One diode section of a 6AL5 tube (V-11B) is used as a D.C. Restorer to develop a positive voltage across resistor #170 which varies with the average level of the negative-going video signal. This bias voltage is fed to the picture tube grid to maintain the proper level of picture brightness.

TV SOUND CIRCUITS

The 4.5 Mc. difference frequency between the 26.75 Mc. video carrier and the 22.25 Mc. sound carrier is separated from the composite video signal at the output of the video detector and fed thru two transformer-coupled stages of sound I.F. amplification using two 6AU6 tubes (V-1 and V-2). The cathodes of these tubes are operated at approximately +160 volts to improve power supply regulation. The 2nd Sound I.F. Amplifier also acts as a grid leak limiter to clip unwanted AM interference.

Further limiting action of the positive portion of the 4.5 Mc. sound signal is accomplished using one diode section of a type 6T8 tube (V-3). The two other diode sections of this tube are connected in a conventional ratio-type Sound Discriminator circuit. This circuit performs the function of converting the constant amplitude FM signal to a varying amplitude audio output. Sound output is thus obtained from an appropriate coupling network connected to the tertiary winding of discriminator transformer #26.

The audio signal is fed thru section #43A of the Band Switch and is coupled to the triode section of the 6T8 tube thru the Volume control. This section of the 6T8 acts as a Sound Amplifier and feeds the audio signal to the 6V6GT (V-4) sound output stage. The output of this stage drives the P.M. dynamic speaker.

COMPOSITE SYNC CIRCUITS

A portion of the composite video signal is removed at the output of the cathode follower stage to control the horizontal and vertical sweep systems. The signal is first injected into the grid of one triode section of a 12AU7 (V-17A) acting as a Sync Clipper. The tube is operated at low plate voltage and is self-biased by grid resistor #188. Plate current flows only when the most positive portion of the video signal is present at the tube grid, namely during the horizontal and vertical sync pulses. Plate current saturation is reached with a further increase in signal, thus clipping the tops of the sync pulses and removing any undesirable interference.

The sync pulses are directly coupled to the grid of the other triode section of the 12AU7 (V-17B) which acts as a Phase Splitter. Positive-going sync pulses are removed at the plate of this tube and negative-going pulses are removed at the cathode. Both types of horizontal sync pulses are used for A.F.C. control while only the positive-going vertical pulses are used in the vertical sweep circuit.

VERTICAL SWEEP CIRCUITS

Positive-going vertical sync pulses from the output of the Phase Splitter are integrated in the Integrator Coupling Unit #262 and are used to control the frequency of a conventional type Blocking Oscillator. This oscillator utilizes one triode section of a 6SN7GT tube (V-25A) and its free-running frequency is determined by the condenser and resistor components (including the Vertical Hold Control) in its grid circuit. The sync pulses are impressed at the tube grid just before the oscillator would normally trigger and are of sufficient amplitude to drive the tube to conduction and cause the oscillator to lock-in at the sync frequency. The output of this stage is controlled by the Height potentiometer.

The Blocking Oscillator drives the other section of the 6SN7GT (V-25B) which is connected as a vertical scanning output stage. Adjustment of vertical linearity is accomplished in the cathode of this circuit by varying bias and thus changing the plate current operating point on the portion of the tube's non-linear characteristic curve. Sawtooth current wave output is applied to the vertical deflection coils thru the Vertical Output transformer #278.

RETRACE LINE SUPPRESSOR CIRCUIT

A portion of the voltage pulse across the vertical deflection coil is reshaped and coupled to the cathode of the picture tube to insure cutoff of the tube during the vertical retrace interval. In this manner, vertical retrace lines ordinarily seen with low Contrast and high Brightness control settings are no longer visible.

HORIZONTAL A.F.C. CIRCUIT

An automatic frequency control arrangement is utilized in this receiver to improve stability of the horizontal sweep system. The two 180° displaced sync pulses from the Phase Splitter are fed to the 6AL5 (V-18) Horizontal A.F.C. Phase Detector. At the same time, a pulse of horizontal output voltage is taken off one side of the Width coil, is reshaped, and its a.c. component is injected into the Phase Detector as a sawtooth wave. Any phase displacement between the feedback sawtooth and the horizontal sync pulses will cause the voltages across the two diode sections to differ. This will result in a d.c. control voltage injected at the Horizontal Scanning Multivibrator grid which will change Multivi-

©John F. Rider

World Radio History

brator speed in a direction to bring its frequency "in step" with the incoming horizontal pulses. This bias voltage will be proportional to the amount of phase shift between the comparison voltage and the sync pulses and its polarity will depend on whether the sawtooth voltage leads or lags the sync pulses.

HORIZONTAL SWEEP CIRCUITS

The d.c. control voltage from the output of the Horizontal A.F.C. Phase Detector controls the frequency of a conventional cathode-coupled Horizontal Scanning Multivibrator, using a 12AU7 tube (V-19). Coarse frequency adjustment of the multivibrator is obtained by varying the position of the slug in the Horizontal Lock coil #202, while fine frequency control is accomplished using the front-panel Horizontal Hold potentiometer #208.

Horizontal Multivibrator output is used to drive a 6BG6G (V-20) horizontal scanning output stage. The plate circuit of this stage is fused to protect transformer #222 and kill high voltage in the event the 6BG6G or the high voltage rectifier circuit draws excessive current. Signal level to the horizontal output tube is controlled by means of Horizontal Drive control condenser #212. The sawtooth current wave output of this tube is applied to the horizontal deflection coils thru the impedance matching Horizontal Output transformer. A portion of the transformer secondary is shunted by the Width coil which adjusts picture width by controlling horizontal output current waveshape

The 6W4 Horizontal Damping tube (V-22) is connected across the transformer secondary to damp out oscillations created during rapid retrace of the sawtooth current wave. This circuit provides control of horizontal linearity and also uses some of the inductive kickback voltage to supply additional B+ for the horizontal and vertical sweep systems.

HIGH VOLTAGE POWER SUPPLY CIRCUIT

High voltage is obtained by using the inductive kickback voltage induced in the Horizontal Output transformer during the retrace period. This kickback voltage is produced in the primary winding of the transformer and is increased by autotransformer action before being applied to the plate of the 1B3GT/8016 High Voltage Rectifier tube (V-21). Filament voltage is obtained by a loop of wire around the transformer. The output of the rectifier (approximately 9,000 volts) is filtered and applied to the high voltage anode of the picture tube.

LOW VOLTAGE POWER SUPPLY CIRCUITS

The low voltage power supply provides heater and plate voltages for all stages except those portions supplied by the high voltage rectifier and horizontal damping circuits. A sturdy power transformer #239 supplies plate voltage to a 6X5GT Rectifier (V-23) and a 5U4G Rectifier (V-24) and also contains a 5 volt filament winding for the 5U4G plus a 6.3 volt winding for the adequately filtered parallel filament string. The output of the 6X5GT double-L-section RC filter supplies the 160 volt B+ buss while the output of the 5U4G pi-section LC filter supplies the 350 volt B+ buss. A 290 volt B+ buss is fed from the low side of the Focus coil. Focus coil current is obtained from the 350 volt B+ supply and this current is regulated by changing the setting of the Focus potentiometer across the coil

The various controls on the receiver may be divided into two classes, Operating and Pre-set. Operating controls are those which control program selection as well as sound and picture quality. All but one of these controls are located on the front panel and their functions are indicated in Figure 2. The built-in television antenna tuning condenser is accessible at the rear of the receiver. The Pre-set controls are those which require adjustment at the time the receiver is installed and they rarely need attention thereafter. There are eight of these controls, four of which are located at the back of the chassis (see Figure 4). Four controls are accessible by removing the Name Plate located directly above the Operating controls.

RECEIVER CONTROLS

AM-FM FINE TUNING CONTROL (outer knob)
Use to tune receiver to desired station after BAND SWITCH is set to either "AM" or "FM" position.

AM-FM COARSE TUNING CONTROL
Has same effect as AM-FM FINE TUNING control except that tuning is faster.

TELEVISION FINE TUNING CONTROL
Use to tune in station after CHANNEL SELECTOR is set to desired channel. See next page for complete description of tuning procedure.

CHANNEL SELECTOR (outer knob)
Set knob so that it points to desired television channel. Then use TELEVISION FINE TUNING control to tune in station.

ON-OFF SWITCH & VOLUME CONTROL (small knob)
Use to turn receiver on or off and to adjust for desired sound volume.

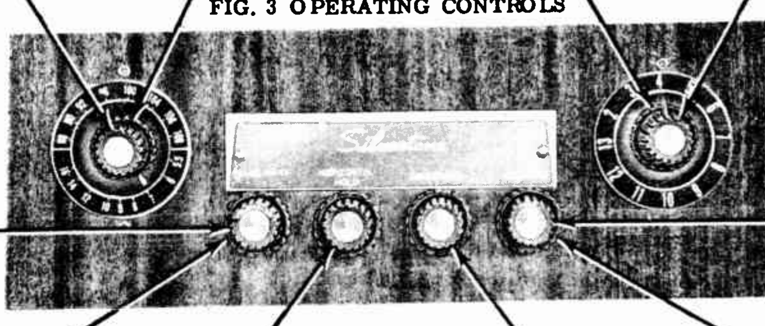

FIG. 3 OPERATING CONTROLS

TONE CONTROL (small knob)
Adjust for most pleasing tone. To increase bass emphasis turn counter-clockwise.

BAND SWITCH (large knob)
Set for desired type of reception. Starting from extreme clockwise position and turning counter-clock wise, the four settings are: (Television); (Phonograph); ("AM" Radio); and ("FM" Radio).

HORIZONTAL HOLD CONTROL
Adjust so that picture is stationary and does not move horizontally or break up into black and white streaks.

BRIGHTNESS CONTROL
Adjust for picture brillance. Re-adjust after setting CONTRAST control.

CONTRAST CONTROL (large knob)
Adjust to receive picture and obtain correct contrast between light and dark shades.

CONTROL ADJUSTMENT PROCEDURE

Although the pre-set controls have been factory adjusted for optimum performance, it is usually necessary to make some fine adjustments of these controls at the time of installation.

To gain access to the centering adjustments and ion trap, it will be necessary to remove the back cover of the cabinet by first removing the built-in antenna tuning knob and then taking out the screws around the rim of the back cover.

Be sure that locking device (see Fig. 5) used to hold the focus coil in position during shipment is removed before attempting to reposition that coil as described in the following procedure.

The receiver is now ready for an operation check.

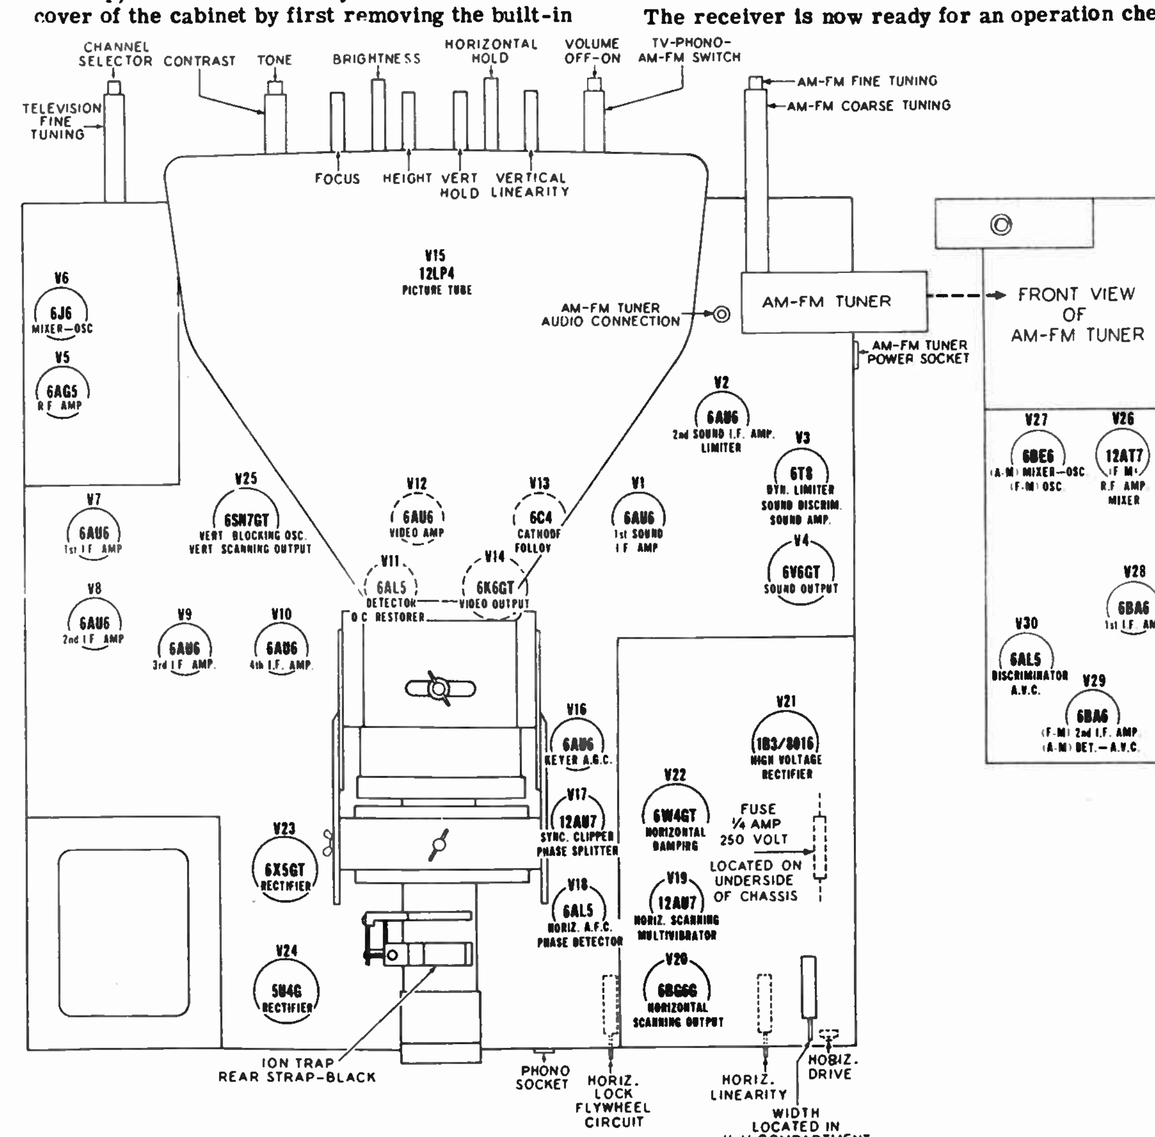

FIG. 2
TUBE LOCATIONS AND FUNCTIONS

©John F. Rider
World Radio History

TO ADJUST CONTROLS FOR RECEPTION OF STANDARD BROADCAST OR FREQUENCY MODULATION STATIONS:

1. TURN SET ON — Rotate "On-Off Switch and Volume" knob clockwise to turn receiver on.

2. POSITION BAND SWITCH — Set "Band Switch" to either its "AM" or "FM" position. Small red indicator lite adjacent to corresponding dial scale will become illuminated.

3. TUNE — Use "AM-FM Fine Tuning" control to select desired station.

4. ADJUST VOLUME — Select "Volume" control setting for desired sound intensity.

5. ADJUST TONE — Select "Tone" control setting for most pleasing tone.

TO ADJUST RECEIVER FOR RECEPTION OF TELEVISION STATIONS:

1. TURN SET ON — Rotate the "On-Off Switch and Volume" knob approximately ½ turn clockwise to turn set on and obtain sufficient sound volume during the tuning process. Allow several minutes for all tubes in the receiver to warm up and for circuits to stabilize before attempting to obtain a picture on the screen.

2. POSITION BAND SWITCH — Set "Band Switch" to "TV" position. Small red indicator light above channel numbers will become illuminated.

3. ADVANCE BRIGHTNESS CONTROL — Turn "Brightness" control clockwise until picture screen is moderately illuminated. The screen may remain dark or dimly illuminated until ion trap is adjusted as described in next step. Should it be noted that a semi-circular portion of the raster is not illuminated, that condition may be disregarded as it will be corrected by subsequent adjustments.

4. ADJUST ION TRAP — The ion trap is located on the neck of the picture tube as shown in Figure 5 and consists of a magnet held in position by metal bands. The magnet identified by the black band must be in the rear position.

   Loosen the clamp screw which secures the ion trap to the tube neck. Then rotate the entire trap assembly while sliding it back and forth until picture tube screen is illuminated to maximum brillance. Reduce "Brightness" control setting and repeat this operation to assure accurate positioning of ion trap.

5. ADVANCE CONTRAST CONTROL — Rotate the "Contrast" control knob fully clockwise.

6. SET CHANNEL SELECTOR TO DESIRED CHANNEL — The "Channel Selector" knob designates the channel to which the television receiver is tuned. Set the "Channel Selector" knob to a channel on which a local television station is known to be broadcasting at the time.

7. FINE TUNING CONTROL — Use the "Television Fine Tuning" control (illustrated in Figure 3) to obtain the correct tuning point for both picture and sound. That is accomplished as follows:

   a. Turn "Television Fine Tuning" control in either direction until sound volume is maximum — if sound cannot be heard, advance the volume control and repeat fine tuning.

   b. When the point of maximum sound volume has been reached it will be noted that the picture has a "ragged" or "sawtooth" appearance or is partially obscured by "sound bars" (dark horizontal bars of varying width).

   THE CORRECT SETTING OF THE "TELEVISION FINE TUNING" CONTROL is now obtained by turning it away from the maximum volume position only far enough to eliminate the "sound bar" interference and permit sharp reproduction oi the picture. If an image is slightly distorted or tears into a series of black and white streaks, reduce the setting of the "Contrast" control and operate the "Horizontal Hold" control knob until picture appears stable and undistorted.

8. BUILT-IN ANTENNA ADJUSTMENT — If the receiver's built-in television antenna system is used, rotate the antenna tuning knob (located at rear of cabinet) until the best picture is obtained. It may be possible to find a single setting for this knob which will give satisfactory performance for a group of stations. In the event that is not the case, adjust the control for optimum performance each time the Channel Selector is rotated to a different station.

9. SOUND VOLUME — Adjust the setting of the "Volume" control by rotating it clockwise until the sound accompanying the television broadcast is received at a satisfactory level.

10. TONE — Adjust "Tone" control setting for most pleasing tonal quality.

11. HORIZONTAL HOLD — Should the picture appear to move horizontally across the screen or break up into a series of light and dark streaks, adjust the "Horizontal Hold" control until the picture remains stationary.

    If this control must be rotated to the end of its range for proper "locking" action, then it will be necessary to reset the position of the "Horizontal Lock" control (see Figure 5) for location). Adjustment is accomplished by first setting the "Horizontal Hold" control in the middle of its range and then changing the setting of the "Horizontal Lock" control until picture locks in horizontally.

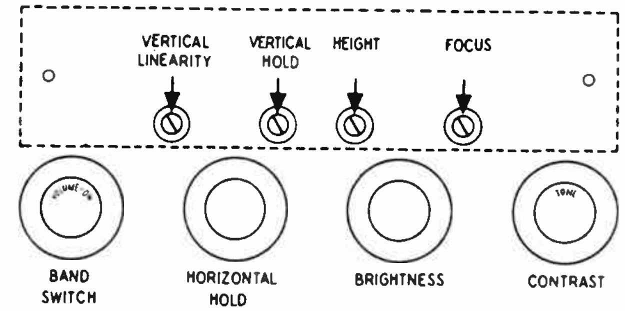

FIG. 4 PRE-SET CONTROLS

12. VERTICAL HOLD — Should the picture roll in a vertical direction or appear as multple vertical images, it will be necessary to adjust the "Vert. Hold" control located behind the Name Plate (see Figure 4).

    After this adjustment is made, reduce contrast until picture is barely visible and check setting of "Vertical Hold" control for proper picture synchronization.

13. INITIAL FOCUS — Adjust the "Focus" control, located behind Name Plate, until picture is clearly defined.

    Fuzzy picture may also be due to reproduction of poor quality film when station is televising a motion picture. Incorrect tuning of receiver, produces a similar effect. Check for proper tuning point as described in step 7.

14. STRAIGHTENING TILTED RASTER — If the pattern should appear on the screen in a tilted position, loosen the deflection yoke locking screw (see Figure 5) and rotate the yoke sufficiently to correct this condition. Be sure to re-tighten the screw securely.

<u>The following adjustments should be made while the station is transmitting its circular test pattern.</u>

15. CENTERING — Before attempting to center the test pattern on the screen, be sure that the focus coil locking device has been removed. This device is used only for clamping during shipment; see Figure 5. The pattern can then be readily centered by properly positioning the focus coil. This is done by turning the coil in the desired direction by hand. If coil does not move freely, loosen wing nuts labeled A and B in Figure 5.

16. WIDTH — Control of picture size in the horizontal direction is accomplished by means of the "Width" control located on the rear of H. V. power supply (see Fig. 5). If abnormally low line voltage makes it difficult to obtain sufficient picture width when using the "Width" control, then changing the setting of the "Horizontal Drive" control may be helpful. The "Drive" control is located at the rear of the chassis and its setting will affect horizontal linearity as well as picture width. Therefore, after adjusting this control for desired width, it may be necessary to re-adjust the "Horizontal Linearity" control as described in paragraph #19.

17. HEIGHT — Control of picture size in the vertical direction is accomplished by means of the "Height" control located behind the Name Plate. Height and width adjustments should be checked for all transmitting stations to be sure that picture properly fills the viewing area.

18. VERTICAL LINEARITY — Improper vertical linearity causes the circular test pattern to appear condensed on the upper edge of the screen and extended on the lower edge or vice versa. Adjust for proper linearity by using "Vert. Lin." control located behind Name Plate. It may be necessary to re-adjust the "Height" control if an appreciable change is made in the linearity control setting.

19. HORIZONTAL LINEARITY — Improper horizontal linearity causes the circular test pattern to appear condensed on the right edge of the screen and extended on the left edge or vice versa. Adjust for proper linearity by using "Horiz. Lin." control located on rear of chassis (see Figure 5). In event that proper horizontal linearity cannot be obtained by adjusting this control, then change the setting of "Horiz. Drive" control (also located at rear of chassis). As width and linearity of the picture are affected by the setting of Horiz. Drive control, it will be necessary to adjust this control in conjunction with the Horiz. Linearity and Width controls to obtain desired picture width and linearity.

20. ELIMINATING SEMI-CIRCULAR SHADOW — This shadow is caused by the electron stream striking the neck of the tube and it can generally be corrected by applying one or a combination of the following procedures:

    a. Reposition the focus coil to the extent permitted by the bracket assembly which supports this coil. Shift entire focus coil assembly forward or backward by

©John F. Rider

World Radio History

loosening wing nuts labeled B in Figure 5.

b. Shift position of deflection yoke forward as far as possible against neck of picture tube. Yoke is held in position by a wing screw as illustrated in Figure 5.

c. In event neck shading cannot be eliminated by the above procedures, release the four wing nuts labeled C in Figure 5 and raise or lower entire yoke and focus coil assembly so that focus coil can be repositioned vertically with respect to the tube neck.

21. FINAL ADJUSTMENTS — Recheck settings of "Brightness," "Contrast" and "Focus" controls for best picture quality. Proper adjustment of all Pre-set and Operating controls on this receiver should result in a clear and stable picture.

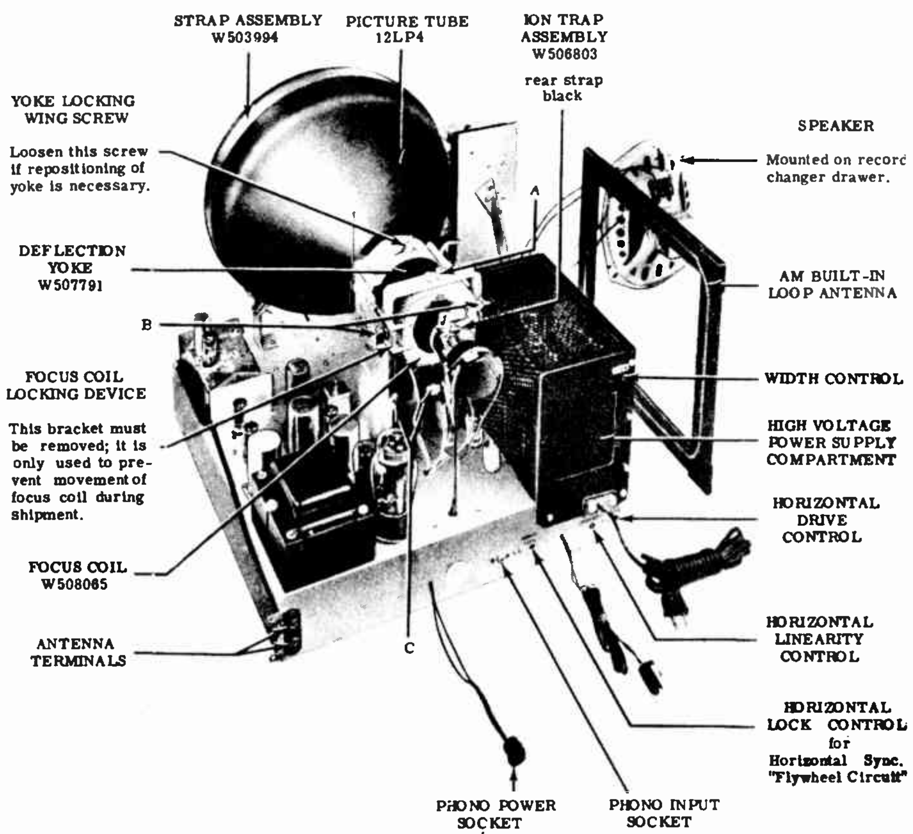

FIG. 5 CHASSIS AND PICTURE TUBE ASSEMBLY

SOCKET VOLTAGES

CAUTION

THE PICTURE TUBE is highly evacuated and if broken, glass fragments will be violently expelled. Scratching, chipping, undue pressure, or careless handling such as lifting the tube by its neck is dangerous and should be avoided. If it is necessary to handle the picture tube, use safety goggles and heavy gloves. Be sure to discharge the voltage developed across the capacitor formed by the inner and outer coating of the picture tube. This can be done by connecting the high voltage socket on the tube to the outer coating with a well insulated metal conductor.

HIGH VOLTAGE (approximately 9,000) is produced in a supply circuit of this receiver. Exercise care to avoid contact with elements of this circuit and particularly the tube terminals which are labeled "CAUTION" in the adjoining voltage chart. If measurement of voltage at these points is necessary, see procedure given below under note "S".

THE HIGH VOLTAGE LEAD, which supplies approximately 9,000 volts to the picture tube, should be momentarily shorted to the chassis whenever it is disconnected for service purposes. This discharges the high voltage filter condensers and prevents a shock hazard when working on the receiver after it has been turned off.

INTERMEDIATE B+ VOLTAGES are dangerous and caution should be observed when the receiver chassis components are exposed for service purposes.

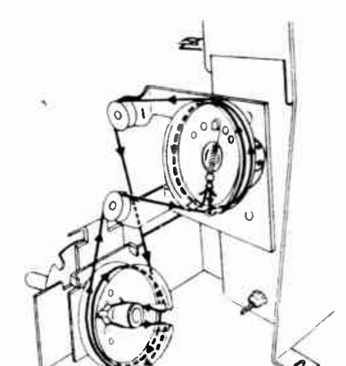
THE VOLTAGES SHOWN IN THE ADJOINING CHART WERE MEASURED UNDER THE FOLLOWING CONDITIONS

1.	Power Supply—117 volts 60 cycle AC.
2.	All voltages are measured between socket terminals and chassis unless otherwise indicated on adjoining chart.
3.	* Measurements made with voltmeter having sensitivity of 1000 ohms per volt except where indicated by (*). The (*) symbol designates a vacuum tube voltmeter measurement.
4.	Band Switch set to "TV" position unless otherwise indicated by the letters "X", "Y", or "Z" following voltages shown in adjoining chart.
5.	Antenna connected for reception of a television broadcast.
6.	Channel Selector and Fine Tuning Controls set for correct reception of a local station.
7.	All other controls set for "normal" reception of the transmitted signal unless the voltage shown on the chart is followed by letters indicating a special condition of measurement as outlined in step 8.
8.	Certain voltages were measured with two different settings of specific controls. It should therefore be understood that in these instances all controls, with the exception of one or two, were set for "normal" reception—letters following the voltage shown on the chart indicate the exceptions and are explained below.

EXPLANATION OF NOTES

A.	Vert. Hold max. counter-clockwise
B.	Brightness max. counter-clockwise
C.	Contrast max. clockwise
D.	Horiz. Drive max. clockwise
E.	Horiz. Hold max. clockwise
F.	Focus Control max. clockwise
G.	Width max. counter-clockwise
H.	Height max. clockwise
J.	Horiz. Hold set for normal picture
K.	Horiz. Lock set for normal picture
L.	Channel Selector set to channel #9
M.	Vertical Linearity max. counter-clockwise
N.	Channel Selector set to channel #5
P.	This measurement should NOT be made with a conventional type voltmeter as circuit may break into oscillation due to coupling thru instrument leads; use a vacuum tube voltmeter with short leads.
Q.	This voltage will vary from —13 to —17 depending upon setting of Horizontal Hold Control and Horizontal Lock Control.
R.	Do not attempt to measure the voltage at the tube cap. There is a high R. F. potential at this point.
S.	If you do not have an instrument capable of directly measuring voltages in this range, the voltage can be measured by using a voltage divider network consisting of twenty 2.2 megohm 2 watt resistors and one 1 megohm 2 watt resistor, all connected in series. Avoid using resistors of higher values as their individual voltage rating may be exceeded. It is also important to use resistors of equal wattage. Solder all connections between resistors. Accurately measure the overall resistance of the entire combination as well as the resistance of the 1 megohm section. With the set turned off, connect the 2.2 megohm end of the resistance voltage divider to the filament of the 1B3GT/8016 tube, or H.V. terminal of the picture tube, and connect the 1 megohm end to chassis. Now, turn the set on and measure the voltage drop across the 1 megohm resistor with a vacuum tube voltmeter. The voltage at the tube terminal can then be calculated as follows: $\left[\text{Volts At Tube Terminal}\right] = \dfrac{\left[\text{Measured Resistance Of Entire Voltage Divider}\right]}{\left[\text{Measured Resistance Of 1 Meg. Section}\right]} \times \left[\text{Volts Measured Across 1 Meg. Section}\right]$
T.	Grounding of center stud on tube socket is necessary to reduce capacity coupling between other pins. Oscillation may result if this ground is omitted.
U.	This voltage will vary from +4 to —4 depending upon setting of Horizontal Hold Control and Horizontal Lock Control.
V.	This voltage measured with antenna disconnected and no signal input to receiver.
W.	This voltage will vary from —6 to —12 depending upon setting of Horizontal Hold Control and Horizontal Lock Control.
X.	Band Switch set to "AM" position, dial tuned to 540 Kc. and AM loop antenna leads grounded.
Y.	Band Switch set to "FM" position, dial turned to 88 Mc. and FM antenna terminal grounded.
Z.	Band Switch set to "PH" position.

DIAL POINTER DRIVE CORD ARRANGEMENT



To string dial cord, first rotate "AM-FM" Coarse Tuning Control (pointer shaft) fully counter-clockwise until stop on drum contacts ear on mounting frame. Now, with gang set to fully meshed position, string dial cord using the following parts.

W114955 Clip on end of cord
W117057 Cord (2 ft. required)
W505161 Spring

MODEL 133, Ch. 100.107

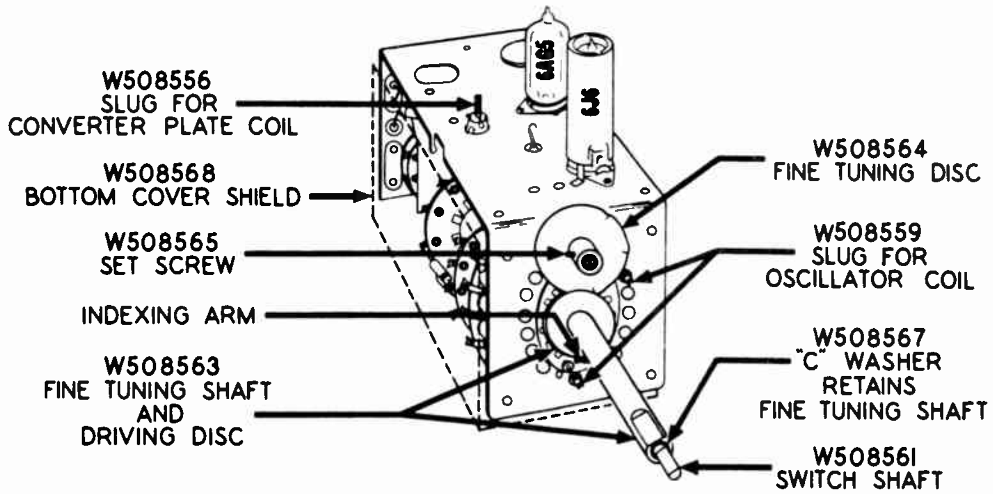
©John F. Rider

REPAIR DATA FOR W508431 RF TUNER UNIT

All replacement parts for the RF Tuner Unit are included in the complete receiver parts list.

This RF Tuner Unit consists of an RF amplifier stage (using 6AG5 tube) and a mixer-oscillator stage (using 6J6 tube). Channel selection is accomplished by a selector switch and fixed coil arrangement. The tuner also incorporates a Fine Tuning control.

Four groups of fixed coils permit tuning over the entire television band. These consist of 12 antenna coils, 12 RF amplifier plate coils, 12 mixer grid coils and 12 oscillator coils. Signal output from the mixer stage is coupled to the IF amplifiers through the converter plate circuit IF coil located on the tuner unit.



SERVICE PRECAUTIONS

SUBJECT	PRECAUTIONS
ELECTRICAL COMPONENTS	The high frequencies used in the RF section of a television receiver make it necessary that considerable care be exercised in servicing the tuner. Lead dress and location of components are very critical at these frequencies. When replacing parts, it is important to use components of identical electrical characteristics and physical size. Always reconnect the replacement item in the same location and position in the tuner as the original component.
TUBES	Replacement of tubes in the Tuner Unit may cause slight detuning of RF circuits due to inherent differences in inter-electrode capacitances. When replacing tubes (especially V6, 6J6 mixer-oscillator tube) make sure that Fine Tuning control will tune in television stations at approximately the middle of its range. If fine tuning cannot be accomplished, try several new tubes in order to obtain one which will permit correct tuning. When tube replacement does not give the desired result, realignment of the tuner is recommended (see "Alignment Procedure").
CHANNEL COILS AND SLUGS	Channel Coils must be handled with care. Do not disturb coil windings or slug positions except when re-aligning the tuner unit.

REMOVAL AND REPLACEMENT OF PARTS

ITEM	PROCEDURE
RF TUNER UNIT	To remove the Tuner Unit from receiver chassis, proceed as follows: 1. Remove TV Channel Lite socket. 2. Remove support bracket which positions front of Tuner Unit and also remove screws which hold tuner to rear support bracket. 3. Disconnect the leads from the tuner to the main chassis. See illustration on circuit diagram page showing tuner connections. After the Tuner Unit is replaced, make sure that TV Channel Lite socket and sleeving are correctly positioned so that small red indicator above channel selector knob will be properly illuminated.
BOTTOM COVER SHIELD	Squeeze upper edges of Bottom Cover Shield together at points adjacent to locking "ears" on top of tuner, and at the same time pull down on shield. When replacing Bottom Cover Shield, make sure it is held securely by the two locking "ears."
SWITCH SHAFT	To remove Switch Shaft from RF Tuner Unit, proceed as follows: 1. Remove tuner from receiver chassis. 2. Rotate Switch Shaft until portion of Indexing Arm which contacts front of tuner is pointing down (this corresponds to setting switch to channel #12). 3. Remove Switch Shaft "C" Washer located behind front plate of tuner. 4. Loosen Set Screw on Fine Tuning Disc. 5. Fine Tuning Disc, Fine Tuning Shaft and Driving Disc and Switch Shaft may now be removed by merely pulling them forward. To replace Switch Shaft: 1. Set Fine Tuning condenser to its completely meshed position. 2. Slip edge of Fine Tuning Disc (furthest from the three "stops" on the disc) into slot of Fine Tuning and Driving Disc. 3. With portion of Indexing Arm (which contacts front of tuner) pointing down, slide Switch Shaft into tuner and Fine Tuning Disc over Fine Tuning Condenser Shaft. 4. Replace "C" Washer on Switch Shaft. 5. Rotate Fine Tuning Shaft and Driving Disc to maximum counter-clockwise position and tighten Set Screw on Fine Tuning Disc. The Fine Tuning condenser range should now be from its fully meshed position (with Fine Tuning and Driving Disc in its maximum counter-clockwise position) to its fully open position (with the tuning control in its maximum clockwise position).

HIGH VOLTAGE POWER SUPPLY SERVICING

The High Voltage Power Supply used with this receiver is of the "fly-back" type and is located in the shielded compartment mounted at the left rear corner of the chassis. It consists of a sturdily constructed and well insulated horizontal sweep output transformer plus a 1B3GT/8016 high voltage rectifier tube and associated filter components.

CAUTION

The high voltage lead, which supplies approximately 9,000 volts to the picture tube, should be momentarily shorted to the chassis whenever it is disconnected for service purposes (that is, after receiver has been turned off). This discharges the high voltage filter condensers and prevents a shock hazard when working on the set.

Access to the horizontal output transformer, high voltage rectifier tube and high voltage filter condenser is accomplished by removing the rear section of the H.V. shield. This compartment shield is held in place by five screws.

REMOVAL OF THE H.V. COMPARTMENT SHIELD AUTOMATICALLY OPENS AN INTERLOCK TO DISCONNECT THE RECEIVER POWER CORD.

CORONA AND ARC-OVER

Corona or arc-over can best be detected by observing the operation of the power supply in a dark room. Several conditions may cause these phenomena

POOR CONNECTIONS — Arcing or corona may be due to poorly soldered connections (rosin joints or sharp points), or defective tube socket-pin connections. If the connectors which hold the high voltage filter condenser do not grasp this component securely, arcing will also result.

Inspect solder connections and resolder those joints which are unsatisfactory. Make sure tubes are firmly positioned in tube sockets and that high voltage filter condenser is held securely in place.

CLOSELY SPACED COMPONENTS — Arcing or corona may occur when H.V. components or leads are placed too close together. Make sure there is sufficient spacing between all parts and wiring. If necessary, the insulation between two elements of the circuit may be improved by coating both objects with a quick-drying liquid polystyrene or polyethylene.

The socket assembly for the 1B3GT/8016 rectifier tube includes a "corona ring" which prevents corona from the tube socket pin connections. The surface of this ring should be smooth and free of scratches, nicks, or sharp protusions.

HORIZONTAL SYNC SYSTEM ADJUSTMENT

If picture "tears" horizontally and cannot be synchronized by operating the Horizontal Hold control on front panel of receiver, this action may be due to incorrect setting of the slug in the Horizontal Lock Coil.

1. Set Horizontal Hold control in center of its range.
2. Adjust slug of Horizontal Lock Coil for picture synchronization (see chassis illustration in installation section of this manual for location of slug).

REDUCTION OF INTERCARRIER BUZZ

If a prominent humming or buzzing sound is noted in the sound reception of a television broadcast, it may be due to a fault in transmission from the station, or incorrect adjustment of the discriminator transformer (tuning of secondary circuit) in the receiver.

This type of disturbance, which is only present when receiving a station signal, is known as "Intercarrier Buzz" and it should not be confused with power supply hum that would occur upon failure of a filter condenser.

The procedure for correct adjustment of the television sound discriminator circuit is presented in the last section of the Television Sound Channel alignment instructions. When the discriminator secondary slug #1 is properly adjusted, intercarrier buzz will be reduced to an acceptable minimum, provided that the transmission from the station is not at fault.

World Radio History

ALIGNMENT PROCEDURE

Alignment of all RF and IF tuned circuits in this receiver may be accomplished by utilizing the procedures described in the following charts.

SEQUENCE OF ALIGNMENT: These procedures should preferably be applied in the order in which they are presented, however, alignment of RF or IF channels for either AM, FM or TV may be accomplished individually if desired.

The Television RF Amplifier and Mixer alignment may also be accomplished independent of the Television IF Channel alignment, but oscillator calibration can only be done after IF Channel has been correctly aligned. Proper IF band pass characteristic is necessary for oscillator alignment as results of circut tuning are observed by means of an oscilloscope connected to the output of the video detector stage.

REMOVAL OF CHASSIS: The receiver chassis must be removed from the cabinet in order to accomplish alignment of all tuned circuits as there are adjustment points located on the underside of the unit and at the front of the AM-FM Tuner.

This can be accomplished by first removing all knobs and releasing the four hold-down screws located on the underside of the cabinet. Then disconnect "phono" pick-up and motor leads, speaker leads and all three "built-in" antennae (TV, AM and FM). Also release indicator lamp from bracket at base of cabinet.

CAUTION

The picture tube is highly evacuated and if broken, glass fragments will be violently expelled. Handle with care, using safety goggles and gloves. Avoid contact with high voltage terminal at side of tube even after it has been disconnected from the receiver—this precaution is necessary as inner and outer coatings on the tube form a capacitor which may carry a high voltage charge for an extended period of time after disconnection from the receiver.

INSTRUMENTS: The following instruments will be required as signal sources and output indicators during the alignment process. Since accurate alignment of a television receiver is heavily dependent upon the performance of your instruments, it is imperative that they meet the essential specifications described here.

1. **STANDARD SIGNAL GENERATOR** to provide signals at the following frequencies. Maximum output on all ranges should be at least .1 volt with provision for attenuation as desired. This instrument must have good frequency stability and be accurately calibrated. Generators which incorporate a separate crystal controlled oscillator and heterodyne circuit are self calibrating and therefore capable of providing the accuracy of frequency calibration required for television circuit alignment.

   A. IF Frequencies:

   455 Kc. (400 cycle modulated) for AM IF.
   4.5 Mc. (Unmodulated) for TV Sound.
   4.5 Mc. (400 cycle modulated) for TV Sound.
   10.7 Mc. (Unmodulated) for FM IF.
   22.25 Mc. (Unmodulated) marker for TV Sound IF carrier.
   22.4 Mc. (Unmodulated) for TV IF Trap.
   23.5 Mc. (Unmodulated) for TV 1st and 3rd IF.
   24.75 Mc. (Unmodulated) for TV 4th IF.
   26.6 Mc. (Unmodulated) for TV Converter and 2nd IF.
   26.75 Mc. (Unmodulated) marker for TV Picture IF carrier.

   B. RF Frequencies:

   550 to 1600 Kc. (400 cycle modulated) for AM RF.
   54 to 88 Mc. (Unmodulated) for TV RF.
   88 to 108 Mc. (400 cycle modulated) for FM RF.
   174 to 216 Mc. (Unmodulated) for TV RF.

2. **RF SWEEP GENERATOR** to provide frequency modulated signals at the following frequencies:

   10.7 Mc. with 300 Kc. sweep width.
   20 to 30 Mc. with 10 Mc. sweep width.
   54 to 88 Mc. with 10 Mc. sweep width.
   174 to 216 Mc. with 10 Mc. sweep width.

   Output adjustable with at least .1 volt maximum.

   Output should be "flat" (no amplitude variation) for all settings of the sweep width control.

   Provision for connection of generator sweep modulating voltage to horizontal deflection system of an oscilloscope.

   Provision for blanking the output signal on each return sweep so that oscillogram will not show retrace.

3. **CATHODE RAY OSCILLOSCOPE**, preferably a unit with vertical amplifier having wide range frequency response and low capacity pick-up probe.
4. **VACUUM TUBE VOLTMETER.** The lowest voltage range of this instrument should preferably permit a 1.0 volt reading to be indicated at not less than one third of full scale deflection.
5. **OUTPUT METER**, preferably a unit equipped with an impedance matching network that will present a 3.2 ohm load when connected to secondary of audio output transformer.

INSTRUMENT CONNECTIONS: The method of connection, including details of matching and coupling networks, for instruments used in this alignment procedure is given in several illustrations on subsequent pages. Specific instructions for each instrument application will also be found in various sections of the alignment charts.

IMPORTANT

AVOID EXCESSIVE INPUT SIGNAL WHEN USING OSCILLOSCOPE AS ALIGNMENT INDICATOR.

When observing the receiver band pass characteristic on an oscilloscope, it is exceedingly important to avoid distortion of that characteristic which would occur when using a large input signal from the sweep generator or standard generator (marker signal). Always set attenuator on sweep generator so that the reading on the vacuum tube voltmeter does not exceed one volt (when meter is connected from high side of video detector load resistor, symbol 139, to receiver chassis). Standard generator output should also be attenuated so that marker signal does not pull or tear the band pass characteristic as shown on the 'scope.

CHECKING SYNCHRONIZATION OF BAND SWITCHES ON AM-FM TUNER AND TV CHASSIS.

Note that the band switch on the AM-FM Tuner chassis is mechanically coupled (by a link arm and lever clamp arrangement) to the band switch on the TV chassis. Do not operate these switches by direct pressure on the link arm—always use a control knob attached to the TV switch shaft. If the mechanical linkage is forced or slips at the clamp on the TV switch shaft so that both switches get out of step, they can be re-synchronized as follows:

1. Loosen screw in actuating lever clamp on TV band switch shaft.
2. Turn both switches to extreme clockwise position and be sure that they detent properly at that position.
3. Retighten screw in actuating lever clamp on TV band switch shaft.

TELEVISION SOUND CHANNEL ALIGNMENT PROCEDURE

1. Short antenna terminals together with a jumper wire.
2. Turn the band switch to "TV" position and set receiver Channel Selector to any inactive television channel; other controls may be left at any desired setting.
3. No special aligning tool is required to adjust the cores in the Sound IF and discriminator transformers. The blade of a small screwdriver will fit the slot in these cores, however, the screwdriver should be of a non-metallic or insulated type to prevent detuning when inserted in the transformer can.

STANDARD SIGNAL GENERATOR		VTVM CONNECTIONS	MISCELLANEOUS INSTRUCTIONS	TRIMMER OR SLUG	TYPE OF ADJUSTMENT AND OUTPUT INDICATION
CONNECTIONS	FREQUENCY				
Connect as shown in Fig. 2.	**4.5 MC.** unmodulated **IMPORTANT** This signal must be accurate within 1/4 of 1% of 4.5 Mc. Check generator calibration against a crystal controlled signal source by "zero beating" (heterodyning) with harmonics of the crystal frequency.	Connect as shown in Fig. 3.	**IMPORTANT** Unsolder lead connected to terminal "T" of Horizontal Linearity coil (see Fig. 1). This will make the horizontal sweep system of the receiver inoperative so that the sweep voltage will not be picked up by stray coupling to leads of instruments used during Sound Channel alignment. Such coupling would otherwise result in spurious oscillation.	**#1** TV Sound Discriminator Secondary	Adjust for maximum reading on VTVM.
				#2 TV Sound Discriminator Primary	Adjust for maximum reading on VTVM.
				#3 2nd TV Sound IF Secondary	Adjust for maximum reading on VTVM.
				#4 2nd TV Sound IF Primary	Adjust for maximum reading on VTVM.
				#5 1st TV Sound IF Secondary	Adjust for maximum reading on VTVM.
				#6 1st TV Sound IF Primary	Adjust for maximum reading on VTVM.
Same as above.	Same as above.	Connect as shown in Fig. 4.	Same as above.	**#1** TV Sound Discriminator Secondary	Note that as slug #1 is rotated, a point will be found where the voltmeter will swing rather sharply from a positive to a negative reading or vice versa. The correct setting of slug #1 is obtained when the meter reads zero as the slug is moved thru this point.

REDUCTION OF INTERCARRIER BUZZ

Slight "dynamic" unbalance of the discriminator secondary can emphasize intercarrier Buzz due to incomplete amplitude modulation rejection. Therefore it is vitally important to obtain an accurate setting of the discriminator secondary slug in the presence of an amplitude modulated signal, as outlined below.

Same as above.	**4.5 MC.** 400 cycle amplitude modulated	Not used.	Same as above. Turn up Volume control until 400 cycle signal can be heard.	**#1** TV Sound Discriminator Secondary	Note that as slug #1 is rotated, a point will be found where the sound volume changes rapidly from maximum to minimum and back to maximum again. The discriminator secondary slug is correctly positioned when this "dip" in volume is reached. Do not confuse the "dip" point with a gradual reduction in volume that occurs when the circuit is considerably detuned.

Resolder lead previously disconnected from terminal "T" of Horizontal Linearity coil (see Fig. 1).

Disconnect all instruments and then connect an antenna to the receiver to obtain program reception from a local station. If intercarrier buzz is still prominent, a slight readjustment of the discriminator secondary slug (#1) should be made to obtain the "dip" point for the buzzing sound. Note that program sound will be clear and free from distortion at this point. Buzz should now be at an acceptable minimum if station transmission is not at fault.

TELEVISION IF CHANNEL ALIGNMENT PROCEDURE

1. A special aligning tool designed to fit the stems on adjustable cores of the IF coils (see points 8, 9, 10 and 11 in Fig. 14) is available and may be obtained by requesting IF Alignment Tool #W507-479.
2. Turn receiver Channel Selector to television channel #12 and short antenna terminals together with a jumper wire.
3. Turn the band switch to the TV position.
4. Connect a 3 volt battery to the receiver AGC system so that negative terminal of battery connects to the AGC line and positive terminal of battery connects to receiver chassis. See Fig. 15 for convenient point of connection.
5. Note location of IF Trap Coil #12 by referring to Fig. 15. Before undertaking the alignment of any of the IF stages, Trap Coil #12 must be detuned so that it does not resonate in the IF pass band. Detuning is accomplished by merely compressing the windings so that they are closely spaced. Failure to detune the Trap Coil can cause the IF system to become regenerative thereby preventing alignment.
6. If the IF channel is badly misaligned and two or more immediately adjoining IF stages are tuned to the same frequency, oscillation may occur. Such oscillation shows up as a voltage across the video detector load resistor, symbol 139, and is indicated by the VTVM that is connected to this point during alignment. It should be noted that voltage due to IF oscillation is unaffected by strength of signal from the generator.

Where IF oscillation is encountered, it is generally possible to correct the condition by detuning the IF coils in different directions. If that does not have the desired effect, increase fixed bias on AGC line by using a 4½ volt battery instead of the 3 volt battery referred to in instruction #4. After stopping the oscillation in this manner it will then be possible to align all IF stages using the following procedure, however, the AGC bias battery must be changed back to 3 volts when using the oscilloscope to observe band pass characteristic. Once all stages have been aligned using the 4½ volt bias, the IF channel should be stable with reduced bias.

STANDARD SIGNAL GENERATOR		SWEEP GENERATOR		VTVM CONNECTIONS	OSCILLOSCOPE CONNECTIONS	MISCELLANEOUS INSTRUCTIONS	TRIMMER OR SLUG	TYPE OF ADJUSTMENT AND OUTPUT INDICATION
CONNECTIONS	FREQUENCY	CONNECTIONS	FREQ.					
Connect as shown in Fig. 6.	26.6 MC.	Use a 330 Mmf. isolating condenser and connect as shown in Fig. 6 but keep power switch turned off during this step.	—	Connect as shown in Fig. 7.	Not used.	—	#7 Converter plate coil	Adjust for maximum reading on VTVM.
							#8 2nd I.F.	Adjust for maximum reading on VTVM.
Same as above.	24.75 MC.	Same as above.	—	Same as above.	Not used.	—	#9 4th I.F.	Adjust for maximum reading on VTVM.
Same as above.	23.5 MC.	Same as above.	—	Same as above.	Not used.	—	#10 1st I.F.	Adjust for maximum reading on VTVM.
							#11 3rd I.F.	Adjust for maximum reading on VTVM.
Same as above.	22.4 MC.	Same as above.	—	Same as above.	Not used.	—	#12 IF Trap Coil	Adjust the spacing of the Trap Coil windings for MINIMUM reading on VTVM.
Same as above.	26.75 MC.	With connections made as shown in Fig. 6, turn on this generator and set controls for operation as specified in next column.	25 MC. Sweeping ± 5 Mc.	Same as above.	Connect as shown in Fig. 7.	IMPORTANT: 1. Remove the 6J6 (Mixer-Oscillator) tube and wrap a piece of fine wire around pins 6 and 7 so as to connect these two pins together. Then reinsert the tube in its socket. Oscillator section of tube will now be inoperative and therefore cannot cause undesirable "beat" response that would otherwise disturb the IF band pass characteristic. 2. Adjust output attenuator on sweep generator so that reading on VTVM is one volt. 3. Set attenuator on standard signal generator so that marker signal does not distort the pattern on the oscilloscope. 4. Be sure that a 3 volt battery is connected to AGC line as specified in instruction #4 at the head of this chart. Do not use a battery of any other voltage.		The IF band pass characteristic now displayed on the 'scope should be compared with the curve shown in Fig. 5. If top of curve is not properly shaped, make a slight readjustment of slug #9. Should that adjustment fail to yield the desired result, then note whether the curve has a peak on the high or low frequency side. Slugs #7 and #8 control high frequency response (26.6 Mc.) and slugs #10 and #11 affect the low frequency response (23.5 Mc.); by making a small change in the settings of the high or low frequency slugs, it will be possible to obtain correct band pass curve.  FIG. 5 The 26.75 Mc. picture IF carrier marker should now appear at the 50% amplitude position on side of the band pass characteristic (see Fig. 5). If position of the marker appears too high or too low, slight readjustment of slugs #7, 8 and 9 is required.
Same as above.	22.25 MC.	Same as above.	Same as above.	Same as above.	Same as above.	Same as above.		The 22.25 Mc. sound IF carrier marker should appear at the position indicated in Fig. 5. If the position of the sound marker is incorrect, readjust winding spacing of Trap Coil #12.

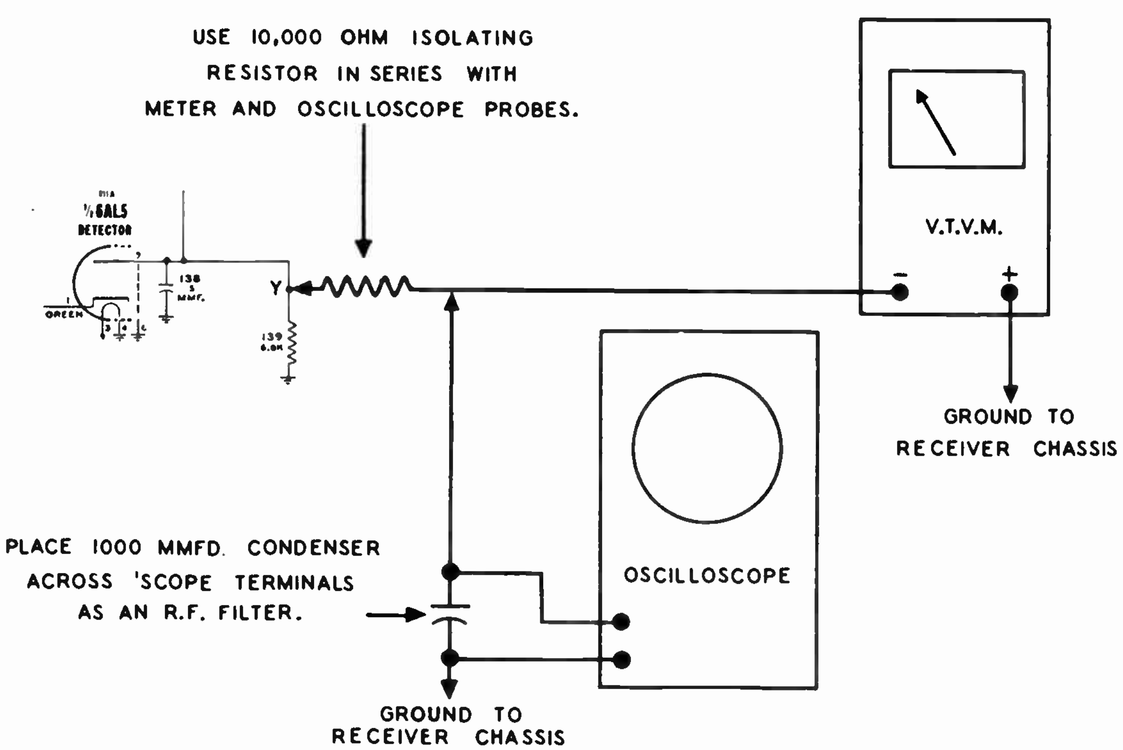

FIG. 7
VTVM and Oscilloscope Connections for Television IF Channel Alignment

TELEVISION RF CHANNEL ALIGNMENT PROCEDURE

1. Turn the band switch to the "TV" position.
2. Remove bottom cover shield of the Television RF Tuner unit.
3. Connect a 3 volt battery to the receiver AGC system so that negative terminal of battery connects to AGC line and positive terminal of battery connects to receiver chassis. (See Fig. 15 for convenient point of connection.)

STANDARD SIGNAL GENERATOR		SWEEP GENERATOR		VTVM CONNECTIONS	OSCILLOSCOPE CONNECTIONS	MISCELLANEOUS INSTRUCTIONS	COIL	TYPE OF ADJUSTMENT AND OUTPUT INDICATION
CONNECTIONS	FREQUENCY	CONNECTIONS	FREQ.					
RF AMPLIFIER AND MIXER ALIGNMENT								
Connect as shown in Fig. 11.	*215.75 MC. ‡211.25 MC.	Connect as shown in Fig. 11 and set controls for sweep width of 10 Mc. on television channel specified in the next column.	CHANNEL #13	Not used.	Connect as shown in Fig. 12	**IMPORTANT: Keep output of standard signal generator at a level that provides a readable marker but does not distort the curve that is being observed on the 'scope.**	CHANNEL #13 Antenna Coil CHANNEL #13 RF Amp. Plate Coil CHANNEL #13 Mixer Grid Coil	Adjust spacing of the turns on these coils to obtain properly shaped RF band pass characteristic as shown in Fig. 8. To determine whether the turns have to be spread or compressed, use a tuning wand having a brass slug in one end and a powdered iron slug in the other end. If the brass slug is placed near (or into) a coil and causes the response curve to approach that shown in Fig. 8, then the turns would have to be spread. On the other hand, if the powdered iron slug is similarly positioned and produces a correctly shaped response curve, then the coil turns should be compressed. Repeat these adjustments on the Antenna, RF Amp. Plate and Mixer Grid coils for Channel 13 to obtain the desired response characteristic. Do not overly broaden the curve as that would result in a loss of sensitivity. **IMPORTANT:** After the Channel #13 coils have been aligned correctly, melt the wax around the turns or apply a small amount of high frequency "coil dope" on the winding to assure that spacing will be maintained.
Same as above.	*209.75 MC. ‡205.25 MC.	Same as above.	CHANNEL #12	Not used.	Same as above.	Set Channel Selector to #12		The RF band pass characteristics of the other television channels should now be checked. Adjust the RF sweep generator and marker generator for operation on each of these television channels and observe position of sound carrier and picture carrier markers. (FIG. 8) The response curve for each channel should conform reasonably well with the curve shown in Fig. 8. If it does not, on channels 10, 11 or 12, then adjust the RF Amp. Plate coil for the particular channel; on channels 7, 8 or 9 adjust RF Amp. Plate and Mixer Grid coils; on channels 2 to 6 adjust RF Amp. Plate, Mixer Grid and Antenna coils. Adjustment consists of pushing the coil (or partial turn) toward or away from switch shaft and spreading or compressing the winding.

STANDARD SIGNAL GENERATOR CONNECTIONS	STANDARD SIGNAL GENERATOR FREQUENCY	SWEEP GENERATOR CONNECTIONS	SWEEP GENERATOR FREQ.	VTVM CONNECTIONS	OSCILLOSCOPE CONNECTIONS	MISCELLANEOUS INSTRUCTIONS	COIL OR SLUG	TYPE OF ADJUSTMENT AND OUTPUT INDICATION
OSCILLATOR ALIGNMENT								
1. **IMPORTANT:** Before undertaking oscillator alignment be sure IF circuits are correctly aligned for band pass characteristic illustrated in Fig. 5. 2. During oscillator alignment, it is necessary to set the Fine Tuning control in the center of its range.								
Connect as shown in Fig. 11.	*215.75 MC. ‡211.25 MC.	Connect as shown in Fig. 11 and set controls for sweep width of 10 Mc. on television channel specified in the next column.	CHANNEL #13	Connect as shown in Fig. 13	Connect as shown in Fig. 13	During this step and thru-out all succeeding steps it is necessary to: 1. Be sure that Fine Tuning control has been set in the center of its range. 2. Keep output of sweep generator at a level that does not allow reading on VTVM to exceed one volt. 3. Keep output of standard signal generator at a level that provides a readable marker but does not distort the curve that is being observed on the 'scope.	#17 High Band Oscillator Slug. #18 Low Band Oscillator Slug.	Adjust the position of both slugs so that approximately 5 threads are visible outside of the fiber plate.
							CHANNEL #13 Oscillator Coil	NOTE: Before making the following adjustment, advance the vertical gain control on the 'scope in order to magnify the sound portion of the response curve. Examine the channel 13 oscillator coil and note that it has a "bucking turn." Adjust the spacing of this turn with respect to the main coil in order to shift the response curve until the sound carrier marker appears at the position shown in Fig. 10. Now, reduce gain control setting of 'scope to restore pattern to normal amplitude and observe position of picture carrier marker. This marker should appear approximately halfway up the low frequency side of the characteristic (see Fig. 10). After both pix and sound markers are correctly located on the curve, then melt the wax on the coil to permanently fix the position of the winding.
Same as above.	*209.75 MC. ‡205.25 MC.	Same as above.	CHANNEL #12	Same as above.	Same as above.	Set Channel Selector to #12		Adjust the RF sweep generator and marker generator for operation on the other television channels; set marker generator to sound carrier frequency. After setting Channel Selector to the corresponding channel, then adjust the oscillator coil  FIG. 10 for that channel so as to shift the response curve and permit the sound carrier marker to appear at the position shown in Fig. 10. Check to see that pix carrier marker falls at 50% amplitude position on opposite side of curve.
	*203.75 MC. ‡199.25 MC.		CHANNEL #11			Set Channel Selector to #11		
	*197.75 MC. ‡193.25 MC.		CHANNEL #10			Set Channel Selector to #10		
	*191.75 MC. ‡187.25 MC.		CHANNEL #9			Set Channel Selector to #9		
	*185.75 MC. ‡181.25 MC.		CHANNEL #8			Set Channel Selector to #8		
	*179.75 MC. ‡175.25 MC.		CHANNEL #7			Set Channel Selector to #7		
	* 87.75 MC. ‡ 83.25 MC.		CHANNEL #6			Set Channel Selector to #6		
	* 81.75 MC. ‡ 77.25 MC.		CHANNEL #5			Set Channel Selector to #5		
	* 71.75 MC. ‡ 67.25 MC.		CHANNEL #4			Set Channel Selector to #4		
	* 65.75 MC. ‡ 61.25 MC.		CHANNEL #3			Set Channel Selector to #3		
	* 59.75 MC. ‡ 55.25 MC.		CHANNEL #2			Set Channel Selector to #2		

Switch back to channel #13 and set both generator signals for that channel. Check position of sound carrier marker. A slight readjustment of slug #17 is usually necessary to reposition the curve so that the sound carrier is correctly located as shown in Fig. 10. If the setting of slug #17 has to be changed by two or more complete turns it should be left in its original position and all of the foregoing oscillator alignment procedure repeated. A similar check should be made for channel #6 using adjustable slug #18 in Fig. 9.

If an unsatisfactory overall response is obtained for a particular channel, observe RF Amp. and Mixer response curve for that channel as described on the preceding page. If characteristic does not conform reasonably well with the typical curve shown in Fig. 8, then attempt to obtain a better compromise for RF response on all channels by realigning Antenna, RF Amp. and Mixer circuits.

BROADCAST BAND—"AM"—ALIGNMENT PROCEDURE

1. After the entire chassis assembly has been removed from the cabinet, remove the AM loop antena and reconnect it to the AM antenna leads extending from the AM-FM tuner chassis. Then wind one turn of insulated wire around frame of loop antenna so as to provide a means of coupling it to the signal generator. Connect one end of coupling turn to receiver chassis and allow other end to remain open until otherwise instructed in the following chart. Space loop antenna same distance away from the chassis as when assembled in the cabinet.
2. Reconnect the speaker to the two audio output leads extending from the main chassis. **IMPORTANT:** Do not confuse these leads with the two loop antenna leads.
3. Place the AM-FM dial scale escutcheon on the AM-FM tuning shaft and install the AM-FM pointer knob and fine tuning knob on their respective shafts. Then rotate these knobs to the extreme counter-clockwise position. At this setting, the gang condenser should be fully meshed; if it is not, loosen the set screws in the hub of the dial drum on the gang condenser and close gang plates manually. Then tighten set screws in hub of dial drum.
4. When aligning the RF circuits and calibrating the oscillator it is necessary to hold the AM-FM dial escutcheon in its normal mounting position so that the heavy lines below 88 and 108 are in a horizontal plane. Note that the pointer knob must point to the heavy line below 88 on the dial when tuning knob is turned fully counter-clockwise and gang plates are completely meshed.
5. **IMPORTANT:** Do not remove the metal bottom plate of AM-FM tuner chassis. Holes are provided for access to IF transformer tuning slugs. Removal of the bottom plate during alignment of the RF circuits will result in detuning when the plate is replaced.
6. Connect output meter across the speaker voice coil.
7. Connect ground lead of signal generator to the receiver chassis.
8. Set volume control to the maximum volume position and use a weak signal from the signal generator.
9. Set tone control to its extreme clockwise position.
10. Set band switch to the "AM" position.
11. After alignment procedure is completed and chassis and loop have been reinstalled in cabinet, arrange leads to loop so that they are separated from each other as much as possible avoid twisting, taping or extending these leads.

VTVM Connections for FM Sound IF Alignment

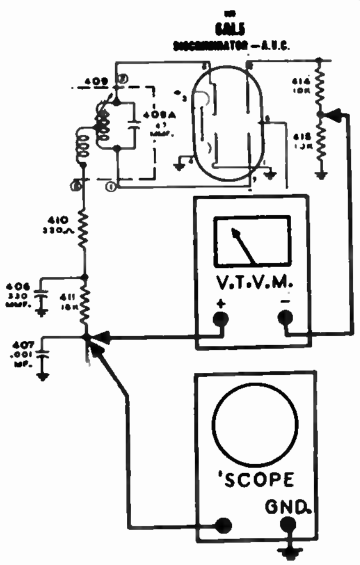

FIG. 19
VTVM and Oscilloscope Connections for FM Sound Discriminator Alignment

FREQUENCY MODULATION—"FM" ALIGNMENT PROCEDURE

1. After the entire chassis has been removed from the cabinet, replace the AM-FM dial escutcheon on the AM-FM tuning shaft and install the AM-FM pointer knob and fine tuning knob on their respective shafts. Then rotate these knobs to the extreme counter-clockwise position. At this setting, the gang condenser should be fully meshed; if it is not, loosen the set screws in the hub of the dial drum on the gang condenser and close gang plates manually. Then tighten set screws in hub of dial drum.
2. When aligning the RF circuits and calibrating the oscillator it is necessary to hold the AM-FM dial escutcheon in its normal mounting position so that the heavy lines below 88 and 108 are in a horizontal plane. Note that the pointer knob must point to the heavy line below 88 on the dial when tuning knob is turned fully counter-clockwise and gang plates are completely meshed.
3. Reconnect the speaker to the two audio output leads extending from the main chassis. **IMPORTANT:** Do not confuse these leads with the two AM loop antenna leads.
4. Remove bottom plate from AM-FM tuner during IF alignment but replace it before starting alignment of RF circuits. DO **NOT REMOVE the AM-FM tuner chassis from the TV chassis during alignment.**
5. Set band switch to the "FM" position.
6. Set volume control to the maximum volume position and use a weak signal from the signal generator.
7. Set tone control to its extreme clockwise position.
8. Dress FM circuit leads as short and straight as possible, particularly those in the oscillator circuit. IF plate and grid leads should also be kept short and straight.

STANDARD SIGNAL GENERATOR		SWEEP GENERATOR		VTVM OR OUTPUT METER CONNECTION	OSCILLOSCOPE CONNECTIONS	RECEIVER DIAL SETTING	TRIMMER OR SLUG NUMBER	TYPE OF ADJUSTMENT AND OUTPUT INDICATION
CONNECTIONS	FREQUENCY	CONNECTIONS	FREQ.					
Connect high side to lug on trimmer #33 (see Fig. 16 for location of trimmer) using a .01 Mfd. condenser in series with generator lead. Connect ground lead to the receiver chassis in vicinity of gang condenser.	10.7 MC. Unmodulated	Not used.	——	Connect VTVM as shown in Fig. 18.	Not used.	Any position where it does not affect the signal.	#26 Discriminator secondary; #27 Discriminator primary; #28—29 2nd IF; #30—31 1st IF	Adjust these trimmers for maximum meter reading — the output voltage will be of negative polarity.
Same as above.	Same as above.	Not used.	——	Connect VTVM as shown in Fig. 19.	Not used.	Same as above.	#26 Discriminator secondary	Note that as slug #26 is rotated, a point will be found where the voltmeter will swing rather sharply from a positive to a negative reading or vice versa. The correct setting is obtained when the meter reads zero as the slug is moved thru this point.
Same as above.	Same as above. —— Attenuate signal to prevent overload and distortion of response curve.	Connect high side to lug on trimmer #33 (see Fig. 16 for location of trimmer) using a .01 Mfd. condenser in series with generator lead. Connect ground lead to the receiver chassis in vicinity of gang condenser.	10.7 MC Sweeping ±300 Kc.	Not used.	Connect as shown in Fig. 19. —— Set vertical amplifier of 'scope for maximum amplification. —— Synchronize oscilloscope with sweep generator by connecting "horizontal input" terminals of 'scope to source of horizontal sweep modulating voltage on the sweep generator.	Same as above.	#26 Discriminator secondary	A pattern similar to that shown in Fig. 20 should appear on the oscilloscope screen. Check for symmetry about the 10.7 Mc. center point and linearity of the slope.  FIG. 20 If the characteristic is not shaped properly, attempt to obtain symmetry by changing the setting of slug #26. Should that fail to produce the desired results, then a slight readjustment of slugs #27, 28, 29 30 and 31 should be undertaken.
IMPORTANT:—Before starting alignment of the RF and Oscillator circuits, be sure to replace the bottom plate on the AM-FM Tuner chassis. Failure to observe this requirement would result in detuning if plate were replaced after alignment is completed.								
Connect high side in series with a 270 ohm carbon resistor to FM antenna terminal near gang condenser (see Fig. 16). Connect ground lead to receiver chassis.	108 MC. with 400 cycle AM Modulation.	Not used.	——	Connect OUTPUT METER across speaker voice coil.	Not used.	108 Mc.	#32 FM Oscillator	Set trimmer #32 to receive 108 Mc. signal as indicated by maximum meter reading.
Same as above.	106 MC. with 400 cycle AM Modulation.	Not used.	——	Same as above.	Not used.	Tune to 106 Mc. generator signal.	#33 FM RF	Adjust trimmer for maximum meter reading.

Check calibration and tracking of receiver with input signals of 88, 90 and 106 MC. If difference between dial pointer setting and the above mentioned frequencies does not exceed ±0.3 MC. and RF circuit is tracking properly, then alignment may be considered satisfactory and no further adjustment is necessary.
Where the calibration error is greater than ±0.3 MC. it is advisable to make the following adjustments:
Tune receiver to an 88 MC. signal and note whether dial pointer is above or below correct calibration point. Then tune receiver so that dial pointer is at the 88 MC. position. If generator signal was previously received at a setting above 88 MC., it will be necessary to slightly spread the windings of the FM oscillator coil (#34 in Fig. 17) so that signal will now be received at the correct dial setting. On the other hand, if generator signal was received at a dial setting below 88 MC., then slightly compress the windings of the oscillator coil until the signal comes in at the correct calibration point.
Check calibration at 108 MC. and if it is in error by more than ±0.3 MC., readjust setting of trimmer #32. Repeat calibration adjustment at 88 and 108 MC. until desired accuracy is obtained.
Observe dial calibration at 106 MC. If it is found to be incorrect by an appreciable amount, then make a very slight adjustment in the spacing of the gang condenser plates to receive the 106 MC. signal at the correct dial setting. Then check adjustment of RF trimmer #33 to obtain maximum output indication at 106 MC.

PARTS LIST FOR CHASSIS

NOTICE: Some parts listed below have special characteristics. Do not use substitutes for replacement purposes.

SCHEMATIC LOCATION	PART NO.	DESCRIPTION
		CONDENSERS
11	W513001	Condenser—ceramic 2.2 Mmfd. 500 volt
12-A, B	W508061	Condenser—ceramic 51 Mmfd. (part of 1st Sound I.F. transformer)
13	W513013	Condenser—ceramic 5000 Mmfd. 450 volt
16	W513013	Condenser—ceramic 5000 Mmfd. 450 volt
18-A, B	W508061	Condenser—ceramic 51 Mmfd. (part of 2nd Sound I.F. transformer)
19	W513013	Condenser—ceramic 5000 Mmfd. 450 volt
21	W513433	Condenser—ceramic 47 Mmfd. ± 10% 500 volt (Temperature compensating)
23	W513013	Condenser—ceramic 5000 Mmfd. 450 volt
25	W513009	Condenser—ceramic 1000 Mmfd. 500 volt
26-A	W507321	Condenser—ceramic 110 Mmfd. (part of discriminator transformer)
27	W512527	Condenser—mica 220 Mmfd. ± 10% 500 volt
29	W513010	Condenser—ceramic 1500 Mmfd. 350 volt
30	W512027	Condenser—.05 Mfd. 200 volt
32	W512007	Condenser—.005 Mfd. 600 volt
34	W512007	Condenser—.005 Mfd. 600 volt
36	W505174	Condenser—electrolytic 10 Mfd. 150 volt
41	W513010	Condenser—ceramic 1500 Mmfd. 350 volt
42	W502547	Condenser—electrolytic 4 Mfd. 150 volt
44	W502527	Condenser—electrolytic 50 Mfd. 25 volt
46	W504719	Condenser—electrolytic 4 Mfd. 450 volt
48	W512003	Condenser—.002 Mfd. 600 volt
50	W504719	Condenser—electrolytic 4 Mfd. 450 volt
52-A, B, C	W508072	Condenser—electrolytic A—40 Mfd. 450 volt, B—40 Mfd. 450 volt, C—40 Mfd. 450 volt
54	W508324	Condenser—trimmer 4-70 Mmfd.
100	W513009	Condenser—ceramic 1000 Mmfd. 500 volt
105	W512532	Condenser—mica 240 Mmfd. ± 5% 500 volt
106	W513009	Condenser—ceramic 1000 Mmfd. 500 volt
109	W513016	Condenser—ceramic 82 Mmfd. ± 10% 500 volt
112	W513009	Condenser—ceramic 1000 Mmfd. 500 volt
114	W513009	Condenser—ceramic 1000 Mmfd. 500 volt
117	W513016	Condenser—ceramic 82 Mmfd. ± 10% 500 volt
120	W513009	Condenser—ceramic 1000 Mmfd. 500 volt
122	W513009	Condenser—ceramic 1000 Mmfd. 500 volt
126	W513016	Condenser—ceramic 82 Mmfd. ± 10% 500 volt
133	W513009	Condenser—ceramic 1000 Mmfd. 500 volt
136	W513433	Condenser—ceramic 47 Mmfd. ± 10% 500 volt (Temperature compensating)
138	W513432	Condenser—ceramic 5 Mmfd. ± 10% 500 volt (Temperature compensating)
140	W512045	Condenser—.25 Mfd. ± 10% 200 volt
145	W512027	Condenser—.05 Mfd. 200 volt
148	W512045	Condenser—.25 Mfd. ± 10% 200 volt
150	W513003	Condenser—ceramic 100 Mmfd. 500 volt
154	W512033	Condenser—.1 Mfd. 200 volt
157	W512027	Condenser—.05 Mfd. 200 volt
167, 168	W512031	Condenser—.05 Mfd. 600 volt
174	W512019	Condenser—.02 Mfd. 600 volt
175	W512031	Condenser—.05 Mfd. 600 volt
176	W513018	Condenser—ceramic 220 Mmfd. 500 volt
183	W513015	Condenser—mica 56 Mmfd. ±10% 500 volt
187	W512045	Condenser—.25 Mfd. ± 10% 200 volt
192, 193	W513009	Condenser—ceramic 1000 Mmfd. 500 volt
196	W512013	Condenser—.01 Mfd. 600 volt
199	W513013	Condenser—ceramic 5000 Mmfd. 450 volt
201	W512027	Condenser—.05 Mfd. 200 volt
204	W512531	Condenser—mica 3300 Mmfd. ± 5% 500 volt
205	W513007	Condenser—ceramic 330 Mmfd. 500 volt
210	W512535	Condenser—mica 390 Mmfd. ± 10% 500 volt
211	W512536	Condenser—mica 270 Mmfd. ± 10% 500 volt
212	W508071	Condenser—trimmer 10-160 Mmfd. (Horizontal Drive Control)
214-A to D	W508074	Condenser—electrolytic A—20 Mfd. 450 volt, B—10 Mfd. 450 volt, C—100 Mfd. 25 volt, D—10 Mfd. 450 volt
217	W512047	Condenser—.25 Mfd. ± 10% 400 volt
		CONDENSERS—Continued
219	W512031	Condenser—.05 Mfd. 600 volt

PARTS LIST FOR CHASSIS (Cont.)

CONTROLS

SCHEMATIC LOCATION	PART NO.	DESCRIPTION
33-A, B	W508182	Volume control—1 Meg. (with switch)
43-A to D	W508458	Band switch (includes volume control)
54	W508324	Built-in Antenna tuning condenser (4-70 Mmfd.)
160-A, B	W508457	Tone and Contrast potentiometer A—Tone control; 500,000 Ohms ¼ watt B—Contrast control; 3000 Ohms ± 10% 4 w.
173	W508056	Brightness potentiometer (50,000 Ohms)
180	W508456	Focus potentiometer (5500 Ohms ± 10% 4 watt)
202	W508077	Horizontal Lock coil (less slug)
	W507429	Slug core for Horizontal Lock coil
208	W508056	Horizontal Hold potentiometer (50,000 Ohms)
212	W508071	Horizontal Drive trimmer condenser (10-160 Mmfd.)
225	W508218	Width coil (includes slug and clip)
	W508435	Slug core for Width coil
233	W162056	Horizontal Linearity coil (includes slug and clip)
	W507429	Slug core for Horizontal Linearity coil
266	W508454	Vertical Hold potentiometer (1 Meg.)
270	W508455	Height potentiometer (2.5 Meg.)
277	W508453	Vertical Linearity potentiometer (6000 Ohms)
346	W508551	Fine Tuning trimmer 1.2 to 2.5 Mmfd. when mounted to chassis
369-A to D	W508185	Band Switch (on AM-FM tuner)

COILS AND TRANSFORMERS

SCHEMATIC LOCATION	PART NO.	DESCRIPTION
12	W508061	Transformer—1st sound I. F.
15	W507373	Coil—choke
18	W508061	Transformer—2nd sound I. F.
26	W507321	Transformer—TV sound discriminator (includes condenser 26-A)
	W508438	Slug core for primary of TV sound discriminator transformer
	W508439	Slug core for secondary of TV sound discriminator transformer
37	W507373	Coil—choke
49	W505912	Transformer—sound output
103	W507567	Coil— I. F. trap
107	W507343	Coil—1st video I. F. (less slug)
	W507357	Slug core for 1st video I. F. coil
115	W507343	Coil—2nd video I. F. (less slug)
	W507357	Slug core for 2nd video I. F. coil
125	W507343	Coil—3rd video I. F. (less slug)
	W507357	Slug core for 3rd video I. F. coil
128	W507367	Coil—choke
134	W507591	Coil—4th video I. F. assembly (includes condenser 136 and choke coil 137)
	W507357	Slug core for 4th video I. F. coil
137	W507367	Coil—choke
143	W507374	Coil—peaking
152	W507374	Coil—peaking
161	W508069	Coil—peaking
163	W508070	Coil—peaking
181	W508065	Coil—focus
184	W507791	Yoke—picture tube deflection
202	W508077	Coil—Horizontal Lock (less slug)
	W507529	Slug core for Horizontal Lock coil
222	W508058	Transformer—horizontal fly-back
225	W508218	Coil—Width (includes slug and clip)
	W508435	Slug core for Width coil
233	W162056	Coil—Horizontal Linearity (includes slug and clip)
	W507429	Slug core for Horizontal Linearity coil
239	W508060	Transformer—power
241	W507586	Coil—choke
244	W507587	Coil—choke
248	W507584	Coil—choke
253	W508341	Choke—filter
254	W507584	Coil—choke
259	W507586	Coil—choke
263	W508076	Transformer—vertical blocking oscillator
278	W508059	Transformer—vertical output
	W508431	R. F. Unit complete with coils and tubes
283	W508553	Coil—antenna; channel #13
284	•	Coil—antenna; channel #12
285	•	Coil—antenna; channel #11
286	•	Coil—antenna; channel #10
287	•	Coil—antenna; channel #9

PARTS LIST FOR CHASSIS

OTHER ELECTRICAL PARTS

SCHEMATIC LOCATION	PART NO.	DESCRIPTION
43-A to D	W508458	Switch-band (includes volume control)
51	W508174	Speaker—P. M. Dynamic (6" x 9")
53	W508466	Built-in antenna (includes condenser 54)
179	W508432	Crystal cartridge
221	W508063	Fuse for horizontal sweep circuit; ¼ Amp. 250 volt
261	W118921	Lamp—TV Channel Lite (Mazda #47) 6-8 V. 150 Ma.
262-A to G	W508062	Integrator coupling unit
280	W508120	Motor—for record changer; 115 volt 60 cyc.
281	W505269	Switch—"ON-OFF" for record changer
282-A to K	•	Channel Selector switch
361	W118921	Lamp—OFF-ON Indicator Lite (Mazda #47) 6-8 V. 150 Ma.
363	W118921	Lamp—AM Channel Lite (Mazda #47) 6-8 V. 150 Ma.
364	W118921	Lamp—FM Channel Lite (Mazda #47) 6-8 V. 150 Ma.
369-A to D	W508185	Switch-band (on AM-FM tuner)
393-A,B,C	W506338	Diode filter unit A—Condenser—ceramic 100 Mmfd. 400 volt B—Resistor—carbon 47,000 Ohms 1/5 watt C—Condenser—ceramic 100 Mmfd. 400 volt
418	W508212	Loop Antenna (AM)

MECHANICAL PARTS OF R.F. TUNER

SCHEMATIC LOCATION	PART NO.	DESCRIPTION
	W508431	R. F. Unit complete with coils and tubes
	W508568	Bottom cover shield
	W508081	Bracket for tuner mounting (front)
	W508426	Bracket for tuner mtg. (rear)
	W508566	"C" washer—retains switch shaft
	W508567	"C" washer—retains fine tuning shaft
	W508564	Fine tuning disc (on trimmer shaft)
	W508565	Set screw for fine tuning disc
	W508563	Shaft, fine tuning and driving disc
	W508561	Shaft, switch (incl. indexing arm)
	W504599	Shield—tube
	W508556	Slug core for converter plate coil
	W508559	Slug—brass core for oscillator coil; channel #6 and 13
	W508562	Socket—miniature for 6J6 (incl. base for shield)
	W507364	Socket—miniature for 6AG5

CABINET PARTS

SCHEMATIC LOCATION	PART NO.	DESCRIPTION
	W508176	Back for cabinet
	W508217	Bracket for mtg. "OFF-ON" Indicator Lite at base of cabinet
	W117131	Bulls eye for "OFF-ON" Indicator Lite at base of cabinet
	W162095	Bulls eye for Channel Lite
	W508430	Cabinet
	W508529	Drawer, record changer compartment
	W508503	Escutcheon—AM-FM dial scale
	W507700	Escutcheon—channel number
	W507911	Glass window
	W502563	Knob—built-in antenna
	W507894	Knob—TV fine tuning
	W507895	Knob—channel selector
	W508471	Knob—AM-FM pointer and coarse tuning
	W508472	Knob—AM-FM fine tuning
	W508473	Knob—band switch
	W508474	Knob—"VOLUME-ON"
	W508475	Knob—horizontal hold or brightness
	W508476	Knob—contrast
	W508477	Knob—"TONE"
	W508331	Mask for picture tube
	W508479	Name plate
	W170193	Nut—retains name plate
	W508293	Rail for drawer ... per set
	W505497	Socket for OFF-ON Indicator Lite at base of cabinet
	W18796	Screw—#10 x 1", mounts chassis
	W162090	Terminal strip for TV antenna connection
	W508478	Washer—felt, for knob

MISCELLANEOUS

SCHEMATIC LOCATION	PART NO.	DESCRIPTION
	W508189	Back for AM-FM tuner
	W301270	Base for mtg. electrolytic condenser
	W508040	Bracket for deflection yoke mtg.
	W507106	Bracket for focus coil mtg.
	W508153	Bracket base for support of yoke and focus coil

MISCELLANEOUS—Continued

SCHEMATIC LOCATION	PART NO.	DESCRIPTION
	W508081	Bracket for tuner mtg. (front)
	W508426	Bracket for tuner mtg. (rear)
	W507214	Bracket, locking—holds focus coil in position during shipment
	W508510	Bracket—retains front of picture tube
	W508190	Bracket—supports AM FM tuner
	W506279	Bracket—supports band switch shaft on AM-FM tuner
	W508198	Bracket—supports band switch shaft on TV chassis
	W508038	Bracket—tube support (bottom front)
	W508154	Bracket ("U" shaped) for support of yoke and focus coil
	W505165	"C" washer for connecting link
	W507286	Connector for H.V. terminal of picture tube
	W117057	Cord—dial drive (2 ft. required) ... per ft.
	W112745	Clip for mtg. AM antenna coil
	W505101	Clip for mounting I.F. transformer
	W507592	Clip for mtg. 4th video I.F. coil
	W507339	Clip for mounting video converter plate coil 1st video I.F., 2nd video I.F., 3rd video I.F., horiz. lock and horiz. linearity coil
	W114955	Clip retainer on end of dial cord
	W508525	Drum—dial: on gang condenser
	W508155	Grounding spring for coating on picture tube
	W506803	Ion trap assy.—includes magnet
	W508527	Lever—band switch actuating (on AM-FM tuner)
	W508526	Lever—band switch actuating (on TV chassis)
	W508194	Link—connects band switch actuating levers
	W162093	Planetary drive and dial drum (incl. mtg. bracket)
	W506652	Plug for AM-FM tuner power cable
	W500966	Plug for Phono Pick-up cable
	W507699	Power cord assembly (incl. plugs at both ends)
	W507361	Rubber cover for H.V. terminal connector
	W508512	Rubber pad—fits between pix tube and bottom front support
	W507793	Rubber spacer support between flared neck of picture tube and yoke bracket
	W507422	Rubber sleeve between neck of picture tube and focus coil
	W18796	Screw—#10 x 1"; mounts chassis
	W162031	Shield—H.V. supply (front section)
	W508088	Shield—H. V. supply (rear section)
	W508506	Shield for Indicator Lite
	W507357	Slug core for 1st, 2nd, 3rd, and 4th video I.F. coils
	W507429	Slug core for Horizontal Lock and Horizontal Linearity coil
	W508438	Slug core for primary of TV sound discriminator transformer
	W508439	Slug core for secondary of TV sound discriminator transformer
	W508435	Slug core for Width coil
	W162038	Socket assembly for 1B3GT/8016 tube (incl. corona ring & mtg. frame)
	W508049	Socket and cable assembly for picture tube
	W507948	Socket for AM-FM tuner power cable
	W508460	Socket for AM or FM Channel Lite
	W508459	Socket for TV Channel Lite
	W508086	Socket for mtg. H.V. condenser 230
	W507932	Socket—male, power cord interlock
	W506576	Socket—miniature (7 pin) (for 6BE6)
	W507364	Socket—miniature (7 pin)
	W506331	Socket—miniature (9 pin) (for 12AT7)
	W508044	Socket—miniature (9 pin)
	W506220	Socket—octal
	W160039	Socket—phono plug
	W501182	Socket—phono motor cable
	W508514	Spring—retains H.V. lead
	W505161	Spring—tension
	W503994	Strap for picture tube support
	W111456	Washer—spring washer connecting link
	W170195	Wing nut #8-32; for yoke and focus coil mounting
	W170741	Wing screw #10-32; for yoke mounting
	W170817	Wing screw #10-24; for height adj. of yoke and focus coil

World Radio History

GENERAL DESCRIPTION

This RL covers Television Receiver, Catalog 149, which utilizes Television Chassis 100.107-1. The chassis is essentially the same as Television Chassis 100.107 which is covered by 57 RL 545. The differences, consisting of slight modifications in the Horizontal Sweep Circuit and a change in Cabinet styling, are described in this RL.

In addition to the above television chassis, Catalog 149, is also equipped with an AM-FM Tuner Chassis 100.043 that is identical to the AM-FM Tuner Chassis described in 57 RL 545.

A combined total of 31 tubes are provided in both chassis of this receiver. Television Chassis 100.107-1 contains 26 tubes, 23 of which are used solely for reproduction of the visual and aural portions of a television broadcast and three other rectifier tubes plus a heavy duty power transformer to provide necessary power for operation of all stages.

The AM-FM Tuner Chassis 100.043 employs 5 additional tubes in a compactly designed, high sensitivity circuit that provides reception of AM and FM broadcasts. Audio output from this chassis is fed into the audio amplifier and output stages located on the television chassis thereby permitting use of a single, high fidelity, audio system for all functions.

SPECIAL INSTRUCTIONS

The following special instructions should be observed when ordering new repair parts or returning defective parts:

1. Order new repair parts per "HOW TO ORDER PARTS" instructions on next page.
2. Return defective parts, within warranty period, to source 100 for no charge replacement. SEE DIV. 57 STANDARD NOMENCLATURE INDEX FOR SOURCE NAME AND ADDRESS.

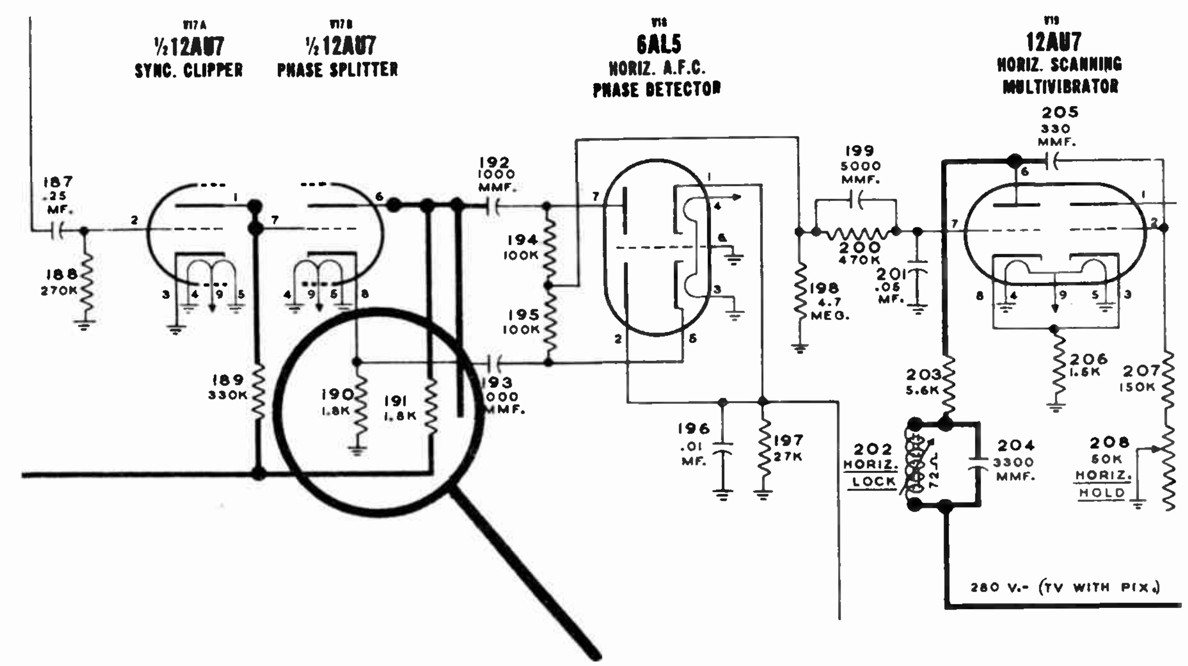
HOW TO ORDER PARTS

1. Use Correct Order Form.
2. On the Purchase Order always give the following information:
   (a) PART NUMBER (number printed on the part if different from that shown in this list) and DESCRIPTION for each part ordered. When no part number is assigned, order by description and rating. Also give PRICE of part (indicate if no selling).
   (b) The CHASSIS NUMBER, which is 100.107-1 or 100.043, will be found on a metal plate (pictured on previous page) at the rear of the chassis.
3. ORDERING INSTRUCTIONS: Send Purchase Orders DIRECT TO SOURCE No. 100. See "DIV. 57 STANDARD NOMENCLATURE INDEX" for source, name and address.
4. MARK-UP: Selling Prices in the following list produce a mark-up of A5, unless otherwise noted in the M.U. Code Column.
5. In all correspondence relating to cabinets, always mention the source code letter stamped into the bottom of table models, and the CATALOG NUMBER shown on the sticker on the back, bottom or inside of cabinet.

REPAIR PARTS LIST SUPPLEMENT

For a complete list of repair parts, refer to 57 RL 545

SCHEMATIC LOCATION	PART NO.	DESCRIPTION
51	W508157	Speaker—P.M. Dynamic (6")
190, 191	W510739	Resistor—carbon 1800 Ohms ± 5% ½ watt
	W508213	Back for cabinet
	W507783	Bottom plate
	W508706	Cabinet



CIRCUIT DIFFERENCES

The components which are encircled in the above diagram represent the only electrical difference between the 100.107-1 chassis and the 100.107 chassis as shown in 57 RL 545. These differences are listed below.

1. Resistor 190 in the cathode circuit of V17B (12AU7) Phase Splitter stage was changed in tolerance rating from ±10% to ±5%.
2. Resistor 191 in the plate circuit of V17B (12AU7) Phase Splitter stage was changed from 2700 Ohms ±10% to 1800 Ohms ±5%.

OSCILLOGRAMS

All oscillograms taken with ground lead of 'scope connected to receiver chassis (unless otherwise indicated) and with receiver controls set for normal reception of a station transmitting its standard test pattern.

Number appearing below asterisk specifies setting of horizontal sweep frequency control on 'scope.

*— This symbol on illustration indicates that wave form was observed on a 'scope whose vertical amplifier had very limited high frequency response (50 to 100 Kc).

**— This symbol indicates that wave form was observed on a 'scope whose vertical amplifier frequency response was flat to within 20% up to 2 Mc.

INDEX

SPECIFICATIONS

POWER REQUIREMENTS

117 volts 60 cycles

Television—230 watts
AM-FM Radio—145 watts
Phonograph—160 watts

FREQUENCY RANGE

Television—channels 2 through 13. For channel frequencies, see table on page 2.

Radio
Standard Broadcast (AM)—540-1600 Kc.
Frequency Modulation (FM)—88-108 Mc.

PICTURE SIZE

Height	Width (at widest point)	Viewing Area (sq. inches)
9"	11"	91.6

SPEAKER

Type	Size	V.C. Imped.
P.M. Dynamic	6" x 9"	3.2 ohms

ANTENNA INPUT IMPEDANCE

Balanced input for ribbon type transmission line—300 ohms.
Unbalanced input for coaxial cable—75 ohms.

BUILT-IN ANTENNA

High "Q" dipole with tunable matching stub.

R. F. TUNER

Fixed coil and selector switch construction. All components are easily accessible for servicing.

"KEYED" AUTOMATIC GAIN CONTROL

Outstanding new development; minimizes "airplane flutter"; reduces contrast variation when changing from one channel to another; increases immunity of sync system to external interference.

INTERMEDIATE FREQUENCIES

AM Sound—455 Kc.
FM Sound—10.7 Mc.
TV Sound Carrier—22.25 Mc.
Picture Carrier—26.75 Mc.

I.F. SYSTEM

AM—One stage (two tuned transformers)
FM—Two stage (three tuned transformers)
TV—Four stage (stagger tuned) for composite signal, and two additional stages for inter-carrier sound.

VIDEO AMPLIFIER

Two Stage—broad band.

RETRACE LINE SUPPRESSOR

Eliminates retrace lines thruout the normal range of picture brightness and contrast.

FOCUS

Magnetic

DEFLECTION

Magnetic

HORIZONTAL SYNCHRONIZATION

Automatic frequency control and "keyed" A.G.C. provide excellent picture stability and noise immunity.

HIGH VOLTAGE POWER SUPPLY

"Fly-back" type. Completely enclosed in a shielded compartment.

SENSITIVITY

Antenna to Picture Tube Grid Sensitivity — To make this measurement, connect negative terminal of 1½ volt battery to A.G.C. line, and positive terminal of battery to chassis. Also, set Contrast control to maximum clockwise position. Connect an **A.C.** vacuum-tube voltmeter between picture tube grid and ground, and place a .005 microfarad condenser across the same points.

Inject R.F. signal (400 cycle modulated) at antenna terminals, using signal whose frequency corresponds to the center frequency of the selected channel, and adjust Television Fine Tuning control for maximum output. Generator must be connected to antenna terminals with a 150 ohm carbon resistor in series with each lead to simulate proper impedance match.

Input signal required to produce standard output of 7.07 volts **A.C.** (r.m.s.) at picture tube grid is indicated in the following table. Since a fixed bias of 1½ volts has been applied to the A.G.C. system in order to provide a reference level for these measurements, it will be understood that the sensitivities specified here are not intended to indicate the full capability of the receiver, but merely serve as a convenient basis for determining proper operation.

Low Band { Average—50 microvolts; Range—25 to 100 microvolts

High Band { Average—80 microvolts; Range—40 to 160 microvolts

Detector to Picture Tube Grid Sensitivity — To make this measurement, remove 6AU6, 4th Video I.F. tube (V-10) and set Contrast control to maximum clockwise position. Inject a 400 cycle (audio) signal across 6800 ohm video detector load resistor. In order to produce the standard output of 7.07 volts **A.C.** (r.m.s.) at the picture tube grid, the input signal at the detector load resistor will be approximately .07 volts **A.C.** An **A.C.** vacuum-tube voltmeter must be used for these voltage measurements.

Television Sound System Sensitivity—Inject 4.5 megacycle frequency modulated signal (400 cycle modulation with 7½ Kc. deviation) across video detector load resistor and measure output at speaker voice coil. An input of 2200 microvolts will produce approximately 500 milliwatts or 1.26 volts across speaker voice coil.

F.M. Sound System Sensitivity—Inject a 98 megacycle frequency modulated signal (400 cycle modulation with 22½ Kc. deviation) at pin 8 of 12AT7, F.M. R.F. Amplifier tube (V-27). Connect generator to this point through a 300 ohm resistor. Tune receiver to 98 Mc. signal. An input of 35 microvolts will produce approximately 500 milliwatts or 1.26 volts across speaker voice coil.

A.M. Sound System Sensitivity—Inject a 1000 Kc. signal (modulated 30% at 400 cycles) at (high side) connection lug on antenna section of gang condenser. Connect generator to this point through a .01 microfarad condenser. Tune receiver to 1000 Kc. signal. An input of 75 microvolts will produce approximately 500 milliwatts or 1.26 volts across speaker voice coil.

V30	6BA6	(FM) 2nd IF Amplifier—(AM) Detector—A.V.C.
V31	6AL5	Discriminator—A.V.C.

RECEIVER OPERATING CONTROLS

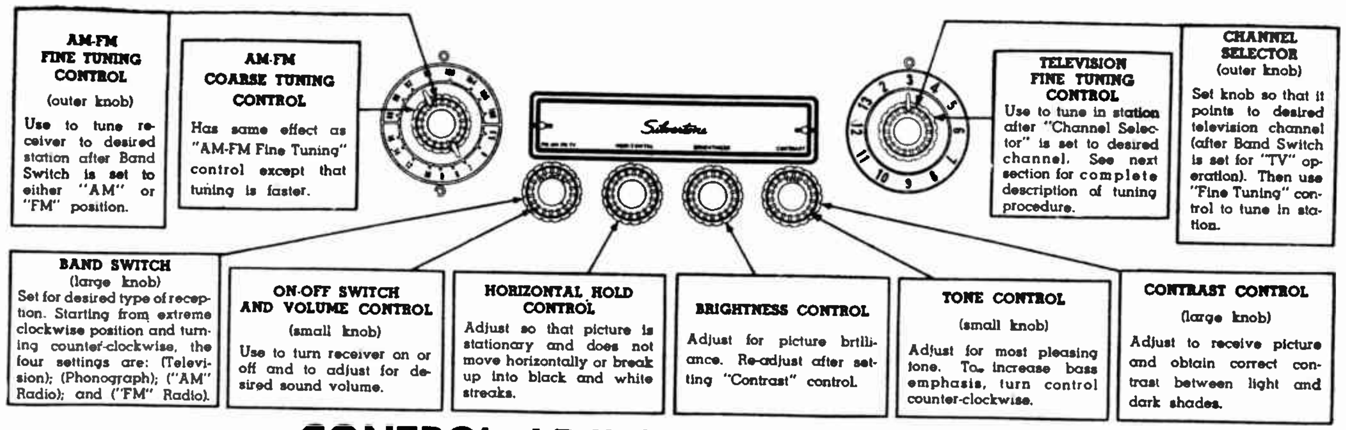
The various controls on the receiver may be divided into two classes, Operating and Pre-set. Operating controls are those which control program selection as well as sound and picture quality.

All but one of the operating controls of the receiver are located on the front panel and the name and use of each are described in Figure 1. The built-in antenna tuning control is accessible at the rear of the receiver. The Pre-set controls are those which require adjustment at the time the receiver is installed and they rarely need attention thereafter. There are eight Pre-set controls, four of which are located at the back of the chassis (see Figure 14). Four controls are accessible by removing the Name Plate located directly above the Operating controls. (see Fig. 6).

©John F. Rider

World Radio History

Fig. 1



CONTROL ADJUSTMENT PROCEDURE

TO ADJUST CONTROLS FOR RECEPTION OF STANDARD BROADCAST OR FREQUENCY MODULATION STATIONS:

1. Turn "On-Off Switch and Volume" knob clockwise to turn set on.
2. Set "Band Switch" to either its "AM" or "FM" position. Small red indicator light adjacent to corresponding dial scale will become illuminated.
3. Use "AM-FM Fine Tuning" control to select desired station.
4. Adjust "Volume" control setting for desired sound intensity.
5. Adjust "Tone" control setting for most pleasing tone.

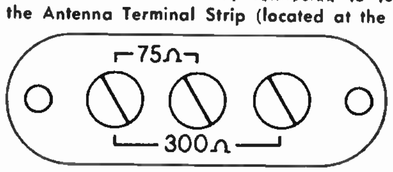
TO ADJUST RECEIVER FOR RECEPTION OF TELEVISION STATIONS:

Although the Pre-set controls have been factory adjusted for optimum performance, it is usually necessary to make some fine adjustments of these controls at the time of installation.

To gain access to the centering adjustments and ion trap, it will be necessary to remove the back cover of the cabinet by first removing the built-in antenna tuning knob and then taking out the screws around the rim of the back cover.

Removal of the cabinet back automatically opens an interlock to disconnect the receiver power cord, therefore, an auxiliary power cord assembly will be required when making centering and ion trap adjustments. This cord may be obtained by requesting Part #W507699. **Do not attempt to supply power to the receiver using any other device.**

CONNECTION OF TRANSMISSION LINE TO RECEIVER—This television receiver has an input circuit which can accommodate either 75 ohm or 300 ohm transmission line. When an outdoor antenna is used, first disconnect the two built-in antenna leads connected to terminals labeled "75 ohm" on the Antenna Terminal Strip (located at the left rear of the cabinet). If 300 ohm line is installed between the outdoor antenna and the receiver, connect the transmission line to the two terminals labeled "300 ohm" on the Antenna Terminal Strip; if low impedance line is installed, connect the transmission line between the two antenna terminals labeled "75 ohm."



TELEVISION ANTENNA TERMINAL STRIP

The receiver is now ready for an operational check.

1. **TURN SET ON**—Rotate the "On-Off Switch and Volume" knob approximately ½ turn clockwise to turn set on and obtain sufficient sound volume during the tuning process. Allow several minutes for all tubes in the receiver to warm up and for circuits to stabilize before attempting to obtain a picture on the screen.
2. **POSITION BAND SWITCH**—Set "Band Switch" to "TV" position. Small red indicator light above channel numbers will become illuminated.
3. **ADVANCE BRIGHTNESS CONTROL**—Turn the "Brightness" control knob clockwise until the picture tube screen is moderately illuminated.
4. **ADJUST ION TRAP**—If screen remains dark or is only dimly illuminated when "Brightness" control is turned clockwise, the ion trap may require adjustment.

   The ion trap is located on the neck of the picture tube as shown in Figure 14 and consists of a magnet held in position by metal bands. Rotate the entire trap assembly while sliding it back and forth until picture tube screen is illuminated to maximum brilliance. Reduce "Brightness" control setting and repeat this operation to assure accurate positioning of ion trap.
5. **ADVANCE CONTRAST CONTROL**—Turn the "Contrast" control knob to its maximum clockwise position.
6. **POSITION CHANNEL SELECTOR** — Set "Channel Selector" knob so that it points to the desired television channel.
7. **ADJUST FINE TUNING CONTROL** — After "Channel Selector" knob has been set, then use the "Fine Tuning" control to obtain the correct tuning point for both picture and sound. That is accomplished as follows:

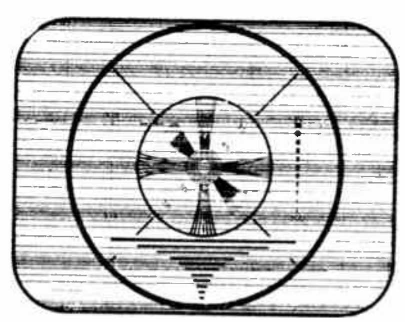


Fig. 2—SOUND INTERFERENCE; CAUSED BY INCORRECT TUNING

   a. Turn "Television Fine Tuning" control in either direction until sound volume is maximum—if sound cannot be heard, advance the volume control and repeat fine tuning.

   b. When the point of maximum sound volume has been reached it will be noted that the picture has a "ragged" or "sawtooth" appearance or is partially obscured by "sound bars" (dark horizontal bars of varying width—see Fig. 2).

   THE CORRECT SETTING OF THE FINE TUNING CONTROL is now obtained by turning it away from the maximum volume position only far enough to eliminate the "sound bar" interference and permit sharp reproduction of the picture.

   If image is slightly distorted or tears into a series of black and white streaks as shown in Fig. 3, reduce the setting of the Contrast control and operate the "Horizontal Hold" control knob until picture appears stable and undistorted.

8. **ADJUST SOUND VOLUME**—Readjust the setting of the "Volume" control until the sound accompanying the television broadcast is received at a satisfactory level.
9. **ADJUST BUILT-IN ANTENNA TUNING CONTROL**—If the receiver's built-in television antenna system is used, rotate the antenna tuning knob (located at rear of cabinet) until the best picture is obtained. It may be possible to find a single setting for this knob which will give satisfactory performance for a group of stations. In the event that is not the case, adjust the control for optimum performance each time the Channel Selector is rotated to a different station.
10. **HORIZONTAL HOLD**—Should the picture appear to move horizontally across the screen or break up into a series of light and dark streaks as shown in Figure 3, adjust the "Horizontal Hold" control until the picture remains stationary. If this control must be rotated to the end of its range for proper "locking" action, then it will be necessary to reset the position of the "Horizontal Lock" control (see Figure 14 for location). Adjustment is accomplished by first setting the "Horizontal Hold" control in the middle of its range and then changing the setting of the "Horizontal Lock" control until picture locks in horizontally.

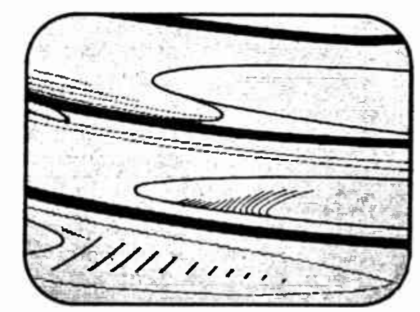

Fig. 3—HORIZONTAL MOVEMENT; ADJUST HORIZ. HOLD CONTROL

11. **VERTICAL HOLD**—Should the picture appear to roll by in a vertical direction or cause multiple vertical images as shown in Figure 4, it will be necessary to adjust the "Vert. Hold" control located behind the Name Plate (see Figure 6).

    After this adjustment is made, reduce contrast until picture is barely visible and check setting of "Vertical Hold" control for proper picture synchronization.

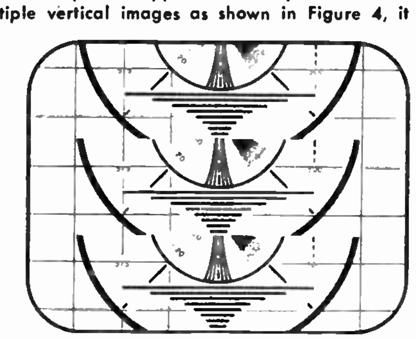

Fig. 4—VERTICAL MOVEMENT; ADJUST VERTICAL HOLD CONTROL

12. **INITIAL FOCUS**—Adjust the "Focus" control, located behind Name Plate, until picture is clearly defined.

    Fuzzy picture may also be due to reproduction of poor quality film when station is televising a motion picture. Incorrect tuning of receiver produces a similar effect. Check for proper tuning point as described in step 7 of this section.

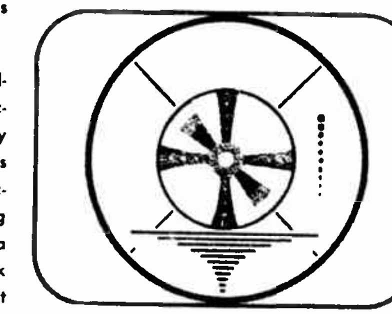

Fig. 5—BLURRED APPEARANCE; ADJUST FOCUS CONTROL

The following adjustments should be made while the station is transmitting its circular test pattern.

13. **STRAIGHTENING TILTED RASTER**—If the pattern should appear on the screen in a tilted position as shown in Figure 7, loosen the deflection yoke locking screw (see Figure 14) and rotate the yoke sufficiently to correct this condition. Be sure to re-tighten the screw securely.

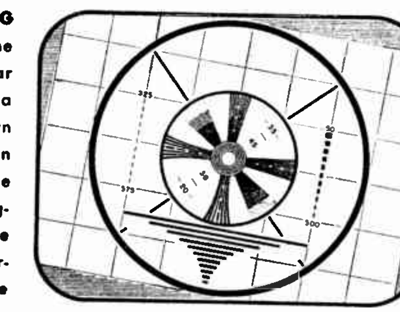

Fig. 7—TILTED PICTURE; ADJUST YOKE POSITION

14. **CENTERING:** To center the test pattern on the screen, proceed as follows:

    a. Make sure focus coil mounting plate is perpendicular to neck of picture tube by adjustment of three nuts labeled A in Figure 14.

    b. Rotate the two magnets in the centering magnet assembly (see Fig. 14). These magnets may be adjusted by grasping the cardboard "ears" attached to each magnet and rotating the magnets with respect to each other and with respect to the picture tube. Adjust the magnet position for best centering of the test pattern.

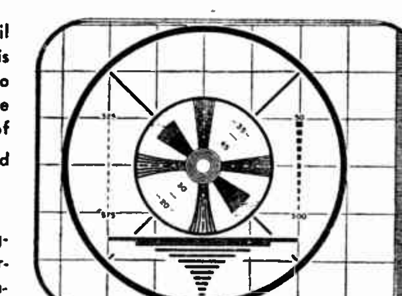

Fig. 8 —OFF CENTER; ADJUST FOCUS COIL POSITION

©John F. Rider

World Radio History

c. If picture is still not centered, loosen four focus coil wing nuts labeled B in Fig. 14 and rotate focus coil for best centering of test pattern.

d. Readjust ion trap for maximum brightness on picture tube screen as explained in step # 4.

e. If picture is still not centered, position focus coil by adjusting the three nuts labeled A in Fig. 14.

In event picture cannot be centered by above procedures, release the four wing nuts labeled D in Fig. 14 and raise or lower entire yoke and focus coil assembly so that focus coil can be repositioned vertically with respect to the tube neck.

16. **HEIGHT** — Control of picture size in the vertical direction is accomplished by means of the "Height" control located behind the Name Plate. Height and width adjustments should be checked for all transmitting stations to be sure that picture properly fills the viewing area. It may be necessary to change the setting of the "Height" control after the "Vertical Linearity" control is adjusted.

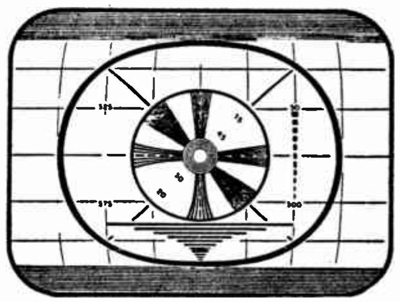

Fig. 10 — TOO SHORT; ADJUST HEIGHT CONTROL

15. **WIDTH** — Control of picture size in the horizontal direction is accomplished by means of the "Width" control located on the rear of H. V. power supply (see Fig. 14). If abnormally low line voltage makes it difficult to obtain sufficient picture width when using the "Width" control, then changing the setting of the "Horizontal Drive" control may be helpful. The "Drive" control is located at the rear of the chassis and its setting will affect horizontal linearity as well as picture width. Therefore, after adjusting this control for desired width, it may be necessary to re-adjust the "Horizontal Linearity" control as described in paragraph #18.

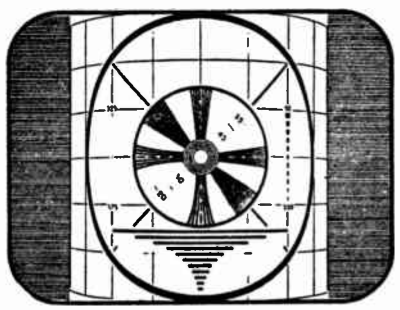

Fig. 9 — TOO NARROW; ADJUST WIDTH CONTROL

17. **HORIZONTAL DRIVE** — The "Horizontal Drive" control located at rear of chassis (see Fig. 14) should be rotated clockwise to the point where any white (or black) vertical lines near the left side of the picture are eliminated. As width and linearity of the picture are affected by the setting of "Horiz. Drive" control, it will be necessary to adjust this control in conjunction with the Horiz. Linearity and Width controls to obtain desired picture width and linearity.

18. **HORIZONTAL LINEARITY** — Improper horizontal linearity causes the circular test pattern to appear condensed on the right edge of the screen and extended on the left edge or vice versa. This effect is illustrated in Figure 11. Adjust for proper linearity by using "Horiz. Lin." control located at rear of chassis (see Figure 14). In event that proper horizontal linearity cannot be obtained by adjusting this control, then change the setting of the "Horiz. Drive" control.

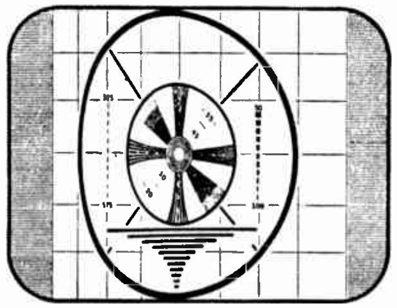

Fig. 11 — HORIZONTAL DISTORTION; ADJUST HORIZONTAL LINEARITY CONTROL

19. **VERTICAL LINEARITY** — Improper vertical linearity causes the circular test pattern to appear condensed on the upper edge of the screen and extended on the lower edge or vice versa. This effect is illustrated in Figure 12. Adjust for proper linearity by using "Vert. Lin." control located behind Name Plate. It may be necessary to readjust the "Height" control if an appreciable change is made in the linearity control setting.

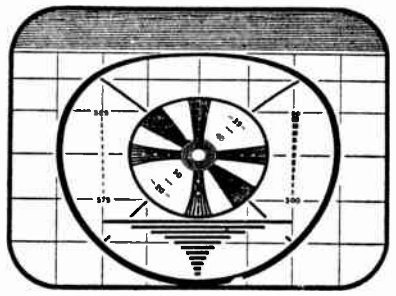

Fig. 12 — VERTICAL DISTORTION; ADJUST VERTICAL LINEARITY CONTROL

20. **ELIMINATING SEMI-CIRCULAR SHADOW** — This shadow is caused by the electron stream striking the neck of the tube and it can generally be corrected by applying one or a combination of the following procedures:

a. Make sure deflection yoke is positioned as far forward as possible by loosening the three wing nuts labeled C in Fig. 14.

b. Reposition the focus coil by readjusting the three nuts labeled A in Fig. 14 to shift the coil forward.

c. In event neck shading cannot be eliminated by the above procedures, release the four wing nuts labeled D in Figure 14 and raise or lower entire yoke and focus coil assembly so that focus coil can be repositioned vertically with respect to the tube neck.

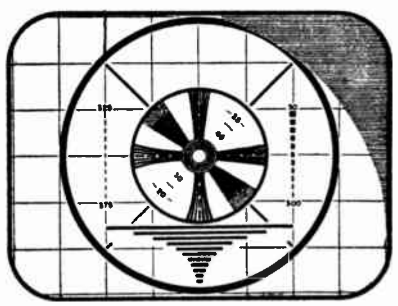

Fig. 13 SEMI-CIRCULAR SHADOW

21. **FINAL ADJUSTMENTS** — Recheck settings of "Brightness," "Contrast" and "Focus" controls for best picture quality.

World Radio History

SOCKET VOLTAGES

CAUTION

THE PICTURE TUBE is highly evacuated and if broken, glass fragments will be violently expelled. Scratching, chipping, undue pressure, or careless handling such as lifting the tube by its neck is dangerous and should be avoided. If it is necessary to handle the picture tube, use safety goggles and heavy gloves. Be sure to discharge the voltage developed across the capacitor formed by the inner and outer coating of the picture tube. This can be done by connecting the high voltage socket on the tube to the outer coating with a well insulated metal conductor.

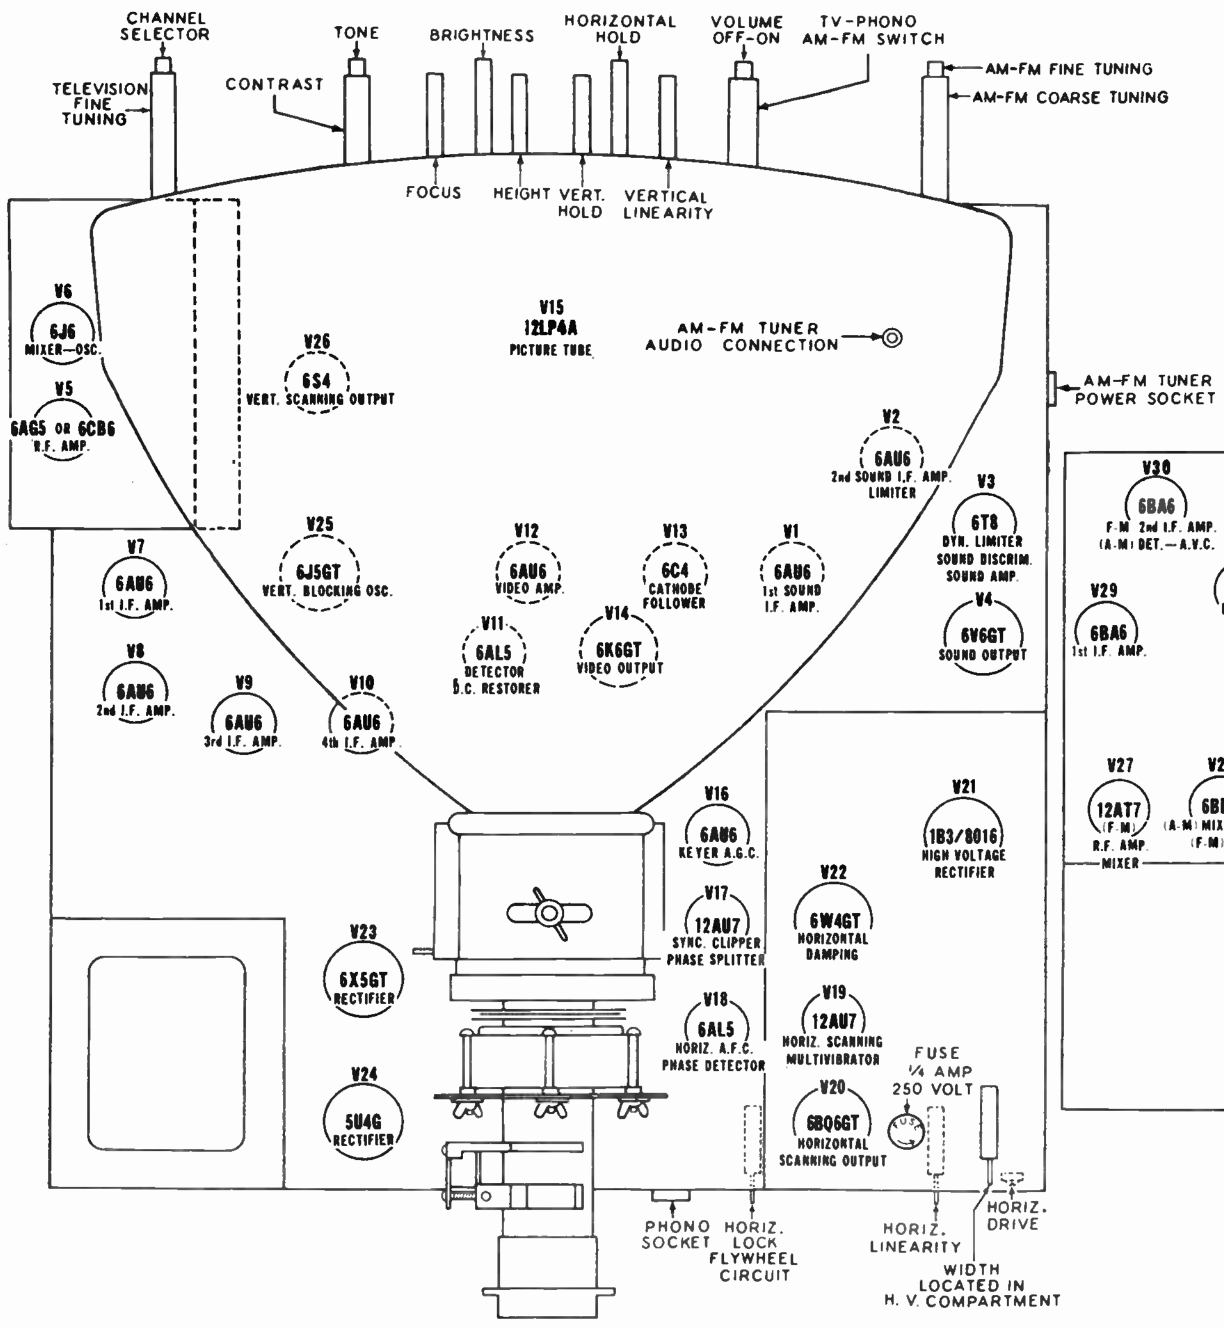
HIGH VOLTAGE (10 to 12 kilovolts) is produced in a supply circuit of this receiver. Exercise care to avoid contact with elements of this circuit and particularly the tube terminals which are labeled "CAUTION" in the adjoining voltage chart. If measurement of voltage at these points is necessary, see procedure given below under the note "E".

THE HIGH VOLTAGE LEAD, which supplies approximately 10 to 12 kilovolts to the picture tube, should be momentarily shorted to the chassis whenever it is disconnected for service purposes. This discharges the high voltage filter condenser and prevents a shock hazard when working on the receiver after it has been turned off.

INTERMEDIATE B+ VOLTAGES, 475 and 365, are dangerous and caution should be observed when the receiver chassis components are exposed for service purposes.

BE SURE TO CHECK FOR PROPER POSITIONING OF BAND SWITCH SECTIONS ON AM-FM and TV chassis when interconnecting link arm has been disengaged and bottom cover of the AM-FM chassis is removed for voltage measurements. DO NOT turn on the receiver until you have first determined that the respective switch sections are correctly synchronized or positioned. Failure to observe this precaution can result in damage to the receiver, as well as erroneous voltage measurements. For more complete discussion of this subject, see text shown adjoining AM-FM socket voltage chart on page 10.

TUBE LOCATIONS & FUNCTIONS



THE VOLTAGES SHOWN IN THE ADJOINING CHART WERE MEASURED UNDER THE FOLLOWING CONDITIONS

1.	Power Supply—117 volts 60 cycle AC.
2.	All voltages are measured between socket terminals and chassis unless otherwise indicated on adjoining chart.
3.	Measurements made with voltmeter having sensitivity of 1000 ohms per volt except where indicated by (*). The (*) symbol designates a vacuum tube voltmeter measurement.
4.	Band Switch set to "TV" position unless otherwise indicated by letters "P", "m" or "n" following voltages shown in adjoining chart.
5.	Channel Selector and Fine Tuning Controls set for normal reception of a local station.
6.	Focus control set to maximum counter-clockwise position. Setting of this control will affect B+ voltage on the 265 volt supply line. This voltage is obtained when control is at maximum counter-clockwise position and increases to 320 as control is rotated to clockwise position.
7.	All other controls (with exception of focus control) are set for normal reception of the transmitted signal unless the voltage shown on the chart is followed by a letter or letters indicating a special condition of measurement as explained in subsequent notes.
8.	Certain voltages were measured with two different settings of specific controls. It should therefore be understood that in these instances all controls, with the exception of one or two, were set for normal reception—letters following the voltage shown on the chart indicate the exceptions and are explained below.
9.	The external or built-in antenna should remain connected to the receiver only when taking voltage measurements in the sweep and sync circuits—for all other measurements, disconnect antenna, short antenna terminals together and connect them to ground.

EXPLANATION OF NOTES

A.	Vert. Hold Control max. counter-clockwise
a.	This voltage will vary from —3.6 to —8.7 depending upon setting of Horizontal Hold Control and Horizontal Lock Control.
B.	Brightness Control max. counter-clockwise
b.	This voltage will vary from 11 to 16 depending upon setting of Horizontal Hold Control and Horizontal Lock Control.
C.	Contrast Control max. clockwise
D.	Horiz. Drive Control max. clockwise
d.	This voltage will vary from 315 to 335 depending upon setting of Horizontal Hold Control and Horizontal Lock Control.
E.	If you do not have an instrument capable of directly measuring voltages in this range, the voltage can be measured by using a voltage divider network consisting of twenty 2.2 megohm 2 watt resistors and one 1 megohm 2 watt resistor, all connected in series. Avoid using resistors of higher values as their individual voltage rating may be exceeded. It is also important to use resistors of equal wattage. Solder all connections between resistors. Accurately measure the overall resistance of the entire combination as well as the resistance of the 1 megohm section. **With the set turned off,** connect the 2.2 megohm end of the resistance voltage divider to the filament of the 1B3GT/8016 tube, or H. V. terminal of the picture tube, and connect the 1 megohm end to chassis. Now, turn the set on and measure the voltage drop across the 1 megohm resistor with a vacuum tube voltmeter. The voltage at the tube terminal can then be calculated as follows: $\left[\text{Volts At Tube Terminal}\right] = \dfrac{\left[\text{Measured Resistance Of Entire Voltage Divider}\right]}{\left[\text{Measured Resistance Of 1 Meg. Section}\right]} \times \left[\text{Volts Measured Across 1 Meg. Section}\right]$
e.	This voltage will vary from —2.7 to +5.8 depending upon setting of Horizontal Hold Control and Horizontal Lock Control.
F.	Height Control max. counter-clockwise
f.	Contrast Control max. counter-clockwise
G.	Width Control max. counter-clockwise
g.	This voltage will vary from 8 to 15 depending upon setting of Horizontal Hold Control and Horizontal Lock Control.

World Radio History

EXPLANATION OF NOTES

H. Height Control max. clockwise

h. This voltage will vary from 10 to 20 depending upon setting of Horizontal Hold Control and Horizontal Lock Control.

J. Horiz. Hold Control set for normal picture.

K. Horiz. Lock Control set for normal picture.

k. This voltage will vary from —5 to —11 depending upon settings of Horizontal Hold Control and Horizontal Lock Control.

L. This voltage will vary from —6 to —16 depending upon setting of Horizontal Hold Control and Horizontal Lock Control.

M. Vertical Linearity Control max. counter-clockwise.

m. Band switch set to "AM" position; dial tuned to 540 Kc. and AM loop antenna leads grounded.

N. Channel Selector set to channel #5

n. Band switch set to "FM" position; dial tuned to 88 Mc. and FM antenna terminal grounded.

P. Band switch set to "PHO" position.

R. Do not attempt to measure the voltage at the tube cap. There is a high R. F. potential at this point.

r. This vacuum tube voltmeter measurement will fluctuate in the vicinity of 0.9 volts.

S. Channel Selector set to channel #9

T. Grounding of center stud on tube socket is necessary to reduce capacity coupling between other pins. Oscillation may result if this ground is omitted.

t. This voltage will vary from —0.04 to +0.06 depending upon setting of Horizontal Hold Control and Horizontal Lock Control.

U. Vertical Hold Control max. clockwise

V. Before measuring this voltage, first connect external antenna and adjust controls for normal reception of station signal; then set Focus Control to maximum counter-clockwise position.

W. This voltage will vary from —10 to —12 depending upon setting of Horizontal Hold Control and Horizontal Lock Control.

X. Brightness Control max. clockwise

Y. Vertical Linearity Control max. clockwise.

Z. The measurement should be made with a vacuum tube voltmeter. The voltage reading will fluctuate in the vicinity of 0.04 volts.

World Radio History

REMOVING BOTTOM COVER OF AM-FM CHASSIS

It will be necessary to remove the bottom cover of the AM-FM chassis in order to service the underside of this unit. Removal of that cover may be accomplished as follows:

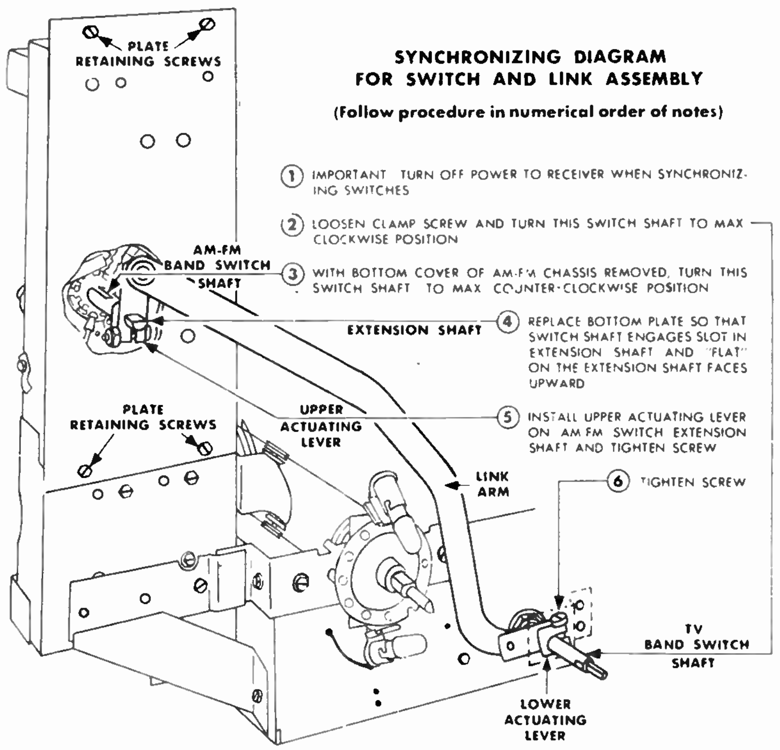
1. Make sure receiver is turned off by removing power cord plug from wall outlet.
2. Loosen screw in upper actuating lever on AM-FM band switch extension shaft and slide lever off the shaft. The link arm will now be disengaged from the AM-FM band switch.
3. Release the screws holding the bottom cover in position and carefully remove cover.

CHECKING SYNCHRONIZATION OF BAND SWITCHES ON AM-FM TUNER AND TV CHASSIS

Note that the band switch on the AM-FM Tuner chassis is mechanically coupled by a link arm and lever arrangement to the band switch on the TV chassis. Do not operate these switches by direct pressure on the link arm—always use a control knob attached to the TV switch shaft.

If the mechanical linkage is forced or slips at the lever on the TV switch shaft or the bottom cover of the AM-FM Tuner is removed for service purposes, it is possible for the respective switch sections to get out of step. As one function of the band switch is to control power supply circuits, the receiver can be damaged if the respective switch sections lose synchronism or are indiscriminately set to random positions.

In order to check for correct synchronization of the band switches, proceed as follows:



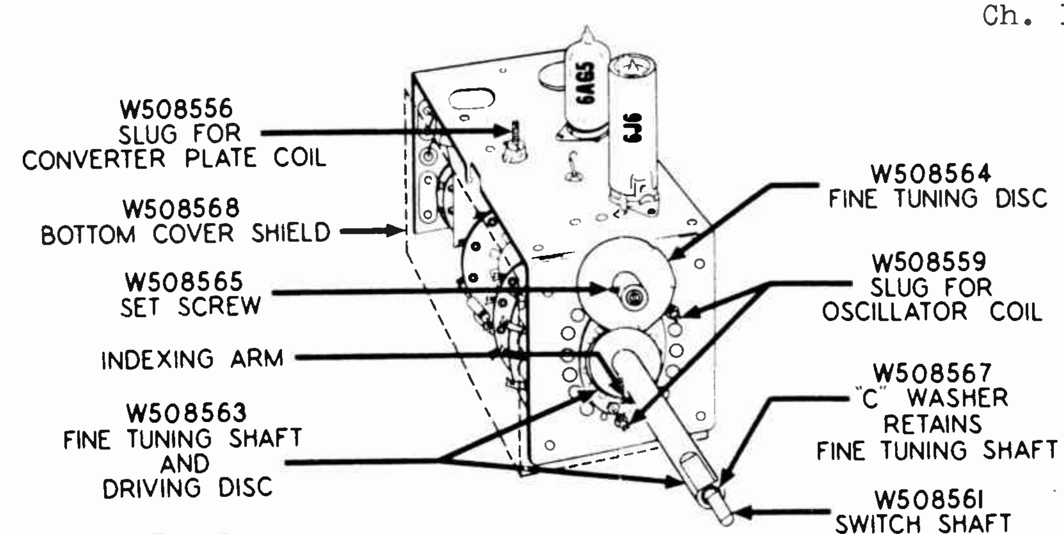
METHOD OF MAINTAINING BAND SWITCH SYNCHRONIZATION DURING VOLTAGE MEASUREMENTS OR OTHER SERVICE OPERATIONS ON AM-FM TUNER

After the bottom cover of the AM-FM chassis has been removed, it should be noted that the link arm is disengaged from the AM-FM band switch shaft, thereby removing mechanical coupling between the TV chassis band switch and AM-FM chassis band switch. For proper operation of the receiver while servicing the AM-FM Tuner, these switches must each be manually positioned so as to maintain correct synchronization. Positioning of these switches may be accomplished as follows:

1. Make sure receiver is turned off by removing power cord plug from wall outlet. **IMPORTANT: — Do not attempt to operate separate sections of band switch while power is on.**
2. Before attempting to select a specific setting (FM, AM, PHONO, or TV) for the respective switch sections, it is important to assure that both sections start at their correct position. That is done by setting the **switch section on the AM-FM chassis to its fully clockwise position** and then setting the **switch section on the TV chassis to its fully counter-clockwise position.** Both switch sections are now in their correct position for "FM" operation of the receiver.
3. To set switch sections for AM, PHONO or TV operation, position them as follows: NOTE THAT AS SWITCH SECTION ON AM-FM CHASSIS IS ADVANCED COUNTER-CLOCKWISE, THE TV CHASSIS SWITCH SECTION MUST BE ADVANCED IN A CLOCKWISE DIRECTION.

RECEIVER FUNCTION	SWITCH POSITION ON TV CHASSIS	SWITCH POSITION ON AM-FM CHASSIS
FM	Fully counter-clockwise	Fully clockwise
AM	2nd position, turning clockwise,	2nd position, turning counter-clockwise
PHONO	3rd position, turning clockwise	3rd position, turning counter-clockwise
TV	Fully clockwise	Fully counter-clockwise

4. When replacing bottom cover of AM-FM chassis and mechanical link arm between switch sections, refer to diagram above for re-assembly instructions.



REPAIR DATA FOR W508431 RF TUNER UNIT

All replacement parts for the RF Tuner Unit are included in the complete receiver parts list.

This RF Tuner Unit consists of an RF amplifier stage (using 6AG5 or 6CB6 tube) and a mixer-oscillator stage (using 6J6 tube). Channel selection is accomplished by a selector switch and fixed coil arrangement. The tuner also incorporates a Fine Tuning control.

Four groups of fixed coils permit tuning over the entire television band. These consist of 12 antenna coils, 12 RF amplifier plate coils, 12 mixer grid coils and 12 oscillator coils. Signal output from the mixer stage is coupled to the IF amplifiers through the converter plate circuit IF coil located on the tuner unit.

SERVICE PRECAUTIONS

SUBJECT	PRECAUTIONS
ELECTRICAL COMPONENTS	The high frequencies used in the RF section of a television receiver make it necessary that considerable care be exercised in servicing the tuner. Lead dress and location of components are very critical at these frequencies. When replacing parts, it is important to use components of identical electrical characteristics and physical size. Always reconnect the replacement item in the same location and position in the tuner as the original component.
TUBES	Replacement of tubes in the Tuner Unit may cause slight detuning of RF circuits due to inherent differences in inter-electrode capacitances. When replacing tubes (especially V6, 6J6 mixer-oscillator tube) make sure that Fine Tuning control will tune in television stations at approximately the middle of its range. If fine tuning cannot be accomplished, try several new tubes in order to obtain one which will permit correct tuning. When tube replacement does not give the desired result, realignment of the tuner is recommended (see "Alignment Procedure").
CHANNEL COILS AND SLUGS	Channel Coils must be handled with care. Do not disturb coil windings or slug positions except when re-aligning the tuner unit.

REMOVAL AND REPLACEMENT OF PARTS

ITEM	PROCEDURE
RF TUNER UNIT	To remove the Tuner Unit from receiver chassis, proceed as follows 1. Remove TV Channel Lite socket. 2. Remove support bracket which positions front of Tuner Unit and also remove screws which hold tuner to rear support bracket. 3. Disconnect the leads from the tuner to the main chassis. See illustration on circuit diagram page showing tuner connections. After the Tuner Unit is replaced, make sure that TV Channel Lite socket and sleeving are correctly positioned so that channel selector knob will be properly illuminated.
BOTTOM COVER SHIELD	Squeeze upper edges of Bottom Cover Shield together at points adjacent to locking "ears" on top of tuner, and at the same time pull down on shield. When replacing Bottom Cover Shield, make sure it is held securely by the two locking "ears."

©John F. Rider

World Radio History

ITEM	PROCEDURE
SWITCH SHAFT	To remove Switch Shaft from RF Tuner Unit, proceed as follows: 1. Remove tuner from receiver chassis. 2. Rotate Switch Shaft until portion of Indexing Arm which contacts front of tuner is pointing down (this corresponds to setting switch to channel #12). 3. Remove Switch Shaft "C" Washer located behind front plate of tuner. 4. Loosen Set Screw on Fine Tuning Disc. 5. Fine Tuning Disc, Fine Tuning Shaft and Driving Disc, and Switch Shaft may now be removed by merely pulling them forward. To replace Switch Shaft: 1. Set Fine Tuning condenser to its completely meshed position. 2. Slip edge of Fine Tuning Disc (furthest from the three "stops" on the disc) into slot of Fine Tuning and Driving Disc. 3. With portion of Indexing Arm (which contacts front of tuner) pointing down, slide Switch Shaft into tuner and Fine Tuning Disc over Fine Tuning Condenser Shaft. 4. Replace "C" Washer on Switch Shaft. 5. Rotate Fine Tuning Shaft and Driving Disc to maximum counter-clockwise position and tighten Set Screw on Fine Tuning Disc. The Fine Tuning condenser range should now be from its fully meshed position (with Fine Tuning and Driving Disc in its maximum counter-clockwise position) to its fully open position (with the tuning control in its maximum clockwise position).

HORIZONTAL SYNC SYSTEM ADJUSTMENT

If picture "tears" horizontally and cannot be synchronized by operating the Horizontal Hold control on front panel of receiver, this action may be due to incorrect setting of the slug in the Horizontal Lock Coil.

1. Set Horizontal Hold control in center of its range.
2. Adjust slug of Horizontal Lock Coil for picture synchronization (see Fig. 14 for location of slug).

REDUCTION OF INTERCARRIER BUZZ

If a prominent humming or buzzing sound is noted in the sound reception of a television broadcast, it may be due to a fault in transmission from the station, or incorrect adjustment of the discriminator transformer (tuning of secondary circuit) in the receiver.

This type of disturbance, which is only present when receiving a station signal, is known as "Intercarrier Buzz" and it should not be confused with power supply hum that would occur upon failure of a filter condenser.

The procedure for correct adjustment of the television sound discriminator circuit is presented in the last section of the Television Sound Channel alignment instructions. When the discriminator secondary slug #1 is properly adjusted, intercarrier buzz will be reduced to an acceptable minimum, provided that the transmission from the station is not at fault.

HIGH VOLTAGE POWER SUPPLY SERVICING

The High Voltage Power Supply used with this receiver is of the "fly-back" type and is located in the shielded compartment mounted at the left rear corner of the chassis. It consists of a sturdily constructed and well insulated horizontal sweep output transformer plus a 1B3GT/8016 high voltage rectifier tube and associated filter components.

The plate circuit of the Horizontal Scanning Output stage is fused to protect the transformer and kill high voltage in the event the 6BQ6GT tube or the high voltage rectifier circuit draws excessive current.

CAUTION

The heavily insulated red lead, which supplies extremely high voltage (10 to 12 kilovolts) to the picture tube, should be momentarily shorted to the chassis whenever it is disconnected for service purposes (that is, after receiver has been turned off). This discharges the high voltage filter condenser and prevents a shock hazard when working on the set.

Access to the horizontal output transformer, high voltage rectifier tube, fuse and high voltage filter condenser is accomplished by removing the rear section of the H.V. shield. This compartment shield is held in place by five screws.

To replace the fuse, depress the cap of the fuse holder (located next to 6BQ6GT tube) and turn the cap counter-clockwise. Install new fuse of the same type (¼ amp., 250 volt, part W508713); do not use any other size.

REMOVAL OF THE CABINET BACK AUTOMATICALLY OPENS AN INTERLOCK TO DISCONNECT THE RECEIVER POWER CORD.

CORONA AND ARC-OVER

Corona or arc-over can best be detected by observing the operation of the power supply in a dark room. Several conditions may cause these phenomena.

POOR CONNECTIONS Arcing or corona may be due to poorly soldered connections (rosin joints or sharp points), or defective tube socket connections. If the leads or connectors to the high voltage filter condenser do not grasp this component securely, arcing will also result.

Inspect solder connections and resolder those joints which are unsatisfactory. Make sure tubes are firmly positioned in tube sockets and that high voltage filter condenser is held securely in place.

CLOSELY SPACED COMPONENTS Arcing or corona may occur when H.V. components or leads are placed too close together. Make sure there is sufficient spacing between all parts and wiring. If necessary, the insulation between two elements of the circuit may be improved by coating both objects with a quick-drying liquid polystyrene or polyethylene.

The socket assembly for the 1B3GT/8016 rectifier tube includes a "corona ring" which prevents corona from the tube socket connections. The surface of this ring should be smooth and free of scratches, nicks, or sharp protrusions.

DIAL POINTER DRIVE CORD ARRANGEMENT

To string dial cord, first rotate "AM-FM" Coarse Tuning Control fully counter-clockwise until stop on drum contacts ear on mounting frame. Now, with gang set to fully meshed position, string dial cord using the following parts:

W114955 Clip on end of cord
W117057 Cord (2½ ft. required)
W505161 Spring

World Radio History

ALIGNMENT PROCEDURE.

Alignment of all RF and IF tuned circuits in this receiver may be accomplished by utilizing the procedures described in the following charts.

SEQUENCE OF ALIGNMENT: These procedures should preferably be applied in the order in which they are presented, however, alignment of RF or IF channels for either AM, FM or TV may be accomplished individually if desired.

The Television RF Amplifier and Mixer alignment may also be accomplished independent of the Television IF Channel alignment, but oscillator calibration can only be done after IF Channel has been correctly aligned. Proper IF band pass characteristic is necessary for oscillator alignment as results of circuit tuning are observed by means of an oscilloscope connected to the output of the video detector stage.

REMOVAL OF CHASSIS: The receiver chassis must be removed from the cabinet in order to accomplish alignment of all tuned circuits as there are adjustment points located on the undersides of both the main chassis and the AM-FM Tuner.

This can be accomplished by first removing all knobs and releasing the hold-down screws located on the underside of the cabinet. Then disconnect speaker leads and all three "built-in" antennae (TV, AM and FM). Release indicator lamp from bracket at base of cabinet.

CAUTION

The picture tube is highly evacuated and if broken, glass fragments will be violently expelled. Handle with care, using safety goggles and gloves. Avoid contact with high voltage terminal at side of tube even after it has been disconnected from the receiver—this precaution is necessary as inner and outer coatings on the tube form a capacitor which may carry a high voltage charge for an extended period of time after disconnection from the receiver.

INSTRUMENTS: The following instruments will be required as signal sources and output indicators during the alignment process. Since accurate alignment of a television receiver is heavily dependent upon the performance of your instruments, it is imperative that they meet the essential specifications described here.

1. **STANDARD SIGNAL GENERATOR** to provide signals at the following frequencies. Maximum output on all ranges should be at least .1 volt with provision for attenuation as desired. This instrument must have good frequency stability and be accurately calibrated. Generators which incorporate a separate crystal controlled oscillator and heterodyne circuit are self calibrating and therefore capable of providing the accuracy of frequency calibration required for television circuit alignment.

A. IF Frequencies:

- 455 Kc. (400 cycle amplitude modulated) for AM IF.
- 4.5 Mc. (Unmodulated) for TV Sound.
- 10.7 Mc. (Unmodulated) for FM IF.
- 22.25 (Unmodulated) marker for TV Sound IF carrier.
- 22.4 Mc. (Unmodulated) for TV 1st IF Trap.
- 22.8 Mc. (Unmodulated) for TV 3rd IF Trap.
- 23.5 Mc. (Unmodulated) for TV 1st and 3rd IF.
- 24.5 Mc. (Unmodulated) for TV 4th IF.
- 26.3 Mc. (Unmodulated) for TV Converter and 2nd IF.
- 26.75 Mc. (Unmodulated) marker for TV Picture IF carrier.

B. RF Frequencies:

- 550 to 1600 Kc. (400 cycle amplitude modulated) for AM RF.
- 54 to 88 Mc. (Unmodulated) for TV RF.
- 88 to 108 Mc. (400 cycle amplitude modulated) for FM RF.
- 174 to 216 Mc. (Unmodulated) for TV RF.

2. **RF SWEEP GENERATOR** to provide frequency modulated signals at the following frequencies:

   10.7 Mc. with 300 Kc. sweep width.
   20 to 30 Mc. with 10 Mc. sweep width.
   54 to 88 Mc. with 10 Mc. sweep width.
   174 to 216 Mc. with 10 Mc. sweep width.

   Output adjustable with at least .1 volt maximum.

   Output should be "flat" (no amplitude variation) for all settings of the sweep width control.

   Provision for connection of generator sweep modulating voltage to horizontal deflection system of an oscilloscope.

   Provision for blanking the output signal on each return sweep so that oscillogram will not show retrace.

3. **CATHODE RAY OSCILLOSCOPE**, preferably a unit with vertical amplifier having wide range frequency response and low capacity pick-up probe.

4. **VACUUM TUBE VOLTMETER.** The lowest voltage range of this instrument should preferably permit a 1.0 volt reading to be indicated at not less than one third of full scale deflection.

5. **OUTPUT METER**, preferably a unit equipped with an impedance matching network that will present a 3.2 ohm load when connected to secondary of audio output transformer.

INSTRUMENT CONNECTIONS: The method of connection, including details of matching and coupling networks, for instruments used in this alignment procedure is given in several illustrations on subsequent pages. Specific instructions for each instrument application will also be found in various sections of the alignment charts.

IMPORTANT

AVOID EXCESSIVE INPUT SIGNAL WHEN USING OSCILLOSCOPE AS ALIGNMENT INDICATOR.

When observing the receiver band pass characteristic on an oscilloscope, it is exceedingly important to avoid distortion of that characteristic which would occur when using a large input signal from the sweep generator or standard generator (marker signal). Always set attenuator on sweep generator so that reading on the vacuum tube voltmeter does not exceed one volt (when meter is connected from high side of video detector load resistor, symbol 139, to receiver chassis). Standard generator output should also be attenuated so that marker signal does not pull or tear the band pass characteristic as shown on the 'scope.

CHECKING SYNCHRONIZATION OF BAND SWITCHES ON AM-FM TUNER AND TV CHASSIS.

Note that the band switch on the AM-FM Tuner chassis is mechanically coupled by a link arm and lever arrangement to the band switch on the TV chassis. Do not operate these switches by direct pressure on the link arm—always use a control knob attached to the TV switch shaft.

If the mechanical linkage is forced or slips at the lever on the TV switch shaft, or the bottom cover of the AM-FM tuner is removed for service purposes, it is possible for the respective switch sections to get out of step. The receiver can be damaged if the switch sections lose synchronization, or are indiscriminately set to random positions. In order to check for proper synchronization of the band switches, refer to procedure on page 10.

BROADCAST BAND—"AM"—ALIGNMENT PROCEDURE

1. After the entire chassis assembly has been removed from the cabinet, remove the AM loop antenna and reconnect it to the AM antenna leads extending from the AM-FM tuner chassis. Then wind one turn of insulated wire around frame of loop antenna so as to provide a means of coupling it to the signal generator. Connect one end of coupling turn to receiver chassis and allow other end to remain open until otherwise instructed in the following chart. Space loop antenna same distance away from the chassis as when assembled in the cabinet.
2. Reconnect the speaker to the two audio output leads extending from the main chassis. IMPORTANT: Do not confuse these leads with the two loop antenna leads.
3. Place the AM-FM dial scale escutcheon on the AM-FM tuning shaft and install the AM-FM pointer knob and fine tuning knob on their respective shafts. Then rotate these knobs to the extreme counter-clockwise position. At this setting, the gang condenser should be fully meshed; if it is not, loosen the set screws in the hub of the dial drum on the gang condenser and close gang plates manually. Then tighten set screws in hub of dial drum.
4. When aligning the RF circuits and calibrating the oscillator it is necessary to hold the AM-FM dial escutcheon in its normal mounting position so that the heavy lines below 88 and 108 are in a horizontal plane. Note that the pointer knob must point to the heavy line below 88 on the dial when tuning knob is turned fully counter-clockwise and gang plates are completely meshed.
5. IMPORTANT: Do not remove the metal bottom plate of AM-FM tuner chassis. Holes are provided for access to IF transformer tuning slugs. Removal of the bottom plate during alignment of the RF circuits will result in detuning when the plate is replaced.
6. Connect output meter across the speaker voice coil.
7. Connect ground lead of signal generator to the receiver chassis.
8. Set volume control to the maximum volume position and use a weak signal from the signal generator.
9. Set tone control to its extreme clockwise position.
10. Set band switch to the "AM" position.
11. After alignment procedure is completed and chassis and loop have been reinstalled in cabinet, arrange leads to loop so that they are separated from each other as much as possible. Avoid twisting, taping or extending these leads.

DUMMY ANT. IN SERIES WITH SIGNAL GENERATOR	CONNECT HIGH SIDE OF SIGNAL GENERATOR TO	SIGNAL GENERATOR FREQUENCY	RECEIVER DIAL SETTING	TRIMMER OR SLUG NUMBER	TRIMMER DESCRIPTION	TYPE OF ADJUSTMENT
.1 MFD. Condenser	Lug on trimmer #23 at bottom of gang (see figure 1 for location of trimmer).	455 KC	Any point where it does not affect the signal.	18 and 19	2nd I.F.	Adjust for maximum output. Then repeat adjustment.
				20 and 21	1st I.F.	
200 MMF. Mica Condenser	Coupling turn on loop antenna.	1500 KC	1500 KC	#22	AM Oscillator.	Adjust for maximum output.
		1500 KC	Tune to 1500 Kc. generator signal.	#23	AM Antenna	Adjust for maximum output.
200 MMF. Mica Condenser	Coupling turn on loop antenna.	600 KC	Tune to 600 Kc. generator signal.	#24	Adjustable core of AM Antenna Coil.	Adjust for maximum output.

Repeat adjustment of trimmers 23 and 24 until one no longer detunes the other.

FREQUENCY MODULATION—"FM"—ALIGNMENT PROCEDURE

1. After the entire chassis has been removed from the cabinet, replace the AM-FM dial escutcheon on the AM-FM tuning shaft and install the AM-FM pointer knob and fine tuning knob on their respective shafts. Then rotate these knobs to the extreme counter-clockwise position. At this setting, the gang condenser should be fully meshed; if it is not, loosen the set screws in the hub of the dial drum on the gang condenser and close gang plates manually. Then tighten set screws in hub of dial drum.
2. When aligning the RF circuits and calibrating the oscillator it is necessary to hold the AM-FM dial escutcheon in its normal mounting position so that the heavy lines below 88 and 108 are in a horizontal plane. Note that the pointer knob must point to the heavy line below 88 on the dial when tuning knob is turned fully counter-clockwise and gang plates are completely meshed.
3. Reconnect the speaker to the two audio output leads extending from the main chassis. IMPORTANT: Do not confuse these leads with the two AM loop antenna leads.
4. Set band switch to the "FM" position.
5. Remove bottom cover from AM-FM tuner during IF alignment but replace it before starting alignment of RF circuits

World Radio History

FREQUENCY MODULATION—"FM" ALIGNMENT PROCEDURE

IMPORTANT: Carefully follow procedure for removal and replacement of this plate, as well as synchronization of band switches on AM-FM tuner and TV chassis, as explained on page 10. Failure to correctly install bottom cover may result in serious damage to receiver.

6. Do not remove the AM-FM tuner chassis from the TV chassis during alignment.
7. Set volume control to the maximum volume position and use a weak signal from the signal generator.
8. Set tone control to its extreme clockwise position.
9. Dress FM circuit leads as short and straight as possible, particularly those in the oscillator circuit. If plate and grid leads should also be kept short and straight.

STANDARD SIGNAL GENERATOR		SWEEP GENERATOR		VTVM OR OUTPUT METER CONNECTION	OSCILLOSCOPE CONNECTIONS	RECEIVER DIAL SETTING	TRIMMER OR SLUG NUMBER	TYPE OF ADJUSTMENT AND OUTPUT INDICATION
CONNECTIONS	FREQUENCY	CONNECTIONS	FREQ.					
Connect high side to lug on trimmer #32 (see Fig. 1 for location of trimmer) using a .01 Mfd. condenser in series with generator lead. Connect ground lead to the receiver chassis in vicinity of gang condenser.	**10.7 MC.** Unmodulated	Not used.	———	Connect VTVM as shown in Fig. 3.	Not used.	Any position where it does not affect the signal.	#25 Discriminator secondary #26 Discriminator primary 27 and 28 2nd IF 29 and 30 1st IF	Adjust these trimmers for maximum meter reading — the output voltage will be of negative polarity.
Same as above.	Same as above.	Not used.	———	Connect VTVM as shown in Fig. 4.	Not used.	Same as above.	#25 Discriminator secondary	Note that as slug #25 is rotated, a point will be found where the voltmeter will swing rather sharply from a positive to a negative reading or vice versa. The correct setting is obtained when the meter reads zero as the slug is moved thru this point.
Same as above.	Same as above. ——— Attenuate signal to prevent overload and distortion of response curve.	Connect high side to lug on trimmer #32 (see Fig. 1 for location of trimmer) using a .01 Mfd. condenser in series with generator lead. Connect ground lead to the receiver chassis in vicinity of gang condenser.	**10.7 MC** Sweeping ±300 Kc.	Not used.	Connect as shown in Fig. 4. ——— Set vertical amplifier of 'scope for maximum amplification. ——— Synchronize oscilloscope with sweep generator by connecting "horizontal input" terminals of 'scope to source of horizontal sweep modulating voltage on the sweep generator.	Same as above.	#25 Discriminator secondary	A pattern similar to that shown in Fig. 5 should appear on the oscilloscope screen. Check for symmetry about the 10.7 Mc. center point and linearity of the slope.  FIG. 5 If the characteristic is not shaped properly, attempt to obtain symmetry by changing the setting of slug #25. Should that fail to produce the desired results, then a slight readjustment of slugs #26, 27, 28, 29 and 30 should be undertaken.
IMPORTANT: Before starting alignment of the RF and Oscillator circuits, be sure to replace the bottom plate on the AM-FM Tuner chassis as explained on page 10. Failure to observe this requirement would result in detuning if plate were replaced after alignment is completed.								
Connect high side in series with a 270 ohm carbon resistor to FM antenna terminal near gang condenser (see Fig. 1). Connect ground lead to receiver chassis.	**108 MC.** with 400 cycle AM Modulation.	Not used.	———	Connect OUTPUT METER across speaker voice coil.	Not used.	108 Mc.	#31 FM Oscillator	Set trimmer #31 to receive 108 Mc. signal as indicated by maximum meter reading.
Same as above.	**106 MC.** with 400 cycle AM Modulation.	Not used.	———	Same as above.	Not used.	Tune to 106 Mc. generator signal.	#32 FM RF	Adjust trimmer for maximum meter reading.

Check calibration and tracking of receiver with input signals of 88, 90 and 106 MC. If difference between dial pointer setting and the above mentioned frequencies does not exceed ±0.3 MC. and RF circuit is tracking properly, then alignment may be considered satisfactory and no further adjustment is necessary.

Where the calibration error is greater than 0.3 MC. it is advisable to make the following adjustments:

Tune receiver to an 88 MC. signal and note whether dial pointer is above or below correct calibration point. Then tune receiver so that dial pointer is at the 88 MC. position. If generator signal was previously received at a setting above 88 MC., it will be necessary to slightly spread the windings of the FM oscillator coil (#33 in Fig. 2) so that signal will now be received at the correct dial setting. On the other hand if generator signal was received at a dial setting below 88 MC., then slightly compress the windings of the oscillator coil until the signal comes in at the correct calibration point.

Adjustment of FM oscillator coil #33 will require removal of bottom cover. Before rechecking calibration, follow procedure on page 10 for removal and replacement of cover.

Check calibration at 108 MC. and if it is in error by more than ±0.3 MC., readjust setting of trimmer #31. Repeat calibration adjustment at 88 and 108 MC. until desired accuracy is obtained.

Observe dial calibration at 106 MC. If it is found to be incorrect by an appreciable amount, then make a very slight adjustment in the spacing of the gang condenser plates to receive the 106 MC. signal at the correct dial setting. Then check adjustment of RF trimmer #32 to obtain maximum output indication at 106 MC.

TELEVISION SOUND CHANNEL ALIGNMENT PROCEDURE

1. Short antenna terminals together with a jumper wire.
2. Turn the band switch to "TV" position and set receiver Channel Selector to any inactive television channel; other controls may be left at any desired setting.
3. No special aligning tool is required to adjust the cores in the Sound IF and discriminator transformers. The blade of a small screwdriver will fit the slot in these cores, however, the screwdriver should be of a non-metallic or insulated type to prevent detuning when inserted in the transformer can.

STANDARD SIGNAL GENERATOR CONNECTIONS	STANDARD SIGNAL GENERATOR FREQUENCY	VTVM CONNECTIONS	MISCELLANEOUS INSTRUCTIONS	TRIMMER OR SLUG	TYPE OF ADJUSTMENT AND OUTPUT INDICATION
Connect as shown in Fig. 6.	**4.5 MC.** unmodulated **IMPORTANT** This signal must be accurate within 1/4 of 1% of 4.5 Mc. Check generator calibration against a crystal controlled signal source by "zero beating" (heterodyning) with harmonic of the crystal frequency.	Connect as shown in Fig. 7.	A "swishing" sound may be heard in the speaker during Sound Channel Alignment. This spurious oscillation is caused by horizontal sweep voltage being picked up in the audio system thru stray coupling of instrument leads; it should be disregarded as it will have no effect on alignment of the sound channel.	#1 Discriminator Secondary	Adjust for maximum reading on VTVM.
				#2 Discriminator Primary	Adjust for maximum reading on VTVM.
				#3 2nd Sound IF Secondary	Adjust for maximum reading on VTVM.
				#4 2nd Sound IF Primary	Adjust for maximum reading on VTVM.
				#5 1st Sound IF Secondary	Adjust for maximum reading on VTVM.
				#6 1st Sound IF Primary	Adjust for maximum reading on VTVM.
Same as above.	Same as above.	Connect as shown in Fig. 8.	Same as above.	#1 Discriminator Secondary	Note that as slug #1 is rotated, a point will be found where the voltmeter will swing rather sharply from a positive to a negative reading or vice versa. The correct setting of slug #1 is obtained when the meter reads zero as the slug is moved thru this point.

REDUCTION OF INTERCARRIER BUZZ

Slight "dynamic" unbalance of the discriminator secondary can emphasize intercarrier buzz due to incomplete amplitude modulation rejection. Therefore it is vitally important to obtain an accurate setting of the discriminator secondary slug under actual reception conditions.

Disconnect all instruments and then connect an antenna to the receiver to obtain program reception from a local station. If intercarrier buzz is prominent, a slight readjustment of the discriminator secondary slug (#1) should be made to obtain the "dip" point for the buzzing sound. Note that program sound will be clear and free from distortion at this point. Buzz should now be at an acceptable minimum if station transmission is not at fault.

TELEVISION IF CHANNEL ALIGNMENT PROCEDURE

1. A special aligning tool designed to fit the stems on adjustable cores of the IF coils (see points 8, 9, 10 and 11 in Fig. 18) is available and may be obtained by requesting IF Alignment Tool #W507479.
2. Turn receiver Channel Selector to television channel #12 and short antenna terminals together with a jumper wire.
3. Turn the band switch to the "TV" position.
4. Connect a 3 volt battery to the receiver AGC system so that negative terminal of battery connects to the AGC line and positive terminal of battery connects to receiver chassis. See Fig. 19 for convenient point of connection.
5. Note location of IF Trap Coils #12 and #13 by referring to Fig. 19. Before undertaking the alignment of any of the IF stages, Trap Coils #12 and #13 must be detuned so that they do not resonate in the IF pass band. Detuning is accomplished by merely compressing the windings so that they are closely spaced. Failure to detune the Trap Coils can cause the IF system to become regenerative, thereby preventing alignment.
6. If the IF channel is badly misaligned and two or more immediately adjoining IF stages are tuned to the same frequency, oscillation may occur. Such oscillation shows up as a voltage across the video detector load resistor, symbol 139, and is indicated by the VTVM that is connected to this point during alignment. It should be noted

©John F. Rider

World Radio History

TELEVISION IF CHANNEL ALIGNMENT PROCEDURE

that voltage due to IF oscillation is unaffected by strength of signal from the generator.

Where IF oscillation is encountered, it is generally possible to correct the condition by detuning the IF coils in different directions. If that does not have the desired effect, increase fixed bias on AGC line by using a 4½ volt battery instead of the 3 volt battery referred to in instruction #4. After stopping the oscillation in this manner it will then be possible to align all IF stages using the following procedure, however, the AGC bias battery must be changed back to 3 volts when using the oscilloscope to observe band pass characteristic. Once all stages have been aligned using the 4½ volt bias, the IF channel should be stable with reduced bias.

STANDARD SIGNAL GENERATOR		SWEEP GENERATOR		VTVM CONNECTIONS	OSCILLOSCOPE CONNECTIONS	MISCELLANEOUS INSTRUCTIONS	TRIMMER OR SLUG	TYPE OF ADJUSTMENT AND OUTPUT INDICATION
CONNECTIONS	FREQUENCY	CONNECTIONS	FREQ.					
Connect as shown in Fig. 9.	26.3 MC.	Use a 330 Mmf. isolating condenser and connect as shown in Fig. 9 but keep power switch turned off during this step.	——	Connect as shown in Fig. 10.	Not used.	——	#7 Converter plate coil	Adjust for maximum reading on VTVM.
							#8 2nd I.F.	Adjust for maximum reading on VTVM.
Same as above.	24.5 MC.	Same as above.	——	Same as above.	Not used.	——	#9 4th I.F.	Adjust for maximum reading on VTVM.
Same as above.	23.5 MC.	Same as above.	——	Same as above.	Not used.	——	#10 1st I.F.	Adjust for maximum reading on VTVM.
							#11 3rd I.F.	Adjust for maximum reading on VTVM.
Same as above.	22.4 MC.	Same as above.	——	Same as above.	Not used.	——	#12 1st IF Trap Coil	Adjust the spacing of the Trap Coil windings for MINIMUM reading on VTVM.
Same as above.	22.8 MC.	Same as above.	——	Same as above.	Not used.	——	#13 3rd IF Trap Coil.	Adjust the spacing of the Trap Coil windings for MINIMUM reading on VTVM.
Same as above.	26.75 MC.	With connections made as shown in Fig. 9, turn on this generator and set controls for operation as specified in next column.	25 MC. Sweeping ± 5 Mc.	Same as above.	Connect as shown in Fig. 10.	IMPORTANT: 1. Remove the 6J6 (Mixer-Oscillator) tube and wrap a piece of fine wire around pins 6 and 7 so as to connect these two pins together. Then reinsert the tube in its socket. Oscillator section of tube will now be inoperative and therefore cannot cause undesirable "beat" response that would otherwise disturb the IF band pass characteristic. 2. Adjust output attenuator on sweep generator so that reading on VTVM is one volt. 3. Set attenuator on standard signal generator so that marker signal does not distort the pattern on the oscilloscope. 4. Be sure that a 3 volt battery is connected to AGC line as specified in instruction #4 at the head of this chart. Do not use a battery of any other voltage.	The IF band pass characteristic now displayed on the 'scope should be compared with the curve shown in Fig. 11. If top of curve is not properly shaped, make a slight readjustment of slug #9. Should that adjustment fail to yield the desired result, then note whether the curve has a peak on the high or low frequency side. Slugs #7 and #8 control high frequency response (26.3 Mc.) and slugs #10 and #11 affect the low frequency response (23.5 Mc.); by making a small change in the settings of the high or low frequency slugs, it will be possible to obtain correct band pass curve.  FIG. 11 I.F. RESPONSE CURVE The 26.75 Mc. picture IF carrier marker should now appear at the 30% amplitude position on side of the band pass characteristic (see Fig. 11). If position of the marker appears too high or too low, slight readjustment of slugs #7, 8 and 9 is require'.	
Same as above.	22.25 MC.	Same as above.	Same as above.	Same as above.	Same as above.		Adjust the vertical gain control on the 'scope in order to magnify the sound portion of the response curve. The 22.25 Mc. sound IF carrier marker should appear at the position indicated in Fig. 11. If the position of the sound marker is incorrect, readjust winding spacing of Trap Coils #12 and #13.	

TELEVISION RF CHANNEL ALIGNMENT PROCEDURE

1. Turn the band switch to the "TV" position.
2. Remove bottom cover shield of the Television RF Tuner unit.
3. Connect a 3 volt battery to the receiver AGC system so that negative terminal of battery connects to AGC line and positive terminal of battery connects to receiver chassis. (See Fig. 19 for convenient point of connection.)

STANDARD SIGNAL GENERATOR		SWEEP GENERATOR		VTVM CONNECTIONS	OSCILLOSCOPE CONNECTIONS	MISCELLANEOUS INSTRUCTIONS	COIL	TYPE OF ADJUSTMENT AND OUTPUT INDICATION
CONNECTIONS	FREQUENCY	CONNECTIONS	FREQ.					
RF AMPLIFIER AND MIXER ALIGNMENT								
Connect as shown in Fig. 15.	*215.75 MC. ‡211.25 MC.	Connect as shown in Fig. 15 and set controls for sweep width of 10 Mc. on television channel specified in the next column.	CHANNEL #13	Not used.	Connect as shown in Fig. 16	Set Channel Selector to #13 IMPORTANT: Keep output of standard signal generator at a level that provides a readable marker but does not distort the curve that is being observed on the 'scope.	CHANNEL #13 Antenna Coil; CHANNEL #13 RF Amp. Plate Coil; CHANNEL #13 Mixer Grid Coil	Adjust spacing of the turns on these coils to obtain properly shaped RF band pass characteristic as shown in Fig. 12. To determine whether the turns have to be spread or compressed, use a tuning wand having a brass slug in one end and a powdered iron slug in the other end. If the brass slug is placed near (or into) a coil and causes the response curve to approach that shown in Fig. 12, then the turns would have to be spread. On the other hand, if the powdered iron slug is similarly positioned and produces a correctly shaped response curve, then the coil turns should be compressed. Repeat these adjustments on the Antenna, RF Amp. Plate and Mixer Grid coils for Channel 13 to obtain the desired response characteristic. Do not overly broaden the curve as that would result in a loss of sensitivity. IMPORTANT: After the Channel #13 coils have been aligned correctly, melt the wax around the turns or apply a small amount of high frequency "coil dope" on the winding to assure that spacing will be maintained.
Same as above.	*209.75 MC. ‡205.25 MC.	Same as above.	CHANNEL #12	Not used.	Same as above.	Set Channel Selector to #12	The RF band pass characteristics of the other television channels should now be checked. Adjust the RF sweep generator and marker generator for operation on each of these television channels and observe position of sound carrier and picture carrier markers.  FIG. 12 The response curve for each channel should conform reasonably well with the curve shown in Fig. 12. If it does not, on channels 10, 11 or 12, then adjust the RF Amp. Plate coil for the particular channel; on channels 7, 8 or 9 adjust RF Amp. Plate and Mixer Grid coils; on channels 2 to 6 adjust RF Amp. Plate, Mixer Grid and Antenna coils. Adjustment consists of pushing the coil (or partial turn) toward or away from switch shaft and spreading or compressing the winding.

CONNECTIONS	FREQUENCY	CONNECTIONS	FREQ.					

OSCILLATOR ALIGNMENT

1. **IMPORTANT:** Before undertaking oscillator alignment be sure IF circuits are correctly aligned for band pass characteristic illustrated in Fig. 11.
2. During oscillator alignment, it is necessary to set the Fine Tuning control in the center of its range.

STANDARD SIGNAL GENERATOR CONNECTIONS	FREQUENCY	SWEEP GENERATOR CONNECTIONS	FREQ.	VTVM CONNECTIONS	OSCILLOSCOPE CONNECTIONS	MISCELLANEOUS INSTRUCTIONS	COIL OR SLUG	TYPE OF ADJUSTMENT AND OUTPUT INDICATION
							#14 High Band Oscillator Slug. #15 Low Band Oscillator Slug.	Adjust the position of both slugs so that approximately 5 threads are visible outside of the fiber plate.
Connect as shown in Fig. 15.	*215.75 MC. ‡211.25 MC.	Connect as shown in Fig. 15 and set controls for sweep width of 10 Mc. on television channel specified in the next column.	CHANNEL #13	Connect as shown in Fig. 17	Connect as shown in Fig. 17	Set Channel Selector to #13 **During this step and thru-out all succeeding steps it is necessary to:** **1. Be sure that Fine Tuning control has been set in the center of its range.** **2. Keep output of sweep generator at a level that does not allow reading on VTVM to exceed one volt.** **3. Keep output of standard signal generator at a level that provides a readable marker but does not distort the curve that is being observed on the 'scope.**	CHANNEL #13 Oscillator Coil	NOTE: Before making the following adjustment, advance the vertical gain control on the 'scope in order to magnify the sound portion of the response curve. Examine the channel 13 oscillator coil and note that it has a "bucking turn." Adjust the spacing of this turn with respect to the main coil in order to shift the response curve until the sound carrier marker appears at the position shown in Fig. 14. Now, reduce gain control setting of 'scope to restore pattern to normal amplitude and observe position of picture carrier marker. This marker should appear at the 35% amplitude position on the low frequency side of the characteristic curve (see Fig. 14). After both pix and sound markers are correctly located on the curve, then melt the wax on the coil to permanently fix the position of the winding.
Same as above.	*209.75 MC. ‡205.25 MC.	Same as above.	CHANNEL #12	Same as above.	Same as above.	Set Channel Selector to #12	Adjust the RF sweep generator and marker generator for operation on the other television channels; set marker generator to sound carrier frequency. After setting Channel Selector to the corresponding channel, then adjust the oscillator coil for that channel so as to shift the response curve and permit the sound carrier marker to appear at the position shown in Fig. 14. Check to see that pix carrier marker falls at 35% amplitude position on opposite side of curve.

	* 65.75 MC. ‡ 61.25 MC.		CHANNEL #3			Set Channel Selector to #3		
	* 59.75 MC. ‡ 55.25 MC.		CHANNEL #2			Set Channel Selector to #2		

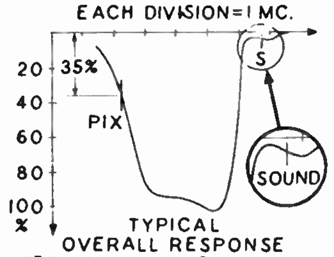

FIG. 14 TYPICAL OVERALL RESPONSE CURVE

Switch back to channel #13 and set both generator signals for that channel. Check position of sound carrier marker. A slight readjustment of slug #14 is usually necessary to reposition the curve so that the sound carrier is correctly located as shown in Fig. 14. If the setting of slug #14 has to be changed by two or more complete turns it should be left in its original position and all of the foregoing oscillator alignment procedure repeated. A similar check should be made for channel #6 using adjustable slug #15 in Fig. 13.

If an unsatisfactory overall response is obtained for a particular channel, observe RF Amp. and Mixer response curve for that channel as described on the preceding page. If characteristic does not conform reasonably well with the typical curve shown in Fig. 14, then attempt to obtain a better compromise for RF response on all channels by realigning Antenna, RF Amp. and Mixer circuits.

PRODUCTION CHANGES

The following tabulation furnishes complete details on changes which occurred during production. Sequence of these changes is indicated by coding in alphabetical order; that is, "SERIES A" "SERIES B" etc., stamped on back surface of chassis.

The circuit shown on this page applies to "SERIES A" chassis.

CHANGE DESIGNATION STAMPED ON CHASSIS	DESCRIPTION OF CHANGE
UNCODED	INITIAL PRODUCTION
SERIES "A"	1. Resistor 420 (1 Meg.) was removed from grid circuit of V25 (6J5GT) Vertical Blocking Osc. 2. Resistor 265, in grid circuit of V25 (6J5GT), was changed from 1.8 Meg. to 1.5 Meg.

141	W510254	Resistor—carbon 10,000 Ohms ± 10% 1 watt
142	W510253	Resistor—carbon 8200 Ohms ± 10% 1 watt
144	W510166	Resistor—carbon 47,000 Ohms ± 10% ½ watt
146	W510164	Resistor—carbon 33,000 Ohms ½ watt
147	W510155	Resistor—carbon 10,000 Ohms ½ watt
149	W510150	Resistor—carbon 5600 Ohms ± 10% ½ watt
151	W510173	Resistor—carbon 100,000 Ohms ½ watt
153	W510150	Resistor—carbon 5600 Ohms ± 10% ½ watt
155	W510191	Resistor—carbon 1 Meg. ½ watt
156	W510356	Resistor—carbon 12,000 Ohms ± 10% 2 watt
158	W510191	Resistor—carbon 1 Meg. ½ watt
159	W510126	Resistor—carbon 270 Ohms ± 10% ½ watt
162	W510723	Resistor—carbon 12,000 Ohms ± 5% ½ watt
164, 165	W510339	Resistor—carbon 1500 Ohms ± 10% 2 watt
166	W510156	Resistor—carbon 12,000 Ohms ± 10% ½ watt
169	W510173	Resistor—carbon 100,000 Ohms ½ watt
170	W510191	Resistor—carbon 1 Meg. ½ watt
171	W510171	Resistor—carbon 82,000 Ohms ± 10% ½ watt
172	W510161	Resistor—carbon 22,000 Ohms ½ watt
177	W510143	Resistor—carbon 2200 Ohms ½ watt
178	W510157	Resistor—carbon 15,000 Ohms ± 10% ½ watt
182	W510332	Resistor—carbon 560 Ohms ± 10% 2 watt
185, 186	W510132	Resistor—carbon 560 Ohms ± 10% ½ watt
188	W510180	Resistor—carbon 270,000 Ohms ± 10% ½ watt
189	W510181	Resistor—carbon 330,000 Ohms ± 10% ½ watt
190, 191	W510739	Resistor—carbon 1800 Ohms ± 5% ½ watt
194, 195	W510172	Resistor—carbon 100,000 Ohms ± 10% ½ watt
197	W510162	Resistor—carbon 27,000 Ohms ± 10% ½ watt
198	W510195	Resistor—carbon 4.7 Meg. ½ watt
200	W510185	Resistor—carbon 470,000 Ohms ½ watt
203	W510150	Resistor—carbon 5600 Ohms ± 10% ½ watt
206	W510139	Resistor—carbon 1500 Ohms ± 10% ½ watt
207	W510172	Resistor—carbon 100,000 Ohms ± 10% ½ watt
209	W510180	Resistor—carbon 270,000 Ohms ± 10% ½ watt
213	W510184	Resistor—carbon 470,000 Ohms ± 10% ½ watt
215	W510116	Resistor—carbon 68 Ohms ½ watt
218	W510716	Resistor—wire wound 220 Ohms ± 10% 5 watt
220	W510356	Resistor—carbon 12,000 Ohms ± 10% 2 watt
226	W510254	Resistor—carbon 10,000 Ohms ± 10% 1 watt
228	W510725	Resistor—carbon 3.3 Ohms ± 10% ½ watt
229	W510195	Resistor—carbon 4.7 Meg. ½ watt
231	W510391	Resistor—carbon 1 Meg. 2 watt
234	W510187	Resistor—carbon 680,000 Ohms ± 10% ½ watt
247	W510319	Resistor—carbon 100 Ohms 2 watt
252	W510726	Resistor—wire wound 850 Ohms 5 watt
262-B	W508062	Resistor—carbon 22,000 Ohms 1/5 watt (part of Integrator Unit)
262-D	W508062	Resistor—carbon 8200 Ohms 1/5 watt (part of Integrator Unit)
262-F	W508062	Resistor—carbon 8200 Ohms 1/5 watt (part of Integrator Unit)
265	W510743	Resistor—carbon 1.8 Meg. ± 5% ½ watt (used in "uncoded" chassis)
265	W510721	Resistor—carbon 1.5 ± 5% ½ watt (used in "series A" chassis)
267	W510172	Resistor—carbon 100,000 Ohms ± 10% ½ watt
268	W510196	Resistor—carbon 6.8 Meg. ½ watt
269	W510738	Resistor—carbon 1.2 Meg. ± 10% ½ watt
272	W510151	Resistor—carbon 6800 Ohms ± 10% ½ watt
275	W510193	Resistor—carbon 2.2 Meg. ½ watt
276	W510338	Resistor—carbon 1200 Ohms ± 10% 2 watt
296	W510142	Resistor—carbon 2200 Ohms ± 10% ½ watt
298	W510143	Resistor—carbon 2200 Ohms ½ watt
316	W510180	Resistor—carbon 270,000 Ohms ± 10% ½ watt
341	W510148	Resistor—carbon 4700 Ohms ± 10% ½ watt
344	W510161	Resistor—carbon 22,000 Ohms ½ watt
348	W510158	Resistor—carbon 15,000 Ohms ½ watt
354	W510185	Resistor—carbon 470,000 Ohms ½ watt
357	W510179	Resistor—carbon 220,000 Ohms ½ watt
358	W510741	Resistor—wire wound 600 Ohms 10 watt
360	W510727	Resistor—wire wound 7500 Ohms ± 10% 5 watt
362	W510136	Resistor—carbon 1000 Ohms ± 10% ½ watt
368	W510173	Resistor—carbon 100,000 Ohms ½ watt
381	W510193	Resistor—carbon 2.2 Meg. ½ watt
333	W510155	Resistor—carbon 10,000 Ohms ½ watt
386	W510136	Resistor—carbon 1000 Ohms ± 10% ½ watt
390	W510152	Resistor—carbon 6800 Ohms ½ watt
392	W510249	Resistor—carbon 4700 Ohms 1 watt
394	W510146	Resistor—carbon 3300 Ohms ½ watt
395	W510246	Resistor—carbon 3300 Ohms 1 watt
399-B	W506338	Resistor—carbon 47,000 Ohms 1/5 watt (part of Diode Filter Unit)
400	W510185	Resistor—carbon 470,000 Ohms ½ watt
402	W510193	Resistor—carbon 2.2 Meg. ½ watt
405	W510240	Resistor—carbon 1500 Ohms 1 watt
410	W510125	Resistor—carbon 220 Ohms ½ watt
411	W510159	Resistor—carbon 18,000 Ohms ± 10% ½ watt
414, 415	W510155	Resistor—carbon 10,000 Ohms ½ watt
420	W510190	Resistor—carbon 1 Meg. ± 10% ½ watt (used in "uncoded" chassis)
422, 423	W510725	Resistor—carbon 3.3 Ohms ± 10% ½ watt
426	W510148	Resistor—carbon 4700 Ohms ± 10% ½ watt
428	W510728	Resistor—wire wound 15,000 Ohms ± 10% 10 watt

CONTROLS

SCHEMATIC LOCATION	PART NO.	DESCRIPTION
33-A,B	W508182	Volume control—1 Meg. (with on-off switch)
43-A to D	W508458	Band switch (includes volume control)
54	W508324	Built-in Antenna Tuning Condenser (4-70 Mmfd.)
160-A,B	W508457	Tone and Contrast potentiometer A—Tone control; 500,000 Ohms ¼ watt; B—Contrast control; 3000 Ohms ± 10% 4 watt
173	W508056	Brightness potentiometer (50,000 Ohms)
180	W508456	Focus potentiometer (5500 Ohms ± 10% 4 watt
202	W508077	Horizontal Lock coil (less slug)
202	W507429	Slug core for Horizontal Lock coil
208	W508056	Horizontal Hold potentiometer (50,000 Ohms)
212	W508071	Horizontal Drive trimmer condenser (10-160 Mmfd.)
225	W508667	Width coil (includes slug and clip)
225	W508784	Slug core for Width coil
233	W162190	Horizontal Linearity coil (includes slug)
233	W507429	Slug core for Horizontal Linearity coil
266	W508454	Vertical Hold potentiometer (1 Meg.)
270	W508455	Height potentiometer (2.5 Meg.)
277	W508453	Vertical Linearity potentiometer (6000 Ohms)
346	W508551	Fine Tuning trimmer (1.2 - 2.5 Mmfd. when mounted to chassis)

COILS AND TRANSFORMERS

SCHEMATIC LOCATION	PART NO.	DESCRIPTION
12	W508061	Transformer—1st TV sound I.F. (includes condensers 12-A and 12-B)
15	W507373	Coil—choke
18	W508061	Transformer—2nd TV sound I.F. (includes condensers 18-A and 18-B)

*—This part is not supplied as a Service replacement item.

MODEL 142,
Ch. 100.115

PARTS LIST FOR CHASSIS (Contd.)

