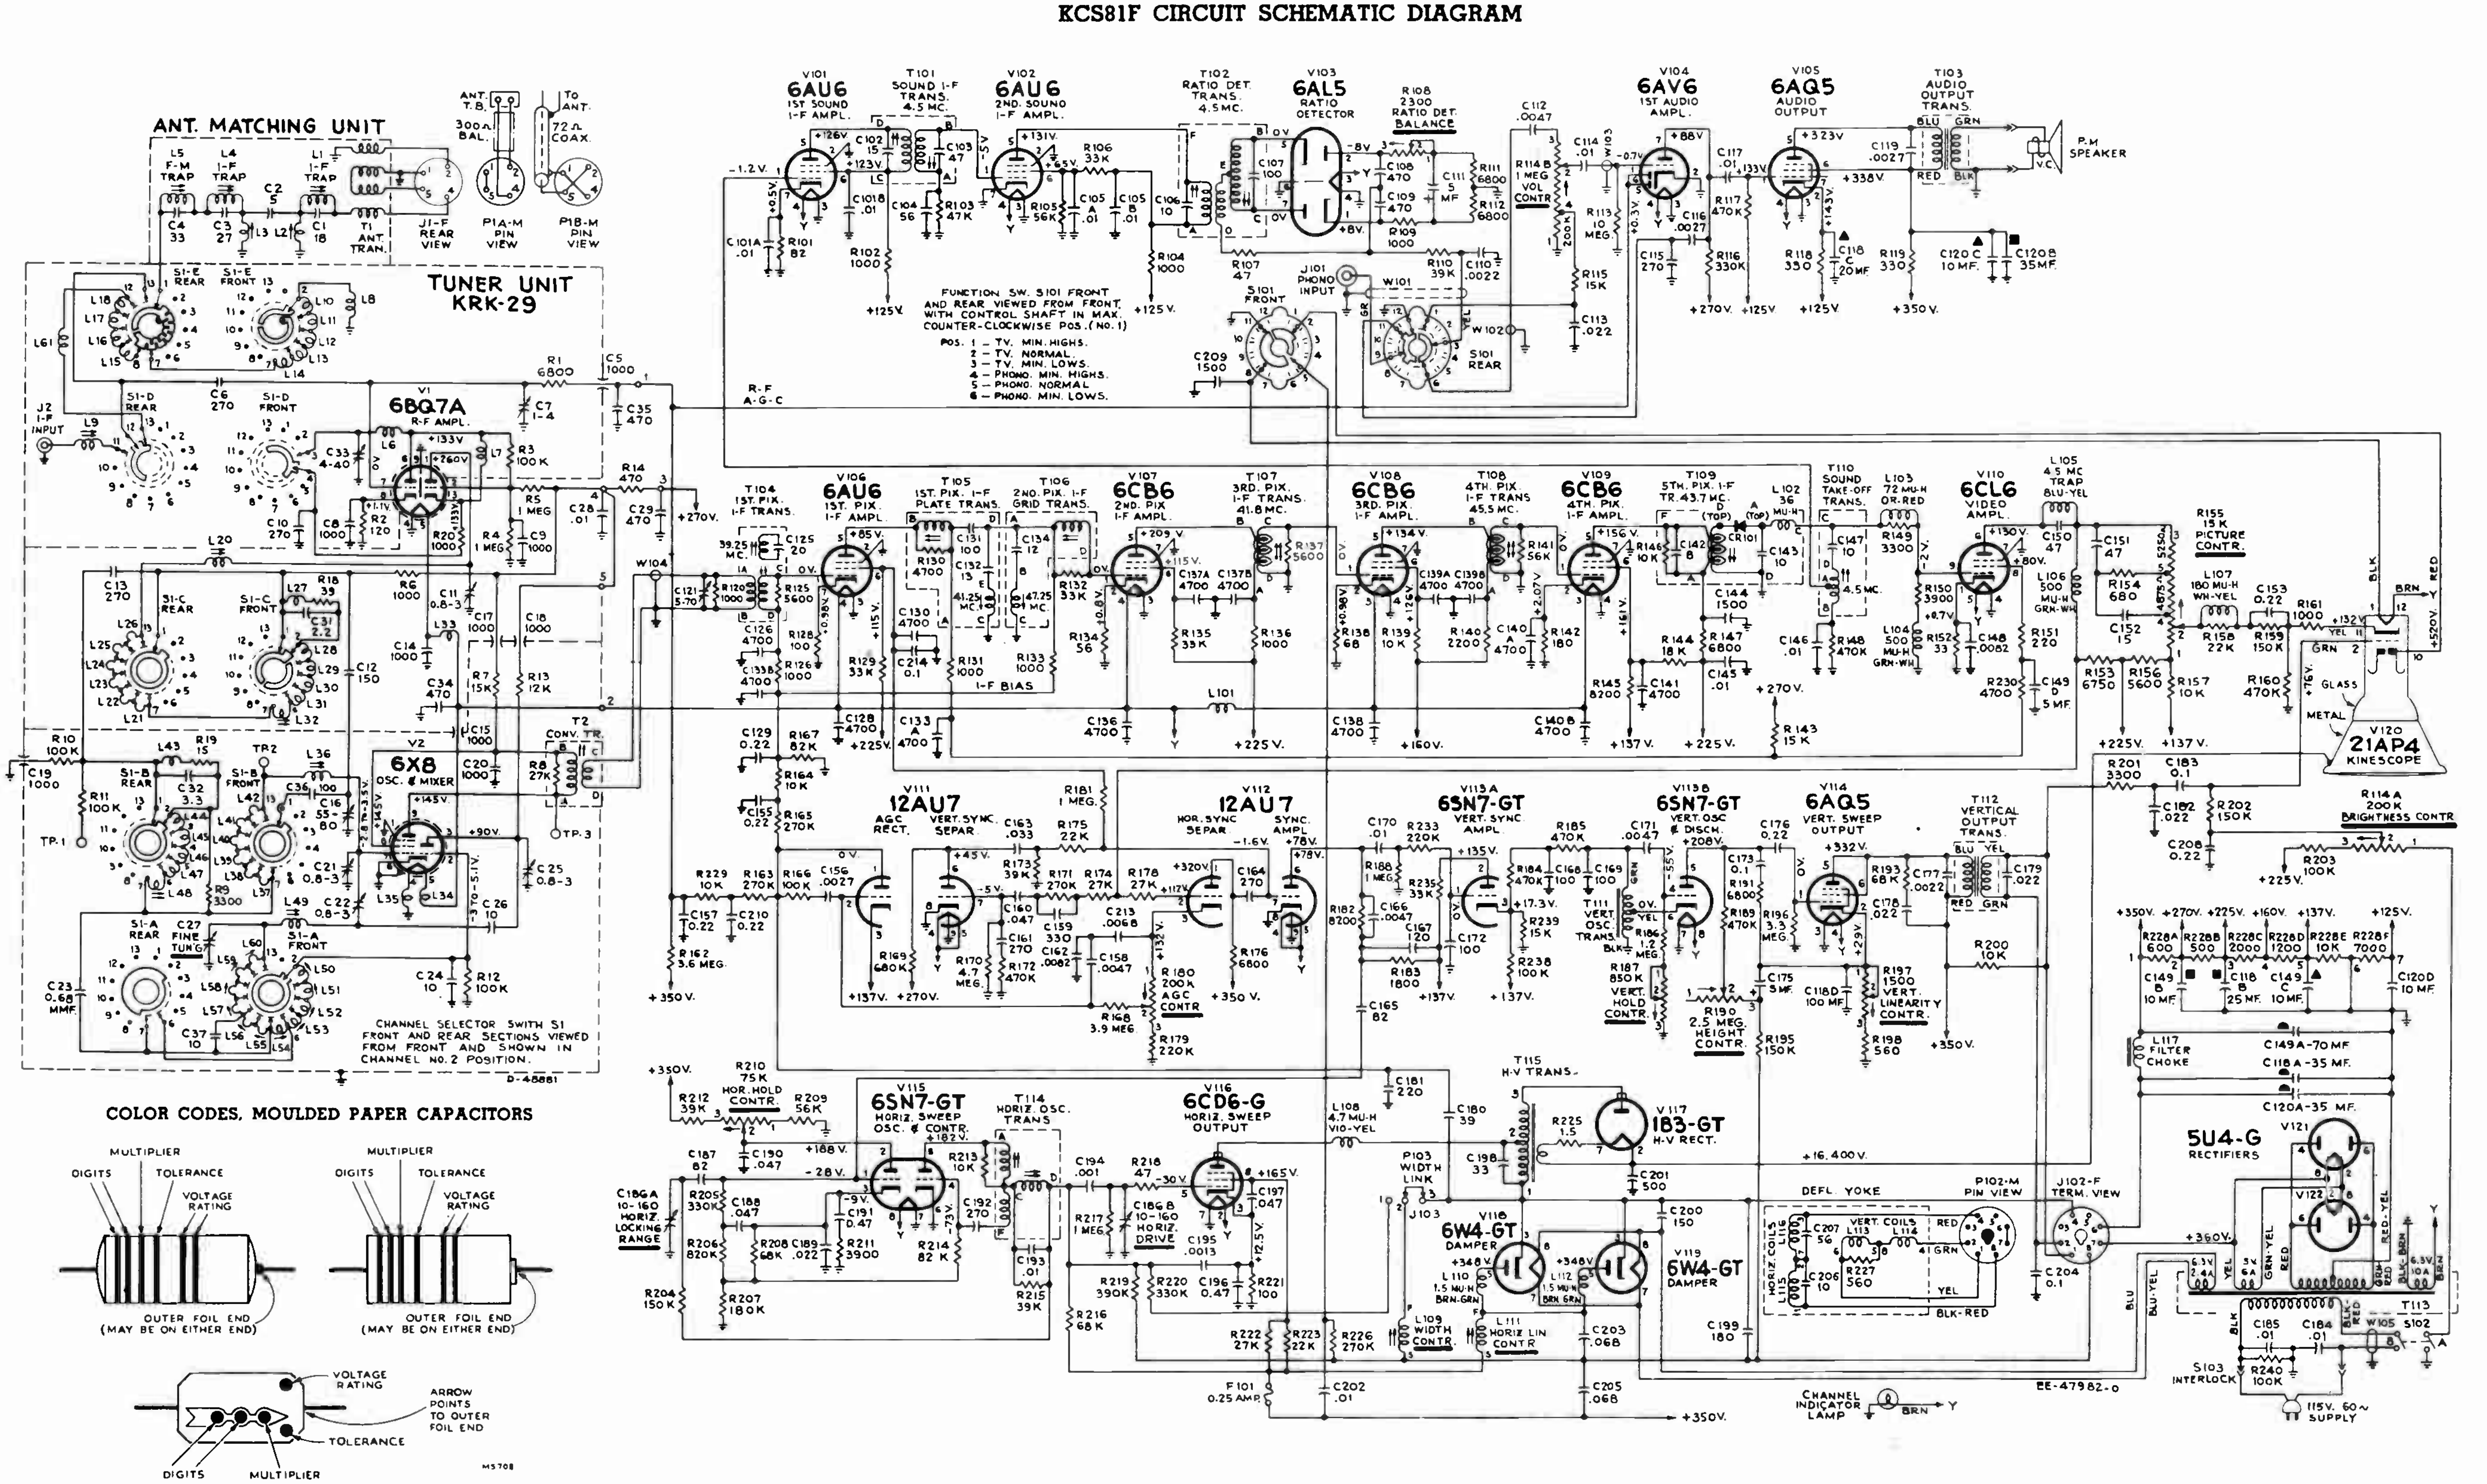
All capacitance values less than 1 in MF and above 1 in MMF unless otherwise noted.

