INDEX

General

BUILT-IN "ROTO-SCOPE" ANTENNA

The built-in "Roto-Scope" antenna is operated by the antenna control lever which extends from the back of the cabinet (near the top). Set the antenna control lever in that one of its three positions (left, center, or right) which gives the clearest picture.

When an external indoor or an outdoor antenna is required, be sure to disconnect the built-in Roto-Scope antenna leads from the antenna terminal board. When disconnected, tape the Roto-Scope antenna lead lugs and place them away from the chassis.

INPUT IMPEDANCE and TRANSMISSION LINES

The input impedance to the receiver is 300 ohm balanced (between antenna terminals). When using a 300 ohm transmission line connect it across the antenna terminals.

Input impedance between one antenna terminal and chassis is approximately 75 ohms. When using 75 ohm coaxial transmission line, connect the outer conductor to the chassis and the inner conductor to either antenna terminal; use the terminal which gives the most satisfactory picture on the weakest station.

FUSE LOCATION

The horizontal output circuit is fused with a 1/4 amp, 250 volt fuse, part #84A4-2. The fuse is located in the back end of the high voltage compartment.

CHASSIS NOTES

Chassis used in the straight TV and combination models differ in that the combination models have connectors for supplying power to the radio and the cabinet pilot light.

To service the television chassis in combination models with the radio disconnected, it will be necessary to complete the heater circuit by connecting a wire jumper from pin "L" to pin "K". See plug and socket drawing on schematic. Since the radio receives its power from the television chassis, it cannot be operated without the television chassis.

Important: If both the radio and television are turned on at the same time, neither unit will operate.

PICTURE TUBE HANDLING PRECAUTION

Due to the high vacuum and large surface area of picture tubes, great care must be exercised when handling these tubes. Shatterproof goggles and heavy gloves should be worn while handling or installing a picture tube. The picture tube must not be scratched or subjected to excessive pressure as fracture of the glass will result in an explosion of considerable violence which may cause personal injury or property damage.

HIGH VOLTAGE WARNING

High voltages are present throughout this receiver. Operation with cabinet removed involves shock hazard. Exercise normal high voltage precautions while working with this set.

Installing the Television Receiver

After the antenna is set properly, make all checks or adjustments given here to insure best performance and ease in tuning. ***It is especially important that the Channel Slugs and Ion Trap be adjusted upon installation or servicing of every set.***

For best results, all checks or adjustments should be made using a transmitted television test pattern. A mirror placed in front of the picture tube screen will be of help in observing the picture while adjusting rear panel controls.

NOTE: If both radio and television are turned on in combination models, neither unit will operate. Be sure set owner has been properly instructed on the operation.

TUNE IN A PICTURE

Tune in a picture as instructed in the customer instruction leaflet; note illustrations on interference effects.

ADJUST CHANNEL SLUGS

Individual channel oscillator adjustment of every receiver should be checked upon installation or servicing. If this adjustment is properly made, it is possible to tune from one station to another by merely turning the CHANNEL control and if necessary, slightly readjusting the TUNING control. With correct oscillator channel adjustment, best picture and satisfactory sound will be located at the approximate center (half rotation) of the range of the Tuning control.

This adjustment can be made without removing the chassis from the cabinet. Adjust as follows:

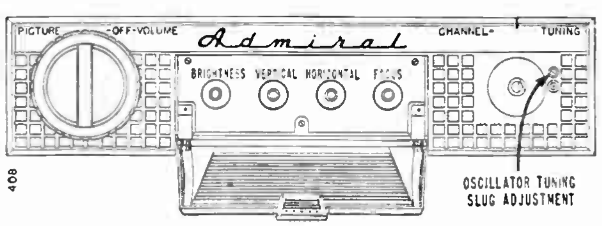
a. Turn the set on and allow 15 minutes to warm up.

b. Set the CHANNEL knob for a station; set other controls for normal picture and sound.

c. Set TUNING control at center of its range by rotating it approximately half-way.

d. Remove the CHANNEL and TUNING knobs.

e. Insert a 1/8" blade, NON-METALLIC screwdriver in the 1/4" hole (to the right of the channel tuning shaft). For each channel in operation, carefully adjust the oscillator slug for clearest picture detail. Then check sound, and if necessary readjust for minimum buzz. Only slight rotation of the slug will be required; turning the slug in too far will cause the slug to fall into the coil. (If an oscillator slug should fall into the channel coil, remove the coil, move the slug retaining spring aside, lightly tap the open end of the coil against a solid object until the slug slips out. Replace slug and set the slug retaining spring into its cut-out slot.)



Control Panel; CHANNEL and TUNING Knobs Removed.

ADJUST THE ION TRAP

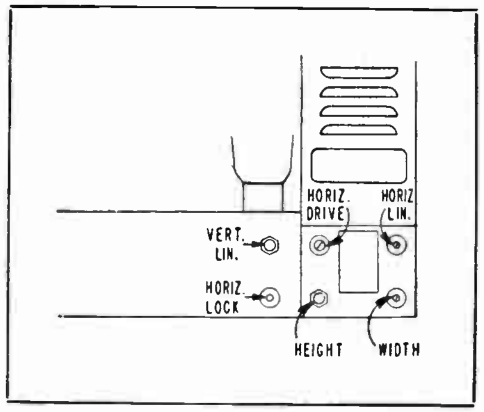
In order to prolong the life of the picture tube, it is important that this adjustment be made on every receiver upon installation or servicing.

These sets use a 16TP4 or 16RP4 picture tube. If the set has the 16TP4 tube, locate the ion trap on the neck of the tube with the blue sleeve on top and the magnet to the left (facing rear of chassis). With the 16RP4 tube, locate the blue sleeve to the left and the magnet at the bottom. Starting from a point close to the tube base, very carefully move the ion trap forward or backward, and at the same time rotate it slightly in either direction; adjust for the brightest picture possible with the BRIGHTNESS control set for average brightness.

Note that there may be two locations where the brightest picture can be produced. The second ion trap location, which is further forward on the tube neck, should not be used.

Important: Should the corners of the picture become rounded off or shaded after adjusting the ion trap, correct this by moving the deflection yoke coil "E" as far forward as possible and then adjusting the picture positioning lever (or the focus coil if necessary) as described below. Do not try to remove shaded corners with adjustment of the ion trap. Be sure to readjust the ion trap after adjusting the picture positioning lever or repositioning the focus coil.

The 16TP4 picture tube uses ion trap, part number 94A15-2; the 16RP4 tube uses ion trap, 94A15-1. The part number is stamped on the ion trap magnet. The wrong ion trap may cause shaded corners or insufficient picture brightness.



Chassis Views Showing Adjustment Locations.

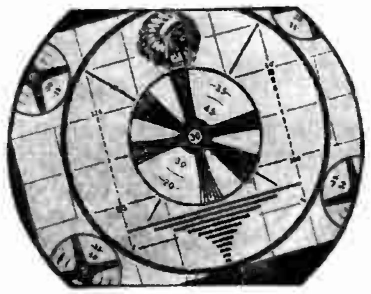
World Radio History

CHECK PICTURE TILT

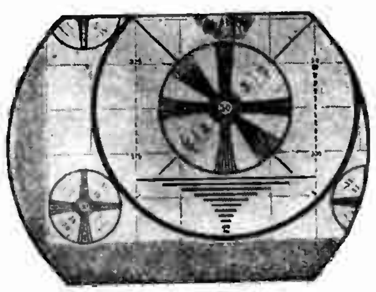
If the picture is tilted, loosen the wing nut "H" on the deflection yoke coil and slightly rotate the yoke "E" until the picture is straight. Before tightening the wing nut, be sure that the yoke is moved as far forward as possible, otherwise corners of the picture may become shaded.



Picture Tilted; Adjust Deflection Yoke Coil.

CHECK PICTURE CENTERING

If the picture is off center, it can be centered by using the picture positioning lever, and when necessary, re-positioning the focus coil around the picture tube neck. Follow the instructions given below. *Note that the picture positioning lever can be moved sideways, or up and down.*



Picture Not Centered; Adjust Picture Positioning Lever.

Picture Slightly Off Center

a. Adjust ion trap as instructed on preceding page.
b. Slightly loosen the screw "A" which locks the picture positioning lever to the focus coil, adjust the lever for correct picture centering.
c. Readjust the ion trap.

Picture Greatly Off Center

a. Adjust ion trap as instructed on preceding page.
b. Slightly loosen the two screws "B" which hold the focus coil to the yoke bracket. Center focus coil around the tube neck; tighten screws.
c. Loosen the screw "A" and center the picture with the picture positioning lever. If the picture cannot be centered with the lever, it may be necessary to locate the focus coil slightly off center and then center the picture with the picture positioning lever.
d. Readjust the ion trap.

Difficulty in Centering Picture or Eliminating Shaded Corners

a. Loosen screws "G", then move the yoke support bracket forward until rubber grommet "F" is firmly against the flare of the picture tube.

b. Push the deflection yoke coil "E" as far forward as possible. In some cases, it may be necessary to loosen the two yoke bracket support screws "D" at the sides of the upper mounting bracket, move the bracket up or down, and then move the deflection yoke coil as far forward as possible.

Shaded corners may also result from use of the wrong ion trap. The 16TP4 picture tube uses ion trap 94A15-2; the 16RP4 picture tubes uses ion trap 94A15-1. The part number is stamped on the ion trap magnet.

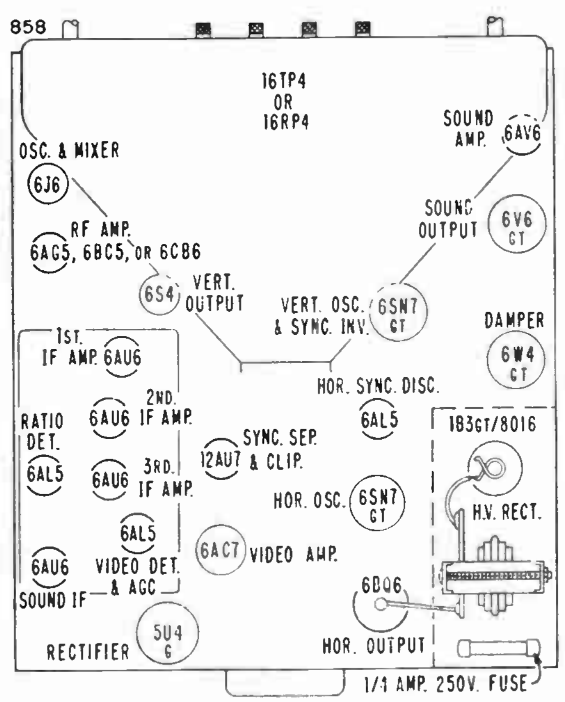
SCHEMATIC NOTES

[1], [2], [3] etc. are run numbers and indicate a production change. Run numbers are rubber stamped at rear of chassis.

(A1), (A2),......(Y), (Z), etc. indicate alignment points and alignment connections.

TV VOLTAGE DATA
(Voltages given on schematic diagram)

- PICTURE control turned fully clockwise. CHANNEL control set on an unused channel. Other front controls set at approximately half rotation. Vert. Lin. and Height set at approximately half rotation.
- Voltages marked with an asterisk * will vary widely with control setting.
  In combination models, B+ voltages in TV chassis will be slightly higher when set is switched to radio position. Alternate voltage readings for radio and TV are shown for sound output tube V204 (6V6GT).
- Line voltage 117 volts AC.
- Voltages measured with a vacuum tube voltmeter between tube socket terminals and chassis, unless otherwise indicated.
  Voltages at V101, V102, V306 measured from top of socket with tube removed.



Top View of Chassis.

- Antenna disconnected from set with terminals shorted.
- Under operating conditions, AGC (Automatic Gain Control) voltage developed at pin 1 of V301 (6AU6) should measure approximately —3 volts. This voltage depends on picture signal strength and Picture control setting.

CAUTION

Pulsed high voltages are present on the cap of the 6BQ6GT tube, and on the filament terminals and cap of the 1B3GT tube. NO ATTEMPT SHOULD BE MADE TO TAKE MEASUREMENTS FROM THESE POINTS UNLESS SUITABLE TEST EQUIPMENT IS AVAILABLE.

Picture tube 2nd anode voltage can be measured from the 2nd anode connector and should be taken only with a high voltage instrument such as a kilovoltmeter. 2nd anode voltage is approximately 12.5 KV. Proper filament voltage check of the 1B3GT tube may be made by observing filament brilliancy as compared with that obtained with a 1.5 volt dry cell battery.

RADIO VOLTAGE DATA
(Voltages given on schematic diagram)

- Line voltage 117 volts AC.
- Voltages measured with a vacuum tube voltmeter, between tube terminals and chassis.
- Voltages measured with band switch on FM position, unless otherwise indicated; an AM reading is given where difference is significant.
- Volume control set at minimum.
- Dial turned to low frequency end.
- Antennas disconnected.

▲When R602 is 240 ohms, voltage on pin 1 of V601 is 152 volts, pin 2 is —.5 volts, pin 6 is 152 volts and pin 8 is 1.9 volts.
When R602 is 1500 ohms, voltage on pin 1 of V601 is 160 volts, pin 2 is —3 volts, pin 6 is 160 volts and pin 8 is 3 volts.

IMPROVED NOISE IMMUNITY IN THE HORIZONTAL SYNC CIRCUIT OF 21B1 AND 21C1 CHASSIS

In some areas where the noise level is high, the noise peaks may affect the sync sircuit and cause the picture to shake horizontally or lose horizontal sync.

A change in resistor value and an additional filter in the sync circuit has been incorporated in late production to reduce this trouble.

The circuit change began with run 2 of 21B1 chassis and run 5 of 21C1 chassis.

Early production receivers may be modified by following the procedure given below:

1. Locate a 9 lug terminal strip adjacent to the vertical output transformer.
2. Remove R323 (8200 ohms) from lugs 4 and 6.
3. Connect an 18,000 ohm 1/2 watt resistor (part number 60B8-183) between lugs 5 and 6.
4. Connect a 140 μμfd condenser (part number 65B1-26 with a 270K 1/2 watt resistor, (part number 60B8-274) in parallel between lugs 4 and 5.

PRODUCTION CHANGES

RUN 1 in 21C1 CHASSIS

Resistor R430 was changed from 12,000 ohms, ½ watt to 12,000 ohms, 2 watt (part #60B20-123). This change was made to prevent possible increase in resistance of R430 due to increased power dissipation.

RUN 2 in 21C1 CHASSIS

In early sets R210 was 270,000 ohms; R211 was 100,000 ohms. In later sets R210 was changed to 150,000 ohms, ½ watt (part #60B8-154); R211 was changed to 47,000 ohms, ½ watt (part #60B8-473). This change resulted in improved audio response on radio operation.

RUN 3 in 21C1 CHASSIS

Condenser C433, .002 mfd, 600 volts (part #64B5-14) was added across width control L402 to increase sweep width.

INTERFERENCE TRAP ADDED

Later production sets have an Adjacent Channel Interference Trap added between the connector lug (terminal of C113) on the TV tuner and pin 1 of 1st video IF amplifier V301 (6AU6). This trap consists of L307 and C314; it has part number 72A102.

IMPORTANT

This preliminary service data contains the complete electrical parts list for models using the 21B1, 21C1 television chassis and for the 5D2 (AM-FM) radio chassis. It also includes cabinet parts for models 36R37, 36R45, 36R46. It contains alignment data for the television chassis.

This TV chassis uses a 16" rectangular picture tube. It uses an improved intercarrier sound system (adjacent channel trap and improved sound take-off) and Automatic Gain Control circuits which are similar to the 20X1, 20Y1, 20Z1 chassis. Sweep circuits are similar to 24D1, 24E1, 24F1, 24G1, 24H1 chassis.

Model RC500 or Model RC550 record changer is used.

MISCELLANEOUS PARTS for TV CHASSIS

Sym.	Description	Part No.
M201	Speaker Socket	88A 5-6
M202	Speaker Plug	88A 5-5
M203	Speaker	
	5" PM	78B 59-1
	8" PM	78B 49-1
	12" PM	78B 56-2
M204	Socket, Audio Input	88A 1
M401	Horizontal Output Fuse, 1/4 amp., 250 volts	84A 4-2
	Fuse Holder	84A 5-1
M501	Interlock Socket (Male)	89A 22-2
M502	Line Cord, with interlock socket	89A 22-1
M503	Cable Socket (Combination models only)	88A 20-2
SW501	Switch, On-Off Power (S.P.D.T.)	Part of R208
V306	Picture Tube	16RP4 or 16TP4
	Bracket, Deflection Yoke Holding	15A 572
	Bracket, Picture Tube Mounting (Supports front of picture tube)	
	Right side (facing tube)	15B 615-1
	Left side (facing tube)	15B 615-2
	Bracket (for mtg. picture tube and focus coil)	
	Top	15C 613
	Bottom	15C 614
	Bracket, Tuner Shaft (Bakelite)	32A 111-1
	Clamp, Picture Tube Front Mounting Bracket (clamps bracket to chassis)	15A 616
	Clamp, Webbing (for mtg. picture tube)	15A 526
	Clip, Tube Cap	
	for 6BQ6GT tube	88A 16-8
	for 1B3GT tube	19A 54
	Connector Lead, 2nd Anode (includes plug)	88A 16-7
	Cover, IF Strip	15B 641
	Fuse Holder	84A 5-1
	Insulating Plate (for 2nd anode filter condenser mtg.)	32A 135-1
	Ion Trap	
	for 16TP4 picture tube	94A 15-2
	for 16RP4 picture tube	94A 15-1
	Lever, Focus Coil Adjusting	15B 574
	Lock, 1B3 Mounting Shell Disk	15A 589
	Pilot Light (#47)	81A 1-8
	Pilot Light Socket (used in combination models)	82A 11-58
	Rubber Channel, 1" long (for picture tube bracket)	12A 9-11
	Rubber Collar (mounted over picture tube neck)	12B 40
	Rubber Grommet, 2nd Anode Housing	12A 2-7
	Rubber Insert, 1" diamter (bottom and side support of picture tube)	12A 16-1
	Rubber Strip, Adhesive (3/16"x3/8"x2" used under webbing band)	12A 5-6
	Shield, Tube	
	plain type	87A 7-7
	slotted type	98A 45-73
	Socket, Jewel Light	87A 6-3
	Socket, Shell (cover for 1B3 tube socket)	88A 27-1
	Socket, Tube	
	miniature bakelite (7 pin)	87A 3-7
	octal, plain	87A 5-1
	octal, ringmount (mica filled)	87A 20-2
	miniature (9 pin)	87A 25-1
	picture tube	87B 31-5
	Socket, Test (4 terminal)	10A 28
	Spring, Picture Tube Grounding	19A 23-2
	Tuner, Television (complete)	94A 18-4
	Webbing, Picture Tube Mtg. Strap (42" length)	50A 3-4

MISCELLANEOUS PARTS for TV TUNER 94C18-4

Sym.	Description	Part No.
M104	Shaft Shell & Rotor Assy. (Sharp Tuning) (with 4 1/16" long brass shaft shell)	98A 45-92
M107	Bracket, Sharp Tuning Rotor Retaining	98A 45-95
M108	Spring, Detent Plate Grounding	98A 45-94
M109	Shield, Tube (Slotted; for 6J6)	98A 45-73
M110	Shield, Tube (Plain; for 6AG5)	87A 7-7
M112	Spring, Slug Retaining (Osc. coil)	98A 45-52
M113	Washer, Fibre Spacer (1/4" IDx1/2" OD)	98A 45-63
M114	Nut, Locking Spring (for trimmers)	98A 45-31
M115	Screw, Trimmer (4-36x5/8")	98A 45-33
M116	Screw, Bracket Mtg. (6-32x1/4")	98A 45-62
M117	Slug, Brass Tuning	98A 45-88
M118	Stator Plate (ungrounded); Silver with Ceramic Insulator, for Sharp Tuning C111 (includes mtg. bracket)	98A 45-86
M120	Tuner, Television (complete)	94C 18-4
M121	Roller, Detent (3/8" dia., 3/32" dia. bearing)	98A 45-82
M122	Spring, Detent (2 5/16" long)	98A 45-81
M123	Contact Plate and Bracket Assembly (Uses Wiping Contacts)	98A 45-84
M124	Spring, Sharp Tuning Rotor Contact (Flat bronze 1 7/16"x1/2")	98A 45-83
M125	Spring, Front and Rear Turret Shaft (Wire 2 3/4" long, 3/64" dia.)	98A 45-85
M126	Turret and Shaft Assembly (less coils) (5 3/8" shaft and 3/16" rounded detent depression)	98A 45-91

MISCELLANEOUS PARTS for 5D2 RADIO

Sym.	Description	Part No.
M601	Socket, Phono Input	88A 1
M606	Socket, Phono Motor	88A 8-7
M607	Plug and Shielded Cable	89A 29-11
M608	Plug, 14 Pin	88A 20-1
	Cover, Plug (for M608)	88A 20-12
	Cable (9 wire), includes plug M608	AB216
	Socket and Leads, Pilot Light	82A 2-3
SW601	Switch, "PH-AM-FM" (includes SW602)	76B 22
SW602	Switch, Phono Motor	76B 23
SW603	Switch, ON-OFF Power (S.P.D.T.)	Part of R619
	Antenna Lead (300 ohm transmission line, 32" length)	95A 16-11
	Bracket, Tuning Sleeve	15A 394
	Clamp, Cable	11A 2-9
	Cover Assembly, Chassis	A1880
	Dial Back and Bracket Assembly	A3153
	Dial Cord (44" length)	50A 1-3
	Dial Scale	22B 22-1
	Escutcheon, Radio	23D 63-1
	Grommet, Rubber (Gang mounting)	12A 1-4
	Pilot Light (#47)	81A 1-8
	Plate, Switch	15A 409
	Pointer, Metal Dial	25A 37
	Pointer Cover, Plastic	25A 38
	Sleeve, Spacer (Gang mounting)	29A 2-10-71
	Sleeve, Spacer (AM loop mounting)	29A 3-15
	Snap Button (for mounting dial scale)	13A 1-1-71
	Socket, Tube	
	for Miniature Tube (7 pin)	87A 3-7
	for Miniature Tube (9 pin)	87A 25-2
	Speed Nut (for mtg. radio escutcheon)	2B 12-4-68
	Spring, Dial Cord Tension	19B 1-3
	Spring, Tube Retainer (for 12AT7)	19A 56-1

RECORD CHANGER PARTS

Model RC500 or Model RC550 record changers are used. The changer model number is on the top rear of the changer pan and also on the changer model label on the underside of the changer. For the RC500 changer refer to Service Manual No. S298; for the RC550 changer, refer to Service Manual No. S327.

Sym.	Description	Part No.
M602	Cable, Shielded (includes plug)	412A 11-2
M603	Cartridge, Push-in Needle Type (includes needle)	409A 13-1
	Cartridge, Knurled Nut Retaining Type (includes needle)	409A 13
M604	Motor (3 speed)	407B 19
M605	Plug, Motor (Male)	88A 8-1
	Adapter, 45 RPM (envelope of 12)	48A 8-1
	Belt, Rubber Drive	406A 20
	Idler Wheel Assembly (includes tire)	G400A 279
	Manual, Service	
	for RC500 changer	S298
	for RC550 changer	S327
	Needle, Phonograph	
	for 409A13 cartridge	98A 15-19
	for 409A13-1 cartridge	98A 15-18
	Needle Retaining Nut (for 409A13 cartridge)	98A 54-2
	Spring, Changer Float	405A 139
	Touch-Up Paint	
	Coppertone	98A 54-3
	Gold Hammertone	98A 54-12

PARTS for TILT-OUT MECHANISM

Description	Part No.
Eye Bolt (for tilt-out spring)	1A 87-1
Grommet, Rubber (for tilt-out spring)	12A 1-1
Hinge Assembly, Tilt-Out	
Left side (facing front)	AC183-1
Right side (facing front)	AC183-2
Screw, Tilt-Out Brkt. Shipping (10-24x3/8")	1A 51-25-71
Screw, Tilt-Out Adjusting Bracket Mtg. (#8-32x1/4" Bd. H.M.S.)	85-250-C2-71
Screw, Tilt-Out Tie Rod Mtg. (#6-32x1/4" Bd. H.M.S.)	365-250-C2-71
Spring, Tilt-Out Coil (2 3/8" unstretched)	19A 15-1
Spring, Tilt-Out Arm Retaining (7 1/4" unstretched)	19A 59
Tie Rod, Tilt-Out	28A 22-1

CABINET PARTS for 36R37 (Blond), 36R45 (Walnut), 36R46 (Mahogany)

The above model numbers may contain the suffix "N"

Part No.	Description
A3060	Antenna, Built-in TV
AB195	Antenna, Built-in FM
43C 129-1	Back, Radio-Phono and Record Compt.
A3224	Back, TV Compt. (Complete)
*35E 123-55	*Base, Cabinet (Legs), Blond
*35E 124-57	*Base, Cabinet (Legs), Walnut
*35E 124-58	*Base, Cabinet (Legs), Mahogany
*35E 123-3	*Cabinet, Blond
*35E 124-1	*Cabinet, Walnut
*35E 124-2	*Cabinet, Mahogany
44B 173	Carton and Fillers, for 36R37
44B 172	Carton and Fillers, for 36R45, 36R46
98A 60-7	Caster (for cabinet leg)
11A 2-6	Clamp, Cable
*35E 123-53	*Door, Record Compt. (Complete) Blond
*35E 124-53	*Door, Record Compt. (Complete) Walnut
*35E 124-54	*Door, Record Compt. (Complete) Mahog.
*35E 123-51	*Doors, TV and Radio-Phono Compt., Blond (matched pair)
*35E 124-50	*Doors, TV and Radio-Phono Compt., Walnut (matched pair)
*35E 124-51	*Doors, TV and Radio-Phono Compt., Mahogany (matched pair)
35E 124-56	Door Catch and Strike Plate, for Walnut and Mahogany
35E 123-59	Door Catch and Strike Plate, for Blond
23D 60-4	Escutcheon, Control (Plastic; less door)
23D 60-1	Escutcheon Door (Plastic)
23D 63-1	Escutcheon, Radio
98A 61-8	Gasket, Sponge Rubber (includes chipboard back for picture window)
36B 16-1	Grille, Metal, for Blond
36B 13	Grille, Metal, for Walnut and Mahogany
36B 13-1	Grille Rosette (for 36B13 grille)
36B 3-20	Grille Cloth (2 pieces) for Blond
36B 3-27	Grille Cloth (2 pieces) for Walnut & Mahog.
37A 23-1	Handle, Door (for upper doors) for Blond
37A 25-1	Handle, Door (for upper doors) for Walnut and Mahogany
33A 41-2	Handle, Door (for blond record compt. door)
35E 123-57	Hinge, Knife (Pair), for Blond
35E 124-55	Hinge, Knife (Pair), for Walnut & Mahog.
82A 10-8	Jewel, Pilot Light (Green)
33D 55-1	Knob, Radio, 'PH-AM-FM', 'Tuning'
33D 55-4	Knob, Radio, 'Off-Volume'
33D 55-5	Knob, Radio, 'Tone'
33C 53-9	Knob, TV, 'Channel'
33C 53-10	Knob, TV, 'Tuning'
33C 53-11	Knob, TV, 'Off-Volume'
33C 53-12	Knob, TV, 'Picture'
81A 1-8	Light, Pilot #47
89A 22-1	Line Cord and Interlock Socket
6A 4-6-0	Line Cord Mounting Rivet
1A 7-23-71	Screw, for mtg. picture window (#6x3/8 R.H.W.S.)
1A 7-9-57	Screw, for mtg. control escutcheon (#4x3/8 R.H.W.S.)
1A 7-24-71	Screw, for mtg. cabinet back (#6x1/2 R.H.W.S.)
1A 67-43-71	Screw, for mtg. TV chassis (1/4-20x1")
98A 44-47	Spacer, Fibre Cabinet Leveler (Kit of 6)
78B 56-2	Speaker, 12 inch PM
2B 10-24-59	Speed Nut (for mtg. radio escutcheon)
18A 45	Spring Clip (for mtg. picture window)
18A 41	Spring, Hinge (for mtg. escutcheon door)
18A 43-2	Spring, TV Knob Tension, "Off-Volume"
18A 43-1	Spring, TV Knob Tension, "Tuning"
18A 43-3	Spring, TV Knob Tension, "Channel"
	Tilt-Out Parts See "Parts For Tilt-Out Mechanism"
5A 4-14	Washer, Felt, behind "Channel" knob
5A 4-15	Washer, Felt, behind "Picture" knob
5A 4-11	Washer, Felt, behind radio knobs
23D 67	Window, Picture
	If only mounting tab is broken on picture window, a new metal tab (part number 15A668) can be installed with a soldering iron. Instructions (Form S340) included with tabs.

* To insure proper matching and fit, also specify cabinet manufacturer's code letters (usually burned or stamped on back rail of cabinet). Wood parts are supplied only if old part cannot be repaired. When ordering describe condition of old part in detail.

TELEVISION ALIGNMENT PROCEDURE

ALIGNMENT ADJUSTMENT IDENTIFICATION

Adj.	Symbol	Frequency	Function	Adj.	Symbol	Frequency	Function
A1	T303	25.3 MC	3rd IF Transformer	A7	T201	4.5 MC	Secondary of Ratio Detector Transformer
A2	T301	25.3 MC	1st IF Transformer	A8	C102		Trimmer (RF Amplifier)
A3	T302	23.1 MC	2nd IF Transformer	A9	C104		Trimmer (RF Amplifier)
A4	L103	23.1 MC	Mixer Plate Coil	A10	C107		Trimmer (Mixer)
A5	T201	4.5 MC	Primary of Ratio Detector Transformer	A11	C110		Trimmer (HF Oscillator)
A6	L201	4.5 MC	Sound Take-off Coil	A12	L102		Slug, HF Oscillator Coils

IF AMPLIFIER ALIGNMENT

a. Before starting alignment, be sure IF cover shield is mounted to chassis.

b. Disconnect antenna and connect a jumper across antenna terminals.

c. Set receiver to channel 13 or other unassigned high channel to prevent signal interference during IF alignment.

d. Set Picture control fully to the right (clockwise). Retain this setting for all IF adjustments.

e. Allow about 15 minutes for receiver and test equipment to warm up.

f. To service TV chassis with radio disconnected, complete the heater circuit by connecting a jumper from pin "L" to pin "K" of socket M503. See schematic.

Step	Signal Gen. Freq. (MC)	VTVM and Signal Generator Connections	Instructions	Adjust
1	25.3	VTVM high side to test jack "T", common to chassis. Connect generator high side to 6J6 (V102) tube shield; insulate shield from chassis. Connect common to chassis near 6J6 tube base.	Use VTVM 3 volt DC scale. When peaking, keep reducing generator output for VTVM reading of approx. 1 volt or less.	A1 and A2 for maximum.
2	23.1			A3 and A4 for maximum.
3	To insure correct IF alignment, make the "IF Response Curve Check" given below, or make the "Overall RF and IF Response Curve Check (Step 1)" given later. The overall check should be made after making all other alignments.			

IF RESPONSE CURVE CHECK

(Using sweep generator and oscilloscope with sweep input to RF Mixer V102.)

Differences in tube gain and component values affect IF response. These differences are not apparent in alignment of IFs when using a signal generator and VTVM (single frequency alignment); hence it is preferable that an IF response curve check be made after completion of the IF amplifier alignment.

The IF response curve check can be made as indicated directly below. However, also note that a better check can be made by feeding the sweep signal through the entire RF and IF system as given under "Overall RF and IF Response Curve Check (Step 1)". The overall check should be made after making all other alignments.

a. Make all control settings and connections as given in the IF amplifier alignment chart; see "a" through "f" above.

b. Connect oscilloscope* between point "V" and chassis ground through a decoupling filter; see fig. 29. Keep leads away from receiver.

c. Connect sweep generator high side to tube shield of 6J6 (V102) osc-mixer tube. Be sure to insulate tube shield from chassis. Connect sweep generator common to chassis close to 6J6 tube base. Set sweep generator to sweep the IF band pass (19 to 29 MC).

d. Loosely couple marker generator high side to the sweep generator lead connected to tube shield on tuner; common to chassis ground.

To avoid distortion of the response curve, keep the sweep generator and marker generator outputs at a very minimum. Marker pips should be just kept barely visible. To minimize distortion, set sweep generator output for VTVM reading of approximately .5 volt DC, measured between test jack "T" and chassis. Connecting a 1½ volt battery (negative to test jack "T", positive to chassis) will allow greater signal input without distorting the response curve.

e. Check curve obtained against the ideal IF response curve shown in figure 28. Since it is not always possible to get ideal curves, it should be noted that the height of opposite peaks should be within 3db or 30% of each other. The dip or valley in the center of the curve should not be greater than 3db or 30% down from the highest peak of the curve. Check video and sound IF carrier points by means of marker generator. It is important that marker pips be in the proper location on the response curve. The 25.75 MC marker, should be 6db below the highest peak (50% point on the high frequency side of the curve). The 22 MC marker should be at the opposite side of the response curve, located approximately 18db (85%) below the highest peak. The 21.25 MC marker should be located at least 26db (95%) below the highest peak, and may or may not be visible.

Consistent with proper band width and correct location of markers, the response curve should preferably have maximum amplitude, symmetry, and flat top appearance.

If the procedure given has been carefully followed and the response curve obtained differs greatly from the curve shown in figure 28, repeat the IF Amplifier Alignment, making sure generator frequencies are precise and adjustments are accurately made.

* In dealing with RF and IF response curves, it is well to remember that an inverted or mirror image may result, depending on the sweep generator and oscilloscope used. The general waveform should still be identical.
When using a wide band oscilloscope for alignment, marker pips will be more distinct if condenser from 100 to 1,000 mmfd. is connected across the oscilloscope input. Caution: Use the smallest condenser possible, since too high a capacity will affect the shape of the response curve.

ALIGNMENT HINT

After becoming familiar with alignment procedure, some servicemen simplify subsequent alignment of sets by merely using the essential alignment data given in figures 29 and 30.

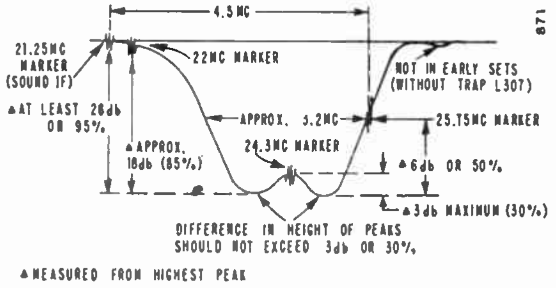

Figure 28. IF Response Curve.

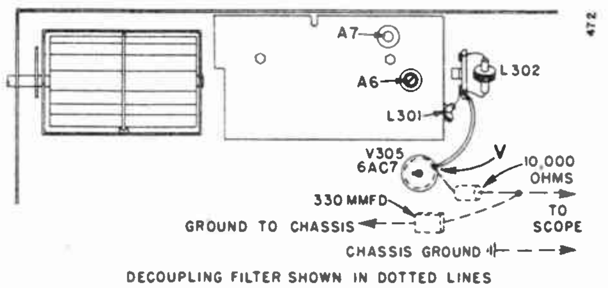

Figure 29. Bottom View Showing Test Point "V".

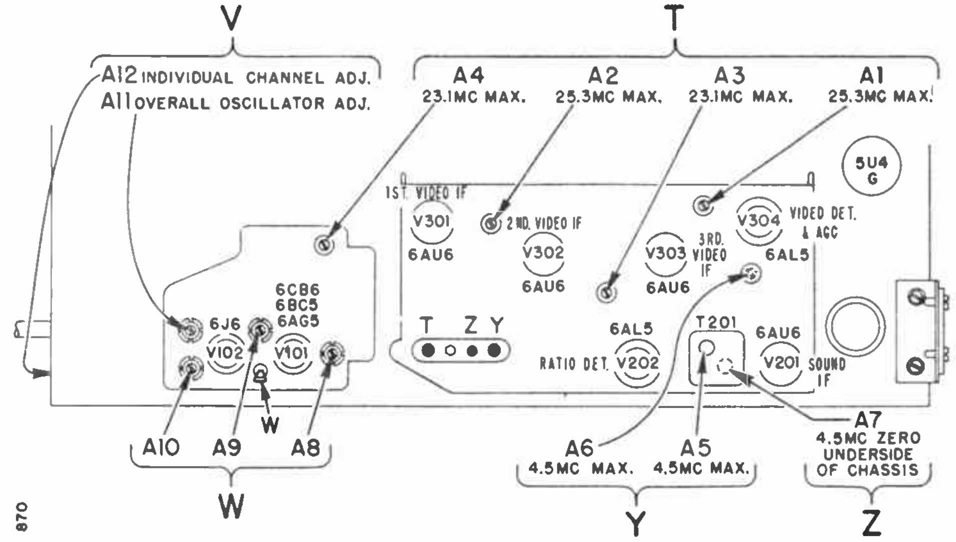

Figure 30. Top View of Chassis Showing Alignment Adjustment Locations.

4.5 MC SOUND IF ALIGNMENT

a. Disconnect antenna and connect a wire jumper across antenna terminals.

b. Set Picture control fully to the right (clockwise).

c. Connect signal generator high side to point "V" through a .01 mfd. condenser.

d. Allow about 15 minutes for receiver and test equipment to warm up.

e. Use a NON-METALLIC alignment tool. If Ratio Det. Transformer (T201) has hollow core slugs, bottom slug adjustment A7 can be made from top of chassis, if you use alignment tool #98A30-7 obtainable from Admiral Distributor. Bottom slug (A7) can be reached through the hole in the core of the upper slug (A5).

f. To service TV chassis with radio disconnected, complete the heater circuit by connecting a jumper from pin "L" to pin "K" of socket M503. See schematic.

Step	Signal Gen. Freq. (MC)	VTVM Connections	Instructions	Adjust
	Since the transmitted video and sound carriers have an accurate 4.5 MC frequency difference, a TV station signal may be used instead of a signal generator for alignment of steps below. When using a television signal, it may be necessary to use a higher scale on the VTVM. IMPORTANT: When using a signal generator, be sure to check it against a crystal calibrator or other frequency standard for accurate frequency calibration at 4.5 MC. Accuracy is required within one kilocycle.			
1	†4.5	To test jack "Y"	Use 3 volt DC scale on VTVM. Keep VTVM leads well separated from signal generator and chassis wiring.	A5 and A6 for maximum (keep reducing generator output to keep VTVM at approx. 1 volt).
2	†4.5	To test jack "Z"	Use 3 volt zero center scale on VTVM, if available. Keep VTVM leads well separated from signal generator and chassis wiring.	**A7 for zero on VTVM (the correct zero point is located between a positive and a negative maximum).

† Signal may be unmodulated or 400 cycle AM modulated.

** If A7 was far off, repeat steps 1 and 2.

©John F. Rider
World Radio History

RF AND MIXER ALIGNMENT

a. Disconnect 1½ volt battery from test jack "T" if used earlier. Connect a wire jumper from test jack "T" (Fig. 30) to chassis. Leave connected for all steps in this alignment.

b. Disconnect antenna from receiver.

c. Connect sweep generator to antenna terminals. If sweep generator does not have a built-in marker generator, loosely couple a marker generator to the antenna terminals. To avoid distortion of the response curve, keep sweep generator output at a minimum, marker pips just barely visible.

d. Connect oscilloscope through a 10,000 ohm resistor to test point "W" on tuner (Fig. 30). Keep scope leads away from chassis.

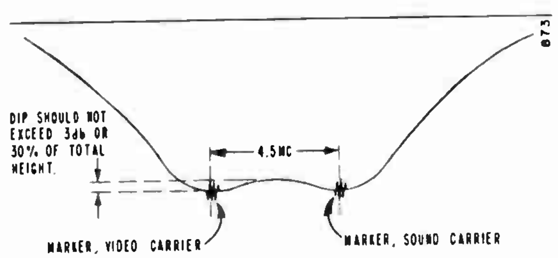
e. Allow about 15 minutes for receiver and test equipment to warm up.

f. To service TV chassis with radio disconnected, complete the heater circuit by connecting a jumper from pin "L" to pin "K" of socket M503. See schematic.

Step	Marker Gen. Freq. (MC)	Sweep Gen. Frequency	Instructions
1	*205.25 **209.75	Sweeping Channel 12	Check for curve resembling RF Response Curve shown below. If necessary, adjust A8, A9 and A10 (Figure 30) as required. Consistent with proper band width and correct marker location, response curve should have maximum amplitude and flat top appearance.
2	See table below.		Check each channel operating in the service area for curve resembling RF Response Curve shown below. When checking any channel, set the sweep and marker generators for the proper frequencies as indicated in the table below. In general, the adjustment performed in step 1 is sufficient to give satisfactory response curves on all channels. However, if reasonable alignment is not obtained on a particular channel, (a) check to see that coils have not been inter-mixed, or (b) try replacing the pair of coils for that particular channel, or (c) repeat step 1 for the weak channel as a compromise adjustment to favor this particular channel. If a compromise adjustment is made, other channels operating in the service area should be checked to make certain that they have not been appreciably affected.

* Video Carrier Frequency (MC). ** Sound Carrier Frequency (MC).

Channel Number	Channel Freq., MC	Video Carrier, MC	Sound Carrier, MC
2	54- 60	55.25	59.75
3	60- 66	61.25	65.75
4	66- 72	67.25	71.75
5	76- 82	77.25	81.75
6	82- 88	83.25	87.75
7	174-180	175.25	179.75
8	180-186	181.25	185.75
9	186-192	187.25	191.75
10	192-198	193.25	197.75
11	198-204	199.25	203.75
12	204-210	205.25	209.75
13	210-216	211.25	215.75



Full skirt of curve will not be visible unless generator sweep width extends beyond 10 MC.

Figure 31. RF Response Curve (see "Oscilloscope Note" below).

OSCILLOSCOPE NOTE

In dealing with RF and IF response curves, it is well to remember that an inverted or mirror image may result, depending on the sweep generator and oscilloscope used. The general waveform should still be identical.

When using a wide band oscilloscope for alignment, marker pips will be more distinct if condenser from 100 to 1,000 mmfd. is connected across the oscilloscope input. Caution: Use the lowest capacity condenser possible, since too high a capacity will affect the shape of the response curve.

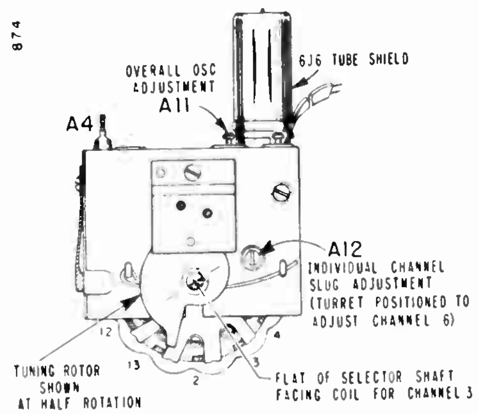


Fig. 32. Front View of Tuner.

OVERALL RF and IF RESPONSE CURVE CHECK (Step 1) and HF OSCILLATOR ALIGNMENT (Step 2)

(Using sweep generator and oscilloscope.)

a. Disconnect antenna.

b. Disconnect signal generator and VTVM (if used earlier).

c. Set the Tuning control at half rotation by rotating it approximately 150° as shown in figure 32. Set Picture control fully to the right (clockwise).

d. Connect sweep generator to antenna terminals. If sweep generator does not have a built-in marker generator, loosely couple a marker generator to the antenna terminals. To avoid distortion of the response curve, keep sweep generator output at a minimum, marker pips just barely visible. Connecting a 1½ volt battery (negative to test jack "T"; positive to chassis) will allow greater signal input without distorting response curve.

e. Connect oscilloscope between point "V" and chassis ground through a decoupling filter (see figure 29). Keep oscilloscope leads away from chassis.

f. Allow about 15 minutes for receiver and test equipment to warm up.

g. When adjusting A12, use a NON-METALLIC alignment screwdriver with a ⅛ inch blade.

h. To service TV chassis with radio disconnected, complete the heater circuit by connecting a jumper from pin "L" to pin "K" of Socket M503. See Schematic.

Step	Marker Gen. Freq. (MC)	Sweep Gen. Frequency	Instructions
1	While sweeping the RF band pass (channel 13 or other unassigned high channel), check the overall response curve obtained against the ideal curve shown below. If shape of curve is not within limits shown, it will be necessary to repeat the IF Amplifier Alignment. The IFs must be accurately aligned before correct oscillator adjustment can be made.		
2	See channel frequency table on previous page.		Check need for oscillator alignment by comparing the response curve obtained (for each channel operating in the service area) with the "Overall RF and IF Response Curve" shown below. With correct oscillator alignment, the video and sound markers should locate at the points shown on the response curve. The Tuning control must be at half rotation (see figure 32) when making this check. If a major number of channels are far off in the same direction, make the overall oscillator adjustment A11. (Touch-up of individual channel slugs A12 may also be required.) If only individual channel adjustment is required, adjust the proper channel slug A12. Make all oscillator adjustments so that the video and sound marker pips appear at the proper points on the response curve. Important: Before making oscillator adjustments, be sure that the Tuning control is set at half rotation; see figure 32. Only slight rotation of the slug (A12) will be required; turning the slug in too far will cause the slug to fall into the coil. (If an oscillator slug should fall into a coil, remove the coil, move the slug retaining spring aside, lightly tap the open end of the coil against a solid object until the slug slips out. Replace slug and set the slug retaining spring into its cut-out slot.)

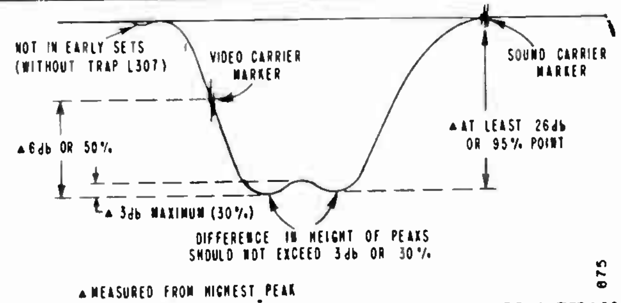

Fig. 33. Overall RF and IF Response Curve.

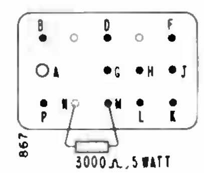
SERVICING RADIO SEPARATELY



The radio receives its operating voltages from the power supply on the TV chassis. It is necessary to use a separate power supply if the radio is to be operated without the TV chassis. The 2PA1 power supply, which is used in radio-phono-television combination sets with the 20Z1 (12" picture) television chassis and 5B2 radio, can be used to operate the 5D2 radio if a 3,000 ohm, 5 watt resistor (part number 61A1-15) is connected between pins M and N of the 2PA1 socket as illustrated.

5D2 RADIO PRODUCTION CHANGE

To improve sensitivity of the 5D2 radio, the 1st IF transformers in the AM and FM stages were changed.

The 1st AM-IF transformer (T604) used in early sets, part 72B97 has been replaced with part 72B97-1.

The 1st FM-IF transformer (T601) used in early sets, part 72B98 has been replaced with part 72B98-1.

To accommodate this change of the IF transformers, C608 has been changed from 40 mmfd (part 65B1-65) to 30 mmfd (part 65B1-69); R602 has been changed from 240 ohms, 5%, 1/2 watt (part 60B7-241) to 1,500 ohms, 1/2 watt (part 60B8-152).

IMPORTANT: All changes mentioned above must be made when replacing early IF transformers with late IF transformers.

©John F. Rider
World Radio History

Form No. S336-2

(1) Additions to the preliminary service data already published on 21B1, 21C1, 5D2 chassis.

(2) Circuit information on 21D1, 21H1, 21J1 television chassis and 3C1 radio chassis.

(3) Revised instructions on Horizontal Drive and Horizontal Linearity adjustments.

(4) Cabinet parts for models 16R12, 26R12, 26X55A to 26X75A, 26R25A to 26R37A, and 39X35, 39X36.

21D1, 21H1 and 21J1 CHASSIS

The 21B1 and 21C1 chassis use a 16" rectangular picture tube. The 21D1 chassis use a 16" round picture tube. The 21H1 and 21J1 chassis use a 19" round picture tube, which is mounted separately from the chassis.

The 21B1, 21C1 chassis (16" rectangular tube) and the 21H1, 21J1 chassis (19" round tube) are the same electrically except for some differences in the deflection yoke. See the schematic and the schematic inset (for the deflection circuit used in 19" sets).

The 21D1 (16" round) chassis differs in that the vertical and horizontal output circuits have differences in some component values, in the tube complement, and in B+ distribution. The vertical output tube is a 6W6GT in the 21D1 chassis; the horizontal output tube is a 6CD6GT. Since there are differences in the horizontal output circuit of the 16" round sets, adjustment of the horizontal drive will be different. See the discussion on the following pages.

3C1 RADIO (AM ONLY)

Combination models 39X35, 39X36 use the 3C1 radio (AM only). See schematic. The radio receives its operating voltage from the TV chassis. The radio can be operated separately from the television chassis by using the 2PA1 power supply as instructed in "Preliminary Service Data", Form No. S336-1.

PRODUCTION CHANGES AND SERVICE NOTES

RUN 4 in 21C1 CHASSIS and RUN 1 in 21B1 CHASSIS

Adjacent Lower Channel Sound Trap (L307 and C314) Added. Later production sets have an Adjacent Lower Channel Sound Trap added between the connector lug (terminal of C113) on the TV tuner and pin 1 of this 1st IF amplifier tube V301 (6AU6). The trap (part number 72A102), consisting of L307 and C314, is pre-tuned at 27.25 MC.

This trap will eliminate the herringbone interference pattern produced by the sound carrier of the adjacent lower channel. Close examination of this type of interference will reveal that the fine lines of the herringbone pattern will vary in accordance with the speech or music on the adjacent lower channel.

Since FM interference from other sources will also produce a herringbone pattern, the presence of interference from a station on the adjacent lower channel should be definitely determined before deciding that the trap is required. This can be checked by quickly turning the channel selector to the adjacent lower channel. After installing the trap, realign slug A4 (mixer plate coil L105) as instructed under "IF Amplifier Alignment" in Preliminary Service Data, Form No. S336-1.

All 21D1, 21H1, 21J1 chassis have this trap.

RUN 5 in 21C1 CHASSIS and RUN 2 in 21B1 CHASSIS

Noise Filter Added to Improve Sync Immunity to Noise. In areas where the noise level is high, noise peaks may affect the horizontal or vertical sync and cause the picture to shake horizontally or lose horizontal or vertical sync. A change in value of resistor R323 and an additional filter (R329 and C315) have been incorporated in the sync circuit of later production chassis to reduce this trouble. See schematic.

This circuit change began with run 2 of 21B1 chassis and run 5 of 21C1 chassis; all 21D1, 21H1, 21J1 chassis will have this sync circuit. Early production receivers may be modified by following the procedure given below:

1. Locate the 9 lug terminal strip adjacent to vertical output transformer T402.
2. Remove resistor R323 (8200 ohms) from between lugs 4 and 6, counting 1 from end of strip near T402.
3. Connect a 18,000 ohms, ½ watt resistor (part number 60B8-183) between lugs 5 and 6.
4. Between lugs 4 and 5, connect a 150 mmfd. mica condenser (part number 65B21-151) with a 270,000 ohm, ½ watt resistor (part number 60B8-274) in parallel.

RUN 2 in 21D1 CHASSIS – CHANGE in 21J1 CHASSIS

In some 21D1 and 21J1 chassis, condenser C433 was changed from .002 mfd, to .0047 mfd, 600 volts (part number 64B9-15). Some sets having this change use a single .0047 mfd. condenser; other sets use two .002 mfd. condenser in parallel. This change was made to increase sweep width. Condenser C433 is .002 mfd, in later sets using an improved horizontal output transformer.

R411 in 21D1 CHASSIS CHANGED to INCREASE RANGE of VERTICAL LINEARITY CONTROL (R410)

Resistor R411 was changed from 820 ohms, 1 watt to 680 ohms, 1 watt (part number 60B14-681). This change was made to increase the range of the VERT. LIN. control R410.

ALTERNATE VERTICAL OUTPUT TUBE (V402) in 21B1, 21C1, 21H1, and 21J1 CHASSIS

Some sets with 16" rectangular or 19" round picture tube may use a 6SN7GT tube as an alternate for the 6S4 vertical output tube (V402). The schematic shows the circuit used with the 6S4 tube; the schematic inset shows the circuit used with the 6SN7GT tube.

ALTERNATE IF TUBE (V301, V302, V303)

Some sets may use a 6AG5 tube as an alternate for the 6AU6 tube in the 3rd IF stage (V303); other sets may use a 6AG5 tube for the 1st. 2nd and 3rd IF stages (V301, V302 and V303). When the 6AG5 tube is used, tube socket terminal 2 is unused (not grounded) as pins 2 and 7 of this tube are connected internally. A tube shield is used in the 1st and 3rd IF stages with the 6AG5 tube.

ALTERNATE TUBE USED IN 3C1 RADIO

Early sets used a 6AV6 tube for V703 (Det-AVC-AF). A few of these early sets used the 6AT6 tube. Later production sets use the 6SQ7 tube, which is the metal tube equivalent.

ALTERNATE CONTROL ESCUTCHEONS

Two alternate control escutcheons are used with these sets. Although the escutcheons are interchangeable as a complete unit, individual parts for the two alternate escutcheons are not interchangeable. The different escutcheons can be identified by the type of door spring used and the differences in the cutout slot which supports the ends of the door springs.

The parts for the control escutcheon having an "I" shaped slot using a flat (bronze) door spring are:

Escutcheon, Control (less door)......23D 60-3
Escutcheon Door....................23D 60-2
Escutcheon Door Spring, Flat (bronze)..18A 41

The parts for the control escutcheon having a "U" shaped slot using a coil (wire) door spring are:

Escutcheon, Control (less door)...... 23D 60-6
Escutcheon Door.................... 23D 60-7
Escutcheon Door Spring, Coil (wire)
right side (facing front)............19A 65-1
left side (facing front)............. 19A 65-2

REPAIRING MOUNTING LUGS on PICTURE WINDOW

If only the mounting lugs are broken on picture windows 23D67, 23E62-1, and 23D61-1, a metal replacement lug can be pressed into the plastic by heating it with a soldering iron. Instructions for installing (Form No. S340) are included with the 3 lugs supplied under part number 15A668.

World Radio History

SERVICE ADJUSTMENTS

The following information on making the Horizontal Drive and Horizontal Linearity adjustment corrects and supercedes the information given in "Installation and Service Notes for 21B1, 21C1 Chassis", Form No. 41A9-13.

HORIZONTAL DRIVE and HORIZONTAL LINEARITY ADJUSTMENT for 21B1, 21C1, 21H1, 21J1 CHASSIS

If the large circle in the center of the test pattern has a cramped or flattened appearance at one side (non-linear horizontally), turn the HOR. DRIVE adjustment screw in fully (to the right), then slowly turn it out while adjusting for best linearity (circular shape). Note that the Horizontal Drive control also affects width and brightness.

If horizontal non-linearity can not be completely corrected with the HOR. DRIVE adjustment, further correction can be made by adjusting the HOR. LIN. control. Alternate adjustment of the Horizontal Drive and Horizontal Linearity controls may be necessary to obtain best linearity.

HORIZONTAL DRIVE ADJUSTMENT for 21D1 CHASSIS

This adjustment should be made so that the adjustment screw is as far out (to the left) as possible without producing vertical lines in the picture. Adjust as follows:

a. Turn the CHANNEL control to an unused channel.

b. Set BRIGHTNESS control at a lower than average setting.

c. Turn the HORIZONTAL control (front panel) completely to the left. (If the Horizontal control is not set at the extreme left position, the vertical lines may be removed in step "d", but may re-appear when the Horizontal control is rotated to the right.)

d. Turn the HORIZ. DRIVE adjustment screw to the left until a vertical line appear near the center of the raster. Then, turn the screw to the right just far enough to make the lines disappear. If the screw is turned further than required to eliminate the vertical lines, picture width and brightness may be affected.

Do not use the Horizontal Drive to correct width or linearity. If necessary, make the Width and Horizontal Linearity adjustments.

HORIZONTAL LINEARITY ADJUSTMENT for 21D1 CHASSIS

If the large circle in the center of the test pattern has a cramped or flattened appearance at either side (non-linear horizontally), adjust the HORIZ. LIN. adjustment screw by turning it to the left or right as required. Note that the Horizontal Drive and the Width adjustments also affect linearity. Be sure that these adjustments are set correctly if difficulty is encountered when making the horizontal linearity adjustment.

If vertical lines appear in the center of the picture when making the horizontal linearity adjustment, see "Horizontal Drive Adjustment for 21D1 Chassis" above.

Form No. S336-3

C433 INCREASED to OBTAIN SUFFICIENT WIDTH

To obtain sufficient width, C433 may be .0047 mfd, 600 V. (part number 64B8-15) in some 21D1, 21H1, 21J1 chassis. Also, some of the 21D1 chassis may use a .01 mfd, 600 V. condenser, part number 64B8-13.

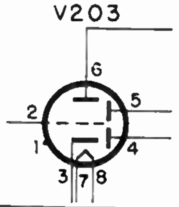
GRID RESISTOR REQUIRED WHEN V303 is 6AG5

When a 6AG5 is used at V303, an 18,000 ohms, ½ watt resistor (part number 60B8-183) is required from grid (pin 1) to ground.

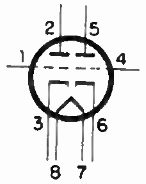
DIFFERENT TUBE USED for SOUND AMPLIFIER (V203)

Some sets may use a 6SQ7 tube instead of a 6AV6 tube at V203. There are no part changes necessary with this substitution. The pin numbering for the 6SQ7 is shown in the adjacent illustration.

6SQ7
V203



6SN7GT
V403



DIFFERENT TUBE USED for SYNC SEP. and CLIPPER (V403)

Some sets may use a 6SN7GT tube instead of a 12AU7 tube at V403. There are no part changes necessary with this substitution. The pin numbering for the 6SN7GT is shown in the adjacent illustration.

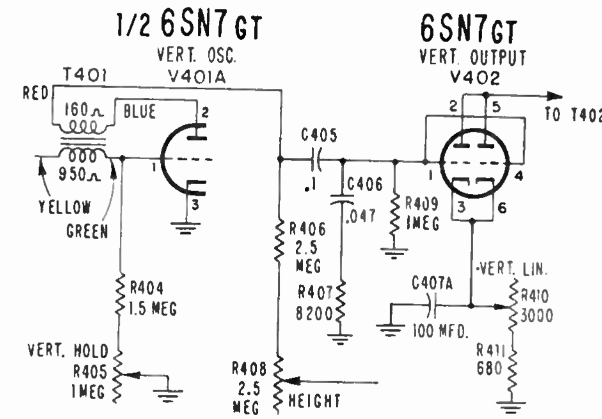
ALTERNATE CIRCUIT WHEN V402 is 6SN7GT

The schematic (in Form No. S336-2) for the 21B1, 21C1, 21H1, 21J1 television chassis shows an alternate circuit for V402 when a 6SN7GT tube is used in place of the 6S4. (See inset in lower left portion of schematic.)

Cross out this schematic inset and in its place use the circuit given in the adjacent illustration.

R404 1.5 megohms, ½ W....... 60B 8-155
R406 2.5 megohms, ½ W....... 60B 8-255

ALTERNATE CIRCUIT WHEN V402 IS 6SN7GT



RESISTOR ADDED in VERTICAL OSCILLATOR STAGE

In sets using a 6S4 or a 6W6GT tube in the vertical output stage (V402), a 150,000 ohms, 1/2 watt resistor (part number 60B8-154) is connected between R404 and the grid (pin 1) of the vertical oscillator (V401A, 6SN7GT). This resistor centers the operating point of the Vertical Hold control.

Add this resistor to both schematics. This resistor has been used since the beginning of production.

SUPPLEMENTARY PARTS LIST

This parts list contains corrections and additions to the parts list given in "Preliminary Service Data for models using 21B1, 21C1, 5D2 Chassis" (Form No. S336-1). Use this parts list FIRST, then use the list in the Preliminary Service Data.

RESISTORS

Sym.	Description	Part No.
§ R401	22,000 ohms, ½ watt	60B 8-223
§ R402	8,200 ohms, ½ watt	60B 8-822
§ R403	8,200 ohms, ½ watt	60B 8-822
R406	1 megohm, ½ watt, in sets using 6S4 vert. output tube (V402)	60B 8-105
	1.5 megohm, ½ watt, in sets using 6SN7GT vert. output tube (V402)	60B 8-155
	680,000 ohms, ½ watt, in sets using 6W6GT vert. output tube (V402)	60B 8-684
R407	8,200 ohms, ½ watt in 21B1, 21C1, 21H1, 21J1	60B 8-822
	10,000 ohms, ½ watt, in 21D1	60B 8-103
R409	1 megohm, ½ watt, in 21B1, 21C1, 21H1, 21J1	60B 8-105
	3.3 megohms, ½ watt, in 21D1, 21E1	60B 8-335
R410	3,000 ohms, Vert. Lin. for 21B1, 21C1, 21H1, 21J1	75B 13-7
	for 21D1, 21E1	75B 13-18
R411	820 ohms, ½ watt, in sets using 6S4 vert. output tube (V402)	60B 8-821
	680 ohms, ½ watt, in sets using 6SN7GT vert. output tube (V402)	60B 8-681
	680 ohms, 1 watt, in sets using 6W6GT vert. output tube (V402)	60B 14-821
	(R411 was 820 ohms in early (21D1) sets using 6W6GT tube, see production changes.)	
R415	820 ohms, 2 watt, in 21B1, 21C1, 21H1, 21J1	60B 20-821
	2,200 ohms, ½ watt, in 21D1, 21E1	60B 8-222
R435	8,200 ohms, 1 watt, in 21B1, 21C1, 21H1, 21J1	60B 14-822
	12,000 ohms, 1 watt, in 21D1, 21E1	60B 14-123
R619A	2 megohms, Volume pot.	75B 11-12
R619B	2 megohms, Tone pot.	
	(R619 includes on-off switch SW603)	

†Part of Diode Filter Unit 63A3-1 consisting of R707, C709, C710.

COILS and TRANSFORMERS

Sym.	Description	Part No.
L404	Focus Coil	
	for 21B1, 21C1, 21H1, 21J1	69C 117-3
	for 21D1, 21E1 (supplied less plug)	69C 117-4
L701	AM Antenna	
	Loop Antenna (includes C701, C702)	69C 116-2
	Iron Core Ant. (includes C701, C702)	69C 121-2
L702	Oscillator Coil	69A 52-1
T202	Audio Output Transformer	
	for TV only sets	79C 33-1
	for combination sets	79C 33-2
T402	Vertical Output Transformer	
	for 21B1, 21C1, 21H1, 21J1	79B 29-1
	for 21D1, 21E1	79B 34-1
T403	Deflection Yoke (includes R412, R413, R445, C430)	
	for 16" rectangular tube	A3222
	for 16" round tube	A3178
	for 19" round tube	A3197
	(A3197 includes connector plug)	
T404	Horizontal Output Transformer (includes tube cap clips)	
	for 21B1, 21C1, 21H1, 21J1	79C 30-2
	for 21D1, 21E1	79C 30-3
T701	1st IF Transformer	72B 28-7
T702	2nd IF Transformer	72B 28-17

MISCELLANEOUS PARTS for TV CHASSIS

Picture tube mounting parts listed below are for 16" tubes. See separate heading for 19" tube mounting parts.

Sym.	Description	Part No.
M203	Speaker	
	5" PM	78B 59-1
	8" PM	78B 49-1
	10" PM	78B 47-2
	12" PM	78B 56-2
M403	Socket, Focus Coil (5 contact wafer)	87A 4-4
M404	Plug, Focus Coil (5 pin)	88A 3-5
	Cover & Insulator (for 88A3-5 plug)	88A 3-4
M405	Socket, Deflection Yoke (6 contact, molded)	87A 30-2
M406	Plug, Deflection Yoke (6 pin)	88A 9-1
	Cover & Insulator (for 88A9-1 plug)	88A 17
M504	Socket, Light (4 contact, wafer; used only in 19" combination sets)	87A 6-3
	Band, Metal Tube (for mtg. 16" round tube)	28A 40-1
	Band, Plastic Insulating (for mounting 16" round tube)	33A 59-1
	Bracket, Picture Tube Mounting (supports front of rectangular picture tube)	
	Right side (facing tube)	15B 615-1
	Left side (facing tube)	15B 615-2
	Bracket, Picture Tube Mounting (supports front of 16" round tube)	15C 576
	Bracket, Top and Bottom (for mounting picture tube and focus coil)	
	for rectangular picture tubes	
	Top	15C 613
	Bottom	15C 614
	for 16" round tubes	
	Top	15C 628-1
	Bottom	15C 627
	Clamp, Picture Tube Front Mtg. Bracket (for mtg. rectangular picture tube)	15A 616
	Clamp, Webbing (for mtg. rectangular tube)	15A 526
	Clip, Tube Cap	
	for 6CD6G tube	88A 16-6
	for 6BQ6GT tube	88A 16-8
	for 1B3GT tube	19A 54
	Connector Lead, 2nd Anode	
	with plug for 16" rectangular tube	88A 16-7
	with contact spring for 16" round tube	A3171
	with female plug for 19" round tube	88A 25-1
	with male plug and contact spring for 19" round tube	A3200
	Ion Trap	
	for round picture tubes	94A 15-2
	for rectangular picture tubes	94A 15-1
	Nut, Tube Band Mounting (8-32)	2A 1-15-71
	Pilot Light (#47)	81A 1-8
	Rubber Channel, 1" long (for rectangular picture tube bracket)	12A 9-11
	Rubber Insert, 1" diameter (bottom and side support of rectangular picture tube)	12A 16-1
	Rubber Grommet (for 2nd anode load)	12A 1-15
	Screw, Wing (for deflection yoke)	1A 101-1-71
	Shield, Tube	87A 7-7
	Shield Base, Tube	87A 7-6
	Socket, Tube	
	miniature bakelite (7 pin)	87A 3-7
	octal, plain	87A 5-1
	octal, ringmount (mica filled)	87A 20-2
	miniature (9 pin)	87A 14-2
	picture tube	87B 31-8
	Spring, HV Contact (for front of round picture tube)	18A 37
	Spring, Picture Tube Grounding (used on rectangular tubes only)	19A 23-2
	Spring, Support (for 2nd anode lead)	19A 66
	Washer, Spring (for mounting picture positioning lever)	4A 5-10-71
	Webbing, Rectangular Picture Tube Mtg. Strap (42" length)	50A 3-4

PARTS for MOUNTING 19" PICTURE TUBE

Sym.	Description	Part No.
M403	Socket, Focus Coil (5 contact wafer)	87A 4-3
M404	Plug, Focus Coil (5 pin)	88A 3-5
	Cover & Insulator (for 88A3-5 plug)	88A 3-4
M405	Socket, Deflection Yoke (6 contact; molded)	87A 30-2
M406	Plug, Deflection Yoke (6 pin-includes interlock)	88A 9-1
	Cover & Insulator (for 88A9-1 plug)	88A 17
	Band, Tube Front Insulating (Plastic)	33B 59-2
	Band, Tube Retaining (Metal)	28A 40-2
	Bracket, Strap (supports yoke coil)	15A 572
	Bracket, Tube Mtg. (supports front of tube)	
	for right side facing tube	15C 564-1
	for left side facing tube	15C 564-2
	Bracket, Yoke (upper mtg. bracket)	15C 628-2
	Bracket, Yoke Base (lower support)	15C 627
	Connector Lead, 2nd Anode	
	with female plug	88A 25-1
	with male plug and contact spring	A3200
	Ground Wire Assembly	A3209
	Ion Trap	94A 15-2
	Lever, Picture Positioning	15B 574
	Nut (8-32 Hex, for tube band)	2A 1-15-71
	Picture Tube 19" TV	19AP4
	Rubber Collar (supports flare of picture tube)	12B 40
	Screw, Wing (for deflection yoke)	1A 101-1-71
	Shim, Focus Coil Mounting	32A 134
	Spacer Sleeve (1/8" in length)	29A 2-3-71
	Spring, HV Contact at front of tube	18A 37
	Tape, Aluminum Foil (order length needed)	52A 1-17
	Washer, Spring (for mtg. picture positioning lever)	4A 5-10-71

MISCELLANEOUS PARTS for 3C1 RADIO

Sym.	Description	Part No.
SW701	Switch, Radio-Phono	77A 28-2
SW702	Switch, On-Off	Part of R710
M701	Socket, Phono Input	88A 1
M706	Socket, Phono Motor	89A 6-1
M707	Shielded Cable Assembly	89A 29-11
M708	Plug, Cable Connector (14 pin rect.)	88A 20-1
	Cover and Insulator (for plug 88A20-1)	88A 20-6
	Cable (12 wire), including 88A20-1 plug and 88A20-6 cover	AB216
	Bracket, Mounting	
	for Off-Volume and Tone control	15A 409
	for Radio-Phono Switch	15A 385
	for Tuning Sleeve	15A 394
	Clip, IF Transformer Mtg.	72B 28-10
	Cover Assembly, Chassis	A1880
	Dial Back and Bracket Assembly	A1881
	Dial Cord (50" length needed)	50A 1-3
	Dial Scale	22B 23-1
	Escutcheon, Radio	23D 63-3
	Grommet, Gang Mounting	12A 1-2
	Hex Nut, Switch Retaining	2A 2-11-71
	Knob, 'Radio-Phono', 'Tuning'	33D 55-1
	Knob, 'Tone'	33D 55-4
	Knob, 'Volume'	33D 55-5
	Lockwasher, Osc. Coil & Gang (#6 I.T.)	3B 1-25-71
	Pilot Light, #47 Mazda	81A 1-8
	Pointer, Dial	25A 38
	Shaft, Tuning	28A 48-1
	Snap Button (for mtg. dial scale)	13A 1-1-71
	Socket, Tube	
	7 pin (for 6BA6, 6AV6)	87A 3-7
	7 pin (for 6BE6)	87A 24-3
	Socket, Pilot Light (includes 14" lead)	82A 2-3
	Socket, Pilot Light (includes 9" lead)	82A 2-9
	Spacer Sleeve (for gang mounting)	29A 2-1-71
	Spacer Sleeve (3 1/4" long, for mounting phono-radio switch)	29A 3-15
	Spring, Dial Cord Tension	19B 1-3
	Washer, Vellutex (Oscillator coil mtg.)	5A 1-21

PARTS for PHONO COMPARTMENT LIGHT and JEWEL LIGHT

Sym.	Description	Part No.
M505	Socket and Leads (miniature)	82A 11-58
M506	Plug (4 pin round)	88B 22-1
	Cover and Insulator for 88B22-1	88B 22-3
M507	Socket and Leads (candelabra)	82A 12-1
SW502	Switch, Light	77A 29
	Bracket, Switch	15B 502
	Bulb, Light (7 watt candelabra Mazda #7C7)	81A 2-4
	Bulb, Light (miniature #47 Mazda)	81A 1-8
	Light Assembly, Complete (less bulbs)	AB209
	Shield, Light	82A 13
	Washer, Insulating	5A 1-31

CABINET PARTS for 36R37 (Blond). 26R45 (Walnut), 36R46 (Mahogany)

When ordering parts for these models, use this list FIRST, then see Form No. S338-1 for any parts not listed here.

Part No.	Description
	Escutcheon, Control (less door)
23D 60-1	with "I" shaped slot, for flat door spring
23D 60-5	with "U" shaped slot, for coil door spring
	Escutcheon, Door
23D 60-4	used with 23D60-1 escutcheon (mounts with flat door spring)
23D 60-8	used with 23D60-5 escutcheon (mounts with coil door spring)
	Spring, Escutcheon Door
18A 41	flat (bronze) spring, used with 23D60-1 escutcheon, for left or right hinge
	coil (wire) spring, used with 23D60-5 escutcheon
19A 65-2	for left hinge (facing front)
19A 65-1	for right hinge (facing front)

CABINET PARTS for 16R12 (Mahogany), 26R12 (Mahogany)

Above model numbers may have the suffix "N".

Part No.	Description
A3131	Antenna, Built-in TV
	Back, Cabinet (includes line cord)
A3287	for table model
A3289	for console model
A3015	Baffle Board, Speaker, for table model
46B 26	" " " for console model
34E 36-2	Cabinet, Plastic, 16R12 (Mahogany)
34E 37-2	" " 26R12 (Mahogany)
44B 183	Carton and Fillers, for table model
44B 187	" " " for console model
98A 60-7	Caster (for cabinet leg)
	Escutcheon, Control (less door)
23D 60-1	with "I" shaped slot, for flat door spring
23D 60-5	with "U" shaped slot, for coil door spring
	Escutcheon, Door
23D 60-4	used with 23D 60-1 escutcheon (mounts with flat door spring)
23D 60-8	used with 23D 60-5 escutcheon (mounts with coil door spring)
12A 32-6	Gasket, Sponge Rubber (for back of pic. window)
36B 3-20	Grille Cloth, for table model
36B 3-44	" " for console model
33C 53-9	Knob, TV, maroon, 'Channel'
33C 53-10	" " maroon, 'Tuning'
33C 53-11	" " maroon, 'Off-Volume'
33C 53-12	" " maroon, 'Picture'
89A 22-1	Line Cord and Interlock Socket
6A 4-10	Mounting Rivet, for line cord

INDEX

General

BUILT-IN "ROTO-SCOPE" ANTENNA

The built-in "Roto-Scope" antenna is operated by the antenna control lever which extends from the back of the cabinet (near the top). Set the antenna control lever in that one of its three positions (left, center, or right) which gives the clearest picture.

When an external indoor or an outdoor antenna is required, be sure to disconnect the built-in Roto-Scope antenna leads from the antenna terminal board, tape them and place them away from the chassis.

INPUT IMPEDANCE and TRANSMISSION LINES

The input impedance to the receiver is 300 ohm balanced (between antenna terminals). When using 300 ohm transmission line, connect it across both antenna terminals.

Input impedance between one antenna terminal and chassis is approximately 75 ohms. When using 75 ohm coaxial transmission line, connect the outer conductor to the chassis and the inner conductor to either antenna terminal; use the terminal which gives the most satisfactory picture on the weakest station.

For best performance, use Admiral transmission line (part number 95A22-1 for 300 ohm line, part number 95A22-2 for 75 ohm line).

FUSE LOCATION

The horizontal output circuit is fused with a ¼ amp, 250 volt fuse, part #84A4-2. The fuse is located on top of the horizontal output transformer in the high voltage compartment.

CHASSIS NOTES

Chassis used in the straight TV and combination models differ in that the combination models have a connector socket for supplying power to the radio.

Important: If both the radio and television are turned on at the same time, neither unit will operate.

PICTURE TUBE HANDLING PRECAUTION

Due to the high vacuum and large surface area of picture tubes, great care must be exercised when handling these tubes. Shatterproof goggles and heavy gloves should be worn while handling or installing a picture tube. The picture tube must not be scratched or subjected to excessive pressure as fracture of the glass will result in an explosion of considerable violence which may cause personal injury or property damage.

HIGH VOLTAGE WARNING

High voltages are present throughout this receiver. Operation of the set outside of the cabinet or with the cabinet back removed involves shock hazard. Exercise normal high voltage precautions while working with this set.

Installing the Television Receiver

After the antenna is set properly, make all checks or adjustments given here to insure best performance and ease in tuning. ***It is especially important that the Channel Slugs and Ion Trap be adjusted upon installation or servicing of every set.***

For best results, all checks or adjustments should be made using a transmitted television test pattern. A mirror placed in front of the picture tube screen will be of help in observing the picture while adjusting rear panel controls. Removing the TV back disconnects the interlocking line cord; use a separate line cord (part number 89A22-1) when servicing.

NOTE: In combination models, if both radio and television are turned on at the same time, neither unit will operate. Be sure to instruct owner on proper operation.

TUNE IN A PICTURE

Tune in a picture as instructed in the customer instruction leaflet; note illustrations on interference effects.

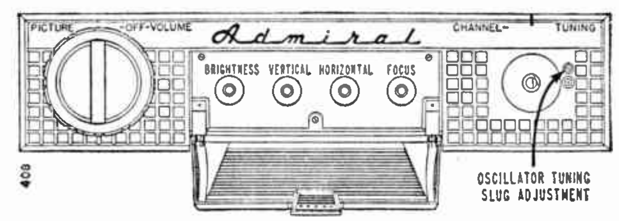
Be sure to check the setting of the auxiliary controls (behind escutcheon door).

ADJUST CHANNEL SLUGS

Individual channel oscillator adjustment of every receiver should be checked upon installation or servicing. If this adjustment is properly made, it is possible to tune from one station to another by merely turning the CHANNEL control and if necessary, slightly readjusting the TUNING control. With correct oscillator channel adjustment, best picture will be located at the approximate center of the range of the Tuning control.

This adjustment can be made without removing the chassis from the cabinet. Adjust as follows:

a. Turn the set on and allow 15 minutes to warm up.
b. Set the CHANNEL knob for a station in operation. Set all other controls for a normal picture.
c. Set TUNING control at center of its range by rotating it approximately half-way.
d. Remove the CHANNEL and TUNING knobs.
e. Insert a ⅛" blade, NON-METALLIC screwdriver in the ¼" hole (to the right of the channel tuning shaft). For each channel in operation, carefully adjust the channel slug for best picture with clear detail. Be sure that the Tuning control is set at the center of its range before adjusting each channel slug. Only slight rotation of the slug will be required; turning the slug in too far will cause it to fall into the coil. (If the slug falls into the coil, remove the coil, move the retaining spring aside, lightly tap the open end of the coil until the slug slips out. Replace slug and re-set retaining spring.)



Control Panel; CHANNEL and TUNING Knobs Removed.

ADJUST THE ION TRAP

To prolong the life of the picture tube, it is important that this adjustment be made on each receiver upon installation, or when servicing.

Position the ion trap on the picture tube neck so that the BLACK sleeve faces upward.

Turn the BRIGHTNESS control (at front of set) for normal brightness.

Starting from a point close to the tube base, very carefully move the ion trap forward or backward and at the same time, rotate it slightly in either direction until maximum brightness is produced.

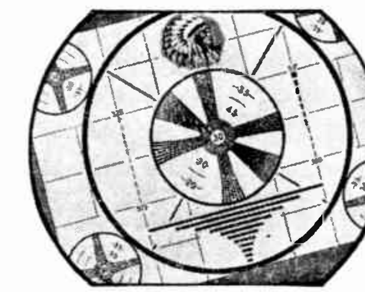
Turn the BRIGHTNESS control until normal brightness is obtained. Adjust the FOCUS control for good focus. Readjust the ion trap again for maximum brightness.

Care must be exercised in adjustment of the ion trap since there may be two locations on the neck of the tube where maximum brightness can be produced. The second ion trap location, which is further forward on the tube neck, should not be used.

Important: If the corners of the picture are shaded, be sure the ion trap has been properly adjusted. Do not sacrifice picture brightness when adjusting the ion trap to remove shaded corners. To eliminate shaded corners, see the discussion under "Check Picture Centering". Be sure to readjust the ion trap after adjusting the picture positioning lever or repositioning the focus coil. Tighten the ion trap mounting screw after adjustment.

CHECK PICTURE TILT

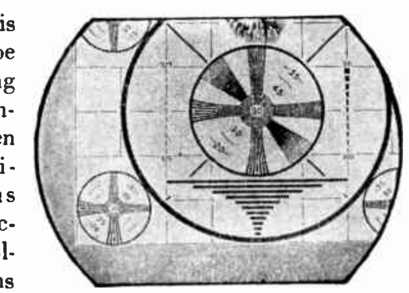
If the picture is tilted, loosen the wing screw "H" on the deflection yoke coil and slightly rotate the yoke "E" until the picture is straight. Before tightening the wing screw, be sure that the yoke is moved as far forward as possible, otherwise corners of the picture may become shaded.



Picture Tilted; Adjust Deflection Yoke Coil.

CHECK PICTURE CENTERING

If the picture is off center, it can be centered by using the picture positioning lever, and when necessary, re-positioning the focus coil around the picture tube neck. Follow the instructions given below. ***Note that the picture positioning lever can be moved sideways, and up and down.***



Picture Not Centered; Adjust Picture Positioning Lever.

Centering the Picture

a. Adjust ion trap as instructed on preceding page.
b. Slightly loosen the screw "A" which locks the picture positioning lever to the focus coil, adjust the lever for correct picture centering.
c. Readjust the ion trap.

Difficulty in Centering the Picture

a. Adjust ion trap as instructed on preceding page.
b. Slightly loosen the two screws "B" which hold the focus coil to the yoke bracket. Center focus coil around the tube neck; tighten screws.
c. Loosen the screw "A" and center the picture with the picture positioning lever. If the picture cannot be centered with the lever, it may be necessary to locate the focus coil slightly off center and then center the picture with the picture positioning lever.
d. Readjust the ion trap.

©John F. Rider

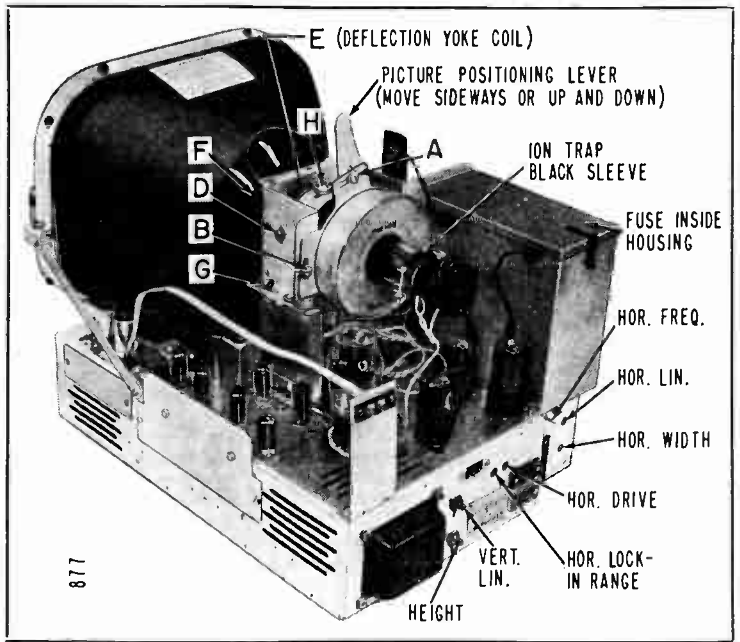
World Radio History

Difficulty in Eliminating Shaded Corners

a. Loosen screws "G", than move the yoke support bracket forward until rubber grommet "F" is firmly against the flare of the picture tube.

b. Push the deflection yoke coil "E" as far forward as possible. In some cases, it may be necessary to loosen the two yoke bracket support screws "D" at the sides of the upper mounting bracket, move the bracket up or down, and then move the deflection yoke coil as far forward as possible.

c. Adjust the ion trap as instructed on preceding page.



Chassis View Showing Adjustment Locations.

SCHEMATIC NOTES

[1],[2],[3] etc. are run numbers and indicate a production change. Run numbers are rubber stamped at rear of chassis.

(A1), (A2),......(Y), (Z), etc. indicate alignment points and alignment connections.

PRODUCTION CHANGES

RUN 1

Condenser C431, .02 mfd, 400 volts (part number 64B5-24) was added across width control L402 to increase width.

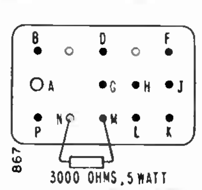
SUBSTITUTE TUBE (V703) USED IN 3C1 RADIO

In some sets a 6AT6 tube was used in place of the 6AV6 (V703) Det-AVC-AF Amplifier. These tubes are directly interchangeable.

SERVICING TV CHASSIS or RADIO SEPARATELY

In combination models, to service the television chassis with the radio disconnected, it will be necessary to complete the heater circuit by connecting a jumper wire between pins "L" and "K" of socket M503. See schematic.

The radio can be operated without the television chassis if a 1PA2 power supply (used with the 4S1 radio) or 2PA1 power supply (used with 5B2 radio) is available. Connect a 3,000 ohm, 5 watt resistor (part number 61A1-15) from pin "M" to "N" on the power supply socket.



Socket, Rear View (Inside Chassis).

TV VOLTAGE DATA

(Voltages given on schematic diagram)

- PICTURE control turned fully clockwise. CHANNEL control set on an unused channel. Other front controls set at approximately half rotation. Vert. Lin. and Height set at approximately half rotation.
- Voltages marked with an asterisk * will vary widely with control setting.

  In combination models, B+ voltages in TV chassis will be slightly higher when set is switched to radio position. Alternate voltage readings for radio and TV are shown for sound output tube V204 (6V6GT).
- Line voltage 117 volts AC.
- Voltages measured with a vacuum tube voltmeter between tube socket terminals and chassis, unless otherwise indicated. Voltages at V101, V102, V306 measured from top of socket with tube removed.
- Antenna disconnected from set with terminals shorted.
- Under operating conditions, AGC (Automatic Gain Control) voltage developed at test point "T" (see schematic) should measure approximately —2.5 volts. This voltage depends on signal strength.

CAUTION

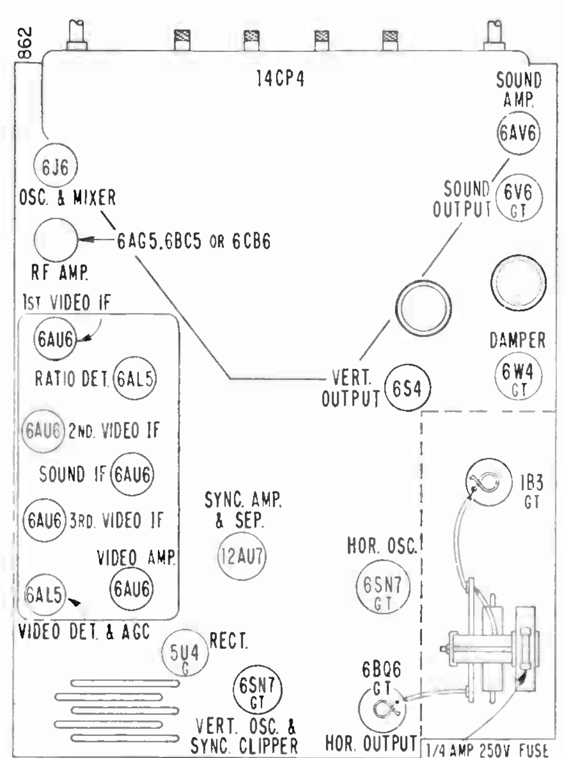
Pulsed high voltages are present on the cap of the 6BQ6GT tube, and on the filament terminals and cap of the 1B3GT tube. NO ATTEMPT SHOULD BE MADE TO TAKE MEASUREMENTS FROM THESE POINTS UNLESS SUITABLE TEST EQUIPMENT IS AVAILABLE.

Picture tube 2nd anode voltage can be measured from the 2nd anode connector and should be taken only with a high voltage instrument such as a kilovoltmeter. 2nd anode voltage is approximately 12 KV. Proper filament voltage check of the 1B3GT tube may be made by observing filament brilliancy as compared with that obtained with a 1.5 volt dry cell battery.

RADIO VOLTAGE DATA

(Voltages given on schematic diagram)

- Line voltage 117 volts AC.
- Voltages measured with a vacuum tube voltmeter, between tube terminals and chassis.
- Volume control set at minimum.
- Dial turned to low frequency end.



Top View of Chassis.

IMPORTANT

This preliminary service data contains the complete chassis parts list for models using the 20T1, 20V1 television chassis and for the 3C1 (AM) radio chassis. It also includes cabinet parts for models 34R15, 34R16. It contains alignment data for the television chassis. Model RC550 record changer is used.

This TV chassis uses a 14" rectangular tube. The IF and sweep circuits are similar to the circuits in the 20X1, 20Y1, 20Z1 chassis. The deflection circuits are similar to those used in the 24D1, 24E1, 24F1, 24G1, 24H1 chassis.

The intercarrier sound has been improved by taking the 4.5 MC sound IF from the video detector through an improved sound take-off coil. Adjacent channel interference has been minimized by the addition of an adjacent channel trap L301. A 4.5 MC trap coil L306 added in the cathode circuit of the picture tube, reduces 4.5 MC beat interference.

TELEVISION ALIGNMENT PROCEDURE

IF AMPLIFIER ALIGNMENT

a. **Before starting alignment, be sure IF cover shield is mounted to chassis.**

b. Disconnect antenna and connect a jumper across antenna terminals.

c. Set receiver to channel 13 or other unassigned high channel to prevent signal interference during IF alignment.

e. Allow about 15 minutes for receiver and test equipment to warm up.

f. To service TV chassis with radio disconnected, complete the heater circuit by connecting a jumper from pin "L" to pin "K" of socket M503. See schematic.

Step	Signal Gen. Freq. (MC)	VTVM and Signal Generator Connections	Instructions	Adjust
1	25.3	VTVM high side to test point "T", common to chassis.	Use VTVM 3 volt DC scale. When peaking, keep reducing generator output for VTVM reading of approx. 1 volt or less.	A1 and A2 for maximum.
2	23.1	Connect generator high side to 6J6 (V102) tube shield; insulate shield from chassis. Connect common to chassis near 6J6 tube base.		A3 and A4 for maximum.
3	To insure correct IF alignment, make the "IF Response Curve Check" given below, or make the "Overall RF and IF Response Curve Check (Step 1)" given later. The overall check should be made after making all other alignments.			

IF RESPONSE CURVE CHECK

(Using sweep generator and oscilloscope with sweep input to RF Mixer V102.)

Differences in tube gain and component values affect IF response. These differences are not apparent in alignment of IFs when using a signal generator and VTVM (single frequency alignment); hence it is preferable that an IF response curve check be made after completion of the IF amplifier alignment.

The IF response curve check can be made as indicated directly below. However, also note that a better check can be made by feeding the sweep signal through the entire RF and IF system as given under "Overall RF and IF Response Curve Check (Step 1)". The overall check should be made after making all other alignments.

a. Make all control settings and connections as given in the IF amplifier alignment chart; see "a" through "f" above.

b. Connect oscilloscope between point "V" and chassis ground through a decoupling filter; see fig. 29. Keep leads away from receiver.

c. Connect sweep generator high side to tube shield of 6J6 (V102) osc-mixer tube. Be sure to insulate tube shield from chassis. Connect sweep generator common to chassis close to 6J6 tube base. Set sweep generator to sweep the IF band pass (19 to 29 MC).

d. Loosely couple marker generator high side to the sweep generator lead connected to tube shield on tuner; common to chassis ground.

To avoid distortion of the response curve, keep the sweep generator and marker generator outputs at a very minimum. Marker pips should be just kept barely visible. To minimize distortion, set sweep generator output for VTVM reading of approximately .5 volt DC, measured between test point "T" and chassis. Connecting a 1½ volt battery (negative to test point "T", positive to chassis) will allow greater signal input without distorting the response curve.

e. Check curve obtained against the ideal IF response curve shown in figure 28. Since it is not always possible to get ideal curves, it should be noted that the height of opposite peaks should be within 3db or 30% of each other. The dip or valley in the center of the curve should not be greater than 3db or 30% down from the highest peak of the curve. Check video and sound IF carrier points by means of marker generator. It is important that marker pips be in the proper location on the response curve. The 25.75 MC marker, should be 6db below the highest peak (50% point on the high frequency side of the curve). The 22 MC marker should be at the opposite side of the response curve, located approximately 18db (85%) below the highest peak. The 21.25 MC marker should be located at least 26db (95%) below the highest peak, and may or may not be visible.

Consistent with proper band width and correct location of markers, the response curve should preferably have maximum amplitude, symmetry, and flat top appearance.

If the procedure given has been carefully followed and the response curve obtained differs greatly from the curve shown in figure 28, repeat the IF Amplifier Alignment, making sure generator frequencies are precise and adjustments are accurately made.

World Radio History

ALIGNMENT HINT

After becoming familiar with alignment procedure, some servicemen simplify subsequent alignment of sets by merely using the essential alignment data given in figures 29 and 30.

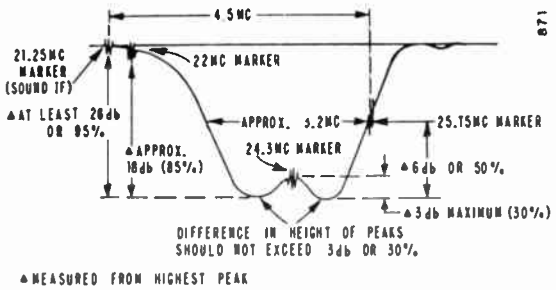

Figure 28. IF Response Curve.

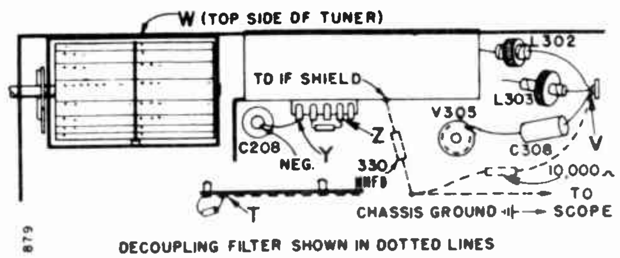

Figure 29. Bottom View Showing Test Point "V".

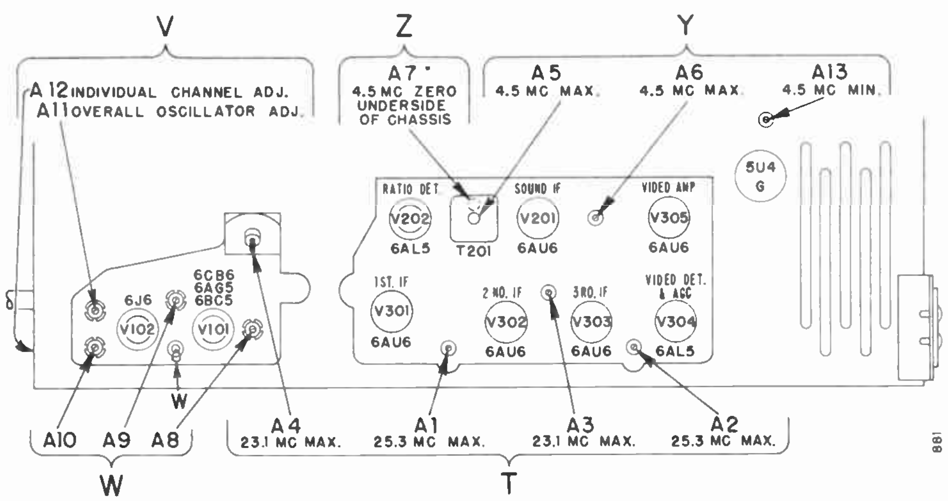

Figure 30. Top View of Chassis Showing Alignment Adjustment Locations.

4.5 MC SOUND IF ALIGNMENT

a. Disconnect antenna and connect a wire jumper across antenna terminals.

c. Connect signal generator high side to point "V" through a .01 mfd. condenser.

d. Allow about 15 minutes for receiver and test equipment to warm up.

e. Use a NON-METALLIC alignment tool. If Ratio Det. Transformer (T201) has hollow core slugs, bottom slug adjustment A7 can be made from top of chassis, if you use alignment tool #98A30-7 obtainable from Admiral Distributor. Bottom slug (A7) can be reached through the hole in the core of the upper slug (A5).

f. To service TV chassis with radio disconnected, complete the heater circuit by connecting a jumper from pin "L" to pin "K" of socket M503. See schematic.

Step	Signal Gen. Freq. (MC)	VTVM Connections	Instructions	Adjust
	Since the transmitted video and sound carriers have an accurate 4.5 MC frequency difference, a TV station signal may be used instead of a signal generator for alignment of steps below. When using a television signal, it may be necessary to use a higher scale on the VTVM. IMPORTANT: When using a signal generator, be sure to check it against a crystal calibrator or other frequency standard for accurate frequency calibration at 4.5 MC. Accuracy is required within one kilocycle.			
1	†4.5	To test point 'Y'	Use 3 volt DC scale on VTVM. Keep VTVM leads well separated from signal generator and chassis wiring.	A5 and A6 for maximum (keep reducing generator output to keep VTVM at approx. 1 volt).
2	†4.5	To test point 'Z'	Use 3 volt zero center scale on VTVM, if available. Keep VTVM leads well separated from signal generator and chassis wiring.	**A7 for zero on VTVM (the correct zero point is located between a positive and a negative maximum).

† Signal may be unmodulated or 400 cycle AM modulated.

** If A7 was far off, repeat steps 1 and 2.

RF AND MIXER ALIGNMENT

a. Disconnect 1½ volt battery from test point "T" if used earlier. Connect a wire jumper from test point "T" (Fig. 30) to chassis. Leave connected for all steps in this alignment.

b. Disconnect antenna from receiver.

c. Connect sweep generator to antenna terminals. If sweep generator does not have a built-in marker generator, loosely couple a marker generator to the antenna terminals. To avoid distortion of the response curve, keep sweep generator output at a minimum, marker pips just barely visible.

d. Connect oscilloscope through a 10,000 ohm resistor to test point "W" on tuner (Fig. 30). Keep scope leads away from chassis.

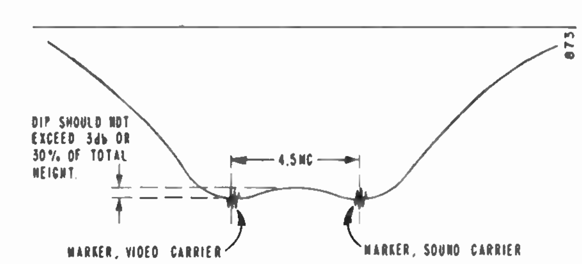
e. Allow about 15 minutes for receiver and test equipment to warm up.

f. To service TV chassis with radio disconnected, complete the heater circuit by connecting a jumper from pin "L" to pin "K" of socket M503. See schematic.

Step	Marker Gen. Freq. (MC)	Sweep Gen. Frequency	Instructions
1	*205.25 **209.75	Sweeping Channel 12	**Check for curve resembling RF Response Curve shown below. If necessary, adjust A8, A9 and A10 (Figure 30) as required. Consistent with proper band width and correct marker location, response curve should have maximum amplitude and flat top appearance.**
2	See table below.		**Check each channel operating in the service area for curve resembling RF Response Curve shown below. When checking any channel, set the sweep and marker generators for the proper frequencies as indicated in the table below. In general, the adjustment performed in step 1 is sufficient to give satisfactory response curves on all channels. However, if reasonable alignment is not obtained on a particular channel, (a) check to see that coils have not been intermixed, or (b) try replacing the pair of coils for that particular channel, or (c) repeat step 1 for the weak channel as a compromise adjustment to favor this particular channel. If a compromise adjustment is made, other channels operating in the service area should be checked to make certain that they have not been appreciably affected.**

* Video Carrier Frequency (MC). ** Sound Carrier Frequency (MC).

Channel Number	Channel Freq., MC	Video Carrier, MC	Sound Carrier, MC
2	54- 60	55.25	59.75
3	60- 66	61.25	65.75
4	66- 72	67.25	71.75
5	76- 82	77.25	81.75
6	82- 88	83.25	87.75
7	174-180	175.25	179.75
8	180-186	181.25	185.75
9	186-192	187.25	191.75
10	192-198	193.25	197.75
11	198-204	199.25	203.75
12	204-210	205.25	209.75
13	210-216	211.25	215.75



Full skirt of curve will not be visible unless generator sweep width extends beyond 10 MC.

Figure 31. RF Response Curve (see "Oscilloscope Note" below).

ALIGNMENT ADJUSTMENT IDENTIFICATION

Adj.	Symbol	Frequency	Function
A1	T303	25.3 MC	3rd IF Transformer
A2	T301	25.3 MC	1st IF Transformer
A3	T302	23.1 MC	2nd IF Transformer
A4	L103	23.1 MC	Mixer Plate Coil
A5	T201	4.5 MC	Primary of Ratio Detector Transformer
A6	L201	4.5 MC	Sound Take-off Coil
A7	T201	4.5 MC	Secondary of Ratio Detector Transformer
A8	C102		Trimmer (RF Amplifier)
A9	C104		Trimmer (RF Amplifier)
A10	C107		Trimmer (Mixer)
A11	C110		Trimmer (HF Oscillator)
A12	L102		Slug, HF Oscillator Coils
A13	L306	4.5 MC	Trap Coil

OSCILLOSCOPE NOTE

In dealing with RF and IF response curves, it is well to remember that an inverted or mirror image may result, depending on the sweep generator and oscilloscope used. The general waveform should still be identical.

When using a wide band oscilloscope for alignment, marker pips will be more distinct if condenser from 100 to 1,000 mmfd. is connected across the oscilloscope input. Caution: Use the lowest capacity condenser possible, since too high a capacity will affect the shape of the response curve.

©John F. Rider

World Radio History

OVERALL RF and IF RESPONSE CURVE CHECK (Step 1) and HF OSCILLATOR ALIGNMENT (Step 2)

(Using sweep generator and oscilloscope.)

a. Disconnect antenna.

b. Disconnect signal generator and VTVM (if used earlier).

c. Set the Tuning control at half rotation by rotating it approximately 150° as shown in figure 32.

d. Connect sweep generator to antenna terminals. If sweep generator does not have a built-in marker generator, loosely couple a marker generator to the antenna terminals. To avoid distortion of the response curve, keep sweep generator output at a minimum, marker pips just barely visible. Connecting a 1½ volt battery (negative to test point "T"; positive to chassis) will allow greater signal input without distorting response curve.

e. Connect oscilloscope between point "V" and chassis ground through a decoupling filter (see figure 29). Keep oscilloscope leads away from chassis.

f. Allow about 15 minutes for receiver and test equipment to warm up.

g. When adjusting A12, use a NON-METALLIC alignment screwdriver with a ⅛ inch blade.

h. To service TV chassis with radio disconnected, complete the heater circuit by connecting a jumper from pin "L" to pin "K" of Socket M503. See Schematic.

Step	Marker Gen. Freq. (MC)	Sweep Gen. Frequency	Instructions
1	While sweeping the RF band pass (channel 13 or other unassigned high channel), check the overall response curve obtained against the ideal curve shown below. If shape of curve is not within limits shown, it will be necessary to repeat the IF Amplifier Alignment. The IFs must be accurately aligned before correct oscillator adjustment can be made.		
2	See channel frequency table on previous page.		Check need for oscillator alignment by comparing the response curve obtained (for each channel operating in the service area) with the "Overall RF and IF Response Curve" shown below. With correct oscillator alignment, the video and sound markers should locate at the points shown on the response curve. The Tuning control must be at half rotation (see figure 32) when making this check. If a major number of channels are far off in the same direction, make the overall oscillator adjustment A11. (Touch-up of individual channel slugs A12 may also be required.) If only individual channel adjustment is required, adjust the proper channel slug A12. Make all oscillator adjustments so that the video and sound marker pips appear at the proper points on the response curve. Important: Before making oscillator adjustments, be sure that the Tuning control is set at half rotation; see figure 32. Only slight rotation of the slug (A12) will be required; turning the slug in too far will cause the slug to fall into the coil. (If an oscillator slug should fall into a coil, remove the coil, move the slug retaining spring aside, lightly tap the open end of the coil against a solid object until the slug slips out. Replace slug and set the slug retaining spring into its cut-out slot.)

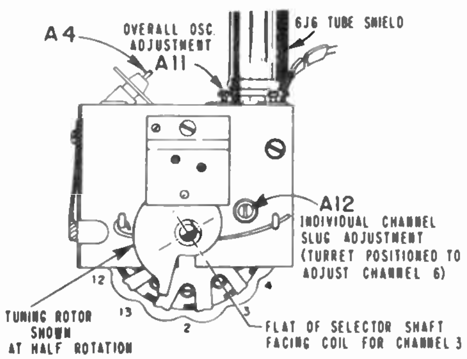


Fig. 32. Front View of Tuner.

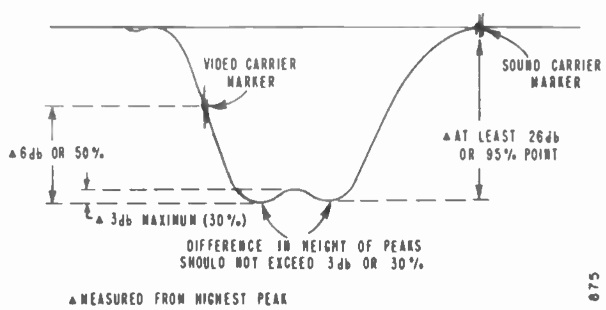

Fig. 33. Overall RF and IF Response Curve.

4.5 MC TRAP ALIGNMENT

A 4.5 MC trap coil (L306) is used in the cathode circuit of the picture tube to minimize 4.5 MC beat interference which might appear in the picture.

Since the transmitted video and sound carriers have an accurate 4.5 MC frequency difference, it may be preferable to use a TV station signal instead of a signal generator for this alignment. When using a television signal, it may be necessary to use a higher scale on the VTVM.

When using a signal generator, be sure to check it against a crystal calibrator or other frequency standard for accurate frequency calibration at 4.5MC.

a. If using a signal generator for this alignment, disconnect antenna and correct a wire jumper across antenna terminals. Set receiver to an unassigned channel to prevent signal interference.

b. Set PICTURE control for normal picture.

c. Allow about 15 minutes for receiver and test equipment to warm up.

d. If using a signal generator, connect generator high side to test point "V" through a .01 mfd. condenser; common to chassis. Signal may be unmodulated or AM modulated. Full generator output may be required for this alignment.

e. Connect a 15 mmfd. condenser from tie point connecting to yellow lead (terminal 11) of V306 to terminal one of L201 (junction of C201, C202 and R201).

f. Connect VTVM high side to test point "Y"; common to chassis. Keep VTVM lead separated from generator and chassis wiring.

g. Using a NON-METALLIC alignment screwdriver, carefully adjust slug A13 for minimum VTVM reading.

HORIZONTAL OSCILLATOR ALIGNMENT

This adjustment should not be required unless it is impossible to obtain horizontal sync with the "Horizontal Frequency and Horizontal Lock-In Range Adjustment" given in the "Installation and Service Notes for 20T1, 20V1 Television Chassis", Form No. 41A9-14.

NOTE: This adjustment requires the use of an oscilloscope, preferably one having a high input resistance and low input capacity. Making this adjustment without an oscilloscope may result in poor horizontal sweep stability.

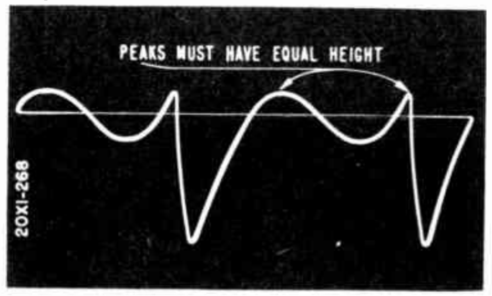
Adjust as follows:

a. Allow receiver to warm up for a few minutes.

b. Sync the picture horizontally with the HORIZONTAL control (on front panel); if necessary, adjust the HOR. LOCK-IN RANGE or HOR. FREQ. adjustments as required. If these adjustments have been greatly disturbed from the original setting, the approximate setting for the HOR. LOCK adjustment L401 (underside of chassis) is about one-quarter to one-half of its range in from its full-out position; the approximate setting for the HOR. LOCK-IN RANGE is about one-third turn out from its full-in position; the approximate setting of the HOR. FREQ. is about five to fifteen turns in from its full-out position.

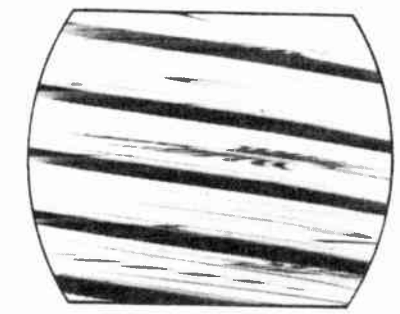
c. Connect oscilloscope high side through a 10 mmfd. condenser to terminal "C" or "2" on the Horizontal Blocking Transformer T404; ground to chassis. Set oscilloscope to horizontal frequency (15.75 KC) or a sub-multiple of it.

d. Tune in a station (preferably one with a test pattern). While keeping the picture in sync, adjust the HOR. LOCK adjustment L401 (underside of chassis) for oscilloscope waveform pattern as illustrated. Adjust for equal height of rounded and pointed peaks. Disconnect oscilloscope after adjusting waveform.



Horizontal Oscillator Waveform

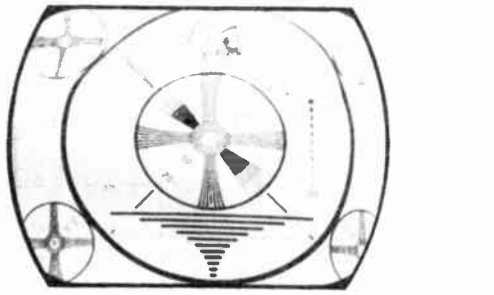
e. Turn the HORIZONTAL control fully to the left, carefully adjust the HOR. LOCK-IN RANGE adjustment until 6 to 10 diagonal bars (of the type shown in the illustration "Picture Out of Horizontal Sync") are visible on the screen.



Picture Out of Horizontal Sync

f. Turn the HORIZONTAL control fully to the right; the picture should fall in sync. If it does not fall in sync, repeat adjustment in step "e". With the Horizontal control set fully to the right, turn the HOR. FREQ. adjustment out (to the left) until the picture just falls out of sync. Then very slowly turn it in (to the right) until the picture falls in sync. If "bending" appears at top of picture (see illustration), correct by very slowly turning the HOR. FREQ. adjustment to the right until the bending is removed. If bending is excessive and cannot be removed with HOR. FREQ. adjustment, repeat all steps above but in step "d", adjust oscilloscope waveform so the rounded peak is from 10 to 20% higher than the pointed peak of the waveform. This compensates for the oscilloscope loading effects.

When the above adjustments are properly made, the picture should hold horizontal sync through at least half-rotation of the Horizontal control.



"Bending" At Top of Picture

	In TV only sets R502A is a single candohm resistor	61A 3-15
R503	15,000 ohms, 2 watt	60B 20-153
R701	22,000 ohms, 1/2 watt	60B 8-223
R702	10,000 ohms, 1 watt	60B 14-103
R703	150 ohms, 1/2 watt	60B 8-151
R704	27,000 ohms, 1 watt	60B 14-273
R705	2,200 ohms, 2 watt	60B 20-222
R706	1 megohm, 1/2 watt	60B 8-105
‡R707	47,000 ohms, 1/2 watt	
R708	4.7 megohms, 1/2 watt	60B 8-475
R709	27,000 ohms, 1/2 watt	60B 8-273
R710A	2 megohms, Tone } pot	75B 11-12
R710B	1 megohm, Volume } pot (includes SW702)	
R711	22 ohms, 1/2 watt	60B 8-220

CONDENSERS

Sym.	Description	Part No.
C101	5 mmfd, 10%, Zero temp. coeff	98A 45-22
C102	.5 to 3 mmfd, ceramic trimmer	98A 45-87
C103	.001 mfd. min, ceramic	98A 45-24
C104	.5 to 3 mmfd, ceramic trimmer	98A 45-23
C105	120 mmfd, 5%, ceramic, -750 temp. coeff.	98A 45-25
C106	100 mmfd, ceramic, -750 temp. coeff	98A 45-26
C107	.5 to 3 mmfd, ceramic trimmer	98A 45-23
C108	20 mmfd, Cer. Zero temp. coeff	98A 45-27
C109	10 mmfd, 5%, ceramic, -750 temp. coeff.	98A 45-79
C110	.5 to 3 mmfd, ceramic trimmer	98A 45-23
C111	Tuning rotor	98A 45-92
C112	10 mmfd, 5%, ceramic, Zero temp. coeff.	98A 45-64
C113	120 mmfd, 10%, silver mica	98A 45-78
C114A	.001 mfd. min. } dual ceramic	98A 45-93
C114B	.001 mfd. min. } dual ceramic	
C201	6.8 mmfd, -.00033 temp. coeff	65B 6-71
C202	20 mmfd, 5%, ceramic	65B 6-51
C203	.005 mfd. min, ceramic	65A 10-1
C204	180 mmfd, 5%, -.00003 temp. coeff	65B 6-59
C205	500 mmfd, ceramic	65B 6-6
C206	4 mfd, 50 volts, electrolytic	67A 4-9
C207	.001 mfd. min, ceramic	65B 6-41
C208	.047 mfd, 600 volts, paper	64B 9-9
C209	.01 mfd, 600 volts, paper	64B 9-13

C713	.01 mfd, 400 volts, paper	64B 5-25
C714	.002 mfd, 600 volts, paper	64B 5-14

COILS and TRANSFORMERS

Sym.	Description	Part No.
L101	Antenna Coil	
	for Channel #2	98A 62-2
	for Channel #3	98A 62-3
	for Channel #4	98A 62-4
	for Channel #5	98A 62-5
	for Channel #6	98A 62-6
	for Channel #7	98A 62-7
	for Channel #8	98A 62-8
	for Channel #9	98A 62-9
	for Channel #10	98A 62-10
	for Channel #11	98A 62-11
	for Channel #12	98A 62-12
	for Channel #13	98A 62-13
L102	Mixer-Oscillator Coil	
	for Channel #2	98A 63-2
	for Channel #3	98A 63-3
	for Channel #4	98A 63-4
	for Channel #5	98A 63-5
	for Channel #6	98A 63-6
	for Channel #7	98A 63-7
	for Channel #8	98A 63-8
	for Channel #9	98A 63-9
	for Channel #10	98A 63-10
	for Channel #11	98A 63-11
	for Channel #12	98A 63-12
	for Channel #13	98A 63-13
	Before inserting replacement coil L101 or L102, see that teeth at inner end of coils fit together when fitted in detent plate at center of turret. If necessary file teeth slightly.	
L103	Mixer Plate Coil	98A 45-77
L104	Heater RF Choke	98A 45-13
L105	Heater Oscillator Choke	98A 45-14
L201	Sound Take-off Coil (includes R201, C201, C202)	72B 99-2
L301	Trap Coil, 27.25 MC (includes C301)	72A 102
L302	Video Peaking Coil (wound on R316)	73A 5-6
L303	Video Peaking Coil	73A 5-7
L304	Video Peaking Coil (wound on R320)	73A 5-8
L305	Video Peaking Coil (wound on R321)	73A 5-9
L306	Trap Coil, 4.5 MC (includes C312)	72B 99-3
L307	Heater RF Choke	73A 2-5
L308	Heater RF Choke	73A 2-5
L401	Horizontal Lock Coil	Part of T404
L402	Width Control	94A 29-2
L403	Horizontal Linearity Control	94A 28
L404	Focus Coil	69C 117-3
L701	AM Loop Antenna (includes C701, C702)	69C 100-1
L702	Oscillator Coil	69A 52-1
T201	Ratio Detector Transformer	72B 68
T202	Audio Output Transformer	
	for 20V1 chassis	79B 31-1
	for 20T1 chassis	79B 31-2
T301	1st IF Transformer (includes R306, R307, C302A, C302B)	72C 96-11
T302	2nd IF Transformer (includes R310)	72C 96-10
T303	3rd IF Transformer (includes C305)	72C 96-9
T401	Blocking Oscillator Transformer	79A 18-3
T402	Vertical Output Transformer	79B 29-2
T403	Deflection Yoke (includes R413, R414, R442, C428)	A3222
T404	Horizontal Blocking Transformer (includes L401)	69B 110
T405	Horizontal Output Transformer (includes tube cap clips)	79C 32-1
T501	Power Transformer	80C 26-2
T701	1st IF Transformer	72B 28-7
T702	2nd IF Transformer	72B 28-17

MISCELLANEOUS PARTS for TV CHASSIS

Sym.	Description	Part No.
M201	Speaker Socket	88A 5-6
M202	Speaker Plug	88A 5-5
M203	Speaker	
	5" PM	78B 60-1
	6" PM	78B 61
	10" PM	78B 47-2
M204	Socket, Audio Input	89A 29-22
M401	Horizontal Output Fuse, 1/4 amp, 250 V.	84A 4-2
	Fuse Holder	84A 5-1
M501	Interlock Socket (Male)	89A 22-2
M502	Line Cord, with interlock socket	89A 22-1
M503	Cable Socket (Combination models only)	88A 32-2
SW501	Switch, On-Off Power	Part of R208
V306	Picture Tube	14CP4
	Bracket, Deflection Yoke Coil Support	15A 572
	Bracket, Picture Tube Mounting (Supports front of picture tube)	
	Upper bracket	15B 652
	Lower bracket assembly	A3332
	Bracket (Yoke and focus coil support)	
	Upper	15C 613
	Lower	15C 650
	Clip, Tube Cap	
	for 6BQ6GT tube	88A 16-9
	for 1B3GT tube	19A 54
	Connector Lead, 2nd Anode (includes connector plug)	88A 16-10
	Cover, IF Strip	15B 531
	Fuse Holder	84A 5-1
	Insulating Plate (for mounting condenser C427)	32A 135-1
	Ion Trap	94A 15-2
	Lever, Picture Positioning	15B 574
	Lock, 1B3 Mounting Shell Disk	15A 589
	Plate, Channel Selector Shaft Bearing (Phenolic)	32A 111-1
	Plate, TV Tuner Inspection (Fibre)	32A 117
	Rubber Channel, 1" long (for front of picture tube bracket)	12A 9-9
	Rubber Collar (supports flare of picture tube)	12B 40
	Rubber Grommet (for 2nd anode housing)	12A 2-7
	Rubber Insert (cushion for picture tube bracket)	
	for top and sides, 9/16" dia	12A 16-2
	for bottom, 5/8" dia	12A 16-3
	Screw, Wing (for deflection yoke)	1A 101-1-71
	Shield, Tube	
	plain type	87A 7-7
	slotted type	98A 45-73
	Socket, Shell (cover for 1B3 tube socket)	84A 27-1
	Socket, Tube	
	miniature bakelite (7 pin)	87A 3-7
	octal, plain	87A 5-1
	octal, ringmount (mica filled)	87A 20-2
	miniature (plain 9 pin)	87A 25-1
	miniature (special 9 pin for 6S4 tube)	87A 25-4
	Spring, Picture Tube Grounding	19A 23-1
	Support Spring (for 2nd anode lead)	19A 68
	Tuner, Television (Complete)	94C 21-2

MISCELLANEOUS PARTS for TV TUNER 94C21-2

Sym.	Description	Part No.
M104	Shaft Shell & Rotor Assy. (Tuning) (with 1 7/8" long brass shaft shell)	98A 45-76
M107	Bracket, Tuning Rotor Retaining	98A 45-95
M108	Spring, Detent Plate Grounding	98A 45-94
M109	Shield, Tube (slotted; for 6J6)	98A 45-73
M110	Shield, Tube (plain; for 6AG5)	87A 7-7
M112	Spring, Slug Retaining (Osc. coil)	98A 45-52
M113	Washer, Fibre Spacer (1/4" IDx1/2" OD)	98A 45-63
M114	Nut, Locking Spring (for trimmers)	98A 45-31

† To secure proper high frequency characteristics, order exact part from Admiral Distributor or use IRC metalized resistor only.

‡ Part of Diode Filter Unit 63A3-1 consisting of R707, C709, C710.

MODELS 34R15, 34R15A, 34R16, 34R16A, Ch. 20T1, 20V1

World Radio History

M115	Screw, Trimmer (4-36x5/8")	98A 45-33
M116	Screw, Bracket Mtg. (6-32x1/4")	98A 45-62
M117	Slug, Brass Tuning	98A 45-88
M118	Stator Plate (ungrounded); Silver with Ceramic Insulator, for Tuning C111 (includes mounting bracket)	98A 45-86
M120	Tuner, Television (Complete)	94C 21-2
M121	Roller, Detent (3/8" dia.. 3/32" dia. bearing)	98A 45-82
M122	Spring, Detent (2 5/16" long)	98A 45-81
M123	Contact Plate and Bracket Assembly (uses wiping contacts)	98A 45-84
M124	Spring, Tuning Rotor Contact (flat bronze 1 7/16"x1/2")	98A 45-83
M125	Spring, Front and Rear Turret Shaft (wire 2 3/4" long, 3/64" dia.)	98A 45-85
M126	Turret and Shaft Assembly (less coils) (3 1/4" shaft and 3/16" rounded detent depression)	98A 45-89

MISCELLANEOUS PARTS for 3C1 RADIO

SW701	Switch, Radio-Phono	77A 28-2
SW702	Switch, On-Off	Part of R710
M701	Socket, Phono Input	88A 1
M706	Socket, Phono Motor	89A 6-1
M707	Shielded Cable Assembly	89A 29-11
M708	Plug, Cable Connector (14 pin rect.)	88A 20-1
	Cover and Insulator (for plug 88A20-1)	88A 20-6
	Cable (12 wire), including 88A20-1 plug and 88A20-6 cover	AB216
	Bracket, Mounting	
	for Off-Volume and Tone control	15A 409
	for Radio-Phono Switch	15A 385
	for Tuning Sleeve	15A 394
	Clip, IF Transformer Mtg	72B 28-10
	Cover Assembly, Chassis	A1880
	Dial Back and Bracket Assembly	A1881
	Dial Cord (50" length needed)	50A 1-3
	Dial Scale	22B 23-1
	Escutcheon, Radio	23D 63-3
	Grommet, Gang Mounting	12A 1-2
	Hex Nut, Switch Retaining	2A 2-11-71
	Knob, 'Radio-Phono', 'Tuning'	33D 55-1
	Knob, 'Tone'	33D 55-4
	Knob, 'Volume'	33D 55-5
	Lockwasher, Osc. Coil & Gang (#6 I.T.)	3B 1-25-71
	Pilot Light, #47 Mazda	81A 1-8
	Pointer, Dial	25A 38
	Shaft, Tuning	28A 48-1
	Snap Button (for mtg. dial scale)	13A 1-1-71
	Socket, Tube	
	7 pin (for 6BA6, 6AV6)	87A 3-7
	7 pin (for 6BE6)	87A 24-3
	Socket, Pilot Light (includes 14" lead)	82A 2-3
	Socket, Pilot Light (includes 9" lead)	82A 2-9
	Spacer Sleeve (for gang mounting)	29A 2-1-71
	Spacer Sleeve (3 1/4" long, for mounting phono-radio switch)	29A 3-15
	Spring, Dial Cord Tension	19B 1-3
	Washer, Vellutex (Oscillator coil mtg.)	5A 1-21

RECORD CHANGER PARTS

Complete service information for the RC550 Record Changer is given in Service Manual No. S327. The changer model number is on the top rear of the changer pan and also on the model label on the underside of the changer pan.

M702	Cable, Shielded (includes plug)	412A 11-2
M703	Cartridge, Push-in Needle Type (includes needle)	409A 13-1
	Cartridge, Knurled Nut Retaining Type (includes needle)	409A 13
M704	Motor (3 speed)	407B 19
M705	Plug, Motor (Male)	88A 8-1
	Adapter, 45 RPM Record (envelope of 12)	48A 8-1
	Belt, Rubber Drive	406A 20
	Idler Wheel Assembly (includes tire)	G400A 279
	Needle, Phonograph	
	for 409A 13 cartridge	98A 15-19
	for 409A 13-1 cartridge	98A 15-18
	Needle Retaining Nut (for 409A13 cartridge)	98A 54-2
	Service Manual, RC550	S327
	Spring, Changer Float	405A 139
	Touch-Up Paint	
	Coppertone	98A 54-3
	Gold Hammertone	98A 54-12

PARTS for TILT-OUT MECHANISM

Eye Bolt (for tilt-out spring)	1A 87-1
Grommet, Rubber (for tilt-out spring)	12A 1-1
Hinge Assembly, Tilt-Out	
Left side (facing front)	AC183-1
Right side (facing front)	AC183-2
Screw, Tilt-Out Brkt.Shipping (#10-24x3/8 ST)	1A 51-25-71
Screw, Tilt-Out Adjusting Bracket Mtg. (#8-32x1/4" Bd. H.M.S.)	85-250-C2-71
Screw, Tilt-Out Tie Rod Mtg. (#6-32x1/4" Bd. H.M.S.)	365-250-C2-58
Spring, Tilt-Out Coil (2 3/8" unstretched)	19A 15-1
Spring, Tilt-Out Arm Retaining (7 1/4" unstretched)	19A 59
Tie Rod, Tilt-Out	28A 22-1

CABINET PARTS for 34R15 (Walnut), 34R16 (Mahogany)

The above model numbers may contain the suffix "N".

A3072	Antenna, Built-in TV
43C 128-1	Back, Radio-Phono and Record Compt.
A3292	Back, TV (includes line cord)
*35E 117-3	*Cabinet, Walnut
*35E 117-4	*Cabinet, Mahogany
44B 181	Carton and Fillers
98A 60-7	Caster (for cabinet leg)
11B 12-6	Clamp, Cable
*35E 117-52	*Door, Record Compt. (Complete) Walnut
*35E 117-53	*Door, Record Compt. (Complete) Mahog.
*35E 117-50	*Doors. TV and Radio-Phono Compt., Walnut (matched pair)
*35E 117-51	*Doors. TV and Radio-Phono Compt., Mahogany (matched pair)
35E 117-63	Door Catch and Strike Plate
23C 58-1	Escutcheon, Control (Plastic; less door)
23C 58-2	Escutcheon Door (Plastic)
23D 63-1	Escutcheon, Radio
12A 32-8	Gasket, Sponge Rubber (for picture window)
36B 3-28	Grille Cloth (2 pieces)
37A 27-1	Handle, Door (for upper doors)
35E 117-62	Hinge, Knife (Pair)
33D 55-1	Knob, Radio 'Radio-Phono', 'Tuning'
33D 55-4	Knob, Radio 'Off-Volume'
33D 55-5	Knob, Radio 'Tone'
33C 53-9	Knob, TV 'Channel'
33C 53-10	Knob, TV 'Tuning'
33C 53-11	Knob, TV 'Off-Volume'
33C 53-12	Knob, TV 'Picture'
81A 1-8	Light, Pilot #47
89A 22-1	Line Cord and Interlock Socket
6A 4-6-0	Line Cord Mounting Rivet

* To insure proper matching and fit, also specify cabinet manufacturer's code letters (usually burned or stamped on back rail of cabinet). Wood parts are supplied only if old part cannot be repaired. When ordering describe condition of old part in detail.

* CORRECTIONS AND ADDITIONS TO PRELIMINARY SERVICE MANUAL 20T1 AND 20V1

CORRECTION:

Form 41A9-14 lists the part number for the video peaking coil L305 as 73A5-6. This is incorrect. The correct part number of L305 video peaking coil is 73A5-9.

PRODUCTION CHANGES

Some brands of 6S4 tubes do not have an internal connection between pins 3 and 6. When replacing the 6S4 tube in an early production 20V1 chassis it may be necessary to connect a wire jumper from terminal 3 to terminal 6 of the tube socket, or the result will be no vertical sweep. This jumper is in all late production 20V1 chassis and in all 20T1 chassis.

RUN 2 IN 20V1 CHASSIS

Sync buzz and plate dissipation in the 20V1 chassis can be reduced by replacing R213, 270 ohm, 1 watt resistor with a 330 ohm, 1 watt resistor (part number 60B14-331). 20V1 chassis having this change are stamped run 2 or higher. All 20T1 chassis will have this change.

Picture Window and Control Escutcheon Difference in Models 34R15, 34R16, and 34R15A, 34R16A

The picture window and the control escutcheon used in models 34R15 and 34R16 are different from those used in models 34R15A and 34R16A. Since the different picture windows and the control escutcheons are not interchangeable, it is important that correct replacement be ordered.

Order these parts from the parts list below. To avoid possibility of ordering incorrect replacements, either modify or cross out the listing for these parts in the parts list.

REPLACING PICTURE TUBES IN 20V1 CHASSIS

Due to the difference in manufacturing tolerance between various brands of picture tubes, it may be found that replacing one brand with another will result in too much brightness, even with the brightness control turned fully off.

This may be corrected by connecting a 470K, 1/2 watt resistor (part number 60B8-474) across condenser C308 (.1 mfd).

The resistor places a negative bias on the video amplifier tube V305 and decreases the current through this tube. By connecting the resistor across C308 instead of between the grid of the video amplifier and ground, the DC reinsertion is also improved.

The 470K resistor is included in current production 20V1 chassis, commencing with run 3, code OP.

All 20T1 chassis will have this resistor.

INDEX

CHARACTERISTICS

Antenna impedance
300 ohm input

Picture area -
150 sq. inches,
14 1/4" by 10 3/4"

Speaker
4 by 6 oval PM

Voice coil impedance
3.2 ohms - 400 cycles

Dimensions
20½" high
23" wide
20" deep

I-F frequencies
Video - 26.1 mc.
Sound - 21.6 mc.
Audio strip - 4.5 mc.

Power Supply
117 volts, 60 cycles, AC

Power consumption
180 Watts

Tube complement
18 tubes - 2 rectifiers
(see parts list for
individual tubes)

The tubes are 6BH6, RF amplifier, 6AG5, converter, and 6J6 oscillator. The 6BH6 RF stage has a grid-cathode 300 ohm balanced input. The RF pass band is achieved by an overcoupled, double-tuned, interstage network which feeds the 6AG5 converter. The 6J6 is a push-pull oscillator of exceptional stability.

All oscillator adjustments are available from the front, and with the exception of channel 2 (which must be adjusted first) they are all independent. The vernier tuning mechanism is extremely rugged and simple. The pass-band of all RF channels is maintained above 75% relative response between picture and sound carriers.

The Video System

Three video i-f amplifiers, V-4, V-5, and V-6, each a 6AU6 tube, are employed. (The schematic, Fig. 9, should be consulted while reading the rest of the circuit analysis.) Four stagger-tuned i-f transformers, L4, L6, L9, and L12, are employed to produce the necessary bandwidth. Both the video and sound i-f signals are passed through this complete amplifier section which functions as a combined i-f system. There is no separation of the sound i-f signal from the video i-f signal, and they are both fed directly into V-7, the video detector. This is the basis upon which the intercarrier system operates. The over-all response of the i-f section is such that the amplitude of the sound i-f carrier is a very small percentage of the video i-f carrier when they are both fed to the video detector, which is one half of a 6AL5 tube. No sound traps are employed. Response shaping is discussed in the alignment section.

The video detector considers the sound i-f signal as a high-frequency sideband of the video i-f signal and detection occurs in the normal manner. The sound and video i-f carriers can be considered as beating together inside the video detector. The carriers of these two i-f signals are always separated by 4.5 mc, so that after detection their difference frequency of 4.5 mc appears in the output of the video detector. This 4.5-mc beat note contains all of the f-m characteristics of the input f-m sound i-f signal and very little a.m. effects. It is the amplitude relationship between the two input i-f signals that determines the character of the 4.5-mc output signal.

The 4.5-mc f-m signal as well as the video signal output from the detector is directly coupled to the grid of V-8, a 6AC7 video amplifier, through an L-R high-frequency compensating network. In this manner, the 4.5-mc signal receives additional amplification. In the plate of the video amplifier is the primary parallel-tuned circuit of a double-tuned 4.5-mc transformer, L2, which selects the f-m 4.5-mc signal to be fed to the sound section of the receiver. The video signal output is fed directly to the grid of the picture tube V-10, through peaking coil L3 and capacitor C223.

World Radio History

AGC and Contrast

The video i-f signal output from the third video i-f stage, V-6, is fed to the plate, pin 7, of the other half of the 6AL5 tube, V-7, which serves as a delayed AGC rectifier. The AGC voltage is supplied to the r-f and first and second video i-f amplifiers. A small positive voltage on the cathode of this diode prevents rectification of the video i-f signal until the i-f signal voltage on the diode plate exceeds whatever voltage is on the cathode. The contrast control, PD4, which is in the cathode circuit of the video amplifier, V-8, besides controlling the bias and hence the gain of this stage, also controls the amount of delay voltage on the cathode of the AGC tube. The influence of the contrast control is such that the delay voltage will be greatest at the time the gain of the video amplifier is greatest. This makes for a better over-all control of the picture contrast.

The Sweep and Sync Circuits

One half of V-9, a 12AU7 tube, serves as the d-c restorer and sync clipper. The sync voltage output from this section is fed to the grid of the other half of V-9, which functions as a sync amplifier to the vertical sync pulses and as a phase splitter to the horizontal sync pulses. The positive sync output signal is taken directly from the plate, pin 6 of V-9, and applied to an integrating network which consists of C301, R301, C302, R302, and C303. This integrating network separates the vertical sync pulses from the horizontal and applies the former to the grid circuit, pin 1, of the vertical sweep oscillator, V-13. This latter circuit utilizes one half of a 6SN7-GT tube as a blocking oscillator. The other half of V-13 functions as the vertical sweep output amplifier. The output from this amplifier feeds into the vertical output transformer, T4, and then to the vertical deflection yoke.

The 1-megohm potentiometer (of dual-control unit PD5) in the grid circuit, pin 1, of the vertical sweep oscillator, controls the frequency of operations and is termed the VERT. HOLD control. The VERT. LINEARITY control is the 5000-ohm potentiometer, P2, in the cathode circuit, pin 6, of the vertical sweep output amplifier. The VERT. SIZE control is a 2.5-megohm potentiometer, P5, located in the B-supply lead to the plate of the vertical sweep oscillator.

The type 6SN7-GT tube, V-14, which is the horizontal sweep oscillator, is employed as a combined cathode-coupled sine wave oscillator and multivibrator. The output from the plate, pin 5, of this oscillator is coupled to the grid of V-15, a 6BQ6G tube serving as the horizontal sweep output amplifier. The output from the plate of this latter tube is fed to tap 2 on the primary of the horizontal output transformer, T5. From the high side of the primary of this transformer, tap 3, the horizontal sweep signal is fed to the plate of V-16, a 1B3-GT tube, serving as the high-voltage rectifier. This rectifier is employed in a kick-back type of high-voltage power supply, which supplies voltage for the second anode of the kinescope.

The horizontal deflection circuits used in this set are designed for a kinescope of 70 degree deflection angle. This is a highly efficient system employing new components that cannot be interchanged with parts used in previous systems.

The secondary of T-5 (ferrite core) consists of taps 4, 5, 6, and 8, and feeds the horizontal deflection yoke. A 6W4 tube, V-17, serves as the horizontal damper. From the secondary winding of the horizontal width coil, some of the sweep signal is applied to the cathode and plate (pins 1 and 2) of the horizontal phase detector, V-11, through an integrating network of R327 and C322. The horizontal sync pulses from the V9 phase splitter are applied to the other cathode and plate of the horizontal phase detector, and these sync pulses are compared with the phase of the horizontal sweep input. If their phases are different, an AFC voltage is developed across R323 and then applied to the grid, pin 1, of the horizontal sweep oscillator.

The 50,000-ohm potentiometer, PD5, in the grid circuit, pin 4, of V-14, regulates the horizontal sweep frequency and is called the HOR. HOLD control, and trimmer capacitor C325 between V-14 and V-15 is the HOR. DRIVE control. Coil L21 in the cathode circuit of the horizontal damper tube V-17 is the HOR. LINEARITY control and coil L20 across taps 5 and 6 of the horizontal output transformer functions as the horizontal WIDTH control.

The Sound Section

The 4.5-mc f-m signal from the secondary of the takeoff transformer L2 is fed to the grid circuit of the ratio detector driver and limiter, V-3, a 6AU6 tube. The output from this driver tube feeds the primary of the ratio detector transformer L1, which is tuned to 4.5 mc. The double diode section of a 6T8 tube, V-2, is used as the ratio detector, and the triode section of this same tube is used as the first audio amplifier. The 500,000-ohm potentiometer P7 in the output circuit of the ratio detector is the VOLUME control. The output from the first audio amplifier is R-C coupled to the grid of V-1, a 6AQ5 tube which is the audio output amplifier. The audio signal output from this latter stage is fed to the audio output transformer, T1, and then to the speaker.

Power Supply and Voltage Regulation

The low-voltage supply incorporates a 5U4-G tube, V-12, as the rectifier. Coil L17 in the output filter system is the focus coil and connected across this coil is the FOCUS control, P6, a 1500-ohm potentiometer. This low-voltage power supply provides a positive 360-volt B-plus source and a negative 2-1/2 volt bias supply. For the r-f and i-f section of the receiver the 360-volt output is decreased to 140 volts for the screens and plates of these tubes while the cathodes are returned to chassis ground. The 360-volt

©John F. Rider

World Radio History

supply is used directly for the deflection circuits and also for the plates and screens of the tubes in the sound section. However, the cathodes of these audio tubes are connected in series with the B supply for the r-f and i-f tubes, which means that the cathodes of the audio section are 140 volts positive with respect to ground. Thus, the effective B supply between the plate and cathode of the tubes in the sound section is 360 less 140, or 220 volts.

The interesting thing about the 6AQ5 tube circuit, V-1, is that it functions as a series automatic voltage regulator for the 140-volt supply and prevents any current variations in the r-f and i-f circuit from changing this voltage. The grid of the 6AQ5 tube is connected to the 360-volt supply through a voltage divider. A positive voltage of 123 volts is applied to the grid, but since the cathode is 140 volts positive, the grid has an effective bias of -17 volts. Any change in the 140 volts will tend to change the bias of the 6AQ5 tube. This, in turn, will cause the tube current to change, which means that the voltage drop across the cathode load will likewise vary. This voltage drop will be such that it will bring the cathode back to the 140 volts.

For instance, if the voltage increases beyond 140 volts, the bias on the 6AQ5 tube will become more negative. Less current will flow in the tube and a smaller voltage drop will occur across the complete cathode load. This decrease in voltage drop will be just enough to offset the previous increase in the cathode voltage.

FUNCTIONING OF CONTROLS

The controls of the receiver are divided into two groups, the front panel operating controls and the rear panel pre-set controls.

FRONT PANEL OPERATING CONTROLS

There are seven front panel operating controls as indicated in Fig. 1, each operating independently of the other. Reading from left to right, the controls and their functions are as follows:

On-Off and Volume

This is a single control. The knob should be turned clockwise, until a click is heard. This supplies a.c. to the receiver. Further clockwise rotation of the control varies the input to the audio amplifier, and, consequently, controls the volume of sound output.

Vertical Hold

This control functions to keep the picture stationary in the vertical direction. Electrically it is a variable resistor which controls the frequency of the vertical sweep oscillator.

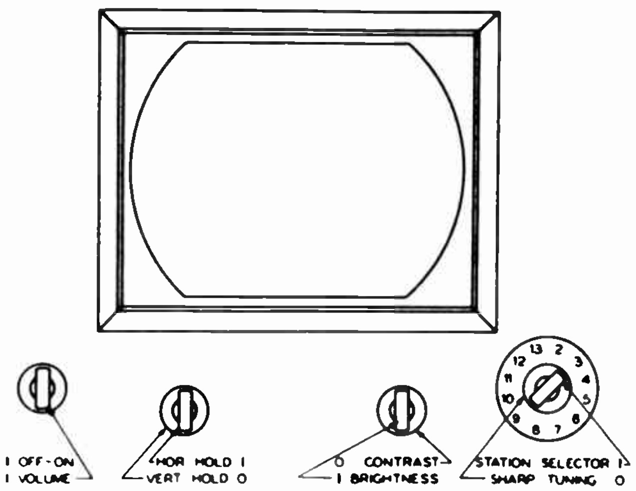

FIG. 1 — OPERATING CONTROLS

Horizontal Hold

The function of this control is to keep the picture stationary in the horizontal direction. It is a variable resistor which affects the frequency of the horizontal sweep oscillator.

Brightness

This control, which is also a variable resistor, affects the cathode voltage on the kinescope, thereby regulating the brightness of the picture.

Contrast

The contrast control provides a means for varying the relative intensities of black and white in the picture. Advancing this control toward excessive contrast will introduce a loud buzz.

Station Selector

This control permits selection of the channel desired.

Fine Tuning

This control varies the frequency of the r-f heterodyne oscillator. It is adjusted for best picture quality and is not used to tune in the sound.

REAR PANEL PRE-SET CONTROLS

There are six so-called pre-set controls at the rear of the chassis as indicated in Fig. 2. They are all screw driver adjustments. The SOUND DISC. is the alignment screw for the secondary of the ratio detector transformer L1, and is not considered a pre-set control.

Vertical Linearity

This control is a variable resistor in the cathode circuit of the vertical sweep output tube. Manipulation of this control affects the upper portion of the picture.

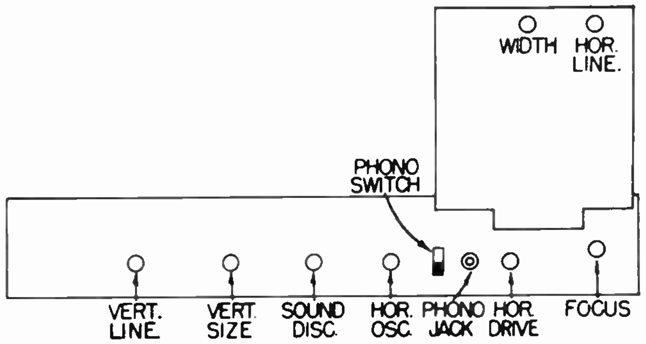

FIG. 2 — PRE-SET CONTROLS

Vertical Size

The vertical size control varies the plate voltage of the vertical sweep oscillator. It primarily causes a change in height of the picture but it also interacts with the vertical linearity so that these controls must be used in conjunction with each other.

Horizontal Oscillator Frequency

This control is a slug adjustment for L18 which controls the frequency of the horizontal oscillator. To set this control properly, connect an antenna to the receiver and tune in a station, preferably one with a test pattern on the air. Center the horizontal hold control. Adjust the L18 slug until the picture locks in. Set the horizontal hold control in the full clockwise position and slowly rotate it in the opposite direction. Just before the picture falls into sync, 3 or 4 black and white bars should appear sloping downward to the right. Repeat the process, but with the horizontal hold control in the full counterclockwise position. The same conditions should be observed except that the bars will slope downward to the left.

©John F. Rider

World Radio History

If the sloping bar effect is as stated, then the picture should remain in sync over 1/4 rotation of the horizontal hold range and drop out of sync on either end of this range.

Horizontal Drive

This trimmer capacitor affects the height of the horizontal pulse, varying the horizontal linearity principally on the left side of the picture.

Focus

A variable resistor which controls the current flow through the focus coil on the neck of the tube.

Width

This slug adjustment inside the high-voltage cage affects the right side of the horizontal axis. The secondary winding of the width coil is used to feed back a comparison voltage for synchronizing the AFC horizontal hold circuit.

NOTE: There are no horizontal or vertical positioning controls. Centering of the picture is accomplished by positioning of the focus coil. The deflection yoke should be placed on the neck of the tube as far forward as possible.

ALIGNMENT PROCEDURE

Test Equipment

The test equipment required for the alignment of this receiver is as follows:

Marker Generator (RCA WR-39A, or equivalent)
Sweep Generator (RCA WR-59A, or equivalent)
Oscilloscope (RCA WO-55A, or equivalent)
VTVM (RCA Junior VoltOhmyst, or equivalent)
Volt-Ohmmeter (Simpson 260, or any 20,000 ohm-per-volt meter)

The marker generator is an r-f signal generator used for peaking the i-f coils and also to supply marker pips on the response pattern. The required frequency range of this generator is approximately from 20 to 30 mc and must also have provision for a 4.5 mc output. The accuracy of the frequency calibration of this generator is very important. It must also have provision for an amplitude modulated, as well as an unmodulated, r-f output.

The sweep generator has its output continually variable in frequency. In this alignment, only one output sweep signal is needed, that sweeping between 20 to 30 mc.

The oscilloscope used is a high-gain, general purpose type employed for test purposes. The size of the screen is unimportant.

The VTVM is of the standard type with a high input impedance. It should have provision for a-c and d-c measurements. A 20,000 ohm-per-volt meter should be used for d-c indications if the VTVM can only measure a.c.

Alignment

For the alignment points refer to the figure indicated in the discussion. Most of the adjustments are located on top of the chassis. The r-f marker generator is used in making most of the alignment adjustments. It is recommended that the order of alignment in the following procedure be adhered to if alignment is found necessary. The ground leads of the test instruments should be connected to the receiver chassis.

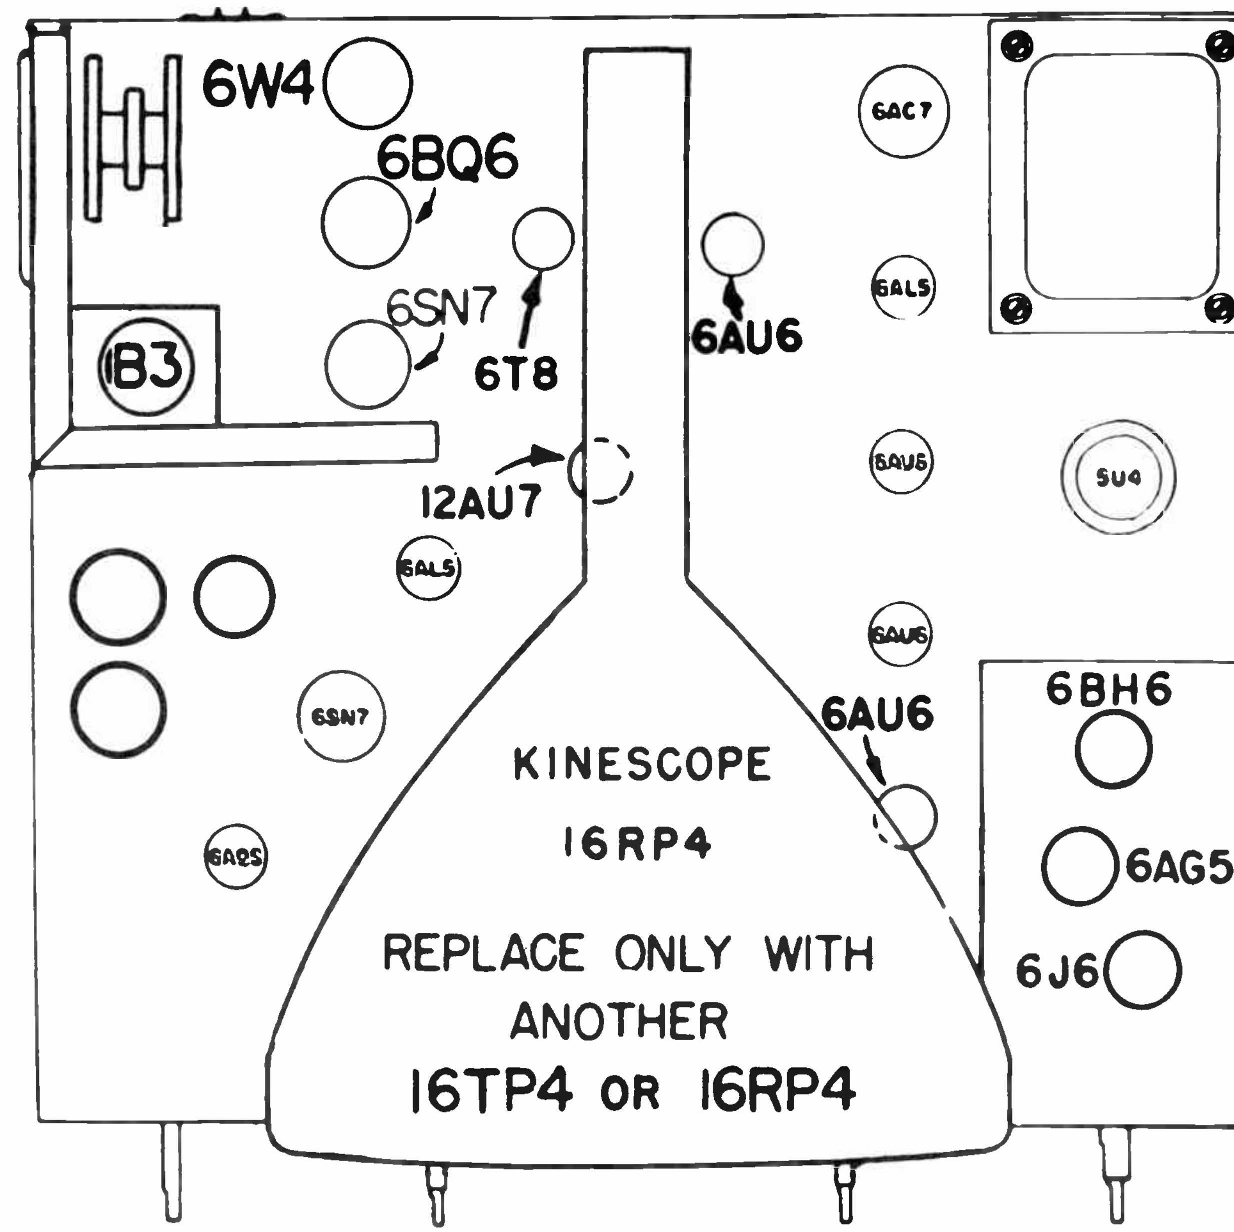

FIG. 3—TOP VIEW OF CHASSIS

©John F. Rider

World Radio History

Picture I-F Alignment (Fig. 3)

Connect the VTVM (a-c scale), or oscilloscope to the grid of the kinescope at the junction of C223 and R222. (Do not attempt to take readings with the VTVM at the video detector.) Adjust the contrast control about 1/8 turn below its maximum setting. Connect the output of the signal generator (marker) to the nipple on top of the 6AG5 mixer tube of either tuner.

Set the generator at 25.6 mc, amplitude-modulated at approximately 400 cycles, and adjust the first and third video i-f coils for maximum response. For those receivers employing tuner TT-1, the first video i-f coil is L4 as indicated in Fig. 3(A). When tuner TT-3 is used, the first video i-f coil is LV-6 and is incorporated in the tuner and not the receiverproper, as shown in Fig. 3(B). Reset the generator to 23.4 mc, still amplitude-modulated, and tune the second and fourth video i-f coils, L6 and L12 respectively, for maximum response. Repeat the above process for fine adjustments of settings.

Over-all Picture Response

With the sweep generator adjusted for a 10-mc sweep, using a center frequency of about 25 mc, connect the generator to nipple of the 6AG5 mixer tube of either tuner. Loosely couple the marker generator to the same mixer tube. The oscilloscope should remain at the grid of the kinescope. Inject individual markers of 26.1 mc, 25.6 mc, 22.6 mc, and 21.6 mc in the order indicated and note positions of marker pips on response curve. Turning the adjustments very slowly, retune the four video i-f coils again for an over-all picture i-f response as indicated in Fig. 4.

NOTE: A 30% variation in amplitude between peaks and from peak to valley, of the response curve is permissible. The most important considerations here are that the video i-f carrier of 26.1 mc is approximately halfway down the right hand slope, and that the sound i-f carrier of 21.6 mc is 20 times down at the other end of the curve.

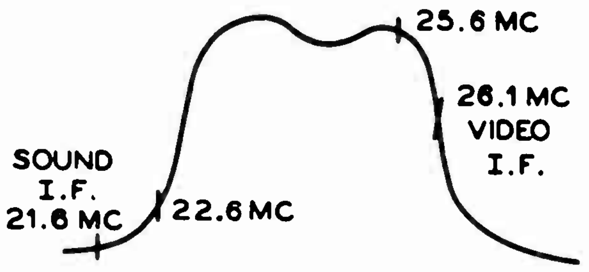

FIG. 4 - OVER-ALL I-F RESPONSE CURVE.

Sound Takeoff and Detector Transformer Alignment

Move the signal generator (marker) output lead to the junction of L13 and R217, between the video detector, V-7, and video amplifier V-8. Set the generator to a 4.5-mc unmodulated signal output. Connect the VTVM (d-c scale) or the 20,000 ohm-per-volt meter across C107 in the output circuit

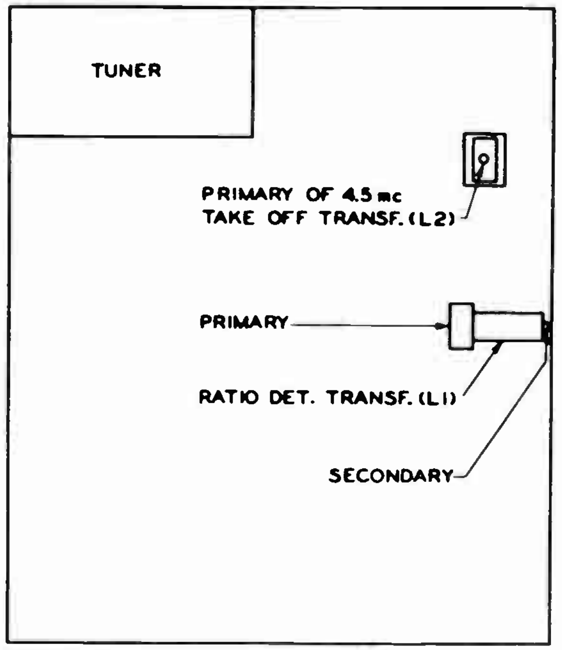

FIG. 5 - BOTTOM VIEW SHOWING ALIGNMENT POINTS FOR L1 AND PRIMARY OF L2

of the ratio detector, V-2. (Remember that the negative lead at this point is actually above -140 volts with respect to ground.)

Adjust the following for maximum reading on the meter in the order indicated. The primary of L1 (the ratio detector transformer), the adjustment of which is shown in Fig. 5. Next tune the secondary of L1; this adjustment, shown in Fig. 5, is also shown in Fig. 2 and indicated as SOUND DISC. Then adjust the primary L2, the 4.5-mc takeoff transformer; see Fig. 5. Next adjust the secondary of L2, shown in Fig. 3. Decrease the signal output from the generator to the minimum required to give a readable deflection on the meter and then repeat the sound alignment process.

After the alignment is complete, remove the generators and meters. Tune in a station. Turn up the contrast control until a buzz is heard. Adjust the secondary of the detector transformer (see Figs. 2 and 5) for minimum buzz.

NOTE: Alignment of the r-f and oscillator sections are not recommended and are therefore not included. If any misalignment of these sections is suspected, consult the manufacturer.

SERVICE NOTES

No Raster

Defective picture tube or misadjusted ion trap magnet.
No high voltage. Check tubes V-14, V-15, V-16, and V-17.
Check horizontal output transformer, T111; and also check C338, R326, and R338.
Check all voltages and waveforms in sweep section. Do not check voltage directly on plate of V-16.

Raster Present -- No Sound or Picture

Open transmission line.
Defective tube in r-f unit, or defective r-f unit.
Check B+ supply for sound and picture sections.
Check tubes V-1, V-2, V-3, V-4, V-5, V-6, V-7, and V-8.

Raster and Sound -- No Picture

Open green lead from picture tube socket.
Check tube V-8 and associated circuit.
Open C223.

Raster and Picture -- No Sound

Defective sound takeoff transformer, T2, or ratio detector transformer, T1.
Check tubes V-1, V-2, and V-3.
Defective audio output transformer, T1, or speaker.

Unable to Synchronize Vertically or Horizontally

Check tube V-9 and associated circuit.

Unable to Synchronize Vertically

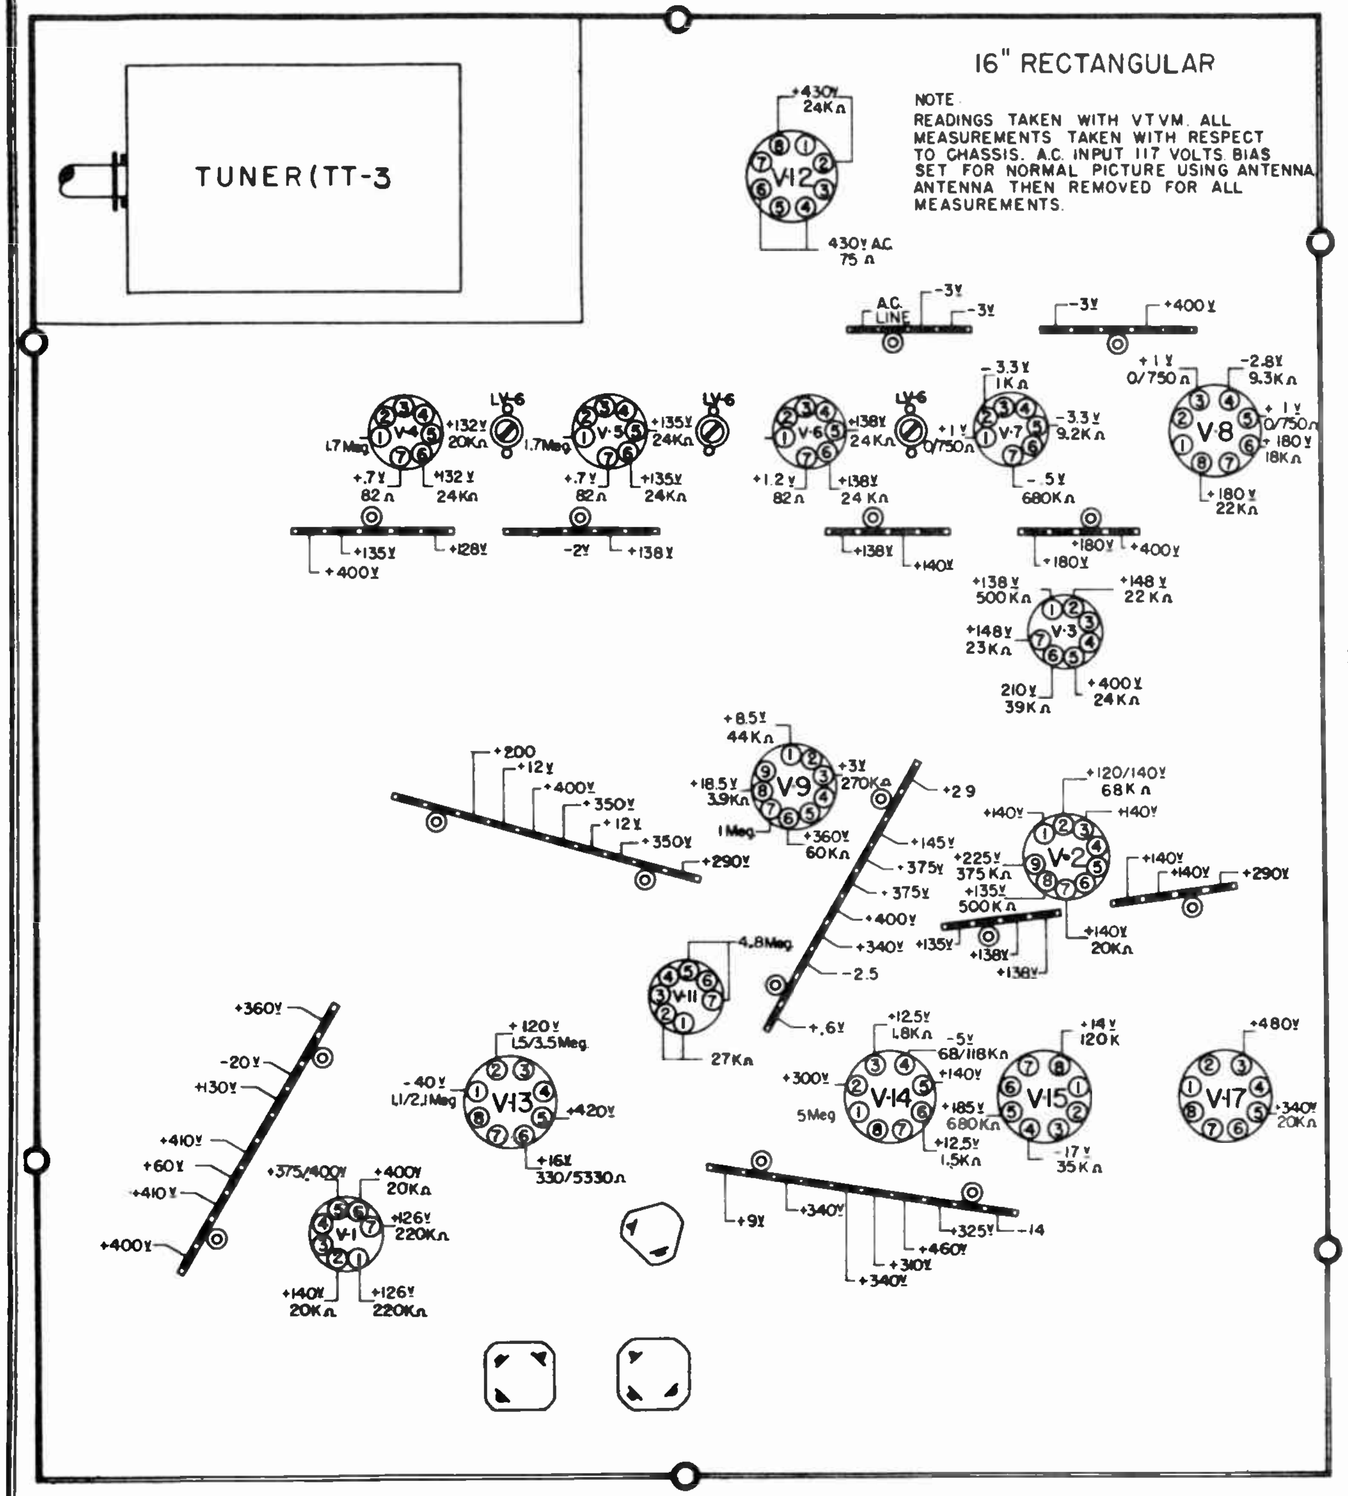
Check tube V-13.
Defective vertical oscillator transformer, T3, or vertical output transformer, T4.

Unable to Synchronize Horizontally

Horizontal sweep oscillator coil L18 misadjusted.
Coil L18 or capacitor C315 defective.
Defective tubes V-11 or V-14, or feedback capacitor C330.
Check voltages, resistances, and waveforms in horizontal sync section.
Open width coil

©John F. Rider

World Radio History



FIG·6- BOTTOM VIEW INDICATING VOLTAGE AND RESISTANCE VALUES

Insufficient Height

Defective vertical oscillator transformer, T3.
C313 increasing in capacity.
R304 and R310 changing in value.

Inability to Center Picture

Blanking on left side may be due to leaky C313.
Carefully try ning CR Tube.

NOTE: Entire audio circuit is at a potential of 140 volts above ground and the grids are hot. Also, V-1, 6AQ5, functions as a series voltage regulator to this 140 volts, as well as an audio output tube. Proper operation of this tube affects B+, and is, therefore, vital to normal operation of other circuits. A primary check of this circuit should be instituted when starting to service receiver.
For voltage and resistance analysis and waveforms, see Fig. 6.

DISASSEMBLY

To remove chassis from the cabinet, first pull off all knobs from controls in front of cabinet. Remove the six mounting bolts to be found underneath the cabinet and lift the chassis from the cabinet. Use care to prevent damage to the kinescope.

The kinescope is mounted on the chassis itself. It is held in place by a strap that is fastened over the outer rim of the bell of the kinescope.

Audio strip, 4.5 mc

Power supply
117 volts, 60 cycles, a.c.
Power consumption
180 Watts
Tube complement
See parts list

CIRCUIT ANALYSIS

The R-F Tuner

One of two r-f tuners is used with any of these receivers. Schematics of each tuner are included. Each tuner is a complete assembly in itself. Both tuners employ a 6BH6 tube as an r-f amplifier and a 6AG5 tube as a mixer.

The Video System

Three video i-f amplifiers, V-4, V-5, and V-6, each a 6AU6 tube, are employed. (The schematic, Fig. 9, should be consulted while reading the rest of the circuit analysis.) Four staggered-tuned i-f transformers, L4, L6, L9, and L12, are employed to produce the necessary bandwidth. Both the video and sound i-f signals are passed through this complete amplifier section which functions as a combined i-f system. There is no separation of the sound i-f signal from the video i-f signal, and they are both fed directly into V-7, the video detector. This is the basis upon which the intercarrier system operates. The over-all response of the i-f section is such that the amplitude of the sound i-f carrier is a very small percentage of the video i-f carrier when they are both fed to the video detector, which is one half of a 6AL5 tube. No sound traps are employed. Response shaping is discussed in the alignment section.

The video detector considers the sound i-f signal as a high-frequency sideband of the video i-f signal and detection occurs in the normal manner. The sound and video i-f carriers can be considered as beating together inside the video detector. The carriers of these two i-f signals are always separated by 4.5 mc, so that after detection their difference frequency of 4.5 mc appears in the output of the video detector. This 4.5-mc beat note contains all of the f-m characteristics of the input f-m sound i-f signal and very little a.m. effects. It is the amplitude relationship between the two input i-f signals that determines the character of the 4.5-mc output signal.

The 4.5-mc f-m signal as well as the video signal output from the detector is directly coupled to the grid of V-8, a 6AC7 video amplifier, through an L-R high-frequency compensating network. In this manner, the 4.5-mc signal receives additional amplification. In the plate of the video amplifier is the primary parallel-tuned circuit of a double-tuned 4.5-mc transformer, L2, which selects the f-m 4.5-mc signal to be fed to the sound section of the receiver. The video signal output is fed directly to the grid of the picture tube V-10, through peaking coil L3 and capacitor C223.

AGC and Contrast

The video i-f signal output from the third video i-f stage, V-6, is fed to the plate, pin 7, of the other half of the 6AL5 tube, V-7, which serves as a delayed AGC rectifier. The AGC voltage is supplied to the r-f and first and second video i-f amplifiers. A small positive voltage on the cathode of this diode prevents rectification of the video i-f signal until the i-f signal voltage on the diode plate exceeds whatever voltage is on the cathode. The contrast control, PD4, which is in the cathode circuit of the video amplifier, V-8, besides controlling the bias and hence the gain of this stage, also controls the amount of delay voltage on the cathode of the AGC tube. The influence of the contrast control is such that the delay voltage will be greatest at the time the gain of the video amplifier is greatest. This makes for a better over-all control of the picture contrast.

The Sweep and Sync Circuits

One half of V-9, a 12AU7 tube, serves as the d-c restorer and sync clipper. The sync voltage output from this section is fed to the grid of the other half of V-9, which functions as a sync amplifier to the vertical sync pulses and as a phase splitter to the horizontal sync pulses. The positive sync output signal is taken directly from the plate, pin 6 of V-9, and applied to an integrating network which consists of C301, R301, C302, R302, and C303. This integrating network separates the vertical sync pulses from the horizontal and applies the former to the grid circuit, pin 1, of the vertical sweep oscillator, V-13. This latter circuit utilizes one half of a 6SN7-GT tube as a blocking oscillator. The other half of V-13 functions as the vertical sweep output amplifier. The output from this amplifier feeds into the vertical output transformer, T4, and then to the vertical deflection yoke.

The 1-megohm potentiometer (of dual-control unit PD5) in the grid circuit, pin 1, of the vertical sweep oscillator, controls the frequency of operations and is termed the VERT. HOLD control. The VERT. LINEARITY control is the 5000-ohm potentiometer, P2, in the cathode circuit, pin 6, of the vertical sweep output amplifier. The VERT. SIZE control is a 2.5-megohm potentiometer, P5, located in the B-supply lead to the plate of the vertical sweep oscillator.

The type 6SN7-GT tube, V-14, which is the horizontal sweep oscillator, is employed as a combined cathode-coupled sine wave oscillator and multivibrator. The output from the plate, pin 5, of this oscillator is coupled to the grid of V-15, a 6BG6-G tube serving as the horizontal sweep output amplifier. The output from the plate of this latter tube is fed to tap 2 on the primary of the horizontal output transformer, T5.

From the high side of the primary of this transformer, tap 3, the horizontal sweep signal is fed to the plate of V-16, a 1B3-GT tube, serving as the high-voltage rectifier. This rectifier is employed in a kick-back type of high-voltage power supply, which supplies voltage for the second anode of the kinescope.

The secondary of T5 consists of taps 4, 5, and 6, and feeds the horizontal deflection yoke. A 6W4-GT tube, V-17, serves as the horizontal damper. From tap 6 of T5, some of the horizontal sweep signal is applied to the cathode and plate (pins 1 and 2 which are tied together) of the horizontal phase detector, V-11, through an integrating network essentially consisting of R327 and C322. The horizontal sync pulses from the V9 phase splitter is applied to the other cathode and plate sections of the horizontal phase detector and these sync pulses are compared with the phase of the horizontal sweep input. If their phases are different, an afc voltage is developed across R323 and then applied to the grid circuit, pin 1, of the horizontal sweep oscillator.

The 50,000-ohm potentiometer, PD5, in the grid circuit, pin 4, of V-14, regulates the horizontal sweep frequency and is called the HOR. HOLD control, and trimmer capacitor C325 between V-14 and V-15 is the HOR. DRIVE control. Coil L21 in the cathode circuit of the horizontal damper tube V-17 is the HOR. LINEARITY control and coil L20 across taps 5 and 6 of the horizontal output transformer functions as the horizontal WIDTH control.

©John F. Rider

World Radio History

The Sound Section

The 4.5-mc f-m signal from the secondary of the takeoff transformer L2 is fed to the grid circuit of the ratio detector driver and limiter, V-3, a 6AU6 tube. The output from this driver tube feeds the primary of the ratio detector transformer L1, which is tuned to 4.5 mc. The double diode section of a 6T8 tube, V-2, is used as the ratio detector, and the triode section of this same tube is used as the first audio amplifier. The 500,000-ohm potentiometer P7 in the output circuit of the ratio detector is the VOLUME control. The output from the first audio amplifier is R-C coupled to the grid of V-1, a 6AQ5 tube which is the audio output amplifier. The audio signal output from this latter stage is fed to the audio output transformer, T1, and then to the speaker.

Power Supply and Voltage Regulation

The low-voltage supply incorporates a 5U4-G tube, V-12, as the rectifier. Coil L17 in the output filter system is the focus coil and connected across this coil is the FOCUS control, P6, a 1500-ohm potentiometer. This low-voltage power supply provides a positive 360-volt B-plus source and a negative 2-1/2 volt bias supply. For the r-f and i-f section of the receiver the 360-volt output is decreased to 140 volts for the screens and plates of these tubes while the cathodes are returned to chassis ground. The 360-volt supply is used directly for the deflection circuits and also for the plates and screens of the tubes in the sound section. However, the cathodes of these audio tubes are connected in series with the B supply for the r-f and i-f tubes, which means that the cathodes of the audio section are 140 volts positive with respect to ground. Thus, the effective B supply between the plate and cathode of the tubes in the sound section is 360 less 140, or 220 volts.

The interesting thing about the 6AQ5 tube circuit, V-1, is that it functions as a series automatic voltage regulator for the 140-volt supply and prevents any current variations in the r-f and i-f circuit from changing this voltage. The grid of the 6AQ5 tube is connected to the 360-volt supply through a voltage divider. A positive voltage of 123 volts is applied to the grid, but since the cathode is 140 volts positive, the grid has an effective bias of -17 volts. Any change in the 140 volts will tend to change the bias of the 6AQ5 tube. This, in turn, will cause the tube current to change, which means that the voltage drop across the cathode load will likewise vary. This voltage drop will be such that it will bring the cathode back to the 140 volts.

For instance, if the voltage increases beyond 140 volts, the bias on the 6AQ5 tube will become more negative. Less current will flow in the tube and a smaller voltage drop will occur across the complete cathode load. This decrease in voltage drop will be just enough to offset the previous increase in the cathode voltage.

FUNCTIONING OF CONTROLS

The controls of the receiver are divided into two groups, the front panel operating controls and the rear panel pre-set controls.

FRONT PANEL OPERATING CONTROLS

There are seven front panel operating controls as indicated in Fig. 1, each operating independently of the other. Reading from left to right, the controls and their functions are as follows:

On-Off and Volume

This is a single control. The knob should be turned clockwise, until a click is heard. This supplies a.c. to the receiver. Further clockwise rotation of the control varies the input to the audio amplifier, and, consequently, controls the volume of sound output.

Vertical Hold

This control functions to keep the picture stationary in the vertical direction. Electrically it is a variable resistor which controls the frequency of the vertical sweep oscillator.

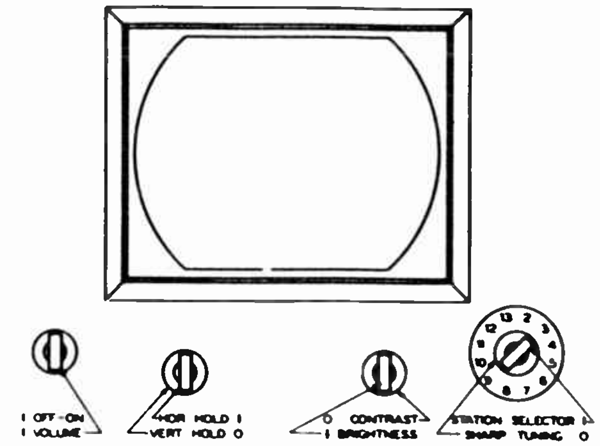

FIG. 1— OPERATING CONTROLS

If the sloping bar effect is as stated, then the picture should remain in sync over 1/4 rotation of the horizontal hold range and drop out of sync on either end of this range.

Horizontal Drive

This trimmer capacitor affects the height of the horizontal pulse, varying the horizontal linearity principally on the left side of the picture.

Focus

A variable resistor which controls the current flow through the focus coil on the neck of the tube.

Width

This slug adjustment inside the high-voltage cage affects the right side of the horizontal axis.

NOTE: There are no horizontal or vertical positioning controls. Centering of the picture is accomplished by positioning of the focus coil. The deflection yoke should be placed on the neck of the tube as far forward as possible.

ALIGNMENT PROCEDURE

Test Equipment

The test equipment required for the alignment of this receiver is as follows:

Marker Generator (RCA WR-39A, or equivalent)
Sweep Generator (RCA WR-59A, or equivalent)
Oscilloscope (RCA WO-55A, or equivalent)
VTVM (RCA Junior VoltOhmyst, or equivalent)
Volt-Ohmmeter (Simpson 260, or any 20,000 ohm-per-volt meter)

The marker generator is an r-f signal generator used for peaking the i-f coils and also to supply marker pips on the response pattern. The required frequency range of this generator is approximately from 20 to 30 mc and must also have provision for a 4.5 mc output. The accuracy of the frequency calibration of this generator is very important. It must also have provision for an amplitude modulated, as well as an unmodulated, r-f output.

The sweep generator has its output continually variable in frequency. In this alignment, only one output sweep signal is needed, that sweeping between 20 to 30 mc.

The oscilloscope used is a high-gain, general purpose type employed for test purposes. The size of the screen is unimportant.

The VTVM is of the standard type with a high input impedance. It should have provision for a-c and d-c measurements. A 20,000 ohm-per-volt meter should be used for d-c indications if the VTVM can only measure a.c.

Alignment

For the alignment points refer to the figure indicated in the discussion. Most of the adjustments are located on top of the chassis. The r-f marker generator is used in making most of the alignment adjustments. It is recommended that the order of alignment in the following procedure be adhered to if alignment is found necessary. The ground leads of the test instruments should be connected to the receiver chassis.

World Radio History

Horizontal Hold

The function of this control is to keep the picture stationary in the horizontal direction. It is a variable resistor which affects the frequency of the horizontal sweep oscillator.

Brightness

This control, which is also a variable resistor, affects the cathode voltage on the kinescope, thereby regulating the brightness of the picture.

Contrast

The contrast control provides a means for varying the relative intensities of black and white in the picture. Advancing this control toward excessive contrast will introduce a loud buzz.

Station Selector

This control permits selection of the channel desired.

Fine Tuning

This control varies the frequency of the r-f heterodyne oscillator. It is adjusted for best picture quality and is not used to tune in the sound.

REAR PANEL PRE-SET CONTROLS

There are six so-called pre-set controls at the rear of the chassis as indicated in Fig. 2. They are all screw driver adjustments. The SOUND DISC. is the alignment screw for the secondary of the ratio detector transformer L1, and is not considered a pre-set control.

Vertical Linearity

This control is a variable resistor in the cathode circuit of the vertical sweep output tube. Manipulation of this control affects the upper portion of the picture.

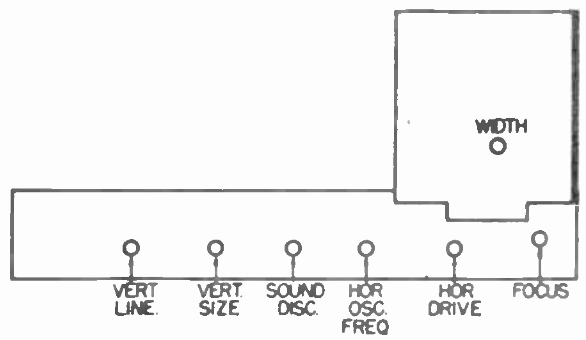

FIG. 2 — PRE-SET CONTROLS

Vertical Size

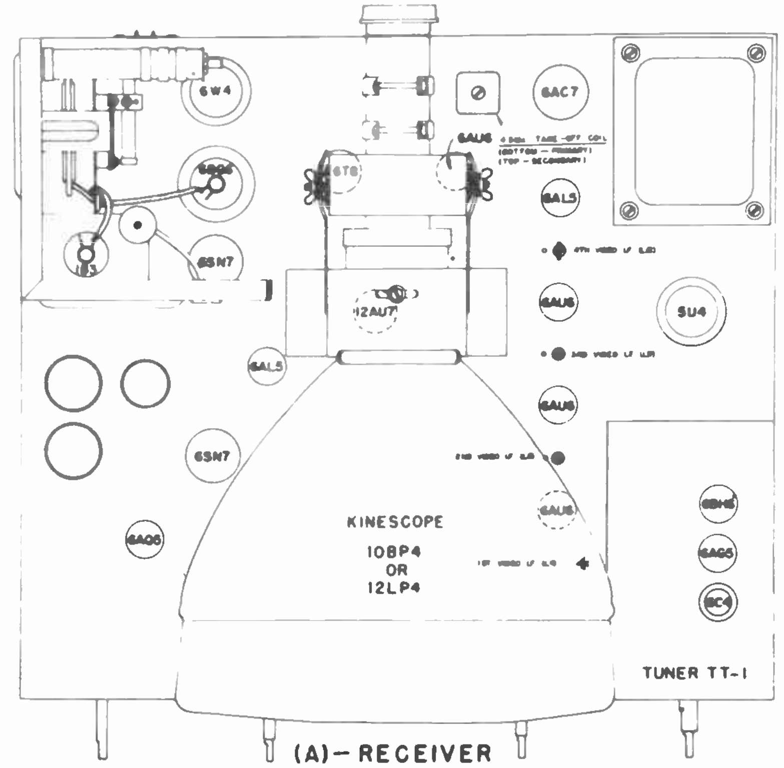
The vertical size control varies the plate voltage of the vertical sweep oscillator. It primarily causes a change in height of the picture but it also interacts with the vertical linearity so that these controls must be used in conjunction with each other.

Horizontal Oscillator Frequency

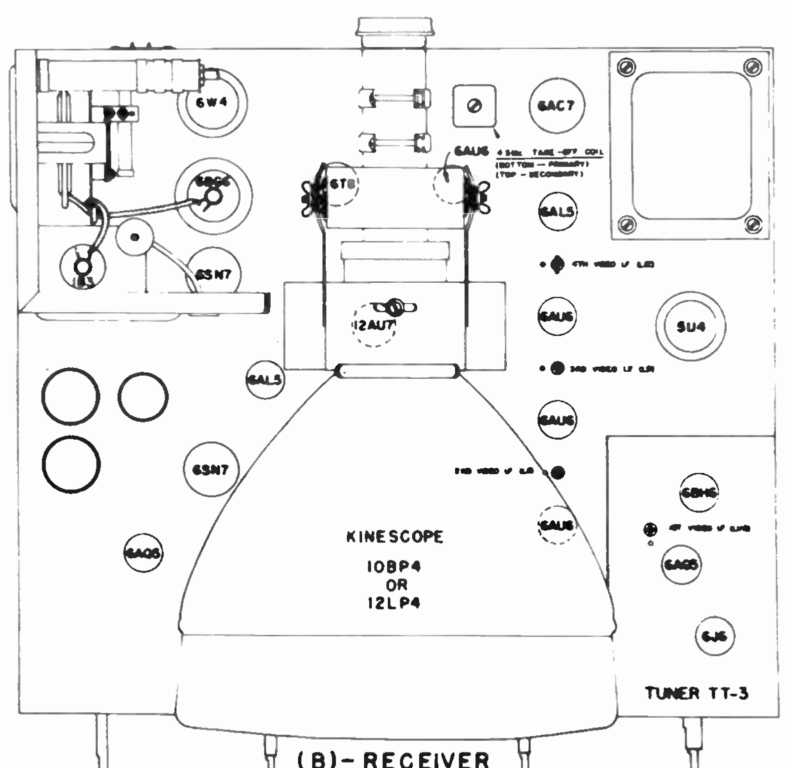
This control is a slug adjustment for L18 which controls the frequency of the horizontal oscillator. To set this control properly, connect an antenna to the receiver and tune in a station, preferably one with a test pattern on the air. Center the horizontal hold control. Adjust the L18 slug until the picture locks in. Set the horizontal hold control in the full clockwise position and slowly rotate it in the opposite direction. Just before the picture falls into sync, 3 or 4 black and white bars should appear sloping downward to the right. Repeat the process, but with the horizontal hold control in the full counterclockwise position. The same conditions should be observed except that the bars will slope downward to the left.

Picture I-F Alignment (Fig. 3)

Connect the VTVM (a-c scale), or oscilloscope to the grid of the kinescope at the junction of C223 and R222. (Do not attempt to take readings with the VTVM at the video detector.) Adjust the contrast control about 1/8 turn below its maximum setting. Connect the output of the signal generator (marker) to the nipple on top of the 6AG5 mixer tube of either tuner.



(A) — RECEIVER INCORPORATING TUNER TT-1.



(B) — RECEIVER INCORPORATING TUNER TT-3

FIG. 3 — TOP VIEW OF CHASSIS

Set the generator at 25.6 mc, amplitude-modulated at approximately 400 cycles, and adjust the first and third video i-f coils for maximum response. For those receivers employing tuner TT-1, the first video i-f coil is L4 as indicated in Fig. 3(A). When tuner TT-3 is used, the first video i-f coil is LV-6 and is incorporated in the tuner and not the receiver proper, as shown in Fig. 3(B). Reset the generator to 23.4 mc, still amplitude-modulated, and tune the second and fourth video i-f coils, L6 and L12 respectively, for maximum response. Repeat the above process for fine adjustments of settings.

Over-all Picture Response

With the sweep generator adjusted for a 10-mc sweep, using a center frequency of about 25 mc, connect the generator to nipple of the 6AG5 mixer tube of either tuner. Loosely couple the marker generator to the same mixer tube. The oscilloscope should remain at the grid of the kinescope. Inject individual markers of 26.1 mc, 25.6 mc, 22.6 mc, and 21.6 mc in the order indicated and note positions of marker pips on response curve. Turning the adjustments very slowly, retune the four video i-f coils again for an over-all picture i-f response as indicated in Fig. 4.

NOTE: A 30% variation in amplitude between peaks and from peak to valley, of the response curve is permissible. The most important considerations here are that the video i-f carrier of 26.1 mc is approximately halfway down the right hand slope, and that the sound i-f carrier of 21.6 mc is 20 times down at the other end of the curve.

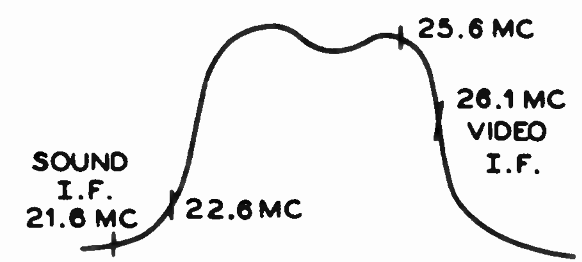


FIG. 4 — OVER-ALL I-F RESPONSE CURVE.

World Radio History

Sound Takeoff and Detector Transformer Alignment

Move the signal generator (marker) output lead to the junction of L13 and R217, between the video detector, V-7, and video amplifier V-8. Set the generator to a 4.5-mc unmodulated signal output. Connect the VTVM (d-c scale) or the 20,000 ohm-per-volt meter across C107 in the output circuit

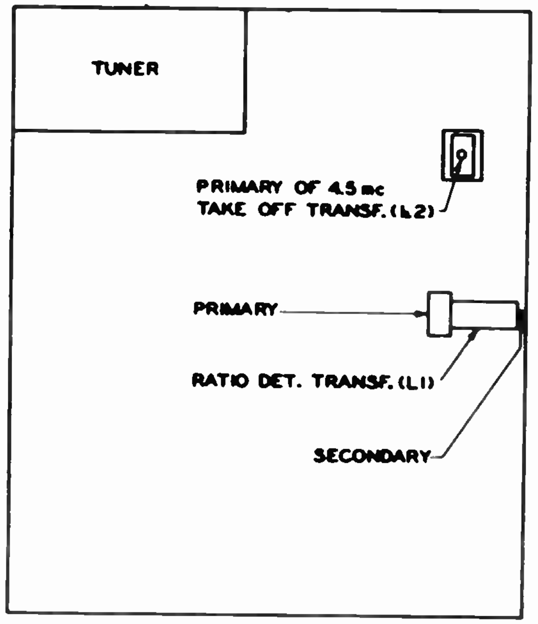

FIG. 5-BOTTOM VIEW SHOWING ALIGNMENT POINTS FOR L1 AND PRIMARY OF L2

of the ratio detector, V-2. (Remember that the negative lead at this point is actually above -140 volts with respect to ground.)

Adjust the following for maximum reading on the meter in the order indicated. The primary of L1 (the ratio detector transformer), the adjustment of which is shown in Fig. 5. Next tune the secondary of L1; this adjustment, shown in Fig. 5, is

also shown in Fig. 2 and indicated as SOUND DISC. Then adjust the primary L2, the 4.5-mc takeoff transformer; see Fig. 5. Next adjust the secondary of L2, shown in Fig. 3. Decrease the signal output from the generator to the minimum required to give a readable deflection on the meter and then repeat the sound alignment process.

After the alignment is complete, remove the generators and meters. Tune in a station. Turn up the contrast control until a buzz is heard. Adjust the secondary of the detector transformer (see Figs. 2 and 5) for minimum buzz.

NOTE: Alignment of the r-f and oscillator sections are not recommended and are therefore not included. If any misalignment of these sections is suspected, consult the manufacturer.

SERVICE NOTES

No Raster

Defective picture tube or misadjusted ion trap magnet.
No high voltage. Check tubes V-14, V-15, V-16, and V-17.
Check horizontal output transformer, T211T3; and also check C335, R326, and R336.
Check all voltages and waveforms in sweep section. Do not check voltage directly on plate of V-16.

Raster Present -- No Sound or Picture

Open transmission line.
Defective tube in r-f unit, or defective r-f unit.
Check B+ supply for sound and picture sections.
Check tubes V-1, V-2, V-3, V-4, V-5, V-6, V-7, and V-8.

Raster and Sound -- No Picture

Open green lead from picture tube socket.
Check tube V-8 and associated circuit.
Open C223.

Raster and Picture -- No Sound

Defective sound takeoff transformer, T2, or ratio detector transformer, T1.
Check tubes V-1, V-2, and V-3.
Defective audio output transformer, T1, or speaker.

Unable to Synchronize Vertically or Horizontally

Check tube V-9 and associated circuit.

Unable to Synchronize Vertically

Check tube V-13.
Defective vertical oscillator transformer, T3, or vertical output transformer, T4.

Unable to Synchronize Horizontally

Horizontal sweep oscillator coil L18 misadjusted.
Coil L18 or capacitor C315 defective.

Defective tubes V-11 or V-14, or feedback capacitor C330.
Check voltages, resistances, and waveforms in horizontal sync section.

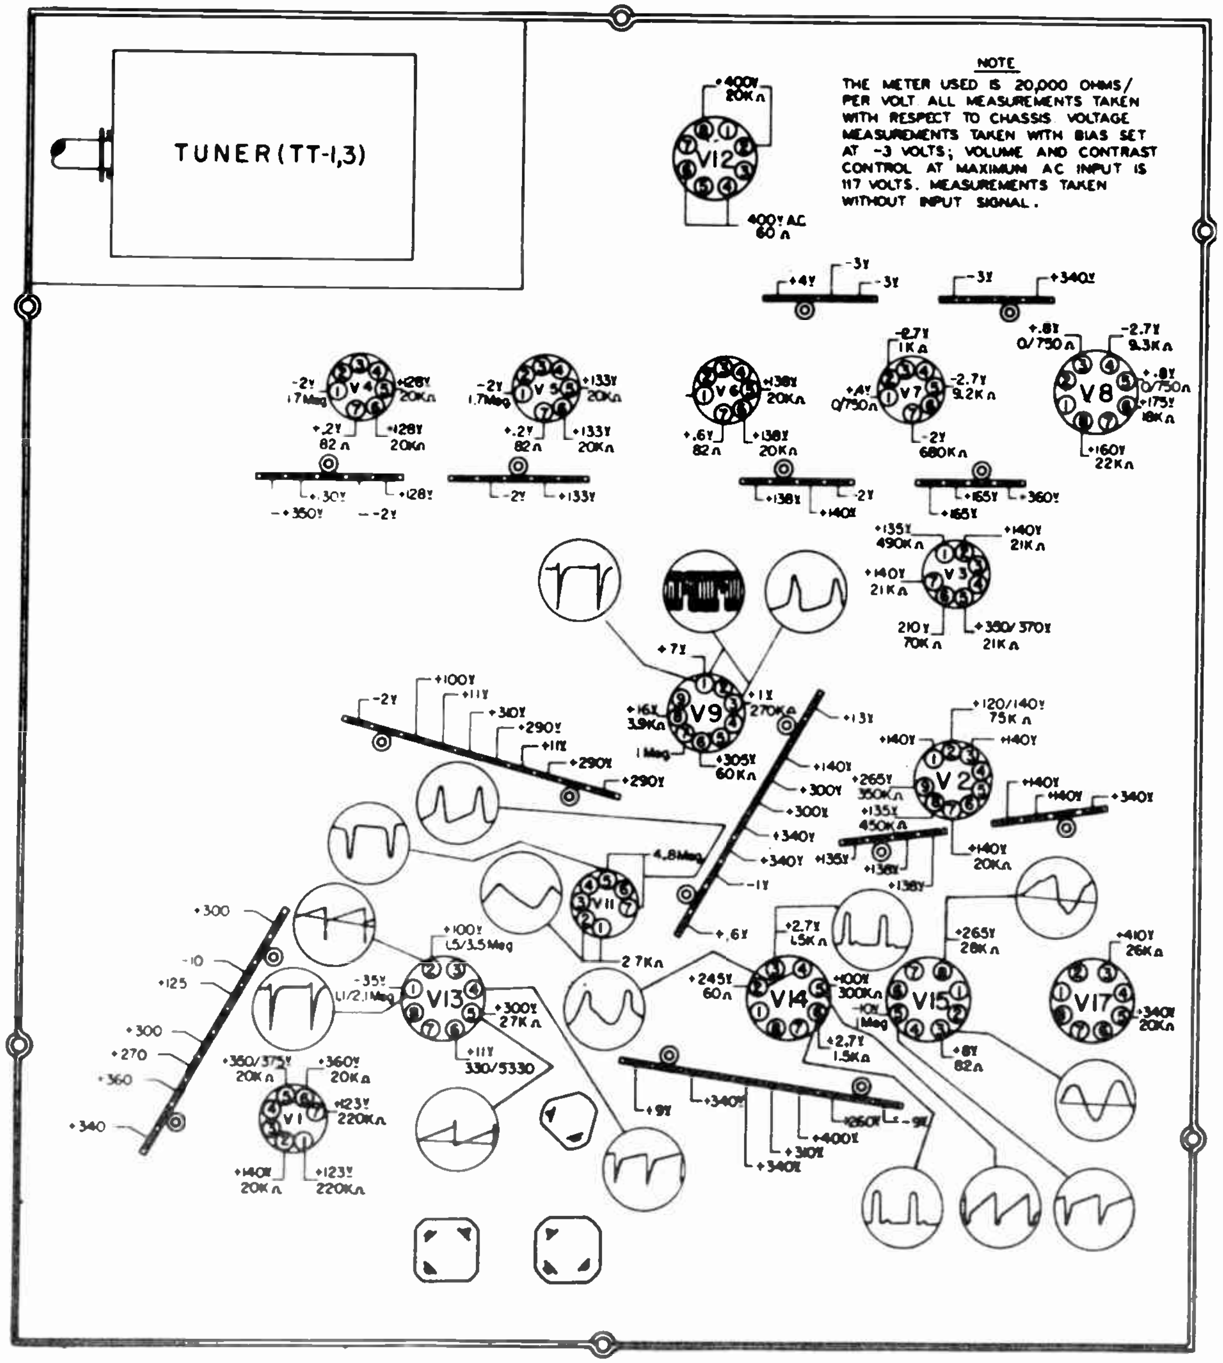

FIG. 6- BOTTOM VIEW INDICATING VOLTAGE AND RESISTANCE VALUES AND ALSO WAVE FORMS.

©John F. Rider

World Radio History

Insufficient Height

Defective vertical oscillator transformer, T3.
C313 increasing in capacity.
R304 and R310 changing in value.

Inability to Center Picture

Blanking on left side may be due to leaky C313.
Carefully try turning CR Tube.

NOTE: Entire audio circuit is at a potential of 140 volts above ground and the grids are hot. Also, V-1, 6AQ5, functions as a series voltage regulator to this 140 volts, as well as an audio output tube. Proper operation of this tube affects B+, and is, therefore, vital to normal operation of other circuits. A primary check of this circuit should be instituted when starting to service receiver.

For voltage and resistance analysis and waveforms, see Fig. 6.

DISASSEMBLY

To remove chassis from the cabinet, first pull off all knobs from controls in front of cabinet. Remove the six mounting bolts to be found underneath the cabinet and lift the chassis from the cabinet. Use care to prevent damage to the kinescope.

The kinescope is mounted on the chassis itself. It is held in place by a strap that is fastened over the outer rim of the bell of the kinescope.

World Radio History

World Radio History

VL 16 , VL 12, VL 19 CHASSIS
(Reference Numbers are for VL 16 in Most Cases)

ADJUSTMENT OF TUNING DIAL

Turn tuning shaft completely clockwise. Slide large dial into shaft. Engage gears so that line on flat surface of dial directly under number 13 lines up with Tuning Indicator marking on cabinet. Slip felt washer onto shaft. Now slide small dial onto shaft. Line up the numeral 1 of number 108 directly under numeral 1 of 13 on large dial and tighten set screw of small dial.

In very high signal strength areas the jumper between resistors R117 and R118 should be removed. This is located directly behind the contrast control.

For chassis with A.G.C. observe the following:

These conditions must be met for proper operation. A manual contrast control potentiometer must be connected by using a separate 10,000 Ohm control connecting one end to chassis, the other end to B- and the arm to the A.G.C. string before proceeding to align or adjust the Video IF, sound IF, head end and sync. adjustments as indicated in the regular service notes.

During sync. adjustment the regular contrast control in the set must be set so that the bias at the video output tube is +5 volts and left at this setting during all sync. adjustment procedure. After all alignment and adjustments are made and manual contrast control removed check operation of the A.G.C. on the air. The hold control will lock in signals at a point about 28% from clockwise rotation and must hold sync. for about 20% of additional rotation. If these conditions are not met the frequency control slug must be adjusted until the above conditions are met.

HEAD-END ALIGNMENT PROCEDURE FOR CHASSIS TYPES: VL-12, VL-16 & VL-19

A. Interstage Circuits:

1. Connect a 220-ohm resistor to pins 5 and 6 of mixer tube (V3).
2. Connect input of wide-band amplifier to pin 5 of V3.
3. Connect ground of wide-band amplifier to chassis of receiver.
4. Remove first video I.F. tube from socket.
5. Disconnect C5 from pin 1 of V1.
6. Connect sweep generator to pin 1 of V1 through a suitable capacitor (500 micro-microfarads). Adjust sweep to cover 44-70 mc range.
7. Set receiver tuning control to Channel 2.
8. Set contrast control at maximum contrast.
9. Couple the output of a suitable frequency marker generator, loosely to the r-f stage.
10. Adjust trimmer C10 and C12 to give the Channel 2 curve shown on INTERSTAGE RESPONSE CURVES, LOW CHANNELS.
11. Be sure that the signal level from the sweep generator is not too high otherwise the wide-band amplifier may be overloaded and produce a flat-topped response curve only as a result of clipping and not because proper tuning has been done.
12. Also, be sure that the signal level is not too low, otherwise, the non-linear detection of the amplifier will give a response curve on which the carriers appear to be located further down the sides than they really are.
13. Set receiver tuning control to Channel 13.
14. Adjust sweep to cover 200 to 226 mc range.
15. Adjust end inductors L5 and L6 to produce a curve similar to that shown in INTERSTAGE RESPONSE CURVES, UPPER CHANNELS for Channel 13. The end inductors are adjusted by unsoldering the junction of the crossed wires and varying the effective wire length in the circuit by sliding them over each other. When the correct adjustment is found, the junctions are resoldered.
16. The other channels should be checked for proper response curves.

B. Antenna Circuit:

1. Disconnect sweep generator from pin 1 of V1.
2. Re-connect C5 to pin 1 of V1.
3. Connect sweep generator to antenna input terminals of receiver through a 10-db. resistance attenuator designed to operate at VHF and having a characteristic resistance of 72 ohms.
4. The wide-band amplifier remains connected to pin 5 of V3 as before.
5. Set receiver tuning control to Channel 2.
6. Set contrast control at maximum contrast.
7. Couple the output of a suitable frequency marker generator, loosely to the r-f stage.
8. Adjust trimmer C4 to give the Channel 2 zero-volt curve shown on HEAD - END RESPONSE CURVES, LOW CHANNELS.
9. Repeat items 11, 12, 13 and 14 of part A.
10. Adjust end inductor L3 to produce a curve similar to that shown on HEAD-END RESPONSE CURVES, UPPER CHANNELS for Channel 13, zero-volt.
11. The other channels should be checked for proper response curves. The response curves should also be checked at -3 volts bias applied to the r-f tube.
12. Restore the receiver to its original condition by removing the 220-ohm resistor and by putting back V4.

C. Oscillator Circuit:

If the dial of the tuning control does not indicate correctly the TV channels or the FM frequencies, proceed as follows:

1. Make sure that the dial is oriented correctly on the tuner shaft by turning it to the extreme clockwise position. In this position the radial index mark on the dial and the numeral 1 of 108 mc should be at 12 O'clock, when the receiver is in normal viewing position.
2. If the dial calibration is still inaccurate, the lower channels are corrected by means of C41; the upper channels by end inductor L16.
3. If C41 is re-adjusted then L16 will require re-adjustment. But if only L16 is re-adjusted C41 will not need re-adjustment since L16 has no appreciable effect on the lower channels. L16 is adjusted by spreading or compressing its turns as required. Spreading the turns raises the oscillator frequency for a given dial setting in the upper channel region.

VIDEO IF ALIGNMENT

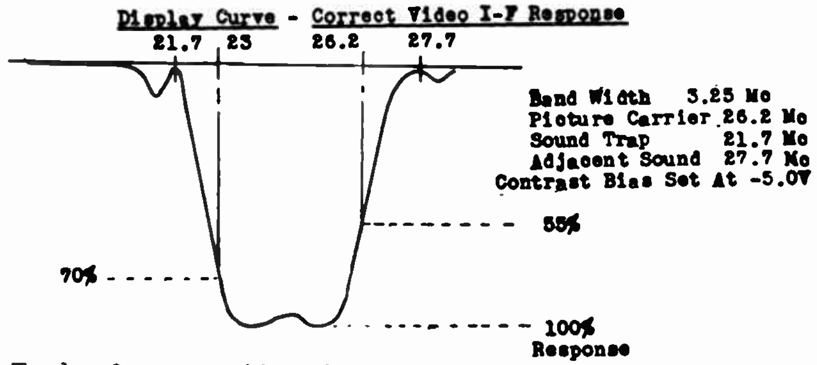
The video I.F. system employs stagger tuner stages consisting of a 6AK5, V3 mixer, three 6CB6, V4, V5. V6, 1st, 2nd and 3rd Video I.F. and 1/2 6AL5 video detector.

The converted pix carrier is 26.2 MC. and is adjusted to 55% down the slope of the Video I.F. pass band from the average top level. When adjusted correctly, the pass band extends from 26.2 MC to a point 70% down at 23 MC. see Figure 1. Traps are provided in the video I.F. system to properly attenuate the accompanying and adjacent sound carrier frequencies at 21.7 MC and 27.7 MC. The 21.7 Mc traps are located in the 2nd and 3rd video I.F. transformers. The 27.7 Mc adjacent sound traps are located in the 1st and 4th video I.F. transformers. The 21.7 Mc traps and 27.7 MC traps provide a 40 to 50 DB attenuation. All traps are tuned from the top of the chassis while all signal circuits are tuned from the bottom.

To align the video I.F., connect the video I.F. sweep generator to the mixer, V3 grid. Disconnect end inductor, L6. Set the sweep generator to cover 19 to 30 Mc and provide markers at 21.7, 23, 26.2 and 27.7 Mc. Connect the oscilloscope to the junction of L7 and L8 Peaking Coils in the circuit of the video detector, V7A. Adjust the contrast control for -5.0 volts. If the response curve obtained on the oscilloscope is appreciably different from that shown in Figure 1, the tuning slugs of the transformers T1, T2, T3 and T5 should be adjusted from the underside of the chassis.

Fig. 1

Display Curve - Correct Video I-F Response



The low frequency skirt of the response curve is principally affected by T1. The high frequency skirt by T3. The flatness of the central region is determined by T2 and T5.

The sound trap of T2, T3 and T4 are adjusted to provide maximum attenuation at 21.7. The traps in T1 and T5 are adjusted to provide maximum attenuation at 27.7 MC.

If T4 is tuned to frequencies above 21.7 Mc, it may cause the video I.F. amplifier to oscillate. This is normal and will stop when the cathode trap is tuned to the correct frequency.

SOUND I.F. ALIGNMENT

Set contrast voltage to 0 bias.
The sound I.F. is aligned stage by stage rather than the overall method.
Disconnect the negative side of C88, 2uf condenser. Connect scope to junction of R101 and R103. Connect FM sweep generator to grid of V19, 6AU6. Adjust bottom slug of T10 until pass band approximates Figure 2.

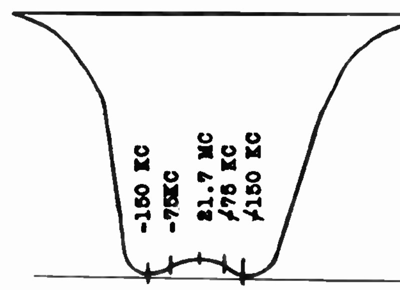


Fig. 2

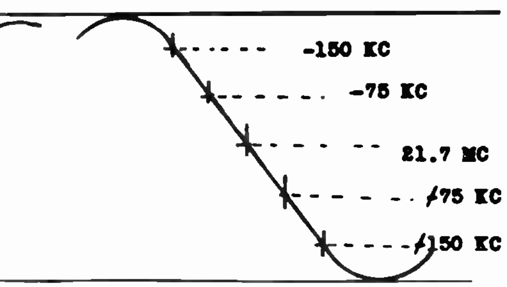

Fig. 3

Move scope to junction of R100 and R105. Adjust top slug on T10 until wave shape approximates Figure 3. This may detune bottom slug slightly. Leaving scope in last position adjust bottom slug of T10, if necessary, until S curve, Figure 3, is symmetrical with respect to center frequency.

Move scope to junction of R101 and 103. Connect FM sweep generator to grid of V18. Adjust primary and secondary, successively, so that wave shape approximates Figure 4.

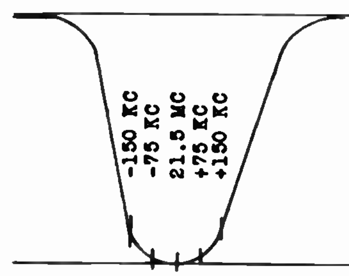

Fig. 4

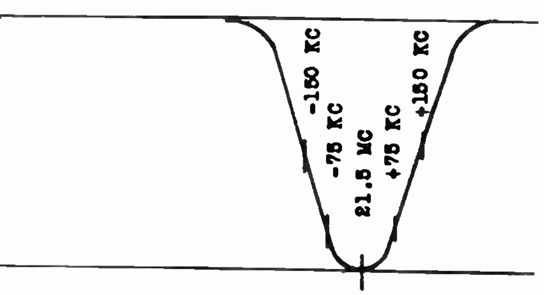

Fig. 5

Temporarily ground or disconnect junction of R94 and R104. Connect high side of R94 to -10 volts (this can be obtained from high side of contrast control through a 12K Resistor). Connect sweep generator to grid of V4. (Blocking condenser of about 500uuf must be used in series with sweep generator lead to prevent upsetting of bias on V4.) Adjust trap in T2 (Top slug) so that wave shape approximates Figure 5.

This completes Sound I.F. alignment.
Be sure to resolder all disconnected wires.

CAUTION: VL16 HORIZONTAL SYNC. ADJUSTMENT

Unless synchronization is carried out in the following manner carefully and accurately, poor Sync. operation will result.

MODELS T-VL12, Saybrook, Ch. VL-12; T-VL16, Mayfield; C-VL16, Sutton; CO-VL16, Fleetwood; Ch. VL16; CO-VL19, Caronia, Ch. VL19

World Radio History

Equipment:

An oscilloscope with a 2 mc Minimum Pass Band and Low Capacity Probe not exceeding 20 uuf. If the Probe Capacity is more than 20 uuf, the Optimum Sync. Adjustment cannot be made.

Sync. Adjustment Procedure:

(A) Set Up in the Following Manner:

1. Tune in a station so that Sync. is available. A Peak to Peak Video Signal of 15-35V at the Grid of the Picture Tube will be satisfactory.
2. Set the Horizontal Hold Control, located in the front of the chassis, to its mid-position.
3. Set the Horizontal Lock in Trimmer. HCV-2120 located on the Rear Apron of the Chassis, to 1/4 turn from its extreme Clockwise position.
4. Set the Horizontal Drive Trimmer, HCV-2120 located on the Rear Apron, to 1/4 turn from its Extreme Clockwise position.
5. Set the Phase adjustment of SA-335, The Horizontal Oscillator Transformer, to 3 turns from its Extreme Counter Clockwise position. This is available from the bottom of SA-335.
6. Set the frequency Adjustment so that the Stud is 1 inch from the can. This is located on the top of SA-335.
7. Place the Low Capacity Probe of the Scope on Point "C" of SA-335, and Sync. the Scope to get 3 or 4 cycles.

(B) Proceed With the Following Adjustments:

1. Turn up the Brightness and Contrast Control until a Raster can be seen. Adjust the Vertical Hold Control until the picture stops rolling. The general appearance of the Raster, with the horizontal Sync. Circuits out of Adjustment, will appear as a number of Diagonal Bars. Then,
2. Observe the Waveform on the oscilloscope which is connected to Terminal "C" of SA-335. This should look like Figure 1.

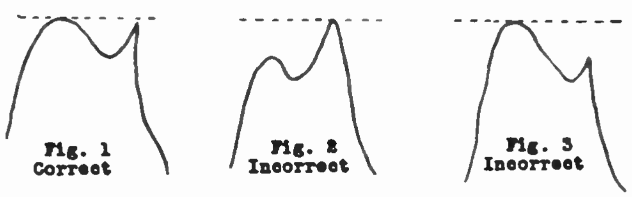

Fig. 1 Correct **Fig. 2** Incorrect **Fig. 3** Incorrect

During the Preliminary Sync. Adjustments, the Amplitude of the Broad and Sharp Peaks of this Waveform should be maintained within about 15% of each other. This may be accomplished by adjusting the Phase Control at the Bottom of SA-335.
3. Now turn the Frequency Adjustment, (Top of SA-335) or Horizontal Hold Control so that the Number of Diagonal Bars on the Cathode Ray Tube decreases until the Horizontal Locks in and a complete Picture is seen. If during the adjustment, the Broad and Sharp Peaks become more than 15% unequal. Reset them by means of the Phase Adjustment.
4. Now Adjust the Horizontal Width, Linearity and Drive Controls and the Vertical Linearity and Width Controls to get the Correct size and best Linearity.
5. Now turn the Phase Adjustment so that the Broad and Sharp Peaks are equal. The Picture may be held in Sync. during this adjustment by means of the Horizontal Hold Control.
6. Set the Horizontal Hold Control to its Extreme Clockwise Position, then turn the Frequency Adjustment until the Picture just holds Sync.
7. Now rotate the Horizontal Hold Control to its Extreme Counter Clockwise position and turn receiver off then on to cause loss of Horizontal Sync.; then, slowly rotate the horizontal Hold Control Clockwise until the picture Syncs. This should occur just after 3 Diagonal Bars appear. If more than 3 Bars are seen just before it pulls into Sync., turn the Horizontal Lock in Trimmer clockwise; If there are less than 3 Bars, turn Horizontal Lock in Trimmer counter-clockwise.
8. Then touch up the Phase Adjustments to equalize the Broad and Sharp Peaks in Amplitude and repeat steps (5) and (7).

The Sync. Adjustment is Optimum when the following conditions exist simultaneously:

1. Equal Amplitude of Broad and Sharp Peaks.
2. Sync. Holds over 90% of Hold Control Rotation with 15-20V Peak to Peak Video at C.R. Tube Grid.
3. Sync. will pull in just after 3 Diagonal Bars are seen.
4. Sync. will hold in at least 90° beyond the pull in point. The operating point should be about 30° beyond the pull-in point.

Caution:

(A) If the Broad Peak is Higher than the Sharp Peak, the pull-in Range is insufficient, while, if the Broad Peak is lower, the noise immunity is poorer.
(B) For Normal Settings of the Horizontal Drive the Grid of the 6CD6G will operate between 6 to 10V. A change of the Horizontal Drive Condenser will require a change in the Frequency Adjustment of SA-335.

Do not adjust Horizontal Drive Unless:

1. A White Bar occurs in the center of the Picture. Turn Horizontal Drive Condenser Clockwise until it disappears.
22. The Width is Insufficient. Turn Horizontal Drive Counter-Clockwise.
If sufficient Width cannot be obtained check tubes and other Circuit Constants.
(C) If Parts in the Horizontal Oscillator circuit have to be replaced tolerances should be observed. In particular if R76, 100K, or C56, 250uuf, are more than 10% above their nominal values, the Frequency Adjustment on SA-335 may not be sufficient to bring the oscillator into Sync.

VL 19 CHASSIS---A.M. ALIGNMENT

Oscillator shunt trimmer is located on chassis beside gang condenser.

Oscillator series padder is located on chassis to the rear of service switch.

A signal generator that supplies a modulated carrier of 455, 600, 1500 and 1650KC is needed plus an output voltmeter.

Step	Connect high side of signal generator to:	tune signal gen.to	tune radio to	Adjust for max. output
1	Grid of 6BE6 through .01 cond.	455KC	quiet spot near 700KC	trimmers on 1st & 2nd I.F.T.
2	Terminal "A" on loop through 250 uuf cond.	1650KC	extreme rt. end of dial	oscillator shunt trimmer
3	Terminal "A" on loop through 240 uuf cond.	1500KC	tune in 1500KC sig.	trimmer on loop.
4	Terminal "A" on loop through 250 uuf cond.	600KC	rock in 600KC sign.	oscillator series trimmer
5	Repeat steps 2 & 3			
6	Repeat step 4 if necessary

SPECIFICATIONS

Power Supply Rating (10 in. - 12 ½ in.)	115 volts, 60 cycles, 225 watts
Power Supply Rating (16 in.)	115 volts, 60 cycles, 250 watts
Audio Power Rating Max. (10 in. - 12 ½ in.)	2.5 watts
Audio Power Rating Max. (16in.)	4.0 watts
Antenna Input Impedance	300 ohms balanced
Video Response	To 4 Mc.
Focus	Magnetic
Sweep Deflection	Magnetic

I. F. Frequencies

Picture Carrier	25.75 Mc.
Adjacent Channel Sound Traps	27.25 Mc.
Adjacent Channel Picture Carrier Traps	19.75 Mc.
Accompanying Sound Traps	21.25 Mc.
Sound Carrier	21.25 Mc.
Sound Discriminator Band Width Between Peaks	350 Kc.

The ARVIN television receiver will in most cases be ready for installation when unpacked from its shipping carton. However, it is advisable to "air-check" the receiver before delivery and make any necessary final adjustments. A critical eye prior to and during installation will minimize service calls and promote a satisfied customer.

ADJUSTMENTS

ION-TRAP. Proper attention to ion-trap adjustment must be given to insure the normal long life and satisfactory operation of the picture tube. Assuming the ion-trap is off to the extent that no raster appears proceed as follows:

With an approximate mid-point setting of the brightness control and the rear pole of the ion-trap magnet positioned over the flags on the tube's gun structure rotate the trap. If no raster appears, slide the ion-trap slightly forward or backward and again rotate. Adjust the ion-trap finally for maximum brilliance with the brightness control set at the maximum position for which good line focus is had. If the ion-trap must be moved more than 1/4 inch away from the flags toward the focus coil, the ion-trap magnet is too weak and should be replaced.

Do not have the brightness control at maximum when positioning the ion-trap and do not use the ion-trap to remove side shadows if in so doing the brilliance of the raster decreases (adjust focus coil centering for this purpose.)

<u>SQUARING THE RASTER.</u> The Yoke Mount and Yoke should be positioned properly as follows:

The large front hole in the Yoke Mount Bracket is rimmed with rubber channel. Loosen the two screws in the feet of the Yoke Mount Bracket and push the mount forward so that the cone of the picture tube fits snugly into the rubber channel (neck of tube co-axially centered.) Loosen the top wing-nut and two side screws holding the Yoke within the bracket and slide the Yoke forward onto the cone of the picture tube-center the Yoke so the tube neck is co-axial and tighten the two side mounting screws. Rotate the Yoke to square the raster and tighten the top wing-nut.

<u>CENTERING.</u> No electrical provision in the circuit is made for centering. The focus coil must be positioned properly for centering of the picture. The focus coil of the 10 in. and 12 in. chassis is mounted by four adjustment screws. The focus coil of the 16 in. chassis is mounted by three adjustment screws. These screws must be properly adjusted for centering of the picture and removal of picture corner-clipping and side shadows.

<u>HEIGHT AND VERTICAL LINEARITY (Front).</u> The picture should fill the mask and be symmetrical from top to bottom. Adjustments of both the Height Control and Vertical Linearity Control will accomplish this if centering of picture by the focus coil is already proper.

<u>HORIZONTAL WIDTH, LINEARITY, AND HOLD.</u> If horizontal adjustments appear necessary, refer to the alignment section for procedure.

<u>FOCUS.</u> Adjust the Focus Control for best definition of the trace lines in the major central area of the picture or raster.

<u>AUTOMATIC GAIN THRESHOLD CONTROL (AGC).</u> The AGC Threshold Control is set at the factory and will seldom have to be readjusted. The effects of adjustment of this control are as follows:

1. Maximum counter-clockwise position allows the maximum AGC voltage to be developed. It will rarely ever have to be left in this position.

2. Advancing the control clock-wise slowly in a strong signal area will cause the blacks in the picture to get darker--advancing the control clockwise further will cause the picture to "bend" along the top--and even further, the picture in some cases could just blank out. At the point of rotation where the picture begins to bend is the overload point-- the bending being caused by sync-clipping in the video stage due to overdriving. On weaker signals the clockwise rotation will darken the blacks somewhat and also brighten the snow.

3. The optimum setting for the AGC Control is as follows:

a. Turn AGC Maximum counter-clockwise.

b. Turn AGC slowly clockwise while observing very closely the vertical interlace of the scanning lines in the raster.

c. Leave the AGC Control set at the point where interlace is best (least jitter and "pairing" between adjacent scanning lines).

d. Never should the control be left close to the overload point where strong signals could cause the picture to bend.

e. Approximately one-eighth of a turn clockwise is the usual best interlace point.

<u>OSCILLATOR TOUCH-UP.</u> All channels should come in best with the same approximate setting of the Fine Tuning Control.

If necessary, improvement of the setting on any channel can be made by slight adjustment of the oscillator screw for the particular channel. Remove the Station Selector Knob, Fine Tuning Knob, and Channel Escutcheon (slide the Escutcheon Spring to one side to free the Escutcheon). The numbered oscillator adjustment screws in the tuner can now be seen. Use an insulated screw driver and adjust the desired channel screw.