COILS and TRANSFORMERS—Continued

SCHEMATIC LOCATION	PART NO.	DESCRIPTION
26	W507321	Transformer—TV sound discriminator (includes condenser 26-A)
	W508438	Slug core (5/16" dia. x ⅜" long) for primary of TV sound discriminator trans.
	W508894	Slug core (¼" dia. x ½" long) for primary of TV sound discriminator trans.
	W508439	Slug core (5/16" dia. x ¾" long) for secondary of TV sound discriminator trans.
	W508894	Slug core (¼" dia. x ½" long) for secondary of TV sound discriminator trans.
37	W507373	Coil—choke
49	W505912	Transformer—sound output
103	W507567	Coil—1st I.F. trap
107	W507343	Coil—1st video I.F. (less slug)
	W507357	Slug core for 1st video I.F. coil
115	W507343	Coil—2nd video I.F. (less slug)
	W507357	Slug core for 2nd video I.F. coil
125	W507343	Coil—3rd video I.F. (less slug)
	W507357	Slug core for 3rd video I.F. coil
128	W507367	Coil—choke
134	W507591	Coil—4th video I.F. assembly (includes condenser 136 and choke coil 137)
	W507357	Slug core for 4th video I.F. coil
137	W507367	Coil—choke
143	W507374	Coil—peaking
152	W507374	Coil—peaking
161	W508069	Coil—peaking
163	W508070	Coil—peaking
181	W508994	Coil—focus
184	W508675	Yoke—picture tube deflection
202	W508077	Coil—Horizontal Lock (less slug)
	W507429	Slug core for Horizontal Lock coil
222	W508883	Transformer—horizontal fly-back
225	W508667	Coil—Width (includes slug and clip)
	W508784	Slug core for Width coil
233	W162190	Coil—Horizontal Linearity (includes slug)
	W507429	Slug core for Horizontal Linearity coil
239	W508702	Transformer—power
241	W507586	Coil—choke
244	W507587	Coil—choke
248	W507584	Coil—choke
253	W508341	Choke—filter
254	W507584	Coil—choke
259	W507586	Coil—choke
263	W508076	Transformer—vertical blocking oscillator
271	W507567	Coil—3rd I.F. trap
278	W508674	Transformer—vertical output
	W508431	R. F. Unit complete with coils and tubes
283	W508553	Coil—antenna; channel #13
284	*	Coil—antenna; channel #12
285	*	Coil—antenna; channel #11
286	*	Coil—antenna; channel #10
287	*	Coil—antenna; channel #9
288	*	Coil—antenna; channel #8
289	*	Coil—antenna; channel #7
290	W508552	Coil—antenna; channel #6
291	*	Coil—antenna; channel #5 (6½ turns #24 wire .080" I. D.)
292	*	Coil—antenna; channel #4 (11½ turns #24 wire .080" I. D.)
293	*	Coil—antenna; channel #3 (11½ turns #24 wire .080" I. D.)
294	*	Coil—antenna; channel #2 (13½ turns #24 wire .080" I. D.)
301	W508554	Coil—R. F.; channel #13
302	*	Coil—R. F.; channel #12
303	*	Coil—R. F.; channel #11
304	*	Coil—R. F.; channel #10
305	*	Coil—R. F.; channel #9
306	*	Coil—R. F.; channel #8
307	*	Coil—R. F.; channel #7
308	*	Coil—R. F.; channel #6 (20½ turns #21 wire .125" I. D.)
309	*	Coil—R. F.; channel #5 (8½ turns #24 wire .080" I. D.)
310	*	Coil—R. F.; channel #4 (8½ turns #24 wire .125" I. D.)
311	*	Coil—R. F.; channel #3 (13½ turns #24 wire .080" I. D.)
312	*	Coil—R. F.; channel #2 (11½ turns #24 wire .080" I. D.)
317	*	Coil—mixer; channel #13 (4½ turns #21 wire .125" I. D.)
318	*	Coil—mixer; channel #12
319	*	Coil—mixer; channel #11
320	*	Coil—mixer; channel #10
321	*	Coil—mixer; channel #9
322	*	Coil—mixer; channel #8
323	*	Coil—mixer; channel #7
324	*	Coil—mixer; channel #6 (18½ turns #21 wire .125" I. D.)
325	*	Coil—mixer; channel #5 (6½ turns #24 wire .080" I. D.)
326	*	Coil—mixer; channel #4 (8½ turns #24 wire .125" I. D.)
327	*	Coil—mixer; channel #3 (11½ turns #24 wire .080" I. D.)
328	*	Coil—mixer; channel #2 (13½ turns #24 wire .080" I. D.)
330	*	Coil—oscillator; channel #12
331	*	Coil—oscillator; channel #11
332	*	Coil—oscillator; channel #10
333	*	Coil—oscillator; channel #9
334	*	Coil—oscillator; channel #8
335	*	Coil—oscillator; channel #7
336	W508558	Coil—oscillator; channel #6
	W508559	Slug for oscillator coil (brass); channel #6
337	*	Coil—oscillator; channel #5 (6½ turns #24 wire .080" I. D.)
338	*	Coil—oscillator; channel #4 (11½ turns #24 wire .080" I. D.)
339	*	Coil—oscillator; channel #3 (8½ turns #24 wire .080" I. D.)
340	*	Coil—oscillator; channel #2 (11½ turns #24 wire .080" I. D.)
345	W508560	Coil—oscillator; channel #13
	W508559	Slug for oscillator coil (brass); channel #13
349	W508555	Coil—converter plate (includes slug and clip)
	W508556	Slug core for converter plate coil
352	W507587	Coil—R. F. choke for 6J6
365	W508184	Coil—AM antenna
370	W507586	Coil—choke
372	W507935	Coil—choke
374	W507942	Coil—FM oscillator
375	W508195	Coil—AM oscillator
379	W507941	Coil—FM R.F.
385	W506581	Coil—R.F. choke (includes resistor 386)
387	W506080	Transformer—1st FM I.F. (includes condensers 387-A and 387-B)
388	W505867	Transformer—1st AM I.F. (includes condensers 388-A and 388-B)
397	W505905	Transformer—2nd FM I.F. (includes condenser 397-A)
398	W505867	Transformer—2nd AM I.F. (includes condensers 398-A and 398-B)
402	W508179	Transformer—FM discriminator (includes condenser 409-A)
418	W508212	Loop antenna (AM)

OTHER ELECTRICAL PARTS

SCHEMATIC LOCATION	PART NO.	DESCRIPTION
43-A to D	W508458	Switch—band (on TV chassis)
51	W508174	Speaker—P.M. Dynamic (6" x 9")
53	W508466	Built-in antenna (includes condenser 54)
179	W508432	Crystal cartridge (includes both needles)
221	W508713	Fuse for horizontal sweep circuit ¼ Amp. 250 volt
261	W118921	Lamp—TV Channel Lite (Mazda #47) 6-8 V. 150 Ma.
262-A to G	W508062	Integrator coupling unit A—Condenser—ceramic .01 Mfd. 450 volt B—Resistor—carbon 22,000 Ohms 1/5 watt C—Condenser—ceramic 2000 Mmfd. 450 volt D—Resistor—carbon 8200 Ohms 1/5 watt E—Condenser—ceramic 5000 Mmfd. 450 volt F—Resistor—carbon 8200 Ohms 1/5 watt G—Condenser—ceramic 5000 Mmfd. 450 volt
280	W508120	Motor—115 volt, 60 cycle
281	W505269	Switch—"ON-OFF" for record changer
282-A to K		Channel switch
361	W118221	Lamp—"OFF-ON" Indicator Lite (Mazda #47) 6-8 volt 150 Ma.
363	W118921	Lamp—AM Channel Lite (Mazda #47) 6-8 v. 150 Ma.
364	W118921	Lamp—FM Channel Lite (Mazda #47) 6-8 v. 150 Ma.
369-A,B	W508753	Switch—band (on AM-FM tuner)
399-A, B,C	W506338	Diode filter unit A—Condenser—ceramic 100 Mmfd. 400 volt B—Resistor—carbon 47,000 Ohms 1/5 watt C—Condenser—ceramic 100 Mmfd. 400 volt
418	W508212	Loop antenna (AM)

MECHANICAL PARTS OF R.F. TUNER

PART NO.	DESCRIPTION
W508431	R. F. Unit complete with coils and tubes
W508558	Bottom cover shield
W508666	Bracket for tuner mounting (front)
W508651	Bracket for tuner mtg. (rear)
W508566	"C" washer—retains switch shaft
W508567	"C" washer—retains fine tuning shaft
W508564	Fine tuning disc (on trimmer shaft)
W508565	Set screw for fine tuning disc
W508563	Shaft, fine tuning and driving disc
W508561	Shaft, switch, (incl. indexing arm)
W504599	Shield—tube
W508556	Slug core for converter plate coil
W508559	Slug—brass core for oscillator coil; channel #6 or #13
W508562	Socket—miniature for 6J6 (incl. base for shield)
W507364	Socket—miniature for 6AG5

CABINET PARTS

PART NO.	DESCRIPTION
W508777	Back for cabinet (less power cord)
W508217	Bracket for mounting OFF-ON indicator lite at base of cabinet
W162095	Bull's-eye for channel lite
W117131	Bull's-eye for OFF-ON indicator lite at base of cabinet
W509015	Cabinet
W508499	Catch for door
W508778	Door—left hand
W508779	Door—right hand
W508781	Drawer—record changer compartment
W508773	Escutcheon—AM-FM dial scale
W508772	Escutcheon—channel number
W508540	Glass Window
W506640	Hinge for door per pair
W508471	Knob—AM-FM Pointer and Coarse Tuning
W508472	Knob—AM-FM Fine Tuning
W508475	Knob—Brightness or Horizontal Hold
W508473	Knob—Band Switch
W502563	Knob—built-in antenna
W507895	Knob—Channel Selector
W508476	Knob—Contrast
W508477	Knob—"TONE"
W507894	Knob—TV Fine Tuning
W508474	Knob—"VOLUME-ON"
W508331	Mask for picture tube
W508771	Name plate
W508774	Nut—retains name plate
W508293	Rail for drawer per set
W508621	Rubber gasket between mask and picture tube
W18796	Screw—#10 x 1"; mounts chassis
W508506	Shield for dial lite
W505497	Socket for OFF-ON indicator lite at base of cabinet
W162206	Terminal strip for TV antenna connection
W508478	Washer—felt for knob

MISCELLANEOUS

PART NO.	DESCRIPTION
W509048	Back cover and switch shaft bearing assembly for AM-FM tuner
W508829	Bracket base for support of yoke and focus coil (left hand)
W508830	Bracket base for support of yoke and focus coil (right hand)
W508613	Bracket for deflection yoke
W301270	Base for mounting electrolytic condenser
W508666	Bracket for mounting RF tuner (front)
W508651	Bracket for mounting RF tuner (rear)
W508728	Bracket for mounting trimmer #26
W508510	Bracket—retains front of picture tube
W508755	Bracket—supports AM-FM tuner
W509198	Bracket—supports band switch shaft on TV chassis
W508038	Bracket—tube support (bottom front) (less rubber pad)
W508154	Bracket ("U" shaped) for support of yoke and focus coil
W505165	"C" washer for connecting link
W505314	"C" washer for extension shaft
W508806	Centering magnet assembly
W112745	Clip for mounting AM antenna coil
W508683	Clip for mounting electrolytic condenser #129
W508681	Clip for mounting electrolytic condenser #224
W508715	Clip for mounting fuse holder
W500245	Clip for mounting H.V. condenser
W505101	Clip for mounting I.F. transformer or FM sound discriminator
W507339	Clip for mounting video converter plate, 1st video I.F., 2nd video I.F., 3rd video I.F., Horiz. Lock or Horiz. Linearity coil
W507592	Clip for mounting 4th video I.F. coil

MISCELLANEOUS—Continued

SCHEMATIC LOCATION	PART NO.	DESCRIPTION
	W114955	Clip—retainer on end of dial cord
	W507286	Connector for H.V. terminal of picture tube
	W117057	Cord—dial drive (2½ ft. required) per ft.
	W508525	Drum—dial; on gang condenser
	W508714	Fuse holder
	W508623	Grounding spring for coating on picture tube
	W506803	Ion trap assy.—includes magnet
	W509047	Lever—band actuating (on AM-FM tuner)
	W509049	Lever—band switch actuating (on TV chassis)
	W508756	Link—connects band switch actuating levers
	W508617	Nut—for retaining focus coil mounting plate
	W162198	Planetary drive and dial drum (includes mounting bracket)
	W508864	Plate—focus coil mounting
	W506652	Plug for AM-FM tuner power cable
	W500966	Plug for audio cable on AM-FM tuner
	W508878	Plug for focus coil leads
	W500966	Plug for phono. pick-up cable
	W507699	Power cord assembly (includes plugs at both ends)
	W507361	Rubber cover for H.V. terminal connector
	W508512	Rubber spacer on picture tube support bracket
	W507793	Rubber spacer support between flared neck of picture tube and yoke bracket

GENERAL DESCRIPTION

Model 9131 is a television table model receiver with a ten inch direct view picture tube. It employs twenty tubes plus a germanium crystal detector. The receiver is complete in one unit and is operated by the use of seven front panel controls. Features of the receiver include full twelve channel coverage, AFC horizontal hold, stabilized vertical hold and FM sound system.

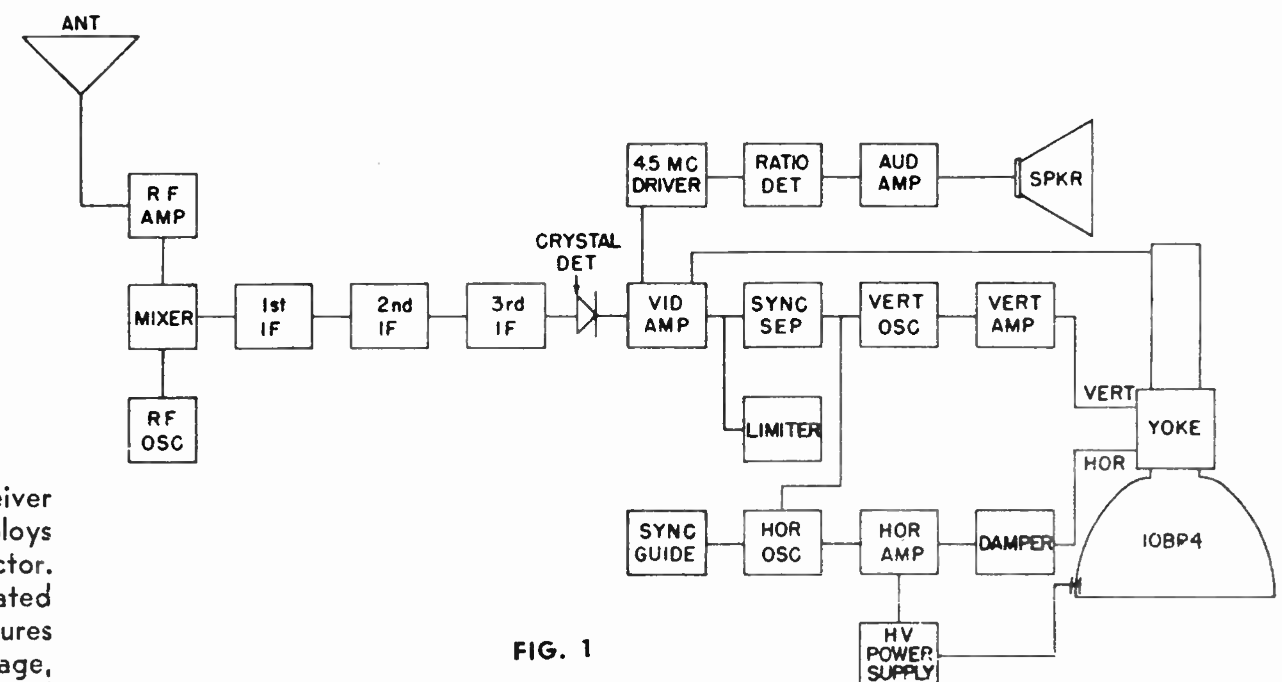

FIG. 1

©John F. Rider

World Radio History

CONTROLS

FRONT PANEL

1 — PICTURE — The Picture or contrast control varies the video IF gain through the AGC diode. Due to the use of AGC the picture control should not require readjustment when channels are switched except where the signal received from different stations varies greatly.

2 — BRIGHTNESS — The Brightness control operates by varying the D.C. voltage on the cathode of the Picture Tube, thereby controlling the light on the face of the tube.

3 — HORIZONTAL — The horizontal control on the front panel is a fine frequency regulator for the horizontal sweep oscillator. Its setting is not critical and is used to restore sync when necessary.

4 — VERTICAL — The Vertical Control regulates the frequency of the vertical oscillator. Misadjustment of this control will cause the picture to "roll" up or down. The setting is not normally critical.

5 — VOLUME — ON-OFF — The volume control varies the input to the audio system. It controls the sound only and should have no effect on the picture. The ON-OFF switch is activated by rotating the control in clockwise direction until a click is heard.

6 — STATION SELECTOR — This control selects the channel desired for viewing.

7 — FINE TUNING — This control varies the local R.F. Oscillator Frequency. Correct adjustment will result in a picture with maximum definition. This is not a control for tuning the sound.

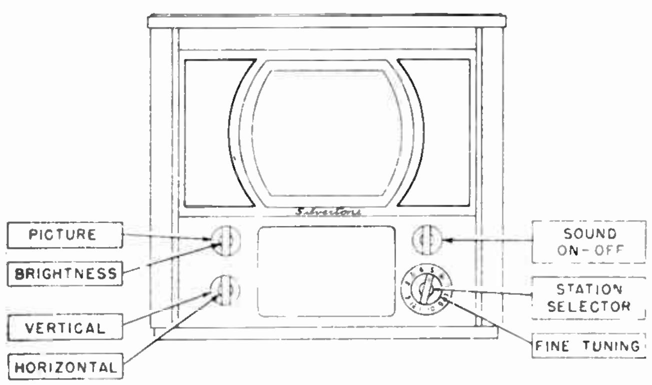

FIG. 2

CHASSIS (See Note)

1 — HEIGHT CONTROL — Varies the input to the vertical sweep amplifier. Since changes in height will effect picture linearity this control should be used in conjunction with the:

2 — VERTICAL LINEARITY CONTROL — Adjusts the vertical sweep waveform and should be used with the height control.

3 — FOCUS CONTROL — Varies the current flowing through the focus coil.

4 — HORIZONTAL LOCKING RANGE — Adjusts the sensitivity of the front panel Horizontal Hold control.

5 — HORIZONTAL FREQUENCY CONTROL —A coarse frequency control for the horizontal sweep oscillator.

6 — HORIZONTAL DRIVE CONTROL —Varies the input to the horizontal sweep amplifier and affects picture brightness and linearity.

7 — WIDTH CONTROL — This control permits variation of the picture width without affecting the high voltage.

8 — HORIZONTAL LINEARITY CONTROL — Adjusts the horizontal sweep waveform.

NOTE: — FOR PROPER ADJUSTMENT OF CHASSIS CONTROLS SEE "PICTURE ADJUSTMENTS"

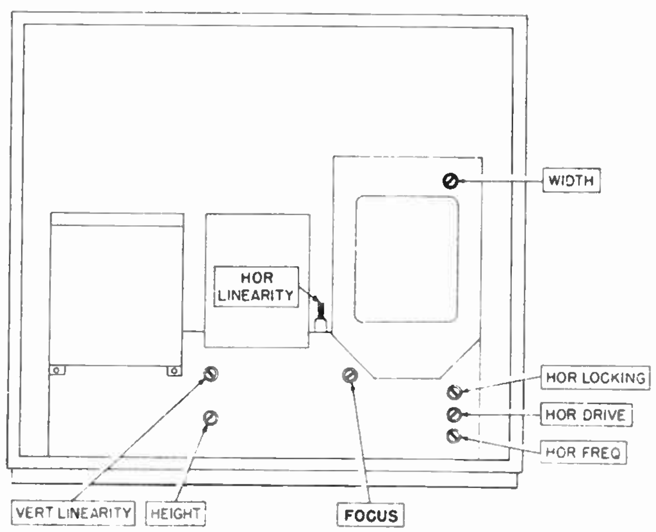

FIG. 3

BRIEF CIRCUIT ANALYSIS

This Television Receiver uses the Inter-Carrier Sound System. The basic difference between this and conventional systems is that in the use of Inter-carrier, the sound and the picture information are both fed through a single I.F. and video channel. The sound is separated after the second video amplifier and is then fed through an amplifier to the ratio detector (discriminator). The picture components of the received signal are split up into sync and pix components, the former being applied to the appropriate sweep circuits and the video intelligence to the grid of the Picture tube. The main advantages of the use of a system of this type are that duplication of I.F. amplifiers is avoided and that drift in the local oscillator does not distort or cut off "sound" reception.

The horizontal sweep circuits employ an improved type of AFC which minimizes picture disturbances caused by ignition and similar types of interference. The sync circuits for the vertical oscillator provide sufficient control to avoid "rolling" in high interference or fringe areas.

R. F. Amplifier — The antenna is fed between the grid and cathode of the R.F. amplifier. The input circuit of this stage is not tuneable. The R.F. stage is tuned by what is, electrically speaking, a single tapped inductance. Mechanically, this coil takes the form of several individual coils which are cut in or out of the plate circuit by the band switch. These coils, as well as the mixer coils, will rarely need touching.

MIXER — The output of the R.F. amplifier and the local oscillator are condenser fed into the control grid of the mixer stage. This circuit is tuned in much the same manner as the output of the R.F. Amplifier, previously described.

OSCILLATOR — The R.F. Oscillator is fairly straightforward in operation. Its main peculiarity is that the coil for Channel 2 is permanently parallel to all other Oscillator coils from 3 to 13. It is therefore necessary, when aligning the oscillators to ALIGN CHANNEL 2 FIRST and the rest of the coils in any order thereafter. They are tuned by brass slugs accessible from the outside of the cabinet by removing the Station Selector knob and the channel Escutcheon. Channel two is found at the top of the right hand slot and the others follow in regular order in a clockwise direction finishing with channel thirteen at the top of the left hand slot (See figure 4). The oscillators in the receiver have a fine tuning control which is operated from the front panel. This control should be set at an approximate mid point when oscillator slugs are being adjusted.

NOTE: THE CHANNEL NUMBERS ON THE ESCUTCHEON DO NOT CORRESPOND TO THE LOCATION OF THE OSCILLATOR COILS.

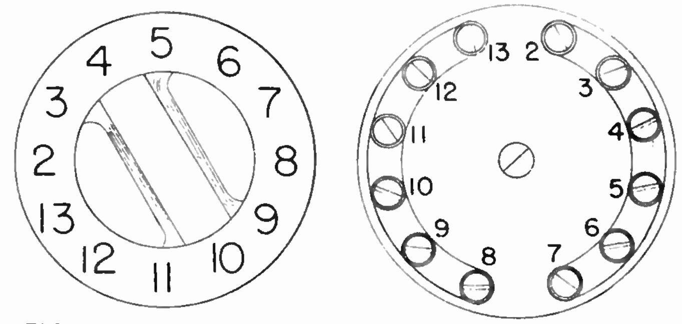

FIG. 4

VIDEO I.F. — Each Video I.F. transformer has one adjustment, a powdered iron slug accessible from the top of the chassis. The Video I.F. string is stagger tuned to two frequencies. The first and third I.F. transformers are tuned to 34.45 Mc. and the second and fourth are tuned to 37.00 Mc. In addition there is a sound trap which should be tuned for minimum output at the Sound Carrier Frequency of 32.8 Mc. The response curve is broad enough to produce good definition.

VIDEO DETECTOR — A crystal detector is used in this receiver. The use of a crystal in this circuit improves the detector sensitivity of the receiver.

VIDEO AMPLIFIERS — FIRST AND SECOND — A 12AU7, dual triode is used in this section of the receiver. The output of the crystal detector is fed to the grid of the first section (pin 2) and ultimately taken off plate of the second section of the tube (pin 6). It is at this point the three basic components of the received signal are separated and fed to their respective circuits. The sound is taken off and sent through the Driver, Ratio Detector and Audio Amplifiers to the speaker. The picture intelli-

©John F. Rider

World Radio History

BRIEF CIRCUIT ANALYSIS (Continued)

gence is fed to the grid of the picture tube and the synchronization pulses to the grid (pin 1) of the Sync Separator and from there to the Horizontal and Vertical oscillators.

D. C. COMPONENT — The D.C. component of the transmitted signal (which controls the backgound brightness) is substantially duplicated in the receiver by direct coupling from the plate of the second video amplifier to the Picture tube grid.

SOUND SYSTEM — The sound Carrier is taken off the plate of the Video Amplifier by a 4.5 Megacycle trap and fed through a 4.5 MC Amplifier to the Ratio Detector, and then to the sound amplifier, audio output and speaker.

SWEEP SYSTEM — VERTICAL — One tube a 6SN7, dual triode serves as the Vertical oscillator, discharge and amplifier tube. The first section used as the oscillator and discharge tube is fed into the second section of the tube which in turn feeds through the vertical output transformer to the Vertical windings of the deflection yoke.

SWEEP SYSTEM — HORIZONTAL — The Horizontal Oscillator is essentially of the Blocking Oscillator type. The operation of the AFC system depends upon a correcting voltage developed in the control tube when the oscillator output and the incoming pulses differ in either phase or frequency. The control tube is maintained at cut-off until such time as the sync pulse is either ahead or behind the oscillator sawtooth peak. When either case occurs the control tube develops a voltage which is applied as a bias to the oscillator grid and alters the oscillator frequency to coincide with the frequency of the incoming pulses. The horizontal oscillator transformer has an adjustable core which is a coarse control of the oscillator frequency. The Horizontal Frequency Control (rear) is a fine adjustment in the same sense. The front panel Horizontal Hold Control permits slight adjustment of the frequency by adjusting the B voltage applied to the control tube plate. The Horizontal Locking range control affects the sensitivity of the control tube thus varying the range over which the AFC circuit will function.

NOTE: Many of the components in the Horizontal circuits are of critical value and therefor should only be replaced by the exact replacement part. Care should also be taken in dressing leads and parts when replaced. This can be accomplished by carefully noting parts positions before removal.

A. G. C. — The receiver uses an AGC circuit operating on the first 2 IF stages. While it is quite effective in most locations, the receiver may overload in regions of very high field intensity. The contrast can generally be adjusted for a normal picture under such conditions but spurious beats, jagged vertical lines (i.e. poor resolution) and a "Moire" pattern may appear. These effects can be eliminated by the use of a resistor network of 3 to 10 db attenuation in series with the antenna lead at the point where it is connected to the receiver.

HIGH VOLTAGE POWER SUPPLY — The energy stored in the horizontal windings of the deflection yoke during the forward sweep produces high voltage surges during retrace. This is "stepped up" by an "auto winding" on the horizontal output transformer and then rectified by a 1B3/8016, to provide approximately 8500 volts for the Picture Tube 2nd anode.

B VOLTAGE POWER SUPPLY — The B Supply of this receiver utilizes a standard type of transformer — rectifier circuit. It should be noted that there is a separate filament winding for the Picture tube (6.3 volts) and a separate 5 volt winding for the 5V4 Damper tube. The return of the B voltage developed by this supply is NOT grounded. Voltages are developed through a bleeder network of plus 225, plus 150, minus 3.5, minus 14, minus 17.5 and minus 85 volts WITH RESPECT TO GROUND (chassis).

ALIGNMENT PROCEDURE

A — TEST EQUIPMENT

CATHODE RAY OSCILLOSCOPE — The main requirement in a Cathode Ray Oscilloscope is that it should have a good high frequency response up to 1 Mc. The tube size is relatively unimportant, however, anything under 5" usually makes fine adjustment quite difficult. A Hickok Model 195B Oscilloscope is recommended.

SWEEP GENERATOR — The sweep generator used should have linear coverage of a center range from 30 to 220 megacycles. The output should be fairly flat over wide frequency variation of the sweep. It should be capable of an output of 0.1 volt with attenuation down to about 50 microvolts. It is preferable that the generator have a deflection output for the test oscilloscope. This is included in the Hickok model 610A Television Signal Generator

AM SIGNAL GENERATOR — This generator should have a frequency of from 4.5 to 220 megacycles. As this generator is used occasionally as a marker generator, accuracy is an important factor. It should be capable of 0.1 volt output with attenuation down to about 50 microvolts and should be linear through the range. These requirements are met in the Hickok model 610A.

VACUUM TUBE VOLTMETER — Almost any standard make VTVM will do. It should have reversible polarity switch. A Sylvania Polymeter is recommended.

B — VIDEO IF ALIGNMENT

An adequate signal may be fed through the I.F. string by feeding the output of the signal generator into a tube shield placed over the mixer tube 6AG5. Care should be taken that this shield is NOT grounded. The ground side of the generator output can be conveniently grounded to the shield of the adjacent oscillator tube.

The contrast control should be set to produce minus 2 volts on the AGC bus (Pin 7 6AL5 — AGC tube).

The vacuum tube voltmeter should be connected across the 5600 ohm detector load resistor, (R43) and should be set on the minus 3 Volt scale. Set channel selector to an unused low band channel.

The Signal generator should be set to a frequency of 34.45 Mc. The output of the generator should be adjusted to the point where the reading on the VTVM is between minus 1 to minus 1.5 volts.

The First (A) and Third (B) I.F. Coils should be peaked for a maximum reading on the VTVM. As the voltage reading increases with tuning, the generator should be attenuated to maintain a maximum of minus 1.5 volts.

Set the Signal Generator to a Frequency of 37.0 Mc and tune the Second (C) and Fourth (D) I.F. coils in the same manner as above.

Set the Signal Generator to a frequency of 32.8 and tune the trap (E) for a MINIMUM reading on the VTVM.

The third (B) I.F. coil should then be readjusted as described previously.

The Generator should now be shut off (or tuned to different band) and the VTVM should read no more than minus 0.20 volts. If there is a higher voltage reading, check for regeneration in the I.F. stages.

By shunting the signal generator with a sweep generator (30 to 40 Mc) and substituting a Cathode Ray Oscilloscope for the Vacuum tube Voltmeter in the above procedure the actual pass band of the Video I.F. circuits may be studied. Ideally the response curve should appear on the face of the oscilloscope in the form indicated in Figure (5) A. A slight slope of the top of the curve in either direction or a small dip in the center are acceptable as indicated in Figure (5) B, and C.

ALIGNMENT PROCEDURE (Continued)

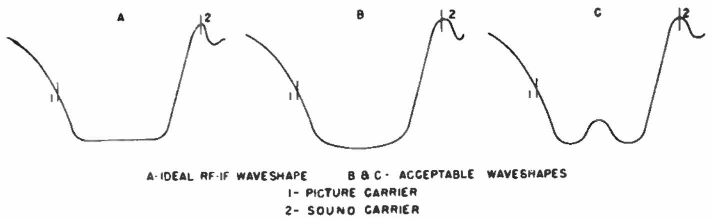

FIG. 5

C — RF ALIGNMENT

In the alignment of the RF section of this receiver three pieces of test equipment are necessary: a sweep generator, a signal generator and a cathode Ray Oscilloscope. For specifications see "Test Equipment" above.

The output of the Sweep Generator should be fed into the antenna. The signal generator (C.W.) should be connected to the antenna terminals of the receiver. The sweeper will provide the overall response curve with the oscilloscope properly connected. The signal generator is used as a marker as described below. Some Sweep generators made today contain their own marker oscillator. In cases where a generator of this type is used the Signal Generator may be eliminated.

The "hot" or "high" side of the Oscilloscope input should be connected to the junction point of the 5600 ohm detector load resistor and the peaking coil. The "low" or ground side should be connected to the nearest convenient ground point on the receiver chassis. Care shoud be taken that the generator and the scope leads are well separated to avoid regeneration.

The R.F. section of the receiver is tuned channel by channel. The proper frequency settings for any given channel can be determined by consulting the Frequency Chart on Page (2). For example in aligning channel 2 the sweep generator should be set to some mid frequency between 54 and 60 megacycles. This adjustment is not a fine one. After setting the sweeper in the general vicinity of the desired frequency it should be tuned to center the response curve on the Oscilloscope face. For picture and sound markers the signal generator should carefully be adjusted to the frequencies indicated in the Frequency chart. For example in the case of channel 2 the picture marker frequency is 55.25 Mc. and the Sound 59.75 Mc.

It is important to note at this point that the oscillator coil for channel 2 is in parallel with every other oscillator coil from 3 to 13. It is therefor imperative that channel 2 be aligned first and the others in any desired order thereafter.

Starting with channel 2 and applying the proper frequencies as indicated above, the output of the sweeper should be attenuated to the point where further attenuation will not affect the wave shape.

The Oscillator should then be adjusted to bring the sound carrier into the 32.8 Mc. trap valley. With the oscillator so adjusted the picture carrier should fall at a point approximatey 50% up on the slope of the opposite side of the band pass curve Certain variations in the waveshape and the location of the picture carrier are acceptable. The picture carrier may vary in position from a point between 45% and 60% of the slope and the overall waveshape may differ from the ideal, flat-topped response by being either slightly rounded or slightly dipped in the center. See figure (6).

If the position of the picture carrier varies beyond the 45% to 60% points on all channels correction may be made by turning to channel 6, applying the proper input signals and slightly realigning the I.F. transformers.

Care should be used not to push slug through coil form. If slug is pushed through, it may be replaced by reinserting slug through bottom of coil form and carefully threaded back to its normal position.

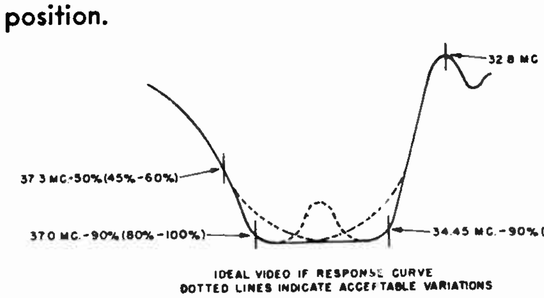

FIG. 6

D — SOUND ALIGNMENT

Sound alignment of the receiver is best accomplished with the AM Signal Generator and a vacuum tube volt meter. By feeding a 4.5 Megacycle signal thru a .01 mfd blocking condenser into the grid (pin 7) of the second section of the 12AU7 Video amplifier and placing the vacuum tube voltmeter between pin 2 of the ratio detector (6AL5) and ground, the primary (F) (Fig. 10) of the ratio detector and the 4.5 megacycle trap (G) (Fig. 10) may be adjusted. The signal generator should be attenuated so that the VTVM does not read more than minus 3 or minus 4 volts. These two slugs should be tuned for maximum deflection of the VTVM and the generator attenuated as needed to keep the above mentioned level. The VTVM (set for zero center operation) should then be placed at the junction of the 47,000 ohm resistor (R19) and the .0015 condenser (C22) and the secondary (H) of the ratio detector should be tuned through a sharp dip between positive and negative voltage. Adjust secondary for exact setting at lowest point of dip.

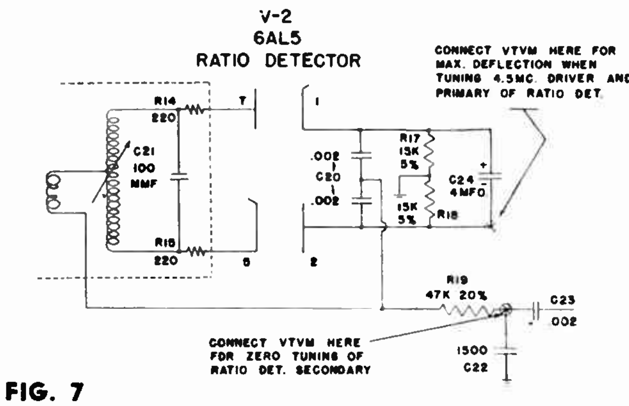

FIG. 7

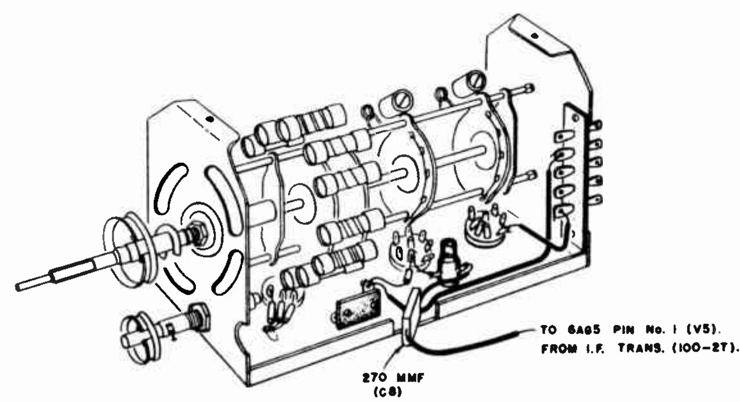

FIG. 8A

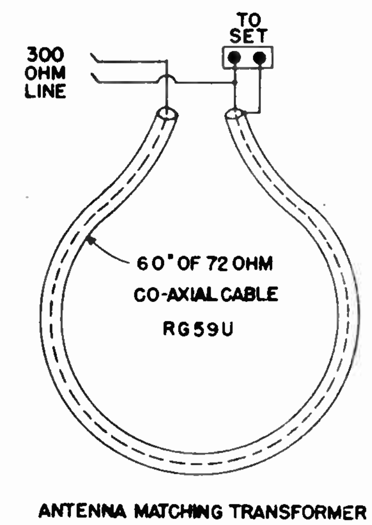

FIG. 8B

The Tuner assembly is a self contained unit utilizing a grounded-grid RF amplifier with 72 ohm unbalanced line input impedance. This mode of operating the RF amplifier (6J6) results in higher gain being delivered by the first amplifier stage with lowered noise and consequent improved receiver operation.

Though the tuning unit is designed to operate at optimum efficiency with the use of a 72 ohm co-axial transmission line as the down lead, a 300 ohm lead-in may be used in installations where the signal strength is low. A method of matching the 300 ohm transmission line to the 72 ohm input impedance of the tuner is shown in the Fig. 8B.

The length of the co-axial cable used as a matching stub shown in Fig. 8B may have to be altered slightly at different frequencies.

World Radio History

PICTURE ADJUSTMENTS

A — ION TRAP, FOCUS AND YOKE

To properly adjust the Ion Trap, Focusing coil and the Deflection Yoke the following procedure should be followed.

The Deflection Yoke should be placed in position closest to the "bell" of the Picture Tube as far forward on the neck of the tube as is possible. Be sure the wire loops on the mounting make positive contact with the coating of the picture tube. The Focus Coil is next in line and the Ion Trap last. The arrow on Ion Trap should point toward picture face and center over flags in tube neck.

The antenna should NOT be connected to the receiver, the set should be turned on, the brilliance control turned to MAXIMUM and the picture contrast control at MINIMUM.

The Ion Trap should be moved forward and backward and at the same time rotated to achieve the brightest raster on the face of the Picture Tube.

Reduce the brilliance control to a point slightly over normal brightness and adjust the Focus Control on the rear of the chassis for clearest and sharpest horizontal sweep lines. The Ion Trap should then be readjusted slightly for the brightest response on the face of the tube at which good focus is maintained.

The Focus Coil itself should be moved to secure a complete raster, approximately centered and with no corners cut off. This being accomplished the Ion trap should be secured by the screws provided.

Finally the Deflection Yoke should be rotated to "square" the raster with the chassis as a reference. The thumb screws on the yoke brackets should then be set.

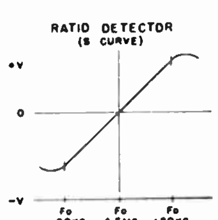

FIG. 9

For oscilloscope view of ratio detector alignment connect scope hot lead at junction of R19 and C22 and ground lead to nearest point on chassis. Set signal generator for 4.5 meg. center frequency with 100 KC deviation on each side of center. The curve should appear as in Fig. 10 above.

B — HORIZONTAL OSCILLATOR ALIGNMENT

To adjust the Horizontal oscillator and its control circuits it is necessary to first connect a working antenna to the receiver. It is preferable to use a test pattern as the incoming signal rather than a picture.

With the receiver turned on and the brightness and picture (contrast) adjusted to a normal position the Horizontal Frequency trimmer (J) (Fig. 12) and the Horizontal Locking trimmer (K) (Fig. 12) (rear of chassis) should be turned clockwise all the way and then backed off to about one turn (counter clockwise).

The Horizontal Hold Control (front panel) should be turned to a maximum clockwise position.

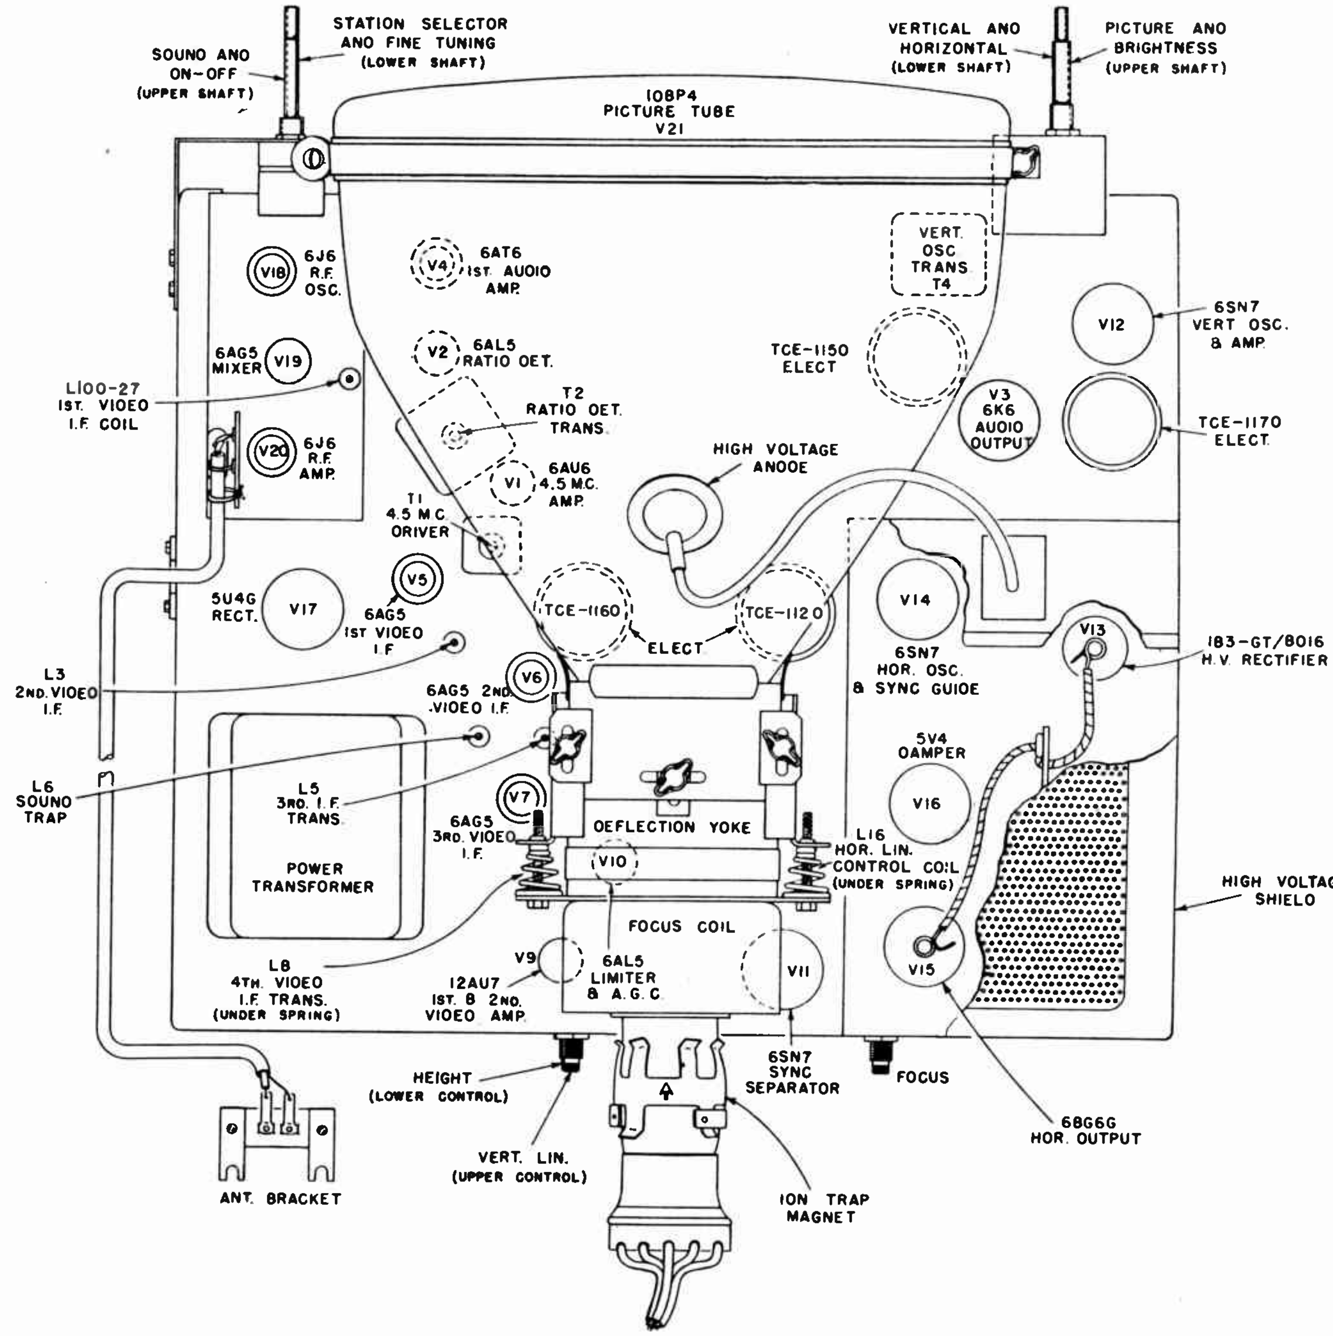
The core of the Horizontal Oscillator Transformer (L) (Fig. 12) should then be adjusted. Variation of this core will cause the pattern to resolve into a series of black and white bars sloping either to the right or the left depending upon the degree of adjustment. The transformer should be adjusted to the point where the picture resolves into a series of from 3½ to 4½ bars sloping downwards to the right.

The Horizontal Hold Control (front panel) should now be rotated to a full counter-clockwise position and the incoming signal momentarily interrupted. This can be done most easily by shorting the antenna terminals for a moment.

The Horizontal Hold Control (front panel) should now be rotated slowly in a clockwise direction. As the control is turned the number of bars sloping downward to the left should decrease. At approximately 90 degrees of rotation there should remain between 3½ and 4½ bars just prior to the time that the picture "falls into" sync. The picture should remain in sync for an additional 90 degrees of rotation. If MORE than 4½ bars are evident just before the picture syncs the Horizontal Locking Range trimmer (K) (Fig. 12) (rear of Chassis) should be tightened slightly. If LESS than 3½ bars the same trimmer should be loosened.

C — HEIGHT, WIDTH AND LINEARITY

To adjust the overall size and linearity of the picture it is almost mandatory that a pattern transmitted from a local station be used. Linearity ad-



TOP VIEW OF TELEVISION CHASSIS

FIG. 10

©John F. Rider

World Radio History

justments, particularly, cannot be accurately made on moving transmissions. It should also be remembered that in areas where more than one station is being received, that pictures transmitted from different stations will vary slightly in size. The smallest transmitted picture should be made to fill the area delineated by the mask.

The first step in linearity and size adjustment is to turn the Width control (M) (Fig. 11) (rear of chassis), Fig.11, all the way in. (clockwise).

The Width Control (M) (Fig.11) should now be re-adjusted to achieve a picture 8½" wide.

The Horizontal Drive trimmer (N) (Fig. 12) should then be adjusted for the best compromise between maximum brightness and good horizontal linearity. This control will affect the left side of the picture primarily. The Horizontal Linearity control (o) (Fig. 12) (top rear of chassis) should then be adjusted for linearity of the right side of the picture.

The high voltage measurement made with a suitable kilo voltmeter with Brightness Control set to minimum should be at least 7500 volts from picture tube anode to ground. (A meter which draws more than 100 micro amperes will disturb the high voltage circuit and give erroneous reading).

The Height (P) (Fig. 12) and Vertical Linearity (Q) (Fig. 12) controls (both rear of chassis) should then be adjusted for a linear picture 6⅜" high.

Picture centering is accomplished by positioning focus coil mechanically by means of (4) hexagon head adjusting screws accessible from rear of chassis as shown in Figure (9). At this point the Focus control (R), (Fig. 12) previously set, should be re-adjusted for maximum definition of the lines in the vertical wedge of the test pattern. Proper adjustment and alignment of the receiver should result in clear and sharp definition.

INDEX

GENERAL DESCRIPTION

The 102 television receiver is a direct view table model receiver employing the new rectangular type picture tube. Full twelve channel station coverage is provided by a rotary type channel selector employing condenser tuning over two frequency ranges. A stagger tuned intermediate frequency amplifier system carries both picture and sound intermediate frequencies, using the inter-carrier sound system. Power is supplied to the receiver through a switch ganged to the Picture control. The audio sound and picture brightness levels are established by the Volume and Brightness controls respectively. Picture brilliance is set by adjustment of the Picture control. The Vertical and Horizontal hold controls provide for synchronization of the horizontal and vertical components of the picture. Other picture adjustments which are not normally made by the operator are located on the rear of the receiver chassis.

SPECIFICATIONS

POWER SUPPLY

All models operate from a 105-125 volts 60 cycle AC source unless otherwise specified. Power consumption is 200 watts.

FREQUENCY RANGE

Channels 2 through 13. For specific channel frequencies see table on page 2.

ANTENNA EQUIPMENT

A dual antenna input is provided on the receiver to accommodate either 72-ohm shielded type lead in or 300-ohm ribbon type lead-in. The cabinet antenna lead, normally shipped connected to the 300-ohm terminals, must be disconnected if an outside antenna lead-in is connected. When connecting the antenna lead-in, connect the 72-ohm shielded type lead-in to the terminals marked "72 Ω" or connect the 300-ohm ribbon type lead-in to the terminals marked "300 Ω." Note that the shield braid on the shielded type lead-in must be connected to the terminal marked "GND". When 72-ohm shielded type lead-in is used, the two red coded leads at the back of the cabinet must be connected to the "300" terminals. When connecting 300-ohm balanced type lead-in, either wire may be connected to either 300-ohm terminal without affecting the quality of reception.

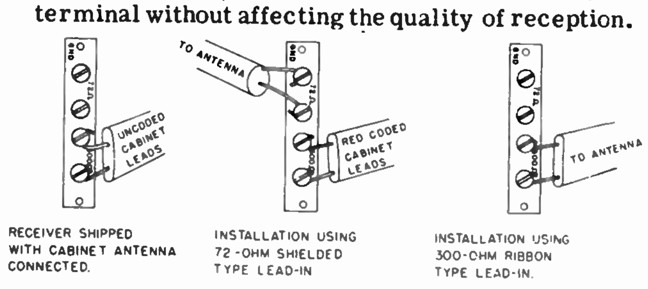

FIG. 1 - ANTENNA CONNECTIONS

TUBES (21, including rectifiers)

Function	Type	Function	Type

Second IF Amplifier	6AU6	Audio IF Amplifier.	6AU6
Third IF Amplifier.	6AU6	FM Detector	6AL5
Video Detector-First Video Amplifier . .	12AU7	Audio Amplifier.	6AV6
Second Video Amplifier - First Sync. Separator	12AU7	Audio Power Amplifier	6AQ5
Sync. Amplifier-Second Sync. Separator. .	12AU7	High Voltage Rectifier.	1X2
Vertical Oscillator.	6J5GT	Low Voltage Rectifier.	5V4G
		Picture Tube.	16RP4

*Note - Field replacement of RF amplifier tubes should be with 6BC5 tubes only. After the start of tuner production, the tube manufacturers reduced the transconductance (Gm) rating of 6AG5 tubes and designated the high Gm version as 6BC5. A reduction in receiver sensitivity will result unless 6BC5 tubes are used for replacement. The 6BC5 tube is completely interchangeable with the 6AG5 tube, so no socket wiring changes are involved.

CIRCUIT DESCRIPTION

The 549.100-2 television receiver chassis operates with eighteen tubes plus one high voltage rectifier, one low voltage rectifier and one 16RP4 rectangular picture tube. The operating controls as viewed from the front left to right are the vertical & horizontal hold (dual), power, switch & picture, volume & brightness (dual) and range selector & station tuning (dual).

For convenience in tracing the circuit, a block diagram of the complete receiver is shown in Fig. 2.

The antenna input circuit of the receiver's tuner is designed to match a 300-ohm impedance. However, a matching transformer and antenna terminals are provided to permit the use of either 72-ohm shielded type lead-in or 300-ohm ribbon type lead-in from an outside antenna system.

The cabinet antenna system permits satisfactory local reception without additional external antenna facilities. It is very important that the cabinet antenna leads be disconnected when an outside antenna system is installed.

©John F. Rider

World Radio History

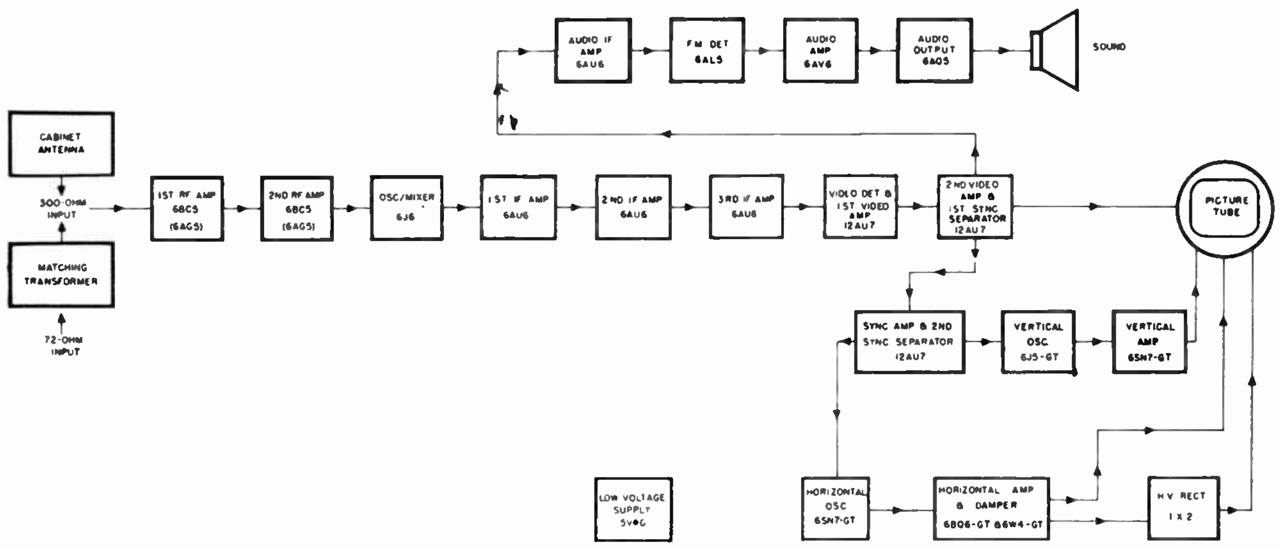

FIG. 2 - CIRCUIT BLOCK DIAGRAM

One of three antenna input systems shown is used for any given installation: i.e. cabinet antenna connected to 300-ohm terminals; outside antenna with shielded cable connected to 72-ohm terminals; or outside antenna with balanced ribbon type line connected to the 300-ohm terminals (Cabinet antenna leads disconnected in the last two cases.) The received signal is fed to the input of the RF tuner. The tuner is capacity tuned covering channels 2 through 6 in the first (Lo) range and 7 through 13 in the second (Hi) range. Continuous tuning is provided in each range. In order to facilitate tuning, a certain amount of additional coverage above the highest and below the lowest tunable channel in each range is provided. The extra coverage is referred to as "overtravel" in this text. A two position switch, actuated by a knob concentric with the station tuning shaft, is used to switch all circuits and will be referred to in this text as a range selector.

Three tubes are employed as follows:

6AG5 or 6BC5 first RF amplifier
6AG5 or 6BC5 second RF amplifier
6J6 oscillator-mixer

A three section gang condenser is used for tuning respectively the 1st RF plate circuit, 2nd RF plate circuit, and the plate circuit of the oscillator.

The antenna input system consists of two band-pass circuits. The required circuit is selected by the range selector. Each antenna band-pass circuit is a double tuned circuit consisting of a center tapped primary coil resonated by a trimmer capacitor and suitably coupled to a secondary coil resonated by the first RF grid input capacity. The tuner circuits are designed to match a 300-ohm transmission line.

Sketches of antenna band pass characteristics are shown below.

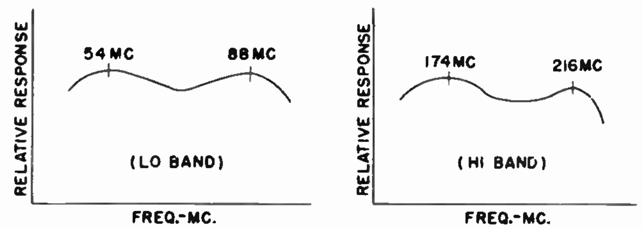

FIG. 3 - ANTENNA BAND-PASS CHARACTERISTICS

The RF amplifiers are used as stagger tuned amplifiers to provide a band-pass circuit of the proper band width. In both Hi and Lo ranges, the plate circuit of the 1st RF amplifier provides the low frequency stagger component, and the plate circuit of the second RF amplifier provides the high frequency stagger component as indicated below in a sketch of a typical RF pass-band.

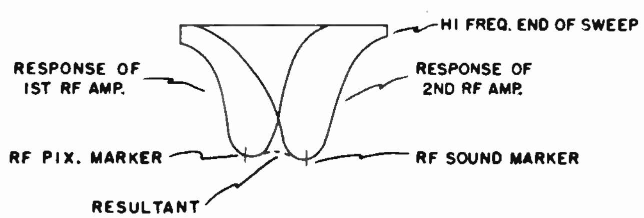

Fig. 4 - TYPICAL RF PASS BAND

With an RF sweep input to the antenna and an oscilloscope suitably connected to the mixer grid return at the LOOKER POINT shown in Fig. 14, the resultant overall RF response, which is a combination of the stagger responses in any channel appears as shown below:

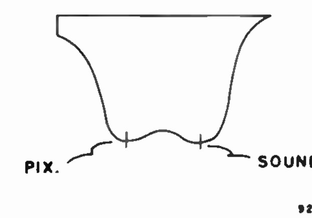

FIG. 5 - TYPICAL OVERALL RESPONSE

The oscillator employs a modified Colpitts circuit with one plate of the 6J6 tuned by the third section of the variable condenser.

In accordance with Fig. 14, the following tuning elements are brought out at the top of the tuner chassis:

Hi and Lo band antenna band-pass primary tuning trimmers•
1st and 2nd RF plate tuning trimmers
Oscillator plate tuning trimmer

The unity coupled, stagger tuned IF amplifier stages amplify both video and sound carriers. At the video detector stage the video intermediate frequencies and 4.5 mc beat frequency, which is the difference between the picture carrier intermediate frequency (26.25 mc) and the sound carrier intermediate frequency (21.75)mc), are detected and passed on to the two video amplifier stages. Note that the 4.5 mc beat still contains the FM modulation at this point.

At the second video amplifier plate, the 4.5 mc signal containing the FM carrier is taken off and fed to one stage of IF amplification before being detected at the FM detector stage. The audio frequency signal is then fed through one stage of voltage amplification to the power output stage and speaker.

The second video amplifier plate also carries the video signal which is fed to the grid of the picture tube.

Automatic gain control voltage is obtained from the rectified diode current flowing in the video detector stage. This negative voltage which is a function of signal level is applied to the grids of the 1st RF amplifier in the tuner and to the first and second IF amplifier stages to control the over-all gain over large variations in received signal levels.

The synchronizing pulses transmitted by the TV transmitter are carried along through the IF amplifier, video detector and first video amplifier stages where they are separated from the video signals by a two stage sync. separator.

The output of the second sync. separator is fed to the vertical and horizontal oscillators through filter networks designed to separate the horizontal and vertical sync. pulses supplied by the TV transmitter.

Vertical synchronizing pulses from the sync. separator are applied to the vertical sweep oscillator to hold this oscillator in step with the scanning equipment at the TV transmitter. The vertical sweep oscillator produces a saw-tooth voltage which is amplified on a second tube and energizes the vertical deflection coils of the picture tube.

Horizontal synchronizing pulses from the sync. separator are fed to the horizontal sweep oscillator stage to control closely the horizontal sweep rate.

The horizontal sweep oscillator stage employs a twin triode tube, one section of which operates as a "saw-tooth" oscillator and the other operates as a frequency controlling device by controlling the DC bias on the grid of the oscillator section. To exercise control over the frequency of the sweep oscillator, the control section of the twin triode samples the integrated wave form of the horizontal oscillator and "kick-back" pulse from the secondary of the horizontal output transformer as well as the synchronizing pulses from the TV transmitter via the sync. separator. The results of this sampling action provides control over the horizontal oscillator frequency for the three possible conditions of normal control, sync. too early, and sync. too late.

The output of the horizontal oscillator stage is amplified by the horizontal amplifier stage and coupled to the horizontal deflection coils of the picture tube by the horizontal output transformer. The output transformer serves the dual purpose of matching the output of the horizontal amplifier tube to the horizontal deflection coils of the picture tube and supplying high voltage for the second anode potential required by the picture tube.

The pulses generated in the transformer winding are rectified by the high voltage rectifier tube which also obtains its filament power from a separate winding on this transformer.

Focusing is accomplished magnetically by a combination permanent and electro-magnet. The load current of the receiver flows through the focusing control and focus coil winding such that the amount of focus coil current is controlled by the setting of the focus control. Since the focus coil contains a permanent magnet, the fields of the permanent magnet and focus coil winding must work together, hence the lead coding of the focus coil winding must be observed. Reversing the leads weakens the magnetic field so that focusing is not possible when this condition exists.

World Radio History

PICTURE TUBE INSTALLATION

DISMANTLING

Remove the four front panel control knobs by pulling them straight from their shafts. The dual control knobs must be removed in two pieces, removing the center unit first.

Remove the back cover. Note that the line cord and half of the interlock connector comes along with the back cover.

Unfasten and remove the speaker to clear the picture tube. Remove the wood screws holding the antenna terminal bracket and matching transformer to the cabinet.

Remove the five chassis bolts holding the receiver chassis in the cabinet and slide the entire assembly from the cabinet.

REMOVING THE PICTURE TUBE

Read all warning notices on both tube and carton.

Disconnect the picture tube socket at the base of the picture tube.

Slip the ion trap from the neck of the picture tube past the picture tube base connector.

Measure the distance from the front edge of the steel band or front edge of the chassis apron to the face of the picture tube. Keep this dimension handy for the installation of the new tube.

Remove the steel band at the front rim of the picture tube and carefully slip the neck of the picture tube out of the focus coil and deflection yoke. If the tube fails to slip out smoothly investigate and remove the cause of the trouble. Do no use force.

INSTALLING THE PICTURE TUBE

Wrap the dust seal around the front rim of the picture tube and position the tube so that the anode contact is located on the left as viewed from the screen.

Slip the neck of the picture tube through the rear support, deflection yoke, and focus coil and seat the tube firmly against the rear support. If it fails to slip into place smoothly, investigate and remove the cause of the trouble. Do not force the tube.

Check the distance from the face of the tube to the front edge of the steel band or chassis apron as measured above. If the dimension is off; loosen the two rear support mtg. screws, position the tube correctly and fasten the steel band firmly about the rim of the tube. As a second check at this point it may be well to slip the chassis into the cabinet to check the installation before proceeding with the remaining adjustments.

Check the rear support. It must seat firmly against the flare of the tube and be securely anchored in place by the two rear support mounting screws. Check the spring contact grounding the outer coating of the picture tube. A high potential is developed on the outer coating of the tube if this contact is faulty.

The deflection yoke must seat firmly against the flare of the picture tube. Check by loosening the single deflection yoke adjusting screw and pushing the deflection yoke forward as far as it will go. Take up the slack in the screw temporarily to hold the coil in place.

Slip the ion trap over the neck of the tube. The arrow points toward the screen of the picture tube.

Reconnect the picture tube socket and anode connector.

Make the adjustments outlined under "Television Service Adjustments" before reassembling the chassis in the cabinet.

TELEVISION SERVICE ADJUSTMENTS

ION TRAP MAGNET ADJUSTMENT

Turn on the receiver and turn up the brightness control. Set the ion trap for maximum raster brilliance, backing off the brightness control adjustment as the maximum point is approached. The ion trap must be rotated about the axis of the tube as well as shifted along the neck of the tube to obtain the proper setting. The arrow on most ion traps points to the second anode connector when properly adjusted, hence a quick initial setting may be made as far as rotation is concerned.

FOCUS AND BRIGHTNESS CONTROL ADJUSTMENT

With the brightness control set for slightly above average brilliance and the picture control full counter-clockwise, adjust the focus control until the line structure of the raster is clearly visible.

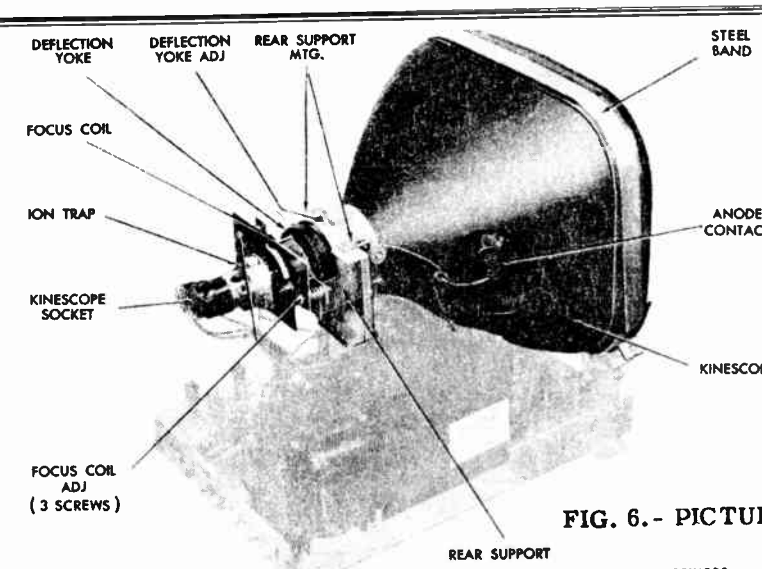

FIG. 6.- PICTURE TUBE MOUNTING DETAIL

Readjust the ion trap, if necessary, for maximum raster brilliance. The final touches on the focus control adjustment should be made with the brightness control at the maximum position with which good line focus can be maintained, then back off the setting of the brightness control until the white, wide spaced, retrace lines just disappear.

DEFLECTION YOKE ADJUSTMENT

If the lines of the raster are not horizontal or square with the escutcheon, loosen the deflection yoke adj. screw and rotate the deflection yoke until this condition is obtained. Tighten the adjustment screw.

PICTURE ADJUSTMENTS

A test pattern is desirable when making the following adjustments. Maintain normal picture contrast and brilliance when making these adjustments.

FOCUS COIL ADJUSTMENT

Check the position and appearance of the test pattern. If the test pattern is off center or shadowed at the corners (electron beam striking the neck of the tube) set the horizontal centering control in the middle of its range and adjust the three focus coil adjusting screws for a centered, evenly illuminated raster. Note that the three spring loaded adjustment screws tilt the focus coil to shift the position of the raster on the face of the picture tube. Do not turn all three screws up tight, use them to tilt the focus coil only.

It is not necessary to tilt the focus coil excessively. Excessive tilt may snap the neck of the picture tube if sufficient force is used. The focus coil may be shifted around the axis of the picture tube, if necessary, by loosening the two knurled nuts holding the coil to the mounting plate. The position of the focus coil that produces a centered, evenly focused pattern on the face of the tube is the correct one. Tighten the nuts after the adjustment has been made. The horizontal centering control may now be used as required without having to reset the focus coil position each time.

A slight adjustment of the ion trap while making the focus coil adjustments may be found effective in obtaining the desired results.

HORIZONTAL OSCILLATOR ADJUSTMENT

Check the action of the horizontal hold control on the front panel. If the control is excessively off center when sync. is established or fails to sync. at all, the horizontal oscillator transformer (See Fig. 9) requires adjustment.

To reset the horizontal transformer, set the horizontal hold control in the center of its range, tune in a TV station and sync. the picture by adjusting the bottom screw adjustment on the horizontal oscillator transformer. Note that the TV station must be carefully tuned for best picture when making this adjustment.

Check the horizontal hold control action on all TV channels and touch up the oscillator transformer adjustment if necessary.

NOTE: The top screw adjustment on the horizontal oscillator transformer has been arbitrarily set at its top limit. This adjustment should not be disturbed unless it is obvious that the adjustment has been tampered with. If this screw has been turned, reset it to the top limit of its travel.

©John F. Rider
World Radio History

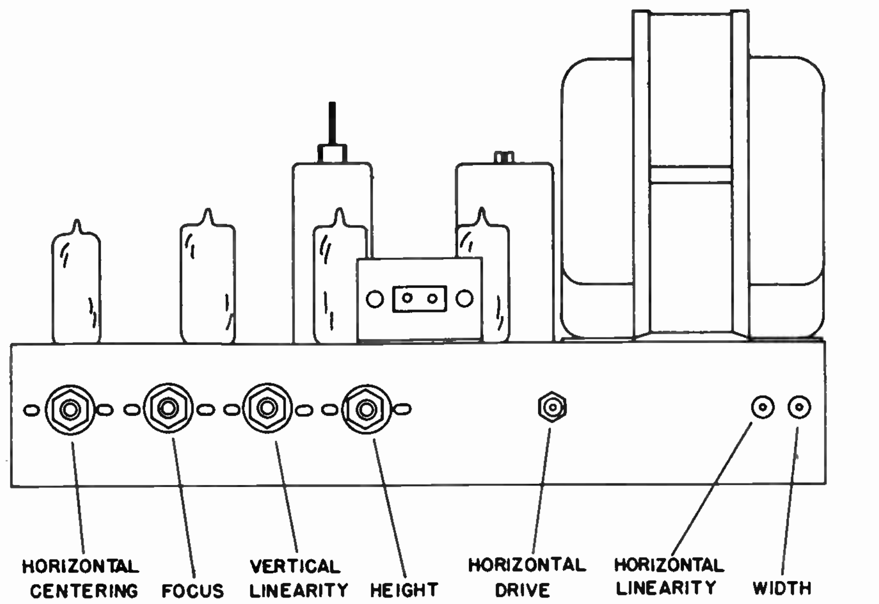

FIG. 7 - REAR CHASSIS VIEW

HORIZONTAL DRIVE ADJUSTMENT

Advance the HORIZONTAL DRIVE control (Fig. 7) as far as possible without causing fold over of the test pattern. (Vertical white line.) Insufficient horizontal drive will cause low second anode voltage with consequent loss of picture brilliance.

HORIZONTAL LINEARITY ADJUSTMENT

Set the HORIZONTAL LINEARITY control for a symmetrical pattern from left to right. A slight re-adjustment of the HORIZONTAL CENTERING control may be necessary when making this adjustment.

WIDTH ADJUSTMENT

Set the WIDTH control so that the test pattern fits the horizontal dimension of the picture tube escutcheon. A minor adjustment of the HORIZONTAL CENTERING control may be required to recenter the pattern.

HEIGHT ADJUSTMENT

Set the HEIGHT control so that the test pattern fits the vertical dimension of the picture tube escutcheon. A minor adjustment of the focus coil position may be required to recenter the pattern.

VERTICAL LINEARITY ADJUSTMENT

Set the VERTICAL LINEARITY control for a symmetrical test pattern in the vertical dimension. A slight readjustment of the height control may be required when making this adjustment.

HORIZONTAL CENTERING ADJUSTMENT

When the picture is not centered horizontally, adjust the HORIZONTAL CENTERING control until the picture is centered left to right. Slight readjustment of the WIDTH control may be necessary.

FOCUS

Carefully adjust the receiver for best picture definition and set the picture and brightness controls for normal picture brilliance. Adjust the FOCUS control for maximum picture definition watching the wedges of the test pattern. An alternate method for focusing consists of switching to an unused TV channel and with the brightness control turned up so that the raster is illuminated, set the focus control for well defined scanning lines.

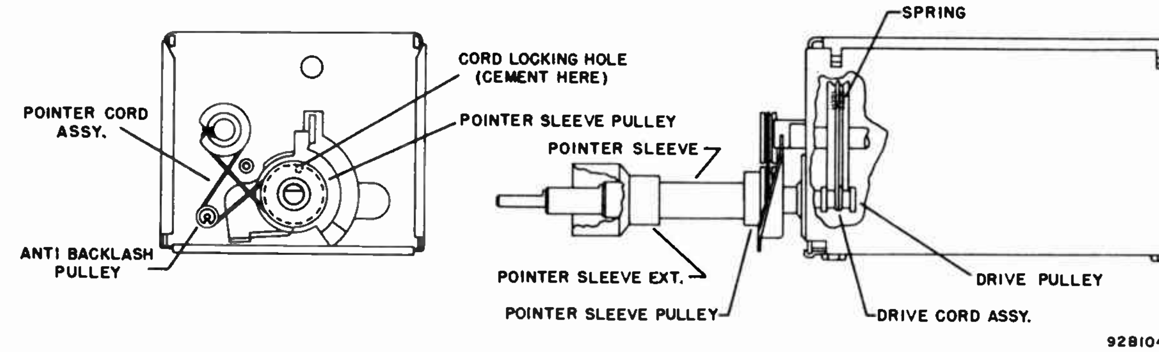

FIG. 8 - DIAL DRIVE DETAIL

RESTRINGING CONDENSER PULLEY DRIVE

Wrap drive cord assembly 1-1/2 turns on drive pulley (Fig. 8) and slip other end over pulley on rotor shaft, keeping prong clip in center of slot, hook one end of spring over cord, and the other end over tab on pulley.

RESTRINGING POINTER PULLEY DRIVE

With condenser at maximum capacity and hole in pointer sleeve pulley in position shown, press prong clip on pointer cord assembly into hole and wrap end of loop around end of condenser rotor shaft (Fig. 8.) making certain that cord is seated in groove in rotor shaft. Loop loose end of cord assembly over anti-backlash pulley as shown. Apply a drop of "Duco" household cement over cord seated in groove in rotor shaft to prevent cord from slipping.

RESETTING POINTER SLEEVE EXTENSION

If pointer cord breaks, it may be necessary to reset the pointer sleeve ferrule after restringing, in order to maintain coincidence of pointer and dial escutcheon.

1. Tune unit to channel 13 (station or signal generator).
2. Unsolder pointer sleeve ferrule and rotate until pointer registers on number 13 of dial escutcheon.
3. Solder pointer sleeve extension to pointer sleeve (Fig. 8.).

TELEVISION ALIGNMENT PROCEDURE

PRELIMINARY

This alignment is an exacting procedure and should be undertaken only when necessary. Before fully deciding that alignment is necessary and before removing the chassis from the customer's house:

1. Be sure of the antenna installation.
2. Check all operating controls and adjustments including the station tuning control.
3. Check reception on all channels
4. Check tubes by substitution of known good tubes.

In the repair shop.

5. Substitute a known good picture tube.
6. If picture definition is still inadequate, observe the overall IF response curve of the receiver.

World Radio History

TEST EQUIPMENT REQUIRED FOR IF ALIGNMENT

Signal generator covering 4 mc to 30 mc.
Electronic voltmeter.

TEST EQUIPMENT REQUIRED FOR TUNER ALIGNMENT

Sweep Generator
Oscilloscope
Electronic Voltmeter
RF Marker Generator
Pix IF Marker Generator
Bias Supply 2-1.5 volt Dry Cells
IN-34 Crystal Detector (See Fig. 11.).

SPECIFICATIONS FOR TUNER TEST EQUIPMENT

Sweep Generator similar to RCA type WR59A, covering frequencies of 54 to 88 Mc, and 174 to 216 Mc with a minimum sweep of 10 Mc in any channel, and a 300-ohm balanced output at least 0.1 volt line to line.

Oscilloscope equivalent in vertical deflection sensitivity to Dumont type 208-B.

Electronic voltmeter similar to Voltohmyst.

RF marker generator similar to RCA type WR-39-A.

Pix IF marker generator may be a crystal controlled oscillator in vicinity of 26.25 Mc. As alternates, either a second WR-39-A or an all wave signal generator of suitable accuracy may be used to supply a picture IF marker.

FM SOUND CHANNEL I-F AMP. ALIGNMENT

1. Connect the low frequency signal generator output across resistor R-118 in the plate circuit of 12AU7 VIDEO DET. tube (V-104). This resistor is located at the terminal strip near the tube socket.

2. Connect the electronic voltmeter between pin 7 of the 6AL5 FM DET. tube (V-109) and chassis ground.

3. With the signal generator (unmodulated) set at 4.5 mc. set the 4.5 MC LIMITER GRID ADJ. (Top side of chassis) and FM DET PRI. ADJ. (Under side of chassis) (See Fig. 9) for maximum d-c voltage as measured by the electronic voltmeter. Adjust the limiter grid transformer (T-105) before adjusting the f-m detector transformer (T-108) primary. Use just enough signal generator output to obtain approximately one volt at the electronic voltmeter.

4. Connect the electronic voltmeter across the 1000 mmf condenser (C-135) at the output of the f-m detector stage and adjust the FM DET. SEC. ADJ. (top side of chassis) of the f-m detector transformer (T-108) for the null.

5. Shift the frequency of the signal generator either side of the 4.5 mc and touch up the FM DET. PRI. ADJ. (under side of chassis) for approximately equal peaks. Use just enough signal generator output to obtain one volt peaks for the best results.

6. After completing the alignment procedure and placing the receiver in operation again, carefully tune in a TV test pattern and adjust the 4.5 MC TRAP ADJ. for maximum vertical wedge definition. This adjustment is located on the under side of the chassis and on the same coil form as the 4.5 MC LIMITER GRID ADJ. shown in Fig. 9.

NOTE - The primary adjustment of T-108, the coarse frequency adjustment of T-111 and the 4.5 mc trap adjustment may all be made through the plugged holes in the cabinet bottom if desired.

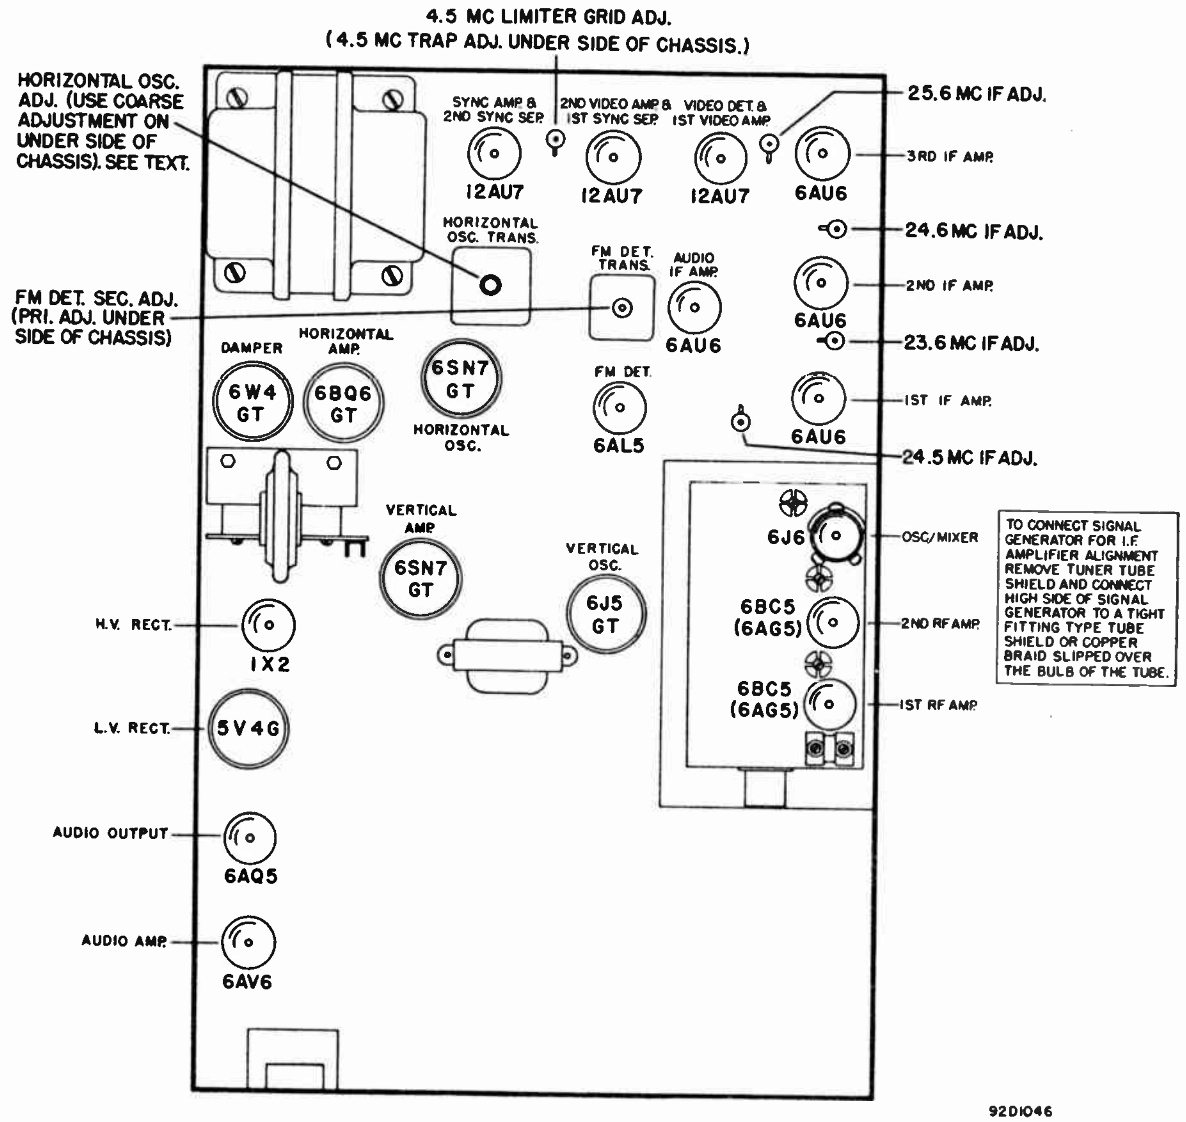

FIG. 9 - TOP VIEW - ALIGNMENT POINTS

I-F AMPLIFIER ALIGNMENT

1. Connect the electronic voltmeter across resistor R-118 in the plate circuit of the 12AU7 VIDEO DET. tube (V-104). This resistor is located on the terminal strip near the tube socket.

2. Couple the high side of the signal generator to the MIXER tube (V-3) by removing its shield and slipping a tight fitting tube shield or length of copper braid over the bulb of the tube and connecting the generator lead to it. Connect the ground side of the signal generator to the frame of the tuning unit.

3. Position the station tuning control at channel 2.

4. Set the signal generator output (unmodulated) to develop one or two volts at the electronic voltmeter and adjust the four i-f amplifier coils, according to the following chart, for maximum d-c voltage as measured by the electronic voltmeter. Since the first IF stage employs an overcoupled input transformer (T-101), it is necessary during the adjustment of this transformer to shunt the winding not being aligned with a 1,000 ohm resistor (i.e. shunt the secondary when aligning the primary and vice-versa). Readjust the signal generator output as required to maintain the two-volt potential at the electronic voltmeter.

©John F. Rider
World Radio History

I-F AMPLIFIER ALIGNMENT CHART

Signal Generator Frequency (No Modulation)	Adjustment (Refer to Fig. 9)	Stage Adjusted
24.5 mc	24.5 MC IF ADJ. *	1st IF amp
23.6 mc	23.6 MC IF ADJ.	2nd IF amp
24.6 mc	24.6 MC IF ADJ.	3rd IF amp
25.6 mc	25.6 MC IF ADJ.	Video detector

* Note - Use 1000 ohm shunt resistor when making this adjustment. See step 4 above.

5. Check the i-f amplifier frequency response by tuning the signal generator from 21 mc through 26.25 mc and observing the change in d-c voltage at the electronic voltmeter. If the signal generator output is set for an electronic voltmeter reading of 1.5 volts at the peak i-f amplifier response, the d-c voltage should not drop below one volt between the two peaks normally obtained with this i-f amplifier. If the response is unsatisfactory, repeat the procedure or try slight modifications of the recommended settings to obtain the desired response. Avoid resonating the coils with the iron core at the bottom end of the coil form. (Adjustment screw near limit of its travel).

If a sweep type signal generator and oscilloscope are available the problem of making the final adjustments will be much easier. Check the two carrier i-f responses, 21.75 mc and 26.25 mc. The 21.75 mc response will be approximately 20 db below the peak response (Approx. 0.15 volt) and the 26.25 mc response will fall approximately 6 db below the peak (Approx. 0.4 volt). Refer to Fig. 10.

The average i-f amplifier sensitivity, when feeding the signal generator output through the receiver as described in step 2, will run approx. 2000 to 5000 microvolts for the one volt d-c peak measured at resistor R-118 (receiver's oscillator operating on channel 2).

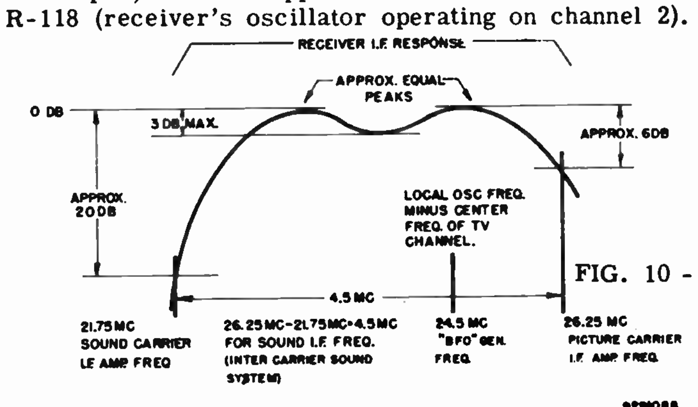

FIG. 10 - I-F AMPLIFIER RESPONSE

TUNER ALIGNMENT

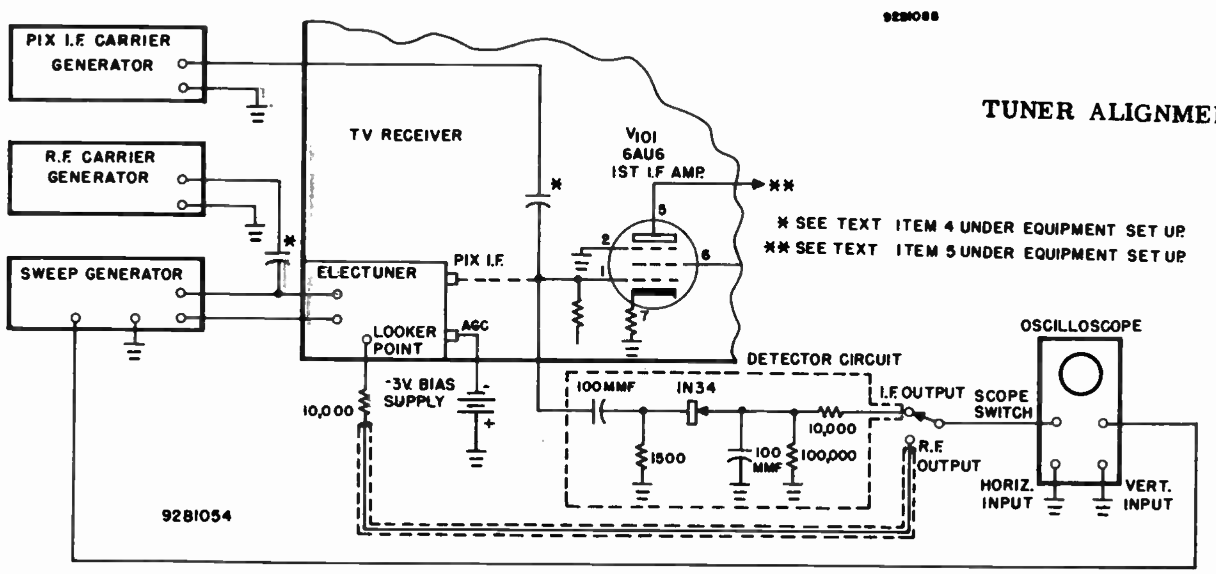

FIG. 11 - RECOMMENDED TEST EQUIPMENT CIRCUITS

Test Equipment Set Up - With reference to Fig. 11, the following precautions should be taken in making the equipment set up.

1. The detector circuit should be so constructed as to maintain leads as short as possible. Connection of the detector circuit to the 1st IF amplifier grid terminal should also be made with short leads.

2. Shielded leads should be used in making the following connections to reduce hum and synchronous voltage pick up.
   (a) The lead for observations of the RF response from the scope isolating resistor (10,000 ohms located at the tuner LOOKER POINT) to the RF output switch position of the scope switch.
   (b) The connection from the IF detector circuit output to the IF switch position of the scope switch.
   (c) The connection from the sweep generator to the horizontal input of the scope. (Use the externally generated sweep instead of internal oscilloscope sweep in order to obtain synchronization).

3. The single pole double throw SCOPE SWITCH should be located at the vertical input terminals of the scope. This switching arrangement will permit observation of either the IF response or the overall RF response. The aforementioned positions will be referred to in subsequent text as the "IF" and "RF" positions respectively.

4. The marker generator coupling condenser should be as small a value as possible to prevent any effect on tuner response, but must be large enough to permit easy observation of markers on either the IF response or overall RF response. (Approximately 2 or 3 mmf should be satisfactory in most cases).

5. For all tests which are outlined in this text, remove the second IF amplifier tube to prevent coupling back from the receiver IF system.

6. In all of the following tests the oscilloscope vertical gain should be as close to maximum gain as possible, consistant with hum and synchronous voltage interference limitations. This precaution will allow the use of low levels from the RF sweep generator and increase the visibility of IF and RF markers.

Procedure For Oscillator Alignment -

OVERTRAVEL CHART FOR OSCILLATOR COVERAGE

Channel No.	Overtravel	RF Overtravel Marker Frequency
13	+ 1.5 Mc	Pix carrier + 1.5 Mc = 212.75 Mc
7	- 2.5 Mc	Pix carrier - 2.5 Mc = 172.75 Mc
6	+ 1.5 Mc	Pix carrier + 1.5 Mc = 84.75 Mc
2	- 1.0 Mc	Pix carrier - 1.0 Mc = 54.25 Mc

High Band Oscillator Alignment

1. Turn range selector of the tuner to the Hi band (counter-clockwise rotation of switch knob), rotate variable condenser to minimum capacity (clockwise rotation of tuning shaft), and adjust sweep generator for channel 13.

2. With the scope switch in IF position, adjust scope gain, RF sweep input level, inject required IF picture marker (i.e. 26.25 Mc), and an RF overtravel marker of 212.75 Mc.

3. Adjust OSC. TRIMMER (Fig. 14) so that picture IF marker and 212.75 Mc overtravel markers coincide on the IF response characteristic on the scope.

4. Remove the two self tapping screws used for fastening the tuner shield and slide shield off until a point is reached where coils on switch are exposed and accessible.

©John F. Rider

World Radio History

5. Rotate variable condenser to maximum capacity (counter-clockwise) and adjust sweep generator for channel 7.

6. Inject RF overtravel markers of 172.75 Mc.

7. With a bakelite alignment tool, adjust the spacing of the turns of the HI BAND OSC. COIL (Fig. 14) so that Pix IF marker and 175.75 Mc markers coincide. Spreading the coils apart will raise the oscillator frequency; squeezing the coils together will lower the frequency. After adjustment, slide shield back into its original position and note any frequency shift of markers. Slide shield off and compensate for the frequency shift by a slight readjustment of the Hi band oscillator coil. Slide shield back into original position and note if markers coincide. If they do not, repeat this process until proper adjustment is made and markers coincide.

8. Repeat steps 1 to 7 inclusive until correct oscillator coverage of entire Hi band is obtained.

Lo Band Oscillator Alignment -

9. Remove tuner shield completely, turn tuner range selector to Lo band position (clockwise), rotate variable condenser to minimum capacity and adjust sweep generator for channel 6.

10. Inject Pix IF marker and RF overtravel marker of 84.75 Mc.

11. With a bakelite alignment tool, adjust LOW BAND OSC. COIL (Fig. 14) so that the Pix IF marker and 84.75 Mc marker coincide.

12. Rotate variable condenser to maximum capacity (counter-clockwise) and adjust sweep generator for channel 2.

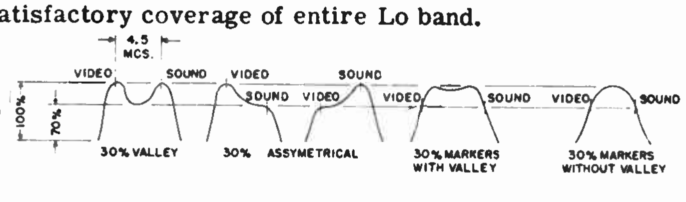
13. Inject RF overtravel marker 54.25 Mc.

14. Adjust LOW BAND OSC. SERIES PAD (See Fig. 14) until Pix IF marker and 54.25 Mc marker coincide.

15. Repeat steps 9 to 14 inclusive for satisfactory coverage of entire Lo band.

Procedure For RF Pass Band Alignment

FIG. 12 - ACCEPTABLE RF PASS BANDS



Hi Band RF Pass Bands -

16. Repeat step 1.

17. Replace tuner shield, set scope switch to IF position, and adjust scope gain.

18. Inject a Pix IF marker and a channel 13 Pix RF marker (211.25 Mc).

19. Rotate tuning shaft until Pix IF marker and 211.25 Mc marker coincide on the IF response. Do no disturb this setting of the variable condenser for the remainder of alignment of channel 13 RF pass band.

20. Set scope switch to RF, adjust scope gain and turn 1ST RF TRIMMER (Fig. 14) for maximum amplitude of first RF amplifier response in the region of the RF Pix marker.

21. Inject channel 13 sound RF marker (215.75 Mc) and adjust 2ND RF TRIMMER (Fig. 14) for maximum amplitude of second RF amplifier response in the vicinity of the RF sound marker.

22. Repeat steps 20 and 21 until desired pass band is obtained. See Fig. 12 for acceptable RF band pass response shapes.

23. Remove tuner shield as in step 4 and repeat step 5.

24. Set scope switch to IF position, adjust scope gain, and inject required Pix IF marker and channel 7 Pix RF marker of 175.25 Mc.

25. Rotate tuning shaft until Pix IF marker and channel 7 RF Pix RF markers coincide in IF response. Do not disturb this setting of the variable condenser for remainder of alignment of channel 7 RF pass band.

26. Set scope switch to RF position and with a bakelite alignment tool, adjust 1ST RF HI BAND COIL (Fig. 14) for maximum amplitude of 1st RF amplifier response in region of the Pix RF marker.

27. Inject a channel 7 RF sound carrier of 179.75 Mc and adjust 2ND RF HI BAND COIL (Fig. 14) for maximum amplitude of 2nd RF amplifier response in the region of the sound RF marker.

28. Repeat steps 26 and 27 until desired pass band is obtained, consistent with shapes shown in Fig. 12.

29. Repeat steps 16 to 28 inclusive for satisfactory coverage of entire Hi band RF response.

Lo Band RF Pass Bands -

30. Repeat step 9 set scope switch to IF position, adjust scope gain, and inject a channel 6 Pix RF marker (83.25 Mc).

31. Rotate tuning shaft until Pix IF marker and 83.25 Mc markers coincide. Do not disturb this setting for remainder of channel 6 RF pass band.

32. Set scope switch to RF position and adjust scope gain.

33. Adjust 1ST RF LO BAND COIL (Fig. 14) for maximum amplitude of 1st RF amplifier response in the region of channel 6 Pix RF marker.

34. Inject channel 6 sound RF marker of 87.75 Mc and adjust 2ND RF LO BAND COIL (Fig. 14) for maximum amplitude of 2nd RF amplifier response in the region of the channel 6 sound RF marker.

35. Repeat step 32 until desired pass band is obtained in accordance with acceptable RF pass bands shown in Fig. 12.

36. Rotate variable condenser to maximum capacity (counter-clockwise) and adjust sweep generator for channel 2.

37. Set scope switch to IF position, adjust scope gain, and inject a channel 2 Pix RF marker (55.25 Mc).

38. Rotate tuning shaft until Pix IF markers and 55.25 Mc markers coincide. Do not disturb this variable condenser setting for remainder of alignment of channel 2 RF pass band.

40. Adjust 1ST RF LO BAND COIL (Fig. 14) for maximum amplitude for 1st RF amplifier response in region of channel 2 Pix RF marker.

41. Inject channel 2 sound RF marker (59.75 Mc) and adjust 2ND RF LO BAND COIL (Fig. 14) for maximum amplifier response in region of channel 2 sound RF marker.

42. Repeat step 40 until desired pass band is obtained in accordance with acceptable RF pass band shown in Fig. 12.

43. Repeat steps 30 to 42 inclusive for satisfactory coverage of entire Lo band RF response.

Procedure For Antenna Pass Band Alignment -

The band pass antenna stages are normally aligned in the factory for minimum standing waves, with a wide range sweep oscillator and a delay line. The coupling between the primaries and secondairies are carefully adjusted and in general should not be disturbed.

Minor corrections of the primary trimmer tuning may be necessary, if they are accidentally or otherwise varied after leaving the factory. The procedure for resetting antenna primary trimmers is outlined below.

Hi Band Primary Antenna Trimmer Alignment -

With scope switch in RF position and equipment set for observation of channel 13 RF pass band (see step 1) turn HI BAND PRIMARY ANT. TRIMMER screw (counter-clockwise) i.e. to a reduced capacity setting. Start turning trimmer screw clockwise (increasing capacity) while observing the channel 13 RF pass band amplitude and shape. It will be noticed that the amplitude will increase to a certain point and thereafter the shape of the response will change as shown in Fig. 13, indicating the antenna to be cutting into the RF pass band. Back out the trimmer screw to a maximum amplitude and minimum "cutting-in" position.

©John F. Rider
World Radio History

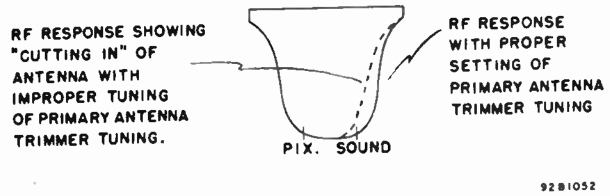


FIG. 13 - EFFECT OF PRIMARY ANTENNA TRIMMER ON RF PASS BAND RESPONSE

Lo Band Primary Antenna Trimmer Alignment

Procedure for aligning LO BAND PRIMARY ANT. TRIMMER is the same as outlined for Hi band primary antenna trimmer except the tuner should be tuned to channel 6 and adjustment of the Lo band antenna primary trimmer screw should be done while observing the RF response characteristic of channel 6.

Final Caution Note -

Upon completion of tuner alignment, remove crystal detector in 1st IF grid. Replace tuner shield and fastening screws, reinsert 2nd IF amplifier tube removed at start of alignment, and check performance of receiver with all available local stations.

Tuner Service Notes

Oscillator Injection Voltage-The oscillator injection voltage is specified as 2 volts minimum with normal B+ applied and is measured from the LOOKER POINT (Fig. 14) to ground with a Voltohmyst through a 10,000 ohms isolating resistor. In the event of a failure to meet these specifications, it is necessary to replace the 6J6 tube.

Tube Replacement-If the oscillator tube (6J6) is changed, it may be necessary to realign the tuner to compensate for the difference in tube characteristics. A slight adjustment of the oscillator trimmer (Fig. 14) will correct for any change of tube capacitance. Follow instructions for alignment of Hi Band and Lo Band oscillator alignment. Low oscillator injection voltage will reduce conversion gain with resulting loss in picture sensitivity.

If either RF tube is replaced, it may be necessary to realign tuner to compensate for a variation of tube characteristics. A slight adjustment of the RF trimmers (Fig. 14) will compensate for this. Follow instructions for alignment of Hi Band and Lo Band RF pass band alignment.

Variable Condenser

Do Not Attempt to bend variable condenser plates, as they have been calibrated in the factory on special equipment.

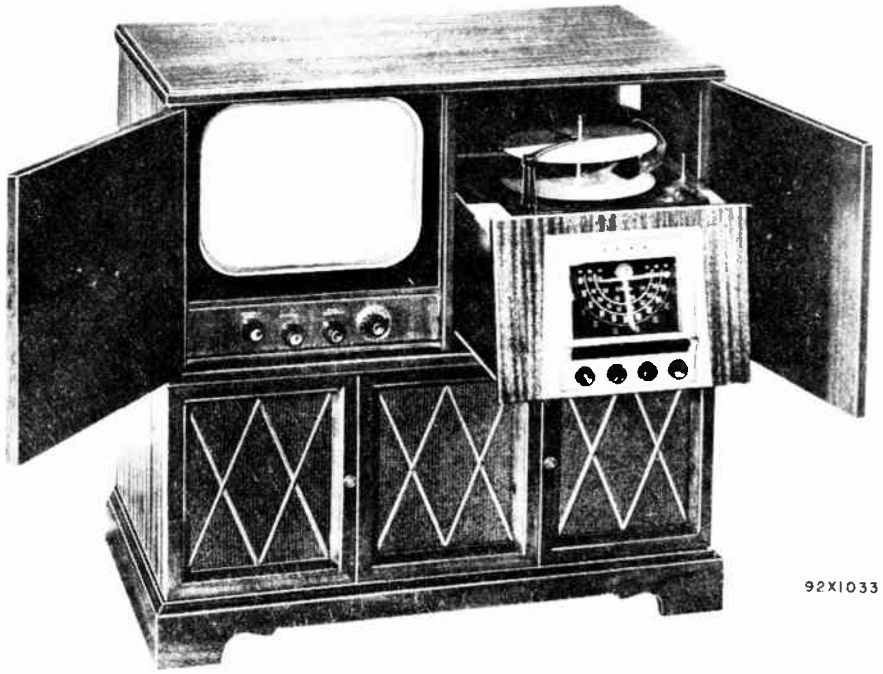
MODEL 102, Ch. 549.100-2

©John F. Rider

World Radio History



92X1033

SPECIFICATIONS

POWER SUPPLY

All models operate from a 105-125 volts 60 cycle AC source unless otherwise specified. Power consumption 200 watts.

FREQUENCY RANGE

For chassis 549.100-3 refer to 57 RL 546 Supplement 4. For cnassis 101.831-1 refer to 57 RL 474.

ANTENNA EQUIPMENT

The antenna connections for the television receiver chassis and the AM/FM receiver chassis are brought out to separate terminal boards. For details on the television chassis antenna terminal board arrangement refer to 57 RL 546 Supplement 4.

The cabinet antenna system for the AM/FM receiver unit consists of a loop for the broadcast band and a folded-doublet type antenna mounted on the rear of the cabinet for shortwave and FM band reception. The receiver is shipped with the doublet antenna connected to terminals "D-D" on the antenna terminal board. When installing the receiver, it may be necessary to rotate the loop slightly to avoid the customary null effects on the broadcast band produced by loop type receivers.

In areas where an outdoor antenna is required for broadcast reception, connect a length of wire to terminal "A" and if desired a ground wire to terminal "G". If an outdoor FM antenna is required, disconnect the FM cabinet antenna leads from terminals "D-D" and connect the outdoor FM antenna lead-in wires to these terminals.

TUBES

For chassis 549.100-1 refer to 57 RL 546 Supplement 4. Note that the rectifier has been replaced by a 5U4G.

For chassis 101.831-1 refer to 57 RL 474. Note that the rectifier tube 5U4G listed in 57 RL 474 has been replaced with a type 5V4G because of space limitations. (No socket wiring changes required.)

SERVICE INFORMATION

The following section covers differences in service data existing between the 549.100-2 and 549.100-3 television receiver chassis. Hence service information not mentioned below is given in 57 RL 546 Supplement 4 which was written for the 549.100-2 chassis.

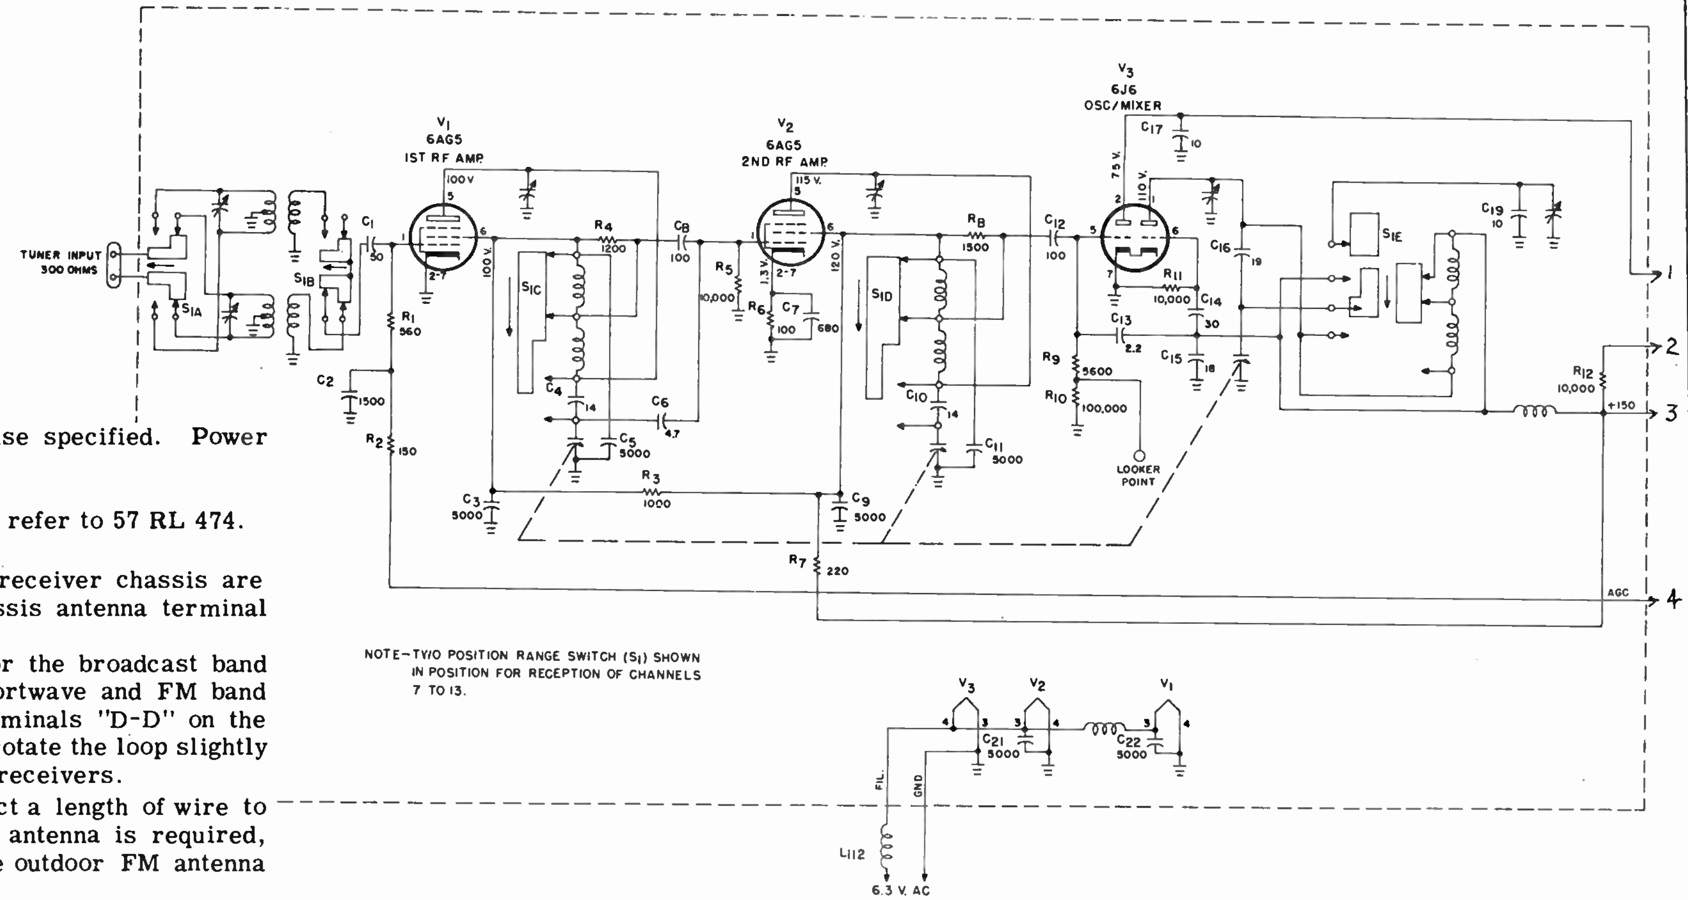
ALIGNMENT

If alignment of the television receiver 549.100-3 follows the procedure given in 57 RL 546 Supplement 4 except that the 2nd IF amplifier stage input transformer (T-102) should be aligned at 23.4 Mc and not 23.6 Mc.

After the sound and video alignment have been completed, it will be necessary to adjust L-113 (Top side of chassis) located electrically in the output of V-101, the 1st IF amplifier. Connect the electronic voltmeter across resistor R-118 and couple the high side of the signal generator to the MIXER tube (V-3) in the same manner as for IF amplifier alignment. With the signal generator set at 21.75 adjust L-113 for minimum voltage at R-118. It may be necessary to retune T-102 because of its interaction with L-113. Alternate "touching up" of both L-113 and T-102 will bring them into correct adjustment.

TUBE REPLACEMENT

A 5U4G has been substituted for a 5V4G as the low voltage rectifier to allow for increased B plus voltage. The socket has been mounted below chassis level to allow ample clearance for the top of the tube. The tube may still be replaced without removing the chassis from the cabinet.



FOR IF AMPLIFIER ALIGNMENT CONNECT THE HIGH SIDE OF THE SIGNAL GENERATOR TO THE OSC/MIXER TUBE (V-3) BY REMOVING ITS SHIELD & SLIPPING A TIGHT FITTING TUBE SHIELD OVER THE BULB OF TUBE & CONNECTING THE GENERATOR TO IT. USE ENOUGH SIGNAL GENERATOR OUTPUT TO OBTAIN APPROX 2 VOLTS AT THE VOLTMETER, WHICH IS CONNECTED ACROSS R-118. L-113 IS ADJUSTED FOR MINIMUM VOLTAGE AS OBSERVED ON VOLTMETER, ALL OTHER IF AMPLIFIER ADJUSTMENTS ARE ADJUSTED FOR MAX. VOLTAGE.

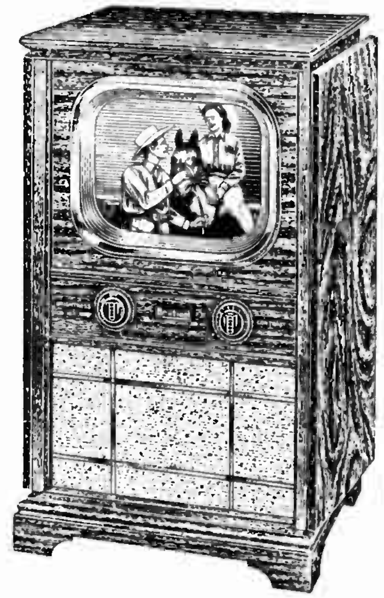
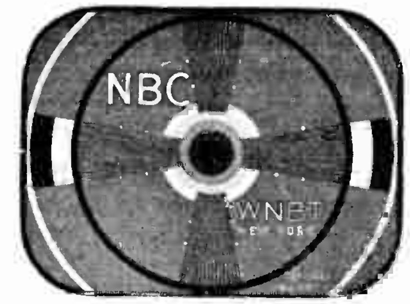
INDEX

THE PHOTO BELOW IDENTIFIES THE CONTROLS ON FRONT OF CABINET AND SHOWS THE FUNCTION OF EACH CONTROL.

The "Contrast" and "Brightness" controls may be adjusted at any time there is picture or test pattern on the air. Because it is easier to adjust the controls with a test pattern picture, television stations usually telecast a pattern before the beginning of and sometimes between, the regularly scheduled programs. The test pattern, used below to illustrate "Correct Pattern," "Too Light Pattern" and "Too Much Con ·t Pattern" is one telecast by a station for this purpose. Wh· ne type of pattern will vary in design and appearance with st. .ons, its purpose is the same — to permit the television owner to adjust the controls before the start of the regular program.



CORRECTLY ADJUSTED PICTURE AND PATTERN: Note that when the receiver is correctly adjusted, the pattern is clear and steady and in the center of the screen with five distinct shades— black, dark gray, medium gray, light gray and white.



When picture is TOO LIGHT and/or has retrace lines, adjust BRIGHTNESS CONTROL. A slight readjustment of the Contrast Control may also be necessary.

NOTE: When the control is turned to the right, the picture will balloon, that is, become larger.

If picture has TOO MUCH CONTRAST as shown, adjust CONTRAST CONTROL to show less contrast. A slight readjustment of the Brightness Control may also be necessary.

CAUTION: If the control is turned too far to the right, picture may become distorted and/or a buzzing sound may be heard. Always adjust below this point.

BRIGHTNESS

CONTRAST

CHANNEL SELECTOR

"OFF-ON-VOLUME"

"OFF-ON-VOLUME" control knob: To turn receiver on, turn knob clockwise. To turn receiver off, turn knob to left until click is heard. Use this knob to adjust volume to desired level.

TURN CHANNEL SELECTOR KNOB to desired channel.

SUBJECT: ELIMINATING SEMI-CIRCULAR SHADOW AROUND CORNER OF PATTERN

REASON: Metal ring inside Focus Magnet shifting position during shipment.

REMEDY: 1. Adjust the HEX STUD, located to the left of the focus adjustment screw, with a circular motion until semi-circular shadow is eliminated.

NOTE: The HEX STUD should be adjusted with a brass, copper, or a non-magnetic tool.

2. Adjust ION TRAP for maximum brightness.

CAUTION! DO NOT USE ION TRAP TO ELIMINATE SEMI-CIRCULAR SHADOW AROUND CORNER OF PATTERN, IF BY SO DOING THE INTENSITY OF THE RASTER IS DECREASED.

If necessary, after completing the above procedures, re-center picture withh the centering controls on the back of the chassis. DO NOT USE THE HORIZONTAL HOLD CONTROL TO CENTER PICTURE.

SUBJECT: FOLD OVER ON LEFT HAND SIDE OF PICTURE - SHOWING UP AS EITHER A WHITE POINTING TOWARDS THE CENTER OF THE PICTURE OR A FAINT MILKY-WHITE AREA EXTENDING BETWEEN THE LEFT HAND EDGE AND CENTER OF THE PICTURE.

REASON: Horizontal hold control out of adjustment. The extent of the area covered by fold-over depends upon the setting of the Horizontal Hold Control.

REMEDY: 1. Turn the Horizontal Centering Control until the left hand edge of the picture becomes visible.

2. Adjust the HORIZONTAL HOLD CONTROL TO THE POINT WHERE the fold-over just disappears. If the extreme top of the picture starts bending or jitter is noticed then adjust HORIZONTAL HOLD CONTROL for minimum fold-over with acceptable stability. To find this setting it may be necessary to readjust the HORIZONTAL LOCK CONTROL.

3. Center picture with HORIZONTAL CENTERING CONTROL-DO NOT AT ANY TIME USE THE HORIZONTAL HOLD CONTROL TO CENTER PICTURE.

DON'T DISTURB THE REAR PANEL CONTROLS UNNECESSARILY—IF THE PICTURE IS GOOD LEAVE THEM ALONE.

REAR PANEL CONTROL ADJUSTMENTS

Normally, after the receiver has been properly installed, only the front panel controls need be adjusted by the owner.

ONLY when the picture is too high or too low or too far to the right or left on the screen, or does not stay locked in the center of the screen, or is egg-shaped or very fuzzy, will it be necessary to adjust one of the rear controls.

If you experience a poor quality television picture, do not immediately assume that the difficulty is in your receiver. The cause may be due to temporary station transmitter difficulties.

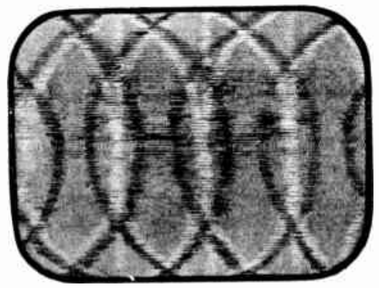
If a poor picture is noticed when a motion picture is being telecast, the difficulty may be due to the quality of the film being used by the station. Turn the "Channel Selector" knob to a different television station or wait until the end of the movie program. If there is no noticeable improvement in the picture, then adjustment of one or more of the controls on the back of the cabinet may be necessary.

Before adjusting any of the rear controls, study the picture you are receiving and compare it with one of the illustrative patterns having similar characteristics. If you find one similar to the picture you are receiving, ADJUST ONLY THE CONTROL INDICATED AS THE ONE TO BE USED to correct that particular type of mis-adjustment.

By placing a mirror in front of the cabinet it is possible to adjust the required control and still look at the screen while making the adjustment. Turn the proper control slowly to the right or left until the picture is centered on the screen, stops rolling, becomes clear, etc.

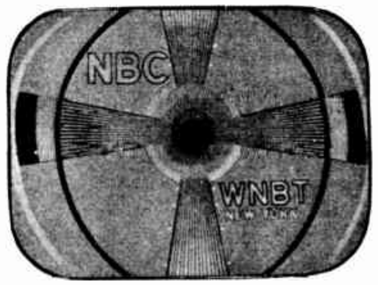
IMPORTANT: Interference caused by electrical equipment, flashing signs, auto ignition systems, electric razors and medical short-wave diathermy machines may cause white streaks or herringbone bands across the picture. Aircraft in the immediate vicinity can cause fluctuation in sound volume and picture brightness. Double images on the screen can be caused by reflections from buildings, mountains. etc. **NONE OF THESE DISTURBANCES CAN BE ELIMINATED BY ADJUSTMENT OF THE FRONT OR REAR CONTROLS.** Illustrations of these types of disturbances are shown in "Interference Patterns"

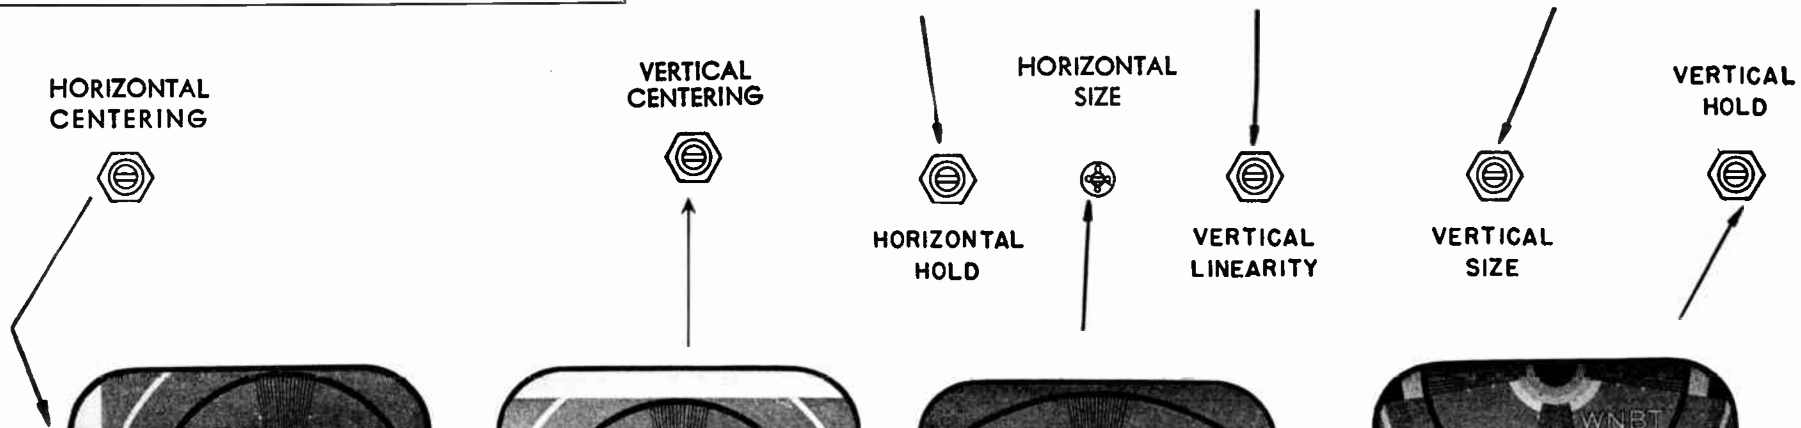
IF PATTERN continuously breaks up in horizontal direction (LEFT TO RIGHT) ACROSS SCREEN, adjust HORIZONTAL HOLD CONTROL to bring pattern to stationary position on screen.

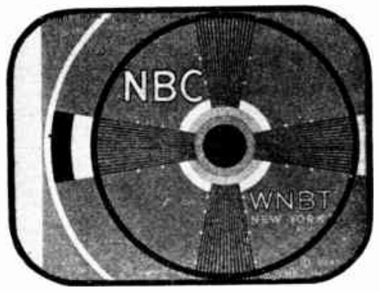


IF PATTERN is egg-shaped in vertical direction (flat on top), adjust VERTICAL LINEARITY CONTROL to make pattern round.
NOTE: If, after this adjustment, circle is round but is too small or too large, a slight adjustment of the VERTICAL SIZE will be necessary to make circle fit on screen properly.

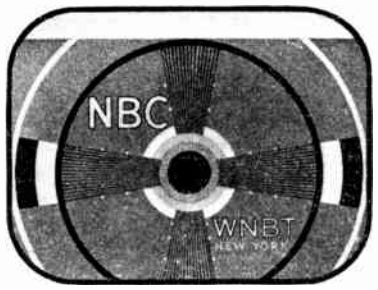
IF PATTERN extends over top and bottom of screen (too large) or is too small, in a vertical direction, adjust VERTICAL SIZE to make circle fit on screen.
NOTE: If, after this adjustment, circle is not uniformly round, a slight adjustment of the VERTICAL LINEARITY CONTROL may be necessary.





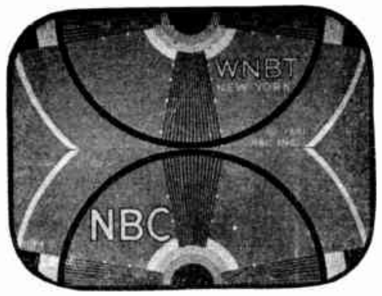


IF PATTERN IS TOO FAR TO THE RIGHT OR LEFT ON SCREEN, adjust HORIZONTAL CENTERING CONTROL to move pattern either right or left.



IF PATTERN IS TOO HIGH OR TOO LOW ON SCREEN, adjust VERTICAL CENTERING CONTROL to move pattern either up or down.

IF PATTERN extends over the right and left edge of the screen, adjust HORIZONTAL SIZE CONTROL to make circle fit on screen.



IF PATTERN continuously rolls across screen in vertical direction (up or down) ADJUST VERTICAL HOLD CONTROL so that pattern stops rolling and remains stationary on screen.

NOTE: IF PATTERN IS FUZZY, insert a screwdriver (non-magnetic preferably) into the hole in the cap on the cabinet back and adjust FOCUS CONTROL SCREW for sharpest definition.

World Radio History

SERVICE NOTES

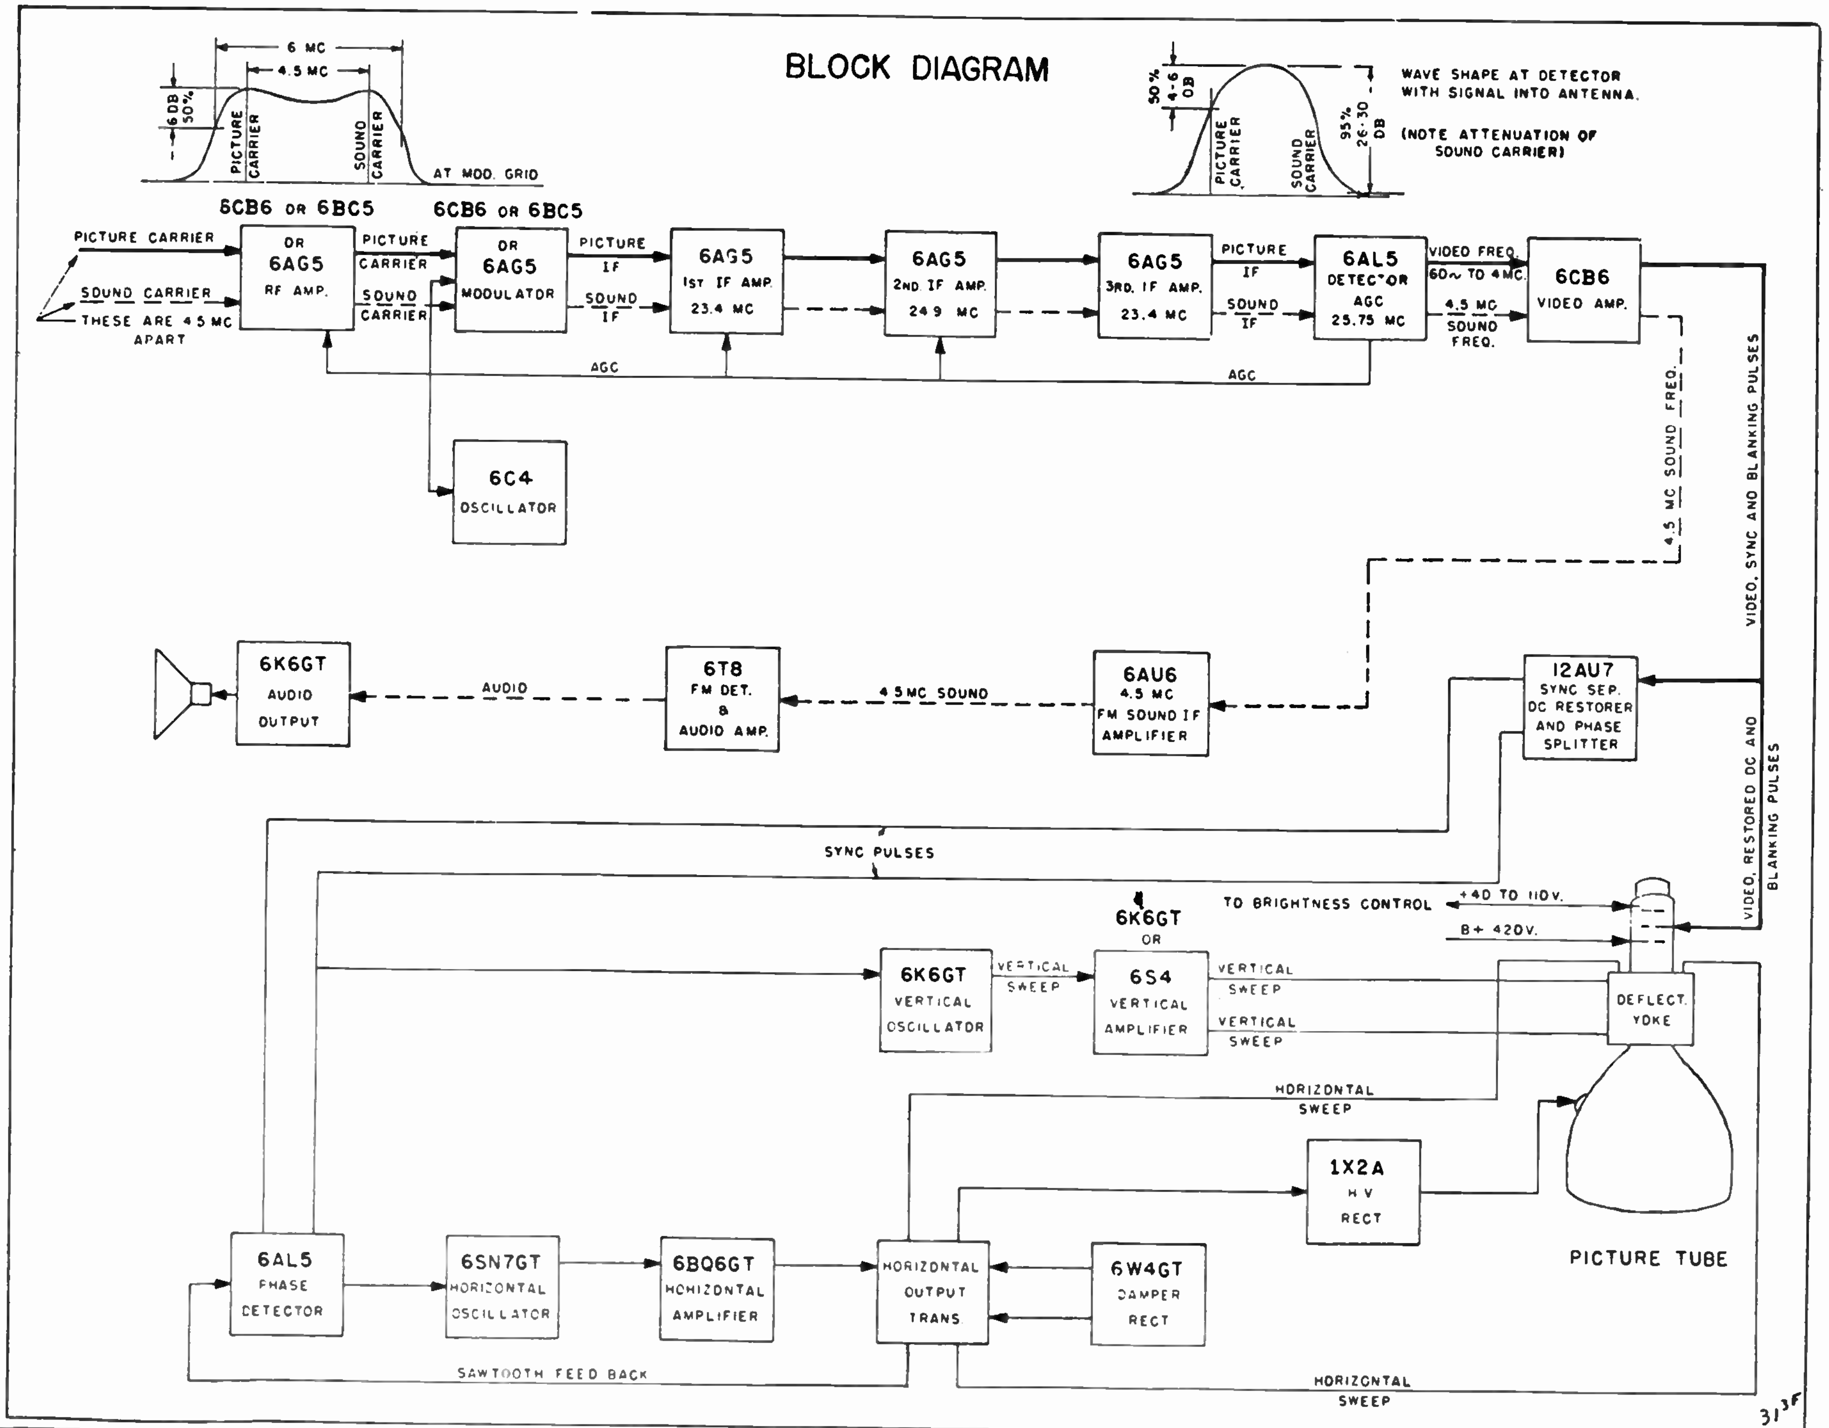
HIGH VOLTAGE WARNING

This television receiver contains high voltages which are dangerous to life or may result in serious burns. Never operate or service the receiver outside of the cabinet or with the high voltage shield cover removed until all the safety precautions necessary for working with high voltage equipment have been observed.

PICTURE TUBE

HANDLING PRECAUTION

Shatterproof goggles and heavy gloves must be worn by individuals while handling or installing the picture tube into the receiver. The picture tube encloses a high vacuum and is subjected to excessive air pressure. HANDLE WITH EXTREME CARE—do not strike or scratch the tube nor subject it to more than moderate pressure when inserting into or removing from its socket. Breakage and the resulting implosion may result in damage to property or injury to an individual.



CHECKING CHANNEL ADJUSTMENTS

WHILE EACH RECEIVER IS CORRECTLY ALIGNED AT THE FACTORY, ROUGH HANDLING in transit, ageing, drift, etc., MAY THROW THE RECEIVER OFF, so we suggest that the proper oscillator trimmers and the discriminator secondary adjustment—be checked for correct adjustment with a transmitted television station pattern, in the customer's home at the time of installation. Be sure to have the set operating for one-half to one hour before making these adjustment checks.

TO CHECK OSCILLATOR TRIMMER ADJUSTMENTS:

(A) Remove the Channel Switch Knob and Contrast Control Knob. This will expose the Oscillator Trimmer adjustment screws located around the Channel Selector Switch Shaft.

The channel number is marked alongside of each Oscillator Trimmer adjustment screw.

The extra adjustment screw located above the Channel 13 adjustment screw is to be used only in case there is not enough range to any oscillator adjustment screw in the Channel 7 to 13 range. If this screw is touched, then all channels from 7 to 13 will have to be re-**checked.**

(B) Turn receiver Channel Selector Switch to channel on which TV station is transmitting its modulated test pattern and adjust "Contrast" and "Brightness" control for best definition of pattern. IMPORTANT—There are 14 positions on the Channel Selector Switch. The MAXIMUM RIGHT and LEFT positions are NOT USED.

(C) Turn proper Oscillator Trimmer adjustment Screw clockwise until sound appears on pattern—indicated by bars across pattern and/or the lower vertical lines in pattern becoming wavy—then turn SAME Oscillator Trimmer adjustment screw counter-clockwise just to the point where the sound bars and/or wavy lines in pattern disappear.

IF STATION BUZZ is excessive and is NOT DUE to "Contrast" control being too far advanced in clockwise direction, adjust Discriminator Secondary adjustment screw for MINIMUM buzz. MAKE SURE THAT THIS POSITION IS BETWEEN the two MAXIMUM buzz peaks that will be noticed when adjusting screw is turned to the right and left of the MINIMUM buzz position. This screw is located on top of the **Discriminator** Coil Shield Can which is mounted between 6T8 Sound Detector tube and 6AU6 Sound I.F. Amplifier tube.

RADIO FREQUENCY RANGES

Channel Number	Channel Freq. (Mc)	Picture Carrier Freq. (Mc)	Sound Carrier Freq. (Mc)
2	54-60	55.25	59.75
3	60-66	61.25	65.75
4	66-72	67.25	71.25
5	76-82	77.25	81.75
6	82-88	83.25	87.75
7	174-180	175.25	179.75
8	180-186	181.25	185.75
9	186-192	187.25	191.75
10	192-198	193.25	197.75
11	198-204	199.25	203.75
12	204-210	205.25	209.75
13	210-216	211.25	215.75

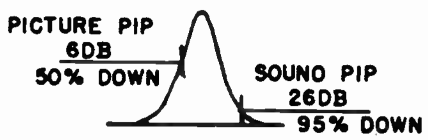
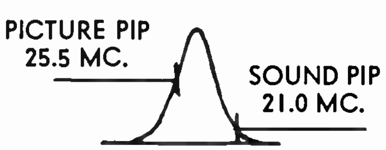
ALIGNMENT CURVES



PICTURE OVERALL RESPONSE CURVE WITH PICTURE AND SOUND CARRIER MARKER PIPS.

FIG. 2



PICTURE I.F. RESPONSE CURVE WITH PICTURE AND SOUND CARRIER MARKER PIPS.

FIG. 3

ALIGNMENT TABLE

Required equipment:

VACUUM TUBE VOLTMETER having a 5 volt and a 10 volt range.

SIGNAL GENERATOR supplying 4.5 M.C. (within .25%), 20 to 30 M.C. and 50 to 216 M.C. (within 1%) signals.

MODULATOR TUBE ADAPTER (Part No. AD6AG5) using 1½ volt battery as shown in Figure 7.

SWEEP GENERATOR capable of covering 20 to 30 M.C. and 50 to 216 M.C. with a 10 M.C. sweep.

4.5 VOLT "A" BATTERY to provide fixed bias during video I.F. alignment.

DISCRIMINATOR AND SOUND I-F ALIGNMENT

Step No.	Connect Signal Generator to	Signal Gen. Freq. MC	Connect Sweep Generator to	Sweep Gen. Freq. MC	Connect Oscilloscope to	Connect Voltmeter to	Miscellaneous Connections and Instructions	Adjust
1	In series with .01 Mfd. to junction of L-5 and C-20. See Fig. 5	4.5	Not used		Not used	In series with 47,000 ohm resistor and across C-39. See Fig. 5	Meter on 5 volt scale and maintain 3 volt reading	T-6 (top) and T-7 (bottom) for max. on meter. See Figs. 4 and 5
2	In series with .01 Mfd. to junction of L-5 and C-20. See Fig. 5	4.5	Not used		Not used	Center of R-14 and R-23 and to tie lug strip end of R-33. See Fig. 5	Meter on 10 volt scale	T-7 (top) for zero on meter. See Fig. 4

NOTE 1: For minimum buzz always adjust T-7 adjustment screw with the sound carrier of a TV station.

PICTURE I-F ALIGNMENT

Step No.	Connect Signal Generator to	Signal Gen. Freq. MC	Connect Sweep Generator to	Sweep Gen. Channel	Connect Oscilloscope to	Connect Voltmeter to	Miscellaneous Connections and Instructions	Adjust
3	Adapter and connect adapter to pin #1 on Mod. Tube. See Fig. 7	25.75	Not used		Not used	In series with 47,000 ohm resistor and across R-43 diode load. See Fig. 5. Contrast control at minimum position.	Connect a 4.5 volt battery, positive side to ground, across C-44. Meter on 5 volt scale and maintain 1 volt reading.	T-5 for maximum reading. See Fig. 4
4	Adapter and connect adapter to pin #1 on Mod. Tube. See Fig. 7	24.9	Not used		Not used	In series with 47,000 ohm resistor and across R-43 diode load. See Fig. 5. Contrast control at minimum position.	Connect a 4.5 volt battery, positive side to ground, across C-44. Meter on 5 volt scale and maintain 1 volt reading.	T-3 for maximum reading. See Fig. 4
5	Adapter and connect adapter to pin #1 on Mod. Tube. See Fig. 7	23.4	Not used		Not used	In series with 47,000 ohm resistor and across R-43 diode load. See Fig. 5. Contrast control at minimum position.	Connect a 4.5 volt battery, positive side to ground, across C-44. Meter on 5 volt scale and maintain 1 volt reading.	T-4 and T-2 for maximum reading. See Fig. 4

NOTE 2: For visual check of I.F. curve (see fig. 3) connect Sweep Generator to adapter and Oscilloscope across R-43.

PICTURE R-F OSCILLATOR ADJUSTMENT — VISUAL

Step No.	Connect Signal Generator to	Signal Gen. Freq. MC	Connect Sweep Generator to	Sweep Gen. Channel	Connect Oscilloscope to	Connect Voltmeter to	Miscellaneous Connections and Instructions	Adjust
6	Loosely couple to sweep Gen. leads	55.25 see fig. 1	300 ohm ant. terminals	2	Across R-43 diode load. See Fig. 5	Not used	Channel switch on channel 2 Adjust Sig. Gen. output for min. distortion of sweep curve	#2 trimmer (fig. 6) so that marker pip is 6 DB (50%) down from top of curve. See Fig. 2
7	Loosely couple to sweep Gen. leads	59.75 see fig. 1	300 ohm ant. terminals	2	Across R-43 diode load. See Fig. 5	Not used	Check pip. Should be 26DB (95%) down on opposite side of curve. See Fig. 2	Repeat step 5 if pip position is not correct
8	Repeat Steps 6 and 7 to Align Channels 3 to 13 Using Correct Frequency (See Fig. 1) and Oscillator Trimmer for Each Channel Being Aligned							

NOTE 3: This trimmer (see fig. 6) is to be used only in case there is not enough range to any oscillator screw from channels 7 to 13. If this screw is touched, then all channels from 7 to 13 will have to be rechecked. If insufficient range is still encountered, proceed as outlined in Note 4.

NOTE 4: Oscillator Padder adjustment screw (see fig. 6) should be used when there is not enough range to any one oscillator trimmer. Adjusting the Padder will necessitate the realignment of all the Oscillator Trimmers.

PICTURE R-F OSCILLATOR ADJUSTMENT — ALTERNATE (USING T.V. STATION TEST PATTERN)

Step No.	Connect Signal Generator to	Signal Gen. Freq. MC	Connect Sweep Generator to	Sweep Gen. Freq. MC	Connect Oscilloscope to	Connect Voltmeter to	Miscellaneous Connections and Instructions	Adjust
9	Not used		Not used		Not used	Not used	Turn channel switch to channel needing alignment	Proper osc. trimmer clockwise until sound bars appear on pattern; then Lack-off trimmer until sound bars disappear and best resolution is obtained. See Fig. 6
10	REPEAT STEP 9 FOR ANY OTHER CHANNELS NEEDING ALIGNMENT

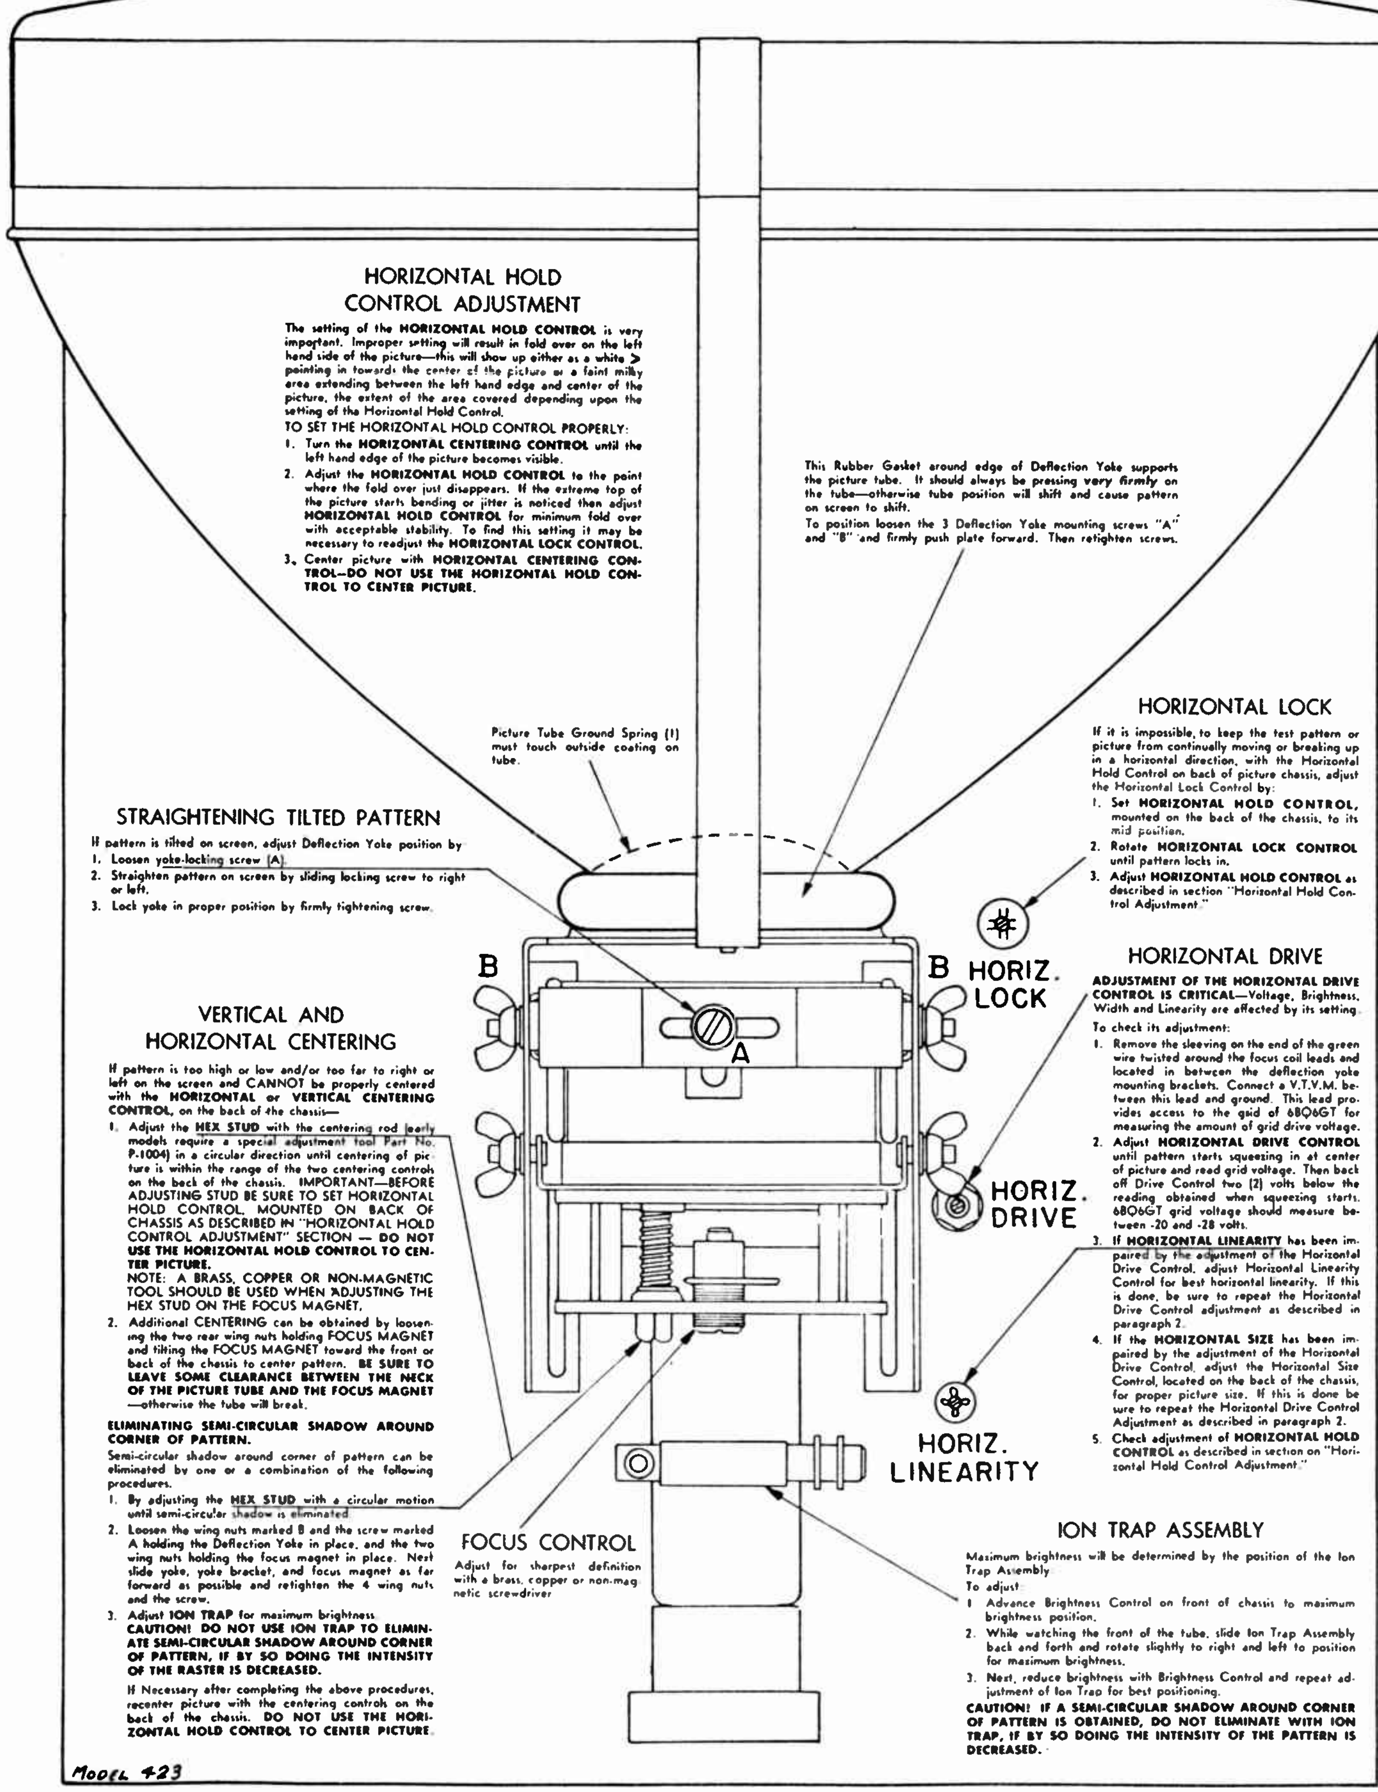
World Radio History



HORIZONTAL HOLD CONTROL ADJUSTMENT

The setting of the **HORIZONTAL HOLD CONTROL** is very important. Improper setting will result in fold over on the left hand side of the picture—this will show up either as a white > pointing in towards the center of the picture or a faint milky area extending between the left hand edge and center of the picture, the extent of the area covered depending upon the setting of the Horizontal Hold Control.

TO SET THE HORIZONTAL HOLD CONTROL PROPERLY:

1. Turn the **HORIZONTAL CENTERING CONTROL** until the left hand edge of the picture becomes visible.
2. Adjust the **HORIZONTAL HOLD CONTROL** to the point where the fold over just disappears. If the extreme top of the picture starts bending or jitter is noticed then adjust **HORIZONTAL HOLD CONTROL** for minimum fold over with acceptable stability. To find this setting it may be necessary to readjust the **HORIZONTAL LOCK CONTROL.**
3. Center picture with **HORIZONTAL CENTERING CONTROL—DO NOT USE THE HORIZONTAL HOLD CONTROL TO CENTER PICTURE.**

STRAIGHTENING TILTED PATTERN

If pattern is tilted on screen, adjust Deflection Yoke position by

1. Loosen yoke-locking screw (A).
2. Straighten pattern on screen by sliding locking screw to right or left.
3. Lock yoke in proper position by firmly tightening screw.

VERTICAL AND HORIZONTAL CENTERING

If pattern is too high or low and/or too far to right or left on the screen and CANNOT be properly centered with the **HORIZONTAL or VERTICAL CENTERING CONTROL**, on the back of the chassis—

1. Adjust the **HEX STUD** with the centering rod (early models require a special adjustment tool Part No. P-1004) in a circular direction until centering of picture is within the range of the two centering controls on the back of the chassis. IMPORTANT—BEFORE ADJUSTING STUD BE SURE TO SET HORIZONTAL HOLD CONTROL, MOUNTED ON BACK OF CHASSIS AS DESCRIBED IN "HORIZONTAL HOLD CONTROL ADJUSTMENT" SECTION — **DO NOT USE THE HORIZONTAL HOLD CONTROL TO CENTER PICTURE.**
   NOTE: A BRASS, COPPER OR NON-MAGNETIC TOOL SHOULD BE USED WHEN ADJUSTING THE HEX STUD ON THE FOCUS MAGNET.
2. Additional CENTERING can be obtained by loosening the two rear wing nuts holding FOCUS MAGNET and tilting the FOCUS MAGNET toward the front or back of the chassis to center pattern. **BE SURE TO LEAVE SOME CLEARANCE BETWEEN THE NECK OF THE PICTURE TUBE AND THE FOCUS MAGNET** —otherwise the tube will break.

ELIMINATING SEMI-CIRCULAR SHADOW AROUND CORNER OF PATTERN.

Semi-circular shadow around corner of pattern can be eliminated by one or a combination of the following procedures.

1. By adjusting the **HEX STUD** with a circular motion until semi-circular shadow is eliminated.
2. Loosen the wing nuts marked B and the screw marked A holding the Deflection Yoke in place, and the two wing nuts holding the focus magnet in place. Next slide yoke, yoke bracket, and focus magnet as far forward as possible and retighten the 4 wing nuts and the screw.
3. Adjust **ION TRAP** for maximum brightness.
   CAUTION! DO NOT USE ION TRAP TO ELIMINATE SEMI-CIRCULAR SHADOW AROUND CORNER OF PATTERN, IF BY SO DOING THE INTENSITY OF THE RASTER IS DECREASED.

If Necessary after completing the above procedures, recenter picture with the centering controls on the back of the chassis. **DO NOT USE THE HORIZONTAL HOLD CONTROL TO CENTER PICTURE.**

FOCUS CONTROL

Adjust for sharpest definition with a brass, copper or non-magnetic screwdriver

HORIZONTAL LOCK

If it is impossible, to keep the test pattern or picture from continually moving or breaking up in a horizontal direction, with the Horizontal Hold Control on back of picture chassis, adjust the Horizontal Lock Control by:

1. Set **HORIZONTAL HOLD CONTROL,** mounted on the back of the chassis, to its mid position.
2. Rotate **HORIZONTAL LOCK CONTROL** until pattern locks in.
3. Adjust **HORIZONTAL HOLD CONTROL** as described in section "Horizontal Hold Control Adjustment."

HORIZONTAL DRIVE

ADJUSTMENT OF THE HORIZONTAL DRIVE CONTROL IS CRITICAL—Voltage, Brightness, Width and Linearity are affected by its setting.

To check its adjustment:

1. Remove the sleeving on the end of the green wire twisted around the focus coil leads and located in between the deflection yoke mounting brackets. Connect a V.T.V.M. between this lead and ground. This lead provides access to the grid of 6BQ6GT for measuring the amount of grid drive voltage.
2. Adjust **HORIZONTAL DRIVE CONTROL** until pattern starts squeezing in at center of picture and read grid voltage. Then back off Drive Control two (2) volts below the reading obtained when squeezing starts. 6BQ6GT grid voltage should measure between -20 and -28 volts.
3. If **HORIZONTAL LINEARITY** has been impaired by the adjustment of the Horizontal Drive Control, adjust Horizontal Linearity Control for best horizontal linearity. If this is done, be sure to repeat the Horizontal Drive Control adjustment as described in paragraph 2.
4. If the **HORIZONTAL SIZE** has been impaired by the adjustment of the Horizontal Drive Control, adjust the Horizontal Size Control, located on the back of the chassis, for proper picture size. If this is done be sure to repeat the Horizontal Drive Control Adjustment as described in paragraph 2.
5. Check adjustment of **HORIZONTAL HOLD CONTROL** as described in section on "Horizontal Hold Control Adjustment."

ION TRAP ASSEMBLY

Maximum brightness will be determined by the position of the Ion Trap Assembly.

To adjust:

1. Advance Brightness Control on front of chassis to maximum brightness position.
2. While watching the front of the tube, slide Ion Trap Assembly back and forth and rotate slightly to right and left to position for maximum brightness.
3. Next, reduce brightness with Brightness Control and repeat adjustment of Ion Trap for best positioning.

CAUTION! IF A SEMI-CIRCULAR SHADOW AROUND CORNER OF PATTERN IS OBTAINED, DO NOT ELIMINATE WITH ION TRAP, IF BY SO DOING THE INTENSITY OF THE PATTERN IS DECREASED.

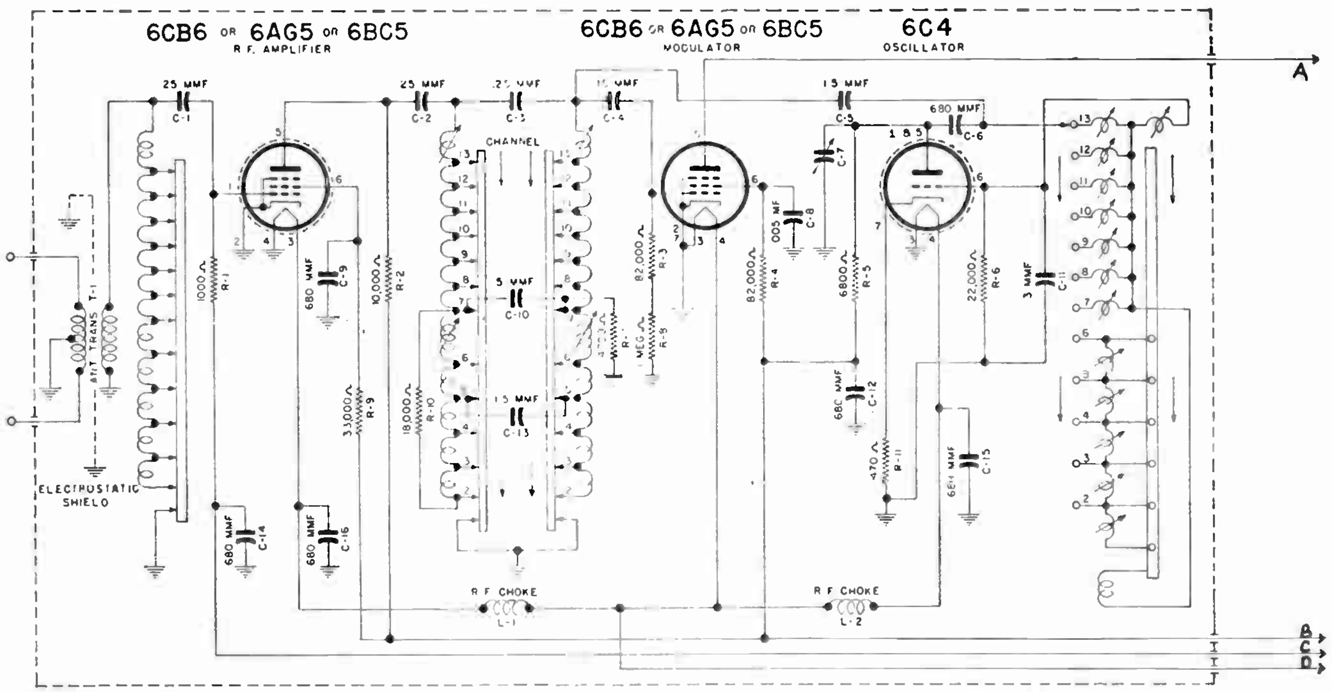
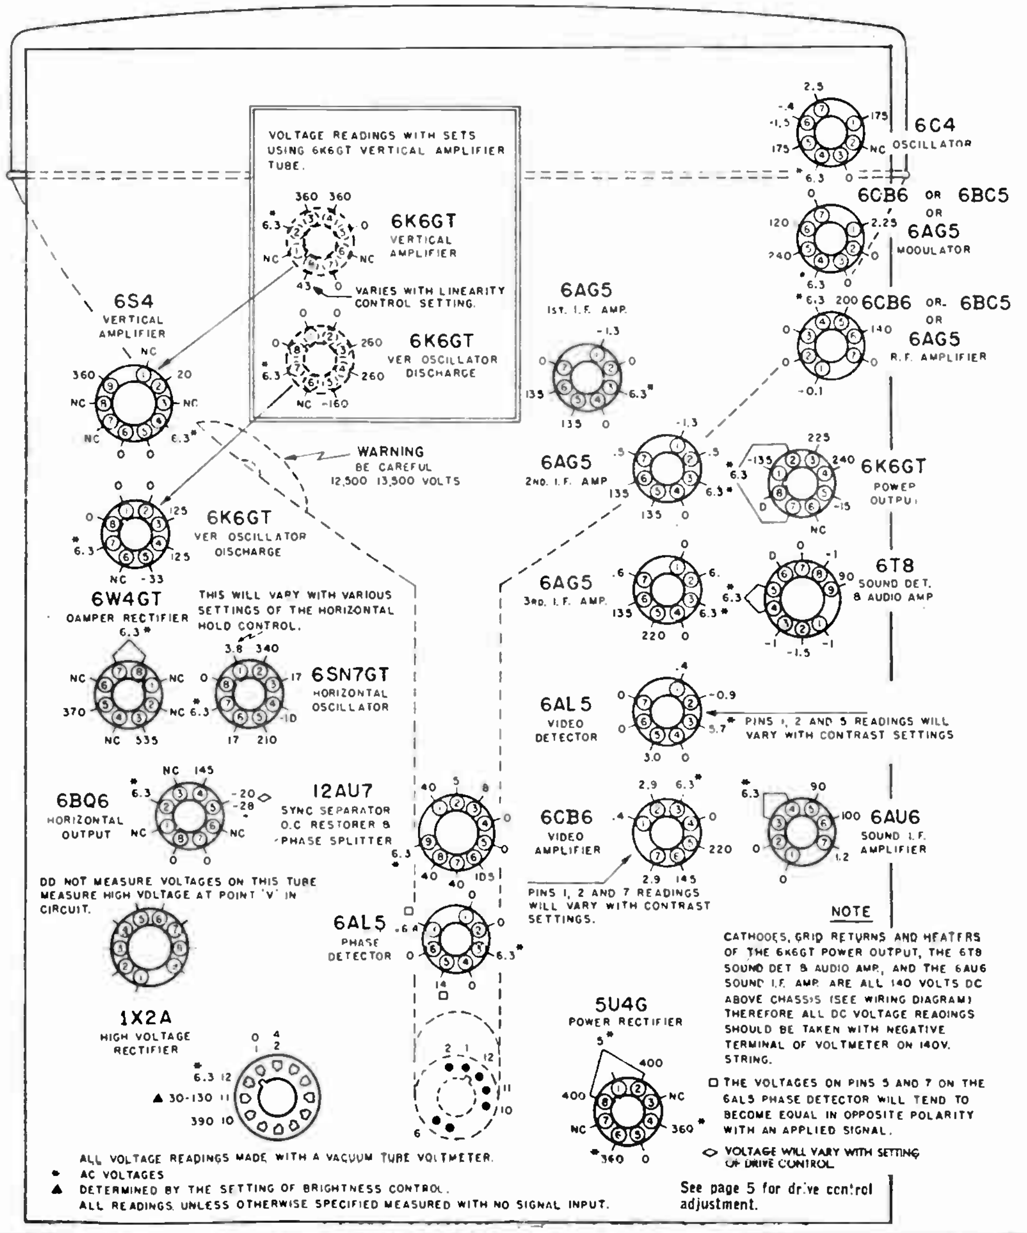
CABINET MISCELLANEOUS

Our Part No.	DESCRIPTION
20E546-13	Cabinet Back Assembly with line cord for Model 420B
20E546-10	Cabinet Back Assembly with line cord for Model 423
20E546-11	Cabinet Back Assembly with line cord for Model 424
9E34	Safety Glass, for Model 420B Mahogany
9E39	Safety Glass, for Model 423 Mahogany
9E39-2	Safety Glass, for Model 423 Blonde
9E36	Safety Glass, for Model 424
36E62-2	Mask, for Model 420B Mahogany
36E62-3	Mask, for Model 423 Mahogany
36E62-4	Mask, for Model 423 Blonde
36E69	Mask, for Model 424 Mahogany & Blonde
33E85	Gasket, Rubber for Mask—44 Inches
48E16	Escutcheon for Safety Glass, for Model 424
20E544-3	**Knob Assembly,** Channel Switch, for Models 420B, 423 & 424 Mahogany
20E544-6	**Knob Assembly,** Channel Switch, for Models 423 & 424 Blonde
20E545-3	**Knob Assembly,** Off-On-Vol., for Models 420B, 423 & 424 Mahogany
20E545-6	**Knob Assembly,** Off-On-Vol., for Models 423 & 424 Blonde
37E59-6	**Knob,** Channel Switch, Less Metal Plate, for Models 420B, 423 & 424 Mahogany
37E59	**Knob,** Channel Switch, Less Metal Plate, for Models 423 & 424 Blonde
37E59-5	**Knob,** Off-On-Vol., Less Metal Plate, for Models 420B, 423 & 424 Mahogany
37E59-11	**Knob,** Off-On-Vol., Less Metal Plate, for Models 423 & 424 Blonde
37E67	**Knob,** Contrast, for Model 420B Mahogany
37E67-7	**Knob,** Contrast, for Models 423 & 424 Mahogany & Blonde
37E67-2	**Knob,** Brightness, for Model 420B Mahogany
37E67-8	**Knob,** Brightness, for Models 423 & 424 Mahogany & Blonde
36E57-2	Metal Plate, for Channel Switch Knob
36E58-2	Metal Plate, for Off-On-Vol. Knob
20E550-4	Built-in Antenna Assembly for Model 423
30E154-4	Trimmer and Shaft Assembly, consists of shaft assembled to trimmer condenser for 20E550-4 Antenna
20E550	Built-in Antenna Assembly for Models 420B and 424
30E154	Trimmer and Shaft Assembly, consists of 9" shaft assembled to trimmer condenser for 20E550 Antenna
37E61	**Knob,** Antenna for Model 423 Mahogany
37E61-2	**Knob,** Antenna for Model 423 Blonde
37E62	**Knob,** Antenna for Models 420B Mahogany and 424 Mahogany and Blonde





NOTE: A 6CB6 or 6AG5 or 6BC5 is used in the R. F. amplifier and modulator tube sockets. Always use the same type tube for replacement. Intermixing these tubes may result in loss in sensitivity caused by the differences in tube capacities detuning the circuits and making it necessary to realign the R. F. amplifier and modulator stages by spreading or squeezing turns on the coils. The 6CB6 cannot be used in the video I. F. amplifier stages.

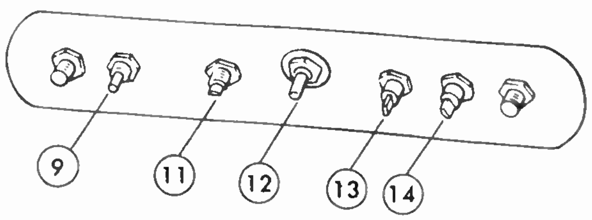
ADDITIONAL TV CONTROLS

The sensitivity of your TV set may be disturbed while being moved, or after the set has been in operation for a long time. The following adjustments can be made by you, or call your dealer for service.

Remove knobs on Brightness and Contrast Dials by pulling toward you. Remove plate (imprinted with Setchell-Carlson name). This is the TV Adjustment Panel:



All controls turn clockwise and counter-clockwise.

FOR BEST RESULTS, ADJUST DURING TEST PATTERN TIME.

9. HORIZONTAL HOLD—When properly adjusted, picture will come to lock-in position from bottom, not from either side. Rotate channel selector off and on station and watch direction that picture locks in.

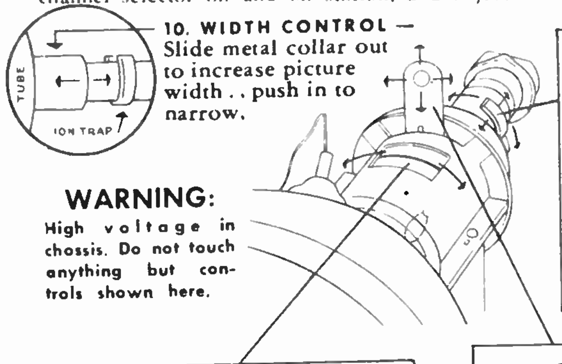
10. WIDTH CONTROL—Located on neck of picture tube. See next page.

11. VERTICAL LINEARITY—Spreads or contracts top portion of picture. Adjust during test pattern time.

12. FOCUS—Before adjusting focus control, set brightness and contrast to normal operating condition, then adjust for sharpest picture.

13. HEIGHT CONTROL—Varies the overall height of the picture. Adjust in connection with No. 11 (Vertical linearity) during test pattern time. Be sure centering control (rear of chassis) is properly adjusted before adjusting height.

14. VERTICAL HOLD—Stops up or down movement of picture. Rotate channel selector off and on station, and adjust for fastest lock-in.



10. WIDTH CONTROL — Slide metal collar out to increase picture width . . push in to narrow.

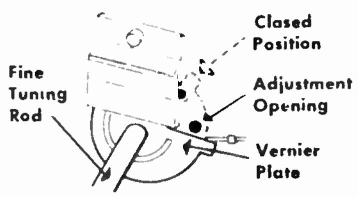
17. ION TRAP—Slowly rotate and slide for brightest picture with level horizontal lines without shadows. (Note: This adjustment is extremely critical and picture will completely disappear when improperly adjusted.)

WARNING:

High voltage in chassis. Do not touch anything but controls shown here.

15. HORIZONTAL PICTURE LEVELER—If picture tilts, rotate with finger until level.

16. PICTURE CENTERING CONTROL—Move horizontally and vertically until picture is properly centered on screen.



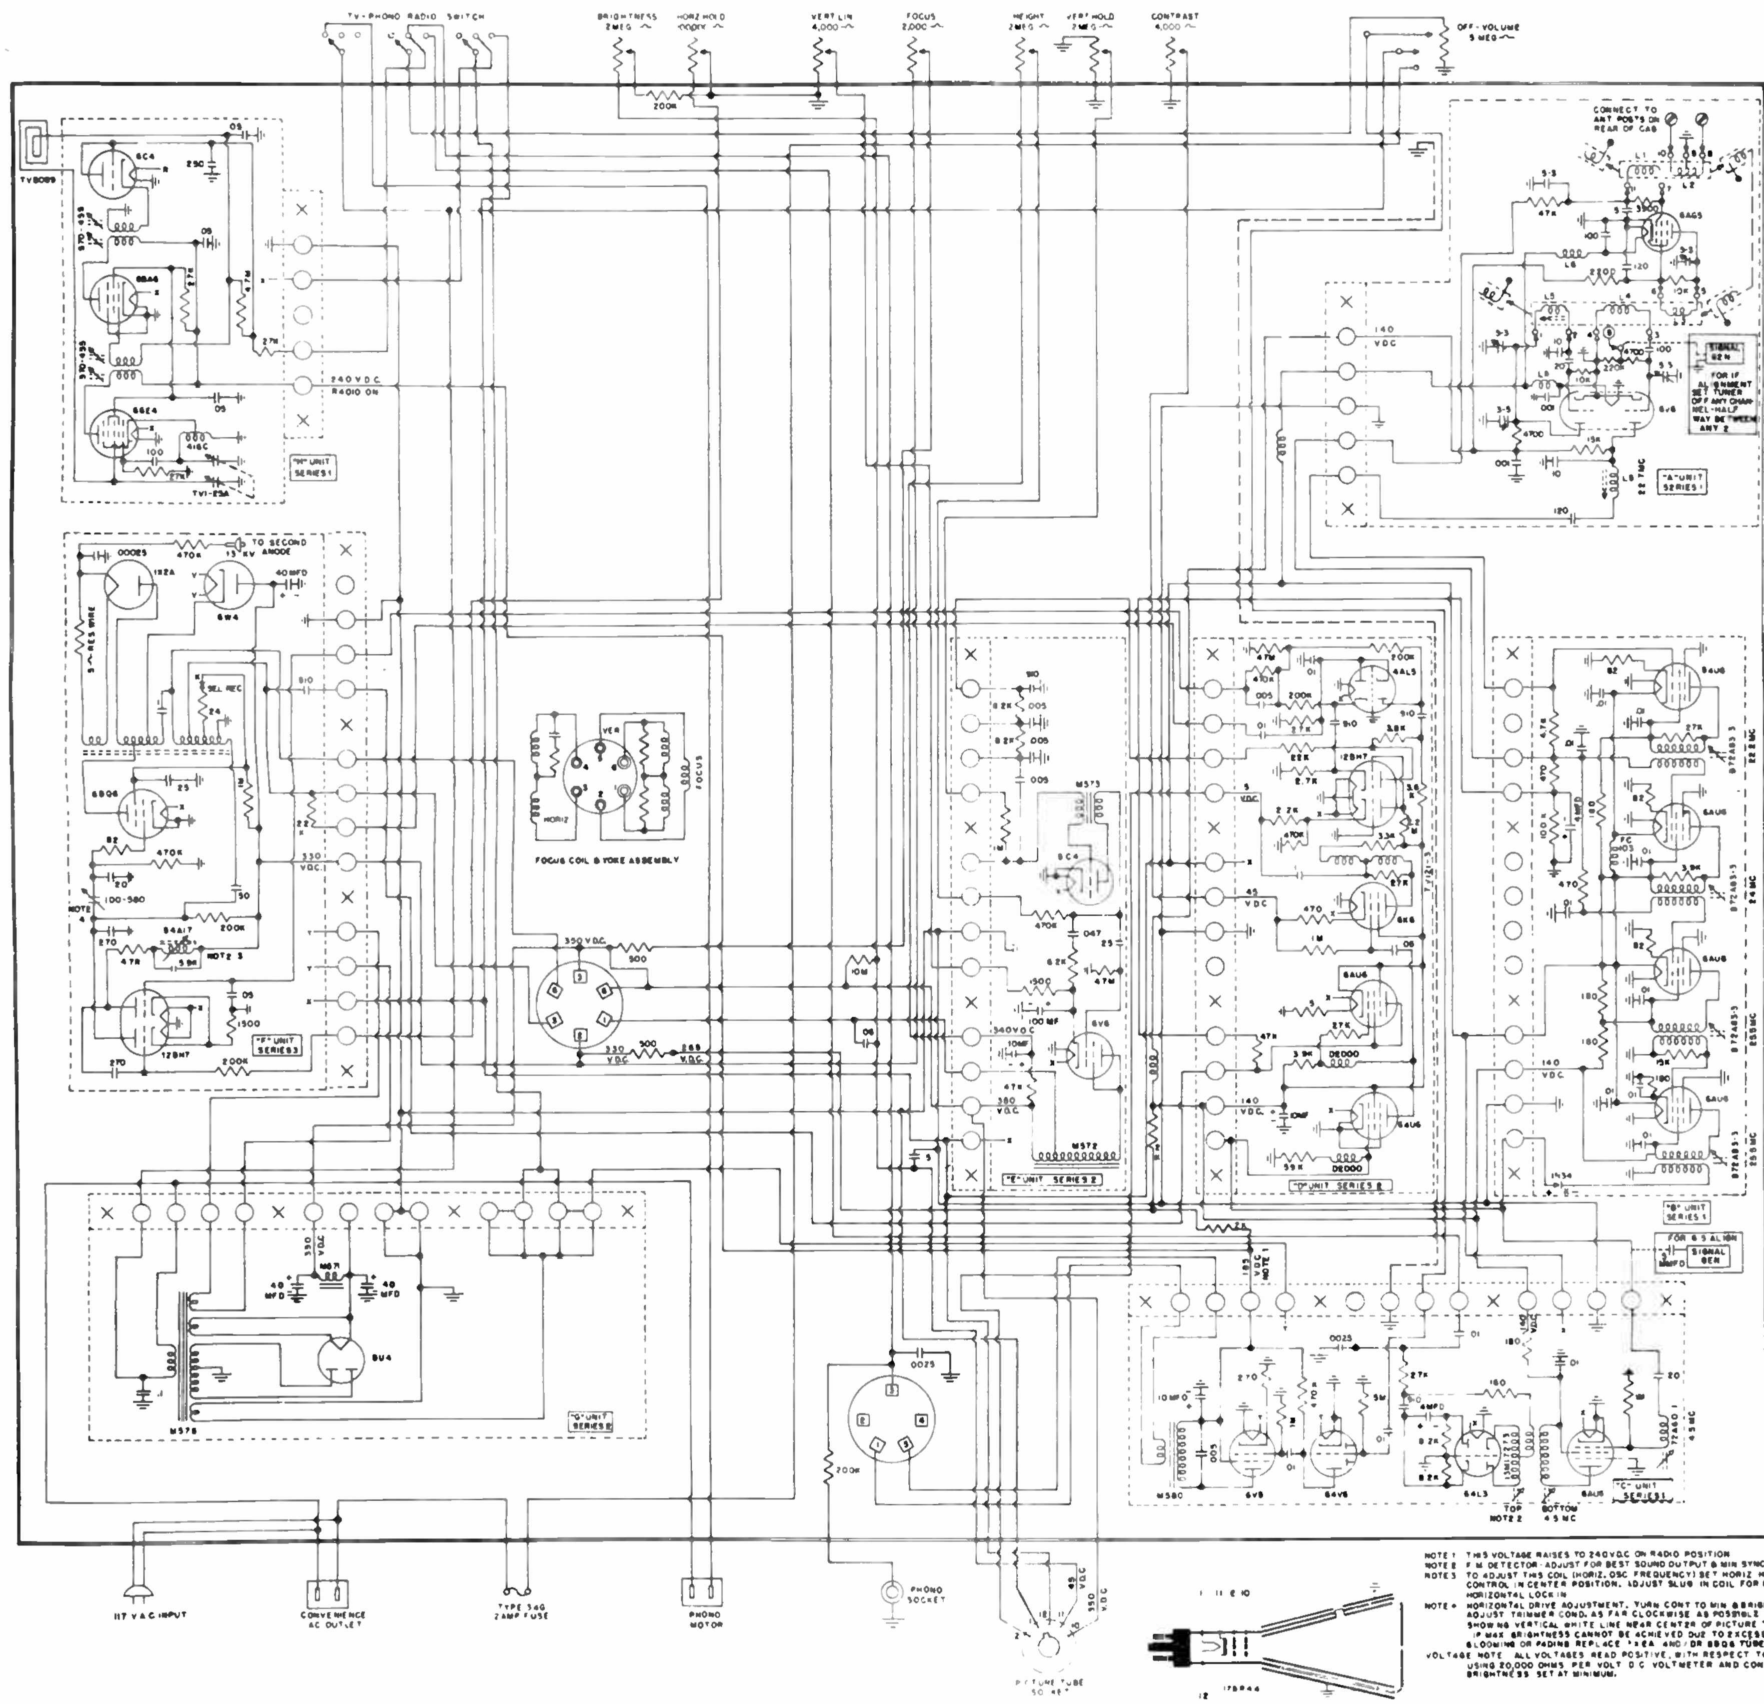
← This is what you see.

Turn fine tuning rod to left or right until the vernier plate is in the position shown, which uncovers the adjustment opening. Place a small screw driver through opening and adjust screw *slightly*, clockwise or counter-clockwise, until picture clears. CAUTION: DO NOT TURN MORE THAN 1½ TURNS EITHER WAY.

Remove screw driver and turn fine tuning rod until vernier plate is in closed position. If picture shows a slight sparkle at this point, adjustment is correct. This operation should be repeated for all channels being used for Telecasting in your locality.

IMPORTANT

If using the Fine Tuning Lever materially disturbs your picture on any channel, or if your sound is not clear, it may be necessary to adjust the fine tuning. Turn the channel selector to the affected channel. Remove the channel selector dial and fine tuning lever by pulling toward you. Then remove the channel selector plate.

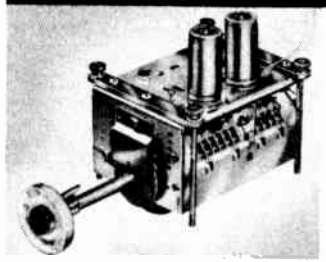


NOTE 1 THIS VOLTAGE RAISES TO 240 V.D.C. ON RADIO POSITION
NOTE 2 F.M. DETECTOR - ADJUST FOR BEST SOUND OUTPUT & MIN SYNC BUZZ
NOTE 3 TO ADJUST THIS COIL (HORIZ. OSC FREQUENCY) SET HORIZ HOLD CONTROL IN CENTER POSITION. ADJUST SLUG IN COIL FOR BEST HORIZONTAL LOCK IN
NOTE 4 HORIZONTAL DRIVE ADJUSTMENT. TURN CONT TO MIN & BRIGHT. TO MAX. ADJUST TRIMMER COND. AS FAR CLOCKWISE AS POSSIBLE WITHOUT SHOWING VERTICAL WHITE LINE NEAR CENTER OF PICTURE TUBE. IF MAX BRIGHTNESS CANNOT BE ACHIEVED DUE TO EXCESSIVE BLOOMING OR FADING REPLACE 1B3GT AND/OR 6BG6 TUBES.
VOLTAGE NOTE ALL VOLTAGES READ POSITIVE, WITH RESPECT TO CHASSIS, USING 20,000 OHMS PER VOLT D.C. VOLTMETER AND CONTRAST & BRIGHTNESS SET AT MINIMUM.

©John F. Rider

World Radio History

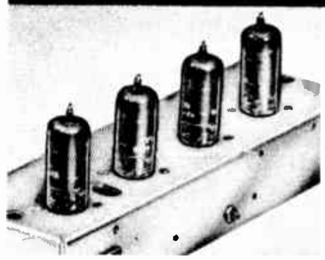
UNIT A - TV CHANNEL SELECTOR



12 channel (2-13 inclusive) with vernier tuning.

Tubes:
1 - 6AG5 RF Amplifier
1 - 6J6 Oscillator-Modulator

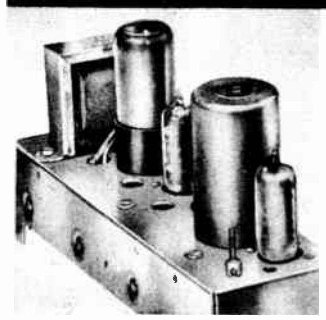
UNIT B - IF AMPLIFIER



4 stages of IF, staggered - tuned, plus germanium crystal detector.

Tubes:
4 - 6AU6

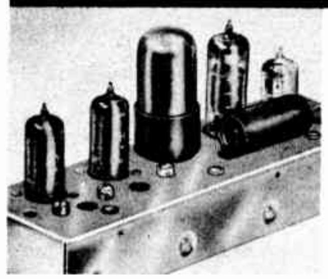
UNIT C - SOUND AMPLIFIER



1 stage of sound IF amplification - 4.5 MC. Ratio detector, 1st & 2nd audio amplifiers and output transformer.

Tubes:
1 - 6AU6 IF Amplifier
1 - 6AL5 Sound Detector
1 - 6AV6 1st Audio Amplifier
1 - 6V6GT Power Output

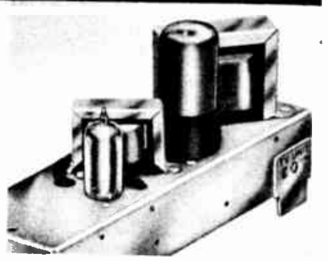
UNIT D - VIDEO AMPLIFIER - A.G.C. - SYNC SEPARATOR



2 stages of video amplification — combined sync-separator & D.C. restorer. Sync-amplifier and horizontal phase detector. Keyed A.G.C. amplifier.

1 - 6AU6 1st video amplifier
1 - 6AU6 Keyed A.G.C. amplifier
1 - 6K6 2nd video amplifier
1 - 12BH7 Sync-separator - D.C. restorer - amplifier
1 - 6AL5 Horizontal phase detector

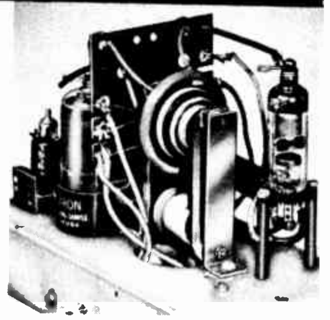
UNIT E - VERTICAL SWEEP AMPLIFIER



A stable vertical oscillator with power output stage and noise disintegrator.

Tubes:
1 - 6C4 Blocking oscillator
1 - 6V6GT power output

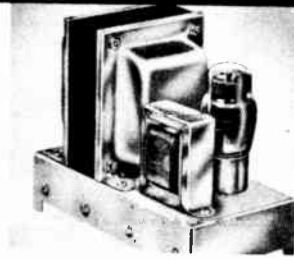
UNIT F - HORIZONTAL SWEEP AMPLIFIER



A stable horizontal oscillator driving an output tube in a fly-back circuit producing approximately 11 KV for picture tube.*

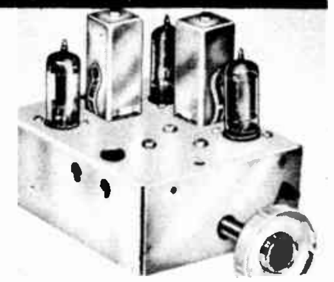
Tubes:
1 - 12BH7 Oscillator
1 - 6BQ6 Power output
1 - 6W4 Damper and
1 - 1X2 HV Rectifier

UNIT G - MAIN POWER SUPPLY



An oversized power transformer which in combination with a rectifier supplies all of the filament and filtered plate voltage.
1 - 5U4G Rectifier

UNIT H - A.M. RADIO TUNER

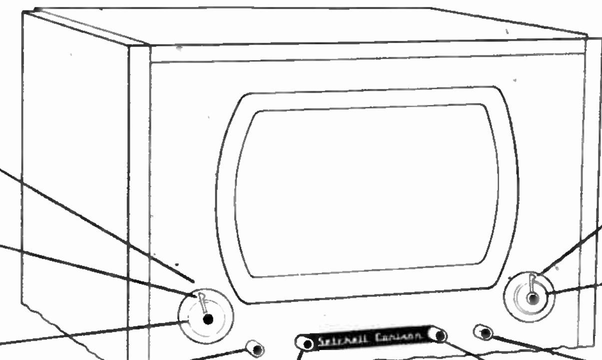


A superheterodyne tuner-535KC to 1650KC. Selective iron-core IF's 456KC. in conjunction with built-in loop antenna and perfect voltage supply, produce exceptional performance.

1 - 6BE6 Mixer
1 - 6BA6 IF amplifier
1 - 6C4 Detector

Radio in operation uses Main Power Supply and 2 tubes of Unit C.

VISIBLE TV AND RADIO TUNING DIALS



AM RADIO CONTROLS

1. SPEED TUNER FOR LOCATING RADIO STATIONS ON DIAL

2. FINER TUNING DIAL FOR EXACT TUNING OF RADIO STATIONS

3. SELECTOR FOR TV, RADIO, OR PHONOGRAPH

4. TV BRIGHTNESS CONTROL DIAL (TURN CLOCKWISE TO INCREASE PICTURE BRIGHTNESS)

5. TV CONTRAST CONTROL DIAL (TURN CLOCKWISE TO INCREASE PICTURE CONTRAST)

6. ON & OFF SWITCH AND VOLUME CONTROL FOR TV, RADIO, AND PHONOGRAPH

7. CHANNEL SELECTOR 2 THROUGH 13

8. FINE TUNING LEVER FOR TV SOUND AND PICTURES

TO OPERATE THE TV:
1. Turn selector No. 3 clockwise to final stop.
2. Turn on and off switch No. 6 to right until click is heard, then a quarter turn beyond.
3. Allow receiver to warm up until picture tube lights up.
4. Select your TV station by turning TV channel selector No. 7 until the marker points to desired channel number.
5. Turn contrast and brightness controls No. 4 and No. 5 to middle of their ranges, and adjust each for best picture detail.
6. Adjust fine TV tuning control No. 8 to best picture detail, and TV sound will automatically be tuned properly.
7. To turn off, turn switch No. 6 to left until click is heard.