Direction of arrows at controls indicates clockwise rotation.

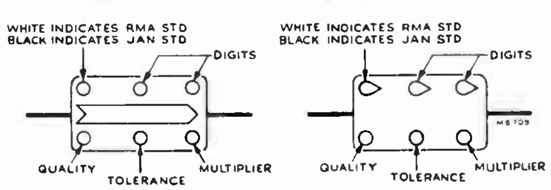
All voltages measured with "Volt-Ohmyst" and with no signal input. Voltages should hold within ±20% with 117 v. a-c supply.

Figure 29—Circuit Schematic Diagram, KCS81J

KCS81F CIRCUIT SCHEMATIC DIAGRAM



RMA COLOR CODE, FIXED MICA CAPACITORS



The schematic is shown in the latest condition at the time of printing.
All resistance values in ohms. K = 1000.

All capacitance values less than 1 in MF and above 1 in MMF unless otherwise noted.

Direction of arrows at controls indicates clockwise rotation.

All voltages measured with "Volt-Ohmyst" and with no signal input. Voltages should hold within ±20% with 117 v. a-c supply.

REPLACEMENT PARTS

STOCK No.	PART DESCRIPTION
	R-F UNIT ASSEMBLIES
	KRK29
76539	Board—Antenna matching transformer terminal board less coils and capacitors
78235	Board—Terminal board, 5 contact and ground
78233	Bracket—Side bracket for mounting coil and stators
77853	Capacitor—Ceramic, variable, for fine tuning capacitor—plunger type (C27)
	Capacitor—Adjustable, mica:
77616	4-40 mmf. (C33)
	Capacitor—Adjustable, steatite:
77151	0.8-3.0 mmf. (C11, C21, C25)
77913	0.8-3.0 mmf. (C22)
76532	1-4 mmf. (C7)
	Capacitor—Ceramic:
77084	Feed-thru, 1,000 mmf. (C5, C15, C17, C18, C19)
	Capacitor—Fixed, ceramic, non-insulated, Temp. coef. = 0:
77865	10 mmf., ±1 mmf., 500 volts (C26, C37)
	Capacitor—Fixed, ceramic, High "K" disc:
77293	470 mmf., +100%, -0%, 500 volts (C29, C34, C35)
77252	1,000 mmf., +100%, -0%, 500 volts (C8, C9, C14, C20)
73960	10,000 mmf., +100%, -0%, 500 volts (C28)
	Capacitor—Fixed, ceramic, insulated, High "K":
75437	100 mmf., ±20%, 500 volts (C36)
78276	150 mmf., ±10%, 500 volts (C12)
75199	270 mmf., ±20%, 500 volts (C6, C10, C13)
	Capacitor—Fixed, ceramic, non-insulated, Temp. coef. = 0:
93056	5 mmf., ±0.5 mmf., 500 volts (C2)
54207	18 mmf., ±10%, 500 volts (C1)
70935	27 mmf., ±10%, 500 volts (C3)
76739	33 mmf., ±10%, 500 volts (C4)
	Capacitor—Fixed, ceramic, non-insulated, Temp. coef. = -750:
78247	10 mmf., ±10%, 500 volts (C24)
	Capacitor—Fixed, headed-lead:
71504	0.68 mmf., ±20%, 500 volts (C23)
71502	2.2 mmf., ±20%, 500 volts (C31)
71503	3.3 mmf., ±20%, 500 volts (C32)
	Capacitor—Mica trimmer:
78397	80-150 mmf. (C16)
77854	Clip—Fine tuning clip for fine tuning core
73591	Coil—Antenna matching coil (Part of T1)
73874	Coil—Channel No. 6 mixer coil (L48)
73460	Coil—Channel No. 6 r-f plate coil (L32)
78401	Coil—Channel No. 6 antenna coil (L61)
77915	Coil—Channel No. 13 oscillator coil (L49)
77919	Coil—Channel No. 13 mixer coil (L36)
77921	Coil—Channel No. 13 r-f plate coil (L20)
78224	Coil—Choke coil (.47 muh) (L27)
77206	Coil—Filament choke coil (L33)
76763	Coil—Heater choke coil (L34, L35)
78271	Coil—I-F input coil complete with adjustable core (L9)
76562	Coil—R-F amplifier coupling coil (L7)
76537	Coil—Shunt coil complete with adjustable core (L3)
76538	Coil—Shunt coil complete with adjustable core (L2)
	Resistor—Fixed, composition:
503015	15 ohms, ±10%, ½ watt (R19)
503039	39 ohms, ±10%, ½ watt (R18)
503112	120 ohms, ±10%, ½ watt (R2)
503147	470 ohms, ±10%, ½ watt (R14)
503210	1,000 ohms, ±10%, ½ watt (R6, R20)
503233	3,300 ohms, ±10%, ½ watt (R9)
503268	6,800 ohms, ±10%, ½ watt (R1)
523312	12,000 ohms, ±10%, 2 watts (R13)
523315	15,000 ohms, ±10%, 2 watts (R7)
503410	100,000 ohms, ±10%, ½ watt (R3, R10, R11, R12)
503510	1 megohm, ±10%, ½ watt (R4, R5)
78396	Transformer—Antenna matching transformer complete (T1)
78399	Transformer—Converter transformer (T2, R8)
76540	Trap—F-M trap complete with adjustable core (L5)
78466	Trap—I-F trap
76542	Trap—I-F trap (41.25 mc.) complete with core (L1)
76541	Trap—I-F trap (45.75 mc.) complete with core (L4)
	R-F UNIT ASSEMBLIES
	KRK12B
	Capacitor—Adjustable, mica:
77616	4-40 mmf. (C16)
	Capacitor—Ceramic:
77084	Feed-thru, 1,000 mmf. (C21, C23, C25)
77615	Stand-off, 1,000 mmf. (C3, C19, C24, C26)
	Capacitor—Fixed, ceramic, crystal holder, Temp. coef. = -750:
77621	22 mmf., ±10% (C11)
	Capacitor—Fixed, ceramic, High "K" disc:
77625	220 mmf., +100%, -0%, 500 volts DC (C18)
77293	470 mmf., +100%, -0%, 500 volts DC (C43)