SERVICE TEST EQUIPMENT

<u>R-F SWEEP GENERATOR.</u>

To provide center Frequency Range--20 Mc. to 30 Mc. with 1 Mc. to 10 Mc. sweep width.

To provide center Frequency Range--50 Mc to 90 Mc.

To provide center Frequency Range--170 Mc. to 225 Mc.

Variable output-at least .1 volt maximum-flat sweep output all ranges.

<u>R-F SIGNAL GENERATOR.</u>

To provide frequencies from 19.75 Mc. to 27.25 Mc -55.25 Mc. to 87.75 Mc.--175.25 Mc. to 215.75 Mc.

©John F. Rider

World Radio History

Variable Output and at least .1 volt maximum.

HETERODYNE FREQUENCY METER.

With crystal calibrator to check R-f Signal Generator.

CATHODE RAY OSCILLOSCOPE.

With wide band vertical deflection and means to calibrate input.

ELECTRONIC VOLT OHMMETER.

With multiplier probe for hi-voltage measurements to 10KV.

ALIGNMENT

It is very important that the proper condition of R-f ground for the test equipment with respect to the receiver be had before attempting alignment. To accomplish this place the receiver and test equipment on a conductive sheet of metal and bond or by-pass the equipment to it. Touching the test leads, test equipment, or receiver chassis should have no effect on the scope pattern or meter reading.

SEQUENCE FOR COMPLETE ALIGNMENT.

1. Sound discriminator.
2. Sound I-f.
3. Picture I-f Traps.
4. Picture I-f.
5. R-f oscillator.
6. R-f and converter.
7. 4.5 Mc. Video Trap.

SOUND DISCRIMINATOR.

1. Signal Generator setting--21.25 Mc.--.1 volt output--connect to pin 1 of V2, 2nd sound I-f.

2. Detune T102 secondary (bottom).

3. Connect voltohmyst through a 1 meg. resistor to the junction of R109, R108 (Test Point A).

4. Adjust primary T102 (top) for maximum meter reading.

5. Connect voltohymst to junction of C114 and R109 (pin 5, V3) (Test Point B).

6. Adjusting T102 (bottom) will vary meter reading from a plus voltage to minus voltage. Adjust for zero (point where it swings from plus to minus).

7. Connect sweep to pin 1 of V2, 2nd sound I-f, -sweep bandwidth approximately 1 mc. with center frequency of 21.25 mc.,-1 volt output.

8. Connect oscilloscope to pin 5 of V3 through 33,000 ohm isolating resistor. If pattern is not symetrical, adjust primary of T102 (top). See Fig. 1.

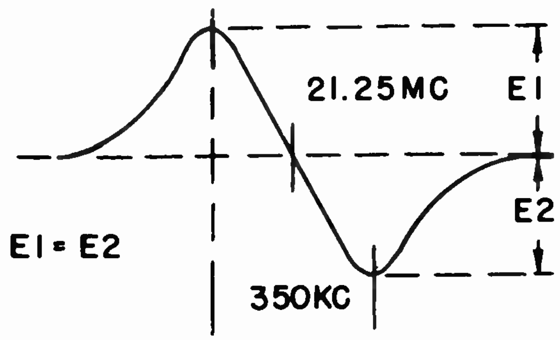

Figure 1

SOUND I-F. Switch Channel Selector to position 14 (kills oscillator).

1. Connect sweep to pin 1 of V1, 1st sound I-f. (Center frequency of 21.25 mc).

2. Connect oscilloscope to point A of T101 through a 33,000 ohm isolating resistor-(Test Point C). (If possible use sweep generator ex-ternal sweep for oscilloscope horizontal sweep).

3. Insert a 21.25 mc. marker from signal generator into pin 1 of V2. (It is best to couple the marker signal generator loosely--for instance, clipping the generator lead to a chassis point near pin 1 of V2).

4. Adjust top and bottom of T101 for maximum gain and symmetry around marker.

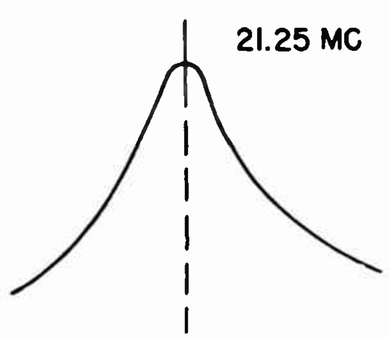

Figure 2

5. Final touch-up of curve should be with sweep input low enough so that the scope reading is not greater than .3 volt peak to peak or greater than .5 volt D-c.

PICTURE I-F TRAPS. Switch Channel Selector to position 14 (Kills oscillator).

1. Connect the voltohymst to junction of R155 and R156-(Test Point D).

2. Remove V12A, AGC Amplifier.

3. Connect a 250,000 ohm potentiometer between pins 5 and 6 of the V12A socket (Note-an old tube base with the 250,000 ohm pot soldered to its pin 5 and 6 is convenient since it can be plugged into the socket just like a tube.) (If the 250,000 ohm potentiometer isn't available, connect the minus terminal of a 4.5V battery to TEST POINT D and the plus terminal to ground).

4. Adjust potentiometer until meter reads (-4.5 volts).

5. Remove converter tube and twist one end of a small piece of wire around pin 1, the grid. Place tube back in socket and connect R-f generator to this wire clip through a small condenser (1500 MMFD).

6. Connect voltohmyst across R134, V10B load resistor (BETWEEN TEST POINTS E AND F). Since both meter leads are now at about minus 120 volts, do not ground meter case or touch it.

7. With a crystal calibrator check the generator setting for each of the following trap frequencies and then adjust each trap for minimum indication on meter:

21.25 mc. T106 (top)
21.25 mc. T108 (top)
27.25 mc. T105 (top)
27.25 mc. T107 (top)
19.75 mc. T104 (top)
19.75 mc. T109 (top)

The correct position of the cores is in the outside end of the form. The core can be run down through the coil for another dip, but in this position the coupling is wrong and overall response will be incorrect.

PICTURE I-F. Switch Channel Selector to position 14 (Kills oscillator).

1. Signal generator on converter grid as in trap adjustment.

2. Set generator to following and adjust transformers for peak reading on meter which is still across R134 (BETWEEN TEST POINTS E AND F).

22.65 mc.	T109 (bottom)	- - - output of V9,	4th Pix I-F
24.8 mc.	T107 (bottom)	- - - output of V8,	3rd Pix I-F
21.95 mc.	T106 (bottom)	- - - output of V7,	2nd Pix I-F
26.3 mc.	T105 (bottom)	- - - output of V6,	1st Pix I-F

3. Reduce input signal during alignment if overloading is indicated by very broad peak.

4. Overcoupled T1 and T104 (bottom) must be aligned by sweep.

5. Connect 330 ohm resistor (composition) across the primary coils of T105, T106, T107, T109.

6. Connect the oscilloscope to pin 1 of V11A, the 1st video amplifier plate, through 33,000 ohm isolating resistor (TEST POINT G).

7. Connect voltohmyst to the junction of R155 and R156 (TEST POINT D), and adjust the potentiometer (step 3 of trap adjustments) to minus 2 volts.

8. Connect a sweep generator (set to sweep from 20 mc. to 30 mc.) to the converter grid, through a 1500 MMFD condenser.

9. Adjust T1 and T104 for the following response:

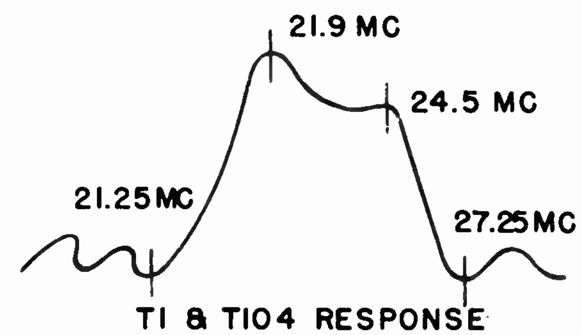

Figure 3

10. Remove the 330 ohm resistors.

11. It will be necessary to touch up the I-f adjustments to get the shown over-all response (Fig. 4).

NOTE: A defective V10B will cause a bad dip in the curve.

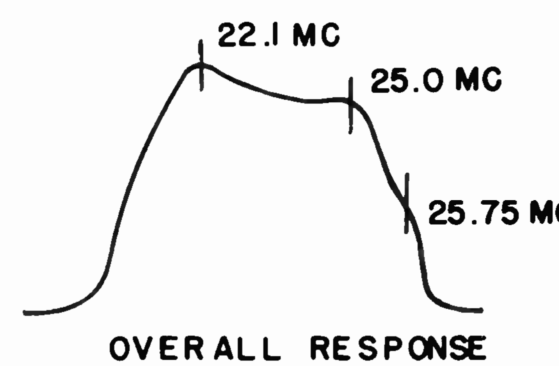

Figure 4

12. Adjust the bias pot for a 15 volt peak to peak signal on the scope (pin 1 of V11A). The measured bias should now be minus 4.5 volts or less.

NOTE: To see the response of any single stage, follow steps 5, 6, 7, 8 except remove the 330 ohm resistor on the particular stage to be observed.

©John F. Rider

World Radio History

13. Remove bias potentiomenter and replace V15.

14. Remove clip from converter grid and replace tube in socket.

NOTE: Picture I-f oscillation can occur in a receiver that is badly misaligned and will show up as a voltage across R134, the video detector load resistor, that is unaffected by R-f input. By approximating the core positions of T104, T105, T106, T107, T108, and T109 as compared to those in a correctly aligned receiver, the oscillation may stop. If still existing, try increasing the bias on V6 and V8. If these attempts fail, shunt the grids of V8, V7, V6 to ground with a 1,000 MMFD capacitor, connect the signal generator to the grid of V9, and align T109. Progressively remove the shunts and align each I-f stage working back to T104. If oscillation is still present, it is not due to misalignment--therefore, an individual component and voltage check must be made in the I-f section.

AN ALTERNATE METHOD OF SWEEP ALIGNMENT OF T1 AND T104 AND PICTURE I-F.

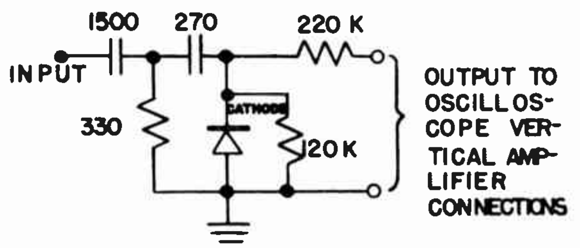

Figure 5

1. Adjust the bias at the junction of R155 and R156 (TEST POINT D) to minus 1.5 volts. (See bias adjustment of Step 3 on PICTURE I-F Traps).

2. Connect the detector input to pin 1 of V7 (See Figure 5).

3. Connect a sweep generator (sweep from 20 mc to 30 mc.) to the converter grid through a 1500 MMFD condenser.

4. Adjust T1 and T104 for the response of Fig. 3.

5. Remove the detector from the scope-input lead.

6. Connect the oscilloscope to pin 1 of V11A (TEST POINT G).

7. Overall I-f response should be as in Fig. 4. Markers should locate as shown.

NOTE: To see the response of any single stage, connect the sweep generator output to the input of the stage to be observed and the input terminal of Figure 5 to the output of the following stage.

FREQUENCY TABLE.

Channel No.	Band Width (mc.)	Picture Carrier (mc.)	Sound Carrier (mc.)	R-F Osc. (mc.)
2	54-60	55.25	59.75	81
3	60-66	61.25	65.75	87
4	66-72	67.25	71.75	93
5	76-82	77.25	81.75	103
6	82-88	83.25	87.75	109
7	174-180	175.25	179.75	201
8	180-186	181.25	185.75	207
9	186-192	187.25	191.75	213
10	192-198	193.25	197.75	219
11	198-204	199.25	203.75	225
12	204-210	205.25	209.75	231
13	210-216	211.25	215.75	237

R-F OSCILLATOR ALIGNMENT. Use non-metallic screw driver.

The oscillator adjustment screws are reached from the front of the tuner through the numbered holes around the channel switch. A few turns of the alignment screw on any channel can be made without concern for the effect on other channels, since for slight adjustments the channels are substantially independent. Channels 8 and 7 are affected by large screw displacement on channels 6 and 5.

The range of electrical effect for the screws is 7 turns from tight. Further turns may cause the coil sleeve to drop out on the high channels.

The following is for complete R-F Oscillator alignment:

1. Set fine tuning trimmer at mid-point as accurately as possible.

2. Set all oscillator alignment screws 4 turns from tight.

3. Align channel 6 as follows:

a. Connect a voltohmyst to pin 5 of V3 (discriminator output) (TEST POINT B).

b. Feed channel 6 sound carrier (87.75 mc.) into antenna terminals. (See Frequency Table).

c. Adjust channel 6 oscillator screw for zero voltage on voltohmyst. This actually indicates the center frequency of the "S" curve, so obviously the discriminator must first be known to be correctly aligned before R-F oscillator alignment can be made using this method.

4. Follow step 3 for channels 5 through 2 in that order.

5. Follow step 3 for channels 7 through 13 in that order.

6. Re-check channels 6 through 2 in that order-touch up if necessary.

7. Re-check channels 13 through 2 in that order-touch up if necessary.

NOTE: If on the high channels the adjustment screw has insufficient range, physical movement of the coils can be made with care for increasing or decreasing inductances.

R-F AND CONVERTER ALIGNMENT. Due to very close design these should require no future adjustments so no provisions have been made for such.

HORIZONTAL OSCILLATOR ALIGNMENT.

1. Turn the Channel Selector to a station.

2. Turn the Horizontal Hold Control Maximum clockwise.

3. Turn the Horizontal Lock Adjustment to almost tight.

4. Connect the oscilloscope to terminal "C" of T112.

5. Turn the T112 Blocking Waveform Adjustment maximum counter-clockwise.

6. Sync the picture by adjusting the Horizontal Frequency Adjustment Screw of T112.

7. Turn the Blocking Waveform Adjustment until the waveform is correct as in Figure 6.

8. Adjust the T112 Frequency Adjustment so that the picture just breaks syncs (the ideal is to have a wide vertical black bar representing horizontal blanking showing somewhere in the picture).

9. Turn the Horizontal Hold maximum counter-clockwise. If picture doewn't break sync, turn the Station Selector off-channel and then back. Picture will now be out-of-sync.

10. Turn the Horizontal Hold Control slowly clockwise and count the diagonal black bars just before "pull-in."

11. There should be 3 bars---adjust Horizontal Locking Range until only 3 bars are present before "pull-in".

12. Turn Horizontal Hold Control maximum clockwise. Picture should just break sync as in Step 8.

13. Adjust T112 Frequency Adjustment to obtain condition of Step 8.

14. Repeat steps 8 thru 12 if necessary to obtain conditions of Steps 8 and 11.

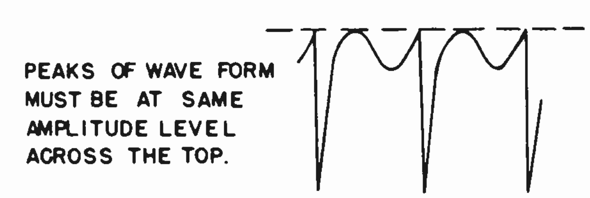

Figure 6

DRIVE, LINEARITY, WIDTH ADJUSTMENTS. The Drive Control, C186A, will have greatest effect on the left side of the picture---stretching or compressing.

The Linearity Control, L116, will have greatest effect on the right side of the picture.

The Width Control L115, adjusts the horizontal width of the raster to compensate for line voltage variations. On the 12 1/2 in. and 16 in. chassis a switch is provided for disconnecting the Width Control, L115, for the condition of maximum width.

4.5 MC. TRAP ADJUSTMENT

1. Tune in a strong station.

2. De-tune the Fine Tuning slightly from best sound.

3. Adjust L105 to eliminate any 4.5 Mc. beat pattern that may appear in the picture.

CRITICAL LEAD DRESS ON CHASSIS TE-272-1 AND TE-272-2 AND TE-276.

1. All by-pass condenser leads on the I-f strip as short as possible.

2. Short lead between body of R111 and pin 5 of V3.

3. Do not re-route bus wire from pin 2 of V2.

4. Filament leads between V3, V4, V5 keep down to chassis and away from grid and plate leads.

5. All leads crossing I-f circuits should be held close to chassis. Movement of such leads could change alignment.

6. Pix I-f coupling capacitors must be away from the chassis. Moving these will affect alignment.

7. All peaking coils should be held away from chassis.

8. Green lead from pin 2 of V11, white-orange lead from pin 8 of V11 away from chassis.

9. Blue lead from pin 5 of V4 close to chassis.

10. C124, C125 away from chassis.

11. R213, R214, R220, R221, R222, R219 should have long leads and held up and away from tube sockets and chassis.

12. Keep leads from L115 (width control) away from transformer frame.

13. Dress filament leads from horizontal transformer T113 away from chassis.

14. Dress lead from top cap of 6BG6 tube away from frame of transformer.

15. Dress lead from top cap of 1B3GT away from chassis.

16. Dress red lead from lug 4 of T113 down

©John F. Rider

World Radio History

against chassis underneath bus wire from chassis to terminal strip to hold it in place.

17. C203 leads should be as short as possible (parasitic oscillations can occur with long leads).

18. White-orange lead from pin 8 of V11 dressed away from the volume control terminals and components.

NOTES ON SERVICING

No Raster.
1. Check ion trap adjustment.
2. Check Brightness Control, R120.
3. Check Hi-Voltage.
   a. Defective V16, V17, V18, or V19.
   b. Open Horizontal Deflection Coils.
   c. Defective C181.
   d. Defective picture tube.

One Vertical Line Only On Picture Tube.
1. No horizontal sweep.
   a. Defective Horizontal Deflection Coils.

Picture Very Narrow (1/2 in. wide or so) in the Center of Tube.
1. Defective Horizontal Output Transformer, T113.

One Horizontal Line Only On the Picture Tube.
1. No vertical sweep.
   a. Defective V14 or V15 or circuits.
   b. Defective Vertical Deflection Coils.

Not Enough Width.
1. Low line voltage.
2. Change V17.
3. Check C188.

Horizontal Linearity Poor Beyond Adjustment.
1. Change V17.
2. Check C183, L116, C182, C184, C185.
3. Check T113.

Vertical Linearity Poor Beyond Adjustment.
1. Check C176B, C175.
2. Defective T111.

Vertical Retrace Lines Showing (Brightness Control Does Not Correct.)
1. Defective T111.

Bright Horizontal Line In the Picture Which Is Moved By the Height Control.
1. Defective V15.

Wide Vertical Black Bar Dividing Picture.
1. High Resistance Short of C167.

No AGC--Possible Negative Picture.
1. Shorted C160.

Very Snowy Picture - No AGC.
1. Shorted C157.

Sound and Raster But No Picture.
1. Check I-F String.
2. Check V10B, V11.

Picture But No Sound.
1. Check T106 Trap.
2. Check V1, V2, V3, V4, V5.
3. Check Speaker.

No Vertical Sync.
1. Check R177, C170, R178, C171, R179, C172.
2. Check C173.

No Horizontal Sync.
1. Check C169.
2. Check V16A and Horizontal Alignment.

Poor Resolution.
1. Check L103, L104, L107, L106.
2. Check I-F Alignment.
3. Check C138, C139.
4. Check D-C Voltages in Video Circuit.

Black Horizontal Bars Moving With Sound.
1. Microphonic tube in tuner.
2. Check sound trap alignment.

No Sync.
1. Check V13, V14.
2. Check I-F Alignment.

PICTURE TUBE WARNING

IMPLOSION OF PICTURE TUBE IS DANGEROUS. AVOID SHARP BLOWS-DROPPING-OR FORCING WHEN MOUNTING. DO NOT HANDLE THE PICTURE TUBE BY ITS NECK. WEAR GOGGLES AND HEAVY GLOVES WHEN HANDLING. PLACE UNUSED PICTURE TUBES IN PROTECTIVE CARTONS.

HI-VOLTAGE WARNING

HI-VOLTAGES EXIST WITHIN THE RECEIVER CHASSIS. ONLY PERSONS FAMILIAR WITH THE LOCATION OF THESE HI-VOLTAGE POINTS AND HAVING KNOWLEDGE OF USUAL HI-VOLTAGE PRECAUTIONS SHOULD MAKE CHASSIS INVESTIGATIONS.

16" PICTURE TUBE WARNING

THE METAL CONE OF THE 16 IN. PICTURE TUBE SERVES AS THE HI-VOLTAGE ANODE HAVING 12.5 KV ON IT. USE EXTREME CAUTION WHEN OPERATING OUTSIDE OF CABINET AND DO NOT REMOVE THE PROTECTIVE HI-VOLTAGE SLEEVE COVER.

REMOVAL OF THE 10 IN. PICTURE TUBE

1. Loosen the screws (don't remove) holding the front picture tube stop bracket.

2. Remove the picture tube socket, ion-trap, and anode connector.

3. Free one end of the hold-down strap.

4. Lift up the front of the picture tube to clear the front stop bracket and slide the tube forward and out. CAUTION: DO NOT EXERT LEVERAGE ON THE TUBE NECK WHICH IS IN THE YOKE AND FOCUS COIL MOUNT.

5. PLACE THE TUBE IN AN UNUSED CARTON.

REMOVAL OF THE $12\frac{1}{2}$ IN. PICTURE TUBE

1. Remove the picture tube socket, ion-trap, and anode connector.

2. Free one end of the hold-down strap.

3. Lift up the front of the picture tube to clear the front stop bracket and slide the tube forward and out. CAUTION: DO NOT EXERT LEVERAGE ON THE TUBE NECK WHICH IS IN THE YOKE AND FOCUS COIL MOUNT.

4. PLACE THE TUBE IN AN UNUSED CARTON.

NOTE: If it is necessary to loosen the bottom-support-bracket, and drop it down to allow the tube to slide out, first mark the fixed position of the bracket on the chassis since this position is correct for proper alignment of the picture tube face with the cabinet mask. When the tube is replaced the front-bottom-support-bracket can then be adjusted to the marked position.

REMOVAL OF THE 16 IN. PICTURE TUBE. Follow the procedure for the 12 1/2 in. picture tube---. When freeing the hold-down strap, also remove the metal strut mounted between the hold-down strap, and the yoke mount. This will allow the hold-down strap to be lifted up.

ARVIN CHASSIS TE 272-1 TE 272-2

CIRCUIT DIAGRAM NOTES

1 ARROWS AT CONTROLS INDICATE CLOCKWISE ROTATION.
2 FOR RESISTANCE AND DC VOLTAGE MEASUREMENTS SET THE AGC THRESHOLD AND BRIGHTNESS CONTROLS MAXIMUM COUNTERCLOCKWISE AND VOLUME CONTROL CLOCKWISE.
3 RESISTANCES SHOWN ARE IN OHMS K=1000.
4 CAPACITANCE VALUES LESS THAN 1 ARE IN MFD AND MORE THAN 1 IN MMFD.
5 DC VOLTAGES BETWEEN TUBE PINS AND CHASSIS ARE READ WITH VOLTOHMYST USING A 100 K OHM ISOLATING RESISTOR ON THE PROBE - ANTENNA TERMINALS SHORTED - LINE VOLTAGE 117 V, 60~.
6 PIN VOLTAGES AFFECTED BY HORIZONTAL AND VERTICAL CONTROLS ARE TYPICAL FOR A PICTURE ADJUSTED TO SYNC AND LINEARITY.
7 PIN VOLTAGES AFFECTED BY PICTURE CONTROL, R131, ARE SHOWN WITH ARROWS GIVING APPROXIMATE RANGE OF VOLTAGE EFFECTED.
8 OSCILLATOR INJECTION VOLTAGE MEASURED FROM THE TUNER TEST POINT TO CHASSIS IS APPROXIMATE 1.8 V ON ALL CHANNELS.
9 WITH THE CONDITION OF A SNOWFREE PICTURE, AGC SET PROPERLY, AND PICTURE IN SYNC THE BIAS ON PIN 2, V11A, SHOULD BE ABOUT -2.4 V, THE DETECTED VIDEO SIGNAL SHOULD BE ABOUT 3.7 V PP, AND FOR WAVESHAPES USE OSCILLOSCOPE WITH 100,000 CYCLE VERTICAL RESPONSE AND USE A 100K OHMS ISOLATING RESISTOR ON SCOPE LEAD.

NOTED CHASSIS DIFFERENCES IN EARLY PRODUCTION-IN SOME CHASSIS.

1 C152 WAS 1500 MMFD.
2 R160 WAS 470K OHMS.
3 T111 WAS A 4 TERMINAL TRANSFORMER AND C178 CONNECTED TO GROUND.

CIRCUIT DIAGRAM NOTES

1 ARROWS AT CONTROLS INDICATE CLOCKWISE ROTATION.
2 FOR RESISTANCE AND DC VOLTAGE MEASUREMENTS SET THE AGC THRESHOLD AND BRIGHTNESS CONTROLS MAXIMUM COUNTERCLOCKWISE AND VOLUME CONTROL CLOCKWISE.
3 RESISTANCES SHOWN ARE IN OHMS K=1000.
4 CAPACITANCE VALUES LESS THAN 1 ARE IN MFD AND MORE THAN 1 IN MMFD.
5 DC VOLTAGES BETWEEN TUBE PINS AND CHASSIS ARE READ WITH VOLTOHMYST USING A 100K OHM ISOLATING RESISTOR ON THE PROBE - ANTENNA TERMINALS SHORTED - LINE VOLTAGE 117 V, 60~.
6 PIN VOLTAGES AFFECTED BY HORIZONTAL AND VERTICAL CONTROLS ARE TYPICAL FOR A PICTURE ADJUSTED TO SYNC AND LINEARITY.
7 PIN VOLTAGES AFFECTED BY PICTURE CONTROL, R131, ARE SHOWN WITH ARROWS GIVING APPROXIMATE RANGE OF VOLTAGE EFFECTED.
8 OSCILLATOR INJECTION VOLTAGE MEASURED FROM THE TUNER TEST POINT TO CHASSIS IS APPROXIMATE 1.8 V ON ALL CHANNELS.
9 WITH THE CONDITION OF A SNOWFREE PICTURE, AGC SET PROPERLY, AND PICTURE IN SYNC THE BIAS ON PIN 2, V11A, SHOULD BE ABOUT -2.4 V, THE DETECTED VIDEO SIGNAL SHOULD BE ABOUT 3.7 V PP, AND FOR WAVESHAPES USE OSCILLOSCOPE WITH 100,000 CYCLE VERTICAL RESPONSE AND USE A 100K OHMS ISOLATING RESISTOR ON SCOPE LEAD.

NOTED CHASSIS DIFFERENCES IN EARLY PRODUCTION-IN SOME CHASSIS.

1 C152 WAS 1500 MMFD.
2 R160 WAS 470K OHMS.
3 T111 WAS A 4 TERMINAL TRANSFORMER AND C178 CONNECTED TO GROUND.
4 R157 WAS 120K OHMS.
5 R198 WAS 10 OHMS (15 OHMS IMPROVES CENTERING)
6 NO PHONO JACK AND PHONO SWITCH WAS USED.
7 R197 WAS 330 OHMS AND R196 WAS 2250 OHMS (10" & 12" CHASSIS ONLY)

World Radio History

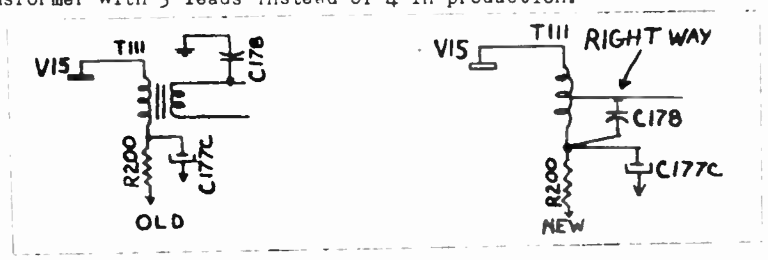
SUBJECT: Condition of One Wide Vertical Black Bar Dividing the Picture in Half Caused by High Resistance Short of C167.

The condition of one wide vertical black bar dividing the picture in half with the normal right side of the picture appearing on the left and left side on the right can be caused by C167 developing a high resistance short of 3 to 4 megohms.

The fault could prove to be difficult to find since normally the logical location of such a horizontal sync trouble would be in the horizontal oscillator and control circuit of V16. C167 connects between pin 2 of V10A and pin 2 of V14A.

SUBJECT: Buzz in the Speaker With Volume Control at Minimum

Recently the vertical output transformer, T111, was changed to an auto-transformer with 3 leads instead of 4 in production.



If C178 is left with one side hooked to ground, vertical buzz will be present in the speaker. In those receivers in which this fault exists C178 should be connected to the junction of R200 and C177C instead of ground. The location of C177C is shown on the "chassis - Bottom View" diagram in the preliminary service manual.

Two other possible sources of audio buzz are as follows:

1. The white and orange lead from pin 8 of V11B, the video amplifier being too loose and dressed close to the volume control terminals. Re-dress this lead.
2. C121C, 80MFD, having an undesirable power factor or being leaky. Replace such a capacitor.

SUBJECT: Focus Control on the 12 1/2" Chassis.

Some 12 1/2" receivers may exhibit lack of sufficient range of the Focus Control to properly focus the raster. A component change is being executed in production to eliminate this possibility for future production.

Any 12 1/2" set in the field can have this fault corrected quickly and easily by the following procedure without pulling the chassis from the cabinet.

1. Remove the bottom cabinet cover exposing a major portion of the chassis wiring.
2. On the front-side flange of the chassis two terminals strips are mounted in line. One of these terminals strips has on its end terminal a 330 ohm, 2 watt, and a 100 ohm, 1/2 watt tied to it. Also, 2 red wires join on this terminal.
3. Connect one side of an 1800 ohm, 2 watt, 10% resistor to this terminal.
4. Viewing the chassis from the bottom, one can see another terminal strip (6 terminals) mounted on the main chassis below the above two which are on the front flange.
5. A Green lead coming from the focus coil connects to a terminal beside the ground lug of the terminal strip.
6. Connect the other end of the 1800 ohm resistor to this point.

This 1800 ohm, 2 watt, shunt resistor across the focus coil will improve the range of the Focus Control satisfactorily.

SUBJECT: Buzz in the Audio on Strong Signals

In some locations of strong signal strength "Vertical buzz" is present in the audio. This buzz can be tuned to minimum by the fine tuning control when tuned carefully for best sound reception. The following change is now incorporated in present production improving the AGC characteristic:

Change R157 from 120K to 75K.

This greatly reduces the buzz in the audio and makes the fine tuning less critical.

SUBJECT: Buzz in the Audio on Strong Signals, Models 3100, 3101, 3120, 3121, 3160

In some locations of strong signal strength "vertical buzz" is present in the audio which can be tuned to a minimum by the fine tuning control when tuned to a minimum by the fine tuning control when tuned carefully for best sound reception. The following change can be made very easily in the field for reducing this buzz in strong signal areas.

Change R157-2 from 120K to 75K

R157-2 connects to pin 5 of V12 and is accessible when the bottom cabinet cover is removed. Soldering a 200K ohm resistor in parallel with the 120K ohm will be the same as replacing it with a 75K ohm resistor, and is probably easier.

SUBJECT: Accentuated white horizontal band near top of raster and touchy vertical sync on some 3100TM, 3121TM, 3121CM, 3121CB, 3160CM television receivers built this year.

It has been noted that some of the T110, Vertical Oscillator transformers, used in production since January 1, 1950 develope a parasitic which superimposes an added spike of voltage onto the return sweep part of the vertical sweep waveform. This results in a "bunching" of retrace lines about 1" from the top of the picture causing an accentuated white horizontal portion which can readily be seen when the brightness is increased.

A 2.2 megohm damping resistor across the primary of T110 (between the green and yellow leads) is being added in production to forestall any such parasitic developing.

The parasitic in some cases results also in very touchy vertical sync.

SUBJECT: Noted differences in the Chassis TE-272, Model 3100-TM (10" Table Model, Mahogany).

1. Early production receivers used the 6C4 tube for the R-f Oscillator. The 6AB4 tube is now used in production. The 6AB4 cannot replace the 6C4 in the early production receivers since the plate of the 6C4 is pin 5 and the plate of the 6AB4 is pin 1. Present production has pin 5 and pin 1 tied together so the tubes can be interchanged. The 6AB4 is preferred and recommended.
2. The 10" receiver chassis does not have a width switch, SW102, in some receivers the width control, L115, will have been disconnected (for maximum width).
3. A 40 ufd electrolytic by-pass to ground on the connection between R101 and the tuner unit does not show on the preliminary manual circuit diagram.
4. C113 connects to the -120V supply instead of ground as shown on the circuit diagram.
5. It has been found that horizontal pulses, coupled into the envelope of V13 by the red horizontal lead from the Hi-V doghouse going to socket, S102, being too close to V13, prevent good interlace. Dressing the lead down to the chassis as close as possible and wedging it away from V13 will aid the condition of good interlace. Future production receivers will have a shield on V13.

SUBJECT: Regeneration in the sound strip of Model 3100-TM, Chassis TE-272, (10" Table Model, Mahogany).

1. In some chassis the blue lead from pin 5 and 6 of V4 to the junction of R158 and R159 runs around the socket and input circuit of V6 and in some cases causes regeneration. The lead is now being rerouted (down close to the chassis) so that it runs between V5 and T109 and between V6 and T107 to the junction of R158 and R159.
2. The shield can of the discriminator transformer, T102, should have its mounting nuts holding the can down very tightly. Leakage radiation from the bottom of the can could cause regeneration - tightening of the mounting nuts in most cases will eliminate this particular cause of regeneration.

SUBJECT: Shorted Capacitors Across the Secondary of the Horizontal Output Transformer, T113, on the 12 1/2" Chassis.

Early production of the 12 1/2" chassis utilized two 270 mmfd condensers in series across terminals 4 and 6 of T113, the Horizontal Output Transformer. These capacitors in effect lower the Hi-Voltage sufficiently to allow greater scan and necessary picture width for the 12 1/2" picture tube. Breakdown of these condensers resulting in a short across terminals 4 and 6 will show up as follows:

1. No Hi-Voltage - therefore no raster.
2. More frequently there will still be some H-Voltage, but no horizontal scan. Only a narrow vertical white trace displaced to the right will appear on the picture tube.

Present production is using a .047mfd, 200V, Molded, Oil-filled capacitor across the width control, L115, instead of the two 270mmfd capacitors across terminals 4 and 6 of T113. This change is recommended whenever the above breakdown trouble occurs and also on any early production 12 1/2" model brought in for service to forestall future trouble of this nature. The best connection for the .047 mfd. capacitor is between terminal 6 of T113 and the switch terminal of SW102 that connects to terminal 5 of T113.

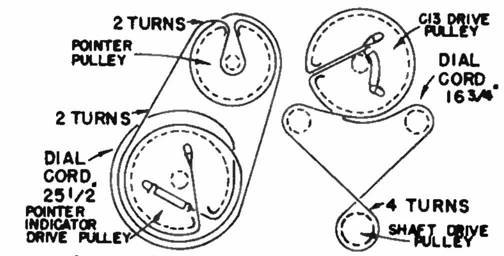
TUNER UNIT AE 23054-2



DIAL STRINGING ARRANGEMENT

SUBJECT: Model TE-2122TM V12, 6AV5GT -- Correcting excessive failure of this tube.

A kit of parts (per change) will be supplied upon request for any Chassis TE-289 in the field that has excessive 6AV5GT failure. Kit Part No. A24033-2.

All Chassis TE-289-2 incorporate the accompanying circuit change to devrease the dissipation in the 6AV5GT, V12, Horizontal Output, and increase the life of this tube. Model 2122TM used Chassis TE-389 in which the life of V12 can be increased by making this change.

a. R186, 850 ohm, 10 watt resistor added between cathode and ground of 6AV5GT tube.
b. Ground side of C166 condenser rerouted to cathode of 6AV5GT.
c. C177, 122 uf., 400V. condenser added to cathode circuit of 6AV5GT tube.
d. R167 Resistor changed to R167-1, 1500 ohm, 10 watt Resistor.
e. Ground side of C167 (.0015 mfd.) Condenser rerouted to 6AV5GT cathode.
f. R169-1 (1 meg.) Resistor ground side rerouted to 6AV5GT cathode.

SPECIFICATIONS

Power Supply Rating	117 Volts, 60 Cycles, 135 Watts
Audio Power Rating	1.0 Watt
Antenna Input Impedance	72 or 300 ohm
Video Response	To 3 MC
Focus	Permanent Magnet (Focalizer)
Sweep Deflection	Magnetic
Picture Carrier	45.75 MC
Adjacent Channel Sound Trap	47.25 MC
Sound Carrier	41.25 MC

The ARVIN television receiver will in most cases be ready for installation when unpacked from its shipping carton. However, it is advisable to "air-check" the receiver before delivery and make any necessary final adjustments. A critical eye prior to and during installation will minimize service calls and promote a satisfied customer.

ADJUSTMENTS

ION TRAP

Proper attention to ion-trap adjustment must be given to insure satisfactory operation of the picture tube. Assuming the ion-trap is off to the extent that no raster appears, proceed as follows:

See that the magnet portion of the ion-trap is over the "top" of the gun with the rear plane of the ion-trap over the spot welds on the gun structure. (Be sure the trademark notations on the magnet portion of the ion-trap are to the rear of the C-R tube.) Now rotate the ion-trap until raster appears. It may be necessary to slide the ion-trap slightly forward or backward for best raster. With the contrast control at minimum (full counter-clockwise) adjust the brightness control for a dim raster, and rotate the ion-trap for maximum brightness.

FOCUS — CENTERING

No electrical provision in the circuit is made for centering. The focalizer must be positioned properly for centering of the picture. Both the focus adjustment screw and the ion-trap have an effect on picture centering, but the focalizer has the most effect. When the focalizer is rotated correctly, the other two are relatively simple and only slight adjustments will be necessary.

The permant magnet focalizer has both a "coarse" and "fine" adjustment. The "coarse" adjustment is made by rotation of the focalizer; the "fine" or vernier adjustment is made by movement of the focus adjustment screw mounted on the top of the focalizer.

Tune in any available station and set the contrast control to approximately ¾ maximum clockwise. Turn Brightness control to maximum and then back it off until retrace lines cannot be seen. Turn the focus adjustment screw in (clockwise) until it is approximately 1/16" from shorting the plates of the focalizer. Loosen the two 5/16" focalizer clamp nuts (see "C" on the top chassis view of the schematic diagram). Rotate the focalizer for best focus, centering and absence of side shadows. Turn the focus adjustment screw for touch-up on best definition and picture focus.

HEIGHT AND VERTICAL LINEARITY (REAR)

The picture should fill the mask and be symmetrical from top to bottom. Adjustments of both the Height Control and Vertical Linearity Control will accomplish this if centering of picture by the focalizer is already proper.

SQUARING THE RASTER

The Yoke Mount and Yoke should be positioned properly as follows:

The large front hole in the Yoke Mount Bracket is rimmed with rubber channel. Loosen the two screws in the feet of the Yoke Mount Bracket and push the mount forward so that the cone of the picture tube fits snugly into the rubber channel. Loosen the top wing-screw and two side wing-screws holding the Yoke and slide the mount forward onto the cone of the picture tube—center the Yoke so the tube neck is co-axial and tighten the two side mounting wing-screws. Rotate the Yoke to square the raster and tighten the top wing-screw.

HORIZONTAL HOLD

If Horizontal adjustments appear necessary, refer to the alignment section for procedure.

SERVICE TEST EQUIPMENT

R-F SWEEP GENERATOR

To provide center Frequency Range—40 Mc. to 50 Mc. with 1 Mc. to 10 Mc. sweep width.

To provide center Frequency Range—50 Mc. to 90 Mc.

To provide center Frequency Range—170 Mc. to 225 Mc.

Variable output—at least .1 volt maximum—flat sweep output all ranges.

R-F SIGNAL GENERATOR

To provide frequencies from 41.25 Mc. to 47.25 Mc.—55.25 Mc. to 130.5 Mc.—175.25 Mc. to 258.5 Mc.

Variable Output and at least .1 volt maximum.

HETERODYNE FREQUENCY METER

With crystal calibrator to check R-F Signal Generator.

CATHODE RAY OSCILLOSCOPE

With wide band vertical deflection and means to calibrate input.

ELECTRONIC VOLT OHMMETER

With multiplier probe for hi-voltage measurements to 10 Kv.

ALIGNMENT

SEQUENCE FOR COMPLETE ALIGNMENT

1. Video I. F. Trap.
2. Video I. F. Overall.
3. Audio take-off and ratio detector.
4. Tuner unit.

VIDEO I. F. ALIGNMENT

1. Connect signal generator to tuner test point.
2. Set contrast control in approximately middle of its range.
3. Connect DC probe of VTVM between junction of L105 and L106 (across the video detector load resistor, R124.)
4. Set unmodulated generator on 47.25 Mc. and adjust bottom of T103 for minimum VTVM deflection. A large signal input may be required.
5. Set unmodulated generator on 45.3 Mc. and adjust L102 and top of T103 for maximum VTVM deflection. NOTE: Reduce input if VTVM reading exceeds (4) volts (prevents overload).
6. Set unmodulated generator on 43.1 Mc. and adjust L7 (converter on tuner unit) and L103 for maximum VTVM deflection. NOTE: Reduce input if VTVM reading exceeds (4) volts.
7. Disconnect generator and VTVM. Connect sweep generator to tuner test point.
8. Connect vertical amplifier of scope to junction of L105 and L106.
9. Set the scope for external sweep and connect the "scope" terminals of the sweep generator to the horizontal amplifier input terminals on the oscilloscope.
10. Adjust sweep output and phasing and scope gains to obtain usable I. F. response curve.
11. Retouch L102 and top of T103, L7 and L103 to obtain proper curve as shown in Fig. 1. NOTE: Extreme care must be taken not to overload the I. F. circuit during test.

NOTE: Should great difficulty be noted in aligning, redressing locations of I. F. coupling condensers, C138, C133, C130, and C125 may be effective in shaping the response curve.

Figure 1—Video I.F. Response

©John F. Rider

World Radio History

SOUND I. F. ALIGNMENT

Method A

1. Connect sweep generator of 4.5 Mc. center frequency to pin 1, of V8. Set sweep width to 500 Kc.
2. Connect AM modulated 4.5 Mc. signal to pin 1 of V8.
3. Connect horizontal amplifier of scope to "scope" terminals of sweep generator.
4. Connect vertical amplifier of scope to junction of R105 and C108. Adjust scope gains, phasing and output of sweep to obtain usable trace on scope.

   NOTE: Extreme care must be taken not to overdrive the circuit under test. (See Fig. 2.)
5. Adjust top of T101 for minimum ripple response on scope.
6. Adjust L101 and bottom of T101 for two equal and maximum curve peaks (See Fig. 2).
7. Disconnect all test equipment and tune in a transmitted signal. Adjust fine tuning and contrast until a low audible buzz is noted in the speaker. Check adjustment of T101 secondary (Top) to be certain it is set for minimum buzz (Maximum AM rejection).

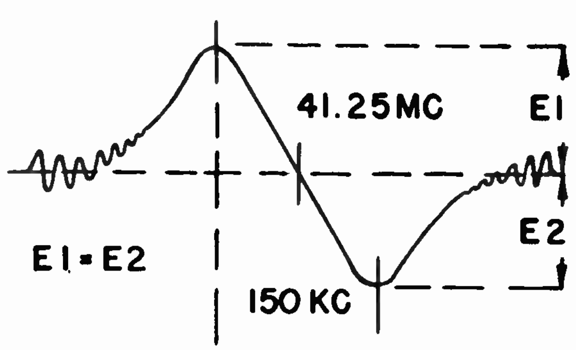

Figure 2

Method B

1. Tune in a transmitted test pattern signal with constant tone.
2. Connect DC probe of VTVM between pin 2, V2 and ground.
3. Adjust L101 and bottom of T101 for maximum deflection of VTVM.

   NOTE: Reduce contrast if meter reading exceeds 6 volts.
4. Adjust fine tuning and contrast until a low audible buzz is noted in the speaker. Adjust top of T101 carefully for minimum buzz.

   NOTE: An accurate 4.5 Mc. signal generator source could be used for step 1—step 2 and 3 would remain the same—AM modulate the 4.5 Mc. signal, connect a scope to the junction of R105 and C108 and adjust T101 (Top) for minimum ripple on the oscilloscope.

TUNER ALIGNMENT

ORDER OF PROCEDURE

1. High-band oscillator ranging.
2. Low-band oscillator ranging.
3. I. F. trap adjustment.
4. High-band antenna tuning.
5. Low-band antenna tuning.
6. High-band tracking.
7. Low-band tracking.

NOTE:

Tuner alignment should not be attempted until I. F. is correctly aligned and set is otherwise operating correctly. The condenser plates of the tuning condenser should never be bent out of correct alignment. The contrast control should be at mid-range. All final checks on the above steps should be made with the tuner shield on.

HIGH-BAND OSCILLATOR RANGING

1. The correct extreme tuning range of the high-band oscillator with the fine tuning is 219.5 Mc. to 258.5 Mc.
2. Connect the vertical input of the oscilloscope to the tuner side of C138 which is the input coupling capacitor to V4, the first I. F. amplifier. (Green lead from tuner)
3. Connect a signal generator to the antenna terminals tuned to 258.5 Mc. The signal generator output should exceed 100,000 microvolts.
4. Turn the band switch to the high channel position.
5. Set the tuning maximum clockwise for the highest frequency position and adjust C19 carefully for a zero beat indication on the oscilloscope.
6. Set the fine tuning maximum counter-clockwise and tune the signal generator around 219 Mc. very carefully to see what the zero beat frequency of the low end is.
7. If the oscillator frequency is above 219.5 Mc., squeeze the turns slightly together of L9 and then repeat the procedure of steps 5 and 6.
8. If the frequency of the oscillator is below, the turns of L9 will have to be spread slightly and the steps of 5 and 6 repeated.
9. By this procedure, the right value of inductance for L9 and the correct setting of C19 trimmer can readily be found in order that the oscillator will properly range from 219.5 Mc. to 258.5 Mc.

LOW-BAND OSCILLATOR RANGING

1. Test equipment as in High-Band oscillator ranging.
2. The correct extreme tuning range of the low-band oscillator with fine tuning is 99 Mc. to 130.5 Mc.
3. Turn the band switch to the low channels position.
4. With the fine tuning maximum clockwise, set the signal generator frequency to 130.5 Mc. and adjust C24 for zero beat on the oscilloscope.
5. Set the fine tuning maximum counter-clockwise and check the local oscillator frequency with the zero beat method as previously described.
6. If the oscillator is above 99 Mc., spread the turns slightly of L8 and repeat steps 4 and 5.
7. Should the local oscillator be below 99 Mc., squeeze the turns slightly together of L8 and repeat steps 4 and 5.
8. By this zero beat method, the range of the local oscillator in the tuner can be adjusted to cover from 99 Mc. to 130.5 Mc. (low-band).

I. F. TRAP ADJUSTMENT (TUNER)

1. Connect a signal generator to the antenna terminals tuned to 44 Mc.
2. Connect a VTVM to the junction of L105 and L106 (across video detector load, R124).
3. Adjust C4 for minimum meter deflection.

HIGH-BAND ANTENNA TUNING

1. Turn the band switch to the high channels position.
2. Connect the sweep generator to the antenna terminals to sweep for channel 11.
3. Adjust the fine tuning until a response curve appears on the scope.
4. Adjust C1A for maximum curve height.

LOW-BAND ANTENNA TUNING

1. Turn the band switch to the low channels position.
2. Connect the sweep generator to the antenna terminals to sweep around channel 5.
3. Connect the oscilloscope to the junction of L105-L106.
4. Tune the fine tuning until a response curve appears on the oscilloscope.
5. Adjust C1B for maximum curve height.

HIGH-BAND R. F. TRACKING

1. Connect sweep generator to antenna terminals and oscilloscope to the junction of L105 and L106.
2. Set the band switch to the high channels position.
3. Set the fine tuning and sweep for channel 11. Adjust the input for a clean response curve without over-loading.
4. Adjust C11 for maximum response curve height. If the response curve peaks are not level as in figure 3B, check the I. F. alignment and the setting of C1A. These peaks must be level.
5. Check the overall response on channel 7 and channel 13. These response curves should fall in the limits of figure 3A and 3C.
6. If the low frequency side of channel 7 curve is low and the high frequency side of channel 13 curve is high, the R. F. section is over-ranging. This condition can be corrected by spreading the turns of L5 slightly and re-adjusting C11 as in step 4.
7. Conversely, squeezing the turns of L5 slightly and re-adjusting C11 as in step 4 will increase the range of the R. F. section.
8. By this procedure it is readily possible to make the R. F. section track with the oscillator, resulting in overall response curves for each channel to fall within the limits as shown in figure 3A and 3C.

NOTE: When it is necessary to adjust the turns slightly of any of the coils, the tuner cover must be replaced during the checking.

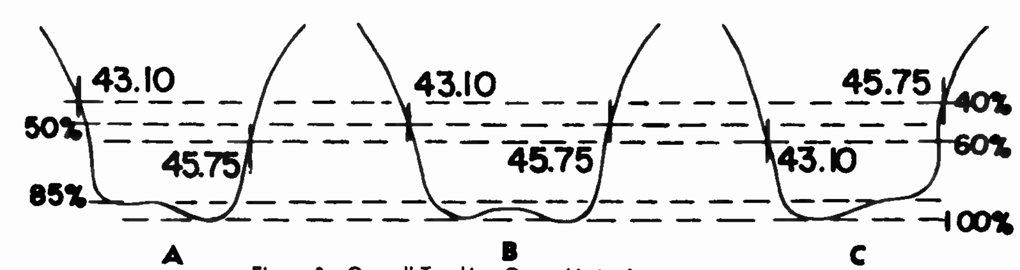

Figure 3—Overall Tracking Curve Limits for any Channel

©John F. Rider

World Radio History

LOW-BAND R. F. TRACKING

1. Set the band switch in the low channels position and equipment as in high-band R. F. tracking.
2. Set the tuning and sweep for channel 5.
3. The overall response curve should be within the limits as shown in figure 3. Check the overall response of all the channels to see that they fall within the limits as shown in figure 3.
4. Adjust the turns spacing of L6 for maximum response curve height on channel 5 should result in having the response curves for all channels within the limits as shown in figure 3. If the response curves are out of limits, check the setting of C1B.

TUNER ADJUSTMENT TABLE

C19	Adjust for high-end of oscillotor	258.3 MC
L9	Squeeze turns to lower low-end of oscillotor	219.5 MC
L9	Spread turns to raise low-end of oscillotor	219.5 MC
C24	Adjust for high-end of oscillotor	130.5 MC
L8	Squeeze turns to raise low-end of oscillotor	99.0 MC
L8	Spread turns to lower low-end of oscillotor	99.0 MC
C11	Adjust to track R.F.	Channel 11
L5	Squeeze turns to lower low-end of R.F.	Channel 7
L5	Spread turns to raise low-end of R.F.	Channel 7
L6	Squeeze turns to lower low-end of R.F.	Channel 2
L6	Spread turns to raise low-end of R.F.	Channel 2
C4	IF Trap Adjustment	44 MC
C1A	R.F. input circuit-tune for maximum	Channel 11
C1B	R.F. input circuit-tune for maximum	Channel 5

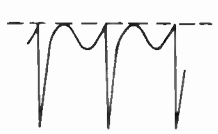
SENSITIVITY MEASUREMENT

Since the calibration in micro-volts output for signal generators varies so greatly between different generators used, it is recommended that a "relative-measurement" of sensitivity be taken as follows:

1. Use a model 4080T that is known to be correctly aligned as proven by a qualitative air-check on available stations.
2. Connect a signal generator to the antenna terminals set for the picture-carrier frequency of any desired channel.
3. Connect a VTVM to the junction of L105 and L106 (video detector load, R124).
4. Tune the station tuning for maximum meter deflection.
5. Adjust the signal generator output for 1 volt VTVM reading.
6. Record the generator's output attenuator reading and use this reading as a comparative standard for sensitivity measurement on other model 4080T receivers (normally, the contact potential across R124 is too little to take into account).

HORIZONTAL OSCILLATOR ADJUSTMENT (COMPLETE)

1. Tune in an available station.
2. Turn the Horizontal Hold Control maximum clockwise.
3. Turn the Horizontal Lock Adjustment to almost tight.
4. Connect the oscilloscope to Terminal "C" of T104.
5. Turn the T104 Blocking Waveform Adjustment maximum counter-clockwise (see chassis view).
6. Sync the picture by adjusting the Horizontal Frequency Adjustment Screw of T104.
7. Turn the Blocking Waveform Adjustment until the waveform is correct as in figure 4 (picture must be in sync when adjusting waveform).
8. Adjust the T104 Frequency Adjustment so that the picture just breaks sync (the ideal is to have a wide vertical black bar representing horizontal blanking showing somewhere in the picture).
9. Turn the Horizontal Hold maximum clockwise. If picture doesn't break sync, momentarily short antenna terminals. Picture will now be out-of-sync.
10. Turn the Horizontal Hold Control slowly conter-clockwise and count the diagonal black bars before "pull-in."
11. There should be 3 bars—adjust Horizontal Locking Range until only 3 bars are present before "pull-in."
12. Turn Horizontal Hold Control maximum counter-clockwise. Picture should just break sync as in Step 8.
13. Adjust T104 Frequency Adjustment to obtain condition of Step 8.
14. Repeat steps 8 thru 12 if necessary to obtain conditions of Steps 8 and 11.



PEAKS OF WAVE FORM MUST BE AT SAME AMPLITUDE LEVEL ACROSS THE TOP.

Figure 4

HORIZONTAL LOCK ADJUSTMENT

The Horizontal Lock can be adjusted without the need of test equipment if the Horizontal Waveform is assumed to be correct. Adjustment is available through marked hole in cabinet bottom.

1. Tune in an available station.
2. Turn the Horizontal Hold maximum clockwise. If picture doesn't break sync, momentarily short antenna terminals. Picture will now be out-of-sync.
3. Turn the Horizontal Hold Control slowly counter-clockwise and count the diagonal black bars just before "pull-in."
4. There should be 3 bars—adjust Horizontal Locking Range until only 3 bars are present before "pull-in."
5. Repeat steps 2 and 3 for the condition of step 4.

HORIZONTAL DRIVE

Slight adjustment of the Drive Trimmer will give an overall width control of the raster. Extreme adjustment counter clockwise will lower the high-voltage too greatly.

FREQUENCY TABLE

Channel No.	Band Width (mc.)	Picture Carrier (mc.)	Sound Carrier (mc.)	R-F Osc. (mc.)
2	54-60	55.25	59.75	101
3	60-66	61.25	65.75	107
4	66-72	67.25	71.75	113
5	76-82	77.25	81.75	123
6	82-88	83.25	87.75	129
7	174-180	175.25	179.75	221
8	180-186	181.25	185.75	227
9	186-192	187.25	191.75	233
10	192-198	193.25	197.75	239
11	198-204	199.25	203.75	245
12	204-210	205.25	209.75	251
13	210-216	211.25	215.75	257

USE OF MARKER SIGNALS

The illustrated response curves show where marker signals fall. For sweep generators that do not have built-in marker signals, calibrated signals from an R.F. generator must be used. Hooking the generator output lead to the chassis near the 1st I.F. input will usually spray enough signal in to be seen on the scope. Marker beats will show best when the sweep-input is low and the scope-gain set high. A .01 MFD condenser across the vertical input terminals of a wide response oscilloscope will cut the response down so the low frequency marker beat can more easily be seen.

TUNER UNIT AE 23054-1

Part No.	Description
C23378	Beam Bender, Ion Trap
C23087	Choke, Filter L116
A23095	Choke, R-F Filament L109, L110
C22500-3	Coil, Peaking L106, L108
C22500-9	Coil, Peaking L105, L107, R121; R126
C22500-6	Coil, Peaking L104
C23093	Coil, Pick-Off, 4.5 Mc. L101
C23058-1	Coil, Focus, P.M.
A23120	Connector, Picture Tube Anode
D22464-16	Control, Volume, Contrast, On-Off R107, R125, SW103
D22464-11	Control, Vertical Hold R156
D22464-13	Control, Horizontal Hold R181
D22464-14	Control, Brightness R119
D22464-10	Control, Height R150
D22464-12	Control, Vertical Linearity R158
A22644	Cord, Power Cord & Plus SW101
A23261	Crystal, 1N64
A22489	Plug, Interlock SW101
A22572	Shield, Min. Tube
A23266	Socket, Picture Tube
A23202	Socket, Speaker Leads SO101
A22868	Switch, Interlock SW102
C23091-2	Transformer, 1st Pix, I. F. L102
C23091-2	Transformer, 2nd Pix, I. F. L103
C23092	Transformer, 3rd Pix, I. F. T103
C23094	Transformer, Ratio Detector T101
C22905-1	Transformer, Vertical Output Choke L111
D22563	Transformer, Horizontal Oscillator T104
E23089	Transformer, Horizontal Output T105
AC23090-1	Transformer, Audio Output T102
E23086	Transformer, Power T106
AE23054-1	Tuner Unit, Assembly, Complete With Tubes
AC23084-1	Yoke, Deflection & Lead Assembly, L112, L113, L114, L115, R159, R160, C152
C23085	Yoke, Deflection
A23130	Capacitor, (10-160) MMF, Double Trimmer, C158
C20205-7	Capacitor, 2.2 MMF, +.5 500 V., N220, Ceramic C101
C20205-9	Capacitor, 5 MMF, 10%, 500 V., N220, Ceramic, C105, C121
C20205-8	Capacitor, 15 MMF, 10%, 500 V., N220, Ceramic, C133, C130
C20205-12	Capacitor, 33 MMF, 10%, 500 V., N220, Ceramic, C125, C103
A22623-2	Capacitor, 47 MMF, 10%, 100 V., Mica, C152
C20205-11	Capacitor, 68 MMF, 10%, 500 V., N220, Ceramic, C102
C20204-101	Capacitor, 100 MMF, 20%, 500 V., Ceramic, C122, C138
C20065-151	Capacitor, 150 MMF, 20%, 500 V., Mica, C142
A22412	Capacitor, 180 MMF, 5%, 1000 V., Mica, C162
C20290-331	Capacitor, 330 MMF, 10%, 500 V., Mica, C107
C20290-391	Capacitor, 390 MMF, 10%, 500 V., Mica, C159
C20351-10	Capacitor, 610 MMF, 10%, 500 V., N4700, Ceramic, Insulated C127, C131, C135
C23099-102	Capacitor, 1000 MMF, 10%, 1000 V., Mica, C148
A23078	Capacitor, 1000 MMF, Minimum, 500 V., Ceramic Disc C134, C136, C137, C141, C120, C128, C129, C132
A21674	Capacitor, 5000 MMF, Minimum, 500 V., Ceramic Disc, C104
C20295-102	Capacitor, .001 MF, 20%, 600 V., Aerolene Paper, C111, C147
C20324-152	Capacitor, .0015 MF, 5%, 600 V., Oil Paper, C160
C20295-222	Capacitor, .0022 MF, 20%, 600 V., Aerolene Paper, C144, C164
C20295-472	Capacitor, .0047 MF, 20%, 600 V., Aerolene Paper, C108, C109 C145, C146
C20324-103	Capacitor, .01 MF, 5%, 600 V., Oil Paper, C161
C20295-103	Capacitor, .01 MF, 20%, 600 V., Aerolene Paper, C114
C20358-103	Capacitor, .01 MF, 20%, 600 V., Aerolene Paper Molded, C154, C155
C20292-223	Capacitor, .022 MF, 20%, 400 V., Aerolene Paper, C112, C139, C165
C20295-333	Capacitor, .033 MF, 20%, 600 V., Aerolene Paper, C151
C20295-473	Capacitor, .047 MF, 20%, 600 V., Aerolene Paper, C163
C20292-473	Capacitor, .047, 20%, 400 V., Aerolene Paper, C115, C140, C143, C157
C-20291-104	Capacitor, .1 MF, 20%, 200 V., Aerolene Paper, C119, C149
C20329-104	Capacitor, .1 MF, 20%, 1000 V., Aerolene Paper, C156
C20292-224	Capacitor, .22 MF, 20%, 400 V., Aerolene Paper, C117
C20291-224	Capacitor, .22 MF, 20%, 200 V., Aerolene Paper, C116, C123, C124, C166
C20291-474	Capacitor, .47 MF, 20%, 200 V., Aerolene Paper, C153
A23025-2	Capacitor, 5 MF, 150 V., Electrolytic, C110
A23025-1	Capacitor, 10 MF, 25 V., Electrolytic, C113
C22422-5	Capacitor, (30, 450 V.—40, 350 V.—40, 350 V.—10, 200 V.) MF Electrolytic, C118
C22422-6	Capacitor, (10, 450 V.—40, 350 V.—80, 200 V.—100, 50 V.) MF Electrolytic, C150
C22381-390	Resistor, 39 Ohms, ½ W., 10%, R122
C22381-470	Resistor, 47 Ohms, ½ W., 10%, R104
C22382-560	Resistor, 56 Ohms, ½ W., 5%, R139
C22381-680	Resistor, 68 Ohms, ½ W., 10%, R136
C20061-101	Resistor, 100 Ohms, ½ W., 20%, R101
C22381-151	Resistor, 150 Ohms, ½ W., 10%, R111, R133
C20103-221	Resistor, 220 Ohms, 1 Watt, 20%, R140
C20061-331	Resistor, 330 Ohms, ½ W., 20%, R165
C20061-471	Resistor, 470 Ohms, ½ W., 20%, R131, R135, R138
C20061-102	Resistor, 1000 Ohms, ½ W., 20%, R103, R162
C22381-122	Resistor, 1200 Ohms, ½ W., 10%, R161, R159, R160
C20061-152	Resistor, 1500 Ohms, ½ W., 20%, R164, R167
C22381-222	Resistor, 2200 Ohms, ½ W., 10%, R145
C22381-272	Resistor, 2700 Ohms, ½ W., 10%, R157
C20061-332	Resistor, 3300 Ohms, ½ W., 20%, R142
C22381-562	Resistor, 5600, ½ W., 10%, R146
C22381-682	Resistor, 6800, ½ W., 10%, R124
C20070-682	Resistor, 6800, 1 W., 10%, R112
C22381-822	Resistor, 8200, ½ W., 10%, R118, R149, R151, R172, R178
C20061-103	Resistor, 10 K., ½ W., 20%, R113, R114, R147, R168
C22382-123	Resistor, 12 K., ½ W., 5%, R134
C22382-183	Resistor, 18 K., ½ W., 5%, R132, R137, R141
C22381-183	Resistor, 18 K., ½ W., 10%, R106
C22381-223	Resistor, 22 K., ½ W., 10%, R148, R171
C22381-273	Resistor, 27 K., ½ W., 10%, R105
C22381-563	Resistor, 56 K., ½ W., 10%, R127, R155
C22381-683	Resistor, 68 K., ½ W., 10%, R180
C22383-913	Resistor, 91 K., 1 W., 5%, R169
C22381-104	Resistor, 100 K., ½ W., 10%, R153
C20061-104	Resistor, 100 K., ½ W., 20%, R102, R115, R117, R120, R154
C22383-104	Resistor, 100 K., 1 W., 5%, R174
C20070-124	Resistor, 120 K., 1 W., 10%, R173
C22381-154	Resistor, 150 K., ½ W., 10%, R176
C22383-154	Resistor, 150 K., 1 W., 5%, R175
C22381-224	Resistor, 220 K., ½ W., 10%, R129, R170
C20061-334	Resistor, 330 K., ½ W., 20%, R166
C20061-474	Resistor, 470 K., ½ W., 20%, R110, R109, R163
C22381-564	Resistor, 560 K., ½ W., 10%, R128, R130
C22382-824	Resistor, 820 K., ½ W., 5%, R179
C20061-105	Resistor, 1 Meg., ½ W., 20%, R116, R123, R143
C22383-275	Resistor, 2.7 Meg., 1 W., 5%, R177
C20061-335	Resistor, 3.3 Meg., ½ W., 20%, R144
C22381-395	Resistor, 3.9 Meg., ½ Watt, 10%, R152
C20061-106	Resistor, 10 Meg., ½ Watt, 20%, R108

A21992	Spring, Compression, Channel Indicator Disc (10)
A23012	Strap, Picture Tube Hold-Down
A23081	Terminal Strip, Antenna Lead-In

SUBJECT: Focusing--Centering--Removing Side Shadows

The new 4080T television receiver utilizes a unique 8 1/2" picture tube with a triode gun structure and a permanent magnet focus coil. To focus, center, and eliminate side shadows involves adjustment of three variables--rotation of the FOCALIZER (PM focus coil), adjustment of the FOCUS ADJUSTMENT SCREW MOUNTED ON THE TOP OF THE FOCALIZER, and proper location of the ION TRAP.

All three adjustments must be proper for a picture that is in focus, centered and without side shadows. The procedure could be somewhat as follows

1. Position the ion-trap with the magnet on top and about 3/4" from the FOCALIZER.
2. Turn the FOCUS ADJUSTMENT SCREW in (clockwise) to the FOCALIZER--in other words, almost shorting between the two plates of the FOCALIZER.
3. Loosen the two mounting screws (see "C" on the TOP CHASSIS VIEW of the schematic diagram) and rotate the FOCALIZER for optimum centering and absence of side shadows.
4. Touch-up the FOCUS ADJUSTMENT SCREW and the ION TRAP ADJUSTMENT for best picture focus and brightness.

NOTE: All three adjustments have some effect on centering, focus and side shadows. When the FOCALIZER is positioned correctly, the other two will be relatively simple. The raster lines should be in excellent detail when these adjustments are proper.

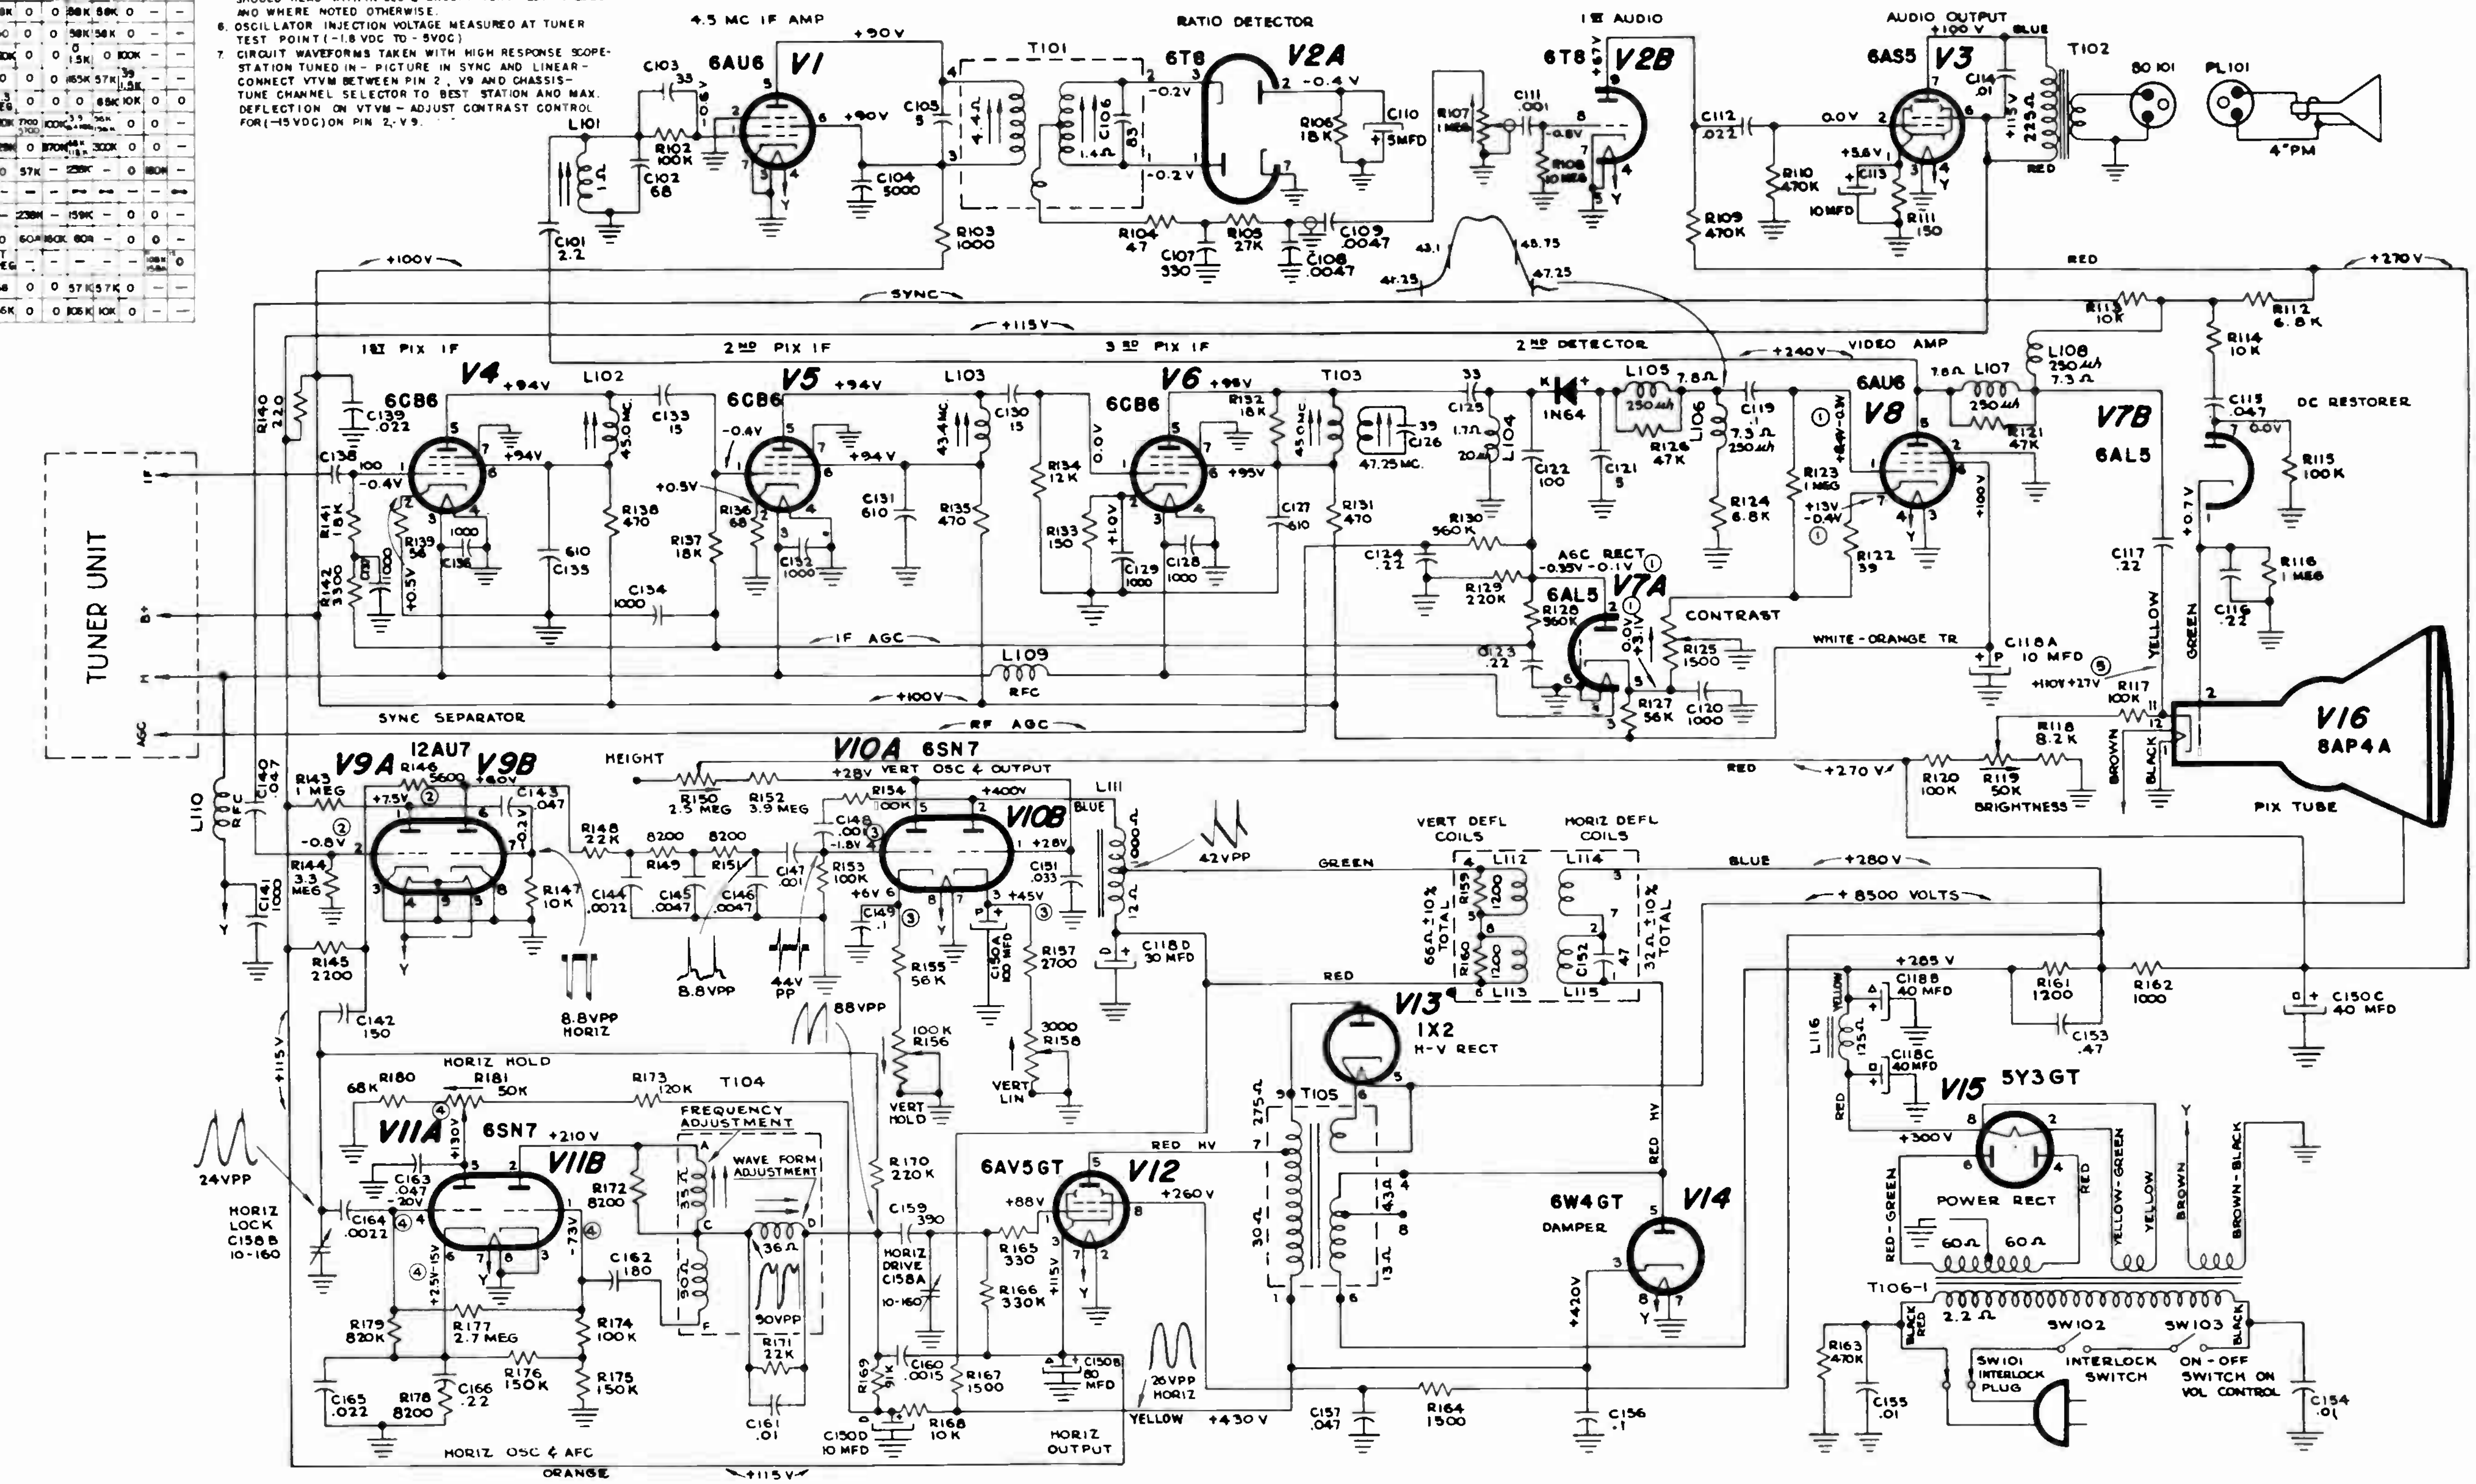
CIRCUIT DIAGRAM NOTES:

1. RESISTANCES SHOWN ARE IN OHMS; K=1000
2. CAPACITANCE VALUES LESS THAN 1 ARE IN MFD AND MORE THAN 1 IN MMFD UNLESS OTHERWISE NOTED.
3. COIL RESISTANCE VALUES LESS THAN 1 OHM ARE NOT SHOWN
4. ARROWS AT CONTROLS INDICATE CLOCKWISE ROTATION.
5. DC VOLTAGES ARE READ WITH VOLTOHMYST USING 100K ISOLATING RESISTOR ON THE PROBE - ANTENNA TERMINALS SHORTED - LINE VOLTAGE 117 V - 60~. VOLTAGES SHOULD READ WITHIN ±20% EXCEPT VERY LOW VALUES AND WHERE NOTED OTHERWISE.
6. OSCILLATOR INJECTION VOLTAGE MEASURED AT TUNER TEST POINT (-1.8 VDC TO -5VDC)
7. CIRCUIT WAVEFORMS TAKEN WITH HIGH RESPONSE SCOPE - STATION TUNED IN - PICTURE IN SYNC AND LINEAR - CONNECT VTVM BETWEEN PIN 2, V9 AND CHASSIS - TUNE CHANNEL SELECTOR TO BEST STATION AND MAX. DEFLECTION ON VTVM - ADJUST CONTRAST CONTROL FOR (-15VDC) ON PIN 2, V9.



Change Note: C167. 390MMF Added From Junction of R174 & R175 to Ground.

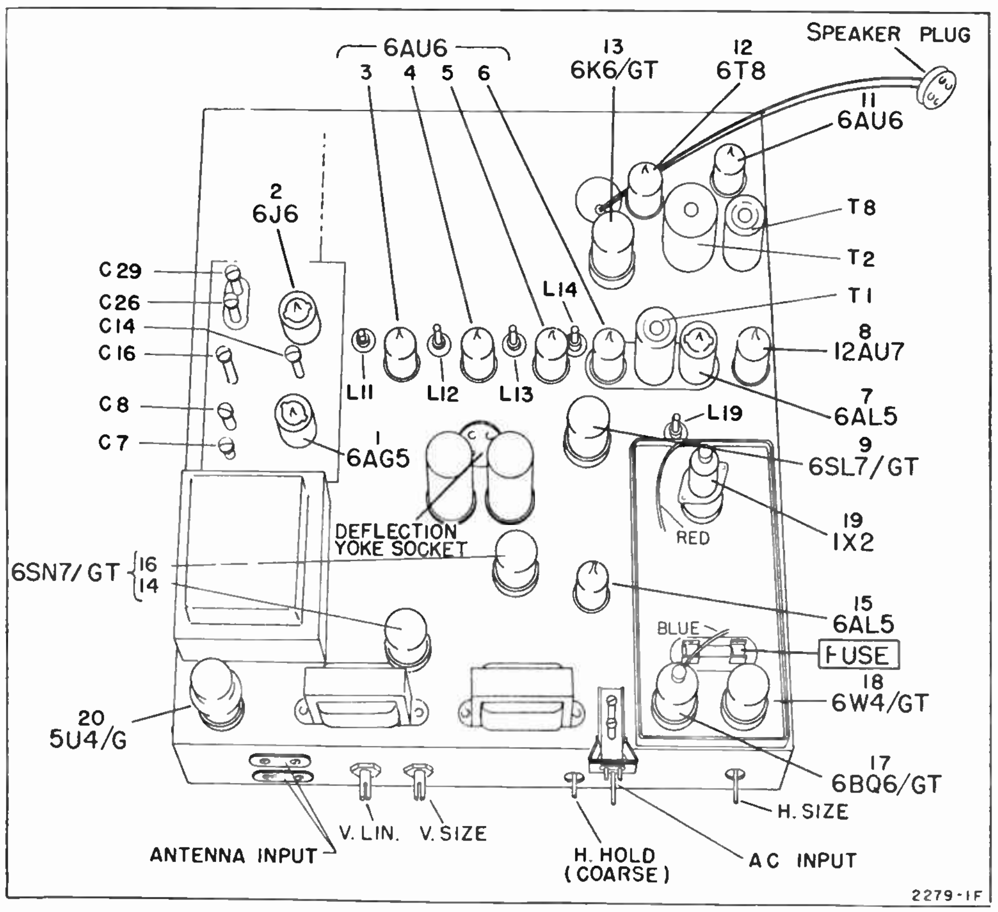
GENERAL DESCRIPTION

The Model M-701 is a 20 tube, AC operated, direct view, 10-inch television receiver. The set is complete in one unit and features complete coverage of all 12 television channels, automatic gain control, automatic frequency control, intercarrier sound system, permanent magnet focused and magnetically deflected picture tube.

On the back of the cabinet is a safety interlock to prevent dangerous electrical shock. As an added safety measure, a fuse is located in the high voltage power supply to protect the set in case of overloading.



Tube Layout

OPERATION OF THE RECEIVER

FUNCTIONS OF THE CONTROLS

All the controls normally used in tuning in a program—both picture and sound—are located on the front of the receiver and at the top of the back of the cabinet. On the rear of the set are several controls which are pre-set at the factory and may need slight readjustment at the time of installation. After installation, they should not be adjusted further, unless required by replacement or aging of tubes, variations in power-line voltage, or other external conditions. The function of each of the controls is described below.

OPERATOR'S CONTROLS

Volume-Off — Turns set on or off and adjusts sound volume.

Contrast—Varies contrast between light and dark portions of picture.

Brightness—Controls brilliance of picture.

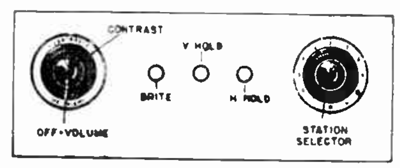
V. Hold—Stops pictures from moving up or down.

H. Hold—Stops pictures from moving left or right.

Station Selector Knob—Tunes set to desired channel (station). May be turned in either direction.

Antenna Tuning Knob — Tunes the antenna for maximum signal.

Model M-701 actually requires only three controls when tuning in a program. These controls are located on the front of the receiver. On the left is a dual knob, the large knob controls picture contrast, while the small outer knob is the off-on switch and volume control. The control on the right is the station selector. The three other controls on the front of the set: brightness, horizontal hold, and vertical hold, need only be adjusted periodically. The six operator's controls are shown below.



Three of the seven serviceman's controls; focus, horizontal centering, and vertical centering, are located on the picture tube assembly. The remaining four controls, vertical linearity, vertical size, horizontal size, and coarse horizontal hold are located on the rear of the set. (See tube layout).

SERVICEMAN'S CONTROLS

Vert. Lin.—Provides vertical distribution of picture.

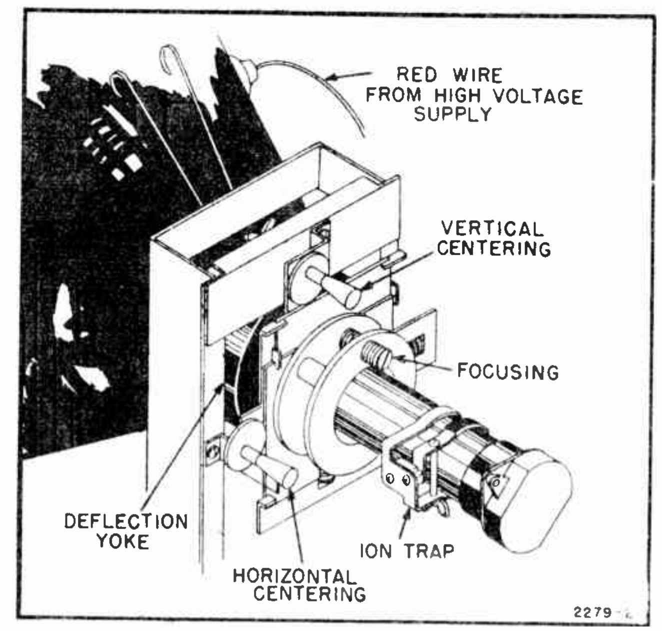
Vert. Size — Changes size of picture vertically. Does not affect horizontal size.

Horiz. Size—Changes size of picture horizontally. Does not affect vertical size.

Focus—Focuses picture on face of picture tube.

H. Centering—Moves entire picture horizontally.

V. Centering—Moves entire picture vertically.



Picture Tube Assembly

TUNING PROCEDURE

1. Turn the VOLUME control clockwise to turn the set on. Allow one-half minute for the set to warm up.
2. Rotate the Station Selector knob to the desired channel.
3. Adjust antenna tuning control for the best picture.
4. Turn the CONTRAST control fully counter-clockwise.
5. Turn the BRIGHTNESS control fully clockwise, and then turn it slowly counter-clockwise until the picture tube just becomes dark. *For any particular installation this adjustment of the BRIGHTNESS control need be made only the first time the set is used, unless required by replacement of tubes.*
6. Adjust the CONTRAST control until the proper contrast between blacks and whites is obtained.
7. Adjust the VOLUME control for the desired sound level.
8. When switching from one station to another, it may be necessary to readjust the CONTRAST control.

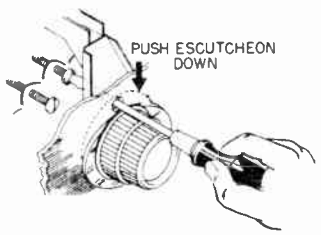
World Radio History

ADJUSTMENT OF STATION SELECTOR

The station selector of your television set has been partially pre-set at the factory, but readjustment of the settings may have to be made at the time of the initial installation. This should be done by the serviceman.

If at a later time a new station comes on the air, or if the receiver is moved to a locality where other stations can be received, adjust the station selector in the following manner.

1. Turn the set on. Allow the set to warm up for 20 minutes.
2. Turn the contrast control approximately two-thirds of the way toward its full clockwise position.
3. Turn the volume control approximately to its mid-position.
4. Set the station selector knob to the desired channel.
5. Turn the antenna tuning knob until maximum sound is heard. (Turn the volume control up if necessary).
6. Grasp the station escutcheon at the upper right edge and slowly push down until the hole above the station selector knob appears.
7. Insert a screwdriver into the hole (see illustration). Turn the screw slowly counter-clockwise (and then clockwise, if necessary) until maximum sound is heard. This may require several turns in one direction or the other. Turn up the volume control if necessary. (Do not at any time turn the screw in either direction more than 3 revolutions. Do not force it if turning becomes difficult as the screw has then reached the end of its travel in that direction and its direction should be reversed.)



8. When the sound is at maximum, the picture will appear on the screen but "sound bars" (dark horizontal bars of varying width) will be seen traveling vertically from bottom to top across the picture. With the screwdriver, turn the station selector screw counter-clockwise only far enough to remove the sound bars from the picture.
9. Push the station escutcheon back into place.

CAUTION!: 11,000 volts on all pins of the 1X2 high voltage rectifier. DO NOT MEASURE this voltage unless a high range voltmeter is used.

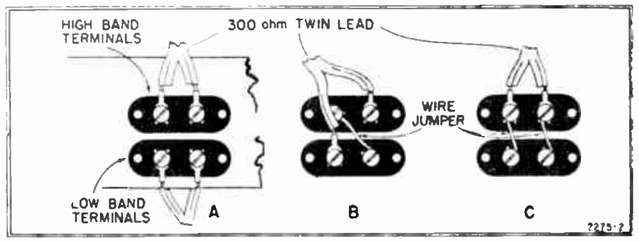
WARNING!: Do not tamper with or attempt to defeat the purpose of the safety interlock.

FUSE: To replace the fuse in the high voltage power supply, lift off the high voltage shield, remove the old fuse, and replace with the same type 1/4 ampere fuse.

ANTENNA CONNECTIONS

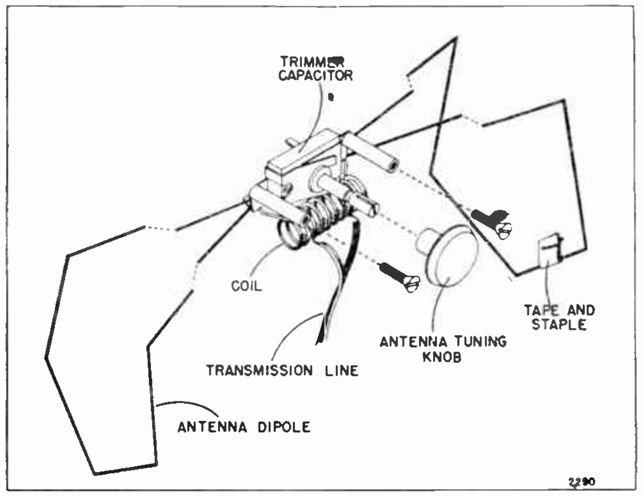
If an outside antenna is used with the receiver, one of the following connections should be made.

1. For those who use separate Hi and Low Band antennae, with two lead-in cables, connect the Hi-Band leads to the two top terminals marked Hi-Band, connect the Lo-Band leads to the two bottom terminals, marked Lo-Band. See fig. 4, sketch A.
2. For those who use a combined Hi-Lo Band antenna, better known as a "All Wave Antenna" with one lead-in cable, connect as shown in fig. 4, sketch B.
3. In some cases due to location or environment of the Receiving antennae, better results can be had by connecting the lead-in as shown in fig. 4, sketch C.
4. An alternate arrangement for those who receive from Hi-Band stations only (Channels 7 thru 13), the All Wave Antenna lead-in may be connected to the two top terminals marked Hi-Band, with no strap or connection to the Lo-Band terminals.
5. Use the arrangement which gives the most satisfactory results.



Alternate Antenna Connections

BUILT-IN TELEVISION ANTENNA



The new Built-In Television Antenna incorporated in the receiver eliminates the need of an outside antenna in many locations. In areas too distant for normal reception with a built-in antenna, provision is made for outside antenna connections. If any other type of antenna is used with the set, disconnect the transmission line from the built-in antenna to the antenna terminals.

The antenna is mounted inside the cabinet and is operated by the use of a knob at the top of the back of the cabinet. Since the antenna is fastened to the cabinet it may be necessary to orient the cabinet to obtain the best reception. It is desirable that either the front or the back of the cabinet face the transmitting station. If however, "ghosts" or multiple images appear, the cabinet may be rotated slightly to minimize this condition. In some cases it may be necessary to face the back or the front of the cabinet toward a window to obtain a television picture. This may be due to walls, water pipes, or a steel structure in the location preventing television reception.

The antenna tuning knob should be used as a fine tuning control and should be adjusted until the best picture is obtained. In order to eliminate "Body effect" when adjusting the antenna tuning knob, stand in front and reach over the top of the set. If at any time the knob becomes difficult to turn, reverse the direction of rotation. Do not force the knob in either direction.

If the receiver fails to operate satisfactorily with the built-in antenna, check for the following trouble:

1. Check the antenna dipole to make sure it is not touching the chassis or any other object.
2. Check the antenna dipole to make sure it is stapled to the side of the cabinet and does not vibrate.
3. Check the connections at the coil, transmission line, and trimmer capacitor.
4. Check to make sure that all four antenna terminal screws are moderately tight. The antenna terminals should be connected in parallel.

PRODUCTION CHANGES

As changes were made in the production of Model M-701 chassis, code numbers were assigned to distinguish the differences in the set. The differences between the different code numbers are explained below.

Code 1 Chassis.

Code 1 chassis are wired as shown in the schematic diagram except the grounded end of C-117 is connected to terminal 1 of T6 and a 1000 mmf capacitor is used in place of the parallel connection of C-109 and C-111.

Code 2 Chassis.

Code 2 chassis are wired as shown in the schematic diagram except a 1000 mmf capacitor is used in place of the parallel connection of C-109 and C-111.

Code 3 Chassis.

Code 3 chassis are wired as shown in the schematic diagram.

For test pattern adjustments, alignment procedure, and trouble-shooting charts, refer to the 12AX22 service manual.

PRODUCTION CHANGES

As changes were made in the production of Model 10AX chassis, code numbers were assigned to distinguish the differences in the sets. The differences between the different code numbers are explained below.

CODE 1, 2, 3 CHASSIS.

Code 1, 2, 3 chassis are wired as explained in the service manual.

CODE 4 CHASSIS.

Code 4 chassis are wired as shown in the service manual schematic diagram except for the addition of capacitor C-116 (.2 mmf).

CODE 5 CHASSIS.

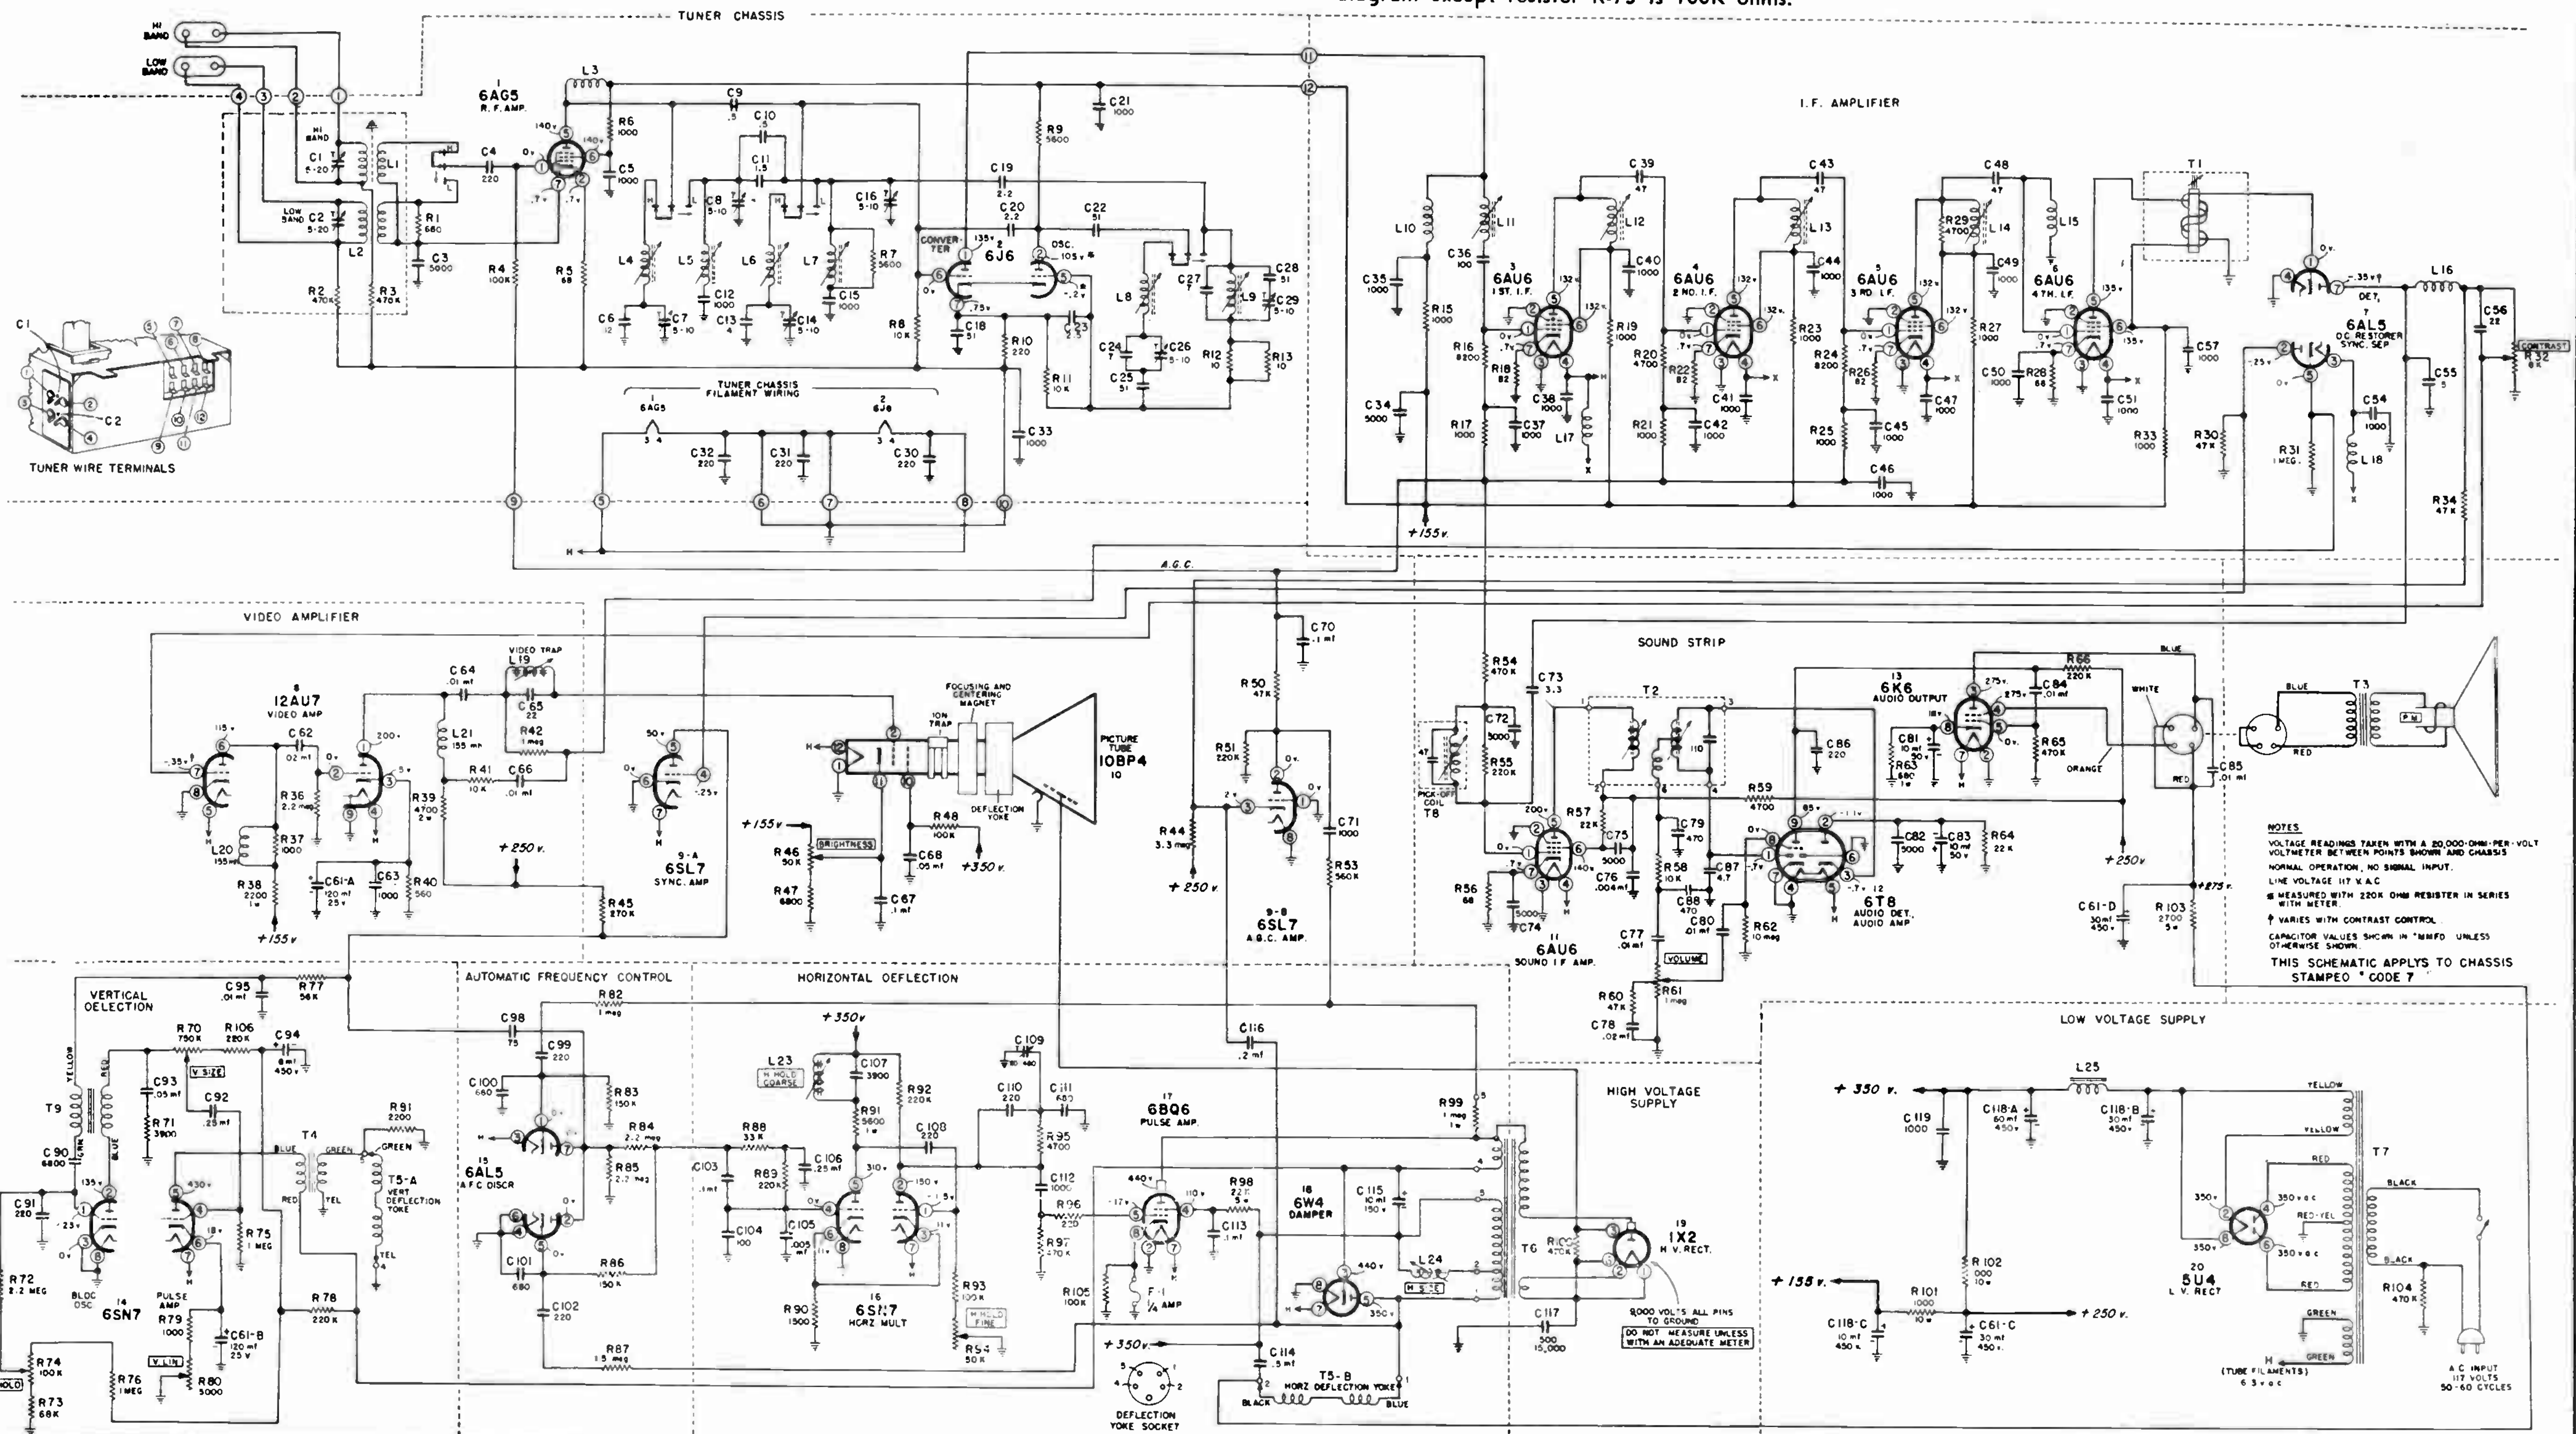
Code 5 chassis are wired as shown in the schematic diagram except resistor R-73 is 100K ohms and capacitor C-119 is not incorporated.

CODE 6 CHASSIS.

Code 6 chassis are wired as shown in the schematic diagram except resistor R-73 is 100K ohms.

CODE 7 CHASSIS.

Code 7 chassis are wired as shown in the schematic diagram.



SCHEMATIC DIAGRAM OF 10AX CHASSIS *(Code 7)*

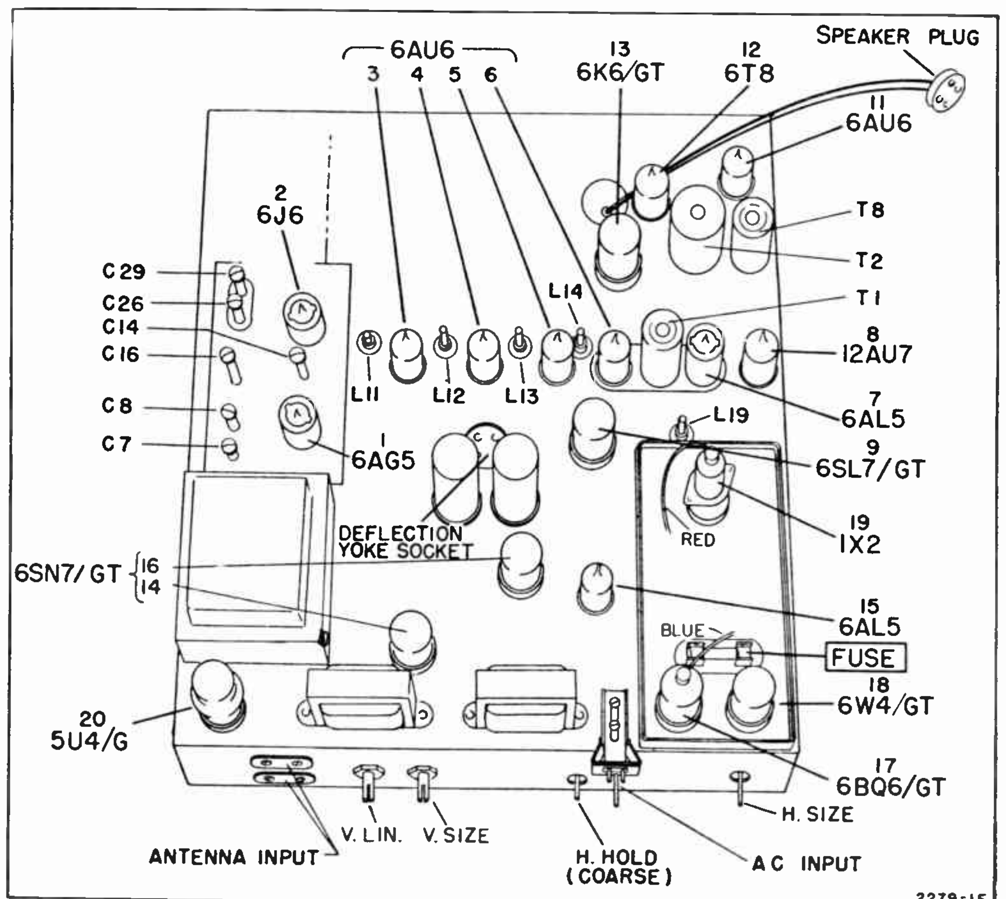
GENERAL DESCRIPTION

The Model 10AXF44 is a combination television, AM-FM radio, and a 45 RPM record changer.

The Television set is a 20-tube, AC operated, direct view, 10-inch television receiver and features complete coverage of all 12 television channels, automatic gain control, automatic frequency control, intercarrier sound system, permanent magnet focused and magnetically deflected picture tube.

On the back of the cabinet is a safety interlock to prevent dangerous electrical shock. As an added safety measure, a fuse is located in the high voltage power supply to protect the set in case of overloading.



Tube Layout

OPERATION OF THE TELEVISION

FUNCTIONS OF THE CONTROLS

All the controls normally used in tuning in a program—both picture and sound—are located on the front of the receiver. On the rear of the set are several controls which are pre-set at the factory and may need slight readjustment at the time of installation. After installation, they should not be adjusted further, unless required by replacement or aging of tubes, variations in power-line voltage, or other external conditions. The function of each of the controls is described below.

OPERATOR'S CONTROLS

Volume-Off — Turns set on or off and adjusts sound volume.

Contrast—Varies contrast between light and dark portions of picture.

Brightness—Controls brilliance of picture.

V. Hold—Stops pictures from moving up or down.

H. Hold—Stops pictures from moving left or right.

Station Selector Knob—Tunes set to desired channel (station). May be turned in either direction.

SERVICEMAN'S CONTROLS

Vert. Lin.—Provides vertical distribution of picture.

Vert. Size — Changes size of picture vertically. Does not affect horizontal size.

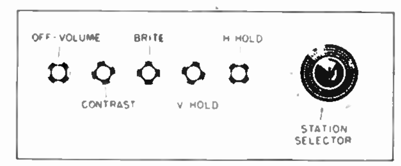
Horiz. Size—Changes size of picture horizontally. Does not affect vertical size.

Focus—Focuses picture on face of picture tube.

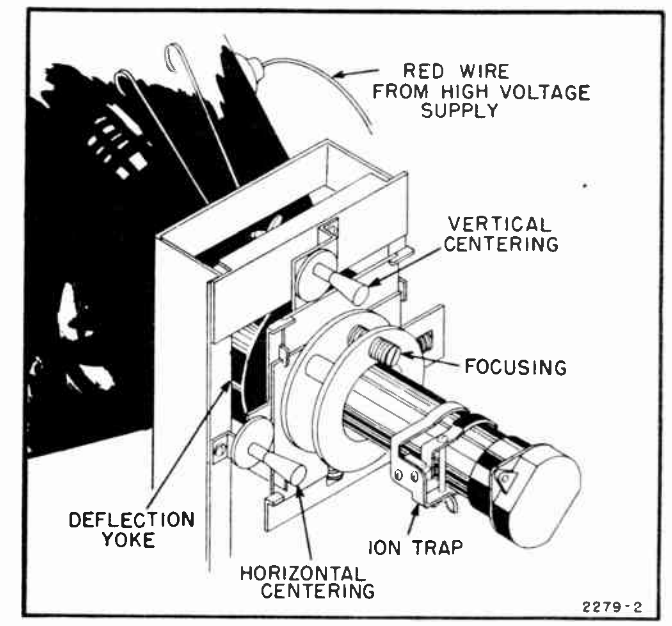
H. Centering—Moves entire picture horizontally.

V. Centering—Moves entire picture vertically.

Model 10AXF44 actually requires only three controls when tuning in a program. The three controls, off-on-volume, contrast and station selector are located on the front of the receiver. The three other controls on the front of the set: brightness, horizontal hold, and vertical hold, need only be adjusted periodically. The six operator's controls are shown below:



Three of the seven serviceman's controls; focus, horizontal centering, and vertical centering, are located on the picture tube assembly. The remaining four controls, vertical linearity, vertical size, horizontal size, and coarse horizontal hold are located on the rear of the set. (See tube layout).



Picture Tube Assembly

TUNING PROCEDURE

1. Turn the VOLUME control clockwise to turn the set on. Allow one-half minute for the set to warm up.
2. Rotate the Station Selector knob to the desired channel.
3. Turn the CONTRAST control fully counter-clockwise.
4. Turn the BRIGHTNESS control fully clockwise, and then turn it slowly counter-clockwise until the picture tube just becomes dark. *For any particular installation this adjustment of the BRIGHTNESS control need be made only the first time the set is used, unless required by replacement of tubes.*
5. Adjust the CONTRAST control until the proper contrast between blacks and whites is obtained.
6. Adjust the VOLUME control for the desired sound level.
7. When switching from one station to another, it may be necessary to readjust the CONTRAST control.

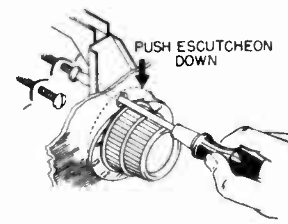
ADJUSTMENT OF STATION SELECTOR

The station selector of your television set has been partially pre-set at the factory, but readjustment of the settings may have to be made at the time of the initial installation. This should be done by the serviceman.

If at a later time a new station comes on the air, or if the receiver is moved to a locality where other stations can be received, adjust the station selector in the following manner.

1. Turn the set on. Allow the set to warm up for 20 minutes.
2. Turn the contrast control approximately two-thirds of the way toward its full clockwise position.
3. Turn the volume control approximately to its mid-position.
4. Set the station selector knob to the desired channel.
5. Grasp the station escutcheon at the upper right edge and slowly push down until the hole above the station selector knob appears.
6. Insert a screwdriver into the hole (see illustration). Turn the screw slowly counter-clockwise (and then clockwise, if necessary) until maximum sound is heard. This may require several turns in one direction or the other. Turn up the volume control if necessary. (Do not at any time turn the screw in either direction more than 3 revolutions. Do not force it if turning becomes difficult as the screw has then reached the end of its travel in that direction and its direction should be reversed.)



7. When the sound is at maximum, the picture will appear on the screen but "sound bars" (dark horizontal bars of varying width) will be seen traveling vertically from bottom to top across the picture. With the screwdriver, turn the station selector screw counter-clockwise only far enough to remove the sound bars from the picture.
8. Push the station escutcheon back into place.

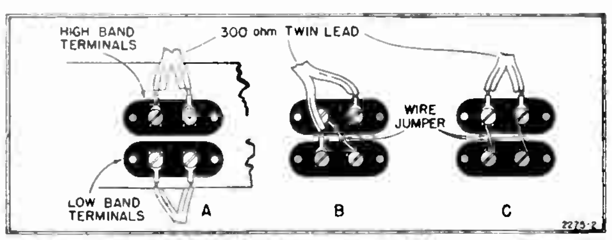
CAUTION!: 9,000 volts on all pins of the 1X2 high voltage rectifier. DO NOT MEASURE this voltage unless a high range voltmeter is used.

WARNING!: Do not tamper with or attempt to defeat the purpose of the safety interlock.

FUSE: To replace the fuse in the high voltage power supply, lift off the high voltage shield, remove the old fuse, and replace with the same type 1/4 ampere fuse.

ANTENNA CONNECTIONS

1. For those who use separate Hi and Low Band antennae, with two lead-in cables, connect the Hi-Band leads to the two top terminals marked Hi-Band, connect the Lo-Band leads to the two bottom terminals, marked Lo-Band. See fig. 4, sketch A.
2. For those who use a combined Hi-Lo Band antenna, better known as a "All Wave Antenna" with one lead-in cable, connect as shown in fig. 4, sketch B.
3. In some cases due to location or environment of the Receiving antennae, better results can be had by connecting the lead-in as shown in fig. 4, sketch C.
4. An alternate arrangement for those who receive from Hi-Band stations only (Channels 7 thru 13), the All Wave Antenna lead-in may be connected to the two top terminals marked Hi-Band, with no strap or connection to the Lo-Band terminals.
5. Use the arrangement which gives the most satisfactory results.



Alternate Antenna Connections

PRODUCTION CHANGES

As changes were made in the production of Model 10AXF44 chassis, code numbers were assigned to distinguish the differences in the set. The differences between the different code numbers are explained below.

Code 1 Chassis.

Code 1 chassis are wired as shown in the schematic diagram except the grounded end of C-117 is connected to terminal 1 of T6 and a 1000 mmf capacitor is used in place of the parallel connection of C-109 and C-111.

Code 2 Chassis.

Code 2 chassis are wired as shown in the schematic diagram except a 1000 mmf capacitor is used in place of the parallel connection of C-109 and C-111.

Code 3 Chassis.

Code 3 chassis are wired as shown in the schematic diagram.

For the alignment procedure and trouble-shooting charts, refer to the M-1101, C-1102 Service Manual.

OPERATION OF THE RADIO

Broadcast Band—This is the tuning band in which the standard broadcast stations operate. The left scale on the dial covers the broadcast range of 535-1620 Kc., and is calibrated in channel numbers. To obtain the kilocycle reading, multiply the number on the dial by 10; thus 80 on the dial corresponds to 800 kilocycles.

FM Band—The FM tuning range covers the newly allocated frequency-modulation band of 88 to 108 megacycles into which all FM stations were required to move. Check with your local newspaper to determine the frequency of your local FM stations.

On-off Switch and Volume Control- The knob second from the bottom is both the on-off switch and the volume control. When this control is turned all the way to the left the set is off. A slight rotation to the right will click the switch and turn the set on. The knob may then be used to regulate the volume. Be sure your set is turned completely off when not in use; otherwise the tubes will wear out unnecessarily.

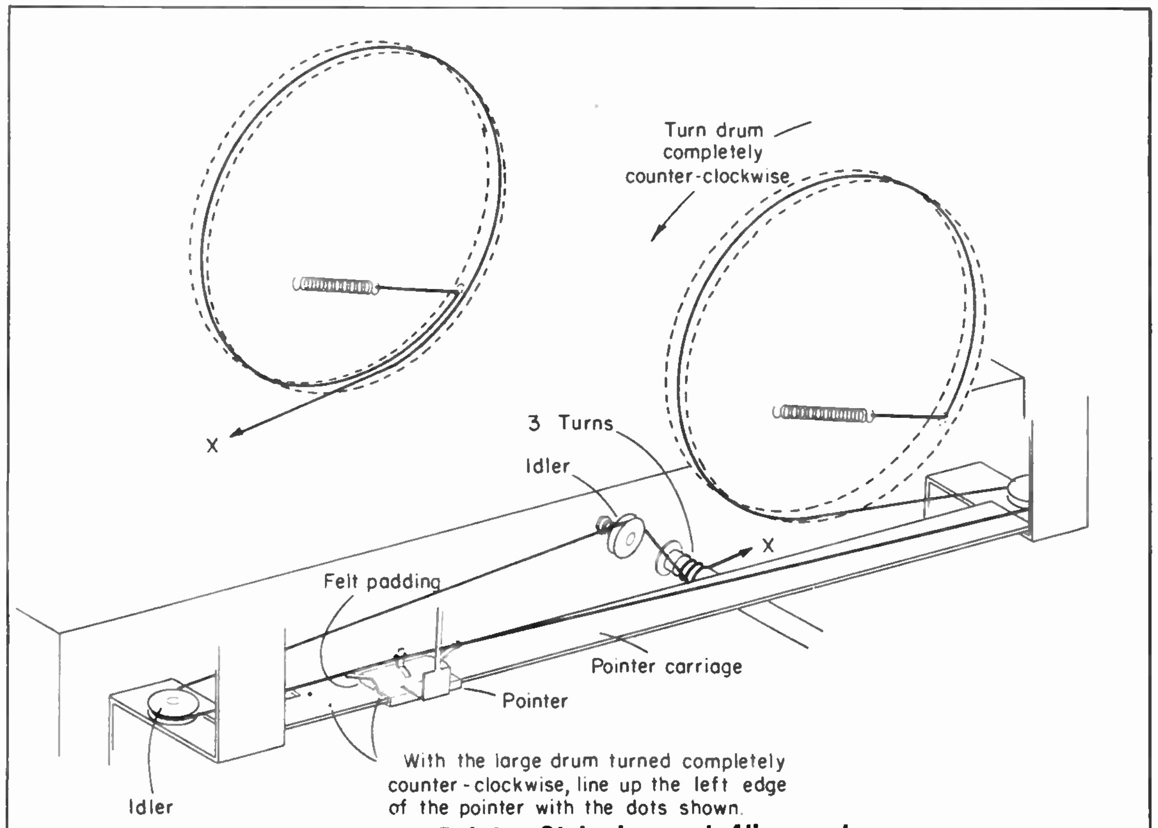
Tone Control—Rotating the bottom knob gives a full variation of the tonal response from a deep bass to a brilliant treble.

Tuning Knob—The knob second from the top is the tuning knob; rotation of this knob moves the indicator along the dial scales. When selecting a station turn the knob back and forth until the tone is clearest and loudest. Do not use the tuning knob to regulate volume; the volume control should be used for that purpose after the station has been tuned in properly. It is particularly important in FM reception to tune the station accurately; otherwise the tone is distorted and the background noise not eliminated.

Band Switch—The knob on the top is used to select FM BAND, BROADCAST BAND, or PHONO. When this knob is turned fully clockwise FM programs can be tuned in. In the center position STANDARD BROADCASTS can be heard.

Phonograph—Turning the Bandswitch fully counterclockwise allows the radio to be used for the playing of phonograph records in conjunction with the automatic record player mounted in this cabinet. This automatic Record Player accommodates eight of the NEW 45 RPM records, approximately 40 minutes of entertainment without attention. For operation of this unit please refer to the Automatic Record Changer Operating Instructions on separate sheet.

REPLACEMENT OF DIAL CORDS



Pointer Stringing and Alignment

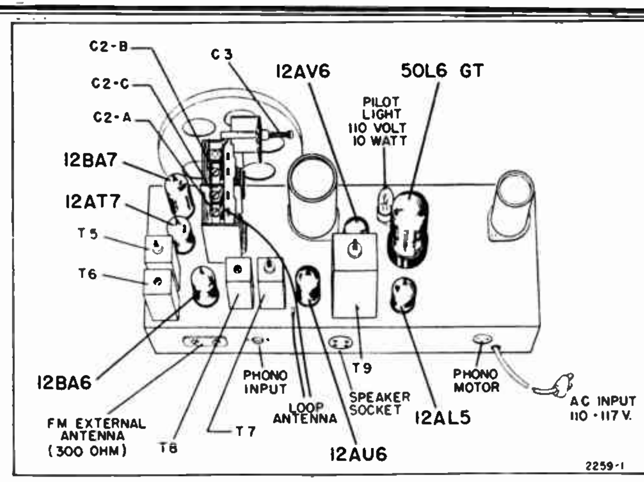
©John F. Rider

ALIGNMENT PROCEDURE

Broadcast Band Section I. F. and R. F.

The alignment procedure below includes the sensitivities at the inputs of various stages. All signal input values are based on an output of .50 watts. This may be measured by disconnecting the speaker voice coil and substituting a 3.2-ohm resistor across the secondary winding of the output transformer. A reading of 1.25 volts AC across this resistor will be approximately equivalent to .50 watt output with the speaker connected. The volume control must be set at maximum. The tone control must be set for maximum treble.

The signal source must be an accurately calibrated signal generator capable of supplying the frequencies designated, modulated 30% with a 400-cycle audio signal. A 400 cycle audio signal is required for the audio measurement. Variations in sensitivities of plus or minus 25% are usually permissable.



Chassis View

AM—I. F. ALIGNMENT

Band Switch in AM Position, Gang Open, Dummy Antenna .1 Mfd.

SIGNAL GENERATOR FREQUENCY	CONNECTION TO RADIO	ADJUSTMENTS TO BE MADE	ADJUST FOR
455 Kc. Use 2500 microvolts	Pin 1 of 12BA6 I.F. Amp. and B minus	Primary and Secondary of T8. See chassis view.	Maximum output should be .5 watts
455 Kc. Use 75 microvolts	Pin 7 of 12BA7 Converter and B minus	Primary and Secondary of T6. See chassis view.	Maximum output should be .5 watts
400 cycles. Use 45 millivolts	High side of Volume Control and B minus	None	Maximum output should be .5 watts

BROADCAST BAND—R. F. ALIGNMENT

Check pointer so that the right hand edge of the pointer skirt coincides with the right hand edge of dial marker at the extreme right when gang is closed. For Adjustment, see dial mechanism illustration.

SIGNAL GENERATOR FREQUENCY	SET POINTER AT	CONNECT TO RADIO	ADJUST
1620 Kc.	Extreme Right Calibration Marker	AM Antenna Clip and B minus	Oscillator trimmer C2-B for maximum
1400 Kc.	Second Calibration from Right	AM Antenna Clip and B minus	Antenna trimmer C2-A for maximum

Check tracking at 1000 Kc, 600 Kc, and 535 Kc to be sure oscillator is set correctly.

ELECTRICAL SPECIFICATIONS

Power Supply ..... 105 to 125 volts, AC, 60-cycles; Chassis only 75 watts. With phono operation 100 watts.

Frequency Ranges ..... Broadcast Band—535 to 1620 kc. FM Band—88 to 108 mc.

Intermediate Freq. ..... AM-455 kc.; FM-10.7 mc.

Selectivity ..... AM-43 kc. broad at 1000 times signal, measured at 1000 kc. I.F. FM-250 kc. broad at 2 times down. I.F. FM-650 kc. broad at 10 times down.

AM. Sensitivity ..... (For .5 watt output with external antenna)—18 microvolts average.

FM Sensitivity ..... (For .5 watt output)—16 microvolts average.

Power Output ..... 2 watts, 10% distortion. 4 watts maximum.

Loud Speaker ..... 10″ PM. Voice coil impedance 3.2 ohms, 400 cycles.

Tube Complement .....
12AT7, FM-RF amp. mixer;
12BA7, AM converter, FM oscillator;
12BA6, IF amplifier;
12AU6, FM driver;
12AL5, FM detector;
12AV6, AM detector, AVC, 1st audio;
50L6GT, output.

Automatic Changer See Manual 5084.

ALIGNMENT PROCEDURE

FM Band Section I. F. and R. F.

A non-metallic alignment tool must be used.

IMPORTANT

No alignment of the FM section of this radio should be attempted unless you are positive that the circuits are in need of adjustment and you have the necessary equipment.

All components used in this radio are extremely stable and the tuned circuits should require no adjustment over a long period of time.

NOTE

The following alignment is based on the use of the new Simpson vacuum tube voltmeter which has a "floating ground". In other words, the meter, when used as a vacuum tube voltmeter, can have both the positive and negative sides connected to points above ground and still give true readings.

A standard AM signal generator is required.

FM—I.F. ALIGNMENT

Band Switch in FM Position. Dummy Antenna .1 Mfd.

SIGNAL GENERATOR FREQUENCY	CONNECTION TO RADIO	VACUUM TUBE VOLT METER CONNECTION TO RADIO	ADJUSTMENTS TO BE MADE	ADJUST FOR
10.7 Mc. Use about .1 volt	Pin No. 1 of 12AU6	Pin No. 7 of 12AL5 and B minus	Bottom Core Primary of T9 Ratio Detector	Resonance should be about 3 volts
10.7 Mc. Use about .1 volt	Pin No. 1 of 12AU6	See note "A"	Top Core Secondary of T9 Ratio Detector	Zero. Use zero center scale See note "B"
10.7 Mc. Use about 330 microvolts	Pin No. 1 of 12BA6	Pin No. 7 of 12AL5 and B minus	Primary and Secondary of T7. FM Driver IF See chassis view.	Resonance should be about 3 volts
10.7 Mc. Use about 600 microvolts	Top end of C2-C	Pin No. 7 of 12AL5 and B minus	Primary and Secondary of T5. Input IF See chassis view.	Resonance should be about 3 volts

NOTES ON FM—I. F. ALIGNMENT

NOTE "A"—Connect two resistors in series, 100K OHMS each, from Pin No. 7 of 12AL5 to B minus (pin no. 5). These resistors must be matched within 5%. Connect vacuum tube voltmeter between the midpoint of the resistors and point zz.

NOTE "B"—If T9 has been tampered with, it is possible that no crossover point will be found at first. Careful adjustment of both primary and secondary is necessary.

NOTE "C"—To use a VTVM which does not have the "floating ground" feature, in step 2 above, connect "ground" side of VTVM to midpoint of resistors (Note "A") and "high" side to point zz.

GENERAL—Input signals should be adjusted to give approximately 3 volts. The ratio detector is operating at a reasonable level at this point and will give the truest indication of correct alignment with the procedure specified.

FM—R. F. ALIGNMENT

Check pointer so that the right hand edge of the pointer skirt coincides with the right hand edge of dial marker at the extreme right when gang is closed. For Adjustment, see dial mechanism illustration.

SIGNAL GENERATOR FREQUENCY	POINTER	CONNECTION TO RADIO	ADJUST	VTVM CONNECTIONS
108 MC.	108 MC. Marker	FM antenna terminals	FM Osc C3 for maximum	Pin No. 7 of 12AL5 to B minus
98 MC.	Tune in Gen. Signal	See Note "B" below	FM Mixer C2-C for maximum	

NOTE "A"—If a signal generator with the above fundamental frequency is not available, it is sometimes possible to use harmonics. Use extreme care in picking harmonics. An alternate procedure is to use a local station carrier of known frequency to align the FM Band and to use the vacuum tube volt-meter as above for resonance indication. A weak carrier, however, will not produce 3 volts.

NOTE "B"—Connect 300 ohms in series with "hot" side of generator and connect to left hand screw of external FM Antenna Terminals. Connect cold side of generator to right hand screw.

World Radio History

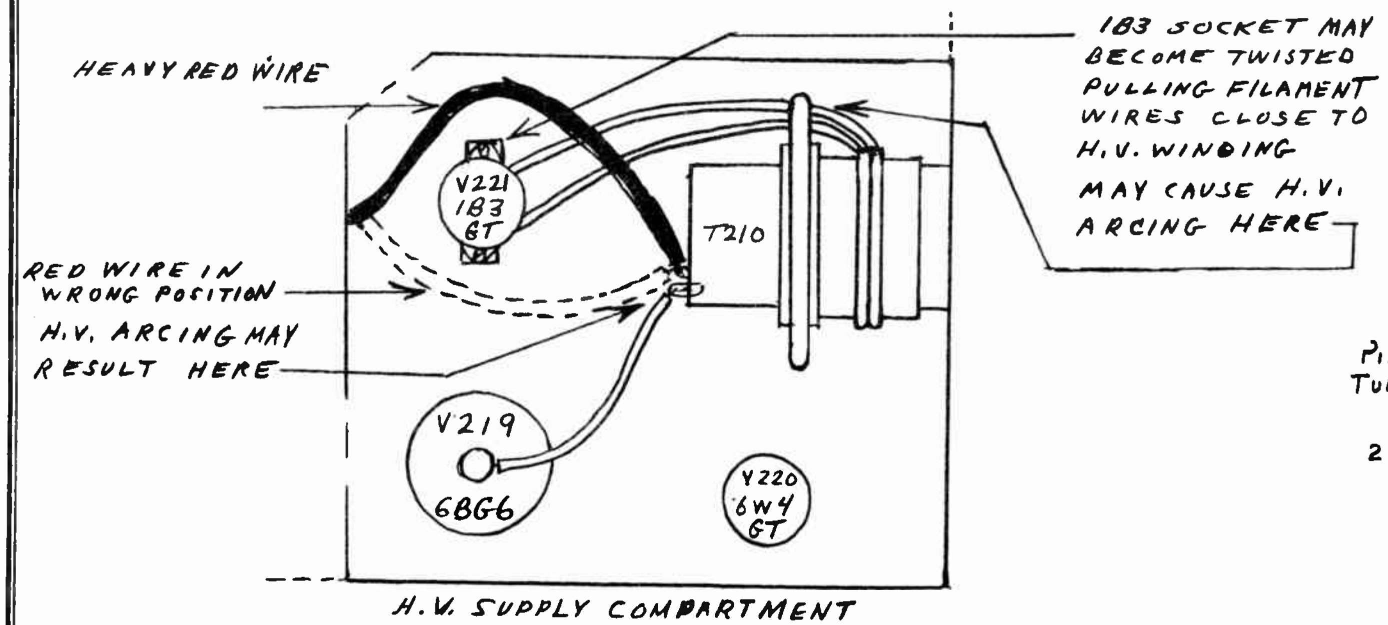
INDEX

LEAD DRESS IMPORTANT IN CX-33 "HV" SECTION

If necessary to replace the 1B3 rectifier tube in the "HV" section of this receiver, it is possible if care is not exercised to disarrange the wiring. This might cause high voltage arcing or a short to develop resulting in a burned out transformer. Note carefully in the sketch below the proper position of the 1B3 socket, so as to avoid drawing the filament supply leads against the transformer coil. Also note correct position of the heavy red wire between the horizontal output transformer and the deflection yoke. It must be between the 1B3 tube and power supply shield -- not between the 1B3 and 6BG6 tubes.



EXPLANATION OF DIFFERENT TYPES OF ION TRAP MAGNETS USED

There are several different types of picture tubes currently being used in the CX-33 Chassis, these can be separated into two categories; the "tilt gun" type and the "straight gun" type. The type of Ion Trap Magnet used depends upon the category in which the picture tube is classified with regard to the electron gun structure. Ion Trap Magnet, part no. 650276A-1 is a "single magnet" type used with the "tilt gun" tubes.
Ion Trap Magnet, part no. 650161A-4 and 650161A-5 are "double magnet" types used with the "straight gun" tubes. (650161A-4 and 650161A-5 differ only in that they are obtained from different suppliers.)
Following is a classification of the different type rectangular tubes and the Ion Trap Magnet to be used with each.

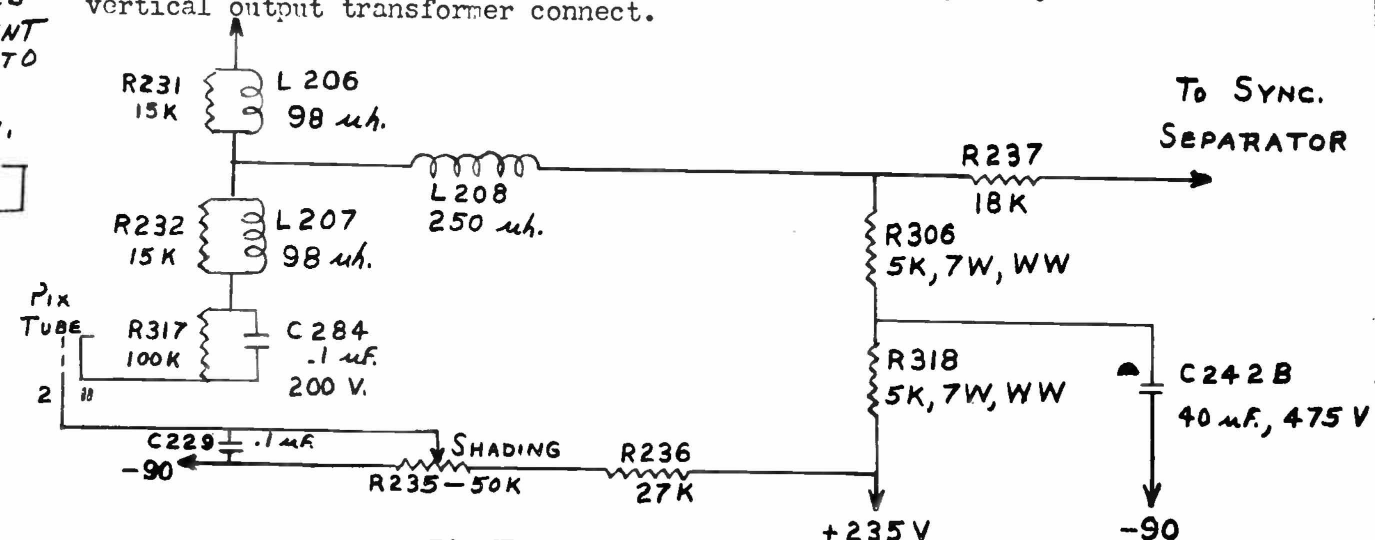
Tube Type		Ion Trap Magnet
16RP4	(Straight Gun)	650161A-4 or 650161A-5
16XP4	" "	" or "
160-AR Farnsworth	" "	" or "
16TP4	(tilt gun)	650276A-1
16KP4	" "	"

The two different types are not interchangeable with the two types of tubes in use. Use of the wrong type trap may result in failure to obtain maximum picture brilliance and possible damage to the tube screen through ion bombardment.

Important: Ion trap Magnets Parts No. 13917 and 650161A-1 are for use with "Round" picture tubes and are not to be used with the "Rectangular" tubes.

TO PREVENT BLOCKING ON STRONG SIGNALS

Remove the present leads from the positive terminal of C242B, connect together and insulate. Connect a 5K, 7 Watt wire-wound resistor between the positive terminals of C243C and C242B. This resistor is indicated in the diagram below as R318. Remove R236 from the plus 135 Volt circuit and connect to the plus 235 Volt circuit. Remove R306 from the plus 135 Volt circuit and connect to C242B. To provide by-passing at the plus 135 Volt tap, add a 20 ufd. 450 Volt tubular condenser between this point and ground. This condenser should be connected to the terminal board to the front of the 4.5 mc. sound I.F. stage and the ground lug of the terminal board to which the primary leads of the vertical output transformer connect.



TO REDUCE BLOOMING OF THE PICTURE

Connect in series with the lead to pin 11 (cathode) of the picture tube a parallel combination of a 100K resistor and a 0.1 ufd. 200V capacitor. Care should be taken that undue stray capacity is not introduced between the cathode lead of the picture tube and ground.

This change is also shown in the diagram above.

TO INCREASE HORIZONTAL SCAN

The 30 mmfd. 6KV condenser, C278, part No. 450954A-3, which was previously connected between the cathode of the 6W4 damper tube and ground to increase width should be re-connected between the 6BG6 plate connection of the high voltage coil and ground to further increase width.

©John F. Rider

World Radio History

A soldering lug should be attached to the inside wall of the power supply housing in line with the present hole through which the yoke lead comes out and approximately 2-$\frac{1}{4}$ inches from the rear of the chassis. Care should be taken when installing the capacitor that it does not come in contact with either the 1B3 or 6BG6 tube. A wire ground should be installed between the terminal lug and the chassis to provide proper grounding. An easy method of connecting this is to run wire through the vent hole closest to the 6BG6 socket and ground the wire to the saddle of the socket.

INTERNAL ARCING IN H.V. CAPACITOR C261 - CX-33 TV CHASSIS

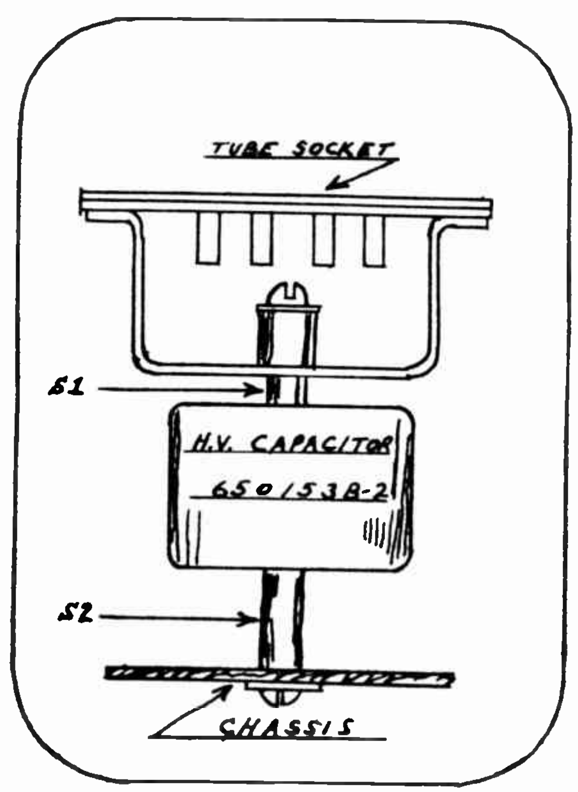
This is the 500 uufd., 20KV high voltage filter capacitor, part No. 650153B-2.

It is possible that the Jeffers Electronics H.V. capacitor, part No. 650153B-2, may be subject to failure, possibly caused by absorption of moisture in the dielectric or to mechanical failure in the event of being abused at time of assembly. This breakdown may not be apparent at once but may possibly show up over a period of several weeks in operation.

There are two colors of Jeffers capacitors -- mustard and tan. Do not confuse these with the Centralab capacitors which will have the trademark CRL stamped on them. We have had reports only of Jeffers capacitor failures although some CRL types might be found similarly defective.

Any of these capacitors found defective should be removed from the CX-33 chassis. These should be held for return to Capehart-Farnsworth on Return Goods Authorization issued by our Field Engineer and not scrapped in the field. We are anxious to receive defective samples for further engineering examination as soon as possible.

The failure of subject capacitors could be the result of a mechanical strain on the solder joint inside the capacitor where the stud is connected to the silver deposit on the ceramic dielectric. Excessive torque applied between the two studs or between the body of the capacitor and a stud during assembly or replacement may break the soldered joint or tear the silver away from the dielectric.

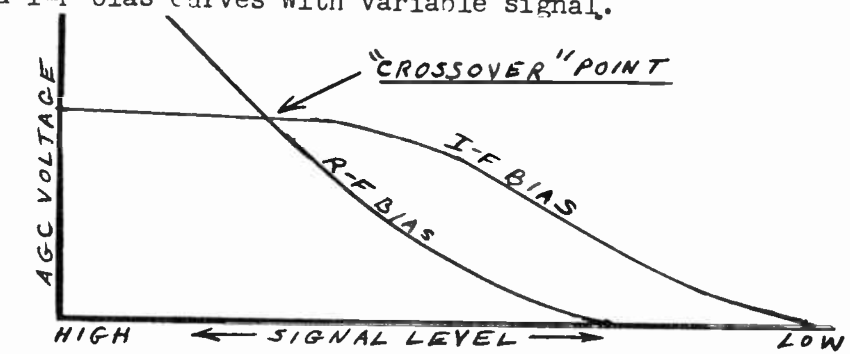


In assemblying the capacitor to the bracket, part No. 450512B-1, the assembly should be held by the bracket, not by the capacitor, as the screw is tightened. The double-D hole in the bracket prevents rotation between the bracket and stud S1.

In mounting the bracket-capacitor assembly on the chassis, stud S2 should be held by a pair of gas pliers as the mounting screw is tightened, so as not to produce any torque between S2 and the body of the capacitor.

VARIATION OF AGC CROSSOVER POINT--CX-33 CHASSIS

The CX-33 Chassis employs an AGC System wherein differential bias is supplied to the R-F and I-F stages. This means that at low signal levels, more AGC voltage is applied to the I-F Stages than to the R-F Stage, while at high signal levels, more AGC is applied to the R-F Stage than to the I-F. Therefore, there is a point of "crossover" at some value of signal level where the I-F and R-F bias is the same. This is illustrated in the following graph showing the R-F and I-F bias curves with variable signal.



Some reports have been received of excessive "snow" in moderate signal areas. This has been found to be caused, in certain cases, by a variation of resistance in R-252 and/or R-248 resulting in the AGC crossover point occurring at too low a signal level. A test is being incorporated in production wherein a 1000 microvolt signal must produce a relatively snow free picture. R-252, 2.4 megohms, R-248, 24K, and R-250, 120k resistors must all be held within their 5% tolerance. In cases of excessive snow these resistors should be checked for proper values. Since R-248 and R-250 are fairly low values, it is difficult to ascertain a 5% change in their resistance without the use of a bridge. Therefore, it is suggested that where a noticeable resistance change is not found in R-248 or R-250, that R-252 be changed to 2.2 meg. or, if snow is still excessive, to 2.0 meg. This has been found to remedy the condition in most cases.

INTERMITTENT DECREASE IN HORIZONTAL SCAN--CX-33 CHASSIS

A chassis developing the above mentioned trouble will have sufficient scan when first turned on. The width will decrease over a ten to fifteen minute period in most cases to about two-thirds original size, then gradually over a period of approximately one hour, the width will increase to normal size.

This trouble has been found to be the result of excessive winding capacity and insufficient baking of isolation transformer in the damper tube heater circuit. This transformer (part no. 650243A-1) is supplied by more than one vendor and this difficulty has been found to exist only in those transformers identified by the code letters "BC" following the part number. All of these transformers so coded should be removed from your stock and returned for credit with approval of your Field Service Representative.

As soon as the vendor in question can correct the above mentioned difficulty his transformer will again be accepted for use. These transformers will bear the code letters "BC", however, they will be identifiable by the code dating which will be 037 or higher.

ADDITIONAL INFORMATION ON 6KV CAPACITOR, C-278

The original capacitor is believed to have failed due to heat from the 6BG6 tube. A new capacitor, part #650310A-2, has a wax coating unaffected by high temperatures. Life tests, and field reports have shown this new capacitor to be entirely satisfactory.

World Radio History

NEW FOCUS COIL MOUNTING FOR SHIPMENT

You were informed in the previous issue of the service bulletin that a special method of mounting the focus coil during shipment would be incorporated shortly.

As of September 12, 1950, the method described of mounting the focus coil under the chassis shelf, was incorporated in all models currently in production with exception of models 320 and 321. This method of mounting the coil is considered temporary and will be superceded, as soon as parts become available, by a second method wherein the coil is mounted on the H.V. Supply Shield. This second method will be applicable to all models including the 320 and 321.

This is an item which should be covered in your Dealer Bulletin specifically stressing the importance of properly installing the focus coil when the receiver is set up. It would be well to have all installation personnel informed of this proper mounting if they are not already familiar with the CX-33 Chassis. By referring to the CX-33 Chassis Maintenance Manual (Chassis Top View) an inexperienced man can determine the correct mounting of the coil. These men should also be cautioned to properly adjust the ion trap since the trap must be removed to install the focus coil.

We expect reports of picture tubes broken in shipment to drop off sharply with the use of this new mounting. In view of the precautions taken by the factory to avoid breakage, we believe no carrier will refuse to accept responsibility in the comparatively few cases where this may still occur. Please check each incoming shipment for glass rattle (not necessary to open) -- where noted, carrier claim should be filed immediately.

INTERMITTENT VERTICAL SYNC BUZZ--CX-33 CHASSIS

Most reports of "intermittent" sync buzz can be attributed to overmodulation at the TV Transmitter for which, of course, there can be no correction at the receiver end. Always check with the TV transmitter's engineers first upon receiving reports of intermittent sync buzz troubles.

At the receiver, this trouble may be the result of insufficient drive at the ratio detector resulting in lowered AM rejection. Increased drive can be obtained by supplementing the coupling of the sound take-off transformer (T204) with a 3 uuf capacitor. Connect the capacitor between terminals 2 and 4 of T204. After adding this capacitor the primary and secondary of T204 must be re-aligned carefully.

In addition to reducing sync buzz, this increased coupling will also provide an increase in sound output. Therefore, on reports of low sound output (where alignment is found to be O.K.), the addition of this capacitor is recommended.

REMOVAL OF SHIPPING SCREW ON VARIABLE CAPACITOR IN RADIO CHASSIS C-282 USED IN MODELS 328M & 337M

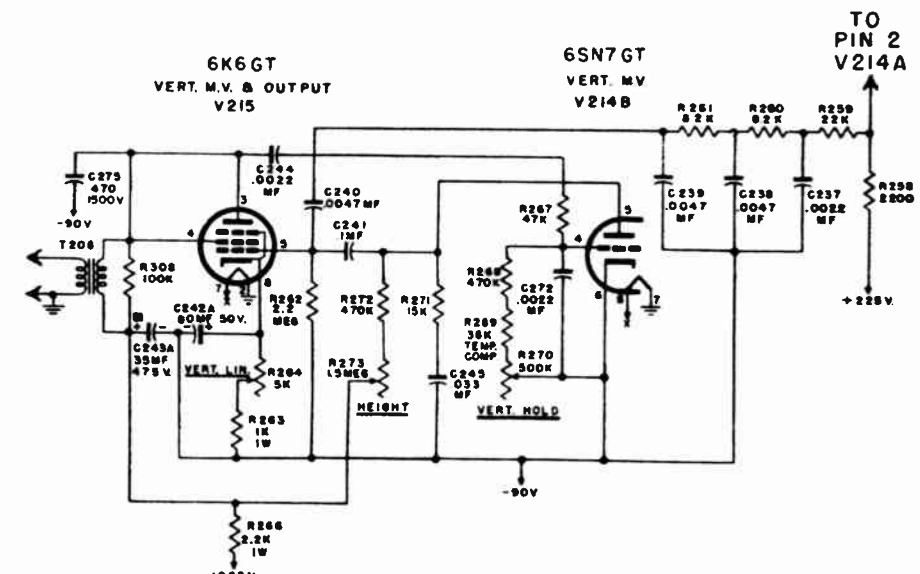
In order to prevent lead breakage during shipment, a method has been devised to fasten the variable capacitor and prevent vibration. A metal bracket is placed in back of the variable and fastened to the chassis. The variable is then secured to the bracket by means of a small screw. This screw should be removed upon installing of the set so that the variable will be "free floating". If the screw is not removed, it is likely that the set will be very microphonic. It is not necessary to remove the bracket; however, it may be necessary to bend it away from the variable in the event that it is touching the back of the variable and hindering its free mounting.

Production Changes

Early Production "CX-33" Chassis.

The following differences exist between the chassis used in early production of Models 3011 and 3012 only and the schematic diagram shown in Figure 6b.

1. The junction of R254 and R253 is connected to chassis ground.
2. R255 is a 22K, 2W resistor.
3. R286 is a 150K resistor.
4. R242 is a 47K resistor.
5. Terminal "B" on T209 is connected directly to plus 235 volts.
6. R314, C278 and C283 are not used.
7. The Vertical M. V. and Output Stage is as shown below.



CX-33, Series "-2" and CX-33F Chassis;

The following differences exist in the CX-33 Chassis, coded with a "-2" and CX-33F Chassis (which employs a 16 inch Round, metal C. R. T.).

In some receivers using these chassis:

1. R286 is a 150K resistor.
2. R267 is a 22K resistor.
3. R262 is a 2.2 megohm resistor.
4. R266 is connected to plus 295 volt
5. C283 is not used.

THE CAPEHART CX-33 SERIES "-2" TELEVISION RECEIVER CHASSIS

The following changes are being incorporated in the CX-33 Chassis. Instruments including these chassis will be received in the field shortly. For identification, these chassis will be coded with a figure "-2" following the serial number; i.e., Serial No. 888888-2.

A schematic diagram of the Series "-2" CX-33 Chassis is attached. The changes may be grouped by their corrective purpose.

1. IMPROVED INTERLACE

The vertical sync take-off point is changed from the plate to the cathode of V214A. A few other changes were made in the vertical multivibrator to improve interlace. Refer to the attached schematic diagram for details.

2. INCREASED RANGE - VERTICAL HOLD

R270, Vertical Hold Control, is changed from 500K pot. to 1.5 meg. potentiometer to increase the "hold" range of this control.

3. IMPROVED SYNC CLIPPING

The junction of R254 and R253 is changed from chassis ground to minus 90V, R242, plate load resistor for V212, is decreased from 47K to 33K. These changes provide improved sync amplification and clipping. R255 in the plate circuit of V213 is changed from 22K, 1W to 47K, 1W and R314 also 47K, 1W is connected in parallel with it. This change is to provide adequate wattage tolerance.

4. INCREASED HORIZONTAL SCAN

C278, a 30 uuf., 6000V capacitor has been added between pin 3 of V220 Damper Tube and chassis ground. The schematic shows C278 to be 25 uuf., 5000V; however, its correct value as in current use is 30 uuf., 6000V. The addition of this capacitor provides approximately one inch additional horizontal scan (or width). A later production change to increase Horizontal Scan adds a .1 ufd. 200V capacitor across R291 in the cathode circuit of V219, 6BG6 Horizontal Output.

5. ELIMINATION OF SOUND MODULATION IN SYNC

Terminal "B" of T209, Horizontal Oscillator Transformer, is now connected to the junction of R283 and R284 rather than directly to plus 235 Volts. This provides the decoupling action of R284 and C254 for the plate supply to V217. Sound modulation in the horizontal sync circuit resulted in a "wiggle" or "swaying" of the picture horizontally.

6. RE-INCORPORATION OF 5 AMP. FUSE

Coincident with the other changes being incorporated in the Series "-2" chassis the 5 amp. fuse is also being put back in production. The required type fuse holders are available and will be mounted on the chassis rear panel. The spare fuse and spare fuse holder will also be returned to production. These items were temporarily removed from production at request of "UL" until approved type of fuse holder could be obtained.

THE CX-33F CHASSIS PRODUCTION NO. C-286 FOR CAPEHART MODEL 323M CONSOLE TV RECEIVER

This CX-33F Chassis is identical with the CX-33 "-2" electrically. It differs only with respect to the C.R.T. mounting bracket, deflection and focus coil mounting. These have been modified in order to support the type 16GP4 (metal envelope) picture tube, which is employed in the Model 323M receiver.

SPECIAL SERVICE INFORMATION CX-33 AND CX-33F CHASSIS

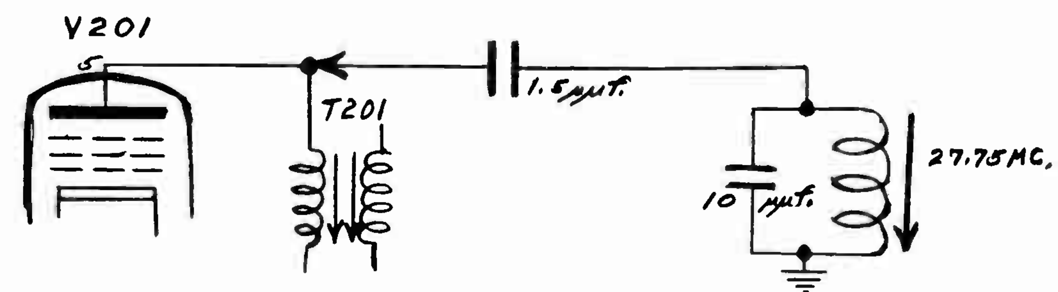
1. INCREASED VERTICAL SCAN IN CX-33 AND CX-33F CHASSIS

A production change has recently been incorporated in CX-33 Series "-2" and CX-33F Chassis to increase the size of the picture vertically.

To increase Vertical Scan, R262 has been changed from 2.2 meg. to 3.9 meg. and R266 is being connected to plus 310V instead of plus 295V. For an additional increase in Vertical Scan, V215, a 6K6GT tube, is being replaced with a 6V6GT (in production) only in those sets which require it. No circuit changes are necessary for this replacement.

2. ADJACENT CHANNEL SOUND TRAP FOR CX-33 CHASSIS

An adjacent channel sound trap tuned to 27.75 mc. will be available shortly for incorporation in the CX-33 Chassis in the field, in those localities in which this type of interference is encountered. The trap is such that it can be easily installed in an already drilled chassis hole near the 1st Pix. I-F Amplifier tube. The trap is to be connected electrically to the plate of the 1st Pix. I-F tube through a 1.5 uuf. capacitor. A sketch showing this trap schematically, follows:



Part number of the trap is 650299A-1; part number of the 1.5 uuf. capacitor is 650030A-9.

A suggested procedure for tuning this trap, after its installation, is to first tune the receiver to the channel on which the interference is obtained (if possible) and then adjust the trap to eliminate the interference. After doing this, check the overall I-f response curve and make adjustment to the I-F transformers, if necessary. The trap then can be re-adjusted slightly if any further interference is noted. In no event should this trap be installed without checking the overall I-F curve.

MODELS 321-B, 321-M, 322-M, 324-M, 325-F, Ch. C-281, CX-33; 323-M, 332-B, 332-M, 334-M, Ch. C-286, CX-33F

SPECIAL SERVICE INFORMATION CX-33 AND CX-33F CHASSIS (CONTINUED)

3.

ADDITIONAL INFORMATION ON H.V. ARCING

SEE SERVICE BULLETIN VOL. VII - NO. 7 - ISSUED MAY 10, 1950

The following changes have been incorporated in production to eliminate the causes of this difficulty.

A. The heavy red lead in the H.V. Supply section has been shortened in order to maintain proper dress.

B. The H.V. Filter Capacitor mounting nut is being soldered to the chassis to prevent it and hence the 1B3 socket from rotating and causing arcing between the 1B3 filament leads and the H.V. Winding of T210.

C. A high voltage insulating material is being applied to the 1B3 plate cap lead at its connection to the H.V. Winding; this is to prevent corona between this point and the H.V. Supply Shield. Additional transformers purchased will be revised to include sufficient insulation at this point.

D. The 1B3 and 6W4 socket terminals and wiring are being coated with a H.V. insulating material to prevent corona.

4.

SHORTING OF FOCUS COILS

Several shorted focus coils have been received from the field and examination shows that these coils have developed shorts due to direct contact between the lead-in to one end of the coil and other portions of the winding.

The short may not show up until the coil has been in operation for a period of time depending upon the insulation of the wires and the pressure exerted between them. (This is why such a difficulty is not detected in final test.) The symptom resulting from this short, of course, is inability to focus. A resistance check will usually show a reduction from a standard of 470 ohms to between 30 and 60 ohms.

All shorted coils to date have been those manufactured by the I.T.E. Circuit Breaker Co. These coils are also supplied by the Guardian Co. This condition has been corrected by the vendor and no receivers are being shipped with the early type coil. This early type can be identified by observing the yellow plastic bobbin. (The bobbin can be seen by looking into the coil through the air gap).

The corrected focus coil, as supplied by I.T.E. can be identified by its use of a gray plastic bobbin.

The Service Department is stocking only the corrected coil with the gray bobbin. It is suggested that you check your stock on this item, and discuss this subject with your Field Service Representative. All focus coils re-ordered on the same part number will be of the corrected type.

On a national basis, the percentage of shorted coils has been low. You may be assured that this condition has been corrected.

SPECIAL SERVICE INFORMATION CX-33 AND CX-33F CHASSIS (CONTINUED)

5.

SUBSTITUTION OF 12AT7 FOR 12AU7 - V212 ONLY

Due to a shortage of 12AU7 tubes, a 12AT7 tube is temporarily being used for V212, Pre-Sync Separator - A.G.C. Detector. The 12AT7 should not be used to substitute for V213. When replacing V212, a type 12AU7 tube should be used.

6.

TEMPORARY REMOVAL OF 5 AMP. FUSE

The 5 amp. fuse, fuse holder and spare fuse and holder were deleted for a short time in production. The fuse, spare fuse and spare fuse holder are now being re-incorporated in production. In the meantime, some chassis have been shipped without the 5 amp. fuse.

7.

FAILURE OF R-258 IN EARLY CX-33 CHASSIS

R-258 is a 2.2K ½W plate load resistor supplying the plate of V214A Sync Clipper tube in early CX-33 Chassis (before the Series "-2" production changes). Some reports have been received stating that this resistor has opened up after a period of operation resulting in a lack of vertical sync. It is suggested, if this resistor is found defective, that it be replaced with a 2.2K, 1W resistor for an additional margin of safety.

8.

PROPER SETTING OF THE AGC SET CONTROL

We are receiving reports from dealers' service men and installation personnel which indicate that they do not understand the function or the proper method for adjusting this control. The adjustment of this control is covered in the Installation and Set-Up Instructions, which accompany each receiver and also in the CX-33 Maintenance Manual. The control does usually require adjustment in the field when setting the receiver up for operation.

If the control is adjusted to either extreme clockwise or counter-clockwise when the receiver is first placed in operation, it is possible that no picture will be seen. If the control is in the extreme counter-clockwise position, the level of the bias applied to the R-F and I-F stages is very high and these stages are operating at minimum gain. If the control is in the maximum clockwise position, the reverse condition exists; the operating bias would be at a very low level and hence, if the received signal is strong, the receiver will overload causing the picture to be blanked out.

For these reasons, the control should be set to approximately the center of its range, and then the adjustment between it and the shading control can be accomplished, arriving at a setting for the AGC control which will provide proper operation of the receiver on all available TV signals.

Please see that your dealers' service and installation men are properly informed on this procedure. Make it the subject of a Special Bulletin to them.

World Radio History

Waveform Analysis

The following waveforms were obtained from a production run CX-33, Series "-2" receiver, with a standard transmitted picture signal connected to the input of the receiver.

The waveforms shown here have been sized for purposes of reproduction and they are not intended to show relative amplitudes. Approximate peak-to-peak voltages are shown on each waveform. These voltages were obtained by calibrating the oscilloscope used to observe the waveforms. The approximate values of peak-to-peak voltage are those that may be expected to be obtained with the AGC Set and Shading controls adjusted for optimum picture contrast and all other controls adjusted for normal operation.

Two separate waveforms are shown at those points where it is intended to show both the vertical and horizontal pulses. For viewing the vertical sync pulse or waveforms in the vertical sweep circuits, the oscilloscope sweep is adjusted to one-half of the vertical sweep rate (30 c.p.s.). For viewing the horizontal sync pulse or waveforms in the horizontal sweep circuits, the oscilloscope sweep is adjusted to one-half the horizontal sweep rate (7875 c.p.s.).

Slight variations in waveform may be noticed in the sync circuits when the receiver is switched to different TV stations. This is due to the slight variation which is tolerated in the transmitted waveform at the station. Some variation in waveform and in peak-to-peak voltage may also be expected due to the response of the particular oscilloscope used to observe the waveforms. When using the waveforms in trouble shooting, these factors should be taken into consideration to avoid possible incorrect conclusions. CAUTION - No waveforms are shown for points in the Horizontal Output Stage other than the control grid and cathode due to the high pulse voltages which exists in the output of this stage. DO NOT attempt to observe waveforms in the horizontal deflection yoke, Horizontal Damper or H. V. Rectifier circuits.

World Radio History

CHASSIS NO.	PRODUCTION NO.	PRODUCTION RUN
CX-33	C-281	Series "-3"
CX-33F	C-286	Series "-3"
CX-33A	C-285	Original
CX-33L	C-289	Original
CX-33M	C-290	Original
CX-33K	C-292	Original

Basic Difference Between Chassis

All of the above listed chassis are of similar design. The CX-33 is a complete unit using a 16 inch Rectangular picture tube; the CX-33F is a complete unit using a 16 inch round (metal) picture tube and the CX-33L is a complete unit using a 17 inch Rectangular picture.tube. The CX-33A is the basic chassis less the audio section (tubes V209 & V210) and using a 16 inch Rectangular picture tube. The CX-33M chassis is identical to the CX-33A chassis with exception that it employs a 17 inch Rectangular picture tube. The CX-33A chassis is used in model 327M in conjunction with C-284, an 11 tube AM chassis. The CX-33M is used in model 328M in conjunction with C-282, an 11 tube AM FM chassis, and C-243 (or C-295) a single tube phono pre-amplifier chassis. The CX-33K chassis is used in model 337M in conjunction with the C-282 radio chassis and C-295 phono pre amp chassis.

The RF Tuner Part Number 850103A

The RF tuner used in this chassis employs two tubes; a 6AG5 RF Amplifier and a 6J6 Mixer Oscillator. The input circuit employed is a balanced 300 ohm tuned input type. The RF Amplifier circuit, using a 6AG5, has a double tuned bandpass coupling to the mixer grid. The Mixer stage employs one triode section of the 6J6 type. Oscillator excitation is inductively coupled to the mixer grid. The oscillator section of the 6J6 tube is employed as a Grounded Cathode Colpitts type oscillator.

Tuning or channel selecting is accomplished in this tuner by switching inductances by means of a rotating turret. Channel sequence of tuning is progressive; channel 2 through 13, with clockwise rotation. The individual coils comprising the tuned circuits for each channel are fabricated on low-loss bakelite moldings which are held in position on the turret by a "key" and "latch spring" construction. All circuit switching in the tuner is accomplished by means of eleven spring pressure contacts. Vernier or "fine" tuning is accomplished by an auxiliary capacitor which is shunted across the plate section of the tank circuit. This capacitor is operated through a dial cord and pulley arrangement by the Balance Control. Average range of the fine tuning control on the low band is approximately + or -0.5 mc and on the high band + or -1.6 mc.

A single tuned inductance (tuned to 23.0 mc) in series with a 120 mmf capacitor form the resonant coupling circuit between the mixer plate and the grid of the 1st IF Amplifier.

This tuner is used in the CX-33 and CX-33F chassis starting with the series "-3" production run. The CX-33A, CX-33M, CX-33K, and CX-33L chassis employ this tuner exclusively.

Alignment Data

IF Amplifier

The IF Amplifier bandpass in these chassis has been increased from 3 mc to approximately 3.5 mc to provide improved picture definition. To accomplish this, the peaking of two of the IF coils in the stagger-tuned IF system have been changed. Therefore, when aligning any of the chassis listed on the front page of this supplement, the following important items should be noted;

1. T101, the coil in the mixer output stage (located on the RF tuner) should be peaked at 23.0 mc instead of 23.5 mc as stated in the CX-33 Maintenance Manual.
2. T202 should be peaked at 25.8 mc instead of 25.9 mc.
3. A co-channel sound trap (T213) has been added in the plate circuit of the 1st IF Amplifier and is located directly in rear of the 1st IF Amplifier tube (V201). This trap should be set up by tuning it for minimum response (as indicated by a VTVM connected across R213) to a 21.75 mc signal at the mixer grid.

The bandpass of the IF stages is shown in figure 1 of this supplement.

RF and Mixer Alignment (RF tuner, Part no. 850103A-1)

1. Connect the sweep and signal generators to the receiver antenna terminals. To avoid distortion keep the output of the signal generator (pix and sound carrier markers) at a minimum, markers just barely visible on the curve.
2. Connect the oscilloscope to the RF test point (wire loop) on the RF tuner, through a 10 K resistor.
3. Connect a "jumper" from the AGC lead to the tuner, to chassis ground. Leave the jumper connected for all steps under RF and Mixer Alignment.
4. Set the Channel Selector to channel 12.
5. Adjust the sweep generator to sweep channel 12 and adjust the signal generator to provide marker signals at the picture and sound carrier frequencies for channel 12.
6. Adjust C104, C103, and C102 (shown in figure 2) for the curve shown in figure 3. Consistent with proper band width and marker location, the response curve should have maximum amplitude and "flat top" appearance.
7. Adjust the sweep and signal generators progressively for each channel. Check the response curve obtained on each channel against the curve shown in figure 3. If the response of a particular channel does not come within these limits, check to see that the correct coils for that channel are being used or try replacing the coils for that channel. As a final step, it is possible that a compromise can be made by re-adjusting C104, C103, and C102 to improve the response of the particular channel that is off. The response of all other channels then should be re-checked to determine the extent to which they were affected by the compromise.

CHASSIS	MODEL NO.
CX-33L	320-M
CX-33	321-M
CX-33	321-B
CX-33	322-M
CX-33	324-M
CX-33	325-F
CX-33L	326-M
CX-33A	327-M
CX-33M	328-M
CX-33F	332-M
CX-33F	332-B
CX-33F	334-M
CX-33K	337-M

RF Oscillator Alignment

1. Connect the sweep and signal generators to the antenna terminals. To avoid destroying the response curve (due to overloading in the video detector) maintain outputs of the sweep and signal (marker) generators at a bare minimum. The marker pips should just be barely visible.
2. Connect a 500K potentiometer (on clip leads) between pins 6 and 8 of V213 and vary the "pot" to set the DC bias at the junction of R248 and R249 to -3 volts.
3. Connect the oscilloscope across R213. Attach the "high side" of the oscilloscope to the junction of R248 and R249 to -3 volts.
4. Adjust the sweep generator to sweep channel 13 and adjust the signal generator to provide markers at the picture and sound carrier frequencies for channel 13. Before attempting alignment, allow 15 minutes for receiver and test equipment to reach normal operating temperature.
5. Check the response curve obtained against the ideal curve shown in figure 4. If the shape of the curve is not within these limits, it will be necessary to repeat the IF Amplifier Alignment. The IF Amplifiers must be correctly aligned before the oscillator adjustments can be correctly made.
6. Set the Balance Control at the center of its mechanical range and adjust the channel 13 oscillator slug (see figure 5) to approximately the center of its range. Use a non-metallic screwdriver with about a 1/8 inch blade for adjustment of the individual oscillator slugs. If one of the slugs should "fall into" the coil form, remove the coil segment from the turret, move the slug retaining spring aside, and tap the coil segment until the slug slips forward. Set the slug retaining spring in place again to secure the slug.
7. If, with the conditions stated in step 6, the picture and sound carrier markers are not within the limits shown in figure 4, adjust the overall oscillator trimmer C105 to bring them within limits.
8. With the Balance Control adjusted to the center of its range, check the response curve on all channels for proper marker location. If adjustment is required on any channel use the individual channel oscillator slug to obtain the proper marker location.

NOTE: The individual channel oscillator slugs are accessible from the front of the cabinet, therefore oscillator "touch up" on any channel can be accomplished without removing the chassis from the cabinet. For further information, refer to "Oscillator Alignment Using a TV Signal" of the CX-33 Manual.

SERVICING SUGGESTIONS

Following is a summary of service conditions which may be observed in the CX-33 chassis and their recommended corrections. These are included herein to assist the service technicians in troubleshooting this chassis.

Condition	Correction
1. "Whistle" in sound and/or lines in picture (similar to Barkhausen oscillation)	a. Additional bypassing may be needed in the B minus circuit. Add a .1 mfd, 200V cap. from -90V point to chassis ground (near 6BG6 tube, junction of R291 & R-290).
2. Insufficient Vertical Scan	(if production run "2" or earlier) a. Change R262 from 2.2 meg to 3.9 meg. b. Connect R266 to 310V bus instead of 295V. c. Change R267 from 22K to 47K (any production run). d. Change 6K6 (Vert. output) to 6V6 or 6F6.
3. Picture "Jitter" Vertical	a. Possibly "leaky" coupling cap. between Sync, Amp., & Sync Clipper C235 (100 mmf)

©John F. Rider

World Radio History

4.	Intermittent Vertical Sync Buzz	a. Over modulation at TV transmitter. b. Insufficient drive at ratio detector. Connect a 3 mmf cap. between terminals 2 and 4 of T204. Check sound alignment.
5.	Small section of Picture Shifts Horizontally	a. Leaky Capacitor C278, 30 mmf., 6KV.
6.	Sound Modulation of Horizontal Oscillation	a. Open or low value capacitor C228 b. R229 wrong value.
7.	Intermittent Narrowing of Picture	a. Possibly excessive winding capacity of Damper Tube heater isolation transformer T212. (if production run 2 or earlier)
8.	Insufficient Horizontal Scan	a. Add .1 mf, 200V across R291 cathode resistor of 6BG6 tube. b. Change R286 to 47K. c. Connect a 30 mmf, 6KV cap. 6W4 cathode to ground. If additional scan is needed connect it from 6BG6 plate to ground.
9.	Inability to Phase Picture Correctly	a. Change C253 to .001 mfd and R282 to 100K. b. Bad Horizontal Oscillator tube. C. C251 (100 uuf) open (on plate of Reactance tube).
10.	High Voltage Circuit Arcing or Corona	a. Check lead dress around 1B3 tube socket. b. Check dress of transformer (T210) leads.
11.	Picture Blooming	a. Connect in series with the cathode of the CRT (pin 11) a 100K resistor and .1 mfd, 200V cap. in parallel.
12.	Blocking on strong signals	a. Check setting of AGC set control. b. Remove present leads from plus terminals of C242B, connect together and insulate. Connect a 5K, 7W, ww resistor between plus terms. of C243C and C242B. Remove R236 and R306 from plus 135V and connect to C242B. Add a 20 mfd, 450V cap. from plus 135V to chassis ground.
13.	Corner cutting of Picture	a. Reposition focus coil by loosening 4 self-tapping screws which hold focus coil in bracket. b. Loosen deflection yoke Mtg. bracket and push yoke as forward as possible. c. Adjust ion trap magnet, within range of max. brilliance to eliminate.
14.	Unable to Properly Align Sound Take-Off Transformer (T204)	a. Possible that due to material variation the tuning range has drifted. If so, connect a 5 mmf cap. between terminals 3 & 4 of T204.
15.	Unable to Obtain Proper Focus	a. Check adjustment of focus control and position of focus coil. b. Check resistance of focus coil (should be 470 ohms) c. Connect a 2.2K, 2w resistor in parallel with R297 and R296B.
16.	Centering Lever too short to make adjustment with rear door closed.	a. Cabinet depth greater on models 332 & 334, therefore extension brackets have been made available. (2) brackets (#452345A-2) & (4) Screws (#2214A-020) required per instrument.
17.	Snow in Moderate signal areas.	a. Check value of R252, R250, & R248 must be within 5% tolerance. b. Replace R252 with a 2.2 meg. resistor, if snow still excessive use a 2.0 meg resistor.
18.	Vertical Instability	a. R269 (38K, Temp. Comp.) changes value. b. R256 decreases in value.
19.	Intermittent Horizontal Sync	a. C247 partially shorted.

Voltage Data

The following are voltage readings for the series -3 chassis which differ from those in the CX-33 Manual. Measurements conditions and notes are the same as those shown in the manual.

Tube No.	Tube Type & Function	Tube Socket Terminal Numbers 1	2	3	4	5	6	7	8	9	Remarks
V101 6AG5	RF Amplifier	G. -.3 -10	K. 0	H. 6.3AC	H. 0	P. +145	S.G. +145	K. 0	----	----	See Special
V102 6J6	Mixer Oscillator	Osc. P. +115	Mix.P. +110	H. 0	H. 6.3AC	Mix.G. -3	Osc.G. -8	K. 0	----	----	Note Below

V215 6K6	Vert. M.V. & Output	N.C. - -	H. 0	P. +310	G2 +310	G1 -65 -90	N.C. - -	H. 6.3AC	K. -60 -70	----	Note 1 Note 3

SPECIAL NOTE: Voltages on pins 1,5 & 6 of V101 can be measured at the terminals on the stator contact strip at the right of the tuner chassis. These terminals are numbered in sequence from the front of the chassis. Pin 1 may be measured at terminal 7, pin 5 at terminal 5, and pin 6 at terminal 6.

Correction to CX-33 Manual

The voltage readings shown in the CX-33 Manual for tubes V213, V214, and V215 do not apply to the series -2 production run. The correct voltages for these tubes in the series -2 run are the same as shown above for the series -3 production run chassis.

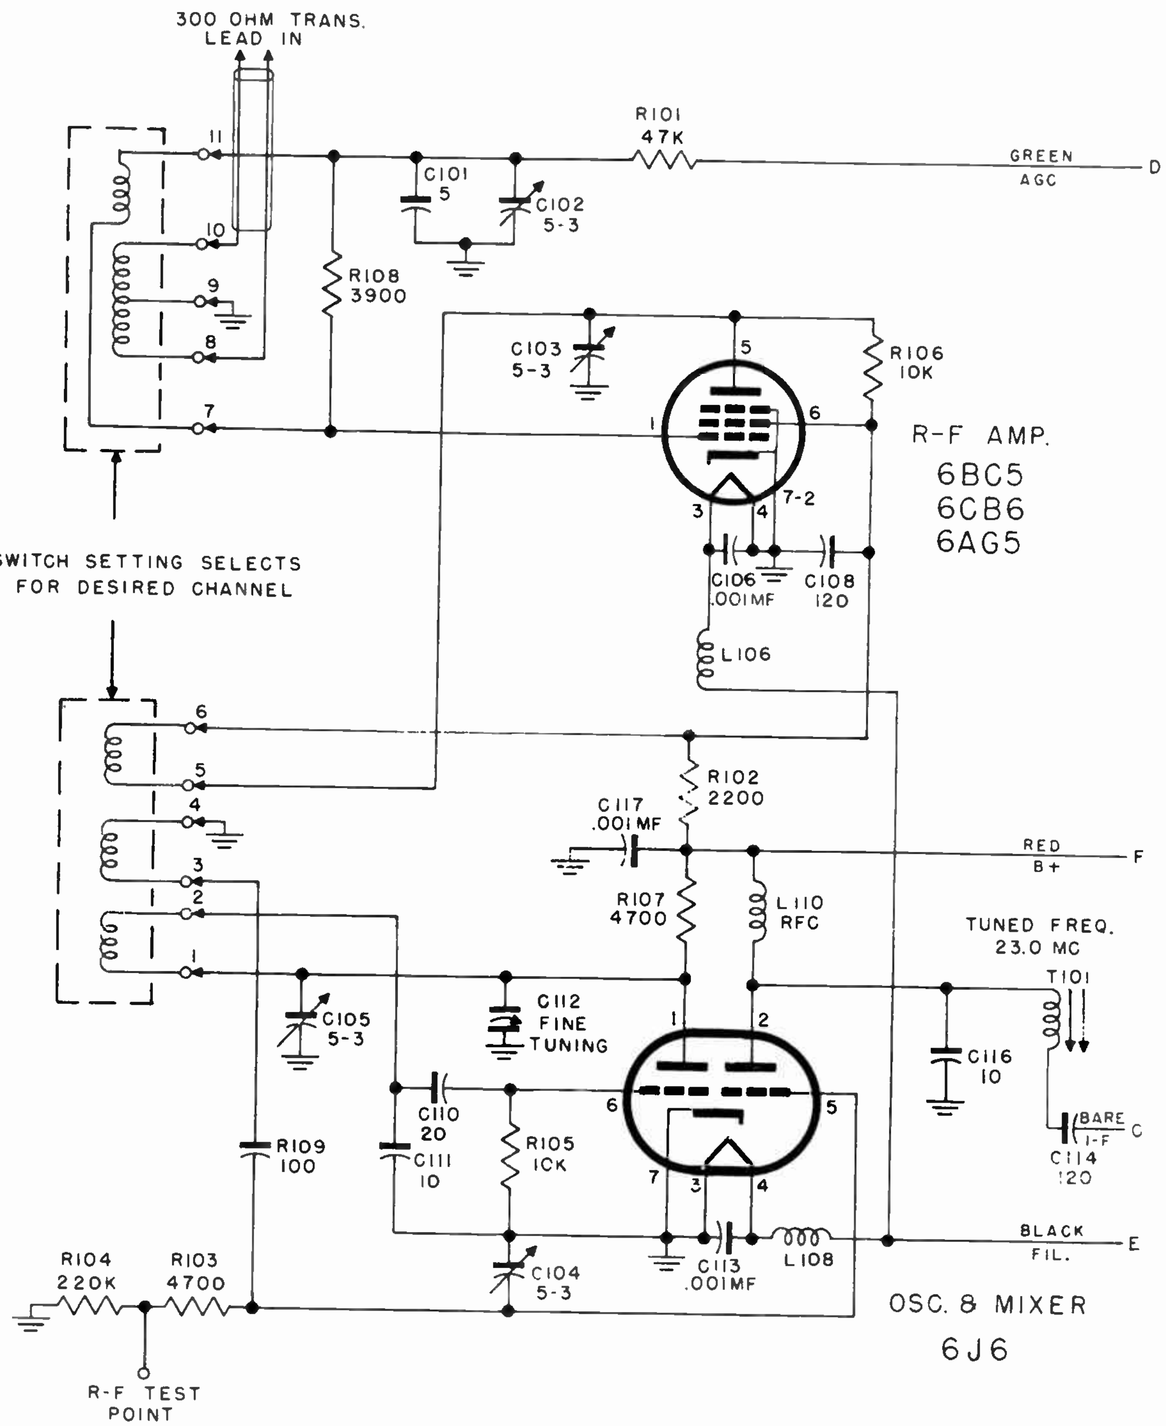
Preliminary
Service Information

STANDARD COIL TV TUNER SCHEMATIC



General Information

Service information on the phono pre-amp chassis C-243 can be found in the Capehart P7,9, &10 Maintenance Manual (Serv. 128). Information on the Phono pre-amp chassis C-295 is included herein.

Receivers Used In:

Model	Radio Chassis	Record Changer	TV Chassis
328-M	C-282 (with pre-amp C-243 or C-295)	333A-VR	CX-33M
337-M	C-282 (with pre-amp C-295)	333A-VR	CX-33K

CHASSIS DESCRIPTION

The C-282 is an 11 tube radio chassis designed for reception of both AM (Broadcast Band) and FM (Frequency Modulation) signals. The chassis contains push-pull audio output amplifiers which are used for reproduction of the television sound as well as radio and phonograph. This chassis is used in conjunction with a phono pre-amplifier chassis in the models 328-M and 337-M. This is necessary since the record changer used in these models employs a variable Reluctance type pickup. The on-off switch on the radio chassis controls the power source for all functions of the receiver. Volume and Tone Controls on the radio chassis also function for television and phonograph operation.

NOTE: With the Operation Selector (Band Switch) in the phonograph position, the record changer will automatically shut off the power source to the entire instrument when it has played the last record. When the Operation Selector is then switched to either TV or radio, the power source will again automatically be turned on.

Specifications

Radio Tuning Range:
AM Band 540 KC to 1620 KC
FM Band 88 MC to 108 MC

Radio IF Frequencies:
AM IF 455 KC
FM IF 10.7 MC

Pre-Amplifier Chassis Tube Complement

Type	Description
6SC7	1st & 2nd Pre-Amplifiers

Speaker (Used for all types of operation) . . . . 12 inch PM
Audio Output . . . . 12 watts
Power Source . . . . 105 to 125 volts, 60 cycle AC only

Alignment Instructions

Equipment Required

AM (Broadcast Band) IF & RF Alignment
1. Calibrated RF Signal Generator (range, 455KC to 1620KC).
2. Low Range Output Meter

FM (Frequency Modulation) IF & RF Alignment
1. FM Sweep Generator (range 10.7MC to 108.5MC)
2. Oscilloscope
3. RF Signal Generator
4. Vacuum Tube Voltmeter

AM Alignment (IF & RF)

a. Set Operation Selector to AM position.
b. See that the dial pointer coincides with the calibration marks at the extremes of the dial scale.
c. Connect the Output Meter across the speaker voice coil.
d. Turn set on and adjust Volume to maximum.

Step	Connect Generator	Set Generator At	Set Gang At	Adjust	To Obtain
1.	Grid of AM Conv., 6BE6 (pin 7 of V103) Through .1 mfd.	455KC	Fully Open	T102, T104 & T106 (IF Slugs)	MAXIMUM OUTPUT
2.	Ant. Section of Gang (through .1 mfd.)	1620KC	1620KC	C156, AM Osc. Trim. & C154, AM RF Trim.	
3.	-Same-	1500KC	1500KC	C152, AM Ant. Trim.	
4.	-Same-	600KC	600KC	L103, Loop Loading Coil & L111* AM Osc. Coil	
5.	"Ant" Terminal (on rear of chassis) with Loop connected.	455KC	Quiet Point	L102, Wave Trap (on Loop Ant.)	Minimum Output

* Adjust while rocking gang condenser.

FM Alignment

a. Connect the oscilloscope and FM or RF generator as shown in the chart.
b. Set the Operation Selector in the FM position.
c. Turn the Receiver on.
d. During alignment, reduce the generator output to keep the signal just above noise level to avoid overloading.

IF Section

Step	Connect FM Generator	Set Generator At	Set Gang At	Connect Oscilloscope	Adjust	Remarks
1.	Grid of 2nd IF 6BA6 (pin 1 V105) thru 1000 uuf.	10.7MC ± 100KC dev.	Fully Open	Across R132 (Disconnect C141)	T105 Ratio Det. Pri. & Sec.	Detune Sec. (top) and connect 350uuf. across Sec. adjust Pro. (botton) for max. Amplitude. Remove 350uuf. and adjust sec. for Max. Amplitude Refer to Fig.1 below
2.	Grid of 1st IF 6BA6 (pin 1, V104) thru 1000 uuf.	10.7MC ±100KC dev.	Fully Open	-Same-	T103 2nd IF Pri. & Sec.	Adjust for Maximum Amplitude
3.	Grid of FM Mixer 12AT7 (pin 2, V102) thru 1000 uuf.	10.7MC ±100KC dev.	Fully Open	-Same-	T101 1st IF Pri. & Sec.	-Same-
4.	-Same-	10.7MC ±100KC dev.	Fully Open	Junction of R148, R129 & C138 (Re-connect C121)	T105 Ratio Det. Secondary	Adjust for symmetrical Ratio Det. "S" curve. Refer to fig.2 below

RF Section

Step	Connect Signal Generator	Set Generator At	Set Gang At	Connect VTVM	Adjust	Remarks
1.	High side of FM dipole thru 330 ohms	108.5MC	108.5 MC	Across R132	C155, FM Osc. Trim.	Adjust for Maximum
2.	-Same-	105MC	105MC	-Same-	C153, Fm Mixer Trim. & C151, FM Ant. Trim.	Adjust for Maximum

Chassis Description

The C-284 is an 11 tube radio chassis designed for reception of AM (Broadcast Band) signals only. The chassis contains push-pull audio output amplifiers which are used for reproduction of the television sound as well as radio and phonograph. The on-off switch on the radio chassis controls the power source for all functions of the receiver. Volume and Tone controls on the radio chassis function also for television and phonograph operation. NOTE: With the Operation Selector (Band Switch) in the phonograph position the record changer will automatically shut off the power source to the entire instrument when it has played the last record. When the Operation Selector is then switched to either TV or Radio the power source will again automatically be turned on.

Radio--Rotatble AM Loop mounted in cabinet. Terminals on rear of radio chassis for connection of outdoor antenna.
Television--Built-in antenna with "Phasing" switch. Terminals on rear of TV chassis for outdoor antenna.

Alignment Instructions

Equipment required:

1. Calibrated RF Signal Generator (Signals from 455KC to 1620KC).
2. Low Range Output Meter.

Alignment:

a. Set Operation Selector to AM position.
b. Turn set on and adjust Volume control to maximum.
c. See that the dial pointer coincides with the calibration marks at the extremes of the dial scale.
d. Connect the Output Meter across the Speaker voice coil.

Step	Connect Generator	Set Generator At	Set Gang At	Adjust	To Obtain
1.	Grid of Mixer, 6SA7 (pin 5 of V102) through .1 mfd.	455KC	Fully Open	IF Slugs T102, T103 & T104	MAXIMUM OUTPUT
2.	RF Section of Gang through 1. mfd.	1620KC	1620KC	C102C Osc. Trim. (on gang)	MAXIMUM OUTPUT
3.		1500KC	1500KC	C102A, Ant. Trim. C102B, RF Trim. (on gang)	MAXIMUM OUTPUT
4.		600KC	600KC	L103, Loop Loading Coil and L104* Osc. Coil	MAXIMUM OUTPUT
5.	Terminal "A" Ant. Term. Strip (with Loop connected)	455KC	Quiet Point	L102, Wave Trap on Loop	MINIMUM OUTPUT

* Adjust while rocking Gang Condenser.

WARNING

In this AC-DC television set, B- of the set is connected directly to one of the AC power lines. If test equipment is connected to chassis, the equipment may be at line voltage potential above ground (depending on how the line plug is inserted). Therefore, contact between equipment and ground may result in severe shock.

Use an isolation transformer between the television AC cord and the power receptacle.

If an isolation transformer is not available, make the following check before any test equipment is connected: Put an AC voltmeter between ground of the set and a good ground connection (radiator, water pipe, etc.). Plug the line cord into the power line. If meter does not read zero, reverse the plug in the receptacle.

Alignment Procedure

Test Equipment

The test equipment required for the alignment of this receiver is as follows:

Marker Generator
R.F. Sweep Generator
Oscilloscope
Electronic Voltmeter
3 Volt bias battery

The Marker Generator is used for peaking the i-f coils and to supply marker pips on the response pattern. The frequency range required of this generator is approximately from 20 to 30 mc. It must also have provision for a 4.5 mc. output. The accuracy of the frequency calibration is very important.

The Sweep Generator must have a continually variable frequency output. Only one output sweep signal is needed, that sweeping signal is needed, that sweeping between 20 to 30 mc.

The Oscilloscope should be a high gain, general purpose type employed for test purposes.

The Electronic Voltmeter is of the standard type.

Video I.F. Alignment

1. Connect the 3-Volt bias battery, minus to A.V.C. and plus, to chassis.
2. Connect the marker generator, through a 47 mmf. capacitor to the nipple located on the tuner, between V1 and V2. Ground the generator at the nearest convenient ground. The marker generator is used in making most of the alignment adjustments.
3. Connect the electronic voltmeter across R99, diode load resistor. Adjust the contrast control about 1/8 turn below its maximum setting.
4. Set the marker generator to each of the following frequencies and peak the specified adjustments for maximum indication on the voltmeter. During the alignment reduce the input signal to prevent overloading.

24.7 L15 (top)
23.2 L14, L12 (top)
26.3 L13, L11 (top)

5. Repeat the above process for fine adjustments of settings.
6. Disconnect the 3 volt bias battery.
7. Disconnect all equipment.

Overall Picture Response

1. With the sweep generator adjusted for a 10 mc sweep, using a center frequency of 26.75 mc, connect the generator to the nipple of the tuner between V1 and V2. Loosely couple the marker generator to the same tube.
2. Connect the oscilloscope across R99.
3. Inject individual markers of 26.3 mc, 24.7 mc, and 23.2 mc in order indicated and note positions of marker pips on response curve. Turning the adjustments very slowly, retune the video i.f. coils again for an overall picture response as indicated in fig. 1. The most important considerations are that the video i.f. carrier of 26.75 is approximately halfway down the slope of the curve and that the sound i.f. carriers 20 times down the other end of the curve.

I.F. RESPONSE CURVE

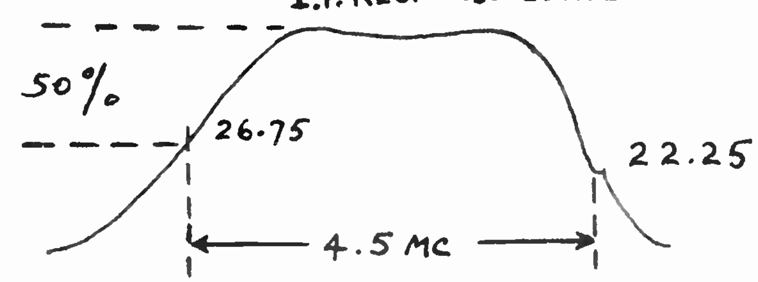

Fig. 1

Audio Take-Off and Ratio Detector Alignment

1. Connect the high side of the signal generator, through a 100 mmf capacitor, to the grid of the first video amplifier tube, V13 and the low side to ground. Tune the generator to 4.5 mc and adjust the output to approximately 10,000 microvolts.
2. From either side of capacitor C48, connect an electronic voltmeter to chassis decoupled through 10,000 ohms.
3. Set the contrast control for maximum gain (clockwise).
4. Peak T1, top and bottom slug for maximum indication on meter.
5. Peak T2, bottom for maximum reading on meter.
6. Disconnect meter and reconnect it to junction of R109 and the lead to the volume control.
7. Adjust T2, top, for zero response on the lowest scale on the meter. This corresponds to the cross over point on the FM detector curve. The symmetry of the curve may be checked by tuning the generator ±25kc from 4.5 mc and noting the voltage produced, reversing the meter connections as necessary. The voltage in each direction should be equal for proper balance of the ratio detector system.
8. If an accurately calibrated generator for 4.5 mc is not available, it is desirable to align the audio section from an actual station signal, since the 4.5 mc. alignment frequency will then be exact.

Note

Alignment of the r-f and oscillator sections are not recommended and are, therefore, not included. If any misalignment is suspected, consult the manufacturer.

CROSLEY TELEVISION SERVICE INFORMATION

MODELS 10-404MU, 10-404M1U, 10-412MU, 10-418MU

This television receiver is designed to operate from a power source of 117 volts, 60 cycle, a.c. The average power consumption is 185 watts. The audio output system is capable of delivering 1.75 watts maximum. The tube complement is as follows:

SYMBOL	TUBE TYPE	FUNCTION
V1	6AB4	R-F Amplifier
V2	6AK5	Mixer
V3	6AB4	V.H.F. Oscillator
V101	6AU6	1st I-F Amplifier
V102	6AU6	2nd I-F Amplifier
V103	6AU6	3rd I-F Amplifier
V104	6AG5	4th I-F Amplifier
V105	6AL5	2nd Detector & AGC Delay

World Radio History

This television receiver is designed to operate from a power source of 117 volts, 60 cycle, a.c. The average power consumption is 185 watts. The audio output system is capable of delivering 1.5 watts maximum. The tube complement is as follows:

SYMBOL	TUBE TYPE	FUNCTION
V1	6AB4	R-F Amplifier
V2	6CB6	Mixer
V3	6AB4	V.H.F. Oscillator
V101	6AU6	1st I-F Amplifier
V102	6AU6	2nd I-F Amplifier
V103	6AU6	3rd I-F Amplifier
V104	6AG5	4th I-F Amplifier
V105	6AL5	2nd Detector & AGC Delay
V106	6AH6	Video Amplifier
V107	12AU7	DC Restorer, 1st sync Separator
V108	16TP4	Picture Tube
V109	6AU6	Sound Det. Driver
V110	6T8	Sound Det. & 1st Audio Ampl.
V111	6V6GT	Audio Output
V112	6SL7GT	Sync Clipper & Sync Output
V113	6C4	Vertical Oscillator
V114	6K6GT	Vert. Amplifier
V115	6SN7GT	A.F.C. & Horizontal Osc.
V116	6BQ6GT	Horizontal Output
V117	6BQ6GT	Horizontal Output
V118	6W4GT	Horizontal Damper
V119	1B3GT	H. V. Rectifier
V120	5Y3GT	L. V. Rectifier
V121	5U4G	L. V. Rectifier
V122	6AU6	AGC Amplifier

SUBJECT— IMPROVE VENTILATION FOR 6BQ6 AND 6W4 TUBES - MODEL 10-421MU

To improve the ventilation of these tubes, remove and discard the tube shield cover.

In the temporary service information parts list for this model, change the tube shield part number from 148154 to 148020.

SUBJECT— CAPACITOR (Symbol No. C168) MODEL 10-421MU

The temporary service information shows that symbol C168 is one 500 mmf., 20 k.v. capacitor (part No. W-147375). However, some sets were equipped with two 500 mmf., 10 k.v. capacitors connected in series.

When either or both of these capacitors require replacing, replacement should be made with one capacitor (part No. W-147375).

SUBJECT— INCREASE HORIZONTAL DRIVE - MODEL 10-421MU.

To increase the horizontal drive, some sets are equipped with an 18,000 ohm, 10%, 1/2 watt resistor (Symbol No. R210, Part No. 39374-40) connected in parallel with R197.

In some areas, the horizontal drive may be excessive on these sets. When this condition is experienced, remove R210.

ADJUSTMENTS

1. The DEFLECTION YOKE is positioned as far forward as possible on the neck of the cathode ray tube and rotated so as to make the top of the raster parallel with the top of the CRT.
2. The FOCUS COIL should be adjusted to be approximately perpendicular to the cathode ray tube axis with the front surface of the focus coil housing approximately 15/32" from the rear surface of the deflection and focus mounting bracket.
3. Adjust size of picture to 13 5/8" x 10 1/4" by the HEIGHT CONTROL, HORIZONTAL DRIVE, VERTICAL LINEARITY and WIDTH CONTROL. The HORIZONTAL DRIVE trimmer should be adjusted to a point where the vertical white bar across the center of the raster disappears.
4. Center the picture by adjusting the three focus coil mounting nuts.
5. The ION TRAP is positioned for maximum brightness, with low setting of the Brightness Control, and for no cutoff of the picture at high setting of the Brightness Control.
6. I-F Alignment (See I-F Alignment).
7. HORIZONTAL HOLD ADJUSTMENT (See Horiz. Blocking Osc. Alignment).
8. HORIZONTAL HOLD CONTROL is adjusted with a weak picture to center of pull in range.
9. VERTICAL HOLD CONTROL is adjusted with a weak picture to center of pull in range.
10. Vertical linearity is adjusted by the VERTICAL LINEARITY CONTROL and the HEIGHT CONTROL. Horizontal size is adjusted by the HORIZONTAL LINEARITY and WIDTH adjustments.
11. The FOCUS CONTROL is adjusted for best focus of the vertical and horizontal wedges at center of test pattern. If there is any astigmatism, the focus should be set to favor the vertical wedge. If corner focus is poor, check position of the DEFLECTION YOKE and ION TRAP.

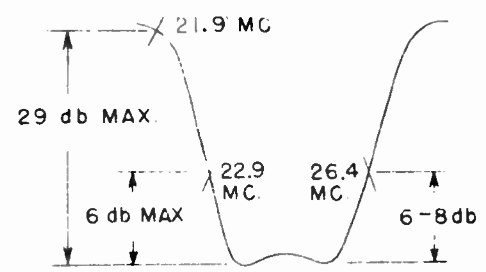
I-F ALIGNMENT

1. Connect a short clip lead from B- (-4 volts) to AGC terminal (white-black lead near V102) of the I-F stages.
2. Connect an electronic voltmeter across R118.
3. Connect "hot" lead of signal generator to grid (pin #1) of V101.

*4. Set signal generator to 25.65 mc. and adjust L107 and L103 for maximum meter deflection.

*5. Reset signal generator to 23.7 mc. and adjust L105 and L102 for maximum meter deflection.

6. Disconnect the electronic voltmeter and signal generator from grid of V101. Connect a scope to the CRT grid. Keep scope leads as far away as possible from the IF stages. Connect a video sweep signal to the adjusting screw (top of chassis on tuner) of C3. Ground lead of sweep signal should be connected to main chassis as close as possible to the hot lead. Remove the oscillator tube V3. Tuner should be approximately 1-1 2 turns counter-clockwise from the high end (Channel #13). Contrast control should be set as low as possible and still obtain reasonable deflection on the scope.



7. Adjust L101 for 26.4 mc. to fall 6 db down from the peak with as flat a curve as possible across the bottom.
8. Disconnect sweep signal and clip lead from B- to AGC terminal.

* NOTE: In steps 4 and 5 limit DC meter deflection to 3.5 volts maximum by adjusting attenuator of signal input.

©John F. Rider

World Radio History

SOUND ALIGNMENT

1. Connect "hot" lead of signal generator to grid (pin #1) of V106. Set signal generator to 4.5 mc. with 400 c.p.s. amplitude modulated 30% or greater.
2. Connect scope to CRT grid through a detector probe.
3. Connect two 100 K ohm resistors (matched within 1%) in series across R139 (pin 2 and 7 of V110A) Connect common lead of electronic voltmeter to junction of the matched 100K ohm resistors and the DC lead to + 150 volt point at junction of C128 (pin #4 of V110).
4. Using a high level signal input and with the contrast control set at maximum, tune the sound takeoff transformer (T101) primary adjustment (bottom of chassis) for minimum deflection on the scope.
5. Reduce signal input to below limiting in V107 and adjust sound take-off transformer (T101) secondary (top of chassis), and ratio detector transformer (T102) primary (top of chassis) for peak meter reading.
6. Repeat steps 4 and 5.
7. Transfer DC lead only of electronic voltmeter to junction of R140 and C131.
8. Return to high level signal input for limiting in V107 and adjust ratio detector transformer (T102) secondary (bottom of chassis) for minimum buzz corresponding with undistorted output.
9. Remove the two 100 K ohm resistors, and all test equipment from the receiver.

AGC ADJUSTMENT

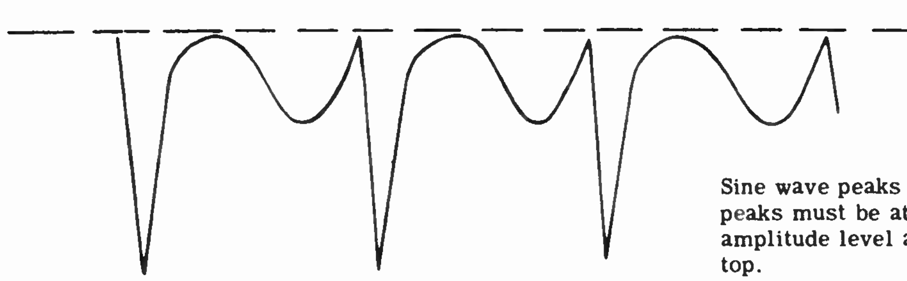
Connect scope (direct) to detector load resistor R118. Tune in a station with a strong signal and adjust the Automatic Gain Control on the rear apron of the chassis for 5 volts + 1/2 volt peak to peak (white to sync tip) detector output.

HORIZONTAL DRIVE ADJUSTMENT

Before alignment of the horizontal blocking oscillator and AFC. circuit. Tune in a station with a strong signal and adjust the HORIZONTAL DRIVE trimmer just below the point where a white line and crowding appears in the center of the picture. Vary CONTRAST CONTROL during this alignment from minimum to maximum.

HORIZONTAL BLOCKING OSCILLATOR ALIGNMENT

1. Tune the receiver to a television signal and adjust the Contrast Control below limiting in the video amplifier (V106).
2. Connect scope thru a 10 mmf. capacitor to terminal #5 of the Horizontal Blocking Oscillator Transformer (T106) and adjust the horizontal BTO Trap (bottom of T106) for the wave form shown at bottom of page. The raster must be kept in sync by means of the Horizontal Hold Control, Horiz. Frequency Control and/ or Horizontal Lock.
3. Remove scope from the receiver and adjust HORIZONTAL LOCK trimmer for minimum capacity.
4. Set the HORIZONTAL HOLD CONTROL fully clockwise and turn the HORIZONTAL FREQUENCY adjustment (top of T106) out until the picture falls out of sync. (This is indicated by a wide black vertical or diagonal bar sloping to the right from top to bottom). Then turn the HORIZONTAL FREQUENCY adjustment slowly in until picture just falls into sync.
5. The final setting of the HORIZONTAL HOLD CONTROL should be made with the CONTRAST CONTROL turned so as to obtain a very weak picture. Rotate the dial on and off the station, and set the HORIZONTAL HOLD CONTROL so that the picture returns completely in sync.



Sine wave peaks and pulse peaks must be at the same amplitude level across the top.

Symbol No.	Part No.	Description
R170	B-144260	Control, Vertical Linearity
R171	39374-117	Resistor, 2200 ohm, 10%, 1w.
R172	Part of L117A	Resistor, 1000 ohm, 10%, ½w.
R173	Part of L117A	Resistor, 1000 ohm, 10%, ½w.
R174	W-148554	Resistor, 400 ohm.
R175	39374-209	Resistor, 4700 ohm, 10%, 2w.
R176	B-147079	Control, Focus
R177	39374-47	Resistor, 68,000 ohm, 10%, ½w.
R178	B-146797	Control, Horizontal Hold
R179	39374-139	Resistor, 150,000 ohm, 10%, 1w.
R180	39374-71	Resistor, 2.7 megohm, 10%, ½w.
R181	39374-60	Resistor, 820,000 ohm, 10%, ½w.
R182	39374-36	Resistor, 8200 ohm, 10%, ½w.
R183	39374-51	Resistor, 150,000 ohm, 10%, ½w.
R184	39374-51	Resistor, 150,000 ohm, 10%, ½w.
R185	39375-97	Resistor, 100,000 ohm, 5%, ½w.
R186	39374-37	Resistor, 10,000 ohm, 10%, ½w.
R187	39374-41	Resistor, 22,000 ohm, 10%, ½w.
R188	39374-137	Resistor, 100,000 ohm, 10%, 1w.
R189	39374-13	Resistor, 100 ohm, 10%, ½w.
R190	39374-57	Resistor, 470,000 ohm, 10%, ½w.
R191	39374-97	Resistor, 47 ohm, 10%, 1w.
R192	39374-223	Resistor, 68,000 ohm, 10%, 2w.
R193	39374-13	Resistor, 100 ohm, 10%, ½w.
R194	39374-13	Resistor, 100 ohm, 10%, ½w.
R195	39374-13	Resistor, 100 ohm, 10%, ½w.
R196	39374-25	Resistor, 1000 ohm, 10%, ½w.
R197	39374-40	Resistor, 18,000 ohm, 10%, ½w.
R198	39374-48	Resistor, 82,000 ohm, 10%, ½w.
R199	39303-19	Resistor, 8.2 ohm, 10%, ½w.
R200	39374-149	Resistor, 1 megohm, 10%, 1w.
R201	39374-93	Resistor, 22 ohm, 10%, 1w.
R202	39374-60	Resistor, 820,000 ohm, 10%, ½w.
R203	39374-44	Resistor, 39,000 ohm, 10%, ½w.
R204	39374-223	Resistor, 68,000 ohm, 10%, 2w.
R205	39374-215	Resistor, 15,000 ohm, 10%, 2w.
R206	39374-209	Resistor, 4700 ohm, 10%, 2w.
R207	39374-142	Resistor, 270,000 ohm, 10%, 1w.
R208	39374-25	Resistor, 1000 ohm, 10%, ½w.
R209	39375-369	Resistor, 10,000 ohm, 5%, 2w.

World Radio History

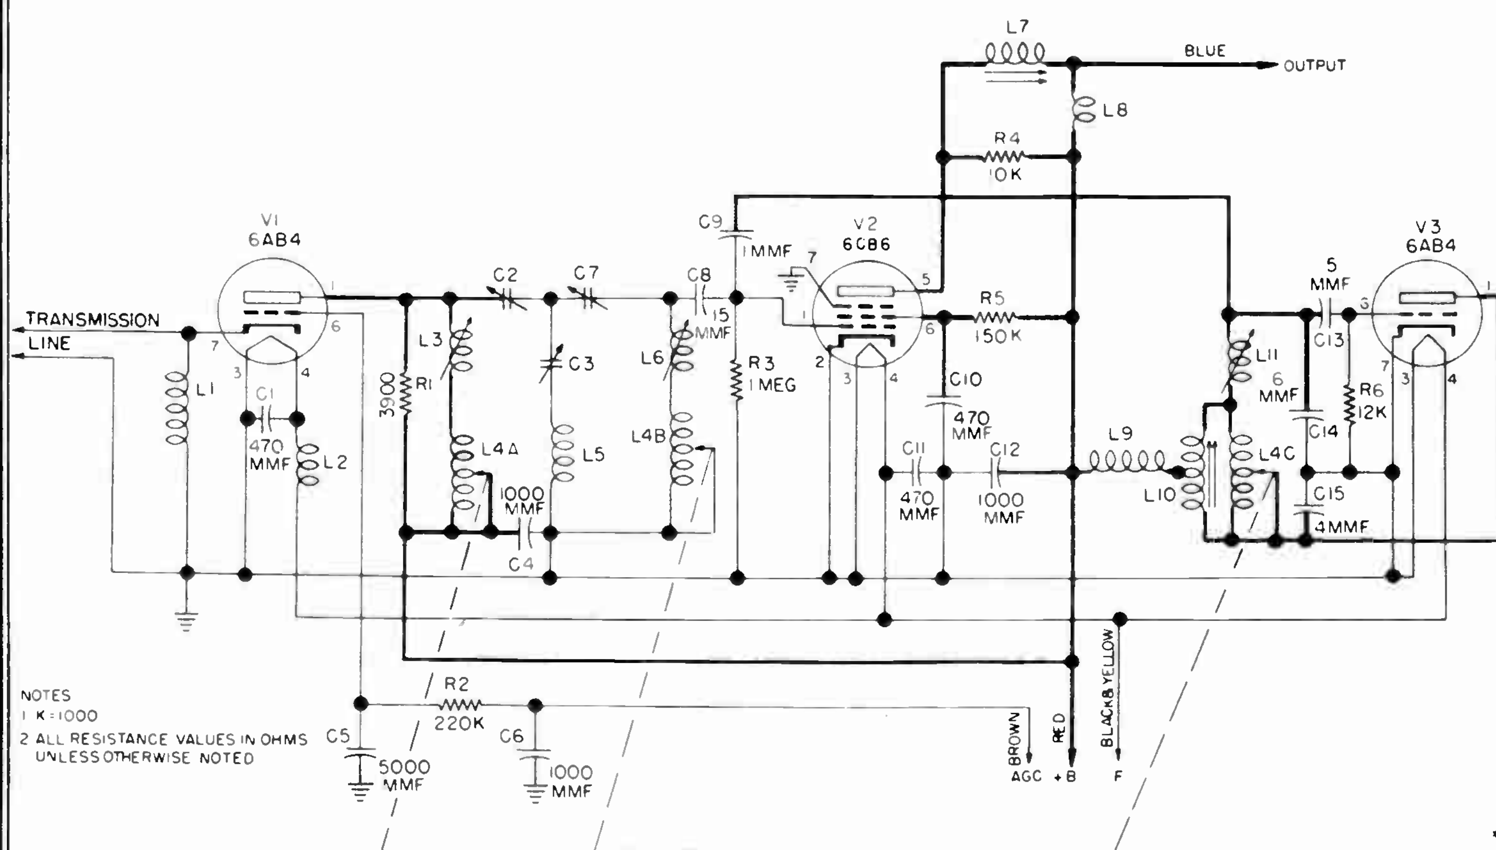
This television receiver is designed to operate from a power source of 117 volts, 60 cycle, a.c. The average power consumption is 195 watts. The audio output system is capable of delivering 1.5 watts maximum. The tube complement is as follows:

SYMBOL	TUBE TYPE	FUNCTION
V1	6AB4	R.F. Amplifier
V2	6CB6	Mixer
V3	6AB4	V.H.F. Oscillator
V101	6AU6	1st I.F. Amplifier
V102	6AU6	2nd I.F. Amplifier
V103	6AU6	3rd I.F. Amplifier
V104	6AG5	4th I.F. Amplifier
V105	6AL5	2nd Detector & AGC Delay
V106	6AU6	Video Amplifier
V107	12AU7	DC Restorer & Sync Separator
V108	14CP4	Picture Tube
V109	6AU6	Sound Det. Driver
V110	6T8	Sound Det. & 1st Audio Ampl.
V111	6V6GT	Audio Output
V112	6SL7GT	Sync Clipper & Sync Output
V113	6C4	Vertical Oscillator
V114	6SN7GT	AFC & Horizontal Oscillator
V115	6BG6GT	Horizontal Output
V116	6W4GT	Horizontal Damper
V117	1X2	H.V. Rectifier
V118	5U4G	L.V. Rectifier
V119	5U4G	L.V. Rectifier
V120	6V6GT	Vertical Amplifier
V121	6AU6	AGC Amplifier



NOTES
1 K=1000
2 ALL RESISTANCE VALUES IN OHMS UNLESS OTHERWISE NOTED

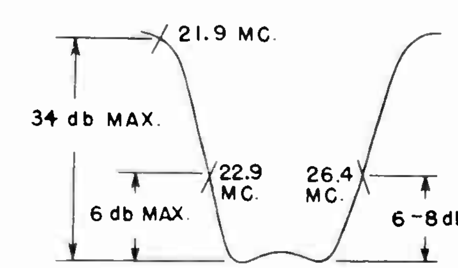
R. F. TUNER SCHEMATIC DIAGRAM

ADJUSTMENTS

1. The DEFLECTION YOKE is positioned as far forward as possible on the neck of the cathode ray tube and rotated so as to make the top of the raster parallel with the top of the CRT.
2. The FOCUS COIL should be adjusted to be approximately perpendicular to the cathode ray tube axis with the front surface of the focus coil housing approximately 15/32" from the rear surface of the deflection and focus mounting bracket.
3. Adjust size of picture to 11 19/32" x 8 23/32" by the HEIGHT CONTROL, HORIZONTAL DRIVE, VERTICAL LINEARITY and WIDTH CONTROL. The HORIZONTAL DRIVE trimmer should be adjusted to a point where the vertical white bar across the center of the raster disappears.
4. Center the picture by adjusting the three focus coil mounting nuts.
5. The ION TRAP is positioned for maximum brightness, with low setting of the Brightness Control, and for no cutoff of the picture (neck shadows) at high setting of the Brightness Control.
6. I-F Alignment (see I-F Alignment).
7. HORIZONTAL HOLD ADJUSTMENT (See Horiz. Blocking Osc. Alignment).
8. HORIZONTAL HOLD CONTROL is adjusted with a weak picture to center of pull in range.
9. VERTICAL HOLD CONTROL is adjusted with a weak picture to center of pull in range.
10. Vertical linearity is adjusted by the VERTICAL LINEARITY CONTROL and the HEIGHT CONTROL. Horizontal size is adjusted by the HORIZONTAL LINEARITY and WIDTH adjustments. Picture size as noted in 3 must be maintained.
11. The FOCUS CONTROL is adjusted for best focus of the vertical and horizontal wedges at center of test pattern. If there is any astigmatism, the focus should be set to favor the vertical wedge. If corner focus poor, check position of the DEFLECTION YOKE and ION TRAP.

I-F ALIGNMENT

1. Connect a short clip lead from B- (-4 volts) to AGC terminal (white-black lead near V102) of the I-F stages
2. Connect an electronic voltmeter across R118.
3. Connect "hot" lead of signal generator to grid (pin 1) of V101.
4. Set signal generator to 25.65 MC and adjust L107 and L103 for maximum meter deflection.
5. Reset signal generator to 23.7 MC and adjust L105 and L102 for maximum meter deflection.
6. Disconnect the electronic voltmeter and signal generator from grid of V101. Connect a video sweep signal to the adjusting screw (top of chassis on tuner) of C3. Ground lead of sweep signal should be connected to main chassis as closely as possible to the hot lead. Remove the oscillator tube V3. Tuner should be approximately 1 1/2 turns counterclockwise from the high end (channel No. 13). Contrast control should be set as low as possible and still obtain reasonable deflection on the scope.



7. Adjust L101 for 26.4 MC to fall 6 db down from the peak with as flat a curve as possible across the bottom.
8. Disconnect sweep signal and clip lead from B- to AGC terminal.

* Note: In steps 4 and 5 limit DC meter deflection to 3.5 volts maximum by adjusting attenuator of signal input.

©John F. Rider

World Radio History

SOUND ALIGNMENT

1. Connect "hot" lead of signal generator to grid (pin 1) of V106. Set signal generator to 4.5 MC. with 400 c.p.s. amplitude modulated 30% or greater.
2. Connect scope to CRT grid through a detector probe.
3. Connect two 100 K ohm resistors (matched within 1%) in series across R139 (pins 2 and 7 of V110A). Connect common lead of electronic voltmeter to junction of the matched 100K ohm resistors and the DC lead to +150 volt point at junction of C128 (pin 4 of V110).
4. Using a high level signal input and with the contrast control set at maximum, tune the sound takeoff transformer (T101) primary adjustment (bottom of chassis) for minimum deflection on the scope.
5. Reduce signal input to below limiting in V107 and adjust sound take-off transformer (T101) secondary (top of chassis), and ratio detector transformer (T102) primary (top of chassis) for peak meter reading.
6. Repeat steps 4 and 5.
7. Transfer DC lead only of electronic voltmeter to junction of resistor R140 and capacitor C131.
8. Return to high level signal input for limiting in V107 and adjust ratio detector transformer (T102) secondary (bottom of chassis) for minimum buzz corresponding with undistorted output.
9. Remove the two 100 K ohm resistors, and all test equipment from the receiver.

AGC ADJUSTMENT

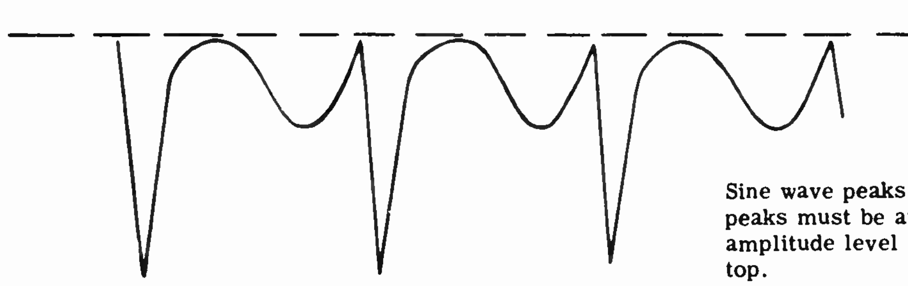
Connect scope (direct) to detector load resistor R118. Tune in a station with a strong signal and adjust the Automatic Gain Control on the rear apron of the chassis for 5 volts ± 1/2 volt peak to peak (white to sync tip) detector output.

HORIZONTAL DRIVE ADJUSTMENT

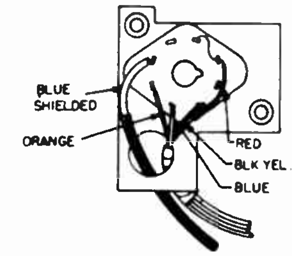
Before alignment of the horizontal blocking oscillator and AFC. circuit. Tune in a station with a strong signal and adjust the HORIZONTAL DRIVE trimmer just below the point where a white line and crowding appears in the center of the picture. Vary CONTRAST CONTROL during this alignment from minimum to maximum.