TO OPERATE THE RADIO:
1. Turn selector No. 3 counter-clockwise to final stop.
2. Turn on and off switch No. 6 to right until click is heard, then a quarter turn beyond.
3. Allow receiver to warm up.
4. Select your station using speed tuner No. 1.
5. Refine station tuning with dial No. 2.
6. Adjust volume control No. 6.
7. To turn off, turn switch No. 6 to left until click is heard.

TO OPERATE PHONOGRAPH (console model 1500):
Note: Table model 150 and console model 1500 LP are equipped with phono sockets for attaching phonograph equipment. After plugging into phono motor and sound plug-ins on rear of set, proceed as follows:
1. Turn selector No. 3 to middle stop.
2. Turn on and off switch No. 6 to left until click is heard, then a quarter turn beyond.
3. Allow receiver to warm up.
4. Follow phono directions furnished (console model 1500 only).
5. To turn off, turn switch No. 6 to left until click is heard.

World Radio History

IMPORTANT: SATISFACTORY OPERATION OF YOUR MASCO BOOSTER DEPENDS UPON YOUR READING AND FOLLOWING THESE INSTRUCTIONS CAREFULLY.

The Masco Sky Chief Booster operates from 110-120 volts, 60 cycles AC.

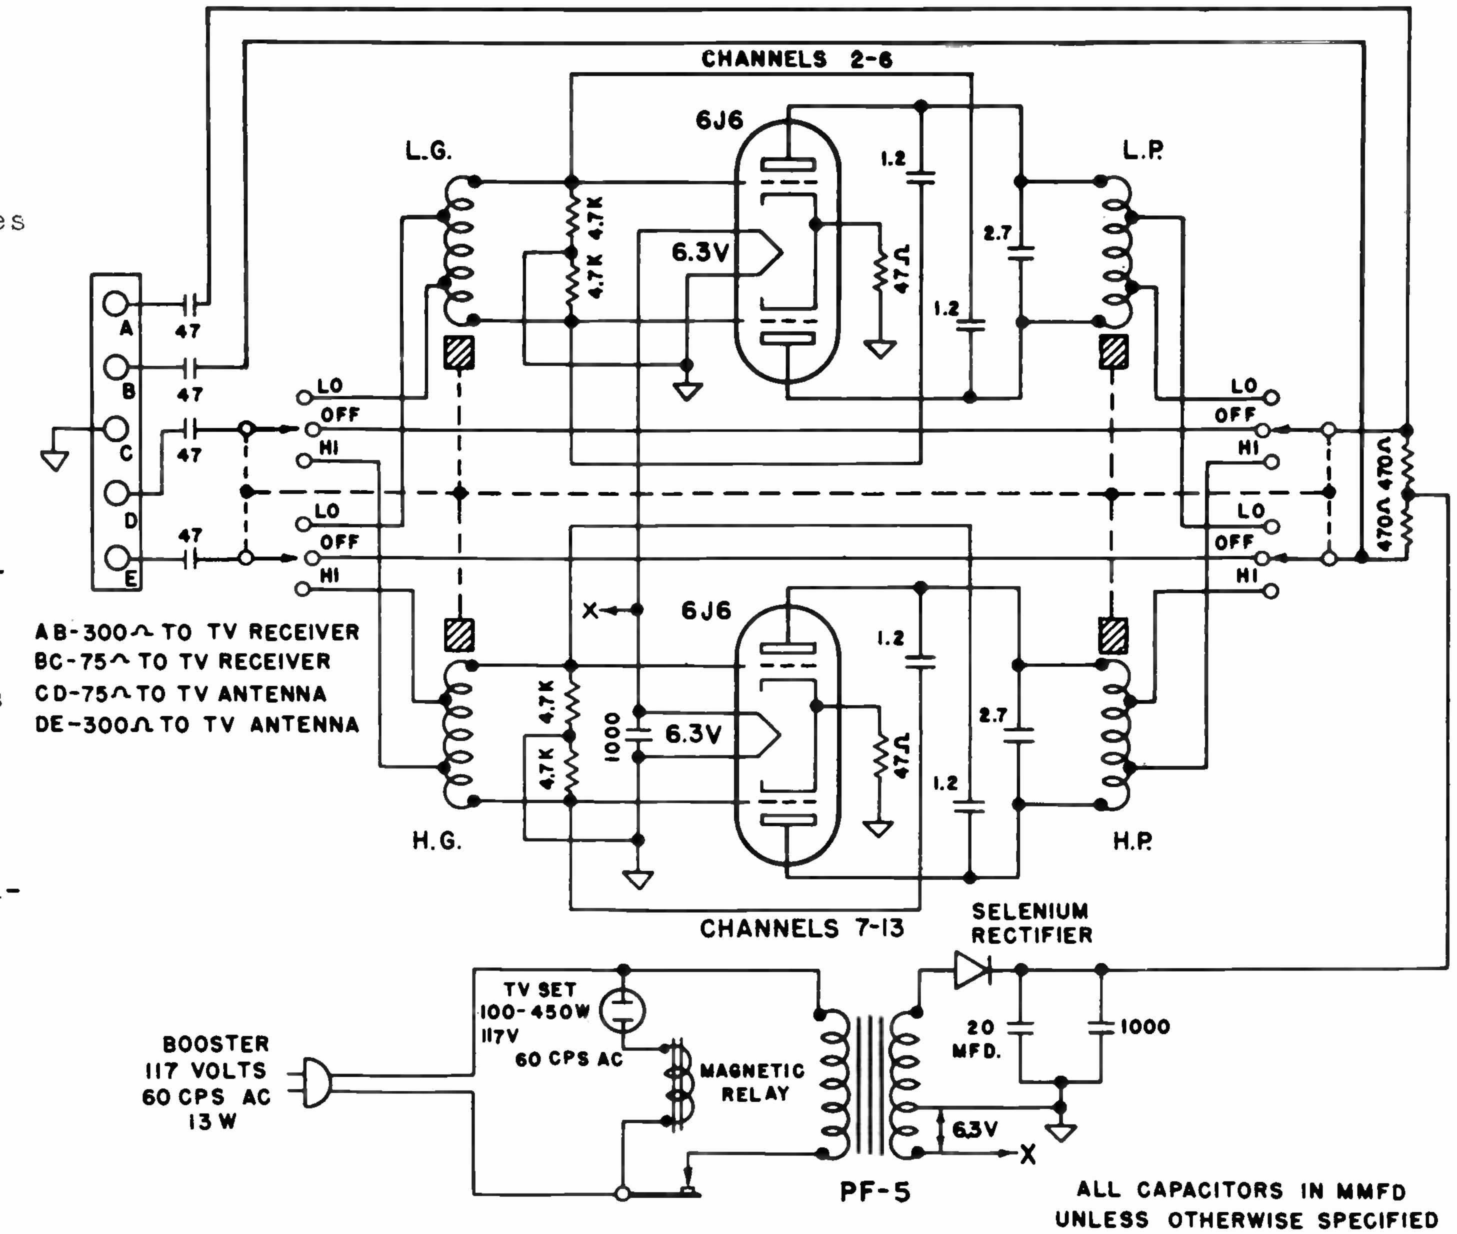
INSTALLATION

1. Remove the antenna lead-in wire from the antenna terminals of your television receiver.
2. Note the pre-tuned length of 300 ohm twin-lead wire which is supplied attached to terminals A and B (TV Receiver terminals). Connect the unused end of this wire to the antenna terminals of your television set.
   If your set uses a 75 ohm coaxial lead-in wire, cut off a three-foot length and connect it to terminals B and C of the Booster (connect shield to the grounded terminal C). Remove the length of 300 ohm line supplied.
3. Attach the 300 ohm twin-lead antenna lead-in wire to terminals D and E (TV ANTENNA) of your MASCO BOOSTER.
   If you have a 75 ohm coaxial lead-in, attach it to terminals C and D of the booster. The shield is connected to the ground terminal C.
4. DO NOT ALLOW INPUT AND OUTPUT LEADS TO CROSS.
5. Twist the bare strands of lead-in wire tightly when making connections to avoid shorting between terminals.

OPERATION

6. Remove the AC power cord of your television receiver from the wall receptacle and insert it into the AC receptacle of your MASCO SKY CHIEF TV BOOSTER. Insert the Booster line cord into the wall receptacle.

(Note: The magnetic switching relay in your MASCO Booster is designed to handle the power requirements of TV sets rated at up to 350 watts -- see the manufacturer's label at the rear of the receiver, in models not containing the relay then the continuously clockwise-rotating switch in your Booster turns both booster and TV set on and off. The pilot light next to the switch will glow when the booster and TV set are ON. If your TV receiver uses more than 350 watts, as TV-Radio-Phonograph consoles sometimes do, plug the AC cord of the TV section only into the Booster receptacle. This plug may be easily located inside the console. In this instance, the AC power plug of the Booster then is inserted into the socket of the TV section just vacated.



MODEL MB-2, Booster

©John F. Rider

World Radio History

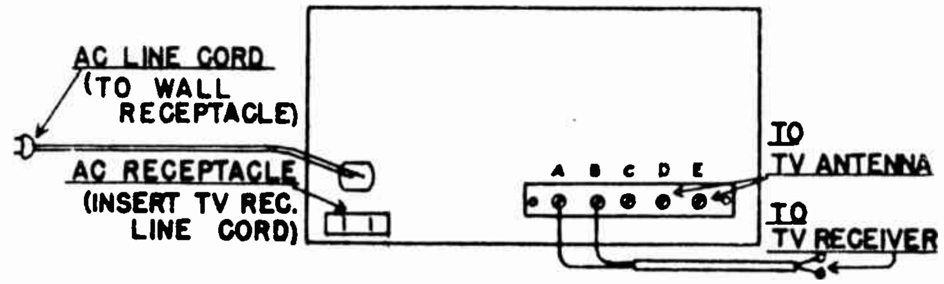
MODEL MB-2, Booster

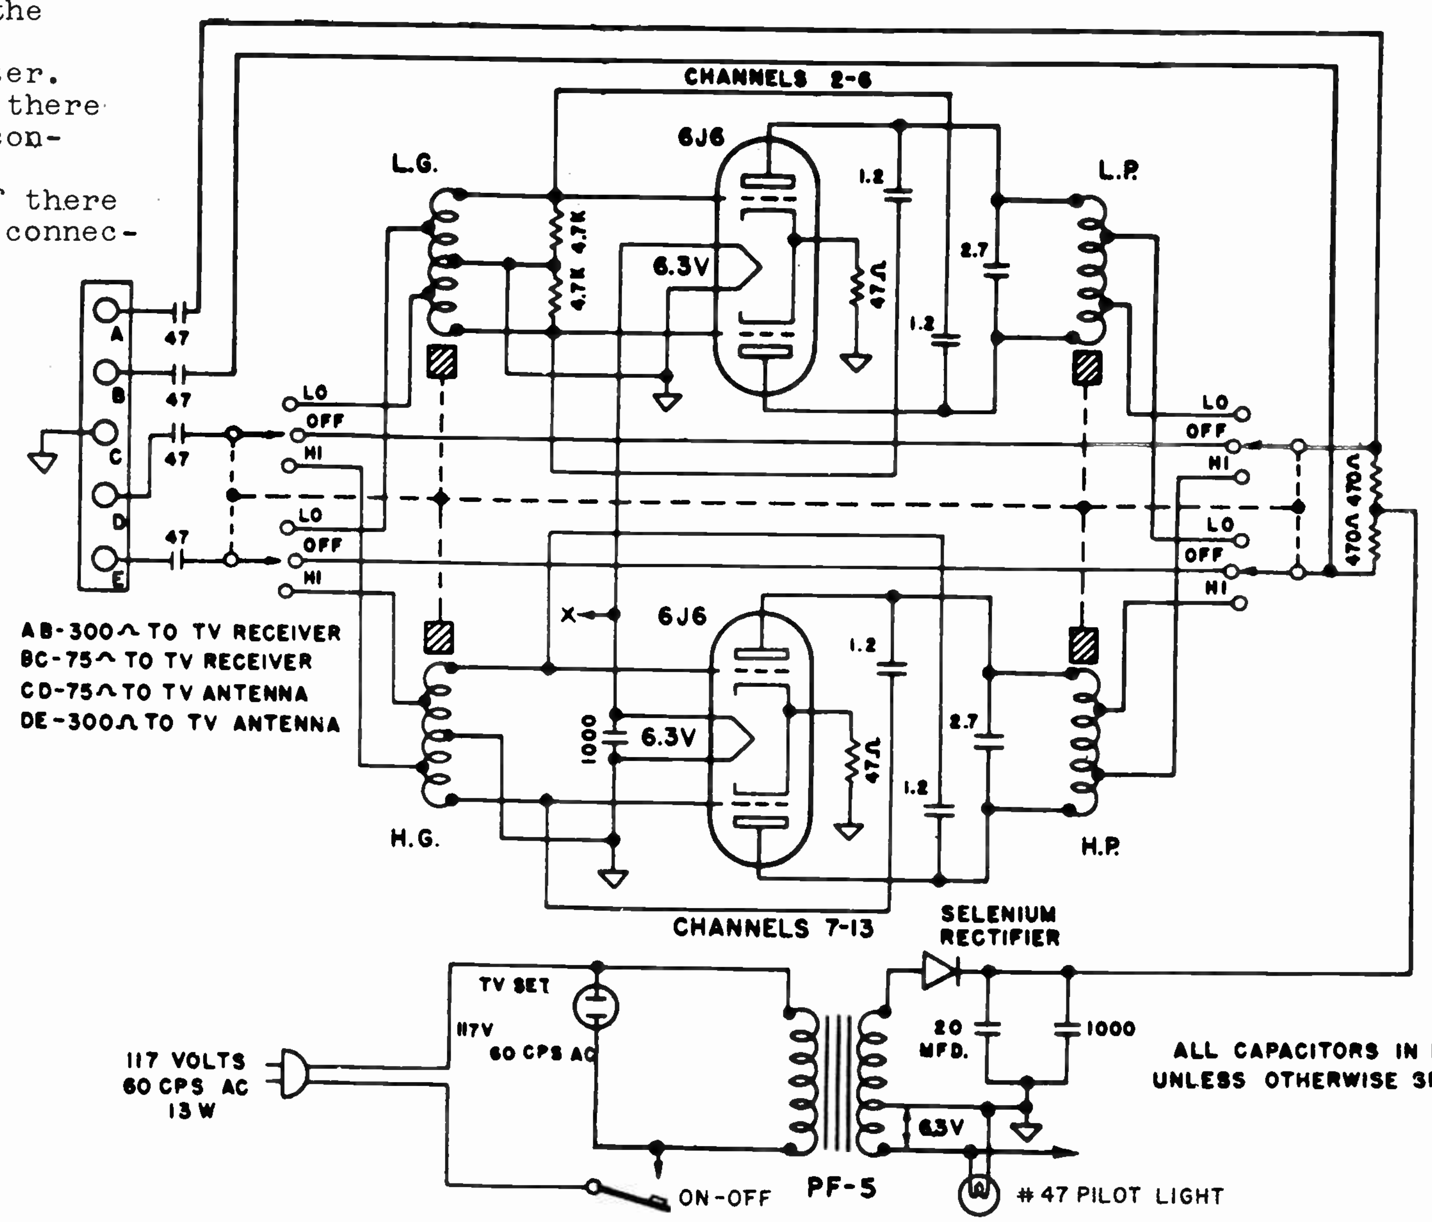
7. Turn the TV set ON. The Booster will now be turned on and off by the ON-OFF Switch of the TV set, only in models containing the magnetic switching relay.
8. Turn Booster CHANNEL SELECTOR KNOB to the desired station.
9. Tune TV receiver to the desired station.
10. KEEP THE RECEIVER CONTRAST CONTROL (ALSO CALLED PICTURE CONTROL) AT THE MINIMUM SETTING NEEDED TO GIVE A SATISFACTORY PICTURE.
11. Re-adjust CHANNEL SELECTOR KNOB for best picture.
12. IF THE STATION SIGNAL IS ORDINARILY STRONG and booster action is not required, place the Booster CHANNEL SELECTOR KNOB AT OFF POSITION. This feeds the signal from the antenna directly to the received while maintaining the Booster in a stand-by condition.

NOTE

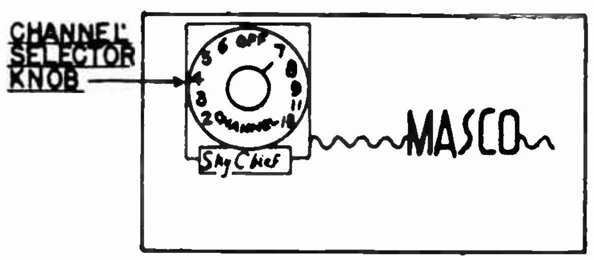
For best results the lead-in line should be tuned. This may be accomplished as follows:

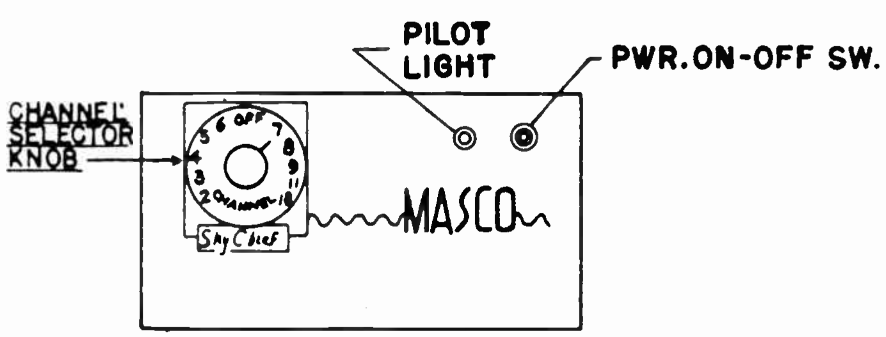
A. Set Booster and TV receiver to the weakest station. Adjust all receiver controls for best picture contrast.
B. Grasp the antenna lead-in line close to the Booster. Observe picture while running hand along this line. At one point the picture will appear brightest.
C. Cut the lead-in line at this point and reconnect to Booster.
D. Reverse antenna input connections on Booster and note if there is an improvement in the picture. If there is, allow the connections to remain reversed.
E. Reverse the output connections on the Booster and note if there is any improvement in the picture. If there is, allow the connections to remain reversed.





ALL CAPACITORS IN MMFD UNLESS OTHERWISE SPECIFIED





©John F. Rider

INDEX

GENERAL DESCRIPTION

These television chassis are twenty-one tube receivers. This includes rectifier and picture tubes. They have a continuous tuning range which permits the reception of the low and high frequency television bands and the FM radio band without interruption.

These chassis incorporate the LYT-L-TUNER. This Tuner is of unique design. It permits the reception of the low and high television bands as though they were but one band. The FM radio band which is situated between the low and high television bands is received with this Tuner at one end of the dial. The advantage of this design is that the television bands may be scanned for the desired program without the interruption of FM radio band reception. The high anode voltage is removed from the picture tube by the Tuner while the FM radio reception is being received.

The television and radio bands are covered by one turn of the coarse tuning knob or eight turns of the fine tuning knob. All stations are tuned for the best sound reception. The design of these chassis is such that when the best sound reception is received, the best television picture is received.

These chassis incorporating the LYT-L-TUNER are designed to operate with all commercial television broadband antennas. The Tuner is designed to match a 300 OHM impedance lead in.

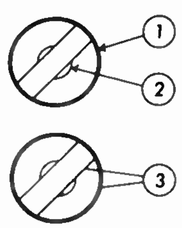
The high fidelity sound amplifier circuits and speaker reproduction capabilities which permit the utmost in enjoyment of FM high fidelity radio reception may be used as a phonograph amplifier. The record player is connected to the chassis by inserting the plug on the record player connecting wire into the phono jack located at the rear of the chassis.

When the phonograph is to be used the receiver should be tuned off any station and the contrast control should be turned to the full counterclockwise position.

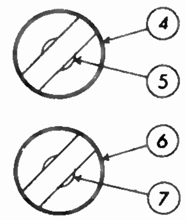
OPERATING CONTROLS

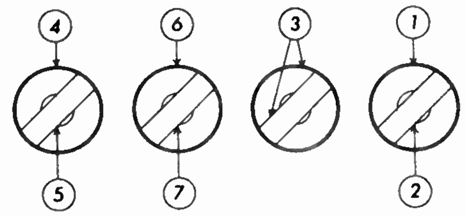
There are seven operating controls located at the front of the television set. These controls are:

1. Tuning-fine
2. Tuning-coarse
3. On-Off volume



4. Vertical Hold
5. Horizontal Hold
6. Contrast
7. Brightness





Operating controls as they will be found on our models

OPERATION

The power cord located at the rear of the cabinet is plugged into any convenient 115 volt AC outlet in the home. The 300 OHM antenna lead in wire is connected to the two terminals located at the rear of the cabinet (on the cabinet back and marked "300 OHM").

TUBE COMPLEMENT

	Tube Used	Function
(1)	RCA 12AT7	R.F. Amplifier
(2)	RCA 6J6	RP Oscillator
(3)	RCA 6AG5	Converter
(4)	RCA 6BA6	1st Sound IF Amplifier
(5)	RCA 6AU6	2nd Sound IF Amplifier
(6)	RCA 6AL5	Sound Discriminator
(7)	RCA 6AT6	1st Audio Amplifier and Bias Clamp
(8)	RCA 6K6GT	Audio Output

Deflection Coil	Top Chassis Screw Adjustment

RECEIVER OPERATING INSTRUCTIONS

The following adjustments are necessary when turning the receiver on for the first time.

1. Turn the receiver ON and advance the volume control to approximately mid-position.
2. Set the RAPID TUNING to the desired channel.
3. Turn the CONTRAST control fully counter clockwise.
4. Turn the BRIGHTNESS control fully counterclockwise then clockwise until a faint glow just appears on the screen.
5. Turn the CONTRAST control approximately three-fourths clockwise.
6. Adjust the FINE TUNING control for best sound fidelity and the Sound control for suitable volume.
7. Adjust the VERTICAL hold control until the pattern stops vertical movement.
8. Adjust the HORIZONTAL hold control until the picture appears on the screen.
9. Adjust the CONTRAST control for suitable picture contrast.
10. After the receiver has been on for some time it may be necessary to readjust the FINE TUNING control slightly for improved sound fidelity.
11. In switching from one station to another it may be necessary to repeat steps number 6 and 9.
12. When the set is turned on again after an idle period, it should not be necessary to repeat the adjustments if the positions of the controls have not been changed. If any adjustment is necessary, step number 6 is generally sufficient.
13. If the positions of the controls have been changed it may be necessary to repeat steps Number 2 through 9.

HIGH VOLTAGE WARNING

OPERATION OF THIS RECEIVER OUTSIDE THE CABINET OR WITH THE COVERS REMOVED INVOLVES A SHOCK HAZARD FROM THE RECEIVER POWER SUPPLIES. WORK ON THE RECEIVER SHOULD NOT BE ATTEMPTED BY ANYONE WHO IS NOT THOROUGHLY FAMILIAR WITH THE PRECAUTIONS NECESSARY WHEN WORKING ON HIGH VOLTAGE EQUIPMENT. DO NOT OPERATE THE RECEIVER WITH THE HIGH VOLTAGE COMPARTMENT SHIELD REMOVED.

KINESCOPE HANDLING PRECAUTIONS

DO NOT OPEN THE KINESCOPE SHIPPING CARTON, INSTALL, REMOVE, OR HANDLE THE KINESCOPE IN ANY MANNER UNLESS SHATTERPROOF GOGGLES AND HEAVY GLOVES ARE WORN. PEOPLE NOT SO EQUIPPED SHOULD BE KEPT AWAY WHILE HANDLING KINESCOPES. KEEP THE KINESCOPE AWAY FROM THE BODY WHILE HANDLING.

The kinescope bulb encloses a high vacuum and due to its large surface area is subjected to considerable air pressure. For these reasons, kinescopes must be handled with more care than ordinary receiving tubes. The large end of the kinescope bulb - particularly the rim of the viewing surface - must not be struck, scratched or subjected to more than moderate pressure at any time. In installation, if the tube sticks or fails to slip smoothly through the deflecting yoke, investigate and remove the cause of the trouble. Do not force the tube. Refer to the Receiver Installation section for detailed instructions on kinescope installation. All kinescopes are shipped in special cartons and should be left in the cartons until ready for installation in the receiver. Keep the carton for possible future use.

©John F. Rider

World Radio History

INSTALLATION INSTRUCTIONS

UNPACKING - To unpack the receiver, tear open the carton flaps, pick the receiver up from the bottom of the cabinet and lift it out of the shipping carton. The operating control knobs are packed in a paper bag which is tied to the focus coil mounting bracket inside the cabinet. Remove the bag, Remove the protective cardboard shield from the 5U4G rectifier. Make sure all tubes are in place and are firmly seated in their sockets.

INSTALLATION OF KINESCOPE - The kinescope second anode contact is a recessed metal well in the side of the bulb. The tube must be installed so that this contact is approximately on top. The final orientation of the tube will be determined by the position of the ion trap flags. Looking at the kinescope gun structure it will be observed that the second cylinder from the base inside the glass neck is provided with two small metal flags as shown in Figure 2. The kinescope must be installed so that when looking down on the chassis, the two flags will be seen as shown in Figure 2.

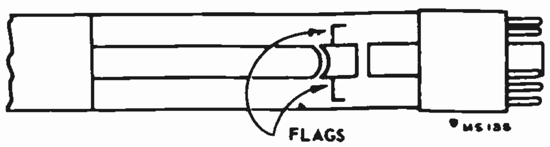

Figure 2. Ion Trap Flags

Slip the ion trap magnet on the neck of the kinescope with the small fingers toward the base of the tube. Connect the kinescope socket to the tube base. Install the control knobs on the proper control shafts. Determine that the deflection yoke is as far forward as possible. See that the high voltage lead to the kinescope second anode socket.

The antenna and power connections should now be made. Turn the power switch to the "ON" position, the brightness control fully clockwise and contrast control counter-clockwise.

ION TRAP MAGNET ADJUSTMENT - The ion trap rear magnet poles should be placed over the ion trap flags as shown in Figure 2. Starting from this position adjust the magnet by moving it forward or backward at the same time rotating it slightly around the neck of the kinescope for the brightest raster on the screen. Tighten the magnet adjustment thumb screw sufficiently to hold it in this position but still free enough to permit further adjustment. Reduce the brightness control setting until the raster is slightly above average brilliance. Adjust the focus control R129 on the chassis rear apron until the line structure of the raster is clearly visible. Readjust the ion trap magnet for maximum raster brilliance. The final touches on this adjustment should be made with the brightness control at the maximum position with which good line focus can be maintained.

FOCUS COIL ADJUSTMENTS - Turn the centering controls R152 and R166 to mid position. See Figure 3 for location of these rear apron controls.

If the corner of the raster is shadowed it indicates that the electron beam is striking the neck of the tube. Loosen the focus coil adjustment nuts and rotate the coil about its vertical and horizontal axes until the entire raster is visible, approximately centered and with no shadowed corners. Tighten the focus coil adjustment nuts with the coil in this position.

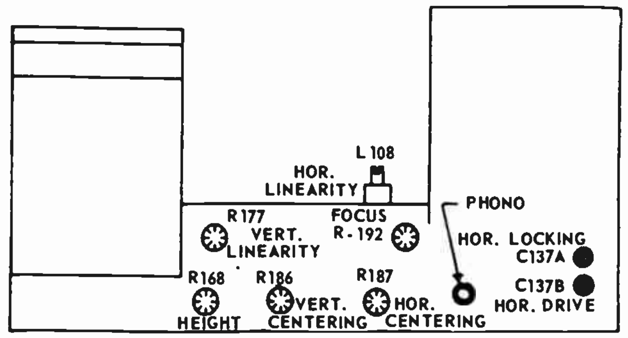

Figure 3. Rear Chassis Adjustment

DEFLECTION YOKE ADJUSTMENT - If the lines of the raster are not horizontal or squared with the picture mask, rotate the deflection yoke until this condition is obtained. Tighten the yoke adjustment screw.

PICTURE ADJUSTMENT - It will now be necessary to obtain a test pattern picture in order to make further adjustments. See steps 2 through 9 of the receiver operating instructions on Page 2.

CHECK OF HORIZONTAL OSCILLATOR ALIGNMENT - Turn the horizontal hold control to the extreme counter-clockwise position. The picture should remain in horizontal sync. Momentarily remove the signal by switching off channel and then back. Normally the picture will be out of sync. Turn the control clockwise slowly. The number of diagonal bars will be gradually reduced and when only 3-1/2 to 4-1/2 bars sloping downward to the left are obtained, the picture will pull into sync upon slight additional clockwise rotation of the control. Pull in should occur when the control is approximately 90 degrees from the extreme counterclockwise position. The picture should remain in sync for approximately 90 degrees of additional clockwise rotation of the control. At the extreme clockwise position, the picture should be out of sync and should show from 3-1/2 to 4-1/2 bars sloping downward to the right.

If the receiver passes the above checks and the picture is normal and stable the horizontal oscillator is properly aligned. Skip "Alignment of Horizontal Oscillator" and proceed with "Focus" adjustment.

ALIGNMENT OF HORIZONTAL OSCILLATOR - If in the above check the receiver failed to hold sync with the hold control at the extreme counterclockwise position or failed to hold sync at least 60 degrees of clockwise rotation of the control from the pull in point it will be necessary to make the following adjustments.

If the trimmer has insufficient range, set the trimmer to mid-position (1 turn out from max. capacity) and adjust the T106 horizontal frequency adjustment until this condition is obtained. See Figure 5 for the location of T106.

HORIZONTAL LOCKING RANGE ADJUSTMENT - Set the horizontal hold control to the full counter-clockwise position. Momentarily remove the signal by switching off channel and then back.

Slowly turn the horizontal hold control clockwise and note the least number of diagonal bars obtained just before the picture pulls into sync.

If more than 4-1/2 bars are present just before the picture pulls into sync, adjust the horizontal locking range trimmer C137A slightly clockwise. If less than 3-1/2 bars are present adjust C137 slightly counterclockwise.

Turn the picture control counter-clockwise, momentarily remove the signal and recheck the number of bars present at the pull in point. Repeat this procedure until 3-1/2 to 4-1/2 bars are present.

Repeat the adjustments under "Horizontal Frequency Adjustment" and "Horizontal Locking Range Adjustment" until the conditions specified under each are fulfilled. When the horizontal hold operates as outlined under "Check of Horizontal Oscillator Alignment," the oscillator is properly adjusted.

HEIGHT AND VERTICAL LINEARITY ADJUSTMENTS - Adjust the height control R168 on chassis rear apron until the picture fills the mask vertically. Adjust vertical linearity (R177 on rear apron) until the test pattern is symmetrical from top to bottom. Adjustment of either control will require a readjustment of the other. Adjust vertical centering to align the picture with the mask.

WIDTH, DRIVE AND HORIZONTAL LINEARITY ADJUSTMENTS - Vary the horizontal drive trimmer C137B to yield the best compromise between brightness and linearity. Adjust the horizontal linearity control of L108 for best linearity of the right half of the picture. Adjust horizontal centering to align the picture with the mask.

FOCUS - Adjust the focus control R192 for maximum definition of the vertical wedge of the test pattern.

Check to see that all cushion, yoke, focus coil and ion trap magnet thumb screws are tight. Replace the cabinet back grille. Make sure that the back is on tight, otherwise it may rattle at high volume.

CHECK OF R.F. OSCILLATOR ADJUSTMENTS - With a crystal calibrated test oscillator or heterodyne frequency meter, check to see if the receiver of oscillator is adjusted to the proper frequency on all channels. If adjustments are required, these should be made by the method outlined in the alignment procedures on Page 8.

Tune in all available Television Stations. Observe the picture for detail for proper interlacing and for the presence of interference or reflections.

RECEIVER LOCATION - The owner should be advised of the importance of placing the receiver in the proper location in the room.

The location should be chose:
- To give easy access for operation and comfortable viewing.
- To permit convenient connection to the antenna.
- Convenient to an electrical outlet.
- To allow adequate ventilation.

VENTILATION CAUTION - The receiver is provided with adequate ventilation holes in the bottom, sides and back of the cabinet. Care should be taken not to allow these holes to be covered or ventilation to be impeded in any way.

ANTENNAS - The finest television receiver built may be said to be only as good as the antenna design and installation. It is therefore important to use a correctly designed antenna, and to use care in its installation. We recommend Amphenol #114-005 or equivalent, on all twelve television channels. This antenna uses the 300 ohm television transmission line.

In most cases the antenna should not be installed permanently until the quality of the picture reception has been observed on a television receiver.

A temporary transmission line can be run between receiver and the antenna allowing sufficient slack to permit moving the antenna. Then, with a telephone system connecting an observer at the receiver and an assistant at the antenna, the antenna can be positioned to give the most satisfactory results on the receiver signal. A shift of direction or a few feet in antenna position may affect a tremendous difference in picture reception.

REFLECTIONS - Multiple images sometimes known as echoes or ghosts are caused by the signal arriving at the antenna by two or more routes. The second or subsequent image occurs when a signal arrives at the antenna after being reflected off a building, a hill or other object. In severe cases of reflections, even the sound may be distorted. In less severe cases, reflections may occur that are not noticeable as reflections but that will instead cause a loss of definition in the picture.

Depending upon the circumstances, it may be possible to eliminate the reflections by rotating the antenna or by moving it to a new location. In extreme cases it may be impossible to eliminate the reflection.

Under certain extremely unusual conditions, it may be possible to rotate or position the antenna so that it received the cleanest picture over a reflected path. If such is the case, the antenna should be so positioned. However, such a position may give variable results as the nature of reflecting surfaces may vary with weather conditions. Wet surfaces have been known to have different reflecting characteristics than dry surfaces.

INTERFERENCE - Auto ignition, street cars, electrical machinery and diathermy apparatus may cause interference which spoils the picture. Whenever possible the antenna location should be removed as far as possible from highways, hospitals, doctors offices and similar sources of interference. In mounting the antenna care must be taken to keep the antenna rods at least 1/4 wave length (at least 6 feet) away from other antennas, metal roofs, gutters or other metal objects.

Short-wave radio transmitting and receiving equipment may cause interference in the picture in the form of moving ripples. In some instances it may be possible to eliminate the interference by the use of a trap in the antenna transmission line. However, if the interfering signal is on the same frequency as the television station, a trap will provide no improvement.

WEAK PICTURE - When the installation is near the limit of the area served by the transmitting station, the picture may be speckled, having a "snow" effect and may not hold steady on the screen. This condition is due to lack of signal strength from the transmitter.

INFORMATION REFERENCES - In short, a television receiving antenna and its installation must conform to much higher standards than an antenna for reception of International Short Wave and Standard Broadcast signals. For further information on antennas and antenna installation see your dealer.

World Radio History

SERVICE SUGGESTIONS

Some of the possible troubles that may be encountered, with their effects and causes, are listed below:

NO RASTER ON KINESCOPE - The effectof no raster can be caused by the following.

Incorrect adjustment of ion trap magnet. Open coil; negative bleeder open, coils reversed.

No high voltage. Check V17 (6BG6-G) and V18 (8016) tubes and circuits. If the horizontal deflection circuits are operating, as evidenced by the correct wave form measured on terminal 4 of horizontal output transformer T108, the trouble can be isolated to the high voltage rectifier (V18) circuit. Either the high voltage winding (points 2 to 3 on T108) is open; the 8016 tube is defective; its filament circuit is open; or the high voltage filter capacitor C163 is shorted.

Damper tube (V20, 5V4G), inoperative. Plate voltage supply for 6BG6-G horizontal output tube is obtained through the damper tube. Check tube, and heater winding on T110. If tube is O.K., check L108 horizontal llinearity coil for continuity and capacitors C157 and C159) for short circuit.

Defective kinescope. Heater open; cathode "return" circuit open.

No plate voltage. Shorted electrolytic capacitor open choke coil. All plus B measurements are accessible for measurement by removing cover from bleeder box.

Horizontal osc. and control tube (V17, 6SN7-GT) inoperative. Check for sawtooth on grid of horizontal output tube (V18, 6BG6-G) if not present, check waveforms, voltages, and components in V17 circuits.

HORIZONTAL DEFLECTION ONLY - If horizontal deflection only is obtained, evidences by a straight line across the face of the kinescope, it can be caused by the following:

(1) Vertical oscillator and output tube (V15 6C4) inoperative. Check waveforms and voltages on grid and plate.

(2) Vertical output transformer (T109) open.

(3) Yoke vertical coils open.

POOR VERTICAL LINEARITY - If adjustment of the vertical height and linearity controls will not correct this condition, any of the following may be the cause.

(1) Vertical output transformer (T109) defective.

(2) Capacitors C160-A or C158-A defective.

(3) V16 - (6SN7-GT) defective. Check waveforms and voltages.

(4) Excess leakage or incorrect value in capacitor C162.

(5) Low plate and bias voltages. Check rectifier tube and capacitors in plus B supply circuits.

(6) Capacitor C161 defective.

POOR HORIZONTAL LINEARITY - If adjustment of controls does not correct this condition, check the following:

(1) Check or replace horizontal output tube (V18, 6BG6-G).

(2) Check or replace damper tube (V20, 5V4-G).

(3) Check waveform on grid of V18.

(4) Check linearity coil L108 for short circuit.

(5) Check capacitors C157 and C159 for defects.

TRAPEZOIDAL OR NON-SYMMETRICAL RASTER - This condition can be caused by; Defective yoke.

WRINKLES ON LEFT SIDE OF RASTER - This condition can be caused by: Defective yoke due to R101, R151, or C141 (internal in yoke assembly) being wrong value or open. These components are mounted in rear of yoke assembly.

SMALL RASTER - This condition can be caused by;

(1) Low plus B or line voltage.

(2) Insufficient output from horizontal output tube V18 (6BG6-G). Replace tube.

RASTER - NO IMAGE, BUT ACCOMPANYING SOUND - This condition can be caused by;

(1) No signal on kinescope grid. Check picture i.f. amplifier tubes V4 (6AG5), V5 (6AG5), V6 (6AG5), second detector V7A (6AL5) and video amplifier V8 (12AU7).

(2) Bad contact to kinescope grid. (Lead to socket broken).

SIGNAL APPEARS ON KINESCOPE GRID BUT IMPOSSIBLE TO SYNCHRONIZE THE PICTURE VERTICALLY AND HORIZONTALLY - A condition of this nature can be caused by:

(1) Defective sync amplifier and separator (V14, 6SN7-GT).

(2) If tube is O.K. check voltages, waveforms and associated circuits.

SIGNAL ON KINESCOPE GRID AND HORIZONTAL SYNC ONLY - If this condition is encountered, check:

Vertical integrating network capacitors C148, C151, C152, C154 and resistors R161, R163, R165.

PICTURE STABLE BUT WITH POOR RESOLUTION - If the picture resolution is not up to standard, it may be caused by any of the following:

(1) Defective picture detector (V7A 6AL5) or video amplifier (V8, 12AU7).

(2) Open video peaking coil. Check all peaking coils (L104, L105, L106, L107) for continuity. Note that L105 and L106 have shunting resistors.

(3) Leakage in V8 grid capacitor C134.

If above components are not found to be defective, check the following:

(1) Check all potentials in video circuits.

(2) Check kinescope grid circuit for poor or dirty contact.

(3) Check adjustment of focus control (R192). It should be effective on either side of proper focus.

(4) Check and realign, if necessary, the picture i-f and r-f circuits.

PICTURE SMEAR -

(1) Normally, smear can be attributed to phase shift at the low frequency end of the video characteristic. This can be caused by improper values of R and C in the video circuits. Check for grid current on video amplifier tube V8.

(2) This trouble can originate in either the transmitter or the receiver. Check reception from another station.

PICTURE JITTER

(1) If regular sections at the left of the picture are displaced, replace the horizontal output tube (V18, 6BG6-G).

(2) Vertical instability may be due to loose connections or noise received with the signal.

(3) Horizontal instability may be due to unstable transmitted sync or to "noise."

ALIGNMENT PROCEDURE

TEST EQUIPMENT - To service this receiver properly, it is recommended that the following test equipment be available.

R-F SWEEP GENERATOR meeting the following requirements.

(a) Frequency ranges
18 to 30 mc, 1 mc sweep width
40 to 190 mc, 10 mc sweep width
170 to 225 mc, 10 mc sweep width

(b) Output adjustable with at least 1 volt maximum.

(c) Output constant on all ranges.

(d) Flat output in all attenuator positions.

CATHODE-RAY OSCILLOSCOPE - Preferably one with a wide band vertical deflection and an input calibrating source.

SIGNAL GENERATOR - To provide the following frequencies: Output on these ranges should be adjustable and at least 1 volt maximum.

(a) Intermediate frequencies;

21.25 mc sound i-f and sound traps
22.8 mc converter transformer
23.9 mc first picture i-f coil
24.5 mc third picture i-f coil
26.0 mc second picture i-f primary
27.25 mc second picture i-f secondary

(b) Radio frequencies

Channel Number	Picture Carrier Freq. Mc.	Sound Carrier Freq. Mc.
2	55.25	59.75
3	61.25	65.75
4	67.25	71.75
5	77.25	81.75
6	83.25	87.75
7	175.25	179.75
8	181.25	185.75
9	187.25	191.75
10	193.25	197.75
11	199.25	203.75
12	205.25	209.75
13	211.25	215.75

HETERODYNE FREQUENCY METER with crystal calibrator if the signal generator is not crystal controlled.

ELECTRONIC VOLTMETER of "Junior VoltOhmyst" type and a high voltage probe for use with this meter to permit measurements up to 10kv.

If possible the chassis should then be serviced without the kinescope. However, if it is necessary to view the raster during servicing, the kinescope should be carefully mounted. The kinescope should never be allowed to support its weight by resting in the deflecting yoke. A bracket should be used to support the tube at its viewing screen.

By turning the chassis on end with the power transformer "UP," all adjustments will be made conveniently available. Since this is the only safe position in which the chassis will rest and still leave adjustments accessible, the trimmer location drawings are oriented similarly for ease of use.

CAUTION: Do not permit the kinescope second anode lead to become shorted to the chassis. To do so will cause a considerable overload on the high voltage filter resistor R167.

ADJUSTMENTS REQUIRED - Normally only the r-f oscillator trimmers will require the attention of the service technician. All other circuits are either broad or very stable and hence will seldom require adjustment.

Due to the high frequencies at which the receiver operates the r-f oscillator adjustment is critical and may be affected by a tube change. The trimmers can be adjusted to the proper frequency on channel 6 and channel 10 with practically any 6J6 tube in the socket.

In replacing, if the old tube can be matched for frequency by trying several new ones, this practice is recommended. At best, however it will probably be necessary to realign the oscillator trimmers completely after changing the tube.

The detailed alignment procedure which follows is intended primarily as a discussion of the method used, precautions to be taken and the reasons for these precautions. Then for more convenient reference during alignment a tabulation of the i.f. alignment method is given. All the information necessary for alignment is given in the table; however, alignment by the table should not be attempted before reading the detailed instructions.

ORDER OF ALIGNMENT - When a complete receiver alignment is necessary, it can be most conveniently performed in the following order:

Sound discriminator
Sound i-f transformers
Picture i-f traps
Picture i-f coils
R-F and converter trimmers
R-F oscillator trimmers
Retouch picture i-f transformers
Sensitivity check

SOUND DISCRIMINATOR ALIGNMENT - Set the signal generator for approximately 1 volt output at 21.25 mc and connect it to the second sound i-f grid.

Detune T102 secondary (bottom).

Set the "VoltOhmyst" on the 10 volt scale.

Connect the meter in series with a one megohm resistor to the junction of diode resistors R106 and R108.

Adjust the primary of T102 (top) for maximum output on the meter.

©John F. Rider

World Radio History

Connect the "VoltOhmyst" to pin 1 of V11 and set on the 3 volt scale.

Adjust T102 secondary (bottom). It will be found that it is possible to produce a positive or negative voltage on the meter dependent upon this adjustment. Obviously to pass from a positive to a negative voltage, the voltage must go through zero. T102 (bottom) should be adjusted so that the meter indicates zero output as the voltage swings from positive to negative. This point will be called discriminator zero output.

Connect the sweep oscillator to the grid of the second sound i-f amplifier.

Adjust the sweep band width to approximately 21.25 and with an output of approximately, 1 volt.

Connect the oscilloscope to pin 1 of V11.

The peak to peak bandwidth of the discriminator should be approximately 350 kc. and should be linear from 21.175 mc to 21.325 mc.

SOUND I-F ALIGNMENT - Connect the sweep and signal generator to the top end of the trap winding (on top of chassis).

Connect the oscilloscope to the second sound i-f grid return (terminal A T101) in series with a 33,000 ohm isolating resistor.

Connect a 5600 ohm resistor from terminal A T101 to ground. Insert a 21.25 mc marker signal from the signal generator into the first sound i-f grid.

Adjust T101 (top and bottom) for maximum gain and symmetry about 21.25 mc. marker. The band width at 80% response from the first sound i-f grid to the second i-f grid should be approximately 250 kc.

The output level from the sweep should be set to produce approximately 3 volt peak-to-peak at the second sound i-f grid return when the final touches on the above adjustment are made. It is necessary that the sweep output voltage should not exceed the specified values, otherwise the response curve will be broadened, permitting slight misadjustment to pass unnoticed and possibly causing distortion on weak signals.

PICTURE I-F TRAP ADJUSTMENT - Connect the "VoltOhmyst" to the junction of R118 and R120, and adjust the picture control for 3 volts on the meter.

Set the channel switch to channel 13.

Connect the "VoltOhmyst" across the picture second detector load resistor R132 and set it on the 3 volt scale.

Connect the output of the signal generator to pin #1 of the 6AG5 converter tube.

Set the generator to 21.25 mc and check it against a crystal calibrator to insure that the generator is exactly on frequency.

Adjust Trap and T105 for minimum indication on the "VoltOhmyst."

Set the generator to 27.25 mc. and adjust T104 secondary for minimum indication on the "VoltOhmyst."

PICTURE I-F COIL ADJUSTMENTS - Set the signal generator to each of the following frequencies, and peak the specified adjustment for maximum indication on the "VoltOhmyst."

22.8 mc T3 (bottom)
23.9 mc L101 (top of chassis)
26.0 mc L104 (top of chassis)
24.5 mc L102 (top of chassis)

PICTURE I-F OSCILLATION - If the receiver is badly misaligned and two or more of the i-f coils are tuned to the same frequency, the receiver may fall into i-f oscillation. I-F oscillation shows up as a voltage in excess of 3 volts at the picture detector load resistor. This voltage is unaffected by r-f signal input and sometimes is independent of picture control setting.

If such a condition is encountered it is sometimes possible to stop oscillation by adjusting the coils approximately to frequency by setting the adjustment stud extensions of T3, L101, T104 and L102 to be approximately equal to those of another receiver known to be in proper alignment. If this does not have the desired effect, it may be possible to stop oscillation by increasing the grid bias. If so, it should be possible to align the coils by the usual method. Once aligned in this manner the i-f should be stable with reduced bias.

If the oscillation cannot be stopped in the above manner, shunt the grids of the first two i-f amplifiers to ground with 1800 mmf capacitors. Connect the signal generator to the third i-f grid and adjust L102 to frequency.

Remove the shunting capacitor from the second i-f grid, connect the signal generator to this grid and align T104. Remove the shunting capacitor from the first i-f grid, connect the signal generator and align L101.

Connect the signal generator to pin #1 of the 6AG5 converter (in the r-f tuning unit) and align T3 to frequency.

If this does not stop the oscillation the difficulty is not due to i-f misalignment as the i-f section is very stable when properly aligned.

Check all i-f by-pass condensers, coil loading resistors, tubes, socket voltages, etc.

R-F AND CONVERTER TRIMMER ADJUSTMENT - Connect the r-f sweep oscillator to the receiver antenna terminals. If the sweep oscillator has a 50 ohm single-ended output, it will be necessary to obtain balanced output by connecting as shown in Figure 4.

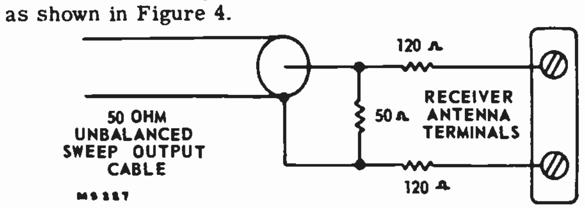

Figure 4. Unbalanced Sweep Cable Terminals

Connect the oscilloscope through a 47,000 ohm resistor to Pin 1 of the 6AG5 converter tube.

By-pass the first picture i-f grid to ground through 1000 mmid capacitor.

Keep the leads to this by-pass as short as possible. If this is not done lead resonance may fall in the r-f range and cause an incorrect picture of the r-f response.

Connect the "VoltOhmyst" to the junction of R115 and R116 and adjust the picture control for 3 volts on the meter.

Connect the signal generator loosely to the receiver antenna terminals.

Rotate the tuner knob to the maximum clockwise position and adjust the position of the pointer to the arrow on the back side of the dial plate.

Rotate the tuner knob until the pointer is aligned with the "6" mark on the back side of the dial plate.

Set the sweep oscillator to cover channel 6.

Insert markers of channel 6 picture carrier and sound carrier at 83.25 mc. and 87.75 mc.

Adjust the low band converter trimmer and low band R.F. trimmer.

Check the response of channels 2 through 5 by first setting the sweep generator to each of these channels and then turning the tuner knob until the pattern appears on the oscilloscope screen.

Rotate the tuner knob until the pointer is aligned with the "10" mark on the back side of the dial plate

Set the sweep oscillator to cover channel 10.

Insert markers of channel 10 picture carrier and sound carrier at 193.25 mc and 197.75 mc.

Adjust the high band converter trimmer, and high band R.F. trimmer, for the "W" shaped response centered about the marker.

Check the response of channels 6, 7, 9, 11, 12 and 13 by setting the sweep generator to each of the channels and then adjusting the tuner knob until the pattern appears.

Remove the 1000 mmf capacitor from the first picture i-f grid.

R.F. OSCILLATOR TRIMMER ADJUSTMENT - The r-f oscillator may be aligned by adjusting it to beat with a crystal calibrated heterodyne frequency meter or by feeding a signal into the receiver at the r-f sound carrier frequency and adjusting the oscillator for zero output from the sound discriminator. In this latter case the sound discriminator must first have been aligned to exact frequency. Either method of adjustment will produce the same results. The method used will depend upon the type of test equipment available.

Regardless of which method of oscillator alignment is used, the frequency standard must be crystal controlled or calibrated.

If the receiver oscillator is to be adjusted by the heterodyne frequency meter method, the frequencies listed under "R-F Sound Carrier" in the table must be available.

If the receiver oscillator is adjusted by feeding in the r-f sound carrier signal the frequencies listed under "R-F Sound Carrier" must be available.

Channel Number	Receiver R-F Osc. Freq. Mc.	R-F Sound Carrier Freq. Mc.
2	81	59.75
3	87	65.75
4	93	71.75
5	103	81.75
6	109	87.75
7	201	179.75
8	207	185.75
9	213	191.75
10	219	197.75
11	225	203.75
12	231	209.75
13	237	215.75

If the heterodyne frequency meter method is used, couple the meter probe loosely to the receiver oscillator.

ALIGNMENT PROCEDURE

Connect the signal generator to the receiver antenna terminals.

The order of alignment remains the same regardless of which method is used.

Rotate the tuner knob until the pointer is aligned with the "6" mark on the back side of the dial plate.

MODELS TV-116-A, TV-116-B, TV-117-A, TV-117-B, Ch. CTV-219-A; CTV-215-A

Adjust the frequency standard to the correct frequency (109.0 mc. for the heterodyne frequency meter of 87.75 mc. for the signal generator).

Adjust the low band oscillator trimmer, C19, for an audible beat on the heterodyne frequency meter of zero voltage from the sound discriminator. Be certain that the voltage across the discriminator varies + and - as the tuner knob is rotated slightly to either side of the channel 6 position.

Set the frequency standard to the proper frequency for channel 2 as listed in the alignment table.

Rotate the tuner knob toward the channel 2 position and see that the discriminator voltage goes through zero or that an audible beat note is obtained from the heterodyne frequency meter.

Rotate the tuner knob until the pointer is aligned with the "10" mark on the back side of the dial plate.

Adjust the high band oscillator trimmer, for an audible beat note on the heterodyne frequency meter or zero voltage from the sound discriminator.

Adjust the frequency standard to the correct frequency (219.0 mc. for the heterodyne frequency meter on 197.75 mc. for the signal generator).

Set the frequency standard to the proper frequency for channel 7 as listed in the alignment table.

Rotate the tuner knob toward the channel 7 position and see that the discriminator voltage goes through zero or that an audible beat note is heard from the heterodyne frequency meter.

Check the tuner coverage of channel 13 following the same general procedure as outlined for channel 7.

RETOUCHING OF PICTURE I-F ADJUSTMENT - The picture i-f response curve varies somewhat with the change of bias and for this reason it should be aligned with approximately the same single input as it will receive in operation.

If the receiver is located at the edge of the service area, it should be aligned with approximately -1 volt i-f grid bias. However, for normal conditions, (signals of 1000 microvolts or greater), it is recommended that the picture i-f be aligned with a grid bias of -3 volts. Set the picture control for -3 volts at the junction of R118 and R120.

Connect the r-f sweep generator to the receiver antenna terminals.

Connect the signal generator to the antenna terminals and feed in the 25.75 mc. i-f picture carrier marker and a 23 mc. marker.

©John F. Rider

World Radio History

Connect the oscilloscope across the picture detector load resistor, R132.

Set the channel switch to channel (between 1 and 6) found to have the best response during the r-f and converter trimmer adjustment.

Set the sweep output to produce approximately .3 volt peak to peak across the picture detector load resistor.

Observe and analyze the response curve obtained. The response will not be ideal and the i-f adjustments must be retouched in order to obtain the desired curve. In making these adjustments care should be taken that no two transformers are tuned to the same frequency as i-f oscillation may result.

On final adjustment the picture carrier marker must be at approximately 50% response. The curve must be approximately flat topped and with the 23 mc. marker at approximately 90% response.

The most important consideration in making the i-f adjustments is to get the picture carrier at the 50% response point. If the picture carrier operates too low on the response curve, loss of low frequency video response, of picture brilliance, of blanking, and of sync may occur. If the picture carrier operates too high on the response curve, the picture definition is impaired by loss of high frequency video response.

SENSITIVITY CHECK - A comparative sensitivity check can be made by operating the receiver on a weak signal from a television station and comparing the picture and sound obtained to that obtained on other receivers under the same conditions.

This weak signal can be obtained by connecting the shop antenna to the receiver through an attenuator pad of the type shown in Figure 5. The number of stages in the pad depends upon the signal strength available at the antenna. A sufficient number of stages should be inserted so that a somewhat less than normal contrast picture is obtained when the picture control is at the maximum clockwise position.

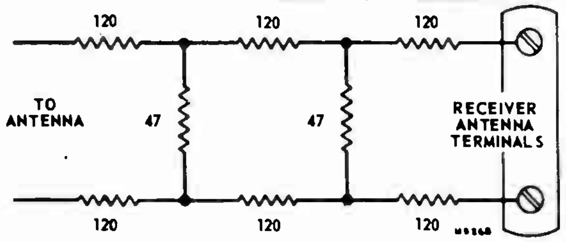

Figure 5. Attenuator Pad

Only carbon type resistors should be used to construct the attenuator pad. Since many of the low value moulded resistors generally available are of wire wound construction, it is advisable to break and examine one of each type of resistor used in order to determine its construction.

ALIGNMENT TABLE - Both methods of oscillator alignment are presented in the alignment table. The service technician may thereby choose the method to suit his test equipment. If it is found that the dual listing is confusing, the unwanted listing can be easily erased.

CRTICAL LEAD DRESS

(1) Dress all video coupling capacitors and peaking coi

CRITICAL LEAD DRESS

(1) Dress all video coupling capacitors and peaking coils up and away from the chassis.

(2) Contact between the R-F Oscillator frequency adjustment screws and the oscillator coils or channel switch eyelets must be avoided.

If any tuner troubles develop which indicate the need for realignment, the tuner should be returned to the factory.

It should be noted that normally replacement of tubes should not necessitate realignment of the tuner.

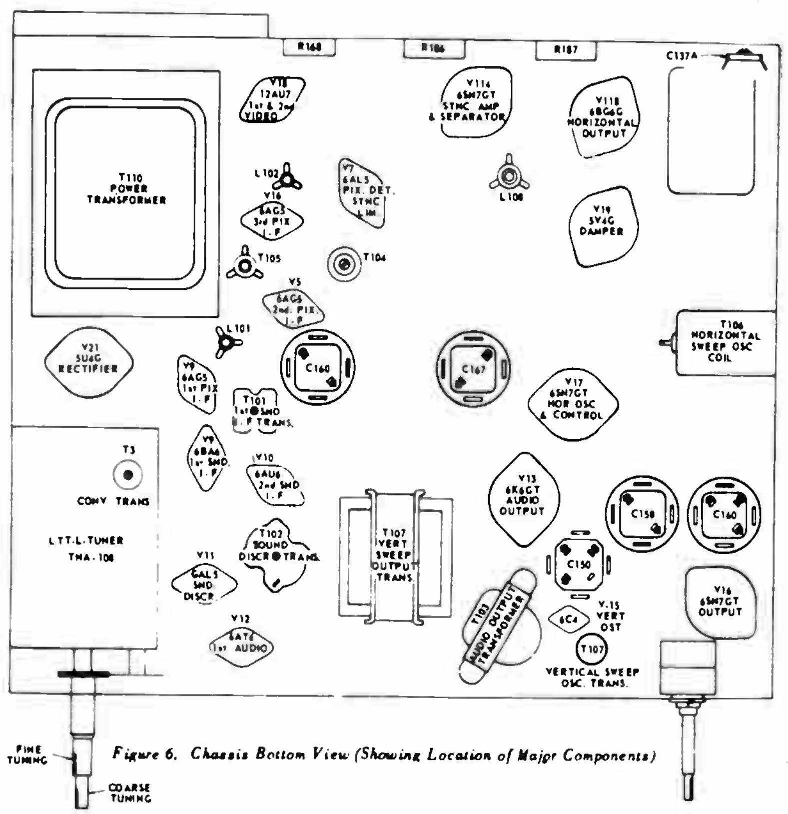

Figure 6. Chassis Bottom View (Showing Location of Major Components)

ALIGNMENT TABLE

The Detailed Alignment Procedure beginning on page 4 should be read before alignment by use of the tables is attempted.

Discrimination and Sound i-f Alignment

Step No.	Connect Signal Generator to	Signal gen. Freq. Mc.	Connect Sweep Generator to	Sweep gen. Freq. Mc.	Connect Oscilliscope to	Connect "VoltOhmyst" to	Misc Connections and Instructions	Adjust
1	2nd Sound i-f grid (pin 1 V10)	21.25 1 volt output	Not Used		Not Used	In series with 1 meg. to junction of R106 and R108	Meter on 10 volt scale	Detune T102 (bottom) adjust T102 (top) for max. on meter
2	2nd Sound i-f grid (pin 1 V10)	21.25 1 volt Output	Not Used		Not Used	Discriminator output (pin 1 of V11)	Meter on 3 Volt Scale	T102 (bottom) for zero on meter
3	2nd Sound i-f grid (pin 1 V10)	21.25 1 volt Output	2nd Sound I-F grid (Pin 1 V10)	21.25 Center 1 MC 1 Volt Output	Discriminator Output (pin 1 of V11)	Not Used	Check for symmetrical response waveform (pos. & neg.). If not equal adjust T102. (Top) until they are equal SEE NOTE 1	
4	Trap winding on T3 (top of chassis)	21.25 Reduced Output	Trap winding on T3	21.25 reduced output	Terminal A T102 in series with 33,000 ohms SEE NOTE 2.	Not Used	Sweep output reduced to provide 3 volts top on Scope SEE NOTE 3.	T101 (top) and bottom for max. gain and symmetrical at 21.25 mc

NOTE 1: The peak-to-peak bandwidth of the discriminator should be approximately 350 kc and should be linear from 21.175 inc. to 1.325 mc.

NOTE 2: If a 60 cycle sweep rate is used it will be necessary to reduce the time constant in the 2nd sound I-F grid circuit in order to reproduce the desired response curve. To do this, shunt R176 Terminal "A" of T107 to chassis with 5600 ohms.

NOTE 3: The sweep generator output should be set to produce approximately 0.3 volt peak-to-peak at the second sound I-F grid return (Terminal "A" of T107) for final touch upon this adjustment. Signal voltage in excess of 0.3 volt will tend to broaden the response curve permitting misadjustment to pass un-noticed.

Picture I-F and Trap Adjustment

Step No.	Connect Signal Generator to	Signal Gen. Freq. Mc.	Connect Sweep Generator to	Sweep Gen. Freq. Mc.	Connect Oscilloscope to	Connect "VoltOhmyst" to	Misc. Connections and Instructions	Adjust
5	Not used		Not used		Not Used	Junction R118 and R120	Set "Station Selector" switch to Channel 13	Adjust "Picture control for 3 volts reading on Voltohmyst
6	Pin No. 1 of 6AG5 Converter	21.25	Not Used		Not Used	Junction of L103 and R132	Meter on 3 volt scale	T3 (top) for min. on meter
7	"	21.25	Not Used		Not Used	Junction of L103 and R132	Meter on 3 volt scale	T105 for min.
8	"	22.8	Not Used		Not Used	Junction of L103 and R132	Meter on 3 volt scale	T3 (bottom) for max.
9	"	23.9	Not Used		Not Used	Junction of L103 and R132	Meter on 3 volt scale	L101 (top chassis) for max.
10	"	26.0	Not Used		Not Used	Junction of L103 and R132	Meter on 3 volt scale	T104 (top chassis) for max.
11	"	24.5	Not Used		Not Used	Junction of L103 and R132	Meter on 3 volt scale	L102 (top chassis) for max.

NOTE: Oscillation may occur if the I-F section is badly out of alignment. This will be evidenced by a meter reading in excess of 3 volts and is caused by the "staggered" I-F stages being tuned to approximately the same frequency. If this condition is encountered adjust the core studs of T3 (bottom) L101, T104 and L102 until oscillation ceases. Oscillation may not be encountered until proceeding with steps 9, 10 or 11 (See "Picture I-F Oscillation

World Radio History

These models use 20 Tubes (Including Picture Tube and Rectifiers) and employ an inter-carrier sound circuit. The picture Tube in both receivers is the 16TP4. Both receivers use ratio detector for the sound.

SAFETY PRECAUTIONS: The kinescope should be handled with extreme care. The person handling this tube should wear gloves and protective goggles as an added precaution.

When the power is connected, care must be taken in servicing the High Voltage Supply of these receivers. The interlock opens one side of the line only leaving one side of the line connected when the back is removed. For servicing with chassis out of the cabinet the interlock-socket can be shorted.

VOLTAGE READINGS: The voltage readings to be obtained at various locations in the receiver have been indicated on the schematic diagram. These voltages will be very advantageous when "trouble shooting". Check voltages, tubes, fuse and inspect for damaged or burned parts before attempting to re-align receiver. A wired-in 1/4 amp fuse is used to protect the high voltage circuit of the receiver.

All voltages were taken with a 117.5 V. line and with no signal input. The contrast control set at the maximum clockwise position; the brightness control at 50% rotation and all other controls in normal operating position. The tuner set for Channel 2. All voltages are positive with respect to ground unless otherwise indicated.

FOCUS ADJUSTMENT AND CENTERING

These receivers use a permanent magnet (PM) type of focusing. This focalizer is attached to a plate which i mounted behind the Yoke.

CENTERING OF PICTURE: The picture may be centered in relationship with the opening of the glass panel at the fac of the receiver by shifting the brass centering stud at the rear of the focalizer. (See top view of chassis)

FOCUS ADJUSTMENT: (The focus adjustment must be made with a screw-driver of non-magnetic material.) The focus adjustment (the large slotted screw) is located at the rear of the focalizer. The picture focus is adjusted by either increasing or decreasing the amount of screw insertion to either decrease or increase the magnetic flux as required.

CONTROL OPERATION

HEIGHT CONTROL (Rear Apron of Chassis) To increase the vertical size of the picture, turn this control in a counter-clockwise rotation. To reduce the size of the picture vertically, turn this control clockwise.

VERTICAL LINEARITY: (Rear Apron of Chassis) As this knob is turned to the left (counter-clockwise) the size of the top half of the picture is increased vertically; as it is turned clockwise, it is reduced.

HORIZONTAL LINEARITY: (Top of Chassis - See Layout) moving the slug out of the coil increases the left hand side of the picture and moving the slug in decreases the left and increases the right hand side.

WIDTH CONTROL: (Top of Chassis - See Layout) Screw slug in to increase width and out to decrease width.

HORIZONTAL FREQUENCY: (Top of Chassis - See Layout) Locate the horizontal hold control (located on front apron) in the center of its rotation. Adjust horizontal frequency screw to lock in picture. When properly adjusted the horizontal hold control should hold in the picture when the picture is turned approximately equal amounts from the center position.

HORIZONTAL DRIVE: (Screw Driver Adjustment on rear apron of chassis) Turn counter-clockwise to increase drive and clockwise to decrease drive. Drive should be as high as possible without producing a bright vertical line on the raster.

CAUTION: INSUFFICIENT DRIVE WILL OVERLOAD HORIZONTAL DRIVER (6BQ6GT).

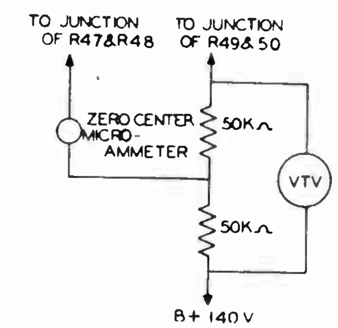
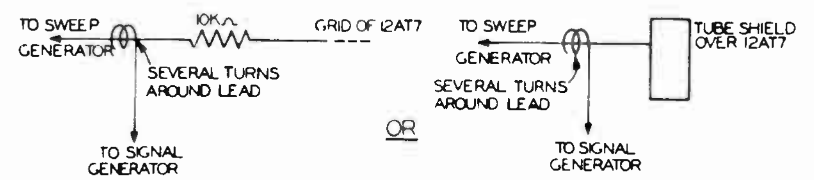
I.F. ALIGNMENT PROCEDURE

STEP NO.	Connect Signal Generator to	Signal Gerator Frequency MC	Connect Sweep Generator to	Sweep Generator Frequency	Connect Oscilloscope to	REMARKS	ADJUSTMENTS (Use peak obtained when screw is farthest out of can or coil.)
1. AUDIO IF ALIGNMENT	Grid of Video Amp. (6CB6) Pin #1. Contrast control at maximum.	4.5 MC. No Modulation. See Adjustments column.	NOT USED		NOT USED	Connect Vacuum Tube Voltmeter and zero center Microammeter as shown in note 1 (50,000 ohm resistors shown in note 1 must match within 5%)	Adjust L17 and T3 (Bottom) for maximum on Vacuum Tube Voltmeter. This adjustment should be made with voltage on Vacuum Tube Voltmeter under 12 Volts. Adjust T3 (Top) for zero on Microammeter. If the receiver is receiving a signal, the above adjustment can be made off a weak station keeping the reading on the Vacuum Tube Voltmeter under 12 Volts.
2. PRELIMINARY VIDEO IF ALIGNMENT	Grid (Pin 2) of 12AT7 through 10,000 ohm resistor or a tube shield and slip over 12AT7. Do Not Ground Shield	25.5 MC. No Modulation.	NOT USED		NOT USED	Connect Vacuum Tube Voltmeter to A.G.C.point. Junction of R19 and R25.	Adjust 2nd and 4th I.F. coils (L8 and L12) for maximum on Vacuum Tube Voltmeter. Adjust at approximately one volt.
3. PRELIMINARY VIDEO IF ALIGNMENT	Grid (Pin 2) of 12AT7 through 10.000 ohm resistor or a tube shield and slip over 12AT7. Do Not Ground Shield	23.0 MC. No Modulation.	NOT USED.		NOT USED	Connect Vacuum Tube Voltmeter to A.G.C.point. Junction of R19 and R25.	Adjust 1st and 3rd I.F. coils (L5 in Tuner and L10) for maximum on Vacuum Tube Voltmeter. Adjust at approximately one volt.
4. FINAL VIDEO IF ALIGNMENT	Signal Generator as shown in note 2.	26.1 and 22.8 MC MC. No Modulation. See Note 3.	Grid of 12AT7 through 10,000 ohm resistor, or a tube shield and slip over 12AT7. See Note 2.	24 MC Center Frequency and at least 6 MC wide.	Junction of R29 and L14.		With signal generator set at 26.1 MC adjust 2nd and 4th I.F. coils to give correct marker position as shown in note 3. Set signal generator at 22.8 MC and adjust 1st and 3rd I.F. coils for pattern shown in note 3. A slight readjustment of 2nd and 4th I.F. coils may be necessary. Curve shape should be between "A" and "C" on note 3 with maximum signal output for a low sweep input.

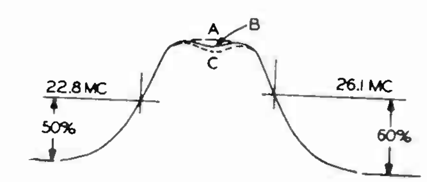
NOTE 1



NOTE 2



NOTE 3



TUNER ALIGNMENT

The tuner should normally retain its alignment and need no realignment in the field. However, if it is tampered with or a condenser or resistor is replaced due to failure, realignment may be necessary but should not be attempted until the video I.F. is aligned. If a part is replaced be careful not to disturb any other parts and the replacement part should be placed in the same position as the previous part and with the same length of leads.
This tuner employs a gang condenser which retains its alignment. The adjusting is accomplished at the high and low ends of the two bands; channels 6 and 2, and 13 and 7.

The oscillator trimmers act independently, but the R.F. and mixer trimmers must be aligned first on the low channels as they are in parallel with high band trimmers.

Connect the antenna lead to the sweep generator which must terminate in 300 ohm. Connect signal generator to piece of wire and wrap around 300 ohm antenna lead. (If sweep generator has sound and picture markers the signal generator is not necessary.)
Adjust channel 6 first. Set the tuner to the center of channel 6 and set the signal generator to the picture carrier (83.25 MC). Adjust the low band oscillator trimmer (C10) to bring the marker approximately 60% up from the base of the curve. As this trimmer is increased in capacity the marker should move towards the top of the curve. If this is not the case, the marker is on the audio side of the curve. Reduce the trimmer until the marker is on the other side of the curve. Next adjust the low band R.F. (C5) and Mixer trimmers (C6) to give maximum sensitivity on the oscilloscope being careful to have sufficent width on the audio side of the curve. Check channel 2 with a marker frequency of 55.25 MC.

Adjust channel 13 in the same manner as for channel 6 except using the High Band trimmers (RF-C15, Mixer C16, and Oscillator C19) and the picture marker frequency which is 211.25 MC. Check channel 7 with a marker frequency of 175.25 MC.

INDEX

UNPACKING INSTRUCTIONS

CAUTION: Before connecting this receiver for operation, be sure to observe the following procedure:

The receiver chassis has been blocked and tightened down for shipment and must be loosened as follows:

1. Remove the drive screw that hold the inter-lock plug and the wood screws that fastens the back cover to the cabinet.

2. Remove the wing nut, washer and plate that fastens the focus coil to back cover for shipping. (Plate should be saved in case re-shipment is necessary).

3. Remove the socket from base of picture tube.

4. Remove Ion Trap from neck of picture tube.

5. Reassemble washer and wing nut to focus coil, loosen wing nut on opposite side and slip focus coil over neck of picture tube so that the coil lead wires will lead from the upper left-hand corner of coil. Slide coil towards yoke assembly until the mounting studs engage the mounting slots in yoke frame. Assemble coil with dished washers between yoke bracket and focus coil housing.

6. Replace ION trap on neck of tube.

7. Attach socket to pix.tube base.

8. Loosen the (4) hex-head chassis mounting screws and pull out the shipping strips. Tighten the (4) mounting screws enough to prevent rattle.

9. Refer to Service Manual and adjust Ion Trap and Focus Coil.

10. Tune in a station and set the horizontal hold control to approximately the Center of its rotation. Adjust the horizontal oscillator coil until the picture is synchronized horizontally. For detailed instructions on this adjustment refer to Service Bulletin 2-33, Manual 7.

11. Replace back cover.

12. This receiver is equipped with a built-in dipole antenna which is hooked up for operation when shipped from the factory. A label on the back cover contains instructions for connecting an outside antenna.

13. NOTE: In the event this receiver is to be re-shipped, the chassis must be blocked and tightened down, the focus coil and Ion Trap remove from picture tube neck and fastened in their shipping positions, otherwise the shipper will assume all RESPONSIBILITY for picture tube breakage in transit and will stand LIABLE for breakage charges.

*CONSTRUCTING A CHANNEL TRAP

*Constructed of a piece of 300 ohm transmission line, shorted on one end to serve as a 1/2 wave length shorting stub. Cut a piece of line slightly longer than given under the "Half-wave Shorted Channel Trap", column and connect the two leads of one end across the receiver antenna terminals.

Using diagonal cutters or razor blade, "short", across the transmission line at a place slightly longer than the calculated length. Care should be taken when "Shorting",the line to cut through the plastic covering only; do not cut the conductors. If the interference is not "Trapped Out", short the line in 1/8" intervals(working toward the terminals) until the critical point is reached. Cut the transmission line and place a carbon resistor across the line. The resistor should be approximately 60 ohms. For strong interference, it may be necessary to drop the resistance to 20 ohms, and for weak interference it may be possible to use a 150 ohm resistor. Do not use any lower value resistor than necessary to minimize the interference.

If the interference frequency is not that of a television station, the line may be cut and the leads shorted together without using the resistor. Generally, this will completely eliminate the interference frequency.

If the interference frequency being eliminated or "Trapped-out" is that of some other television station operating in the vicinity, the interfering frequency will also be eliminated or attenuated on its own channel. If the interference frequency is so strong that it can not be attenuated enough using a resistor across the line, it will be necessary to install a double-pole, single-throw switch on one of the trap leads so that the "Channel Trap", can be opened when the receiver is switched to this channel.

If the interference frequency is known, the transmission line can be cut by using the following formula.

$$\text{Half wave shorting stub in inches} = \frac{4841}{\text{Freq.(MC)}}$$

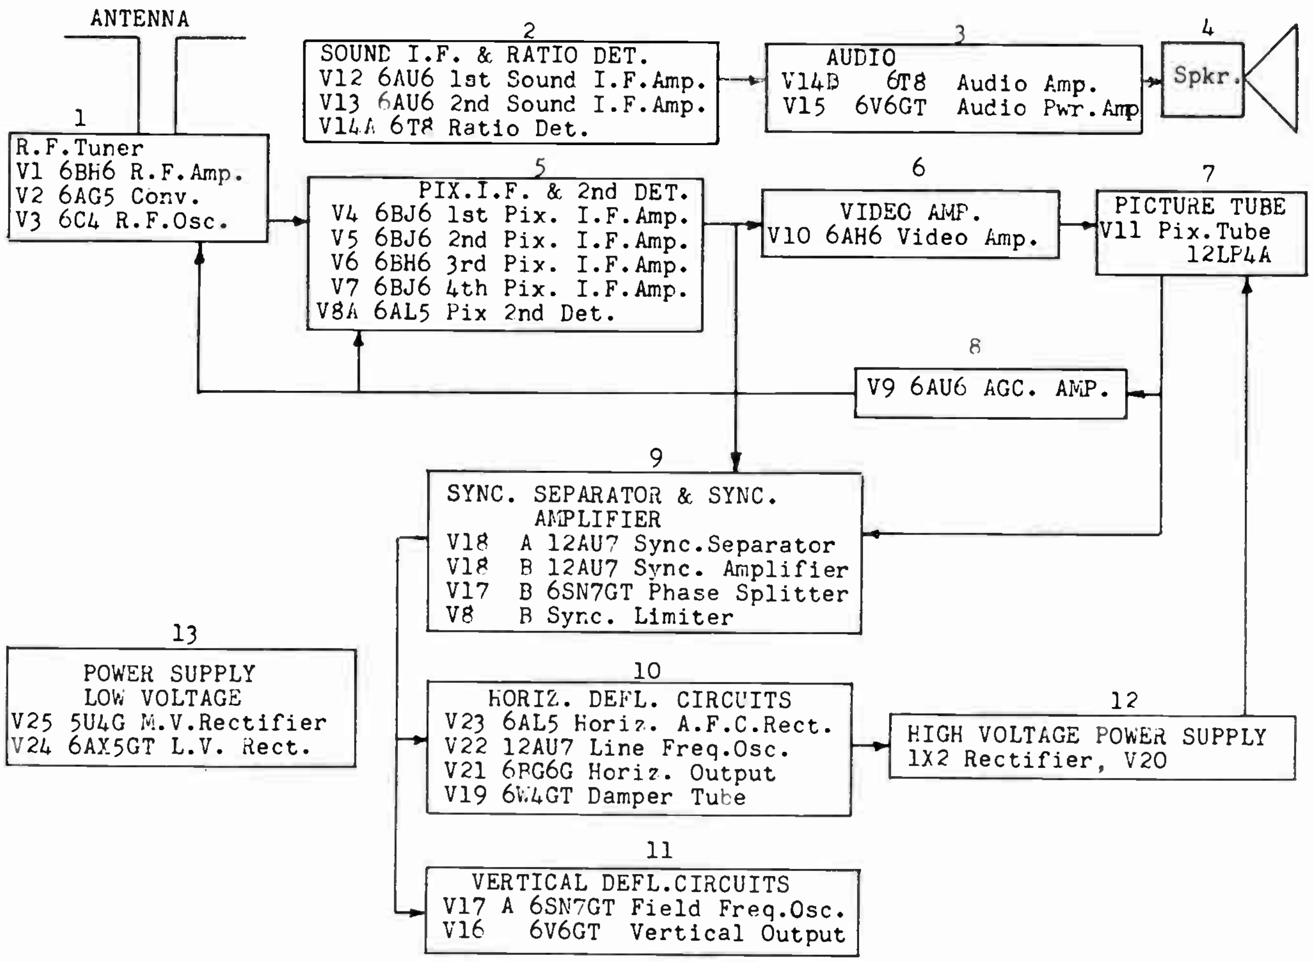
CIRCUIT DESCRIPTION

GENERAL: The following circuit description for Sparton Television Models provides all pertinent information necessary for proper servicing of these receivers. In the compliation of this data it is assumed that the service engineer is familiar with the basic electronic principles of modern television.

Fig. 2(below) shows a fundamental block diagram breakdown of the receiver circuits. The description for these circuits follows in the same order as the blocks appear on the diagram.



FUNCTIONAL BLOCK DIAGRAM FIG. 2.

R.F. TUNER (BLOCK #1)

SPECIAL SERVICE NOTE: Service replacement for the R.F. Tuning unit will be made only as a complete assembly including tubes. This unit will be shipped from the factory under part no. AD93152-2.

The R.F. Tuner is a separate sub-assembly of the receiver. It contains the R.F. amplifier, converter, local oscillator, fine tuning control, station selector switch, input transformers, R.F. amplifier coils, oscillator coils and the individual tuning adjustments for the transformers and coils. The unit provides operation on all twelve of the television channels. It serves to select the desired picture and sound carriers and associated side bands. It amplifies the selected R.F. signal and provides at the converter plate a picture I.F. carrier of 26.25 Mc. and a sound I.F. carrier of 21.75 Mc.

R.F. AMPLIFIER As shown in the schematic diagram (page 13), T1 to T9 together with incremental inductances L2,L3 and L4 are input transformers tuned to channels 2 to 13 respectively. The secondary of each of these transformers forms a parallel resonant circuit with the input capacity of V1 the 6BH6 R.F. amplifier. The inductances of the secondaries of the transformers T1 through T5, tuned to channels 2 to 6 respectively are adjusted by means of individual slugs placed within these coils. Incremental inductances L2,L3, and L4 are added in series with the slug tuned secondaries of transformers T6, T7 and T8, tuned to channels 8, 10 and 12 respectively, to form the tuned circuits for channels 7, 9, and 11. Thus the secondary of T6 tuned to channel 8 with an added series inductance L2 forms the tuned circuit for channel 7 and so on with channels 9-10 and 11 - 12. The secondary of transformer T9 is slug tuned for channel 13. On channels 7 through 13 small capacitors (C1,C2,C3,C4) are placed in series with the secondaries of transformers T6 through T9. In this way, the effective shunt capacity with which these coils resonate is decreased, and the use of larger inductance values is permitted.

CONVERTER Each of the inductances L5 through L16 forms a tuned pi-network with the input capacity of the converter (V2) and the output capacity of V1. These resonant circuits are tuned to channels 2 to 13 respectively and couple R.F. energy to the grid of V2. Since the oscillator output and the R.F. signal are both fed to the grid of V2 the heterodyne products (I.F. frequencies) will appear at the converter plate.

The inductance of coils L5 through L9, tuned to channels 2 through 6 respectively, is adjustable by means of individual slugs placed within these coils. Incremental inductances are added to the slug tuned coils for channels 8, 10 and 12 to form tuned curcuits for channels 7, 9, and 11. L16 is slug tuned to channel 13.

In the plate of the converter there are two tuned curcuits. They are the following:

FIRST: L32 with C21 forms a paralleled resonant circuit tuned to 94 Mc. that acts as a series trap preventing the oscillator voltage injected on the converter plate from developing bias on the grid of V4, the first video I.F. stage.

SECOND: L34 in conjunction with the output capacity of V2 and the input capacity of V4 forms a parallel resonant curcuit tuned to 22.4 Mc. This is the first stage of the stagger tuned video I.F. system.

R.F. OSCILLATOR: The local oscillator is a Colpitts type. The inductances L17 through L28 together with the incremental inductances L23, L25 and L27, form the oscillator tank circuits and are tuned above the R.F. frequencies at channels 2 to 13 respectively. Fine tuning is accomplished by means of C14, which has a capacity range sufficient to produce a ∠ 600 Kc. variation in oscillator output frequency on channel 2 and a variation of approximately ∠ 2.5 Mc. on channel 13.The output of the oscillator is coupled to the grid of the converter by means of capacitor C10. The oscillator operates at a frequency above that of the received signal.

SOUND I.F. AND RATIO DETECTOR (BLOCK #2) The sound and picture I.F. signals are common to stages V4 and V5. At V6 sound energy is taken off by means of the sound take off loop, which is part of L43, the 21.75 Mc. cathode trap inductance. This energy is fed to the first sound I.F. stage V12. Two stages of sound I.F. amplification are employed in order to secure adequate gain. Inductors L56 and L59 are 1" pieces of straight, tinned copper wire. They are employed in the cathode circuits of V12 and V13 to neutralize a regenerative condition in the 6AU6 tube produced by mutual inductance between suppressor and control grid leads.

T13 in conjunction with V14A forms a conventional ratio detector system that operates on a center frequency of 21.75 Mc. and has a peak-to-peak band width of approximately 500 Kc.

AUDIO AMPLIFIER AND SPEAKER(BLOCKS #3 AND #4)Tubes V14B and V15 form a conventional two stage audio amplifier that feeds a permanent magnet speaker. A compensated volume control R61A is employed. Continuous tone control is provided by means of R61B and its associated circuit. Maximum power output of the system is approximately 3. watts in the speaker voice coil.

PICTURE I.F. AMPLIFIER AND SEC. DET (BLOCK #5) The primary requirements of the picture I.F. system are wide overall response and adequate overall gain. To meet these requirements four stages of stagger tuned video I.F. amplification are employed.

As noted on the schematic diagram (page 19) these stages are V4, V5, V6 and V7. Single tuned I.F. coils are utilized in the plate circuit of the converter and each of the four successive stages. Starting with the coil L34 in the converter plate each of the coils L36,L40,L44,L47 in the following stages are tuned to a different frequency. Thus by virtue of stagger tuning the several stages, wide band picture I.F. response is obtained.

World Radio History

CIRCUIT DESCRIPTION (CONT'D)

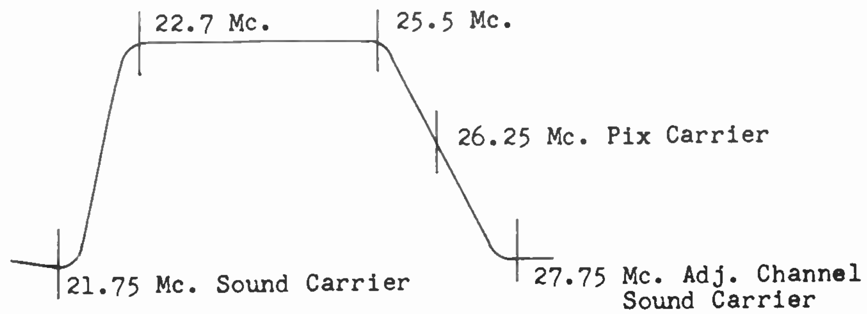

Figure (3) Pix. I.F. Response

In order to obtain a band pass as pictured in Figure (3), the I.F. coils are peaked to approximately the following fixed frequencies:

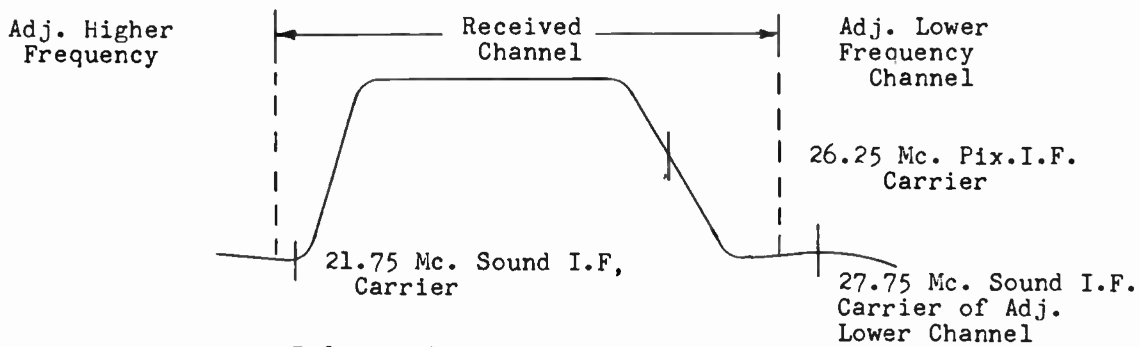
L34	Plate of the Conv.	(V2)	22.4 Mc.
L36	1st Pix. I.F.	(V4)	22.5 Mc.
L40	2nd Pix. I.F.	(V5)	25.9 Mc.
L44	3rd Pix. I.F.	(V6)	24.1 Mc.
L47	4th Pix. I.F.	(V7)	26.0 Mc.

In addition the trap L37 for the adjacent channel sound I.F. carrier, 27.75 Mc., and the traps L43 and L48 for the sound I.F. carrier, 21.75 Mc., are peaked for minimum output at the pix detector load. The overall response of the picture I.F. is observed with the aid of an I.F. sweep and an oscilloscope. Deviations in the observed response from that pictured in Figure (3) are compensated for by slight variations in the tuning of the pix. I.F. coils.

Under normal conditions replacement of any of the tubes in the picture I.F. strip will have little effect on the shape of the overall pass band. The information on physical location of the various transformers and traps will be found in the section on alignment.

TRAPS Referring to figure (4) it is evident that the I.F. frequency of the adj. channel sound carrier and the I.F. frequency of the received channel sound carrier are quite close to the frequencies passed by the picture I.F. system. If some means of attenuating these sound carriers is not provided in the picture I.F. they will pass through the pix detector where they will be demodulated and passed on to the kinescope grid as video information. Once there, these signals would appear as interference in the observed picture.

Figure 4



Relation between Pix. and Sound I.F. Carriers

Note that with the R.F. oscillator operating above the channel being received the I.F. relation of the pix to sound carriers is the reverse of their R.F. relation.

In order to prevent this interference, trap circuits L37, L43 and L48 are provided to attenuate the undesired sound carriers. L37 functions as a series trap in the plate circuit of V4 and is tuned to 27.75 Mc., the I.F. frequency of the adjacent channel sound carrier as noted in figure 4. The trapping action of this stage is sufficient to keep the sound interference from this source at a negligible value. L43 and L48 are tuned traps inserted in the cathode circuits of V6& V7 respectively.

VOLTAGE CHART AND ALIGNMENT TEST POINTS

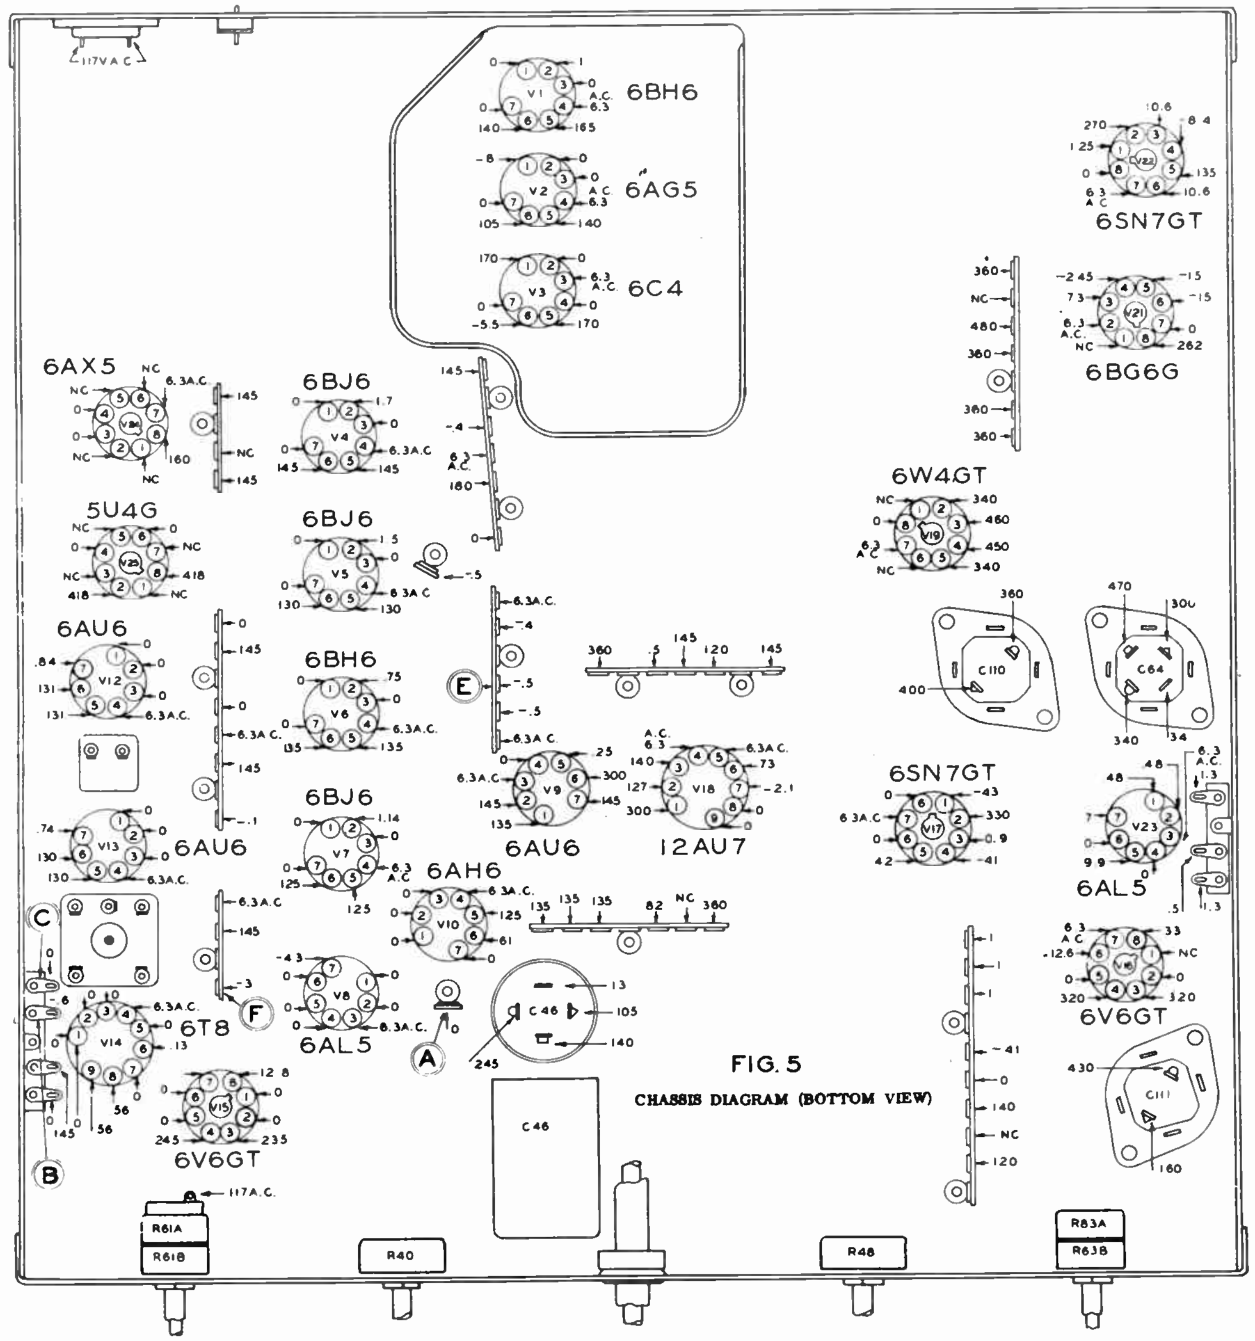


FIG. 5
CHASSIS DIAGRAM (BOTTOM VIEW)

World Radio History

CIRCUIT DESCRIPTION (CONT'D)

These traps are tuned to 21.75 Mc., the sound I.F. frequency. At this frequency, the voltage developed across these traps will function as a degenerative voltage opposing the 21.75 Mc. sound I.F. signal at the grids of the respective stages. The combined attenuation offered by stages V6 and V7 is sufficient to suppress the 21.75 Mc. sound carrier before it reaches the pix detector. Inductors L42 and L46 are used to minimize changes in input impedance of stages V6 and V7. The neutralized changes in input impedance occur with frequency and are due to the respective cathode traps.

PIX DETECTOR The pix second detector is a conventional diode, V8A. It is D.C. coupled to the video amplifier and connected to produce a sync. signal of negative polarity across its load.

VIDEO AMPLIFIER BLOCK #6 The video amplifier is a D.C. coupled 6AH6 stage V10 having a maximum gain of approximately 35. The frequency response of the amplifier extends from DC. to 4 megacycles. A 4.5 megacycle trap (L52,C45) seems to prevent the beat note set up by picture and sound carriers from appearing in the picture as a fine interference pattern. L51, L53, L54 and L55 are peaking coils inserted in the circuit to get the desired frequency response.

The gain of the stage is varied by changing the screen grid voltage by means of the contrast control R40. The 6AH6 is a sharp cut-off high gain tube with the operating conditions adjusted in such a manner that noise pulses of sync. polarity are clipped off in the grid circuit and noise of opposite polarity is clipped off in the plate circuit.

Due to the fact that the video system is D.C. coupled from the picture detector to the kinescope cathode, no D.C. restorer is necessary in the receiver.

KINESCOPE BLOCK #7 The kinescope utilized in the receiver is a conventional 12" tube, This tube employs magnetic focus and deflection systems. An ion trap is used to prevent the ion beam from forming a dark spot on the kinescope screen. The flaring portion of the kinescope bulb has a metallic coating on both the inside and outside surfaces. The coating on the inside of the bulb forms the kinescope second anode and has the high voltage connected to it. The outside coating is grounded so that the capacity between the outside and inside coating acts as a filter for the high voltage power supply. The outside coating also serves as an electrostatic and external light shield to the tube.

A.G.C. AMPLIFIER BLOCK #8 A keyed A.G.C.amplifier tube V9 is used in order to get the best possible A.G.C. characteristic and to minimize the effects of noise in the A.G.C.circuit.

In a receiver using a conventional A.G.C. circuit any noise signals present at the Picture Detector will develop A.G.C. voltage and reduce the gain of the receiver. If the noise is of greater strength than the incoming signal which is often the case in weak signal areas the video signals will be so reduced by the A.G.C.voltage developed by noise that the pictures will become very unsteady and drop out of sync. entirely.

In the keyed A.G.C.system, the plate voltage for the A.G.C.amplifier tube is a high narrow positive pulse of about 300 volts taken from a winding on the horizontal width coil. This pulse is synchronized with the incoming horizontal sync. pulses and no plate voltage is applied to the tube except at the time a sync. pulse is present on its grid. Any noise pulses arriving between sync. pulses cannot generate A.G.C. because no plate voltage is applied to the plate and the tube cannot function. Therefore, the A.G.C.system is upset very little by noise.

Full A.G.C. is applied to the I.F.tubes but only approximately 1/3 of the A.G.C. is applied to the R.F.amplifier tube. This allows the R.F. stage to operate with a better signal-to-noise ratio than if full A.G.C.were applied.

SYNC. STRIPPER, AMPLIFIER AND CLIPPER(BLOCK #9) Synchronizing signals of positive polarity are taken from the plate load resistor of the video amplifier tube and fed to the grid of the first section of V18. This triode is biased beyond cut-off so that only the synchronizing pulses appear in the plate circuit. These sync. pulses are then amplified and partially clipped by the second section of V18 and applied to the grid of the phase splitter V17B and the plate of the sync.limiter diode V8B. The limiter diode (V8B) clips off the sync. and holds the level essentially constant

TRIMMER AND SLUG LOCATIONS

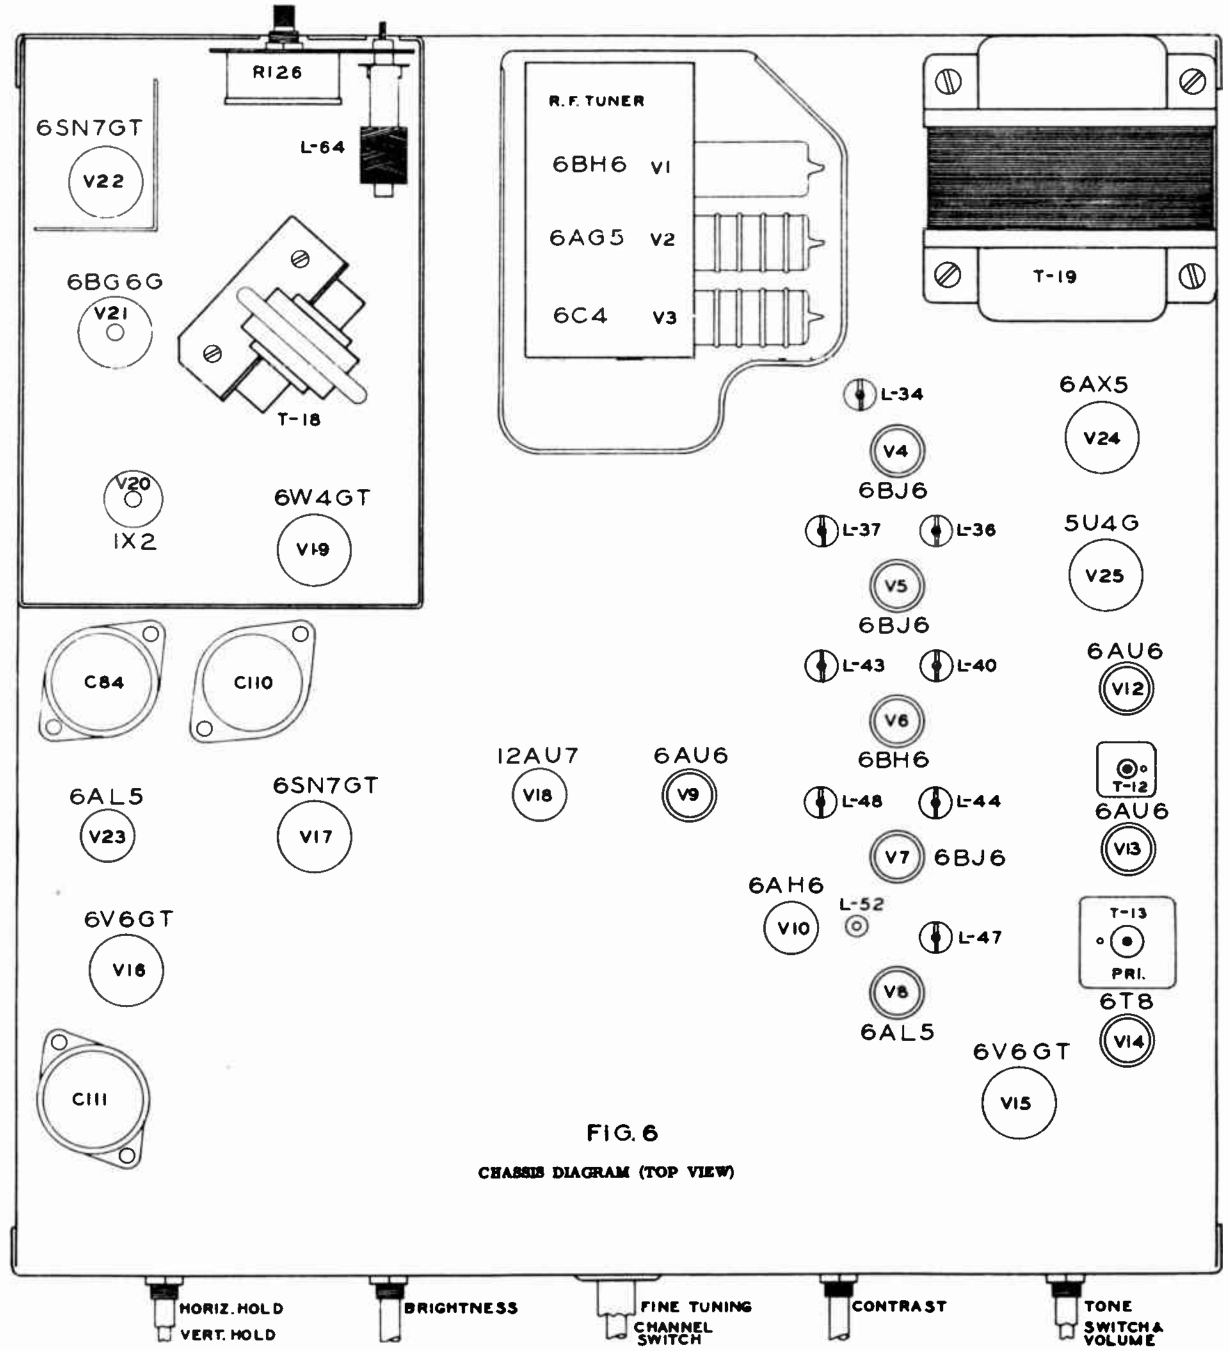

FIG. 6

CHASSIS DIAGRAM (TOP VIEW)

over a wide range of input signals. The phase splitter V17B further clips the sync. signals and provides both positive and negative sync.pulses in its output which are required for the horizontal AFC system.

HORIZONTAL DEFLECTION CIRCUITS (BLOCK #10) The horizontal deflection system is incorporated to provide a stable, linear, scanning current in the horizontal winding of the deflection yoke. This results in accurate horizontal reproduction of the transmitted picture.

World Radio History

CIRCUIT DESCRIPTION (CONT'D)

HORIZONTAL OSCILLATOR AND AFC SYSTEM The horizontal oscillator V22 is a composite circuit incorporating a cathode coupled multivibrator and a tank circuit (L65 and C100) resonant at approximately 15, 750 cycles per second to produce a stabilizing sine wave voltage. This circuit possesses the RC time constand and grid bias frequency control characteristics of a typical multivibrator; but it achieves some of the operational frequency stability of a sine wave system. The free-running frequency of the oscillator is controlled primarily by the horizontal hold control R83B. This control is set for approximately 15,750 cycles per second. The oscillator is then locked into synchronism with the incoming signal by means of an automatic D.C.control voltage bias applied to one grid (pin #1) of the oscillator.

This D.C. voltage is developed by the horizontal A.F.C. rectifier V23. This circuit is a conventional duo-diode phase comparitor which compares the phase of the incoming sync. pules with the saw-tooth voltage across the horizontal output transformer secondary, the sawtooth being fed through C103 and R114. Any discrepancy in the exact phase relationship of these two voltages produces a change in D.C. voltage across C102 (at the oscillator grid). This changes the oscillator frequency to assure exact phase and frequency coincidence between the output sawtooth and the incoming sync.pulses from the signal. In this manner, the horizontal scanning of the receiver is locked in to synchronism with the signal sync.pulses.

The output of the horizontal oscillator is a aswtooth voltage(developed by the RC network R108 and C98) puls a peaking component(fed back through C95 from the horizontal output) across R107). The peaking component is sufficient to produce adequate high voltage and fast retrace time. The amount of this drive to the grid of the horizontal output tube V21 is controlled by a capacity divider consisting of C97 and a variable mica trimmer C96. This trimmer is adjusted for optimum horizontal linearity of picture

HORIZONTAL OUTPUT AND DAMPER The horizontal output tube and the damper tube V19 produce the required linear sawtooth scanning current in the horizontal deflection coil. The two tubes plus the horizontal output transformer also produce a high voltage pulse which is used to obtain the kinescope high voltage supply. The output system is a conventional kick-back type except that no electrical horizontal centering is provided. Capacitor C92 is employed to isolate direct current from the yoke. Centering is therefore accomplished by actual physical motion of the focus coil. The output transformer as far as deflection is concerned, is an impedance matching device for the output tube and yoke.

The width control L64 is provided to vary the output and hence the picture width. This is accomplished by shunting a portion of the secondary winding to change the effective transformation ratio. Clockwise rotation of L64 increases the shunting inductance and hence the width.

Because the horizontal transformer, deflection coil, and associated circuits are designed to resonant at a high frequency (period = 14 microseconds) for fast retrace time, they are shocked into resonance when the magnetic field collapses during the retrace. To prevent continued oscillatory currents in the deflection yoke, the damper diode, V19 is incorporated. During the first half cycle (7 microsecond) of retrace resonance, the circuit oscillates freely to insure rapid retrace time. During the next half cycle, however, the damper plate goes positive and conduction of the 6W4G occurs. This puts a very heavy load on the deflection coil so that it cannot oscillate.

The 6BG6G plate voltage is supplied through the 6W4G which is conducting over the major portion of the trace. Capacitor C93 is charged during this period and this charge is sufficient to supply the 6BG6G plate when the 6W4G is not conducting.

The charge is placed on this capacitor by the receiver d-c supply and by the current from the collapse of the field in the horizontal deflecting coil. The a-c axis of the sweep voltage is 360 volts above ground since the secondary is connected to the receiver, 350V volt bus. The charge placed on this capacitor by the coil kick-back is therefore in addition to that from the d-c supply and thus the capacitors are charged to a voltage greater than the d-c supply. This permits operation of the 6BG6G at a higher voltage than is obtainable from the receiver power supply and produces an increase in the system efficiency by salvaging energy that would otherwise have been wasted.

VERTICAL DEFLECTION SYSTEM(BLOCK #11) This section of the receiver functions to supply vertical scanning for the kinescope. A conventional system is utilized. Stage V17A operates as a field frequency oscillator whose output signal is used to drive the vertical output stage V16. The combined action of these stages and their associated circuits provides a linear deflection current of proper polarity and frequency in the vertical deflection yoke.

VERTICAL INTEGRATING NETWORK The integrating network composed of R79,R80,R81 and C82 A-B-C functions to separate the horizontal from the vertical sync.and to pass the vertical sync. pulse developed on to thefield frequency oscillator. In operation the network can be considered as a low pass filter that by-passes the horizontal sync. pulses and permits the low frequency vertical sync.to pass on through to the grid of V17A.

TRIMMER AND SLUG LOCATIONS

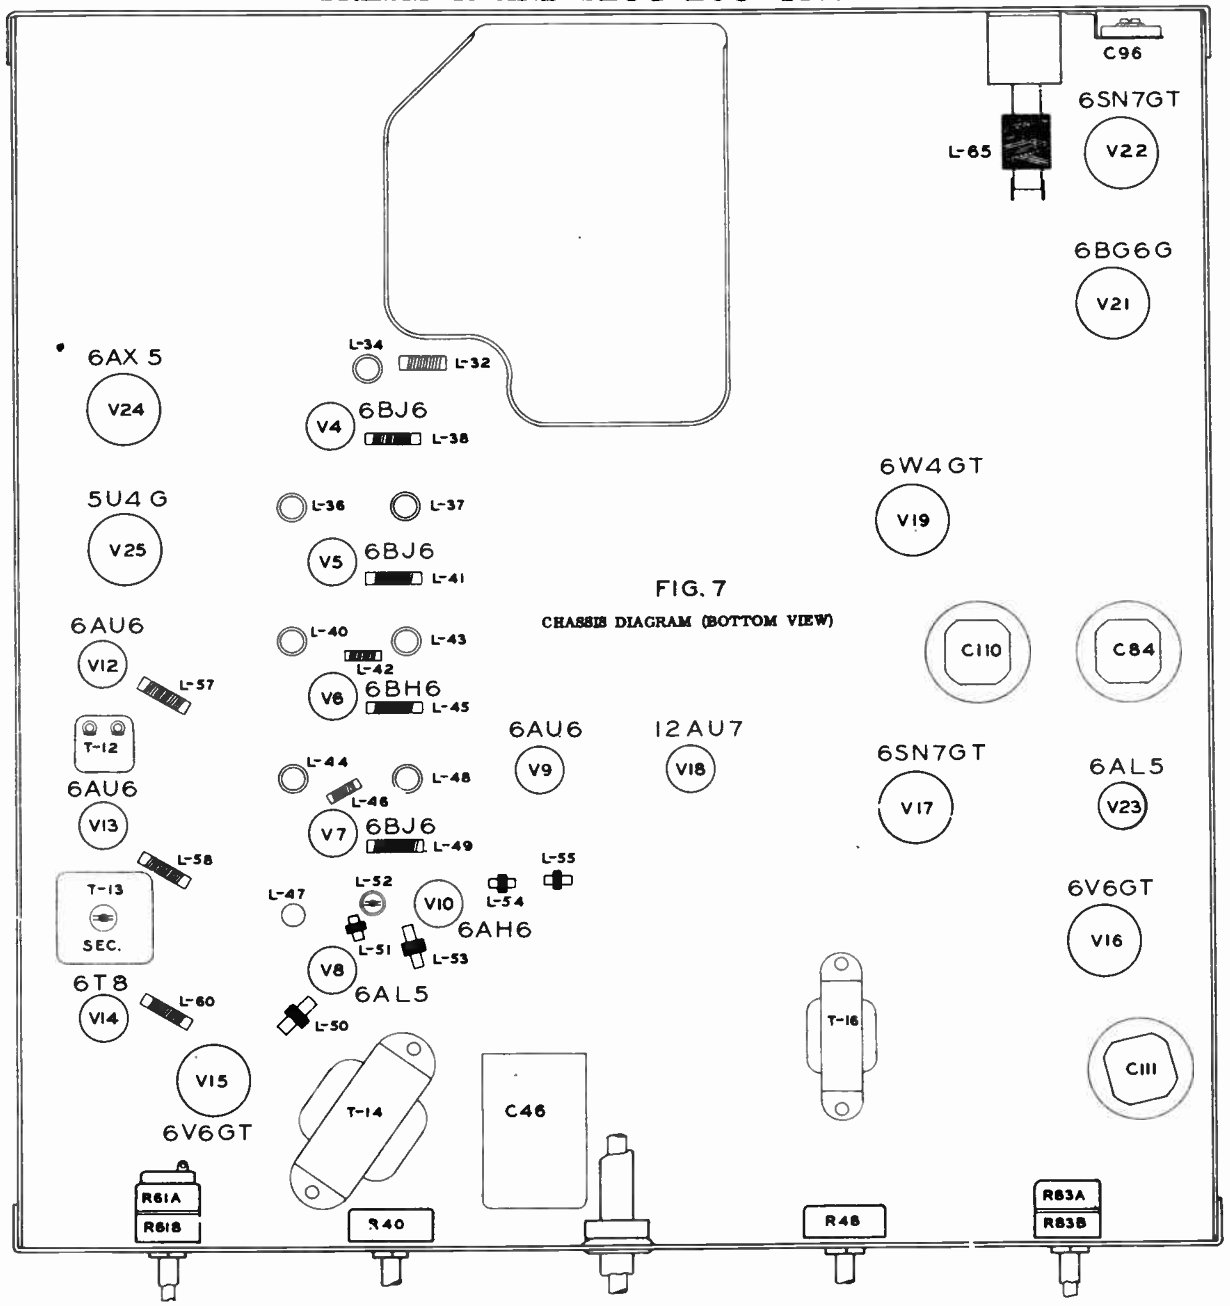

FIG. 7
CHASSIS DIAGRAM (BOTTOM VIEW)

World Radio History

CIRCUIT DESCRIPTION (CONT'D)

FIELD FREQUENCY OSCILLATOR The field frequency oscillator V17A is a conventional blocking oscillator system. In actual operation the free running frequency of the oscillator is adjusted by means of the vertical hold control R83A. The oscillator is locked in sync.at field frequency by means of the vertical sync. pulses which are injected into its grid circuit by the integrator network. The cut off and conduction action of the oscillator charges and discharges capacitor C86 and the resulting sawtooth output is used to drive the output stage.V16.

VERTICAL OUTPUT The peaked sawtooth output of the blocking oscillator system is used to drive the grid of the vertical output stage. An impedance matching transformer, T17 is used to couple the output stage to the vertical deflection yoke,L63A.Picture height is controlled by means of R87 which varies the B+voltage supplied to the vertical system. Vertical trace linearity is adjustable by means of R91 in the cathode circuit of the output stage. In operation, adjustment of this control varies the bias and consequently the operating point of the stage.

HIGH VOLTAGE POWER SUPPLY(BLOCK #12) The kinescope high voltage supply is obtained from the energy stored in the deflection inductances during each horizontal scan. When the 6BG6G plate current is cut off by the incoming signal, a positive pulse appears on the T18 primary due to the collapsing field in the deflection coil. This pulse of voltage is stepped up, rectified by V20, filtered and applied to the second anode of the kinescope (V11). Since the frequency of the supply voltage is high (15,750 C.P.S.), relatively little filter capacity is necessary. Since the filter capacity is small, the stored energy is small, and the high voltage supply is made less dangerous.

LOW AND MEDIUM VOLTAGE POWER SUPPLY (BLOCK #13) This part of the receiver supplies the heater and plate supply voltages for all tubes. A 5U4G rectifier V25 supplies 350 volts at 170 ma. which is filtered by the speaker field and the focus coil and their associated capacitors C111A, C110A, C110B.

The focus control R126 allows adjustment of the amount of current flowing thru the focus coil in order that correct focusing of the electron beam in the kinescope is obtained.

A 6AX5GT rectifier V24 supplies 140 volts at 120 Ma. which is filtered by a choke L67 and its associated capacitors C11B and C46D.

BUILT-IN DIPOLE ANTENNA
Both Models, 5006X and 5007X are equipped with a built-in Dipole antenna which is hooked up for operation when shipped from the factory.

The antenna proper consists of two copper plates in the top of the cabinet. The dipole tuning is accomplished by capacitor C19 which is a 2-80 MMF. trimmer and a matching stub in the 300 Ohm. ribbon. A control knob has been provided on the right-hand side of the cabinet for individual station tuning.

This type of antenna is designed for operation on local stations only, and in locations where it will give satisfactory results. This antenna is not designed to work in conjunction with another antenna and must be disconnected when another antenna is attached.

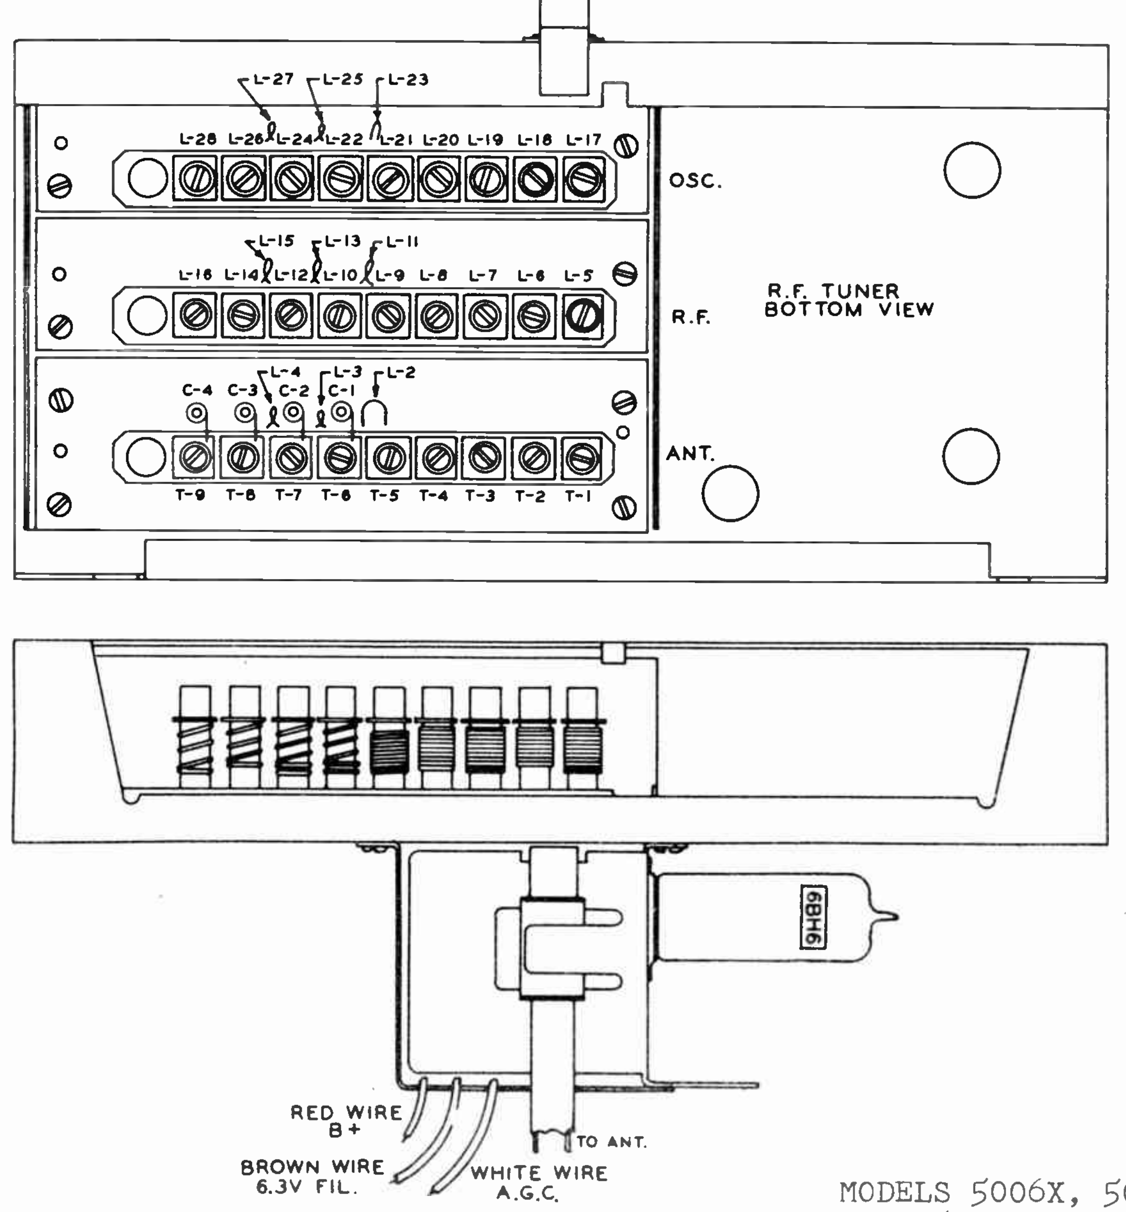
VOLTAGE TEST SPECIFICATIONS

1. Line Voltage = 117 Volts A.C.
2. Channel Switch Position = Channel #2.
3. Brightness Control Position = Average Brilliance on Picture Tube.
4. Contrast Control Position = Maximum (Clockwise).
5. Horizontal and Vertical Hold Control Positions = Set correct position to lock in picture.
6. Horizontal Width and Vertical Size Controls Positions = Set for Correct Size Raster = Height 8 3/4", Width 11 1/2".
7. Horizontal and vertical Linearity Control Position = Set for Best Linearity.
8. Focus Control Position = Properly focused.
9. Volume Control Position= Maximum Counter-Clockwise.
10. Tone Control Position = Maximum Counter-Clockwise.
11. Instrument (Meter) Used =(V.T.V.M.) Vacuum Tube Volt Meter.
12. Unless Otherwise Designated All Voltages Measured In Respect To Chassis Ground.

NOTE: The Points indicated by the letters A, B, C. E & F are the alignment test points referred to in the following alignment procedure. These points indicate the terminals for attaching Generator Leads.

R. F. TUNER SUB-CHASSIS ASSEMBLY

FIG.8



©John F. Rider

ALIGNMENT PROCEDURE

TEST EQUIPMENT: In order to align and service Sparton television receivers properly the following test equipment should be available:

FIRST: AN R.F. SWEEP GENERATOR of reliable quality that performs the following functions:

A. Provides sweep outputs in the following frequency ranges:

19 to 30 Mc.	10 Mc. sweep width
40 to 90 Mc.	10 Mc. sweep width
170 to 225 Mc.	10 Mc. sweep width

B. Provides an output signal that can be varied by means of an attenuator up to a maximum of at least .1 volt.

SECOND: AN R.F. SIGNAL GENERATOR that will provide an adjustable output signal up to a maximum of at least .1 volt on the following fixed frequencies:

A. I.F. Frequencies

21.75 Mc.	Sound I.F. and sound traps
22.4 Mc.	1st video I.F. coil
22.5 Mc.	2nd video I.F. coil
24.1 Mc.	4th video I.F. coil
25.9 Mc.	3rd video I.F. coil
26.0 Mc.	5th video I.F. coil
26.25 Mc.	Picture I.F. carrier
27.75 Mc.	Adjacent channel sound traps

B. R.F. Frequencies

Channel No.	Picture Carrier	Sound Carrier
2	55.25 Mc.	59.75 Mc.
3	61.25 Mc.	65.75 Mc.
4	67.25 Mc.	71.75 Mc.
5	77.25 Mc.	81.75 Mc.
6	83.25 Mc.	87.75 Mc.
7	175.25 Mc.	179.75 Mc.
8	181.25 Mc.	185.75 Mc.
9	187.25 Mc.	191.75 Mc.
10	193.25 Mc.	197.75 Mc.
11	199.25 Mc.	203.75 Mc.
12	205.25 Mc.	209.75 Mc.
13	211.25 Mc.	215.75 Mc.

THIRD: A CATHODE-RAY OSCILLOSCOPE of good quality that has a fairly wide band vertical amplifier and a low capacity input probe.

FOURTH: AN ELECTRONIC VOLTMETER on which the input probes are all insulated from the meter case.

FIFTH: A CRYSTAL CALIBRATOR that can be used for checks on the accuracy of the output frequencies of the R.F. signal generator.

GENERAL INSTRUCTIONS: Practically all servicing with the exception of some tube replacement will require removal of the receiver chassis from the cabinet.
A convenient arrangement that makes both the top and bottom of the chassis accessible for alignment and servicing can be realized by orienting the receiver chassis in such a manner that it rests on its side and on the horizontal output shield can

ALIGNMENT REQUIREMENTS: Under normal conditions complete receiver realignment will seldom be necessary in the field. However, a detailed description of the overall alignment procedure is included to provide all necessary information if it should be required.

In general it is not recommended that the R.F. and converter circuits of the R.F. tuner be realigned by the service engineer unless absolutely necessary. In cases where tuner components have been damaged, or where complete realignment is indicated, the R.F. tuner assembly should be removed from the chassis and sent back to the factory in exchange for a new unit which will be shipped complete with tubes.
When the new R.F. unit is assembled to the chassis it will be necessary in all cases to realign L34 which is located on the receiver chassis. Normally this is the only adjustment that will be required with tuner change but a check on overall receiver alignment and sensitivity should be made for the sake of certainty and assured customer satisfaction.

EFFECTS OF TUBE REPLACEMENT ON THE ALIGNMENT OF R.F. TUNER CIRCUITS: The alignment of the R.F. and converter circuits of the R.F. tuner is critical and may be affected by a tube change. In cases where these tubes (6BH6 or 6AG5) are replaced it will be necessary for the service engineer to check for satisfactory receiver operation. If realignment is indicated it can usually be avoided by selection of replacement tubes until receiver operation is realized.

Replacement of the 6C4 local oscillator can usually be made with little or no effect on the alignment and operation of the oscillator circuits. However, when a replacement is made, a check should be performed to make certain that the vernier capacitor range is sufficient to tune in the sound carriers on all channels.

ORDER OF ALIGNMENT: When complete receiver realignment is indicated it should be performed in the following order:

1. Sound traps
2. Picture I.F.
3. Sound I.F.
4. Ratio Detector Transformer
5. Retouch Picture I.F.
6. Sound and Picture I.F. Sensitivity Check
7. RF.Oscillator Circuits
8. R.F.and Converter Circuits(not recommended)
9. Overall Sensitivity Check

PRELIMINARY ADJUSTMENTS: Before alignment the receiver controls should be adjusted to the approximated operating positions specified in the table below. The controls should remain in these positions for all checks unless otherwise specified.

Contrast Control - to center position
Brightness Control - to position where raster is visible on the kinescope
Focus Control - to position where focus is obtained
Vertical Hold - to center position
Vertical Linearity - to center position
Vertical Size - adjusted to give normal raster height
Horizontal Hold - to center position
Horizontal Size - adjusted to give normal raster width

TEST EQUIPMENT SET UP: A certain amount of experimentation must be employed to secure a stable test set up before alignment or service of the receiver is attempted. It is recommended that the top of the test bench be covered with a sheet of aluminum to insure good grounds between the various pieces of test equipment and the receiver chassis. In general all test signal input leads should be kept away from output leads as much as possible.

PICTURE I.F. INSTABILITY: If the picture I.F. strip is badly out of alignment it may become unstable and fall into oscillation. When this condition occurs a comparatively large voltage is developed across the picture detector load resistor. This voltage is independent of I.F.signal input at the converter grid.
It is usually possible to stop I.F. oscillation due to misalignment by adjusting the iron cores in the various picture I.F. coils and traps according to the information given in the table below:

L34	Slug in (Max. L.)
L37	Slug out
L36	Slug in
L40	Slug out
L44	Slug out
L43	Slug in
L47	Slug out
L48	Slug in

The actual physical location of the various coils and traps is shown in Figure 6 and 7. As soon as the oscillation has been stopped, continue with the alignment as outlined in the following sections.

SOUND TRAP ALIGNMENT: FIRST, remove VI (6BH6 R.F. amplifier) and V-3 (6C4 local oscillator tubes)from the RF.tuner, connect the R.F.signal generator to the grid of V-2 by means of the I.F. input adapter as shown in Fig. 9..

ALIGNMENT PROCEDURE (CONT'D)

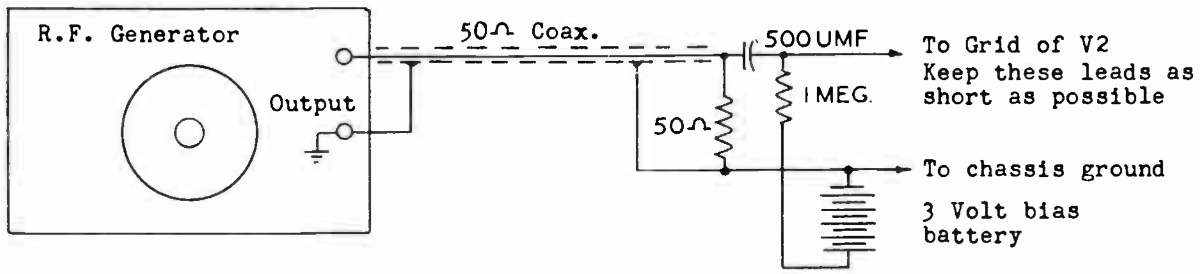

Figure 9 I.F. Input Adapter

SECOND: Set the R.F.tuner to channel #2.

THIRD: Connect a 3 volt bias battery between the A.G.C. buss (point E, Fig. 5) and chassis ground so that the voltage on the A.G.C. buss is-3 volts in respect to the chassis.

FOURTH: Connect the electronic voltmeter across the picture detector load resistor R37, Point A,Fig. 5 and set the voltmeter on the low DC.volt scale.

FIFTH: Set the R.F. signal generator to each of the frequencies shown in the table below and in each case tune the specified adjustment for minimum indication on the voltmeter. It is advisable to check the output of the generator with the crystal calibrator to make certain that it is exactly on frequency in each case.

27.75 Mc.	L37	(Top of chassis as shown in Fig. 6)
21.75 Mc.	L43	(Top of chassis as shown in Fig. 6)
21.75 Mc.	L48	(Top of chassis as shown in Fig. 6)

PICTURE I.F. ALIGNMENT: FIRST: Connect the R.F. signal generator, voltmeter and bias battery to the receiver as described in steps 1,2,3 and 4 of the sound trap alignment instructions.

SECOND: Set the signal generator to each of the following frequencies and peak the specified adjustments for maximum indication of the voltmeter.

22.4 Mc.	L-34	(Top of chassis as shown in Fig. 6)
22.5 Mc.	L-36	(Top of chassis as shown in Fig. 6)
25.9 Mc.	L-40	(Top of chassis as shown in Fig. 6)
24.1 Mc.	L-44	(Top of chassis as shown in Fig. 6)
26.0 Mc.	L-47	(Top of chassis as shown in Fig. 6)

NOTE: On some receivers it is possible to tune through resonance on L-40 and set the I.F. strip in oscillation. When this occurs the voltage across the picture detector load resistor will increase to a point where the effects of the oscillation may be mistaken for the actual resonance peak of L-40. If trouble of this nature is encountered tune L-40 to the point where I.F.oscillation ceases and go on to peak L44 and L47 at their respective frequencies and then return to peak L-40.

SOUND I.F. ALIGNMENT: FIRST: Connect the R.F. signal generator and bias battery to the receiver as described in steps 1,2 and 3 of sound trap alignment instructions.

SECOND: Connect the electronic voltmeter across C-69 (from point B to ground) as shown in Fig. 5 . Set the voltmeter on the low D.C. volt scale.

THIRD: Set the R.F.signal generator to 21.75 Mc. and peak the following coils for maximum indication on the voltmeter.

T-12	(Top of chassis as shown in Fig. 6)
T-13	(Primary (Ratio Det.) top of chassis as shown in Fig.6)

RATIO DETECTOR TRANSFORMER ALIGNMENT: FIRST: Connect the R.F. signal generator and bias battery to the receiver as described in steps 1,2 and 3 of the sound trap alignment instructions.

SECOND: Connect the electronic voltmeter from the junction of R63 and R64, Point F to the Junction of R59,C62 and C65. Point C as shown in Figure 5.

THIRD: Set the signal generator output to 21.75 Mc. Adjust the secondary of T13 (Bottom view of chassis as shown in Fig. 7). Notice that it is possible to produce a positive or negative voltage indication on the meter by varying this adjustment. As the voltage swings from positive to negative, adjust T13 for zero output as indicated by the voltmeter. This point is called zero ratio detector output and indicates correct alignment of T13 transformer. If the secondary of T13 is found to be way out of alignment it will be necessary to re-peak the primary as described in the preceeding section on sound I.F.alignment.

PICTURE I.F. TOUCH UP: Connect the R.F. sweep generator output to the grid of V-2 by means of the I.F. input adapter shown in Figure 9.

SECOND: Remove V-1 and V-2 from the R.F. tuner. Set R.F. Selector to channel #2.

THIRD: Connect the oscilloscope across the picture detector load resistor R37(point A, Fig. 5) by means of the shielded cable and the filter system shown in Fig. 10.

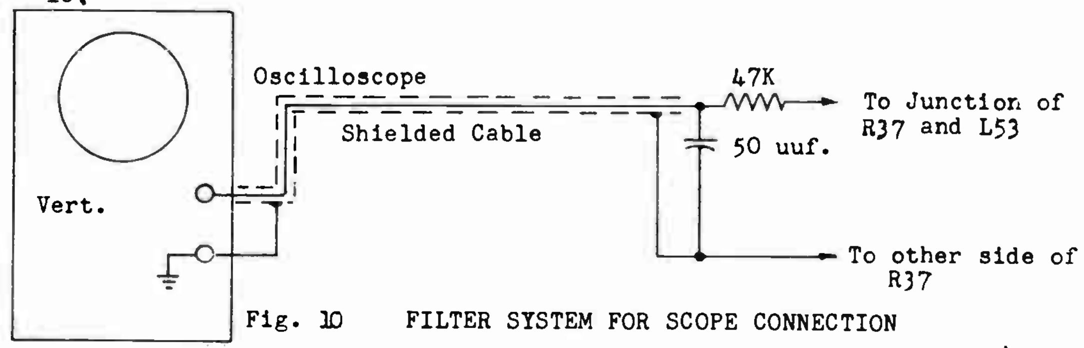

Fig. 10 FILTER SYSTEM FOR SCOPE CONNECTION

FOURTH: Set the R.F. sweep genterator so that it sweeps from approximately 20 to 30 Mc.

FIFTH: Adjust the oscilloscope so that the swept I.F. response is visible on the cathode-ray tube screen.

SIXTH: Loosely couple the output of the R.F. signal generator to the grid of V-2 so that marker signals of proper frequency can be mixed in with the R.F. sweep signal.

SEVENTH: Observe the band width, relative position of the picture carrier, and flatness of the overall I.F. response curve. If necessary slightly vary the tuning of the picture I.F. coils L-34,L-36,L-40,L-44 & L-47 until the picture I.F. response shown in Figure 11 is obtained. The solid curve in Figure 11 depicts the ideal I.F. response while the dotted curves show permissable variations.

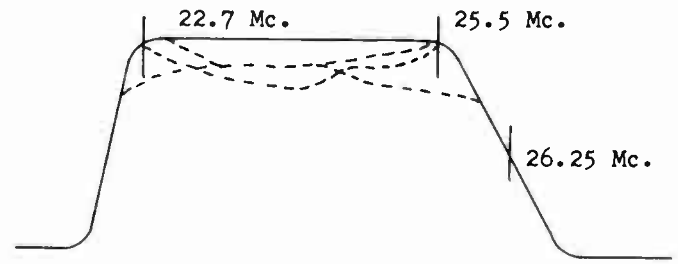

Fig. 11 IDEAL I.F. RESPONSE WITH PERMISSABLE VARIATIONS

The picture I.F. carrier should appear approximately half way down the I.F. response curve as shown in Figure 11. Variation in the pix carrier position should not exceed ± 10% from the half way point.

PICTURE I.F. SENSITIVITY CHECK: FIRST: Connect the R.F. signal generator to the receiver as specified in steps 1 and 2 of the sound trap alignment instructions. (When making sensitivity checks no bias battery is connected to the A.G.C. buss.)

SECOND: Connect the electronic voltmeter across the picture detector load resistor R37 Point A, Fig. 5, and set the meter on the low D.C. volts scale.

THIRD: Set the generator output frequency at approximately 23 Mc. Adjust the generator output until the voltmeter reads approximately 1.0 volt. Record the R.F.signal input in microvolts. Repeat the procedure with the generator output frequency set at 24.2 and 25.4 Mc. In all cases the I.F. input voltage should be 100 Microvolts or less. The sensitivity at the I.F. picture carrier 26.25 Mc..

World Radio History

ALIGNMENT PROCEDURE (CONT'D)

should be approximately half of the I.F. sensitivity between 24.2 Mc. (Maximum of 200 microvolts.).
If the generator output is not calibrated in microvolts, comparative sensitivity measurements can be made by using another receiver that is known to be in good operating condition as a standard. This applies to all sensitivity measurements and good results can be obtained if sufficient care is used.

SOUND I.F. SENSITIVITY: FIRST: Connect the R.F. signal generator to the receiver chassis as specified in steps 1 and 2 of the sound trap alignment instructions.

SECOND: Connect the electronic voltmeter across C67 (from point B to ground) as shown in Figure 5. Set the meter on the low D.C. volts scale.

THIRD: Set the generator output frequency at 21.75 Mc. Adjust the output signal level until the voltmeter indicates 8 volts across C67. The generator output signal should then be 250 microvolts or less.

R.F. OSCILLATOR ALIGNMENT: The R.F. oscillator circuits may be aligned by feeding signals at the R.F. sound carrier frequencies into the receiver antenna terminals and adjusting the oscillator frequency on each channel for zero output from the ratio detector. The ratio detector should be aligned exactly before this method of R.F. oscillator adjustment is attempted.

Since incremental inductances are placed in series with the tuned circuits for channels 8, 10 and 12 to form the tuned circuits for channels 7, 9 and 11, the order in which these channels are aligned becomes important. In these cases it is necessary to align the higher channel of each connected pair before the alignment of the lower channel is attempted. For example, L22 forms the tuned circuit for channel 8 but with the additional series inductance L23 also forms the tuned circuit for channel 7. Note that the tuning of L22 not only affects oscillator operation on channel 8 but also on channel 7 since L22 is common to both circuits. L23, however, affects only channel 7 since it is switched out of curcuit when the tuner operates on channel 8. For these reasons it is necessary to first tune L22 for correct oscillator frequency on channel 8, and then to adjust L23 for correct oscillator frequency on channel 7. In practice the inductance of the incremental coils is adjusted by actual mechanical distortion of the incremental coils themselves.
The following description gives a step by step procedure that simplifies oscillator circuit alignment.

FIRST: Insert V-1 and V-3 in the R.F. tuner. Connect the signal generator to the receiver antenna terminals.

SECOND: Set the oscillator vernier capacitor (fine tuning) at approximately the center of its effective capacity range. This can best be determined by finding the maximum and minimum capacity settings of the vernier and then interpolating between the two extremes for the center position.

THIRD: Connect the electronic voltmeter from the junction of R63 and R64, Point F Figure 5 to the Junction of R59, C62 and C65. Point C as shown in Fig. 5.

FOURTH: Set the R.F. signal generator to each of the following sound R.F. carrier frequencies, thetuner to the corresponding R.F. channel, and peak the specified adjustment for zero output of the ratio detector as observed on the voltmeter. (Zero output of the ratio detector is explained in the section on ratio detector alignment.)

ADJUST R.F. GENERATOR FREQUENCY TO	SET TUNER TO CHANNEL	ADJUST INDUCTANCE OF COIL NO.
215.75 Mc.	13	L28 (Slug tuned)

203.75 Mc.	11	L27 (Incremental)
197.75 Mc.	10	L24 (Slug tuned)
191.75 Mc.	9	L25 (Incremental)

ADJUST R.F. GENERATOR FREQUENCY TO	SET TUNER TO CHANNEL	ADJUST INDUCTANCE OF COIL NO.
185.75 Mc.	8	L22 (Slug tuned)
179.75 Mc.	7	L23 (Incremental)
87.75 Mc.	6	L21 (Slug tuned)
81.75 Mc.	5	L20 (Slug tuned)
71.75 Mc.	4	L19 (Slug tuned)
65.75 Mc.	3	L18 (Slug tuned)
59.75 Mc.	2	L17 (Slug tuned)

The physical location of all coils and adjustments is shown in Figure 6, and 7
The output of the R.F. generator should be checked by means of the crystal calibrator tomake certain that it is exactly on frequency in all cases.

CAUTION: In manufacture the slugs in the R.F. tuner coils are firmly held in place by means of wax which is put into the forms after alignment. This wax must be removed before tuning of the coils is attempted and must be replaced after re-alignment is completed.

R.F. AND CONVERTER CIRCUIT ALIGNMENT: The alignment of the R.F. and converter circuits of the tuner is a difficult and tedious task when it must be performed without benefit of special factory test equipment. For this reason it is not recommended that the complete re-alignment of these circuits be attempted by the service engineer.
The information provided in the paragraphs below is intended primarily for descriptive purposes and cases where only one or two of the coils may require readjustment. In general, where complete tuner re-alignment is indicated, it is recommended the the complete tuner assembly be removed and returned to the factory for a replacement unit.
On channels 2 through 6 the R.F. and converter circuits of the tuner are stagger tuned to obtain wide band R.F. response. In alignment the R.F. transformers T1 through T5 are peaked to the R.F. sound carrier frequencies on their respective channel while the converter coils L5 through L9 are peaked at the corresponding R.F. picture carrier frequencies. Slight deviations in the tuning of these coils are made to obtain an essentially flat R.F. pass band characteristic.

On the high channels, 7 through 13, the R.F. and converter coils are synchronously tuned to the center of each band. At these frequencies the tuned circuits are broad enough to provide an essentially broad, flat, pass band without stagger tuning.
The alignment of these circuits can best be accomplished in the following manner.
FIRST: Make certain all tubes are in place.

SECOND: Connect the R.F. signal generator to the receiver antenna terminals. If the R.F. generator has an unbalanced output it must be converted to a balanced system as shown in Figure 12. The component values indicated are for generators whose output impedance is approximately 50Ω. All specified resistors should be of the non-inductive type.

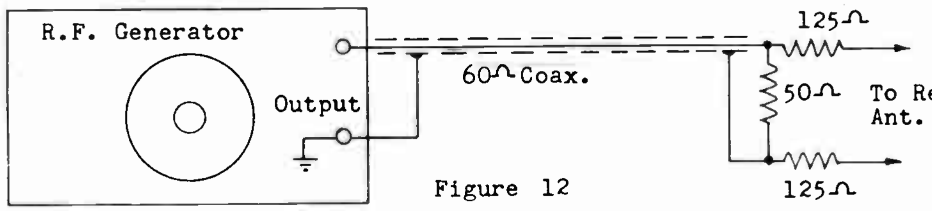

Figure 12

UNBALANCED OUTPUT CONVERSION SYSTEM

THIRD: Perform the operations indicated in the following table and in the order that they are shown. In all cases keep the R.F. signal input as low as possible so that the resonance peaks of the various coils are not masked by A.G.C. circuit action. (Shorting of the A.G.C. buss to chassis ground is recommended when aligning these circuits).

SET R.F. TUNER TO CHANNEL NO.	SET R.F. GEN. OUTPUT FREQ.TO.	ADJUST OSC. VERNIER CAP. IN EACH CASE FOR	CONNECT VOLTMETER	ADJUST THESE COILS FOR MAXIMUM INDICATION ON VOLTMETER

World Radio History

ALIGNMENT PROCEDURE (CONT'D)

FIFTH: Connect a cathode-ray oscilloscope across R37 as described in step #2 of the picture I.F. touch up instructions (Page 26).

SIXTH: Perform the operations indicated in the following table. In each case adjust the specified coils for flat wide band overall response with maximum gain as indicated on the oscilloscope screen. The oscillator vernier capacitor must be correctly adjusted (as indicated by zero ratio detector output) for the sound R.F.carrier on each channel before any adjustment of the R.F. or converter circuits is made.

The shape of the overall response curve on all channels should be approximately the same as that of the video I.F. response curve shown in Figure 11. Marker pulses of proper frequency should be mixed in with the R.F. sweep input to check overall bandwidth and relative position of the picture carrier on each channel. Always keep the R.F.input signal low so that slight variations in the tuning of the various coils are easily discernable on the oscilloscope screen. The physical location of all the adjustments is shown in Figure 6 and 7, page 17 and 18.

SET TUNER TO CHANNEL NO.	SET SWEEP GENERATOR CENTER FREQ. AT	SET SWEEP WIDTH AT APPROX.	SLIGHTLY ADJUST FOLLOWING WHERE NECESSARY
13	213 Mc.	10 Mc.	T9 and L16 (Slug tuned)
12	207 Mc.	10 Mc.	T8 and L14 (Slug tuned)

SET TUNER TO CHANNEL NO.	SET SWEEP GENERATOR CENTER FREQ. AT.	SET SWEEP WIDTH AT APPROX.	SLIGHTLY ADJUST FOLLOWING WHERE NECESSARY
11	201 Mc.	10 Mc.	L4 and L15(Incremental)
10	195 Mc.	10 Mc.	T7 and L12(Slug tuned)
9	189 Mc.	10 Mc.	L3 and L13(Incremental)
8	183 Mc.	10 Mc.	T6 and L10(Slug tuned)
7	177 Mc.	10 Mc.	L2 and L11 (Incremental)
6	85 Mc.	10 Mc.	L9 and T5 (Slug tuned)
5	79 Mc.	10 Mc.	L8 and T4 (Slug tuned)
4	69 Mc.	10 Mc.	L7 and T3
3	63 Mc.	10 Mc.	L6 and T2 (Slug tuned)
2	57 Mc.	10 Mc.	L5 and T1 (Slug tuned)

NOTE: If the output of the sweep generator cannot be adjusted to a satisfactory low level, an attenuator pad, (as shown in Figure 13) should be used in series with the receiver antenna terminals and the output connections of the sweep. (Several sections can be cascaded for increased attenuation if necessary.

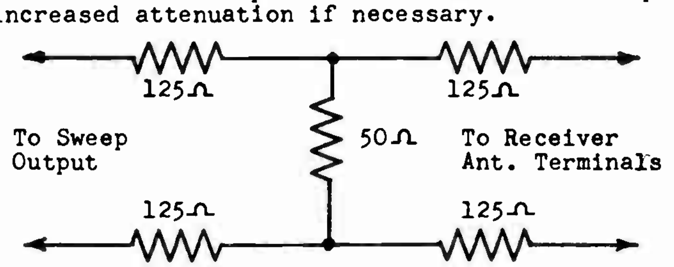

FIGURE 13

ATTENUATOR PAD

The same type of pad can be used in series with the receiver antenna terminals and the antenna lead in areas where the R.F. signal level is high enough to overload the receiver.

OVERALL PICT. SENSITIVITY CHECK: After alignment of the various sections of the receiver has been completed the following overall sensitivity checks should be made. (In cases where the signal generator output is not calibrated in microvolts comparative sensitivity measurements can be made by using another receiver which is known to be in good operation condition as a standard).

FIRST: Connect the R.F. signal generator to the receiver antenna terminals as described in step #2 of the R.F. and converter circuit alignment data.

SECOND: Connect the D.C. voltmeter across R37 as previously described. Set the voltmeter on the low D.C. volts scale.

THIRD: Perform the operations indicated in the following table. In each case the oscillator vernier should be tuned for zero detector output at the sound R.F. frequency of the channel being checked before any measurements are made.

SET R.F. TUNER TO CHANNEL NO.	SET R.F. GENERATOR OUTPUT FREQUENCY TO	ADJUST R.F. INPUT LEVEL UNTIL VOLTMETER READS	GENERATOR OUTPUT SHOULD BE
2	57 Mc.	1.0 V.D.C.	150 UV or less
3	63 Mc.	1.0 V.D.C.	150 UV or less
4	69 Mc.	1.0 V.D.C.	150 UV or less
5	79 Mc.	1.0 V.D.C.	150 UV or less
6	85 Mc.	1.0 V.D.C.	150 UV or less
7	177 Mc.	1.0 V.D.C.	150 UV or less
8	183 Mc.	1.0 V.D.C.	150 UV or less
9	189 Mc.	1.0 V.D.C.	150 UV or less
10	195 Mc.	1.0 V.D.C.	150 UV or less
11	201 Mc.	1.0 V.D.C.	150 UV or less
12	207 Mc.	1.0 V.D.C.	150 UV or less
13	213 Mc.	1.0 V.D.C.	150 UV or less

OVERALL SOUND SENSITIVITY CHECK: After proper circuit operation and alignment has been realized, with volume and tone controls set at maximum, the vernier capacitor (fine tuning) properly adjusted on each channel, the overall sound sensitivity can be checked as indicated in the table below:

SET R.F. TUNER TO CHANNEL NO.	SET R.F. GENERATOR FREQUENCY OUTPUT TO	SET GENERATOR MODULATION TO	ADJUST GEN. OUTPUT TO GIVE	GENERATOR OUTPUT
2	59.75 Mc.	400 ~	.5 Watts	200 UV or less
3	65.75 Mc.	± 7.5 Kc.		200 UV or less
4	71.75 Mc.		in speaker	200 UV or less
5	81.75 Mc.	deviation		200 UV or less
6	87.75 Mc.		Voice Coil	200 UV or less
7	179.75 Mc.			200 UV or less
8	185.75 Mc.		(Approx.	200 UV or less
9	191.75 Mc.		1.25 V.	200 UV or less
10	197.75 Mc.		A.C.	200 UV or less
11	203.75 Mc.		Across	200 UV or less
12	209.75 Mc.		Voice	200 UV or less
13	215.75 Mc.		coil	200 UV or less

COMPLETE HORIZONTAL OSCILLATOR AND DEFLECTION CIRCUIT ALIGNMENT

FIRST: Remove the safety-back on the receiver and by means of a separate line cord place the set in operation.

SECOND: Tune in a television station that is transmitting a test pattern and adjust the fine tuning control for best sound quality.

THIRD: With the horizontal hold control at the center of rotation, adjust the slug in the horizontal oscillator tank coil(L65 as shown in Fig. 7 Page 18) until the picture is synchronized horizontally. This is indicated by the fact that any vertical lines in the test pattern will be straight in the upper portion of the picture and not curved to the right or left. Picture must be synchronized vertically when making this adjustment.

FOURTH: Adjust the horizontal drive control (Trimmer C96 as shown in Fig.7 Page 18) by turning the adjusting screw counter clockwise until one or more white lines appear in the picture. Then back off the adjustment till the white lines just disappear and the linearity is best. This adjustment may affect the frequency of the horizontal oscillator in which case readjust as in Step 3.

FIFTH: Adjust the width control (L64 available through hole in H.V. case as shown in Fig. 6,Page 2-17).) until the picture just fills the mask horizontally.

SIXTH: Tune the receiver to channel No. 13 and check the raster for Barkhausen oscillations.

The flyback type of horizontal output and high voltage circuits used in this receiver can produce Barkhausen oscillations under certain conditions. These oscillations are at television R.F. frequencies and can be picked up by the tuner and appear as vertical black lines or smudges on the left hand side of the raster, particularly when a weak or no television is being received.

These oscillations can be minimized by adjustment of the horizontal drive control (trimmer C96) With his trimmer screwed tight (minimum drive) the oscillations are strongest; too tight a trimmer will also reduce the high voltage and increase the plate current of the horizontal output tube (6BG6) beyond safe limits. With the trimmer open(maximum drive) a vertical white bar or shading can occur in the left hand side of the roster accompanied by a linearity distortion at the white area. The optimum adjustment of the horizontal drive (C96) control lies between these two conditions and should be made in that manner.

After making the final adjustment check all channels to make sure that optimum operating condition for all channels has been realized.

SEVENTH: Recheck and touch up all adjustments as may be necessary.

MODELS 5010, 5011, 5014, 5015, 5056, 5057, 5071, 5072, Ch. 19TS10, 19TS10A, 19TW10, 19TW10A

INDEX

BRIEF DESCRIPTION

MECHANICALLY: The 19TS10 and 19TS10A receivers are constructed on a single base with mechanical dimensions approximately 16" X 17". These new receivers are used in both table and console models. The mechanical difference between the 19TS10 and 19TS10A receiver are the 19TS10A uses only a 12LP4(12") Picture tube which necessitates higher Pix tube mounting brackets and longer control shafts.

These receivers are controlled by the "Six" controls on the front panel. The extreme left-hand control is a dual control and are the adjustments for vertical and horizontal hold. For diagram showing operating control position and function, see Index for page number in this bulletin.

Controls to adjust the focus, height and vert. linearity are mounted on back of chassis and are adjusted with the fingers. Adjustments for horiz. osc. and width are also located on back of chassis and is made with a screw-driver. For diagram, see drawing showing Trimmer and Slug Locations in this Bulletin.In all models described in this bulletin the picture tube and yoke Assembly are mounted on the chassis proper.

ELECTRICALLY: The 19TS10 chassis is equipped with type 10BP4(10") Picture Tube and the capacitor C93 across the horizontal yoke winding should be 68 uuf. at 1200 volts. Table Model 5011 is shipped with 10" Pix tube.

The 19TS10A chassis is equipped with Type 12LP4(12") pix tube and C93 capacitor across the horizontal yoke winding should be 150 uuf. with a voltage rating of 1500 volts.

Table models 5010,5014,5015 and Console Models 5056, 5057 and 5072 are shipped only with (12") pix tubes. An entirely new R.F. Tuner is used in all models listed in this bulletin and complete technical data is given in the circuit description and Schematic Diagram.

*CONSTRUCTING A CHANNEL TRAP

*Constructed of a piece of 300 ohm transmission line, shorted on one end to serve as a 1/2 wave length shorting stub. Cut a piece of line slightly longer than given under the "Half-wave Shorted Channel Trap", column and connect the two leads of one end across the receiver antenna terminals.

Using diagonal cutters or razor blade, "short", across the transmission line at a place slightly longer than the calculated length. Care should be taken when "Shorting" the line to cut through the plastic covering only; do not cut the conductors. If the interference is not "Trapped Out", short the line in 1/8" intervals(working toward the terminals) until the critical point is reached. Cut the transmission line and place a carbon resistor across the line. The resistor should be approximately 60 ohms. For strong interference, it may be necessary to drop the resistance to 20 ohms, and for weak interference it may be possible to use a 150 ohm resistor. Do not use any lower value resistor than necessary to minimize the interference.

If the interference frequency is not that of a television station, the line may be cut and the leads shorted together without using the resistor. Generally, this will completely eliminate the interference frequency.

If the interference frequency being eliminated or "Trapped-out" is that of some other television station operating in the vicinity, the interfering frequency will also be eliminated or attenuated on its own channel. If the interference frequency is so strong that it can not be attenuated enough using a resistor across the line, it will be necessary to install a double-pole, single-throw switch on one of the trap leads so that the "Channel Trap", can be opened when the receiver is switched to this channel.

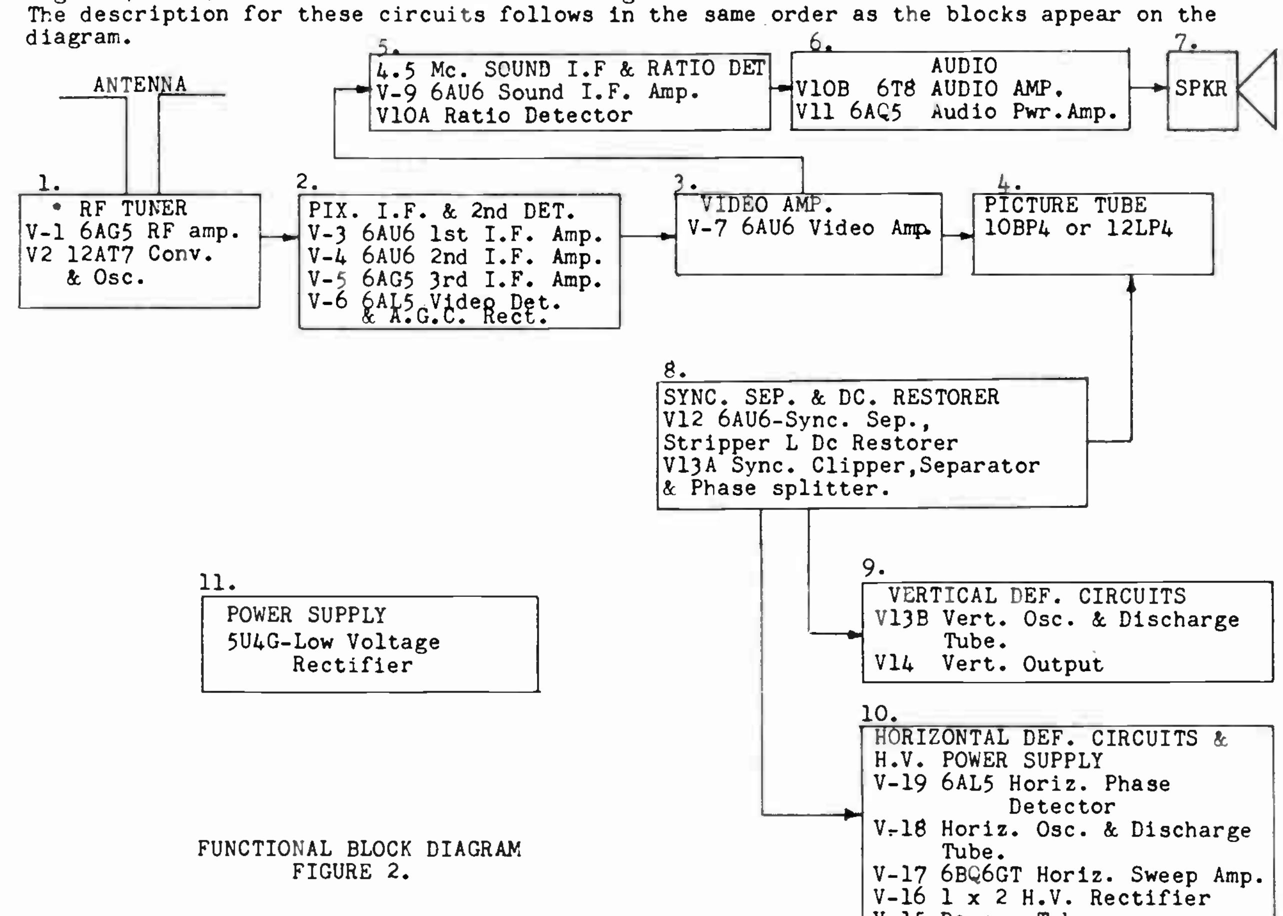
If the interference frequency is known, the transmission line can be cut by using the following formula.

$$\text{Half wave shorting stub in inches} = \frac{4841}{\text{Freq.(MC)}}$$

CIRCUIT DESCRIPTION

GENERAL: The following circuit description for Sparton Television Models provides all pertinent information necessary for proper servicing of these receivers. In the compilation of this data it is assumed that the service engineer is familiar with the basic electronic principles of modern television.

Fig. 2 (below) shows a fundamental block diagram breakdown of the receiver circuits. The description for these circuits follows in the same order as the blocks appear on the diagram.



FUNCTIONAL BLOCK DIAGRAM
FIGURE 2.

World Radio History

CIRCUIT DESCRIPTION (CONT'D)

R.F. TUNER (BLOCK #1)

The R.F. Tuner is a separate sub-assembly of the receiver. This tuner is continuously variable and tunes the 12 TV channels in two ranges, channels 2 through 6 in the low range and channels 7 through 13 in the high range. The range is automatically selected by means of a cam operated switch on the tuning shaft. Tuning is accomplished by means of ganged tuning capacitors. The tuner serves to select the desired picture and sound carriers and associated side bands. It amplifies the selected R.F. signals and provides at the converter plate a picture I. F. carrier of 26.25 Mc. and a sound I.F. carrier of 21.75 Mc.

R.F. AMPLIFIER

The antenna input is fed to V1 the 6AG5 R.F. amplifier tube through fixed tuned input transformers T-1 for the low band and L-1 for the high band.

CONVERTER

The plate circuit of the R.F. amplifier and the grid circuit of V-2 the 12AT7 converter tube are coupled by means of overcoupled tuned circuits which are tuned by the ganged variable capacitor sections C8A and C8B.
In the plate circuit of the converter coil L-6 in conjunction with the output capacity of V-2 and the input capacity of V-3 forms a parallel tuned circuit tuned to 24.0 Mc. This is the first stage on the stagger tuned video I.F.system.

OSCILLATOR

The local oscillator uses one triode section of V-2. The 12AT7 in a Colpitts oscillator circuit tuned by the ganged capacitors C8C in the low band and C8D in the high band., Oscillator injection to the converter grid takes place through mutual inductance between coils in transformer T-2. The oscillator operates at a frequency above that of the received signal in all channels.

PICTURE I.F. & SECOND DETECTOR (BLOCK #2)

The primary requirements of the picture I.F. system are wide overall response and adequate overall gain. To meet these requirements three stages of video I.F. amplification are employed.
As noted on the schematic diagram these stages are V-3, V-4 and V-5. Single tuned I.F. coils are utilized in the plate circuit of the converter and each of the three successive stages. Starting with the coil L-6 in the converter plate each of the coils L-11, L-13 and L-15 in the following stages are tuned to a different frequency. Thus by virtue of stagger tuning the several stages, wide band picture I.F. response is obtained.

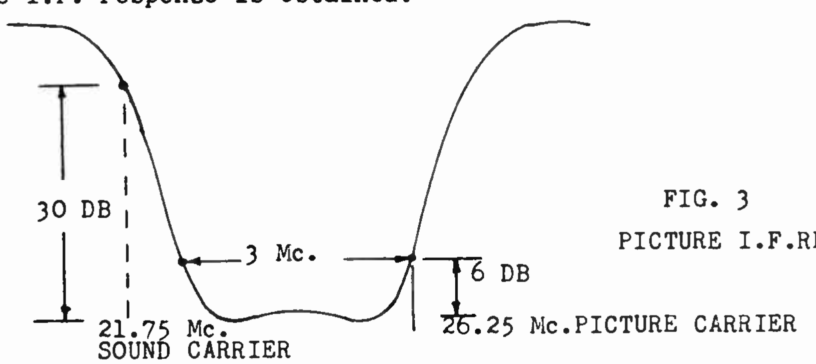

FIG. 3

PICTURE I.F.RESPONSE

In order to obtain a band pass as pictured in Fig. 3 the I.F. coils are peaked to the following fixed frequencies:

L-6	Plate of the converter	(V-2)	24.0 Mc.
L-11	1st picture I.F.	(V-3)	25.7 Mc.
L-13	2nd picture I.F.	(V-4)	23.7 Mc.
L-15	3rd picture I.F.	(V-5)	26.0 Mc.

Under normal conditions replacement of any of the tubes in the picture I.F. strip will have little effect on the shape of the overall pass band. The information on physical location of the various coils will be found in the section on alignment. The picture I.F. must amplify both picture and sound carriers, however the sound carrier must be attenuated below the picture carrier to prevent sound interference in the picture. For this reason the sound carrier is placed approximately 30 DB down from the top of the I.F. response curve.

PICTURE DETECTOR AND A.G.C. RECTIFIER

V-6 is a type 6AL5 double diode rectifier. One diode section is used as the video detector and is connected so as to provide an output signal of negative polarity across its output load. The other diode is used as an A.G.C. rectifier connected so as to produce a negative A.G.C. voltage across its load resistance. This voltage is applied to the grids of V-1, V-3, and V-4. It's action on these stages is such that it effectively varies the gain of the receiver to compensate for changes in R.F. input level to the antenna terminals. A positive delay voltage is applied to the cathode of the A.G.C. rectifier from the contrast control so that full delay is present at maximum contrast settings and zero delay at minimum contrast position. This delay action is such that full contrast must be attained before any A.G.C. voltage is developed.

VIDEO AMPLIFIER(BLOCK #3)

A single 6AU6 (V-7) video amplifier stage is fed from the output of the video detector. The frequency response extends to 3.5 Mc. while the overall gain is approximately 20x.

The video signal at the kinescope grid must be of such polarity that the syng. and blanking pulses will drive the grid in the negative direction. For this reason with a single video stage it is necessary to apply the video signal to the kinescope cathode.

Since the sync. is negative from the picture detector any large noise pulses above sync. level will drive the grid beyond cut-off. This results in a desirable peak noise limiting action by the video amplifier that effectively improves the overall signal to noise ratio of the receiver. Contrast control takes place by cathode circuit degeneration which controls gain without disturbing grid bias conditions most favorable to noise clipping.

SOUND I.F. AND RADIO DETECTOR

The picture I.F. carrier at 26.25 Mc. and the sound I.F. carrier at 21.75 Mc. are 4.5 Mc. apart. This is determined by the transmission standards and is controlled at the transmitter. Both carriers are present at the picture detector, the sound carrier being approximately 30 DB down as previously shown. (Under picture I.F. & 2nd. Det.) Due to non-linearity in the detecting diode a 4.5 Mc. beat frequency is produced. The picture carrier is amplitude modulated by the video signal while the sound carrier is frequency modulated, by the sound. The 4.5 Mc. beat is therefore frequency modulated by sound and also carries amplitude modulation from both sound and picture.

4.5 Mc. SOUND TRAP

The 4.5 Mc. beat frequency containing the frequency modulated sound and incidental amplitude modulation is applied to the video amplifier grid along with the detected video and sync. signals. A trap circuit in the video amplifier plate acts as a load impedance for 4.5 Mc. and at the same time appears as a series trap which prevents the 4.5 Mc. signal from reaching the kinescope.

The 4.5 Mc. signal across the trap coil L-20 is fed to the 6AU6 sound I. F. amplifier V-9. T-4 and V10A constitutes a conventional ratio detector operating at 4.5 Mc. The ratio detector has sufficient A.M. rejection to remove the incidental A.M. component. The detected F.M. sound modulation is then fed to the volume control.

SYNC. SEPARATOR, STRIPPER & DC RESTORER(BLOCK #8)

The video signal containing the sync. pulses is taken from across the video amplifier plate load resistor and applied to V-12. The cathode bias of V-12 is of the proper magnitude to place all picture information beyond cut-off and only the sync. pulses appear in the plate current. The sync. pulses are then applied to the grid of V-13A where further amplification takes place and vertical sync. pulses of proper phase are applied to the vertical deflection system.
V-13A also acts as a phase splitter and sync. pulses of opposity phase are taken from plate and cathode load resistors to feed the horizontal deflection system.
Since the grid of V13A is operating near cut-off positive noise pulses which were not clipped in the grid of V12 are now of negative polarity and are clipped in the grid of V13A, thus the sync. pulses have been clipped on both sides and are relatively free from noise pulses.

©John F. Rider

World Radio History

CIRCUIT DESCRIPTION (CONT'D)

AUDIO AMPLIFIER & SPEAKER (BLOCKS 6 & 7)

Tubes V-10B and V-11 form a conventional two-stage audio amplifier which develops approximately 1.5 watts in the speaker voice coil. A tapped compensated volume control is used which provides increased bass compensation at low volume settings.

VERTICAL DEFLECTION SYSTEM (BLOCK #9)

This section of the receiver functions to supply vertical scanning for the kinescope. A conventional system is utilized. V-13B operates as a field frequency oscillator whose output signal is used to drive the vertical output stage V-14. The combined action of these stages and their associated circuits provides a linear deflection current of proper polarity and frequency in the vertical deflection yoke.

VERTICAL INTEGRATING NETWORK

The integrating network composed of R-73, R-74, R-76 and C-81 A- B-C functions to separate the horizontal from the vertical sync. and to pass the vertical sync. pulse developed on to the field frequency oscillator. In operation the network can be considered as a low pass filter that by-passes the horizontal sync. pulses and permits the low frequency vertical sync. to pass on through to the grid of V-13B.

FIELD FREQUENCY OSCILLATOR

The field frequency oscillator V-13B is a conventional blocking oscillator system. In operation the free running frequency of the oscillator is adjusted by means of the vertical hold control R-78A. The oscillator is locked in sync. at field frequency by means of the vertical sync. pulses which are injected into it's grid circuit from the integrator network. The cut-off and conduction action of the oscillator charges and discharges capacitor C-83and the resulting sawtooth output drives the output stage V-14.

VERTICAL OUTPUT

The peaked sawtooth output of the blocking oscillator system drives the grid of the vertical output stage. An impedance matching transformer T-6 couples V-14 to the vertical deflection yoke L-22A. Picture height is controlled by means of R-82 which varies the B+ voltage supplied to the vertical system. Vertical trace linearity is adjustable by means of R-86 in the cathode circuit of V-14. Adjustment of this control varies the bias and consequently the operating point of the tube.

HORIZONTAL DEFLECTION CIRCUITS(BLOCK #10)

The horizontal deflection system provides a stable, linear scanning current in the horizontal winding of the deflection yoke. This results in accurate horizontal reproduction of the transmitted picture.

HORIZONTAL OSCILLATOR AND A.F.C. SYSTEM

The horizontal oscillator V-18 is a composite circuit incorporating a cathode coupled multivibrator and a tank circuit(L-24 and C103) resonant at approximately 15,750 cycles per second to produce a stabilized sine wave voltage. This circuit possesses the RC time constant and grid bias frequency control characteristics of a multivibrator; but it achieves some of the frequency stability of a sine wave system. The free running frequency is controlled by the horizontal hold control R-78B. This control is set for approximately 15,750 cycles per second. The oscillator is then locked into synchronism with the incoming signal by means of an automatic D.C. control bias voltage applied to one grid (Pin #4) of the oscillator.

This D.C. voltage is developed by the horizontal A.F.C. rectifier V-19. This circuit is a conventional duo-diode phase comparitor which compares the phase of the incoming sync. pulses with the sawtooth voltage developed across the width control on the horizontal output transformer secondary. The sawtooth voltage being fed through R-111 and C107. Any discrepancy in the exact phase relationship of these two voltages produces a change in D.C. voltage across C105(at the oscillator grid). This changes the oscillator frequency to assure exact phase and frequency coincidence between the output sawtooth and the incoming sync. pulses from the signal. In this manner the horizontal scanning of the receiver is locked into synchronism with the signal sync. pulses.

The output of the horizontal oscillator is a sawtooth voltage plus a peaking component fed back through C-98 from the horizontal output. The peaking component is sufficient to produce adequate high voltage and fast retrace time. The amount of drive to the grid of the horizontal output tube V-17 is controlled by a capacity divider consisting of C99 and a variable mica trimmer C100. This trimmer is adjusted for optimum horizontal linearity of picture.

HORIZONTAL OUTPUT AND DAMPER

The horizontal output tube V-17 and the damper tube V-15 produce the required linear sawtooth scanning current in the horizontal deflection coil. The two tubes plus the horizontal output transformer also produce a high voltage pulse which is used to obtain the kinescope high voltage supply. The output system is a conventional kick-back type except that no electrical horizontal centering is provided. Capacitor C92 is employed to isolate direct current from the yoke. Centering is therefore accomplished by actual physical movement of the focus coil and, to some degree, the ion trap. The output transformer, as far as deflection is concerned, is an impedance matching device for the output tube and yoke.

The width control L-23 is provided to vary the output and hence the picture width. This is accomplished by shunting a portion of the secondary winding to change the effective transformation ratio. Clockwise rotation of L-23 increases the shunting inductance and hence the width.

Because the horizontal transformer (T-8), deflection coil and associated circuits are designed to resonate at a high frequency(Period =14 microseconds) for fast retrace time, they are shocked into resonance when the magnetic field collapses during retrace. To prevent continued oscillatory currents in the deflection yoke, the damper diode V-15 is used. During the first half cycle of retrace resonance, the circuit oscillates freely to insure rapid retrace time. During the next half cycle the damper plate goes positive and conduction occurs. This puts a heavy load on the deflection coil so that it cannot oscillate.

The 6BQ6GT plate voltage is supplied through the 6W4GT which is conducting over the major portion of the trace. Capacitor C96 is charged during this period and this charge is sufficient to supply the 6BQ6GT plate when the 6W4GT is not conducting.

The charge is placed on capacitor C96 by the receiver D.C. supply and by the current from the collapse of the field in the horizontal deflecting coil. The A.C. axis of the sweep voltage is 330 volts above ground since the T-8 secondary is connected to the receiver 330 volt bus. The charge on capacitor C96 by the coil kick-back is therefore in addition to that from the D.C. supply and so the capacitor C96 is charged to a voltage greater than the D.C. supply. This permits operation of the 6BQ6GT at a higher voltage than is obtainable from the receiver power supply and produces an increase in the system efficiency by salvaging energy that otherwise would be wasted.

HIGH VOLTAGE POWER SUPPLY

The kinescope high voltage supply is obtained from the energy stored in the deflection inductances during each horizontal scan. When the 6BQ6GT plate current is cut off by the incoming signal, a positive pulse appears on the T-8 primary due to the collapsing field in the deflection coil. This pulse of voltage is stepped up, rectified by V-16, filtered and applied to the second anode of the kinescope (V8). Since the frequency of the supply voltage is high(15,750 C.P.S.), relatively little filter capacity is necessary.Since the filter capacity is small, the stored energy is small and the high voltage supply is made less dangerous.

KINESCOPE & D.C. RESTORER(BLOCK #4)

A sync. positive video signal is applied to the kinescope cathode. The brightness control R-41 is part of a voltage divider from +140 volts to ground which permits the operating bias for the kinescope to be adjusted to the proper value(where sweep retrace lines are just extinguished). The kinescope grid returns to ground through R67 and R68 in the cathode circuit of V12. Since the video amplifier is an A.C. coupled system, the D.C. component of the video signal which represents the average background brightness of the televised scene is lost. If a white signal or a black signal is applied to the grid of V12, the D.C. voltage developed across the cathode resistors R67 and R68 changes and is a function of the average value of the signal. This potential is applied to the kinescope grid to re-insert the D.C. component.

The kinescope is a conventional 10" or 12" tube. These tubes employ magnetic focus and deflection systems. An ion trap prevents the ion beam from forming a dark spot on the kinescope screen.

World Radio History

CIRCUIT DESCRIPTION (CONT'D)

LOW VOLTAGE POWER SUPPLY (BLOCK #11)

The low voltage power supply provides the filament and plate voltages for the receiver. The unit employs a single 5U4G rectifier (V20) to supply 330 volts at 160 Ma. Filtering is accomplished by the speaker field, the focus coil and their associated electrolytic condensers to ground.

The deflection circuits are supplied from +330 volts to ground. The audio output tube V11 and the sound I.F. amplifier V-9 operate with their plates at +330 volts and their cathodes at +140 volts, tubes V1, V2,V3,V4,V5,V7,V12 and V13A operating from +140 volts to ground. This system is self regulating since a change in the +140 volts to ground results in a bias change in V11 which increases or decreases the cathode current of V11 in a manner to oppose the change. Filament power is supplied by the two 6,3V.A.C. windings.

LINE CORD ANTENNA

All of the television models listed in this bulletin are equipped with a built-in line cord antenna which is hooked up for operation when shipped from the factory.

This type of antenna is designed for operation on local stations only, and in locations where it will give satisfactory results. Line cord antennas are not designed to work in conjunction with other type antennas and must be disconnected when another antenna is to be attached to the receiver.

A 3-point terminal strip on the back of the cabinet has been provided with a jumper connection which must be used when changing from line cord to outside antenna or vice-versa.

When the line cord antenna is to be used the lead wire from the chassis should be placed under the right-hand terminal marked "A" and the jumper link on terminal "G" must be connected to the center terminal "A".

When an outside antenna is to be connected the jumper link between terminals "G" and "A" must be disconnected.

The line cord antenna is composed of components L-27 choke coil and capacitor C115 (30 MMF)

ALIGNMENT EQUIPMENT AND TEST SET UP

TEST EQUIPMENT

In order to align and service Sparton television receivers properly the following test equipment should be available:

FIRST: AN R.F. SWEEP GENERATOR of reliable quality that performs the following functions:

A. Provides sweep outputs in the following frequency ranges:

19 to 30 Mc.	10 Mc. sweep width
40 to 90 Mc.	10 Mc. sweep width
170 to 225 Mc.	10 Mc. sweep width

B. Provides an output signal that can be varied by means of an attenuator up to a maximum of at least .1 volt.

SECOND: AN R.F. SIGNAL GENERATOR that will provide an adjustable output signal up to a maximum of at least .1 volt on the following fixed frequencies:

A. I. F. Frequencies

4.5 Mc.	Sound I.F.
21.75Mc.	Sound I.F. Carrier
24.0 Mc.	1st Video I.F.Coil
25.7 Mc.	2nd video I.F. coil
23.7 Mc.	3rd video I.F. coil
26.0 Mc.	4th video I.F. coil
26.25Mc.	Picture I.F. carrier

B. R.F. Frequencies

Channel No.	Picture Carrier	Sound Carrier
2	55.25 Mc.	59.75 Mc.
3	61.25 Mc.	65.75 Mc.
4	67.25 Mc.	71.75 Mc.
5	77.25 Mc.	81.75 Mc.
6	83.25 Mc.	87.75 Mc.
7	175.25 Mc.	179.75 Mc.
8	181.25 Mc.	185.75 Mc.
9	187.25 Mc.	191.75 Mc.
10	193.25 Mc.	197.75 Mc.
11	199.25 Mc.	203.75 Mc.
12	205.25 Mc.	209.75 Mc.
13	211.25 Mc.	215.75 Mc.

THIRD: A CATHODE-RAY OSCILLOSCOPE of good quality that has a fairly wide band vertical amplifier and a low capacity input probe.

FOURTH: AN ELECTRONIC VOLTMETER on which the input probes are all insulated from the meter case.

FIFTH: A CRYSTAL CALIBRATOR that can be used for checks on the accuracy of the output frequencies of the R.F. signal generator.

GENERAL INSTRUCTIONS: Practically all servicing with the exception of some tube replacement will require removal of the receiver chassis from the cabinet.

A convenient arrangement that makes both the top and bottom of the chassis accessible for alignment and servicing can be realized by orienting the receiver chassis in such a manner that it rests on its side and on the horizontal output shield can.

ALIGNMENT PROCEDURE

ALIGNMENT REQUIREMENTS: Under normal conditions complete receiver realignment will seldom be necessary in the field. However, a detailed description of the overall alignment procedure is included to provide all necessary information if it should be required.

In general it is not recommended that the R.F. and converter circuits of the R.F. tuner be realigned by the service engineer unless absolutely necessary. In cases where tuner components have been damaged, or where complete realignment is indicated, the R.F. tuner assembly should be removed from the chassis and sent back to the factory in exchange for a new unit which will be shipped complete with tubes. When the new R.F. unit is assembled to the chassis it will be necessary in all cases to realign L-6 the 1st picture I.F. @ 24 Mc. which is located on the tuner unit. Normally this is the only adjustment that will be required with tuner change but a check on overall receiver alignment and sensitivity should be made for the sake of certainty and assured customer satisfaction.

EFFECTS OF TUBE REPLACEMENT ON THE ALIGNMENT OF R.F. TUNER CIRCUITS: The alignment of the R.F. and converter circuits of the R.F. tuner is critical and may be affected by a tube change. In cases where these tubes (6AG5 or 12AT7) are replaced it will be necessary for the service engineer to check for satisfactory receiver operation. If realignment is indicated it can usually be avoided by selection of replacement tubes until receiver operation is realized.

ALIGNMENT PROCEDURE (CONT'D)

MODELS 5010, 5011, 5014, 5015, 5056, 5057, 5071, 5072, Ch. 19TS10, 19TS10A, 19TW10, 19TW10A

ORDER OF ALIGNMENT: When complete receiver realignment is indicated it should be performed in the following order:

1. Picture I.F.
2. Sound I.F. Trap
3. Ratio Detector Transformer
4. Sound and Picture I.F.Sensitivity Check
5. R.F. Oscillator Circuits
6. R.F. and Converter Circuits(not recommended)
7. Overall sensitivity check

PRELIMINARY ADJUSTMENTS: Before alignment the receiver controls should be adjusted to the approximated operating positions specified in the table below. The controls should remain in these positions for all checks.unless otherwise specified.

Contrast Control - Full clockwise
Brightness Control - to position where raster is visible on the kinescope
Focus Control - to position where focus is obtained
Vertical Hold - to center position
Vertical Linerity - to center position
Vertical Size - adjusted to give normal raster height

Horizontal Hold - to center position
Horizontal Size - adjusted to give normal raster width

TEST EQUIPMENT SET UP: A certain amount of experimentation must be employed to secure a stable test set up before alignment or service of the receiver is attempted. It is recommended that the top of the test bench be covered with a sheet of aluminum to insure good grounds between the various pieces of test equipment and the receiver chassis. In general all test signal input leads should be kept away from output leads as much as possible.

PICTURE I.F. INSTABILITY: If the picture I.F. strip is badly out of alignment it may become unstable and fall into oscillation. When this condition occurs a comparatively large voltage is developed across the picture detector load resistor. This voltage is independent of I.F. signal input at the converter grid.

It is usually possible to stop I.F. oscillation due to misalignment by adjusting the iron cores in the various picture I.F. coils and traps according to the information given in the table below:

L-6 Slug in (Max. L.)
L-11 Slug out
L-13 Slug in
L-15 Slug out

The actual physical location of the various coils and traps is shown in Figure 4 and 5, pages 15 & 16. As soon as the oscillation has been stopped, continue with the alignment as outlined in the following sections.

PICTURE I.F. ALIGNMENT: First: Connect the R.F. signal generator to the grid of V-2 #2 pin. by means of the I.F. input adapter as shown in Fig. 7.

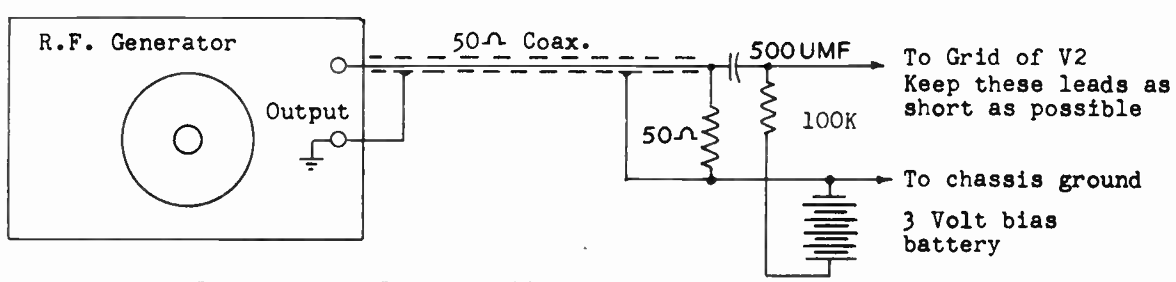

Figure 7 I.F. Input Adapter

SECOND: Set the R.F. tuner to channel #2.

THIRD: Connect a 3 volt bias battery between the A.G.C. buss(point D Fig.6 and chassis ground so that the voltage on the A.G.C. buss is -3 volts in respect to the chassis.

FOURTH: Connect the electronic voltmeter across the picture detector load resistor R30, point A Fig. 6 and set the voltmeter on the low D.C. volt scale.

FIFTH: Set the R.F. signal generator to each of the frequencies shown in the table below and in each case tune the specified adjustment for maximum indication on the voltmeter. It is advisable to check the output of the generator with the crystal calibrator to make certain that it is exactly on frequency in each case.

26.0 Mc.	L15	(Top of chassis as shown in Fig.14)
23.7 Mc.	L13	(Top of chassis as shown in Fig.14)
25.7 Mc.	L11	(Top of chassis as shown in Fig.14)
24.0 Mc.	L6	(Top of chassis as shown in Fig.14) (On Tuner)

PICTURE I.F. TOUCH UP: FIRST: Connect the R.F. sweep generator output to the grid of V-2 (Pin #2) by means of the I.F. input adapter shown in Fig. 7.

SECOND: Set R.F. Selector to channel #2.

THIRD: Connect the oscilloscope across the picture detector load resistor R-30 (point A, Fig. 6 by means of the shielded cable and the filter system shown in Fig. 8.

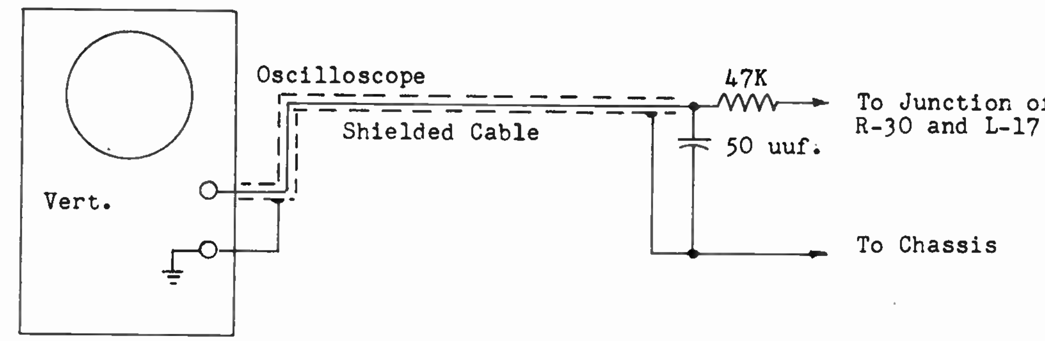

Fig. 8 FILTER SYSTEM FOR SCOPE CONNECTION

FOURTH: Set the R.F. sweep generator so that it sweeps from approximately 20 to 30 Mc.

FIFTH: Adjust the oscilloscope so that the swept I.F. response is visible on the cathode-ray tube screen.

SIXTH: Loosely couple the output of the R.F. signal generator to the grid of V-2 so that marker signals of proper frequency can be mixed in with the R.F. sweep signal.