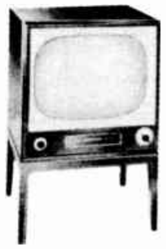
74182	6 mmf., ±0.5 mmf., 500 volts DC (C5)
	Capacitor—Fixed, ceramic, non-insulated, Temp. coef. = -750
71924	56 mmf., ±10%, 500 volts DC (C10)
	Capacitor—Fixed, headed-lead type:
77691	.33 mmf., ±10%, 500 volts DC (C33, C35)
77689	.82 mmf., ±10%, 500 volts DC (C37)
77690	1.0 mmf., ±10%, 500 volts DC (C40)
71500	1.5 mmf., ±10%, 500 volts DC (C39)
78047	2 mmf., ±10%, 500 volts DC (C42)
77628	Coil—I-F trap (L7)
77634	Coil—I-F neutralizing coil (L12)
77629	Coil—Oscillator cathode coil (L9)
77632	Coil—Oscillator heater coil (L15)
77631	Coil—Oscillator heater coil (L14)
78224	Coil—Oscillator plate coil (L11)
77627	Coil—Peaking coil (L6, R11)
77695	Coil—R-F plate coil (L8)
77633	Connector—Formed grounding connector
77612	Contact—Bracket and spring contact assembly for grounding rotor—assembled to base
77618	Contact—Bracket and spring contact assembly for grounding rotor—assembled to oscillator shield
77606	Contact—Contact and support assembly—"L" shape—complete with two (2) contacts
78415	Contact—Contact and support assembly complete with one (1) contact
77620	Contact—Contact and support assembly complete with four (4) contacts and holder for crystal rectifier
77607	Contact—Contact and support assembly complete with five (5) contacts—rear of chassis
77614	Control—Oscillator voltage control (R6)
77617	Control—UHF oscillator injection adjustment control
77489	Rectifier—Germanium rectifier IN82 (CR1)
	Resistor—Fixed, composition:
503047	47 ohms, ±10%, ½ watt (R16)
503110	100 ohms, ±10%, ½ watt (R10, R17)
503112	120 ohms, ±10%, ½ watt (R2, R9)
503210	1,000 ohms, ±10%, ½ watt (R14)
503310	10,000 ohms, ±10%, ½ watt (R12)
503322	22,000 ohms, ±10%, ½ watt (R1)
503410	100,000 ohms, ±10%, ½ watt (R18, R19)
503412	120,000 ohms, ±10%, ½ watt (R5)
503427	270,000 ohms, ±10%, ½ watt (R4)
503447	470,000 ohms, ±10%, ½ watt (R8)
503582	8.2 megohm, ±10%, ½ watt (R3, R7)
	CHASSIS ASSEMBLIES
	KCS81F — VHF Chassis
	KCS81J — UHF Chassis
77609	Transformer—Mixer I-F transformer complete with adjustable cores (T1)
77610	Transformer—Primary I-F link transformer complete with adjustable cores (T2, R15)
77626	Trap—I-F trap (L1, C1, L2, C2)
	Capacitor—Ceramic:
76488	500 mmf., 30,000 volts (C201)
75166	Stand-off, 1,500 mmf. (C144)
	Capacitor—Fixed, ceramic:
76577	33 mmf., 6,000 volts (C198)
76574	39 mmf., 3,500 volts (C180)
76576	150 mmf., 2,000 volts (C200)
76575	180 mmf., 3,500 volts (C199)
	Capacitor—Fixed, ceramic, High "K" disc:
73748	1,500 mmf., +100%, -0%, 500 volts (C209)
73473	4,700 mmf., +100%, -0%, 500 volts (C126, C128, C130, C136, C138, C141
76470	Dual 4,700 mmf., +100%, -0%, 500 volts (C133A, C133B, C137A, C137B, C139A, C139B, C140A, C140B)
73960	10,000 mmf., +100%, -0%, 500 volts (C145, C146)
75877	Dual 10,000 mmf., +100%, -0%, 500 volts (C101A, C101B, C105A, C105B)
	Capacitor—Fixed, ceramic, non-insulated, Temp. coef. = -750
39044	15 mmf., ±10%, 500 volts (C152)
39042	47 mmf., ±10%, 500 volts (C151)
71924	56 mmf., ±10%, 500 volts (C104)
39396	100 mmf., ±10%, 500 volts (C168, C169, C172)
71614	120 mmf., ±10%, 500 volts (C167)
47617	270 mmf., ±10%, 500 volts (C115, C164)
	Capacitor—Fixed, mica:
76474	82 mmf., 1,000 volts (C165, C187)
75248	220 mmf., 1,000 volts (C181)
39638	270 mmf., 500 volts (C161)
76579	270 mmf., 1,000 volts (C192)
39640	330 mmf., 500 volts (C159)
39644	470 mmf., 500 volts (C108, C109)
	Capacitor—Mica trimmer:
71496	5-70 mmf. (C121)
75217	10-160 mmf. dual (C186A, C186B)
	Capacitor—Electrolytic:
74521	5 mfd., 50 volts (C111)
28417	5 mfd., 450 volts (C175)
76486	Comprising: 1 section of 35 mfd., 450 volts, 1 section of 25 mfd., 450 volts, 1 section of 20 mfd., 200 volts, and 1 section of 100 mfd., 50 volts (C118A, C118B, C118C, C118D)
76485	Comprising: 2 sections of 35 mfd., 450 volts, 1 section of 10 mfd., 450 volts, and 1 section of 10 mfd., 200 volts (C120A, C120B, C120C, C120D)
77657	Comprising: 1 section of 70 mfd., 450 volts, 2 sections of 10 mfd., 450 volts, and 1 section of 5 mfd., 450 volts (C149A, C149B, C149C, C149D)
	Capacitor—Fixed, moulded paper:
73594	.01 mfd., 600 volts (C184, C185)
	Capacitor—Fixed, tubular, paper, oil impregnated:
75643	.001 mfd., 1,000 volts (C194)
73595	.0022 mfd., 600 volts (C110)
73803	.0022 mfd., 1,000 volts (C177)
73599	.0027 mfd., 600 volts (C116, C119, C156)
73920	.0047 mfd., 600 volts (C112, C158, C166)
73789	.0068 mfd., 400 volts (C213)
73808	.0082 mfd., 1,000 volts (C148, C162)
73561	.01 mfd., 400 volts (C114, C117, C170, C202)
73562	.022 mfd., 400 volts (C113, C178, C179, C189)
73798	.022 mfd., 600 volts (C182)
73552	.033 mfd., 400 volts (C163)
73553	.047 mfd., 400 volts (C160, C188, C190)
73592	.047 mfd., 600 volts (C197)
73815	.068 mfd., 1,000 volts (C203, C205)
73551	0.1 mfd., 400 volts (C183, C214)
73557	0.1 mfd., 600 volts (C173, C204)
73794	0.22 mfd., 400 volts (C129, C153, C155, C157, C208, C210)
74957	0.22 mfd., 600 volts (C176)
73787	0.47 mfd., 200 volts (C191, C196)
	Capacitor—Fixed, tubular, moulded paper, oil impregnated:
77727	.0013 mfd., 600 volts (C195)
73920	.0047 mfd., 600 volts (C171)
73594	.01 mfd., 600 volts (C193)
77676	Choke—Filter choke (L117)
76143	Clip—Mounting clip for stand-off capacitor
73477	Coil—Choke coil (L101)
76672	Coil—Filament winding only for hi-voltage transformer (Part of T115)
76483	Coil—Horizontal linearity coil complete with adjustable core (L111)
76646	Coil—Peaking coil (72 muh) (L103, R149)
76647	Coil—Peaking coil (180 muh) (L107, R158)
75252	Coil—Peaking coil (500 muh) (L104, L106)
76640	Coil—R-F choke coil (1.5 muh) (L110, L112)
76510	Coil—R-F choke coil (4.7 muh) (L108)
76484	Coil—Width coil complete with adjustable core (L109)
77654	Control—AGC control (R180)
77655	Control—Brightness control, volume control and power switch (R114A, R114B, S102)
77640	Control—Height control (R190)
77639	Control—Horizontal hold control (R210)
76445	Control—Picture control (R155)
77199	Control—Ratio detector balance control (R108)
77652	Control—Vertical hold control (R187)
77653	Control—Vertical linearity control (R197)
77647	Coupling—Coupling (nylon) for picture control
77136	Cover—Back cover for hi-voltage compartment
76985	Cover—Side cover for hi-voltage compartment
73600	Fuse—0.25 amp., 250 volts (F101)
76459	Grommet—Rubber grommet for 2nd anode lead exit
76480	Lead—Anode lead complete with eyelet
76500	Plate—Hi-voltage plate (bakelite) complete less transformer, socket and lead
76649	Radiator—Heat dissipating radiator for V116
76675	Rectifier—Picture detector crystal rectifier (CR101)
	Resistor—Fixed, wire wound:
76468	1.5 ohms, 1/3 watt (R225)
74015	100 ohms, 2 watts (R221)
77651	Comprising: 1 section of 600 ohms, 16 watts, 1 section of 500 ohms, 6 watts, 1 section of 2,000 ohms, 5 watts, 1 section of 1,200 ohms, 1 watt, 1 section of 10,000 ohms, 5 watts, and 1 section of 7,000 ohms, 5 watts (R228A, R228B, R228C, R228D, R228E, R228F)
76642	6,750 ohms, 10 watts (R153)
	Resistor—Fixed, composition:
503033	33 ohms, ±10%, ½ watt (R152)
503047	47 ohms, ±10%, ½ watt (R107, R218)
502056	56 ohms, ±5%, ½ watt (R134)
502068	68 ohms, ±5%, ½ watt (R138)
502082	82 ohms, ±5%, ½ watt (R101)
502110	100 ohms, ±5%, ½ watt (R128)
503118	180 ohms, ±10%, ½ watt (R142)
503122	220 ohms, ±10%, ½ watt (R151)
513133	330 ohms, ±10%, 1 watt (R118, R119)
503156	560 ohms, ±10%, ½ watt (R198)
503168	680 ohms, ±10%, ½ watt (R154)
503210	1,000 ohms, ±10%, ½ watt (R102, R104, R109, R120, R126, R131, R133, R136, R161)
502218	1,800 ohms, ±5%, ½ watt (R183)
503222	2,200 ohms, ±10%, ½ watt (R140)
502233	3,300 ohms, ±10%, ½ watt (R201)
502239	3,900 ohms, ±5%, ½ watt (R150)
503239	3,900 ohms, ±10%, ½ watt (R211)
503247	4,700 ohms, ±10%, ½ watt (R230)
502256	5,600 ohms, ±5%, ½ watt (R137)
513256	5,600 ohms, ±10%, 1 watt (R156)
14659	6,800 ohms, ±5%, ½ watt (R111, R112, R191)
503268	6,800 ohms, ±10%, ½ watt (R176)
513268	6,800 ohms, ±10%, 1 watt (R147)
503282	8,200 ohms, ±10%, ½ watt (R145)
513282	8,200 ohms, ±10%, 1 watt (R182)
503310	10,000 ohms, ±10%, ½ watt (R139, R164, R200, R213, R229)
513310	10,000 ohms, ±10%, 1 watt (R157)
503315	15,000 ohms, ±10%, ½ watt (R115, R239)
523315	15,000 ohms, ±10%, 2 watts (R143)
503318	18,000 ohms, ±10%, ½ watt (R144)
503322	22,000 ohms, ±10%, ½ watt (R175)
522322	22,000 ohms, ±10%, 2 watts (R223)
503327	27,000 ohms, ±10%, ½ watt (R174, R178)
523327	27,000 ohms, ±10%, 2 watts (R222)
503333	33,000 ohms, ±10%, ½ watt (R106, R129, R132, R135, R235)
503339	39,000 ohms, ±10%, ½ watt (R110, R173, R212, R215)
503347	47,000 ohms, ±10%, ½ watt (R103)
502356	56,000 ohms, ±5%, ½ watt (R141)
503356	56,000 ohms, ±10%, ½ watt (R105, R209)
503368	68,000 ohms, ±10%, ½ watt (R208)
512368	68,000 ohms, ±5%, 1 watt (R193)
513368	68,000 ohms, ±10%, 1 watt (R216)
8064	82,000 ohms, ±5%, ½ watt (R167)
513382	82,000 ohms, ±10%, 1 watt (R214)
503410	100,000 ohms, ±10%, ½ watt (R166, R203, R238)
513510	100,000 ohms, ±10%, 1 watt (R240)
503415	150,000 ohms, ±10%, ½ watt (R159, R195, R202, R204)
503418	180,000 ohms, ±10%, ½ watt (R207)
502422	220,000 ohms, ±5%, ½ watt (R179)
503422	220,000 ohms, ±10%, ½ watt (R233)
502427	270,000 ohms, ±5%, ½ watt (R163, R165)
503427	270,000 ohms, ±10%, ½ watt (R171, R226)
503433	330,000 ohms, ±10%, ½ watt (R116, R205, R220)
503439	390,000 ohms, ±10%, ½ watt (R219)
503447	470,000 ohms, ±10%, ½ watt (R117, R148, R160, R172, R184, R185, R189)
503468	680,000 ohms, ±10%, ½ watt (R169)
503482	820,000 ohms, ±10%, ½ watt (R206)
503510	1 megohm, ±10%, ½ watt (R181, R188, R217)
503512	1.2 megohm, ±10%, ½ watt (R186)
503533	3.3 megohm, ±10%, ½ watt (R196)
512536	3.6 megohm, ±5%, 1 watt (R162)
503539	3.9 megohm, ±10%, ½ watt (R168)
503547	4.7 megohm, ±10%, ½ watt (R170)
503610	10 megohm, ±10%, ½ watt (R113)
77198	Transformer—1st pix I-F grid transformer complete with adjustable cores (T104, C125, R125)
77197	Transformer—1st pix I-F plate transformer complete with adjustable cores (T105, C131, C132, R130)
76435	Transformer—2nd pix I-F grid transformer complete with adjustable cores (T106, C134)
76433	Transformer—3rd or 4th pix I-F transformer (T107, T108)
76436	Transformer—5th pix I-F transformer (T109, C142, C143, CR101, L102, R146)
76501	Transformer—Hi-voltage transformer (Part of T115)
76440	Transformer—Horizontal oscillator transformer complete with adjustable cores (T114)
76997	Transformer—Output transformer (T103)
77649	Transformer—Power transformer, 117 volts, 60 cycle (T113)
76439	Transformer—Ratio detector transformer complete with adjustable cores (T102, C106, C107)
76437	Transformer—Sound take-off transformer complete with adjustable core (T110, C147)
76438	Transformer—Sound I-F transformer complete with adjustable cores (T101, C102, C103)
77650	Transformer—Vertical oscillator transformer (T111)
76494	Transformer—Vertical output transformer (T112)
76482	Trap—4.5 M-C trap (L105, C150)
77585	Washer—"C" washer for picture control extension shaft (2 required)
	YOKE AND MAGNET ASSEMBLIES
76863	Connector—Anode connector complete with contact and terminal
75542	Connector—6 contact male connector for deflection yoke leads (P102)
78309	Cushion—Round rubber cushion for deflection yoke
74956	Cushion—Rubber cushion for deflection yoke hood
78308	Hood—Deflection yoke hood less rubber cushions
76168	Magnet—Focus magnet
76141	Magnet—Ion trap magnet
78307	Plate—Metal plate for deflection yoke
78445	Spring—Grounding spring (coil) for deflection yoke
76636	Stud—Adjusting stud complete with guard for focus magnet
78278	Yoke—Deflection yoke complete with 6 contact male connector (L113, L114, L115, L116, C206, C207, R227, P102)
	SPEAKER ASSEMBLIES
	971490-3W 971490-3R
	RL105E6
	RMA-274 RMA-285
	(For Table Models)
75024	Cone—Cone and voice coil for speakers stamped 971490-3W
77129	Cone—Cone and voice coil for speaker stamped 971490-3R
75022	Speaker—8" P.M. speaker complete with cone and voice coil (3.2 ohms)
	SPEAKER ASSEMBLIES
	92569-12W
	RL111A1
	RMA-274
	(For Console Models)
75682	Cone—Cone and voice coil (3.2 ohms)
76093	Speaker—12" P.M. speaker complete with cone and voice coil (3.2 ohms)