HORIZONTAL BLOCKING OSCILLATOR ALIGNMENT

1. Tune the receiver to a television signal and adjust the CONTRAST CONTROL below limiting in the video amplifier (V106).
2. Connect scope through a 10 mmf. capacitor to terminal 5 of the Horizontal Blocking Oscillator Transformer (T106) and adjust the horizontal BTO Trap (bottom of T106) for the wave form shown at bottom of page. The raster must be kept in sync by means of the HORIZONTAL HOLD CONTROL, HORIZ. FREQUENCY CONTROL and/or HORIZONTAL LOCK.
3. Remove scope from the receiver and adjust HORIZONTAL LOCK trimmer for minimum capacity.
4. Set the HORIZONTAL HOLD CONTROL fully clockwise and turn the HORIZONTAL FREQUENCY adjustment (top of T106) out until the picture falls out of sync. (This is indicated by a wide black vertical or diagonal bar sloping to the right from top to bottom). Then turn the HORIZONTAL FREQUENCY adjustment slowly in until picture just falls into sync.
5. The final setting of the HORIZONTAL HOLD CONTROL should be made with the CONTRAST CONTROL turned so as to obtain a very weak picture. Rotate the dial on and off the station, and set the HORIZONTAL HOLD CONTROL so that the picture returns completely in sync.



Sine wave peaks and pulse peaks must be at the same amplitude level across the top.



VIII SOCKET CONNECTIONS TO WIRING JUNCTION SOCKET

REPLACEMENT PARTS LIST
Main Chassis

Symbol No.	Part No.	Description
R168	39374-69	Resistor, 2.2 megohm, 10%, ½ w.
R169	39373-33	Resistor, 1000 ohm, ½ w.
R170	B-144260	Control, Vertical Linearity (5000 ohm)
R171	39374-117	Resistor, 2200 ohm, 10%, 1 w.
R172	Part of L117A	Resistor, 1000 ohm, 10%, ½ w.
R173	Part of L117A	Resistor, 1000 ohm, 10%, ½ w.
R174	39374-197	Resistor, 470 ohm, 10%, 2 w.
R175	39374-197	Resistor, 470 ohm, 10%, 2 w.
R176	B-147079	Control, Focus (1500 ohm)
R177	39374-47	Resistor, 68,000 ohm, 10%, ½ w.
R178	B-146797	Control, Horizontal Hold (50,000 ohm)
R179	39374-139	Resistor, 150,000 ohm, 10%, 1 w.
R180	39374-71	Resistor, 2.7 megohm, 10%, ½ w.
R181	39374-60	Resistor, 820,000 ohm, 10%, ½ w.
R182	39374-36	Resistor, 8200 ohm, 10%, ½ w.
R183	39374-51	Resistor, 150,000 ohm, 10%, ½ w.
R184	39374-51	Resistor, 150,000 ohm, 10%, ½ w.
R185	39375-97	Resistor, 100,000 ohm, 5%, ½ w.
R186	39374-37	Resistor, 10,000 ohm, 10%, ½ w.
R187	39374-41	Resistor, 22,000 ohm, 10%, ½ w.
R188	39374-137	Resistor, 100,000 ohm, 10%, 1 w.
R189	39374-9	Resistor, 47 ohm, 10%, ½ w.
R190	39374-61	Resistor, 1 megohm, 10%, ½ w.
R191	39374-100	Resistor, 82 ohm, 10%, 1 w.
R192	39374-118	Resistor, 2700 ohm, 10%, 1 w.
R193	39374-40	Resistor, 18,000 ohm, 10%, ½ w.
R194	39374-48	Resistor, 82,000 ohm, 10%, ½ w.
R195	39303-17	Resistor, 5.6 ohm, 10%, ½ w.
R196	39374-149	Resistor, 1 megohm, 10%, 1 w.
R197	39374-60	Resistor, 820,000 ohm, 10%, ½ w.
R198	39374-44	Resistor, 39,000 ohm, 10%, ½ w.
R199	39374-213	Resistor, 10,000 ohm, 10%, 2 w.
R200	39374-25	Resistor, 1000 ohm, 10%, ½ w.
R201	39374-52	Resistor, 180,000 ohm, 10%, ½ w.
R202	39374-25	Resistor, 1000 ohm, ½ w.
R203	39374-93	Resistor, 22 ohm, 10%, 1 w.

1. DESCRIPTION

Crosley Models 11-441MU, 11-461WU and 11-471BU are console model television receivers housed in attractive mahogany, walnut and limed oak cabinets. They are equipped with twelve and one-half inch picture tubes and are designed for operation on 117 volt, 60 cycle alternating current.

The chassis incorporates twenty tubes including the picture tube and two rectifiers.

These receivers will produce high definition pictures with fine detail and excellent brilliance and contrast on all twelve television channels. However, in no one area are there stations operating on all channels.

Features include:

1. Simplified tuning (tunes like a radio) with a continuous type tuner that permits precise tuning to the station's channel without the use of an extra vernier control that is necessary when a switch type or push-button tuner is used.

2. Intercarrier sound system in conjunction with the continuous tuner has the following advantages: (a) Permits tuning for best quality, high definition pictures. When the picture is clear the sound is also right. (b) In weak signal areas, permits tuning for maximum picture, thus assuring the best signal-to-noise ratio. (c) Eliminates re-tuning; once the station has been "tuned-in" properly, no re-adjustment of the tuning control is necessary. (d) Minimizes number of operating controls.

3. Auxilliary controls concealed behind a trap door on the front of the cabinet within easy reach.

4. Automatic Frequency control with "Stabilock" circuits holds pictures firm and steady even through electrical disturbances.

5. "Keyed" Automatic Gain Control Fade Eliminator removes interference from flying aircraft and other brightness fluctuations; it also eliminates re-adjustment of the brightness and contrast controls when tuning from one station to another and minimizes fading in areas of low signal strength.

6. Specially designed built-in antenna that needs no tuning.

7. Tilted picture tube window, prevents reflected light from interfering with the picture on the tube screen. The window is easily removed from the front of the cabinet so that picture tube screen may be cleaned.

8. Wide angle viewing and "Procenium Arch" styling of the picture tube window.

9. New "Black Face" picture tube provides better contrast and less glare.

10. FM sound system in conjunction with the audio amplifier and large permanent magnet speaker provides true, clear sound.

PRECAUTIONS

HIGH VOLTAGE WARNING — Operation of this receiver with the interlock by-passed, or the chassis removed from the cabinet involves a shock hazard from the receiver power supplies. Work on the receiver should not be attempted by anyone not thoroughly familiar with the precautions necessary when working on high voltage equipment. When handling the high voltage lead to the picture tube the receiver power plug should be disconnected from the power receptacle.

HANDLING PICTURE TUBE — Do not remove or handle the picture tube in any manner unless heavy gloves and protective goggles are worn. Persons not so equipped should be kept away while handling picture tube. Keep the tube away from the body while handling. NEVER GRASP THE TUBE BY ITS NECK OR ALLOW PRESSURE TO BE EXERTED ON THE NECK.

CLEANING PICTURE TUBE WINDOW — The window in front of the picture tube is made of a plastic material. It is possible to scratch or damage the surface of the window by using any abrasive material to clean it. USE ONLY A SOFT CLOTH TO REMOVE DUST OR OTHER FOREIGN MATTER. WINDOW MAY BE CLEANED WITH SOAP AND WATER.

2. CIRCUIT DESCRIPTION

2.01 Preliminary:

The "intercarrier" sound system used in this receiver differs from the "conventional" type of television circuit where the video and sound R.F. carriers are converted to their respective intermediate frequencies in the mixer tube. The video and sound I.F. are usually divided into two separate I.F. channels of different frequencies, separated by 4.5 mc. after leaving the plate of the mixer tube or at the plate of the 1st. I.F. amplifier. As it is important to keep the audio component off the picture tube grid, traps must be inserted in the video I.F. and/or video amplifier circuits to absorb the sound frequency.

In the "intercarrier" sound system the R.F. carriers are converted to their respective intermediate frequencies in the same manner as above (in the mixer tube), but the video and sound I.F. frequencies are not separated after leaving the mixer plate; instead they are amplified together in a common I.F. channel and both signals appear at the input to the video detector. As the video and sound carriers are always separated by a fixed difference frequency of 4.5 megacycles that must be maintained by the transmitting station in accordance with FCC regulations, both I.F. signals that appear at the grid of the video detector are separated exactly 4.5 megacycles. The video detector not only functions as a detector, but also as a mixer for the two I.F. signals. In the mixing process of the sound I.F. carrier with the video I.F. carrier, a 4.5 mc. beat signal is produced. This beat signal is frequency modulated in unison with the sound I.F. carrier.

The manner in which the 4.5 mc. beat signal is obtained is comparable to the mixer action in a superheterodyne radio receiver.

In place of a local oscillator, the incoming video I.F. carrier beats against the incoming sound I.F. carrier to produce the sum and difference frequencies at the output of the detector. As the sum frequency falls outside the range of the pass-band of the video amplifier, only the difference frequency need be considered.

After being amplified in the video amplifier, the 4.5 mc. signal is trapped or "sucked out" of the video signal and fed to the sound driver stage by means of the sound take-off transformer. The transformer serves a dual purpose of providing a 4.5 mc. trap to reduce sound interference in the picture and providing a sharp pass band for 4.5 mc. injection to the grid of the sound driver stage. The 4.5 mc. signal is amplified and limited in the sound driver which provides sufficient signal to operate the sound detector. FM demodulation of the sound I.F. signal is accomplished by the two diode sections (V110A) of V110, that function as an unbalanced ratio detector which converts frequency deviations of the I.F. carrier to audio frequencies and suppresses amplitude modulation interference. The I.F. input is applied to the diodes by mutual coupling between the tuned primary and secondary of the ratio detector transformer T102. The applied I.F. carrier rectified by the diodes, charges the electrolytic capacitor C135. The bias voltage developed across R142 holds the conduction level of the diodes at a definite value determined by the applied carrier. Any sudden change, such as may be caused by instantaneous noise impulses, cannot change the bias due to the relatively long time constant (approx. .8 sec.) of R142-C135. The rectified audio frequencies pass through the tertiary winding that is connected to the center tap of the secondary, and the sound volume control to the grid of the 1st. Audio Amplifier tube V110B. The audio amplifier consists of two stages of amplification, a triode 1st. stage coupled to a beam power output stage that drives the speaker.

2.02 R. F. Unit:

The incoming signals picked up by the antenna are applied to the tuned antenna circuit, L2A, L3, C4 and C2. This circuit passes the signal to which the tuner dial is set, and attenuates all other signals, and thus acts to reduce interference. The input circuit is shunted by the choke inductance L1, which provides additional attenuation to AM Broadcast signals and acts as a high-pass, radio-frequency filter, to suppress broadcast band and other low-frequency, cross-modulation interference that may be encountered when the receiver is located in an extremely intense field of a local AM Broadcast Station or other radiators.

The plate of the 6CB6 R.F. Amplifier V1, is coupled to the grid of the 12AT7 mixer section of V2A by means of the coupling capacitor C8.

The R.F. tuning assembly consists of three variable inductors mounted on a common shaft. The first (L2A) and second (L2B) inductors, in conjunction with their associated capacities, tune to any desired frequency between 53 mc. and 217 mc., while the third variable inductor circuit covers a range of approximately 77 mc. to 241 mc., and is used as the tuning circuit for the local oscillator V2B.

The VHF oscillator utilizes the second triode section of 12AT7, V2B, in a modified Colpitts oscillator circuit. The feedback voltage from the plate to the grid of the oscillator tube is obtained by means of the interelectrode capacity of the vacuum tube. The oscillator frequency is tuned by movement of the tap on the coil L2C which shorts a portion of the coil. The oscillator circuit is factory aligned to track with the signal circuits located in the grid and plate of the R.F. amplifier V1.

The oscillator output is coupled to the grid of the mixer tube section (V2A) of 12AT7 by means of capacitor C12 and coupling coil L10.

Both the incoming signal from the antenna and the local oscillator signal are fed into the grid of the mixer tube. The output of V2A has a wide band of frequencies. It includes both the video and sound intermediate frequencies which are fed into the 1st. I.F. primary inductor L6. L7 couples L6 to L101. The secondary of the 1st. I.F. inductor L101 is coupled to the grid of V101 through capacitor C101.

A.G.C. voltage is applied to the grid of the R.F. amplifier tube V1, through R150 and the choke inductance L11. This voltage controls the gain of the tube and tends to keep the contrast constant when tuning to stations of varying signal intensity and to minimize fading in areas of low signal strength. It also tends to prevent blocking on very strong signals.

2.03 I. F. Amplifier:

The I.F. amplifier consists of four stagger tuned stages using three 6AU6 and one 6AG5 or 6BC5 sharp cutoff high gain pentodes V101, V102, V103 and V104. Each I.F. coupling network consists of a variable iron core tuned inductance, which, with their respective tube capacities are resonated to the proper frequency. The 4th and 5th I.F. coils have a close coupled secondary winding over the primary of the coils. Interstage coupling is obtained by capacitors in the first three stages while the fourth stage and the 2nd. detector are coupled directly to the secondaries. Stagger tuning of the I.F. system provides a simple means of securing a sufficiently broad pass-band to accept both the video and sound I.F. carriers of the intercarrier sound system of this receiver. Alignment of the I.F. system is a simple matter as there are only six circuits to be tuned and trap circuits are eliminated. The A.G.C. voltage besides being applied to the R.F. stage is also applied to the 1st. and 2nd. I.F. stages in order to maintain constant output under varying signal intensity. To provide stabilizing degenerative feedback, the cathode resistors R102 and R109 of V101 and V102 are unbypassed.

World Radio History

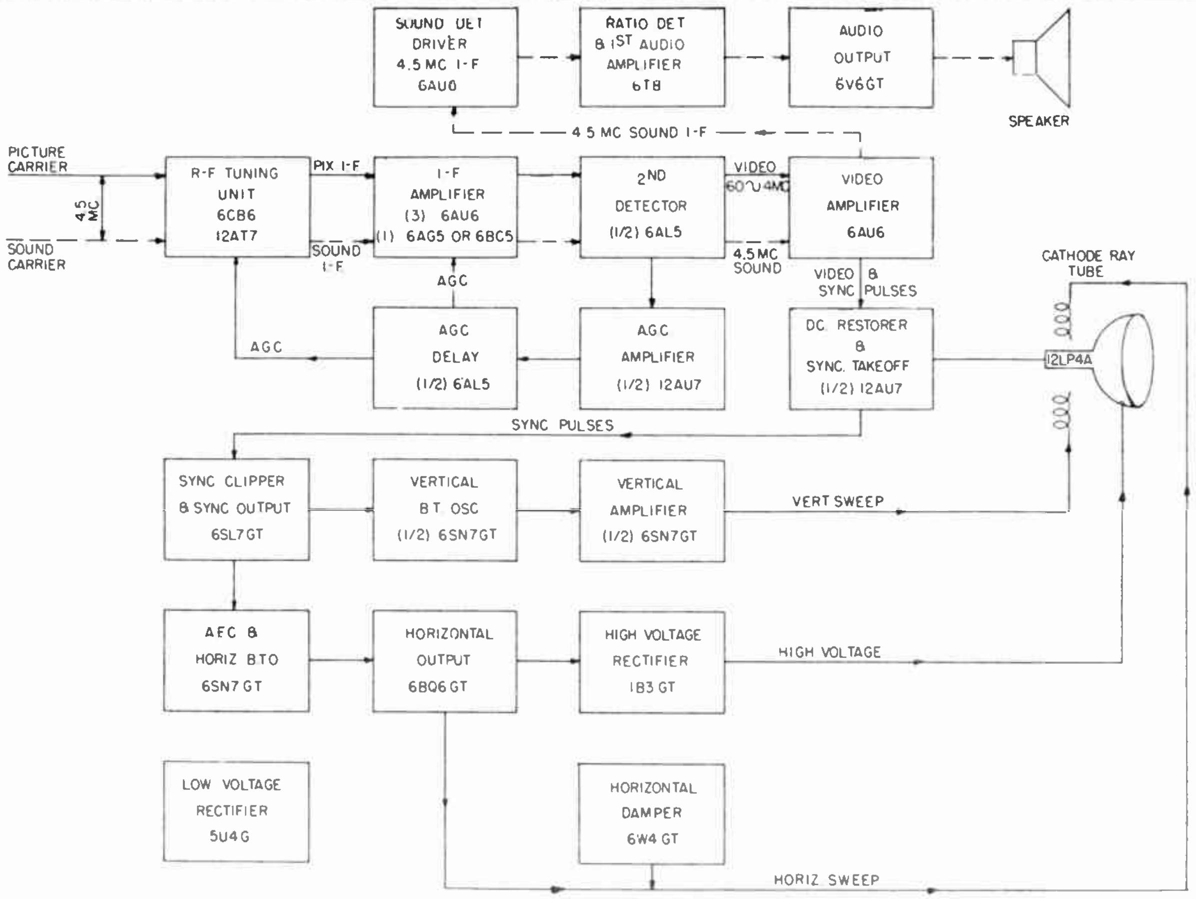

Figure 2. Receiver Block Diagram

2.04 2nd. Detector:

The 2nd. Detector is a diode type detector, the I.F. signal being applied to one plate of the 6AL5 twin diode (V105). The cathode of the 2nd Detector is directly coupled to the grid of the video amplifier (V106) through the series peaking coil L106 shunted by the damping resistor R116, and to the grid of the A.G.C. amplifier V107B through the shunt peaking coil L107 and the isolating resistor R119.

2.05 A. G. C. Circuit:

The purpose of the A.G.C. circuit is to maintain a constant output at the picture tube as the signal input varies due to different field strengths of the television station or flutter of field strength due to aeroplane interference.

The pulsed type A.G.C. circuit that is employed provides considerable immunity from the effects of impulse noise. A d.c. amplifier is used to maintain constant output over a greater range of signal input, and a delay diode is employed to improve signal to noise ratio at medium strength signal inputs.

Operation of the circuit is as follows: The plate voltage of the A.G.C. amplifier tube, V107B, is a positive pulse derived from half of the A.G.C. winding of the horizontal output transformer T107. In order to neutralize the grid to plate capacity of the tube a negative pulse from the other half of the A.G.C. winding is fed to the grid through the neutralizing capacitor C126.

The positive pulse is in time phase with the positive horizontal sync pulse fed to the grid through an isolating resistor R119 from the output of the detector V105A. Therefore, current flows through V107B during the interval when the plate and grid are pulsed and the capacitor C174 is charged. Part of the voltage across C174 leaks off through R151 and R152 during the time between sync pulses. This leakage voltage is governed by the time constant of C174, R151 and R152. The voltage across C174 is the A.G.C. control voltage, which is applied to the R.F. amplifier V1 and the I.F. amplifiers V101 and V102 through a special divider network. The voltage divider network composed of R151, R152, R153 and R202 applies a positive delay voltage to the plate of V105B which makes it conduct and assume ground potential so that until the output of the A.G.C. amplifier is sufficient to overcome the delay bias, no control voltage is developed at the grid of V1. However, the voltage divider R151 and R152 applies less delay to V101 and V102 so that control is applied to the two video I.F. tubes before it is applied to the R.F. amplifier tube V1. This increases signal to noise ratio at medium strength signal inputs. The performance of the system is such that as the detector level tends to rise or fall, the control voltage increases or decreases accordingly to maintain constant output level.

2.06 Video Amplifier: (V106)

A single stage of video amplification is used, the grid of the Video Amplifier tube V106, being directly coupled to the output of the 2nd. Detector. The cathode of V106 is connected through R121 to one end of the contrast control R124B. The other end of the contrast control is connected to the plate of the A.G.C. amplifier V107B with the control arm returning to ground. Connected in this manner the setting of the contrast control determines the bias on both the video amplifier and the A.G.C. amplifier. Increasing the contrast applies less bias voltage to the video amplifier and more bias voltage to the A.G.C. amplifier. Decreasing the contrast reverses the condition. At the plate of the Video Amplifier, both the 60 cycle to 4 megacycle video signal and the 4.5 megacycle sound I.F. signal are present. These signals are fed through the series peaking coil L108 to the primary winding of the Sound Takeoff Transformer T101. This winding traps the 4.5 mc. sound I.F. signal preventing it from reaching the grid of the picture tube, but passes the video signal on to the picture tube grid through the coupling capacitor C123.

2.07 Sound Channel : (V109, V110 & V111)

See last paragraph of "Preliminary Circuit Description" (2.01).

2.08 D. C. Restorer & 1st. Sync Separator: (V107A)

As the video amplifier is A.C. coupled to the CRT grid, the D.C. component of the video signal must be reinserted to maintain the background illumination equivalent to that of the original picture being transmitted.

One section (V107A) of the 12AU7 dual triode functions as a D.C. Restorer and 1st. Sync Separator. The cathode (pin 3) and the grid (pin 2) serves as a diode which performs the D.C. restoration. The output of the video amplifier is applied to the cathode of V107A through R127 and C124.

At the same time the grid and cathode of V107A are functioning as a D.C. Restorer, the entire triode including the plate (pin 1) serves as a sync clipper.

2.09 Picture Tube: (V108)

The picture tube, V108, is a 12½" direct viewing tube. Electromagnetic fields are used for both deflection and focus. The high voltage for the second anode is furnished by the H.V. power supply at approximately 8.5 kilovolts.

The Brightness control R135 varies the cathode bias and thus the tube illumination. The permanent magnet Ion Trap must be properly positioned on the neck of the picture tube for maximum brightness.

2.10 Sync Clipper & Sync Amplifier: (V112)

The vertical and horizontal sync pulses from the plate of V107A are coupled by C144 to the second Sync Clipper stage V112A. This stage and the second half of the 6SL7GT, V112B are voltage amplifiers that amplify and clip the sync pulses sufficiently for proper operation of the deflection circuits. The sync pulses developed at the cathode of the sync output stage remain substantially constant in amplitude over a wide range of input signal levels.

The sync signal is taken from the cathode of V112B to obtain a low impedance output of the correct polarity (positive).

2.11 Integrating Network:

To separate the horizontal from the vertical sync, an integrating network composed of R158, R159, R160, C148, C149 and C150 is used. This RC network acting as a low pass filter will pass the low frequency of the vertical sync, while the higher frequency of the horizontal sync is attenuated.

2.12 Vertical Oscillator & Amplifier: (V113)

The purpose of these circuits is to provide a sawtooth current of the proper amplitude and frequency to move the scanning beam across the picture tube screen slowly (16,000 µs) from top to bottom during the time the image is being placed on the screen and rapidly (250 µs) from the bottom to the top during retrace time. A blocking oscillator and discharge circuit is formed by the first section of the 6SN7GT dual triode V113 and its associated components. The operating frequency is determined by C151, R161 and R162, when no sync pulse is present. The Vertical Hold control R162, adjusts the free running frequency of the blocking oscillator. When the grid wave form goes negative the tube is held at cut-off and C152 is charged at a rate determined by C152, R164, and R165. When the grid wave form goes positive and plate current begins to flow, C152 discharges more rapidly, the rate of discharge being determined primarily by the plate resistance of the conducting tube and C152. This slow charging and rapid discharging of C152 generates a sawtooth voltage.

The peaking action of R166 provides a sharp negative pulse to insure that the second half of V113 will remain cut off during retrace time. By controlling the charging rate of C152 the amplitude of the sawtooth voltage is varied; this is accomplished by adjusting the Height Control R165.

Although the voltage on the plate of the vertical oscillator is of the basic shape to produce a sawtooth current in the vertical deflection coil, it must be amplified in the second section of V113 to obtain sufficient power.

©John F. Rider

World Radio History

The plate of the Vertical Output section V113B is coupled to the Vertical Output Auto-transformer T105 that matches the impedance of the vertical deflection coils to the plate impedance of the vertical output tube.

The Vertical Linearity control R169 varies the cathode bias of the Vertical Output tube, so that the position of the applied sawtooth voltage is shifted along its operating characteristic. The Vertical Linearity and Height controls have a considerable amount of interaction and any change in adjustment of one may need to be accompanied by a change in the other.

2.13 A. F. C. & Horizontal Oscillator: (V114)

Automatic frequency control (A.F.C.) of the horizontal sweep is obtained from the circuit composed of one portion of V114 (pins 4, 5, and 6) and its associated components. Its operation is based on what may be described as "width modulation" of the synchronizing pulse.

Satisfactory operation of this circuit depends upon the proper wave shape being formed to apply to the grid of the A.F.C. section of the tube.

The synchronizing pulse, appearing across the network R157 and C146 in the cathode of V112B, is attenuated by capacitors C147 and C162A and is applied to the grid of the A.F.C. section of the tube through capacitor C155. The wave form shown in Fig. 3(A) is obtained from the grid circuit of the horizontal oscillator section of V114, at the junction of R181 and R182.

(A) Figure 3 (B)

This waveform has the advantage of a steep slope near the peak and a fast fall immediately following the peak, and therefore provides increased gating. It is fed to the grid of the A.F.C. section of V114 through L111 and R204. The inductance L111 (delay coil) serves two purposes: (1) It blocks the sharp negative peak and dampens out the rings of the waveform in Fig. 3(A) resulting in the waveform shown in Fig. 3(B): and (2) It delays the arrival of this waveform to the A.F.C. grid in order to center the action of its phase relationship with the synchronizing pulse, being so phased that a varying portion of the synchronizing pulse will fall atop the positive corner of this waveform while the remaining portion slides down the steep sides. The peak amplitude of the combined wave being essentially constant, the control voltage is a function of the width of the pulse atop the positive corner of this waveform. The combined wave which is coupled to the grid of the A.F.C. portion of the tube is shown below for three different conditions of the phase relationship between the horizontal oscillator and the synchronizing signal: (Fig. 4A) when most of the sync pulse is atop the waveform: (Fig. 4B) when one-half of the sync pulse is atop the waveform; and (Fig. 4C) when most of the sync pulse is down the slope.

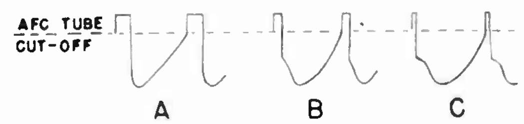

Figure 4

The A.F.C. portion of V114 is biased near cut-off by the D.C. component of the oscillator grid voltage applied through resistors R177 and R178. Its plate current consists essentially of pulses whose width is determined by the relative position of the sync pulse atop the peak of the waveform. The voltage developed across R181 by this average plate current is the control voltage injected from the cathode circuit of V114 into the grid of the oscillator section of V114 through resistor R182, and thus maintains the phase of the oscillator with respect to the synchronizing signal within very close limits.

The cathode circuit is an integrating network with the following properties: (1) a fast response as C157 is relatively small, and (2) a slow response as C156, R180 and R181 are relatively large. The former integrates the pulse of current and also tends to prevent "hunting", while the latter maintains control over a longer period of time, and filters out disturbances of greater duration. The Horizontal Hold Control in the plate circuit not only varies the plate voltage but also functions as a vernier speed control.

Capacitor C162A (Horizontal Lock) is made adjustable, so that the grid voltage of the A.F.C. tube can be varied to suit the characteristics of the individual tube, and thus maintain the control range at a uniform level.

The second triode portion (pins 1, 2 and 3) of V114 functions as a blocking tube oscillator. The Horizontal Oscillator Transformer T106 uses an adjustable powdered iron core, permitting a certain amount of frequency adjustment. The tertiary winding (terminals 5 and 6) of T106 shunted by the capacitor C159 and the damping resistor R184 tends to stabilize the horizontal frequency with relation to the line frequency (15,750 cps). The second section of V114 not only functions as the blocking tube oscillator; but also as the discharge tube. A sawtooth voltage is developed across C160, and is used for horizontal deflection. This sawtooth voltage is then fed to the grid of the output tube V115 through the divider network C161 and C162B. The Horizontal Drive capacitor C162B is made variable to adjust the amplitude of the sawtooth voltage in order to obtain optimum performance from each individual horizontal amplifier tube.

2.14 Horizontal Output, Damper & High Voltage Rectifier: (V115, V116 & V117)

The purpose of the Horizontal Output tube, V115 is to amplify the output of the Horizontal Oscillator so that sufficient current of the proper wave form is available to excite the horizontal deflection coils in order to provide horizontal scanning of the picture tube. During the return trace of the sweep, the current, which was flowing in the horizontal deflection coil, reverses. The induced voltage pulse in the primary winding of the Horizontal Output Transformer T107 appears in the form of a very sharp positive pulse. This pulse is increased by Auto-transformer action in the primary winding and is rectified by the High Voltage Rectifier V117. The rectified energy that is stored in the high voltage capacitor C169 is used to accelerate the electron beam in the picture tube. The Damper tube V116 helps to provide a linear trace by damping out oscillations of the energy stored in the horizontal deflection coil. It critically dampens the ringing in the horizontal deflection yoke which occurs just at the end of the line retrace period. Part of the energy so absorbed is utilized to boost the plate voltage of V115 by feeding the "B" supply in series with the voltage developed across C168 by the Damper Tube V116.

2.15 Low Voltage Power Supply: (V118)

The low voltage power supply of the television receiver is obtained from a 5U4G full wave rectifier with conventional filtering. This power supply furnishes all the plate and screen voltages required by the tubes of the receiver. The filter choke mounted on the speaker frame is in series with the B+ voltage. Therefore, the speaker plug must be connected in the socket on the chassis at all times. The focus coil L113 is in series with the section of the power supply that delivers 350 volts to most of the circuits. The current drain of these circuits provides more than sufficient current for proper focus. The focus current is adjusted to bring the picture tube to precise focus by means of the Focus Control R201 which is in series with the parallel combination of R199 and R200. This series combination is shunted across the Focus Coil.

Since several stages of the receiver require no more than half of the power supply output voltage for normal operation, these stages are connected in a series-parallel combination (See Figure 5). Connected in this manner, dropping resistors are eliminated, resulting in a more efficient use of the power supply output. Considering only the power supply connections, the sound detector driver V109, the ratio detector and first audio amplifier V110, the audio output V111, and the sync clipper and sync output V112 are all connected in parallel.

The R.F. amplifier (V1), VHF oscillator and mixer (V2), the I.F. stages (V101, V102, V103 and V104) and Video amplifier (V106) are connected in parallel with the stabilizer circuit of V111 and get their plate supply from the cathodes of V109, V110, V111, and V112. The vertical amplifier V113B is connected in parallel across the above series string and receives the full voltage of the power supply. Booster voltage from the cathode of the damper tube V116, that is added to the power supply voltage, furnishes the plate voltage for the parallel combination: V113A the vertical oscillator, V114 the A.F.C. and horizontal oscillator, and V115 the horizontal output.

3. ANTENNAS

3.01 Built-In Antenna:

An antenna, that in some localities will eliminate the need of an external TV antenna, is built into the receiver. The built-in antenna lead that is coded with paint is the ground lead and is connected to the screw on the antenna terminal board marked "G". The built-in antenna serves both the low (channel 2 to 6) and the high (channel 7 to 13) television bands.

For the high band, section "A" is the ½ wave folded dipole resonating at 200 mc. Section "B" is the lead-in and section "C" a ½ wave shorted stub resonating at 200 mc. For the low band, A, B, and C resonate at 70 mc.

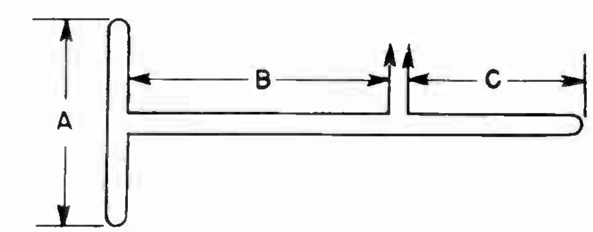

Figure 6. Schematic of Built-in Antenna

The antenna is mounted on a cardboard form fastened in the cabinet. For proper operation of the antenna, do not shorten or lengthen the leads as this will change the resonating frequencies. The results obtained by using the built-in antenna are limited by the distance between the receiver and the transmitter and the location and type of building in which the receiver is used.

Unless the signal transmitted by the television station is of sufficient strength to reach the area where the receiver is located, NO television receiver can reproduce the picture. Due to the high frequencies used for television transmission, the signals reach only to the "line of sight". This is determined by the height of the transmitting and receiving antennas. In addition, steel frame work buildings, mountains, hills etc. reflect the television signals so that even though the television station is only a short distance away, the built-in antenna may not function satisfactorily.

In locations where it is impossible to obtain satisfactory results with the built-in

©John F. Rider

World Radio History

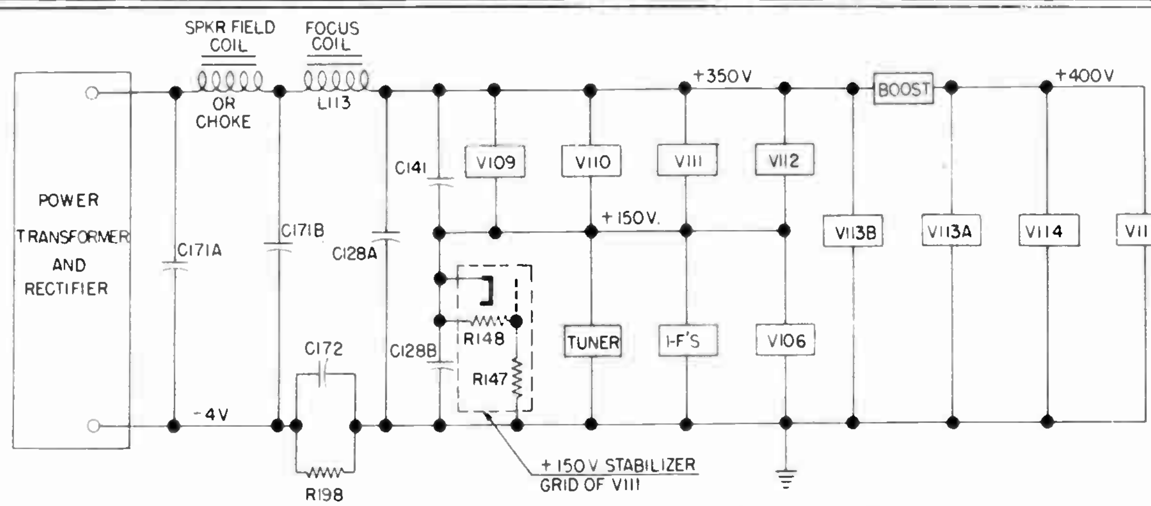

Figure 5. Block Diagram of Power Supply and Voltage Distribution System

antenna, due to shielding effects of buildings or mountains or if the receiver is located too far from the television station, it will be necessary to install an external indoor or outdoor antenna.

3.02 External Antenna:

A proper antenna installation is the most important factor in avoiding reflections in a picture, or a weak picture, although, in some localities where there are a number of stations operating, it may be impossible to eliminate all reflections. The Service Man should suggest the proper type of antenna to be used in the specific location and install and adjust the antenna for the best picture quality.

This television receiver has been designed to operate from a 300 ohm parallel lead transmission line.

3.03 Connecting External Antenna to Receiver:

1. Remove the two wires from the built-in antenna fastened to the two screws on the terminal board mounted on the rear apron of the chassis and fasten the lead-in from the external antenna under these screws. Tape the loose ends of the wires from the built-in antenna, as noisy reception would result if these wires come in contact with the antenna terminal screws.

NOTE: If a co-axial transmission line is used, see that the shield of the co-axial cable is connected to the terminal marked "G".

4. INSTALLATION

4.01 Unpacking:

The cabinet of this receiver is shipped in first class condition with considerable attention given to protecting the finish. Handle With Care. To remove the cabinet from the shipping container, turn the carton on its side and tear open the carton bottom flaps. Fold the flaps up along the side of the carton and turn the carton back up. Lift the carton up and off the cabinet. Tilt cabinet and carefully knock off the skid that is nailed to the bottom of the cabinet. Remove the screws in the cabinet back and swing back open. Check to see that all tubes are in place and firmly seated in their sockets. Check high voltage lead to see that it is connected to the CRT second anode connector socket on the bell of the tube. After inspection close cabinet back and reinsert and tighten the screws.

4.02 Location of the Receiver:

The receiver should be located to permit viewing from the proper distance. For best results in detail, the picture should be observed from a distance of five to ten feet. Locate the receiver where no bright light will fall directly on the picture. Care should be taken not to block the ventilating holes in the back or the bottom of the cabinet. The back of the cabinet should be kept at least two inches away from a wall or other obstructing surfaces.

5. OPERATING INSTRUCTIONS

The receiver is adjusted at the factory and is ready for operation after being connected to a 117 volt, 60-cycle a.c. outlet. To set the receiver in operation, follow the procedure outlined under "Normal Operation".

5.01 Normal Operation:

1. Turn the Off-On Contrast control knob half-way clockwise; this will turn the receiver "On". Wait one minute for the tubes to warm-up to the proper operating temperature.

2. Turn the Tuning control to the desired channel and move the dial slowly over this point until the best quality picture is obtained. The Contrast control might require slight adjustment.

3. Turn the Volume control to obtain the desired sound level. On some stations it may be necessary to make a slight readjustment of the tuning control to minimize noise in the sound.

4. Adjust Off-On-Contrast control for desired contrast.

5. To turn the receiver "Off", turn the Off-On-Contrast control completely counter-clockwise. Normally, only the main controls need be adjusted. At rare intervals it may be necessary to adjust the Auxiliary Controls due to the normal ageing of the tubes and other components.

5.02 Auxiliary Control Adjustment:

1. Turn the receiver "On" as described in paragraph "1" of "Normal Operation".

2. Adjust the Brightness control for moderate brightness, below the point where the raster size increases.

NOTE: If normal brilliance is not obtained at this point it may be necessary to adjust the Ion trap on the neck of the picture tube. For Ion trap adjustment, see "Ion Trap Magnet Adjustment" in section 6.01.

3. Turn the Brightness control counter-clockwise until the raster just becomes invisible.

4. Rotate the Tuning control to the desired channel and move the dial slowly over this point until the best quality picture is obtained. This may require adjustment of the Contrast control to obtain the proper contrast between the blacks and whites of the picture, or adjustment of the Focus control for greatest clarity of the lines in the center of the raster.

5. Adjust the Volume control to obtain the desired sound level. On some stations, a readjustment of the Tuning control may be necessary to minimize the noise in the sound.

6. If the picture rolls or jumps vertically, turn Contrast control counter-clockwise to obtain a weak picture and adjust the Vertical Hold control until the picture remains stationary. Then readjust Contrast control.

7. If the picture pulls to the right or tears, adjust the Horizontal Hold control until the picture remains stationary on the screen then set the control in the center of the range in which it makes the picture stationary. This adjustment should also be made with the Contrast control set to obtain a weak picture.

6. SERVICE NOTES

All controls are adjustable without removing the chassis from the cabinet. The back of the cabinet must be opened for the Width and Horizontal Frequency adjustments that are on the top of the chassis.

WARNING

An A.C. interlock is provided at the rear of the receiver so that when the back is removed, the power is off. Bypassing the interlock involves a shock hazard from the receiver high voltage power supply and the anode lead to the picture tube. Work on the receiver should not be attempted by anyone not thoroughly familiar with the precautions necessary when working on high voltage equipment.

6.01 Adjustments & Operating Check:

Remove the screws in the cabinet back and swing open the back. Connect an auxiliary power cord with suitable socket to the interlock receptacle on the rear of the receiver chassis.

1. ION TRAP MAGNET ADJUSTMENT - When making this adjustment do not exert pressure on the neck of the picture tube. Position the Ion trap for maximum brightness of the raster on the picture tube screen by moving the trap forward or backward and at the same time rotating it slightly around the neck of the tube. Reduce the brightness control setting until the raster is slightly above average brilliance. Adjust the Focus control until the line structure of the raster is clearly visible. Readjust the Ion trap for maximum brilliance. The final setting should be made with the Brightness control set to maximum position with which good line focus can be maintained.

2. DEFLECTION YOKE ADJUSTMENT - Position the Deflection Yoke as far forward as possible on the picture tube. If the lines of the raster are not horizontal, rotate the Deflection Yoke so as to make the top of the raster parallel with the top of the chassis, then tighten the yoke adjusting wing screw.

3. FOCUS COIL ADJUSTMENT - The Focus Coil should be adjusted to be approximately perpendicular to the picture tube axis with the front surface of the focus coil housing approximately 15/32" from the rear surface of the deflection and focus coil mounting bracket. Center The Picture by adjusting the three Focus Coil mounting nuts. If Focus Coil adjustment is made, the Ion trap may need readjustment, see "Ion Trap Magnet Adjustment".

4. HEIGHT AND WIDTH ADJUSTMENT - Picture size is adjusted to slightly overscan the mask both vertically and horizontally by the width adjustment on top of the chassis and the Height Control that is accessible through a hole in the front chassis apron.

5. HORIZONTAL OSCILLATOR ADJUSTMENT - The Horizontal Oscillator may re-

©John F. Rider
World Radio History

quire adjustment when installing the television receiver. See "HORIZONTAL OSCILLATOR ALIGNMENT", Bulletin No. 412.

6. VERTICAL LINEARITY ADJUSTMENT - The Vertical Linearity control has the effect of expanding the picture at an increasing rate from the bottom to the top of the picture. Adjustment of this control has the greatest effect on the top portion of the picture, some effect on the middle and very little effect on the bottom of the picture. The Height Control and Focus control may need readjustment as a result of the change in position of the Vertical Linearity Control.

6.02 Horizontal Drive Adjustment:

The Horizontal Drive is a trimmer adjustment on the rear chassis apron. This Control should normally be all the way out (minimum capacity). In some receivers, a white vertical line may appear in the raster under this condition. If so, turn the trimmer screw in just far enough to eliminate the white line. The Width Control may need adjusting to reduce or increase the horizontal size.

6.03 Horizontal Lock-in Adjustment:

See "HORIZONTAL OSCILLATOR ALIGNMENT", Bulletin No. 412.

6.04 Removing Picture Tube Window:

The Picture Tube window may be removed from the cabinet by removing the four wood screws in the border of the window.

6.05 Cleaning Picture Tube Window:

See "CLEANING PICTURE TUBE WINDOW", page 16

6.06 Removal of the Chassis from the Cabinet: (Be Sure Power is Disconnected)

1. Remove the (slip-on type) knobs from the front panel controls. Remove the metal pointer from the tuning control shaft.
2. Remove the screws in the cabinet back and swing open the back.
3. Remove the built-in antenna leads from the antenna terminal board screws.
4. Disconnect the speaker plug from the chassis socket on the rear apron.
5. Remove the five hex head machine screws that secure the chassis in the cabinet. These are accessible from the bottom of the chassis shelf.
6. Slide the chassis from the cabinet.
7. To reinsert the television chassis in the cabinet, repeat steps 2 to 6 in reverse order, then proceed as follows: -
   (a) Replace the large and small knobs on the Volume Control and Off-On-Contrast control shafts.
   (b) Turn the tuning control completely clockwise to stop.
   (c) Push on the metal pointer over knurled portion of shaft so that the pointer is lined-up with the calibration mark of channel 13.
   (d) Push the dual knob on the Tuning control shaft.
   (e) Place the receiver in operation and tune in a station on a known channel. If the pointer is slightly to one side of the calibration mark, reset the pointer to the correct position.

6.07 Removal and Replacement of the Picture Tube:

HANDLING PRECAUTIONS - Do not remove or handle the picture tube in any manner unless heavy gloves and protective goggles are worn. KEEP THE TUBE AWAY FROM THE BODY WHILE HANDLING.

1. Remove the television chassis from the cabinet as outlined above.
2. Disconnect the tube socket and high voltage anode lead from the picture tube. Remove the Ion Trap from the neck of the tube.
3. Remove the corrugated paper around the neck of the picture tube within the focus coil.
4. Loosen the Phillips head screw on the picture tube strap, near the top of the tube, sufficiently to unhook the strap from the chassis.
5. Grasp the picture tube firmly with both hands along the outer edge and gently slide it out of the focus and deflection coils.

CAUTION NEVER GRASP THE PICTURE TUBE BY ITS NECK OR ALLOW PRESSURE TO BE EXERTED ON THE NECK.

6. Place the picture tube face down, on a flat surface covered by a clean cloth, in a location where it will not be disturbed.
7. When the picture tube is ready to be replaced in the receiver chassis, slide the picture tube gently back into the deflection coils and focus coil until the center of its face surface extends 1-3/32" beyond the front edge of the chassis and rotated so that the anode cap is 45° counter-clockwise from top when viewed from the front of the chassis.
8. Bottom of tube should rest on the rubber strips on the two angle brackets on the front of the chassis. Also, see that the neck of the tube is centered in the focus coil. This centering must be accomplished by proper seating of the front part of the picture tube. DO NOT ALLOW PRESSURE TO BE EXERTED ON THE NECK OF THE TUBE. Fasten the picture tube strap.
9. Slide the deflection coil bracket forward as far as possible until the rubber cushion fits snugly against the flare of the picture tube and the two grounding springs make good contact on the tube. Also make sure that the deflection coils are positioned firmly against the flare of the tube.
10. Replace the corrugated paper around the neck of the picture tube.
11. Replace the Ion Trap.
12. Connect the anode (high voltage) lead to tube.
13. Connect the tube socket to base of tube.

6.08 Removal and Replacement of the R. F. Unit:

1. Remove the two screws that hold the antenna board to the rear chassis apron and unhook shielded antenna leads from clamps on the bottom of the side chassis apron.
2. Unsolder - (a) blue lead to the lug on L101
   (b) the ground strap from the tuner to the chassis next to L101
   (c) the red, brown and black leads from the tuner.

   DO NOT CUT THE LEADS: KEEP THEM FULL LENGTH. Record the color coding of the wires and the terminals from which the wires were removed.
3. Remove the three hex head screws that fasten the R.F. Unit to the front chassis apron and carefully remove the unit from the bottom of the chassis.
4. To remove and replace Gear, Sleeve Assembly and Bracket: —
   (a) Remove the "C" washer that holds the gear sleeve to the tuner shaft.
   (b) Remove the gear sleeve and the two spring washers behind the gear.
   (c) To remove the gear on the bracket, remove the "C" washer and slide off the gear and the washer behind the gear.
   (d) To remove the bracket, remove the two hex head self tapping screws on the front of the tuner.
   (e) To replace Gear, Sleeve Assembly and Bracket, reverse the removal procedure in steps (a), (b), (c), and (d). Be sure the gears are firmly meshed, but loose enough to prevent binding. This adjustment is made by the hex head screw and lock-nut on the offset portion of the tuner bracket. After adjusting, tighten locknut.
5. To install the new R.F. TUNER UNIT, reverse steps "1" to "3". Replacement of the R.F. Unit may also require a slight readjustment of the 1st. I.F. Secondary Coil L101.

6.09 Critical Lead Dress R. F. Unit:

1. The Blue lead from the tuner to L101 should pass between the tuner ground strap and main chassis.
2. The Red and the Black-Yellow lead from the tuner should be dressed around the lance in the main chassis and then doubled back to remove all slack from lance to I.F. strip terminal board.
3. The Brown tuner lead should be dressed close to main chassis and directly to terminal socket.

6.10 Test Equipment:

Equipment Needed	Required Characteristics
A. *Trouble Shooting* Cathode-Ray Oscilloscope	Very high input impedance. Must readily synchronize with "Y" axis signal. Must have excellent frequency and phase response from 10 cycles to at least two megacycles and should be capable of passing a 60 cycle square wave without appreciable distortion. Must not compress input signal until a reasonably sized wave form appears. Wide range input attenuator.
Voltage Calibrator	Suitable for calibrating the amplitude of the wave shapes on the "Y" axis of the oscilloscope.
Electronic Voltmeter	Very high input impedance for d.c. voltage measurements. Having at least one megohm of d.c. resistance on the 3 volt scale.
B. *I.F. and Video Alignment* R.F. Sweep Generator or Wobbulator	Frequency range 20 to 250 megacycles, sweep width 10-12 megacycles (adjustable). Output adjustable with at least .1 volt maximum. Output constant on all ranges. Center frequency variable over the complete television spectrum of channels 2-13. Output impedance 150 ohms unbalanced.

©John F. Rider

World Radio History

Signal Generator	High frequency signal generator: minimum frequency range 40-250 mc.; frequency calibrations reliable to better than 100KC. Attenuator should be adjustable and very accurate; modulation up to 30%.
Cathode-Ray Oscilloscope	Same as in "A".
Probe Detector	For connecting scope to circuits ahead of second detector. (See Fig. 7 for schematic diagram).
Non-Capacitive Screwdriver	Made of 1/4" fiber rod having screwdriver ends.

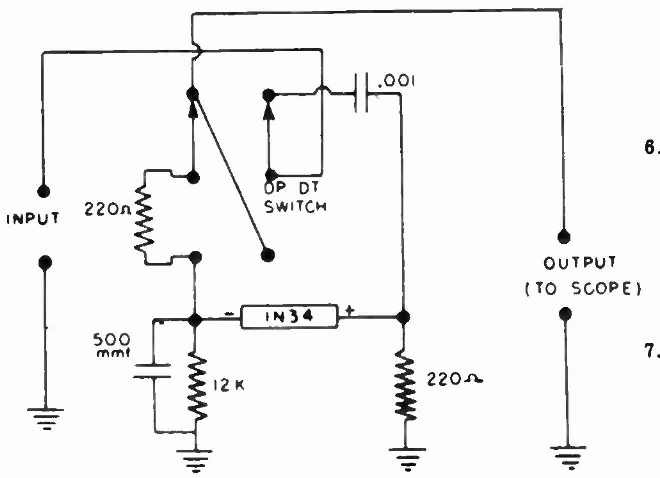

Figure 7 Probe Detector

6.11 Possible Failures:

NOTE: The following failures and possible solutions will aid the serviceman to locate and remedy the trouble.

Tubes should be changed first and if this will not remedy the trouble, check voltages.

1. DEAD RECEIVER:
   a. A.C. interlock not making connection.
   b. Power cord broken, check cord at interlock.
   c. Power switch SW101 contacts open.
   d. Primary winding of T108 open.

2. NO RASTER OR SOUND BUT TUBES LIGHT UP:
   a. Low voltage rectifier tube V118.
   b. Speaker plug disconnected.
   c. Open choke L115.
   d. Open Focus coil L113.

3. PICTURE BUT NO SOUND:
   a. Audio Tubes (V110, V111).
   b. Sound Det. Driver tube (V109).
   c. Defective Speaker voice coil.
   d. Receiver not tuned properly.
   e. T103 or T142 defective.

4. NO RASTER WITH SOUND PRESENT:
   a. Ion trap magnet not set properly.
   b. No high voltage cuased by 1B3 GT rectifier, T107 Horizontal output transformer, V114, V115 or V116.
   c. C169 shorted or R197 open.
   d. Defective Picture tube.

5. NO PICTURE OR SOUND WITH RASTER PRESENT:
   a. I.F. tubes V101, V102, V103 or V104.
   b. 2nd. detector tube V105 or Video amplifier V106.
   c. R.F. Unit.
   d. Antenna Lead-in.

6. NO VERTICAL DEFLECTION:
   a. Open Vert. Osc. Transformer T104.
   b. Shorted electrolytic capacitor C120.
   c. Vertical Output Transformer T105 open.
   d. Open deflection coil L112A.
   e. V113 tube defective or burnt out.
   f. C153 open.
   g. C152 shorted or R166 open.

7. NO HORIZONTAL DEFLECTION:
   a. Tubes V114, V115 or V116.
   b. Fuse F101 burnt out (Replace with same type and value).
   c. Horizontal B.T.O. Transformer T106.
   d. Open deflection coil L112B.

8. SOUND BARS OR GRAIN IN PICTURE:
   a. Station not "tuned-in" properly.
   b. Sound take-off Trans. T102 primary not adjusted properly.
   c. Microphonic tubes. (V2, V101, V102, V103 or V104).
   d. Oscillation in I.F. system due to lead dress or open by-pass capacitor.
   e. R.F. or I.F. not aligned properly.

9. SIGNAL BUT NO VERTICAL SYNC:
   a. Defective vertical oscillator Trans. T104.
   b. V113 tube.
   c. Resistors R158, R159, or R160 open.
   d. Vertical Hold Control R162 arm not making good contact.
   e. Capacitors C148, C149 or C150 defective.

10. SIGNAL BUT NO HORIZONTAL SYNC:
    a. Tube V114.
    b. C162A Plates grounded.
    c. Capacitors C147 or C155 open.
    d. L111 or R204 open.
    e. Horizontal frequency adjustment of T106 or Horizontal lock trimmer not properly adjusted.
    f. Horizontal Hold control R175 or resistor R174 open.

11. SIGNAL BUT NO VERT. OR HORIZ. SYNC:
    a. Tubes V107 or V112.
    b. C144 or C145 open.
    c. R155 open.

12. SHADOWS IN CORNERS OF PICTURE:
    a. Ion trap magnet adjustment
    b. Misadjusted Focus Coil.

13. "SNOW" IN PICTURE:
    a. Weak signal; check antenna and lead-in.
    b. Noisy tube V2 in R.F. Unit.
    c. Corona discharge from High Voltage power supply due to improper lead dress.

14. SMALL PICTURE:
    a. Low line voltage
    b. Horizontal Drive trimmer not properly adjusted.
    c. Width Inductance L110 shorted.
    d. V116 tube.

15. PICTURE WITH VERTICAL LINES: AND HORIZONTAL NON-LINEARITY:
    a. V116 tube.

16. WHITE VERTICAL BAR IN CENTER OF PICTURE:
    a. Horizontal Drive Trimmer not adjusted properly (See, "Horizontal Drive Adjustment", 6.02).

6.12 Critical Lead Dress:

CIRCUIT OR LEAD

R.F. TUNING UNIT:
1. Blue lead from tuner to L101 should pass between tuner ground strap and main chassis.
2. The Red and Black-Yellow lead from the tuner should be dressed around the lance in the main chassis and then doubled back to remove all slack from lance to I.F. strip terminal board.
3. The Brown Tuner lead should be dressed close to main chassis and directly to terminal socket.

I.F. STRIP:
4. All leads running parallel to the I.F. strip should be dressed away from the strip as far as possible, and down to chassis.

PICTURE TUBE:
5. Picture tube grid coupling capacitor .05 mfd, 400 V., C123 should be wired and dressed away from the chassis.

DISC CAPACITORS:
6. All composition disc type capacitors wherever used should be wired with leads as short as possible.

PEAKING COILS:
7. All peaking coils should be wired with short leads. Note connections before removing: when replacing, connect in the same manner.

A.G.C. NEUTRALIZING CAPACITOR C126:
8. The variable capacitor (transmission line) C126, should be dressed away from the I.F. strip.

RATIO DET. TRANS. T102:
9. The 22 ohm resistor. R143 and the 27 K ohm resistor, R144, connected to terminal "B" of T102, the ratio detector transformer, should be wired with short leads, as should be the 1000 mmf. capacitor C133.

OUTPUT TUBE V111:
10. The Blue lead going from pin 3 of the 6V6GT Audio Output tube, V111 to lug 5 of the speaker socket S101, should be reasonably free of slack so as to stand above other wiring.

CONTRAST CONTROL:
11. The White lead from the 22 ohm resistor, R121 on pin 7 of the 6AU6 Video Amplifier, V106, socket to the contrast control, should pass under other wiring and be dressed close to the chassis. The end going to the contrast control should be dressed against the shield away from the audio coupling capacitors, C138 and C139, on the Volume Control.

VERTICAL INTEGRATOR:
12. In receivers using separate components in the integrator circuit, capacitors C148, .002 mfd., 600 V; C149, .005 mfd. 600 V; C150, .005 mfd. 600 V. should be dressed to the chassis.

VERTICAL CIRCUIT:
13. All leads that cross (vertical circuit) terminal board next to the H.V. shield should be dressed to lay directly over the terminal board mounting foot in order to assure clearance in mounting shield.
14. The Red and the Red-Black lead in the vertical circuit should be placed under the .0047 mfd. capacitor lead and over the terminal board mounting foot, then dressed away from main chassis and behind center of control shield.

HORIZONTAL OUTPUT:
15. The fiberglass tubing on the 6BQ6 GT, V115, plate cap lead should be placed all the way up on the lead toward the plate connector.
16. The 6BQ6 GT, V115, grid lead to the Horizontal Drive trimmer should be dressed away from the chassis, short enough to stand above other wiring.

DEFLECTION YOKE:
17. Knots in deflection yoke leads should be loose enough to use up slack and keep leads under yoke bracket away from tubes.

HIGH VOLTAGE:
18. The plate cap lead and the filament leads of the 1B3 GT tube, V117, should be dressed to assure maximum clearance between them.

HIGH VOLTAGE COMPARTMENT:
19. Each lead leaving the H.V. compartment should be dressed to the chassis with no overlapping of leads to insure clearance when the H.V. shield is placed in position.

ANODE LEAD:
20. Force anode lead through slot in anode support (W-149322) before doubling over. Do not crease anode support. This will secure the anode lead.

6.13 Alignment and Adjustment Notes:

1. The sound I.F. and video I.F. carriers of this receiver are 21.9 megacycles and 26.4 megacycles respectively. Sound I.F. frequency 4.5 mc.
2. When the television receiver is repaired or aligned, always turn the chassis on its side with I.F. strip and R.F. Tuning unit up and block up the deflection coil mounting bracket to prevent the tube from resting on the bench.
3. Never disconnect the speaker while the power is on as the filter choke mounted on the speaker is in the B- circuit.
4. If the television receiver must be operated with the picture tube removed from the chassis, tape or cover the exposed end of the high voltage anode lead.
5. All lead connections from the signal generator and wobbulator must be shielded. Keep the exposed ends and ground leads as short as possible (about one inch).
6. Always locate the ground lead connections as close as possible to their respective "hot" leads in the television receiver chassis.
7. The wobbulator, signal generator output, and contrast control must be kept low enough to prevent over loading the television circuits.
8. The alignment procedure must be followed in the order shown in Bulletin No. 412.

V108	12LP4A	Picture Tube			

SOCKET VOLTAGE TABLE

The following voltages are measured with an electronic voltmeter from socket lugs to ground (chassis) while the set is operating on a 117 volt, 60 cycle A. C. current. Controls are set to obtain a normal picture with +10 volts D. C. on grid (Pin 2) of the picture tube. Some A. C. voltages measured between socket lugs as noted.

Voltages may vary depending upon the setting of the various controls.

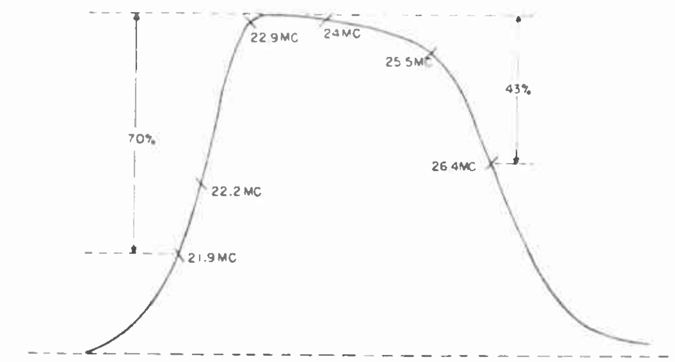
All voltages plus volts unless otherwise noted.
The following symbols denote:

* = A. C. voltage
N. C. = No connection
W. J. = Wiring junction
< = less than
▲ = A.G.C. voltage (variable with signal strength)

ALIGNMENT PROCEDURE

I.F. ALIGNMENT:

1. Connect a short clip lead from B- (-4 volts; white wire on C171) to the A.G.C. lead (orange wire) of the I.F. stages on the terminal board mounted to the I.F. strip close to L102.
2. Connect an electronic voltmeter across the 2nd Detector load resistor R117.
3. Set tuner near low frequency end of range, approximately 4 to 5 turns clockwise, at a point where there are no spurious responses.
4. Connect signal generator to the antenna terminals of the receiver (ground lead of generator to ground terminal of antenna terminal board). If when connected in this manner the signal from the generator is not of sufficient strength for indication on the electronic voltmeter, connect "hot" lead of signal generator through a 1000 mmf. capacitor to the junction of L101 and the 100 mmf. capacitor C101.
5. Set signal generator to 24 mc. and adjust L105 for maximum meter deflection, limiting meter deflection to 2 volts d.c. by adjusting input attenuator.
6. Reset signal generator to 22.2 mc. and tune L104 in a similar manner.
7. Next set signal generator to 26.55 mc. and tune L103.
8. Reset signal generator to 22.9 mc. and tune L102.
9. Repeat steps 5, 6, 7 and 8.
10. If signal generator was connected to the junction of L101 and C101 for steps 5, 6, 7, and 8, remove the generator from this point and connect the signal generator to antenna terminals. Set generator to 25.5 mc.
11. Set tuner near low frequency end of range approximately 4 to 5 turns clockwise at a point where there are no spurious responses.
12. Adjust L101 for maximum meter deflection.
13. Disconnect signal generator and electronic voltmeter.
14. To check alignment on oscilloscope:
    (a) Connect the oscilloscope across the detector load resistor R117.
    (b) Connect sweep signal generator to antenna terminals. Set the generator to sweep from 20 mc. to 30 mc. and adjust output to provide a 2 volt peak to peak signal on the scope.
    (c) Connect marker generator to sweep generator output leads and adjust to provide markers at 21.9 mc., 22.9 mc., 24 mc., 25.5 mc. and 26.4 mc.
    (d) Observe curve and position of markers (See response curve). 21.9 mc. should be approximately 70% down from the peak and 20.4 mc. approximately 43% down.



OVERALL I-F RESPONSE CURVE
SIGNAL CONNECTED TO ANTENNA TERMINALS

15. Disconnect generators, scope and the clip lead from B- to the A.G.C. terminal.

SOUND ALIGNMENT:

1. Connect "hot" lead of signal generator to grid (pin #1) of V106. Set signal generator to 4.5 mc. with 400 cps. amplitude modulated 30% or greater.
2. Connect scope to picture tube grid (pin #2) through a detector probe.
3. Connect two 100 K ohm resistors (matched within 1%) in series across R142. Connect common lead of the electronic voltmeter to junction of the matched 100 K ohm resistors and to D. C. lead to the + 150 volt point at junction of C135 and R142 on the lug of T101.
4. Using a high level signal input and with the contrast control set at maximum, tune the sound take-off transformer (T101) primary adjustment (bottom of chassis) for minimum deflection on the scope.
5. Reduce signal input to below limiting in V109 and adjust sound take-off transformer (T101) secondary (top of chassis), and ratio detector transformer (T102) primary (top of chassis) for peak meter reading.
6. Repeat steps 4 and 5.
7. Transfer D. C. lead only of the electronic voltmeter to junction of R144 and C137.
8. Return to high level input, for limiting in V109 and adjust ratio detector transformer (T102) secondary (bottom of chassis) for zero meter reading.
9. Remove the two 100 K ohm resistors, and all test equipment from the receiver.

A.G.C. NEUTRALIZING CAPACITOR ADJUSTMENT:

Adjust C126 (loop of transmission line under chassis) to neutralize amplifier by changing spacing in center of leads. Adjust with no signal input to the receiver. Remove one of the I.F. tubes from the receiver and set the Contrast control completely counter-clockwise. Neutralization is accomplished when no change in the A.G.C. amplifier D.C. output voltage is noticed (measured between cathode and ground) while an 0.1 mfd. capacitor is intermittently connected between the A.G.C. amplifier grid and ground.

HORIZONTAL OSCILLATOR ALIGNMENT:

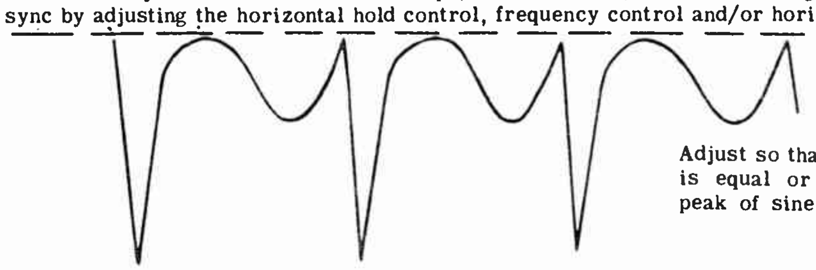
1. Tune receiver to a television signal and adjust contrast control for normal picture, below limiting in the video amplifier (V106).

©John F. Rider

World Radio History

2. Adjust the horizontal frequency adjustment (top of T106) and the horizontal hold control until picture is in sync.

3. Connect scope to terminal #5 of the horizontal blocking oscillator transformer (T106) with a 10 mmf. capacitor in series and adjust the horizontal BTO trap (bottom of T106) for the following wave form; keeping raster in sync by adjusting the horizontal hold control, frequency control and/or horizontal lock adjustment.



Adjust so that the peak of pulse is equal or 10% higher than peak of sine wave.

4. Turn the horizontal hold control fully clockwise. Adjust the horizontal frequency control (top of T106) by turning out until the raster is just out of sync, and then turning the frequency control in slowly until the raster is just ready to fall into sync (indicated by a wide black vertical or diagonal horizontal blanking bar).

5. Turn the horizontal hold control fully counter-clockwise. Picture should normally be in sync. Remove the signal by tuning off the station, then retune to the signal. If more than seven bars are present, adjust the Horizontal Lock trimmer slightly counter-clockwise, until five to seven bars appear before the picture falls into sync when the Horizontal Hold control is set in the extreme counter-clockwise position. If less than five bars are present, adjust the Lock trimmer clockwise. As the lock-in trimmer adjustment effects the horizontal frequency, the adjustments of both the horizontal frequency control and the lock-in trimer must be repeated until the conditions outlined above, in steps 4 and 5, exist simultaneously at the extreme positions of the Horizontal Hold Control. Check pull-in range. Pull-in range should be 120° minimum and 220° maximum.

6. The final setting of the Horizontal Hold control should be made with a very weak picture. Rotate the dial on and off the station, and set the Horizontal Hold control so that the picture returns completely in sync.

NOTES:

1A. SOCKET VOLTAGES MEASURED WITH AN ELECTRONIC VOLTMETER CONNECTED FROM SOCKET LUG TO CHASSIS.

B. SUPPLY VOLTAGE 117V. 60 CYCLE AC.

C. VOLTAGE MEASURED WITH CONTROLS SET TO OBTAIN A NORMAL PICTURE AND + 10 VOLTS DC. ON GRID PIN 2 OF PICTURE TUBE.

D. VOLTAGES MAY VARY DEPENDING UPON THE SETTING OF THE VARIOUS CONTROLS.

2. K = 1000 <= LESS THAN.

3. ALL CAPACITANCE VALUES IN MMF. AND ALL RESISTANCE VALUES IN OHMS UNLESS OTHERWISE NOTED.

4. DIRECTION OF ARROWS AT CONTROLS INDICATES CLOCKWISE ROTATION.

5. IN SOME RECEIVERS C148, C149, C150, R158, R159, AND R160 ARE A RESISTOR-CAPACITOR UNIT (PART NO. W-149878). SEE DIAGRAM ABOVE.

6. ON SOME SETS LUG 2 OF V103 IS CONNECTED TO GROUND AND NOT TO LUG 7. THESE SETS ARE EQUIPPED WITH A 6AU6 TUBE. BY CONNECTING LUG 2 TO LUG 7 AS SHOWN BY THE SOLID LINES IN SCHEMATIC, EITHER A 6AG5, 6AU6, OR 6BC5 TUBE MAY BE USED IN THE V103 SOCKET. WHEN REPLACING THIS TUBE, RE-ALIGN THE 3RD. I.F. STAGE.

7. IN EARLY PRODUCTION RECEIVERS C140 IS CONNECTED AS SHOWN BY DOTTED LINES. IN LATER PRODUCTION RECEIVERS, C140 IS CONNECTED AS SHOWN BY SOLID LINES TO PREVENT PARASITIC OSCILLATION IN THE AUDIO OUTPUT TUBE.

SOCKET VOLTAGE TABLE

The following voltages are measured with an electronic voltmeter from socket lugs to ground (chassis) while the set is operating on a 117 volt, 60 cycle A. C. current. Controls are set to obtain a normal picture with +15 volts D. C. on grid (Pin 2) of the picture tube. Some A. C. voltages measured between socket lugs as noted.

Voltages may vary depending upon the setting of the various controls.

Symbol	Tube Type	Pin 1	Pin 2	Pin 3	Pin 4	Pin 5	Pin 6	Pin 7	Pin 8	Pin 9

V122	5U4G	N. C.	400	W. J.	*360	N. C.	*360	W. J.	400	....

All voltages plus volts unless otherwise noted.

The following symbols denote:

* = A. C. voltage
N. C. = No connection
W. J. = Wiring junction
< = less than
▲ = A.G.C. voltage (variable with signal strength)

Note: Models 11-444MU and 11-474BU are equipped with a Radio-Phone Unit (Radio chassis 332-Phone Unit V-950). For service information and parts lists refer to Radio Bulletin No. 418 and Record Changer Bulletin No. 408.

ADJUSTMENTS

1. The cathode ray tube should be located so that the center of its face is 6-1/2 inches above the chassis surface with the anode connector on the left when viewed from the front of the chassis.
2. I. F. Alignment (See I. F. Alignment).
3. The DEFLECTION YOKE is positioned as far forward as possible on the cathode ray tube and rotated so as to make the top and bottom of the raster parallel with the top of the chassis.
4. The FOCUS COIL should be adjusted to be approximately perpendicular to the cathode ray tube axis with the front surface of the focus coil housing approximately 15/32 inch from the rear surface of the deflection and focus coil mounting bracket.
5. The ION TRAP is positioned for maximum brightness, with low to medium setting of the Brightness Control, and for no cutoff of the picture at high setting of the Brightness Control.
6. Center the picture by adjusting the three FOCUS COIL mounting nuts.
7. Adjust size of picture to fill screen (as viewed from face of CRT) by the HEIGHT CONTROL, HORIZONTAL DRIVE, and WIDTH CONTROL.
8. HORIZONTAL HOLD ADJUSTMENT (See Horiz. Blocking Osc. Alignment).
9. HORIZONTAL HOLD CONTROL is adjusted with a weak picture to center of pull-in range.
10. VERTICAL HOLD CONTROL is also adjusted with a weak picture to center of pull-in range.
11. Vertical linearity is adjusted by the VERTICAL LINEARITY CONTROL and the HEIGHT CONTROL. Horizontal size is adjusted by the HORIZONTAL LINEARITY AND WIDTH adjustments.
12. The FOCUS CONTROL is adjusted for best focus of the vertical and horizontal wedges at center of test pattern. If there is any astigmatism, the focus should be set to favor the vertical wedge. If corner focus is poor, check position of DEFLECTION YOKE and ION TRAP.

I. F. ALIGNMENT

1. To check I. F. alignment on oscilloscope:

   a. Connect a short clip lead from B- (-6.3 volts, white wire on C141) on the AGC terminal (orange lead) on the terminal board mounted on the I. F. strip close to L102.

   b. Connect high side of scope to the bare lead on pin 1 of the Video Amplifier V106, and the low side to ground (chassis).

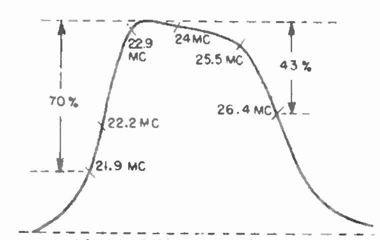
   c. Connect sweep signal generator to the grid (pin 2) of the Mixer tube V2 (see illustration below) making sure that the leads are as short and direct as possible, connecting ground terminal of generator to the tube shield and the "hot" terminal through a 5 mmf. capacitor to the grid pin.

   d. Set generator to sweep from 20 mc. to 30 mc. and adjust output to provide a 2 volt peak to peak signal on the scope.

   e. Set tuner near the low frequency end of the range approximately 4 to 5 turns clockwise at a point where there are no spurious responses.

   f. Connect marker generator to sweep generator output leads and adjust to provide markers at 21.9 mc, 22.9 mc, 24 mc, 25.5 mc, and 26.4 mc.

   g. Observe curve and position of markers (see nominal response curve in column two), 21.9 mc. should be approximately 70% down from the peak and 26.4 approximately 43% down. Slight deviation in shape from the nominal response curve is permissible, but if any great variation is noted it will be necessary to realign the I. F. Amplifier. NOTE: The response curve may be distorted unless care is used in the method of connection to prevent feedback and regeneration.



NOMINAL OVERALL I-F RESPONSE CURVE

   h. Disconnect the generators, scope and the clip lead from B- to AGC terminal.

2. Connect a short clip lead from B- (-6.3 volts, white wire on C141) to the AGC terminal (orange lead) on the terminal board mounted on the I. F. strip close to L102.
3. Connect an electronic voltmeter across the 2nd Detector load resistor R117.
4. Connect signal generator as in (c) of "I. F. Alignment Check."
5. Set tuner near low frequency end of range approximately 4 to 5 turns clockwise at a point where there are no spurious responses.
6. Set signal generator to 24 mc. and adjust L105 for maximum meter deflection, limiting meter deflection to 2 volts d.c. by adjusting input attenuator.
7. Reset signal generator to 22.2 mc. and tune L104, in a similar manner.
8. Next set signal generator to 26.55 mc. and tune L103 for maximum meter deflection.
9. Reset signal generator to 22.9 mc. and tune L102.
10. Set signal generator to 25.5 mc. and tune L101 for maximum meter deflection.
11. Repeat steps 6, 7, 8, 9, and 10.
12. Disconnect signal generator, electronic voltmeter and clip lead from B- to the AGC terminal.

SOUND ALIGNMENT

1. Connect "hot" lead of signal generator to grid (pin #1) of V106. Set signal generator to 4.5 mc. with 400 cps. amplitude modulated signal modulated 30% or greater.

2. Connect scope to picture tube grid (pin #2) through detector probe.

3. Connect two 100 K ohm resistors (matched to within 1%) in series across ratio detector load resistor R143 (pin 2 of V110 to chassis). Connect common lead of the electronic voltmeter to the junction of the matched 100 K ohm resistors and the D.C. lead of the voltmeter to ground (chassis).

4. Using a high level signal input and with the Contrast control set at maximum, tune the Sound Take-off Transformer (T101) primary adjustment (bottom of chassis) for minimum deflection on the scope.

5. Reduce signal input to below limiting in V109 and adjust the Sound Take-off Transformer (T101) Secondary (Top of Chassis), and the Ratio Detector Transformer (T102) *primary for peak meter reading.

6. Repeat Steps 4 and 5.

7. Remove detector probe and scope from the picture tube grid.

8. Transfer D.C. lead only of the electronic voltmeter to junction of R144 and C133. (lower of T.V. phono switch terminal toward speaker socket.)

9. Return to high level signal input for limiting V109 and adjust the Ratio Detector Transformer (T102) *secondary for zero meter reading.

10. Remove the two 100 K ohm resistors and all test equipment from the receiver.

HORIZONTAL DRIVE

The setting of the HORIZONTAL DRIVE trimmer should be checked to see that no change in linearity in the center of the picture occurs with change in Contrast setting. When using two driver tubes in parallel operation, this setting becomes more critical than in single tube circuits. In adjusting the HORIZONTAL DRIVE trimmer it is necessary to observe the picture width and set the trimmer to the point of maximum width (toward minimum capacity). To set up this trimmer correctly, turn it counterclockwise until the picture width starts to decrease or until a compression in the center of the picture is noted, whichever condition occurs first. In the extreme case the compression in the center of the picture will appear as a vertical white line. A check should then be made to see if the horizontal linearity in the center of the picture changes with Contrast control setting. If it does, turn the drive trimmer slightly clockwise just enough to eliminate this change in linearity.

If the drive trimmer is misadjusted so that insufficient drive is applied to the tubes, they will draw excessive current which will seriously shorten their life. This condition corresponds to the drive trimmer being adjusted too far in the clockwise direction.

When it becomes necessary to replace one of the horizontal output tubes, two new tubes, matched to draw equal plate current should be chosen and both the driver tubes should be replaced.

After tube replacement, readjust the drive trimmer as outlined in the paragraph above. The best horizontal linearity coincides with the lowest plate dissipation of the horizontal driver tubes and this linearity should be obtained with the adjusting screw of the HORIZONTAL LINEARITY inductance as far out of the coil as possible. It should be noted that changing the linearity adjustment makes it necessary to readjust the HORIZONTAL DRIVE trimmer.

NOTE: In rare cases where low B+ voltage is encountered, it may be necessary to change the screen resistor connection of V117 and V118 to obtain sufficient width (see note 5 on schematic). Do not overdrive the tubes, make this change only if the width of the raster is not sufficient to cover face of the CRT.

A.G.C. ADJUSTMENT

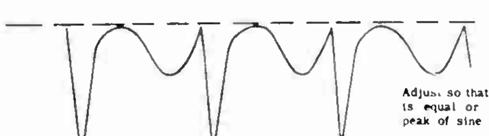
Tune in a station with a weak signal and adjust the A.G.C. threshold control on the rear apron of chassis to a point where the receiver will just begin to overload with the CONTRAST control set at maximum. If the receiver overloads on a strong signal, turn the CONTRAST control toward minimum to prevent overload.

HORIZONTAL BLOCKING OSCILLATOR ALIGNMENT

1. Tune receiver to a television signal and adjust CONTRAST control for normal picture below limiting in the video amplifier.

2. Adjust the HORIZONTAL HOLD control and the HORIZONTAL FREQUENCY adjustment (top of T106) until picture is in sync.

3. Connect scope in series with a 10 mmf. capacitor to terminal #5 of the HORIZONTAL BTO Transformer (T106) and adjust the HORIZONTAL BTO TRAP (bottom of T106) for the following wave form; keeping raster in sync by adjusting the HORIZONTAL HOLD control. HORIZONTAL FREQUENCY and/or HORIZONTAL LOCK adjustment.



Adjust so that the peak of pulse is equal or 10% higher than peak of sine wave.

4. Turn the HORIZONTAL HOLD control fully clockwise. Adjust the HORIZONTAL FREQUENCY control (top of T106) by turning out until the raster is just out of sync. and then turning the FREQUENCY control slowly in until the raster is just ready to fall into sync (indicated by a wide black vertical or diagonal horizontal blanking bar).

5. Turn the HORIZONTAL HOLD control fully counter-clockwise. Picture should normally be in sync. Remove the signal by tuning off the station then retune to the signal. If more than seven bars are present, adjust the HORIZONTAL LOCK trimmer slightly counter-clockwise until five to seven bars appear before the picture falls into sync when the HORIZONTAL HOLD control is set in the extreme counter-clockwise position. If less than five bars are present, adjust the LOCK trimmer clockwise. As the lock-in trimmer adjustment effects the horizontal frequency, the adjustments of both the horizontal frequency control and the lock-in trimmer must be repeated until the conditions outlined above in steps 4 and 5 exist simultaneously at the extreme positions of the horizontal hold control. Check pull-in range. Pull-in range should be 120° minimum and 220° maximum.

6. The final setting of the horizontal hold control should be made with a very weak picture.

Rotate the dial on and off the station and set the horizontal hold control so that the picture returns completely in sync.

The most important points in the Horizontal Oscillator and the AFC Alignment for most stable operation are: (1) that the raster just falls in sync at the clockwise end of the HORIZONTAL HOLD control, and (2) that the pull-in range is between 120° and 220°.

*Transformers (T102) with a red or green color code have the primary adjustment on bottom and the secondary adjustment on top. Transformers without a color code have the primary adjustment on top and the secondary adjustment on bottom.

R. F. TUNER SCHEMATIC DIAGRAM

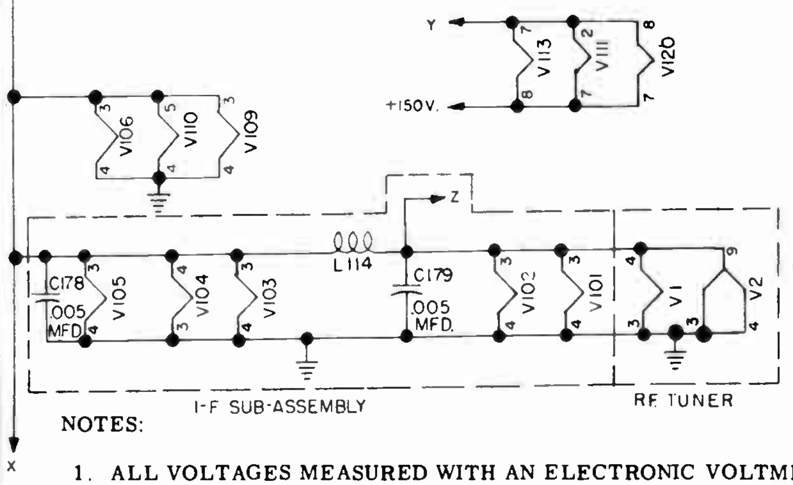

DIAGRAM OF VERTICAL INTEGRATOR SEE NOTE 7

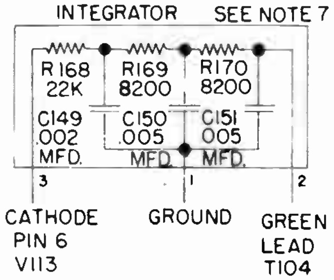

DIAGRAM OF AUDIO COUPLING SEE NOTE 8

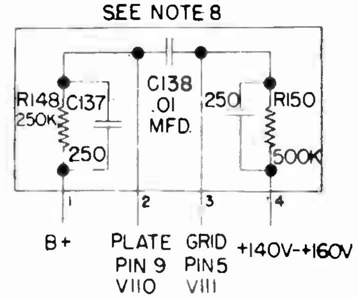

NOTES:

1. ALL VOLTAGES MEASURED WITH AN ELECTRONIC VOLTMETER CONNECTED FROM SOCKET LUG TO CHASSIS.
2. SUPPLY VOLTAGE 117V., 60 CYCLE AC.
3. K = 1000
4. ALL CAPACITANCE VALUES IN MMF. & ALL RESISTANCE VALUES IN OHMS UNLESS OTHERWISE NOTED.
5. SCREEN VOLTAGE ADJUSTMENT FOR V117 & V118

   NOMINAL — TERMINAL B
   HIGH — TERMINAL A
   LOW — TERMINAL C
6. SOME SETS ARE EQUIPPED WITH A BARE WIRE SHUNTING R207. IF HORIZONTAL DRIVE IS EXCESSIVE, REMOVE THE BARE WIRE ACROSS R207.
7. IN SOME RECEIVERS, C149, C150, C151, R168, R169, AND R170 ARE A RESISTOR-CAPACITOR UNIT, (PART NO. W-149878). SEF DIAGRAM ABOVE.
8. IN SOME RECEIVERS C137, C138, R148 AND R150 ARE A RESISTOR-CAPACITOR UNIT (PART NO. W-149881). SEE DIAGRAM ABOVE.
9. ON SOME SETS LUG 2 OF V103 IS CONNECTED TO GROUND AND NOT TO LUG 7. THESE SETS ARE EQUIPPED WITH A 6AU6 TUBE. BY CONNECTING LUG 2 TO LUG 7 AS SHOWN BY THE SOLID LINES IN SCHEMATIC, EITHER A 6AG5, 6AU6, OR 6BC5 TUBE MAY BE USED IN THE V103 SOCKET. WHEN REPLACING THIS TUBE, RE-ALIGN THE 3rd. I.F. STAGE.
10. ON SETS LABELED TO USE A 175 M.A. DELAY TYPE FUSE (PART NO. W-150065), C167 AND R200 ARE DELETED; THE CATHODES OF V117 AND V118 ARE THEN GROUNDED. IN THE FIELD, IT IS NOT NECESSARY TO REMOVE C167 AND R200 AND TO GROUND THE CATHODES WHEN REPLACING THE FUSE WITH A DFLAY TYPE FUSE.
11. SOME SETS ARE EQUIPPED WITH A 68 OHM, 10%, 1/2 WATT RESISTOR (PART NO. 39374-11).
12. IN EARLY PRODUCTION RECEIVERS, C140 IS CONNECTED AS SHOWN BY DOTTED LINES. IN LATER PRODUCTION SETS, C140 IS CONNECTED AS SHOWN BY SOLID LINES TO PREVENT PARASITIC OSCILLATION IN THE AUDIO OUTPUT TUBE.

SUBJECT— SERVICE SUGGESTIONS - 1951 TELEVISION RECEIVERS

To Reduce Hum or Buzz:

1. Make certain that electrolytic capacitor (C120) has a good ground connection by soldering a wire from the chassis to one of the ground lugs on the capacitor. This should be done on all sets contacted in the field to prevent trouble developing as the set ages. Later production sets have the capacitor grounded in this manner.
2. Make certain that the sections of the electrolytic capacitor (C120) are properly connected as shown by the schematic.
3. If the shield in back of the contrast control has been removed, be sure to replace it.
4. On sets equipped with a resistor-capacitor unit (Part No. W-149881), dress the coupling capacitor (C122) as far as possible away from the resistor-capacitor unit.
5. If necessary, remove the resistor (R141).
6. Adjust the ratio-detector transformer (T102) secondary for minimum hum or buzz, while the set is tuned to the station. Only a slight adjustment is required. If the screw is turned too far, the result may be weak or distorted audio output.
7. Check overall alignment according to the service information bulletin.

Preventing Corona Or Arcing On Glass Portion (behind metal bell) Of 16 or 19-inch Metal Picture Tube.

1. To retard the accumulation of dust collecting on the glass area behind the metal bell of the picture tube, this area was sprayed with silicon lacquer. In some cases this lacquer was hydroscopic, permitting moisture to be absorbed which resulted in corona or arcing. When this condition is experienced, thoroughly clean all the silicon lacquer from the tube with acetone.

SUBJECT—INCREASE PICTURE WIDTH - TELEVISION MODELS USING CHASSIS 321, 321-1, 321-2 AND 331, 331-1, 331-2.

If it is necessary to increase the width of the picture beyond the range of the width control, remove the 15,000 ohm resistor (R214) and connect a wire from lug 2 to lug 3 of the Horizontal Output transformer (T107). Also connect a 220 mmf., 2000 volt capacitor (Part No. 137498-62) from lug 6 to lug 8 of the transformer.

DESCRIPTION

TYPE: Eight-tube, single band, Superheterodyne.

FREQUENCY RANGE: 540 to 1600 kc.

INTERMEDIATE FREQUENCY: 455 kc.

POWER SUPPLY: 60 cycle, a.c. only.

VOLTAGE RATING: 105-125 volts.

POWER CONSUMPTION:

Radio Position .... 65 watts

Phono Position........................ 85 watts

Phono Motor only..................... 20 watts

TUBE COMPLEMENT:

Symbol No.	Type	Function
V301	6BA6	R.F. Amplifier
V302	6BE6	Converter
V303	6BA6	I.F. Amplifier
V304	6SQ7GT	Diode Det., AVC, Audio Amplifier
V305	6K6GT	Audio Output
V306	6SQ7GT	Phase Inverter
V307	6K6GT	Audio Output
V308	5Y3GT	Rectifier

DIAL BULB: Type 47, 6.3V., .15 amp.

World Radio History

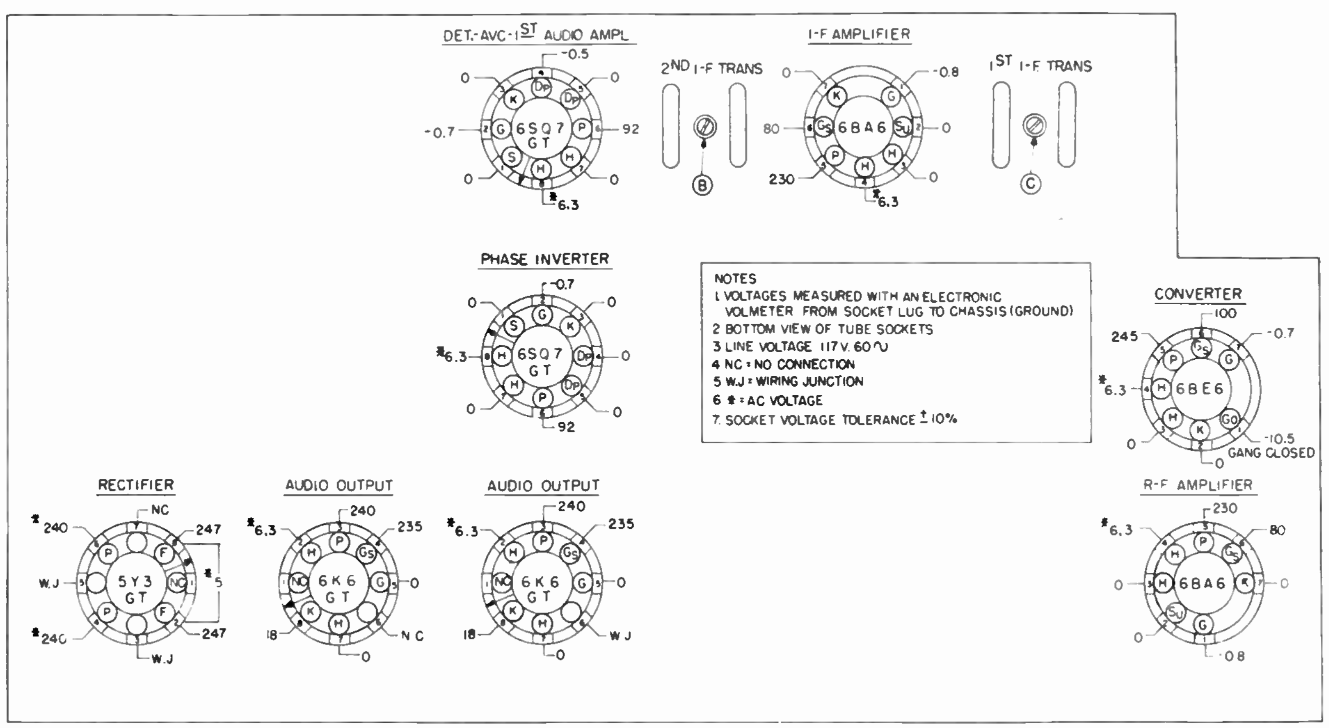
ALIGNMENT PROCEDURE

1. Turn the tuning capacitor to full mesh against stop and set the dial pointer to the reference point on the dial to the left of "55".
2. Connect output meter across speaker voice coil leads.
3. Feed an r.f. signal modulated 30% at 400 cycles to the receiver as indicated in the Alignment chart. Connect the signal generator ground terminal to the chassis of the receiver.
4. Turn the volume control to maximum clockwise position and the tone control to maximum treble position. Adjust the signal generator output to produce a noticeable output meter reading, keeping the signal generator output as low as possible to prevent AVC action in the receiver.
5. For all alignments the loop antenna must remain connected.

ALIGNMENT CHART

Alignment adjustment locations are shown on page 2, "CHASSIS, TOP VIEW."

Alignment Sequence	Signal Generator Output			Position of Tuning Dial or Tun. Cap.	Adjust for Maximum Output
	Frequency in kc.	In Series with	To		
1	455	.05 mfd.	Stator plates of C301B (center sect.)	Gang open	A & B
2	455	.05 mfd.	Stator plates of C301B (center sect.)	Gang open	C & D
3	1400	200 mmf.	Ext. Ant. Term.	1400	E (See Note 1)
4	1400	200 mmf.	Ext. Ant. Term.	1400	F (See Note 1)
5	1400	200 mmf.	Ext. Ant. Term.	1400	G (See Notes 1 & 2)



SOCKET VOLTAGE CHART

ALIGNMENT NOTES

1. Rock gang while adjusting r.f. and antenna trimmers for maximum sensitivity.
2. Antenna trimmer must be realigned at 1400 kc., after chassis is installed in its cabinet. A weak signal must be used so that the trimmer can be adjusted to maximum receiver sensitivity.

SOCKET VOLTAGE TABLE

The following voltages are measured with an electronic voltmeter from socket lugs to ground (chassis) while the set is operating on a 117 volt, 60 cycle A. C. current. Controls are set to obtain a normal picture with +7 volts D. C. on grid (Pin 2) of the picture tube. Some A. C. voltages measured between socket lugs as noted.

Voltages may vary depending upon the setting of the various controls.

Symbol	Tube Type	Pin 1	Pin 2	Pin 3	Pin 4	Pin 5	Pin 6	Pin 7	Pin 8	Pin 9

All voltages plus volts unless otherwise noted.
The following symbols denote:

• = A. C. voltage
N. C. = No connection
W. J. = Wiring junction
< = less than
▲ = A.G.C. voltage (variable with signal strength)

CAUTION - HIGH VOLTAGE

The metal cone of the picture tube operates at high voltage. Do not touch while in operation. Ground cone before touching after power is turned off.

HANDLE WITH EXTREME CARE

Breakage of the picture tube, which contains a high vacuum, may result in injury from flying glass. Do not scratch tube face or subject to more than moderate pressure. NEVER GRASP THE TUBE BY THE NECK OR THE GLASS SURFACE BETWEEN THE NECK AND METAL CONE.

CONNECTING EXTERNAL ANTENNA

Remove the two wires from the built-in antenna fastened to the two screws on the antenna terminal board mounted on the rear apron of the chassis. Tape the ends of the wires from the built-in antenna. Keep the lead-in from the external antenna away from the power cord and speaker leads. Drape the transmission line over the two hinges on the back of the cabinet at the top and bring the line down to the antenna terminal board. Fasten the lead-in wires under the two screws on the antenna terminal board.

ADJUSTMENTS

1. Adjust height of deflection bracket to center cathode ray tube neck in focus coil housing. Key on tube base should point to chassis.
2. I.F. Alignment (See I-F Alignment).
3. The DEFLECTION YOKE is positioned as far forward as possible on the cathode ray tube and rotated so as to make the top and bottom of the raster parallel with the tube mounting board.
4. The FOCUS COIL should be adjusted to be approximately perpendicular to the cathode ray tube axis with the front surface of the focus coil housing approximately 15/32 inch from the rear surface of the deflection and focus coil mounting bracket.
5. The ION TRAP is positioned for maximum brightness, with low to medium setting of the Brightness Control, and for no cutoff of the picture at high setting of the Brightness Control.
6. Center the picture by adjusting the three FOCUS COIL mounting nuts.
7. Adjust size of picture (to fill screen horizontally and 13-3/32 inches vertically) by the HEIGHT CONTROL, HORIZONTAL DRIVE, and WIDTH CONTROL.
8. HORIZONTAL HOLD ADJUSTMENT (See Horiz. Blocking Osc. Alignment).
9. HORIZONTAL HOLD CONTROL is adjusted with a weak picture to center of pull-in range.
10. VERTICAL HOLD CONTROL is also adjusted with a weak picture to center of pull-in range.
11. Vertical linearity is adjusted by the VERTICAL LINEARITY CONTROL and the HEIGHT CONTROL. Horizontal size is adjusted by the HORIZONTAL LINEARITY and WIDTH adjustments.
12. The FOCUS CONTROL is adjusted for best focus of the vertical and horizontal wedges at center of test pattern. If there is any astigmatism, the focus should be set to favor the vertical wedge. If corner focus is poor, check position of DEFLECTION YOKE and ION TRAP.

I.F. ALIGNMENT

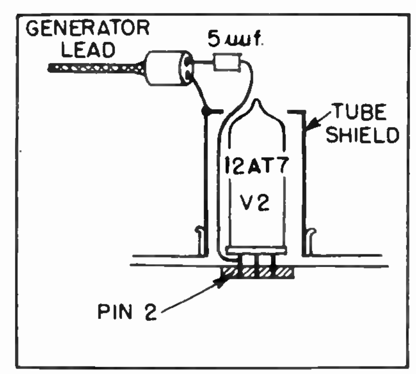
1. To check I.F. Alignment on Oscilloscope:

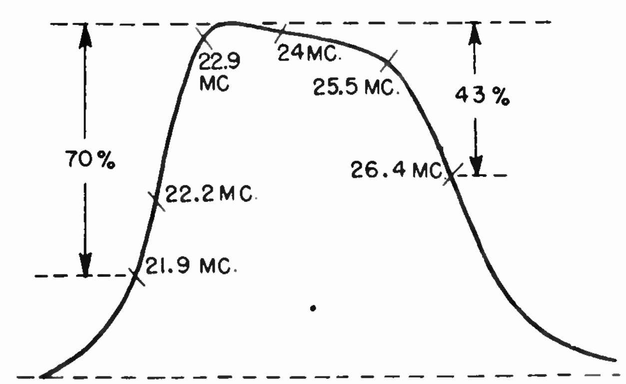
(a) Connect a short clip lead from B-(-6.3 volts, white wire on C141) to the AGC terminal (orange lead) on the terminal board mounted on the I.F. strip close to L102.
(b) Connect high side of scope to the bare lead on pin 1 of the Video Amplifier V106, and the low side to ground (chassis).
(c) Connect sweep signal generator to the grid (pin 2) of the Mixer tube V2 (see illustration below) making sure that the leads are as short and direct as possible, connecting ground terminal of generator to the tube shield and the "hot" terminal through a 5 mmf. capacitor to the grid pin.
(d) Set generator to sweep from 20 mc. to 30 mc. and adjust output to provide a 2 volt peak to peak signal on the scope.
(e) Set tuner near the low frequency end of the range, approximately 4 to 5 turns clockwise, at a point where there are no spurious responses.
(f) Connect marker generator to sweep generator output leads and adjust to provide markers at 21.9 mc., 22.9 mc., 24 mc., 25.5 mc., and 26.4 mc.
(g) Observe curve and position of markers (see nominal response curve below), 21.9 mc. should be approximately 70% down from the peak and 26.4 mc. approximately 43% down.

Slight deviation in the shape from the nominal response curve is permissible, but if any great variation is noted it will be necessary to realign the I.F. Amplifier.

NOTE: The response curve may be distorted unless care is used in the method of connection to prevent feedback and regeneration.

(h) Disconnect the generators, scope and the clip lead from B- to AGC terminal.





NOMINAL OVERALL I-F RESPONSE CURVE

2. Connect a short clip lead from B- (-6.3 volts, white wire on C141) to the AGC terminal (orange lead) on the terminal board mounted on the I.F. strip close to L102.
3. Connect an electronic voltmeter across the 2nd. Detector load resistor R117.
4. Connect signal generator as in (c) of "I.F. Alignment Check".
5. Set tuner near low frequency end of range approximately 4 to 5 turns clockwise at a point where there are no spurious responses.
6. Set signal generator to 24 mc. and adjust L105 for maximum meter deflection, limiting meter deflection to 2 volts d.c. by adjusting input attenuator.
7. Reset signal generator to 22.2 mc. and tune L104 in a similar manner.
8. Next, set signal generator to 26.55 mc. and tune L103 for maximum meter deflection.
9. Reset signal generator to 22.9 mc. and tune L102.
10. Set Signal generator to 25.5 mc. and tune L101 for maximum meter deflection.
11. Repeat steps 5, 6, 7, 8 and 9.
12. Disconnect signal generator, electronic voltmeter and clip lead from B- to the AGC terminal.

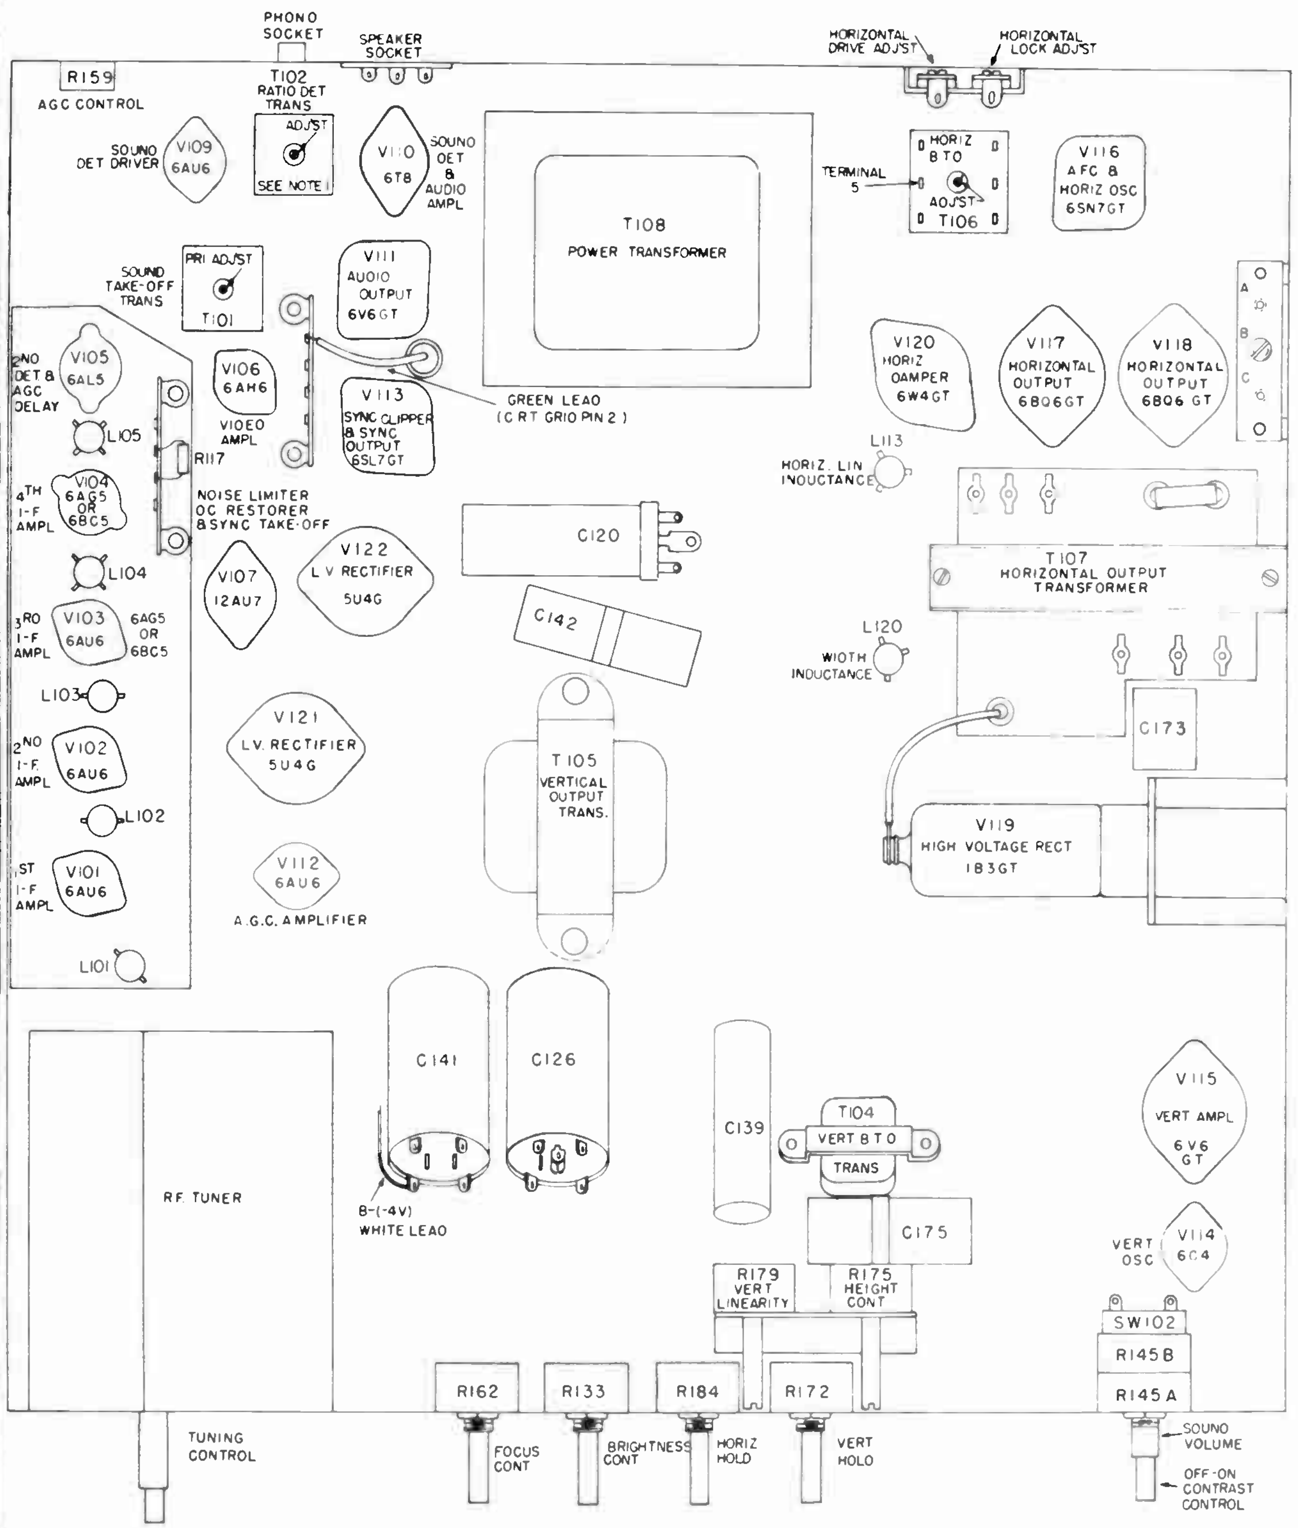
World Radio History



NOTE: 1. RATIO DETECTOR TRANSFORMERS (T102) WITH A RED OR GREEN COLOR CODE HAVE THE PRIMARY ADJUSTMENT ON THE BOTTOM AND THE SECONDARY ADJUSTMENT ON TOP. TRANSFORMERS WITHOUT A COLOR CODE HAVE THE PRIMARY ADJUSTMENT ON THE TOP AND THE SECONDARY ADJUSTMENT ON THE BOTTOM.

Chassis Bottom View Showing Tube Socket and Alignment Locations

SOUND ALIGNMENT

1. Connect "hot" lead of signal generator to grid (pin #1) of V106. Set signal generator to 4.5 mc. with 400 cps. amplitude modulated signal modulated 30% or greater.
2. Connect scope to picture tube grid (pin #2) through detector probe.
3. Connect two 100 K ohm resistors (matched to within 1%) in series across ratio detector load resistor R143. Connect common lead of the electronic voltmeter to the junction of the matched 100 K ohm resistors and the D.C. lead of the voltmeter to ground (chassis).
4. Using a high level signal input and with the Contrast control set at maximum, tune the Sound Take-off Transformer (T101) primary adjustment (bottom of chassis) for minimum deflection on the scope.
5. Reduce signal input to below limiting in V109 and adjust the Sound Take-off Transformer (T101) Secondary, and the Ratio Detector Transformer (T102) primary for peak meter reading.
6. Repeat steps 4 and 5.
7. Remove detector probe and scope from the picture tube grid.
8. Transfer D.C. lead only of the electronic voltmeter to junction of R141 and C133.
9. Return to high level signal input for limiting in V109 and adjust the Ratio Detector Transformer (T102) secondary for zero meter reading.
10. Remove the two 100 K ohm resistors and all test equipment from the receiver.

HORIZONTAL DRIVE

The setting of the HORIZONTAL DRIVE trimmer should be checked to see that no change in linearity in the center of the picture occurs with change in Contrast setting. In adjusting the HORIZONTAL DRIVE trimmer it is necessary to observe the picture width and set the trimmer to the point of maximum width (toward minimum capacity). This represents the optimum drive setting. Unless the DRIVE trimmer can be adjusted to either side of this point and a shrinkage noted in either case, the setting is incorrect. The best horizontal linearity coincides with the lowest plate dissipation of the horizontal driver tubes and this linearity should be obtained with the adjusting screw of the HORIZONTAL LINEARITY inductance as far out of the coil as possible. It should be noted, that changing the linearity adjustment makes it necessary to readjust the HORIZONTAL DRIVE trimmer setting to optimum.

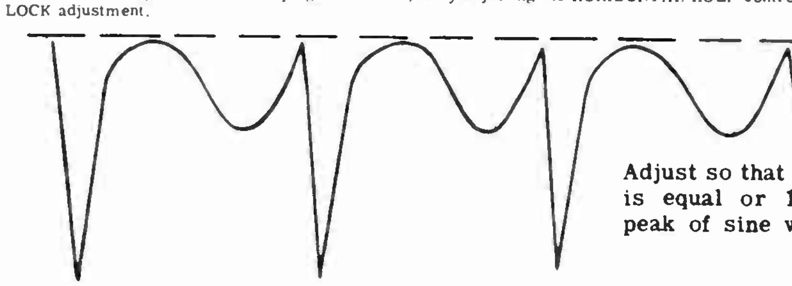
NOTE: In rare cases where low B+ voltage is encountered, it may be necessary to change the screen resistor connection of V117 and V118 to obtain sufficient width (see note 5 on schematic). Do not overdrive the tubes, make this change only if the width of the raster is not sufficient to cover the face of the tube.

A.G.C. ADJUSTMENT

Tune in a station with a weak signal and adjust the AGC threshold control on the rear apron of chassis to a point where the receiver will just begin to overload with the CONTRAST control set at maximum. If the receiver overloads on a strong signal, turn the CONTRAST control toward minimum to prevent overload.

HORIZONTAL BLOCKING OSCILLATOR ALIGNMENT

1. Tune receiver to a television signal and adjust CONTRAST control for normal picture below limiting in the video amplifier.
2. Adjust the HORIZONTAL HOLD control and the HORIZONTAL FREQUENCY adjustment (top of T106) until picture is in sync.
3. Connect scope in series with a 10 mmf. capacitor to terminal #5 of the HORIZONTAL BTO Transformer (T106) and adjust the HORIZONTAL BTO TRAP (bottom of T106) for the following wave form: keeping raster in sync by adjusting the HORIZONTAL HOLD control, HORIZONTAL FREQUENCY and/or HORIZONTAL LOCK adjustment.



Adjust so that the peak of pulse is equal or 10% higher than peak of sine wave.

4. Turn the HORIZONTAL HOLD control fully clockwise. Adjust the HORIZONTAL FREQUENCY control (top of T106) by turning out until the raster is just out of sync, and then turning the FREQUENCY control slowly in until the raster is just ready to fall into sync (indicated by a wide black vertical or diagonal horizontal blanking bar).
5. Turn the HORIZONTAL HOLD control fully counter-clockwise. Picture should normally be in sync. Remove the signal by tuning off the station, then retune to the signal. If more than seven bars are present, adjust the HORIZONTAL LOCK trimmer slightly counter-clockwise until five to seven bars appear before the picture falls into sync when the HORIZONTAL HOLD control is set in the extreme counter-clockwise position. If less than five bars are present, adjust the LOCK trimmer clockwise. As the lock-in trimmer adjustment effects the horizontal frequency, the adjustments of both the horizontal frequency control and the lock-in trimmer must be repeated until the conditions outlined above in steps 4 and 5 exist simultaneously at the extreme positions of the horizontal hold control. Check pull-in range. Pull-In range should be 120° minimum and 220° maximum.
6. The final setting of the horizontal hold control should be made with a very weak picture. Rotate the dial on and off the station, and set the horizontal hold control so that the picture returns completely in sync.

The most inportant points in the Horizontal Oscillator and the AFC Alignment for most stable operation are: (1) that the raster just falls in sync at the clockwise end of the HORIZONTAL HOLD control, and (2) that the pull-in range is between 120° and 220°.

DIAGRAM OF VERTICAL INTEGRATOR
SEE NOTE 7

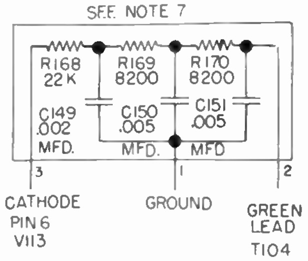

DIAGRAM OF AUDIO COUPLING
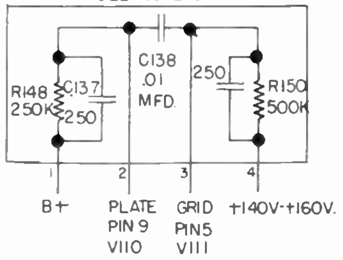
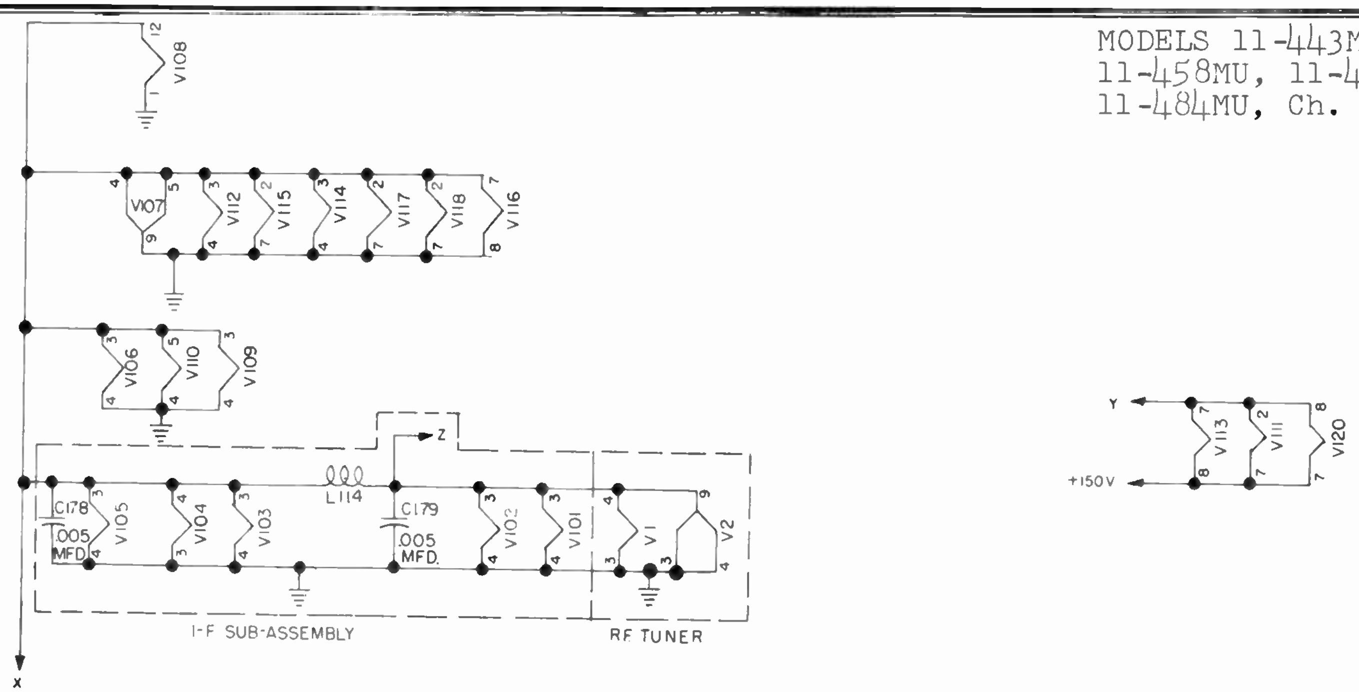
SEE NOTE 8





NOTES:

1. ALL VOLTAGES MEASURED WITH AN ELECTRONIC VOLTMETER CONNECTED FROM SOCKET LUG TO CHASSIS.
2. SUPPLY VOLTAGE 117V. 60 CYCLE AC.
3. K = 1000
4. ALL CAPACITANCE VALUES IN MMF. & ALL RESISTANCE VALUES IN OHMS UNLESS OTHERWISE NOTED.
5. SCREEN VOLTAGE ADJUSTMENT FOR V117 & V118

   NOMINAL — TERMINAL B
   HIGH — TERMINAL A
   LOW — TERMINAL C
6. SOME SETS ARE EQUIPPED WITH A BARE WIRE SHUNTING R207. IF HORIZONTAL DRIVE IS EXCESSIVE, REMOVE THE BARE WIRE ACROSS R207.
7. IN SOME RECEIVERS, C149, C150, C151, R168, R169, and R170 ARE A RESISTOR-CAPACITOR UNIT, (PART NO. W-149878). SEE DIAGRAM ABOVE.
8. IN SOME RECEIVERS C137, C138, R148 and R150 ARE A RESISTOR-CAPACITOR UNIT (PART NO. W-149881). SEE DIAGRAM ABOVE.
9. ON SOME SETS LUG 2 OF V103 IS CONNECTED TO GROUND AND NOT TO LUG 7. THESE SETS ARE EQUIPPED WITH A 6AU6 TUBE. BY CONNECTING LUG 2 TO LUG 7 AS SHOWN BY THE SOLID LINES IN SCHEMATIC, EITHER A 6AG5, 6AU6, or 6BC5 TUBE MAY BE USED IN THE V103 SOCKET. WHEN REPLACING THIS TUBE, RE-ALIGN THE 3rd. I.F. STAGE.
10. EARLY PRODUCTION SETS ARE EQUIPPED WITH C167 AND R200 CONNECTED IN THE CIRCUIT AS SHOWN BY THE DOTTED LINES.
11. SOME SETS ARE EQUIPPED WITH A 68 OHM, 10%, 1/2 WATT RESISTOR (PART NO. 39374-11).
12. IN EARLY PRODUCTION RECEIVERS, C140 IS CONNECTED AS SHOWN BY DOTTED LINES. IN LATER PRODUCTION SETS, C140 IS CONNECTED AS SHOWN BY SOLID LINES TO PREVENT PARASITIC OSCILLATION IN THE AUDIO OUTPUT TUBE.

MODELS: 11-454 MU, 11-458 MU, 11-484 MU
(Chassis 323)

NOTE:- These Models are the same as Model 11-443MU Except for the following:

To calibrate receiver connect the output of signal generator to the flexible antenna lead attached to the loop antenna. Connect the low side of signal generator through a 1/10 mfd. condenser to receiver chassis. Tighten the wave trap condenser. Adjust signal generator to 455 kilocycles and adjust both I.F. transformers for maximum signal. Re-peak the wave trap condenser for minimum 455 K.C. signal. Open the receiver variable condenser for minimum capacity. Set signal generator at 1700 kilocycles. Peak oscillator section of receiver condenser for maximum signal. Next set signal generator at 1500 kilocycles. Tune in this signal. Adjust R.F. section of receiver variable condenser for maximum signal strength. Keep the signal generator output as low as possible when making all of these measurements.

MODELS DT-162R, DT-163A, DT-163AR, DT-190D, DT-191, ET-140R, ET-141R, ET-170, ET-171, ET-172

OPERATING INSTRUCTIONS

TUNING:

The following adjustments are necessary when turning the receiver on.

1. Turn ON-OFF VOLUME control slightly clockwise to switch receiver on. Then turn 1/2 turn clockwise for SOUND VOLUME.
2. Set the STATION SELECTOR so that the desired channel number is seen in the window.
3. Allow 15 to 20 seconds for the tubes to warm up.
4. Turn CONTRAST control fully counterclockwise.
5. Turn the BRIGHTNESS control fully counterclockwise, then clockwise until a faint glow just appears on the screen.
6. Turn CONTRAST control clockwise until a glow or a pattern appears on the screen.
7. If the desired channel is broadcasting, music or speech should now be heard and the FINE TUNING control be reset for best picture quality. Adjust VOLUME control for desired amount of sound.
8. Adjust the VERTICAL hold control until the pattern stops moving up or down.
9. Adjust the HORIZONTAL hold control until a picture is obtained and centered from side to side.
10. Adjust the CONTRAST control so that the picture is clear on the screen.

TO CHANGE FROM ONE CHANNEL TO ANOTHER:

11. Turn the STATION SELECTOR so that the desired channel number is seen in the window.
12. It may be necessary to repeat Steps 7 and 10 when switching from one channel to another.
13. When the set is turned on again after an idle period, it should not be necessary to repeat the adjustments if the positions of the controls have not been changed. If any adjustment is necessary, step 7 is generally sufficient.
14. If the position of the controls has been changed it may be necessary to repeat steps 1 through 10.

NOTE: If any difficulty is experienced with steps 8 or 9, turn the CONTRAST control 1/4 turn counterclockwise and repeat adjustments 8 and/or 9.

INSTALLATION:

The complete installation of your new DeWald Television Receiver and the Television Antenna (if needed) must be made by a qualified DeWald Television Service Technician. The dealer from whom you purchased the receiver will advise you so that a DeWald Service Technician will install and demonstrate DeWald Television Reception. Only an antenna which is designed to match the receiver circuits should be used. Reception up to and sometimes beyond the line of sight to the transmitter antenna may be obtained if local interference conditions permit. It is recommended that a combination low frequency and high frequency antenna with separate lead-ins be used when installing this receiver in poor reception areas. It is further advised that a double pole, double throw switch be used for switching either the high or low frequency antenna to the receiver input.

REPLACEMENT OF KINESCOPE:

For Models ET-170, ET-171, ET-172. Remove all control knobs, masonite back of cabinet, four mounting screws under cabinet and connecting plug from speaker. The chassis can now be removed from the cabinet. To replace the kinescope, remove the kinescope socket, ion trap and disconnect the second anode cap connector. Loosen and remove the screw which holds the tube straps together on top of kinescope tube. The tube may now be withdrawn from the yoke and focalizer. When installing the new kinescope do not force it into the yoke or focalizer if they are not properly aligned. The tube must be installed so that the second anode contact is about 45 degrees toward the high voltage can from the vertical position. Replace the screw which holds together the tube straps and the ion trap and kinescope socket. Slide the chassis back into the cabinet, replace the speaker connecting plug, push on the second anode cap connector, push on all control knobs, and tighten the four chassis mounting screws.

For the Model Et-140R, the procedure indicated above must be followed with the exception that to remove tube strap, slide strap forward.

For the Models DT-163R, DT-163A, ET-191, DT-190D, the procedure for replacement of the kinescope is as follows: Remove the front panel from cabinet by removing the two wing screws from behind the top of the panel. Take off this panel, the masonite back of the cabinet, the kinescope socket and the ion trap. The kinescope can now be removed from the set. To put the new kinescope in place, orient the tube with the key at the base of the tube pointing downward and reverse the above procedure.

CAUTION: FAILURE TO CONNECT THE SPEAKER TO THE CHASSIS BEFORE TURNING THE RECEIVER ON MAY RESULT IN SERIOUS DAMAGE TO THE FIRST FILTER CONDENSER AND 5U4 RECTIFIER.

NOTE: THE METAL ENVELOPE OF THE KINESCOPE PICTURE TUBE HAS HIGH VOLTAGE CONNECTED TO IT.

ION TRAP ADJUSTMENT:

The ion trap is to be put on with the magnet poles approximately over the Kinescope flags. Starting from this position adjust the ion trap by moving it forward or backward at the same time rotating it slightly around the neck of the tube for the brightest raster on the screen.

CENTERING AND FOCUSING ADJUSTMENTS:

Move the focalizer back 1/4" away from the back of the Deflection Yoke. Centering is then performed with the focalizer. Loosen the two wing screws on the sides of the focalizer and move it in the direction required to center the picture. When best centering is obtained, tighten the wing screws. When the picture is off center either horizontally or vertically it may be adjusted on some sets with the "beamadjuster" and on others with the focalizer centering lever. The "beamadjuster" is accessible just in front of the focalizer and movement of the flange will result in movement of the picture position. The focalizer centering lever projects from the rear of the focus unit and moves the picture horizontally & vertically. The focusing procedure is as follows: Turn the bottom focalizer screw in until it will go no further, then turn it out 2 turns. Next adjust the top screw for best focus. Readjust the ion trap for maximum brilliance and then touch up the focus with the top screw.

NOTE: If no pattern is on, turn contrast control counterclockwise fully and turn up brightness control so that the raster lines are visible. The adjustment of the focalizer adjusting screw can be made by getting the sharpest line detail.

DEFLECTION YOKE ADJUSTMENT:

If the lines of the raster are not horizontal or squared with the picture mask, rotate the deflection yoke until this condition is obtained. Tighten the yoke adjustment screw.

PLACEMENT:

The location in the room for your television receiver should be given careful consideration. Choose the location:

A - Where no bright light will fall directly on the picture (some illumination in the room is desirable).
B - To give easy access for operation and comfortable viewing.
C - To permit a convenient connection to an outdoor antenna if it is needed.
D - Convenient to an A-C electrical outlet of the proper voltage and frequency.
E - To allow adequate ventilation.

CAUTION: The receiver is provided with adequate ventilation apertures, under, in back of, and on the sides of the cabinet. THESE APERTURES SHOULD NOT BE ALLOWED TO BE COVERED OR VENTILATION IMPEDED IN ANY WAY.

NOTE: Always keep the rear of this television receiver at least 6 inches away from the wall to allow for proper ventilation.

ANTENNA:

This television receiver features a self-contained antenna which makes use of an external antenna unnecessary in many locations. For best results rotate the cabinet while checking the picture quality on all stations. Use the receiver in a position which gives best results.

If an external antenna is necessary, take both leads off the antenna connector at the left of the chassis rear, and connect the lead-in wires of the external antenna to this connector.

REPLACEMENT OF FUSE:

This receiver is provided with a pigtail Glass Tube Fuse on the left bottom side of the chassis. This is a protective fuse for the H.V. Transformer. If it blows out, replace the 6BG6G tube. Use a 0.2 amp. - 250 volt pigtail fuse when replacement is necessary.

POWER SUPPLY:

This receiver is designed to operate on 105-125 volts, A.C. 60 cycle power only. If plugged into an incorrect power supply, damage to the receiver may result. If in doubt about your power supply, call your power company.

HIGH VOLTAGE CHECK:

If there is no raster on the kinescope tube after the ion trap has been adjusted, the high voltage may be checked as follows: Place the metal portion of a well insulated screwdriver near the top cap of the 1B3 tube. Hold only the insulated portion of the screwdriver. The metal part of the screwdriver should draw approximately a 1/4" spark from this cap. If a spark is present and there is still no high voltage at the anode lead replace the 1 Megohm Filter Resistor underneath the 1B3 socket.

ALIGNMENT PROCEDURE:

TO ADJUST SOUND I.F.'S:

1. Set A.M. Signal generator to 4.5 Mc and connect high side of generator, thru a .01 MFD condenser, to grid of the Video Amplifier Tube (6AH6 Pin 1). Low side of generator to go to chassis ground.
2. Connect a VTVM between Pins 2 and 7 of the 6T8 sound ratio detector tube (across 5MFD electrolytic condenser or points A and B on schematic diagram). Connect the plus side of the VTVM to Pin 7 and the negative side in series with a 33K ohm resistor to Pin 2.
3. With the signal generator (unmodulated) set at 4.5 Mc, adjust the sound takeoff coil (L8) and ratio detector primary T1 (bottom slug) for maximum DC voltage on the VTVM.
4. Adjust the takeoff coil before adjusting the ratio detector primary. Use just enough signal generator output to obtain approximately 1 volt on the VTVM. Connect the plus side of the VTVM to the junction of the two 18K ohm resistors connected between Pins 2 and 7 of the 6T8 tube (point C on schematic). Connect the minus side of the VTVM to the junction point of the 47K ohm resistor and the .01 MFD condenser (point D on schematic) going to the sound volume control. Adjust the ratio detector (T1) secondary (top slug) for zero voltage output. It will be found that it is possible to procure a plus or minus voltage on the VTVM depending upon the adjustment. Obviously to pass from a plus to a minus voltage, the voltage must pass through zero. The top slug should be adjusted so that the meter indicates zero output as the voltage swings from plus to minus. This point then will be called ratio detector zero adjustment.
5. Shift the frequency of the signal generator either side of 4.5 Mc and touch up the ratio detector primary for approximately equal peaks. Use just enough signal generator output to obtain 1 volt peaks for the best results.
6. When using an oscilloscope and a wide band oscillator for calibrating sound I.F., connect the sweep generator high side, through a .01 MFD condenser, to grid of the Video Amplifier Tube (6AH6 Pin 1). Connect the oscilloscope high side (in series with a .01 MFD condenser and a 40K ohm resistor) to the point indicated in step 4 and the ground terminal to chassis. Adjust the bottom slug of the ratio detector (primary) to produce maximum amplitude and the top slug (secondary) to produce the correct center point and best linearity on the response curve. The curve should be "S" shaped.
7. Connect sweep generator to the point indicated in step 1. Connect oscilloscope high side (in series with a .01 MFD condenser and 40K ohm resistor) to pin 2 of the 6T8 sound ratio detector and the ground terminal to chassis. Remove minus side of the 5 MFD stabilizer capacitor from pin 2 of the 6T8 tube. Adjust takeoff coil to produce maximum amplitude at 4.5 Mc.

NOTE: During sound I.F. alignment the common lead of VTVM is connected to approximately 140 volts, with respect to chassis. Avoid touching or grounding the VTVM case. Keep Contrast control fully clockwise.

TO ADJUST PICTURE I.F.'S:

1. Connect the negative terminal of a 3 volt "A" battery to the junction of the 1 megohm and .25 Mfd in the AGC bias line, (point E on schematic) and positive terminal to a chassis ground. Set the contrast control to the fully clockwise position. Set fine tuning control with flat in horizontal position.
2. Set channel switch to channel 3 or any clear channel.
3. Connect a VoltOhmyst across the second picture detector load resistor of 4700 ohms. Plus end to go to junction point of peaking coil L-5 and 4700 ohm resistor and minus end to other side of load resistor (junction of 4700 ohm, 1K ohm and .1 Mfd condenser).
4. Couple the high side of the signal generator to the mixer tube of tuner by slipping a tight fitting insulated tube shield over the tube envelope and connecting the generator lead to it. Connect the ground side of the signal generator to the frame of the tuning unit.
5. Set A.M. Signal generator to 25.2 Mc and peak detector I.F. (L-3) and first picture I.F. coil (L-1) for maximum gain on VoltOhmyst.
6. Set A.M. Signal generator to 23 Mc and peak second I.F. coil (L-2) and converter I.F. coil on top of tuner for maximum output on VoltOhmyst.
7. When using an oscilloscope and a wide band oscillator for calibrating and checking bandwidth of the I.F.'s, connect sweep generator to the point indicated under step 4. Connect the oscilloscope high side (in series with a 40K ohm resistor) to the junction of the peaking coil L-5 and 4700 ohm resistor, and the ground terminal to chassis. Align the picture I.F. to produce a response curve similar to the one shown.

NOTE: During picture I.F. alignment the common lead of VoltOhmyst is connected to approximately minus 2.5 volts with respect to chassis. Avoid grounding the VoltOhmyst case.

INTRODUCTION

The Model RA-112A Teleset is produced in the following styles:

Name	Model No.	Cabinet	Services
Ardmore	RA-112-A1	Mahogany Open Console	FM and TV
	RA-112-A4	Blonde Open Console	FM and TV
Westerly	RA-112-A2	Mahogany Console/Doors	FM and TV
	RA-112-A5	Blonde Console/Doors	FM and TV
Mt. Vernon	RA-112-A3	Mahogany Console/Doors	FM and TV
	RA-112-A6	Blonde Console/Doors	

	Picture Tube	Speaker
All Models	19"	10"

The Model RA-113 Teleset is produced in the following styles:

Name	Model No.	Cabinet	Services
Brookville	RA-113-B1	Mahogany Open Console	FM and TV
	RA-113-B2	Blonde Open Console	FM and TV
Revere	RA-113-B3	Mahogany Console/Doors	FM and TV
	RA-113-B4	Blonde Console/Doors	FM and TV
Burlingame	RA-113-B5	Mahogany Console/Doors	FM and TV
	RA-113-B6	Blonde Console/Doors	FM and TV
Tarrytown	RA-113-B7	Mahogany Console/Doors	AM, FM, TV and 3 Speed Record Player
	RA-113-B8	Blonde Console/Doors	AM, FM, TV and 3 Speed Record Player

	Picture	Speaker
All Models	17 in. Rectangular	10" (Except Tarrytown 12")

The chassis used in the RA-112A and RA-113 Telesets is basically the same chassis that was used in the RA-111 models. The horizontal output and high voltage circuits have been modified to supply adequate sweep and high voltage to the larger picture tubes. Certain other circuit improvements as outlined in the circuit description portion of these notes have been made.

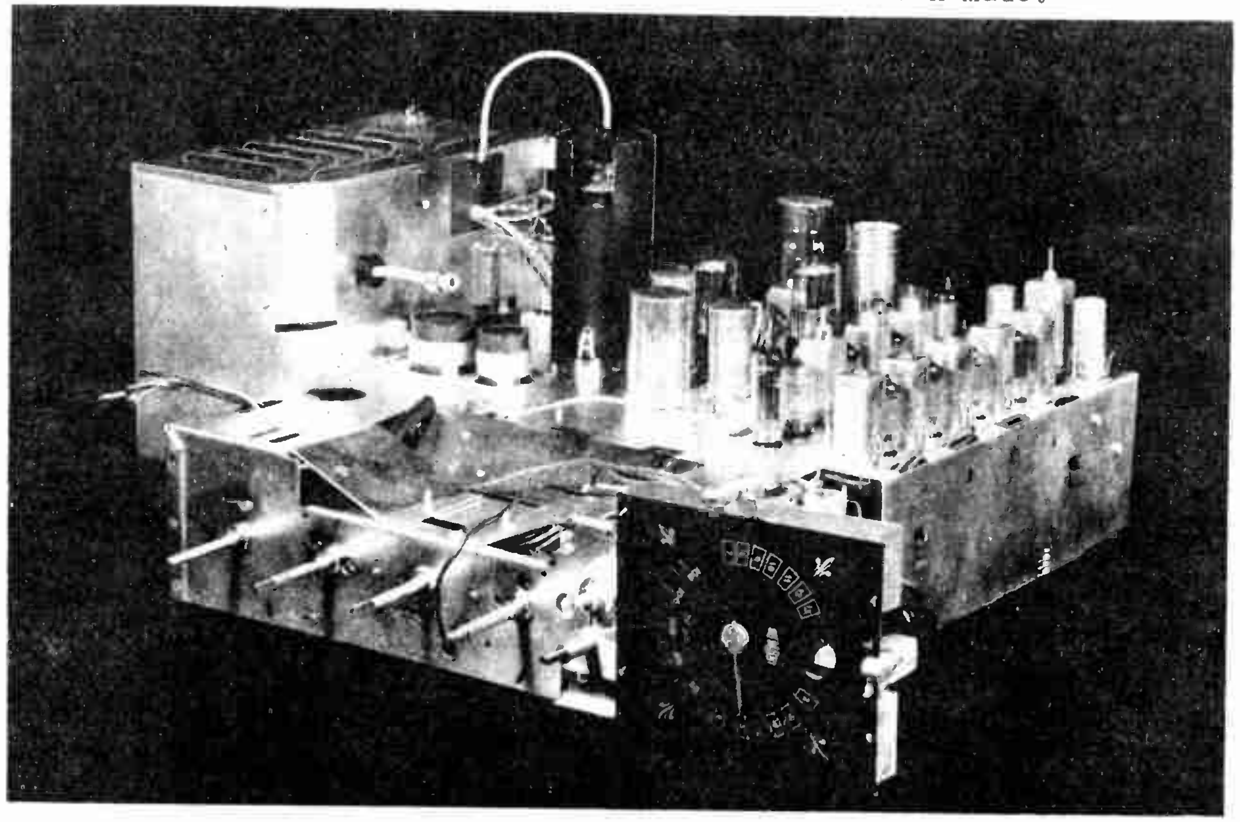

Figure 1 - RA-112A - RA-113 Chassis

2.0 Circuit Description

2.1 RF Tuning Assembly

The RA-112A RA-113 Telesets incorporate the latest Du Mont Four Section Inputuner. Up to and including serial no. 122695 in the RA-112A models and serial no. 132211 in the RA-113 models, the Inputuner used is electrically the same as that used in the RA-111A Telesets.

Starting with serial no. 122696 in the RA-112A models and serial no. 132212 in the RA-113 models the IF transformer in the plate circuit of the mixer is different than that in the above-mentioned tuner. The Inputuner schematic diagram appearing on the RA-112A RA-113 Service Sheet includes the new IF transformer in the mixer plate circuit.

The essential differences between this transformer and that previously used are as follows:

1. The coupling is fixed in the transformer. (The coupling adjustment now consists of an adjustable coil on the receiver chassis.)

2. An additional trap to attenuate the sound carrier of the lower adjacent channel to which the Teleset is tuned is included in this transformer. This is any absorption type trap and is tuned in the alignment procedure for maximum attenuation of 27.75 mc. With the new IF's of 21.75 mc for sound and 26.25 mc for picture, the beat produced between the local oscillator and the lower adjustment channel sound carrier is now 27.75 mc instead of 27.9 mc.

All post war Du Mont Telesets normally utilized a 26.4 mc IF for the video carrier and 21.9 mc for sound. In some receivers, this resulted in strong beat interference on channel 7 as a result of the 8th harmonic (175.2 mc) of the sound IF (21.9 mc) beating against the video carrier of channel 7, (175.25 mc) and producing a 50 kc beat. The result was a streaking of the picture. Although this condition could be cured by certain modifications, a change to a lower IF (21.75 mc) resulted in the complete elimination of the beat.

All RA-112A Telesets beginning with serial no. 12702 and all RA-113 Telesets beginning with serial no. 13580 are aligned to the new IF's as outlined in the enclosed alignment sheet. The new IF's are 26.25 mc for video and 21.75 mc for sound.

2.2 Video IF Strip

The video IF strip used in the RA-112A - RA-113 Telesets is basically the same as is used in the RA-11A chassis. The important differences which can be readily be seen by comparing the two schematics are as follows:

A. All RA-112A Telesets starting with serial number 122696 and all RA-113 Telesets starting with serial number 132212 utilize a different type of transformer at Z204, the input to the IF strip. The important difference in this transformer is that the method of coupling from the Inputuner output to the IF strip input has been changed. This transformer change took place at the same time that the IF transformer in the plate circuit of the mixer stage was changed. The coupling adjustment in the receiver is now made by adjusting L213, which is mounted on the receiver chassis proper.

B. The fourth video IF tube (V208) has been changed from a 6AU6 to a 6BC5. The purpose of this change is to improve the overall sen-

©John F. Rider

World Radio History

sitivity and signal-to-noise ratio. In conjunction with this change the cathode resistor R231 was changed from a 120 ohm resistor to a 220 ohm resistor. In order to obtain proper alignment of this stage using a 6BC5, it was necessary to replace the transformer Z208 with a different type.

Other than the changes mentioned above, this strip is identical to the RA-111A.

2.3 Video Detector and Amplifier

The same tube lineup is used in this section as was used in the RA-111A.
R234, the 10K resistor that was connected across L202 in the early RA-111A models, was deleted. (All RA-111A models effective with chassis serial number 112214 also contained the same change.) In addition to the deletion of the resistor, the coil L202 was changed.

The purpose of these changes is to improve picture quality.

2.4 Sound IF Strip

As in the RA-111A, the sound take-off point is from the plate circuit of the first video IF stage. The coupling capacitor C280 has a value of 2.5 mmf in these models whereas it was 1.7 mmf in the early RA-111A models. The reason for this change is to improve sound attenuation.

The discriminator transformer Z203 has been changed. The purpose of the change is to produce more sound output. Examination of the schematic indicates the following changes:

The secondary winding of the discriminator is not center-tapped. Instead, two capacitors are connected across the secondary winding and the tap is taken off at the junction of these capacitors.

2.5 Audio Amplifier Section

The Audio Amplifier Section is practically identical to the RA-111A circuit.

The triode section of the 6T8 (V203) functions as the voltage amplifier. The output from this tube is then used to drive the sound output stage (V204) which uses a 6AQ5.

This chassis will also be used in a combination model to be known as the Tarrytown (includes AM radio and three speed record changer). Certain provisions have been made in the audio output stage for use in the Tarrytown only.

The AM radio used in the Tarrytown will include a tone control. The shielded lead shown between pin #1 of V204 and pin #1 of the connector J201 is used to connect the tone control in the AM tuner back to the grid of the audio output stage, thus permitting control of tone in the television chassis.

The short shown across R323 (grid circuit of V204) is not an error. This will be removed when the AM tuner is used. R323 is a new resistor and was not used on the RA-111A models. C279 (plate circuit of V204) will also be removed when this chassis is used in the Tarrytown.

2.6 Composite Sync Section

The composite sync section is substantially the same as it was in the RA-111 Telesets.

The differences in the circuit between the RA-111A and the RA-112A and RA-113 Telesets are as follows:

The video IF signal is coupled from the cathode (pin 1) of the video detector (V209A) to the grid of the narrow band sync amplifier (V212) through a 20 mmf capacitor, C298. In the RA-111A Telesets, this connection was direct with no capacitor. A coil, identified as L214, is connected from grid to ground in the narrow band sync. amplifier stage (V212). C298 and L124 were added to reduce sync compression. The remainder of the narrow band sync amplifier is identical to the RA-111A.

The sync detector half of V213 remains unchanged but the AGC circuit is slightly different. The change consists of the addition of a "Local-Distent" switch to permit the reduction of AGC voltage when operating the Teleset in fringe areas. This circuit was included in the later RA-111 Telesets.

2.7 Vertical Sweep Section

The vertical sweep circuit is practically identical to that used in the RA-111A.

The differences in the circuit between the RA-111A and the RA-112A and RA-113 Telesets are as follows:

R288 in the plate circuit of V220A, is changed from 2.7K to 3.3K to improve vertical sync.

C271 in the grid circuit of V220B is changed from .003 to .01 mf and R293 is changed from 1.8 meg to 390K to reduce the pulse voltage on the vertical deflection amplifier plate.

R296 in the plate circuit of V220B, is changed from 5.1K to 4.7K in order to reduce the packing at the top of the raster.

A 30 mf capacitor (C294) shown below V220B is added in series with C248A to reduce the possibility of C248A breaking down inasmuch as this part of the circuit is connected to the boosted B+ line.

The plate circuits of the vertical saw generator (V220B) and vertical deflection amplifier (V221) are returned to the boosted B+ line from terminal 5 of the flyback transformer (T401). This source of voltage has improved regulation under varying operating conditions. It also provides a higher voltage for the plates of the vertical deflection amplifier than is available from the low voltage supply. This insures adequate vertical size for the larger picture tube sizes.

The vertical output transformer usually used in Du Mont Telesets had a turns ratio from primary to secondary of 10 to 1. The vertical output transformer used in these Telesets has a turns ratio of 11 to 1. The specifications of the vertical output transformer were changed to accomodate the yoke used with these models.

©John F. Rider

World Radio History

2.8 Horizontal Sync, Sweep and High Voltage Section

Five tubes are responsible for the function of horizontal sync, sweep and high voltage. The horizontal AFC and saw generator circuit (V214) is practically identical to that used in the RA-111A. The horizontal deflection amplifier (V215) has been replaced with a 6BG6 because of the greater sweep requirements of the Teleset. The circuitry of the high voltage section has been modified by the incorporation of cascade voltage doublers utilizing two 1X2 tubes (V401 and V402). This is necessary because of the increased high voltage required in the larger Teletron sizes. A single 6W4 (V217) performs the function of damping, as in the RA-111A.

2.9 Horizontal Deflection Circuit

The horizontal deflection amplifier circuit is substantially the same as that used in the RA-111A except that the cathode bias resistor and its associated condenser has been deleted and the value of the screen dropping resistor R271 has been changed due to the different operating characteristics of the 6BG6.

Examination of the simplified schematic shown on the following page shows that the secondary of the flyback transformer T401 (terminals 5 and 6) is essentially in series with primary, thus forming an auto-transformer circuit. This configuration permits tighter coupling between primary and secondary windings, resulting in a highly efficient output circuit and thus permitting the use of smaller wire size in order to produce a more compact transformer. Tighter coupling also reduces the possibility of Barkhausen oscillation. The screen voltage for the 6BG6 (V215) is taken from terminal 5 of T401. This source of voltage has improved regulation under varying operating conditions.

A horizontal size switch (S401) is used in this circuit. With this switch in the position shown in the schematic, maximum picture size will be obtained, but there will be no control of the size because L401 is not in the circuit. Somewhat reduced size will be obtained when S401 is turned to connect its pins 1 and 3 together, but then the horizontal size control, L401, will be effective. Further reduction in size will occur when S401 is turned to connect L403 in parallel with L401 and the size winding of T401.

The sweep signal is capacitively coupled to the horizontal deflection coil in order to prevent DC from flowing through the yoke and depositioning the beam. A 68 mmf capacitor is shunted across one-half of the horizontal deflection coil to prevent ringing in the yoke. If ringing persisted beyond the time required for horizontal retrace, vertical white and black bars would appear on the left side of the raster.

No static damping resistors are needed across the secondary of the horizontal output transformer because the application of the boosted voltage to the vertical deflection circuit provides adequate damping.

The horizontal linearity control adjusts the point at which the damper tube stops providing the sweep energy and the 6BG6 starts. Therefore, this control affects the linearity at the center of the picture where this effect takes place.

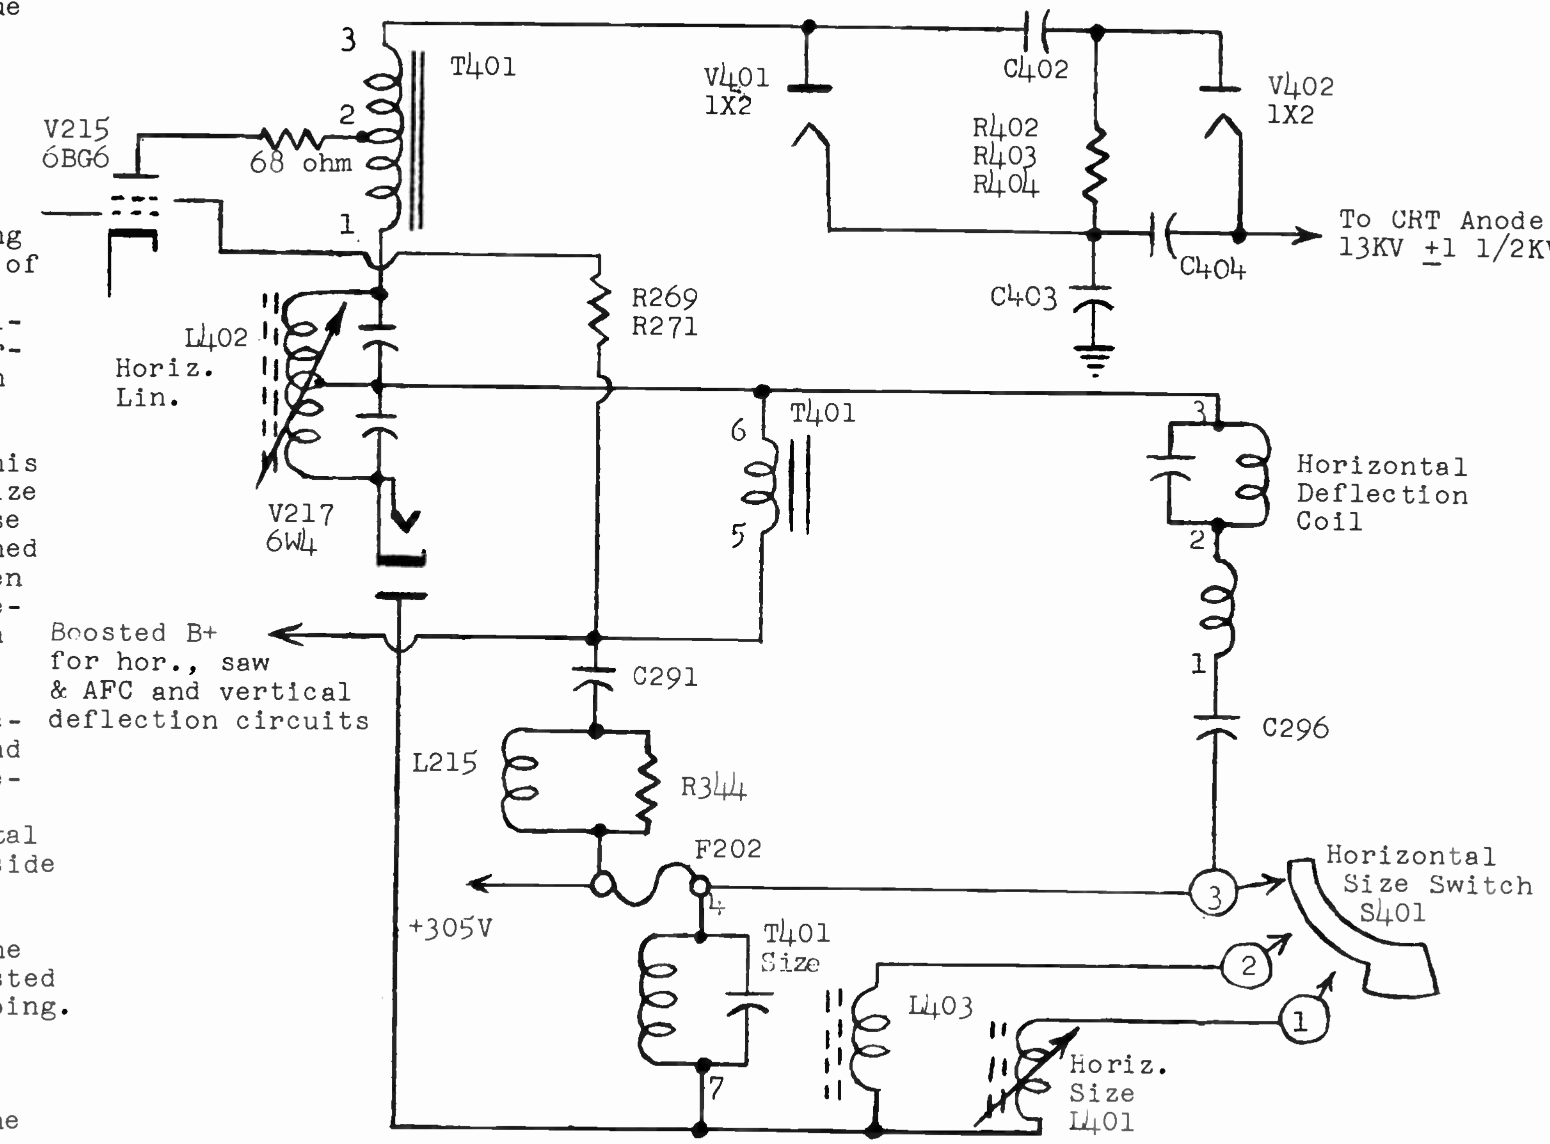
2.10 High Voltage Supply

The high voltage supply used in this Teleset is a voltage doubler type using two 1X2 rectifiers in cascade. The method of operation is the familiar "flyback" type. The high voltage pulse which appears between the 6BG6 tap (terminal 2) on transformer T401 and ground is stepped up in the conventional auto-transformer manner to a higher voltage pulse at terminal 3 of this transformer. These pulses are rectified and each 1X2 handles half of the total output high voltage of 13 KV ± 1 1/2 KV (at zero brightness). The high voltage appears across C403 and C404 in series to ground.

2.11 Low Voltage Power Supply

The low voltage power supply is very similar to that used in the RA-111A.

The differences in the circuit between the RA-111A and the RA-112A and RA-113 Telesets are as follows:



Simplified Schematic of Horizontal Flyback Circuit
RA-112A - RA-113

MODELS RA-112-A1, -A2, -A3, -A4, -A5, -A6, RA-113-B1, -B2, -B3, -B4, -B5, -B6, -B7, -B8

©John F. Rider

World Radio History

A separate filament transformer (T205) insulated for 5000 volts is used for the 6W4 (V217) due to the higher peak voltage found in this circuit.

A 100K resistor (R324) has been added from one side of the AC line to ground to reduce the shock hazard.

Three dial lamps (I201, I202 and I203), rather than one, are used and the dial lamp dropping resistor (R309) found in the RA-111A has been deleted in order to adequately light the different type of dial used in these Telesets.

The values of R280 and R281 have been changed due to the different focus coil (L209) used in these Telesets.

3.0 Installation Section

The serviceman should encounter no particular difficulty when installing one of the RA-112A or RA-113 Telesets. It is suggested, however, that if these are the first Du Mont Telesets he will install, that reference be made to the Installation Section of the RA-111A Service Notes for further information.

Particular attention should be given to the use of the proper coaxial cable. This will depend upon the signal strengths of the stations at the location where the set is to be installed.

4.0 Service Sheets

Although the basic RA-111A chassis is used in these models, sufficient changes warranted the issuance of a special schematic diagram.

As indicated on the RA-112A - RA-113 Alignment Sheet, the procedure will apply to the RA-111A Telesets as well as these models.

No new block diagram was issued since the block diagram will be the same as the RA-111A except for the additional tubes and, in the case of the 4th video IF and horizontal deflection amplifier, different tubes.

All adjustments on this model are identical to those in the RA-111A and the servicemen should refer to the "Block Diagram, Adjustments and Trouble Shooting Sheet for the model RA-111A".

5.0 Service Procedures and Troubleshooting Hints

This section of the service notes for the RA-112A RA-113 Telesets will include information pertaining to various servicing and troubleshooting procedures that require detailed information. Additions to this section will be made whenever necessary.

NOISY INPUTUNER

(See Section 5 of the RA-111A service notes for information on cleaning the Inputuner.)

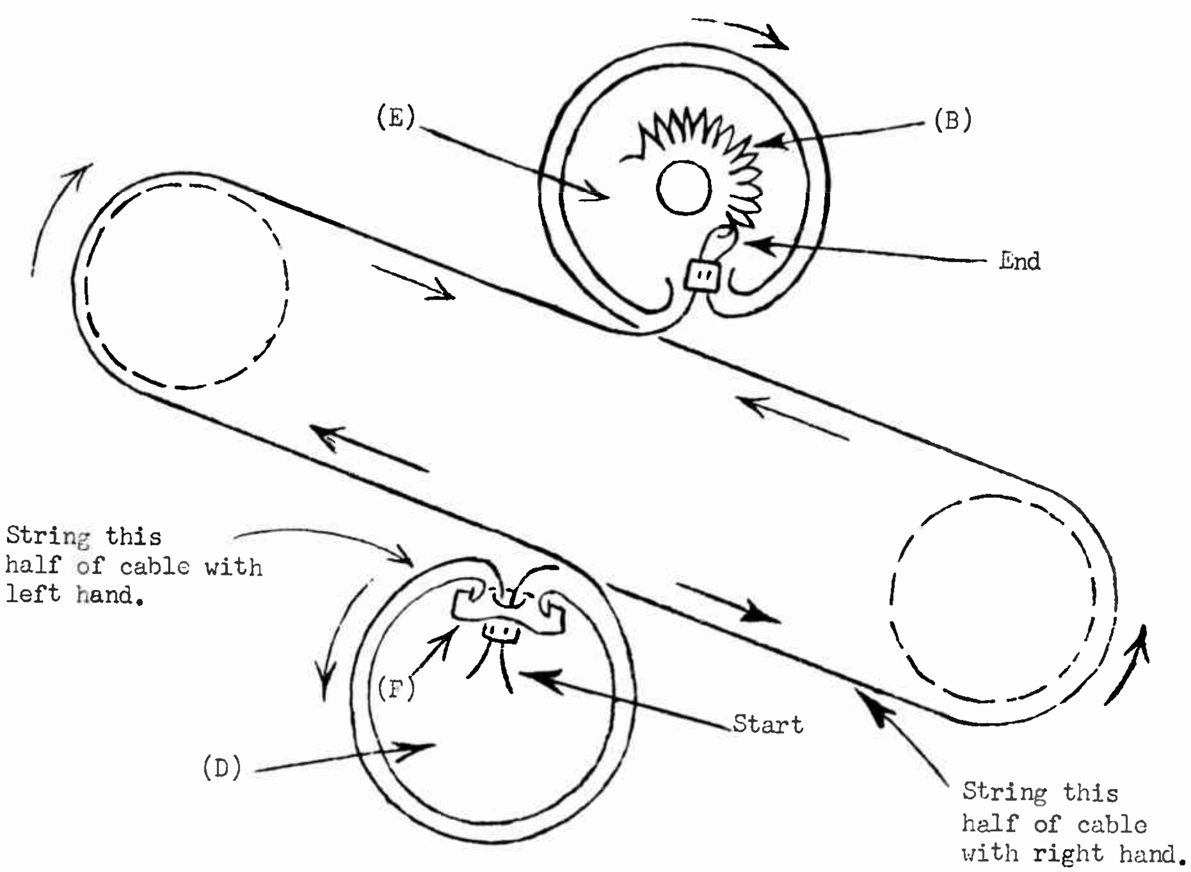
World Radio History

PROCEDURE FOR REPLACEMENT OF DIAL CABLE (30008310)

1. Remove three pilot lights, with their clips.
2. Remove dial pointer by pulling outward.
3. Twist four tabs (A) holding dial to mounting plate, and remove dial.
4. Remove defective dial cable, taking care to retain cable tension spring (B). If spring is missing, it may be obtained by ordering part #30014401.
5. Rotate Inputuner tuning shaft (C) full counter-clockwise. This will place the cam assembly (D) in the position shown.
6. Place pointer pulley (E) in position shown.
7. Fasten cable tension spring (B) to loop at end of dial cable.
8. String dial cable as shown, starting by placing cable guard (F) in position. Use both hands and string two halves of cable as illustrated. Make sure that cam follower (G) is not disengaged from cam (D).

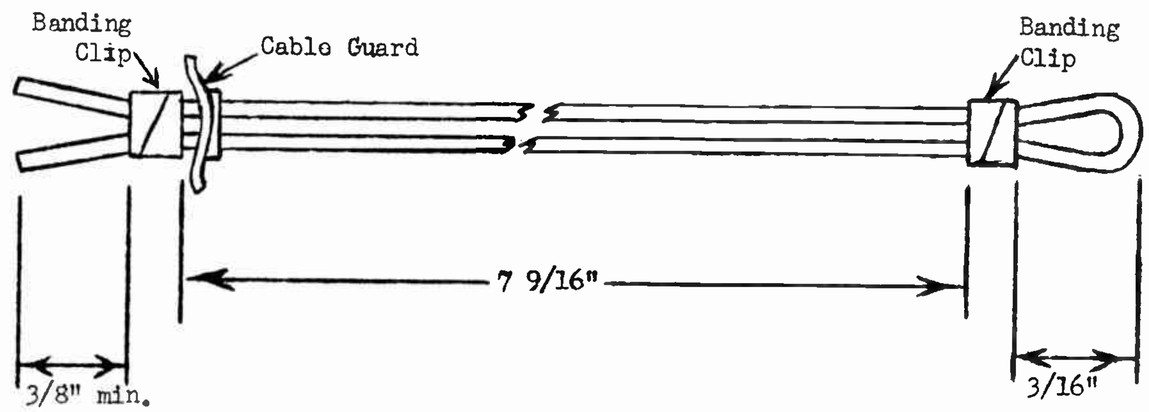
Note: If insufficient tension in cable, run cable tension spring (B) around pointer pulley (E) hub in direction opposite to that shown.

9. Replace dial, fastening by slight twisting of four tabs (A).
10. Replace three pilot lights.
11. Place Teleset in operation, tune in a known high channel station, and place dial pointer in correct position. Pointer should then fall in proper calibration for lower channels. If, necessary, minor adjustment of pointer position may be made to correct calibration. Take care that pointer does not rub against dial at any point.



DIAL STRINGING SKETCH

If dial cable not readily available, make up as follows:



PROCEDURE FOR DIAL CALIBRATION
(RA-112A below serial #126293 and RA-113 below serial #135323)

1. Remove three pilot lights, with their clips.
2. Remove dial pointer by pulling outward.
3. Slightly twist four tabs (A) holding dial to mounting plate, and remove dial. Care should be exercised not to break tabs(A).
4. If dial cable requires restringing, follow procedure shown previously.
5. If side (M) of dial mechanism is not parallel with side (N) of bearing bracket (O), loosen screws (I), (J) and (L) and square dial mechanism by aligning sides (M) and (N). Then tighten screws (I), (J) and (L).
6. Loosen screws (H) and (K).
7. Turn tuning shaft (C) fully counter-clockwise.
8. Turn cam (D) one turn clockwise until hole (P) in cam is aligned with hole (Q) in dial plate (R) behind cam (D).
9. Push gear (S) downwards until gears (S) and (T) mesh completely. Back gear (S) off slightly to prevent binding.
10. Re-check alignment of holes (P) and (Q).
11. Tighten screws (H) and (K).
12. Cautiously rotate tuning shaft (C) to check for binding of gears (S) and (T). If binding occurs, repeat steps 8, 9, 10 and 11.
13. Replace dial, fastening by <u>slight</u> twist of four tabs (A)!
14. Replace three pilot lights.
15. Return tuning shaft (C) to fully counter-clockwise position. Replace dial pointer so that it falls on high frequency side of channel 13 box by the width of the pointer.
16. Place Teleset in operation. Pointer should fall in proper calibration on all channels. Minor adjustment of pointer position may be made to correct calibration, if necessary, or four flanges at (A)(not tabs) may be bent slightly downwards. This will move calibration upwards on high channels (7-13) and downwards on low channels (2-6). Take care that neither pointer shaft nor pointer rubs against dial at any point.

Note: Calibration has been altered in some cases reported from the field due simply to the pointer sticking against the plastic dial window. To overcome this condition, the bolts holding the chassis mounting boards should be loosened and the chassis moun-

MODELS RA-112-A1, RA-112-A2, RA-112-A3, RA-112-A4, RA-112-A5, RA-112-A6, RA-113-B1, RA-113-B2, RA-113-B3, RA-113-B4, RA-113-B5, RA-113-B6, RA-113-B7, RA-113-B8

World Radio History

ting board moved backward as far as possible. The bolts should then be re-tightened. This will provide sufficient clearance between the dial pointer and the plastic window. The pointer should then be reset according to steps 15 and 16 above.

PROCEDURE FOR REPLACEMENT OF DIAL CABLE ON SKIP BAND TUNER 69003911 (used in RA-112A above serial #126293 and RA-113 above serial #135323)

1. Remove three pilot lights with their clips.
2. Remove dial pointer by pulling outward.
3. Twist four tabs (A) holding dial to mounting plate and remove dial.
4. Remove defective dial cable. (It consists of two identical cables. referred to as #1 and #2.)
5. Rotate the Inputuner tuning shaft (B) fully counter-clockwise (extreme high frequency position) and place pointer pulley (G) in position shown in dial stringing sketch.
6. Be sure that idler tension spring (C) is in place. If it is missing, it may be obtained by ordering part #30015901.
7. Wedge knotted end of dial cable #1 so that it is held in place by post on gear behind spiral pulley at (D).
8. String dial cable (1 in direction of arrows shown on dial stringing sketch. Dial cable #1 must ride in idler pulleys at (E) and (F) and must be strung on inside of groove of pointer (G) towards dial plate (M), making one complete turn around pointer pulley (G). Make sure that idler pulleys (E) and (F) are free to turn and move in and out.
9. Insert loop end of dial cable #1 over lance (H).
10. Hold pointer pulley (G) in position shown in photograph with rubber band (I) placed temporarily between (J) and upper left-hand tab (A).
11. Insert knotted end of dial cable #2 in hole at (K) and string in counter-clockwise grooves approximately four turns as shown in sketch.
12. String dial cable #2 in direction of arrows around pointer pulley (G) approximately one-half turn, as shown. Dial cable #2 must be strung on outside of groove of pointer pulley (G) away from dial plate (M).
13. Insert loop end of dial cable #2 over lance (L). Center dial cable #2 over extrusion(N).
14. Remove rubber band (I).
15. Cement knotted end of dial cable #2 in plate at (K).
16. Replace dial, fastening by slight twist of four tabs (A).
17. Replace three pilot lights.
18. With tuning shaft (B) fully counter-clockwise, replace dial pointer so that it falls just inside of high frequency side of channel 13 box by the width of the pointer.
19. Place Teleset in operation. Pointer should fall in proper calibration on all channels. Minor adjustment of pointer position may be made to correct calibration, if necessary. Take care that pointer does not rub against dial at any point.

PROPER POSITION OF AGC LOCAL-DISTANT SWITCH

If a condition is encountered in a strong signal area where the strongest station rolls vertically, whereas other stations hold sync properly, the trouble may be caused by improper setting of the local-distant switch. If the local-distant switch is set at the distant position in a strong signal area, it is possible that sync compression may result on the strongest stations, thus causing the picture to roll.

World Radio History

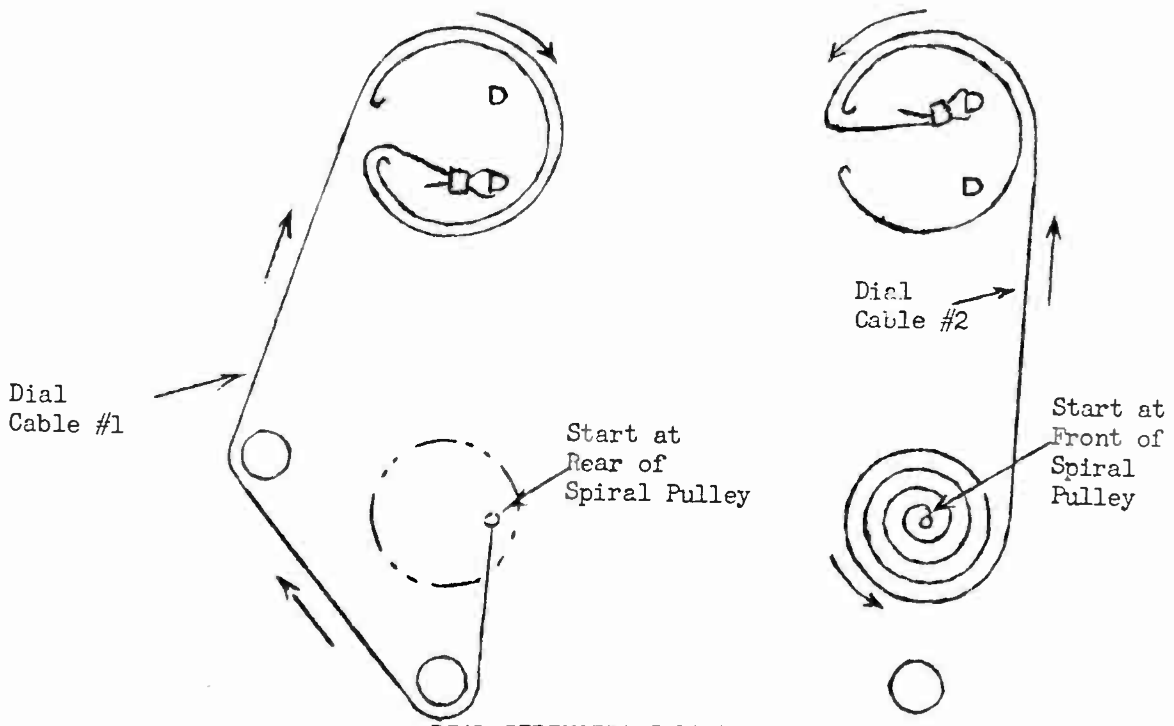
REDUCTION OF AM RADIO INTERFERENCE

Several cases of AM radio interference caused by sweep radiation have been reported. By-passing each side of the AC line at the Teleset with .02 mfd, 600 volt capacitors will reduce this interference. The capacitor leads should be kept as short as possible. The part number of these capacitors is 03018570. This change is incorporated in RA-112A Telesets beginning with serial number 1211601 and RA-113 Telesets beginning with serial number 1313901.

IMPROVEMENT OF SOUND SENSITIVITY

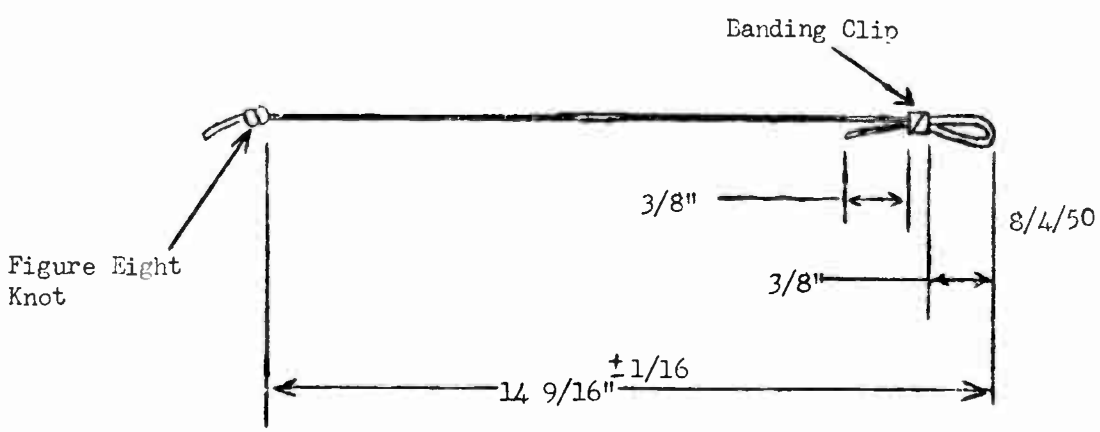
In any location where it is found that the sound output is insufficient, it may be substantially increased by making the following simple modification:

Connect a 10 mfd (or larger), 25 volt capacitor in parallel with R126 the cathode resistor of the 6AQ5 sound output stage. The part number for the 10 mfd, 25 volt capacitor is 03016730. This capacitor is being installed in current production.



DIAL STRINGING SKETCH
(above serial #126293 and #135353)
(Skip Band Tuner)

If dial cables are not readily available, make up as follows (two required):



ION TRAP MAGNET ADJUSTMENT

You have probably noticed that on current Telesets it is necessary to place the ion trap magnet over the base of the cathode-ray tube in order to get the correct adjustment for maximum brightness.

Although contrary to the installation instructions, this new position is the result of a slight change in the design of the electron gun in the cathode-ray tube. Due to this design change, the magnetic field necessary for proper beam bending is decreased. Therefore, the position of the magnet indicates that it is too strong to be placed on the glass neck and, therefore, must be placed back over the base. Under no conditions should this magnet be placed next to the focus coil.

DEFECTIVE VIDEO IF TRANSFORMERS

Some complaints of breakdown of the ceramic coupling condenser in the video IF transformers have been received. The condition encountered was an arc-over between the end of the silvered ceramic tube and the bare wire that fits in it. These transformers are used in the RA-112A and RA-113 Telesets. The condition was corrected by the use of a synthetic coated wire. It is not necessary to replace the entire transformer to correct this defect. Instead, the bare wire should be removed from the ceramic tube and a 1.5 mmfd 400 volt type GA-3 Stackpole capacitor, or equivalent, should be connected between terminals 2 and 4 (grid to plate) of the transformer. After making this change, a slight amount of rephasing of the grid and plate coils of the respective transformers will usually be necessary.

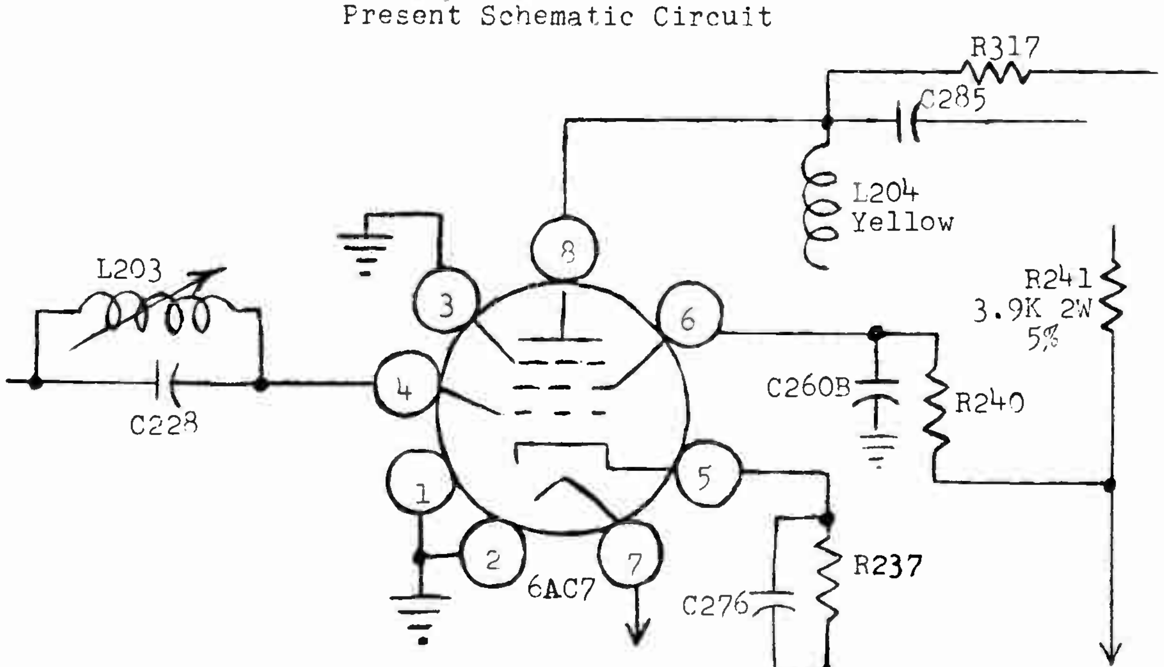
Video Amplifier Substitution
Present Schematic Circuit



9/1/50

Video Amplifier Substitution
New Schematic Circuit

CRITICAL TUBE SUBSTITUTIONS

(4811) 1. The type 6BA6 tube may be used as a replacement for the type 6AU6 in the first and second video IF stages, providing that both 6AU6's are replaced by two 6BA6's simultaneously. (This substitution may be made in the field in any of the current Telesets.)

(4812) 2. A type 6CB6 tube may be substituted for the 6AU6 in the second sound IF amplifier of the RA-112A and RA-113. This substitution requires the addition of a tube shield, part number 42002530, and a shield base, part number 42002540. The latter may be readily soldered in place in the field, rather than riveted or bolted.

(4813) 3. A 6CB6 may be substituted for the 6AH6 video amplifier, V210, in the RA-112A and RA-113 without any component changes but with a simple wiring change. Pins 2 and 7 must be interchanged and the plate circuit must be tied to a 200 volt point rather than 305 volts, as shown in the sketch following.

(4814) 4. A 6BC5 may be substituted for the 6AU6 first sync clipper, V219, in the RA-112A and RA-113. This change does not require the addition of parts or wiring.

(4789) 5. The type 6AC7 may be substituted for the 6Ah6 video amplifier in the RA-112A and RA-113 Telesets. This tube is not a direct substitute and several items will have to be changed. These are as follows:

(a) The socket is to be changed from a miniature (part number 34001220) to an octal (part number 34002380).
(b) R241 is to be changed from 4.3K 5% 2W (part number 92036631) to 2 3.9K 5" 2W (part number 02036620 alternate parts are: 02046620 and 02056620).

Any of the above substitutions that have been made can be determined by identifying the code number stamped on the back of the chassis and referring to the following table. Normally, you will find a large letter stamped on the rear of the chassis. Alongside of this letter will be a number. The significance of the letter designation will be found in the service notes pertaining to the model Teleset in question, providing it has a bearing on the service information. The numerical designation refers to one of those listed below and thus indicates the substitutions that are made.

Obviously, future additional substitutions will result in higher code numbers (5, 6, etc. for example). However, these code numbers will apply each time the substitution is made.

Substitution	Code Stamped on Chassis	Model	Teleset Serial Numbers Affected
4813	1	RA-113	1311027 to 1311736, Incl.
			1312719 to 1312999 "
4813, 4814	2	RA-113	1311737 to 1312718 "
4811, 4814	3	RA-112A	1213901 to 1214650 "
4811	4	RA-112A	1214651 - still in effect.

Although any of the above substitutions may be made in the field to Telesets not already incorporating these changes, it is important that the combination of substitutions 4811 and 4813 not be made together. The reason is that if both substitutions are applied to one set, a loss of gain will result. This will not be apparent in the strong signal areas. However, in the weak signal areas, the decrease in sensitivity will be noticed.

The substitution listed below has been incorporated in the chassis designated under the heading "Serial Numbers". No code number appears on these chassis as this procedure was not in effect at the time the substitution was made.

Substitution	Model	Serial Numbers
4789	RA-112A	1210824 to 1212823

MODELS RA-112-A1, RA-112-A2, RA-112-A3, RA-112-A4, RA-112-A5, RA-112-A6, RA-113-B1, RA-113-B2, RA-113-B3, RA-113-B4, RA-113-B5, RA-113-B6, RA-113-B7, RA-113-B8

World Radio History

6.0 Production Changes

Change #1 (M-117)

On Some early runs of RA-112A and RA-113 chassis, the sound discriminator transformer Z203 which was used was the same as that used in the RA-111A chassis. The circuit diagram of the discriminator circuit using the old type transformer is the same as that shown on the RA-111A Schematic Diagram (second edition, May 8, 1950.

This change with the addition of C299, coupling capacitor, is shown on the RA-112A, RA-113 Schematic Diagram (first edition, July 3, 1950) and was first incorporated in the following chassis starting with the serial number shown:

RA-112A - #123594
RA-113 - #132957

Purpose of Change - To increase the sound sensitivity.

Change #2 (M-132)

This change was made to alleviate interference on channel 7 by adding capacitor C230, .005 mf from pin 4 of V203 to ground. This change is shown on the RA-112A and RA-113 Schematic Diagram (first edition, July 3, 1950).

This change was first incorporated in the following chassis starting with serial number shown:

RA-112A - #12029
RA-113 -- #13497

Change #3 (M154) (ECN-4418)

The following changes are made to relieve regeneration, and to increase accompanying sound attenuation.

1. Add a 10K, (R305) 1/2 watt resistor across L202.
2. Add resistor R272, 68K ohms, across Z208-1 and Z208-2.
3. Change a .005 capacitor C230 from present location, pin 4 of V203 to ground, and connect it from ground to pin 4 of V207.
4. Change L213 from part #21005902 to part #21006781. This coil has lower inductance range obtained by using fewer turns.
5. Redress and shorten lead from junction of R237, C276 (cathod circuit of video amplifier, V210) to contrast control R239A, as shown in the sketch. Keep this lead away from the Inputuner.
6. Capacitor C290, .005 mf condenser is connected at junction of R246 and S135 volt line to ground.
7. Change C238 from .001 paper to .001 ceramic or mica, part #03015810 or part #03020730; and move to AGC lead closest to narrow band sync shield.
8. Add L205, part #21004465 between video detector and video detector peaking coil.
9. Add tube shield on 6BC5 fourth video IF amplifier tube.
10. L201 is to be changed from part #21006629 to part #21006627.

New parts are identified as follows:

Symbol	Part Number	Description
C238	03015810 03020730	Cap Ce .001 mf 20% 350V
C290	03015610	Cap Ce .005 mf min
L201	21006627	Coil Video Peaking
L205	21004465	Coil Video Peaking
L213	21006781	Coil Coupling
R272	02031990 02041990 02051990	Res F C 68K 10% 1/2W
R305	02031890 02041890 02051890	Res F C 10K 10% 1/2W
	42002530	Shield Tube
	42002540	Base Shield

These changes were first incorporated in the following chassis starting with the serial number shown:

RA-112A - #125274
RA-113 - #134415

All Telesets which have the above changes made - from change #1 to change #3 are stamped with letter "F" on rear of chassis.

Change #4 (M-164)

The following change is made on the RA-113 chassis only:

Resistor R296 (Pin 2, V220B) is changed from 4.7K to 5.1K.

New part is identified as follows:

Symbol	Part Number	Description
R296	02030650 02040650 02050650	Res F C 5.1K 5% 1/2W

Purpose of Change

Change is made due to a difference in the DC resistance of the yokes used in the RA-112A and RA-113.
This change was first incorporated in RA-113 chassis #138072 and letter "H" is stamped on rear of chassis.

Change #5 (M-169)

The following change is made in order to provide a glass window dial in place of the plastic window.
The part should read as follows in the Miscellaneous Parts List for the RA-112A and RA-113.

Part Number	Description
45002491	Window dial

©John F. Rider

World Radio History

Change #6 (M-172)

Capacitor C216, 10 mf is added in parallel with R216, 270 ohm, cathode resistor of 6AQ5 second sound amplifier.
New part is listed as follows:

Symbol	Part Number	Description
C216	03016730	Cap E 10 mf 25V
	03014100	
	03015310	

Purpose of Change - To increase the sound sensitivity.

Change #7 (M-188)

Add capacitors C304 and C305, .02 mf condensers from each side of the AC line to ground.
New parts are identified as follows:

Symbol	Part Number	Description
C304	03018570	Cap Pa .02 mf 20% 600V
	03100230	
C305	Same as C304	

Purpose of Change - To reduce sweep radiation.
This change was first incorporated in the following chassis starting with the serial numbers shown:
RA-112A - #1213901
RA-113 - #1311795

These chassis are identified by a letter "J" stamped on rear of chassis.

Change #8 (ECN-4396)

The following changes are made to the RA-112 - RA-113 Schematic Diagram (first edition, July 3, 1950):

Color of peaking coil L201 changed from red to white.
Color of peaking coil L202 changed from white to orange.
Color of peaking coil L204 changed from yellow to blue.

New parts are identified as follows:

Symbol	Part Number	Description
L201	21006627	Coil Video Peaking
L202	21006624	Coil Video Peaking
L204	Same as L201	

Change #9 (ECN-4406)

Delete coupling capacitor C299 connected from pin 1 of V203 to ground.
Purpose of Change - Part is not required.

Change #10 (ECN-4419)

Inputuner assembly is replaced by new Skip Band Inputuner.
(See Note)
New unit is identified as follows:

Old Part Number	New Part Number	Description
89003902	89003911	Inputuner Assembly

The new Skip Band Inputuner was first incorporated in the following chassis starting with the serial numbers shown:
RA-112A - #126293
RA-113 - #135323

Note: If the tuner (Part #89003902) being replaced is in an RA-112A Teleset the serial number of which is 122696 or later, or if it is in an RA-113, the serial number of which is 132212 or later, the Skip Band Tuner is directly replaceable. However, if the tuner (Part #89003901) being replaced is in a Teleset the serial number of which is under those mentioned above, it will be necessary to remove the IF transformer mounted on the defective Inputuner and substitute it in place of the IF transformer mounted on the replacement tuner. The reason for this change is that the method of coupling with the new type tuner is different from that in earlier tuner.

Change #11 (ECN-4428)

Change value of capacitor C237 (V213-1 to ground) from 150 mmf to .05 mf.
New part is identified as follows:

Symbol	Part Number	Description
C237	03000950	Cap Pa .05 mf 20% 200V
	03100030	

Purpose of Change - To reduce tuneable hum.

This change was first incorporated in the following chassis starting with the serial numbers shown:
RA-112A - #1214676
RA-113 - #1312685
These chassis are identified by a letter "K" stamped on rear of chassis.

Change #12 (ECN-4391)

Specifications for the 19" CRT (V215) used in RA-112 models are changed due to change in color of face plate.
Cathode ray tube is now identified as follows:

Symbol	Part Number	Description
V211	25002640	Tube CRT 19AP4A

Change #13 (M-192)

The following changes in fuse connections (F202 are made as shown in sketch. This is done to reduce AC current through the fuse.

Dotted lines indicate old fuse connections.
Solid lines indicate new connections

7.0 PARTS LIST CHANGES

The following changes of part numbers and additions of alternate part numbers (items 1 - 4) are to be made to the Parts List of the first edition (July 3, 1950) of the Schematic Diagram for the RA-112A, RA-113 (issue #4 through M-146).

1. Part number changes in Main Chassis Parts List (June 17, 1950)

Symbol	Part Number	Description
C216	03016730	Cap E 10 mf 250
	13014100	
	03015310

Change in Fuse Connection (F202)
To Reduce AC Current Through The Fuse

©John F. Rider

World Radio History

Note: Chassis incorporating all changes up to and including change #13 are stamped "V" on the right-hand side of the power supply.

Change #14(ECN-4366)
This change was made to prevent breakage of the AC interlock; the mounting bracket being redesigned.

The parts affected:

Old Part No.	New Part No.	Description	Model
35008761	35008762	Bracket AC Interlock	RA-112
09016450	09005000	Connector Male 2 contact	RA-112 RA-113
	35008763	Bracket AC Interlock	RA-113

Telesets incorporating this change are stamped with a letter "G" on the back of the chassis starting with the following serial numbers:
RA-112A - 127168 RA-113 - 136278

Note: Chassis incorporating all changes up to and including change #14 are stamped "W" on the right-hand side of the power supply.

Change #15 (M-198)

The following changes are made to increase the sound sensitivity and improve the limiting action in the RA-112, RA-113 chassis:

1. Change V205 and V207 from 6AU6's to 6BA6's.
2. Remove R222, the 8.2K in the screen supply circuit of V205. Connect the junction of R220, (screen dropping resistor of V205) and R225 (screen dropping resistor of V206) to the +135 volt line.
3. Remove R220 (1K screen dropping resistor of V205) and R229 (1K screen dropping resisotr of V207) and replace each with a 10K 1/2W 10% resistor.
4. Connect a 100K 1/2W 20% resistor between terminals 1 and 2 of Z202. This will be identified as R278.
5. Connect a 47K 1/2W 20% resistor between terminals 3 and 4 of Z201. This will be identified as R277.
6. Disconnect Z205 (blue dot) and Z206 (red dot) and exchange the positions of these two transformers.
7. Remove R227 (39 ohm cathode resistor of V206) and replace with a 120 ohm 1/2W resistor.
8. Remove C219 (.005 mfd cathode bypass of V207) and connect from pin 7 of V206 to ground.
9. Remove R228 (120 ohm cathode resistor of V207) and replace with a 68 ohm 1/2W resistor.
10. Disconnect terminal #3 of Z206 from ground.
11. Disconnect C217 (.005 mfd) and R223 (10K) from pin #3 of Z205 and reconnect to pin #3 of Z206 (see step 10.)
12. Connect terminal #3 of Z205 to ground.
13. Disconnect C280 (2.5 mmfd) from terminal 2 of Z205 and reconnect to terminal 2 of Z206.

Note: All of the above changes appear in the second edition of the schematic diagram for the RA-112, RA-113, dated October 2, 1950.

After making the above changes Z205 and Z206 should be realigned. Z205 should be aligned for the response curve listed for Z206 and Z206 should, therefore, be aligned for the response curve of Z205.

New Parts are identified as follows:

Symbol	Part Number	Description
C280	03016898	Cap Coupling 2.5 mmf
R220	02032480 02042480 02052480	Res F C 10K 10% 1/2W
R224	02031660 02051660	Res F C 120 ohm 10% 1/2W
R228	02031630 02051630	Res F C 68 ohm 10% 1/2W
R229	Same as R220	
R277	02032520 02042520	Res F C 47K 20% 1/2W
R278	02032540 02042540 02052540	Res F C 100K 20% 1/2W
V205	25000240	6BA6 1st video IF
V207	25000240	6BA6 3rd video IF
Z205	20004741	Trans video IF
Z206	20004711	Trans video IF

This change was first incorporated in the following chassis starting with the serial numbers as shown:
RA-112A - 1216694 RA-113 - 1314251

These chassis are identified by the letter "L" stamped on the rear of the chassis.

Change #16 (M-202)
The following changes are made in order to eliminate video smear in the video amplifier section of the RA-112A - RA-113 chassis.

1. Change value of R235 between L201 and ground from 4.3K to 3.9K 5% 1/2W.
2. Change value of R241 between L204 and +305 V from 4.3K to 3.9K 5% 2W.
3. Change value of R240 between V210-6 and +305 V from 62K to 68K 5% 1W.
4. Change value R305 between L205 and L203 from 10% to 10K 5% 1/2W. (See change #3).
5. Disconnect parallel combination of R305 and L202 and replace with solid connection.
6. Add R305 and L202 in series with V210-5 and the junction of R317, C285 and L204.
7. Change value of L202 from orange to red.
8. Disconnect C231 from junction of L204, C285, R317, and connect to V210-5.

New parts are identified as follows:

Symbol	Part Number	Description
R235	02030620 02040620 02050620	Res F C 3.9K 5% 1/2W
R240	02033920 02043920 02053920	Res F C 68K 5% 1W
R241	Same as R235	
R305	02030720 02040720 02050720	Res F C 10K 5% 1/2W
L202	21006623	Coil video peaking.

World Radio History

This change was first incorporated in the following chassis starting with serial numbers as shown:

RA-112A - 1213684 RA-113 - 1314090

These chassis are identified by the letter "L" or "N" stamped on the rear of the chassis.

Change #17 (M-204)
The following change is made to eliminate video from sync which is occurring in some receivers and causing slight displacement of some parts of the picture. This condition can also cause a "whip" in the picture.

Change value of C298 between V212-1 and V209A-1 from 20 mmfd to 47 mmfd 10% 500V ceramic.

Symbol	Part Number	Description
C298	03012730 03015300 03020080	Capacitor Ce 47 mmfd 10% 500V.

This change was first incorporated in the following chassis starting with serial numbers as shown:
RA-112A - 1213684 RA-113 - 1314090

These chassis are identified by the letter "L" or "N" stamped on the rear of the chassis.

Change #18 (M-208)
The following change is desirable to provide greater surge protection for capacitor C291.

Change value of C291 from .02 mfd 10% 400V to .02 mfd 20% 600V.

New part numbers:

Symbol	Part Number	Description
C291	03015550 03100230	Cap .02 mfd 20% 600V

Change #19 (M-206)
In order to minimize horizontal frequency drift the present capacitor C246 is to be replaced by an oil impregnated type of the same value.

New part number:

Symbol	Part Number	Description
C246	03101540	Cap .01 5% 600V

Change #20 (M-212)

The following change is made in order to increase the sensitivity of the AM Tuner (in RA-113 Tarrytown).

Procedure:

Delete R419, 270K resistor replacing it with a wire jumper.

Change #21 (M-215)
The following change is to be made to reduce the possibility of vertical frequency drift.
Procedure:
Change value of C271 from .01 10% 400V to .01 5% 600V.

New part numbers:

Symbol	Part Number	Description
C271	03101540	Cap Pa .01 mfd 5% 600V

All production changes prior to this point are incorporated in the Main Chassis Schematic RA-112A RA-113, Second Edition, 10/2/50, and Tarrytown AM Tuner Schematic, First Edition, 8/15/50.

Change #22 (M-222)
The following change was made in order to decrease audio distortion at rated output.

Procedure:

1. Delete R308.
2. Change value of R307 from 3.9K to 1K 2W 10%.
   Both these resistors are located near V204-6.

New Part numbers:

Symbol	Part Number	Description
R307	02037770	Resistor F C 1K 2W 10%

Change "23 (M-239)
The following change should be made to prevent the shrinkage or complete loss of vertical size due to the increasing resistance of R294 caused by overheating.

Procedure:

Change R294, near V220B, from 910K 5% 1/2W to 910K 5% 1W.

Part Numbers affected:

Symbol	Part Number	Description
R294	02034190	Res F C 910K 5% 1W

Change #24 (M-213)
Several wiring changes have been made to simplify the manufacturing process and eliminate certain difficulties that existed due to lead dress and component location. None of these changes require new mechanical parts or electrical components.
The most significant change as far as servicemen are concerned is the relocation of R324 and C305. The new location will reduce sweep radiation and improve the audio noise level.
These parts have been removed from the front of the chassis (formerly connected from the terminal of power switch to ground) to a terminal strip at the rear of the chassis near the power transformer.
The chassis containing these changes are identified by a large letter "P" on the rear fold of the chassis. The serial numbers of the chassis containing these changes are:
RA-112A - 1216766 RA-113 1314928
The number 5 which follows the letter P signifies that a 6BC5 is substituted for a 6AU6 in the first sync clipper stage.

©John F. Rider

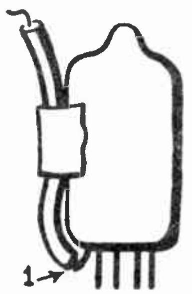
World Radio History

PRELIMINARY STEPS

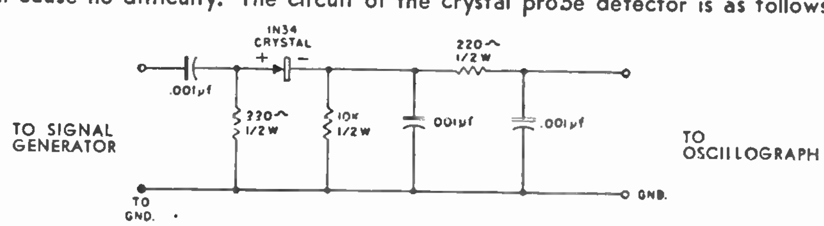
CAUTION: IT IS IMPORTANT THAT ALL NOTES BE READ IN CONJUNCTION WITH ALIGNMENT.

The following preliminary steps should be followed:
Remove 6W4 (V217) damper, 6AK5 (V102) mixer, 6AB4 (V103) oscillator, 6AQ5 (V204) AF output (note 1) and 6AU6 (V219) first sync clipper.
Adjust AGC control (R250) fully counter-clockwise. Turn selector switch to tele. position.

ALIGNMENT NOTES



1. 6AQ5 (V204) may be left in position only if speaker is connected.
2. Insert 6AU6 adapter at V219. This is a 6AU6 with pins 3 & 4 clipped off and an extension attached to pin 1. (Pin 1 is not clipped.)
3. If the sweep generator has no internal marker, a signal generator may be connected to the output cable of the sweep generator through a 100 mmf condenser to act as a marker generator.
4. Insert 6AK5 adapter at the mixer, V102. This adapter is a 6AK5 with pin 1 clipped off and an extension attached to the remainder of pin 1, as shown.
5. Inputuner should be tuned to channel 7, or higher.
   L213 adjusts the coupling. The bottom adjustment of T202 is reached through top of can with hex head alignment tool. Whenever the Inputuner is replaced, Steps 7 and 8 must be performed. RA-112A chassis bearing a serial number below 122696, and RA-113 below 132212, do not contain L213 and the following pertains: The bandwidth of the 1st stage of video IF is controlled by a coupling loop in the mixer transformer, T202. This is adjusted and sealed in position at the factory and should not be touched. However, in case of replacement of the Inputuner, it should be adjusted for the curve shown in Step No. 8. Steps No. 7 and 8 may have to be performed in order to obtain the proper curve. After adjustment, fasten the coupling loop in T202 with Miracle Adhesive C2M55 (obtainable from Du Mont Spare Parts Sales).
6. Maximum possible output of the sweep generator should be used, checking for overload.
7. If this curve cannot be obtained, proceed to Step 7, followed by Step 6.
8. If difficulty is encountered obtaining the proper bandwidth, heat the wire protruding from the bottom of this transformer with a soldering iron to soften the adhesive. Then slide the wire in (for increased bandwidth) or out (for decreased bandwidth) of the sleeve. Seal the wire in place with Miracle Adhesive C2M55 (obtainable from Du Mont Spare Parts Sales).
9. Reference is made in the Alignment Table to the use of a crystal probe. This device is merely a crystal rectifier with the necessary filter. The polarity of the curve will be reversed if the terminals of the 1N34 crystal are reversed. This will cause no difficulty. The circuit of the crystal probe detector is as follows:



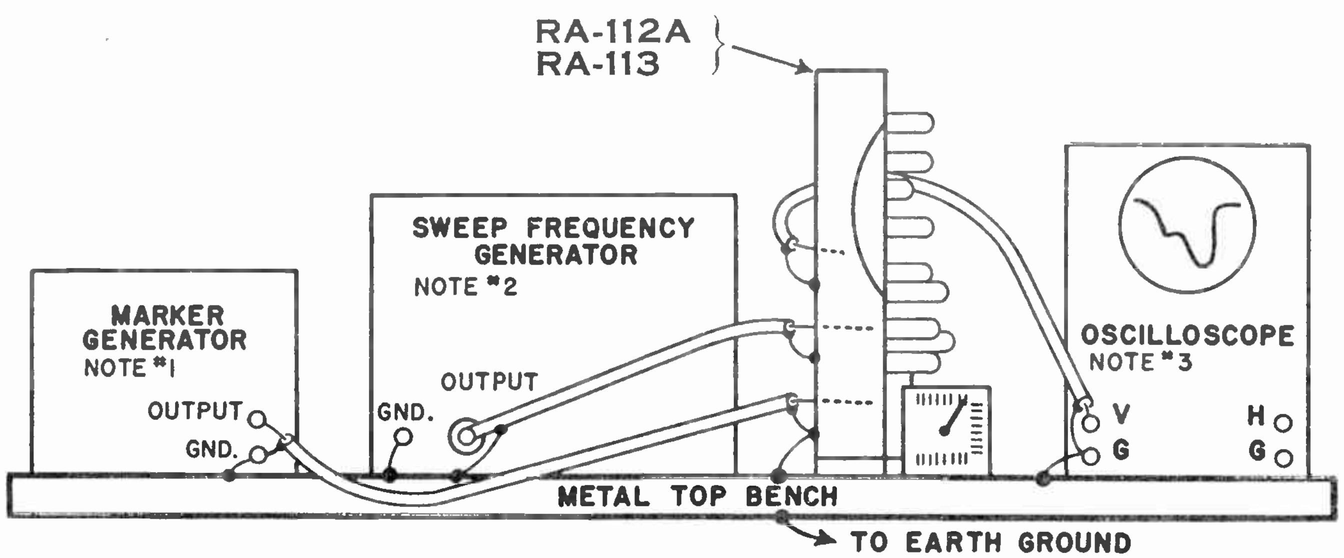
PROBE DETECTOR

10. Tune by tuning eye to the strongest station. Turn AGC control fully clockwise. Then turn this control counter-clockwise until the picture brightens. Finally, turn slowly clockwise to point where picture just starts to dim.
11. Even though the alignment has been performed properly, it is usually necessary to correct the phase response of the video IF strip in order to remove smearing and ringing from the picture. This is done in the factory by applying a 61.25 mc signal modulated by a 100 kc square wave to the front end of the Teleset and displaying the detected square wave (which has passed through the video strip) on an oscillograph after amplifying it by means of a special wideband amplifier. The alignment is checked by observation of the square wave and SLIGHTLY re-adjusted, if necessary. If slight re-adjustment does not correct the square waveform, the chassis is completely re-aligned. A practical approach to this method in the shop (after completing the alignment procedure) is to tune in a strong test pattern known to be of good quality and ghost-free (by observation on several normal Telesets). If smearing or ringing is observed, the following adjustments are recommended. No other adjustments should be made. Limit adjustments only to those absolutely necessary.

    SMEAR: Re-adjust Z204 bottom slug not more than 1 turn.
    Re-adjust Z208 bottom slug not more than 1/2 turn.
    RING: Re-adjust Z205 top slug not more than 1/2 turn.
    Re-adjust Z207 top slug not more than 1/2 turn.

ALIGNMENT SET-UP

1. Keep all coax cables as short and as well shielded as possible.
2. Ground metal bench to a good earth ground.
3. To test set-up feed signal into grid of mixer thru a 100 mmf condenser. If placing hand on any chassis or adding additional grounds at any point affects waveform or if Teleset has a tendency to oscillate, grounding must be added until these effects disappear.



NOTES:

1. Unmodulated and amplitude modulated RF should cover 20 to 30 mc range. Also 4.5 mc. Not necessary if marker is built into sweep frequency generator.
2. Should have center frequency range from 20 to 30 mc. Sweep should be adjustable up to 6 mc at least.
3. We recommend use of internal saw-tooth sweep. Waveforms shown were taken using this sweep. External sweep from sweep frequency generator may be used if preferred.

14	Adjust AGC control, R250. Note 10					
15	Phase correction. Note 11					

CP indicates that oscillograph is connected through crystal probe.
DIR indicates that oscillograph is connected directly.
Refer to top and bottom photos on reverse side of this sheet for reference points.

*RA-112A chassis bearing a serial number below 12702 and RA-113 below 13580 utilize a sound IF of 21.9 mc. and a video IF of 26.4 mc. For re-alignment of these chassis, use the RA-111A Alignment Procedure. In areas where the 8th harmonic of the 21.9 mc. sound IF causes a beat pattern on channel 7, these early chassis may be re-aligned to a sound IF of 21.75 mc., using this Alignment Procedure.

NOTE: THIS PROCEDURE MAY BE USED ON THE RA-111A WHENEVER THE 8TH HARMONIC OF THE 21.9 MC. SOUND *IF* CAUSES A BEAT PATTERN ON CHANNEL 7.

RESISTANCE READINGS OF COILS

(All readings in ohms)

All coil readings shown were taken with coils disconnected.

Symbol	Reading
L201	10.5
L202	7.3
L203	2.5
L204	5.6
L212	.2
L214	1.5
L215	3

NOTES

1. Issue No. 4 through M-146.
2. Voltage, resistance and waveform measurements.
   a. Instrument used—RCA Model 195-A Voltohmyst (for voltage and resistance).
   b. Voltage measurements taken to ground, no signal input.
   c. Voltage measurements made with switch in TV position; contrast and brightness minimum.
   d. All coil readings were taken with coils disconnected.
   e. Video waveforms measured with contrast set for 30 volts p—p at cathode of CRT.
   f. Local-Distance Switch in local position.
3. Selector Switch section viewed from front end of switch. Rotor in TV position. Switch positions: 1. Phono, 2. TV, 3. F.M.

ALIGNMENT PROCEDURE FOR TARRYTOWN AM TUNER

The alignment should be made with the volume control fully on and tone control set for high frequency response. The output from the signal generator should be maintained as low as possible to prevent A. V. C. action from interfering with the correct alignment.

Connect an output meter across the voice coil of the speaker. Turn on signal generator and AM Tuner for approximately five minutes to stabilize. Connect a common ground to each unit. When connecting the signal generator output leads to the receiver, place a .25 mfd condenser in series with the inner conductor of the signal generator output lead.

1. Turn the tuning dial to the extreme low frequency end (gang condenser fully closed). At this position the tuning dial pointer should be halfway below the 550KC mark and the ends of the two concentric semi-circles.
2. Connect the signal generator output lead to the converter stator of tuning capacitor C401.
3. Set signal generator to 455KC and adjust tuning slugs (secondary and primary) on IF coils Z402 and Z401 in the order given for maximum deflection, reducing generator output as required. Repeat tuning until maximum output is obtained.
4. Connect generator to antenna input terminal.
5. Turn tuning dial pointer to 600 KC. Feeding in a 600KC signal from generator adjust oscillator coil L403 for maximum output.
6. Turn tuning dial pointer to 1500KC. Feeding in a 1500KC signal from generator adjust RF, converter and oscillator trimmers on tuning capacitor C401 for maximum audio output.

INDEX

Placement of Receiving Tubes

1. The receiving tubes shall be placed in the following sockets:

Socket	Tube type
A	5U4G L. V. Rectifier
O	5V4 Damper
Q	1B3/8016 H. V. Rectifier
I	6SN7 Vertical Osc. & Amp.
(in tuner)	6AK5 and 12AT7
E	6AU6 First Sound I.F.
F	6AU6 Second Sound I.F.
G	6T8 Sound Discriminator
H	6V6GT Audio Output
D	6AG5 First Video I.F.
C	6AG5 Second Video I.F.
B	6AG5 Third Video I.F.
K	6SN7 Video detector and 1st Video Amp.
L	6SN7 Video Output
M	6SN7 Separator and Sync. Amp.
N	6SN7 Hor. A.F.C. and Oscillator
Q	6AU5 Horizontal Output
Horizontal Transformer	2 - 1V2 High Voltage Rectifiers

The Picture Tube

The picture tube used with this kit is the 16GP4 metal shell, short, wide angle cathode ray tube. Before installing the picture tube be sure that all tubes are in place and firmly seated in their sockets. The picture tubes should be removed from its carton and handled carefully with both hands on the mètal portion. Try not to touch the flared glass portion of the tube immediately ahead of the neck as this is an insulating barrier between the charged portion (shell) and the deflection components (yoke, etc.) and finger marks can cause a leakage path for the high voltage to flow to ground. Never handle the tube by the neck unless it is held face down as this is a dangerous way to handle picture tubes. Note that there is a metal lip around the circumference of the tube at the screen end. This serves the purpose of allowing the anode connector to clip on and also serves to engage the plastic insulating ring which should be mounted at this time after snapping connector in place. The connector can be mounted at any point along the lip. The neck of the tube should now be inserted through the deflection yoke and focus coil assembly and pushed back until it is firmly seated against the exposed coils of the yoke. The plastic ring should rest on the thin portion of the tube rest. The beam bender should then be slipped on the neck of the picture tube. The correct adjustment of the beam bender will be determined later when testing for the raster of light, its function being to insure brightest illumination on screen. Do not connect high voltage anode wire to connector or connect picture tube socket to tube yet. CAUTION. DO NOT PLUG SET INTO A. C. OUTLET YET. ALSO ON HIGH VOLTAGE CHECK YOU MUST REALIZE AT ALL TIMES THAT THE METAL SHELL IS HIGHLY CHARGED AND CONTACT WITH ANY PART OF THE SHELL WILL RESULT IN A SHOCK. (STARTLING, BUT NOT DANGEROUS).

Alignment of Picture and Sound

Before attempting alignment, be sure that your antenna lead-in is connected.

1. Check with your local television station to find what hours during the day the static test pattern and sound signal is being transmitted. The station provides this service to assist in the alignment of receivers.

2. Procure these items:

   One (1) Pair Earphones
   One (1) .1 Condenser at 400 V.
   One (1) Tuning Stick (preferably plastic, non-metallic)

3. Proceed to align Receiver as Follows:

   (a) Turn set off, connect the .1 condenser to one of the earphone leads. Leave the other lead of the condenser open. Attach an alligator or similar clip to the other earphone lead and another clip to the open lead of the condenser. Clip the earphone lead to the chassis and the condenser lead to the #2 lug of socket L. Turn the channel selector to the number of your local television station. Turn on set. You can now "listen in" on the picture signal when it comes through. Be sure that volume control and contrast control are at full clockwise setting.

   (b) Rotate fine tuning condenser shaft and listen for buzz in earphones. If buzz gets too loud or blocks out reduce contrast control setting slightly. Keep brightness about halfway.

   (c) If no buzz is heard on this channel position of tuner, try same procedure on the channel above and channel below the channel number of your local station. If signal is heard there then it indicates that your I.F. Coils

©John F. Rider

World Radio History

are set too high or too low. If results are negative then check antenna connections and positioning. If everything appears normal but still no buzz then check wiring and refer to technical section of your service notes.

(d) If buzz is heard picture content should appear on raster but probably will be streaking or jumping. Adjust vertical hold control to keep picture from jumping or sliding. If picture elements are streaking across screen then try to stop them with horizontal hold control.

(e) If a vertical bright bar appears on the left side of picture then slowly adjust the horizontal drive trimmer until it disappears. This trimmer also aids in adjusting for maximum high voltage. Adjust slowly until picture appears brightest. This adjustment should be clockwise.

(f) Adjust focus control until clearest line formation is obtained on picture. Adjust brightness control until satisfactory brilliance is achieved. Do not make too bright as it will impair picture quality. Note: it is sometimes necessary to move focus coil slightly along neck of tube and rotate slightly to secure focus. Before doing this adjust focus control to about mid-setting so that it will take picture through focus point after focus coil adjustment is made. After adjusting coil secure that position with shim.

(g) Remove earphone clip from set and locate the second sound I. F. coil. This is coil in hole #12. Rotate slug until sound is heard in speaker. Adjust for maximum volume. Adjust slug on top of discriminator can for maximum volume. Adjust slug which is mounted in the bottom of the can for best quality of sound with least incidental noise. For all difficulties encountered, refer to the technical section for service notes.

(h) A simple and effective means of aligning the picture I.F. coils is by the measuring of the brass tuning shafts from chassis to tip with a ruler. The Telekit is properly aligned when the measurements are as follows:

Coil	Inches
Hole 27 (second video)	3/4
Hole 12 (second sound)	3/4
Hole 24 (third video)	3/4
Hole 31 (fourth video)	7/8
Hole 23 (sound trap under chassis)	0 (all way in)
Top of Discriminator	1/2
Bottom of Discriminator	5/8

This sould provide pictures and sound of excellent quality. The fine tuning control will enable you to center the sound with the picture. For more precise information on coil alignment look under "Alignment of Telekit with Instruments" in technical section. If sound bars are seen in picture when picture and sound are coming in together turn out sound trap slug (hole #23) until they disappear.

(i) After all adjustments have been made on the I. F. coils, they should be locked with liquid cement or dope. This is important if the set is to be moved about much, as vibration will cause the slugs in the coils to change position.

(j) This television receiver will perform best with a television antenna kit and a 300 ohm lead in line. These may be purchased for a small cost from your jobber. For urban use, a single dipole kit or a folded dipole kit may be used. For suburban use, a multi-element antenna kit should be used. Antenna installations should be of sufficient height as to clear any "line of sight" obstacles between the transmitter and receiver. In some remote instances a "tower" may have to be used to secure satisfactory reception.

(k) Always locate your television receiver in a part of the room where no direct sunlight or window light falls on screen. After set is mounted in cabinet, it should be placed in its permanent place and should not be moved about. Always be sure to turn off your set when not in use. This will extend the life of your picture tube.

The following is a list of possible failures and an indication of procedure for their corrections:

	Indication	Possible Trouble
A.	No raster on kinescope No light	(1) No high voltage - see notes on "Checking High Voltage". (2) Defective Kinescope - heater open, open brightness control. (3) Incorrect adjustment of beam bender. (4) Damper inoperative. Check heater winding. (5) No B plus, shorted electrolytic or choke open. (6) Open peaking coil or resistor in plate circuit of video output. Check also for open cathode resistor. (7) Wrong or defective connections on picture tube socket. (8) A.F.C. coil slug screwed in too tightly.
B.	Wrinkles on left side of raster:	(1) Resistors on yoke, or condenser in yoke wrong value or defective. (2) Defective yoke.
C.	Trapezoid or non-symmetrical raster:	(1) Defective yoke. (2) Improper adjustment of focus coil or ion trap magnets.
D.	Bright horizontal line No vertical sweep	(1) Defective 6SN7 vertical tube. (2) Vertical size control improperly set. (3) Check for voltages.
E.	Poor vertical linearity:	(1) Check value of 40 MFD condenser on cathode of vertical amplifier. (2) Check 20 MFD condenser at vertical output transformer. (3) Check .1 condenser in vertical oscillator plate circuit. (4) Check voltage on vertical oscillator section of tube. (5) Low B plus. Check rectifiers and capacitors in supply circuits.
F.	Poor horizontal linearity:	(1) Horizontal drive trimmer adjustment incorrectly set. (2) Horizontal linearity control incorrectly set. (3) Low B plus or line voltage. (4) Check voltages in horizontal circuit.
G.	Raster - no image, but accompanying sound:	(1) No signal on kinescope grid, check for signal with earphones as explained in alignment procedure. Check I. F. amplifier tube, second detector, video amplifier. (2) Bad contact on kinescope tube socket. (3) The stage by stage method of trouble shooting should be used to isolate the defective stage.
H.	Signal on kinescope grid, but no sync:	(1) Check sync. amplifier tube and circuit. (2) Check sync. separator circuit. (3) Check voltages on above and associated circuits.
I.	Signal on kinescope grid and horizontal sync. only:	(1) Check vertical oscillator and associated circuit. Vertical oscillator transformer. (2) Vertical oscillator grid input condensers. (3) Check vertical oscillator input network.
J.	Signal on kinescope grid and vertical sync. only:	(1) Check horizontal hold control adjustment. (2) Check horizontal input network. (3) Check value of horizontal grid resistor to hold control. (4) Check drive control trimmer adjustment.
K.	Picture stable, but poor resolution:	(1) Check grid loading resistors on I. F. tubes. (2) Test all peaking coils for continuity. (3) Check plate loading resistor on detector and amplifier. (4) Measure all potentials on above tubes. (5) Make sure that the focus control operates on both sides of proper focus. If not readjust focus coil. If no improvement reverse focus coil wire connections in set. (6) Realign I. F. Circuits. (7) Peaking coils mixed. Change to proper places.
L.	Picture smear:	(1) This trouble can originate in either transmitter or signal source. Normally, smear can be attributed to phase shift at the low frequencies. This can be caused by improper values of R and C. Check for open or leaking electrolytic condenser in 1st video plate circuit. (2) Improper alignment. Re-align. (3) Open peaking coil. (4) Incorrect antenna orientation for observed station.

©John F. Rider

World Radio History

Indication	Possible Trouble
M. Picture jumpy:	(1) If regular sections at the left of picture are displaced, check horizontal amplifier tube 6AU5 (2) Vertical instability may be due to loose connections or noise. (3) Vertical hold control not set properly. (4) Horizontal instability may be due to unstable transmitted sync. (5) Synchro-lock circuit improperly aligned. (6) Voltage on plate of separator tube too high. (7) Signal too strong or I. F. coils peaked instead of being staggered, overloading.
N. Oscillation or interference in video output: Most noticeable when contrast controls are advanced.	(1) Improper alignment of I. F. coils or cathode trap. (2) Condenser is open between 30,000 ohm resistor and ground in plate and screen circuits of the I. F., or (3) Wrong value or defective resistor between grid and ground of video I. F. tubes; or (4) Outside interference, such as excessive ignition interference, diathermy or beat frequency interference. (5) Improper lead or parts dress. Instructions not followed properly.
O. When detail is milky or not sharp: NOTE: Before proceeding, make sure focus control is set properly.	(1) Loss of high video frequencies due to I. F. coils being tuned too sharply. Re-align. (2) Peaking coils in wrong places. (3) The resistors connected to the plate of the first and second video output tubes may be off value. The resistor to the plate of the first video output tube should be of 2000 ohms; to the plate of second video output tube should be of 5000 ohms. (4) Poor antenna installation or improper orientation.
P. If focus control is set properly and sympton continues:	(1) Fine tuner improperly set. (2) Station switch on wrong channel.
Q. If picture is too small horizontally only:	(1) Trouble is in horizontal oscillator or amplifier circuit. Check parts. (2) Screen resistor of 6AU5 tube too low in value. Increase.
R. If picture is too large both horizontally and vertically:	(1) Indicates high voltage is not high enough - refer to notes on checking horizontal oscillator and high voltage circuit. (2) High voltage leakage due to High voltage wires touching grounded metal. Leaky high voltage condenser.
S. If sight and sound do not synchronize.	(1) Sight and sound I. F. frequencies may not be right. The should be separated by 4.5 megacycles. (2) TELEKIT tuner set on wrong channel. (3) Normal for remote or "fringe" areas. A more sensitive antenna or a booster required.
T. If picture is crowded top and bottom and spread in middle:	(1) Check 40 MFD condenser on cathode of vertical amplifier tube. (2) Defective yoke. (3) Check .25 MFD coupling condenser from vertical oscillator to vertical amplifier. (4) Check voltage on vertical oscillator.
U. Picture cannot be centered or Shadows exist in corners of picture:	(1) See that picture tube is pushed into yoke as far as it will go. (2) Manipulate focus coil. (3) After above readjust beam bender.

Circuit Description of Horizontal Deflection & High-Voltage Circuits

A 6AU5 beam deflection tube is used for producing the necessary amplitude of the sawtooth currents in the deflection coils. The high voltage for the second anode supply is also produced from the energy stored in the deflection inductances during each horizontal scan. The sawtooth voltage applied to the grid of the 6AU5 deflection amplifier produces a sawtooth of current in its plate circuit. The plate of this tube is connected to the primary winding of the deflection transformer. A sudden change of current in the primary will produce a high inductive pulse on the plate of the tube 6AU5. The sudden ceasing of plate current caused by the cutoff of the tube during retrace will cause the circuit to oscillate. The voltage across the yoke must be maintained uniformly constant during trace. In order to obtain this uniformity the 5V4 damper tube is connected across the deflection coils to remove the oscillation following the retrace pulse. Thus, during the trace period, the voltage is constant across the yoke which produces the desired linear sawtooth of current through the yoke for deflection. The pulse voltage on the plate of 6AU5 is stepped up and rectified, and the rectified voltage is filtered, doubled, and applied to the second anode of the kinescope.

Returning to the 5V4 damper, the B plus voltage is supplied to the 6AU5 through this tube which is conducting over the major portion of the trace. The condenser in the cathode circuit (10MFD.) is fully charged during this period and at the time when the damper is not conducting, this charge is sufficient to supply the 6AU5 plate.

The width control functions to increase or decrease horizontal scanning as required by variations of tube and circuit constants. Capacitor and resistor on the horizontal yoke coil and the resistors across the vertical coil serve to decrease the effects of crosstalk between the horizontal and vertical yoke coils, eliminating the effect of ringing of the horizontal output transformer due to leakage reactance.

Checking Horizontal Oscillator and High Voltage

1. Equipment necessary:

   1 pair earphones
   1 .005 - 600 Volt condenser
   1 Neon test lamp (readily obtainable - 59¢ variety)
   1 1000 ohm per volt volt-ohm-meter (volt-meter scale to 600 volts)

2. The neon lamp will be used to test for high A. C. voltage. The lamp will glow because of the high frequency of this voltage (15,750 cycles.). It is only necessary to hold lamp (glass end, not leads) within ½ inch of the 1V2 tube base

World Radio History

Checking Horizontal Oscillator and High Voltage (Cont'd)

near yoke mount on horizontal output transformer, being cautious not to get fingers near terminal, as your finger will draw an arc from this terminal if high voltage is present.