SEVENTH: Observe the band width, relative position of the picture carrier, and flatness of the overall I.F. response curve. If necessary slightly vary the tuning of the picture I.F. coils L-6,L11,L13 and L15 until the picture I.F. response shown in Figure 9 is obtained. The solid curve in Figure 9 depicts the ideal I.F. response while the dotted curves show permissable variations.

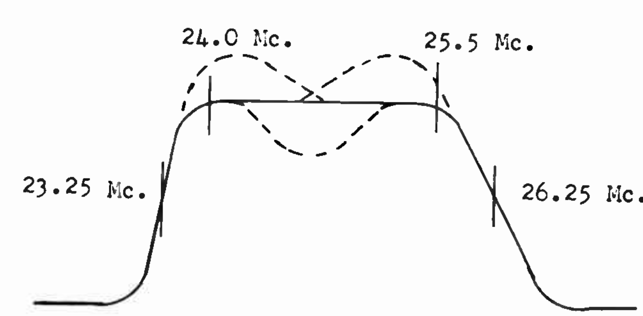

Fig. 9 IDEAL I.F. RESPONSE WITH PERMISSABLE VARIATIONS

©John F. Rider

World Radio History

ALIGNMENT PROCEDURE (CONT'D)

The picture I.F. carrier should appear approximately half way down the I.F. response curve as shown in Figure 9. Variation in the pix carrier position should not exceed ∠ 10% from the half way point.

PICTURE I.F. SENSITIVITY CHECK: FIRST: Connect the R.F. signal generator to the receiver as specified in steps 1 and 2 of the sound trap alignment instructions. (When making sensitivity checks no bias battery is connected to the A.G.C. buss.)

SECOND: Connect the electronic voltmeter across the picture detector load resistor R-30 and set the meter on the low D.C. volts scale.

THIRD: Set the generator output frequency at approximately 23 Mc. Adjust the generator output until the voltmeter reads approximately 1.0 volt. Record the R.F. signal input in microvolts. Repeat the procedure with the generator output frequency set at 24.2 and 25.4 Mc. In all cases the I.F. input voltage should be 300 microvolts or less. The sensitivity at the I.F. picture carrier 26.25 Mc., should be approximately half of the I.F. sensitivity between 24.2 Mc. (Maximum of 400 microvolts.).
If the generator output is not calibrated in microvolts, comparative sensitivity measurements can be made by using another receiver that is known to be in good operating condition as a standard. This applies to all sensitivity measurements and good results can be obtained if sufficient care is used.

SOUND I.F. ALIGNMENT: FIRST: Connect the R.F. signal generator to the grid of V-7 (point E) Fig. 6.

SECOND: Connect the electronic voltmeter across C-64 (Point P) Fig.6. Set the voltmeter on a low D.C. scale.

THIRD: Set the R.F. signal generator to 4.5 Mc. and adjust L-20 and T-4 (both top of chassis) for maximum reading on meter. Repeat both adjustments.
NOTE: The 4.5 Mc. signal must be as accurately calibrated as possible, since alignment of the sound channel at an improper frequency may cause distortion or even complete loss of sound.

FOURTH: Connect the electronic voltmeter from the junction of R55 and R56 to the junction of R51, C59 and C61 (Point C as shown in Fig. 6).

FIFTH: With the signal generator still accurately set at 4.5 Mc. adjust the secondary of T-4 (bottom view of chassis as shown in Fig. 5). Notice that it is possible to produce a positive or negative voltage indication on the meter by varying this adjustment. As the voltage swings from positive to negative, adjust T-4 for zero output as indicated by the voltmeter. This point is called zero ratio detector output and indicates correct alignment of transformer T-4.

TUNER ALIGNMENT: The alignment of the R.F. circuits of the tuner is a difficult and tedious task when it must be performed without benefit of special factory test equipment. For this reason it is not recommended that the re-alignment of these circuits be attempted by the service engineer. The information provided in the paragraphs below is intended primarily for descriptive purposes and cases where slight adjustments may be necessary.

An overcoupled tuned circuit is used between the R.F. plate and the converter grid. This overcoupled circuit is tracked with the oscillator. All circuits are gang condenser tuned and shunt trimmer condensers are used. The capacity curves of the gang condenser sections and the high frequency series tracking condensers have been carefully chosen to guarantee a minimum of tuning condenser mistracking. It should never be necessary to adjust the gang condenser capacity by knifing the plates.

In order to correctly track the R.F. and mixer coils to achieve maximum tuner gain and to obtain best response curve symmetry, a system of padding double tuned, overcoupled transformers is used utilizing capacity loading. Capacity loading may be achieved by using a small blade screw driver, and adding additional capacity by touching the screw driver shank with one or more of the fingers. This additional capacity severely detunes one side of the double tuned, overcoupled transformer, so that the single peaked, resonant response of the other side may be observed.

TO ALIGN THE TUNER PROCEED AS FOLLOWS: FIRST: Picture I.F. must be properly aligned.

SECOND: Connect R.F. sweep generator to antenna Terminals through 300 ohm balanced dummy antenna. Dummy antenna may consist of two 150 ohms carbon resistors, one from each terminal of the generator to the antenna terminals marked "A".

THIRD: Connect oscilloscope across the picture detector load resistor R-30 (point A Fig. 6) by means of the shielded cable and the filter system shown in Fig.8.

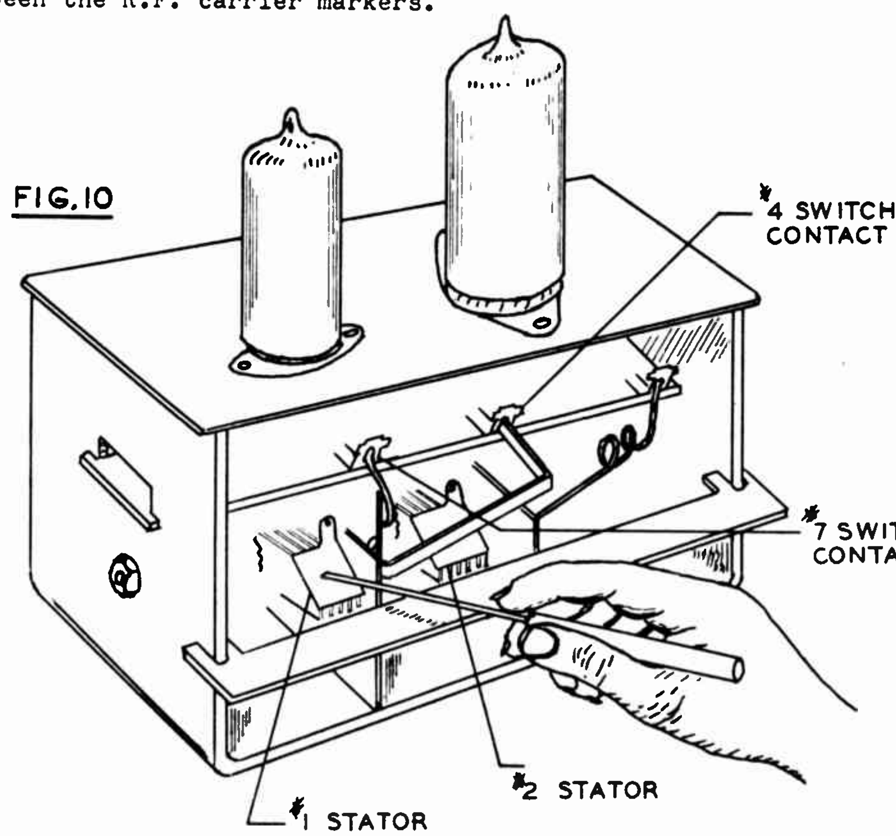
FOURTH: Perform the operations listed below. In each case adjust for flat wide band overall response with maximum gain as indicated on the oscilloscope screen. The shape of the overall response curve on all channels should be approximately the same as that of the video I.F. response curve shown in Fig.9. Marker pulses of proper frequency should be mixed in with the R.F. sweep input to check overall band width and relative position of the picture carrier on each channel. Always keep the R.F. input signal low so that slight variations in the tuning of the circuits are easily discernable on the oscilloscope screen. The physical location of all the adjustments is shown in Fig. 11, 12 & 13.

FIRST: Rotate the tuner to the channel 6 index position.

SECOND: Capacity load the R.F. coil (first stator plate) and adjust the low band mixer trimmer so that the single peaked response curve falls midway between the R.F. carrier markers. (See Figure 10 below)

THIRD: Capacity load the mixer coil (second stator plate) and adjust the low band R.F. trimmer, so that the single peaked response curve falls midway between the R.F. carrier markers.

FIG. 10



MODELS 5010, 5011, 5014, 5015, 5056, 5057, 5071, 5072, Ch. 19TS10, 19TS10A, 19TW10, 19TW10A

World Radio History

ALIGNMENT PROCEDURE (CONT'D)

FOURTH: With no loading on the double tuned circuits adjust the low band oscillator trimmer so that the channel 6 picture carrier marker falls at the 50% voltage reference level. Without loading, the response curve should have symmetrical double humps, the valley between them not being more than 30% down from the peaks.

FIFTH: Turn station selector to channel 2 and adjust the low band antenna trimmer C1A and pad for maximum gain and symmetry.

SIXTH: Check all low band channels. The response curve should remain substantially unchanged through all channels.

HIGH BAND ALIGNMENT: FIRST: Rotate the tuner to the channel 13 index position.

SECOND: Capacity load the R.F. coil (#7 switch lug) and adjust the high band mixer trimmer so that the single peaked response curve falls midway between the R.F. carrier markers.

THIRD: Repeat step 2, loading the mixer coil(#4 switch lug) and adjust the high band R.F. trimmer.

FOURTH: With no loading on the double tuned circuits adjust the high band oscillator trimmer so that the channel 13 picture carrier marker falls at the 50% voltage reference level.

FIFTH: Turn station selector to channel #7 and adjust the high band antenna trimmer C1B for maximum gain regardless of the shape of the response curve. At channel 13, because of the relatively large grid-plate capacity of the GAG5 R.F. amplifier, there is some frequency drag between the antenna coil padding and the R.F. coil padding,(i.e.), large detuning of the antenna causes detuning of the R.F. This action will be indicated by a sharply peaked response curve. A slight readjustment of the R.F. padder will restore symmetry.

SIXTH: Check all high band channels. The response curve should remain substantially unchanged through all channels.

OVERALL PICTURE SENSITIVITY CHECK:

After alignment of the various sections of the receiver has been completed, the following overall sensitivity checks should be made. (In cases where the signal generator output is not calibrated in microvolts comparative sensitivity measurements can be made by using another receiver which is known to be in good operating condition as a standard.).

FIRST: Connect the R.F. signal generator to the receiver antenna terminals through 300 ohm balanced dummy antenna as described in step #2 of tuner alignment.

SECOND: Connect the D.C. voltmeter across R30 as previously described. Set the voltmeter on the low D.C. volts scale.

THIRD: Set the signal generator at the center frequency of the channel to be measured and tune receiver dial for maximum reading of the D.C. meter. Adjust R.F. level until meter reads 1.5 volts(contrast control in maximum clockwise position). Generator output should be 250 microvolts or less in the low bands and 350 microvolts or less in the high bands.

SOUND SENSITIVITY CHECK:

Two R.F. signal generators are required, one of which shall be frequency modulated ∠ 7.5 Kc. at 400 cycles.

FIRST: Connect both R.F. signal generators to the receiver antenna terminals through separate dummy antenna resistors, doubling the resistance value used for the picture sensitivity test.

SECOND: Open speaker voice coil and connect a 3.ohm audio output meter across output transformer secondary.

THIRD: Connect the D.C. voltmeter across R-30 as previously described.

FOURTH: Set the unmodulated signal generator at the picture carrier frequency of the channel desired. Set the F.M. modulated signal generator at the sound carrier frequency. Keep the two generator outputs equal at all times. Tune receiver for maximum reading of the D.C. meter and then detune toward a lower frequency until the D.C. meter reading is reduced to half. Rock dial of frequency modulated generator for maximum reading on audio meter. Set signal generator outputs for 1/2 watt reading on audio meter. Divide generator microvolts by two since there is a 6DB insertion loss due to the dummy antenna used. This sensitivity reading should be 150 microvolts or less in all channels.

MAXIMUM AUDIO OUTPUT:

With signals applied as in the sound sensitivity check above, and the output of each generator set at 10,000 microvolts, the audio power output should be 2 watts or more.

HIGH BAND COUPLING

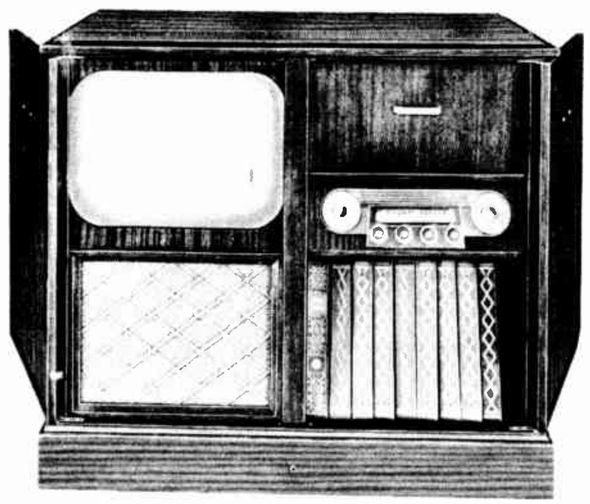
INDEX



GENERAL SPECIFICATIONS

DIMENSIONS
36¼" x 42" x 24".

WEIGHT (packed)
260 lbs. (approx.)

POWER REQUIREMENTS
117 volts 60 cycles.
Television — 300 watts.
AM-FM Radio — 150 watts.
Phonograph — 170 watts.

PROJECTION SYSTEM
The projection system used in this receiver is an adaptation of the Schmidt optical principle which is recognized as the most efficient and practical method of picture projection. The sturdy and well engineered construction of the "Optical Box" provide optical stability which eliminates the need for frequent adjustment.

PICTURE SIZE

Height	Width	Viewing Area
13"	18"	226 sq. inches

SPEAKER
12" P.M. Dynamic.
Voice Coil Imped. — 3.2 ohms.

ANTENNA INPUT IMPEDANCE
300 ohms — balanced to ground.

BUILT-IN ANTENNA
High "Q" dipole with tunable matching stub.

R.F. TUNER
Turret type construction; individually removable coil assemblies for all channels. All components are easily accessible for servicing.

"KEYED" AUTOMATIC GAIN CONTROL
Outstanding new development; minimizes "airplane flutter"; reduces contrast variation when changing from one channel to another; increases immunity of sync system to external interference.

PICTURE TUBE PROTECTIVE CIRCUIT
An additional stage has been added to this receiver to protect the face of the picture tube in event of failure of either the horizontal or vertical sweep circuits. This added precaution is taken to prevent burning of the picture tube face which would otherwise be encountered in the event of sweep failure for only a few seconds.

INTERMEDIATE FREQUENCIES
AM Sound — 455 Kc.
FM Sound — 10.7 Mc.
TV Sound Carrier — 22.25 Mc.
Picture Carrier — 26.75 Mc.

I.F. SYSTEM
AM — One stage (two tuned transformers).
FM — Two stage (three tuned transformers).
TV — Four stage (stagger tuned) for composite signal and two additional stages for inter-carrier sound.

VIDEO AMPLIFIER
Two Stage — broad band.

RETRACE LINE SUPPRESSOR
Eliminates retrace lines thruout the normal range of picture brightness and contrast.

FOCUS
Magnetic.

DEFLECTION
Magnetic.

HORIZONTAL SYNCHRONIZATION
Automatic frequency control and "keyed" A.G.C. provide excellent picture stability and noise immunity.

HIGH VOLTAGE POWER SUPPLY
Separate oscillator (blocking type) generates the high voltage through a step-up transformer and voltage tripler circuit which is completely sealed in oil.

SENSITIVITY
Antenna to Picture Tube Grid Sensitivity — To make this measurement, connect negative terminal of 1½ volt battery to A.G.C. line, and positive terminal of battery to chassis. Also, set Contrast control to maixmum clockwise position. Connect an A.C. vacuum-tube voltmeter between picture tube grid and ground, and place a .005 microfarad condenser across the same points.

Inject R.F. signal (modulated 30% at 400 cycles) at antenna terminals, using signal whose frequency corresponds to the center frequency of the selected channel, and adjust Fine Tuning control for maximum output. Generator must be connected to antenna terminals with a 150 ohm carbon resistor in series with each lead to simulate proper impedance match.

CAUTION

HIGH VOLTAGES are used in the operation of this receiver. The back cover, while in place, prevents accidental contact with this voltage and therefore should not be opened by anyone except a qualified television serviceman.

THE HIGH VOLTAGE LEAD, which supplies approximately 25,000 volts to the picture tube, should be momentarily shorted to the chassis whenever it is disconnected for service purposes. This discharges the high voltage filter condenser and prevents a shock hazard when working on the receiver after it has been turned off.

THE PICTURE TUBE is highly evacuated and if broken, glass fragments will be violently expelled. Scratching, chipping, undue pressure, or careless handling such as lifting the tube by its neck is dangerous and should be avoided. If it is necessary to handle the picture tube, use safety goggles and heavy gloves.

Do not operate the picture tube outside the protective Optical Box. Prolonged exposure to the very soft X-Ray radiation from this tube may prove harmful.

The plate lead of the 6BG6G tube in the High Voltage power supply must be dressed to clear all objects by ¼" to prevent corona discharge. When replacing the cover on this unit, the high voltage lead must go directly up through the cover and not cross over inside the box. Severe arcing may result if the cover is reversed.

Extreme care should be exercised in handling the reflecting mirror. Organic matter deposited on the front surface of this mirror by handling may cause permanent stains.

Input signal required to produce standard output of 7.07 volts A.C. (r.m.s.) at picture tube grid is indicated in the following table. Since a fixed bias of 1½ volts has been applied to the A.G.C. system in order to provide a reference for these measurements, it will be understood that the sensitivities specified here are not intended to indicate the full capability of the receiver, but merely serve as a convenient basis for determining proper operation.

Low Band { Average — 25 microvolts.
Range — 10 to 40 microvolts.

High Band { Average — 40 microvolts.
Range — 20 to 80 microvolts.

Detector to Picture Tube Grid Sensitivity — To make this measurement, remove 6AU6, 4th Video I.F. tube (V-10) and set Contrast control to maximum clockwise position. Inject a 400 cycle (audio) signal across 6800 ohm video detector load resistor. In order to produce the standard output of 7.07 volts A.C. (r.m.s.) at the picture tube grid, the input signal at the detector load resistor will be approximately .07 volts A.C. An A.C. vacuum-tube voltmeter must be used for these measurements.

Television Sound System Sensitivity — Inject 4.5 megacycle frequency modulated signal (400 cycle modulation with 7½ Kc. deviation) across viedo detector load resistor and measure output at speaker voice coil. An input of 2200 microvolts will produce approximately 500 milliwatts or 1.26 volts across speaker voice coil.

A.M. Sound System Sensitivity — Inject a 1000 Kc. signal (modulated 30% at 400 cycles) at (high side) connection lug on antenna section of gang condenser. Connect generator to this point through a .01 microfarad condenser. Tune receiver to 1000 Kc. signal. An input of 75 microvolts will produce approximately 500 milliwatts or 1.26 volts across speaker voice coil.

F.M. Sound System Sensitivity — Inject a 98 megacycle frequency modulated signal (400 cycle modulation with 22½ Kc. deviation at pin 8 of 12AT7, F.M. R.F. Amplifier tube (V-26). Connect generator to this point through a 300 ohm resistor. Tune receiver to 98 Mc. signal. An input of 35 microvolts will produce approximately 500 milliwatts or 1.26 volts across speaker voice coil.

INSTALLATION INSTRUCTIONS

Television receiver performance is greatly dependent upon proper installation and correct initial adjustment of certain pre-set controls. It is therefore essential that the installation of the receiver be made by highly skilled television technicians. Installation consists of (1) unpacking and set-up, (2) adjustment of pre-set controls, and (3) instructing the customer how to operate the receiver. In addition the installation technician will determine whether television signals are sufficiently strong at the receiver location to permit satisfactory operation of the set when using its built-in antenna or whether an outdoor type antenna is necessary. In locations where signals are quite weak or reflected signals prove troublesome, the use of an outdoor antenna is generally recommended.

Should unfavorable reception conditions make it necessary to use an outdoor antenna, then the installation technician must select an antenna that best meets the requirements of the particular location. Careful assembly and mounting of the antenna on the roof of the home, as well as the selection and routing of transmission line, are factors that are also important if best reception is to be achieved, especially in a weak signal or "fringe" area.

Detailed instructions for accomplishing each of the installation operations are given in the following paragraphs and it is preferable to proceed in the order in which these subjects are discussed.

INSTALLING CABINET MIRROR — The special "front surface" mirror used to reflect the picture onto the receiver screen is packed separately in the compartment directly behind the screen. To gain access to it, remove the screws on that half of the cabinet back (section to which the name label is attached). The mirror can then be released by removing the screw blocks which hold it in place during shipment. Carefully unpack mirror and lay it flat on the protective tissue in which it was packed. **Extreme care should be exercised in handling it so that the front surface is not marred or stained by finger marks. Cleaning should be done with a soft clean cotton cloth, using light pressure.**

To determine which side of this mirror is the front surface, carefully approach one surface with any opaque object. **The front surface is that side on which the mirror image seems to touch the object when the object contacts the glass.** On the reverse side, the image will appear to be separated from the object by the thickness of the glass.

This front surface on which the silver has been deposited, must face towards the front of the receiver when the mirror is mounted in the cabinet. Failure to place the correct surface forward will result in optical distortion of the image on the screen.

Before attempting to install the mirror, remove the envelope which is stapled to the side wall of this compartment. This envelope contains the built-in antenna tuning knob which must be installed in accordance with the instructions in the next section. The mirror locking blocks, which are located at the top end of the mirror mounting rails (see Figure 1), must be positioned parallel to the rails before the mirror can be installed.

While holding the mirror carefully at its front and back edges with its front surface forward, slide it into position on the mounting rails until it clears the V-cleats at the bottom end of these rails. Then slide the mirror back on the rails until it is firmly seated in the cleats. The locking blocks should now be turned down to hold the mirror against the rails.

©John F. Rider

World Radio History

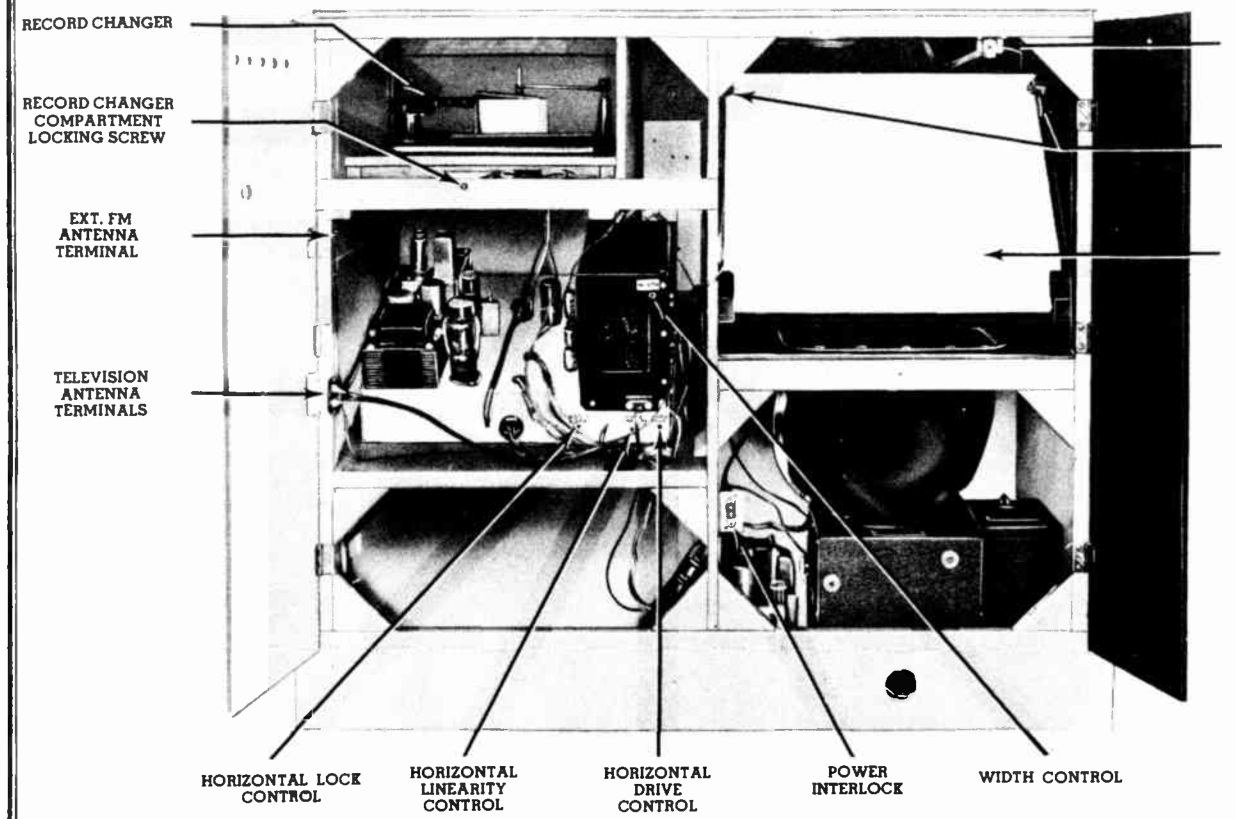


FIG. 1 — REAR VIEW — CABINET BACKS OPEN

ADJUSTING LIGHT SHROUD — Note the black shroud which is suspended from the shelf beneath the front surface mirror and extends to the Optical Box. The purpose of this shroud is to prevent spurious light from entering into the optical path of the projection system and also to prevent dust from settling on the face of corrector lens of the Optical Box. Untie the cord at the bottom edge of the shroud and lift it from the Optical Box to inspect the corrector lens for dust. If necessary, wipe this lens gently with a soft clean cloth to remove all foreign matter from its surface. Re-tie the shroud securely around the four upright studs on the Optical Box and make sure that it does not sag into the optical path.

RECEIVER CONTROLS

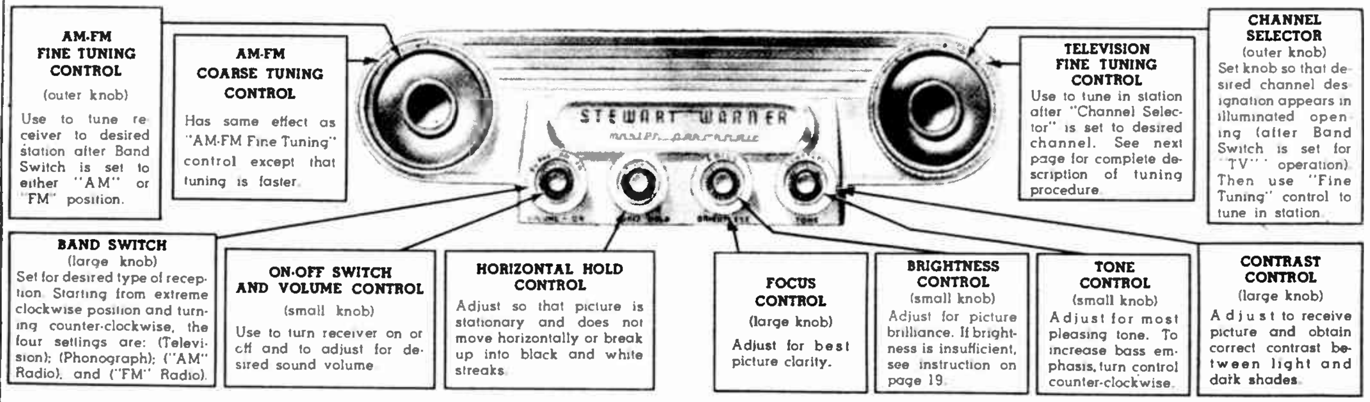

FIG. 2

The various controls on the receiver may be divided into two classes, Operating and Pre-set. Operating controls are those which control program selection as well as sound and picture quality. All but one of these controls are located on the front panel and their functions are indicated in Figure 2. The built-in television antenna tuning condenser is accessible at the rear of the receiver.

The Pre-set controls are those which require adjustment at the time the receiver is installed and they rarely need attention thereafter. There are nine of these controls, four of which are located at the back of the chassis (see Figure 1). Four controls are accessible by removing the Name Plate located directly above the Operating controls. Access to the "Auxiliary Fine Tuning" screw can be gained by removing the "Channel Selector" and "Fine Tuning" knobs.

CONTROL ADJUSTMENT PROCEDURE

Power interlocks are provided on the half of the cabinet back located behind the picture screen and on the speaker grille panel (see Figures 1 and 7). Should either the cabinet back or speaker grille panel be opened, the power supply to the receiver will be interrupted and a special power cord (Stewart-Warner part No. 507699) will be required to supply power to the receiver. If the speaker grille panel is removed, power must be supplied to the receiver through the interlock located at the front. If only the cabinet back is opened, power can be supplied to the receiver through the interlock at the rear.

CAUTION

When by-passing the power interlocks through the use of a special power cord, extreme care should be exercised to avoid contact with the high voltage components used for operation of this receiver.

Although the pre-set controls have been factory adjusted for optimum performance, it is usually necessary to make some fine adjustments of these controls at the time of installation.

To gain access to the centering adjustments and optical focusing it will be necessary to open the cabinet back, behind the picture screen, be removing screws around the rim of the back. The speaker grille panel must also be removed by grasping the grille frame at the upper edge and pulling outward.

Be sure that the locking brackets used to hold the Tailpiece Assembly to the Optical Box during shipment (see Figure 7) are removed before undertaking any optical adjustments as described in the following procedure. In addition, the felt block between the focus coil housing and picture tube clamp plate must be removed.

The receiver is now ready for an operational check.

TO ADJUST CONTROLS FOR RECEPTION OF STANDARD BROADCAST OR FREQUENCY MODULATION STATIONS:

1. **TURN SET ON** — Rotate "On-Off" Switch and Volume knob clockwise to turn receiver on.
2. **POSITION BAND SWITCH** — Set "Band Switch" to either its "AM" or "FM" position. Dial scale of corresponding band will be illuminated on face of "AM-FM Fine Tuning" knob.
   If the Channel Lite behind either the AM or FM dial scale does not light, and receiver otherwise operates satisfactorily, then that Channel Lite may be burned out and replacement should be undertaken. To gain access to Lites, remove all knobs on front of receiver (pull each knob forward) and remove Name Plate by grasping its upper edge and pulling it away from the cabinet. The Control Panel Escutcheon must then be removed by taking out the four wood screws which hold it in place. Replace Channel Lite with Stewart-Warner part #118921. Be sure to replace sleeving over new Channel Lite.
3. **TUNE** — Use "AM-FM" Fine Tuning" control to select desired station.
4. **ADJUST VOLUME** — Select "Volume" control setting for desired sound intensity.
5. **ADJUST TONE** — Select "Tone" control setting for most pleasing tone.

TO ADJUST RECEIVER FOR RECEPTION OF TELEVISION STATIONS:

1. **TURN SET ON** — Rotate the "On-Off Switch and Volume" knob approximately $\frac{1}{2}$ turn clockwise to turn set on and obtain sufficient sound volume during the tuning process. Allow several minutes for all tubes in the receiver to warm up and for circuits to stabilize before attempting to obtain a picture on the screen.
2. **POSITION BAND SWITCH** — Set "Band Switch" to "TV" position. The TV Channel Lite, located behind the "Channel Selector" knob, illuminates the particular television station designation corresponding to the setting of the Channel Selector.
   If the TV Channel Lite does not light, and receiver otherwise operates satisfactorily, then the Lite may be burned out and replacement should be undertaken. Follow the same procedure previously indicated for removal of AM-FM Channel Lites.
3. **ADVANCE BRIGHTNESS CONTROL** — Turn "Brightness" control clockwise until picture screen is moderately illuminated. The screen may remain dark or dimly illuminated until the "Coarse Brightness" control is adjusted as described in next step. If it should be found that the picture "blooms" or grows in size as the "Brightness" control is advanced, this condition can be corrected by adjustment of the "Coarse Brightness" control.
4. **ADJUST COARSE BRIGHTNESS CONTROL** — This control is located behind the Name Plate escutcheon (see Figure 5) which can be removed by grasping it at the upper edge and pulling forward. With the "Brightness" control on the front panel set to its maximum clockwise position, adjust the "Coarse Brightness" control for maximum brightness. The point of maximum brightness will occur just before the picture "blooms" or grows in size.
   Since maximum light transfer through the picture screen takes place perpendicular to its face, this adjustment should be undertaken with the operator looking directly into the screen.
5. **ADVANCE CONTRAST CONTROL** — Rotate the "Contrast" control knob fully clockwise.
6. **SET CHANNEL SELECTOR TO DESIRED CHANNEL** — The "Channel Selector" knob designates the channel to which the television receiver is tuned. (NOTE: Call letter or channel number tabs must be inserted into the "Channel Selector" knob for proper station identification — see paragraph #23 of this section of Installation Instructions for method of inserting these tabs.) Numbered positions indicated by the knob correspond to the station channel number. Set the "Channel Selector" knob to a channel on which a local television station is known to be broadcasting at the time.
7. **FINE TUNING CONTROL** — Use the "Television Fine Tuning" control (illustrated in Figure 2) to obtain the correct tuning point for both picture and sound. That is accomplished as follows:
   a. Turn "Television Fine Tuning" control in either direction until sound volume is maximum — if sound cannot be heard, advance the volume control and repeat fine tuning. If sound still cannot be heard, then refer to step 8.

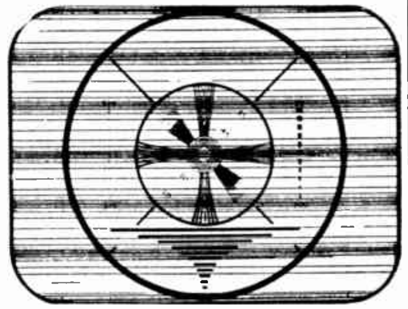

FIG. 3 — SOUND INTERFERENCE CAUSED BY INCORRECT TUNING

   b. When the point of maximum sound volume has been reached it will be noted that the picture has a "ragged" or "sawtooth" appearance or is partially obscured by "sound bars" (dark horizontal bars of varying width — see Figure 3).
   THE CORRECT SETTING OF THE "TELEVISION FINE TUNING" CONTROL is now obtained by turning it away from the maximum volume position only far enough to eliminate the "sound bar" interference and permit sharp reproduction of the picture. If an image is slightly distorted or tears into a series of black and white streaks as shown in Figure 6, reduce the setting of the "Contrast" control and operate the "Horizontal Hold" control knob until picture appears stable and undistorted.
8. **AUXILIARY FINE TUNING ADJUSTMENT** — If it is found that the tuning range of the "Television Fine Tuning" control is inadequate to permit correct tuning of a station in its assigned channel, then adjustments of the "Auxiliary Fine Tuning" screw will be necessary. This special screw is accessible after removal of the "Channel Selector" and "Television Fine Tuning" knobs. They may be removed by merely pulling them forward.

Adjustment of the "Auxiliary Fine Tuning" screw may now be undertaken in accordance with the following procedure.

a. Set "Channel Selector" to desired channel; then remove this knob.

b. Set "Television Fine Tuning" knob to the center of its range; then remove this knob. The flat portion of the main tuning shaft (outer brass shaft) should now be in the uppermost position. Note the location of the "Auxiliary Fine Tuning" adjustment screw on receiver chassis — see Figure 5.

©John F. Rider

World Radio History

c. Using a thin screwdriver (preferably non-metallic), adjust the setting of "Auxiliary Fine Tuning" screw for correct tuning of the desired television station — **CAUTION: Do not attempt to rotate this screw more than two full turns in either direction, as further rotation may release it from the thread clip within the tuning mechanism and the TV chassis would then have to be removed from the cabinet in order to restore the screw to the correct position.** If a metal screwdriver is used, detuning occurs when the screwdriver is removed but it will be noted that this degree of detuning can now be compensated by resetting the "Television Fine Tuning" control (brass shaft). Thus the range of the "Television Fine Tuning" control (after knob is replaced on the shaft) will be adequate to tune in the station.

d. This completes the adjustment of the "Auxiliary Fine Tuning" screw for one channel. Identical screws are provided on each channel and they are all accessible thru the same opening in the tuning mechanism as each successfully moves into position when the "Channel Selector" knob is rotated.

9. **BUILT-IN ANTENNA ADJUSTMENT** — If the receiver's built-in television antenna system is used, rotate the antenna tuning knob (located at rear of cabinet) until the best picture is obtained. It may be possible to find a single setting for this knob which will give satisfactory performance for a group of stations. In the event that is not the case, adjust the control for optimum performance each time the Channel Selector is rotated to a different station.

10. **SOUND VOLUME** — Adjust the setting of the "Volume" control by rotating it clockwise until the sound accompanying the television broadcast is received at a satisfactory level.

11. **TONE** — Adjust "Tone" control setting for most pleasing tonal quality.

12. **HORIZONTAL HOLD** — Should the picture appear to move horizontally across the screen or break up into a series of light and dark streaks as shown in Figure 6, adjust the "Horizontal Hold" control until the picture remains stationary.

If this control must be rotated to the end of its range for proper "locking" action, then it will be necessary to reset the position of the "Horizontal Lock" control (see Figure 1) for location. This control is appropriately labeled on the cabinet back and is accessible without opening the back. Adjustment is accomplished by first setting the "Horizontal Hold" control in the middle of its range and then changing the setting of the "Horizontal Lock" control until picture locks in horizontally.

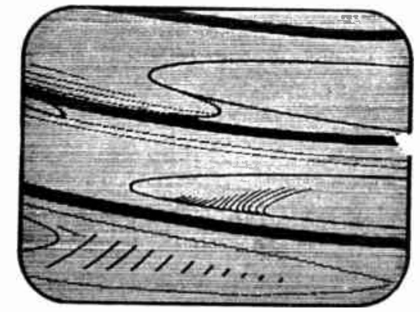

FIG. 6 — HORIZONTAL MOVEMENT; ADJUST HORIZONTAL HOLD CONTROL

13. **VERTICAL HOLD** — Should the picture roll in a vertical direction or appear as multiple vertical images as shown in Figure 8, it will be necessary to adjust the "Vert. Hold" control located behind the Name Plate (see Figure 5).

After this adjustment is made, reduce contrast until picture is barely visible and check setting of "Vertical Hold" control for proper picture synchronization.

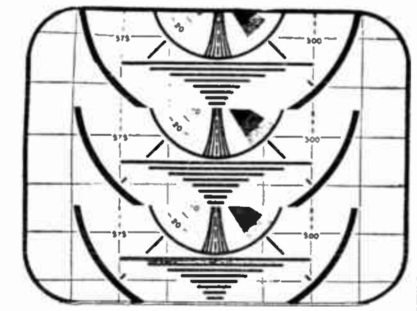

FIG. 8 — VERTICAL MOVEMENT; ADJUST VERTICAL HOLD CONTROL

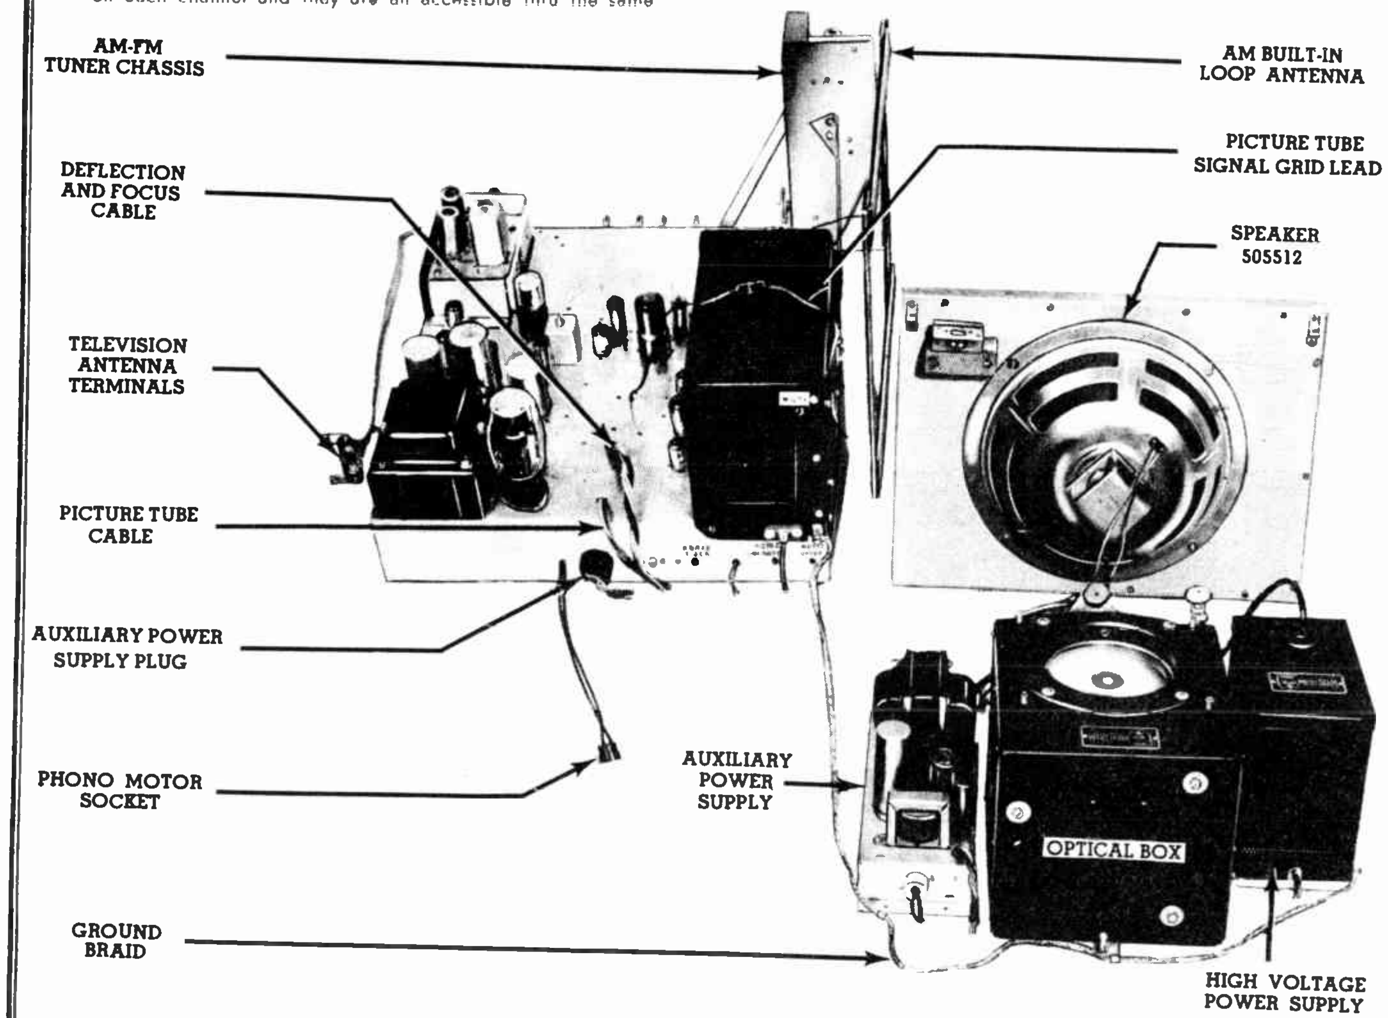

FIG. 4 — CHASSIS LOCATIONS

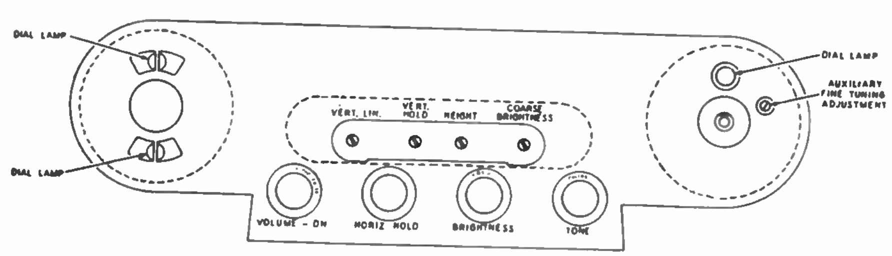

FIG. 5 — LOCATION OF PRE-SET CONTROLS

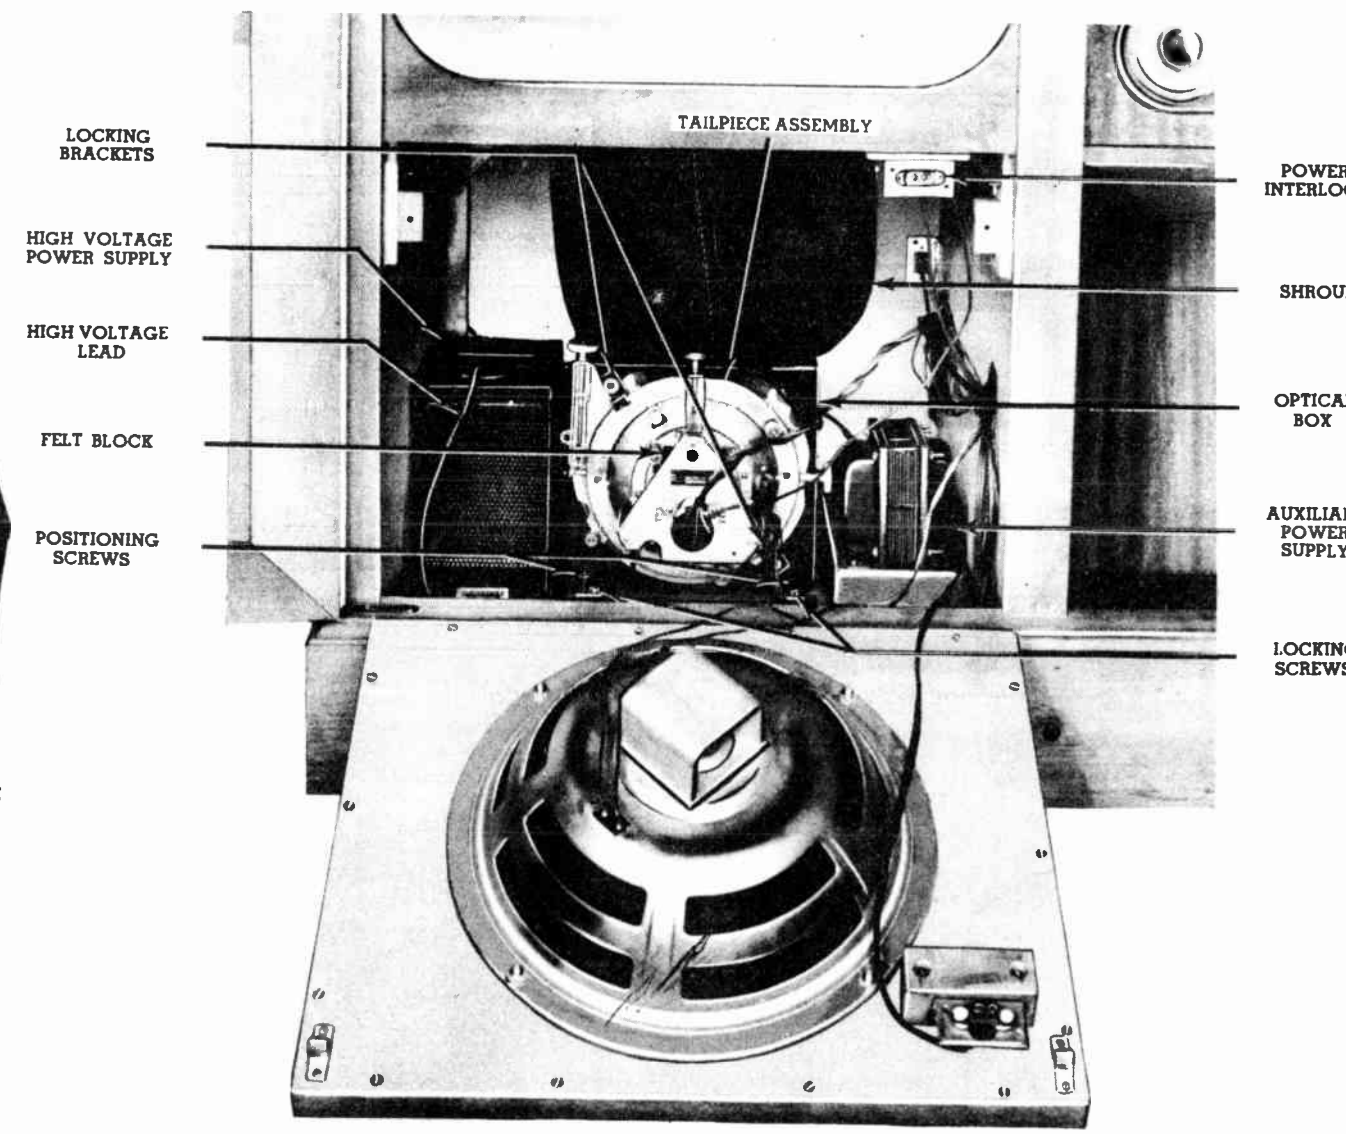

FIG. 7 — SPEAKER GRILLE PANEL REMOVED

©John F. Rider

World Radio History

14. **INITIAL FOCUS**— Adjust the "Focus" control until picture is most clearly defined. In the event that proper overall focus cannot be obtained, or if a portion of the picture will not focus sharply, it will be necessary to make adjustments on the Optical Box. Be sure that Tailpiece shipping brackets and felt block are removed from Tailpiece assembly before attempting to make these adjustments.

a. Set "Focus" control to position of best focus.

b. Remove speaker grille panel and open cabinet back behind picture screen. Power must be supplied to the receiver through the interlock at the speaker grille opening. **CAUTION: Exercise care to avoid contact with high voltage components.**

c. Loosen two thumb nut "L" and three thumb screws "N" (see Figure 11).

d. Adjust thumbscrew "O" for overall focus, with sharp focusing occurring in the center of the picture.

e. Adjust thumbscrew "H" so that top and bottom of picture focus equally well.

f. Adjust thumbscrew "V" so that both sides of picture are in focus.

g. Repeat step "d".

h. Repeat steps "e", "f" and "g" if necessary.

i. Hand tighten thumb nuts "L" and thumbscrews "N".

If adjustment of thumbscrew "O" will not give overall focusing, check to see that tube clamp (see Figure 21) is securly holding the picture tube in position. Since the face of this tube is the first lens of the optical system, its position is critical and the tube must be well seated in the Tailpiece assembly. Loosen tube clamp screw and grasp tube neck, pulling back gently until it firmly seats itself. Exercise care in tightening tube clamp so as not to crack the tube neck.

Fuzzy picture may also be due to reproduction of poor quality film when station is televising a motion picture. Incorrect tuning of receiver produces a similar effect. Check for proper tuning point as described in step 7.

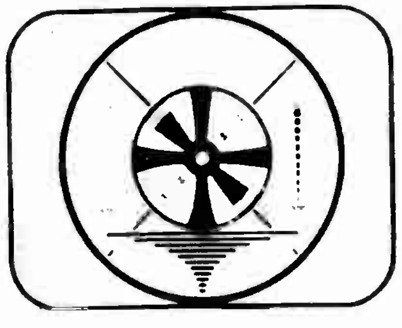

FIG. 9 — BLURRED APPEARANCE; ADJUST FOCUS CONTROL

15. **STRAIGHTENING TILTED RASTER** — If the pattern should appear on the screen in a tilted position as shown in Figure 10, loosen four thumb nuts "M" and rotate the entire Tailpiece assembly sufficiently to correct this condition. Be sure to re-tighten these four nuts securely.

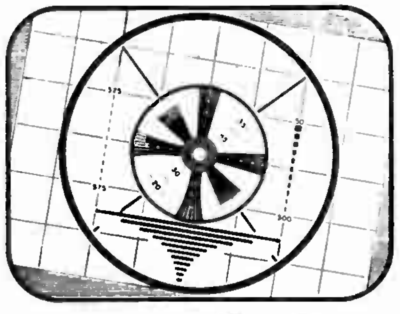

FIG. 10 — TILTED PICTURE; ADJUST TAILPIECE POSITION

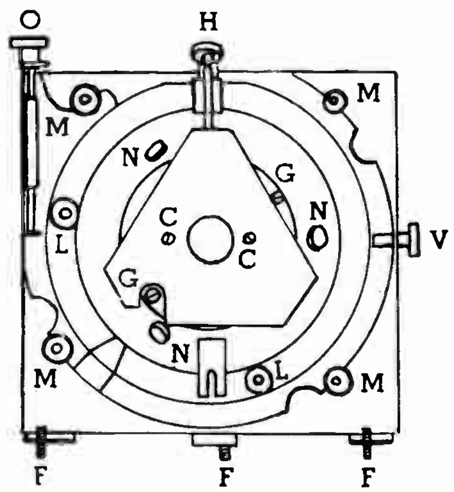

FIG. 11 — OPTICAL ADJUSTMENT CONTROLS

The following adjustments should be made while the station is transmitting its circular test pattern.

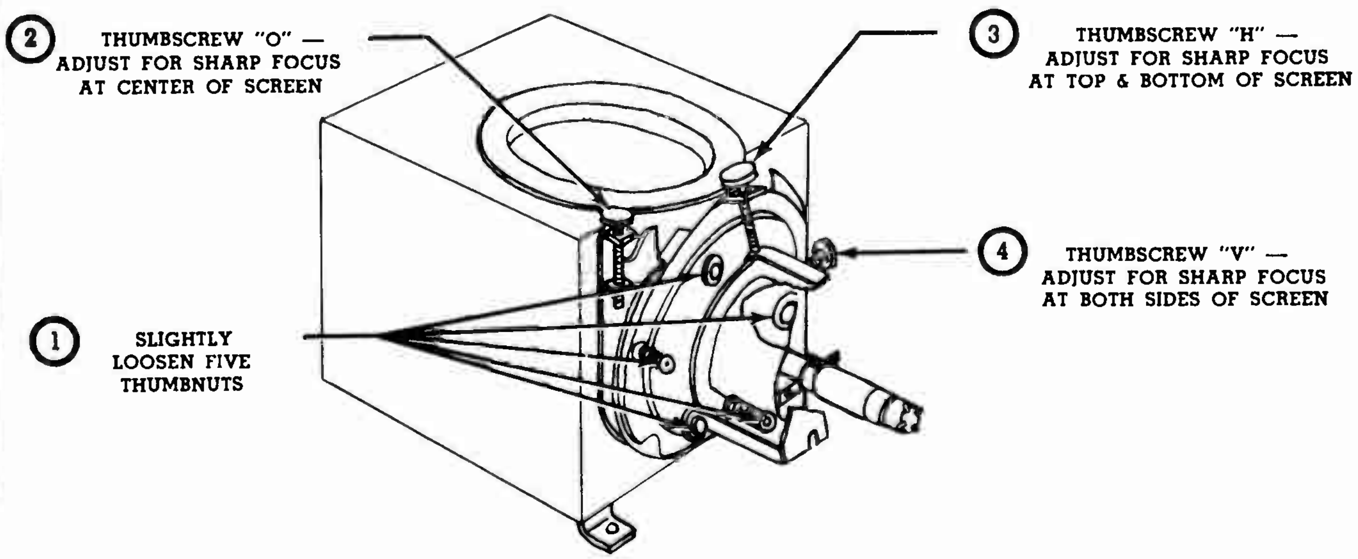

FIG. 12 — OPTICAL FOCUSING ADJUSTMENT

16. **CENTERING** — The position of the neck of the picture tube in the Tailpiece assembly will affect the position of the pattern on the screen. Loosen the two screws "C" on the back of the triangular tube clamp plate and center the neck of the tube in the hole in the plate and re tighten the screws.

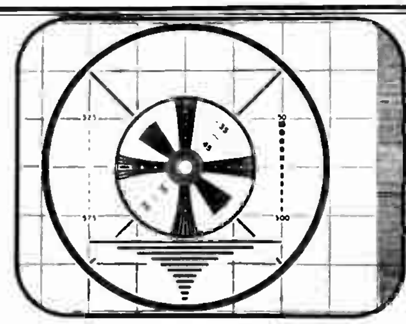

FIG. 13 — OFF CENTER; ADJUST FOCUS COIL POSITION

Further positioning of the raster on the screen can be accomplished by adjusting the position of the focus coil with respect to the tube. The position of the focus coil is adjusted by means of two screws located on the front edge of the focus coil housing assembly (see screws labeled "G" in Figure 11). If considerable displacement of the raster is encountered, full correction should not be undertaken by re-positioning the focus coil. This should be done by re-positioning the Optical Box as follows:

Loosen the three locking screws which hold the Optical Box fast to the bottom of the cabinet. Then adjust the three positioning screws "F" (see Figure 11) until the pattern is properly centered. Re-tighten the locking screws.

17. **WIDTH** — Control of picture size in the horizontal direction is accomplished by means of the "Width" control located on the rear of the screen cage on the television chassis (see Figure 1). If abnormally low line voltage makes it difficult to obtain sufficient picture width when using the "Width" control, then changing the setting of the "Horizontal Drive" control may be helpful. The "Drive" control is located at the rear of the chassis and its setting will affect horizontal linearity as well as picture width. Therefore, after adjusting this control for desired width, it may be necessary to re-adjust the "Horizontal Linearity" control as described in paragraph #18. The three controls referred to in this copy are all accessible through properly labeled openings on the cabinet back.

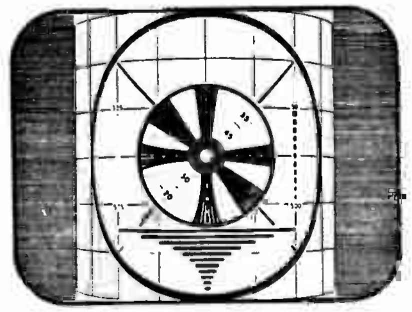

FIG. 14 — TOO NARROW; ADJUST WIDTH CONTROL

18. **HORIZONTAL LINEARITY** — Improper horizontal linearity causes the circular test pattern to appear condensed on the right edge of the screen and extended on the left edge or vice versa. This effect is illustrated in Figure 15. Adjust for proper linearity by using "Horiz. Lin." control located on rear of chassis (see Figure 1). In event that proper horizontal linearity cannot be obtained by adjusting this control, then change the setting of the "Horiz. Drive" control (also located at rear of chassis). As width and linearity of the picture are affected by the setting of Horiz. Drive control, it will be necessary to adjust this control in conjunction with the Horiz. Linearity and Width controls to obtain desired picture width and linearity.

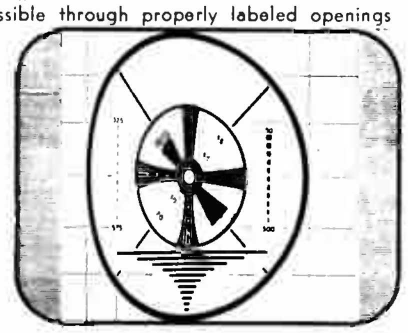

FIG. 15 — HORIZONTAL DISTORTION; ADJUST HORIZONTAL LINEARITY CONTROL

19. **HEIGHT** — Control of picture size in the vertical direction is accomplished by means of the "Height" control located behind the Name Plate. Height and width adjustments should be checked for all transmitting stations to be sure that picture properly fills the viewing area.

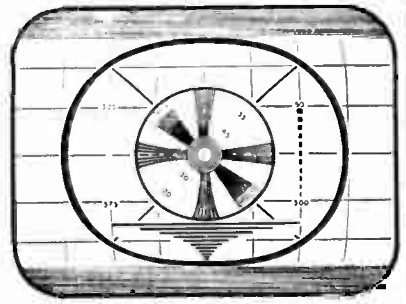

FIG. 16 — TOO SHORT; ADJUST HEGHT CONTROL

20. **VERTICAL LINEARITY** — Improper vertical linearity causes the circular test pattern to appear condensed on the upper edge of the screen and extended on the lower edge or vice versa. This effect is illustrated in Figure 17. Adjust for proper linearity by using "Vert. Lin." control located behind Name Plate. It may be necessary to readjust the "Height" control if an appreciable change is made in the linearity control setting.

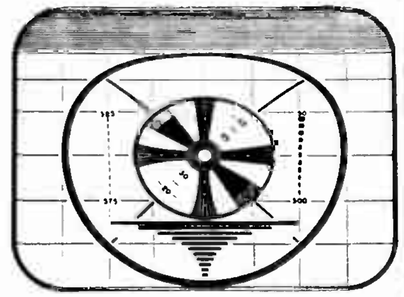

FIG. 17 — VERTICAL DISTORTION; ADJUST VERTICAL LINEARITY CONTROL

21. **FINAL OPTICAL FOCUSING** — Receiver adjustments which have been made since the original optical focusing was undertaken may cause a slight amount of de-focusing. It is therefore advisable to once more go through the optical focusing procedure as described in step 14.

22. **FINAL ADJUSTMENTS** — Recheck settings of "Brightness" "Contrast" and "Focus" control for best picture quality. Proper adjustment of all Pre-set and Operating controls on this receiver should result in the type of picture indicated in Figure 18.

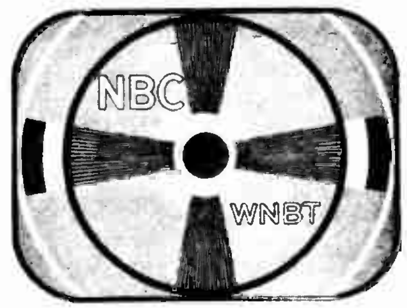

FIG. 18
CORRECTLY ADJUSTED PICTURE

23. **INSERTING STATION TABS** — A set of television station call letter tabs and channel numbers is supplied with each receiver and is to be used to identify the local television stations. To install these tabs, merely remove the "Channel Selector" knob, and insert either the correct station call letters or channel numbers into the proper circular recesses on the rear surface of the knob. The correct recess may be identified by the station channel number stamped on the outer edge of the "Channel Selector" knob adjacent to each recess. Insert black tabs in the remainder of the circular holes.

The unused tabs should be retained. The list of call letter tabs includes many of the television stations which are not yet on the air. When a new local station begins broadcasting, remove the "Channel Selector" knob, remove the previously inserted black tab for that channel, and insert the correct call letter tab.

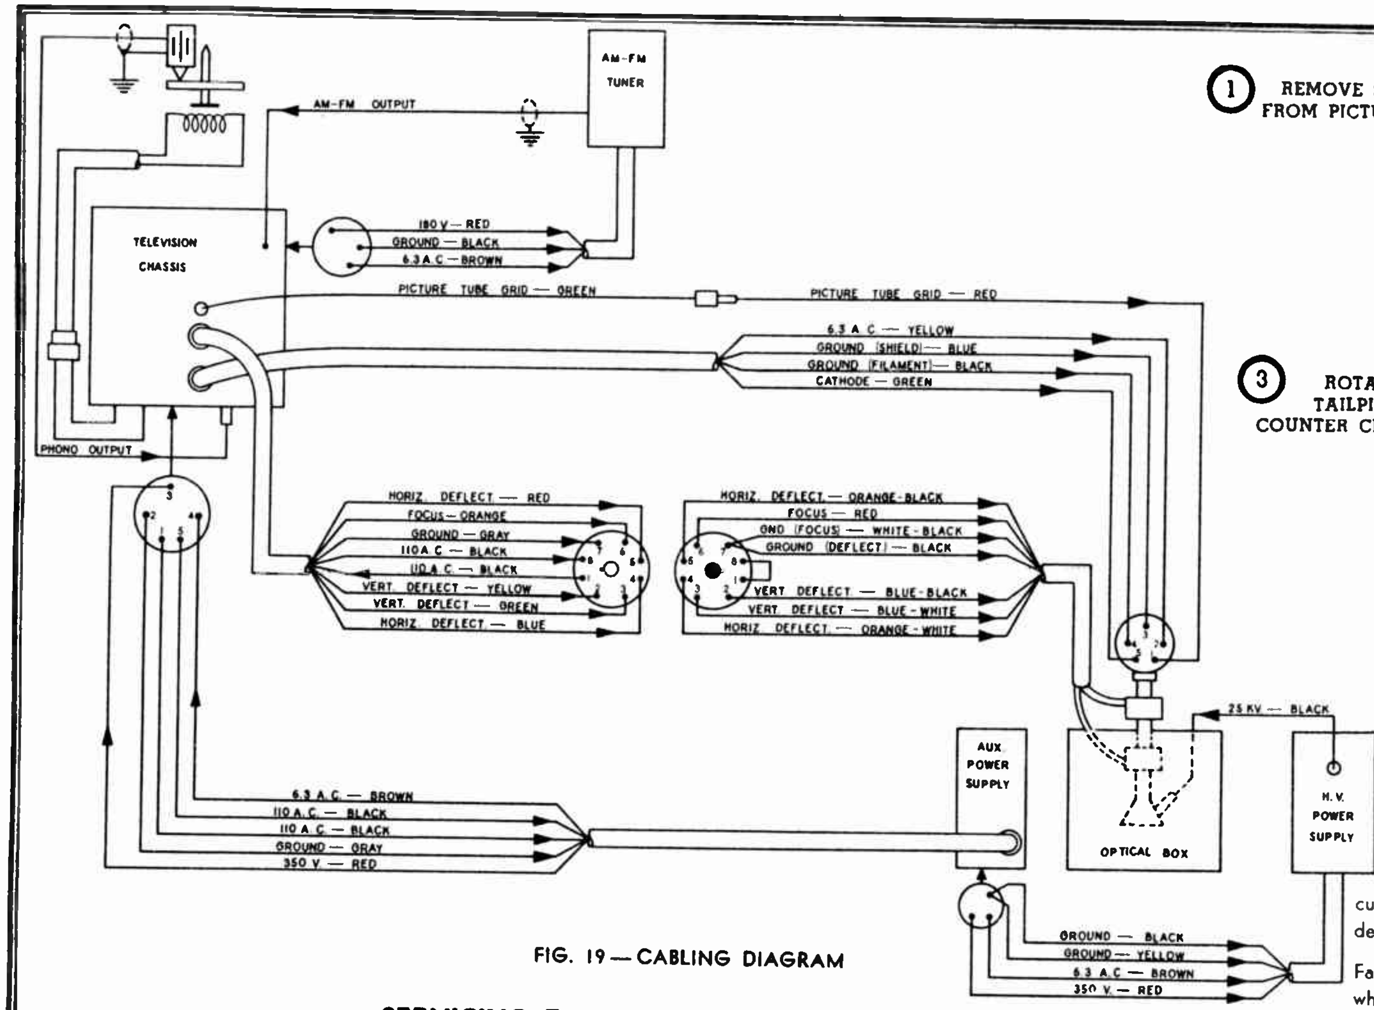

FIG. 19 — CABLING DIAGRAM

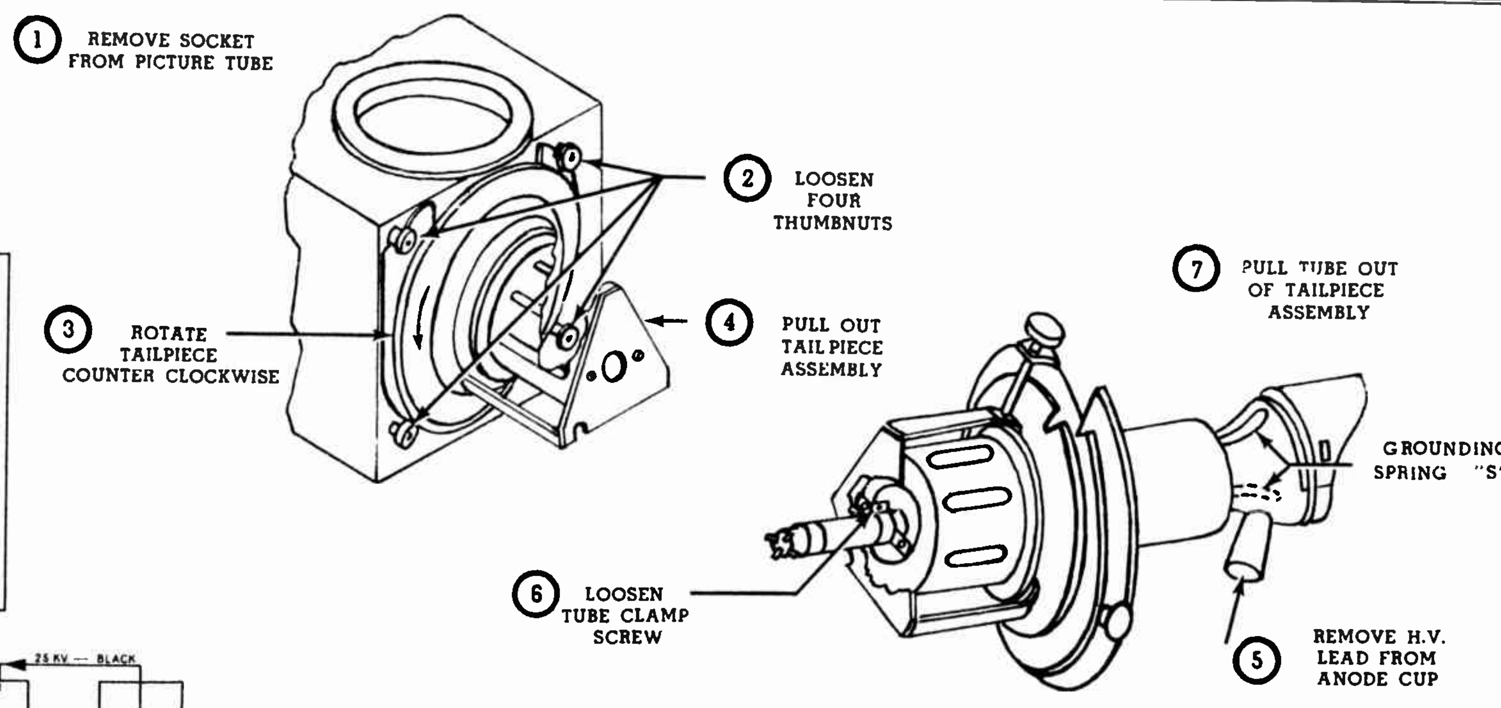

FIG. 21 — REMOVAL OF PICTURE TUBE

SERVICING THE HIGH VOLTAGE POWER SUPPLY

CAUTION

This unit supplies the 25,000 volts required for operation of the 3NP4 cathode ray tube. Although it is a reduced-hazard, pulse type power supply, whose power output capabilities are limited to the requirements of the 3NP4 tube, extreme care should be exercised while working on it.
If replacement of the 6BG6G tube is undertaken, care must be exercised to dress the plate lead at least ¼" from all objects so as to prevent corona discharge.
When replacing the cover on the high voltage unit, be sure that it is not reversed. The high voltage lead must go directly up through the cover and not cross over inside the box. Severe arcing may result if the cover is reversed.

The 6SR7 tube in the high voltage supply operates as a blocking oscillator whose frequency must be maintained at 1000 ±70 c.p.s. A frequency controlling trimmer condenser is accessible at the base of the high voltage power supply, **but adjustment should not be undertaken unless some frequency determining component has been replaced.** This 1000 cycle adjustment has a negligible effect on the output voltage or current regulation and should not be tampered with in an effort to correct for insufficient brightness or "blooming". Its only function is to provide the proper frequency which determines the correct amount of power delivered to the heaters of the three high voltage rectifier tubes inside the sealed can, and thereby assures maximum life for these tubes.

Adjustment of this trimmer should be done with an oscilloscope and a dependable 1000 cycle generator. Blocking oscillator voltage to operate the vertical amplifier of the oscilloscope can be obtained from the 350 volt B+ line to the High Voltage Supply. With a 1000 cycle signal from the generator applied to the horizontal sweep amplifier of the oscilloscope, adjust the trimmer condenser until a single stable oscillogram is obtained as indicated in Figure 20.

If the High Voltage supply does not operate, first check the 6SR7 and 6BG6G tubes by replacing them. Should this fail to correct the difficulty, check to see that the blocking oscillator is functioning as evidenced by a bias of −50 volts on the grid of the 6SR7 tube (V32).

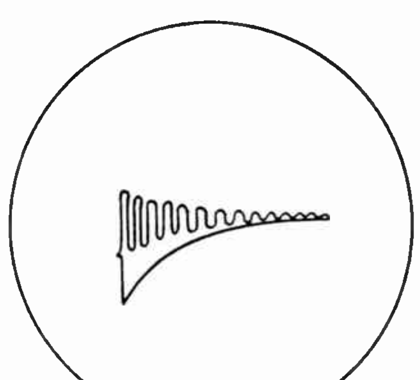

FIG. 20 — OSCILLOGRAM OBTAINED FOR CORRECT ADJUSTMENT OF H.V. OSCILLATOR TRIMMER

Failure of a component in the sealed can in the High Voltage supply, which contains the high voltage transformer and three rectifier tubes (V34, V35 and V36), can cause reduced high voltage on complete absence of this voltage. Since it is impractical to attempt replacement of any of these components individually, the entire can must be replaced. Exercise care when soldering to the glass insulator connections, as excessive heat may result in damage to the oil seals.

It should be kept in mind that action of the 6SN7 Protector Tube (V21) can cause the picture tube V15 to be biased to cut-off thereby causing the picture screen to go dark. In the event that the screen should go dark and it has been determined that the High Voltage supply is not at fault, check to see if the failure of one or both of the sweep circuits has caused the 6SN7 Protector Tube to bias the 3NP4 picture tube to cut-off.

REPLACEMENT OF 3NP4 PICTURE TUBE

To replace the 3NP4 picture tube, mounted in the Optical Box proceed as follows:

1. Remove tube socket from base of tube.
2. Loosen four thumb nuts "M" (see Figure 11).
3. Carefully rotate entire Tailpiece assembly counter-clockwise.
4. Use extreme care to gently pull entire Tailpiece assembly and picture tube out of Optical Box. This operation must be done very carefully to prevent the tube from hitting the plane mirror in the Optical Box.
5. Disconnect the High Voltage lead from the picture tube anode cup by pulling it straight out.
6. Loosen the screw on the tube clamp (see Figure 21) and pull tube out of Tailpiece assembly.
7. A light shield and neoprene band are packed with each 3NP4 replacement tube. Place this light shield over top of tube, (opposite high voltage anode cup) locating it over the two projecting lugs on the tube and hold it in place with the neoprene band as shown in Figure 21. The two grounding springs "S" (see Figure 21) must make good contact with the aquadag (black coating) on the outside of the tube. Therefore these springs must be kept clear of the light shield or placed under it.
8. Carefully insert the tube into the Tailpiece assembly, with the anode cup facing down.
9. Push the tube into the deflection yoke as far as it will go and tighten the screw in the tube clamp. Although care must be exercised to prevent cracking the tube neck, this screw must be sufficiently tight to prevent the tube from moving forward in the Tailpiece Assembly. Do not attempt to hold the Tailpiece Assembly by the deflection yoke.
10. Place the high voltage cable connector in the anode cup of the picture tube, making sure that the clip securely grips the metal button.
11. Carefully insert the Tailpiece Assembly in the Optical Box making sure that the tube and light shield properly clear the plane mirror.
12. Rotate the Tailpiece Assembly clockwise until the slots engage the four nuts "M". Keep the bottom edge of the triangular endplate parallel to the bottom of the Optical Box.
13. Connect the tube socket to the tube while holding the neck so as to avoid the possibility of pushing it out of position in the deflection yoke.

If picture tube replacement is undertaken, it will be necessary to re-adjust the optical focus as described in step 14 of the preceding section. It may also be necessary to re-center the picture on the screen as indicated in step 16 and to straighten the raster as outlined in step 15.

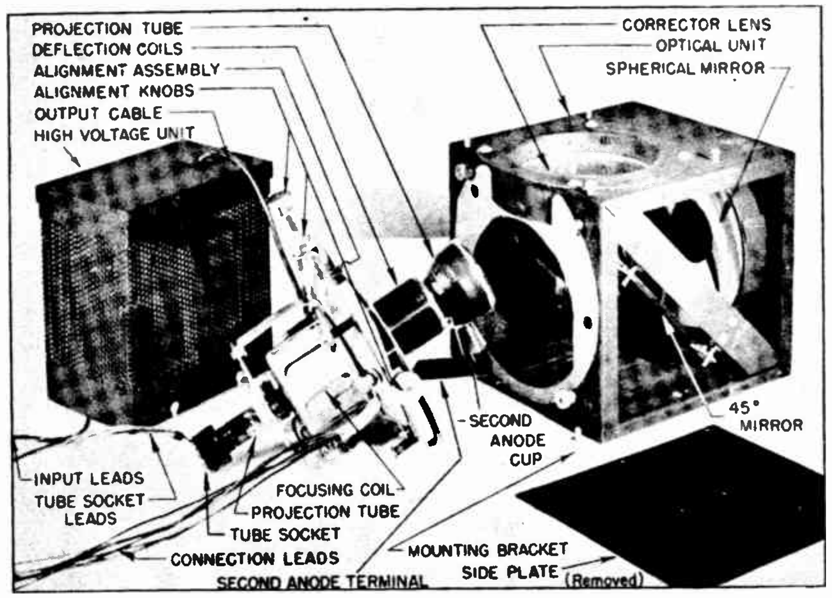
World Radio History

SERVICE NOTES FOR PROJECTION SYSTEM



CAUTIONS

HIGH VOLTAGES are used in the operation of this receiver. The back cover, while in place, prevents accidental contact with this voltage and therefore should not be opened by anyone except a qualified television serviceman.

THE HIGH VOLTAGE LEAD, which supplies approximately 25,000 volts to the picture tube, should be momentarily shorted to the chassis whenever it is disconnected for service purposes. This discharges the high voltage filter condenser and prevents a shock hazard when working on the receiver after it has been turned off.

THE PICTURE TUBE is highly evacuated and if broken, glass fragments will be violently expelled. Scratching, chipping, undue pressure, or careless handling such as lifting the tube by its neck is dangerous and should be avoided. If it is necessary to handle the picture tube, use safety goggles and heavy gloves.

Do not operate the picture tube outside the protective Optical Box. Prolonged exposure to the very soft X-ray radiation from this tube may prove harmful.

The plate lead of the 6BG6G tube in the High Voltage power supply must be dressed to clear all objects by ¼" to prevent corona discharge. When replacing the cover on this unit, the high voltage lead must go directly up through the cover and not cross over inside the box. Severe arcing may result if the cover is reversed.

Extreme care should be exercised in handling the reflecting mirror. Organic matter deposited on the front surface of this mirror by handling may cause permanent stains.

The Tailpiece Assembly should not be handled by grasping the Deflection Yoke. Undue strain on this yoke may cause breakage or distortion which cannot be compensated for through normal adjustments.

SERVICING THE OPTICAL BOX

The Optical Box contains a concave mirror, a plane mirror mounted at a 45° angle and the aspherical corrector lens. Optical alignment of these elements requires a special fixture and such adjustment should not be undertaken in the field. In the event that adjustment of these elements is required, the Optical Box should be returned to Stewart-Warner Electric. Do not return the Tailpiece Assembly (containing Picture Tube, Focus Coil and Deflection Yoke) as those components are not needed when making this adjustment.

The Optical Box is a dust-proof unit and the mirrors should seldom require cleaning. In cases where dust or grease conditions are unusually severe, a deposit on the optical surfaces may cause decreased picture brightness. Under those circumstances, cleaning of the optical surfaces should be undertaken as follows:

1. Remove Tailpiece Assembly from Optical Box as indicated in section entitled "REPLACEMENT OF 3NP4 PICTURE TUBE" on page 5.
2. Untie the light and dust shroud from around the studs on top of the Optical Box.
3. The Optical Box can now be removed from the cabinet by releasing the three locking screws which fasten it to the bottom.
4. The two sides of the box may now be removed by taking out the screws around the edges. This will expose all optical surfaces for cleaning. Do not touch the mirrors as they are front surface mirrors and organic deposits from the fingers will cause permanent stains.
5. Remove all dust from the optical surfaces with a camel's hair brush and then polish with lens tissue. Where dust deposit or discoloration is excessive, use a commercial spray such as "Windex."

The top surface of the corrector lens is covered with a glass plate and accordingly may be cleaned with a soft cloth without scratching.

Replacement of the Focus Coil or Deflection Yoke entails partial disassembly of the Tailpiece and this should be done in accordance with the applicable instructions. Care should be exercised in undertaking this disassembly and particular attention should be given to correct placement of parts during re-assembly. The exploded view of the Tailpiece Assembly (see Fig. 2) will be of valuable assistance in both dismantling and re-assembly.

REPLACEMENT OF FOCUS COIL ASSEMBLY

1. Remove 3NP4 picture tube from Tailpiece Assembly as indicated on Page 5.
2. Remove triangular Tube Clamp Plate (518 in Fig. 2).
3. Unsolder red and black-white wires from deflection yoke and focus coil plug. Loosen cable clamp and withdraw these wires which lead to focus coil.
4. Remove two centering screws "G" (See Fig. 1).
5. Remove "C" washer on spring-loaded stud at flange of Focus Coil. (Exercise care in doing this since spring is still under tension.) A similar "C" washer, located on the plain stud on opposite side of Focus Coil, must also be removed. The Coil may now be lifted free from the Tailpiece Assembly.
6. Place new Focus Coil Assembly on studs and replace spring and washers removed in Step 5.
7. Replace centering screws "G", thread Focus Coil wires through cable clamp and tighten clamp. Resolder wires into correct pins on cable plug (see circuit diagram Page 19,20). Replace triangular Tube Clamp Plate on end of Tailpiece Assembly.
8. Replace Picture Tube and Tailpiece Assembly as indicated on Page 5.
9. Re-focus, re-center and straighten raster as indicated on Pages 3 and 4.

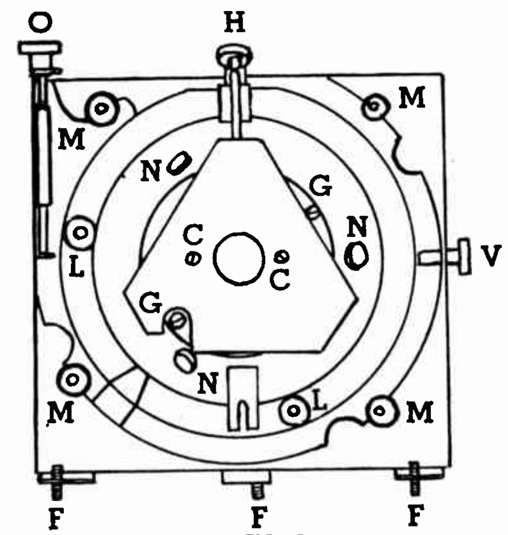


FIG. 1
OPTICAL ADJUSTMENT CONTROLS

REPLACEMENT OF DEFLECTION YOKE

1. Remove Focus Coil as indicated above.
2. Remove rubber ring around Deflection Yoke (diagram #500 in Fig. 2) by merely pulling it forward.
3. Note the exact mounting position of the Deflection Yoke with respect to the mounting plate. This is very important because the replacement yoke must be installed in the same position.
4. Remove three thumbscrews "N" and completely unscrew thumbscrew "H" (see Fig. 1). The Deflection Yoke and mounting plate can now be removed for convenient servicing.
5. Remove the screw which grounds the Deflection Yoke shield lug to the mounting plate.
6. The Deflection Yoke can now be released from the mounting plate by removing the four screws which hold it in position. Before removing the yoke, again check its position with respect to the mounting plate. Unsolder all cable wires from yoke connection lugs. It is not necessary to remove the two 560 ohm resistors since the replacement yoke is supplied with those components.
7. Resolder the cable leads to the correct lugs on the new Deflection Yoke. For correct connection of all wires, see the circuit diagram on page 19,20.
8. Place the Deflection Yoke Insulator (521 in Fig. 2) in position on the mounting plate and then properly locate the yoke in the same relative position as the original one. Be sure that the extrusions on the back side of the yoke fit into the holes in the mounting plate. The yoke should now be secured in position by the four mounting screws.
9. Properly dress the cable leads and then replace the screw which connects the yoke shield lug to the mounting plate.
10. Re-insert this assembly into the front section of the Tailpiece and engage thumbscrew "H" in the threaded hole in bracket. Replace three thumbscrews "N" (see Fig. 1).
11. The Focus Coil should now be replaced as indicated in the previous section entitled "REPLACEMENT OF FOCUS COIL ASSEMBLY."
12. Re-focus, re-center and straighten raster as indicated on pages 3 and 4.

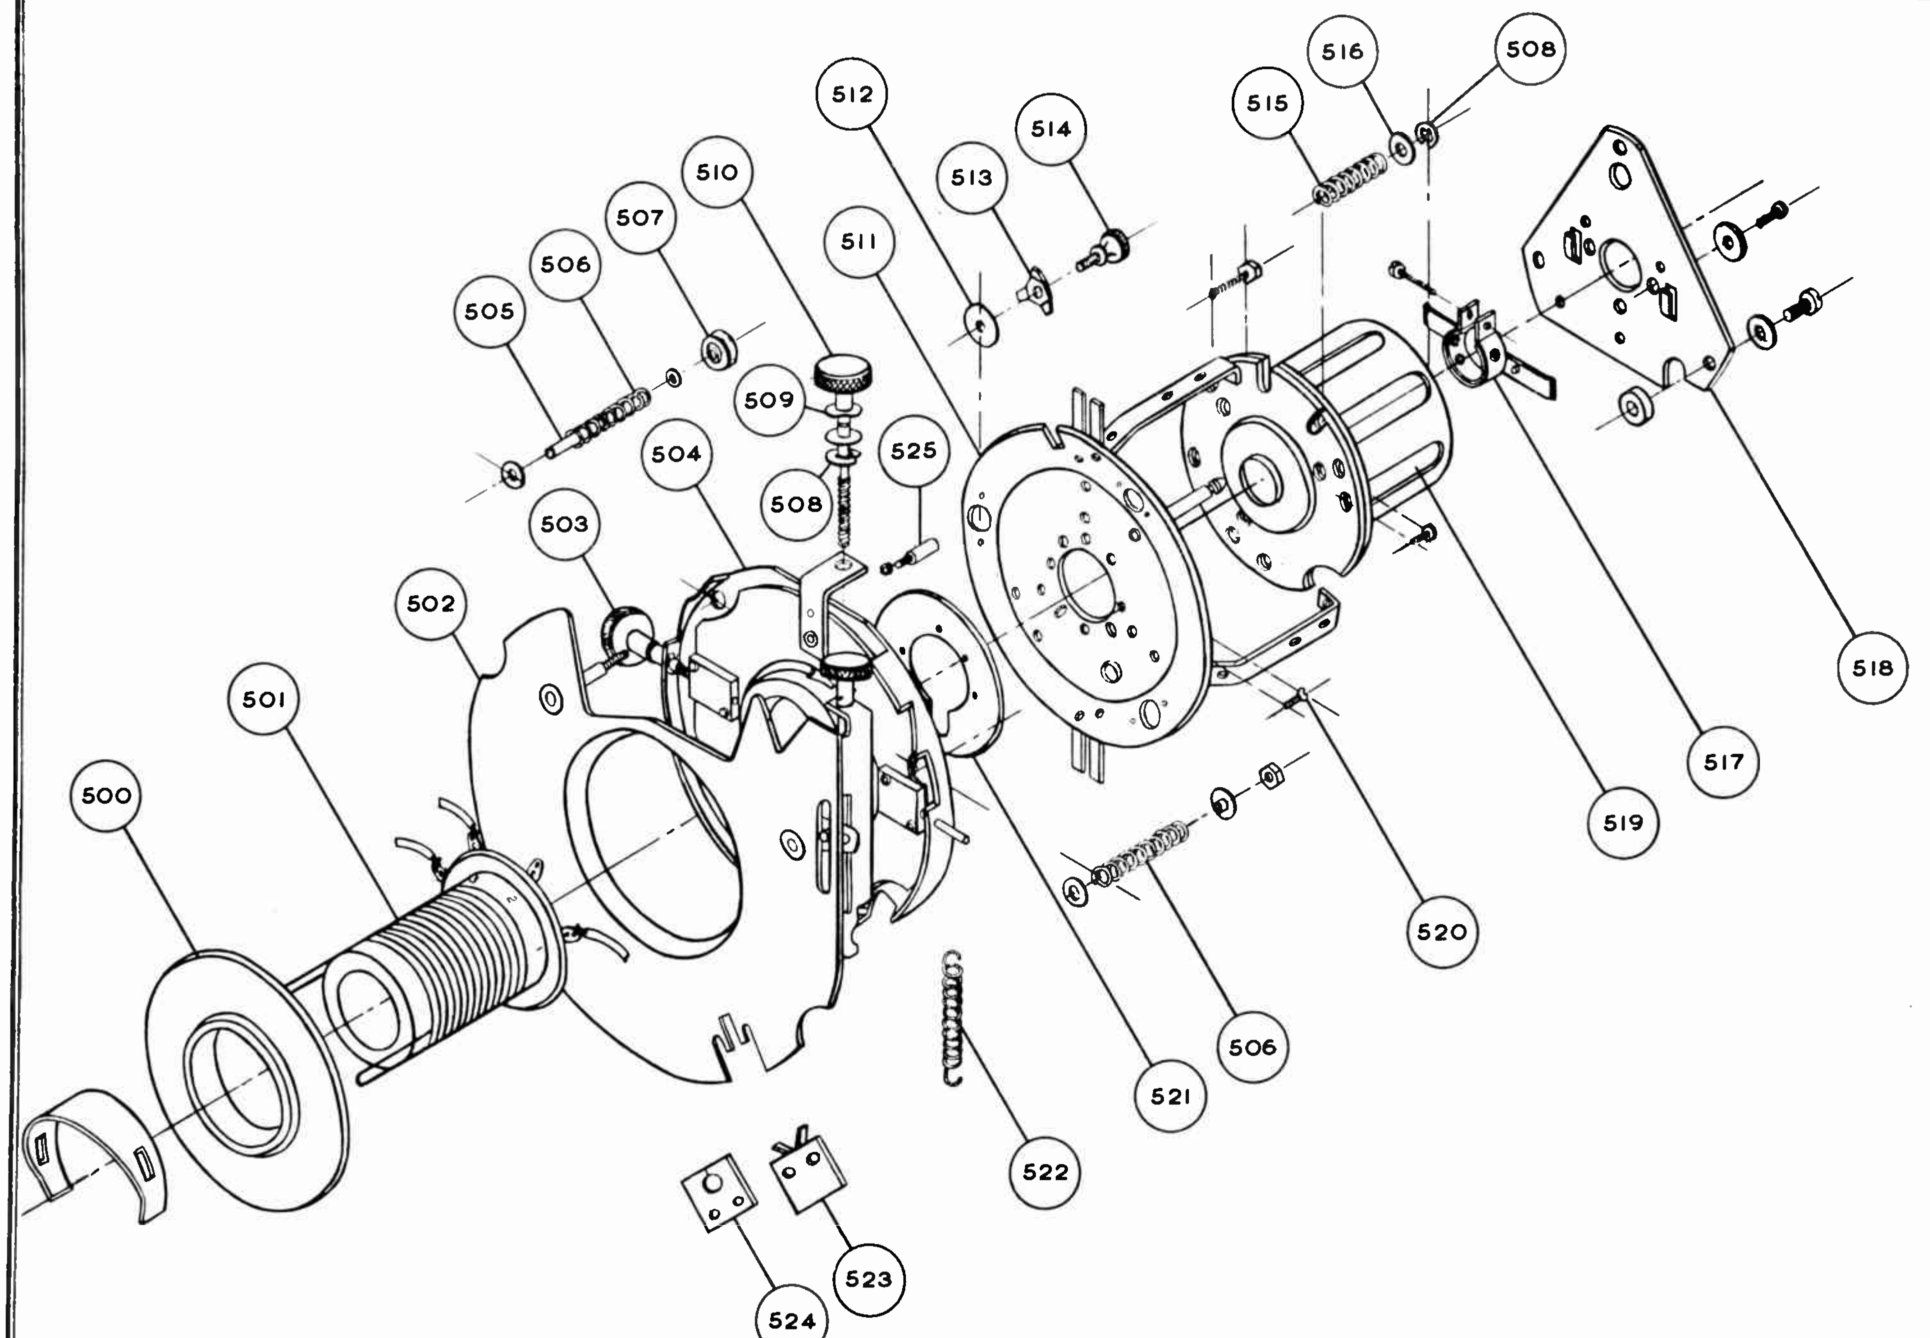

FIG. 2
EXPLODED VIEW OF TAILPIECE ASSEMBLY

REMOVAL AND RE-INSTALLING OF CHASSIS

In the event that complete overhaul service is required on this receiver, it is not necessary to remove the entire cabinet to the service shop. Each chassis can be removed independently and a final performance check of the receiver can be made by projecting the picture onto a flat white surface which is parallel to the plane surface of the corrector lens. This can be done by placing the Optical Box on its side with the top surface of the corrector lens 32 inches from the temporary projection surface. The "throw distance" of 32 inches is the projected picture distance when the Optical Box is properly installed in the cabinet.

If it can be determined that a particular receiver fault is in no way related directly to the High Voltage Power Supply, Deflection Yoke or Focus Coil, Picture Tube, Protector Tube or Auxiliary Power Supply, it will only be necessary to remove the TV chassis from the receiver for servicing. All stages on this chassis, with the exception of the 6SN7 Protector Tube (V21) and 6W4 Horizontal Damping Tube (V22), will be functioning and normal trouble shooting techniques can be applied. At such time as service is required on this receiver, careful analysis of the fault may eliminate unnecessary chassis removal.

TV CHASSIS (REMOVAL) — To remove TV chassis, disconnect auxiliary power supply cable, deflection yoke and focus cable, phone motor cable, speaker leads, AM loop antenna leads, phono pick-up plug, picture tube grid lead, picture tube socket and built-in TV antenna leads which are connected to TV antenna terminal strip. Unclip indicator lamp socket from bracket at base of cabinet. Also unscrew external FM antenna clip and external TV antenna terminal strip from cabinet frame. Remove back of shielded compartment on TV chassis by taking out 5 screws on rear surface.

All control knobs on front panel of receiver must be pulled off and the TV chassis can then be released by removing the four hold-down screws. Two of these screws are accessible from inside the record storage compartment and the other two are accessible from the rear. Before removing the chassis, be sure that all leads have been dressed so that they can be freely withdrawn from the cabinet with the chassis.

TV CHASSIS (RE-INSTALLATION) — When re-installing the chassis in the cabinet be sure that all leads and cables are properly routed. Special attention must be given to the picture tube grid lead which is to be routed independent of the picture tube cable. Failure to observe this precaution will result in deterioration of picture quality. Note that this lead is routed through the center partition wall and then to the picture tube socket.

Also be sure that the braided ground strap, connecting TV chassis to other units, is securely connected at each chassis.

AM-FM TUNER CHASSIS — Do not attempt to service this tuner assembly by using a separate power supply after removing it from the TV chassis. That would affect the tuned R.F. circuits and give incorrect results. If service is required on the AM-FM tuner, it should remain connected to the TV chassis for its power supply. Back cover plate of tuner may be removed to expose underside of tuner chassis. Where necessary, the AM loop antenna can be unscrewed from the center partition wall of the cabinet.

OPERATION OF PROTECTOR TUBE CIRCUIT

The acceleration of the electron beam in the picture tube is so great in this type of projection system that even a momentary failure of one or both of the sweep circuits will cause a burned spot to appear on the tube face. Consequently, a form of protection against such an occurrence has been devised through the use of the 6SN7GT Protector Tube V21. Referring to the circuit on page 1950-45, it will be noted that the plates of this dual triode tube are fed from the B+ developed in the Auxiliary Power Supply. The reason for this is to maintain the Protector Tube operative in the event of interruption of the TV chassis B+ system, as such interruption could cause failure of the sweep circuits. Since the Deflection Yoke can be disconnected from the sweep output, the picture tube face could be burned in the event that the receiver was inadvertently turned on with the deflection cable disconnected. To prevent this, the A.C. input to the Auxiliary Power Supply is also opened when the deflection yoke plug is disconnected. This interrupts the B+ to the High Voltage power supply and with no high voltage on the picture tube, the face cannot be burned.

Action of the 6SN7GT Protector Tube V21 is dependent upon positive sync pulses from both the horizontal and vertical sweep systems being fed to the grids of this tube. The positive horizontal sync pulse is taken from terminal 6 of the horizontal output transformer and fed through condenser 429 to grid pin 1 of the 6SN7GT (see circuit diagram page 19,20). These large positive pulses cause grid current to flow and the developed grid leak bias is sufficient to practically drive the triode to cut-off. This same action occurs on the other triode section which is fed by vertical sync pulses. In the absence of one or both of these pulses, the associated triode will pass a comparatively large current which causes the cathode voltage to become more positive. This positive voltage is fed to the cathode of the picture tube and biases it to cut-off so that the electron beam cannot burn the tube face.

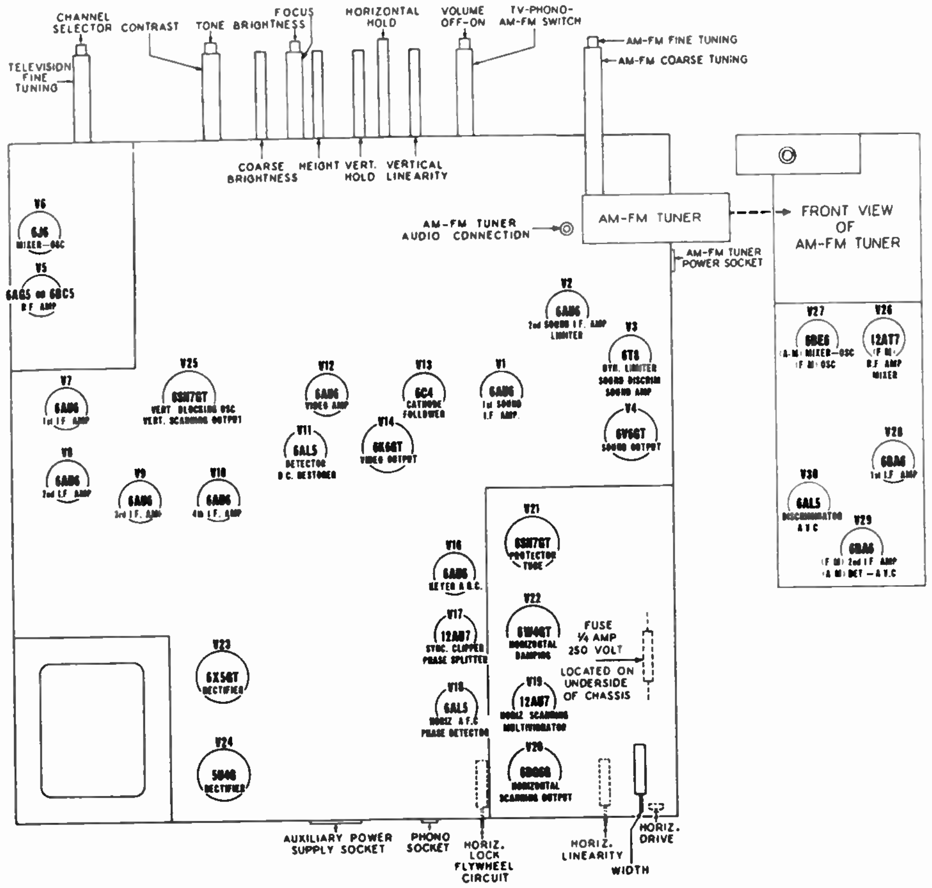
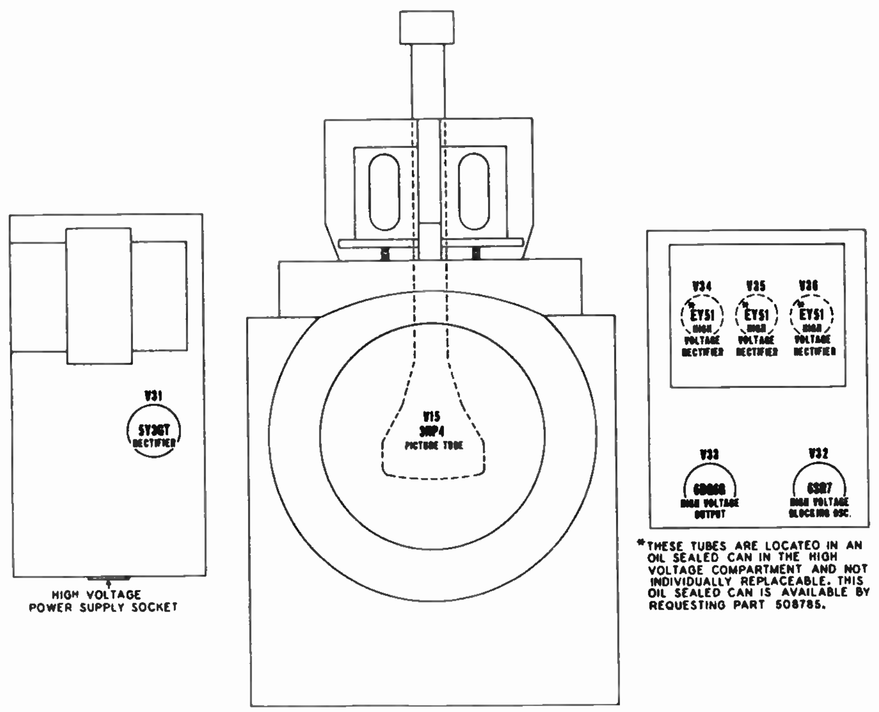
World Radio History



REAR OF RECEIVER CHASSIS



REAR OF PROJECTION SYSTEM CHASSIS

CAUTION

THE PICTURE TUBE is highly evacuated and if broken, glass fragments will be violently expelled. Scratching, chipping, undue pressure, or careless handling such as lifting the tube by its neck is dangerous and should be avoided. If it is necessary to handle the picture tube, use safety goggles and heavy gloves.

HIGH VOLTAGE (approximately 24,000) is produced in a supply circuit of this receiver. Exercise care to avoid contact with elements of this circuit and particularly the tube terminals which are labeled "CAUTION" in the adjoining voltage chart. If measurement of voltage at these points is necessary, see procedure given below under note "S".

THE HIGH VOLTAGE LEAD, which supplies approximately 24,000 volts to the picture tube, should be momentarily shorted to the chassis whenever it is disconnected for service purposes. This discharges the high voltage filter condensers and prevents a shock hazard when working on the receiver after it has been turned off.

INTERMEDIATE B+ VOLTAGES are dangerous and caution should be observed when the receiver chassis components are exposed for service purposes.

THE VOLTAGES SHOWN IN THE ADJOINING CHART WERE MEASURED UNDER THE FOLLOWING CONDITIONS

1.	Power Supply—117 volts 60 cycle AC.
2.	All voltages are measured between socket terminals and chassis unless otherwise indicated on adjoining chart.
3.	* Measurements made with voltmeter having sensitivity of 1000 ohms per volt except where indicated by (*). The (*) symbol designates a vacuum tube voltmeter measurement.
4.	Band Switch set to "TV" position unless otherwise indicated by the letters "X", "Y", or "Z" following voltages shown in adjoining chart.
5.	Antenna connected for reception of a television broadcast.
6.	Channel Selector and Fine Tuning Controls set for correct reception of a local station.
7.	All other controls set for "normal" reception of the transmitted signal unless the voltage shown on the chart is followed by letters indicating a special condition of measurement as outlined in step 8.
8.	Certain voltages were measured with two different settings of specific controls. It should therefore be understood that in these instances all controls, with the exception of one or two, were set for "normal" reception—letters following the voltage shown on the chart indicate the exceptions and are explained below.

EXPLANATION OF NOTES

A.	Vert. Hold max. counter-clockwise
B.	Brightness max. counter-clockwise (also set "Coarse" Brightness control fully clockwise).
C.	Contrast max. clockwise
D.	Horiz. Drive max. clockwise
E.	Horiz. Hold max. clockwise
F.	Focus Control max. clockwise
G.	Width max. counter-clockwise
H.	Height max. clockwise
J.	Horiz. Hold set for normal picture
K.	Horiz. Lock set for normal picture
L.	Channel Selector set to channel #9
M.	Vertical Linearity max. counter-clockwise
N.	Channel Selector set to channel #5
P.	This measurement should NOT be made with a conventional type voltmeter as circuit may break into oscillation due to coupling thru instrument leads; use a vacuum tube voltmeter with short leads.
Q.	This voltage measured with TV antenna terminals grounded.
R.	Do not attempt to measure the voltage at the tube cap. There is a high R. F. potential at this point.
S.	Exercise extreme care when undertaking measurement of this voltage. Use a voltmeter designed for measurement in the 25,000 volt range and be sure that the leads and probes are well insulated.
T.	Grounding of center stud on tube socket is necessary to reduce capacity coupling between other pins. Oscillation may result if this ground is omitted.
U.	This voltage will vary from +5.5 to —3.5 depending upon setting of Horizontal Hold Control and Horizontal Lock Control.
V.	This voltage measured with antenna disconnected and no signal input to receiver.
W.	This voltage will vary from —3.5 to —8.5 depending upon setting of Horizontal Hold Control and Horizontal Lock Control.
X.	Band Switch set to "AM" position, dial tuned to 540 Kc. and AM loop antenna leads grounded.
Y.	Band Switch set to "FM" position, dial turned to 88 Mc. and FM antenna terminal grounded.
Z.	Band Switch set to "PHO" position.

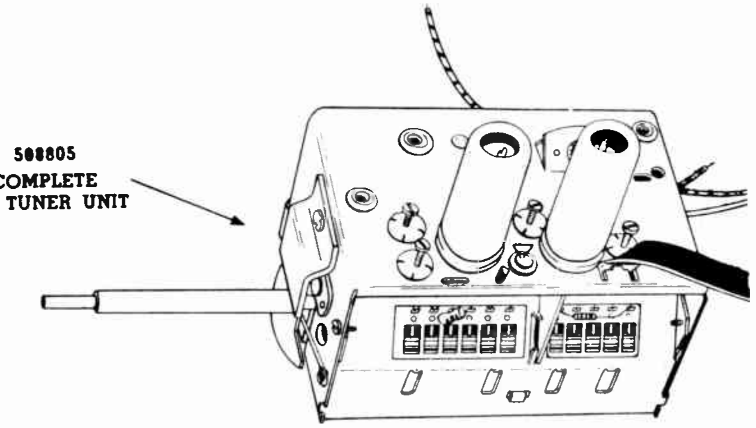
REPAIR DATA FOR 508805 RF TUNER UNIT

All replacement parts for the RF Tuner Unit are included in the complete receiver parts list.

This RF Tuner Unit consists of an RF amplifier stage (using 6AG5, 6BC5, or 6CB6 tube) and a mixer-oscillator stage (using 6J6 tube). Channel selection is accomplished by rotation of a turret assembly having 2 sets of snap-in coils for each of the 12 channels. The tuner also incorporates a Fine Tuning control.

Antenna Coils for each channel consist of a center-tapped primary and an RF amp. grid winding (secondary). The individual RF-Oscillator Coils include an RF amplifier plate section, a mixer grid section and an oscillator winding. Signal output from the mixer stage is coupled to the IF amplifiers through the input IF coil located on the tuner unit.

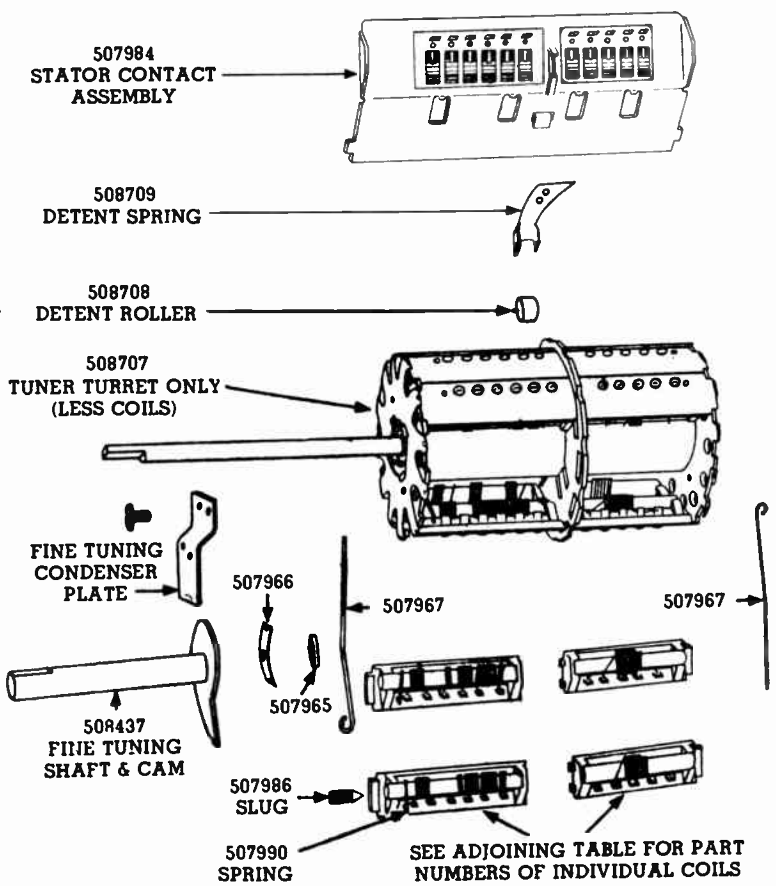


SERVICE PRECAUTIONS

SUBJECT	PRECAUTIONS
ELECTRICAL COMPONENTS	The high frequencies used in the RF section of a television receiver make it necessary that considerable care be exercised in servicing the tuner. Lead dress and location of components are very critical at these frequencies. When replacing parts, it is important to use components of identical electrical characteristics and physical size. Always reconnect the replacement item in the same location and position in the tuner as the original component.
TUBES	Replacement of tubes in the Tuner Unit may cause slight detuning of RF circuits due to inherent differences in inter-electrode capacitances. When replacing tubes (especially V6, 6J6 mixer-oscillator tube) make sure that Fine Tuning control will tune in television stations at approximately the middle of its range. It may be necessary to change the setting of the individual oscillator coil slugs for some channels to accomplish this.
CHANNEL COILS AND SLUGS	Channel Coils must be handled with care. Do not disturb coil windings. If an oscillator slug "falls into" its coil form during adjustment, remove the Channel Coil from the turret assembly and lift the Slug Retaining Spring aside. By tapping the coil form it should be possible to make the slug move toward the end so that its threads will be engaged by the Slug Retaining Spring when that spring is returned to its normal position.
FINE TUNING CONTROL	Rubbing of the bakelite Fine Tuning Cam against the Fine Tuning Condenser Plate is intentional in order to avoid vibration with resulting microphonics. However, the Fine Tuning Cam should not rub or contact the small circular plate located on the body of the tuner.

REMOVAL AND REPLACEMENT OF PARTS

ITEM	PROCEDURE
RF TUNER UNIT	To remove the Tuner Unit from receiver chassis, proceed as follows: 1. Remove metal plate which covers side of RF Tuner Unit nearest edge of chassis. This plate is held in place by two screws at side of chassis. 2. Remove channel selector dial lamp socket. 3. Remove support bracket which positions front of Tuner Unit and also remove screws which hold tuner to rear support bracket. 4. Disconnect the leads from the tuner to the main chassis. See illustration on page 1950-45 (circuit diagram page) showing tuner connections. After the Tuner Unit is replaced, make sure that channel selector dial lamp socket is correctly positioned so that channel selector knob will be properly illuminated.
CHANNEL COILS	Insert a screwdriver blade between Coil Retainer Spring and the end of the Tuner Turret. Twist the blade to pull spring away from the molded body of Channel Coil. Lift this end of coil body upward and remove individual coil assembly from tuner. When replacing Channel Coils, be sure they are reinstalled in their correct positions. Coil numbers should increase consecutively in a counter-clockwise direction when tuner is viewed from the front. If all the Channel Coils have been removed from the Tuner Turret, rotate turret until flat surface on end of tuner shaft points down. Install #3 Channel Coils into bottom position on turret. Then follow the correct sequence indicated above to replace other coils.
TUNER TURRET ASSEMBLY	To remove turret from RF Tuner Unit, proceed as follows: 1. Remove tuner from receiver chassis. 2. Remove rear Turret Shaft Retaining Spring by disengaging straight end of spring from projection on tuner. 3. Remove Fine Tuning Condenser Plate from front of Tuner Unit. This plate forms one side of Fine Tuning control condenser and is held in place by one screw. 4. Slide Fine Tuning Cam and Brass Shaft off of main Channel Selector Shaft. 5. Remove Contactor Washer Spring and Fiber Spacer Washer from Channel Selector Shaft. 6. Remove Shaft Retaining Spring at front of tuner by disengaging straight end of spring from projection on case. 7. Remove turret assembly from case. To replace turret, reverse the above procedure. Tooth on bakelite Fine Tuning Cam should point downward during assembly so that it does not become locked between the stops on the Fine Tuning Condenser Plate.
STATOR CONTACT ASSEMBLY	To remove this assembly, proceed as follows: 1. Remove the two screws at the front and rear of the Stator Contact Assembly. 2. Unsolder all electrical connections to contact plate. 3. Unsolder five soldered joints between Stator Contact Assembly and Tuner Unit. 4. Contact Assembly may now be withdrawn from case. To reinstall this assembly: 1. Place Stator Contact Assembly in position and replace, but do not tighten, the two screws at the front and rear of the assembly. 2. Remove 3 consecutive pairs of Channel Coils from the turret (for example, the antenna and rf-osc. coils for channels #5, 6 and 7). 3. Position Tuner Turret so that the edges of the next highest Channel Coils (in this case, the coils for channel #8) just pass the row of 11 contacts on the Stator Contact Assembly. 4. Adjust position of the Stator Contact Assembly so that there are a few thousandths of an inch spacing between the contacts on the contact plate and the molded body of the Channel Coils. 5. The Contact Assembly is now correctly positioned and screws at front and rear may be tightened. 6. Solder Stator Contact Assembly to tuner frame at same points that were used previously. 7. Make all electrical connections to contact plate. 8. Replace Channel Coils.



CHANNEL NUMBER	ANTENNA COIL PART NUMBER	RF & OSC COIL PART NUMBER
2	507952	507972
3	507953	507973
4	507954	507974
5	507955	507975
6	507956	507976
7	507957	507977
8	507958	507978
9	507959	507979
10	507960	507980
11	507961	507981
12	507962	507982
13	507963	507983

World Radio History

ALIGNMENT PROCEDURE

Alignment of all RF and IF tuned circuits in this receiver may be accomplished by utilizing the procedures described in the following charts.

SEQUENCE OF ALIGNMENT: These procedures should preferably be applied in the order in which they are presented, however, alignment of RF or IF channels for either AM, FM or TV may be accomplished individually if desired.

The Television RF Amplifier and Mixer alignment may also be accomplished independent of the Television IF Channel alignment, but oscillator calibration can only be done after IF Channel has been correctly aligned. Proper IF band pass characteristic is necessary for oscillator alignment as results of circuit tuning are observed by means of an oscilloscope connected to the output of the video detector stage.

REMOVAL OF CHASSIS: The TV receiver chassis must be removed from the cabinet in order to accomplish alignment of all tuned circuits, as there are adjustment points located on the underside of the chassis and at the front of the AM-FM Tuner. Complete instrument alignment of the TV chassis can be accomplished without interconnection to any of the other units—do not remove other chassis unnecessarily.

To remove TV chassis, disconnect auxiliary power supply cable, deflection yoke and focus cable, phono motor cable, speaker leads, AM loop antenna leads, phono pick-up plug, picture tube grid lead, picture tube socket and built-in TV antenna leads which are connected to TV antenna terminal strip. Unclip indicator lamp socket from bracket at base of cabinet. Also unscrew external FM antenna clip and external TV antenna terminal strip from cabinet frame. Remove back of shielded compartment on TV chassis by taking out 5 screws on rear surface.

All control knobs on front panel of receiver must be pulled off and the TV chassis can then be released by removing the four hold-down screws. Two of these screws are accessible from inside the record storage compartment and the other two are accessible from the rear. Before removing the chassis, be sure that all leads have been dressed so that they can be freely withdrawn from the cabinet with the chassis.

INSTRUMENTS: The following instruments will be required as signal sources and output indicators during the alignment process. Since accurate alignment of a television receiver is heavily dependent upon the performance of your instruments, it is imperative that they meet the essential specifications described here.

1. **STANDARD SIGNAL GENERATOR** to provide signals at the following frequencies. Maximum output on all ranges should be at least .1 volt with provision for attenuation as desired. This instrument must have good frequency stability and be accurately calibrated. Generators which incorporate a separate crystal controlled oscillator and heterodyne circuit are self calibrating and therefore capable of providing the accuracy of frequency calibration required for television circuit alignment.

   A. IF Frequencies:

   455 Kc. (400 cycle amplitude modulated) for AM IF.
   4.5 Mc. (Unmodulated) for TV Sound.
   4.5 Mc. (400 cycle amplitude modulated) for TV Sound.
   10.7 Mc. (Unmodulated) for FM IF.
   22.25 Mc. (Unmodulated) marker for TV Sound IF carrier.
   22.4 Mc. (Unmodulated) for TV IF Trap.
   23.5 Mc. (Unmodulated) for TV 1st and 3rd IF
   24.75 Mc. (Unmodulated) for TV 4th IF (on chassis equipped with 508075 RF Tuner).
   25.0 Mc. (Unmodulated) for TV 4th IF (on chassis equipped with 508080 RF Tuner).
   26.1 Mc. (Unmodulated) for TV Converter and 2nd IF (on chassis equipped with 508080 RF Tuner).
   26.6 Mc. (Unmodulated) for TV Converter and 2nd IF (on chassis equipped with 508075 RF Tuner).
   26.75 Mc. (Unmodulated) marker for TV Picture IF carrier.

   B. RF Frequencies:

   550 to 1600 Kc. (400 cycle amplitude modulated) for AM RF.
   54 to 88 Mc. (Unmodulated) for TV RF.
   88 to 108 Mc. (400 cycle amplitude modulated) for FM RF.
   174 to 216 Mc. (Unmodulated) for TV RF.

2. **RF SWEEP GENERATOR** to provide frequency modulated signals at the following frequencies:

   10.7 Mc. with 300 Kc. sweep width.
   20 to 30 Mc. with 10 Mc. sweep width.
   54 to 88 Mc. with 10 Mc. sweep width.
   174 to 216 Mc. with 10 Mc. sweep width.

   Output adjustable with at least .1 volt maximum.

   Output should be "flat" (no amplitude variation) for all settings of the sweep width control.

   Provision for connection of generator sweep modulating voltage to horizontal deflection system of an oscilloscope.

   Provision for blanking the output signal on each return sweep so that oscillogram will not show retrace.

3. **CATHODE RAY OSCILLOSCOPE**, preferably a unit with vertical amplifier having wide range frequency response and low capacity pick-up probe.

4. **VACUUM TUBE VOLTMETER.** The lowest voltage range of this instrument should preferably permit a 1.0 volt reading to be indicated at not less than one third of full scale deflection.

5. **OUTPUT METER**, preferably a unit equipped with an impedance matching network that will present a 3.2 ohm load when connected to secondary of audio output transformer.

INSTRUMENT CONNECTIONS: The method of connection, including details of matching and coupling networks, for instruments used in this alignment procedure is given in several illustrations on subsequent pages. Specific instructions for each instrument application will also be found in various sections of the alignment charts.

IMPORTANT

AVOID EXCESSIVE INPUT SIGNAL WHEN USING OSCILLOSCOPE AS ALIGNMENT INDICATOR.

When observing the receiver band pass characteristic on an oscilloscope, it is exceedingly important to avoid distortion of that characteristic which would occur when using a large input signal from the sweep generator or standard generator (marker signal). Always set attenuator on sweep generator so that the reading on the vacuum tube voltmeter does not exceed one volt (when meter is connected from high side of video detector load resistor, symbol 139, to receiver chassis). Standard generator output should also be attenuated so that marker signal does not pull or tear the band pass characteristic as shown on the scope.

CHECKING SYNCHRONIZATION OF BAND SWITCHES ON AM-FM TUNER AND TV CHASSIS.

Note that the band switch on the AM-FM Tuner chassis is mechanically coupled (by a link arm and lever clamp arrangement) to the band switch on the TV chassis. Do not operate these switches by direct pressure on the link arm—always use a control knob attached to the TV switch shaft. If the mechanical linkage is forced or slips at the clamp on the TV switch shaft so that both switches get out of step, they can be re-synchronized as follows:

1. Loosen screw in actuating lever clamp on TV band switch shaft.
2. Turn both switches to extreme clockwise position and be sure that they detent properly at that position.
3. Retighten screw in actuating lever clamp on TV band switch shaft.

BROADCAST BAND—"AM"—ALIGNMENT PROCEDURE

1. After the entire chassis assembly has been removed from the cabinet, remove the AM loop antena and reconnect it to the AM antenna leads extending from the AM-FM tuner chassis. Then wind one turn of insulated wire around frame of loop antenna so as to provide a means of coupling it to the signal generator. Connect one end of coupling turn to receiver chassis and allow other end to remain open until otherwise instructed in the following chart. Space loop antenna same distance away from the chassis as when assembled in the cabinet.
2. Reconnect the speaker to the two audio output leads extending from the main chassis. **IMPORTANT:** Do not confuse these leads with the two loop antenna leads.
3. Replace **AM-FM Coarse and Fine Tuning knobs and rotate Fine Tuning knob to its extreme counter-clockwise position. At this setting, the gang condenser should be fully meshed and the heavy line next to 5.5 on the dial scale should be pointing straight up; if they are not, loosen the set screws in the hub of the dial drum on the gang condenser and close gang plates manually; also, position the dial scale correctly. Then tighten set screws in hub of dial drum.**
4. The Control Panel Escutcheon at the front of the cabinet normally provides a "position indicator" for the **AM-FM** dial scale, however, when the chassis is removed from the cabinet it becomes necessary to install a "temporary pointer." That can be readily accomplished by binding a piece of heavy wire around the planetary drive support brackets and shaping the free end of the wire so that it can be placed in a vertical position (pointing downward) between the dial knob and the lamp behind it (wire will then cast a shadow on the dial scale and show the frequency to which the receiver is tuned.

   With the gang condenser fully meshed, the "temporary pointer" should appear directly behind the heavy line preceding 5.5 on the dial scale.
5. **IMPORTANT:** Do not remove the metal bottom plate of AM-FM tuner chassis. Holes are provided for access to IF transformer tuning slugs. Removal of the bottom plate during alignment of the RF circuits will result in detuning when the plate is replaced.
6. Connect output meter across the speaker voice coil.
7. Connect ground lead of signal generator to the receiver chassis.
8. Set volume control to the maximum volume position and use a weak signal from the signal generator.
9. Set tone control to its extreme clockwise position.
10. Set band switch to the "AM" position.
11. After alignment procedure is completed and chassis and loop have been reinstalled in cabinet, arrange leads to loop so that they are separated from each other as much as possible avoid twisting, taping or extending these leads.

DUMMY ANT. IN SERIES WITH SIGNAL GENERATOR	CONNECT HIGH SIDE OF SIGNAL GENERATOR TO	SIGNAL GENERATOR FREQUENCY	RECEIVER DIAL SETTING	TRIMMER OR SLUG NUMBER	TRIMMER DESCRIPTION	TYPE OF ADJUSTMENT
.1 MFD. Condenser	Lug on trimmer #24 at bottom of gang (see figure 1 for location of trimmer).	455 KC	Any point where it does not affect the signal.	19 and 20	2nd I.F.	Adjust for maximum output. Then repeat adjustment.
				21 and 22	1st I.F.	
200 MMF. Mica Condenser	Coupling turn on loop antenna.	1500 KC	1500 KC	23	AM Oscillator. This trimmer is accessible thru small hole in bottom of TV chassis.	Adjust for maximum output.
		1500 KC	Tune to 1500 Kc. generator signal.	24	AM Antenna	Adjust for maximum output.
200 MMF. Mica Condenser	Coupling turn on loop antenna.	600 KC	Tune to 600 Kc. generator signal.	25	Adjustable core of AM Antenna Coil.	Adjust for maximum output.

Repeat adjustment of trimmers 24 and 25 until one no longer detunes the other.

FREQUENCY MODULATION—"FM"— ALIGNMENT PROCEDURE

1. After the entire chassis has been removed from the cabinet, replace AM-FM Coarse and Fine Tuning knobs and rotate Fine Tuning knob to its extreme counter-clockwise position. At this setting, the gang condenser should be fully meshed and the heavy line next to 88 on the dial scale should be pointing straight up; if they are not, loosen the set screws in the hub of the dial drum on the gang condenser and close gang plates manually; also, position the dial scale correctly. Then tighten set screws in hub of dial drum.
2. The Control Panel Escutcheon at the front of the cabinet normally provides a "position indicator" for the AM-FM dial scale, however, when the chassis is removed from the cabinet it becomes necessary to install a "temporary pointer." That can be readily accomplished by binding a piece of heavy wire around the planetary drive support brackets and shaping the free end of the wire so that it can be placed in a vertical position (pointing upward) between the dial knob and the lamp behind it (wire will then cast a shadow on the dial scale and show the frequency to which the receiver is tuned).

   With the gang condenser fully meshed, the "temporary pointer" should appear directly behind the heavy line next to 88 on the dial scale.

3. Reconnect the speaker to the two audio output leads extending from the main chassis. **IMPORTANT:** Do not confuse these leads with the two AM loop antenna leads.
4. Remove bottom plate from AM-FM tuner during IF alignment but replace it before starting alignment of RF circuits. **DO NOT REMOVE the AM-FM tuner chassis from the TV chassis during alignment.**
5. Set band switch to the "FM" position.
6. Set volume control to the maximum volume position and use a weak signal from the signal generator.
7. Set tone control to its extreme clockwise position.
8. Dress FM circuit leads as short and straight as possible, particularly those in the oscillator circuit. IF plate and grid leads should also be kept short and straight.

STANDARD SIGNAL GENERATOR		SWEEP GENERATOR		VTVM OR OUTPUT METER CONNECTION	OSCILLOSCOPE CONNECTIONS	RECEIVER DIAL SETTING	TRIMMER OR SLUG NUMBER	TYPE OF ADJUSTMENT AND OUTPUT INDICATION
CONNECTIONS	FREQUENCY	CONNECTIONS	FREQ.					
Connect high side to lug on trimmer #33 (see Fig. 1 for location of trimmer) using a .01 Mfd. condenser in series with generator lead. Connect ground lead to the receiver chassis in vicinity of gang condenser.	**10.7 MC.** Unmodulated	Not used.	—	Connect VTVM as shown in Fig. 3.	Not used.	Any position where it does not affect the signal.	#26 Discriminator secondary; #27 Discriminator primary; #28—29 2nd IF; #30—31 1st IF	Adjust these trimmers for maximum meter reading — the output voltage will be of negative polarity.
Same as above.	Same as above.	Not used.	—	Connect VTVM as shown in Fig. 4.	Not used.	Same as above.	#26 Discriminator secondary	Note that as slug #26 is rotated, a point will be found where the voltmeter will swing rather sharply from a positive to a negative reading or vice versa. The correct setting is obtained when the meter reads zero as the slug is moved thru this point.
Same as above.	Same as above. — Attenuate signal to prevent overload and distortion of response curve.	Connect high side to lug on trimmer #33 (see Fig. 1 for location of trimmer) using a .01 Mfd. condenser in series with generator lead. Connect ground lead to the receiver chassis in vicinity of gang condenser.	**10.7 MC** Sweeping ±300 Kc.	Not used.	Connect as shown in Fig. 4. — Set vertical amplifier of 'scope for maximum amplification. — Synchronize oscilloscope with sweep generator by connecting "horizontal input" terminals of 'scope to source of horizontal sweep modulating voltage on the sweep generator.	Same as above.	#26 Discriminator secondary	A pattern similar to that shown in Fig. 5 should appear on the oscilloscope screen. Check for symmetry about the 10.7 Mc. center point and linearity of the slope.  10.7 MC. FIG. 5 If the characteristic is not shaped properly, attempt to obtain symmetry by changing the setting of slug #26. Should that fail to produce the desired results, then a slight readjustment of slugs #27, 28, 29 30 and 31 should be undertaken.

IMPORTANT: Before starting alignment of the RF and Oscillator circuits, be sure to replace the bottom plate on the AM-FM Tuner chassis. Failure to observe this requirement would result in detuning if plate were replaced after alignment is completed.

Connect high side in series with a 270 ohm carbon resistor to FM antenna terminal near gang condenser (see Fig. 1) Connect ground lead to receiver chassis.	**108 MC.** with 400 cycle AM Modulation.	Not used.	—	Connect OUTPUT METER across speaker voice coil.	Not used.	108 Mc.	#32 FM Oscillator	Set trimmer #32 to receive 108 Mc. signal as indicated by maximum meter reading.
Same as above.	**106 MC.** with 400 cycle AM Modulation.	Not used.	—	Same as above.	Not used.	Tune to 106 Mc. generator signal.	#33 FM RF	Adjust trimmer for maximum meter reading.

Check calibration and tracking of receiver with input signals of 88, 90 and 106 MC. If difference between dial pointer setting and the above mentioned frequencies does not exceed ±0.3 MC. and RF circuit is tracking properly, then alignment may be considered satisfactory and no further adjustment is necessary.
Where the calibration error is greater than ±0.3 MC. it is advisable to make the following adjustments:
Tune receiver to an 88 MC. signal and note whether dial pointer is above or below correct calibration point. Then tune receiver so that dial pointer is at the 88 MC. position. If generator signal was previously received at a setting above 88 MC., it will be necessary to slightly spread the windings of the FM oscillator coil (#34 in Fig. 2) so that signal will now be received at the correct dial setting. On the other hand, if generator signal was received at a dial setting below 88 MC., then slightly compress the windings of the oscillator coil until the signal comes in at the correct calibration point.
Check calibration at 108 MC. and if it is in error by more than ±0.3 MC., readjust setting of trimmer #32. Repeat calibration adjustment at 88 and 108 MC. until desired accuracy is obtained.
Observe dial calibration at 106 MC. If it is found to be incorrect by an appreciable amount, then make a very slight adjustment in the spacing of the gang condenser plates to receive the 106 MC. signal at the correct dial setting. Then check adjustment of RF trimmer #33 to obtain maximum output indication at 106 MC.

TELEVISION SOUND CHANNEL ALIGNMENT PROCEDURE

1. Short antenna terminals together with a jumper wire.
2. Turn the band switch to "TV" position and set receiver Channel Selector to any inactive television channel; other controls may be left at any desired setting.
3. No special aligning tool is required to adjust the cores in the Sound IF and discriminator transformers. The blade of a small screwdriver will fit the slot in these cores, however, the screwdriver should be of a non-metallic or insulated type to prevent detuning when inserted in the transformer can.

STANDARD SIGNAL GENERATOR CONNECTIONS	STANDARD SIGNAL GENERATOR FREQUENCY	VTVM CONNECTIONS	MISCELLANEOUS INSTRUCTIONS	TRIMMER OR SLUG	TYPE OF ADJUSTMENT AND OUTPUT INDICATION
Connect as shown in Fig. 7.	**4.5 MC.** unmodulated. **IMPORTANT** This signal must be accurate within ¼ of 1% of 4.5 Mc. Check generator calibration against a crystal controlled signal source by "zero beating" (heterodyning) with harmonics of the crystal frequency.	Connect as shown in Fig. 8.	**IMPORTANT** Unsolder lead connected to terminal "T" of Horizontal Linearity coil (see Fig. 6). This will make the horizontal sweep system of the receiver inoperative so that the sweep voltage will not be picked up by stray coupling to leads of instruments used during Sound Channel alignment. Such coupling would otherwise result in spurious oscillation.	**#1** TV Sound Discriminator Secondary	Adjust for maximum reading on VTVM.
				#2 TV Sound Discriminator Primary	Adjust for maximum reading on VTVM.
				#3 2nd TV Sound IF Secondary	Adjust for maximum reading on VTVM.
				#4 2nd TV Sound IF Primary	Adjust for maximum reading on VTVM.
				#5 1st TV Sound IF Secondary	Adjust for maximum reading on VTVM.
				#6 1st TV Sound IF Primary	Adjust for maximum reading on VTVM.
Same as above.	Same as above.	Connect as shown in Fig. 9.	Same as above.	**#1** TV Sound Discriminator Secondary	Note that as slug #1 is rotated, a point will be found where the voltmeter will swing rather sharply from a positive to a negative reading or vice versa. The correct setting of slug #1 is obtained when the meter reads zero as the slug is moved thru this point.

REDUCTION OF INTERCARRIER BUZZ

Slight "dynamic" unbalance of the discriminator secondary can emphasize intercarrier buzz due to incomplete amplitude modulation rejection. Therefore it is vitally important to obtain an accurate setting of the discriminator secondary slug in the presence of an amplitude modulated signal, as outlined below.

Same as above.	**4.5 MC.** 400 cycle amplitude modulated	Not used.	Same as above. Turn up Volume control until 400 cycle signal can be heard.	**#1** TV Sound Discriminator Secondary	Note that as slug #1 is rotated, a point will be found where the sound volume changes rapidly from maximum to minimum and back to maximum again. The discriminator secondary slug is correctly positioned when this "dip" in volume is reached. Do not confuse the "dip" point with a gradual reduction in volume that occurs when the circuit is considerably detuned.

Resolder lead previously disconnected from terminal "T" of Horizontal Linearity coil (see Fig. 6).

Disconnect all instruments and then connect an antenna to the receiver to obtain program reception from a local station. If intercarrier buzz is still prominent, a slight readjustment of the discriminator secondary slug (#1) should be made to obtain the "dip" point for the buzzing sound. Note that program sound will be clear and free from distortion at this point. Buzz should now be at an acceptable minimum if station transmission is not at fault.

TELEVISION IF CHANNEL ALIGNMENT PROCEDURE

1. A special aligning tool designed to fit the stems on adjustable cores of the IF coils (see points 8, 9, 10 and 11 in Fig. 19) is available and may be obtained from Stewart-Warner by requesting IF Alignment Tool #507479.
2. Turn receiver Channel Selector to television channel #12 and short antenna terminals together with a jumper wire.
3. Turn the band switch to the "TV" position.
4. Remove metal plate which covers side of RF tuner unit nearest edge of chassis. This plate is held in place by two screws on the side of the chassis.
5. Connect a 1½ volt battery to the receiver AGC system so that negative terminal of battery connects to the AGC line and positive terminal of battery connects to receiver chassis. See Fig. 20 for convenient point of connection.
6. Note location of IF Trap Coil #12 by referring to Fig. 20. Before undertaking the alignment of any of the IF stages, Trap Coil #12 must be detuned so that it does not resonate in the IF pass band. Detuning is accomplished by merely compressing the windings so that they are closely spaced. Failure to detune the Trap Coil can cause the IF system to become regenerative thereby preventing alignment.
7. If the IF channel is badly misaligned and two or more immediately adjoining IF stages are tuned to the same frequency, oscillation may occur. Such oscillation shows up as a voltage across the video detector load resistor, symbol 139, and is indicated by the VTVM that is connected to this point during alignment. It should be noted that voltage due to IF oscillation is unaffected by strength of signal from the generator.

Where IF oscillation is encountered, it is generally possible to correct the condition by detuning the IF coils in different directions. If that does not have the desired effect, increase fixed bias on AGC line by using a 3 or 4½ volt battery instead of the 1½ volt battery referred to in instruction #5. After stopping the oscillation in this manner it will then be possible to align all IF stages using the following procedure, however, the AGC bias battery must be changed back to 1½ volts when using the oscilloscope to observe band pass characteristic. Once all stages have been aligned using the 3 to 4½ volt bias, the IF channel should be stable with reduced bias.

STANDARD SIGNAL GENERATOR		SWEEP GENERATOR		VTVM CONNECTIONS	OSCILLOSCOPE CONNECTIONS	MISCELLANEOUS INSTRUCTIONS	TRIMMER OR SLUG	TYPE OF ADJUSTMENT AND OUTPUT INDICATION
CONNECTIONS	FREQUENCY	CONNECTIONS	FREQ.					
Connect as shown in Fig. 10.	26.1 MC.	Use a 330 Mmf. isolating condenser and connect as shown in Fig. 10 but keep power switch turned off during this step.	—	Connect as shown in Fig. 11	Not used.	—	#7 Converter plate coil	Adjust for maximum reading on VTVM.
							#8 2nd I.F.	Adjust for maximum reading on VTVM.
Same as above.	25.0 MC.	Same as above.	—	Same as above.	Not used.	—	#9 4th I.F.	Adjust for maximum reading on VTVM.
Same as above.	23.5 MC.	Same as above.	—	Same as above.	Not used.	—	#10 1st I.F.	Adjust for maximum reading on VTVM.
							#11 3rd I.F.	Adjust for maximum reading on VTVM.
Same as above.	22.4 MC.	Same as above.	—	Same as above.	Not used.	—	#12 IF Trap Coil.	Adjust the spacing of the Trap Coil windings for MINIMUM reading on VTVM.
Same as above.	26.75 MC.	With connections made as shown in Fig. 10 turn on this generator and set controls for operation as specified in next column.	25 MC. Sweeping ± 5 Mc.	Same as above.	Connect as shown in Fig. 11	IMPORTANT: 1. Adjust output attenuator on sweep generator so that reading on VTVM is one volt. 2. Set attenuator on standard signal generator so that marker signal does not distort the pattern on the oscilloscope. 3. Be sure that a 1½ volt battery is connected to AGC line as specified in instruction #5 at the head of this chart. Do not use a battery of any other voltage.	The IF band pass characteristic now displayed on the 'scope should be compared with the curve shown in Fig. 12. If top of curve is not properly shaped, make a slight readjustment of slug #9. Should that adjustment fail to yield the desired result, then note whether the curve has a peak on the high or low frequency side. Slugs #7 and #8 control high frequency response (26.1 Mc.) and slugs #10 and #11 affect the low frequency response (23.5 Mc.); by making a small change in the settings of the high or low frequency slugs, it will be possible to obtain correct band pass curve.  FIG. 12 IF RESPONSE CURVE. The 26.75 Mc. picture IF carrier marker should now appear at the 35% amplitude position on side of the band pass characteristic (see Fig. 12). If position of the marker appears too high or too low, slight readjustment of slugs #7, 8 and 9 is required.	
Same as above.	22.25 MC.	Same as above.	Same as above.	Same as above.	Same as above.	Same as above.	The 22.25 Mc. sound IF carrier marker should appear at the position indicated in Fig. 12 If the position of the sound marker is incorrect, readjust winding spacing of Trap Coil #12.	

TELEVISION RF CHANNEL ALIGNMENT PROCEDURE

1. Turn the band switch to the "TV" position.
2. Replace metal plate which covers exposed terminal side of RF tuner unit. This plate was previously removed for IF channel alignment.
3. Connect a 1½ volt battery to the receiver AGC system so that the negative terminal of battery connects to AGC line and positive terminal of battery connects to receiver chassis. (See Fig. 20 for convenient point of connection.)

STANDARD SIGNAL GENERATOR		SWEEP GENERATOR		VTVM CONNECTIONS	OSCILLOSCOPE CONNECTIONS	MISCELLANEOUS INSTRUCTIONS	TRIMMER OR SLUG	TYPE OF ADJUSTMENT AND OUTPUT INDICATION
CONNECTIONS	FREQUENCY	CONNECTIONS	FREQ.					
RF AMPLIFIER AND MIXER ALIGNMENT								
Connect as shown in Fig. 16.	*209.75 MC. ‡205.25 MC.	Connect as shown in Fig. 16 and set controls for sweep width of 10 Mc. on television channel specified in the next column.	CHANNEL #12	Not used.	Connect as shown in Fig. 17	IMPORTANT: Keep output of standard signal generator at a level that provides a readable marker but does not distort the curve that is being observed on the 'scope.	#13 Mixer Grid.	Adjust these trimmers to obtain properly shaped RF band pass characteristic as shown in Fig. 13. Use Mixer Grid trimmer #13 and RF Amplifier Plate trimmer #14 to obtain correct amplitude of characteristic in vicinity of picture and sound carrier markers. Then adjust RF Amp. Grid trimmer #15 to equalize overall amplitude. Repeat adjustment of trimmers to be sure correct response has been obtained.
							#14 RF Amp. Plate.	
							#15 RF Amp. Grid.	IMPORTANT: When adjusting trimmers #13, 14 and 15 it will be noted that the band pass characteristic can be broadened by sacrificing amplitude. It is undesirable to overly broaden the curve as that would result in a loss of sensitivity.
Same as above.	*215.75 MC. ‡211.25 MC.	Same as above.	CHANNEL #13	Not used.	Same as above.	Set Channel Selector to #13	The RF band pass characteristic of the other television channels should now be checked without disturbing the settings of trimmers #13, 14 and 15. Adjust the RF sweep generator and marker generator for operation on the other television channels, observing position of both the sound carrier and picture carrier markers.	
	*203.75 MC. ‡199.25 MC.		CHANNEL #11			Set Channel Selector to #11		
	*197.75 MC. ‡193.25 MC.		CHANNEL #10			Set Channel Selector to #10		
	*191.75 MC. ‡187.25 MC.		CHANNEL #9			Set Channel Selector to #9		
	*185.75 MC. ‡181.25 MC.		CHANNEL #8			Set Channel Selector to #8	 FIG. 13	
	*179.75 MC. ‡175.25 MC.		CHANNEL #7			Set Channel Selector to #7		
	* 87.75 MC. ‡ 83.25 MC.		CHANNEL #6			Set Channel Selector to #6		
	* 81.75 MC. ‡ 77.25 MC.		CHANNEL #5			Set Channel Selector to #5	Band pass characteristic of these channels should conform to the RF response curve in Fig. 13. If necessary, a compromise may be obtained to compensate for small variations in channel response by returning to channel #12 and making slight changes in the settings of trimmers #13, 14 and 15.	
	* 71.75 MC. ‡ 67.25 MC.		CHANNEL #4			Set Channel Selector to #4		
	* 65.75 MC. ‡ 61.25 MC.		CHANNEL #3			Set Channel Selector to #3		
	* 59.75 MC. ‡ 55.25 MC.		CHANNEL #2			Set Channel Selector to #2

CONNECTIONS	FREQUENCY	CONNECTIONS	FREQ.					

OSCILLATOR ALIGNMENT

1. **IMPORTANT:** Before undertaking oscillator alignment be sure IF circuits are correctly aligned for band pass characteristic illustrated in Fig. 13.
2. During oscillator alignment, it is necessary to set the Fine Tuning control so that the tooth on the bakelite fine tuning cam points down (correct position for this control is shown in Fig. 14).

CONNECTIONS	FREQUENCY	CONNECTIONS	FREQ.	VTVM CONNECTIONS	OSCILLOSCOPE CONNECTIONS	MISCELLANEOUS INSTRUCTIONS	TRIMMER OR SLUG	TYPE OF ADJUSTMENT AND OUTPUT INDICATION
Connect as shown in Fig. 16	*209.75 MC. ‡205.25 MC.	Connect as shown in Fig. 16 and set controls for sweep width of 10 Mc. on television channel specified in the next column.	CHANNEL #12	Connect as shown in Fig. 18	Connect as shown in Fig. 18	Be sure that Fine Tuning control has been properly positioned (tooth on the cam pointing down—see Fig. 14). During this step and thru-out all succeeding steps it is necessary to: 1. Keep output of sweep generator at a level that does not allow reading on VTVM to exceed one volt. 2. Keep output of standard signal generator at a level that provides a readable marker but does not distort the curve that is being observed on the 'scope.	#16 Oscillator	Adjust height of Oscillator trimmer #16 to be approximately 3/8" from the top of trimmer screw to the top surface of RF tuner unit (see Fig. 14). NOTE: Before making the following adjustment, advance the vertical gain control on the 'scope in order to magnify the sound portion of the response curve. Then, use a non-metallic screwdriver to adjust channel #12 oscillator slug (accessible thru hole on front of RF Tuner Unit—see Fig. 14) and shift response curve so that sound carrier marker is located at the position indicated in Fig. 15. Now, reduce gain control of 'scope to restore pattern to normal amplitude and observe position of picture carrier marker. This marker should appear approximately halfway up the low frequency side of the characteristic (see Fig. 15).
Same as above.	*215.75 MC. ‡211.25 MC.	Same as above.	CHANNEL #13	Same as above.	Same as above.	Set Channel Selector to #13		Adjust the RF sweep generator and marker generator for operation on the other television channels; set marker generator to sound carrier frequency. After setting Channel Selector to corresponding channel, adjust oscillator slug thru hole on front of RF Tuner Unit (see Fig. 14). This permits response curve to be shifted so that sound carrier marker will appear at the position indicated in Fig. 15. The picture carrier marker for the corresponding channel should then appear at the 50% amplitude position on the opposite side of the band pass characteristic curve. NOTE: Make sure that cam on fine tuning control shaft remains properly positioned during this step (tooth on the cam pointing down—see Fig. 14).
	*203.75 MC. ‡199.25 MC.		CHANNEL #11			Set Channel Selector to #11		
	*197.75 MC. ‡193.25 MC.		CHANNEL #10			Set Channel Selector to #10		
	*191.75 MC. ‡187.25 MC.		CHANNEL #9			Set Channel Selector to #9		
	*185.75 MC. ‡181.25 MC.		CHANNEL #8			Set Channel Selector to #8		
	*179.75 MC. ‡175.25 MC.		CHANNEL #7			Set Channel Selector to #7		
	* 87.75 MC. ‡ 83.25 MC.		CHANNEL #6			Set Channel Selector to #6		
	* 81.75 MC. ‡ 77.25 MC.		CHANNEL #5			Set Channel Selector to #5		
	* 71.75 MC. ‡ 67.25 MC.		CHANNEL #4			Set Channel Selector to #4		
	* 65.75 MC. ‡ 61.25 MC.		CHANNEL #3			Set Channel Selector to #3		
	* 59.75 MC. ‡ 55.25 MC.		CHANNEL #2			Set Channel Selector to #2		

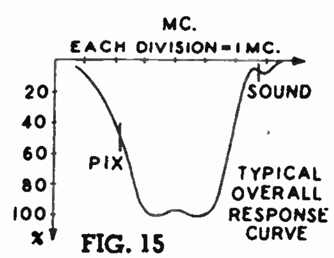

FIG. 15

If an oscillator slug "falls into" its coil form during adjustment, remove the Channel Coil from the turret assembly and lift the Slug Retaining Spring aside. By tapping the coil form it should be possible to make the slug move toward the end so that its threads will be engaged by the Slug Retaining Spring when that spring is returned to its normal position.

If an unsatisfactory overall response is obtained for a particular channel, observe RF Amp. and Mixer response curve for that channel (as described on page 1950-34). If characteristic does not conform reasonably well with the typical curve shown in Fig. 13, then, (1) attempt to obtain a better compromise for RF response on all channels by realigning RF Amp. and Mixer circuits, or (2) try replacing Antenna, RF and Oscillator coils for the particular channels.

459	510128	Resistor—carbon 330 Ohms ½ watt
464	508919	Resistor—1.5 Meg. (in end of H. V. Lead)
466	510710	Resistor—wire wound 1700 Ohms ± 5% 10 watt
467, 468	510132	Resistor—carbon 560 Ohms ± 10% ½ watt

CONTROLS

DIAGRAM NO.	PART NO.	DESCRIPTION
33-A, B	508182	Volume control—1 Meg. (with "On-Off" switch)
43-A to D	508416	Band switch (includes volume control 33-A, "On-Off" switch 33-B and auxiliary power supply switch 437)
54	508324	Built-in Antenna Tuning condenser (4-70 Mmfd.)
88	•	Fine Tuning condenser (3-5 Mmfd.)
160-A, B	508201	Tone and Contrast potentiometer A—Tone control; 500,000 Ohms ¼ watt B—Contrast control; 3000 Ohms ± 10% 4 watt
173-A,B	508417	Brightness and Focus potentiometer A—Brightness control; 50,000 Ohms ¼ w. B—Focus control; 10,000 Ohms ± 10% 4 w.
202	508077	Horizontal Lock coil (less slug)
	507429	Slug core for Horizontal Lock coil
208	508202	Horizontal Hold potentiometer (50,000 Ohms)
212	508071	Horizontal Drive trimmer condenser (10-160 Mmfd.)
225	508218	Width coil (includes slug and clip)
	508435	Slug core for Width coil

CONTROLS—Continued

DIAGRAM NO.	PART NO.	DESCRIPTION
233	162056	Horizontal Linearity coil (includes slug and clip)
	507429	Slug core for Horizontal Linearity coil
266	508051	Vertical Hold potentiometer (1 Meg.)
270	508052	Height potentiometer (2.5 Meg.)
277	508053	Vertical Linearity potentiometer (6000 Ohms)
369-A to D	508185	Band Switch (on AM-FM tuner)
425	508057	Coarse Brightness potentiometer (5500 Ohms ± 10% 4 watt)
446	508915	High Voltage oscillator trimmer (110-560 Mmfd.)

COILS AND TRANSFORMERS

DIAGRAM NO.	PART NO.	DESCRIPTION
12	508061	Transformer—1st TV sound I.F. (includes condensers 12-A and 12-B)
15	507373	Coil—choke
18	508061	Transformer—2nd TV sound I.F. (includes condensers 18-A and 18-B)
26	507321	Transformer—TV sound discriminator (includes condenser 26-A)
	508438	Slug core (5/16" dia. x ⅜" long) for primary of TV sound discriminator trans.
	508439	Slug core (5/16" dia. x ¾" long) for secondary of TV sound discriminator transformer
37	507373	Coil—choke
49	505912	Transformer—sound output
	508805	R.F. Unit complete with coils and tubes
55	507952	Coil—antenna; Channel #2
56	507953	Coil—antenna; Channel #3

	508204	Dial Scale, AM-FM
	508401	Door—cabinet (left side)
	508402	Door—cabinet (right side)
	508403	Door—record changer compartment
	508523	Escutcheon—control panel
	508405	Handle—cabinet door
	508404	Handle—record changer door
	508406	Hinge—cabinet door (per pair)
	508407	Hinge—record changer door
	508204	Knob—AM-FM coarse tuning and dial scale
	508205	Knob—AM-FM fine tuning
	502563	Knob—built-in antenna
	507916	Knob—channel selector
	508209	Knob—"CONTRAST"
	508521	Knob—"FOCUS"
	508206	Knob—horizontal hold
	507917	Knob—TV fine tuning
	508208	Knob—"TV-PHONO-AM-FM"
	508207	Knob—volume, brightness or tone
	508537	Mirror—front surface
	508524	Name plate (Master Panoramic)
	508408	Rail for drawer—(supplied in sets) (per set)
	508536	Screen—picture
	18796	Screw—#10 x 1"; mounts chassis
	508422	Socket—indicator lamp at base of cabinet
	508410	Speaker grille assembly (includes wood frame, grille cloth and metal grille)
	507351	Terminal strip for TV antenna connection

MISCELLANEOUS

DIAGRAM NO.	PART NO.	DESCRIPTION
	508189	Back for AM-FM tuner
	301270	Base for mounting electrolytic condenser
	508081	Bracket for mounting 508805 tuner (front)
	508082	Bracket for mounting 508805 tuner (rear)
	508190	Bracket—supports AM-FM tuner
	506279	Bracket—supports band switch shaft on AM-FM tuner
	508198	Bracket—supports band switch shaft on TV chassis
	505165	"C" washer for connecting link
	507930	Call letter tabs
	508948	Clamp assembly—mounts oil sealed can
	112745	Clip for mounting AM antenna coil
	505101	Clip for mounting I.F. transformer
	507592	Clip for mounting 4th video I.F. coil
	507339	Clip for mounting video converter plate coil, 1st video I.F., 2nd video I.F., 3rd video I.F., horiz. lock and horiz. linearity coil
	114955	Clip—retainer on end of dial cord
	117057	Cord—dial drive (2 ft. required) per foot

MISCELLANEOUS—Continued

DIAGRAM NO.	PART NO.	DESCRIPTION
	508525	Drum—dial; on gang condenser
	508949	Grommet—on lid of H.V. power supply
	508527	Lever—band switch actuating (on AM-FM tuner)
	508526	Lever—band switch actuating (on TV chassis)
	508194	Link—connect band switch actuating levers
	162059	Planetary drive and dial drum (includes mounting bracket)
	507699	Power cord assembly (includes plugs at both ends)
	508704	Power cord—for shielded compartment on TV chassis
	508918	Power interlock (includes plug and bracket for mounting to speaker grille frame)
	506652	Plug for AM-FM tuner power cable
	500966	Plug for audio cable on AM-FM tuner
	502984	Plug for auxiliary power supply cable
	508515	Plug for deflection yoke cable
	508518	Plug for high voltage power supply (3 prong)
	500966	Plug for phono. pick-up cable
	508517	Plug for picture tube grid lead
	18796	Screw—#10 x 1"; mounts chassis
	162031	Shield—on TV chassis (front section)
	508088	Shield—on TV chassis (rear section)
	507357	Slug core for 1st, 2nd, 3rd and 4th video I.F. coils
	507429	Slug core for Horizontal Lock or Horizontal Linearity coil
	508435	Slug core for Width coil
	508438	Slug core for primary of TV sound discriminator transformer
	508439	Slug core for secondary of TV sound discriminator transformer
	509062	Slug core for converter plate coil
	507468	Socket and cable assembly for picture tube
	508156	Socket and mounting bracket for TV channel lite
	160039	Socket—AM-FM tuner output
	508419	Socket—deflection and focus coil cable
	508335	Socket for AM or FM channel lite
	507948	Socket for AM-FM tuner power cable
	508423	Socket for auxiliary power supply cable (on TV chassis)
	507948	Socket for H.V. supply power cable
	162152	Socket—male, power cord interlock (includes mounting bracket)
	506576	Socket—miniature (7 pin) (for 6BE6)
	507364	Socket—miniature (7 pin)
	506331	Socket—miniature (9 pin) (for 12AT7)
	508044	Socket—miniature (9 pin)
	508703	Socket—octal
	160039	Socket—phono.-plug
	508516	Socket—picture tube grid lead
	508917	Spring clip—on end of H.V. lead
	505161	Spring, dial cord tension
	111456	Washer—spring washer for connecting lug

*—This part is not supplied as a Service replacement item.

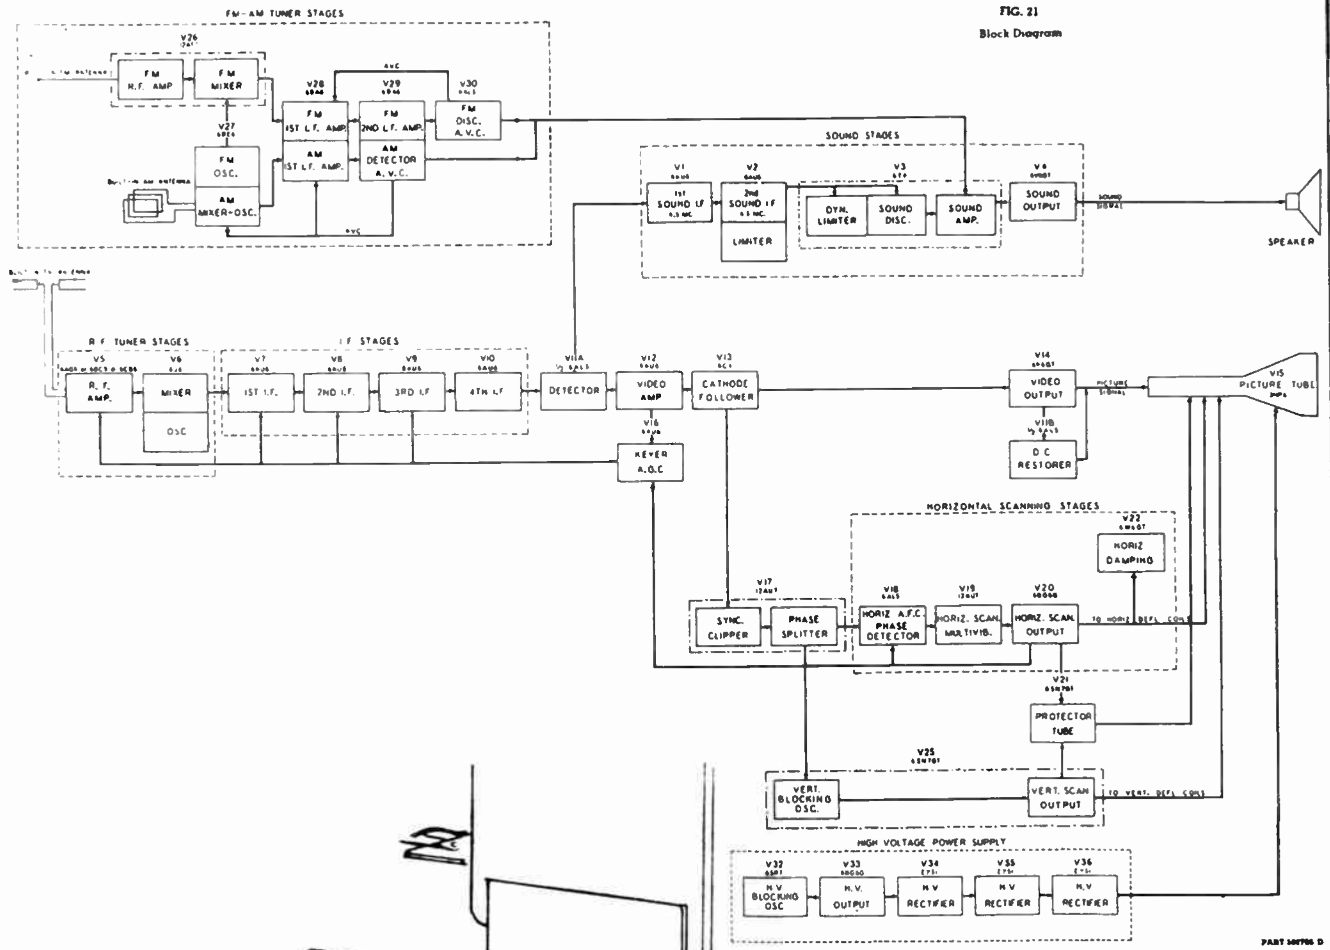

FIG. 21
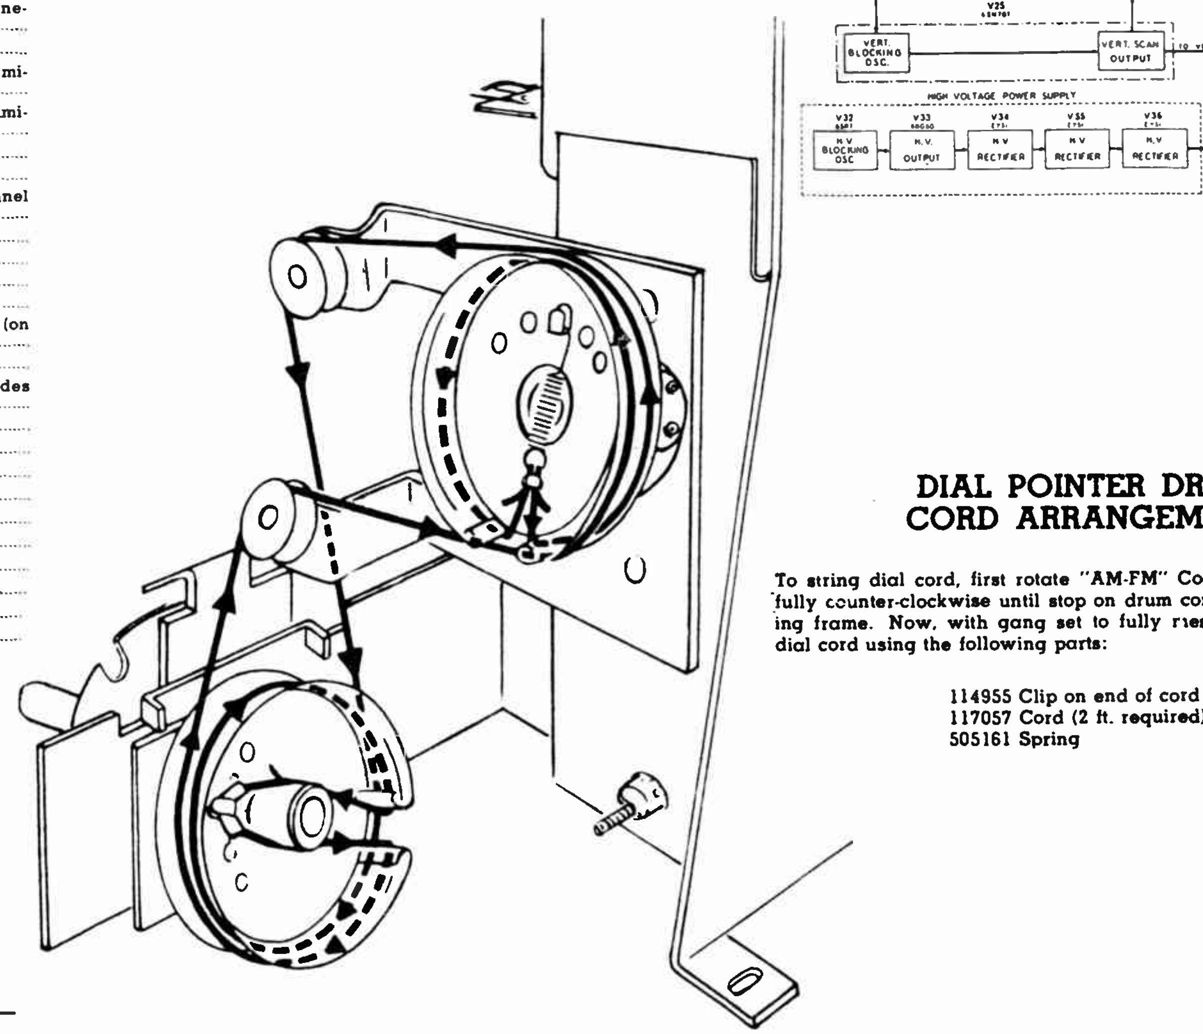
Block Diagram



DIAL POINTER DRIVE CORD ARRANGEMENT

To string dial cord, first rotate "AM-FM" Coarse Tuning Control fully counter-clockwise until stop on drum contacts ear on mounting frame. Now, with gang set to fully meshed position, string dial cord using the following parts:

114955 Clip on end of cord
117057 Cord (2 ft. required)
505161 Spring

INDEX

MODEL 9109-A
14" RECTANGULAR PIX TUBE

MODEL 9109-B
14" RECTANGULAR PIX TUBE

CAUTION

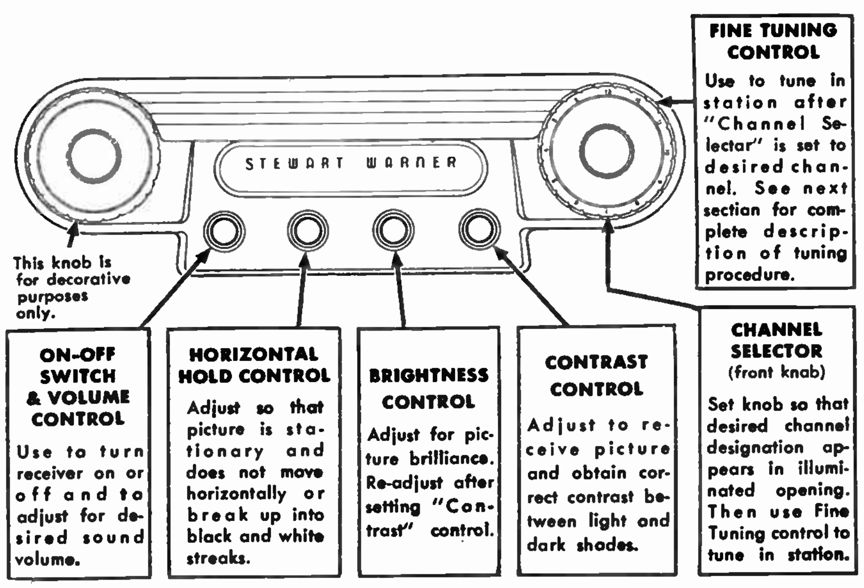
HIGH VOLTAGES are used in the operation of this receiver. The back cover, while in place, prevents accidental contact with this voltage and therefore should not be removed by anyone except a qualified television serviceman.

THE HIGH VOLTAGE LEAD, which supplies 10 to 12.5 kilovolts to the picture tube, should be momentarily shorted to the chassis whenever it is disconnected for service purposes. This discharges the high voltage filter condenser and prevents a shock hazard when working on the receiver after it has been turned off.

THE PICTURE TUBE is highly evacuated and if broken, glass fragments will be violently expelled. Scratching, chipping, undue pressure, or careless handling such as lifting the tube by its neck is dangerous and should be avoided. If it is necessary to handle the picture tube, use safety goggles and heavy gloves. Be sure to discharge the voltage developed across the capacitor formed by the inner and outer coating of the picture tube. This can be done by connecting the high voltage socket on the tube to the outer coating.

RECEIVER OPERATING CONTROLS

Fig. 1



REPLACING CHANNEL LITE

A dial lamp, located behind the "Channel Selector" knob, illuminates the particular television station designation corresponding to the setting of the Channel Selector.

If the dial lamp does not light, and receiver otherwise operates satisfactorily, then the dial lamp may be burned out and replacement should be undertaken. To gain access to lamp, remove all knobs on front of receiver (pull each knob forward) and remove name plate escutcheon by grasping its upper edge and pulling it away from the cabinet. The large escutcheon must then be removed by taking out the four wood screws which hold it in place. Replace dial lamp with Stewart-Warner Part #118921. Be sure to replace sleeving over new dial lamp.

CONTROL ADJUSTMENT PROCEDURE

The various controls on the receiver may be divided into two classes, Operating and Pre-set. Operating controls are those which control program selection as well as sound and picture quality and their functions are indicated in Fig. 1.

The Pre-set controls are those which require adjustment at the time the receiver is installed and they rarely need attention thereafter. Although they have been factory adjusted for optimum performance, it is usually necessary to make some fine adjustments of these controls at the time of installation.

There are nine Pre-set controls, four of which are located at the back of the chassis (see Figure 18). Four controls are accessible by removing the Name Plate located directly above the Operating controls. Access to the "Auxiliary Fine Tuning" screw can be gained by removing the "Channel Selector" and "Fine Tuning" knobs.

To gain access to the centering adjustments and ion trap, it will be necessary to remove the back cover of the cabinet by first removing the built-in antenna tuning knob and then taking out the screws around the rim of the back cover.

Removal of the cabinet back automatically opens an interlock to disconnect the receiver power cord. Centering and ion trap adjustments will require access to circuit components while the receiver is in operation, therefore an auxiliary power cord assembly will be needed. This cord may be ordered from Stewart-Warner by requesting Part #507699.

Operate the receiver according to the instructions given in the section of this manual entitled "How To Tune The Receiver" and make the following adjustments as required.

1. **ADJUST ION TRAP**—If screen remains dark or is only dimly illuminated when "Brightness" control is turned clockwise, the ion trap may require adjustment.

   The ion trap is located on the neck of the picture tube as shown in Figure 18 and consists of a magnet held in position by metal bands.

   Rotate the entire trap assembly while sliding it back and forth until picture tube screen is illuminated to maximum brilliance. Reduce "Brightness" control setting and repeat this operation to assure accurate positioning of ion trap.

2. **AUXILIARY FINE TUNING ADJUSTMENT**—If it is found that the tuning range of the "Fine Tuning" control is inadequate to permit correct tuning of a station in its assigned channel, then adjustment of the "Auxiliary Fine Tuning" screw will be necessary. This special screw is accessible after removal of the "Channel Selector" and "Fine Tuning" knobs. They may be removed by merely pulling them forward.

   Adjustment of the "Auxiliary Fine Tuning" screw may now be undertaken in accordance with the following procedure.

   a. Set "Channel Selector" to desired channel; then remove this knob.

   b. Set "Fine Tuning" knob to the center of its range; then remove this knob. The flat portion of the main tuning shaft (outer brass shaft) should now be in the uppermost position. Note the location of the "Auxiliary Fine Tuning" adjustment screw on receiver chassis —see Fig. 14.

   c. Using a thin screwdriver (preferably non-metallic), adjust the setting of "Auxiliary Fine Tuning" screw for correct tuning of the desired television station—**CAUTION: Do not attempt to rotate this screw more than two full turns in either direction, as further rotation may release it from the thread clip within the tuning mechanism and the coil for that channel (located in R.F. Tuner Unit) would then have to be removed in order to restore the screw to the correct position.** If a metal screwdriver is used, detuning occurs when the screwdriver is removed but it will be noted that this degree of detuning can now be compensated by resetting the "Fine Tuning" control (brass shaft). Thus the range of the "Fine Tuning" control (after knob is replaced on the shaft) will be adequate to tune in the station.

   d. This completes the adjustment of the "Auxiliary Fine Tuning" screw for one channel. Identical screws are provided on each channel

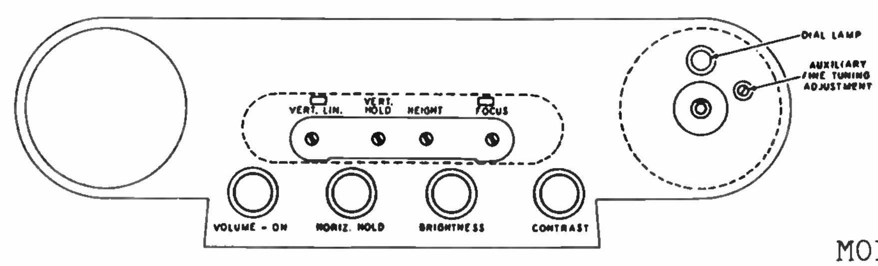


Fig. 14—LOCATION OF PRE-SET CONTROLS

©John F. Rider

World Radio History

and they are all accessible thru the same opening in the tuning mechanism as each successively moves into position when the "Channel Selector" knob is rotated.

3. **HORIZONTAL HOLD**—Should the picture appear to move horizontally across the screen or break up into a series of light and dark streaks as shown in Figure 3, adjust the "Horizontal Hold" control until the picture remains stationary.

If this control must be rotated to the end of its range for proper "locking" action, then it will be necessary to reset the position of the "Horizontal Lock" control (see Figure 18 for location). Adjustment is accomplished by first setting the "Horizontal Hold" control in the middle of its range and then changing the setting of the "Horizontal Lock" control until picture locks in horizontally.

4. **VERTICAL HOLD**—Should the picture appear to roll by in a vertical direction or cause multiple vertical images as shown in Figure 15, it will be necessary to adjust the "Vert. Hold" control located behind the Name Plate (see Figure 14).

After this adjustment is made, reduce contrast until picture is barely visible and check setting of "Vertical Hold" control for proper picture synchronization.

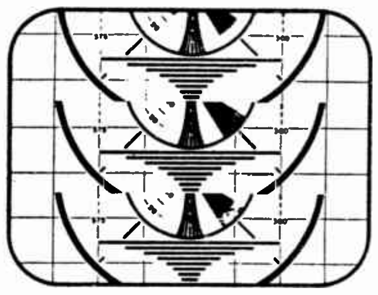

Fig. 15—VERTICAL MOVEMENT; ADJUST VERTICAL HOLD CONTROL

5. **INITIAL FOCUS**—Adjust the "Focus" control, located behind Name Plate, until picture is clearly defined.

Fuzzy picture may also be due to reproduction of poor quality film when station is televising a motion picture. Incorrect tuning of receiver produces a similar effect. Check for proper tuning point as described in step 6 of section entitled "How To Tune the Receiver."

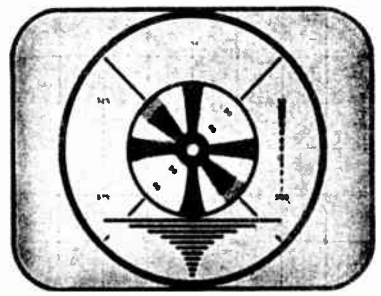

Fig. 16—BLURRED APPEARANCE; ADJUST FOCUS CONTROL

6. **STRAIGHTENING TILTED RASTER**—If the pattern should appear on the screen in a tilted position as shown in Figure 17, loosen the deflection yoke locking screw (see Figure 18) and rotate the yoke sufficiently to correct this condition. Be sure to re-tighten the screw securely.

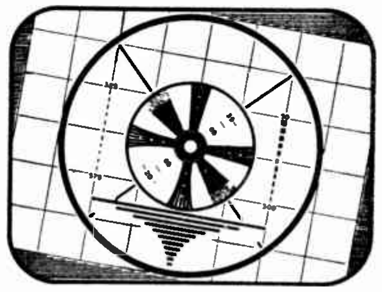

Fig. 17—TILTED PICTURE; ADJUST YOKE POSITION

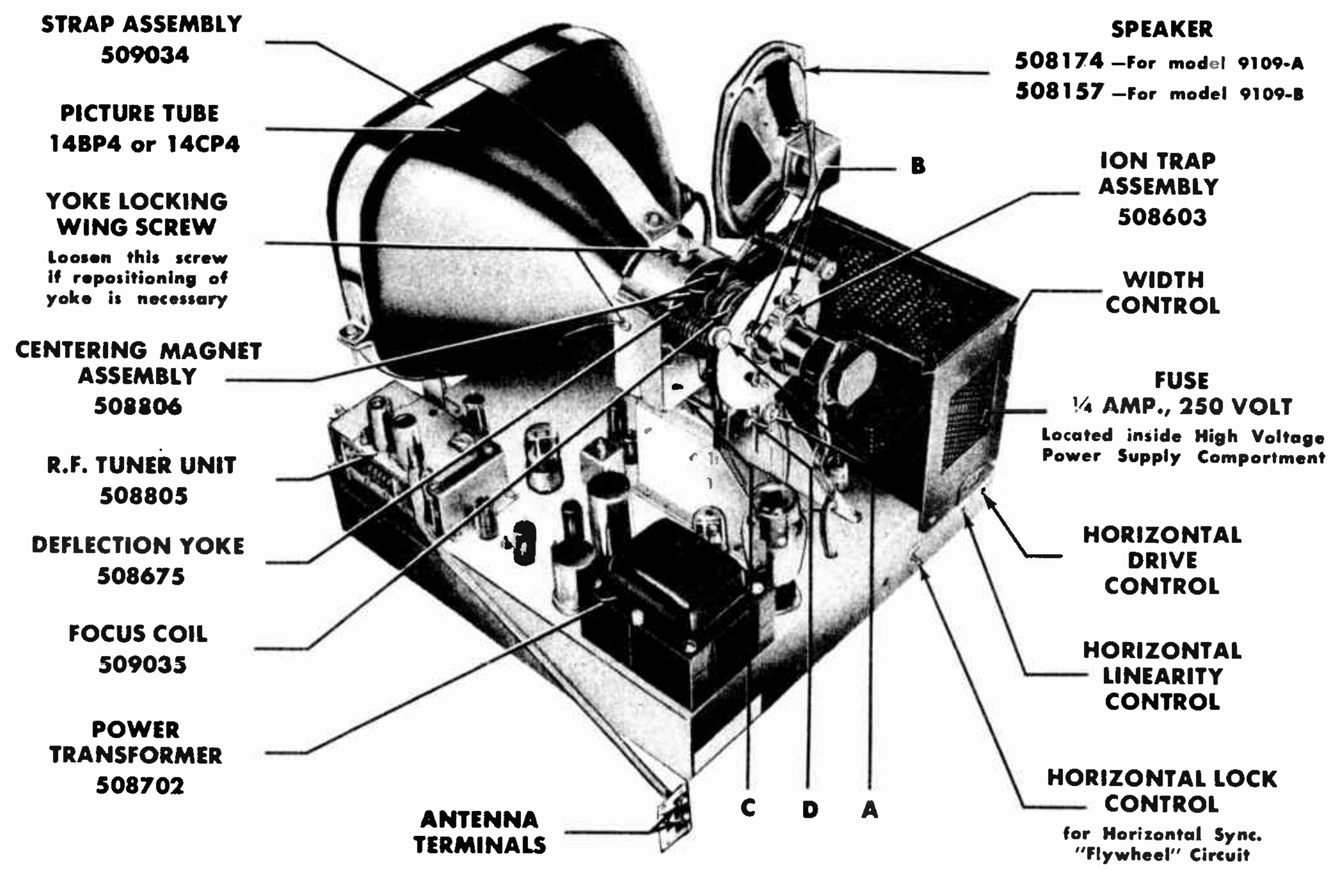

Fig. 18—CHASSIS AND PICTURE TUBE ASSEMBLY

The following adjustments should be made while the station is transmitting its circular test pattern.

7. **CENTERING:** To center the test pattern on the screen, proceed as follows:

a. Make sure focus coil mounting plate is perpendicular to neck of picture tube by adjustment of three nuts labeled A in Figure 18.

b. Rotate the two magnets in the centering magnet assembly (see Fig. 18). These magnets may be adjusted by grasping the "ears" attached to each magnet and rotating the magnets with respect to each other and with respect to the picture tube. Adjust the magnet position for best centering of the test pattern.

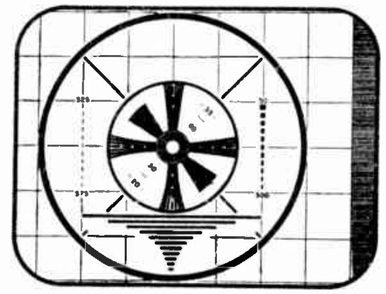

Fig. 19—OFF CENTER; ADJUST FOCUS COIL POSITION

c. If picture is still not centered, loosen four focus coil wing nuts labeled B in Fig. 18 and rotate focus coil for best centering of test pattern.

d. Readjust ion trap for maximum brightness on picture tube screen as explained in step #1.

e. If picture is still not centered, position focus coil by adjusting the three nuts labeled A in Fig. 18.

In event picture cannot be centered by above procedures, release the four wing nuts labeled D in Fig. 18 and raise or lower entire yoke and focus coil assembly so that focus coil can be repositioned vertically with respect to the tube neck.

8. **WIDTH** — Control of picture size in the horizontal direction is accomplished by means of the "Width" control located on the rear of H. V. power supply (see Fig. 18). If abnormally low line voltage makes it difficult to obtain sufficient picture width when using the "Width" control, then changing the setting of the "Horizontal Drive" control may be helpful. The "Drive" control is located at the rear of the chassis and its setting will affect horizontal linearity as well as picture width. Therefore, after adjusting this control for desired width, it may be necessary to re-adjust the "Horizontal Linearity" control as described in paragraph #12.

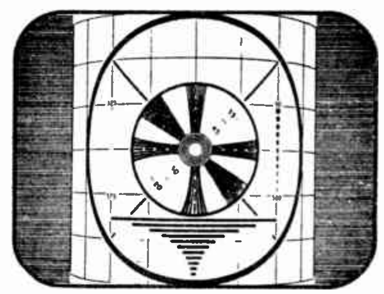

Fig. 20—TOO NARROW; ADJUST WIDTH CONTROL

9. **HEIGHT** — Control of picture size in the vertical direction is accomplished by means of the "Height" control located behind the Name Plate. Height and width adjustments should be checked for all transmitting stations to be sure that picture properly fills the viewing area. It may be necessary to change the setting of the "Height" control after the "Vertical Linearity" control is adjusted.

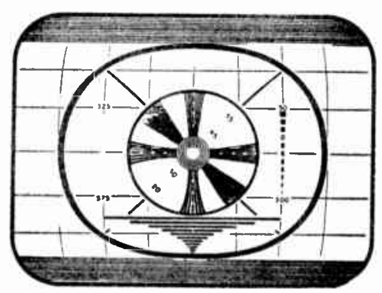

Fig. 21—TOO SHORT; ADJUST HEIGHT CONTROL

10. **VERTICAL LINEARITY** — Improper vertical linearity causes the circular test pattern to appear condensed on the upper edge of the screen and extended on the lower edge or vice versa. This effect is illustrated in Figure 22. Adjust for proper linearity by using "Vert. Lin." control located behind Name Plate. It may be necessary to readjust the "Height" control if an appreciable change is made in the linearity control setting.

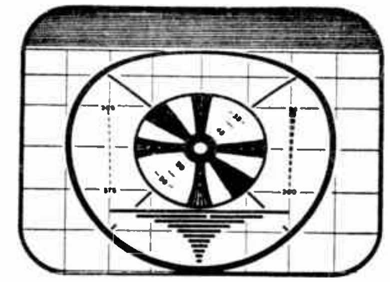

Fig. 22—VERTICAL DISTORTION; ADJUST VERTICAL LINEARITY CONTROL

11. **HORIZONTAL DRIVE** — The "Horizontal Drive" control located at rear of chassis (see Fig. 18) should be rotated clockwise to the point where any white (or black) vertical lines near the left side of the picture are eliminated. As width and linearity of the picture are affected by the setting of "Horiz. Drive" control, it will be necessary to adjust this control in conjunction with the Horiz. Linearity and Width controls to obtain desired picture width and linearity.

12. **HORIZONTAL LINEARITY** — Improper horizontal linearity causes the circular test pattern to appear condensed on the right edge of the screen and extended on the left edge or vice versa. This effect is illustrated in Figure 23. Adjust for proper linearity by using "Horiz. Lin." control located at rear of chassis (see Figure 18). In event that proper horizontal linearity cannot be obtained by adjusting this control, then change the setting of the "Horiz. Drive" control.

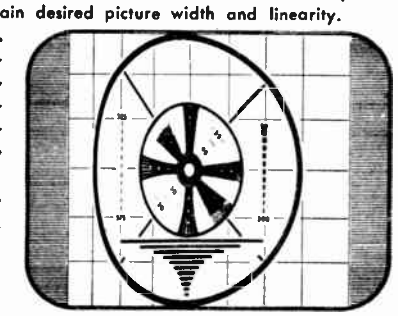

Fig. 23—HORIZONTAL DISTORTION; ADJUST HORIZONTAL LINEARITY CONTROL

13. **ELIMINATING SEMI-CIRCULAR SHADOW** — This shadow is caused by the electron stream striking the neck of the tube and it can generally be corrected by applying one or a combination of the following procedures:

a. Make sure deflection yoke is positioned as far forward as possible by loosening the three wing nuts labeled C in Fig. 18.

b. Reposition the focus coil by readjusting the three nuts labeled A in Fig. 18 to shift the coil forward.

c. In event neck shading cannot be eliminated by the above procedures, release the four wing nuts labeled D in Figure 18 and raise or lower entire yoke and focus coil assembly so that focus coil can be repositioned vertically with respect to the tube neck.

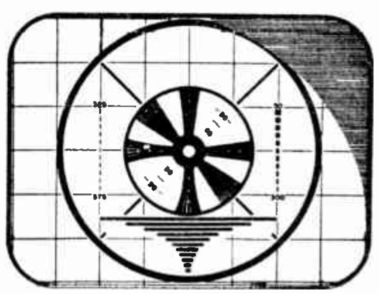

Fig. 24 SEMI-CIRCULAR SHADOW

14. **FINAL ADJUSTMENTS** — Recheck settings of "Brightness," "Contrast" and "Focus" controls for best picture quality.

GENERAL SPECIFICATIONS

DIMENSIONS

Model	Height	Width	Depth
9109-A	36¾"	26¼"	20¾"
9109-B	17⅞"	19"	20¾"

WEIGHTS (packed)

Model 9109-A—138 lbs.
Model 9109-B—100 lbs.

POWER REQUIREMENTS

117 volts   60 cycles   240 watts

PICTURE SIZE

Height	Width	Viewing Area (sq. inches)
8½"	11½"	94

SPEAKER

P.M. Dynamic

Model	Size	V.C. Imped.
9109-A	6" x 9"	3.2 ohms
9109-B	6"	3.2 ohms

ANTENNA INPUT IMPEDANCE

300 ohms—balanced to ground.

BUILT-IN ANTENNA

High "Q" dipole with tunable matching stub.

R. F. TUNER

Turret type construction; individually removable coil assemblies for all channels. All components are easily accessible for servicing.

"KEYED" AUTOMATIC GAIN CONTROL

Outstanding new development; minimizes "airplane flutter"; reduces contrast variation when changing from one channel to another; increases immunity of sync system to external interference.

INTERMEDIATE FREQUENCIES

Sound Carrier—22.25 Mc.
Picture Carrier—26.75 Mc.

I.F. SYSTEM

Four Stage—stagger tuned—for composite signal.
Two additional stages for sound channel.

VIDEO AMPLIFIER

Two Stage—broad band.

RETRACE LINE SUPPRESSOR

Eliminates retrace lines thruout the normal range of picture brightness and contrast.

FOCUS

Magnetic

DEFLECTION

Magnetic

HORIZONTAL SYNCHRONIZATION

Automatic frequency control and "keyed" A.G.C. provide excellent picture stability and noise immunity.

HIGH VOLTAGE POWER SUPPLY

"Fly-back" type. Completely enclosed in a shielded compartment.