NOTE: If stamping on speaker in instrument does not agree with above speaker number, order replacement parts by referring to model number of instruments, number stamped on speaker and full description of part required.



Models 21-S-348, 21-S-348U, 21-S-348G, 21-S-348GU "Master 21" Ebony, Brown Maroon

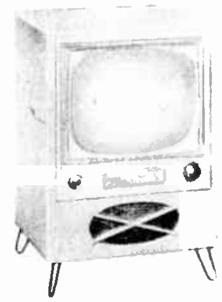
Models 21-S-353, 21-S-353U, 21-S-353G, 21-S-353GU "Barton" Ebony

Models 21-S-357G, 21-S-357GU "Modernette" Oak

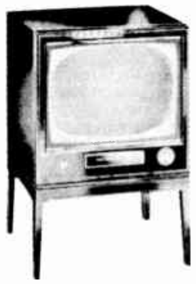
Models 21-S-359G, 21-S-359GU "Barnes" Maroon

Models 21-S-362M, 21-S-362MU, 21-S-362G, 21-S-362GU "Talbot" Mahogany, Oak

Models 21-S-367, 21-S-367U, 21-S-367G, 21-S-367GU "Ft. Knox" Mahogany, Oak



Models 21-S-369G, 21-S-369GU "Farrell" Oak



Models 21-S-354, 21S-354U, 21-S-354G, 21-S-354GU "Blake" Mahogany, Blonde

Models 21-S-355, 21-S-355U, 21-S-355G, 21-S-355GU "Cameron" Brown Maroon

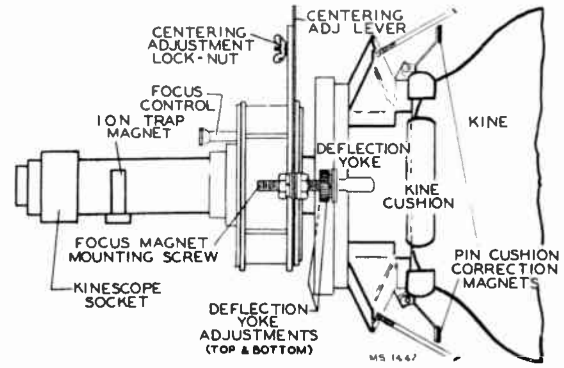


Figure 2—Ion Trap and Centering Magnet Adjustments

GENERAL DESCRIPTION

All models are "21 inch" television receivers. Models without a "U" designation in the model number are VHF only and feature full 12 channel VHF coverage. Models with the "U" designation in the model number are UHF/VHF and feature full 12 channel VHF coverage plus any UHF channels desired. All models have an auxiliary audio input jack to permit the use of an external record playing attachment except Models 21-S-348(U)(G)(GU).

ELECTRICAL AND MECHANICAL SPECIFICATIONS

PICTURE SIZE .... 227 square inches on a 21AP4, 21EP4A or 21ZP4A Kinescope

TELEVISION R-F FREQUENCY RANGE

All Models without "U" Suffix (VHF only)

All 12 television channels, 54 mc. to 88 mc., 174 mc. to 216 mc.

All Models with "U" Suffix (UHF/VHF)

Any of 70 UHF channels .... 470 mc. to 890 mc.
Any of 12 VHF channels .... 54 mc. to 88 mc., 174 mc. to 216 mc.

INTERMEDIATE FREQUENCIES

Picture I-F Carrier Frequency .... 45.75 mc.
Sound I-F Carrier Frequency .... 41.25 mc.

POWER RATING .... 215 watts

AUDIO POWER OUTPUT RATING .... 4 watts max.

VIDEO RESPONSE .... To 3.5 mc.

SWEEP DEFLECTION .... Magnetic

FOCUS .... Magnetic

ANTENNA INPUT IMPEDANCE

Models with VHF only

Choice: 300 ohms balanced or 72 ohms unbalanced.

UHF/VHF Models

UHF—300 ohms balanced.
VHF—300 ohms balanced.

RCA TUBE COMPLEMENT

Tube Used	Function
Tuners KRK22C & KRK29 (Models with VHF only)	
(1) RCA 6BQ7A	R-F Amplifier
(2) RCA 6X8	R-F Oscillator and Mixer

RCA TUBE COMPLEMENT

Tube Used	Function
Tuner KRK29A/27 (UHF/VHF Models)	
(1) RCA 6AF4	UHF Oscillator
(2) RCA 6BQ7A	VHF R-F Amplifier UHF I-F Amplifier
(3) RCA 6X8	VHF R-F Oscillator & Mixer UHF I-F Amplifier
A IN82 crystal is used as the UHF mixer	
All Models	
(1) RCA 6CF6	1st Picture I-F Amplifier
(2) RCA 6CF6	2nd Picture I-F Amplifier
(3) RCA 6CB6	3rd Picture I-F Amplifier
(4) RCA 12AU7	Picture 2nd Det. and Horiz. Sync. Sep.
(5) RCA 6X8	Video Amplifier and Vert. Syn. Sep.
(6) RCA 12AU7	Video Output & AGC
(7) RCA 6AU6	1st Sound I-F Amplifier
(8) RCA 6AU6	2nd Sound I-F Amplifier
(9) RCA 6AL5	Ratio Detector
(10) RCA 6AV6	1st Audio Amplifier
(11) RCA 6K6GT	Audio Output
(12) RCA 6SN7GT	Vert. Osc. and Disch. & Sync. Output
(13) RCA 6K6GT	Vertical Sweep Output
(14) RCA 6SN7GT	Horizontal Sweep Oscillator and Control
(15) RCA 6BQ6GT	Horizontal Sweep Output
(16) RCA 6AX4GT	Damper
(17) RCA 1B3-GT/8016	High Voltage Rectifier
*(18) RCA 21AP4, 21EP4A or 21ZP4A	Kinescope
(19) RCA 5U4G	Rectifier
(20) RCA 5Y3GT	Rectifier

*Refer to Chassis Designations

21-S-348 to 21-S-369G incl. 21-S-348U to 21-S-369GU incl. ELECTRICAL AND MECHANICAL SPECIFICATIONS (cont'd)

ALIGNMENT PROCEDURE

TEST EQUIPMENT.—To properly service the television chassis of these receivers, it is recommended that the following test equipment be available:

VHF Sweep Generator meeting the following requirements:

(a) Frequency Ranges
35 to 90 mc., 1 mc. to 12 mc. sweep width
170 to 225 mc., 12 mc. sweep width

(b) Output adjustable with at least .1 volt maximum.

(c) Output constant on all ranges.

(d) "Flat" output on all attenuator positions.

VHF Signal Generator to provide the following frequencies with crystal accuracy:

(a) Intermediate frequencies
4.5 mc., 39.25 mc., 41.25 mc., 43.5 mc., 45.75 mc., 47.25 mc.

(b) Radio frequencies

Channel Number	Picture Carrier Freq. Mc.	Sound Carrier Freq. Mc.	Receiver R-F Osc. Freq. Mc.
2	55.25	59.75	101
3	61.25	65.75	107
4	67.25	71.75	113
5	77.25	81.75	123
6	83.25	87.75	129
7	175.25	179.75	221
8	181.25	185.75	227
9	187.25	191.75	233
10	193.25	197.75	239
11	199.25	203.75	245
12	205.25	209.75	251
13	211.25	215.75	257

(c) Output of these ranges should be adjustable and at least .1 volt maximum.

VHF Heterodyne Frequency Meter with crystal calibrator if the signal generator is not crystal controlled.

UHF Sweep Generator with a frequency range of 470 mc. to 890 mc. RCA types 40A or 41A or their equivalent.

UHF Signal Generator to provide the following frequencies with crystal accuracy if RCA Type 41A is used.

Channel Number	Picture Carrier Freq. Mc.	Sound Carrier Freq. Mc.	Receiver R-F Osc. Freq. Mc.
14	471.25	475.75	517
15	477.25	481.75	523

Cathode Ray Oscilloscope.—An oscilloscope with a sensitivity of 5 millivolts per inch is required. A suitable preamplifier may be employed with oscilloscopes of lesser sensitivity.

Electronic Voltmeter.—A voltmeter with a 1.5 volt DC scale is required. RCA Senior "VoltOhmyst" or equivalent.

PICTURE I-F TRANSFORMER ADJUSTMENTS.—

Models 21-S-348 to 21-S-369G Incl.

Connect the i-f signal generator across the link circuit on terminals A and B of T104.

Connect the "VoltOhmyst" to the junction of R123 and C142. Turn the AGC control fully clockwise.

Obtain two 7.5 volt batteries capable of withstanding appreciable current drain and connect the ends of a 1,000 ohm potentiometer across each. Connect the battery positive terminal of one to the chassis and the potentiometer arm to the junction of R123 and C142. The second battery will be used later.

Set the bias to produce approximately —5.0 volt of bias at the junction of R123 and C142.

Connect the "VoltOhmyst" to the junction of R135 and L102 and to ground.

Set the VHF signal generator to each of the following frequencies and peak the specified adjustment for maximum indication on the "VoltOhmyst." During alignment, reduce the input signal if necessary in order to produce 3.0 volts of d-c at R135 and L102 with —5.0 volts of i-f bias at the junction of R123 and C142.