3. Assuming you have no light on picture tube and you have tried all preliminary adjustments of ion trap etc., it is necessary to determine whether or not you have high voltage. Use the above test with neon lamp to find out if high voltage is present.

4. If neon lamp does not glow at all when held close to this terminal, it is safe to assume that no high voltage is present. You must now determine the cause of the missing voltage. Referring to the circuit diagram, you will note that the development of high voltage depends upon the proper functioning of the horizontal oscillator and amplifier circuits. The pulses from the horizontal circuit produce the high voltage. It is necessary, therefore, to check each stage to see if it is operating correctly.

5. To determine if oscillator is working, connect a pair of earphones with a .005 MFD condenser in series with one lead to pin #5 of horizontal oscillator tube 6SN7. Connect the condenser end to pin #5 and the other end of earphones to chassis. Turn set on. If a high pitched squeal or note is heard and if it changes in frequency as horizontal oscillator hold control is varied, the horizontal oscillator tube is operating.

6. If you do not hear the above-mentioned note in your earphones, you have localized the trouble as being in the horizontal oscillator circuit. You should then check voltages on this tube (6SN7). Refer to voltage chart. If this fails to bring the trouble to light, it will be necessary to turn set off and check component parts of the circuit.

7. Assuming you have heard the note in the earphones, the next step in localizing the trouble is to remove the earphone lead (with condenser) from pin #5 of 6SN7. Connect lead to pin #1 of horizontal amplifier tube (6AU5). This check is to determine whether or not coupling condenser is functioning properly. Turn set on. The same note should be heard. If not, turn set off an replace coupling condenser.

8. After this procedure, earphones can no longer be used as a test instrument. Caution! Never connect earphones to pin #5 of 6AU5 horizontal output tube, as there is high A.C. voltage present which would be dangerous to earphones as well as yourself!

9. Now that you have arrived at this point in the checking procedure and still have no high voltage as evidenced by the neon lamp not glowing (when held near 1V2 socket on horizontal output transformer), proceed to the next step in trouble-shooting.

10. Turn set off and check component parts of horizontal output circuit and tube 6AU5 Make certain that circuit is wired properly according to wiring diagram. If all is well, turn set on and check for voltages on this tube (6AU5). There should be 320 volts on pin #8 of 6AU5 which is screen grid and 400 volts on Pin #5 of 6AU5. Take care in measuring these voltages, so as not to make physical contact with yourself and the voltage points.

11. To check damper circuit 5V4 take two voltage readings - one from pin #6 on 5V4 tube to ground (350 to 400 volts) and one from terminal #5 on horizontal output transformer to ground (chassis). This voltage should be about 50 volts more than the preceding measurement (400 to 450 volts). If not, the damper tube is not functioning properly and tube and circuit should be checked.

12. These are the usual sources of trouble in the high voltage circuits. The correction of these faults should produce high A. C. voltage.

13. To check presence of high A. C. voltage, again use the neon lamp tester, a glow should appear in the neon lamp when held close to 1V2 socket of horizontal output transformer. The high A. C. voltage is then rectified and doubled in going through the 1V2 tubes and the resulting D. C. voltage is applied to the second anode of the picture tube.

14. The only source of trouble encountered in the H.V. rectifier circuit will be:

(a) Bad rectifier tubes.
(b) Leakage or arcing of high voltage from tube filament lugs to mounted components.
(c) Corona effects.
(d) Open or shortcircuited components.

The first is self explanatory; check tube filaments for continuity. The second case can be corrected by keeping maximum distance between filament pins on 1V2 tube sockets and compnents. If dirt, grease or dampness accumulates on sockets, it will provide a path for the high voltage to arc to components. Clean sockets thoroughly with carbon tetrachloride. The third trouble, corona effects, will be noticed by turning off all lights in the room with set on and observing a blue glow existing on any of the wires in the high voltage circuits or coming from the filament pins of the 1V2 tubes themselves. Pay particular attention to the filament pins. If the blue glow or corona discharge comes from these points, it can be prevented very simply by resoldering these pins, making sure that the finished pin is round and smooth and has not sharp, projecting points or edges. Corona effects will become apparent at these points if joints are not carefully made. Open or short circuited components can be checked with an ohmeter.

15. This brings you to the final check which includes the picture tube and associated coils. Assuming you have tried to position your beam bender to secure brightest illumination on screen, you should next check the voltages on the picture tube socket. Be sure the pins are connected properly. If you still have no light, remove cover from yoke housing and check wiring. Be sure there are no short circuits inside, due to burning of the insulation when soldering lugs.

16. We are quite sure any trouble originating in the horizontal oscillator, amplifier and high voltage circuits will be found if the above step by step procedure is followed.

Voltage Analysis

1. Do not attempt to read high voltage on the television receiver unless you are familiar with high tension circuits and have the proper equipment to do so. In order to get accurate readings in the high voltage circuits, it is essential that an extremely high resistance voltmeter be used (20,000 ohms per volt or more). A vacuum tube voltmeter is preferred. In our laboratories we use a 20,000 ohm per volt movement, in conjunction with a General Electric high voltage multiplier probe which has an internal resistance of 200 megohms.

2. Remember - DO NOT tamper unnecessarily with the high voltage circuits because of the shock and burn hazard involved.

3. A low voltage chart is supplied with each TELEKIT for your convenience in locating trouble.

4. The readings for the voltage chart were taken under certain conditions. These conditions should be duplicated if identical results are to be obtained. The constructor should bear in mind that it is not necessary to obtain identical readings. All voltage readings are taken with a 20,000 ohm per volt meter which is readily obtainable. The readings are taken from the pin numbers to ground of chassis. Negative being chassis. The chart has been based on an A. C. Line voltage of 110 volts. Consequently, if the line voltage is different, the entire set of voltages will be higher or lower in proportion to the line voltage change. All variable resistances (controls) should be turned in maximum clockwise direction (on full). No antenna or signal should be connected to the set.

World Radio History

Alignment of TELEKIT

We have found through experience that it is relatively easy to align the video stages to get a preliminary picture as the video I.F. system is sufficiently broad to pass some signal at almost any setting.

It is, however, more difficult to adjust the sound channel because these circuits are sharply tuned. We, therefore, advise that a signal generator be used for this purpose. Our sound channel will be tuned to exactly 21.25 Mc. To simplify this adjustment it is recommended that the following procedure be used. Signal can be observed with either the speaker or output meter.

1. Tune signal generator to 21.25 Mc. (Using a 400 cycle note or tone).
2. Connect hot lead of generator through a .005 MFD. condenser to grid of second sound I. F. tube (#1 pin). Connect ground lead to chassis. Turn volume control to full clockwise setting. Turn on set and allow a one minute warmup period.
3. Tune primary of F. M. Transformer, which is the upper slug, for maximum sound in speaker. If too loud reduce generator output.
4. Move generator lead with condenser to grid of first sound I. F. tube.
5. Adjust slug which controls tuning of the sound I. F. coil for maximum intensity of signal.
6. Tune secondary of F. M. Transformer by means of the lower slug of discriminator mounted in the underside of chassis for null point. You will notice in making this adjustment that you will get maximum signal response from loud speaker or output meter on two settings of this slug very close together. Between these two settings there will be a null point; that is, a point that is considerably lower in intensity than on either side of this adjustment. It is this point that is desired. When this is found the operation is completed. Notice the signal will not completely disappear with this adjustment if the volume control is turned on full. This completes the sound adjustment.
7. Connect signal lead of generator through the .005 MFD. condenser to the grid lug (#1) of the first video I. F. tube (tube D). Clip the ground lead of the generator to chassis at base of tube D. Advance contrast control to maximum setting. Clip earphone lead through a .01 MFD. to lug #2 of video output tube (tube L). Clip other earphone lead to chassis. You can now listen to the modulated signal as you make coil adjustments. An output meter connected through a .1 MFD. condenser can be connected to the same points in lieu of earphones.

8. Keeping the signal generator set at 21.25 Mc. proceed to adjust cathode sound trap (hole #23). Adjust for minimum signal output. Keep signal generator attenuator low for all I. F. adjustments but do not reduce contrast control setting. Also keep signal generator and phones connected at same points throughout video I. F. alignment.

9. Set signal generator to 23.9 Mc. Adjust fourth video I. F. coil (hole #31) for maximum output at that frequency. Note that on these adjustments the coil should go through the desided points. Be sure that you can go through these points to be certain that the coils are in the correct frequency range. Then adjust to maximum or minimum as specified.

10. Set signal generator to 26 Mc. Adjust third video I. F. coil for maximum output at that frequency. If signal becomes too loud reduce generator output.

11. Set signal generator at 24.5 Mc. Adjust second video coil for maximum output at that frequency. If signal becomes too loud reduce generator output.

12. The first video coil (mixer output) is in the Telekit tuner. This has been adjusted at the factory to the frequency of 22.8 Mc. The sound take-off coil is also on the tuner and it has been prealigned to 21.25 Mc. at the factory. The sound coil adjustment is on the top of the large coil and the video adjustment is on the underside of the coil. Do not make any adjustments to this coil.

13. The above adjustments will produce a broad band frequency response of 4.5 Mc. which will insure pictures of high definition and sound of excellent clarity. If sweep generator and oscilloscope data is required it can be secured by written request.

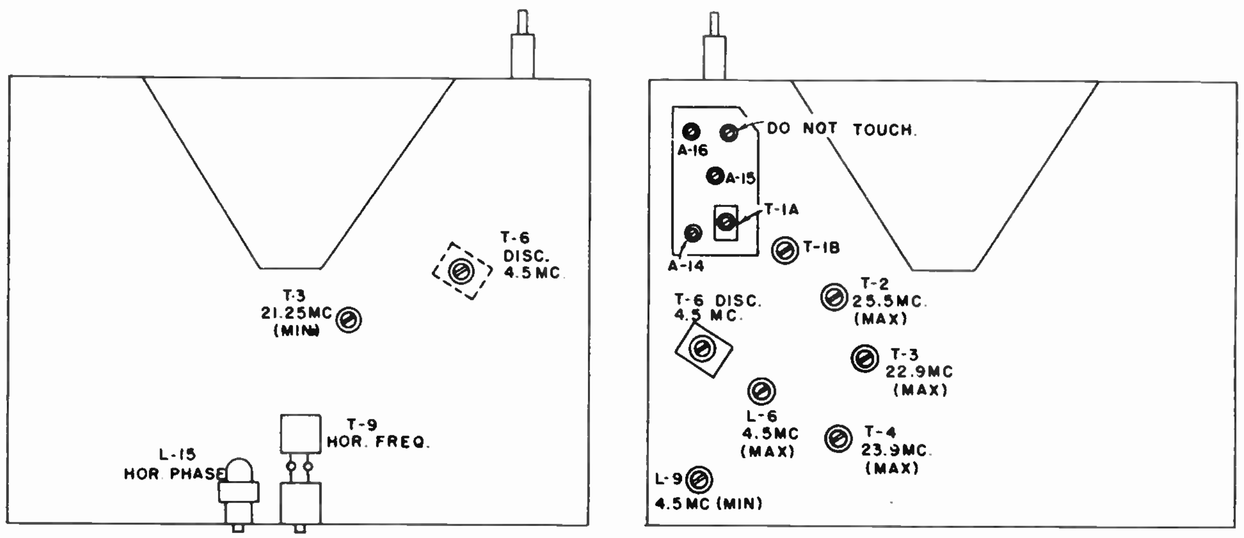
MODELS 614D AND 637A
CHASSIS MODEL 120095-B

I. ALIGNMENT

a. **Equipment Required** - A sweep generator, accurate marker generator, oscilloscope, and v.t.v.m. are required for alignment. The marker generator must be very accurate and supply frequencies of 4.5 MC., and 20 to 28 MC.

b. **Response Curves** - The i-f response curves for the video i-f stages are shown in figure 2.

c. **Alignment Points** - The location of all i-f transformers, tuned circuits, and trimmers is shown in figure 1.



BOTTOM OF CHASSIS   TOP OF CHASSIS

FIGURE 1 - LOCATION OF ALIGNMENT POINTS

d. **TV I-F Alignment** -

1) Tune receiver to Channel 3.
2) Connect 3 volt bias battery negative terminal from junction of C31 and R27 (positive terminal) to B-.
3) Shape overall response curve, after individual peaking of stagger-tuned and over-coupled i-fs, as indicated in steps 1-6 below. See curves A and B.

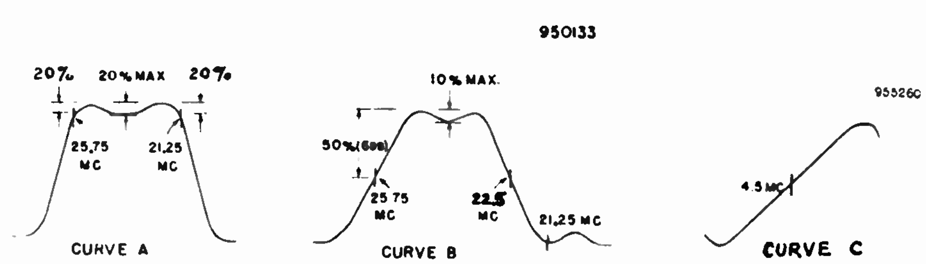


FIGURE 2 - RESPONSE CURVES

TABLE I - VIDEO I-F ALIGNMENT

STEP	SIGNAL GENERATOR INPUT: CONNECTION	SIGNAL GENERATOR INPUT: FREQUENCY	INSTRUMENT CONNECTION	ADJUST	PROCEDURE
1	Connect marker generator to pin 1 (grid) of V-1 (6AU6) through .001 mfd. condenser. Low side to chassis.	25.5 MC	Connect d.c. v.t.v.m. to pin 7 (grid of V4 (12AT7). Use 3 or 5 volt range.	T2	Peak for maximum response. Adjust generator signal level to produce one volt at grid of V4.
2	"	22.9 MC	"	T3 (Top)	"
3	"	21.25 MC	"	T3 (Bottom)	Adjust for minimum response. Repeat step 2.
4	"	23.9 MC	"	T4	Peak for maximum response.
5	Connect sweep generator to converter (V-20) input, using three turn loop of wire slipped over tube. Connect marker gen. in parallel.	Sweep-24.5 MC (10 MC sweep) Marker-21.25 MC and 25.75 MC	Connect vertical input of scope through "detector network to pin 1 (grid) of V-2 (6AU6). *Low input impedance of about 200 ohms	T1(A) T1(B)	Set markers as shown on response curve A, fig. 2. Note that the markers should be 20% down for this stage.
6	"	Sweep-24.5 MC (10 MC sweep) Marker-22.6 and 25.75 MC	Connect vertical input of scope in series with 10K resistor to pin 7 (grid) of V4 (12AT7).	T2, T3, and T4	Adjust for overall response as shown in curve B, fig. 2. Adjust T2 to position 25.75 MC marker; adjust T3 (Top) to set 22.6 MC marker. Do not readjust trap. Equalize peaks of response curve by adjusting T4.

e. **TV Sound Alignment** -

1) Set receiver to Channel 3.
2) Use accurate, crystal-controlled, marker generator.

STEP	SIGNAL GENERATOR INPUT: CONNECTION	SIGNAL GENERATOR INPUT: FREQUENCY	MEASURING INSTRUMENT	ADJUST	PROCEDURE
1	Marker generator through .001 mf to pin 2 of V-4 low side to B-.	Marker-4.5 MC.	Connect v.t.v.m. through 10K resistor to pin 1 (grid) of V5.	L6	Peak for maximum response. Adjust generator input to produce one volt at grid of V5. (Above no signal value).
2	Connect sweep generator in parallel with marker gen.	Sweep-4.5 MC (450 KC sweep) Marker-4.5 MC	Replace v.t.v.m. with scope connected through 10K resistor to junction of R21 and C22.	T6 (Secondary)	Position 4.5 MC. marker at center of S-curve, by adjusting secondary. (See Fig. 2, - curve C)
3	"	"	"	T6 (Primary)	Peak primary for maximum amplitude and linearity. Repeat step 2. (See Fig. 2 - curve C)
4	Marker generator through .001 mfd. to pin 7 of V4 (12AT7)	Marker-4.5 MC	A.C. v.t.v.m. or D.C. v.t.v.m. used with a peak detector probe to junction of R52, C47.	L9	Adjust for min. reading of v.t.v.m. Keep contrast control set for maximum contrast.

TABLE II - AUDIO I-F AND DISC ALIGNMENT

f. **TV R-F Alignment** -

1) Set fine tuning control to mechanical center. Retain this setting for entire r-f alignment.
2) Use 300 ohm carbon resistor as dummy antenna.
3) Couple marker generator in parallel with sweep generator.

©John F. Rider

World Radio History

4) Use 10 MC. sweep for sweep generator. Couple generator to antenna terminals of receiver.

5) Connect vertical input of scope in series with 10K resistor to junction of R39 and L8 (pin 7 grid of V4).

I. ALIGNMENT

a. Equipment Required - A sweep generator, accurate marker generator, oscilloscope, and v.t.v.m. are required for alignment. The marker generator must be very accurate and supply frequencies of 4.5 MC., and 20 to 28 MC.

b. Response Curves - The i-f response curves for the video i-f stages are shown in figure 2.

c. Alignment Points - The location of all i-f transformers, tuned circuits, and trimmers is shown in figure 3.

NOTE: The Tail Piece as shown in Fig. I, will have to be removed so that the deflection yoke and focus coil will remain connected while the set is aligned. In order to do this, the high voltage lead must be removed from the picture tube cup. Plugs P-5 and P-2 must also be removed from chassis.

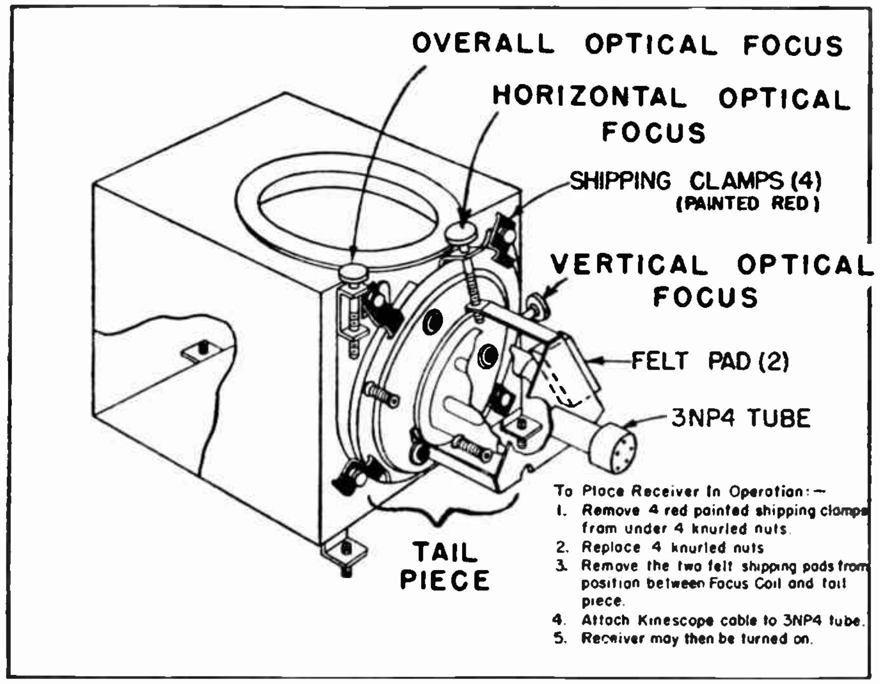

FIGURE 1

NOTE: In order to protect the picture tube, the optical box is shipped with (4) shipping clamps and (2) felt pads. See Figure I. These must be removed before the set is put in operation. While the Picture Tube is shipped in place, it is disconnected and must be plugged into its socket before set will operate.

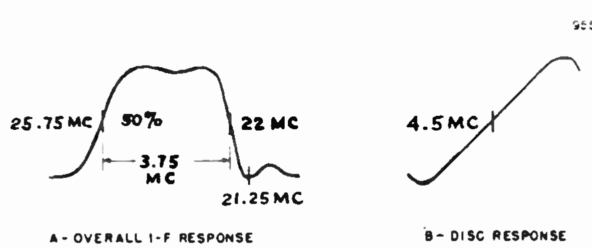

FIGURE 2 . IF AND DISC RESPONSE CURVE

d. TV I-F Alignment

1) Tune receiver to Channel 3.

2) Connect 3 volt bias battery from junction of R17 and C17 (negative terminal) to ground (positive terminal).

3) Shape overall response curve, after individual peaking of stagger-tuned and over-coupled i-fs, as indicated in steps 1-8 below. See curve A.

STEP	SIGNAL GENERATOR INPUT CONNECTION	SIGNAL GENERATOR INPUT FREQUENCY	MEASURING INSTRUMENT	ADJUST	PROCEDURE
1	Connect marker generator to pin 1 (grid) of V1 (6AU6), through .001 mfd. condenser. Low side to chassis.	25.75 MC	Connect d.c.probe of v.t.v.m. to (junction of L6 and R40). Low side to chassis.	L5	Peak for maximum response. Adjust generator signal level to produce approx. 1 volt at junction of L6 and R40.
2	"	25 MC	"	L3	"
3	"	22.3 MC	"	T3 (Bottom)	"
4	"	23 MC	"	T2 (Top)	"
5	"	21.25 MC	" (Use three or five volt meter scale)	T3 (Top)	Adjust for minimum response. Two peaks may be noted. The correct position is with the core at the outside end of the coil.
6	NOTE: TRAP SHORTED; NO ADJUSTMENT NECESSARY			T2 (Bottom)	
7	Connect marker generator to pin 1 (grid) of V1 (6AU6), through .001 mfd. condenser. Low side to chassis.		Connect d.c.probe of v.t.v.m. to (junction of L6 and R40). Low side to chassis.	L5, L4 T3, T2	Repeat steps 1 through 6. Readjust T3 (Bottom) after adjusting 21.25 MC trap.
8	Connect sweep generator to three turn loop of wire slipped over converter tube V22. Connect marker gen. in parallel.	Sweep Gen. 23.0 MC (10 MC Sweep) Marker Gen. 21.75 MC and 25.75 MC	Connect vertical input of scope in series with 10K resistor to (junction of L6 and R40).	T1 Both Slugs	Adjust to position markers as shown on the overall response curve, figure 2-A. It is essential that the video carrier marker (25.75 MC) be at the 50% point (6db down). Adjust T5 and T4 if necessary to correctly position this marker.

TABLE I - VIDEO IF ALIGNMENT

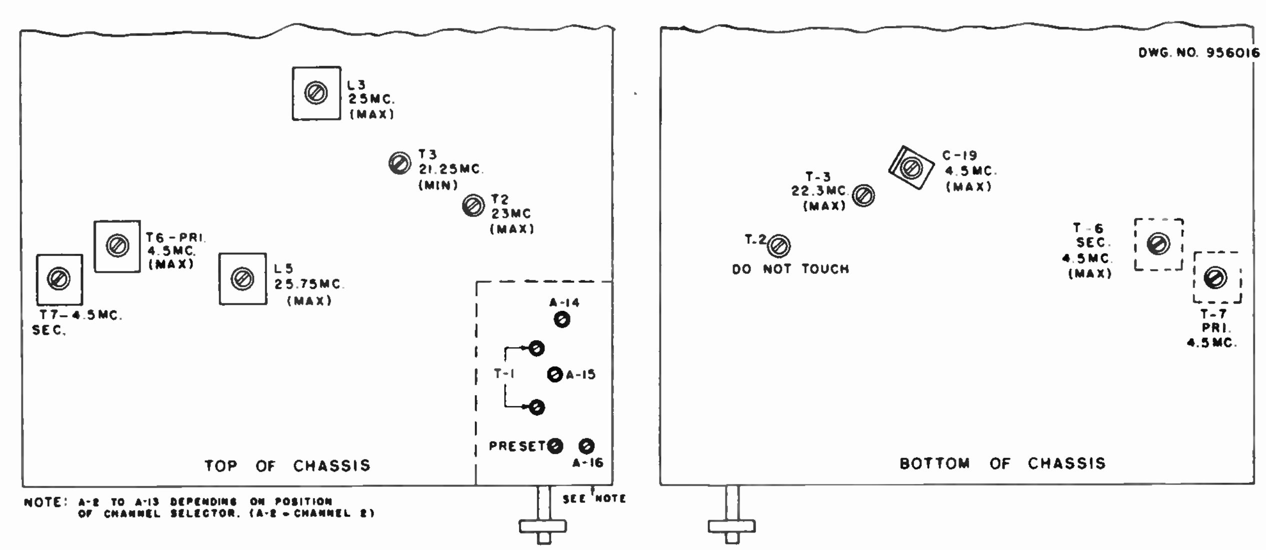

FIGURE 3 . LOCATION OF ALIGNMENT POINTS

©John F. Rider

World Radio History

e. TV Sound Alignment -

1) Set receiver to Channel 3.

2) Use accurate, crystal-controlled, marker generator.

STEP	SIGNAL GENERATOR INPUT CONNECTION	SIGNAL GENERATOR INPUT FREQUENCY	MEASURING INSTRUMENT	ADJUST	PROCEDURE
1	Connect marker generator to pin 2 (plate) of V5 (6AL5), through 100K resistor.	4.5 MC	Connect d.c. probe of v.t.v.m. (junction of C22 and R22, T4). Low side to chassis.	C19	Peak for maximum response.
2	"	"	"	T4 (Top and Bottom)	"
3	"	"	Connect d.c. probe of v.t.v.m. to point D (pin 3 of V19): Low side to chassis.	T5 (Top)	Adjust secondary for minimum response.
4	Connect sweep generator in parallel with marker generator.	Sweep Gen. 4.5 MC (450 KC sweep) Marker Gen. 4.5 MC (Unmod.)	Connect vertical input of scope in series with 10K resistor to pin 3 of V19, in place of v.t.v.m.	T5 (Bottom)	Adjust primary for maximum linearity and symmetry. Adjust secondary to center marker, as shown in figure 2. curve B.

TABLE II IF AND DISC ALIGNMENT

f. TV R-F Alignment -

1) Set fine tuning control to mechanical center. Retain this setting for entire r-f alignment.
2) Use 300 ohm carbon resistor as dummy antenna.
3) Couple marker generator in parallel with sweep generator.
4) Use of 10 MC. sweep for sweep generator. Couple generator to antenna terminals of receiver.
5) Connect vertical input of scope in series with 10K resistor to junction of L6 and R40.

STEP	SIGNAL GENERATOR INPUT SWEEP GEN.	SIGNAL GENERATOR INPUT MARKER GEN.	CHANNEL	ADJUST	PROCEDURE
1	207.0 MC.	209.75 MC.	12	A12	Adjust for placement of 21.25 MC. marker as per response curve A.
2	"	"	12	A14, A15, A16	Adjust shape of response curve A for maximum amplitude and band-width.
3	213.0 MC.	215.75 MC.	13	A13	Adjust as in Step 1.
4	201.0 MC.	203.75 MC.	11	A11	"

VOLTAGE AND RESISTANCE READINGS FOR CHASSIS 120094-A - MODEL 649A

The voltage and resistance measurements listed below are for chassis 120094-A with no triangle code number.

Due to component variations, voltage and resistance readings may vary slightly from those given in tables here. Slight variations may also be noticed if chassis is not coded as stated above.

CONDITIONS FOR TAKING VOLTAGE AND RESISTANCE READINGS:

1. Antenna disconnected and antenna terminals shorted.
2. Line voltage 117 volts.
3. All controls in position for normal picture.
4. All measurements taken with a vacuum tube voltmeter and ohmeter.
5. All readings listed in tables were taken between points shown and chassis.
6. Resistance readings are given in ohms unless otherwise noted.
7. N.C. denotes no connection.

N.C. Denotes no connection.

INF. Denotes infinity.

The voltage and resistance measurements listed below are for chassis 120118-B stamped with triangle code 8.

Due to component variations, voltage and resistance readings may vary slightly from those given in tables here. Slight variations may also be noticed if chassis is not coded as shown above.

CONDITIONS FOR TAKING VOLTAGE AND RESISTANCE READINGS:

1. Antenna disconnected and antenna terminals shorted.
2. Line voltage 117 volts.
3. All controls in position for normal picture.
4. All measurements taken with a vacuum tube voltmeter and ohmeter.
5. All readings listed in tables were taken between points shown and chassis.
6. Resistance readings are given in ohms unless otherwise noted.
7. N.C. denotes no connection.

I. GENERAL DESCRIPTION (See figure I)

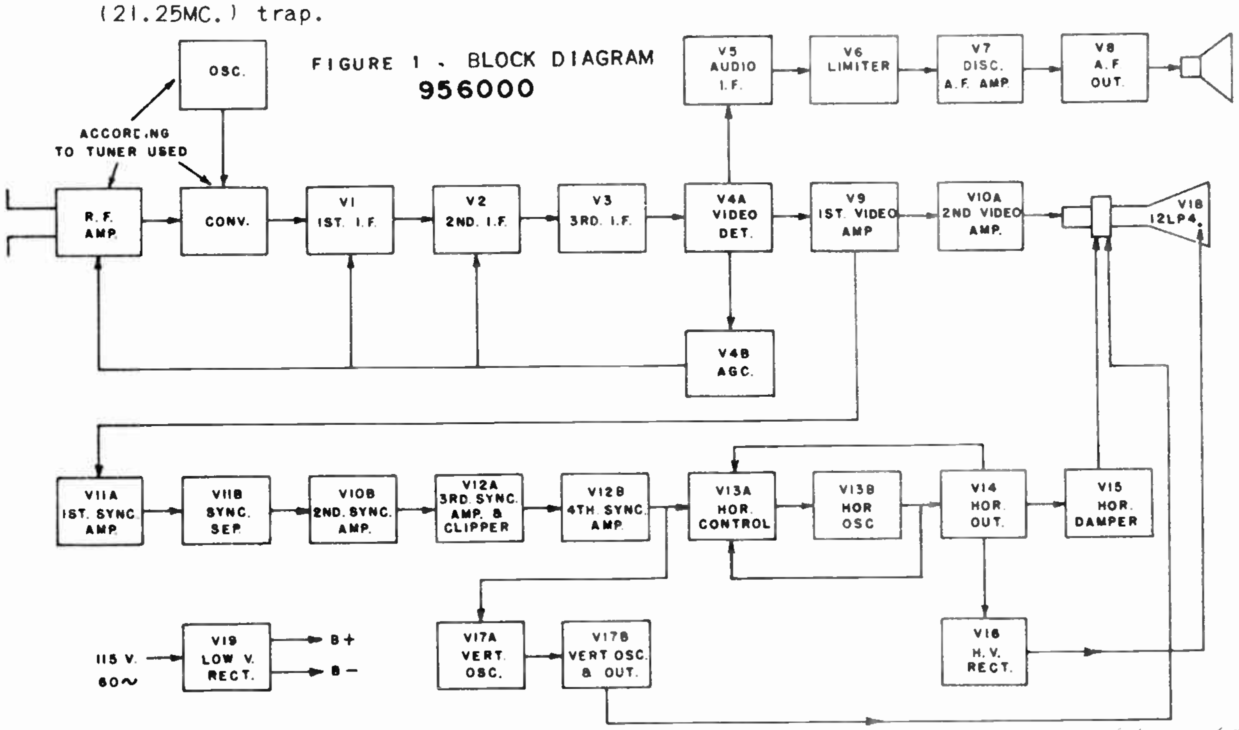
Model 650 uses chassis 120113C * and 120118B. Model 654 uses chassis 120118B only. Both models use a 12½ inch direct view kinescope tube type 12LP4 and both are housed in wooden cabinets. Model 650 is a table model television receiver while model 654 is a consolette receiver. These models feature Built-In Antenna, Inter-Carrier Sound, Automatic Gain Control and Miracle Picture Lock.

* For all information pertaining to chassis 120113C refer to Service Manual on models 614, 637, 644 and 647.

a. Tuner - Tuners 470606 and 470607 are used in the above mentioned models. Information pertaining to tuner 470607 will be found on pages 9 and 10 It uses a type 6J6 as the oscillator and converter (V21) and a type 6AG5 as the r-f amplifier (V22). This tuner contains the first i-f transformer (T-A), which is an overcoupled unit. Tuner 470606 will be used in later sets, therefore, information on this tuner will be released at a future date.

b. Video I-F Amplifiers - Both video (25.75MC.) and audio (21.25MC.) i-f carriers are amplified by the video i-f stages. Two stagger-tuned i-f transformers (T1 and T2) and an over-coupled i-f (T3) complete the i-f amplifier. (T3) feeds the video detector and AGC (V4). (T1) is provided with a (21.25MC.) trap.

FIGURE 1 . BLOCK DIAGRAM 956000



©John F. Rider

World Radio History

c. **Video Detector and Amplifiers** - The output of the video-detector (V4A), one-half of a type 6AL5, is coupled to the first video amplifier (V9). The output of the second video amplifier (V10A), feeds the grid of the kinescope (V18).

NOTE: The 120118B chassis is also used in some sets on models 644C and 647B. See service note covering models 614, 637, 644 and 647 for photographs and cabinet parts list.

d. **Intercarrier Sound** - The (4.5MC.) heterodyne between video and audio i-f carriers is taken from the shunt-tuned circuit (L3,C16) at the output of the video detector. The (4.5MC.) signal feeds the sound i-f amplifier (V5), whose output is connected to the limiter (V6). The discriminator (V7) feeds the output stage (V8).

e. **AGC** - The other half of the 6AL5 (V4B) supplies a delayed AGC voltage to the r-f amplifier (V22) and first and second video i-f amplifiers (V1 and V2).

f. **Sync and Deflection** - The output of the first video amplifier (V9-6AU6) feeds the first sync amplifier (V11A-12AU7). The output of this tube is then fed to the sync separator (V11B-12AU7) where it is then amplified by a chain of sync amplifiers (V10B-12AU7, V12A-12SN7GT, and V12B-12SN7GT). The output of the fourth sync amplifier is then fed by means of an intergrating network to the vertical oscillator (V17A-12SN7GT) and also by means of a capacity voltage dividing network to the horizontal oscillator control tube (Miracle Picture Lock, V13A-12SN7GT).

The horizontal oscillator (V13B-12SN7GT) is controlled by the horizontal oscillator control tube (Miracle Picture Lock, V13A-12SN7GT). This is done by properly phasing three wave forms at the input grid of (V13A, See figure 2). The phasing coil C and D has a fly-wheel effect and helps greatly in stabilizing the sync. A sawtooth voltage is built up across condenser (C53) which is charged through resistor (R72) and is then coupled to the grid of the 19BG6-G. The drive padder (C55), adjusts the amount of sawtooth input required for most efficient operation of the 19BG6-G. The damper tube (V15-25W4GT) is effectively connected across the horizontal deflection yoke.

NOTE: Care must be taken not to load these circuits too much due to excessive scope input capacity or low resistance, otherwise erroneous adjustments will result.

956002

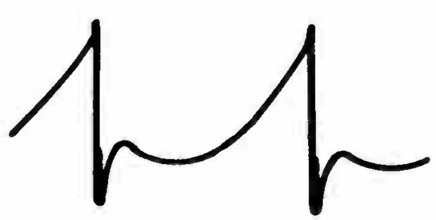


FIGURE 2 . COMPOSITE INPUT WAVEFORM AT CONTROL TUBE GRID OF V13A. (OBTAINED BY USING A LOW CAPACITY PROBE).

The vertical oscillator (V17A, V17B-12SN7GT) is controlled by the vertical sync pulses fed to pin 4 of (V17A-12SN7GT). The output of (V17B) is fed to the vertical deflection yoke by means of a matching transformer, (T9).

g. **High-Voltage Supply** - The high-voltage supply is the conventional flyback type. The high-voltage winding of (T8) is connected to the high-voltage rectifier (V16), a type 1B3GT, and produces about 9½ kilovolts for the kinescope.

h. **Low-Voltage Supply** - The low-voltage supply uses a full-wave rectifier (V19-5U4G) and transformer (T10). A series arrangement is used to supply a positive and negative voltage with respect to chassis. As a result, separate filament windings are used to keep the heater-cathode potentials within ratings, and the electrolytic filter condensers are not grounded to the chassis. (V8, V11, V10, V13, V14, V15, V17 and V12) have their filaments connected in series directly across the line.

i. **Chassis Adjustments** - These receivers are provided with normal vertical and horizontal adjustment controls. Vertical and horizontal centering however, is accomplished by mechanically adjusting the focus coil.

j. **Check of Miracle Picture Lock Alignment** - Turn the horizontal hold control to the extreme clockwise position. The picture should remain in horizontal sync. Momentarily remove the signal by switching off channel then back again. Normally the picture will be out of sync. Turn the control counter-clockwise slowly. The number of diagonal black bars will be gradually reduced and when only 3 or 4 bars sloping downward to the left are obtained, the picture will pull into sync upon slight additional clockwise rotation of the control. Pull-in should occur when the control is approximately 90 degrees from the extreme counter-clockwise position. The picture should remain in sync for approximately 90 degrees of additional counter-clockwise rotation of the control.

If the receiver passes the above checks and the picture is normal and stable, the horizontal oscillator is properly aligned. Skip "Horizontal Oscillator Adjustment".

k. **Miracle Picture Lock Adjustment** - Normally the adjustment of the horizontal oscillator is not considered to be a part of the alignment procedure, but since the oscillator waveform adjustment requires the use of an oscilloscope, it can not be done conveniently in the field. The waveform adjustment is made at the factory and normally should not require readjustment in the field. However, the waveform adjustment should be checked whenever the receiver is aligned or whenever the horizontal oscillator operation is improper.

l. **Horizontal Frequency Alignment** - With a clip lead, short circuit the coil between terminals C and D of the horizontal oscillator transformer (T7). Tune in a television station and sync the picture if possible.

a) Turn the horizontal hold control (R70) to the extreme counter-clockwise position. Adjust the (T7) Frequency Adjustment (under the chassis) so that the picture is just out of sync and the horizontal blanking appears in the picture as a vertical bar. The position of the bar is unimportant. See figure 3.

b) Turn the hold control approximately one quarter of a turn from the extreme clockwise position and examine the width and linearity of the picture. If picture width or linearity is incorrect, adjust the horizontal drive control (C55), the width control (L8) and the linearity control (L9) until the picture is correct. If (C55, L8 or L9) was adjusted, repeat step (a) above.

956001

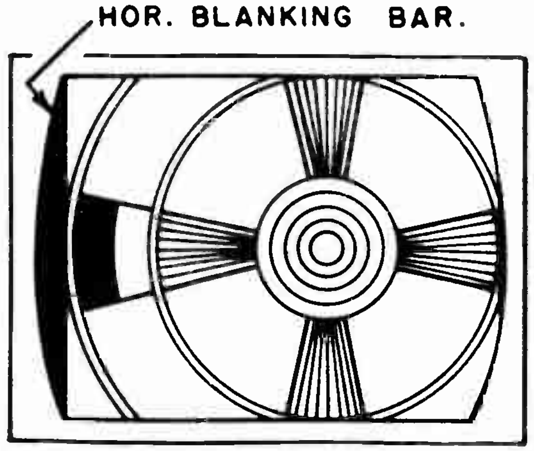

FIGURE 3 MIRACLE PICTURE LOCK ADJUSTMENT

©John F. Rider

World Radio History

m. **Horizontal Oscillator Waveform Adjustment** - Remove the shorting clip from terminals C and D of (T7). Turn the horizontal hold control to the extreme counter-clockwise position. With a thin fibre screwdriver, adjust the Horizontal Phasing Slug of (T7 on the rear of the chassis) until the horizontal blanking bar appears in the raster.

a) Connect the vertical input of the scope in series with a 22,000 ohm de-coupling resistor to terminal C of (T7) and with the low side to chassis. Turn the horizontal hold control one quarter turn from the clockwise position so that the picture is in sync. The pattern on the oscilloscope should be as shown in figure 4. Adjust the Horizontal Phasing Slug of (T7) until the two peaks are at the same height. During this adjustment, the picture must be kept in sync by readjusting the hold control if necessary.

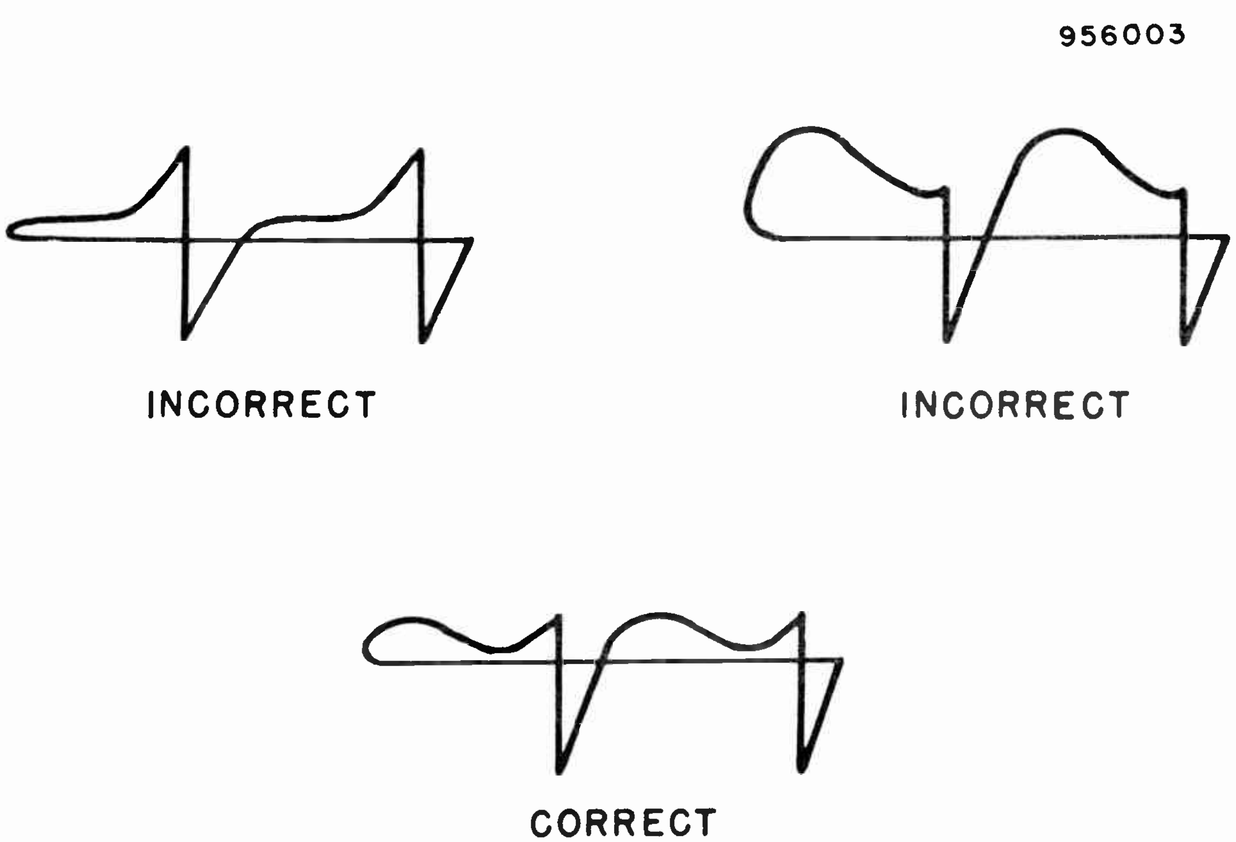

FIGURE 4 - HORIZONTAL OSCILLATOR WAVEFORMS

This adjustment is very important for correct operation of the circuit. If the broad peak of the wave on the oscilloscope is lower than the sharp peak, the noise immunity becomes poorer, the stabilizing effect of the tuned circuit is reduced and drift of the oscillator becomes more serious. On the other hand, if the broad peak is higher than the sharp peak, the oscillator is overstabilized, the pull-in range becomes inadequate and the broad peak can cause double triggering of the oscillator when the hold control approaches the clock-wise position.

Remove the oscilloscope upon completion of this adjustment.

2. TUBE COMPLEMENT (See figure 5)

The tube complement of Chassis 120118B is listed in the following table:

TUBE COMPLEMENT FOR CHASSIS 120118B

SYMBOL	TUBE TYPE	FUNCTION	SYMBOL	TUBE TYPE	FUNCTION
V1	6AG5	First video i-f amplifier	V13	12SN7GT	Miracle picture lock hor. osc.
V2	6AG5	Second video i-f amplifier	V14	19BG6-G	Hor. output amplifier
V3	6AU6	Third video i-f amplifier	V15	25W4GT	Hor. damper
V4	6AL5	Video detector	V16	1B3-GT 8016	H.V. rectifier
V5	6AU6	Sound i-f amplifier	V17	12SN7GT	Vert. oscillator
V6	6AU6	Sound i-f limiter	V18	12LP4	Kinescope
V7	6T8	Sound Discr. & a-f amplifier	V19	5U4G	Low voltage rect.
V8	12L6GT	Sound output			
V9	6AU6	First video amplifier	V21	6J6	•A Converter •B Oscillator
V10	12AU7	•A Second video amplifier •B Second sync amplifier	V22	6AG5	R-f amplifier
V11	12AU7	•A First sync amplifier •B Sync separator			
V12	12SN7GT	•A Third sync ampl. & clipper •B Fourth sync. ampl. & clipper			

•NOTE: Looking at the schematic, left side of tube is referred to as (A) - the right side is referred to as (B).

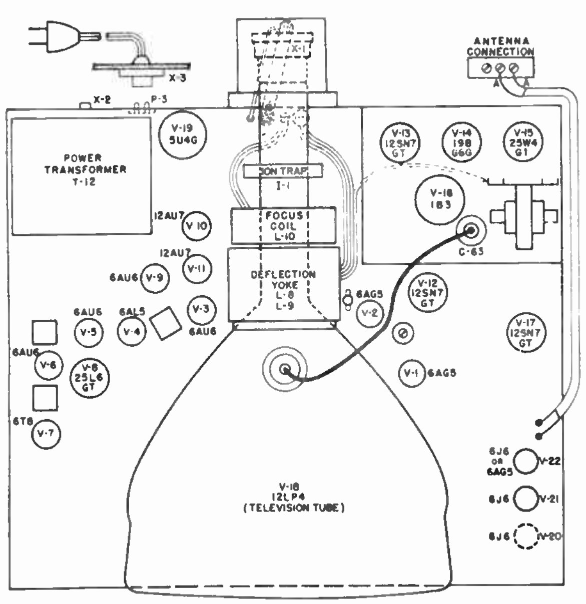

FIGURE 5 - TUBE LOCATION DIAGRAM

3. CHASSIS CONTROLS (See figure 6)

a. **Front** - The front panel of Chassis 120118B is provided with the following four controls: 1. Selector, 2. Fine Tuning, 3. Contrast - R32, 4. Off-Volume - R26 - SW-1

b. **Rear** - The rear controls are as follows:

1. Hor. Size - L8	4. Hor. Phasing - T7	7. Vert. Size - R90
2. Hor. Linearity - L9	5. Hor. Hold - R70	8. Vert. Linearity - R95
3. Hor. Drive - C55	6. Vert. Hold - R89	9. Focus - R30

c. **Centering** - Centering, both vertically and horizontally, is accomplished by positioning of the focus coil which is mounted on a swivel bracket with an adjustment arm protruding from the back cover of the set. See figure 6.

World Radio History

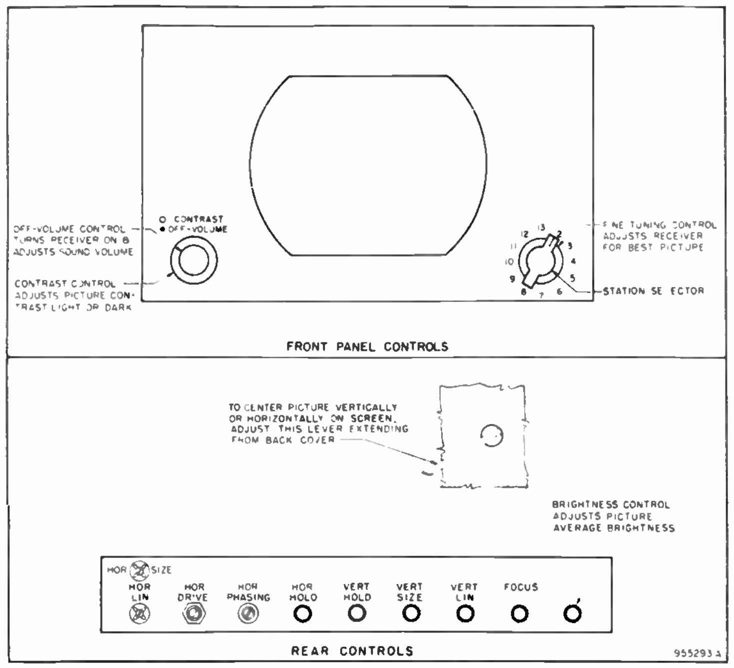

FIGURE 6 - FRONT AND REAR CONTROLS

4. ALIGNMENT

a. **Equipment Required** - A sweep generator, accurate marker generator, oscilloscope, and v.t.v.m. are required for alignment. The marker generator must be very accurate and supply frequencies of (4.5MC.), and (20 to 28MC.).

b. **Response Curves** - The i-f response curves for the video i-f stages are shown in the alignment tables.

c. **Alignment Points** - The location of all i-f transformers, tuned circuits, and trimmers is shown in figure 7.

d. **Sound I-F Alignment** -

(1) Set receiver to Channel 3.
(2) Use accurate marker generator.
(3) Return v.t.v.m. to B minus, not chassis.

STEP	SIGNAL GENERATOR INPUT CONNECTION	SIGNAL GENERATOR INPUT FREQUENCY	MEASURING INSTRUMENT	ADJUST	PROCEDURE
1	Marker generator through .001 mfd. to pin 2 of V4 low side to B-.	Marker-4.5 MC.	Connect v.t.v.m. to junction of R19 and C17. Low side to B-.	C16	Peak for maximum response. Adjust generator input to produce one volt reading on v.t.v.m.
2	"	Marker-4.5 MC.	"	T4 (Top and bottom)	Peak for max. response.
3	Marker generator through .001 mfd. to pin one of V6 (6AU6).	4.5 MC. max input 1 volt	Vert. input of scope to junction R24, C21, C22. Low side to chassis.	T5 (Top and bottom)	(a) Slightly detune discriminator secondary (T-5 bottom pt. 708017, T-5 top pt. 708018) until scope shows an increase in vert. deflection. (b) Adjust discriminator primary (T-5 top pt. 708017, T-5 bottom pt. 708018) for max. vertical deflection. (c) Adjust discriminator secondary for minimum vert. deflection.

e. **Video I-F Alignment** -

(1) Set receiver to Channel 3.

(2) Connect 3 volt bias battery from junction of R1, R6, and R11 (negative terminal) to chassis (positive terminal) for step 5.

(3) Waveforms may be inverted depending on number of stages in the vertical amplifier of the scope being used.

STEP	SIGNAL GENERATOR INPUT CONNECTION	SIGNAL GENERATOR INPUT FREQUENCY	MEASURING INSTRUMENT	ADJUST	PROCEDURE
1	Lightly couple marker gen. to pin 1 of V3; sweep gen. from pin 1 to chassis, through .001 mfd.	Sweep-23.5 MC. (10 MC. sweep) Marker-25.75 MC.	Connect vertical input of scope through 10K resistor to junction of L1, R16, and C16. Low side to chassis.	T4 (Top and bottom)	Set marker as shown on response curve; marker should be 10% down. Adjust sweep generator input to produce one volt at junction of L1, R16, and C16. 2	Connect marker and sweep generators to pin 1 of V2, through .001 mfd. Low side to chassis.	Sweep-23.5 MC. (10 MC. sweep) Marker-25.25 MC.	"	T3	Set marker as shown on response curve. 3	Sweep generator coupled to converter (V27) input, using three turn loop slipped over tube. Marker gen. in parallel. Low side to chassis.	Sweep-23.5 MC. (10 MC. sweep) Marker-25.75 MC.	Connect scope through detector network to pin 1 of V2. Low side to chassis.	T1 (L7 and L9)	Set marker as shown on response curve. 4	"	Sweep-23.5 MC. (10 MC. sweep) Markers-22.8 and 21.25 MC.	Connect scope through detector network to pin 1 of V3. Low side to chassis.	T2 (Top and bottom)	Adjust primary of T2 (Top) to position 22.8 MC. marker; adjust T2 trap (Bottom) to position 21.25 MC. marker 5	" Connect AGC bias battery as indicated above.	Sweep-23.5 MC. (10 MC. sweep) Markers-25.75 and 22.25 MC.	Connect scope through 10K resistor to junction of L1, R16, and C16. Low side to chassis.	T2, T3	Adjust T2 (Top) and T3 to give overall response shown. T2 (Top) adjusts bandwidth; T3 positions video carrier (25.75 MC.) depending on accuracy of adjustment of T1 (25.75 MC. marker). 
f. **R-f Alignment** -

(1) Set fine tuning control to 50% rotation (approximately at center) to expose oscillator slugs. Retain this setting for all channels.
(2) Use 300 ohm carbon resistor as dummy antenna.
(3) Couple marker generator in parallel with sweep generator.
(4) Use 10 MC. sweep for sweep generator. Couple generator to antenna terminals of receiver.
(5) Connect vertical input of scope in series with 10K resistor to junction of L1, R15, and C34.
(6) A14, A15, A16 are r-f amplifier and converter trimmers and are adjusted on Channel 12; A13-A2 are oscillator slugs for the corresponding channels.

PRODUCTION CHANGES

Triangle codes will appear stamped next to the A.C. input on the chassis. For every production change, the triangle code number will change.

△1 These sets use power transformer 730022.

△2 Covering circuit modifications to reduce horizontal foldover.

a) Disconnect C-73, 5 uuf from junction of C4, .002 - C-46, 68 uuf and C-45, 150 uuf.

b) Insert 47,000 ohm resistor between C-73 and junction of C-47, C-66 and C-45.

c) Insert 68 uuf between junction of C-73 new 47,000 ohm resistor and B minus.

△3 Covering circuit modifications to improve picture sharpness and contrast.

a) Change 33,000 ohm resistor R16, connected from Pin 2 to Pin 5 of the 6AL5 video detector to a 68,000 ohm resistor.

b) Change the 47 mmfd. condenser C13, connected from Pin 2 to Pin 1 of the 6AL5 video detector to a 24 mmfd. condenser.

c) Change the 6800 ohm resistor R15, which is connected between the low end of the secondary of the 3rd video IF transformer to the low end of the peaking coil which runs to Pin 7 of the 6AL5 video detector to a 4700 ohm resistor.

NOTICE:

It will be noted in the service note on Models 650,654 using chassis 120118B, that two tuners are listed in the parts list:

1. Standard Tuner - Part No. 470607
2. General Instrument Tuner - Part No. 470606

A third alternative tuner has been added to Models 650,654. Some sets have been made incorporating the new Emerson tuner part no. 470640.

Since this tuner was added to Models 650,654 after the temporary service note on these sets was released, preliminary information on it is given in this addendum.

Complete information on the Emerson tuner will be furnished when the final service note on Models 650,654 is released.

TUNER ALIGNMENT

SIGNAL GENERATOR: Frequency range 40 to 225 mc.
Accurately calibrated.
AM modulated, 400 cycle.

The Emerson Tuner departs from the conventional type in that the individually tuned coils are replaced with a pretuned, tapped inductance. Channel selection is effected by switching in various values of inductance which combine with stray and tube capacitance to produce a given resonant frequency. Trimmers are provided in the oscillator and RF sections to compensate for the variable stray capacitances.

Assuming the trimmers to be properly set, the only cause of misalignment would be the distortion of the coil sections due to shipping, handling, etc. The coils are neither delicate nor critical, and must be bent considerably before detuning will occur. It follows, however, that should this be the case for a given coil section, all channels of lower frequency will be detuned to varying degrees. For this reason, the high channels are checked first and channel 2 last.

If, for any reason, it becomes advisable to replace a certain section or sections of coil, it is recommended that the entire coil be replaced. This is easily accomplished since the switch soldering lugs are slotted to receive the coil.

CAUTION: Switch lugs should be clean before new coil is installed.

It is possible, though not recommended, to replace individual sections. The section may be clipped from a new coil, or in an emergency, wound from #18 solid AWG, double nylon enamel (or similar) wire. Care should be taken to avoid overheating the wire and melting the insulation.

OSCILLATOR ADJUSTMENT

Proceed as follows:

1) If the oscillator has been disconnected during the IF alignment, put it back into circuit.

2) Connect the signal generator to the antenna terminal by means of a generator matching network.

3) Connect the vertical input terminals of the oscilloscope from cathode of V-2A (pin 8) to B minus through a shielded lead. Decouple this lead with 4.7K resistor. Set the vertical gain control at maximum. Synchronize the oscilloscope to 60 cycles or a harmonic of 60 cycles.

4) Set Fine Tuner to mid-capacity.

5) Set the generator to the oscillator frequency of channel 10 (170.35 mc) and adjust the oscillator trimmer C-1 (see Fig. 3) for zero beat viewed on the oscilloscope. Zero beat is indicated by a sharply defined minimum deflection that appears between two maximum deflections as the trimmer is tuned through resonance. Check all high channels (7-13) (see Fig. 4) to determine if zero beat occurs with fine tuner within 22½ degrees of mid-setting. It may be necessary to adjust coil L-1 (high band oscillator coil, Fig. 1) to bring channel 13 within this range. Adjustment is made by compressing or spreading the coil with an insulated screwdriver. If L-1 is adjusted, it may be necessary to retune trimmer to channel 10 to bring channels 7 to 10 within the 22½ degree range.

6) The low channels (2-6) are adjusted by starting at channel 6 and progressing through channel 2 (see Table 1).

7) Touching up a particular coil section is accomplished by spreading or compressing the individual coils. (See Fig. 1 for location of various coil sections).

CAUTION: Before checking a given channel, make certain the station selector switch is in the proper position.

To make certain that the trimmer is adjusted correctly, tune through the zero beat point and then back again to obtain the exact setting. Also, it is advisable when close to the zero beat setting, to vary the signal generator input voltage so as to obtain maximum response on the oscilloscope. However, before making the final trimmer setting, reduce the generator input as low as possible so as to reduce the lock-in range and obtain a sharp zero beat setting.

DWG. NO. 956010

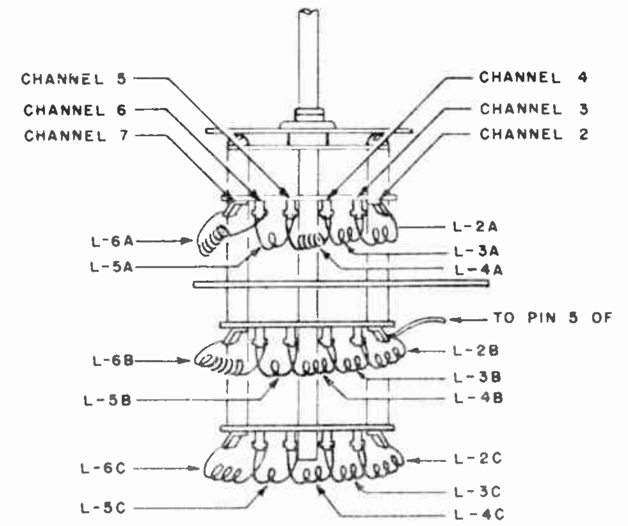

FIGURE 1 - ANTENNA, RF AND OSCILLATOR COILS

ANTENNA AND RF ALIGNMENT PROCEDURE

1) Connect the sweep generator to the antenna terminal by means of a generator matching network.

2) Disconnect choke (L-3) in cathode of oscillator tube V-2B at dummy lug.

3) Connect oscilloscope, through a decoupling resistor, across (R-1) in cathode circuit of mixer tube (V-2A).

4) Turn the station selector switch to channel 10. Set the center frequency of the sweep generator to the center frequency of channel 10 (195 mc). Adjust the RF trimmer (see Fig. 3) to place a (195 mc) marker at maximum amplitude of curve. This is the only RF adjustment and the RF stage of all high channels (7-13) should be properly tuned. Conversely, if channel 10 is not tuned properly, all high channels will be misaligned.

©John F. Rider

World Radio History

5) Check channels 7 and 13, noting whether the mid-frequencies of these channels produce maximum amplitude on curve. The RF coil for channel 13 (L-2) is a straight piece of wire (Fig. 1). As its position with respect to the adjacent lead affects the tuning of the high channels, moving it is a simple means of touching up the curve. A slight readjustment of the RF trimmer may be necessary if (L-2) is moved.

NOTE: As the bandwidth of the high channels is very broad, the mid-frequency marker may not fall exactly at peak of curves for channels 7 and 13. A slight variation is permissible.

6) Check the low channels starting at channel 6 and moving downward to channel 2.

NOTE: If channel 6 is not tuned properly, all low channels will be misaligned. Therefore, it is important that a good response curve be obtained from this channel.

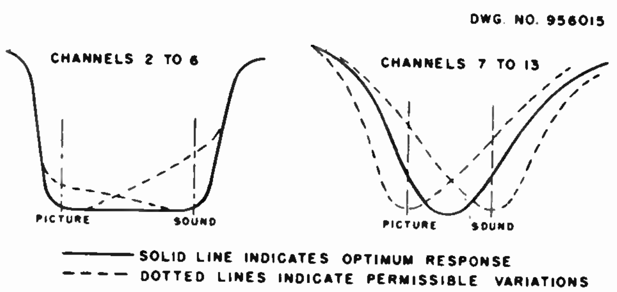

FIGURE 2 - R.F. RESPONSE CURVES

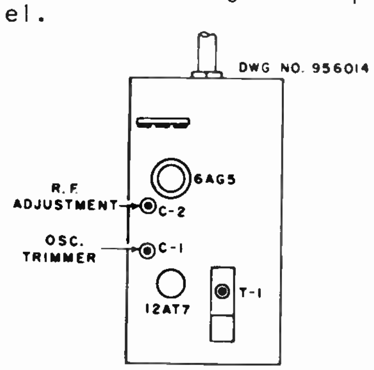

FIGURE 3 ALIGNMENT ADJUSTMENT LOCATIONS

In each case, with the center frequency of sweep at the channel center frequency, introduce markers corresponding to sound and picture carriers (see Fig. 2). It is permissible for the markers to appear slightly down on the skirt, but if they are too low (more than 6 db down), the curve may be changed by spreading or compressing the particular coil section with an insulated screwdriver.

NOTE: The RF coil is tuned to sound carrier. The antenna coil is tuned to video carrier.

CAUTION: Be sure to turn station selector switch to correct channel before checking band pass of that channel.

FREQUENCY CHART

CHANNEL	FREQUENCY	PICTURE	SOUND	OSCILLATOR
2	54-60	55.25	59.75	81 MC
3	60-66	61.25	65.75	87 MC
4	66-72	67.25	71.75	93
5	76-82	77.25	81.75	103
6	82-88	83.25	87.75	109
7	174-180	175.25	179.75	153
8	180-186	181.25	185.75	159
9	186-192	187.25	191.75	165
10	192-198	193.25	197.75	171
11	198-204	199.25	203.75	177
12	204-210	205.25	209.75	183
13	210-216	211.25	215.75	189

TABLE 1 FREQUENCY CHART

It should be noted that from channels 7 to 13, the oscillator frequency is lower than the incoming signal by the IF frequency, therefore the relative positions of the video and audio carriers reverse themselves on the overall response curve.

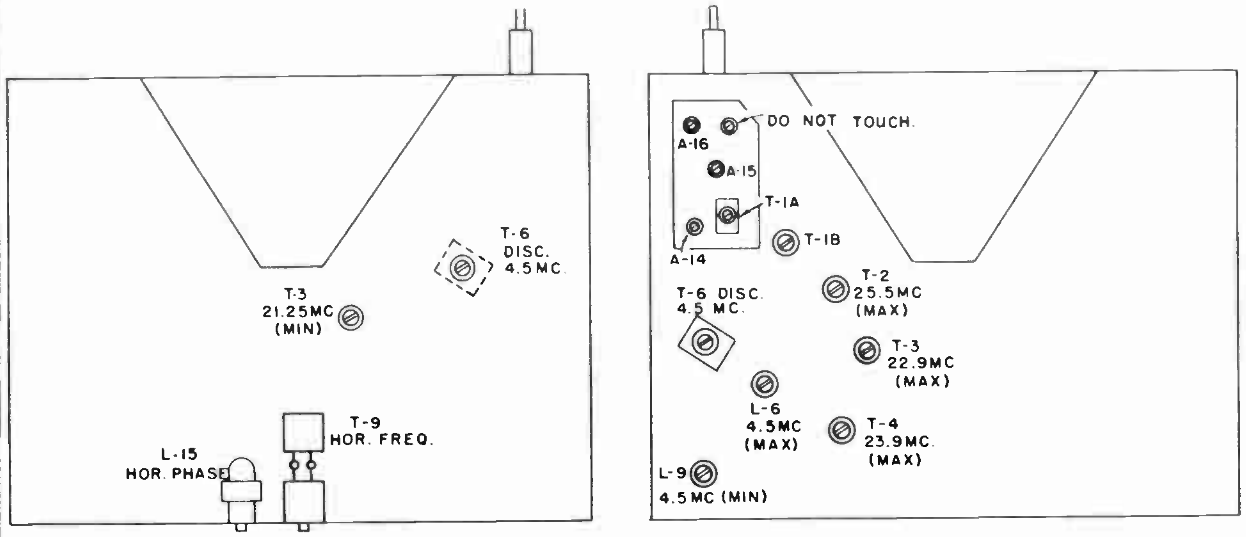
RECEIVER CHARACTERISTICS

ITEM	DESCRIPTION
Voltage Rating	115 volts, 60 cycles A.C.
Power Consumption	All Models - 155 watts
Current Drain (at 115 volts A.C.)	All Models - 1.4 Amps.
Frequency Range	54-88 MC; 174-216 MC.
Intermediate Frequencies	Video - 25.75 MC. Audio - 4.5 MC.
Antenna Input Impedance	300 Ohms, Balanced
Channel Selection	Twelve Position Rotary Turret
Chassis - Models	Models - 650D 654D, 655B Chassis - 120123-B

ALIGNMENT

a. **Equipment Required** - A sweep generator, accurate marker generator, oscilloscope, and v.t.v.m. are required for alignment. The marker generator must be very accurate and supply frequencies of 4.5 MC., and 20 to 28 MC.



BOTTOM OF CHASSIS TOP OF CHASSIS

FIGURE I . LOCATION OF ALIGNMENT POINTS

b. **Response Curves** - The i-f response curves for the video i-f stages are shown in figure 2.

c. **Alignment Points** - The location of all i-f transformers, tuned circuits, and trimmers is shown in figure I.

d. **TV I-F Alignment** -

1) Tune receiver to Channel 3.

2) Connect 3 volt bias battery negative terminal from junction of C31 and R27 (positive terminal) to B-.

3) Shape overall response curve, after individual peaking of stagger-tuned and over-coupled i-fs, as indicated in steps 1-6 below. See curves A and B.

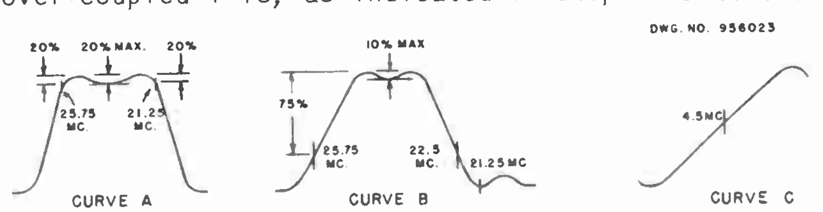


FIGURE 2 . RESPONSE CURVES

STEP	SIGNAL GENERATOR INPUT - CONNECTION	SIGNAL GENERATOR INPUT - FREQUENCY	INSTRUMENT CONNECTION	ADJUST	PROCEDURE
1	Connect marker generator to pin 1 (grid) of V-1 (6AU6) through .001 mfd. condenser. Low side to B neutral.	25.5 MC	Connect d.c. v.t.v.m. to pin 7 (grid of V4 12AT7). Low side to pin 8 of V4. Use 3 or 5 volt range.	T2	Peak for maximum response. Adjust generator signal level to produce one volt at grid of V4.
2	"	22.9 MC	"	T3 (Top)	"
3	"	21.25 MC	"	T3 (Bottom)	Adjust for minimum response. Repeat step 2.
4	"	23.9 MC	"	T4	Peak for maximum response.
5	Connect sweep generator to converter (6J6 or 12AT7) input, using three turn loop of wire slipped over tube. Connect marker gen. in parallel.	Sweep-24.5 MC (10 MC sweep) Marker-21.25 MC and 25.75 MC	Connect vertical input of scope through *detector network to pin 1 (grid) of V-2 (6AU6). Low side to B+ (130V). *Low input impedance of about 200 ohms	T1(A) T1(B)	Set markers as shown on response curve A, fig. 2. Note that the markers should be 20% down for this stage.
6	"	Sweep-24.5 MC (10 MC sweep) Marker-22.6 and 25.75 MC	Connect vertical input of scope in series with 10K resistor to pin 7 (grid) of V4 (12AT7). Low side to pin 8 of V4.	T2, T3, and T4	Adjust for overall response as shown in curve B, fig. 2. Adjust T2 to position 25.75 MC marker; adjust T3 (Top) to set 22.6 MC marker. Do not readjust trap. Equalize peaks of response curve by adjusting T4.

TABLE I . VIDEO I-F ALIGNMENT

e. **TV Sound Alignment** -

1) Set receiver to Channel 3.

2) Use accurate, crystal-controlled, marker generator.

STEP	SIGNAL GENERATOR INPUT - CONNECTION	SIGNAL GENERATOR INPUT - FREQUENCY	MEASURING INSTRUMENT	ADJUST	PROCEDURE
1	Marker generator through .001 mf to pin 2 of V-4 low side to B+ (130V).	Marker-4.5 MC.	Connect v.t.v.m. through 10K resistor to pin 1 (grid) of V5. Low side to B+ (130V).	L6	Peak for maximum response. Adjust generator input to produce one volt at grid of V5. (Above no signal value).
2	Connect sweep generator in parallel with marker gen.	Sweep-4.5 MC (450 KC sweep) Marker-4.5 MC	Replace v.t.v.m. with scope connected through 10K resistor to junction of R21 and C22. Low side to B neutral.	T6 (Secondary)	Position 4.5 MC. marker at center of S-curve, by adjusting secondary. (See Fig. 2 - curve C)
3	"	"	"	T6 (Primary)	Peak primary for maximum amplitude and linearity. Repeat step 2. (See Fig. 2 - curve C)
4	Marker generator through .001 mfd. to pin 7 of V4 (12AT7) low side to pin 8 of V4.	Marker-4.5 MC	A.C. v.t.v.m. or D.C. v.t.v.m. used with a peak detector probe to junction of R52,C47. Low side to B neutral.	L9	Adjust for min. reading of v.t.v.m. Keep contrast control set for maximum contrast.

TABLE II . AUDIO I-F AND DISC ALIGNMENT

f. **TV R-F Alignment** -

1) Set fine tuning control to mechanical center. Retain this setting for entire r-f alignment.

2) Use 300 ohm carbon resistor as dummy antenna.

3) Couple marker generator in parallel with sweep generator.

©John F. Rider

World Radio History

4) Use 10 MC. sweep for sweep generator. Couple generator to antenna terminals of receiver.

5) Connect vertical input of scope in series with 10K resistor to junction of R39 and L8 (pin 7 grid of V4).

STEP	SIGNAL GENERATOR INPUT		CHANNEL	ADJUST	PROCEDURE
	SWEEP GEN.	MARKER GEN.			
1	207.0 MC.	209.75 MC.	12	A12	Adjust for placement of 21.25 MC. marker as per response curve B.
2	•	•	12	A14, A15, A16	Adjust shape of response curve B for maximum amplitude and bandwidth.
3	213.0 MC.	215.75 MC.	13	A13	Adjust as in Step 1.

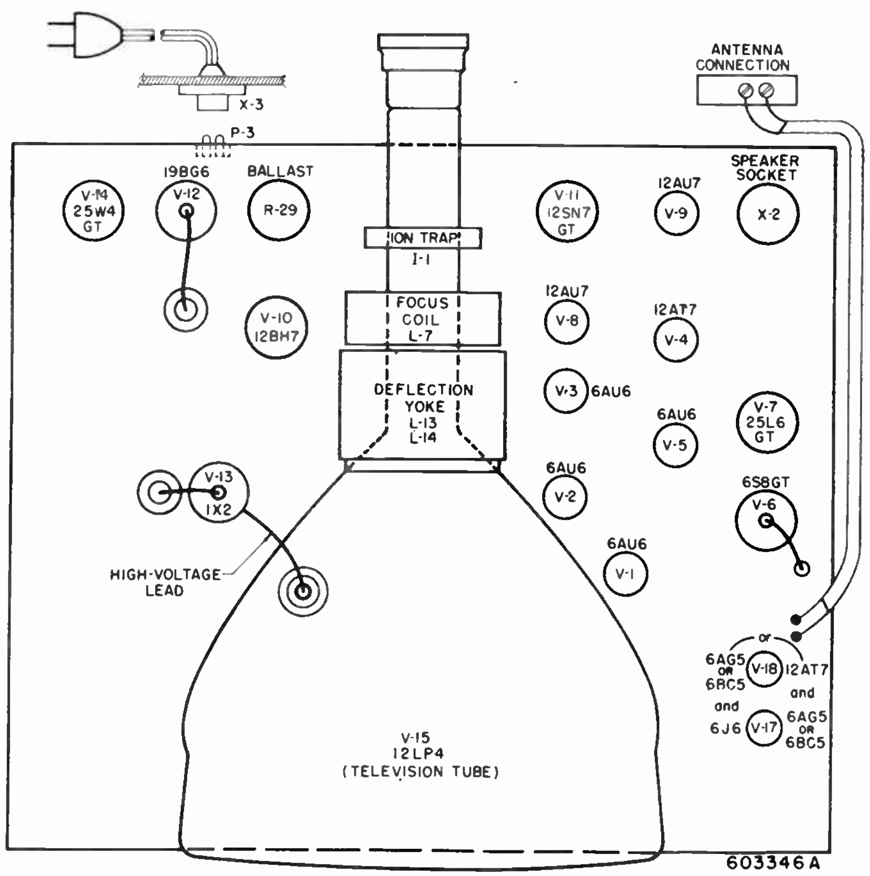
TABLE III . R.F. ALIGNMENT

TUBE LOCATIONS



FRONT

FIGURE 4. TUBE LOCATION DIAGRAM (FOR CHASSIS 120123B)

OPERATING CONTROLS

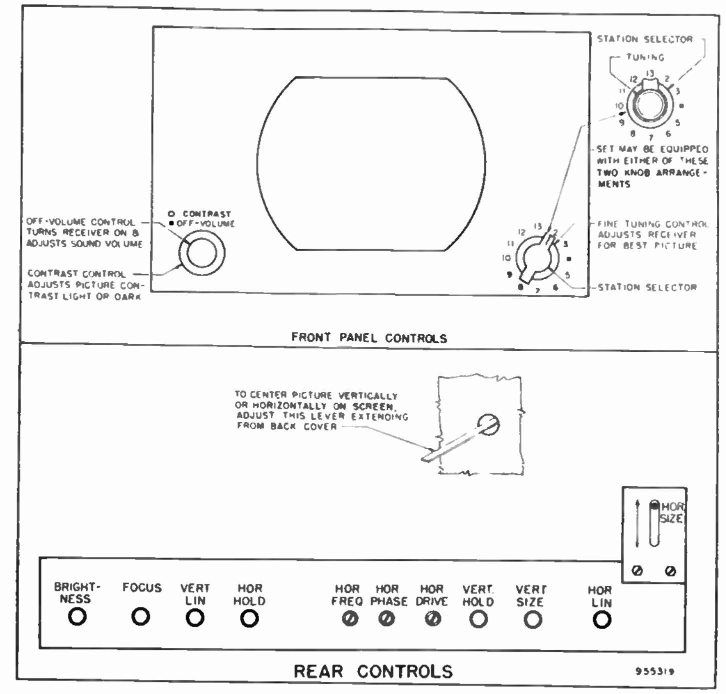


FIGURE 3. OPERATING CONTROLS (FOR MODELS 650D, 654D AND 655B)

ALIGNMENT OF MIRACLE PICTURE LOCK (Horizontal Sweep Automatic Freq. Control)

This must be done with chassis removed from cabinet and a scope.

1. Short phasing coil by using a clip lead across C-74 (.01 mf.)
2. Turn horizontal hold control counter clockwise when viewed from front of control. (Center tap at lowest B+ voltage).
3. Starting with frequency slug (T-9) all the way out rotate in until picture locks into synchronization.
4. Remove short from phasing coil and adjust in following manner.
   a) Place scope lead in series with 10,000 ohm resistor to junction R-83, L-15 low side to B neutral (B-).
   b) Set sweep frequency of scope to 8,000 and adjust fine frequency until pattern on scope is stationary (Note picture should be in synch during this adjustment.)
   c) Phasing slug (L-15) should be adjusted so that you have even peaks as shown in Figure 5 below.

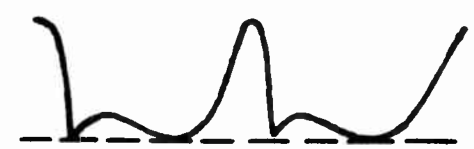

FIGURE 5

5. Switch tuner to off channel then back. Picture should be out of synch and from 4 to 5 black horizontal bars visible. If more or less, adjust horizontal frequency slug (T-9) until the 4 to 5 bars are seen.
6. Turn horizontal hold control slowly clockwise. Picture should synch in at about 1/4 of a turn. The picture should then remain in synchronization over the whole range of the horizontal hold control.

World Radio History

Subject: Modifications to nullify effects of intercarrier buzz on Models 650D, 654D, 655B-Chassis 120123B.

I. Remove following components from circuit.

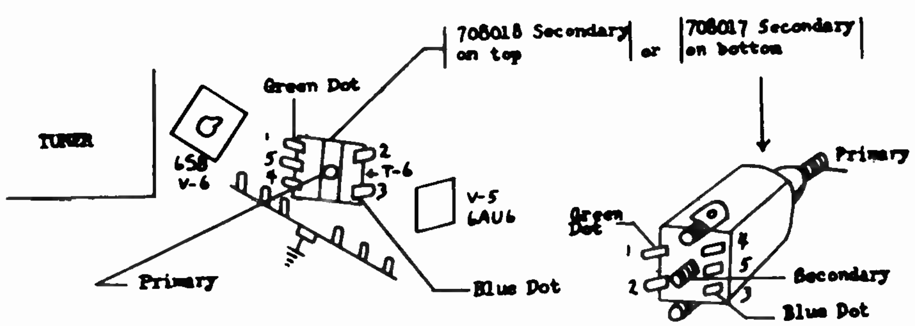
a) C-21 (110 mmf) connected between Pin #5 and Pin #2 of V-6 (6S8).
b) 2 - 100K (R-19, R-20) resistors from lug 5 of discriminator transformer (T-6).
c) R-16, C-19 (8200 ohms and 1500 mmf) from Pin #6 of V-5 (6AU6).
d) R-18 (2200) resistor from B+ point on terminal strip to lug 4 of T-6.

II Reconnect the following components

a) Remove pigtail of R-21 (68K) going to Pin #5 of 6S8 and connect to lug #5 of T-6.
b) Remove lead from Pin #3 of V-6 (6S8) and connect to Pin #5 of V-6.
c) Add a jumper wire from lug #4 of T-6 to Pin #6 of V-5 (6AU6).

III Add the following components

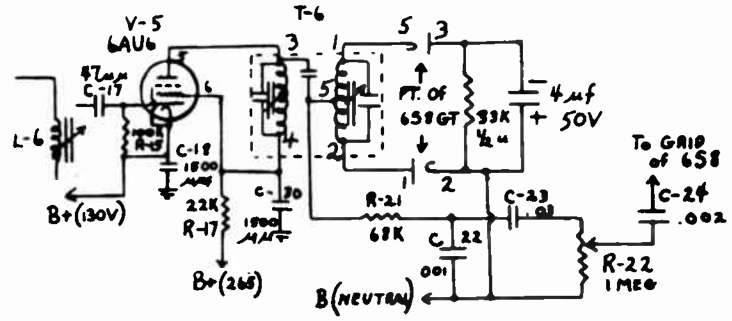
a) Place a 33K 1/2 watt resistor in parallel with a 4 mf 50 volt electrolytic condenser, part #925070-2 and connect from Pin #3 of V-6 (6S8GT) to neutral on nearby terminal board (2nd lug from tuner) with negative side of electrolytic to Pin #3, V-6 (6S8GT).
b) Add a .001 mf., 400 volt condenser from Pin #6 of V-6 (6S8GT) to B neutral.



IV Sound Alignment.

a) Place a D.C., V.T.V.M. (negative scale) across the 4 mf electrolytic ground terminal to B neutral (+side of electrolytic).
b) Tune in a good television station.
c) Adjust L-6 and primary of T-6 for maximum meter deflection.
d) Remove meter and adjust secondary (T-6) for maximum sound with minimum buzz.

NOTE: If buzz is not eliminated try changing the 6S8 tube and then repeat step IV.

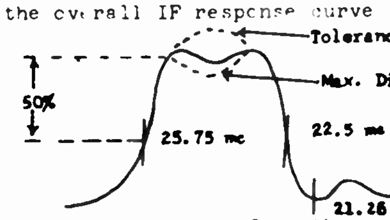


Subject: Change in overall I.F. response curve as shown in following preliminary service notes.

Models	Chassis
614D, 637A	120095B
650D, 654D, 655B	120123B
650F, 654F, 655F	120138B

Performance can be frequently be improved if the 25.75 mc picture IF marker and the 22.5 mc, IF bandpass marker appear at the 50% response point instead of the 75% down point as shown previously in the service notes for the above models.

When modified the overall IF response curve should appear as follows:



With 10 mc sweep width the output from the sweep generator should be adjusted to produce about .5 volts D.C. across the detector load (R-39, 4700 ohms).

Note: The above is particularly helpful when other expedients fail to minimize effects caused by station modulation variations.

VOLTAGE AND RESISTANCE READINGS

FOR CHASSIS 120123-B - MODELS 650D, 654D, 655B

NOTE: Voltage and resistance measurements listed here are for chassis 120123-B stamped with code marking triangle 2.

Voltages may vary slightly from table figures shown here if chassis is not coded as stated above. The peak to peak voltage given may vary slightly due to component variations.

CONDITIONS FOR TAKING VOLTAGE READINGS: (See table below).

1. Antenna disconnected and antenna terminals shorted.
2. Line voltage 117 volts.
3. All controls set for normal picture.
4. All readings taken with R.C.A. voltohmyst from points to B neutral (pin 8 of V9).

FOR A QUICK OVERALL RESISTANCE CHECK:

1. B plus (pin 6 of V2) to B neutral should read 80K approx.
2. B minus (pin 8 of V4) to B neutral should read 100K approx.
3. B neutral to chassis should read 300K approx.

CONDITIONS FOR TAKING RESISTANCE READINGS: (See table on other side).

1. Due to high leakage resistance between B plus, B neutral and B minus, these three points must be connected to obtain quick readings.
2. Connect pin 6 of V2 and pin 8 of V4 with B neutral.
3. After taking resistance readings remove shorting leads.

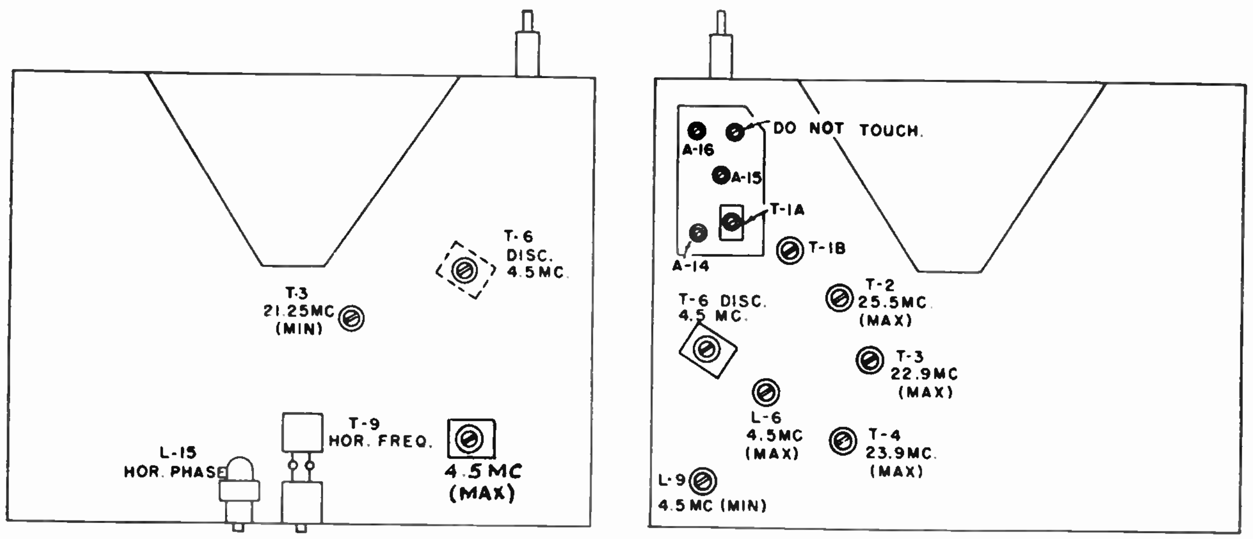
World Radio History

RECEIVER CHARACTERISTICS

ITEM	DESCRIPTION
Voltage Rating	115 volts, 60 cycles A.C.
Power Consumption	All Models - 155 watts
Current Drain (at 115 volts A.C.)	All Models - 1.4 Amps.
Frequency Range	54-88 MC; 174-216 MC.
Intermediate Frequencies	Video - 25.75 MC. Audio - 4.5 MC.
Antenna Input Impedance	300 Ohms, Balanced
Channel Selection	Twelve Position Rotary Turret
Chassis - Models	Models - 650F, 654F, 655F Chassis - 120138-B

I. ALIGNMENT

a. **Equipment Required** - A sweep generator, accurate marker generator, oscilloscope, and v.t.v.m. are required for alignment. The marker generator must be very accurate and supply frequencies of 4.5 MC., and 20 to 28 MC.



BOTTOM OF CHASSIS TOP OF CHASSIS

FIGURE I . LOCATION OF ALIGNMENT POINTS

b. **Response Curves** - The i-f response curves for the video i-f stages are shown in figure 2.

c. **Alignment Points** - The location of all i-f transformers, tuned circuits, and trimmers is shown in figure I.

d. **TV I-F Alignment** -

1) Tune receiver to Channel 3.

2) Connect 3 volt bias battery negative terminal from junction of C3I and R27 (positive terminal) to B-.

3) Shape overall response curve, after individual peaking of stagger-tuned and over-coupled i-fs, as indicated in steps I-6 below. See curves A and B.

STEP	SIGNAL GENERATOR INPUT CONNECTION	FREQUENCY	INSTRUMENT CONNECTION	ADJUST	PROCEDURE
1	Connect marker generator to pin 1 (grid) of V-1 (6AU6) through .001 mfd. condenser. Low side to B neutral.	25.5 MC	Connect d.c. v.t.v.m. to pin 7 (grid of V8 12AT7). Low side to pin 8 of V8. Use 3 or 5 volt range.	T2	Peak for maximum response. Adjust generator signal level to produce one volt at grid of V8.
2	"	22.9 MC	"	T3 (Top)	"
3	"	21.25 MC	"	T3 (Bottom)	Adjust for minimum response. Repeat step 2.
4	"	23.9 MC	"	T4	Peak for maximum response.
5	Connect sweep generator to converter (6J6 or 12AT7) input, using three turn loop of wire slipped over tube. Connect marker gen. in parallel.	Sweep-24.5 MC (10 MC sweep) Marker-21.25 MC and 25.75 MC	Connect vertical input of scope through *detector network to pin 1 (grid) of V-2 (6AU6). Low side to B+ (130V). *Low input impedance of about 200 ohms	T1(A) T1(B)	Set markers as shown on response curve A, fig. 2. Note that the markers should be 20% down for this stage.
6	"	Sweep-24.5 MC (10 MC sweep) Marker-22.6 and 25.75 MC	Connect vertical input of scope in series with 10K resistor to pin 7 (grid) of V8 (12AT7). Low side to pin 8 of V8.	T2, T3, and T4	Adjust for overall response as shown in curve B, fig. 2. Adjust T2 to position 25.75 MC marker; adjust T3 (Top) to set 22.6 MC marker. Do not readjust trap. Equalize peaks of response curve by adjusting T4.

TABLE I . VIDEO I-F ALIGNMENT

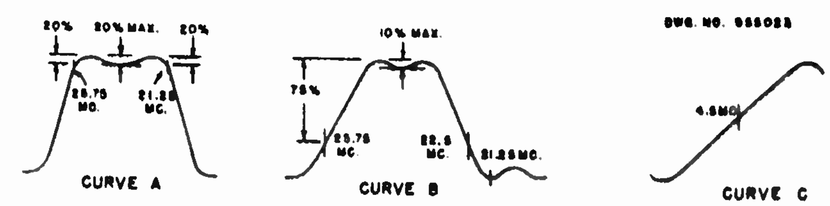


FIGURE 2 . RESPONSE CURVES

e. **TV Sound Alignment** -

1) Set receiver to Channel 3.

2) Use accurate, crystal-controlled, marker generator.

f. **TV R-F Alignment** -

1) Set fine tuning control to mechanical center. Retain this setting for entire r-f alignment.

2) Use 300 ohm carbon resistor as dummy antenna.

World Radio History

4. ALIGNMENT OF MIRACLE PICTURE LOCK (Horizontal Sweep Automatic Freq. Control)

This must be done with chassis removed from cabinet and a scope.

1. Short phasing coil by using a clip lead across C-74 (.01 mf.)
2. Turn horizontal hold control counter clockwise when viewed from front of control. (Center tap at lowest B+ voltage).
3. Starting with frequency slug (T-9) all the way out rotate in until picture locks into synchronization.
4. Remove short from phasing coil and adjust in following manner.
   a) Place scope lead in series with 10,000 ohm resistor to junction R-83, L-15 low side to B neutral (B-).
   b) Set sweep frequency of scope to 8,000 and adjust fine frequency until pattern on scope is stationary (Note picture should be in synch during this adjustment.)
   c) Phasing slug (L-15) should be adjusted so that you have even peaks as shown in Figure 5 below.

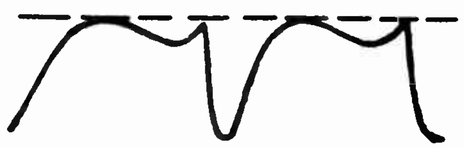

FIGURE 5

5. Switch tuner to off channel then back. Picture should be out of synch and from 4 to 5 black horizontal bars visible. If more or less, adjust horizontal frequency slug (T-9) until the 4 to 5 bars are seen.
6. Turn horizontal hold control slowly clockwise. Picture should synch in at about 1/4 of a turn. The picture should then remain in synchronization over the whole range of the horizontal hold control.

5. TUBE LOCATIONS

The tube complements of chassis 120138B are listed in the following table:

SYMBOL	TUBE TYPE	FUNCTION	SYMBOL	TUBE TYPE	FUNCTION
V-1	6AU6	1st Video I.F. Ampl.	V-14	25W4GT	Horizontal Damper
V-2	6AU6	2nd Video I.F. Ampl.	V-15	2LP4	Kinescope

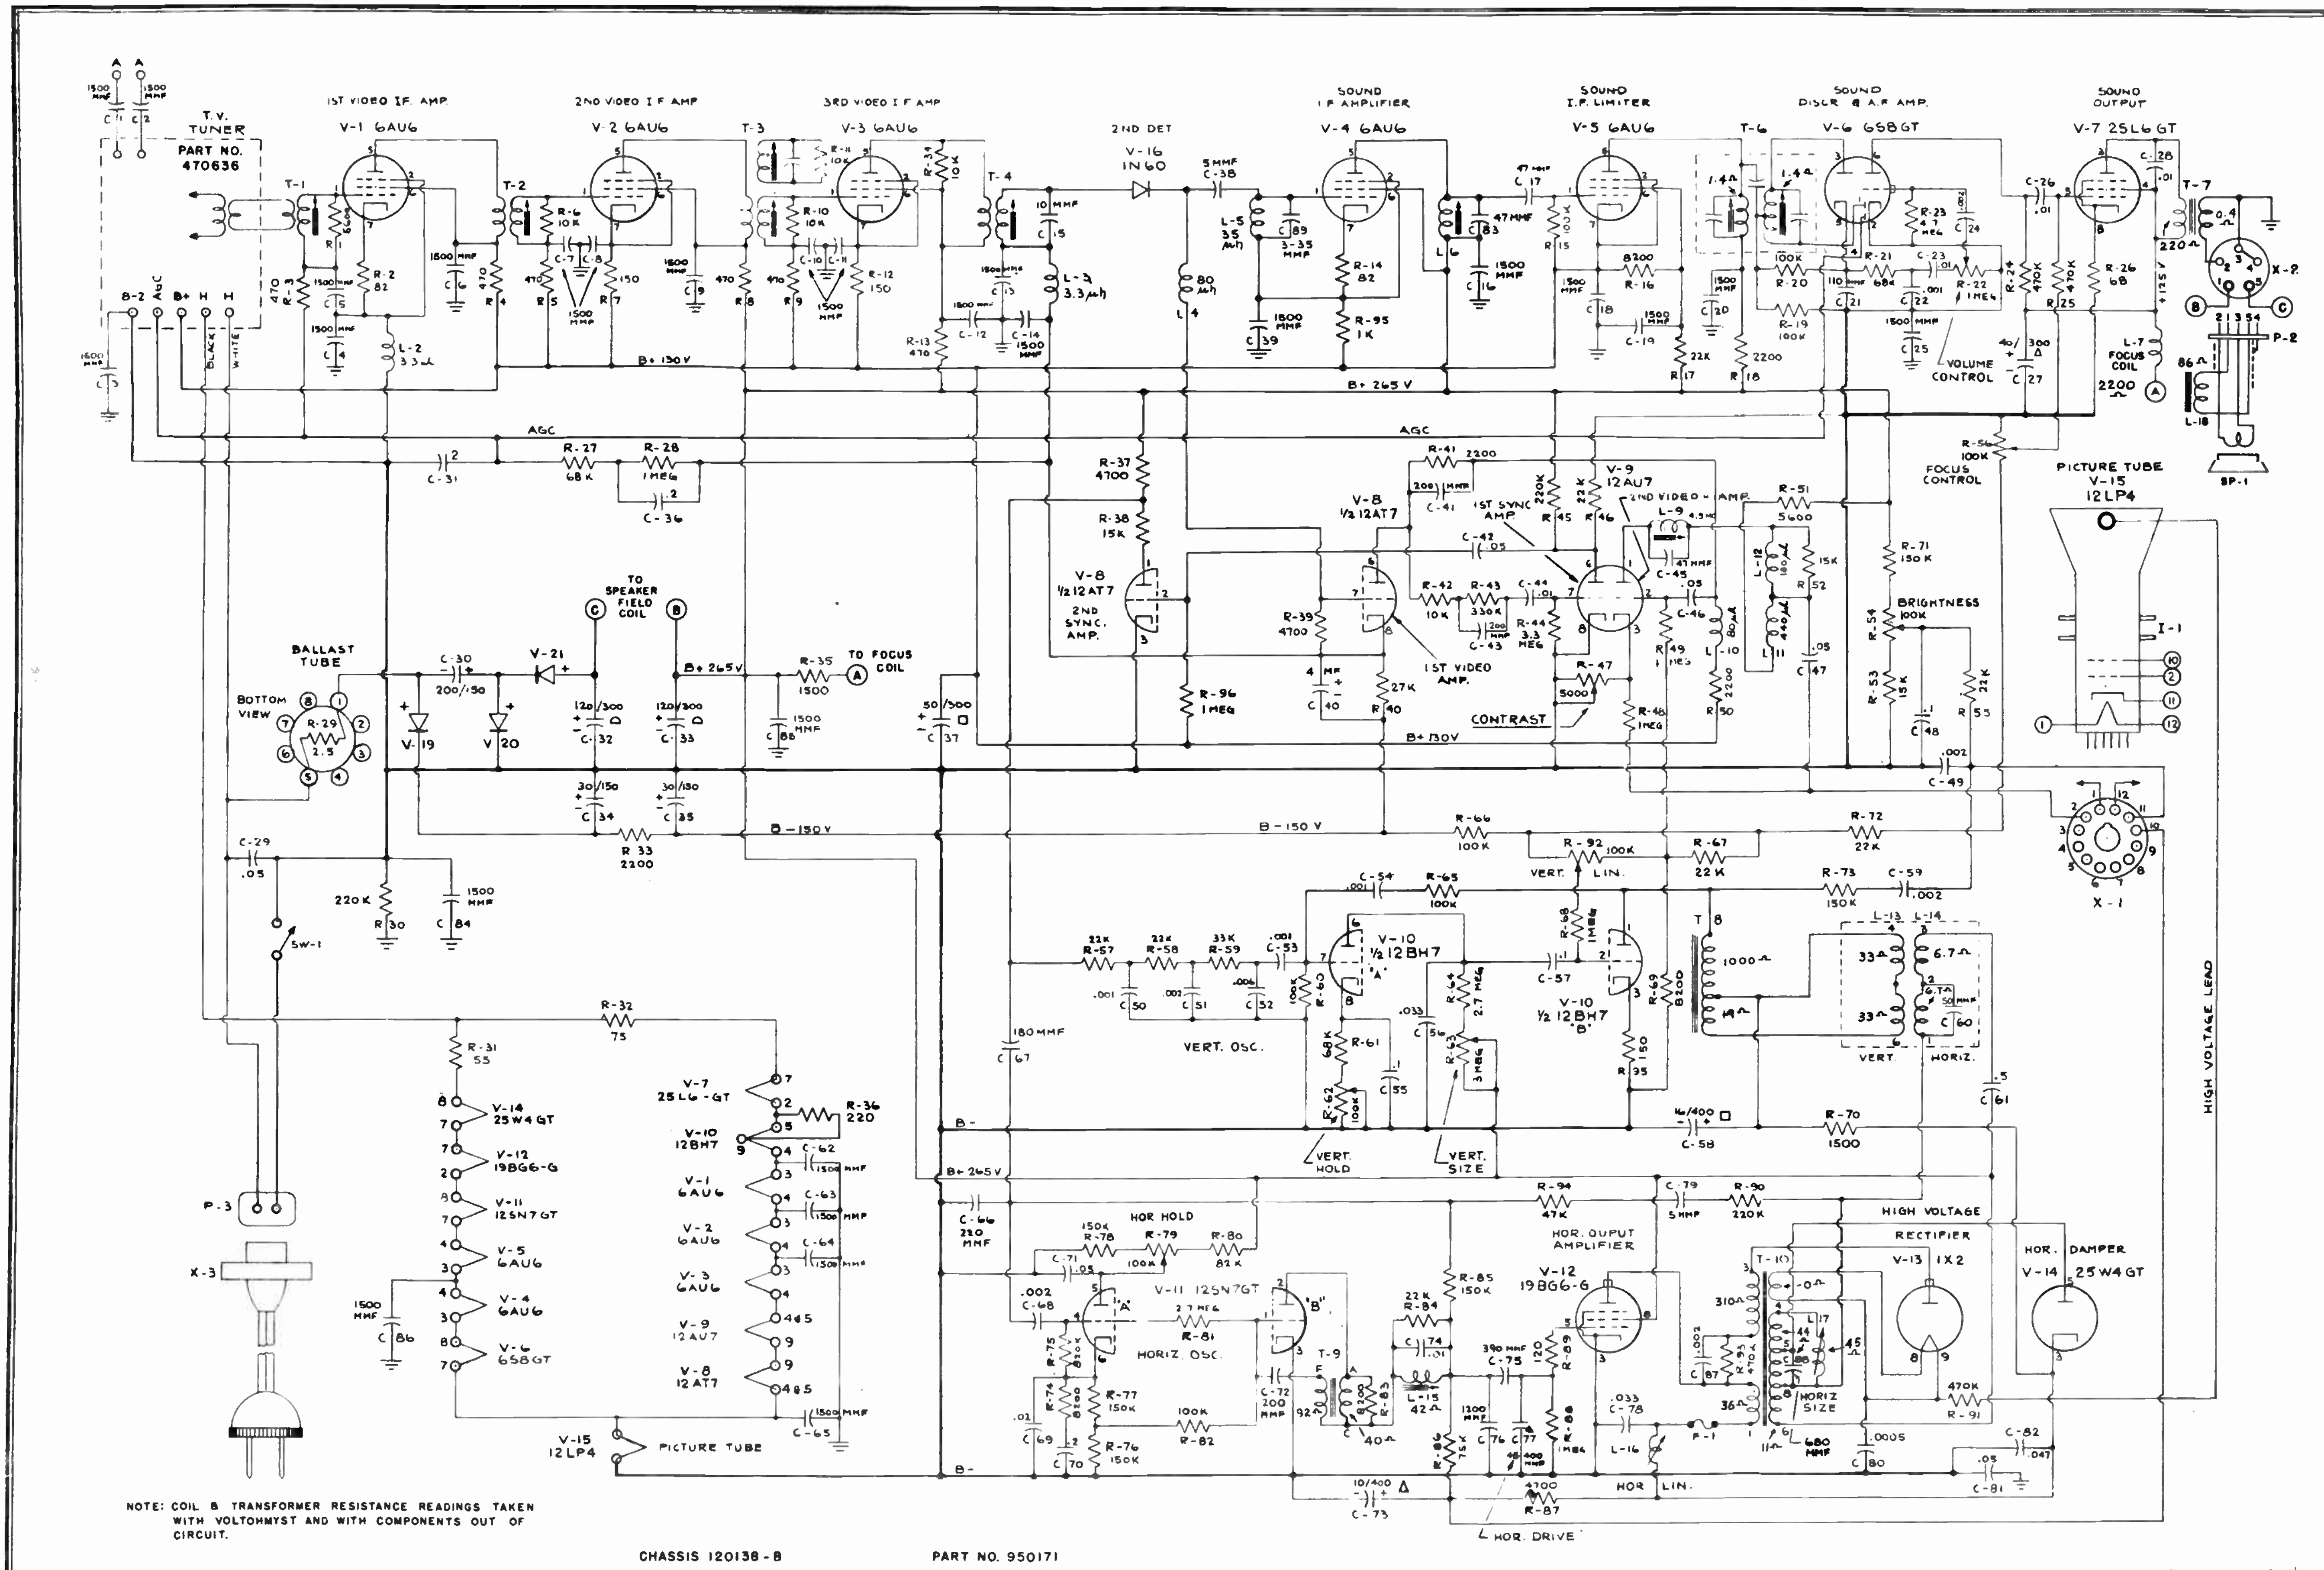

FIGURE 6 - SCHEMATIC DIAGRAM (CHASSIS 120138B)

MODELS 650F, 654F, 655F, Ch. 120138-B

World Radio History

Subject: Circuit modifications in Models 650F, 654F, 655F using Chassis 120138B.

Sets coded Triangle 1 have the following changes incorporated to reduce the effects caused by station modulation variation and to make tuning easier.

1. R-16 (8200 ohms), R-17 (22K ohms) R-95 (1K ohms), C-19 (1500 mmf.) are removed from the circuit.
2. The junction of C-20, R-13 and T-6 is connected to Pin 6 of V-5 (6AU6) by means of a jumper wire.
3. The value of R-18 has been changed from 2200 ohms to 68K ohms, 1/2 watt.
4. All leads to junction of (L-5, C-89), C-39, R-14, and Pin 2 of V-4 are disconnected from one another and rewired as follows:

Note: L-5 and C-89 are left connected to one another.
a) R-14 (82 ohms) is wired to B+ (130 volt line).
b) Pin 2 of V-4 (6AU6) is wired to Pin 7 of the same tube.
C) C-39 (1500 mmf.) is wired to Pin 7 of V-4.

5. The following components have been added.
   a) A 1 megohm, 1/2 watt resistor from Pin 1 of V-5 to junction of L-5, C-89.
   b) A .01 mf., 200 volt condenser from junction L-5, C-89, 1 meg. to Pin 7 of V-4 (6AU6).
   c) A 33K ohm, 1 watt resistor from Pin 6 of V-8 (12AT7) to B+ (265 volt line).

VOLTAGE AND RESISTANCE READINGS FOR CHASSIS 120138-B - MODELS 650F, 654F, 655F

NOTE: Voltage and resistance measurements listed here are for chassis 120138-B stamped with a triangle but without a number stamped within the triangle.

Voltages may vary slightly from table figures shown here if chassis is not coded as stated above. The peak to peak voltage given may vary slightly due to component variations.

CONDITIONS FOR TAKING VOLTAGE READINGS: (See table below)

1. Antenna disconnected and antenna terminals shorted.
2. Line voltage 117 volts.
3. All controls set for normal picture.
4. All readings taken with R.C.A. voltohmyst from point to B neutral (pin 8 of V9).

FOR A QUICK OVERALL RESISTANCE CHECK:

1. B plus (pin 6 of V2) to B neutral should read 0.1M.
2. B neutral to chassis should read 220K.
3. B minus (pin 8 of V8) to B neutral should read 120K.

CONDITIONS FOR TAKING RESISTANCE READINGS: (See table)

1. Due to high leakage resistance between B plus, B neutral and B minus, these three points must be connected to obtain quick readings.
2. Connect B plus (pin 6 of V2) and B minus (pin 8 of V8) to B neutral (pin 8 of V9) to obtain resistance readings.
3. After taking resistance readings remove shorting leads.

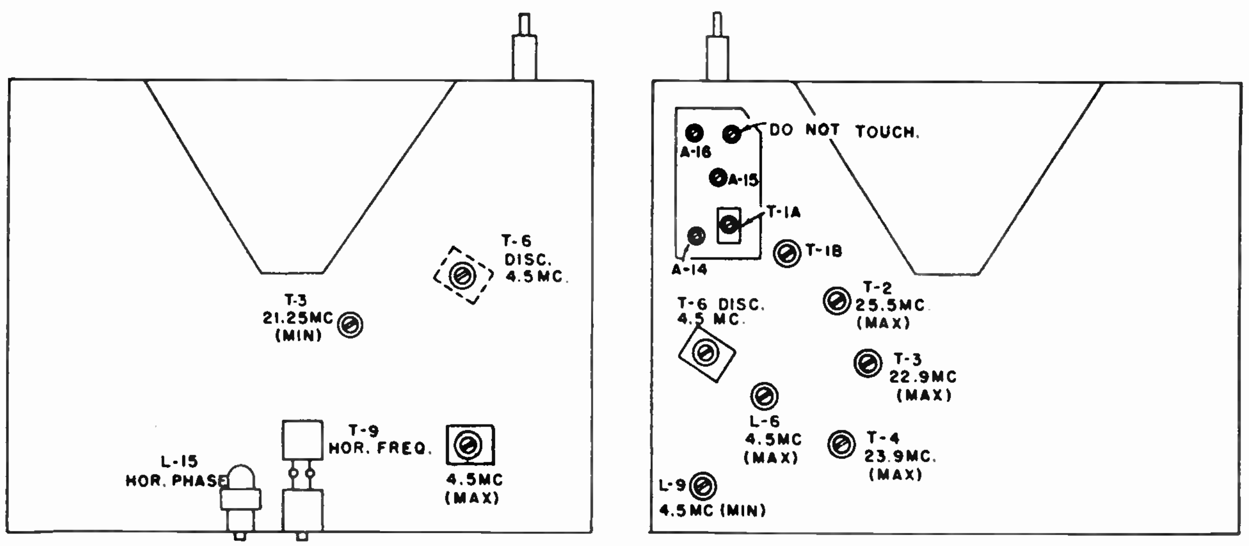
INDEX

RECEIVER CHARACTERISTICS

ITEM	DESCRIPTION
Voltage Rating	115 volts, 60 cycles A.C.
Power Consumption	All Models - 155 watts
Current Drain (at 115 volts A.C.)	All Models - 1.4 Amps.
Frequency Range	54-88 MC; 174-216 MC.
Intermediate Frequencies	Video - 25.75 MC. Audio - 4.5 MC.
Antenna Input Impedance	300 Ohms, Balanced
Channel Selection	Twelve Position Rotary Turret
Chassis - Models	Models - 660B, 664B, 673B Chassis - 120133-B

I. ALIGNMENT

a. **Equipment Required** - A sweep generator, accurate marker generator, oscilloscope, and v.t.v.m. are required for alignment. The marker generator must be very accurate and supply frequencies of 4.5 MC., and 20 to 28 MC.



BOTTOM OF CHASSIS TOP OF CHASSIS

FIGURE 1 - LOCATION OF ALIGNMENT POINTS

b. **Response Curves** - The i-f response curves for the video i-f stages are shown in figure 2.

c. **Alignment Points** - The location of all i-f transformers, tuned circuits, and trimmers is shown in figure 1.

d. **TV I-F Alignment** -

1) Tune receiver to Channel 3.

2) Connect 3 volt bias battery negative terminal from junction of C31 and R27 (positive terminal) to B-.

3) Shape overall response curve, after individual peaking of stagger-tuned and over-coupled i-fs, as indicated in steps 1-6 below. See curves A and B.

STEP	SIGNAL GENERATOR INPUT: CONNECTION	SIGNAL GENERATOR INPUT: FREQUENCY	INSTRUMENT CONNECTION	ADJUST	PROCEDURE
1	Connect marker generator to pin 1 (grid) of V-1 (6AU6) through .001 mfd. condenser. Low side to B neutral.	25.5 MC	Connect d.c. v.t.v.m. to pin 7 (grid of V8 12AT7). Low side to pin 8 of V8. Use 3 or 5 volt range.	T2	Peak for maximum response. Adjust generator signal level to produce one volt at grid of V8.
2	"	22.9 MC	"	T3 (Top)	"
3	"	21.25 MC	"	T3 (Bottom)	Adjust for minimum response. Repeat step 2.
4	"	23.9 MC	"	T4	Peak for maximum response.
5	Connect sweep generator to converter (6J6 or 12AT7) input, using three turn loop of wire slipped over tube. Connect marker gen. in parallel.	Sweep-24.5 MC (10 MC sweep) Marker-21.25 MC and 25.75 MC	Connect vertical input of scope through *detector network to pin 1 (grid) of V-2 (6AU6) Low side to B+ (130V). *Low input impedance of about 200 ohms	T1(A) T1(B)	Set markers as shown on response curve A, fig. 2. Note that the markers should be 20% down for this stage.
6	"	Sweep-24.5 MC (10 MC sweep) Marker-22.6 and 25.75 MC	Connect vertical input of scope in series with 10K resistor to pin 7 (grid) of V8 (12AT7). Low side to pin 8 of V8.	T2, T3, and T4	Adjust for overall response as shown in curve B, fig. 2. Adjust T2 to position 25.75 MC marker; adjust T3 (Top) to set 22.6 MC marker. Do not readjust trap. Equalize peaks of response curve by adjusting T4.

e. **TV Sound Alignment -**

1) Set receiver to Channel 3.

2) Use accurate, crystal-controlled, marker generator.

STEP	SIGNAL GENERATOR INPUT CONNECTION	SIGNAL GENERATOR INPUT FREQUENCY	MEASURING INSTRUMENT	ADJUST	PROCEDURE
1	Marker generator through .001 uf to junction of L-4, C-38. Low side to chassis.	Marker- 4.5 MC.	Connect v.t.v.m. through 10K resistor to pin 1 (grid of V-5). Low side to B+ (130V).	C-89	Peak for maximum negative response. Adjust generator input to produce one volt at grid of V5. (Above no signal value.
2	"	"	"	L6	"
3	Connect sweep generator in parallel with marker gen.	Sweep- 4.5 MC (450 KC sweep) Marker- 4.5 MC	Replace v.t.v.m. with scope connected through 10K resistor to junction of R21 and C22. Low side to B neutral.	T6 (Secondary)	Position 4.5 MC. marker at center of S-curve, by adjusting secondary. (See Fig. 2 - curve C).
4	"	"	"	T6 (Primary)	Peak primary for maximum amplitude and linearity. Repeat step 3. (See Fig. 2 - curve C)
5	Marker generator through .001 mfd. to pin 7 of V8 (12AT7) low side to pin 8 of V8.	Marker- 4.5 MC	A.C. v.t.v.m. or D.C. v.t.v.m. used with a peak detector probe to junction of R52, C47. Low side to B neutral.	L9	Adjust for min. reading of v.t.v.m. Keep contrast control set for maximum contrast.

TABLE II - AUDIO I-F AND DISC ALIGNMENT

f. **TV R-F Alignment -**

1) Set fine tuning control to mechanical center. Retain this setting for entire r-f alignment.

2) Use 300 ohm carbon resistor as dummy antenna.

3) Couple marker generator in parallel with sweep generator.

4) Use 10 MC. sweep for sweep generator. Couple generator to antenna terminals of receiver.

5) Connect vertical input of scope in series with 10K resistor to junction of R39 and L4 (pin 7 grid of V8), low side to pin 8 of V8.

STEP	SIGNAL GENERATOR INPUT SWEEP GEN.	SIGNAL GENERATOR INPUT MARKER GEN.	CHANNEL	ADJUST	PROCEDURE
1	207.0 MC.	209.75 MC.	12	A12	Adjust for placement of 21.25 MC. marker as per response curve B.
2	"	"	12	A14, A15, A16	Adjust shape of response curve B for maximum amplitude and bandwidth.
3	213.0 MC.	215.75 MC.	13	A13	Adjust as in Step 1.

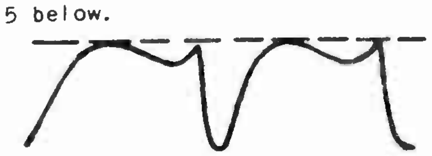
World Radio History

4. ALIGNMENT OF MIRACLE PICTURE LOCK (Horizontal Sweep Automatic Freq. Control)

This must be done with chassis removed from cabinet and a scope.

1. Short phasing coil by using a clip lead across C-74 (.01 mf.)
2. Turn horizontal hold control counter clockwise when viewed from front of control. (Center tap at lowest B+ voltage).
3. Starting with frequency slug (T-9) all the way out rotate in until picture locks into synchronization.
4. Remove short from phasing coil and adjust in following manner.
   a) Place scope lead in series with 10,000 ohm resistor to junction R-83, L-15 low side to B neutral (B-).
   b) Set sweep frequency of scope to 8,000 and adjust fine frequency until pattern on scope is stationary (Note picture should be in synch during this adjustment.)
   c) Phasing slug (L-15) should be adjusted so that you have even peaks as shown in Figure 5 below.

FIGURE 5



5. Switch tuner to off channel then back. Picture should be out of synch and from 4 to 5 black horizontal bars visible. If more or less, adjust horizontal frequency slug (T-9) until the 4 to 5 bars are seen.
6. Turn horizontal hold control slowly clockwise. Picture should synch in at about 1/4 of a turn. The picture should then remain in synchronization over the whole range of the horizontal hold control.

5. TUBE LOCATIONS

The tube complements of chassis 120133B are listed in the following table:

SYMBOL	TUBE TYPE	FUNCTION	SYMBOL	TUBE TYPE	FUNCTION
V-1	6AU6	1st Video I.F. Ampl.	V-14	25W4GT	Horizontal Damper
V-2	6AU6	2nd Video I.F. Ampl.	V-15	2LP4	Kinescope
V-3	6AU6	3rd Video I.F. Ampl.	V-16	IN60	2nd Det. (Video) Germanium Crystal
V-4	6AU6	Sound I.F. Amplifier			
V-5	6AU6	Sound I.F. Limiter	V-17	6J6	Oscillator & Converter
V-6	6SBGT	Sound Discr. & A.F. Ampl.			
V-7	25L6GT	Sound Output			
V-8	12AT7	2nd Sync. Ampl.	V-18	6CB6 or 6AG5 or 6BC5	R.F. Amplifier
V-9	12AU7	2nd Video Ampl.			
V-10	12BH7	Vertical Osc. & Output			
V-11	12SN7GT	Horizontal Oscillator	V-19		Selenium Rectifier
V-12	19BG6	Hor. Output Ampl.	V-20		Selenium Rectifier
V-13	1X2	High Voltage Rectifier	V-21		Selenium Rectifier

TABLE IV - TUBE COMPLEMENTS

Sets coded Triangle 1 have the following changes incorporated to reduce the effects caused by station modulation variation and to make tuning easier.

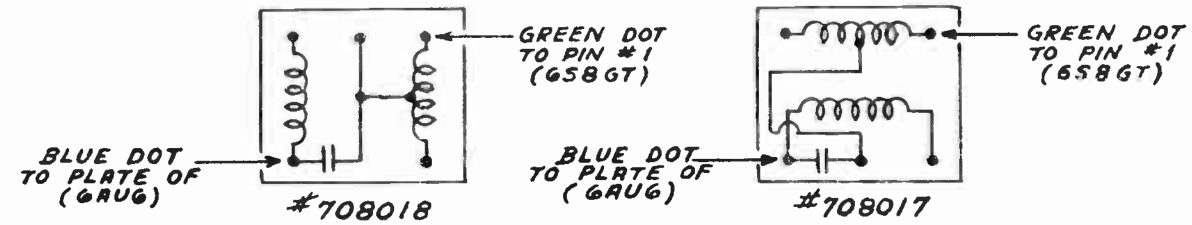
1. R-16 (6200 ohms), R-17 (22K ohms) R-95 (1K ohms), C-19 (1500 mmf.) are removed from the circuit.
2. The junction of C-20, R-18 and T-6 is connected to Pin 6 of V-6 (6AU6) by means of a jumper wire.
3. The value of R-18 has been changed from 2200 ohms to 68K ohms, 1/2 W.
4. All leads to junction of (L-5, C-89), C-39, R-14 and Pin 2 of V-4 are disconnected from one another and rewired as follows:

   Note: L-5 and C-89 are left connected to one another.
   (a) R-14 (82 ohms) is wired to B+ (130 volt line).
   (b) Pin 2 of V-4 (6AU6) is wired to Pin 7 of the same tube.
   (c) C-39 (1500 mmf.) is wired to Pin 7 of V-4.

5. The following components have been added.
   a) A 1 megohm, 1/2 watt resistor from Pin 1 of V-5 to junction of L-5, C-89.
   b) A .01 mf., 200 volt condenser from junction L-5, C-89, 1 meg. to pin 7 of V-4 (6AU6).
   c) A 33K ohm, 1 watt resistor from Pin 6 of V-8 (12AT7) to B+ (265 volt line).

Chassis coded with Triangle 2 have a .001 mf., 600 volt condenser from Pin 6 of 6S8GT to B neutral. The body of this condenser is dressed close to the rear of the tuner unit.

In production, two types of discriminator transformers are used. Electrically these transformers are identical, the difference being in the mechanical layout of the coils.



Chassis using part #708017 are coded with the letter S inside the code triangle. The secondary slug of this transformer is located underneath the chassis.

CORRECTION OF PRELIMINARY SERVICE NOTE FOR MODELS 660B, 664B, 673B, Chassis 120133B.

Please refer to overall video I.F. response curve in preliminary note. The 25.75 mc picture I.F. marker and the 21.5 mc I.F. bandpass marker should be at the 50% reference point instead of at the 75% point as shown.

Sets coded Triangle 3 have the following changes incorporated to facilitate sound alignment.

1. C-3 has been changed from 1500 mmf. to .005 mf. ceramic.
2. R-14 has been changed from 82 to 150 ohms 1/2 watt.
3. A 150 ohm 1/2 watt resistor has been inserted between Pin #2 of V-5 and B+130 volts.
4. A 470 ohm 1/2 watt resistor has been added from B+ 265 volt line to lug where L-6 is connected.

The following wiring changes have been made.
1. The 265 volt lines connected between dummy lug near V-5 and L-6 and also between L-6 and dummy lug near speaker socket have been removed.
2. A new 265 volt line has been added between dummy lug near V-5 and dummy lug near speaker socket.
3. The wire going from Pin #2 of V-5 has been removed from C-37 (50 mfd. 300 volt) and connected to B+ 130 volt point on dummy lug near V-5.

Sets coded Triangle 4 have the following changes:
1. C-80 (.0005 mf., 10KV) condenser has been removed.
2. C-87 has been changed from .002 mf., 600 volts to .002 mf., 1600 volts.
3. R-91 (470K ohms) has been removed and the high voltage lead connected directly to Pin #9 of V-13 (1X2).
4. Pigtail of R-93 has been removed from junction.
5. R-93 has been changed from 470K ohms to 940K ohms which is actually composed of R-93 (470K ohms) and R-91 (470K ohms) in series.

©John F. Rider

World Radio History

CONDITIONS FOR TAKING VOLTAGE READINGS: (See table below)

1. Antenna disconnected and antenna terminals shorted.
2. Line voltage 117 volts.
3. All controls set for normal picture.
4. All readings taken with R.C.A. voltohmyst from point to B neutral (pin 8 to V9).

FOR A QUICK OVERALL RESISTANCE CHECK:

1. B plus (pin 6 of V2) to B neutral should read 0.1M.
2. B neutral to chassis should read 220K.
3. B minus (pin 8 to V8) to B neutral should read 120K.

CONDITIONS FOR TAKING RESISTANCE READINGS: (See table on page 5).

1. Due to high leakage resistance between B plus, B neutral and B minus, these three points must be connected to obtain quick readings.
2. Connect B plus (pin 6 of V2) and B minus (pin 8 of V8) to B neutral (pin 8 of V9) to obtain resistance readings.
3. After taking resistance readings remove shorting leads.

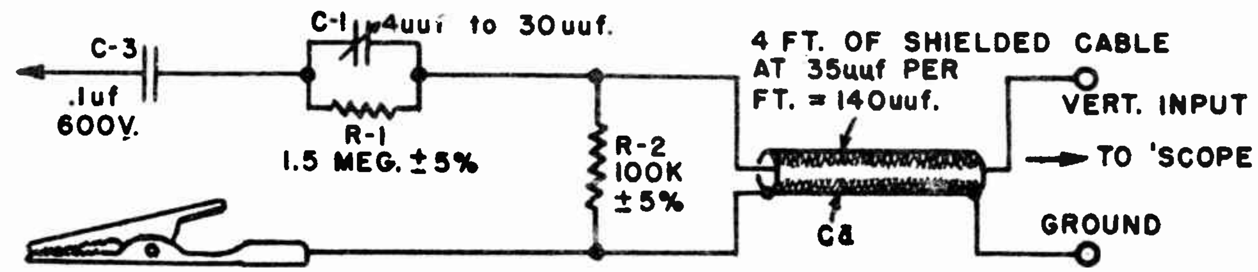
NOTE: Voltage and resistance measurements listed here are for chassis 120133-B stamped with a triangle 2A.

Voltages may vary slightly from table figures shown here if chassis is not coded as stated above. The peak to peak voltage given may vary slightly due to component variations.

EMERSON LOW CAPACITY PROBE

A low capacity probe must be used in order to faithfully reproduce high frequency waveshapes (15 kc and higher) and to prevent loading of the circuit under observation. Such a probe can be readily constructed with parts on hand.



Mount parts on a small sheet of bakelite, preferably inside a paper or mica tube. A shielded cable must be used because it prevents stray pickup. The length of this cable is very important since its capacity is used in the design of the probe.

Due to the construction of the probe, the signal at the oscilloscope terminals is approximately 1/15 of its actual value. This means that a scope with at least .05 RMS volts per inch vertical sensitivity is required. The average scope will meet these requirements. Since the 'scope is calibrated on a 60 cycle sine wave through the probe, the attenuation of the probe will not effect the accuracy of the peak to peak voltage readings.

In trouble-shooting, it is of great value to know the peak to peak voltages of the various wave shapes. The oscilloscope can be easily calibrated to read these voltages. For information on calibrating the oscilloscope, see items (a to d) listed on next page.

TO CALIBRATE THE PROBE:

The probe must be calibrated for the oscilloscope in use due to the differences in oscilloscope input impedances. The following steps should be taken:

(a) Connect probe to the output of the video detector (across detector load resistor).

(b) With the scope sweep set at 30 c.p.s., adjust C-1 so that the vertical blanking pulses and the horizontal blanking pulses line up as shown in the drawing marked (RIGHT) listed below. The probe is now calibrated for the particular oscilloscope in use and should not be readjusted unless the oscilloscope is changed.

C-1 CORRECTLY ADJUSTED

©John F. Rider

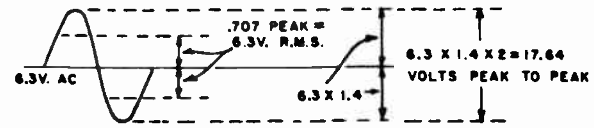
World Radio History

FOR TAKING WAVE SHAPES PROCEED AS FOLLOWS:

a) Observe the signal under test on the oscilloscope and set the gain control so that the whole signal is well within the screen limits.

b) Observe different 60 cycle sine wave voltages (12V, 25V, 117V, 350V a.c. etc.) on the oscilloscope with the same gain setting as before until one is found that is of the same peak to peak value, or less than the formerly observed signal. By measuring the 60 cycle voltage with a common a.c. meter, and then comparing the two signals on the oscilloscope, a good estimation can be made as to the peak to peak voltage of the signal.

c) An A.C. voltmeter is calibrated to read the R.M.S. value of 1/2 a sine wave and not the peak value. To convert from an R.M.S. value to a peak value, use the correction factor which is 1.4. The peak to peak value will therefore have a correction factor of 1.4 x 2 or 2.8.



The diagram at right should make this clear.

d) With a square celluloid face mask on the screen it is very easy to obtain accurate measurements.

For example: Take the 6.3 volt filament voltage, set the vertical gain control on the oscilloscope so that the wave covers 17.6 (6.3 x 2.8) boxes vertically from peak to peak. If the gain control is not moved the oscilloscope will read 1 volt peak to peak per box on any signal. For a very weak signal the calibration on a 6.3 volt AC wave can be made with the vertical distance from peak to peak to 176 boxes instead of 17.6 boxes. The oscilloscope will then read 0.1 volt peak to peak per box instead of 1 volt peak to peak per box.

If a stronger signal is encountered, the 117V. A.C. line can be used. The peak to peak value of this voltage is 117V. x 2.8 = 328 volts.

It is advisable that the serviceman familiarize himself with the above procedure on a good TV chassis.

WAVE SHAPE ANALYSIS CHART FOR CHASSIS 120133-B

For models 660B, 664B and 673B. The information listed below was taken from a chassis which was code marked triangle 2A

Slight peak to peak voltage differences may be noticed if chassis is not coded as shown above.

The wave shapes shown here are arranged so as to give the serviceman an easy method of signal tracing. The peak to peak voltage given may vary slightly depending on signal strength and component variations.

To accurately observe the following wave shapes, the relatively high input capacity of an oscilloscope must be reduced so as not to change the operating characteristics of the television set. Failure to do this will result in wrong wave shape readings.

The use of a special low capacity probe (as outlined on pages 5 and 6 of this manual), will reduce this input capacity to a minimum.

Connect antenna and tune receiver to channel where best reception has been obtained in the past.

Low end of the probe is connected to B neutral except where otherwise noted. Contrast control is set at MAXIMUM CONTRAST.

The 30 and 7875 C.P.S. oscilloscope sweep settings are used so as to permit the serviceman to observe two cycles of the wave shape.

Note: A wave shape seen in your oscilloscope may be upside down from same wave shape shown here. This will depend on the number of stages of amplification in the oscilloscope used.

I. VIDEO AND/OR SYNC. TROUBLES (LACK OF CONTRAST, TEAR, OVERLOAD, ETC.)

MODELS S4T15, S4T30, S4C20, S4C40

GENERAL INFORMATION

Check all shipping instructions, tags and labels carefully. To avoid special handling problems the receiver is shipped complete with the kinescope tube, focus coil and ion trap securely installed.

The receiver is completely adjusted at the factory, so normally none other than the front panel operating instructions need be followed to put the receiver in operation. However, to provide for any misadjustment of the service controls due to handling, the following instructions are in order.

ION TRAP, FOCUS MAGNET AND
DEFLECTION YOKE ADJUSTMENTS

Before any adjustments can be made to the above, the back will have to be removed from the cabinet.

Remove all screws on sides and top of back, and lift cover back and away from cabinet. Since the power cord circuit is broken by the interlock when the cabinet back is removed, it will be necessary to obtain an extra power cord with the female interlock receptical in order to make a power connection to the receiver. A mirror placed in front of the receiver will help in making the adjustments.

1. ION TRAP ADJUSTMENT

Turn on the receiver and switch to one of the TV channels not in use in your area. With the brightness control in the maximum clockwise position and the picture control fully counter-clockwise, adjust the ion trap by moving it forward or backward at the same time rotating it slightly around the neck of the kinescope for the brightest raster on the screen. Reduce the brightness control setting until the raster is just visible on the screen, readjust the ion trap for maximum brilliance. Adjust the focuser adjustment (shown in Figure 1) until the line structure of the raster is clearly visible. Readjust the ion trap for maximum raster brilliance. The final touches of this adjustment should be made with the brightness control at the maximum position with which good line focus can be maintained.

2. FOCUS MAGNET ADJUSTMENT

The focus magnet should be adjusted so that there is approximately three-eighths inch of space between the rear cardboard shell of the yoke and the flat of the front face of the focus magnet. This spacing gives best average focus over the face of the tube.

The axis of the hold through the focus magnet should be parallel with the axis of the kinescope neck. See Figure 1.

3. DEFLECTION YOKE ADJUSTMENT

If the lines of the raster are not horizontal or squared with the picture mask, loosen the wing screw on the yoke (shown in Figure 1) and rotate the yoke until this condition is obtained. Tighten the wing screw.

CENTERING ADJUSTMENTS

No electrical centering controls are provided. Centering is accomplished by means of a separate plate on the focus magnet. See Figure 1. The centering plate has a locking screw which must be loosened before centering.

Up and down adjustment of the plate moves the picture side to side and sidewise adjustment moves the picture up and down.

If a corner of the raster is shadowed, check the position of the ion trap. Reposition the ion trap within the range of maximum raster brightness to eliminate the shadow and recenter the picture by adjustment of the focus centering plate. In no case should the ion trap be adjusted to cause any loss of brightness since such operation may cause immediate or eventual damage to the kinescope. In some cases it may be necessary to shift the position of the focus magnet in order to eliminate a center shadow.

NON-OPERATING CONTROL ADJUSTMENTS (Figure 2)

With the deflection system of the kinescope in proper mechanical alignment, the "non-operating" controls may be adjusted. The mechanical adjustments ordinarily will not require further attention until the kinescope tube is replaced. Using a test pattern from a local TV station, make the "non-operating" control adjustments as follows: (Normal picture contrast and brightness should be maintained during the adjustment for best results).

(1) Set the HORIZONTAL and VERTICAL HOLD controls for a steady test pattern. If Horizontal synchronization cannot be effected within the normal range of the HORIZONTAL HOLD control, set this control in the center of its range and adjust the Horizontal Frequency control for a steady clear picture. This screw driver adjustment is reached from the top rear part of the chassis.

(2) Set the PICTURE control at minimum (counter-clockwise) and advance the BRIGHTNESS control (clockwise) to the point where the retrace lines (wide spaced lines) on the raster begin to show, then back off the Brightness control slightly to eliminate the lines. Reset the PICTURE control for the desired picture contrast. If necessary, readjust Brightness control for most desirable picture.

(3) Advance the HORIZONTAL DRIVE control (clockwise) as far as possible without causing fold over of the test pattern, (Vertical white line). Insufficient horizontal drive will cause the raster to fall short of filling the mask horizontally or cause the picture to lack the brilliance normally obtained with a correct adjustment.

(4) Set the WIDTH control so that the test pattern fills the horizontal dimension of the kinescope mask. A minor adjustment of the focus centering position may be required to recenter the pattern.

(5) Set the HORIZONTAL LINEARITY control so that the test pattern is symmetrical from left to right. A slight readjustment of the HORIZONTAL DRIVE control may be necessary when making this adjustment.

(6) Set the HEIGHT control so that the test pattern fills the vertical dimension of the kinescope mask. A minor adjustment of the focus centering position may be required to recenter the pattern.

(7) Set the VERTICAL LINEARITY control for a symmetrical test pattern in the vertical dimension. A slight readjustment of the Height control may be required when making this adjustment.

(8) Set the BRIGHTNESS and PICTURE controls for a normal test pattern and adjust the FOCUSER adjustment for best definition.

IMPORTANT NOTE: If difficulty is experienced in obtaining sufficient picture width, or if the picture lacks brilliance after all of the adjustments have been made, the input line voltage may be lower than 110 volts A.C. Carefully check this voltage with a suitable meter.

If the line voltage is lower than 110 volts A.C. remove chassis from cabinet. Lay chassis on side, with the power transformer down. Locate the

©John F. Rider

World Radio History

five lug terminal strip adjacent to the power transformer. Remove gray wire from the lug stamped No. 4 replace on lug No. 2. Replace chassis in cabinet.

CAUTION: Never change the input connection until it has been accurately determined that the line voltage is less than 110 volts A.C.

BUILT-IN-ANTENNA

The receiver is normally shipped with the built-in-antenna connected. If the installation is located in a "good signal" area, this antenna should bring in the picture satisfactorily without further antenna problems.

To check the operation of the built-in antenna, turn on the receiver and check the reception on all the active high and low channels. Adjust the operating controls as outlined under operation. If reception is poor, try other locations in the room, since a few feet may make a big difference in signal strength.

If satisfactory reception cannot be obtained with the built-in antenna, you may assume that it will be necessary to install an outdoor antenna. Disconnect the built-in antenna leads from the terminal board and connect the two transmission line leads from the terminal board and connect the two transmission line leads of the outdoor antenna to the same terminals. It is immaterial which lead is connected to which terminal. It is very important that the built-in antenna be disconnected from the antenna terminals when the outdoor antenna is used.

EQUIPMENT REQUIRED FOR ALIGNMENT

RF sweep generator meeting the following requirements:

18 to 30 MC	10 MC sweep width
40 to 90 MC	10 MC sweep width
170 to 225 MC	10 MC sweep width

Signal generator to cover all I.F. frequencies of from 4.5 MC to 28 MC and all picture and sound carrier frequencies.

CATHODE RAY OSCILLOSCOPE -Electronic Voltmeter of junior voltohmyst type.

R.F. UNIT

Normally the R.F. Tuner will not require any adjustments. If realignment is necessary, refer to attached Service Notes before attempting to align the Unit.

ORDER OF ALIGNMENT

Sound Radio Detector
Sound I.F. Transformer
Picture I.F. Transformers. (preliminary and flat topping)

PRECAUTION

Before proceeding with I.F. Alignment the following precautions should be observed:
Disconnect antenna. Set contrast control for minimum (Maximum counter clockwise Position). Adjust channel tuning to non-assigned channel (2-3-4-7-8-9 Depending Upon Location) to prevent T.V. signal from interfering with alignment.

For all I.F. alignment insert a 47 K ohm resistor in series with the V.T.V.M. probe; also, a 47 K ohm resistor should be inserted between the take-off point and oscilloscope lead for decoupling.

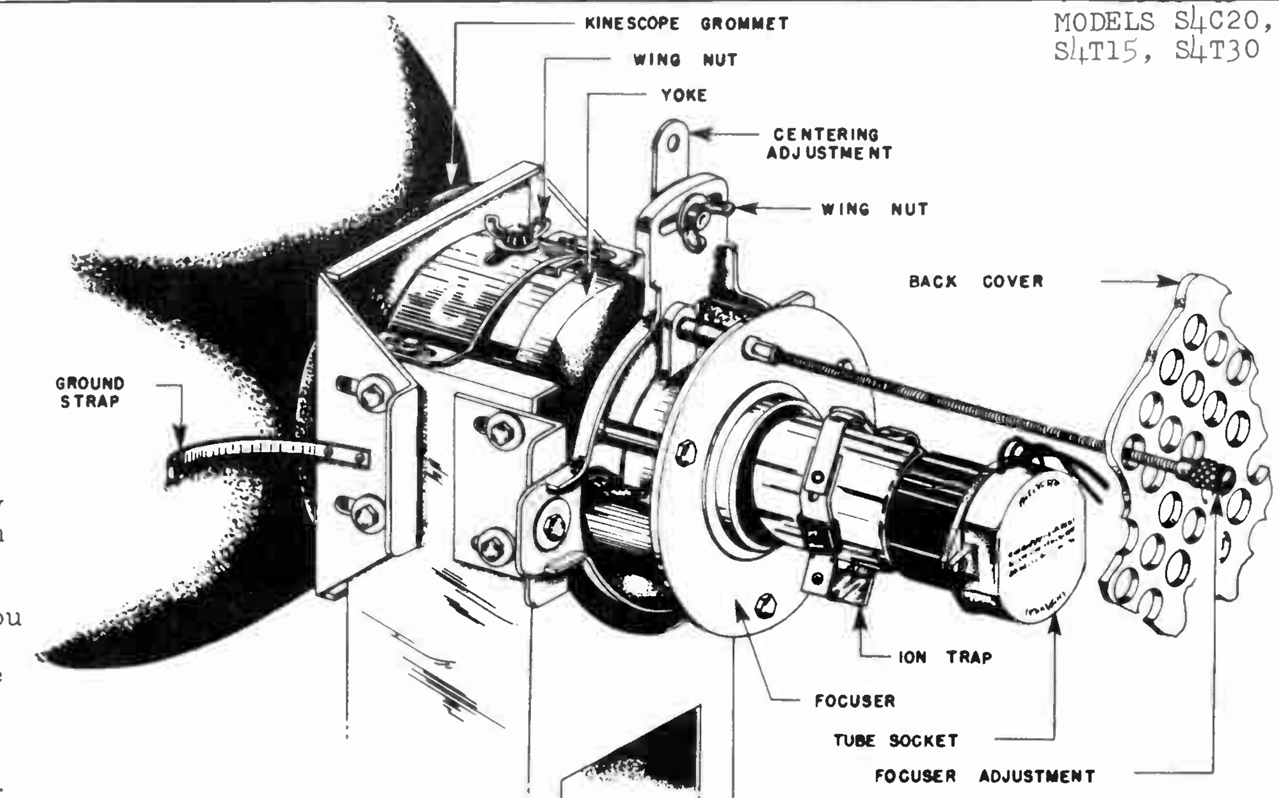

FIG. I

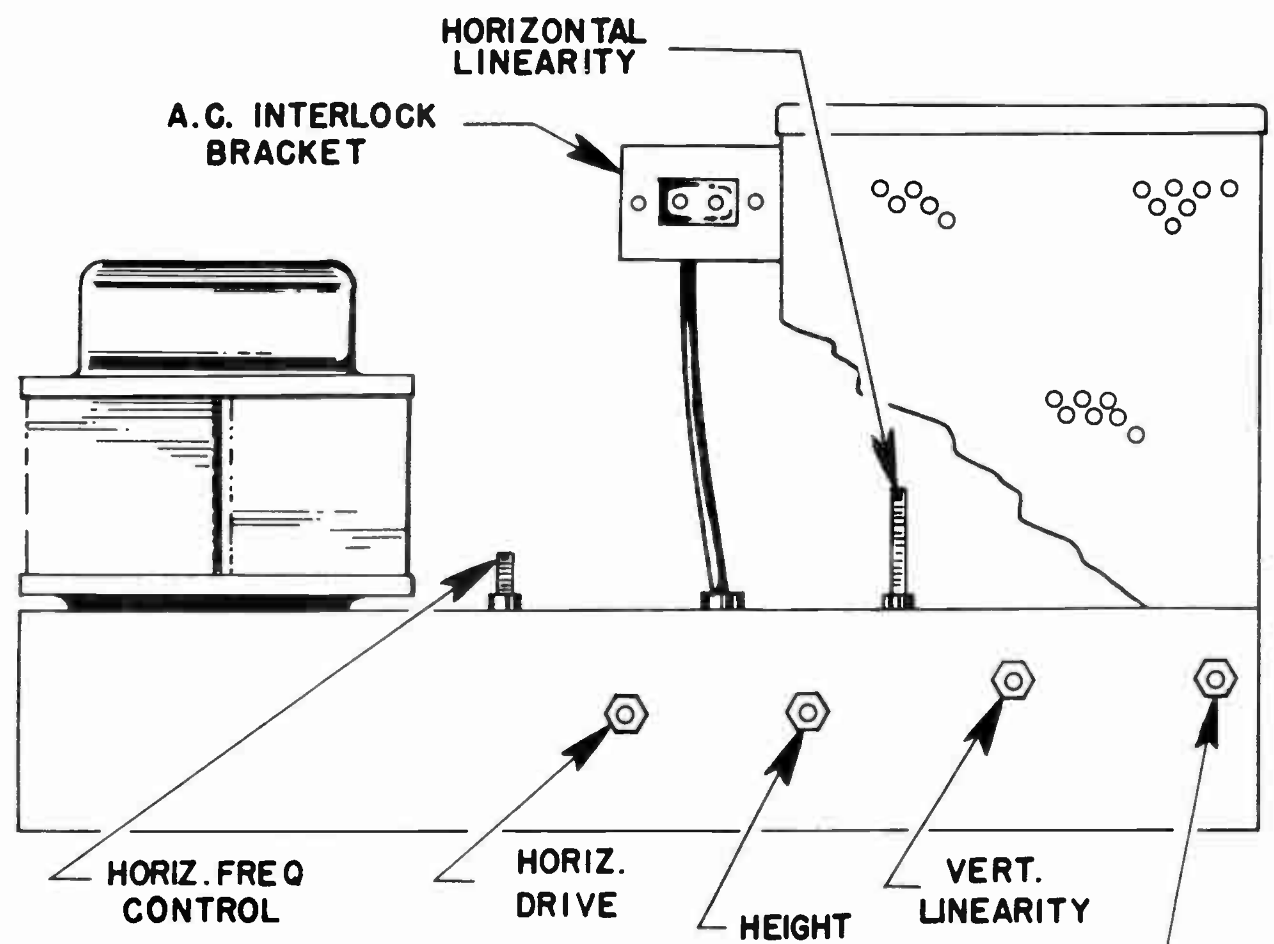

FIG. II

World Radio History

SOUND RATIO DETECTOR AND I.F. ALIGNMENT

(1) Connect V.T.V.M. common lead to chassis and probe to Pin #2 of 6T8 tube.
(2) Connect signal generator to Pin #1 of 6AU6 Ratio Detector Driver Tube.
(3) Adjust signal generator (4.5 MC) output so that the V.T.V.M. voltage will not exceed 3 volts during entire alignment.
(4) Adjust L16 (Bottom) for MAXIMUM.
(5) Adjust L17 (Top) for MAXIMUM.
(6) Adjust attenuator of generator to give exactly 3 volts on the V.T.V.M.
(7) Move probe of V.T.V.M. to junction of R35 - C28 & C29.
(8) Adjust L17 (Top) for exactly 1.5 volts.
(9) Move signal generator to Pin #4 of 6AC7 Video Output Tube and repeat steps #1 and #3.
(10) Adjust L12 (Bottom) and L13 (Top) for MAXIMUM.
(11) Repeat with care steps 1-3-4-5-6-7-8.

ALTERNATIVE PROCEDURE FOR STEPS 6-7-8:
Connect common lead of V.T.V.M. to junction of R33 and R34.
Connect probe of V.T.V.M. to junction of R35 - C28 and C29.
Adjust L17 (Top) for zero reading on V.T.V.M.

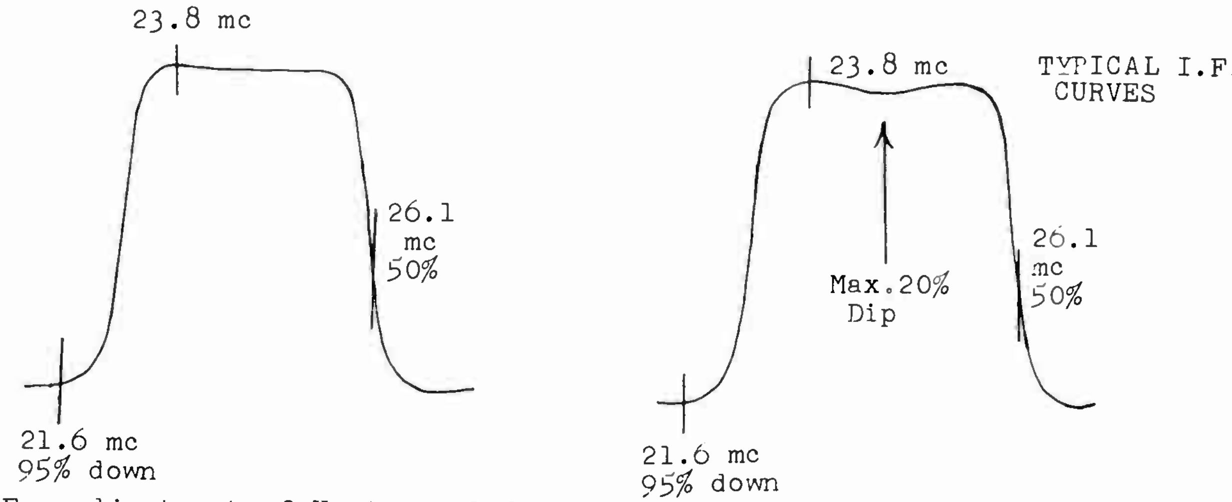
PICTURE I.F. TRANSFORMER

Rough I.F. Alignment:

1. Lift shield of 6J6 converter tube. Use cut down goat shield placed over 6J6 converter tube to spray signal into receiver in all of the following alignment procedures. The original tube shield can also be used if care is taken so that the shield does not touch the shield grounding springs.
2. Connect the signal generator to shield.
3. Connect probe of V.T.V.M. to junction of L11 and R16. Connect common lead of V.T.V.M. to ground end of R16.
4. Set signal generator to 23.4 MC and output of generator is to be kept as low as possible.
5. Align First Video I.F. Coil (Located on R.F. Unit "Left Rear Corner") and L6 (Third Video I.F. Coil) for maximum.
6. Set generator to 25.7 MC and adjust L3 (Second Video I.F. Coil) and L9 (Fourth Video I.F. Coil) for maximum.

PICTURE I.F. FLATTOPPING:
1. Remove signal generator and V.T.V.M.
2. Connect sweep generator to converter shield.
3. Connect scope between junction of L11 and R16.
4. Place signal generator lead near 6J6 tube shield. Ground both leads of the generator near the rear apron of the R.F. Unit.
5. For best results the Video I.F. should be aligned on an non-assigned channel (2-3-4-7-8-9). If signal pips are noticed on the curve adjust the channel tuning control. (The Shape of the I.F. Curve Should Not Change When Tuning Control Is Adjusted).
6. Adjust signal generator to zero output and place a V.T.V.M. on the A.G.C. buss. Vary the output of the sweep generator until minus 1.5 volts is read on the V.T.V.M.
7. Adjust signal generator to 26.1 MC and advance the generator output until a marker pip is visible on the Video I.F. curve. Adjust L3 and L9 so that the marker is at the 50% point (SEE CURVE BELOW).
8. Set signal generator to 23.8 MC and flat top video curve by adjusting I.F. on R.F. Tuner and L6. Marker should be close to the end of the curve.
(See Curve

9. Repeat steps 7 & 8 until an acceptable curve is achieved.
10. Set generator to 21.6 MC. This marker should appear at the bottom of the curve (See Curve Below). The exact position of the 23.8 MC marker is governed by where the 21.6 MC marker falls. Should the 21.6 marker be more than 5% up on the curve intercarrier buzz will result and if the marker is too low, weak audio will result. The 21.6 MC marker should be kept as low as possible and yet give enough audio signal.



For adjustment of Horizontal frequency oscillator and non-operating controls refer to attached Installation Instructions.

V24	5U4G	Rectifier
V25	6J5GT	Vertical Blocking Oscillator
V26	*6S4 or 6SN7GT	Vertical Scanning Output

* CAUTION: Some of these alternate type tubes are not directly interchangeable; see circuit diagram or Name Label for correct tube complement and complete explanation of alternate tube.

RECEIVER OPERATING CONTROLS

The various controls on the receiver may be divided into two classes, Operating and Pre-set. Operating controls are those which control program selection as well as sound and picture quality.

All but one of the operating controls of the receiver are located on the front panel and the name and use of each are described in Figure 1. The built-in antenna tuning control is accessible at the rear of the receiver. The Pre-set controls are those which require adjustment at the time the receiver is installed and they rarely need attention thereafter. There are nine Pre-set controls, three of which are located at the back of the chassis (see Figure 9). Five controls are accessible by removing the Name Plate located directly above the Operating controls—see Fig. 4.

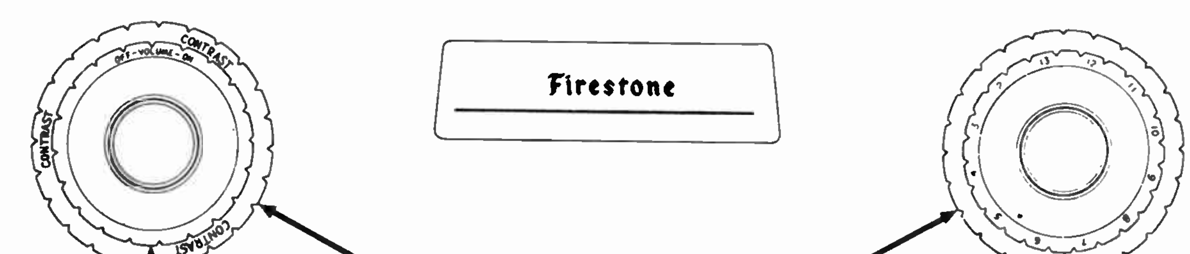

Fig. 1

CONTROL ADJUSTMENT PROCEDURE

Although the Pre-set controls have been factory adjusted for optimum performance, it is usually necessary to make some fine adjustments of these controls at the time of installation.

There are nine Pre-set controls, three of which are located at the back of the chassis (see Figure 9). Five controls are located under the Name Plate on the front panel. This plate can be removed by grasping it at its ends and pulling forward. The Auxiliary Fine Tuning Screw can be reached by removing the "Channel Selector" and "Television Fine Tuning" knobs.

A Centering Arm, used to center the picture on the screen, is accessible at the back of the cabinet. Two holes are also provided in the cabinet back for adjustment of the Focusing Slugs (see Figure 9).

To gain access to the ion trap, it will be necessary to remove the back cover of the cabinet by first removing the built-in antenna tuning knob and then taking out the screws around the rim of the back cover. Removal of the cabinet back automatically opens an interlock to disconnect the receiver power cord, therefore, an auxiliary power cord assembly will be required when making ion trap adjustment. This cord may be obtained by requesting Part #507699. **Do not attempt to supply power to the receiver using any other device.**

The receiver is now ready for an operational check.

1. **TURN SET ON**—Rotate the "On-Off Switch and Volume" knob approximately ½ turn clockwise to turn set on and obtain sufficient sound volume during the tuning process. Allow several minutes for all tubes in the receiver to warm up and for circuits to stabilize before attempting to obtain a picture on the screen.

   A Channel Lite, located behind the "Channel Selector" knob, illuminates the particular television station designation corresponding to the setting of the Channel Selector.

2. **ADJUST ION TRAP**—If screen remains dark or is only dimly illuminated when "Brightness" control is turned clockwise, the ion trap may require adjustment.

   The ion trap is located on the neck of the picture tube as shown in Figure 9 and consists of a magnet held in position by metal bands.

   With "Brightness" control (located behind Name Plate) set approximately ¾ turn clockwise, rotate the entire ion trap assembly while sliding it back and forth until picture tube screen is illuminated to maximum brilliance. Reduce "Brightness" control setting and repeat this operation to assure accurate positioning of ion trap.

   Do not turn "Brightness" control to its maximum clockwise position until ion trap is correctly adjusted—failure to observe this precaution may result in damage to the picture tube.

3. **ADVANCE CONTRAST CONTROL**—Turn the "Contrast" control knob to its maximum clockwise position.

4. **POSITION CHANNEL SELECTOR**—Set "Channel Selector" knob so that the call letters or channel number of the desired television channel appears in the illuminated opening. If the call letter tabs were not previously inserted in this knob when receiver was installed, you can readily do so by following the procedure given in the next section of this booklet.

5. **ADJUST FINE TUNING CONTROL**—After "Channel Selector" knob has been set, then use the "Television Fine Tuning" control to obtain the correct tuning point for both picture and sound. That is accomplished as follows:

   a. Turn "Television Fine Tuning" control in either direction until sound volume is maximum—if sound cannot be heard, advance the volume control and repeat fine tuning.

   b. When the point of maximum sound volume has been reached it will be noted that the picture has a "ragged" or "saw-tooth" appearance or is partially obscured by "sound bars" (dark horizontal bars of varying width—see Fig. 2).

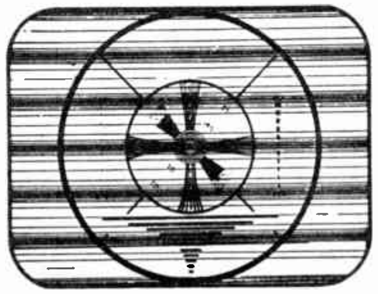

Fig. 2—SOUND INTERFERENCE CAUSED BY INCORRECT TUNING

THE CORRECT SETTING OF THE TELEVISION FINE TUNING CONTROL is now obtained by turning it away from the maximum volume position only for enough to eliminate the "sound bar" interference and permit sharp reproduction of the picture.

6. **AUXILIARY FINE TUNING ADJUSTMENT**—If it is found that the tuning range of the "Fine Tuning" control is inadequate to permit correct tuning of a station in its assigned channel, then adjustment of the "Auxiliary Fine Tuning" screw will be necessary. This special screw is accessible after removal of the "Channel Selector" and "Fine Tuning" knobs. They may be removed by merely pulling them forward.

   Adjustment of the "Auxiliary Fine Tuning" screw may be undertaken in accordance with the following procedure.

   a. Set "Channel Selector" to desired channel; then remove this knob.

   b. Set "Fine Tuning" knob to the center of its range; then remove this knob. The flat portion of the main tuning shaft (outer brass shaft) should now be in the uppermost position. Note the location of the "Auxiliary Fine Tuning" adjustment screw on receiver chassis—see Fig. 4.

   c. Using a thin screwdriver (preferably non-metallic), adjust the setting of "Auxiliary Fine Tuning" screw for correct tuning of the desired television station—**CAUTION: Do not attempt to rotate this screw more than two full turns in either direction, as further rotation may release it from the thread clip within the tuning mechanism and the coil for that channel (located in R.F. Tuner Unit) would then have to be removed in order to restore the screw to the correct position.** If a metal screwdriver is used, detuning occurs when the screwdriver is removed but it will be noted that this degree of detuning can now be compensated by resetting the "Fine Tuning" control (brass shaft). Thus the range of the "Fine Tuning" control (after knob is replaced on the shaft) will be adequate to tune in the station.

   d. This completes the adjustment of the "Auxiliary Fine Tuning" screw for one channel. Identical screws are provided on each channel and they are all accessible thru the same opening in the tuning mechanism as each successively moves into position when the "Channel Selector" knob is rotated.

7. **ADJUST SOUND VOLUME**—Readjust the setting of the "Volume" control until the sound accompanying the television broadcast is received at a satisfactory level.

8. **ADJUST BUILT-IN ANTENNA TUNING CONTROL**—If the receiver's built-in television antenna system is used, rotate the antenna tuning knob (located at rear of cabinet) until the best picture is obtained. It may be possible to find a single setting for this knob which will give satisfactory performance for a group of stations. In the event that this is not the case, adjust the control for optimum performance each time the Channel Selector is rotated to a different station.

9. **HORIZONTAL HOLD**—Should the picture appear to move horizontally across the screen or break up into a series of light and dark streaks as shown in Figure 3, adjust the "Horizontal Hold" control (located behind Name Plate) until the picture remains stationary and does not slip horizontal sync when operating "Channel Selector" knob.

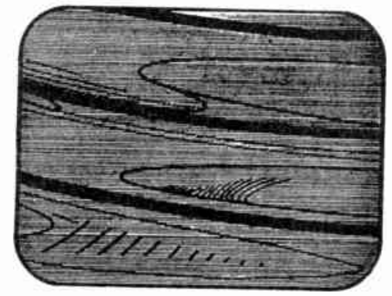

Fig. 3—HORIZONTAL MOVEMENT; ADJUST HORIZ. HOLD CONTROL

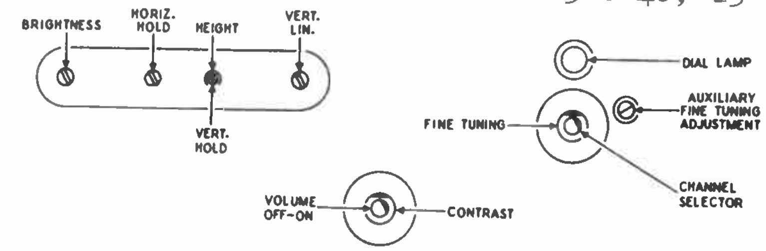

Fig. 4—LOCATION OF PRE-SET CONTROLS

10. **VERTICAL HOLD**—Should the picture appear to roll by in a vertical direction or cause multiple vertical images as shown in Figure 5, it will be necessary to adjust the "Vert. Hold" control located behind the Name Plate (see Figure 4).

    After this adjustment is made, reduce contrast until picture is barely visible and check setting of "Vertical Hold" control for proper picture synchronization.

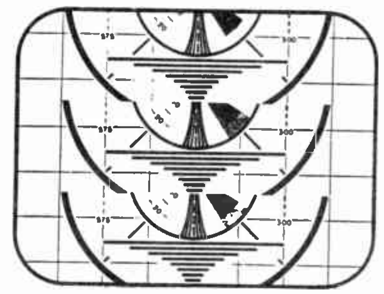

Fig. 5—VERTICAL MOVEMENT; ADJUST VERTICAL HOLD CONTROL

11. **INITIAL FOCUS**—Set Channel Selector knob to an inactive television channel. Then set the Brightness control to its maximum clockwise position and the Contrast control to its maximum counter-clockwise position, and adjust the position of the Focusing Slugs (see Fig. 9) until scanning lines in center of raster are most clearly defined; this should provide best focusing over the entire area of the picture when controls are returned to their normal positions.

    If picture brilliance decreases while adjusting picture focus, readjust ion trap as explained in step #2. Fuzzy picture may also be due to reproduction of poor quality film when station is televising a motion picture. Incorrect tuning of receiver produces a similar effect. Check for proper tuning point as described in step 5 of this section.

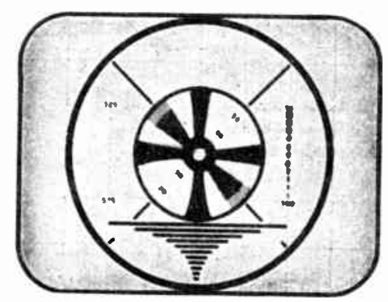

Fig. 6—BLURRED APPEARANCE; ADJUST FOCUSING SLUGS

The following adjustments should be made while the station is transmitting its circular test pattern.

12. **STRAIGHTENING TILTED RASTER**—If the pattern should appear on the screen in a tilted position as shown in Figure 7, loosen the deflection yoke locking screw (see Figure 9) and rotate the yoke sufficiently to correct this condition. Be sure to retighten the screw securely.

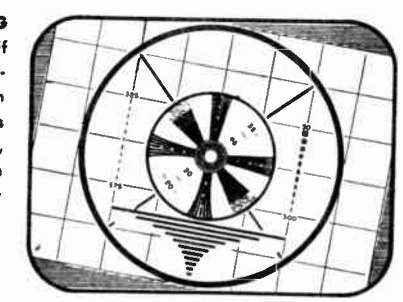

Fig. 7—TILTED PICTURE; ADJUST YOKE POSITION

13. **CENTERING**—To center the test pattern on the screen, proceed as follows:

    a. Position Centering Arm (see Figure 9) for correct centering of test pattern.

    b. If picture cannot be centered using this arm, change the position of the focus magnet assembly by adjusting the three knurled nuts labeled A in Figure 9.

    NOTE: If a decrease in picture tube brilliance is noted when making the centering adjustment, readjust ion trap as explained in step #2.

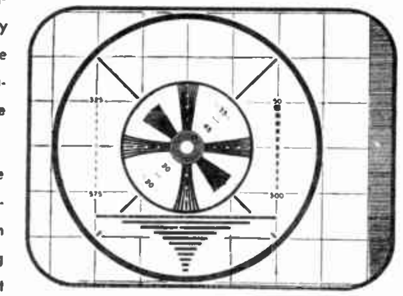

Fig. 8—OFF CENTER; ADJUST CENTERING ARM

14. **HEIGHT** — Control of picture size in the vertical direction is accomplished by means of the "Height" control located behind the Name Plate. Height and width adjustments should be checked for all transmitting stations to be sure that picture properly fills the viewing area. It may be necessary to change the setting of the "Height" control after the "Vertical Linearity" control is adjusted.

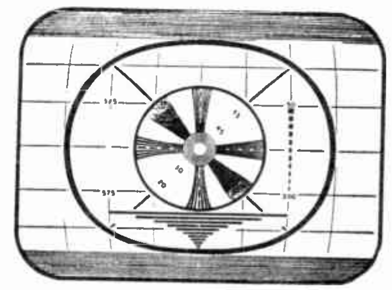

Fig. 10—TOO SHORT; ADJUST HEIGHT CONTROL

15. **WIDTH** — Control of picture size in the horizontal direction is accomplished by means of the "Width" control located on the rear of H. V. power supply (see Fig. 9).

    If abnormally low line voltage makes it difficult to obtain sufficient picture width when using the "Width" control, then the setting of the "Horizontal Drive" control may be incorrect. The method of adjusting this control is explained in paragraph #18.

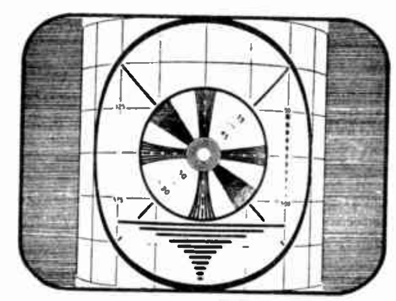

Fig. 11—TOO NARROW; ADJUST WIDTH CONTROL

©John F. Rider

World Radio History

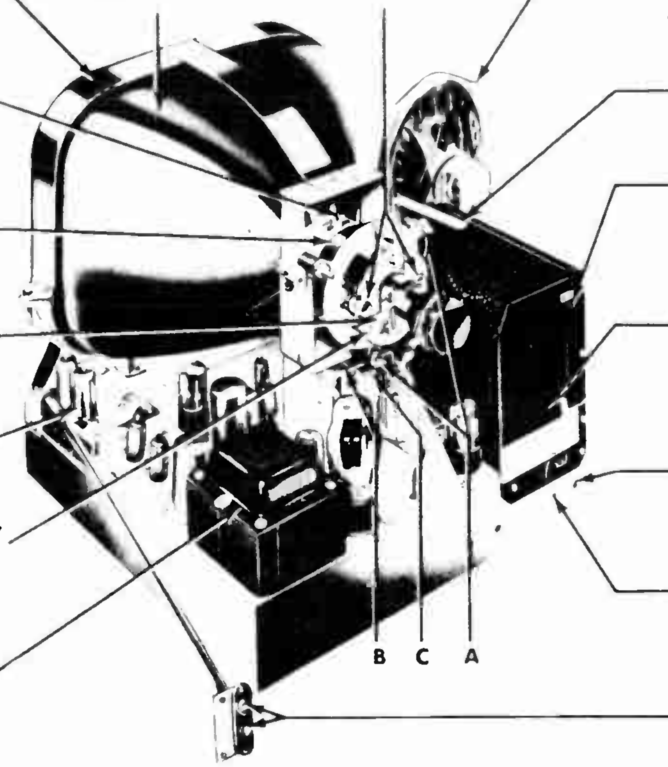

Fig. 9—CHASSIS AND PICTURE TUBE ASSEMBLY

16. **VERTICAL LINEARITY** — Improper vertical linearity causes the circular test pattern to appear condensed on the upper edge of the screen and extended on the lower edge or vice versa. This effect is illustrated in Figure 12. Adjust for proper linearity by using "Vertical Linearity" control located behind Name Plate. It may be necessary to readjust the "Height" control if an appreciable change is made in the linearity control setting.

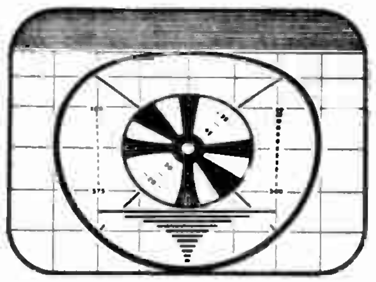

Fig. 12—VERTICAL DISTORTION; ADJUST VERTICAL LINEARITY CONTROL

17. **HORIZONTAL DRIVE** — The "Horizontal Drive" control located at rear of chassis (see Fig. 9) should be rotated clockwise to the point where any white (or black) vertical lines near the left side of the picture are eliminated. As width and linearity of the picture are affected by the setting of "Horizontal Drive" control, it will be necessary to adjust this control in conjunction with the Horiz. Linearity and Width controls to obtain desired picture width and linearity.

18. **HORIZONTAL LINEARITY** — Improper horizontal linearity causes the circular test pattern to appear condensed on the right edge of the screen and extended on the left edge or vice versa. This effect is illustrated in Figure 13. Adjust for proper linearity by using "Horizontal Linearity" control located at rear of chassis (see Figure 9). In event that proper horizontal linearity cannot be obtained by adjusting this control, then check the setting of the "Horizontal Drive" control.

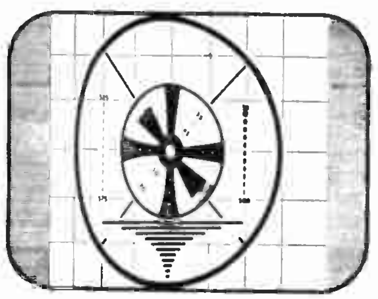

Fig. 13—HORIZONTAL DISTORTION; ADJUST HORIZONTAL LINEARITY CONTROL

19. **ELIMINATING SEMI-CIRCULAR SHADOW** — This shadow is caused by the electron stream striking the neck of the tube and it can generally be corrected by applying one or a combination of the following procedures:

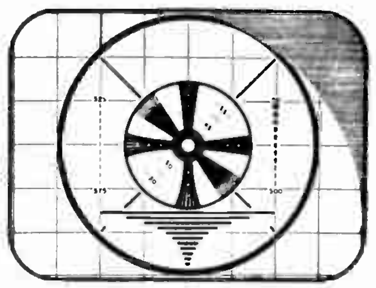

Fig. 14 SEMI-CIRCULAR SHADOW

a. Make sure deflection yoke is positioned as far forward as possible by loosening the three wing nuts labeled B in Fig. 9.

b. Reposition the focus magnet assembly by readjusting the three nuts labeled A in Fig. 9 to shift the assembly forward.

c. In event neck shading cannot be eliminated by the above procedures, release the four wing nuts labeled C in Figure 9 and raise or lower entire yoke and focus magnet assembly so that focus magnet can be repositioned vertically with respect to the tube neck.

20. **BRIGHTNESS** — The "Brightness" control (located behind Name Plate) should be initially adjusted in conjunction with the "Contrast" control for the brightness level desired by set owner—check on all active station channels. Too much brightness will have the same effect as too little contrast, and vice versa, therefore, it is necessary to strike a proper balance between contrast and brilliance.

21. **FINAL ADJUSTMENT** — Recheck settings of Focusing Slugs for best picture focus.

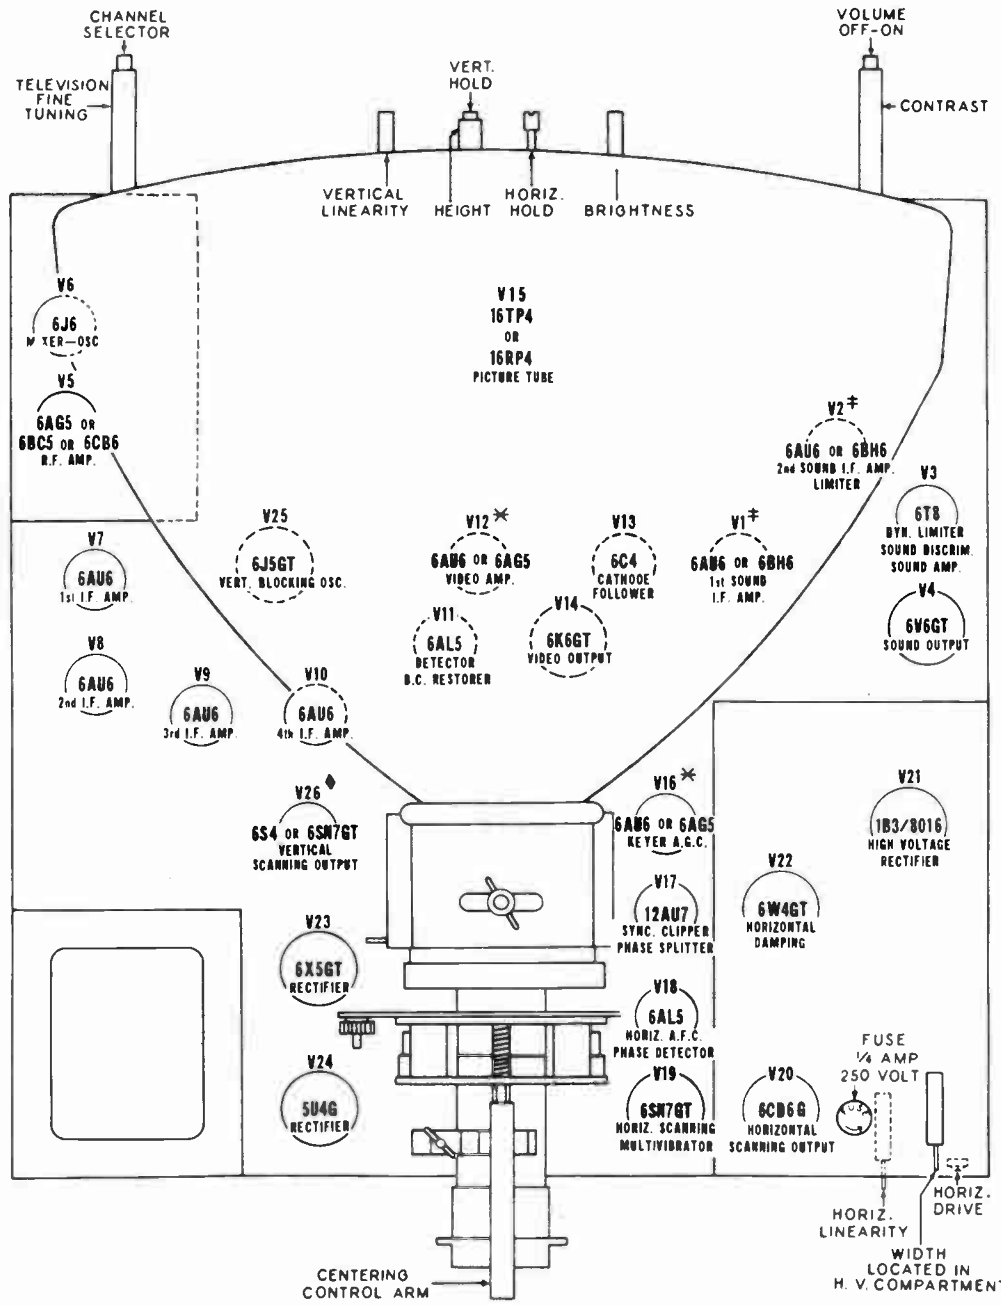
INSERTING STATION CALL LETTER TABS

A set of television station call letter tabs and channel numbers is supplied with this receiver and is to be used for labelling the Channel Selector knob. To install these tabs, merely remove the Channel Selector knob by pulling it forward, and insert either the correct station call letters or channel numbers into the proper circular recesses on the rear surface of the knob. The correct recess may be identified by the station channel number stamped on the outer edge of this knob adjacent to each recess.

(Information on channel numbers and corresponding station call letters may be obtained from the radio page of your local newspaper.) Insert blank tabs in the remainder of the circular holes.

Retain any unused tabs. Your list of call letter tabs includes some television stations which are not yet on the air. When a new station begins broadcasting in your area, its call letter tab may be inserted in the Channel Selector knob as described above.

TUBE LOCATIONS & FUNCTIONS



©John F. Rider

World Radio History

TUBE REPLACEMENT

Some chassis use alternate type tubes in the positions designated by V1, V2, V12, V16 and V26 in the above chart. **These alternate type tubes are not interchangeable and failure to install the correct type tube may result in damage to the receiver.**

When replacing these tubes, check for series designation stamped on rear of chassis adjacent to model number. This identification may consist of one or more letters following the word SERIES.

The following symbols refer to similar symbols on the above tube location chart.

* A type 6AG5 tube is used when the letter "A" is included in the series designation. A type 6AU6 tube is used when letter "A" is **not** included in the series designation.

‡ A type 6BH6 tube is used when the letter "B" is included in the series designation. A type 6AU6 tube is used when letter "B" is **not** included in the series designation.

♦ A type 6SN7GT tube is used when the letter "C" is included in the series designation. A type 6S4 tube is used when letter "C" is **not** included in the series designation.

SOCKET VOLTAGES

CAUTION

THE PICTURE TUBE is highly evacuated and if broken, glass fragments will be violently expelled. Scratching, chipping, undue pressure, or careless handling such as lifting the tube by its neck is dangerous and should be avoided. If it is necessary to handle the picture tube, use safety goggles and heavy gloves. Be sure to discharge the voltage developed across the capacitor formed by the inner and outer coating of the picture tube. This can be done by connecting the high voltage socket on the tube to the outer coating with a well insulated metal conductor.

HIGH VOLTAGE (11 to 13.5 kilovolts) is produced in a supply circuit of this receiver. Exercise care to avoid contact with elements of this circuit and particularly the tube terminals which are labeled "CAUTION" in the adjoining voltage chart. If measurement of voltage at these points is necessary, see procedure given below under the note "L".

THE HIGH VOLTAGE LEAD, which supplies approximately 11 to 13.5 kilovolts to the picture tube, should be momentarily shorted to the chassis whenever it is disconnected for service purposes. This discharges the high voltage filter condenser and prevents a shock hazard when working on the receiver after it has been turned off.

INTERMEDIATE B+ VOLTAGES, 480 and 360, are dangerous and caution should be observed when the receiver chassis components are exposed for service purposes.

THE VOLTAGES SHOWN IN THE ADJOINING CHART WERE MEASURED UNDER THE FOLLOWING CONDITIONS

1.	Power Supply—117 volts 60 cycle AC.
2.	All voltages are measured between socket terminals and chassis unless otherwise indicated on adjoining chart.
3.	* Measurements made with voltmeter having sensitivity of 20,000 ohms per volt except where indicated by (*). The (*) symbol designates a vacuum tube voltmeter measurement.
4.	Channel Selector and Fine Tuning Controls set for normal reception of a local station.
5.	All controls are set for normal reception of the transmitted signal unless the voltage shown on the chart is followed by a letter or letters indicating a special condition of measurement as explained in subsequent notes.
6.	The external or built-in antenna should remain connected to the receiver only when taking voltage measurements in the sweep and sync circuits—for all other measurements, disconnect antenna, short antenna terminals together and connect them to ground.
7.	Certain voltages were measured with two different settings of specific controls. It should therefore be understood that in these instances all controls, with the exception of one or two, were set for normal reception—letters following the voltage shown on the chart indicate the exceptions and are explained below.

EXPLANATION OF NOTES

A.	Vert. Hold Control max. counter-clockwise
B.	Brightness Control max. counter-clockwise
b.	This voltage will vary from 11 to 15 depending upon setting of Horizontal Hold Control.
C.	Contrast Control max. clockwise
D.	Horiz. Drive Control max. clockwise
d.	This voltage will vary from 300 to 320 depending upon setting of Horizontal Hold Control.
E.	Before making this measurement, remove one of the four 6AU6 IF Amplifier tubes (V7, V8, V9 or V10). This will prevent noise in the RF stages from affecting the voltage measured at this point.
e.	This voltage will vary from —4.2 to —7.6 depending upon setting of Horizontal Hold Control.
F.	Height Control max. counter-clockwise
G.	Width Control max. counter-clockwise
H.	Height Control max. clockwise
h.	This voltage will vary from +8 to —2 depending upon setting of Horizontal Hold Control.
J.	Horiz. Hold Control set for normal picture
K.	The measurement should be made with a vacuum tube voltmeter. The voltage reading will fluctuate in the vicinity of 0.15 volts.
k.	This voltage will vary from 10 to 15 depending upon setting of Horizontal Hold Control.
L.	If you do not have an instrument capable of directly measuring voltages in this range, the voltage can be measured by using a voltage divider network consisting of twenty 2.2 megohm 2 watt resistors and one 1 megohm 2 watt resistor, all connected in series. Avoid using resistors of higher values as their individual voltage rating may be exceeded. It is also important to use resistors of equal wattage. Solder all connections between resistors. Accurately measure the overall resistance of the entire combination as well as the resistance of the 1 megohm section. **With the set turned off,** connect the 2.2 megohm end of the resistance voltage divider to the filament of the 1B3GT/8016 tube, or H. V. terminal of the picture tube, and connect the 1 megohm end to chassis. Now, turn the set on and measure the voltage drop across the 1 megohm resistor with a vacuum tube voltmeter. The voltage at the tube terminal can then be calculated as follows: $\left[\text{Volts At Tube Terminal}\right] = \dfrac{\left[\text{Measured Resistance Of Entire Voltage Divider}\right]}{\left[\text{Measured Resistance Of 1 Meg. Section}\right]} \times \left[\text{Volts Measured Across 1 Meg. Section}\right]$
M.	Vertical Linearity Control max. counter-clockwise.
N.	Channel Selector set to channel #4
n.	This voltage will vary from —3.6 to —7.5 depending upon setting of Horizontal Hold Control.
q.	This voltage will vary from 9 to 14 depending upon setting of Horizontal Hold Control.
R.	Do not attempt to measure the voltage at the tube cap. There is a high R. F. potential at this point.
r.	Contrast Control max. counter-clockwise
S.	Channel Selector set to channel #10
T.	Grounding of center stud on tube socket is necessary to reduce capacity coupling between other pins. Oscillation may result if this ground is omitted.
t.	This voltage will vary from —3.5 to —4.5 depending upon setting of Horizontal Hold Control.
U.	Vertical Hold Control max. clockwise
u.	This voltage will vary from —7 to —12 depending upon setting of Horizontal Hold Control.
V.	Before measuring this voltage, connect external antenna and adjust controls for normal reception of station signal.
W.	This voltage will vary from +0.01 to —0.25 depending upon setting of Horizontal Hold Control.
X.	Brightness Control max. clockwise
Y.	Vertical Linearity Control max. clockwise.
Z.	This voltage will vary from +6.2 to —1.8 depending upon setting of Horizontal Hold Control.

NOTE

The socket voltages shown in the three charts below indicate measurements made on certain alternate tubes used in coded chassis. This coding consists of one or more letters following the word "SERIES" stamped on rear surface of chassis. A chassis incorporates only that change indicated by letter designation i.e., chassis stamped "SERIES BD" does not include changes "A" or "C".

For complete description of these changes, refer to Production Change column on circuit diagram page.

REPAIR DATA FOR 508890 RF TUNER UNIT

All replacement parts for the RF Tuner Unit are included in the complete receiver parts list.

This RF Tuner Unit consists of an RF amplifier stage (using 6AG5, 6BC5, or 6CB6 tube) and a mixer-oscillator stage (using 6J6 tube). Channel selection is accomplished by rotation of a turret assembly having 2 sets of snap-in coils for each of the 12 channels. The tuner also incorporates a Fine Tuning control.

Antenna Coils for each channel consist of a center-tapped primary and an RF amp. grid winding (secondary). The individual RF-Oscillator Coils include an RF amplifier plate section, a mixer grid section and an oscillator winding. Signal output from the mixer stage is coupled to the IF amplifiers through the input IF coil located on the tuner unit.

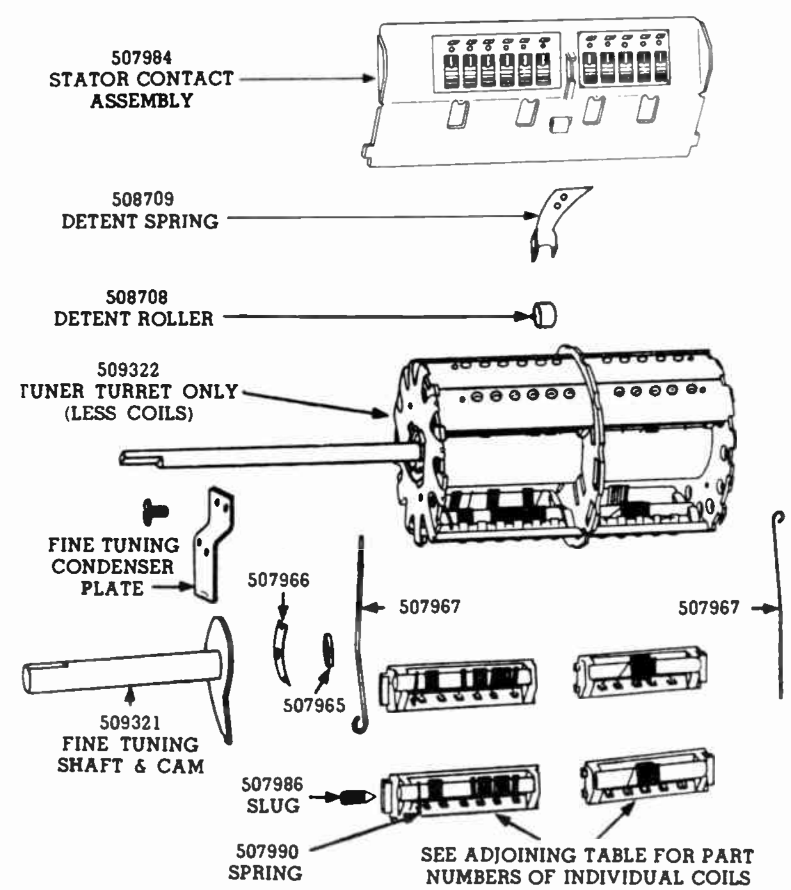
SERVICE PRECAUTIONS

SUBJECT	PRECAUTIONS
ELECTRICAL COMPONENTS	The high frequencies used in the RF section of a television receiver make it necessary that considerable care be exercised in servicing the tuner. Lead dress and location of components are very critical at these frequencies. When replacing parts, it is important to use components of identical electrical characteristics and physical size. Always reconnect the replacement item in the same location and position in the tuner as the original component.
TUBES	Replacement of tubes in the Tuner Unit may cause slight detuning of RF circuits due to inherent differences in inter-electrode capacitances. When replacing tubes (especially V6, 6J6 mixer-oscillator tube) make sure that Fine Tuning control will tune in television stations at approximately the middle of its range. It may be necessary to change the setting of the individual oscillator coil slugs for some channels to accomplish this.
CHANNEL COILS AND SLUGS	Channel Coils must be handled with care. Do not disturb coil windings. If an oscillator slug "falls into" its coil form during adjustment, remove the Channel Coil from the turret assembly and lift the Slug Retaining Spring aside. By tapping the coil form it should be possible to make the slug move toward the end so that its threads will be engaged by the Slug Retaining Spring when that spring is returned to its normal position.
FINE TUNING CONTROL	Rubbing of the bakelite Fine Tuning Cam against the Fine Tuning Condenser Plate is intentional in order to avoid vibration with resulting microphonics. However, the Fine Tuning Cam should not rub or contact the small circular plate located on the body of the tuner.

REMOVAL AND REPLACEMENT OF PARTS

ITEM	PROCEDURE
RF TUNER UNIT	To remove the Tuner Unit from receiver chassis, proceed as follows: 1. Remove channel selector dial lamp socket. 2. Remove support bracket which positions front of Tuner Unit and also remove screws which hold tuner to rear support bracket. 3. Disconnect the leads from the tuner to the main chassis. See illustration on circuit diagram page showing tuner connections. After the Tuner Unit is replaced, make sure that channel selector dial lamp socket is correctly positioned so that channel selector knob will be properly illuminated.
CHANNEL COILS	Insert a screwdriver blade between Coil Retainer Spring and the end of the Tuner Turret. Twist the blade to pull spring away from the molded body of Channel Coil. Lift this end of coil body upward and remove individual coil assembly from tuner. When replacing Channel Coils, be sure they are reinstalled in their correct positions. Coil numbers should increase consecutively in a counter-clockwise direction when tuner is viewed from the front. If all the Channel Coils have been removed from the Tuner Turret, rotate turret until flat surface on end of tuner shaft points down. Install #3 Channel Coils into bottom position on turret. Then follow the correct sequence indicated above to replace other coils.
TUNER TURRET ASSEMBLY	To remove turret from RF Tuner Unit, proceed as follows: 1. Remove tuner from receiver chassis. 2. Remove rear Turret Shaft Retaining Spring by disengaging straight end of spring from projection on tuner. 3. Remove Fine Tuning Condenser Plate from front of Tuner Unit. This plate forms one side of Fine Tuning control condenser and is held in place by one screw. 4. Slide Fine Tuning Cam and Brass Shaft off of main Channel Selector Shaft. 5. Remove Contactor Washer Spring and Fiber Spacer Washer from Channel Selector Shaft. 6. Remove Shaft Retaining Spring at front of tuner by disengaging straight end of spring from projection on case. 7. Remove turret assembly from case. To replace turret, reverse the above procedure. Tooth on bakelite Fine Tuning Cam should point downward during assembly so that it does not become locked between the stops on the Fine Tuning Condenser Plate.

ITEM	PROCEDURE
STATOR CONTACT ASSEMBLY	To remove this assembly, proceed as follows: 1. Remove the two screws at the front and rear of the Stator Contact Assembly. 2. Unsolder all electrical connections to contact plate. 3. Unsolder five soldered joints between Stator Contact Assembly and Tuner Unit. 4. Contact Assembly may now be withdrawn from case. To reinstall this assembly: 1. Place Stator Contact Assembly in position and replace, but do not tighten, the two screws at the front and rear of the assembly. 2. Remove 3 consecutive pairs of Channel Coils from the turret (for example, the antenna and rf-osc. coils for channels #5, 6 and 7). 3. Position Tuner Turret so that the edges of the next highest Channel Coils (in this case, the coils for channel #8) just pass the row of 11 contacts on the Stator Contact Assembly. 4. Adjust position of the Stator Contact Assembly so that there are a few thousandths of an inch spacing between the contacts on the contact plate and the molded body of the Channel Coils. 5. The Contact Assembly is now correctly positioned and screws at front and rear may be tightened. 6. Solder Stator Contact Assembly to tuner frame at same points that were used previously. 7. Make all electrical connections to contact plate. 8. Replace Channel Coils.



CHANNEL NUMBER	ANTENNA COIL PART NUMBER	RF & OSC COIL PART NUMBER
2	507952	507972

World Radio History

ALIGNMENT PROCEDURE

Alignment of all RF and IF tuned circuits in this receiver may be accomplished by utilizing the procedures described in the following charts.

SEQUENCE OF ALIGNMENT: These procedures should preferably be applied in the order in which they are presented, however, alignment of the Sound Channel or IF Channel may be accomplished individually if desired.

The RF Amplifier and Mixer alignment may also be accomplished independent of Sound or IF Channel alignment, but oscillator calibration can only be done after IF Channel has been correctly aligned. Proper IF band pass characteristic is necessary for Oscillator alignment as results of RF circuit tuning are observed by means of an oscilloscope connected to the output of the detector stage.

REMOVAL OF CHASSIS: The receiver chassis must be removed from the cabinet in order to accomplish alignment of all tuned circuits as there are adjustment points located on the underside of the unit.

This can be accomplished by first removing all knobs and disconnecting the receiver "built-in" antenna and speaker. The chassis may then be removed by releasing the hold-down screws located on the underside of the cabinet.

Removal of the cabinet back automatically opens an interlock to disconnect the receiver power cord, therefore, an auxiliary power cord assembly will be required when aligning this receiver. This cord may be ordered from Firestone by requesting Part #507699. **Do not attempt to supply power to the receiver by using any other device.**

CAUTION

The picture tube is highly evacuated and if broken, glass fragments will be violently expelled. Handle with care, using safety goggles and gloves. Avoid contact with high voltage terminal at side of tube even after it has been disconnected from the receiver—this precaution is necessary as inner and outer coatings on the tube form a capacitor which may carry a high voltage charge for an extended period of time after disconnection from the receiver.

INSTRUMENTS: The following instruments will be required as signal sources and output indicators during the alignment process. Since accurate alignment of a television receiver is heavily dependent upon the performance of your instruments, it is imperative that they meet the essential specifications described here.

1. **STANDARD SIGNAL GENERATOR** to provide unmodulated (pure RF) signals at the following frequencies. Maximum output on all ranges should be at least .1 volt with provision for attenuation as desired. This instrument must have good frequency stability and be accurately calibrated. Generators which incorporate a separate crystal controlled oscillator and heterodyne circuit are self calibrating and therefore capable of providing the accuracy of frequency calibration required for television circuit alignment.

   a. IF Frequencies:

   4.5 Mc. Sound Channel
   22.25 Mc. Sound IF marker
   22.4 Mc. 1st IF Trap Coil
   23.5 Mc. 1st and 3rd IF stages
   24.75 Mc. 4th IF stage
   26.3 Mc. Converter and 2nd IF stages
   26.75 Mc. Picture IF marker

   b. RF Frequencies:

   54 to 88 Mc.
   174 to 216 Mc.

2. **RF SWEEP GENERATOR** to provide frequency modulated signals at the following frequencies:

   20 to 30 Mc. with 10 Mc. sweep width.
   54 to 88 Mc. with 10 Mc. sweep width.
   174 to 216 Mc. with 10 Mc. sweep width.

   Output adjustable with at least .1 volt maximum.

   Output should be "flat" (no amplitude variation) for all settings of the sweep width control.

   Provision for connection of generator sweep modulating voltage to horizontal deflection system of an oscilloscope.

   Provision for blanking the output signal on each return sweep so that oscillogram will not show retrace.

3. **CATHODE RAY OSCILLOSCOPE**, preferably a unit with vertical amplifier having wide range frequency response and low capacity pick-up probe.

4. **VACUUM TUBE VOLTMETER.** The lowest voltage range of this instrument should preferably permit a 1.0 volt reading to be indicated at not less than one third of full scale deflection.

INSTRUMENT CONNECTIONS: The method of connection, including details of matching and coupling networks, for instruments used in this alignment procedure is given in several illustrations on subsequent pages. Specific instructions for each instrument application will be found in various sections of the alignment charts.

GENERAL INSTRUCTIONS: When aligning IF and RF circuits it is necessary to apply a fixed bias voltage to the AGC system of the receiver. This fixed bias is obtained by using a 3 volt battery and connecting it as described in Fig. 14.

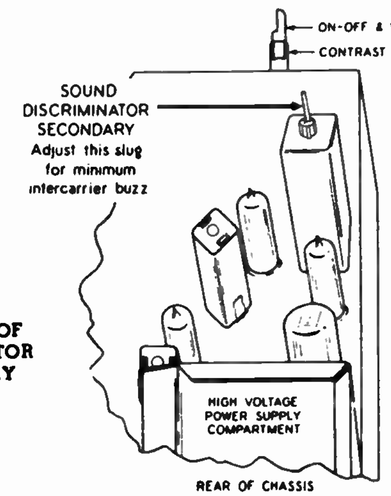
IMPORTANT

When observing the receiver band pass characteristic on an oscilloscope, it is exceedingly important to avoid distortion of that characteristic which would occur when using a large input signal from the sweep generator or standard generator (marker signal). Always set attenuator on sweep generator so that the reading on the vacuum tube voltmeter does not exceed one volt (when meter is connected from high side of video detector load resistor, symbol 196, to receiver chassis). Standard generator output should also be attenuated so that marker signal does not pull or tear the band pass characteristic as shown on the 'scope.

SOUND CHANNEL ALIGNMENT PROCEDURE

1. Short antenna terminals together with a jumper wire.
2. Set receiver Channel Selector to any inactive television channel; other controls may be left at any desired setting.
3. No special aligning tool is required to adjust the cores in the Sound IF and discriminator transformers. The blade of a small screwdriver will fit the slot in these cores, however, the screwdriver should be of a non-metallic or insulated type to prevent detuning when inserted in the transformer can.

STANDARD SIGNAL GENERATOR — CONNECTIONS	STANDARD SIGNAL GENERATOR — FREQUENCY	VTVM CONNECTIONS	MISCELLANEOUS INSTRUCTIONS	TRIMMER OR SLUG	TYPE OF ADJUSTMENT AND OUTPUT INDICATION
Connect as shown in Fig 1.	**4.5 MC.** unmodulated **IMPORTANT** This signal must be accurate within 1/4 of 1% of 4.5 Mc. Check generator calibration against a crystal controlled signal source by "zero beating" (heterodyning) with harmonics of the crystal frequency.	Connect as shown in Fig. 2.	A "swishing" sound may be heard in the speaker during Sound Channel Alignment. This spurious oscillation is caused by horizontal sweep voltage being picked up in the audio system thru stray coupling of instrument leads; it should be disregarded as it will have no effect on alignment of the sound channel.	**#1** Discriminator Secondary	Adjust for maximum reading on VTVM.
				#2 Discriminator Primary	Adjust for maximum reading on VTVM.
				#3 2nd Sound IF Secondary	Adjust for maximum reading on VTVM.
				#4 2nd Sound IF Primary	Adjust for maximum reading on VTVM.
				#5 1st Sound IF Secondary	Adjust for maximum reading on VTVM.
				#6 1st Sound IF Primary	Adjust for maximum reading on VTVM.
Same as above.	Same as above.	Connect as shown in Fig 3.	Same as above.	**#1** Discriminator Secondary	Note that as slug #1 is rotated, a point will be found where the voltmeter will swing rather sharply from a positive to a negative reading or vice versa. The correct setting of slug #1 is obtained when the meter reads zero as the slug is moved thru this point.



LOCATION OF DISCRIMINATOR SECONDARY SLUG

REDUCTION OF INTERCARRIER BUZZ

Slight "dynamic" unbalance of the discriminator secondary can emphasize intercarrier buzz due to incomplete amplitude modulation rejection. Therefore it is vitally important to obtain an accurate setting of the discriminator secondary slug under actual reception conditions.

Disconnect all instruments and then connect an antenna to the receiver to obtain program reception from a local station. If intercarrier buzz is prominent, a slight readjustment of the discriminator secondary slug (#1) should be made to obtain the "dip" point for the buzzing sound. Note that program sound will be clear and free from distortion at this point. Buzz should now be at an acceptable minimum if station transmission is not at fault.

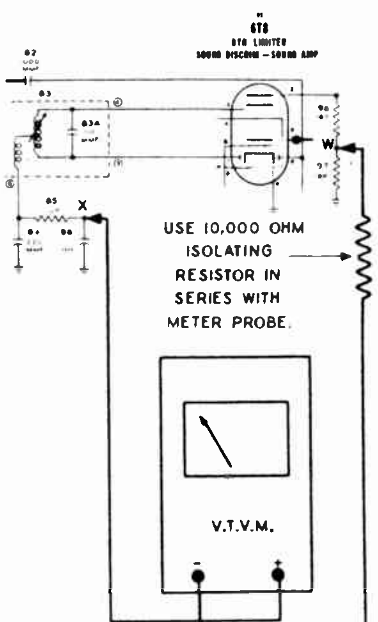

FIG. 3
VTVM Connections for Sound Discriminator Alignment

INSTRUMENT CONNECTIONS FOR IF CHANNEL ALIGNMENT

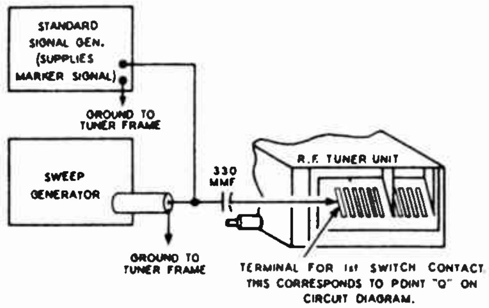

FIG. 4
Generator Connections for IF Channel Alignment

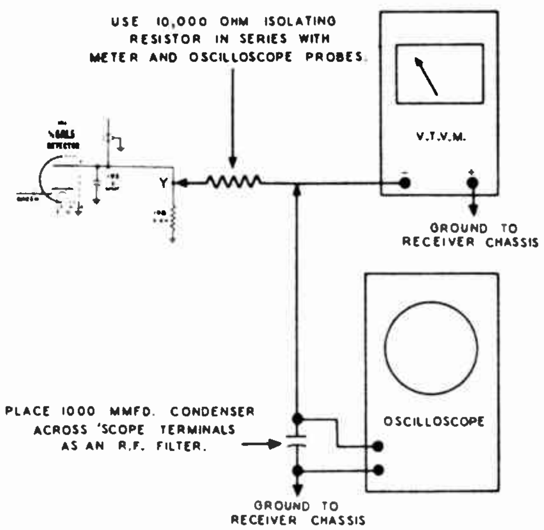

FIG. 5
VTVM and Oscilloscope Connections for IF Channel Alignment

IF CHANNEL ALIGNMENT PROCEDURE

1. A special aligning tool designed to fit the stems on adjustable cores of the IF and Trap coils (see points 8, 9, 10, 11 and 12 in Fig. 13) is available and may be obtained by requesting IF Alignment Tool #507479.
2. Turn receiver Channel Selector to television channel #12 and short antenna terminals together with a jumper wire.
3. Connect a 3 volt battery to the receiver AGC system so that negative terminal of battery connects to the AGC line and positive terminal of battery connects to receiver chassis. See Fig. 14 for convenient point of connection.
4. If the IF channel is badly misaligned and two or more immediately adjoining IF stages are tuned to the same frequency, oscillation may occur. Such oscillation shows up as a voltage across the video detector load resistor, symbol 196, and is indicated by the VTVM that is connected to this point during alignment. It should be noted that voltage due to IF oscillation is unaffected by strength of signal from the generator.

Where IF oscillation is encountered, it is generally possible to correct the condition by detuning the IF coils in different directions. If that does not have the desired effect, increase fixed bias on AGC line by using a 4½ volt battery instead of the 3 volt battery referred to in instruction #3. After stopping the oscillation in this manner it will then be possible to align all IF stages using the following procedure, however, the AGC bias battery must be changed back to 3 volts when using the oscilloscope to observe band pass characteristics. Once all stages have been aligned using the 4½ volt bias, the IF channel should be stable with reduced bias.

STANDARD SIGNAL GENERATOR		SWEEP GENERATOR		VTVM CONNECTIONS	OSCILLOSCOPE CONNECTIONS	MISCELLANEOUS INSTRUCTIONS	TRIMMER OR SLUG	TYPE OF ADJUSTMENT AND OUTPUT INDICATION
CONNECTIONS	FREQUENCY	CONNECTIONS	FREQ.					
Connect as shown in Fig. 4.	26.3 MC. or 26.1 MC. "E" See note below.	Use a 330 Mmf. isolating condenser and connect as shown in Fig. 4 but keep power switch turned off during this step.	——	Connect as shown in Fig. 5.	Not used.	——	#7 Converter plate coil	Adjust for maximum reading on VTVM.
							#8 2nd I.F.	Adjust for maximum reading on VTVM.
Same as above.	24.75 MC.	Same as above.	——	Same as above.	Not used.	——	#9 4th I.F.	Adjust for maximum reading on VTVM.
Same as above.	23.5 MC.	Same as above.	——	Same as above.	Not used.	——	#10 1st I.F.	Adjust for maximum reading on VTVM.
							#11 3rd I.F.	Adjust for maximum reading on VTVM.
Same as above.	22.4 MC.	Same as above.	——	Same as above.	Not used.	——	#12 1st IF Trap Coil	Adjust for minimum reading on VTVM.
Same as above.	26.75 MC.	With connections made as shown in Fig. 4, turn on this generator and set controls for operation as specified in next column.	25 MC. Sweeping ± 5 Mc.	Same as above.	Connect as shown in Fig. 5.	IMPORTANT: 1. Adjust output attenuator on sweep generator so that reading on VTVM is approximately one volt. 2. Set attenuator on standard signal generator so that marker signal does not distort the pattern on the oscilloscope. 3. Be sure that a 3 volt battery is connected to AGC line as specified in instruction #3 at the head of this chart. Do not use a battery of any other voltage.	The IF band pass characteristic now displayed on the 'scope should be compared with the curve shown in Fig. 6. If top of curve is not properly shaped, make a slight readjustment of slug #9. Should that adjustment fail to yield the desired result, then note whether the curve has a peak on the high or low frequency side. Slugs #7 and #8 control high frequency response (26.3 Mc.) and slugs #10 and #11 affect the low frequency response (23.5 Mc.): by making a small change in the settings of the high or low frequency slugs, it will be possible to obtain correct band pass curve. FIG. 6. The 26.75 Mc. picture IF carrier marker should now appear at the 40% amplitude position on side of the band pass characteristic (see Fig. 6). If position of the marker appears too high or too low, slight readjustment of slugs #7, 8 and 9 is required.	
Same as above.	22.25 MC.	Same as above.	Same as above.	Same as above.	Same as above.	Same as above.	Adjust the vertical gain control on the 'scope in order to magnify the sound portion of the response curve. The 22.25 Mc. sound IF carrier marker should appear at the position indicated in Fig. 6. If the position of the sound marker is incorrect, readjust Trap Coil #12.	

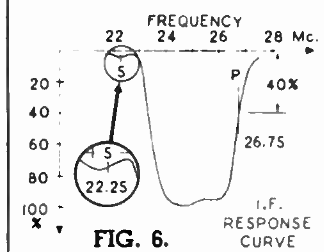

FIG. 6.

NOTE: Chassis which have the letter "E" in the series designation on rear of chassis must be aligned using 26.1 Mc. at these two points. See circuit diagram page for details of complete change.

TELEVISION RF CHANNEL ALIGNMENT PROCEDURE

1. Turn the band switch to the "TV" position.
2. Connect a 3 volt battery to the receiver AGC system so that negative terminal of battery connects to AGC line and positive terminal of battery connects to receiver chassis. (See Fig. 19 for convenient point of connection.)

RF AMPLIFIER AND MIXER ALIGNMENT

STANDARD SIGNAL GENERATOR CONNECTIONS	STANDARD SIGNAL GENERATOR FREQUENCY	SWEEP GENERATOR CONNECTIONS	SWEEP GENERATOR FREQ.	VTVM CONNECTIONS	OSCILLOSCOPE CONNECTIONS	MISCELLANEOUS INSTRUCTIONS	TRIMMER OR SLUG	TYPE OF ADJUSTMENT AND OUTPUT INDICATION
Connect as shown in Fig. 15.	*209.75 MC. ‡205.25 MC.	Connect as shown in Fig. 15 and set controls for sweep width of 10 Mc. on television channel specified in the next column.	CHANNEL #12	Not used.	Connect as shown in Fig 16.	Set Channel Selector to #12 IMPORTANT: Keep output of standard signal generator at a level that provides a readable marker but does not distort the curve that is being observed on the scope.	#13 Mixer Grid. #14 RF Amp. Plate. #15 RF Amp. Grid.	Adjust these trimmers to obtain properly shaped RF band pass characteristic as shown in Fig 12. Use Mixer Grid trimmer #13 and RF Amplifier Plate trimmer #14 to obtain correct amplitude of characteristic in vicinity of picture and sound carrier markers. Then adjust RF Amp. Grid trimmer #15 to equalize overall amplitude. Repeat adjustment of trimmers to be sure correct response has been obtained. IMPORTANT: When adjusting trimmers #13, 14 and 15 it will be noted that the band pass characteristic can be broadened by sacrificing amplitude. It is undesirable to overly broaden the curve as that would result in a loss of sensitivity.
Same as above.	*215.75 MC. ‡211.25 MC.	Same as above.	CHANNEL #13	Not used	Same as above.	Set Channel Selector to #13		The RF band pass characteristic of the other television channels should now be checked without disturbing the settings of trimmers #13, 14 and 15. Adjust the RF sweep generator and marker generator for operation on the other television channels, observing position of both the sound carrier and picture carrier markers.

OSCILLATOR ALIGNMENT

1. IMPORTANT: Before undertaking oscillator alignment be sure IF circuits are correctly aligned for band pass characteristic illustrated in Fig. 6.
2. During oscillator alignment, it is necessary to set the Fine Tuning control so that the tooth on the bakelite fine tuning cam points downward (correct position for this control is shown in Fig. 8).

The picture carrier marker for the corresponding channel should then appear at the 50% amplitude position on the opposite side of the band pass characteristic curve. NOTE: Make sure that cam on fine tuning control shaft remains properly positioned during this step (tooth on the cam pointing downward—see Fig. 8).
	* 71.75 MC. ‡ 67.25 MC.		CHANNEL #4			Set Channel Selector to #4		
	* 65.75 MC. ‡ 61.25 MC.		CHANNEL #3			Set Channel Selector to #3		
	* 59.75 MC. ‡ 55.25 MC.		CHANNEL #2			Set Channel Selector to #2		

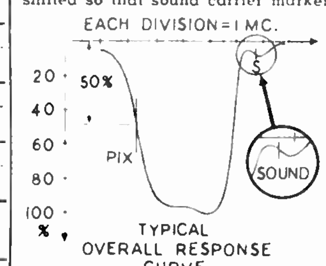

FIG. 9

If an oscillator slug "falls into" its coil form during adjustment, remove the Channel Coil from the turret assembly and lift the Slug Retaining Spring aside. By tapping the coil form it should be possible to make the slug move toward the end so that its threads will be engaged by the Slug Retaining Spring when that spring is returned to its normal position.

If an unsatisfactory overall response is obtained for a particular channel, observe RF Amp. and Mixer response curve for that channel as described on preceding page. If characteristic does not conform reasonably well within the typical curve shown in Fig. 7, then, (1) attempt to obtain a better compromise for RF response on all channels by realigning RF Amp. and Mixer circuits, or (2) try replacing Antenna, RF and Oscillator coils for the particular channels.

TUBE REPLACEMENT

Some chassis use alternate type tubes in the positions designated by V1, V2, V12, V16 and V26 in the above chart. **These alternate type tubes are not interchangeable and failure to install the correct type tube may result in damage to the receiver.**

When replacing these tubes, check for series designation stamped on rear of chassis adjacent to model number. This identification may consist of one or more letters following the word SERIES.

The following symbols refer to similar symbols on the above tube location chart.

* A type 6AG5 tube is used when the letter "A" **is** included in the series designation. A type 6AU6 tube is used when letter "A" **is not** included in the series designation.

‡ A type 6BH6 tube is used when the letter "B" **is** included in the series designation. A type 6AU6 tube is used when letter "B" **is not** included in the series designation.

♦ A type 6SN7GT tube is used when the letter "C" is included in the series designation. A type 6S4 tube is used when letter "C" **is not** included in the series designation.

MECHANICAL PARTS OF R. F. TUNER—Continued

DIAGRAM NO.	PART NO.	DESCRIPTION
	509321	Fine Tuning cam and brass shaft
	508708	Roller—detent
	507989	Shield—tube; miniature (fits solid ring type clip)
	505367	Shield—tube; miniature (fits wing type clip)
	509062	Slug core for converter plate coil
	507986	Slug for osc. coil fine tuning adjustment
	507987	Socket—miniature (for 6J6) (includes solid ring type clip for shield)
	509065	Socket—miniature (for 6J6) (includes wing type clip for shield)
	507988	Socket—miniature (for 6AG5) (includes solid ring type clip for shield)
	509066	Socket—miniature (for 6AG5) (includes wing type clip for shield)
	507966	Spring contactor washer (on front turret shaft)
	508709	Spring—detent
	507990	Spring—retains osc. fine tuning slug
	507967	Spring—turret shaft retaining
	507984	Stator contact assembly (includes 11 contacts and metal frames)
	509322	Tuner turret and shaft assembly (less coils)
	507965	Washer, fiber spacer (on turret shaft)

CABINET PARTS

DIAGRAM NO.	PART NO.	DESCRIPTION
	509085	Back for cabinet; Stack 13-G-46 (less power cord)
	509124	Back for cabinet; Stack 13-G-47 (less power cord)
	507783	Bottom plate for Stock 13-G-46
	509100	Cabinet for Stock 13-G-46
	509110	Cabinet for Stack 13-G-47
	507930	Call letter tabs
	509081	Escutcheon for glass window
	509082	Glass window
	502563	Knob—built-in antenna
	509088	Knob—"OFF-VOLUME-ON"
	507916	Knob—Channel Selector
	509087	Knob—"Contrast"
	507917	Knob—Fine Tuning
	509079	Mask for picture tube
	509117	Name plate
	509131	Rubber (flat sponge type) gasket between mask and picture tube
	18796	Screw—#10x1"; mounts chassis
	162163	Terminal strip for TV antenna connection
	509482	Washer, felt for contrast knob

MOUNTING PARTS FOR YOKE AND FOCUS MAGNET ASSEMBLY

Chassis which utilize four wing screws for height adjustment (located on both the left inside and right inside of base bracket) have the following parts:

DIAGRAM NO.	PART NO.	DESCRIPTION
	508829	Bracket base for support of yoke and focus magnet assembly (left hand)
	508830	Bracket base for support of yoke and focus magnet assembly (right hand)
	509005	Bracket for deflection yoke mounting
	508154	Bracket ("U" shaped) for support of yoke and focus magnet assembly
	507793	Rubber spacer support between flared neck of picture tube and yoke bracket
	170817	Wing screw—#10-24; for height adj. of yoke and focus magnet assembly
	170741	Wing screw—#10-32; for mounting yoke
	170195	Wing nut—#8-32; for mounting yoke and focus magnet assembly

Chassis which utilize two wing nuts and bolts for height adjustment (located only on the left outside of base bracket) have the following parts:

DIAGRAM NO.	PART NO.	DESCRIPTION
	14045	Bolt—1/4"-20 x 3 3/4"; for height adjustment of yoke and focus magnet assembly
	509389	Bracket base for support of yoke and focus magnet assembly (bottom left hand)
	509390	Bracket base for support of yoke and focus magnet assembly (bottom right hand)

MOUNTING PARTS—Continued

DIAGRAM NO.	PART NO.	DESCRIPTION
	509391	Bracket base for support of yoke and focus magnet assembly (top left hand)
	509392	Bracket base for support of yoke and focus magnet assembly (top right hand)
	509395	Bracket, mounts yoke and focus magnet assembly (circular type)
	507793	Rubber spacer support between flared neck of picture tube and yoke bracket
	509393	Spacer for base mounting brackets of yoke and focus magnet assembly
	50876	Wing nut—1/4"-20; for height adjustment of yoke and focus magnet assembly
	170741	Wing screw—#10-32; for mounting or forward adjustment of yoke

MISCELLANEOUS PARTS

DIAGRAM NO.	PART NO.	DESCRIPTION
	301270	Base for mounting electrolytic condenser
	508666	Bracket for mounting R.F. tuner (front)
	508955	Bracket for mounting R.F. tuner (rear)
	508976	Bracket—tube support (bottom front; less rubber pad
	509132	Call letter tabs
	509007	Centering arm
	508681	Clip for mounting electrolytic condenser #287
	508715	Clip for mounting fuse holder
	505101	Clip for mounting I.F. sound discriminator transformer
	507339	Clip for mounting video converter plate, 1st video I.F., 2nd video I.F., 3rd video I.F., 1st I.F. trap, or Horizontal Linearity coil
	507592	Clip for mounting 4th video I.F. coil
	508964	Clip for mounting Horizontal Hold coil
	507286	Connector for H.V. terminal of picture tube
	509595	Focus magnet assembly
	508714	Fuse holder
	508623	Grounding spring for coating on picture tube
	508603	Ion trap
	508617	Nut—for retaining focus magnet assembly mounting plate
	508962	Nut on end of Horizontal Hold control slug
	507699	Power cord assembly (includes plugs at both ends)
	507361	Rubber cover for H.V. terminal connector
	508619	Rubber spacer on picture tube support bracket
	18796	Screw—#10 x 1"; mounts chassis
	170182	Screw—#10-32 x 1 1/2"; retains tube support strap
	162138	Shield—H.V. supply (front section)
	508088	Shield—H.V. supply (rear section)
	509086	Shield—rubber, for Centering Arm
	162324	Shield for TV channel lite
	509062	Slug core for converter plate coil
	507357	Slug core for 1st, 2nd, 3rd or 4th video I.F. coil and 1st I.F. trap coil
	508963	Slug core for Horizontal Hold coil
	507429	Slug core for Horizontal Linearity coil
	508438	Slug core (5/16" dia. x 3/8" long) for primary of TV sound discriminator transformer
	508894	Slug core (1/4" dia. x 1/2" long) for primary of TV sound discriminator transformer
	508439	Slug core (5/16" dia. x 3/4" long) for secondary of TV sound discriminator transformer
	508894	Slug core (1/4" dia. x 1/2" long) for secondary of TV sound discriminator transformer
	508784	Slug core for Width coil
	508049	Socket and cable assembly for picture tube
	508957	Socket and mounting bracket for TV Channel Lite
	162259	Socket assembly for 1B3GT/8016 tube (includes corona ring and mounting frame)
	507932	Socket—male, power cord interlock
	507364	Socket—miniature (7 pin)
	508044	Socket—miniature (9 pin)
	508044	Socket—miniature (9 pin) (for 6S4 tube; when small mtg. hole is used)
	509507	Socket—miniature (9 pin) (for 6S4 tube; when large mtg. hole is used)
	508703	Socket—octal
	506469	Socket, octal (for 6W4 tube)
	509006	Spring—compression for focus magnet assembly mounting
	508514	Spring—retains H.V. lead
	508838	Strap for picture tube support (includes rubber pad)

*—This part is not supplied as a Service replacement item.

PRODUCTION CHANGES

The following tabulation furnishes complete details on changes which occurred during receiver production. The receivers incorporating these changes are identified by coding stamped on rear surface of chassis. This coding consists of one or more letters following the word SERIES, as SERIES B, SERIES AC, etc., and corresponds to similarly lettered changes shown below. Chassis incorporate only that change indicated by letter designation i.e., chassis stamped "SERIES BE" does not include changes "A" or "C" or "D".

The circuit shown on this page applies to "SERIES DEF" chassis.