SENSITIVITY

Antenna to Picture Tube Grid Sensitivity — To make this measurement, connect negative terminal of 1½ volt battery to A.G.C. line, and positive terminal of battery to chassis. Also, set Contrast control to maximum clockwise position. Connect an **A.C.** vacuum-tube voltmeter between picture tube grid and ground, and place a .005 microfarad condenser across the same points.

Inject R.F. signal (400 cycle modulated) at antenna terminals, using signal whose frequency corresponds to the center frequency of the selected channel, and adjust Fine Tuning control for maximum output. Generator must be connected to antenna terminals with a 150 ohm carbon resistor in series with each lead to simulate proper impedance match.

Input signal required to produce standard output of 7.07 volts **A.C.** (r.m.s.) at picture tube grid is indicated in the following table. Since a fixed bias of 1½ volts has been applied to the A.G.C. system in order to provide a reference level for these measurements, it will be understood that the sensitivities specified here are not intended to indicate the full capability of the receiver, but merely serve as a convenient basis for determining proper operation.

Low Band { Average—50 microvolts; Range—25 to 100 microvolts

High Band { Average—80 microvolts; Range—40 to 160 microvolts

Detector to Picture Tube Grid Sensitivity — To make this measurement, remove 6AU6, 4th Video I.F. tube (V-10) and set Contrast control to maximum clockwise position. Inject a 400 cycle (audio) signal across 6800 ohm video detector load resistor. In order to produce the standard output of 7.07 volts **A.C.** (r.m.s.) at the picture tube grid, the input signal at the detector load resistor will be approximately .07 volts **A.C.** An **A.C.** vacuum-tube voltmeter must be used for these voltage measurements.

Sound System Sensitivity — Inject 4.5 megacycle frequency modulated signal (400 cycle modulation with 7½ Kc. deviation) across video detector load resistor and measure output at speaker voice coil. An input of 2200 microvolts will produce approximately 500 milliwatts or 1.26 volts across speaker voice coil.

HORIZONTAL SYNC SYSTEM ADJUSTMENT

If picture "tears" horizontally and cannot be synchronized by operating the Horizontal Hold control on front panel of receiver, this action may be due to incorrect setting of the slug in the Horizontal Lock Coil.

1. Set Horizontal Hold control in center of its range.
2. Adjust slug of Horizontal Lock Coil for picture synchronization (see Fig. 18 for location of slug).

REDUCTION OF INTERCARRIER BUZZ

If a prominent humming or buzzing sound is noted in the sound reception of a television broadcast, it may be due to a fault in transmission from the station, or incorrect adjustment of the discriminator transformer (tuning of secondary circuit) in the receiver.

This type of disturbance, which is only present when receiving a station signal, is known as "Intercarrier Buzz" and it should not be confused with power supply hum that would occur upon failure of a filter condenser.

The procedure for correct adjustment of the television sound discriminator circuit is presented in the last section of the Television Sound Channel alignment instructions. When the discriminator secondary slug #1 is properly adjusted, intercarrier buzz will be reduced to an acceptable minimum, provided that the transmission from the station is not at fault.

HIGH VOLTAGE POWER SUPPLY SERVICING

The High Voltage Power Supply used with this receiver is of the "fly-back" type and is located in the shielded compartment mounted at the left rear corner of the chassis. It consists of a sturdily constructed and well insulated horizontal sweep output transformer plus a 1B3GT/8016 high voltage rectifier tube and associated filter components.

The plate circuit of the Horizontal Scanning Output stage is fused to protect the transformer and kill high voltage in the event the 6BQ6GT tube or the high voltage rectifier circuit draws excessive current.

CAUTION

> The heavily insulated red lead, which supplies extremely high voltage (10 to 12.5 kilovolts) to the picture tube, should be momentarily shorted to the chassis whenever it is disconnected for service purposes (that is, after receiver has been turned off). This discharges the high voltage filter condenser and prevents a shock hazard when working on the set.

Access to the horizontal output transformer, high voltage rectifier tube, fuse and high voltage filter condenser is accomplished by removing the rear section of the H.V. shield. This compartment shield is held in place by five screws.

To replace the fuse, depress the cap of the fuse holder (located next to 6BQ6GT tube) and turn the cap counter-clockwise. Install new fuse of the same type (¼ amp., 250 volt, part 508713); do not use any other size.

REMOVAL OF THE CABINET BACK AUTOMATICALLY OPENS AN INTERLOCK TO DISCONNECT THE RECEIVER POWER CORD.

CORONA AND ARC-OVER

Corona or arc-over can best be detected by observing the operation of the power supply in a dark room. Several conditions may cause these phenomena.

POOR CONNECTIONS — Arcing or corona may be due to poorly soldered connections (rosin joints or sharp points), or defective tube socket connections. If the leads or connectors to the high voltage filter condenser do not grasp this component securely, arcing will also result.

Inspect solder connections and resolder those joints which are unsatisfactory. Make sure tubes are firmly positioned in tube sockets and that high voltage filter condenser is held securely in place.

CLOSELY SPACED COMPONENTS — Arcing or corona may occur when H.V. components or leads are placed too close together. Make sure there is sufficient spacing between all parts and wiring. If necessary, the insulation between two elements of the circuit may be improved by coating both objects with a quick-drying liquid polystyrene or polyethylene.

The socket assembly for the 1B3GT/8016 rectifier tube includes a "corona ring" which prevents corona from the tube socket connections. The surface of this ring should be smooth and free of scratches, nicks, or sharp protrusions.

PICTURE TUBE REPLACEMENT

INTERCHANGEABLE TYPES—Two types of picture tubes are used interchangeably in all model 9109 receivers and they differ only in the manner in which their electron guns are constructed. The 14CP4 tube utilizes a bent gun, while the 14BP4 tube contains a straight gun.

It is preferable to use a replacement tube of the same type as that originally furnished with the particular receiver on which you are working. Substitution of a 14BP4 for a 14CP4 or vice versa (as well as slight manufacturing variances between tubes produced by different suppliers) can occasionally give rise to a focusing or centering problem. Suggested remedies for those conditions are discussed in a subsequent paragraph.

REPLACEMENT PROCEDURE—When replacement of a picture tube is necessary, proceed as follows:

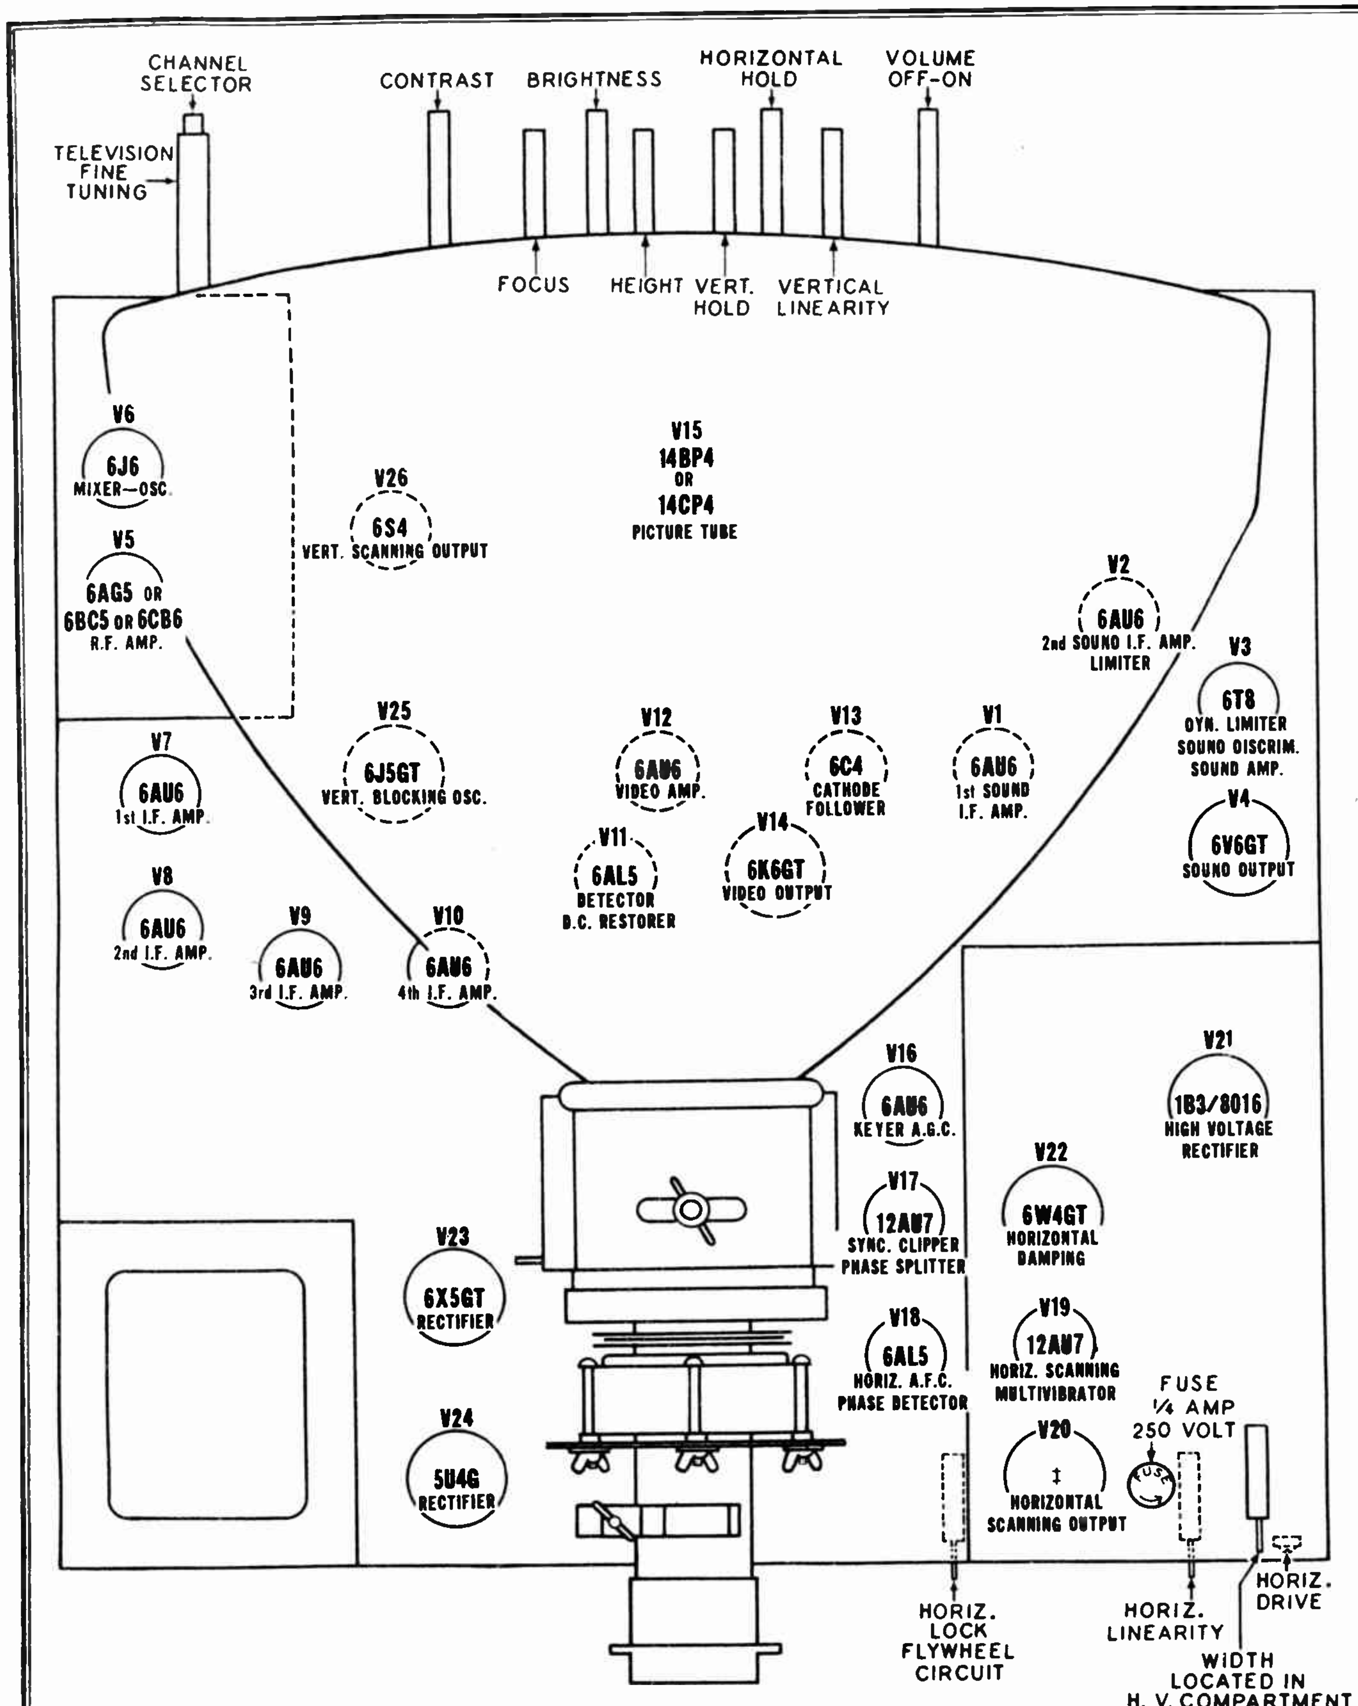
1. Disconnect power cord from wall outlet.
2. Remove chassis from cabinet.
3. Remove high voltage lead from side of picture tube and **momentarily short this lead to chassis to discharge high voltage filter condenser.**
4. **Discharge the voltage developed across the capacitor formed by the inner and outer coatings of the picture tube by connecting the high voltage socket on the tube to the outer coating.**
5. Remove the tube socket at base of picture tube.
6. Disengage ion trap from neck of tube.
7. Release three nuts labeled A in Fig. 18 and carefully remove Focus Coil and Focus Coil Mounting Plate. Slide large springs off the studs on the Deflection Yoke Mounting Bracket.
8. Remove Centering Magnet Assembly.
9. Loosen the two bolts on the ends of the Strap Assembly that encircles the front rim of the tube.
10. Carefully remove picture tube by pulling it forward.
11. Install the new tube and be sure that it has the same type number as the tube that is being replaced. Also be sure that Focus Coil Mounting Plate is replaced so that the two focus coil leads point downward.

SPECIAL FOCUSING AND CENTERING INSTRUCTIONS—If correct focusing or centering of the picure cannot be accomplished after installing a replacement picture tube, then the following recommendations should prove effective.

1. Slide Centering Magnet Assembly as close to Deflection Yoke as possible, then recheck focusing and centering.
2. If picture still will not focus, remove Centering Magnet Assembly from its position in front of the Focus Coil and then reinstall it on the neck of the tube but located behind the focus coil. In some instances, proper focus can only be obtained by completely removing the Centering Magnet Assembly.
3. If picture cannot be centered by adjusting the position of the Focus Coil and Centering Magnet Assembly, then remove tube and reinstall it so that the high voltage socket is on the **left** side of the tube when viewed from the rear.

©John F. Rider

World Radio History



‡ Two different type Horizontal Scanning Output tubes are used in this receiver. All "uncoded" chassis contain a 6BQ6GT tube, while all chassis stamped "Series A" utilize a 6CD6G tube. These tubes are not interchangeable and failure to install the correct type tube may result in serious damage to the receiver.

CAUTION

THE PICTURE TUBE is highly evacuated and if broken, glass fragments will be violently expelled. Scratching, chipping, undue pressure, or careless handling such as lifting the tube by its neck is dangerous and should be avoided. If it is necessary to handle the picture tube, use safety goggles and heavy gloves. Be sure to discharge the voltage developed across the capacitor formed by the inner and outer coating of the picture tube. This can be done by connecting the high voltage socket on the tube to the outer coating with a well insulated metal conductor.

HIGH VOLTAGE (10 to 12.5 kilovolts) is produced in a supply circuit of this receiver. Exercise care to avoid contact with elements of this circuit and particularly the tube terminals which are labeled "CAUTION" in the adjoining voltage chart. If measurement of voltage at these points is necessary, see procedure given below under the note "E".

THE HIGH VOLTAGE LEAD, which supplies approximately 10 to 12.5 kilovolts to the picture tube, should be momentarily shorted to the chassis whenever it is disconnected for service purposes. This discharges the high voltage filter condenser and prevents a shock hazard when working on the receiver after it has been turned off.

INTERMEDIATE B+ VOLTAGES, 455 and 355, are dangerous and caution should be observed when the receiver chassis components are exposed for service purposes.

THE VOLTAGES SHOWN IN THE ADJOINING CHART WERE MEASURED UNDER THE FOLLOWING CONDITIONS

1. Power Supply—117 volts 60 cycle AC.

2. All voltages are measured between socket terminals and chassis unless otherwise indicated on adjoining chart.

*

3. Measurements made with voltmeter having sensitivity of 1000 ohms per volt except where indicated by (*). The (*) symbol designates a vacuum tube voltmeter measurement.

4. Channel Selector and Fine Tuning Controls set for normal reception of a local station.

5. Focus control set to maximum counter-clockwise position unless otherwise instructed by Note V on voltages in adjoining chart. Setting of this control will affect B+ voltage on the 260 volt supply line. This voltage is obtained when control is at maximum counter-clockwise position and increases to 300 as control is rotated to clockwise position.

6. All other controls (with exception of focus control) are set for normal reception of the transmitted signal unless the voltage shown on the chart is followed by a letter or letters indicating a special condition of measurement as explained in subsequent notes.

7. Certain voltages were measured with two different settings of specific controls. It should therefore be understood that in these instances all controls, with the exception of one or two, were set for normal reception—letters following the voltage shown on the chart indicate the exceptions and are explained below.

8. The external or built-in antenna should remain connected to the receiver only when taking voltage measurements in the sweep and sync circuits—for all other measurements, disconnect antenno, short antenna terminals together and connect them to ground.

EXPLANATION OF NOTES

A. Vert. Hold Control max. counter-clockwise

a. This voltage will vary from —4.7 to —9.5 depending upon setting of Horizontal Hold Control and Horizontal Lock Control.

B. Brightness Control max. counter-clockwise

b. This voltage will vary from 13 to 17 depending upon setting of Horizontal Hold Control and Horizontal Lock Control.

C. Contrast Control max. clockwise

D. Horiz. Drive Control max. clockwise

d. This voltage will vary from 280 to 310 depending upon setting of Horizontal Hold Control and Horizontal Lock Control.

E. If you do not have an instrument capable of directly measuring voltages in this range, the voltage can be measured by using a voltage divider network consisting of twenty 2.2 megohm 2 watt resistors and one 1 megohm 2 watt resistor, all connected in series. Avoid using resistors of higher values as their individual voltage rating may be exceeded. It is also important to use resistors of equal wattage. Solder all connections between resistors. Accurately measure the overall resistance of the entire combination as well as the resistance of the 1 megohm section.

With the set turned off, connect the 2.2 megohm end of the resistance voltage divider to the filament of the 1B3GT/8016 tube, or H. V. terminal of the picture tube, and connect the 1 megohm end to chassis. Now, turn the set on and measure the voltage drop across the 1 megohm resistor with a vacuum tube voltmeter. The voltage at the tube terminal can then be calculated as follows:

$$\left[\text{Volts At Tube Terminal}\right] = \left[\frac{\text{Measured Resistance Of Entire Voltage Divider}}{\text{Measured Resistance Of 1 Meg. Section}}\right] \times \left[\text{Volts Measured Across 1 Meg. Section}\right]$$

e. This voltage will vary from +6.8 to —1.6 depending upon setting of Horizontal Hold Control and Horizontal Lock Control.

F. Height Control max. counter-clockwise

f. Contrast Control max. counter-clockwise

G. Width Control max. counter-clockwise

g. This voltage will vary from 10 to 16 depending upon setting of Horizontal Hold Control and Horizontal Lock Control.

H. Height Control max. clockwise

h. This voltage will vary from +0.06 to —0.04 depending upon setting of Horizontal Hold Control and Horizontal Lock Control.

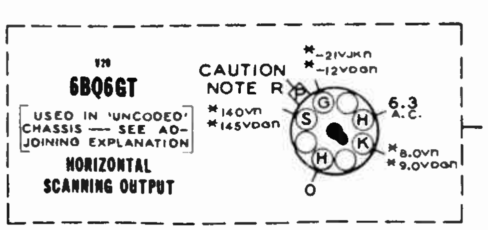
EXPLANATION OF NOTES

(Continued from preceding page)

J.	Horiz. Hold Control set for normal picture.
K.	Horiz. Lock Control set for normal picture.
L.	This voltage will vary from 13 to 21 depending upon setting of Horizontal Hold Control and Horizontal Lock Control.
M.	Vertical Linearity Control max. counter-clockwise.
m.	This voltage applies only to chassis stamped "Series A."
N.	Channel Selector set to channel #4
n.	This voltage applies only to "uncoded" chassis, not to units stamped "Series A," etc.
P.	This voltage will vary from —6 to —12 depending upon setting of Horizontal Hold Control and Horizontal Lock Control.
R.	Do not attempt to measure the voltage at the tube cap. There is a high R. F. potential at this point.
r.	Before making this measurement, remove one of the four 6AU6 IF Amplifier tubes (V7, V8, V9 or V10). This will prevent noise in the RF stages from affecting the voltage measured at this point.
S.	Channel Selector set to channel #10
T.	Grounding of center stud on tube socket is necessary to reduce capacity coupling between other pins. Oscillation may result if this ground is omitted.
t.	This voltage will vary from —8 to —16 depending upon setting of Horizontal Hold Control and Horizontal Lock Control.
U.	Vertical Hold Control max. clockwise
V.	Before measuring this voltage, first connect external antenna and adjust controls for normal reception of station signal; then set Focus Control to maximum counter-clockwise position.
W.	This voltage will vary from —2 to —3 depending upon setting of Horizontal Hold Control and Horizontal Lock Control.
X.	Brightness Control max. clockwise.
Y.	Vertical Linearity Control max. clockwise.
Z.	The measurement should be made with a vacuum tube voltmeter. The voltage reading will fluctuate in the vicinity of 0.05 volts.



Two different type Horizontal Scanning Output tubes are used in this receiver. All "uncoded" chassis contain a 6BQ6GT tube, while all chassis stamped "Series A" utilize a 6CD6G tube. **These tubes are not interchangeable and failure to install the correct type tube may result in serious damage to the receiver.**

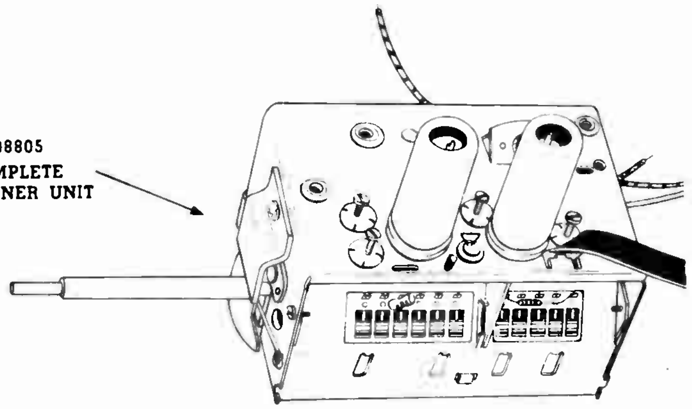
REPAIR DATA FOR 508805 RF TUNER UNIT

All replacement parts for the RF Tuner Unit are included in the complete receiver parts list.

This RF Tuner Unit consists of an RF amplifier stage (using 6AG5, 6BC5, or 6CB6 tube) and a mixer-oscillator stage (using 6J6 tube). Channel selection is accomplished by rotation of a turret assembly having 2 sets of snap-in coils for each of the 12 channels. The tuner also incorprates a Fine Tuning control.

Antenna Coils for each channel consist of a center-tapped primary and an RF amp. grid winding (secondary). The individual RF-Oscillator Coils include an RF amplifier plate section, a mixer grid section and an oscillator winding. Signal output from the mixer stage is coupled to the IF amplifiers through the input IF coil located on the tuner unit.



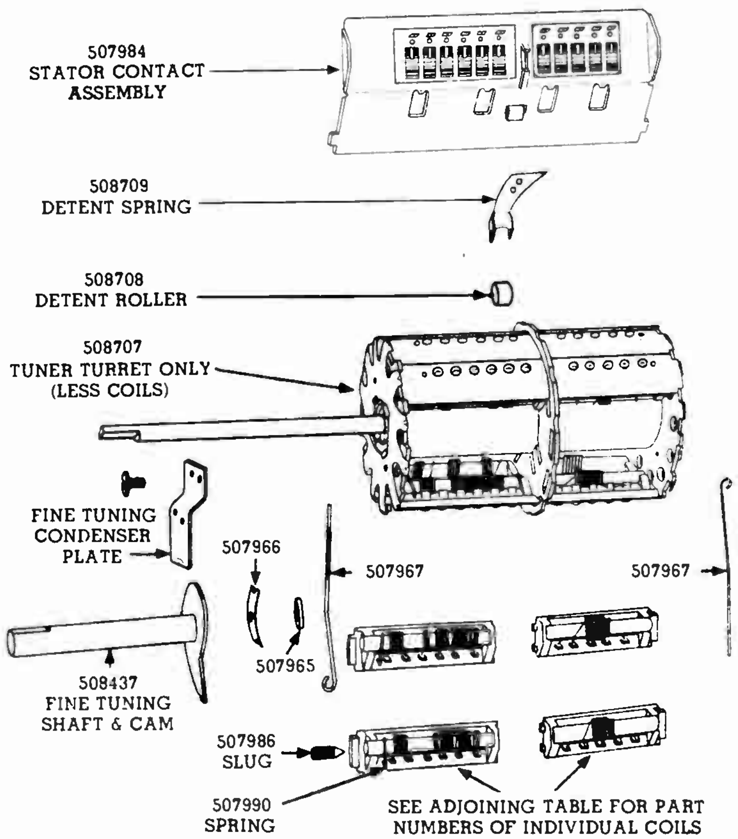
SERVICE PRECAUTIONS

SUBJECT	PRECAUTIONS
ELECTRICAL COMPONENTS	The high frequencies used in the RF section of a television receiver make it necessary that considerable care be exercised in servicing the tuner. Lead dress and location of components are very critical at these frequencies. When replacing parts, it is important to use components of identical electrical characteristics and physical size. Always reconnect the replacement item in the same location and position in the tuner as the original component.
TUBES	Replacement of tubes in the Tuner Unit may cause slight detuning of RF circuits due to inherent differences in inter-electrode capacitances. When replacing tubes (especially V6, 6J6 mixer-oscillator tube) make sure that Fine Tuning control will tune in television stations at approximately the middle of its range. It may be necessary to change the setting of the individual oscillator coil slugs for some channels to accomplish this.
CHANNEL COILS AND SLUGS	Channel Coils must be handled with care. Do not disturb coil windings. If an oscillator slug "falls into" its coil form during adjustment, remove the Channel Coil from the turret assembly and lift the Slug Retaining Spring aside. By tapping the coil form it should be possible to make the slug move toward the end so that its threads will be engaged by the Slug Retaining Spring when that spring is returned to its normal position.
FINE TUNING CONTROL	Rubbing of the bakelite Fine Tuning Cam against the Fine Tuning Condenser Plate is intentional in order to avoid vibration with resulting microphonics. However, the Fine Tuning Cam should not rub or contact the small circular plate located on the body of the tuner.

REMOVAL AND REPLACEMENT OF PARTS

ITEM	PROCEDURE
RF TUNER UNIT	To remove the Tuner Unit from receiver chassis, proceed as follows: 1. Remove metal plate which covers side of RF Tuner Unit nearest edge of chassis. This plate is held in place by two screws at side of chassis. 2. Remove channel selector dial lamp socket. 3. Remove support bracket which positions front of Tuner Unit and also remove screws which hold tuner to rear support bracket. 4. Disconnect the leads from the tuner to the main chassis. See illustration on page 21, 22 (circuit diagram page) showing tuner connections. After the Tuner Unit is replaced, make sure that channel selector dial lamp socket is correctly positioned so that channel selector knob will be properly illuminated.
CHANNEL COILS	Insert a screwdriver blade between Coil Retainer Spring and the end of the Tuner Turret. Twist the blade to pull spring away from the molded body of Channel Coil. Lift this end of coil body upward and remove individual coil assembly from tuner. When replacing Channel Coils, be sure they are reinstalled in their correct positions. Coil numbers should increase consecutively in a counter clockwise direction when tuner is viewed from the front. If all the Channel Coils have been removed from the Tuner Turret, rotate turret until flat surface on end of tuner shaft points down. Install #3 Channel Coils into bottom position on turret. Then follow the correct sequence indicated above to replace other coils.

ITEM	PROCEDURE
TUNER TURRET ASSEMBLY	To remove turret from RF Tuner Unit, proceed as follows: 1. Remove tuner from receiver chassis. 2. Remove rear Turret Shaft Retaining Spring by disengaging straight end of spring from projection on tuner. 3. Remove Fine Tuning Condenser Plate from front of Tuner Unit. This plate forms one side of Fine Tuning control condenser and is held in place by one screw. 4. Slide Fine Tuning Cam and Brass Shaft off of main Channel Selector Shaft. 5. Remove Contactor Washer Spring and Fiber Spacer Washer from Channel Selector Shaft. 6. Remove Shaft Retaining Spring at front of tuner by disengaging straight end of spring from projection on case. 7. Remove turret assembly from case. To replace turret, reverse the above procedure. Tooth on bakelite Fine Tuning Cam should point downward during assembly so that it does not become locked between the stops on the Fine Tuning Condenser Plate.
STATOR CONTACT ASSEMBLY	To remove this assembly, proceed as follows: 1. Remove the two screws at the front and rear of the Stator Contact Assembly. 2. Unsolder all electrical connections to contact plate. 3. Unsolder five soldered joints between Stator Contact Assembly and Tuner Unit. 4. Contact Assembly may now be withdrawn from case. **To reinstall this assembly:** 1. Place Stator Contact Assembly in position and replace, but do not tighten, the two screws at the front and rear of the assembly. 2. Remove 3 consecutive pairs of Channel Coils from the turret (for example, the antenna and rf-osc. coils for channels #5, 6 and 7). 3. Position Tuner Turret so that the edges of the next highest Channel Coils (in this case, the coils for channel #8) just pass the row of 11 contacts on the Stator Contact Assembly. 4. Adjust position of the Stator Contact Assembly so that there are a few thousandths of an inch spacing between the contacts on the contact plate and the molded body of the Channel Coils. 5. The Contact Assembly is now correctly positioned and screws at front and rear may be tightened. 6. Solder Stator Contact Assembly to tuner frame at same points that were used previously. 7. Make all electrical connections to contact plate. 8. Replace Channel Coils.



CHANNEL NUMBER	ANTENNA COIL PART NUMBER	RF & OSC COIL PART NUMBER
2	507952	507972
3	507953	507973
4	507954	507974
5	507955	507975
6	507956	507976
7	507957	507977
8	507958	507978
9	507959	507979
10	507960	507980

World Radio History

ALIGNMENT PROCEDURE

MODELS 9109-A & 9109-B

Alignment of all RF and IF tuned circuits in this receiver may be accomplished by utilizing the procedures described in the following charts.

SEQUENCE OF ALIGNMENT: These procedures should preferably be applied in the order in which they are presented, however, alignment of the Sound Channel or IF Channel may be accomplished individually if desired.

The RF Amplifier and Mixer alignment may also be accomplished independent of Sound or IF Channel alignment, but oscillator calibration can only be done after IF Channel has been correctly aligned. Proper IF band pass characteristic is necessary for Oscillator alignment as results of RF circuit tuning are observed by means of an oscilloscope connected to the output of the detector stage.

REMOVAL OF CHASSIS: The receiver chassis must be removed from the cabinet in order to accomplish alignment of all tuned circuits as there are adjustment points located on the underside of the unit.

This can be accomplished by first removing all knobs and disconnecting the receiver "built-in" antenna and speaker. The chassis may then be removed by releasing the hold-down screws located on the underside of the cabinet.

Removal of the cabinet back automatically opens an interlock to disconnect the receiver power cord, therefore, an auxiliary power cord assembly will be required when aligning this receiver. This cord may be ordered from Stewart-Warner by requesting Part #507699. **Do not attempt to supply power to the receiver by using any other device.**

CAUTION

The picture tube is highly evacuated and if broken, glass fragments will be violently expelled. Handle with care, using safety goggles and gloves. Avoid contact with high voltage terminal at side of tube even after it has been disconnected from the receiver— this precaution is necessary as inner and outer coatings on the tube form a capacitor which may carry a high voltage charge for an extended period of time after disconnection from the receiver.

The metal plate which covers the side of the RF tuner unit must be removed for IF alignment as IF signal injection is accomplished at a terminal located behind this plate (see Fig. 4). That plate must be replaced when RF alignment is undertaken.

INSTRUMENTS: The following instruments will be required as signal sources and output indicators during the alignment process. Since accurate alignment of a television receiver is heavily dependent upon the performance of your instruments, it is imperative that they meet the essential specifications described here.

1. **STANDARD SIGNAL GENERATOR** to provide unmodulated (pure RF) signals at the following frequencies. Maximum output on all ranges should be at least .1 volt with provision for attenuation as desired. This instrument must have good frequency stability and be accurately calibrated. Generators which incorporate a separate crystal controlled oscillator and heterodyne circuit are self calibrating and therefore capable of providing the accuracy of frequency calibration required for television circuit alignment.

   a. IF Frequencies:
   - 4.5 Mc. Sound Channel
   - 22.25 Mc. Sound IF marker
   - 22.4 Mc. 1st IF Trap Coil
   - 22.8 Mc. 3rd IF Trap Coil
   - 23.5 Mc. 1st and 3rd IF stages
   - 24.5 Mc. 4th IF stage
   - 26.3 Mc. Converter and 2nd IF stages
   - 26.75 Mc. Picture IF marker

   b. RF Frequencies:
   - 54 to 88 Mc.
   - 174 to 216 Mc.

2. **RF SWEEP GENERATOR** to provide frequency modulated signals at the following frequencies:
   - 20 to 30 Mc. with 10 Mc. sweep width.
   - 54 to 88 Mc. with 10 Mc. sweep width.
   - 174 to 216 Mc. with 10 Mc sweep width.

   Output adjustable with at least .1 volt maximum.

   Output should be "flat" (no amplitude variation) for all settings of the sweep width control.

   Provision for connection of generator sweep modulating voltage to horizontal deflection system of an oscilloscope.

   Provision for blanking the output signal on each return sweep so that oscillogram will not show retrace.

3. **CATHODE RAY OSCILLOSCOPE**, preferably a unit with vertical amplifier having wide range frequency response and low capacity pick-up probe.

4. **VACUUM TUBE VOLTMETER.** The lowest voltage range of this instrument should preferably permit a 1.0 volt reading to be indicated at not less than one third of full scale deflection.

INSTRUMENT CONNECTIONS: The method of connection, including details of matching and coupling networks, for instruments used in this alignment procedure is given in several illustrations on subsequent pages. Specific instructions for each instrument application will be found in various sections of the alignment charts.

GENERAL INSTRUCTIONS: When aligning IF and RF circuits it is necessary to apply a fixed bias voltage to the AGC system of the receiver. This fixed bias is obtained by using a 3 volt battery and connecting it as described in Fig. 14.

IMPORTANT

When observing the receiver band pass characteristic on an oscilloscope, it is exceedingly important to avoid distortion of that characteristic which would occur when using a large input signal from the sweep generator or standard generator (marker signal). Always set attenuator on sweep generator so that the reading on the vacuum tube voltmeter does not exceed one volt (when meter is connected from high side of video detector load resistor, symbol 139, to receiver chassis). Standard generator output should also be attenuated so that marker signal does not pull or tear the band pass characteristic as shown on the 'scope.

SOUND CHANNEL ALIGNMENT PROCEDURE

1. Short antenna terminals together with a jumper wire.
2. Set receiver Channel Selector to any inactive television channel; other controls may be left at any desired setting.
3. No special aligning tool is required to adjust the cores in the Sound IF and discriminator transformers. The blade of a small screwdriver will fit the slot in these cores, however, the screwdriver should be of a non-metallic or insulated type to prevent detuning when inserted in the transformer can.

STANDARD SIGNAL GENERATOR: CONNECTIONS	STANDARD SIGNAL GENERATOR: FREQUENCY	VTVM CONNECTIONS	MISCELLANEOUS INSTRUCTIONS	TRIMMER OR SLUG	TYPE OF ADJUSTMENT AND OUTPUT INDICATION
Connect as shown in Fig. 1.	**4.5 MC.** unmodulated **IMPORTANT** This signal must be accurate within ¼ of 1% of 4.5 Mc. Check generator calibration against a crystal controlled signal source by "zero beating" (heterodyning) with harmonics of the crystal frequency.	Connect as shown in Fig. 2.	A "swishing" sound may be heard in the speaker during Sound Channel Alignment. This spurious oscillation is caused by horizontal sweep voltage being picked up in the audio system thru stray coupling of instrument leads; it should be disregarded as it will have no effect on alignment of the sound channel.	**#1** Discriminator Secondary	Adjust for maximum reading on VTVM.
				#2 Discriminator Primary	Adjust for maximum reading on VTVM.
				#3 2nd Sound IF Secondary	Adjust for maximum reading on VTVM.
				#4 2nd Sound IF Primary	Adjust for maximum reading on VTVM.
				#5 1st Sound IF Secondary	Adjust for maximum reading on VTVM.
				#6 1st Sound IF Primary	Adjust for maximum reading on VTVM.
Same as above.	Same as above.	Connect as shown in Fig. 3.	Same as above.	**#1** Discriminator Secondary	Note that as slug #1 is rotated, a point will be found where the voltmeter will swing rather sharply from a positive to a negative reading or vice versa. The correct setting of slug #1 is obtained when the meter reads zero as the slug is moved thru this point.

REDUCTION OF INTERCARRIER BUZZ

Slight "dynamic" unbalance of the discriminator secondary can emphasize intercarrier buzz due to incomplete amplitude modulation rejection. Therefore it is vitally important to obtain an accurate setting of the discriminator secondary slug under actual reception conditions.

Disconnect all instruments and then connect an antenna to the receiver to obtain program reception from a local station. If intercarrier buzz is prominent, a slight readjustment of the discriminator secondary slug (#1) should be made to obtain the "dip" point for the buzzing sound. Note that program sound will be clear and free from distortion at this point. Buzz should now be at an acceptable minimum if station transmission is not at fault.

IF CHANNEL ALIGNMENT PROCEDURE

1. A special aligning tool designed to fit the stems on adjustable cores of the IF coils (see points 8, 9, 10 and 11 in Fig. 13) is available and may be obtained from Stewart-Warner by requesting IF Alignment Tool #507479.
2. Turn receiver Channel Selector to television channel #12 and short antenna terminals together with a jumper wire.
3. Remove metal plate which covers side of RF tuner unit nearest edge of chassis. This plate is held in place by two screws on the side of the chassis.
4. Connect a 3 volt battery to the receiver AGC system so that negative terminal of battery connects to the AGC line and positive terminal of battery connects to receiver chassis. See Fig. 14 for convenient point of connection.
5. Note location of IF Trap Coils #12 and #13 by referring to Fig. 14. Before undertaking the alignment of any of the IF stages, Trap Coils #12 and #13 must be detuned so that they do not resonate in the IF pass band. Detuning is accomplished by merely compressing the windings so that they are closely spaced. Failure to detune the Trap Coils can cause the IF system to become regenerative, thereby preventing alignment.
6. If the IF channel is badly misaligned and two or more immediately adjoining IF stages are tuned to the same frequency, oscillation may occur. Such oscillation shows up as a voltage across the video detector load resistor, symbol 139, and is indicated by the VTVM that is connected to this point during alignment. It should be noted

IF CHANNEL ALIGNMENT PROCEDURE

that voltage due to IF oscillation is unaffected by strength of signal from the generator.

Where IF oscillation is encountered, it is generally possible to correct the condition by detuning the IF coils in different directions. If that does not have the desired effect, increase fixed bias on AGC line by using a 4½ volt battery instead of the 3 volt battery referred to in instruction #4. After stopping the oscillation in this manner it will then be possible to align all IF stages using the following procedure, however, the AGC bias battery must be changed back to 3 volts when using the oscilloscope to observe band pass characteristic. Once all stages have been aligned using the 4½ volt bias, the IF channel should be stable with reduced bias.

STANDARD SIGNAL GENERATOR		SWEEP GENERATOR		VTVM CONNECTIONS	OSCILLOSCOPE CONNECTIONS	MISCELLANEOUS INSTRUCTIONS	TRIMMER OR SLUG	TYPE OF ADJUSTMENT AND OUTPUT INDICATION
CONNECTIONS	FREQUENCY	CONNECTIONS	FREQ.					
Connect as shown in Fig. 4.	26.3 MC.	Use a 330 Mmf. isolating condenser and connect as shown in Fig. 4 but keep power switch turned off during this step.	—	Connect as shown in Fig. 5.	Not used.	—	#7 Converter plate coil	Adjust for maximum reading on VTVM.
							#8 2nd I.F.	Adjust for maximum reading on VTVM.
Same as above.	24.5 MC.	Same as above.	—	Same as above.	Not used.	—	#9 4th I.F.	Adjust for maximum reading on VTVM.
Same as above.	23.5 MC.	Same as above.	—	Same as above.	Not used.	—	#10 1st I.F.	Adjust for maximum reading on VTVM.
							#11 3rd I.F.	Adjust for maximum reading on VTVM.
Same as above.	22.4 MC.	Same as above.	—	Same as above.	Not used.	—	#12 1st IF Trap Coil	Adjust the spacing of the Trap Coil windings for MINIMUM reading on VTVM.
Same as above.	22.8 MC.	Same as above.	—	Same as above.	Not used.	—	#13 3rd IF Trap Coil.	Adjust the spacing of the Trap Coil windings for MINIMUM reading on VTVM.
Same as above.	26.75 MC.	With connections made as shown in Fig. 4, turn on this generator and set controls for operation as specified in next column.	25 MC. Sweeping ± 5 Mc.	Same as above.	Connect as shown in Fig. 5	IMPORTANT: 1. Adjust output attenuator on sweep generator so that reading on VTVM is approximately one volt. 2. Set attenuator on standard signal generator so that marker signal does not distort the pattern on the oscilloscope. 3. Be sure that a 3 volt battery is connected to AGC line as specified in instruction #4 at the head of this chart. Do not use a battery of any other voltage.	The IF band pass characteristic now displayed on the 'scope should be compared with the curve shown in Fig. 6. If top of curve is not properly shaped, make a slight readjustment of slug #9. Should that adjustment fail to yield the desired result, then note whether the curve has a peak on the high or low frequency side. Slugs #7 and #8 control high frequency response (26.3 Mc.) and slugs #10 and #11 affect the low frequency response (23.5 Mc.); by making a small change in the settings of the high or low frequency slugs, it will be possible to obtain correct band pass curve.  FIG. 6 The 26.75 Mc. picture IF carrier marker should now appear at the 30% amplitude position on side of the band pass characteristic (see Fig. 6). If position of the marker appears too high or too low, slight readjustment of slugs #7, 8 and 9 is required.	
Same as above.	22.25 MC	Same as above.	Same as above.	Same as above.	Same as above.	Same as above.	Adjust the vertical gain control on the 'scope in order to magnify the sound portion of the response curve. The 22.25 Mc. sound IF carrier marker should appear at the position indicated in Fig. 6. If the position of the sound marker is incorrect, readjust winding spacing of Trap Coils #12 and #13.

RF CHANNEL ALIGNMENT PROCEDURE

1. Replace metal plate which covers exposed terminal side of RF tuner unit. This plate was previously removed for IF channel alignment.

2. Connect a 3 volt battery to the receiver AGC system so that negative terminal of battery connects to AGC line and positive terminal of battery connects to receiver chassis. (See Fig. 14 for convenient point of connection.)

STANDARD SIGNAL GENERATOR		SWEEP GENERATOR		VTVM CONNECTIONS	OSCILLOSCOPE CONNECTIONS	MISCELLANEOUS INSTRUCTIONS	TRIMMER OR SLUG	TYPE OF ADJUSTMENT AND OUTPUT INDICATION
CONNECTIONS	FREQUENCY	CONNECTIONS	FREQ.					
RF AMPLIFIER AND MIXER ALIGNMENT								
Connect as shown in Fig. 10.	*209.75 MC. ‡205.25 MC.	Connect as shown in Fig. 10 and set controls for sweep width of 10 Mc. on television channel specified in the next column.	CHANNEL #12	Not used.	Connect as shown in Fig. 11.	Set Channel Selector to #12 — IMPORTANT: Keep output of standard signal generator at a level that provides a readable marker but does not distort the curve that is being observed on the 'scope.	#14 Mixer Grid. / #15 RF Amp. Plate. / #16 RF Amp. Grid.	Adjust these trimmers to obtain properly shaped RF band pass characteristic as shown in Fig. 7. Use Mixer Grid trimmer #14 and RF Amplifier Plate trimmer #15 to obtain correct amplitude of characteristic in vicinity of picture and sound carrier markers. Then adjust RF Amp. Grid trimmer #16 to equalize overall amplitude. Repeat adjustment of trimmers to be sure correct response has been obtained. IMPORTANT: When adjusting trimmers #14, 15 and 16 it will be noted that the band pass characteristic can be broadened by sacrificing amplitude. It is undesirable to overly broaden the curve as that would result in a loss of sensitivity.
Same as above.	*215.75 MC. ‡211.25 MC.	Same as above.	CHANNEL #13	Not used.	Same as above.	Set Channel Selector to #13		The RF band pass characteristic of the other television channels should now be checked without disturbing the settings of trimmers #14, 15 and 16. Adjust the RF sweep generator and marker generator for operation on the other television channels, observing position of both the sound carrier and picture carrier markers.
	*203.75 MC. ‡199.25 MC.		CHANNEL #11			Set Channel Selector to #11		
	*197.75 MC. ‡193.25 MC.		CHANNEL #10			Set Channel Selector to #10		
	*191.75 MC. ‡187.25 MC.		CHANNEL #9			Set Channel Selector to #9		
	*185.75 MC. ‡181.25 MC.		CHANNEL #8			Set Channel Selector to #8		
	*179.75 MC. ‡175.25 MC.		CHANNEL #7			Set Channel Selector to #7		
	* 87.75 MC. ‡ 83.25 MC.		CHANNEL #6			Set Channel Selector to #6		
	* 81.75 MC. ‡ 77.25 MC.		CHANNEL #5			Set Channel Selector to #5		Band pass characteristic of these channels should conform to the RF response curve in Fig. 7. If necessary, a compromise may be obtained to compensate for small variations in channel response by returning to channel #12 and making slight changes in the settings of trimmers #14, 15 and 16.
	* 71.75 MC. ‡ 67.25 MC.		CHANNEL #4			Set Channel Selector to #4		
	* 65.75 MC. ‡ 61.25 MC.		CHANNEL #3			Set Channel Selector to #3		
	* 59.75 MC. ‡ 55.25 MC.		CHANNEL #2			Set Channel Selector to #2

CONNECTIONS	FREQUENCY	CONNECTIONS	FREQ.					
OSCILLATOR ALIGNMENT								
Connect as shown in Fig. 10.	*209.75 MC. ‡205.25 MC.	Connect as shown in Fig. 10 and set controls for sweep width of 10 Mc. on television channel specified in the next column.	CHANNEL #12	Connect as shown in Fig. 12	Connect as shown in Fig. 12	Set Channel Selector to #12 — Be sure that Fine Tuning control has been properly positioned (tooth on the cam pointing down—see Fig. 8). — During this step and thru-out all succeeding steps it is necessary to: 1. Keep output of sweep generator at a level that does not allow reading on VTVM to exceed one volt. 2. Keep output of standard signal generator at a level that provides a readable marker but does not distort the curve that is being observed on the 'scope.	#17 Oscillator	Adjust height of Oscillator trimmer #17 to be approximately 3/8" from the top of trimmer screw to the top surface of RF tuner unit (see Fig. 8). NOTE: Before making the following adjustment, advance the vertical gain control on the 'scope in order to magnify the sound portion of the response curve. Then, use a non-metallic screwdriver to adjust channel #12 oscillator slug (accessible thru hole on front of RF Tuner Unit—see Fig. 8) and shift response curve so that sound carrier marker is located at the position indicated in Fig. 9. Now, reduce gain control setting of 'scope to restore pattern to normal amplitude and observe position of picture carrier marker. This marker should appear at the 35% amplitude position on the low frequency side of the characteristic curve (see Fig. 9).
Same as above.	*215.75 MC. ‡211.25 MC.	Same as above.	CHANNEL #13	Same as above.	Same as above.	Set Channel Selector to #13		Adjust the RF sweep generator and marker generator for operation on the other television channels; set marker generator to sound carrier frequency. After setting Channel Selector to corresponding channel, adjust oscillator slug thru hole on front of RF Tuner Unit (see Fig. 8). This permits response curve to be shifted so that sound carrier marker will appear at the position indicated in Fig. 9. The picture carrier marker for the corresponding channel should then appear at the 35% amplitude position on the opposite side of the band pass characteristic curve. NOTE: Make sure that cam on fine tuning control shaft remains properly positioned during this step (tooth on the cam pointing downward—see Fig. 8).
	*203.75 MC. ‡199.25 MC.		CHANNEL #11			Set Channel Selector to #11		
	*197.75 MC. ‡193.25 MC.		CHANNEL #10			Set Channel Selector to #10		
	*191.75 MC. ‡187.25 MC.		CHANNEL #9			Set Channel Selector to #9		
	*185.75 MC. ‡181.25 MC.		CHANNEL #8			Set Channel Selector to #8		
	*179.75 MC. ‡175.25 MC.		CHANNEL #7			Set Channel Selector to #7		
	* 87.75 MC. ‡ 83.25 MC.		CHANNEL #6			Set Channel Selector to #6		
	* 81.75 MC. ‡ 77.25 MC.		CHANNEL #5			Set Channel Selector to #5		
	* 71.75 MC. ‡ 67.25 MC.		CHANNEL #4			Set Channel Selector to #4		
	* 65.75 MC. ‡ 61.25 MC.		CHANNEL #3			Set Channel Selector to #3		
	* 59.75 MC. ‡ 55.25 MC.		CHANNEL #2			Set Channel Selector to #2		

1. IMPORTANT: Before undertaking oscillator alignment be sure IF circuits are correctly aligned for band pass characteristic illustrated in Fig. 6.

2. During oscillator alignment, it is necessary to set the Fine Tuning control so that the tooth on the bakelite fine tuning cam points downward (correct position for this control is shown in Fig. 8).

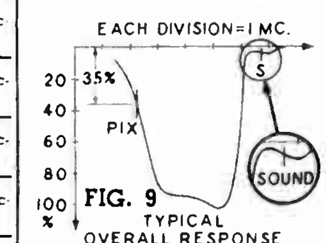

FIG. 9

If an oscillator slug "falls into" its coil form during adjustment, remove the Channel Coil from the turret assembly and lift the Slug Retaining Spring aside. By tapping the coil form it should be possible to make the slug move toward the end so that its threads will be engaged by the Slug Retaining Spring when that spring is returned to its normal position.

If an unsatisfactory overall response is obtained for a particular channel, observe RF Amp. and Mixer response curve for that channel (as described on page 31.) If characteristic does not conform reasonably well with the typical curve shown in Fig. 7, then, (1) attempt to obtain a better compromise for RF response on all channels by realigning RF Amp. and Mixer circuits, or (2) try replacing Antenna, RF and Oscillator coils for the particular channels.

275	510193	Resistor—carbon 2.2 Meg. ½ watt
276	510338	Resistor—carbon 1200 Ohms ± 10% 2 watt
357	510179	Resistor—carbon 220,000 Ohms ½ watt
362	510136	Resistor—carbon 1000 Ohms ± 10% ½ watt

CONTROLS

DIAGRAM NO.	PART NO.	DESCRIPTION
33-A,B	508054	Volume control (1 Meg.) (with switch)
54	508324	Built-in Antenna Tuning Condenser (4-70 Mmfd)
88	*	Fine Tuning condenser (3-5 Mmfd.)
160	508055	Contrast potentiometer (3000 Ohms ± 10% 2 w.)
173	508056	Brightness potentiometer (50,000 Ohms)
180	508057	Focus potentiometer (5500 Ohms ± 10% 4 watt)
202	508077	Horizontal Lock coil (less slug)
202	507429	Slug core for Horizontal Lock coil
208	508056	Horizontal Hold potentiometer (50,000 Ohms)
212	508071	Horizontal Drive trimmer condenser (10-160 Mmfd)
225	508667	Width coil (includes slug and clip)
225	508784	Slug core for Width coil
233	162190	Horizontal Linearity coil (includes slug and clip)
233	507429	Slug core for Horizontal Linearity coil
266	508051	Vertical Hold potentiometer (1 Meg.)
270	508052	Height potentiometer (2.5 Meg.)
277	508053	Vertical Linearity potentiometer (6000 Ohms)

COILS AND TRANSFORMERS

DIAGRAM NO.	PART NO.	DESCRIPTION
12	508061	Transformer—1st TV sound I.F. (includes condensers 12-A and 12-B)
15	507373	Coil—choke
18	508061	Transformer—2nd TV sound I.F. (includes condensers 18-A and 18-B)
26	507321	Transformer—TV sound discriminator (includes condenser 26-A)
26	508438	Slug core (5/16" dia. x ⅜" long) for primary of TV sound discriminator trans.
26	508894	Slug core (¼" dia. x ½" long) for primary of TV sound discriminator trans.
26	508439	Slug core (5/16" dia. x ¾" long) for secondary of TV sound discriminator trans.
26	508894	Slug core (¼" dia. x ½" long) for secondary of TV sound discriminator trans.
37	507373	Coil—choke
49	505912	Transformer—sound output

78	507977	Coil—R.F. and osc.; Channel #7
79	507978	Coil—R.F. and osc.; Channel #8
80	507979	Coil—R.F. and osc.; Channel #9
81	507980	Coil—R.F. and osc.; Channel #10
82	507981	Coil—R.F. and osc.; Channel #11
83	507982	Coil—R.F. and osc.; Channel #12
84	507983	Coil—R.F. and osc.; Channel #13
	507986	Slug for osc. coil fine tuning adjustment
98	509061	Coil—converter plate (I.F.)
98	509062	Slug core for converter plate coil
103	507567	Coil—1st I.F. trap
107	507343	Coil—1st video I.F. (less slug)
107	507337	Slug core for 1st video I.F. coil
115	507343	Coil—2nd video I.F. (less slug)
115	507357	Slug core for 2nd video I.F. coil
125	507343	Coil—3rd video I.F. (less slug)
125	507357	Slug core for 3rd video I.F. coil
128	507367	Coil—choke
134	507591	Coil—4th video I.F. assembly (includes condenser 136 and choke coil 137)
134	507357	Slug core for 4th video I.F. coil
137	507367	Coil—choke
143	507374	Coil—peaking
152	507374	Coil—peaking
161	508069	Coil—peaking
163	508070	Coil—peaking
181	509035	Coil—focus
184	508675	Yoke—picture tube deflection
202	508077	Coil—Horizontal Lock (less slug)
202	507429	Slug core for Horizontal Lock coil
222	508883	Transformer—horizontal sweep (used in "Uncoded" chassis)
222	509055	Transformer—horizontal sweep (used in "Series A" chassis)
225	508667	Coil—Width (includes slug and clip)
225	508784	Slug core for Width coil
233	162190	Coil—Horizontal Linearity (includes slug and clip)
233	507429	Slug core for Horizontal Linearity
239	508702	Transformer—power
241	507586	Coil—choke
244	507587	Coil—choke
248	507584	Coil—choke
253	508341	Choke filter
254	507584	Coil—choke
255	507970	Coil—choke
257	507971	Coil—choke
259	507586	Coil—choke
263	508076	Transformer—vertical blocking oscillator
271	507567	Coil—3rd I.F. trap
278	508674	Transformer—vertical output

OTHER ELECTRICAL PARTS

DIAGRAM NO.	PART NO.	DESCRIPTION
51	508174	Speaker—P.M. Dynamic (6" x 9"); Model 9109-A
51	508157	Speaker—P.M. Dynamic (6"); Model 9109-B
53	508325	Built-in antenna (includes condenser 54)
127	505858	Audio coupling unit A—Resistor—carbon 470,000 Ohms 1/5 watt B—Condenser—ceramic 250 Mmfd. 450 volt C—Condenser—ceramic .005 Mfd. 450 volt D—Resistor—carbon 470,000 Ohms 1/5 watt
221	508713	Fuse for horizontal sweep circuit ¼ Amp. 250 volt
261	118921	Lamp—TV Channel Lite (Mazda #47) 6-8 V. 150 Mo.
262-A to G	508062	Integrator coupling unit A—Condenser—ceramic .01 Mfd. 450 volt B—Resistor—carbon 22,000 Ohms 1/5 watt C—Condenser—ceramic 2000 Mmfd. 450 volt D—Resistor—carbon 8200 Ohms 1/5 watt E—Condenser—ceramic 5000 Mmfd. 450 volt F—Resistor—carbon 8200 Ohms 1/5 watt G—Condenser—ceramic 5000 Mmfd. 450 volt

MECHANICAL PARTS OF R.F. TUNER

(for electrical parts see preceding classified listings of condensers, resistors and coils)

PART NO.	DESCRIPTION
508805	R.F. Unit complete with coils and tubes
508081	Bracket for mtg. tuner (front)
508082	Bracket for mtg. tuner (rear)
508437	Fine Tuning cam and brass shaft
508708	Roller—detent
507989	Shield—tube; miniature (fits solid ring type clip)
505367	Shield—tube; miniature (fits wing type clip)
509062	Slug core for converter plate coil
507986	Slug for osc. coil fine tuning adjustment
507987	Socket—miniature (for 6J6) (includes solid ring type clip for shield)
509065	Socket—miniature (for 6J6) (includes wing type clip for shield)
507988	Socket—miniature (for 6AG5) (includes solid ring type clip for shield)
509066	Socket—miniature (for 6AG5) (includes wing type clip for shield)
507966	Spring contactor washer (on front turret shaft)
508709	Spring—detent
507990	Spring—retains osc. fine tuning slug
507967	Spring—turret shaft retaining
507984	Stator contact assembly (includes 11 contacts and metal frames)
508707	Tuner turret and shaft assembly (less coils)
507965	Washer, fiber spacer (turret shaft)

CABINET PARTS

PART NO.	DESCRIPTION
508855	Back for cabinet; Model 9109-A (less power cord)
508857	Back for cabinet; Model 9109-B (less power cord)
507783	Bottom plate for Model 9109-B
508640	Cabinet for Model 9109-A
508720	Cabinet for Model 9109-B
507930	Call letter tabs
508159	Escutcheon—control panel
508852	Glass window
502563	Knob—built-in antenna
507916	Knob—Channel Selector
509205	Knob—Dummy
507918	Knob for any control except Channel Selector and Fine Tuning
507917	Knob—TV Fine Tuning
508853	Mask for picture tube
508854	Name plate for Model 9109-A (Royal De Luxe 14)
508858	Name plate for Model 9109-B (Super De Luxe 14)
508621	Rubber gasket between mask and picture tube
162163	Terminal strip for TV antenna connection
18796	Screw—#10 x 1"; mounts chassis
162016	Shaft and mounting plate for Dummy knob

MISCELLANEOUS

PART NO.	DESCRIPTION
301270	Base for mounting electrolytic condenser
508829	Bracket base for support of yoke and focus coil (left hand)
508830	Bracket base for support of yoke and focus coil (right hand)
508613	Bracket for deflection yoke mounting
508081	Bracket for mounting R.F. tuner (front)
508082	Bracket for mounting R.F. tuner (rear)
508832	Bracket—tube support (bottom front) (less rubber pad)
508834	Bracket ("U" shaped) for support of yoke and focus coil
507930	Call letter tabs
508806	Centering magnet assembly
508681	Clip for mounting electrolytic condenser #224
508683	Clip for mounting electrolytic condenser #129
508715	Clip for mounting fuse holder
500245	Clip for mounting H.V. condenser
505101	Clip for mounting I.F. sound transformer
507339	Clip for mounting video converter plate, 1st video I.F., 2nd video I.F., 3rd video I.F., Horizontal Lock or Horizontal Linearity coil
507592	Clip for mounting 4th video I.F. coil
507286	Connector for H.V. terminal of picture tube
508714	Fuse holder
508623	Grounding spring for coating on picture tube
508603	Ion trap
508617	Nut—for retaining focus coil mounting plate
508864	Plate—mounts focus coil
509089	Plate—mounts horizontal sweep transformer (used in "Series A" chassis)
508878	Plug for focus coil leads
507699	Power cord assembly (includes plugs at both ends)
507361	Rubber cover for H.V. terminal connector
508619	Rubber spacer on picture tube support bracket
507793	Rubber spacer support between flared neck of picture tube and yoke bracket
18796	Screw—#10 x 1"; mounts chassis
170182	Screw—#10-32 x 1½"; retains tube support strap
162138	Shield—H.V. supply (front section)
508088	Shield—H.V. supply (rear section)
507357	Slug core for 1st, 2nd, 3rd or 4th video I.F. coil
507429	Slug core for Horizontal Lock or Horizontal Linearity coil
508438	Slug core (5/16" dia. x ⅜" long) for primary of TV sound discriminator transformer
508894	Slug core (¼" dia. x ½" long) for primary of TV sound discriminator transformer
508439	Slug core (5/16" dia. x ¾" long) for secondary of TV sound discriminator transformer
508894	Slug core (¼" dia. x ½" long) for secondary of TV sound discriminator transformer
508784	Slug core for Width coil
508049	Socket and cable assembly for picture tube
508156	Socket and mounting bracket for TV Channel Lite
162038	Socket assembly for 1B3GT/8016 tube (includes corona ring and mounting frame)
508879	Socket for focus coil leads
508086	Socket for mounting H.V. condenser #230
507932	Socket—male, power cord interlock
507364	Socket—miniature (7 pin)
508044	Socket—miniature (9 pin)
508703	Socket—octal
508514	Spring—retains H.V. lead
508608	Spring—tension for focus coil mounting
509034	Strap for picture tube support (includes rubber pad)
170851	Wing nut—#5-40; for mounting focus coil to plate
170195	Wing nut—#8-32; for yoke and focus coil mounting
170817	Wing screw—#10-24; for height adj. of yoke and focus coil
170741	Wing screw—#10-32; for yoke mounting

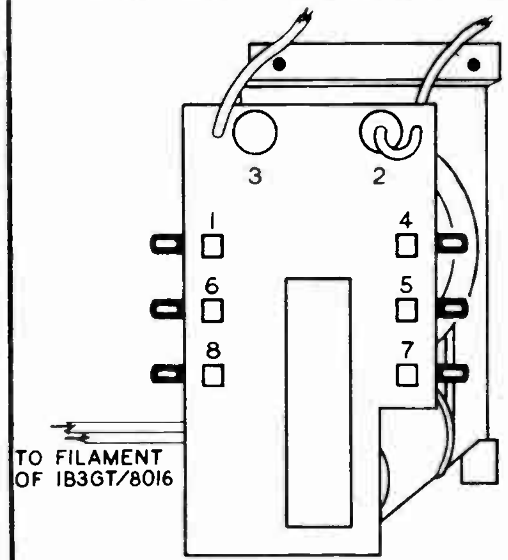
PRODUCTION CHANGES

The following tabulation furnishes complete details on changes which occurred during production. Sequence of these changes is indicated by coding in alphabetical order; that is, "SERIES A" "SERIES B", etc., stamped on back surface of chassis.

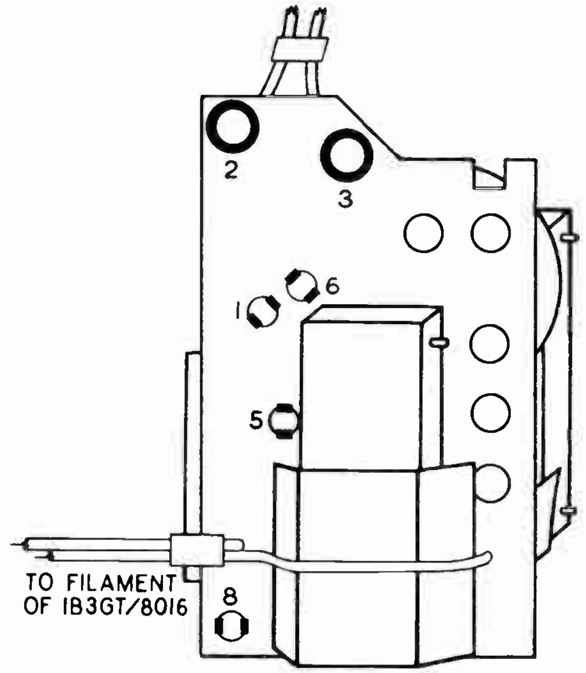
The circuit shown on this page applies to "series A" chassis.

CHANGE DESIGNATION STAMPED ON CHASSIS	DESCRIPTION OF CHANGE
UNCODED	**INITIAL PRODUCTION**—All uncoded chassis utilized a horizontal scanning output circuit as shown below. Conversion of this circuit arrangement to the type used in "Series A" chassis (illustrated in complete wiring diagram) was undertaken so as to permit use of a Horizontal Sweep Transformer produced by a different supplier. Identification of the two alternate type Sweep Transformers can be accomplished by means of the two illustrations at the bottom of this page. It should be understood that there is no performance advantage of a "Series A" chassis over an "Uncoded" chassis—the sweep circuit and associated transformer in either chassis performs equally well.  **CAUTION**—Note that a type 6BQ6GT output tube must be used with the sweep transformer incorporated in "Uncoded" chassis and a type 6CD6G output tube must be used with the alternate type transformer in "Series A" chassis. Do not attempt indiscriminate substitution of these tubes—it is vitally important to use the correct output tube and sweep transformer combination.
SERIES "A"	The differences between chassis containing the "Series A" coding and the "Uncoded" chassis described above are solely concerned with the use of an alternate type horizontal sweep output transformer and power output tube (see preceding explanation). Details on these differences are as follows:

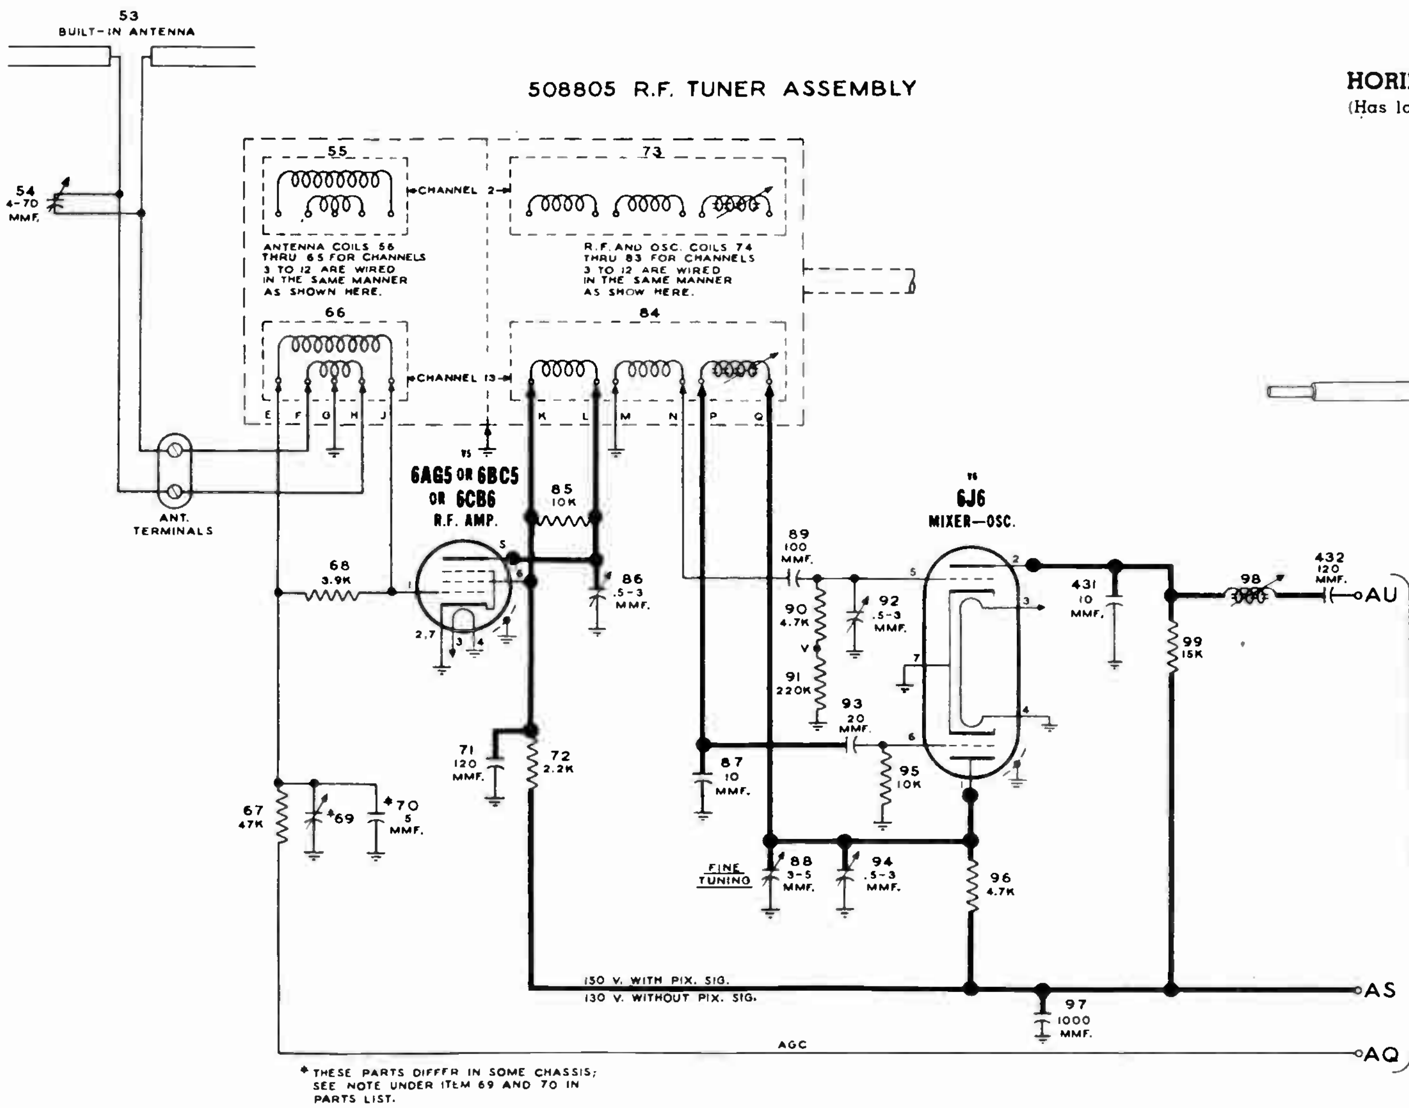
	"UNCODED"	"SERIES A"
Output Tube	6BQ6T	6CD6G
Horizontal Sweep Transformer	Part #508883	Part #509055
Resistor 218	82 Ohms 2 watt.	220 Ohms, wire wound 5 watt.
Condenser 219	Low potential side grounded.	Low potential side connected to cathode of V20.
Resistor 220	15,000 Ohms 2 watt.	12,000 Ohms 2 watt.
Condenser 223	3.3 Mmfd.; one terminal connects to terminal 8 of Horizontal Sweep Transformer and other terminal connects to junction of Resistors 213 and 215.	15 Mmfd.; one terminal connects to terminal 5 of Horizontal Sweep Transformer and other terminal is in series with condenser 430.
Condenser 430	Not used.	Connected in series with condenser 223 and other terminal connects to junction of Resistors 213 and 215.
Resistor 228	3.3 Ohms.	Not used. Pin 7 (filament) of V21 1B3GT/8016 connects directly to filament winding of Horizontal Sweep Transformer.
Yoke Connection	Terminal 1 of deflection yoke connects to terminal 8 of Horizontal Sweep Transformer.	Terminal 1 of deflection yoke connects to terminal 5 of Horizontal Sweep Transformer.



508883
HORIZONTAL SWEEP TRANSFORMER
(Has molded powdered iron core)



509055
HORIZONTAL SWEEP TRANSFORMER
(Has laminated iron core and entire unit is coated with grey Hollowax)



* THESE PARTS DIFFER IN SOME CHASSIS; SEE NOTE UNDER ITEM 69 AND 70 IN PARTS LIST.

INDEX

INSTALLATION INSTRUCTIONS

MODEL 9113-A
12" PIX TUBE

CAUTION

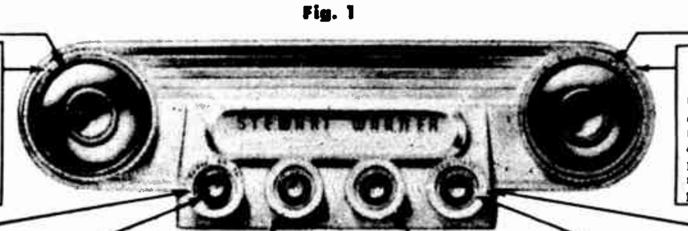
HIGH VOLTAGES are used in the operation of this receiver. The back cover, while in place, prevents accidental contact with this voltage and therefore should not be removed by anyone except a qualified television serviceman.

THE HIGH VOLTAGE LEAD, which supplies 10 to 12 kilovolts to the picture tube, should be momentarily shorted to the chassis whenever it is disconnected for service purposes. This discharges the high voltage filter condenser and prevents a shock hazard when working on the receiver after it has been turned off.

THE PICTURE TUBE is highly evacuated and if broken, glass fragments will be violently expelled. Scratching, chipping, undue pressure, or careless handling such as lifting the tube by its neck is dangerous and should be avoided. If it is necessary to handle the picture tube, use safety goggles and heavy gloves. Be sure to discharge the voltage developed across the capacitor formed by the inner and outer coating of the picture tube. This can be done by connecting the high voltage socket on the tube to the outer coating.

RECEIVER OPERATING CONTROLS

Fig. 1



AM-FM FINE TUNING CONTROL (outer knob)
Use to tune receiver to desired station after Band Switch is set to either "AM" or "FM" position.

AM-FM COARSE TUNING CONTROL
Has same effect as "AM-FM Fine Tuning" control except that tuning is faster.

BAND SWITCH (large knob)
Set for desired type of reception. Starting from extreme clockwise position and turning counter-clockwise, the four settings are: (Television); (Phonograph); ("AM" Radio); and ("FM" Radio).

ON-OFF SWITCH AND VOLUME CONTROL (small knob)
Use to turn receiver on or off and to adjust for desired sound volume.

HORIZONTAL HOLD CONTROL
Adjust so that picture is stationary and does not move horizontally or break up into black and white streaks.

BRIGHTNESS CONTROL
Adjust for picture brilliance. Re-adjust after setting "Contrast" control.

TONE CONTROL (small knob)
Adjust for most pleasing tone. To increase bass emphasis, turn control counter-clockwise.

CONTRAST CONTROL (large knob)
Adjust to receive picture and obtain correct contrast between light and dark shades.

TELEVISION FINE TUNING CONTROL
Use to tune in station after "Channel Selector" is set to desired channel. See next page for complete description of tuning procedure.

CHANNEL SELECTOR (outer knob)
Set knob so that desired channel designation appears in illuminated opening (after Band Switch is set for "TV" operation). Then use "Fine Tuning" control to tune in station.

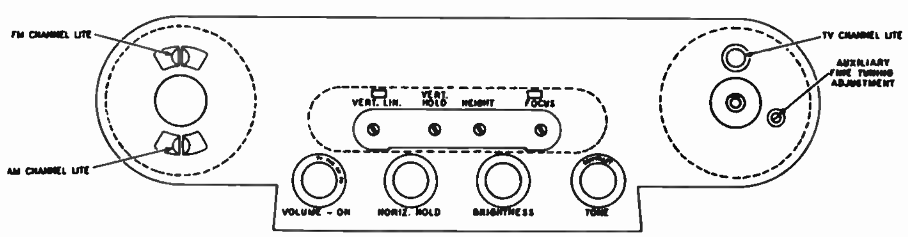


Fig. 14—LOCATION OF PRE-SET CONTROLS

CONTROL ADJUSTMENT PROCEDURE

The various controls on the receiver may be divided into two classes, Operating and Pre-set. Operating controls are those which control program selection as well as sound and picture quality and their functions are indicated in Fig. 1.

The Pre-set controls are those which require adjustment at the time the receiver is installed and they rarely need attention thereafter. Although they have been factory adjusted for optimum performance, it is usually necessary to make some fine adjustments of these controls at the time of installation.

There are nine Pre-set controls, four of which are located at the back of the chassis (see Figure 18). Four controls are accessible by removing the Name Plate located directly above the Operating controls. Access to the "Auxiliary Fine Tuning" screw can be gained by removing the "Channel Selector" and "Fine Tuning" knobs.

To gain access to the centering adjustments and ion trap, it will be necessary to remove the back cover of the cabinet by first removing the built-in antenna tuning knob and then taking out the screws around the rim of the back cover.

Removal of the cabinet back automatically opens an interlock to disconnect the receiver power cord. Centering and ion trap adjustments will require access to circuit components while the receiver is in operation, therefore an auxiliary power cord assembly will be needed. This cord may be ordered from Stewart-Warner by requesting Part #507699.

Operate the receiver according to the instructions given in the section of this manual entitled "How To Tune The Receiver" and make the following adjustments as required.

1. **ADJUST ION TRAP**—If screen remains dark or is only dimly illuminated when "Brightness" control is turned clockwise, the ion trap may require adjustment.

   The ion trap is located on the neck of the picture tube as shown in Figure 18 and consists of two magnets held in position by metal bands. The magnet identified by the **black** band must be in the rear position.

   Rotate the entire trap assembly while sliding it back and forth until picture tube screen is illuminated to maximum brilliance. Reduce "Brightness" control setting and repeat this operation to assure accurate positioning of ion trap.

2. **AUXILIARY FINE TUNING ADJUSTMENT**—If it is found that the tuning range of the "Television Fine Tuning" control is inadequate to permit correct tuning of a station in its assigned channel, then adjustment of the "Auxiliary Fine Tuning" screw will be necessary. This special screw is accessible after removal of the "Channel Selector" and "Television Fine Tuning" knobs. They may be removed by merely pulling them forward.

   Adjustment of the "Auxiliary Fine Tuning" screw may now be undertaken in accordance with the following procedure.

   a. Set "Channel Selector" to desired channel; then remove this knob.

   b. Set "Television Fine Tuning" knob to the center of its range; then remove this knob. The flat portion of the main tuning shaft (outer brass shaft) should now be in the uppermost position. Note the location of the "Auxiliary Fine Tuning" adjustment screw on receiver chassis—see Fig. 14.

   c. Using a thin screwdriver (preferably non-metallic), adjust the setting of "Auxiliary Fine Tuning" screw for correct tuning of the desired television station—**CAUTION: Do not attempt to rotate this screw more than two full turns in either direction, as further rotation may release it from the thread clip within the tuning mechanism and the coil for that channel (located in R.F. Tuner Unit) would then have to be removed in order to restore the screw to the correct position.** If a metal screwdriver is used, detuning occurs when the screwdriver is removed but it will be noted that this degree of detuning can now be compensated by resetting the "Fine Tuning" control (brass shaft). Thus the range of the "Fine Tuning" control (after knob is replaced on the shaft) will be adequate to tune in the station.

   d. This completes the adjustment of the "Auxiliary Fine Tuning" screw for one channel. Identical screws are provided on each channel **and they are all accessible thru the same opening in the tuning mechanism as each successively moves into position when the "Channel Selector" knob is rotated.**

3. **HORIZONTAL HOLD—Should the picture appear to move horizontally across the screen or break up into a series of light and dark streaks as shown in Figure 3, adjust the "Horizontal Hold" control until the picture remains stationary.**

   If this control must be rotated to the end of its range for proper "locking" action, then it will be necessary to reset the position of the "Horizontal Lock" control (see Figure 18 for location). Adjustment is accomplished by first setting the "Horizontal Hold" control in the middle of its range and then changing the setting of the "Horizontal Lock" control until picture locks in horizontally.

4. **VERTICAL HOLD**—**Should the picture appear to roll by in a vertical direction or cause multiple vertical images as shown in Figure 15, it will be necessary to adjust the "Vert. Hold" control located behind the Name Plate (see Figure 14).**

   After this adjustment is made, reduce contrast until picture is barely visible and check setting of "Vertical Hold" control for proper picture synchronization.

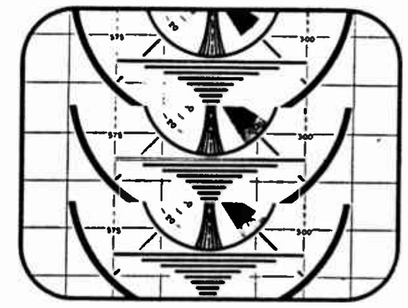

Fig. 15—VERTICAL MOVEMENT; ADJUST VERTICAL HOLD CONTROL

5. **INITIAL FOCUS—Adjust the "Focus" control, located behind Name Plate, until picture is clearly defined.**

   Fuzzy picture may also be due to reproduction of poor quality film when station is televising a motion picture. Incorrect tuning of receiver produces a similar effect. Check for proper tuning point as described in step 7 of section entitled "How To Tune the Receiver."

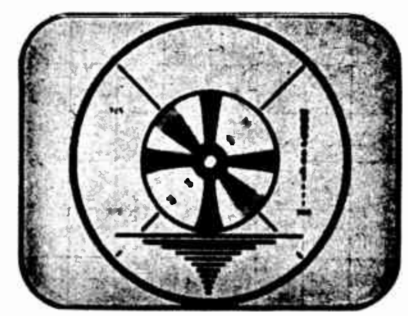

Fig. 16—BLURRED APPEARANCE; ADJUST FOCUS CONTROL

©John F. Rider

World Radio History

6. **STRAIGHTENING TILTED RASTER**—If the pattern should appear on the screen in a tilted position as shown in Figure 17, loosen the deflection yoke locking screw (see Figure 18) and rotate the yoke sufficiently to correct this condition. Be sure to re-tighten the screw securely.

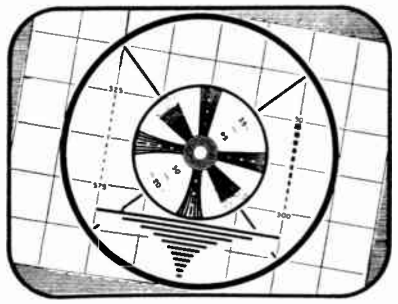

Fig. 17—TILTED PICTURE; ADJUST YOKE POSITION

The following adjustments should be made while the station is transmitting its circular test pattern.

7. **CENTERING:** To center the test pattern on the screen, proceed as follows:

a. Make sure focus coil mounting plate is perpendicular to neck of picture tube by adjustment of three nuts labeled A in Figure 18.

b. Rotate the two magnets in the centering magnet assembly (see Fig. 18). These magnets may be adjusted by grasping the "ears" attached to each magnet and rotating the magnets with respect to each other and with respect to the picture tube. Adjust the magnet position for best centering of the test pattern.

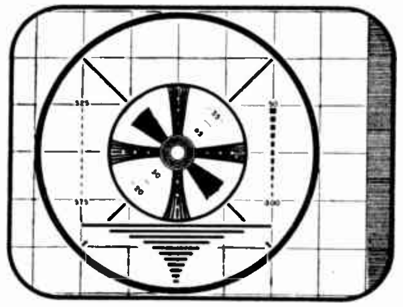

Fig. 19—OFF CENTER; ADJUST FOCUS COIL POSITION

c. If picture is still not centered, loosen four focus coil wing nuts labeled B in Fig. 18 and rotate focus coil for best centering of test pattern.

d. Readjust ion trap for maximum brightness on picture tube screen as explained in step #1.

e. If picture is still not centered, position focus coil by adjusting the three nuts labeled A in Fig. 18.

In event picture cannot be centered by above procedures, release the four wing nuts labeled D in Fig. 18 and raise or lower entire yoke and focus coil assembly so that focus coil can be repositioned vertically with respect to the tube neck.

8. **WIDTH** — Control of picture size in the horizontal direction is accomplished by means of the "Width" control located on the rear of H. V. power supply (see Fig. 18). If abnormally low line voltage makes it difficult to obtain sufficient picture width when using the "Width" control, then changing the setting of the "Horizontal Drive" control may be helpful. The "Drive" control is located at the rear of the chassis and its setting will affect horizontal linearity as well as picture width. Therefore, after adjusting this control for desired width, it may be necessary to re-adjust the "Horizontal Linearity" control as described in paragraph #12.

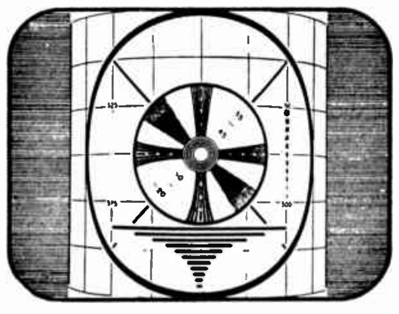

Fig. 20—TOO NARROW; ADJUST WIDTH CONTROL

9. **HEIGHT** — Control of picture size in the vertical direction is accomplished by means of the "Height" control located behind the Name Plate. Height and width adjustments should be checked for all transmitting stations to be sure that picture properly fills the viewing area. It may be necessary to change the setting of the "Height" control after the "Vertical Linearity" control is adjusted.

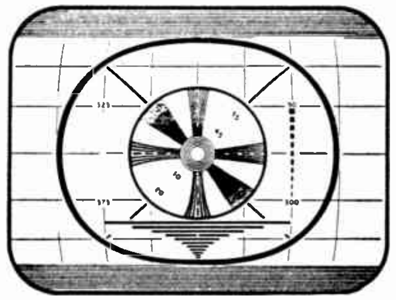

Fig. 21—TOO SHORT; ADJUST HEIGHT CONTROL

10. **VERTICAL LINEARITY** — Improper vertical linearity causes the circular test pattern to appear condensed on the upper edge of the screen and extended on the lower edge or vice versa. This effect is illustrated in Figure 22. Adjust for proper linearity by using "Vert. Lin." control located behind Name Plate. It may be necessary to readjust the "Height" control if an appreciable change is made in the linearity control setting.

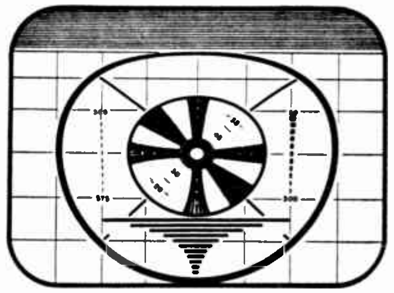

Fig. 22—VERTICAL DISTORTION; ADJUST VERTICAL LINEARITY CONTROL

11. **HORIZONTAL DRIVE** — The "Horizontal Drive" control located at rear of chassis (see Fig. 18) should be rotated clockwise to the point where any white (or black) vertical lines near the left side of the picture are eliminated. As width and linearity of the picture are affected by the setting of "Horiz. Drive" control, it will be necessary to adjust this control in conjunction with the Horiz. Linearity and Width controls to obtain desired picture width and linearity.

12. **HORIZONTAL LINEARITY** — Improper horizontal linearity causes the circular test pattern to appear condensed on the right edge of the screen and extended on the left edge or vice versa. This effect is illustrated in Figure 23. Adjust for proper linearity by using "Horiz. Lin." control located at rear of chassis (see Figure 18). In event that proper horizontal linearity cannot be obtained by adjusting this control, then change the setting of the "Horiz. Drive" control.

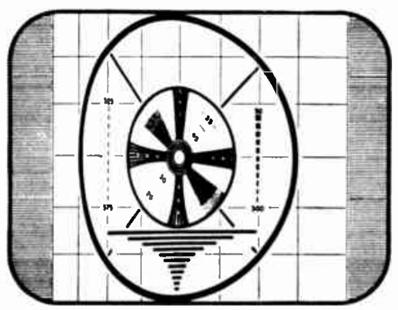

Fig. 23—HORIZONTAL DISTORTION; ADJUST HORIZONTAL LINEARITY CONTROL

13. **ELIMINATING SEMI-CIRCULAR SHADOW** — This shadow is caused by the electron stream striking the neck of the tube and it can generally be corrected by applying one or a combination of the following procedures:

a. Make sure deflection yoke is positioned as far forward as possible by loosening the three wing nuts labeled C in Fig. 18.

b. Reposition the focus coil by readjusting the three nuts labeled A in Fig. 18 to shift the coil forward.

c. In event neck shading cannot be eliminated by the above procedures, release the four wing nuts labeled D in Figure 18 and raise or lower entire yoke and focus coil assembly so that focus coil can be repositioned vertically with respect to the tube neck.

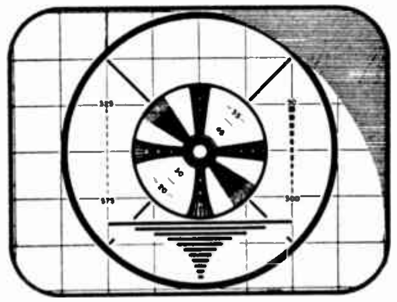

Fig. 24 SEMI-CIRCULAR SHADOW

14. **FINAL ADJUSTMENTS** — Recheck settings of "Brightness," "Contrast" and "Focus" controls for best picture quality.

GENERAL SPECIFICATIONS

DIMENSIONS

Model	Height	Width	Depth
9113-A	36¾"	26¼"	20¾"

WEIGHTS (packed)

Model 9113-A—138 lbs.

POWER REQUIREMENTS

117 volts 60 cycles
Television—230 watts
AM-FM Radio—145 watts

PICTURE SIZE

Height	Width (at widest point)	Viewing Area (sq. inches)
9"	11"	91.6

SPEAKER

Type	Size	V.C. Imped.
P.M. Dynamic	6" x 9"	3.2 ohms

ANTENNA INPUT IMPEDANCE

300 ohms—balanced to ground.

BUILT-IN ANTENNA

High "Q" dipole with tunable matching stub.

R. F. TUNER

Turret type construction; individually removable coil assemblies for all channels. All components are easily accessible for servicing.

"KEYED" AUTOMATIC GAIN CONTROL

Outstanding new development; minimizes "airplane flutter"; reduces contrast variation when changing from one channel to another; increases immunity of sync system to external interference.

World Radio History

INTERMEDIATE FREQUENCIES

AM Sound—455 Kc.
FM Sound—10.7 Mc.
TV Sound Carrier—22.25 Mc.
Picture Carrier—26.75 Mc.

I.F. SYSTEM

AM—One stage (two tuned transformers)
FM—Two stage (three tuned transformers)
TV—Four stage (stagger tuned) for composite signal, and two additional stages for inter-carrier sound.

VIDEO AMPLIFIER

Two Stage—broad band.

RETRACE LINE SUPPRESSOR

Eliminates retrace lines thruout the normal range of picture brightness and contrast.

FOCUS

Magnetic

DEFLECTION

Magnetic

HORIZONTAL SYNCHRONIZATION

Automatic frequency control and "keyed" A.G.C. provide excellent picture stability and noise immunity.

HIGH VOLTAGE POWER SUPPLY

"Fly-back" type. Completely enclosed in a shielded compartment.

SENSITIVITY

Antenna to Picture Tube Grid Sensitivity — To make this measurement, connect negative terminal of 1½ volt battery to A.G.C. line, and positive terminal of battery to chassis. Also, set Contrast control to maximum clockwise position. Connect an **A.C.** vacuum-tube voltmeter between picture tube grid and ground, and place a .005 microfarad condenser across the same points.

Inject R.F. signal (400 cycle modulated) at antenna terminals, using signal whose frequency corresponds to the center frequency of the selected channel, and adjust Television Fine Tuning control for maximum output. Generator must be connected to antenna terminals with a 150 ohm carbon resistor in series with each lead to simulate proper impedance match.

Input signal required to produce standard output of 7.07 volts **A.C.** (r.m.s.) at picture tube grid is indicated in the following table. Since a fixed bias of 1½ volts has been applied to the A.G.C. system in order to provide a reference level for these measurements, it will be understood that the sensitivities specified here are not intended to indicate the full capability of the receiver, but merely serve as a convenient basis for determining proper operation.

Low Band	Average—50 microvolts	Range—25 to 100 microvolts
High Band	Average—80 microvolts	Range—40 to 160 microvolts

Detector to Picture Tube Grid Sensitivity — To make this measurement, remove 6AU6, 4th Video I.F. tube (V-10) and set Contrast control to maximum clockwise position. Inject a 400 cycle (audio) signal across 6800 ohm video detector load resistor. In order to produce the standard output of 7.07 volts **A.C.** (r.m.s.) at the picture tube grid, the input signal at the detector load resistor will be approximately .07 volts **A.C.** An **A.C.** vacuum-tube voltmeter must be used for these measurements.

Television Sound System Sensitivity—Inject 4.5 megacycle frequency modulated signal (400 cycle modulation with 7½ Kc. deviation) across video detector load resistor and measure output at speaker voice coil. An input of 2200 microvolts will produce approximately 500 milliwatts or 1.26 volts across speaker voice coil.

F.M. Sound System Sensitivity—Inject a 98 megacycle frequency modulated signal (400 cycle modulation with 22½ Kc. deviation) at pin 8 of 12AT7, F.M. R.F. Amplifier tube (V-27). Connect generator to this point through a 300 ohm resistor. Tune receiver to 98 Mc. signal. An input of 35 microvolts will produce approximately 500 milliwatts or 1.26 volts across speaker voice coil.

A.M. Sound System Sensitivity—Inject a 1000 Kc. signal (modulated 30% at 400 cycles) at (high side) connection lug on antenna section of gang condenser. Connect generator to this point through a .01 microfarad condenser. Tune receiver to 1000 Kc. signal. An input of 75 microvolts will produce approximately 500 milliwatts or 1.26 volts across speaker voice coil.

REDUCTION OF INTERCARRIER BUZZ

If a prominent humming or buzzing sound is noted in the sound reception of a television broadcast, it may be due to a fault in transmission from the station, or incorrect adjustment of the discriminator transformer (tuning of secondary circuit) in the receiver.

This type of disturbance, which is only present when receiving a station signal, is known as "Intercarrier Buzz" and it should not be confused with power supply hum that would occur upon failure of a filter condenser.

The procedure for correct adjustment of the television sound discriminator circuit is presented in the last section of the Television Sound Channel alignment instructions. When the discriminator secondary slug #1 is properly adjusted, intercarrier buzz will be reduced to an acceptable minimum, provided that the transmission from the station is not at fault.

HIGH VOLTAGE POWER SUPPLY SERVICING

The High Voltage Power Supply used with this receiver is of the "fly-back" type and is located in the shielded compartment mounted at the left rear corner of the chassis. It consists of a sturdily constructed and well insulated horizontal sweep output transformer plus a 1B3GT/8016 high voltage rectifier tube and associated filter components.

The plate circuit of the Horizontal Scanning Output stage is fused to protect the transformer and kill high voltage in the event the 6BQ6GT tube or the high voltage rectifier circuit draws excessive current.

CAUTION

The heavily insulated red lead, which supplies extremely high voltage (10 to 12 kilovolts) to the picture tube, should be momentarily shorted to the chassis whenever it is disconnected for service purposes (that is, after receiver has been turned off). This discharges the high voltage filter condenser and prevents a shock hazard when working on the set.

Access to the horizontal output transformer, high voltage rectifier tube, fuse and high voltage filter condenser is accomplished by removing the rear section of the H.V. shield. This compartment shield is held in place by five screws.

To replace the fuse, depress the cap of the fuse holder (located next to 6BQ6GT tube) and turn the cap counter-clockwise. Install new fuse of the same type (¼ amp., 250 volt, part 508713); do not use any other size.

CORONA AND ARC-OVER

Corona or arc-over can best be detected by observing the operation of the power supply in a dark room. Several conditions may cause these phenomena.

POOR CONNECTIONS—Arcing or corona may be due to poorly soldered connections (rosin joints or sharp points), or defective tube socket connections. If the leads or connectors to the high voltage filter condenser do not grasp this component securely, arcing will also result.

Inspect solder connections and resolder those points which are unsatisfactory. Make sure tubes are firmly positioned in tube sockets and that high voltage filter condenser is held securely in place.

CLOSELY SPACED COMPONENTS—Arcing or corona may occur when H.V. components or leads are placed too close together. Make sure there is sufficient spacing between all parts and wiring. If necessary, the insulation between two elements of the circuit may be improved by coating both objects with a quick-drying liquid polystyrene or polyethylene.

The socket assembly for the 1B3GT/8016 rectifier tube includes a "corona ring" which prevents corona from the tube socket connections. The surface of this ring should be smooth and free of scratches, or sharp protrusions.

TUBE LOCATIONS & FUNCTIONS
MODEL 9113-A

SOCKET VOLTAGES

MODEL 9113-A

CAUTION

THE PICTURE TUBE is highly evacuated and if broken, glass fragments will be violently expelled. Scratching, chipping, undue pressure, or careless handling such as lifting the tube by its neck is dangerous and should be avoided. If it is necessary to handle the picture tube, use safety goggles and heavy gloves. Be sure to discharge the voltage developed across the capacitor formed by the inner and outer coating of the picture tube. This can be done by connecting the high voltage socket on the tube to the outer coating with a well insulated metal conductor.

HIGH VOLTAGE (10 to 12 kilovolts) is produced in a supply circuit of this receiver. Exercise care to avoid contact with elements of this circuit and particularly the tube terminals which are labeled "CAUTION" in the adjoining voltage chart. If measurement of voltage at these points is necessary, see procedure given below under the note "E."

THE HIGH VOLTAGE LEAD, which supplies approximately 10 to 12 kilovolts to the picture tube, should be momentarily shorted to the chassis whenever it is disconnected for service purposes. This discharges the high voltage filter condenser and prevents a shock hazard when working on the receiver after it has been turned off.

INTERMEDIATE B+ VOLTAGES, 475 and 365, are dangerous and caution should be observed when the receiver chassis components are exposed for service purposes.

BE SURE TO CHECK FOR PROPER POSITIONING OF BAND SWITCH SECTIONS ON AM-FM and TV chassis when interconnecting link arm has been disengaged and bottom cover of the AM-FM chassis is removed for voltage measurements. DO NOT turn on the receiver until you have first determined that the respective switch sections are correctly synchronized or positioned. Failure to observe this precaution can result in damage to the receiver, as well as erroneous voltage measurements. For more complete discussion of this subject, see text shown adjoining AM-FM socket voltage chart on page 40.

THE VOLTAGES SHOWN IN THE ADJOINING CHART WERE MEASURED UNDER THE FOLLOWING CONDITIONS

1. Power Supply—117 volts 60 cycle AC.

2. All voltages are measured between socket terminals and chassis unless otherwise indicated on adjoining chart.

*

3. Measurements made with voltmeter having sensitivity of 1000 ohms per volt except where indicated by (*). The (*) symbol designates a vacuum tube voltmeter measurement.

4. Band Switch set to "TV" position unless otherwise indicated by letters "P", "m" or "n" following voltages shown in adjoining chart.

5. Channel Selector and Fine Tuning Controls set for normal reception of a local station.

6. Focus control set to maximum counter-clockwise position. Setting of this control will affect B+ voltage on the 265 volt supply line. This voltage is obtained when control is at maximum counter-clockwise position and increases to 320 as control is rotated to clockwise position.

7. All other controls (with exception of focus control) are set for normal reception of the transmitted signal unless the voltage shown on the chart is followed by a letter or letters indicating a special condition of measurement as explained in subsequent notes.

8. Certain voltages were measured with two different settings of specific controls. It should therefore be understood that in these instances all controls, with the exception of one or two, were set for normal reception—letters following the voltage shown on the chart indicate the exceptions and are explained below.

9. The external or built-in antenna should remain connected to the receiver only when taking voltage measurements in the sweep and sync circuits—for all other measurements, disconnect antenna, short antenna terminals together and connect them to ground.

EXPLANATION OF NOTES

A. Vert. Hold Control max. counter-clockwise

a. This voltage will vary from —3.6 to —8.7 depending upon setting of Horizontal Hold Control and Horizontal Lock Control.

B. Brightness Control max. counter-clockwise

b. This voltage will vary from 11 to 16 depending upon setting of Horizontal Hold Control and Horizontal Lock Control.

C. Contrast Control max. clockwise

D. Horiz. Drive Control max. clockwise

d. This voltage will vary from 315 to 335 depending upon setting of Horizontal Hold Control and Horizontal Lock Control.

E. If you do not have an instrument capable of directly measuring voltages in this range, the voltage can be measured by using a voltage divider network consisting of twenty 2.2 megohm 2 watt resistors and one 1 megohm 2 watt resistor, all connected in series. Avoid using resistors of higher values as their individual voltage rating may be exceeded. It is also important to use resistors of equal wattage. Solder all connections between resistors. Accurately measure the overall resistance of the entire combination as well as the resistance of the 1 megohm section.

With the set turned off, connect the 2.2 megohm end of the resistance voltage divider to the filament of the 1B3GT/8016 tube, or H. V. terminal of the picture tube, and connect the 1 megohm end to chassis. Now, turn the set on and measure the voltage drop across the 1 megohm resistor with a vacuum tube voltmeter. The voltage at the tube terminal can then be calculated as follows:

$$\left[\text{Volts At Tube Terminal}\right] = \frac{\left[\text{Measured Resistance Of Entire Voltage Divider}\right]}{\left[\text{Measured Resistance Of 1 Meg. Section}\right]} \times \left[\text{Volts Measured Across 1 Meg. Section}\right]$$

e. This voltage will vary from —2.7 to +5.8 depending upon setting of Horizontal Hold Control and Horizontal Lock Control.

F. Height Control max. counter-clockwise

f. Contrast Control max. counter-clockwise

G. Width Control max. counter-clockwise

g. This voltage will vary from 8 to 15 depending upon setting of Horizontal Hold Control and Horizontal Lock Control.

H. Height Control max. clockwise

h. This voltage will vary from 10 to 20 depending upon setting of Horizontal Hold Control and Horizontal Lock Control.

J. Horiz. Hold Control set for normal picture.

K. Horiz. Lock Control set for normal picture.

k. This voltage will vary from —5 to —11 depending upon setting of Horizontal Hold Control and Horizontal Lock Control.

L. This voltage will vary from —6 to —16 depending upon setting of Horizontal Hold Control and Horizontal Lock Control.

M. Vertical Linearity Control max. counter-clockwise.

m. Band switch set to "AM" position; dial tuned to 540 Kc. and AM loop antenna leads grounded.

N. Channel Selector set to channel #4

n. Band switch set to "FM" position; dial tuned to 88 Mc. and FM antenna terminal grounded.

P. Band switch set to "PHO" position.

R. Do not attempt to measure the voltage at the tube cap. There is a high R. F. potential at this point.

r. This vacuum tube voltmeter measurement will fluctuate in the vicinity of 0.9 volts.

S. Channel Selector set to channel #10

T. Grounding of center stud on tube socket is necessary to reduce capacity coupling between other pins. Oscillation may result if this ground is omitted.

t. This voltage will vary from —0.04 to +0.06 depending upon setting of Horizontal Hold Control and Horizontal Lock Control.

U. Vertical Hold Control max. clockwise

V. Before measuring this voltage, first connect external antenna and adjust controls for normal reception of station signal; then set Focus Control to maximum counter-clockwise position.

W. This voltage will vary from —10 to —12 depending upon setting of Horizontal Hold Control and Horizontal Lock Control.

X. Brightness Control max. clockwise

Y. Vertical Linearity Control max. clockwise.

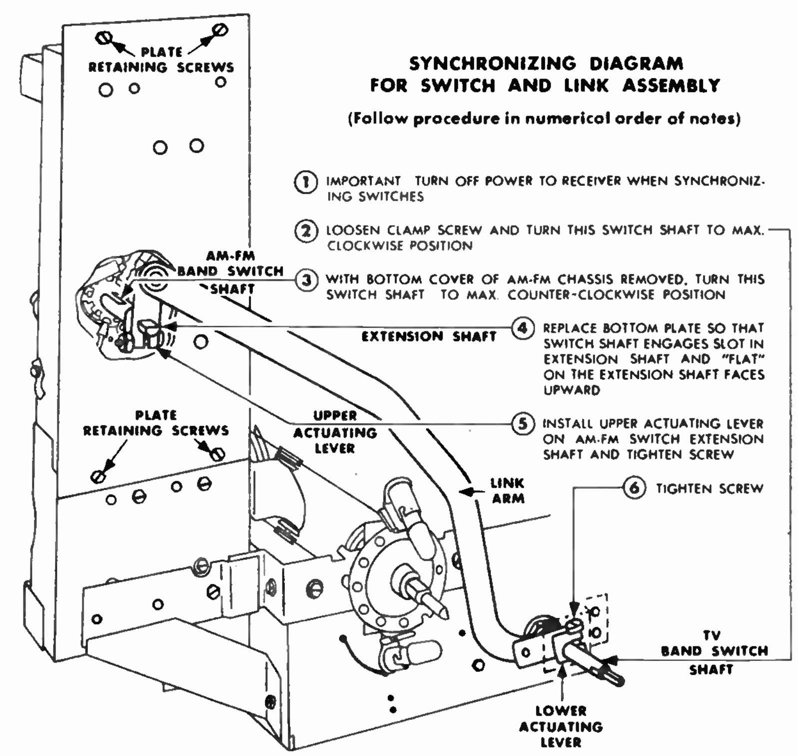
Z. The measurement should be made with a vacuum tube voltmeter. The voltage reading will fluctuate in the vicinity of 0.04 volts.

CHECKING SYNCHRONIZATION OF BAND SWITCHES ON AM-FM TUNER AND TV CHASSIS

Note that the band switch on the AM-FM Tuner chassis is mechanically coupled by a link arm and lever arrangement to the band switch on the TV chassis. Do not operate these switches by direct pressure on the link arm—always use a control knob attached to the TV switch shaft.

If the mechanical linkage is forced or slips at the lever on the TV switch shaft or the bottom cover of the AM-FM Tuner is removed for service purposes, it is possible for the respective switch sections to get out of step. As one function of the band switch is to control power supply circuits, the receiver can be damaged if the respective switch sections lose synchronism or are indiscriminately set to random positions.

In order to check for correct synchronization of the band switches, proceed as follows:



SYNCHRONIZING DIAGRAM FOR SWITCH AND LINK ASSEMBLY
(Follow procedure in numerical order of notes)

World Radio History

REMOVING BOTTOM COVER OF AM-FM CHASSIS

It will be necessary to remove the bottom cover of the AM-FM chassis in order to service the underside of this unit. Removal of that cover may be accomplished as follows:

1. Make sure receiver is turned off by removing power cord plug from wall outlet.
2. Loosen screw in upper actuating lever on AM-FM band switch extension shaft and slide lever off the shaft. The link arm will now be disengaged from the AM-FM band switch.
3. Release the screws holding the bottom cover in position and carefully remove cover.

METHOD OF MAINTAINING BAND SWITCH SYNCHRONIZATION DURING VOLTAGE MEASUREMENTS OR OTHER SERVICE OPERATIONS ON AM-FM TUNER

After the bottom cover of the AM-FM chassis has been removed, it should be noted that the link arm is disengaged from the AM-FM band switch shaft, thereby removing mechanical coupling between the TV chassis band switch and AM-FM chassis band switch. For proper operation of the receiver while servicing the AM-FM Tuner, these switches must each be manually positioned so as to maintain correct synchronization. Positioning of these switches may be accomplished as follows:

1. Make sure receiver is turned off by removing power cord plug from wall outlet. **IMPORTANT: — Do not attempt to operate separate sections of band switch while power is on.**
2. Before attempting to select a specific setting (FM, AM, PHONO, or TV) for the respective switch sections, it is important to assure that both sections start at their correct position. That is done by setting the **switch section on the AM-FM chassis to its fully clockwise position** and then setting the **switch section on the TV chassis to its fully counter-clockwise position.** Both switch sections are now in their correct position for "FM" operation of the receiver.
3. To set switch sections for AM, PHONO or TV operation, position them as follows: NOTE THAT AS SWITCH SECTION ON AM-FM CHASSIS IS ADVANCED COUNTER-CLOCKWISE, THE TV CHASSIS SWITCH SECTION MUST BE ADVANCED IN A CLOCKWISE DIRECTION.

RECEIVER FUNCTION	SWITCH POSITION ON TV CHASSIS	SWITCH POSITION ON AM-FM CHASSIS
FM	Fully counter-clockwise	Fully clockwise
AM	2nd position, turning clockwise	2nd position, turning counter-clockwise
PHONO	3rd position, turning clockwise	3rd position, turning counter-clockwise
TV	Fully clockwise	Fully counter-clockwise

4. When replacing bottom cover of AM-FM chassis and mechanical link arm between switch sections, refer to diagram above for re-assembly instructions.

REPAIR DATA FOR 508080 RF TUNER UNIT

All replacement parts for the RF Tuner Unit are included in the complete receiver parts list.

This RF Tuner Unit consists of an RF amplifier stage (using 6AG5, 6BC5, or 6CB6 tube) and a mixer-oscillator stage (using 6J6 tube). Channel selection is accomplished by rotation of a turret assembly having 2 sets of snap-in coils for each of the 12 channels. The tuner also incorporates a Fine Tuning control.

Antenna Coils for each channel consist of a center-tapped primary and an RF amp. grid winding (secondary). The individual RF-Oscillator Coils include an RF amplifier plate section, a mixer grid section and an oscillator winding. Signal output from the mixer stage is coupled to the IF amplifiers through the input IF coil located on the tuner unit.

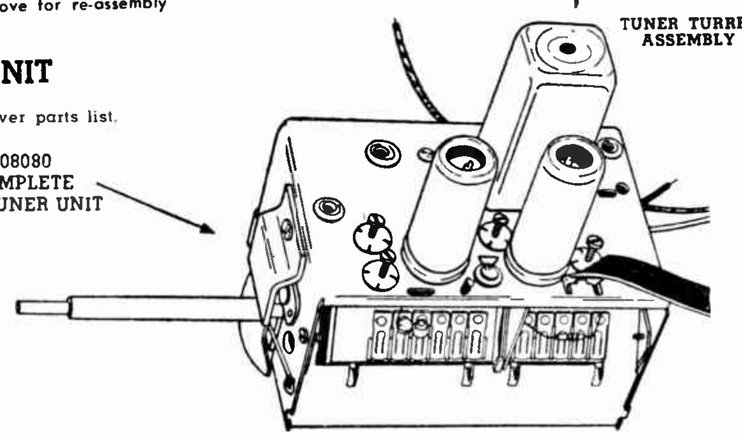
COMPLETE
R.F. TUNER UNIT



SERVICE PRECAUTIONS

SUBJECT	PRECAUTIONS
ELECTRICAL COMPONENTS	The high frequencies used in the RF section of a television receiver make it necessary that considerable care be exercised in servicing the tuner. Lead dress and location of components are very critical at these frequencies. When replacing parts, it is important to use components of identical electrical characteristics and physical size. Always reconnect the replacement item in the same location and position in the tuner as the original component.
TUBES	Replacement of tubes in the Tuner Unit may cause slight detuning of RF circuits due to inherent differences in inter-electrode capacitances. When replacing tubes (especially V6, 6J6 mixer-oscillator tube) make sure that Fine Tuning control will tune in television stations at approximately the middle of its range. It may be necessary to change the setting of the individual oscillator coil slugs for some channels to accomplish this.
CHANNEL COILS AND SLUGS	Channel Coils must be handled with care. Do not disturb coil windings. If an oscillator slug "falls into" its coil form during adjustment, remove the Channel Coil from the turret assembly and lift the Slug Retaining Spring aside. By tapping the coil form it should be possible to make the slug move toward the end so that its threads will be engaged by the Slug Retaining Spring when that spring is returned to its normal position.
FINE TUNING CONTROL	Rubbing of the bakelite Fine Tuning Cam against the Fine Tuning Condenser Plate is intentional in order to avoid vibration with resulting microphonics. However, the Fine Tuning Cam should not rub or contact the small circular plate located on the body of the tuner.

REMOVAL AND REPLACEMENT OF PARTS

ITEM	PROCEDURE
RF TUNER UNIT	To remove the Tuner Unit from receiver chassis, proceed as follows: 1. Remove metal plate which covers side of RF Tuner Unit nearest edge of chassis. This plate is held in place by two screws at side of chassis. 2. Remove channel selector dial lamp socket. 3. Remove support bracket which positions front of Tuner Unit and also remove screws which hold tuner to rear support bracket. 4. Disconnect the leads from the tuner to the main chassis. See illustration on page 1950-216 (circuit diagram page) showing tuner connections. After the Tuner Unit is replaced, make sure that channel selector dial lamp socket is correctly positioned so that channel selector knob will be properly illuminated.
CHANNEL COILS	Insert a screwdriver blade between Coil Retainer Spring and the end of the Tuner Turret. Twist the blade to pull spring away from the molded body of Channel Coil. Lift this end of coil body upward and remove individual coil assembly from tuner. When replacing Channel Coils, be sure they are reinstalled in their correct positions. Coil numbers should increase consecutively in a counter-clockwise direction when tuner is viewed from the front. If all the Channel Coils have been removed from the Tuner Turret, rotate turret until flat surface on end of tuner shaft points down. Install #3 Channel Coils into bottom position on turret. Then follow the correct sequence indicated above to replace other coils.

ITEM	PROCEDURE
TUNER TURRET ASSEMBLY	To remove turret from RF Tuner Unit, proceed as follows: 1. Remove tuner from receiver chassis. 2. Remove rear Turret Shaft Retaining Spring by disengaging straight end of spring from projection on tuner. 3. Remove Fine Tuning Condenser Plate from front of Tuner Unit. This plate forms one side of Fine Tuning control condenser and is held in place by one screw. 4. Slide Fine Tuning Cam and Brass Shaft off of main Channel Selector Shaft. 5. Remove Contactor Washer Spring and Fiber Spacer Washer from Channel Selector Shaft. 6. Remove Shaft Retaining Spring at front of tuner by disengaging straight end of spring from projection on case. 7. Slide turret assembly out of case and remove Detent Roller. To replace turret, reverse the above procedure. Tooth on bakelite Fine Tuning Cam should point downward during assembly so that it does not become locked between the stops on the Fine Tuning Condenser Plate.

©John F. Rider

World Radio History

STATOR CONTACT ASSEMBLY	To remove this assembly, proceed as follows: 1. Remove the two screws at the front and rear of the Stator Contact Assembly. 2. Unsolder all electrical connections to contact plate. 3. Unsolder four soldered joints between Stator Contact Assembly and Tuner Unit. 4. Contact Assembly may now be withdrawn from case. To reinstall this assembly: 1. Place Stator Contact Assembly in position and replace, but do not tighten, the two screws at the front and rear of the assembly. 2. Remove 3 consecutive pairs of Channel Coils from the turret (for example, the antenna and rf-osc. coils for channels #5, 6 and 7). 3. Position Tuner Turret so that the edges of the next highest Channel Coils (in this case, the coils for channel #8) just pass the row of 11 contacts on the Stator Contact Assembly. 4. Adjust position of the Stator Contact Assembly so that there are a few thousandths of an inch spacing between the contacts on the contact plate and the molded body of the Channel Coils. 5. The Contact Assembly is now correctly positioned and screws at front and rear may be tightened. 6. Solder Stator Contact Assembly to tuner frame at same four points that were used previously. 7. Make all electrical connections to contact plate. 8. Replace Channel Coils. 9. Reset Detent Spring as indicated in next section of this chart.
DETENT SPRING	When servicing the Detent Spring, or when replacing Stator Contact Assembly, it will be necessary to correctly set the position of this spring so that coil contacts will properly engage stator contacts. To release the Detent Spring, loosen mounting screw. Then, position the Detent Spring and Roller so that the contacts on the Stator Contact Assembly engage coil contacts (proper contact position is indicated when contact springs on stator reach point of maximum displacement). Detent Spring can then be positioned so that Detent Roller exactly fits into notch on center plate of turret.

CHANNEL NUMBER	ANTENNA COIL PART NUMBER	RF & OSC COIL PART NUMBER
2	507952	507972
3	507953	507973

ALIGNMENT PROCEDURE
MODEL 9113-A

Alignment of all RF and IF tuned circuits in this receiver may be accomplished by utilizing the procedures described in the following charts.

SEQUENCE OF ALIGNMENT: These procedures should preferably be applied in the order in which they are presented, however, alignment of RF or IF channels for either AM, FM or TV may be accomplished individually if desired.

The Television RF Amplifier and Mixer alignment may also be accomplished independent of the Television IF Channel alignment, but oscillator calibration can only be done after IF Channel has been correctly aligned. Proper IF band pass characteristic is necessary for oscillator alignment as results of circuit tuning are observed by means of an oscilloscope connected to the output of the video detector stage.

REMOVAL OF CHASSIS: The receiver chassis must be removed from the cabinet in order to accomplish alignment of all tuned circuits as there are adjustment points located on the undersides of both the main chassis and the AM-FM Tuner.

This can be accomplished by first removing all knobs and releasing the hold-down screws located on the underside of the cabinet. Then disconnect speaker leads and all three "built-in" antennae (TV, AM and FM). Release indicator lamp from bracket at base of cabinet.

CAUTION

The picture tube is highly evacuated and if broken, glass fragments will be violently expelled. Handle with care, using safety goggles and gloves. Avoid contact with high voltage terminal at side of tube even after it has been disconnected from the receiver—this precaution is necessary as inner and outer coatings on the tube form a capacitor which may carry a high voltage charge for an extended period of time after disconnection from the receiver.

INSTRUMENTS: The following instruments will be required as signal sources and output indicators during the alignment process. Since accurate alignment of a television receiver is heavily dependent upon the performance of your instruments, it is imperative that they meet the essential specifications described here.

1. **STANDARD SIGNAL GENERATOR** to provide signals at the following frequencies. Maximum output on all ranges should be at least .1 volt with provision for attenuation as desired. This instrument must have good frequency stability and be accurately calibrated. Generators which incorporate a separate crystal controlled oscillator and heterodyne circuit are self calibrating and therefore capable of providing the accuracy of frequency calibration required for television circuit alignment.

A. IF Frequencies:

455 Kc. (400 cycle amplitude modulated) for AM IF.
4.5 Mc. (Unmodulated) for TV Sound.
10.7 Mc. (Unmodulated) for FM IF.
22.25 (Unmodulated) marker for TV Sound IF carrier.
22.4 Mc. (Unmodulated) for TV 1st IF Trap.
22.8 Mc. (Unmodulated) for TV 3rd IF Trap.
23.5 Mc. (Unmodulated) for TV 1st and 3rd IF.
24.5 Mc. (Unmodulated) for TV 4th IF.
26.3 Mc. (Unmodulated) for TV Converter and 2nd IF.
26.75 Mc. (Unmodulated) marker for TV Picture IF carrier.

B. RF Frequencies:

550 to 1600 Kc. (400 cycle amplitude modulated) for AM RF.
54 to 88 Mc. (Unmodulated) for TV RF.
88 to 108 Mc. (400 cycle amplitude modulated) for FM RF.
174 to 216 Mc. (Unmodulated) for TV RF.

2. **RF SWEEP GENERATOR** to provide frequency modulated signals at the following frequencies:

10.7 Mc. with 300 Kc. sweep width.
20 to 30 Mc. with 10 Mc. sweep width.
54 to 88 Mc. with 10 Mc. sweep width.
174 to 216 Mc. with 10 Mc. sweep width.

Output adjustable with at least .1 volt maximum.

Output should be "flat" (no amplitude variation) for all settings of the sweep width control.

Provision for connection of generator sweep modulating voltage to horizontal deflection system of an oscilloscope.

Provision for blanking the output signal on each return sweep so that oscillogram will not show retrace.

3. **CATHODE RAY OSCILLOSCOPE**, preferably a unit with vertical amplifier having wide range frequency response and low capacity pick-up probe.

4. **VACUUM TUBE VOLTMETER.** The lowest voltage range of this instrument should preferably permit a 1.0 volt reading to be indicated at not less than one third of full scale deflection.

5. **OUTPUT METER**, preferably a unit equipped with an impedance matching network that will present a 3.2 ohm load when connected to secondary of audio output transformer.

INSTRUMENT CONNECTIONS: The method of connection, including details of matching and coupling networks, for instruments used in this alignment procedure is given in several illustrations on subsequent pages. Specific instructions for each instrument application will also be found in various sections of the alignment charts.

IMPORTANT

AVOID EXCESSIVE INPUT SIGNAL WHEN USING OSCILLOSCOPE AS ALIGNMENT INDICATOR.

When observing the receiver band pass characteristic on an oscilloscope, it is exceedingly important to avoid distortion of that characteristic which would occur when using a large input signal from the sweep generator or standard generator (marker signal). Always set attenuator on sweep generator so that reading on the vacuum tube voltmeter does not exceed one volt (when meter is connected from high side of video detector load resistor, symbol 139, to receiver chassis). Standard generator output should also be attenuated so that marker signal does not pull or tear the band pass characteristic as shown on the 'scope.

CHECKING SYNCHRONIZATION OF BAND SWITCHES ON AM-FM TUNER AND TV CHASSIS.

Note that the band switch on the AM-FM Tuner chassis is mechanically coupled by a link arm and lever arrangement to the band switch on the TV chassis. Do not operate these switches by direct pressure on the link arm—always use a control knob attached to the TV switch shaft.

If the mechanical linkage is forced or slips at the lever on the TV switch shaft, or the bottom cover of the AM-FM tuner is removed for service purposes, it is possible for the respective switch sections to get out of step. The receiver can be damaged if the switch sections lose synchronization, or are indiscriminately set to random positions. In order to check for proper synchronization of the band switches, refer to procedure on page 40.

BROADCAST BAND—"AM"—ALIGNMENT PROCEDURE

1. After the entire chassis assembly has been removed from the cabinet, remove the AM loop antenna and reconnect it to the AM antenna leads extending from the AM-FM tuner chassis. Then wind one turn of insulated wire around frame of loop antenna so as to provide a means of coupling it to the signal generator. Connect one end of coupling turn to receiver chassis and allow other end to remain open until otherwise instructed in the following chart. Space loop antenna same distance away from the chassis as when assembled in the cabinet.
2. Reconnect the speaker to the two audio output leads extending from the main chassis. **IMPORTANT:** Do not confuse these leads with the two loop antenna leads.
3. Replace AM-FM Coarse and Fine Tuning knobs and rotate Fine Tuning knob to its extreme counter-clockwise position. At this setting, the gang condenser should be fully meshed and the heavy line next to 5.5 on the dial scale should be pointing straight up; if they are not, loosen the set screws in the hub of the dial drum on the gang condenser and close gang plates manually; also, position the dial scale correctly. Then tighten set screws in hub of dial drum.
4. The Control Panel Escutcheon at the front of the cabinet normally provides a "position indicator" for the AM-FM dial scale, however, when the chassis is removed from the cabinet it becomes necessary to install a "temporary pointer." That can be readily accomplished by binding a piece of heavy wire around the planetary drive support brackets and shaping the free end of the wire so that it can be placed in a vertical position (pointing downward) between the dial knob and the lamp behind it (wire will then cast a shadow on the dial scale and show the frequency to which the receiver is tuned).

   With the gang condenser fully meshed, the "temporary pointer" should appear directly behind the heavy line preceding 5.5 on the dial scale.
5. **IMPORTANT:** Do not remove the metal bottom plate of AM-FM tuner chassis. Holes are provided for access to IF transformer tuning slugs. Removal of the bottom plate during alignment of the RF circuits will result in detuning when the plate is replaced.
6. Connect output meter across the speaker voice coil.
7. Connect ground lea of signal generator to the receiver chassis.
8. Set volume control to the maximum volume position and use a weak signal from the signal generator.
9. Set tone control to its extreme clockwise position.
10. Set band switch to the "AM" position.
11. After alignment procedure is completed and chassis and loop have been reinstalled in cabinet, arrange leads to loop so that they are separated from each other as much as possible. Avoid twisting, taping or extending these leads.

DUMMY ANT. IN SERIES WITH SIGNAL GENERATOR	CONNECT HIGH SIDE OF SIGNAL GENERATOR TO	SIGNAL GENERATOR FREQUENCY	RECEIVER DIAL SETTING	TRIMMER OR SLUG NUMBER	TRIMMER DESCRIPTION	TYPE OF ADJUSTMENT
.1 MFD. Condenser	Lug on trimmer #23 at bottom of gang (see figure 1 for location of trimmer).	455 KC	Any point where it does not affect the signal.	18 and 19	2nd I.F.	Adjust for maximum output. Then repeat adjustment.
				20 and 21	1st I.F.	
200 MMF. Mica Condenser	Coupling turn on loop antenna.	1500 KC	1500 KC	#22	AM Oscillator.	Adjust for maximum output.
		1500 KC	Tune to 1500 Kc. generator signal.	#23	AM Antenna	Adjust for maximum output.
200 MMF. Mica Condenser	Coupling turn on loop antenna.	600 KC	Tune to 600 Kc. generator signal.	#24	Adjustable core of AM Antenna Coil.	Adjust for maximum output.
Repeat adjustment of trimmers 23 and 24 until one no longer detunes the other.						

FREQUENCY MODULATION—"FM"—ALIGNMENT PROCEDURE

1. After the entire chassis has been removed from the cabinet, replace AM-FM Coarse and Fine Tuning knobs and rotate Fine Tuning knob to its extreme counter-clockwise position. At this setting, the gang condenser should be fully meshed and the heavy line next to 88 on the dial scale should be pointing straight up; if they are not, loosen the set screws in the hub of the dial drum on the gang condenser and close gang plates manually; also, position the dial scale correctly. Then tighten set screws in hub of dial drum.
2. The Control Panel Escutcheon at the front of the cabinet normally provides a "position indicator" for the AM-FM dial scale, however, when the chassis is removed from the cabinet it becomes necessary to install a "temporary pointer." That can be readily accomplished by binding a piece of heavy wire around the planetary drive support brackets and shaping the free end of the wire so that it can be placed in a vertical position (pointing upward) between the dial knob and the lamp behind it (wire will then cast a shadow on the dial scale and show the frequency to which the receiver is tuned).

   With the gang condenser fully meshed, the "temporary pointer" should appear directly behind the heavy line next to 88 on the dial scale.
3. Reconnect the speaker to the two audio output leads extending from the main chassis. **IMPORTANT:** Do not confuse these leads with the two AM loop antenna leads.
4. Set band switch to the "FM" position.
5. Remove bottom cover from AM-FM tuner during IF alignment but replace it before starting alignment of RF circuits.

VTVM Connections for FM Sound IF Alignment

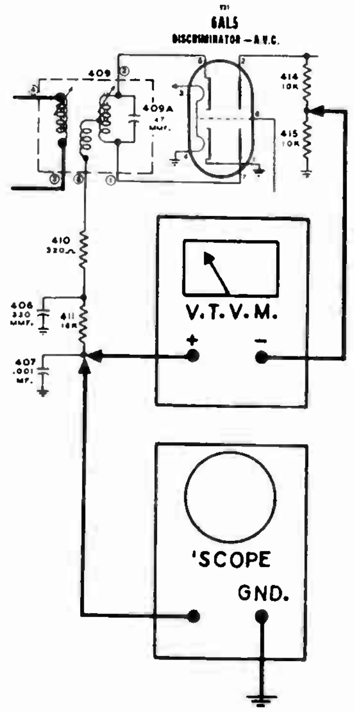

FIG. 4
VTVM and Oscilloscope Connections for FM Sound Discriminator Alignment

FREQUENCY MODULATION—"FM" ALIGNMENT PROCEDURE

IMPORTANT: Carefully follow procedure for removal and replacement of this plate, as well as synchronization of band switches on AM-FM tuner and TV chassis, as explained on page 40. **Failure to correctly install bottom cover may result in serious damage to receiver.**

6. **Do not remove the AM-FM tuner chassis from the TV chassis during alignment.**

7. Set volume control to the maximum volume position and use a weak signal from the signal generator.

8. Set tone control to its extreme clockwise position.

9. Dress FM circuit leads as short and straight as possible, particularly those in the oscillator circuit. IF plate and grid leads should also be kept short and straight.

STANDARD SIGNAL GENERATOR		SWEEP GENERATOR		VTVM OR OUTPUT METER CONNECTION	OSCILLOSCOPE CONNECTIONS	RECEIVER DIAL SETTING	TRIMMER OR SLUG NUMBER	TYPE OF ADJUSTMENT AND OUTPUT INDICATION
CONNECTIONS	FREQUENCY	CONNECTIONS	FREQ.					
Connect high side to lug on trimmer #32 (see Fig. 1 for location of trimmer) using a .01 Mfd. condenser in series with generator lead. Connect ground lead to the receiver chassis in vicinity of gang condenser.	10.7 MC. Unmodulated	Not used.	——	Connect VTVM as shown in Fig. 3.	Not used.	Any position where it does not affect the signal.	#25 Discriminator secondary #26 Discriminator primary 27 and 28 2nd IF 29 and 30 1st IF	Adjust these trimmers for maximum meter reading — the output voltage will be of negative polarity.
Same as above.	Same as above.	Not used.	——	Connect VTVM as shown in Fig. 4.	Not used.	Same as above.	#25 Discriminator secondary	Note that as slug #25 is rotated, a point will be found where the voltmeter will swing rather sharply from a positive to a negative reading or vice versa. The correct setting is obtained when the meter reads zero as the slug is moved thru this point.
Same as above.	Same as above. —— Attenuate signal to prevent overload and distortion of response curve.	Connect high side to lug on trimmer #32 (see Fig. 1 for location of trimmer) using a .01 Mfd. condenser in series with generator lead. Connect ground lead to the receiver chassis in vicinity of gang condenser.	10.7 MC Sweeping ±300 Kc.	Not used.	Connect as shown in Fig. 4. —— Set vertical amplifier of 'scope for maximum amplification. —— Synchronize oscilloscope with sweep generator by connecting "horizontal input" terminals of 'scope to source of horizontal sweep modulating voltage on the sweep generator.	Same as above.	#25 Discriminator secondary	A pattern similar to that shown in Fig. 5 should appear on the oscilloscope screen. Check for symmetry about the 10.7 Mc. center point and linearity of the slope. 10.7 MC.  FIG. 5 If the characteristic is not shaped properly, attempt to obtain symmetry by changing the setting of slug #25. Should that fail to produce the desired results, then a slight readjustment of slugs #26, 27, 28, 29 and 30 should be undertaken.
IMPORTANT:—Before starting alignment of the RF and Oscillator circuits, be sure to replace the bottom plate on the AM-FM Tuner chassis as explained on page 1950-198. Failure to observe this requirement would result in detuning if plate were replaced after alignment is completed.								
Connect high side in series with a 270 ohm carbon resistor to FM antenna terminal near gang condenser (see Fig. 1). Connect ground lead to receiver chassis.	108 MC. with 400 cycle AM Modulation.	Not used.	——	Connect OUTPUT METER across speaker voice coil.	Not used.	108 Mc.	#31 FM Oscillator	Set trimmer #31 to receive 108 Mc. signal as indicated by maximum meter reading.
Same as above.	106 MC. with 400 cycle AM Modulation.	Not used.	——	Same as above.	Not used.	Tune to 106 Mc. generator signal.	#32 FM RF	Adjust trimmer for maximum meter reading.

Check calibration and tracking of receiver with input signals of 88, 90 and 106 MC. If difference between dial pointer setting and the above mentioned frequencies does not exceed ±0.3 MC. and RF circuit is tracking properly, then alignment may be considered satisfactory and no further adjustment is necessary.

Where the calibration error is greater than ±0.3 MC. it is advisable to make the following adjustments:

Tune receiver to an 88 MC. signal and note whether dial pointer is above or below correct calibration point. Then tune receiver so that dial pointer is at the 88 MC. position. If generator signal was previously received at a setting above 88 MC., it will be necessary to slightly spread the windings of the FM oscillator coil (#33 in Fig. 2) so that signal will now be received at the correct dial setting. On the other hand, if generator signal was received at a dial setting below 88 MC., then slightly compress the windings of the oscillator coil until the signal comes in at the correct calibration point.

Adjustment of FM oscillator coil #33 will require removal of bottom cover. Before rechecking calibration, follow procedure on page 1950-198 for removal and replacement of cover.

Check calibration at 108 MC. and if it is in error by more than ±0.3 MC., readjust setting of trimmer #31. Repeat calibration adjustment at 88 and 108 MC. until desired accuracy is obtained.

Observe dial calibration at 106 MC. If it is found to be incorrect by an appreciable amount, then make a very slight adjustment in the spacing of the gang condenser plates to receive the 106 MC. signal at the correct dial setting. Then check adjustment of RF trimmer #32 to obtain maximum output indication at 106 MC.

INSTRUMENT CONNECTIONS FOR IF CHANNEL ALIGNMENT

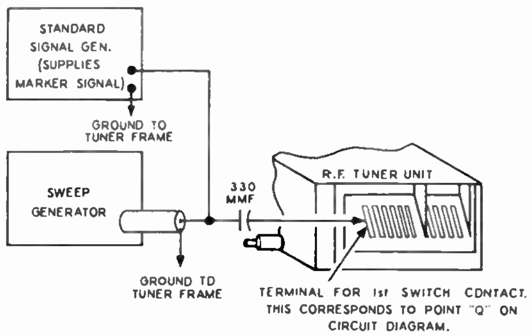

FIG. 9
Generator Connections for Television IF Channel Alignment

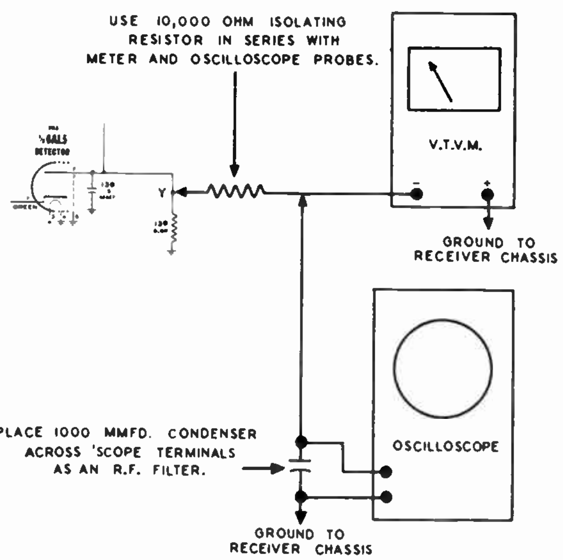

FIG. 10
VTVM and Oscilloscope Connections for Television IF Channel Alignment

TELEVISION SOUND CHANNEL ALIGNMENT PROCEDURE

1. Short antenna terminals together with a jumper wire.
2. Turn the band switch to "TV" position and set receiver Channel Selector to any inactive television channel: other controls may be left at any desired setting.
3. No special aligning tool is required to adjust the cores in the Sound IF and discriminator transformers. The blade of a small screwdriver will fit the slot in these cores, however, the screwdriver should be of a non-metallic or insulated type to prevent detuning when inserted in the transformer can.

STANDARD SIGNAL GENERATOR		VTVM CONNECTIONS	MISCELLANEOUS INSTRUCTIONS	TRIMMER OR SLUG	TYPE OF ADJUSTMENT AND OUTPUT INDICATION
CONNECTIONS	FREQUENCY				
Connect as shown in Fig. 6.	**4.5 MC.** unmodulated **IMPORTANT** This signal must be accurate within ¼ of 1% of 4.5 Mc. Check generator calibration against a crystal controlled signal source by "zero beating" (heterodyning) with harmonics of the crystal frequency.	Connect as shown in Fig. 7.	A "swishing" sound may be heard in the speaker during Sound Channel Alignment. This spurious oscillation is caused by horizontal sweep voltage being picked up in the audio system thru stray coupling of instrument leads: it should be disregarded as it will have no effect on alignment of the sound channel.	#1 Discriminator Secondary	Adjust for maximum reading on VTVM.
				#2 Discriminator Primary	Adjust for maximum reading on VTVM.
				#3 2nd Sound IF Secondary	Adjust for maximum reading on VTVM.
				#4 2nd Sound IF Primary	Adjust for maximum reading on VTVM.
				#5 1st Sound IF Secondary	Adjust for maximum reading on VTVM.
				#6 1st Sound IF Primary	Adjust for maximum reading on VTVM.
Same as above.	Same as above.	Connect as shown in Fig. 8.	Same as above.	#1 Discriminator Secondary	Note that as slug #1 is rotated, a point will be found where the voltmeter will swing rather sharply from a positive to a negative reading or vice versa. The correct setting of slug #1 is obtained when the meter reads zero as the slug is moved thru this point.

REDUCTION OF INTERCARRIER BUZZ

Slight "dynamic" unbalance of the discriminator secondary can emphasize intercarrier buzz due to incomplete amplitude modulation rejection. Therefore it is vitally important to obtain an accurate setting of the discriminator secondary slug under actual reception conditions.

Disconnect all instruments and then connect an antenna to the receiver to obtain program reception from a local station. If intercarrier buzz is prominent, a slight readjustment of the discriminator secondary slug (#1) should be made to obtain the "dip" point for the buzzing sound. Note that program sound will be clear and free from distortion at this point. Buzz should now be at an acceptable minimum if station transmission is not at fault.

TELEVISION IF CHANNEL ALIGNMENT PROCEDURE

1. A special aligning tool designed to fit the stems on adjustable cores of the IF coils (see points 8, 9, 10 and 11 in Fig. 18) is available and may be obtained from Stewart-Warner by requesting IF Alignment Tool #507479.
2. Turn receiver Channel Selector to television channel #12 and short antenna terminals together with a jumper wire.
3. Turn the band switch to the "TV" position.
4. Remove metal plate which covers side of RF tuner unit nearest edge of chassis. This plate is held in place by two screws on the side of the chassis.
5. Connect a 3 volt battery to the receiver AGC system so that negative terminal of battery connects to the AGC line and positive terminal of battery connects to receiver chassis. See Fig. 19 for convenient point of connection.
6. Note location of IF Trap Coils #12 and #13 by referring to Fig. 19. Before undertaking the alignment of any of the IF stages, Trap Coils #12 and #13 must be detuned so that they do not resonate in the IF pass band. Detuning is accomplished by merely compressing the windings so that they are closely spaced. Failure to detune the Trap Coils can cause the IF system to become regenerative, thereby preventing alignment.
7. If the IF channel is badly misaligned and two or more immediately adjoining IF stages are tuned to the same frequency, oscillation may occur. Such oscillation shows up as a voltage across the video detector load resistor, symbol 139, and is indicated by the VTVM that is connected to this point during alignment. It should be noted

©John F. Rider

World Radio History

TELEVISION IF CHANNEL ALIGNMENT PROCEDURE

that voltage due to IF oscillation is unaffected by strength of signal from the generator.

Where IF oscillation is encountered, it is generally possible to correct the condition by detuning the IF coils in different directions. If that does not have the desired effect, increase fixed bias on AGC line by using a 4½ volt battery instead of the 3 volt battery referred to in instruction #5. After stopping the oscillation in this manner it will then be possible to align all IF stages using the following procedure, however, the AGC bias battery must be changed back to 3 volts when using the oscilloscope to observe band pass characteristic. Once all stages have been aligned using the 4½ volt bias, the IF channel should be stable with reduced bias.

STANDARD SIGNAL GENERATOR		SWEEP GENERATOR		VTVM CONNECTIONS	OSCILLOSCOPE CONNECTIONS	MISCELLANEOUS INSTRUCTIONS	TRIMMER OR SLUG	TYPE OF ADJUSTMENT AND OUTPUT INDICATION
CONNECTIONS	FREQUENCY	CONNECTIONS	FREQ.					
Connect as shown in Fig. 9.	26.3 MC.	Use a 330 Mmf. isolating condenser and connect as shown in Fig. 9 but keep power switch turned off during this step.	———	Connect as shown in Fig. 10.	Not used.	———	#7 Converter plate coil	Adjust for maximum reading on VTVM.
							#8 2nd I.F.	Adjust for maximum reading on VTVM.
Same as above.	24.5 MC.	Same as above.	———	Same as above.	Not used.	———	#9 4th I.F.	Adjust for maximum reading on VTVM.
Same as above.	23.5 MC.	Same as above.	———	Same as above.	Not used.	———	#10 1st I.F.	Adjust for maximum reading on VTVM.
							#11 3rd I.F.	Adjust for maximum reading on VTVM.
Same as above.	22.4 MC.	Same as above.	———	Same as above.	Not used.	———	#12 1st IF Trap Coil	Adjust the spacing of the Trap Coil windings for MINIMUM reading on VTVM.
Same as above.	22.8 MC.	Same as above.	———	Same as above.	Not used.	———	#13 3rd IF Trap Coil.	Adjust the spacing of the Trap Coil windings for MINIMUM reading on VTVM.
Same as above.	26.75 MC.	With connections made as shown in Fig. 9, turn on this generator and set controls for operation as specified in next column.	25 MC. Sweeping ± 5 Mc.	Same as above.	Connect as shown in Fig. 10.	IMPORTANT: 1. Adjust output attenuator on sweep generator so that reading on VTVM is approximately one volt. 2. Set attenuator on standard signal generator so that marker signal does not distort the pattern on the oscilloscope. 3. Be sure that a 3 volt battery is connected to AGC line as specified in instruction #5 at the head of this chart. Do not use a battery of any other voltage.	The IF band pass characteristic now displayed on the 'scope should be compared with the curve shown in Fig. 11. If top of curve is not properly shaped, make a slight readjustment of slug #9. Should that adjustment fail to yield the desired result, then note whether the curve has a peak on the high or low frequency side. Slugs #7 and #8 control high frequency response (26.3 Mc.) and slugs #10 and #11 affect the low frequency response (23.5 Mc.); by making a small change in the settings of the high or low frequency slugs, it will be possible to obtain correct band pass curve.  FIG. 11 I.F. RESPONSE CURVE The 26.75 Mc. picture IF carrier marker should now appear at the 30% amplitude position on side of the band pass characteristic (see Fig. 11). If position of the marker appears too high or too low, slight readjustment of slugs #7, 8 and 9 is required.	
Same as above.	22.25 MC.	Same as above.	Same as above.	Same as above.	Same as above.	Same as above.	Adjust the vertical gain control on the 'scope in order to magnify the sound portion of the response curve. The 22.25 Mc. sound IF carrier marker should appear at the position indicated in Fig. 11. If the position of the sound marker is incorrect, readjust winding spacing of Trap Coils #12 and #13.	

TELEVISION RF CHANNEL ALIGNMENT PROCEDURE

1. Turn the band switch to the "TV" position.
2. Replace metal plate which covers exposed terminal side of RF tuner unit. This plate was previously removed for IF channel alignment.
3. Connect a 3 volt battery to the receiver AGC system so that negative terminal of battery connects to AGC line and positive terminal of battery connects to receiver chassis. (See Fig. 19 for convenient point of connection.)

STANDARD SIGNAL GENERATOR		SWEEP GENERATOR		VTVM CONNECTIONS	OSCILLOSCOPE CONNECTIONS	MISCELLANEOUS INSTRUCTIONS	TRIMMER OR SLUG	TYPE OF ADJUSTMENT AND OUTPUT INDICATION
CONNECTIONS	FREQUENCY	CONNECTIONS	FREQ.					
RF AMPLIFIER AND MIXER ALIGNMENT								
Connect as shown in Fig. 15.	*209.75 MC. †205.25 MC.	Connect as shown in Fig. 15 and set controls for sweep width of 10 Mc. on television channel specified in the next column.	CHANNEL #12	Not used.	Connect as shown in Fig. 16.	IMPORTANT: Keep output of standard signal generator at a level that provides a readable marker but does not distort the curve that is being observed on the 'scope.	#14 Mixer Grid.	Adjust these trimmers to obtain properly shaped RF band pass characteristic as shown in Fig. 12. Use Mixer Grid trimmer #14 and RF Amplifier Plate trimmer #15 to obtain correct amplitude of characteristic in vicinity of picture and sound carrier markers. Then adjust RF Amp. Grid trimmer #16 to equalize overall amplitude. Repeat adjustment of trimmers to be sure correct response has been obtained.
							#15 RF Amp. Plate.	
							#16 RF Amp. Grid.	IMPORTANT: When adjusting trimmers #14, 15 and 16 it will be noted that the band pass characteristic can be broadened by sacrificing amplitude. It is undesirable to overly broaden the curve as that would result in a loss of sensitivity.
Same as above.	*215.75 MC. †211.25 MC.	Same as above.	CHANNEL #13	Not used.	Same as above.	Set Channel Selector to #13	The RF band pass characteristic of the other television channels should now be checked without disturbing the settings of trimmers #14, 15 and 16. Adjust the RF sweep generator and marker generator for operation on the other television channels, observing position of both the sound carrier and picture carrier markers.	
	*203.75 MC. †199.25 MC.		CHANNEL #11			Set Channel Selector to #11		
	*197.75 MC. †193.25 MC.		CHANNEL #10			Set Channel Selector to #10	 FIG. 12	
	*191.75 MC. †187.25 MC.		CHANNEL #9			Set Channel Selector to #9		
	*185.75 MC. †181.25 MC.		CHANNEL #8			Set Channel Selector to #8		
	*179.75 MC. †175.25 MC.		CHANNEL #7			Set Channel Selector to #7		
	* 87.75 MC. † 83.25 MC.		CHANNEL #6			Set Channel Selector to #6		
	* 81.75 MC. † 77.25 MC.		CHANNEL #5			Set Channel Selector to #5		
	* 71.75 MC. † 67.25 MC.		CHANNEL #4			Set Channel Selector to #4	Band pass characteristic of these channels should conform to the RF response curve in Fig. 12. If necessary, a compromise may be obtained to compensate for small variations in channel response by returning to channel #12 and making slight changes in the settings of trimmers #14, 15 and 16.	
	* 65.75 MC. † 61.25 MC.		CHANNEL #3			Set Channel Selector to #3		
	* 59.75 MC. † 55.25 MC.		CHANNEL #2			Set Channel Selector to #2

OSCILLATOR ALIGNMENT

1. **IMPORTANT:** Before undertaking oscillator alignment be sure IF circuits are correctly aligned for band pass characteristic illustrated in Fig. 11.
2. During oscillator alignment, it is necessary to set the Fine Tuning control so that the tooth on the bakelite fine tuning cam points downward (correct position for this control is shown in Fig. 13).

STANDARD SIGNAL GENERATOR CONNECTIONS	STANDARD SIGNAL GENERATOR FREQUENCY	SWEEP GENERATOR CONNECTIONS	SWEEP GENERATOR FREQ.	VTVM CONNECTIONS	OSCILLOSCOPE CONNECTIONS	MISCELLANEOUS INSTRUCTIONS	TRIMMER OR SLUG	TYPE OF ADJUSTMENT AND OUTPUT INDICATION
Connect as shown in Fig. 15.	*209.75 MC. ‡205.25 MC.	Connect as shown in Fig. 15 and set controls for sweep width of 10 Mc. on television channel specified in the next column.	CHANNEL #12	Connect as shown in Fig. 17	Connect as shown in Fig. 17	Be sure that Fine Tuning control has been properly positioned (tooth on the cam pointing down—see Fig. 13). During this step and thru-out all succeeding steps it is necessary to: 1. Keep output of sweep generator at a level that does not allow reading on VTVM to exceed one volt. 2. Keep output of standard signal generator at a level that provides a readable marker but does not distort the curve that is being observed on the 'scope.	#17 Oscillator	Adjust height of Oscillator trimmer #17 to be approximately 3/8" from the top of trimmer screw to the top surface of RF tuner unit (see Fig. 13). NOTE: Before making the following adjustment, advance the vertical gain control on the 'scope in order to magnify the sound portion of the response curve. Then, use a non-metallic screwdriver to adjust channel #12 oscillator slug (accessible thru hole on front of RF Tuner Unit —see Fig. 13) and shift response curve so that sound carrier marker is located at the position indicated in Fig. 14. Now, reduce gain control setting of 'scope to restore pattern to normal amplitude, and observe position of picture carrier marker. This marker should appear at the 35% amplitude position on the low frequency side of the characteristic curve (see Fig. 14).
Same as above.	*215.75 MC. ‡211.25 MC.	Same as above.	CHANNEL #13	Same as above.	Same as above.	Set Channel Selector to #13	Adjust the RF sweep generator and marker generator for operation on the other television channels; set marker generator to sound carrier frequency. After setting Channel Selector to corresponding channel, adjust oscillator slug thru hole on front of RF Tuner Unit (see Fig. 13). This permits response curve to be shifted so that sound carrier marker (see FIG. 14) will appear at the position indicated in Fig. 14. The picture carrier marker for the corresponding channel should then appear at the 35% amplitude position at the opposite side of the band pass characteristic curve. NOTE: Make sure that cam on fine tuning control shaft remains properly positioned during this step (tooth on the cam pointing downward—see Fig. 13).	
	*203.75 MC. ‡199.25 MC.		CHANNEL #11			Set Channel Selector to #11		
	*197.75 MC. ‡193.25 MC.		CHANNEL #10			Set Channel Selector to #10		
	*191.75 MC. ‡187.25 MC.		CHANNEL #9			Set Channel Selector to #9		
	*185.75 MC. ‡181.25 MC.		CHANNEL #8			Set Channel Selector to #8		
	*179.75 MC. ‡175.25 MC.		CHANNEL #7			Set Channel Selector to #7		
	* 87.75 MC. ‡ 83.25 MC.		CHANNEL #6			Set Channel Selector to #6		
	* 81.75 MC. ‡ 77.25 MC.		CHANNEL #5			Set Channel Selector to #5		
	* 71.75 MC. ‡ 67.25 MC.		CHANNEL #4			Set Channel Selector to #4		
	* 65.75 MC. ‡ 61.25 MC.		CHANNEL #3			Set Channel Selector to #3		
	* 59.75 MC. ‡ 55.25 MC.		CHANNEL #2			Set Channel Selector to #2		

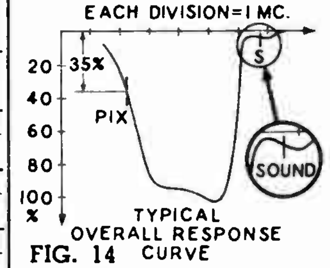

FIG. 14

If an oscillator slug "falls into" its coil form during adjustment, remove the Channel Coil from the turret assembly and lift the Slug Retaining Spring aside. By tapping the coil form it should be possible to make the slug move toward the end so that its threads will be engaged by the Slug Retaining Spring when that spring is returned to its normal position.

If an unsatisfactory overall response is obtained for a particular channel, observe RF Amp. and Mixer response curve for that channel (as described on page 45.) If characteristic does not conform reasonably well within the typical curve shown in Fig. 12, then, (1) attempt to obtain a better compromise for RF response on all channels by realigning RF Amp. and Mixer circuits, or (2) try replacing Antenna, RF and Oscillator coils for the particular channels.

119	510137	Resistor—carbon 1000 Ohms ½ watt
121	510120	Resistor—carbon 120 Ohms ±10% ½ watt
123	510153	Resistor—carbon 8200 Ohms ±10% ½ watt
124	510137	Resistor—carbon 1000 Ohms ½ watt
130	510119	Resistor—carbon 100 Ohms ½ watt
131	510713	Resistor—carbon 3000 Ohms ±5% 2 watt
132	510153	Resistor—carbon 8200 Ohms ±10% ½ watt
135	510137	Resistor—carbon 1000 Ohms ½ watt
139	510151	Resistor—carbon 6800 Ohms ±10% ½ watt
141	510254	Resistor—carbon 10,000 Ohms ±10% 1 watt
142	510253	Resistor—carbon 8200 Ohms ±10% 1 watt

RESISTORS—Continued

DIAGRAM NO.	PART NO.	DESCRIPTION
144	510166	Resistor—carbon 47,000 Ohms ±10% ½ watt
146	510164	Resistor—carbon 33,000 Ohms ½ watt
147	510155	Resistor—carbon 10,000 Ohms ½ watt
149	510150	Resistor—carbon 5600 Ohms ±10% ½ watt
151	510173	Resistor—carbon 100,000 Ohms ½ watt
153	510150	Resistor—carbon 5600 Ohms ±10% ½ watt
155	510191	Resistor—carbon 1 Meg. ½ watt
156	510356	Resistor—carbon 12,000 Ohms ±10% 2 watt
158	510191	Resistor—carbon 1 Meg. ½ watt
159	510126	Resistor—carbon 270 Ohms ±10% ½ watt
162	510723	Resistor—carbon 12,000 Ohms ±5% ½ watt
164, 165	510339	Resistor—carbon 1500 Ohms ±10% 2 watt
166	510156	Resistor—carbon 12,000 Ohms ±10% ½ watt
169	510173	Resistor—carbon 100,000 Ohms ½ watt
170	510191	Resistor—carbon 1 Meg. ½ watt
171	510171	Resistor—carbon 82,000 Ohms ±10% ½ watt
172	510161	Resistor—carbon 22,000 Ohms ½ watt
177	510143	Resistor—carbon 2200 Ohms ½ watt
178	510157	Resistor—carbon 15,000 Ohms ±10% ½ watt
182	510332	Resistor—carbon 560 Ohms ±10% 2 watt
185, 186	510132	Resistor—carbon 560 Ohms ±10% ½ watt
188	510180	Resistor—carbon 270,000 Ohms ±10% ½ watt
189	510181	Resistor—carbon 330,000 Ohms ±10% ½ watt
190, 191	510739	Resistor—carbon 1800 Ohms ±5% ½ watt
194, 195	510172	Resistor—carbon 100,000 Ohms ±10% ½ watt
197	510162	Resistor—carbon 27,000 Ohms ±10% ½ watt
198	510195	Resistor—carbon 4.7 Meg. ½ watt
200	510185	Resistor—carbon 470,000 Ohms ½ watt
203	510150	Resistor—carbon 5600 Ohms ±10% ½ watt
206	510139	Resistor—carbon 1500 Ohms ±10% ½ watt
207	510172	Resistor—carbon 100,000 Ohms ±10% ½ watt
209	510180	Resistor—carbon 270,000 Ohms ±10% ½ watt
213	510184	Resistor—carbon 470,000 Ohms ±10% ½ watt
215	510116	Resistor—carbon 68 Ohms ½ watt
218	510716	Resistor—wire wound 220 Ohms ±10% 5 watt
220	510356	Resistor—carbon 12,000 Ohms ±10% 2 watt
226	510254	Resistor—carbon 10,000 Ohms ±10% 1 watt
228	510725	Resistor—carbon 3.3 Ohms ±10% ½ watt
229	510195	Resistor—carbon 4.7 Meg. ½ watt
231	510391	Resistor—carbon 1 Meg. 2 watt
234	510187	Resistor—carbon 680,000 Ohms ±10% ½ watt
247	510319	Resistor—carbon 100 Ohms 2 watt
252	510726	Resistor—wire wound 850 Ohms 5 watt
262-B	508062	Resistor—carbon 22,000 Ohms 1/5 watt (part of Integrator Unit)
262-D	508062	Resistor—carbon 8200 Ohms 1/5 watt (part of Integrator Unit)
262-F	508062	Resistor—carbon 8200 Ohms 1/5 watt (part of Integrator Unit)
265	510721	Resistor—carbon 1.5 Meg. ±5% ½ watt
267	510172	Resistor—carbon 100,000 Ohms ±10% ½ watt
268	510196	Resistor—carbon 6.8 Meg. ½ watt
269	510738	Resistor—carbon 1.2 Meg. ±10% ½ watt
272	510151	Resistor—carbon 6800 Ohms ±10% ½ watt
275	510193	Resistor—carbon 2.2 Meg. ½ watt
276	510338	Resistor—carbon 1200 Ohms ±10% 2 watt
354	510185	Resistor—carbon 470,000 Ohms ½ watt
357	510179	Resistor—carbon 220,000 Ohms ½ watt
358	510741	Resistor—wire wound 600 Ohms 10 watt
360	510727	Resistor—wire wound 7500 Ohms ±10% 5 watt
362	510136	Resistor—carbon 1000 Ohms ±10% ½ watt
368	510173	Resistor—carbon 100,000 Ohms ½ watt
381	510193	Resistor—carbon 2.2 Meg. ½ watt
383	510155	Resistor—carbon 10,000 Ohms ½ watt
386	510136	Resistor—carbon 1000 Ohms ±10% ½ watt
390	510152	Resistor—carbon 6800 Ohms ½ watt
392	510249	Resistor—carbon 4700 Ohms 1 watt
394	510146	Resistor—carbon 3300 Ohms ½ watt
395	510246	Resistor—carbon 3300 Ohms 1 watt

PARTS LIST (Contd.)

RESISTORS—Continued

DIAGRAM NO.	PART NO.	DESCRIPTION
399-B	506338	Resistor—carbon 47,000 Ohms 1/5 watt (part of Diode Filter Unit)
400	510185	Resistor—carbon 470,000 Ohms ½ watt
402	510193	Resistor—carbon 2.2 Meg. ½ watt
405	510240	Resistor—carbon 1500 Ohms 1 watt
410	510125	Resistor—carbon 220 Ohms ½ watt
411	510159	Resistor—carbon 18,000 Ohms ±10% ½ watt
414, 415	510155	Resistor—carbon 10,000 Ohms ½ watt
428	510728	Resistor—carbon 15,000 Ohms ± 10% 10 watt

CONTROLS

DIAGRAM NO.	PART NO.	DESCRIPTION
33-A, B	508182	Volume control—1 Meg. (with on-off switch)
43-A to D	508203	Band switch (includes volume control)
54	508324	Built-in Antenna Tuning condenser (4-70 Mmfd.)
88	*	Fine Tuning condenser (3-5 Mmfd.)
160-A, B	508201	Tone and Contrast potentiometer A—Tone control; 500,000 Ohms ¼ watt B—Contrast control; 3000 Ohms ±10% 4 w.
173	508202	Brightness potentiometer (50,000 Ohms)
180	508057	Focus potentiometer (5500 Ohms ±10% 4 watt)
202	508077	Horizontal Lock coil (less slug)
	507429	Slug core for Horizontal Lock coil
208	508202	Horizontal Hold potentiometer (50,000 Ohms)
212	508071	Horizontal Drive trimmer condenser (10-160 Mmfd.)
225	508667	Width coil (includes slug clip)
	508784	Slug core for Width coil
233	162190	Horizontal Linearity coil (includes slug)
	507429	Slug core for Horizontal Linearity coil
266	508051	Vertical Hold potentiometer (1 Meg.)
270	508052	Height potentiometer (2.5 Meg.)
277	508053	Vertical Linearity potentiometer (6000 Ohms)

COILS AND TRANSFORMERS

DIAGRAM NO.	PART NO.	DESCRIPTION
12	508061	Transformer—1st TV sound I.F. (includes condensers 12-A and 12-B)
15	507373	Coil—choke
18	508061	Transformer—2nd TV sound I.F. (includes condensers 18-A and 18-B)
26	507321	Transformer—TV sound discriminator (includes condenser 26-A)
	508438	Slug core (5/16" dia. x ⅜" long) for primary of TV sound discriminator transformer
	508894	Slug core (¼" dia. x ½" long) for primary of TV sound discriminator transformer
	508439	Slug core (5/16" dia. x ¾" long) for secondary of TV sound discriminator transformer
	508894	Slug core (¼" dia. x ½" long) for secondary of TV sound discriminator transformer
37	507373	Coil—choke
49	505912	Transformer—sound output
	508080	R.F. Unit complete with coils and tubes
55	507952	Coil—antenna; Channel #2
56	507953	Coil—antenna; Channel #3
57	507954	Coil—antenna; Channel #4
58	507955	Coil—antenna; Channel #5
59	507956	Coil—antenna; Channel #6
60	507957	Coil—antenna; Channel #7
61	507958	Coil—antenna; Channel #8
62	507959	Coil—antenna; Channel #9
63	507960	Coil—antenna; Channel #10
64	507961	Coil—antenna; Channel #11
65	507962	Coil—antenna; Channel #12
66	507963	Coil—antenna; Channel #13
73	507972	Coil—R.F. and osc.; Channel #2
74	507973	Coil—R.F. and osc.; Channel #3
75	507974	Coil—R.F. and osc.; Channel #4
76	507975	Coil—R.F. and osc.; Channel #5
77	507976	Coil—R.F. and osc.; Channel #6
78	507977	Coil—R.F. and osc.; Channel #7
79	507978	Coil—R.F. and osc.; Channel #8
80	507979	Coil—R.F. and osc.; Channel #9
81	507980	Coil—R.F. and osc.; Channel #10
82	507981	Coil—R.F. and osc.; Channel #11
83	507982	Coil—R.F. and osc.; Channel #12
84	507983	Coil—R.F. and osc.; Channel #13
	507986	Slug for osc. coil fine tuning adjustment
98	507985	Coil—converter plate (includes condensers 98-A, 98-B, resistor 99 and slug)
103	507567	Coil—1st I.F. trap
107	507343	Coil—1st video I.F. (less slug)
	507357	Slug core for 1st video I.F. coil
115	507343	Coil—2nd video I.F. (less slug)
	507357	Slug core for 2nd video I.F. coil
125	507343	Coil—3rd video I.F. (less slug)
	507357	Slug core for 3rd video I.F. coil

COILS AND TRANSFORMERS—Continued

DIAGRAM NO.	PART NO.	DESCRIPTION
128	507367	Coil—choke
134	507591	Coil—4th video I.F. assembly (includes condenser 136 and choke coil 137)
	507357	Slug core for 4th video I.F. coil
137	507367	Coil—choke
143	507374	Coil—peaking
152	507374	Coil—peaking
161	508069	Coil—peaking
163	508070	Coil—peaking
181	508994	Coil—focus
184	508675	Yoke—picture tube deflection
202	508077	Coil—Horizontal Lock (less slug)
	507429	Slug core for Horizontal Lock coil
222	508883	Transformer—horizontal fly-back
225	508667	Coil—Width (includes slug and clip)
	508784	Slug core for Width coil
233	162190	Coil—Horizontal Linearity (includes slug)
	507429	Slug core for Horizontal Linearity Coil
239	508702	Transformer—power
241	507586	Coil—choke
244	507587	Coil—choke
248	507584	Coil—choke
253	508341	Choke—filter
254	507584	Coil—choke
255	507970	Coil—choke
257	507971	Coil—choke
259	507586	Coil—choke
263	508076	Transformer—vertical blocking oscillator
271	507567	Coil—3rd I.F. trap
278	508674	Transformer—vertical output
365	508184	Coil—AM antenna
370	507586	Coil—choke
372	507935	Coil—choke
374	507942	Coil—FM oscillator
375	508195	Coil—AM oscillator
379	507941	Coil—FM R.F.
385	506581	Coil—R.F. choke (includes resistor 386)
387	506080	Transformer—1st FM I.F. (includes condensers 387-A and 387-B)
388	505867	Transformer—1st AM I.F. (includes condensers 388-A and 388-B)
397	505905	Transformer—2nd FM I.F. (includes condenser 397-A)
398	505867	Transformer—2nd AM I.F. (includes condensers 398-A and 398-B)
409	508179	Transformer—FM discriminator (includes condenser 409-A)
418	508212	Loop antenna (AM)

OTHER ELECTRICAL PARTS

DIAGRAM NO.	PART NO.	DESCRIPTION
43-A to D	508203	Switch—band (on TV chassis)
51	508174	Speaker—P.M. Dynamic (6" x 9")
53	508325	Built-in antenna (includes condenser 54)
221	508713	Fuse for horizontal sweep circuit; ¼ Amp. 250 volt
261	118921	Lamp—TV Channel Lite (Mazda #47) 6-8 v. 150 Ma.
262-A to G	508062	Integrator coupling unit A—Condenser—ceramic .01 Mfd. 450 volt B—Resistor—carbon 22,000 Ohms 1/5 watt C—Condenser—ceramic 2000 Mmfd. 450 volt D—Resistor—carbon 8200 Ohms 1/5 watt E—Condenser—ceramic 5000 Mmfd. 450 volt F—Resistor—carbon 8200 Ohms 1/5 watt G—Condenser—ceramic 5000 Mmfd. 450 volt
361	118921	Lamp—OFF-ON Indicator Lite (Mazda #47) 6-8 v. 150 Ma.
363	118921	Lamp—AM Channel Lite (Mazda #47) 6-8 v. 150 Ma.
364	118921	Lamp—FM Channel Lite (Mazda #47) 6-8 v. 150 Ma.
369-A, B	508753	Switch—band (on AM-FM tuner)
399-A, B, C	506338	Diode filter unit A—Condenser—ceramic 100 Mmfd. 400 volt B—Resistor—carbon 47,000 Ohms 1/5 watt C—Condenser—ceramic 100 Mmfd. 400 volt
418	508212	Loop antenna (AM)

MECHANICAL PARTS OF R.F. TUNER

(For electrical parts see preceding classified listings of condensers, resistors and coils.)

DIAGRAM NO.	PART NO.	DESCRIPTION
	508080	R.F. Unit complete with coils and tubes
	508666	Bracket for mounting tuner (front)
	508665	Bracket for mounting tuner (rear)
	508437	Fine Tuning cam and brass shaft
	508708	Roller—detent
	507989	Shield—tube; miniature for 6J6 or 6AG5
	507986	Slug for osc. coil fine tuning adjustment

MECHANICAL PARTS of R.F. TUNER—Continued

DIAGRAM NO.	PART NO.	DESCRIPTION
	507987	Socket—miniature for 6J6
	507988	Socket—miniature for 6AG5
	507966	Spring contactor washer (on front turret shaft)
	508709	Spring—detent
	507990	Spring—retains osc. fine tuning slug
	507967	Spring—turret shaft retaining
	507984	Stator contact assembly (includes 11 contacts and metal frames)
	508707	Tuner turret and shaft assembly (less coils)
	507965	Washer, fiber spacer (turret shaft)

CABINET PARTS

DIAGRAM NO.	PART NO.	DESCRIPTION
	508722	Back for cabinet (less power cord)
	508217	Bracket for mounting OFF-ON indicator lite at base of cabinet
	117131	Bull's-eye for OFF-ON indicator lite at base of cabinet
	508550	Cabinet
	507930	Call letter tabs
	508204	Dial scale, AM-FM
	508210	Escutcheon, control panel
	508540	Glass window
	508204	Knob—AM-FM Coarse Tuning and dial scale
	508205	Knob—AM-FM Fine Tuning
	508206	Knob—Brightness or Horizontal Hold
	502563	Knob—built-in antenna
	508627	Knob—Channel Selector
	508209	Knob—"CONTRAST"
	507917	Knob—TV Fine Tuning
	508208	Knob—"TV-PHONO-AM-FM"
	508207	Knob—Volume or Tone
	508331	Mask for picture tube
	508211	Name plate (Custom Deluxe 12)
	508621	Rubber gasket between mask and picture tube
	18796	Screw—#10 x 1"; mounts chassis
	505497	Socket for OFF-ON indicator lite at base of cabinet
	162163	Terminal strip for TV antenna connection

MISCELLANEOUS

DIAGRAM NO.	PART NO.	DESCRIPTION
	509048	Back cover and switch shaft bearing assembly for AM-FM tuner
	301270	Base for mounting electrolytic condenser
	508829	Bracket base for support of yoke and focus coil (left hand)
	508830	Bracket base for support of yoke and focus coil (right hand)
	508613	Bracket for deflection yoke mounting
	508728	Bracket for mounting trimmer #26
	508666	Bracket for mounting tuner (front)
	508665	Bracket for mounting tuner (rear)
	508510	Bracket—retains front of picture tube
	508755	Bracket—supports AM-FM tuner
	508198	Bracket—supports band switch shaft on TV chassis
	508038	Bracket—tube support (bottom front) (less rubber pad)
	508154	Bracket ("U" shaped) for support of yoke and focus coil
	505165	"C" washer for connecting link
	505314	"C" washer for extension shaft
	507930	Call letter tabs
	508806	Centering magnet assembly
	112745	Clip for mounting AM antenna coil
	508683	Clip for mounting electrolytic condenser #129
	508681	Clip for mounting electrolytic condenser #224
	507339	Clip for mounting, 1st video I.F., 2nd video I.F., 3rd video I.F., horiz. lock or horiz. linearity coil
	507592	Clip for mounting 4th video I.F. coil
	508715	Clip for mounting fuse holder

MISCELLANEOUS—Continued

DIAGRAM NO.	PART NO.	DESCRIPTION
	500245	Clip for mounting H.V. condenser
	505101	Clip for mounting I.F. transformer or FM sound discriminator
	114955	Clip—retainer on end of dial cord
	507286	Connector for H.V. terminal of picture tube
	117057	Cord—dial drive (2½ ft. required) per ft.
	508525	Drum—dial; on gang condenser
	508714	Fuse holder
	508623	Grounding spring for coating on picture tube
	506803	Ion trap
	509047	Lever—band switch actuating (on AM-FM tuner)
	509049	Lever—band switch actuating (on TV chassis)
	508756	Link—connects band switch actuating levers
	508617	Nut—for retaining focus coil mounting plate
	162183	Planetary drive and dial drum (includes mounting bracket)
	508864	Plate—focus coil mounting
	506652	Plug for AM-FM tuner power cable
	500966	Plug for audio cable on AM-FM tuner
	508878	Plug for focus coil leads
	507699	Power cord assembly (includes plugs at both ends)
	507361	Rubber cover for H.V. terminal connector
	508512	Rubber spacer on picture tube support bracket
	507793	Rubber spacer support between flared neck of picture tube and yoke bracket
	18796	Screw—#10 x 1"; mounts chassis
	508732	Shaft, extension for band switch on AM-FM tuner
	162138	Shield—H.V. supply (front section)
	508088	Shield—H.V. supply (rear section)
	508862	Shield—protector for band switch
	507357	Slug core for 1st, 2nd, 3rd or 4th video I.F. coil
	507429	Slug core for Horizontal Lock or Horizontal Linearity coil
	508438	Slug core (5/16" dia. x ⅜" long) for primary of TV sound discriminator transformer
	508894	Slug core (¼" dia. x ½" long) for primary of TV sound discriminator transformer
	508439	Slug core (5/16" dia. x ¾" long) for secondary of TV sound discriminator transformer
	508894	Slug core (¼" dia. x ½" long) for secondary of TV sound discriminator transformer
	508784	Slug core for Width coil
	160039	Socket—AM-FM tuner output
	162038	Socket assembly for 1B3GT/8016 tube (includes corona ring and mounting frame)
	508049	Socket and cable assembly for picture tube
	508156	Socket and mounting bracket for TV channel lite
	507948	Socket for AM-FM tuner power cable
	508335	Socket for AM or FM channel lite
	508879	Socket for focus coil leads
	508086	Socket for mounting H. V. condenser #230
	507932	Socket—male, power cord interlock
	506576	Socket—miniature (7 pin) for 6BE6)
	507364	Socket—miniature (7 pin)
	506331	Socket—miniature (9 pin) (for 12AT7)
	508044	Socket—miniature (9 pin)
	508703	Socket—octal
	160039	Socket—phono. plug
	505161	Spring—dial cord tension
	508514	Spring—retains H.V. lead
	508608	Spring—tension for focus coil mounting
	503994	Strap for picture tube support (includes rubber pad)
	111456	Washer—spring washer for connecting link
	170195	Wing nut—#8-32; for yoke and focus coil mounting
	170851	Wing nut—#5-40; for mounting focus coil to plate
	170817	Wing screw—#10-24; for height adj. of yoke and focus coil
	170741	Wing screw—#10-32; for yoke mounting

*—This part is not supplied as a Service replacement item.

World Radio History

1. DESCRIPTIVE SPECIFICATIONS.

Power Supply — 117 volts, 60 cycle, 210 watts.

Kinescope — 12QP4, 12LP4, or 12KP4, kinescope, magnetic, deflection, mechanical picture centering, and magnetic focus. (Focus coil permanent magnet with electromagnetic vernier.)

Sweep Circuits.

Horizontal — Oscillator and driver tube, sweep amplifier tube, damper tube, and H.V. rectifier tube. Sweep frequency is automatically controlled.

Vertical — Oscillator, driver, and sweep amplifier tubes. Frequency is manually controlled.

Radio Frequency and Intermediate Frequency Circuits.

AM Picture — Superhetrodyne, tuned RF stage, converter and 4 I.F. stages. 2nd Detector and Video Amplifier. (Sound traps in 1st and 3rd I.F. stages.) Keyed A.G.C. operating from video detector.

FM Sound — Intercarrier system, limiter, ratio detector, triode audio driver, and beam power amplifier.

Number of Tubes — 24 including kinescope and rectifiers.

Frequency Ranges — Low Band, 54 mc. thru 88 mc. High band 147 mc. thru 216 mc.

Intermediate Frequencies.

Picture Carrier — 26.4 mc., 3.7 bandwidth at 50% response points.

Sound Carrier — 21.9 mc. Beat with picture carrier at 2nd detector to produce 4.5 mc.

Front Controls.

Top — Dual Control
 Center Knob — Vertical Hold.
 Outside Knob — Horizontal Hold.

2nd from Top — Dual Control
 Center Knob — Off-On-Volume.
 Outside Knob — Picture Control.

3rd from Top — Dual Control.
 Center Knob — Brightness Control.
 Outside Knob — Hi-Lo Channel Switch.

Bottom — Dual Control.
 Center Knob — Opera Glass.
 Outside Knob — Tuning Control.

Rear Controls.

1 — Horizontal Linearity.
2 — Horizontal Damping.
3 — Horizontal Size.
4 — Vertical Size Small.
5 — Vertical Linearity Small.
6 — Tone Switch.
7 — Vertical Linearity Large.
8 — Vertical Size Large.
9 — Focus.

Speaker Equipment

12" Permanent Magnet — 3.2 ohm impedence.

Audio Power Rating.

2.0 watts at 400 cycles with 10% distortion.

Tubes — Types and Function.

V-1	12AU7	Vertical Sweep Output.
V-2	6SN7-GT	Horizontal Sweep Oscillator.
V-3	6BG6-G	Horizontal Sweep Output.
V-4	6W4-GT	Damper.
V-5	1B3-GT 8016	High Voltage Rectifier.
V-6	6AL5	Horizontal Phase Detector.
V-7	12AU7	Sync Splitter and DC Restorer.
V-8	6AC7	Video Amplifier.
V-9	6AL5	Video Detector and Limiter.
V-10	6BH6	3rd Video I.F. Amplifier.
V-11	6BH6	2nd Video I.F. Amplifier.
V-12	6BH6	1st Video I.F. Amplifier.
V-13	6AU6	Ratio Detector Driver.
V-14	6T8	Ratio Detector and Audio Amplifier.
V-15	6V6-GT G	Audio Output.
V-16	6J6	Hi-Band Converter and Oscillator.
V-17	6J6	Lo-Band Converter and Oscillator.
V-18	6BC5	Hi-Band R.F. Amplifier.
V-19	6BH6	Lo-Band R.F. Amplifier
V-20	5U4-G	Power Rectifier.
V-21	12KP4 / 12LP4 / 12QP4	Kinescope.
V-22	12AU7	Vertical Sweep Oscillator and Sync Clipper.
V-23	6AH6	4th I.F.-Video I.F. Amplifier.
V-24	6AU6	A.G.C.

2. ALIGNMENT PROCEDURE.

General.

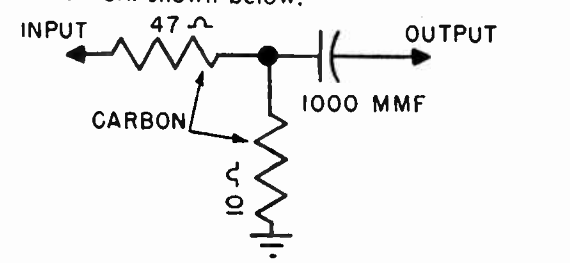
All precautions for aligning high frequency devices should be observed. Signal generators and oscilloscope leads should be well shielded and as short as possible. If necessary to reduce regeneration, a metal plate should be placed on the bench where the alignment work is done.

Video I.F. Alignment.

The video I.F. system consists of a double tuned converter plate transformer followed by four single tuned stages. These four are the 1st, 2nd, 3rd, and 4th I.F. Stages. They are aligned as a "quadruple" unit previous to the adjustment of the double-tuned stage.

Alignment of the "Quadruple".

1. Set the contrast control at the maximum contrast position.
2. Apply an external bias of approximately 3V D.C. to the AGC line at the junction of R-119, 100 ohms, R-73, 27,000 ohms, and C-7, 10 MF.
3. Connect the oscilloscope to the grid of the video amplifier, pin 4 of V-8 (6AC7). The lead used for this connection should be a low capacity type shielded cable. A 47,000 ohm isolating resistor at the input end of the cable is advisable to minimize disturbances caused by I.F. energy pickup on the cable. Failure to observe this precaution may result in incorrect alignment of the receiver.
4. Connect the output of the sweep generator to the grid of the 1st I.F. amplifier V-12 (6BH6) thru the network shown below.



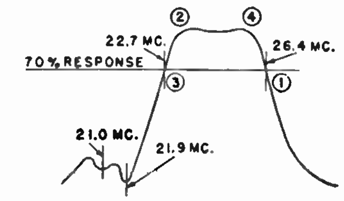
The 47 ohm and 10 ohm resistor network is recommended to give proper terminaton to the generator output cable and also to provide a low grid to ground impedance to minimize feedback from other receiver circuits.

5. Adjust the gain of the scope and the signal input to produce a 2 volt peak to peak output on the oscilloscope screen. This level of output should be maintained throughout the alignment procedure by re-adjusting the bias and/or the input.
6. Adjust the 21.9 mc. trap L-2 so that the 21.9 marker is coincident with the valley of the trap as shown below.
7. The 21 mc. L-5 trap may then be adjusted (without using a marker) to give the response curve the approximate shape as shown below. The response between the 21.9 mc. and 21 mc. should be kept at a minimum.
8. The tuning slugs are identified in accordance with their approximate frequency settings as follows:

No. 1 — 1st I.F. Plate coil, T-9 hi-hi frequency.
No. 2 — 2nd I.F. Plate coil, T-10 hi-lo frequency.
No. 3 — 3rd I.F. Plate coil, T-11 lo-lo frequency.
No. 4 — 4th I.F. Plate coil, T-12 lo-hi frequency.

Refer to the circled numbers on the response curve shown below for the relative positions.

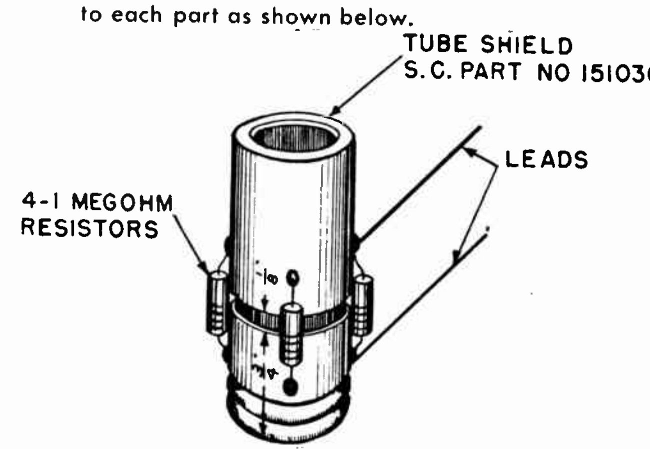
Maintaining these relative frequency positions, the slugs should be set to produce a curve approximately as shown below with 26.4 mc. and 22.7 mc. markers at the 70% response.



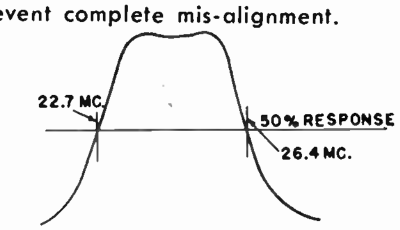
9. It is suggested the traps be checked to insure correct frequency setting after finishing Step No. 8.

Alignment of the Double-Tuned Stage.

1. The band switch is turned to the Lo Band position and the external bias is still applied to the AGC bus.
2. The output from the sweep generator is coupled into the plate of the Lo Band converter tube V-17, 6J6, by means of the special tube shield. This special shield is constructed by cutting tube shield SC No. 151036 in two, ¾" from the base. Separate the two pieces by ⅛" and secure by soldering 4-1 meg. ohm ½ watt carbon resistors to each part as shown below.



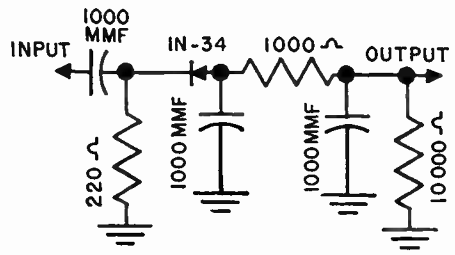
3. Adjust the primary L-26 and secondary T-8 of the double-tuned pair until the 26.4 mc. and 22.7 mc. markers are at 50% response as shown below.
4. It may be necessary to make slight adjustments on the "Quadruple" in order to achieve the desired response, but caution should be exercised to prevent complete mis-alignment.



Sound I.F. Alignment.

1. Apply a modulated 4.5 mc. signal to the grid of the video amplifier, pin 4 of V-8 (6AC7). Connect the input of the oscilloscope thru the crystal detector shown below to the grid of the kinescope tube.

©John F. Rider
World Radio History

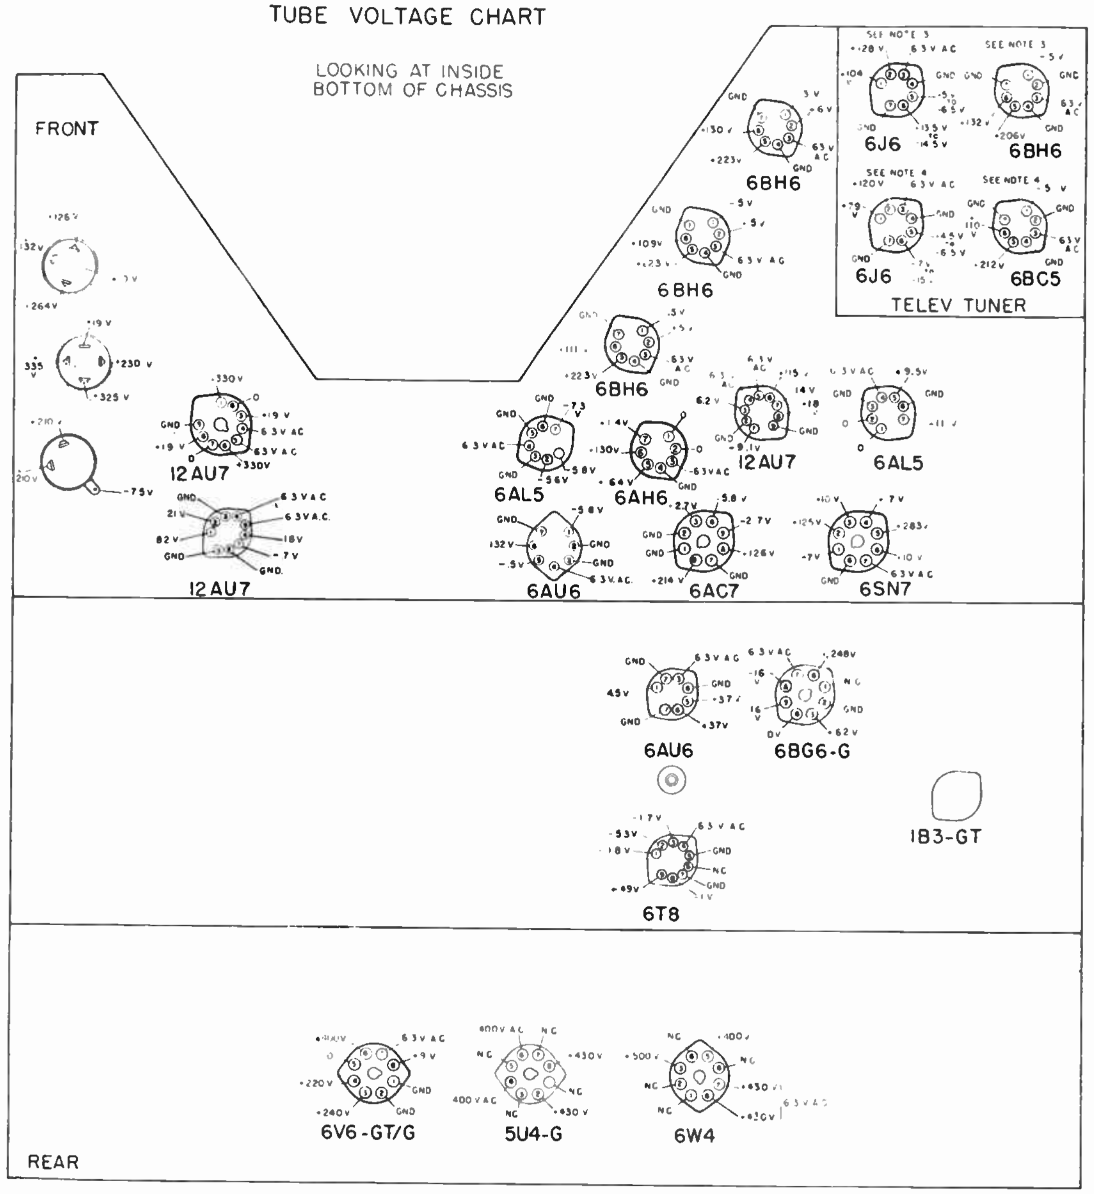


2. Adjust the core of T-5 the 4.5 mc. sound take-off coil for minimum response.

3. Remove the modulation on the 4.5 mc. signal and adjust the primary of the ratio detector transformer T-6 for maximum AGC voltage. This voltage is measured across the 5.0 MF electrolytic capacitor C-56 in the ratio detector diode circuit.