44.5 mc. T108
45.5 mc. T107
43.0 mc. T106

Set the VHF signal generator to the following frequency and adjust the picture i-f trap for minimum d-c output at R135, L102. Use sufficient signal input to produce 3.0 volts of d-c on the meter when the adjustment is made.

47.25 mc. L118

Models 21-S-348U to 21-S-369GU Incl.

Connect the i-f signal generator across the link circuit on terminals A and B of T104.

Connect the "VoltOhmyst" to the junction of R123 and C142.

Turn the AGC control fully clockwise.

Obtain a 7.5 volt battery capable of withstanding appreciable current drain and connect the ends of a 1,000 ohm potentiometer across it. Connect the battery positive terminal to chassis and the potentiometer arm to the junction R123 and C142. Adjust the potentiometer for —5.0 volts indication on the "VoltOhmyst."

Connect the "VoltOhmyst" to the junction of R135 and L102 and to ground.

Set the VHF generator to each of the following frequencies and with a thin fiber screwdriver tune the specified adjustment for maximum indication on the "VoltOhmyst." In each instance the generator should be checked against a crystal calibrator to insure that the generator is on frequency.

During alignment, reduce the input signal if necessary in order to produce 3.0 volts of d-c at R135 and L102 with —5.0 volts of i-f bias at the junction of R123 and C142.

44.5 mc. T108
45.5 mc. T107
43.0 mc. T106

Set the signal generator to the following frequency and adjust the picture i-f trap for minimum d-c output at junction of R135 and L102. Use sufficient signal input to produce 3.0 volts of d-c on the meter when adjustment is made.

47.25 mc. L118

SWEEP ALIGNMENT OF PICTURE I-F.—

Models 21-S-348 to 21-S-369G Incl.

To align T2 and T104, connect the sweep generator to the mixer grid test point TP2, in series with a 1500 mmf. ceramic capacitor. Use the shortest leads possible, with not more than one inch of unshielded lead at the end of the sweep cable. Connect the sweep ground lead to the top of the tuner.

Set the channel selector switch to channel 4.

Clip 330 ohm resistors across terminals A and B of T107 and T108.

Preset C122 to minimum capacity.

Adjust the bias box potentiometer to obtain —5.0 volts of bias as measured by a "VoltOhmyst" at the junction of R123 and C142. Set the AGC control fully clockwise.

Connect a 180 ohm composition resistor from pin 5 of V106 to terminal A of T106. Connect the oscilloscope diode probe to pin 5 of V106 and to ground.

Couple the signal generator loosely to the diode probe in order to obtain markers.

Adjust T2 (top) and T104 (top) for maximum gain and with 45.75 mc. at 75% of maximum response.

Set the sweep output to give 0.3 volt peak-to-peak on the oscilloscope when making the final touch on the above adjustment.

Adjust C122 until 42.5 mc. is at 70% response with respect to the low frequency shoulder of the curve as shown in Figure 10. Maximum allowable tilt is 20%.

Disconnect the diode probe, the 180 ohm and two 330 ohm resistors.

Connect the oscilloscope to the junction of R135 and L102.

Leave the sweep generator connected to the mixer grid test point TP2 with the shortest leads possible.

Adjust the output of the sweep generator to obtain 3.0 volts peak-to-peak on the oscilloscope.

Couple the signal generator loosely to the grid of the first pix i-f amplifier. Adjust the output of the signal generator to produce small markers on the response curve.

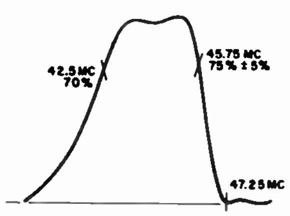

Figure 10—
KRK22C or KRK29
T2 and T104
Response

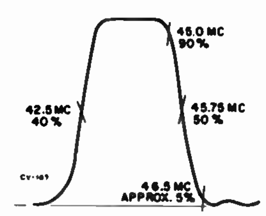

Figure 11—
Overall I-F
Response
with KRK22C or KRK29

Retouch T106, T107 and T108 to obtain the response shown in Figure 11.

Models 21-S-348U to 21-S-369GU Incl.

To align T2 and T104, connect the sweep generator to the mixer grid test point TP2, in series with a 1500 mmf. ceramic capacitor. Use the shortest leads possible, with not more than one inch of unshielded lead at the end of the sweep cable. Connect the sweep ground lead to the top of the tuner.

Set the channel selector switch to channel 4.

Clip 330 ohm resistors across terminals A and B of T107 and T108.

Preset C122 to minimum capacity.

Adjust the bias box potentiometer to obtain —5.0 volts of bias as measured by a "VoltOhmyst" at the junction of R123 and C142. Set the AGC control fully clockwise.

Connect a 180 ohm composition resistor from pin 5 of V106 to terminal A of T106. Connect the oscilloscope diode probe to pin 5 of V106 and to ground.

Couple the signal generator loosely to the diode probe in order to obtain markers.

Adjust T2 (top) and T104 (top) for maximum gain and with 45.75 mc. at 75% of maximum response.

Set the sweep output to give 0.3 volt peak-to-peak on the oscilloscope when making the final touch on the above adjustment.

Adjust C122 until 42.5 mc. is at 70% response with respect to the low frequency shoulder of the curve as shown in Figure 12.

Disconnect the diode probe, the 180 ohm and two 330 ohm resistors.

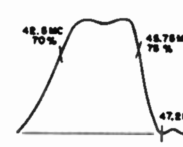

Figure 12—
KRK29A/27-T2
and T104
Response

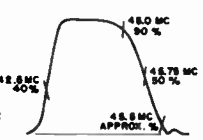

Figure 13—
Overall
I-F Response
with KRK29A/27

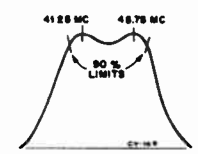

Figure 14—
KRK29A/27
L9 and L307
I-F Response

Connect the oscilloscope to the junction of R135 and L102.

Leave the sweep generator connected to the mixer grid test point TP2 with the shortest leads possible.

Adjust the output of the sweep generator to obtain 3.0 volts peak-to-peak on the oscilloscope.

Couple the signal generator loosely to the grid of the first pix i-f amplified. Adjust the output of the signal generator to produce small markers on the response curve.

Retouch T106, T107 and T108 to obtain the response shown in Figure 13.

To align the I-F amplifier circuit of the KRK29A/27, connect the VHF sweep generator to the rear terminal of the 1N82 crystal holder in series with a 1000 ohm resistor and a 1500 mmf. ceramic capacitor. Use the shortest leads possible, grounding the sweep ground lead to the tuner case.

Set the UHF CHANGEOVER switch to the UHF position, and the UHF TUNING to channel 47 at 670 mc.

Connect a 180 ohm composition resistor and a 1500 mmf. capacitor in series between test point TP3 and ground with the capacitor connected to TP3 and the resistor to ground. Connect the oscilloscope diode probe to the junction between the resistor and capacitor. (See Figure 25.)

Couple the VHF signal generator loosely to the diode probe in order to obtain markers.

Connect the potentiometer arm of the second bias supply to the AGC terminal on the tuner and ground the battery positive terminal to the tuner case. Adjust the bias potentiometer to produce —3.0 volts of bias, as measured by the "VoltOhmyst" at the AGC terminal on the tuner.

Set the sweep generator to produce 0.3 or less peak-to-peak on the oscilloscope.

Adjust L307, on the KRK27 section, and L9, on the KRK29A section, of the tuner for maximum gain with picture and sound carrier markers as shown in figure 14.

ALIGNMENT PROCEDURE

Remove the resistor, capacitor and diode probe from TP3 and connect the oscilloscope to the junction of R135 and L102. Use 3.0v. peak-to-peak on the oscilloscope.

Retouch L307 and L9 slightly, if necessary, to produce the curve shown in figure 14. Do not retouch T2, T104, T106, T107 or T108.

Connect the VHF sweep generator to the antenna terminals. Keep the AGC bias at —3.0 V and the I.F bias at —5.0 volts.

Couple the signal generator loosely to the grid of the first picture I-F amplifier.

Switch through all VHF channels and check for proper curve shape as in figure 13. Retouch T107 and T108 slightly to correct for any overall tilt that is essentially the same on all channels.

Disconnect the VHF sweep generator and connect the UHF sweep generator to the antenna terminals. Check on all UHF channels for proper wave shape as shown in figure 13, retouching T107 and T108 if necessary to correct any overall tilt.

Remove the sweep and marker generators and the bias supplies.

KRK22C TUNER ALIGNMENT.—

Models 21-S-348 to 21-S-369G Incl.

A tuner unit which is operative and requires only touch up adjustments, requires no presetting of adjustments. For such units, skip the remainder of this paragraph. For units which are completely out of adjustment, preset C2 all the way out. Set channel 7 to 13 oscillator slugs one turn from tight. Turn T2 slug all the way out. Do not change any of the adjustments in the antenna matching unit.

Disconnect the link from terminals "A" and "B" of T104 and terminate the link with a 39 ohm composition resistor.

Turn the receiver channel selector switch to channel 2.

The 43.5 mc. trap is adjusted with zero bias. To insure that the bias will remain constant, take a clip lead and short circuit the AGC terminal of the tuner at the terminal board to ground.

Connect the oscilloscope to the test point TP1 on top of the tuner unit. Set the oscilloscope to maximum gain.

Connect the output of the VHF signal generator to the output of the antenna matching unit at the junction of L53 and C24 at the bottom of the FM trap L53.

Tune the signal generator to 43.5 mc. and modulate it 30% with a 400 cycle sine wave. Adjust the signal generator for maximum output.

Adjust C19 on top of the tuner, for minimum 400 cycle indication on the oscilloscope. If necessary, this adjustment can be retouched in the field to provide additional rejection to one specific frequency in the i-f band pass. However, in such cases, care should be taken not to tune C19 into channel 2, thereby reducing sensitivity on channel 2.

Connect the potentiometer arm of one of the bias supplies to the AGC terminal on the tuner and ground the battery positive terminal to the tuner case. Adjust the bias potentiometer to produce —3.0 volts of bias, as measured by the "VoltOhmyst" at the AGC terminal on the tuner.

Set the channel selector switch to channel 8.

Preset C5 to read —3.0 volts at the test point TP1, as read on the "VoltOhmyst". The limits for oscillator injection voltage are 2 volts minimum and not exceeding a maximum of 5.5 volts.

Turn the fine tuning control fully clockwise.

Adjust C3 for proper oscillator frequency, 227 mc. This may be done in several ways. The easiest way and the way which will be recommended in this procedure will be to use the signal generator as a heterodyne frequency meter and beat the oscillator against the signal generator. To do this, tune the signal generator to 227 mc. with crystal accuracy. Insert one end of a piece of insulated wire into the tuner unit through the hole provided for the adjustment of C10. Be careful that the wire does not touch any of the tuned circuits as it may cause the frequency of the tuner oscillator to shift. Connect the other end of the wire to the "r-f in" terminal of the signal generator. Adjust C3 to obtain an audible beat with the signal generator.