LETTER INCLUDED IN DESIGNATION FOLLOWING THE WORD "SERIES"	CHANGE INCORPORATED IN CHASSIS
"A"	There is no performance advantage to a chassis containing this change—circuit revisions are due to short supply of certain tubes. 1. Tube V12 (Video Amp.) was changed from a type 6AU6 to a type 6AG5. 2. Tube V16 (Keyer A.G.C.) was changed from a type 6AU6 to a type 6AG5. **In order for this receiver to operate properly, V12 and V16 must be the same type tube.**
"B"	There is no performance advantage to a chassis containing this change—circuit revisions are due to short supply of certain tubes. 1. Tube V1 (1st Sound I. F. Amp.) was changed from a type 6AU6 to a type 6BH6. 2. Connection point of resistor 70 (82 Ohms) was changed from pin 7 of tube V1 (1st Sound I.F. Amp.) to pin 2 of this tube. 3. Connection point of blue lead from pin 2 of transformer 68 (1st Sound I.F. transformer) was changed from pin 2 of tube V1 (1st Sound I.F. Amp.) to pin 7 of this tube. 4. Tube V2 (2nd Sound I.F. Amp.-Limiter) was changed from a type 6AU6 to a type 6BH6. 5. Connection point of resistor 79 (82 Ohms) was changed from pin 7 of tube V2 (2nd Sound I.F. Amp.-Limiter) to pin 2 of this tube. 6. Connection point of blue lead from pin 2 of transformer 74 (2nd Sound I. F. transformer) was changed from pin 2 of tube V2 (2nd Sound I.F. Amp.-Limiter) to pin 7 of this tube. **In order for this receiver to operate properly, V1 and V2 must be the same type tube.**
"C"	There is no performance advantage to a chassis containing this change—circuit revisions are due to short supply of certain tubes. 1. Tube socket for V26 (Vertical Scanning Output) was changed from 7 pin miniature to octal base. 2. Tube V26 (Vertical Scanning Output) was changed from a type 6S4 to a type 6SN7GT. 3. Connections to tube socket of V26 (Vertical Scanning Output) were changed to those shown in schematic illustrated below. 4. Condenser 353 (.02 Mfd.) was added in parallel with condenser 327 (.05 Mfd.) as shown in schematic, illustrated

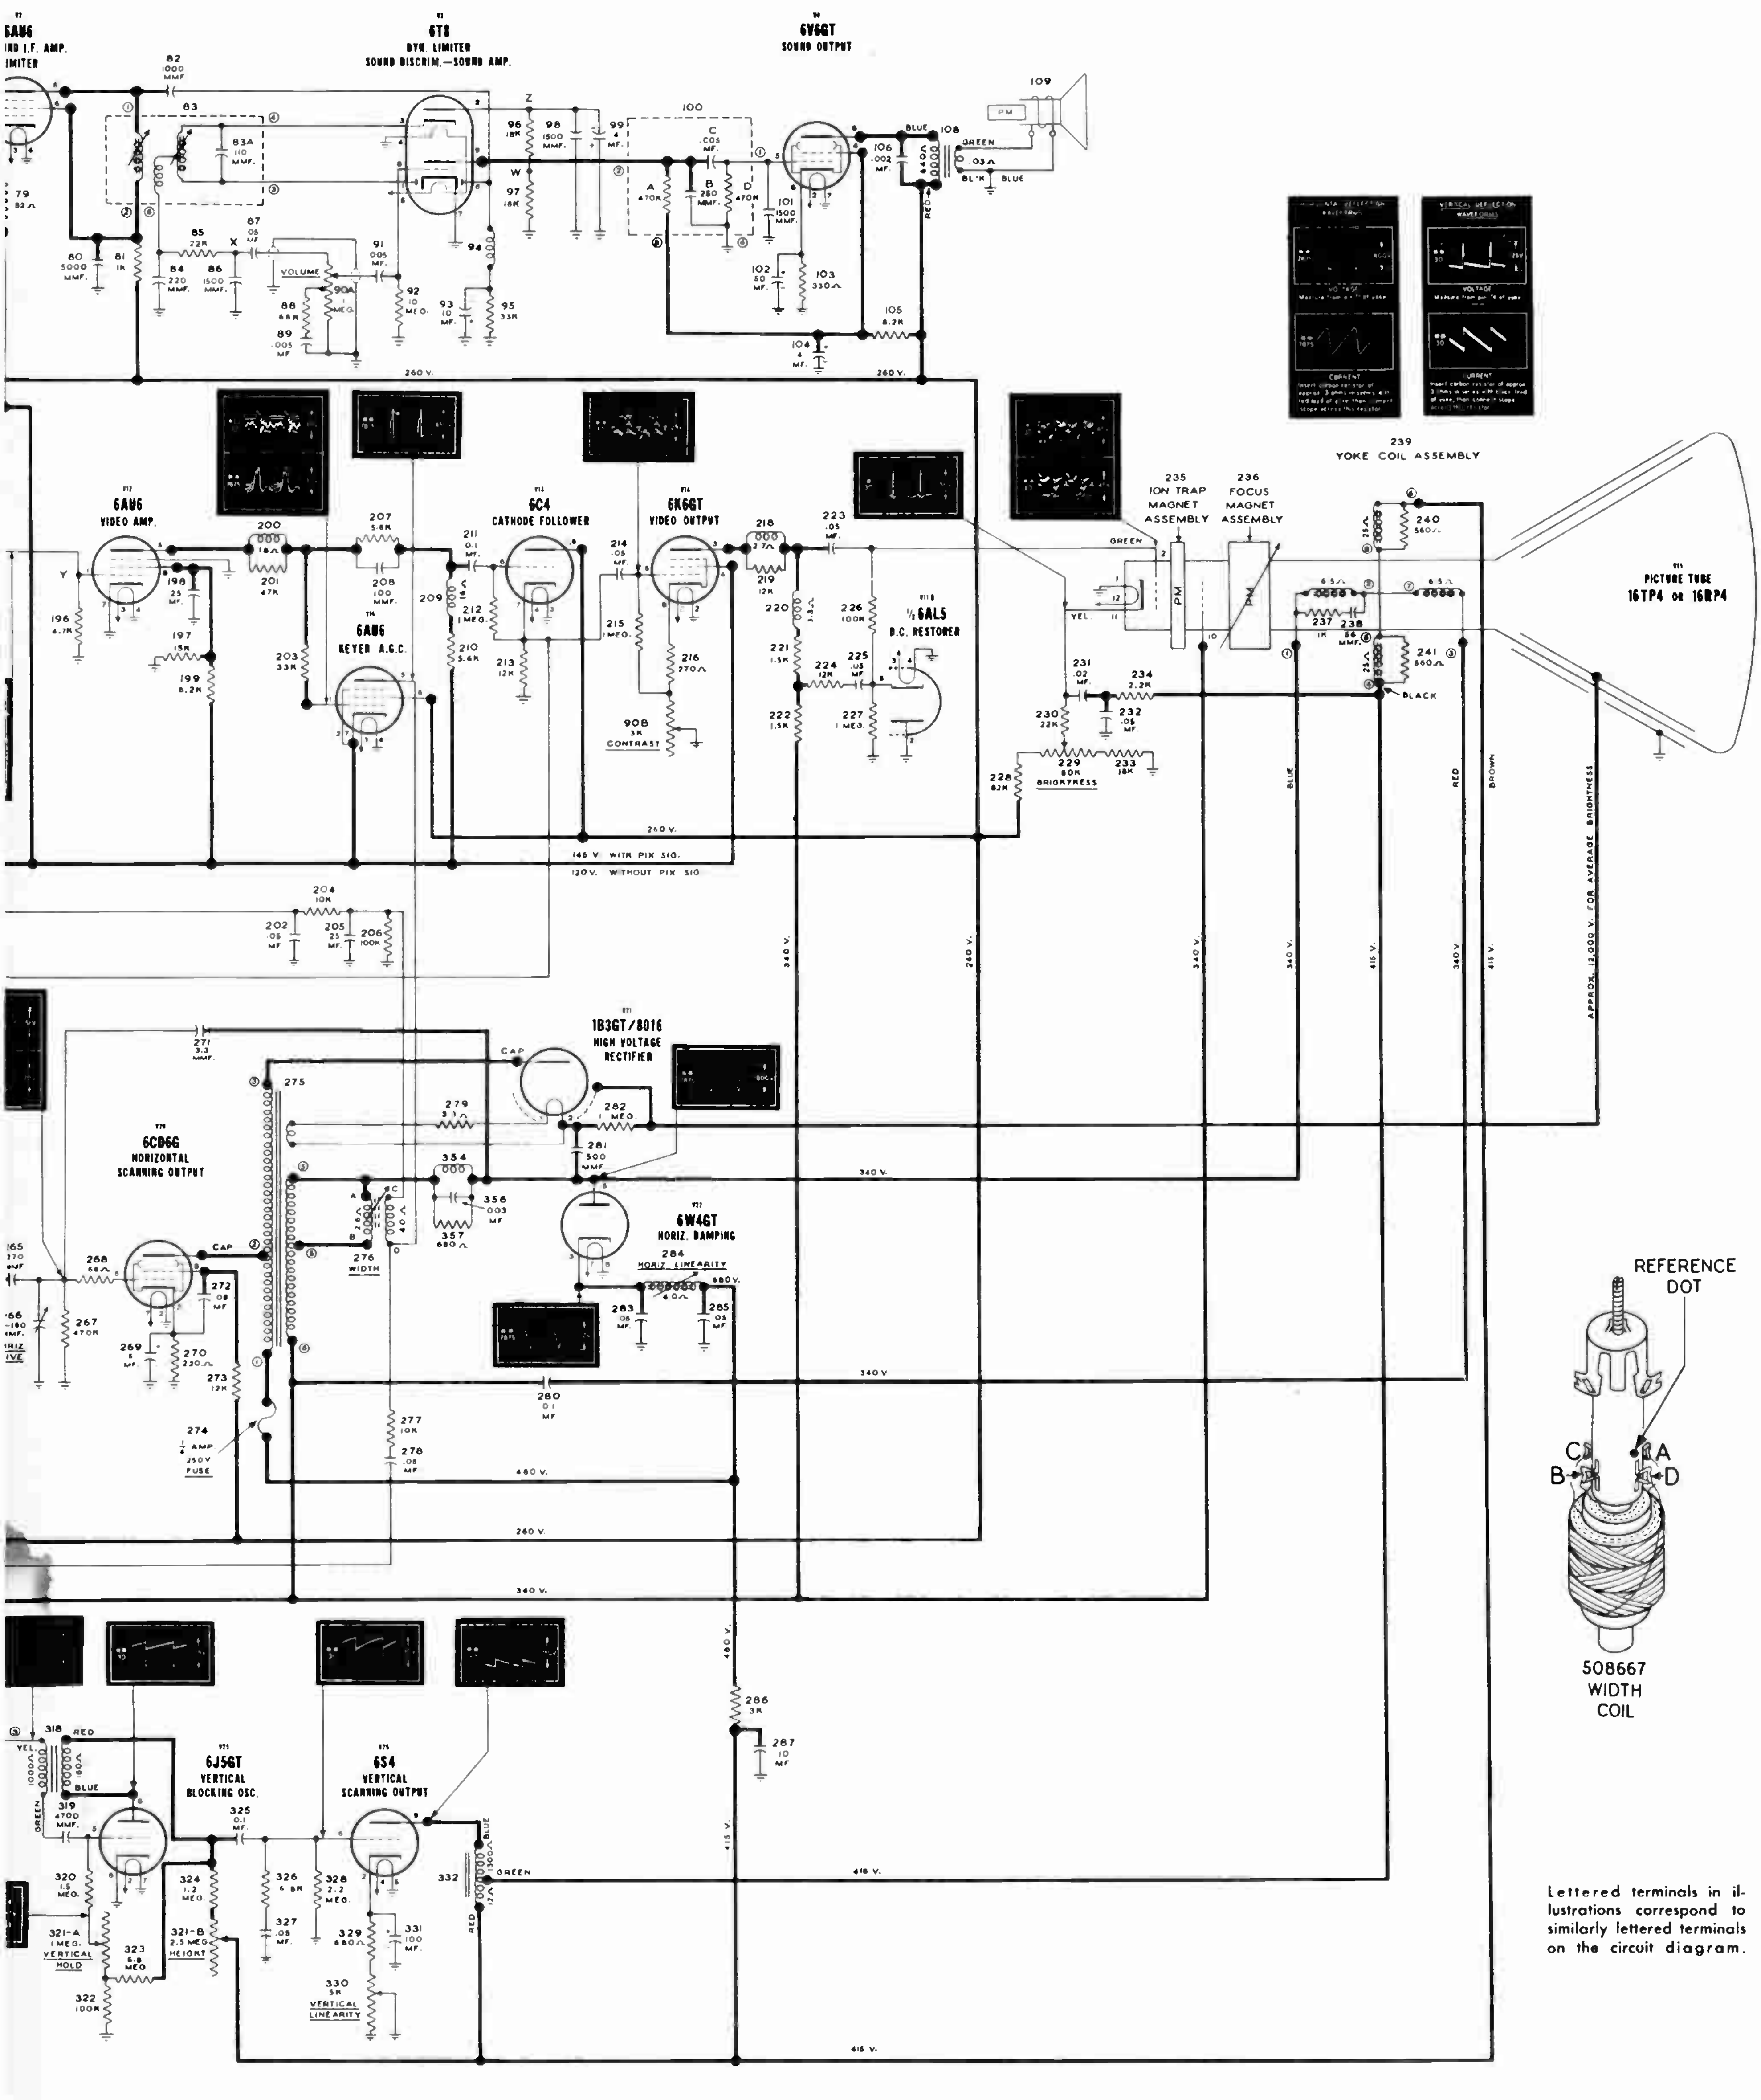
World Radio History

MODELS 13-G-46, 13-G-47



Lettered terminals in illustrations correspond to similarly lettered terminals on the circuit diagram.

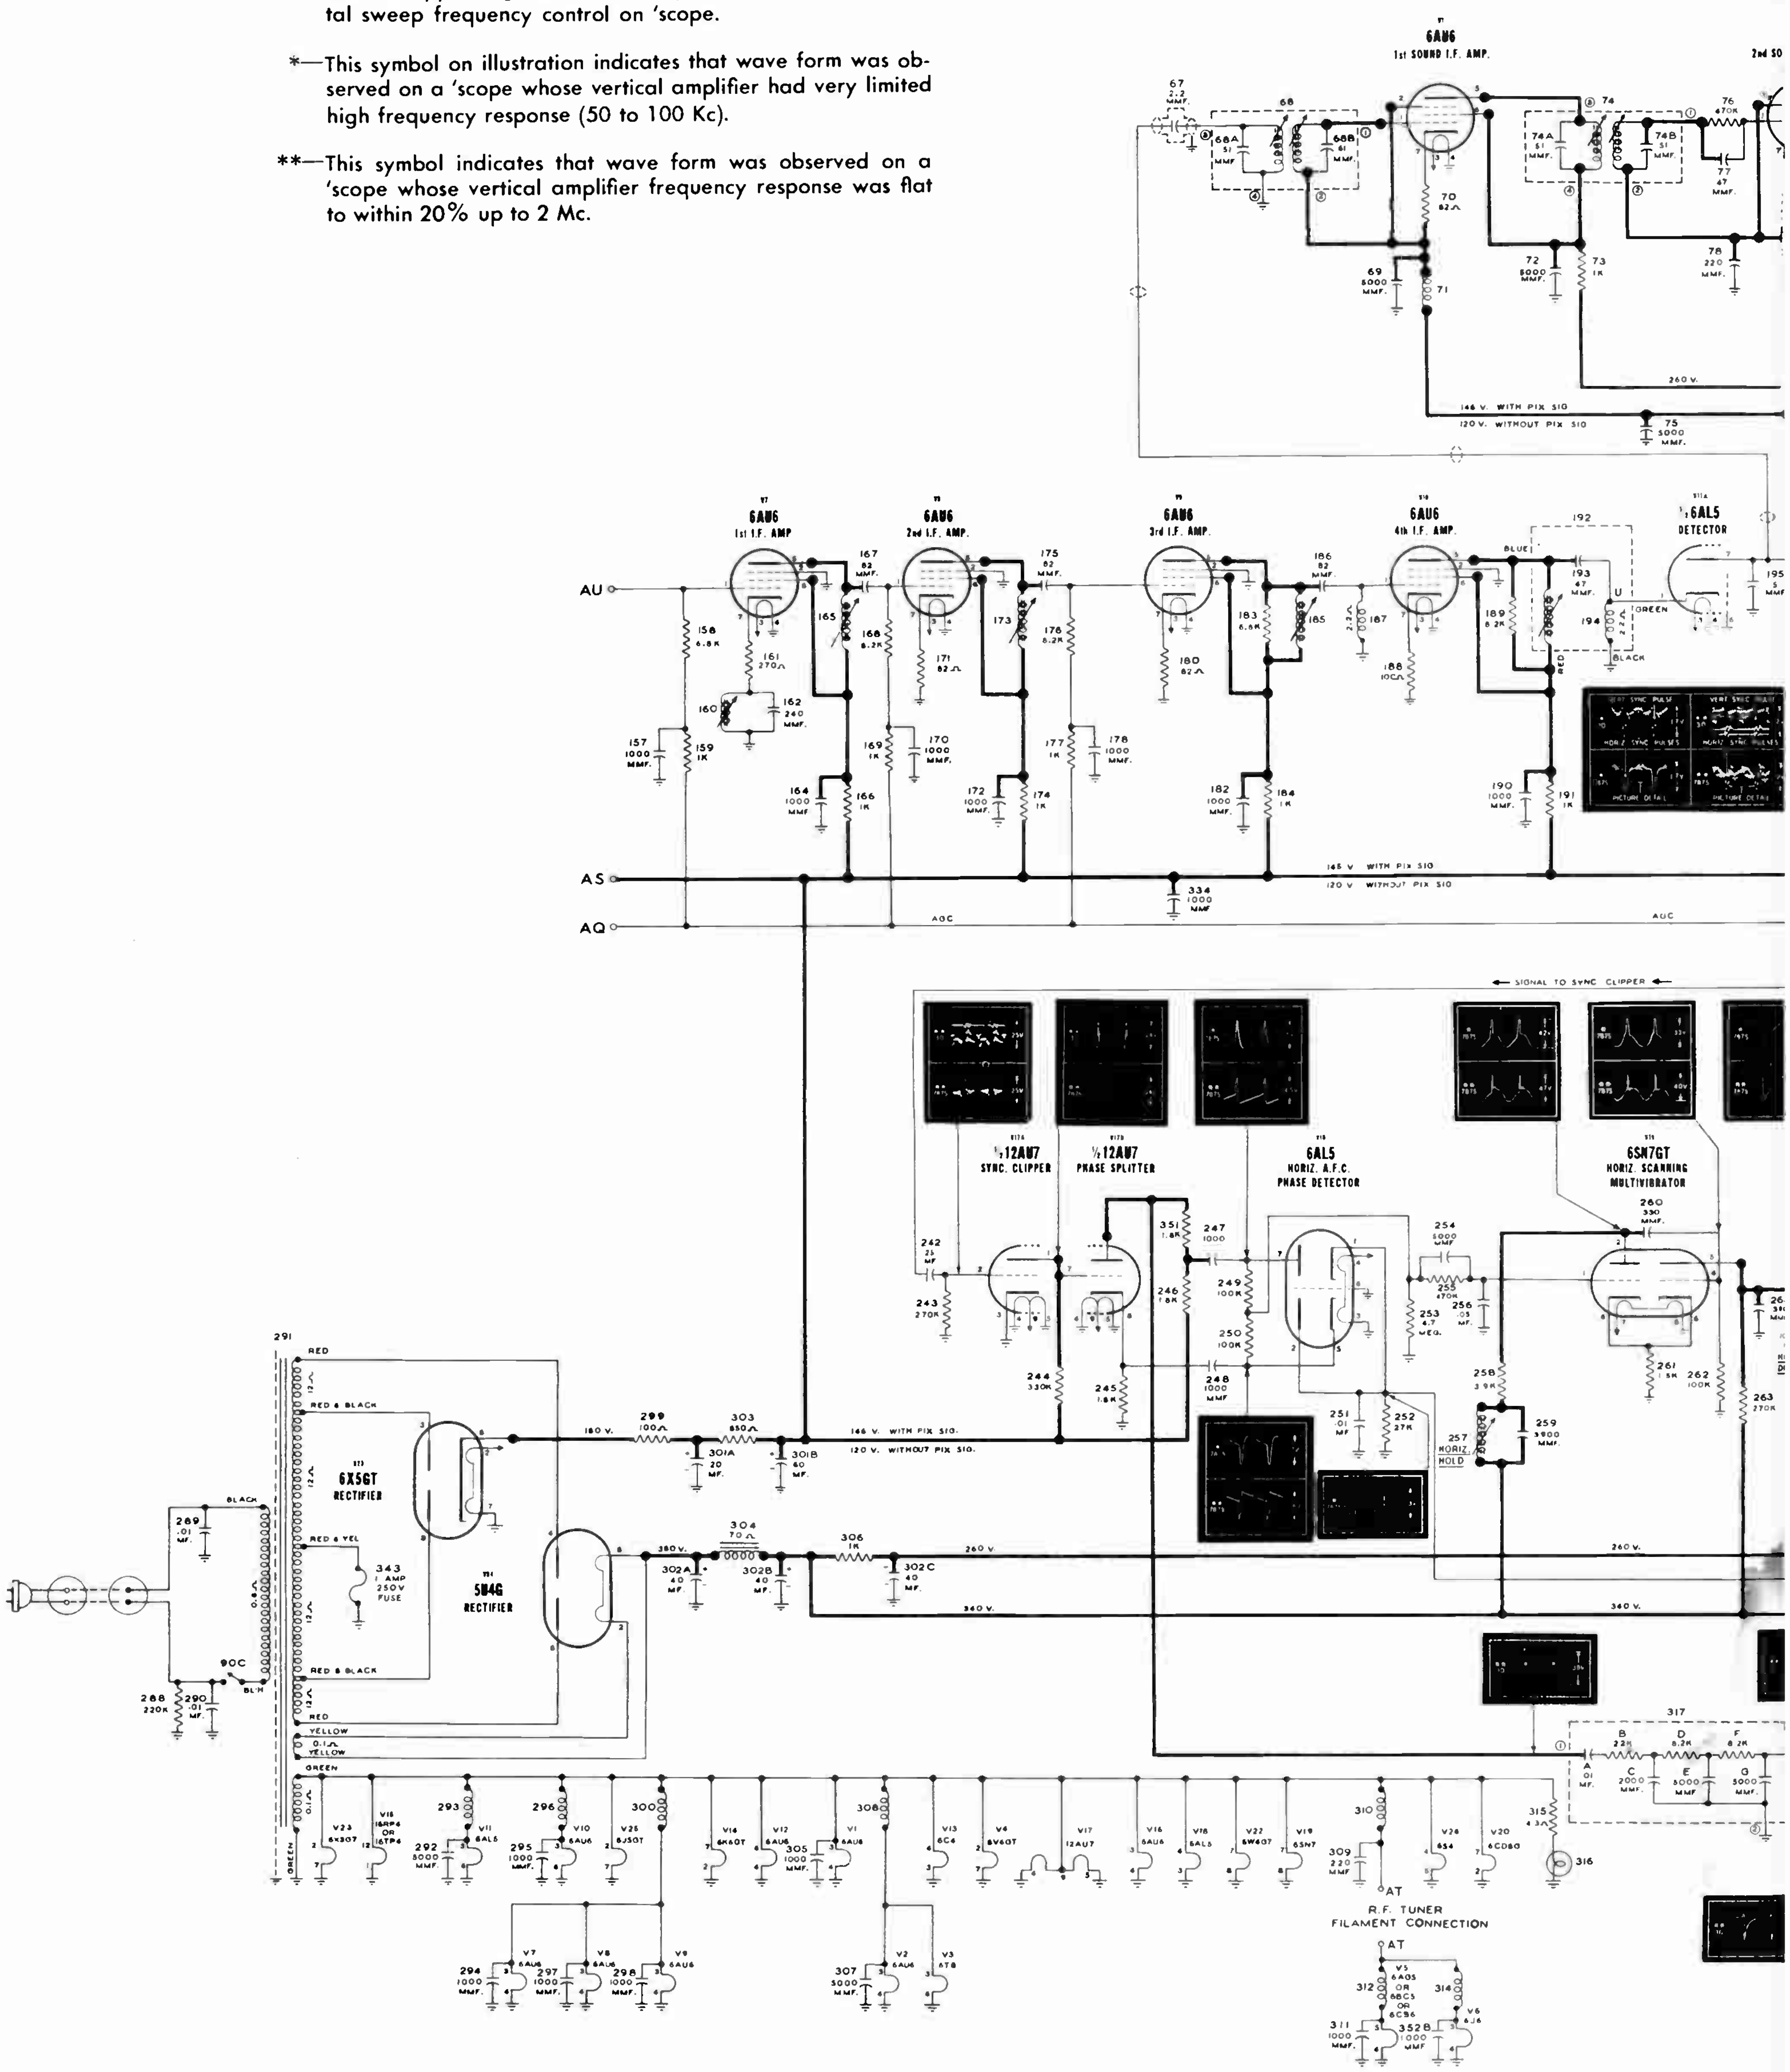
OSCILLOGRAMS

All oscillograms taken with ground lead of 'scope connected to receiver chassis (unless otherwise indicated) and with receiver controls set for normal reception of a station transmitting its standard test pattern.

Number appearing below asterisk specifies setting of horizontal sweep frequency control on 'scope.

*—This symbol on illustration indicates that wave form was observed on a 'scope whose vertical amplifier had very limited high frequency response (50 to 100 Kc).

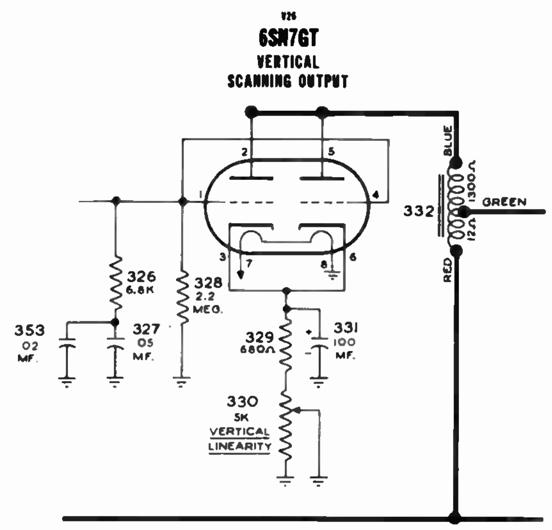
**—This symbol indicates that wave form was observed on a 'scope whose vertical amplifier frequency response was flat to within 20% up to 2 Mc.



©John F. Rider

World Radio History

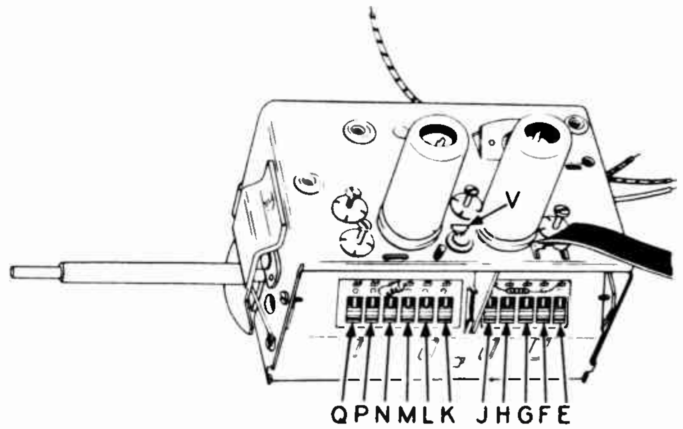
MODELS 13-G-46, 13-G-47



"D"	This change was incorporated in the chassis to improve vertical and horizontal sync. stability. 1. Resistor 351 (1800 Ohms) was added in plate circuit of V17B (12AU7) Phase Splitter. The junction of resistor 246 (1800 Ohms) and condenser 247 (1000 Mmfd.) was formerly connected directly to pin 6 of this tube. 2. Resistor 258 in plate circuit of V19 (6SN7GT) Horizontal Scanning Multivibrator stage was changed from 5600 Ohms to 3900 Ohms. 3. Fuse 343 (1 Amp. 250 Volt) was added between red and yellow lead of power transformer 291 and chassis ground.
"E"	This change was incorporated to decrease tube noise level and improve picture quality. 1. Resistor 161 in the cathode circuit of V7 was changed from 82 Ohms to 270 Ohms. 2. Resistor 176 in grid circuit of V9 (6AU6) 3rd I.F. Amp. stage was changed from 4700 Ohms to 8200 Ohms. 3. Resistor 183 in plate circuit of V9 (6AU6) 3rd I.F. Amp. stage was changed from 8200 Ohms to 6800 Ohms. 4. Resistor 196 in plate circuit of V11A (6AL5) Detector stage was changed from 6800 Ohms to 4700 Ohms. In addition the alignment frequency of the Converter Plate coil and 2nd I.F. coil was changed from 26.3 Mc. to 26.1 Mc. **Voltages** measured at certain tube socket terminals on a chassis which includes the letter "E" in the series designation will differ from those shown on the voltage chart. New measurements are as follows: Pin 7 of V7 (6AU6) .... 1.5 volts Pin 1 of V9 (6AU6) .... .4 volts In chassis that have been stamped with the letter "E" as a series designation, the Focus Magnet Assembly 236 (Part #509003) was changed to a new type (Part #509595) which uses a single focusing slug. This new unit provides an easier means of obtaining focus.
"F"	In order to reduce the "ringing effect" of the horizontal sweep transformer and defection yoke, which appears as white (or black) vertical lines on left side of picture screen, the following change was undertaken. 1. Trap coil 354 was added in series with yoke lead. 2. Condenser 355 (.003 mfd.) was placed in shunt across coil 354. 3. Resistor 356 (680 Ohms) was placed in shunt across coil 354. The following change was made to limit Picture tube beam current. 1. Connection to pin 10 of tube V15 (16TP4 or 16RP4) picture tube was changed from the 415 B+ Boost voltage bus to the 340 B+ bus.

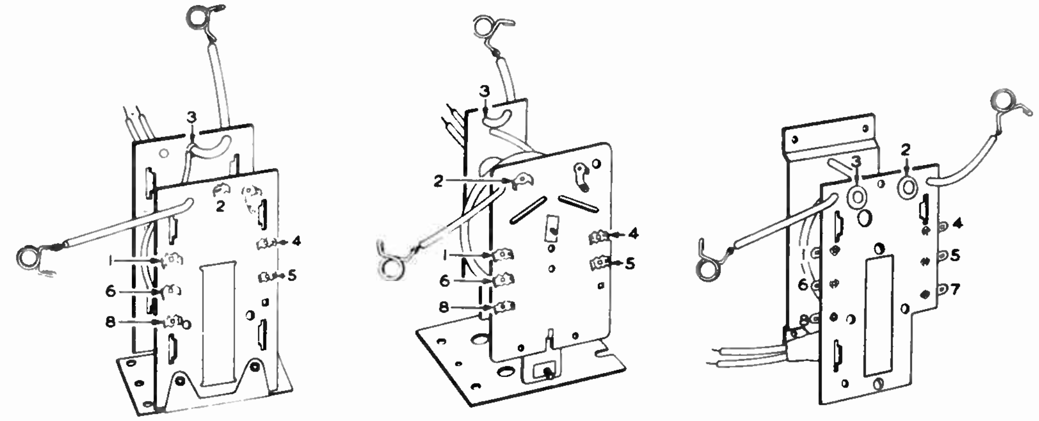
Voltages measured at certain tube socket terminals on a chassis which includes the letter "F" in the series designation will differ from those shown on the voltage chart. New measurements are as follows:

Pin 10 of V15 (16TP4 or 16RP4) .... 340 volts



508890 TUNER UNIT

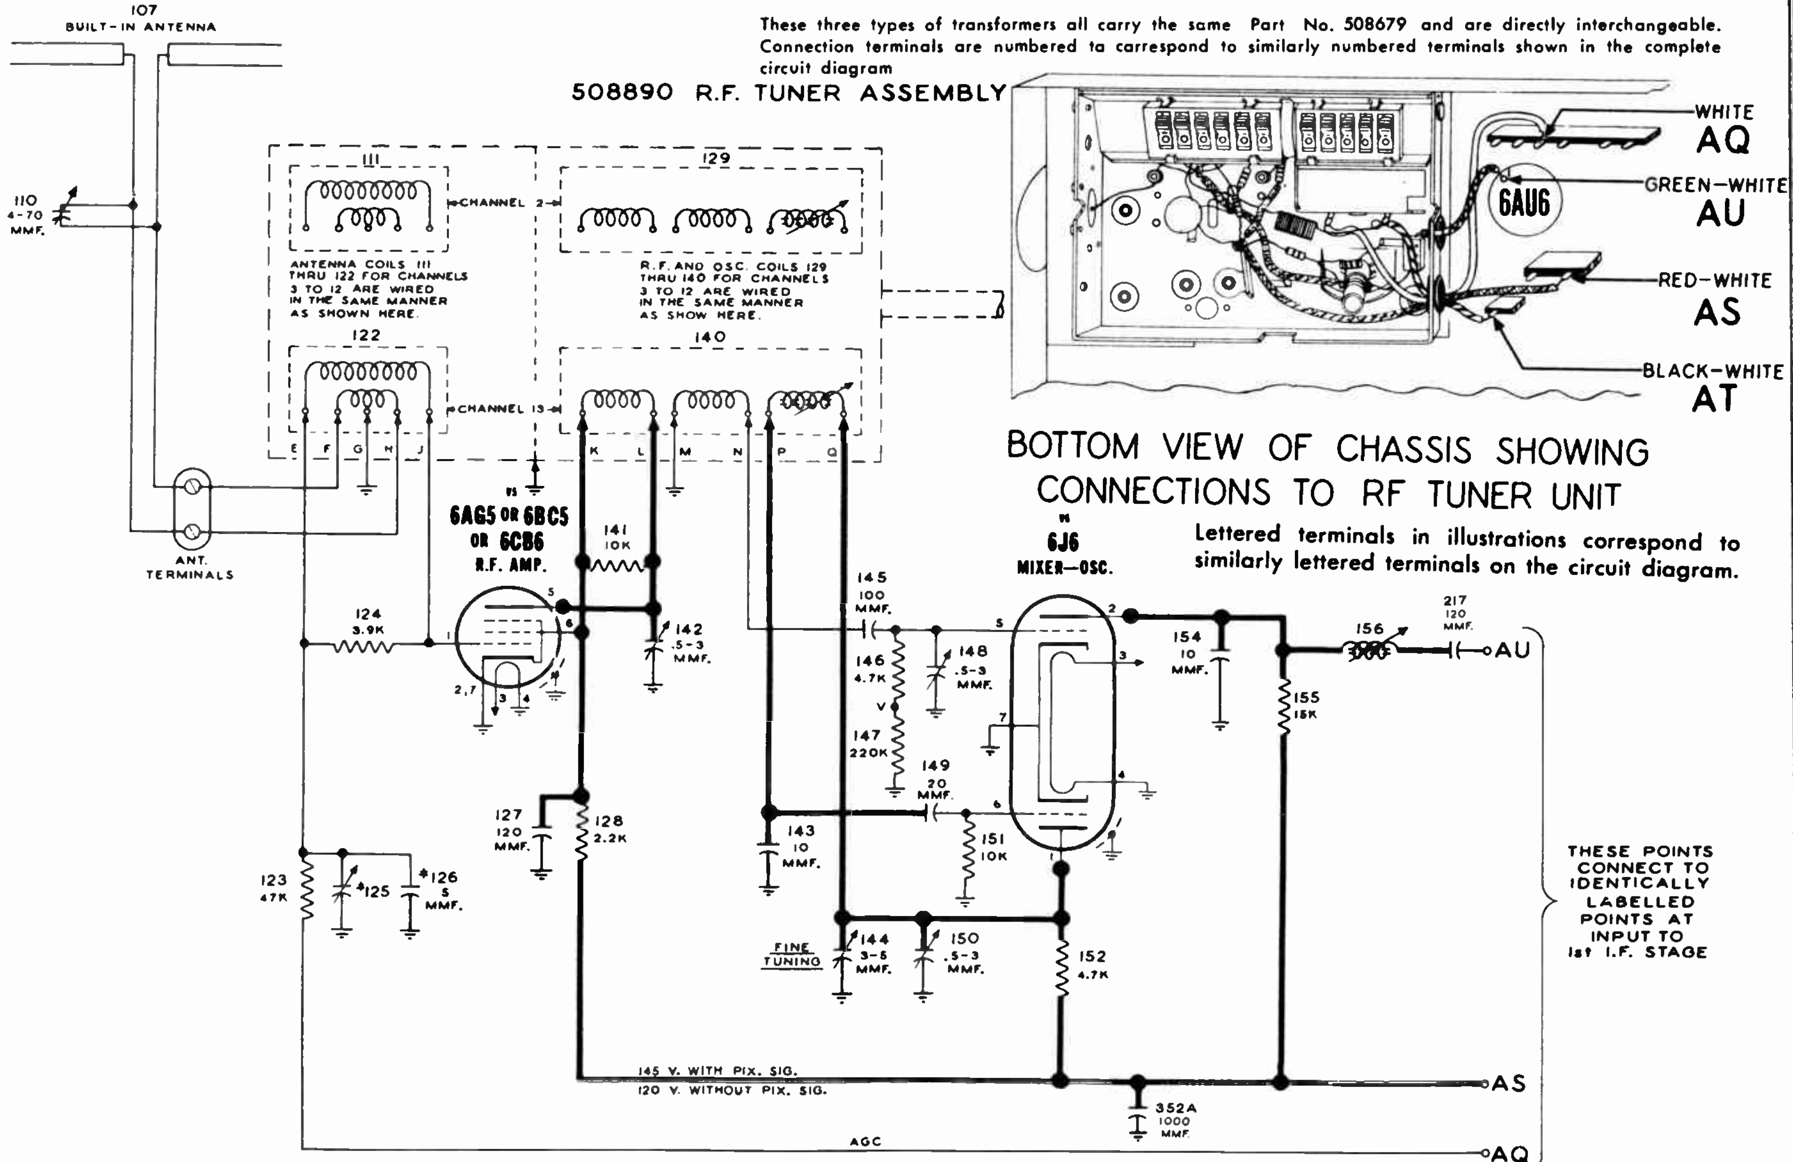
ALTERNATE HORIZONTAL SWEEP TRANSFORMERS



RESISTANCE MEASUREMENT	RESISTANCE MEASUREMENT	RESISTANCE MEASUREMENT
Between terminal 1 & 2— 40 Ohms	Between terminal 1 & 2— 40 Ohms	Between terminal 1 & 2— 40 Ohms
Between terminal 2 & 3—400 Ohms	Between terminal 2 & 3—400 Ohms	Between terminal 2 & 3—400 Ohms
Between terminal 5 & 8— 13 Ohms	Between terminal 5 & 8— 11 Ohms	Between terminal 5 & 8— 5 Ohms
Between terminal 6 & 8— 6.5 Ohms	Between terminal 6 & 8— 5.5 Ohms	Between terminal 6 & 8— 2.5 Ohms

These three types of transformers all carry the same Part No. 508679 and are directly interchangeable. Connection terminals are numbered to correspond to similarly numbered terminals shown in the complete circuit diagram

508890 R.F. TUNER ASSEMBLY



* THESE PARTS DIFFER IN SOME CHASSIS; SEE NOTE UNDER ITEM 125 AND 126 IN PARTS LIST.

BOTTOM VIEW OF CHASSIS SHOWING CONNECTIONS TO RF TUNER UNIT

Lettered terminals in illustrations correspond to similarly lettered terminals on the circuit diagram.

ELECTRICAL SPECIFICATIONS

Power Supply	105-125 Volts AC 60 Cycles Only
Power Consumption	150 Watts
Power Output	3.5 Watts Maximum 2 Watts Undistorted
Antenna Input Impedance	300 Ohms Balanced
Picture Area	90 Square Inch
Tuning Range	12 Channel
Intermediate Frequencies	Picture—25.75 MC Sound—4.5 MC
Loud Speaker	5" PM Dynamic
Voice Coil Impedance	3.2 Ohms 400 Cycles
Video Response	to 3 MC
Focus	Magnetic
Sweep Deflection	Magnetic
Scanning	Interlaced, 525 Line
Horizontal Scanning Frequency	15,750 CPS
Vertical Scanning Frequency	60 CPS
Frame Frequency	30 CPS

THIS RECEIVER CONTAINS THE FOLLOWING:

Symbol	Type	Function
V1	6AU6	1st I.F. Amplifier
V2	6AU6	2nd I.F. Amplifier
V3	6AU6	3rd I.F. Amplifier
V4	6AU6	Video Amplifier
V5	12LP4	Kinescope—12½"
V6	6AQ5	Audio Output
V7	6T8	FM Detector and 1st Audio
V8	6AU6	Sound I.F.
V9	6SN7GT	Vertical blocking oscillator and amplifier
V10	6AL5	Phase detector
V11	12AU7	Sync limiter and DC restorer
V13	6SN7GT	Horizontal oscillator
V14	6BG6G	Horizontal output
V16	6W4	Diode damper
V17	6AG5 or 6BC5	R.F. Amplifier
V18	6J6	Oscillator and Mixer
V12	5U4G	Low Voltage Rectifier
V15	1B3	High Voltage Rectifier

HIGH VOLTAGE WARNING

This television receiver contains high voltages which are dangerous to life. Never operate or service the receiver outside of the cabinet or with the covers removed until all the safety precautions necessary for working with high voltage equipment have been observed.

RADIO FREQUENCY RANGES

Channel Number	Channel Frequency Mc.	Picture Carrier Frequency Mc.	Sound Carrier Frequency Mc.	Receiver R-F Osc. Frequency Mc.
2	54-60	55.25	59.75	81
3	60-66	61.25	65.75	87
4	66-72	67.25	71.75	93
5	76-82	77.25	81.75	103
6	82-88	83.25	87.75	109
7	174-180	175.25	179.75	201
8	180-186	181.25	185.75	207
9	186-192	187.25	191.75	213
10	192-198	193.25	197.75	219
11	198-204	199.25	203.75	225
12	204-210	205.25	209.75	231
13	210-216	211.25	215.75	237

RECEIVER LOCATION—Advise the owner as to the proper location for the television receiver. The following may be used as a guide:

1. Choose an area in the home where sunlight or light from lamps do not strike the face of the picture tube and cause glare.
2. Remember the necessity of an electrical outlet and the location of the point at which the antenna leads enter the room.
3. The receiver should be placed a short distance from the wall to allow adequate ventilation.
4. The receiver should be placed to permit easy access for operation and comfortable viewing from all angles.
5. Try the set in various locations in room for best clarity.

ANTENNA—This television receiver contains a built-in antenna, which is sufficient for satisfactory reception in areas where average strength television signals are received. At the rear of the cabinet and on the left side of the chassis (as viewed from behind) are the terminals for the antenna. There are three wires with spade lugs for connection. In a given locality one connection may result in better performance than another. Try various combinations of the three wires, two at a time, and use the two which give the best picture. Be sure that the line cord is unfolded its full length. In the event that the signal strength in your locality is not sufficient to give a satisfactory picture with the self-contained antenna, it is recommended that an external antenna installation be made. This receiver has been designed to use an antenna with a 300 ohm balanced transmission line. When an external antenna installation is to be used, disconnect the wires referred to above, and connect the transmission line to the terminals instead. This line must be as short as possible because the longer the line the greater the chances are for picking up electrical disturbances. Stand off insulation should be used to keep the line away from the mast, metal or walls. Twist the line about one turn per foot throughout the line to cancel out direct signal and/or noise pickup by the transmission line. It should also be securely anchored in place so that a change in weather will not affect its position.

KINESCOPE (Picture Tube)

HANDLING PRECAUTION

Shatterproof goggles and heavy gloves must be worn by individuals while handling the kinescope or installing the kinescope into the receiver.

The kinescope encloses a high vacuum and due to the large surface area, is subjected to excessive air pressure. Therefore, care should be taken not to bump or scratch the picture tube accidentally as it may cause the tube to implode resulting in damage to property or injury to an individual.

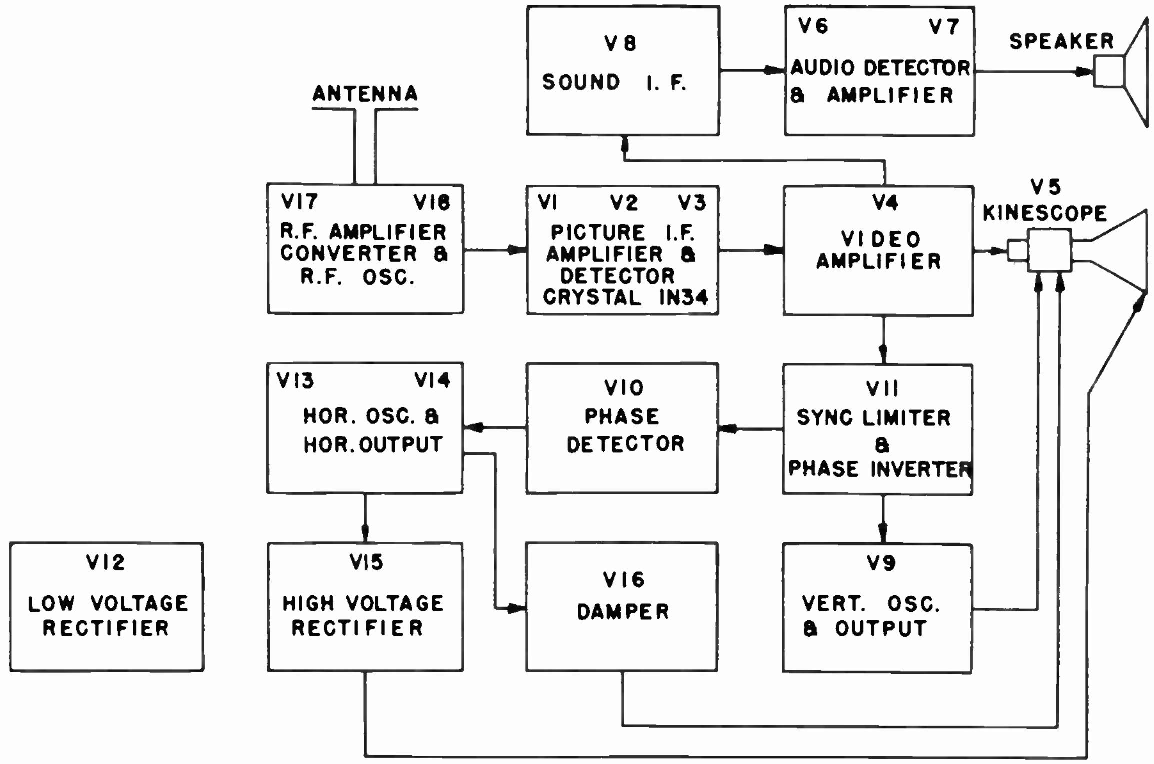

Fig. 1—Block Diagram

TUNING PROCEDURE

To turn the receiver on, rotate the ON-OFF-VOLUME control (center knob) about half a turn to the right (clockwise), and allow about thirty seconds for the tubes to warm up. After the station has been tuned in, turning this knob farther to the right increases the volume, to the left decreases the volume. Turn the left hand control, PICTURE, about half way clockwise. On the right hand there is a dual control, the CHANNEL SELECTOR and FINE TUNING, with two knobs. The bar type knob is the CHANNEL SELECTOR. Turn this knob, one step at a time, until the line on the bar is opposite the number of the channel you wish to tune in. The round knob on this same control is the FINE TUNING. Rotate this knob in either direction until the best picture is obtained. The left hand control, PICTURE, should now be turned in either direction to bring the picture to the proper brightness and contrast level.

When the receiver is first turned on and tuned to a station, the picture may not stand still, but keep moving upward. This is a result of the initial temperature changes taking place within the set and preventing the vertical hold from locking the picture in place. After a few moments for warm-up this symptom will disappear.

INSTALLATION ADJUSTMENTS—The receiver is shipped with the kinescope in place. However, some of the kinescope adjustments may have been jarred loose in shipment. Some adjustments may be necessary. The following should be used as a guide:

1. After the receiver has been unpacked, take off the cabinet back and make sure that all the tubes are properly mounted in their respective sockets.
2. Insert the line cord plug into a convenience outlet, turn on the receiver and wait about thirty seconds for the tubes to warm up.
3. Turn the channel selector to a station that is transmitting and check the picture. If the picture is not centered on the screen or not visible at all, make adjustments on the deflection yoke, focus coil and ion trap magnet assemblies as outlined on page four.

KINESCOPE REPLACEMENT—Should the kinescope have to be replaced, remove the defective kinescope in the following manner:

1. Remove the front panel control knobs by pulling them straight from their shafts.
2. Remove the four screws (bottom of cabinet) which secure the chassis, remove the cabinet back and take the chassis out of the cabinet.
3. Disconnect the kinescope socket connector at the base of the tube and the high voltage anode lead from the front of the kinescope. WARNING: REMOVE THE STATIC CHARGE FROM THE ANODE LEAD BY GROUNDING IT AGAINST THE CHASSIS.
4. Remove the ion trap magnet, slipping it from the neck of the tube past the socket.
5. Remove the rubber sleeve (under the focus coil) from the neck of the tube.
6. Loosen one of the self-tapping screws, and remove the second one, on the front stop bracket and turn the bracket down.
7. Remove the screw from the retaining strap which secures the kinescope at the front and withdraw the kinescope toward the front of the chassis.
8. To install a new kinescope, reverse the above procedure, making sure that the kinescope is fitted closely against the kinescope cushion and that the high voltage well connector is at the top of the kinescope. If the kinescope sticks or fails to slip into place smoothly, investigate and remove the source of trouble. Never force the tube.

KINESCOPE WINDOW—Clean the kinescope window with a dampened cloth or a soft lint-free cloth if dust or finger marks are present.

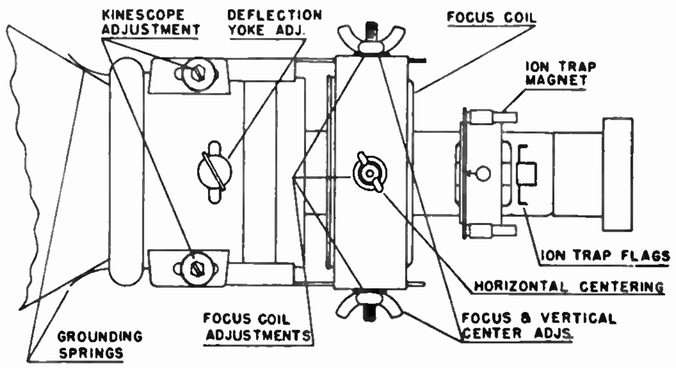

Fig. 2—Focusing Adjustments

NON-OPERATING CONTROLS
(Rear of Chassis)

Brilliance	R13
Vertical Linearity	R41
Vertical Hold	R43
Height	R45
Focus	R65
Horizontal Hold	R67
Width Control (H.V. cage)	L9
Horizontal Drive	C45
Horizontal Osc. Coil (H.V. cage)	L8
Focus Coil	Wing nut adjustment
Deflection Coils	Wing nut adjustment
Ion trap magnet	

Turn on the set and tune to a channel on which a station is operating.

1. Adjust the Horizontal Hold (R67) to the center of its rotation. With the control in this position adjust the Horizontal Oscillator coil (L8) until a picture appears. If no raster or pattern appears on the screen, leave this control in the center position and continue with the following instructions until a picture does appear then return for this adjustment.
2. Advance the Brilliance control (R13) in a clockwise direction until a raster appears. Allow this to remain in a clockwise position whether a raster appears or not.
3. Adjust the ion trap magnet for maximum brightness by moving it forward or backward along the neck of the picture tube, rotating it about the neck of the tube at the same time. The Brilliance should then be reduced to a suitable level by means of control R13.
4. Adjust the Vertical Hold control (R43) until the test pattern remains stationary. The Contrast (R9, front panel) and Brilliance (R13) should then be adjusted for normal picture contrast.
5. At this point the Focus control (R65) should be adjusted for the sharpest horizontal lines at the center of the pattern.
6. Adjust the Height control (R45) until the proper height is attained. Adjustment of this control may effect the Vertical Hold (R43), in which case, that control will have to be re-adjusted to maintain a stationary pattern.
7. The Vertical Linearity (R41) control should be adjusted to give maximum linearity in the upper portion of the raster.
8. Adjust the Horizontal Drive (C45) to give the best linearity.
9. Loosen the wing-nut on top of the yoke housing and square the pattern with the screen escutcheon by rotating the yoke. Be sure that the yoke is pushed as far forward as possible.
10. Loosen the wing-nut on top of the focus coil and center the picture horizontally by rotating the coil. Tighten the wing-nut to lock the coil in final position. Loosen the wing-nuts on the side of the focus coil mounting, and center the picture vertically by rocking the cradle that holds the coil backward and forward. Tighten the wing-nuts to lock the cradle in final position.
11. The Width control (L9) is a screw-driver adjustment located on top of the high voltage cage. The width is increased by turning this control in a clockwise direction.

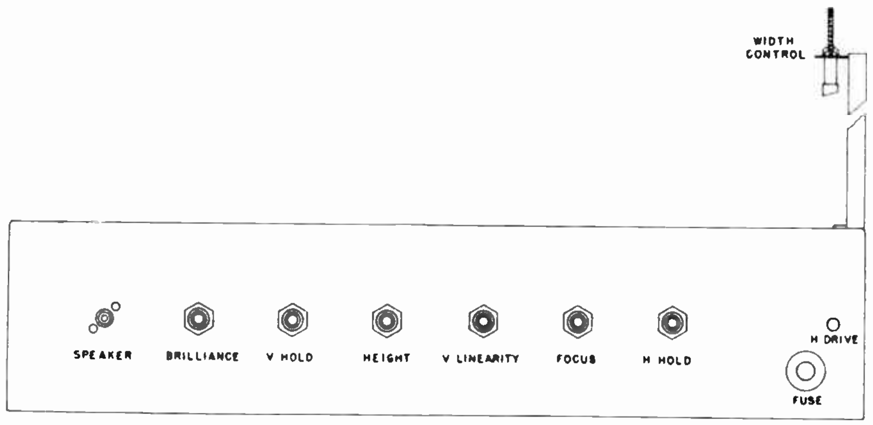

Fig. 3—Rear View of Chassis

SERVICE SUGGESTIONS

NO RASTER ON KINESCOPE—If raster cannot be obtained, check below for possible causes.

1. Ion trap magnet adjustment is incorrect.
2. Check .25 amp. fuse in plate circuit of V14.
3. No high voltage—check V14 (6BG6-G) and V15 (1B3-GT) tubes and circuits. If the horizontal deflection circuits are operating as evidenced by the correct waveform measured on terminal 4 of horizontal output transformer (T9), the trouble can be isolated to the high voltage rectifier circuit (V15). Either the high voltage winding (points 2 to 3 on T9) is open, tube V15 is defective or its filament circuit is open.
4. Damper tube (V16) (6W4) defective. Plate voltage supply for V14 (6BG6-G) horizontal output tube is obtained through the damper tube. Check tube and heater winding on power transformer (T7).
5. Defective kinescope. Heater open, cathode return circuit open.
6. No plate voltage. Electrolytic capacitor shorted. All B voltages are accessible for measurement underneath the chassis.

HORIZONTAL DEFLECTION ONLY—If only horizontal deflection is obtained as evidenced by a straight line across the face of the kinescope, it can be caused by the following:

1. Vertical oscillator and output tube V9 (6SN7-GT) inoperative. Check voltages on grid and plate.
2. Vertical output transformer (T5) open.
3. Yoke vertical coils (L6) open.
4. Vertical blocking transformer (T6) open or shorted.

POOR VERTICAL LINEARITY—If adjustment of the vertical height and linearity controls will not correct this condition, any of the following may be the cause:

1. Vertical output transformer (T5), capacitors C30, C31, C32, or resistor R38.
2. V9 (6SN7GT) defective; check voltages.
3. Low plate and bias voltages. Check rectifier tube and capacitors in B supply.

POOR HORIZONTAL LINEARITY—Check the following:

1. V14 (6BG6-G) screen voltage.
2. Horizontal drive (C45) for incorrect adjustment.
3. Horizontal output tube V14 (6BG6-G).
4. Damper tube V16 (6W4).

TRAPEZOIDAL OR NON-SYMMETRICAL RASTER — Check for:

1. Improper adjustment of focus coil or ion trap magnet.
2. Defective yoke.

WRINKLES ON LEFT SIDE OF RASTER—This condition can be caused by incorrect adjustment of the horizontal drive C45.

SMALL RASTER—This condition can be caused by:

1. Low B or line voltage.
2. Insufficient output from horizontal output tube (V14) (6BG6-G). Replace tube.
3. Insufficient output from vertical output tube V9 (6SN7GT). Replace tube.
4. Damper tube V16 (6W4) filament to cathode short.

RASTER; NO IMAGE, BUT ACCOMPANYING SOUND —This condition can be caused by:

1. No signal on kinescope cathode. Check for open coupling condenser C11.
2. Bad contact to kinescope or lead to socket broken.

SIGNAL APPEARS ON KINESCOPE CATHODE BUT IMPOSSIBLE TO SYNCHRONIZE THE PICTURE HORIZONTALLY AND VERTICALLY—A condition of this nature can be caused by:

1. Defective sync limiter V11 (12AU7) or phase detector V10 (6AL5).
2. If tubes are O.K. check voltages and associated circuits.

SIGNAL ON KINESCOPE CATHODE AND HORIZONTAL SYNC ONLY—Check:

1. Vertical integrating network capacitors C18, C19, C33, and resistors R20, R21, R22.

PICTURE STABLE BUT WITH POOR RESOLUTION— If the picture resolution is not up to standard, it may be caused by any of the following:

1. Defective picture detector (crystal 1N34) or video amplifier V4 (6AU6).
2. Open video peaking coil. Check coils L1, L2, L3 and L4 for continuity. Note that L1 and L3 have shunting resistors.
3. Leakage in V4 (6AU6) grid capacitor C10, or C11 on V5 (kinescope).

If the above components are not found to be defective, check the following:

A. Check all potentials in video circuits.

B. Check the kinescope grid for poor or dirty contacts.

C. Check adjustment of focus control R48. It should be effective on either side of proper focus.

D. Check and re-align if necessary, the picture I.F. and the local oscillator.

E. Check for proper coils in turret switch.

PICTURE SMEAR:

1. Normally, smear can be attributed to phase shift at the low frequency end of the video characteristic. This can be caused by improper values of resistors and capacitors in the video circuits.
2. This trouble can also originate at the transmitter. Check reception from another station.

PICTURE JITTER:

1. Vertical instability may be due to loose connections or noise received with the signal.
2. Horizontal instability may be due to unstable transmitted sync or to noise.

ALIGNMENT PROCEDURE

TEST EQUIPMENT—To service this receiver properly, it is recommended that the following test equipment be available:

R-F SWEEP GENERATOR meeting the following requirements:

(a) Frequency range: 4 to 5 MC; 1 MC sweep width.
(b) Output adjustable with at least .1 volt maximum.
(c) Output constant on all ranges.
(d) Flat output in all attenuator positions.

CATHODE RAY OSCILLOSCOPE preferably one with a wide band vertical deflection and an input calibrating source.

SIGNAL GENERATOR to provide the following frequencies:

(Output on these ranges should be adjustable and at least .1 volt max.)

(a) Intermediate frequencies:
4.5 MC Sound I.F.
21.25 MC Trap (L18)
22.8 MC 1st I.F. (L20)
25.3 MC 2nd I.F. (T1)
24.6 MC 3rd I.F. (T2)
23.4 MC 4th I.F. (T3)

(b) Radio frequencies:

Channel Number	Picture Carrier Freq. Mc	Sound Carrier Freq. Mc
2	55.25	59.75
3	61.25	65.75
4	67.25	71.75
5	77.25	81.75
6	83.25	87.75
7	175.25	179.75
8	181.25	185.75
9	187.25	191.75
10	193.25	197.75
11	199.25	203.75
12	205.25	209.75
13	211.25	215.75

HETERODYNE FREQUENCY METER with crystal calibrator if the signal generator is not crystal controlled.

ELECTRONIC VOLTMETER and a high voltage probe for use with this meter to permit measurements up to 10 kilovolts.

SERVICE PRECAUTIONS—To service the receiver remove the chassis from the cabinet. To do so, remove the knobs, the cabinet back and the three chassis mounting bolts (bottom of cabinet). The chassis should normally be serviced without the kinescope. However, if it is necessary to view the raster during servicing, turn the chassis on its side, with the power transformer and high voltage cage down. In this position the chassis is self-balancing, and all controls and components are readily accessible for adjustment or measurement.

CAUTION: Do not permit the kinescope second-anode lead to become shorted to the chassis.

SENSITIVITY CHECK—A comparative sensitivity check can be made by operating the receiver on a weak signal from a television station and comparing the picture and sound obtained to that obtained on other receivers under the same conditions.

This weak signal can be obtained by connecting the shop antenna to the receiver through an attenuator pad of the type shown in figure 11. The number of stages in the pad depends upon the signal strength available at the antenna. A sufficient number of stages should be inserted so that a somewhat less than normal contrast picture is obtained when the picture control is at the maximum clockwise position.

Only carbon type resistors should be used to construct the attenuator pad. Since many of the low value moulded resistors generally available are of wire wound construction, it is advisable to break and examine one of each type of resistor used in order to determine its construction.

OSCILLATOR ADJUSTMENT—The oscillator slug for each channel can be adjusted by removing the chassis from the cabinet. Use only an insulated alignment tool. When adjusting the slugs to be sure that the fine tuning control is at the mid-capacity position (tip pointing down, as illustrated in Fig. 10).

RESISTORS

Ref. No.	Part No.	Description
R-1, R-10	60-760	Resistor, carbon; 10 K ohm ½ w.
R-2, R-4, R-6, R-36	60-776	Resistor, carbon; 82 ohm ½ w.
R-3, R-5, R-20, R-21, R-46	60-778	Resistor, carbon; 8.2 K ohm ½ w.
R-7, R-54, R-59	60-759	Resistor, carbon; 4.7 K ohm ½ w.
R-8	60-782	Resistor, carbon; 1.2 megohm ½ w.
R-9	25-18	Resistor, variable; 1.5 K ohm Contrast
R-11	60-785	Resistor, carbon; 6.8 K ohm 1 w.
R-12, R-24, R-28, R-48, R-58	60-727	Resistor, carbon; 100 K ohm ½ w.
R-13, R-67	25-10	Resistor, variable; 50 K ohm Brilliance Horiz. Hold
R-14, R-34, R-37	60-790	Resistor, carbon; 680 ohm ½ w.
R-15	60-668	Resistor, carbon; 1 megohm ½ w.
R-16, R-17	60-743	Resistor, carbon; 100 ohm ½ w.
R-18, R-56	60-747	Resistor, carbon; 270 K ohm ½ w.
R-19	60-786	Resistor, carbon; 6.8 K ohm ½ w.
R-22, R-52	60-744	Resistor, carbon; 22 K ohm ½ w.
R-23, R-51	60-714	Resistor, carbon; 2.2 K ohm ½ w.
R-25	60-710	Resistor, carbon; 3.9 K ohm ½ w.
R-26	60-799	Resistor, carbon, 820 K ohm ½ w.
R-27	60-787	Resistor, carbon; 330 K ohm ½ w.
R-29	60-788	Resistor, carbon; 180 K ohm ½ w.
R-30, R-50	60-779	Resistor, carbon; 4.7 megohm ½ w.
R-31	24-189	Resistor, variable; 500 K ohm Volume
R-32	60-730	Resistor, carbon; 47 K ohm ½ W.
R-33	60-753	Resistor, carbon; 220 ohm ½ w.
R-35	60-783	Resistor, carbon; 15 K ohm ½ w.
R-38	60-775	Resistor, carbon; 68 K ohm ½ w.
R-39, R-53	60-726	Resistor, carbon; 2.2 megohm ½ w.
R-40	60-758	Resistor, carbon; 560 ohm ½ w.
R-41	25-13	Resistor, variable; 2.5 K ohm Vertical Linearity
R-42	60-780	Resistor, carbon; 1.5 megohm ½ w.
R-43	25-17	Resistar, variable; 1 megohm Vert. Hold
R-44	60-761	Resistor, carbon; 3.3 megohm ½ w.
R-45	25-15	Resistor, variable; 2 megohm Height
R-47, R-60	60-731	Resistor, carbon; 470 K ohm ½ w.
R-49	60-745	Resistor, carbon; 27 K ohm ½ w.
R-55		Resistor, 5.6 K ohm Part of L-8
R-57	60-756	Resistor, carbon; 1.2 K ohm ½ w.
R-61, R-63	60-798	Resistor, carbon; 47 ohm ½ w.
R-62	60-752	Resistor, carbon; 100 ohm ½ w.
R-64	60-720	Resistor, carbon; 12 K ohm 2 w.
R-65	25-14	Resistor, variable; 2250 ohm Focus
R-66	60-797	Resistor, carbon; 680 ohm 1 w.
R-68	60-814	Resistor, carbon; 330 ohm 2 w.

TRANSFORMERS AND COILS

MISCELLANEOUS CHASSIS PARTS

Part No.	Description
22-158	Connector, H.V.
48-45	Crystal, 1N34
43-11	Fuse, .25 amp. 250 volt
43-12	Fuse, 5 amp. 250 volt
83-651	Ion trap magnet
37-122	Insulator, ceramic, socket support
22-133	Jack, speaker
84-386	Line cord and shield assembly
28-106	Pad, cork, 1½" x 2"
28-114	Pad, sponge rubber, 10"
28-115	Pad, sponge rubber, 20"
31-126	Plate, electrolytic mounting
45-125	Plug, speaker
95-20	R.F. tuner
68-18	Socket, octal, molded
68-43	Socket, miniature, 7 pin
68-44	Socket, miniature, 9 pin
68-45	Socket, octal, wafer
68-46	Socket, kinescope
27-17	Strap, kinescope support, 11⅜"
27-18	Strap, kinescope support, 21⅛"
79-388	Speaker, 5" P.M.
83-652	Yoke, mounting hood

CABINET PARTS

Part No.	Description
32-12	Back
42-472	Cabinet
48-48	Glass, TV
98-11	Grille cloth
52-311	Knob, PICTURE and OFF-VOLUME
52-312	Knob, CHANNEL SELECTOR
52-313	Knob, FINE TUNING
31-163	Plate, mask
36-127	Wire screen mesh

INDEX

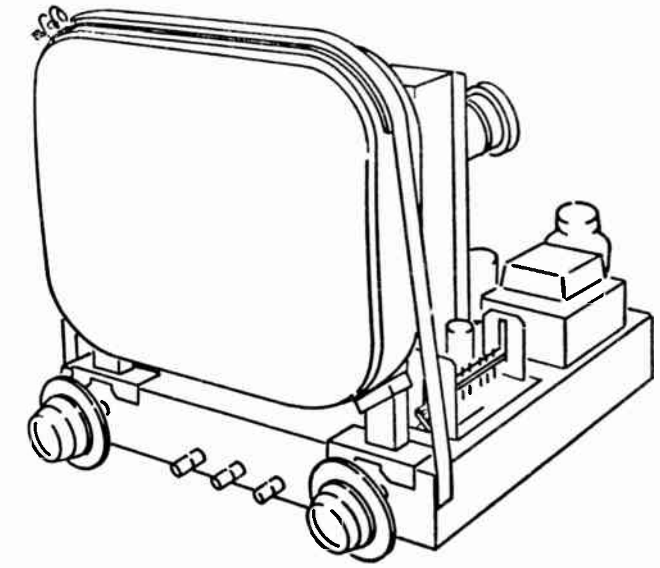
Model 05TV1-43-9014A

GENERAL DESCRIPTION

The above models are a 22 tube, AC operated, direct view, 16-inch rectangular television receivers. The sets are complete in one unit and feature complete coverage of all 12 television channels, automatic gain control, automatic horizontal frequency control, intercarrier sound system, permanent magnet focused and magnetically deflected picture tube.

On the back of the cabinet is a safety interlock to prevent dangerous electrical shock. As an added safety measure, a fuse is located in the power supply to protect the set in case of overloading.

Located on the rear of the chassis are a phono input plug and phono TV switch for connection of a phonograph.



Television Chassis

FUNCTIONS OF THE CONTROLS

All the controls normally used in tuning in a program —both picture and sound—are located on the front of the receiver and at the top of the back of the cabinet. At the rear of the set are several controls which are preset at the factory and may need slight readjustment at the time of installation. After installation, they should not be adjusted further, unless required by replacement or aging of tubes, variations in power-line voltage, or other external conditions.

The receiver actually requires only four controls when tuning in a program. On the left is a dual knob, the large knob controls picture contrast, while the small outer knob is the off-on switch and volume control. The control on the right is the station selector and the antenna tuning knob is located at the top of the back of the cabinet.

The three other controls on the front of the set; brightness, horizontal hold, and vertical hold need only be adjusted periodically. The six front controls are shown below in figure 1.

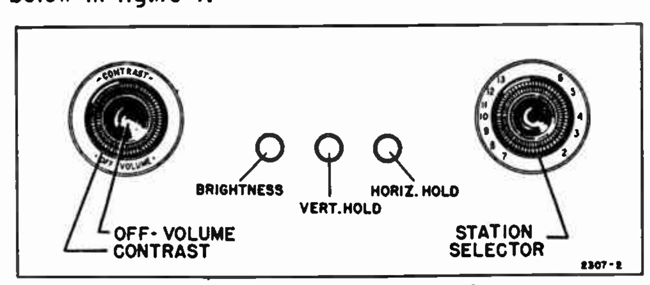


Figure 1. Front Controls

The focus and centering controls are located on the picture tube assembly (figure 2). These controls can be operated through the opening provided in the cabinet back. The remaining six controls, vertical linearity, vertical size, horizontal size, horizontal drive, horizontal linearity and coarse horizontal hold are located on the rear of the chassis (figure 3).

OPERATOR'S CONTROLS

Volume-Off — Turns set on or off and adjusts sound volume.

Contrast—Varies contrast between light and dark portions of picture.

Brightness—Controls brilliance of picture.

V. Hold—Stops picture from moving up or down.

H. Hold—Stops picture from moving left or right.

Station Selector Knob—Tunes set to desired channel (station). May be turned in either direction.

Antenna Tuning Knob—Tunes the antenna for maximum signal.

Centering—Moves entire picture both horizontally and vertically.

SERVICEMAN'S CONTROLS

V. Linearity—Provides vertical distribution of picture.

V. Size—Changes size of picture vertically. Does not affect horizontal size.

H. Size — Changes size of picture horizontally. Does not affect vertical size.

Focus—Focuses picture on face of picture tube.

H. Linearity — Provides horizontal distribution of picture.

H. Drive—Controls the drive to the Pulse Amplifier.

Coarse H. Hold — Stops picture from moving left or right.

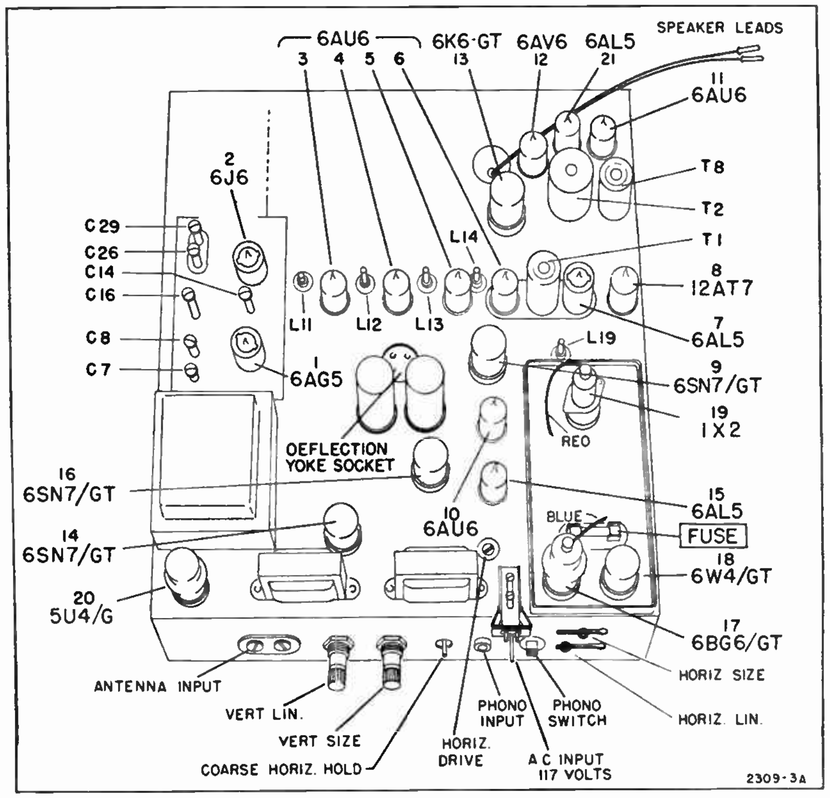

Figure 3. Tube Layout

INSTALLATION

Power Source.

The receiver should be operated from a 115 Volt, 60-Cycle A.C. power source. The power consumption is 235 watts.

Location of Receiver.

The set should be so located in the room that no direct light strikes the face of the picture tube. However, some indirect illumination in the room is desirable; it is not necessary to darken the room completely for proper viewing of the picture. Due consideration should be given also to the convenience of the electric outlet, and to the position of the receiver which gives the best reception with the built-in antenna.

Built-In Antenna.

The new Built-In Television Antenna incorporated in the receiver eliminates the need of an outside antenna in many locations. In areas too distant for normal reception with a built-in antenna, provision is made for outside antenna connections. If any other type of antenna is used with the set, disconnect the transmission line from the built-in antenna to the antenna terminals.

The antenna is mounted inside the cabinet and is operated by the use of a knob at the top of the back of the cabinet. Since the antenna is fastened to the cabinet it may be necessary to orient the cabinet to obtain the best reception. It is desirable that either the front or the back of the cabinet face the transmitting station. If however, "ghosts" or multiple images appear, the cabinet may be rotated slightly to minimize this condition. In some cases it may be necessary to face the back or the front of the cabinet toward a window to obtain a television picture. This may be due to walls, water pipes, or a steel structure in the location preventing television reception.

The antenna tuning knob should be used as a fine tuning control and should be adjusted until the best picture is obtained. In order to eliminate "Body effect" when adjusting the antenna tuning knob, stand in front and reach over the top of the set. If at any time the knob becomes difficult to turn, reverse the direction of rotation. Do not force the knob in either direction.

If the receiver fails to operate satisfactorily with the built-in antenna, check the following trouble:

1. Check the antenna dipole to make sure it is not touching the chassis or any other object.
2. Check the antenna dipole to make sure it is stapled to the side of the cabinet and does not vibrate.
3. Check the connections at the coil, transmission line, and trimmer capacitor.
4. Check to make sure that the antenna terminal screws are moderately tight.

Final Adjustments.

The television receiver has been completely assembled and adjusted for operation before shipment. It is recommended, however, that the adjustments discussed in this section be checked over at the time the set is installed.

While the required adjustments, if any, will probably be slight, the instructions may also be used for receivers which are considerably misadjusted because of replacement parts, etc.

Deflection Yoke.

If the picture seems to be tilted or the edges of the raster are not vertical, loosen the deflection coil adjusting wing nut (located at the top of the picture tube assembly, Figure 2) and using the wing nut as a handle, rotate clockwise or counter-clockwise until the edges of the raster are exactly vertical.

The correct position for the deflection yoke is as far forward on the neck of the picture tube as the shape of the tube will allow. Tube shadow may be the result of an incorrectly positioned deflection yoke.

To correctly position the yoke, loosen the wing nut and push the yoke as far forward as the tube will allow and while keeping the edges of the raster vertical tighten the wing nut.

Ion Trap Magnet.

The initial setting for the Ion trap magnet is over the "L" shape metallic flags inside the glass neck of the picture tube. See figure 2. From this starting position rotate the magnet about the neck of the tube and slide forward and backward until the position that gives maximum illumination with minimum tube shadow is found. This adjustment should be made with the brightness control set at slightly less than ½ its clockwise rotation.

If the ion trap magnet interferes with the centering control, rotate the magnet 180° and readjust for maximum illumination.

Each time an adjustment of either the centering or focus control is made, the ion trap magnet should be readjusted.

Centering.

The receiver may require centering at the time of installation. To recenter the picture follow the centering instructions on page 5.

Other Adjustments.

Refer to the "Service Adjustments" section and touch up each control following the instructions carefully.

World Radio History

SERVICE ADJUSTMENTS

Station Selector.

The station selector pointer should not rub or scrape against the channel indicator plate, and the knob should not rub against the pointer, otherwise the control may slip between channel 6 and 13. This condition can be corrected either by a fast turn or moving the pointer itself.

Brightness Control (R-46).

The brightness control located behind the front name plate need only be adjusted at the time of installation. The control is adjusted in conjunction with the contrast control. Turn the contrast control fully counter-clockwise. Then turn the brightness control clockwise until the picture tube just becomes dark. The contrast control may then be adjusted for proper picture quality.

H. and V. Hold Controls (R-94 and R-74).

For the best results the H. and V. Hold controls should be adjusted at low contrast levels. After a station has been tuned in, turn the contrast control fully counter-clockwise and then turn the brightness control clockwise until the picture reappears. Adjust the H. Hold control (if necessary) for a steady picture. Adjust the V. Hold control until the picture stops moving up or down. The controls should be set mid-way between positions where the picture is effected.

If you cannot obtain a steady picture at minimum contrast, turn the contrast control slightly clockwise.

After the H. and V. Hold controls have been properly set, they will not have to be used when tuning in a station.

Centering Control.

The centering control is located on the picture tube assembly (figure 2). This control is operated through the opening provided in the cabinet back. The control should be operated in the following manner.

1. Place a screwdriver in the centering tube.
2. Observe the face of the picture tube while making the adjustment.
3. Moving the control to the left will move the entire picture (looking at the face of the picture tube) upward.
4. Moving the control to the right will move the picture downward.
5. Moving the control up will move the picture to the left. Down will move the picture to the right.

V. Size and V. Linearity Controls (R-70 and R-80).

The V. Size and V. Linearity controls should both be adjusted at the same time while a test pattern is being transmitted. The Linearity control effects the upper portion of the picture while the Size control effects the lower portion of the picture. Adjust both the controls simultaneously until the test pattern is symmetrical and fills the entire screen vertically. Readjust the V. Hold control if necessary.

H. Size and H. Linearity Controls (L-24 and L-26).

The H. Size and H. Linearity controls should be adjusted only when a test pattern is being transmitted. The Size control should be adjusted until the test pattern fills the entire screen horizontally, and the Linearity control should be adjusted for a horizontal symmetrical test pattern. The H. Drive control must be readjusted after adjusting either the H. Size or H. Linearity controls.

Coarse and Fine Hold Controls (L-23 and R-94).

The coarse horizontal hold control should be adjusted in the following manner.

Set the Fine H. Hold control to the center of its range.

Set the contrast control to the normal operating position. Adjust the Coarse H. Hold control until there is a steady picture (no horizontal movement).

When the Coarse H. Hold control is adjusted properly, a fast turn of the Fine H. Hold control in either direction (clockwise or counter-clockwise) will make the picture go out of sync (only in low signal areas). Turning the Fine H. Hold control slowly in either direction should not make the picture go out of sync. If the Coarse H. Hold control is not adjusted properly, the horizontal sync will not come in immediately (or not at all) when the tuner is switched from one station to another.

Focus Control.

The permanent magnet focus assembly is essentially a magnet within an assembly so designed as to provide a flexible means of adjusting focus and centering on the face of the picture tube. Do not use a steel screwdriver or any magnetic material when adjusting the focus control. A non-magnetic material should be used, as a magnetic material will increase the flux density of the assembly and a correct adjustment cannot be obtained. This control is located on the picture tube assembly and can be operated through the hole provided in the cabinet back. A long adjusting tool is necessary for the adjustment.

There are two focus screws on the focus magnet assembly. The focus screw on the side is preset at the factory and should be all the way in. Only the top screw should be used for the focus adjustment.

Adjust the focus screw for the best focus. Reset the ion trap magnet and again re-focus the picture. If the focus is best at the edge turn the slug in, if best at center turn the slug out. Turn in or out until the best average focus is obtained and then reset the ion trap magnet.

H. Drive Control.

The H. Drive control is located next to the A.C. input at the rear of the chassis (figure 3). The control requires a small screwdriver for adjustment. The control should be adjusted in the following manner.

1. Tune in a station.
2. Turn the drive control counter-clockwise until a fold-over (white vertical line) appears at the left side of the picture.
3. Turn the drive control clockwise until the fold-over just disappears.
4. Turn the drive control one-half turn clockwise.

SERVICE DATA

SPECIFICATIONS

Sensitivity at the Antenna
Video — 100 microvolts
Audio — 100 microvolts

Power Supply Rating
115 volts, 50-60 cycles, AC, 235 watts.

Audio Output Rating
Undistorted — 3 watts.
Maximum — 4½ watts.

Speaker
Permanent magnet type,
3.2 ohm voice coil impedance.

Antenna Impedance Requirements
Balanced 300-ohm.

Dimensions
Chassis — 16" x 16¼" x 2¾".

R. M. A. WIRE COLOR CODE

Listed below is a R. M. A. wire color code chart to aid in circuit tracing.

Wire Color	Where used
Black	B- or Ground leads
Brown	Filament leads
Red	B+ leads
Orange	Screen leads
Yellow	Cathode leads
Green	Grid or Control leads
Blue	Plate leads
Violet	Not used
Gray	A.C. leads
White	Bias leads

WARNING.

High voltage on all pins of the 1X2 high voltage rectifier and the plate cap of the 6BG6. DO NOT MEASURE this voltage unless a high range voltmeter is used.

Replacing ¼ amp. Fuse.

To check or replace the fuse, first turn off the set. Remove the High Voltage shield cover, short the 6BG6 plate cap to chassis, and remove the 6W4 tube and then take out the fuse. Replace fuse and reverse procedure.

Schematic Diagram.

The schematic diagram located at the rear of the manual shows all the values of resistance and capacitance and gives all the proper voltages at the pins of the tube sockets. The voltage readings were taken with a 20,000 ohm/volt voltmeter with normal operation, no signal input, and line voltage at 117 V. A. C.

Replacing Tubes

Before replacing any tubes the cabinet back must first be removed. Removing the cabinet back disengages the safety interlock and removes the power to the receiver. Do not tamper with or attempt to defeat the purpose of the safety interlock.

Before replacing the High Voltage tubes first be sure the power is turned off and then short the plate caps of the 6BG6 and 1X2 tubes to the chassis.

WARNING: Do not remove any tubes while the receiver is in operation as overloading and component failures may result.

If the receiver has been in operation for some time, the tubes become hot and gloves should be used when replacing tubes to prevent finger burns.

Phono T V Switch.

The phono T V switch is located on the rear flange of the chassis and should be in the "off" position (up) for T V operation. In the "on" position there will be **no** sound or raster, and the audio input plug can be utilized.

World Radio History

GENERAL DESCRIPTION

Tuner.

The tuner is composed of a separate sub-chassis using a 6AG5 (pentode) R.F. Amplifier and a 6J6 tube (twin triode) for the Oscillator and Converter. Separate high and low band coils and trimmers are used with a switching device to change bands. The tuner selects and amplifies the station signal and converts it to the carrier IF frequencies of 26.75 Mc for video and 22.25 Mc for sound which in turn is then fed to the IF amplifiers for further amplification.

Video IF Amplifiers.

The IF Amplifiers, video detector and DC restorer stages are all mounted on a sub-chassis. The IF amplifier section consists of four (4) stagger-tuned stages using 6AU6 (pentode) tubes with self-resonant slug tuned coils. Since the receiver is of the intercarrier type, both the video and sound IF frequencies are amplified simultaneously. The signal is then detected by one half of the 6AL5 (twin diode) and coupled to the video amplifier. The other half of the 6AL5 is used as the DC Restorer.

Sound Section.

The sound section is also mounted on a sub-chassis and consists of a 6AU6 (pentode) IF amplifier, 6AL5 (twin diode) detector, 6AV6 (triode) amplifier and a 6K6 (pentode) output tube. Due to the hetrodyne action between the video and sound IF frequencies a 4.5 mc signal is obtained containing the audio information. After the video detector, the audio information is separated from the video signal by the pick-off coil T8. The signal is then amplified, detected and further amplified by the 6AV6 and the 6K6.

Video Amplifier.

The video section is a conventional two stage amplifier using the 12AT7 (twin triode) tube. The parallel resonant video trap coil (L-19 and C-65) is tuned to 4.5 MC to separate the audio from the video. A combination of shunt and series peaking coils are used with a degenerative contrast control to vary the signal to the grid of the cathode-ray tube.

DC Restorer.

One half of the 6AL5 tube is used as the DC restorer. Since the video is coupled to the grid of the CRT by capacitor C-64 the DC component of video signal will not be passed, therefore the background level of the picture will vary. A bias voltage proportional to the average video signal level will be developed across resistor R-31 and maintain the proper brightness level.

Sync Separator and V. Sync Amplifier.

The sync pulses from the plate of the first video amplifier are coupled to the sync separator tube (½ of 6SN7) thru capacitor C-103. The sync pulses are then separated from the blanking pedestal and due to the low plate voltage sync clipping is accomplished. The horizontal pulses are coupled to the AFC Discriminator thru capacitor C-91 and the vertical pulses are coupled thru capacitor C-121 and amplified by the other half of the 6SN7 before being fed to the intergrating network of the vertical deflection circuit.

Vertical Deflection.

The vertical deflection circuit consists of a 6SN7 (twin triode) tube one half used as a blocking oscillator and the other half as a pulse amplifier. The V. Hold control varies the oscillators operation point thus providing an adustment for synchronization. The V. Size control varies the amplitude of the pulse to the grid of the amplifier and controls the amount of vertical deflection. Thus V. linearity control varies the cathode resistance thus changing the operating characteristics of the amplifier tube to obtain a linear sawtooth pulse. Therefore, it can be seen that the V. Size and V. Linearity controls must be operated in conjunction with one another.

AFC Discriminator.

The automatic frequency control section utilizes a 6AL5 (twin diode) tube. The sync separator feeds the horizontal sync pulses to the AFC tube while at the same time two voltages of opposite polarity are fed back from the horizontal deflection transformer. Any phase shift between the horizontal sync pulses and the horizontal multivibrator signal will cause the input voltage applied to one diode section to differ from that of the other. This results in a DC bias voltage applied to the grid of the multivibrator. The output of the AFC discriminator thus synchronizes the horizontal multivibrator to the horizontal pulse of the video signal. This arrangement improves horizontal stability and offers ease of operation.

Horizontal Multivibrator.

The horizontal multivibrator circuit (6SN7 tube) is of the conventional cathode coupled type using a parallel resonant circuit (L-23 and C-107) as a coarse hold adjustment to control the frequency of oscillation. The fine hold adjustment R-94 varies the grid resistance thus slightly controlling frequency of oscillation. The horizontal sawtooth pulse is then fed to the grid of the pulse amplifier.

Pulse Amplifier.

The horizontal drive control, C-109 in the grid circuit controls the amount of voltage applied to the pulse amplifier. (Increasing the capacity decreases the drive.) The 6BG6 is a beam tetrode used to develop the necessary power for the flyback pulse and the horizontal deflection coil. The Horizontal size coil, L-24 shunts a portion of the horizontal deflection transformer winding. Varying the inductance of the H. size coil varies the high voltage which in turn controls the size of the picture.

Damper.

The damper tubes (6W4) main function is to damp out oscillations which occur over part of the horizontal scanning cycle. The damper tube is connected in such a way as to give an crease in plate supply voltage for the vertical output amplifier. This additional voltage is developed across capacitor C-115 and gives an additional 90 volts increase in plate supply voltage. Varying the inductance of the H. Linearity coil, L-26 changes the damper tubes operating point and thus controls the linearity of the horizontal sweep.

High Voltage Supply.

The high voltage is obtained from the auto-transformer type primary winding of the horizontal output transformer. When the plate current of the pulse amplifier tube is cut off, the field built up in the primary winding collapses and induces a high voltage surge which is rectified by the 1X2 tube, filtered by the aqua-dag coating of the Cathode-ray tube and applied to the second anode.

Automatic Gain Control.

Plate voltage for the 6AU6 (pentode) gated AGC tube is obtained from a separate winding on the horizontal deflection transformer. The plate voltage is thus applied at a horizontal rate while the grid signal is obtained from the output of the first video amplifier. The AGC voltage is developed across resistor R-50 and fed to the first three IF amplifiers. Due to the divider network of R-44 and R51 only a portion of this voltage is fed to the RF amplifier. The AGC voltage will vary considerably according to the strength of the transmitted signal but should be in the vicinity of the voltage across R-37 (detector output).

SERVICE HINTS

Tuner.

If the receiver is "dead" and the picture tube shows nothing but a raster (no snow) first check the I.F. and video amplifier stages before looking into the tuner. If the set is dead and snow appears on the face of the picture tube, first determine whether a signal is being transmitted and then check the antenna or lead-in connections before suspecting the tuner for trouble.

The tuner can easily be serviced by removing the three (3) hex-head screws holding the bottom cover in place. Removing the bottom cover makes all the tuner components within easy reach and all parts can be serviced. When working inside the tuner do not move any component a great distance as a change in the distributed capacity will result and offset the alignment. When replacing components be sure to obtain the same lead lengths and replace the components in the same position.

A majority of tuner troubles are often open and high resistance ground or coil solder connections, defective trimmers or coils and defective contacts.

Open or high resistance connections can easily be repaired by placing a hot soldering iron at the solder connection.

Defective contacts may cause an intermittent condition or the loss of one or both bands. Contact replacement is easily accomplished by following the simple procedure on page 14, figure C.

The tuner should never be removed from the chassis unless contact replacement is necessary.

CAUTION:—If the 6AG5 (RF Amp.) is placed in the 6J6 (osc.-con.) socket resistors R-9 and R-10 will burn up.

Speaker Leads.

To insure minimum video interference, dress the speaker leads away from the 6AL5 (detector tube 7) as shown in figure 3, on page 3.

A.G.C.

A defective AGC system will not effect the sound but over-load the video amplifier circuit and the result will be a loss of both horizontal and vertical sync and very weak video. This condition can easily be noticed and checked by measuring the AGC voltage and the voltage across resistor R-37. Under normal operating conditions these two voltages will be approximately the same. A defective AGC system will cause a large increase in voltage across R-37 and a decrease in AGC voltage.

To determine the cause for trouble check the 6AU6 tube, capacitors C-70 and C-59 and resistors R-44, R-50, R-51 and R-107. To check the AGC winding of the horizontal deflection transformer, place a scope on pin 5 of AGC tube and a horizontal pulse similar to wave shape number 20, on page 13, should be obtained with a peak-to-peak voltage of 400 volts.

CORRESPONDING CATHODE-RAY TUBES

Due to the fact that 16RP4 and 16TP4 Cathode-Ray tubes from various suppliers are not directly interchangeable, different focus or ion trap magnets must be used. A B.R.C. part number sticker will be pasted on the tubes coating in 16AY210 chassis. When replacement is necessary be sure to state the B.R.C. part number of the picture tube. This is necessary as a supplier may manufacture two of the same RMA tube types which will differ in construction.

Listed below is a chart showing the various 16-inch rectangular tubes used in the 16AY210 chassis.

SUPPLIER	BRC NUMBER	FOCUS MAGNET	ION TRAP MAGNET

TROUBLE-SHOOTING

Trouble	Probable Location
No Raster No Sound	1. Phono TV switch defective or in "ON" position. 2. Defective 5U4 tube (20). 3. Defective power transformer (T-7). 4. Defective filter choke (L-25 or L-28). 5. Defective filter condenser (C-61 or C-94) 6. Defective fuse.
No Raster Sound Normal	1. High voltage lead disconnected. 2. Ion trap magnet incorrectly positioned. 3. Yoke plug not in place or loose. 4. Insufficient or no high voltage, (refer to "No high voltage section"). 5. Defective resistors R46-47-48-100 and capacitor C-67. 6. Defective picture tube.
No Picture No Sound Raster Normal	1. Defective antenna or lead-in. 2. Defective tubes 1 through 7, or associated circuits. 3. Improper voltages or resistances at sockets of tubes 1 through 7. 4. Improper alignment.
No Sound Picture Normal	1 Defective tubes 11, 12, 13, and 21 or associated circuits. 2. Improper voltages or resistances at sockets of tubes 11, 12, 13 and 21. 3. Speaker leads broken or not in place. 4. Improper alignment of transformer T2, T8 (see page 14).
No Picture Raster Normal Sound Normal	1. Defective tubes 7, 8, 10. 2. Improper voltages or resistances at sockets of tubes 7, 8, 10. 3. Defective capacitors C-64-70, and L-20-21-30.
No Sync	1. Defective tubes 8, 9, 10. 2. Defective capacitors C-103, 121 and resistors R-45, 114.
No Vertical Sync Picture otherwise normal	1. Defective capacitors C-71, C-90, C-95. 2. Defective tube 9. 3. Defective resistors R-73, R-77, R-88.
No Horiz. Sync Picture otherwise normal	1. Defective tubes 15, 16. 2. Defective resistors R-81-82-83-84-85-86-87, and capacitors C-91-98-99-100-101-102-105-125. 3. Defective Horizontal transformer T-6.
No Vertical Sweep	1. Defective tube 14. 2. Defective transformers T-9, T-4, T-5A. 3. Defective capacitors C-92, 95, 116 and resistors R-75, 78.
Picture cannot be Centered	1. Defective ion trap magnet. 2. Defective focus magnet. 3. Defective picture tube. 4. Defective capacitor C-114.
Picture cannot be Focused	1. Focus magnet not properly located or centered on the picture tube neck. 2. Ion trap magnet not properly adjusted or defective. 3. Defective picture tube. 4. Improper high voltage.
No High Voltage	1. Defective tubes 16, 17, 18, 19. 2. Defective transformer T-6, yoke T-5B. 3. Defective capacitors C-108, 112, 113, 114 or resistors R-90 through R-98 and R-112-118-119-120.
Bunching or folding at side of Picture	1. Improper adjustment of horizontal drive control C-109. 2. Defective tubes 17, 18. 3. Defective C-115 or H. Linearity coil.
Audio in Picture	1. Improper alignment and ratio of video carrier to sound response (see page 14).
Snow or poor Signal	1. Improper adjustment of antenna tuning knob (see page 6). 2. Cabinet (built-in antenna) not properly oriented. 3. Check alignment of C-1 and C-2 (see page 15). 4. Insufficient signal input. 5. Defective capacitors C-59, C-62 or peaking coil L-21.

WAVE FORM ANALYSIS

The drawings in this section illustrate the wave shapes at various positions within the set. These wave shapes are not theoretical but exact copies of the oscilloscope wave shapes taken with a transmitted signal.

The peak-to-peak voltage indicated was measured by a calibrated oscilloscope under typical operating conditions.

When analyzing a particular wave shape, the peak-to-peak voltage may vary somewhat depending upon the setting of the contrast control and the strength of the signal. The wave shapes may vary somewhat in video section depending on the picture being transmitted.

When checking these wave shapes connect the ground lead from the oscilloscope to the chassis and the hot lead to the position shown in the chart.

The chart below lists the test point, peak-to-peak voltage and the corresponding wave shape number. Under each drawing is the type of wave shape referring either to a Horizontal (15,750 cycles) or Vertical pulse (60 cycles).

Test Point	Taken At	Peak-to-peak Voltage	Wave Form Number
1	Pin 7 of Tube 7	8	1 and 2
2	Pin 7 of Tube 8	8	1 and 2
3	Pin 6 of Tube 8	42	3 and 4
4	Pin 2 of Tube 8	12	3 and 5
5	Pin 1 of Tube 8	32	1 and 2
6	Pin 4 of Tube 9	26	3 and 5
7	Pin 5 of Tube 9	11	6
8	Pin 1 of Tube 9	11	6
9	Pin 2 of Tube 9	40	7
10	Pin 5 of Tube 10	410	20

TUNER ALIGNMENT

1. Preset trimmer screws C7, 8, 14, 16, 26, 29 to dimensions shown on page 14, figure E.
2. Preset coil cores L4, 5, 6, 7, 8, 9 in the following manner.
   (a) In low band position, turn tuner shaft to top of stroke as on page 14, figure B.
   (b) The switch will be in low band position.
   (c) Adjust coil cores 1.6" from core to coil mounting strip. (Use core aligning tool if available).
   (d) Turn L-9 core (low band oscillator) an additional four (4) turns out of coil.

LOW BAND TRACKING

Turn tuner to channel 6. See page 12, figure B.

Step No.	Signal Generator Freq. (mc.)	Sweep Generator Freq. (mc.)	Signal Input Point	Output Point	Adjust	Remarks	Response
1	——	Channel 6	Antenna Terminals	Scope across R-37	C-2	Adjust for maximum response with symmetrical peaks	2	——	Channel 6	Antenna Terminals	Scope across R-37	C-8 C-16	Adjust for maximum response with symmetrical peaks	3	83.25	Channel 6	Antenna Terminals	Scope across R-37	C-29	Adjust until marker is 50% down on low frequency slope. Repeat step 2 if necessary.	4	(a) 61.25 (b) 67.25 (c) 77.25 (d) 55.25	(a) Channel 3 (b) Channel 4 (c) Channel 5 (d) Channel 2	Antenna Terminals	Scope across R-37	C-8 C-16	Adjust tuner until response curve appears on scope. Adjust trimmers for compromise which will give the best overall response across band.	
NOTE: If trimmer C-8 reaches maximum and additional capacity is needed, turn L-5 core, into coil.

HIGH BAND TRACKING

Turn tuner to channel 13. See page 12, figure B.

1	——	Channel 13	Antenna Terminals	Scope across R-37	C-1	Adjust for maximum response with symmetrical peaks	
2	——	Channel 13	Antenna Terminals	Scope across R-37	C-7 C-14	Adjust for maximum response with symmetrical peaks	3	211.25	Channel 13	Antenna Terminals	Scope across R-37	C-26	Adjust until marker is 50% down on low frequency slope. Repeat step 2 if necessary.	4	(a) 205.25 (b) 199.25 (c) 193.25 (d) 187.25 (e) 181.25 (f) 175.25	(a) Channel 12 (b) Channel 11 (c) Channel 10 (d) Channel 9 (e) Channel 8 (f) Channel 7	Antenna Terminals	Scope across R-37	C-7 C-14	Adjust tuner until response curve appear on scope. Adjust trimmers for compromise which will give the best overall response across band.	
VIDEO I F ALIGNMENT

Turn to any high band channel. Connect the generator thru a 1000 mmf capacitor and set the contrast control to maximum.

Step No.	Signal Generator Freq. (mc.)	Sweep Generator Freq. (mc.)	Signal Input Point	Output Point	Adjust	Remarks	Response
1	26.4	——	Converter Grid	VTVM across R-37	L-11 L-13	Adjust generator output approx. 1 volt	Maximum Reading
2	23.4	——	Converter Grid	VTVM across R-37	L-12 L-14	Adjust generator output approx. 1 volt	Maximum Reading
3	25.0	——	Converter Grid	VTVM across R-37	T-1	Adjust generator output approx. 1 volt	Maximum Reading
4	25.0	——	Converter Grid	VTVM across R-37	——	SENSITIVITY Generator output should be less than 100 microvolts. (If not, repeat alignment).	1 volt VTVM Reading
5	26.75 23.0	25.0	Converter Grid	Scope across R-37	——	SELECTIVITY Markers should be as shown in response column. (If not, repeat alignment).	6	——	Channels 2-4-6-8-10-12	Antenna Terminal	Scope across R-37	T-1 for flat response	Check channels for band width (3.5 to 4 mc. at 6db points).	
Picture I.F. frequency 26.75 mc — Sound I.F. frequency 22.25 mc.

SOUND I-F ALIGNMENT

Short antenna to ground and connect generator thru a 1000 mmf capacitor.

1	4.5	——	Pin 1 of Tube 11	VTVM junction of R-53 and C-77	T-8 and T-2 primary (bottom of can)	——	Maximum Reading
2	——	4.5	Pin 1 of Tube 11	Scope junction of R-58 and C-77	T-2 secondary (top of can)	Sweep approx. 100 kc. Adjust for max linearity	3	——	4.5	Pin 1 of Tube 11	Scope junction of R-58 and C-77	T-2 primary (bottom of can)	Sweep approx. 100 kc. Adjust for symmetry of peaks	4	4.5	——	Pin 1 of Tube 11	VTVM junction of R-58 and C-77	——	Generator output should be less than .01 volt	.05 watt output

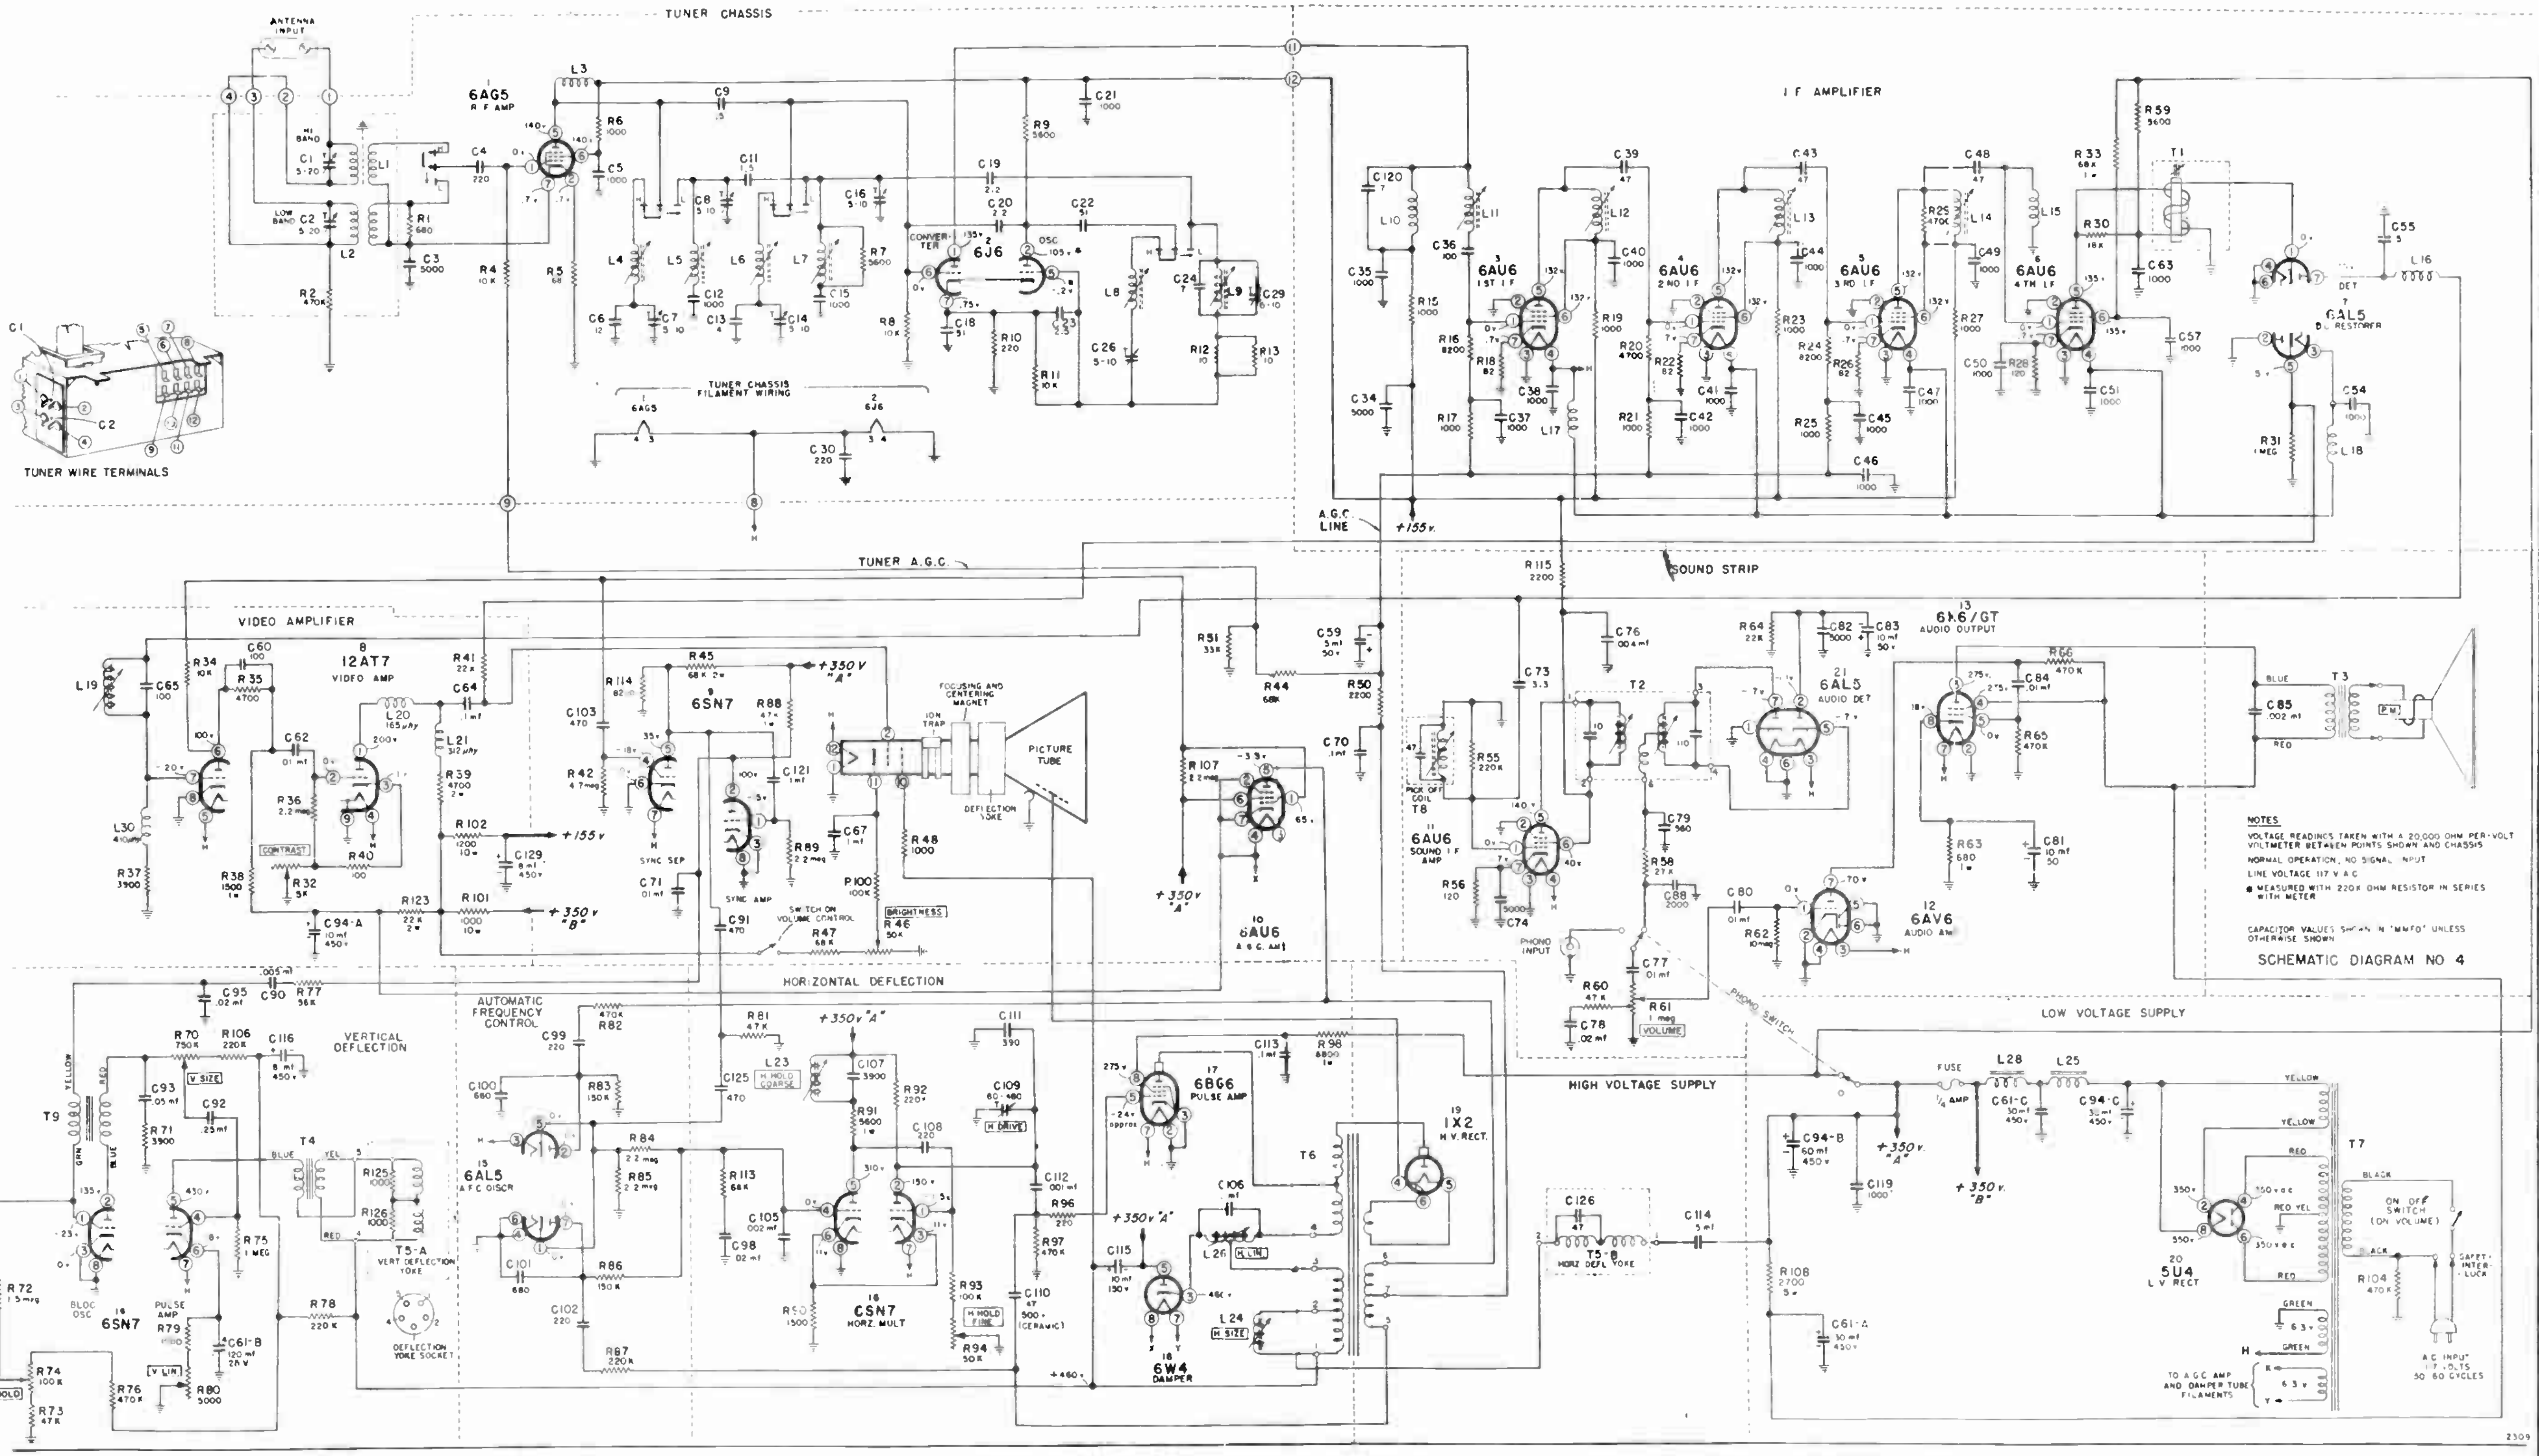
Video trap Coil (L-19) Adjustment.

(a) Tune in a station.
(b) Adjust the tuner until sound bars just appear.
(c) Turn L-19 slug all the way out (counter-clockwise).
(d) Turn the slug in (clockwise) until the horizontal scanning lines are smooth and continuous.

©John F. Rider

World Radio History



NOTE: Resistor R98 should be 4700 ohms, 1 watt.

13	210-216	211.25	215.75	237.45

RECEIVER LOCATION—Advise the owner as to the proper location for the television receiver. The following may be used as a guide:

1. Choose an area in the home where sunlight or light from lamps does not strike the face of the picture tube and cause glare.
2. Remember the necessity of an electrical outlet and the location of the point at which the antenna leads enter the room.
3. The receiver should be placed a short distance from the wall to allow adequate ventilation.
4. The receiver should be placed to permit easy access for operation and comfortable viewing from all angles.

ANTENNA—This receiver has been designed to use an antenna with a 300 ohm balanced transmission line. This line must be as short as possible because the longer the line the greater the chances are for picking up electrical disturbances. Stand-off insulation should be used to keep the line away from the mast, metal or walls. Twist this line about one turn per foot throughout the line to cancel out direct signal and/or noise pickup by the transmission line. It should also be securely anchored in place so that a change in weather will not affect its position.

HIGH VOLTAGE WARNING

This television receiver contains high voltages which are dangerous to life. Never operate or service the receiver outside of the cabinet or with the covers removed until all the safety precautions necessary for working with high voltage equipment have been observed.

PICTURE TUBE HANDLING PRECAUTION

Shatterproof goggles and heavy gloves must be worn by individuals while handling the picture tube or installing the picture tube into the receiver.

The picture tube encloses a high vacuum and due to the large surface area, is subjected to excessive air pressure. Therefore, care should be taken not to bump or scratch the picture tube accidentally as it may cause the tube to implode resulting in damage to property or injury to an individual.

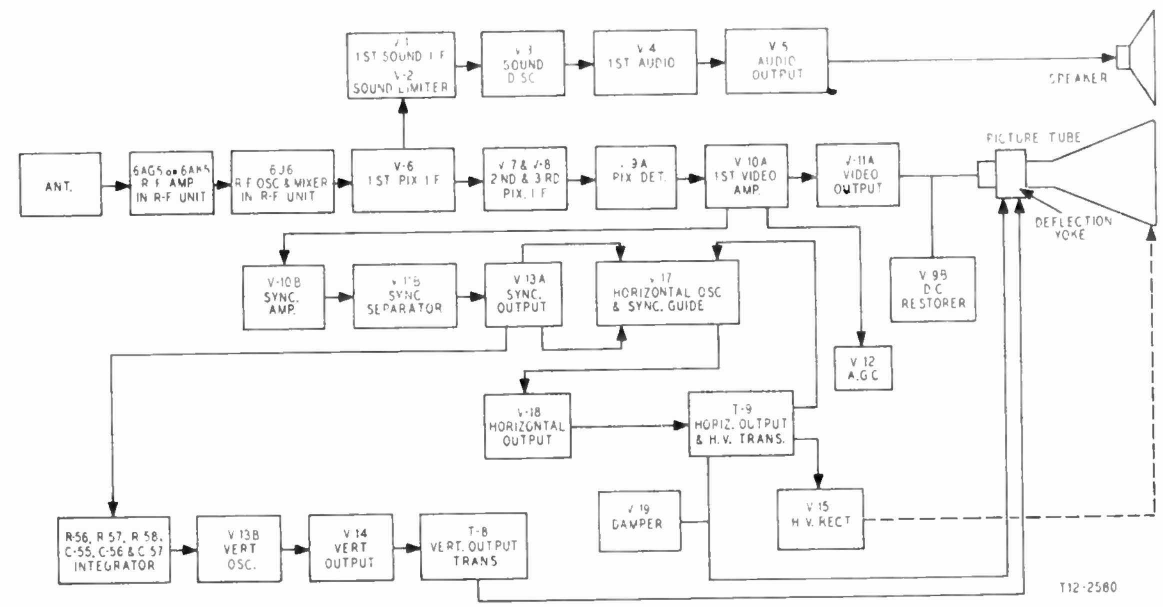

Fig. 4—Block Diagram (12½" Pix Tube Receivers)

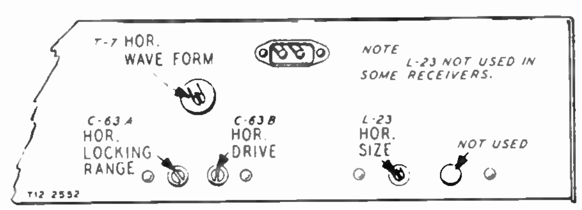

Fig. 5—Rear Chassis Adjustments (12½" Pix Tube Receivers)

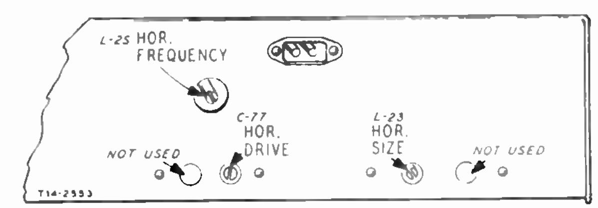

Fig. 6—Rear Chassis Adjustments (16" Pix Tube Receivers)

TUNING PROCEDURE

1. To turn the television receiver on, turn the OFF-ON SOUND CONTROL clockwise until a click is heard. Allow approximately 30 seconds for the tubes to warm up.
2. Turn the STATION SELECTOR CONTROL to the desired channel. This control may be turned in either direction.
3. Turn the CONTRAST CONTROL clockwise until activity or definite form is noted on the screen.
4. Adjust the FINE TUNING CONTROL for best tonal quality and the SOUND CONTROL for desired volume.
5. After the receiver has been on for a while it may be necessary to readjust the FINE TUNING CONTROL for best sound quality.
6. To turn off the receiver, turn only the OFF-ON SOUND CONTROL counterclockwise until a click is heard.

OCCASIONAL ADJUSTMENTS TO IMPROVE PICTURE RECEPTION

There are six controls at the front of the chassis. These controls are accessible after the removal of the control panel cover at the front of the cabinet. (See illustration) The controls are pre-set at the factory and may occasionally need adjustment due to aging of the components in the receiver and the fluctuating line voltages in different areas.

If any adjustments are necessary, follow the instructions under "Controls and Functions."

IMPORTANT—Be sure that the fine tuning control has been set for best tonal quality and clearest picture before adjusting any controls.

CONTROLS AND FUNCTIONS

HORIZONTAL HOLD—Stops horizontal movement (diagonal bars.)
BRIGHTNESS—Adjusts for desired picture brilliance.
VERTICAL LINEARITY—Adjusts picture symmetry, top to bottom.
HEIGHT—Adjusts picture to fit mask vertically.
VERTICAL HOLD—Stops upward or downward picture movement.
FOCUS—Adjusts picture sharpness and clarity.

©John F. Rider

World Radio History

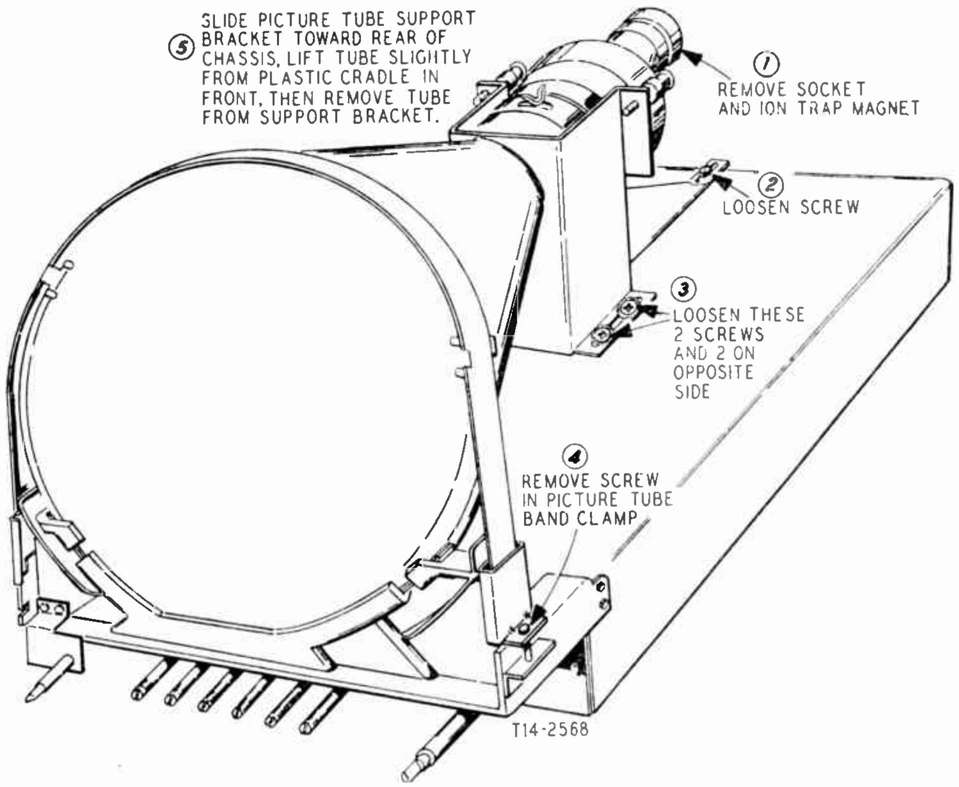

Fig. 7—Removal of Picture Tube

PICTURE TUBE — All receivers are shipped with the picture tube in place. However, to prevent picture tube breakage in 16" pix tube receivers the three focus coil mounting screws were drawn up tight. To place the receiver in operation the following must be performed:

1. Remove the interlocked cabinet back. Make sure that all the tubes are firmly seated in their respective sockets and note the location of the focus coil mounting screws. Back out the focus coil mounting screws until there is approximately a 3/8 inch space between the focus coil and the deflection yoke. Replace the cabinet back.

2. Connect the receiver to a power outlet and turn the receiver on. Turn the channel selector knob to a channel that you know is operating.

3. Observe the picture and adjust the three focus coil mounting screws (through the openings in the cabinet back with a screwdriver which has a seven inch blade) until proper horizontal and vertical centering is obtained.

WARNING — If a screwdriver with a blade longer than seven inches is used, it may accidentally touch a portion of the receiver that carries a high potential.

4. If adjustments are necessary on the deflection yoke or the ion trap magnet, follow the procedures on page 20.

PICTURE TUBE REPLACEMENT — To replace the picture tube it is necessary to remove the chassis from the cabinet. This may be accomplished in the following manner:

1. Remove the front panel control knobs by pulling them straight from their shafts.

2. Remove the cabinet back. You will note that the interlocked line cord disconnects the power when the cabinet back is removed.

3. Disconnect the leads to the speaker, remove the antenna terminal board at rear of cabinet, remove the five chassis mounting bolts and pull the chassis CAREFULLY out of the cabinet.

WARNING — Before handling the picture tube, it will be necessary to remove the static charge. In receiv rs with glass picture tubes, ground the anode lead to chassis, and insert an insulated wire from the well in the tube to chassis. In receivers with metal picture tubes, remove the static charge by grounding an insulated wire from the chassis to the metal portion of the tube.

4. Remove the picture tube as shown and outlined in the illustration. To install a new picture tube, reverse the procedure making sure that the picture tube is fitted closely against the picture tube cushion. If the picture tube sticks or fails to slip into place smoothly, investigate and remove the source of the trouble. Never force the tube. It is important that all the clips and shims used in mounting the tube be replaced, otherwise difficulty may be encountered when horizontal or vertical centering is required.

ION TRAP MAGNET ADJUSTMENT — The ion trap magnet should be positioned exactly as shown in Figure 8. Adjust the magnet by moving it back and forth and at the same time rotating it slightly around the neck of the picture tube until the brightest raster is obtained on the picture screen. Reduce the brightness control setting until the raster is slightly above average brilliance. Adjust the Focus Control R-81 (see Figure 2) until the line structure of the raster is clearly visible. Readjust the ion trap magnet for maximum raster brilliance.

DEFLECTION YOKE ADJUSTMENT — If the lines of the raster are not horizontal or squared with the picture mask, rotate the deflection yoke until this condition is obtained. Tighten the yoke adjustment wing screw.

FOCUS COIL ADJUSTMENT — If horizontal or vertical centering is required, adjust the three focus coil mounting screws until proper centering is obtained. See Fig. 8.

PICTURE ADJUSTMENT — For further adjustments, obtain a test pattern on the receiver. Turn on receiver and follow tuning procedure on page18. When a test pattern is obtained it may be necessary to slightly re-adjust the focus control for maximum picture detail.

12½" PIX RECEIVER ADJUSTMENTS

CHECK OF HORIZONTAL OSCILLATOR ALIGNMENT — Turn the horizontal hold control to the extreme counter-clockwise position. The picture should remain in horizontal sync. Momentarily remove the signal by switching off channel and then back. Normally the picture will be out of sync. Turn the control clockwise slowly. The number of diagonal bars will be gradually reduced and when only 3-1/2 to 4-1/2 bars sloping downward to the left are obtained, the picture will pull into sync upon slight additional clockwise rotation of the control. The pull-in should occur when the control is approximately 90 degrees from the extreme counter-clockwise position. The picture should remain in sync for approximately 90 degrees of additional clockwise rotation of the control.

At the extreme clockwise position the picture should be just starting to pull out of sync. Usually one vertical bar will be seen.

If the receiver passes the above checks and the picture is normal and stable, the horizontal oscillator is properly aligned.

ALIGNMENT OF HORIZONTAL OSCILLATOR — If in the above check the receiver failed to hold sync with the hold control at the extreme counter-clockwise position or failed to hold sync for at least 60 degrees of clockwise rotation of the control from the pull in point, it will be necessary to make the following adjustments.

World Radio History

HORIZONTAL FREQUENCY ADJUSTMENT — Turn the horizontal hold control to the extreme clockwise position. Tune in a station and adjust the horizontal frequency control (T-7-See Fig. 17) until the picture is just out of sync and shows one vertical bar. In order to obtain this condition it may be necessary to slightly re-adjust the horizontal locking range trimmer (C-63A) on the rear apron.

HORIZONTAL WAVE FORM ADJUSTMENT — This is a factory adjustment and it should not be necessary to re-adjust unless the setting has been disturbed. However, if it is found that re-adjustment is required, follow this procedure: With the picture in sync, connect an oscilloscope through about a 10 mmf isolation condenser to Terminal C of T-7. Adjust the horizontal wave form (T-7 See Fig. 5) until the two peaks of the wave form shown in Fig. 9 are equal. NOTE: Picture must be in sync during this adjustment.

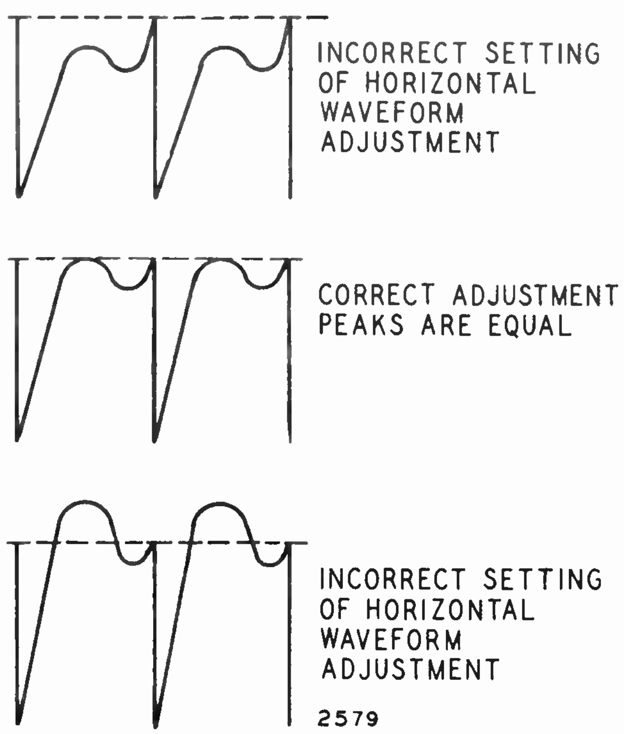

Fig. 9—Horizontal Wave Form Adjustment

HORIZONTAL LOCKING RANGE ADJUSTMENT — Set the horizontal hold control to the extreme counter-clockwise position. Momentarily remove the signal by switching off channel and then back. Slowly turn the horizontal hold control clockwise and note the least number of diagonal bars obtained just before the picture pulls into sync. If more than 4-1/2 bars are present just before the picture pulls into sync, adjust the horizontal locking range trimmer C-63A (See Figure 5) slightly clockwise. If less than 3-1/2 bars are present, adjust trimmer C-63A slightly counter-clockwise. Turn the horizontal hold control counter-clockwise, momentarily remove the signal and recheck the number of bars present at the pull-in point. Repeat this procedure until 3-1/2 to 4-1/2 bars are present. Repeat the adjustments under "Horizontal Frequency Adjustment" and "Horizontal Locking Range Adjustment" until the condition specified under each are fulfilled. When the horizontal hold operates as outlined under "Check of Horizontal Oscillator Alignment" the oscillator is properly adjusted.

16" PIX RECEIVER ADJUSTMENTS

CHECK OF HORIZONTAL OSCILLATOR ALIGNMENT —Tune in a station and adjust the horizontal hold control until the picture falls into sync. Momentarily remove the signal by switching off channel and then back. The picture should pull into sync over a range of 90° rotation of the horizontal hold control. If in the above check the receiver fails to hold sync or the pull-in range is at the extreme end of the control, and is less than 60°, it will be necessary to make the following adjustment.

HORIZONTAL FREQUENCY ADJUSTMENT - With the horizontal hold control set to the center of its range of rotation, adjust the horizontal frequency control (L-25) until the picture pulls into sync. Recheck the "Horizontal Oscillator Alignment."

THE FOLLOWING ADJUSTMENTS ARE APPLICABLE TO 12½" AND 16" PIX TUBE RECEIVERS.

HEIGHT AND LINEARITY ADJUSTMENTS —Adjust the height control (R-63) until the picture fills the mask vertically. Adjust the vertical linearity control (R-87) until the picture is symmetrical from top to bottom. Adjustment of either control will require a re-adjustment of the other control. Adjust vertical centering (3 focus coil mounting screws) to align picture with the mask.

HORIZONTAL SIZE AND DRIVE ADJUSTMENTS—Turn the horizontal size control L-23 (See Fig. 5 & 6) to the maximum clockwise position. Vary the horizontal drive trimmer (C-63B on 12-1/2" Pix Tube Receiver) (C-77 on 16" Pix Tube Receiver) to yield the best linearity. Re-adjust the horizontal size control L-23 until the picture just fills the mask. Adjust horizontal centering (3 focus coil mounting screws) to align the picture with the mask.

If the horizontal drive trimmer is opened too far counter-clockwise, a white line may appear to the left of the center of the picture.

CHECK OF R-F OSCILLATOR ADJUSTMENTS

With an accurately calibrated signal generator (crystal calibrated type preferred check to see if the receiver R-F oscillator is adjusted to the proper frequency on all channels. For this check, it will be necessary to remove the chassis from the cabinet. Illustrated on this page are the two types of tuners used in these receivers. For switch-type tuners adjust as shown in Fig. 10. When Channel 6 (low) and Channel 13 (high) trimmers are adjusted properly, other channels in the high and low frequency band will fall in automatically.

For turret type tuners adjust each channel through the clearance hole as shown in Fig. 11.

SERVICE SUGGESTIONS

NO RASTER ON PICTURE TUBE —If raster cannot be obtained check below for the possible causes.

1. Ion trap magnet adjustment is incorrect.
2. No +B voltage. Check 1/4 ampere fuse (F-1). *Replace if defective. If fuse continually burns out, check (A) Horizontal output tube V-18 (6BG6-G in 12-1/2" pix tube receivers) or V-18 and V-21 (6BQ6-GT's) in 16" pix tube receivers. (B) Check damper tube V-19 (6W4-GT). (C) Check horizontal oscillator V-17 (6SN7-GT) for proper operation. In the 16" pix tube models, connect a jumper wire from the +B side of F-1 to the junction of C-79 and R-85. For the 12-1/2" pix tube models use a similar wire from the +B side to the junction of R-70 and R-73. (D) With an ohm-meter, check for a short between terminal 2 of the horizontal output transformer T-9 and the chassis. (E) Check capacitors C-22C and C-73C.
3. No high voltage. Check V-15 and V-18 tubes and circuits. If the horizontal deflection circuits are operating as evidenced by the correct voltage measured on terminal 2 of the horizontal output transformer T-9, the trouble can be isolated to the high voltage rectifier V-15 circuit. Either the high voltage winding (points 6 to 7 on T-9) is open, tube V-15 is defective, its filament circuit is open, or the high voltage filter capacitor C-86 or C-83 on 12-1/2" models is shorted.
4. Defective picture tube. Heater open or cathode return circuit open.

*This fuse is accessible from bottom of cabinet. Remove wire screen, unsolder old fuse, solder in the new fuse and replace wire screen.

HORIZONTAL DEFLECTION ONLY —If only horizontal deflection is obtained as evidenced by a straight line across the face of the picture tube, it can be caused by the following:

1. Vertical oscillator V-13 (6SN7-GT) or vertical output tube V-14 (6K6-GT) inoperative. Check voltages on grid and plate.
2. Vertical output transformer (T-8) open.
3. Yoke vertical coils open.
4. Vertical hold, height or linearity controls may be defective.

POOR VERTICAL LINEARITY —If adjustment of the vertical hold, height or linearity controls will not correct this condition, any of the following may be the cause.

1. Vertical output transformer (T-8) defective.
2. Capacitors C-73A or C-73B defective.
3. V-13 (6SN7-GT) or V-14 (6K6-GT) defective, check voltages.
4. Excess leakage or incorrect value in capacitor C-64.
5. Low plate voltages. Check rectifier tubes and capacitors in +B supply circuits.
6. Capacitor C-65 defective.

POOR HORIZONTAL LINEARITY—If adjustment of the Horizontal drive control does not correct this condition, check the following:

1. Check or replace horizontal output tubes V18 & V-21.
2. Check or replace damper tube V-19 (6W4-GT).
3. Check capacitor C-82 for defects.

TRAPEZOIDAL OR NONSYMMETRICAL RASTER

1. Improper adjustment of focus coil or ion trap magnet.
2. Defective yoke.
3. Open condenser C-85 on horizontal yoke coil L-21.

WRINKLES ON LEFT SIDE OF RASTER—This condition can be caused by:

Defective yoke due to C-85 (internal in yoke assembly) being wrong value or open. This component is mounted in rear of yoke assembly.

SMALL RASTER —This condition can be caused by:

1. Low +B or line voltage.
2. Insufficient output from horizontal output tubes V-18 or V-21. Replace tubes.
3. Insufficient output from vertical oscillator V-13 or vertical output tube V-14. Replace tubes.

RASTER; NO IMAGE, BUT ACCOMPANYING SOUND —This condition can be caused by:

1. No signal on picture tube grid. Check picture I-F amplifier tubes V-6, 7 and 8 (6AG5's), second detector V-9A (6AL5) and video amplifiers V-10 (12AT7) and V-11 (12AU7).
2. Bad contact to picture tube grid (lead to socket broken).

SIGNAL APPEARS ON PICTURE TUBE GRID BUT IMPOSSIBLE TO SYNCHRONIZE THE PICTURE VERTICALLY AND HORIZONTALLY —A condition of this nature can be caused by:

1. Defective sync amplifier and separator V-11 (12AU7-V-10 (12AT7) or V-13 (6SN7-GT).
2. If tubes are O.K. check voltages, and associated circuits.
3. AGC system inoperative. Check V-12 (6AU6) AGC tube and associated circuits.

SIGNAL ON PICTURE TUBE GRID AND HORIZONTAL SYNC ONLY —If this condition is encountered, check:

1. Vertical integrating network capacitors C-55, C-56, and C-57; and resistors R-56, R-57 and R-58.
2. Vertical hold control R-60 defective.

PICTURE STABLE BUT WITH POOR RESOLUTION —If the picture resolution is not up to standard, it may be caused by any of the following:

1. Defective picture detector V-9A (6AL5) or video amplifier V-10 (12AT7) and V-11 (12AU7).
2. Open video peaking coil. Check all peaking coils L-9, L-10, L-11, L-12 and L-13 for continuity. Note that L-10 and L-12 have shunting resistors.
3. Leakage in V-11 (12AU7) grid capacitor C-90. If the above components are not found to be defective, check the following:

1. Check all potentials in video circuits.
2. Check picture tube grid circuit for poor or dirty contact.
3. Check adjustment of focus control R-81. It should be effective on either side of proper focus.
4. Check and realign, if necessary, the picture I-F and R-F circuits.

PICTURE SMEAR:

1. Normally, smear can be attributed to phase shift at the low frequency end of the video characteristic. This can be caused by improper values of resistors and capacitors in the video circuits. Check for grid current on video output tube V-11 (12AU7).
2. This trouble can also originate at the transmitter. Check reception from another station.
3. Check and realign, if necessary, the picture I-F and R-F circuits.

PICTURE JITTER:

1. If regular sections at left of the picture are displaced, replace the horizontal output tubes V-18 or V-21.
2. Vertical instability may be due to loose connections or noise received with the signal.
3. Horizontal instability may be due to unstable transmitted sync or to noise.
4. Check receiver AGC system for proper operation.

ALIGNMENT PROCEDURE

TEST EQUIPMENT —To service this receiver properly, it is recommended that the following test equipment be available:

R-F SWEEP GENERATOR meeting the following requirements:
(a) Frequency ranges:
18 to 30 mc, 10 mc sweep width
40 to 90 mc, 10 mc sweep width
170 to 225 mc, 10 mc sweep width
(b) Output adjustable with at least .1 volt maximum.
(c) Output constant on all ranges.
(d) Flat output in all attenuator positions.

CATHODE-RAY OSCILLOSCOPE preferably one with a wide band vertical deflection and an input calibrating source.

SIGNAL GENERATOR to provide the following frequencies:
(Output on these ranges should be adjustable and at least .1 volt maximum.)
(a) Intermediate alignment frequencies:
*17.0 mc adjacent picture trap
20.2 mc adjacent picture trap
22.7 mc first picture I-F coil
**24.1 mc third picture I-F coil
25.7 mc second picture I-F coil
27.7 mc adjacent sound trap
21.7 mc sound trap (takeoff)
4.5 mc video trap

* This frequency is not used in receivers with the turret type tuner.

** If turret type tuner is used the frequency will be 23.7 mc.

7	175.25	179.75
8	181.25	185.75
9	187.25	191.75
10	193.25	197.75
11	199.25	203.75
12	205.25	209.75
13	211.25	215.75

HETERODYNE FREQUENCY METER with crystal calibrator if the signal generator is not crystal controlled.

ELECTRONIC VOLTMETER and a high voltage probe for use with this meter to permit measurements up to 20 kilovolts.

SERVICE PRECAUTIONS — To service the receiver remove the chassis from the cabinet. To do so, remove the knobs, the cabinet back, the antenna terminal board at rear of cabinet and the 5 chassis mounting bolts. The chassis may be serviced with the picture tube in place provided the chassis is turned on its side with the power transformer on the bottom. The weight of the chassis will be supported against the high voltage housing.

CAUTION: Do not permit the kinescope second-anode lead to become shorted to the chassis. To do so will cause a considerable overload on the high voltage filter resistor R-79 on 12½" receivers or R-97 on 16" receivers.

World Radio History

ALIGNMENT PROCEDURE (continued)

B. I-F Sweep Generator into converter grid (through tube shield insulated from chassis) with markers at 21.7 MC, and 26.2 MC.

Connect oscilloscope probe to plate of 1st I-F tube V-6 (Pin 5 of 6AG5).

Ground A-G-C Line.

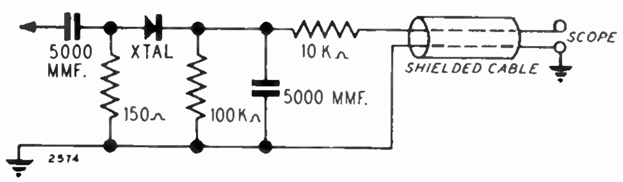

Fig. 19—Oscilloscope Connection

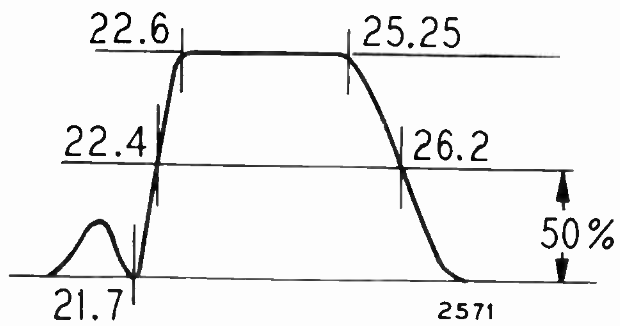

Fig. 22—Overall Response Curve

SWITCH TYPE TUNERS

Adjust converter plate coil (L-2) and 1st Pic. I-F grid coil (L-4) (top of chassis) to give the response shown below in figure 20.

A slight re-adjustment of L-3 converter plate trap may be necessary.

TURRET TYPE TUNERS

Adjust converter plate coil (L-2) to give response shown in dotted line in figure 20.

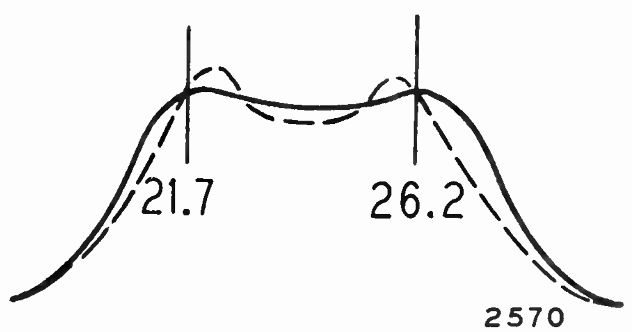

Fig. 20—Response Curve

C. With same I-F sweep input, connect scope probe to second detector (junction of peaking coil (L-9) and 4700 ohm resistor (R-31) off Pin 7, 6AL5). Input should be adjusted to give 2 volt P to P output.

Apply 3 V, bias (dc) to AGC line. (battery).

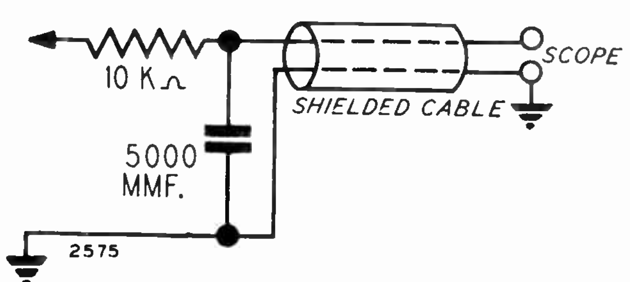

Fig. 21—Oscilloscope Connection

Observe overall I-F response, which should be as shown in Figure 22. Slight touch-up may be required.

D. Sweep generator with balanced 300 ohm output into antenna for each channel. Adjust fine tuning to receive sound and observe overall response at second detector as in C. above.

If 26.2 marker is not at 50% point, a slight touch-up of 2nd Pix-IF transformer (L-24 on top of chassis) is required.

If there is a noticeable peak near 23 MC, a slight touch-up of 1st Pix-IF transformer (L-5 sound take-off coil on bottom of chassis) is required.

If the top of the curve is tilted, a slight re-adjustment of the 3rd Pix-IF transformer L-7 (bottom of chassis) may be necessary.

AUDIO I-F

With 21.7 CW Carrier into converter grid as in A., and VTVM connected to terminal "C" of sound discriminator transformer, adjust sound I-F transformer (T-1) pri. and sec., and pri. (top of can) of discriminator (T-2) for max. dc. Input should be adjusted for 2 volts out.

Connect VTVM to Pin 1 of 6AL5 discriminator and adjust secondary of discriminator (T-2) (bottom of can) for cross-over. (Zero voltage).

VIDEO

With 4.5 MC CW Carrier from a high impedance source, (10,000 ohms in series with generator), into grid of 1st video tube (Pin 7 of 6AL5 second detector) and VTVM on picture tube grid, tune 4.5 MC trap L-8 (top of chassis) for minimum response.

REPLACEMENT PARTS LIST (16" PIX TUBE)

Ref. No.	DESCRIPTION	Part No.
	CAPACITORS

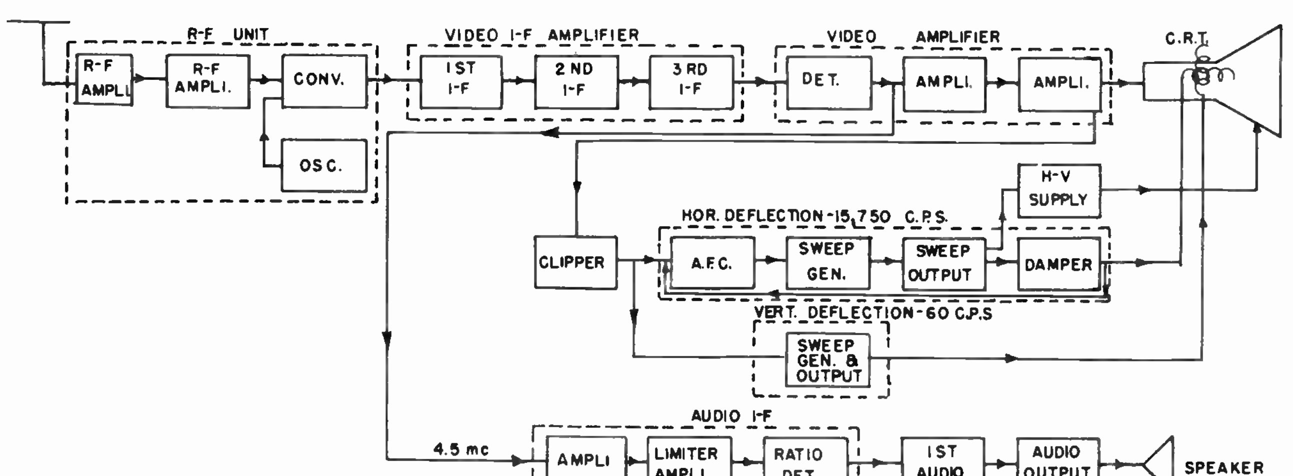

Fig. 1. Block Diagram, Model 12T7

CAUTION NOTICE

THE REGULAR B+ VOLTAGES ARE DANGEROUS AND PRECAUTIONS SHOULD BE OBSERVED WHEN THE CHASSIS IS REMOVED FROM THE CABINET FOR SERVICING. THE HIGH VOLTAGE SUPPLY (10,000 VOLTS) AT THE PICTURE TUBE ANODE WILL GIVE AN UNPLEASANT SHOCK BUT DOES NOT SUPPLY ENOUGH CURRENT TO GIVE A FATAL BURN OR SHOCK. HOWEVER, SECONDARY HUMAN REACTIONS TO OTHERWISE HARMLESS SHOCKS HAVE BEEN KNOWN TO CAUSE INJURY. SINCE THE HIGH VOLTAGE IS OBTAINED FROM THE B+ VOLTAGE, CERTAIN PORTIONS OF THE HIGH VOLTAGE GENERATING CIRCUIT ARE DANGEROUS AND EXTREME PRECAUTIONS SHOULD BE OBSERVED.

THE PICTURE TUBE IS HIGHLY EVACUATED AND IF BROKEN, GLASS FRAGMENTS WILL BE VIOLENTLY EXPELLED. IF IT IS NECESSARY TO CHANGE THE PICTURE TUBE OR TO REMOVE CHASSIS FROM CABINET ALWAYS WEAR SAFETY GOGGLES.

GENERAL INFORMATION

The General Electric Model 12T7 is a table model type television receiver providing reception on all twelve commercial television channels. The picture is produced on a $12\frac{1}{2}$-inch picture tube with electromagnetic deflection.

Features of this television receiver include a built-in antenna, a two stage r-f amplifier, balanced input impedance, selenium type rectifier, intercarrier sound system, ratio detector, efficient high voltage supply for picture tube, automatic frequency control for horizontal sweep synchronization. The head-end assembly which contains the r-f amplifier, the oscillator and converter section is mounted on a separate chassis which is isolated from the main chassis and is readily demounted. The local oscillator operates on the high-frequency side of the r-f channel frequencies for all channels. The r-f amplifier uses stagger tuned circuits on both high and low channels.

The video i-f is stagger tuned to pass the video i-f of 45.75 mc and the sound carrier of 41.25 mc. As this receiver uses intercarrier sound i-f, the video signal is detected at Y1 as well as a 4.5 mc FM television sound signal which is the beat frequency between the 45.75 mc video i-f and the 41.25 mc sound carrier.

The horizontal and vertical sync signals are available at the plate load of V7B and fed into the sync amplifier and clipper, V10. The vertical sweep generator and output (V9) is a 12SN7 connected as a multivibrator. The horizontal sync circuit contains a 6AL5 (V11) tube which is the automatic frequency control discriminator and a reactance tube (V12A) which is one section of a 12SN7 tube.

Tube section V12B operates as a sine-wave oscillator and sawtooth generator. V13 is a type 19BG6 tube which serves as the horizontal sweep output tube. V15 (25W4GT) is a damper tube in the horizontal sweep output circuit. V14 (1B3GT/8016) is a rectifier tube to supply high-voltage d-c from the kick voltage during the retrace period of the horizontal sweep developed at the horizontal output transformer, T351.

The 4.5 mc FM sound signal is taken from the diode load of Y1 and is fed into tube V16 (6AU6) which is a sound i-f amplifier.

Tube V16 is coupled by a transformer T401 to the tube V17 (6AU6) which is a limiter amplifier. Tube V17 is coupled to tube V18 (6AL5) ratio detector by the ratio detector transformer T402. The television audio is then amplified by V19 tube (6SQ7) and coupled to the audio output tube V20, (25L6GT) and then to the loudspeaker through the output transformer T403.

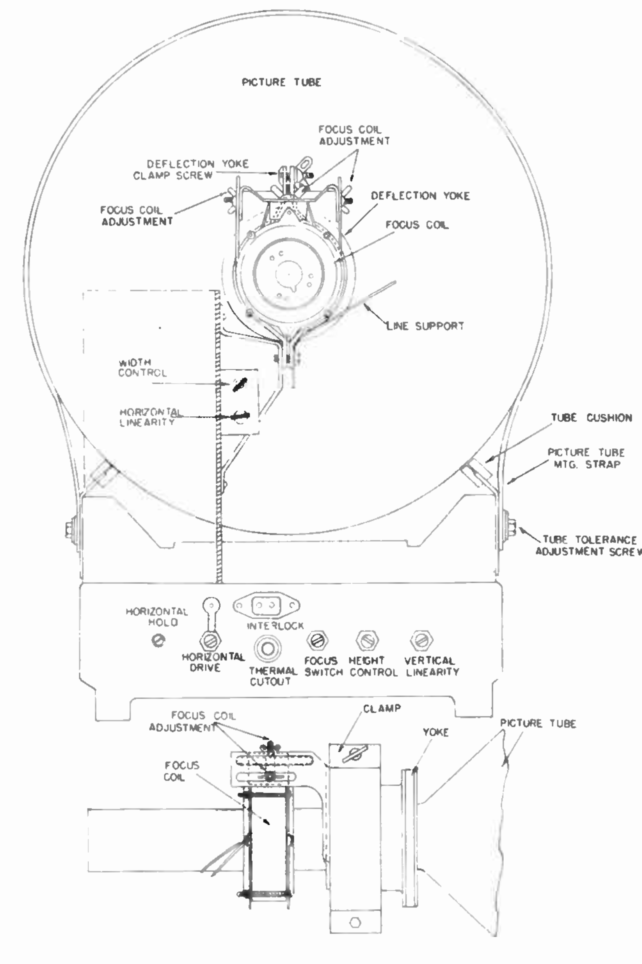

Fig. 2. Preset Controls

INSTALLATION AND SERVICE ADJUSTMENTS

NOTE: ALWAYS WEAR SAFETY GLASSES WHEN HANDLING PICTURE TUBE.

RECEIVER INSTALLATION

The receiver leaves the factory with the picture tube installed. Use care to unpack the receiver. For shipping purposes, the rectifier tube 1B3GT is secured in its socket by means of a rubber band and the horizontal output Type 19BG6 to its socket with a piece of glass tying tape. However, it is not necessary to remove rubber band and tying tape when installing the receiver, but they should be removed the first time the chassis is taken out of the cabinet for service. The two tubes are easily accessible by opening the hinged high voltage compartment shield.

In order to prevent damage to the picture tube during transit, the focus coil is moved close to the yoke assembly and a shipping sleeve is slipped between the focus coil and the tube neck. Loosen all wing nuts on the focus coil bracket, remove the shipping sleeve and move the focus coil back. Then focus and center the picture using a temporary power cord. (See Preset Control Adjustments.)

1. This receiver incorporates a built-in antenna system which

©John F. Rider

World Radio History

allows reception without the use of an outdoor antenna installation in many locations. In order to obtain best reception it is advisable to observe the reception in various locations of the room.

2. In case an outdoor antenna has to be used, the antenna lead-in should be as short as possible. The built-in antenna is connected to the dipole terminal, therefore, it is necessary to disconnect the wires of the built-in antenna altogether and connect the transmission line (impedance 300 ohms) of the outdoor antenna installation to the dipole terminals. Any type of antenna system may be used as long as it is connected through a balanced transmission line to the 300 ohm input of the receiver. The choice of the antenna depends on the operating area of the receiver, the number and location of stations to be received. In order to avoid multiple images (ghosts) and interferences, careful experimentation with the antenna system is necessary to obtain satisfactory reception. These problems may be aggravated in fringe areas and sometimes an elaborate installation has to be made to obtain satisfactory results.

Lightning Protection—All outdoor antenna installations must conform to certain standards as set up by the National Electric Code which is usually supplemented by Local Code requirements. In general, some of the requirements are as follows:

1. The metal mast supporting the antenna should be permanently and effectively grounded. Use a ground wire of minimum size as specified in the Local Code.

2. An approved television lightning arrester must be used with the antenna lead-in conductors at a point of entrance to the building. If shielded lead-in cable is used, the shield may be permanently grounded in lieu of using the lightning arrester.

For detailed information on antenna installations, refer to Chapter XIII of the Television Course RSM-4-13.

3. A power outlet providing 115 volts at 60 cycles per second must be in easy reach of the television receiver.

4. Locate so that the room illumination, in daytime or nighttime, falling on the screen of the picture tube may be controlled. If this cannot be done, locate the receiver in such a position that light from a window does not fall directly on the screen of the picture tube. For nighttime use, it is unnecessary to turn out all lights when viewing.

5. Ventilation of the television receiver is very important. Slots are provided in the cabinet back and bottom for ventilation. These slots should not be obstructed. Do not locate the receiver on or too near any heating device.

PRESET CONTROL ADJUSTMENTS
(See Figure 2)

Remove the shipping sleeve between the focus coil and the tube neck and move the focus coil backwards towards the tube base. Then adjust the ion trap for maximum illumination of the screen. The adjustments of the preset controls should be made during transmission of a picture and are greatly enhanced by viewing a station test pattern.

1. ION TRAP—After the receiver is turned on, start with the ion trap set on the picture neck midway between the focus coil assembly and picture tube base. Leaving the receiver with maximum setting of brightness control without adjusting the ion trap might damage the gun structure of the picture tube. Alternately rotate and the move the trap forward and backward along the neck of the tube for maximum brightness of the screen. As the screen becomes brighter, reduce brightness by adjusting the front panel Brightness control. Power should not be applied for any great length of time without the ion trap adjusted for some illumination.

2. FOCUS—The focus switch, S401, on the rear panel should be set to the position which allows the front control, R421, to focus the picture nearest the center of its rotation and to give uniform focus over the greatest picture area.

NOTE: The focus coil should be located as near to the picture tube base as possible when centering the picture to give most uniform focus. (See Picture Centering.) It is important to readjust the ion trap for maximum brilliance after the focus coil has been adjusted.

3. PICTURE TILT—If the picture or raster does not square with the picture tube mask, loosen the wing nut at the top of the yoke clamping bracket and rotate the deflection yoke in the proper direction until the picture squares with the mask. Clamp the yoke tightly in place.

4. PICTURE CENTERING—Centering of the picture or raster is accomplished by loosening the wing nuts which secure the focus coil and adjusting the position of the focus coil until the raster or the picture is centered.

The focus coil may be moved slightly in various directions: it may be moved vertically by loosening the two side wing nuts; it may be moved horizontally or rotated about its vertical axis by loosening the top wing nut. Furthermore, it may be tilted about a horizontal axis by loosening the two side wing nuts.

When making the adjustment, it is advisable to loosen all three wing nuts and make an approximate adjustment of the focus coil. Tighten the three wing nuts enough to maintain the focus coil in place but loose enough so it may be moved to a final position. After a final position has been found which gives good centering of the picture, tighten the three wing nuts securely.

Do not leave the focus coil set in such a position as to give neck shadow at one edge of the picture. (Fig. 13.)

5. HORIZONTAL HOLD—Rotate the front panel Horizontal Hold control R365 to the middle of its range. Adjust the core of the rear panel Horizontal Hold control L351 until the picture is synced and is phased at the center of the raster.

The pull in range should be equally distributed either side of the front panel horizontal hold control center position. Readjust the rear panel hold control if necessary.

Check pull in sensitivity by switching from an empty channel to a station with the receiver properly tuned to that station.

6. HORIZONTAL LINEARITY—The Horizontal Linearity control (L352) adjusts the picture for correct horizontal proportions. For best adjustment, use a test pattern and adjust the Horizontal Linearity control until the distance from the center of the test pattern to the left- and right-hand edges of the test pattern measures approximately the same. The adjustment of this control is very broad and it should be made simultaneously with the adjustment of the Width control (L353) to get proper picture width and correct horizontal linearity. (See Fig. 12.)

7. HORIZONTAL DRIVE—The Horizontal Drive control (R369) should be set approximately 1/3 of its total rotation from the counterclockwise end of its rotation. If white vertical bars or black beaded lines appear in the picture, the Drive control should be turned in either direction to just remove these white vertical bars or beaded lines.

8. WIDTH—Adjust the Width control (L353) so that the edges of the picture extend approximately one-eighth inch past the right- and left-hand edge of the mask and are not visible (Fig. 11).

9. VERTICAL LINEARITY—This control (R311) should be adjusted to give good vertical proportions to the picture. The adjustment should be made on a test pattern so that the distance from the center to the top and bottom edges of the pattern measures approximately the same. This adjustment will alter the height of the picture slightly. (See Fig. 9.)

10. HEIGHT—This control (R308) changes the picture height and should be adjusted so that the picture extends approximately 1/8 inch beyond the top and bottom edges of the mask. This adjustment should be made simultaneously with the Vert. Linearity Control R311.

11. THERMAL CUT-OUT—This is a protective device to remove line voltage from the receiver in case of excessive current drain or excessive heat, within the chassis. A five minute period should be allowed after this control has tripped before resetting. If the control continues to trip out, the receiver should be checked.

12. HIGH CHANNEL TRAP—This receiver incorporates a trap on the head-end unit which is switched into the antenna circuit on all low-band channels and will eliminate high channel interference on these channels. If the receiver is tuned to Channel No. 5, a strong station operating on Channel No. 11 may beat with the second harmonic of the local oscillator to form an i-f frequency which will ride through unhindered and appear on the picture screen. In order to prevent the interfering signal from reaching the converter, a trap consisting of a fixed inductance and a variable capacitance is adjusted for maximum rejection of the interfering station. This type of interference is also possible on Channels No. 4 and No. 6 due to interfering stations on Channels No. 8 and No. 13, respectively. The trap is adjusted at the factory approximately for Channel No. 11 rejection. It may be necessary to readjust the trap slightly for maximum rejection of Channel No. 11.

The adjustment of the trap can be made by means of a signal generator and an oscilloscope or an a-c meter as indicating device. The signal generator must be terminated to match 300 ohms impedance. For elimination of Channel No. 8, No. 11, or No. 13 interference, feed a strong signal of the picture carrier frequency of the interfering station modulated with an audio signal into the antenna terminals and connect the indicating device to the picture grid tube. Set the band selector to the Channel No. 4, No. 5, or No. 6, respectively, and tune local oscillator of receiver for maximum deflection on indicating device. Then tune trimmer C206 for minimum signal on picture tube grid.

The adjustment of the trap can be made without instruments as follows: When the channel interference appears in the picture, set the tuning control for maximum interference. Then tune trimmer C206 for minimum interference or maximum rejection.

PICTURE DEFECTS

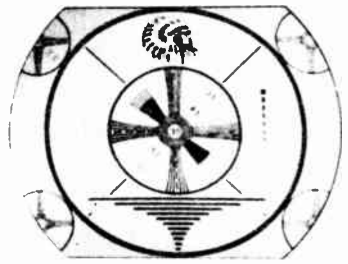

Fig. 3
Normal picture.

The following illustrations show picture defects which are caused by incorrect setting of operation controls, the preset controls or by interference picked up by the antenna. The possible remedy is indicated for each defect.

The adjustment of controls is most efficiently accomplished by the use of a test pattern, similar to that illustrated to the left, which is normally transmitted just prior to the scheduled program.

The normal picture should show good focus and a good contrast between blacks and whites with intermediate shades of gray. The picture should not tend to either move vertically or horizontally out of sync. It should show good vertical and horizontal linearity.

PICTURE	DEFECT	REMEDY
	**Fig. 4** **Picture too light.**	1. Increase Picture control setting and/or reduce brightness. 2. Weak signal. This may be caused by insufficient pickup on antenna or defective lead-in. Insufficient pickup at maximum contrast usually is accompanied by "snow" on the picture.
	**Fig. 5** **Picture too dark (contrast).**	1. Reduce Picture control setting and/or increase Brightness control setting. 2. Too strong signal. If it is not possible to reduce signal adequately with Picture control, install suitable resistor pad in antenna input circuit.
	**Fig. 6** **Picture defocussed.**	1. Adjustment of Focus controls. 2. Check for optimum uniformity of focus by moving focus coil (see installation and service adjustments, page 1). 3. Mistuning of receiver or misalignment of electrical circuits.
	**Fig. 7** **Horizontal sync.**	1. Adjust Horizontal Hold control (front panel control). 2. Check adjustment of rear panel Horizontal Hold control. 3. Horizontal Drive control set too far clockwise. 4. Signal improperly tuned.
	**Fig. 8** **Vertical sync.**	1. Adjust Vertical Hold control until picture shows no tendency to slide up or down or lock out of frame.

PICTURE	DEFECT	REMEDY
	**Fig. 9** Vertical linearity.	1. Adjust Vertical Linearity control. This adjustment may alter the Height control adjustment.
	**Fig. 10** Vertical height.	1. Adjust Height control so that the top and bottom picture edges are just covered by mask. Recheck Vertical Linearity control setting.
	**Fig. 11** Picture too wide.	1. Adjust Width control so that the right and left picture edges are just covered by the mask.
	**Fig. 12** Horizontal linearity.	1. Adjust Horizontal Linearity control. This adjustment may require resetting of Width control. 2. Adjust Drive control as described under Installation and Service Adjustments, page 1.
	**Fig. 13** Neck shadow.	1. Misadjustment of Focus coils—tilted too far. 2. Deflection yoke too far back. 3. Readjust Ion Trap.
	**Fig. 14** Barkhausen oscillation.	One or several vertical dark lines when program is being received. 1. Readjust horizontal drive control, R369. 2. Change 19B6G sweep output tube.

PICTURE INTERFERENCES

PICTURE	DEFECT	REMEDY
	**Fig. 15** Herringbone pattern over picture.	This interference is caused by a television station operating on the next lower channel or by a short-wave radio transmitting and receiving equipment. Police and "ham" transmitters in your locality will usually cause the most severe conditions. The interference produces moving ripples or diagonal streaks or, in some cases, may cause loss of contrast of the picture. The use of an antenna wavetrap tuned to the interfering signal may assist. If the interference is from a TV or FM station, a transmission line shorted stub may remove the interference. If the pickup is on the lead-in, a shielded lead-in will help correct the trouble.
	**Fig. 16** Diathermy interference	Diathermy equipment is used by hospitals and doctors and can be very annoying because it might ruin the reception completely. This interference manifests itself in a herringbone pattern or one or two dark bars moving slowly up or down the picture. If the disturbance is extremely strong, the interference pattern will remain stationary while the picture floats in the background. Improve your antenna installation using directive antenna systems and shielded transmission line.
	**Fig. 17** Horizontal bars on picture.	This interference is caused by adjacent channel sound or microphonics in receiver. If adjacent channel sound is responsible for this defect, readjust the adjacent channel trap. See Video IF alignment. A microphonic video amplifier tube, V7, may cause this condition.
	**Fig. 18** Ignition interference.	Ignition interference from trucks, automobiles, and airplanes may be identified by streaks and splashes on the picture. The ignition system of trucks will produce the most intense interference pattern. Install antenna away from road carrying traffic. Shielded lead-in may help if interference is picked up on it.
	**Fig. 19** Multiple images (ghosts).	This is caused by the television signal following a multiple path, one of which is the direct path, and the other is reflected from some object such as a tall building or a large storage tank or hills. The signal following the longer reflected path arrives later at the receiver producing the second image. In case a built-in antenna is used, try to turn the cabinet until the ghost picture is a minimum. If your receiver is connected to an outdoor installation, a reorientation of the antenna might improve the reception.
	**Fig. 20** "Snow."	1. Too weak signal; increase efficiency of antenna installation 2. Adjust tuning control.

CIRCUIT ALIGNMENT

TO PROTECT TEST EQUIPMENT ALWAYS USE AN ISOLATION TRANSFORMER

GENERAL

A complete alignment of the receiver tuned circuits is given in the following charts. Read all alignment notes before making an alignment. The alignment procedure described follows the sweep method using General Electric test equipment. When other test equipment is used, check that they meet the different requirements for proper alignment. Suitable test equipment is essential for proper alignment of the receiver and under no circumstances try to align with inadequate test equipment. For a detailed discussion of this problem, refer to our publication Television Principles and Practice, Chapter 14. In order to speed up the alignment procedure, it is advisable to use the service diagram, Figure 29, page 8, and the tube and trimmer location, Figure 22, page 5.

In connecting the test equipment to the points indicated on the charts, make the leads as short as possible. This is particularly necessary of the ground leads of the test equipment which should be connected to the B− bus of the receiver.

Always allow test equipment and receiver to warm up for at least 15 minutes before starting the alignment.

It is often advisable to perform the alignment with the picture tube removed. The filament circuit can be completed by using a Type 6SN7 tube with all pins clipped off except pins No. 7 and No. 8 which must be plugged into No. 1 and No. 12 of the picture tube socket.

TEST EQUIPMENT

The following test equipment is necessary in order to affect alignment of the tuned circuits of the receiver:

1. R-F SWEEP GENERATOR.
(G-E Type ST-4A or Equivalent)

a.) Frequency Requirements:

4.5 MC with 500 KC and 2 MC sweep width.
40–50 MC with approximately 10 MC sweep width.
50–90 MC, 170–220 MC with 15 MC sweep width

b.) Constant output in the sweep range.

c.) Minimum output 0.1 volt.

2. MARKER GENERATOR.
(G-E Type ST-5A or Equivalent)

The marker generator must have good frequency stability, accurate calibration and must cover the following frequencies:

a.) 41.25 MC for video IF
42.50 MC for video IF
44.20 MC for video IF
44.50 MC for video IF
45.00 MC for video IF
45.75 MC for video IF
47.25 MC for video IF

b.) 4.5 MC for sound IF and trap alignment.

c). Picture and sound carrier frequencies for Channel No. 2 through No. 13.

3. BALANCED OUTPUT ADAPTER.
(G-E ST-8A or Equivalent)
See RF Alignment, note 1.

4. OSCILLOSCOPE.
(G-E Type ST-2A or Equivalent)

The oscilloscope should have good sensitivity and preferably a 5-inch screen with a good wide-band frequency response on the vertical deflection circuits. Although the high frequency response is not necessary for alignment, it is imperative when making waveform measurements.

5. VACUUM TUBE VOLTMETER.

A vacuum tube voltmeter (VTVM) is necessary to measure the bias of 4 volts required for video and RF alignment.

6. DETECTOR NETWORK.

A crystal detector network as shown in Figure 27 is necessary when aligning the 4.5 mc trap, L260.

7. MISCELLANEOUS.

a.) One 10,000 ohm resistor to isolate the scope as noted in the charts.

b.) One .01 mf. capacitor for isolation of sweep generator.

c.) One 680 ohm resistor for IF coil shunt (RF alignment).

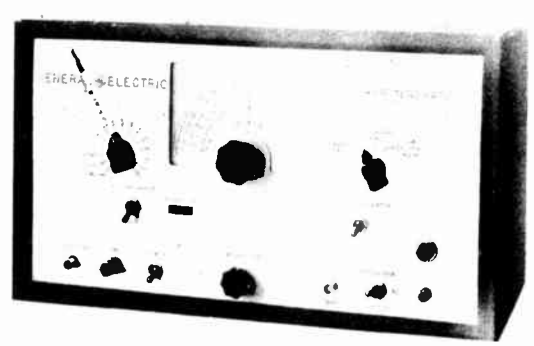
d.) One 400 mf. electrolytic capacitor, 350 volt for reducing hum (RF alignment).

e.) One 100 ohm resistor for reducing hum (RF alignment).

f.) Impedance matching pad for RF alignment as shown in Figure 28.

g.) Bias battery to supply −4 volts as noted for Video IF and RF Alignment.

GENERAL ELECTRIC
R-F SWEEP GENERATOR
MODEL ST-4A



GENERAL ELECTRIC
MARKER GENERATOR, MODEL ST-5A

VIDEO I-F ALIGNMENT

NOTES:

1. The sweep generator should be properly terminated in its characteristic impedance. Couple the signal to the input point through a .01 mf. capacitor and adjust signal input to give a video response curve of ¾ volt as shown in Figure 21.

2. Connect a bias battery from junction of C261, R263, and the picture control R262 to B− with the positive side of the battery connected to B−. Adjust picture control to give a −4 volt bias at the grid pin 1 of tube V4 measured with a VTVM. Disconnect its leads during alignment.

3. The traps L227 and L253 must be detuned before aligning the video i-f amplifier by turning the cores all the way out of the coil. When returning these traps to 47.25 mc (as in step 6), for minimum amplitude, increase scope gain as amplitude at 47.25 mc marker point is attenuated, to provide optimum setting.

4. Set channel switch to Channel #12 or #13 and check for oscillator influence by turning the tuning control. If response curve is affected, switch to another channel where oscillator influence is absent.

5. In general, it is only necessary to perform an over-all alignment of the video i-f, as in step 7 of the Video Alignment Chart, in order to obtain i-f response curve of Figure 21-E.

When aligning the i-f coils, L251 will adjust the audio or low frequency side of the i-f response curve, while L252 will adjust the video or high frequency side of the i-f response curve. L226 and L254 should be adjusted simultaneously to reduce the saddle-back at the peak of the curve and to give maximum gain and retain 45.75 mc and 42.50 mc markers at the 50% mark.

6. It is necessary to detune the i-f coils by shorting as noted in the alignment chart to prevent the coil preceding the signal input point from influencing the response curve.

7. It is important that the 45.75 mc marker should fall at the 50% response point to give proper curve of Figure 21-E.

8. After adjustment of the two sound traps, readjust the i-f curve to obtain the proper response curve as illustrated in Figure 21-E.

AUDIO I-F ALIGNMENT

NOTES:

1. Feed a 4.5 mc signal with a 500 kc sweep and adjust for proper response curve as indicated in the chart.

2. Transformer T401 is adjusted for maximum amplitude and symmetry of the response curve about 4.5 mc marker (Figure 23-A).

3. The secondary of T402 is adjusted for curve, Figure 23-B. This adjustment should give as straight a slope as possible between the positive and negative peaks with the center of the 4.5 mc marker falling midway between the peaks.

4. The primary of T402 is adjusted for maximum of the positive and negative peaks. If necessary, readjust the secondary of T402 so that the marker falls midway between the peaks.

5. Keep the input signal of the sweep generator low enough so that limiting does not take place, otherwise the response curve will broaden out preventing correct adjustment. Check by increasing the output generator: the response curve should increase in amplitude.

6. As a final check (step 12), readjust the secondary of T402 for minimum buzz on all available stations.

7. An alternate method to the visual alignment is the sound output method using an operating television station, preferably when transmitting tone modulation during test pattern transmission.

a. Tune the receiver for best detail.

b. Set the picture control to give reduced contrast or by using a resistor pad in the antenna circuit.

c. Adjust transformer T401 and primary of T402 for maximum sound output.

d. Adjust the secondary of T402 for best quality audio reception and for minimum buzz in the output.

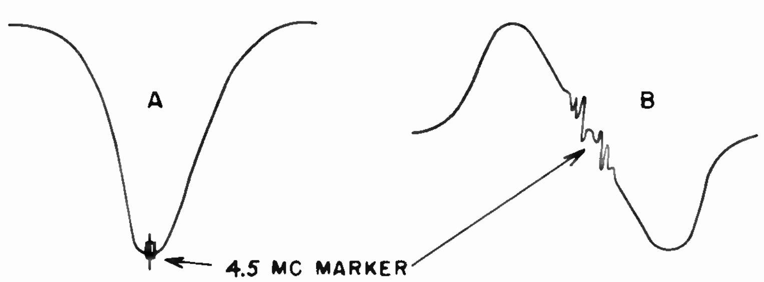

Fig. 23. Audio I-F Curve

R-F ALIGNMENT

Notes:

1. Disconnect the transmission line to the antenna from the head-end. Couple the input of the sweep generator to the head-end terminals through balanced output adapter G-E ST-8A, or equivalent. Couple this to the head-end terminals through a piece of 300-ohm transmission line. Terminate the 300 ohm line in a pad, as shown in Figure 28-A, page 6

If a balanced output is not available for the sweep generator a matching network as shown in Figure 28-B may be used. A balanced output is recommended since a matching network as shown in Figure 28-B may introduce frequency shift and cause a misleading tilt to the response curve.

Ro shown in Figure 28-B is the terminating resistor. If this resistor is not already incorporated in the output of the sweep generator, it should be added to the matching network as shown.

2. It is necessary to connect a bias battery from the junction of the picture control, C261, and R263 to B− with plus of bias battery to B−. Adjust the picture control to give a −4 volts bias measured from pin 1 of V2 to the head-end chassis B−.

3. Shunt L226 with a 680 ohm; ½ watt resistor during r-f alignment to prevent the oscillator from influencing the response curve. To reduce the effect of hum on the response curve, connect a 100 ohm resistor between the head-end B+ and the chassis B+ and connect an electrolytic capacitor of approximately 400 mf., 350 volt from head-end B+ to head-end B−.

4. On all channels the picture carrier marker should not be less than 75% of the peak of the r-f response curve. The sound carrier marker should not be less than 50% of the peak of the response curve. On the high channels the picture carrier marker should ride up nearer to the top of the curve provided the sound carrier marker does not go below 50%. On the low channels the picture carrier marker should ride as high up on the curve as possible and still keep the sound carrier marker above 50%.

5. Coils for Channels #12 through #7 are fixed inductances. Check the alignment on these channels as in steps 16 through 21 for proper response curve. Readjust L210 and L217 on Channel #13 and C207 and C230 on Channel #7 if necessary.

6. Coils for Channels #5 and #4 are fixed inductance. Check the alignment on these channels for proper curve. Readjust coils L208 and L215 to give proper curve on Channels #6, #5, and #4.

7. The coil for Channel #2 is a fixed inductance. Check the alignment on this channel for proper curve. Readjust L205 and L212 to give proper curve on Channels #3 and #2.

8. The trimmers C207 and C230 may be used to compensate for differences in tube capacities which affect tracking when it is necessary to change the tubes V1 or V2. The variations in tube capacities has normally little effect on the over-all performance of the head-end.

OSCILLATOR ALIGNMENT

Notes:

Before attempting this oscillator alignment, it must be certain that the video i-f stages and r-f stages are properly aligned as outlined previously.

1. Disconnect the 300 ohm line from the r-f head-end terminals and connect sweep generator to head-end properly terminating sweep generator output cable as shown in Figure 28-A or 28-B. See Note 1 of RF Alignment.

2. Alignment is made by viewing the response curve at the output of the video i-f detector.

3. Use a video carrier marker as shown in each step of the Alignment Chart.

4. The oscillator inductance for Channels #12 through #7 are fixed. The alignment on these channels should be checked to see that the tuning control C213 will move the video carrier marker up and down the entire high frequency side of the response curve. Readjust L225 if necessary.

5. When adjusting L225 as in step 27, the tracking on Channels #12 through #7 should be checked. Set C213 at the center of its rotation. Adjust L225 so that the video carrier marker falls as near as possible to the 50% point on the high frequency slope as the receiver is switched to each channel from 7 through 13 with this setting of C213 for all channels from 7 through 13.

6. On Channels #6 through #2 set the tuning control C213 at the center of its rotation and make the indicated adjustment so that the video carrier marker falls at the 50% mark on the high frequency slope of the response curve.

ADJUSTMENT OF VIDEO AMPLIFIER 4.5 MC TRAP (L260)

Notes:

This trap is used to remove 4.5 mc audio i-f from the video amplifier which shows up in the picture as a cross-hatch pattern. This trap will vary rarely require adjustment. Adjustment is as follows:

1. The trap (L260, C271, C270) is adjusted for minimum amplitude of the 4.5 mc marker. Use a detector network as shown in Figure 27 connected from junction of L264 and C275 to B− to detect the signal.

2. Adjust the vertical hold control to remove the vertical pulses from the response curve.

3. Short horizontal oscillator coil L351 to remove horizontal oscillator interference in the response curve.

4.5 MC TRAP (L260) ALIGNMENT CHART

STEP	MARKER GENERATOR FREQUENCY	SWEEP GENERATOR FREQUENCY	SIGNAL INPUT POINT	OSCILLOSCOPE	ADJUST	SEE NOTE
39	4.5 MC	4.5 MC ±1 MC	Junction L256, R265, C268 and B− thru .01 mf.	Across 100K resistor as shown in Fig. 27. (See Note 1.)	L260 for min. amplitude of 4.5 mc marker. Increase scope gain as amplitude at 4.5 mc is attenuated	1, 2, 3

TROUBLE SHOOTING SECTION

In order to speed up trouble shooting procedure, this trouble shooting section is divided in two parts: Trouble Shooting Charts and Trouble Shooting Analysis. The charts are subdivided according to the symptoms as they affect the picture or sound so that it is an easy matter to find the symptoms observed on the particular receiver. The second columns of the charts indicate the part or section to be checked. The third columns refer to the respective paragraphs in the following Trouble Shooting Analysis which describe in detail the possible source of defect or the necessary adjustments to obtain normal operation of the receiver.

TROUBLE SHOOTING CHARTS

Symptom	Check	Analysis No.
Picture Quality Defects		
1. No picture, no raster, no sound.	(a) Power supply.	
2. No picture, no raster, sound normal.	(a) Picture tube. (b) High voltage power supply. (c) Ion trap.	
3. No picture, no sound, raster normal.	(a) RF and video IF circuit.	A, 1
4. No picture, raster and sound normal.	(a) Video amplifier.	B, 1
5. Poor focus. (See Fig. 6)	(a) Focus coil. (b) Focus coil circuit.	
6. Poor focus and picture blooming.	(a) For gassy picture tube.	C, 3
7. Neck shadow. (See Fig. 13)	(a) Focus coil adjustment. (b) Ion trap adjustment. (c) Yoke assembly adjustment.	G, 1 G, 2 G, 4
8. Ghost. (See Fig. 9)	(a) Antenna orientation. (b) Antenna lead-in. (See page 3)	
9. "Snow." (See Fig. 20)	(a) Antenna installation. (See page 3)	
10. Poor detail.	(a) RF and video IF circuits. (b) Picture control circuit.	A, 1 A, 4
11. Insufficient brightness.	(a) Ion trap adjustment. (b) Picture tube. (c) Pix tube anode or bus voltage.	G, 2
12. Excessive contrast. (See Fig. 5)	(a) Sync Section.	F, 1
13. Excessive contrast with shaky picture.	(a) Sync Section.	F, 2
14. Very bright, fuzzy picture.	(a) Picture tube circuit.	C, 5
15. No picture on one channel.	(a) Channel switch.	A, 6
16. Distorted picture.	(a) Video amplifier.	B, 1
17. Smeared picture.	(a) Video amplifier.	B, 4

TROUBLE SHOOTING SECTION (Cont'd)

Symptom	Check	Analysis No.
Raster Defects		
1. Raster not centered.	(a) Focus coil adjustment.	G, 1
2. Tilted raster.	(a) Focus coil adjustment.	G, 1
3. Excessive raster size.	(a) Low anode voltage to pix tube.	
4. Raster width too small.	(a) Circuit of horizontal sweep output tube. (b) Width control shorted or misadjusted.	
5. Raster height too small.	(a) Height control circuit. (b) Circuit of vertical sweep output tube.	G, 5
6. Unsymmetrical, trapezoidal raster.	(a) Deflection yoke position.	G, 3
7. Barrel distortion.	(a) Deflection yoke position.	G, 3
Sweep and Sync Defects		
1. No horizontal or vertical sync.	(a) Clipper circuit of V10.	D, 6
2. Insufficient sweep width.	(a) Horizontal sweep circuit.	D, 2
3. No raster, one horizontal line.	(a) Vertical sweep circuit. (b) Vertical deflection yoke.	E, 1 G, 3
4. No raster, one vertical line.	(a) Horizontal deflection yoke.	G, 3
5. Raster not stable.	(a) High voltage power supply.	
6. Poor horizontal linearity.	(a) Horizontal sweep circuit. (b) Horizontal linearity control.	D, 3
7. Poor vertical linearity.	(a) Vertical linearity control. (b) Vertical sweep circuit.	E, 3
8. Picture not centered.	(a) Focus coil adjustment. (b) Horizontal sweep circuit.	D, 4
9. Unstable horizontal sync.	(a) Horizontal sweep circuit.	D, 5
10. Unstable vertical sync.	(a) Vertical sync input.	E, 5
11. Reduction of height.	(a) Height control. (b) Vertical sweep circuit.	E, 3, 4, 6
12. Small picture.	(a) Picture tube circuit.	C, 5
13. Retrace lines increasing towards top.	(a) Picture tube circuit.	C, 4
14. Vertical does not sync.	(a) Vertical sweep circuit.	E, 2
Audio Defects		
1. No sound, picture normal.	(a) Audio section.	H, 1
2. Hum or buzz.	(a) Audio section.	H, 2
3. Distortion.	(a) Crystal Y1. (b) Audio IF alignment. (See page 7)	
Miscellaneous		
1. Sound bars.	(a) Picture tube circuit.	C, 2
2. Light and dark vertical bars, poor horizontal linearity.	(a) Damper tube.	
3. Two heavy black horizontal bars across screen.	(a) Power supply (electrolytic capacitor)	
4. Excessive contrast with bright lines on bottom and top.	(a) Sync section.	F, 2
5. Picture distorted and reverse action of picture control.	(a) Sync section.	F, 3
6. Picture flutters at 60 cycles rate.	(a) Capacitor C251 in video IF circuit.	A, 5
7. "Window shade" effect.	(a) Picture tube circuit.	C, 5
8. Barkhausen oscillation. (See Fig. 14)	(a) Drive control, R369. (b) 19BG6 tube.	
9. "Busy background" on trailing edge.	(a) Video amplifier.	B, 2
10. Black lines across picture.	(a) Video amplifier.	B, 3
11. Very bright picture with black lines.	(a) Video amplifier.	B, 5

TROUBLE SHOOTING ANALYSIS

A. R-F and Video I-F Circuit

1. Misalignment of RF, video IF stages or sound traps will cause poor picture detail. If some stages are totally detuned, the signal might not get through at all, failing to produce a picture.

2. If the oscillator circuit fails to produce the required frequencies, no IF signal is formed and no signal will get through: No picture and no sound will be the result. Any defective component in the oscillator circuit may have this effect.

3. Any interruption of the signal path through the RF and video IF stages will result in a distorted picture or no picture at all. The location of an open component is easily accomplished by methods used in radio service work.

4. An overloading of the stages will result in loss of picture detail; check picture control circuit.

5. In case the capacitor C251 is short circuited, sound bars will appear in the picture and trailing white shadows. If this capacitor opens up, the picture will flutter at a 60-cycle rate and at minimum picture control audio motorboating will start.

6. A defective channel switch will result in intermittent reception of one channel or in extreme cases a channel might be interrupted completely. Clean switch with a cleaning fluid or bend the contacts to increase contact pressure. In some cases it is best to replace head-end unit.

B. Video Amplifier

1. If the path of the signal within the video amplifier is broken, the picture will be distorted or wiped out completely. This may be caused by open chokes L259, L261, L262 or coupling capacitor C268.

2. Misalignment of the 4½ mc trap will cause a "busy background" effect on the trailing edge of the picture.

3. If choke L264 or coupling capacitor C275 is open, there will be always enough coupling capacity to carry along at least a fraction of the signal. The resultant picture will have black lines across the picture.

4. Open or shorted resistances are easily located. Before resistors open up completely, they often show high resistance value. If this happens with the resistors R269 and R272, the effect will be a smeared picture. A high resistance of R273 will cause picture distortion at high values of picture control.

5. A shorted capacitor C275 will have the following effects: The picture is very bright with black lines across it. Brightness control does not reduce the brightness.

C. Picture Tube Circuit

1. A defective picture tube can be the cause of a faint picture, a distorted and unsteady picture or no picture at all.

2. Parts of the electron gun structure might vibrate under the influence of a strong loudspeaker output, resulting in sound bars in the picture.

3. A gassy picture tube will cause a blooming picture which is out of focus.

4. In case the capacitor C279 on the cathode of the picture tube breaks down, a high voltage will be right on the cathode blanking out the picture. If this capacitor opens up, horizontal lines appear on the picture increasing towards the top.

5. A leaking capacitor C278 will cause a small picture with poor brightness and vertical linearity. If the other capacitor C277 becomes defective, the following effects occur: A shorted capacitor will produce a fuzzy and very bright picture while an open capacitor will produce a bright horizontal area advancing towards the top with increasing brightness control setting ("window shade" effect).

D. Horizontal Sweep Section

1. No raster on the picture tube indicates a lack of high voltage or horizontal sweep voltage.
This may be caused by a defect in the high voltage rectifier circuit (V14), in the horizontal sweep output circuit (V13); the horizontal oscillator (V12B) may not be functioning properly or there may be a short in the horizontal deflection circuits (the secondary of T351, width control L353 or deflection coils D351).

2. Insufficient sweep width may be caused by defective components in the horizontal deflection circuits. Check the secondary circuits of T351 for defective components. When L353 is shorted or has shorted turns, the picture will be too narrow and L353 will have no or little control on the width.

3. Poor horizontal linearity may be caused by a short in L352, resulting in L352 having no control on the horizontal linearity. High leakage in capacitor C370 will cause poor linearity and also will increase the width.

4. A short in capacitor C377 will change the d-c component through the horizontal deflection coils which will shift the picture horizontally such that it may not be centered with the focus coil setting.

5. Poor horizontal sync with good vertical sync may be caused by a defect in the circuits of V11, or V12-A or -B.

6. No vertical or horizontal sync may be caused by defects in the clipper circuits of V10.

E. Vertical Sweep Section

1. The vertical sweep generator contains a multivibrator circuit which is made inoperative by the defects of the following capacitors: If shorted capacitor C304, C305 or C308. If the capacitor C305 is open, the oscillator is stopped.

2. The frequency of the generator is thrown off by a short circuit of the capacitors C301 and C302 with the effect that the vertical does not sync.

3. The linearity of the vertical sweep is impaired when the electrolytic capacitor C309 loses its capacity to an appreciable extent. If it opens up completely, the height reduces to approx. 1/5 of the normal size.

4. If the paper capacitor C308 develops any leakage, the vertical size is reduced so that the height control R308 does not suffice to obtain the desired height.

5. In case the capacitor C302 has an open circuit, the vertical sync becomes less stable.

6. If the B+ voltages supplied to the circuit is too low, the deflection voltages will not suffice to deflect the beam across the entire surface of the tube.

7. Microphonic tubes might give rise to a very unstable operation, resulting in a jumpy picture.

F. Common Sync Section

1. A shorted capacitor C354 on pin 1 of V10 tube will produce excessive contrast which cannot be reduced to normal by the picture control. If this capacitor opens up, both horizontal and vertical sync will be inoperative.

2. An open capacitor, C353 on the plate (pin 5) of tube V10 will produce a shaky picture with excessive contrast, while an open capacitor on the grid (pin 4) of tube V10 (C351) will produce bright lines on bottom and top together with poor horizontal and vertical sync which is independent of picture control setting.

3. Distorted picture and reverse action of picture control is caused by an open capacitor C261 on the picture control. If C261 is open, increasing picture control will decrease picture control and vice-versa.

G. Focus Coil, Ion Trap and Deflection Yoke

1. To obtain good focus and centered raster, the focus coil must be carefully positioned as outlined under Preset Control Adjustment, #2.
No sharp picture will be possible with an open or shorted coil. A partial short will throw the picture out of focus. Before looking for obscure trouble, be sure to check the focus control circuit for defective components.

2. The correct adjustment of the ion trap will result in maximum brilliance and at the same time will insure long tube life. For adjustment of this trap, see Preset Control Adjustment, #1.

3. Any unsymmetry of the deflection yoke will cause picture distortion. A shorted coil or shorted turns will cause barrel distortion and unsymmetric trapezoidal distortion. An open deflection yoke will produce a horizontal or vertical line across the screen: An open horizontal deflection coil produces a vertical line while an open vertical deflection coil produces a horizontal line.

4. The yoke assembly must be pressed against the bell of the picture tube to avoid neck shadow.

5. The correct picture size is obtained by adjusting the width and height control, as outlined under Preset Control Adjustment, #8 and #11.

H. Audio Stages

1. The FM modulated signal can reach the 1st audio tube only when the two IF transformers are aligned properly. In localizing defective components, follow normal radio trouble shooting procedure.

2. In case of improper alignment especially of discriminator secondary, a buzz or hum is heard when receiving a television station.

3. In case of no sound output the following components should be checked in turn: tubes (V16 through V20) output transformer T403, capacitors C419, C421, C418, C409, C403. and defective speaker.

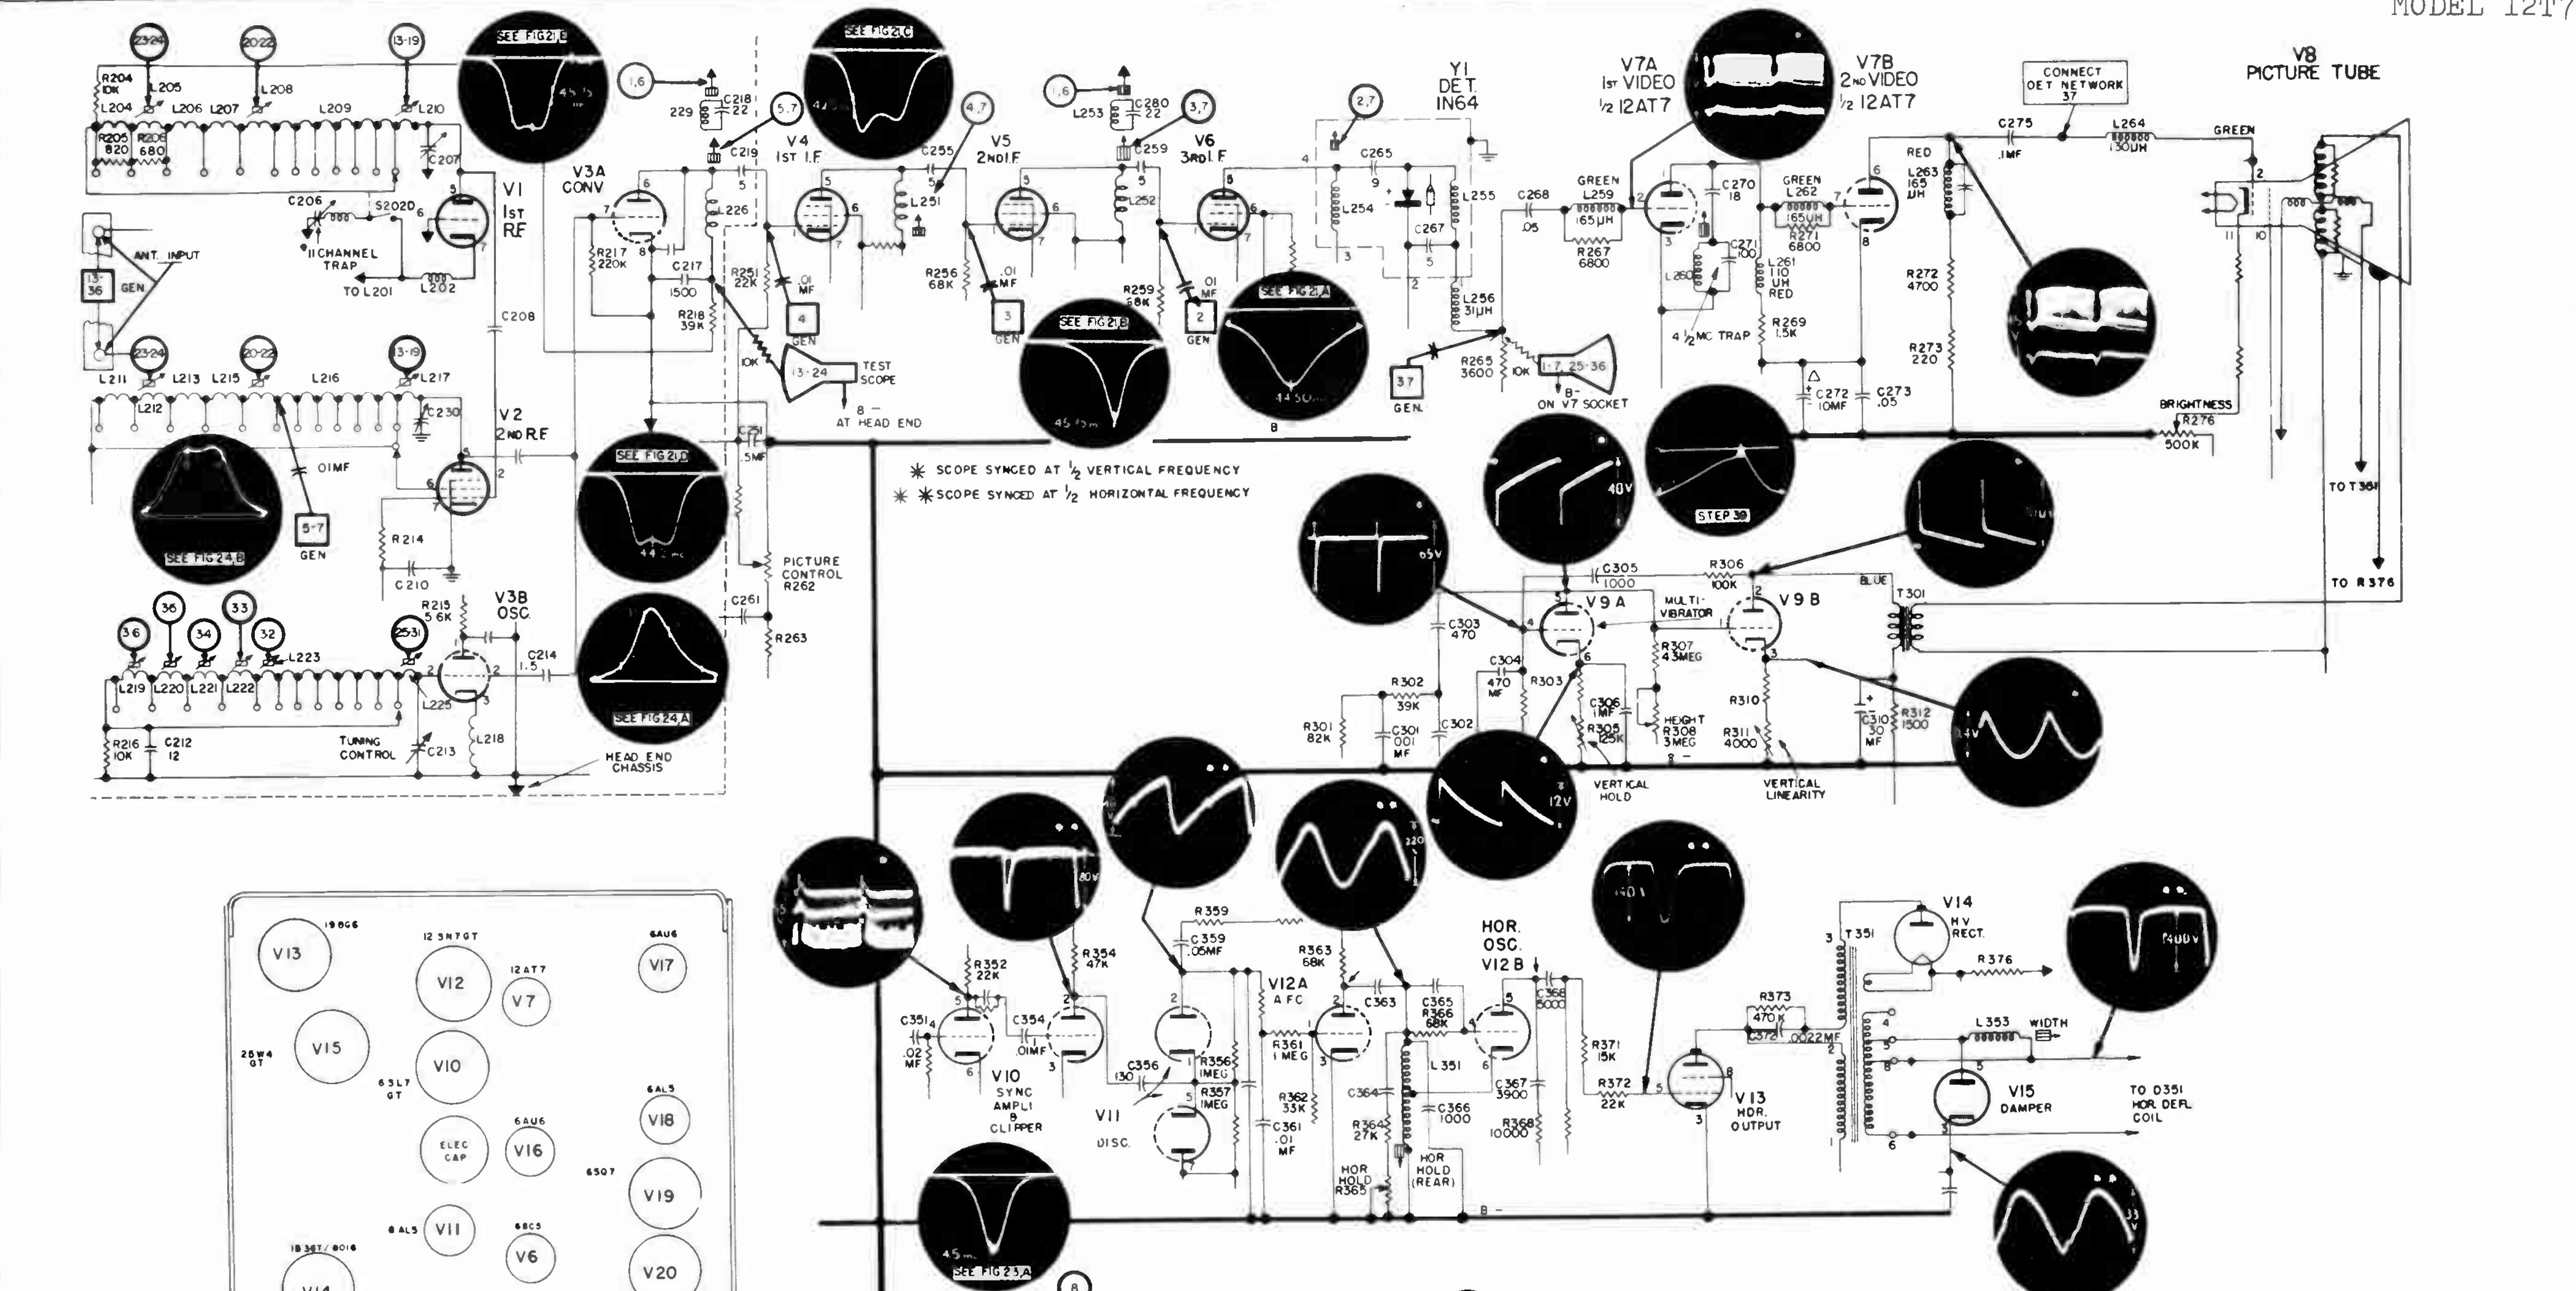

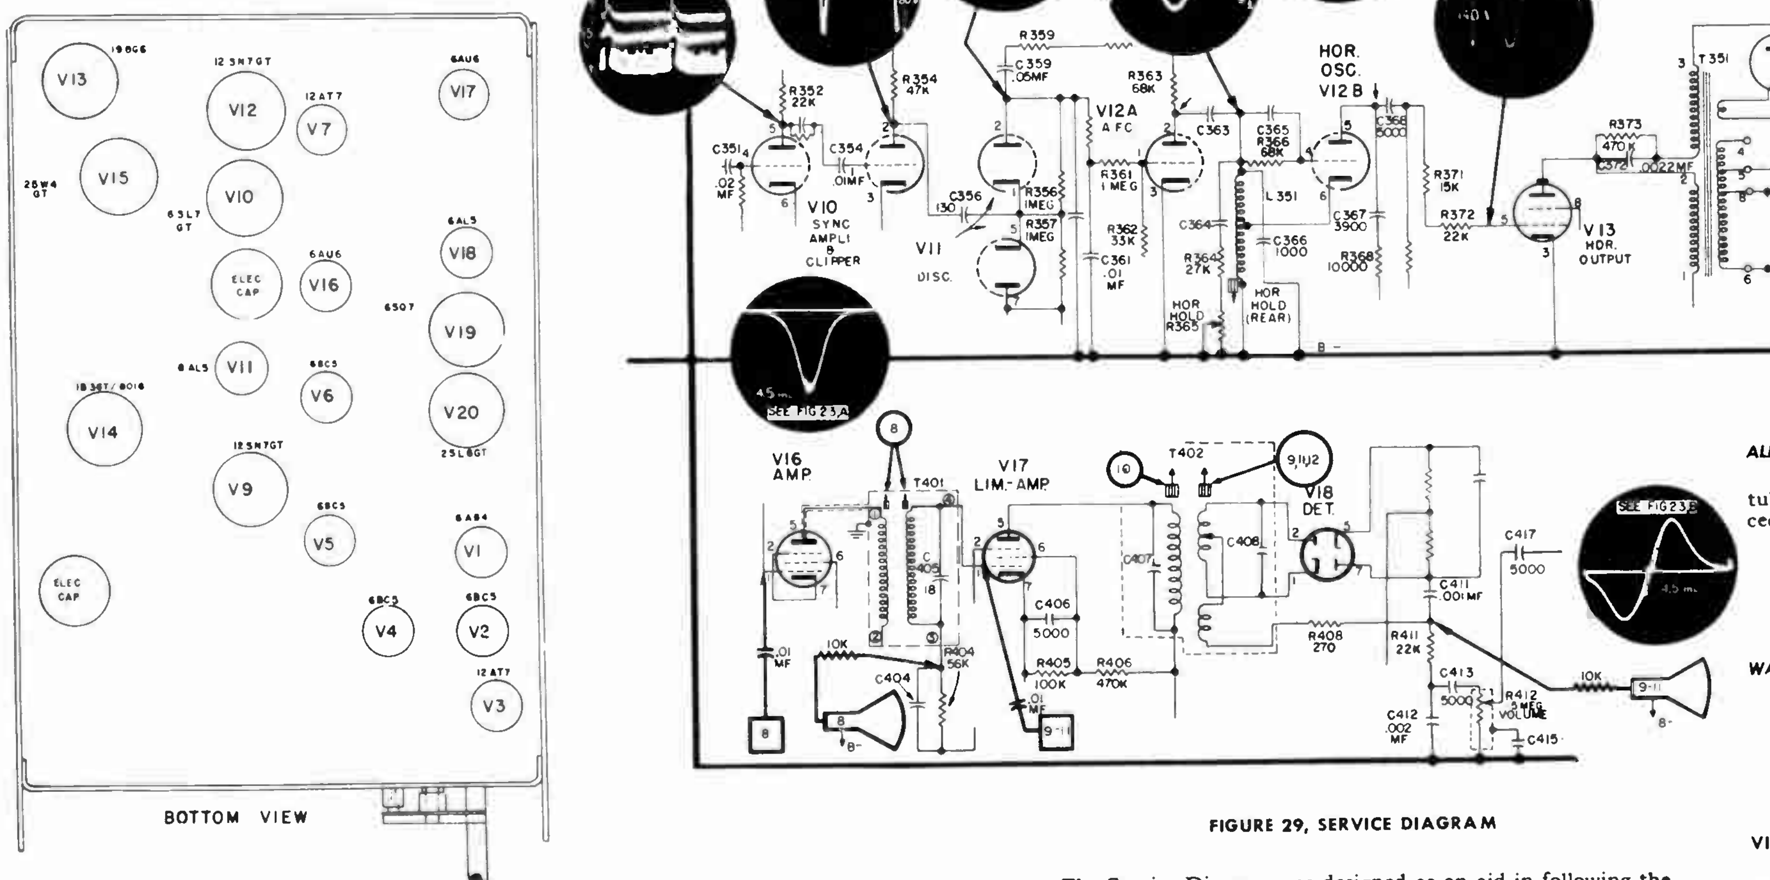

FIGURE 29, SERVICE DIAGRAM

The Service Diagram was designed as an aid in following the alignment procedure and in trouble shooting by observing waveforms at important points of the various circuits.

ALIGNMENT

The numbers enclosed by symbols—square, circle and C-R tube—refer to the various step numbers in the alignment procedure.

(a) The square indicates the point of connection for the sweep and/or signal generator.
(b) The circle indicates the trimmer or slug to be adjusted.
(c) The picture tube symbol indicates the point where the test oscilloscope is connected.

WAVEFORMS

(a) For waveform measurement use a scope with good wide band frequency response.
(b) The waveforms shown were taken from a typical receiver, tuned to a good signal, properly adjusted for sync and linearity. Measurement is made from the points indicated and ground.

VIDEO IF-CURVE

Referring to the final curve (E) take note that the markers are spaced 1.5 mc apart.

*RWL-019	I371	POWER CORD—Interlock female
RWX-029		SOCKET—Picture tube socket assembly
*1N64††	Y1	DETECTOR—Germanium crystal detector

*Parts used on previous models. ††Obtainable from tube distributor.

PRODUCTION CHANGES

1. SUPPRESSION OF RF OSCILLATION

To minimize the tendency to oscillate on Channel #12 and #13, a ceramic capacitor, C226, 800 mmf., has been added from pin 3 of the tube V3 to chassis in the head-end unit. Part number is RCW-3026.

2. INCREASE OF HORIZONTAL SWEEP

In order to increase horizontal sweep, the following changes were incorporated during production: a capacitor, C380, was added across the terminals 6 and 8 of the horizontal sweep transformer. The type used is a 220 mmf. capacitor, 1500 volt, with a parts number of RCU-295. At the same time the wiring of capacitor C376 was changed to connect to terminal 5 of the damper tube V15, 25W4GT.

In case a capacitor of 220 mmf., 1500 volts is not available, use two capacitors of values 390 mmf. (part number UCU-1042, or 470 mmf. (part number UCU-1044,) in series connection.

3. INCREASE OF LOW FREQUENCY RESPONSE

To increase the low frequency response of the video amplifier, the capacitor C268 was changed from a .02 mf. to a .05 mf. value. The new number is UCC-045.

4. IMPROVEMENT OF HORIZONTAL PULL-IN RANGE

In the biasing network for the horizontal control tube, V12A, the resistor R379 was changed from a 180,000 to a 270,000 value with a part number of URD-107.

5. TEMPORARY SUBSTITUTION

Because of temporary procurement difficulties, some receivers were wired with the following changes:

Resistor R277: a substitution of 180,000 ohms was used instead of the correct value of 220,000 ohms.

Resistor R379: a substitution of 220,000 ohms was used instead of the correct value of 270,000 ohms.

CAUTION

HIGH VOLTAGES ARE USED IN THE OPERATION OF THIS TELEVISION RECEIVER. THE BACK COVER, WHILE IN PLACE, PREVENTS ACCIDENTAL CONTACT WITH THESE HIGH VOLTAGES AND SHOULD NOT BE REMOVED EXCEPT BY A QUALIFIED TELEVISION TECHNICIAN.

THE PICTURE TUBE IS A HIGH VACUUM TUBE AND, IF BROKEN, PIECES OF GLASS MAY FLY WITH FORCE IN ALL DIRECTIONS. ANY WEAKENING OF THE GLASS, AS MAY BE CAUSED BY CHIPPING, SCRATCHING, OR MORE THAN NORMAL PRESSURE, MAY CAUSE THIS TUBE TO BREAK. THE USE OF SAFETY GLASSES IS RECOMMENDED WHEN IT IS NECESSARY TO REMOVE OR REPLACE THE PICTURE TUBE.

ALWAYS USE AN ISOLATING TRANSFORMER IN THE POWER LINE, WHEN SERVICING THESE RECEIVERS, TO PROTECT TEST EQUIPMENT.

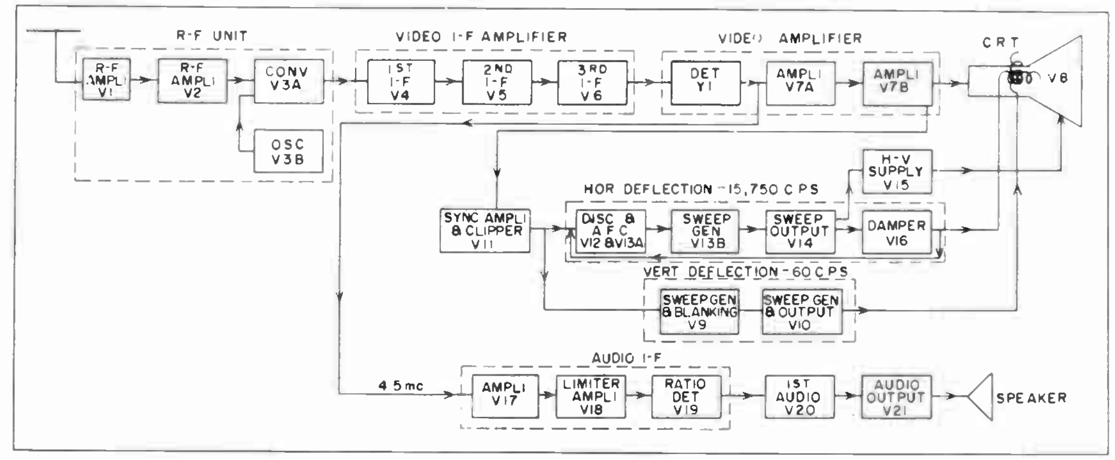

Fig. 1. Block Diagram

GENERAL INFORMATION

The General Electric Models 14T2, 14T3, 14C102, and 14C103 provide reception on all the twelve commercial television channels as specified on page 12. The picture is reproduced on a 14-inch picture tube.

Features of these television receivers include; a two stage r-f amplifier, balanced antenna input circuit, selenium type rectifiers, intercarrier sound, ratio detector, safe high voltage supply for the picture tube, automatic frequency control for horizontal sweep synchronization and electromagnetic deflection.

The r-f tuner assembly is mounted on a separate chassis which is readily demounted from the main chassis. The coils which tune the 1st and 2nd r-f stages and the oscillator are mounted on individual wafers of the selector switch. The local oscillator V3B operates on the high frequency side of the incoming r-f signal. The picture carrier is converted to a 45.75 mc video i-f frequency, while the FM sound carrier is converted to a 41.25 mc frequency.

The video i-f is stagger tuned to pass the video i-f (45.75 mc) and the (41.25 mc) with the proper amplitude relationship between the two frequencies. The video information is detected by the detector Y1 as well as a 4.5 mc FM signal which is the beat frequency between the video i-f (45.75 mc) and (41.25 mc). The 4.5 mc audio FM is amplified and limited by V17 and V18 and detected by the ratio detector V19. The audio is amplified by V20. V21 is the audio output tube.

The horizontal and vertical sync signals are taken off at the plate circuit of V7B and amplified and separated from the video signal by V11. The vertical sweep is generated by one section of a 12SN7 (V9) and a 12AU7 (V10) connected in a multivibrator circuit. The 12AU7 (V10) also serves as the vertical sweep output tube. The other section of the 12SN7 (V9) is used to produce the vertical retrace blanking signal. The horizontal sync signal is mixed with a sawtooth signal from the plate of the damper tube (V16) by the discriminator (V12). A change in phase between these two signals increases or decreases the bias voltage which is applied to the grid of V13A. V13A is a reactance tube which changes the frequency of the horizontal oscillator V13B. V14, the horizontal sweep output, is coupled to the horizontal deflection coils by T351.

V15 is the high voltage rectifier for rectifying the kickback voltage, produced in T351 by the horizontal retrace current, to supply approximately 12 kilovolts to the picture tube high voltage anode.

These receivers use two selenium rectifiers in a half-wave voltage doubling circuit to supply the B+ voltage of approximately 255 volts. The tube filaments are a series parallel connection across the 117 volt a-c line.

RECEIVER INSTALLATION

The receiver is shipped from the factory with the picture tube installed and all components preadjusted and checked for normal operation. Upon unpacking the receiver and removing the wood shipping skid from the bottom of the cabinet it is necessary only to connect the power cord into the 115 volt a-c power outlet to make it ready for use. However, if in checking receiver performance, should an analysis indicate a service control out of adjustment due to handling, shipping, or that incurred through normal service to the chassis, the receiver should be prepared for making the adjustments outlined for the Service Controls and Adjustment Procedure.

To prepare the receiver for adjustment remove the cabinet back, connect the antenna to the dipole terminals and connect the input power to the interlock receptacle by way of a power cord terminated in a matching plug. Make certain that the deflection yoke sets up against the bell of the picture tube. If it is not, loosen each deflection yoke clamp adjustment screw slightly and push yoke assembly against bell of tube. Remove tape holding ion trap to tube neck. A study of the following paragraphs and use of the adjustment procedures given will give satisfactory results with a minimum of time and effort.

ANTENNA REQUIREMENTS

GENERAL—The receiver circuit is designed with a balanced input circuit whose impedance is 300 ohms. This receiver is equipped with a built-in antenna giving favorable reception from television signals within their prime service area. Where reception is weak due to less favorable receiving conditions with the built-in antenna, an outdoor antenna, properly matched with transmission line of 300 ohms impedance in a balanced feed system and designed for operation at the television channel frequencies is recommended.

When an external antenna system is connected to the dipole terminals, the built-in antenna connecting leads must be disconnected.

OUTDOOR ANTENNA—In receiving areas of moderate signal strength, the simple folded dipole and transmission line of 300 ohms will be found adequate for favorable reception. Receiving areas of less than moderate signal strength (fringe areas) require the more complex antenna systems designed for higher gain. The high gain antennas are usually more directive and in addition provide a favorable reduction in pickup of undesirable signals or noise from the back side of such an antenna system.

World Radio History

INSTALLATION AND SERVICE ADJUSTMENTS

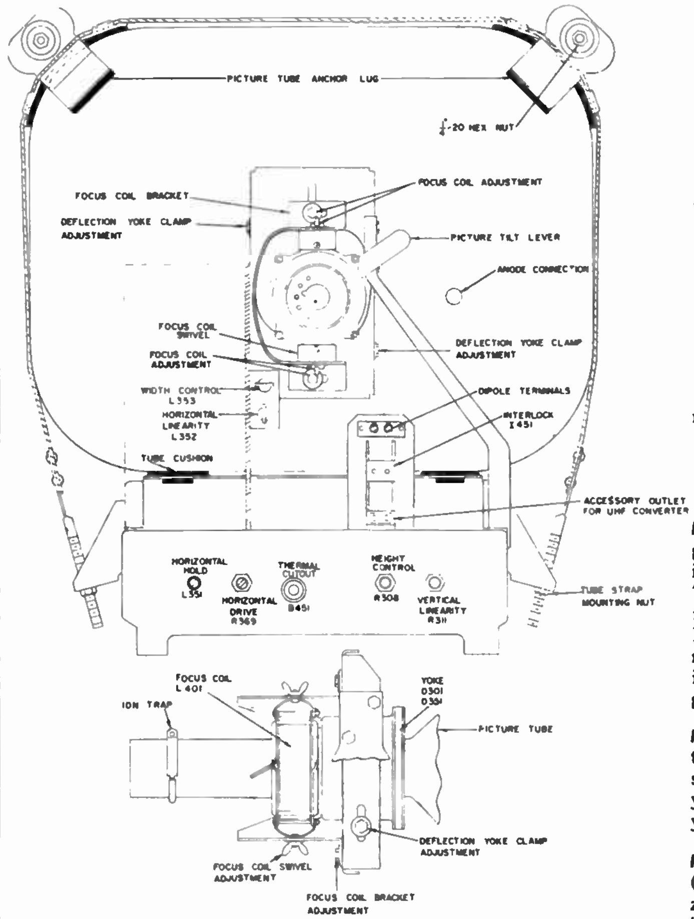

Fig. 2. Service Adjustments and Yoke Assembly

LIGHTNING PROTECTION—All outdoor antenna installations must conform to certain standards as set up by the National Electrical code which is usually supplemented by Local Code requirements. In general, some of the requirements are as follows:

1. The metal mast supporting the antenna should be permanently and effectively grounded. This should be grounded by a wire of size as specified in the codes.

2. An approved lightning arrester must be used with the antenna lead-in conductors at a point of entrance to the building. If shielded lead-in cable is used, the shield may be permanently grounded in lieu of using the lightning arrester.