4. Adjust the secondary of the ratio detector transformer for zero voltage from the junction of R-79, 22K and R-80, 22K to the junction of C-58, .047 MF and R-78, 18K. This voltage in adjustment should pass thru zero between positive and negative swings on the VTVM.

TUBE VOLTAGE CHART



NOTES:
1- MEASUREMENTS ARE MADE AT 117 V LINE USING 11 MEGOHM VACUUM TUBE VOLTMETER ALL VOLTAGES ARE D C AND ARE POSITIVE WITH RESPECT TO CHASSIS GROUND EXCEPT WHERE NOTED.
2- ALL VOLTAGES ARE THE SAME IN ANY POSITION OF THE RANGE SWITCH EXCEPT AS SHOWN IN NOTES 3 AND 4.
3- VOLTAGES SHOWN ARE FOR LOW BAND (CHANNELS 2 TO 6)
4- VOLTAGES SHOWN ARE FOR HIGH BAND (CHANNELS 7 TO 13)
5- CONTRAST CONTROL SET MINIMUM, ANTENNA DISCONNECTED, NORMAL PICTURE SIZE.

SERVICE INSTRUCTIONS FOR THE 116-C, 116-T, AND 116-RP TELEVISION RECEIVERS

1. DESCRIPTIVE SPECIFICATIONS.

Power Supply — 117 volts, 60 cycle, 240 watts.

Kinescope — 16GP4, 16KP4, 16RP4, or 16TP4, kinescope, magnetic, deflection, mechanical picture centering, and magnetic focus. (Focus coil permanent magnet with electromagnetic vernier.)

Sweep Circuits.

Horizontal — Oscillator and driver tube, sweep amplifier tube, damper, and 2 H.V. rectifier tubes. Sweep frequency is automatically controlled.

Vertical — Oscillator and sweep amplifier tubes. Frequency is manually controlled.

Radio Frequency and Intermediate Frequency Circuits.

AM Picture — Superhetrodyne, tuned RF stage, converter and 4 I.F. stages. 2nd Detector and Video Amplifier. (Sound traps in 1st and 3rd I.F. stages.) Keyed A.G.C. operating from video detector.

FM Sound — Intercarrier system, limiter, ratio detector, triode audio driver, and beam power amplifier.

Number of Tubes — 26 including kinescope and rectifiers.

Frequency Ranges — Low Band, 54 mc. thru 88 mc. High band 147 mc. thru 216 mc.

Intermediate Frequencies.

Picture Carrier — 26.4 mc., 3.7 bandwidth at 50% response points.

Sound Carrier — 21.9 mc. Beat with picture carrier at 2nd detector to produce 4.5 mc.

Front Controls.

Top — Dual Control
- Center Knob — Vertical Hold.
- Outside Knob — Horizontal Hold.

2nd from Top — Dual Control
- Center Knob — Off-On-Volume.
- Outside Knob — Picture Control.

3rd from Top — Dual Control.
- Center Knob — Brightness Control.
- Outside Knob — Hi-Lo Channel Switch.

Bottom — Dual Control.
- Center Knob — Fine Tuning Control.
- Outside Knob — Tuning Control.

Rear Controls.

1 — Horizontal Linearity.
2 — Horizontal Drive.
3 — Horizontal Size.
4 — Vertical Size.
5 — Vertical Linearity.
6 — Focus.
7 — Tone.

Speaker Equipment

116-C — RP — 12″ Permanent Magnet — 3.2 ohm impedance.

116-T — 5½″ Permanent Magnet — 3.2 ohm impedance.

Audio Power Rating.

2.0 watts at 400 cycles with 10% distortion.

Tubes — Types and Function.

V-1	12AU7	Vertical Sweep Output.
V-2	6SN7-GT	Horizontal Sweep Oscillator.
V-3	6BG6-G	Horizontal Amplifier.
V-4	6W4-GT	Damper.
V-5	16GP4, 16KP4, 16RP4, 16TP4	Kinescope.
V-6	6AL5	Horizontal Phase Detector.
V-7	12AU7	Sync Splitter and DC Restorer.
V-8	6AC7	Video Amplifier.
V-9	6AL5	Video Detector and Limiter.
V-10	6BH6	3rd Video I.F. Amplifier.
V-11	6BH6	2nd Video I.F. Amplifier.
V-12	6BH6	1st Video I.F. Amplifier.
V-13	6AU6	Ratio Detector Driver.
V-14	6T8	Ratio Detector and Audio Amplifier.
V-15	6V6-GT/G	Audio Output.
V-16	6J6	Hi-Band Converter and Oscillator.
V-17	6J6	Lo-Band Converter and Oscillator.
V-18	6BC5	Hi-Band R.F. Amplifier.
V-19	6CB6	Lo-Band R.F. Amplifier.
V-20	5U4-G	Power Rectifier.
V-21	1X2	High Voltage Rectifier.
V-22	12AU7	Vertical Sweep Oscillator and Sync Clipper.
V-23	6AH6	4th I.F.-Video I.F. Amplifier.
V-24	6AU6	A.G.C.
V-25	6AU6	Sound I.F. Amp.
V-26	1X2	High-Voltage Rectifier.

2. ALIGNMENT PROCEDURE.

General.

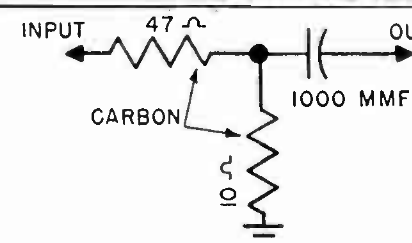
All precautions for aligning high frequency devices should be observed. Signal generators and oscilloscope leads should be well shielded and as short as possible. If necessary to reduce regeneration, a metal plate should be placed on the bench where the alignment work is done.

Video I.F. Alignment.

The video I.F. system consists of a double tuned converter plate transformer followed by four single tuned stages. These four are the 1st, 2nd, 3rd, and 4th I.F. Stages. They are aligned as a "quadruple" unit previous to the adjustment of the double-tuned stage.

Alignment of the "Quadruple".

1. Set the contrast control at the maximum contrast position.
2. Apply an external of approximately —3V D.C. to the AGC line at the junction of R-119, 100 ohms, R-73, 27,000 ohms, and C-7, 10 MF.
3. Connect the oscilloscope to the grid of the video amplifier, pin 4 of V-8 (6AC7). The lead used for this connection should be a low capacity type shielded cable. A 47,000 ohm isolating resistor at the input end of the cable is advisable to minimize disturbances caused by I.F. energy pickup on the cable. Failure to observe this precaution may result in incorrect alignment of the receiver.
4. Connect the output of the sweep generator to the grid of the 1st I.F. amplifier V-12 (6BH6) thru the network



The 47 ohm and 10 ohm resistor network is recommended to give proper terminaton to the generator output cable and also to provide a low grid to ground impedance to minimize feedback from other receiver circuits.

5. Adjust the gain of the scope and the signal input to produce a 2 volt peak to peak output on the oscilloscope screen. This level of output should be maintained throughout the alignment procedure by re-adjusting the bias and/or the input.
6. Adjust the 21.9 mc. trap L-2 so that the 21.9 marker is coincident with the valley of the trap as shown in Fig. 1.
7. The 21 mc. L-5 trap may then be adjusted (without using a marker) to give the response curve the approximate shape as shown in Fig. 1. The response between the 21.9 mc. and 21 mc. should be kept at a minimum.
8. The tuning slugs are identified in accordance with their approximate frequency settings as follows:

   No. 1 — 1st I.F. Plate coil, T-9 hi-hi frequency.
   No. 2 — 2nd I.F. Plate coil, T-10 hi-lo frequency.
   No. 3 — 3rd I.F. Plate coil, T-11 lo-lo frequency.
   No. 4 — 4th I.F. Plate coil, T-12 lo-hi frequency.

   Maintaining these relative frequency positions, the slugs should be set to produce a curve approximately as shown below with 26.4 mc. and 22.7 mc. markers at the 70% response.
9. It is suggested the traps be checked to insure correct frequency setting after finishing Step No. 8.

Alignment of the Double-Tuned Stage.

1. The band switch is turned to the Lo Band position and the external bias is still applied to the AGC bus.

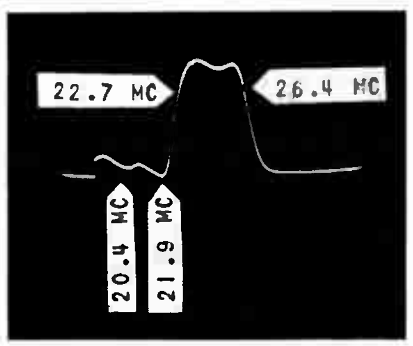


FIG. 1

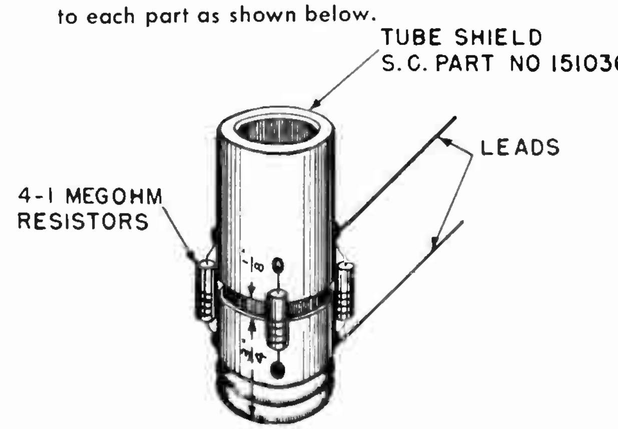
2. The output from the sweep generator is coupled into the plate of the Lo Band converter tube V-17, 6J6, by means of the special tube shield. This special shield is constructed by cutting tube shield SC No. 151036 in two, ¾″ from the base. Separate the two pieces by ⅛″ and secure by soldering 4-1 meg. ohm ½ watt carbon resistors to each part as shown below.



3. Adjust the primary L-26 and secondary T-8 of the double-tuned pair until the 26.4 mc. and 22.7 mc. markers are at 50% response as shown in Fig. 2.
4. It may be necessary to make slight adjustments on the "Quadruple" in order to achieve the desired response, but caution should be exercised to prevent complete mis-alignment.

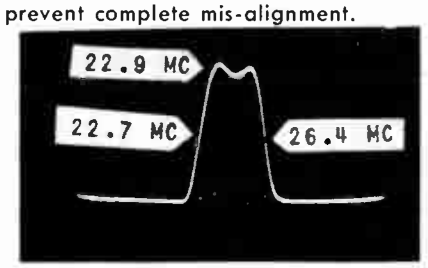


FIG. 2

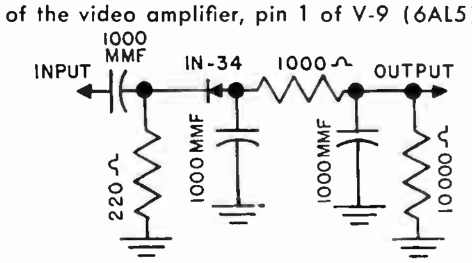
Sound I.F. Alignment.

1. Apply an unmodulated 4.5 mc. signal to the grid of the video amplifier, pin 1 of V-9 (6AL5).



2. Adjust T-5, L-7, and the primary of the ratio detector transformer T-6 for maximum AGC voltage. This voltage is measured across the 5.0 MF electrolytic capacitor C-56 in the ratio detector diode circuit.
3. Adjust the secondary of the ratio detector transformer for zero voltage from the junction of R-79, 22K and R-80, 22K to the junction of C-58, .047 MF and R-78, 18K. This voltage in adjustment should pass thru zero between positive and negative swings on the VTVM.

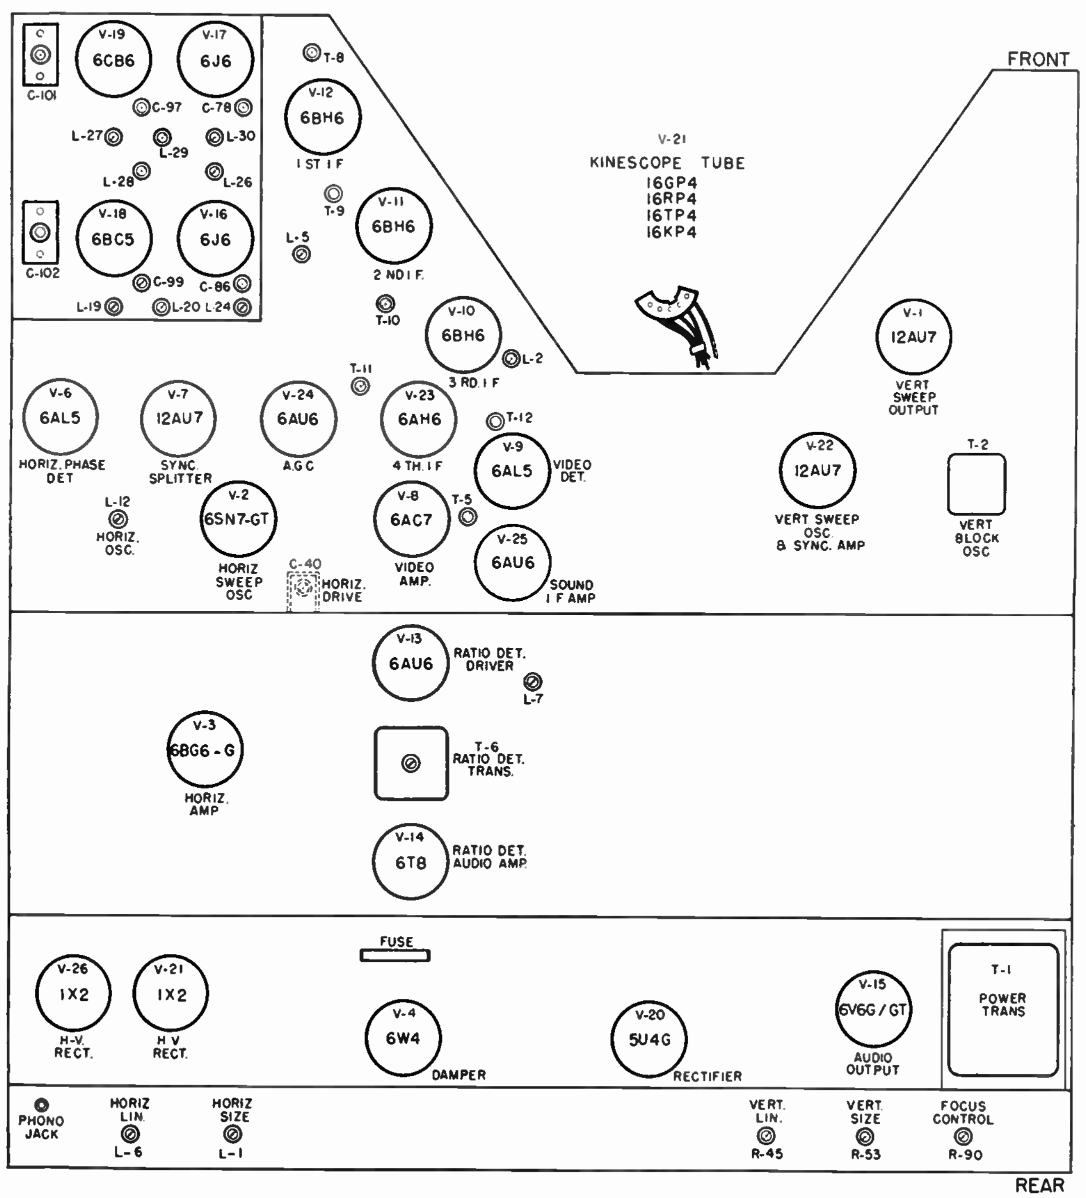
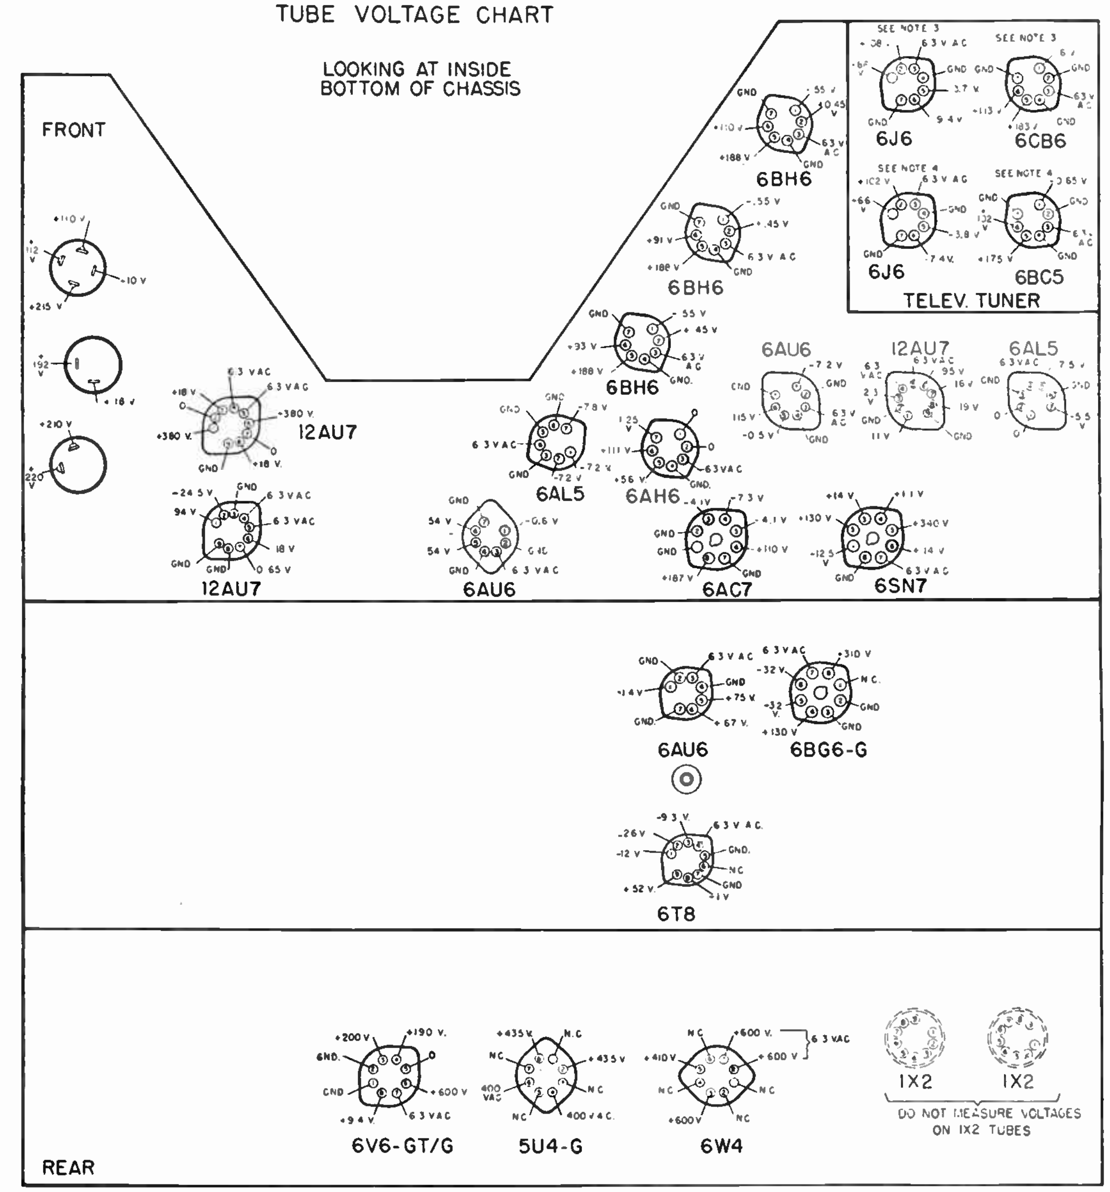
116-SERIES TUBE LOCATION AND TRIMMER CHART



TUBE VOLTAGE CHART

LOOKING AT INSIDE BOTTOM OF CHASSIS



NOTES:
1- MEASUREMENTS ARE MADE AT 117 V. LINE USING. 11 MEGOHM VACUUM TUBE VOLTMETER. ALL VOLTAGES ARE D.C. AND ARE POSITIVE WITH RESPECT TO CHASSIS GROUND EXCEPT WHERE NOTED.
2- ALL VOLTAGES, SHOWN, ARE MEASURED WITH THE RANGE SWITCH IN EITHER HIGH OR LOW BAND POSITION EXCEPT AS SHOWN IN NOTES 3 AND 4.
3- VOLTAGES SHOWN ARE FOR LOW BAND (CHANNELS 2 TO 6).
4- VOLTAGES SHOWN ARE FOR HIGH BAND (CHANNELS 7 TO 13).
5- CONTRAST AND BRIGHTNESS CONTROLS SET AT MINIMUM. ANTENNA DISCONNECTED.

ANTENNA NOTE

ANTENNA CONNECTIONS SHOWN ARE FOR USING INTERNAL ANTENNA SYSTEM. TO USE OUTSIDE ANTENNA, REMOVE BOTH LEADS WITH SPADE TERMINALS FROM 1 AND 2 ON STRIP AND CONNECT OUTSIDE ANTENNA LEAD-IN TO 1 AND 2. TO USE SEPARATE HIGH AND LOW BAND EXTERNAL ANTENNAE, FOLLOW INSTRUCTIONS ON TAG INSIDE RECEIVER.

NOTES:

1. C-62 IS .01 MF 600V (110555) IN 17RP (112111) AND .0047 MF 600V (110553) IN 17RP (112117) AND 17RP2 (112117)
2. PICTURE TUBE IS 16RP4, 16KP4 OR 16TP4 (116208) IN 116RP (112111) AND 17AP4 (162097) IN 17RP & 17RP2 (112117)
3. FOCUS COIL IS 114683 OR 114887, DEPENDING ON PICTURE TUBE TYPE
4. RANGE SWITCH SHOWN IN EXTREME COUNTER-CLOCKWISE (PHONO) POSITION, WITH CONTROL TERMINALS TOWARD BOTTOM. POSITIONS IN CLOCKWISE ROTATION ARE PHONO, FM, AM, TV LOW BAND, TV HIGH BAND
5. FOR 116RP AND 17RP AM FM TUNER SEE SCHEMATIC S-91012
6. FOR 17RP2 AM FM TUNER SEE SCHEMATIC S-91016

INDEX

MODEL 5140B

(19" Picture - Blonde)
available also in Mahogany

MODEL 6140M

(16" Picture - Mahogany)
available also in Walnut

MODEL 5130W

(19" Picture - Walnut)
available also in Blonde and Mahogany

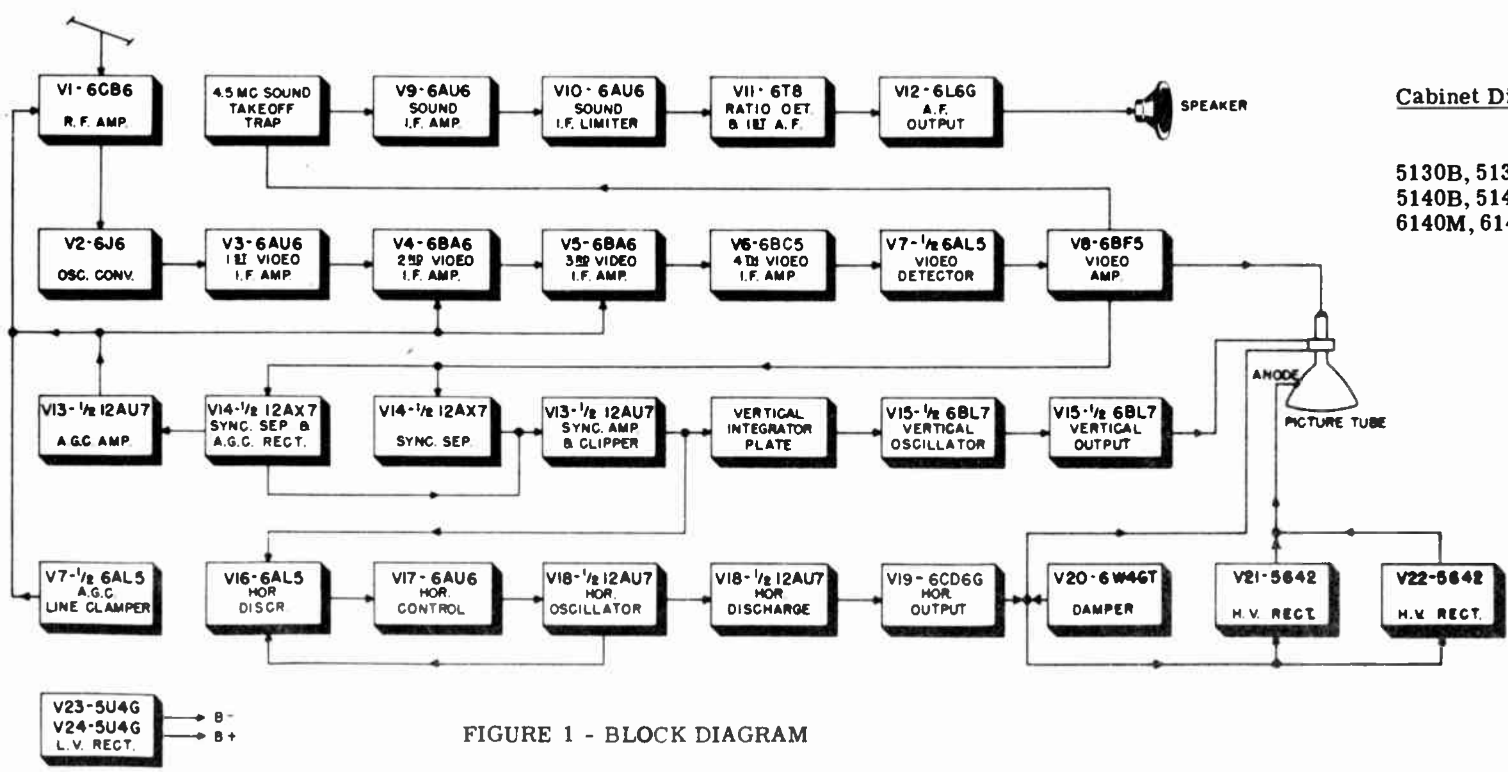

FIGURE 1 - BLOCK DIAGRAM

GENERAL DESCRIPTION

All models are direct viewing television receivers providing reception of all 12 commercial television channels. The television picture is reproduced on either a 16 inch rectangular or a 19 inch round, black-faced, electromagnetically deflected, tetrode type picture tube. The receivers are electrically similar except for picture tubes. Chassis 1-271 (16 inch picture tube) is used in models 6140M and 6140W. Chassis 1-290 (19 inch picture tube) is used in models 5130B, 5130M, 5130W, 5140B, and 5140M.

SPECIFICATIONS

Frequency Range

All 12 television channels,	54 Mc. to 88 Mc.
	174 Mc. to 216 Mc.
Picture IF Carrier	26.4 Mc.
Sound IF Carrier	4.5 Mc. and 21.9 Mc.

Power Supply

105-128 Volts 60cycle AC, 300 Watts

Loud Speaker

5130B, 5130M, 5130W, 5140B, 5140M, 6140M, 6140W	12" P.M.

Cabinet Dimensions (inches)	Width	Height	Depth
5130B, 5130M, 5130W	27.5	39.4	22.9
5140B, 5140M	27.5	39.4	24.7
6140M, 6140W	24.3	37.3	21.3

Antenna Input Impedance

These receivers have an antenna input impedance of 300 ohms, and are shipped to the customer with the built-in antenna connected. However, this must be disconnected in those locations where an external antenna is used.

SYLVANIA TUBE COMPLEMENT

(includes rectifiers and picture tube)

V25	Picture Tube (Models 6140W, 6140M)	16KP4
V25	Picture Tube (Models 5130W, 5130M, 5130B, 5140M, 5140B)	19AP4A

CAUTION NOTICE

THE HIGH VOLTAGE LEAD TO THE PICTURE TUBE HAS A POTENTIAL OF 13,500 VOLTS. PRECAUTIONS SHOULD BE OBSERVED WHEN THE CHASSIS IS REMOVED FROM THE CABINET FOR SERVICE PURPOSES. DO NOT OPERATE THE RECEIVER WITH THE H V COVER REMOVED.

ALWAYS USE SAFETY GOGGLES AND GLOVES IF IT IS NECESSARY TO REMOVE THE PICTURE TUBE.

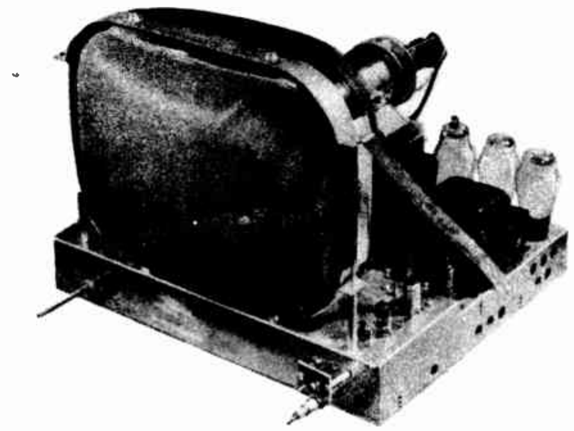
CHASSIS 1-290
19 inch picture tube



CHASSIS 1-271
16 inch picture tube

CIRCUIT DESCRIPTION

The Sylvania television receiver chassis 1-271, 1-290 operate with twenty tubes plus two high voltage rectifiers, two low voltage rectifiers, and one picture tube. The operating controls on the front panel have been reduced to a minimum: Brightness, Volume, and Tuning. The remaining controls, which are seldom adjusted, are located at the rear of the chassis. Special features of this receiver are as follows:

Rotary Channel Selector

A compact, low drift, 12 channel rotary tuner is provided in these chassis for simplicity of operation. Continuous tuning eliminates the need of a fine tuning control.

Built-In Antenna

Eliminating the cost and inconvenience of an external antenna a Sylvania tuned dipole type antenna is built-in to provide satisfactory reception in most locations. The antenna is peaked for resonance to the individual channel by rotating the trimmer knob on the top of the receiver.

Automatic Gain Control

Simplified customer operation is provided by a very flat AGC system which has a high degree of noise immunity. Very little, if any, readjustment of controls is required in going from one station to another.

Direct-Coupled Video System

A direct coupled video system eliminates all video coupling capacitors and D.C. Restorer. This reduces the visible effects of noise.

Horizontal Automatic Frequency Control

A sine wave Horizontal AFC is employed, providing excellent picture stability, even in the presence of noise and weak signals.

For convenience in tracing circuits a block diagram is shown in Figure 1. The antenna is connected to the input of the RF tuner. This tuner functions to select the desired television channel by continuous tuning. The output of the tuner is at intermediate frequency and of sufficient band width to pass both picture and sound carriers of the desired signal.

The output of the tuner is then applied to the video IF Amplifier consisting of 3 stagger-tuned stages and one bandpass stage. The adjacent channel carriers and co-sound carrier are attenuated by this IF Amplifier.

The video signal out of the video detector is amplified by a single stage and impressed on the picture tube.

Automatic gain control is obtained from the AGC Rectifier, amplified by the AGC Amplifier and applied to the RF and IF Amplifiers. The AGC Line Clamper prevents the Tuner AGC Line from going positive under weak signal conditions.

The sync pulses are separated from the video signal, amplified, and clipped and then fed to the Horizontal Discriminator and Vertical Integrator plate. The Vertical Sync information from the vertical integrator plate is applied to Vertical Oscillator to keep this oscillator in step with the vertical sync pulses from the station. The Vertical Oscillator produces a peaked saw-tooth wave which is applied to the Vertical Output stage energizing the Vertical Deflection coils.

Horizontal Sync information from the Sync clipper is supplied to the Horizontal Discriminator. A voltage from the Horizontal Oscillator is also supplied to the Horizontal Discriminator. The output of the Horizontal Discriminator is then applied to the Horizontal Control tube which functions to hold the Horizontal Oscillator in synchronism with the incoming horizontal sync pulses.

The Horizontal Oscillator actuates the Horizontal Discharge tube through the Horizontal Ringing Coil producing a peaked saw-tooth wave. Approximately one-half of the saw-tooth component of this wave causes current to flow in the plate circuit of the Horizontal Output tube. This current energizes the Horizontal Deflection Coils through the Horizontal Scanning Transformer to provide the right half of the horizontal scan. During the right half of the scan, a small amount of current is also flowing through the Damper tube. At the end of the saw-tooth, the inverse pulse component acts on the grid of the Horizontal Output Tube to cut off plate current flow. When this occurs, the energy in the Horizontal Deflection circuit transfers rapidly from the inductive branch of the circuit to the capacitive branch resulting in a voltage peak of approximately 2000 Volts across the Horizontal Deflection Coils. This voltage is stepped up to approximately 6750 Volts by the turns ratio of the Horizontal Scanning Transformer and fed to the voltage doubling rectifier circuit to provide approximately 13,500 Volts for the picture tube H.V. anode.

The damper tube does not conduct during the high voltage pulse period because of the polarity of the pulse. During this pulse period, when the energy transfers from the inductive branch of the horizontal deflection circuit to the capacitive branch and back again to the inductive branch, the electron beam in the picture tube is moved rapidly from the right to the left edge of the raster to accomplish retrace.

At the completion of retrace, energy again flows out of the inductive branch of the circuit. The horizontal output tube is still cut off during this time and a strong current flows through the damper tube. This current decreases to zero linearly to provide the left half of the scan. As the current approaches zero, the horizontal output tube again begins to conduct and the entire cycle is repeated.

ANTENNA INSTALLATION

The 1-271, 1-290 chassis models are shipped with a built-in antenna connected to the two terminal antenna board. For most receiver installations the built-in antenna will provide satisfactory reception.

A variable capacitor controlled from above the picture tube screen adjusts the antenna circuit to resonance. At each individual channel this capacitor should be adjusted for best picture quality.

If an external antenna is desirable for satisfactory reception, the Sylvania Hideaway Antenna, Part 580-0005, gives optimum performance where an indoor installation is indicated, and the Sylvania Conical Fan Television Antenna, Part 580-0001, is available in one, two and

TELEVISION CHANNELS & FREQUENCIES

World Radio History

four bay arrays, providing superior performance in an outside installation. When using the Sylvania Hideaway Antenna or the Sylvania Conical Fan Antenna, remove the leads to the built-in antenna from the antenna terminal and then connect matching 300 Ohm twin lead from the antenna installation in its place. A 300 Ohm lead is especially recommended where the lead-in is in excess of 100 feet.

A 75 Ohm shielded coaxial input may be used with the 1-271, 1-290 chassis if impedance matching coils, Sylvania Part No. 111-0007, are wired between the lead-in and the antenna terminals. A coaxial lead-in may be the only solution in those areas where high noise signals prevail.

OPERATING INSTRUCTIONS

A. To adjust and tune this receiver, proceed as follows:

1. Turn Volume Control (3) clockwise until it clicks.
2. Allow several minutes warm-up period.
3. Turn band switch (5) either way to the appropriate band (i. e. channels 2-6 or channels 7-13).
4. Rotate the Channel Selector (4) until the channel number of the desired station appears in the dial opening.
5. Turn Brightness Control (2) to mid position.
6. Adjust the Channel Selector (4) for best picture quality.
7. Adjust Volume Control (3) for desired volume.
8. Adjust Brightness Control (2) for best picture.

B. To change from one station to another:

1. Turn Band Switch (5) to the appropriate band (i. e. channels 2-6 or channels 7-13).
2. Rotate the Channel Selector (4) until the channel number of the desired station appears in the dial opening.
3. If necessary, adjust the Brightness Control (2) for best picture. Only slight adjustment of this control should be necessary.

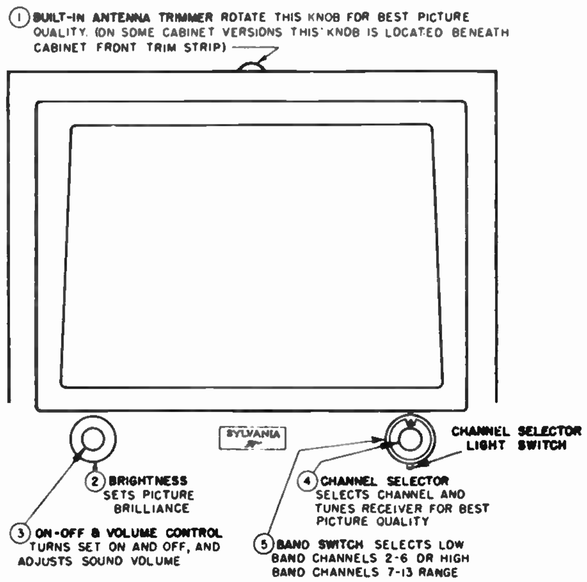

FIGURE 2 - FRONT OF CABINET CONTROLS

C. To turn on the dial light:

1. Push the dial light switch to the left.

INSTALLATION AND SERVICE INSTRUCTIONS

Picture Tube Handling

All Sylvania Television receivers incorporating chassis 1-271, 1-290 are shipped complete with picture tube installed on the chassis and connected for operation. However, if it becomes necessary to re-install a picture tube due to replacement or servicing, the following precautions should be observed.

1. Do not open the picture tube carton until ready to install the picture tube.
2. Do not handle the picture tube unless protective goggles and gloves are worn. People not so equipped with safety devices should be kept at a distance while the picture tube is being handled.
3. Keep the picture tube as far from the body as possible while handling.

Picture Tube Replacement

For Model 271 (16" rectangular tube)

To remove the picture tube from the chassis, remove the picture tube socket, high voltage anode connector, and ion trap magnet. Remove the tube holddown strap by removing the two screws on either side. When the rim of the tube is free of the strap, carefully pull the picture tube out through the focus magnet and deflection coils.

For Model 290 (19" round tube)

To remove the picture tube from the chassis, remove the picture tube socket, high voltage anode connector, and ion trap magnet. Loosen the #10-32 bolt on the holddown strap at the upper right of the tube. Remove the holddown strap. Pull the tube braces away from the sides of the tube. Lift the tube clear of the front edge of the chassis and move it forward gently until the tube base is clear of the focus magnet and yoke. The plastic rim around the face of the tube may then be removed.

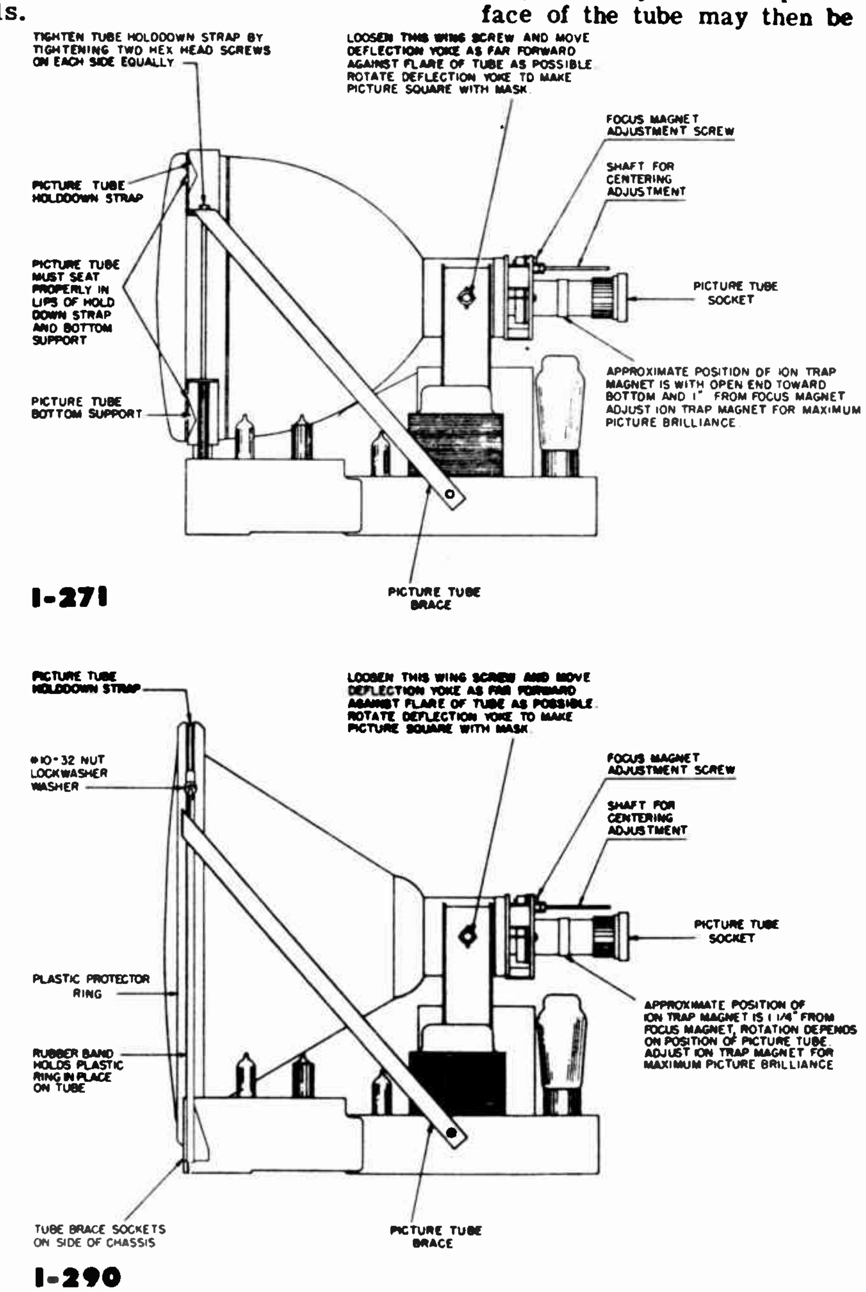

FIGURE 3 - PICTURE TUBE INSTALLATION

©John F. Rider

World Radio History

To replace the 16" rectangular tube, reverse the removal procedure, being careful not to force the tube if the neck binds. Be sure the tube is properly placed before securing the holddown strap.

To replace the 19" round tube, replace the plastic rim and reverse the removal procedure, being careful not to force the tube if the neck binds. There is no specified angle of rotation for the picture tube although the opening in the plastic rim must be in the lower right and the anode clip fastened at the lower left. Be certain the tube is properly placed before tightening the holddown strap. There is no specified angle of rotation for the approximate initial setting of the ion trap. (See "Adjustment of Ion Trap Magnet, Focus Magnet, and Centering Shutter").

On all chassis dress the yellow picture tube cable lead away from the H.V. scan box and the other leads in the cable.

Chassis Removal

To remove the chassis from the cabinet, proceed as follows:

1. Remove all panel control knobs from the front of cabinet.
2. Remove the holddown screws from the underside of the chassis shelf. Access to these screws is from the rear of the cabinet.
3. Disconnect the built-in antenna, remove the interlock cover screws and remove interlock cover.
4. Remove speaker plug from socket on chassis.
5. Slide the chassis all the way out the back of the cabinet.

To replace the chassis, reverse the above procedure.

Preset Controls Adjustments

All preset controls are located at the rear of the receiver and are readily available without removing the interlock cover.

<u>AGC - See AGC Control Adjustment</u>

Horizontal Hold - See "Adjustment of Horizontal AFC Operation".

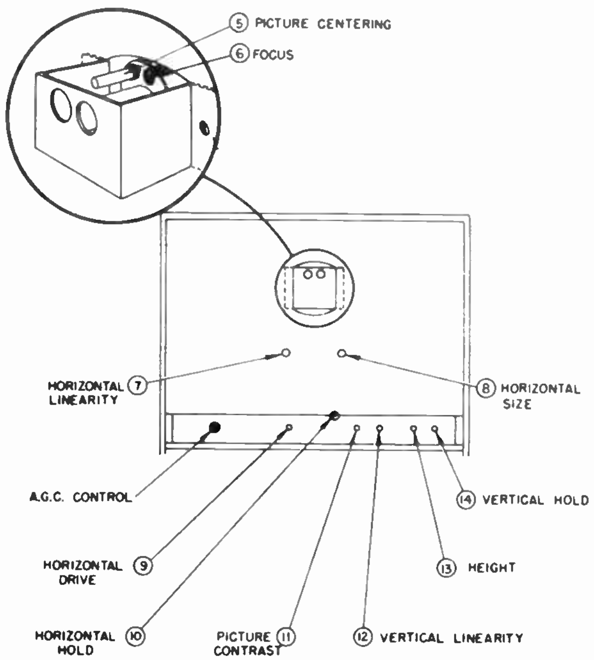

FIGURE 4 - REAR PANEL CONTROLS

Contrast - Adjust contrast control to obtain best contrast with a good picture or test pattern.

Vertical Linearity and Height - Adjust the height control until the picture fills the screen vertically. Adjust the Vertical Linearity control until the pattern is symmetrical from top to bottom. Adjustment of either control will require a readjustment of the other.

Vertical Hold - Rotate the Vertical Hold control until the pattern is slowly moving downward. Back off on the control to a point just beyond where the vertical motion stops.

Horizontal Drive - Turn the horizontal drive control clockwise as far as possible without crowding of center of the picture.

Horizontal Size - Adjust the horizontal size control until picture fills the mask horizontally.

Horizontal Linearity - Adjust the horizontal linearity control until the picture is symmetrical left to right. Re-check Horizontal Drive after adjusting Horizontal Size and Horizontal Linearity.

Adjustment of Ion Trap Magnet, Focus Magnet, and Centering Shutter

These adjustments are interdependent and, therefore, it is necessary to check all three at the same time.

Before making any adjustments, the function of each magnet should be noted.

The ion trap magnet is used to obtain maximum brilliance of the raster or picture and should be adjusted to obtain maximum brilliance as described below.

The focus magnet is used to obtain correct focus of the picture.

The centering shutter is an integral part of the focus magnet assembly. Its function is to position the picture, both horizontally and vertically.

Before making any adjustments, check that the deflection yoke is positioned so that it is pressing against the flare of the picture tube. To ensure this, loosen the thumb-screws located at each side of the yoke and push the yoke as far forward as it will go. If the picture is not square with the screen mask, rotate the yoke.

Next, check that the focus magnet is held firmly by both brass screws against the yoke; there should not be any gap between the yoke and the focus magnet.

When adjusting the focus of the receiver it is to be noted that optimum focus of the picture does not necessarily result when either the vertical or the horizontal is adjusted for maximum definition. Optimum focus is frequently a compromise between these two settings. It is highly desirable, therefore, that a transmitted picture, containing both vertical and horizontal lines, be available for correct focusing of the receiver.

Before proceeding with the adjustment of the focus of the receiver, first ensure that the ion trap magnet is correctly adjusted.

Set the contrast control at minimum and the brightness control at maximum. The ion trap magnet should first be positioned so that there is approximately 1 inch for 1-271 and 1 1/4 inch for 1-290 between the ion trap magnet and the focus magnet. The ion trap magnet should be slowly rotated until a picture (or raster, if the receiver is not yet tuned to a station) is visible on the screen. The brightness should now be reduced by means of the brightness control and the ion trap magnet carefully twisted and moved a small amount backwards and forwards on the neck of the tube, to obtain maximum brightness.

Finally, adjust the brightness control to obtain maximum brightness on the screen and then carefully adjust the ion trap magnet. It may be possible to increase the brightness still more by turning the contrast control towards maximum and again adjusting the ion trap magnet. The correct position of the ion trap magnet is that which ensures the greatest possible brightness of the raster of picture before it enlarges and "blooms" as the setting of the brightness control is increased. <u>Do not leave the brightness control in this position as the condition causes overload of the picture tube.</u>

A preliminary adjustment of the screw on the focus magnet should now be made to obtain a raster or picture which is focused - this preliminary adjustment will not, of course, be necessary if the raster or picture is already in focus. (Note: Use a non-magnetic screw driver to adjust the focus screw.)

If the picture is not centered on the screen, either horizontally or vertically, properly position it by adjustment of the centering shutter. This centering adjustment will move the picture up, down, left or right as required to center the picture. With the brightness control at a low level, check the horizontal size and height of the picture to insure that when the picture is properly positioned it just fills the mask with no corner cutting.

Carefully make final adjustments of the focus screw for optimum focus in both horizontal and vertical directions. Best focus of the picture does not necessarily result when either the vertical or horizontal focus is optimum and the final setting should, therefore, be a compromise between the two. A test pattern with both vertical and horizontal lines is, therefore, highly desirable when making focus adjustment.

Finally, check that the adjustment of the ion trap magnet is such that the brightest possible picture is obtained, as previously mentioned.

Since all these adjustments are interdependent, recheck the adjustment of all three until the best possible picture is obtained.

World Radio History

ADJUSTMENT OF HORIZONTAL AFC CIRCUIT

Check of Operation

The operation of the AFC circuit should be checked as follows:

A. Tune the receiver to a channel on which no signal is received and return to the original channel. The picture should immediately fall into synchronization.

B. Switch off the power to the receiver for about five minutes and then switch back on. Picture should immediately fall into sync.

C. Check for correct phasing of Horizontal AFC circuit oy noting that there is approximately 1/8" of blanking visible on the right hand edge of the picture. It will be necessary to turn the contrast control almost to minimum, readjust the brightness control and reduce picture size slightly to see the blanking.

NOTE: Before making check C above, be sure the horizontal drive control is correctly adjusted. Refer to "Preset Controls Adjustment," page 8. If the receiver passes the above checks, no adjustments to the horizontal AFC circuits need be made.

If the receiver cannot pass checks "A," "B," or "C" the adjustment of the Horizontal Hold Control as noted under "Horizontal Hold Adjustment" should be made.

Horizontal Hold Adjustment

(A) Tune in a station and adjust the tuning control for best picture quality. Adjust the contrast and brightness controls for normal picture.

(B) Remove V16 - 6AL5 - Horizontal Discriminator tube.

(C) Turn the Horizontal Hold Control until the picture moves back and forth across the screen with blanking bars vertical.

(D) Replace the Horizontal Discriminator tube and repeat A, B, and C under "Check of Operation".

(E) If receiver still will not pass these checks, it will be necessary to proceed with "Phase Adjustment".

Phase Adjustment

(A) Turn the core in the horizontal "ringing" coil all the way out (counterclockwise). Short out the 4700 ohm horizontal charge circuit peaking resistor R226.

With the horizontal size coil set for approximately the correct picture width, and with the horizontal linearity coil adjusted for best linearity, rotate the horizontal drive control fully counterclockwise. Slowly turn the drive control clockwise until crowding is visible in the center of the picture. Now carefully turn the control back (counterclockwise) only sufficient to remove the crowding in the picture or pattern. On some chassis, it may not be possible to obtain crowding of the picture. In such cases the control should be set to the fully clockwise position.

NOTE: Do not operate the receiver with the horizontal drive control mis-adjusted.

(B) Remove the 6AL5 horizontal discriminator tube from its socket.

(C) Carefully turn the frequency adjustment screw (top of discriminator transformer T62) until the picture moves back and forth across the screen of the picture tube with the blanking bar vertical.

(D) Insert the 6AL5 horizontal discriminator tube back into its socket.

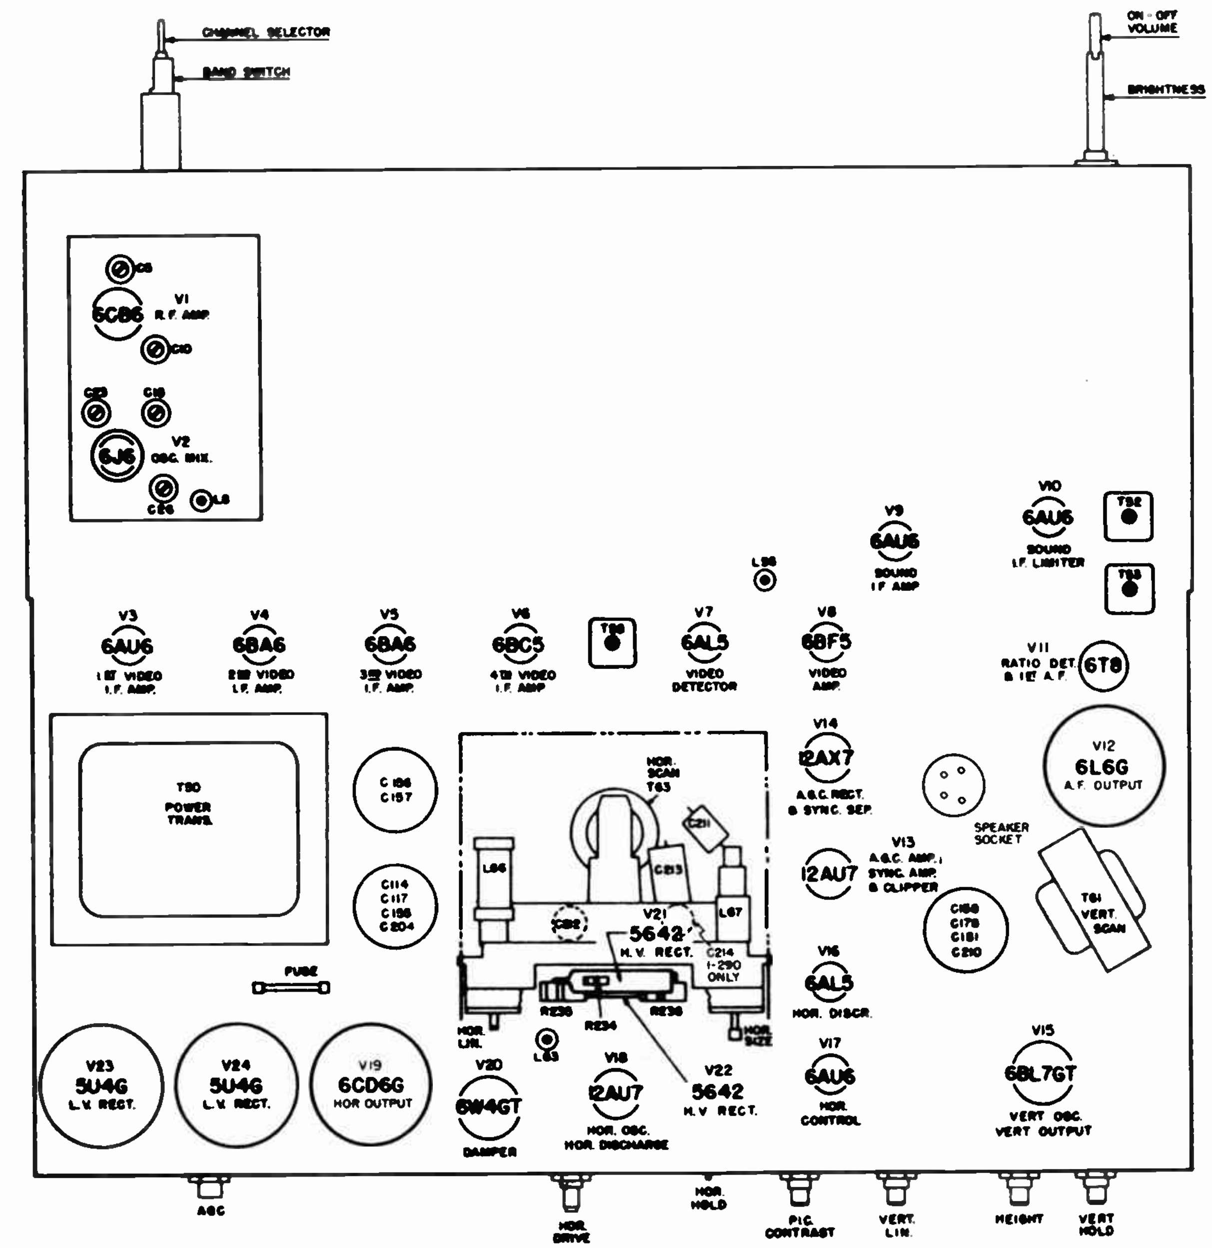

FIGURE 5 - CHASSIS TOP LAYOUT

©John F. Rider
World Radio History

(E) Adjust the phase adjustment screw (underside of discriminator transformer T62) until approximately 1/8" of "blanking" is visible on the right-hand edge of the picture. In order to see the "blanking", it will be necessary to turn the contrast control almost to minimum, re-adjust the brightness control and reduce picture size.

(F) Check the "free-running" of the horizontal oscillator as described under paragraphs "B," "C," and "D," and, if necessary, readjust the frequency adjustment screw on top of horizontal discriminator transformer.

(G) Make a final check of the phasing as described in paragraph "E" above. It is important that both the "free-running" and the phasing are correct.

(H) Remove the short from across the 4700 ohm resistor R226 and readjust the horizontal drive control as described in (A). Turn the core in the horizontal "ringing" coil clockwise until approximately 1/8" of "blanking" is again visible on the right-hand edge of the picture.

(I) Before the horizontal synchronization circuit is adjusted to the final position, it will be necessary to check the operation as follows:

Slowly turn the oscillator frequency adjustment screw (top of transformer T62) in either direction until the picture suddenly falls out of synchronization as indicated by the presence of a number of diagonal bars. The total number of bars visible must not be less than six. These bars may consist of either several full bars and two half bars for the total number or they may be all full bars for the same total number. Slowly turn the adjustment screw so as to decrease the number of bars and note the total number of bars visible just before the picture again falls into synchronization. The last number of bars visible must not be less than three, or more than four. The adjustment screw must be turned very slowly and carefully after the number of bars has been reduced to four or five in order to get an accurate indication of the minimum number of bars it is possible to obtain.

Turn the adjustment screw in the opposite direction until the picture suddenly falls out of synchronization in the opposite direction and repeat the foregoing procedure. Again, the total number of bars visible when the picture falls out of synchronization must not be less than six and not less than three or more than four bars must be visible just before the picture falls into synchronization.

(J) After checking the operation as in I, it is necessary to repeat the procedure described in paragraphs "B," "C," and "D."

(K) Remove the signal by tuning to a "free" channel, then retuning to the original channel. The picture should immediately fall into synchronization.

(L) Switch "off" the power to the receiver for about five minutes and then switch receiver "on" and check that the picture pulls into synchronization.

AGC CONTROL ADJUSTMENT

This control has been correctly adjusted at the factory and should require no further adjustment. If adjustment becomes necessary as evidenced by poor horizontal or vertical sync; poor video signal (poor contrast). Adjust as follows:

1. Connect a good antenna installation to the receiver.

2. Tune the receiver to a channel on which no picture is received.

3. Set the contrast control to mid-position.

4. Turn the AGC control fully clockwise. The AGC control is located on the rear panel of the chassis.

5. Connect a VTVM from the AGC Amplifier plate to ground (V13, 12AU7, pin 6) and set the AGC control to obtain a negative 0.1 volt reading.

Note: On some receivers the closest approacn to this reading will be the fully clockwise position.

6. With the AGC Control set as above, turn the contrast control to almost maximum (about 7/8) and tune in the strongest station available in the area.

7. Again read the AGC Amplifier plate voltage; if reading is less than a negative 2.0 volts leave the control as set.

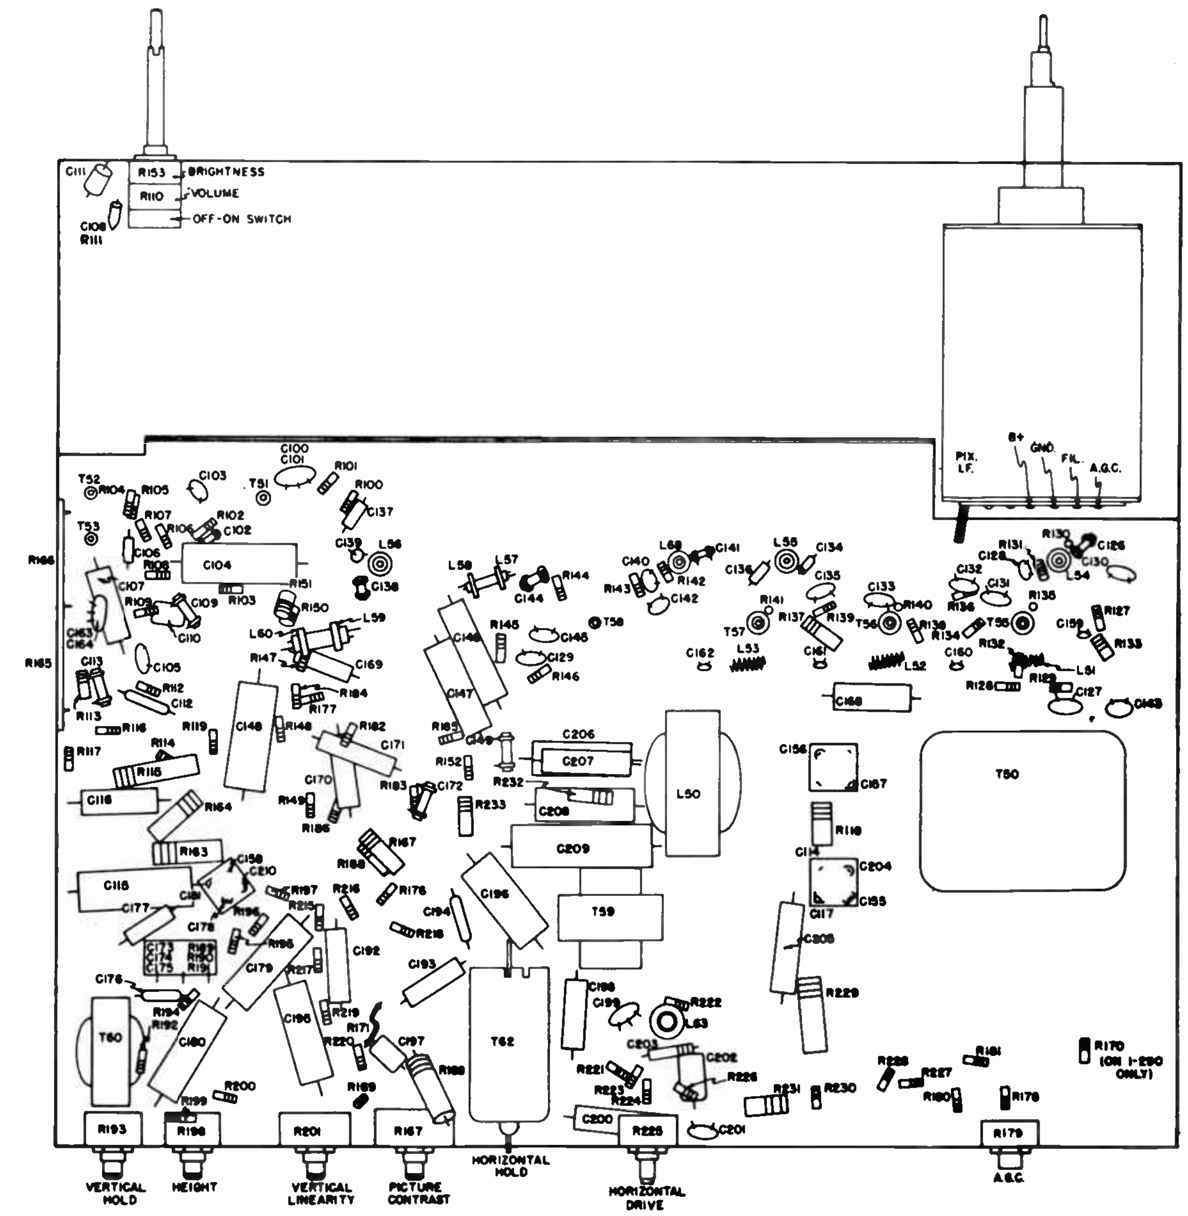

FIGURE 6 - CHASSIS BOTTOM LAYOUT

©John F. Rider

World Radio History

8. If the AGC Amplifier plate voltage is more than 2 volts negative, slowly turn the AGC control counterclockwise observing the picture.

9. The picture will get darker and then finally start to fall out of sync as evidenced by a sudden shift or jittering of the picture in either the horizontal or vertical direction. Do not turn beyond this point.

10. Back off (clockwise) slowly on the control until the picture holds in sync without flutter and turn slightly beyond. (Experience will dictate how far beyond to turn).

11. Rock the tuning control slightly either side of the best tuning point to insure picture stays in sync; if not, turn slightly further clockwise and check again.

12. As a final check, turn the volume control up to normal level. Intercarrier buzz should be negligible.

13. Remove objectionable intercarrier buzz by turning the AGC control slightly further clockwise. (Note: The intercarrier buzz is merely a reference for correct adjustment of the AGC control and only a slight touch-up should be necessary. If much adjustment is required to remove intercarrier buzz, the sound section is maladjusted and requires realignment).

14. Rock the tuning control slightly either side of the best tuning point and turn the AGC control slightly more clockwise as necessary to remove objectionable intercarrier buzz.

The intent of the above AGC control adjustment is to provide a maximum of AGC action consistent with proper sync and minimum intercarrier buzz on strong signals.

TEST EQUIPMENT REQUIREMENTS

1. RF sweep generator or generators with frequency range from 4-220 Mc. having sweep width adjustable from 50 Kc. to 10 Mc. with an output of at least 0.1 volt, a marker system, either built-in or external type and flat within + 1 Db.
2. Signal generator or generators with a frequency range from 4-222 Mc. and an adjustable output of at least 0.1 volt.
3. Sylvania cathode ray oscilloscope type 132 or equivalent capable of passing a 60 cycle square wave.
4. Sylvania Polymeter type 221 or equivalent vacuum tube voltmeter.
5. Sylvania High Voltage Probe Adapter type 225 or equivalent with 0-30 KV DC range (not shown).
6. Sylvania tube tester type 220 or equivalent capable of testing shorts with proper voltages and performance under dynamic conditions.
7. Jig Tube Shield - made by cutting off or insulating the tube shield used on the 6J6 converter tube on the tuner so that the shield does not ground when in place on the tube.

FIGURE 7

SYLVANIA POLYMETER TYPE 221 | SYLVANIA TUBE TESTER TYPE 220 | SYLVANIA OSCILLOSCOPE TYPE 132

ALIGNMENT PROCEDURE

Should any chassis under service require complete realignment, the alignment procedure should be carried out in the following listed order.

PRE-ALIGNMENT INSTRUCTIONS - READ CAREFULLY BEFORE ATTEMPTING ALIGNMENT.

Lay chassis on left side for alignment. Ground all equipment to receiver chassis. Use special alignment tool Service Part No. 898-0003.

VIDEO IF ALIGNMENT

1. Connect signal generator to the jig shield on the 6J6 Oscillator-Mixer. Allow set to warm-up for 15 minutes.

2. Connect the negative lead of a 3 volt battery to the AGC Line, positive lead to ground.

3. Connect D. C. VTVM across the diode load resistor R145 - 3300 Ohm.

4. Adjust the cores of the IF traps in the following order. Keep Voltmeter reading between 1 and 2 volts by reducing Generator Output as required.

Set Signal Generator At:	Adjust:
21.9 Mc.	Core on 4th IF Trap L68 for minimum output
27.9 Mc.	Core on 3rd IF Trap L55 for minimum output
21.9 Mc.	Core on 1st IF Trap L54 for minimum output

5. Adjust the cores of the Video IF Transformers in the following order. Reduce generator output to keep voltmeter reading between 1 and 2 volts.

Set Signal Generator At:	Adjust:
26.0 Mc.	Core on 3rd Video IF Transformer T57 for maximum output
22.7 Mc.	Core on 2nd Video IF Transformer T56 for maximum output
25.3 Mc.	Core on 1st Video IF Transformer T55 for maximum output
23.5 Mc.	Core on Converter Coil L8 for maximum output

Repeat tuning of cores on Trap Coils as described in step 4 above.

6. Disconnect Signal Generator and VTVM.

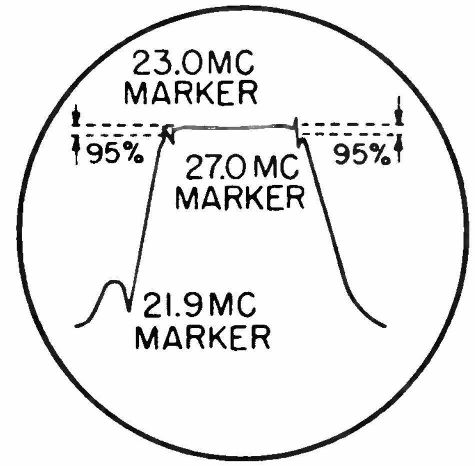

FIGURE 8 - IF BANDPASS RESPONSE

7. Connect sweep generator (frequency 24 Mc., sweeping 10 Mc.) using a .005 Mfd. capacitor to pin 1 of the 4th Video IF 6BC5.

8. Connect oscilloscope to junction of diode load R145 - 3300 Ohm - and coil L58.

9. Adjust primary (top core) and then secondary (lower core) of IF Bandpass T58 to obtain curve shown in Figure 8. (Both adjusted from bottom of Transformer with hex end of special alignment tool.)

10. Disconnect Sweep Generator from 4th IF Grid and connect it to the Jig Shield on Converter 6J6. Loosely couple signal generator at this point for markers.

11. Observe IF Response Curve and if necessary adjust IF transformer cores slightly to obtain response curve shown in Figure 9. Keep oscilloscope gain high enough to prevent overload of the receiver which will distort the curve.

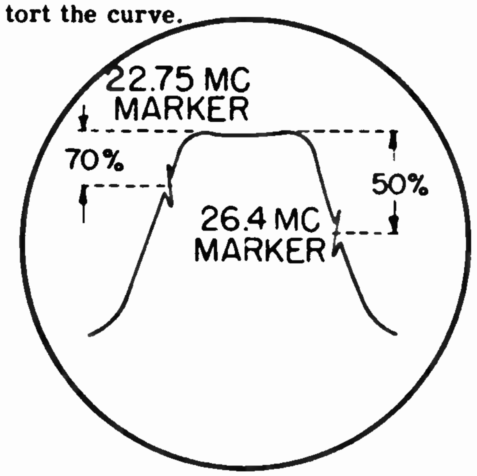

FIGURE 9 - OVERALL IF RESPONSE

©John F. Rider

World Radio History

SOUND TAKE OFF & 4.5 MC. TRAP ALIGNMENT

1. Connect a 4.5 Mc. Signal Generator through .005 Mfd. to pin 1 of Video Amplifier Tube - 6BF5. Loosely couple signal generator for use as markers.

2. Connect probe of High Frequency Vacuum Tube Voltmeter at the junction of peaking coil L59 and R148 - 39,000 ohms.

3. With enough output from signal source to give a readable indication on the VTVM, adjust the core on Sound Take-Off Trap - L56 - For a sharp dip.

INTERSTAGE TRANSFORMER ALIGNMENT

1. Disconnect the 4.5 Mc. signal from the Video Amplifier. Connect a 4.5 Mc. sweep oscillator having a 250Kc. deviation through a .005 Mfd. capacitor to pin 1 of Video Amplifier - 6BF5. Connect oscilloscope input across the limiter grid resistor R102 47,000 Ohms - using a 10,000 Ohm carbon resistor between scope lead and receiver chassis.

2. Adjust the primary and secondary of the Interstage Transformer T51 so that the 4.5 Mc. marker appears in the exact center of the response curve and so the curve has the greatest attainable amplitude. The response curve should appear as shown in Figure 10.

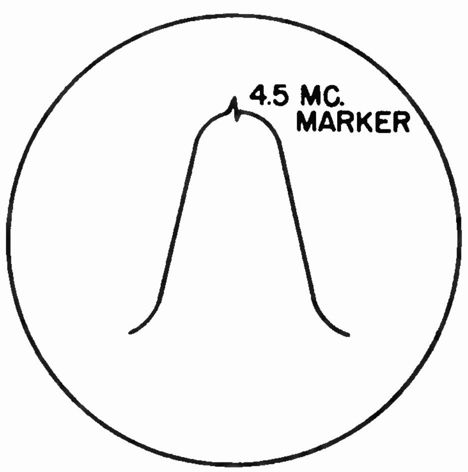

FIGURE 10 - SOUND IF RESPONSE

SOUND DISCRIMINATOR ALIGNMENT

1. With the 4.5 Mc. Sweep Oscillator connected as described in step 1 of "Interstage Transformer Alignment," disconnect the oscilloscope from the limiter grid resistor and connect the oscilloscope across the volume control.

2. Adjust cores of the Discriminator Transformers T52 and T53 until the discriminator curve corresponds to that in Figure 11. Note especially that:

   (a) 4.5 Mc. marker is exactly in the center of the curve.
   (b) The curve is linear between the two adjacent markers.
   (c) The amplitude is the greatest obtainable.

RF TUNER ALIGNMENT

NOTES ON TUNER ALIGNMENT SETUP

In reference to Figure 12, the following precautions should be taken in making the equipment setup.

1. The detector circuit should be so constructed as to maintain leads as short as possible. Connection of the detector circuit to the 1st IF grid terminal (see Fig. 12 for location) should also be made with short leads.

2. Shielded leads should be used in making the following connections to reduce hum and synchronous voltage pick-up.

   (a) The lead for observation of the RF response from the scope isolating resistor (10 K ohms located at the tuner "looker point") to the RF output switch position of the scope switch.
   (b) The connection from the IF detector circuit output to the IF switch position of the scope switch.
   (c) The connection from the sweep generator to the horizontal input of the scope. (Use externally generated sweep instead of internal oscilloscope sweep in order to obtain synchronization).

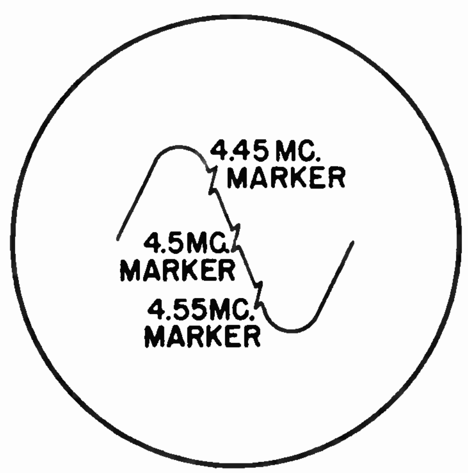

FIGURE 11 - SOUND DISCRIMINATOR RESPONSE

3. The single pole double throw "Scope Switch" should be located at the vertical input terminals of the scope. This switching arrangement will permit observation of either the IF response or the overall RF response. The aforementioned positions will be referred to in subsequent text as the "IF" and "RF" positions respectively.

4. The marker generator coupling condenser should be as small a value as possible to prevent any effect on tuner response, but must be large enough to permit easy observation of markers on either the IF response or overall RF response. (Approximately 2 or 3 MMF should be satisfactory in most cases).

5. For all tuner alignment tests which are outlined in this text, remove the second IF amplifier tube or bypass its plate circuit with approximately 1000 MMF to prevent coupling back from the receiver IF system.

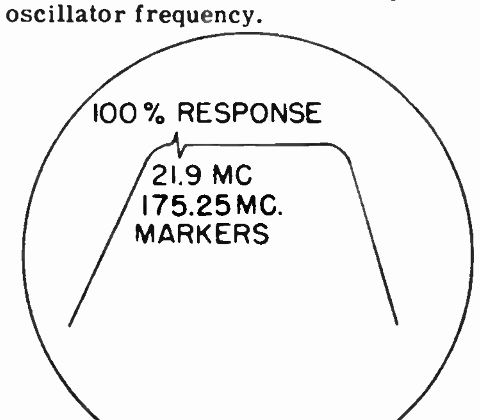
6. In all of the following tests the oscilloscope vertical gain should be as close to maximum gain as possible, consistent with hum and synchronous voltage interference limitations. This precaution will allow the use of low levels from RF sweep Generator and increase the visibility of IF and RF markers.

OSCILLATOR ALIGNMENT

In making adjustments of the oscillator alignment it should be noted that any change in the setting of the high band oscillator trimmer will also effect the low band oscillator tuning, however, because of switching the adjustment of the low band oscillator trimmer will not affect high band oscillator tuning. Also, there is a slight shift of oscillator frequency in the high band position only when the bottom cover is removed.

High Band Oscillator Alignment

1. Remove the bottom cover and rotate the band switch to the high band position.
2. Rotate variable condenser to maximum capacity position (fully counterclockwise position of tuning control knob).
3. Tune sweep generator to channel 7 and set scope switch to IF output position.
4. Inject 175.25 Mc. and 21.9 Mc. markers.
5. With a non-metallic pick vary the turns spacing on the high band oscillator coil L9 until markers coincide (squeezing the coil lowers the oscillator frequency and spacing the turns farther apart raises oscillator frequency.



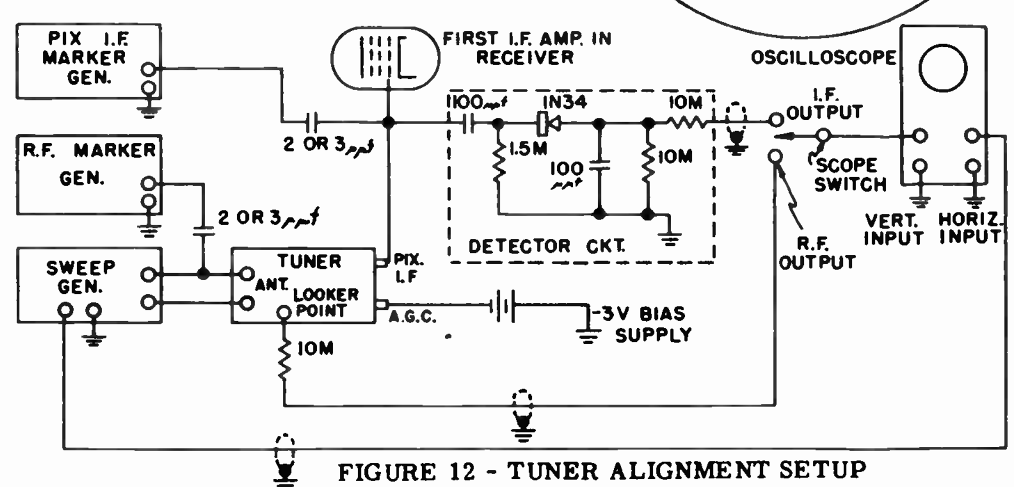


FIGURE 12 - TUNER ALIGNMENT SETUP

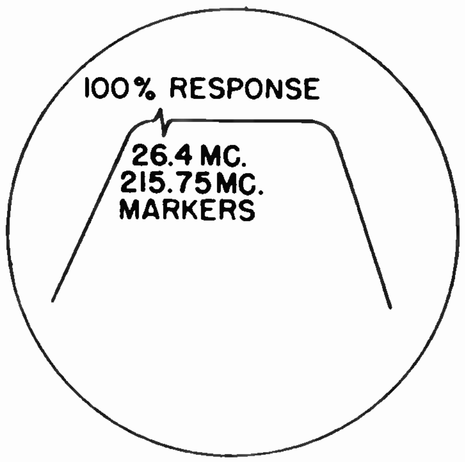
©John F. Rider

World Radio History

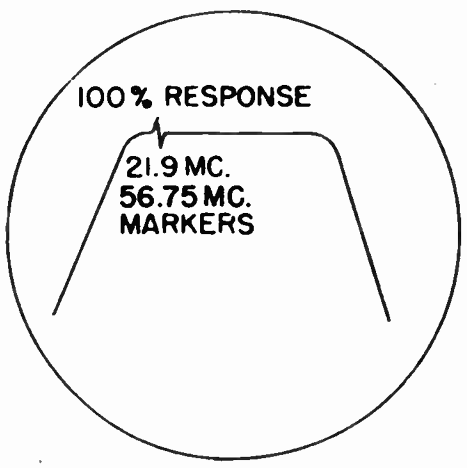
6. Replace bottom cover and check for shift of markers. If there is a shift remove the bottom cover and compensate by re-adjusting L9 as necessary. Repeat until markers coincide with bottom cover in place.
7. Rotate variable condenser to minimum capacity (fully clockwise position of tuning control knob).
8. Tune sweep generator to channel 13.
9. Inject 215.75 Mc. and 26.4 Mc. markers.
10. With bottom cover in place, adjust oscillator grid trimmer C23 to make markers coincide.



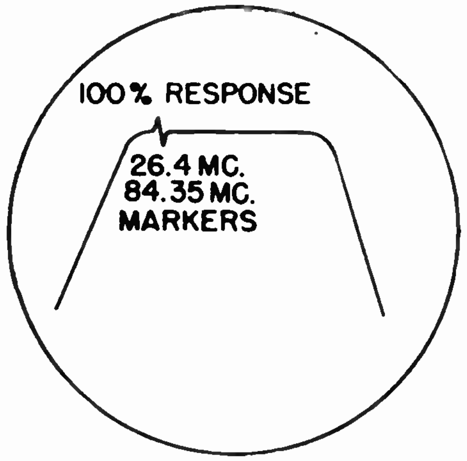
11. Repeat steps one through ten until proper end frequencies are reached at maximum and minimum capacity settings.

Low Band Oscillator Alignment

12. Remove bottom cover, turn band switch to low band position and rotate variable condenser to maximum capacity (tuning control knob fully counterclockwise).
13. Tune sweep generator to channel 2.
14. Inject 56.75 Mc. and 21.9 Mc. markers.
15. Using a non-metallic pick adjust the spacing between turns on the low band oscillator coil L9 until the markers coincide.



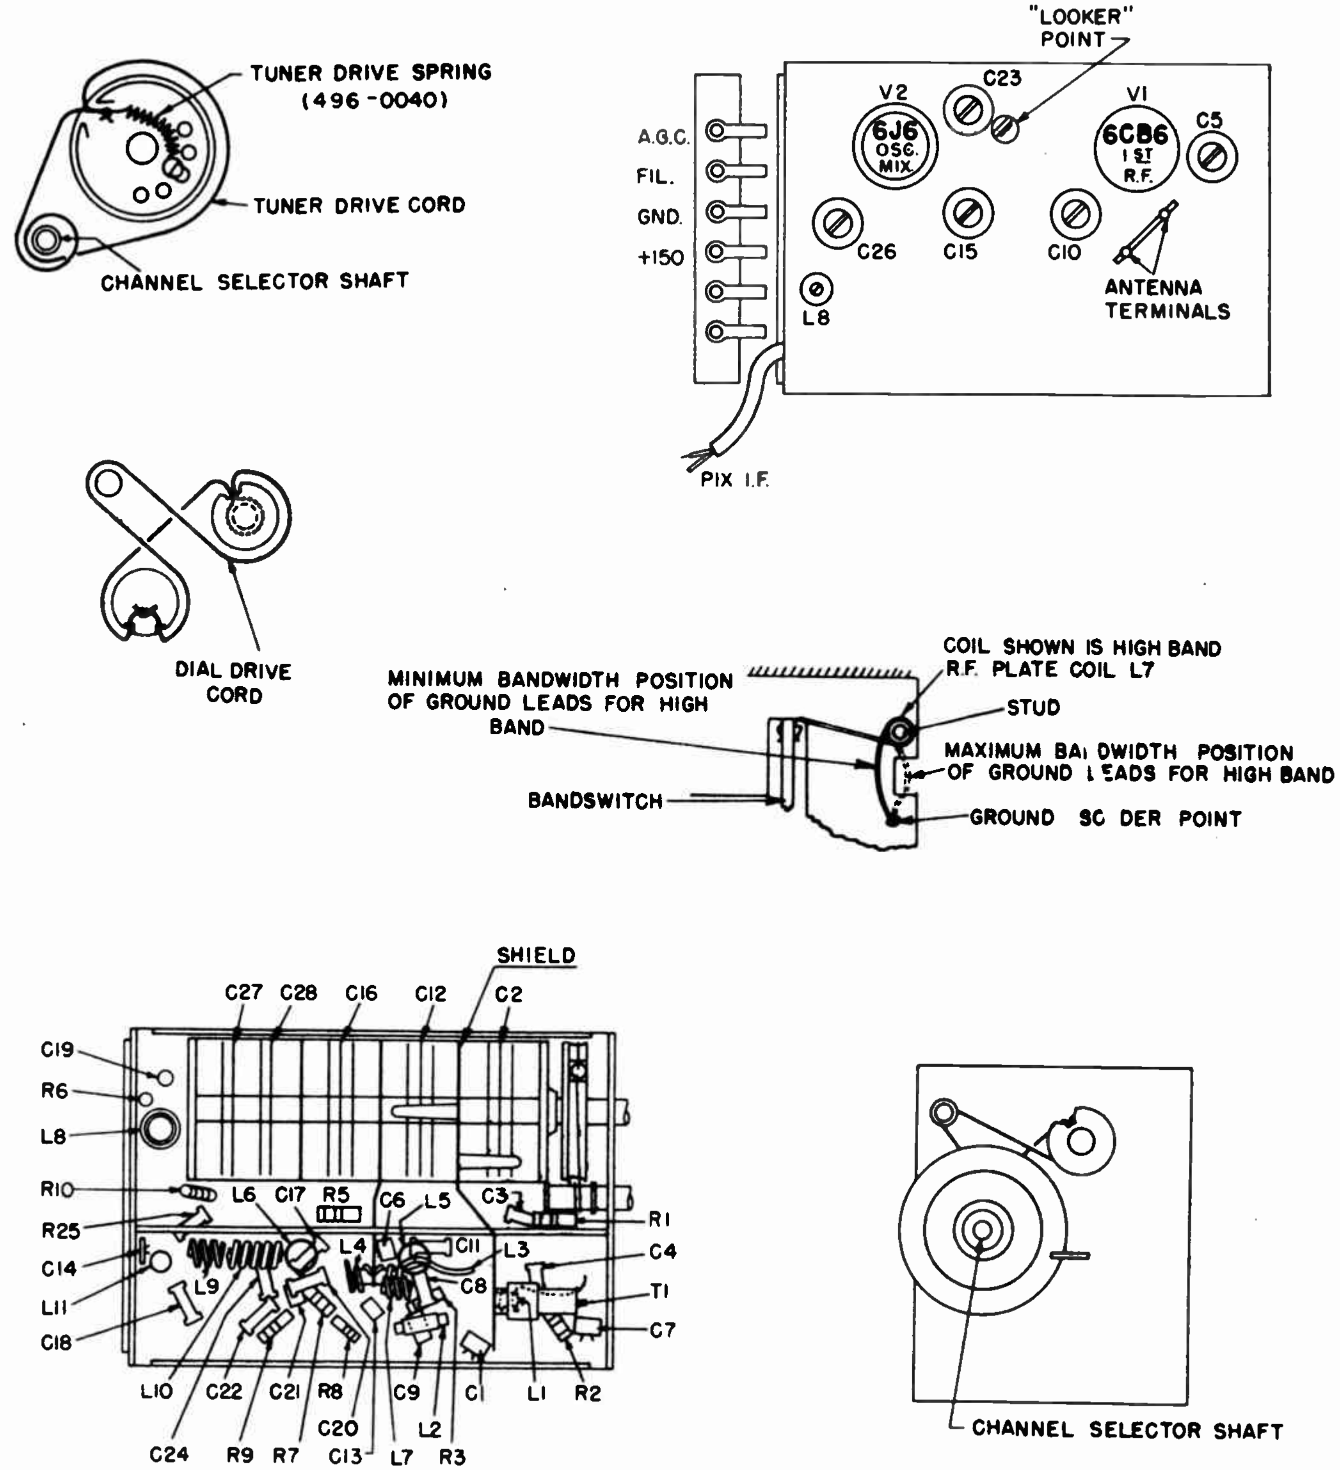
16. Rotate the variable condenser to minimum capacity (tuning control knob fully clockwise).
17. Tune sweep generator to channel 6.
18. Inject 84.35 Mc. and 26.4 Mc. markers.
19. Adjust oscillator plate trimmer C26 to make markers coincide.



20. Replace bottom cover and recheck in steps 12-19.
21. Recheck all four oscillator frequencies as in-steps 1-19.

R. F. PASSBAND ALIGNMENT

1. If only the RF Passband is being aligned it is advisable to check oscillator coverage as noted under Oscillator Alignment step 21 above.
2. Remove bottom cover and turn band switch to high band position.
3. Rotate tuning control so that pointer is at channel 7 on the dial calibration.
4. Tune sweep generator to channel 7. Set scope switch to the IF output.
5. Inject 175.25 Mc. and 26.4 Mc. markers and adjust tuning control so the markers coincide. Leave tuning control at this setting for the remainder of channel 7 adjustment.
6. Change scope switch to the RF output.
7. Check that the RF response curve is similar to those shown in Figure 14.
8. If the response curve differs much from those shown in Figure 14, the inductance and coupling of the high band RF plate coil L3, the high band mixer grid coil L4 and the high band antenna coil L1 for proper band width and symmetry. In determining the band width, it will be necessary to switch the marker generator alternately between channel 7 picture carrier (175.25 Mc.) and sound carrier (179.75).
9. The high band RF plate coil L3 and the high band mixer grid coil L4 are properly adjusted when a slight variation in the inductance of either coil will result in a



Note: This RF tuner has been thoroughly tested at the factory and should provide trouble-free reception throughout the life of the chassis. However, if service other than alignment is required, return the complete tuner to the factory for replacement.

FIGURE 13 - TUNER LAYOUT

World Radio History

frequency shift of the entire response with no noticeable narrowing of the band width.

10. The high band antenna coil L1 is properly adjusted when a slight variation of its inductance will cause both peaks to rock slightly. If only one peak moves, the high band antenna coil L1 is staggered away from the center of the passband.
11. The inductance of these coils (L1, L3, L4) is varied by pushing the coil on or off the brass stud. Pushing the coil on the stud will raise the frequency and pushing the coil off the stud will lower the frequency.
12. The band width of channel 7 interstage transformer (L3, L4) is controlled by dressing the ground leads of these coils past the cut out in the RF shield plate (see Fig. 13). When both leads cross the cutout the greater separation of peak occurs. For maximum gain the band width should be adjusted so that the response is no greater than that required to keep the sound and picture carrier frequency markers on the peaks of the overall RF curves.
13. Replace tuner bottom cover and check RF passband response.
14. If necessary, remove bottom cover and make slight compensating adjustments. Replace bottom cover and recheck.
15. With the bottom cover in place, rotate the tuning control knob so that the pointer indicates channel 13.
16. Tune sweep generator to channel 13 and change scope switch to IF output.
17. Inject 215.75 Mc. and 21.9 Mc. markers and adjust tuning control so markers coincide. Leave tuning control as set for remainder of channel 13 adjustments.
18. Change scope switch to RF output position. If RF response differs noticeably from the curves in Figure 14, the antenna trimmer (C5), the RF plate trimmer (C10) and mixer grid trimmer (C15) must be adjusted for proper passband and maximum amplitude of response.
19. Return tuner and sweep generator to channel 7 and check response as in part 13 above. A slight compensation of coils L1, L3, and L4 may be necessary.
20. Recheck passband on both channel 7 and channel 13, compromising adjustments for tilt as necessary until satisfactory High Band RF passband responses are obtained.

Low Band RF Alignment

21. Rotate band switch to Low Band position.
22. Turn the tuning control knob so that the pointer indicates channel 2 on the dial.
23. Set the scope switch to the IF output position and inject 59.75 Mc. and 21.9 Mc. markers. Adjust the tuning control so the markers coincide. Leave the tuning control as set for the remainder of the channel 2 adjustments.
24. Change the scope switch to the RF output position.
25. If the desired passband response is not obtained (as shown in Fig. 14) the Low Band RF coil L5, the low band mixer coil (L6), and the low band antenna transformer (T1) secondary must be adjusted until the desired passband is obtained.
26. When the low band RF coil (L5) and the low band mixer coil are aligned slight variation in the inductance of either should cause no noticeable narrowing of the passband.
27. When the secondary of the low band antenna transformer is properly adjusted, a slight variation in its inductance should cause both peaks to rock slightly. If only one peak moves, the T1 secondary is staggered away from the center of the double tuned circuit response.
28. The low band mutual coil (L7) varies the band width of the interstage coupling circuit. Squeezing the turns together broadens the band width and separating the turns narrows the band width. The band width should be adjusted so that it is not greater than that required to keep both the picture carrier and sound carrier markers at the peaks of the response curve.
29. Replace the tuner bottom cover and check passband response.
30. Remove bottom cover and make any compensating adjustments as needed.
31. With the bottom cover in place, rotate the tuning control knob to align the pointer with channel 6 on the dial.
32. Tune the sweep generator to channel 6 and change the scope output switch to the IF output position.
33. Inject 83.25 Mc. and 26.4 Mc. markers and adjusting tuning control to make the markers coincide. Leave the tuning control at this setting for the remainder of the channel 6 adjustments.
34. Change the scope switch to the RF output position.
35. Check the response curve. If not as desired, remove the bottom cover and slightly readjust the inductance of the low band RF coil L5, the low band mixer coil (L6), the low band mutual coil (L7) and the secondary of the low band antenna transformer (T1) as necessary, keeping in mind that these adjustments must be compromised with those made for channel 2 in steps 21-30 above.
36. Recheck passband on channel 2 and channel 6 and re-adjust as necessary to obtain acceptable passband on both channel 2 and 6.

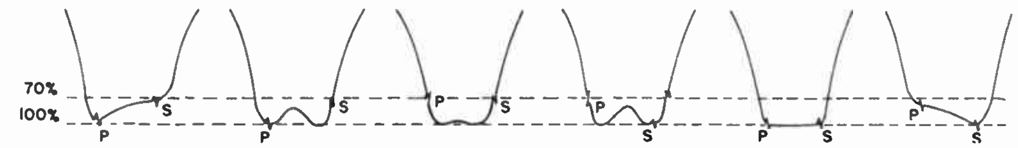

FIGURE 14 - ACCEPTABLE RF RESPONSE CURVES FOR TUNER

WAVEFORMS

Note 1: The terms "Horizontal," "Vertical" or "60 cps sine wave" refer to the oscilloscope sweep employed.

Note 2: All waveforms are taken with the oscilloscope horizontal sweep direction from left to right and with upward deflection corresponding to positive polarity.

Note 3: In some instances the waveforms obtained will not be identical with those shown, due to the electrical characteristics of the oscilloscope used.

Note 4: All waveforms are measured with respect to chassis unless otherwise indicated.

Note 5: Contrast maximum unless otherwise indicated.

*The peak to peak (P/P) voltages of these waveforms are dependent on the depth of modulation of the transmitted signal; voltages shown are obtained when modulation is approximately 90 percent.

CHASSIS 1-271 C01
CHASSIS 1-290 C01

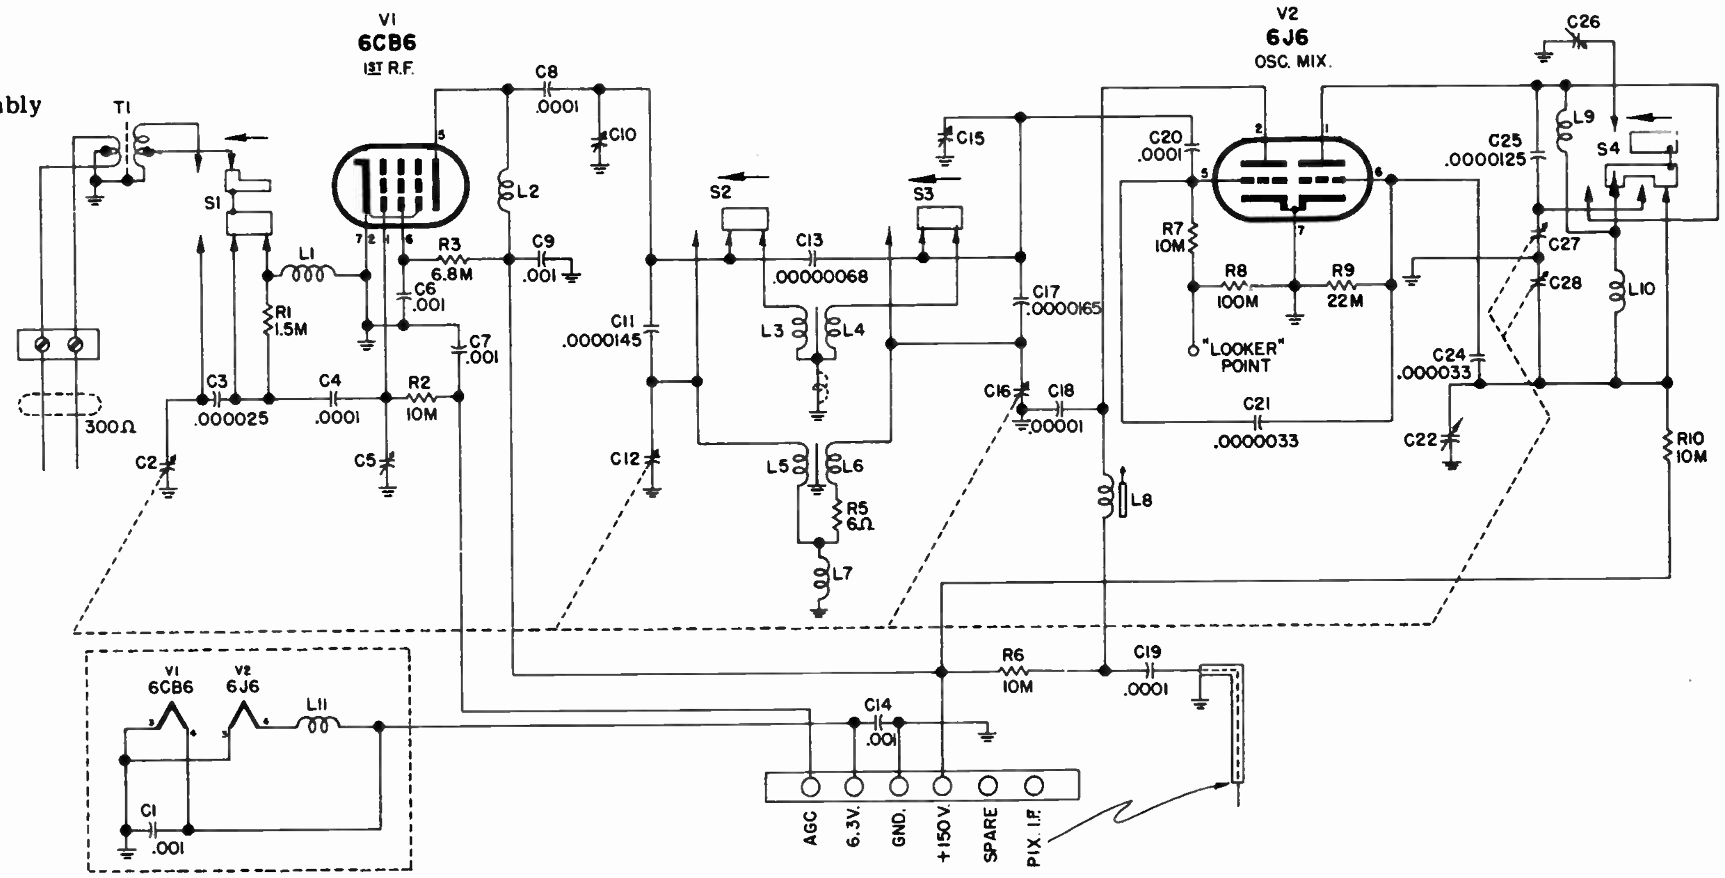
This supplement covers the code C01 change in the 1-271, 1-290 television chassis.

Code C01 changes the value of resistors in the schematic as follows: R148 from 39 M to 180 M
R149 from 270 M to 1.2 Meg
R186 from 2.2 Meg to 1.2 Meg

To correct the parts list to this change, the following additions and deletions should be made.

REPAIR PARTS LIST

SCHEMATIC LOCATION	SERVICE PART NUMBER	DESCRIPTION
	DELETE	
R148	181-03935	Resistor - 39,000 Ohm - 1/2 W.
R149	181-0274	Resistor - 270,000 Ohm - 1/2 W.
R186	181-0225	Resistor - 2.2 Megohm - 1/2 W.
	ADD	
R148	181-01845	Resistor - 180,000 Ohm - 1/2 W.
R186	181-0125	Resistor - 1.2 Megohm - 1/2 W.
R149	181-01255	Resistor - 1.2 Megohm - 1/2 W.



NOTE:
1. SWITCH SECTIONS 1-4 ARE PARTS OF A TWO POSITION SLIDE SWITCH. SWITCH SHOWN IN POSITION FOR HI BAND RECEPTION. ARROW INDICATES SWITCH DIRECTION FOR LO TV RECEPTION.

Addition of Chassis 1-356, Models 7140M, 7140W.

GENERAL DESCRIPTION

Models 7140M, 7140W are direct viewing television receivers providing reception of all 12 commercial television channels. The television picture is reproduced on a 17 inch rectangular, black faced, electromagnetically deflected, tetrode type picture tube. The cabinets are identical in appearance to 6140M and 6140W.

SPECIFICATIONS

The 1-356 chassis is electrically similar to the 1-271 chassis except for minor circuit changes.

All servicing data for the 1-271 also applies to the 1-356, except for the Repair Parts List which is given below.

REPAIR PARTS LIST

INDEX

MODEL 7150M

MODEL 7160B

GENERAL DESCRIPTION

Chassis 1-357, Models 7150M and 7160B, are combinations providing a direct viewing television receiver capable of receiving all 12 commercial television channels, a radio capable of receiving the standard broadcast band and frequency modulation band, and an automatic record changer. The television picture is reproduced on a 17 inch rectangular, black faced, tetrode type picture tube using electromagnetic deflection.

SPECIFICATIONS

Frequency Range

Television	
All 12 television channels	54-88 Mc., 174-216 Mc.
Picture IF Carrier	26.4 Mc.

CIRCUIT DESCRIPTION

The Sylvania television and AM-FM receiver chassis 1-357 operates with twenty-four tubes, plus two low-voltage rectifiers, two high-voltage rectifiers, and one picture tube. The operating controls on the front panel have been reduced to a minimum; which are Tone, AM-FM Radio Tuning, Volume, Function Switch, Brightness, and TV Channel Selector and Band Switch. The remaining controls, which are seldom ad-

CAUTION NOTICE

THE HIGH VOLTAGE LEAD TO THE PICTURE TUBE HAS A POTENTIAL OF 13,500 VOLTS. PRECAUTIONS SHOULD BE OBSERVED WHEN THE CHASSIS IS REMOVED FROM THE CABINET FOR SERVICE PURPOSES. DO NOT OPERATE THE RECEIVER WITH THE H V COVER REMOVED.

ALWAYS USE SAFETY GOGGLES AND GLOVES IF IT IS NECESSARY TO REMOVE THE PICTURE TUBE.

World Radio History

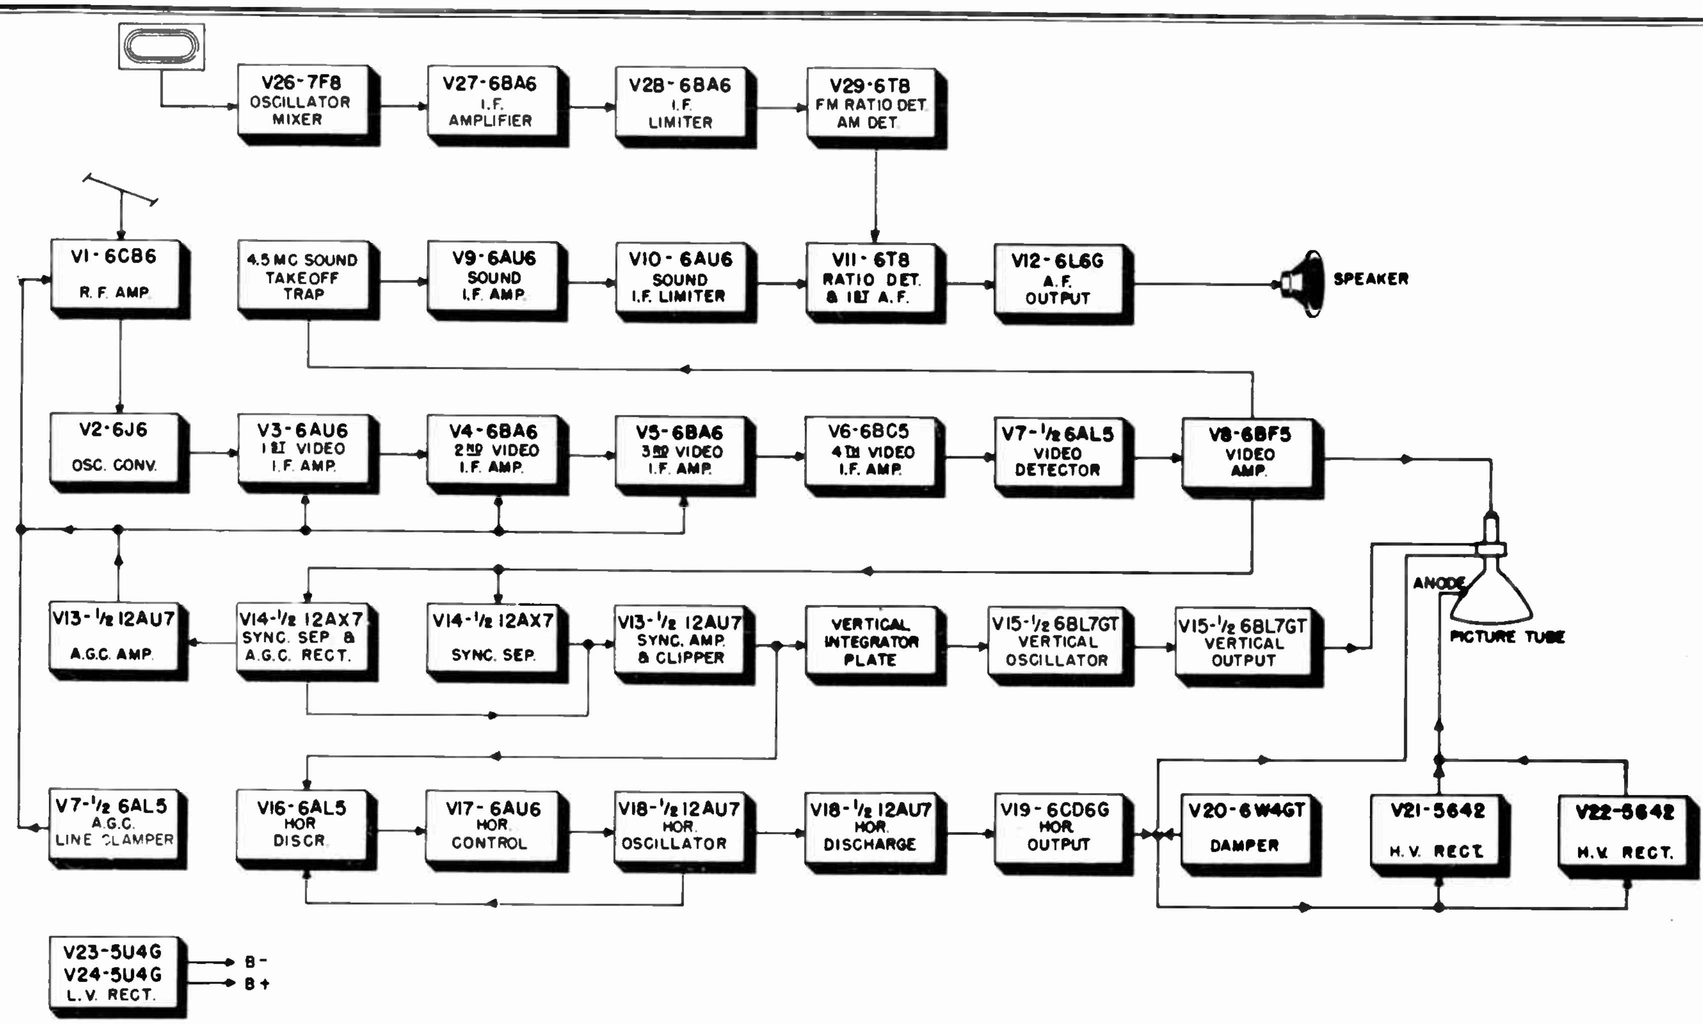

FIGURE 1 - BLOCK DIAGRAM

justed, are located at the rear of the chassis. Special features of this receiver are as follows:

Rotary Channel Selector

A compact, low drift, 12 channel rotary tuner is provided in these chassis for simplicity of operation. Continuous tuning eliminates the need of a fine tuning control.

Built-In Antenna

Eliminating the cost and inconvenience of an external antenna a Sylvania tuned dipole type antenna is built-in to provide satisfactory reception in most locations. The antenna is peaked for resonance to the individual channel by rotating the trimmer knob on the top of the receiver.

Automatic Gain Control

Simplified customer operation is provided by a very flat AGC system which has a high degree of noise immunity. Very little, if any, readjustment of controls is required in going from one station to another.

Direct-Coupled Video System

A direct coupled video system eliminates all video coupling capacitors and D.C. Restorer. This reduces the visible effects of noise.

Horizontal Automatic Frequency Control

A sine wave Horizontal AFC is employed, providing excellent picture stability, even in the presence of noise and weak signals.
For convenience in tracing circuits a block diagram is shown in Figure 1. The antenna is connected to the input of the RF tuner. This tuner functions to select the desired television channel by continuous tuning. The output of the tuner is at intermediate frequency and of sufficient band width to pass both picture and sound carriers of the desired signal.

The output of the tuner is then applied to the video IF Amplifier consisting of 3 stagger-tuned stages and one bandpass stage. The adjacent channel carriers and co-sound carrier are attenuated by this IF Amplifier.

The video signal out of the video detector is amplified by a single stage and impressed on the picture tube.

Automatic gain control is obtained from the AGC Rectifier, amplified by the AGC Amplifier and applied to the RF and IF Amplifiers. The AGC Line Clamper prevents the Tuner AGC Line from going positive under weak signal conditions.

The sync pulses are separated from the video signal, amplified, and clipped and then fed to the Horizontal Discriminator and Vertical Integrator plate. The Vertical Sync information from the vertical integrator plate is applied to Vertical Oscillator to keep this oscillator in step with the vertical sync pulses from the station. The Vertical Oscillator produces a peaked saw-tooth wave which is applied to the Vertical Output stage energizing the Vertical Deflection coils.

Horizontal Sync information from the Sync clipper is supplied to the Horizontal Discriminator. A voltage from the Horizontal Oscillator is also supplied to the Horizontal Discriminator. The output of the Horizontal Discriminator is then applied to the Horizontal Control tube which functions to hold the Horizontal Oscillator in synchronism with the incoming horizontal sync pulses.

The Horizontal Oscillator actuates the Horizontal Discharge tube through the Horizontal Ringing Coil producing a peaked saw-tooth

World Radio History

wave. Approximately one-half of the saw-tooth component of this wave causes current to flow in the plate circuit of the Horizontal Output tube. This current energizes the Horizontal Deflection Coils through the Horizontal Scanning Transformer to provide the right half of the horizontal scan. During the right half of the scan, a small amount of current is also flowing through the Damper tube. At the end of the saw-tooth, the inverse pulse component acts on the grid of the Horizontal Output Tube to cut off plate current flow. When this occurs, the energy in the Horizontal Deflection circuit transfers rapidly from the inductive branch of the circuit to the capacitive branch resulting in a voltage peak of approximately 2000 Volts across the Horizontal Deflection Coils. This voltage is stepped up to approximately 6750 Volts by the turns ratio of the Horizontal Scanning Transformer and fed to the voltage doubling rectifier circuit to provide approximately 13,500 Volts for the picture tube H.V. anode.

The damper tube does not conduct during the high voltage pulse period because of the polarity of the pulse. During this pulse period, when the energy transfers from the inductive branch of the horizontal deflection circuit to the capacitive branch and back again to the inductive branch, the electron beam in the picture tube is moved rapidly from the right to the left edge of the raster to accomplish retrace.

At the completion of retrace, energy again flows out of the inductive branch of the circuit. The horizontal output tube is still cut off during this time and a strong current flows through the damper tube. This current decreases to zero linearly to provide the left half of the scan. As the current approaches zero, the horizontal output tube again begins to conduct and the entire cycle is repeated.

ANTENNA INSTALLATION

Television

The 1-357 chassis model is shipped with a built-in antenna connected to the antenna board. For most installations the built-in antenna will provide satisfactory reception.

A variable capacitor controlled from the top of the receiver adjusts the antenna circuit to resonance. At each individual channel the capacitor should be adjusted for best picture quality.

If an external antenna is desirable, the Sylvania Hideaway Antenna, Part 580-0005, gives optimum performance where an indoor installation is indicated, and the Sylvania Conical Fan Television Antenna, Part 580-0001, is available in one, two and four bay arrays, providing superior performance in an outside installation. When using the Sylvania Hideaway Antenna or the Sylvania Conical Fan Antenna, remove the leads to the built-in antenna from the antenna terminal and then connect matching 300 Ohm twin lead from the antenna installation in its place. A 300 Ohm lead is especially recommended where the lead-in is in excess of 100 feet.

A 75 Ohm shielded coaxial input may be used with the chassis if impedance matching coils, Sylvania Part No. 111-0007, are wired between the lead-in and the antenna terminals. A coaxial lead-in may be necessary in those areas where high noise signals prevail.

AM-FM Radio

AM RECEPTION - Excellent local reception may be obtained by the use of only the built-in loop which is installed on all 1-357 chassis models. However, if an outside installation is desirable, connect the antenna lead-in to the terminal provided at back of loop.

FM RECEPTION - Provisions are also made on this chassis for FM reception without the use of an external antenna. For this circuit operation, connect the metal jumper between terminals 2 and 3 as shown in Figure 2. In this manner, one side of the AC power line is used as an FM antenna. If reception is not satisfactory and an external installation is desirable, remove the jumper from terminals 2 and 3 and connect antenna lead-in to terminals 1 and 2.

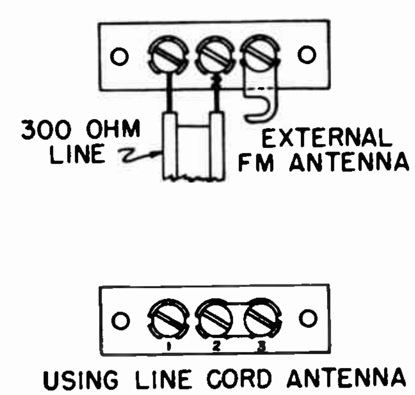

FIGURE 2 - ANTENNA HOOKUP

The FM antenna terminal board, shown in Figure 2 is located at the right on the rear of the television chassis.

OPERATING INSTRUCTIONS

TELEVISION RECEPTION

A. To adjust and tune this receiver for television reception, proceed as follows:

1. Turn On-Off, Tone Control (18) to On.
2. Turn the Function switch (19) to TV.
3. Allow several minutes warm-up period.
4. Turn band switch (5) either way to the appropriate band (i.e. channels 2-6 or channels 7-13).
5. Rotate the Channel Selector (4) so that the desired channel number is seen in the window and until you can see the picture.
6. Turn the Brightness control (2) fully counterclockwise, and then slowly clockwise until activity is clearly visible on the screen.
7. Adjust the Channel Selector (4) and Antenna Trimmer (1) for best picture quality.
   Note: Adjustment of the Antenna Trimmer is not necessary if an external antenna is used.
8. Adjust the Volume control (3) for desired volume and Tone control (18) for desired tone.
9. Slight adjustment of the Brightness control (2) may be necessary to obtain the best possible picture.

B. To change from one television station to another:

1. Turn the Band switch (5) fully clockwise to tune any channel from 2 through 6 or fully counterclockwise to tune any channel from 7 through 13.
2. Rotate the Channel Selector (4) so that the desired channel number is seen in the window and adjust for best picture quality.
3. If necessary, adjust the Brightness control (2) for best picture. Only slight adjustment of this control should be necessary.

C. To turn on dial light, push dial light switch to left.

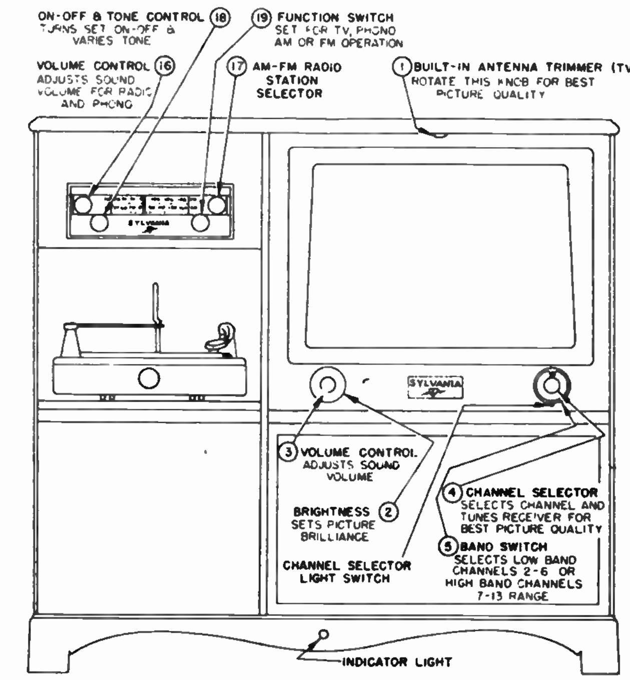

FIGURE 3 - FRONT OF CABINET CONTROLS

AM-FM & PHONO OPERATION

For AM, FM, or Phonograph operation, proceed as follows:

1. Turn On-Off, Tone Control (18) to On.
2. Turn Function Switch (19) to AM, FM, or Phono position. Starting at counterclockwise position, settings of this switch are: FM, AM, Phono, TV.
3. Select desired AM or FM station by turning AM-FM Radio Station Selector (17) until the approximate frequency of the desired station is indicated behind the dial pointer. Read bottom dial scale for AM, top scale for FM band. Tune carefully for clearest reception.
4. If phonograph operation has been selected, follow the record changer operating instructions given on Page 2 of Bulletin 9-14.
5. Radio or phonograph volume may be adjusted by turning the Volume Control (16). Tone may be changed to individual taste by turning the Tone Control (18).

World Radio History

INSTALLATION AND SERVICE INSTRUCTIONS

Picture Tube Handling

All Sylvania Television receivers incorporating chassis 1-357 are shipped complete with picture tube installed on the chassis and connected for operation. However, if it becomes necessary to re-install a picture tube due to replacement or servicing, the following precautions should be observed.

1. Do not open the picture tube carton until ready to install the picture tube.
2. Do not handle the picture tube unless protective goggles and gloves are worn. People not so equipped with safety devices should be kept at a distance while the picture tube is being handled.
3. Keep the picture tube as far from the body as possible while handling.

Picture Tube Replacement

To remove the picture tube from the chassis, remove the picture tube socket, anode connector, and ion trap magnet. Remove the tube holddown strap by removing the two screws on either side. When the rim of the picture tube is free of the strap, carefully pull the picture tube out through the focus magnet and deflection coils.

To replace picture tube follow the above procedure in reverse order being careful not to force the picture tube if neck binds. Be sure the tube is properly held by the lips of the holddown straps before tightening the holddown screws.

Chassis Removal

To remove the chassis from the cabinet, proceed as follows:

1. Remove all panel control knobs from the front of cabinet.
2. Remove the holddown screws from the underside of the chassis shelf. Access to these screws is from the rear of the cabinet.
3. Disconnect the built-in antenna, remove the interlock cover screws and remove interlock cover.
4. Remove plugs from the power, speaker, indicator light, and audio sockets on the TV chassis.
5. Slide the chassis all the way out the back of the cabinet.

To replace the chassis, reverse the above procedure.

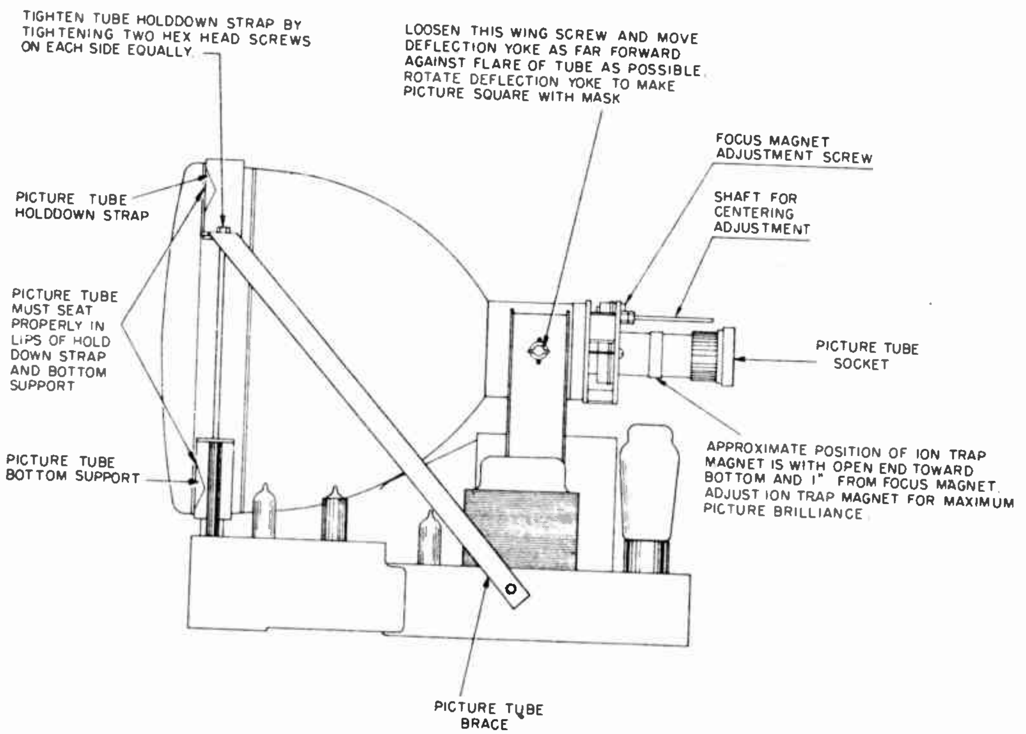

FIGURE 4 - PICTURE TUBE INSTALLATION

Preset Controls Adjustments

All preset controls are located at the rear of the receiver and are readily available without removing the interlock cover.

AGC - See AGC Control Adjustment

Horizontal Hold - See "Adjustment of Horizontal AFC Operation".

Contrast - Adjust contrast control to obtain best contrast with a good picture or test pattern.

Vertical Linearity and Height - Adjust the height control until the picture fills the screen vertically. Adjust the Vertical Linearity control until the pattern is symmetrical from top to bottom. Adjustment of either control will require a readjustment of the other.

Vertical Hold - Rotate the Vertical Hold control until the pattern is slowly moving downward. Back off on the control to a point just beyond where the vertical motion stops.

Horizontal Drive - Turn the horizontal drive control clockwise as far as possible without crowding of center of the picture.

Horizontal Size - Adjust the horizontal size control until picture fills the mask horizontally.

Horizontal Linearity - Adjust the horizontal linearity control until the picture is symmetrical left to right. Re-check Horizontal Drive after adjusting Horizontal Size and Horizontal Linearity.

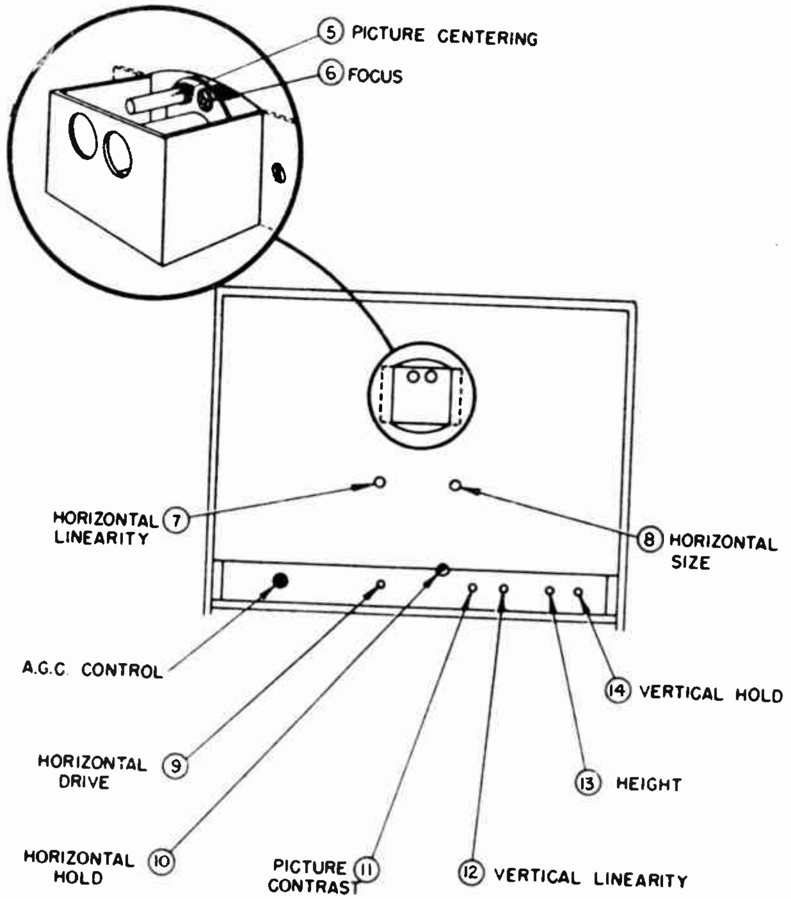

FIGURE 5 - REAR PANEL CONTROLS

World Radio History

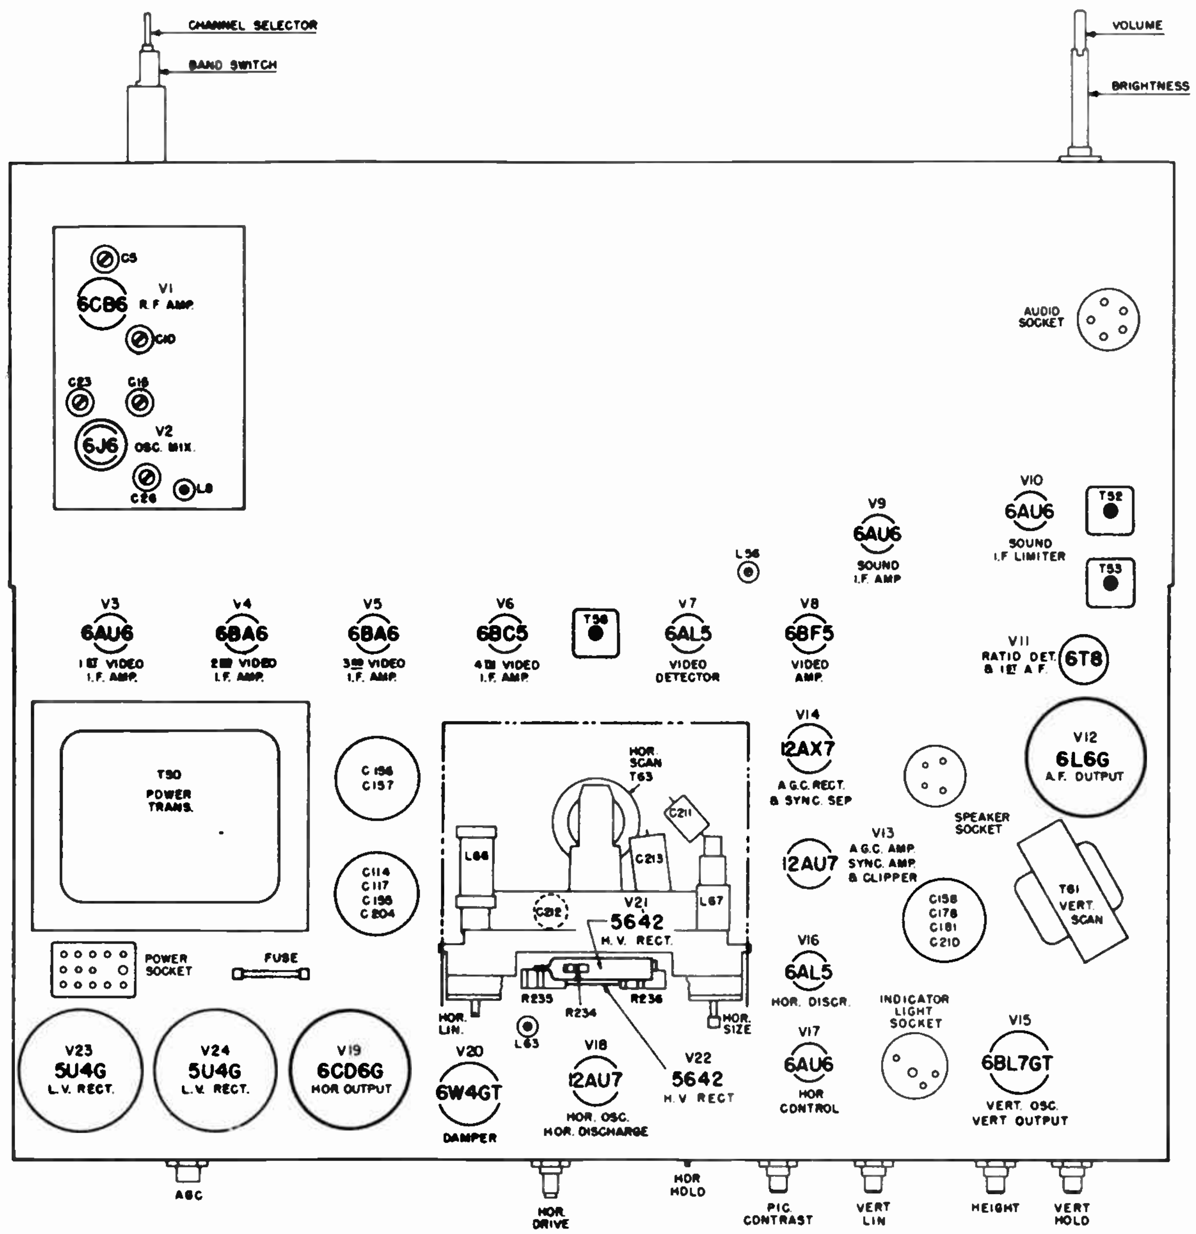

FIGURE 6 - CHASSIS TOP LAYOUT

Adjustment of Ion Trap Magnet, Focus Magnet, and Centering Shutter

These adjustments are interdependent and, therefore, it is necessary to check all three at the same time.

Before making any adjustments, the function of each magnet should be noted.

The ion trap magnet is used to obtain maximum brilliance of the raster or picture and should be adjusted to obtain maximum brilliance as described below.

The focus magnet is used to obtain correct focus of the picture.

The centering shutter is an integral part of the focus magnet assembly. Its function is to position the picture, both horizontally and vertically.

Before making any adjustments, check that the deflection yoke is positioned so that it is pressing against the flare of the picture tube. To ensure this, loosen the thumb-screws located at each side of the yoke and push the yoke as far forward as it will go. If the picture is not square with the screen mask, rotate the yoke.

Next, check that the focus magnet is held firmly by both brass screws against the yoke; there should not be any gap between the yoke and the focus magnet.

When adjusting the focus of the receiver it is to be noted that optimum focus of the picture does not necessarily result when either the vertical or the horizontal is adjusted for maximum definition. Optimum focus is frequently a compromise between these two settings. It is highly desirable, therefore, that a transmitted picture, containing both vertical and horizontal lines, be available for correct focusing of the receiver.

Before proceeding with the adjustment of the focus of the receiver, first ensure that the ion trap magnet is correctly adjusted.

Set the contrast control at minimum and the brightness control at maximum. The ion trap magnet should first be positioned so that there is approximately one inch between the ion trap magnet and the focus magnet. There is no specific angle of rotation for the initial setting of the ion trap. The ion trap magnet should be slowly rotated until a picture (or raster, if the receiver is not yet tuned to a station) is visible on the screen. The brightness should now be reduced by means of the brightness control and the ion trap magnet carefully twisted and moved a small amount backwards and forwards on the neck of the tube, to obtain maximum brightness.

Finally, adjust the brightness control to obtain maximum brightness on the screen and then carefully adjust the ion trap magnet. It may be possible to increase the brightness still more by turning the contrast control towards maximum and again adjusting the ion trap magnet. The correct position of the ion trap magnet is that which ensures the greatest possible brightness of the raster or picture before it enlarges and "blooms" as the setting of the brightness control is increased. Do not leave the brightness control in this position as the condition causes overload of the picture tube.

A preliminary adjustment of the screw on the focus magnet should now be made to obtain a raster or picture which is focused - this preliminary adjustment will not, of course, be necessary if the raster or picture is already in focus. (Note: Use a non-magnetic screw driver to adjust the focus screw.)

If the picture is not centered on the screen, either horizontally or vertically, properly position it by adjustment of the centering shutter. This centering adjustment will move the picture up, down, left or right as required to center the picture. With the brightness control at a low level, check the horizontal size and height of the picture to insure that when the picture is properly positioned it just fills the mask with no corner cutting.

Carefully make final adjustments of the focus screw for optimum focus in both horizontal and vertical directions. Best focus of the picture does not necessarily result when either the vertical or horizontal focus is optimum and the final setting should, therefore, be a compromise between the two. A test pattern with both vertical and horizontal lines is, therefore, highly desirable when making focus adjustment.

Finally, check that the adjustment of the ion trap magnet is such that the brightest possible picture is obtained, as previously mentioned.

Since all these adjustments are interdependent, recheck the adjustment of all three until the best possible picture is obtained.

World Radio History

ADJUSTMENT OF HORIZONTAL AFC CIRCUIT

Check of Operation

The operation of the AFC circuit should be checked as follows:

A. Tune the receiver to a channel on which no signal is received and return to the original channel. The picture should immediately fall into synchronization.

B. Switch off the power to the receiver for about five minutes and then switch back on. Picture should immediately fall into sync.

C. Check for correct phasing of Horizontal AFC circuit by noting that there is approximately 1/8" of blanking visible on the right hand edge of the picture. It will be necessary to turn the contrast control to minimum and readjust the brightness control and reduce picture size to see the blanking.

NOTE: Before making check C above, be sure the horizontal drive control is correctly adjusted. Refer to "Preset Controls Adjustment," page 8. If the receiver passes the above checks, no adjustments to the horizontal AFC circuits need be made.

If the receiver cannot pass checks "A," "B," or "C" the adjustment of the Horizontal Hold Control as noted under "Horizontal Hold Adjustment" should be made.

Horizontal Hold Adjustment

A. Tune in a station and adjust the tuning control for best picture quality. Adjust the contrast and brightness controls for normal picture.

B. Remove V16 - 6AL5 - Horizontal Discriminator tube.

C. Turn the Horizontal Hold Control until the picture moves back and forth across the screen with blanking bars vertical.

D. Replace the Horizontal Discriminator tube and repeat A, B, and C under "Check of Operation."

E. If receiver still will not pass these checks, it will be necessary to proceed with "Phase Adjustment."

Phase Adjustment

A. Turn the core in the horizontal "ringing" coil all the way out (counterclockwise). Short out the 4700 ohm horizontal charge circuit peaking resistor R226.

With the horizontal size coil set for approximately the correct picture width, and with the horizontal linearity coil adjusted for best linearity, rotate the horizontal drive control fully counterclockwise. Slowly turn the drive control clockwise until crowding is visible in the center of the picture. Now carefully turn the control back (counterclockwise) only sufficient to remove the crowding in the picture or pattern. On some chassis, it may not be possible to obtain crowding of the picture. In such cases the control should be set to the fully clockwise position.

NOTE: Do not operate the receiver with the horizontal drive control mis-adjusted.

B. Remove the 6AL5 horizontal discriminator tube from its socket.

C. Carefully turn the frequency adjustment screw (top of discriminator transformer T62) until the picture moves back and forth across the screen of the picture tube with the blanking bar vertical.

D. Insert the 6AL5 horizontal discriminator tube back into its socket.

E. Adjust the phase adjustment screw (underside of discriminator transformer T62) until approximately 1/8" of "blanking" is visible on the right-hand edge of the picture. In order to see the "blanking", it will be necessary to turn the contrast control almost to minimum, re-adjust the brightness control and reduce picture size.

F. Check the "free-running" of the horizontal oscillator as described under paragraphs "B," "C," and "D," and, if necessary, readjust the frequency adjustment screw on top of horizontal discriminator transformer.

G. Make a final check of the phasing as described in paragraph "E" above. It is important that both the "free-running" and the phasing are correct.

H. Remove the short from across the 4700 ohm resistor R226 and readjust the horizontal drive control as described in (A). Turn the core in the horizontal "ringing" coil clockwise until approximately 1/8" of "blanking" is again visible on the right-hand edge of the picture.

I. Before the horizontal synchronization circuit is adjusted to the final position, it will be necessary to check the operation as follows:

Slowly turn the oscillator frequency adjustment screw (top of transformer T62) in either direction until the picture suddenly falls out of synchronization as indicated by the presence of a number of diagonal bars. The total number of bars visible must not be less than six. These bars may consist of either several full bars and two half bars for the total number or they may be all full bars for the same total number. Slowly turn the adjustment screw so as to decrease the number of bars and note the total number of bars visible just before the picture again falls into synchronization. The last number of bars visible must not be less than three, or more than four. The adjustment screw must be turned very slowly and carefully after the number of bars has been reduced to four or five in order to get an accurate indication of the minimum number of bars it is possible to obtain.

Turn the adjustment screw in the opposite direction until the picture suddenly falls out of synchronization in the opposite direction and repeat the foregoing procedure. Again, the total number of bars visible when the picture falls out of synchronization must not be less than six and not less than three or more than four bars must be visible just before the picture falls into synchronization.

J. After checking the operation as in "I," it is necessary to repeat the procedure described in paragraphs "B," "C," and "D."

K. Remove the signal by tuning to a "free" channel, then retuning to the original channel. The picture should immediately fall into synchronization.

L. Switch "off" the power to the receiver for about five minutes and then switch receiver "on" and check that the picture pulls into synchronization.

AGC CONTROL ADJUSTMENT

This control has been correctly adjusted at the factory and should require no further adjustment. If adjustment becomes necessary as evidenced by poor horizontal or vertical sync; poor video signal (poor contrast). Adjust as follows:

1. Connect a good antenna installation to the receiver.
2. Tune the receiver to a channel on which no picture is received.
3. Set the contrast control to mid-position.
4. Turn the AGC control fully clockwise. The AGC control is located on the rear panel of the chassis.
5. Connect a VTVM from the AGC Amplifier plate to ground (V13, 12AU7, pin 6) and set the AGC control to obtain a negative 0.1 volt reading.

Note: On some receivers the closest approach to this reading will be the fully clockwise position.

6. With the AGC Control set as above, turn the contrast control to almost maximum (about 7/8) and tune in the strongest station available in the area.
7. Again read the AGC Amplifier plate voltage; if reading is less than a negative 2.0 volts leave the control as set.
8. If the AGC Amplifier plate voltage is more than 2 volts negative, slowly turn the AGC control counterclockwise observing the picture.
9. The picture will get darker and then finally start to fall out of sync as evidenced by a sudden shift or jittering of the picture in either the horizontal or vertical direction. Do not turn beyond this point.

©John F. Rider
World Radio History

10. Back off (clockwise) slowly on the control until the picture holds in sync without flutter and turn slightly beyond. (Experience will dictate how far beyond to turn).

11. Rock the tuning control slightly either side of the best tuning point to insure picture stays in sync; if not, turn slightly further clockwise and check again.

12. As a final check, turn the volume control up to normal level. Intercarrier buzz should be negligible.

13. Remove objectionable intercarrier buzz by turning the AGC control slightly further clockwise. (Note: The intercarrier buzz is merely a reference for correct adjustment of the AGC control and only a slight touch-up should be necessary. If much adjustment is required to remove intercarrier buzz, the sound section is maladjusted and requires realignment).

14. Rock the tuning control slightly either side of the best tuning point and turn the AGC control slightly more clockwise as necessary to remove objectionable intercarrier buzz.

The intent of the above AGC control adjustment is to provide a maximum of AGC action consistent with proper sync and minimum intercarrier buzz on strong signals.

TEST EQUIPMENT REQUIREMENTS

1. RF sweep generator or generators with frequency range from 4-220 Mc. having sweep width adjustable from 50 Kc. to 10 Mc. with an output of at least 0.1 volt, a marker system, either built-in or external type and flat within ± 1 Db.
2. Signal generator or generators with a frequency range from 4-222 Mc. and an adjustable output of at least 0.1 volt.
3. Sylvania cathode ray oscilloscope type 132 or equivalent capable of passing a 60 cycle square wave.
4. Sylvania Polymeter type 221 or equivalent vacuum tube voltmeter.
5. Sylvania High Voltage Probe Adapter type 225 or equivalent with 0-30 KV DC range (not shown).
6. Sylvania tube tester type 220 or equivalent capable of testing shorts with proper voltages and performance under dynamic conditions.
7. Jig Tube Shield - made by cutting off or insulating the tube shield used on the 6J6 converter tube on the tuner so that the shield does not ground when in place on the tube.

ALIGNMENT PROCEDURE

Should any chassis under service require complete realignment, the alignment procedure should be carried out in the following listed order.

PRE-ALIGNMENT INSTRUCTIONS - READ CAREFULLY BEFORE ATTEMPTING ALIGNMENT.

Lay chassis on left side for alignment. Ground all equipment to receiver chassis. Use special alignment tool Service Part No. 898-0003.

VIDEO IF ALIGNMENT

1. Connect signal generator to the jig shield on the 6J6 Oscillator-Mixer. Allow set to warm-up for 15 minutes.

2. Connect the negative lead of a 3 volt battery to the AGC Line, positive lead to ground.

3. Connect D.C. VTVM across the diode load resistor R145 - 3300 Ohm.

4. Adjust the cores of the IF traps in the following order. Keep Voltmeter reading between 1 and 2 volts by reducing Generator Output as required.

Set Signal Generator At:	Adjust:
21.9 Mc.	Core on 4th IF Trap L68 for minimum output
27.9 Mc.	Core on 3rd IF Trap L55 for minimum output
21.9 Mc.	Core on 1st IF Trap L54 for minimum output

5. Adjust the cores of the Video IF Transformers in the following order. Reduce generator output to keep voltmeter reading between 1 and 2 volts.

Set Signal Generator At:	Adjust:
26.0 Mc.	Core on 3rd Video IF Transformer T57 for maximum output
22.7 Mc.	Core on 2nd Video IF Transformer T56 for maximum output
25.3 Mc.	Core on 1st Video IF Transformer T55 for maximum output
23.5 Mc.	Core on Converter Coil L8 for maximum output

Repeat tuning of cores on Trap Coils as described in step 4 above.

6. Disconnect Signal Generator and VTVM.

7. Connect sweep generator (frequency 24Mc., sweeping 10 Mc.) using a .005 Mfd. capacitor to pin 1 of the 4th Video IF 6BC5.

8. Connect oscilloscope to junction of diode load R145 - 3300 Ohm - and coil L58.

9. Adjust primary (top core) and then secondary (lower core) of IF Bandpass T58 to obtain curve shown in Figure 8. (Both adjusted from bottom of Transformer with hex end of special alignment tool.)

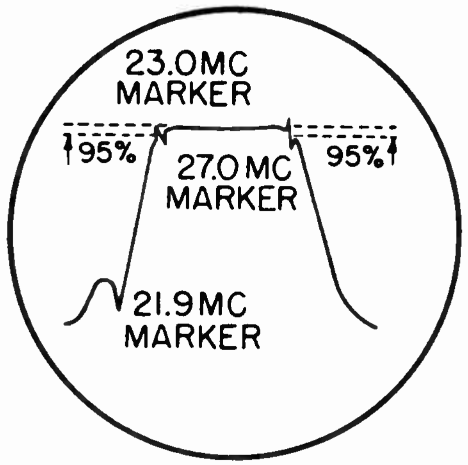

FIGURE 8 - IF BANDPASS RESPONSE

10. Disconnect Sweep Generator from 4th IF Grid and connect it to the Jig Shield on Converter 6J6. Loosely couple signal generator at this point for markers.

11. Observe IF Response Curve and if necessary adjust IF Transformer Core slightly to obtain response curve shown in Figure 9. Keep oscilloscope gain high enough to prevent overload of the receiver which will distort the curve.

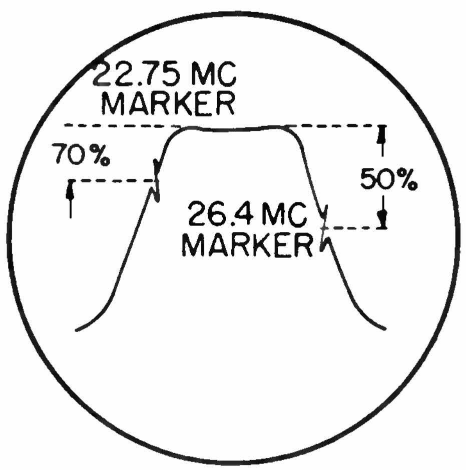

FIGURE 9 - OVERALL IF RESPONSE

SOUND TAKE OFF & 4.5 MC. TRAP ALIGNMENT

1. Connect a 4.5 Mc. Signal Generator through .005 Mfd. to pin 1 of Video Amplifier Tube - 6BF5. Loosely couple signal generator for use as markers.

2. Connect probe of High Frequency VTVM at junction of coil L59 and R148.

3. With enough output from signal source to give a readable indication on the VTVM, adjust the core on Sound Take-Off Trap - L56 - For a sharp dip. The dip should have an output 4 to 1 less than the output obtained when the signal source is tuned to 2 Mc. (Note: The above tests shall be made with the picture tube removed and a VTVM having an input capacity of 5 Mmfd. $\pm$ 2 Mmfd.

INTERSTAGE TRANSFORMER ALIGNMENT

1. Disconnect the 4.5 Mc. signal from the Video Amplifier. Connect a 4.5 Mc. sweep oscillator having a 250Kc. deviation through a .005 Mfd. capacitor to pin 1 of Video Amplifier - 6BF5. Connect oscilloscope input across the limiter grid resistor R102 47,000 Ohms - using a 10,000 Ohm carbon resistor between scope lead and receiver chassis.

2. Adjust the primary and secondary of the Interstage Transformer T51 so that the 4.5 Mc. marker appears in the exact center of the response curve and so the curve has the greatest attainable amplitude. The response curve should appear as shown in Figure 10.

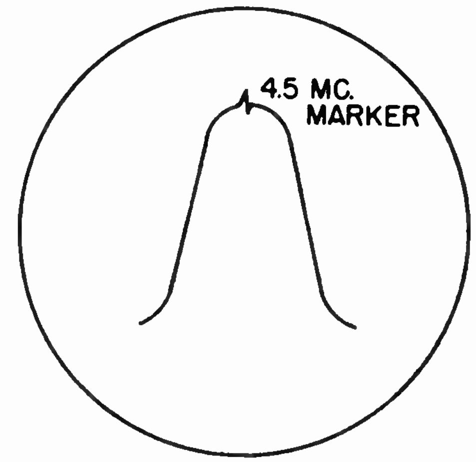

FIGURE 10 - SOUND IF RESPONSE

SOUND DISCRIMINATOR ALIGNMENT

1. With the 4.5 Mc. Sweep Oscillator connected as described in step 1 of "Interstage Transformer Alignment," disconnect the oscilloscope from the limiter grid resistor and connect the oscilloscope across the volume control.

2. Adjust cores of the Discriminator Transformers T52 and T53 until the discriminator curve corresponds to that in Figure 11. Note especially that:

(a) 4.5 Mc. marker is exactly in the center of the curve.
(b) The curve is linear between the two adjacent markers.
(c) The amplitude is the greatest obtainable.

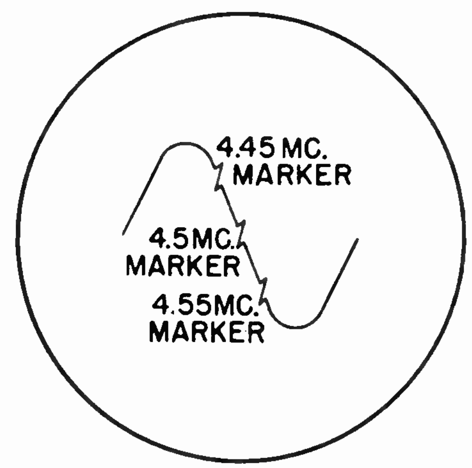

FIGURE 11 - SOUND DISCRIMINATOR RESPONSE

R F TUNER ALIGNMENT

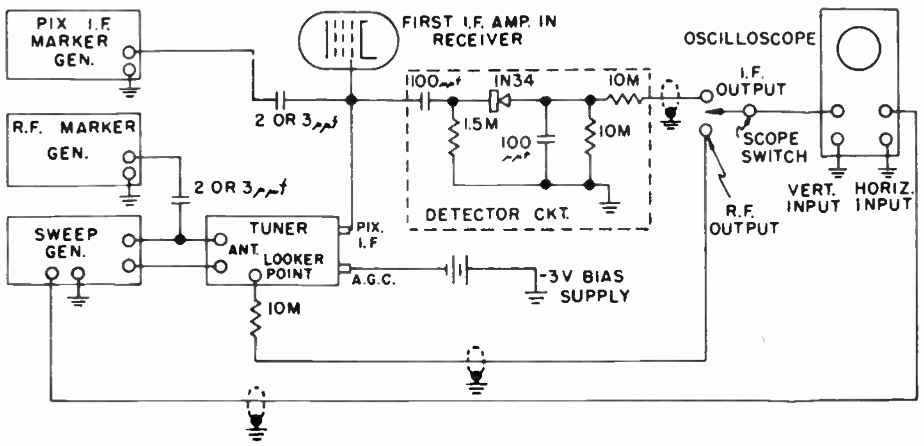

FIGURE 12 - TUNER ALIGNMENT SETUP

NOTES ON TUNER ALIGNMENT SETUP

In reference to Figure 12, the following precautions should be taken in making the equipment setup.

1. The detector circuit should be so constructed as to maintain leads as short as possible. Connection of the detector circuit to the 1st IF grid terminal (see Fig. 12 for location) should also be made with short leads.

2. Shielded leads should be used in making the following connections to reduce hum and synchronous voltage pick-up.
   (a) The lead for observation of the RF response from the scope isolating resistor (10 K ohms located at the tuner "looker point") to the RF output switch position of the scope switch.
   (b) The connection from the IF detector circuit output to the IF switch position of the scope switch.
   (c) The connection from the sweep generator to the horizontal input of the scope. (Use externally generated sweep instead of internal oscilloscope sweep in order to obtain synchronization).

3. The single pole double throw "Scope Switch" should be located at the vertical input terminals of the scope. This switching arrangment will permit observation of either the IF response or the overall RF response. The aforementioned positions will be referred to in subsequent text as the "IF" and "RF" positions respectively.

4. The marker generator coupling condenser should be as small a value as possible to prevent any effect on tuner response, but must be large enough to permit easy observation of markers on either the IF response or overall RF response. (Approximately 2 or 3 MMF should be satisfactory in most cases).

5. For all tuner alignment tests which are outlined in this text, remove the second IF amplifier tube or bypass its plate circuit with approximately 1000 MMF to prevent coupling back from the receiver IF system.

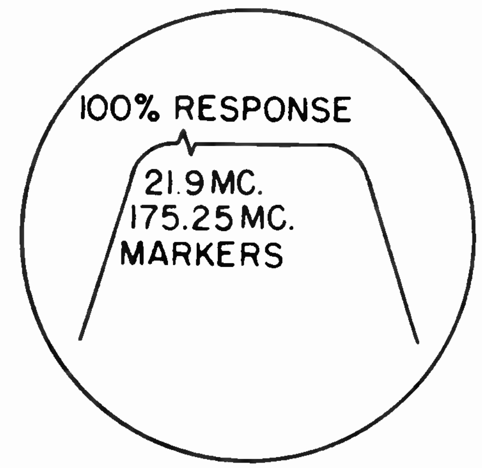
6. In all of the following tests the oscilloscope vertical gain should be as close to maximum gain as possible, consistent with hum and synchronous voltage interference limitations. This precaution will allow the use of low levels from RF sweep Generator and increase the visibility of IF and RF markers.

OSCILLATOR ALIGNMENT

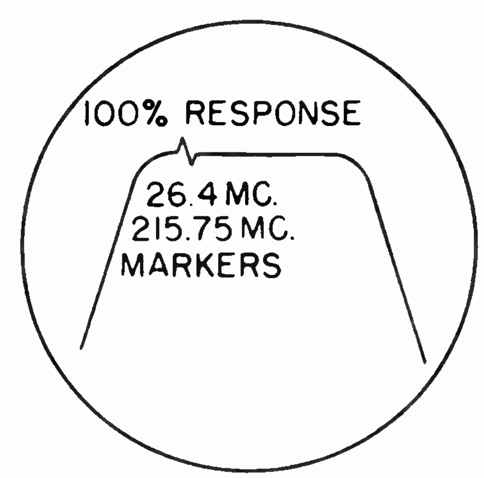
In making adjustments of the oscillator alignment it should be noted that any change in the setting of the high band oscillator trimmer will also effect the low band oscillator tuning, however, because of switching, the adjustment of the low band oscillator trimmer will not affect high band oscillator tuning. Also, there is a slight shift of oscillator frequency in the high band position only when the bottom cover is removed.

High Band Oscillator Alignment

1. Remove the bottom cover and rotate the band switch to the high band position.
2. Rotate variable condenser to maximum capacity position (fully counterclockwise position of tuning control knob).
3. Tune sweep generator to channel 7 and set scope switch to IF output position.
4. Inject 175.25 Mc. and 21.9 Mc. markers.
5. With a non-metallic pick vary the turns spacing on the high band oscillator coil L9 until markers coincide (squeezing the coil lowers the oscillator frequency and spacing the turns farther apart raises oscillator frequency.



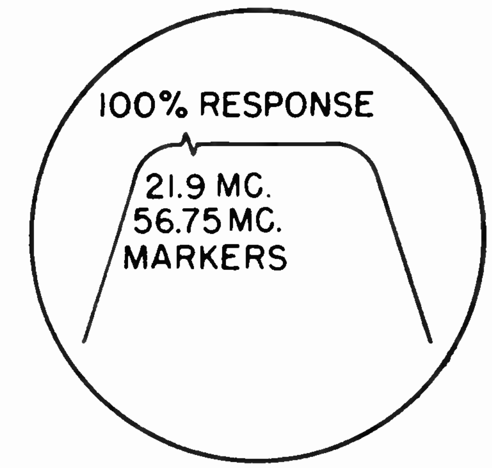
6. Replace bottom cover and check for shift of markers. If there is a shift remove the bottom cover and compensate by re-adjusting L9 as necessary. Repeat until markers coincide with bottom cover in place.
7. Rotate variable capacitor to minimum capacity (fully clockwise position of tuning control knob).
8. Tune sweep generator to channel 13.
9. Inject 215.75 Mc. and 26.4 Mc. markers.
10. With bottom cover in place, adjust oscillator grid trimmer C23 to make markers coincide.



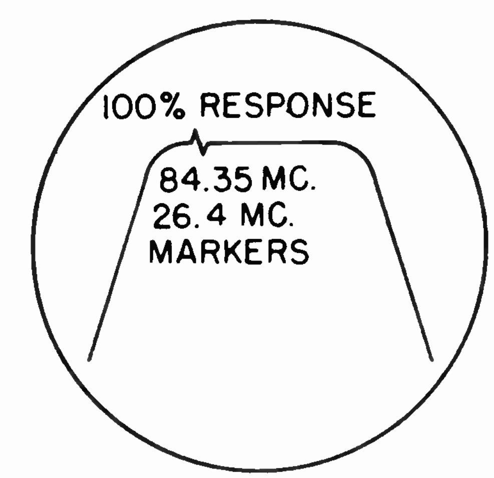
11. Repeat steps one through ten until proper end frequencies are reached at maximum and minimum capacity settings.

Low Band Oscillator Alignment

12. Remove bottom cover, turn band switch to low band position and rotate variable capacitor to maximum capacity (tuning control knob fully counterclockwise).
13. Tune sweep generator to channel 2.
14. Inject 56.75 Mc. and 21.9 Mc. markers.
15. Using a non-metallic pick adjust the spacing between turns on the low band oscillator coil L9 until the markers coincide.



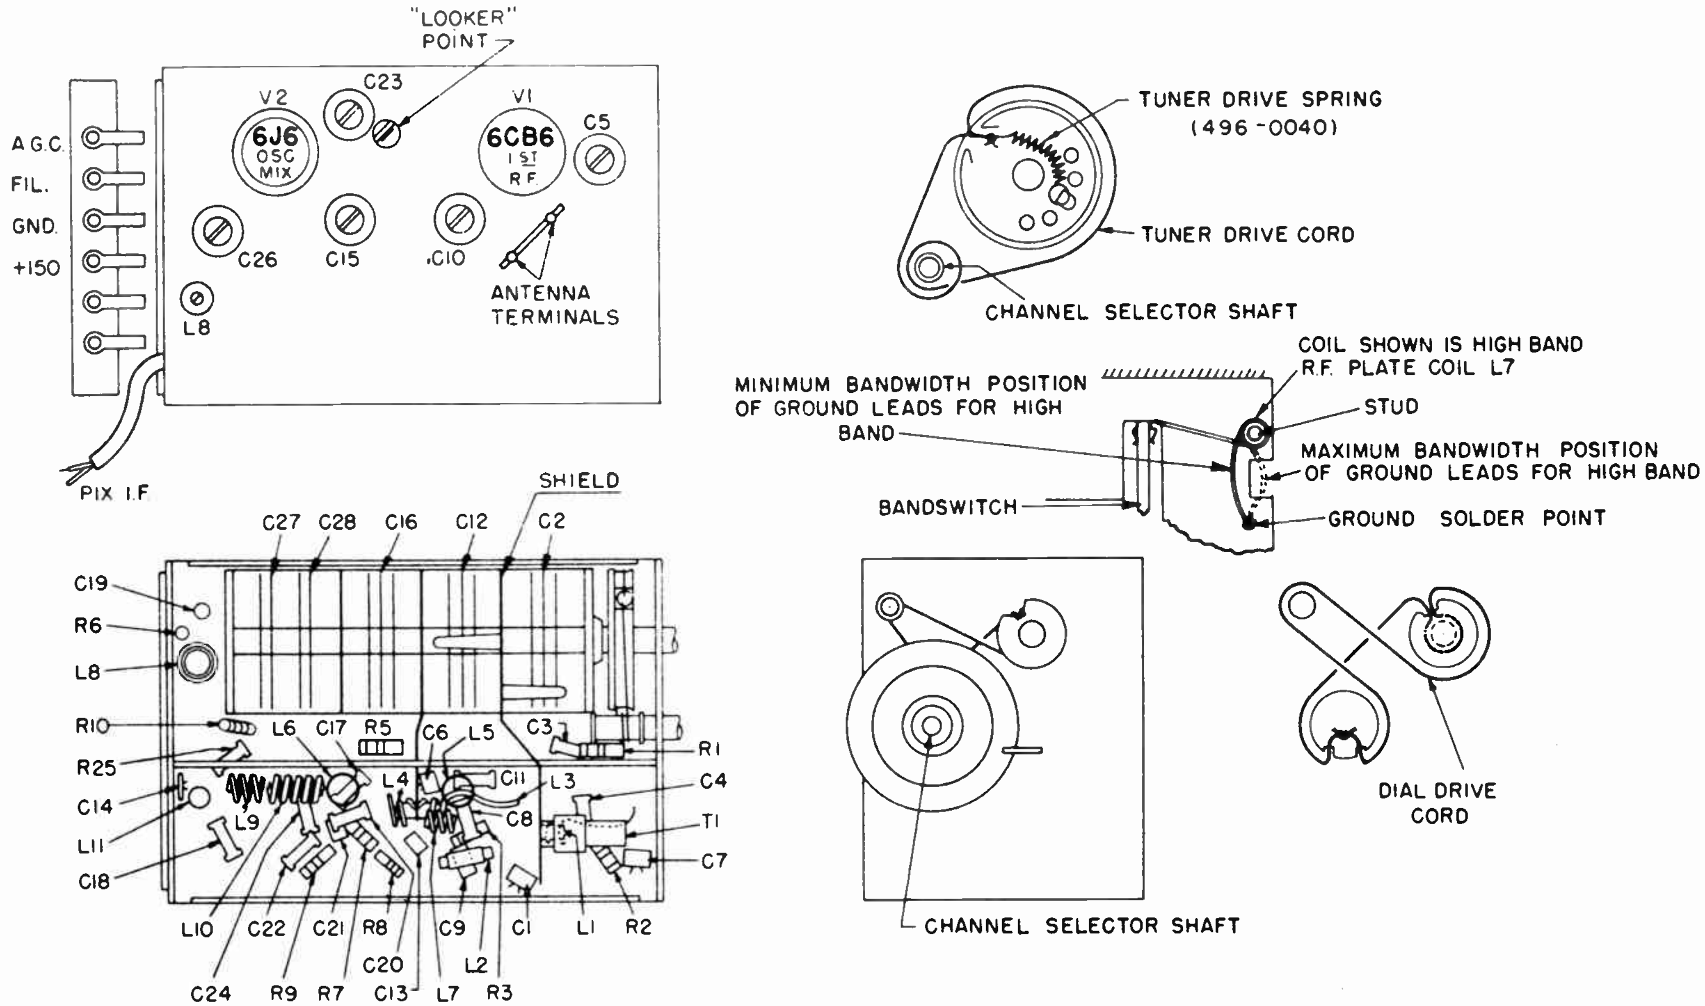
16. Rotate the variable capacitor to minimum capacity (tuning control knob fully clockwise).
17. Tune sweep generator to channel 6.
18. Inject 84.35 Mc. and 26.4 Mc. markers.
19. Adjust oscillator plate trimmer C26 to make markers coincide.



20. Replace bottom cover and recheck in steps 12-19.
21. Recheck all four oscillator frequencies as in steps 1-19.

© John F. Rider

World Radio History



Note: This RF tuner has been thoroughly tested at the factory and should provide trouble-free reception throughout the life of the chassis. However, if service other than alignment is required, return the complete tuner to the factory for replacement.

FIGURE 13 - TUNER LAYOUT

R. F. PASSBAND ALIGNMENT

1. If only the RF Passband is being aligned it is advisable to check oscillator coverage as noted under Oscillator Alignment step 21 above.
2. Remove bottom cover and turn band switch to high band position.
3. Rotate tuning control so that pointer is at channel 7 on the dial calibration.
4. Tune sweep generator to channel 7. Set scope switch to the IF output.
5. Inject 175.25 Mc. and 26.4 Mc. markers and adjust tuning control so the markers coincide. Leave tuning control at this setting for the remainder of channel 7 adjustment.
6. Change scope switch to the RF output.
7. Check that the RF response curve is similar to those shown in Figure 14.
8. If the response curve differs much from those shown in Figure 14, the inductance and coupling of the high band RF plate coil L3, the high band mixer grid coil L4 and the high band antenna coil L1 for proper band width and symmetry. In determining the band width, it will be necessary to switch the marker generator alternately between channel 7 picture carrier (175.25Mc.) and sound carrier (179.75 Mc.).
9. The high band RF plate coil L3 and the high band mixer grid coil L4 are properly adjusted when a slight variation in the inductance of either coil will result in a frequency shift of the entire response with no noticeable narrowing of the band width.
10. The high band antenna coil L1 is properly adjusted when a slight variation of its inductance will cause both peaks to rock slightly. If only one peak moves, the high band antenna coil L1 is staggered away from the center of the passband.
11. The inductance of these coils (L1, L3, L4) is varied by pushing the coil on or off the brass stud. Pushing the coil on the stud will raise the frequency and pushing the coil off the stud will lower the frequency.
12. The band width of channel 7 interstage transformer (L3, L4) is controlled by dressing the ground leads of these coils past the cut out in the RF shield plate (see Fig. 13). When both leads cross the cutout the greater separation of peak occurs. For maximum gain the band width should be adjusted so that the response is no greater than that required to keep the sound and picture carrier frequency markers on the peaks of the overall RF curves.
13. Replace tuner bottom cover and check RF passband response.
14. If necessary, remove bottom cover and make slight compensating adjustments. Replace bottom cover and recheck.
15. With the bottom cover in place, rotate the tuning control knob so that the pointer indicates channel 13.
16. Tune sweep generator to channel 13 and change scope switch to IF output.
17. Inject 215.75 Mc. and 21.9 Mc. markers and adjust tuning control so markers coincide. Leave tuning control as set for remainder of channel 13 adjustments.
18. Change scope switch to RF output position, if RF response differs noticeably from the curves in Figure 14. The antenna trimmer(C5), the RF plate trimmer (C10) and mixer grid trimmer (C15) must be adjusted for proper passband and maximum amplitude of response.
19. Return tuner and sweep generator to channel 7 and check response as in part 13 above. A slight compensation of coils L1, L3, and L4 may be necessary.
20. Recheck passband on both channel 7 and channel 13, compromising adjustments for tilt as necessary until satisfactory High Band RF passband responses are obtained.

Low Band RF Alignment

21. Rotate band switch to Low Band position.
22. Turn the tuning control knob so that the pointer indicates channel 2 on the dial.
23. Set the scope switch to the IF output position and inject 59.75 Mc. and 21.9 Mc. markers. Adjust the tuning control so the markers coincide. Leave the tuning control as set for the remainder of the channel 2 adjustments.
24. Change the scope switch to the RF output position.
25. If the desired passband response is not obtained (as shown in Fig. 14) the Low Band RF coil L5, the low band mixer coil (L6), and the low band antenna transformer (T1) secondary must be adjusted until the desired passband is obtained.
26. When the low band RF coil (L5) and the low band mixer coil are aligned, slight variation in the inductance of either should

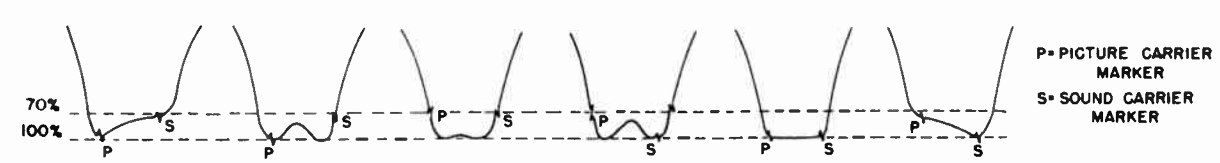


FIGURE 14 - ACCEPTABLE RF RESPONSE CURVES FOR TUNER

©John F. Rider
World Radio History

cause no noticeable narrowing of the pass-band.

27. When the secondary of the low band antenna transformer is properly adjusted, a slight variation in its inductance should cause both peaks to rock slightly. If only one peak moves, the T1 secondary is staggered away from the center of the double tuned circuit response.
28. The low band mutual coil (17) varies the band width of the interstage coupling circuit. Squeezing the turns together broadens the band width and separating the turns narrows the band width. The band width should be adjusted so that it is not greater than that required to keep both the picture carrier and sound carrier markers at the peaks of the response curve.
29. Replace the tuner bottom cover and check passband response.
30. Remove bottom cover and make any compensating adjustments as needed.
31. With the bottom cover in place, rotate the tuning control knob to align the pointer with channel 6 on the dial.
32. Tune the sweep generator to channel 6 and change the scope output switch to the IF output position.
33. Inject 83.25 Mc. and 26.4 Mc. markers and adjust the tuning control to make the markers coincide. Leave the tuning control at this setting for the remainder of the channel 6 adjustments.
34. Change the scope switch to the RF output position.
35. Check the response curve. If not as desired, remove the bottom cover and slightly readjust the inductance of the low band RF coil L5, the low band mixer coil (L6), the low band mutual coil (L7) and the secondary of the low band antenna transformer (T1) as necessary, keeping in mind that these adjustments must be compromised with those made for channel 2 in steps 21-30 above.
36. Recheck passband on channel 2 and channel 6 and re-adjust as necessary to obtain acceptable passband on both channel 2 and 6.

WAVEFORMS

Note 1: The terms "Horizontal," "Vertical" or "60 cps sine wave" refer to the oscilloscope sweep employed.

Note 2: All waveforms are taken with the oscilloscope horizontal sweep direction from left to right and with upward deflection corresponding to positive polarity.

Note 3: In some instances the waveforms obtained will not be identical with those shown, due to the electrical characteristics of the oscilloscope used.

Note 4: All waveforms are measured with respect to chassis unless otherwise indicated.

Note 5: Contrast maximum unless otherwise indicated.

*The peak to peak (P/P) voltages of these waveforms are dependent on the depth of modulation of the transmitted signal; voltages shown are obtained when modulation is approximately 90 percent.

AM-FM RADIO

APPROXIMATE FM IF ALIGNMENT

1. Connect vacuum tube DC voltmeter (with a high input resistance) across 33,000 ohm 6T8 cathode resistor (R70).
2. Connect generator ground lead to receiver chassis and generator positive lead to oscillator-mixer grid (pin 1) using a .1 Mfd. dummy antenna.
3. Set generator modulation to off position and generator frequency to 10.7 Mc.
4. Set Function Switch to FM position, volume and tone controls fully clockwise and Tuner fully closed. (With the tuner fully closed, the pointer should be at the last line below the 88 Mc. calibration mark on the dial).
5. Adjust the IF cores for maximum reading on the voltmeter in the following order: T27-Top, T27-Bottom, T25-Top, T25-Bottom As cores are adjusted decrease the output of the generator to maintain approximately 2.5 volts.

AM ALIGNMENT

1. Connect an output meter across loudspeaker voice coil terminals.
2. Connect signal generator "ground" lead to tuner chassis; the "high" lead through a .1 Mfd. capacitor to grid (pin 1) of Oscillator-Mixer 7F8, V26.
3. Set generator to 455 Kc. with 400 cycle modulation. Allow tuner and generator to warm up for several minutes.
4. Disconnect any external antenna and set receiver Function Switch to A M position. Turn volume and tone controls fully clockwise.
5. Rotate Tuner variable capacitor to maximum capacity position (plates fully in mesh).
6. With the least usable generator output, adjust I.F. transformer cores in this sequence to obtain maximum output meter indication: T29 - Bottom, T28 - Top, T28 - Bottom, T26 - Top, T26 - Bottom.
7. Connect generator output to a Hazeltine Loop to radiate a signal into the Tuner Loop antenna.
8. Set Tuner and generator to 1600 Kc.
9. Adjust oscillator trimmer, C79 (on rear section of variable capacitor front gang), for maximum output reading.
10. Set generator and Tuner to 1400 Kc.
11. Adjust antenna trimmer, C51 (on loop antenna), for maximum output.

FINAL FM ALIGNMENT

A. Repeat APPROXIMATE FM-IF ALIGNMENT to obtain exact maximum on DC voltmeter connected across 33,000 ohm 6T8 cathode resistor R70.

B. If a 10.7 Mc. frequency modulated generator is available, connect to oscillator-mixer grid (pin 1) through a 270 to 500 ohm resistor and proceed to Section D.

C. If a 10.7 Mc. frequency modulated generator is not available, connect an RF-FM generator to antenna terminals through two 120 ohm resistors, one in series with each terminal of the generator.

D. Connect the sweep output of the generator to the X-axis (horizontal) amplifier of the oscilloscope.

E. Connect the Y-axis (vertical) amplifier of the oscilloscope across 100,000 ohm resistor R72 through 10,000 to 100,000 ohms at receiver end of one lead.

F. Adjust the generator for 300 Kc. deviation. Use full gain of the oscilloscope Y-axis amplifier and only as much output from the generator as is necessary.

G. Adjust T29-Top for maximum output, vertically.

Adjust T30-Top and T30-Bottom until the center of the pattern becomes a straight line diagonally across the oscilloscope screen. Repeat these three cores to obtain a symmetrical pattern of maximum vertical amplitude. See oscilloscope pattern in Figure 15.

H. Connect an RF-FM generator to antenna terminals through two 120 resistors, one in series with each terminal of the generator. Adjust the generator for 22.5 Kc. deviation.

I. Remove the dial background. Set the pointer to 108 Mc. on the dial. Tune the generator to 108 Mc. Adjust C57 to maximum output meter reading. If two such points are found by tuning C57, use the higher frequency. (Lowest capacity setting of C57).

J. Tune the generator and receiver to 106 Mc. and peak C53 for maximum output meter reading.

K. Remove the signal generator, oscilloscope, and resistors, restoring receiver to normal operating condition.

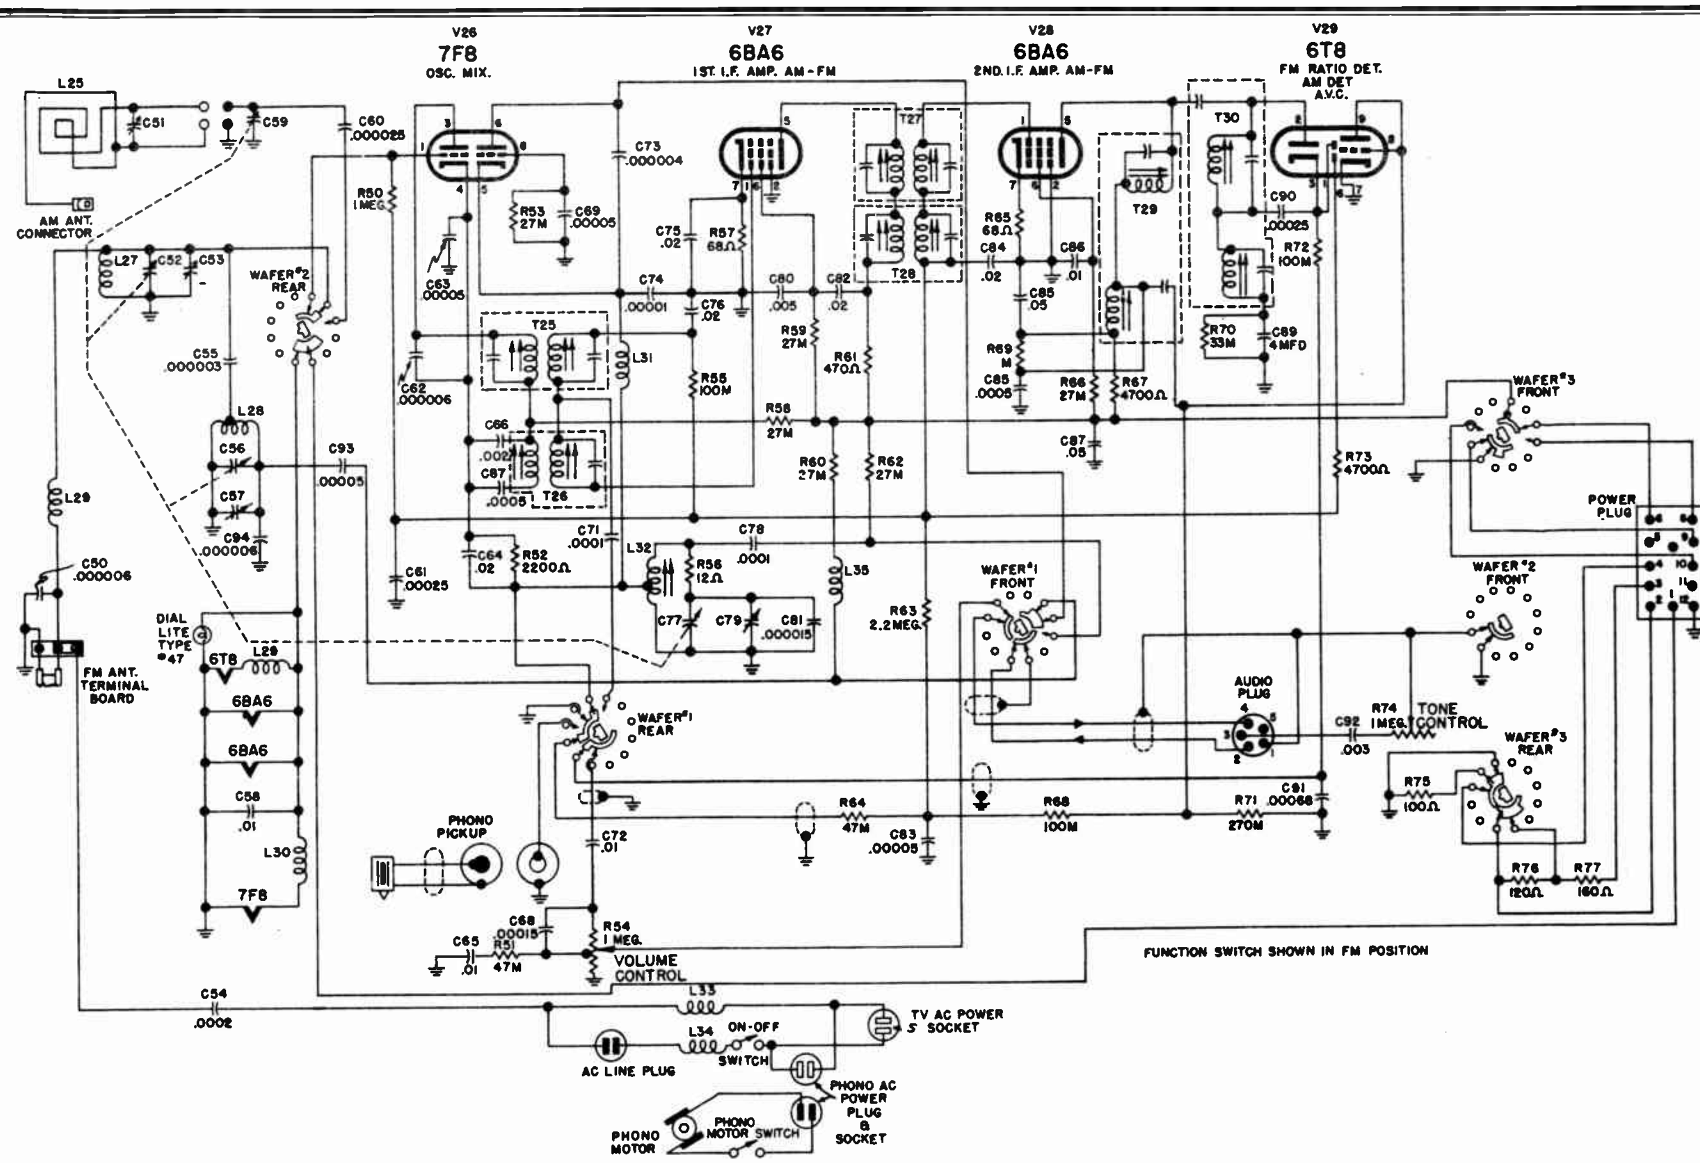

FIGURE 18 - AM-FM RADIO SCHEMATIC DIAGRAM

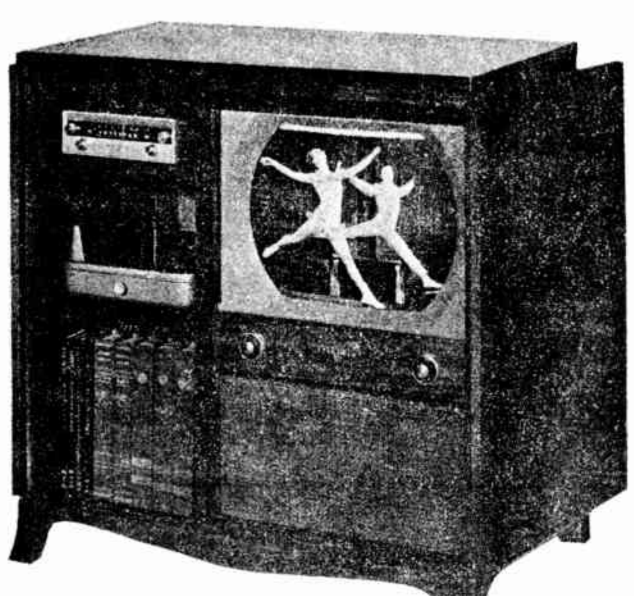

MODEL 5150M
(19" Picture - Mahogany)
available only in
Mahogany

ADDITION OF CHASSIS 1-274, MODEL 5150M

GENERAL DESCRIPTION

Chassis 1-274, Model 5150M, is a direct viewing television, radio, and record changer combination providing reception of all 12 commercial television channels, standard broadcast band, and frequency modulation band. The television picture is reproduced on a 19 inch electromagnetically deflected tetrode type black face picture tube.

SPECIFICATIONS

Cabinet Dimensions (inches)	Width	Height	Depth
	40.4	40	24.6
Weight (pounds)	Net		Gross
	185		215

The 1-274 chassis, Model 5150M, very closely resembles the 1-357 chassis, Models 7150M and 7160B, whose technical service data appears in Bulletin 9-13. Circuitwise, these chassis are similar except for the mechanical and electrical changes necessary to accommodate the 19 inch picture tube. Servicing data for the 1-274 is the same as for the 1-357 other than the following:

Picture Tube Replacement

To remove the picture tube from the chassis, remove the picture tube socket, high voltage anode connector, and ion trap magnet. Loosen the #10-32 bolt on the holddown strap at the upper right of the tube. Remove holddown strap. Pull the tube braces away from the sides of the tube. Lift the tube clear of the front edge of the chassis and move it forward gently until the tube base is clear of the focus magnet and yoke. The plastic rim around the face of the tube may then be removed.

To replace the picture tube reverse the removal procedure being careful not to force the tube if the neck binds. There is no specific angle of rotation for the picture tube. The yellow lead of the picture tube socket cable must be dressed away from the remainder of the picture tube leads and high voltage box. The high voltage anode connector should be positioned in the lower left hand corner and the gap in the plastic rim should be positioned in the lower right hand corner. Be sure the plastic rim is in place before replacing the tube and that the tube is properly placed before tightening the holddown strap. Note: There is no specific angle of rotation for the initial setting of the ion trap.

R186, R192	181-0125	Resistor - 1.2 Megohm - 1/2 W.
R149	181-01255	Resistor - 1.2 Megohm - 1/2 W.

CHASSIS 1-274 C01, C02

Under code C01 the values of the following resistors have been changed:
R148 from 39,000 Ohm to 180,000 Ohm
R149 from 270,000 Ohm to 1.2 Megohm
R186 from 2.2 Megohm to 1.2 Megohm

Under code C02 the values of the following resistors have been changed:
R183 from 2.2 Megohm to 1.0 Megohm
R192 from 1.5 Megohm to 1.2 Megohm

The Repair Parts List information covering these revised values is as follows:

World Radio History

The alignment of Models 1930, 1930D and 1531-1631 are similar to the RCA 630 type of chassis, except for the following modifications:

1-Remove V132 (6AU6 AGC control tube) and also V115 (6AU6 first Video amplifier).

2-Apply -3 volts bias to the AGC line, (i.e., junction of R125, C122, and C230).

3-Proceed as per instructions for RCA 630 or 8TS30.

ALL RESISTANCE VALUES IN OHMS K=1000
CAPACITANCE VALUES IN MMFD UNLESS OTHERWISE NOTED
DIRECTION OF ARROWS AT CONTROLS INDICATE CLOCKWISE ROTATION
ALL VOLTAGES MEASURED WITH VOLT-OHMYST AND WITH PICTURE AT MIN VOLTAGES SHOULD HOLD WITHIN ± 20% WITH 117V A-C SUPPLY

MODEL 1930 D with keyed AGC

NOTE:- For alignment data, See RCA Model 630TS, Pgs. *1-76 to *1-116.

KINESCOPE INSTALLATION

1. Remove the knobs.
2. Remove the four chassis retaining screws from the bottom of the cabinet.
3. Remove the chassis from the cabinet.
4. Loosen the strap holding bracket screws, the yoke mounting hood screws, and the focus coil wing nut.
5. Insert the kinescope with the high voltage connect cap toward the power transformer.
6. Insert the high voltage connector.
7. Place the kinescope strapping over the tube and tighten.
8. Tighten the yoke mounting hood screws such that the rubber bumpers are tight against the kinescope.
9. Put on the ion trap, attach the kinescope socket, and proceed with the adjustments as given below.

ION TRAP ADJUSTMENTS

The ion trap magnet should be approximately over the ion trap flags. Rotate the ion trap slightly and move it back and forth until a full raster is obtained. Adjust the ion trap in this manner for greatest brilliance.

FOCUS COIL ADJUSTMENT

Rotate the focus coil on its vertical and horizontal axis until a full raster is visible.

CENTERING

Centering is accomplished both vertically and horizontally by careful manipulation of the focus coil. This may be better accomplished by noting that the raster moves at right angles to the direction that the focus coil points. The deflection yoke should be as far forward as possible.

DEFLECTION YOKE ADJUSTMENT

Adjust the picture to the proper horizontal plane by loosening the deflection yoke wing nut and rotating the yoke.

SWEEP ALIGNMENT

VERTICAL: Set the height and linearity controls to approximately full clockwise position, and slowly rotate the vertical hold control until the picture looks vertically. After the picture is locked, adjust the height control for the proper vertical scan, and the linearity control for proper picture symmetry. Adjustment of any of these three controls may require readjustment of one or both of the other controls.