Turn C2 clockwise until the beat note just begins to change, then turn one full turn in the same clockwise direction.

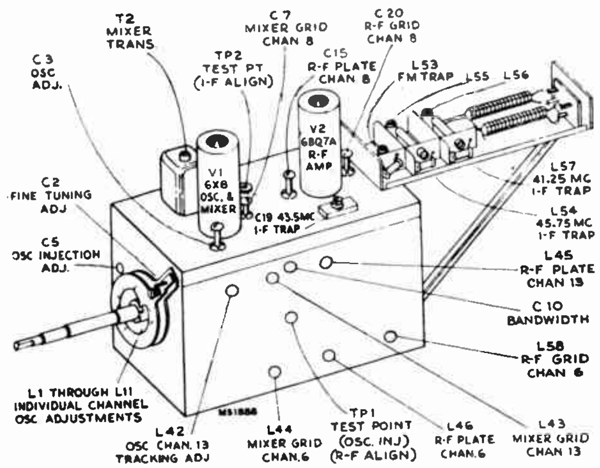

Figure 15—KRK22C Tuner Adjustment

Return the fine tuning control to the mechanical center of its range.

Note.—If on some units, it is not possible to reach the proper channel 8 oscillator frequency by adjustment of C3, switch to channel 13 and adjust L42 to obtain proper channel 13 oscillator frequency as indicated in the table on page 8. Then, switch to channel 12 and adjust L11 to obtain proper channel 12 oscillator frequency. Continue down to channel 8, adjusting the appropriate oscillator trimmer to obtain the proper frequency on each channel. Then again on channel 8, adjust C3 to obtain proper channel 8 oscillator frequency. Switch back to channel 13 and readjust L42 and back to channel 8 and adjust C3.

Set the T2 core for maximum inductance (core turned counter-clockwise).

Connect the sweep generator through a suitable attenuator, as shown in figure 16, to the input terminals of the antenna matching unit.

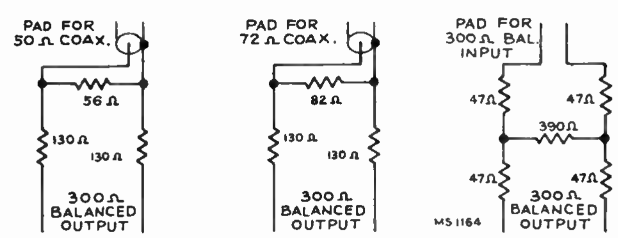

Figure 16—Sweep Attenuator Pads

Connect the signal generator loosely to the antenna terminals.

Set the sweep generator to cover channel 8.

Set the oscilloscope to maximum gain and use the minimum input signal which will produce a usable pattern on the oscilloscope. Excessive input can change oscillator injection during alignment and produce consequent misalignment even though the response as seen on the oscilloscope may look normal.

Insert markers of channel 8 picture carrier and sound carrier, 181.25 mc. and 185.75 mc.

Adjust C7, C10, C15 and C20 for approximately correct curve shape, frequency, and band width as shown in figure 17.

The correct adjustment of C20 is indicated by maximum amplitude of the curve midway between the markers. C15 tunes the r-f amplifier plate circuit and affects the frequency of the pass band most noticeably. C7 tunes the mixer grid circuit and affects the tilt of the curve most noticeably (assuming that C20 has been properly adjusted). C10 is the coupling adjustment and hence primarily affects the response band width.

Connect the "VoltOhmyst" to test point TP 1. Adjust C5 to read —3.0 volts dc on the "VoltOhmst" at TP1. Readjust C2, C7, C10 and C15 for proper response. Adjust C20 for maximum gain at midpoint of the curve. Repeat if necessary until the proper response is obtained.

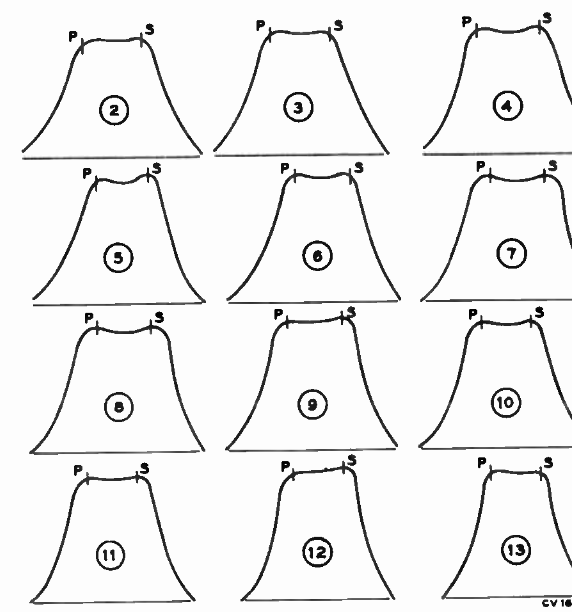

Figure 17—KRK22C R-F Response

Set the receiver channel switch to channel 13.

Adjust the signal generator to the channel 13 oscillator frequency 257 mc.

Turn the fine tuning control fully clockwise.

Adjust L42 to obtain an audible beat. Slightly overshoot the adjustment of L42 by turning the slug an additional turn in the same direction from the original setting, then reset the oscillator to proper frequency by adjusting C2 to again obtain the beat.

Set the sweep generator to channel 13.

From the signal generator, insert channel 13 sound and picture carrier markers, 211.25 mc. and 215.75 mc.

Adjust L43 and L45 for proper response as shown in figure 17.

Turn off the sweep and signal generators.

Connect the "VoltOhmyst" to the tuner test point TP1.

Check the oscillator injection voltage to be within limits as previously specified. Adjust if necessary to bring within range.

If it was necessary to readjust C5, turn the sweep and signal generators back on and recheck the channel 13 response. Readjust L43 and L45 if necessary.

Set the receiver channel selector switch to channel 8 and readjust C2 for proper oscillator frequency, 227 mc.

Set the sweep generator and signal generator to channel 8.

Readjust C7, C10, C15 and C20 for correct curve shape, frequency and band width.

Turn off the sweep and signal generators, switch back to channel 13 and check the oscillator injection voltage at TP1 if C7 was adjusted in the recheck of channel 8 response.

If the initial setting of the oscillator injection trimmer was far off, it may be necessary to adjust the oscillator frequency and response on channel 8, adjust the oscillator injection on channel 13 and repeat the tracking procedure several times before the proper setting is obtained.

Turn off the sweep generator and switch the receiver to channel 6.

Adjust the signal generator to the channel 6 oscillator frequency 129 mc.

Set the fine tuning control to the center of its mechanical range.

Adjust L5 for an audible beat. Adjust L44, L46 and L58 for proper curve shape as shown in figure 17. Recheck the oscillator injection voltage at TP1, to insure that it is within the limits specified. Readjust C5 if necessary.

If C5 required adjustment, switch the receiver and the signal generator to channel 8. Readjust C7 for correct curve shape and recheck C2 and C3 for proper oscillator frequency.

Check the response of channels 2 through 6 by switching the receiver channel switch, sweep generator and marker generator to each of these channels and observing the response and oscillator injection voltage obtained. See figure 17 for typical response curves. It should be found that all these channels have the proper response with the markers above 80% response.

If the markers fail to fall within this requirement readjust L44, L46 and L58 in order to obtain curves within the proper limits.

Switch the channel selector, signal generator and marker generator through channels 7 to 13 and observe the response curves, referring to figure 17 for proper wave shape. Check the injection voltage at each channel to be within limits. If necessary readjust C15, C7, or C10 to obtain the proper response.

With the receiver and signal generator on channel 13 adjust L42 for an audible beat with the signal generator.

Adjust the oscillator to frequency on all channels by switching the receiver and the frequency standard to each channel and adjusting the appropriate oscillator slug to obtain the audible beat. It should be possible to adjust the oscillator to obtain the audible beat on each channel. Recheck the oscillator injection voltage on each channel to verify that the voltage is within the specified limits.

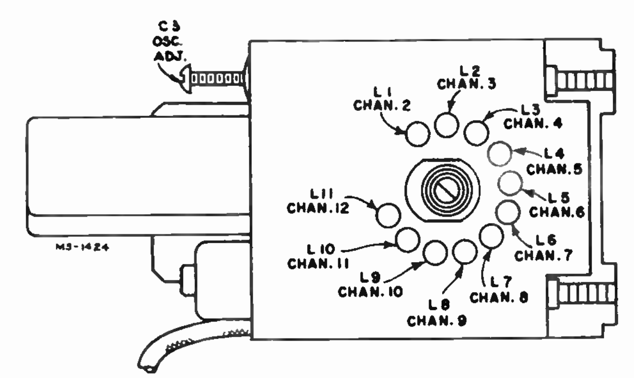

Figure 18—KRK22C Oscillator Adjustments

KRK22C ANTENNA MATCHING UNIT ALIGNMENT.—The antenna matching unit is accurately aligned at the factory. Adjustment of this unit should not be attempted in the customer's home since even slight misalignment may cause serious attenuation of the signal especially on channel 2. The r-f unit is aligned with a particular antenna matching transformer in place. If for any reason, a new antenna matching transformer is installed, the r-f unit should be realigned.

The F-M Trap which is mounted in the antenna matching unit may be adjusted without adversely affecting the alignment of the unit.

To align the antenna matching unit disconnect the lead from the F-M trap L53 to the channel selector switch S4.

With a short jumper, connect the output of the matching unit through a 1000 mmf. capacitor to the grid of the second pix i-f amplifier, pin 1 of V107.

Replace the cover on the matching unit while making all adjustments.

Remove the first pix i-f amplifier tube V106.

ALIGNMENT PROCEDURE

Connect the positive terminal of a bias box to the chassis and the potentiometer arm to the junction of R123 and C142. Set the potentiometer to produce approximately —5.0 volts of bias at the junction of R123 and C142.

Connect an oscilloscope to the junction of R138 and L105 and set the oscilloscope gain to maximum.

Connect a VHF signal generator to the antenna input terminals. Modulate the signal generator 30% with an audio signal.

Tune the signal generator to 45.75 mc. and adjust the generator output to give an indication on the oscilloscope. Adjust L54 in the antenna matching unit for minimum audio indication on the oscilloscope.

Tune the signal generator to 41.25 mc. and adjust L57 for minimum audio indication on the oscilloscope.

Remove the jumper from the output of the matching unit.

Connect a 300 ohm ½ watt composition resistor from L53 to ground, keeping the leads as short as possible.

Connect an oscilloscope low capacity crystal probe from L53 to ground. The sensitivity of the oscilloscope should be approximately 0.03 volts per inch. Set the oscilloscope gain to maximum.