ANTENNA PLACEMENT AND ORIENTATION—All television antenna systems have directional characteristics and their location may have a pronounced effect upon the results obtained. Therefore, the antenna should be turned in a horizontal plane for maximum signal pickup. Several antenna locations may have to be tried, since nearby objects, especially those of metal, may affect picture quality or even cause dead spots in reception to occur. Relocating the antenna, at increments of as much as a few feet, may produce a better picture.

GHOST RECEPTION—Ghost images are sometimes encountered, appearing as a second picture image in various degrees of contrast and displacement from the main picture. If ghosts are evident in the received picture, a relocation of the antenna should be made. In many cases this will eliminate reception of these signals which are received from some other than the direct signal path from the television transmitter. If the ghost images cannot be eliminated in this manner, a compromise in antenna orientation for maximum signal pickup and image rejection may be made without seriously impairing picture quality.

SERVICE CONTROLS AND ADJUSTMENT PROCEDURE

It will be noted that some adjustments react upon each other and therefore should be adjusted alternately and as a final step all adjustments rechecked.

Power should not be applied to the receiver for any great length of time without the ion trap adjusted for some illumination.

The ion trap, deflection yoke, focus coil and the installation adjustment controls are adjusted in the procedure given below. These are described in greater detail under their respective titles immediately following this procedure.

Reference is made to Figure 2 for the service adjustments and yoke assembly.

1. Adjust ion trap to get brightest raster.
2. Adjust for no tilt of raster and tighten yoke clamp screws.
3. Tune in a television signal.
4. Adjust Horizontal Hold controls.
5. Adjust Drive control.
6. Adjust for good Horizontal and Vertical linearity.
7. Adjust Horizontal and Vertical size controls.
8. Adjust Focus coil for centering of test pattern, removal of neck shadow and for most uniform focus.
9. Readjust ion trap.
10. Recheck adjustments of steps 6, 7, 8 and 9.
11. Tighten Focus Coil adjustment screws and wing nuts.

ION TRAP—Power should not be applied to the receiver for any great length of time without the ion trap adjusted for some illumination. Set the Brightness control to maximum (clockwise). To adjust ion trap, rotate the trap on the neck of the tube and move it forward and backward to give maximum brightness. Reduce the picture Brightness during ion trap adjustment, if raster becomes too bright as maximum brightness with the trap is approached. Always make certain the ion trap is finally set to give maximum brightness of the raster

PICTURE TILT—If the picture or raster does not lie squarely within the picture tube mask, loosen one of the Yoke Adjustment Clamp screws and by grasping the Picture Tilt Lever, turn lever to rotate yoke until picture or raster squares with the mask. Tighten the yoke clamp screws after squaring picture with mask.

HORIZONTAL HOLD—Set the front panel Horizontal Hold control (R365) to the center of its range. Adjust the core of the Horizontal Hold control (L351) at the rear of chassis, until the picture is synchronized and is phased at the center of the raster—a slight rotation of the front panel control in either direction will move the picture slightly to the left or right without losing synchronization.

The pull-in to synchronization range should be equally distributed each side of the front panel Horizontal Hold control's center range and may be checked with the control set at center, observing the pull-in to synchronization sensitivity as the Channel Selector switch is flipped alternately back and forth from the received channel to an adjacent channel having no signal. For any other setting of the front panel Horizontal Hold control, the pull-in to synchronization time will be longer.

HORIZONTAL DRIVE—Adjust the Horizontal Drive control (R369) for optimum drive indicated by a maximum width of picture.

If any compression of picture is noted on the right-hand side of the raster, the condition may be corrected by a slight decrease of drive (clockwise rotation). If a vertical beaded line appears in the picture at this setting, a further clockwise adjustment should be made to eliminate it.

HORIZONTAL LINEARITY—The Horizontal Linearity control (L352) adjusts the picture for correct horizontal proportions. For best adjustment, use a test pattern and adjust the Horizontal Linearity control until the distances from the center of the test pattern to the left- and right-hand edges of the test pattern measure approximately the same. The adjustment of this control is very broad and it should be made simultaneously with the adjustment of the Width control (L353) to get proper picture width and correct horizontal linearity.

VERTICAL LINEARITY—This control (R311) should be adjusted to give best symmetry to the test pattern for correct vertical proportions in the picture. The adjustment should be made on a test pattern so that the distances from the center to the top and bottom edges of the test pattern measure approximately the same. This adjustment will alter the height of the picture slightly.

WIDTH—Adjust the Width control (L353) so that the edges of the picture extend approximately one-eighth inch past the right- and left-hand edge of the mask so that raster edges are not visible.

HEIGHT—The Height control (R308) changes the picture height and should be adjusted so that the picture extends approximately ⅛ inch beyond the top and bottom edges of the mask. This adjustment should be made simultaneously with the Vertical Linearity control (R311).

FOCUS COIL ADJUSTMENT—The Focus coil bracket adjustment screws and the swivel wing nuts are loosened in preparation for adjustment of the focus coil. These should not be too loose but should allow movement of the coil and yet retain each new position of coil adjustment.

The focus coil and bracket may be moved up and down, to the right or left, or the coil may be tilted in any direction by the swivel mounting. In addition, the coil may be moved forward or backward.

Adjust position of the focus coil to center picture test pattern within picture tube mask and to eliminate neck shadow. The focus coil should be as far back toward the base of the picture tube as possible for best focus consistent with maximum picture brightness.

MISCELLANEOUS SERVICE DATA

REMOVAL OF CHASSIS FROM CABINET—

1. Remove knobs and cabinet back.
2. Disconnect speaker leads.
3. Remove ¼-20 nuts and washers which hold picture tube anchor lugs to top inside corners of cabinet.
4. Remove chassis mounting screws.

PICTURE TUBE AND CHASSIS REPLACEMENT—

1. The deflection yoke clamp screws and focus coil adjustments should be loosened before attempting to install the picture tube—this will prevent any strain upon the tube neck when positioning and fastening the tube later.

2. Install the picture tube as shown in Figure 1. The bottom rim of tube should be forward against rubber stop on chassis front apron.

3. Place picture tube strap around rim of tube, inserting the picture tube anchor lugs between tube rim and strap as shown in Figure 1. Center tube approximately with regard to front of chassis and install tube strap mounting nuts to hold tube lightly.

4. Place chassis and tube into the receiver cabinet, repositioning tube anchor lugs to fit over stud screws in top corners of cabinet.

5. Install chassis mounting screws and tighten to fasten chassis securely.

6. Move picture tube if necessary to center tube in mask, as viewed from front of the cabinet.

7. Tighten tube strap mounting nuts, accessible from bottom of cabinet.

8. Install washer and ¼ inch-20 hex nut over picture tube anchor lug screws and tighten to hold lugs securely to cabinet.

9. Push deflection yoke forward to set against bell of picture tube and tighten yoke clamp screws.

10. Place ion trap on picture tube neck as shown in figure 2.

11. Connect picture tube socket to base of tube and high voltage lead to anode connection.

12. Install control knobs.

HIGH CHANNEL TRAP—This receiver incorporates a trap circuit (C206, L203, S202D) on the head-end unit which is switched into the antenna circuit on the low band channels. The trap may be used to eliminate any one of the following high channel interferences on the corresponding lower channel shown.

Channel #8 on Channel #4
Channel #11 on Channel #5
Channel #13 on Channel #6

The receiver is adjusted at the factory approximately for rejection of Channel #11 interference on Channel #5. It may be necessary to readjust the trap slightly, if Channel #11 interference is experienced when operating the receiver on Channel #5.

High channel interference manifests itself as horizontal bars, a herringbone pattern in the picture, or the high channel station picture superimposed upon the low channel picture for which the receiver has been tuned.

If none of the above combinations of channels exist in the locality where the receiver is to be used, the trap need not be adjusted.

THERMAL CUT-OUT—This is a protective device, which operates in a similar manner to a fuse, removing line voltage from the receiver in case of excessive current drain due to circuit overload. A five minute period should be allowed after the cut-out has tripped, before depressing the reset button to restore power to the receiver. If the receiver does not return to normal operation within a reasonable warm-up time after the cut-out has been reset, an analysis of the receiver circuit should be made to determine the cause of overload.

PICTURE DEFECTS

Fig. 3 Normal picture.

The following illustrations show picture defects which are caused by incorrect setting of operating controls, the preset controls or by interference picked up by the antenna. A possible remedy is indicated for each defect.

The adjustment of controls is most efficiently accomplished by the use of a test pattern, similar to that illustrated to the left, which is normally transmitted just prior to the scheduled program.

The normal picture should show good focus and a good contrast between blacks and whites with intermediate shades of gray. The picture should not tend to move either vertically or horizontally and should have good linearity.

PICTURE	DEFECT	REMEDY
	**Fig. 4 Picture too light.**	1. Increase Picture control setting and/or reduce brightness. 2. Weak signal. This may be caused by insufficient pickup on antenna or defective lead-in. Insufficient pickup at maximum contrast usually is accompanied by "snow" on the picture.
	**Fig. 5 Picture too dark (contrast).**	1. Reduce Picture control setting and/or increase Brightness control setting. 2. Too strong signal. If it is not possible to reduce signal adequately with Picture control, install suitable resistor antenna pad.

PICTURE DEFECTS (Cont'd)

PICTURE	DEFECT	REMEDY
	**Fig. 6 Picture defocussed.**	1. Adjustment of front panel focus control, R421. 2. Check for uniformity of focus by moving focus coil (see Installation and Service Adjustments, page 3). 3. Mistuning of receiver or misalignment.
	**Fig. 7 Horizontal sync.**	1. Adjust Horizontal Hold control (front panel control). 2. Check adjustment of rear panel Horizontal Hold control. 3. Signal improperly tuned. 4. Defective horizontal sync circuit.
	**Fig. 8 Vertical sync.**	1. Adjust Vertical Hold control until picture shows no tendency to slide up or down or lock out of frame. 2. Check the vertical sync circuits.
	**Fig. 9 Vertical linearity.**	Adjust Vertical Linearity control. This adjustment may alter the Height control adjustment.
	**Fig. 10 Vertical height.**	Adjust Height control so that the top and bottom picture edges are just covered by mask. Recheck Vertical Linearity control setting.
	**Fig. 11 Picture too wide.**	Adjust Width control so that the right and left picture edges are just covered by the mask.
	**Fig. 12 Horizontal linearity.**	1. Adjust Horizontal Linearity control. This adjustment may require resetting of Width control. 2. Adjust drive control as described under Installation Adjustments, page 3.
	**Fig. 13 Neck shadow.**	1. Misadjustment of Focus coil—tilted too far. 2. Move the deflection yoke forward against the bell of the picture tube.
	**Fig. 14 Herringbone pattern.**	This interference is caused by a television station operating on the next lower channel or by short-wave radio transmitting and receiving equipment. Police and "ham" transmitters in your locality will usually cause the most severe conditions. The interference produces moving ripples or diagonal streaks, or in some cases, may cause loss of contrast of the picture. The use of an antenna wavetrap tuned to the interfering signal may assist. If the interference is from a TV or FM station, a transmission line shorted stub may remove the interference. If the pickup is on the lead-in, a shielded lead-in will help correct the trouble. See page 4 for high channel trap adjustment.
	**Fig. 15 Horizontal bars.**	This interference is caused by adjacent channel sound or microphonics in receiver. If adjacent channel sound is responsible for this defect, readjust the adjacent channel traps L227 and L253 as outlined on page 8. A microphonic video amplifier tube, V7, may cause this condition.
	**Fig. 16 Ignition interference**	Ignition interference from trucks, automobiles, and airplanes may be identified by black or white streaks and splashes on the picture. The ignition system of trucks will produce the most intense interference pattern. Install antenna away from road carrying traffic. Shielded lead-in may help if interference is picked up on it.
	**Fig. 17 Multiple images. (ghosts).**	This is caused by the television signal following multiple paths, one of which is the direct path, and the other is reflected from some object such as a tall building or a large storage tank or hills. The signal following the longer reflected path arrives later at the receiver producing the second image. In case a built-in antenna is used, try to turn the cabinet until the ghost picture is dimmed out. If your receiver is connected to an outdoor installation, a reorientation of the antenna might improve the reception.
	**Fig. 18 "Snow."**	1. Too weak signal; increase efficiency of antenna installation. 2. Adjust tuning control.

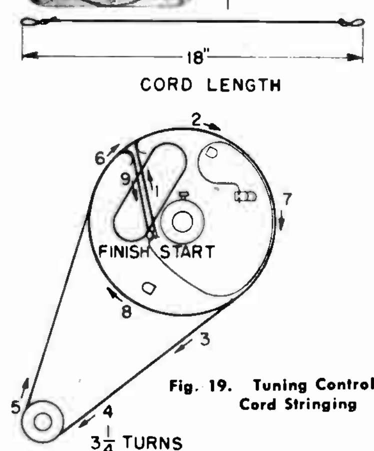

Fig. 19. Tuning Control Drive Cord Stringing

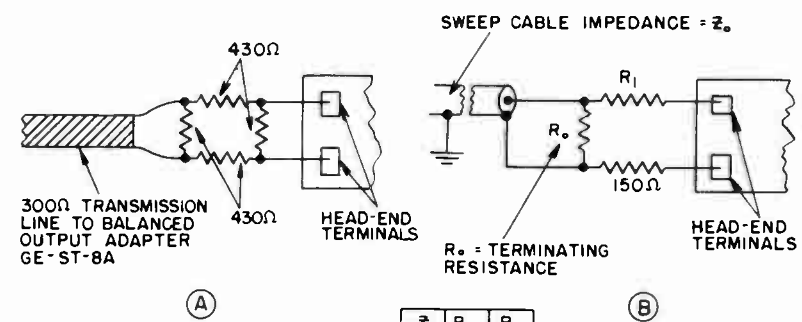

Z_o	R_o	R_1

72Ω	82Ω	110Ω
92Ω	110Ω	100Ω

Fig. 20. Sweep Generator Termination

CAUTION: TO PROTECT TEST EQUIPMENT ALWAYS USE AN ISOLATION TRANSFORMER

GENERAL—A complete alignment of the receiver tuned circuits is given in the following charts. Read all alignment notes prior to making an alignment. The procedure shown in the charts is based upon the use of the G-E test equipment specified and if other equipment is used which has different characteristics, the charts may have to be modified slightly. A diagram showing the location of adjustments used in alignment is shown in Figure 22 on page 9. Use the alignment service diagram, Figure 29, on page 15 with the charts.

The illustrations of Figure 30 and 33 show the alignment equipment connection points given in the alignment charts.

It is necessary to connect the low side of the test equipment to the B— bus of the receiver keeping the lead as short as possible.

Dress signal generator and oscilloscope cables away from both vertical and horizontal oscillator sweep circuits to prevent their interference from influencing the output response curve.

Always permit a 15 minute warm-up period for the receiver and test equipment prior to attempting alignment.

To align the receiver with the picture tube removed, a Type 6SN7 tube with all pins clipped off except pins #7 and #8 may be used to complete the filament circuit. Plug pins #7 and #8 of the 6SN7 into pins #1 and #12 of the picture tube socket.

To protect the test equipment, always use an isolation transformer between the power line and the TV receiver. See caution notice at top of page 2.

TEST EQUIPMENT—The following test equipment is necessary.

1. R-F Sweep Generator (G-E Type ST-4A or Equivalent).

a. Frequency Requirements.
4.5 MC with 500 KC and 2 MC sweep width.
40-50 MC with approximately 10 MC sweep width.
50-90 MC, 170-220 MC with 15 MC sweep width.

b. Constant output in the sweep range.

c. At least 0.1 volt output

2. Marker Generator (G-E Type ST-5A or Equivalent).

The marker generator must have good frequency stability, must be accurately calibrated and must cover the following frequencies.

41.25 MC for video I-F
42.50 MC for video I-F
44.20 MC for video I-F
44.50 MC for vidoe I-F
45.00 MC for video I-F
45.75 MC for video I-F
47.25 MC for video I-F
4.5 MC for sound I-F and trap alignment

Picture and sound carrier frequencies for Channels #2 through #13.

3. Balanced Output Adapter G-E ST-8A or Equivalent (See Figure 2.0 and RF Alignment, Note 1, page 10).

4. Oscilloscope (G-E Type ST-2A or Equivalent)—The oscilloscope should have good sensitivity and preferably a 5-inch screen with a good wide-band frequency response on the vertical deflection circuits. Although the high frequency response is not necessary for alignment, it is important when making waveform measurements shown in Figure 29, page 15.

5. Vacuum Tube Voltmeter—A vacuum tube voltmeter is necessary to measure the bias of —2.7 volts required for video and r-f alignments.

6. Detector Network—A crystal detector network as shown in Figure 27 is necessary to detect the video output response when aligning L260, the 4.5 mc trap.

7. Miscellaneous—One 10,000 ohm resistor to isolate the scope as noted in the charts.

One .01 mfd. capacitor to isolate the sweep generator as noted in the chart.

Impedance matching pad for r-f alignment as shown in Figure 20.

Bias battery to supply —2.7 volts as noted for video i-f and r-f alignment.

Resistor, 680 ohms, to shunt L226 described in note 3 of R-F Alignment on page 10.

Capacitor, 400 mf., 350 volt, to reduce hum on R-F response curve. See note 3. page 10.

©John F. Rider

World Radio History

VIDEO I-F ALIGNMENT

1. Connect a bias battery from junction of C261, R263 and the Picture control to B −. Connect positive of battery to B −. Adjust the Picture control to give a −2.7 volts bias at the grid, pin 1, of V4 as measured with a vacuum tube voltmeter. Adjust the signal generator for a ¾ volt video output response on a calibrated oscilloscope. Disconnect VTVM leads during alignment.

2. The sweep generator should be properly terminated in its characteristic impedance. Couple the signal to the point of input through a .01 mf. capacitor.

3. The traps L227 and L253 must be detuned before aligning the amplifier by turning the cores all the way out of the coil. These traps are to be retuned for minimum amplitude at 47.25 mc in step 6 of the procedure. This adjustment is greatly enhanced by increasing the scope gain.

4. Set the Channel switch to Channel #12 or #13. Check for oscillator influence by turning the tuning control. If the shape of the response curve changes, switch to another channel where oscillator influence is not noted.

5. In most cases it is only necessary to perform an over-all alignment of the video i-f, as in Step 7 of the Video Alignment Chart, to obtain i-f response curve of Figure 21-E.

When aligning the i-f coils, L251 will adjust the audio or low frequency side of the i-f response curve, while L252 will adjust the video or high frequency side of the i-f response curve. L226 and L254 should be adjusted simultaneously to reduce the saddleback at the peak of the curve and to give maximum gain and retain 45.75 mc and 42.50 mc markers at the 50% mark.

6. It is necessary to detune the i-f coils by shorting as noted in the alignment chart to prevent the coil preceding the signal input point from influencing the response curve.

7. The 45.75 mc marker should fall at the 50% point to give proper sideband response. See Fig. 21E.

8. After adjustment of the two adjacent sound traps, make the final adjustments to obtain the proper curve and markers as illustrated in Fig. 21E, in step 7.

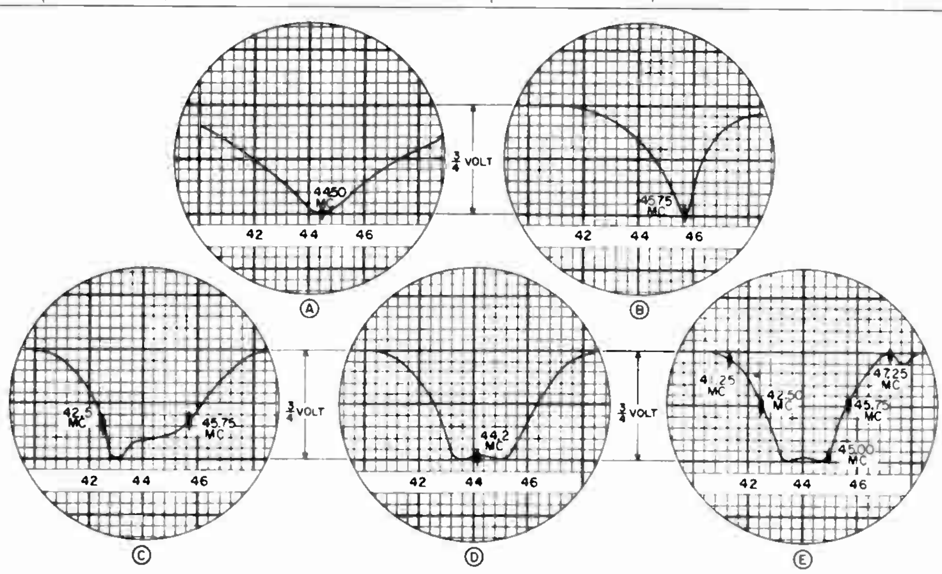

Fig. 21. Video I-F Curves

AUDIO I-F ALIGNMENT

1. Audio i-f alignment is performed by putting in a 4.5 mc ±500 kc sweep and viewing the response curve as noted in the audio i-f chart.

2. As a final check, step 12, the secondary of T402 adjustment, should be checked on a television signal if possible. Try several operating television stations and if buzz in the audio is heard, the secondary of T402 should be readjusted as follows.

Tune in the station and adjust the contrast control for a weak sound output. Readjust the secondary of T402 until the buzz is a minimum or disappears and the best quality audio is obtained.

3. Keep the input of the sweep generator low enough so that limiting does not take place, otherwsie the response curve will broaden out resulting in a slight misadjustment. Check by increasing the output of the sweep generator; the response curve should increase in amplitude.

4. T401 is adjusted for maximum amplitude and symmetry of the response curve about the 4.5 mc marker as shown in Fig. 23-A.

5. The secondary of T402 is adjusted for the curve of Figure 23-B. This adjustment should give as straight a slope as possible between the positive and negative peaks of the curve with the center of the 4.5 mc marker falling midway between the peaks.

6. The primary of T402 is adjusted for maximum amplitude of the positive and negative peaks with as straight a trace as possible between the peaks. If necessary, readjust the secondary of T402 so that the marker falls midway between the peaks.

7. An alternate method to the visual alignment is the sound output method using an operating television station, preferably when transmitting tone modulation during the test pattern.

(a) Tune the receiver for optimum detail.
(b) Keep the input below limiting level by reducing the contrast by the Picture control or by using a resistor pad in the antenna circuit.
(c) Adjust primary and secondary of T401 for maximum sound output. Adjust primary of T402 for maximum audio output.
(d) Adjust the secondary of T402 for best quality audio (low distortion, least noise) and for minimum buzz in the output.

R-F ALIGNMENT

R-F Alignment Notes

1. Disconnect the transmission line to the antenna terminals at the head-end. Couple the output of the sweep generator to the balanced output adapter G-E ST-8A, or an equivalent adapter for the particular type sweep generator used. Couple the adapter to the head-end terminals through a piece of 300-ohm transmission line and the pad network shown in Figure 20A.

If a balanced output adapter is not available for the sweep generator, a matching network as shown in Figure 20B may be used. A balanced output is recommended, since a matching network as shown in Figure 20B may introduce frequency shift and cause a misleading tilt to the response curve. Ro shown in Figure 20B is the terminating resistor. If this resistor is not already incorporated in the output of the sweep generator, it should be added to the matching network as shown in the table for the impedance Zo of the particular signal generator used.

2. It is necessary to connect a bias battery from the junction of the Picture control, C261, and R263 to B−. Connect plus of bias battery to B−. Adjust the Picture control to give a −2.7 volts bias measured from pin 1 of V2 to the head-end chassis B−.

3. Shunt L226 with a 680 ohm, ½ watt resistor during r-f alignment to prevent the oscillator from influencing the response. curve. In order to reduce the effect of hum on the response curve, connect a 100 ohm resistor in series with the B+ line to the head-end chassis and connect an electrolytic capacitor of approximately 400 mf, 350 volt from head-end B+ to head-end B−.

4. On all channels the picture carrier marker should not be less than 75% of the peak of the r-f response curve. The sound carrier marker should not be less than 50% of the peak of the response curve. However, the two minimum values should not occur simultaneously. On the high channels the picture carrier marker should ride up nearer to the top of the curve provided the sound carrier marker does not go below 50%. On the low channels the picture carrier marker should ride as high up on the curve as possible and still keep the sound carrier marker above 50%.

5. Coils for Channel No. 12 through No. 7 are fixed inductances. Check the alignment on these channels as in steps 16 through 21 for proper response curve. Readjust L210 and L217 on Channel No. 13 and C207 and C220 on Channel No. 7 if necessary.

6. Coils for Channels No. 5 and No. 4 are fixed inductances. Check the alignment on these channels for proper curve. Readjust coils L208 and L215 if necessary to give proper curve on Channels No. 6, No. 5 and No. 4.

7. The coil for Channel No. 2 is a fixed inductance. Check the alignment on this channel for proper-curve. Readjust L205 and L212 if necessary to give proper curve on Channels No. 3 and No. 2.

8. The trimmers C207 and C220 may be used to compensate for differences in tube capacities which affect tracking when it is necessary to change the tubes V1 or V2. The variations in tube capacities normally have little effect on the over-all performance of the head-end.

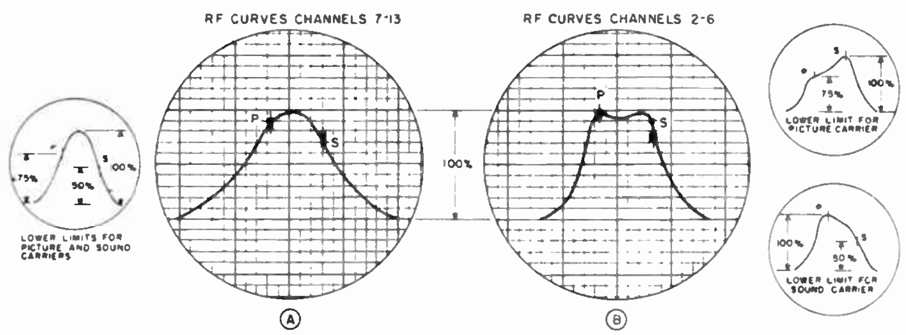

Fig. 24. R-F Alignment Curves

OSCILLATOR ALIGNMENT

Before attempting this oscillator alignment, it must be certain that the video i-f stages and r-f stages are properly aligned as outlined previously.

1. Disconnect the 300-ohm line from the r-f head-end terminals and connect sweep generator to head-end properly terminating sweep generator output cable as shown in Figure 20. See RF Alignment Note 1.

2. Alignment is made by viewing the response curve at the output of the video i-f detector.

3. Use a video carrier marker as shown in each step of the Alignment Chart.

4. Set the tuning control C213 at the center of its rotation. Adjust L225 to place the video carrier marker at the 50% point on the high frequency slope of the curve for step 28. The oscillator inductance L224 for channels #12 through #7 is fixed. The alignment on these channels is checked to see that the picture marker falls at the 50% point on the high frequency slope of the curve. If the picture marker position does not meet these conditions, it is necessary to readjust L225 for a compromise on channels #13 through #7. The tuning range of C213 on channels #13 through #7 should be sufficient to move the video carrier marker up and down the entire high frequency side of the response curve. Readjust L225 if necessary.

5. On Channel #6 through #2 set the tuning control C213 at the center of its rotation and make the indicated adjustment so that the video carrier marker falls at the 50% mark on the high frequency slope of the response curve.

World Radio History

ADJUSTMENT OF VIDEO AMPLIFIER 4.5 MC TRAP (L260).

This trap is used to remove 4.5 mc audio i-f from the video amplifier which shows up in the picture as a cross-hatch pattern. This trap will very rarely require adjustment. Adjustment is as follows:

1. The trap (L260, C271, C270) is adjusted for minimum amplitude of the response curve at the 4.5 mc marker point. Use a detector network as shown in Figure 27, connected from junction of L264 and C275 (Fig. 30, point K) to B−, to detect the signal.

2. Adjust the vertical hold control to remove the vertical pulses from the response curve.

4.5 MC TRAP (L260) ALIGNMENT CHART

Step	Marker Generator Frequency	Sweep Generator Frequency	Signal Input Point	Oscilloscope	Adjust	See Notes
39	4.5 MC	4.5 MC ±1 MC	Fig. 30, point A Junction L256, R265, C268, R266 and B− thru .01 mf.	Across 100K resistor of detector network as shown in Fig. 27. (See Note 1.)	L260 for min. amplitude of response curve at the 4.5 mc marker. Increase scope gain.	1, 2, 3

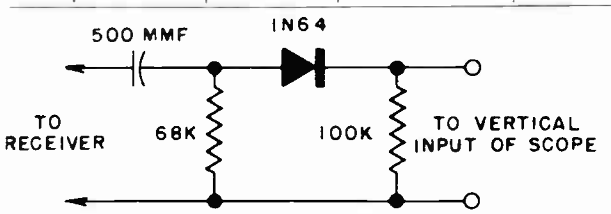

Fig. 27. Detector Network.

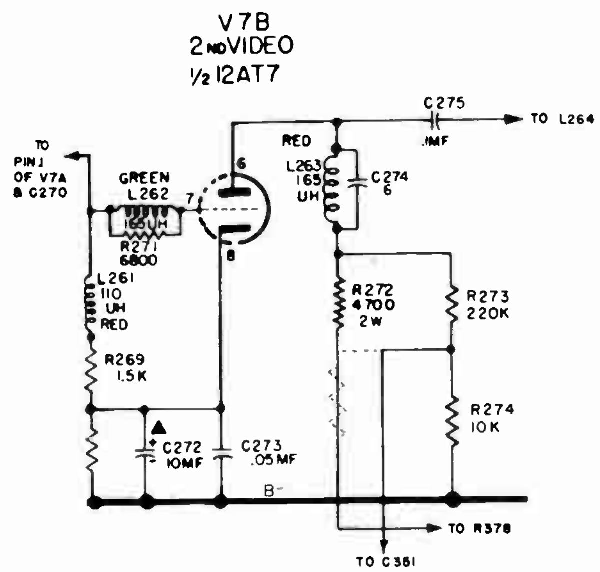

Fig. 28. Early Sync Take-off Circuit

PRODUCTION CHANGES

1. TO CORRECT BENDING AT TOP OF PICTURE

In early production receivers R273, R274 and the sync voltage take-off capacitor C351 was connected as shown in Figure 28.

In late production R274 was deleted. R273 was changed to 220 ohms and is reconnected in series with R272. C351, the sync coupling capacitor, is now connected at the junction of R272 and R273 as shown in the schematic diagram of Figure 32, page 17.

2. ELIMINATION OF VERTICAL LINES AT LEFT SIDE OF PICTURE (ADDITION OF C371)

Capacitor C371, .05 mfd., 600 volts, was added to later production receivers, to by-pass transient voltages developed by the horizontal sweep circuit at the B+ supply. These voltages would produce the effect of vertical, light and dark bars in the left part of the picture.

The capacitor, C371, is connected from the B+ terminal of the terminal strip adjacent to the damper tube, V16, on the chassis side apron and to the B− bus connection of C374.

TROUBLE SHOOTING

This trouble shooting chart is divided into sections for quick trouble shooting. In most cases a trouble may be localized by noting the condition of the picture or test pattern and the presence or absence of sound.

In general, the tubes in the defective circuit should be checked first since they are fairly easy to check. When substituting tubes in the RF or video IF circuits, the original tube should be replaced in the socket if it is found not to be defective. When a tube is replaced in the video IF or RF circuits, alignment should be checked.

The block diagram (Figure 1), the waveforms of the service diagram (Figure 29), and the socket voltage and resistance diagram (Figure 31) may be used to locate troubles. Alignment equipment may be used to isolate defective RF, video IF or audio IF stages by checking for the response curves as given in the alignment procedure.

Defects of the R-F and I-F Circuits.

A. NO PICTURE, NO SOUND, RASTER NORMAL.

1. Check the RF head end circuits of V1 and V2.
2. Check to see that local oscillator, V3B, is operating properly.
3. Check Video IF amplifier circuits of V4, V5 and V6.
4. Check crystal detector, Y1.
5. Check channel switch.

B. SNOW IN PICTURE.

1. Open input circuit in C278, C279 or L201.
2. Defective antenna installation or transmission line.
3. Antenna orientation.

C. LACK OF PICTURE DETAIL (FOCUS SATISFACTORY).

1. Misalignment of Video I-F.
2. Misalignment of R-F amplifier.
3. Mismatch of input impedances at antenna input terminals of receiver.
4. Overloading of r-f stages.

D. MOTORBOAT OR FLUTTER IN PICTURE AND AUDIO.

1. Open by-pass, C251.
2. Open filament by-passes C222 and C458.
3. Misalignment of video I-F and R-F amplifiers.

E. WIGGLES IN PICTURE BACKGROUND, TRAILING WHITES ON PICTURE, SOUND NORMAL.

1. Misalignment of R-F and I-F amplifier.
2. Improper tuning of receiver.

F. SOUND BARS IN PICTURE (BLACK HORIZONTAL BARS).

1. Microphonic tubes, V3, V4, V7 or picture tube V8.
2. Misalignment of adjacent channel sound traps, L253, L227.

Defects of the Video Amplifier

A. NO PICTURE, SOUND SATISFACTORY, RASTER SATISFACTORY.

1. Open chokes L263, L261, L264.
2. Shorted capacitor C270, C272, C273.
3. Open capacitor, C268.
4. Open resistors R269, R272.
5. Short from pin 2 to pin 11 of V8 picture tube.

B. POOR LOW FREQUENCY RESPONSE (TRAILING WHITES AFTER BLACK).

1. Low value of resistors R269, R272, R265.
2. Low capacity or open capacitor C272.
3. Low capacity of C268, C275.

C. LACK OF PICTURE DETAIL, FOCUS SATISFACTORY (SMEARING OF VERTICAL WEDGES OF TEST PATTERN).

1. Shorted chokes L259, L261, L262.
2. Open chokes L259, L262.
3. High resistance of R272, R269, R265.

D. BRIGHT PICTURE WITH BLACK LINES.

A shorted capacitor C275 will give a very bright picture with black lines across the picture. The picture control will have no effect.

E. PICTURE DISTORTED AT HIGH SETTINGS OF PICTURE CONTROL.

Check for high resistance of R273.

Defects of the Sync Section

A. NO VERTICAL SYNC, HORIZONTAL SYNC SATISFACTORY.

1. Check waveform of sync input, V9 pin 5.
2. Check C303, R301, R302, C301 for leakage or shorted.
3. Check components C306, R304, R305.
4. Check for leakage of C305.

B. WEAK VERTICAL SYNC, HORIZONTAL SYNC AND PICTURE NORMAL.

1. Leakage or low value of capacitor of C303.
2. Leakage of C301, C302 or incorrect values.
3. Check frequency determining components C306, R304, R305 for value or defective.

C. WEAK OR NO VERTICAL AND HORIZONTAL SYNC. PICTURE INFORMATION PRESENT AND SOUND NORMAL.

1. Check waveform at pin 4 of V11 for proper waveform from video amplifier.
2. Improper B+ voltage on V11.
3. Incorrect value of R354.
4. Open or low capacity of C351.
5. Defective coupling capacitor C353, C354.

D. WEAK OR NO HORIZONTAL SYNC, VERTICAL SYNC SATISFACTORY.

1. Check waveform at pin 2 of V12.
2. Check sweep frequency determining components L351, C366, C364, R365, R364.
3. Check for leakage in V12 components, C356, C357, C360, C358.
4. Check for proper value of resistors R356, R357, R358, R361.
5. Check C359, R359 and R360 in the feedback circuit.
6. Check coupling between V13A and V13B (C363, C365, R366).

Defects of the Vertical Sweep

A. KEYSTONING (PICTURE NARROWS AT TOP OR BOTTOM).

1. Defective vertical deflection coil, D301.
2. Check R314, R315.

B. NO VERTICAL DEFLECTION (SINGLE WHITE HORIZONTAL LINE ON SCREEN).

1. Open deflection coil, D301.
2. Defective sweep output transformer, T301.
3. Multivibrator V9 and V10 defective, no B+ to V10, open R312 or shorted C310.

C. INSUFFICIENT HEIGHT.

1. Open C310.
2. High resistance of R307.
3. Excessive leakage of C308.
4. Defective T301.
5. Incorrect voltage values on V10.
6. Low capacity of C309 (this also results in poor vertical linearity).

D. POOR VERTICAL LINEARITY, SIZE NORMAL.

1. Leaky or improper value of C309.
2. Check B+ to V10 (leaky capacitor C310).
3. Check C303 for leakage.

E. POOR VERTICAL LINEARITY, INSUFFICIENT HEIGHT.

1. Defective output tube, V10.
2. Inadequate drive voltage from V9. Check waveform at pin 5 of V9.
3. Low plate voltage to V9 or V10.
4. Open or low capacity of C309.

F. EXCESSIVE VERTICAL SIZE, SYNC SATISFACTORY.

1. Low value of R307 or defective size control R308.
2. Open or low capacity of C308.
3. Low picture tube anode voltage.
4. Open R309.

G. NO VERTICAL SYNC, VERTICAL HOLD HAS NO EFFECT, INSUFFICIENT HEIGHT.

1. Shorted capacitor C306.
2. Shorted R305.

H. POOR VERTICAL LINEARITY, FOLD-OVER AT BOTTOM OF PICTURE, TOO MUCH HEIGHT.

1. Shorted or high leakage of C303.
2. Low capacity of C308.

I. CURTAIN RAISING EFFECT (PICTURE ROLLS UP FROM BOTTOM AS VERTICAL HOLD IS ADVANCED).

1. Leaky capacitor, C304.
2. Low resistance of R303.

Defects of the Horizontal Sweep

A. INADEQUATE SWEEP WIDTH.

1. Low B+ boost to plate of V14 or low B+ to screen of V14.
2. Shorted turns of width control, L353.
3. Shorted turns or arc-over in T351.
4. Parasitic oscillations in V14 (open filament by-pass C462, or defect V14).

B. TOO GREAT SWEEP WIDTH.

1. Open width control, L353.
2. Low value of picture tube anode voltage.
3. Check voltages of V14.
4. High value of C382.

C. POOR HORIZONTAL LINEARITY.

1. Check for shorted, or shorted turns of L352.
2. Leaky capacitor C370 in grid of V14.
3. Check screen by-pass capacitor C380.
4. Defective transformer T351.

D. SINGLE WHITE VERTICAL LINE ON SCREEN.

1. Open deflection coil, D351.

E. BLACK BEADY VERTICAL LINE OR LINES (BARKHAUSEN OSCILLATION).

1. Check sweep output tube, V14.
2. Check for open C382.

F. KEYSTONING (PICTURE NARROWS AT TOP OR BOTTOM).

1. Check for shorted capacitor, C378.
2. Shorted turns of Horizontal Deflection coil D351.

G. NO HORIZONTAL SYNC, BRIGHT VERTICAL BAR OR BARS IN PICTURE.

1. Shorted, open or leaky C365.
2. Shorted R366.

H. GEAR-TOOTH EFFECT, TEARING OF PICTURE (HUNTING OF HORIZONTAL SYNC).

1. Open or low capacity of C375.
2. Open or high resistance of R362.

I. POOR HORIZONTAL LINEARITY, BRIGHT VERTICAL BARS, INADEQUATE HORIZONTAL SIZE.

1. Open or low capacity of C374.

J. DIM PICTURE, POOR HORIZONTAL LINEARITY, INSUFFICIENT WIDTH AND HEIGHT.

1. Open or low capacity of C377.

Audio Defects

NO SOUND, PICTURE NORMAL.

1. This indicates a defect in the circuits of V17, V18, V19, V20, V21 or the loudspeaker.
2. Misalignment of T401 or T402 may also cause no sound to be received.

BUZZ OR HUM IN THE SOUND.

1. Misalignment of T402 secondary may cause buzz.
2. Reverse power plug in power outlet.

Power Supply and Picture Tube Circuits

A. NO RASTER, NO SOUND (NO B+).

1. Check power input circuit (cord and interlock).
2. Check rectifier (X451, X452, L451, C451, R451).
3. Check thermal cutout.

©John F. Rider

World Radio History

B. *PICTURE SIZE SMALL, BRILLIANCE LOW, SOUND NORMAL (LOW B+)*
1. Open or low value of C452.
2. Low emission of X451 or X452.

C. *LOW PICTURE BRILLIANCE, SOUND SATISFACTORY.*
1. Misadjustment of ion trap.
2. Low voltage at high voltage anode of picture tube caused by leaky C376, defective V15, or shorted L353.
3. Low B+ to V14 (check B+ boost at pin 3 of V16. V16 may be defective).
4. Improper waveform at grid of pin 5 of V14.
5. Defective Brightness control circuit or improper voltages to Brightness control R276.
6. Low voltage at second grid (pin 10) of picture tube.
7. Defective picture tube.

D. *NO RASTER, SOUND SATISFACTORY.*
1. No high anode voltage to picture tube.
2. Ion trap misadjusted.
3. Brightness control circuit open.
4. No voltage at pin 10 of V8 pix tube.
5. Defective picture tube.
6. No drive voltage from V14. Check waveform at pin 5 of V14.
7. Open L352.

Miscellaneous Defects

A. *RETRACE LINES VISIBLE.*
1. Check waveform of V9, pin 2.
2. R316, C311, R318 open.
3. C311 shorted.

B. *BRIGHTNESS CONTROL R276 PARTIALLY OR TOTALLY INOPERATIVE.*
1. Defective R276.
2. Too low or too high B+ to R276.
3. Short or leaky capacitor, C275 or C277.
4. Gassy picture tube.

C. *PICTURE CONTRAST EXCESSIVE (PICTURE CONTROL WILL NOT REDUCE CONTRAST).*
1. Excessive antenna input signal.
2. Defective picture control.
3. Shorted or leaky coupling capacitor, C354.
4. Open capacitor C353, C354.
5. Shorted AGC by-pass capacitor, C251.

D. *PICTURE CONTROL INEFFECTIVE.*
1. Shorted C261 (this will make the picture control work backwards).
2. Open choke L258.
3. AGC by-pass C251 shorted.
4. Check waveform at pin 4 of V11.

E. *POOR FOCUS.*
1. Open or shorted focus coil.
2. Defective audio output tube V21.
3. Demagnetized permanent magnet of focus coil.
4. Defective picture tube V8.

F. *NECK SHADOW (SEE FIGURE 13).*
1. Misadjustment of focus coil or ion trap.
2. Deflection yoke not forward against the bell of the picture tube.

G. *WAVY LEFT OR WHITE EDGES OF PICTURE (HUM).*
1. Check tube V11, V12, V13 for filament to cathode leakage.
2. Check C379 or C355.

H. *WIDE BLACK HORIZONTAL BAR IN PICTURE, WAVY LEFT OR RIGHT EDGES OF PICTURE (HUM).*
1. Check filter capacitors C452, C453, C272.

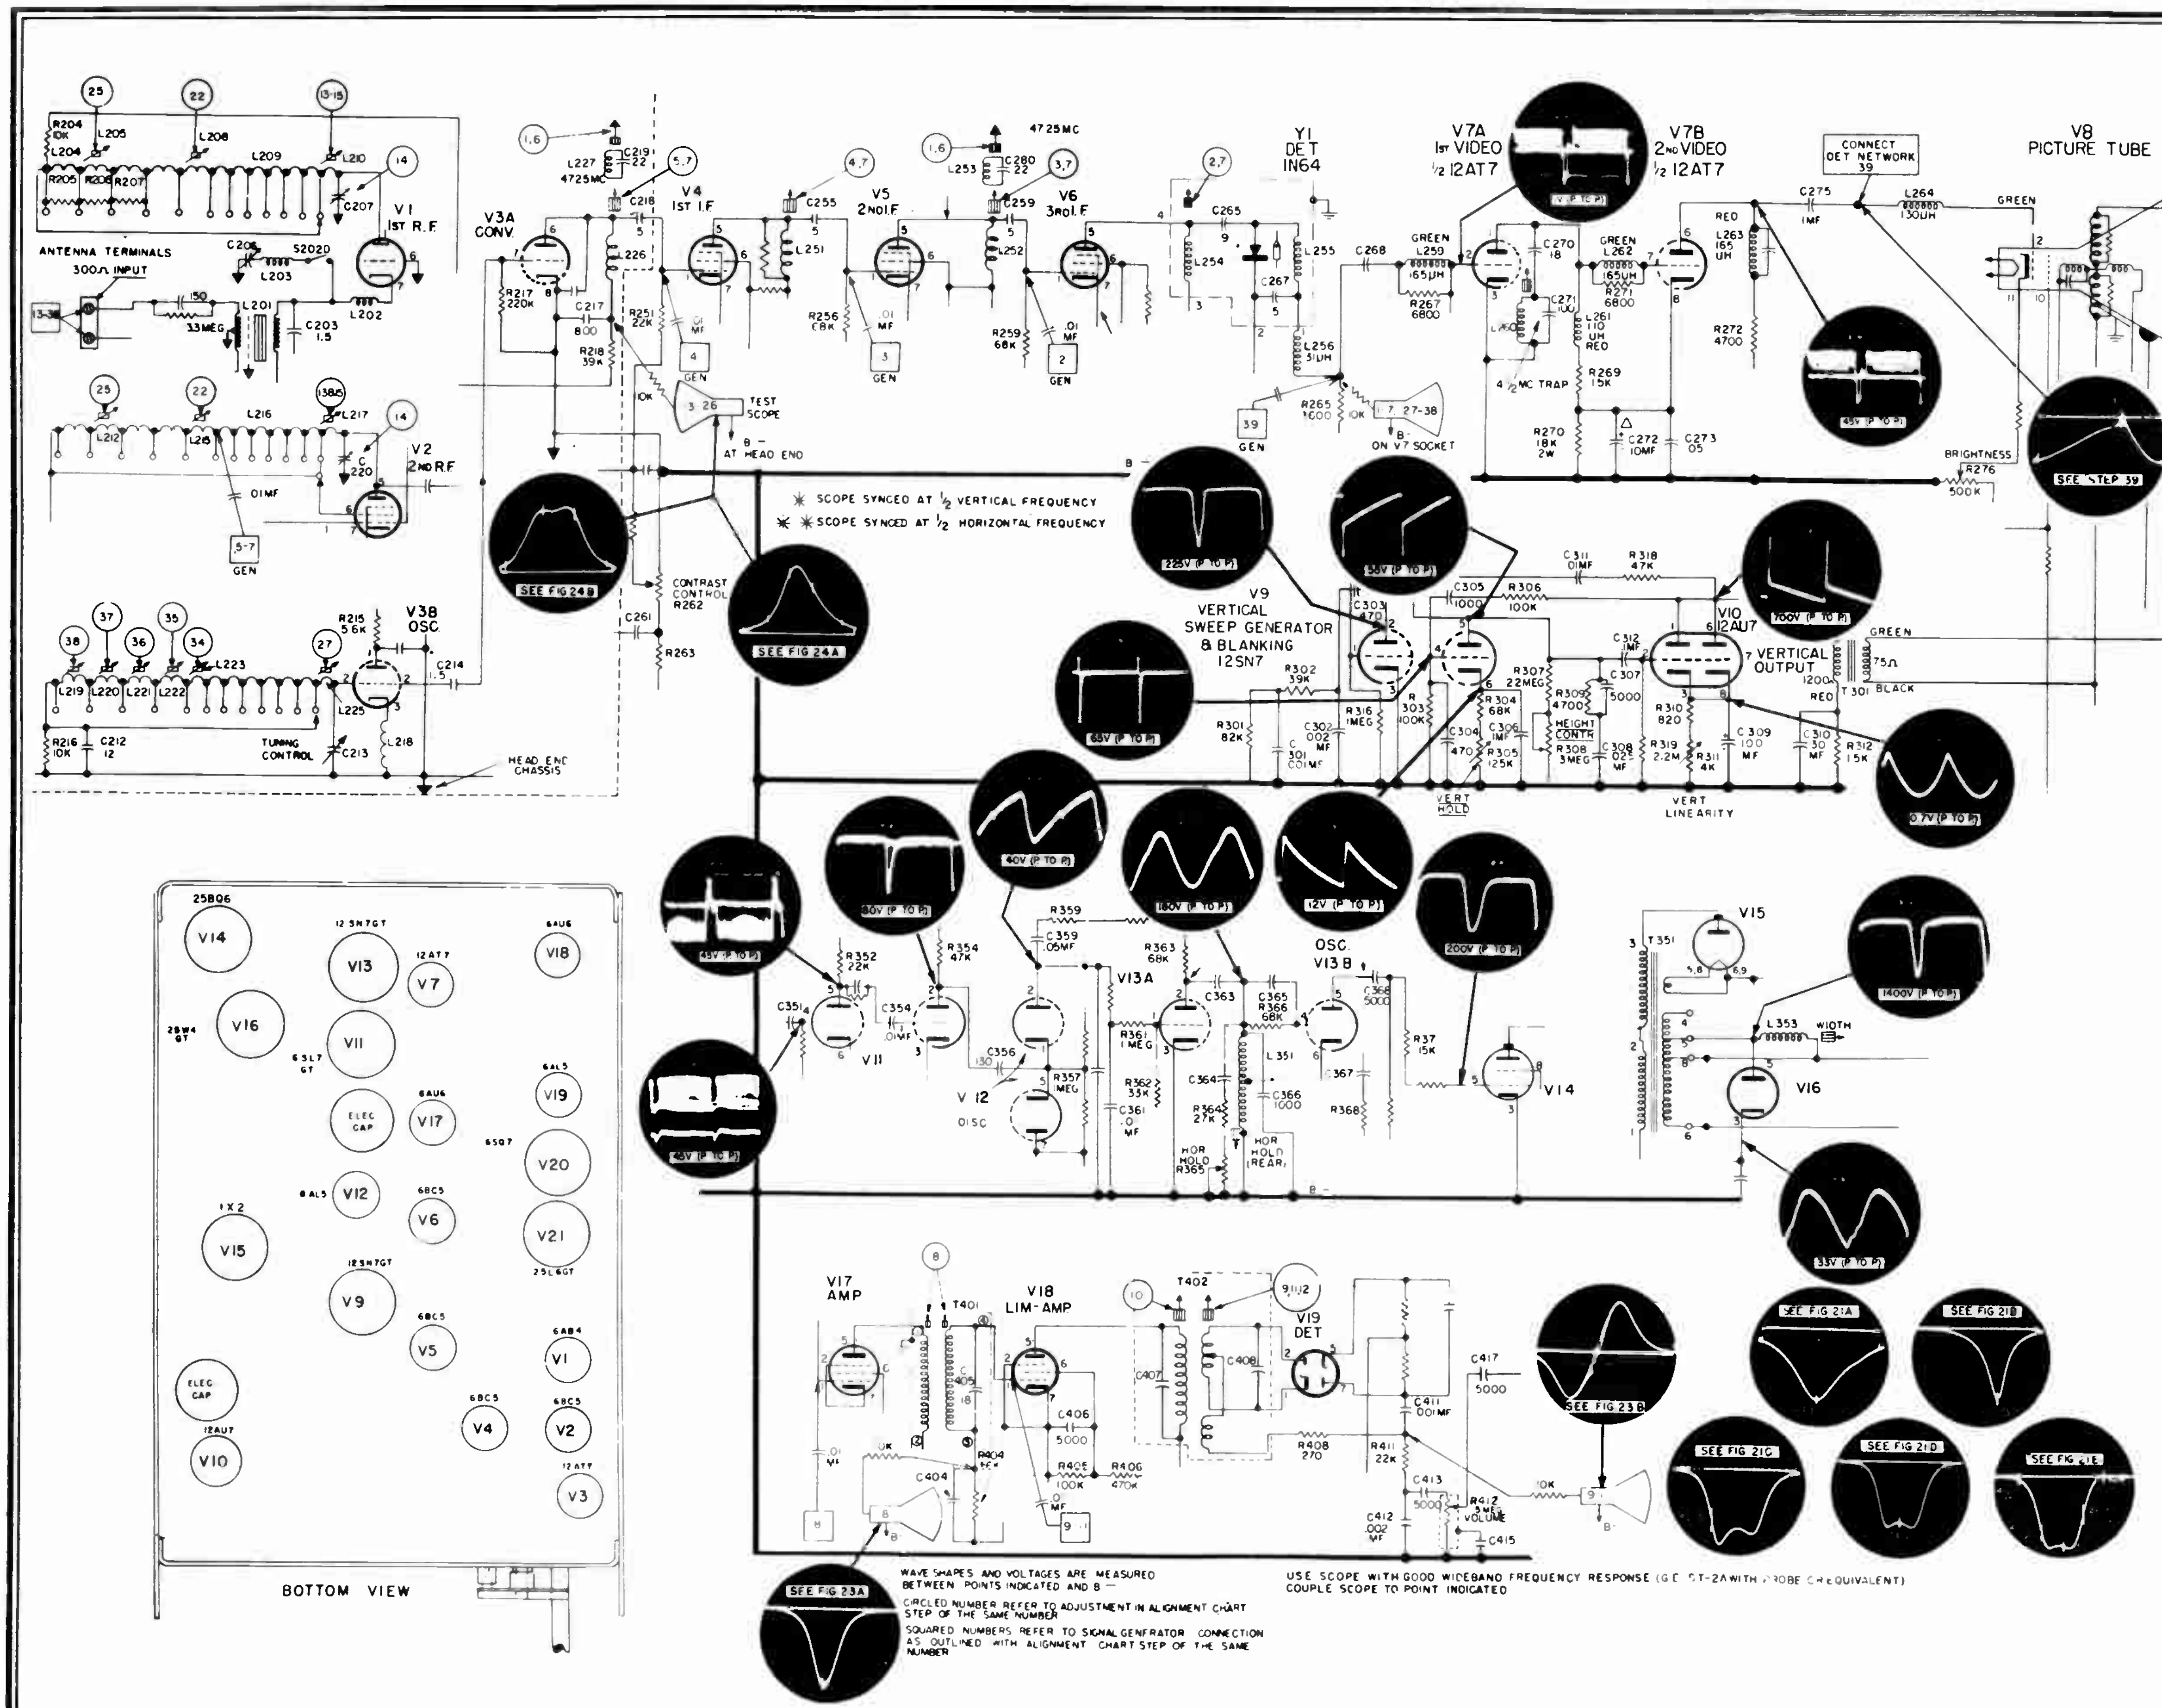

Fig. 29. Service Diagram

SERVICE DIAGRAM

The alignment procedure is shown in table form on pages 7 through 12. In order to accelerate the whole procedure, the service diagram (Figure 29) should be consulted. The encircled numbers indicate the number of the step of the alignment chart and the arrow points to the component to be adjusted. The generator is symbolized by a square with the number of the step of the alignment chart. The exact point of feed-in is indicated by the arrow connected with the numbered square. The oscilloscope is represented by the symbol of the cathode ray tube. The number inside the symbol refers to the step of the alignment chart. On the left side of the diagram is shown the tube location inside the chassis so that it is easy to locate the correct points for connection to the generator and the oscilloscope. In order to clarify the diagram only those parts of the circuits are shown which are needed for location of the test points. Within the large circles are shown the actual photo waveforms of an average television receiver, wherein the controls have been adjusted for a normal picture with correct height, width and linearity, and the picture control set for 1 volt peak to peak output of the waveshape shown at pin 2 of V7A. Waveshape voltages are peak to peak (P to P)—the asterisks note the following:

* Scope synced at 1/2 of vertical sweep frequency.
** Scope synced at 1/2 of horizontal sweep frequency.

Most measurements must be made when a signal is being received.

The oscilloscope of which the vertical amplifier has been precalibrated is used to make measurements at the point indicated by the arrow connected to the individual waveshape within the circle.

Alignment waveform photos are supplemented in graphic detail in the curves of Figures 21, 23 and 24. R-F alignment waveform photos are shown with markers at intervals of 4.5 megacycles.

CAUTION NOTICE

HIGH VOLTAGES ARE USED IN THE OPERATION OF THIS TELEVISION RECEIVER. THE BACK COVER, WHILE IN PLACE, PREVENTS ACCIDENTAL CONTACT WITH THESE HIGH VOLTAGES AND SHOULD NOT BE REMOVED EXCEPT BY A QUALIFIED TELEVISION TECHNICIAN.
THE PICTURE TUBE IS A HIGH VACUUM TUBE AND, IF IT IS BROKEN, PIECES OF GLASS MAY FLY WITH FORCE IN ALL DIRECTIONS. ANY WEAKENING OF THE GLASS, AS MAY BE CAUSED BY CHIPPING, SCRATCHING, OR MORE THAN NORMAL PRESSURE, MAY CAUSE THIS TUBE TO BREAK. THE USE OF SAFETY GLASSES IS RECOMMENDED WHEN IT IS NECESSARY TO REMOVE OR REPLACE THE PICTURE TUBE.

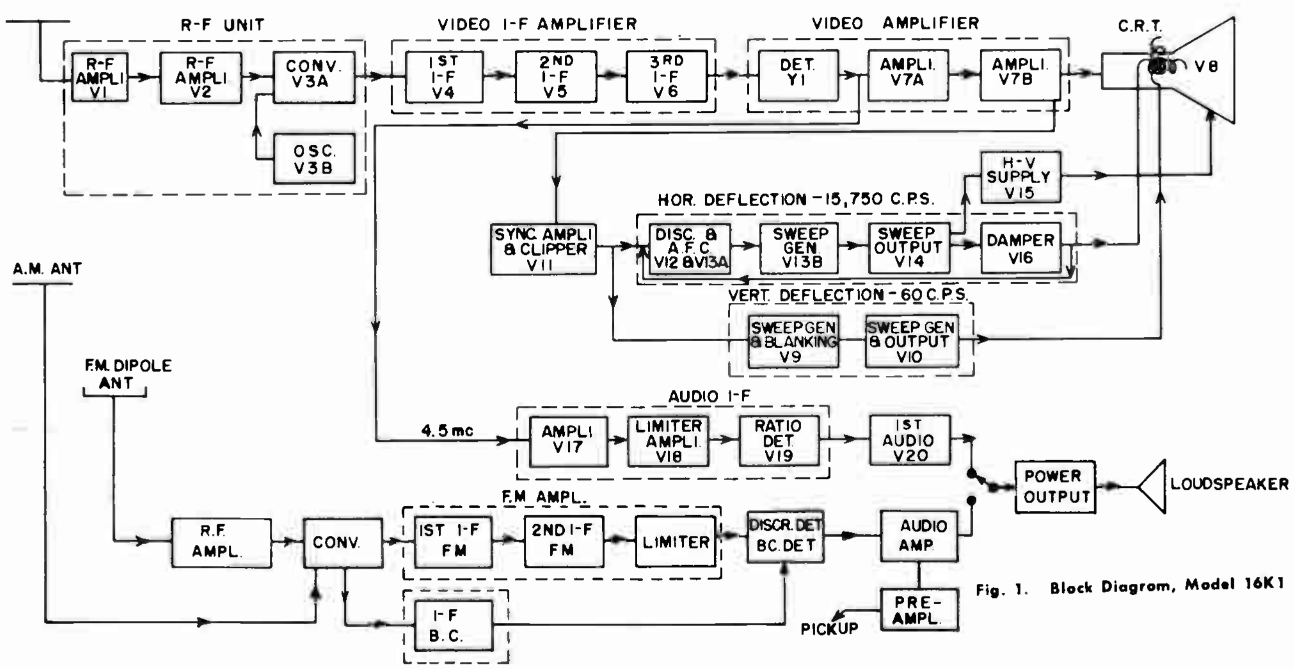

Fig. 1. Block Diagram, Model 16K1

GENERAL INFORMATION

The General Electric Model 16K1 is a television-radio receiver and phonograph, console type, 29-tube instrument providing reception of all 12 commercial television channels, radio reception in the AM and FM bands using a 752 radio chassis, and triple-speed phonograph operation (33 rpm, 45 rpm and 78 rpm) using the new General Electric Variable Reluctance Pickups. The television picture is reproduced on a 16-inch electromagnetically deflected picture tube. This receiver uses a P15 record changer to play 10-inch or 12-inch records intermixed or 7-inch records. The records with speeds of 33⅓, 45 or 78 rpm cannot be played intermixed.

The service information on the Model 16K1 record changer P15 is contained in ER-S-P15.

The instrument contains one television chassis, one radio chassis with loudspeaker which is used for both radio and television operation, and a record changer chassis with a two styli pickup head.

Features of this television receiver include a two stage r-f amplifier, balanced input to the r-f, selenium type rectifiers, intercarrier sound, ratio detector, safe high voltage supply for the picture tube, automatic frequency control for horizontal sweep synchronization and electromagnetic deflection.

The r-f tuner assembly is mounted on a separate chassis which is readily demounted from the main chassis. The coils which tune the 1st and 2nd r-f stages and the oscillator are mounted on individual wafers of the selector switch. The local oscillator V3B operates on the high frequency side of the incoming r-f signal. The picture carrier is converted to a 45.75 mc video i-f frequency, while the FM sound carrier is converted to a 41.25 mc frequency.

The video i-f is stagger tuned to pass the video i-f (45.75 mc) and the sound carrier (41.25 mc) with the proper amplitude relationship between the two frequencies. The video information is detected by the detector Y1 as well as a 4.5 mc FM signal which is the beat frequency between the video i-f (45.75 mc) and 41.25 mc.

The 4.5 mc audio FM is amplified and limited by V17 and V18 and detected by the ratio detector V19. The audio is amplified by V20.

The horizontal and vertical sync signals are taken off at the plate circuit of V7B and amplified and separated from the video signal by V11. The vertical sweep is generated by one section of a 12SN7 (V9) and a 12AU7 (V10) connected in a multivibrator circuit. The 12AU7 (V10) also serves as the vertical sweep output tube. The other section of the 12SN7 (V9) is used to produce the vertical retrace blanking signal. The horizontal sync signal is mixed with a sawtooth signal from the plate of the damper tube (V16) by the discriminator (V12). A change in phase between these two signals increases or decreases the bias voltage which is applied to the grid of V13A. V13A is a reactance tube which changes the frequency of the horizontal oscillator V13B. V14 the horizontal sweep output is coupled to the horizontal deflection coils by T351.

V15 is the high voltage rectifier for rectifying the kickback voltage, produced in T351 by the horizontal retrace current, to supply approximately 12 kilovolts to the picture tube high voltage anode.

This receiver uses two selenium rectifiers in a half-wave voltage doubler circuit to supply the B+ voltage of approximately 255 volts. The tube filaments are a series parallel connection across the 117 volt a-c line.

The television chassis and the radio chassis are connected by a push-button switch. To operate the television receiver, it is necessary to have the "ON" button depressed. The television sound portion is coupled from the television chassis to the audio amplifier of the radio chassis which is used to amplify the television sound. To operate the radio receiver, it is necessary to have the television "OFF" button depressed. The radio may then be turned on and operated on AM, FM or Phono. To turn this receiver off completely, the television "OFF" button must be depressed and the radio tone switch turned to "OFF."

INSTALLATION AND SERVICE ADJUSTMENTS

GENERAL—This receiver is equipped with a built-in television antenna giving good reception within the primary service area. Where reception is weak due to less favorable receiving conditions, an outdoor antenna is recommended. Since the receiver is designed with a balanced input of 300 ohms impedance, a 300 ohm transmission line should be used to connect the outdoor antenna to the receiver. When the external antenna system is connected to the dipole terminals, the built-in antenna connecting leads must be disconnected.

PREPARATION FOR USE—Remove receiver from carton and place the cabinet on its back and remove the shipping skids from the base of the cabinet. Remove the two screws (¼-28 and 10-32) which hold the record changer in position. Remove the block spacer underneath the record shelf and unpack turntable and spindle assemblies. After the turntable has been put in place, cut the rubber band which is tied around the control knob, thereby releasing the drive wheel and remove the rubber. Remove the two shipping bolts which hold the motor board tight for shipment. Small metal snap covers are provided to cover the holes exposed when the shipping screws are removed. They will be found in a small envelope in the phono compartment. A metal clip which clamps over the stylus of the pickup arm should be removed.

The receiver is shipped with the picture tube installed in place. Normally, it is not necessary to make any centering adjustments since a positive clamping mechanism has been employed to insure picture centering.

In case Installation Adjustments must be made, it is only necessary to remove the cabinet back, connect the antenna to the dipole terminals and connect input power to the interlock receptacle by way of a power cord terminated in a matching plug.

Make certain that the deflection yoke sets up against the bell of the picture tube. If this is not the case, loosen each deflection yoke clamp adjustment screw slightly and push yoke assembly against bell of tube.

OUTDOOR ANTENNA—The simple folded dipole will suffice in areas with medium signal strength. In fringe areas with weak field strength, a more elaborate antenna system must be installed. These high gain antennas are usually more directive which is desirable in many cases to reduce undesired signal or noise pickup.

ANTENNA PLACEMENT AND ORIENTATION—All television antenna systems have directional characteristics and their very location may have a pronounced effect upon the results obtained. Therefore, the antenna (or in case the built-in antenna is used, the receiver) should be turned in a horizontal plane for maximum signal pickup. Since nearby objects, especially those of metal may affect the picture, several antenna locations may have to be tried. Sometimes relocation of only a few feet may produce a great improvement.

GHOST RECEPTION—This name is given to a second picture image in various degrees of contrast and displacement from the main picture. A relocation of the antenna might drive out any ghost present. If the ghost images cannot be eliminated totally in this manner, a compromise in antenna orientation for maximum signal pickup and image rejection may be made without seriously impairing picture quality.

LIGHTNING PROTECTION—The outdoor antenna installations must conform to the National Electrical Code Standards which are usually supplemented by Local Code requirements. When installing the antenna, observe the following rules:

1. The metal mast supporting the antenna should be permanently and effectively grounded by a wire of a size specified in the codes.
2. An approved lightning arrester must be used with the antenna lead-in conductors at the point of entrance to the building. If a shielded lead-in cable is used, the shield may be permanently grounded instead of using the lightning arrester.

ADJUSTMENT PROCEDURE

It will be noted that some adjustments react upon each other and therefore should be adjusted alternately and as a final step all adjustments should be rechecked.

Power should not be applied to the receiver for any great length of time without the ion trap adjusted for some illumination.

The ion trap, deflection yoke, focus coil and the installation adjustment controls are adjusted in the procedure given below. These are described in greater detail under their respective titles immediately following this procedure.

1. Adjust ion trap to get brightest raster.
2. Adjust for no tilt of raster and tighten yoke clamp screws.
3. Tune in a television signal.
4. Adjust Horizontal Hold controls.
5. Adjust Drive control.
6. Adjust for good Horizontal and Vertical linearity.
7. Adjust Horizontal and Vertical size controls.
8. Adjust Focus coil for centering of test pattern, removal of neck shadow and for most uniform focus.
9. Readjust ion trap.
10. Recheck adjustments of steps 6, 7, 8 and 9.
11. Tighten Focus Coil adjustment screws and wing nuts.

©John F. Rider
World Radio History

ION TRAP—Power should not be applied to the receiver for any great length of time without the ion trap adjusted for some illumination. Set the Brightness control to maximum (clockwise). To adjust ion trap, rotate the trap on the neck of the tube and move it forward and backward to give maximum brightness. Reduce the picture Brightness during ion trap adjustment, if raster becomes too bright as maximum brightness with the trap is approached. Always make certain the ion trap is finally set to give maximum brightness of the raster.

PICTURE TILT—If the picture or raster does not lie squarely within the picture tube mask, loosen one of the Yoke Adjustment Clamp screws and by grasping the Picture Tilt Lever, turn lever to rotate yoke until picture or raster squares with the mask. Tighten the yoke clamp screws after squaring picture with mask.

HORIZONTAL HOLD—Set the front panel Horizontal Hold control (R381) to the center of its range. Adjust the core of the Horizontal Hold control (L351) at the rear of chassis, until the picture is synchronized and is phased at the center of the raster—a slight rotation of the front panel control in either direction will move the picture slightly to the left or right without losing synchronization.

The pull-in to synchronization range should be equally distributed each side of the front panel Horizontal Hold control's center range and may be checked with the control set at center, observing the pull-in to synchronization sensitivity as the Channel Selector switch is flipped alternately back and forth from the received channel to an adjacent channel having no signal. For any other setting of the front panel Horizontal Hold control, the pull-in to synchronization time will be longer.

HORIZONTAL DRIVE—Adjust the Horizontal Drive control (R369) for optimum drive indicated by a maximum width of picture.

If any compression of picture is noted on the right-hand side of the raster, the condition may be corrected by a slight decrease of drive (clockwise rotation). If a vertical beaded line appears in the picture at this setting, a further clockwise adjustment should be made to eliminate it.

HORIZONTAL LINEARITY—The Horizontal Linearity control (L352) adjusts the picture for correct horizontal proportions. For best adjustment, use a test pattern and adjust the Horizontal Linearity control until the distances from the center of the test pattern to the left- and right-hand edges of the test pattern measure approximately the same. The adjustment of this control is very broad and it should be made simultaneously with the adjustment of the Width control (L353) to get proper picture width and correct horizontal linearity.

VERTICAL LINEARITY—This control (R311) should be adjusted to give best symmetry to the test pattern for correct vertical proportions in the picture. The adjustment should be made on a test pattern so that the distances from the center to the top and bottom edges of the test pattern measure approximately the same. This adjustment will alter the height of the picture slightly.

WIDTH—Adjust the Width control (L353) so that the edges of the picture extend approximately one-eighth inch past the right- and left-hand edge of the mask so that raster edges are not visible.

HEIGHT—The Height control (R308) changes the picture height and should be adjusted so that the picture extends approximately 1/8 inch beyond the top and bottom edges of the mask. This adjustment should be made simultaneously with the Vertical Linearity control (R311).

FOCUS COIL ADJUSTMENT—The Focus coil bracket adjustment screws and the swivel wing nuts are loosened in preparation for adjustment of the focus coil. These should not be too loose but should allow movement of the coil and yet retain each new position of coil adjustment.

The focus coil and bracket may be moved up and down, to the right or left, or the coil may be tilted in any direction by the swivel mounting. In addition, the coil may be moved forward or backward.

Adjust position of the focus coil to center picture test pattern within picture tube mask and to eliminate neck shadow. The focus coil should be as far back toward the base of the picture tube as possible, for best focus consistent with maximum picture brightness.

PICTURE TUBE AND CHASSIS REPLACEMENT

1. The deflection yoke clamp screws and focus coil adjustments should be loosened before attempting to install the picture tube—this will prevent any strain upon the tube neck when positioning and fastening the tube later.

2. Install the picture tube as shown in Figure 2. The bottom rim of tube should be forward against rubber stop on chassis front apron.

3. Place picture tube strap around rim of tube, inserting the picture tube support bracket between tube rim and strap as shown in Figure 2. Center tube approximately with regard to front of chassis and install tube strap mounting nuts to hold tube lightly.

4. Place chassis and tube into the receiver cabinet, repositioning tube support bracket to fit over stud screws in top corners of cabinet, making sure that chassis is pushed forward against cabinet.

5. Install chassis mounting screws and tighten to fasten chassis securely.

6. Move picture tube if necessary to center tube in mask, as viewed from front of the cabinet.

7. Tighten tube strap mounting nuts, accessible from bottom of cabinet.

8. Install spacer and 1/4 inch-20 hex nut over picture tube support bracket screws and tighten to hold brackets securely to cabinet.

9. Push deflection yoke forward to set against bell of picture tube and tighten yoke clamp screws.

10. Connect picture tube socket to base of tube and high voltage lead to anode connection.

11. Install control knobs.

HIGH CHANNEL TRAP—This receiver incorporates a trap circuit (C206, L203, S202D) on the head-end unit which is switched into the antenna circuit on the low band channels. The trap may be used to eliminate any one of the following high channel interferences on the corresponding lower channel shown.

Operating Channel	Interfering Channel
No. 4	No. 8
No. 5	No. 11
No. 6	No. 13

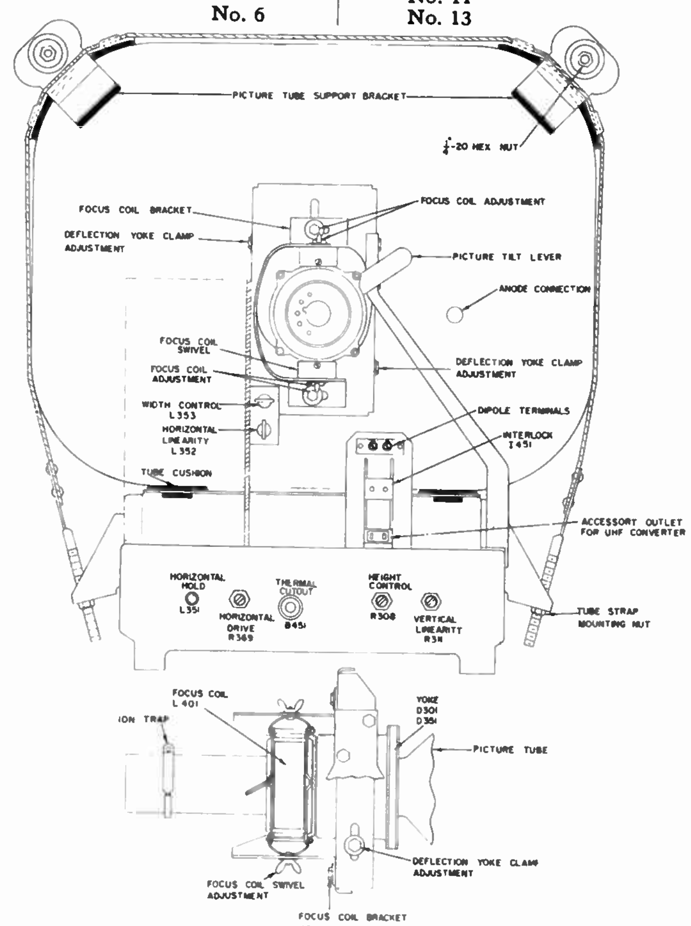

Fig. 2. Preset Controls

The receiver is adjusted at the factory approximately for rejection of Channel #11 interference on Channel #5. It may be necessary to readjust the trap slightly, if Channel #11 interference is experienced when operating the receiver on Channel #5.

High channel interference manifests itself as horizontal bars, a herringbone pattern in the picture, or the high channel station picture superimposed upon the low channel picture for which the receiver has been tuned.

If none of the above combinations of channels exist in the locality where the receiver is to be used, the trap need not be adjusted.

THERMAL CUT-OUT—This is a protective device, which operates in a similar manner to a fuse, removing line voltage from the receiver in case of excessive current drain due to circuit overload. A five minute period should be allowed after the cut-out has tripped, before depressing the reset button to restore power to the receiver. If the receiver does not return to normal operation within a reasonable warm-up time after the cut-out has been reset, a check-up of the receiver circuit should be made to determine the cause of overload.

PICTURE DEFECTS

Fig. 3 Normal picture.

The following illustrations show picture defects which are caused by incorrect setting of operating controls, the preset controls or by interference picked up by the antenna. A possible remedy is indicated for each defect.

The adjustment of controls is most efficiently accomplished by the use of a test pattern, similar to that illustrated to the left, which is normally transmitted just prior to the scheduled program.

The normal picture should show good focus and a good contrast between blacks and whites with intermediate shades of gray. The picture should not tend to move either vertically or horizontally and should have good linearity.

PICTURE	DEFECT	REMEDY
	**Fig. 4 Picture too light.**	1. Increase Picture control setting and/or reduce brightness. 2. Weak signal. This may be caused by insufficient pickup on antenna or defective lead-in. Insufficient pickup at maximum contrast usually is accompanied by "snow" on the picture.
	**Fig. 5 Picture too dark (contrast).**	1. Reduce Picture control setting and/or increase Brightness control setting. 2. Too strong signal. If it is not possible to reduce signal adequately with Picture control, install suitable resistor antenna pad.
	**Fig. 6 Picture defocussed.**	1. Adjustment of front panel focus control, R435. 2. Check for uniformity of focus by moving focus coil (see Installation Adjustments, page 3). 3. Mistuning of receiver or misalignment.
	**Fig. 7 Horizontal sync.**	1. Adjust Horizontal Hold control (front panel control). 2. Check adjustment of rear panel Horizontal Hold control. 3. Signal improperly tuned. 4. Defective horizontal sync circuits.
	**Fig. 8 Vertical sync.**	1. Adjust Vertical Hold control until picture shows no tendency to slide up or down or lock out of frame. 2. Check the vertical sync circuits.
	**Fig. 9 Vertical linearity.**	Adjust Vertical Linearity control. This adjustment may alter the Height control adjustment.

PICTURE DEFECTS (Cont'd)

PICTURE	DEFECT	REMEDY
	**Fig. 10** **Vertical height.**	Adjust Height control so that the top and bottom picture edges are just covered by mask Recheck Vertical Linearity control setting.
	**Fig. 11** **Picture too wide.**	Adjust Width control so that the right and left picture edges are just covered by the mask.
	**Fig. 12** **Horizontal linearity.**	1. Adjust Horizontal Linearity control. This adjustment may require resetting of Width control. 2. Adjust Drive control as described under Installation Adjustments, page 3.
	**Fig. 13** **Neck shadow.**	1. Misadjustment of Focus coil—tilted too far. 2. Move the deflection yoke forward against the bell of the picture tube.
	**Fig. 14** **Herringbone pattern over picture.**	This interference is caused by a television station operating on the next lower channel or by short-wave radio transmitting and receiving equipment. Police and "ham" transmitters in your locality will usually cause the most severe conditions. The interference produces moving ripples or diagonal streaks, or in some cases, may cause loss of contrast of the picture. The use of an antenna wavetrap tuned to the interfering signal may assist. If the interference is from a TV or FM station, a transmission line shorted stub may remove the interference. If the pickup is on the lead-in, a shielded lead-in will help correct the trouble. See page 3 for high channel trap adjustment.
	**Fig. 15** **Horizontal bars on picture.**	This interference is caused by adjacent channel sound or microphonics in receiver. If adjacent channel sound is responsible for this defect, readjust the adjacent channel traps L227, L253 as outlined on page 8. A microphonic video amplifier tube, V7, may cause this condition.
	**Fig. 16** **Ignition interference**	Ignition interference from trucks, automobiles, and airplanes may be identified by black or white streaks and splashes on the picture. The ignition system of trucks will produce the most intense interference pattern. Install antenna away from road carrying traffic. Shielded lead-in may help if interference is picked up on it.
	**Fig. 17** **Multiple images (ghosts).**	This is caused by the television signal following multiple paths, one of which is the direct path, and the other is reflected from some object such as a tall building or a large storage tank or hills. The signal following the longer reflected path arrives later at the receiver producing the second image. In case a built-in antenna is used, try to turn the cabinet until the ghost picture is dimmed out. If your receiver is connected to an outdoor installation, a reorientation of the antenna might improve the reception.
	**Fig. 18** **"Snow."**	1. Too weak signal; increase efficiency of antenna installation. 2. Adjust tuning control.

CIRCUIT ALIGNMENT

TO PROTECT TEST EQUIPMENT ALWAYS USE AN ISOLATION TRANSFORMER

GENERAL

A complete alignment of the receiver tuned circuits is given in the following charts. Read all alignment notes before making an alignment. The alignment procedure described follows the sweep method using General Electric test equipment. When other test equipment is used, check that they meet the different requirements for proper alignment. Suitable test equipment is essential for proper alignment of the receiver and under no circumstances try to align with inadequate test equipment. For a detailed discussion of this problem, refer to our publication Television Principles and Practice, Chapter 14. In order to speed up the alignment procedure, it is advisable to use the service diagram, Figure 30, page 15, and the tube and trimmer location, Figure 22, page 9.

In connecting the test equipment to the points indicated on the charts, make the leads as short as possible. This is particularly necessary of the ground leads of the test equipment which should be connected to the B— bus of the receiver.

Always allow test equipment and receiver to warm up for at least 15 minutes before starting the alignment.

It is often advisable to perform the alignment with the picture tube removed. The filament circuit can be completed by using a Type 6SN7 tube with all pins clipped off except pins No. 7 and No. 8 which must be plugged into No. 1 and No. 12 of the picture tube socket.

TEST EQUIPMENT

The following test equipment is necessary in order to effect alignment of the tuned circuits of the receiver:

1. *R-F SWEEP GENERATOR.*

(G-E Type ST-4A or Equivalent)

a. Frequency Requirements:
4.5 MC with 500 KC and 2 MC sweep width.
40–50 MC with approximately 10 MC sweep width.
50–90 MC, 170–220 MC with 15 MC sweep width

b. Constant output in the sweep range.

c. Minimum output 0.1 volt.

2. *MARKER GENERATOR.*

(G-E Type ST-5A or Equivalent)

The marker generator must have good frequency stability, accurate calibration and must cover the following frequencies:

a. 41.25 MC for video IF
42.50 MC for video IF
44.20 MC for video IF
44.50 MC for video IF
45.00 MC for video IF
45.75 MC for video IF
47.25 MC for video IF

b. 4.5 MC for sound IF and trap alignment.

c. Picture and sound carrier frequencies for Channel No. 2 through No. 13.

3. *BALANCED OUTPUT ADAPTER.*

(G-E ST-8A or Equivalent)
See RF Alignment, note 1.

4. *OSCILLOSCOPE.*

(G-E Type ST-2A or Equivalent)

The oscilloscope should have good sensitivity and preferably a 5-inch screen with a good wide-band frequency response on the vertical deflection circuits. Although the high frequency response is not necessary for alignment, it is imperative when making waveform measurements.

5. *VACUUM TUBE VOLTMETER.*

A vacuum tube voltmeter (VTVM) is necessary to measure the bias of 2.7 volts required for video and RF alignment.

6. *DETECTOR NETWORK.*

A crystal detector network as shown in Figure 27 is necessary when aligning the 4.5 mc trap, L260.

7. *MISCELLANEOUS.*

a. One 10,000 ohm resistor to isolate the scope as noted in the charts.

b. One 1000 mmf. mica &.01 mf. capacitors for isolation of sweep generator.

c. One 680 ohm resistor for IF coil shunt (RF alignment).

d. One 400 mf. electrolytic capacitor, 350 volt for reducing hum (RF alignment).

e. One 100 ohm resistor for reducing hum (RF alignment).

f. Impedance matching pad for RF alignment as shown in Figure 28.

g. Bias battery to supply —2.7 volts as noted for Video IF and RF Alignment.

World Radio History

VIDEO I-F ALIGNMENT

NOTES:

1. The sweep generator should be properly terminated in its characteristic impedance. Couple the signal to the input point through a 1000 mmf. mica capacitor and adjust signal input to give a video response curve of ¾ volt as shown in Figure 21.

2. Connect a bias battery from junction of C261, R263, and the picture control R285 to B− with the positive side of the battery connected to B−. Adjust picture control to give a −2.7 volt bias at the grid pin 1 of tube V4 measured with a VTVM. Disconnect its leads during alignment.

3. The traps L227 and L253 must be detuned before aligning the video i-f amplifier by turning the cores all the way out of the coil. When retuning these traps to 47.25 mc (as in step 6), for minimum amplitude, increase scope gain as amplitude at 47.25 mc marker point is attenuated, to provide optimum setting.

4. Set channel switch to Channel 2 or 3 and check for oscillator influence by turning the tuning control. If response curve is affected, switch to another channel where oscillator influence is absent.

5. In general, it is only necessary to perform an over-all alignment of the video i-f, as in step 7 of the Video Alignment Chart, in order to obtain i-f response curve of Figure 21-E.

When aligning the i-f coils, L251 will adjust the audio or low frequency side of the i-f response curve, while L252 will adjust the video or high frequency side of the i-f response curve. L226 and L254 should be adjusted simultaneously to reduce the saddle-back at the peak of the curve and to give maximum gain and retain 45.75 mc and 42.50 mc markers at the 50% mark.

6. It is necessary to detune the i-f coils by shorting as noted in the alignment chart to prevent the coil preceding the signal input point from influencing the response curve.

7. It is important that the 45.75 mc marker should fall at the 50% response point to give proper curve of Figure 21-E.

8. After adjustment of the two sound traps, readjust the i-f curve to obtain the proper response curve as illustrated in Figure 21-E.

VIDEO I-F ALIGNMENT CHART

Step	Marker Generator Frequency	Sweep Generator Frequency	Signal Input Points Between	Connect Oscilloscope Between	Adjust	See Note No.
1	—	—	—	—	Detune L227 and L253 by turning cores out of coil.	3
2	44.50 MC	40–50 MC	Point B (Fig. 31) V6 grid (pin 1) thru 1000 mmf. mica cap. and B − on head-end shield; short L252.	Point A (Fig. 31) Junction L256, R265, C268 thru 10K ohms and B − on V7 socket.	Core of L254 for curve of Fig. 21-A.	1, 2, 4, 6
3	45.75 MC		Point C (Fig. 31) V5 grid (pin 1) thru 1000 mmf. mica cap. and B − on head-end shield. Short L251. Remove short on L252.		Core of L252 for curve of Fig. 21-B.	
4	42.50 MC, 45.75 MC		Point D (Fig. 31) V4 grid (pin 1) thru 1000 mmf. mica cap. and B − on head-end shield. Short L226. Remove short on L251.		Core of L251 for curve of Fig. 21-C.	
5	44.2 MC		Point E (Fig. 31) Junction L215 and L216 on second RF switch wafer thru 1000 mmf. mica cap. and B − on head-end shield. Remove short on L226.		Core of L226 for curve of Fig. 21-D.	1, 2, 3, 4, 7
6	47.25 MC				Cores of L227 and L253 for min. output at 47.25 MC (Fig. 21-E).

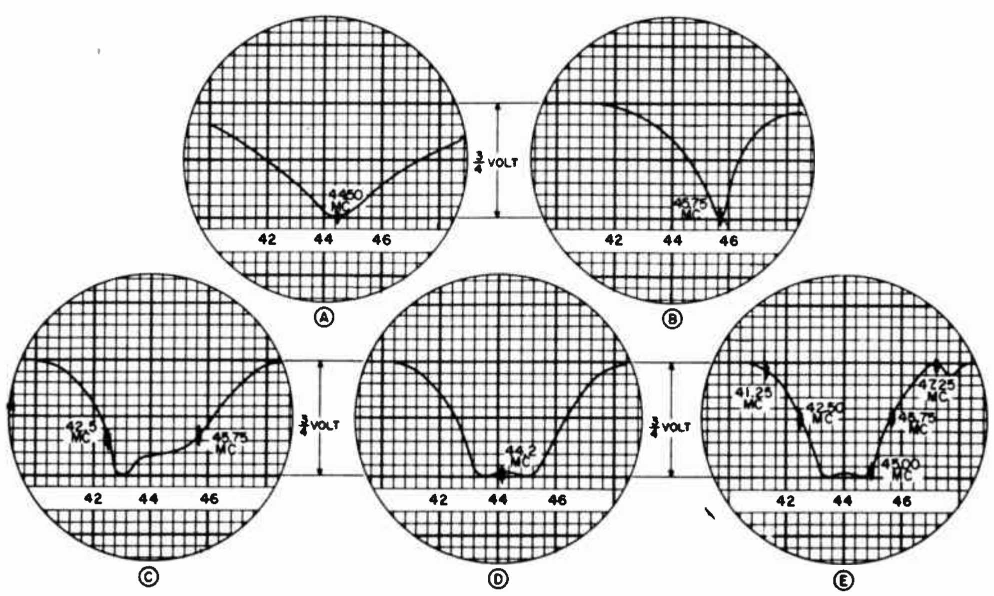

Fig. 21. Video I-F Curves

AUDIO I-F ALIGNMENT

1. Feed a 4.5 mc signal with a 500 kc sweep and adjust for proper response curve as indicated in the chart.

2. Transformer T401 is adjusted for maximum amplitude and symmetry of the response curve about 4.5 mc marker (Figure 23-A).

3. The secondary of T402 is adjusted for curve, Figure 23-B. This adjustment should give as straight a slope as possible between the positive and negative peaks with the center of the 4.5 mc marker falling midway between the peaks.

4. The primary of T402 is adjusted for maximum of the positive and negative peaks. If necessary, readjust the secondary of T402 so that the marker falls midway between the peaks.

5. Keep the input signal of the sweep generator low enough so that limiting does not take place, otherwise the response curve will broaden out, preventing correct adjustment. Check by increasing the output generator: the response curve should increase in amplitude.

6. As a final check (step 12), readjust the secondary of T402 for minimum buzz on all available stations.

7. An alternate method to the visual alignment is the sound output method using an operating television station, preferably when transmitting tone modulation during test pattern transmission.

a. Tune the receiver for best detail.

b. Set the picture control to give reduced contrast or by using a resistor pad in the antenna circuit.

c. Adjust transformer T401 and primary of T402 for maximum sound output.

d. Adjust the secondary of T402 for best quality audio reception and for minimum buzz in the output.

World Radio History

R-F ALIGNMENT

1. Disconnect the transmission line to the antenna from the head-end. Couple the input of the sweep generator to the head-end terminals through balanced output adapter G-E ST-8A, or equivalent. Couple this to the head-end terminals through a piece of 300-ohm transmission line. Terminate the 300 ohm line in a pad, as shown in Figure 28-A.

If a balanced output is not available for the sweep generator a matching network as shown in Figure 28-B may be used. A balanced output is recommended since a matching network as shown in Figure 28-B may introduce frequency shift and cause a misleading tilt to the response curve.

Ro shown in Figure 28-B is the terminating resistor. If this resistor is not already incorporated in the output of the sweep generator, it should be added to the matching network as shown.

2. It is necessary to connect a bias battery from the junction of the picture control, C261, and R263 to B− with plus of bias battery to B−. Adjust the picture control to give a −2.7 volts bias measured from pin 1 of V2 to the head-end chassis B−.

3. Shunt L226 with a 680 ohm, ½ watt resistor during r-f alignment to prevent the oscillator from influencing the response curve. To reduce the effect of hum on the response curve, connect a 100 ohm resistor between the head-end B+ and the chassis B− and connect an electrolytic capacitor of approximately 400 mf., 350 volt from head-end B+ to head-end B−.

4. On all channels the picture carrier marker should not be less than 75% of the peak of the r-f response curve. The sound carrier marker should not be less than 50% of the peak of the response curve. On the high channels the picture carrier marker should ride up nearer to the top of the curve provided the sound carrier marker does not go below 50%. On the low channels the picture carrier marker should ride as high up on the curve as possible and still keep the sound carrier marker above 50%.

5. Coils for Channels #12 through #7 are fixed inductances. Check the alignment on these channels as in steps 16 through 21 for proper response curve. Readjust L210 and L217 on Channel #13 and C207 and C220 on Channel #7 if necessary.

6. Coils for Channels #5 and #4 are fixed inductance. Check the alignment on these channels for proper curve. Readjust coils L208 and L215 to give proper curve on Channels #6, #5, and #4.

7. The coil for Channel #2 is a fixed inductance. Check the alignment on this channel for proper curve. Readjust L205 and L212 to give proper curve on Channels #3 and #2.

8. The trimmers C207 and C220 may be used to compensate for differences in tube capacities which affect tracking when it is necessary to change the tubes V1 or V2. The variation in tube capacities has normally little effect on the over-all performance of the head-end.

R-F ALIGNMENT CHART

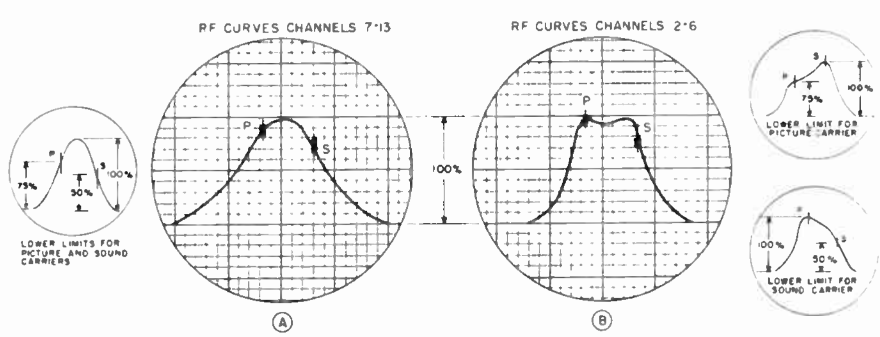

Fig. 24. R-F Alignment Curves

OSCILLATOR ALIGNMENT

Before attempting this oscillator alignment, it must be certain that the video i-f stages and r-f stages are properly aligned as outlined previously.

1. Disconnect the 300 ohm line from the r-f head-end terminals and connect sweep generator to head-end properly terminating sweep generator output cable as shown in Figure 28. See RF Alignment Note 1.

2. Alignment is made by viewing the response curve at the output of the video i-f detector.

3. Use a video carrier marker as shown in each step of the Alignment Chart.

4. Set the tuning control C213 at the center of its rotation. Adjust L225 to place the video carrier marker at the 50% point on the high frequency slope of the curve for step 28. The oscillator inductance L224 for Channels #12 through #7 is fixed. The alignment on these channels is checked to see that the picture marker falls at the 50% point on the high frequency slope of the curve. If the picture marker position does not meet these conditions, it is necessary to readjust L225 for a compromise on Channels #13 through #7. The tuning range of C213 on Channels #13 through #7 should be sufficient to move the video carrier marker up and down the entire high frequency side of the response curve. Readjust L225 if necessary.

5. On Channel #6 through #2 set the tuning control C213 at the center of its rotation and make the indicated adjustment so that the video carrier marker falls at the 50% mark on the high frequency slope of the response curve.

ADJUSTMENT OF VIDEO AMPLIFIER 4.5 MC TRAP (L260)

NOTES:

This trap is used to remove 4.5 mc audio i-f from the video amplifier which shows up in the picture as a cross-hatch pattern. This trap will very rarely require adjustment. Adjustment is as follows:

1. The trap (L260, C271, C270) is adjusted for minimum amplitude of the 4.5 mc marker. Use a detector network as shown in Figure 27 connected from junction of L264 and C275 to B− to detect the signal.

2. Adjust the vertical hold control to remove the vertical pulses from the response curve.

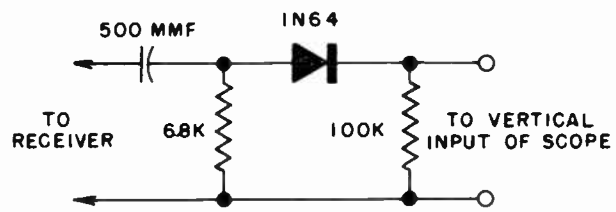

Fig. 27. Detector Network

4.5 MC TRAP (L260) ALIGNMENT CHART

Step	Marker Generator Frequency	Sweep Generator Frequency	Signal Input Point	Oscilloscope	Adjust	See Note
39	4.5 MC	4.5 MC ±1 MC	Point A (Fig. 31) Junction L256, R265, C268 and B− thru .01 mf.	Across 100K resistor as shown in Fig. 27. (See Note 1.)	L260 for min. amplitude of 4.5 mc marker. Increase scope gain as amplitude at 4.5 MC is attenuated.	1, 2

TROUBLE SHOOTING

This trouble shooting chart is divided into sections for quick trouble shooting. In most cases a trouble may be localized by noting the condition of the picture or test pattern and the presence or absence of sound.

In general, the tubes in the defective circuit should be checked first since they are fairly easy to check. When substituting tubes in the RF or video IF circuits, the original tube should be replaced in the socket if it is found not to be defective. When a tube is replaced in the video IF or RF circuits, alignment should be checked.

The block diagram (Figure 1), the waveforms of the service diagram (Figure 30), and the socket voltage and resistance diagram (Figure 32) may be used to isolate defective RF, video IF or audio IF stages by checking for the response curves as given in the alignment procedure.

DEFECTS OF THE R-F AND I-F CIRCUITS

A. No Picture, No Sound, Raster Normal.

1. Check the R-F head-end circuits of V1 and V2.
2. Check to see that local oscillator, V3B, is operating properly.
3. Check Video I-F amplifier circuits of V4, V5 and V6.
4. Check crystal detector, Y1.
5. Check channel switch.

B. Snow in Picture.

1. Open input circuit in C278, C279 or L201.
2. Defective antenna installation or transmission line.
3. Antenna orientation.

C. Lack of Picture Detail (Focus Satisfactory).

1. Misalignment of Video I-F.
2. Misalignment of R-F amplifier.
3. Mismatch of input impedances at antenna input terminals of receiver.
4. Overloading of r-f stages.

D. Motorboat or Flutter in Picture and Audio.

1. Open by-pass, C251.
2. Open filament by-passes C222, and C458.
3. Misalignment of video I-F and R-F amplifiers.

E. Wiggles in Picture Background, Trailing Whites on Picture, Sound Normal.

1. Misalignment of R-F and I-F amplifiers.
2. Improper tuning of receiver.

F. Sound Bars in Picture (Black Horizontal Bars).

1. Microphonic tubes, V3, V4, V7 or picture tube V8.
2. Misalignment of adjacent channel sound traps, L227, L253.

DEFECTS OF THE VIDEO AMPLIFIER

A. No Picture, Sound Satisfactory, Raster Satisfactory.

1. Open chokes L261, L263, L264.
2. Shorted capacitor C270, C272, C273.
3. Open capacitor, C268.
4. Open resistors R269, R272.
5. Short from pin 2 to pin 11 of V8 picture tube.

B. Poor Low Frequency Response (Trailing Whites after Black).

1. Low value of resistors R269, R272, R265.
2. Low capacity or open capacitor C272.
3. Low capacity of C268, C275.

C. Lack of Picture Detail, Focus Satisfactory (Smearing of Vertical Wedges of Test Pattern).

1. Shorted chokes L259, L261, L262.
2. Open chokes L259, L262.
3. High resistance of R272, R269, R265.

D. Bright Picture with Black Lines.

A shorted capacitor C275 will give a very bright picture with black lines across the picture. The picture control will have no effect.

E. Picture Distorted at High Settings of Picture Control.

Check for high resistance of R273.

DEFECTS OF THE SYNC SECTION

A. No Vertical Sync, Horizontal Sync Satisfactory.

1. Check waveform of sinc input, V9 pin 5.
2. Check C303, R301, R302, C301 for leakage or shorted.
3. Check components C306, R304, R305.
4. Check for leakage of C305.

B. Weak Vertical Sync, Horizontal Sync and Picture Normal.

1. Leakage or low value of capacitor of C303.
2. Leakage of C301, C302 or incorrect values.
3. Check frequency determining components C306, R304, R305 for exact value.

C. Weak or no Vertical and Horizontal Sync, Picture Information Present and Sound Normal.

1. Check waveform at pin 4 of V11 for proper waveform from video amplifier.
2. Improper B+ voltage on V11.
3. Incorrect value of R354.
4. Open or low capacity of C351.
5. Defective coupling capacitor C353, C354.

D. Weak or no Horizontal Sync, Vertical Sync Satisfactory.

1. Check waveform at pin 2 of V12.
2. Check sweep frequency determining components L351, C366, C364, R381, R364.
3. Check for leakage in V12 components, C356, C357, C360, C358.
4. Check for proper value of resistors R356, R357, R358, R361.
5. Check C359, R359 and R360 in the feedback circuit.
6. Check coupling between V13A and V13B (C363, C365, R366).

DEFECTS OF THE VERTICAL SWEEP

A. Keystoning (Picture Narrows at Top or Bottom).

1. Defective vertical deflection coil, D301.
2. Check R314, R315.

B. No Vertical Deflection (Single White Horizontal Line on Screen).

1. Open deflection coil, D301.
2. Defective sweep output transformer, T301.
3. Multivibrator V9 and V10 defective, no B+ to V10, open R312 or shorted C310.

C. Insufficient Height.

1. Open C310.
2. High resistance of R307.
3. Excessive leakage of C308.
4. Defective T301.
5. Incorrect voltage values on V10.
6. Low capacity of C309 (this also results in poor vertical linearity).

D. Poor Vertical Linearity, Size Normal.

1. Leaky or improper value of C309.
2. Check B+ to V10 (leaky capacitor C310).
3. Check C303 for leakage.

E. Poor Vertical Linearity, Insufficient Height.

1. Defective output tube, V10.
2. Inadequate drive voltage from V9. Check waveform at pin 5 of V9.
3. Low plate voltage to V9 or V10.
4. Open or low capacity of C309.

F. Excessive Vertical Size, Sync Satisfactory.

1. Low value of R307 or defective size control R308.
2. Open or low capacity of C308.
3. Low picture tube anode voltage.
4. Open R309.

G. No Vertical Sync, Vertical Hold has no Effect, Insufficient Height.

1. Shorted capacitor C306.
2. Shorted R305.

H. Poor Vertical Linearity, Fold-over at Bottom of Picture, Too Much Height.

1. Shorted or high leakage of C303.
2. Low capacity of C308.

I. Curtain Raising Effect (Picture Rolls up from Bottom as Vertical Hold is Advanced).

1. Leaky capacitor, C304.
2. Low resistance of R303.

©John F. Rider

World Radio History

DEFECTS OF THE HORIZONTAL SWEEP

A. *Inadequate Sweep Width.*

1. Low B+ boost to plate of V14 or low B+ to screen of V14.
2. Shorted turns of width control, L353.
3. Shorted turns or arc-over in T351.
4. Parasitic oscillations in V14 (open filament by-pass C462, or defective V14).

B. *Too Great Sweep Width.*

1. Open width control, L353.
2. Low value of picture tube anode voltage.
3. Check voltages of V14.
4. High value of C382.

C. *Poor Horizontal Linearity.*

1. Check for short, or shorted turns of L352.
2. Leaky capacitor C370 in grid of V14.
3. Check screen by-pass capacitor C380.
4. Defective transformer T351.

D. *Single White Vertical Line on Screen.*

1. Open deflection coil, D351.

E. *Black Beady Vertical Line or Lines (Barkhausen Oscillation).*

1. Check sweep output tube, V14.
2. Check for open C382.

F. *Keystoning (Picture Narrows at Top or Bottom).*

1. Check for shorted capacitor, C378.
2. Shorted turns of Horizontal Deflection coil D351.

G. *No Horizontal Sync, Bright Vertical Bar or Bars in Picture.*

1. Shorted, open or leaky C365.
2. Shorted R366.

H. *Gear-tooth Effect, Tearing of Picture (Hunting of Horizontal Sync).*

1. Open or low capacity of C375.
2. Open or high resistance of R362.

I. *Poor Horizontal Linearity, Bright Vertical Bars, Inadequate Horizontal Size.*

1. Open or low capacity of C374.

J. *Dim Picture, Poor Horizontal Linearity, Insufficient Width and Height.*

1. Open or low capacity of C377.

AUDIO DEFECTS

A. *No Sound, Picture Normal.*

1. This indicates a defect in the circuits of V17, V18, V19, V20.
2. Misalignment of T401 or T402 may also cause no sound to be received.

B. *Buzz or Hum in the Sound.*

1. Misalignment of T402 secondary may cause buzz.
2. Reverse power plug in power outlet.

POWER SUPPLY AND PICTURE TUBE CIRCUITS

A. *No Raster, No Sound (No B+).*

1. Check power input circuit (cord and interlock).
2. Check rectifier (X451, X452), check L451, C451, R451.
3. Check thermal cutout.

B. *Picture Size Small, Brilliance Low, Sound Normal (Low B+).*

1. Open or low value of C452.
2. Defective rectifiers X451 or X452.

C. *Low Picture Brilliance, Sound Satisfactory.*

1. Misadjustment of ion trap.
2. Low voltage at high voltage anode of picture tube caused by leaky C376, defective V15, or shorted L353.
3. Low B+ to V14 (check B+ boost at pin 3 of V16. V16 may be defective).
4. Improper waveform at grid of pin 5 of V14.
5. Defective Brightness control circuit or improper voltages to Brightness control R286.
6. Low voltage at second grid (pin 10) of picture tube.
7. Defective picture tube.

D. *No Raster, Sound Satisfactory.*

1. No high anode voltage to picture tube.
2. Ion trap misadjusted.
3. Brightness control circuit open.
4. No voltage at pin 10 of V8 pix tube.
5. Defective picture tube.
6. No drive voltage from V14. Check waveform at pin 5 of V14.
7. Open L352.

MISCELLANEOUS DEFECTS

A. *Retrace Lines Visible.*

1. Check waveform of V9, pin 2.
2. R316, C311, R318 open.
3. C311 shorted.

B. *Brightness Control R286 Partially or Totally Inoperative.*

1. Defective R286.
2. Too low or too high B+ to R286.
3. Short or leaky capacitor, C275 or C277.
4. Gassy picture tube.

C. *Picture Contrast Excessive (Picture Control will not Reduce Contrast).*

1. Excessive antenna input signal.
2. Defective picture control.
3. Shorted or leaky coupling capacitor, C354.
4. Open capacitor C353, C354.
5. Shorted AGC by-pass capacitor, C251.

D. *Picture Control Ineffective.*

1. Shorted C261 (this will make the picture control work backwards).
2. Open choke L258.
3. AGC by-pass C251 shorted.
4. Check waveform at pin 4 of V11.

E. *Poor Focus.*

1. Open or shorted focus coil.
2. Defective focus control tube V21.
3. Demagnetized permanent magnet of focus coil.
4. Defective picture tube V8.

F. *Neck Shadow (See Figure 13).*

1. Misadjustment of focus coil or ion trap.
2. Deflection yoke not forward against the bell of the picture tube.

G. *Wavy Left or White Edges of Picture (Hum).*

1. Check tube V11, V12, V13 for filament to cathode leakage.
2. Check C379 or C355.

H. *Wide Black Horizontal Bar in Picture, Wavy Left or Right Edges of Picture (Hum).*

1. Check filter capacitors C452, C453, C272.

PRODUCTION CHANGES

1. *REDUCTION OF AUDIO BUZZ.*

The following changes were made in the receiver at the start of production to reduce vertical sweep buzz in the audio output. These changes are incorporated in all receivers shipped.

a. In the cathode circuit of the audio amplifier tube V20 two capacitors, C426 (5000 mmf.) and C423 (50 mf.), were removed.

b. At the secondary of the audio interstage transformer (T406), a 330,000 ohm, ½ watt resistor, R429, was connected.

2. *REDUCTION OF "TWEET" ON CHANNEL #4 AND OSCILLATION ON CHANNEL #6.*

a. A capacitor of 800 mmf. was connected between the head-end unit and the main receiver. The change-over should be made as follows: With as short a lead as possible, solder one end of an 800 mmf. ceramic capacitor (C227) to the mounting clip of the trap trimmer (C206) on the head-end unit. The other end of the capacitor is soldered to a lug fastened securely at the punched receiver chassis hole adjacent to the tube socket, V21.

b. Relocation of the ceramic capacitor C252 from its present termination at the 7th B− bus hole of the terminal board #1 and the chassis weld between tube sockets, V5 and V6. Relocate this capacitor by soldering one end of it to the 1st hole in the B− bus of the same terminal strip. The other end is soldered to the chassis hole nearest L251. For convenience, the capacitor lead may be inserted through the ⅜ inch hole nearest L251 and then soldered from the top of the chassis to a cleaned and tinned top edge of the hole.

CRITICAL LEAD DRESS AND COMPONENT REPLACEMENT

Since the operating frequencies are relatively high in a television receiver, it is essential that all components be placed in exactly the same position they occupied when they were wired in the factory; all leads should be made as short as possible and exact replacement parts to be used when replacing components. Leads in wiring between components are usually critical as to placement against chassis or proximity to other components. Some of critical wiring precautions are listed below:

1. *YELLOW LEAD ON TUBE V18.*

The yellow lead should be as short as possible to connect to pin #7 of V18. All leads which run past the terminal board to which the yellow lead is connected are pushed down against the chassis and dressed as far away as possible from the yellow lead.

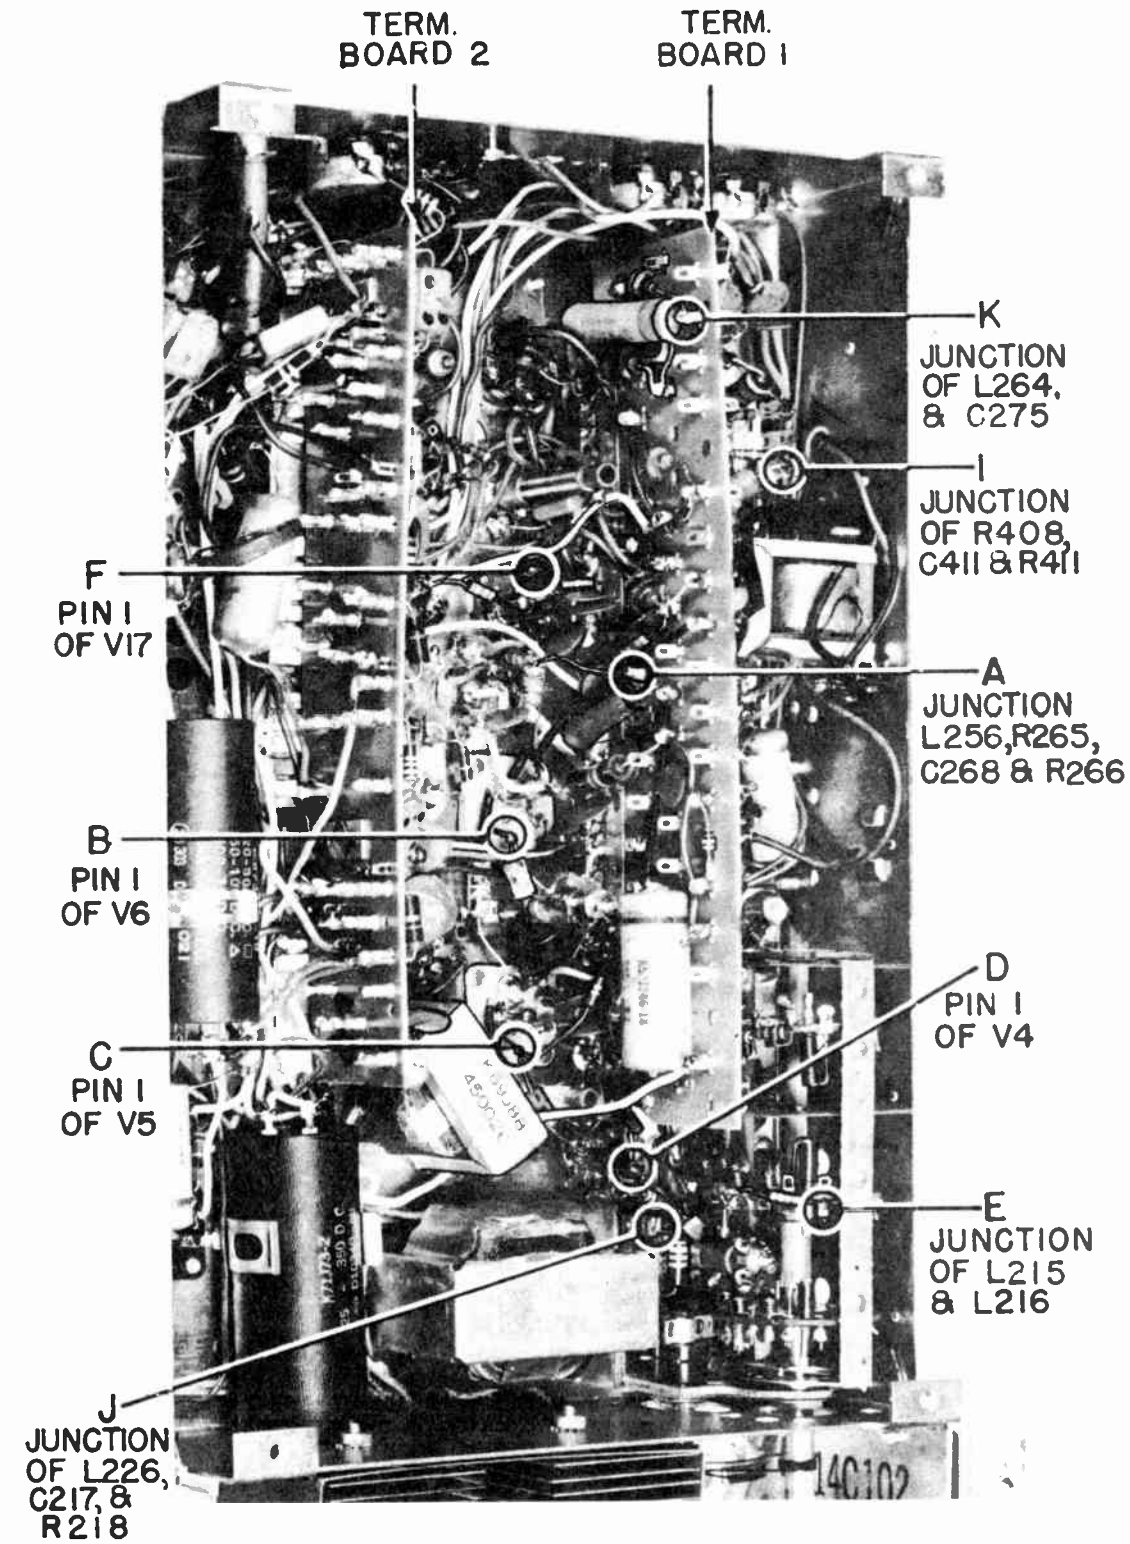

Fig. 31. Alignment Connection Points

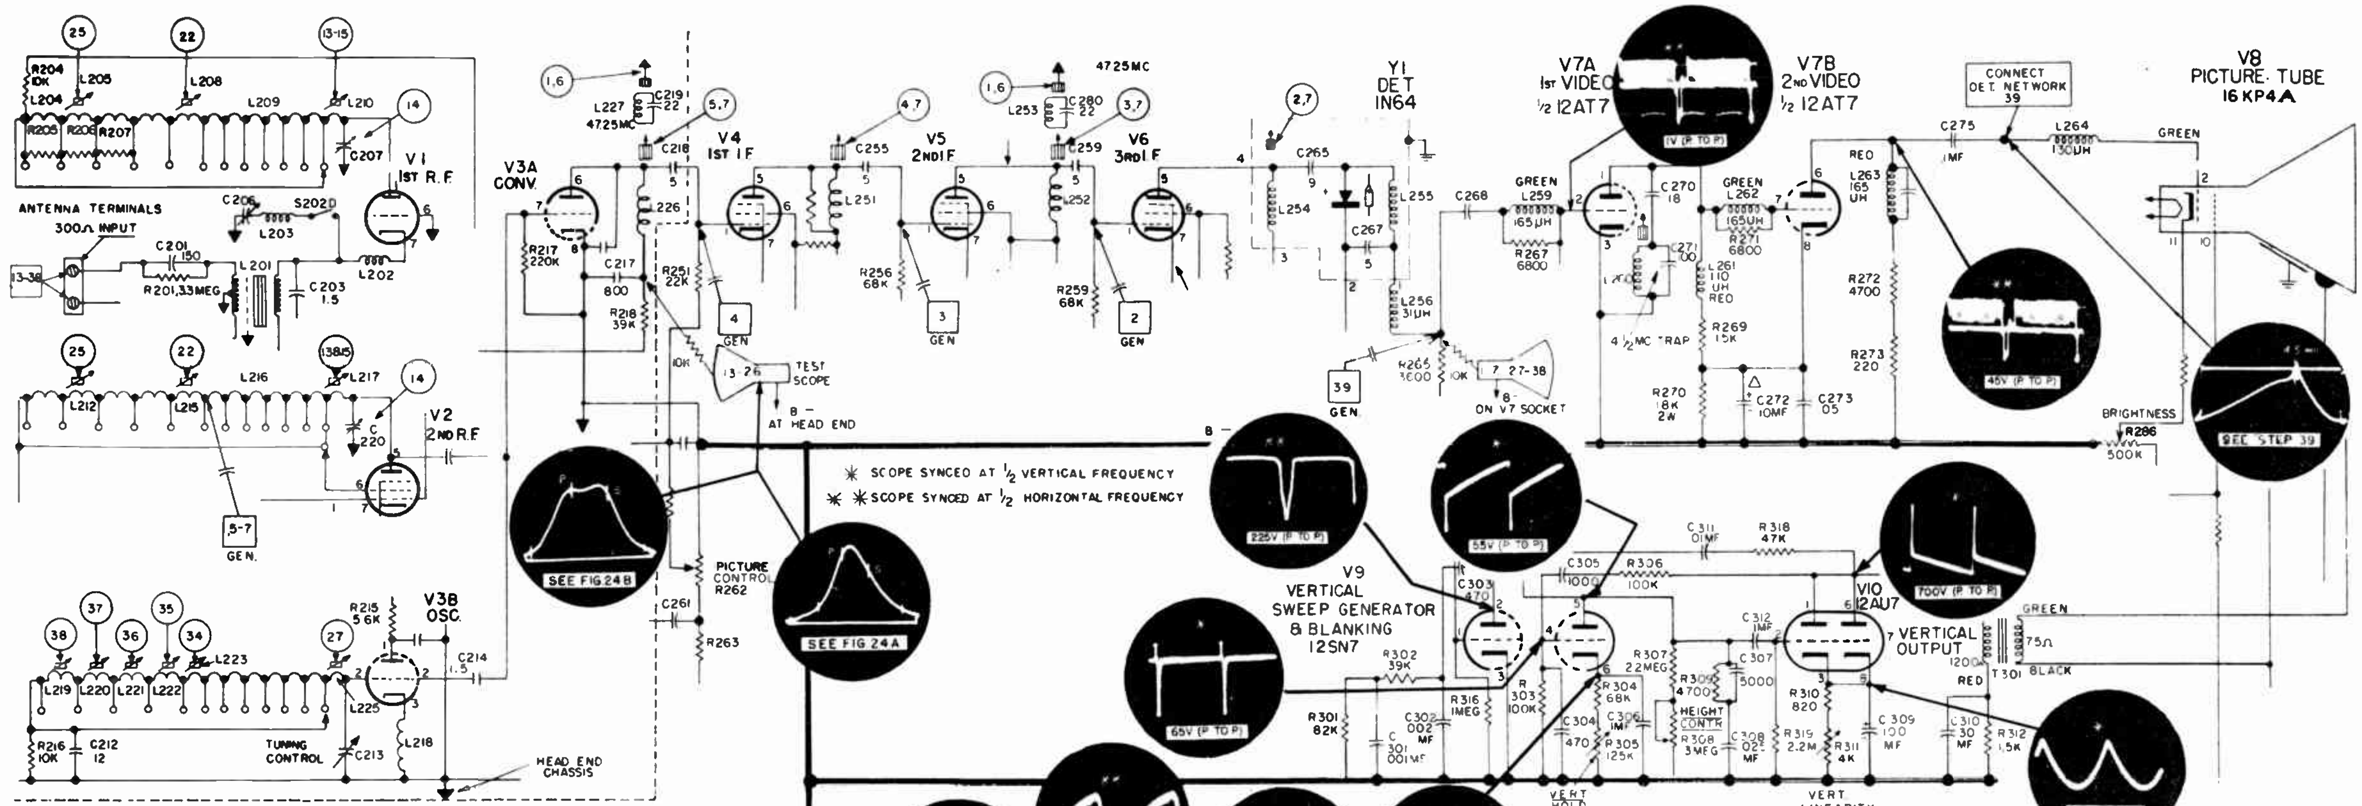
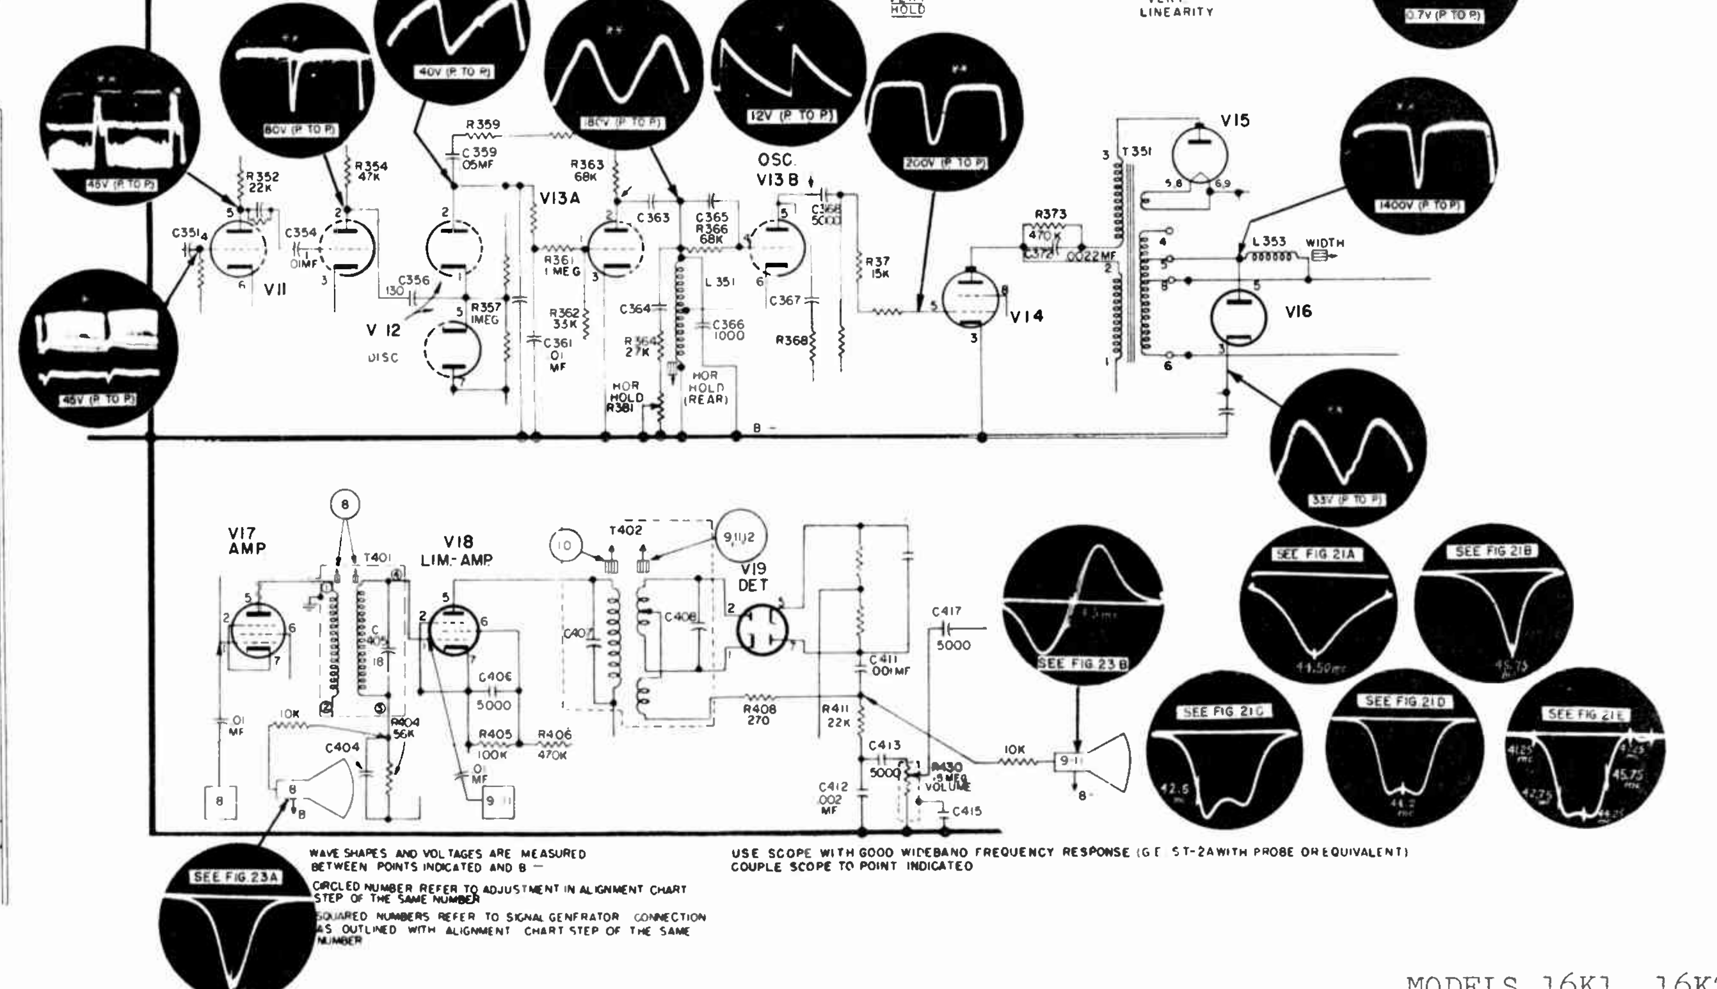
World Radio History

Fig. 30. Service Diagram, Television Chassis, Model 16K1





SERVICE DIAGRAM

The alignment procedure is shown in table form on pages 24 through 27. In order to accelerate the whole procedure, the service diagram (Figure 29) should be consulted. The encircled numbers indicate the number of the step of the alignment chart and the arrow points to the compartment to be adjusted. The generator is symbolized by a square with the number of the step of the alignment chart. The exact point of feed-in is indicated by the arrow connected with the numbered square. The oscilloscope is represented by the symbol of the cathode ray tube. The number inside the symbol refers to the step of the alignment chart. On the left side of the diagram is shown the tube location inside the chassis so that it is easy to locate the correct points for connection to the generator and the oscilloscope. In order to clarify the diagram, only those parts of the circuits are shown which are needed for location of the test points. Within the large circles are shown the waveform of an average television receiver, wherein the controls have been adjusted for a normal picture with correct contrast, height, width and linearity. Most measurements must be made when a signal is being received. Adjust picture control for 1-volt peak to peak at pin 2 of V7A as shown.

The oscilloscope of which the vertical amplifier has been precalibrated is used to make measurements at the point indicated. The oscilloscope is synced at half of the respective sweep frequency of the circuit being analyzed.

World Radio History

RADIO RECEIVER

GENERAL.

The receiver is designed to operate either from the built-in antenna or from an external FM 300 ohm dipole antenna. The receiver may be operated on an external FM antenna by disconnecting from the antenna terminal strip the wire extending from the rear of the radio chassis. The 300 ohm transmission line should be connected to the antenna terminals on the radio chassis.

On AM operation, the receiver operates with the signal fed directly into the converter grid. On FM, the receiver uses a reflex circuit, the Armstrong type discriminator and a special limiter circuit.

In the reflex circuit V2 (6BA6) works both as an r-f amplifier and as the 1st i-f amplifier. The FM r-f signal is fed into the grid of the V2 tube through the secondary of transformer T1. It is amplified by the tube and tuned at the converter grid by L4, C1B and trimmer C6. The converter changes the r-f to 10.7 mc i-f and is fed into the primary of transformer T1 and again applied to the grid of tube V2 which works now as an i-f amplifier. The i-f signal is fed from the plate of V2 through choke L9 into the second i-f transformer. Capacitor C4 and coil L2 are designed to peak at 98 mc to increase the FM r-f sensitivity. At the FM r-f frequencies, the capacitor C46 offers little series impedance to the r-f signal. Coil L9 and capacitor C7 form a high-pass filter to pass the FM r-f signal into the converter grid and to shunt the FM i-f frequency into the primary of the second FM i-f transformer.

STAGE GAIN AND VOLTAGE CHECKS

In order to check circuit performance and to facilitate trouble shooting stage gain measurements by vacuum tube voltmeter or similar measuring device may be used. The gain values listed may have tolerances of ±20%. Readings should be taken with low signal input applied through IRE dummy antenna so that AVC is not effective.

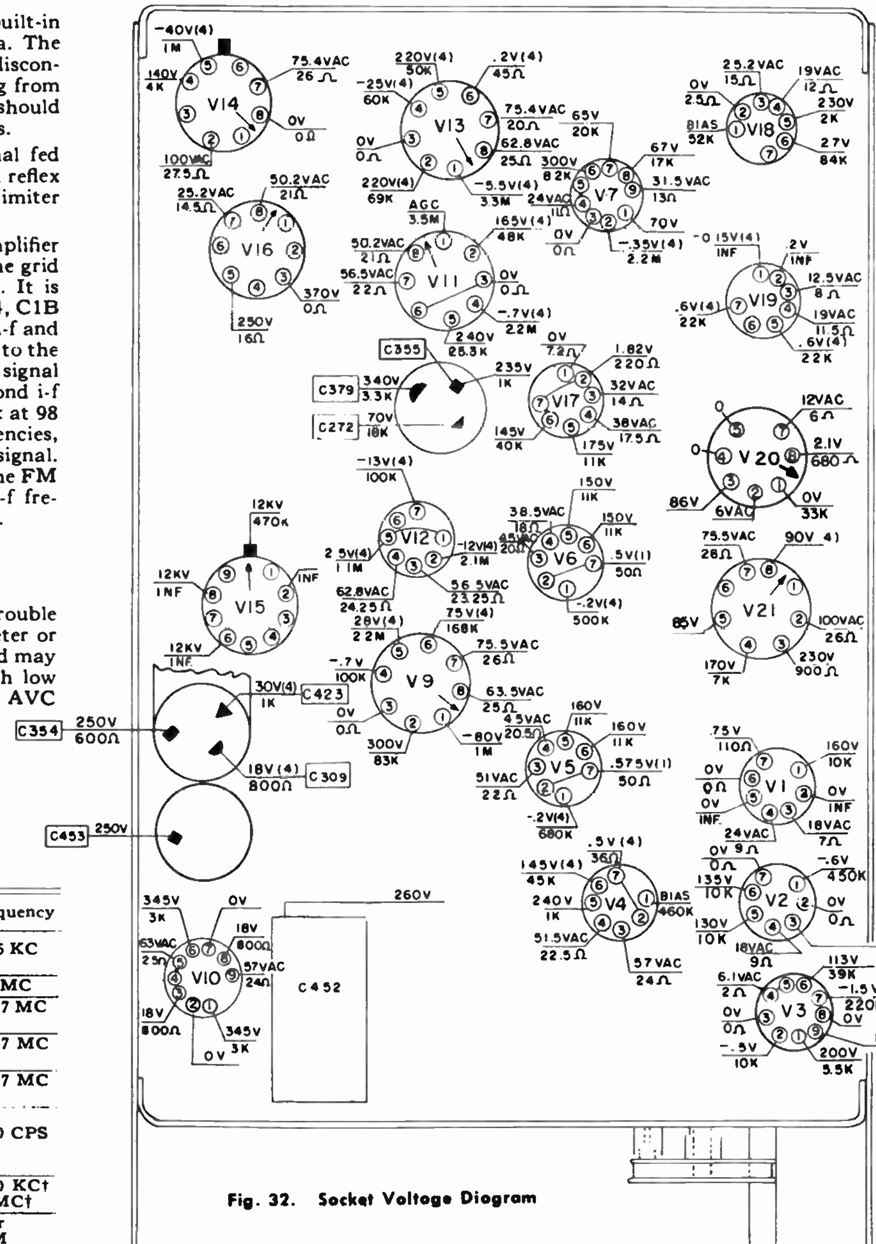
Stage Gains	Stage	Stage Gain	Frequency
	Converter grid 6BE6 (V1) to grid of IF amplifier, 6BA6 (V3)	40	455 KC
	Dipole terminal to grid of V2	1.0	98 MC
	Converter, 6BE6 (V1) grid to grid of V2 (6BA6)	1.5	10.7 MC
	Grid of V2 (6BA6) to i-f amplifier grid (6BA6, V3)	50	10.7 MC
	I-f amplifier (6BA6, V3) grid to limiter grid (6AU6, V4)	22	10.7 MC
Audio Gain	Volume Control (R18) to speaker voice coil	Input .07V* Output 0.5W**	400 CPS
Oscillator Grid Bias	Voltage across R3	7 volts 3 volts	1000 KC† 98 MC†
Hum Measurements	Measured across voice coil of speaker with volume control at minimum	Maximum 7 millivolts	For AM
	Measured across voice coil of speaker with volume control at max.; ground limiter grid through .01 capacitor	Maximum 15 millivolts	FM
Socket Voltages	Fig. 37 shows typical tube pin voltages. AM readings should be made from tube pin to chassis, unless otherwise indicated.		

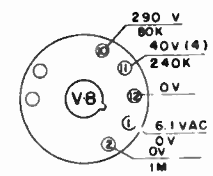
*Across R18.
**Across voice coil.
† Use resistor of 220,000 ohms to isolate VTVM.

CIRCUIT ALIGNMENT

GENERAL.

Two methods of alignment may be used: (1) The regular meter alignment as used for standard AM radios and (2) the visual alignment, which is more exact in aligning the circuits, particularly the discriminator where it is necessary that the negative and positive half cycles of the output wave have equal amplitude and symmetry.





VOLTAGE MEASUREMENTS
INPUT 117V, 60
ALL CONTROLS SET FOR NORMAL SWEEPS, FOCUS AND BRIGHTNESS
MEASUREMENTS ARE IN RESPECT TO B- WITH A 20,000Ω/VOLT METER
(1) 2.5 VOLT RANGE
(2) 10 " "
(3) 25 " "
(4) VOLTAGE WILL VARY MORE THAN 20%

Fig. 32. Socket Voltage Diagram

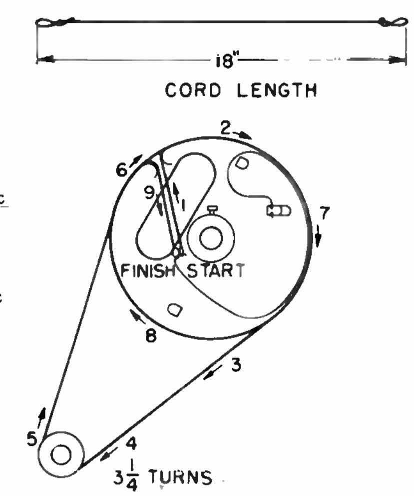

Fig. 33. Tuning Control Stringing Diagram

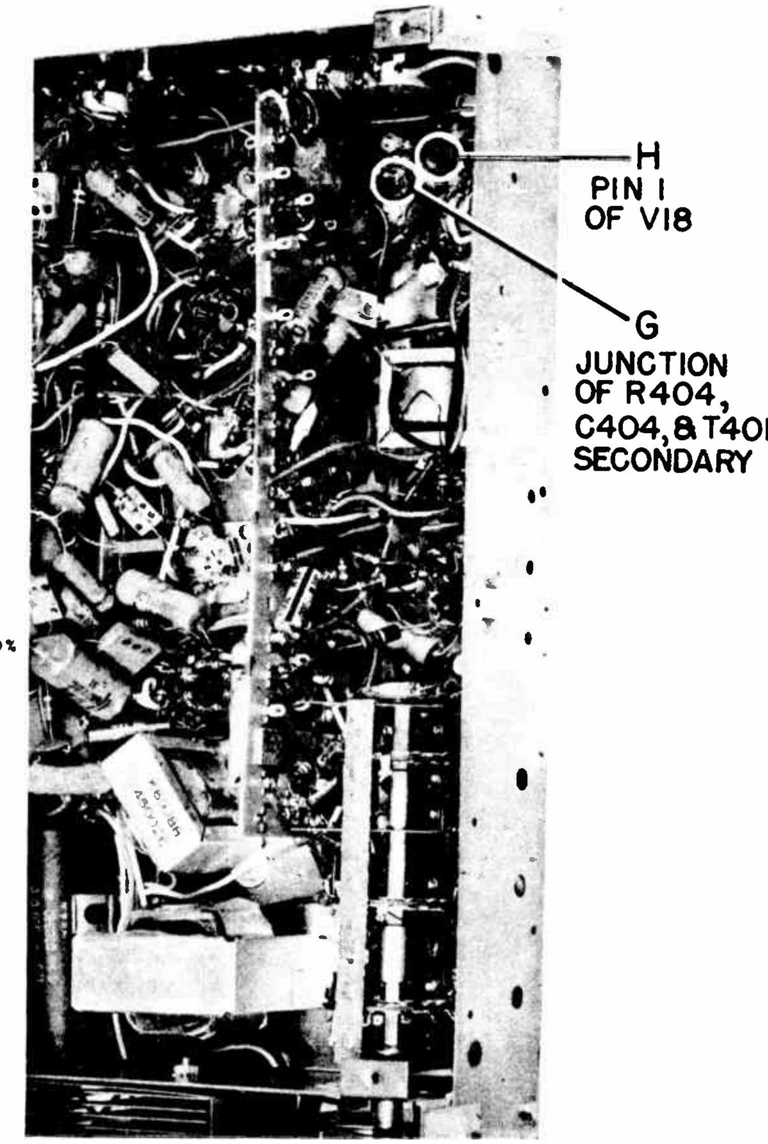

Fig. 35. Alignment Connection Points

METER ALIGNMENT

EQUIPMENT REQUIRED FOR METER ALIGNMENT.

1. Test oscillator with tone modulation to cover 455 kc, 520 to 1620 kc, 10.7 mc and 88 to 108 mc.
2. Voltmeter, 20,000 ohm-per-volt or VTVM.
3. Output Meter.
4. Paper Capacitor, .01 mf.
5. Resistor, ½ watt, 200,000 ohms.
6. Loop Antenna, see note 6.

METER ALIGNMENT NOTES.

1. Use an unmodulated signal.

2. Connect a meter (20,000 ohms/volt) from junction of resistor R26 and capacitor C27 to chassis; use 10-volt scale, steps 4 and 5.

3. Connect a meter (20,000 ohms/volt) from pin 1 of limiter tube V4 (6AU6) to ground in series with a resistor of 200,000 ohms. The resistor must be connected directly to the grid pin to minimize capacity loading and to isolate the i-f signal from the meter. Keep input signal so that meter indicates not more than 1 volt with VTVM or 5 microamps through 200,000 ohms with standard meter.

4. Use 400 cycle modulation.

5. Connect standard output meter across speaker voice coil, turn volume control full on and keep signal down so that output meter indicates not more than ½ watt output.

6. For alignment of the AM oscillator and RF trimmer, the signal should be inductively coupled to the loop antenna of the receiver by connecting a four turn, six inch diameter loop of wire across the signal generator terminals, and then locate the loop about one foot from the radio loop antenna which should be kept at the same distance and position (relative to the chassis) as it is mounted in the cabinet. To prevent possible errors in peak readings, the position of the loop in respect to the radio loop should not be changed during any set of adjustments.

7. In order to align the first FM i-f transformer T1, it is necessary to disconnect the copper strap from the band switch to pin 7 of converter tube 6BE6 (V1) by unsoldering the strap from the tube pin connection. Resolder the strap after T1 is aligned.

8. When tuning the secondary of the discriminator transformer T6, three minimum points will be obtained of which the center one is the correct setting. As the transformer is tuned either side of 10.7 mc, the meter reading should increase.

9. Termination impedance of signal generator should be 300 ohms.

10. When detuning the signal generator in step 4, two maximum readings will be obtained, one on each side of 10.7 mc. The primary of the discriminator transformer T6 should be aligned for maximum when the signal generator is tuned to the smaller of these two peaks.

11. Make all chassis connections for FM i-f alignment as short as possible. In step 9 connect the ground side of the signal generator at the chassis ground in the center of the 6BE6 socket using a short ground connection.

13	98 MC ±300 KC at 60 cps sweep rate.			For max. ampl. of curve		C6 for max. ampl. & sym. of curve	1, 2, 3

VISUAL ALIGNMENT

EQUIPMENT REQUIRED FOR VISUAL ALIGNMENT.

1. Signal Generator, AM and FM, G-E Type YGS-3, or equivalent.
2. Oscilloscope, G-E Type ST-2A, or equivalent.
3. Voltmeter, 20,000 ohms/volt.
4. Resistors, 200,000 ohms, ½ watt, and 1 megohm, ½ watt.
5. Paper Capacitor, .01 mf.

NOTES FOR VISUAL ALIGNMENT.

1. The termination resistance of the signal generator should be 300 ohms to match the input impedance of this receiver for FM r-f alignment.

2. In some cases tuning of the converter grid will cause "pulling" of the oscillator producing a change in the oscillator frequency.

3. If peaking of C5 on AM alignment or C6 on FM alignment causes the curve to move off the screen after centering, it will be necessary to recalibrate the oscillator as in steps 3 and 12.

4. For alignment of the AM oscillator and r-f trimmers, the signal should be inductively coupled to the loop antenna of the radio receiver by connecting a four turn, six inch diameter loop of bell wire across the signal generator terminals, and then locate this loop about one foot from the radio loop antenna which should be kept at the same distance and position relative to the chassis as it is mounted in the cabinet. To prevent possible errors in peak readings, the position of the loop with respect to the radio loop should not be changed during any one set of adjustments.

5. When using a sweep signal, it is necessary to apply the same sweep voltage to the horizontal plates of the oscilloscope which is used to sweep the r-f frequency.

It may be necessary to use an RF phase shift network to properly phase the input to the scope. This may be done by shunting a capacitor of .005 mf. across the horizontal plate terminals of the scope and by using a ½ megohm potentiometer in series with the high side of the horizontal sweep voltage line. Adjust the potentiometer to superimpose the retrace on the trace.

6. Make all chassis connections for FM i-f alignment as short as possible. In step 7 connect the ground side of the signal generator at the chassis ground at the center pin of the 6BE6 socket (V1).

7. To align the 1st i-f FM transformer T1, it is necessary to disconnect the copper strap from pin 7 of converter tube V1 (6BE6) to the band switch by unsoldering it from the tube pin; resolder strap after aligning T1.

8. If slight distortion is encountered on weak FM stations, it may be necessary to increase the FM-IF bandwidth to a minimum of 120 kc or a maximum of 140 kc width at 50% of peak amplitude. This should be done by stagger tuning T3 only. The amplitude of the video IF response should not be reduced more than 20%. Use a signal generator accurately calibrated to supply markers for the bandwidth measurement.

In order to stagger tune transformer T3, use a sweep voltage as in step 7. Connect a scope as in note 1, then turn the primary transformer T3 (bottom core) slightly clockwise and turn the secondary of T3 (top core) counterclockwise to center the 10.7 mc marker at the peak of the curve and check bandwidth according to specification given.

URF-113	R453	RESISTOR—470,000 ohms, 2 w.
1N64		DIODE—Crystal diode
P15		RECORD CHANGER—3 speed changer
*S1212D-7		SPEAKER—12-inch PM speaker
*RCN-029	C265	CAPACITOR—9 mmf., silver mica.
RCN-030	C311	CAPACITOR—.01 mf., 1000 v. molded
*RCN-033	C365, 367	CAPACITOR—1800 mmf., 600 v., paper.
*RCN-034	C362	CAPACITOR—3900 mmf. ±10%, 600 v., paper
RCN-035	C376	CAPACITOR—500 mmf., 20,000 v., high voltage capacitor
*RCU-286	C369	CAPACITOR—6 mmf., 800 v., mica
*RCU-290	C305	CAPACITOR—1000 mmf., 1000 v., mica
*RCU-293	C313	CAPACITOR—18 mmf., 1500 v., mica
*RCU-294	C360	CAPACITOR—680 mmf. ±20%, 500 v., mica.
*RCU-296	C382	CAPACITOR—180 mmf., 1500 v., mica
*RCW-1056	C203, 214	CAPACITOR—1.5 mmf., ±0.25 mmf.
*RCW-1076	C208, 211	CAPACITOR—3.3 mmf., ±0.25 mmf.
*RCW-3014	C252, 253, 254, 256, 257, 258, 260, 261, 263, 264, 266, 269, 307, 368, 381, 401, 402, 403, 406, 409, 415, 417, 424 425, 455 460, 461	CAPACITOR—5000 mmf., 450 volt, ceramic.
*RCW-3027		CAPACITOR—680 mmf., ceramic
RCW-3035	C214	CAPACITOR—1.5 mmf., 500 v., ceramic
*RCW-3037	C204, 209, 210, 215, 217, 221, 222, 223, 224, 225, 226	CAPACITOR—800 mmf., 350 v., ceramic
*RCY-048	C207	CAPACITOR—Trimmer.
*RCY-059	C213	CAPACITOR—Trimmer.
*RCY-060	C206	CAPACITOR Trimmer for high channel trap
RCY-063	C220	CAPACITOR—Trimmer.
*RDB-019		BUTTON—Pushbutton (ON-OFF), 16K1
RDB-023		BUTTON—Pushbutton, for 16K2
*RDC-032		CORD—For tuning control.
*RDE-077		OVERLAY—Metal mask
RDE-096		ESCUTCHEON—For radio compartment
RDE-103		ESCUTCHEON—For television compartment
*RDK-212		PULL—Phono drawer pull
RDK-213		KNOB—Radio knob
RDK-214		KNOB—Radio knob with arrow
RDK-222		KNOB—Tuning control.
RDK-223		KNOB—Volume control
RDK-224		KNOB—For selector switch
RDK-225		KNOB—Picture control
RDK-226		KNOB—For brightness & vertical hold
RDK-227		KNOB—For focus and horizontal hold.
*RDW-040		GLASS—Safety glass
REC-006		CAP—For high voltage rectifier
*REI-014		CORE—Brass screw for L210, L217
*REI-016		CORE—Iron core for L254
*RER-008	X451, 452	RECTIFIER—Selenium, 350 ma.
*RET-003		TRAP—Ion trap
RHC-008		CLIP—1-inch for mounting electrolytic.
*RHC-024		CLIP—For mounting electrolytic
RHC-036		CLIP—For knob door pin spring
RHG-004		GROMMET—5/16 in. for chassis
RHG-010		GROMMET—Shock mounting
RHG-013		GROMMET—For speaker
RHG-030		GROMMET—½ inch for voltage shield
RHG-031		GROMMET—Chassis grommet
RHN-014		WING NUT—No. 8-32.
*RHS-045		SCREW—Headless for L223, L205, L208
*RHS-046		SCREW—Headless for L219, L220, L221, L222
RHS-050		SCREW—Hex. Head screw
RHS-051		SCREW—Round H for television chassis mounting
RHS-052		SCREW—R. H. Philips for phono slide mounting
RHS-053		SCREW—Hex H. for radio chassis mounting
RHS-056		SCREW—Flat H. for phono slide mounting
RHS-057		SCREW—For cabinet back and loop
RHS-058		SCREW—For radio and television escutcheon
RHS-059		SCREW—Round head Philips for television top escutcheon
RHS-060		SCREW—Self tapping for pushbutton switch
RHY-020		DOOR PULL—Small, for 16K1
RHY-21		DOOR PULL—Large, for 16K1
RHY-022		DOOR PULL—Small, for 16K2
RHY-023		DOOR PULL—Large, for 16K2
*RII-021		INSULATOR—For mounting control
*RII-023		INSULATOR—For yoke
*RII-026		INSULATOR—Grommet in high voltage shield
RII-038		GUIDE—Insulating guide
*RII-041		INSULATOR—For mounting rectifier.
*RII-044		SUPPORT—For power cord
*RJC-013	J3	PLUG—(Eby) for connection to radio chassis
*RJC-018		CONNECTOR—High voltage anode connector
RJJ-003	J5	CONNECTOR—(Plug, female)
RJJ-008		RECEPTACLE—Power receptacle
RJJ-010		RECEPTACLE—For power cord
RJP-003		PLUG—AC power plug
RJP-004		PLUG—Phono plug
*RJP-008	P4, P5	PLUG—Amphenol octal plug
*RJS-003		SOCKET—Octal tube socket for V11, V9, V20
RJS-004		PLATE—For electrolytic condenser
*RJS-024		PLATE—Mounting plate for elec. cond.
*RJS-026		SOCKET—Tube socket, octal, for V21
*RJS-031		SOCKET—Tube socket for V14
*RJS-085		SOCKET—Tube socket for V16
*RJS-127		SOCKET—Tube socket, 9-pin, for V3
*RJS-132		SOCKET—Tube socket, 7-pin, for V12, V19
*RJS-133		SOCKET—Tube socket, 7-pin, shielded, for V5, V6, V18
*RJS-135		SOCKET—Shock mounting for V13.
*RJS-138		SOCKET—Tube socket, 9 pin, for V7 miniature
*RJS-139		SOCKET—Tube socket, 9 pin, for V10
*RJS-144		SOCKET—Tube socket, 7 pin, for V4, V17
RJS-148		SOCKET—Tube socket for high voltage rectifier
RJS-149		SOCKET—Tube socket for V1 and V2
RJS-150		SHELL—Connector shell for P5
*RJX-043		R-F HEAD-END—R-F tuner, aligned & incl. tubes
*RLA-036	L201	TRANSFORMER—Input transformer.
*RLC-091	L351	COIL—Horizontal oscillator
*RLC-095	L219	COIL—Oscillator coil, Channel #2
*RLC-096	L220, 214, 207	COIL—Oscillator coil for Channel #3, 1st and 2nd R-F Channel #5
*RLC-097	L222	COIL—Oscillator for Channel #5
*RLC-098	L223	COIL—Oscillator for Channel #6
*RLC-099	L225	COIL—Oscillator for Channel #13
*RLD-014	L353	COIL—Width control
*RLD-016	L352	COIL—Horizontal linearity
RLD-025	D301, 351	YOKE—Deflection yoke
*RLF-024	L256	CHOKE COIL—R-F coil, 31 uh
RLF-039	L401	COIL—Focus coil
*RLI-003	L218	COIL—Cathode choke
*RLI 006	L202	COIL—Coil choke
*RLI-038	L257, 263	COIL—Video choke coil, 165 uh.
*RLI-072	L206, 212	COIL—1st R-F Channel #4, 2nd R-F Channel #3
*RLI-077	L205	COIL—1st R-F Channel #3
*RLI-093	L259, R262	COIL—Video choke, 165 uh.
*RLI-096	L251	COIL—2nd video I-F coil
*RLI-097	T401	COIL—1st audio I-F coil
*RLI-099	L221	COIL—Oscillator coil, Channel #4
*RLI-100	L260, 270, 271	TRAP—4.5 mc video trap
*RLI-108	L261	CHOKE—Video choke, 110 uh.
*RLI-109	L264	CHOKE—Video choke.
*RLI-110	L252, 253	COIL—I-F coil
*RLI-114	L203	COIL—Trap coil.
*RLI-116	L208, 215	COIL—1st and 2nd R-F, Channel #6
*RLI-117	L204	COIL—Channel #2, 1st R-F
*RLI-118	L213	COIL—2nd R-F, Channel #4
*RLI-119	L211	COIL—2nd R-F, Channel #2.
*RLI-120	L210	COIL—1st R-F, Channel #13
*RLI-121	L217	COIL—2nd R-F Channel #13.
*RLI-122	L258, 452, 453, 402, 454, 455, 456	COIL—Heater choke, 2 uh.
RLL-040		LOOP—AM loop assembly
*RLP-016	L226, 227	COIL—Converter plate
RLX-029	L254, 255, 1N64, C265, 267	VIDEO DETECTOR ASSEMBLY—With crystal
*RMC-017		CLIP—⅜ in. for electrolytic
RMC-051		CLAMP—For yoke
RMM-146		SHIELD—Socket shield on V2
*RMM-147		TUBE CUSHION—Under pix tube, 2 required
*RMM-148		TUBE CUSHION—Front pix tube, 1 required
*RMM-149		TUBE CUSHION—Top pix tube, under tube support brackets, 2 required
RMM-151		RUBBER—Channel rubber
*RMM-153		SLIDE—For record changer
RMM-155		CUSHION—For safety glass
RMR-009		CASTERS—Casters with sleeves
*RMS-130		SPRING—Tension spring for tuning control cord
*RMS-220		CLIP—Spring grounding clip, contacts pix tube
RMS-221		SPRING—Stabilizer spring
RMS-222		SPRING—Right-hand spring for knob door
RMS-223		SPRING—Left-hand spring for knob door
*RMU-055		EXTENSION SHAFT—For L352 and L353
RMU-065		SHAFT—Insulator shaft
RMX-169		PULLEY AND HUB ASSEMBLY.
RQB-001		BRUSH—For pickup styli
*RRC-096	R308	POTENTIOMETER—Vertical size, 3 meg.
*RRC-127	R311	POTENTIOMETER—Vertical linearity, 4000 ohms, 2 w.
*RRC-140	R369	POTENTIOMETER—Horizontal drive, 25,000 ohms
RRC-144	R435, 286	POTENTIOMETER—Focus and brightness
RRC-146	R381, 305	POTENTIOMETER—Dual Hor. (100K) and Vert. Hold (125K).
RRC-147	R430, 285	POTENTIOMETER—Dual control, volume
*RRW-048	R451	RESISTOR—4.6 ohms, 5 w., w.w.
*RRW-049	R220	RESISTOR—43 ohms, 4 w.
*RRW-051	R454	RESISTOR—20 ohms, Globar, temperature compensating.
*RRW-052	R382	RESISTOR—10,500 ohms, Globar, voltage sensitivity resistance
RRW-053	R380	RESISTOR—4000 ohms, 7 w., w.w.
*RSR-002	B451	CUT-OUT—Thermal cut-out
RSW-082		SWITCH—Channel selector switch
RSW-083	S403, 407	SWITCH—Pushbutton switch
*RTD-008	T402	TRANSFORMER—Ratio detector
*RTL-096	L451	REACTOR—Filter reactor
RTM-005	T406	TRANSFORMER—Interstage
*RTO-064	T301	TRANSFORMER—Vertical sweep output transformer
RTO-090	T351	TRANSFORMER—Horizontal output transformer
*RWL-027	I452	POWER CORD AND FEMALE PLUG
RWX-030		OCTAL CABLE ASSEMBLY
RXW-034		SOCKET—Picture tube socket assembly

*Parts used on previous models.

*UCU-016	C26	CAPACITOR—33 mmfd., 500 v., mica
*UCU-020	C2, 36	CAPACITOR—47 mmfd., 500 v., mica
*UCU-044	C35	CAPACITOR—470 mmfd., 500 v., mica
*UCU-1036	C27	CAPACITOR—220 mmfd., 500 v., mica
UJB-004		STRIP—Terminal strip for antenna
*URD-025	R4, 10, 38	RESISTOR—100 ohms, ½ w., carbon
*URD-031	R21	RESISTOR—180 ohms, ½ w., carbon
*URD-049	R30	RESISTOR—1000 ohms, ½ w., carbon
*RCC-059	C38	CAPACITOR—.005 mf.—1000 v.
*RCE-039	C39A, 39B, 39C, 39D	CAPACITOR—Electrolytic capacitor
RCE-068	C43	CAPACITOR—Electrolytic capacitor, 10 mf.
RCT-043	C1A, 1B, 1C, 1D	CAPACITOR—Tuning capacitor
*RCW-1043		CAPACITOR—47 mmf., ceramic cap.
*RCW-1047	C14	CAPACITOR—100 mmf., ceramic
*RCW-1053	C8	CAPACITOR—22 mmf., ceramic
*RCW-1060	C7, 10	CAPACITOR—10 mmf., 0-coef., ceramic
*RCW-2031	C13	CAPACITOR—18 mmf., ceramic
*RCW-1043	C11	CAPACITOR—47 mmf., ceramic
RCY-055	C12	CAPACITOR—Trimmer
*RDC-032		DRIVE CORD
RDP-053		POINTER
RDS-099		PLATE—Backplate & dial scale
*RHC-017		COIL CLIP—For mounting L5
*RHC-034		CLIP—For mounting IF can
*RHG-010		GROMMET RUBBER (tube).
*RHG-015		GROMMET—For tuning condenser.
RHI-011		STRAIN RELIEF—On power cord
*RHJ-006		SPACER—For tuning condenser
RII-047		INSULATING WASHER—Under phono jack
RJC-012	P3	PLUG—Chassis power plug
*RJC-019		SPEAKER LEAD PINS
RJJ-003	J4	CONNECTOR—Octal connector
RJP-003	P2	AC POWER PLUG
*RJP-004	P1	PHONO PLUG
*RJP-010	J1	PHONO JACK & PLUG (female)
RJS-003		SOCKET—Tube socket for V6, V7.
RJS-012		MOUNTING PLATE—For electrolytic
*RJS-049	J2	PHONO POWER SOCKET (female).
*RJS-085		SOCKET—Tube socket
RJS-118		SOCKET—Tube socket for V5
*URD-053	R32	RESISTOR—1500 ohms, ½ w., carbon
*URD-057	R7, 12	RESISTOR—2200 ohms, ½ w., carbon
URD-061	R6, 5	RESISTOR—3300 ohms, ½ w., carbon
*URD-069	R49	RESISTOR—6800 ohms, ½ w. carbon
*URD-081	R3, 23	RESISTOR—22,000 ohms, ½ w., carbon
URD-083	R47	RESISTOR—27,000 ohms, ½ w., carbon
*URD-085	R40, 42	RESISTOR—33,000 ohms, ½ w., carbon
*URD-089	R13, 14, 43	RESISTOR—47,000 ohms, ½ w.
*URD-093	R41	RESISTOR—68,000 ohms, ½ w., carbon
*URD-097	R17, 26, 37	RESISTOR—100,000 ohms, ½ w.
*URD-099	R24, 25	RESISTOR—120,000 ohms, ½ w.
*URD-105	R15	RESISTOR—220,000 ohms, ½ w.
*URD-113	R28,29	RESISTOR—470,000 ohms, ½ w.
*URD-121	R20	RESISTOR—1 meg., ½ w.
*URD-129	R16	RESISTOR—2.2 meg., ½ w.
*URD-133	R44, 51	RESISTOR—3.3 meg., ½ w.
*URD-141	R27	RESISTOR—6.8 meg., ½ w.
*URD-1104	R46	RESISTOR—200,000 ohms, ½ w., carbon
URE-037	R31	RESISTOR—330 ohms, 1 w.
RJS-145		SOCKET—Tube socket for V1, V2, V3, V4
RJS-147		PILOT LIGHT SOCKET
RJS-150		SHELL—Connector shell
*RLB-029	L4	COIL—FM R-F coil
*RLC-066	L5	COIL—B-C oscillator coil
*RLC-102	L8	COIL—FM oscillator coil
RLI-044		CHOKE—In FM line
RLI-087	L7	COIL—Choke coil
*RLI-088	L2	CHOKE COIL—FM antenna coil
*RLI-122	L6, 10, 11	CHOKE COIL
RLI-124	L9	CHOKE COIL—FM R-F pl. oscillator cathode
RLL-039	L3	LOOP ASSEMBLY
*RMS-111		SPRING (DIAL CORD)
RMX-171		DRIVE SHAFT AND BUSHING ASSEMBLY
RMX-177		DRUM AND SHAFT ASSEMBLY
RRC-141	R18	VOLUME CONTROL, 2 meg.
*RRT-003	R33, 34	RESISTOR—1220-6500 ohms, 9 w., w.w.
RSW-079	S1A, 1B, 1C, 1D	BAND CHANGE SWITCH
RSW-080	S2A, 2B, 2C, 2D	TONE CONTROL SWITCH
*RTD-010	T6, C55, C56, 57	DISCRIMINATOR TRANSFORMER
*RTL-097	T2, C74, C48	1ST I-F TRANSFORMER—AM
*RTL-098	T5, C25, C24, 53, 54	2ND I-F TRANSFORMER—AM
*RTL-099	T1, 3, C45, 46, 49, 50	1ST, 2ND I-F TRANSFORMER—FM
*RTL-114	T9	FM COIL
RTO-089	T7	OUTPUT TRANSFORMER
RTP-302	T8	POWER TRANSFORMER

MODEL 16C115

CAUTION

HIGH VOLTAGES ARE USED IN THE OPERATION OF THIS TELEVISION RECEIVER. THE BACK COVER, WHILE IN PLACE, PREVENTS ACCIDENTAL CONTACT WITH THESE HIGH VOLTAGES AND SHOULD NOT BE REMOVED EXCEPT BY A QUALIFIED TELEVISION TECHNICIAN.

THE PICTURE TUBE IS A HIGH VACUUM TUBE AND, IF BROKEN, PIECES OF GLASS MAY FLY WITH FORCE IN ALL DIRECTIONS. ANY WEAKENING OF THE GLASS, AS MAY BE CAUSED BY CHIPPING, SCRATCHING, OR MORE THAN NORMAL PRESSURE, MAY CAUSE THIS TUBE TO BREAK. THE USE OF SAFETY GLASSES IS RECOMMENDED WHEN IT IS NECESSARY TO REMOVE OR REPLACE THE PICTURE TUBE.

ALWAYS USE AN ISOLATING TRANSFORMER IN THE POWER LINE, WHEN SERVICING THESE RECEIVERS, TO PROTECT TEST EQUIPMENT.

GENERAL INFORMATION

The General Electric Models 16T1, 16T2, 16C110, 16C111, and 16C115 provide reception on all the twelve commercial television channels as specified on page 35 The picture is reproduced on a 16-inch picture tube.

Features of these television receivers include a two stage r-f amplifier, balanced input to the r-f, selenium type rectifiers, intercarrier sound, ratio detector, safe high voltage supply for the picture tube, automatic frequency control for horizontal sweep synchronization and electromagnetic deflection.

The r-f tuner assembly is mounted on a separate chassis which is readily demounted from the main chassis. The coils which tune the 1st and 2nd r-f stages and the oscillator are mounted on individual wafers of the selector switch. The local oscillator V3B operates on the high frequency side of the incoming r-f signal. The picture carrier is converted to a 45.75 mc video i-f frequency, while the FM sound carrier is converted to a 41.25 mc frequency.

The video i-f is stagger tuned to pass the video i-f (45.75 mc) and the (41.25 mc) with the proper amplitude relationship between the two frequencies. The video information is detected by the detector Y1 as well as a 4.5 mc FM signal which is the beat frequency between the video i-f (45.75 mc) and (41.25 mc). The 4.5 mc audio FM is amplified and limited by V17 and V18 and detected by the ratio detector V19. The audio is amplified by V20. V21 is the audio output tube.

The horizontal and vertical sync signals are taken off at the plate circuit of V7B and amplified and separated from the video signal by V11. The vertical sweep is generated by one section of a 12SN7 (V9) and a 12AU7 (V10) connected in a multivibrator circuit. The 12AU7 (V10) also serves as the vertical sweep output tube. The other section of the 12SN7 (V9) is used to produce the vertical retrace blanking signal. The horizontal sync signal is mixed with a sawtooth signal from the plate of the damper tube (V16) by the discriminator (V12). A change in phase between these two signals increases or decreases the bias voltage which is applied to the grid of V13A. V13A is a reactance tube which changes the frequency of the horizontal oscillator V13B. V14 the horizontal sweep output is coupled to the horizontal deflection coils by T351.

V15 is the high voltage rectifier for rectifying the kickback voltage, produced in T351 by the horizontal retrace current, to supply approximately 12 kilovolts to the picture tube high voltage anode.

These receivers use two selenium rectifiers in a half-wave voltage doubler circuit to supply the B+ voltage of approximately 255 volts. The tube filaments are a series parallel connection across the 117 volt a-c line.

INSTALLATION AND SERVICE ADJUSTMENTS

NOTE: ALWAYS WEAR SAFETY GLASSES WHEN HANDLING PICTURE TUBE

PREPARATION FOR USE

These receivers are shipped with the picture tube installed. Carefully unpack the receiver.

In order to prevent damage to the picture tube, all receivers have their focus coil moved close to the yoke assembly and a shipping sleeve slipped between the focus coil and the tube neck. Loosen all wing nuts on the focus coil bracket, remove the shipping sleeve and move the focus coil back. Then focus and center the picture, using a temporary test power cord (see Preset Control Adjustment Fig. 2).

It is necessary to remove the speaker to allow the chassis to be removed from the cabinet.

When the picture tube is removed from the chassis and replaced, it is necessary to replace the tube support brackets, as shown in Fig. 2, to support the picture tube. Secure these two support brackets to the front of the cabinet when the chassis is replaced in the cabinet.

RECEIVER INSTALLATION

1. If the built-in antenna is used, it is advisable to observe the reception in various locations of the room in order to obtain best results.

2. In case an outdoor antenna has to be used, the antenna lead-in should be as short as possible. The built-in antenna is connected to the dipole terminals, therefore, it is necessary to disconnect the wires of the built-in antenna and connect the transmission line (impedance 300 ohms) of the outdoor antenna installation to the dipole terminals. Any type of antenna system may be used as long as it is connected by a balanced transmission line to the balanced input of 300 ohms of the receiver. The choice of the antenna depends on the operating area of the receiver, the number and location of stations to be received. In order to avoid multiple images (ghosts) and interferences, careful experimentation with the antenna system is necessary to obtain satisfactory reception. These problems may be aggravated in fringe areas and sometimes an elaborate installation has to be made to obtain satisfactory results.

LIGHTNING PROTECTION—All outdoor antenna installations should conform to standards set by the National Electric Code which is usually supplemented by Local Electrical Code requirements. In general, some of the requirements are as follows:

1. The metal mast supporting the antenna should be permanently and effectively grounded. Use a ground wire of minimum size as specified in the Electrical Code.

2. An approved television lightning arrester should be used in the antenna lead-in conductors at the point of entrance to the building. If shielded lead-in cable is used, the shield may be permanently grounded in lieu of using the lightning arrester.

For detailed information on antenna installations, refer to Chapter XIII of the Television Course RSM-4-13.

3. A power outlet providing 110 volts at 60 cycles per second must be in easy reach of the television receiver.

4. Locate so that the room illumination, in daytime or nighttime, falling on the screen of the picture tube may be controlled. If this cannot be done, locate the receiver in such a position that light from a window does not fall directly on the screen of the picture tube. For nighttime use, it is unnecessary to turn out all lights when viewing.

5. Ventilation of the television receiver is very important. Slots are provided in the cabinet back and bottom for ventilation. These slots should not be obstructed. Do not locate the receiver on or too near any heating device.

PRESET CONTROLS

THERMAL CUT-OUT—This is a protective a-c circuit breaker which disconnects the line voltage in case of excessive current drain of the receiver caused by an internal short circuit or breakdown of components. In case this cut-out cuts off, a five minute period should be allowed to elapse before resetting this cut-out. Depress this cutout button to reset.

ION TRAP—An ion trap is placed around the neck of the picture tube between the focus coil and the picture tube base. It is important that the Ion Trap be always adjusted for maximum brilliance. When adjusting the Ion Trap if the raster gets too bright, reduce the brilliance control and readjust Ion Trap for maximum brilliance.

To adjust, rotate the Ion Trap on the neck of the tube and move it forwards or backwards to give maximum brightness.

FOCUS—The focus switch, S401, S402 on the rear panel should be set to the position which allows the front control, R421, to focus the picture nearest the center of rotation of R421 and to give uniform focus over the greatest picture area.

Note: The focus coil should be located as near to the picture tube base as possible, when centering the picture, to give most uniform focus. (See Picture Centering.) As the focus coil is moved near to the base of the picture tube, brilliance will be diminished. It is advisable to sacrifice some brilliance to achieve uniform focus.

PICTURE TILT—If the picture or raster does not square with the picture tube mask, loosen the wing nut at the top of the yoke clamping bracket and rotate the deflection yoke in the proper direction until the picture squares with the mask. Clamp the yoke tightly in place.

PICTURE CENTERING—Centering of the test pattern is accomplished by loosening the wing nuts which secure the focus coil and adjusting the position of the focus coil until the test pattern is centered.

The focus coil may be moved slightly in various directions: it may be moved vertically by loosening the two side wing nuts; it may be moved horizontally or rotated about its vertical axis by loosening the top wing nut. Furthermore, it may be tilted about a horizontal axis by loosening the two side wing nuts.

NOTE: The focus coil should be kept as far back towards the base of the picture tube as possible to give uniformity of focus over the greatest picture area.

When making the adjustment, it is advisable to loosen all three wing nuts and make an approximate adjustment of the focus coil. Tighten the three wing nuts enough to maintain the focus coil in place but loose enough so it may be moved to a final position. After a final position has been found which gives good centering of the picture, tighten the three wing nuts securely.

A slight dimming of the picture may be encountered as the focus coil is moved towards the base of the picture tube. It may be necessary to lose some brightness to obtain good centering and uniformity of focus, since the brightness may be regained by increasing the brightness control.

Do not leave the focus coil set in such a position as to give neck shadow at one edge of the picture. (Fig. 13.)

HORIZONTAL HOLD—Rotate the front panel Horizontal Hold control (R365) to the middle of its range. Adjust the core of the rear panel Horizontal Hold control (L351) until the picture is synched and is phased at the center of the raster. Slight rotation of the front panel Horizontal Hold control (R365) either way should move the picture slightly left or right without losing horizontal sync.

The pull in range should be equally distributed either side of the front panel horizontal hold control center position. Readjust the rear panel hold control if necessary.

Check pull in sensitivity by switching from an empty channel to a station with the receiver properly tuned to that station. If the picture snaps into synchronization immediately, the adjustment is satisfactory.

HORIZONTAL LINEARITY—The Horizontal Linearity control (L352) adjusts the picture for correct horizontal proportions. For best adjustment, use a test pattern and adjust the Horizontal Linearity control until the distance from the center of the test pattern to the left- and right-hand edges of the test pattern measures approximately the same. The adjustment of this control is very broad and it should be made simultaneously with the adjustment of the Width control (L353) to get proper picture width and correct horizontal linearity. (See Fig. 12.)

HORIZONTAL DRIVE—The Horizontal Drive control (R369) should be set approximately ⅓ of its total rotation from the counterclockwise end of its rotation. If white vertical bars appear in the picture, the Drive control should be turned slightly in either direction to just remove these white vertical bars.

The Drive control R369, on late production receivers, connected as shown in the schematic diagram, should be set to give maximum width of the picture or raster. The control should be rotated counterclockwise to just remove any picture compression which appears at the right-hand edge of the raster.

WIDTH—Adjust the Width control (L353) so that the edges of the picture extend approximately one-eighth inch past the right- and left-hand edge of the mask and are not visible (Fig. 11).

VERTICAL LINEARITY—This control (R311) should be adjusted to give good vertical proportions to the picture. The adjustment should be made on a test pattern so that the distance from the center to the top and bottom edges of the pattern measures approximately the same. This adjustment will alter the height of the picture slightly. (See Fig. 9.)

HEIGHT—This control (R308) changes the picture height and should be adjusted so that the picture extends approximately ⅛ inch beyond the top and bottom edges of the mask. This adjustment should be made simultaneously with the Vert. Linearity control (R311).

HIGH CHANNEL TRAP—This receiver incorporates a trap (C206, L203) on the head-end unit which is switched into the antenna circuit on all low-band channels and will eliminate high-channel interference on these channels. This interference manifests itself as horizontal bars or herringbone pattern or as a picture in the background. If the receiver is tuned to Channel #5, a strong station operating on Channel #11 will beat with the second harmonic of the local oscillator to form an i-f frequency which will ride through unhindered and appear on the picture screen. In order to prevent the interfering signal from reaching the converter, a trap consisting of a fixed inductance and a variable capacitance is adjusted for maximum rejection of the interfering station. This type of interference, is also possible on the Channels #4 and #6 due to interfering stations on Channel #8 and #13, respectively. The trap is adjusted at the factory approximately for Channel #11 rejection. It may be necessary to readjust the trap slightly for maximum rejection of Channel #11.

ADJUSTMENT OF TRAP—The adjustment of the trap can be made by means of a signal generator and an oscilloscope or an a-c meter as indicating device. The signal generator must be terminated to match 300 ohms impedance. For elimination of Channel #8, #11 or #13 interference, feed a strong signal of the picture carrier of the interfering station modulated with an audio signal into the antenna terminals and connect the indicating device to the picture tube grid. Set the band selector to the Channel #4, #5 or #6, respectively, and tune local oscillator of receiver for maximum deflection on indicating device. Then tune trimmer C206 for minimum signal on picture tube grid.

The adjustment of the trap can be made without instruments as follows: When the channel interference appears in the picture, set the tuning control for maximum interference. Then tune trimmer C206 for minimum interference or maximum rejection.

PICTURE DEFECTS

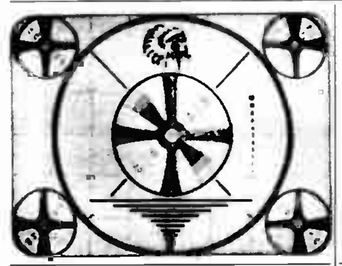

Fig. 3
Normal picture.

The following illustrations show picture defects which are caused by incorrect setting of operating controls, the preset controls or by interference picked up by the antenna. A possible remedy is indicated for each defect.

The adjustment of controls is most efficiently accomplished by the use of a test pattern, similar to that illustrated to the left, which is normally transmitted just prior to the scheduled program.

The normal picture should show good focus and a good contrast between blacks and whites with intermediate shades of gray. The picture should not tend to move either vertically or horizontally and have good linearity.

PICTURE	DEFECT	REMEDY
	**Fig. 4** **Picture too light.**	1. Increase Picture control setting and/or reduce brightness. 2. Weak signal. This may be caused by insufficient pickup on antenna or defective lead-in. Insufficient pickup at maximum contrast usually is accompanied by "snow" on the picture.
	**Fig. 5** **Picture too dark (contrast).**	1. Reduce Picture control setting and/or increase Brightness control setting. 2. Too strong signal. If it is not possible to reduce signal adequately with Picture control, install suitable resistor antenna pad.
	**Fig. 6** **Picture defocussed.**	1. Adjustment of front panel focus control, R421. 2. Check for optimum uniformity of focus by moving focus coil (see installation and service adjustments, page 3). 3. Check coarse focus control at rear of chassis. 4. Mistuning of receiver or misalignment.
	**Fig. 7** **Horizontal sync.**	1. Adjust Horizontal Hold control (front panel control). 2. Check adjustment of rear panel Horizontal Hold control. 3. Signal improperly tuned. 4. Defective horizontal sync circuits.

©John F. Rider

World Radio History

PICTURE	DEFECT	REMEDY
	**Fig. 8** Vertical sync.	1. Adjust Vertical Hold control until picture shows no tendency to slide up or down or lock out of frame. 2. Check the vertical sync circuits.
	**Fig. 9** Vertical linearity.	Adjust Vertical Linearity control. This adjustment may alter the Height control adjustment.
	**Fig. 10** Vertical height.	Adjust Height control so that the top and bottom picture edges are just covered by mask. Recheck Vertical Linearity control setting.
	**Fig. 11** Picture too wide.	Adjust Width control so that the right and left picture edges are just covered by the mask.
	**Fig. 12** Horizontal linearity.	1. Adjust Horizontal Linearity control. This adjustment may require resetting of Width control. 2. Adjust Drive control as described under Installation and Service Adjustments, page 3.
	**Fig. 13** Neck shadow.	1. Misadjustment of Focus coils—tilted too far. 2. Move the deflection yoke forward against the bell of the picture tube.

PICTURE INTERFERENCES

PICTURE	DEFECT	REMEDY
	**Fig. 14** Herringbone pattern over picture.	This interference is caused by a television station operating on the next lower channel or by a short-wave radio transmitting and receiving equipment. Police and "ham" transmitters in your locality will usually cause the most severe conditions. The interference produces moving ripples or diagonal streaks, or in some cases, may cause loss of contrast of the picture. The use of an antenna wavetrap tuned to the interfering signal may assist. If the interference is from a TV or FM station, a transmission line shorted stub may remove the interference. If the pickup is on the lead-in, a shielded lead-in will help correct the trouble. See page 3 for high channel trap adjustment.
	**Fig. 15** Diathermy interference.	Diathermy equipment is used by hospitals and doctors and can be very annoying because it might ruin the reception completely. This interference manifests itself in a herringbone pattern or one or two dark bars moving slowly up or down the picture. If the disturbance is extremely strong, the interference pattern will remain stationary while the picture floats in the background. Improve the antenna installation using directive antenna systems and shielded transmission line.
	**Fig. 16** Horizontal bars on picture.	This interference is caused by adjacent channel sound or microphonics in receiver. If adjacent channel sound is responsible for this defect, readjust the adjacent channel trap as outlined on page 8. A microphonic video amplifier tube, V7, may cause this condition.
	**Fig. 17** Ignition interference.	Ignition interference from trucks, automobiles, and airplanes may be identified by streaks and splashes on the picture. The ignition system of trucks will produce the most intense interference pattern. Install antenna away from road carrying traffic. Shielded lead-in may help if interference is picked up on it.
	**Fig. 18** Multiple images (ghosts).	This is caused by the television signal following multiple paths, one of which is the direct path, and the other is reflected from some object such as a tall building or a large storage tank or hills. The signal following the longer reflected path arrives later at the receiver producing the second image. In case a built-in antenna is used, try to turn the cabinet until the ghost picture is dimmed out. If your receiver is connected to an outdoor installation, a reorientation of the antenna might improve the reception.
	**Fig. 19** "Snow."	1. Too weak signal; increase efficiency of antenna installation. 2. Adjust tuning control.

CIRCUIT ALIGNMENT

CAUTION: TO PROTECT TEST EQUIPMENT ALWAYS USE AN ISOLATION TRANSFORMER

GENERAL—

A complete alignment of the receiver tuned circuits is given in the following charts. Read all alignment notes prior to making an alignment. The procedure shown in the charts is based upon the use of the G-E test equipment specified and if other equipment is used which has different characteristics, the charts may have to be modified slightly. A diagram showing the location of adjustments used in alignment is shown in Figure 22 on page39. Use the alignment service diagram, Figure 29 on page 42 with the charts.

It is necessary to connect the low side of the test equipment to the B− bus of the receiver keeping the lead as short as possible.

Always permit a 15 minute warm-up period for the receiver and test equipment prior to attempting alignment.

To align the receiver with the picture tube removed, a Type 6SN7 tube with all pins clipped off except pins #7 and #8 may be used to complete the filament circuit. Plug pins #7 and #8 of the 6SN7 into pins #1 and #12 of the picture tube socket.

To protect the test equipment, always use an isolation transformer between the power line and the TV receiver.

TEST EQUIPMENT—The following test equipment is necessary.

1. R-F Sweep Generator (G-E Type ST-4A or Equivalent).

a. Frequency Requirements.

4.5 MC with 500 KC and 2 MC sweep width.
40-50 MC with approximately 10 MC sweep width.
50-90 MC, 170-220 MC with 15 MC sweep width.

b. Constant output in the sweep range.

c. At least 0.1 volt output.

2. Marker Generator (G-E Type ST-5A or Equivalent).

The marker generator must have good frequency stability, must be accurately calibrated and must cover the following frequencies.

41.25 MC for video I-F
42.50 MC for video I-F
44.20 MC for video I-F
44.50 MC for video I-F
45.00 MC for video I-F
45.75 MC for video I-F
47.25 MC for video I-F
4.5 MC for sound I-F and trap alignment

Picture and sound carrier frequencies for Channels #2 through #13

3. Balanced Output Adapter G-E ST-8A or Equivalent (See RF Note 1).

4. Oscilloscope (G-E Type ST-2A or Equivalent)—The oscilloscope should have good sensitivity and preferably a 5-inch screen with a good wide-band frequency response on the vertical deflection circuits. Although the high frequency response is not necessary for alignment, it is important when making waveform measurements.

5. Vacuum Tube Voltmeter—A vacuum tube voltmeter is necessary to measure the bias of −4 volts required for video and r-f alignments.

6. Detector Network—A crystal detector network as shown in Figure 27 is necessary to detect the response when aligning L260, the 4.5 mc trap.

7. Miscellaneous—One 10,000 ohm resistor to isolate the scope as noted in the charts.

One .01 mfd. capacitor to isolate the sweep generator as noted in the chart.

Impedance matching pad for r-f alignment as shown in Figure 20.

Bias battery to supply −4 volts as noted for video i-f and r-f alignment.

VIDEO I-F ALIGNMENT

1. Connect a bias battery from junction of C261, R263 and the Picture control to B−. Connect positive of battery to B−. Adjust contrast control to give a −4 volts bias at the grid pin 1 of V4 measured with a VTVM. Disconnect VTVM leads during alignment.

2. The sweep generator should be properly terminated in its characteristic impedance. Couple the signal to the point of input through a .01 mf. capacitor. See Fig. 20.

3. The traps L227 and L253 must be detuned before aligning the amplifier by turning the cores all the way out of the coil. Retune these traps to 47.25 mc (as in step 6) for minimum amplitude. This adjustment is greatly enhanced by increasing the scope gain.

4. Set the Channel switch to Channel #12 or #13. Check for oscillator influence by turning the tuning control. If the shape of the response curve changes, switch to another channel where oscillator influence is not noted.

5. In most cases it is only necessary to perform an over-all alignment of the video i-f, as in Step 7 of the Video Alignment Chart, to obtain i-f response curve of Figure 21-E.

When aligning the i-f coils, L251 will adjust the audio or low frequency side of the i-f response curve, while L252 will adjust the video or high frequency side of the i-f response curve. L226 and L254 should be adjusted simultaneously to reduce the saddleback at the peak of the curve and to give maximum gain and retain 45.75 mc and 42.50 mc markers at the 50% mark.

6. It is necessary to detune the i-f coils by shorting as noted in the alignment chart to prevent the coil preceding the signal input point from influencing the response curve.

7. The 45.75 mc marker should fall at the 50% point to give proper sideband response. See Fig. 21E.

8. After adjustment of the two adjacent sound traps, readjust the i-f curve to obtain the proper curve and marker as illustrated.

9. Adjust the signal input to give a video response curve of ¾ volt, as shown in Figure 21.

VIDEO I-F ALIGNMENT CHART

Step	Marker Generator Frequency	Sweep Generator Frequency	Signal Input Points Between	Connect Oscilloscope Between	Adjust	See Note No.
1					Detune L227 and L253 by turning cores out of coil.	3
2	44.50 MC		V6 grid (pin 1) thru .01 mf. cap. and B− on head-end shield. Pins 5-6 shorted on V5.		Core of L254 for curve of Fig. 21-A.

6	47.25 MC,		Junction L215 and L216 on second r-f switch wafer thru .01 mf. cap. and B− on head-end shield. Remove short on L226.		Cores of L227 and L253 for min. output at 47.25 MC (Fig. 21-E).	1, 2, 3, 4, 7, 9
7	41.25 MC, 42.50 MC, 45.00 MC, 45.75 MC, 47.25 MC				Cores of L251, L252, L254 and L226 for curve of Fig. 21-E.	1, 2, 4, 5, 7, 8, 9

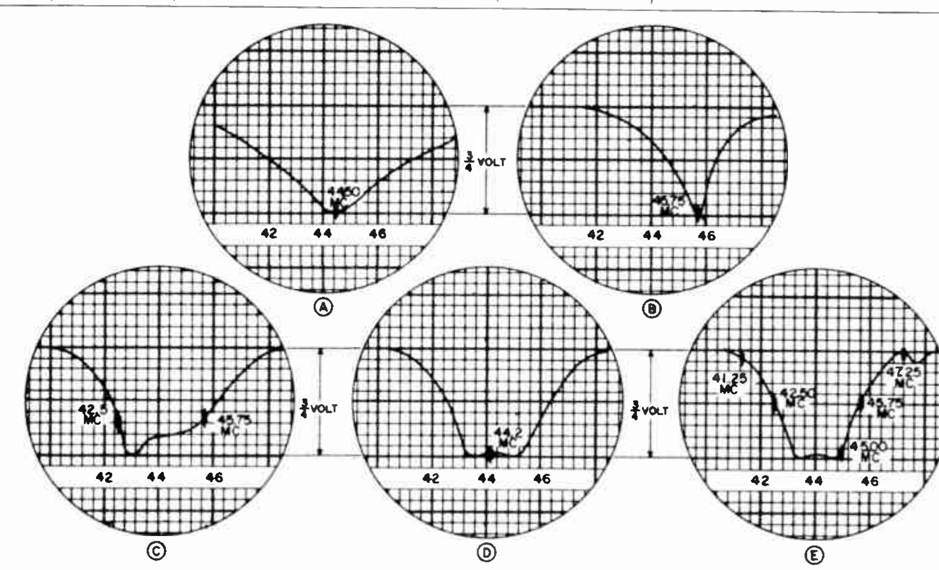

Fig. 21. Video I-F Curves

World Radio History

AUDIO I-F ALIGNMENT

1. Audio i-f alignment is performed by putting in a 4.5 mc ±500 kc sweep and viewing the response curve as noted in the audio i-f chart.

2. As a final check, step 12, the secondary of T402 adjustment, should be checked on a television signal if possible. Try several operating television stations and if buzz in the audio is heard, the secondary of T402 should be readjusted as follows.

Tune in the station and adjust the contrast control for a weak sound output. Readjust the secondary of T402 until the buzz is a minimum or disappears and the best quality audio is obtained.

3. Keep the input of the sweep generator low enough so that limiting does not take place, otherwise the response curve will broaden out, permitting slight misadjustment. Check by increasing the output of the sweep generator; the response curve should increase in amplitude.

4. T401 is adjusted for maximum amplitude and symmetry of the response curve about 4.5 mc marker as shown in Fig. 23-A.

5. The secondary of T402 is adjusted for the curve of Figure 23-B. This adjustment should give as straight a slope as possible between the positive and negative peaks of the curve with the center of the 4.5 mc marker falling midway between the peaks.

6. The primary of T402 is adjusted for maximum of the positive and negative peaks with as straight a trace as possible between the peaks. If necessary, readjust the secondary of T402 so that the marker falls midway between the peaks.

7. An alternate method to the visual alignment is the sound output method using an operating television station, preferably when transmitting tone modulation during the test pattern.

(a) Tune the receiver for optimum detail.
(b) Keep the input below limiting level by reducing the contrast by the Picture control or by using a resistor pad in the antenna circuit.
(c) Adjust primary and secondary of T401 for maximum sound output. Adjust primary of T402 for maximum audio output.
(d) Adjust the secondary of T402 for best quality audio (low distortion, least noise) and for minimum buzz in the output.

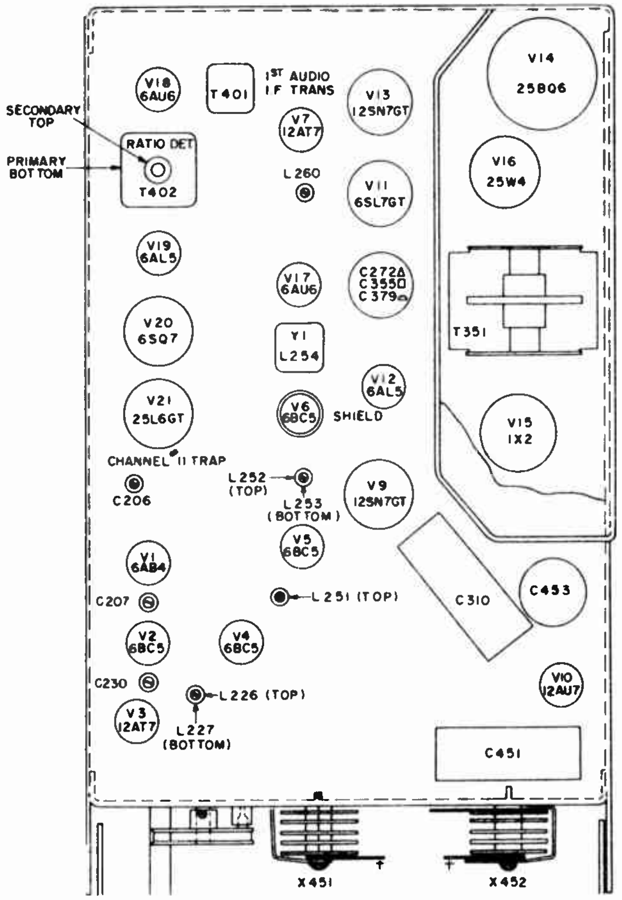

Fig. 22. Tube and Trimmer Location

AUDIO I-F ALIGNMENT CHART

Step	Marker Generator Frequency	Sweep Generator Frequency	Signal Input Points Between	Connect Oscilloscope Between	Adjust	See Note No.
8	4.5 MC	4.5 MC ±500 KC keep signal below limiting level of receiver.	Pin 1 of V17 through .01 mfd. cap. and B−.	Junction of R404 and C404 & sec. of T401 through 10K and B−.	Primary and secondary of T401. See Figure 23-A.	1, 3, 4

R-F ALIGNMENT

R-F Alignment Notes

1. Disconnect the transmission line to the antenna terminals from the head-end. Couple the input of the sweep generator to the head-end terminals through balanced output adapter G-E ST-8A, or equivalent. Couple this to the head-end terminals through a piece of 300-ohm transmission line. Terminate the 300-ohm line in a pad, as shown in Figure 20A.

If a balance output is not available for the sweep generator a matching network as shown in Figure 20B may be used. A balanced output is recommended since a matching network as shown in Figure 20B may introduce frequency shift and cause a misleading tilt to the response curve.

Ro shown in Figure 20B is the terminating resistor. If this resistor is not already incorporated in the output of the sweep generator, it should be added to the matching network as shown.

2. It is necessary to connect a bias battery from the junction of the Picture control, C261, and R263 to B−. Connect plus of bias battery to B−. Adjust the Picture control to give a −4 volts bias measured from pin 1 of V2 to the head-end chassis B−.

3. Shunt L226 with a 680 ohm, ½ watt resistor during r-f alignment to prevent the oscillator from influencing the response curve. In order to reduce the effect of hum on the response curve, connect a 100 ohm resistor between the head-end B+ and the chassis B+ and connect an electrolytic capacitor of approximately 400 mf, 350 volt from head-end B+ to head-end B−.

4. On all channels the picture carrier marker should not be less than 75% of the peak of the r-f response curve. The sound carrier marker should not be less than 50% of the peak of the response curve. However, the two minimum values should not occur simultaneously. On the high channels the picture carrier marker should ride up nearer to the top of the curve provided the sound carrier marker does not go below 50%. On the low channels the picture carrier marker should ride as high up on the curve as possible and still keep the sound carrier marker above 50%.

5. Coils for Channel No. 12 through No. 7 are fixed inductances. Check the alignment on these channels as in steps 16 through 21 for proper response curve. Readjust L210 and L217 on Channel No. 13 and C207 and C230 on Channel No. 7 if necessary.

6. Coils for Channels No. 5 and No. 4 are fixed inductances. Check the alignment on these channels for proper curve. Readjust coils L208 and L215 to give proper curve on Channels No. 6, No. 5 and No. 4.

7. The coil for Channel No. 2 is a fixed inductance. Check the alignment on this channel for proper curve. Readjust L205 and L212 to give proper curve on Channels No. 3 and No. 2.

8. The trimmers C207 and C230 may be used to compensate for differences in tube capacities which affect tracking when it is necessary to change the tubes V1 or V2. The variations in tube capacities have normally little effect on the over-all performance of the head-end.

R-F ALIGNMENT CHART

World Radio History

OSCILLATOR ALIGNMENT

Before attempting this oscillator alignment, it must be certain that the video i-f stages and r-f stages are properly aligned as outlined previously.

1. Disconnect the 300-ohm line from the r-f head-end terminals and connect sweep generator to head-end properly terminating sweep generator output cable as shown in **Figure 20**. See RF Alignment Note 1.

2. Alignment is made by viewing the response curve at the output of the video i-f detector.

3. Use a video carrier marker as shown in each step of the Alignment Chart.

4. Set C213 at the center of its rotation. Adjust L225 to place marker at the 50% point on the high frequency slope of the curve for step 27. The oscillator inductance L224 for Channels #12 through #7 are fixed. The alignment on these channels should be checked to see that the tuning control, C213, will move the video carrier marker up and down the entire high frequency side of the response curve. Readjust L225 if necessary.

5. When adjusting L225 as in step 27, the tracking on Channels #12 through #7 should be checked. Set C213 at the center of its rotation. Adjust L225 so that the video carrier marker falls as near as possible to the 50% point on the high frequency slope as the receiver is switched to each channel from 7 through 13 with this setting of C213 for all channels from 7 through 13.

6. On Channel #6 through #2 set the tuning control C213 at the center of its rotation and make the indicated adjustment so that the video carrier marker falls at the 50% mark on the high frequency slope of the response curve.

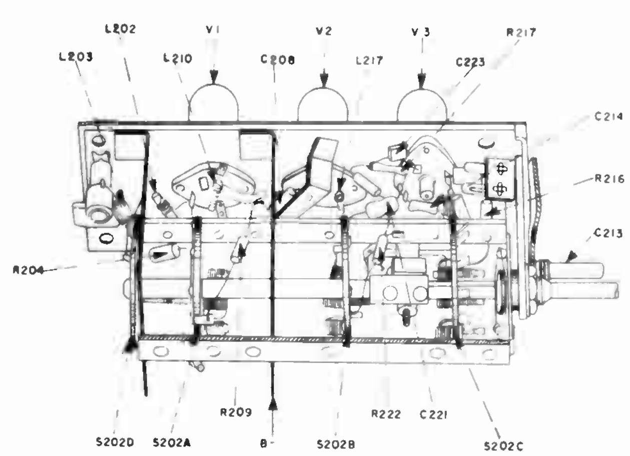

Fig. 26. Head-end Unit

ADJUSTMENT OF VIDEO AMPLIFIER 4.5 MC TRAP (L260).

This trap is used to removed 4.5 mc audio i-f from the video amplifier which shows up in the picture as a cross-hatch pattern. This trap will very rarely require adjustment. Adjustment is as follows:

1. The trap (L260, C271, C270) is adjusted for minimum amplitude of the 4.5 mc marker. Use a detector network as shown in **Figure 27**, connected from junction of L264 and C275 to **B** −, to detect the signal.

2. Adjust the vertical hold control to remove the vertical pulses from the response curve.

3. Short horizontal oscillator coil L351 to remove horizontal oscillator interference in the response curve.

4.5 MC TRAP (L260) ALIGNMENT CHART

Step	Marker Generator Frequency	Sweep Generator Frequency	Signal Input Point	Oscilloscope	Adjust	See Notes
39	4.5 MC	4.5 MC ±1 MC	Junction L256, R265, C268 and B− thru .01 mf.	Across 100K resistor as shown in Fig. 27. (See Note 1.)	L260 for min. amplitude of 4.5 mc marker. Increase scope gain	1, 2, 3

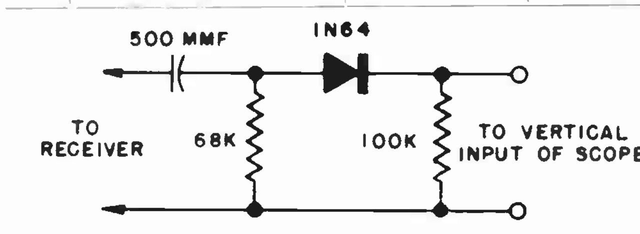

Fig. 27. Detector Network

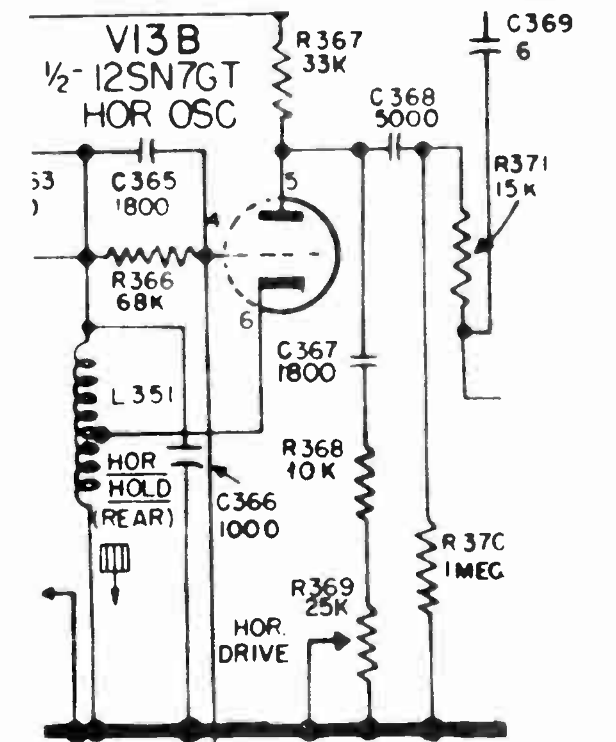

Fig. 28. Hor. Drive Control connections, early production

PRODUCTION CHANGES

1. The Horizontal Drive control R369 has been reconnected, as shown in the schematic, to remove the effect of the drive control setting on the horizontal pull-in sensitivity.

If any early production receivers are wired as shown in the schematic diagram, R369 potentiometer should be changed to one of higher wattage rating. Catalog number for the higher wattage rating R369, 25K potentiometer, is RRC-140.

Figure 28 shows the drive control (R369) connections for early production receivers.

2. Capacitor C268 has been changed from .02 mfd. to .05 mfd., Cat. No. UCC-045. This change was made to improve the low frequency response of the video amplifier.

3. To eliminate Barkhausen oscillation (vertical black beady lines in raster when not receiving a station) the following resistor was added to early production receivers.

Pin 8 of V14 was connected to B − through a 47 ohm, 1 watt, resistor, Cat. No. URE-017.

4. Two mica capacitors, 390 mmf., 500 volt each, were connected in series between terminals 6 and 8 of T351 as a substitute for C382, 180 mmf.

TROUBLE SHOOTING CHART

This trouble shooting chart is divided into two parts: Trouble Shooting Chart and analysis which explains in more detail the particular defect. The chart is divided into five sections. 1. Picture defects, 2. Deflection defects, 3. Sync defects, 4. Audio defects, 5. Miscellaneous defects.

When trouble shooting, full use should be made of the block diagram Fig. 1, the socket voltage diagram Fig. 30, page **41**, and the Service diagram Fig. 29, page **42**, to help localize defective components.

It is not possible to cover all troubles, which may occur in this receiver, in this publication. However this information will serve as a guide in locating troubles.

Picture Defects

SYMPTOM	CHECK
1. No picture or sound. Raster normal.	(a) RF and Video IF circuits #3.
2. Poor picture detail.	(a) Misalignment see Defects of RF and Video IF circuits #1. (b) Misalignment of L260 see Defects of Video amplifier circuits #4.
3. Faint picture	(a) Low signal input. (b) Loss of gain in video amplifier, video IF or RF amplifier (c) Misalignment
4. Ghosts in picture (secondary images)	(a) Antenna installation. See Fig. 18
5. Snow effect in picture	(a) Defective head end or low signal input to the television receiver.

©John F. Rider

World Radio History

6. Reverse action of picture control and distorted picture. Excessive contrast. — (a) C261 shorted see miscellaneous defects section #3

7. Sound bars in picture (black horizontal bars) — (a) Alignment of L227 and L253 see RF and Video IF Circuits #2. (b) See defects of the picture tube circuit #3. (c) Microphonic tubes V3, V4, V7.

8. No Raster. Sound normal. — (a) No high voltage to picture tube. (b) See defects of the horizontal sweep section #1. (c) Picture tube.

Deflection Defects

1. Barrel distortion of picture or Keystoning (picture narrow at top or bottom or side). — (a) Shorted turns of deflection yoke.
2. Insufficient sweep width — (a) See defects of horizontal sweep section #2.
3. Poor horizontal linearity See Fig. 12 — (a) L352 shorted (b) High leakage of C370. (c) Damper tube V16.
4. Picture not centered horizontally — (a) Shorted capacitor C3 77. See defects of the horizontal deflection circuit #4.
5. No vertical deflection — (a) Defect in T301 or D301. See defects of vertical sweep section #4.
6. Poor vertical linearity. Height reduced. — (a) Check capacitor C309. See defects of vertical sweep section #2.
7. Insufficient height. — (a) See defects of vertical sweep section #3.

Sync Defects

SYMPTOM	CHECK
1. Picture unstable. Excessive contrast.	(a) Open capacitor C353. See defects of Common Sync section #2.
2. No vertical sync. Hor. sync normal.	(a) C301, C302, C303, R301, R302.
3. No horizontal sync, vertical sync normal.	(a) Defect in circuits of V12, V13A, and V13B.

Audio Defects

1. No sound. Picture normal.	(a) T401, T402, T403. (b) Speaker. (c) Circuits of V17, V18, V19, V20, and V21.
2. Hum or buzz.	(a) Alignment of T402.
3. Distorted sound.	(a) Crystal. (b) Alignment of T402.

Miscellaneous Defects

1. Excessive contrast	(a) C354 shorted see common sync section #1 (b) Shorted C251, C354.
2. Poor focus, picture very bright and no control of brightness.	(a) C277 shorted.
3. Poor focus	(a) Setting of focus coil or switch S401-S402. (b) Defect in focus coil circuit (c) Check for open or shorted focus coil.
4. Neck shadow See Fig. 13.	(a) Misadjustment of focus coil or Ion Trap. (b) Deflection yoke not forward against bell of picture tube.
5. Picture flutters	(a) C251 capacitor open
6. No picture on one operating channel.	(a) Defective channel switch or head end.

DETAILED ANALYSIS

Defects of the RF and Video IF Circuits

1. POOR PICTURE DETAIL

(a) Misalignment of the video IF coils or the RF coils may cause poor detail. See Fig. 21E for the over-all response curve of the video IF. Check Video IF alignment RF and Oscillator alignment.

(b) Any overloading of the r-f, i-f or Video amplifier stages will cause distortion. Check the operation of the picture control to see that the bias may be varied by the control.

2. SOUND BARS IN PICTURE

Misalignment of traps L227 and L253 may allow adjacent channel sound to get onto the picture tube grid causing horizontal sound bars in the picture.

3. NO PICTURE, NO SOUND. RASTER NORMAL

This condition indicates a defect in the circuits of the RF head end, the video IF or the detector circuits of Y1.
Defective antenna connections.

Defects of the Video Amplifier

1. NO PICTURE, SOUND AND RASTER NORMAL

Open chokes L259, L261 or L262, L263 or open capacitor C268 in the video amplifier circuit will cause no picture.

2. BRIGHT PICTURE WITH BLACK LINES

A shorted capacitor C275 will give a very bright picture with black lines across the picture. The picture control will have no effect.

3. PICTURE DISTORTED OR SMEARED

If the resistance of R273 has increased the picture will be distorted at high values of picture control setting.
If the resistance of R269 and R272 has increased a smeared picture will result.

4. POOR DETAIL

Misalignment of the 4½ mc trap (L260, C270, C271) will cause a (busy background) or a trailing edge on picture elements.

5. WEAK PICTURE WITH BLACK LINES

If either L264 or C275 is open only a fraction of the signal will be coupled to the picture tube grid by the stray coupling.

Defects of the Picture Tube Circuit

1. NO PICTURE, NO RASTER, SOUND NORMAL

(a) Defective picture tube.
(b) An open brightness control (R276) circuit.
(c) No High Voltage to picture tube.

2. BLOOMING PICTURE AND POOR FOCUS

A gassy picture tube will cause the picture to bloom and will also cause poor focus. If C277 becomes shorted the picture will appear fuzzy or out of focus.

3. SOUND BARS IN PICTURE

Parts of the electron gun structure may vibrate under the influence of strong loudspeaker output causing sound bars in the picture tube.

Defects of the Horizontal Sweep Section

1. NO RASTER OR DIM RASTER

No raster indicates a lack of high voltage to the picture tube. This may be caused by a defect in the High Voltage Rectifier circuit V15, the Horizontal Oscillator V13B or the Horizontal Sweep Output Circuits V14 may not be functioning properly.
A short in the Horizontal Deflection circuits may result in low High Voltage to the picture tube and a dim raster.
Width control L353 may be shorted causing low High Voltage to the picture tube.

2. INSUFFICIENT SWEEP WIDTH

Insufficient sweep width may be caused by defects in the horizontal deflection circuits such as shorted Width control L353. Low B+ to V14.
Check waveform at grid of V14.

3. POOR HORIZONTAL LINEARITY

A short in L352 will cause poor horizontal linearity.
High leakage in C370 will cause poor linearity and increased sweep width.

4. PICTURE WILL NOT CENTER HORIZONTALLY

A short in C377 will increase the d-c current through the horizontal deflection coils which will shift the picture horizontally so that it may not be centered with the focus coil adjustment.

5. NO HORIZONTAL SYNC VERTICAL SYNC NORMAL

Check for defects in circuits of V12, V13A or V13B.

Defects of the Vertical Sweep Section

1. NO VERTICAL SYNC

Check capacitors C301, C302, C303.
Check resistors R301, R302.

2. POOR VERTICAL LINEARITY

If the capacitor C309 has lost its original capacity, linearity will be poor and height will be reduced.

3. INSUFFICIENT HEIGHT

If the B+ voltages are low to tubes V9 and V10 the Vertical height will be small.
If C308 develops excessive leakage Vertical height will be reduced.

4. NO VERTICAL DEFLECTION

Check for shorted capacitors C304, C305, C308.
Check for open Deflection coils of yoke.
Defective transformer T301.
Check circuits of V9 and V10.

Defects of the Common Sync Section

1. EXCESSIVE CONTRAST

A shorted capacitor C354 on pin 1 of V11 will result in excessive contrast which cannot be controlled by the picture control.

2. UNSTABLE PICTURE WITH EXCESSIVE CONTRAST

An open capacitor C353 will cause the picture to be shaky with excessive contrast.

3. POOR SYNC HOR. AND VERT. WITH BRIGHT LINES

An open capacitor C351 on pin 4 or V11 will cause bright lines at the top and bottom of the picture and poor vertical and horizontal sync.

4. NO VERTICAL OR HORIZONTAL SYNC

Open capacitor C354 will cause no horizontal or vertical sync.

Miscellaneous Defects

1. BARREL DISTORTION OF THE PICTURE

A shorted coil or shorted turns will cause barrel distortion and unsymmetrical trapezoidal distortion of the raster or picture.

2. NECK SHADOW

The deflection yoke should be pushed forward against the bell of the picture tube to avoid neck shadow.

3. DISTORTED PICTURE AND REVERSE ACTION OF PICTURE CONTROL

If C261 is shorted the picture control will have a reverse action, that is increasing the picture control will cause the contrast to diminish while decreasing the picture control will cause the contrast to increase.

Audio Defects

NO SOUND. PICTURE NORMAL

This indicates a defect in the circuits of V17, V18, V19, V20, V21 or the loudspeaker.
Misalignment of T401 or T402 may also cause no sound to be received.

BUZZ OR HUM IN THE SOUND

Misalignment of T402 secondary may cause buzz. Reverse the power plug in the power outlet.

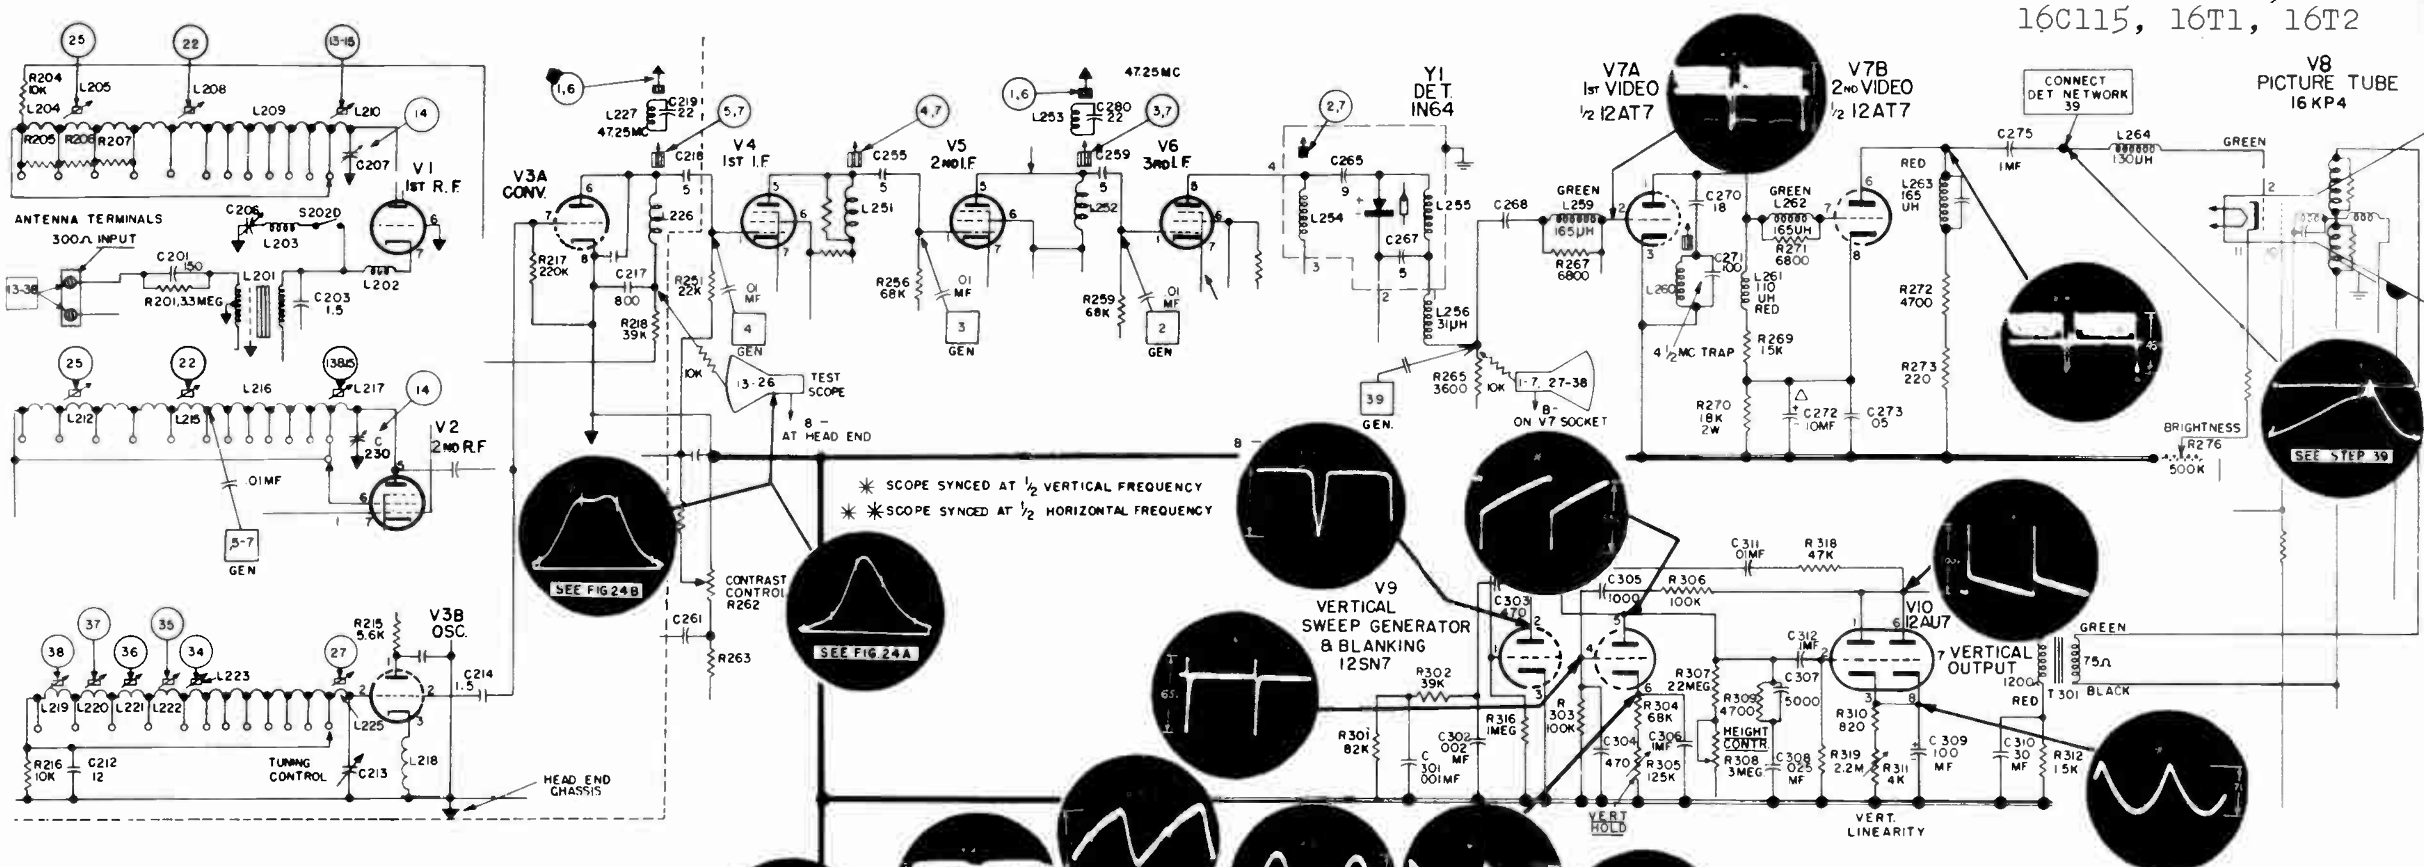
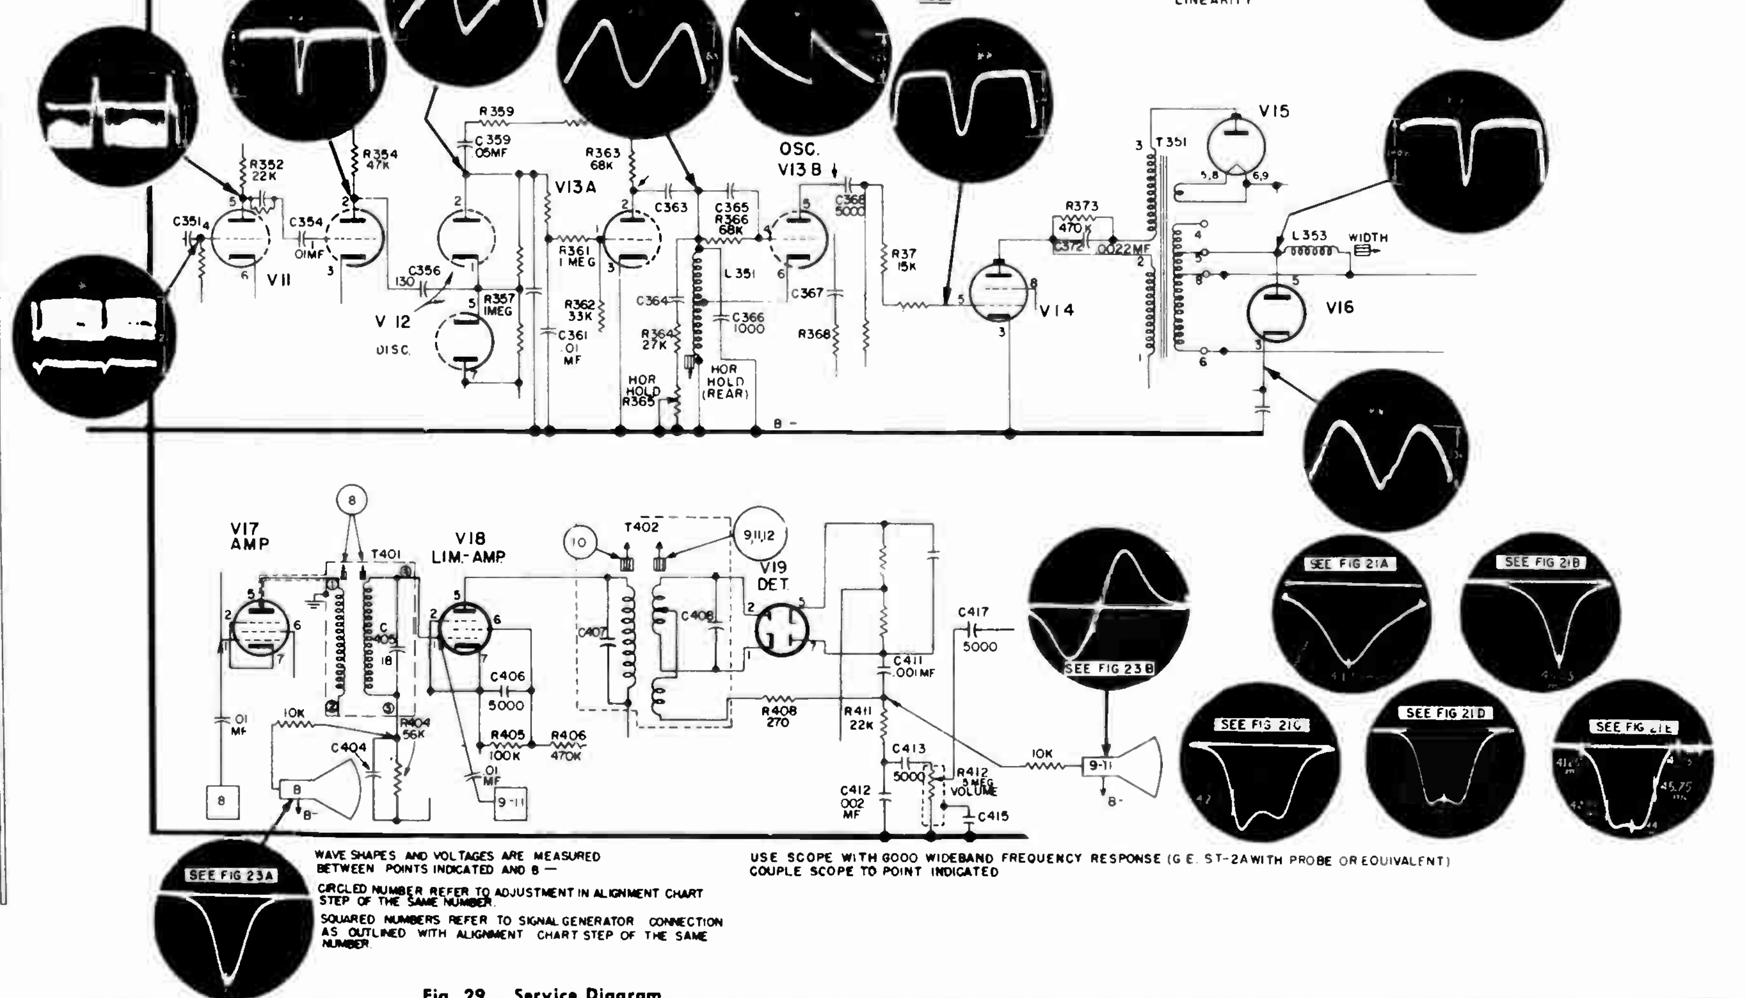
MODELS 16C110, 16C111, 16C115, 16T1, 16T2





SERVICE DIAGRAM

The alignment procedure is shown in table form on pages 38 through 40. In order to accelerate the whole procedure, the service diagram (Figure 29) should be consulted. The encircled numbers indicate the number of the step of the alignment chart and the arrow points to the component to be adjusted. The generator is symbolized by a square with the number of the step of the alignment chart. The exact point of feed-in is indicated by the arrow connected with the numbered square. The oscilloscope is represented by the symbol of the cathode ray tube. The number inside the symbol refers to the step of the alignment chart. On the left side of the diagram is shown the tube location inside the chassis so that it is easy to locate the correct points for connection to the generator and the oscilloscope. In order to clarify the diagram, only those parts of the circuits are shown which are needed for location of the test points. Within the large circles are shown the waveform of an average television receiver, wherein the controls have been adjusted for a normal picture with correct contrast, height, width and linearity. Most measurements must be made when a signal is being received.