HORIZONTAL OSCILLATOR ALIGNMENT CHECK: Allow five minutes for the receiver to warm up. Turn the horizontal hold control fully clockwise; then fully counter-clockwise. The picture should remain locked except at the fully clockwise position. With the horizontal hold control fully counterclockwise, momentarily remove the signal by switching to another channel and back again. The picture should then be out of lock. As the hold control is turned slowly clockwise, the number of diagonal bars on the picture tube screen will reduce to four or five. At this point more rotation should pull the picture into lock.

HORIZONTAL OSCILLATOR ALIGNMENT: If the above conditions do not occur, set the horizontal hold control fully clockwise, set the horizontal locking range trimmer to approximately three turns of maximum tightness. Tune to the station. Turn the horizontal control until the picture pulls into lock. It may be necessary to alternately readjust the horizontal locking range trimmer so that the picture reduces to four or five bars before pulling into lock. Repeat the horizontal alignment check.

HORIZONTAL LINEARITY: Adjust the horizontal drive control so that there is no excessive scan. Adjust the horizontal linearity control for the best horizontal linearity.

World Radio History

TROUBLESHOOTING

1. No raster.
   (a) Improperly adjusted brightness control.
   (b) Check for proper setting of the ion trap.
   (c) No high voltage. Check 6BG6 (V15), 1B3 (V17), 5U4 (V16) tubes, and the high voltage circuit components. Check the ¼ A fuse, and the 400 MMF coupling condenser at the grid of the 6BG6.
   (d) No "B" supply.
   (e) Defective horizontal oscillator and AFC tube 6SN7 (V14) or circuit components.
   (f) Defective kinescope or kinescope circuit.

2. No video.
   (a) Check IF and RF circuits and tubes. Check video coupling circuit to kinescope.

3. No sound.
   (a) Check IF and RF circuits and tubes. Check 6AU6 (V10), 6T8 (V11), 6AQ5 (V12), and the speaker and connections.

4. Raster too small horizontally.
   (a) Improper horizontal drive adjustment.
   (b) Line voltage too low.
   (c) Replace 6BG6 (V15).
   (d) Replace 6SN7 (V14).
   (e) Low "B" supply. Check 5U4 (V18), and for shorts.
   (f) Check .2 mfd isolating condenser of the horizontal deflection coils for open.
   (g) Check the flyback transformer and the yoke.

5. Vertical jittering.
   (a) Reset vertical hold for the least jitter.
   (b) Replace 6SN7 or 6J5 (V13), vertical blocking oscillator.
   (c) Replace 12AU7 (V9) sync clipper.
   (d) Check sync clipper for proper clipping.

6. Lack of height.
   (a) Replace 6SN7 or 6J5 (V13) vertical blocking oscillator.
   (b) Replace 6V6 (V3) Vertical output tube.
   (c) Check "B" supply.
   (d) Check blocking oscillator transformer for short or open.
   (e) Check integrating circuit for short.
   (f) Check cathode capacitor (100mfd) for open.
   (g) Check vertical deflection coil.

7. Elimination of Audio Buzz
   (a) Set the fine tuning control properly.
   (b) Set the contrast control for a normal contrast.
   (c) Readjust the tuning slug on top of the ratio detector transformer (T8) for minimum buzz and maximum audio signal.
   (d) Replace 6T8 (V11) and retune T8.
   (e) Readjust the RF oscillator tuning slug for any particular station concerned.

8. Station not tuning properly.
   (a) Remove the channel marker plate.
   (b) Retune the RF Oscillator tuning slug for the channel concerned.

IF AND RF ALIGNMENT PROCEDURE

TEST EQUIPMENT

The following test equipment is necessary for proper alignment of the TELEQUIP receiver:

RF SWEEP GENERATOR:

18 - 30 MC range	10 MC sweep width
50 - 90 MC range	10 MC sweep width
170 - 225 MC range	10 MC sweep width

OUTPUT IMPEDANCE: 300 Ohms balanced to ground for RF ranges.

OUTPUT VOLTAGE: Adjustable

MARKER GENERATOR:

18 - 30 MC frequency range
50 - 90 MC frequency range
170 - 225 MC frequency range

SIGNAL GENERATOR:

Accurate signal generator, range 30-225 MC with calibrated output attenuator and low impedance output.

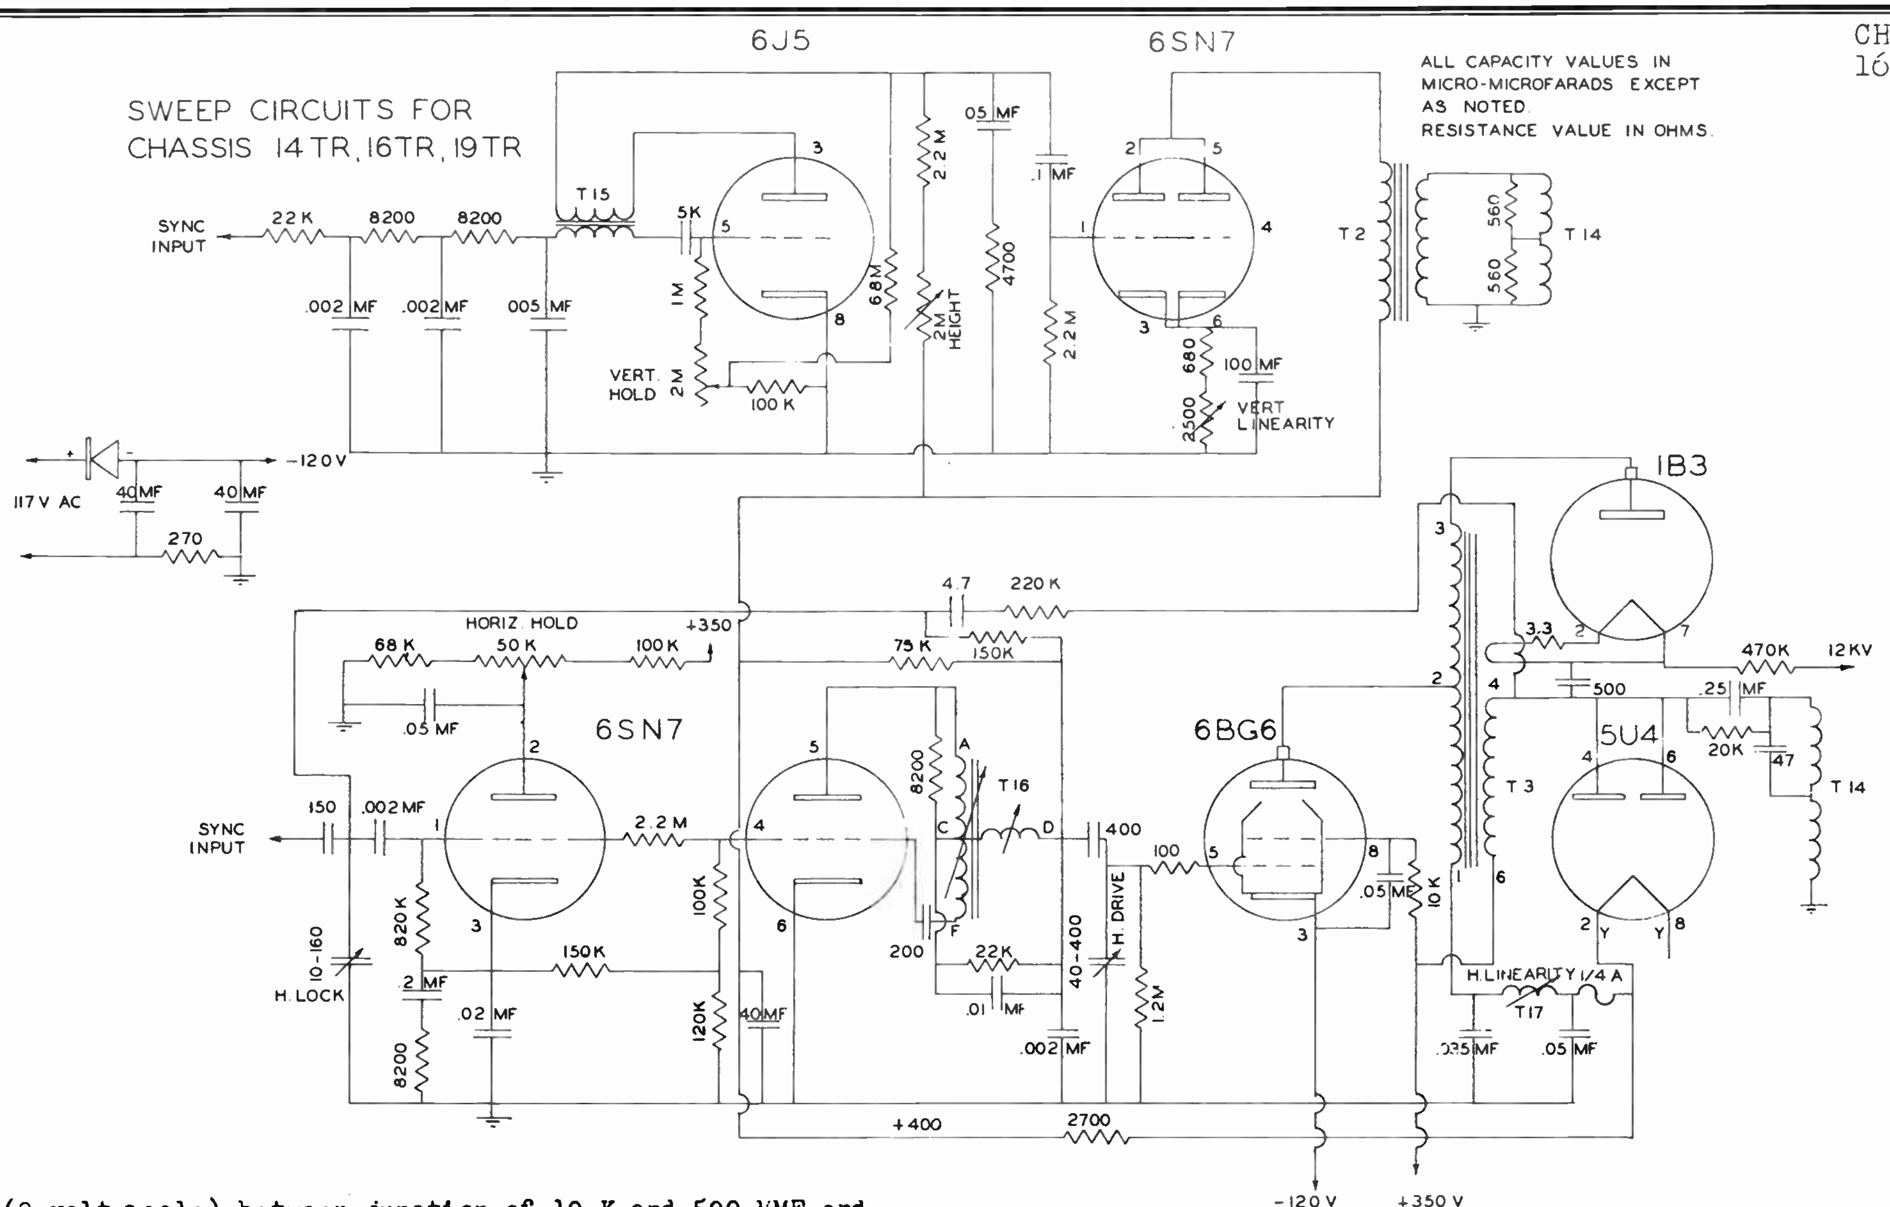
OSCILLOSCOPE: Standard oscilloscope with wide band vertical deflection.

VOLTMETER: Vacuum tube voltmeter or 20,000 ohms per voltmeter preferably with a zero center low voltage scale.

IF AMPLIFIER ALIGNMENT:

1. Remove one section of oscillator mixer coil (6 terminal) from turret to this position.
2. Connect 10 K resistor and 500 MMF mica capacitor between pin 7 of 6AL5 and ground.

©John F. Rider



3. Connect voltmeter (3 volt scale) between junction of 10 K and 500 MMF and chassis ground.
4. With TV 138 tuner, connect signal generator hot side to point #9, loop on top of the tuner chassis, ground side to chassis ground. With TV 100 tuner disconnect 100 MMF coupling condenser for grid of 6AU6-V2 mixer tube from switch and connect hot side of signal generator to 100 MMF.
5. Set signal generator frequency for 25.3 MC unmodulated, adjust second and fourth IF coil for maximum deflection on the voltmeter.
6. Set signal generator frequency for 23.1 MC unmodulated, adjust L9 and 3rd IF for maximum deflection on the voltmeter.
7. Disconnect signal generator and connect sweep generator between point D and ground. Set sweep to IF band 20-30 MC.
8. Disconnect voltmeter and connect input of scope between junction of 10 K and 500 MMF and ground.
9. Loosely couple the marker generator to the high side of the sweep generator.
10. To avoid distortion it is important to keep the sweep generator and marker generator outputs as low as possible.
11. Check the response curve obtained against the ideal overall IF response curve and retouch the IF coils as required.
12. It is important that the marker pips be in the proper location as shown on the ideal response curve.

4.5 MC AUDIO IF ALIGNMENT

1. The accuracy of the signal generator used in this alignment should be within 1 kilocycle. If this quality signal generator is not available, it is recommended that touch-up of the zero setting adjustment be made, using a television station signal rather than the 4.5 MC signal from the signal generator.
2. Set the frequency of the signal generator at 4.5 MC unmodulated.
3. Connect hot side signal generator through a .01 condenser to the grid of 6AU6 video amplifier, ground side to chassis ground.
4. Connect 2-12K resistors across ratio detector as shown on schematic.
5. Connect voltmeter across (A) and tune T13 and bottom slug of T8 for maximum reading.

©John F. Rider

World Radio History

6. Connect voltmeter using 3V zero center scale across (B) and tune top slug of T8 for a zero point. A correct zero center point is between a positive and negative maximum point.

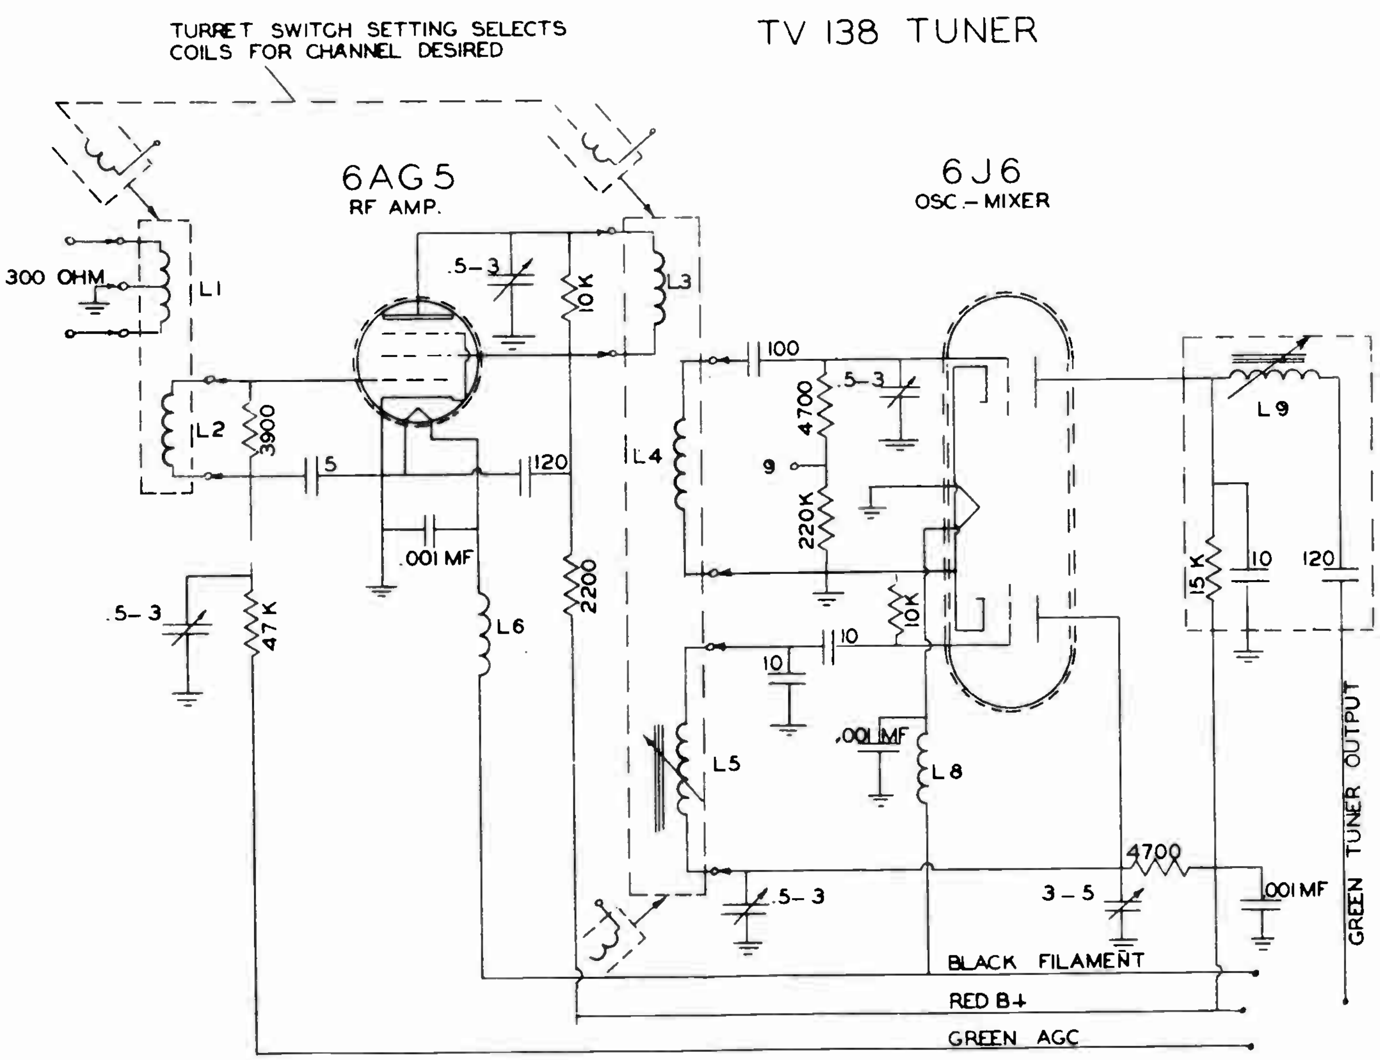
7. Retouch, if necessary, as outlined in 1 above.

TV 138 RF TUNER ALIGNMENT REQUIREMENTS

With normal use or operating conditions, tuner alignment is seldom necessary. The RF mixer coils have been designed for stable band pass operation, and under normal operating conditions will seldom need realignment. The high frequency oscillator coils may require some slight readjustment, if the oscillator mixer tube has been replaced.

RF and mixer coils are self tuned by distributed and tube capacities. Since the tuner features replaceable channel snap-in coil, individual RF and mixer coil adjustments are not provided. Overall adjustment covering all channels can be made with capacitors C2, C3, and C7. These adjustments should be made on a higher channel, preferably channel 12.

TV 138 TUNER



TV 138 RF AMPLIFIER ALIGNMENT

RF MIXER ALIGNMENT:

1. Connect sweep generator to antenna terminals.

2. Loosely couple marker generator to antenna terminals. Marker generator output should be kept at a minimum, such that the marker pips are just barely visible.

3. Connect oscilloscope through a 10,000 ohm resistor to point 9, the loop on top of the tuner chassis.

Step	Marker Gen. Freq. MC	Sweep Generator Frequency	Adjustment
1	205.25 209.75	Sweeping Channel 12	Check for curve resembling RF response curve. If necessary, adjust C2, C3, and C7 as required.
2	211.25 215.75	13	Check channel for curve resembling RF response curve shown below. In general, the adjustment performed in step 1 is sufficient to give satisfactory response curves on all channels. However, if reasonable alignment is not obtained on a particular channel, (a) check to see that coils have not been intermixed, or (b) try replacing a pair of coils for that particular channel, or (c) repeat step 1 for this particular weak channel as a compromise adjustment to favor this channel. If a compromise adjustment is made, other channels should be checked to see that they have not been appreciably affected.

TV 138 H. F. OSCILLATOR ALIGNMENT

1. Connect sweep generator to antenna terminals.
2. Loosely couple marker generator to antenna terminal.
3. Connect oscilloscope between function of 10 K and 500 MMF network and ground.
4. Set vernier control to the center of its range.
5. Use a non-metallic screwdriver for all H.F. oscillator adjustments.

HIGH FREQUENCY ALIGNMENT

Step	Marker Generator Frequency (MC)	Sweep Generator Frequency	Adjustment
1			Before aligning the HF oscillator, check the IF response curve. Retouch if necessary.
2	211.25 215.75	Sweeping Channel 13	Check to see if the video carrier marker appears at the 50% point on the response curve when the sharp tuning control is tuned to the center of its range. If adjustment is needed, check to see if the misalignment is apparent on channel 13 only, or also exists on all channels. If overall adjustment is needed, adjust C10; otherwise A12.
3	205.25 209.75	12	Check all channels individually for proper marker location; if overall adjustment has been made, it may not be necessary to make any further adjustments. If necessary, however, make individual HF oscillator adjustments (A 12 to A23) for individual channels.
4	199.25 203.75	11	
5	193.25 197.75	10

World Radio History

INSTALLATION

WARNING

This receiver is designed for use on 105 to 125 Volt 60 cycle AC only. Do not connect to Direct Current (DC) power supply. If in doubt, check your local power supply company.

GENERAL — For best results this Tele-tone receiver should be installed by a competent television serviceman who is properly equipped to make necessary adjustments to the receiver and determine the most suitable type of antenna installation.

OUTDOOR ANTENNA —For best results with your Tele-tone Television Receiver an outdoor antenna is recommended. In areas where both Low (Channels 2 to 6) and High (channels 7 to 13) are received a separate antenna should be used for each band.

In areas where both high band and low band reception is available, these antennas may be used in the form of a stacked array.

Where a stacked array is used, it may prove advantageous in some locations to connect separate down leads from each antenna and connect a suitable switch at the receiver as shown in figure 1.

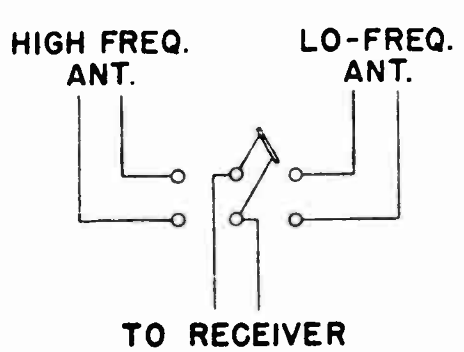

FIG. 1

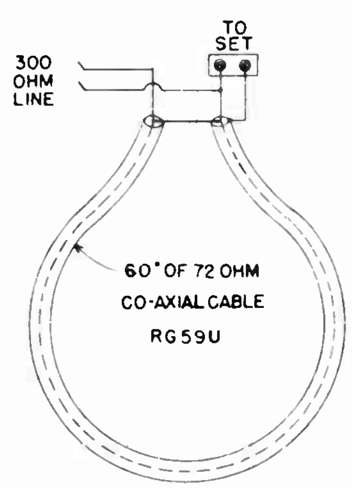
INDOOR ANTENNA — Indoor antennas, although acceptable in many cases, are subject to many disturbing factors. For example; viewers approaching the antenna, electrical appliances within the home, defective lighting fixtures, etc., all of which will affect the receiver where an indoor antenna is used and would probably be eliminated with an outdoor installation. However, in cases where an indoor antenna is acceptable, or becomes a necessity because of local restrictions, etc., we recommend the adjustable type indoor antenna.

TRANSMISSION LINE — In non-critical locations, satisfactory results may be obtained with a 300 ohm down lead connected directly to the receiver antenna terminals. In more critical locations (insufficient signal) increased pick-up may be obtained by using the 300 ohm down lead in conjunction with a suitable matching transformer at the receiver. (See figure 2). In unusually noisy locations considerably improved performance may be obtained by the use of 72 ohm co-axial transmission line.



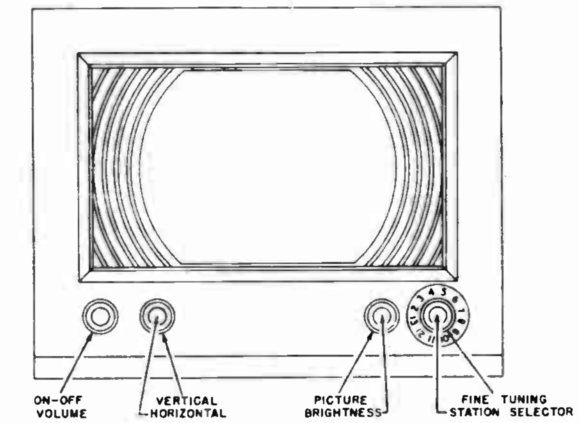
ANTENNA MATCHING TRANSFORMER

FIG. 2

NOTE: — When using 72 ohm co-axial down lead, it is important that its outer lead be connected to the shield side of the receiver transmission line. Check antenna terminal connections to determine shield side.

CONTROL FUNCTIONS

RECEIVER FRONT PANEL CONTROLS



CONTROLS IDENTICAL ON MODELS TV-284, 286, 287, 288

FIG. 3

VOLUME — ON — OFF — The volume control is an audio control only and has no effect on the picture. It is connected in the grid circuit of the audio amplifier (V-11). The power on and off switch is combined with the volume control.

HORIZONTAL HOLD — The Horizontal Sweep Oscillator uses Automatic Frequency control. As a result the Horizontal Hold Control will only be used if the picture should resolve into a series of heavy, oblique, black and white lines. A slight readjustment of the knob will then cause the picture to correct itself.

VERTICAL HOLD — The vertical hold control should be adjusted in the event of picture roll. Slight readjustment will cause the picture to lock vertically. It is found in the grid circuit of the vertical oscillator (V-15).

PICTURE — This control is primarily a picture control. It operates in the cathode circuit of the video amplifier. It controls the picture strength by varying the gain of this stage.

BRIGHTNESS — This control operates by varying the DC potential on the cathode of the Kinescope.

STATION SELECTOR — The (inner) bar knob of this control will operate the station selector. The (outer) circular knob will activate the Fine Tuning control which is a vernier adjustment of the RF oscillator.

RECEIVER REAR CHASSIS CONTROLS

WIDTH — The Horizontal Sweep is determined by the current flowing through the Horizontal Yoke Coil. The current through this coil (L23) is controlled by Width Control (L21) which is a variable reactor having the effect of changing the turns ratio of this winding of the Horizontal Output and H.V. Transformer (T6). This is a screwdriver adjustment.

RECEIVER REAR CHASSIS CONTROLS

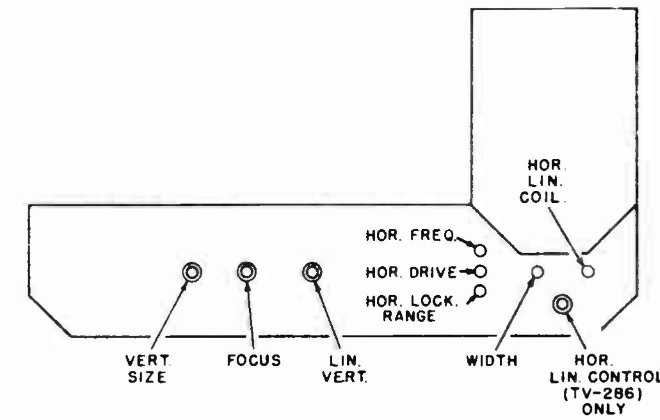


FIG. 4

HORIZONTAL LINEARITY —Horizontal linearity in all models is controlled by a coil (Horizontal Linearity Coil), and in Model 286 by a potentiometer in addition (Horizontal Linearity Control). Both controls are located at the lower right rear of the chassis (see Fig. 4) and operate in the Horizontal Output Stage of the receiver. For complete adjustment data see page 8.

HEIGHT — This control is a voltage dropping rheostat operating in the plate circuit of the Vertical Sweep Oscillator first half (V-15). It changes the voltage delivered to the Vertical Amplifier (V-16) feeding current to transformer coupled Vertical Yoke Coil (L-19). Since changes in height will affect picture linearity, this Height Control must be adjusted in conjunction with Vertical Linearity Control.

VERTICAL LINEARITY CONTROL — This is a variable resistor control (R70) in the cathode of the Vertical Output Tube (V-16) which changes the plate current curve of the tube thus affecting the linearity of the Vertical Sweep Wave form. To be adjusted as height control is adjusted.

FOCUS CONTROL — This is a Variable Resistor (R64) which varies the current through focus coil (L18).

HORIZONTAL AND VERTICAL CENTERING —Centering of the picture area is accomplished in this receiver by finding that position for the focus coil in the horizontal and vertical planes that produces this result. The focus coil bracket is arranged so that if the four hexagon-head screws are loosened it can be shifted up and down and from side to side enabling the centering position to be found by trial. The four hexagon-head adjusting screws shown in figure (10) should be tightened to hold the coil firmly.

©John F. Rider

World Radio History

BRIEF CIRCUIT ANALYSIS

The Tele-tone Television Receiver Models TV-284, 286, 287, 288 uses the Inter-Carrier sound system. In this system the RF section of the receiver receives both the picture and sound carriers which are converted by mixer (V-2) into the IF. This IF is fed through a single IF channel. The sound signals are separated at the video amplifier (V-8) and fed through a 4.5 Megacycle Trap into a Ratio Detector Driver (V-9) and to the Ratio Detector (V-10).

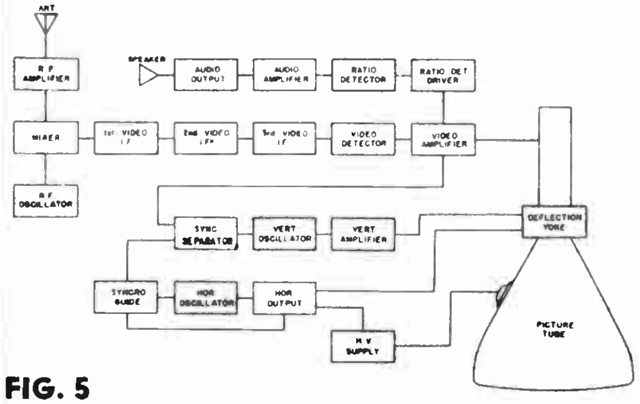

FIG. 5

TUNER — The tuner in this model covers 12 channels (2 to 13 inclusive). The local oscillator is tuned to the high side on all channels and is adjusted to provide a picture I.F. of 37.3 Mc and a sound I.F. of 32.8 Mc.

The tuning inductance for channel 2 is across the oscillator at all times. The tuning inductances for channels 3 to 13 respectively is shunted across the channel 2 inductance as these channels are selected.

In aligning the receiver channel 2 must first be adjusted and channel 3 to 13 then adjusted. Misalignment of channel 2 will detune the other channels. Appreciable readjustment of channel 2 may require retuning of several low frequency channels. This effect is of less importance on channels 7 to 13. Alignment should be attempted only after the receiver has been operating for 5 minutes.

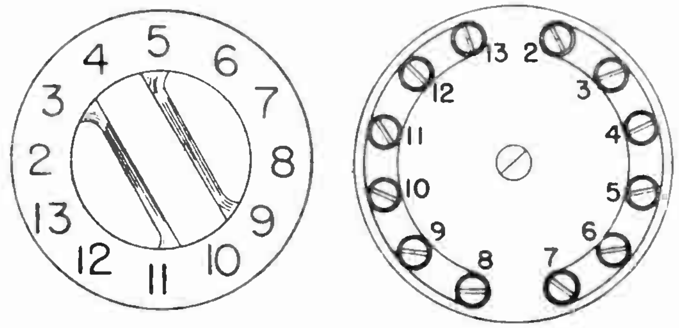
R.F. AMPLIFIER — The antenna is fed between cathode and grid of the grounded grid RF amplifier (V-1), the input circuits of which are untuned. Double tuned interstage coupling is used between the plate of the RF Amplifier (V-1) and the grid of the mixer (V-2). Mechanically, the series inductances used take the form of several individual coils which are cut in or out of their respective circuits by means of the band switch. These coils will rarely need readjustment.

MIXER — The output of the RF Amplifier (V-1) and the Local Oscillator are condenser fed into the Control Grid Mixer Stage (V-2). This circuit is tuned in much the same manner as the output of the RF Amplifier, previously decribed.

OSCILLATOR — The RF Oscillator (V-3) is fairly straight-forward in operation. Its main peculiarity previously mentioned is that the coil for Channel 2 is permanently parallel to all other Oscillator coils from 3 to 13. It is therefore necessary, when aligning the oscillators to ALIGN CHANNEL 2 FIRST and the rest of the coils in any order thereafter. They are tuned by brass slugs accessible through two slots in the front of the receiver chassis. Channel 2 is found at the top of the right hand slot and the others follow in regular order in a clockwise direction finishing with Channel 13 at the top of the left hand slot.

NOTE: The channel numbers on the escutcheon do not correspond to the location of the oscillator coils.

FIG. 6



VIDEO IF — Each Video IF transformer has only one adjustment, a powdered iron slug accessible from the top of the chassis. The Video IF String is stagger tuned to two frequencies. The first and third IF transformers are tuned to 34.45 Megacycles and the second and fourth are tuned to 36.8 Megacycles. The response curve is fairly flat topped and should produce a picture with good definition.

VIDEO AMPLIFIER — A 6AC7 pentode is used in this section of the receiver. The output of the detector is directly coupled into the grid (pin 4) and taken off the plate (pin 8). It is at this point that the three basic components of the received signal are separated and fed to their respective circuits. The sound is picked off by the Sound-Take-off Trap and sent through the Ratio Detector Driver (V-9), the Ratio Detector (V-10) and Audio Amplifiers (V-11 and 12) to the speaker. The picture intelligence is fed to the grid of the Picture Tube, and the sync pulses are fed into the sync seperator and from there to the Vertical oscillator and the horizontal sync. guide.

SOUND SYSTEM — The sound Carrier is taken off the plate of the Video Amplifier (V-9) by a 4.5 Megacycle trap and fed through a Ratio Detector Driver (V-9) to the Ratio Detector (V-10), and then to the audio amplifier (V-11), audio output (V-12) and speaker.

D. C. COMPONENT — D. C. restoration is accomplished through the use of one half of a 6AL5 (V-13A). The Voltage developed at the cathode of this tube is fed to the grid of the Cathode Ray Tube to maintain a constant blanking level and to restore the original background illumination.

SWEEP SYSTEM — VERTICAL — The Vertical Sync pulses are fed by an integrating network into the Vertical Oscillator (V-15) thereby controlling the oscillator frequency. The output of the oscillator is then amplified by the output stage (V-16). The plate of the Vertical Output stage is transformer coupled to the Vertical windings of the Deflection Yoke.

SWEEP SYSTEM — HORIZONTAL — The Horizontal Oscillator is essentially of the Blocking Oscillator type. The operation of the AFC system depends upon a correcting voltage developed in the control tube when the oscillator output and the incoming pulses differ in either phase or frequency. The control tube, first section (V-17), is maintained at cut-off until such time as the sync pulse is either ahead or behind the oscillator, (second section V-17), sawtooth peak. When either case occurs the control tube develops a voltage which is applied as a bias to the oscillator grid and alters the oscillator frequency to coincide with the frequency of the incoming pulses. The horizontal oscillator transformer has an adjustable core which is a coarse control of the oscillator frequency. The Horizontal Frequency Control (rear) is a fine adjustment in the same sense. The front panel Horizontal Hold Control permits slight adjustment of the frequency by adjusting the B voltage applied to the control tube plate. The Horizontal Locking range control affects the sensitivity of the control tube thus varying the range over which the AFC circuit will function.

NOTE: Many of the components in the Horizontal circuits are of critical value and therefor should only be replaced by the exact replacement part. Care should also be taken in dressing leads and parts when replaced. This can be accomplished by carefully noting parts positions before removal. For complete alignment procedure on these circuits see page 8.

A.G.C. — The receiver uses an AGC circuit operating on the first 2 IF stages (V-4) (V-5). While it is quite effective in most locations, the receiver may overload in regions of very high field intensity. The contrast can generally be adjusted for a normal picture under such conditions but spurious beats, jagged vertical lines (i.e. poor resolution) and a "Moire" pattern may appear. These effects can be eliminated by the use of a resistor network of 3 to 10 db attenuation in series with the antenna lead at the point where it is connected to the receiver.

HIGH VOLTAGE POWER SUPPLY—The energy stored in the horizontal windings of the deflection yoke during the forward sweep produces high voltage surges during retrace. This is stepped up by the "auto-transformer" winding of the Horizontal Output Transformer and then rectified by the 1B3 (V-20) (and doubled in the TV286 by the second 1B3 (V-21) to provide approximately 12,500 volts for the anode of the Cathode Ray Tube.)

B VOLTAGE POWER SUPPLY —The B Supply utilizes a conventional Transformer-rectifier circuit. The only feature of this section which might be considered slightly unusual is that the Focus Coil is used as a part of the Filter system. The focus Control shunts the coil and thereby varies the current flowing through the coil itself. The use of a bleeder is eliminated by placing the audio output, audio amplifier and ratio detector driver tubes in series with the tubes in the IF and tuner stages as far as B plus supply is concerned.

ALIGNMENT PROCEDURE

The alignment of this Receiver can be broken down into three basic parts.

1 — Video IF Alignment 2 — RF Alignment
3 — Sound Alignment

CATHODE RAY OSCILLOSCOPE — The tube size is relatively unimportant, however, anything under 5" usually makes fine adjustment quite difficult.

SWEEP GENERATOR —The sweep generator used should have linear coverage of a center range from 30 to 220 megacycles. The output should be fairly flat over wide frequency variation of the sweep. It should be capable of an output of about 0.1 volt with attenuation. It is preferable that the generator have a deflection output for the test oscilloscope.

AM SIGNAL GENERATOR — This generator should have a frequency range of from 4.5 to 220 megacycles. As this generator is used occasionally as a marker generator, accuracy is an important factor. It should be capable of 0.1 volt output with attenuation and should be linear through the range.

VACUUM TUBE VOLTMETER — Almost any standard make VTVM will do. It should preferably have a reversible polarity switch.

VIDEO IF ALIGNMENT

An adequate signal can be fed through the video IF string by feeding the output of the sweep generator into a tube shield placed over the mixer tube (6AG5) (V-2). Care should be taken that this shield is NOT grounded. The ground side of the generator output can be conveniently grounded to the shield of the adjacent oscillator tube.

A vacuum tube voltmeter should be connected just after the first series peaking coil (L-6) with the Gnd. lead to the junction of R45 and R46 it should be set to the plus 3 Volt scale. Set channel selector to an unused low band channel.

The Signal generator should be set to a frequency of 34.45 Mc. The output of the generator should be adjusted to the point where the reading on theVTVM is between plus 1 to plus 1.5 volts.

The first and third IF coils should be peaked for a maximum reading on the VTVM. As the voltage reading increases with tuning, the generator should be attenuated to maintain a maximum of plus 1.5 volts.

Set the Signal Generator to a Frequency of 36.8 Mc. and tune the second and fourth IF coils in the same manner as above.

Set the Signal Generator to a frequency of 32.8 and tune the trap for a MINIMUM reading on the VTVM.

The third IF coil should then be readjusted as described previously.

The Generator should now be shut off (or tuned to different band) and the VTVM should read no more than 0.50 volts. If there is a higher voltage reading, check for regeneration in the IF stages.

By shunting the signal generator with a sweep generator (30 to 40 Mc.) and substituting a Cathode Ray Oscilloscope for the Vacuum tube Voltmeter in the above procedure the actual pass band of the Video IF circuits may be studied. Ideally the response curve should appear on the face of the oscilloscope in the form indicated in Figure (7). A slight slope of the top of the curve in either direction or a small dip in the center are acceptable as indicated in Figure (8).

World Radio History

MODELS TV-284, TV-287, TV-288, Ch. TT; TV-286, Ch. TH, TJ, Rev.

In the alignment of the RF section of this receiver three pieces of test equipment are necessary. A sweep generator, a signal generator and a cathode Ray Oscilloscope. For specifications see "Test Equipment" above.

The output of the Sweep Generator should be fed into the antenna. The signal generator (C.W.) should be connected to the antenna terminals of the receiver. The sweeper will provide the overall response curve with the oscilloscope properly connected. The signal generator is used as a marker as described below. Some Sweep generators made today contain their own marker oscillator. In cases where a generator of this type is used the Signal Generator may be eliminated.

The "hot" or "high" side of the Oscilloscope input should be connected to the junction point of the 8200 ohm detector load resistor and the peaking coil. The "low" or ground side should be connected to the nearest convenient ground point on the receiver chassis. Care should be taken that the generator and the scope leads are well separated to avoid regeneration.

The R.F. section of the receiver is tuned channel by channel. The proper frequency settings for any given channel can be determined by consulting the Frequency Chart on Page (2). For example in aligning channel 2 the sweep generator should be set to some mid frequency between 54 and 60 megacycles. This adjustment is not a fine one. After setting the sweeper in the general vicinity of the desired frequency it should be tuned to center the response curve on the Oscilloscope face. For picture and sound markers the signal generator should carefully be adjusted to the frequencies indicated in the Frequency chart. For example in the case of channel 2 the picture marker frequency is 55.25 Mc. and the Sound 59.75 Mc.

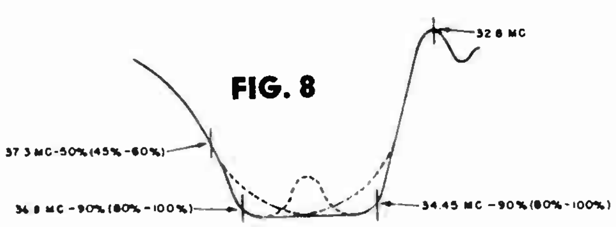
It is important to note at this point that the oscillator coil for channel 2 is in parallel with every other oscillator coil from 3 to 13. It is therefor imperative that channel 2 be aligned first and the others in any desired order thereafter.

Starting with channel 2 and applying the proper frequencies as indicated above, the output of the sweeper should be attenuated to the point where further attenuation will not affect the wave shape.

The Oscillator should then be adjusted to bring the sound carrier into the 32.8 Mc. trap valley. With the oscillator so adjusted the picture carrier should fall at a point approximately 50% up on the slope of the opposite side of the band pass curve. Certain variations in the waveshape and the location of the picture carrier are acceptable. The picture carrier may vary in position from a point between 45% and 60% of the slope and the overall waveshape may differ from the ideal, flat-topped response by being either slightly rounded or slightly dipped in the center. See Figure (8).

If the position of the picture carrier varies beyond the 45% to 60% points on all channels correction may be made by turning to channel 6, applying the proper input signals and slightly realigning the I.F. transformers.

FIG. 8



IDEAL VIDEO IF RESPONSE CURVE
DOTTED LINES INDICATE ACCEPTABLE VARIATIONS

SOUND ALIGNMENT

Sound alignment of the receiver is best accomplished with the AM Signal Generator and Vacuum Tube Voltmeter. By feeding a 4.5 Megacycle signal through a .01 mfd blocking condenser into the grid of the video amplifier and placing the vacuum tube voltmeter probe on pin (7) of the ratio detector and the ground lead at the junction point of the two 15,000 ohm resistors in the ratio detector circuit, the primary of the ratio detector and the 4.5 megacycle trap may be adjusted. The signal generator should be attenuated so that the VTVM does not read more than minus 3 or minus 4 volts. The two slugs should be tuned for maximum deflection of the VTVM and the generator attenuated as needed to keep the above mentioned level. The VTVM probe (set for zero center operation) should then be placed at the junction of the 47,000 ohm resistor and the .0015 condenser and the secondary of the ratio detector should be tuned for zero reading on the VTVM. This adjustment is very sharp between a plus and minus swing. For oscilloscope view of ratio detector alignment connect scope hot lead at junction of 47000 ohm resistor and the 1500 MMF condenser and the ground lead connected to nearest point on chassis. Shown in Figure (9A). Set signal generator for 4.5 meg. center frequency with 100 KC deviation on each side of center. The curve should appear as in Figure (9B).

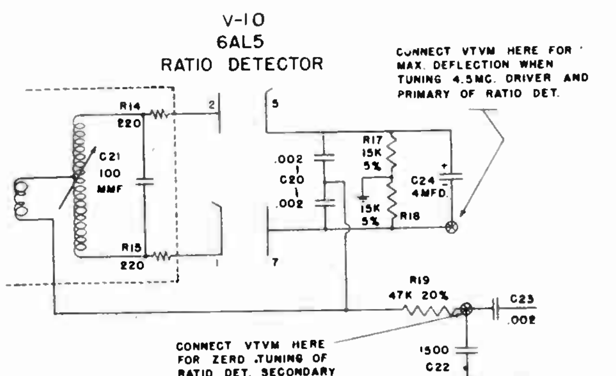


FIG. 9A

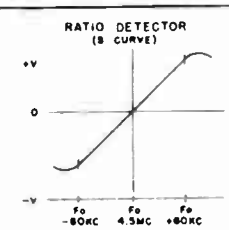

FIG. 9B

PICTURE ADJUSTMENTS

ION TRAP, FOCUS AND YOKE

To properly adjust the Ion Trap, Focusing coil and the Deflection Yoke the following procedure should be followed.

The Deflection Yoke should be placed in position closest to the "bell" of the Picture Tube as far forward on the neck of the tube as is possible. Be sure the wire loops on the mounting make positive contact with the coating of the picture tube. The Focus Coil is next in line and the Ion Trap last.

Turn the set on. The antenna should NOT be connected to the receiver and the picture contrast control should be set at MINIMUM.

With the brilliance control set at about one-quarter turn back from maximum, the Ion trap should be adjusted to achieve the brightest raster on the face of the Picture Tube. Trap should be simultaneously rotated and moved back and forth on the neck of tube until exact setting is obtained.

Adjust the brilliance control to a point slightly over normal brightness and adjust the Focus Control on the rear of the chassis for clearest and sharpest horizontal sweep lines. The Ion Trap should then be readjusted slightly for the brightest response on the face of the tube at which good focus is maintained.

The Focus Coil itself should be moved to secure a complete raster, approximately centered and with no corners cut off. This being accomplished it should be secured by the screws provided.

Finally the Deflection Yoke should be rotated to "square" the raster with the chassis as a reference. The thumb screws on the yoke brackets should then be set.

HORIZONTAL OSCILLATOR ALIGNMENT

HORIZONTAL OSCILLATOR ALIGNMENT — To adjust the horizontal oscillator and its control circuits it is necessary to first connect a working antenna to the receiver. It is preferable to use a test pattern as the incoming signal rather than a picture.

The following steps should then be taken:

1 — With the receiver turned on and the brightness and picture controls adjusted to a normal position the Horizontal Frequency trimmer and the Horizontal Locking trimmer (both rear of chassis) should be turned clockwise all the way and then back off about $1\frac{1}{2}$ turns (counter-clockwise).

2 — The Horizontal Hold Control (front panel) should be turned to a maximum clockwise position.

3 — The core of the Horizontal Oscillator Transformer (see figure 11 parts location) should then be adjusted. Variation of this core will cause the pattern to resolve into a series of black and white bars sloping either to the right or to the left depending upon the degree of adjustment. The transformer should be adjusted to the point where the picture resolves into a series of from $3\frac{1}{2}$ to $4\frac{1}{2}$ bars sloping downwards to the right.

4 — The Horizontal Hold Control (front panel) should now be rotated to a full counter-clockwise position and the incoming signal momentarily interrupted. (This can be done most easily by shorting the antenna terminals for a moment). This should cause the picture to again resolve into a series of black and white bars slanting now downward to the left.

5 — The Horizontal Hold Control (front panel) should now be rotated slowly in a clockwise direction. As the control is turned the number of bars sloping downward to the left should decrease. At approximately 90° of rotation there should remain between $3\frac{1}{2}$ and $4\frac{1}{2}$ bars just prior to the time that the picture "falls into" sync. The picture should remain in sync for an additional 90° of clockwise rotation. If MORE than $4\frac{1}{2}$ bars are evident just before the picture syncs the Horizontal Locking Range trimmer (rear of chassis) should be tightened slightly. If LESS than $3\frac{1}{2}$ bars, the same trimmer should be loosened.

HEIGHT, WIDTH AND LINEARITY

To adjust the overall size and linearity of the picture it is necessary that a pattern transmitted from a local station be used. Linearity adjustments, particularly, cannot be accurately made on moving transmissions. It should also be remembered that in areas where more than one station is being received, pictures transmitted by different stations will vary slightly in size and linearity. In view of this the smallest transmitted picture should be made to fill the area of the Picture tube delineated by the mask.

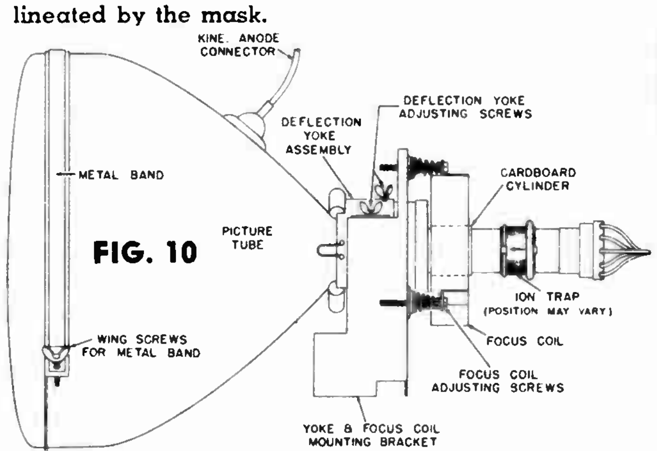

FIG. 10

Following is the recommended procedure for complete height, width and linearity adjustment; (see Fig. 4 for location of controls).

1 — Turn the Width Control coil screw all the way in (clockwise).

2 — Adjust Horizontal Drive Trimmer for the best compromise between maximum brightness and good horizontal linearity. This control will primarily affect the overall width and the left side of the picture.

3 — Adjust the Horizontal Linearity Coil, (and the Horizontal Linearity control in Model 286) for best overall horizontal linearity. It will be noted that the Horizontal Linearity Coil will have most effect on the center of the picture while the Control will adjust the center and right half. These two adjustments will interact and the setting of one will affect the range and effect of the other.

4 — The width control coil should now be adjusted to give a picture that will fill the mask horizontally.

5 — The Height and Vertical Linearity controls should be adjusted for a linear picture that will fill the mask vertically.

6 — Picture centering is accomplished by positioning the focus coil mechanically by means of four 4 hex-head adjusting screws (3 in Model 286) accessible from the rear of the chassis as shown in Fig. 10.

7 — Adjust the Focus Control for clearest delineation of the horizontal sweep lines. This adjustment should be made with a picture rather than with a raster.

PARTS LIST NOTES

(1) - C 102 is not used in models 284, 287, 288

(2) - R 104 & 105 are 4.7 Ohms in model 286
R 104 is 3.3 Ohms in models 284, 287, 288
R 105 is 1M-1W in models 284, 287, 288

(3) - R 98 is 47 Ohms in model 286 and 68 Ohms in models 284, 287, 288

(4) - R 102, 103 are 27 K 2 W in model 286
R 102 only in models 284, 287, 288 is 8200 Ohms 2 W 10%

(5) - In models 284, 287, 288, C 97 is .25 - 400 V and C 98 is .1 - 1000 V.

(6) - In models 284, 287, 288, C 100 is 56 MMF in yoke

(7) - In models 284, 287, 288, C 99 is .035 - 600 V.

(8) - In models 284, 287, 288, C 101 is 10 MMF - 1500 V Mica.

(9) - R 111 - 500 Ohm Lin. Control not used in models 284, 287, 288

(10) - TLF - 505 is used in models 284, 287, 288

(11) - TLF - 506 is used in models 284, 287, 288

(12) - TLF - 545 - D is used in models 284, 287, 288

(13) - TTR - 183 - D is used in models 284, 287, 288

INSTALLATION

WARNING

This Receiver is designed for use on 105 to 125 Volt 60 Cycle AC only. Do NOT connect to Direct Current (DC) power supply. If in doubt check with your local Power Supply Company.

TELE-TONE BUILT-IN ANTENNA

Models 300, 301, 304 and 305 are equipped with the Teletone Automatic Built-in Antenna. The efficiency of this antenna is very high and normally will perform as well as or better than most indoor antennas. It consists of two concentric circular antennas and an auxiliary counterpoise type antenna. The circular antennas are mounted on the inside top of the cabinet while the auxiliary is found on the back cover. Electrically the Teletone Automatic Built-in Antenna functions as a double dipole. The auxiliary aids reception on the lower channels. If the area or location in which the receiver is installed precludes the use of an indoor type antenna the Built-in antenna should be disconnected by loosening the two screws on the antenna terminal on the back of the set and removing the black and red leads connected thereto. A regular outdoor installation should be made and the lead-in connected to the same two screws on the antenna terminal strip.

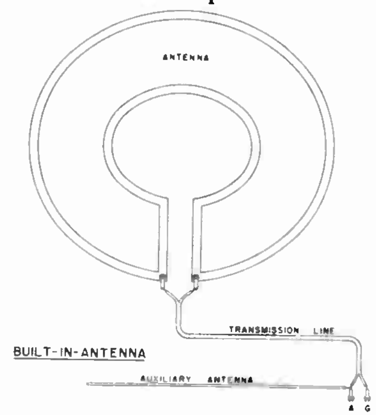

FIG. 1

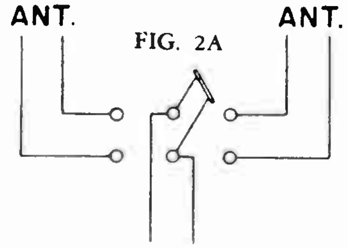
OUTDOOR ANTENNA

In areas where both high band and low band reception is available, antennas may be used in the form of a stacked array. Where a stacked array is used, it may prove advantageous in some locations to connect separate down leads from each antenna and connect a suitable switch at the receiver as shown in figure 2A.

HIGH FREQ. ANT. LO-FREQ. ANT.

FIG. 2A



TO RECEIVER
TRANSMISSION LINE

In non-critical locations, satisfactory results may be obtained with a 300 ohm down lead connected directly to the receiver antenna terminals. In more critical locations (insufficient signal) increased pick-up may be obtained by using the 300 ohm down lead in conjunction with a suitable matching transformer at the receiver. (See figure 2B). In unusually noisy locations considerably improved performance may be obtained by the use of 72 ohm co-axial transmission line.

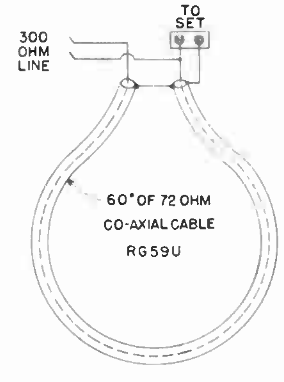


FIG. 2B

ANTENNA MATCHING TRANSFORMER

NOTE: — When using 72 ohm co-axial down lead, it is important that its outer lead be connected to the shield side of the receiver transmission line. Check antenna terminal connections to determine shield side.

CONTROL FUNCTIONS

RECEIVER FRONT PANEL CONTROLS

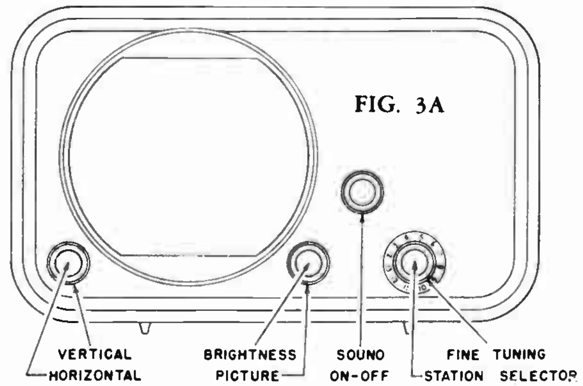

FIG. 3A

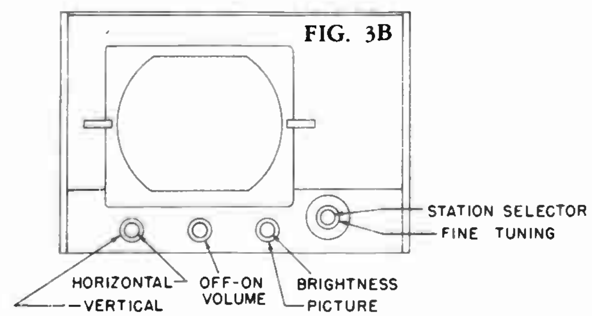

FIG. 3B

©John F. Rider

World Radio History

VOLUME — ON-OFF — The volume control is an audio control only and has no effect on the picture. It is connected in the grid circuit of the audio amplifier (V-4). The power on and off switch is combined with the volume control.

HORIZONTAL HOLD — The Horizontal Sweep Oscillator uses Automatic Frequency control. As a result the Horizontal Hold Control will only be used if the picture should resolve into a series of heavy, oblique, black and white lines. A fast twist of the knob will then cause the picture to correct itself.

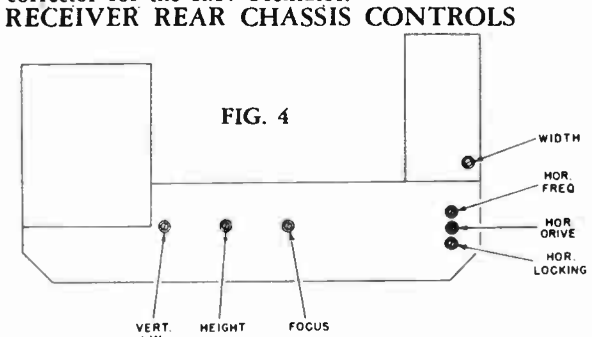
VERTICAL HOLD — The vertical hold control is not a critical control. This control is in the grid circuit of the first half of the vertical oscillator (V-8B).

PICTURE — Controls video gain through the AGC diode cathode (V-10A). It should be remembered that this receiver uses AGC and therefore will rarely overload despite contrast setting.

BRIGHTNESS — This control operates by varying the DC potential on the cathode of the Kinescope (V-21).

STATION SELECTOR — The inner (bar) knob of this control will operate the station selector. The outer (circular) knob will activate the Fine Tuning control, a corrector for the R.F. Oscillator.

RECEIVER REAR CHASSIS CONTROLS



WIDTH — The Horizontal Sweep is determined by the current flowing through the Horizontal Yoke Coil. The current through this coil (L13B) is controlled by Width Control (L15) which is a variable reactor having the effect of changing the turns ratio of this winding of the Horizontal Output and H.V. Transformer (T6).

HEIGHT — This control is a voltage dropping rheostat operating in the plate circuit of the Vertical Sweep Oscillator (V8B). It changes the voltage delivered to (V-12) Vertical Amplifier feeding current to transformer coupled Vertical Yoke Coil (L13A). Since changes in height will affect picture linearity, this Height Control must be adjusted in conjunction with Vertical Linearity Control.

VERTICAL LINEARITY CONTROL — This is a variable resistor control (R69) in the cathode of (V-12) which provides inverse feedback variation affecting the linearity of the Vertical Sweep Wave form. To be adjusted as height control is adjusted.

FOCUS CONTROL — This is a Variable Resistor (R80) which varies the current through focus coil (L-12).

HORIZONTAL AND VERTICAL CENTERING — Centering of the picture area is accomplished in this receiver by finding that position for the focus coil in the horizontal and vertical planes that produces this result. The focus coil bracket is adjusted so that if the four hexagon-head screws are loosened it can be shifted up and down and from side to side enabling the centering position to be found by trial.

BRIEF CIRCUIT ANALYSIS

The Tele-tone Television receivers Models, TV 300, 301, 304 and 305 use the Intercarrier sound systems. In this system the RF section of the receiver receives both the picture and the sound carriers which are converted by the mixer (V19) and then fed into the IF. No separation takes place until after the Video Amplifier (V9). At this point the sound component of the dual signal is picked off by the 4.5 trap (T1) and fed through the Ratio Detector, the sound Amplifier and the Audio output stages. The Picture IF frequency is 37.3 Mc and the Sound IF is 32.8. For individual stage frequencies see "Video IF Alignment". (Page 7).

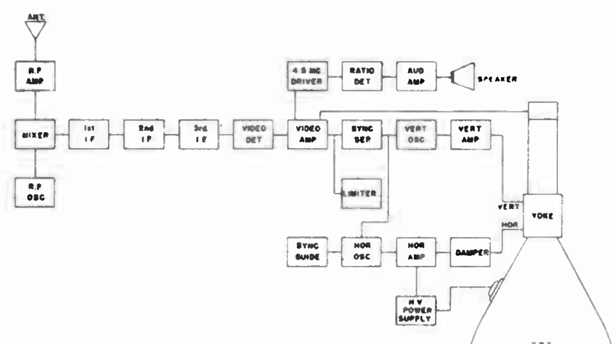


FIG. 5

TUNER — In the initial runs of this model a 12 coil tuner, much the same as previous Tele-tone tuners is used. In later runs a new type 7 coil tuner is employed. The terms "12 coil" and "7 coil" refer to the variable oscillator coils only. The RF and Mixer sections remain essentially the same.

RF AMPLIFIER — The antenna is fed between cathode and grid of the grounded grid RF amplifier (V-20). The input circuits of which are untuned. Double tuned interstage coupling is used between the plate of the RF Amplifier (V-20) and the grid of the mixer (V-19). Mechanically, the series inductances used take the form of several individual coils which are cut in or out of their respective circuits by means of the band switch. These coils will rarely need adjustment.

MIXER — The output of the RF Amplifier (V-20) and the Local Oscillator are condenser fed into the Control Grid Mixer Stage (V-19). This circuit is tuned in much the same manner as the output of the RF Amplifier, previously described.

OSCILLATOR—12 COIL TUNER—The RF Oscillator (V-18) is fairly straight-forward in operation. Its main peculiarity is that the coil for Channel 2 is permanently parallel to all other Oscillator coils from 3 to 13. It is therefore necessary, when aligning the oscillators to ALIGN CHANNEL 2 FIRST and the rest of the coils in any order thereafter. They are tuned by brass slugs accessible through two slots in the front of the receiver chassis. Channel 2 is found at the top of the right hand slot and the others follow in regular order in a clockwise direction finishing with Channel 13 at the top of the left hand slot.

OSCILLATOR—7 COIL TUNER—As stated above, in later runs of these models a new type, 7 coil tuner is employed. In these tuners the only change is in the arrangement of the Oscillator coils. Where, previously, 12 individual coils were used (one for each channel) 7 coils are now substituted. The coils for Channels 2 and 13 will remain substantially as before. The other channels will be paired with one variable and two small fixed coils, as shown in Fig. 6B. Typically, channels 3 and 4 have only one adjustment. This adjustment may be made on either station and the other will be found to be properly tuned. Any slight variations will be more than compensated for by the fine tuner. A study of Fig. 6B will show that, as previously, channel two must be tuned first, if at all, and the remaining channels in any order thereafter. The seven adjustments are for the following groups of channels; — Channel 2 — Channels 3 and 4 — Channels 5 and 6 — Channels 7 and 8 — Channels 9 and 10 — Channels 11 and 12 — Channel 13.

NOTE: The channel numbers on the escutcheon do not correspond to the location of the oscillator coils.

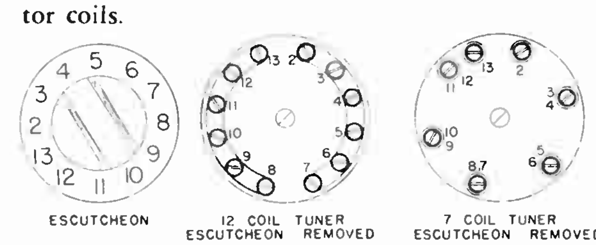

FIG. 6A

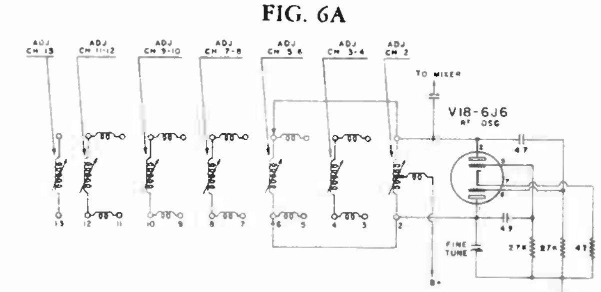

FIG. 6B

VIDEO IF — Each Video IF transformer has only one adjustment, a powdered iron slug accessible from the top of the chassis. The Video IF String is stagger tuned to two frequencies. The first and third IF transformers are tuned to 34.9 Megacycles and the second and fourth are tuned to 36.8 Megacycles. The response curve is fairly flat topped and should produce a picture with good definition.

VIDEO AMPLIFIERS — FIRST AND SECOND — A 12AU7 (V-9), dual triode is used in this section of the receiver. The output of the detector is fed to the grid of the first section (pin 2) and ultimately taken off plate of the second section of the tube (pin 6). It is at this point the three basic components of the received signal are separated and fed to their respective circuits. The picture intelligence is fed to the grid of the Picture Tube (V-21) and the synchronization pulses to the grid (pin 1) of the Sync Separator (V-11) and from there to the Horizontal (V-14) and Vertical oscillators (V-8B), also see "Sound System" below.

D. C. COMPONENTS — The D.C. component of the transmitted signal (which controls the background brightness) is substantially duplicated in the receiver by direct coupling from the plate of the second video amplifier to the Picture Tube grid.

SOUND SYSTEM — The sound Carrier is taken off the plate of the Video Amplifier (V-9) by a 4.5 Megacycle trap and fed through a 4.5 MC Amplifier (V-1) to the Ratio Detector (V-2), and then to the sound amplifier (V-4), audio output (V-3) and speaker.

SWEEP SYSTEM — VERTICAL — The triode section of a 6BF6 (V8B) serves as the Vertical oscillator and discharge tube. A 6K6 (V12) is utilized as the Vertical Sweep Amplifier. The plate circuit of the 6K6 (V12) is transformer coupled to the vertical windings of the Deflection Yoke (L13-A).

SWEEP SYSTEM — HORIZONTAL — The Horizontal Oscillator is essentially of the Blocking Oscillator type. The operation of the AFC system depends upon a correcting voltage developed in the control tube when the oscillator output and the incoming pulses differ in either phase or frequency. The control tube, first section (V-14), is maintained at cut-off until such time as the sync pulse is either ahead of or behind the oscillator, (second section V-14), sawtooth peak. When either case occurs the control tube develops a voltage which is applied as a bias to the oscillator grid and alters the oscillator frequency to coincide with the frequency of the incoming pulses. The horizontal oscillator transformer has an adjustable core which is a coarse control of the oscillator frequency. The Horizontal Frequency Control (rear) is a fine adjustment in the same sense. The front panel Horizontal Hold Control permits slight adjustment of the frequency by adjusting the B voltage applied to the control tube plate. The Horizontal Locking Range Control affects the sensitivity of the control tube thus varying the range over which the AFC circuit will function.

NOTE: Many of the components in the Horizontal circuits are of the critical value and therefore should only be replaced by the exact replacement part. Care should also be taken in dressing leads and parts when replaced. This can be accomplished by carefully noting parts positions before removal. For complete alignment procedure on these circuits see page (8).

©John F. Rider

World Radio History

A.G.C. — The receiver uses an AGC circuit operating on the first 2 IF stages (V-5) (V-6). While it is quite effective in most locations, the receiver may overload in regions of very high field intensity. The contrast can generally be adjusted for a normal picture under such conditions but spurious beats, jagged vertical lines (i.e. poor resolution) and a "Moire" pattern may appear. These effects can be eliminated by the use of a resistor network of 3 to 10 db attenuation in series with the antenna lead at the point where it is connected to the receiver.

HIGH VOLTAGE POWER SUPPLY — The energy stored in the horizontal windings of the deflection yoke during the forward sweep produces high voltage surges during retrace. This is "stepped up" by the "auto-transformer" winding of the horizontal output transformer (T-6) and then rectified by a 1B3/8016 (V-13) to provide approximately 9000 volts for the picture tube (V-21) anode.

B VOLTAGE POWER SUPPLY — The B Supply of these models utilizes a standard type of transformer-rectifier circuit. It should be noted that the transformer contains a separate filament winding (6.3 volts) to heat the Cathode Ray Tube (V21) and the Damper (V16). The use of a center-grounded bleeder network provides a B Supply with the following voltages measured with respect to ground; plus 240 volts, plus 140 volts, plus 4 volts, minus 3.5 volts, minus 14 volts, and minus 90 volts.

ALIGNMENT PROCEDURE

The alignment of this Receiver can be broken down into three basic parts.

1 — Video IF Alignment   2 — RF Alignment
3 — Sound Alignment

TEST EQUIPMENT

CATHODE RAY OSCILLOSCOPE — The tube size is relatively unimportant, however, anything under 5" usually makes fine adjustment quite difficult.

SWEEP GENERATOR — The sweep generator used should have linear coverage of a center range from 30 to 220 megacycles. The output should be fairly flat over wide frequency variation of the sweep. It should be capable of an output of about 0.1 volt with attenuation. It is preferable that the generator have a deflection output for the test oscilloscope.

AM SIGNAL GENERATOR — This generator should have a frequency range of from 4.5 to 220 megacycles. As this generator is used occasionally as a market generator, accuracy is an important factor. It should be capable of 0.1 volt output with attenuation and should be linear through the range.

VACUUM TUBE VOLTMETER — Almost any standard make VTVM will do. It should preferably have a reversible polarity switch.

TEST SOCKET

In each of these models a Test Socket is provided which gives convenient access to the various points where either a vacuum tube voltmeter or an oscilloscope must be inserted for proper alignment. A letter diagram in the margin of the schematic will locate these points by means of corresponding letters in the schematic proper. A typical Octal socket is used and it should be noted that the diagram shows an UNDERSIDE VIEW. Two ground points are supplied on separate pins of the test socket for easy metering. Reference is made, in the following Alignment Procedures, to the pins on this Test Socket.

VIDEO IF ALIGNMENT

An adequate signal can be fed through the video IF string by feeding the output of the signal generator into a tube shield placed over the mixer tube (6AG5) (V-19). Care should be taken that this shield is NOT grounded. The ground side of the generator output can be conveniently grounded to the shield of the adjacent oscillator tube.

The contrast control should be set to produce minus 2 volts on Pin 7 6AL5-AGC tube. (V-10A).

The vacuum tube voltmeter should be connected across the 8200 ohm detector load resistor (Pin B Test Socket) and should be set on the minus 3 Volt scale. Set channel selector to an unused low band channel.

The Signal generator should be set to a frequency of 34.9 Mc. The output of the generator should be adjusted to the point where the reading on the VTVM is between minus 1 to minus 1.5 volts.

The First and Third I.F. coils should be peaked for a maximum reading on the VTVM. As the voltage reading increases with tuning, the generator should be attenuated to maintain a maximum of minus 1.5 volts.

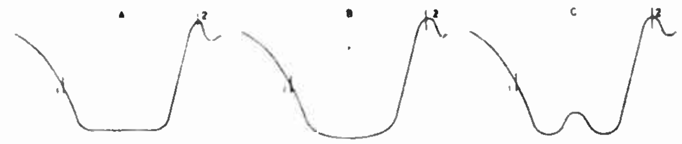
Set the Signal Generator to a Frequency of 36.8 Mc and tune the Second and Fourth I.F. coils in the same manner as above.

Set the Signal Generator to a frequency of 32.8 and tune the trap (L6) for a MINIMUM reading on the VTVM.

The Third I.F. coil should then be readjusted as described previously.

The Generator should now be shut off (or tuned to different band) and the VTVM should read no more than minus 0.20 volts. If there is a higher voltage reading, check for regeneration in the I.F. stages.

By shunting the signal generator with a sweep generator (30 to 40 Mc) and substituting a Cathode Ray Oscilloscope for the Vacuum tube Voltmeter in the above procedure the actual pass band of the Video I.F. circuits may be studied. Ideally the response curve should appear on the face of the oscilloscope in the form indicated in Figure (7A). A slight slope of the top of the curve in either direction or a small dip in the center are acceptable as indicated in Figure (7B & C).



A IDEAL RF IF WAVESHAPE   B & C ACCEPTABLE WAVESHAPES
1- PICTURE CARRIER
2- SOUND CARRIER

FIG. 7

RF ALIGNMENT

In the alignment of the RF section of this receiver three pieces of test equipment are necessary. A sweep generator, a signal generator and a cathode Ray Oscilloscope. For specifications see "Test Equipment" above.

The output of the Sweep Generator should be fed into the antenna. The signal generator (C.W.) should be connected to the antenna terminals of the receiver. The sweeper will provide the overall response curve with the oscilloscope properly connected. The signal generator is used as a marker as described below. Some Sweep generators made today contain their own marker oscillator. In cases where a generator of this type is used the Signal Generator may be eliminated.

The "hot" or "high" side of the Oscilloscope input should be connected to the junction point of the 8200 ohm detector load resistor and the peaking coil. (Pin B Test Socket). The "low" or ground side should be connected to the nearest convenient ground point. Care should be taken that the generator and the scope leads are well separated to avoid regeneration.

The R.F. section of the receiver is tuned channel by channel. The proper frequency settings for any given channel can be determined by consulting the Frequency Chart on Page (2). For example in aligning channel 2 the sweep generator should be set to some mid frequency between 54 and 60 megacycles. This adjustment is not a fine one. After setting the sweeper in the general vicinity of the desired frequency it should be tuned to center the response curve on the Oscilloscope face. For picture and sound markers the signal generator should carefully be adjusted to the frequencies indicated in the Frequency chart. For example in the case of channel 2 the picture marker frequency is 55.25 Mc. and the Sound 59.75 Mc.

It is important to note at this point that the oscillator coil for channel 2 is in parallel with every other oscillator coil from 3 to 13. It is therefor imperative that channel 2 be aligned first and the others in any desired order thereafter.

Starting with channel 2 and applying the proper frequencies as indicated above, the output of the sweeper should be attenuated to the point where further attenuation will not affect the wave shape.

The Oscillator should then be adjusted to bring the sound carrier into the 32.8 Mc trap valley. With the oscillator so adjusted the picture carrier should fall at a point approximately 50% up on the slope of the opposite side of the band pass curve. Certain variations in the waveshape and the location of the picture carrier are acceptable. The picture carrier may vary in position from a point between 45% and 60% of the slope and the overall waveshape may differ from the ideal, flat-topped response by being either slightly rounded or slightly dipped in the center. See Figure (8).

If the position of the picture carrier varies beyond the 45% to 60% points on all channels correction may be made by turning to channel 6, applying the proper input signals and slightly realigning the I.F. transformers.

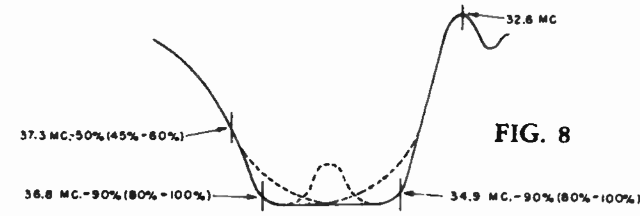


FIG. 8

IDEAL VIDEO IF RESPONSE CURVE
DOTTED LINES INDICATE ACCEPTABLE VARIATIONS

SOUND ALIGNMENT

Sound alignment on these receivers is best accomplished by using an actual transmission received on an antenna and fed in the normal manner to the antenna terminals. A Vacuum Tube Voltmeter should first be inserted between the output plate of the Ratio Detector Diode (pin 2 V2) and ground. This point may be reached through pin C of the Test Socket. The meter should be set on the *minus* 10 volt scale. With the equipment so placed the 4.5 Mc trap (T1) and the primary of the Ratio Detector Transformer (bottom adjustment, T2) should be adjusted for a maximum deflection of the meter. The hot lead of the meter should now be moved to the junction point of R19, C22 and C23 (Pin A Test Socket), and the secondary of the Ratio Detector Transformer should be adjusted for a *ZERO* reading. (Note: There are 3 points at which the meter will zero. Only one of these is correct. At the proper setting the meter should swing negative on one side and positive on the other side of zero). In cases where it is necessary to align the sound section when no station transmission is available a Single frequency signal generator tuned to 4.5 megacycles may be fed into the output circuit of the Video Detector (Pin B Test Socket). The receiver should then be aligned in the same manner as described above. The disadvantage of this method is that any inaccuracy in your signal generator will show up as misalignment when the set is in actual operation, since proper adjustment is very critical.

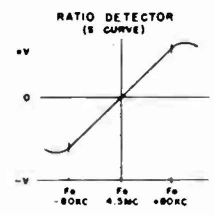

FIG. 9B

PICTURE ADJUSTMENTS

ION TRAP, FOCUS AND YOKE

To properly adjust the Ion Trap, Focusing coil and the Deflection Yoke the following procedure should be followed.

The Deflection Yoke should be placed in position closest to the "bell" of the Picture Tube as far forward on the neck of the tube as is possible. Be sure the wire loops on the mounting make positive contact with the coating of the picture tube. The Focus Coil is next in line and the Ion Trap last.

Turn the set on. The antenna should NOT be connected to the receiver and the picture contrast control should be set at MINIMUM.

With the brilliance control set at about one-quarter turn back from maximum, the Ion trap should be adjusted to achieve the brightest raster on the face of the Picture Tube. Trap should be simultaneously rotated and moved back and forth on the neck of tube until exact setting is obtained.

Adjust the brilliance control to a point slightly over normal brightness and adjust the Focus Control on the rear of the chassis for clearest and sharpest horizontal sweep lines. The Ion Trap should then be readjusted slightly for the brightest response on the face of the tube at which good focus is maintained.

The focus Coil itself should be moved to secure a complete raster approximately centered and with no corners cut off.

Finally the Deflection Yoke should be rotated to "square" the raster with the chassis as a reference. The thumb screws on the yoke brackets should then be set.

HORIZONTAL OSCILLATOR ALIGNMENT

To adjust the Horizontal oscillator and its control circuits it is necessary to first connect a working antenna

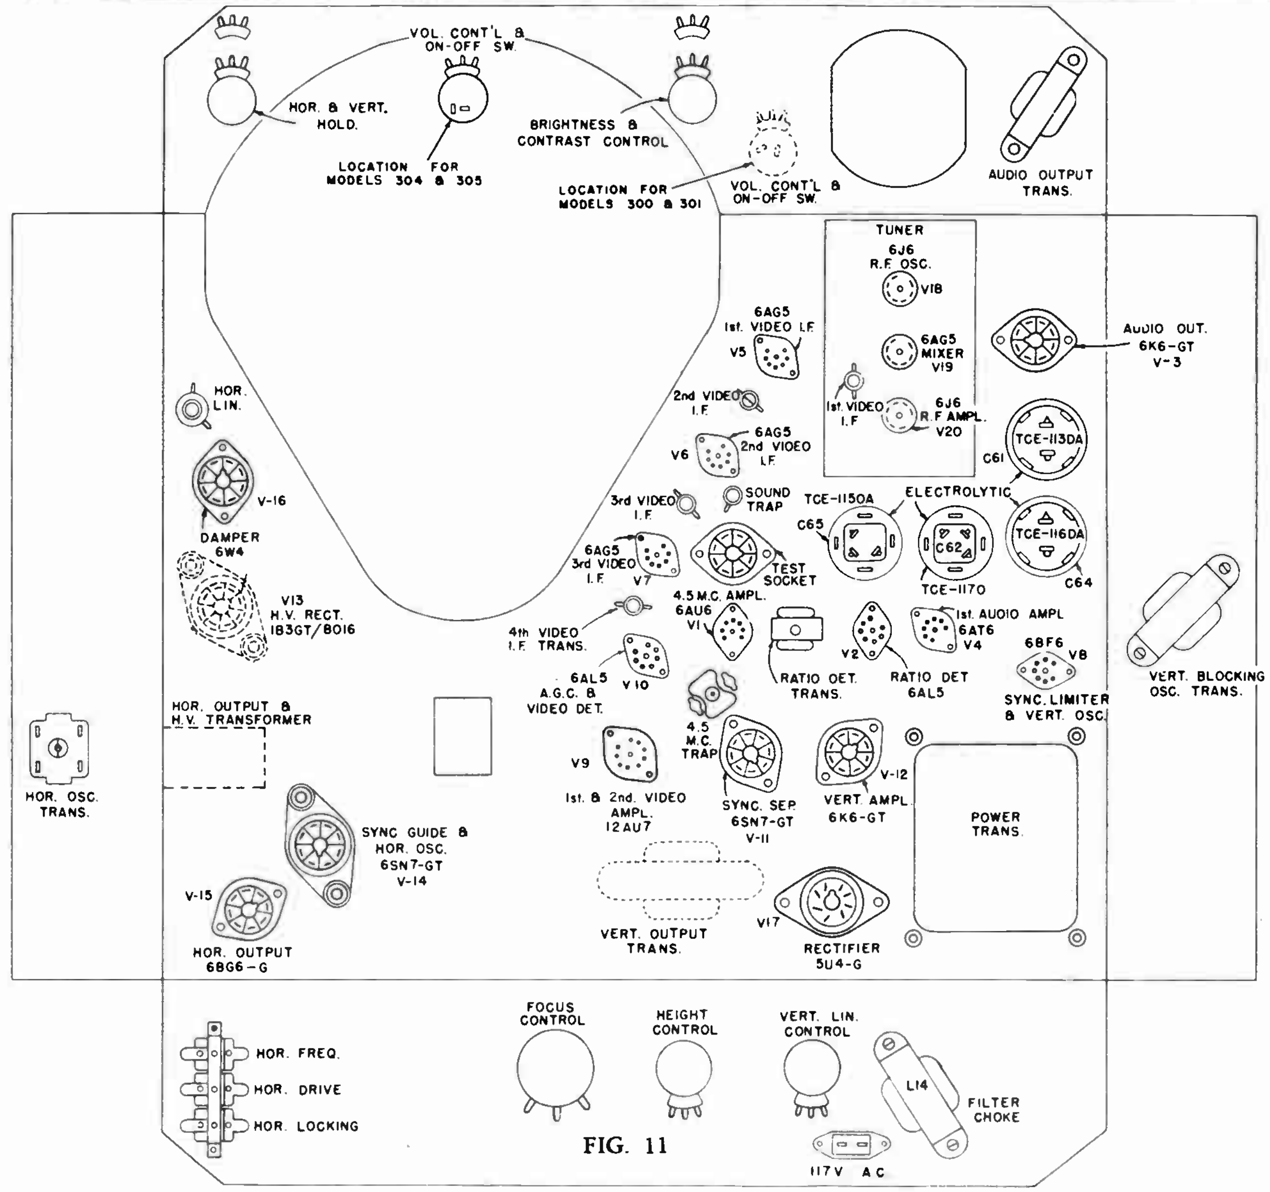

FIG. 11

PARTS LOCATION — MAIN CHASSIS — UNDERSIDE VIEW

to the receiver. It is preferable to use a test pattern as the incoming signal rather than a picture.

With the receiver turned on and the brightness and the picture contrast controls adjusted to a normal position the Horizontal Frequency trimmer and the Horizontal Locking trimmer (rear of chassis) should be turned clockwise all the way and then backed off to about one turn (counter-clockwise).

The Horizontal Hold Control (front panel) should be turned to a maximum clockwise position.

The core of the Horizontal Oscillator Transformer should then be adjusted. Variation of this core will cause the pattern to resolve into a series of black and white bars sloping either to the right or the left depending upon the degree of adjustment. The transformer should be adjusted to the point where the picture resolves into a series of from 3½ to 4½ bars sloping downwards to the right.

The Horizontal Hold Control (front panel) should now be rotated to a full counter-clockwise position and the incoming signal momentarily interrupted. This can be done most easily by shorting the antenna terminals for a moment.

The Horizontal Hold Control (front panel) should now be rotated slowly in a clockwise direction. As the control is turned the number of bars sloping downward to the left should decrease. At approximately 90 degrees of rotation there should remain between 3½ and 4½ bars just prior to the time that the picture "falls into" sync. The picture should remain in sync for an additional 90 degrees of rotation. If MORE than 4½ bars are evident just before the picture syncs the Horizontal Locking Range trimmer (rear of Chassis) should be tightened slightly. If LESS than 3½ bars the same trimmer should be loosened.

HEIGHT, WIDTH AND LINEARITY

To adjust the overall size and linearity of the picture it is almost mandatory that a pattern transmitted from a local station be used. Linearity adjustments, particularly, cannot be accurately made on moving transmissions. It should also be remembered that in areas where more than one station is being received, that pictures transmitted from different stations will vary slightly in size. The smallest transmitted picture should be made to fill the area delineated by the mask.

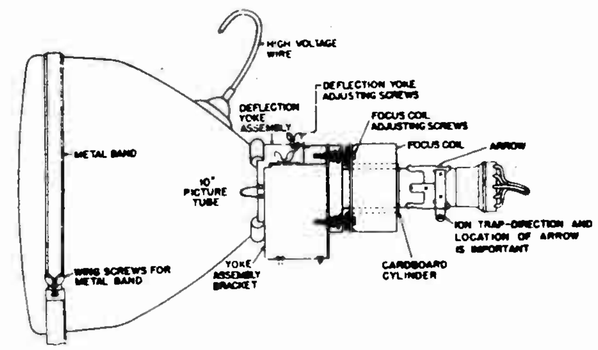

FIG. 10

The first step in linearity and size adjustment is to turn the Width control (rear of chassis Figure 4) all the way in (clockwise).

The Horizontal Drive trimmer should then be adjusted for the best compromise between maximum brightness and good horizontal linearity. This control will affect the left side of the picture primarily. The Horizontal Linearity control (top rear of chassis) should then be adjusted for linearity of the right side of the picture.

The Width Control should now be readjusted to achieve a picture that will fill the mask horizontally.

The Height and Vertical Linearity controls (both rear of chassis) should then be adjusted for a linear picture that will fill the mask vertically.

Picture centering is accomplished by positioning focus coil mechanically by means of 4 hexagon-head adjusting screws accessible from rear of chassis as shown in Figure (10). At this point the Focus control, previously set, should be retouched for maximum definition of the lines in the vertical wedge of the test pattern. Proper adjustment and alignment of the receiver should result in clear and sharp definition.

SPECIFICATIONS

POWER SUPPLY
105 to 125 Volts - 60 Cycle A.C.

POWER CONSUMPTION
225 Watts

POWER OUTPUT
2 Watt (Undistorted)

INPUT IMPEDANCE
72 and/or 300 Ohm

PICTURE TUBE SIZE
12-1/2" Round

SPEAKER
4" x 6" Oval PM - Voice Coil 3 Ohms

DIMENSIONS
21-1/2" Wide x 18" Deep x 12-1/2" High

SHIPPING WEIGHT
App. 71 Lbs.

INSTALLATION

WARNING

This Receiver is designed for use on 105 to 125 Volt 60 Cycle AC only. Do NOT connect to Direct Current (DC) power supply. If in doubt check with your local Power Supply Company.

TELE-TONE BUILT-IN ANTENNA

Models TV 306 and 307 are equipped with the Teletone Automatic Built-in Antenna. The efficiency of this antenna is very high and normally will perform as well as or better than most indoor antennas. It consists of two concentric circular antennas and an auxiliary counterpoise type antenna. The circular antennas are mounted on the inside top of the cabinet while the auxiliary is found on the back cover. Electrically the Teletone Automatic Built-in Antenna functions as a double dipole. The auxiliary aids reception on the lower channels. If the area or location in which the receiver is installed precludes the use of an indoor type antenna the Built-in antenna should be disconnected by loosening the two screws on the antenna terminal on the back of the set and removing the black and red leads connected thereto. A regular outdoor installation should be made and the lead-in connected to the same two screws on the antenna terminal strip.

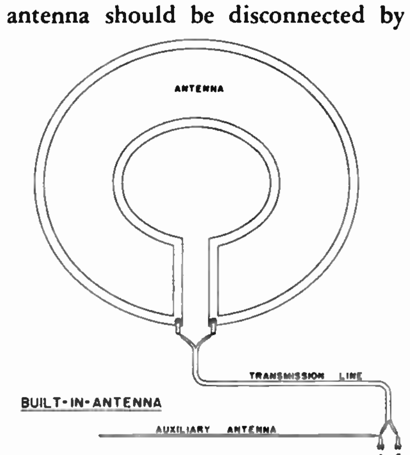

FIG. 1

OUTDOOR ANTENNA

In areas where both high band and low band reception is available, antennas may be used in the form of a stacked array. Where a stacked array is used, it may prove advantageous in some locations to connect separate down leads from each antenna and connect a suitable switch at the receiver as shown in figure 2A.

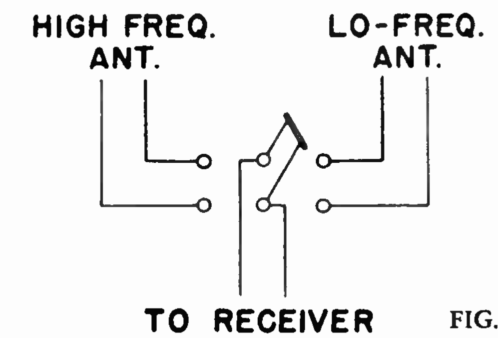

FIG. 2A

TRANSMISSION LINE

In non-critical locations, satisfactory results may be obtained with a 300 ohm down lead connected directly to the receiver antenna terminals. In more critical locations (insufficient signal) increased pick-up may be obtained by using the 300 ohm down lead in conjunction with a suitable matching transformer at the receiver. (See figure 2B). In unusually noisy locations considerably improved performance may be obtained by the use of 72 ohm co-axial transmission line.

©John F. Rider

World Radio History

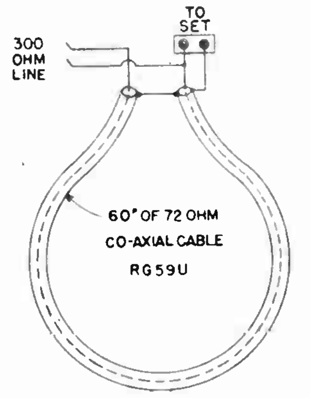

FIG. 2B ANTENNA MATCHING TRANSFORMER

NOTE: — When using 72 ohm co-axial down lead, it is important that its outer lead be connected to the shield side of the receiver transmission line. Check antenna terminal connections to determine shield side.

CONTROL FUNCTIONS

RECEIVER FRONT PANEL CONTROLS

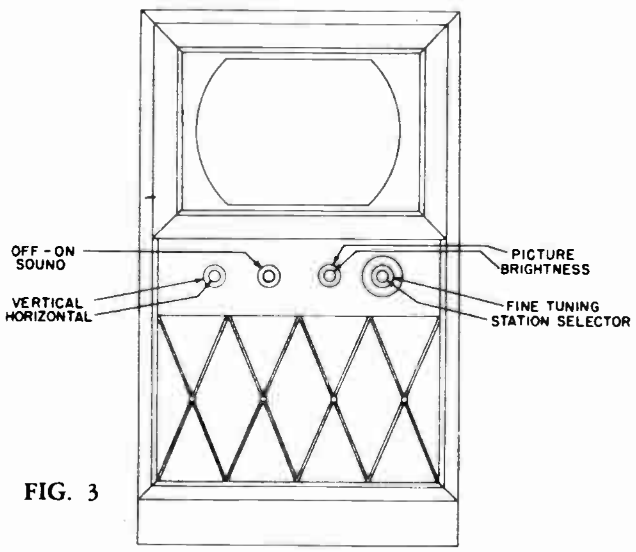

FIG. 3

VOLUME — ON-OFF — The volume control is an audio control only and has no effect on the picture. It is connected in the grid circuit of the audio amplifier (V-4). The power on and off switch is combined with the volume control.

HORIZONTAL HOLD — The Horizontal Sweep Oscillator uses Automatic Frequency control. As a result the Horizontal Hold Control will only be used if the picture should resolve into a series of heavy, oblique, black and white lines. A fast twist of the knob will then cause the picture to correct itself.

VERTICAL HOLD — The vertical hold control is not a critical control. This control is in the grid circuit of the first half of the vertical oscillator (V-8B).

PICTURE — Controls video gain through the AGC diode cathode (V-10A). It should be remembered that this receiver uses AGC and therefore will rarely overload despite contrast setting.

BRIGHTNESS — This control operates by varying the DC potential on the cathode of the Kinescope (V-21).

STATION SELECTOR — The inner (bar) knob of this control will operate the station selector. The outer (circular) knob will activate the Fine Tuning control, a corrector for the R.F. Oscillator.

RECEIVER REAR CHASSIS CONTROLS

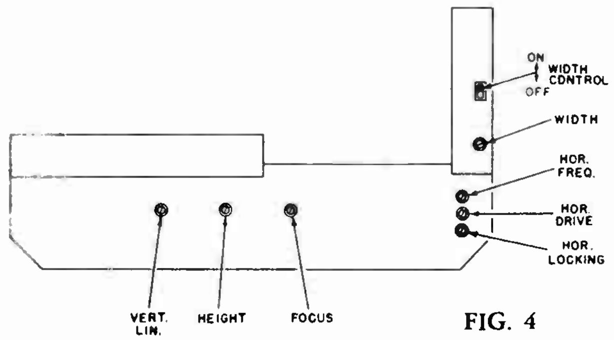

FIG. 4

WIDTH — The Horizontal Sweep is determined by the current flowing through the Horizontal Yoke Coil. The current through this coil (L13B) is controlled by Width Control (L15) which is a variable reactor having the effect of changing the turns ratio of this winding of the Horizontal Output and H.V. Transformer (T6).

HEIGHT — This control is a voltage dropping rheostat operating in the plate circuit of the Vertical Sweep Oscillator (V8B). It changes the voltage delivered to (V-12) Vertical Amplifier feeding current to transformer coupled Vertical Yoke Coil (L13A). Since changes in height will affect picture linearity, this Height Control must be adjusted in conjunction with Vertical Linearity Control.

VERTICAL LINEARITY CONTROL — This is a variable resistor control (R69) in the cathode of (V-12) which provides inverse feedback variation affecting the linearity of the Vertical Sweep Wave form. To be adjusted as height control is adjusted.

FOCUS CONTROL — This is a Variable Resistor (R80) which varies the current through focus coil (L-12).

HORIZONTAL AND VERTICAL CENTERING — Centering of the picture area is accomplished in this receiver by finding that position for the focus coil in the horizontal and vertical planes that produces this result. The focus coil bracket is adjusted so that if the four hexagon-head screws are loosened it can be shifted up and down and from side to side enabling the centering position to be found by trial.

BRIEF CIRCUIT ANALYSIS

The Tele-tone Television receivers Models, TV 300, 301, 304 and 305 use the Intercarrier sound systems. In this system the RF section of the receiver receives both the picture and the sound carriers which are converted by the mixer (V19) and then fed into the IF. No separation takes place until after the Video Amplifier (V9). At this point the sound component of the dual signal is picked off by the 4.5 trap (T1) and fed through the Ratio Detector, the sound Amplifier and the Audio output stages. The Picture IF frequency is 37.3 Mc and the Sound IF is 32.8. For individual stage frequencies see "Video IF Alignment". (Page 7).

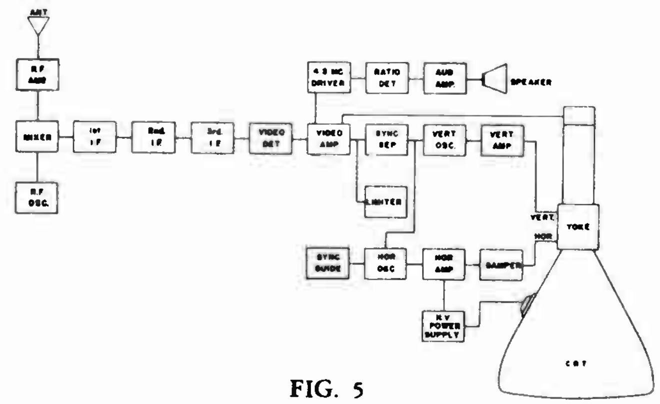

FIG. 5

TUNER — In the initial runs of this model a 12 coil tuner, much the same as previous Tele-tone tuners is used. In later runs a new type 7 coil tuner is employed. The terms "12 coil" and "7 coil" refer to the variable oscillator coils only. The RF and Mixer sections remain essentially the same.

RF AMPLIFIER — The antenna is fed between cathode and grid of the grounded grid RF amplifier (V-20). The input circuits of which are untuned. Double tuned interstage coupling is used between the plate of the RF Amplifier (V-20) and the grid of the mixer (V-19). Mechanically, the series inductances used take the form of several individual coils which are cut in or out of their respective circuits by means of the band switch. These coils will rarely need adjustment.

MIXER — The output of the RF Amplifier (V-20) and the Local Oscillator are condenser fed into the Control Grid Mixer Stage (V-19). This circuit is tuned in much the same manner as the output of the RF Amplifier, previously described.

OSCILLATOR—12 COIL TUNER—The RF Oscillator (V-18) is fairly straight-forward in operation. Its main peculiarity is that the coil for Channel 2 is permanently parallel to all other Oscillator coils from 3 to 13. It is therefore necessary, when aligning the oscillators to ALIGN CHANNEL 2 FIRST and the rest of the coils in any order thereafter. They are tuned by brass slugs accessible through two slots in the front of the receiver chassis. Channel 2 is found at the top of the right hand slot and the others follow in regular order in a clockwise direction finishing with Channel 13 at the top of the left hand slot.

OSCILLATOR—7 COIL TUNER—As stated above, in later runs of these models a new type, 7 coil tuner is employed. In these tuners the only change is in the arrangement of the Oscillator coils. Where, previously, 12 individual coils were used (one for each channel) 7 coils are now substituted. The coils for Channels 2 and 13 will remain substantially as before. The other channels will be paired with one variable and two small fixed coils, as shown in Fig. 6B. Typically, channels 3 and 4 have only one adjustment. This adjustment may be made on either station and the other will be found to be properly tuned. Any slight variations will be more than compensated for by the fine tuner. A study of Fig. 6B will show that, as previously, channel two must be tuned first, if at all, and the remaining channels in any order thereafter. The seven adjustments are for the following groups of channels; — Channel 2 — Channels 3 and 4 — Channels 5 and 6 — Channels 7 and 8 — Channels 9 and 10 — Channels 11 and 12 — Channel 13.

NOTE: The channel numbers on the escutcheon do not correspond to the location of the oscillator coils.

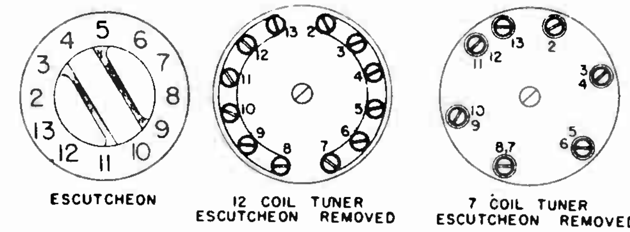

FIG. 6A

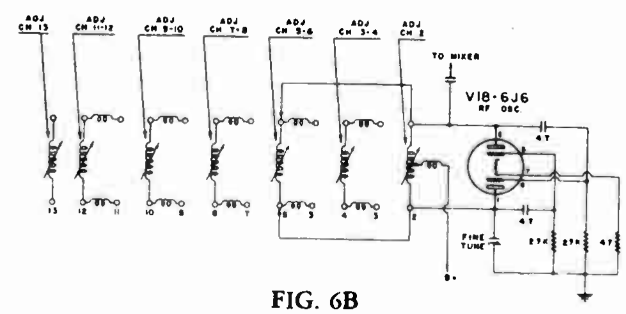

FIG. 6B

VIDEO IF — Each Video IF transformer has only one adjustment, a powdered iron slug accessible from the top of the chassis. The Video IF String is stagger tuned to two frequencies. The first and third IF transformers are tuned to 34.8 Megacycles and the second and fourth are tuned to 36.9 Megacycles. The response curve is fairly flat topped and should produce a picture with good definition.

World Radio History

VIDEO AMPLIFIERS — FIRST AND SECOND — A 12AU7 (V-9), dual triode is used in this section of the receiver. The output of the detector is fed to the grid of the first section (pin 2) and ultimately taken off plate of the second section of the tube (pin 6). It is at this point the three basic components of the received signal are separated and fed to their respective circuits. The picture intelligence is fed to the grid of the Picture Tube (V-21) and the synchronization pulses to the grid (pin 1) of the Sync Separator (V-11) and from there to the Horizontal (V-14) and Vertical oscillators (V-8B), also see "Sound System" below.

D. C. COMPONENTS — The D.C. component of the transmitted signal (which controls the background brightness) is substantially duplicated in the receiver by direct coupling from the plate of the second video amplifier to the Picture Tube grid.

SOUND SYSTEM — The sound Carrier is taken off the plate of the Video Amplifier (V-9) by a 4.5 Megacycle trap and fed through a 4.5 MC Amplifier (V-1) to the Ratio Detector (V-2), and then to the sound amplifier (V-4), audio output (V-3) and speaker.

SWEEP SYSTEM — VERTICAL — The triode section of a 6BF6 (V8B) serves as the Vertical oscillator and discharge tube. A 6V6 (V12) is utilized as the Vertical Sweep Amplifier. The plate circuit of the 6V6 (V12) is transformer coupled to the vertical windings of the Deflection Yoke (L13-A).

SWEEP SYSTEM — HORIZONTAL — The Horizontal Oscillator is essentially of the Blocking Oscillator type. The operation of the AFC system depends upon a correcting voltage developed in the control tube when the oscillator output and the incoming pulses differ in either phase or frequency. The control tube, first section (V-14), is maintained at cut-off until such time as the sync pulse is either ahead of or behind the oscillator, (second section V-14), sawtooth peak. When either case occurs the control tube develops a voltage which is applied as a bias to the oscillator grid and alters the oscillator frequency to coincide with the frequency of the incoming pulses. The horizontal oscillator transformer has an adjustable core which is a coarse control of the oscillator frequency. The Horizontal Frequency Control (rear) is a fine adjustment in the same sense. The front panel Horizontal Hold Control permits slight adjustment of the frequency by adjusting the B voltage applied to the control tube plate. The Horizontal Locking Range Control affects the sensitivity of the control tube thus varying the range over which the AFC circuit will function.

NOTE: Many of the components in the Horizontal circuits are of the critical value and therefore should only be replaced by the exact replacement part. Care should also be taken in dressing leads and parts when replaced. This can be accomplished by carefully noting parts positions before removal. For complete alignment procedure on these circuits see page (9).

A.G.C. — The receiver uses an AGC circuit operating on the first 2 IF stages (V-5) (V-6). While it is quite effective in most locations, the receiver may overload in regions of very high field intensity. The contrast can generally be adjusted for a normal picture under such conditions but spurious beats, jagged vertical lines (i.e. poor resolution) and a "Moire" pattern may appear. These effects can be eliminated by the use of a resistor network of 3 to 10 db attenuation in series with the antenna lead at the point where it is connected to the receiver.

HIGH VOLTAGE POWER SUPPLY — The energy stored in the horizontal windings of the deflection yoke during the forward sweep produces high voltage surges during retrace. This is "stepped up" by the "auto-transformer" winding of the horizontal output transformer (T-6) and then rectified by a 1B3/8016 (V-13) to provide approximately 12,000 volts for the picture tube (V-21) anode.*

B VOLTAGE POWER SUPPLY — The B Supply of these models utilizes a standard type of transformer-rectifier circuit. It should be noted that the transformer contains a separate filament winding (6.3 volts) to heat the Cathode Ray Tube (V21) and the Damper (V16). The use of a center-grounded bleeder network provides a B Supply with the following voltages measured with respect to ground; plus 235 volts, plus 140 volts, plus 4 volts, minus 3.5 volts, minus 14 volts, and minus 90 volts.

ALIGNMENT PROCEDURE

The alignment of this Receiver can be broken down into three basic parts: 1 — Video IF Alignment 2 — RF Alignment 3 — Sound Alignment

TEST EQUIPMENT

CATHODE RAY OSCILLOSCOPE — The tube size is relatively unimportant, however, anything under 5" usually makes fine adjustment quite difficult.

SWEEP GENERATOR — The sweep generator used should have linear coverage of a center range from 30 to 220 megacycles. The output should be fairly flat over wide frequency variation of the sweep. It should be capable of an output of about 0.1 volt with attenuation. It is preferable that the generator have a deflection output for the test oscilloscope.

AM SIGNAL GENERATOR — This generator should have a frequency range of from 4.5 to 220 megacycles. As this generator is used occasionally as a marker generator, accuracy is an important factor. It should be capable of 0.1 volt output with attenuation and should be linear through the range.

VACUUM TUBE VOLTMETER — Almost any standard make VTVM will do. It should preferably have a reversible polarity switch.

*11,500V in the TV 307

TEST SOCKET

In each of these models a Test Socket is provided which gives convenient access to the various points where either a vacuum tube voltmeter or an oscilloscope must be inserted for proper alignment. A letter diagram in the margin of the schematic will locate these points by means of corresponding letters in the schematic proper. A typical Octal socket is used and it should be noted that the diagram shows an UNDERSIDE VIEW. Two ground points are supplied on separate pins of the test socket for easy metering. Reference is made, in the following Alignment Procedures, to the pins on this Test Socket.

VIDEO IF ALIGNMENT

An adequate signal can be fed through the video IF string by feeding the output of the signal generator into a tube shield placed over the mixer tube (6AG5) (V-19). Care should be taken that this shield is NOT grounded. The ground side of the generator output can be conveniently grounded to the shield of the adjacent oscillator tube.

The contrast control should be set to produce minus 2 volts on Pin 7 6AL5-AGC tube. (V-10A).

The vacuum tube voltmeter should be connected across the 8200 ohm detector load resistor (Pin B Test Socket) and should be set on the minus 3 Volt scale. Set channel selector to an unused low band channel.

The Signal generator should be set to a frequency of 34.8 Mc. The output of the generator should be adjusted to the point where the reading on the VTVM is between minus 1 to minus 1.5 volts.

The First and Third I.F. coils should be peaked for a maximum reading on the VTVM. As the voltage reading increases with tuning, the generator should be attenuated to maintain a maximum of minus 1.5 volts.

Set the Signal Generator to a Frequency of 36.9 Mc and tune the Second and Fourth I.F. coils in the same manner as above.

The Generator should now be shut off (or tuned to different band) and the VTVM should read no more than minus 0.20 volts. If there is a higher voltage reading, check for regeneration in the I.F. stages.

By shunting the signal generator with a sweep generator (30 to 40 Mc) and substituting a Cathode Ray Oscilloscope for the Vacuum tube Voltmeter in the above procedure the actual pass band of the Video I.F. circuits may be studied. Ideally the response curve should appear on the face of the oscilloscope in the form indicated in Figure (7). A slight slope of the top of the curve in either direction or a small dip in the center are acceptable.

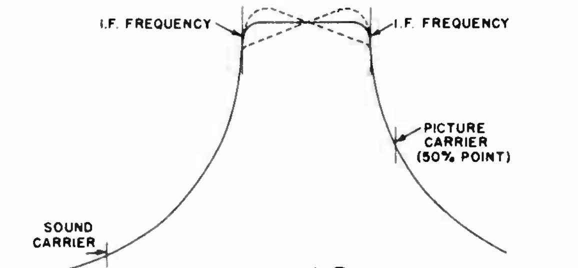

FIG. 7

RF ALIGNMENT

In the alignment of the RF section of this receiver three pieces of test equipment are necessary. A sweep generator, a signal generator and a cathode Ray Oscilloscope. For specifications see "Test Equipment" above.

The output of the Sweep Generator should be fed into the antenna. The signal generator (C.W.) should be connected to the antenna terminals of the receiver. The sweeper will provide the overall response curve with the oscilloscope properly connected. The signal generator is used as a marker as described below. Some Sweep generators made today contain their own marker oscillator. In cases where a generator of this type is used the Signal Generator may be eliminated.

The "hot" or "high" side of the Oscilloscope input should be connected to the junction point of the 8200 ohm detector load resistor and the peaking coil. (Pin B Test Socket). The "low" or ground side should be connected to the nearest convenient ground point. Care should be taken that the generator and the scope leads are well separated to avoid regeneration.

The R.F. section of the receiver is tuned channel by channel. The proper frequency settings for any given channel can be determined by consulting the Frequency Chart on Page (2). For example in aligning channel 2 the sweep generator should be set to some mid frequency between 54 and 60 megacycles. This adjustment is not a fine one. After setting the sweeper in the general vicinity of the desired frequency it should be tuned to center the response curve on the Oscilloscope face. For picture and sound markers the signal generator should carefully be adjusted to the frequencies indicated in the Frequency chart. For example in the case of channel 2 the picture marker frequency is 55.25 Mc. and the Sound 59.75 Mc.

It is important to note at this point that the oscillator coil for channel 2 is in parallel with every other oscillator coil from 3 to 13. It is therefor imperative that channel 2 be aligned first and the others in any desired order thereafter.

Starting with channel 2 and applying the proper frequencies as indicated above, the output of the sweeper should be attenuated to the point where further attenuation will not affect the wave shape.

©John F. Rider

World Radio History

The Oscillator should then be adjusted to bring the sound carrier into the 32.8 Mc trap valley. With the oscillator so adjusted the picture carrier should fall at a point approximately 50% up on the slope of the opposite side of the band pass curve. Certain variations in the waveshape and the location of the picture carrier are acceptable. The picture carrier may vary in position from a point between 45% and 60% of the slope and the overall waveshape may differ from the ideal, flat-topped response by being either slightly rounded or slightly dipped in the center. See Figure (8).

If the position of the picture carrier varies beyond the 45% to 60% points on all channels correction may be made by turning to channel 6, applying the proper input signals and slightly realigning the I.F. transformers.

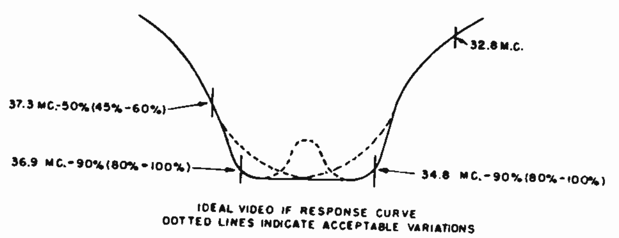

FIG. 8

SOUND ALIGNMENT

Sound alignment on these receivers is best accomplished by using an actual transmission received on an antenna and fed in the normal manner to the antenna terminals. A Vacuum Tube Voltmeter should first be inserted between the output plate of the Ratio Detector Diode (pin 2 V2) and ground. This point may be reached through pin C of the Test Socket. The meter should be set on the *minus* 10 volt scale. With the equipment so placed the 4.5 Mc trap (T1) and the primary of the Ratio Detector Transformer (bottom adjustment, T2) should be adjusted for a maximum deflection of the meter. The hot lead of the meter should now be moved to the junction point of R19, C22 and C23 (Pin A Test Socket), and the secondary of the Ratio Detector Transformer should be adjusted for a *ZERO* reading. (Note: There are 3 points at which the meter will zero. Only one of these is correct. At the proper setting the meter should swing negative on one side and positive on the other side of zero). In cases where it is necessary to align the sound section when no station transmission is available a Single frequency signal generator tuned to 4.5 megacycles may be fed into the output circuit of the Video Detector (Pin B Test Socket). The receiver should then be aligned in the same manner as described above. The disadvantage of this method is that any inaccuracy in your signal generator will show up as misalignment when the set is in actual operation, since proper adjustment is very critical.

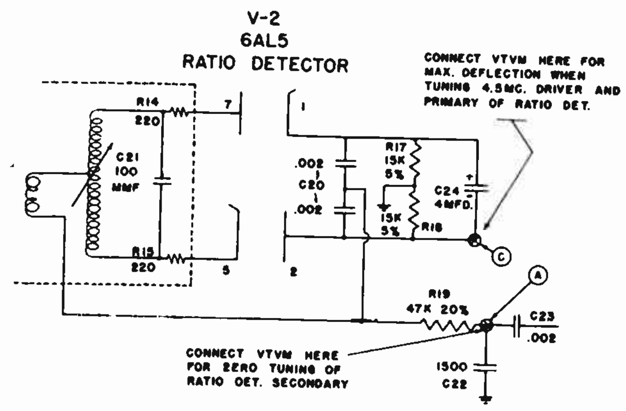

FIG. 9A

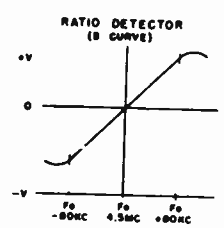

FIG. 9B

PICTURE ADJUSTMENTS

ION TRAP, FOCUS AND YOKE

To properly adjust the Ion Trap, Focusing coil and the Deflection Yoke the following procedure should be followed.

The Deflection Yoke should be placed in position closest to the "bell" of the Picture Tube as far forward on the neck of the tube as is possible. Be sure the wire loops on the mounting make positive contact with the coating of the picture tube. The Focus Coil is next in line and the Ion Trap last.

Turn the set on. The antenna should NOT be connected to the receiver and the picture contrast control should be set at MINIMUM.

With the brilliance control set at about one-quarter turn back from maximum, the Ion trap should be adjusted to achieve the brightest raster on the face of the Picture Tube. Trap should be simultaneously rotated and moved back and forth on the neck of tube until exact setting is obtained.

Adjust the brilliance control to a point slightly over normal brightness and adjust the Focus Control on the rear of the chassis for clearest and sharpest horizontal sweep lines. The Ion Trap should then be readjusted slightly for the brightest response on the face of the tube at which good focus is maintained.

The focus Coil itself should be moved to secure a complete raster, approximately centered and with no corners cut off.

Finally the Deflection Yoke should be rotated to "square" the raster with the chassis as a reference. The thumb screws on the yoke brackets should then be set.

HORIZONTAL OSCILLATOR ALIGNMENT

To adjust the Horizontal oscillator and its control circuits it is necessary to first connect a working antenna to the receiver. It is preferable to use a test pattern as the incoming signal rather than a picture.

With the receiver turned on and the brightness and the picture contrast controls adjusted to a normal position the Horizontal Frequency trimmer and the Horizontal Locking trimmer (rear of chassis) should be turned clockwise all the way and then backed off to about one turn (counter-clockwise).

The Horizontal Hold Control (front panel) should be turned to a maximum clockwise position.

The core of the Horizontal Oscillator Transformer should then be adjusted. Variation of this core will cause the pattern to resolve into a series of black and white bars sloping either to the right or the left depending upon the degree of adjustment. The transformer should be adjusted to the point where the picture resolves into a series of from 3½ to 4½ bars sloping downwards to the right.

The Horizontal Hold Control (front panel) should now be rotated to a full counter-clockwise position and the incoming signal momentarily interrupted. This can be done most easily by shorting the antenna terminals for a moment.

The Horizontal Hold Control (front panel) should now be rotated slowly in a clockwise direction. As the control is turned the number of bars sloping downward to the left should decrease. At approximately 90 degrees of rotation there should remain, between 3½ and 4½ bars just prior to the time that the picture "falls into" sync. The picture should remain in sync for an additional 90 degrees of rotation. If MORE than 4½ bars are evident just before the picture syncs the Horizontal Locking Range trimmer (rear of Chassis) should be tightened slightly. If LESS than 3½ bars the same trimmer should be loosened.

HEIGHT, WIDTH AND LINEARITY

To adjust the overall size and linearity of the picture it is almost mandatory that a pattern transmitted from a local station be used. Linearity adjustments, particularly, cannot be accurately made on moving transmissions. It should also be remembered that in areas where more than one station is being received, that pictures transmitted from different stations will vary slightly in size. The smallest transmitted picture should be made to fill the area delineated by the mask.

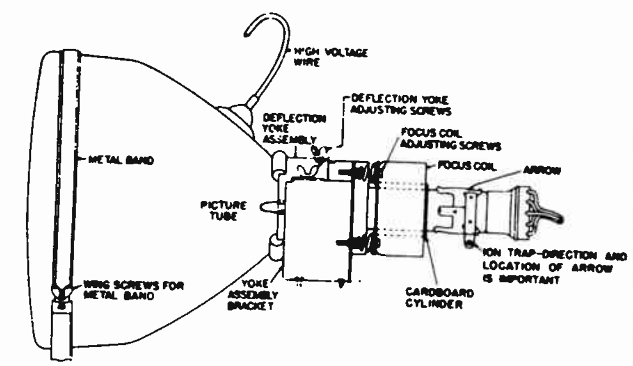

FIG. 10

The first step in linearity and size adjustment is to turn the Width control (rear of chassis Figure 4) all the way in (clockwise).

The Horizontal Drive trimmer should then be adjusted for the best compromise between maximum brightness and good horizontal linearity. This control will affect the left side of the picture primarily. The Horizontal Linearity control (top rear of chassis) should then be adjusted for linearity of the right side of the picture.

The Width Control should now be readjusted to achieve a picture that will fill the mask horizontally. If necessary the width coil may be removed entirely by use of a switch on rear of chassis.

The Height and Vertical Linearity controls (both rear of chassis) should then be adjusted for a linear picture that will fill the mask vertically.

Picture centering is accomplished by positioning focus coil mechanically by means of 4 hexagon-head adjusting screws accessible from rear of chassis as shown in Figure (10). At this point the Focus control, previously set, should be retouched for maximum definition of the lines in the vertical wedge of the test pattern. Proper adjustment and alignment of the receiver should result in clear and sharp definition.

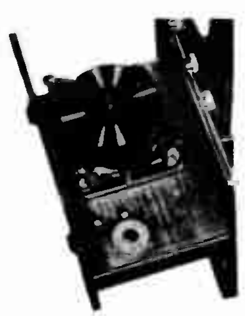

FIG. 11

DESCRIPTION

The Model TV 316B includes the TELE-TONE TV 316 Televison receiver and the automatic Radio-Phono Base which is designed as a stand for this receiver. The two units can be used separately if desired.

TELEVISION SPECIFICATIONS

CHASSIS DESCRIPTION

TZ CHASSIS

POWER SUPPLY
105 to 125 Volts - 60 Cycle AC

POWER CONSUMPTION
220 Watts

POWER OUTPUT (AUDIO)
2 Watts (undistorted)

INPUT IMPEDANCE
300 or 72 Ohms

PICTURE TUBE SIZE
16" Rectangular

SPEAKER
4" x 6" PM OVAL

DIMENSIONS
18-1/4" Deep
23" Wide
18-1/4" High

SHIPPING WEIGHT
Approx. 92 Lbs.

TUBE COMPLEMENT

1.	6J6	V20	RF Amplifier
2.	6AG5	V19	Mixer
3.	6J6	V18	RF Oscillator
4.	6AG5	V5	1st Video IF Amplifier
5.	6AG5	V6	2nd Video IF Amplifier
6.	6AG5	V7	3rd Video IF Amplifier
7.	6AL5	V10-A	Video Detector
		V10-B	A.G.C.
8.	12AU7	V9	1st and 2nd Video Amplifier
9.	6AU6	V1	4.5 Mc. Amplifier
10.	6AL5	V2	Ratio Detector
11.	6AT6	V4	1st Audio Amplifier
12.	6K6	V3	Audio Output
13.	6SN7	V11	Sync Separator
14.	6BF6	V8-A	Limiter
		V8-B	Vertical Sweep Oscillator
15.	6V6	V12	Vertical Sweep Amplifier
16.	6SN7	V14	Horizontal Sweep Oscillator and Sync Guide
17.	6BG6	V15	Horizontal Sweep Output
18.	6W4	V16	Damper
19.	1B3	V13	High Voltage Rectifier
20.	5U4	V17	Power Rectifier
21.	16TP4	V21	Picture Tube TV 306

RADIO SPECIFICATIONS

RADIO CHASSIS
BN (with built-in loop antenna)

IF FREQUENCY
455 Kc

FREQUENCY RANGE
532 Kc - 1620 Kc

(SEE PARTS LIST ON PAGE 4)

TUBE COMPLEMENT

1.	R.F. OSC.	12BE6
2.	I.F. AMP.	12BA6
3.	DET.-AGC	12SQ7
4.	AUDIO AMP.	50L6
5.	RECTIFIER	35Z5

RECORD CHANGER SPECIFICATIONS

MODEL
V-M 406 3-SPEED TRI-O-MATIC CHANGER

POWER SUPPLY
105 - 125 Volts 60 Cycle AC

FEATURES
Plays and automatically changes as many as ten 12", twelve 10" or any assortment of 10 records intermixed.
Plays a full stack of twelve 7", 33-1/3 RPM or a full stack of twelve 7", 45 RPM records (with adapter inserted in the record).

RADIO PHONO BASE SPECIFICATIONS

DIMENSIONS
24-1/2" Wide, 18-1/2" Deep, 23-1/2" High

SHIPPING WEIGHT
62 Lbs.

ALIGNMENT PROCEDURE FOR MODEL 1621W

PART #1
Tools required:
1. Vacuum Tube Volt Meter (similer to RCA 75A)
2. Sweep Generator with marker (similar to Philco 7008)
3. Scope (similar to Philco 7008)
4. Insulated Screwdriver

PART#2

1. Connect all associated components of T.V. receiver together, making sure speaker plug is making good contact.
2. Set contrast control in full counter-clockwise position and brilliance control to full clockwise position.
3. Adjust Ion Trap (Beam Bender) for brightest raster.

PART #3 Front End Alignment
1. Set contrast to 1.5 volts negative. The terminals at which you take your reading are in the rear of the front end.
2. Setting channel selector at channel #12, connect sweep generator to antenna terminals and set marker generator for 204.0Mc to 210.0Mc.
3. Connect scope with 10k ohm resistor in series with hot lead to #1 of Fig. 1.
4. Adjust peaks for symmetrical waveform at 204.0Mc and 210.0Mc.
5. Adjust screws 2 and 4 for 204.0Mc and 210.0Mc.
6. Adjust screw 5 for symmetrical waveform.

PART #4 Video Alignment
1. Remove all test leads from set and set channel selector switch between any two channels. Set contrast so that you do not distort waveform when aligning Video I.F..
2. Connect sweep generator to pin #4 of 3rd I.F. (6AC7) and ground.
3. Connect scope to point "A" and "B" of Fig. 3. The hot side of scope connect to "A". Ground of scope connect to "B". Adjust video coil between 6AC7 and 6AL5 for 26.0Mc. Remove sweep lead and connect to pin #4 of preceding 6AC7, adjusting coil between these two 6AC7 tubes for 23.5Mc. Remove sweep lead and connect to pin #1 of 6AG5, adjusting video coil between 6AG5 and 6AC7 tubes for 26.0Mc. Connect sweep lead to shield of 6J6 tube in front end, taking care that shield does not touch chassis. Align top slug of converter can for waveform, as shown in Fig. 4.

PART #5 Sound Alignment
1. Remove all test leads. Connect VTVM for 10 volt scale with selector switch set at positive. Take hot leed of VTVM and connect to pin #1 of discriminator tube (6AL5). Connect coil lead to pin #2 of same tube.
2. Connect signal generator to points "A" and "B" in Fig. 3, setting generator for 4.5Mc.
3. Adjust top and bottom slugs of sound take-off for maximum voltage readings.
4. Remove VTVM leads and connect VTVM leads between points "A" and ground, as shown in Fig. 5. Set VTVM at zero center.
5. Adjust bottom slug of discriminator transformer for maximum positive or negative voltage.
6. Adjust top slug for zero center.

PART #6 Final Check
1. Remove all test leads and connect antenna to antenna posts.
2. Set controls for best picture.
3. Adjust Ion Trap for brightest picture without shadows.
4. Put fine tuning control in center and take insulated screwdriver and insert in hole next to channel selector and adjust for best picture on all channels, being careful to remove insulated screwdriver when switching from channel to channel.

PART #7
1. Using 10v. scale on VTVM, connect hot lead to pin #5 of 6BG6G and cold lead to pin #6 of 6SN7GT, Hor. Block. Osc.
2. Adjust trimmer on pin #5 of 6BG6G in conjunction with Hor. drive control (part #17), in maximum counter-clockwise position.
3. Voltage should not read more than 10 volts with proper setting of Trimmer Cond.
4. Then adjust Hor. drive Control so that this voltage reads between 4-5 volts with proper width on Cathode-Ray Tube.
5. This Trimmer Cond. should never again need re-setting unless circuit constants are changed.

SERVICE NOTES
MODEL A CHASSIS

ALIGNMENT PROCEDURE

If turning on the set for the first time check all controls front and rear to be sure they are not more than half advanced in the clockwise direction, with the exception of the brightness control which should be turned towards the OFF position and the volume control which may be adjusted to give a comfortable volume level.

The brightness and contrast controls also operate a switch at the counter clockwise end. Be sure that these switches are not in the OFF position before attempting the following adjustments.

Adjust the brightness control and ion trap. The ion trap should be adjusted for maximum light output in the picture tube.
Set the station selector to the desired channel, the strongest and most reliable station in your locality should be used.
Advance the contrast control until a picture or horizontal streaks appear.
If picture frame is in motion or if it tears, synchronize it by adjusting the horizontal hold or vertical hold controls. rols.
Adjust the focus control for best focus.
Adjust the fine tuner or the tuner on deluxe models for best picture.
After the picture has been locked, adjust the height control and vertical linearity controls for proper picture proportion.
Adjust the horizontal linearity control, horizontal linearity coil, and horizontal drive control for proper horizontal linearity.
Again check the focus control for best definition of the vertical wedges of a test pattern.

I.F. ADJUSTMENT

Observe carefully the resolution of the vertical wedges and other fine detail. In the case of the deluxe model, rotate the tuner in the clockwise direction very slowly, meanwhile watching for a noticeable brightening of the picture accompanied by sharp resolution of the vertical wedge. In either case, when the sharpest detail has been achieved, desist from further tuning and do not again adjust either the sound sensitivity control or the tuner until all other adjustments have been made.

On both types of tuners the adjustment on the top of the tuner should be set to about 25.75 Mc, or for a maximum of picture (dim picture). The other slug coil on the tuner plate should be set to about 22 mc or for a high level of sound.

The tuner adjustment may be made by observing the AGC voltage on a VTVM with a received signal and setting the coil to a frequency just slightly below that which gives a maximum on the meter.

ALIGNMENT OF SOUND IF AND DETECTOR TRANSFORMERS

Turn volume control full on. A slight hiss only may be heard. Adjust top and bottom slug of can #317 for maximum sound output and minimum distortion. A dip on either side of peak indicates proper operation.

Connect a high resistance D.C. Voltmeter between the AVC line and ground.

Adjust the trap on transformer #175 for maximum deflection of meter.

Adjust first the top slug and then the bottom slug of transformer #319 for maximum deflection of the meter.

Recheck the adjustment of the top and bottom slug of sound detector transformer #317 at low volume. This is a critical adjustment.

Tighten trimmer of video I.F. trap on transformer #174 and back off slightly for best picture. Look for a decrease and final elimination of sound bars, beads, dark streaks and striations from the picture.

AUTOMATIC GAIN CONTROL

The A.G.C. in this set consists of a filter network after the video detector and individual decoupling filters to supply the A.G.C. voltage to the tuner, the 6AG5 and the first two 6AC7 video I.F. amplifiers.

In the event that the A.G.C. does not function, trouble may be expected in a defective 2.2 meg resistor or 0.1 condenser, or defective tubes V-22, V-1 or V-7.

Under extreme strong signal conditions, the deluxe set may develop a slight buzz in the sound which is the result of an overload in the tuner. Padding of the antenna to reduce the signal to the set will help in this condition.

A.F.C. CIRCUIT

PRINCIPLE OF OPERATION:

The TRANSVISION A.F.C. CIRCUIT is basicly a phase converter for converting the phase difference between the incoming horizontal sync pulse and the horizontal flyback pulse to D.C. of the correct polarity and applying this voltage to control the frequency of the horizontal oscillator.

The TRANSVISION set uses a conventional blocking oscillator in the horizontal circuit. The frequency is controlled by the time constant of the grid blocking condenser and the grid resistor. In the A.F.C. circuit an additional element of control has been added. This is the bias voltage applied by the cathode follower to the bottom end of the grid resistor and is derived from the A.F.C. converter.

With no signal input, it should be possible to go completely through the hold frequency by turning the hold control end to end. The frequency range should roughly be from 10,000 to 20,000 cycles.

A rough check can be made by watching the size or width of the raster. A frequency too high will give a small dim raster. A frequency too low will give a wide bright raster and may be accompanied by an audible whistle from the horizontal transformer.

A-If the voltage reading is different from the normal reading; check the following:
1. 6AL5 Tube
2. 100K resistors connected to pins 5 & 7 of 6AL5 tube.
3. Peaking coil (#77) for continuity, approximately 50 ohms.
4. 47K 2 watt resistor from 6X5 tube plates and .001 condenser to pins 1 & 2 of 6AL5 tube.
5. 500 mmfd condenser from the junction of 47k & .001 to pins 5 & 7 of 6AL5 tube.

If sync is erratic or unstable, but the hold control can obviously carry sweep frequency either side of sync, the trouble will be with the 6AL5 tube or its associated-circuits.

B- Severe hacking at the edges of the picture and sharp displacement of sections of the picture may be caused by one of the following:
1. Defective 6RG6G tube.
2. Open .01 condenser.

C- Picture locks good but wavers or is unsteady:
1. Picture getting into sync., see poor synchronizing instructions.
2. Standard and deluxe sets - Interaction between horizontal output leads and other circuits. Dress both leads to the horizontal hold control well away from all other leads. They may be pulled away from the chassis and run directly to hold control.

D- Picture locks good but jumps out of sync with change of contrast control.
1. Poor limiting action in sync amplifiers. Check sync tubes, grid and plate resistors for value and coupling condensers for leakage.
2. Unbalance to sync input diodes. Check plate and cathode resistors of sync output circuit (phase inverter).
3. Check values of sync coupling condensers .0005.
4. Check diode resistor 100K.
5. Check 6AL5 tube.

E- Fold over on right side of picture.
1. May be caused by poor adjustment at transmitter. Check on other stations. Defective 6BG6G tube.
2. Too much inductance in diode output filter coil, unscrew slug a few turns.
3. Open output filter coil on 6AL5 tube PC3.

F- Lateral ripples at top of picture or large lateral waves in picture. Standard or Deluxe.
Off-value 4700 ohm resistor or 0.1 mfd condenser.

G- Slow sync recovery when changing stations.
1. Improver adjustment of hold control.
2. Re-adjust hold control after set has been running about an hour. Turn hold control till sync is lost on low frequency side, (large bright raster) then turn control back slowly till picture locks. Do not try to center control.

H- Sync locks at half frame or with black vertical bars some place in middle of screen.
1. Output filter coil slug out too far.
2. Shorted filter coil.

VERTICAL SYNC AND SWEEP CIRCUITS
Insufficient or erratic

Check for:

1 - Tubes V20, V21
2 - Voltages on above tubes
3 - All condensers and resistors used in above tube circuits
4 - Vertical oscillator and output transformers
5 - Vertical yoke winding
6 - Vertical, size, linearity and hold controls

HORIZONTAL SYNC CIRCUITS
Insufficient or erratic

1 - Tubes V11, V12, V13, V14
2 - Voltages on above tubes
3 - Condensers, resistors and slug coils in above circuits
4 - Horizontal oscillator transformer
5 - Horizontal size, linearity and hold controls

HORIZONTAL SWEEP CIRCUITS
Insufficient or erratic

1 - Tubes V14, V15, V16, V17
2 - Voltages on above tubes
3 - Condensers and resistors in above circuits
4 - Horizontal oscillator transformer #307 and horizontal output transformer #1279
5 - Horizontal linearity coil slug
6 - Horizontal linearity, size, and hold controls.

World Radio History

SOUND AND PICTURE CIRCUITS

Picture OK - No Sound
Check for: -
1 - Check tubes V2, V3, V4, V5, V6
2 - Voltages on the above tubes
3 - All condensers and resistors in the above tube circuits
4 - I.F. Transformers #175, #317, and #318
5 - Audio output transformer, part #21
6 - Speaker
7 - Shorts in shielded leads
8 - Open volume control or defective switch section on phono-contrast switch

No Picture - Sound OK
1 - Tubes V7, V8, V9, V10
2 - Voltages on the above tubes
3 - All condensers and resistors in the above tube circuits
4 - All peaking coils for open circuits
5 - I.F. Transformers #174, #175. and #176
6 - Open contrast control

No picture or sound - Raster OK
1 - Tubes V1, V22 and tuner tubes
2 - Voltages on above tubes
3 - All condensers and resistors in above tube circuits
4 - All coils in above circuits
5 - Antenna system

No raster or sound
1 - Make sure set is plugged in and turned on
2 - Check fuse
3 - If fuse is open check for shorted filter condensers, CF1, CF2 and CF3
4 - Open focus coil, centering control or filter choke
5 - Tubes V18 and V19
6 - B plug voltage at output filter condenser

No raster - Sound OK
1 - Check for proper ion trap placement
2 - Tubes V10, V14, V15. V16, V17, CRT
3 - Voltages on the above tubes. CAUTION CRT 2nd anode is approximately 12K.V.
4 - Horizontal oscillator and output transformers
5 - Horizontal drive, Horizontal size and brightness controls
6 - Condensers and resistors on tubes V14,V15,V16,V17, V10
7 - Open yoke or linearity coil
8 - Opne HV fuse

MISCELLANEOUS

Poor high voltage regulation is evident by varying the brightness control which causes the screen to become very dim or extinguished. Replace the 1B3 tube.

A hissing or cracking noise is sometimes due to arcing between the focus coil and ion trap. A short wire connected between the trap and focus coil will prevent this.

In some cases the brightness drops when the set has been placed in the cabinet. This may be due to the cup on the cabinet either becoming magnetized or distorting the magnetic field of the ion trap. Try to center the cup with reference to the axis of the tube neck or replace cup with one of non-magnetic material.

Horizontal tearing is sometimes due to break down of the resistor in series with the anode cap lead.

* Approximate. depending upon control settings
**Due to D.C. leakage in tube. This is normal.
All readings to ground with 20,000 OHM per volt meter.

IMPROPER FOCUS

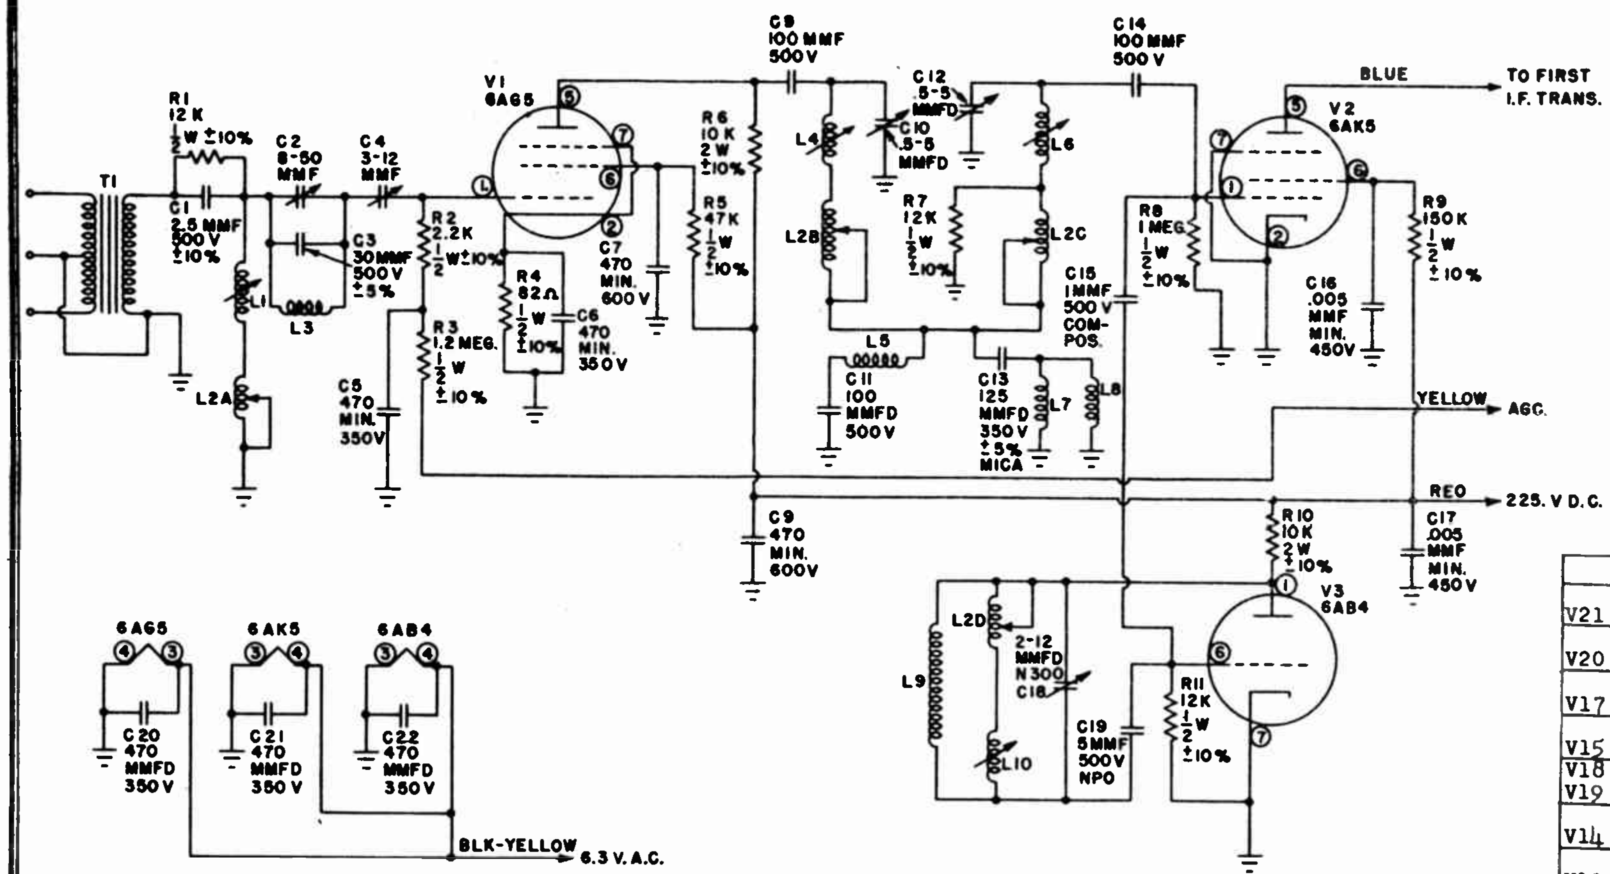
1- Check focus coil (May have shorted turn. Try substitute if in doubt)
2- Check focus control.
3- Check for leaky filter condenser, CF1, CF2, or CF3.
4- Check for correct placement of ion trap.
5- Focus coil may be set too far back on neck of cathode ray tube.

NOTES

MAKE THE FOLLOWING CHANGES:
1- On voltage chart on V17 pin 2, the reading should be 0-100 volts.
2- On resistance chart V22 pin 4, reading should be 0.1 ohms.

©John F. Rider

World Radio History



DUMONT SERIES T4A INPUTUNER

3- Certain sets may come through with type 6AG7 instead of 6AC7's in sockets V2 and V3. This change may be necessary due to shortage of type 6AC7. This change will not affect the operation of the set. The only change will take place at the point where the slug coils peak during alignment. If the 6AG7's are replaced at a future date it will be necessary to re-align the #317 - #318 transformers.

4- A few models will have a 10,000 ohm 10 watt bleeder resistor connected from B plus to ground. This is shown on the diagram directly above V10 (6AG7). Current production will not have this bleeder.

5- The B plus dropping resistor to the tuner should be 10,000 ohms 10 watts for the model TT-4 tuner and 5,000 ohms 10 watt as shown for the Deluxe model. This resistor is located on the circuit diagram directly above V11 A (6SN7).

6- Certain models may have a Bucking transformer. The windings of which will be connected in series with the 5U4 plates to decrease the voltage. If necessary to replace this unit the correct polarity must be observed.

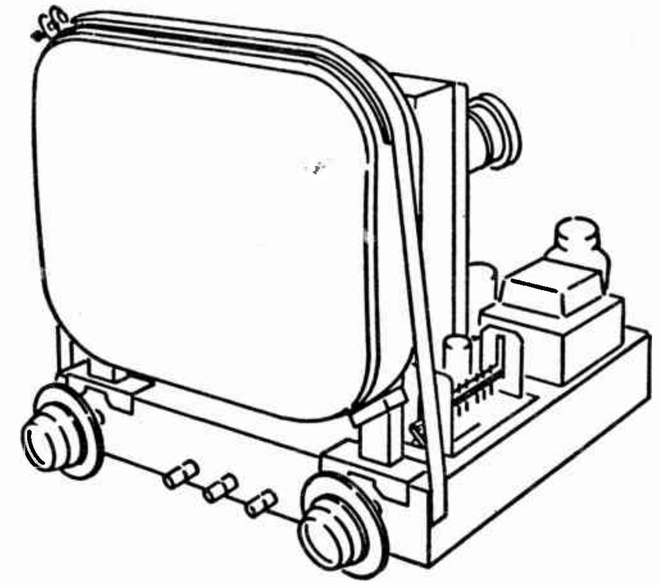
INDEX



16AY210 Television Chassis

Model 660 (BRC 16AY210)

GENERAL DESCRIPTION

The model shown above is a 22 tube, AC operated, direct view, 16-inch rectangular television receiver. The set is complete in one unit and features complete coverage of all 12 television channels, automatic gain control, automatic horizontal frequency control, intercarrier sound system, permanent magnet focused and magnetically deflected picture tube.

On the back of the cabinet is a safety interlock to prevent dangerous electrical shock. As an added safety measure, a fuse is located in the power supply to protect the set in case of overloading.

Located on the rear of the chassis are a phono input plug and phono TV switch for connection of a phonograph.

FUNCTIONS OF THE CONTROLS

All the controls normally used in tuning in a program—both picture and sound—are located on the front of the receiver and at the top of the back of the cabinet. At the rear of the set are several controls which are preset at the factory and may need slight readjustment at the time of installation. After installation, they should not be adjusted further, unless required by replacement or aging of tubes, variations in power-line voltage, or other external conditions.

The receiver actually requires only four controls when tuning in a program. On the left is a dual knob, the large knob controls picture contrast, while the small outer knob is the off-on switch and volume control. The control on the right is the station selector and the antenna tuning knob is located at the top of the back of the cabinet.

The three other controls under the name plate; brightness, horizontal hold, and vertical hold need only be adjusted periodically. The six front controls are shown below in figure 1.

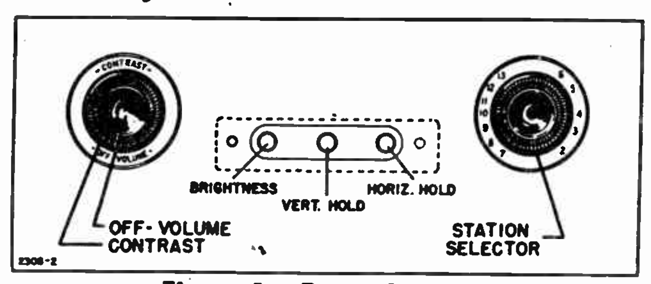


Figure 1. Front Controls

The focus and centering controls are located on the picture tube assembly (figure 2). These controls can be operated through the opening provided in the cabinet back. The remaining six controls, vertical linearity, vertical size, horizontal size, horizontal drive, horizontal linearity and coarse horizontal hold are located on the rear of the chassis (figure 3).

OPERATOR'S CONTROLS

Volume-Off — Turns set on or off and adjusts sound volume.

Contrast—Varies contrast between light and dark portions of picture.

Brightness—Controls brilliance of picture.

V. Hold—Stops picture from moving up or down.

H. Hold—Stops picture from moving left or right.

Station Selector Knob—Tunes set to desired channel (station). May be turned in either direction.

Antenna Tuning Knob—Tunes the antenna for maximum signal.

Centering—Moves entire picture both horizontally and vertically.

SERVICEMAN'S CONTROLS

V. Linearity—Provides vertical distribution of picture.

V. Size—Changes size of picture vertically. Does not affect horizontal size.

H. Size — Changes size of picture horizontally. Does not affect vertical size.

Focus—Focuses picture on face of picture tube.

H. Linearity — Provides horizontal distribution of picture.

H. Drive—Controls the drive to the Pulse Amplifier.

Coarse H. Hold — Stops picture from moving left or right.

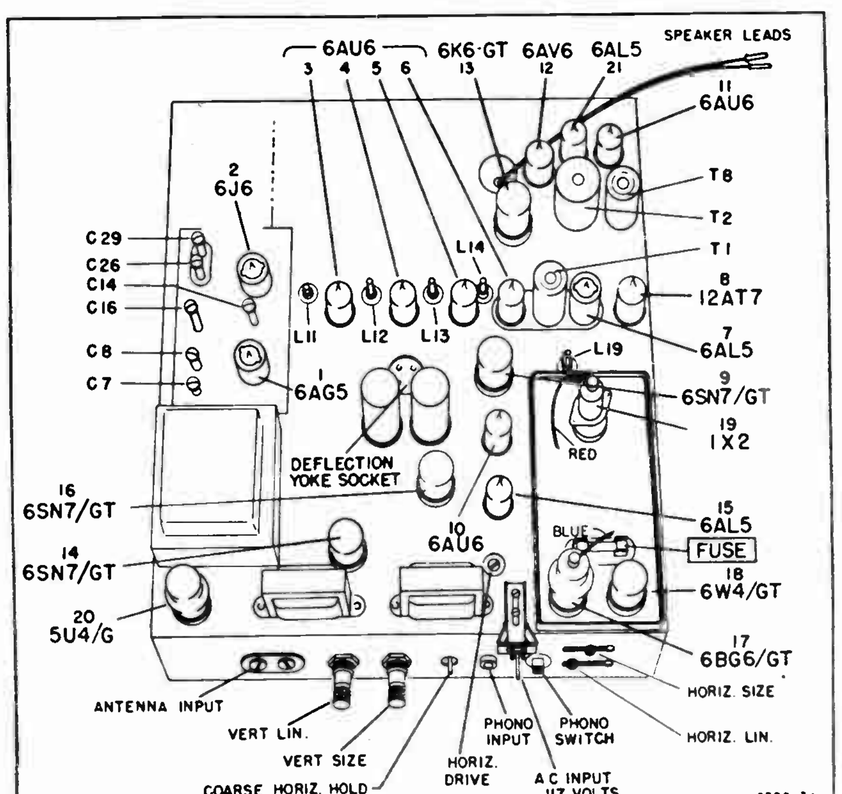

Figure 3. Tube Layout

INSTALLATION

Power Source.

The receiver should be operated from a 115 Volt, 60-Cycle A.C. power source. The power consumption is 235 watts.

Location of Receiver.

The set should be so located in the room that no direct light strikes the face of the picture tube. However, some indirect illumination in the room is desirable; it is not necessary to darken the room completely for proper viewing of the picture. Due consideration should be given also to the convenience of the electric outlet, and to the position of the receiver which gives the best reception with the built-in antenna.

Built-In Antenna.

The new Built-In Television Antenna incorporated in the receiver eliminates the need of an outside antenna in many locations. In areas too distant for normal reception with a built-in antenna, provision is made for outside antenna connections. If any other type of antenna is used with the set, disconnect the transmission line from the built-in antenna to the antenna terminals.

The antenna is mounted inside the cabinet and is operated by the use of a knob at the top of the back of the cabinet. Since the antenna is fastened to the cabinet it may be necessary to orient the cabinet to obtain the best reception. It is desirable that either the front or the back of the cabinet face the transmitting station. If however, "ghosts" or multiple images appear, the cabinet may be rotated slightly to minimize this condition. In some cases it may be necessary to face the back or the front of the cabinet toward a window to obtain a television picture. This may be due to walls, water pipes, or a steel structure in the location preventing television reception.

The antenna tuning knob should be used as a fine tuning control and should be adjusted until the best picture is obtained. In order to eliminate "Body effect" when adjusting the antenna tuning knob, stand in front and reach over the top of the set. If at any time the knob becomes difficult to turn, reverse the direction of rotation. Do not force the knob in either direction.

If the receiver fails to operate satisfactorily with the built-in antenna, check the following trouble:

1. Check the antenna dipole to make sure it is not touching the chassis or any other object.
2. Check the antenna dipole to make sure it is stapled to the side of the cabinet and does not vibrate.
3. Check the connections at the coil, transmission line, and trimmer capacitor.
4. Check to make sure that the antenna terminal screws are moderately tight.

Final Adjustments.

The television receiver has been completely assembled and adjusted for operation before shipment. It is recommended, however, that the adjustments discussed in this section be checked over at the time the set is installed.

While the required adjustments, if any, will probably be slight, the instructions may also be used for receivers which are considerably misadjusted because of replacement parts, etc.

Deflection Yoke.

If the picture seems to be tilted or the edges of the raster are not vertical, loosen the deflection coil adjusting wing nut (located at the top of the picture tube assembly, Figure 2) and using the wing nut as a handle, rotate clockwise or counter-clockwise until the edges of the raster are exactly vertical.

The correct position for the deflection yoke is as far forward on the neck of the picture tube as the shape of the tube will allow. Tube shadow may be the result of an incorrectly positioned deflection yoke.

To correctly position the yoke, loosen the wing nut and push the yoke as far forward as the tube will allow and while keeping the edges of the raster vertical tighten the wing nut.

Ion Trap Magnet.

The initial setting for the Ion trap magnet is over the "L" shape metallic flags inside the glass neck of the picture tube. See figure 2. From this starting position rotate the magnet about the neck of the tube and slide forward and backward until the position that gives maximum illumination with minimum tube shadow is found. This adjustment should be made with the brightness control set at slightly less than ½ its clockwise rotation.

If the ion trap magnet interferes with the centering control, rotate the magnet 180° and readjust for maximum illumination.

Each time an adjustment of either the centering or focus control is made, the ion trap magnet should be readjusted.

Centering.

The receiver may require centering at the time of installation. To recenter the picture follow the centering instructions on page 5.

Other Adjustments.

Refer to the "Service Adjustments" section and touch up each control following the instructions carefully.

World Radio History

SERVICE ADJUSTMENTS

Station Selector.

The station selector pointer should not rub or scrape against the channel indicator plate, and the knob should not rub against the pointer, otherwise the control may slip between channel 6 and 13. This condition can be corrected either by a fast turn or moving the pointer itself.

Brightness Control (R-46).

The brightness control located behind the front name plate need only be adjusted at the time of installation. The control is adjusted in conjunction with the contrast control. Turn the contrast control fully counter-clockwise. Then turn the brightness control clockwise until the picture tube just becomes dark. The contrast control may then be adjusted for proper picture quality.

H. and V. Hold Controls (R-94 and R-74).

For the best results the H. and V. Hold controls should be adjusted at low contrast levels. After a station has been tuned in, turn the contrast control fully counter-clockwise and then turn the brightness control clockwise until the picture reappears. Adjust the H. Hold control (if necessary) for a steady picture. Adjust the V. Hold control until the picture stops moving up or down. The controls should be set mid-way between positions where the picture is effected.

If you cannot obtain a steady picture at minimum contrast, turn the contrast control slightly clockwise.

After the H. and V. Hold controls have been properly set, they will not have to be used when tuning in a station.

Centering Control.

The centering control is located on the picture tube assembly (figure 2). This control is operated through the opening provided in the cabinet back. The control should be operated in the following manner.

1. Place a screwdriver in the centering tube.
2. Observe the face of the picture tube while making the adjustment.
3. Moving the control to the left will move the entire picture (looking at the face of the picture tube) upward.
4. Moving the control to the right will move the picture downward.
5. Moving the control up will move the picture to the left. Down will move the picture to the right.

V. Size and V. Linearity Controls (R-70 and R-80).

The V. Size and V. Linearity controls should both be adjusted at the same time while a test pattern is being transmitted. The Linearity control effects the upper portion of the picture while the Size control effects the lower portion of the picture. Adjust both the controls simultaneously until the test pattern is symmetrical and fills the entire screen vertically. Readjust the V. Hold control if necessary.

H. Size and H. Linearity Controls (L-24 and L-26).

The H. Size and H. Linearity controls should be adjusted only when a test pattern is being transmitted. The Size control should be adjusted until the test pattern fills the entire screen horizontally, and the Linearity control should be adjusted for a horizontal symmetrical test pattern. The H. Drive control must be readjusted after adjusting either the H. Size or H. Linearity controls.

Coarse and Fine Hold Controls (L-23 and R-94).

The coarse horizontal hold control should be adjusted in the following manner.

Set the Fine H. Hold control to the center of its range.

Set the contrast control to the normal operating position. Adjust the Coarse H. Hold control until there is a steady picture (no horizontal movement).

When the Coarse H. Hold control is adjusted properly, a fast turn of the Fine H. Hold control in either direction (clockwise or counter-clockwise) will make the picture go out of sync (only in low signal areas). Turning the Fine H. Hold control slowly in either direction should not make the picture go out of sync. If the Coarse H. Hold control is not adjusted properly, the horizontal sync will not come in immediately (or not at all) when the tuner is switched from one station to another.

Focus Control.

The permanent magnet focus assembly is essentially a magnet within an assembly so designed as to provide a flexible means of adjusting focus and centering on the face of the picture tube. Do not use a steel screwdriver or any magnetic material when adjusting the focus control. A non-magnetic material should be used, as a magnetic material will increase the flux density of the assembly and a correct adjustment cannot be obtained. This control is located on the picture tube assembly and can be operated through the hole provided in the cabinet back. A long adjusting tool is necessary for the adjustment.

There are two focus screws on the focus magnet assembly. The focus screw on the side is preset at the factory and should be all the way in. Only the top screw should be used for the focus adjustment.

Adjust the focus screw for the best focus. Reset the ion trap magnet and again re-focus the picture. If the focus is best at the edge turn the slug in, if best at center turn the slug out. Turn in or out until the best average focus is obtained and then reset the ion trap magnet.

H. Drive Control.

The H. Drive control is located next to the A.C. input at the rear of the chassis (figure 3). The control requires a small screwdriver for adjustment. The control should be adjusted in the following manner.

1. Tune in a station.
2. Turn the drive control counter-clockwise until a fold-over (white vertical line) appears at the left side of the picture.
3. Turn the drive control clockwise until the fold-over just disappears.
4. Turn the drive control one-half turn clockwise.

SERVICE DATA

SPECIFICATIONS

Sensitivity at the Antenna
Video — 100 microvolts
Audio — 100 microvolts

Power Supply Rating
115 volts, 50-60 cycles, AC, 235 watts.

Audio Output Rating
Undistorted — 3 watts.
Maximum — 4½ watts.

Speaker
Permanent magnet type,
3.2 ohm voice coil impedance.

Antenna Impedance Requirements
Balanced 300-ohm.

Dimensions
Chassis — 16" x 16¼" x 2¾".

WARNING.

High voltage on all pins of the 1X2 high voltage rectifier and the plate cap of the 6BG6. DO NOT MEASURE this voltage unless a high range voltmeter is used.

Replacing ¼ amp. Fuse.

To check or replace the fuse, first turn off the set. Remove the High Voltage shield cover, short the 6BG6 plate cap to chassis, and remove the 6W4 tube and then take out the fuse. Replace fuse and reverse procedure.

Schematic Diagram.

The schematic diagram located at the rear of the manual shows all the values of resistance and capacitance and gives all the proper voltages at the pins of the tube sockets. The voltage readings were taken with a 20,000 ohm/volt voltmeter with normal operation, no signal input, and line voltage at 117 V. A. C.

R. M. A. WIRE COLOR CODE

Listed below is a R. M. A. wire color code chart to aid in circuit tracing.

Wire Color	Where used
Black	B- or Ground leads
Brown	Filament leads
Red	B+ leads
Orange	Screen leads
Yellow	Cathode leads
Green	Grid or Control leads
Blue	Plate leads
Violet	Not used
Gray	A.C. leads
White	Bias leads

Replacing Tubes

Before replacing any tubes the cabinet back must first be removed. Removing the cabinet back disengages the safety interlock and removes the power to the receiver. Do not tamper with or attempt to defeat the purpose of the safety interlock.

Before replacing the High Voltage tubes first be sure the power is turned off and then short the plate caps of the 6BG6 and 1X2 tubes to the chassis.

WARNING: Do not remove any tubes while the receiver is in operation as overloading and component failures may result.

If the receiver has been in operation for some time, the tubes become hot and gloves should be used when replacing tubes to prevent finger burns.

Phono T V Switch.

The phono T V switch is located on the rear flange of the chassis and should be in the "off" position (up) for T V operation. In the "on" position there will be no sound or raster, and the audio input plug can be utilized.

COIL DC RESISTANCE CHART

The DC resistance readings shown in the chart below have been taken with an ohmmeter directly across the coil being measured. Only a few of the coils were disconnected to obtain a correct reading and these are indicated by an asterisk after the coil reference number. All the coils not listed in the chart have a DC resistance reading of approximately zero ohms.

13	210-216	211.25	215.75	238

GENERAL DESCRIPTION

Tuner.

The tuner is composed of a separate sub-chassis using a 6AG5 (pentode) R.F. Amplifier and a 6J6 tube (twin triode) for the Oscillator and Converter. Separate high and low band coils and trimmers are used with a switching device to change bands. The tuner selects and amplifies the station signal and converts it to the carrier IF frequencies of 26.75 Mc for video and 22.25 Mc for sound which in turn is then fed to the IF amplifiers for further amplification.

Video IF Amplifiers.

The IF Amplifiers, video detector and DC restorer stages are all mounted on a sub-chassis. The IF amplifier section consists of four (4) stagger-tuned stages using 6AU6 (pentode) tubes with self-resonant slug tuned coils. Since the receiver is of the intercarrier type, both the video and sound IF frequencies are amplified simultaneously. The signal is then detected by one half of the 6AL5 (twin diode) and coupled to the video amplifier. The other half of the 6AL5 is used as the DC Restorer.

Sound Section.

The sound section is also mounted on a sub-chassis and consists of a 6AU6 (pentode) IF amplifier, 6AL5 (twin diode) detector, 6AV6 (triode) amplifier and a 6K6 (pentode) output tube. Due to the hetrodyne action between the video and sound IF frequencies a 4.5 mc signal is obtained containing the audio information. After the video detector, the audio information is separated from the video signal by the pick-off coil T8. The signal is then amplified, detected and further amplified by the 6AV6 and the 6K6.

Video Amplifier.

The video section is a conventional two stage amplifier using the 12AT7 (twin triode) tube. The parallel resonant video trap coil (L-19 and C-65) is tuned to 4.5 MC to separate the audio from the video. A combination of shunt and series peaking coils are used with a degenerative contrast control to vary the signal to the grid of the cathode-ray tube.

DC Restorer.

One half of the 6AL5 tube is used as the DC restorer. Since the video is coupled to the grid of the CRT by capacitor C-64 the DC component of video signal will not be passed, therefore the background level of the picture will vary. A bias voltage proportional to the average video signal level will be developed across resistor R-31 and maintain the proper brightness level.

Sync Separator and V. Sync Amplifier.

The sync pulses from the plate of the first video amplifier are coupled to the sync separator tube (½ of 6SN7) thru capacitor C-103. The sync pulses are then separated from the blanking pedestal and due to the low plate voltage sync clipping is accomplished. The horizontal pulses are coupled to the AFC Discriminator thru capacitor C-91 and the vertical pulses are coupled thru capacitor C-121 and amplified by the other half of the 6SN7 before being fed to the intergrating network of the vertical deflection circuit.

Vertical Deflection.

The vertical deflection circuit consists of a 6SN7 (twin triode) tube one half used as a blocking oscillator and the other half as a pulse amplifier. The V. Hold control varies the oscillators operation point thus providing an adustment for synchronization. The V. Size control varies the amplitude of the pulse to the grid of the amplifier and controls the amount of vertical deflection. Thus V. linearity control varies the cathode resistance thus changing the operating characteristics of the amplifier tube to obtain a linear sawtooth pulse. Therefore, it can be seen that the V. Size and V. Linearity controls must be operated in conjunction with one another.

AFC Discriminator.

The automatic frequency control section utilizes a 6AL5 (twin diode) tube. The sync separator feeds the horizontal sync pulses to the AFC tube while at the same time two voltages of opposite polarity are fed back from the horizontal deflection transformer. Any phase shift between the horizontal sync pulses and the horizontal multivibrator signal will cause the input voltage applied to one diode section to differ from that of the other. This results in a DC bias voltage applied to the grid of the multivibrator. The output of the AFC discriminator thus synchronizes the horizontal multivibrator to the horizontal pulse of the video signal. This arrangement improves horizontal stability and offers ease of operation.

Horizontal Multivibrator.

The horizontal multivibrator circuit (6SN7 tube) is of the conventional cathode coupled type using a parallel resonant circuit (L-23 and C-107) as a coarse hold adjustment to control the frequency of oscillation. The fine hold adjustment R-94 varies the grid resistance thus slightly controlling frequency of oscillation. The horizontal sawtooth pulse is then fed to the grid of the pulse amplifier.

Pulse Amplifier.

The horizontal drive control, C-109 in the grid circuit controls the amount of voltage applied to the pulse amplifier. (Increasing the capacity decreases the drive.) The 6BG6 is a beam tetrode used to develop the necessary power for the flyback pulse and the horizontal deflection coil. The Horizontal size coil, L-24 shunts a portion of the horizontal deflection transformer winding. Varying the inductance of the H. size coil varies the high voltage which in turn controls the size of the picture.

Damper.

The damper tubes (6W4) main function is to damp out oscillations which occur over part of the horizontal scanning cycle. The damper tube is connected in such a way as to give an increase in plate supply voltage for the vertical output amplifier. This additional voltage is developed across capacitor C-115 and gives an additional 90 volts increase in plate supply voltage. Varying the inductance of the H. Linearity coil, L-26 changes the damper tubes operating point and thus controls the linearity of the horizontal sweep.

©John F. Rider

World Radio History

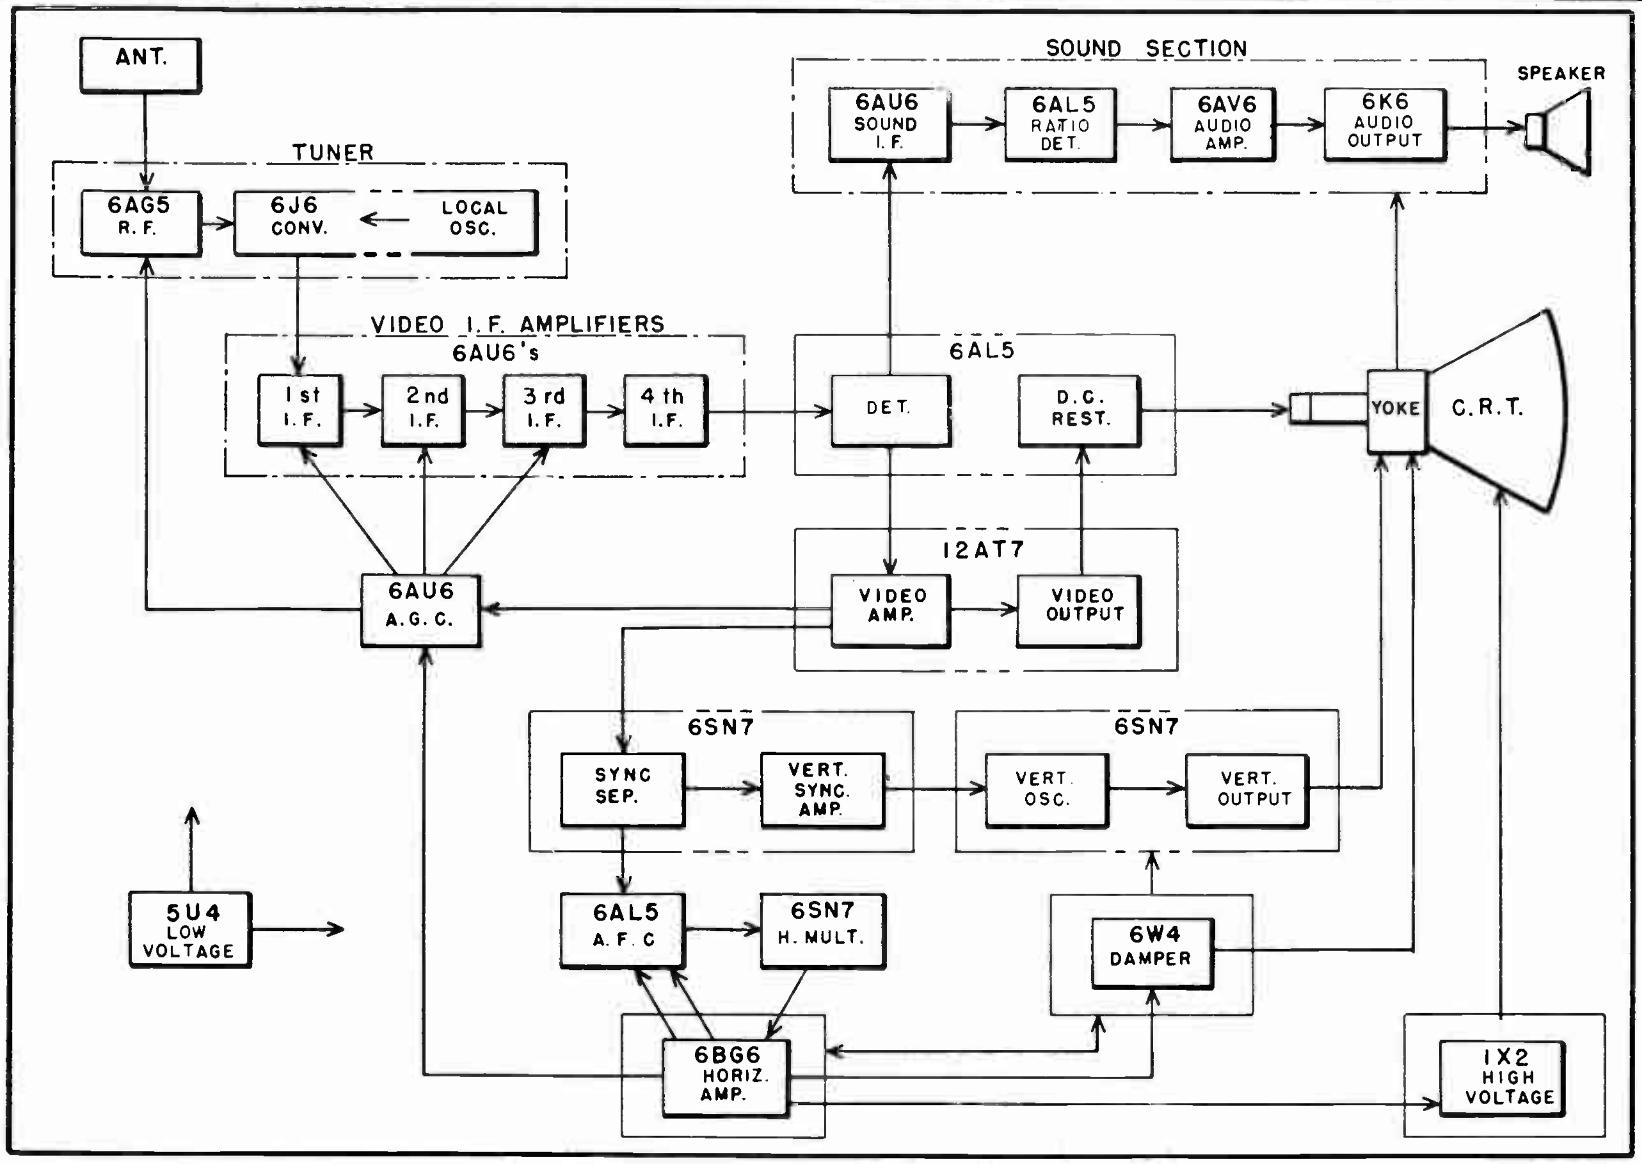

Figure 5. Block Diagram of the Receiver

GENERAL DESCRIPTION

High Voltage Supply.

The high voltage is obtained from the auto-transformer type primary winding of the horizontal output transformer. When the plate current of the pulse amplifier tube is cut off, the field built up in the primary winding collapses and induces a high voltage surge which is rectified by the 1X2 tube, filtered by the aqua-dag coating of the Cathode-ray tube and applied to the second anode.

Automatic Gain Control.

Plate voltage for the 6AU6 (pentode) gated AGC tube is obtained from a separate winding on the horizontal deflection transformer. The plate voltage is thus applied at a horizontal rate while the grid signal is obtained from the output of the first video amplifier. The AGC voltage is developed across resistor R-50 and fed to the first three IF amplifiers. Due to the divider network of R-44 and R51 only a portion of this voltage is fed to the RF amplifier. The AGC voltage will vary considerably according to the strength of the transmitted signal but should be in the vicinity of the voltage across R-37 (detector output).

SERVICE HINTS

Tuner.

If the receiver is "dead" and the picture tube shows nothing but a raster (no snow) first check the I.F. and video amplifier stages before looking into the tuner. If the set is dead and snow appears on the face of the picture tube, first determine whether a signal is being transmitted and then check the antenna or lead-in connections before suspecting the tuner for trouble.

The tuner can easily be serviced by removing the three (3) hex-head screws holding the bottom cover in place. Removing the bottom cover makes all the tuner components within easy reach and all parts can be serviced. When working inside the tuner do not move any component a great distance as a change in the distributed capacity will result and offset the alignment. When replacing components be sure to obtain the same lead lengths and replace the components in the same position.

A majority of tuner troubles are often open and high resistance ground or coil solder connections, defective trimmers or coils and defective contacts.

Open or high resistance connections can easily be repaired by placing a hot soldering iron at the solder connection.

Defective contacts may cause an intermittent condition or the loss of one or both bands. Contact replacement is easily accomplished by following the simple procedure on page 14, figure C.

The tuner should never be removed from the chassis unless contact replacement is necessary.
CAUTION:—If the 6AG5 (RF Amp.) is placed in the 6J6 (osc.-con.) socket resistors R-9 and R-10 will burn up.

Speaker Leads.

To insure minimum video interference, dress the speaker leads away from the 6AL5 (detector tube 7) as shown in figure 3, on page 3.

A.G.C.

A defective AGC system will not effect the sound but over-load the video amplifier circuit and the result will be a loss of both horizontal and vertical sync and very weak video. This condition can easily be noticed and checked by measuring the AGC voltage and the voltage across resistor R-37. Under normal operating conditions these two voltages will be approximately the same. A defective AGC system will cause a large increase in voltage across R-37 and a decrease in AGC voltage.

To determine the cause for trouble check the 6AU6 tube, capacitors C-70 and C-59 and resistors R-44, R-50, R-51 and R-107. To check the AGC winding of the horizontal deflection transformer, place a scope on pin 5 of AGC tube and a horizontal pulse similar to wave shape number 20, on page 13, should be obtained with a peak-to-peak voltage of 400 volts.

CORRESPONDING CATHODE-RAY TUBES

Due to the fact that 16RP4 and 16TP4 Cathode-Ray tubes from various suppliers are not directly interchangeable, different focus or ion trap magnets must be used. A B.R.C. part number sticker will be pasted on the tubes coating in 16AY210 chassis. When replacement is necessary be sure to state the B.R.C. part number of the picture tube. This is necessary as a supplier may manufacture two of the same RMA tube types which will differ in construction.
Listed below is a chart showing the various 16-inch rectangular tubes used in the 16AY210 chassis.

TROUBLE-SHOOTING

Trouble	Probable Location
No Raster No Sound	1. Phono TV switch defective or in "ON" position. 2. Defective 5U4 tube (20). 3. Defective power transformer (T-7). 4. Defective filter choke (L-25 or L-28). 5. Defective filter condenser (C-61 or C-94) 6. Defective fuse.
No Raster Sound Normal	1. High voltage lead disconnected. 2. Ion trap magnet incorrectly positioned. 3. Yoke plug not in place or loose. 4. Insufficient or no high voltage, (refer to "No high voltage section"). 5. Defective resistors R46-47-48-100 and capacitor C-67. 6. Defective picture tube.
No Picture No Sound Raster Normal	1. Defective antenna or lead-in. 2. Defective tubes 1 through 7, or associated circuits. 3. Improper voltages or resistances at sockets of tubes 1 through 7. 4. Improper alignment.
No Sound Picture Normal	1 Defective tubes 11, 12, 13, and 21 or associated circuits. 2. Improper voltages or resistances at sockets of tubes 11, 12, 13 and 21. 3. Speaker leads broken or not in place. 4. Improper alignment of transformer T2, T8 (see page 14).
No Picture Raster Normal Sound Normal	1. Defective tubes 7, 8, 10. 2. Improper voltages or resistances at sockets of tubes 7, 8, 10. 3. Defective capacitors C-64-70, and L-20-21-30.
No Sync	1. Defective tubes 8, 9, 10. 2. Defective capacitors C-103, 121 and resistors R-45, 114.
No Vertical Sync Picture otherwise normal	1. Defective capacitors C-71, C-90, C-95. 2. Defective tube 9. 3. Defective resistors R-73, R-77, R-88.

Trouble	Probable Location
No Horiz. Sync Picture otherwise normal	1. Defective tubes 15, 16. 2. Defective resistors R-81-82-83-84-85-86-87, and capacitors C-91-98-99-100-101-102-105-125. 3. Defective Horizontal transformer T-6.
No Vertical Sweep	1. Defective tube 14. 2. Defective transformers T-9, T-4, T-5A. 3. Defective capacitors C-92, 95, 116 and resistors R-75, 78.
Picture cannot be Centered	1. Defective ion trap magnet. 2. Defective focus magnet. 3. Defective picture tube. 4. Defective capacitor C-114.
Picture cannot be Focused	1. Focus magnet not properly located or centered on the picture tube neck. 2. Ion trap magnet not properly adjusted or defective. 3. Defective picture tube. 4. Improper high voltage.
No High Voltage	1. Defective tubes 16, 17, 18, 19. 2. Defective transformer T-6, yoke T-5B. 3. Defective capacitors C-108, 112, 113, 114 or resistors R-90 through R-98 and R-112-118-119-120.
Bunching or folding at side of Picture	1. Improper adjustment of horizontal drive control C-109. 2. Defective tubes 17, 18. 3. Defective C-115 or H. Linearity coil.
Audio in Picture	1. Improper alignment and ratio of video carrier to sound response (see page 14).
Snow or poor Signal	1. Improper adjustment of antenna tuning knob (see page 6). 2. Cabinet (built-in antenna) not properly oriented. 3. Check alignment of C-1 and C-2 (see page 15). 4. Insufficient signal input. 5. Defective capacitors C-59, C-62 or peaking coil L-21.

WAVE FORM ANALYSIS

The drawings in this section illustrate the wave shapes at various positions within the set. These wave shapes are not theoretical but exact copies of the oscilloscope wave shapes taken with a transmitted signal.

The peak-to-peak voltage indicated was measured by a calibrated oscilloscope under typical operating conditions. When analyzing a particular wave shape, the peak-to-peak voltage may vary somewhat depending upon the setting of the contrast control and the strength of the signal. The wave shapes may vary somewhat in video section depending on the picture being transmitted.

When checking these wave shapes connect the ground lead from the oscilloscope to the chassis and the hot lead to the position shown in the chart.

The chart below lists the test point, peak-to-peak voltage and the corresponding wave shape number. Under each drawing is the type of wave shape referring either to a Horizontal (15,750 cycles) or Vertical pulse (60 cycles).

Test Point	Taken At	Peak-to-peak Voltage	Wave Form Number
1	Pin 7 of Tube 7	8	1 and 2
2	Pin 7 of Tube 8	8	1 and 2
3	Pin 6 of Tube 8	42	3 and 4
4	Pin 2 of Tube 8	12	3 and 5
5	Pin 1 of Tube 8	32	1 and 2
6	Pin 4 of Tube 9	26	3 and 5
7	Pin 5 of Tube 9	11	6
8	Pin 1 of Tube 9	11	6
9	Pin 2 of Tube 9	40	7
10	Pin 5 of Tube 10	410	20
11	Junction of R77 and C90	13	8
12	Junction of C90 and C95	27	9
13	Pin 1 of Tube 14	40	10
14	Pin 2 of Tube 14	76	11
15	Pin 4 of Tube 14	28	12
16	Pin 5 of Tube 14	650	13
17	Pin 5 of Yoke Socket	42	13
18	Pin 1 of Tube 15	8	14
19	Pin 2 of Tube 15	7	22
20	Pin 7 of Tube 15	11	21
21	Pin 4 of Tube 16	1	15
22	Pin 5 of Tube 16	48	16

TUNER ALIGNMENT

1. Preset trimmer screws C7, 8, 14, 16, 26, 29 to dimensions shown on page 14, figure E.
2. Preset coil cores L4, 5, 6, 7, 8, 9 in the following manner.
   (a) In low band position, turn tuner shaft to top of stroke as on page 14, figure B.
   (b) The switch will be in low band position.
   (c) Adjust coil cores 1.6" from core to coil mounting strip. (Use core aligning tool if available).
   (d) Turn L-9 core (low band oscillator) an additional four (4) turns out of coil.

LOW BAND TRACKING

Turn tuner to channel 6. See page 12, figure B.

Step No.	Signal Generator Freq. (mc.)	Sweep Generator Freq. (mc.)	Signal Input Point	Output Point	Adjust	Remarks	Response
1	——	Channel 6	Antenna Terminals	Scope across R-37	C-2	Adjust for maximum response with symmetrical peaks	2	——	Channel 6	Antenna Terminals	Scope across R-37	C-8 C-16	Adjust for maximum response with symmetrical peaks	3	83.25	Channel 6	Antenna Terminals	Scope across R-37	C-29	Adjust until marker is 50% down on low frequency slope. Repeat step 2 if necessary.	4	(a) 61.25 (b) 67.25 (c) 77.25 (d) 55.25	(a) Channel 3 (b) Channel 4 (c) Channel 5 (d) Channel 2	Antenna Terminals	Scope across R-37	C-8 C-16	Adjust tuner until response curve appears on scope. Adjust trimmers for compromise which will give the best overall response across band.	
NOTE: If trimmer C-8 reaches maximum and additional capacity is needed, turn L-5 core, into coil.

HIGH BAND TRACKING

Turn tuner to channel 13. See page 12, figure B.

Step No.	Signal Generator Freq. (mc.)	Sweep Generator Freq. (mc.)	Signal Input Point	Output Point	Adjust	Remarks	Response
1	——	Channel 13	Antenna Terminals	Scope across R-37	C-1	Adjust for maximum response with symmetrical peaks	2	——	Channel 13	Antenna Terminals	Scope across R-37	C-7 C-14	Adjust for maximum response with symmetrical peaks	3	211.25	Channel 13	Antenna Terminals	Scope across R-37	C-26	Adjust until marker is 50% down on low frequency slope. Repeat step 2 if necessary.	4	(a) 205.25 (b) 199.25 (c) 193.25 (d) 187.25 (e) 181.25 (f) 175.25	(a) Channel 12 (b) Channel 11 (c) Channel 10 (d) Channel 9 (e) Channel 8 (f) Channel 7	Antenna Terminals	Scope across R-37	C-7 C-14	Adjust tuner until response curve appear on scope. Adjust trimmers for compromise which will give the best overall response across band.	
VIDEO IF ALIGNMENT

Turn to any high band channel. Connect the generator thru a 1000 mmf capacitor and set the contrast control to maximum

Step No.	Signal Generator Freq. (mc.)	Sweep Generator Freq. (mc.)	Signal Input Point	Output Point	Adjust	Remarks	Response
1	26.4	——	Converter Grid	VTVM across R-37	L-11 L-13	Adjust generator output approx. 1 volt	Maximum Reading
2	23.4	——	Converter Grid	VTVM across R-37	L-12 L-14	Adjust generator output approx. 1 volt	Maximum Reading
3	25.0	——	Converter Grid	VTVM across R-37	T-1	Adjust generator output approx. 1 volt	Maximum Reading
4	25.0	——	Converter Grid	VTVM across R-37	——	SENSITIVITY Generator output should be less than 100 microvolts. (If not, repeat alignment).	1 volt VTVM Reading
5	26.75 23.0	25.0	Converter Grid	Scope across R-37	——	SELECTIVITY Markers should be as shown in response column. (If not, repeat alignment).	6	——	Channels 2-4-6-8-10-12	Antenna Terminal	Scope across R-37	T-1 for flat response	Check channels for band width (3.5 to 4 mc. at 6db points).	
Picture I.F. frequency 26.75 mc — Sound I.F. frequency 22.25 mc.

SOUND I-F ALIGNMENT

Short antenna to ground and connect generator thru a 1000 mmf capacitor.

1	4.5	——	Pin 1 of Tube 11	VTVM junction of R-59 and C-77	T-8 and T-2 primary (bottom of can)	——	Maximum Reading
2	——	4.5	Pin 1 of Tube 11	Scope junction of R-58 and C-77	T-2 secondary (top of can)	Sweep approx. 100 kc. Adjust for max linearity	3	——	4.5	Pin 1 of Tube 11	Scope junction of R-58 and C-77	T-2 primary (bottom of can)	Sweep approx. 100 kc. Adjust for symmetry of peaks	4	4.5	——	Pin 1 of Tube 11	VTVM junction of R-58 and C-77	——	Generator output should be less than .01 volt	.05 watt output

Video trap Coil (L-19) Adjustment.

(a) Tune in a station.
(b) Adjust the tuner until sound bars just appear.
(c) Turn L-19 slug all the way out (counter-clockwise).
(d) Turn the slug in (clockwise) until the horizontal scanning lines are smooth and continuous.

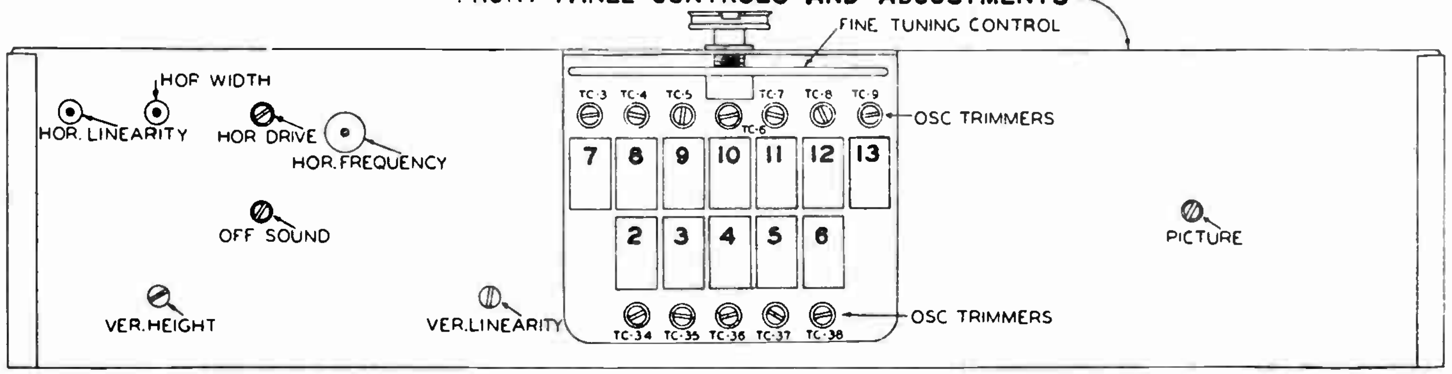
FRONT PANEL CONTROLS AND ADJUSTMENTS



FIGURE—1

REAR PANEL CONTROLS AND ADJUSTMENTS

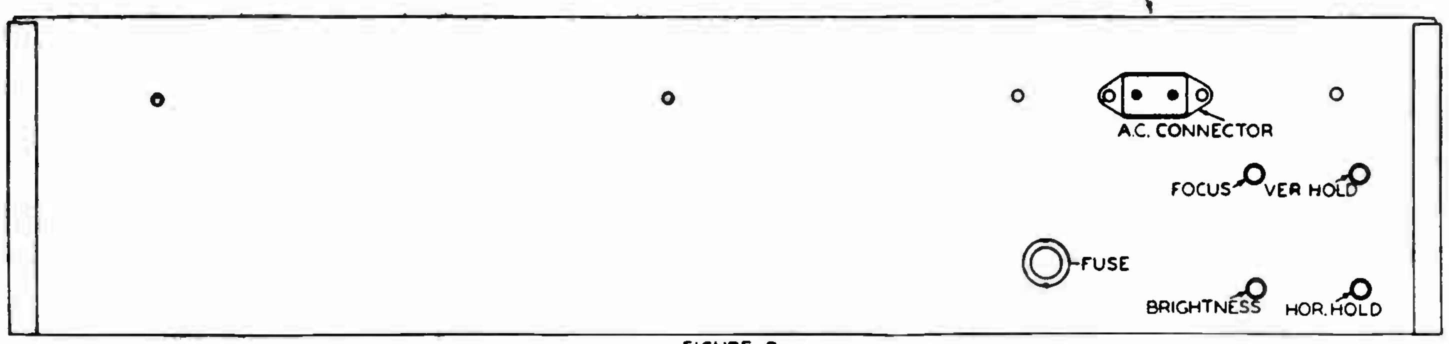


FIGURE-2

INSTALLATION AND SERVICE INSTRUCTIONS

Service and adjustment controls are located on both the front and rear aprons of the chassis. (See Fig. #1 & #2.) The front controls are accessible by removing the two round control knobs. It will not be necessary to remove the push buttons. Lift the control panel straight up so that the bottom of the panel comes out of the bottom groove in the cabinet. Pull the control panel down at an angle at the bottom so that the top of the panel comes out of the top groove. When reinstalling the panel reverse the foregoing procedure.