Connect the VHF sweep generator to the matching unit antenna input terminals. In order to prevent coupling reactance from the sweep generator into the matching unit, it is advisable to employ a resistance pad at the matching unit terminals. Figure 16 shows three different resistance pads for use with sweep generators with 50 ohm co-ax output, 72 ohm co-ax output or 300 ohm balanced output. Choose the pad to match the output impedance of the particular sweep employed.

Connect the signal generator loosely to the matching unit antenna terminals.

Set the sweep generator to sweep from 45 mc. to 54 mc. With RCA Type WR59A sweep generators, this may be accomplished by retuning channel number 1 to cover this range. With WR59B sweep generators this may be accomplished by retuning channel number 2 to cover the range. In making these adjustments on the generator, be sure not to turn the core too far clockwise so that it becomes lost beyond the core retaining spring.

Adjust L55 and L56 to obtain the response shown in figure 19. L55 is most effective in locating the position of the shoulder of the curve at 52 mc. and L56 should be adjusted to give maximum amplitude at 53 mc. and above consistent with the specified shape of the response curve. The adjustments in the matching unit interact to some extent. Repeat the above procedure until no further adjustments are necessary.

Remove the 300 ohm resistor and crystal probe connections. Restore the connection between L53 and S4. Replace V106.

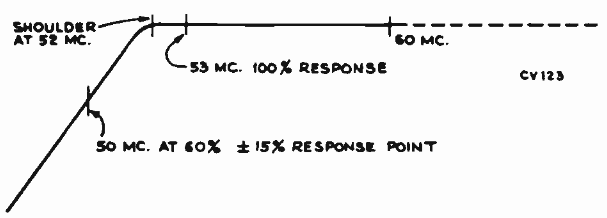

Figure 19—KRK22A Antenna Matching Unit Response

KRK29 TUNER ALIGNMENT

Models 21-S-348 to 21-S-369G Incl.

A tuner unit which is operative and requires only touch up adjustments, requires no presetting of adjustments. For such units, skip the remainder of this paragraph. For units which are completely out of adjustment, preset C27 all the way out. Set channel 7 to 13 oscillator slugs one turn from tight. Turn T2 slug all the way out. Do not change any of the adjustments in the antenna matching unit.

Disconnect the link from terminals "A" and "B" of T104 and terminate the link with a 39 ohm composition resistor.

Turn the receiver channel selector switch to channel 2.

The 43.5 mc. trap is adjusted with zero bias. To insure that the bias will remain constant, take a clip lead and short circuit the AGC terminal of the tuner at the terminal board to ground.

Connect the oscilloscope to the test point TP1 on top of the tuner unit. Set the oscilloscope to maximum gain.

Connect the output of the VHF signal generator to the output of the antenna matching unit at the junction of L5 and C4 at the bottom of the FM trap L5.

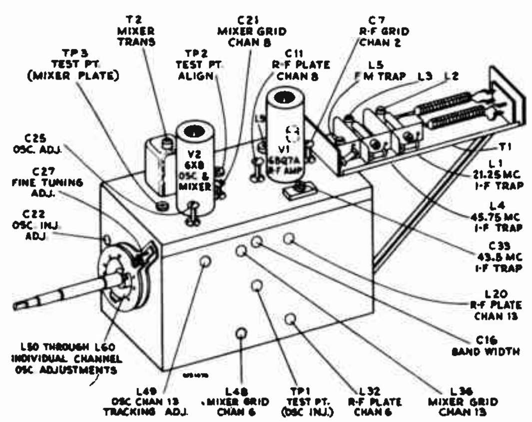

Figure 20—KRK29 Tuner Adjustments

Tune the signal generator to 43.5 mc. and modulate it 30% with a 400 cycle sine wave. Adjust the signal generator for maximum output.

Adjust C33 on top of the tuner, for minimum 400 cycle indication on the oscilloscope. If necessary, this adjustment can be retouched in the field to provide additional rejection to one specific frequency in the i-f band pass. However, in such cases, care should be taken not to tune C33 into channel 2, thereby reducing sensitivity on channel 2.

Connect the potentiometer arm of one of the bias supplies to the AGC terminal on the tuner and ground the battery positive terminal to the tuner case. Adjust the bias potentiometer to produce —3.0 volts of bias, as measured by the "VoltOhmyst" at the AGC terminal on the tuner.

Set the channel selector switch to channel 8.

Preset C22 to read —3.0 volts at the test point TP1, as read on the "VoltOhmyst." The limits for oscillator injection voltage are 2 volts minimum and not exceeding a maximum of 5.5 volts.

Turn the fine tuning control fully clockwise.

Adjust C25 for proper oscillator frequency, 227 mc. This may be done in several ways. The easiest way and the way which will be recommended in this procedure will be to use the signal generator as a heterodyne frequency meter and beat the oscillator against the signal generator. To do this, tune the signal generator to 227 mc. with crystal accuracy. Insert one end of a piece of insulated wire into the tuner unit through the hole provided for the adjustment of C16. Be careful that the wire does not touch any of the tuned circuits as it may cause the frequency of the tuner oscillator to shift. Connect the other end of the wire to the "r-f in" terminal of the signal generator. Adjust C25 to obtain an audible beat with the signal generator.

Turn the C27 clockwise until the beat note just begins to change, then turn one full turn in the same clockwise direction.

Return the fine tuning control to the mechanical center of its range.

Note.—If on some units, it is not possible to reach the proper channel 8 oscillator frequency by adjustment of C25, switch to channel 13 and adjust L49 to obtain proper channel 13 oscillator frequency as indicated in the table on page 8. Then, switch to channel 12 and adjust L60 to obtain proper channel 12 oscillator frequency. Continue down to channel 8, adjusting the appropriate oscillator trimmer to obtain the proper frequency on each channel. Then again on channel 8, adjust C25 to obtain proper channel 8 oscillator frequency. Switch back to channel 13 and readjust L49 and back to channel 8 and adjust C25.

Set the T2 core for maximum inductance (core turned counter-clockwise).

Connect the sweep generator through a suitable attenuator, as shown in Figure 16, to the input terminals of the antenna matching unit.

Connect the signal generator loosely to the antenna terminals.

Set the sweep generator to cover channel 8.

Set the oscilloscope to maximum gain and use the minimum input signal which will produce a usable pattern on the oscilloscope. Excessive input can change oscillator injection during alignment and produce consequent misalignment even though the response as seen on the oscilloscope may look normal.

Insert markers of channel 8 picture carrier and sound carrier, 181.25 mc. and 185.75 mc.

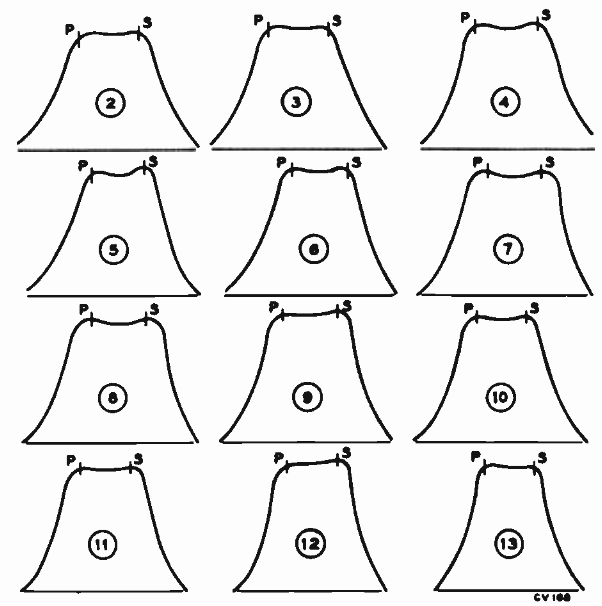

Figure 21—KRK29 R-F Response

Adjust C21, C16, C11 and C7 for approximately correct curve shape, frequency, and band width as shown in Figure 21.

The correct adjustment of C7 is indicated by maximum amplitude of the curve midway between the markers. C11 tunes the r-f amplifier plate circuit and affects the frequency of the pass band most noticeably. C21 tunes the mixer grid circuit and affects the tilt of the curve most noticeably (assuming that C7 has been properly adjusted). C16 is the coupling adjustment and hence primarily affects the response band width.

Connect the "VoltOhmyst" to test point TP1. Adjust C22 to read —3.0 volts dc on the "VoltOhmyst" at TP1. Readjust C27, C21, C16 and C11 for proper response. Adjust C7 for maximum gain at midpoint of the curve. Repeat if necessary until the proper response is obtained.

Set the receiver channel switch to channel 13.

Adjust the signal generator to the channel 13 oscillator frequency 257 mc.

Turn the fine tuning control fully clockwise.

Adjust L49 to obtain an audible beat. Slightly overshoot the adjustment of L49 by turning the slug an additional turn in the same direction from the original setting, then reset the oscillator to proper frequency by adjusting C27 to again obtain the beat.

Set the sweep generator to channel 13.

From the signal generator, insert channel 13 sound and picture carrier markers, 211.25 mc. and 215.75 mc.

Adjust L36 and L20 for proper response as shown in Figure 21.

Turn off the sweep and signal generators.

Connect the "VoltOhmyst" to the tuner test point TP1.

Check the oscillator injection voltage to be within limits as previously specified. Adjust if necessary to bring within range.

If it was necessary to readjust C22, turn the sweep and signal generators back on and recheck the channel 13 response. Readjust L36 and L20 if necessary.

Set the receiver channel selector switch to channel 8 and readjust C27 for proper oscillator frequency, 227 mc.

Set the sweep generator and signal generator to channel 8.

Readjust C21, C16, C11 and C7 for correct curve shape, frequency and bandwidth.

Turn off the sweep and signal generators, switch back to channel 13 and check the oscillator injection voltage at TP1 if C21 was adjusted in the recheck of channel 8 response.

If the initial setting of the oscillator injection trimmer was far off, it may be necessary to adjust the oscillator frequency and response on channel 8, adjust the oscillator injection on channel 13 and repeat the tracking procedure several times before the proper setting is obtained.

Turn off the sweep generator and switch the receiver to channel 6.

Adjust the signal generator to the channel 6 oscillator frequency 129 mc.

Set the fine tuning control to the center of its mechanical range.

Adjust L54 for an audible beat. Adjust L48, and L32 for proper curve shape as shown in Figure 21. Recheck the oscillator injection voltage at TP1, to insure that it is within the limits specified. Readjust C22 if necessary.

If C22 required adjustment, switch the receiver and the signal generator to channel 8. Readjust C21 for correct curve shape and recheck C27 and C25 for proper oscillator frequency.

Check the response of channels 2 through 6 by switching the receiver channel switch, sweep generator and marker generator to each of these channels and observing the response and oscillator injection voltage obtained. See Figure 21 for typical response curves. It should be found that all these channels have the proper response with the markers above 80% response.