The oscilloscope of which the vertical amplifier has been precalibrated is used to make measurements at the point indicated by the arrow connected to the individual waveshape within the circle. The oscilloscope is synced at half of the respective sweep frequency of the circuit being analyzed.

*RII-043		INSULATOR—For antenna terminals
*RII-044		SUPPORT—Power cord
RJC-001		PIN—Speaker contact pin
RJC-008		CONNECTOR—High voltage anode connector
*RJJ-007	I451	RECEPTACLE—For power cord, male rivets to chassis
*RJS-003		SOCKET—Octal tube socket for V11, V9, V20
*RJS-026		SOCKET—Tube socket, octal, for V21
*RJS-031		SOCKET—Tube socket for V14
*RJS-085		SOCKET—Tube socket for V16
*RJS-127		SOCKET—Tube socket, 9-pin, for V3
*RJS-132		SOCKET—Tube socket, 7-pin, for V12, V19
*RJS-133		SOCKET—Tube socket, 7-pin, shielded, for V5, V6, V18
*RJS-135		SOCKET—Shock mounting, V13
*RJS-138		SOCKET—Tube socket, 9-pin, V7
*RJS-139		SOCKET—Tube socket, 9-pin, miniature for V10
*RJS-144		SOCKET—Tube socket, 7-pin, for V4, V1, V2, V17
*RJX-040		RF HEAD-END—RF tuner
*RLA-034	L201	TRANSFORMER—Input
*RLC-091	L351	COIL—Horizontal oscillator
*RLC-095	L219	COIL—Oscillator, for Channel #2
*RLC-096	L220, 207, 214	COIL—Oscillator, for Channel #3, Channel #5, 1st and 2nd RF
*RLC-097	L222	COIL—Oscillator, for Channel #5
*RLC-098	L223	COIL—Oscillator, for Channel #6
*RLC-099	L225	COIL—Oscillator, for Channel #13
*RLD-014	L353	COIL—Width control
*RLD-016	L352	COIL—Horizontal linearity
RLD-024	D351, 301	YOKE—Deflection
*RLF-024	L256	CHOKE COIL—RF coil
RLF-038	L401	COIL—Focus
*RLI-003	L218	COIL—Cathode choke
*RLI-038	L257, 263	COIL—Video choke coil
*RLI-072	L206, 212	COIL—Channel #4, 1st RF, Channel #3, 2nd RF
*RLI-077	L205	COIL—Channel #3, 1st RF
RLI-085	L402	COIL—Choke coil
*RLI-093	L259, T401, R262, 267, 271	COIL—Video choke
*RLI-096	L251	COIL—2nd video IF coil
*RLI-097	T401	COIL—First audio IF coil
*RLI-099	L221	COIL—Oscillator coil, Channel #4
*RLI-100	L260, 270, 271	TRAP—4.5 mc video trap
*RLI-106	L202	COIL—Choke coil
*RLI-108	L261	CHOKE—Video choke
*RLI-109	L264	CHOKE—Video choke
*RLI-110	L252, 253	COIL—IF coil
*RLI-114	L203	COIL—Trap coil
*RLI-116	L208, 215	COIL—Channel #6, 1st and 2nd RF

World Radio History

GENERAL DISCUSSION OF THE ELECTUNER DESIGN

The Electuner Model 45 is a capacity tuned TV Tuner covering Channels 2 through 6 in the first (Lo) range and 7 through 13 in a second (Hi) range. Continuous tuning is provided in each range. In order to facilitate tuning, a certain amount of additional coverage above the highest and below the lowest tunable channel in each range is provided. The extra coverage is referred to as "overtravel" in this text. A two position switch, actuated by a knob concentric with the fine tuning shaft, is used to switch all circuits and will be referred to as the "Range Switch".

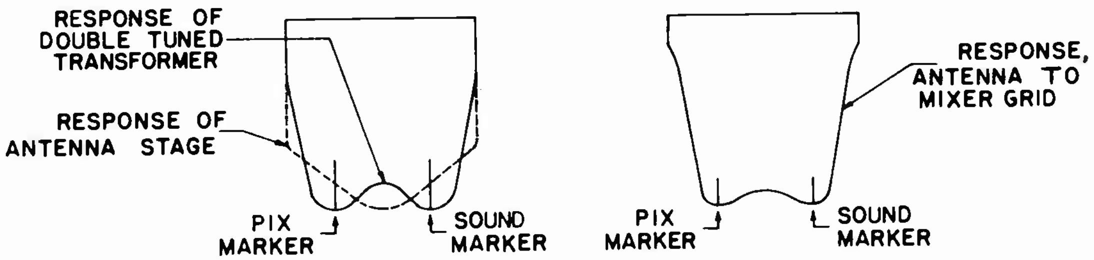
Two tubes are employed as follows:

Model 45-A		Model 45-B	
1 - 6AK5	RF Amplifier	1 - 6CB6	RF Amplifier
1 - 6J6	Oscillator-Mixer	1 - 6J6	Oscillator-Mixer

A four section 180° rotation gang condenser is used for tuning. A mechanical drive ratio of approximately 5 to 1 is provided between the main tuning shaft and the gang condenser shaft.

The following circuits are tuned in both ranges: Antenna, RF Plate, Mixer Grid, and the Oscillator Plate - Grid circuit. A split stator design is incorporated in the gang condenser section used for tuning the oscillator. All circuits are designed to track continuously through both the Hi and Lo ranges.

The overall RF response from the antenna terminals to the mixer grid is determined in each range by the combined selectivities of a single tuned antenna circuit and a double tuned overcoupled inter-stage transformer circuit as shown in the sketches below.



The antenna stage transformer consists of a tuned secondary suitably coupled to a primary designed to match a 300 ohm antenna transmission line. In the Lo range, the entire secondary inductance is tuned. In the Hi range, by means of a tap, only a part of the secondary inductance is tuned in conjunction with a suitable inductance shunt. The primary is common to both the Hi and Lo ranges. An electrostatic shield is provided between the primary and secondary to minimize the asymmetrical capacitance coupling which generally impairs the balance to unbalance response of an antenna input system.

Two overcoupled double-tuned interstage transformers are provided, one for the Lo range, and a second for the Hi range. In each transformer low side mutual inductance is employed to provide the coupling necessary to obtain the required bandwidth. A 0.68 MMF high side coupling condenser is employed to oppose the low side mutual inductive coupling and thereby minimize variations of bandwidth as a function of operation frequency.

In the Model 45B, which employs a 6CB6 RF Amplifier, a slight amount of inductance is intentionally introduced in series with the screen bypass capacitor so as to partially neutralize the input grid conductance in the high channels, thereby reducing the loading on the antenna transformer secondary. The inductance takes the form of about 3/8" of wire in each connecting lead of the bypass condenser. Because of the higher input resistance of the grid of the 6AK5, neutralization of input conductance is not required in the Model 45A.

The Model 45A differs principally from the Model 45B in Hi range performance. The use of the 6AK5 in the Model 45A results in an increased gain and lower noise factor in channels 7 - 13. However, because of the difference in grid loading and interelectrode capacities the tubes are not directly interchangeable. Attempts at substitution of the 6AK5 for the 6CB6 or vice versa will result in considerable mistracking of the antenna and RF tuning and in some instances may produce instability in the RF amplifier section.

The oscillator stage utilizes one triode section of the 6J6 in a stable low drift Colpitts circuit. Circuit parameters have been chosen to guarantee satisfactory operation over a wide range of operating voltages. Sufficient oscillator injection is provided to the mixer stage to accomodate power line voltage fluctuations and variations in +B caused by AGC action in normal receiver applications. The oscillator operates above the signal frequency in both ranges.

The mixer circuit uses the second triode section of the 6J6, its grid is tuned by a section of the gang condenser. Its plate circuit may feed either a series IF output coil or some form of double tuned IF transformer, depending on the receiver manufacturer's requirements.

Various sound and picture IF frequencies are used in both the 20 Mc and 40 Mc regions and in every instance the Electuner is tracked to the required IF of the receiver design. For any installation, the receiver manufacturer's service notes should be consulted for the applicable intermediate frequencies, inasmuch as both tracking and frequency coverage are involved.

Either a shunt fed heater system or a series heater connection may be used. Tuners employing either system are not strictly interchangeable since some modification in the heater filter system is generally involved and internal connections which are not readily accessible in the final assembly are encountered.

The normally recommended B+ voltage is 125V. The actual operating value may vary between 90 and 160 volts depending on the receiver application. With a B+ voltage of 125 volts and -1 volt on the AGC terminals of the tuner a +B drain of approximately 20 milliamperes is normal.

In accordance with Figure 2, the following tuning adjustments are available at the top of the tuner chassis:

Antenna trimmer; RF amplifier plate trimmer; mixer grid trimmer; oscillator grid trimmer; oscillator plate trimmer; and IF adjustments. The recommended use of each of the adjustments is discussed in the alignment procedure outlines in this text.

EQUIPMENT REQUIRED FOR ALIGNMENT

(1) Sweep Generator
(2) Oscilloscope
(3) Electronic Voltmeter
(4) RF Marker Generator
(5) Pix and Sound IF Marker Generator
(6) Bias supply 2-1.5 volt Dry Cells
(7) IN 34 Crystal Detector

©John F. Rider

World Radio History

SUGGESTED SUITABLE EQUIPMENT

(1) Sweep Generator similar to RCA type WR59A, covering frequencies of 54 to 88 Mc, and 174 to 216 Mc with a minimum sweep of 10 Mc in any channel, and a 300 ohm balanced output at least .1 volt line to line.
(2) Oscilloscope equivalent in vertical deflection sensitivity to DuMont type 208-B.
(3) Electronic voltmeter similar to the Voltohmyst.
(4) RF marker generator similar to RCA type WR-39A.
(5) Pix and sound IF marker generator may be crystal controlled oscillators in the vicinity of 25.75 Mc and 21.25 Mc (actually whatever frequency receiver manufacturer lists as the correct pix and sound IF frequency for the particular set in question). As alternates, either a second WR-39-A or an all wave signal generator of suitable accuracy may be used to supply IF markers.

EQUIPMENT SET-UP See Fig. 1

DISCUSSION OF EQUIPMENT SET-UP

In reference to Figure 1, the following precautions should be taken in making the equipment set-up.
(1) The detector circuit should be so constructed as to maintain leads as short as possible. Connection of the detector circuit to the 1st IF grid terminal (See Fig. 1 for location) should also be made with short leads.
(2) Shielded leads should be used in making the following connections to reduce hum and synchronous voltage pick-up.
   (A) The lead for observation of the RF response from the scope isolating resistor (10 K ohms located at the tuner "looker point") to the RF output switch position of the scope switch.
   (B) The connection from the IF detector circuit output to the IF switch position of the scope switch.
   (C) The connection from the sweep generator to the horizontal input of the scope. (Use externally generated sweep instead of internal oscilloscope sweep in order to obtain synchronization).
(3) The single pole double throw "Scope Switch" should be located at the vertical input terminals of the scope. This switching arrangement will permit observation of either the IF response or the overall RF response. The aforementioned positions will be referred to in subsequent text as the "IF" and "RF" positions respectively.
(4) The marker generator coupling condenser should be as small a value as possible to prevent any effect on tuner response, but must be large enough to permit easy observation of markers on either the IF response or overall RF response. (Approximately 2 or 3 MMF should be satisfactory in most cases.
(5) For all tuner alignment tests which are outlined in this text, remove the second IF amplifier tube from the receiver, or bypass its plate circuit with approximately 1000 MMF to prevent coupling back from the receiver IF system.
(6) In all of the following tests the oscilloscope vertical gain should be as close to maximum gain as possible, consistent with hum and synchronous voltage interference limitations. This precaution will allow the use of low levels from RF Sweep Generator and increase the visibility of IF and RF markers.

PROCEDURE FOR OSCILLATOR ALIGNMENT

OVERTRAVEL CHART FOR OSCILLATOR COVERAGE

CHANNEL	OVERTRAVEL	MARKER FREQ. MC	OSC END FREQ. MC
13	+4.5 Mc	215.75	(215.75 +Pix IF)
7	-4.5 Mc	175.25	(175.25 +Sound IF)
6	+1.5 Mc	84.75	(84.75 +Pix IF)
2	-3.0 Mc	56.75	(56.75 +Sound IF)

REFERENCE DATA - TV ALLOCATIONS

CHANNEL NO.	PICTURE CARRIER Mc	SOUND CARRIER Mc
2	55.25	59.75
3	61.25	65.75
4	67.25	71.75
5	77.25	81.75
6	83.25	87.75
7	175.25	179.75
8	181.25	185.75
9	187.25	191.75
10	193.25	197.75
11	199.25	203.75
12	205.25	209.75
13	211.25	215.75

The design of all Electuners is such that the oscillator will automatically track, separated by IF, with the tuning indicator dial calibration in each range when the total oscillator frequency range is adjusted to tune the channel assignments of 7-13 and 2-6 plus and minus the additional frequency coverages listed in the overtravel chart above. In other words, it is only necessary to set the oscillator to prescribed end points in each tuning range for proper tuning.

In making adjustments of oscillator tuning it should be noted that any change in the setting of the Hi range oscillator trimmer will also affect the Lo range oscillator tuning. However, because of the switching arrangements. adjustments of the Lo range oscillator trimmer will not affect the Hi range oscillator frequency adjustment.

A step by step outline of oscillator adjustments based on an equipment set up as shown in Fig. 1 and related to the tuning elements illustrated in Fig. 2 follows. For purposes of illustration only a sound IF of 21.25 Mc and a picture IF of 25.75 Mc are assumed. For any actual receiver application consult the set manufacturer's service notes for the exact IF's.

HI RANGE OSCILLATOR ALIGNMENT

It must be noted that there is a slight shift of the oscillator frequency in the Hi range only when the bottom cover shield is removed from the tuner. Generally, if the oscillator overtravel is correctly adjusted at the low end of the Hi range with the cover off, a frequency shift of about .1 to .2 Mc to a higher frequency is encountered when the cover is mounted in place. Therefore, final checks must be made with the shield cover in place.

(1) Align oscillator frequency at low end of Hi range as follows:

Remove bottom cover. Turn tuner range switch to Hi range. Rotate variable condenser of tuner to maximum capacity (counter clockwise rotation of fine tuning knob). Turn sweep generator to channel 7. Adjust sweep width to maximum. Feed in an RF marker generator frequency of 175.25 Mc. Set scope switch (Fig.1) to IF output position. Inject required sound IF marker (i.e. 21.25 Mc). Using a non-metallic alignment tool (bakelite or plastic) vary the spacing of the turns of the Hi range oscillator coil (See Fig.2) so as to make the RF and IF markers coincide on the IF response curve viewed on the oscilloscope. Replace tuner bottom cover, and note any frequency shift between markers. Remove tuner cover and make a compensating adjustment if necessary, and repeat until proper oscillator setting is obtained. Increasing the separation between turns will raise the oscillator frequency. Conversely pushing turns closer together will lower the oscillator frequency.

©John F. Rider

World Radio History

(2) Align Oscillator frequency at high end of Hi range as follows:

With the bottom cover in place, rotate the tuner variable condenser to minimum capacity (maximum clockwise rotation at the fine tuning knob). Turn sweep generator to channel 13. Feed in an RF marker generator frequency of 215.75 Mc and an IF picture marker (i.e. 25.75 Mc). Adjust the oscillator grid trimmer (Hi range Osc. trimmer Fig.2) to make the RF and IF markers coincide on the IF response curve viewed on the oscilloscope.

(3) Repeat steps (1) and (2) until proper end frequencies are reached at maximum and minimum capacity settings of the variable condenser. This completes the Hi range oscillator tuning.

LO RANGE OSCILLATOR ALIGNMENT

(4) Align oscillator frequency at low end of Lo range as follows:

Remove bottom cover of tuner and turn the range switch to Lo range setting. Rotate variable condenser of tuner to maximum capacity (max. counter clockwise rotation of fine tuning knob). Turn sweep generator to channel 2. Feed in an RF marker generator frequency of 56.75 Mc and a sound IF marker (i.e. 21.25 Mc). Using a non-metallic alignment tool, vary the spacing between turns of the Lo range oscillator coil (See Fig.2) to make the RF and IF markers coincide on the IF response as viewed on the oscilloscope.

(5) Align oscillator frequency at high end of Lo range as follows:

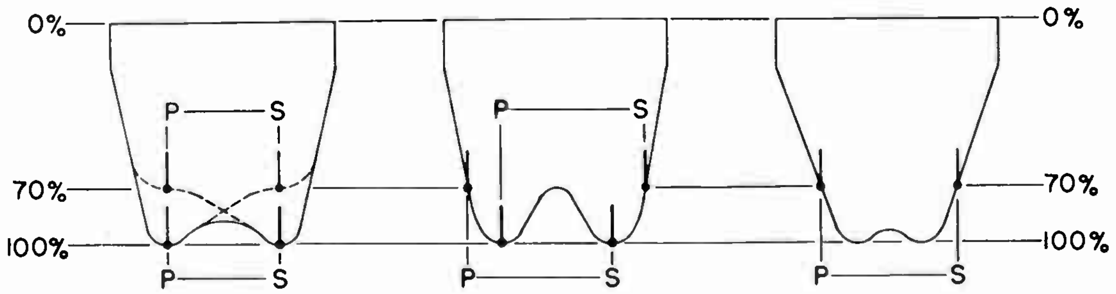
Rotate the tuner variable condenser to minimum capacity (maximum clockwise rotation of the fine tuning knob). Turn the sweep generator to channel 6. Feed in an RF marker generator frequency of 84.35 Mc and an IF picture marker (i.e. 25.75 Mc). Adjust the oscillator plate trimmer (Lo range osc. trimmer - Fig. 2) to make the RF and IF markers coincide on the IF response as viewed on the oscilloscope.

(6) Replace cover on tuner and recheck alignment of steps (4) and (5) making slight adjustments if necessary.

(7) Recheck all four oscillator frequencies as per steps (1), (2), (4), and (5) for final recheck.

PROCEDURE FOR RF PASSBAND ALIGNMENT

Since continuous tracking over each entire range (Hi and Lo) is functional to the Electuner design, the tracking problem is simplified to the extend that alignment of only four channels, that is 2 and 6 in the Lo range, and 7 and 13 in the Hi range automatically results in alignment of all channels from 2-13 inclusive.



ACCEPTABLE RF PASS BANDS AND TRACKING

Before undertaking RF pass band alignment, it is advisable to check oscillator coverage as per steps (1) through (7).

In order to check alignment of the RF pass bands, an equipment set up as per Fig. 1 is required. Refer to Fig. 2 for location of the various RF coils and trimmer capacitors mentioned in the following alignment procedure.

In checking RF pass bands it is important that all extra capacity at the antenna input terminals be kept at a minimum. Short leads from the sweep generator are necessary and if any form of clips are used, the clips should be separated as much as possible. The sweep generator should be fed in directly at the antenna terminals of the tuner, and the antenna feed line from the rear of the receiver disconnected from the tuner.

(8) Align Channel 7 RF Pass Band as follows:

Remove the tuner bottom cover and with the tuner range switch set for Hi range reception turn the fine tuning knob so that the pointer is at channel 7 on the dial calibration. Set the sweep generator to channel 7. Feed in a channel 7 RF picture marker signal of 175.25 Mc and an IF picture marker (i.e. 25.75 Mc). With the scope switch (Fig. 1) at IF output adjust the fine tuning knob so that the RF and IF markers coincide on the IF response as viewed on the oscilloscope. Leave the fine tuning in the latter setting for the remainder of channel 7 RF pass band alignment. Switch the scope switch to the RF output position. If the RF response differs noticeably from those illustrated under the heading of acceptable RF passbands shown above, proceed as follows:--Adjust the inductance of the Hi range RF plate coil (See Fig. 2) and then the Hi range mixer grid coil for proper bandwidth and the Hi range antenna coil for symmetry. In determining bandwidth, it will be necessary to adjust the RF marker generator alternately between the channel 7 picture and sound carrier frequencies 175.25 Mc and 179.75 Mc respectively. Proper alignment of the RF coils is attained when a slight variation of the inductance of either the RF plate coil or mixer grid coil results in a frequency shift of the entire response and no noticeable narrowing of bandwidth. When the antenna coil is properly adjusted, a slight variation of its inductance will cause both response peaks to rock slightly. If only one peak moves, the antenna is staggered away from the center of the passband. The inductance of the Hi range coils is controlled by pushing the respective coils on and off brass studs. Pushing any coil on to the stud will decrease its inductance (raise the frequency) and conversely pulling the coil away from the stud increases its inductance. The bandwidth of the response in channel 7 interstage transformer is controlled by the lead dressing of the returns of the RF plate coil and mixer grid coil with respect to the cut-out or window in the RF shield plate. If the ground ends of both coils are pulled out so as to cross the window, the coupling increases and a greater separation or peaks is encountered. For maximum gain the bandwidth should be adjusted so that the response is no greater than required to keep the sound and picture carrier frequencies on the peaks of the overall RF response. After alignment replace the tuner bottom cover and observe RF pass band. It may be necessary to remove the cover and make a slight compensating adjustment of the coils.

(9) Align Channel 13 RF Pass Band as follows:

With the bottom cover on the tuner, turn the fine tuning knob so that the pointer falls on channel 13 on the dial. Turn the sweep generator to channel 13. Feed in a channel 13 RF sound marker (215.75 Mc) and an IF sound marker (i.e. 21.25 Mc). With the scope switch (Fig.1) at IF output, adjust the fine tuning knob so that the RF and IF markers coincide on the IF response as viewed on the scope. Leave the fine tuning in the latter setting for the rest of the RF passband alignment procedure which follows. Switch the scope to RF output position. If the RF response differs noticeably from the acceptable RF passbands shown, proceed as follows:

©John F. Rider

World Radio History

Adjust the antenna trimmer, the RF plate trimmer, and mixer grid trimmer for proper bandpass and maximum amplitude of response. Normally the antenna trimmer operates in the middle of its range; the RF plate operates toward maximum capacity and the mixer grid trimmer operates toward its minimum capacity setting (least screw engagement). In determining bandwidth, it will be necessary to shift the RF marker generator back and forth between the sound and picture carrier frequencies of channel 13, that is, 215.75 Mc and 211.25 Mc.

(10) After aligning the RF channel 13 with the bottom cover on the tuner, return to channel 7 and examine its pass band, as per step (8). A slight compensating change in inductance may be necessary if the trimmer settings were changed in step (9). Repeat the checks outlined in steps (8) and (9) compromising the adjustments for tilt if necessary, until satisfactory Hi range RF pass bands are obtained.

(11) Align Channel 2 RF Passband as follows:

With the tuner range switch set for Lo range reception, turn the fine tuning knob so that the pointer is at channel 2 according to the dial calibration. Set the sweep generator to channel 2. Feed in an RF marker signal of 59.75 Mc and an IF sound marker (i.e. 21.25 Mc). With the scope switch (Fig. 1) at IF output, adjust the fine tuning knob so that the RF and IF markers coincide on the IF response as viewed on the oscilloscope. Leave the tuning in the latter setting for the remainder of Channel 2 RF passband alignment. Switch the scope switch to the RF output position. If the RF passband does not appear satisfactory, in accordance with the acceptable RF passbands shown, proceed as follows:

Alternate the RF marker generator between channel 2 sound and picture carrier frequencies, that is 59.75 Mc and 55.25 Mc while performing the alignment of the RF so as to simultaneously determine proper bandwidth and tuning. The Lo range RF plate, mixer grid and antenna transformer secondary inductance are to be adjusted by spacing their respective turns until the desired passband is obtained. The bandwidth of the interstage overcoupled circuit may be altered by the Lo range mutual coil (See Fig.1). At proper alignment, slight variations of the RF plate or mixer grid coil inductance should cause no narrowing of the passband, and variations of the antenna transformer secondary inductance should cause a rocking of both peaks of the overall response. If only one peak of the response is affected by a slight change in antenna secondary inductance, the antenna is staggered away from the center of the double tuned circuit response. As regards to the Lo range mutual coil, squeezing the turns together will increase inductance and broaden the response, spacing turns apart will narrow the response. After alignment replace bottom cover and note if any compensating adjustment is necessary.

(12) Align Channel 6 RF Pass Band as follows:

With the bottom cover of the tuner in place, turn the fine tuning knob so that the pointer falls on channel 6 on the dial. Turn the Sweep generator to channel 6. Feed in an RF marker of 83.25 Mc and a picture IF marker (i.e. 25.75 Mc). With the scope switch (fig.1) at IF output, adjust the fine tuning knob so that the RF and IF markers coincide on the IF response as viewed on the oscilloscope. Leave the tuning at the latter setting for the remainder of channel 6 alignment. Switch the scope switch to the RF output position. If the RF response is not satisfactory as per the illustrations, proceed as follows:

Alternate the RF marker generator between channel 6 sound and picture carrier frequencies, that is 87.75 Mc and 83.25 Mc as required while performing the alignment so as to simultaneously determine bandwidth and tuning. Remove the bottom cover of the tuner and slightly alter the inductance of the Lo range RF plate and mixer grid coils and antenna secondary bearing in mind that Channel 2 response will be altered. Therefore, keep the changes at a minimum.

(13) Return to channel 2 and examine its passband as per step (11) and if tilt is excessive, select a compromise tuning of the Lo range coils which gives satisfactory passbands in both channels 2 and 6 with the tuner bottom cover in place.

SERVICE NOTES

(1) Tube replacement

In replacing defective tubes in the Electuner, use the same tube type as called for by the receiver manufacturer's Service Notes. Do not attempt to substitute alternate pentode types such as the 6AC5, 6BC5, or 6AK5 for the type 6CB6 RF amplifier in the Model 45-B. Similarly, in the Model 45-A, use only type 6AK5 tubes in the RF amplifier socket.

In general, RF amplifier tubes may be replaced by the same type without the need of tuner RF realignment. An occasional extreme limit tube may be encountered which will call for a minor correction of the antenna trimmer setting. However, in the latter event, it will undoubtedly be found more expedient to select another tube and avoid the necessity of aligning the RF pass bands.

In replacing type 6J6 tubes, check for injection voltage at the "Looker Point" (Fig.1) to determine that adequate oscillator injection voltage is provided to the mixer grid. Use a Voltohmyst or equivalent vacuum tube type voltmeter. Normal injection should be at least -2.0 volts. Some variations of tube capacity will be encountered from one 6J6 to another. The capacity variations will affect the oscillator coverage and tracking to some extent. If after replacement of the 6J6, an air check of the receiver indicates that the end channels 2, 6, 7, and 13 to be within the tuning range and in agreement with the dial calibration, no oscillator adjustments are necessary. Minor changes of oscillator tuning range due to tube capacity variation may be accommodated by the oscillator grid trimmer. Adjustment should be made with the receiver tuned in the vicinity of channel 13.

(2) Replacement of Parts.

Any component replacement should be made with parts of equivalent physical size and value within the specified tolerance. All Hi range series pads are specified to be within ±5% of published values. Replacement of any component in frequency determining circuits should be followed with an electrical check of oscillator coverage and RF alignment as outlined in these notes.

The gang condenser is closely tracked from section to section and also to a prescribed capacity vs. rotation curve. Any attempt to alter the capacity to favor any one channel will disturb other channels in both ranges. In working inside the tuner, every caution should be exercised to avoid bending the gang condenser plates.

(3) Drive Cord Replacement.

Figure 3 illustrates the details of the drive cord arrangement. Details of cord length, stringing and fastening are shown. The details must be adhered to closely in order to avoid slippage, excessive torque, and wear. The cord should be of the fibre glass core, nylon braid variety.

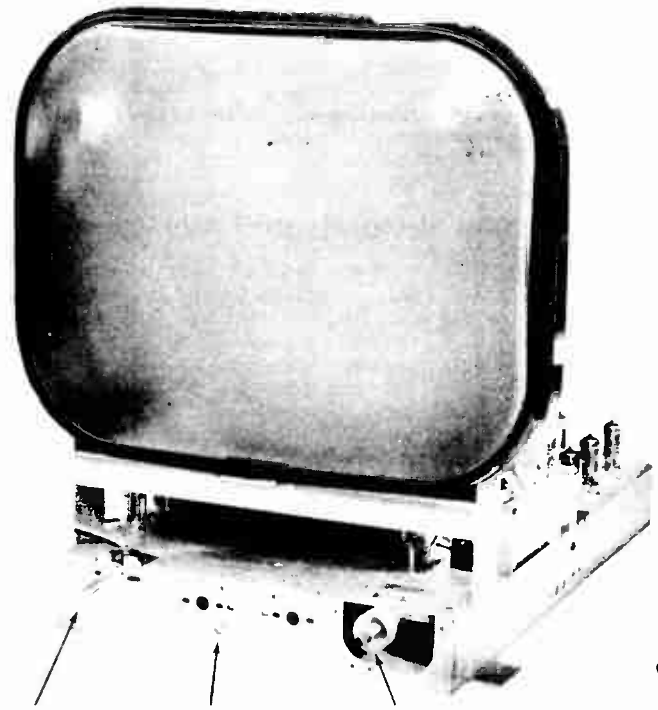
INDEX

GENERAL

Picture Area . . . . 139 square inches
Tubes . . . . Nineteen plus two rectifiers
Speaker . . . . Model 745, 747 & 748 - 5-inch P.M. (3.2 ohm V.C.) Models 750/751/760/761 - 8-inch P.M. (3.2 ohm V.C.)
Antenna . . . . Built-in cabinet antenna with provision for external antenna using 300-ohm transmission line.
Tuning. . . . . Two step range selector plus manual station tuning adjustment.
Tuning Range . . . . Twelve channels in two ranges.

1st Range		2nd Range	
Channel No.	Frequency (mc)	Channel No.	Frequency (mc)
2	54-60	7	174-180
3	60-66	8	180-186
4	66-72	9	186-192
5	72-82	10	192-198
6	82-88	11	198-204
		12	204-210
		13	210-216

Intermediate Frequency
Picture carrier. . . . . 26.25 mc
Sound carrier . . . . 21.75 mc
Intercarrier sound system. . 4.5 mc
Power Supply . . . . 105-125 V. 60 cycles AC
Power Consumption . . . . 200 Watts
Model Differences . . . . Model 745 - Wood table model finished in mahogany
Model 747 Pyroxylin covered table model finished in mahogany brown.
Model 748 Pyroxylin covered table model finished in mahogany blonde.
Models 750/760 - Wood consolette finished in mahogany.
Models 751/761 - Wood consolette finished in limed oak.



Chassis D919120

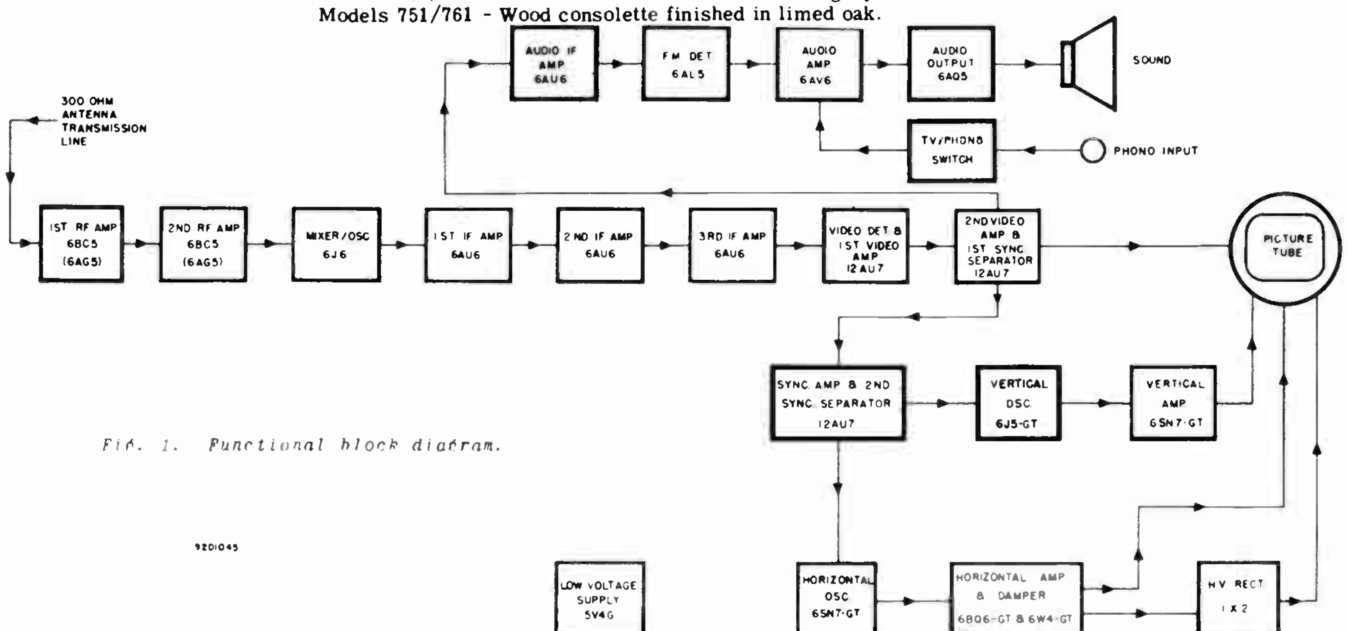


Fig. 1. Functional block diagram.

CARE OF THE KINESCOPE WINDOW

The window in front of the picture tube is made of safety glass, hence may be cleaned by any of the conventional window cleaning processes. Abrasive or strong solvent type cleaning solutions that may scratch the glass or damage the cabinet finish, however, should be avoided.

HIGH VOLTAGE WARNING

Operation of the receiver chassis outside of the cabinet involves a shock hazard. An interlock in the line cord disconnects the power when the back cover is removed. The HIGH VOLTAGE supply, while of low current capacity, operates at a 11,000 volt potential. Exercise all normal HIGH VOLTAGE precautions while working this equipment.

KINESCOPE HANDLING PRECAUTIONS

The kinescope housing provides adequate protection against possible tube implosure while in the cabinet. Do not expose the kinescope or handle it in any way without providing personal protection in the form of shatterproof goggles and heavy gloves. The kinescope should be handled by qualified personnel only.

The kinescope envelope encloses a high vacuum and with the large surface area of glass involved, the stresses set up, particularly at the front rim of the tube, are considerable. An abnormal handling stress, accidental blow at a highly stressed surface, or even a scratch on the surface of the tube could cause it to implode or collapse with destructive violence.

NON-OPERATING CONTROLS ADJUSTMENTS

The "non-operating" or screw-driver adjustments normally will require an occasional minor adjustment if any circuit work or tube changing is required. A test pattern, generated either locally in the shop or obtained from a television station is recommended for best results. Normal picture contrast and brightness should be maintained during the following adjustments for best results.

HORIZONTAL HOLD, VERTICAL HOLD, HORIZONTAL OSC., BRIGHTNESS AND FOCUS ADJUSTMENTS

1. Set the HORIZONTAL and VERTICAL HOLD controls for a steady test pattern. Should the HORIZONTAL HOLD control fail to hold the test pattern in the normal manner, set the HORIZONTAL HOLD control in the center of its range and adjust the HORIZONTAL OSC. ADJ. screw on the under side of the chassis for horizontal sync. (See Fig. 11 for location). If the adjustment of the top slug has been tampered with, turn the top screw to its top limit and adjust the bottom slug for sync.

2. The focus adjustment may be made with or without the aid of a TV station. If a test pattern is available, adjust the receiver for best picture and set the FOCUS control for best picture detail, watching the wedges of the test pattern. If no signal is available, turn the picture control counter-clockwise, advance the brightness control until the scanning lines just begin to show distinctly and adjust the FOCUS control for sharp clean lines. Note that a misadjustment of the ion trap or focus coil positions may prevent even focusing over the entire raster.

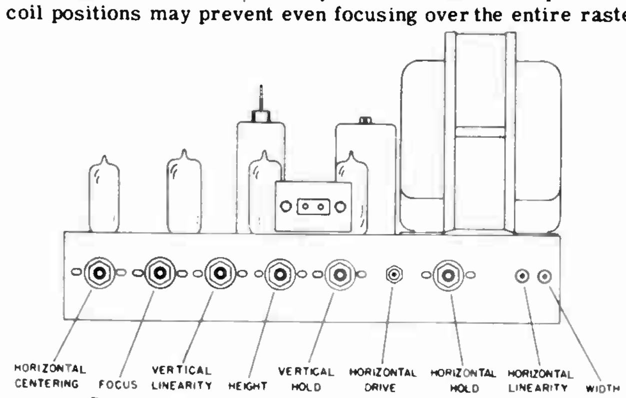

Fig. 2. Rear chassis view, location of "non-operating" controls.

HORIZONTAL — DRIVE, — LINEARITY, — CENTERING AND WIDTH ADJUSTMENTS

HORIZONTAL DRIVE CONTROL MISADJUSTMENT

1. Advance the HORIZONTAL DRIVE control (clockwise) as far as possible without causing fold over of the test pattern. (Vertical white line.) Insufficient horizontal drive will cause low second anode voltage with consequent loss of picture brilliance.

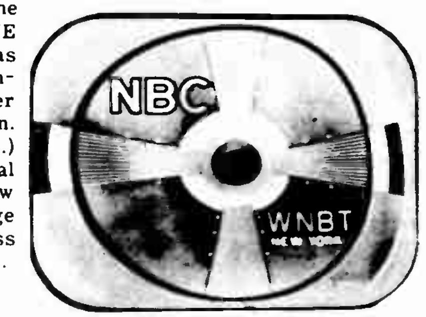

Figure 3.

WIDTH CONTROL MISADJUSTMENT

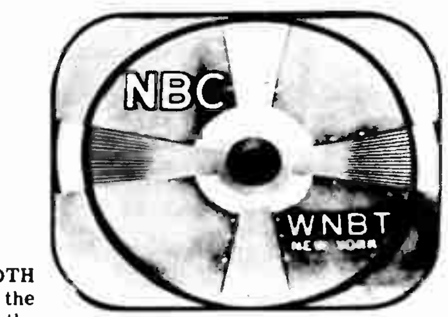

Figure 4.

2. Set the WIDTH control so that the test pattern fits the horizontal dimension of the kinescope escutcheon. A minor adjustment of the focus coil position may be required to recenter the pattern.

HORIZONTAL CENTERING MISADJUSTMENT

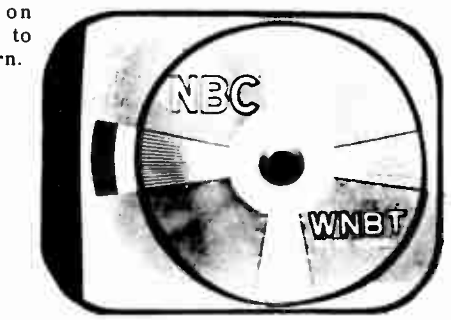

Figure 5.

HORIZONTAL LINEARITY CONTROL MISADJUSTMENT

3. Set the HORIZONTAL LINEARITY control so that the test pattern is symmetrical from left to right. A slight readjustment of the HORIZONTAL DRIVE control may be necessary when making this adjustment.

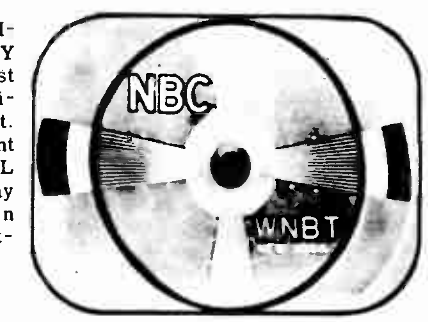

Figure 6.

©John F. Rider

World Radio History

VERTICAL — CENTERING, — LINEARITY, AND HEIGHT ADJUSTMENTS

HEIGHT CONTROL MISADJUSTMENT

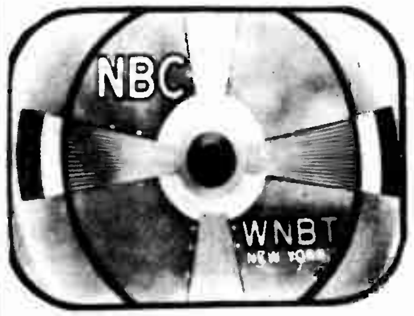

Figure 7.

1. Set the HEIGHT control so that the test pattern fits and centers in the vertical dimension of the kinescope escutcheon. A minor adjustment of the focus coil position may be required to recenter the pattern.

VERTICAL CENTERING MISADJUSTMENT

Figure 8.

VERTICAL LINEARITY CONTROL MISADJUSTMENT

Figure 9.

2. Set the VERTICAL LINEARITY control for a symmetrical test pattern in the vertical dimension. A slight readjustment of the HEIGHT control may be required when making this adjustment.

Note - The sequence of "non-operating" control adjustments outlined above is suggested as a convenient method of approach and not an arbitrary procedure. Variations of the procedure is permitted to obtain the final result.

DISMANTLING FOR KINESCOPE REPLACEMENT OR ALIGNMENT ADJUSTMENTS

1. Remove the three front panel control knobs by pulling them straight from their shafts. The dual control knob must be removed in two pieces, removing the center unit first.

2. Remove the back cover disconnecting the cable connector for the phono socket and switch mounted on the back cover. Note that the line cord and half of the interlock connector come along with the back cover.

3. Disconnect the speaker and remove the two wood screws holding the antenna terminal strip bracket to the cabinet. Note that for the table models the speaker will have to be removed to clear the picture tube.

4. Remove the five chassis bolts holding the receiver chassis in the cabinet and slide the entire assembly from the cabinet. The KINESCOPE is now accessible for replacement or adjustment.

REMOVING THE KINESCOPE

Refer to the warning KINESCOPE HANDLING PRECAUTIONS. Read all warning notices on both tube and carton. Follow the dismantling instructions above to expose the KINESCOPE and proceed as follows:

1. Disconnect the KINESCOPE SOCKET at the base of the kinescope.

2. Disconnect the high voltage anode lead.

3. Slip the ION TRAP from the neck of the tube past the kinescope base connector.

4. Measure the distance from the front edge of the steel band to the face of the tube. Keep this dimension handy for installation of a new tube.

5. Remove the steel band at the front rim of the kinescope and carefully slip the neck of the kinescope out of the FOCUS COIL and DEFLECTION YOKE. If the tube fails to slip out smoothly, investigate and remove the cause of the trouble. Do not use force.

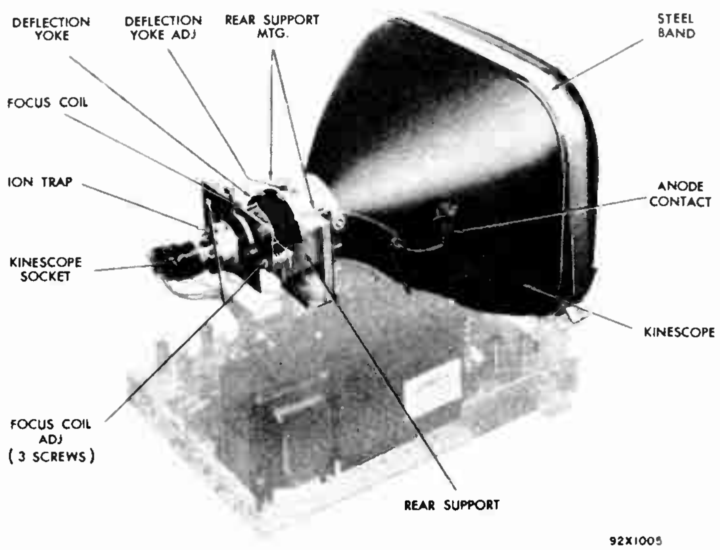

Fig. 10. Kinescope mounting detail.

INSTALLING AND ADJUSTING THE KINESCOPE

1. Wrap the RUBBER STRIP around the front rim of the kinescope and position the tube so that the anode contrast is located at the left side of the tube as viewed from the screen.

2. Slip the neck of the kinescope through the REAR SUPPORT, DEFLECTION YOKE and FOCUS COIL and seat the tube firmly against the REAR SUPPORT. If it fails to slip into place smoothly, investigate and remove the cause of the trouble. Do not force the tube. Check the distance from the face of the tube to the front edge of the steel band. Refer to the measurement made in step 3 above. If this dimension is off; loosen the two REAR SUPPORT MTG. screws, position the tube correctly and fasten the steel band firmly about the rim of the tube.

3. The REAR SUPPORT must seat firmly against the flare of the tube and be securely anchored in place by the two REAR SUPPORT MTG. screws. Check the SPRING CONTACT grounding the outer coating of the kinescope tube. A high potential is developed on the outer coating of the tube if this contact is faulty.

4. The DEFLECTION YOKE must seat firmly against the flare of the kinescope. Check by loosening the single DEFLECTION YOKE ADJ. screw and pushing the DEFLECTION YOKE forward as far as it will go. Take up the slack in the screw temporarily to hold the coil in place.

5. Slip the ION TRAP over the neck of the tube; the arrow points toward the face of the tube.

6. Reconnect the KINESCOPE SOCKET and anode connector and turn on the receiver.

7. After allowing a few minutes for warm up, turn up the BRIGHTNESS control and set the ION TRAP for maximum raster brilliance, backing off the brightness control adjustment as the maximum point is approached. The ION TRAP must be rotated about the axis of the tube as well as shifted along the neck of the tube to obtain the proper setting. The arrow on the ion trap will generally point at the HV anode connector when properly positioned as far as rotation is concerned, hence a rough setting may be obtained immediately with this type of trap.

With the BRIGHTNESS control set for slightly above average brilliance and the PICTURE control full counter-clockwise, adjust the FOCUS control until the line structure of the raster is clearly visible and reajust the ION TRAP for maximum raster brilliance. The final touches on this adjustment should be made with the BRIGHTNESS control at the maximum position with which good line focus can be maintained, then back off the setting of the BRIGHTNESS control until the retrace lines disappear.

8. Check the position and appearance of the test pattern. If the test pattern is off center or shadowed at the corners (Electron beam striking the neck of the tube), adjust the three FOCUS COIL ADJ. screws for a centered, evenly illuminated raster. Note that the three spring loaded adjustment screws tilt the focus coil to shift the position of the raster on the face of the kinescope. Do not turn all three screws up tight, use them to tilt the FOCUS COIL only.

CAUTION - It is not necessary to tilt the focus coil excessively. Excessive tilt may snap the neck of the kinescope if sufficient force is used.

The position of the test pattern may also be shifted by rotating the focus coil. To rotate the coil, loosen the two knurled nuts holding the coil to the mounting plate. Tighten the nuts after the adjustment has been made.

9. If the lines of the raster are not horizontal or square with the escutcheon, loosen the DEFLECTION YOKE ADJ. screw and rotate the DEFLECTION YOKE until this condition is obtained. Tighten the adjustment.

10. Follow the procedure under NON-OPERATING CONTROL ADJUSTMENTS and make any minor adjustments of the FOCUS COIL or DEFLECTION YOKE necessary to obtain the desired results. The final adjustment of the focus coil should leave the test pattern approximately centered.

MEASUREMENT OF H.V. POTENTIAL ON KINESCOPE ANODE

The second anode potential will be approx. 11,000 V. on a receiver that is functioning properly. Since the high potential for the kinescope anode is obtained from the horizontal output transformer, the "non-operating" control adjustments outlined above must be made or be known to be in proper adjustment before the H.V. measurement will have any meaning. Improper operation of the horizontal sweep circuit or circuit faults in the high voltage filter will generally account for an abnormal anode potential. If the anode potential is low, check the HORIZONTAL DRIVE adjustment outlined above.

CAUTION HIGH VOLTAGE

Do not use hand held flexible test leads when making the following measurement. Keep the hands clear of the circuit during measurement. A 11 KV. potential exists in this circuit. Exercise all normal high voltage precautions.

1. Connect a 50-megohm resistor string in series with a 300 microampere meter. Connect the free meter terminal to the chassis and the high side of the resistor string to the anode cap of the kinescope. The connection to the anode cap may be made with a fine wire slipped under the connector. Make up the resistor string with 5-megohm one or two watt resistors to provide a safety factor for voltage breakdown. If 5-megohm resistors are used, a total of ten will be required to obtain the 50 megohms. Make the setup self-supporting and allow adequate clearance between the resistor string and chassis parts to prevent high voltage breakdown.

2. Turn on the receiver and set the BRIGHTNESS and PICTURE controls at minimum. The microammeter will read approx. 220 microamperes for 11,000 V. at the kinescope anode. The anode potential is measured in this manner (PICTURE and BRIGHTNESS control at minimum; meter current approx. 200 microamperes) to simulate the kinescope load on the high voltage power supply.

I-F AMP. ALIGNMENT PROCEDURE

Note - The following alignment adjustments do not require the use of the kinescope tube. It is recommended that the tube be removed if extensive alignment adjustments are to be made.

CAUTION - Removal of the kinescope tube exposes the HIGH VOLTAGE anode connector contact. Keep this lead and contact clear of personnel servicing equipment and grounded objects on the service bench. Exercise all normal high voltage precautions while working with the exposed units.

EQUIPMENT REQUIRED

Signal generator covering 4 mc to 30 mc

Electronic voltmeter

F-M SOUND CHANNEL I-F ALIGNMENT

1. Connect the low frequency signal generator output across resistor (R-118) in the plate circuit of the 12AU7 VIDEO DET. tube (V-104). This resistor is located at the terminal strip near the tube socket.

2. Connect the electronic voltmeter between pin 7 of the 6AL5 FM DET. tube (V-109) and chassis ground.

3. With the signal generator (unmodulated) set at 4.5 mc. set the 4.5 MC LIMITER GRID ADJ. and FM DET PRI. ADJ. (See Fig. 11) for maximum d-c voltage as measured by the electronic voltmeter. Adjust the limiter grid transformer (T-105) before adjusting the f-m detector transformer (T-108) primary. Use just enough signal generator output to obtain approximately one volt at the electronic voltmeter.

4. Connect the electronic voltmeter across the 1000 mmf condenser (C-135) at the output of the f-m detector stage and adjust the FM DET. SEC. ADJ. of the f-m detector transformer (T-108) for the null.

5. Shift the frequency of the signal generator either side of 4.5 mc and touch up the FM DET. PRI. ADJ. for approximately equal peaks. Use just enough signal generator output to obtain one volt peaks for the best results.

6. After completing the alignment procedure and placing the receiver in operation again, carefully tune in a TV test pattern and adjust the 4.5 MC TRAP ADJ. for maximum vertical wedge definition. This adjustment is located on the under side of the chassis and on the same coil form as the 4.5 MC LIMITER GRID ADJ. shown in Fig. 11.

NOTE - The primary adjustment of T-108, the coarse frequency adjustment of T-111 and the 4.5 mc trap adjustment may all be made through the holes in the cabinet bottom or chassis mtg. board.

I-F AMPLIFIER ALIGNMENT

1. Connect the electronic voltmeter across resistor R-118 in the plate circuit of the 12AU7 VIDEO DET. tube (V-104). This resistor is located on the terminal strip near the tube socket.

2. Couple the high side of the signal generator to the OSC./MIXER tube (V-3) by removing its shield and slipping a tight fitting tube shield or length of copper braid over the bulb of the tube and connecting the generator lead to it. Connect the ground side of the signal generator to the frame of the tuning unit.

3. Set the channel selector at channel 2.

©John F. Rider

World Radio History

4. Set the signal generator output (unmodulated) to develop one or two volts at the electronic voltmeter and adjust the four i-f amplifier coils, according to the following chart, for maximum d-c voltage as measured by the electronic voltmeter. Readjust the signal generator output as required to maintain the two-volt potential at the electronic voltmeter.

I-F AMPLIFIER ALIGNMENT CHART

Signal Generator Frequency (No Modulation)	Adjustment (Refer to Fig. 11)	Stage Adjusted
24.5 Mc	*24.5 Mc IF Adj.	1st IF amp.
23.4 Mc	23.4 Mc IF Adj.	2nd IF amp.
24.6 Mc	24.6 Mc IF Adj.	3rd IF amp.
25.6 Mc	25.6 Mc IF Adj.	Video Detector
21.75 Mc	21.75 Mc Sound Trap Adj.	*Sound Trap Adj. for Null (Min. Voltage)

*Note; After adjusting the 21.75 Mc Sound Trap recheck the setting of the 1st IF Transformer (T101).

5. Check the i-f amplifier frequency response by tuning the signal generator from 21 mc through 26.25 mc and observing the change in d-c voltage at the electronic voltmeter. If the signal generator output is set for an electronic voltmeter reading of 1.5 volts at the peak i-f amplifier response, the d-c voltage should not drop below one volt between the two peaks normally obtained with this i-f amplifier. If the response is unsatisfactory, repeat the procedure or try slight modifications of the recommended settings to obtain the desired response. Avoid resonating the coils with the iron core at the bottom end of the coil form. (Adjustment screw near limit of its travel).

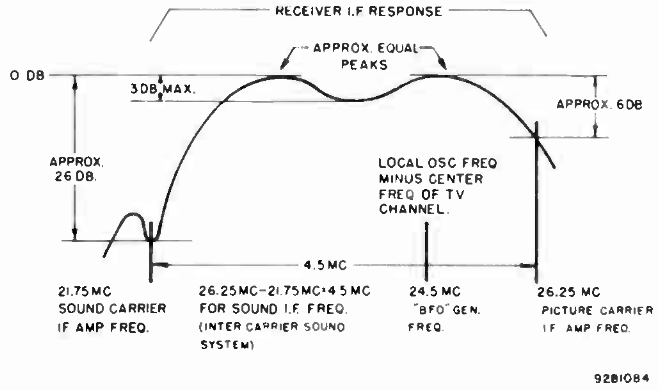

Fig. 12. I-F amplifier response

If a sweep type signal generator and oscilliscope is available the problem of making the final adjustments will be much easier. Check the two carrier i-f responses, 21.75 mc and 26.25 mc. The 21.75 mc response will be approximately 20 db below the peak response (Approx. 0.15 volt) and the 26.25 mc response will fall approximately 6 db below the peak (Approx. 0.4 volt). Refer to Fig. 12.

The average i-f amplifier sensitivity, when feeding the signal generator output through the receiver as described in step 2, will run approx. 2000 to 5000 microvolts for the one volt d-c peak measured at resistor R-118. (Receiver's oscillator operating on channel 2.)

CARRIER vs I-F FREQUENCY CHART

Channel No.	Channel Freq. (mc)	Picture Carrier Freq. (mc)	Sound Carrier Freq. (mc)	Receiver Osc. Freq. (mc)	Picture IF Freq. (mc)	Sound IF Freq. (mc)	Picture IF less Sound IF (mc)
2	54-60	55.25	59.75	81.5	26.25	21.75	4.5
3	60-66	61.25	65.75	87.5	26.25	21.75	4.5
4	66-72	67.25	71.75	93.5	26.25	21.75	4.5
5	76-82	77.25	81.75	103.5	26.25	21.75	4.5
6	82-88	83.25	87.75	109.5	26.25	21.75	4.5
7	174-180	175.25	179.75	201.5	26.25	21.75	4.5
8	180-186	181.25	185.75	207.5	26.25	21.75	4.5
9	186-192	187.25	191.75	213.5	26.25	21.75	4.5
10	192-198	193.25	197.75	219.5	26.25	21.75	4.5
11	198-204	199.25	203.75	225.5	26.25	21.75	4.5
12	204-210	205.25	209.75	231.5	26.25	21.75	4.5
13	210-216	211.25	215.75	237.5	26.25	21.75	4.5

*NOTE - The 1st IF amp coil (T-101) has two iron cores and must be adjusted from both top and bottom for 24.5 mc. response. Since this is an overcoupled transformer with a broad response, it will be necessary with this method of alignment to connect a 1000 ohm resistor across the primary winding (at the tuner terminals) when tuning the secondary (bottom core) and then connect the same resistor across the secondary winding when adjusting the primary (top) core.

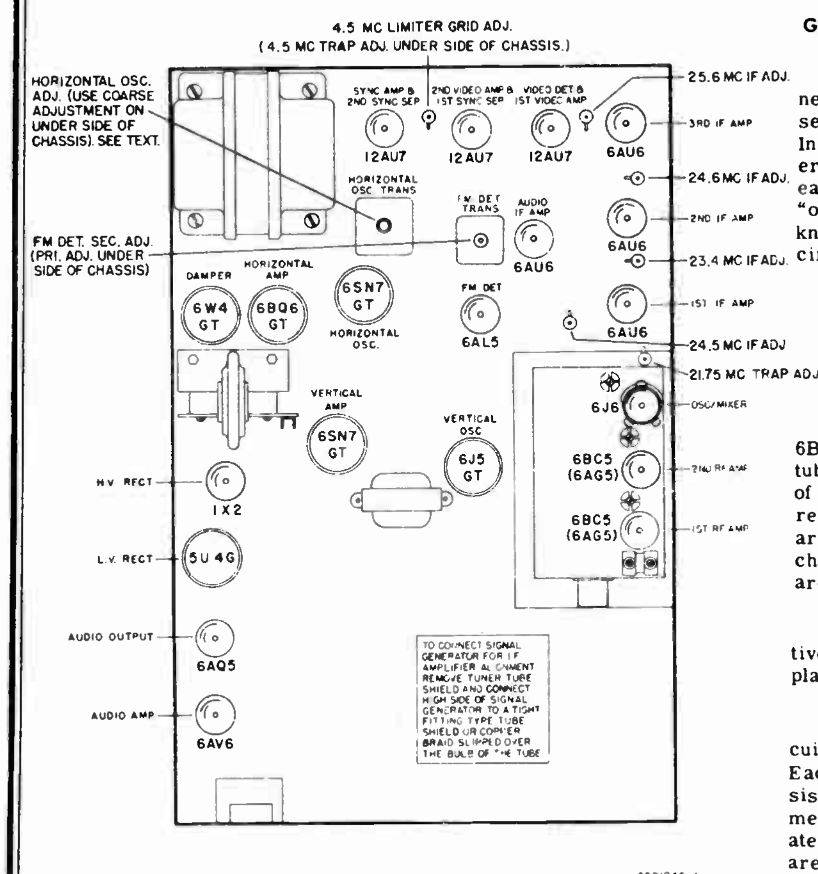

Fig. 11. Top view, i-f amplifier alignment points

TUNER ALIGNMENT PROCEDURE

GENERAL

The Electuner is a capacity tuned TV tuner covering channels 2 through 6 in the first (Lo) range and 7 through 13 in the second (Hi) range. Continuous tuning is provided in each range. In order to facilitate tuning, a certain amount of additional coverage above the highest and below the lowest tunable channel in each range is provided. The extra coverage is referred to as "overtravel" in this text. A two position switch, actuated by a knob concentric with the fine tuning shaft, is used to switch all circuits and will be referred to in this text as a "Range Switch".

Three tubes are employed as follows:

6AG5 or 6BC5 *first r-f amplifier
6AG5 or 6BC5 *second r-f amplifier
6J6 oscillator-mixer

* Field replacement of r-f amplifier tubes should be with 6BC5 tubes only. After the start of Electuner production, the tube manufacturers reduced the transconductance (Gm) rating of 6AG5 tubes and designated the high Gm version as 6BC5. A reduction in receiver sensitivity will result unless 6BC5 tubes are used for replacement. The 6BC5 tube is completely interchangeable with the 6AG5 tube, so no socket wiring changes are involved.

A three section gang condenser is used for tuning respectively the 1st r-f plate circuit, 2nd r-f plate circuit, and the plate circuit of the oscillator.

The antenna input system consists of two band-pass circuits. The required circuit is selected by the range switch. Each antenna band-pass circuit is a double tuned circuit consisting of a center tapped primary coil resonated by a trimmer capacitor and suitably coupled to a secondary coil resonated by the first r-f grid input capacity. The antenna circuits are designed to match a 300-ohm transmission line.

Sketches of antenna band-pass characteristics are shown in Fig. 13.

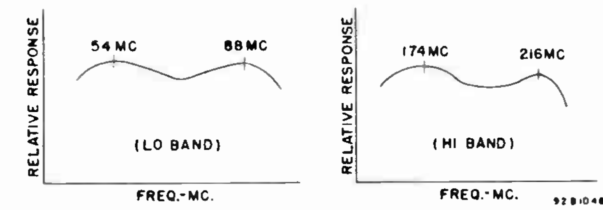

Fig. 13. Antenna band pass characteristics

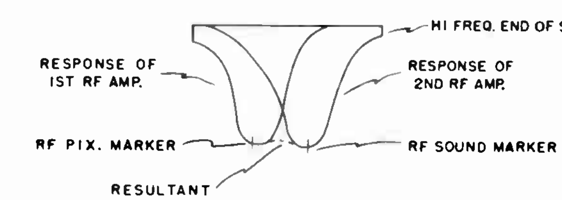

Fig. 14. Typical r-f pass band

The r-f amplifiers are used as stagger tuned amplifiers to provide a band pass circuit of the proper band width. In both Hi and Lo ranges, the plate circuit of the 1st r-f amplifier provides the low frequency stagger component, and the plate circuit of the second r-f amplifier provides the high frequency stagger component as indicated below in a sketch of a typical r-f pass band.

With an r-f sweep input to the antenna and an oscilloscope suitably connected to the mixer grid return at the LOOKER POINT shown in Fig. 19, the resultant overall r-f response, which is a combination of the stagger responses, in any channel appears as shown below:

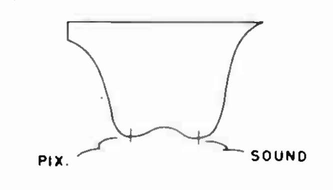

Fig. 15. Typical overall response

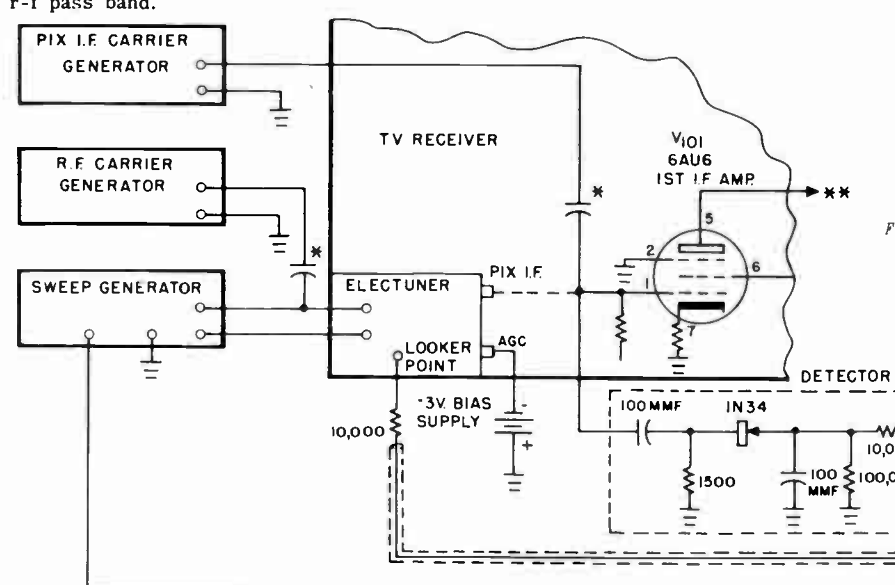

Fig. 16. Recommended test equipment circuits

MODELS 745, 747, 748, 750, 751, 760, 761, Ch. D919120

©John F. Rider

World Radio History

The oscillator employs a modified Colpitts circuit with one plate of the 6J6 tuned by the third section of the variable condenser.

In accordance with Fig. 19, the following tuning elements are brought out at the top of the tuner chassis:

Hi and Lo band antenna band-pass primary tuning trimmers
1st and 2nd r-f plate tuning trimmers
Oscillator plate tuning trimmer

EQUIPMENT REQUIRED

Sweep Generator
Oscilloscope
Electronic Voltmeter
R-F Marker Generator
Pix I-F Marker Generator
Bias supply 2-1.5 volt Dry Cells
IN-34 Crystal Detector

EQUIPMENT SPECIFICATIONS

Sweep Generator similar to RCA type WR59A, covering frequencies of 54 to 88 Mc, and 174 to 216 Mc with a minimum sweep of 10 Mc in any channel, and a 300-ohm balanced output at least 0.1 volt line to line.

Oscilloscope equivalent in vertical deflection sensitivity to Dumont type 208-B.

Electronic voltmeter similar to the Voltohymist.

RF maker generator similar to RCA type WR-39-A.

Pix IF marker generator may be a crystal controlled oscillator in vicinity of 26.25 Mc. As alternates, either a second WR-39-A or an all wave signal generator of suitable accuracy may be used to supply a picture IF marker.

EQUIPMENT SETUP

In reference to Fig. 16, the following precautions should be taken in making the equipment set up.

(1) The detector circuit should be so constructed as to maintain leads as short as possible. Connection of the detector circuit to the 1st i-f amplifier grid terminal should also be made with short leads.

(2) Shielded leads should be used in making the following connections to reduce hum and synchronous voltage pick up.

(a) The lead for observations of the r-f response from the scope isolating resistor (10,000 ohms located at the tuner LOOKER POINT) to the RF output switch position of the scope switch.
(b) The connection from the i-f detector circuit output to the IF switch position of the scope switch.
(c) The connection from the sweep generator to the horizontal input of the scope. (Use the externally generated sweep instead of internal oscilloscope sweep in order to obtain synchronization).

(3) The single pole double throw SCOPE SWITCH should be located at the vertical input terminals of the scope. This switching arrangement will permit observation of either the i-f response or the overall r-f response. The aforementioned positions will be referred to in subsequent text as the "IF" and "RF" positions respectively.

(4) The marker generator coupling condenser should be as small a value as possible to prevent any effect on tuner response, but must be large enough to permit easy observation of markers on either the i-f response or overall r-f response. (Approximately 2 or 3 mmf should be satisfactory in most cases).

(5) For all tests which are outlined in this text, remove the second i-f amplifier tube to prevent coupling back from the receiver i-f system.

PROCEDURE FOR OSCILLATOR ALIGNMENT

TV CHANNEL VS. PIX AND SOUND CARRIER FREQUENCY

Channel No.	Picture Carrier (Mc)	Sound Carrier (Mc)
2	55.25	59.75
3	61.25	65.75
4	67.25	71.75
5	77.25	81.75
6	83.25	87.75
7	175.25	179.75
8	181.25	185.75
9	187.25	191.75
10	193.25	197.75
11	199.25	203.75
12	205.25	209.75
13	211.25	215.75

OVERTRAVEL CHART FOR OSCILLATOR COVERAGE

Channel No.	Overtravel	RF Overtravel Marker Frequency
13	+ 1.5 Mc	Pix carrier + 1.5 Mc = 212.75 Mc
7	- 2.5 Mc	Pix carrier - 2.5 Mc = 172.75 Mc
6	+ 1.5 Mc	Pix carrier + 1.5 Mc = 84.75 Mc
2	- 1.0 Mc	Pix carrier - 1.0 Mc = 54.25 Mc

In all of the following tests the oscilloscope vertical gain should be as close to maximum gain as possible, consistent with hum and synchronous voltage interference limitations. This precaution will allow the use of low levels from the r-f sweep generator and increase the visibility of i-f and r-f markers.

HI BAND OSCILLATOR ALIGNMENT

(1) Turn range switch of the tuner to the Hi band (counter-clockwise rotation of switch knob), rotate variable condenser to minimum capacity (clockwise rotation of tuning shaft), and adjust sweep generator for channel 13.

(2) With the scope switch in IF position, adjust scope gain, r-f sweep input level, inject required i-f picture marker, (i.e. 26.25 Mc), and an r-f overtravel marker of 212.75 Mc.

(3) Adjust OSC. TRIMMER (Fig. 19) so that picture i-f marker and 212.75 Mc overtravel markers coincide on the i-f response characteristic on the scope.

(4) Remove the two self tapping screws used for fastening the tuner shield and slide shield off until a point is reached where coils on switch are exposed and accessible.

(5) Rotate variable condenser to maximum capacity (counter-clockwise) and adjust sweep generator for channel 7.

(6) Inject r-f overtravel marker of 172.75 Mc.

(7) With a bakelite alignment tool, adjust the spacing of the turns of the HI BAND OSC. COIL (Fig. 19) so that Pix i-f marker and 172.75 Mc markers coincide. Spreading the coils apart will raise the oscillator frequency; squeezing the coils together will lower the frequency. After adjustment, slide shield back into its original position and note any frequency shift of markers. Slide shield off and compensate for the frequency shift by a slight readjustment of the Hi band oscillator coil. Slide shield back into original position and note if markers coincide. If they do not, repeat this process until proper adjustment is made and markers coincide.

(8) Repeat steps 1 to 7 inclusive until correct oscillator coverage of entire Hi band is obtained.

LO BAND OSCILLATOR ALIGNMENT

(9) Remove tuner shield completely, turn tuner range switch to Lo band position (clockwise), rotate variable condenser to minimum capacity and adjust sweep generator for channel 6.

(10) Inject Pix i-f marker and r-f overtravel marker of 84.75 Mc.

(11) With a bakelite alignment tool, adjust LOW BAND OSC. COIL (Fig. 19) so that the Pix i-f marker and 84.75 Mc marker coincide.

(12) Rotate variable condenser to maximum capacity (counter-clockwise) and adjust sweep generator for channel 2.

(13) Inject r-f overtravel marker of 54.25 Mc.

(14) Adjust LOW BAND OSC. SERIES PAD (See Fig. 19) until Pix i-f marker and 54.25 Mc marker coincide.

(15) Repeat steps (9) to (14) inclusive for satisfactory coverage of entire Lo band.

PROCEDURE FOR RF PASS BAND ALIGNMENT

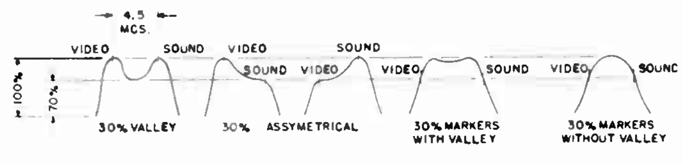

Fig. 17. Acceptable r-f pass bands

HI BAND RF PASS BANDS

(16) Repeat step (1).

(17) Replace tuner shield, set scope switch to i-f position, and adjust scope gain.

(18) Inject a Pix i-f marker and a channel 13 Pix r-f marker (211.25 Mc).

(19) Rotate tuning shaft until Pix i-f marker and 211.25 Mc marker coincide on the i-f response. Do not disturb this setting of the variable condenser for the remainder of alignment of channel 13 r-f pass band.

(20) Set scope switch to RF, adjust scope gain and turn 1ST RF TRIMMER (Fig. 19) for maximum amplitude of first r-f amplifier response in the region of the r-f Pix marker.

(21) Inject Channel 13 sound r-f marker (215.75 Mc) and adjust 2ND RF TRIMMER (Fig. 19) for maximum amplitude of second r-f amplifier response in the vicinity of the r-f sound marker.

(22) Repeat steps (20) and (21) until desired pass band is obtained. See Fig. 17. for acceptable r-f band pass response shapes.

(23) Remove tuner shield as in step (4) and repeat step (5).

(24) Set scope switch to IF position, adjust scope gain, and inject required Pix i-f marker and channel 7 Pix r-f marker of 175.25 Mc.

(25) Rotate tuning shaft until Pix i-f marker and channel 7 Pix r-f markers coincide in i-f response. Do not disturb this variable setting for remainder of alignment of channel 7 r-f pass band.

(26) Set scope switch to RF position and with a bakelite alignment tool, adjust 1ST RF HI BAND COIL (Fig. 19) for maximum amplitude of 1st r-f amplifier response in the region of the Pix r-f marker.

(27) Inject a channel 7 r-f sound marker of 179.75 Mc and adjust 2ND RF HI BAND COIL (Fig. 19) for maximum amplitude of 2nd r-f amplifier response in the region of the sound r-f marker.

(28) Repeat steps (26) and (27) until desired pass band is obtained, consistent with shapes shown in Fig. 17.

(29) Repeat steps (16) to (28) inclusive for satisfactory coverage of entire Hi band r-f response.

LO BAND RF PASS BANDS

(30) Repeat step (9), set scope switch to IF position, adjust scope gain, and inject a channel 6 Pix r-f marker (83.25 Mc).

(31) Rotate tuning shaft until Pix i-f marker and 83.25 Mc markers coincide. Do not disturb this variable condenser setting for remainder of alignment of channel 6 r-f pass band.

(32) Set scope switch to RF position and adjust scope gain.

(33) Adjust 1ST RF LO BAND COIL (Fig. 19) for maximum amplitude of 1st r-f amplifier response in the region of channel 6 Pix r-f marker.

(34) Inject channel 6 sound r-f marker of 87.75 Mc and adjust 2ND RF LO BAND COIL (Fig. 19) for maximum amplitude of 2nd r-f amplifier response in the region of the channel 6 sound r-f marker.

(35) Repeat step (32) until desired pass band is obtained in accordance with acceptable r-f pass bands shown in Fig. 17.

(36) Rotate variable to maximum capacity (counter-clockwise) and adjust sweep generator for channel 2.

(37) Set scope switch to IF position, adjust scope gain, and inject a channel 2 Pix r-f marker (55.25 Mc).

(38) Rotate fine tuning shaft until Pix i-f markers and 55.25 Mc markers coincide. Do not disturb this variable condenser setting for remainder of alignment of channel 2 r-f pass band.

(39) Set scope switch to RF position and adjust scope gain.

(40) Adjust 1ST RF LO BAND COIL (Fig. 19) for maximum amplitude for 1st r-f amplifier response in region of channel 2 Pix r-f marker.

(41) Inject channel 2 sound r-f marker (59.75 Mc) and adjust 2ND RF LO BAND COIL (Fig. 19) for maximum amplitude for 2nd r-f amplifier response in region of channel 2 sound r-f marker.

(42) Repeat step (40) until desired pass band is obtained in accordance with acceptable r-f pass band shown in Fig. 17.

(43) Repeat steps (30) through (42) inclusive for satisfactory coverage of entire Lo band r-f response.

PROCEDURE FOR ANTENNA PASS BAND ALIGNMENT

The band pass antenna stages are normally aligned in the factory for minimum standing waves with a wide range sweep oscillator and a delay line. The coupling between the primaries and secondaries are carefully adjusted and in general should not be disturbed. Minor corrections of the primary trimmer tuning may be necessary, if they are accidentally or otherwise varied after leaving the factory. The procedure for resetting antenna primary trimmers is outlined below.

HI BAND PRIMARY ANTENNA TRIMMER ALIGNMENT

With scope switch in RF position and equipment set for observation of channel 13 r-f pass band (see step 1) turn HI BAND PRIMARY ANT. TRIMMER screw (counter-clockwise) i.e. to a reduced capacity setting. Start turning trimmer screw clockwise (increasing capacity) while observing the channel 13 r-f pass band amplitude and shape. It will be noticed that the amplitude will increase to a certain point and thereafter the shape of the response will change as shown in Fig. 18, indicating the antenna to be cutting into the r-f pass band. Back out the trimmer screw to a maximum amplitude and minimum "cutting-in" position.

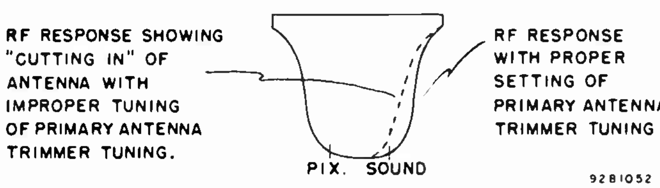

Fig. 18. Effect of primary antenna trimmer on r-f pass band response

LO BAND PRIMARY ANTENNA TRIMMER ALIGNMENT

Procedure for aligning LO BAND PRIMARY ANT. TRIMMER is the same as outlined for Hi band primary antenna trimmer except the tuner should be tuned to channel 6 and adjustment of the Lo band antenna primary trimmer screw should be done while observing the r-f response characteristic of channel 6.

FINAL CAUTION NOTE

Upon completion of tuner alignment, remove crystal detector in 1st IF grid. Replace tuner shield and fastening screws, reinsert 2nd i-f amplifier tube removed at start of alignment, and check performance of receiver with all available local stations.

TUNER SERVICE NOTES

OSCILLATOR INJECTION VOLTAGE

The oscillator injection voltage is specified as 2 volts minimum with normal B+ applied and is measured from the LOOKER POINT (Fig. 19) to ground with a Voltohymst through a 10,000 ohms isolating resistor.

In the event of failure to meet these specifications, it is necessary to replace the 6J6 tube.

NOTE - If a tube is changed, it may be necessary to realign tuner to compensate for difference of tube characteristics. A slight adjustment of the oscillator trimmer (Fig. 19) will correct for any change of tube capacitance. Follow instructions for alignment of Hi Band and Lo Band oscillator alignment. Low oscillator injection voltage will reduce conversion gain with resulting loss in picture sensitivity.

REPLACING TUBES

See note under Oscillator Injection Voltage concerning replacement of oscillator - converter tube (6J6).

If either r-f tube is replaced, it may be necessary to realign tuner to compensate for a variation of tube characteristics. A slight adjustment of the r-f trimmers (Fig. 19) will compensate for this. Follow instructions for alignment of Hi band and Lo band r-f pass band alignment.

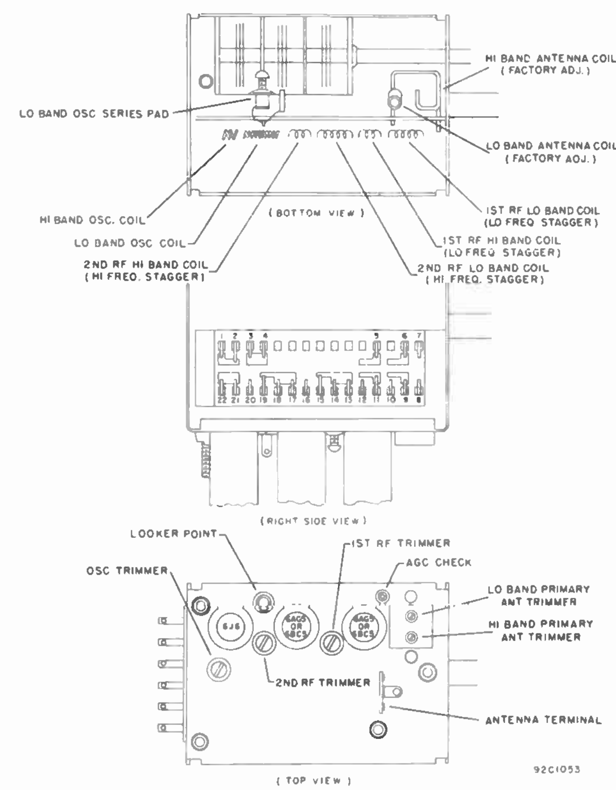

Fig. 19. Location of tuner alignment adjustments.

VARIABLE CONDENSER

Do Not Attempt to bend variable condenser plates, as they have been calibrated in the factory on special equipment.

RESTRINGING PULLEY DRIVE

CONDENSER DRIVE

Wrap drive cord assembly 1-1/2 turns on drive pulley (Fig. 20) and slip other end over pulley on rotor shaft, keeping prong clip in center of slot, hook one end of spring over cord, and the other end over tab on pulley.

POINTER DRIVE

With condenser at maximum capacity and hole in pointer sleeve pulley in position shown, press prong clip on pointer cord assembly into hole and wrap end of loop around end of condenser rotor shaft (Fig. 20), making certain that cord is seated in groove in rotor shaft. Loop loose end of cord assembly over anti-backlash pulley as shown. Apply a drop of "Duco" household cement over cord seated in groove in rotor shaft to prevent cord from slipping.

RESETTING POINTER SLEEVE EXTENSION

If pointer cord breaks, it may be necessary to reset the pointer sleeve ferrule after restringing in order to maintain coincidence of pointer and dial escutcheon.

(1) Tune unit to channel 13 (station or signal generator).
(2) Unsolder pointer sleeve ferrule and rotate until pointer registers on number 13 of dial escutcheon.
(3) Solder pointer sleeve extension to pointer sleeve (Fig. 20).

TROUBLE SHOOTING GUIDE

(1) No sound or picture, but no B+ short.	Defective oscillator - mixer tube (6J6); open filament; prongs on sockets shorted to each other; open cathode to ground; open i-f coil; open converter plate lead. Open i-f coupling condenser.
(2) No sound or picture with B+ short.	Tube shorted internally; r-f trimmer shorted; screen by-pass shorted; r-f choke shorting; B+ by-pass condenser shorted; leads from variable to switch shorting.
(3) One tube does not light.	Bad tube; open filament return (from socket to chassis).
(4) All tubes do not light.	Filament short at socket to chassis; open filament lead; filament by-pass shorted.
(5) No high band response.	Open contact; high band antenna trimmer shorted; open or shorted high band oscillator or r-f coils.
(6) No low band response	Open low band r-f or oscillator coil; low band antenna coil open; antenna trimmer shorted; open contact on switch.
(7) Intermittents.	Socket pins not tight; switch contacts loose; accidental shorting between components.

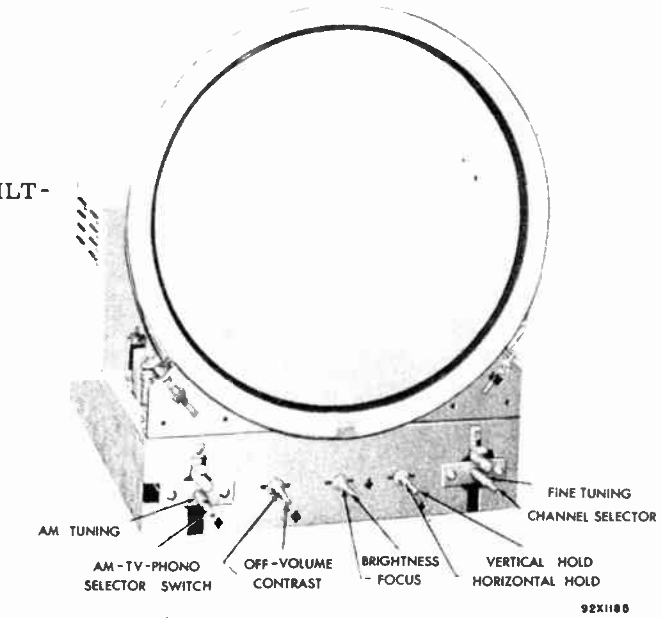

FIG. 2. CHASSIS FRONT VIEW

SERVICE ADJUSTMENTS

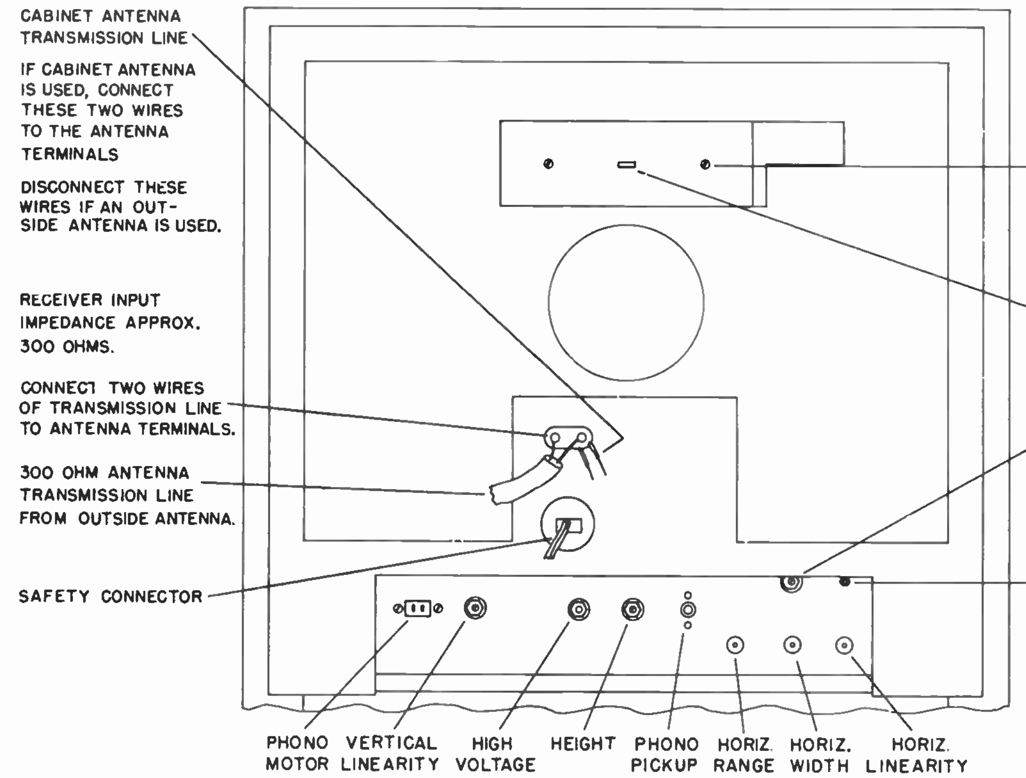

FIG. 3. REAR VIEW

The service adjustments normally will require an occasional minor adjustment if any circuit work or tube replacement is required. A test pattern, generated either locally in the shop or obtained from a television station is recommended for best results. The operating and auxiliary controls, located on the front panel, should be set for as good a pattern as possible before making the following adjustments.

TUBE COMPLEMENT

V 1	6CB6	RF AMPLIFIER	V 111	6AV6 or 6SQ7	1ST AUDIO AMPLIFIER
V 2	6J6	OSC/MIXER	V 112	6AQ5	AUDIO OUTPUT
V 101	6CB6	1ST IF AMPLIFIER	V 113	6AX5GT or 6X5GT	LV RECTIFIER
V 102	6CB6	2ND IF AMPLIFIER	V 114	5U4G	LV RECTIFIER
V 103	6CB6	3RD IF AMPLIFIER	V 115	6SN7GT	HORIZONTAL OSC.
V 104	6AL5	VIDEO DETECTOR	V 116	6AU5GT or 6AV5GT	HORIZONTAL AMP.
V 105	6CB6	VIDEO AMPLIFIER			
V 106	12AU7 or 6SN7	SYNC AMP & SEP	V 117	6W4GT	DAMPER
V 107	12AU7 or 6SN7	SYNC CLIPPER & VERTICAL OSC.	V 118	1B3GT	HV RECTIFIER
			V 119	16GP4	16" BLACK PICTURE TUBE
V 108	6S4	VERTICAL AMPLIFIER	V 201	6BA6	RF AMPLIFIER (AM)
V 109	6AU6	AUDIO IF AMPLIFIER	V 202	6BE6	CONVERTER (AM)
V 110	6AL5	AUDIO DETECTOR	V 203	6BA6	IF AMPLIFIER (AM)

PRODUCTION CHANGES

Chassis in which minor changes or substitutions were made during production may be identified as follows:

CHASSIS STAMP	CHANGE OR SUBSTITUTIONS
A.	Fuse added to the circuit
1.	Tube type 6SQ7 substituted for type 6AV6
4.	Tube type 6SN7 substituted for type 12AU7
5.	Both of the above tube substitutions.

Note: See notation on the schematic diagram for those changes above that involve changes in wiring or connections.

FIG. 4. CENTERING MISADJUSTMENT

If the picture is not properly centered remove the two centering control lock screws and move the centering control lever a short distance in any direction required to recenter the picture. Do not use undue force in making this adjustment as excessive strain may be exerted on the neck of the picture tube. If proper centering cannot be restored in this manner a slight readjustment of the deflection yoke mounting may be necessary.

HIGH VOLTAGE WARNING

OPERATION OF THE RECEIVER CHASSIS OUTSIDE OF THE CABINET INVOLVES DANGER OF ELECTRICAL SHOCK.

EXERCISE ALL NORMAL HIGH VOLTAGE PRECAUTIONS WHEN WORKING WITH THIS RECEIVER.

©John F. Rider

World Radio History

FIG. 5. HEIGHT CONTROL MISADJUSTMENT

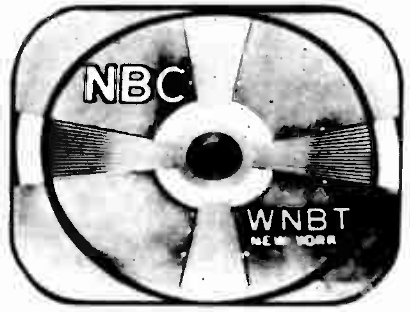

FIG. 6. WIDTH CONTROL MISADJUSTMENT

Adjust the HEIGHT and WIDTH controls so that the picture fills out the dimensions of the screen. A slight readjustment of the CENTERING control may then be necessary.

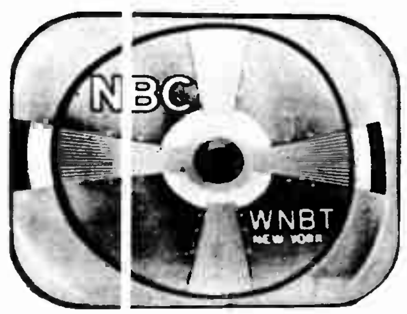

FIG. 7. HORIZONTAL DRIVE CONTROL MISADJUSTMENT

The HORIZONTAL DRIVE is adjusted by advancing the adjustment to a point where a vertical white line appears in the pattern and then backing it off just beyond the point where the white line disappears.

Note - The sequence of "non-operating" control adjustments outlined is suggested as a convenient method of approach and not an arbitrary procedure. Variations of the procedure are permitted to obtain the final result.

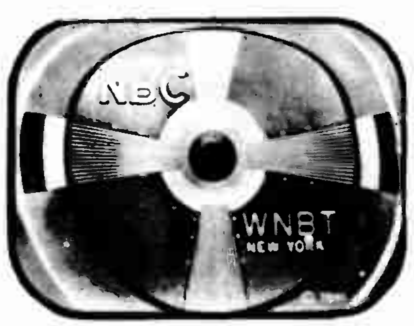

FIG. 8. VERTICAL LINEARITY CONTROL MISADJUSTMENT

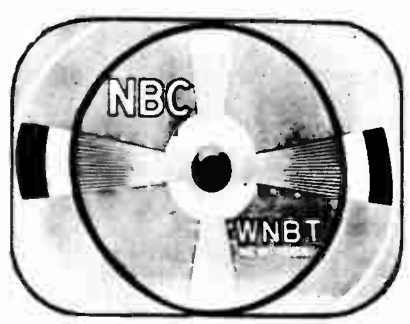

FIG. 9. HORIZONTAL LINEARITY CONTROL MISADJUSTMENT

Adjust the HORIZONTAL LINEARITY and VERTICAL LINEARITY adjustments for a symmetrical pattern. A slight readjustment of the HEIGHT and WIDTH controls may then be necessary.

WARNING

PICTURE TUBE HANDLING PRECAUTIONS

The picture tube envelope encloses a high vacuum and with the large surface area of glass involved, the stresses created are considerable. Any accidental blow or rough handling could cause the tube to implode with extreme violence. The picture tube should be handled only by qualified persons protected by heavy gloves and shatterproof goggles.

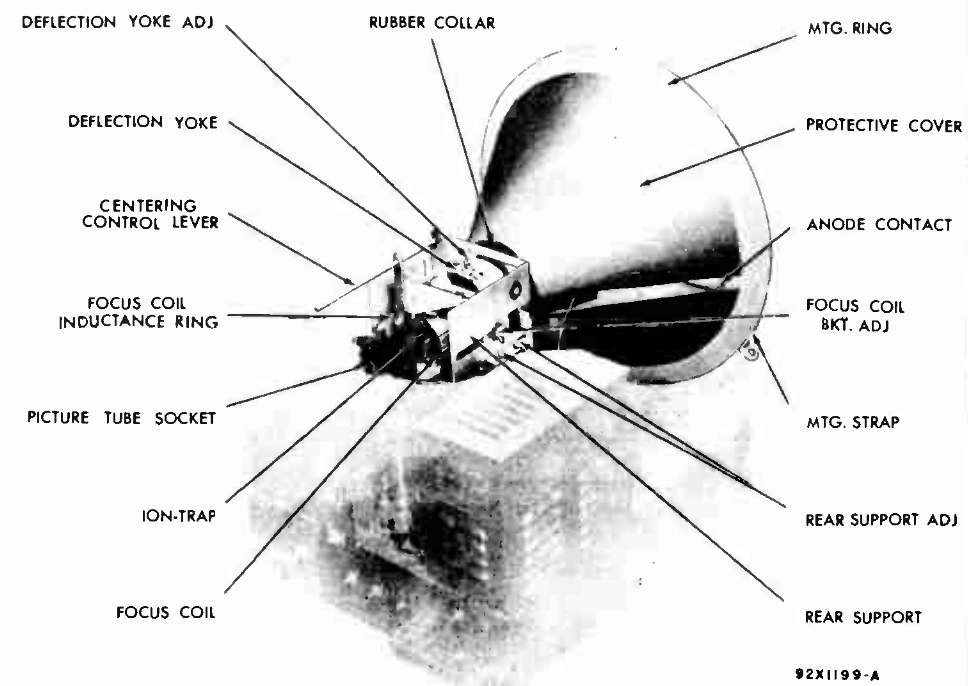

FIG. 10. PICTURE TUBE MOUNTING DETAIL

TO REMOVE THE CHASSIS FROM THE CABINET

1. Remove the knobs on the front panel by pulling in the forward direction.
2. Remove the slotted cover through which the centering lever protrudes on the cabinet back. This is accomplished by removing the two fastening screws from the cover.
3. Unscrew the fastening bolt located directly above the AC cord insert.
4. Remove the screws holding the cabinet back. The back cover may then be set aside.
5. Remove the speaker plug at the chassis. On table model remove the speaker mounting nuts and lift out the speaker.
6. Remove the leads from the built-in antenna at the terminals on the chassis.
7. Removal of the chassis may now be completed by removing the five chassis mounting bolts.

REMOVING THE PICTURE TUBE

1. Remove the chassis from the cabinet by following the above procedure.
2. Insure the discharge of the high voltage filter condenser by shorting the ANODE CONTACT (PL-104) to chassis through a well insulated wire or test lead.
3. Disconnect the ANODE CONTACT (PL-104).
4. Disconnect the TUBE SOCKET at the base of the tube.
5. Slip the ION TRAP from the neck of the tube.
6. Remove the MOUNTING STRAP at the front rim of the tube.
7. Loosen the four REAR SUPPORT ADJUSTMENT SCREWS and then, while holding the tube near the face, carefully slip the neck of the tube out of the DEFLECTION YOKE and FOCUS COIL. Use a slight twisting pull in order to break the cone of the tube away from the RUBBER COLLAR. If the tube fails to slip out smoothly, investigate and remove the cause of trouble. DO NOT USE FORCE.
8. If the tube is to be replaced, remove the rubber band from around the plastic MOUNTING RING. The PROTECTIVE COVER and the MOUNTING RING can now be removed.

©John F. Rider

World Radio History

INSTALLING AND ADJUSTING THE PICTURE TUBE

1. Slip the PROTECTIVE COVER over the cone of the tube and fit the plastic MOUNTING RING over the edge of the PROTECTIVE COVER at the front rim of the tube. Make sure that the ANODE CONTACT makes a good electrical connection with the metal cone of the tube.

2. Adjust the MOUNTING RING and the PROTECTIVE COVER so that the ends of the MOUNTING RING come together approximately 90 degrees counterclockwise from the ANODE CONTACT on the PROTECTIVE COVER, when facing the front of the tube. Place the rubber band in the groove of the MOUNTING RING.

3. Slip the neck of the tube through the RUBBER COLLAR, DEFLECTION YOKE, and FOCUS COIL; seating the groove of the MOUNTING RING on the two rubber channels mounted on the two curved brackets at the front of the chassis. Position the tube so that the joint in the MOUNTING RING is centered at the bottom, next to the chassis.

4. Place the MOUNTING STRAP in the MOUNTING RING groove and tighten firmly.

5. Move the REAR SUPPORT so that the RUBBER COLLAR rests firmly against and supports the cone of the tube. Tighten the REAR SUPPORT ADJUSTMENT SCREWS.

6. Check the ION TRAP for any markings and slip it over the neck of the tube. If the TRAP is stamped with an arrow, the arrow should point towards the face of the tube.

7. Connect the PICTURE TUBE SOCKET and the ANODE CONNECTOR.

8. Turn the receiver on and allow a few minutes for warm up.

9. Turn up the BRIGHTNESS control and set the ION TRAP for maximum raster brilliance, backing off the BRIGHTNESS control as the maximum point is approached. The ION TRAP must be rotated about the axis of the tube as well as shifted along the neck in order to obtain proper setting. With the BRIGHTNESS control set for slightly above normal brilliance and the CONTRAST control full counterclockwise, adjust the FOCUS control until the raster is clearly visible. Readjust the ION TRAP for maximum raster brilliance and set the BRIGHTNESS control for normal reception.

10. Connect the antenna and tune in a test pattern.

11. Readjust the CONTRAST control until the different shades of the gray scale are clearly visible on the test pattern.

12. Check the position and appearance of the test pattern. If it is off center or shadowed at the corners (electron beam striking the neck of the tube) adjust the centering lever. Set the focus control at the center of its range and adjust the FOCUS COIL ADJUSTMENT, if one is provided, and FOCUS COIL INDUCTANCE RING as necessary so that a clear sharp picture may be obtained well within the range of the focus control.

CAUTION - It will not be necessary to turn the CENTERING LEVER excessively. Excessive force on the lever will snap the neck of the tube.

13. If the lines of the raster are not horizontal or square with the escutcheon loosen the DEFLECTION YOKE ADJ. screw and rotate the DEFLECTION YOKE until this condition is obtained. Tighten this adjustment.

14. Follow the procedure under the NON-OPERATING CONTROL ADJUSTMENTS and make any minor adjustment of the FOCUS COIL or DEFLECTION YOKE necessary to obtain the desired results.

ADJUSTMENT OF THE HIGH VOLTAGE ON THE PICTURE TUBE ANODE

The second anode potential should be slightly less than 14,000 volts on a receiver that is functioning properly. Since the high voltage is obtained from the horizontal output transformer, the service adjustments must be made, or known to be in proper adjustment, before a high voltage measurement will have any meaning.

Improper operation of the horizontal sweep circuit or circuit faults in the high voltage filter will generally account for an abnormal anode potential. If the anode potential is low, check the HORIZONTAL DRIVE adjustment outlined above.

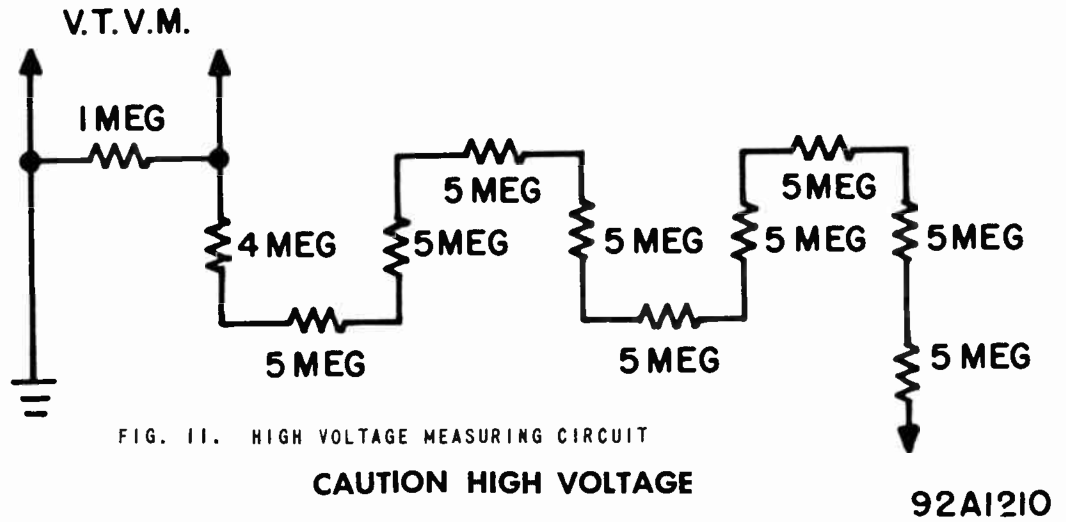

FIG. 11. HIGH VOLTAGE MEASURING CIRCUIT

CAUTION HIGH VOLTAGE

DO NOT USE HAND HELD FLEXIBLE TEST LEADS WHEN MAKING THE FOLLOWING MEASUREMENT. KEEP THE HANDS CLEAR OF THE CIRCUIT DURING MEASUREMENT. A 11 TO 14 KV. POTENTIAL EXISTS IN THIS CIRCUIT. EXERCISE ALL NORMAL HIGH VOLTAGE PRECAUTIONS.

To measure the second anode potential, set the CONTRAST and BRIGHTNESS controls at minimum. With the controls in this position, the resistance of the test circuit will simulate the load presented to the high voltage power supply of the picture tube. Connect a test circuit as shown in Fig. 11. Make the resistor string self-supporting and allow adequate clearance between the resistors and chassis parts to prevent high voltage breakdown. A meter scale of 0 to 300 volts or larger should be used. Observe the reading on the meter scale and multiply this reading by 50 to obtain the voltage across the circuit. As an example, if the V.T.V.M. reads 260 volts, the potential is 260 x 50 or 13,000 volts.

After it has been determined that the receiver is otherwise in good working order and properly adjusted, the High Voltage adjustment on the rear of the chassis (See Fig. 3) should be set for a potential slightly less than 14,000 volts. This adjustment has been provided mainly to compensate for variation in line voltage.

HORIZONTAL OSCILLATOR ALIGNMENT

If the Horizontal Hold control on the front panel fails to restore synchronization the Horizontal Range and Horizontal Lock adjustments should be reset.

1. Turn the Hold control to the full clockwise position. Adjust the Horizontal Range adjustment until a vertical bar appears in the pattern.

©John F. Rider

World Radio History

2. Turn the Hold control to the full counter-clockwise position. Momentarily switch off the station. Three or four horizontal bars should then appear on the screen. If too many or too few bars appear, the number may be decreased by turning the Horizontal Lock adjustment in the clockwise direction, or increased by turning the Horizontal Lock adjustment in the counter-clockwise direction.

3. Repeat step #1.

4. Check the action of the front controls on on all active channels. Repeat the above steps if necessary to maintain stable synchronization.

If the above procedure fails to restore stable synchronization, a waveform adjustment may be made with the aid of an oscilloscope.

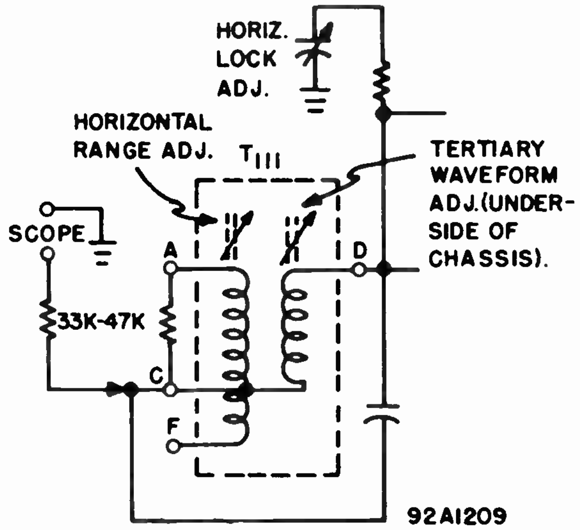

FIG. 12. OSCILLOSCOPE CONNECTION, FOR HORIZONTAL OSCILLATOR ALIGNMENT

5. Connect the oscilloscope as shown in Fig. 12. Adjust the Tertiary Waveform adjustment until the sine wave is equal in amplitude to the peak of the sawtooth (see Fig. 13), while maintaining the picture in synchronization with the Horizontal range adjustment.

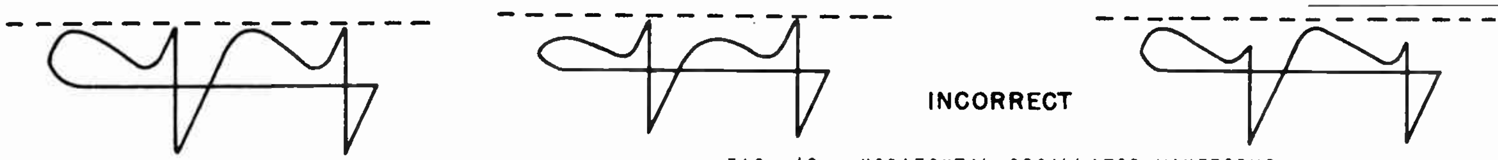

FIG. 13. HORIZONTAL OSCILLATOR WAVEFORMS

CARRIER vs. I-F FREQUENCY CHART

Channel No.	Channel Freq. (mc)	Picture Carrier Freq. (mc)	Sound Carrier Freq. (mc)	Receiver Osc. Freq. (mc)	Picture IF Freq. (mc)	Sound IF Freq. (mc)	Picture IF less Sound IF (mc)
2	54-60	55.25	59.75	81.5	26.25	21.75	4.5
3	60-66	61.25	65.75	87.5	26.25	21.75	4.5
4	66-72	67.25	71.75	93.5	26.25	21.75	4.5
5	76-82	77.25	81.75	103.5	26.25	21.75	4.5
6	82-88	83.25	87.75	109.5	26.25	21.75	4.5
7	174-180	175.25	179.75	201.5	26.25	21.75	4.5
8	180-186	181.25	185.75	207.5	26.25	21.75	4.5
9	186-192	187.25	191.75	213.5	26.25	21.75	4.5
10	192-198	193.25	197.75	219.5	26.25	21.75	4.5
11	198-204	199.25	203.75	225.5	26.25	.21.75	4.5
12	204-210	205.25	209.75	231.5	26.25	21.75	4.5
13	210-216	211.25	215.75	237.5	26.25	21.75	4.5

This adjustment is very important for correct operation of the circuit. If the broad peak of the wave on the oscilloscope is lower than the sharp peak, the noise immunity becomes poorer, the stabilizing effect of the tuned circuit is reduced and drift of the oscillator becomes more serious.

On the other hand, if the broad peak is higher than the sharp peak, the oscillator is overstabilized, the pull-in range becomes inadequate and the broad peak can cause double triggering of the oscillator when the hold control approaches the clockwise position.

6. Remove the oscilloscope and repeat step #1 and 2 if necessary.

7. Check the action of the front panel controls and repeat above steps as required to provide positive synchronization on all channels.

AM TUNER ALIGNMENT

Connect the VTVM across R-215 at the terminal strip on the under side of the chassis as shown in Fig. 15. Set the SELECTOR SWITCH to the AM position. Follow the steps in the chart below using just enough signal generator output to give a useful indication on the VTVM (approximately 2 volts).

Step	Dummy Ant.	Signal Generator Coupling To	Signal Generator Frequency (AM Modulated 30%)	Radio Dial Setting	Adjust	Remarks
1	.01 Mfd. capacitor	Pin No. 7 of the 6BE6 Converter tube	455 KC	1000 KC	A,B,C,D	Adjust for maximum indication on the VTVM
2	Same	Stator of C-202A	455 KC	1000 KC	C-207	Adjust for minimum indication on the VTVM
3	200 mmf. capacitor	Loop Antenna Primary	1600 KC	1600 KC	C-201B C-201A	Adjust for maximum indication on the VTVM

FM SOUND CHANNEL ALIGNMENT

EQUIPMENT REQUIRED

Signal generator covering 4 MC to 30 MC

Electronic voltmeter

IN34 crystal detector circuit as shown in Fig. 14.

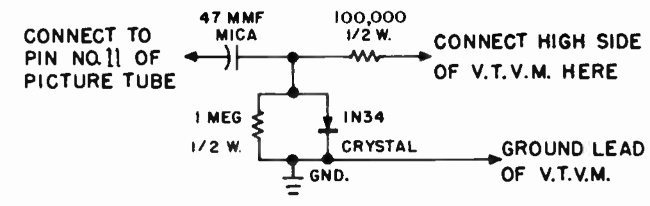

FIG. 14. SOUND ALIGNMENT TEST CIRCUIT

PROCEDURE

1. Connect the low frequency signal generator output, through a .005 capacitor, across the IF test terminals. (See Fig. 15).
2. Connect the detector circuit and VTVM as shown in Fig. 14.
3. Set the signal generator to 4.5 MC using just enough output to give approximately one volt reading at the electronic voltmeter.
4. Adjust the 4.5 MC TRAP ADJUSTMENT located on the under side of the chassis for minimum voltage as shown on the meter.
5. Disconnect the detector test circuit.
6. Connect the VTVM to pin #2 of the 6AL5 FM DETECTOR tube (V110).
7. Adjust the LIMITER GRID adjustment (L106) and the primary of T-108 (bottom adjustment) for maximum indication on the voltmeter.
8. Connect the electronic voltmeter across the 1000 mmf condenser (C130) (see Fig. 24.) at the output of the FM detector stage and adjust the FM DET. SEC. ADJ. of the FM detector transformer (T-108) for the null. If a null (0-volts) appears at more than one setting use the position nearest to the top limit of the tuning slug.
9. Shift the frequency of the signal generator either side of 4.5 MC and touch up the FM DETECTOR PRIMARY ADJUSTMENT (Bottom of T-108) for approximately equal peaks. Use just enough signal generator output to obtain one volt peaks for best results.
10. After completing the alignment procedure and placing the receiver in operation again, carefully tune in a TV test pattern and adjust the 4.5 MC TRAP ADJ. for maximum vertical wedge definition.

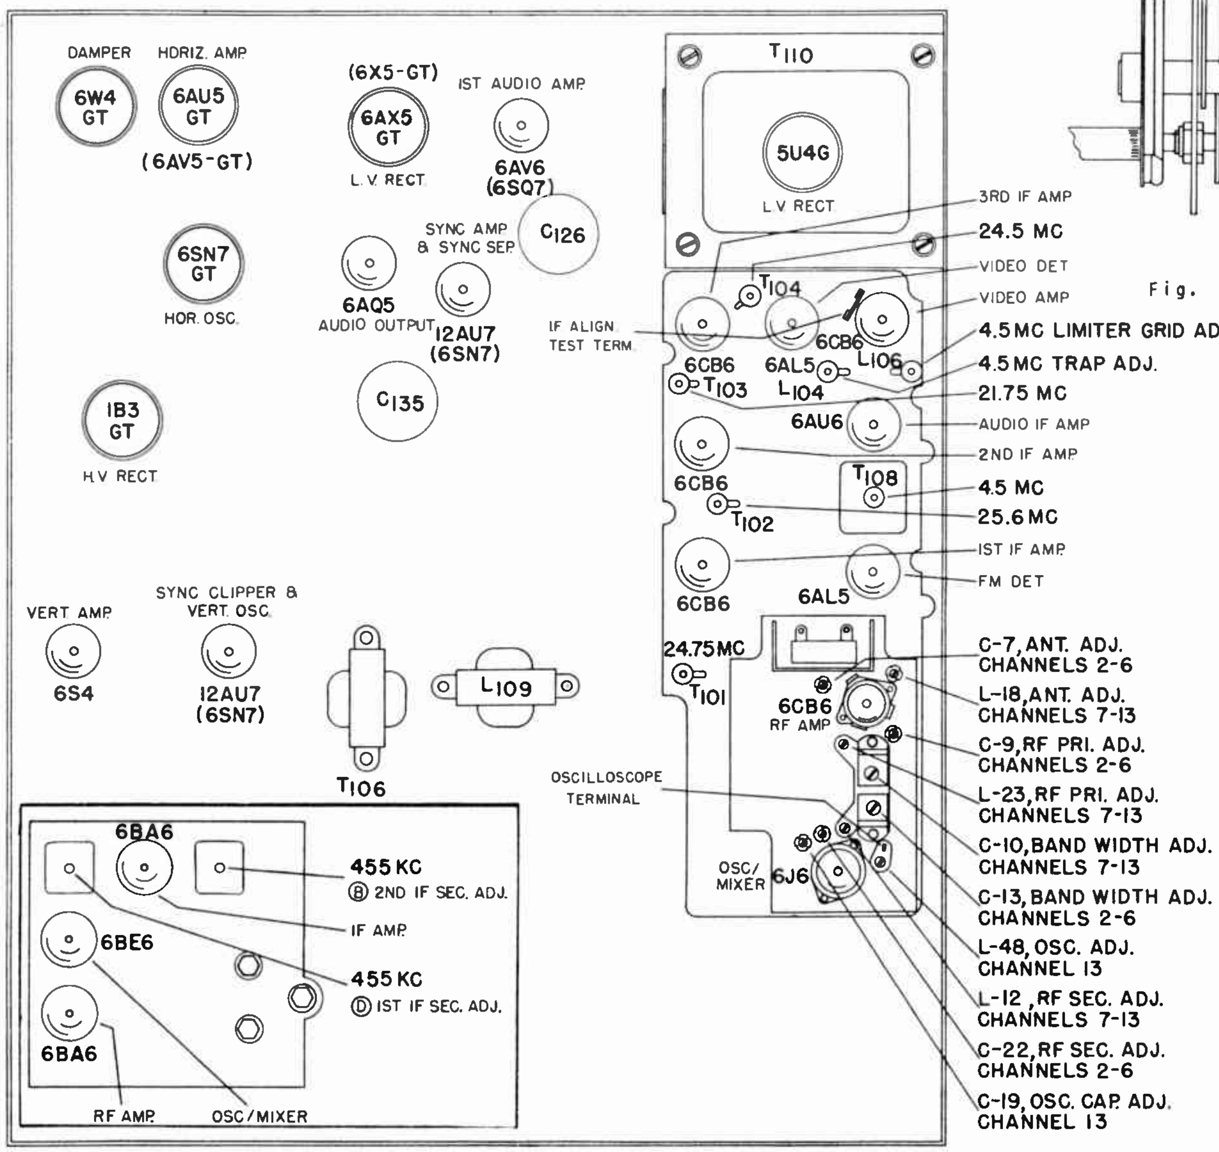

FIG. 15B. TOP VIEW ALIGNMENT LOCATIONS

92D1178-E
92A1182

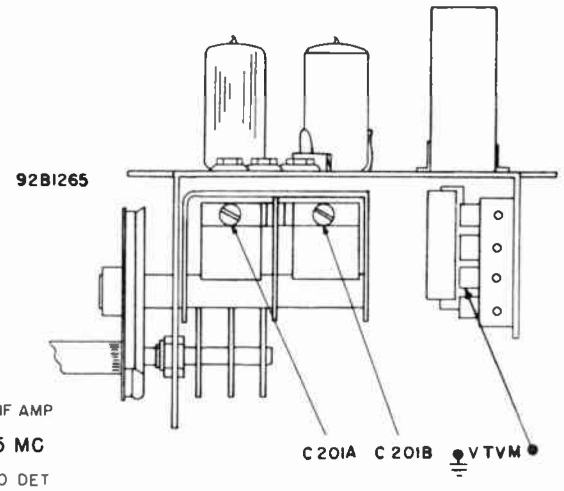

Fig. 15A. AM TUNER SIDE VIEW

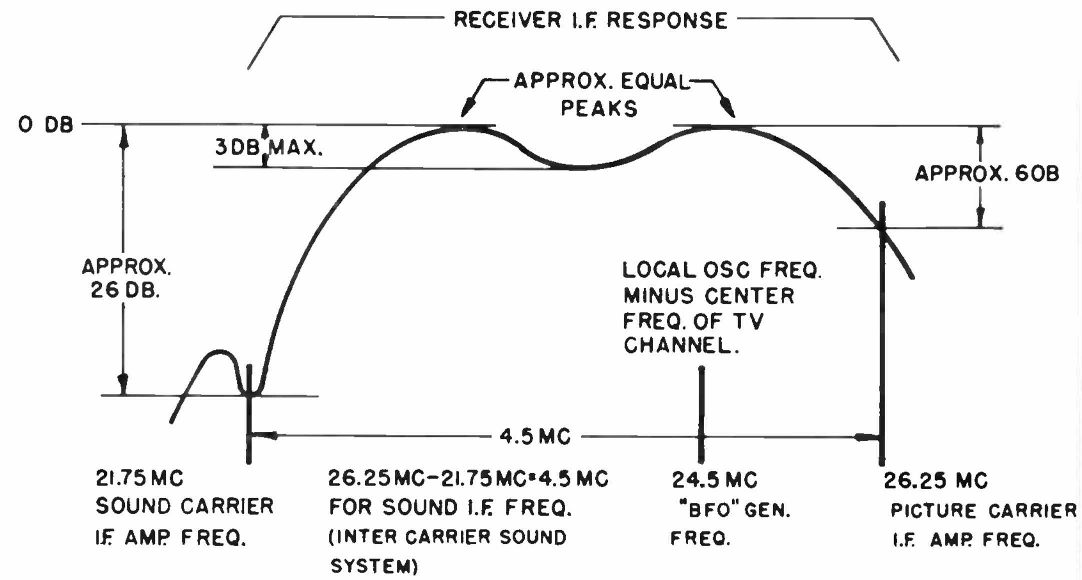

FIG. 16. IF AMPLIFIER RESPONSE.

92B1084

*NOTE - The 1st IF amp coil (T-101) has two iron cores and must be adjusted from both top and bottom for 24.75 MC response. Since this is an overcoupled transformer with a broad response, it will be necessary with this method of alignment to connect a 1000 ohm resistor across the primary winding (at the tuner terminals), when tuning the secondary (bottom core) and then connect the same resistor across the secondary winding when adjusting the primary (top) core.

IF AMPLIFIER ALIGNMENT

1. Connect the electronic voltmeter across the IF test terminals (see Fig. 15).

2. Couple the high side of the signal generator to the OSC/MIXER tube (V-2) by removing its shield and slipping a tight fitting tube shield or length of copper braid over the bulb of the tube and connecting the generator lead to it. Connect the ground side of the signal generator to the frame of the tuning unit.

3. Set the channel selector at channel 2.

4. Set the signal generator output (unmodulated) to develop one or two volts at the electronic voltmeter and adjust the four IF amplifier coils, according to the following chart, for maximum DC voltage as measured by the electronic voltmeter. Readjust the signal generator output as required to maintain the two-volt potential at the electronic voltmeter.

IF AMPLIFIER ALIGNMENT CHART

Signal Generator Frequency (No Modulation)	Adjustment (Refer to Fig. 15)	Stage Adjusted
24.75 MC	T101 24.75 MC IF Adj. (Top & Bottom)	1st IF amplifier
25.6 MC	T102 25.6 MC IF Adj.	2nd IF amplifier
23.1 MC	T103 23.1 MC IF Adj. Top	3rd IF amplifier
24.5 MC	T104 24.5 MC IF Adj.	Video Detector
21.75 MC	T103 21.75 MC Sound Bottom Trap Adj.	Sound Trap Adj. (Adj. for Min. Voltage)

Note: After adjusting the 21.75 MC Sound Trap recheck the setting of the 3rd IF Transformer (Top of T-103).

5. Check the i-f amplifier frequency response by tuning the signal generator from 21 mc through 26.25 mc and observing the change in d-c voltage at the electronic voltmeter. If the signal generator output is set for an electronic voltmeter reading of 1.5 volts at the peak i-f amplifier response, the d-c voltage should not drop below one volt between the two peaks normally obtained with this i-f amplifier. If the response is unsatisfactory, repeat the procedure or try slight modifications of the recommended settings to obtain the desired response. Avoid resonating the coils with the iron core at the bottom end of the coil form. (Adjustment screw near limit of its travel). If a sweep type signal generator and oscilliscope are available the problem of making the final adjustments will be much easier. Check the two carrier i-f responses, 21.75 mc and 26.25 mc. The 21.75 mc response will be approximately 20 db below the peak response (approx. 0.15 volt) and the 26.25 mc response will fall approximately 6 db below the peak (Approx. .75 volt). Refer to Fig. 16.

The average i-f amplifier sensitivity, when feeding the signal generator output through the receiver as described in step 2, will run approx. (800 to 1500 microvolts) for the one volt d-c peak measured at resistor R-116. (Receiver's oscillator operating on channel 2).

TUNER ALIGNMENT

The tuner is of the turret type employing printed-circuit coils and covering television channels 2 through 13. It has been carefully aligned and adjusted at the factory using precision equipment. Alignment or replacement of individual tuner components in the field is not recommended. If the tuner fails to operate properly by reason of part failure within the unit or in the event it should become badly misaligned, the complete unit should be replaced. The tuner may be exchanged for a new one, through the factory service department, at a very reasonable cost providing it has not been damaged or abused. In some cases the exchange can be effected without charge under the terms of the warranty.

Minor alignment adjustments may be desirable after tube replacement in the RF or oscillator-mixer stage. For those service engineers who are properly equipped, as specified below, the following alignment procedure is included.

©John F. Rider

World Radio History

EQUIPMENT REQUIRED:

1. Sweep Generator - RCA-WR-59A or equivalent.
2. Marker Generator - RCA-WR-39A Television Calibrator or equivalent.
3. Cathode-Rav Oscilloscope - RCA-WO-60C or equivalent.
4. Electronic Voltmeter - RCA-195A Voltohmyst or equivalent.
5. Crvstal Diode Circuit as shown in Fig. 17.

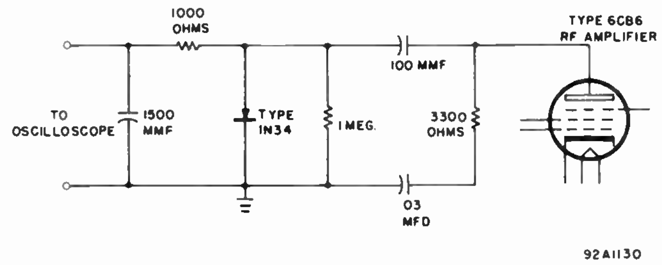

Fig. 17

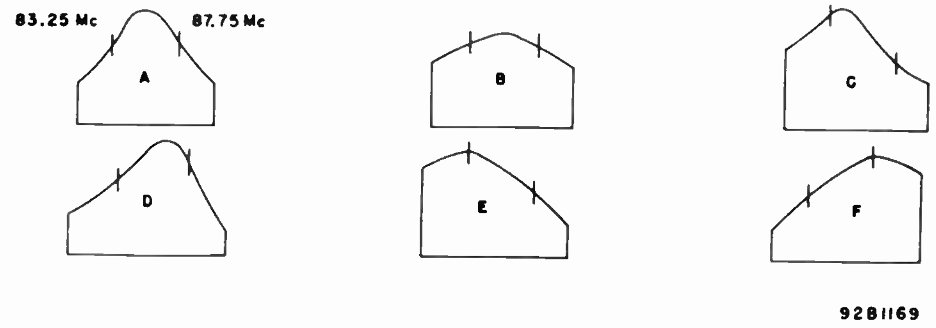

FIG. 19. ANTENNA CIRCUIT ALIGNMENT CURVES

SET-UP PROCEDURE:

1. Connect all test equipment and the television receiver to a common ground.
2. Connect the equipment as shown in Fig. 18.
3. Adjust the contrast control so that the tuner bias is 1.5 volts. This voltage is measured across terminal #1 and chassis ground.
4. Rotate C-10 and C-13 clockwise (fully in). See Fig. 15.

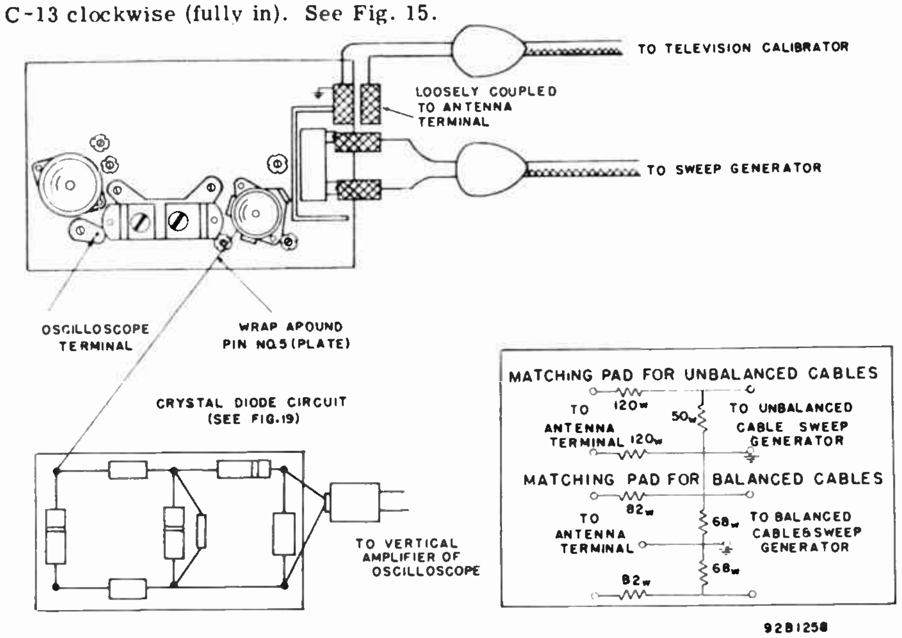

FIG. 18. TUNER ALIGNMENTS, TEST EQUIPMENT CONNECTIONS

ANTENNA CIRCUIT ALIGNMENT

See Figure 15 for location of all adjustment in this section.

5. Set test equipment and tuner to channel #6. (82-88 MC).
6. Adjust C-7 for required response curve on the cathode-ray oscilloscope (Fig. 19A). Peak in center with marker "pips" down equally on either side of curve.
7. Tune test equipment and tuner to channel #7.
8. Adjust L-18 for required response curve on the cathode-ray oscilloscope (Fig. 19B). Peak in center with marker "pips" down equally on either side of curve.
9. If L-18 requires a large adjustment, repeat steps 5 through 8 until the required response curves are obtained.
10. Check the response curves on channels #2, #3, #4, #5 and #6 and readjust C-7 for a compromise response curve for each channel. If the curves are more similar to 19C than they are to 19D, adjust C-7, counterclockwise. If the curves are more similar to 19D than they are to 19C, adjust C-7 clockwise. Curves for each of the channels #2 through #6 should be similar to Fig. 19A although alignment is complete if some curves are similar to Fig. 19C and some curves are similar to Fig. 19D. Adjustment is necessary only if all curves resemble Fig. 19C or Fig. 19D, rather than a compromise between Fig. 19C and Fig. 19D.
11. Check the response curves on channels #7, #8, #9, #10, #11, #12 and #13 and readjust L-18 for a compromise response curve for each channel. If the curves are more similar to Fig. 19E than they are to Fig. 19F, adjust L-18 clockwise. If the curves are more similar to Fig. 19F than they are to Fig. 19E, adjust L-18 counterclockwise. Curves for each of these channels should appear similar to that of Fig. 19B, although this portion of the alignment is complete if some curves are similar to Fig. 19E and some curves are similar to Fig. 19F. Adjustment is necessary only if all curves resemble Fig. 19E or Fig. 19F rather than a compromise between Fig. 19E and Fig. 19F.
12. Remove crystal diode circuit and connect oscilloscope directly to Oscilloscope Terminal.

RF ALIGNMENT

See Fig. 15 for location of all adjustments in this section.

13. Set tuner and test equipment to channel #6.
14. Adjust C-9, C-13 and C-22 to obtain a response curve on the oscilloscope similar to that shown on the normal curve in Fig. 20. This may be accomplished in the following manner:
    a. Rotate C-13 counterclockwise approximately one-half turn.
    b. Refer to Fig. 20 to determine the effects of tuning C-9, C-13 and C-22. C-9 primarily controls the center frequency of the response curve. C-22 primarily controls tilt of the curve and C-13 its bandwidth.
    c. It may be necessary to adjust C-22 after adjusting C-13.

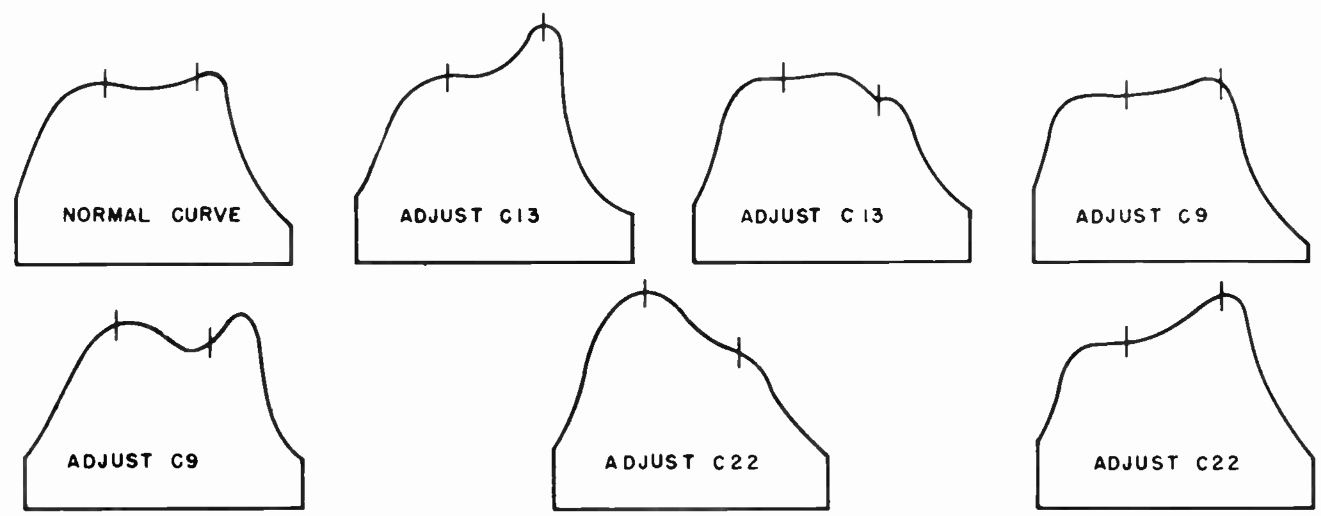

FIG. 20. RF ALIGNMENT CURVES

92B1167

C-9 and C-22 have an effect on the response of channel #7, #8, #9 and #10. It may be necessary to include adjustment of these capacitors in the adjustment of those channels. This should be done ONLY if two or more curves on the high channels slant in opposite directions. Care must be exercised so that curves of channels #2 through #6 will not be thrown far out of line. A recheck of channels #2 through #6 may be necessary.

15. Check the response curve for each of channels #2 through #6. Make compromise adjustments to C-9, C-13 and C-22 as is required so that i-f response curves for each channel will approximate those shown in Fig. 22.

World Radio History

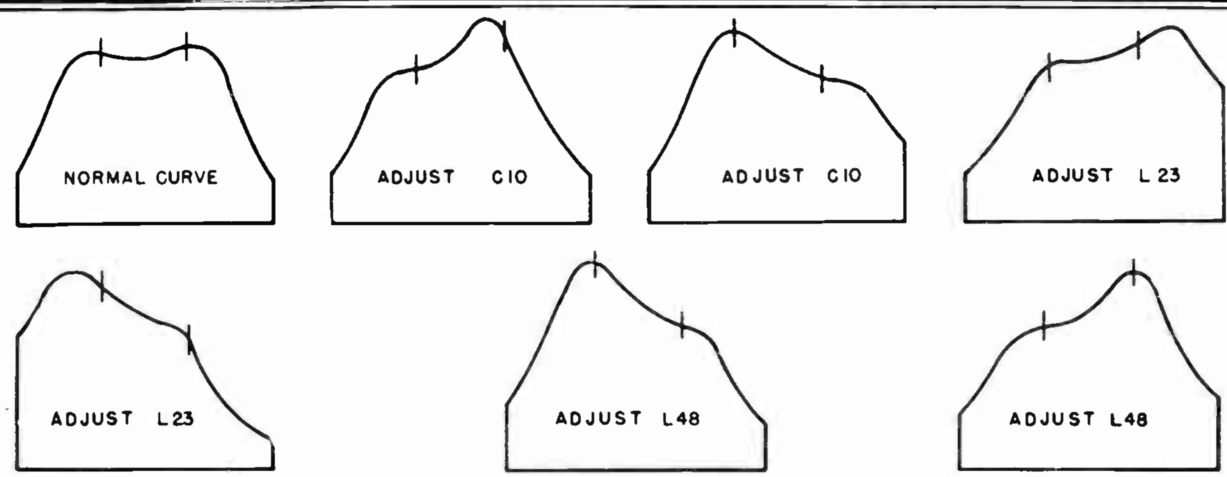

FIG. 21. RF RESPONSE CURVES

92B1168-A

16. Set tuner and test equipment to channel #12.

17. Adjust C-10, L-23 and L-48 to obtain a response curve on the oscilloscope similar to that shown as the normal curve in Fig. 21. This may be accomplished in the following manner:

   a. Rotate C-10 counterclockwise approximately one-half turn.

   b. Refer to Fig.21 to determine the effects of tuning C-10, L-23 and L-48. L-23 primarily controls the center frequency of the response curve. L-48 primarily controls tilt of the curve and C-10 its bandwidth.

   c. It may be necessary to adjust L-48 after adjusting C-10.

18. Check the response curve for each of channels #7 through #13. Make compromise adjustments to C-10, L-23 and L-48 as is required so that RF response curves for each channel will approximate those shown in Fig. 22.

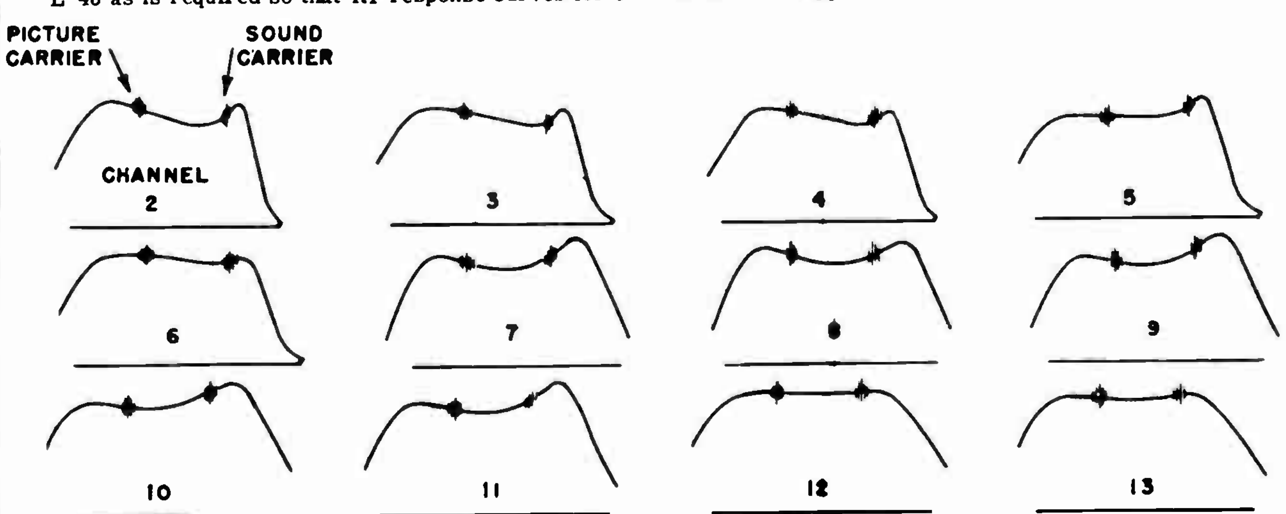

FIG. 22. CHANNEL RF RESPONSE CURVES

92B1166

OSCILLATOR ALIGNMENT

19. Connect the electronic voltmeter from pin #2 of the 6AL5 FM DET. TUBE to ground. Set the electronic voltmeter indicator at mid scale with no voltage.

20. Turn fine tuning control to mid-range.

21. Disconnect cathode-ray oscilloscope.

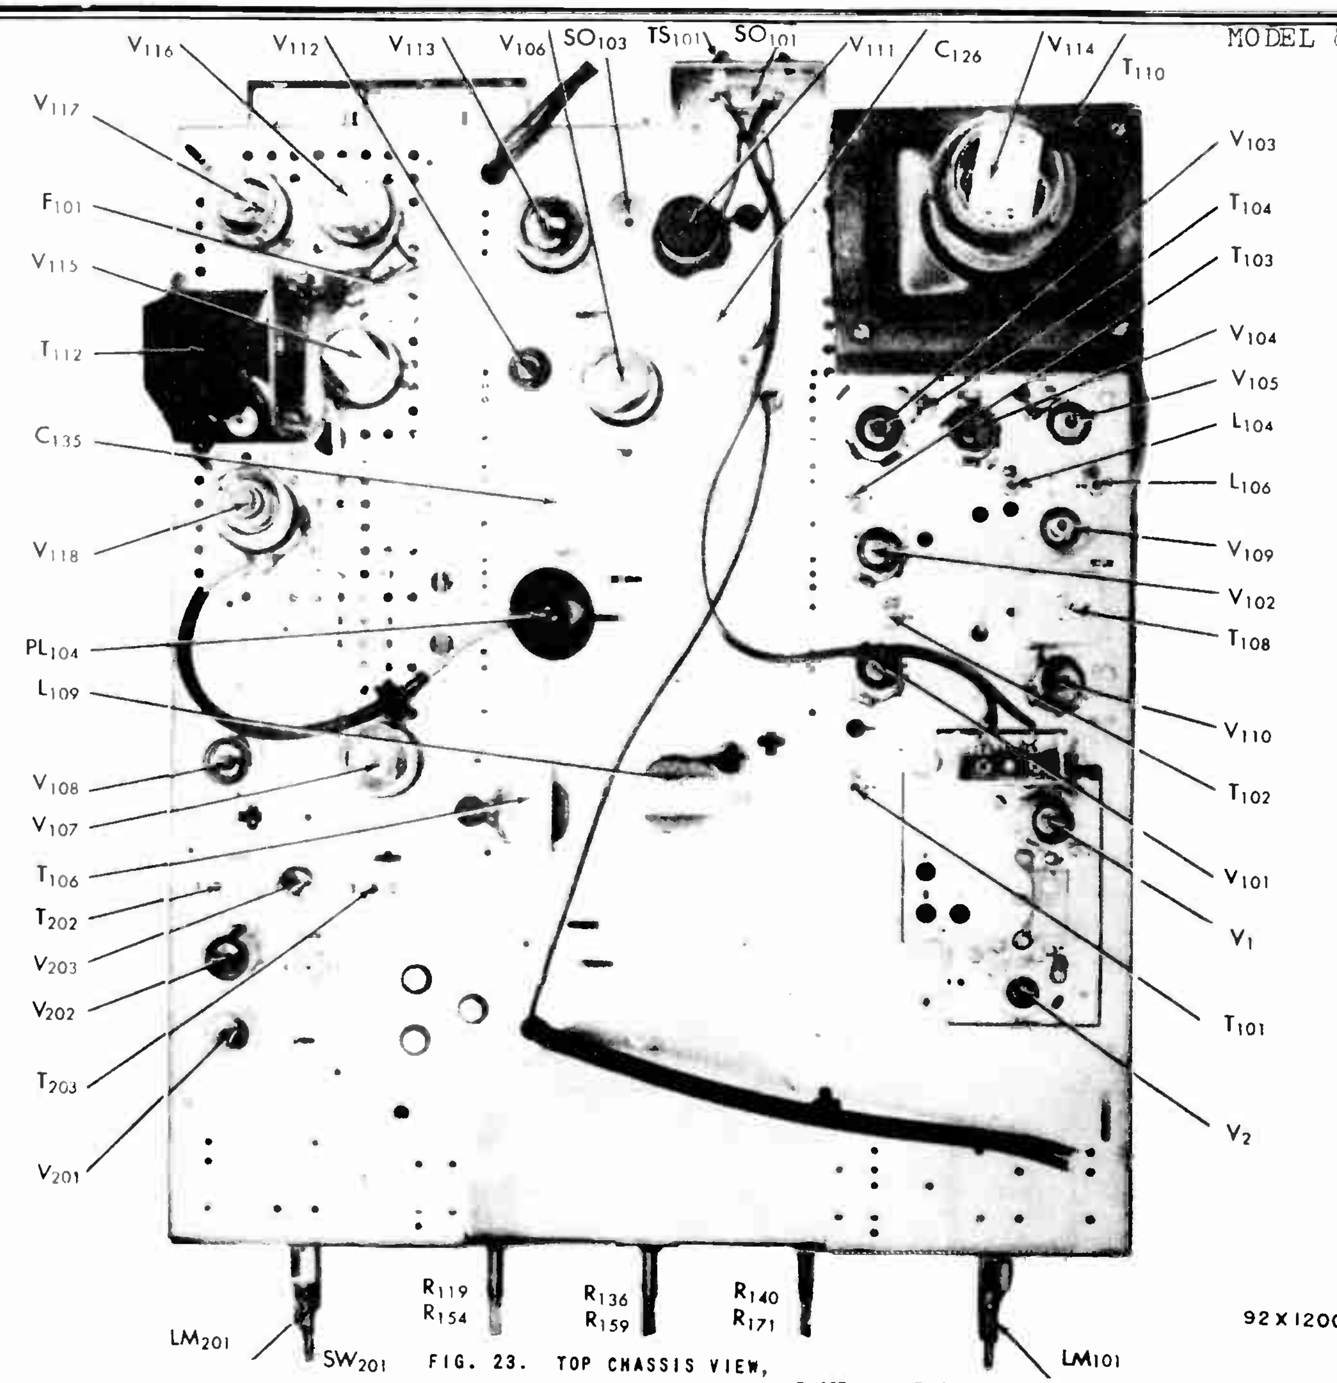
22. Connect television calibrator to antenna terminals.

23. Turn television calibrator to exactly 215.75 MC.

24. Adjust C-19 for zero-voltage. Rotating the tuner control should swing the needle either side of its center position.

25. Set television calibrator to exactly the sound carrier of each channel #12 to #2 in turn and adjust each individual oscillator coil for zero voltage as read on the electronic voltmeter. If one channel has insufficient range with individual oscillator adjustment, readjust C-19 to effect proper adjustment on this channel. Then readjust all other individual oscillator adjustments for zero voltage.

26. Recheck RF response curves as shown in Fig. 21.



92X1200

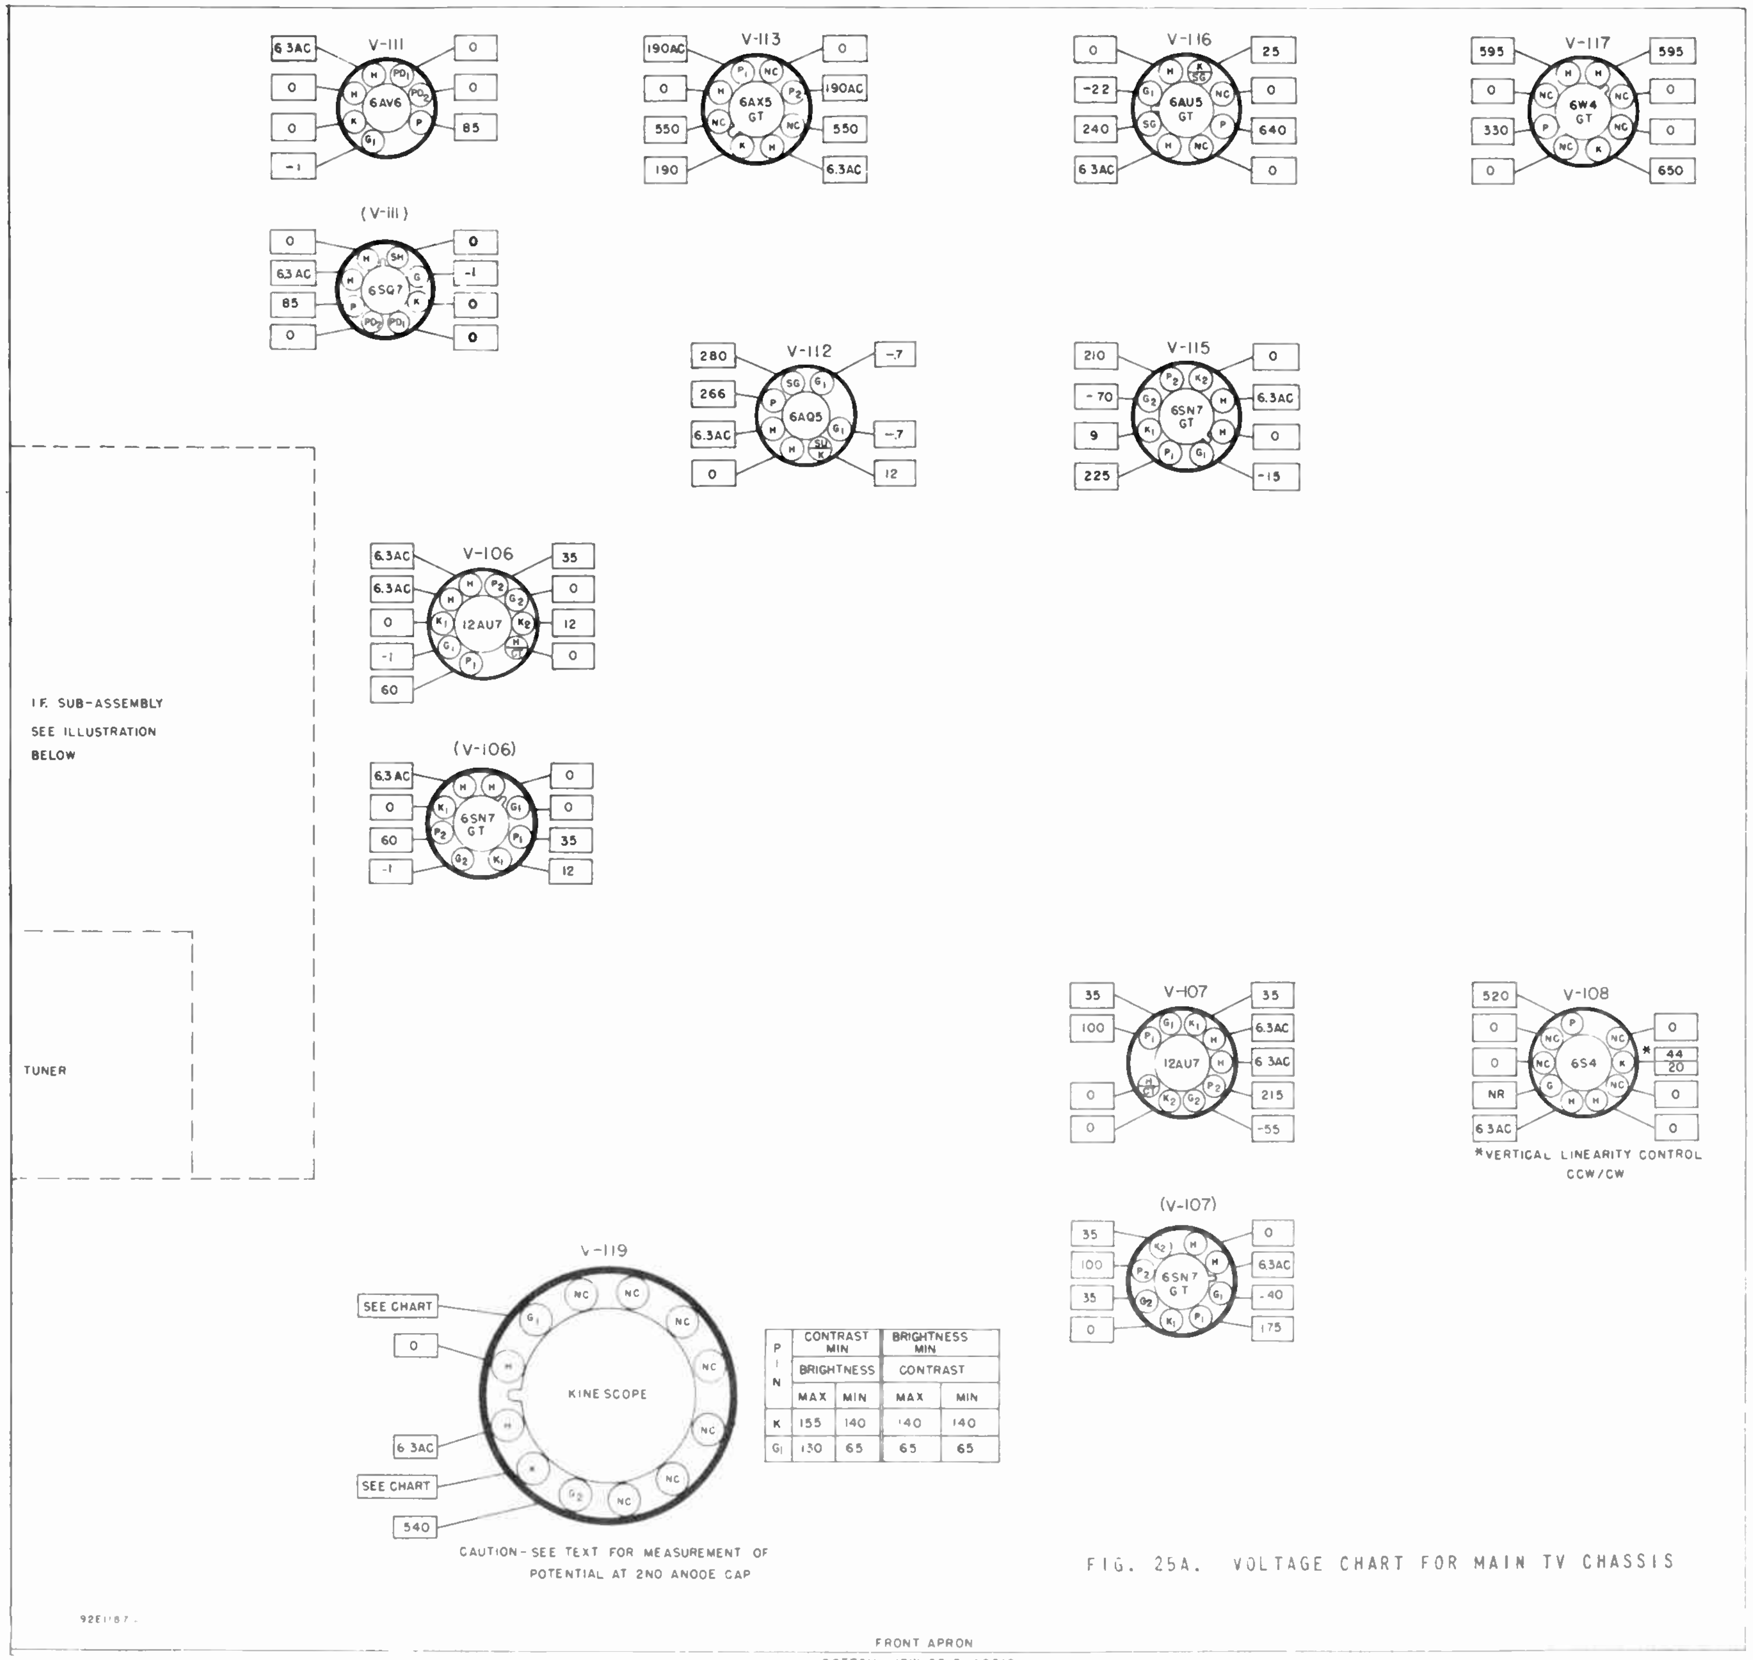

FIG. 25A. VOLTAGE CHART FOR MAIN TV CHASSIS

NOTES -

1 SOCKET VIEWS ARE BOTTOM VIEWS
2 ALL VOLTAGES ARE MEASURED BETWEEN TUBE SOCKET TERMINALS & CHASSIS WITH ZERO SIGNAL INPUT
3 LINE VOLTAGE — 117 V AC
4 ALL VOLTAGES SHOWN ARE DC UNLESS OTHERWISE SPECIFIED
5 DC VOLTAGES WERE MEASURED WITH AN ELECTRONIC VOLTMETER
6 "NC" - NO CONNECTION. VOLTAGE SHOWN FOR THIS TERMINAL ONLY WHEN TERMINAL IS USED AS A TIE LUG
7 "NR" - NOT READABLE. VOLTAGES MEASURED AT THESE TERMINALS GENERALLY MEANINGLESS
8 ALL VOLTAGES ON PICTURE TUBE WERE TAKEN AT TIE POINTS OF TUBE SOCKET LEADS
9 OPERATING CONTROLS SET FOR NORMAL PICTURE UNLESS OTHERWISE SPECIFIED.
10 NON-OPERATING CONTROLS SET FOR NORMAL OPERATION
11 MEASURMENT OF 2ND ANODE POTENTIAL AT PICTURE TUBE AS EXPLAINED IN TEXT IS RECOMMENDED FOR CHECK ON 1B3 RECTIFIER

World Radio History

INDEX

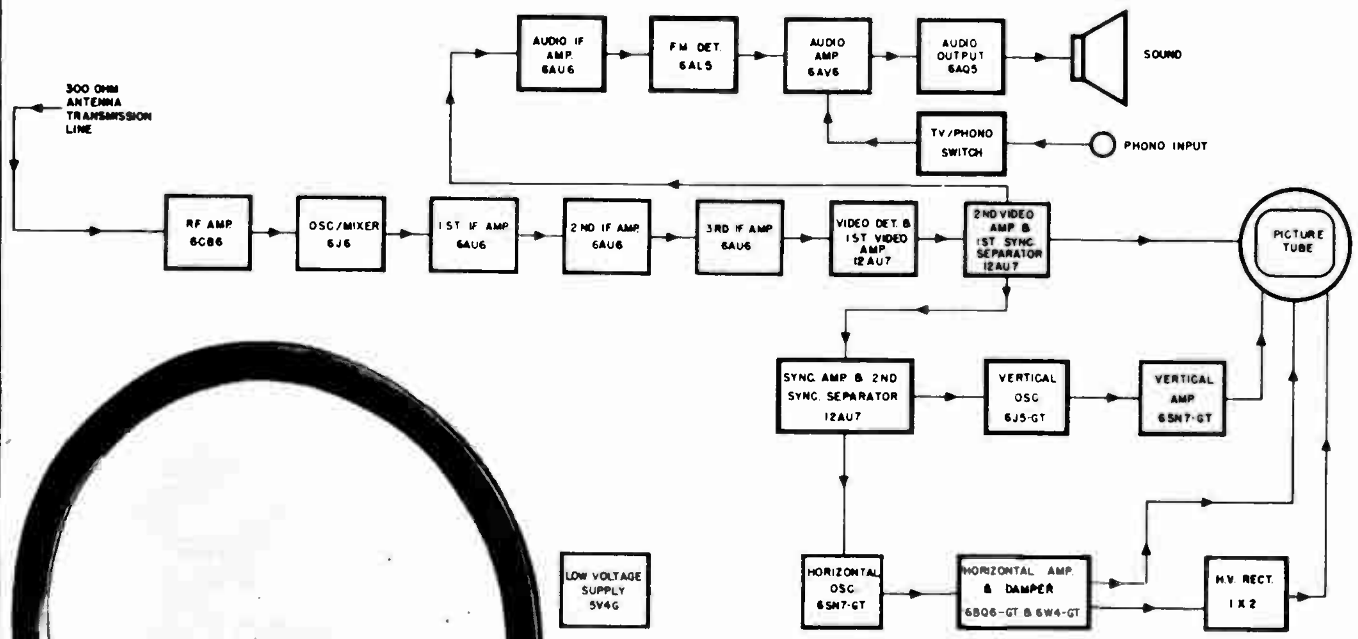

Fig. 1. Functional block diagram

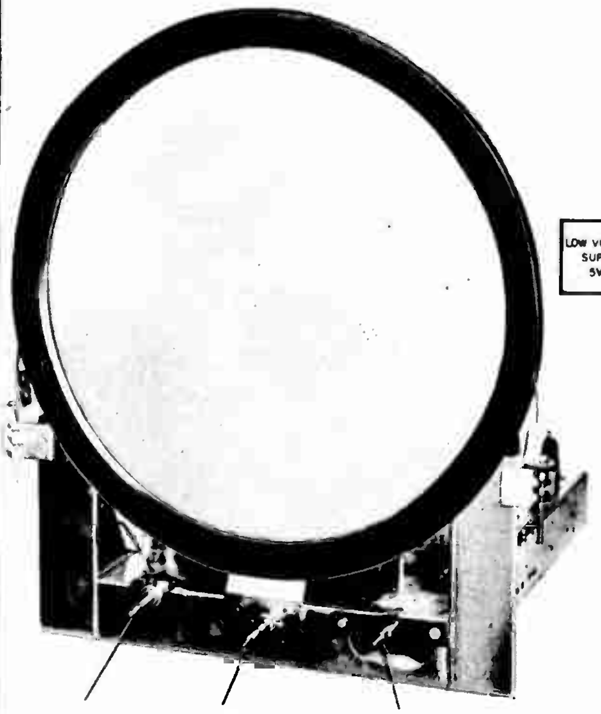

GENERAL

Picture Area . . . 135 square inches

Tubes . . . . Eighteen plus two rectifiers

Speaker . . . . 8-inch P.M. (3.2 ohm V.C.)

Antenna . . . . Built-in cabinet antenna with provision for external antenna using 300-ohm transmission line.

Tuning . . . . 12 position channel selector plus fine tuning adjustment.

Tuning Range. . . . Twelve channels 2-13.

Channel No.	Frequency (mc)	Channel No.	Frequency (mc)
2	54-60	7	174-180
3	60-66	8	180-186

Intermediate Frequency
- Picture carrier . . . . 26.25 mc
- Sound carrier . . . . 21.75 mc
- Intercarrier sound system. . 4.5 mc

Power Supply. . . . . 105-125 V. 60 cycles AC

Power Consumption . . . . 200 Watts

Model Differences . . . . Model 832 - Wood consolette finished in mahogany.
Model 833 - Wood consolette finished in blonde.

CARE OF THE KINESCOPE WINDOW

The window in front of the picture tube is made of safety glass, hence may be cleaned by any of the conventional window cleaning processes. Abrasive or strong solvent type cleaning solutions that may scratch the glass or damage the cabinet finish, however, should be avoided.

HIGH VOLTAGE WARNING

Operation of the receiver chassis outside of the cabinet involves a shock hazard. An interlock in the line cord disconnects the power when the back cover is removed. The HIGH VOLTAGE supply, while of low current capacity, operates at a 11,000 volt potential. Exercise all normal HIGH VOLTAGE precautions while working this equipment.

KINESCOPE HANDLING PRECAUTIONS

The kinescope housing provides adequate protection against possible tube implosure while in the cabinet. Do not expose the kinescope or handle it in any way without providing personal protection in the form of shatterproof goggles and heavy gloves. The kinescope should be handled by qualified personnel only.

The kinescope envelope encloses a high vacuum and with the large surface area of glass involved, the stresses set up, particularly at the front rim of the tube, are considerable. An abnormal handling stress, accidental blow at a highly stressed surface, or even a scratch on the surface of the tube could cause it to implode or collapse with destructive violence.

NON-OPERATING CONTROLS ADJUSTMENTS

The "non-operating" or screw-driver adjustments normally will require an occasional minor adjustment if any circuit work or tube changing is required. A test pattern, generated either locally in the shop or obtained from a television station is recommended for best results. Normal picture contrast and brightness should be maintained during the following adjustments for best results.

HORIZONTAL HOLD, VERTICAL HOLD, HORIZONTAL OSC., BRIGHTNESS AND FOCUS ADJUSTMENTS

1. Set the HORIZONTAL and VERTICAL HOLD controls for a steady test pattern. Should the HORIZONTAL HOLD control fail to hold the test pattern in the normal manner, set the HORIZONTAL HOLD control in the center of its range and adjust the HORIZONTAL OSC. ADJ. screw on the under side of the chassis for horizontal sync. (See Fig. 12 for location). If the adjustment of the top slug has been tampered with, turn the top screw to its top limit and adjust the bottom slug for sync.

2. The focus adjustment may be made with or without the aid of a TV station. If a test pattern is available, adjust the receiver for best picture and set the FOCUS control for best picture detail, watching the wedges of the test pattern. If no signal is available, turn the picture control counter-clockwise, advance the brightness control until the scanning lines just begin to show distinctly and adjust the FOCUS control for sharp clean lines. Note that a misadjustment of the ion trap or focus coil positions may prevent even focusing over the entire raster.

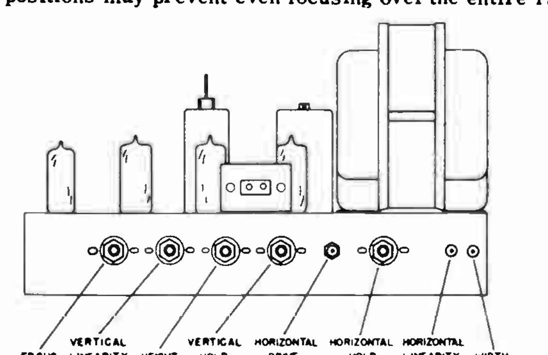

Fig. 2. Rear chassis view, location of "non-operating" controls.

HORIZONTAL — DRIVE, — LINEARITY, — CENTERING AND WIDTH ADJUSTMENTS

1. Advance the HORIZONTAL DRIVE control (clockwise) as far as possible without causing fold over of the test pattern. (Vertical white line.) Insufficient horizontal drive will cause low second anode voltage with consequent loss of picture brilliance.

HORIZONTAL DRIVE CONTROL MISADJUSTMENT

Figure 3.

2. Set the WIDTH control so that the test pattern fits the horizontal dimension of the kinescope escutcheon. A minor adjustment of the focus coil position may be required to recenter the pattern.

WIDTH CONTROL MISADJUSTMENT

Figure 4.

HORIZONTAL CENTERING MISADJUSTMENT

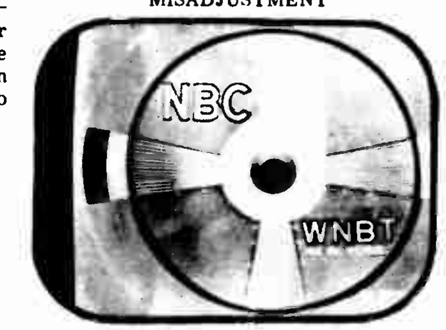

Figure 5.

3. Set the HORIZONTAL LINEARITY control so that the test pattern is symmetrical from left to right. A slight readjustment of the HORIZONTAL DRIVE control may be necessary when making this adjustment.

HORIZONTAL LINEARITY CONTROL MISADJUSTMENT

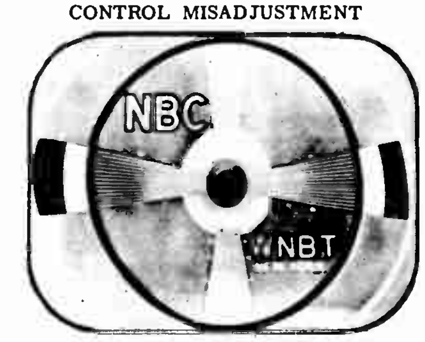

Figure 6.

©John F. Rider

World Radio History

VERTICAL – CENTERING, – LINEARITY, AND HEIGHT ADJUSTMENTS

HEIGHT CONTROL MISADJUSTMENT

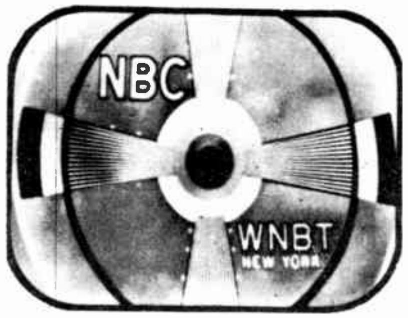

Figure 7.

1. Set the HEIGHT control so that the test pattern fits and centers in the vertical dimension of the kinescope escutcheon. A minor adjustment of the focus coil position may be required to recenter the pattern.

VERTICAL CENTERING MISADJUSTMENT

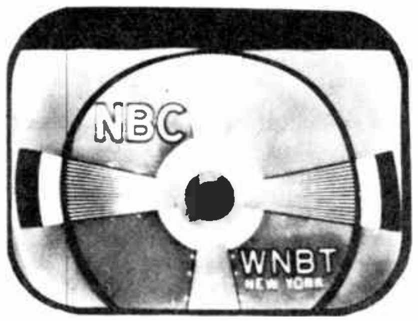

Figure 8.

VERTICAL LINEARITY CONTROL MISADJUSTMENT

Figure 9.

2. Set the VERTICAL LINEARITY control for a symmetrical test pattern in the vertical dimension. A slight readjustment of the HEIGHT control may be required when making this adjustment.

Note - The sequence of "non-operating" control adjustments outlined above is suggested as a convenient method of approach and not an arbitrary procedure. Variations of the procedure is permitted to obtain the final result.

DISMANTLING FOR KINESCOPE REPLACEMENT OR ALIGNMENT ADJUSTMENTS

1. Remove the three front panel control knobs by pulling them straight from their shafts. The dual control knob must be removed in two pieces, removing the center unit first.
2. Remove the back cover disconnecting the cable connector for the phono socket and switch mounted on the back cover. Note that the line cord and half of the interlock connector come along with the back cover.
3. Disconnect the speaker and remove the two wood screws holding the antenna terminal strip bracket to the cabinet. Note that for the table models the speaker will have to be removed to clear the picture tube.
4. Remove the five chassis bolts holding the receiver chassis in the cabinet and slide the entire assembly from the cabinet. The KINESCOPE is now accessible for replacement or adjustment.

REMOVING THE KINESCOPE

Refer to the warning KINESCOPE HANDLING PRECAUTIONS. Read all warning notices on both tube and carton. Follow the dismantling instructions above to expose the KINESCOPE and proceed as follows:

1. Disconnect the KINESCOPE SOCKET at the base of the kinescope.

2. Slip the ION TRAP from the neck of the tube past the kinescope base connector.

3. Measure the distance from the front edge of the steel band to the face of the tube. Keep this dimension handy for installation of a new tube.

4. Remove the steel band at the front rim of the kinescope and carefully slip the neck of the kinescope out of the FOCUS COIL and DEFLECTION YOKE. If the tube fails to slip out smoothly, investigate and remove the cause of the trouble. Do not use force.

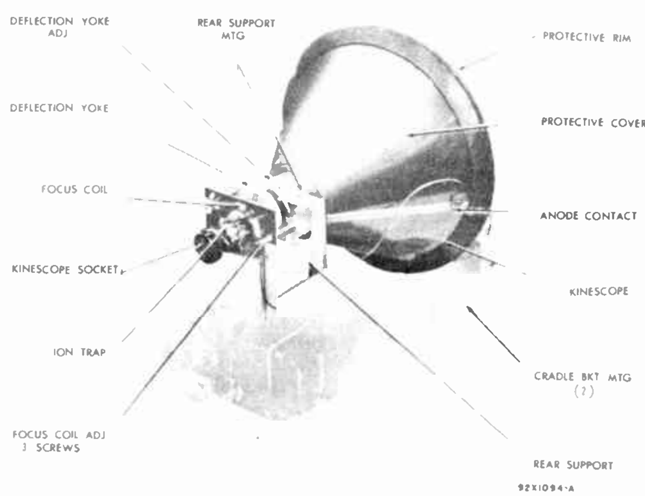

Fig. 10. Kinescope mounting detail.

INSTALLING AND ADJUSTING THE KINESCOPE

1. Wrap the RUBBER STRIP around the front rim of the kinescope and position the tube so that the anode contrast is located at the left side of the tube as viewed from the screen.

2. Slip the neck of the kinescope through the REAR SUPPORT, DEFLECTION YOKE and FOCUS COIL and seat the tube firmly against the REAR SUPPORT. If it fails to slip into place smoothly, investigate and remove the cause of the trouble. Do not force the tube. Check the distance from the face of the tube to the front edge of the steel band. Refer to the measurement made in step 3 above. If this dimension is off; loosen the two REAR SUPPORT MTG. screws, position the tube correctly and fasten the steel band firmly about the rim of the tube.

3. The REAR SUPPORT must seat firmly against the flare of the tube and be securely anchored in place by the two REAR SUPPORT MTG. screws. Check the SPRING CONTACT grounding the outer coating of the kinescope tube. A high potential is developed on the outer coating of the tube if this contact is faulty.

4. The DEFLECTION YOKE must seat firmly against the flare of the kinescope. Check by loosening the single DEFLECTION YOKE ADJ. screw and pushing the DEFLECTION YOKE forward as far as it will go. Take up the slack in the screw temporarily to hold the coil in place.

5. Slip the ION TRAP over the neck of the tube; the arrow points toward the face of the tube.

6. Reconnect the KINESCOPE SOCKET and anode connector and turn on the receiver.

7. After allowing a few minutes for warm up, turn up the BRIGHTNESS control and set the ION TRAP for maximum raster brilliance, backing off the brightness control adjustment as the maximum point is approached. The ION TRAP must be rotated about the axis of the tube as well as shifted along the neck of the tube to obtain the proper setting. The arrow on the ion trap will generally point at the HV anode connector when properly positioned as far as rotation is concerned, hence a rough setting may be obtained immediately with this type of trap.

With the BRIGHTNESS control set for slightly above average brilliance and the PICTURE control full counter-clockwise, adjust the FOCUS control until the line structure of the raster is clearly visible and readjust the ION TRAP for maximum raster brilliance. The final touches on this adjustment should be made with the BRIGHTNESS control at the maximum position with which good line focus can be maintained, then back off the setting of the BRIGHTNESS control until the retrace lines disappear.

8. Check the position and appearance of the test pattern. If the test pattern is off center or shadowed at the corners (Electron beam striking the neck of the tube), adjust the three FOCUS COIL ADJ. screws for a centered, evenly illuminated raster. Note that the three spring loaded adjustment screws tilt the focus coil to shift the position of the raster on the face of the kinescope. Do not turn all three screws up tight, use them to tilt the FOCUS COIL only.

CAUTION - It is not necessary to tilt the focus coil excessively. Excessive tilt may snap the neck of the kinescope if sufficient force is used.

The position of the test pattern may also be shifted by rotating the focus coil. To rotate the coil, loosen the two knurled nuts holding the coil to the mounting plate. Tighten the nuts after the adjustment has been made.

9. If the lines of the raster are not horizontal or square with the escutcheon, loosen the DEFLECTION YOKE ADJ. screw and rotate the DEFLECTION YOKE until this condition is obtained. Tighten the adjustment.

10. Follow the procedure under NON-OPERATING CONTROL ADJUSTMENTS and make any minor adjustments of the FOCUS COIL or DEFLECTION YOKE necessary to obtain the desired results. The final adjustment of the focus coil should leave the test pattern approximately centered.

MEASUREMENT OF H.V. POTENTIAL ON KINESCOPE ANODE

The second anode potential will be approx. 11,000 V. on a receiver that is functioning properly. Since the high potential for the kinescope anode is obtained from the horizontal output transformer, the "non-operating" control adjustments outlined above must be made or be known to be in proper adjustment before the H.V. measurement will have any meaning. Improper operation of the horizontal sweep circuit or circuit faults in the high voltage filter will generally account for an abnormal anode potential. If the anode potential is low, check the HORIZONTAL DRIVE adjustment outlined above.

CAUTION HIGH VOLTAGE

Do not use hand held flexible test leads when making the following measurement. Keep the hands clear of the circuit during measurement. A 11 KV. potential exists in this circuit. Exercise all normal high voltage precautions.

1. Connect a 50-megohm resistor string in series with a 300 microampere meter. Connect the free meter terminal to the chassis and the high side of the resistor string to the anode cap of the kinescope. The connection to the anode cap may be made with a fine wire slipped under the connector. Make up the resistor string with 5-megohm one or two watt resistors to provide a safety factor for voltage breakdown. If 5-megohm resistors are used, a total of ten will be required to obtain the 50 megohms. Make the setup self-supporting and allow adequate clearance between the resistor string and chassis parts to prevent high voltage breakdown.

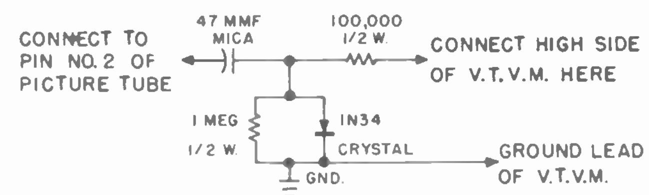
2. Turn on the receiver and set the BRIGHTNESS and PICTURE controls at minimum. The microammeter will read approx. 220 microamperes for 11,000 V. at the kinescope anode. The anode potential is measured in this manner (PICTURE and BRIGHTNESS control at minimum; meter current approx. 200 microamperes) to simulate the kinescope load on the high voltage power supply.

I-F AMP. ALIGNMENT PROCEDURE

Note - The following alignment adjustments do not require the use of the kinescope tube. It is recommended that the tube be removed if extensive alignment adjustments are to be made.

CAUTION - Removal of the kinescope tube exposes the HIGH VOLTAGE anode connector contact. Keep this lead and contact clear of personnel servicing equipment and grounded objects on the service bench. Exercise all normal high voltage precautions while working with the exposed units.

Fig. A.



EQUIPMENT REQUIRED

Signal generator covering 4 mc to 30 mc

Electronic voltmeter

IN-34 crystal detector circuit as shown in Fig. A.

F-M SOUND CHANNEL ALIGNMENT

1. Connect the low frequency signal generator output, through a .005 capacitor, across resistor (R-118) in the plate circuit of the 12AU7 VIDEO DETECTOR tube (V-104). This resistor is located at the terminal strip near the tube socket.

2. Connect the detector circuit and V.T.V.M. as shown in fig. A.

©John F. Rider

World Radio History

3. Set the signal generator to 4.5 mc. using just enough output to give approximately one volt reading at the electronic voltmeter.

4. The LIMITER GRID adjustment on the top side of the chassis see fig. 12 should be set to its top limit. Adjust the 4.5 MC TRAP ADJUSTMENT located on the under side of the chassis for minimum voltage as shown on the meter.

5. Disconnect the detector test circuit.

6. Connect the V.T.V.M. to pin #7 of the 6AL5 FM DETECTOR tube (V-109).

7. Adjust the LIMITER GRID adjustment and the primary of T-108 for maximum indication on the voltmeter.

8. Connect the electronic voltmeter across the 1000 mmf condenser (C-135) at the output of the f-m detector stage and adjust the FM DET. SEC. ADJ. of the f-m detector transformer (T-108) for the null.

9. Shift the frequency of the signal generator either side of 4.5 mc and touch up the FM DET. PRI. ADJ. for approximately equal peaks. Use just enough signal generator output to obtain one volt peaks for the best results.

10. After completing the alignment procedure and placing the receiver in operation again, carefully tune in a TV test pattern and adjust the 4.5 MC TRAP ADJ. for maximum vertical wedge definition. This adjustment is located on the under side of the chassis and on the same coil form as the 4.5 MC LIMITER GRID ADJ. shown in fig. 12.

NOTE - The primary adjustment of T-108, the coarse frequency adjustment of T-111 and the 4.5 mc trap adjustment may all be made through the holes in the cabinet bottom or chassis mtg. board.

I-F AMPLIFIER ALIGNMENT

1. Connect the electronic voltmeter across resistor R-118 in the plate circuit of the 12AU7 VIDEO DET. tube (V-104). This resistor is located on the terminal strip near the tube socket.

2. Couple the high side of the signal generator to the OSC./MIXER tube (V-3) by removing its shield and slipping a tight fitting tube shield or length of copper braid over the bulb of the tube and connecting the generator lead to it. Connect the ground side of the signal generator to the frame of the tuning unit.

3. Set the channel selector at channel 2.

4. Set the signal generator output (unmodulated) to develop one or two volts at the electronic voltmeter and adjust the four i-f amplifier coils, according to the following chart, for maximum d-c voltage as measured by the electronic voltmeter. Readjust the signal generator output as required to maintain the two-volt potential at the electronic voltmeter.

I-F AMPLIFIER ALIGNMENT CHART

Signal Generator Frequency (No Modulation)	Adjustment (Refer to Fig. 11)	Stage Adjusted
24.5 Mc	*24.5 Mc IF Adj.	1st IF amp.
23.4 Mc	23.4 Mc IF Adj.	2nd IF amp.
24.6 Mc	24.6 Mc IF Adj.	3rd IF amp.
25.6 Mc	25.6 Mc IF Adj.	Video Detector
21.75 Mc	21.75 Mc Sound Trap Adj.	*Sound Trap Adj. Adj. for Min. Voltage

*Note: After adjusting the 21.75 Mc Sound Trap recheck the setting of the 1st IF Transformer (T101).

5. Check the i-f amplifier frequency response by tuning the signal generator from 21 mc through 26.25 mc and observing the change in d-c voltage at the electronic voltmeter. If the signal generator output is set for an electronic voltmeter reading of 1.5 volts at the peak i-f amplifier response, the d-c voltage should not drop below one volt between the two peaks normally obtained with this i-f amplifier. If the response is unsatisfactory, repeat the procedure or try slight modifications of the recommended settings to obtain the desired response. Avoid resonating the coils with the iron core at the bottom end of the coil form. (Adjustment screw near limit of its travel). If a sweep type signal generator and oscilliscope is available the problem of making the final adjustments will be much easier. Check the two carrier i-f responses, 21.75 mc and 26.25 mc. The 21.75 mc response will be approximately 20 db below the peak response (Approx. 0.15 volt) and the 26.25 mc response will fall approximately 6 db below the peak (Approx. 0.4 volt). Refer to Fig. 11.

The average i-f amplifier sensitivity, when feeding the signal generator output through the receiver as described in step 2, will run approx. 2000 to 5000 microvolts for the one volt d-c peak measured at resistor R-118. (Receiver's oscillator operating on channel 2).

*NOTE - The 1st IF amp coil (T-101) has two iron cores and must be adjusted from both top and bottom for 24.5 mc. response. Since this is an overcoupled transformer with a broad response, it will be necessary with this method of alignment to connect a 1000 ohm resistor across the primary winding (at the tuner terminals), when tuning the secondary (bottom core) and then connect the same resistor across the secondary winding when adjusting the primary (top) core.

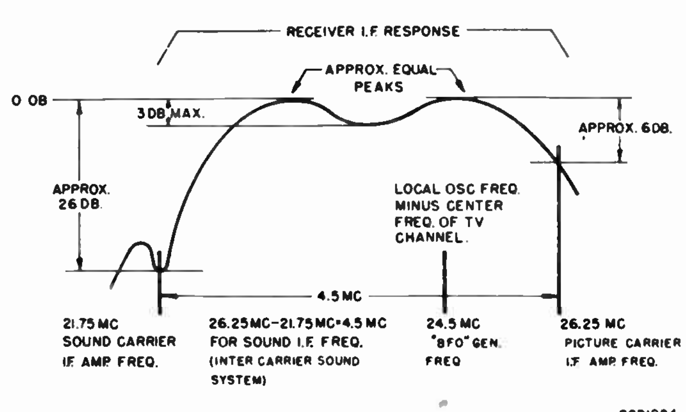


Fig. 11. I-F amplifier response.

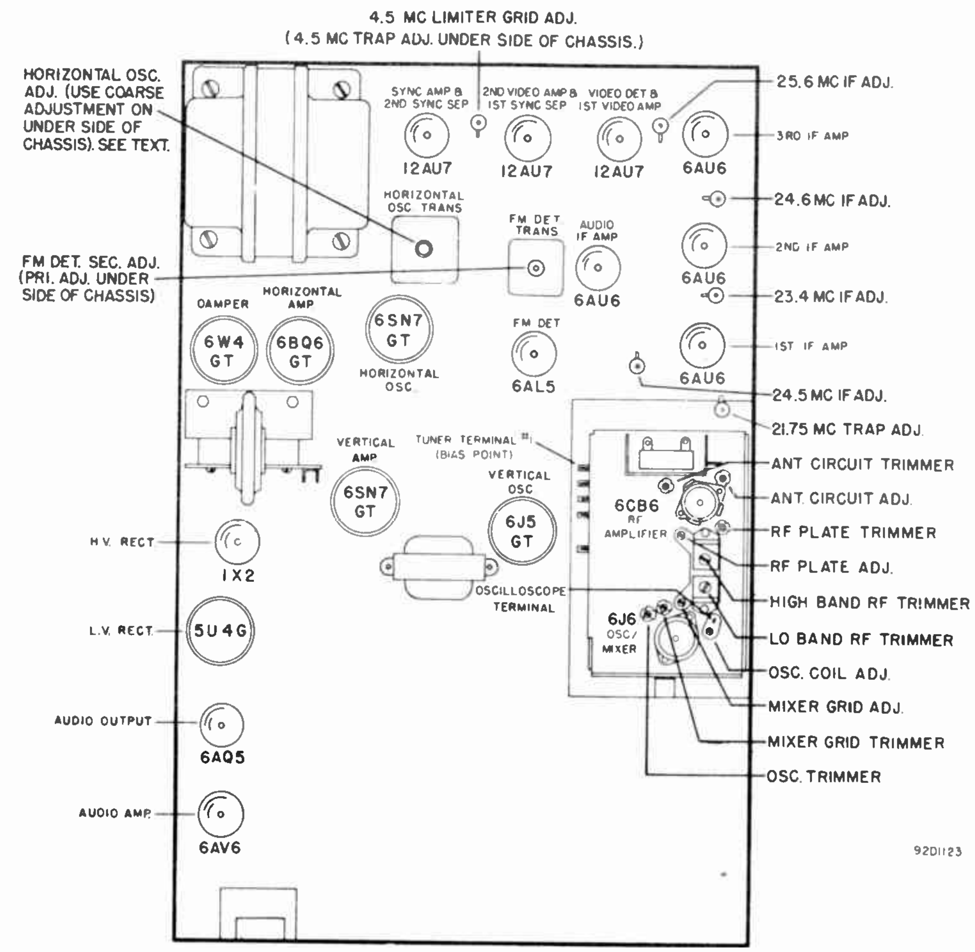

Fig. 12. Top view, i-f amplifier alignment points

CARRIER vs I-F FREQUENCY CHART

Channel No.	Channel Freq. (mc)	Picture Carrier Freq. (mc)	Sound Carrier Freq. (mc)	Receiver Osc. Freq. (mc)	Picture IF Freq. (mc)	Sound IF Freq. (mc)	Picture IF less Sound IF (mc)

TUNER ALIGNMENT

The tuner is of the turret type employing printed-circuit coils and covering television channels 2 through 13. It has been carefully aligned and adjusted at the factory using precision equipment. Alignment or replacement of individual tuner components in the field is not recommended. If the tuner fails to operate properly by reason of part failure within the unit or in the event it should become badly misaligned, the complete unit should be replaced. The tuner may be exchanged for a new one, through the factory service department, at very reasonable cost providing it has not been damaged or abused. In some cases the exchange can be effected without charge under the terms of the warranty.

Minor alignment adjustments may be desirable after tube replacement in the RF or oscillator-mixer stage. For those service engineers who are properly equipped, as specified below, the following alignment procedure is included.

Equipment Required:

Sweep Generator - Similar to RCA type WR59A, covering frequencies of 54 to 88 Mc and 174 to 216 MC with a minimum sweep of 10 Mc in each channel, and a 300 ohm balanced output at least 0.1 volt line to line.

Cathode Ray Oscilloscope - equivalent to the RCA W060C.

Television Calibrator - equivalent to the RCA WR39A.

Electronic Voltmeter - equivalent to the RCA Voltohmyst 195A.

Crystal Diode Circuit - for coupling the oscilloscope to the RF amplifier. (See Fig. 13.)

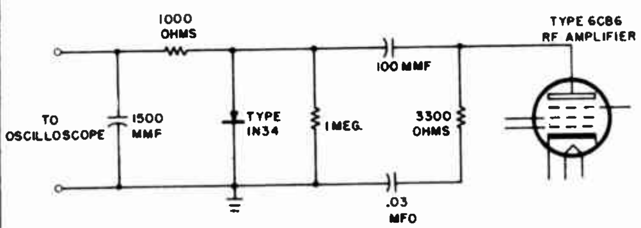

Fig. 13

NOTE: If equipment used is not calibrated by television channels, see CARRIER vs IF FREQUENCY CHART (column #1) for the correct frequencies to use for each channel.

For location of all adjustments see Fig. 12.

For response on each channel see Fig. 14.

ANTENNA CIRCUIT:

(1) Apply - 1.5 volts fixed bias to the tuner by connecting a 1.5 volt cell between tuner terminal number 1 (see Fig. 12.) and chassis ground.

(2) Connect the sweep generator to the antenna terminals, using a 300 ohm matching pad if necessary.

(3) Connect the oscilloscope to the plate of the 6CB6 RF amplifier tube (pin #5) through the crystal diode circuit (see Fig. 13.)

(4) Adjust the antenna circuit trimmer for maximum response on the oscilloscope between the picture and sound carriers of channel #6.

(5) Adjust the antenna circuit adjustment for maximum response on the oscilloscope between the picture and sound carriers of channel #7.

(6) Observe the response of all channels on the oscilloscope. Readjust the antenna circuit trimmer for channels #2 through #6, and the antenna circuit adjustment for channels #7 through #13 so that the best compromise is obtained in making the response of each channel look like that shown in Fig. 14.

(7) Remove the oscilloscope connection.

RF ALIGNMENT:

(8) Connect the oscilloscope to the oscilloscope terminal on top of the chassis (see Fig. 12.)

(9) Adjust the RF plate adjustment, the high band RF trimmer and the mixer grid adjustment for the proper curve shape of channel #13.

(10) Adjust the RF plate trimmer and mixer grid trimmer for the proper curve shape of channel #7.

(11) Adjust the Lo band RF trimmer for proper curve shape of channel #6.

(12) Observe the response of channels #2 through #6 on the oscilloscope. Readjust the RF plate trimmer, the Lo band RF trimmer and the mixer grid trimmer so that the best compromise is obtained in making the response of each channel look like that shown in Fig. 14.

(13) Observe the response of channels #7 through #13 on the oscilloscope. Readjust the high band RF trimmer, the RF plate adjustment and the mixer grid adjustment so that the best compromise is obtained in making the response of each channel look like that shown in Fig. 14.

(14) Remove oscilloscope and sweep generator.

OSCILLATOR ALIGNMENT:

(15) Connect the electronic voltmeter across C-135 at the output of the discriminator circuit. (see Fig. 16.)

(16) Connect the television calibrator to the antenna terminals.

(17) Tune the calibrator to 59.75 Mc and set the tuner to channel #2. Set the fine tuning control to mid range.

(18) Adjust the oscillator trimmer for zero voltage on the electronic voltmeter.

(19) Tune the television calibrator to 215.75 Mc and set the tuner to channel #13. Set the fine tuning adjustment to mid range.

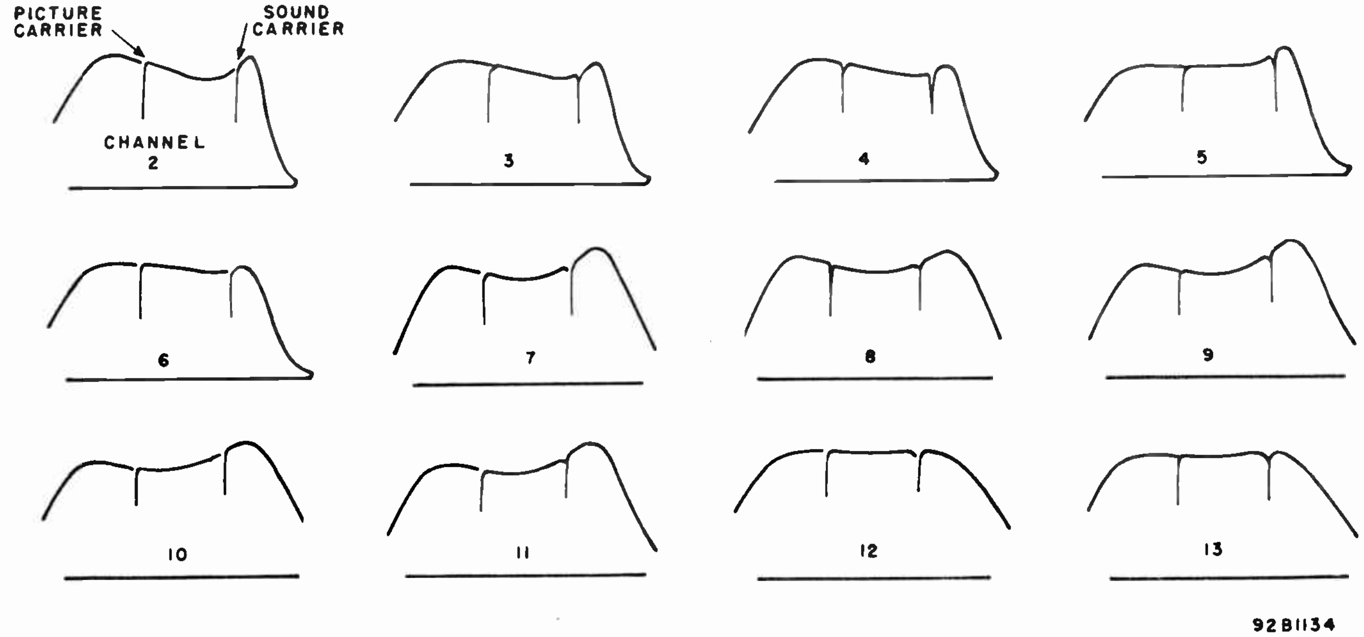
(20) Adjust the oscillator coil adjustment for zero voltage on the electronic voltmeter.

(21) Tune the television calibrator to the sound carrier of channels #3 through #12. (See CARRIER VS IF FREQUENCY CHART, column 3). With the fine tuning control set at mid range, adjust the oscillator adjustment of each band for zero voltage on the electronic voltmeter. These adjustments are accessible through the hole provided in the front of the tuner chassis.

Note: Oscillator adjustments for channels #2 and #13 have been set by the factory. Their positions have been chosen as reference points in the event that the tuner becomes completely misaligned.

(22) Recheck RF alignment and repeat procedure #9, #10, #11, #12 and #13 where necessary.

(23) Remove the electronic voltmeter, oscilloscope connections, and bias cell.



TYPICAL RF RESPONSE CURVES MEASURED AT THE OSCILLOSCOPE TERMINAL

IDENTIFICATION

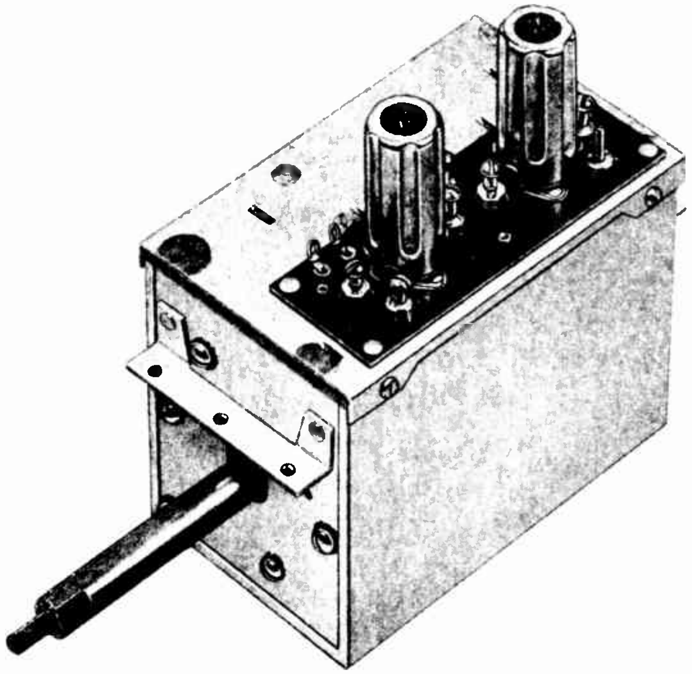

Figure 1. Hoffman Tuning Unit

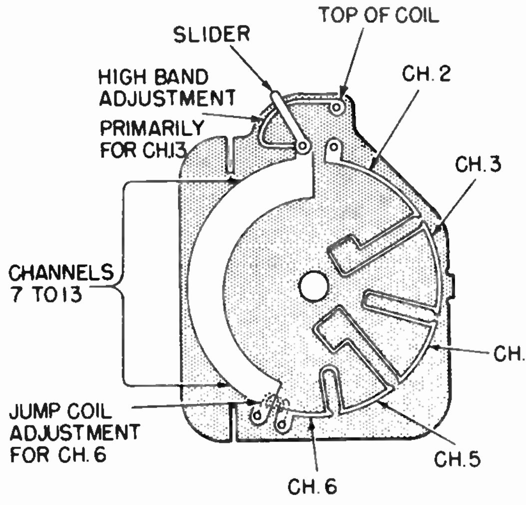
CIRCUIT OPERATION

The Hoffman Tuning Unit is a continuous type tuner which covers television channels 2 through 13. The circuit employs a 6J6 as a push-pull RF amplifier, and a 6J6 as an oscillator and converter.

The tuned circuits are pairs of plates of specially prepared bakelite on which silver has been printed to form a tuned line resonant circuit. Variation of the electrical length of line is accomplished by shorting across the line with a shorting contactor. This variation in electrical length resonates the line to the proper frequency for each channel. Lumped inductance in the form of jump coils are connected between the distributed high and low band lines so that the tuning skips the frequencies between 88 mc and 174 mc. This skip is designed to eliminate all outside frequencies between channels 6 and 7.

The antenna input circuit has an impedance of 300 ohms, balanced, with center ground. The antenna line is printed on the same plates as the tuned grid circuit for the RF amplifier, which gives inductive coupling between the two circuits. The configuration of the tuned lines are such that the center neutral portion of the antenna line is adjacent to the high band lines of the RF amplifier grid circuit. As the shorting bar contactor is moved up the tuned grid line from channel 2 position, a shorted loop is developed in the low band circuit of the grid lines between the neutral center and



Oscillator Plate Showing
Resonant Line Tuned Circuits

Figure 2. Left Hand Plate

the shorting bar. This shorted loop has the effect of canceling a portion of the antenna lines which in turn reduces the amount of coupling between the antenna and grid lines. This system of varying coupling with frequency maintains a constant bandpass characteristic and input impedance for the tuner.

The RF amplifier grid circuit (Z1 in figure 11-schematic) is tuned by distributed capacity plus the trimmer, C1. The amplifier is a push-pull connected 6J6. Cross neutralization is accomplished through C2 and C3, the latter being adjustable to allow for exact neutralization. AGC voltage is applied to the RF amplifier grids through R1, and is fed into the neutral center of the tuned lines. The RF amplifier plate circuit (shown as Z_2) is a tuned line similar in configuration to the grid circuit, and tuned to the same frequency as the grid circuit. A metal shield is physically placed between the two sets of plates to prevent any coupling or feedback which would cause oscillation. Plate voltage for the RF stage is applied through the dropping resistor, R2, and associated by-pass capacitors, C19 and C20.

The converter grid circuit tuned line (shown as Z_3) is identical to the RF amplifier plate circuit. The circuits are coupled by a combination inductive, capacitive arrangement which provides slight over coupling at all frequencies. High band coupling is achieved through condensers C6 and C7, C7 being adjustable. Low band coupling is carried out through the coupling loop printed on the plates adjacent to the low band sections, plus mutual coupling between jump coils L8 and L9. It can be observed, as the shorting contactors are moved from the high band toward the low bands and down to the channel 2 position, increased inductive coupling circuits come into effect. The increased coupling is required to maintain constant bandwidth as the base frequency is decreased, and the pass band becomes a larger percentage of the base frequency.

The converter grid circuit (shown as Z3) is resonated by distributed capacity plus C9 and the variable trimmer, C10. Tuning for different channels is accomplished by changing the electrical length of the tuned lines with a shorting bar as in all other sections.

The resistor, R4, serves as a grid leak return for the converter. Condenser C8, 5 mmf, is used to balance the grid-cathode and grid-plate capacity of the 6J6 converter section. Balancing is necessary when going from the push-pull RF amplifier to the single ended converter stage. The resistor, R3, is inserted between the ends of the lines to prevent forming a completely shorted loop (as in the antenna-RF section) which would reduce the effectiveness of the coupling loop on the low bands. RF grounding of the neutral center of Z_3 is provided through C21.

The oscillator circuit is a modified form of the Pierce oscillator, with the tuned circuit forming the feedback path between plate and grid circuits. The tuned lines are resonated by C12 and the variable trimmer, C15. C12 is shown connected directly between grid and plate, and is located physically near the 6J6 tube base to reflect heating changes. This capacitor has a negative 750 parts/million temperature coefficient and compensates for variations of inductance in the oscillator line which result from temperature changes. The neutral ends of the oscillator line are not connected together. This is done to avoid leaving a complete loop which would be tuned to channel 2 at any time when the shorting bar is not making contact such as when crossing over jumps between channels. Plate voltage is supplied through R6, the plate dropping resistor.

C14 is used for blocking DC from the oscillator grid and R5 is the grid leak return for the oscillator section of the 6J6. The oscillator signal is coupled back to the converter through C11.

The converter output circuit forms a mutual inductance coupled circuit with the grid circuit of the 1st IF amplifier tube. The capacitor, C13, and coil, L17, are resonated at 23 mc. Adjustment of L17 is part of the alignment procedure. The coil, L18, and condenser, C16, and associated distributed capacities are resonant at about 16 mc, and present an inductive reactance of about 100 ohms to the intermediate frequencies. This inductive reactance forms the mutual circuit between C13-L17 and the input coil and tube capacities of the 1st IF amplifier. In addition, L18-C16 form a trap circuit which removes part of the adjacent channel signals. However, L18 cannot be adjusted for complete adjacent channel trapping because the mutual inductance would not be correct to provide mutual coupling in the IF pass band.

Converter plate voltage is supplied through R7. The converter output provides a composite video-sound IF signal of 26.1 mc video and 21.6 mc sound. This output is suitable for use directly in the intercarrier IF system of the Hoffman 21 tube TV receiver chassis.

FIELD SERVICE

Field service of the Hoffman Tuner is limited primarily to maintenance and sub-assembly replacement. If a tuner requires major servicing, it should be removed from the TV receiver and returned to the Hoffman distributor for replacement. The exploded view diagram is for the purpose of location of parts and explanation.

TUBE REPLACEMENT.

Replacement of tubes in the Hoffman Tuner will have an effect on the alignment or tracking characteristics. However, this effect can be minimized until the changes are negligible if replacement is made with a tube by the same manufacturer as the original tube, and with a tube designed for TV use. The RF amplifier, being cross neutralized, may oscillate if a tube with different interelectrode capacities is used.

Replacement of the oscillator tube may require retrimming of C15 to bring the tuning into the middle of the channel.

Selection of tubes may be made by trying several tubes until one is obtained which has approximately the same interelectrode capacity as the original tube.

SHORTING BAR CONTACT MAINTENANCE

The shorting bars for the tuned lines are in the form of solid silver leaf springs with a small detent on each tip which rides on the silver surface of the printed distributed line.

Smooth and silent operation of the tuner requires proper oiling of the contact surfaces. Contact noise usually shows up as black streaks across the raster during tuning.

©John F. Rider
World Radio History

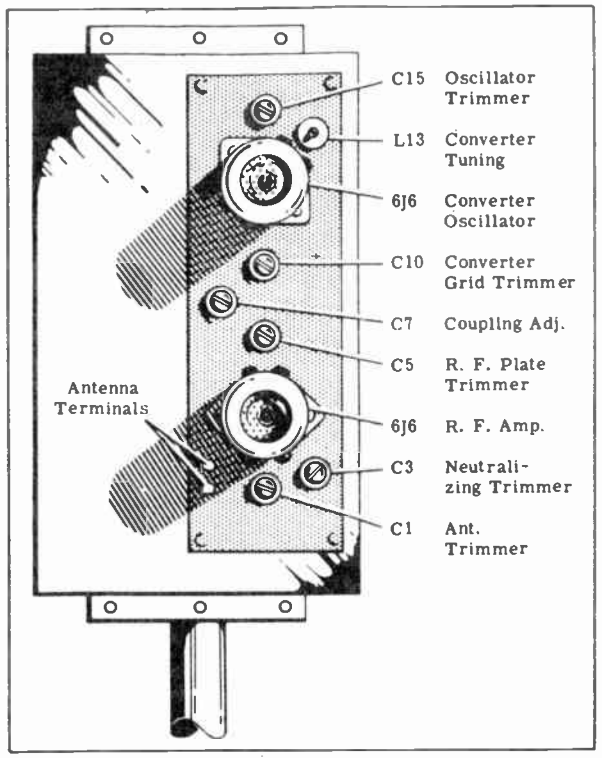


Figure 3. Top View

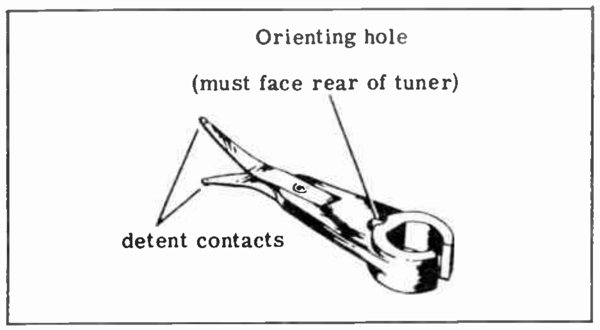

Figure 4. Shorting bar

A special oil for use in high frequency circuits which has no effect on the Q of the circuit or will not disturb the electrical properties of the tuned lines must be used. Factory production uses #7059 Solidified Switch Oil manufactured by the Viscosity Oil Co. of Chicago, Ill.

A soft, non-shedding brush, such as camel's hair, should be used to apply the oil to the outer surface of each tuned line around the entire circumference where the contactor shorting bar rides on the silver surface. Turn the contactor shorting bar to the opposite side of the plates being oiled to avoid bending or springing the contactor with the oil brush. Make sure that brush hairs or other particles are completely removed from the plates after oiling.

The small loop and slide bar used for high band inductance adjustment do not require oiling.

SHORTING BAR CONTACTOR REPLACEMENT

The detent contact of the shorting bar is subject to the greatest amount of wear of any portion of the tuner. If the contactor becomes noisy and cannot be corrected by oiling, the entire shorting bar should be replaced. Refer to the exploded view diagram, and follow these steps for replacement:

1. Loosen the shaft-holding setscrew. This is a 6-32 Allen head screw and uses a No. 6 Allen wrench.

2. Grasp the metal tuner shaft through the access hole in the back plate of the tuner and pull it straight out, or part way out until the desired shorting bar drops loose.

3. Replace the noisy contactors with new parts. The hole through which the shaft passes is flat on one side so that misalignment of the contactor is impossible. The hole size tolerance is +.00 - .001 so that the hole must be lined up squarely with the shaft before the shaft will pass through. The bakelite material forming the hole is split so that a snug fit will result when the shaft is pushed through.

A small hole is molded in the bakelite material just above the flat portion of the shaft assembly hole. (See drawing of shorting bar contactor.) Insert the contactor between the plates with the small hole facing toward the back of the tuner.

4. Slide the shaft into the oscillator section (rear plates), line up the contactor hole, and lightly force the shaft through the contactor. Proceed to each successive pair of plates, lining up the contactor and forcing the shaft through one at a time.

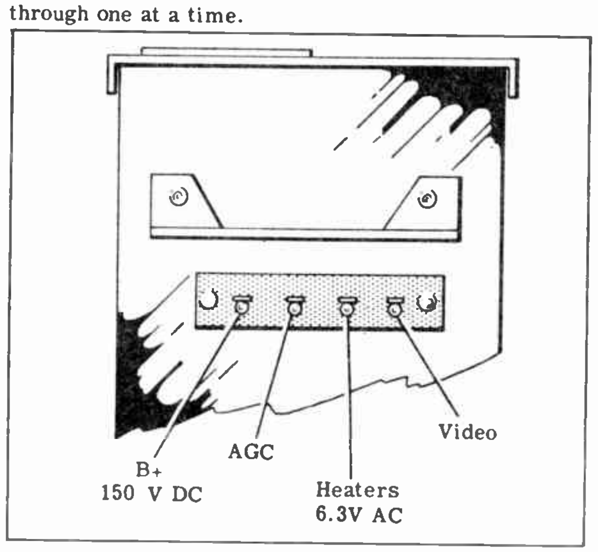

Figure 5. Rear View

5. Press the shaft into the brass drive collar. The setscrew must set against the flatted side of the shaft. The shaft will slide forward until the rear end of the shaft is approximately flush with the metal back plate of the tuner. Tighten the setscrew.

ALIGNMENT PROCEDURE

RF AMPLIFIER - CONVERTER INPUT ALIGNMENT.

SETUP.

Using a 300 ohm source, insert signal into the antenna terminals. Loop one wire lead of a 100 K isolating resistor around the screw adjustment of C10, converter tuning. Connect the other end of the resistor through a shielded lead to the vertical input terminals of a scope. Ground the shielded lead to the tuner chassis and scope ground.

Load L17 by soldering an 1800 ohm, 1/2 watt, composition resistor across the coil terminals.

Since the chassis has been removed from the cabinet, there is no index mark for the channel dial. A suitable index can be fashioned from a piece of stiff wire soldered to the main TV chassis, and set to a point directly above the tuning shaft center.

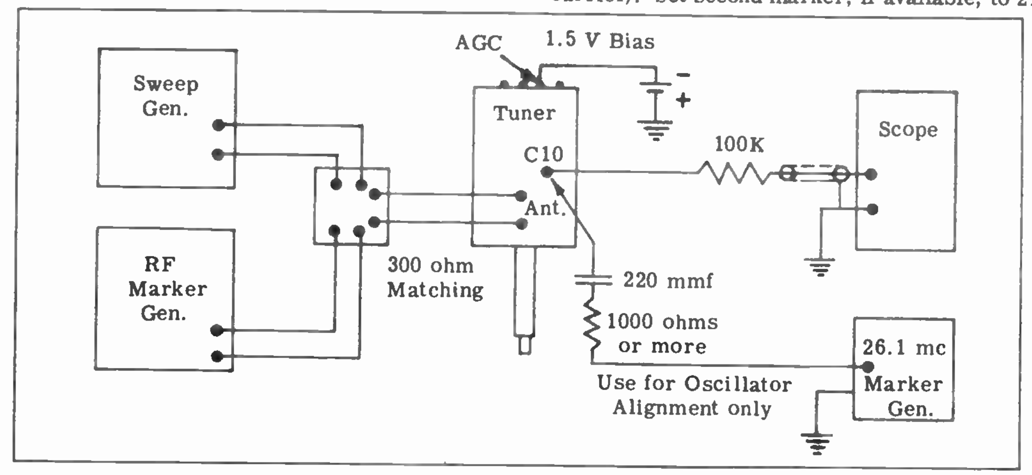

Figure 6. Connection Diagram

Solder a 1-1/2 volt battery in the main TV chassis between ground and the tie point near L101 which will provide bias for the tuning unit during alignment.

DETAILED PROCEDURE.

The alignment of the Hoffman continuous tuner is a process of compatibly adjusting the three variables of each section of tuned plates; i. e., trimmer capacitor, high-band loop sliders and low-band jump coils. Adjustment of coupling and neutralization are another important part of alignment. The general procedure to be followed is:

a. Preliminary adjustment of trimmers.
b. Adjustment of slide bars.
c. Final adjustment of trimmers.
d. Adjustment of jump coils.
e. Recheck of all channels and compromise retrimming of all adjustments.

Exact details of the alignment procedure are given below, and are outlined in a step by step process in the alignment chart. Alignment of the RF and converter input section is completed first; then alignment and tracking of the oscillator section is accomplished.

Set the sweep generator to Channel 6, 85.5 mc center, with 10 mc sweep width. The input signal level should be .02 to .05 volt. Insert a marker signal at 83.25 mc (picture carrier frequency). If a second marker signal is available, it should be set to 87.75 mc, sound carrier frequency. If only one marker is available, it can be swung back and forth to the two frequencies during alignment. Using the dial knob, set Channel 6 opposite the index. This should place the shorting bar contactor approximately in the center of the Channel 6 segment. Adjust C1 (antenna trimmer), C5 (RF amplifier plate), and C10 (converter grid circuit) to give maximum overall response with a symmetrical waveform. Do not tune for a maximum peaked response, but develop a symmetrical waveform. This is a preliminary adjustment of the trimmers; so, exact shaping of Channel 6 is not required at this point. Adjust C3 for proper neutralization. Extreme cases of improper neutralization will cause oscillation in the RF amplifier which shows as "grass" on the scope waveform. Lesser degrees of improper neutralization will produce a peak on one side or the other of the waveform. See figure 7 for example of improper neutralization.

Set the tuner to Channel 13. Set sweep generator at 213 mc., and marker generator at 211.25 mc (picture carrier). Set second marker, if available, to 215.75 mc. Adjust the high band loop slide bars to obtain a maximum symmetrical waveform. Adjustment order, although not critical, should be antenna section, RF plate section, and converter grid section, in that order. At final adjustment, both sliders of any one section should be in approximately the same position. Usually, the antenna section will be set for nearly maximum inductance, and the RF and converter sections will be at about 3/4 of maximum inductance. A band pass of 6 to 7 mc can be obtained. C7 (coupling) may be adjusted to obtain coupling to produce greater than the minimum of 6 mc. The picture carrier marker should appear on or just outside the maximum amplitude point of the high frequency side of the waveform. The band pass decreases as the frequency is reduced to Channel 7, so widest bandpass is required on Channel 13.

Set tuner to Channel 7. Set the sweep generator to 177.5 mc with 10 mc sweep. Set marker generators to 175.25 and 179.75 mc. It may occur that the markers do not lie on the most desirable portions of the pass band (on each side of the peak), when the knob is set with 7 exactly at the index. Reset the knob slightly to move the pass band to the proper position relative to the markers. The new knob position should be within 3 or 4 tenths of the exact position. The condition where this rotation is excessive will be taken up later.

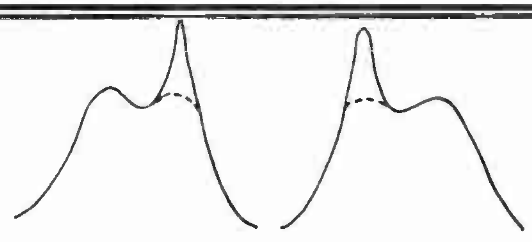
World Radio History



Adjust C3 To Bring Peak
Down To Dotted Line

Figure 7. Improper Neutralization

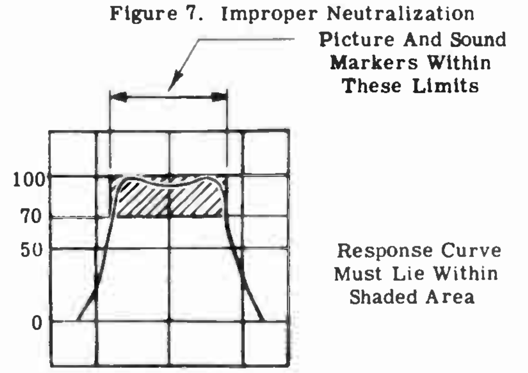


Figure 8. Ideal Band Pass Characteristic

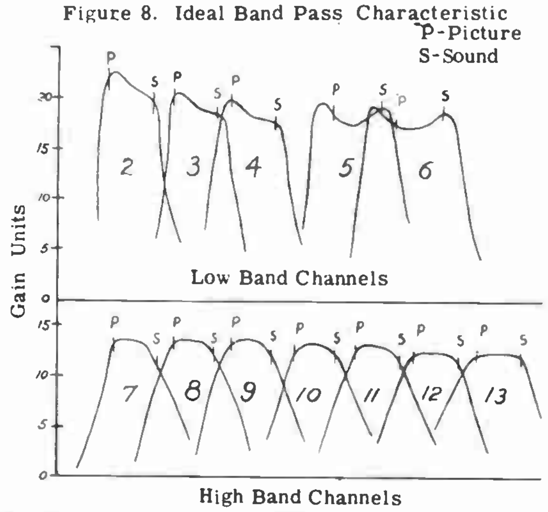

Figure 9. Typical Band Pass Characteristic

> The waveform and bandpass response curves shown in this manual are illustrated in the conventional manner, with amplitude upward and frequency from left to right, low frequency being on the left. In actual practice, depending on polarity of scope and signal generators, the waveforms may be inverted or reversed from right to left. Accurate location of marker indicators will quickly orient the waveforms for practical use.

With the markers in best position, adjust C1, C5 and C10 to produce a symmetrical waveform with greatest amplitude. It may be necessary to slightly retrim C7 to provide proper coupling. Adjustment of C7 influences the setting of C5 and C10, so that the three trimmers should be adjusted alternately. If considerable readjustment of the trimmers was required on Channel 7, then Channel 13 should be rechecked as described above. The adjustment of loop sliders and trimmers should be "rocked in" to obtain the best possible conditions for all the high band channels. If rotation of the channel knob for proper placement of the markers on Channel 7 as described above, was excessive, the knob should be set exactly at the index on Channel 7, and the trimmers C1, C5 and C10 adjusted to bring the waveform as close as possible to the best positioned symmetrical shape. It is then imperative to repeat slide bar adjustments on Channel 13, plus again returning to Channel 7 for final retrimming.

Set tuner to Channel 6. Set sweep generator to 85 mc, 10 mc sweep. Set markers to 83.25 mc (picture) and 87.75 mc (sound). Reset tuner knob until markers lie within the peaks of the curve. Again, it is not necessary that 6 be set exactly at the index, but should be within 3 or 4 tenths of the exact position. Inspection of the position of the shorting contactor will indicate its position which should be within approximately the center third of the Channel 6 segment. If the knob calibration is excessively in error, or the shorting contactor is near the edge of the segment, adjustment of the jump coils is required. The inductance of the coils can be decreased or increased by spreading or squeezing the coil. Use a nonmetalic alignment tool for spreading the turns, or a long nose pliers insulated with tape for squeezing the coils. Set the tuning knob to place Channel 6 opposite the index. Start with the antenna section coils L1 and L4. Next adjust the outside coils (L5 and L12) of the RF and converter sections. Adjust the coupling coils L8 and L9 for best band-width. Observing the curves of Figure 9, the coupling on Channel 6 provides a band-width of 7 to 8 mc. This wide pass band is necessary to give sufficient coupling on the lower channels. Overall adjustment of the jump coils should result in a smooth symmetrical double peaked curve.

Set tuner to Channel 2 (approximately). Set the sweep generator to 57.5 mc, 10 mc sweep. Set markers to 55.25 mc (picture) and 59.75 mc (sound). Check the waveform on Channel 2. The picture marker should be located just outside the maximum peak. The waveform will not be completely symmetrical, and the sound marker will fall at a lower point on the opposite side of the curve. The difference between amplitudes at marker points should not exceed 3 db. If the waveform is not acceptable, retrim C3 and C1 slightly. This is a compromise adjustment and it will be necessary to recheck Channels 13 and 6. Some deterioration of waveforms on the other channels may be tolerated to allow better performance on 2. The average overall performance should be considered in these cases.

OSCILLATOR SECTION ADJUSTMENT

SETUP

The oscillator adjustment should be made after the RF section is aligned. Tracking of the oscillator is accomplished by accurately marking the 26.1 mc picture IF output point, and then adjusting the oscillator to make a converted RF picture marker coincide with the reference 26.1 mc marker.

Input isolation must be used to avoid loading the converter grid circuit too heavily. A network consisting of a 1000 ohm composition resistor and a 220 mmf condenser in series with the signal lead will give sufficient isolation and transmit enough signal to produce a readily apparent marker. However, this loading of the converter grid circuit will distort the RF waveform, so it is desirable to use a larger resistor if sufficient signal amplitude is available from the 26.1 mc source. Distortion of the RF waveform is not serious, because the oscillator adjustment is for frequency only, and does not affect the waveform.

The 26.1 mc reference marker should be derived from a source which will allow the signal to be injected into the circuit separately from the sweep signal. Any unmodulated C.W. signal which can be accurately calibrated to 26.1 mc will be satisfactory. The output should be 0.1 volt or greater.

The sweep generator and scope are connected as in the RF alignment. Inject the 26.1 mc source into the circuit at the scope takeoff point by coupling to the metal screw of C10.

PROCEDURE

Set the sweep generator to 85 mc, 10 mc sweep. Set the RF marker to 83.25 mc. Turn the tuning knob to approximately the center of Channel 6 so that the RF marker is in a suitable position on the waveform. If may be desirable to remove the extra loading of the 26.1 mc marker during this adjustment. Insert the 26.1 mc marker, and adjust the oscillator trimmer C15 until the RF marker and the 26.1 mc marker coincide.

Set the sweep generator to 213 mc, 10 mc sweep. Set RF marker at 211.25 mc. Turn tuning knob to place RF marker at suitable position on the waveform. Adjust the oscillator section high band loop sliders to make markers coincide.

Set sweep generator to 177.5 mc, 10 mc sweep. Set RF marker to 175.25 mc. Turn tuning knob to Channel 7. If markers approximately coincide, no further adjustment is required. If necessary, readjust C15, then repeat Channel 13 adjustments.

World Radio History

Set sweep generator to 85 mc, 10 mc sweep and RF marker at 83.25 mc. Turn tuning knob to approximately Channel 6. If required, adjust the oscillator section jump coils L13 and L16 to make markers coincide.

Set sweep generator to 57.5 mc, 10 mc sweep. Set RF marker at 55.25 mc. Turn tuning knob within the range of Channel 2 segment and check for coincidence of markers. If coincidence occurs at edge of range, it will be necessary to compromise the Channel 6 setting and readjust the jump coils slightly.

The oscillator alignment is described as a separate step, but may be combined with the RF alignment after experience is gained in handling the adjustments and compromises required.

With a continuous type tuner, a considerable range is available for tuning on each channel. For this reason, there are no individual channel oscillator adjustments. Slight retuning of C15 will change the oscillator frequency on all channels.

CHANNEL FREQUENCIES

Channel No.	Limit Frequencies Mc.	Picture Carrier Mc.	Sound Carrier Mc.	Oscillator Frequency Mc.
2	54-60	55.25	59.75	81.35

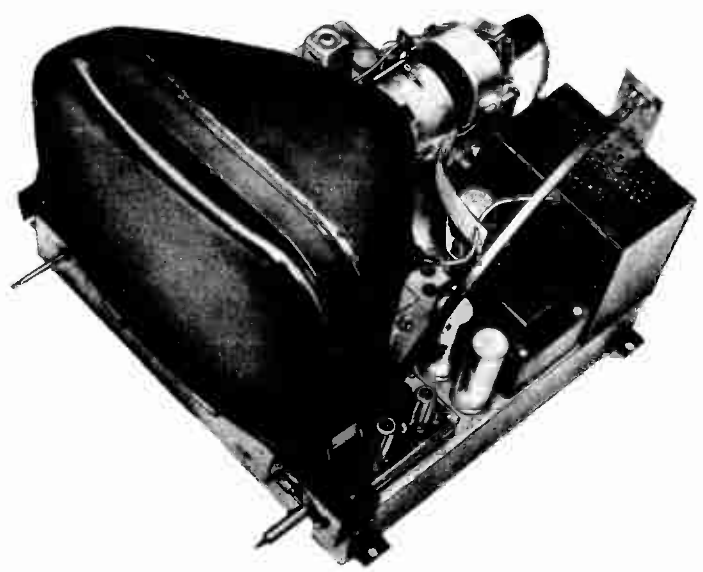

Figure 2. Chassis 160

SPECIFICATIONS

Line Voltage	115V AC 60 cps
Number of Tubes	21
Picture Tube Size	16" Rect.
Power Consumption	205 Watts
TV Channels	2 through 13
Audio Power Ouput	3 Watts

Speaker Type	6" x 12" Oval PM
Cabinet Height	18 3/8"
Cabinet Width	22"
Cabinet Depth	18 1/2"

PHONOGRAPH CONNECTIONS

Circuit connections are built into these models for attaching an external phonograph. A crystal pickup type record player must be used. A 45 rpm 7" record changer, a Long Playing changer, or a standard changer will produce good results. The phono AC power cord may be conveniently plugged into a socket marked AC PHONO located directly below the AC line cord lock at the left rear portion of the chassis. The phono audio lead goes into an audio jack marked INPUT PHONO located at the right rear portion of the chassis. The audio amplifier system of the TV receiver is controlled by the slide switch located adjacent to the INPUT PHONO jack. When this switch is placed in the PHONO position, the output of the record player pickup is amplified through the TV audio system. The volume is controlled in the normal manner with the volume control at the left front of the chassis. The slide switch marked TV-PHONO has no effect on the picture circuits of the receiver. The CONTRAST control may be turned full off to remove the picture. (Brightness should have been previously set so that light just begins to appear at minimum contrast setting.) All power to the phonograph is turned off when the TV receiver is turned off.

ELECTRICAL AND MECHANICAL DATA

Power Requirements:	
Operating Voltage	115 V AC 60 cps
Watts	205
Tuning Range:	
TV	Channels 2 through 13
Audio Power Output	3 Watts
Output Impedance (Audio)	3.2 ohms at 400 cps
Video Bandpass	3 MC
Intermediate Frequencies:	
Video Carrier	26.1 MC
Intercarrier Sound	4.5 MC
Antenna Input Impedance	300 ohms, balanced
Picture Tube:	
Chassis 159	14BP4
Chassis 160	16TP4

Chassis 159 and 160 are 21 tube TV receivers. An intercarrier sound system is used with the 4.5 mc sound IF being taken off after the video second detector. Three stages of video IF and two stages of sound IF are used. The interstage IF transformers are double-tuned, over-coupled type. The high voltage and deflection circuits are designed to operate a 70° deflection system for a 14 inch or 16 inch rectangular tube. The picture tube is mounted directly on the chassis on specially designed support brackets.

Servicing of the receiver without removal from the cabinet is facilitated by the easily removable metal bottom plate. The metal plate forms the bottom of the receiver cabinet, and is held in place by four screws.

©John F. Rider

World Radio History

Chassis 159 and 160 are identical except for the variations required to handle either the 14BP4 tube for chassis 159 or the 16TP4 tube for chassis 160. The parts which are different are the tube holddown strap, the focus coil mounting bracket, the deflection yoke mounting bracket, and the metal bracket for supporting the front of the picture tube. The screen resistor, R162, of the 6BG6G, is increased from 8.2 K to 15 K ohms to decrease the horizontal drive and high voltage for the 14 inch tube. Alternate part numbers are shown in the parts list. All other electrical and mechanical components are the same for both chassis.

TUNING UNITS

Two types of tuning units are used interchangeably in the chassis 159 and 160. The turret tuner, RF6, used in previous types of Hoffman receivers is used in early production of chassis 160. The Hoffman continuous type tuner is used in production of both 159 and 160 chassis, although the two tuners are operationally interchangeable and may be used alternately at any time.

Separate mounting plates are used in conjunction with each type tuner, so that direct mechanical interchangeability is possible.

The style of knobs for the front panel controls are different for the two types of tuners, and each tuner must be used with the set of knobs specifically designed for it.

INSTALLATION AND OPERATING INSTRUCTIONS

FRONT PANEL CONTROLS

The front panel operating controls consist of the TUNING control, the OFF-VOLUME control, and the CONTRAST control. With the AGC system used for maintaining constant signal level, the contrast control becomes primarily useful in setting background level for best viewing under various room lighting levels or different average program contrast levels.

BEAM BENDER ADJUSTMENTS

The single magnet type beam bender is used with either the 14 inch or 16 inch tube. The rated flux density is 60 gauss, which is higher than previously used magnets. There is no indication to show a forward or back direction for the installation of the magnet on the tube neck. The direction of installation is immaterial, except that if the magnet is turned over, it must be rotated 180° on the neck of the tube.

The method of installation is to slip the beam bender on the neck of the tube and move it forward toward the tube face until it approaches a space over the "flags" of the first anode. Set the brightness control about midway of its range, never full on, to avoid damaging the tube's electron gun prior to proper adjustment of the beam bender. Rotate the magnet 180° or more on the tube neck until light appears on the screen. After initial light has been obtained, move the beam bender forward or back, and further rotate it to obtain the brightest raster. With the strong, 60 gauss magnet, there are two positions which will give screen illumination. One occurs near the tube base as the magnet approaches a position over the "flags" and the second occurs as the magnet is pushed beyond the "flags" and near the focus coil. The first position is preferred because it allows greater space for adjustment range. The strong magnet also allows a wider adjustment range and the setting will affect the centering and focus. A last check should be made on beam bender adjustment after focus and deflection adjustments have been made.

BRIGHTNESS CONTROL

The brightness control provides adjustment of control grid bias voltage. Automatic retrace elimination circuits are incorporated, so that retrace lines are visible only at maximum setting of the brightness control. Proper setting of the brightness is such that light is just visible on the screen when the contrast control is set at minimum with a signal tuned in.

HORIZONTAL CONTROLS

The HORIZONTAL HOLD and HORIZONTAL DRIVE controls are interdependent and should be adjusted simultaneously. Tune in a test pattern and set the tuning so that sound and picture are both present. Set the HORIZONTAL DRIVE to the middle of its range. Turn the HORIZONTAL HOLD until the picture is properly in sync. Approach from either clockwise or counter-clockwise direction is permissible. There will be a range of 2 or 3 turns of the L108 tuning slug which will hold the picture in sync. Adjust to approximately the center of this range. From these preliminary adjustments, final adjustments can be made, if required. One, or several picture discrepancies may appear which can be corrected by slight readjustment of the Drive control and retrimming of the Hold control. These symptoms are:

(1) a vertical white line or band through the center of the picture;

(2) thin vertical black lines on either left or right side of picture;

(3) vertical wedges of test pattern or vertical lines of picture are crooked or bent over at the top of the picture;

(4) sync at edge of range, evidenced by failure of picture to immediately come into sync horizontally when the tuner is turned away from and back on channel;

(5) horizontal non-linearity of test pattern.

All of these discrepancies can be corrected by simultaneous readjustment of the Drive and Hold controls.

The HORIZONTAL SIZE, or width control, L109, provides a wide range of linear width adjustment. Clockwise rotation (slug moving into coil) increases the width of the picture.

FOCUS CONTROL AND RASTER CENTERING ADJUSTMENTS

Electromagnetic focusing is used, with the focus coil being used as a choke in the B+ supply circuit. The Focus control, R195, shunts the focus coil. Adjust the Focus control until clear, well-defined horizontal sweep lines can be observed.

Vertical and Horizontal Centering controls are mechanical type which operate by positioning the focus coil. The vertical centering is operated by a spring-loaded screw on the right of the focus coil, and horizontal centering is operated by a similar screw on the left. If difficulty is encountered in focusing or centering, or neck shadows appear, a reversal of the leads to the focus coil will often remedy the situation.

VERTICAL CONTROLS

The VERTICAL HOLD control has a "hold-in" range of adjustment over which the picture will stay in sync. The control should be set in about the middle of the "hold-in" range.

The VERTICAL SIZE and VERTICAL LINEARITY operate together to aujust the vertical height and proportion of the picture. The Size control affects the vertical size of the entire picture, but not in a linear manner. The bottom portion of the picture is expanded and the picture center tends to move toward the top of the tube. The linearity control operates to expand the upper portions of the picture, and compensate for non-linearity created by the Size control.

ALIGNMENT

This alignment procedure describes alignment of the double-tuned IF system and intercarrier sound circuits only; the procedure for the RF tuning unit is described in separate bulletins on the tuning units. The general order of alignment should be as follows:

Sound Takeoff Coil
Sound IF and Ratio Detector Primary
Ratio Detector Secondary
4.5 MC Video Trap
Adjacent Channel IF Traps
Picture IF Transformers
Converter Output Coils

The detailed alignment procedure deals with methods used and precautions to be observed during alignment. For actual alignment, it is suggested that the alignment table be followed after reading the detailed procedure.

SOUND IF ALIGNMENT

Equipment Setup

Set the sweep generator at 4.5 mc center frequency with approximately 400 kc sweep width. Insert a marker signal of exactly 4.5 mc.

Connect the signal to the short wire leading to the grid, pin 1,of V108. This is shown as point "C" on the schematic diagram. Use shielded lead from the sweep generator, and connect a 50 ohm, composition resistor from point C to ground. This resistor is not required if the generator has a low impedance output.

Unsolder one end of C113.

Connect the scope from pin 2 of the 6T8 to ground. Use a 10 K ohm, isolating resistor between pin 2 and the scope lead, and use shielded lead for making the scope connection.

Procedure

Adjust L100, T101 primary (bottom), T101 secondary (top), and T102 primary (bottom) to obtain a flat-topped, symmetrical band pass with the 4.5 mc marker in the center of an approximately 75 kc bandwidth. See Figure 3. It is essential that the slugs be moved from the outer ends of the coil form toward the center, by turning the slugs clockwise. If the slug has been run past the center, so that resonance is reached with the slug coming out of the coil, then the slug must be backed out, counter-clockwise, completely through the coil and the tuning procedure started over again. If the slugs are run into the center of the double-tuned coils, the mutual coupling will be adversely affected and proper alignment will be impossible. This applies to all double-tuned transformers.

RATIO DETECTOR ALIGNMENT

Equipment Setup

The sweep and marker generators remain connected as above.

Reconnect C113.

Connect the scope, with isolating resistor, to the junction of R105, R106.

Procedure

Adjust the secondary (top) of T102 for an "S" curve which is symmetrical, and has the 4.5 mc marker in the center of the linear or straight line portion of the curve. Inasmuch as the center of the "S" curve is a zero or null point, very little 4.5 mc marker will come through. However, the marker does produce a series of irregular traces which appear on opposite sides of the linear portion of the curve. These traces may be evenly distributed about the center for proper adjustment of T102 secondary.

ALTERNATE SOUND ALIGNMENT

If no 4.5 mc sweep generator is available, the sound may be peak aligned using an unmodulated 4.5 mc source and a 20,000 ohm/volt DC meter. Connect the generator to pin 1, V108 as with the sweep generator. Leaving C113 in the circuit, connect the DC meter across R107. Tune all 4.5 mc sound coils as above to produce a peak reading on the meter.

Adjustment of the ratio detector secondary may be accomplished by connecting one terminal of the DC meter to the junction of R105, R106, and the other terminal to the junction of two 10 K ohm resistors connected in series and soldered in the circuit across R107. Adjust T102 secondary (top) until a zero or null is produced.

If no equipment is available, the sound may be aligned on a station signal without the use of a signal generator or scope. Tune in a station normally, and while listening to the sound output from the speaker, tune L100, T101 primary (bottom), T101 secondary (top) and T102 primary (bottom) to obtain maximum sound output. Tune T102 secondary (top) for maximum output, best quality, and minimum buzz. It may be necessary to go through the series twice to obtain the best performance.

©John F. Rider

World Radio History

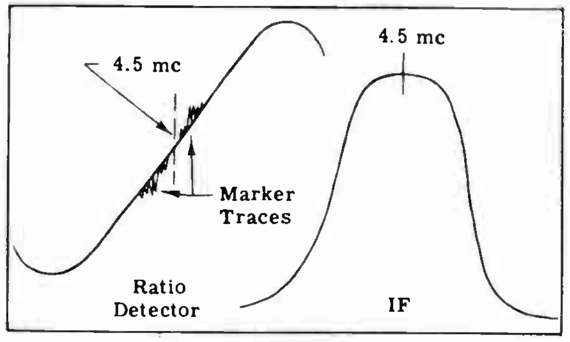

Figure 3. Sound Alignment Curves

TUNING 4.5 MC VIDEO TRAP

Equipment Setup

Connect an unmodulated 4.5 mc signal to pin 1, V108. Connections are the same as for sound alignment. Use a detector and isolating network as shown in Figure 4, connected to the output side of video peaking coil, L105. The 2.5 V scale of a volt-ohmmeter or a 50 microamp meter with a limiting resistor in series may be used for the indicator.

Procedure

Adjust the slug of L106 for minimum reading on the meter. Increase the input signal to produce greater output as the trap is tuned.

Alternate Procedure

If the service man is familiar with the appearance of 4.5 mc beat pattern as produced on the picture tube, then adjustment may be made without external signal generator or meters.

Tune in any channel, and then mis-tune to a point that would be equivalent to placing the sound IF carrier "up" on the IF response curve. This will produce and be indicated by a maximum 4.5 mc beat pattern in the picture. Tune L106 for minimum beat note. This will minimize the beat pattern when the station is properly tuned.

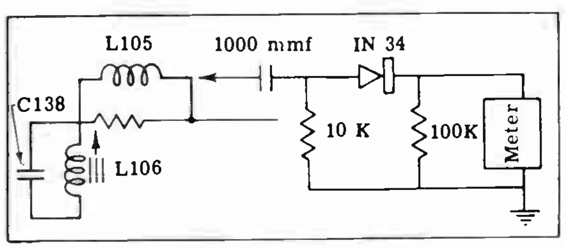

Figure 4. 4.5 MC Beat Pattern Detector Circuit

TUNING ADJACENT CHANNEL TRAPS

Equipment Setup

Connect a voltmeter to the short wire between the output of the picture 2nd detector circuits and pin 1 of V108. This is shown as point "C" on the schematic. Set meter to 10 V DC scale. The scale may be reduced later.

Connect a signal generator, through an isolation network, to the grid, pin 1, of V107. The isolation network is shown in Figure 5.

Use composition resistors and a disc type, ceramic condenser.

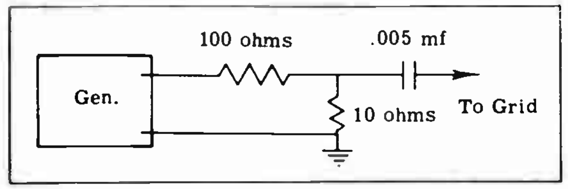

Figure 5. Input Isolation Network

Procedure

Apply an unmodulated, 28.1 mc signal to the grid of V107. Use sufficient output from the generator to produce an appreciable reading on the DC meter. Tune L103 to produce a minimum on the meter. This dip may be only a small change of reading if the IF amplifiers are misaligned, but will be located properly regardless of amplitude. It may be necessary to decrease the meter scale and increase signal as L103 is tuned.

Move the signal generator and isolation network to the grid, pin 1, of V106. Set the unmodulated signal to 28.5 mc. The tuning procedure for L102 is the same as described for L103.

PICTURE IF ALIGNMENT

The picture IF alignment procedure is a process of separately adjusting a series of double-tuned, over-coupled stages. Adjustment of each stage is complete in itself and provides a band pass of about 3 mc for each stage. The cascading of three amplifiers and the equivalent of four double-tuned transformers produces a high gain broad band amplifier. The band pass waveform is the conventional, double-humped characteristic of the over-coupled circuit.

Equipment Setup

Connect a scope between point "C" and ground through a 10 K series resistor as shown in Figure 6. The scope should have a sensitivity of .1 volt RMS/inch or better.

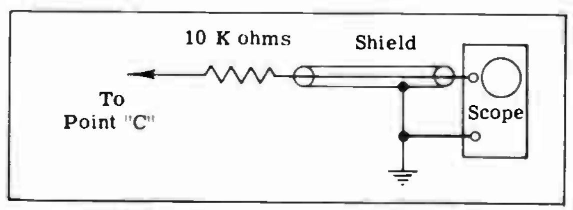

Figure 6. Scope Connection Network

Connect the negative terminal of a 3 V battery to the junction of R124 and C127, and connect the positive terminal to ground. This provides bias in place of the AGC voltage for alignment procedure.

For first stage alignment, connect the sweep generator through the network shown in Figure 5 to pin 1 of V107. For successive stages, move the generator and network to each grid in succession.

Procedure

Set the sweep generator to a center frequency of about 24 mc with 10 mc sweep.

Insert a marker signal set to 24.3 mc.

For alignment of the 3rd picture IF, adjust the primary (bottom) and secondary (top) of T106 to obtain a pass band whose flat top is symmetrical about the marker. Skirt positions and slopes will not be symmetrical. See Figure 7. Correct alignment of the overcoupled, double-tuned stages is indicated by a curve having a nearly flat top with equal amplitude peaks. The bandwidth of each stage is predetermined by design of the transformers and is not controlled by alignment. A dip may be noticed as indicated by a dotted line in Figure 7. This condition may be eliminated by shorting the primary of the transformer in the plate circuit of the stage preceding the stage under alignment. The sweep generator is connected to the secondary of the transformer whose primary will be shorted.

World Radio History

Move sweep generator and isolation network to pin 1 of V106, 2nd picture IF. Alignment of T105 is accomplished by tuning the primary and secondary to give a symmetrically topped curve as previously described. It is imperative that T105 only be adjusted. The previously aligned T106 must not be touched because a false alignment can be obtained even though the overall response may appear satisfactory. If the transformer primary was shorted for previous alignment, the short must be removed prior to alignment of this stage.

Move the sweep generator and isolation network to pin 1 of V105, 1st picture IF. Align T104 as was done in previous stages. Do not readjust T105 or T106. See Figure 7 for approximate shape of the overall band pass.

It can be noted that the center dip is greater, and the total band pass is slightly less than that of a single stage. Note also the position of the dips caused by the 28.1 and 28.5 mc traps.

Connect the signal generator and isolation network to the converter grid in the RF tuning unit. The converter output coil and the picture IF peaking coil, L101, form an over-coupled circuit comparable to the IF transformers. Using the converter output coil as the primary, and L101 as the secondary, align the IF input circuit to produce an overall response curve as shown in Figure 7. Again, it is emphasized that previously aligned stages must not be touched.

ALIGNMENT TABLE

This alignment table is for quick reference during alignment. Detailed instructions beginning on page 4. should be studied before alignment by use of the table is attempted.

Step No.	Connect Signal To	Sweep Gen. Freq.	Marker Gen. Freq.	Output Indicator	Adjust	Instructions
1	Point "C"	4.5 mc 400 kc sweep	4.5 mc	Scope to Pin 2 of 6T8	L100 T101 Pri, Sec T102 Pri	Disconnect C113. See Fig. 3 for waveform.
2	"	"	"	Scope to junction R105, R106	T102 Sec	Reconnect C113. Adjust for "S" curve.
3	"	None	"	Detector Network and Meter to L105	L106	Adjust for minimum reading on meter.
4	Pin 1 V107	None	28.1 mc	Meter to Pin 1 of V108	L103	Use isolation net on input. Adjust for dip on meter.
5	Pin 1 V106	None	28.5 mc	"	L102	Adjust for dip on meter.
6	Pin 1 V107	24.3 mc 10 mc sweep	24.3 mc	Scope to point "C"	T106 Pri, Sec	Adjust for symmetrical waveform. See Fig. 7.
7	Pin 1 V106	"	"	"	T105 Pri, Sec	"
8	Pin 1 V105	"	"	"	T104 Pri, Sec	"
9	Converter Grid	"	"	"	Converter Output and L101	"

Use −3 V battery connected to AGC line for alignment bias.
See text for isolation networks.

SAFETY FACTOR CHANGE FOR PICTURE TUBE USED IN CHASSIS 159 AND 160

Field reports indicate that a number of Chassis 159 and Chassis 160 receivers are experiencing intermittent picture tube trouble as evidenced by loss of raster. This trouble occurs in receivers that use a picture tube that has an abnormally low heater to cathode breakdown potential characteristic. In order to provide a greater safety factor in the receiver the CR tube heater D.C. potential should be lowered from the 265 volts originally used to 180 volts. The figure indicates the necessary change in wiring.

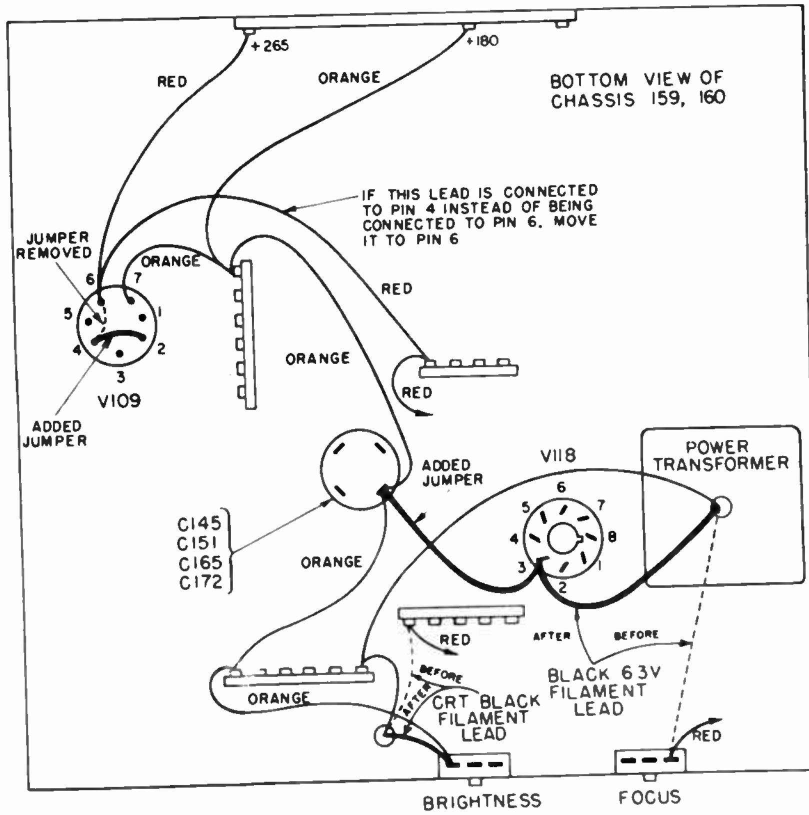

Figure 1. CR Tube Safety Factor Wiring Change

Dotted lines indicate wiring before change is made. Heavy black lines indicate wiring that is changed or added.

World Radio History

REGENERATION IN I.F. AMPLIFIERS

SYMPTOMS: Regeneration in the I.F. amplifiers, particularly at low signal level where little AGC bias is developed, may result from feedback through the B+ lines on sets produced prior to Serial No. D035142. Two effects may be produced, one when a station is tuned in and another on unused channels when no signal is present.

The effect on a picture is production of a vertical, 1/8 to 1/4 inch wide band, spaced about 1/4 inch from the left edge of the raster. The band contains variable width diagonal stripes, alternate dark and light, which produce a "barber pole" effect.

The effect when no signal is present, is known as "Christmas tree". The white raster, with brightness turned up, will appear with several variable width sections, giving it an appearance of a Christmas tree. In severe cases, the raster disintegrates into "layers" of bright horizontal lines filling approximately the center 50% of the raster area. The lines are accompanied by a loud singing of the horizontal output transformer. This latter effect disappears when a station is tuned in.

The Christmas tree condition is associated with horizontal sync and is covered further in Service Bulletin No. 132.

REMEDY: The following changes can be made in the wiring layout of chassis 159 and 160 to aid in reducing regeneration. Schematically, no changes have been made in the circuit.

1. Remove the co-ax lead running from the Tuning Unit video output to coil L101.

2. Replace connection with wire, dressing wire against chassis.

3. Remove two red +265 V wires (in some sets these wires are orange) from the 80 mf, 475 V, electrolytic condenser (shown as present C171 on schematic).

4. Remove orange +345 V wire from the 80 mf, 475 V, electrolytic condenser (shown as present C170 on schematic). Remove one end of R193 (150 ohms) from same electrolytic.

5. Reconnect one +265 V red wire (from R195, focus control) to the electrolytic condenser formerly occupied by +345 V orange wire.

6. Reconnect orange +345 V wire to electrolytic formerly occupied by two red wires.

7. Reconnect free lead of R193 to new position of +345 V wire as in step 6 above.

The steps 3 through 7 are for the purpose of exchanging the physical locations of C170 and C171. Schematically, no changes have been made.

8. Disconnect one blue wire (going to R197 voltage divider) from the +140 V point at C173.

9. Reconnect blue wire to +140 V tie-point in sound I.F. strip (junction of R102, R104).

10. Reconnect red wire (+265 V lead from R196, previously disconnected in step 3) to junction of pins 4 and 6 at tube socket of V109, 6AU6, AGC keyer.

If heater leads of V109 are connected directly to the tube socket, the following change should be made.

11. Remove V109 heater wires (black, twisted leads from power transformer) from tube socket pins. Leave all other wires in place. Connect one wire to +265 V string at junction of R195, L113, on focus potentiometer. Connect other black wire to tie-point junction of brown wires running to heater of cathode-ray tube and heater of V109.

These changes have been made on all sets produced after Serial No. D035142.

On early production receivers, prior to Serial No. C023200, one additional change is required. A white wire, carrying AGC voltage, runs along the front of the I.F. strip, between the adjacent channel traps, L102, L103, and the I.F. amplifier tubes. This wire should be rerouted so that it lies outside the I.F. strip, and against the main chassis, under the lip of the I.F. strip subchassis.

An easy way to make the wiring changes is to obtain a recent production chassis and follow the new wiring layout.

To realize full benefit from the wiring changes to reduce regeneration, the chassis should be realigned after completion of the rewiring.

The metal bottom plate for the chassis may provide an additional feedback path in some cases, particularly in fringe areas where the signal is low and little AGC bias is developed. This condition will be characterized and aggravated by the 3rd I.F. stage being "hot" or regenerative. To alleviate this situation, a non-metallic bottom plate has been developed and is available on order from the Hoffman distributor under Part No. 3735.

ADJACENT CHANNEL TRAP ADJUSTMENTS

The adjacent channel traps, L102 and L103, may require adjustment to a different set of frequencies to give optimum operation in some locations. Alignment data in Service Data No. 125 shows 28.1 mc for L103 and 28.5 mc for L102. Factory production is aligning to 27.6 mc for L103 and 28.1 mc for L102. The frequency 27.6 mc represents the adjacent channel carrier and more efficient trapping is obtained, particularly in fringe areas.

Setting the traps to the lower frequencies tends to steepen the side of the I.F. bandpass characteristic and may result in a sharper sound tuning characteristic.

In setting the adjacent channel traps, two positions of the iron slug will produce resonance. The trap will be most effective if the slug is set in a position going into the electrical "bottom" of the coil. The electrical "bottom" is the grounded end of the winding. Physically, the "bottom" end is opposite from the end held in the chassis by the tinnerman nut. In practice, the slug may protrude out of the coil form by an amount of one or two threads. This slug position is most effective for either set of trap frequencies.

The trap settings materially affect the I.F. alignment, so it is suggested that no adjustments be made on the traps unless complete realignment can be completed.

ALTERNATE CRYSTAL TYPES

The crystal used as the picture second detector is shown as a Sylvania type 1N60 in Service Data No. 125. Several alternate types listed below may be used interchangeably for replacement.

Raytheon	CK703
	CK704
	CK705
Sylvania	1N34
G. E.	G5A

LETTERING SYSTEM ON SECOND DETECTOR COMPONENT CAN

The can in which the picture second detector crystal and components are housed has its bottom terminals identified by letters. On present production, the lettering on connections A and C is interchanged as compared to the lettering shown on the schematic diagram. If field replacement of the can is required, it is desirable to check the D.C. resistance to ground from each point before wiring the can in the circuit. The component connections and values are correct as shown on the schematic in Service Data No. 125.

HIGH VOLTAGE RECTIFIER FILAMENT

The chassis 159, with 14 inch picture tube, has a 4.7 ohm resistor in series with the 1X2, high voltage rectifier, filament. This resistor drops the filament operating temperature below the most desirable condition for long tube life. Reduce this resistor, R164, to 2.2 ohms, 10%, 1/2 watt, Part No. 4735.

The corresponding part in the 160 chassis should remain at 4.7 ohms. The reason for the difference between the two chassis is that the 14 inch tube requires less high voltage and horizontal sweep than the 16 inch tube. As a result, the 6BG6-G screen resistor, R162, is 15K ohms on chassis 159, which reduces the drive to the horizontal output transformer, T107, and in turn reduces the available 1X2 filament voltage.

NO CONTROL OF BRIGHTNESS

The failure of C166, .005 mf, Part No. 4069, causes the brightness control to have no effect. Shorting of C166 places a constant positive voltage on pin 2 of the picture tube, and the screen remains lighted at all times. Replacement of the condenser affords temporary correction, but the condenser may fail again due to voltage spikes in the vertical deflection circuit, temporary arcs in the picture tube, or shorting of R145 to ground. This condition can be permanently remedied by physically and schematically interchanging the positions of C166 and R145 (1 meg., 1/2 watt). The two components form a series circuit, so that the operation of the receiver is not affected. However, the 1 megohm R145 will protect C166 from voltage spikes. The two components should be interchanged whenever replacement of C166 is necessary. This change has been made on all sets produced after Serial No. D037401.

FOCUSING OF VARIOUS PICTURE TUBES

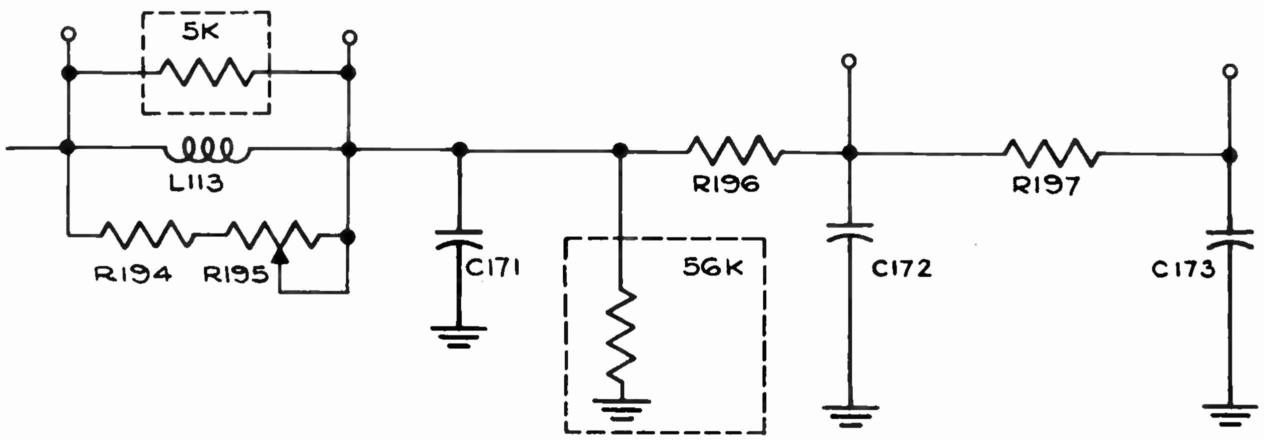
Rectangular picture tubes, 14" and 16", of various manufacturers require different focus coil field strengths. The present focus coil is suitable for use with all types, provided that circuit arrangements are made to give the proper amount of current flow through the focus coil.

©John F. Rider

World Radio History

Hytron and G.E. tubes require less current and a 5K ohm, 5 watt resistor must be shunted across the focus coil, L113.

Sylvania tubes require more current, and a 56K ohm, 2 watt resistor should be shunted across C171 to increase the current through the focus coil. These changes are illustrated schematically below.



The appropriate circuit modification for the tube used is made in the factory. However, if a tube is changed in the field for any reason, circuit modifications may be necessary. These circuits apply in most cases. Occasionally a tube will require slightly different resistance values.

PICTURE TUBE COATING TO BE GROUNDED

On some picture tubes, the aqua-dag coating is not formed down far enough to contact the ground springs attached to the deflection yoke bracket. Most tubes are satisfactory. The Hoffman production department will paint extra coating on initial equipment tubes which require this treatment. However, the length of coating must be considered if tube replacement or change is made by the service man. The coating can be extended with a paint formed of graphite held in a lacquer vehicle suspension.

BUZZ IN SOUND

A buzz of basically 60 cycle frequency may appear on some stations and not on others in the same area. The buzz is different from a 60 cycle hum in that it is rough or raucous sounding. The cause of the buzz is in the transmitting station characteristics, and may result from excessive video amplitude modulation, or phase modulation of the video carrier in the final stages of the transmitter.

Three things may be done which will materially aid in eliminating buzz reception by the receiver.

1. Retrim the tuning of the ratio detector secondary. Tune the receiver to the station which gives the greatest buzz. Tune the top slug of T102 for minimum buzz. This slug may be reached from the top of the chassis. The results obtained by tuning the slug for minimum buzz while listening to an offending station will be better than those obtained when aligning to a 4.5 mc signal generator.

2. Change the value of R107, ratio detector load resistor, from 12K ohms to 6.8K ohms. This change affords a considerable improvement in the buzz rejection, and has been made on all sets produced after Serial No. E040192.

3. Increase the capacity of C109, from .0047 mf to .01 mf. A 200 V paper condenser is suitable for use. This change has been made on all sets produced after Serial No. C023200 and will aid the previously described changes in reducing buzz.

VERTICAL SIZE CONTROL RANGE

The vertical output is sufficient to more than fill the entire tube screen. In some cases, particularly on the 159 chassis, the vertical size control will not decrease the size of the picture sufficiently to have all of the picture appear on the tube. Increasing the value of R181 from 1.5 to 2.2 megohms will reduce the vertical output to within normal range of the vertical size control. In extreme cases it may be necessary to increase R181 to 3.3 megohms.

A convenient arrangement for changing to 2.2 megohms is to interchange the resistors, R181 and R166. This will result in values of 2.2 megohms for R181 and 1.5 megohms for R166. This change has been made on all sets produced after Serial No. E040192.

The horizontal synchronizing and sweep circuits are designed to be an integrated and controlled system, using a feedback circuit from the horizontal output to provide a comparison voltage for the horizontal oscillator control tube. Therefore, it is necessary when making any changes in the circuit, to consider an overall viewpoint and determine what effect the change will have on any other operating characteristic of the receiver.

The various conditions and changes will be discussed separately, but any interlocking effects will be pointed out.

HORIZONTAL SYNC INSTABILITY

Horizontal jitter, or sync instability is very often caused by noise upsetting the sync circuits, particularly in weak signal areas.

Several modifications of the original circuit, as shown in Service Data No. 125, have been made on different production runs of the chassis 159 and 160 to aid in stabilizing the horizontal sync.

The correct modified values are listed below, along with serial numbers indicating when the change was made. Sets produced after the listed serial number will have the modification included.

Symbol	Part	Serial No.
C144	.1 mf 20% 200 V paper	D034300
C144	Outside foil grounded (See below)	D034738
C179	47 mmf 20% 500 V ceramic or mica (In parallel with R166, pin 1 V115 to ground)	D033610
R148	68K ohms 20% 1/2 watt	C023576
C143	.01 mf 20% 200 V	D037401

Sync instability in sets with the proper constants, produced prior to Serial No. D034738, may be caused by the inversion of C144. This condenser is a molded phenolic, paper dielectric type. It is imperative that the outside foil be connected to ground. If this condenser is inverted, with the outside foil connected in the grid circuit, stray pulses will be picked up which cause severe instability. In construction of this condenser, one of the leads has a solder bump located just outside the phenolic case. This lead is connected to the outside foil and must be connected to ground. Careful control of the polarity of this condenser has been exercised in sets produced after Serial No. D034738. Leads should be kept short and the condenser mounted close to the chassis.

HORIZONTAL SYNC PULL-IN RANGE

When tuning from station to station, or when the receiver is first turned on, there may be a momentary delay before the picture will pull into horizontal sync. To increase the pull-in range and improve the pull-in characteristics of the receiver, a modification has been made on all receivers produced after Serial No. D037401. The changes are:

C143 changed from .0047 to .01 mf, 20%, 200 V, Part No. 4142

C141 changed from .0047 to .022 mf, 20%, 1000 V, Part No. 4135

©John F. Rider

World Radio History

An additional result of changing C141 is that a different phasing relationship is obtained between the horizontal sweep voltage and the sync signals in the horizontal oscillator control tube. This causes the picture to start at a point further to the right and allows for easier centering without neck shadows. When this change is made, check the values of R147, R149, and C140 to make sure they are the correct values as shown on the schematic for chassis 159, 160.

The pull-in range is controlled by the setting of the horizontal hold control (L108). The pull-in range should be checked and the control adjusted according to the following sequence.

1. Set horizontal drive control (R154) at minimum resistance (full counterclockwise) or as close as possible. See instructions on setting drive under the section on "Christmas tree effect."

2. Turn hold control counterclockwise (slug coming out of coil) while turning channel selector on and off station until sync is lost.

3. Turn control clockwise (slug going in) and check the number of bars (picture segments) before pull-in. There should be a snap-in from at least one bar (60 cycles).

4. Continue turning control clockwise while turning channel selector until sync is lost as in step 2 above.

5. Turn control counterclockwise (slug coming out) and check number of bars before pull-in, as in step 3 above.

6. Turn slug an additional 1/4 turn counterclockwise if one-bar pull-in occurs, or approximately 1/2 turn if two-bar pull-in occurs. This setting provides best operating characteristics for sync pull-in and drift, and is approximately correct for the least amount of "hook."

The amplified AGC system used in this receiver is very positive in its action. When the receiver is first turned on and warming up, it may be possible for the AGC action to lock and hold the picture out of sync as well as in sync. In this case, all that is required is to turn the channel selector off and on station, momentarily releasing the AGC, and the picture will immediately lock into correct sync.

DRIFT

Coupled with pull-in range is long term frequency stability of the horizontal multivibrator, V111. Actually, the oscillator operates at a frequency of 15,750 cps at all times when in sync. However, as the natural, or uncontrolled frequency of the horizontal oscillator tends to drift due to component value changes as the parts heat up, more control voltage is required at the grid, pin 1, of V111. Eventually, if enough drift takes place, the available control voltage will be exceeded and the receiver will lose sync.

To aid in eliminating drift, the condenser C149, 250 mmf, Part No. 4086, must be a ceramic NPO (zero temperature coefficient). In sets produced prior to Serial No. E047496, C149 has been a GP type ceramic, with no rated temperature characteristic. In some instances, a 330 mmf condenser may be found as C149. The 330 mmf should be replaced with the proper 250 mmf NPO ceramic. The capacity 250 mmf is critical, and no other value should be used. If a ceramic NPO condenser is not available, a silver mica type with a low temperature characteristic is suitable.

The change of C149 will eliminate most drift problems. However, further stabilization may be obtained by changing C146, .0039 mf, from its present ordinary mica type to a silver mica type with low temperature characteristic.

CHRISTMAS TREE EFFECT (Improper Horizontal Multivibrator Operation)

The Christmas tree effect, with symptoms as described in Service Bulletin No. 128, will appear on unused channels, when no signal is present, such as when switching from channel to channel. In addition to evidences on the picture tube, the effect is characterized by loud frying or singing sound from the horizontal output transformer. Although this singing causes no apparent harm, it is annoying and sounds destructive.

The primary cause of Christmas tree effect is regeneration, and this should be eliminated on sets requiring wiring changes

A second cause is excessive resistance in the horizontal drive circuit. Set the drive control, R154, at minimum resistance (maximum counterclockwise rotation). This position can be used when setting up the horizontal controls unless a vertical white bar appears in the center of the picture. In this case, the control can be set to eliminate the white bar. In some receivers, the potentiometer may be 250K ohms instead of the rated 100K. Replace these 250K controls or shunt them with a fixed 220K ohm to bring the total resistance to the proper value.

A third possible cause is too high capacity value of C149. Too much capacity in this component tends to cause Christmas tree effect and poor sync hold-in.

CURVATURE IN VERTICAL LINES (Hook)

Curvature in vertical lines in the top portion of the picture is commonly called "hook." This curvature is particularly apparent on a test pattern, or a picture with distinct vertical lines, such as the sides of a door or folds in a drapery. The curvature is normally in the form of a bow or a bend to the right in the top portion of the picture.

The hook can be materially decreased by addition of a 12K ohm, 20%, 1/2 watt, composition resistor (R198) and a .005 mf ceramic capacitor (C180) in the grid circuit of the horizontal oscillator control tube, V110A. Refer to the schematic diagram with this bulletin for location of these components. A further change which will improve the hook and Christmas tree condition is the change of C142 from .0047 mf to .01 mf, 400 V, paper type capacitor. However, this change reduces the horizontal sync hold-in range, and it is imperative that C146 and C149 be changed to a zero temperature coefficient type as described under "Drift", if the change of C142 is made.

PHONOGRAPH CONNECTIONS

Circuit connections are built into these models for attaching an external phonograph. A crystal pickup type record player must be used. A 45 rpm 7" record changer, a Long Playing changer, or a standard changer will produce good results. The phono AC power cord may be conveniently plugged into a socket marked AC PHONO located directly below the AC line cord lock at the left rear portion of the chassis. The phono audio lead goes into an audio jack marked INPUT PHONO located at the right rear portion of the chassis. The audio amplifier system of the TV receiver is controlled by the slide switch located adjacent to the INPUT PHONO jack. When this switch is placed in the PHONO position, the output of the record player pickup is amplified through the TV audio system. The volume is controlled in the normal manner with the volume control at the left front of the chassis. The slide switch marked TV-PHONO has no effect on the picture circuits of the receiver. The CONTRAST control may be turned full off to remove the picture. (Brightness should have been previously set so that light just begins to appear at minimum contrast setting.) All power to the phonograph is turned off when the TV receiver is turned off.

Watts	205 watts
Tuning Range:	
TV	Channels 2 through 13
Audio Power Output	3 watts
Output Impedance (Audio)	3.2 ohms at 400 cps
Video Bandpass	3.8 MC
Intermediate Frequencies:	
Video Carrier	26.1 MC
Sound Carrier	21.6 MC
Antenna Input Impedance	300 ohms, balanced
Picture Tube:	
Chassis 170	14CP4
Chassis 171	16TP4,16RP4,or 16KP4
Chassis 173	17BP4
Chassis 175	19AP4

Chassis 170, 171, 173 and 175 are 21 tube TV receivers. Separate sound and video IF amplifiers are used, with the sound being taken off after the 2nd video IF amplifier. Three stages of video IF and two stages of sound IF are used. The interstage IF transformers are double-tuned, over-coupled type.

Chassis 170, 171, 173 and 175 are all electrically and mechanically similar except for slight variations as follows:

Chassis 170, 171 and 173 employ 14 inch, 16 inch and 17 inch rectangular picture tubes respectively. These picture tubes mount directly on their respective chassis on specially designed support brackets. Chassis 175 employs a 19 inch round picture tube which is mounted on a specially designed support frame that is separate from the chassis. The chassis 175, unlike the chassis 170, 171 and 173 which mount horizontally in the cabinet, is mounted in the vertical position that occupies the upper left-hand side of the cabinet as viewed from the back. The chassis is mounted so that it travels on a slide arrangement and it is held in place by bolts that fit through the chassis side brackets and thread into the upper slide. With this arrangement the

©John F. Rider

World Radio History

bolts and front control knobs may be removed and the chassis pulled about two-thirds of its length out of the cabinet. In this position the chassis may be conveniently serviced throughout most of its entirety. Chassis 170, 171 and 173 side brackets run in horizontal slides on each side of the cabinet and are held in place by bolts which fit through the brackets and into the threaded slides. Chassis 170, 171 and 173 are covered by metal bottom plates which may be removed easily.

The deflection systems of the four chassis are the same with the exception that the 6BG6 G screen resistor is increased from 8.2K to 15K in the chassis 170. This change is made to decrease the horizontal drive and high voltage on the 14 inch tube. Otherwise the sweep requirements of the various size picture tubes are taken care of by adjustment of the horizontal and vertical size controls. In the case of the Chassis 175, the 6BG6 G horizontal output tube is mounted outside of the high voltage cage so that better ventilation is affected, and R 167, 470K resistor, is not used because the picture tube is of the metal type. Also a heat shield is placed between the power transformer and 5U4 low voltage rectifier.

TUNING UNITS

Two types of tuning units are used interchangeably in chassis 170, 171, 173 and 175. The turret tuner, RF6* used in previous types of Hoffman receivers and the Hoffman continuous type tuner are each being used in production of the above chassis. The two tuners are operationally inter-changeable and may be used alternately at any time. Separate mounting plates are used in conjunction with each type tuner, so that direct mechanical interchangeability is possible. The style of knobs for the front panel controls are different for the two types of tuners, and each tuner must be used with the set of knobs specifically designed for it.

* Present unit does have a modified converter output circuit and is known by Part No. 9684. The modification consists of eliminating L6, Part No. 5311 and changing values of L5 (.8µh) and C14 (135 mmf).

OPERATING INSTRUCTIONS

FRONT PANEL CONTROLS

The front panel operating controls consist of the TUNING control, the OFF-VOLUME control, and the CONTRAST control. With the AGC system used for maintaining constant signal level, the contrast control becomes primarily useful in setting background level for best viewing under various room lighting levels or different average program contrast levels.

BEAM BENDER ADJUSTMENTS

The single magnet type beam bender is used with all the picture tubes. The rated flux density is 60 gauss. There is no indication to show a forward or back direction for the installation of the magnet on the tube neck. The direction of installation is immaterial, except that if the magnet is turned over, it must be rotated 180° on the neck of the tube.

The method of installation is to slip the beam bender on the neck of the tube and move it forward toward the tube face until it approaches a space over the "flags" of the first anode. Set the brightness control about midway of its range, never full on, to avoid damaging the tube's electron gun prior to proper adjustment of the beam bender. Rotate the magnet 180° or more on the tube neck until light appears on the screen. After initial light has been obtained, move the beam bender forward or back, and further rotate it to obtain the brightest raster. With the strong, 60 gauss magnet, there are two positions which will give screen illumination. One occurs near the tube base as the magnet approaches a position over the "flags" and the second occurs as the magnet is pushed beyond the "flags" and near the focus coil. The first position is preferred because it allows greater space for adjustment range. The strong magnet also allows a wider adjustment range and the setting will affect the centering and focus. A last check should be made on beam bender adjustments after focus and deflection adjustments have been made.

BRIGHTNESS CONTROL

The brightness control provides adjustment of picture tube control grid bias voltage. Automatic retrace elimination circuits are incorporated, so that retrace lines are visible only at maximum setting of the brightness control. Proper setting of the brightness is such that light is just visible on the screen when the contrast control is set at minimum with a signal tuned in.

HORIZONTAL CONTROLS

The design of the chassis covered in this bulletin is such that no horizontal linearity control is needed, and no horizontal linearity control will be found on the chassis.

When adjusting the horizontal and vertical controls, it is necessary to have a test pattern or program tuned in on the receiver. Set the tuning of the tuner unit so that sound and picture are both present.

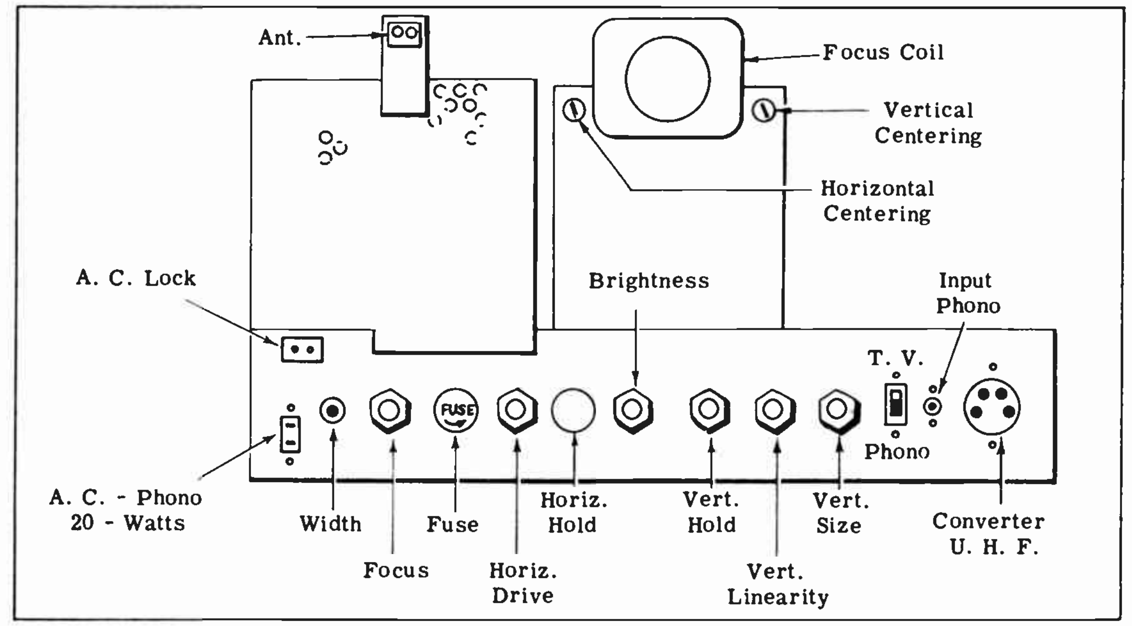

Figure 3. Rear Chassis Controls

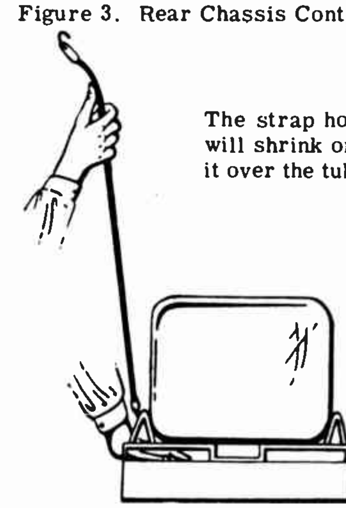
WARNING

The strap holding the picture tube in this receiver will shrink on removal. Do not attempt to restretch it over the tube rim. To reinstall, follow these steps:

Stretch as shown to approximate total length required.



Immediately hook one end of the strap to chassis and re-stretch to required length.

Maintain tension on the strap, bring it over the tube, and hook the free end while holding top.

Figure 4. Strap Installation

The HORIZONTAL DRIVE control (R156) should be adjusted for minimum resistance (full counter-clockwise) or as close as possible. In some instances the minimum setting will permit a vertical white bar to appear in the center of the picture. In such cases the control must be rotated clockwise until the white bar disappears. Once the drive control is adjusted as described, it should not be changed in order to vary the horizontal width or frequency. The HORIZONTAL SIZE control (L110) has a large range of width control, and it should be used to vary the picture width. Minimum resistance of the drive control is recommended so that the tendency toward regeneration ("Christmas tree effect") will be reduced.

The HORIZONTAL HOLD control should be adjusted as follows: Turn the hold control (L109) counter-clockwise (slug coming out of coil) while switching the channel selector on and off channel until sync is lost. Turn the control clockwise (slug going into coil) and check the number of bars or picture segments which appear just before pull-in of the picture. There should be a pull-in from at least one segment for normal operation. Continue turning hold control clockwise while switching channel selector on and off channel until sync is lost again. Turn the hold control counter-clockwise (slug coming

©John F. Rider
World Radio History

out) and check the number of segments that appear before pull-in. Turn the slug an additional 1/4 turn counter-clockwise if one-segment pull-in occurs, or turn slug approximately 1/2 turn counter-clockwise if two-segment pull-in occurs. This setting of the hold control provides best operating characteristics for sync pull-in and drift of the horizontal oscillator, and it is approximately correct for least amount of "hook".

The amplified AGC system used in the receivers covered in this bulletin is very positive in its action. When the receiver is first turned on and warming up, it may be that the AGC action will lock and hold the picture out of sync as well as holding it in sync. In this case, all that is required is to turn the channel selector off and on channel, momentarily releasing the AGC, and the picture will lock into correct sync.

The hold control should be adjusted as described above for best horizontal sync stability, and any horizontal centering of the picture should be taken care of with the HORIZONTAL CENTERING control.

VERTICAL CONTROLS

The VERTICAL HOLD control has a "hold-in" range of adjustment over which the picture will stay in sync. The control should be set in about the middle of the "hold-in" range.

The VERTICAL SIZE and VERTICAL LINEARITY operate together to adjust the vertical height and proportion of the picture. The Size control affects the vertical size of the entire picture, but not in a linear manner. The bottom portion of the picture is expanded and the picture center tends to move toward the top of the tube. Counter-clockwise rotation of the VERTICAL SIZE control increases the vertical size. The linearity control operates to expand the upper portions of the picture, and compensate for non-linearity created by the Size control. Clockwise rotation of VERTICAL LINEARITY control expands the upper portions of the picture.

FOCUS CONTROL AND RASTER CENTERING ADJUSTMENTS

Electromagnetic focusing is used, with the focus coil being used as a choke in the B+ supply circuit. The Focus control, R196, shunts the focus coil. Adjust the Focus control until clear, well-defined horizontal sweep lines can be observed.

Vertical and Horizontal Centering controls are mechanical type which operate by positioning the focus coil. The vertical centering is operated by a spring-loaded screw on the right of the focus coil, and horizontal centering is operated by a similar screw on the left. If difficulty is encountered in focusing or centering, or neck shadows appear, a reversal of the leads to the focus coil will often remedy the situation.

ALIGNMENT

The following alignment procedure describes alignment of the double-tuned video and sound IF circuits used in the chassis dealt with in this bulletin. The procedure for the RF tuning unit is described in separate bulletins, bulletin number 80 covering the turret type tuner unit and bulletin number 124 covering the continuous type tuner unit. The following discussion deals with recommended methods and equipment to be used and precautions to be observed during the alignment procedure. For actual alignment procedure, it is suggested that the alignment table be followed after reading the more detailed procedure.

For best results it is important that alignment be performed on a metal topped bench with all instruments and equipment securely bonded together and to ground. All leads should be as short as is practicable, particularly in the input grid circuits. Isolation circuits will be required for both the input and output connections. It is important that composition resistors, preferably the half watt size, and disc type ceramic condensers be used in making up these isolation networks, so that a minimum amount of external inductance is added to the tuned circuits being adjusted.

A sweep signal generator with a frequency range which includes 24.25 MC, and a sweep width of 10 MC will be required. A marker generator whose fixed frequencies include 4.5 MC, 20.1 MC, 21.6 MC, 24.25 MC, 26.1 MC and 27.6 MC will be needed if not already combined with the sweep generator. A voltmeter with sensitivity of 20,000 ohms per volt or higher and with voltage scale ranges from 50 volts on down as low as 2.5 volts or lower must be on hand. Also included in the instrument list is an oscilloscope with at least a moderately high vertical gain. In general the output signal level from the signal generator should be kept as low as the output indicator being used will permit if overdriving of the receiver stage (s) with its adverse results is to be avoided. In general, too, the RF tuner unit should be tuned to the vicinity of the channel 12 frequency range, but individual circumstances may require that the tuner be set on one of the low channels, depending upon what interfering frequencies are being radiated about the alignment bench. A 3 volt battery should be connected with negative terminal to the AGC bus and positive terminal to ground for the alignment procedure. This is done to establish a circuit gain reference standard which approaches the average value found in the field. It will also reduce any interference pick-up since the gain will be lower than the gain available without AGC. Where receivers are known to be operated in weak signals areas, a lower value of fixed bias voltage may prove more desirable.

ORDER OF ALIGNMENT

The general order of alignment should be as follows:

Sound IF and Ratio Detector Primary
Ratio Detector Secondary
4.5 MC Trap
Sound Takeoff Coil
27.6 MC Adjacent Channel Sound Traps
20.1 MC Adjacent Channel Video Trap
Picture IF Transformers
Converter Output Coil

SOUND IF ALIGNMENT

Equipment:

Set the signal generator to 21.6 MC. Connect the signal to the grid, pin 1 of V101. If the generator does not have a low impedance output, it is suggested that a 75 ohm resistor be shunted across the output terminals. Connect the voltmeter in series with a 10K ohm, isolating resistor to pin 7 of V103.

Procedure:

Adjust T101 primary (bottom), T101 secondary (top), and T102 primary (bottom) to obtain a maximum reading on the meter. The maximum voltage reading should be kept below 3 volts by decreasing the generator output as the windings are tuned to resonance. It is essential that the slugs be moved from the outer ends of the coil form toward the center, by turning the slugs clockwise. If the slug has been moved past the center so that resonance is reached with the slug coming out of the coil, then the slug must be moved out, counter-clock-wise, completely through the coil and the tuning procedure undertaken again. This is necessary because the mutual coupling will be adversely affected and proper alignment will be impossible if the slugs are run into the center of the double-tuned coils.

RATIO DETECTOR ALIGNMENT

Equipment:

Generator and input circuit remain as connected above. Meter should be switched to one of its higher scales, and in the case of a VTVM the zero point can be set up scale to the center position. No isolation resistor is used. Connect one voltmeter lead to the junction of R 107 and R 108 and the other lead to the junction of R 106 and C 114. Temporarily short the grid pin 1, of V 102 to ground.

Procedure:

Adjust the secondary of T 102 for a zero reading on the voltmeter. The polarity of the reading will depend upon which side of resonance the secondary winding is tuned. As the resonant position is approached, the voltmeter scale should be reduced so that a more sensitive zero indication is available. Do not increase the generator output beyond the level which produced the maximum reading above, however.

ALTERNATE RATIO DETECTOR ALIGNMENT

The following procedure is considered less desirable than the one described above because the zero point obtained is not always a true indication of balance due to slight production variations of ratio detector transformers.

The input equipment remains the same as in the first procedure with the addition of a sweep signal of 400 KC width and a 21.6 MC marker signal being added. The voltmeter is replaced by an oscilloscope and isolation network shown in Figure 8. Connect the

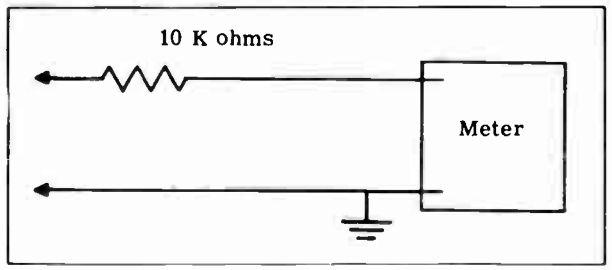


Figure 5.

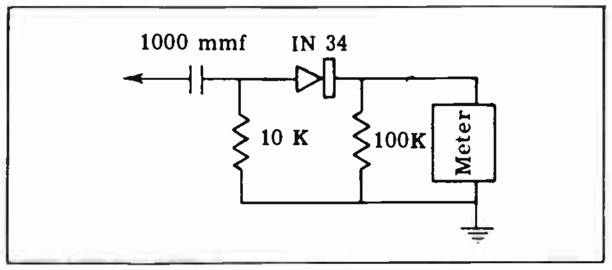

Figure 6.

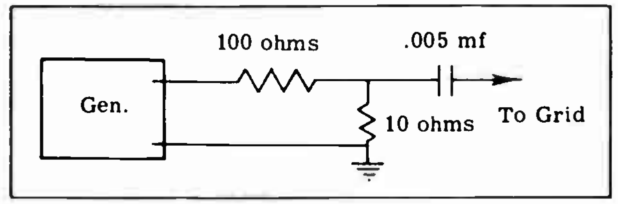

Figure 7.

isolating resistor to the junction of R 106 and C 114. Adjust the secondary (top) of T 102 for an "S" curve which is symmetrical, and has the 21.6 MC marker in the center of the linear or straight line portion of the curve as indicated in Figure 11. Because the center of the "S" curve is a zero or null point, very little 21.6MC marker will come through. However, the marker does produce a series of irregular traces which appear on opposite sides of the linear portion of the curve. These traces should be evenly distributed about the center for correct adjustment of T 102 secondary.

ALTERNATE SOUND IF AND RATIO DETECTOR ALIGNMENT

This alternate procedure offers the advantage of requiring less time to perform, and the results obtained from its employment are independent of whether or not R 107 and R 108 are identical in value. If this unbalance does exist, the zero adjustment determined by the meter method would be slightly in error.

SOUND IF

Equipment:

Connect the sweep generator to pin 1, V101, using the network shown in Figure 7. Set the generator center frequency at 21.6 MC and use a sweep of about 400 KC. The blanking control should be in the on position, so that a baseline is established as a reference. Connect a scope to the junction of R 106 and C 114, using the network shown in Figure 8.

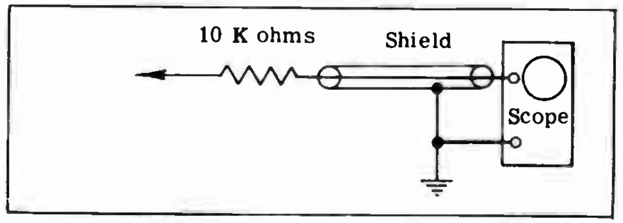

Figure 8.

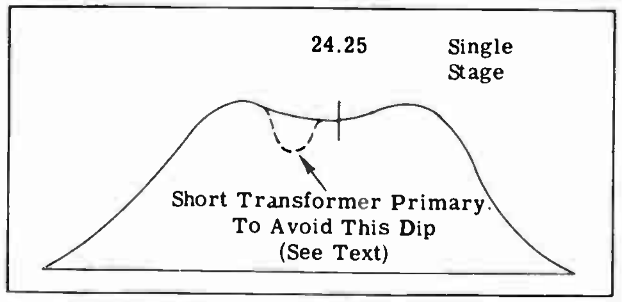

Figure 9.

©John F. Rider

World Radio History

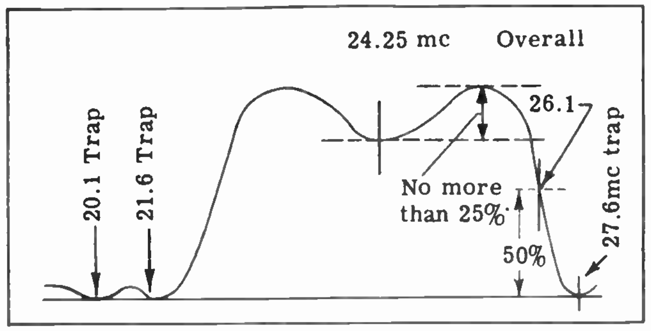

Figure 10.

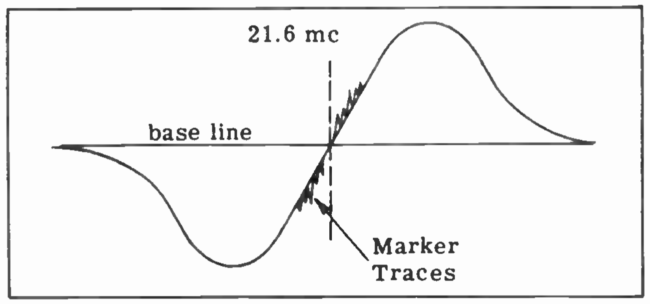

Figure 11.

Procedure:

With the equipment connected as described, some sort of "S" curve will be seen on the scope if the alignment is not too far off from the correct condition. Adjust the primary and secondary of T 101 and the primary of T 102, so that the "S" curve appears symmetrical on both sides of the baseline, so that it has maximum amplitude, and so that it has best linearity over the straight portion.

RATIO DETECTOR SECONDARY

Equipment:

Same as used in sound IF alignment but with the addition of injecting a 400 cycle modulated, 21.6 MC marker signal into the sweep signal.

Procedure:

Now a sine wave should appear along the baseline of the "S" curve as shown in Figure 12.

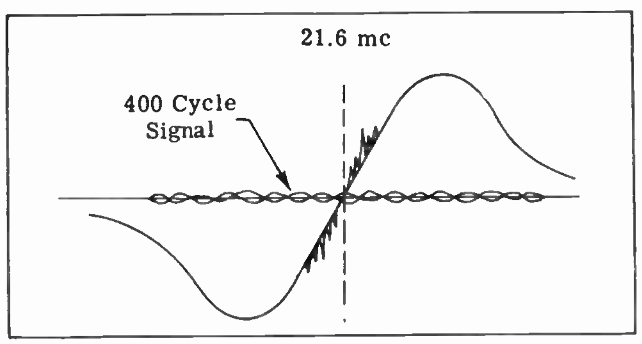

Figure 12.

The 400 cycle signal will not remain stationary, but will appear as a wiggle about the baseline. Adjust the secondary of T 102 until the 400 cycle signal decreases and finally disappears. When this is done, the ratio detector offers the maximum amount of AM rejection.

TUNING 4.5 MC VIDEO TRAP

Equipment:

Connect an unmodulated 4.5 MC signal to pin 1, V 109, using network shown in Figure 7. Use a detector and isolating network with the voltmeter as shown in Figure 6. Connect the detector to the junction of R 141, C 145, and the picture tube cathode lead.

Set the contrast control to mid-range. Adjust the slug of L 108 for minimum reading on the voltmeter. As the null reading is approached, the voltmeter range should be reduced and the input signal increased somewhat to produce a more sensitive indication. If the output level of the generator is less than .25 volts, it will be necessary to connect the 5000 mmf condenser shown in Figure 7 to the generator side of the 100 ohm resistor.

Alternate Procedure:

If the service man is familiar with the appearance of 4.5 MC beat pattern as produced on the picture tube, then adjustment may be made without external signal, generator or indicating device. Tune in a channel, and then mis-tune to a point that would be equivalent to placing the sound IF carrier "up" on the IF response curve. This will produce and be indicated by a relatively weak 4.5 MC beat pattern in the picture. Tune L 108 for minimum beat pattern. This will minimize the beat pattern when the station is properly tuned.

TUNING SOUND TAKEOFF COIL

Equipment:

The equipment complement remains the same as for the 4.5 MC trap procedure, but the signal generator is set at 21.6 MC and moved to pin 1, V 106. The detector-meter combination (see figure 6) is connected to pin 1, V 109.

Procedure:

Adjust the slug of L 104 for minimum reading on the voltmeter. Contrast control should be left at mid-range. The voltmeter range should be progressively reduced and the signal increased slightly as L 104 is tuned to resonance.

TUNING ADJACENT CHANNEL SOUND TRAPS

Equipment:

Equipment complement remains as above, the signal generator unmodulated frequency is set at 27.6 MC. Input and output connections are left undisturbed.

Procedure:

L 105 and L 103 are tuned to give a null indication as above. While tuning one trap, the other trap can be de-tuned by touching the winding with the fingers, giving a more sensitive null for either trap.

TUNING ADJACENT CHANNEL VIDEO TRAP

There are two alternate video input circuits which will be found in early production chassis. Figure 13 shows one circuit which excludes an adjacent channel video trap. Figure 14 shows the other alternate input circuit which includes an adjacent channel video trap.

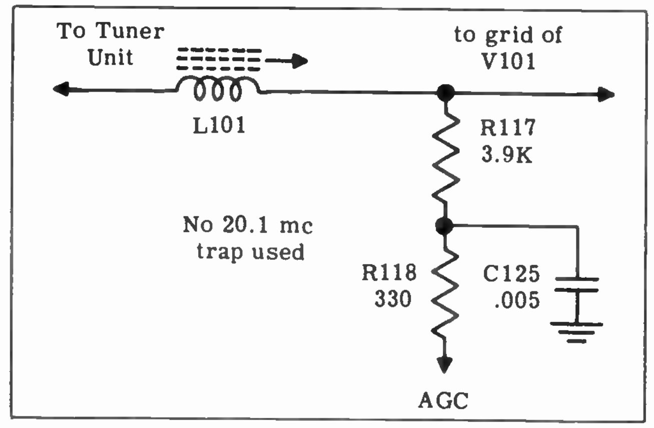

Figure 13.

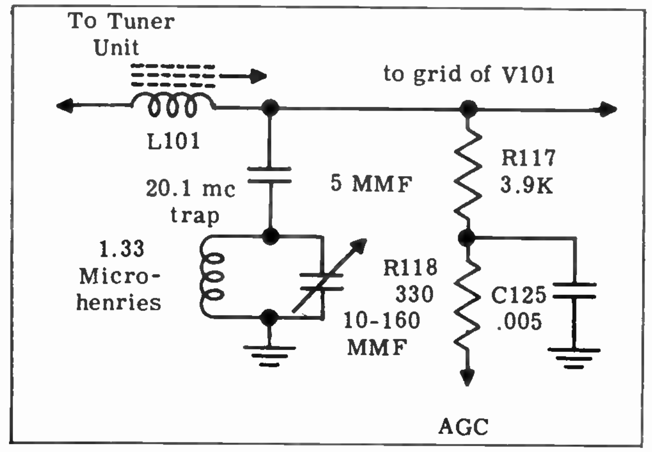

Figure 14.

Equipment:

Equipment complement remains unchanged, (see fig. 6&7). and the unmodulated signal frequency is set at 20.1 MC. The signal generator is moved to the grid of the converter tube, pin 5 of the 6J6 in the tuning unit.

Procedure:

L 102 is tuned for a minimum reading on the voltmeter.

PICTURE IF ALIGNMENT

The picture IF alignment procedure is a process of separately tuning a series of double-tuned, overcoupled stages. Adjustment of each stage is complete in itself and provides a band pass of about 3.8 MC for each stage. No attempt should be made to re-adjust the tuning of an IF transformer once it has been aligned and the signal generator has moved on to the next stage. An erroneous alignment can result even though the overall response may appear satisfactory.

Equipment:

Connect a scope between pin 1, V 109 and ground through the isolating network shown in Figure 8. For first stage alignment connect the sweep generator through the isolation network shown in Figure 7 to pin 1, V 108.

For successive stages, move the generator to each grid in succession. The input signal should be kept low enough so that the stage (s) are not overdriven, but the level should not be so low that the gain of the vertical amplifiers in the scope have to be increased to a point that gives a distorted waveform and overemphasis of any "hash" that may be present.

Procedure:

Set the sweep generator to a center frequency of about 24 MC with 10 MC sweep. Insert a marker signal at 24.25 MC.

For alignment of the 3rd picture IF, adjust the primary (bottom) and secondary (top) of T 106 to obtain a pass band whose top is symmetrical about the marker pip. Skirt positions and slopes will not be symmetrical. See Figure 9. Correct alignment of the stages is indicated by a curve having nearly flat top with equal amplitude peaks. The band-width of each stage is predetermined by design of the transformers and is not varied to any appreciable extent by alignment. A dip may be noticed as indicated by a dotted line in Figure 9. This condition may be eliminated by shorting the primary of the transformer in the plate circuit of the stage preceding the stage under alignment. The sweep generator is connected to the secondary of the transformer whose primary will be shorted. When alignment of a particular stage is completed, remove the short just mentioned.

Next, move sweep generator and isolation network to pin 1, V 107, 2nd picture IF. Alignment of T 105 is accomplished by tuning the primary and secondary to give a symmetrically topped curve as previously described.

Move the sweep generator and isolation network to pin 1, of V 106, 1st picture IF. Align T 104 as was done in previous stages. Response curve should begin to appear approximately as shown in Figure 10. It can be noted that the center dip is greater and the total band pass is slightly less than that of a single stage. Note also the effect of the dips caused by the 27.6 MC adjacent channel sound traps, 21.6 sound trap, and 20.1 MC adjacent channel picture trap.

Connect the signal generator and isolation network to the converter grid in the RF tuning unit. Insert a 26.1 marker. The converter output coil and the picture IF peaking coil, L 101, form a circuit comparable to the IF transformers. Using the converter output coil as the primary and L 101 as the secondary align the IF input circuit to produce an overall response curve as shown in Figure 10. At the same time, tuning of these two coils will position the 26.1 MC point near the 50% point on the response curve slope. The 26.1 MC point (picture carrier) should never be down the slope of the video pass band to more than the 40% point. If this condition is permitted to exist, the sound and picture will not tune to a maximum together, and the low frequency response will be adversely affected. Again, it is emphasized that previously aligned stages must not be touched.

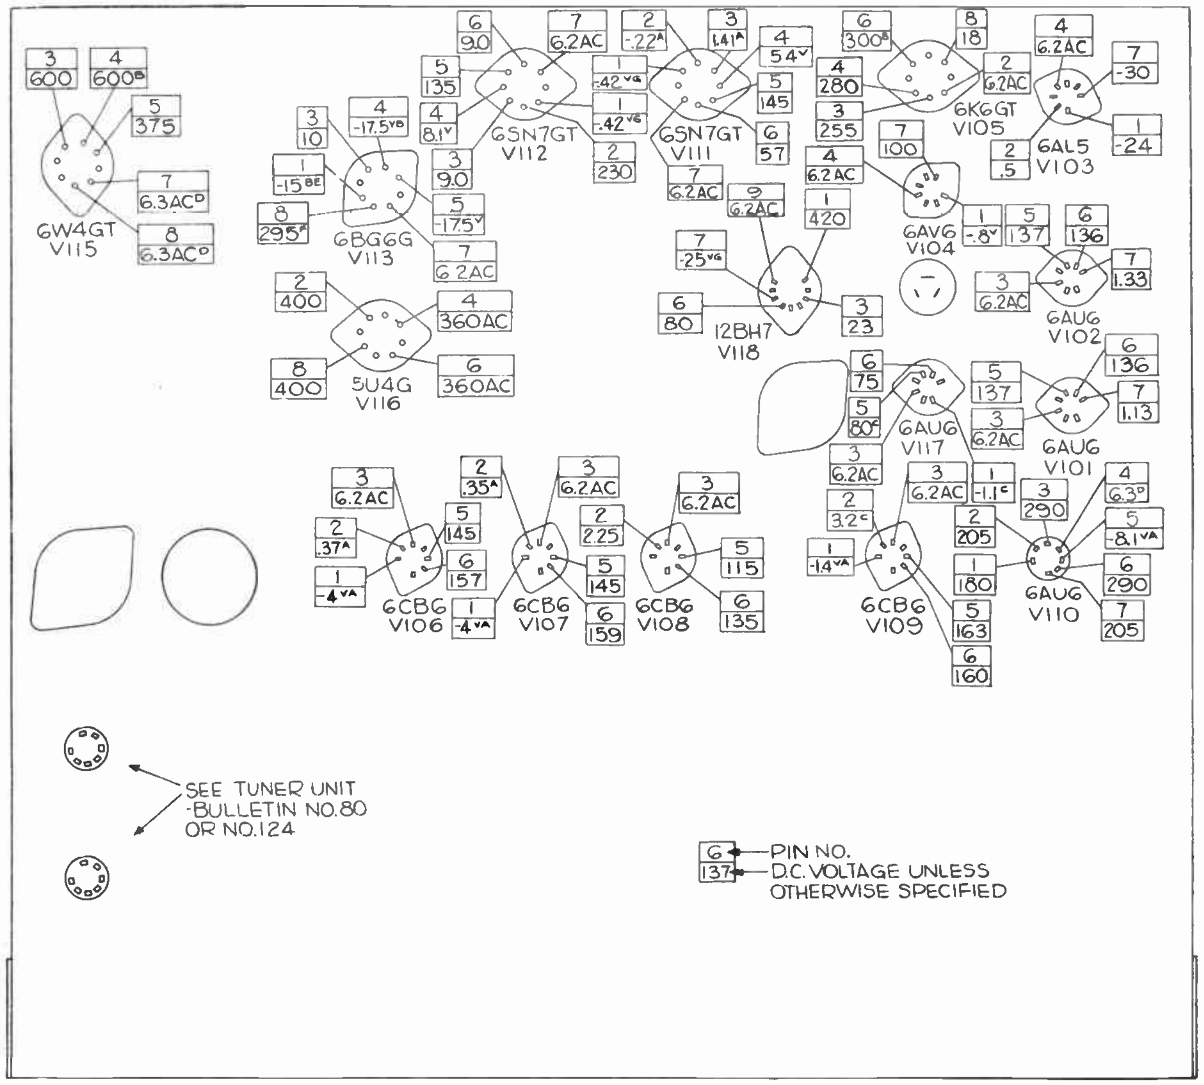
BOTTOM VIEW TUBE LAYOUT
CHASSIS 170, 171, 173, 175



All voltages measured with set receiving picture and sound adjusted for normal operation, medium signal, medium volume and contrast level.

Line Voltage = 115V AC

All bus voltages run about 10 to 20 volts higher than shown on circuit schematic.

Slight variations in voltage values are to be expected due to variations in line voltage and variations from component nominal values.

A - Varies with signal level.
B - Pin used as tie point only.
C - Contrast set at minimum.
D - Measured to other heater pin.
E - No connection on chassis 175.
F - About 40V. less on chassis 170.
G - Depends upon setting of hold control.
V - Measured with V.T.V.M.

BLOCK DIAGRAM

IMPROVEMENT IN DEFLECTION CIRCUITS

A .047 mf capacitor has been added across the vertical deflection coils of the high impedance yoke only. The purpose of this addition was to reduce light vertical bars in the raster due to internal deflection yoke coupling. Since this internal coupling varies among deflection yokes, only a relatively few sets contain yokes that give noticeable indication of these bars. Only those sets in the field that give evidence of these light vertical bars need be serviced regarding this addition. The change was added to all current production as an insurance measure. The physical location of the capacitor is under the chassis. One side is connected to the black vertical deflection coil lead. The other side is connected to a red plastic-covered jumper wire that is in turn connected to the green vertical deflection coil lead.

Old Part	New Part	Difference
--	C193 (4148)	.047, 400V, 20% added across vertical deflection coils

This change has been made on all sets produced after Serial No. I089886

A recent change in the internal structure of some 6BG6G horizontal output tubes has brought about a condition of beam modulation in the 6BG6G. This condition shows up in the raster as a 120 cps horizontal wave of about a quarter inch peak to peak amplitude in extreme cases. This condition will be made negligible by changing the .047 mf screen by-pass capacitor for the 6BG6G to a 4 mf electrolytic or greater. Anything between 4 mf and 20 mf is recommended. Procurement difficulties have delayed the use of the 4 mf electrolytic, and an alternate modification is being used for a short time until the 4 mf electrolytics are delivered. This information is mentioned here in order to aid the service man in recognizing the modification at such time as he may be called upon to service a set that employs the modification. A brief description is as follows: R164 was replaced by two 3.3K, 2 watt in series. R154 was eliminated, and the junction of C153, L109, C154, and R156 was connected to the screen of the 6BG6G.

Old Part	New Part	Difference
C159 (4133)	C159 (4236)	6BG6G screen by-pass capacitor increased to 4 mf, 450V.

PRODUCTION CHANGES IN VERTICAL CIRCUIT

The following production change has been made in order that the vertical circuit be made more flexible for shifting to different types of vertical oscillator-vertical output amplifier tubes as procurement conditions demand.

Old Part	New Part	Difference
R181 (4571)	--	100K resistor between Vertical Hold potentiometer is deleted, potentiometer being connected directly to ground.
R182 (4604)	--	6.8 meg resistor between Vertical Hold potentiometer and plate circuit of blocking oscillator deleted.
--	R206 (4724)	A 5K, 3 watt wire-wound resistor added between vertical deflection coil and R189.
R146 (4511)		100K resistor in 1st anode circuit of CR tube deleted, and 1st anode connected to junction of R189 and R206.
	C194 (4144)	0.1 mf, 600V, 20% added between ground and junction of R189 and R206.

This change has been made on all sets produced after Serial No. J106134

Production is now using a single unit vertical integrator network when the units are available. Because the supply is sporadic, the single unit network will be used interchangeably with the previously used network.

Old Part	New Part	Difference
R176 (4628) R177 (4515) R178 (4515) C169 (4145) C170 (4128) C171 (4128)	Z7 (9695)	Single unit network with three leads replaces six individual components.

Audio Power Output	3 Watts	Cabinet Depth	18 1/2"

PHONOGRAPH CONNECTIONS

Circuit connections are built into these models for attaching an external phonograph. A crystal pickup type record player must be used. A 45 rpm 7" record changer, a Long Playing changer, or a standard changer will produce good results. The phono AC power cord may be conveniently plugged into a socket marked AC PHONO located directly below the AC line cord lock at the left rear portion of the chassis. The phono audio lead goes into an audio jack marked INPUT PHONO located at the right rear portion of the chassis. The audio amplifier system of the TV receiver is controlled by the slide switch located adjacent to the INPUT PHONO jack. When this switch is placed in the PHONO position, the output of the record player pickup is amplified through the TV audio system. The volume is controlled in the normal manner with the volume control at the left front of the chassis. The slide switch marked TV-PHONO has no effect on the picture circuits of the receiver. The CONTRAST control may be turned full off to remove the picture. (Brightness should have been previously set so that light just begins to appear at minimum contrast setting.) All power to the phonograph is turned off when the TV receiver is turned off.

Service information on chassis 170 and 171 is given in Service Data No. 136, and should be referred to when chassis servicing is required.

It may happen that chassis 173 with the 17" picture tube will be found in cabinets similar to those used with Models 634 and 635. Such sets will be designated as Models 634A and 635A, and are identical to Models 634 and 635 respectively except for picture tube and associated hardware.

PRODUCTION CHANGES

CHASSIS 170, 171, 173, 175

SAFETY FACTOR FOR CATHODE RAY TUBE

An additional safety factor on the cathode ray tube heater-cathode potential has been provided in the above listed chassis. This has been accomplished by tying the CR tube filament to a +180 v potential instead of the +265 v potential formerly used.

The following wiring changes have been made in production in order to achieve the above objective. At the AGC keyer tube, V110, the jumper between pins 4 and 6 has been removed. The red (orange in some chassis) wire that formerly was connected to pin 4 of V110 has been moved to pin 6 of V110 so

©John F. Rider

World Radio History

that both red (and/or orange) wires are connected to the same pin. In some early receivers only the jumper need be removed since both wires are already connected to pin 6. A jumper has been run between pins 2 and 4 of V110. So far, then, the result has been to change the filament connection from the +265 v string to the +180 v string. This was necessary because the V110 filament shares its filament winding with the CR tube, and the B+ string leads included in the wiring change serve the dual function of completing the filament circuit of these two tubes and of providing the correct B+ potential to the filament. Continuing the wiring change detail, the transformer filament lead that formerly connected to the +265 v side of the focus control, R196, was moved to pin 3 of the 5U4, V116. Formerly, pin 3, had not been used. An additional orange wire 8 inches long was connected to this same pin 3 and to the tie lug on C183. The black CR tube filament lead was removed from the +265 v string tie lug and wired to the +180 v side of the brightness control (R142). The final result was to change the B+ leads that made up part of the filament circuit shared by the CR tube and AGC keyer tube so that the filament potential of the CR tube was brought closer to its cathode potential. In this manner the safety factor on the CR tube heater-cathode potential has been increased.

IMPROVED TUNING CHARACTERISTIC

A production change involving the audio IF section of the TV receiver has been made in order to make the point of optimum sound reproduction less critical when the head end is tuned. This objective has been accomplished by broadening the sound IF bandpass. Therefore, just as the broad bandpass of the video IF stages makes it possible for the RF oscillator to be detuned slightly, giving a higher or lower center IF frequency without serious changes in picture reproduction, so the broader bandpass of the sound IF stages permits a less critical tuning of the RF oscillator.

In order to increase the bandpass, the following circuit and part changes were made.

Old Part	New Part	Difference
C103, C109 (4029)	C103, C109 (4090)	V101, V102 Screen bypass condensers reduced from .005 mfd to 1500 mmfd.
C108 (4029)	---	Remove from circuit.

REDUCTION OF PICTURE SMEAR

A production change concerning the retrace line elimination circuit has been made in order to reduce picture smear present when the CR tube draws grid current. A study of the schematic diagram, of chassis 170, 171, 173 and 175 will reveal that the retrace line elimination circuit can act as a grid leak biasing circuit for the CR tube grid. When the grid draws grid current as it will when the cathode is driven by relatively high negative peaks (high contrast levels), a negative bias is produced which, tends to bring the CR grid to its cut-off potential. This negative bias remains on the grid until it has has time to leak off via the RC path of the circuits involved. By reducing the RC time constant of the effective grid leak, the grid is not held near cut-off for so long a time, relatively speaking, and the faster recovery makes it possible for the grid to follow the transmitted video information.

The RC time constant was reduced by making the following circuit and part changes.

Old Part	New Part	Difference
R145 (4513)	---	1 meg resistor deleted to reduce time constant.
C146 (4149)	C146 (4029)	Coupling capacitor value change from .0047 mfd to .005 mfd and voltage rating changed from 1000 V to 500 V.
---	C185 (4029)	.005 mfd capacitor added to complete capacity voltage divider.

The circuit changes are indicated in figure 1 below.

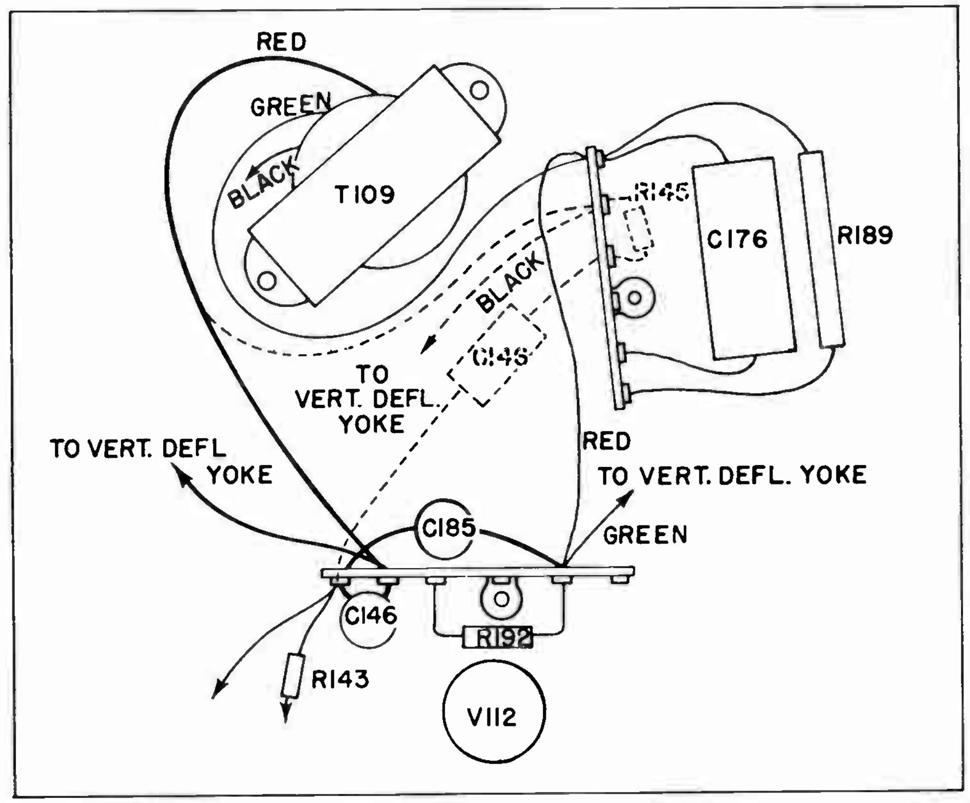

Figure 1

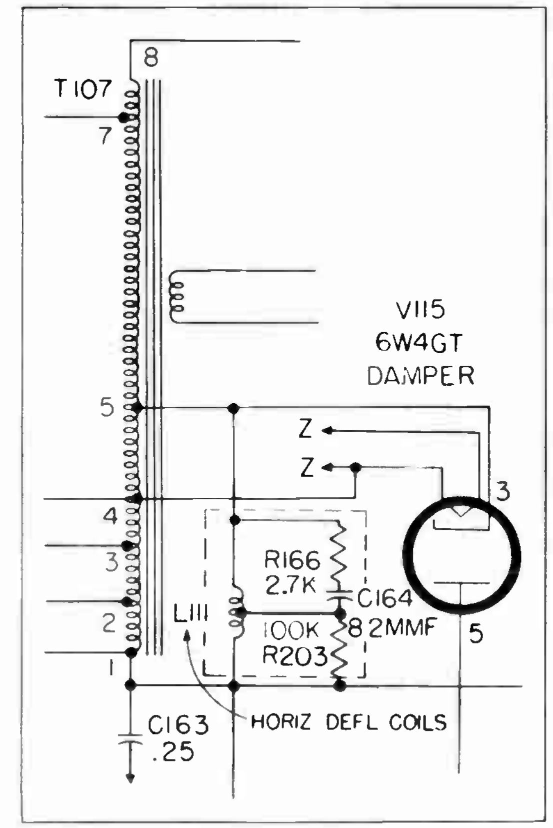
Note: Dotted lines indicate wiring and components before change was made. Heavy black lines indicate wiring and components changed.

PRODUCTION CHANGE
IN DEFLECTION YOKE
CHASSIS 170 SERIES*

A production change involving the deflection yoke assembly has been made in production. The horizontal windings in the yoke assembly used just prior to this change have an inductance of 10.3 millihenries. This value of inductance offered a higher resonant frequency than does the new 25 millihenry winding. The change provides a reduction in the vertical light bars seen on the screen of some early production chassis.

Figure 1 shows the revised portion of the circuit under discussion. Attention is directed to the error in Figure 8, Service Bulletin No. 139. The junction of, L111 and R166 should be shown connected to lug 5 of the horizontal output transformer. The only wiring change made, external to the yoke, is that of moving the connection of the red yoke lead from pin 7 to pin 3 on the 6W4, V115, tube socket. In effect, this change, places the horizontal deflection coils between lugs 1 and 5 instead of between lugs 1 and 4 of the horizontal, output transformer. The reason for moving the yoke lead from lug 4 to lug 5 lies in correct impedance, matching between output transformer and load (deflection coils).

The circuit changes require the change in deflection yoke (L111 and L112), R166, C164, and an addition of a resistor, R203.



Symbol	Value	Tol.	Watts or Volts	Type	Part No.
L111,L112	-	-	-	-	5389
R166	2.7 K	20%	1/2 W	Comp.	4673
R203	100 K	20%	1 W	Comp.	4558
C164	82 Mmfd	20%	1500 V	Mica	4087

The above change will appear on all sets produced after Serial No. H074558

NOTE

*The term "170 Series" includes Chassis 170, 171, 172, 173, 174, 175, 176, and any possible future chassis that are closely related to those listed here. The term will be used in all future bulletins dealing with these chassis.

World Radio History

ALIGNMENT IMPROVEMENT

CHASSIS 170 SERIES

This service note deals with production changes which result in simplification of the alignment procedure and a more nearly ideal video IF bandpass characteristic.

Figure 1 shows identification of parts, and may be used in conjunction with previous schematic diagrams of chassis 170 series in order to accentuate what changes were made. The changes result in an approximately flat topped IF response curve by introducing more resistance loading into the first two video IF transformers and by decreasing the coupling in the second video IF transformer. The loss in gain brought about by these changes is more than balanced by eliminating the by-passed portion of the cathode resistance in the first two video IF stages. The resulting decrease in bias in no way causes the operating ratings of the tubes to be exceeded.

Old Part	New Part	Difference
*R117, R122 (4671)	R117, R122 (4648)	Decreased from 3.9K to 3.3K
R120, R126 (4616) C126, C132 (4029)	---	150 ohm portion of cathode resistance and associated by-pass capacitors not used.
R119 (4639)	R119 (4620)	Resistance reduced from 47 ohms to 39 ohms. No change in rating.
C133 (4082)	C133 (4074)	Capacitance reduced from 1.5 mmf to 1.2 mmf.

The wiring of the two 3.3K resistors and the 1.5 mmf capacitor should duplicate the old components, regarding position and lead length. However, the new R119 resistor and previous R125 resistor should be returned to the suppressor grid ground point rather than returning the resistors to the grounded tie lugs of the tie point strips. The latter connection would introduce unwanted inductance into the IF circuits.

These changes have been made on all sets produced after Serial No. G067626.

*R117 should be reduced to 1.8K (4640) in those chassis which employ the alternate adjacent channel sound trap shown in figure 14, Service Bulletin No. 136. This alternate trap may be easily identified by the ceramic trimmer capacitor mounted on the lip of the IF sub-chassis near the first video IF stage.

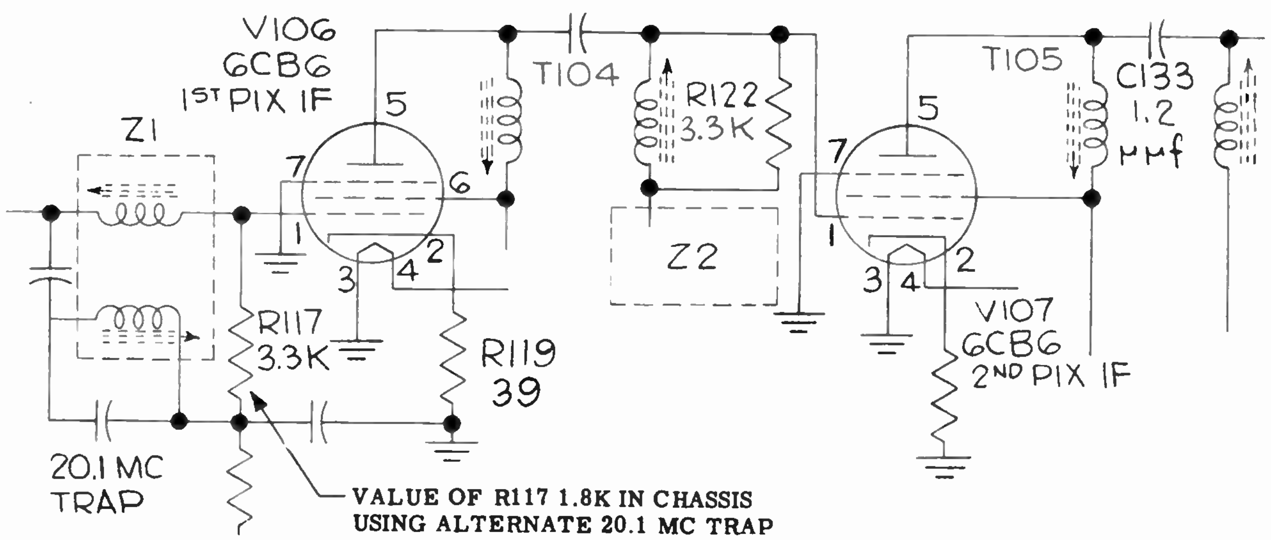

Figure 1. Portion of schematic diagram, TV chassis 170 series, showing component changes for improved alignment. Only changed components have been labeled with numerical values.

PRODUCTION CHANGES
ELIMINATION OF "CHRISTMAS TREE" EFFECT
SHADING AT TOP OF PICTURE
ELIMINATION OF SMEAR
CONTRAST IMPROVEMENT

CHASSIS 170 SERIES

ELIMINATION OF "CHRISTMAS TREE" EFFECT

There are some receivers in the field that are troubled by "Christmas tree" under certain operating conditions, such as occurs during between-channel tuning or tuning to one particular channel. This condition may be remedied by reducing the resistance value of R157, the 220K resistor that is in series with the HORIZONTAL DRIVE potentiometer.

Old Part	New Part	Difference
R157 (4618)	R157 (4589)	Value of R157 reduced from 220K to 150K. No change in rating.

This change has been made on all sets produced after Serial No. G067626.

SHADING AT TOP OF PICTURE

In order to eliminate the dark shading at the upper portion of the picture that occurs on some receivers at low contrast settings, the following changes are recommended:

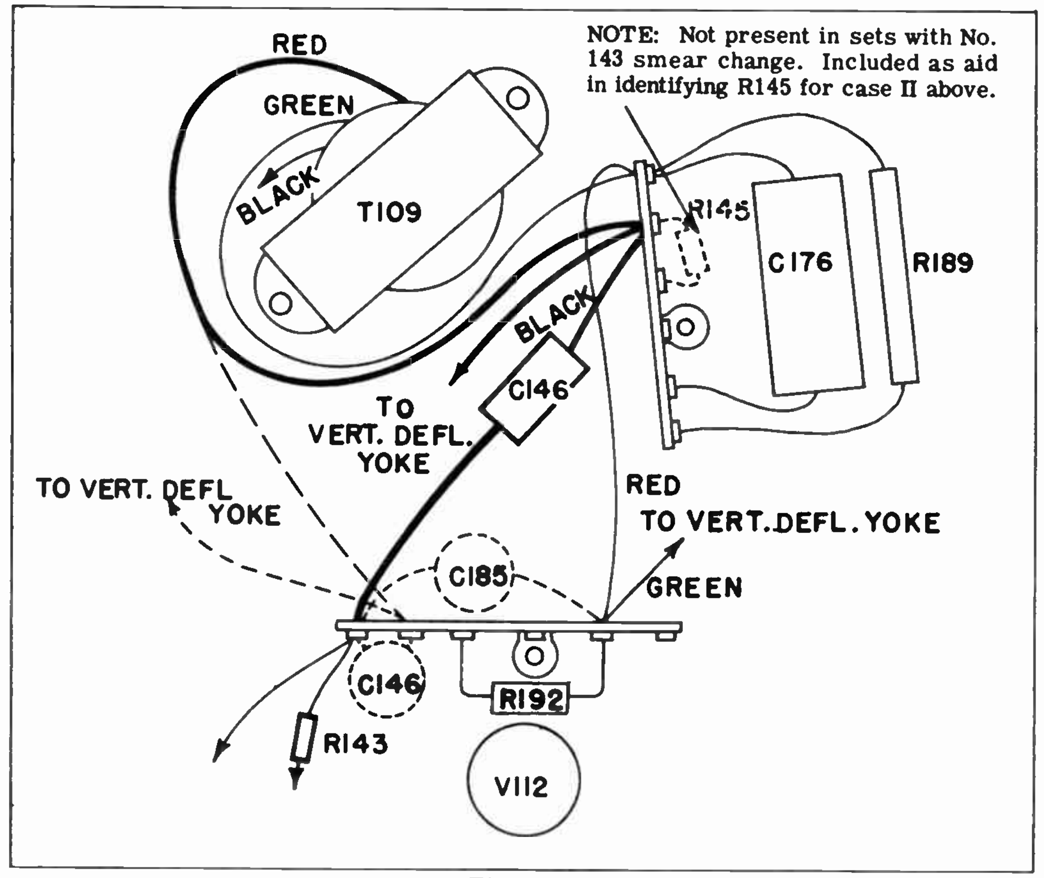

Figure 1

Dotted lines indicate wiring and components before shading change was made on those sets in which the smear change of Bulletin No. 143 was made. Heavy black lines indicate wiring and components changed.

©John F. Rider

World Radio History

Case I - Sets containing smear change indicated in Figure 1.

Remove C185 and reduce the resistance value of R143 to 100K ohms. Change C146 to a higher voltage rating and rewire as indicated in figure 1.

Case II - Sets that do not contain smear change shown in Figure 1.

Move C146 lead to other side of R145, eliminating R145 from the circuit. Reduce resistance value of R143 to 100K ohms.

Old Part	New Part	Difference
C185 (4029)	---	C185, .005 mfd Hi-K removed from circuit.
R143 (4513)	R143 (4511)	R143 reduced from 1 meg to 100K. No rating change.
C146 (4029)	C146 (4149)	C146 change from .005 mfd, 500 v to .0047 mfd, 1000 v. (Case I only)

This change has been made on all sets produced after Serial No. G067626.

NOTE: C146 and C185 shown in Figure 1 have their "C" numbers erroneously interchanged in the circuit schematic, Figure 8, Service Bulletin No. 139. This must be kept in mind if reference is made to this schematic concerning the change described above.

ELIMINATION OF SMEAR

Smear, as exemplified on the screen by trailing shades from black toward white after large dark objects and white toward black after large white objects, and a general fuzzy appearance throughout the picture, is still present in some sets incorporating the smear change covered in Service Bulletin No. 143. The remaining smear is caused by insufficient low frequency response of the video amplifier, and it may be eliminated by an increase in low frequency response. To accomplish this, the coupling capacitor between the video amplifier and the CR tube should be increased in value.

Old Part	New Part	Difference
C145 (4029)	C145 (4131)	C145 increased from .005 mfd, 500 v to .22 mfd, 200 v.

This change has been made on all sets produced after Serial No. G067626.

CONTRAST IMPROVEMENT.

Field reports have indicated that more picture contrast is desirable at high level settings of the CONTRAST control. The condition shows up as a washed out appearance of the picture. The effect has been due to the linear relationship between increase in contrast and increase in brightness. In order to obtain a picture that appears to have more contrast at high contrast levels, the relationship can be made non-linear by the following change. Increase the resistance value of R141. When this has been done the picture brightness will increase at a slower rate than the rate of increase in picture contrast.

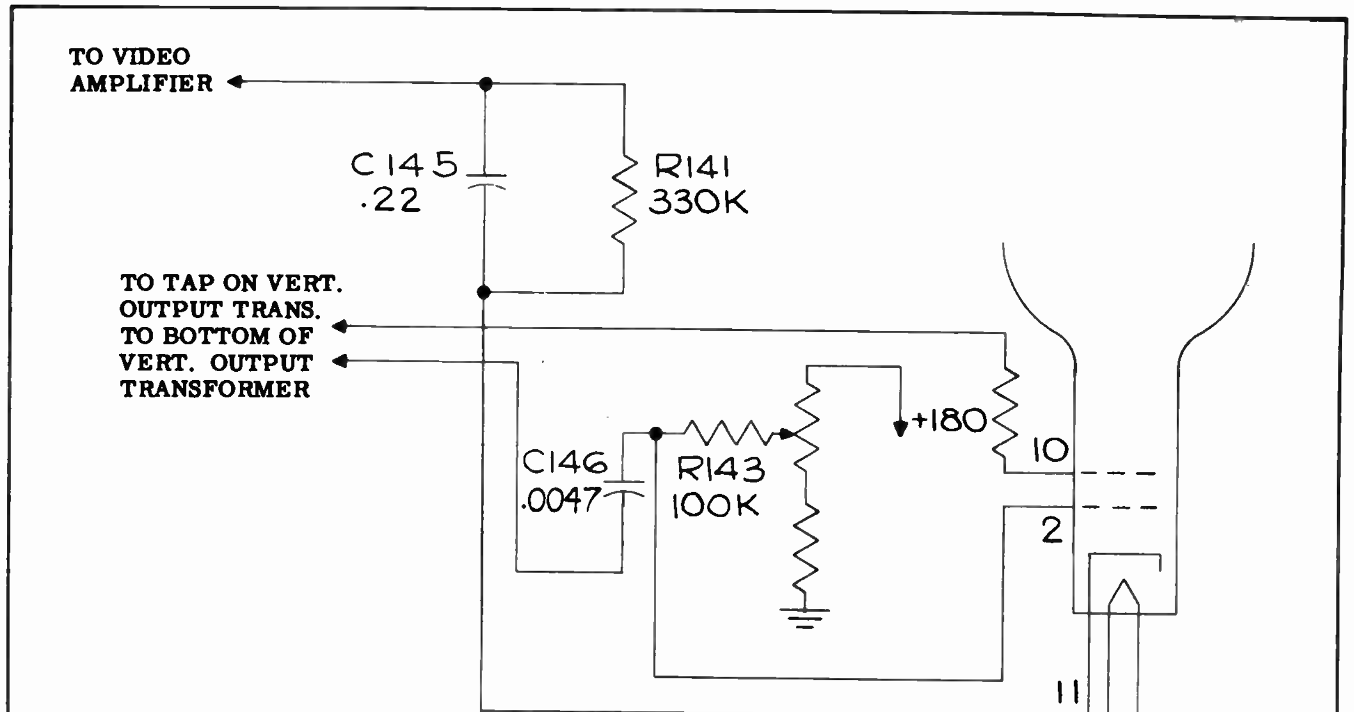
Old Part	New Part	Difference
R141 (4511)	R141 (4677)	R141 increased from 100K to 330K. No rating change.

This change has been made on all sets produced after Serial No. G067626.

CONTRAST CHANGE

All 170 Series chassis are being produced with a 680-ohm resistor connected in shunt across the contrast potentiometer. The physical location of the new resistor is from pin 2 of V109, the video amplifier, to ground. The maximum resistance in the cathode circuit of the video amplifier is lowered, and the minimum contrast level previously obtained is raised. This means that the seldom used lower third of the contrast range is dispensed with, and the more useful range that remains is spread out over a greater scale. It is important to note that the recommendations for setting the brightness control are now different. The recommended procedure for setting the brightness control is to set the control for medium brightness at minimum contrast setting. This will produce a picture with average background characteristics at about three-quarters contrast setting. For individual tastes that vary from this recommendation, the brightness control may be set so that it is most pleasing to the observer.

Old Part	New Part	Difference
-----	R207 (4514)	680 ohms, 1/2 watt, 20% resistor added in parallel with contrast potentiometer.



Portion of schematic diagram, TVchassis 170 series, showing component changes covered in this bulletin. Only changed components have been labeled with numerical values.

Figure 2.

DEFINITION IMPROVEMENT

CHASSIS 170 SERIES

Closely associated with the smear effect as far as picture appearance is concerned, is the general lack of contrast which shows up in the picture as a reduction of fine detail. This effect is caused by a falling off of the high frequency end of video response in the video amplifier circuit. The response may be improved by making the following changes which may be identified in Figure 1. Remove R139 and replace it with a short piece of hook-up wire. It is suggested that the leads of R139 be kept as long as possible during its removal so that it may be used to replace R138. Remove R138 and connect a 47K resistor between the junction of L106, L107 and the tie lug previously used for connecting R138 to C166. Change C166 to 220 mmf. Change R168 to 10 meg. Remove C167. These changes will introduce less loading on the video amplifier without changing the noise immunity going into the 1st sync separator.

©John F. Rider

World Radio History

Old Part	New Part	Difference
R139 (4504)	---	R139 replaced by direct connection.
R138 (4515)	R138 (4504)	R138 increased from 10K to 47K. No rating change.
C166 (4146)	C166 (4026)	C166 decreased from .001 mfd. to 220 mmf, 20%, ceramic.
R168 (4605)	R168 (4505)	R168 increased from 1.5 meg. to 10 meg. No change in rating.
C167 (4009)	---	C167 removed from circuit.

These changes have been made on all sets produced after Serial No. H070169.

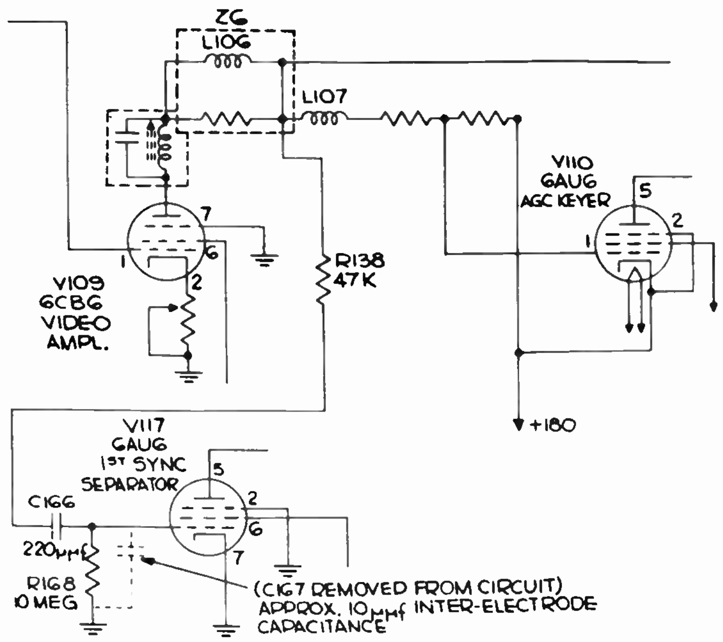


Figure 1
Portion of circuit schematic for chassis 170 series. Only those components affected in the changes are labled with numerical values.

INCREASE 21.6 MC TRAPPAGE

CHASSIS 170 SERIES

Some receivers are being troubled by excess 4.5 mc beat interference and sound in the picture. This unwanted situation makes it impossible to obtain a clear picture when the tuner is adjusted correctly for best sound. The difficulty may be eliminated by increasing the 21.6 mc trappage.

Figure 1 may be used as an aid in identifying the following changes. The additional 21.6 mc trap is obtained by converting Z4, at present one of the two 27.6 adjacent channel sound traps. Z4 is converted by increasing the capacitance in the parallel tuned circuit to 15 mmf. This is accomplished by shunting C143 with an additional 5 mmf condenser and peaking the converted trap to 21.6 mc. Conversion of Z4 to 21.6 mc results in less 27.6 mc trappage, so the connections on Z2, the other adjacent channel sound trap must be changed to provide the additional trappage. To alter Z2 disconnect the bare lead from the tap on the trap inductance. The tap connection is the one that is not connected to either side of the 10 mmf parallel condenser. Reconnect the bare lead to the trap lug that also has the 330 ohm resistor and .005 mfd condenser connected to it. Connect a 1.5 mmf condenser between pin 1 of the second video IF amplifier, V107, and the lug on the trap inductance to which only the parallel condenser C129 is connected, keeping the leads as short as possible. Peak Z2 for 27.6 mc.

Old Part	New Part	Difference
---	C190 (4081)	Shunts C143 with 5 mmf.
---	C189 (4082)	Add 1.5 mmf condenser between high side of trap and grid of V107.
Wiring change		Bare lead moved from tap on trap to low side of trap.

It is recommended that this change be made at the time the alignment change (bulletin No. 145) is made.

The additional 21.6 mc trappage has eliminated the need for the 4.5 mc trap, and factory production has eliminated its usage. It is recommended that the slug for the 4.5 mc trap be removed in all sets so that there will be no possibility of this trap causing a dip in high frequency response should it be misadjusted below 4.5 mc toward the high frequency end of the video response.

These changes have been made on all sets produced after Serial No. H069463

There are several hundred sets with serial numbers lower than the given number which also incorporate the change. However, in these sets the 4.5 mc trap is present, but the slug has been removed.

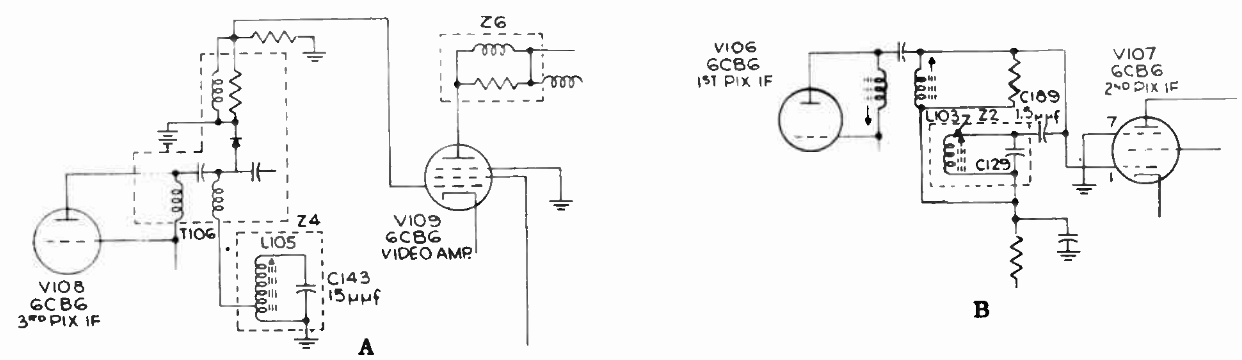

Figure 1.

Portions of circuit schematic for chassis 170 series showing trap changes. Only components included in change have been given numerical values.

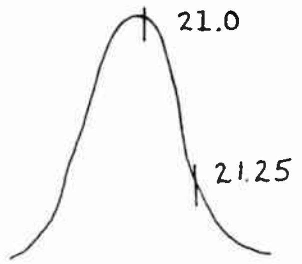
I.F. Alignment Procedure, IT-61R
Models 761, 1161, 1261, and 1361

REFERENCES: Circuit Diagram E-585
EQUIPMENT: Component Location Label 33D-583

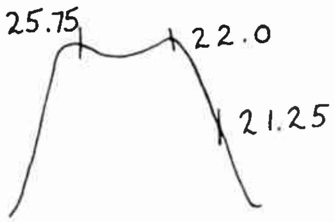
1. Sweep generator, 23.5 mc. center frequency, 10 mc. sweep width.
2. Marker generator, 21.25 mc., 22.0 mc., and 25.75 mc.
3. Crystal oscillator, variable output, 4.5 mc. unmodulated.
4. Oscilloscope.
5. 20,000 ohm per volt meter.

PROCEDURE, VIDEO I.F.:

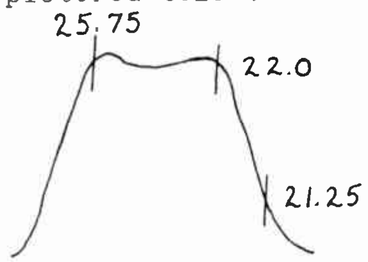
1. Connect oscilloscope to J1 test point.
2. Move tuner between channels to disconnect coils.
3. Short circuit the two component mounting lugs next to detector socket (V6) which are (1) the junction of R21 and C20, and (2) the junction of R26, C26, and R25. This places fixed bias on the A.G.C. line.
4. Connect sweep generator, decoupled with 1000 uuf., to pin 1 of V5. Turn the slug on L18 until it is centered in the coil. (This narrows the band pass of this stage.) Adjust L19 and L17 until the pass appears as below:



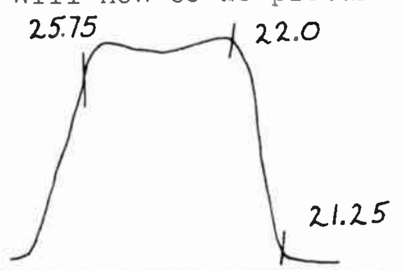
Now adjust L18 until pass is as pictured:

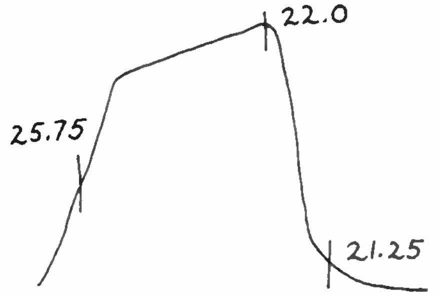


5. Move sweep generator to pin 1 of V4. Adjust L16 until pass balances, adjust L14 until pass balances. When properly adjusted, pass will look as pictured below:



6. Move sweep generator to pin 1 of V3. Adjust L13 and L11 as in above step. Pass will now be as pictured.





7. Move sweep generator to test point on tuner chassis); adjust L8 (square can on tuner) until the pass rocks through a tilt and leave adjusted with a 10% tilt in the pass, as pictured below:

The video I.F. is now correctly aligned.

INTERCARRIER SOUND SYSTEM:

1. Connect voltmeter, set on 10 volt scale across C42, observing polarity.
2. Insert 4.5 mc. generator, capacity decoupled, in J1.
3. Reduce signal so that voltmeter reads a maximum of 3.0 volts, and continue to reduce as adjustments are made so as not to exceed this value.

Adjust in the order given, the following transformer slugs for maximum output:

a. Bottom slug, T3.
b. L23.
c. Top slug, T3.

Repeat to insure accurate setting.

Intercarrier sound system is now properly aligned.

INDEX

GENERAL DESCRIPTION

Television chassis model 231 is a television receiver employing 19 tubes, plus 1 power rectifier, 2 high voltage rectifiers and a television picture tube. Television chassis model 242 has an additional tube for keyed AGC. Chassis model No. 231 is used in the following models:

231	Open Face Table Model	16" Rectangular Picture Tube
232	Table Model With Doors	16" Rectangular Picture Tube
233	Open Face Console	16" Round Picture Tube
234	"Hide-Away"	16" Round Picture Tube
235	"Windsor"	16" Round Picture Tube
236	"Normandy"	16" Round Picture Tube
237	"Cambridge"	16" Round Picture Tube
238	Open Face Console	19" Round Picture Tube
239	"Hide-away"	19" Round Picture Tube
240	"Windsor"	19" Round Picture Tube
241	"Normandy"	19" Round Picture Tube
731	Open Face Table Model	17" Rectangular Picture Tube
733	Open Face Console	17" Rectangular Picture Tube

SPECIFICATIONS

Overall Dimensions:

Model	Height	Width	Depth	Shipping Weight
231	19"	23¾"	21¼"	90 lbs.
232	21¾"	23"	23½"	104 lbs.
233	38⅛"	24"	21-9 16"	115 lbs.
234	38¼"	27"	24"	170 lbs.
235	38"	28½"	23½"	164 lbs.
236	40"	27"	24½"	165 lbs.
237	42½"	26"	24½"	134 lbs.
238	38⅛"	24"	21-9 10"	119 lbs.
239	38¼"	27"	24"	172 lbs.
240	38"	28½"	23½"	166 lbs.
241	40"	27"	24½"	160 lbs.

OPERATION OF KAYE-HALBERT MODEL 231 TELEVISION CHASSIS

1. Turn the left inside bar knob slightly to the right to turn on the set. This knob also controls the volume. Allow a few minutes for the set to warm up. The sound will come on first, followed by the picture.
2. Turn the right inside bar knob until the number at the top of the dial indicates the channel desired. This is the channel selector.
3. Adjust the outside ring of the knob on the right until the picture is clearest and sharpest. Disregard any change in sound volume that may occur and tune for the best picture. This is the fine tuning control and adjusts the positions of the I.F. pass band and traps in relation to the sound and picture carriers. When adjusted so that the picture is clearest, the sound carrier will be centered on its trap at a very low part of the I.F. curve.
4. Adjust the outside ring of the left knob for contrast of the picture; if turned too high the whites may be saturated. It may be necessary to adjust this control before turning for best picture with the fine tuning control.
5. Adjust the sound volume.

No other adjustment is necessary while operating the receiver and in most cases the channel selector may be turned from station to station without touching any other control.

ADJUSTMENT OF SET WHEN PUTTING INTO SERVICE

All external rear controls should be checked by the dealer.

Brightness is set by turning the brightness control until the black areas of the picture are dark. If set too low, the picture will have an unpleasant dark and contrasty appearance. If too high, the blacks will appear gray and the picture will have a washed out appearance.

The vertical hold control is turned until the picture moves in from the bottom with a slight snap. The vertical hold, height, and linearity controls are slightly interactont so it is well to check the hold control if the others are moved.

Adjust the height and linearity by means of a test pattern. Make the distance from the center of the pattern to the top of the picture about the same as from the center to the bottom. Our circuits are capable of excellent horizontal and vertical linearity but a slight non-linearity will never show on the picture.

The horizontal frequency control is adjusted until the picture pulls in on a weak signal. Remove or short the antenna until the picture becomes faint, turn the tuner off channel to break the sync lock-in and return the tuner to a station. The horizontal should pull in. If it does not, adjust the horizontal frequency control until it does. This is usually all that is required. If there is a wide latitude between left and right pull-in, set the horiz-freq control in the center of these two positions.

Note that lock-in has a much greater range than pull-in. It is unlikely that any adjustment is necessary as the horizontal hold is set at the factory.

Focus is set by turning the focus control until the picture is sharpest. It is usually noted at a point off center of the tube so that edge focus is not deteriorated too much. In the absence of a picture the raster lines may be focused to as sharp a line as possible.

Horizontal drive is normally nearly full on (clockwise). If a predominant vertical white line appears, or in some cases horizontal picture instability, reduce the drive slightly. Too little drive will result in poor width and a dim picture.

Horizontal linearity adjustment is controlled by a screw located on top of the chassis near the 6W4 tube. Sometimes a vertical white line may occur with improper linearity adjustment. Turn until this line disappears.

The width adjustment is controlled by a screw on top of the chassis near the 6AU5 tubes. To increase width, turn clockwise.

CENTERING AND ION TRAP ADJUSTMENTS

Adjust the ion trap for brightest picture. Do not leave the ion trap out of adjustment any longer than necessary as it is possible to burn the tube aperture. The ion trap may be used to help center the picture if necessary, but do not move it appreciably from the brightest position.

Vertical centering is accomplished by the top and bottom elastic stop nuts on the focus coil mounting. Use a ⅜" spintite wrench. Horizontal centering is accomplished by the elastic stop nuts to the left and right of the focus coil. There is some interaction between these two adjustments.

70° deflection tubes tend to have a shadow on the screen if the focus coil is moved too far. Shadow may be caused by the yoke, focus coil or ion trap, usually the focus coil and ion trap. To help in centering, move the focus coil left or right by loosening the screw on top. This screw locks the yoke coil after adjusting the picture "level" on the screen. The yoke should be as far forward on the tube as possible. The focus coil should be up close to the back of the yoke and centered around the neck of the tube. It should also be parallel with the back of the yoke (not bent or tipped).

If the focus coil is angled and not close to the back of the yoke, picture weave may be noticed. To test for this effect, move the focus control back and forth. If the picture moves back and forth horizontally, weave will occur. One quarter inch of movement is satisfactory.

To help meet all of these conditions, electrical horizontal centering has been used in the set. Some sets have fixed electrical centering. This can be altered by putting, or changing, a resistor (less than 1000 ohm) across the selemium rectifier.

FRONT END OSCILLATOR ADJUSTMENT (Standard Tuner)

The front end is adjusted at the factory and ordinarily need never be changed. Once properly set it does not need to be adjusted. It will not be necessary to do so at the customer's installation, as handling or different antennas will not affect it. Any slight drift will be compensated for by the fine tuning control.

To adjust, pull straight forward on both double knobs on the right side of the set and remove. Set the inside shaft, using the knob if necessary, so that the tuner is on the right channel. (This is important as it is possible to tune channel 13 on channel 12.) Then set the fine tuning (outside shaft) to center position (flag pointing down). Using an insulated screw driver, turn the small brass slug through the hole in the tuner frame. One quarter turn will probably be sufficient. *Do Not Turn Too Far In*, as the slug will drop inside the coil, requiring a special tool or removal of the chassis to recover it. Turning too far out may cause the slug to come out. Turning the slug in will cause the picture to go negative. Back off from this position by unscrewing the slug until the picture is clear, as under operating instructions, fine tuning. Now note the sound. If the sound is extremely weak, not present, or fuzzy, you probably tuned on adjacent channel. (13 on 12 for example.)

Due to the extreme sensitivity of this receiver you may see a picture on an adjacent channel (such as 4 on 3). This is due to the slight remaining sideband not suppressed at the transmitter.

Do not be confused by it. No sound or very weak sound will be present in this case.

SERVICE SUGGESTIONS

1. No picture, no sound, no raster:

A. 5U4 filaments do not light:
   1) AC switch defective
   2) AC plug or leads open
   3) Make sure set is connected to 117 volt supply.

B. No (B+) voltage:
   1) 5U4 rectifier
   2) Open focus coil
   3) Shorted or leaky electrolytic filter condensers.

2. Picture ok, no sound:

Trouble lies in sound IF or audio section:
Speaker or speaker leads open, 6K6, 6AV6, 6AL5, 6AU6 sound IF, or open volume control.

3. Sound and raster ok, no picture:

Open peaking coil or open .1 mf condenser, both in series in picture tube grid circuit.

MODELS 231, 232, 233, 234, 235, 236, 237, 238, 239, 240, 241, 731, 733, Chassis 231, 242

©John F. Rider

World Radio History

4. Sound ok, no picture, no raster:
Indicates possible trouble in high voltage circuit:
1) Open .1 mf condenser from grid (pin 4) horiz osc to ground (in some cases).
2) One of two .22 mf condensers open (pin 8 to pin 3, and pin 3 to ground) of horizontal output tubes.
3) Open cathode resistor (100 ohm, pin 3 to ground) of horizontal output tubes.
4) Leaky coupling condenser (330 mmf, pin 5 to pin 1) of the horizontal oscillator.
5) Either of two 1 meg resistors in voltage doubling high voltage circuit may have changed values.
6) Either or several of these tubes: 6SN7 horiz osc, 6AU5 horizontal output, 1V2 HV rect, 6W4 damper, 6AL5 horiz phase, or the CR tube.

5. Raster ok, no picture, no sound:
Tuner, 12AU7 video out, any 6CB6 IF tube, open IF coils, shorted screen bypass condenser in IF stages.

6. Picture rolls vertically, horiz ok:
Leaky integrator, 12AU7 sync separator, leaky .05 sync coupler to pin 3 of 12AU7 sync separator open or leaky. .1 mf cond to pin 6 of 6S4 vert out, open or leaky .05 mf cond joining above mentioned .1 mf and 8200 ohm resistor connected to pin 2 of vert out 6S4.

7. Diagonal bars (horiz freq), vertical ok:
Adjust horiz hold control, replace 6SN7 horiz osc, 12AU7 sync sep, leaky .05 sync coupling cond connected to pin 3 of 12AU7 sync sep, 6AL5 horiz phase, leaky 1000 mmf cond from 12AU7 sync sep to pins 5 & 7 of horiz phase.

8. Vertical and horizontal roll:
Shorted integrator block, 12AU7 sync sep, shorted or open .05 connected to pin 3 of 12AU7 sync sep, leaky .1 mf connected to grid of CR tube, physical shorting at base pins of 12AU7 sync separator.

9. Sound bars:
A. Volume control at zero:
1) replace 6AU6 sound IF
2) check setting of 20.5 mc trap
3) check setting of ratio det null
4) check alignment.
B. Sound bars only with advance of vol control:
1) replace 6K6 audio output
2) replace 6AL5 ratio det tube and 6AV6 first audio tube
3) in extreme cases, remove all leads from screen grid of 6K6 audio out (pin 4) and reconnect these leads to the same grid through a 1000 ohm, 1 watt resistor, and place an 8 mf 450 volt electrolytic from pin 4 to ground.

10. Miscellaneous troubles:
A. Intermittent blowing of fuses—6W4 damper or 6AU5 horiz out.
B. Low IF screen voltage—shorted screen cond in tuner.
C. Can't cut down brightness in CR tube—short in CR tube, replace.
D. Tuner fine tuning changes horiz freq—trouble in horiz phase circuit. Suggest check for shorts, change 6AL5 horiz phase; or either of two 1000 mmf coupling cond to 6AL5 phase tube leaky.
E. Picture shakes in horiz motion when contrast control is advanced—cut out and remove 10 mmf condenser connected between pins 1 & 9 of 12AU7 sync sep, if cond is in circuit.
F. Sound and picture not together—may be weak antenna. Weak signal of any sort can exaggerate this condition. Realign sound IF and ratio detector. Check IF curve.
G. Focus pot and parallel 1200 ohm resistor burn—focus coil open.
H. "Pie Crust" effect—may be one of two types:
1) Change 6SN7 horiz osc.
2) Dress green lead from grid of CR tube away from 6SN7 horiz osc.
3) .1 mf cond between pin 4 and ground of 6SN7 horiz osc open.
I. Picture weave—electrolytic open. Also see modification sheet for weave (involves changing filter network from 40 mf input and 80 mf output to 80 mf input and 40 mf output).
J. Raster looks like an ancient "scroll"—electrolytic open.
K. Corona at HV trans—look for sharp pointed solder joints, especially near final 1V2 filament.

EFFECT OF CONDENSOR FAILURES IN DEFLECTION CIRCUIT

PART	OPEN	SHORTED

C-48	Stretch in Horiz. Dir. of left side of pict.	Same as open.
S-1	Horiz. Centering control inoperative.	
C-50	Faint picture due to low H.V.-H.V. falls to 6000 V.	Very faint picture. H.V. falls to about 3000 V.
C-51	No loss of H.V. slight jitter.	Very faint picture H.V. falls to about 3000 V.
C-57		No H.V.
C-40	Loss of H.V. due to Horiz. Osc. Waveform at pins 1 & 2 of Horiz. phase tube jitters.	Loss of Horiz. Sync.
C-37	Reduced Vert. sweep roll	Extended Vert. sweep.
C-36	Vert. Osc. Changes Freq.	Vert. sweep reduced greatly.
C-34	Loss of vertical.	Same as open.
C-27	Vertical bright bands at left of picture.	Excessive brightness. No brightness control action.
C-28	No change.	

BEND

Bend can be caused by unbalance of the horizontal sync pulses to the 6AL5 Horizontal phase tube or the tube itself. To check balance, tune in a station and connect a VTVM across R-50 (4.7M).

Remove the sawtooth wave by connecting pins 1 and 2 of the 6AL5 Horizontal phase tube to ground. The VTVM will then read the sync unbalance voltage. It should be no more than plus or minus .5 volts. To balance temporarily, place approximately 33 K ohms across R-46 or R-43 (12AU7 phase inverter) whichever improves the balance.

After determining whether R-46 or R-43 needs correcting, select a value of resistor which brings the balance voltage within tolerance, then solder in place. Sometimes bend can be compensated by a little unbalance, but do not exceed the tolerance given.

BUZZ AND HUM

Buzz can be traced to many sources. Some of the most common will be mentioned. The first source of both buzz and hum may be the station. Station technique may not always be perfect. The station may also cause buzz in intercarrier sets by too much modulation of the video carrier. This results in the tips of the sync pulses cutting off or nearly cutting off the video carrier. The 4½ MC intercarrier is formed by the beat between the sound carrier and the picture carrier. If one becomes zero, the intercarrier also becomes zero. Sync occurs at a 60 cycle rate (frame) so the carrier may drop out 60 times a second, causing buzz. This buzz is characterized by a sharp wave front containing high frequency components, as compared to hum. This type of buzz may change as cameras are changed at the studio, due to the video level of one camera being set at a slightly different value than the others.

Buzz occurring in the receiver has been experienced by not having the IF curve and the cathode trap aligned to produce very low response at the 20.5 MC sound carrier; not having the ratio detector correctly tuned, especially by being on the wrong secondary null; and by having an unbalanced ratio detector coil. The latter can usually be corrected by connecting a 330 Mmfd condenser from the junction of C-4, R-5 and R-4 to ground. Re-peak the 4½ MC IF coil also. Be sure the fine tuning control is tuned correctly. A slight buzz can be obtained on strong station by turning the contrast full on, causing the video amplifier to overload and clipping sync with the same effect as previously described. This effect is normal and at normal contrast setting may not be noticed.

Another type of buzz is caused by the vertical sweep coupling into the audio. As the vertical has a sharp wave front and fairly high amplitude, a very slight coupling may pick it up. Test for it by turning the volume control completely off and listen. A shield installed between the 6J5 vertical oscillator and the 6AV6 (or 6SN7) will remove it.

Hum is usually power supply hum and requires an electrolytic filter on the 290V bus.

I. F. ALIGNMENT

Equipment Required:
1 VTVM.
1 Oscilloscope.
1 Sweep generator, 10 MC sweep centering about 23 MC. RF channels desirable but not necessary. The sweep generator should have very low harmonic content or it will produce signal in the RF while the IF is being aligned.
Markers, preferably crystal control, at 4.5 MC, 20.5 MC, 25 MC and 21.4 MC. It is desirable to be able to operate 25 MC and 21.4 MC markers at the same time to facilitate alignment. Additional frequencies of 23.4, 24.3, 21.8 and 24.2 may be obtained from a variable signal generator. If an accurate signal generator is available a 25 MC marker used with it will give good results.

Set Up:
Loosen the tube shield from ground of the 6J6 in the Standard tuner (front tube). Connect the output of the sweep generator to this tube shield and ground. Connect the horizontal terminals of the scope to the sweep sync. terminals. Connect the vertical terminals of the scope across ground and the picture detector load resistor (R-27). If the scope has a Z terminal, 110 VAC through a 2.2 M ohm resistor may be conected to it to blank out the return trace. Reverse the plug if necessary. Be sure the sweep generator is connected to the receiver chassis by a short ground wire. If at any time the curve shape changes due to touching the equipment or changing leads around, check all grounds and do not proceed until corrected. It is not necessary that the set-up be connected to an earth ground, but that it be connected together by short ground leads. In an extreme case it may be necessary to place the equipment on a sheet of metal.

Procedure:
Set the tuner on Channel 12 and obtain the IF response curve on the scope. Adjust scope height, width, centering and perhaps phase. Set the sweep amplitude for medium output. Turn the tuner on two or three adjacent channels; the curve should remain substantially the same. If it does not, pick a channel which has the same curve as two or three others. Note any superfluous response or extra markers. The tuner oscillator may produce a marker. Tune the fine tuning control to identify it and place in an inconspicuous place. Try to identify if not remove all other signals. The IF may be oscillating if improperly aligned. Place a finger on an IF coil or put in an iron or brass slug to identify or move. Do not try to align before stopping any oscillation. This can also be done by turning the coil slug but is not recommended for those aligning for the first time as the slug position may be lost. Turn the sweep generator amplitude down and then up and note how the curve follows. If a station is on the channel being used, try another channel or reduce the signal from the station. Remove the antenna to remove noise and other signals. Set the contrast control about one-half on. In receivers using keyed AGC, connect —3 volt of battery bias to the AGC bus and ground before sweeping. Connect the markers loosely to the receiver. This can usually be done by connecting to the receiver chassis, tuner chassis or between tuner chassis and receiver chassis.

Note how the markers appear on the scope IF curve. Run the marker attenuators up and down. Always use the minimum amount of marker signal possible as it will distort the curve. When it is necessary to use a large amount of marker in the first steps of alignment, reduce it later and check curve.

Alignment:
Introduce 23.4 MC marker and adjust last IF slug (3rd IF) for maximum. This can be done by watching the marker on the scope and adjusting for maximum excursion from zero axis. An alternate method is to shut off the sweep and use a VTVM at the picture detector load resistor. Change marker to 24.3 and peak 2nd IF. Set marker to 21.8 and peak 1st IF. Set marker to 24.2 and peak tuner converter. Set marker to 20.5 and null cathode trap. When the IF coils are set to frequency, a rough curve, approximating the IF curve, will appear on the scope. Then turn the IF slugs, watching the scope, to obtain the curve shape and marker position desired. (This curve is reproduced on the circuit diagram. It will result in a full resolution 350 line picture. Band width is measured at 50% points.) A considerable amount of skill is required to perform this operation quickly. Here are some hints to help. Never turn any one slug too far. Don't try to do it all on one IF coil but pick up a little bit on each one. Sometimes turning a slug to obtain a desired portion of the surve will apparently make the curve worse but it may be compensated for in another IF stage. If you get too far from the desired result, re-peak the IF's on marker frequencies and start over. While aligning, note the gain by the amplitude on the scope as it is possible to get a good looking curve with low gain. In this case one or more of the IF stages will have gain off to one side of the curve. This is sometimes evidenced by considerable "suck out" of the cathode trap. The 20.5 MC sound carrier (cathode trap frequency) should be very low and very little response will be noted on the other side of the trap. If the trap is incorrectly aligned or not working, buzz may occur in the sound and 4½ MC beat in the picture. Usually, but not always, the 3rd IF rocks the curve; the 2nd IF moves the 25 MC marker and broadens the curve; the 1st IF broadens the curve on the 21.4 MC side; and the tuner converter broadens the 21.4 MC side, moves 25 MC marker, and rocks the curve.

©John F. Rider

World Radio History

Sound Alignment:
Turn off the sweep and connect the VTVM to the ratio detector load (marked "maximum" on the circuit). Inject 4.5 MC and peak sound take off coil and primarily of ratio detector transformer (bottom). Null 4½ MC trap if one is used, by placing VTVM on picture tube grid and ground. Adjust the secondary of the ratio detector for zero. There are three responses to the ratio detector transformer. The correct one is in the middle. At the correct zero a slight turn of the slug will move the VTVM needle rapidly positive or negative. Reset to zero. If the secondary slug was moved appreciably, recheck the tuning of the primary slug.

CIRCUIT INFORMATION

CHASSIS	HORIZ. DEFLECTION	R-F TUNER	AUDIO AMPL.
CT 232	As shown in full-size schematic uses only the 16AP4 tube	Type "S" untuned input	123 A
CT 236	Same as CT 232	Type "R"	123 A
CT 239	Same as CT 232	Same as CT 232	123 B
CT 240	Same as CT 232	Same as CT 236	123 B
CT 244	Two 6BG6G tubes, shown in excerpt of schematic. May use either the 16AP4 (long) or 16EP4 (short) picture tube	Type "S" tuned input, with 6AB4 oscillator	123 B
CT 245	Same as CT 244	Same as CT 244	123 A
CT 246	Same as CT 244	Same as CT 244	None
	Uses 6J5 for AGC gating diode which is a diode in the audio amplifier of chassis using an audio amplifier. Also uses 10 watt Bleeder resistor to provide current drain the same as though an audio amplifier were used, and so the same +B voltage. Connects an 11.7K 10 watt resistor from +B 250V, to ground.		
Audio Ampl. 123 A	is the same as 123 B except part No. of output transformer. 123 A uses transformer No. 320027-3 while 123 B uses No. 320027-4.		

- R-F tuner having tuned input; gives improved signal-noise ratio, sensitivity.
- 4 stages of video I-F amplification, stagger-tuned for reduced phase distortion and for increased stability and for ease of alignment.
- Three stages of high gain sound I-F amplification.
- Two stages of video amplification, two stages of audio amplification.
- Direct-coupled video amplifiers, eliminating necessity for DC reinsertion.
- Either self-contained audio system (except CT 246) or plug connection to use the audio amplifier and speaker system of a companion radio-chassis.
- MAGNALOK horizontal AFC circuit. Frequency control is by variable width of a converted sync pulse, rather than variable amplitude. Since interference is for the most part AM, this results in improved noise immunity in horizontal scanning.
- Amplified automatic gain control. Affords maximum uniformity of reproduction when switching between stations and reduces fading. Less necessity for adjusting picture and brightness controls.
- Non-hazardous high voltage supply.
- 16 inch picture tube—either short or long tube in the CT 244-45-46.

TUBE COMPLEMENT

R-F amplifier (untuned input)	6BH6	6SN7GT	1st video ampl., 1st sync ampl.
R-F amplifier (tuned input)	6AK5	6V6GT	2nd video ampl.
Mixer	6AG5	6SN7GT	AGC rect., 2nd sync ampl.
Oscillator (untuned input)	6C4 or 6AB4	6SN7GT	AGC ampl., vert. osc.
1st sound I-F	6BA6	6SN7GT	Sync leveler, clipper
2nd sound I-F	6BA6	6V6GT	Vert. output
3rd sound I-F	6AU6	6SN7GT	Hor. AFC, oscillator
Discriminator	6AL5	6BG6G	Hor. output (two in parallel), CT 244-45-46
1st A-F amplifier	6SF7		
Audio output	6V6GT	1B3GT(2)	H. V. rectifiers
1st Video I-F	6AG5	6W4GT	Damper
2nd Video I-F	6AG5	5U4G(2)	L. V. rectifiers
3rd Video I-F	6AG5	16AP4	Long picture tube
4th Video I-F	6AG5	or	
		16EP4	Short picture tube

TOTAL CT 232-36-39-40—27 tubes
CT 244-45-46 —28 tubes

TELEVISION FREQUENCIES, MC.

Picture I-F	25.75	21.25	Co-channel sound trap
Sound I-F	21.25	19.75	Adjacent channel picture trap
Adjacent channel sound trap	27.25	.30	Discriminator band width

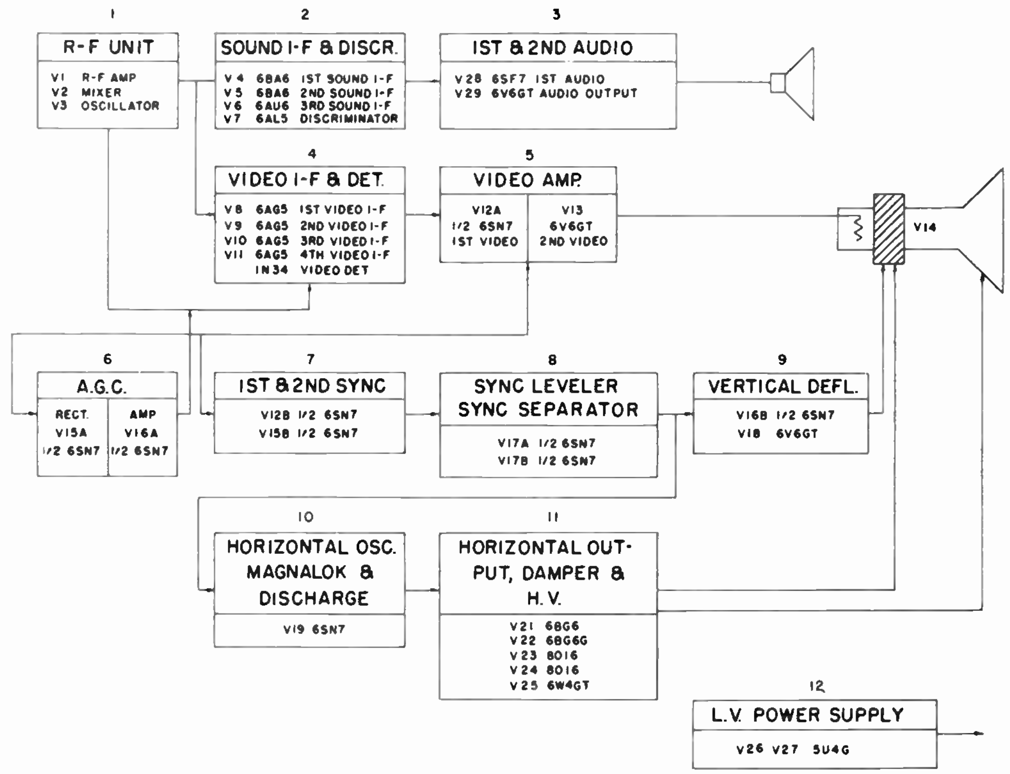
FUNCTIONAL DIAGRAM



RECEIVER OPERATING INSTRUCTIONS

1. Turn the CONTRAST OFF-ON control to the right ½ turn.
2. Set the STATION SELECTOR to the desired channel number.
3. Adjust the FINE TUNING control for best quality sound and the VOLUME control for suitable sound volume.
4. Adjust the BRIGHTNESS control for suitable picture brilliance. Adjust FOCUS for best detail.
5. Now adjust the PICTURE control until the picture has the proper degree of contrast.

6. If necessary adjust the BRIGHTNESS and SOUND control on radio chassis for best picture and sound quality.

The small control knobs marked VERTICAL and HORIZONTAL will rarely require adjustment after they are properly set. If the picture "roll" up or down, turn the VERTICAL knob to the left as far as possible—then advance to the right until the picture stops moving. If the picture is not centered horizontally or if it is broken up, adjust the HORIZONTAL control knob to frame the picture.

PART II

PART III

PRELIMINARY ADJUSTMENTS

ALIGNMENT OF HORIZONTAL DEFLECTION CIRCUITS

a. Check of Horizontal Hold Control

(1) Allow a five minute warm up period before making this check.

(2) Rotate the Horizontal Hold Control from its extreme counterclockwise position. The picture should remain in synchronization. Return the control to its extreme counterclockwise position and momentarily interrupt the signal by switching to another channel and back again. The picture should fall out of synchronization and show from 4 to 5 bars slanting *upward to the right.*

(3) If this condition does not occur adjust the Horizontal Speed Control (rear chassis adjustment) until synchronization of the picture is obtained as described above.

b. Alignment of Horizontal Sync. Circuits

If the Horizontal Hold Control fails to perform as described above and it cannot be corrected by adjusting the Horizontal Speed Control it will be necessary to make the following adjustments:

(1) Set the Horizontal Hold Control to the full counterclockwise position.

(2) Adjust the Horizontal Lock Trimmer to at least two turns counterclockwise from maximum tightness. Do not force the tight adjustment to determine this setting.

(3) Short circuit the Horizontal Speed Coil which is mounted in metal can, terminal C and D. Access to this coil may be attained by removing the metal shield located on the bottom of the receiver cabinet.

(4) With the Horizontal Hold Control counterclockwise, adjust the iron core of the Magnalok transformer to frame the picture. This adjustment is located at the opposite end of the transformer from the horizontal speed coil.

(5) Remove the short from the Horizontal Speed Coil and adjust the Horizontal Speed Control for proper synchronization as described in check of Horizontal Hold Control.

PICTURE ADJUSTMENTS

a. Height and Vertical Linearity

Adjust the Height control until the picture just fills the mask vertically. Adjust VERTICAL LINEARITY control until the test pattern is symmetrical from top to bottom. Adjustment of either control will require a readjustment of the other. Adjust vertical centering control to align the picture with the mask.

b. Width Compensating Switch

The serviceman is provided with a switch which will compensate the horizontal width for different values of line voltage. It is a four position switch as follows:

Position 1	Low line voltage	(Approx. 105V)
Position 2	Nominal line voltage but weak horizontal sweep amp. tube	(Approx. 117V)
Position 3	Nominal line voltage	(Approx. 117V)
Position 4	High line voltage	(Approx. 125V)

When installing the receiver the serviceman should check the average line voltage at customer's home. The switch should then be set to position corresponding to his measurements.

In positions 3 and 4 the size control is operative and the picture can be adjusted to the exact width. In positions 1 and 2 the size control is inoperative and the picture may sometimes go slightly beyond the edges of the mask.

Positions 1 and 2 are provided for the location where the line voltage is low or the condition where the horizontal sweep amplifier tube is weak. They should only be used under these conditions.

Caution should be observed when adjusting the switch as improper position may result in the horizontal sweep amplifier tube operating with excessive screen dissipation. In all cases the serviceman can check his setting by observing if the picture width greatly exceeds the mask. If this happens the switch should be set to the next higher position.

Position 3 is recommended for most installations. The size control will then take care of normal variations encountered. If any doubt exists, the size control should be set for maximum size and starting with position 4, the switch should be turned until the picture size conforms with the mask or is slightly larger than the mask. The picture width (for positions 3 and 4) can then be reduced by the size control.

c. Width and Linearity

Adjust width control (recessed, upper right rear of H. V. compartment) for maximum width. Then, adjust Horizontal drive and linearity for proper width and linearity of picture.

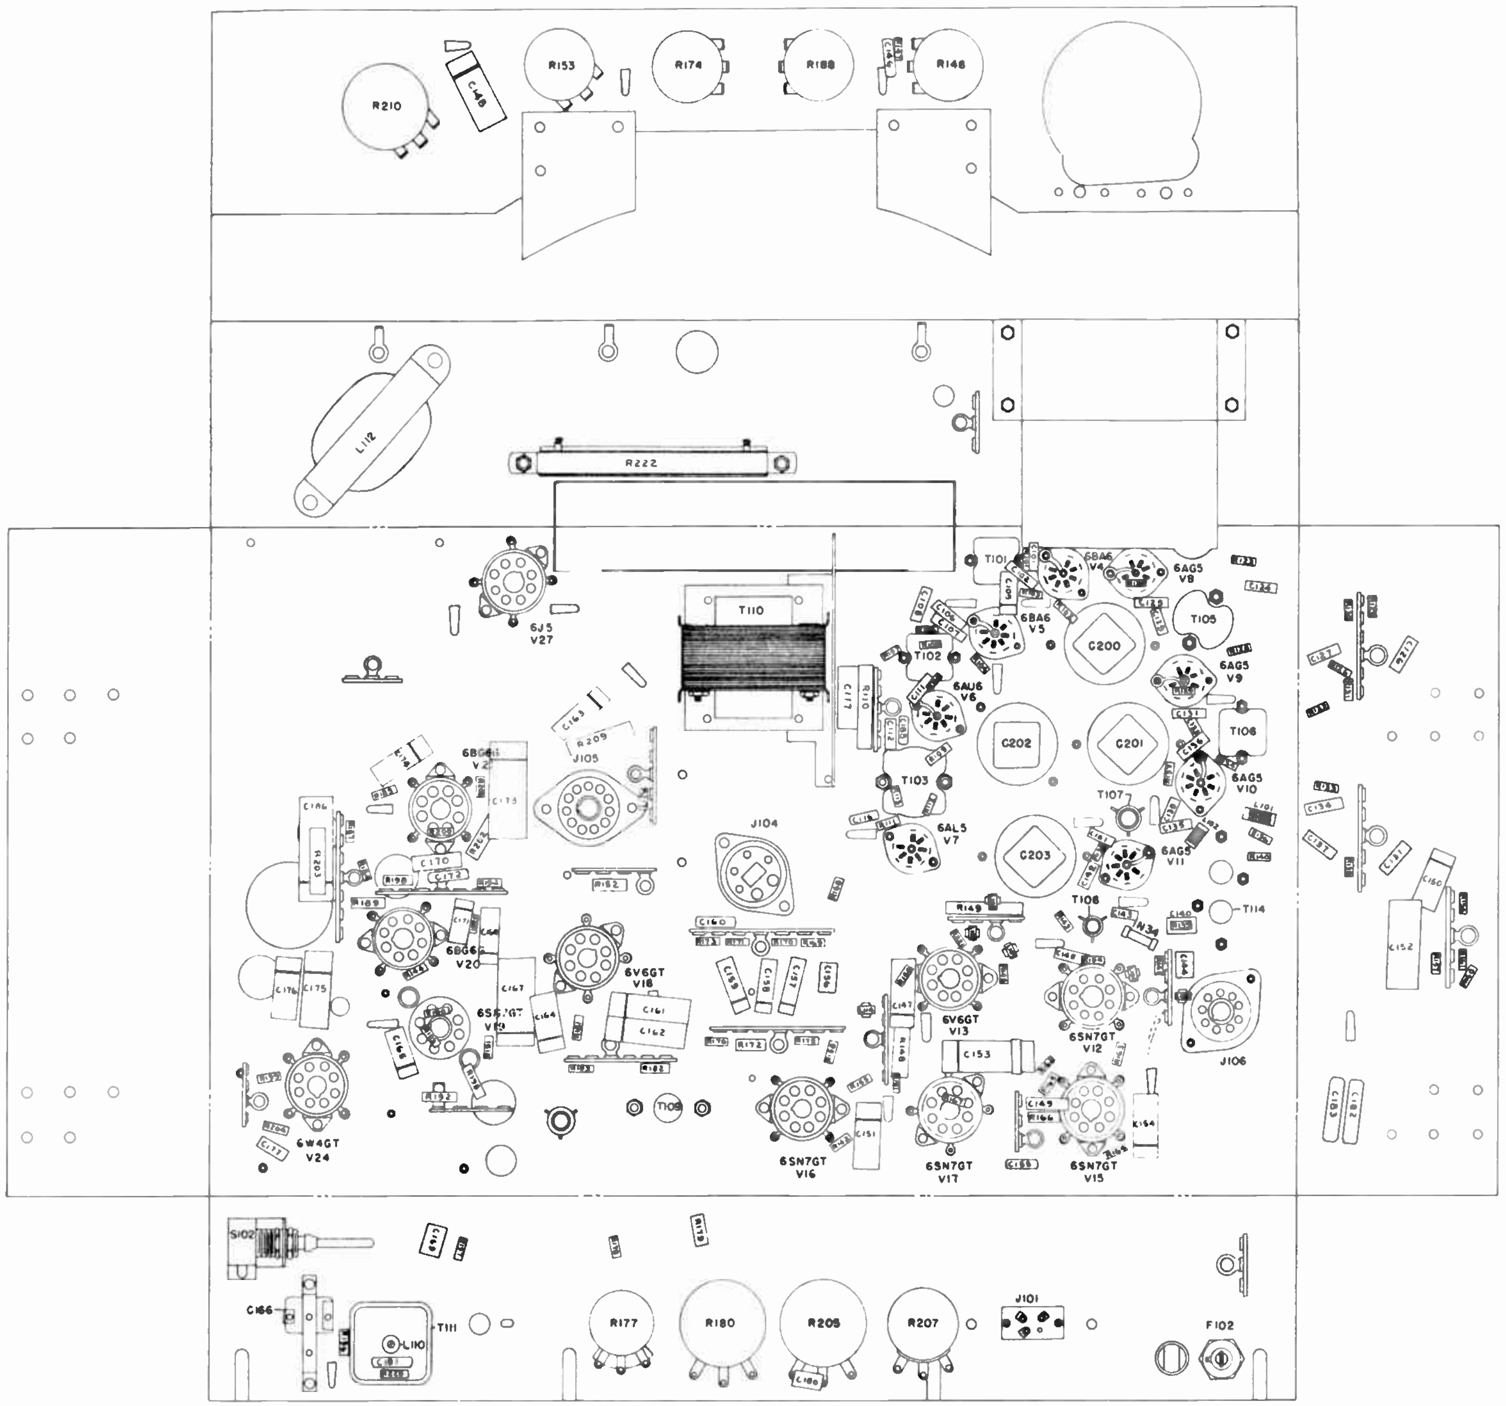
PARTS IDENTIFICATION



BOTTOM VIEW OF THE CHASSIS

CHECKING A. G. C. THRESHOLD CONTROL

1. Tune in a strong signal.

2. Sync the picture, then turn PICTURE control to maximum CW, and note that there is sufficient contrast.

3. Turn BRIGHTNESS until retrace lines are just invisible. Remove signal by switching momentarily to another channel.

4. If picture returns immediately, the control is properly set. If an appreciable part of a second is required for picture return the receiver is overloading and the threshold control should be readjusted.

ADJUSTING THE CONTROL

There are two methods of adjusting the AGC Control, and it is unnecessary to remove the receiver from the cabinet when using either.

1. WHEN AN OSCILLOSCOPE IS AVAILABLE.
   a. Connect the scope to the grid of the picture tube.
   b. Tune in a television signal for proper sound.
   c. Turn the contrast control clockwise to maximum.
   d. Adjust the AGC control for a 70 volt peak to peak video pattern on the scope.

   If a calibrated scope is not available, a convenient way to calibrate one is to connect the scope probe to a 6.3 volt filament pin, and set the vertical gain control so the sine wave pattern is ½ inch high. Without changing the vertical gain control, move the probe to the picture tube grid and set the AGC control to obtain a pattern 2 inches high. This is equal to 70 volts peak to peak. (Explanation: The peak voltage is 1.4 times the RMS voltage, therefore 1.4 x6.3=8.82 volts, the peak value of the filament voltage from zero to positive. The scope pattern shows both positive and negative half cycles, so 2x8.82=17.64 volts. Therefor 6.3 volts RMS = 17.65 volts peak to peak = ½ inch vertical deflection on the scope. A 70 volt calibration is required, so 4x17.65=70.6 volts p-p = 2 inches vertical deflection).

   e. As a precaution, turn the AGC control so the p-p voltage is higher than the required 70 volts, and examine the pattern for signs of overload. If overloading occurs at or very near the 70V. range, set the AGC control so the signal is slightly below that value.

2. WHEN NO OSCILLOSCOPE IS AVAILABLE.
   a. Tune in a television signal for maximum clarity.
   b. Turn the contrast control to mid-range, half way between maximum and minimum rotation.
   c. Without changing the contrast control, adjust the brilliance control and the AGC control for a medium brilliance and medium contrast picture.
   d. As a precaution, turn the AGC control farther than necessary in step c, and examine the picture for signs of overload. If overloading occurs at or very near the setting just established, advance the contrast control a quarter of an inch, and adjust the brilliance and AGC controls for the best obtainable picture.

ADJUSTING THE ANTENNA TRAPS

In some instances interference may be encountered from FM stations that are on the image frequency of a television station.

The CT 232-239-244-245-246 incorporates a series resonant trap across the R-F amplifier grid circuit to eliminate this type of interference.

©John F. Rider

World Radio History

To adjust the trap, tune in the station on which the interference is observed, tune both cores of the trap for minimum interference in the picture. Keep both cores approximately the same by visual inspection, then turn one core ½ turn from the original position and repeak the second for maximum rejection. Repeat this process until the best rejection is obtained. The R-F unit of the CT 236 and 240 having greater selectivity, no traps are, as a rule, necessary.

PART IV

I-F, R-F ALIGNMENT

In aligning the amplifiers, it must be remembered that feedback between output and input circuits leads to regeneration and, if feedback be appreciable, to oscillation. It may be determined whether the amplifier is oscillating as follows:

Increasing signal generator output by a factor of (for example) two should result in a rise in output voltage in approximately the same degree. If, instead, a decrease in output with increased input is noted and if there be a steady output voltage as indicated on the V.T.V.M. even without input signal, the circuit is oscillating.

Regeneration insufficient to cause oscillation gives rise to distortion of the reproduced response curve, and proper alignment is not possible in such event.

Regeneration may be caused by poor bonding between the chassis of the receiver and of test equipment being used. Connection should be made by short, heavy leads. Many service organizations use a metallic sheet (galvanized iron is satisfactory) atop the bench which affords good R-F grounding between chassis, even though they are not conductively connected thereto.

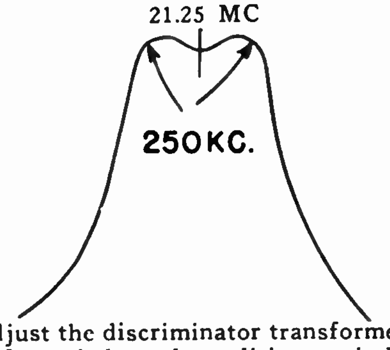
After the several connections of equipment are made and a pattern being reproduced, it must be possible to place the hand at various points of the equipment chassis and along the interconnecting cables, with no visible change in output potential or wave form. Failure to attain this probably means that regeneration is present, better grounding is necessary and subsequent alignment adjustments are questionable.

It may be necessary, to realize such a condition in the absence of a metal-topped bench, to employ two or more short bonding wires between chassis, connected at different points.

SOUND DISCRIMINATOR ALIGNMENT

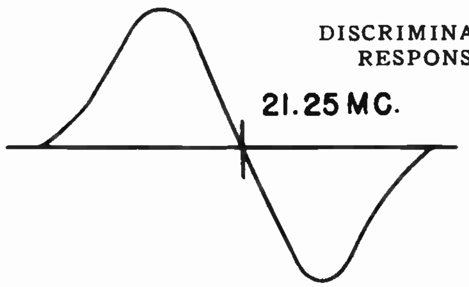
1. Connect the marker generator to the grid of the converter tube. Set the marker generator to exactly 21.25 MC.
2. Connect the Electronic Voltmeter to the discriminator output. Audio output terminal block may be used for this purpose. Set voltmeter to a low scale.
3. Detune the discriminator secondary (bottom adjustment transformer (3)) and then adjust discriminator primary (top adjustment) for maximum indication on the voltmeter. Adjust I-F transformer (2) and I-F transformer (1) top and bottom adjustment for maximum output.
4. Connect sweep generator to converter grid to a center frequency of 21.25 MC with a 1 MC sweep. Loosely couple marker generator at this point. Connect oscilloscope through 22K isolating resistor to high end of resistor (108) 3rd I-F grid. Retouch I-F adjustments so that output is maximum and symmetrical about the 21.25 MC marker as shown.

SOUND I-F AMPL. RESPONSE 21.25 MC



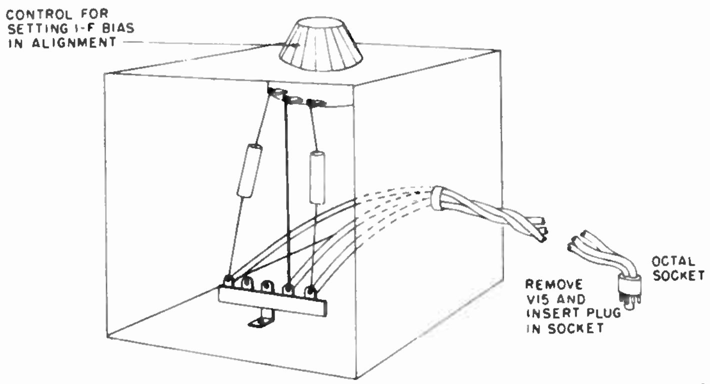
5. Adjust the discriminator transformer (3) secondary for a balanced condition as indicated by zero reading on the electronic voltmeter. When proper balance is obtained, positive and negative peaks will be observed as the marker generator is tuned to either side of the 21.25 MC sound I-F frequency. Keep P/P scope deflection at about one volt.
6. Observe the response curve at the output of the discriminator by connecting oscilloscope to the discriminator output. Connect the sweep generator to the converter grid and loosely couple the marker generator into the converter grid circuit. The marker generator 21.25 MC pip should occur at the midpoint of the linear portion of the discriminator response curve and will be attenuated at this point.

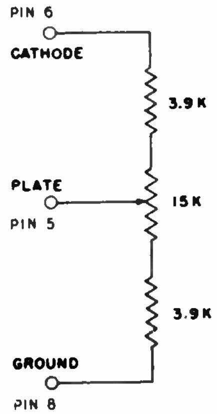
DISCRIMINATOR RESPONSE



VIDEO I-F ALIGNMENT

1. Remove the A. G. C. rectifier and sync amplifier tube (V15) and connect a variable resistor as shown in the accompanying sketch. Using this control set bias on I-F bus to approximately —3 volts.





Control for setting I-F bias. Use Plug Adaptor to plug into AGC tube socket.

2. Connect AM signal generator to mixer grid through a small capacitor. Connect oscilloscope between grid of 1st video amplifier tube (pin 1, V12A) and chassis ground. Set the signal generator to the 19.75 MC position with modulation and adjust the 2nd video I-F trap for minimum response (top adjustment). If the signal generator has no AM, use the VTVM across the detector load resistor as an indicating device.
3. Set the signal generator to the 21.25 MC position. Adjust the cathode trap (top adjustment) and then the converter trap on the R-F unit for minimum response (top adjustment).
4. Set the signal generator to the 27.25 MC position and adjust the trap to the 1st video I-F transformer (top adjustment) for minimum response. This completes the preliminary adjustments of the trap circuits.

Note: A VTVM may be used as an indicating device, when connected across the video detector load resistor. CAUTION—these points are approximately at minus 100 volts below ground.

I-F TRANSFORMERS

1. Set the signal generator to the 21.8 MC position and adjust the converter transformer primary (bottom adjustment) for maximum output. Caution should be taken so that the signal does not overload the circuit. With the signal generator set up for the appropriate frequencies, tune the plate coils of the 1st video I-F transformer to 25.3 MC, 2nd video I-F transformer to 22.3 MC (after making this adjustment it will be necessary to realign the trap circuit to 19.75 MC) 3rd video I-F coil to 25.2 MC and 4th video I-F coil to 23.4 MC for maximum response.

RETOUCHING VIDEO I-F ALIGNMENT

1. Connect the sweep generator to the receiver antenna terminals. Set the channel selector and sweep generator to channel 13. Loosely couple the marker generator into the grid circuit of the converter stage. Sufficient coupling may be obtained by connecting the high side of the generator output to the R-F unit sub chassis to form a ground loop. Connect the oscilloscope between the plate of the 1st video amplifier (pin 2, V12A) and ground. The A. G. C. circuit should be inoperative as has been indicated and the I-F bus voltage set to —3 volts.
2. Observe the response curve obtained. The response will not be ideal and it will be necessary to retouch the I-F adjustments in order to obtain the desired curve as shown. The most important factor in the retouching procedure is that the video I-F carrier will fall within the limits as shown on the response curve. If the video carrier operates too low on the curve, loss of low frequency video response, of picture brilliance, of blanking and of sync may occur. If the video carrier operates too high on the response curve the picture definition is reduced by lack of high frequency video response. In making these adjustments care should be taken that no two I-F transformers are tuned to same frequency or I-F oscillation may occur.

OVERALL VIDEO RESPONSE

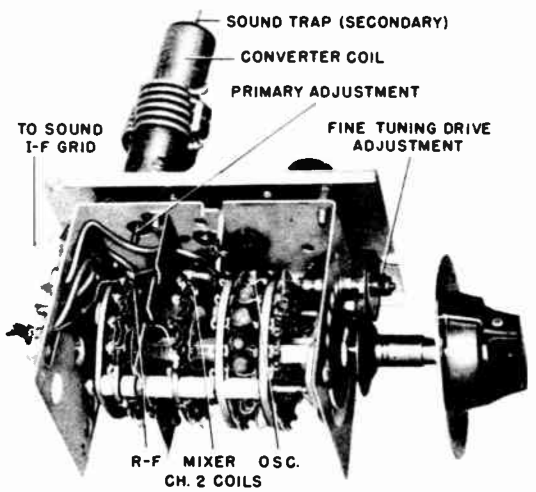
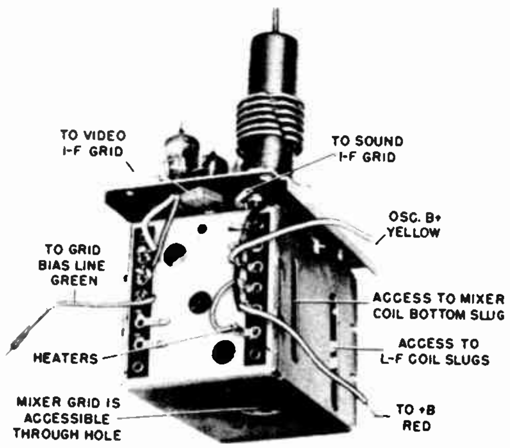
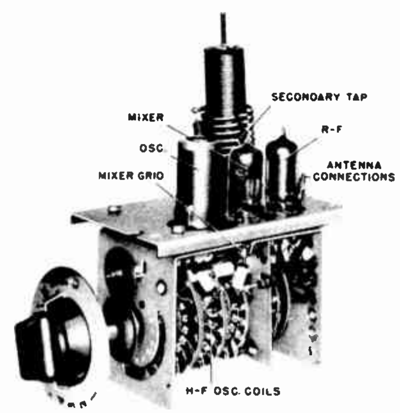
R-F UNIT OF THE CT 236-240 CHASSIS





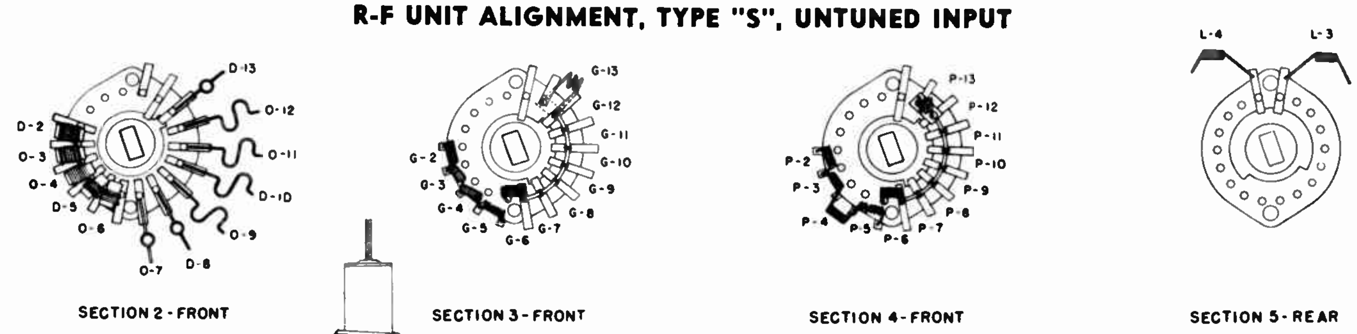


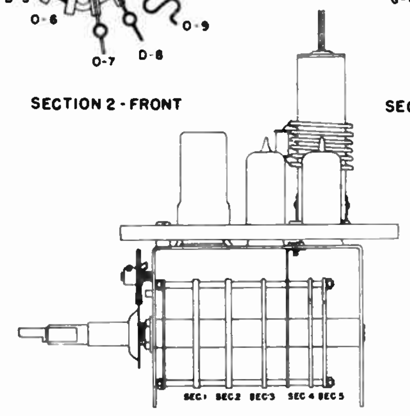
OSC 6C4, MIXER 6AG5, R-F AMP 6BH6

R-F UNIT OF THE CT 232-239 CHASSIS

R-F unit having tuned input physically similar to above, but oscillator is adjustable on all channels by means of slugs accessible from front of tuner. May be adjusted without removing chassis, by removing channel selector dial. Uses 6AB4 osc., 6AG5 mixer, 6AK5 R-F ampl.

R-F UNIT ALIGNMENT, TYPE "S", UNTUNED INPUT





R.F. UNIT ADJUSTMENT
ALL SECTIONS VIEWED FROM SHAFT END

OSCILLATOR ALIGNMENT

1. Oscillator adjustment should be made only when the fine tuning control tunes in the extreme clockwise or counterclockwise position from its center or if it will not tune at all within its tuning range. Such a condition may be brought about by changes in the inductance of the oscillator coils or changes in the circuit capacitance which might occur when the oscillator tube is replaced.

2. Method 1. (Adjustments to be made with R-F unit shield in place.)

a. The criteria of proper alignment using this method is that the combination of the assigned sound carrier and the local oscillator produce a signal that falls in the center of the sound discriminator characteristic. It is important that the sound I-F of the discriminator circuits have first been properly aligned.

b. To check the existing alignment of the local oscillator.

(1) Set the fine tuning control in the middle of its range.

(2) Turn the channel selector switch to channel 13. Connect signal generator to antenna terminals. If the generator has single ended output of low impedance a sufficiently accurate balance can be realized if two equal resistances are inserted between the generator output and the receiver antenna terminals and a terminating resistor equal in value to the generator cable impedance across the generator output. The value of the resistors is such that the sum of their resistance plus the terminating resistor equals approximately 300 ohms.

(3) Tune the signal generator to each side of the 215.75 MC Sound Carrier until its modulation is heard in the speaker. The signal generator should be tuned for a minimum signal located between two maximum points.

(4) Observe whether the signal generator reading obtained is above or below the 215.75 MC sound carrier. Repeat for the remaining high band channels tuning the signal generator about the corresponding sound carrier frequency in each case. See table page 4 for these sound carrier frequencies.

(5) If all of the high band oscillator coils or the majority of them are off in the same direction as shown by the signal generator dial reading they may usually be brought into alignment by adjusting the wheel which turns the fine tuning capacitor, or by changing oscillator tube.

3. Readjusting the Fine Tuning Wheel

a. Reset the channel selector switch to channel 13 and set the signal generator to the sound carrier for that channel. Tune the fine tuning control until the receiver is precisely tuned to the sound carrier.

b. Loosen the Allen set screws which fasten the wheel to the shaft of the fine tuning capacitor. Reset the wheel until it is mechanically in the center of its tuning range and tighten the set screw. When making this adjustment be sure that the fine tuning control does not move from its center position.

c. Recheck the settings of the channels as has been shown. Channels which are not

World Radio History

properly aligned must be adjusted individually. This procedure would also be followed in cases where the adjustments are off in random fashion and present no definite pattern to be followed in setting the fine tuning control.

4. Individual Adjustments of the Oscillator Coils, 12 Channel Unit

a. Having determined the direction in which the oscillator is misaligned on any high band channel remove the shield from the R-F unit and adjust the oscillator coil for that channel.

b. Coils having a one turn loop (Channels 13, 8 and 7) may be tuned higher by spreading the loop apart or making it smaller. They may be tuned lower by squeezing the loop closer, making the loop as large as possible and making the adjacent parts of the loop as parallel as possible.

c. Coils consisting of a single bent wire (Channels 12, 11, 10 and 9) may be adjusted from minimum to maximum inductance by adjusting them as shown below.

Care should be taken to prevent any coil from touching an adjacent one and to prevent a part of the coil from touching the switch stator contact in any place except where it is soldered to that contact.

d. To adjust the low band coils turn the brass slugs in and out as required with a small screwdriver, reheating the wax around them after the final adjustment.

e. In order to avoid repeated removal and replacement of the R-F unit shield during oscillator adjustment the fine tuning control may be set 120 degrees away from its mid point position in the direction of less capacity. (Corresponding to clockwise rotation of the fine tuning control). It will be found that when the coils are adjusted in this manner with the shield removed, the fine tuning control will be in the center of its range when the shield is in place.

SWITCH WAFER

MINIMUM INDUCTANCE

MEDIUM INDUCTANCE

MAXIMUM INDUCTANCE

R-F AMPLIFIER AND CONVERTER ALIGNMENT*

a. Set channel selector on channel 13. Connect sweep generator to the antenna terminals using a balanced resistor network for those generators having an unbalanced output. Set the sweep generator to sweep channel 13. Connect oscilloscope between the plate of the first video amplifier and chassis ground.

b. Loosely couple the marker generator to the antenna terminals. Set the generator to the channel 13 sound carrier and tune the receiver to that carrier. Adjust the sweep input in such a manner as to avoid overload in the R-F amplifier. Adjust the R-F amplifier plate coil (P13) and the converter grid coil (G13) for maximum response. Set the marker generator to the channel 13 video carrier frequency and adjust these coils for proper bandpass with optimum gain. The video carrier marker should be approximately at the 50% point on the response curve.

c. Set the R-F channel selector switch and sweep generator successively to channels 12 down to 7. If the channel 13 R-F amplifier plate coil (P13) and the converter grid coil (G13) are correctly tuned, channels 12 to 7 will give symmetrical bandpass patterns and the height of the pattern will not vary by more than 3 to 1 between channels 13 and 7.

LOW BAND

a. Connect the sweep generator and marker signal generator to the antenna terminals as has been shown for the high band alignment. Set the channel selector switch to channel 6. Set sweep generator to sweep channel 6 and the marker generator to the channel 6 sound carrier frequency.

b. Connect the oscilloscope between the plate of the first video amplifier and chassis ground.

c. Set the fine tuning control to the center of its range. Observe the response and adjust the R-F amplifier plate coil (P6) and the converter grid coil (G6) for maximum response. Set the marker generator to the channel 6 video carrier frequency and adjust these coils for proper bandpass with optimum gain. The video carrier marker should be at the 50% point on the response curve.

d. Align channels 5, 4, 3 and 2 in a similar fashion. The difference between peaks on any channel should be no more than 30% of the total height of the response curve.

e. It should be noted that maximum height and symmetry of the response curve should occur at the mid range of the fine tuning control where it will properly tune in the sound carrier frequency.

*The AGC circuit should be made inoperative as has previously been shown.

R-F UNIT ALIGNMENT, TYPE "S" WITH TUNED INPUT

OSCILLATOR ALIGNMENT

The oscillator coils in this R-F unit are all tunable by slug adjustments, and alignment of one does not appreciably effect the tuning of the other coils. The order of alignment is from channel 6-2, 13-7, 6-2 and 13-7. The repeated adjustment is necessary to correct any detuning caused by the capacity change due to slug adjustments of adjacent coils.

1. Set the sweep generator and channel switch to No. 6 channel. Adjust as outlined in instructions for untuned input tuner.
2. Proceed through channels 5-2 in the same manner.
3. Align channels 13-7.
4. Proceed as above through channels 6-2 and 13-7, and retouch if necessary.

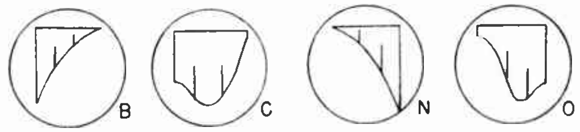
ANTENNA, R-F AMPLIFIER AND CONVERTER ALIGNMENT

There are three variables which will give the desired pattern. If the antenna coil (wafer nearest the rear of the tuner is first expanded, then the grid coil and finally the plate coil is expanded, the proper pattern will appear. These coils must be very carefully adjusted with only slight movement, particularly the plate coil. The final pattern is obtained by working back and forth between these three coils.

1. Remove the AGC rectifier-amplifier tube and connect bias control.
2. Connect sweep generator to antenna terminals, using a balanced resistor network if generator has unbalanced output cable. Connect 'scope to terminal provided on the tuner.
3. Set the sweep generator and channel switch to No. 13 channel. If the coils are very badly aligned, the pattern on the scope will probably be either of these:

The meaning of "A" is that some coils must be opened up. The meaning of "M" is that some coils should be closed or squeezed together.

4. When they are far off from their proper tuning, all three coil circuits have their main effect on pattern height, so tune for increasing height of the pattern.
5. As a coil is changed, one side of the picture will get higher and then a hump will start to move across the screen.

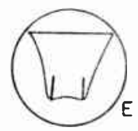


If the first pattern was like "A", the next will be "B" and then "C" as the coil is opened. If the first pattern was like "M", the next will be "N" and then "O" as the coil is closed. When the hump, due to the tuning of that coil, is between the markers, it indicates that this coil is very close to where it it should be. So leave it and immediately go to another coil.

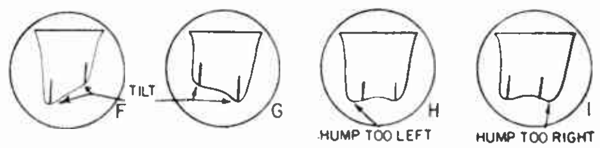
6. The side of the picture which is higher indicates what to do to the next coil. In "C", the left hand side is higher, which indicates that said coil should be opened. In "O", the right side is higher, indicating that said coil should be closed. A picture similar to "D" or "P" should be then obtained.

The fact that there are now two humps in the pattern shows that both converter wafer and R-F wafer are tuned nearly right. If picture height is near what it should be with the scope settings unchanged, the antenna wafer is near correct. It should be adjusted a bit to see if pattern height improves.

7. When all three coils are nearly tuned, the antenna wafer controls the tilt, the RF wafer controls the left hand hump, and the converter wafer controls the right hand hump. Adjust them for a perfect flat pattern on channel 13 as below.



8. Proceeding through channels 12, 11, 10, etc. The pattern will change slightly as shown below. In general, three things occur: (1) tilt (2) hump too far left or (3) hump too far right.

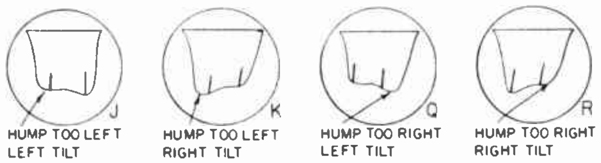


©John F. Rider

World Radio History

For right tilt as in "F", press down the loops on the antenna wafer. For left tilt as in "G", pull up the loops on the antenna wafer. For hump to left as in "H", push down on the loops on the R-F wafer. For hump to right as in "I", use iron and screwdriver and pull out channel 12 or channel 7 loops on converter wafer.

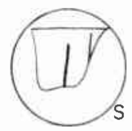
9. Combinations of detuning also occur.



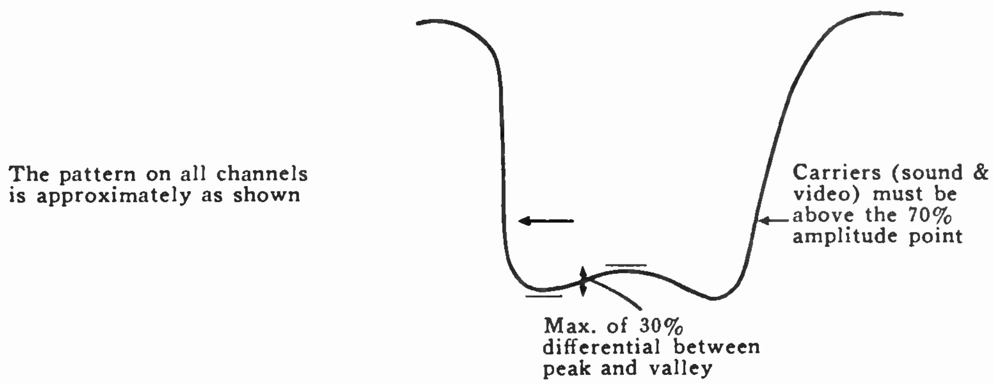
In these cases, two wafers must be adjusted to bring in the best picture. For a case like "J", R-F wafer must be adjusted to bring in the hump and antenna wafer to correct the tilt. In a case like "Q", the converter wafer should be adjusted to bring in the hump and the antenna wafer to correct the tilt. In combination cases like these where the antenna wafer and one of the other two must be adjusted, always adjust the antenna wafer for tilt correction after all adjustments have been made on the other two wafers.

10. It is best to prevent the left hump from going so far to the left that it cannot be brought back, or the tilt to become so bad that it cannot be corrected. If the best possible pattern is obtained on each successive channel, then proper adjustment of the next one will always be within its range.

11. When both coils are near to proper tuning, a slight adjustment of either R-F or converter wafer will give a flat pattern, with very little tilt, and the humps right on the markers; but only the correct coil will give this correct pattern shape plus best pattern height.



When the pattern is like "S" on a low band, opening a coil on either wafer will move the pattern to the right, but try both slightly and make the final adjustment by opening that coil which causes the pattern to become higher as it moves toward the right.



R-F UNIT ADJUSTMENT, TYPE "R" TUNER

1. Oscillator Alignment

   a. The criteria of proper alignment using this method is that the assigned sound carrier and the local oscillator produce a signal that falls in the center of the sound discriminator characteristic (21.25 MC), when the fine tuning control is in the center of its tuning range. The sound I-F and Discriminator circuits must be in alignment before making any adjustments to the oscillator circuit.

2. High Band Alignment

   a. Set the fine tuning control in the center of its tuning range. Set the selector switch to channel 13.

   b. Connect the signal generator to the antenna terminals and set to the channel 13 sound carrier frequency (215.75 MC). This signal should be amplitude modulated.

   c. Adjust L77 and L78 for a minimum signal located between two maximum points. Note: When making these adjustments allow for the change in circuit capacity which occurs when the alignment tool is brought into the vicinity of the oscillator tuning circuit.

   d. Switch the channel selector to channel 12 and set the signal generator to the channel 12 sound carrier frequency (209.75 MC). Tune the channel 12 oscillator tuning screw as has been indicated. Repeat for channels 11 to 7, in each case switching the channel selector to the correct channel and the signal generator to the corresponding sound carrier frequency.

3. Low Band Alignment

   a. Set the channel switch to channel 6. Adjust the signal generator to the channel 6 sound carrier frequency (87.75 MC). Adjust L63 and L64 as described in step (c) of the high band alignment. Set the signal generator to channel 5 and switch the channel selector to channel 5. Tune the channel 5 oscillator tuning slug as has been shown. Repeat for channels 4 to 2, in each case, changing the selector switch to the correct channel and the signal generator to the corresponding sound carrier frequency.

R-F AMPLIFIER AND CONVERTER ALIGNMENT

1. Set I-F bias line to —3V as previously outlined.

   (1) Set channel selector switch to channel 13. Connect sweep generator to the antenna terminals using a balanced resistor network for those generators having an unbalanced output. Set the sweep generator to sweep channel 13. Connect the oscilloscope between the plate of the 1st video amplifier and chassis ground. The marker generator should be loosely coupled into the grid circuit of the converter stage, this can best be done, without placing a load on the converter grid circuit, by connecting the high side of the generator output to the R-F unit chassis and increasing the output of the marker generator until the marker signal is visible on the response curve.

   (2) Set the fine tuning control in the center of its range where it will correctly tune in the sound carrier. Set the sweep generator to sweep channel 13. Observe the overall video response and adjust L25, L26, L51, and L52 for proper bandpass with optimum gain. The overall response should approximate the curve shown in figure 4. L25 and L26 are both primary of R-F amplifier plate coil adjustments and the stud extensions of these cores should be kept equal. The same applies to L51 and L52 which are the secondary or converter grid coil adjustments. When channel 13 is properly adjusted channels 12 to 7 inclusive should be checked for proper overall video response. It may be necessary to compromise between channels 7 and 13 to get the response within the desired limits.

3. Low Band Alignment

   a. Channel 6 can now be aligned in the same manner as channel 13. Inductances L11 and L12 being the primary adjustments and L37 and L38 the secondary adjustment. Again the stud extensions of the adjustable cores are maintained equal. Channels 5 to 2 should now be checked for proper response, again it may be necessary to compromise between channels.

WHY THE VOLTAGES VARY

Assuming normal operation of the television receiver, voltage waveforms often do not appear as shown. This is a function of the type of oscilloscope used, and its input cable.

These waveforms are as reproduced on a Dumont 208B instrument but another, having greater or lesser frequency fidelity, may show a waveform quite different in shape and/or size. Therefore, the service technician must be familiar with his oscilloscope, must recognize its limitations and must make mental correction if waveforms do not appear to be "normal."

The same logic applies to the measure of D-C voltages. Measurements shown here are on an RCA Voltohmyst, Jr. and the use of a 20,000 ohm per volt movement will indicate some D-C voltages to differ greatly from those shown. Again, logic and reasoning must be applied, realizing that in a high impedance circuit, the indicated voltage will be less than the actual operating voltage.

Allowances for 'scope waveforms and D-C meter readings may be computed if all pertinent factors are known, but the experienced technician makes mental correction and allowances to the end that high fidelity instruments are not required.

PARTS LIST FOR THE CT 244 AND CT 245 TELEVISION CHASSIS (Continued)

Ref. No.	Part No.	Description
R135	230104-52	Resistor, Carbon, 150 ohms, ½W
R136	230104-62	Resistor, Carbon, 1000 ohms, ½W
R137	230104-67	Resistor, Carbon, 2700 ohms, ½W
R138	230104-71	Resistor, Carbon, 5600 ohms, ½W
R139	230104-52	Resistor, Carbon, 150 ohms, ½W
R140	230104-62	Resistor, Carbon, 1000 ohms, ½W
R141	230104-67	Resistor, Carbon, 2700 ohms, ½W
R142	230104-91	Resistor, Carbon, 270,000 ohms, ½W
R143	230084-38	Resistor, Carbon, 10 ohms, ½W
R144	230104-45	Resistor, Carbon, 39 ohms, ½W
R145	230104-69	Resistor, Carbon, 3900 ohms, ½W
R146	220076-16	Control, Contrast
R147	230104-54	Resistor, Carbon, 220 ohms, ½W
R148A	230105-80	Resistor, Carbon, 33,000 ohms, 1W
R148B	230105-81	Resistor, Carbon, 39,000 ohms, 1W
R149A	230105-71	Resistor, Carbon, 5600 ohms, 1W
R149B	230105-71	Resistor, Carbon, 5600 ohms, 1W
R150	230104-102	Resistor, Carbon, 2.2 megohm, ½W
R151	230104-102	Resistor, Carbon, 2.2 megohm, ½W
R152	230105-85	Resistor, Carbon, 82,000 ohms, 1W
R153	220076-7	Control, Brilliance
R154	230104-74	Resistor, Carbon, 10,000 ohms, ½W
R155	230104-85	Resistor, Carbon, 560,000 ohms, ½W
R156	230104-102	Resistor, Carbon, 2.2 megohm, ½W
R157	230104-86	Resistor, Carbon, 100,000 ohms, ½W
R158	230104-94	Resistor, Carbon, 470,000 ohms, ½W
R159	220076-18	Control, AGC Threshold
R160	230104-77	Resistor, Carbon, 18,000 ohms, ½W
R161	230104-71	Resistor, Carbon, 5600 ohms, ½W
R162	230104-96	Resistor, Carbon, 680,000 ohms, ½W
R163	230104-79	Resistor, Carbon, 27,000 ohms, ½W
R164	230104-98	Resistor, Carbon, 1 megohm, ½W
R165	230104-54	Resistor, Carbon, 220 ohms, ½W
R166	230105-78	Resistor, Carbon, 22,000 ohms, 1W
R167	230104-105	Resistor, Carbon, 3.9 megohm, ½W
R168	230104-58	Resistor, Carbon, 470 ohms, ½W
R169	230104-78	Resistor, Carbon, 22,000 ohms, ½W
R170	230104-73	Resistor, Carbon, 8200 ohms, ½W
R171	230104-73	Resistor, Carbon, 8200 ohms, ½W
R172	230104-76	Resistor, Carbon, 4.7 megohm, ½W
R173	230104-98	Resistor, Carbon, 1 megohm, ½W
R174	220076-12	Control, Vertical Speed
R175	230104-86	Resistor, Carbon, 100,000 ohms, ½W
R176	230105-91	Resistor, Carbon, 270,000 ohms, ½W
R177	220076-5	Control, Height
R178	230104-83	Resistor, Carbon, 56,000 ohms, ½W
R179	230105-59	Resistor, Carbon, 560 ohms, 1W
R180	220076-20	Control, Vertical Linearity
R181	230104-102	Resistor, Carbon, 2.2 megohm, ½W
R182	230105-13	Resistor, Carbon, 1000 ohms, 1W
R183	230104-69	Resistor, Carbon, 3900 ohms, ½W
R184	230104-50	Resistor, Carbon, 100 ohms, ½W
R185	230104-50	Resistor, Carbon, 100 ohms, ½W
R186	230091-1	Resistor, Temperature Compensating, 380,000 ohms, ½W
R187	230104-87	Resistor, Carbon, 120,000 ohms, ½W
R188	220076-15	Control, Horizontal Hold
R189	230105-91	Resistor, Carbon, 270,000 ohms, 1W
R190	230094-225	Resistor, Carbon, 270,000 ohms, 1W
R191	230094-213	Resistor, Carbon, 180,000 ohms, ½W
R192	230095-211	Resistor, Carbon, 150,000 ohms, 1W
R193	230104-103	Resistor, Carbon, 2.7 megohm, ½W
R194	230104-73	Resistor, Carbon, 8200 ohms, ½W
R195	230092-1	Resistor, Temperature Compensating, 100,000 ohms, ½W

World Radio History

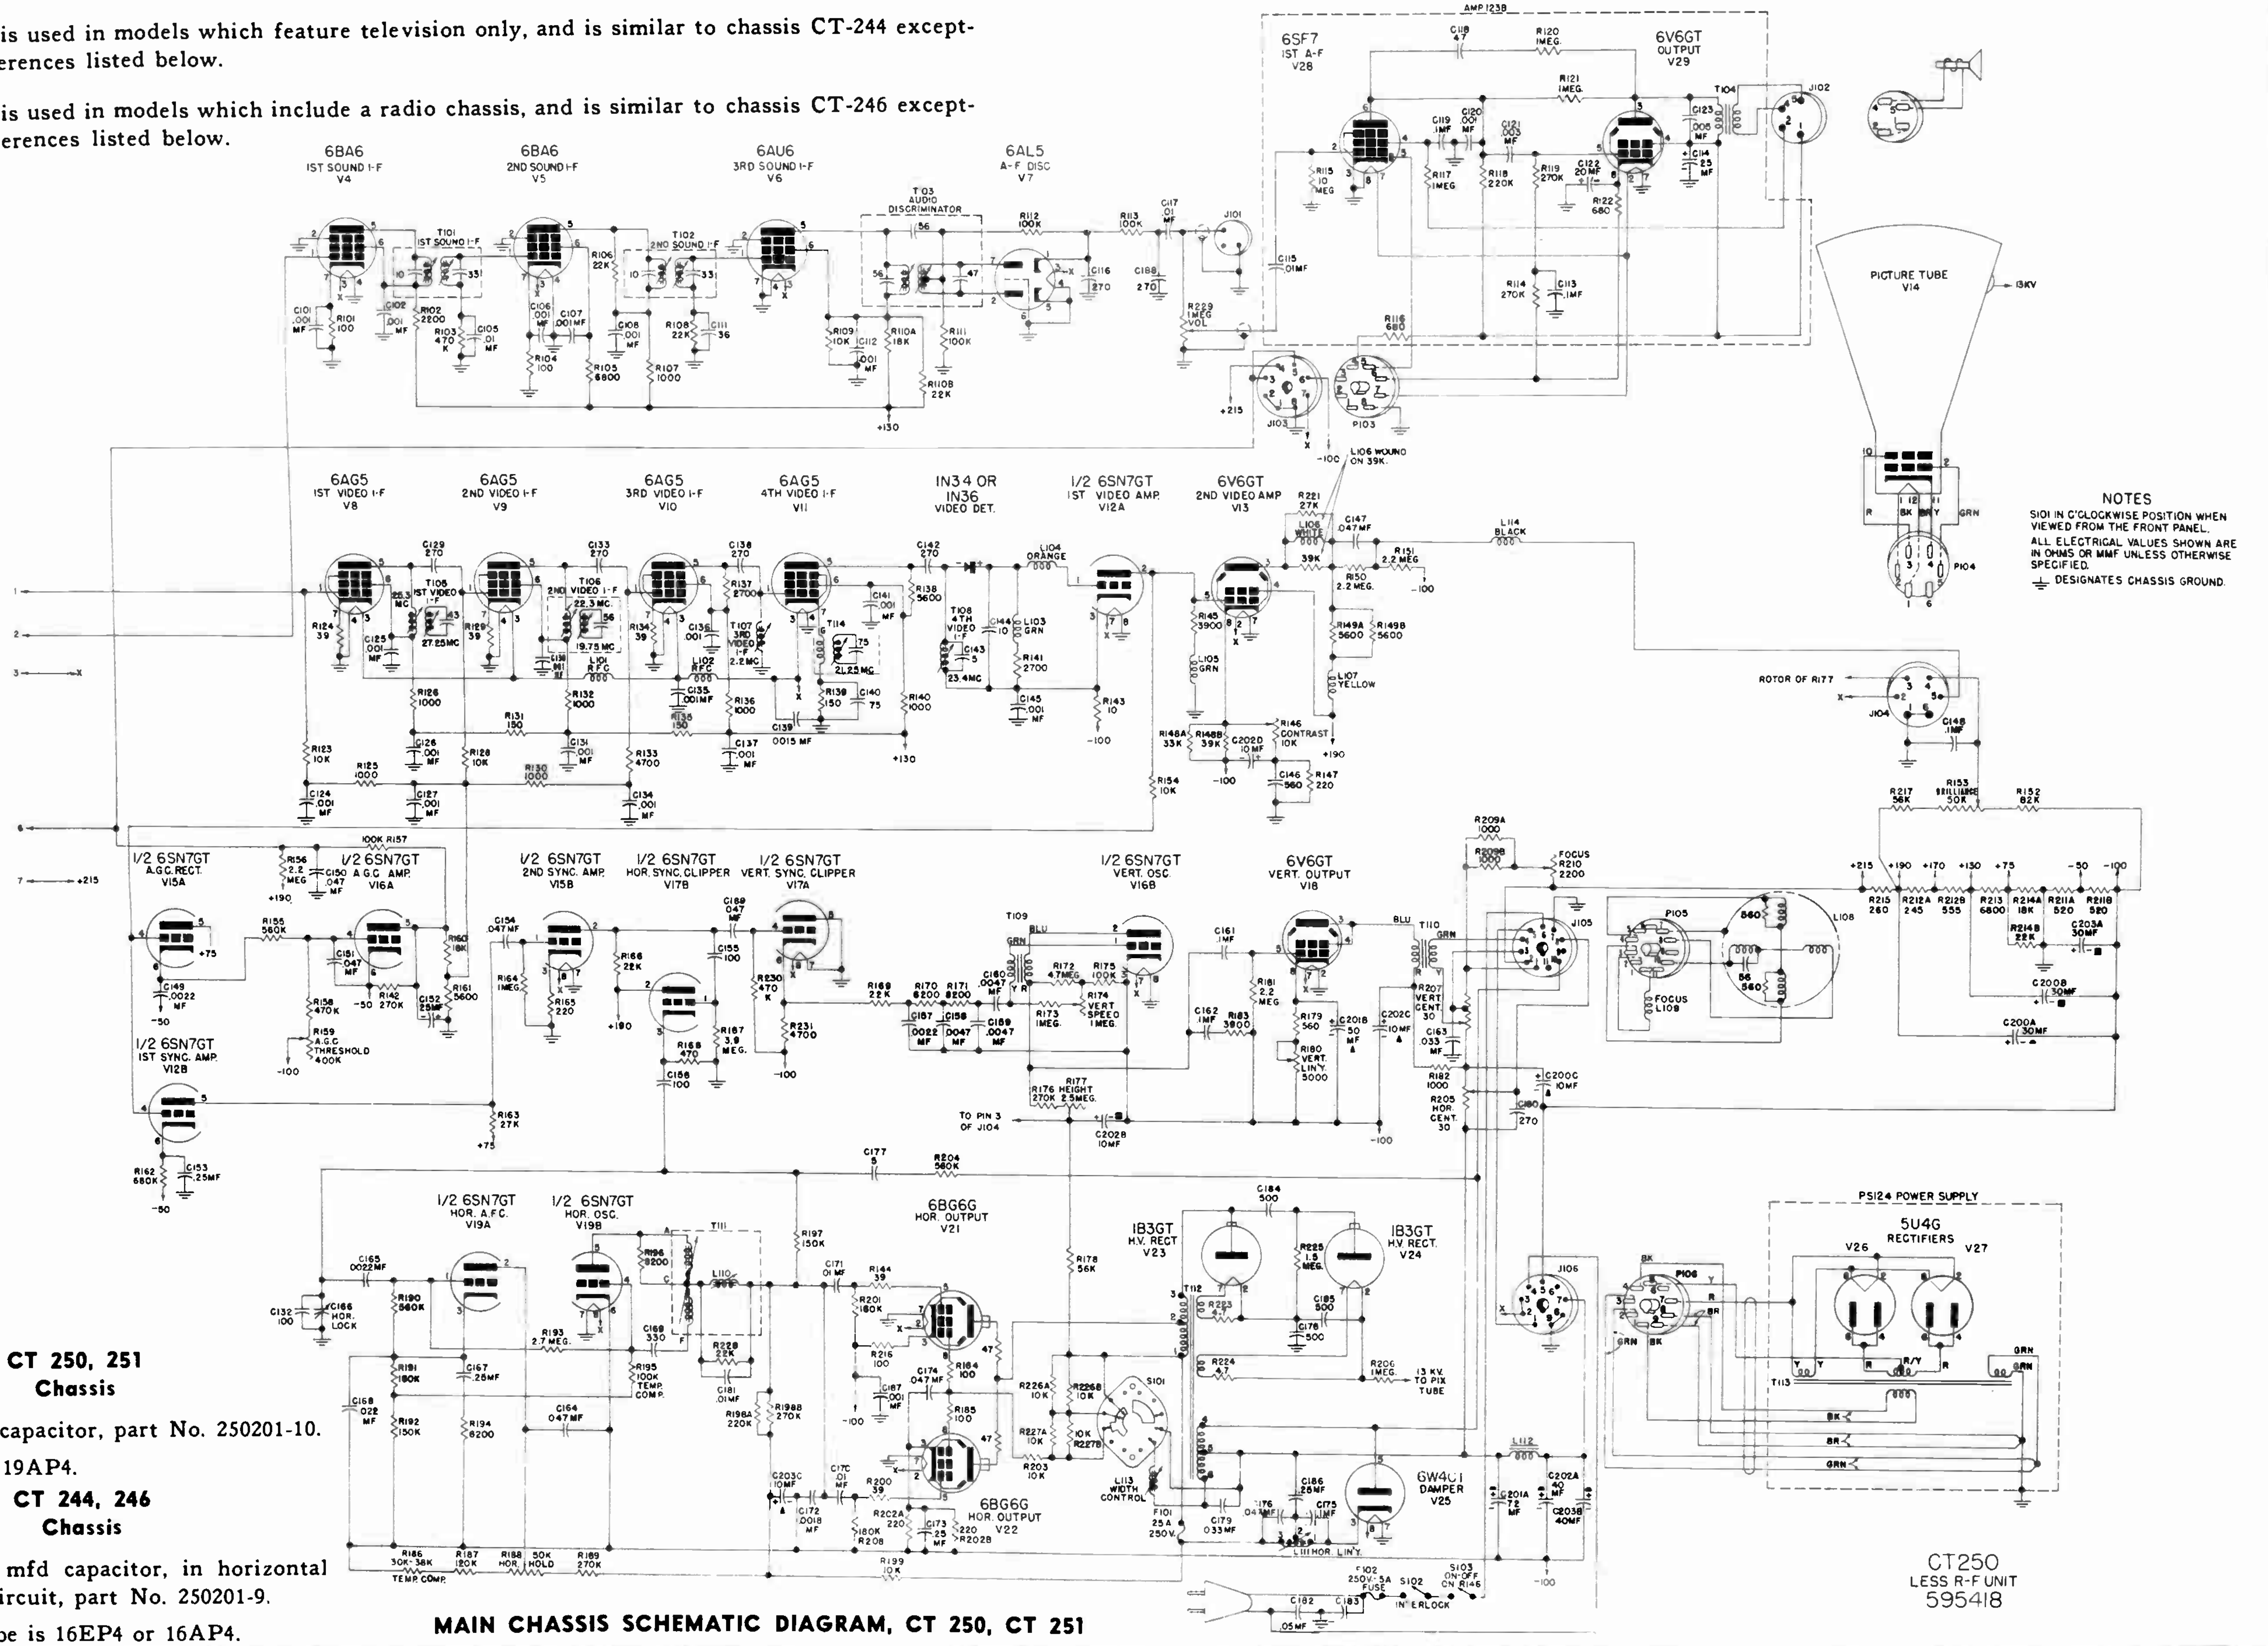
This maintenance information covers Magnavox television receiver chassis CT-250 and CT-251.

Chassis CT-250 is used in models which feature television only, and is similar to chassis CT-244 excepting for the differences listed below.

Chassis CT-251 is used in models which include a radio chassis, and is similar to chassis CT-246 excepting for the differences listed below.



CT 250, 251 Chassis

C179, .033 mfd capacitor, part No. 250201-10.

Picture tube is 19AP4.

CT 244, 246 Chassis

(1) C179, .022 mfd capacitor, in horizontal linearity circuit, part No. 250201-9.

(2) Picture tube is 16EP4 or 16AP4.

PART I
DESCRIPTION

Magnavox Television chassis number CT 247, 248 and 249 are direct view chassis with self contained power supplies. All include an intercarrier I-F system. Their differences are outlined in Part III of this manual.

The advanced design of these receivers provides equivalent or better performance comparing to any existing television receiver regardless of the tube complements involved. Technical features include:

- Direct-coupled video amplifier, which eliminates the need for D-C reinsertion and provides better noise immunity.
- Intercarrier I-F amplifiers for ease of alignment, simplified tuning, increased stability, reduced phase discrepancies, and freedom from the effect of oscillator drift.
- Discriminator-type horizontal automatic frequency control.
- Ratio-detector type sound detector.
- Cathode modulation of the picture tube.
- Minimum number of operating controls.
- MAGNALOK horizontal AFC circuit. Frequency control is accomplished by comparing the sine wave oscillator frequency with the sync pulses. The result is applied to a reactance tube, which in turn controls the oscillator frequency.

TUBE COMPLEMENT

[a]R-F Amplifier	6AK5
[b]Converter	6AG5
Oscillator	6AB4
I-F Amplifier	6AG5
I-F Amplifier	6AG5
I-F Amplifier	6AG5
Video Det. and Sync Leveler	6AL5
Video Amplifier	6AU6
Sound I-F Amplifier	6AU6
Ratio Detector	6AL5
[c-d]1st Audio Ampl. and AGC Clamp	6AV6
[d]Audio Output	6K6GT/G
12AU7	AGC Det. and Pre Sync Sep.
12AU7	AGC Ampl. and Sync Ampl.
6AN7GT	Vert. Sync Clipper and Multi-Vib.
6SN7GT	Vert. Sync. Clipper and Multi-Vib.
6AL5	AFC Detector
6AU6	AFC Reactance
6SN7GT	Hor. Sine Wave Osc. and Disch.
6BG6G	Hor. Output
6W4GT	Damper
1B3GT	H. V. Rectifier
5U4G	L. V. Rectifier
[e]12LP4	Picture Tube
[f]12KP4	Picture Tube

Note A 6AK5 used in early models only. 6BC5 used in later models may not be used as replacement for 6AK5.

Note B 6AG5 used in early models only. 6BC5 used in later models may be used as replacement for 6AG5.

Note C 6C4 used in CT-248 as AGC clamp.

Note D 6AV6 and 6K6GT/G not used in CT-248.

Note E Used in CT-247 chassis only.

Note F Used in CT-248 and CT-249 chassis.

GENERAL DESCRIPTION

300 Ohm—Antenna Input	**IMPEDANCE**	Speaker Voice Coil 3.2 Ohms
195 W. at 117 V., 60 C. P. S.	**POWER**	Audio—2.5 W. Undistorted, 4 W Max.
Chassis 17"x13¾"x9½"	**SIZE**	Picture—8 29/32"x11¼"

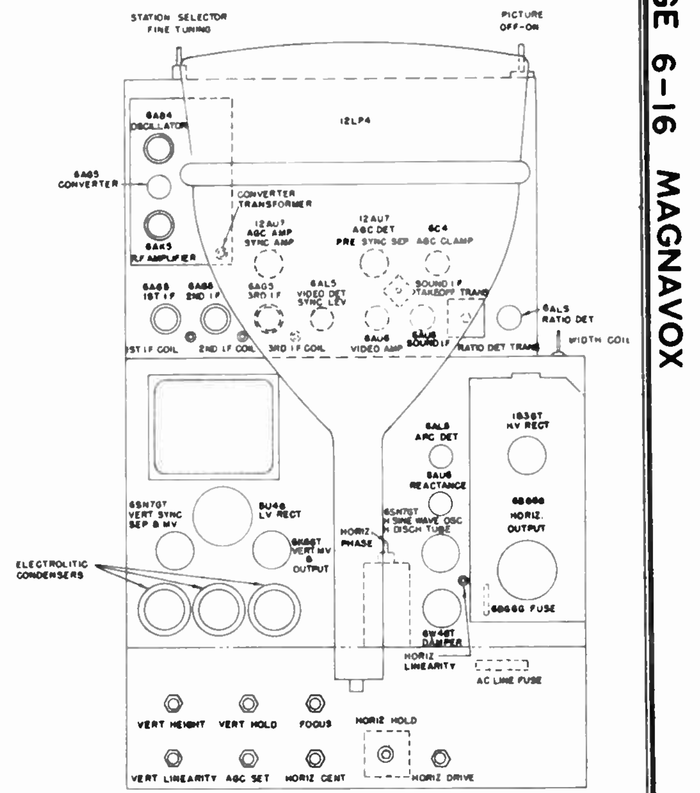
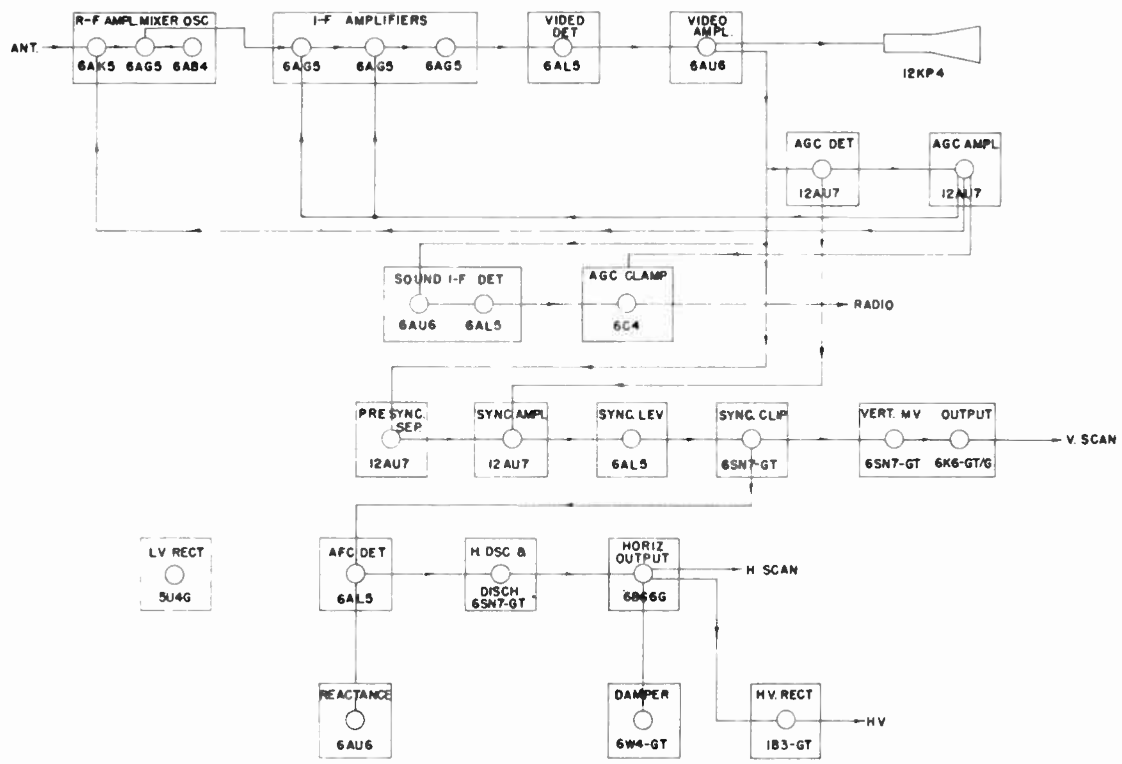
LAYOUT DIAGRAM, CT 247-CT 249



LAYOUT DIAGRAM, CT 248



FUNCTIONAL DIAGRAM, CT 248

RECEIVER OPERATION INSTRUCTIONS

CT 247 AND 249

1. Turn the PICTURE OFF-ON control to the right, about one-half turn.
2. Adjust the CHANNEL SELECTOR to the desired channel number.
3. Adjust the FINE TUNING control for best picture quality.

   If the Fine Tuning Control is improperly adjusted, the picture may be blurred or streaked, or the sound reproduction may have a "buzzing" sound.
4. The PICTURE OFF-ON control adjusts the picture brightness. It should be set for the most pleasing picture.
5. The SOUND control adjusts the volume of sound reproduction.

A picture framing control is located at the rear of the instrument, and is identified by a small control knob. It may be necessary to reset this control should the picture roll. Turn it to the left so the roll is downward, then advance it to the right until the picture stops moving.

CT 248

1. Turn OFF-ON BASS control on the radio receiver to the right, about one-half turn.
2. Set the INPUT SELECTOR SWITCH on the radio to TV.
3. Turn the PICTURE OFF-ON control to the right about one-half turn.
4. Adjust the CHANNEL SELECTOR to the desired channel number.
5. Adjust the FINE TUNING control for best picture quality.
6. Adjust PICTURE OFF-ON control for most pleasing picture.
7. Adjust the VOLUME, BASS and TREBLE controls for the desired TV sound reproduction.

CHASSIS DIFFERENCES

Chassis	Picture Tube	Ion Trap	Audio Amplifier
CT-247	12LP4	360404-2	On TV Chassis
CT-248	12KP4	None	Uses audio in radio chassis
CT-249	12KP4	None	On TV Chassis

These chassis are very similar, and differ only in the audio stages and the picture tubes used.

The CT-247 is used in models which feature television only, and is designed for a 12LP4 picture tube. It uses a 6K6GT/G audio power amplifier, and the triode section of a 6AV6 as an audio amplifier. It also uses the diode section of the 6AV6 as AGC Clamp.

The C-248 is used in models which include a radio chassis, and has no audio amplifier or speaker. AGC clamping is accomplished by a 6C4. The picture tube is a 12KP4.

The CT-249 is the same as the CT-247 except that it uses a 12KP4 picture tube.

R-F UNIT

The R-F Unit consists of an R-F Amplifier, an Oscillator and a Converter or Mixer. A 12-position switch selects the proper antenna, R-F amplifier, oscillator and converter tuned circuits for the desired television channel. The oscillator frequency may be further adjusted by means of the fine tuning control, which is a variable dielectric capacitor.

I-F AMPLIFIERS

The three I-F amplifiers are stagger turned for simplicity, for increased stability, and for ease of alignment. This last feature is further emphasized by the fact that there are no traps to adjust, or to affect the frequency of the other coils.

The first I-F plate coil and the second I-F grid coil are bi-filar wound, (in the same direction) on the same coil form, which is tuned with an adjustable iron core. Coupling between stages is by the capacity and inductive coupling between windings. The same conditions exist between the second I-F plate coil and third I-F grid coil, and the third I-F plate coil and detector primary coil.

The I-F passband is 3 Mc. wide. The audio carrier

©John F. Rider

World Radio History

is approximately 25 db down on the curve, and the video carrier is 6 db down on the curve.

DETECTOR

The detector operates in the conventional manner, and also detects the 4.5 Mc. beat between the video I-F and sound I-F carriers. As these carriers result from crystal controlled carrier frequencies at the television transmitter, their resultant 4.5 Mc. beat is much more stable than if it were produced by beating the sound carrier with a local oscillator.

VIDEO AMPLIFIER

The video amplifier is direct coupled, and eliminates the necessity for DC reinsertion. As the output from the detector is negative, noise pulses drive the video amplifier tube beyond cut-off, so it also acts as a noise limiter. The output from the amplifier is in a positive direction, so the signal is applied to the picture tube cathode. This is identical to grid modulation with a negative signal. The DC bias on the picture tube governs the brightness of the tube, and is adusted by the PICTURE CONTROL.

SYNC CIRCUITS

The Pre Sync Separator provides a boost of vertical pulses, and the triode section of the AGC Detector provides a boost of horizontal pulses. The combined output from these stages is amplified by the Sync Amplifier, held at a predetermined level by the Sync Leveler, and the desired pulses are accepted by the Sync Clipper.

VERTICAL DEFLECTION

The vertical pulses are separated by the integrating network, and used to synchronize the Vertical Multivibrator and Output stages, which provides the necessary vertical deflection.

AUTOMATIC GAIN CONTROL

A rectified DC voltage is taken from the cathode of the AGC Detector, amplified by the AGC Amplifier, and used to bias the first and second I-F amplifiers and the R-F amplifier. The operating range of this bias is controlled by the AGC SET CONTROL.

AUTOMATIC FREQUENCY CONTROL