If the markers fail to fall within this requirement readjust L48 and L32 in order to obtain curves within the proper limits.

Switch the channel selector, signal generator and marker generator through channels 7 to 13 and observe the response curves, referring to Figure 21 for proper wave shape. Check the injection voltage at each channel to be within limits. If necessary readjust C11, C21, or C16 to obtain the proper response.

With the receiver and signal generator on channel 13 adjust L49 for an audible beat with the signal generator.

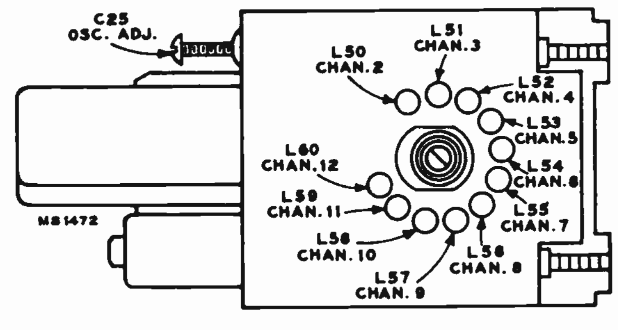

Figure 22—KRK29 R-F Oscillator Adjustments

Adjust the oscillator to frequency on all channels by switching the receiver and the frequency standard to each channel and adjusting the appropriate oscillator slug to obtain the audible beat. It should be possible to adjust the oscillator

ALIGNMENT PROCEDURE

to obtain the audible beat on each channel. Recheck the oscillator injection voltage on each channel to verify that the voltage is within the specified limits.

KRK29 OR KRK29A ANTENNA MATCHING UNIT ALIGNMENT.—The antenna matching unit is accurately aligned at the factory. Adjustment of this unit should not be attempted in the customer's home since even slight misalignment may cause serious attenuation of the signal especially on channel 2. The r-f unit is aligned with a particular antenna matching transformer in place. If for any reason, a new antenna matching transformer is installed, the r-f unit should be realigned.

The F-M Trap which is mounted in the antenna matching unit may be adjusted without adversely affecting the alignment of the unit.

To align the antenna matching unit disconnect the lead from the F-M Trap L5 to the channel selector switch S1-E.

With a short jumper, connect the output of the matching unit through a 1000 mmf. capacitor to the grid of the second pix i-f amplifier, pin 1 of V107.

Replace the cover on the matching unit while making all adjustments.

Remove the first pix i-f amplifier tube V106.

Connect the positive terminal of a bias box to the chassis and the potentiometer arm to the junction of R123 and C142. Set the potentiometer to produce approximately —5.0 volts of bias at the junction of R123 and C142.

Connect an oscilloscope to the junction of R138 and L105 and set the oscilloscope gain to maximum.

Connect a VHF signal generator to the antenna input terminals. Modulate the signal generator 30% with an audio signal.

Tune the signal generator to 45.75 mc. and adjust the generator output to give an indication on the oscilloscope. Adjust L4 in the antenna matching unit for minimum audio indication on the oscilloscope.

Tune the signal generator to 41.25 mc. and adjust L1 for minimum audio indication on the oscilloscope.

Remove the jumper from the output of the matching unit.

Connect a 300 ohm ½ watt composition resistor from L5 to ground, keeping the leads as short as possible.

Connect an oscilloscope low capacity crystal probe from L5 to ground. The sensitivity of the oscilloscope should be approximately 0.03 volts per inch. Set the oscilloscope gain to maximum.

Connect the VHF sweep generator to the matching unit antenna input terminals. In order to prevent coupling reactance from the sweep generator into the matching unit, it is advisable to employ a resistance pad at the matching unit terminals. Figure 16 shows three different resistance pads for use with sweep generators with 50 ohm co-ax output, 72 ohm co-ax output or 300 ohm balanced output. Choose the pad to match the output impedance of the particular sweep employed.

Connect the signal generator loosely to the matching unit antenna terminals.

Set the sweep generator to sweep from 45 mc. to 54 mc. With RCA Type WR59A sweep generators, this may be accomplished by returning channel number 1 to cover this range. With WR59B sweep generators this may be accomplished by retuning channel number 2 to cover the range. In making these adjustments on the generator, be sure not to turn the core too far clockwise so that it becomes lost beyond the core retaining spring.

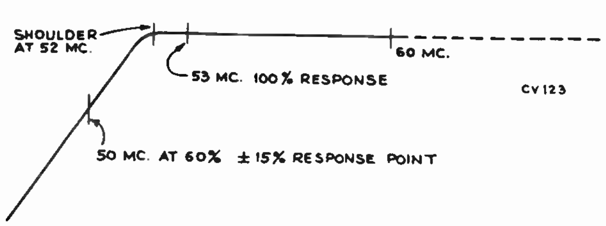

Figure 23—KRK29 or KRK29A Antenna Matching Unit Response

Adjust L2 and L3 to obtain the response shown in figure 23. L3 is most effective in locating the position of the shoulder of the curve at 52 mc. and L2 should be adjusted to give maximum amplitude at 53 mc. and above consistent with the specified shape of the response curve. The adjustments in the matching unit interact to some extent. Repeat the above procedure until no further adjustments are necessary.

Remove the 300 ohm resistor and crystal probe connections. Restore the connection between L5 and S1-E. Replace V106.

KRK29A/27 TUNER ALIGNMENT

Models 21-S-348U to 21-S-369GU Incl.

VHF ALIGNMENT.—A tuner unit which is operative and requires only touch up adjustments, requires no presetting of adjustments. For such units, skip the remainder of this paragraph. For units which are completely out of adjustment, preset C27 all the way out. Set channel 7 to 13 oscillator slugs one turn from tight. Turn T2 slug all the way out. Do not change any of the adjustments in the antenna matching unit.

Disconnect the link from terminals "A" and "B" of T104 and terminate the link with a 39 ohm composition resistor.

Turn the receiver channel selector switch to channel 2.

The 43.5 mc. trap is adjusted with zero bias. To insure that the bias will remain constant, take a clip lead and short circuit the AGC terminal of the tuner at the terminal board to ground.

Connect the oscilloscope to the test point TP2 on top of the tuner unit. Set the oscilloscope to maximum gain.

Connect the output of the VHF signal generator to the output of the antenna matching unit at the junction of L5 and C4 at the bottom of the FM trap L5.

Tune the signal generator to 43.5 mc. and modulate it 30% with a 400 cycle sine wave. Adjust the signal generator for maximum output.

Adjust C33 on top of the tuner, for minimum 400 cycle indication on the oscilloscope. If necessary, this adjustment can be retouched in the field to provide additional rejection to one specific frequency in the i-f band pass. However, in such cases, care should be taken not to tune C33 into channel 2, thereby reducing sensitivity on channel 2.

Connect the potentiometer arm of one of the bias supplies to the AGC terminal on the tuner and ground the battery positive terminal to the tuner case. Adjust the bias potentiometer to produce —3.0 volts of bias, as measured by the "VoltOhmyst" at the AGC terminal on the tuner.

Turn the fine tuning control fully clockwise.

Adjust C25 for proper oscillator frequency, 227 mc. This may be done in several ways. The easiest way and the way which will be recommended in this procedure will be to use the signal generator as a heterodyne frequency meter and beat the oscillator against the signal generator. To do this, tune the signal generator to 227 mc. with crystal accuracy. Insert one end of a piece of insulated wire into the tuner unit through the hole provided for the adjustment of C16. Be careful that the wire does not touch any of the tuned circuits as it may cause the frequency of the tuner oscillator to shift. Connect the other end of the wire to the "r-f" in terminal of the signal generator. Adjust C25 to obtain an audible beat with the signal generator.

Turn C27 clockwise until the beat note just begins to change, then turn one full turn in the same clockwise direction.

Return the fine tuning control to the mechanical center of its range.

NOTE:—If on some units, it is not possible to reach the proper channel 8 oscillator frequency by adjustment of C25, switch to channel 13 and adjust L49 to obtain proper channel 13 oscillator frequency as indicated in the table on page 8. Then, switch to channel 12 and adjust L60 to obtain proper channel 12 oscillator frequency. Continue down to channel 8, adjusting the appropriate oscillator trimmer to obtain the proper frequency on each channel. Then again on channel 8, adjust C25 to obtain proper channel 8 oscillator frequency. Switch back to channel 13 and readjust L49 and back to channel 8 and adjust C25.

Set the T2 core for maximum inductance (core turned counter-clockwise).

Connect the sweep generator through a suitable attenuator, as shown in figure 16 to the input terminals of the antenna matching unit.

Connect the signal generator loosely to the antenna terminals.

Set the sweep generator to cover channel 8.

Set the oscilloscope to maximum gain and use the minimum input signal which will produce a usable pattern on the oscilloscope. Excessive input can change oscillator injection during alignment and produce consequent misalignment even though the response as seen on the oscilloscope may look normal.

Insert markers of channel 8 picture carrier and sound carrier, 181.25 mc. and 185.75 mc.

Adjust C21, C16, C11 and C7 for approximately correct curve shape, frequency, and band width as shown in figure 24.

The correct adjustment of C7 is indicated by maximum amplitude of the curve midway between the markers. C11 tunes the r-f amplifier plate circuit and affects the frequency of the pass band most noticeably. C21 tunes the mixer grid circuit and affects the tilt of the curve most noticeably (assuming that C7 has been properly adjusted). C16 is the coupling adjustment and hence primarily affects the response band width.

Connect the "VoltOhmyst" to test point TP1. Adjust C22 to read —3.0 volts dc on the "VoltOhmyst" at TP1. Readjust C27, C21, C16 and C11 for proper response. Adjust C7 for maximum gain at midpoint of the curve. Repeat if necessary until the proper response is obtained.

Set the receiver channel switch to channel 13.

Adjust the signal generator to the channel 13 oscillator frequency 257 mc.

Turn the fine tuning control fully clockwise.

Adjust L49 to obtain an audible beat. Slightly overshoot the adjustment of L49 by turning the slug an additional turn in the same direction from the original setting, then reset the oscillator to proper frequency by adjusting C27 to again obtain the beat.

Set the sweep generator to channel 13.

From the signal generator, insert channel 13 sound and picture carrier markers, 211.25 mc. and 215.75 mc.

Adjust L36 and L20 for proper response as shown in figure 24.

Turn off the sweep and signal generators.

Connect the "VoltOhmyst" to the tuner test point TP1.

Check the oscillator injection voltage to be within limits as previously specified. Adjust if necessary to bring within range.

If it was necessary to readjust C22, turn the sweep and signal generators back on and recheck the channel 13 response. Readjust L36 and L20 if necessary.

Set the receiver channel selector switch to channel 8 and readjust C27 for proper oscillator frequency, 227 mc.

Set the sweep generator and signal generator to channel 8.