HORIZONTAL FREQUENCY:

Turn the horizontal hold control to the center of its rotation. Turn the picture control all the way to the left. Adjust the horizontal frequency until the picture is stationary. Push different buttons to select other channels. Each channel should lock in. If the picture does not lock in, readjust the horizontal frequency until it does. This adjustment should only be made after the receiver has warmed up for about 15 minutes.

HORIZONTAL DRIVE:

Adjust for best balance of brightness and linearity. If this adjustment is turned too far to the left a vertical white line will appear near the center of the picture.

HORIZONTAL WIDTH:

The horizontal width should be turned in until the picture covers the full width of the picture opening.

HORIZONTAL LINEARITY:

The horizontal linearity control should be adjusted for best horizontal linearity after the horizontal drive and width controls have been properly adjusted.

CENTERING:

If the picture is not centered in the picture opening, it may be centered by removing the cabinet back and adjusting the mechanical position of the focus coil. The coil can be moved in any direction after its mounting screws have been loosened. If the picture is tilted at an angle, it may be straightened by loosening the deflection yoke locking screw and adjusting the deflection yoke.

Make sure that all screws and nuts are well tightened after adjustment.

ION TRAP AND FOCUS CONTROL:

If the picture tube does not appear to be bright enough or if the tube dims when the brightness control is turned all the way to the right, the ion trap must be adjusted. Remove the cabinet back, turn the picture control all the way to the right. Turn the brightness control all the way to the right. Move the ion trap forward or backward very slowly and at the same time turn it to the right or left until the brightest picture is obtained.

OSCILLATOR AND FINE TUNING:

The fine tuning control is set at our factory so that the picture just begins to appear and the sound is at maximum, when the fine tuning control is turned all the way to the left. If it is necessary, each push button may be adjusted individually so that practically all transmitting channels may be received with the same picture and sound. The oscillator trimmers for channels #7 through #13 are located above their corresponding switch shaft. The trimmers for channels #2 through #6 are located below their corresponding switch shafts.

A non-metallic screw driver with a 3/16" wide tip and about 8 inches long should be used for oscillator alignment. Select a transmitting channel and push the corresponding button. Set the fine tuning control in the center of its range. Insert the screw driver into the trimmer adjustment for the button that has been pushed. Turn the screw driver very slowly to the right until the fine grainey appearance just disappears from the picture. With the fine tuning control still set, push another button and adjust its oscillator trimmer. Continue to do this until all buttons have been adjusted. It will now be possible to push each button and receive each channel, that is transmitting, within normal receiving range, without resetting the fine tuning condenser for each station. After the receiver has warmed up thoroughly it will be possible to adjust the receiver, on one channel, then select any other channels without having to readjust the hold, fine tuning, contrast or brightness controls.

INSTALLATION AND SERVICE INSTRUCTIONS

Service and adjustment controls are located on both the front and rear aprons of the chassis. (See Fig. #1 & #2.) The front controls are accessible by removing the two round control knobs. It will not be necessary to remove the push buttons. Lift the control panel straight up so that the bottom of the panel comes out of the bottom groove in the cabinet. Pull the control panel down at an angle at the bottom so that the top of the panel comes out of the top groove. When reinstalling the panel reverse the foregoing procedure.

HORIZONTAL FREQUENCY:

Turn the horizontal hold control to the center of its rotation. Turn the picture control all the way to the left. Adjust the horizontal frequency until the picture is stationary. Push different buttons to select other channels. Each channel should lock in. If the picture does not lock in, readjust the horizontal frequency until it does. This adjustment should only be made after the receiver has warmed up for about 15 minutes.

HORIZONTAL DRIVE:

Adjust for best balance of brightness and linearity. If this adjustment is turned too far to the left a vertical white line will appear near the center of the picture.

HORIZONTAL WIDTH:

The horizontal width should be turned in until the picture covers the full width of the picture opening.

HORIZONTAL LINEARITY:

The horizontal linearity control should be adjusted for best horizontal linearity after the horizontal drive and width controls have been properly adjusted.

CENTERING:

If the picture is not centered in the picture opening, it may be centered by removing the cabinet back and adjusting the mechanical position of the focus coil. The coil can be moved in any direction after its mounting screws have been loosened. If the picture is tilted at an angle, it may be straightened by loosening the deflection yoke locking screw and adjusting the deflection yoke.

Make sure that all screws and nuts are well tightened after adjustment.

ION TRAP AND FOCUS CONTROL:

If the picture tube does not appear to be bright enough or if the tube dims when the brightness control is turned all the way to the right, the ion trap must be adjusted. Remove the cabinet back, turn the picture control all the way to the right. Turn the brightness control all the way to the right. Move the ion trap forward or backward very slowly and at the same time turn it to the right or left until the brightest picture is obtained.

OSCILLATOR AND FINE TUNING:

The fine tuning control is set at our factory so that the picture just begins to appear and the sound is at maximum, when the fine tuning control is turned all the way to the left. If it is necessary, each push button may be adjusted individually so that practically all transmitting channels may be received with the same picture and sound. The oscillator trimmers for channels #7 through #13 are located above their corresponding switch shaft. The trimmers for channels #2 through #6 are located below their corresponding switch shafts.

A non-metallic screw driver with a 3/16" wide tip and about 8 inches long should be used for oscillator alignment. Select a transmitting channel and push the corresponding button. Set the fine tuning control in the center of its range. Insert the screw driver into the trimmer adjustment for the button that has been pushed. Turn the screw driver very slowly to the right until the fine grainey appearance just disappears from the picture. With the fine tuning control still set, push another button and adjust its oscillator trimmer. Continue to do this until all buttons have been adjusted. It will now be possible to push each button and receive each channel, that is transmitting, within normal receiving range, without resetting the fine tuning condenser for each station. After the receiver has warmed up thoroughly it will be possible to adjust the receiver, on one channel, then select any other channels without having to readjust the hold, fine tuning, contrast or brightness controls.

I GENERAL DESCRIPTION

Subject models are direct-viewing receivers using 16" and 19" all-glass cathode-ray tubes. The receivers are complete in one unit. Features of the receivers include U.S.T. FM sound, syncrolok system for horizontal framing, one stage RF, four stages video IF, two stages sound IF, one stage sound limiter, one high power stage, video amplifier, non-hazardous high voltage supply using a voltage doubler circuit.

POWER SUPPLY RATING
115 volts -- 60 cycles -- 276 watts

ANTENNA INPUT IMPEDANCE
72 ohms or 300 ohms on F.M. models *
300 ohms on straight T.V. receivers

* Note: When 300 ohm tape is used for antenna downlead to FM models, the shielded lead must be removed from the tuner and the 300 ohm downlead must be wired to the indicated 300 ohm terminals on the tuner.

II MAINTENANCE

A. WARNING

Operation of this equipment outside of the overall enclosure involves a shock hazard from the 400 volt supply and an explosion hazard in handling the kinescope. The second anode supply does not involve a dangerous shock hazard, but lack of caution may result in an unpleasant shock or burn. Be sure to wear some form of eye protection while handling the kinescope.

B. TEST EQUIPMENT

To properly service the television receiver, it is recommended that the following test equipment be available.

1. R-F sweep generator meeting the following requirements:
   a. Frequency ranges — 18 to 30 Mc., 40 to 90 Mc., 170 to 225 Mc.
   b. Sweep width adjustable from 1 to 12 Mc.
   c. Output at least 0.1 volts.

2. Cathode-ray oscillograph, preferably one with a wide band vertical deflection and a calibrating input source.

3. Electronic voltmeter with high-voltage probe, such as RCA Junior Voltohmyst with multiplier probe, capable of measuring up to 15 kv.

4. An accurate R.F. signal generator covering the following frequency ranges with can be used to set traps, local oscillators, and for frequency markers.

Intermediate frequencies. (21.25 Mc. (25.75 Mc.

Trap frequencies (19.75 Mc. (27.25 Mc.

CHANNEL NUMBER	MC.	PIX MCS	SOUND MCS	HETERODYNE OSC. FREQ. MC.
2	54-60	55.25	59.75	81
3	60-66	61.25	65.75	87
4	66-72	67.25	71.75	93
5	76-82	77.25	81.75	103
6	82-88	83.25	87.75	109
7	174-180	175.25	175.75	201
8	180-186	181.25	185.75	207
9	186-192	187.25	191.75	213
10	192-198	193.25	197.25	219
11	198-204	199.25	203.75	225
12	204-210	205.25	209.75	231
13	210-216	211.25	215.75	237

III INTERMEDIATE FREQUENCY ALIGNMENT PROCEDURE:

The signal generator should be calibrated with the crystal at 21.25 and 25.75. If the frequency stability of the signal generator is known to be poor, a check should be made with the crystal each time one of these frequencies is used.

1. SOUND DISCRIMINATOR ALIGNMENT

Connect output of the signal generator to the third i-f grid, pin 1 of V6, and set output of signal generator for approximately one volt at 21.25 Mc. Connect Junior Voltohmyst in series with one megohm resistor to junction of diode load resistors (R60 and R62). Adjust primary core (top) of T5 for maximum d-c output. Move Junior Voltohmyst to output of discriminator (V7, Pin 1) and adjust secondary core (bottom) of T5 for zero d-c output. Readjust T5 primary for symmetrical plus or minus d-c output on either side of 21.25 Mc.

The sweep, in conjunction with marker signals, can also be used to align the discriminator but the center position of the sound carrier cannot be set as accurately using this method.

The peak to peak bandwidth of the discriminator should be approximately 350 Kc. and it should be linear from 21.75 Mc. to 21.325 Mc.

2. SOUND INTERMEDIATE FREQUENCY ALIGNMENT

Connect sweep output to first I-f grid, pin 1 of V4. Connect oscilloscope to third i-f grid return (high end of R57) and adjust T3 and T4 for maximum gain at 21.25 Mc. and symmetry about 21.25 Mc. The output level from the sweep should be set to produce approximately 0.3 volt peak-to-peak at the third sound i-f grid return. The bandwidth at 70% response from the first sound i-f grid to the third sound i-f grid should be approximately 200 Kc. (Refer to Figure 8) If a 60 cycle sweep rate is used, it will be necessary to reduce the time constant in the second sound i-f grid circuit in order to reproduce the response curve. To do this, shunt R57 with approximately 5,600 ohms. For overall S curve response connect oscilloscope to junction of C66 and R63 and compare to curve in Figure 7.

3. PICTURE INTERMEDIATE FREQUENCY ALIGNMENT

Open jumper on tie point where C98 is located. This disables the A.G.C. feed to the R.F.-I.F. gain control stages. Apply minus three volts, d-c, where C98 is wired to the tie point. Connect oscilloscope vertical amplifier lead through a 10,000 ohm isolating resistor to high side of R105 video detector load resistor. Connect VTVM to the same point. The meter needle is the indicating means for the alignment and the oscilloscope's primary function is to indicate over-load of the circuits under test. When this is indicated, the signal source level should be reduced. Capacity couple A.M. signal generator to tuner converter tube by slipping tight-fitting, ungrounded shield over converter tube and connect generator to this ungrounded shield.

Set signal generator to 19.75, audio modulated, and adjust T8 secondary for minimum reading on VTVM.
Set signal generator to 21.25 Mc., audio modulated, and adjust T15 secondary and T9 secondary for minimum indication on VTVM.
Set signal generator to 27.25 Mc., audio modulated, and adjust T7 secondary for minimum indication on VTVM.
For proper indication of these trap adjustments, high level output is required from signal generator.
Set signal generator to 21.8 Mc. and adjust T15 primary for maximum indication on VTVM.
Set signal generator to 25.3 Mc. and adjust T7 primary for maximum indication on VTVM.
Set signal generator to 22.3 Mc. and adjust T8 primary for maximum indication on VTVM.
Set signal generator to 25.2 Mc. and adjust L5 for maximum indication on VTVM.
Set signal generator to 23.4 Mc. and adjust L6 for maximum indication on VTVM.

Disconnect signal generator from shield and apply sweep generator output to shield. Adjust sweep generator to give an I.F. amplitude frequency response curve on the oscilloscope. The picture intermediate frequency can now be retouched, if necessary to secure the standard i-f response curve with the picture carrier at approximately 55% on the response curve. For curve comparison refer to Figure 6.

In making any final touch-up adjustments on the picture i-f amplifier, it should be remembered that the converter stage and second picture intermediate frequency are relatively high Q circuits and tend to control the I-f response at the high and low frequency ends of the pass-band respectively. The first and third picture intermediate frequencies are relatively low Q circuits and tend to control the response of the center portion of the pass-band.

The picture I.F. amplifiers can also be aligned without first peaking the individual stages to the specified single frequencies, but by using the sweep and markers only. If the receiver is completely mis-aligned, this method is not recommended.

Since there is some shift in response in both the picture and sound i-f amplifiers with bias, the recommended bias levels should always be used when aligning these circuits.

IV ALIGNMENT OF STRAIGHT T.V. STANDARD COIL TUNER

Open jumper on tie point where C98 is located. (Refer to Figure 2.) This disables the A.G.C. bias feed to the RF and IF gain controlled stages. Apply minus three volts d-c where C98 is wired to the tie point.

©John F. Rider

World Radio History

V CONVERTER COIL I.F. & TRAP ALIGNMENT (if adjusted in I.F. alignment procedure do not repeat) REFER TO FIGURES 1 & 2

Connect VTVM to second detector video load resistor R105 on main chassis. Remove tube shield from 6J6 on tuner. Capacity couple A.M. signal generator to 6J6 by slipping tight-fitting ungrounded shield over 6J6 and connect generator to ungrounded shield. Set frequency of generator to 21.25 Mc. Tune L12 for minimum voltage on VTVM. Set generator to 21.8 Mc. and tune L11 for maximum voltage on VTVM. Use high output on signal generator at 21.25 Mc. and low output on 21.8 Mc. for above alignment procedure.

VI RF & MIXER ALIGNMENT

1. Having first aligned PIX I.F. section set station selector switch to channel 12.
2. Connect oscilloscope through 10,000 ohms to second detector video output on main chassis.
3. Feed sweep generator into antenna terminals, sweeping channel 12.
4. Adjust C2, C3 and C4 for flat top response curve. Check markers on all channels. They should fall in automatically on all channels.

OSCILLATOR ALIGNMENT

1. Turn station selector switch to channel 12. Flat on fine tuning facing upwards to 12 o'clock.
2. Connect signal generator using A.M. or F.M. modulation to one antenna terminal and ground. Set to sound carrier frequency 209.75 Mc.
3. Connect vacuum tube voltmeter to D.C. output of discriminator in main chassis.
4. Adjust C5 for zero reading on VTVM between a positive and negative peak for A.M. modulation or maximum reading for F.M. modulation.
5. Check all channels for zero or maximum reading on VTVM. It is usually not necessary to make any further adjustments. If you find it necessary to touch up the oscillator coils, the following procedure is recommended.

OSCILLATOR COIL TOUCH-UP (usually not necessary)

a. Fine tuning control in mid-position.
b. Place a non-metallic screwdriver through opening, and adjust oscillator coil on channel 12.
c. Turn channel selector switch to channel 13 and repeat adjustment.
d. This adjustment can be repeated for all channels or, if necessary, on any single channel.

VII ALIGNMENT OF HORIZONTAL CIRCUITS

The horizontal drive control should be kept at or close to maximum clockwise position. Syncrolok speed control on rear of chassis should be adjusted so that for either extreme position of the horizontal hold control, (refer to Figures 1 and 2 for control locations), the picture will lock horizontally when the station is returned from either frequency side. The phasing slug, located underneath the chassis on the rear of the horizontal discriminator can, should be adjusted so that for either extreme position of the horizontal hold control there is no squeezing at either end of the picture and no white line smears. The horizontal hold control should then be set at mid position.

It is important that the AFC bias measured with a vacuum tube voltmeter at pin 5 on V22 socket does not exceed minus 2.4 volts, d-c. This voltage may exceed the specified value if the drive control is not advanced far enough in the clockwise direction. This will limit the pull-in range of the horizontal scanning oscillator.

VIII ION TRAP, YOKE & FOCUS COIL ADJUSTMENT

The brightness control should be gradually advanced clockwise as ion trap motions about the kinescope gun internal flags are made. When the raster appears, the ion trap should be adjusted for maximum brightness. Dark corners or neck cutoff are to be eliminated by adjustment of the focus coil. At all times check that the yoke is up against the kinescope neck flair as far as it can go. Any adjustments of the focus coil, or focus control, should be followed by a readjustment of the ion trap. Insofar as wide angle kinescope deflection is used, the adjustments of yoke, focus coil and ion trap are more critical and require more attention.

IX A.G.C. THRESHOLD CONTROL SETTING

The picture must first be framed with proper size, linearity and focus. The channel selector must be set to the station having the strongest signal. Contrast control should be set to mid-position. The A.G.C. threshold control, located top-side of the chassis, (refer to Figure 1) is to be advanced clockwise to the point where the picture is over driven and then very slightly backed down. The service man must carefully switch through on all channels with the contrast fully clockwise to make certain that the picture pulls in without going out of synchronization.

Another means of making this adjustment is by putting the vertical amplifier lead of an oscilloscope on the kinescope cathode. The threshold control is advanced clockwise to the point where the top of the sync starts to contract.

X LINE VOLTAGE VARIATIONS

The synchronizing circuits will hold the visible picture regardless of the line voltage. When the horizontal size is not sufficient due to low line voltage (between 100 and 109 R.M.S. volts), the following changes can be made for corrections of horizontal size in the indicated order.

16" Receivers

1. Wire in one .01 to .027 microfarad 600 volt capacitor as shown in figure 5. This places the capacitor electrically across 5 and 6 terminals on the horizontal flyback transformer. Reset the horizontal and vertical dimensions and the focus.

19" Receivers

1. Add a capacitor from .003 to .005 microfarads 600 volts as shown in Figure 4. This is in addition to the .022 microfarad 600 volt capacitor which is in the receiver.

XI PERFORMANCE SUMMARY

These receivers are by design and components used, high quality receivers. The synchronizing circuits have the greatest degree of noise immunity available in the field. The interlace is very good. The synchronizing circuits are entirely independent of the contrast control. The horizontal scanning oscillator system is very stable with respect to temperature and time. It is decidedly the most superior type system used. All of this contributes to a steady picture with all the attendant advantages.

The A.G.C. circuit is a gated, fast, high gain type system. As a result, the noise figure is very good and amplitude changes of input signal introduced by airplanes and similar disturbances are definitely controlled. An additional advantage is that the different T.V. channels available may be selected with no necessity of brightness and contrast readjustments unless required by personal taste. These features make the receivers extremely simple to operate. For marginal area application these models will give the finest performance obtainable, due to their high sensitivity and high signal to noise ratio.

The models with F.M. have a function switch for selection of F.M., T.V. or Phono. Features of this circuit are the switching out of possible interfering circuits with the function switch setting and instantaneous action of any of the selected functions.

SUBJECT: Proper Operation of the Syncrolok

General: Proper adjustment of the Syncrolok becomes an increasingly important factor in the proper operation of the receiver, since the keyed AGC action is entirely dependent upon the relative phase between the sync pulse and the keying pulse.

Although careful and complete adjustment of the Syncrolok is made at the factory before each receiver is shipped, vibration in shipment may cause the syncrolok to become out of optimum adjustment when the set arrives at its installation point. The following procedure is recommended for checking the operation of the syncrolok and adjusting it if necessary.

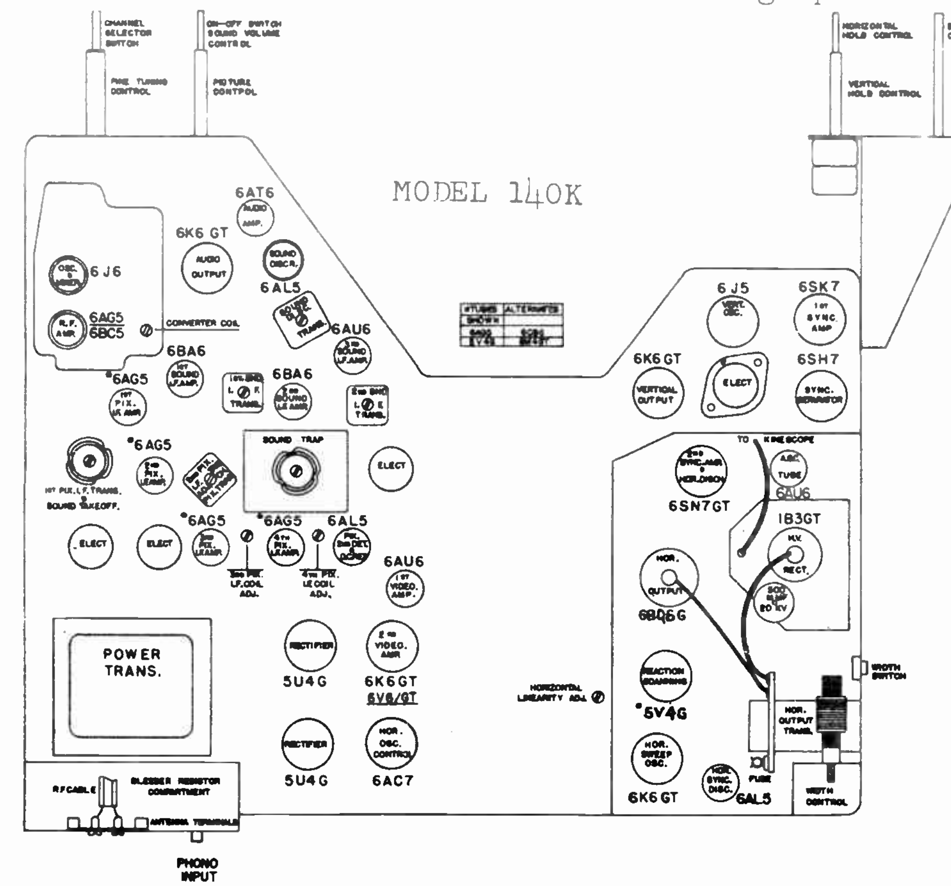
1. Checking the Syncrolok for Normal Frequency and Phasing.
a. Rotate the horizontal hold control to its extreme clockwise position.
b. Then adjust the vertical hold control to a point where the vertical is just about to jump a frame upwards, but doesn't quite tear out.
c. Then rotate the horizontal hold control to its extreme counter-clockwise position.
d. If the vertical should lose a frame, jump, or go out of frequency then the Syncrolok is out of adjustment with respect to proper phasing.
e. Frequency may be checked in the normal Syncrolok manner by rotating the horizontal hold control to its extreme clockwise and counter-clockwise positions while switching the tuner from a picture channel to an off-channel and determining whether the horizontal will lock in.

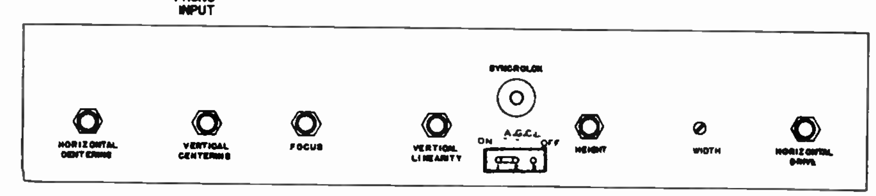
2. Adjustment of the Syncrolok When Not in Normal Frequency.
To adjust the Syncrolok in frequency, the normal procedure is followed. Should the picture break at either end of the hold control, adjust the Syncrolok control, located at the rear of the chassis, and then recheck in the manner outlined above in Paragraph 1.

3. Adjustment of the Syncrolok When Phasing is Out of Adjustment.
If the phasing is found to be out of adjustment, the normal phasing procedure is used except that the right-hand edge of the picture is used as the guide rather than the left. The phasing adjustment is a slotted screw control on the inside of the Syncrolok coil and can only be reached from underneath the chassis. If unfamiliar with the proper Syncrolok phasing procedure, then proceed with the following steps.

a. Move the picture to the left by means of the horizontal centering control until the right hand edge of the picture is exposed from the mask.
b. Reduce the contrast and advance the brightness until the blanked out raster appears behind the picture.
c. Then, with the horizontal hold control in its extreme clockwise position, adjust the phasing screw so that the end of the picture and the end of the sweep lines almost coincide.
d. When performing step C, note that a slight cramping will appear at the extreme right-hand edge, indicating the start of a fold-over.

The optimum adjustment of the phasing control is at a point just before such cramping occurs.
e. After these adjustments have been made, recheck for normal operation of the Syncrolok as described in Paragraph 1.





IMPORTANT * Dress Kinescope Socket Leads away from Deflection Yoke Leads. Do Not Permit Yoke Plug to touch any part of chassis.

MODELS 140K and 140KB

SUBJECT: Adjustments for Optimum Width and Brightness

A. With Width Switch in Normal Position (down):
1. Adjust Width Coil in cage with slug completely out.
2. Adjust Horizontal Drive Control fully clockwise, then readjust slightly for good linearity.
3. Adjust Horizontal Linearity Coil for proper Linearity (Located on top of chassis next to High Voltage Cage)
4. Width Coil on rear apron of chassis is adjusted for proper width.

B. In Low Line Voltage areas or whenever picture Width isn't sufficient, place Width Switch in E X P A N D E D (up) position and:

1. Adjust Width Coil in cage for proper width.

INDEX

General Description

The 600 and 900 series television receivers are 18 tube direct view types, featuring clear, bright pictures. The circuit is of advanced design using multi-purpose tubes, and featurers full channel coverage, Automatic Gain Control, high sensitivity, excellent horizontal frequency stability, low power consumption, and the Plakron Compensator circuit.

The receiver operates from a 115 volt 60 cycle power source and consumes 180 watts.

Tube complement

R. F. Tuner - R. F. Amplifier	6AG5
R. F. oscillator - converter	6J6
1st Video Amplifier (I.F.)	6AU6
2nd Video Amplifier (I.F.)	6AU6
3rd Video Amplifier (I.F.)	6AU6
Video Detector, A.G.C. Diode	6AL5
Video Amplifier	6AC7
Sync Clipper, D.C. Restorer, Sync Amplifier	12AU7
Ratio Detector Driver (4.5 mc)	6AU6
Ratio Detector, First Audio Amplifier	6T8
Audio Power Amplifier	6V6
Horizontal Deflection Amplifier	6BQ6
Horizontal Deflection Oscillator	6SN7
High Voltage Rectifier	1B3GT
Horizontal Damper Diode	6W4GT
Vertical Deflection Oscillator, Vertical Output	6SN7
Power Rectifier	5V4

The receiver operates with a 300 ohm balanced antenna input. The audio output is 2.5 watts undistorted, with a maximum output of 4 watts.

Operating Controls (Front of Receiver)

Horizontal Hold - Stops sideways motion of picture.
Vertical Hold --- Stops up or down rolling action of picture.
Volume-Off - - - -Adjusts sound volume; turns set on and off.
Contrast - - - - Varies contrast between light and dark areas.
Brightness - - - -Varies overall picture brightness.
Bandswitch - - - -Selects TV Channel.

NOTE: Sets employing the intercarrier sound system, such as this one, are tuner, not for the maximum sound, but for the sharpest, clearest picture.

Non-Operating Controls

Vertical Size - - - -	Varies height of picture.
Vertical Linearity -	Adjusts ratio between top and bottom of picture.
Horiz. Linearity ---	Varies ratio between right and left side of picture.
Horiz. Drive - - - -	Varies width and linearity.
Horiz. Waveform - - -	Maintains horizontal synchronization.
Width Control - - - -	Varies width of picture.
Focus - - - - - - - -	Focuses picture on screen.
Horiz. Centering - -	Shifts picture from left to right.

OPERATING INSTRUCTIONS

The following adjustments are necessary when turning the receiver on for the first time.

1. Turn the receiver "ON" and advance the SOUND VOLUME control to approximately mid-position. Wait a few moments.

2. Set the STATION SELECTOR to the desired channel.

3. Adjust the FINE TUNING control for sharpest, clearest picture.

4. Turn the BRIGHTNESS control fully counterclockwise, then clockwise until a light pattern appears on the screen.

5. Adjust the VERTICAL hold control until the picture stops vertical movement.

6. Adjust the HORIZONTAL hold control until a picture is obtained and centered.

7. Turn the BRIGHTNESS control counterclockwise until retrace lines just disappear.

8. Adjust the PICTURE control for suitable picture contrast.

9. After the receiver has been on for some time, it may be necessary to readjust the FINE TUNING control for improved picture clearness.

10. In switching from one station to another, it may be necessary to repeat steps numbers 3 and 8.

11. When the set is turned on again after an idle period, it should not be necessary to repeat the adjustments if the positions of the controls have not been changed. If any adjustment is necessary, step number 3 is generally sufficient.

12. If the positions of the controls have been changed, it may be necessary to repeat step numbers 1 through 8.

INSTALLATION INSTRUCTIONS

Receivers are shipped complete in one carton except for the kinescope. The kinescope is shipped in a special carton and should not be unpacked until ready for installation.

UNPACKING

The table models are shipped in an air cushioned carton. To open the carton, tear open the carton top flaps, remove the cardboard side packing material and with men on either side of the cabinet, lift it out of the carton.

Console models are also shipped in cartons. To unpack, turn the shipping carton on its side and tear open the carton bottom flaps. Fold the flaps up along the side of the carton and turn the carton back on its base. Lift the carton up and off the cabinet. Remove the cabinet back grille. Next, remove the speaker plug located on the rear apron of the chassis. Remove all shipping materials. Remove the envelope containing the door handles. Make sure all tubes are in place and are firmly seated in their sockets. Remove all knobs and the four bolts on the bottom of the cabinet, that hold the chassis from the cabinet, and insert the large tube strap in the slot near the front apron on the chassis or in the case of the 19 inch metal CRT, screw the bracket into sides of chassis. The tube mounting straps are usually shipped in the carton with the kinescope. Plug the deflection assembly into the six prong socket on top of chassis.

Kinescope Handling Precautions

Do not open the kinescope shipping carton, install, remove or handle the kinescope in any manner unless shatterproof goggles, and heavy gloves are worn. People not so equipped should be kept away while handling kinescopes. Keep the kinescope away from the body while handling. The kinescope bulb encloses a high vacuum and, due to its large surface area, is subjected to considerable air pressure. For these reasons, kinescopes must be handled with more care than ordinary receiving tubes. The large end of the kinescope bulb--particularly that part at the rim of the viewing surface--must not be struck, scratched or subjected to more than moderate pressure at any time. In installation, if the tube sticks or fails to slip smoothly into its socket, or deflecting yoke, investigate and remove the cause of the trouble. Do not force the tube. Refer to the Receiver Installation section for detailed instructions on kinescope installation. All kinescopes are shipped in special cartons and should be left in the carton until ready for installation in the receiver. Keep the carton for possible future use.

KINESCOPE INSTALLATION

Turn the tube so that the key on the base of the tube will be down and insert the neck of the kinescope through the deflection and focus coils so that the rim of the viewing surface rests on the rubber cushions. If the tube sticks, or fails to slip into place smoothly, investigate and remove the cause of the trouble. Do not force the tube. Insert the kinescope straps in the chassis slots and tighten with the wing nut and screw until the rubber cushions just begin to compress.

The focusing unit is shipped separately and must be installed. It is provided with a mechanical centering arrangement. Inspection will reveal it consists of a moveable plate with an opening slightly smaller than that of the focusing unit. Center these two opening by hand. Slip the focusing unit assembly over the neck of the kinescope with the centering adjustment and focusing slug toward the base of the tube. Fasten the unit to the CRT brackets placing the unit approximately one- half inch behind the deflection yoke. Slip the ion trap magnet over the neck of the kinescope with the large magnet towards the base of the tube.

Wipe the kinescope screen surface and front panel safety glass or mask clean of all dust and finger marks with a soft cloth moistened with the Drackett Co.'s "Windex" or similar cleaning agent.

Slide the deflection yoke as far forward as possible. If this is not done, difficulty will be encountered in adjusting the ion trap magnet and focus coil because of shadows on the corner of the raster.

Replace the chassis with CRT in cabinet being careful to properly center all controls. Slide the chassis up as far as possible so that the CRT fills the mask and is properly centered. Replace the four bolts in the bottom of the chassis. Reconnect the speaker plug. The antenna and power connections should now be made. Install the front panel control knobs.

WARNING

The high voltage supply in this receiver delivers 14,000 volts! If it is necessary to remove the kinescope after the receiver has been operating, short the kinescope lead to the chassis before attempting removal of, or adjustments to, the kinescope. A.C. interlocks are provided so that when the back of the high voltage cage is removed--so is the power.

Ion Trap Magnet Adjustment

Looking at the kinescope gun structure, it will be observed that the second cylinder from the base inside the glass neck is provided with two small metal flags as shown in Figure 2

©John F. Rider

World Radio History

Turn the power switch to the "on" position, the brightness control fully clockwise, and contrast control counterclockwise.

The ion trap rear magnet poles should be approximately over the ion trap flags. Starting from this position adjust the magnet by moving it forward or backward at the same time rotating it slightly around the neck of the kinescope for the brightest raster on the screen. Reduce the brightness control setting until the raster is slightly above average brilliance. Adjust the focus control until the line structure of the raster is clearly visible. Readjust the ion trap magnet for maximum raster brilliance. The final touches on this adjustment should be made with the brightness control at the maximum position with which good line focus can be maintained.

DEFLECTION YOKE ADJUSTMENT

If the lines of the raster are not horizontal or squared with the picture mask, rotate the deflection yoke until this condition is obtained. Tighten the yoke adjustment wing screw.

Picture Adjustment

It will now be necessary to obtain a test pattern picture in order to make further adjustments. See steps 2 through 8 of the receiver operating instructions on page 3.

If the horizontal oscillator is operating properly, it should be possible to sync the picture at this point.

Check of Horizontal Oscillator Alignment

Turn the horizontal hold control to the extreme counterclockwise position. The picture should remain in horizontal sync. Momentarily remove the signal by switching off channel then back. Normally the picture will be out of sync. Turn the control clockwise slowly. The number of diagonal black bars will be gradually reduced and when only 3 bars sloping downward to the left are obtained, the picture will pull into sync upon slight additional clockwise rotation of the control. Pull in should occur when the control is approximately 90 degrees from the extreme counterclockwise position. The picture should remain in sync for approximately 90 degrees of additional clockwise rotation of the control. At the extreme clockwise position, the picture should be out of sync and should show 1 vertical or diagonal black bar in the raster.

If the receiver passes the above checks and the picture is normal and stable, the horizontal oscillator is properly aligned. Skip "Alignment of Horizontal Oscillator" and proceed with "Centering Adjustment".

ALIGNMENT OF HORIZONTAL OSCIALLATOR

If in the above check the receiver failed to hold sync with the hold control at the extreme counterclockwise position or failed to hold sync over 90 degrees of clockwise rotation of the control from the pull in point, it will be necessary to make the following adjustments:

Horizontal Frequency Adjustment

Turn the horizontal hold control to the extreme clockwise position. Tune in a television station and adjust T7 horizontal frequency adjustment (under the chassis) until the picture is just out of sync and the horizontal blanking appears as a vertical or diagonal black bar in the raster.

Horizontal Lock-in Range Adjustment

Set the horizontal hold control to the full counterclockwise position. Momentarily remove the signal by switching off channel then back. Slowly turn the horizontal hold control clockwise and note the least number of diagonal bars obtained just before the picture pulls into sync.

If more than 3 bars are present just before the picture pulls into sync, adjust the horizontal locking range trimmer C62 slightly clockwise. If less than 3 bars are present, adjust C62 slightly counterclockwise. Turn the picture control counterclockwise, momentarily remove the signal and recheck the number of bars present at the pull in point. Repeat this procedure until 3 bars are present.

Repeat the adjustments under "Horizontal Frequency Adjustment" and "Horizontal Lock-in Range Adjustment" until the conditions specified under each are fulfilled. When the horizontal hold operates as outlined under "Check of Horizontal Oscillator Alignment" the oscillator is properly adjusted.

If it is possible to sync the picture at this point and the AGC system is operating properly it will be necessary to adjust the Horizontal Oscillator by the method outlines in the alignment procedure on page 23. For field purposes paragraph "A" under Oscillator Waveform Adjustment may be omitted.

CENTERING ADJUSTMENTS

Centering is accomplished by mechanically orienting the focus coil. Moving the focus coil up and down, causes the picture to move sideways, and a sideward movement of the coil causes the picture to move up or down. The focus coil is supported on a set of brackets provided with slots which allow for its proper orientation. An additional amount of centering is provided by a centering adjustment screw on the rear of the focusing unit. The focusing unit should be installed as outlined under "Installation Instructions" and centered without the use of this auxiliary centering device except for final "fine" adjustment.

In some cases the electron gun of the kinescope is not properly centered and the picture tends to pull to one side, making horizontal centering difficult. To overcome this difficulty, a horizontal centering potentiometer has been provided. The procedure for centering as outlined above should first be followed, then an additional sideward movement as may be necessary, is provided for by this control.

After the centering has been accomplished, readjust the ion trap as outlined under "Ion Trap Magnet Adjustment".

Focus Adjustments

In most cases, the focus coil is placed approximately a half-inch away from the deflection coil. The contrast control should be turned counterclockwise and the brightness control turned clockwise until the desired viewing brightness is on the screen. Adjust the focus control screw using a brass screwdriver for maximum definition in the test pattern vertical "Wedge" and best focus in the white areas of the pattern. Readjust the position of the ion trap magnet to insure that maximum brilliance is obtained. For PM-Type Focalizer Units, a brass screwdriver should be used to adjust the shorting slug to prevent inter-action between focus unit and ion trap.

Height and vertical linearity

Adjust the vertical size control until the picture fills the mask vertically. Adjust the vertical linearity control until the test pattern is symmetrical from top to bottom.

Adjustment of either control will require a readjustment of the other. Adjust vertical centering to align the picture with the mask.

HORIZONTAL DRIVE, WIDTH AND LINEARITY

Adjustments

Adjust the horizontal drive control to give a picture of maximum width within the limits of good linearity. Usually the picture width is too great and must be reduced by turning out the width control slug. Adjustments of the horizontal drive control affect the horizontal oscillator hold and locking range. If the drive control was adjusted, recheck the oscillator alignment.

Check of R.F. Oscillator

Tune in all available stations to see if the receiver r.f. oscillator is adjusted to the proper frequency on all channels. The fine tuning control should be adjusted for the sharpest, clearest picture--not for maximum sound volume. Adjustments usually are not required, but if so, these should be made by the method outlined in the alignment procedure.

CIRCUIT DESCRIPTION

It is assumed in this description that the reader is familiar with recent television principles as well as the operation of conventional circuits used in radio receivers.

Low Voltage Power Supply

The power supply has been designed to eliminate all high wattage bleeders thus reducing considerably the amount of heat generated inside the chassis. This has been accomplished by connecting the circuits operating at lower voltages, in series, across the higher voltages necessary for the deflection system.

The deflection circuit operates at the higher voltage (360 volts) while the RF, If and audio circuits are connected in series across the deflection circuits, thus saving a substantial amount of current.

Referring to the schematic diagram, the RF and If plates and screens are at 140 volts while the cathodes return to ground. The audio cathodes are at the same 140 volts while the audio plates are at 360 volts or 220 volts with respect to their cathodes. The 390 ohm resistor together with the 40 mf condenser act as a filter, preventing the current variations from modulating the B voltage.

Automatic voltage regulation of the 140 volts is accomplished by the 6V6 which acts as a series regulator. Current variations in the RF and IF circuits changing the 140 volts, changes the effective grid cathode voltage of the 6V6 since its grid is connected to the divider going from 360 volts to ground. Thus the change in the 140 volt system is only about 10% with AGC bias changes although the current change is much greater.

360 volts at 175 ma. is obtained from a conventional transformer power supply circuit using a 5V4G full wave rectifier. The 8016/1B3GT functions as the high voltage rectifier, while a 6W4GT is used as the horizontal damper tube.

R.F. Unit

The R.F. unit covers all 12 channels, (2 to 13 inclusive), and operates from a balanced input of 300 ohms. The local oscillator is tuned to the high side of the channels and provides a picture I.F. of 25.75 mc and a sound I.F. of 21.25 mc.

I.F. Amplifier

This amplifier consists of 3 6AU6 tubes in a simple but sensitive circuit. Alignment is also simple since only two frequencies are utilized. Since the intercarrier sound system is used, no sound traps in the video I.F. are necessary, further simplifying align-

©John F. Rider

World Radio History

ment. The tubes are operated at a slightly higher voltage than is usually found in regular I.F. amplifiers resulting in a substantial increase in gain yet not affecting the life of the tubes. Automatic Gain Control is applied to the R. F. Amplifier and first two video I.F. stages.

Automatic Gain Control

The function of the AGC circuit is to maintain a constant signal at the kinescope grid in the presence of fading and to reduce the amount the contrast control must be rotated when switching from a weak to a strong signal or vice versa.

The slide arm of the contrast control R40 and the 39K resistor R37 form a voltage divider which provides a variable positive voltage on the cathode of the AGC diode (pin 1). The I.F. signal is coupled to the AGC diode through C34 and appears across R36 and the diode in parallel. In order for the diode to conduct, the peak amplitude of the I.F. signal must exceed the d.c. voltage on the cathode of the AGC diode. When this occurs, the rectification current develops a voltage across R36 which is then suitably filtered by R35 and C35 and utilized as bias. For a weak signal the contrast control is rotated to give maximum gain from the video amplifier and a higher positive voltage is applied to the AGC diode cathode, thus reducing the bias on the I.F. video amplifier and increasing its gain. The contrast control, then, has performed two functions: (1) increased the gain of the video amplifier and (2) increased the gain of the I.F. video amplifier.

Video Amplifier

A 6AC7 is used as a d.c. coupled video amplifier and its output is capacitively coupled to the kinescope grid. It has high gain and good noise clipping action that is independent of picture content.

The video amplifier grid bias of 2.5 volts is developed across a 12 ohm resistor R55 in the B minus circuit. A filter capacitor (C51) with low impedance to all video frequencies is used across this bias resistor so as to prevent charging in the presence of noise pulses that draw grid current.

The screen voltage is taken from a bleeder connected between 360 volts and ground (R41 and R42). The internal impedance is low enough to maintain the screen voltage at approxiamtely 150 volts over a normal operating range, yet high enough to keep screen dissipation within limits even if the set is improperly operated.

The video amplifier plate load consists of two resistors, R47 connected from plate to 140 volts and the other R45 from plate to 360 volts. They are effectively in parallel for AC and give an effective plate supply voltage of 190 volts.

In order that the clipping level and maximum output may be obtained from the weakest to the strongest signals, the contrast control provides variable AC degeneration and bias for the video amplifier. It controls the gain of the video amplifier stage and at the same time provides the proper cathode bias to offset the positive voltage developed across the diode load resistor which would otherwise be applied to the control grid of the 6AC7.

Plakron Compensator

Tests and experience have shown that a crisper picture results if the overall video circuit response is not flat but rises with frequency. Partly, this is so because the output of commonly used camera tubes fall off with frequency and in addition even a perfect picture may appear better when viewed from the normal viewing distance if the high frequencies are boosted. The result is a transient which sharpens up all video detail.

However, boosting the high frequencies would increase apparent picture noise but in this case, the boost is varied with the contrast control setting so that it is present when signals are strong and absent when signals are weak.

The 750 ohm contrast control is tapped as in fig. 4 with a 680mmf capacitor from the tap to the 6AC7 cathode a 480 mmf capacitor from the tap to ground. With the contrast control set at full gain, as in the case of a weak signal, there is zero resistance in the cathode circuit and all frequencies are amplified equally. On a stronger signal, the gain is reduced and by-passed resistance is introduced in the cathode circuit. Since the capacitor is of low value, only the higher frequencies are by-passed, and the circuit becomes degenerate at the low frequencies. Thus the higher frequencies receive more amplification than the lower ones.

D. C. Restorer - Sync Clipper - Sync Amplifier

The first half of the 12AU7, serves the dual purpose of d. c. restorer and sync clipper. The cathode and grounded grid forms a diode which acts as the d. c. restorer. A very low voltage is applied to the plate, and the cathode resistor, R 49, is adjusted so that little or no plate current flows except when the sync pulses drive the cathode sufficiently negative so as to cause conduction. The sync pulses then appear across R50, and are coupled to the horizontal and vertical oscillators after further amplification in the second half of the 12AU7.

Vertical Deflection Circuit

One triode of the 6SN7 is used as a blocking oscillator and sawtooth generator, while the other triode section is the vertical deflection amplifier. This type of circuit permits more reliable interlace than most other types of oscillators. The frequency is varied by the potentiometer R58 in the front of the receiver. Vertical linearity is varied with the 5K potentiometer R61, while height is varied with the 2.5 megohm potentiometer R63, both located in the front of the set.

HORIZONTAL OSCILLATOR AND SAWTOOTH GENERATOR

The first section of V12 is used as a control tube to maintain the frequency of the second section which operates as a blocking oscillator.

Referring to the schematic diagram, (Fig. 6), T7 is seen to have three windings. The windings from A to C and C to F from the blocking oscillator transformer. C67, R77 and R78 are the frequency determining elements as in ordinary blocking oscillators. The frequency is controlled by regulating the voltage across R78 instead of varying the resistance of this element which is usually the method employed.

The blocking oscillator grid bias is about -85 volts and a portion of this negative voltage is applied through R76 to the grid of the first section of V12, the control tube. Due to the negative voltage and the high value of cathode resistance, this tube is normally cut off in the absence of sync pulses.

A sawtooth voltage, an integrated square wave, and the sync pulse appear across C62 and are coupled to the control tube grid by C63. The sawtooth is derived from the sawtooth generator through R81. The integrated square wave is fed from the horizontal output transformer T8, through R89 and C79, and the sync pulse from the sync amplifier through C61. The three voltages combine to produce a wave shape as shown in Fig. 7.

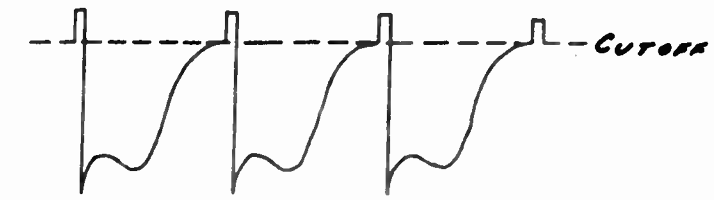

FIGURE 7- WAVE SHAPE AT PIN 1

C62 is adjusted so that the amplitude of the wave shape of Fig. 7 is such as to cause the control tube section of V12 to conduct only on the sync pulses. With this adjustment, conduction takes place only for the time of duration of the sync pulses as shown in Fig. 8 which depends upon the phase relation of the sync pulse and the horizontal oscillator frequency. When the control tube conducts, the average current produced by the pulse develops a voltage drop across R78 which subtracts from the negative voltage normally across it. As the duration of the sync pulses increases, the average current increases, and the voltage across R78 becomes less negative. With less bias on the blocking oscillator tube grid, the frequency increases and the phase relation between the sync pulses and feed-back voltages change in such a direction as to shorten the conduction time. Normal operation produces a conduction time such as "t2", fig. 8

FIGURE 8 - VARIATION IN SYNC. PULSE DURATION

WHEN THE HOLD CONTROL (R74) is in mid-position, so that the conduction time may vary in both directions and compensate for frequency drift. C65, C66 and R72 provide a filter network which eliminates hunting and gives smooth operation. The winding from C to D in T7 is a resonant circuit which impresses a sine wave on the sawtooth voltage from point C to ground and provides additional synchronization of the blocking oscillator. C65 is the charging capacitor and the sawtooth output is coupled to the grid of V13 (6GQ6) through a capacity voltage divider C70 and C71.

The horizontal sweep output circuit is of popular design and should require no explanation.

Sound System

The intercarrier sound system is employed in this receiver. The 4.5 mc sound I.F. frequency is taken from the plate of the video amplifier by T1, which also serves as a trap at this frequency. The 4.5 mc signal is then fed through an I.F. amplifier to the ratio detector and audio amplifier.

An important advantage of this type of sound system is that even if the local oscillator drifts, the difference between the sound and picture carrier remains at 4.5 mc so that the sound is unaffected.

ALIGNMENT PROCEDURE

Test Equipment

To properly service this receiver it is recommended that the following test equipment be available:

R.F. Sweep Generator

Specifications:

(a) Frequency Ranges
18 to 30 mc., 1 mc. sweep width
40 to 90 mc., 10 mc. sweep width
170 to 225 mc., 10 mc. sweep width

(b) Output adjustable with at least 0.1 volt maximum.
(c) Output constant on all ranges and on all attenuator positions.

Cathode Ray Oscilloscope - Preferably one with a wide band vertical deflection, an input calibrating source and a low sapacity probe.

Signal Generator - To provide the following frequencies

(a) I.F. Frequencies
23.3 mc., First and Third I.F. Transformer
25.36mc., Second and Fourth I.F. Transformer
21.25mc., Sound carrier Marker
25.75mc., Picture Carrier Marker

(b) R.F. Frequencies

Channel Number	Picture Carrier Freq. Mc.	Sound Carrier Freq. Mc.
2	55.25	59.75
3	61.25	65.75
4	67.25	71.75
5	77.25	81.75
6	83.25	87.75
7	175.25	179.75
8	181.25	185.75
9	187.25	191.75
10	193.25	197.75
11	199.25	203.75
12	205.25	209.75
13	211.25	215.75

(c) Output on these ranges should be adjustable and at least 0.1 volt maximum.

Heterodyne Frequency meter with Crystal calibrator if the signal generator is not crystal controlled. Electronic Voltmeter of Junior "Volt Ohmyst" type and a high voltage multiplier probe for use with this meter to permit measurements up to 15 KV.

Adjustments Required

Normally, only the RF oscillator will require a slight "touching up". All other circuits are either broad or very stable and hence will seldom require attention. It is recommended that when making replacements the oscillator tube be selected for this service to make the "touching up" as easy as possible or, in some cases, to eliminate it.

Order of Alignment

When a complete receiver alignment is necessary, it can be most conveniently performed in the following order:

1. Picture I.F. transformer
2. Sound I.F. transformer
3. Sound I.F. transformer
4. R.F. Tuner
5. Sensitivity check

Picture I.F. Transformer Adjustment

Remove all tubes from the tuner leaving only the 6J6 converter. Place a miniature tube shield cut in half over the glass envelope of the 6J6 and connect the signal generator to this cap. The cap forms a low capacity coupling to the plate of the converter and loosely couples the signal generator into the I.F. amplifier. Connect the low side of the generator to ground (or chassis). All leads from the generator should be as short as possible. Connect the electronic voltmeter (VTVM) across the opposite ends of R38 in the video detector circuit.

Set the generator to 23.3 mcs and the contrast control to maximum. Adjust coils LI and L3 for maximum d.c. voltage reading on the VTVM. Decrease the generator output so that the maximum voltage reading is in the order of one volt. Set the generator to 25.3 mcs and adjust coils L_2 and L_4 as outlined above. (LI is located in the tuner.) Tune the sound trap coil to minumum response at 21.25 mcs.

It is necessary to use a sweep generator for a more accurate alignment. Replace the signal generator with the sweep generator. Disconnect the VTVM and connect an oscilloscope to the junction of L_5 and L_6. Adjust the sweep generator output to a point below that at which limiting, or over-load takes place. Retune L_1, L_2, L_3, and L_4 as necessary to obtain the response curve as shown in Fig. 9

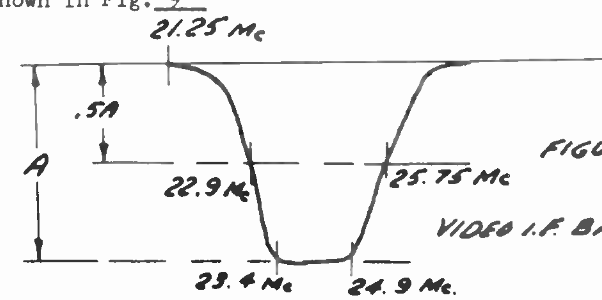

FIGURE 9
VIDEO I.F. BAND PASS

The 22.9 mc marker must be at the 50% response point to insure buzz-free sound. Similarly, the 25.75 mcs marker must be at 50% response point on the right side of the curve to insure good picture quality. If the curve tends to become "peaky" at one end of the response curve, replace C22, C26 or C30. Check all ground connections.

Sound I.F. Adjustment

1. Set the signal generator to 4.5 mc and the output to approximately 5000 microvolts. Connect the high side of the signal generator through a 1000 MMF capacitor to the video amplifier (V8) control grid and ground.

2. Connect the VTVM in series with a 10,000 ohm decoupling resistor across R9 with ground lead to pin 7, V2.

3. Peak the primary and secondary of T1 for maximum reading on the VTVM.

4. Peak the primary of T2 (bottom of chassis) for maximum reading on VTVM.

5. Remove the meter and decoupling resistor from across R9. Connect two well matched 150K resistors in series across R9. Connect the high side of the meter to the junction of the 150K resistors and the low side to the junction of C7 and R7.

6. Adjust secondary of T2 for zero reading on the VTVM.

IMPORTANT: As the adjustments are brought to resonance, reduce the signal input to prevent overloading. Inasmuch as using too much signal input will result in misalignment and a buzz in the audio output, use as low a signal input amplitude as possible.

If desired, the symmetry of the curve may be checked by tuning the secondary to both sides of zero and noting the maximum voltage produced. For proper balance of the ratio detector, the maximum voltages in each direction should be equal. If not, T1 and the primary of T2 should be returned.

R.F. Tuner Alignment

The present series includes four different styles of tuners, three of which are of the turret type and the remaining one -- the R-C tuner -- is of the continuous tuning variety. The circuit diagrams of all four are included below, along with the alignment procedure recommended for the Standard Coil Co's., and the RCA tuners. The other tuners are not treated separately. The remaining turret type tuner is made by the Leonard Electric Products Co. and is similar to the Standard Coil Co. tuner for alignment purposes. The R-C tuner alignment procedure requires special equipment and it is not recommended that the Service Man make these adjustments. However, should such information be desired, it may be obtained by writing to the Video Corporation of America.

Standard TV Tuner

For circuit diagram refer to Fig. 10 . The location of the trimmer capacitors is given in Fig. 11.

RF and Mixer Alignment

1. Set station selector switch to channel 12.

2. Connect oscilloscope through 10,000 ohms to test point 9 (wire loop on top of tuner).

3. Set sharp tuning control at approximately mid point of its tuning range.

4. Feed sweep generator into antenna terminals (properly matched) sweeping channel 12.

5. Adjust C2, C3, and C4 for flat top response curve. Check markers on all channels. They should fall in automatically on all channels.

Oscillator Alignment

1. Turn station selector switch to channel 12.

2. Connect R.F. Sweep generator marker generator and oscilloscope so as to boserve overall band pass characteristics.

3. Set marker generator to channel 12 video carrier frequency, 205.25 mcs.

4. With the fine tuning control in its center position, adjust C5 until the marker is 50% or half way up the left side of the curve.

A 1000 mmf capacitor connected across the oscilloscope input will facilitate observing the marker.

5. Check all channels for above result. It is usually not necessary to make any further adjustments.

6. If some channels are off, place a non-metallic screw driver through opening in front of tuner and adjust the slug for those channels where needed.

RCA Type TV Tuner

For circuit diagram refer to fig. 12. The location of trimmer capacitors is given in fig. 13. Symbols used refer to circuit diagram.

World Radio History

Antenna Alignment

1. Connect sweep generator to terminals of T1.
2. Connect scope through crystal diode unit to pin 5 of V1.
3. Adjust C7 for required response curve of channel 6 on scope.
4. Adjust L18 for required response curve of channel 7 on scope.
5. View channels 2 to 6 and readjust C7 if a compromise is necessary.
6. View channels 7 to 13 and readjust L18 if a compromise is necessary.
7. Remove scope from pin 5.

R.F. Alignment

1. Connect scope to oscilloscope connection "Y".
2. Adjust L11, C10, L13, for required response curve of channel 13 on scope.
3. Adjust C9 and C22 for required response curve of channel 7 on scope.
4. Adjust C13 for required response curve of channel 6 on scope.
5. View channels 2 to 6 and readjust C9, C13, C22, if a compromise is necessary.
6. View channels 7 to 13 and readjust L11, C10, L13, if a compromise is necessary.
7. Remove scope and sweep generator.

Oscillator Alignment

1. Connect sweep generator to terminals of T1.
2. Connect "marker" frequency generator to terminals of T1.
3. Connect oscilloscope to junction of L5 and L6.
4. Set sweep generator to Channel 2 and marker frequency to 55.25 mcs
5. With the fine tuning control in its center position, adjust C19 until the marker is 50% or half-way up the left side of the curve. (A 1000 mmf capacitor connected across the oscilloscope input will facilitate observing the marker.
6. Switch tuner and sweep generator to channel 13 and marker to 211.25 mcs.
7. Adjust L12 for same result as in step 5 above.
8. Check channels 3 to 12 and set individual strip oscillator adjustment screws.

If necessary. Channel 2 and 13 strip adjustments have been made at the factory, and resetting C19 and L12, makes readjustment of these strips unnecessary.

Recheck RF Alignment for curve shape as outlined above and repeat steps 5 and 6 of RF Alignment if necessary.

Horizontal Frequency Adjustment

With a clip lead, short circuit the coil between terminals C and D of the horizontal oscillator transformer T7. Tune in a television station and sync the picture if possible.

A. Turn the horizontal hold control to the extreme clockwise position. Adjust the T7 Frequency Adjustment (under the chassis) so that the picture is just out of sync and the horizontal blanking appears in the picture as a vertical bar. The position of the bar is unimportant.

B. Turn the hold control approximately one quarter of a turn from the extreme clockwise position and examine the width and linearity of the picture. If picture width or linearity is incorrect, adjust the horizontal drive control, C71, the width control and the linearity control until the picture is correct. If C71, or either control, was adjusted, repeat Step A above.

Horizontal Oscillator Alignment

Normally the adjustment of the horizontal oscillator is not considered to be a part of the alignment procedure, but since the oscillator waveform adjustment requires the use of an oscilloscope, it can not be done conveniently in the field. The waveform adjustment is made at the factory and normally should not require readjustment in the field. However, the waveform adjustment should be checked whenever the receiver is aligned or whenever the horizontal oscillator operation is improper.

Horizontal Locking Range Adjustment

Turn the horizontal hold control fully counterclockwise. Momentarily remove the signal by switching off channel then back. Slowly turn the horizontal hold control clockwise and note the least number of diagonal bars obtained just before the picture pulls into sync.

If more than 9 bars are present just before the picture pulls into sync adjust the horizontal locking range trimmer C62 slightly clockwise. If less than 7 bars are present, adjust C62 slightly counterclockwise. Turn the horizontal hold control counterclockwise, momentarily remove the signal and recheck the number of bars present at the pull-in-point Repeat this procedure until 7 to 9 bars are present.

Horizontal Oscillator Waveform Adjustment

Remove the shorting clip from terminals C and D of T7. Turn the horizontal hold control to the extreme clockwise position. With a thin fibre screwdriver, adjust the Oscillator Waveform Core of T7 (on the outside of the chassis) until the horizontal blanking bar appears in the raster.

A. Connect the low capacity probe of an oscilloscope to terminal C of T7. Turn the horizontal hold control one quarter turn from the clockwise position so that the picture is in sync. The pattern on the oscilloscope should be as shown in Fig. 15. Adjust the Oscillator Waveform Adjustment Core of T7 until the two peaks are at the same height. During this adjustment, the picture must be kept in sync by readjusting the hold control if necessary.

This adjustment is very important for correct operation of the circuit. If the broad peak of the wave on the oscilloscope is lower than the sharp peak, the noise immunity becomes poorer, the stabilizing effect of the tuned circuit is reduced and drift of the oscillator becomes more serious. On the other hand, if the broad peak is higher than the sharp peak, the oscillator is overstabilized, the pull-in range becomes inadequate and the broad peak can cause double triggering of the oscillator when the hold control approaches the clockwise position.

Remove the oscilloscope upon completion of this adjustment.

Check of Horizontal Oscillator Adjustments

Set the horizontal hold control to the full counterclockwise position. Momentarily remove the signal by switching off channel then back. Slowly turn the horizontal hold control clockwise and note the least number of diagonal bars obtained just before the picture pulls into sync.

If more than 3 bars are present just before the picture pulls into sync, adjust the horizontal locking range trimmer C62 slightly clockwise. If less than 3 bars are present, adjust C62 slightly counterclockwise. Turn the horizontal hold control counterclockwise momentarily remove the signal and recheck the number of bars present at the pull-in point. Repeat this procedure until 3 bars are present.

Turn the horizontal hold control to the maximum clockwise position. The picture should be just out of sync to the extent that the horizontal blanking bar appears as a single vertical or diagonal bar in the picture. Adjust the T7 Frequency Adjustment until this condition is fulfilled.

SENSITIVITY CHECK

A comparative sensitivity check can be made by operating the receiver on a weak signal from a television station and comparing the picture and sound obtained to that obtained on other receivers under the same conditions.

This weak signal can be obtained by connecting the shop antenna to the receiver through a ladder type attenuator pad. The number of stages in the pad depends upon the signal strength available at the antenna. A sufficient number of stages should be inserted so that a somewhat less than normal contrast picture is obtained when the picture control is at the maximum clockwise position. Only carbon type resistors should be used to construct the pad.

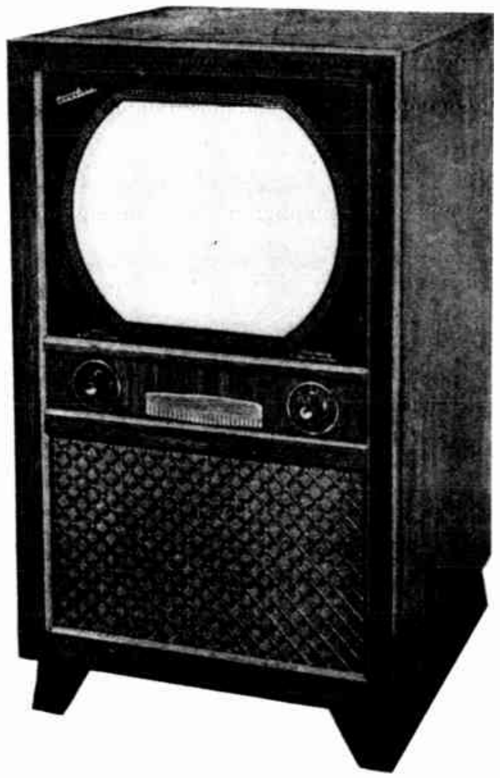
INDEX



MODEL 2D1088 (12½" PIX TUBE)
MODEL 2D1089 (16" PIX TUBE)

ELECTRICAL SPECIFICATIONS

Power Supply . . . . .105-125 Volts AC
60 cycles only

Power Consumption . . . . . . .12½" Tube Receivers—220 watts
16" Tube Receivers — 250 watts

Power Output . . . . .2.4 watts Maximum
1.8 watts Undistorted

Antenna Input Impedance . .300 Ohms Balanced

Picture Area (12½" Tube). .90 Sq. In.

Picture Area (16" Tube). . . .144 Sq. In.

Tuning Range . . . . .12 Channel

Intermediate Frequencies . . .Picture—26.20 MC
Sound—21.70 MC

ELECTRICAL SPECIFICATIONS—continued

Loud Speaker . . . . .12" PM Dynamic

Voice Coil Impedance . . . . .3.2 Ohms 400 Cycles

Video Response . . . . .To 3.9 MC

Focus . . . . .Magnetic

Sweep Deflection . . . . .Magnetic

Scanning . . . . .Interlaced, 525 Line

Horizontal Scanning Freq. . . .15,750 CPS

Vertical Scanning Freq. . . . .60 CPS

Frame Frequency . . . . .30 CPS

Anode Voltage (12½" Tube) 11,000 V.
(16" Tube). .12,500 V.

Mask Size (12½" Tube). . . .10-7/8" x 9-3/8"
(16" Tube). . . . .14-5/8" x 11"

13	210-216	211.25	215.75	237.45

RECEIVER LOCATION—Advise the owner as to the proper location for the television receiver. The following may be used as a guide:

1. Choose an area in the home where sunlight or light from lamps does not strike the face of the picture tube and cause glare.
2. Remember the necessity of an electrical outlet and the location of the point at which the antenna leads enter the room.
3. The receiver should be placed a short distance from the wall to allow adequate ventilation.
4. The receiver should be placed to permit easy access for operation and comfortable viewing from all angles.

ANTENNA—This receiver has been designed to use an antenna with a 300 ohm balanced transmission line. This line must be as short as possible because the longer the line the greater the chances are for picking up electrical disturbances. Stand-off insulation should be used to keep the line away from the mast, metal or walls. Twist this line about one turn per foot throughout the line to cancel out direct signal and/or noise pickup by the transmission line. It should also be securely anchored in place so that a change in weather will not affect its position.

HIGH VOLTAGE WARNING

This television receiver contains high voltages which are dangerous to life. Never operate or service the receiver outside of the cabinet or with the covers removed until all the safety precautions necessary for working with high voltage equipment have been observed.

©John F. Rider

World Radio History

PICTURE TUBE HANDLING PRECAUTION

Shatterproof goggles and heavy gloves must be worn by individuals while handling the picture tube or installing the picture tube into the receiver.

The picture tube encloses a high vacuum and due to the large surface area, is subjected to excessive air pressure. Therefore, care should be taken not to bump or scratch the picture tube accidentally as it may cause the tube to implode resulting in damage to property or injury to an individual.

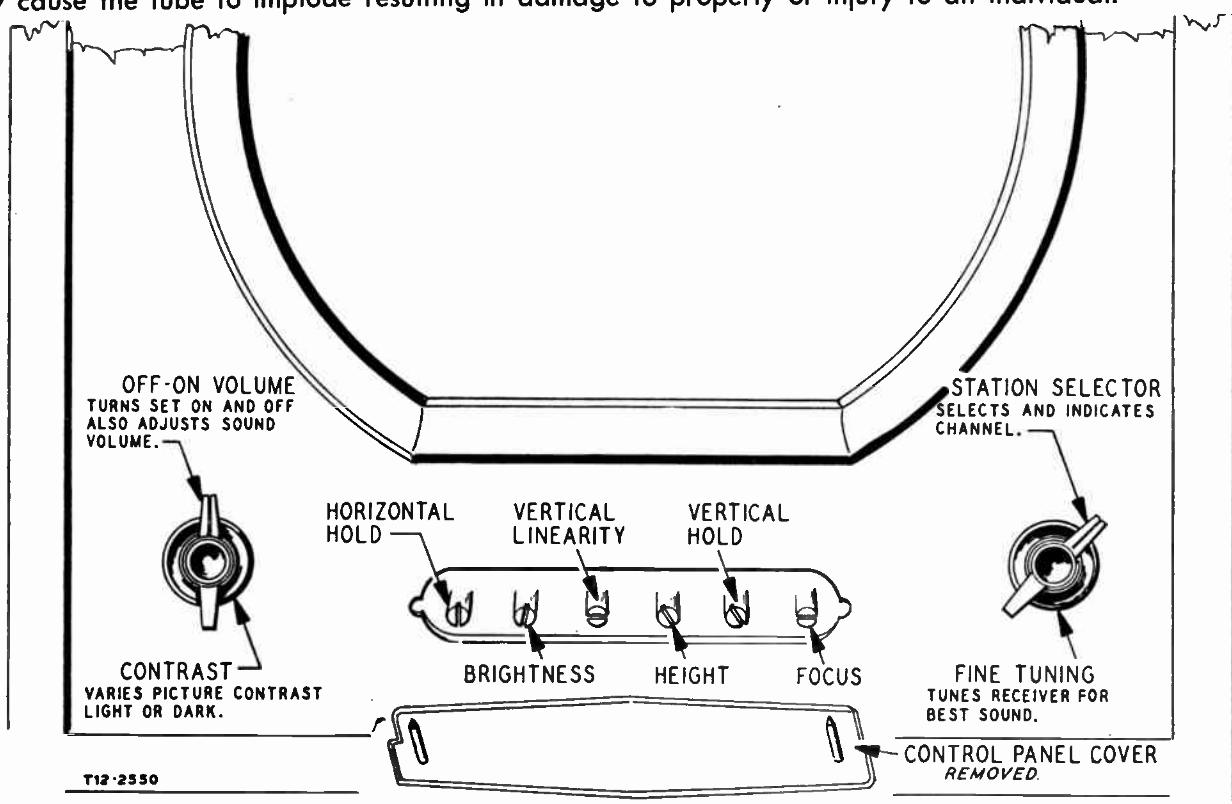

Fig. 2—Front Panel Controls

TUNING PROCEDURE

1. To turn the television receiver on, turn the OFF-ON SOUND CONTROL clockwise until a click is heard. Allow approximately 30 seconds for the tubes to warm up.
2. Turn the STATION SELECTOR CONTROL to the desired channel. This control may be turned in either direction.
3. Turn the CONTRAST CONTROL clockwise until activity or definite form is noted on the screen.
4. Adjust the FINE TUNING CONTROL for best tonal quality and the SOUND CONTROL for desired volume.
5. After the receiver has been on for a while it may be necessary to readjust the FINE TUNING CONTROL for best sound quality.
6. To turn off the receiver, turn only the OFF-ON SOUND CONTROL counterclockwise until a click is heard.

OCCASIONAL ADJUSTMENTS TO IMPROVE PICTURE RECEPTION

There are six controls at the front of the chassis. These controls are accessible after the removal of the control panel cover at the front of the cabinet. (See illustration) The controls are pre-set at the factory and may occasionally need adjustment due to aging of the components in the receiver and the fluctuating line voltages in different areas.

If any adjustments are necessary, follow the instructions under "Controls and Functions."

IMPORTANT—Be sure that the fine tuning control has been set for best tonal quality and clearest picture before adjusting any controls.

CONTROLS AND FUNCTIONS

HORIZONTAL HOLD—Stops horizontal movement (diagonal bars.)
BRIGHTNESS—Adjusts for desired picture brilliance.
VERTICAL LINEARITY—Adjusts picture symmetry, top to bottom.

HEIGHT—Adjusts picture to fit mask vertically.

VERTICAL HOLD—Stops upward or downward picture movement.

FOCUS—Adjusts picture sharpness and clarity.

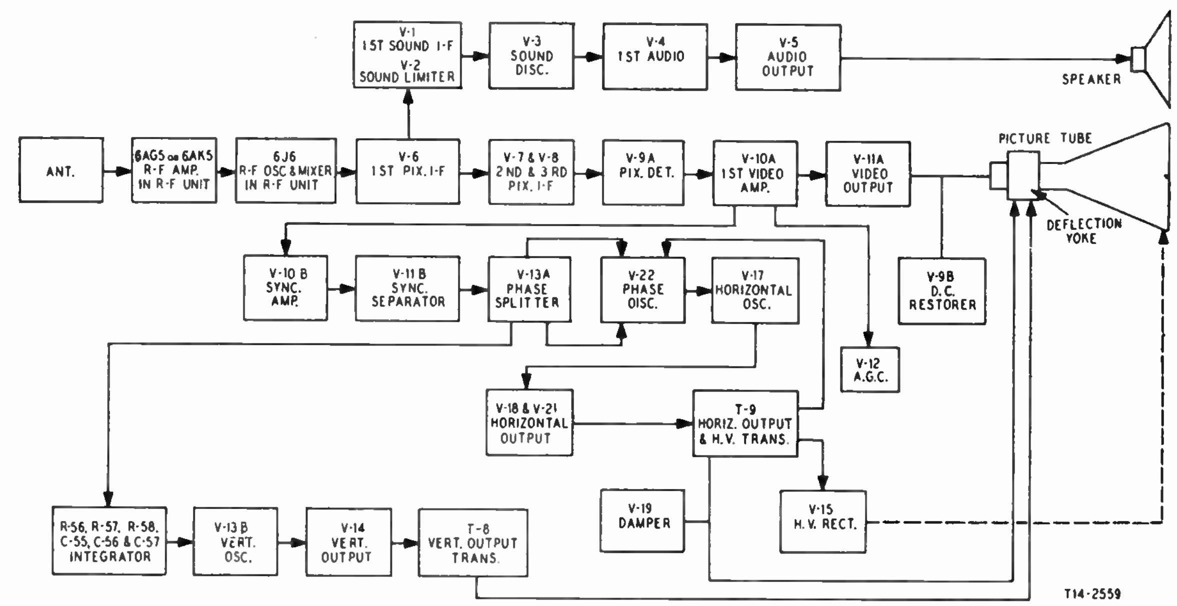

Fig. 3—Block Diagram (16" Pix Tube Receivers)

World Radio History

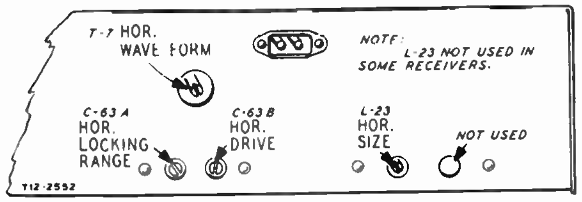

Fig. 5—Rear Chassis Adjustments (12½" Pix Tube Receivers)

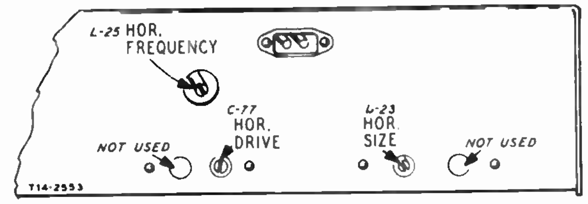

Fig. 6—Rear Chassis Adjustments (16" Pix Tube Receivers)

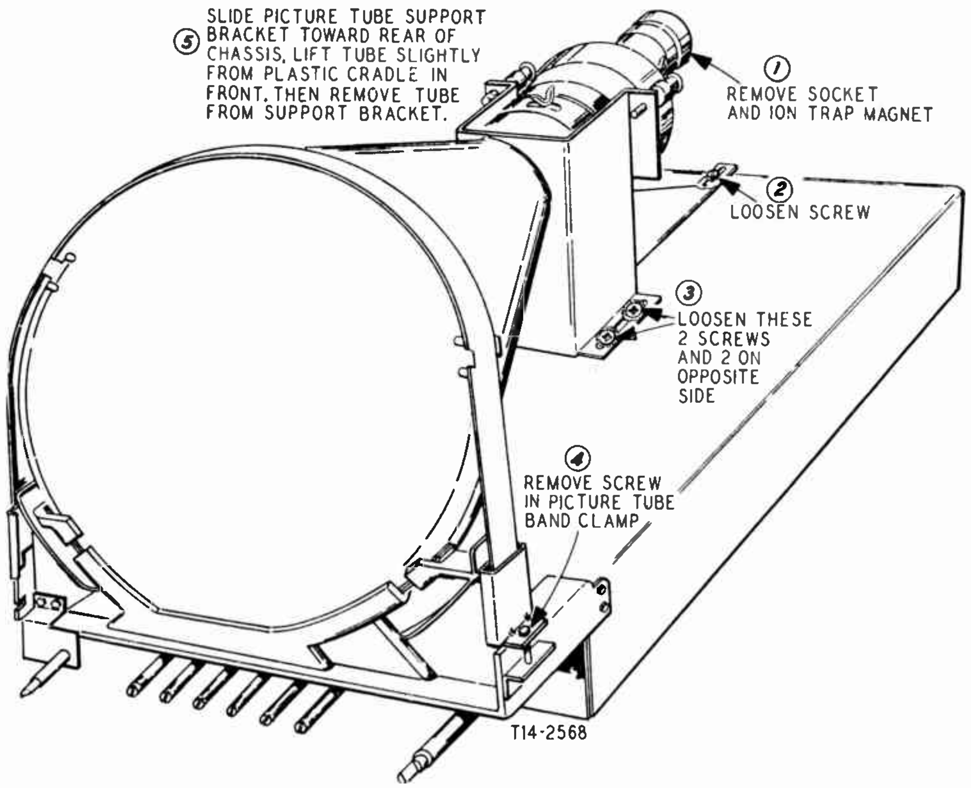

Fig. 7—Removal of Picture Tube

PICTURE TUBE — All receivers are shipped with the picture tube in place. However, to prevent picture tube breakage in 16" pix tube receivers the three focus coil mounting screws were drawn up tight. To place the receiver in operation the following must be performed:

1. Remove the interlocked cabinet back. Make sure that all the tubes are firmly seated in their respective sockets and note the location of the focus coil mounting screws. Back out the focus coil mounting screws until there is approximately a 3/8 inch space between the focus coil and the deflection yoke. Replace the cabinet back.
2. Connect the receiver to a power outlet and turn the receiver on. Turn the channel selector knob to a channel that you know is operating.
3. Observe the picture and adjust the three focus coil mounting screws (through the openings in the cabinet back with a screwdriver which has a seven inch blade) until proper horizontal and vertical centering is obtained.

WARNING — If a screwdriver with a blade longer than seven inches is used, it may accidentally touch a portion of the receiver that carries a high potential.

4. If adjustments are necessary on the deflection yoke or the ion trap magnet, follow the procedures on page 20.

PICTURE TUBE REPLACEMENT — To replace the picture tube it is necessary to remove the chassis from the cabinet. This may be accomplished in the following manner:

1. Remove the front panel control knobs by pulling them straight from their shafts.
2. Remove the cabinet back. You will note that the interlocked line cord disconnects the power when the cabinet back is removed.
3. Disconnect the leads to the speaker, remove the antenna terminal board at rear of cabinet, remove the five chassis mounting bolts and pull the chassis CAREFULLY out of the cabinet.

WARNING — Before handling the picture tube, it will be necessary to remove the static charge. In receivers with glass picture tubes, ground the anode lead to chassis, and insert an insulated wire from the well in the tube to chassis. In receivers with metal picture tubes, remove the static charge by grounding an insulated wire from the chassis to the metal portion of the tube.

4. Remove the picture tube as shown and outlined in the illustration. To install a new picture tube, reverse the procedure making sure that the picture tube is fitted closely against the picture tube cushion. If the picture tube sticks or fails to slip into place smoothly, investigate and remove the source of the trouble. Never force the tube. It is important that all the clips and shims used in mounting the tube be replaced, otherwise difficulty may be encountered when horizontal or vertical centering is required.

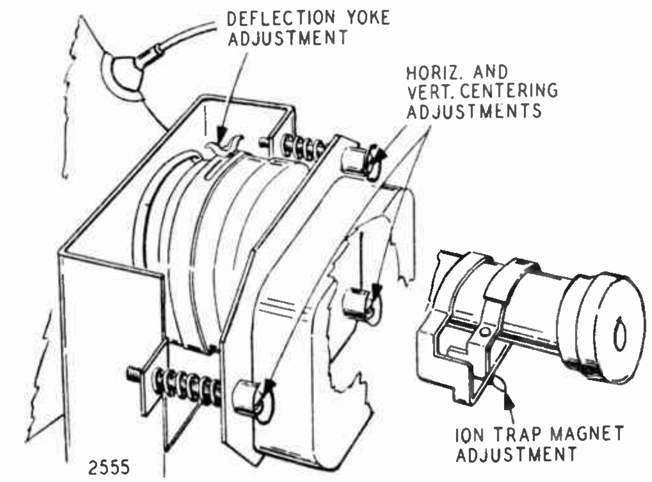

Fig. 8—Ion Trap, Focus and Yoke Adjustments.

ION TRAP MAGNET ADJUSTMENT — The ion trap magnet should be positioned exactly as shown in Figure 8. Adjust the magnet by moving it back and forth and at the same time rotating it slightly around the neck of the picture tube until the brightest raster is obtained on the picture screen. Reduce the brightness control setting until the raster is slightly above average brilliance. Adjust the Focus Control R-81 (see Figure 2) until the line structure of the raster is clearly visible. Readjust the ion trap magnet for maximum raster brilliance.

DEFLECTION YOKE ADJUSTMENT — If the lines of the raster are not horizontal or squared with the picture mask, rotate the deflection yoke until this condition is obtained. Tighten the yoke adjustment wing screw.

FOCUS COIL ADJUSTMENT — If horizontal or vertical centering is required, adjust the three focus coil mounting screws until proper centering is obtained. See Fig. 8.

PICTURE ADJUSTMENT — For further adjustments, obtain a test pattern on the receiver. Turn on receiver and follow tuning procedure on page 3. When a test pattern is obtained it may be necessary to slightly re-adjust the focus control for maximum picture detail.

12½" PIX RECEIVER ADJUSTMENTS

CHECK OF HORIZONTAL OSCILLATOR ALIGNMENT — Turn the horizontal hold control to the extreme counter-clockwise position. The picture should remain in horizontal sync. Momentarily remove the signal by switching off channel and then back. Normally the picture will be out of sync.

©John F. Rider

World Radio History

Turn the control clockwise slowly. The number of diagonal bars will be gradually reduced and when only 3-1/2 to 4-1/2 bars sloping downward to the left are obtained, the picture will pull into sync upon slight additional clockwise rotation of the control. The pull-in should occur when the control is approximately 90 degrees from the extreme counter-clockwise position. The picture should remain in sync for approximately 90 degrees of additional clockwise rotation of the control.

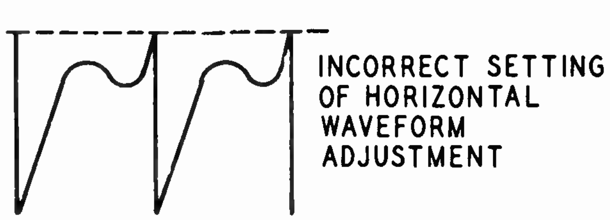
At the extreme clockwise position the picture should be just starting to pull out of sync. Usually one vertical bar will be seen.

If the receiver passes the above checks and the picture is normal and stable, the horizontal oscillator is properly aligned.

ALIGNMENT OF HORIZONTAL OSCILLATOR — If in the above check the receiver failed to hold sync with the hold control at the extreme counter-clockwise position or failed to hold sync for at least 60 degrees of clockwise rotation of the control from the pull in point, it will be necessary to make the following adjustments.

HORIZONTAL FREQUENCY ADJUSTMENT — Turn the horizontal hold control to the extreme clockwise position. Tune in a station and adjust the horizontal frequency control (T-7 See Fig. 17) until the picture is just out of sync and shows one vertical bar. In order to obtain this condition it may be necessary to slightly re-adjust the horizontal locking range trimmer (C-63A) on the rear apron.

HORIZONTAL WAVE FORM ADJUSTMENT — This is a factory adjustment and it should not be necessary to re-adjust unless the setting has been disturbed. However, if it is found that re-adjustment is required, follow this procedure: With the picture in sync, connect an oscilloscope through about a 10 mmf isolation condenser to Terminal C of T-7. Adjust the horizontal wave form (T-7 See Fig. 5) until the two peaks of the wave form shown in Fig. 9 are equal. NOTE: Picture must be in sync during this adjustment.



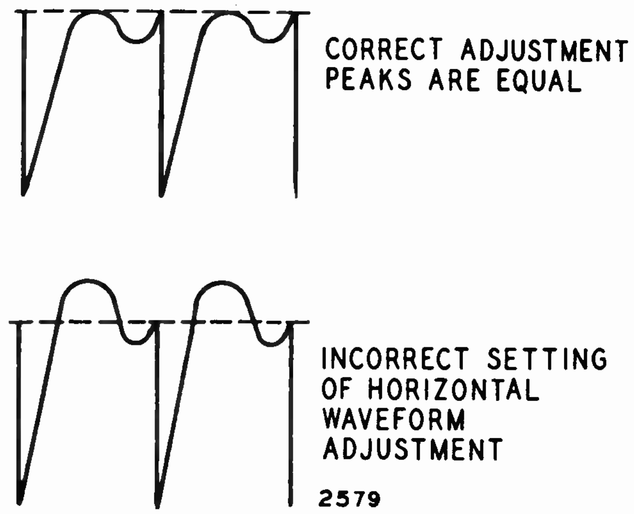


Fig. 9—Horizontal Wave Form Adjustment

HORIZONTAL LOCKING RANGE ADJUSTMENT — Set the horizontal hold control to the extreme counter-clockwise position. Momentarily remove the signal by switching off channel and then back. Slowly turn the horizontal hold control clockwise and note the least number of diagonal bars obtained just before the picture pulls into sync. If more than 4-1/2 bars are present just before the picture pulls into sync, adjust the horizontal locking range trimmer C-63A (See Figure 5) slightly clockwise. If less than 3-1/2 bars are present, adjust trimmer C-63A slightly counter-clockwise. Turn the horizontal hold control counter-clockwise, momentarily remove the signal and recheck the number of bars present at the pull-in point. Repeat this procedure until 3-1/2 to 4-1/2 bars are present. Repeat the adjustments under "Horizontal Frequency Adjustment" and "Horizontal Locking Range Adjustment" until the condition specified under each are fulfilled. When the horizontal hold operates as outlined under "Check of Horizontal Oscillator Alignment" the oscillator is properly adjusted.

16" PIX RECEIVER ADJUSTMENTS

CHECK OF HORIZONTAL OSCILLATOR ALIGNMENT —Tune in a station and adjust the horizontal hold control until the picture falls into sync. Momentarily remove the signal by switching off channel and then back. The picture should pull into sync over a range of 90° rotation of the horizontal hold control. If in the above check the receiver fails to hold sync or the pull-in range is at the extreme end of the control, and is less than 60°, it will be necessary to make the following adjustment.

HORIZONTAL FREQUENCY ADJUSTMENT —With the horizontal hold control set to the center of its range of rotation, adjust the horizontal frequency control (L-25) until the picture pulls into sync. Recheck the "Horizontal Oscillator Alignment."

THE FOLLOWING ADJUSTMENTS ARE APPLICABLE TO 12½" AND 16" PIX TUBE RECEIVERS.

HEIGHT AND LINEARITY ADJUSTMENTS —Adjust the height control (R-63) until the picture fills the mask vertically. Adjust the vertical linearity control (R-87) until the picture is symmetrical from top to bottom. Adjustment of either control will require a re-adjustment of the other control. Adjust vertical centering (3 focus coil mounting screws) to align picture with the mask.

HORIZONTAL SIZE AND DRIVE ADJUSTMENTS—Turn the horizontal size control L-23 (See Fig. 5 & 6) to the maximum clockwise position. Vary the horizontal drive trimmer (C-63B on 12-1/2" Pix Tube Receiver) (C-77 on 16" Pix Tube Receiver) to yield the best linearity. Re-adjust the horizontal size control L-23 until the picture just fills the mask. Adjust horizontal centering (3 focus coil mounting screws) to align the picture with the mask.

If the horizontal drive trimmer is opened too far counter-clockwise, a white line may appear to the left of the center of the picture.

CHECK OF R-F OSCILLATOR ADJUSTMENTS

With an accurately calibrated signal generator (crystal calibrated type preferred check to see if the receiver R-F oscillator is adjusted to the proper frequency on all channels. For this check, it will be necessary to remove the chassis from the cabinet. Illustrated on this page are the two types of tuners used in these receivers. For switch-type

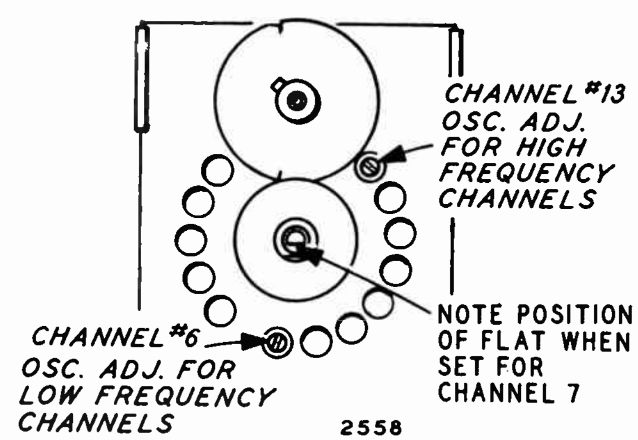

Fig. 10—Switch Type Tuner Adjustment

tuners adjust as shown in Fig. 10. When Channel 6 (low) and Channel 13 (high) trimmers are adjusted properly, other channels in the high and low frequency band will fall in automatically.

For turret type tuners adjust each channel through the clearance hole as shown in Fig. 11.

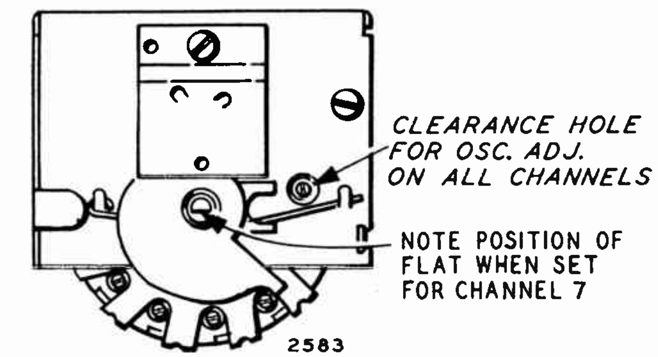

Fig. 11—Turret Type Tuner Adjustment

SERVICE SUGGESTIONS

NO RASTER ON PICTURE TUBE—If raster cannot be obtained check below for the possible causes.

1. Ion trap magnet adjustment is incorrect.
2. No +B voltage. Check 1/4 ampere fuse (F-1). *Replace if defective. If fuse continually burns out, check (A) Horizontal output tube V-18 (6BG6-G in 12-1/2" pix tube receivers) or V-18 and V-21 (6BQ6-GT's) in 16" pix tube receivers. (B) Check damper tube V-19 (6W4-GT). (C) Check horizontal oscillator V-17 (6SN7-GT) for proper operation. In the 16" pix tube models, connect a jumper wire from the +B side of F-1 to the junction of C-79 and R-85. For the 12-1/2" pix tube models use a similar wire from the +B side to the junction of R-70 and R-73. (D) With an ohm-meter, check for a short between terminal 2 of the horizontal output transformer T-9 and the chassis. (E) Check capacitors C-22C and C-73C.
3. No high voltage. Check V-15 and V-18 tubes and circuits. If the horizontal deflection circuits are operating as evidenced by the correct voltage measured on terminal 2 of the horizontal output transformer T-9, the trouble can be isolated to the high voltage rectifier V-15 circuit. Either the high voltage winding (points 6 to 7 on T-9) is open, tube V-15 is defective, its filament circuit is open, or the high voltage filter capacitor C-86 or C-83 on 12-1/2" models is shorted.
4. Defective picture tube. Heater open or cathode return circuit open.

*This fuse is accessible from bottom of cabinet. Remove wire screen, unsolder old fuse, solder in the new fuse and replace wire screen.

HORIZONTAL DEFLECTION ONLY—If only horizontal deflection is obtained as evidenced by a straight line across the face of the picture tube, it can be caused by the following:

1. Vertical oscillator V-13 (6SN7-GT) or vertical output tube V-14 (6K6-GT) inoperative. Check voltages on grid and plate.
2. Vertical output transformer (T-8) open.
3. Yoke vertical coils open.
4. Vertical hold, height or linearity controls may be defective.

POOR VERTICAL LINEARITY—If adjustment of the vertical hold, height or linearity controls will not correct this condition, any of the following may be the cause.

1. Vertical output transformer (T-8) defective.
2. Capacitors C-73A or C-73B defective.
3. V-13 (6SN7-GT) or V-14 (6K6-GT) defective, check voltages.
4. Excess leakage or incorrect value in capacitor C-64.
5. Low plate voltages. Check rectifier tubes and capacitors in +B supply circuits.
6. Capacitor C-65 defective.

POOR HORIZONTAL LINEARITY—If adjustment of the Horizontal drive control does not correct this condition, check the following:

1. Check or replace horizontal output tubes V18 & V-21.
2. Check or replace damper tube V-19 (6W4-GT).
3. Check capacitor C-82 for defects.

TRAPEZOIDAL OR NONSYMMETRICAL RASTER

1. Improper adjustment of focus coil or ion trap magnet.
2. Defective yoke.
3. Open condenser C-85 on horizontal yoke coil L-21.

WRINKLES ON LEFT SIDE OF RASTER—This condition can be caused by:

Defective yoke due to C-85 (internal in yoke assembly) being wrong value or open. This component is mounted in rear of yoke assembly.

SMALL RASTER—This condition can be caused by:

1. Low +B or line voltage.
2. Insufficient output from horizontal output tubes V-18 or V-21. Replace tubes.
3. Insufficient output from vertical oscillator V-13 or vertical output tube V-14. Replace tubes.

RASTER; NO IMAGE, BUT ACCOMPANYING SOUND—This condition can be caused by:

1. No signal on picture tube grid. Check picture I-F amplifier tubes V-6, 7 and 8 (6AG5's), second detector V-9A (6AL5) and video amplifiers V-10 (12AT7) and V-11 (12AU7).
2. Bad contact to picture tube grid (lead to socket broken).

SIGNAL APPEARS ON PICTURE TUBE GRID BUT IMPOSSIBLE TO SYNCHRONIZE THE PICTURE VERTICALLY AND HORIZONTALLY—A condition of this nature can be caused by:

1. Defective sync amplifier and separator V-11 (12AU7-V-10 (12AT7) or V-13 (6SN7-GT).
2. If tubes are O.K. check voltages, and associated circuits.
3. AGC system inoperative. Check V-12 (6AU6) AGC tube and associated circuits.

SIGNAL ON PICTURE TUBE GRID AND HORIZONTAL SYNC ONLY—If this condition is encountered, check:

1. Vertical integrating network capacitors C-55, C-56, and C-57; and resistors R-56, R-57 and R-58.
2. Vertical hold control R-60 defective.

PICTURE STABLE BUT WITH POOR RESOLUTION—If the picture resolution is not up to standard, it may be caused by any of the following:

1. Defective picture detector V-9A (6AL5) or video amplifier V-10 (12AT7) and V-11 (12AU7).
2. Open video peaking coil. Check all peaking coils L-9, L-10, L-11, L-12 and L-13 for continuity. Note that L-10 and L-12 have shunting resistors.
3. Leakage in V-11 (12AU7) grid capacitor C-90. If the above components are not found to be defective, check the following:

1. Check all potentials in video circuits.
2. Check picture tube grid circuit for poor or dirty contact.
3. Check adjustment of focus control R-81. It should be effective on either side of proper focus.
4. Check and realign, if necessary, the picture I-F and R-F circuits.

PICTURE SMEAR:

1. Normally, smear can be attributed to phase shift at the low frequency end of the video characteristic. This can be caused by improper values of resistors and capacitors in the video circuits. Check for grid current on video output tube V-11 (12AU7).
2. This trouble can also originate at the transmitter. Check reception from another station.
3. Check and realign, if necessary, the picture I-F and R-F circuits.

PICTURE JITTER:

1. If regular sections at left of the picture are displaced, replace the horizontal output tubes V-18 or V-21.
2. Vertical instability may be due to loose connections or noise received with the signal.
3. Horizontal instability may be due to unstable transmitted sync or to noise.
4. Check receiver AGC system for proper operation.

World Radio History

ALIGNMENT PROCEDURE

TEST EQUIPMENT—To service this receiver properly, it is recommended that the following test equipment be available:

R-F SWEEP GENERATOR meeting the following requirements:
(a) Frequency ranges:
18 to 30 mc, 10 mc sweep width
40 to 90 mc, 10 mc sweep width
170 to 225 mc, 10 mc sweep width
(b) Output adjustable with at least .1 volt maximum.
(c) Output constant on all ranges.
(d) Flat output in all attenuator positions.

CATHODE-RAY OSCILLOSCOPE preferably one with a wide band vertical deflection and an input calibrating source.

SIGNAL GENERATOR to provide the following frequencies:

(Output on these ranges should be adjustable and at least .1 volt maximum.)
(a) Intermediate alignment frequencies:
*17.0 mc adjacent picture trap
20.2 mc adjacent picture trap
22.7 mc first picture I-F coil
**24.1 mc third picture I-F coil
25.7 mc second picture I-F coil
27.7 mc adjacent sound trap
21.7 mc sound trap (takeoff)
4.5 mc video trap

* This frequency is not used in receivers with the turret type tuner.

** If turret type tuner is used the frequency will be 23.7 mc.

(b) Radio frequencies:

Channel Number	Picture Carrier Freq. Mc.	Sound Carrier Freq. Mc.
2	55.25	59.75
3	61.25	65.75
4	67.25	71.75
5	77.25	81.75
6	83.25	87.75
7	175.25	179.75
8	181.25	185.75
9	187.25	191.75
10	193.25	197.75
11	199.25	203.75
12	205.25	209.75
13	211.25	215.75

HETERODYNE FREQUENCY METER with crystal calibrator if the signal generator is not crystal controlled.

ELECTRONIC VOLTMETER and a high voltage probe for use with this meter to permit measurements up to 20 kilovolts.

SERVICE PRECAUTIONS — To service the receiver remove the chassis from the cabinet. To do so, remove the knobs, the cabinet back, the antenna terminal board at rear of cabinet and the 5 chassis mounting bolts. The chassis may be serviced with the picture tube in place provided the chassis is turned on its side with the power transformer on the bottom. The weight of the chassis will be supported against the high voltage housing.

CAUTION: Do not permit the kinescope second-anode lead to become shorted to the chassis. To do so will cause a considerable overload on the high voltage filter resistor R-79 on 12½" receivers or R-97 on 16" receivers.

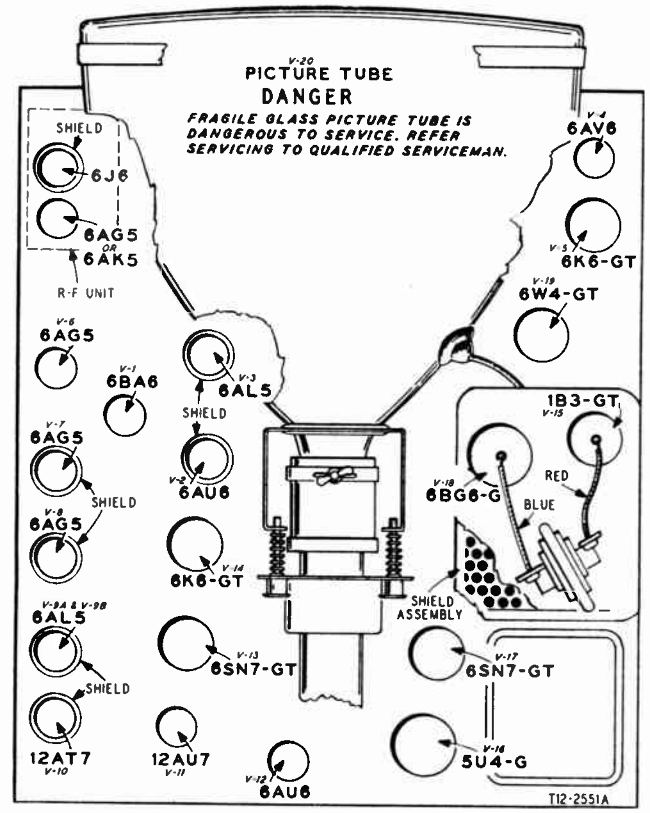

Fig. 15—Tube Layout—12½" Pix Tube Receivers

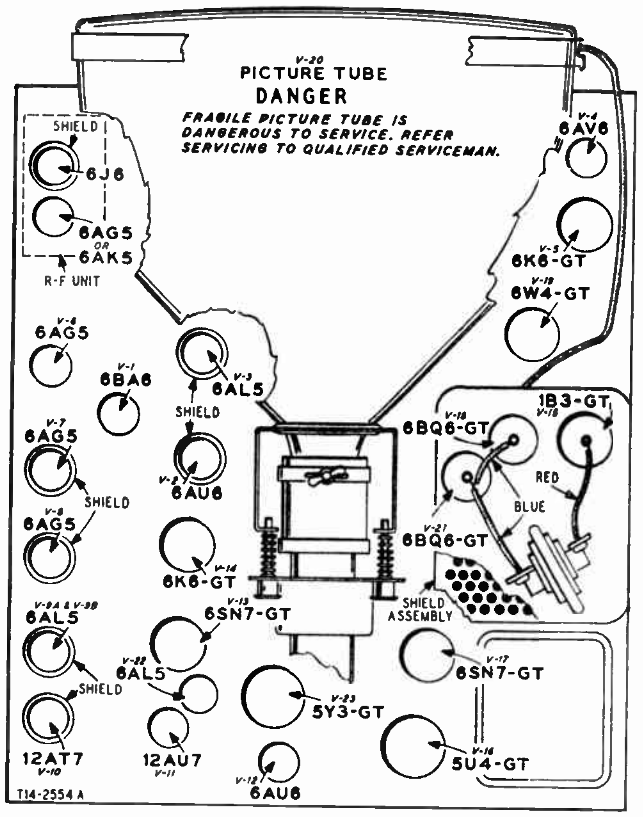

Fig. 14—Tube Layout—16" Pix Tube Receivers

ALIGNMENT PROCEDURE PIX I-F

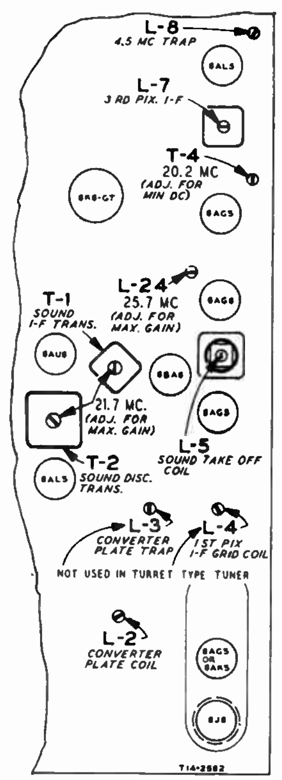

Fig. 16. Top Chassis Video and Audio I-F Adjustments

A. CW Carrier into Converter Grid. VTVM with filter in lead of 10 K ohms and 5000 uuf connected to pic. det. load resistor, (R-31) 4700 ohms, in series with peaking coil (L-9) from Pin 7 of 6AL5. Input level should be such that output is less than 2 volts DC.

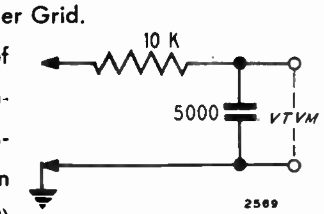

Fig. 18—VTVM Connections

	FREQUENCY	ADJUST
1.	20.2	Adjacent pix trap (T-4) — (3rd P-IF Cathode Coil) (above chassis) for minimum dc at picture detector.
2.	22.7	1st pix IF (L-5) (Sound Take-off Coil) primary (below chassis) for maximum dc at picture detector.
3.	25.7	2nd pix IF (L-24) (top of chassis) for maximum dc at picture det.

©John F. Rider

World Radio History

ALIGNMENT PROCEDURE (continued)

	FREQUENCY	ADJUST
4.	24.1 (Switch Type Tuner) 23.7 (Turret Type Tuner)	3rd pix IF (L-7) (below chassis) for maximum dc at picture detector.
5.	27.7	2nd pix IF (L-24) transformer (below chassis) for minimum dc at picture detector.
6.	21.7	Sound Take-off Coil (L-5) (1st picture IF) (top of coil) For minimum dc at picture detector.
7.	21.7	3rd pix IF (L-7) (top of can) adjust for minimum dc at picture detector.
*8.	17 MC (2 volts required)	Converter plate trap coil (L-3) for minimum dc at pic. detector.

*Step 8 omitted in Receivers with turret type tuner.

B. I-F Sweep Generator into converter grid (through tube shield insulated from chassis) with markers at 21.7 MC, and 26.2 MC.
Connect oscilloscope probe to plate of 1st I-F tube V-6 (Pin 5 of 6AG5).
Ground A-G-C Line.

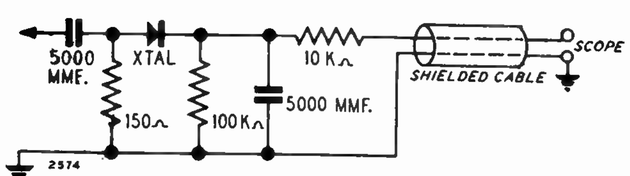

Fig. 19—Oscilloscope Connection

SWITCH TYPE TUNERS

Adjust converter plate coil (L-2) and 1st Pic. I-F grid coil (L-4) (top of chassis) to give the response shown below in figure 20.
A slight re-adjustment of L-3 converter plate trap may be necessary.

TURRET TYPE TUNERS

Adjust converter plate coil (L-2) to give response shown in dotted line in figure 20.

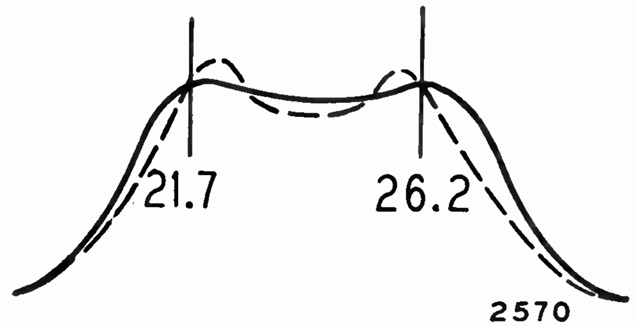

Fig. 20—Response Curve

C. With same I-F sweep input, connect scope probe to second detector (junction of peaking coil (L-9) and 4700 ohm resistor (R-31) off Pin 7, 6AL5). Input should be adjusted to give 2 volt P to P output.
Apply 3 V, bias (dc) to AGC line. (battery).

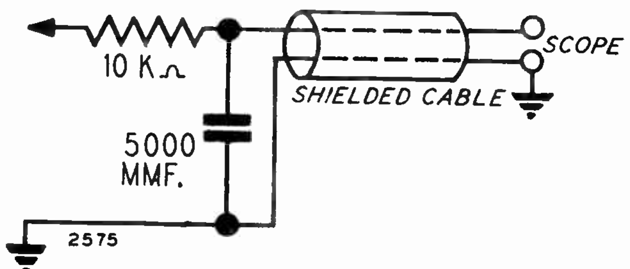

Fig. 21—Oscilloscope Connection

Observe overall I-F response, which should be as shown in Figure 22. Slight touch-up may be required.

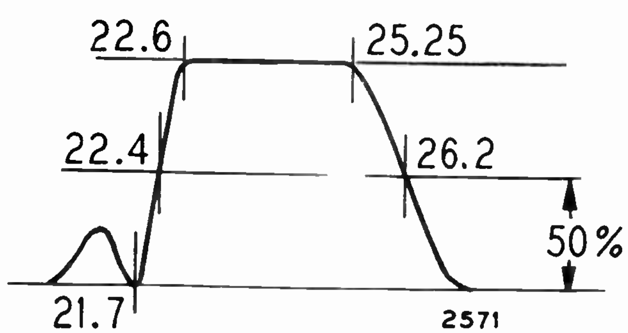

Fig. 22—Overall Response Curve

D. Sweep generator with balanced 300 ohm output into antenna for each channel. Adjust fine tuning to receive sound and observe overall response at second detector as in C. above.

If 26.2 marker is not at 50% point, a slight touch-up of 2nd Pix-IF transformer (L-24 on top of chassis) is required.

If there is a noticeable peak near 23 MC, a slight touch-up of 1st Pix-IF transformer (L-5 sound take-off coil on bottom of chassis) is required.

If the top of the curve is tilted, a slight re-adjustment of the 3rd Pix-IF transformer L-7 (bottom of chassis) may be necessary.

AUDIO I-F

With 21.7 CW Carrier into converter grid as in A., and VTVM connected to terminal "C" of sound discriminator transformer, adjust sound I-F transformer (T-1) pri. and sec., and pri. (top of can) of discriminator (T-2) for max. dc. Input should be adjusted for 2 volts out.

Connect VTVM to Pin 1 of 6AL5 discriminator and adjust secondary of discriminator (T-2) (bottom of can) for cross-over. (Zero voltage).

VIDEO

With 4.5 MC CW Carrier from a high impedance source, (10,000 ohms in series with generator), into grid of 1st video tube (Pin 7 of 6AL5 second detector) and VTVM on picture tube grid, tune 4.5 MC trap L-8 (top of chassis) for minimum response.

MODEL 2D1088B (12½" PIX TUBE)

SUPPLEMENTARY MANUAL

All service information applicable to the issue "B" series of Model 2D1088 is contained in Service Manual No. 69X2092 and this Supplementary Service Manual.

The differences between issue "A" and "B" series receivers are as follows:

1. A 6AL5 horizontal Phase Discriminator Tube (V-22, see illustration) was added to the circuit to improve receiver performance.

2. The synchro-guide transformer (T-7) was removed and replaced with a horizontal frequency coil (L-25).

3. Because of various electrical changes that have been made in the receiver, it was necessary to include in this supplement a complete parts list and a schematic diagram.

   When ordering parts, for the issue "B" receivers, use the part numbers listed in this Supplementary Manual.

4. For test patterns, alignment procedure and other service information, refer to Manual No. 69X2092 and use all data pertaining to the 16" picture tube receiver.

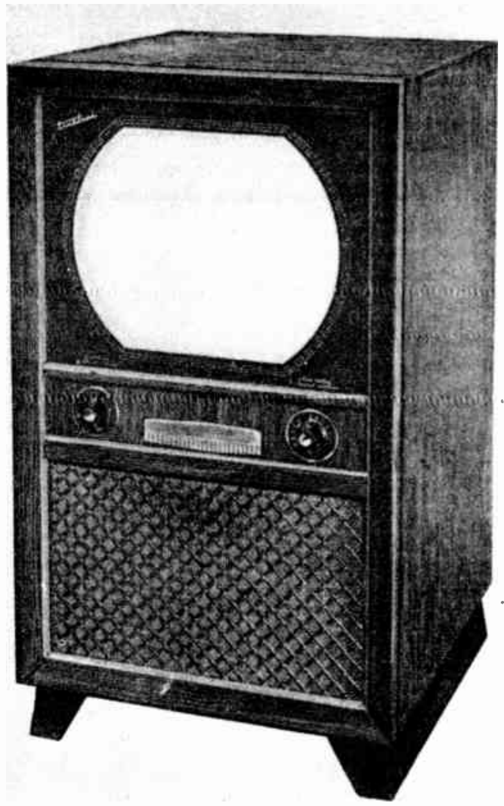
L-1, L-16, L-17, L-18	9A2033	Filament Choke

TRANSFORMER AND COILS—Cont.

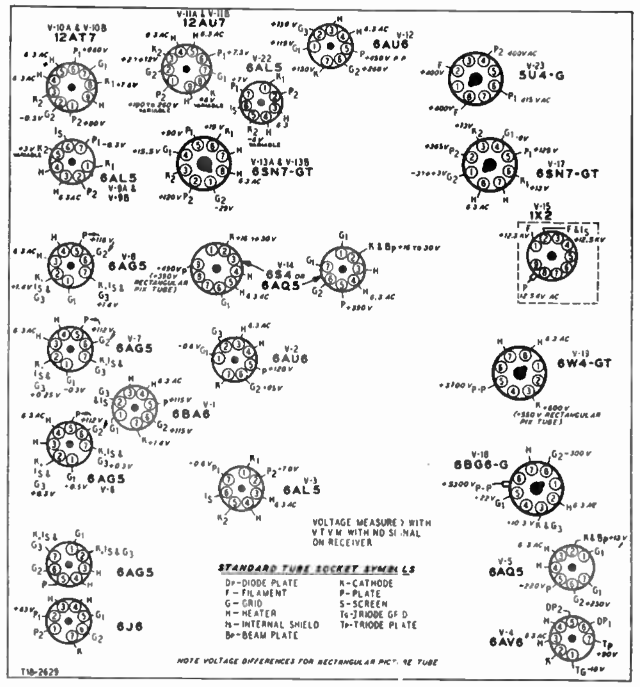
Ref. No.	Part No.	Description
L-2		Part of Tuner Assembly
L-3	9A2059	Converter Plate Trap
L-4	9A2072	1st I.F. Grid Coil
L-5	9A2076	Sound Take-Off Coil
L-6	9A1979	Plate Choke
L-7	9A2071	3rd Pix Trans.
L-8	9A2074	4.5 M.C. Trap
L-9	9A2090	Peaking Coil
L-10	9A2086	Peaking Coil
L-11	9A2088	Peaking Coil
L-12	9A2089	Peaking Coil
L-13	9A2087	Peaking Coil
L-14	52X88	Filter Choke
L-15	9A2107	Focus Coil
L-19, L-20, L-21, L-22		Part of 9A2069 Deflection Coil (See Miscellaneous)
L-23	9A1976	Horizontal Size Control
L-24	9A2055	2nd Pix I.F. Coil
L-25	9A2096	Horizontal Frequency
T-1	9A1986	Sound I-F Trans.
T-2	9A2049	Sound Disc. Trans.
T-3	51X146	Audio Output Trans.
T-4	9A2073	Cathode Trap
T-5	53X298	Power Trans.
T-6	54X5	Vert. Osc. Trans.
T-8	51X147	Vert. Output Trans.
T-9	53X307	Horiz. Output Trans.

MISCELLANEOUS

Part No.	Description
12A490	12" P.M. Speaker
25A1071	R-F Tuner Assembly (Turret Type)
25A1075	R-F Tuner Assembly (Switch Type)
9A2069	Deflection Yoke Assembly
2A382	Ion Trap Magnet
3A428	Tube Socket (miniature)
3A455	Tube Socket (12AU7—12AT7)
3A303	Tube Socket (Octal)
3A454	Tube Socket (H.V. Rectifier)
13X751	Tube Socket (Pix. Tube)
32X390	Tube Shield
32X401	Tube Shield (12AT7)
17X104	Pix Crystal
4X1076	Pix Mask
8X218	Rubber Cushion
25X1654	Support Bracket (Mtg. Rear of Tube)
28X589	Ground Spring
S-25X60	Tube Strap & Mtg. Bracket Assembly
25X1658	Tube Mtg. Bracket (Front Right)
25X1659	Tube Mtg. Bracket (Front Left)
20X1646	Eyelet (Screwdriver Guide) — Mtg. Focus Coil
28X578	Mounting Spring; No. 10—32x1¾" Fillister Head Steel—Machine Screw — Mtg. Focus Coil
20X1558	Wing Screw (Mtg. Def. Yoke)
16X147	Fuse (1/4 Amp.)
S-14X20	Cabinet Back & Power Cord Assembly
14X485	Ventilator Grille
4X1065	Escutcheon (Channel Selector)
4X1029	Escutcheon (Off-Volume & Contrast)
10A741	Knob (Channel Selector)
10A742	Knob (Fine Tuning)
10A752	Knob (Contrast)
10A753	Knob (Off-Volume)
4X1072	Front Panel Cover
6A314	Anode Connector



MODEL 2D1089B (16" PIX TUBE)



BOTTOM SOCKET VOLTAGES

SUPPLEMENTARY MANUAL

Model 2D1089B is similar to Model 2D1089A except for minor mechanical and electrical changes. Because of these changes, it was necessary to include in this supplementary service manual a complete parts list and a schematic diagram. For test patterns, alignment procedure and other service information, refer to Manual 69X2092 and use all data pertaining to the 16" picture tube receiver.

NOTE: When ordering parts for the issue "B" receivers, use the part numbers listed in this Supplementary Service Manual.

TUBE COMPLEMENT

Symbol	Type	Function
	6J6	R-F Osc. & Mixer
	6AG5	R-F Amplifier
V1	6BA6	1st Sound I-F
V2	6AU6	Sound Limiter
V3	6AL5	Sound Discriminator
V4	6AV6 or 6AT6	1st Audio
V5	6AQ5	Audio Output
V6	6AG5	1st Pix I-F Amp.
V7	6AG5	2nd Pix I-F Amp.
V8	6AG5	3rd Pix I-F Amp.
V9 A & B	6AL5	Picture Det. and D. C. Restorer
V10 A & B	12AT7	1st Video Amp. and 1st Sync Amp.
V11 A & B	12AU7	Video Output and Sync Separator
V12	6AU6	Automatic Gain Control
V13 A & B	6SN7-GT	Phase Splitter & Vert. Osc.
V14	6S4 or 6AQ5	Vertical Output
V15	1X2	High Voltage Rectifier
V17	6SN7-GT	Horizontal Osc.
V18	6BG6-G	Horizontal Output
V19	6W4-GT	Damper
V20	16GP4	Picture Tube 16" Round
V22	6AL5	Horizontal Phase Disc.
V23	5U4GT	Low Voltage Rectifier

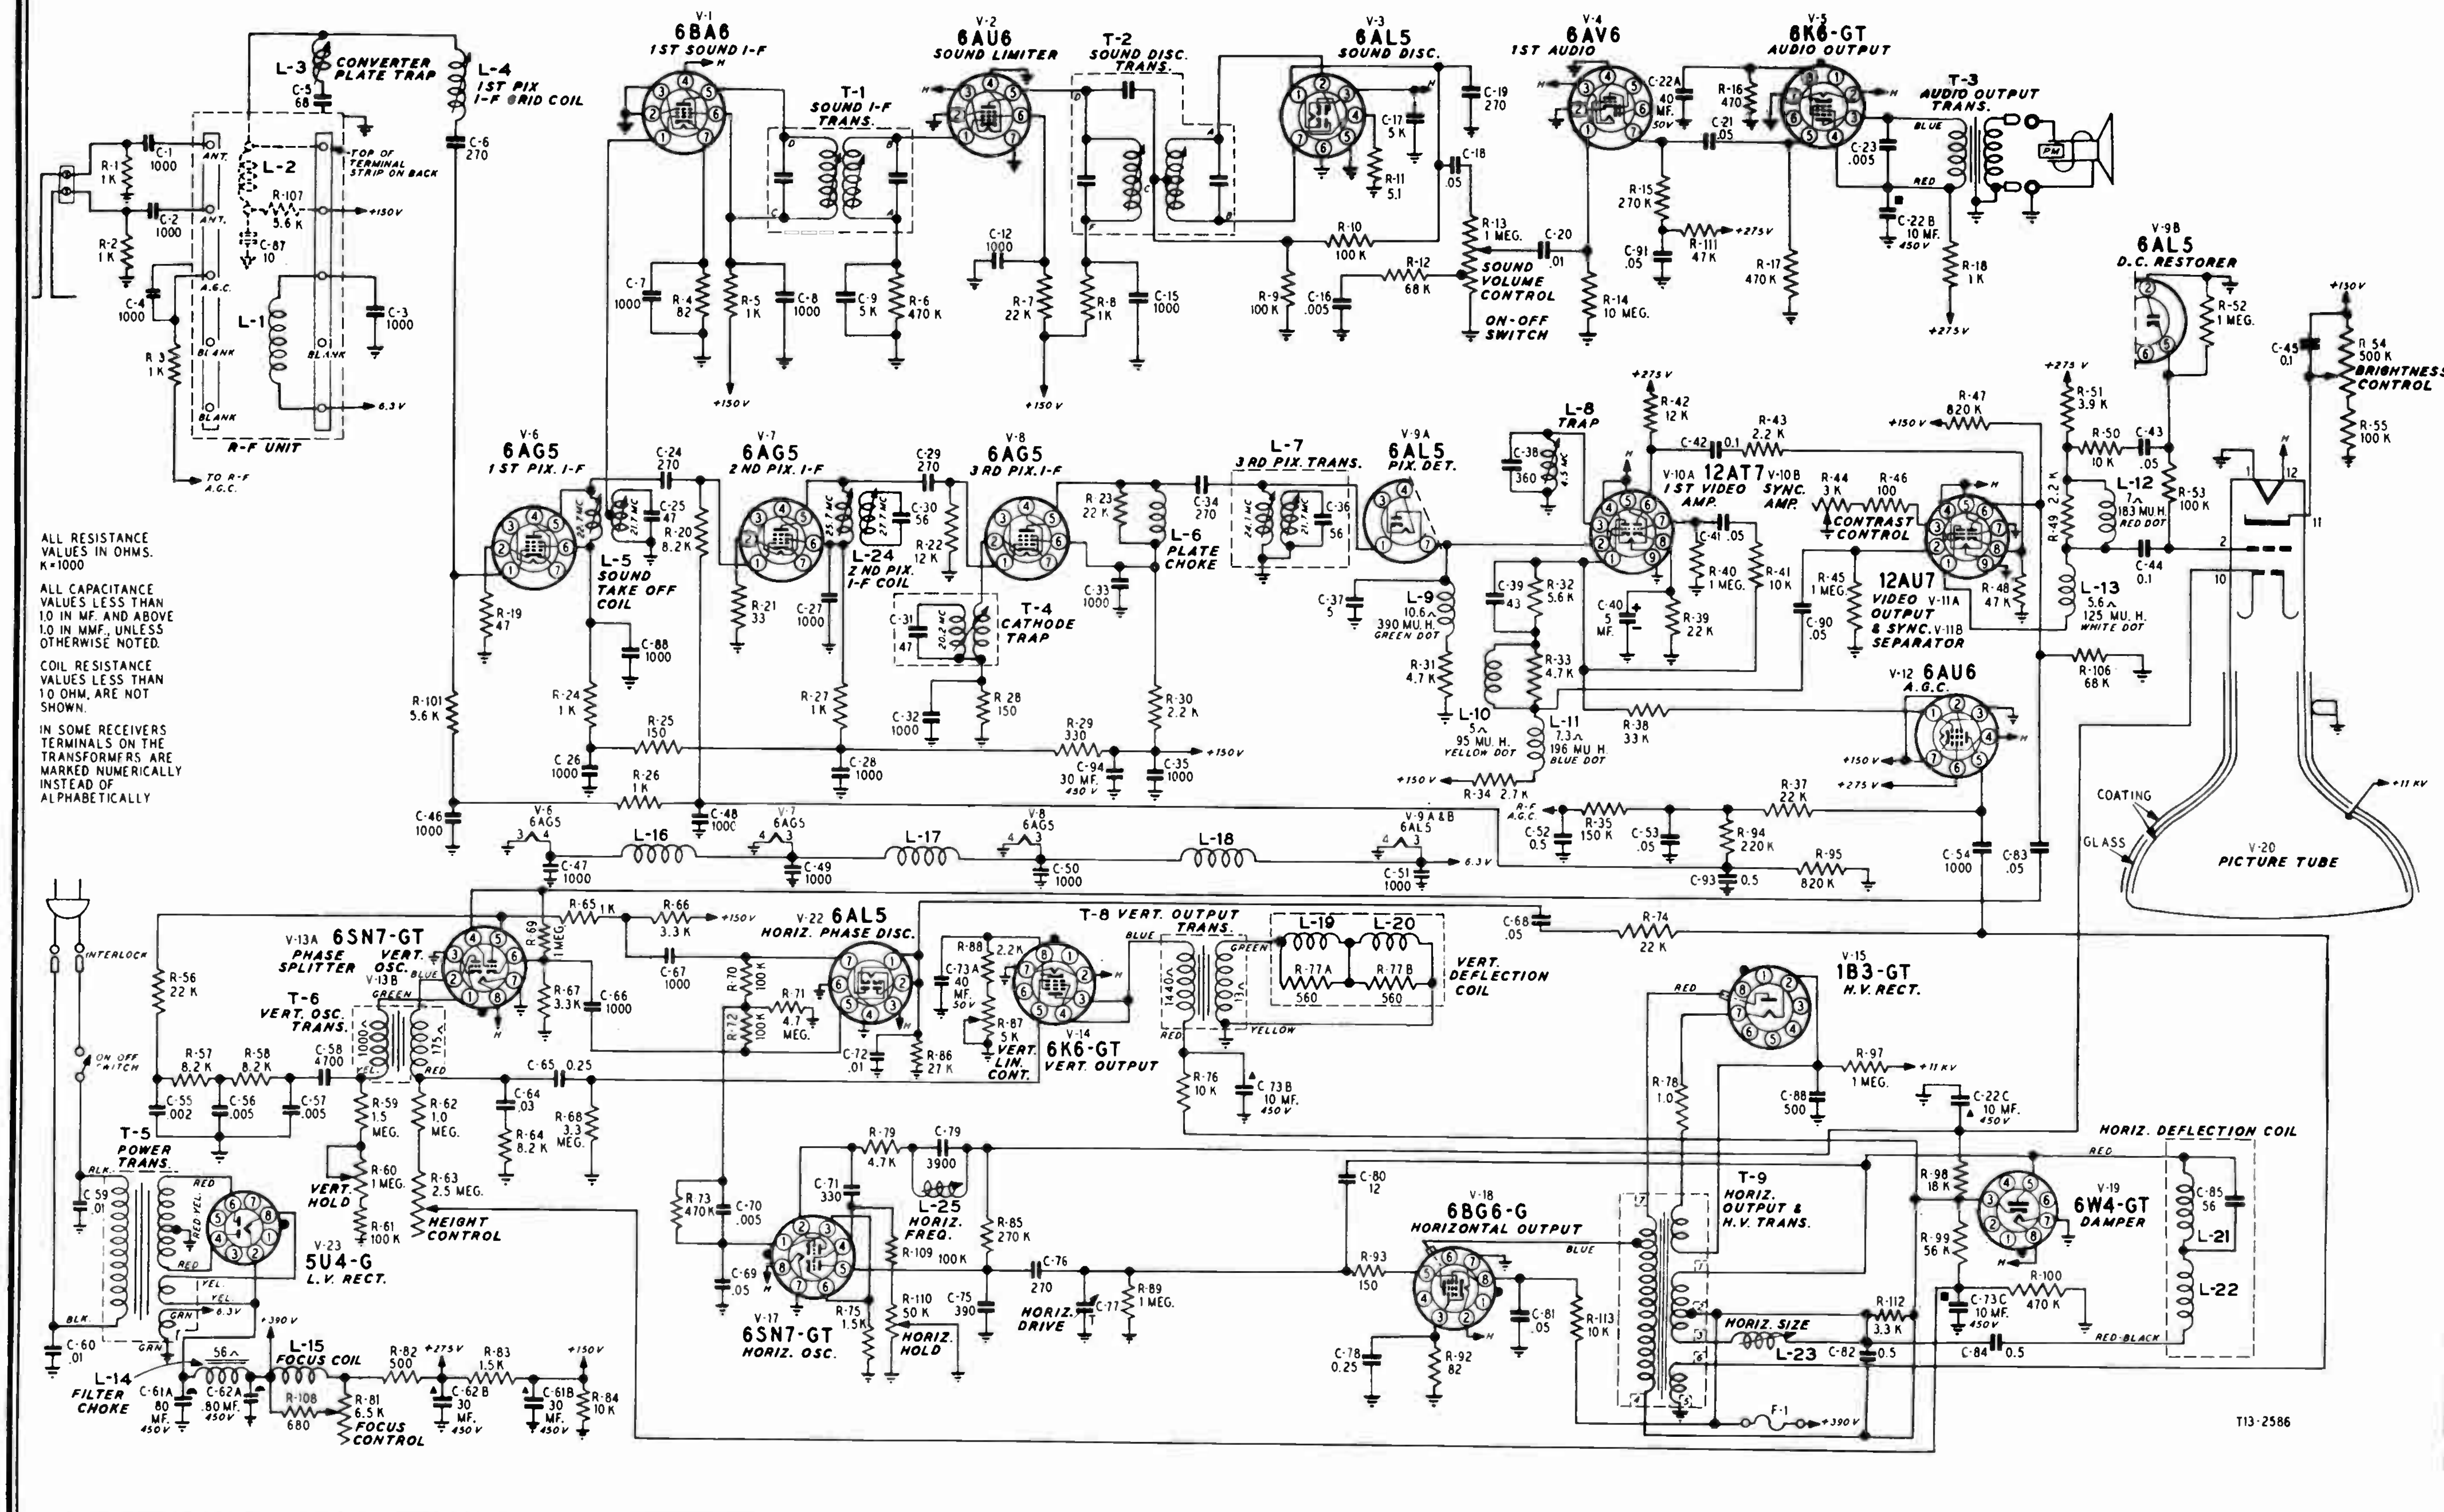
12½" MODEL 2D1088B



©John F. Rider

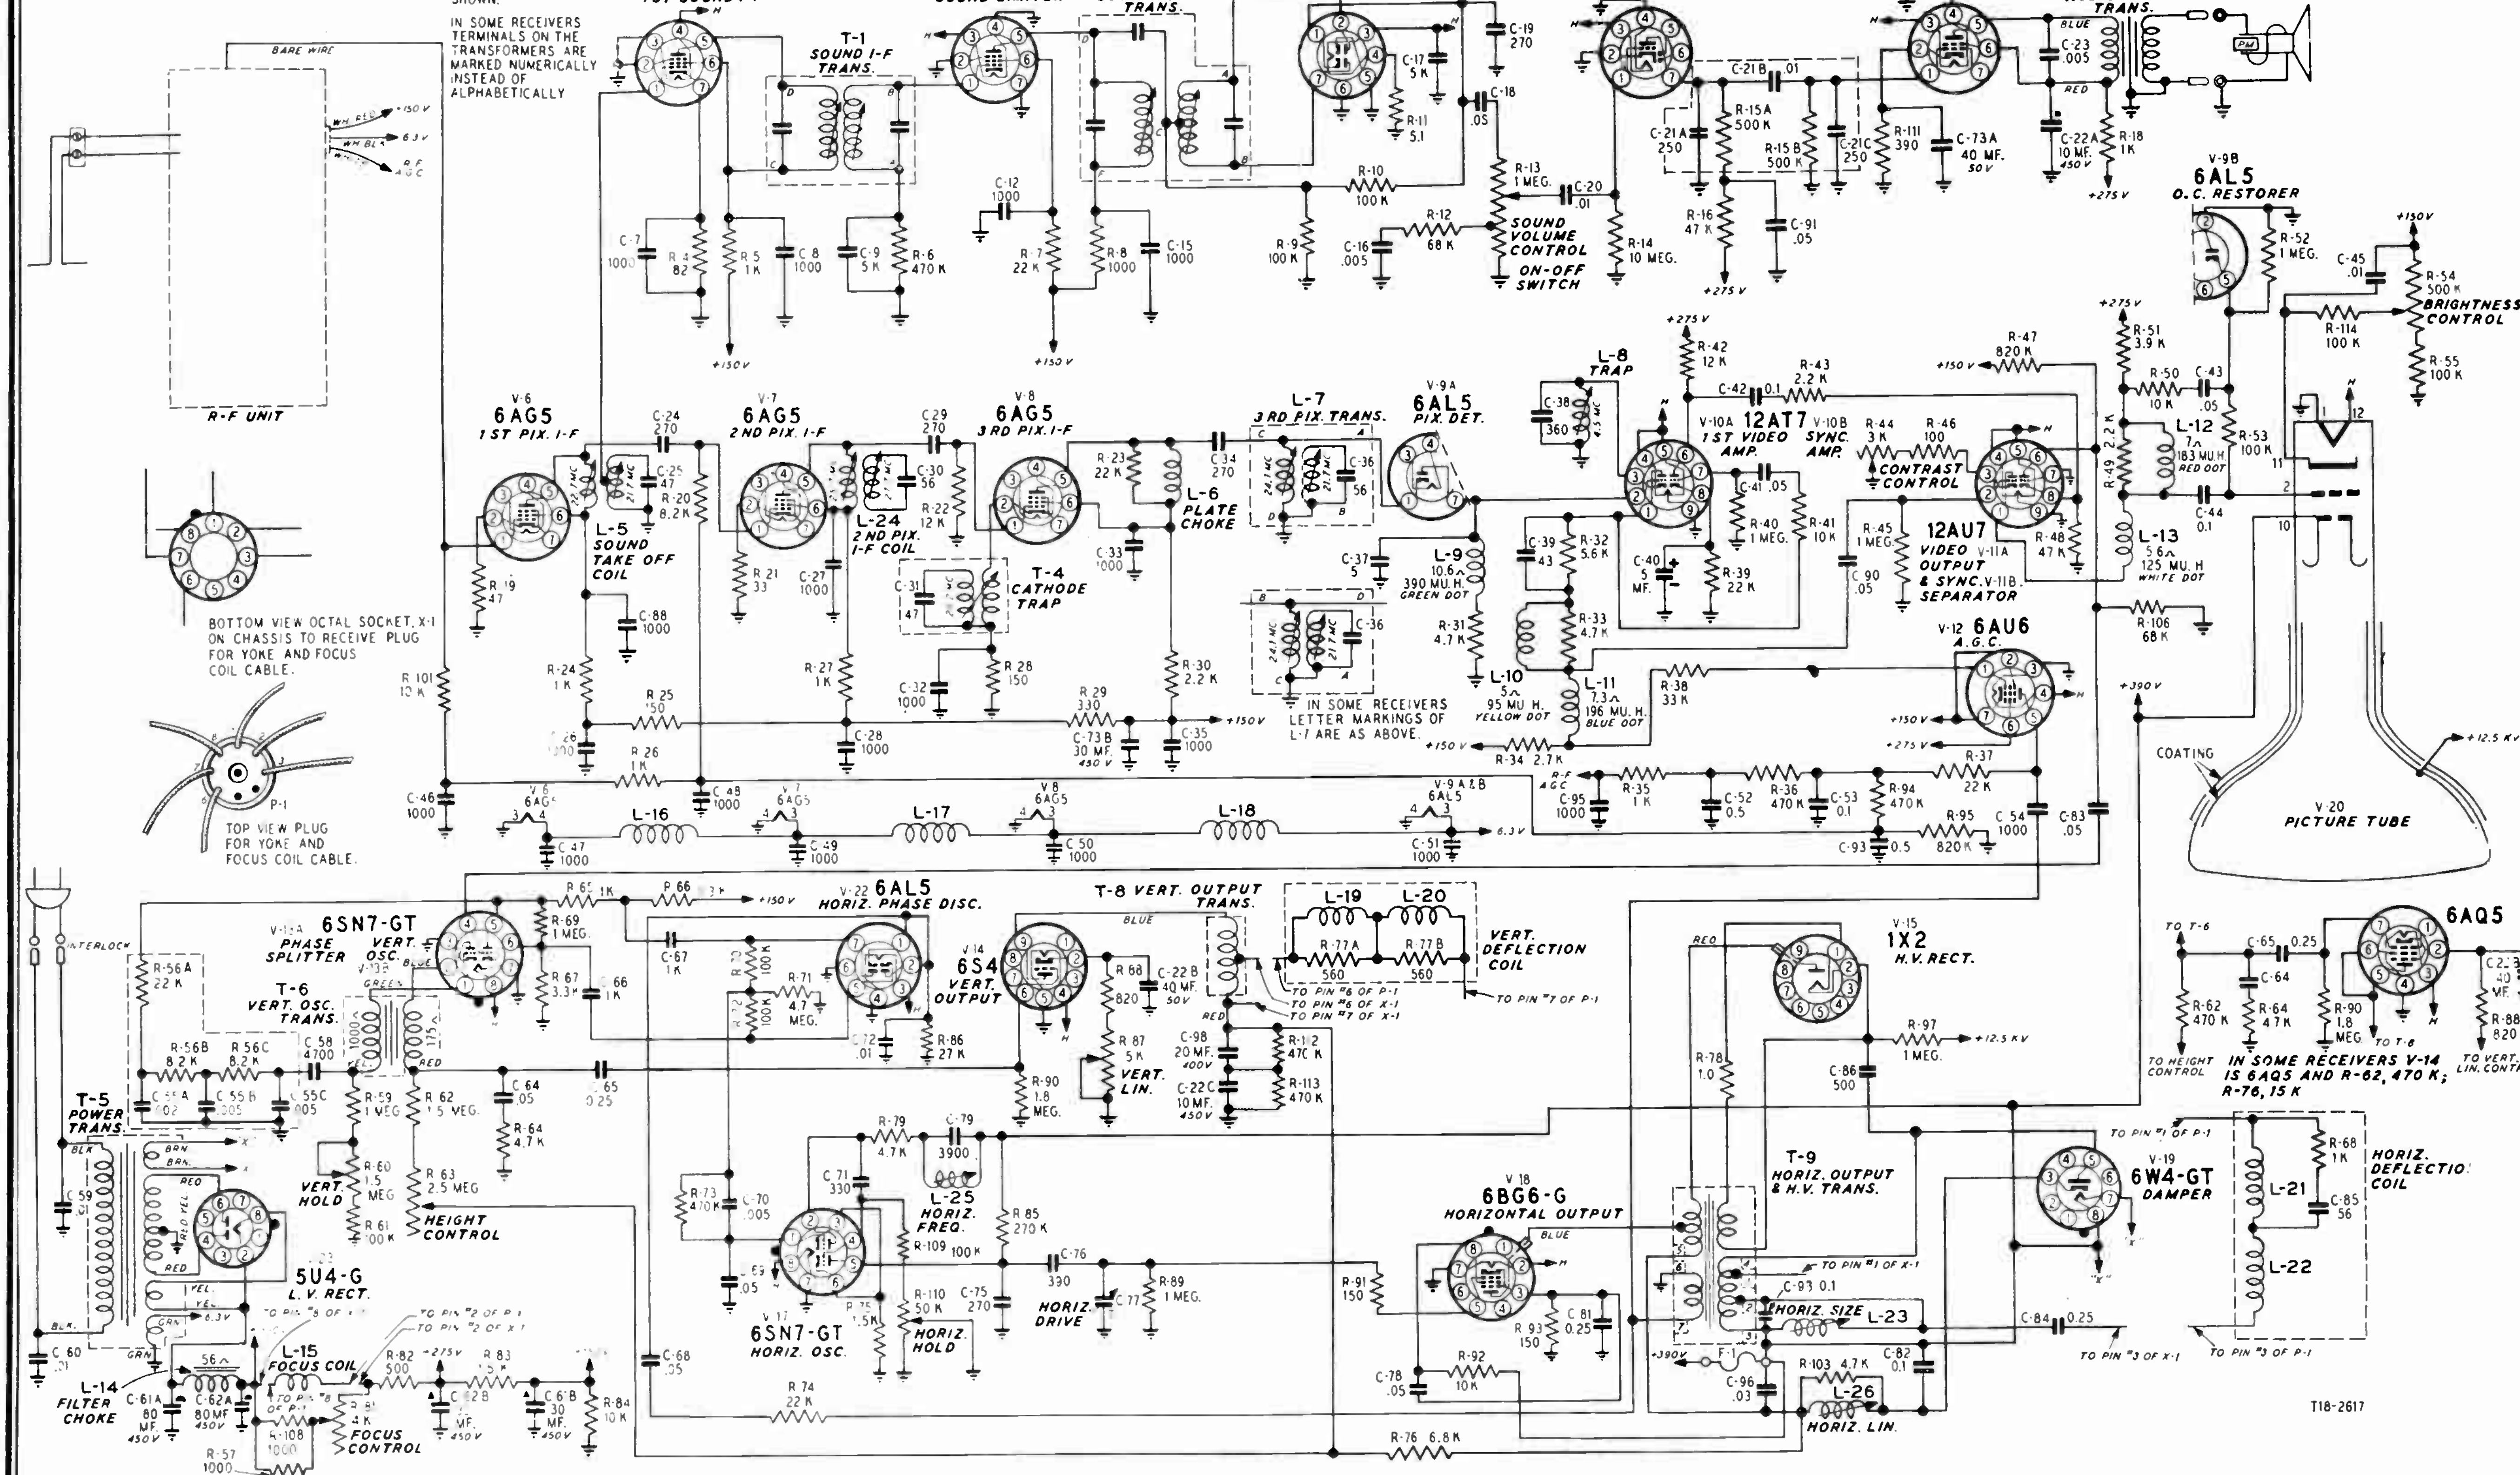
16" MODEL 2D1089B

ALL RESISTANCE VALUES IN OHMS. K=1000

ALL CAPACITANCE VALUES LESS THAN 1.0 IN MF AND ABOVE 1.0 IN MMF, UNLESS OTHERWISE NOTED.

COIL RESISTANCE VALUES LESS THAN 1.0 OHM, ARE NOT SHOWN.

IN SOME RECEIVERS TERMINALS ON THE TRANSFORMERS ARE MARKED NUMERICALLY INSTEAD OF ALPHABETICALLY



NOTE—In later production R-78 is 3.3 ohms.

TELEVISION SPECIFICATIONS

Sensitivity at the Antenna
Video—100 microvolts
Audio—100 microvolts

Power Supply Rating
115 volts, 50-60 cycles, AC
235 watts.

Audio Power Output Rating
Undistorted—3 watts
Maximum—4½ watts

Speaker
10" PM
3.2 ohm voice coil impedance

Picture Size
70 square inches

Antenna Impedance Requirements
Balanced 300-ohm

Dimensions
Chassis—16"x 16"x 2½"

Tube Complement
6AG5, RF-Amplifier
6J6, Oscillator-Converter
6AU6's, (4) IF-Amplifier
6AL5, Detector, DC Restorer and Sync Separator
12AU7, Video Amplifier

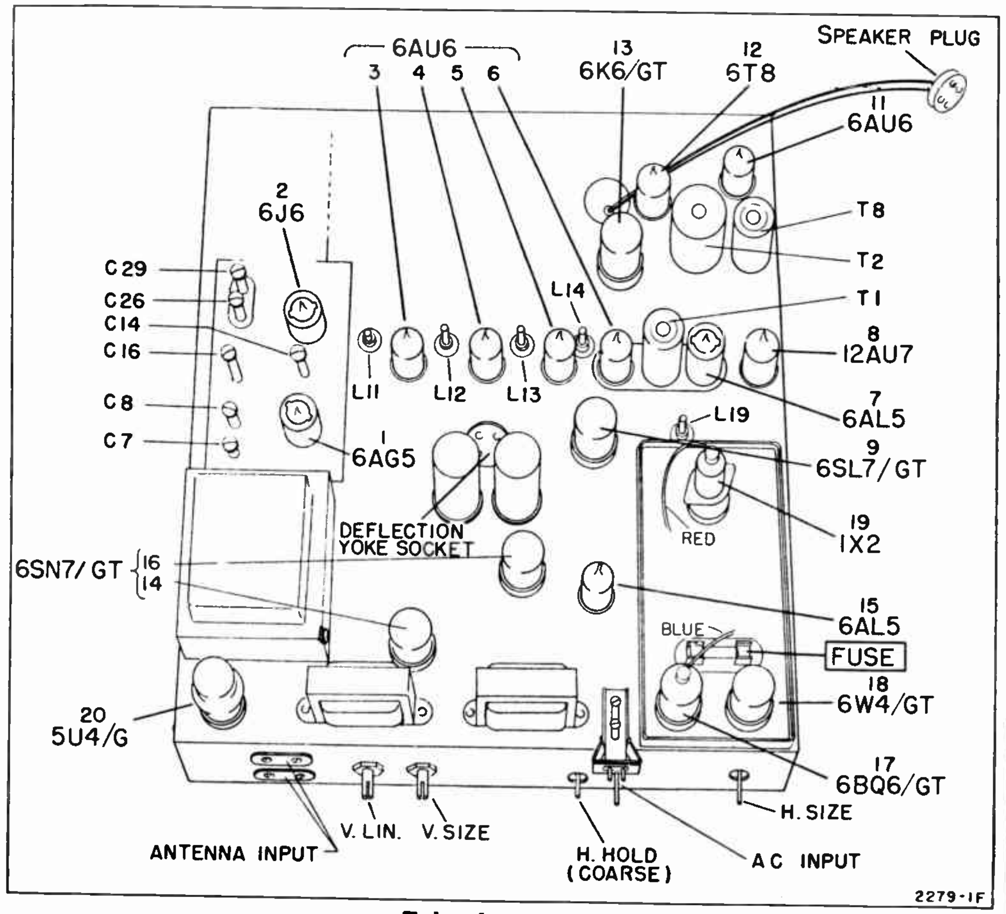
GENERAL DESCRIPTION

The Model 10AXF44 is a combination television, AM-FM radio, and a 45 RPM record changer.

The Television set is a 20-tube, AC operated, direct view, 10-inch television receiver and features complete coverage of all 12 television channels, automatic gain control, automatic frequency control, intercarrier sound system, permanent magnet focused and magnetically deflected picture tube.

On the back of the cabinet is a safety interlock to prevent dangerous electrical shock. As an added safety measure, a fuse is located in the high voltage power supply to protect the set in case of overloading.



Tube Layout

OPERATION OF THE TELEVISION

FUNCTIONS OF THE CONTROLS

All the controls normally used in tuning in a program—both picture and sound—are located on the front of the receiver. On the rear of the set are several controls which are pre-set at the factory and may need slight readjustment at the time of installation. After installation, they should not be adjusted further, unless required by replacement or aging of tubes, variations in power-line voltage, or other external conditions. The function of each of the controls is described below.

OPERATOR'S CONTROLS

Volume-Off — Turns set on or off and adjusts sound volume.

Contrast—Varies contrast between light and dark portions of picture.

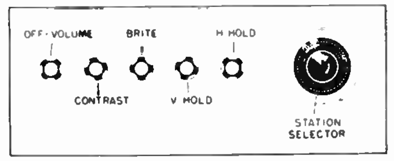
Brightness—Controls brilliance of picture.

V. Hold—Stops pictures from moving up or down.

H. Hold—Stops pictures from moving left or right.

Station Selector Knob—Tunes set to desired channel (station). May be turned in either direction.

Model 10AXF44 actually requires only three controls when tuning in a program. The three controls, off-on-volume, contrast and station selector are located on the front of the receiver. The three other controls on the front of the set: brightness, horizontal hold, and vertical hold, need only be adjusted periodically. The six operator's controls are shown below:



Three of the seven serviceman's controls; focus, horizontal centering, and vertical centering, are located on the picture tube assembly. The remaining four controls, vertical linearity, vertical size, horizontal size, and coarse horizontal hold are located on the rear of the set. (See tube layout).

SERVICEMAN'S CONTROLS

Vert. Lin.—Provides vertical distribution of picture.

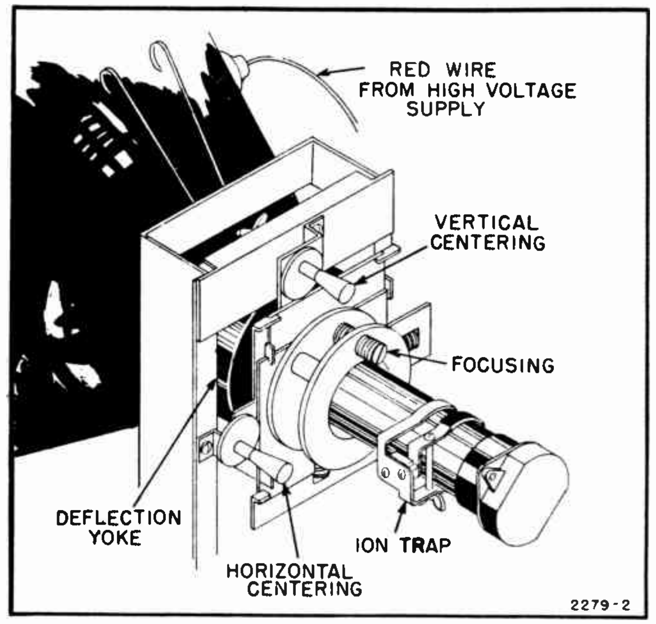
Vert. Size — Changes size of picture vertically. Does not affect horizontal size.

Horiz. Size—Changes size of picture horizontally. Does not affect vertical size.

Focus—Focuses picture on face of picture tube.

H. Centering—Moves entire picture horizontally.

V. Centering—Moves entire picture vertically.



Picture Tube Assembly

TUNING PROCEDURE

1. Turn the VOLUME control clockwise to turn the set on. Allow one-half minute for the set to warm up.
2. Rotate the Station Selector knob to the desired channel.
3. Turn the CONTRAST control fully counter-clockwise.
4. Turn the BRIGHTNESS control fully clockwise, and then turn it slowly counter-clockwise until the picture tube just becomes dark. *For any particular installation this adjustment of the BRIGHTNESS control need be made only the first time the set is used, unless required by replacement of tubes.*
5. Adjust the CONTRAST control until the proper contrast between blacks and whites is obtained.
6. Adjust the VOLUME control for the desired sound level.
7. When switching from one station to another, it may be necessary to readjust the CONTRAST control.

ADJUSTMENT OF STATION SELECTOR

The station selector of your television set has been partially pre-set at the factory, but readjustment of the settings may have to be made at the time of the initial installation. This should be done by the serviceman.

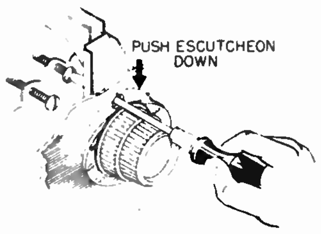
If at a later time a new station comes on the air, or if the receiver is moved to a locality where other stations can be received, adjust the station selector in the following manner.

1. Turn the set on. Allow the set to warm up for 20 minutes.
2. Turn the contrast control approximately two-thirds of the way toward its full clockwise position.
3. Turn the volume control approximately to its mid-position.
4. Set the station selector knob to the desired channel.
5. Grasp the station escutcheon at the upper right edge and slowly push down until the hole above the station selector knob appears.
6. Insert a screwdriver into the hole (see illustration). Turn the screw slowly counter-clockwise (and then clock-

© John F. Rider

World Radio History

wise, if necessary) until maximum sound is heard. This may require several turns in one direction or the other. Turn up the volume control if necessary. (Do not at any time turn the screw in either direction more than 3 revolutions. Do not force it if turning becomes difficult as the screw has then reached



the end of its travel in that direction and its direction should be reversed.)

7. When the sound is at maximum, the picture will appear on the screen but "sound bars" (dark horizontal bars of varying width) will be seen traveling vertically from bottom to top across the picture. With the screwdriver, turn the station selector screw counter-clockwise only far enough to remove the sound bars from the picture.

8. Push the station escutcheon back into place.

ANTENNA CONNECTIONS

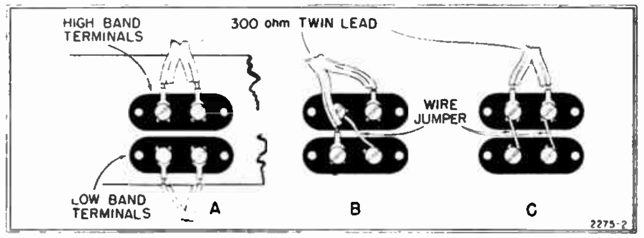
1. For those who use separate Hi and Low Band antennae, with two lead-in cables, connect the Hi-Band leads to the two top terminals marked Hi-Band, connect the Lo-Band leads to the two bottom terminals, marked Lo-Band. See fig. 4, sketch A.

2. For those who use a combined Hi-Lo Band antenna, better known as a "All Wave Antenna" with one lead-in cable, connect as shown in fig. 4, sketch B.

3. In some cases due to location or environment of the Receiving antennae, better results can be had by connecting the lead-in as shown in fig. 4, sketch C.

4. An alternate arrangement for those who receive from Hi-Band stations only (Channels 7 thru 13), the All Wave Antenna lead-in may be connected to the two top terminals marked Hi-Band, with no strap or connection to the Lo-Band terminals.

5. Use the arrangement which gives the most satisfactory results.



Alternate Antenna Connections

CAUTION!: 9,000 volts on all pins of the 1X2 high voltage rectifier. DO NOT MEASURE this voltage unless a high range voltmeter is used.

WARNING!: Do not tamper with or attempt to defeat the purpose of the safety interlock.

FUSE: To replace the fuse in the high voltage power supply, lift off the high voltage shield, remove the old fuse, and replace with the same type 1/4 ampere fuse.

PRODUCTION CHANGES

As changes were made in the production of Model 10AXF44 chassis, code numbers were assigned to distinguish the differences in the set. The differences between the different code numbers are explained below.

Code 1 Chassis.

Code 1 chassis are wired as shown in the schematic diagram except the grounded end of C-117 is connected to terminal 1 of T6 and a 1000 mmf capacitor is used in place of the parallel connection of C-109 and C-111.

Code 2 Chassis.

Code 2 chassis are wired as shown in the schematic diagram except a 1000 mmf capacitor is used in place of the parallel connection of C-109 and C-111.

Code 3 Chassis.

Code 3 chassis are wired as shown in the schematic diagram.

SERVICE NOTES

Lubrication — The automatic record changer leaves the factory oiled and lubricated. Under normal conditions further lubrication will not be required for at least one year or 1,000 hours of operation. We recommend periodic lubrication thereafter by a competent serviceman.

If Needle Skips Groove—Check the following points:

1. Record Changer not level.
2. Foreign matter in record groove.
3. Badly worn record groove.
4. Badly worn or bent needle.

OPERATION OF THE RADIO

Broadcast Band—This is the tuning band in which the standard broadcast stations operate. The left scale on the dial covers the broadcast range of 535-1620 Kc., and is calibrated in channel numbers. To obtain the kilocycle reading, multiply the number on the dial by 10; thus 80 on the dial corresponds to 800 kilocycles.

FM Band—The FM tuning range covers the newly allocated frequency-modulation band of 88 to 108 megacycles into which all FM stations were required to move. Check with your local newspaper to determine the frequency of your local FM stations.

On-off Switch and Volume Control- The knob second from the bottom is both the on-off switch and the volume control. When this control is turned all the way to the left the set is off. A slight rotation to the right will click the switch and turn the set on. The knob may then be used to regulate the volume. Be sure your set is turned completely off when not in use; otherwise the tubes will wear out unnecessarily.

Tone Control—Rotating the bottom knob gives a full variation of the tonal response from a deep bass to a brilliant treble.

Tuning Knob—The knob second from the top is the tuning knob; rotation of this knob moves the indicator along the dial scales. When selecting a station turn the knob back and forth until the tone is clearest and loudest. Do not use the tuning knob to regulate volume; the volume control should be used for that purpose after the station has been tuned in properly. It is particularly important in FM reception to tune the station accurately; otherwise the tone is distorted and the background noise not eliminated.

Band Switch—The knob on the top is used to select FM BAND, BROADCAST BAND, or PHONO. When this knob is turned fully clockwise FM programs can be tuned in. In the center position STANDARD BROADCASTS can be heard.

Phonograph — Turning the Bandswitch fully counterclockwise allows the radio to be used for the playing of phonograph records in conjunction with the automatic record player mounted in this cabinet. This automatic Record Player accommodates eight of the NEW 45 RPM records, approximately 40 minutes of entertainment without attention. For operation of this unit please refer to the Automatic Record Changer Operating Instructions on separate sheet.

ALIGNMENT PROCEDURE

Broadcast Band Section I. F. and R. F.

The alignment procedure below includes the sensitivities at the inputs of various stages. All signal input values are based on an output of .50 watts. This may be measured by disconnecting the speaker voice coil and substituting a 3.2-ohm resistor across the secondary winding of the output transformer. A reading of 1.25 volts AC across this resistor will be approximately equivalent to .50 watt output with the speaker connected. The volume control must be set at maximum. The tone control must be set for maximum treble.

The signal source must be an accurately calibrated signal generator capable of supplying the frequencies designated, modulated 30% with a 400-cycle audio signal. A 400 cycle audio signal is required for the audio measurement. Variations in sensitivities of plus or minus 25% are usually permissable.

ALIGNMENT PROCEDURE

FM Band Section I. F. and R. F.

A non-metallic alignment tool must be used.

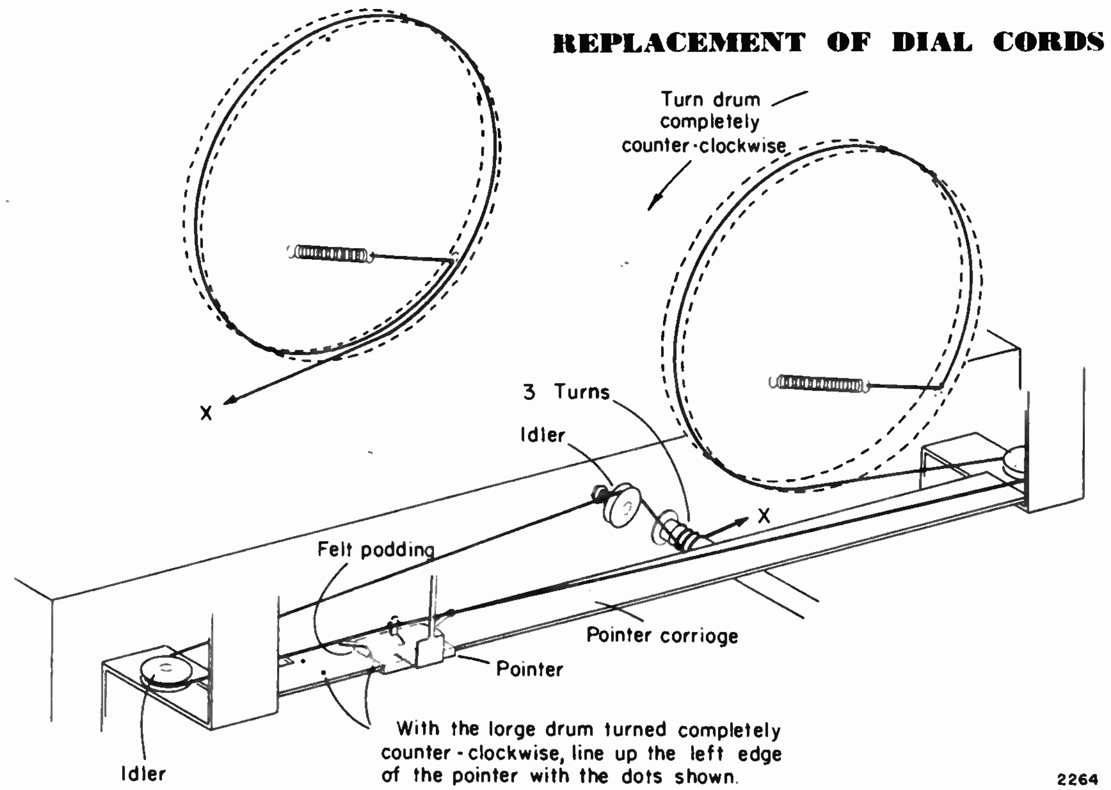
BROADCAST BAND—R. F. ALIGNMENT

Check pointer so that the right hand edge of the pointer skirt coincides with the right hand edge of dial marker at the extreme right when gang is closed. For Adjustment, see dial mechanism illustration.

SIGNAL GENERATOR FREQUENCY	SET POINTER AT	CONNECT TO RADIO	ADJUST
1620 Kc.	Extreme Right Calibration Marker	AM Antenna Clip and B minus	Oscillator trimmer C2-B for maximum
1400 Kc.	Second Calibration from Right	AM Antenna Clip and B minus	Antenna trimmer C2-A for maximum

Check tracking at 1000 Kc, 600 Kc, and 535 Kc to be sure oscillator is set correctly.

REPLACEMENT OF DIAL CORDS



Pointer Stringing and Alignment

ELECTRICAL SPECIFICATIONS

Power Supply .... 105 to 125 volts, AC, 60-cycles; Chassis only 75 watts. With phono operation 100 watts.

Frequency Ranges .... Broadcast Band—535 to 1620 kc. FM Band—88 to 108 mc.

Intermediate Freq. .... AM-455 kc.; FM-10.7 mc.

Selectivity .... AM-43 kc. broad at 1000 times signal, measured at 1000 kc. I.F. FM-250 kc. broad at 2 times down. I.F. FM-650 kc. broad at 10 times down.

AM Sensitivity .... (For .5 watt output with external antenna)—18 microvolts average.

FM Sensitivity .... (For .5 watt output)—16 microvolts average.

Power Output .... 2 watts, 10% distortion. 4 watts maximum.

Loud Speaker .... 10" PM. Voice coil impedance 3.2 ohms, 400 cycles.

Tube Complement ....
12AT7, FM-RF amp. mixer;
12BA7, AM converter, FM oscillator;
12BA6, IF amplifier;
12AU6, FM driver;
12AL5, FM detector;
12AV6, AM detector, AVC, 1st audio;
50L6GT, output.

Automatic Changer See Manual 5084.

IMPORTANT

No alignment of the FM section of this radio should be attempted unless you are positive that the circuits are in need of adjustment and you have the necessary equipment.

All components used in this radio are extremely stable and the tuned circuits should require no adjustment over a long period of time.

NOTE

The following alignment is based on the use of the new Simpson vacuum tube voltmeter which has a "floating ground". In other words, the meter, when used as a vacuum tube voltmeter, can have both the positive and negative sides connected to points above ground and still give true readings.

A standard AM signal generator is required.

FM—I.F. ALIGNMENT

Band Switch in FM Position. Dummy Antenna .1 Mfd.

SIGNAL GENERATOR FREQUENCY	CONNECTION TO RADIO	VACUUM TUBE VOLT METER CONNECTION TO RADIO	ADJUSTMENTS TO BE MADE	ADJUST FOR
10.7 Mc. Use about .1 volt	Pin No. 1 of 12AU6	Pin No. 7 of 12AL5 and B minus	Bottom Core Primary of T9 Ratio Detector	Resonance should be about 3 volts
10.7 Mc. Use about .1 volt	Pin No. 1 of 12AU6	See note "A"	Top Core Secondary of T9 Ratio Detector	Zero. Use zero center scale See note "B"
10.7 Mc. Use about 330 microvolts	Pin No. 1 of 12BA6	Pin No. 7 of 12AL5 and B minus	Primary and Secondary of T7. FM Driver IF See chassis view.	Resonance should be about 3 volts
10.7 Mc. Use about 600 microvolts	Top end of C2-C	Pin No. 7 of 12AL5 and 8 minus	Primary and Secondary of T5. Input IF See chassis view.	Resonance should be about 3 volts

NOTES ON FM—I. F. ALIGNMENT

NOTE "A"—Connect two resistors in series, 100K OHMS each, from Pin No. 7 of 12AL5 to B minus (pin no. 5). These resistors must be matched within 5%. Connect vacuum tube voltmeter between the midpoint of the resistors and point zz.

NOTE "B"—If T9 has been tampered with, it is possible that no crossover point will be found at first. Careful adjustment of both primary and secondary is necessary.

NOTE "C"—To use a VTVM which does not have the "floating ground" feature, in step 2 above, connect "ground" side of VTVM to midpoint of resistors (Note "A") and "high" side to point zz.

GENERAL—Input signals should be adjusted to give approximately 3 volts. The ratio detector is operating at a reasonable level at this point and will give the truest indication of correct alignment with the procedure specified.

FM—R. F. ALIGNMENT

Check pointer so that the right hand edge of the pointer skirt coincides with the right hand edge of dial marker at the extreme right when gang is closed. For Adjustment, see dial mechanism illustration.

SIGNAL GENERATOR FREQUENCY	POINTER	CONNECTION TO RADIO	ADJUST	VTVM CONNECTIONS
108 MC.	108 MC. Marker	FM antenna terminals	FM Osc C3 for maximum	Pin No. 7 of 12AL5 to B minus
98 MC.	Tune in Gen. Signal	See Note "B" below	FM Mixer C2-C for maximum	

NOTE "A"—If a signal generator with the above fundamental frequency is not available, it is sometimes possible to use harmonics. Use extreme care in picking harmonics. An alternate procedure is to use a local station carrier of known frequency to align the FM Band and to use the vacuum tube volt-meter as above for resonance indication. A weak carrier, however, will not produce 3 volts.

NOTE "B"—Connect 300 ohms in series with "hot" side of generator and connect to left hand screw of external FM Antenna Terminals. Connect cold side of generator to right hand screw.

World Radio History

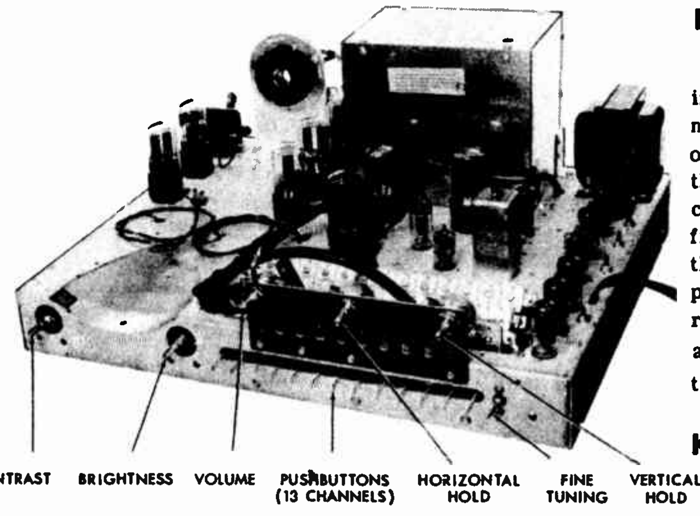
GENERAL

Picture Area	23 square inches
Tubes	Nineteen plus three rectifiers
Speaker	5 x 7-inch P.M.
Speaker V.C. Impedance	3.2 ohms
Antenna	Provision for external antenna using 300-ohm transmission line.
Tuning	Pushbutton plus manual trimming adjustment.
Tuning Range	Thirteen pre-set channels

Channel No.	Frequency (mc)	Channel No.	Frequency (mc)
1	44-50	7	174-180
2	54-60	8	180-186
3	60-66	9	186-192
4	66-72	10	192-198
5	76-82	11	198-204
6	82-88	12	204-210
		13	210-216

Intermediate Frequency
- Picture carrier . . . . . 26.25 mc
- Sound carrier . . . . . . 21.75 mc
- Inter-carrier sound system . . . . 4.5 mc

Power Supply	105-125 V. 60 cycles AC
Power Consumption	135 Watts
Model Differences	Model T-54 - Metal cabinet Model 505, 506 - Wood cabinet



CARE OF THE KINESCOPE WINDOW

Certain cleaning solutions will fog the clear plastic window located in front of the kinescope tube. Clean the window with a soft dry cloth only. In the event the plastic is fogged accidently, it may be readily replaced.

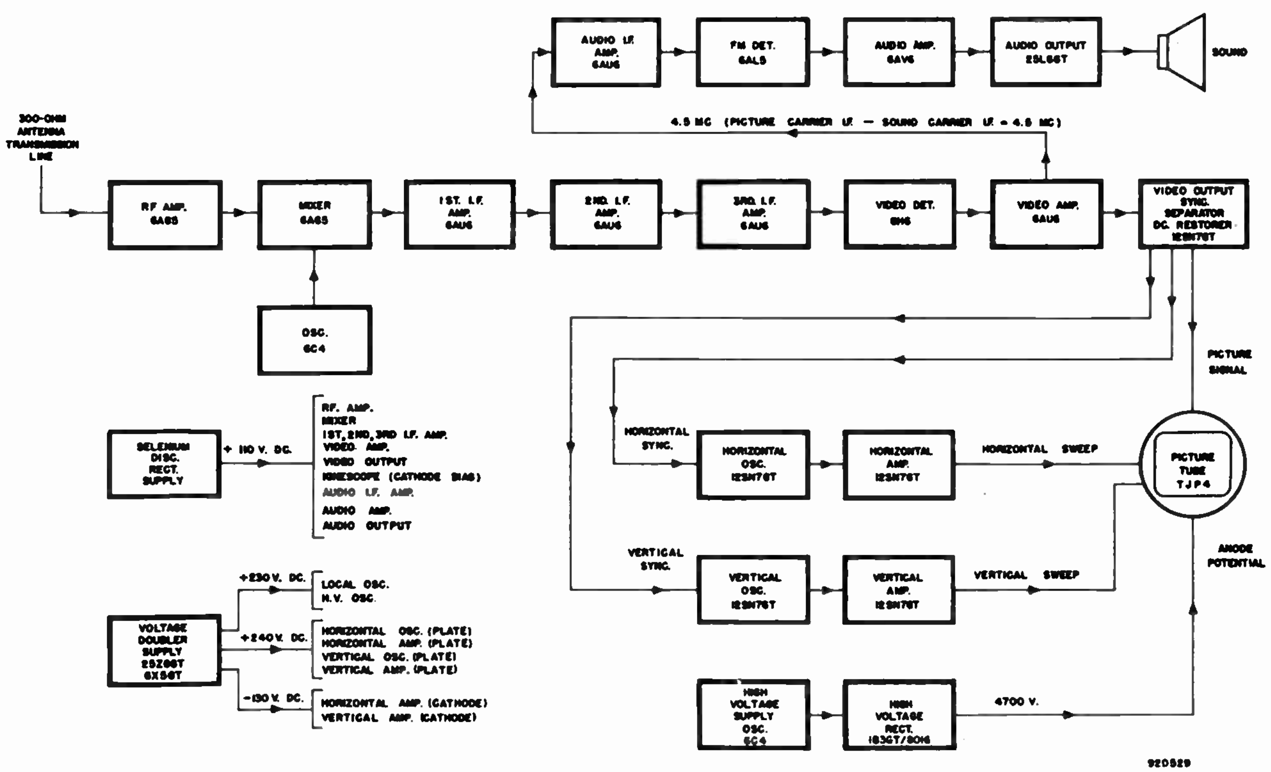


Fig. 1. Functional block diagram.

HIGH VOLTAGE WARNING

Operation of the receiver chassis outside of the cabinet involves a shock hazard. An interlock in the line cord disconnects the power when the Model T-54 cabinet cover is lifted or the Model 505/506 cabinet back is removed. When operating the chassis outside of the cabinet, keep in mind the chassis is connected to one side of the a-c line and must be isolated from ground unless the power plug is correctly polarized so that the chassis is at ground potential with respect to the power source. The HIGH VOLTAGE supply while of low current capacity operates at a 4700 VOLT potential. Exercise all normal HIGH VOLTAGE precautions while working with this equipment.

KINESCOPE HANDLING PRECAUTIONS

The kinescope housing provides adequate protection against possible tube implosure while in the cabinet. Do not expose the kinescope or handle it in any way without providing personal protection in the form of shatterproof goggles and heavy gloves. The kinescope tube should be handled by qualified personnel only.

The kinescope envelope encloses a high vacuum and with the large surface area of glass involved, the stresses set up particularly at the front rim of the tube, are considerable. An abnormal handling stress, accidental blow at a highly stressed surface, or even a scratch on the surface of the tube could cause it to implode or collapse with destructive violence

DISMANTLING FOR KINESCOPE TUBE REPLACEMENT OR ALIGNMENT ADJUSTMENTS

1. Remove the five front panel control knobs and front panel. The control knobs pull straight off their shafts. The panel is fastened to the cabinet with two panel screws accessible from the outside and two screws accessible from the inside of the cabinet. The speaker is fastened to the front panel and must be disconnected at the speaker connector mounted on the speaker frame. Leave the rubber escutcheon fastened to the kinescope tube for additional protection. The kinescope tube may now be removed for replacement. When installing a new tube, the two screws holding the tube socket to the mounting bracket, may have to be loosened to permit rotation of the tube for picture alignment. Note that the oscillator mixer and r-f amplifier adjustments are now accessible. To expose the remaining alignment adjustments, the following dismantling procedure must be carried out.

2. Detach the cabinet interlock receptacle from the cabinet. This is held on with two machine screws.

3. Release the chassis from the cabinet by removing the four rubber mounting feet at the bottom of the cabinet and pull the chassis from the cabinet.

4. Detach the cover half of the interlock connector from the cabinet cover and use it to supply power to the unit while it is being serviced outside the cabinet.

1. Remove the five front panel control knobs. They pull straight off their shafts.

2. Remove the back cover. It is fastened with wood screws. The line cord and half of the interlock connector will come along with the back cover.

3. Detach the cabinet half of the interlock connector fastened to the cabinet with two wood screws.

4. Release the chassis by removing the four mounting screws at the bottom of the cabinet and pull the chassis clear of the cabinet. The kinescope tube may now be removed for replacement. When installing a new tube, the two screws holding the tube socket to the mounting bracket, may have to be loosened to permit rotation of the tube for picture alignment. Caution - The rubber escutcheon on the kinescope tube should be left on the tube for additional protection.

5. Reconnect the interlock connector for power while making adjustments on the bench and the receiver is ready for alignment.

HIGH VOLTAGE SUPPLY OSCILLATOR ADJUSTMENTS

CAUTION HIGH VOLTAGE

Do not use hand held flexible test leads when making the following measurement. Tack solder the resistor string in place and keep the hands clear of the circuit while making measurements or adjustments.

A 5000 V. potential exists in this circuit. Exercise all normal high voltage precautions while working with this circuit.

1. Connect a 50-megohm resistor string in series with a 0-150 microampere meter across the .001 mfd 6000 V. filter condenser (C-82). The resistor string should be made up of 10-megohm resistors or less to provide a safety factor for voltage breakdown. If 10-megohm resistors are used, a total of five will be required to obtain the 50-megohms required. Connect the meter on the ground side of the string.

2. A meter reading of 95 microamperes (4700 V.) should be obtained under normal conditions. To obtain the desired voltage adjust the H.V. OSC. TRIMMER through the adjustment hole in the top of the H.V. power supply housing with a non-metallic screwdriver. The trimmer is a compression type condenser, hence should be set on the maximum capacity side of oscillator resonance, i.e., increasing trimmer capacity decreases the supply voltage. The BRIGHTNESS control must be set at minimum or full counter-clockwise when making the high voltage adjustment.

MODELS D2988, D2989

©John F. Rider

World Radio History

ALIGNMENT PROCEDURE

EQUIPMENT REQUIRED

Signal generator covering 4 mc to 30 mc.

Signal generator covering 40 mc to 215 mc.

Electronic voltmeter.

Two 150-ohm carbon resistors

One 0.01 mfd. 600 V. tubular paper condenser.

F-M SOUND CHANNEL I-F ALIGNMENT

1. Connect the low frequency signal generator output between the control grid (pin 1) of the 6AU6 VIDEO AMP. tube (V-11) and chassis ground.

2. Connect the electronic voltmeter between pin 7 of the 6AL5 FM DET tube (V-2) and chassis ground.

3. With the signal generator (unmodulated) set at 4.5 mc, set the 4.5 mc LIMITER GRID ADJ. and FM DET. PRIMARY ADJ. for maximum d-c voltage as measured by the electronic voltmeter. Adjust the limiter grid coil (L-23) before adjusting the FM detector transformer (T-1) primary. Use just enough signal generator output to obtain approximately 1 volt at the electronic voltmeter.

4. Connect the electronic voltmeter across the 1000 mmf condenser (C-22) at the output of the FM detector stage and adjust the SEC. ADJ. of the FM detector transformer (T-1) for the null.

5. Shift the frequency of the signal generator either side of 4.5 mc and touch up the FM DET. PRIMARY ADJ. for approximately equal peaks. Use just enough signal generator output to obtain one volt peaks for best results.

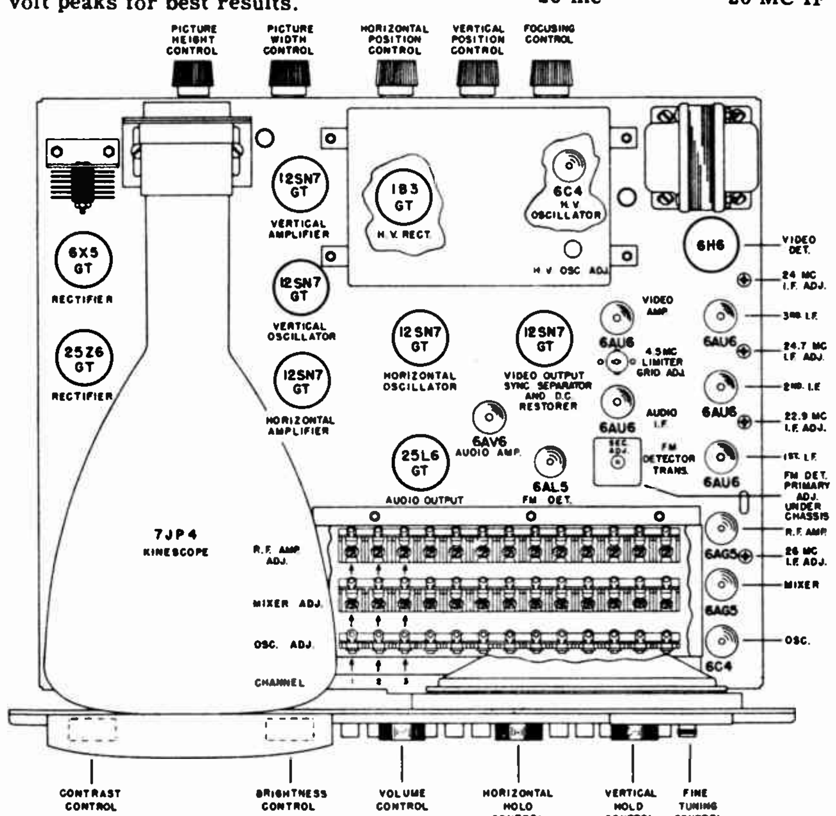

Fig. 2. Top view, alignment points.

I-F AMPLIFIER ALIGNMENT

1. Connect the electronic voltmeter across the 5600-ohm resistor (R-43) in the 6H6 VIDEO DET. (V-10) plate circuit.

This resistor is located at the terminal strip next to the 6H6 tube socket.

2. Connect the low frequency signal generator output to the receiver's antenna transmission line through two 150-ohm carbon resistors, one connected in each side of the transmission line.

3. Use just enough signal generator output (unmodulated) to develop about a volt at the electronic voltmeter and adjust the four i-f amplifier coils, according to the following chart, for maximum d-c voltage as measured by the electronic voltmeter. To avoid the effects of the local oscillator when feeding the i-f signal through the mixer stage, disable the oscillator by triggering out all of the pushbuttons. Do not leave all the buttons out longer than necessary as certain resistors dissipate more heat than normal with the oscillator disabled.

I-F AMPLIFIER ALIGNMENT CHART

Signal Generator Frequency (No Modulation)	Adjustment (Refer to Fig. 2)	Stage Adjusted
24 mc	24 MC IF ADJ.	Video detector
24.7 mc	24.7 MC IF ADJ.	2nd IF amp.
22.9 mc	22.9 MC IF ADJ.	1st IF amp.
26 mc	26 MC IF ADJ.	Mixer

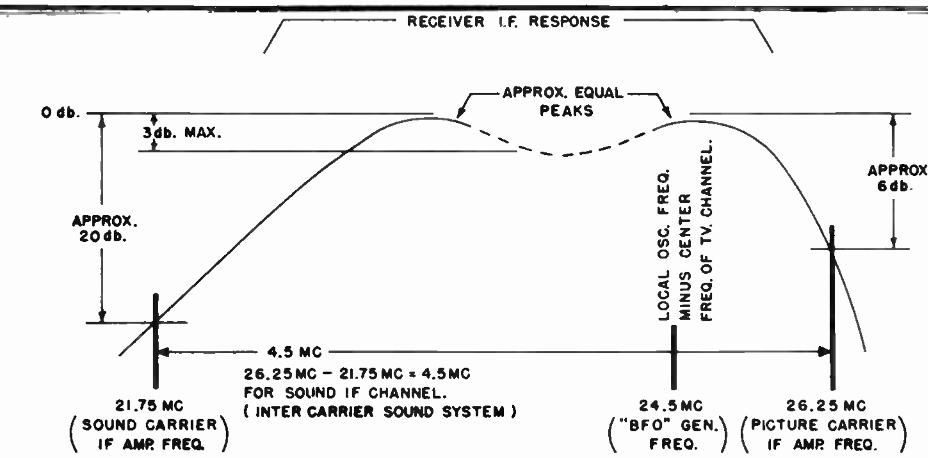

Fig. 3. IF amplifier response.

4. With the local oscillator disabled, check the i-f amplifier frequency response by tuning the signal generator from 21 mc through 26.25 mc and observing the change in d-c voltage at the electronic voltmeter. If the signal generator output is set for an electronic voltmeter reading of 1.5 volts at the peak i-f amplifier response, the d-c voltage should not drop below 1 volt between the two peaks normally obtained with this i-f amplifier. Should the two peaks be unequal in amplitude, the 24.7 MC IF ADJ. slug may be readjusted slightly to equalize them.

Check the two carrier i-f responses, 21.75 mc and 26.25 mc. The 21.75 mc response will be approximately 20 db below the peak response and the 26.25 mc response will fall approximately 6 db below the peak. Refer to Fig. 3.

The average i-f amplifier sensitivity when feeding the signal generator in through the antenna input as described above will run approximately 8000-10,000 microvolts for the 1.5 volt d-c peaks measured at resistor R-43. (5600 ohms).

STATION CHANNEL ALIGNMENT

1. Due to the broad frequency response of the i-f amplifier, it is necessary to use a 24.5 mc signal generator or oscillator (unmodulated) as a beat frequency oscillator (BFO) is used in conventional superheterodyne receivers in order to locate the center frequency of the i-f amplifier response for the correct local oscillator adjustment. This "BFO" generator should be loosely coupled by means of a wire from the generator output placed in close proximity to the 6H6 VIDEO DET. tube (V-10).

2. Connect the high frequency signal generator output to the receiver's antenna transmission line through two 150-ohm carbon resistors, one connected in each side of the transmission line.

3. Connect the electronic voltmeter across the 5600-ohm resistor (R-43) in the 6H6 VIDEO DET. (V-10) plate circuit.

4. Alignment of the individual channels is carried out as follows: Each channel may be aligned independently without affecting the alignment of the others.

(a) Set the FINE TUNING control condenser in the center of its capacity range.

(b) Press the channel button corresponding to the channel number to be aligned.

(c) Set the "BFO" generator at 24.5 mc (no modulation).

(d) Set the high frequency signal generator per the alignment chart. (Generator unmodulated).

(e) Clip on a 0.01 mfd. condenser between pin 3 of the 12SN7GT VIDEO OUTPUT tube (V-12) and pin 1 of the 6AV6 AUDIO AMP tube (V-3) and adjust the OSC. ADJ. trimmer corresponding to the channel being aligned for a rough audio beat note using the speaker output as a detector.

(f) Disconnect the 0.01 mfd. condenser, shut off the "BFO" signal generator, and adjust the MIXER ADJ. and RF AMP. ADJ. trimmers for maximum d-c voltage as measured by the electronic voltmeter. Use just enough signal generator output to obtain approximately one volt at the electronic voltmeter. This completes the alignment of any one channel, and all other channels may be treated alike.

CHANNEL ALIGNMENT CHART

Channel No.	Channel Freq. (mc)	H.F. Signal Generator Freq. (No modulation)	Channel No.	Channel Freq. (mc)	H.F. Signal Generator Freq. (No modulation)
1	44-50	47 mc	7	174-180	177 mc
2	54-60	57 mc	8	180-186	183 mc
3	60-66	63 mc	9	186-192	189 mc
4	66-72	69 mc	10	192-198	195 mc
5	76-82	79 mc	11	198-204	201 mc
6	82-88	85 mc	12	204-210	207 mc
			13	210-216	213 mc

The overall sensitivity for the receiver will run approximately 200-400 microvolts for 1 volt DC at resistor R-43 when measured in the above manner.

SERVICE PARTS LIST

Ref. No.	Description	Part Number
	CONDENSERS	
C-1,2	Trimmer assembly, mixer and r-f amp. stage, 13 sections	44B358
C-3	Trimmer assembly, osc. stage, 13 sections	44B357
C-4,7,9,11, 36,78	4.7 mmf. 500 V., bakelite	47A160-6
C-5,49	10 mmf. 500 V., bakelite	47A160-11
C-6,8,96,97	3.3 mmf. 500 V., bakelite	47A160-5
C-10	2.2 mmf. 500 V., bakelite	47A160-4
C-12,13,14	39 mmf. 500 V., ceramic	47B20390K5
C-15,48,55, 68,69	100 mmf. 500 V., ceramic	47B20101K5
C-16,21,26	.02 mfd. 200 V., tubular	46AU203J
C-17,50,52, 83,84	.1 mfd. 200 V., tubular	46AU104J
C-18,22,28, 29,32,34,41, 42,43,44,45, 46,56,79,86, 87,88,89,90, 91,92,93,94, 102	1000 mmf. 150 V., ceramic	47B20A102N1
C-19,54	5 mfd. 50 V., electrolytic	45A109
C-20,99	330 mmf. 500 V., ceramic	47B0331K5
C-25	.01 mfd. 200 V., tubular	46AU103J
C-27	1 mmf. 500 V., bakelite	47A160-2
C-30,31	47 mmf. 500 V., ceramic	47B20470K5
C-33,100	1.5 mmf. 500 V., bakelite	47A160-3
C-35	0.68 mmf. 500 V., bakelite	47A160-1
C-37	Trimmer, FINE TUNING	48A199
C-38,39,47	50 mmf. 500 V., ceramic	47B20500K5
C-40,53	.25 mfd. 200 V., tubular	46AT254J
C-51,66	.05 mfd. 200 V., tubular	46AU503J
C-57	60-30 mfd. 300-450 V., electrolytic	45B126
C-58	40-40 mfd. 300 V., electrolytic	45B125
C-59	30-30 mfd. 200 V., electrolytic	45B123
C-60	100-100 mfd. 150 V., electrolytic	45B124
C-62	.005 mfd. 200 V., tubular	46AU502J
C-63,65, 67,76,77	.25 mfd. 600 V., tubular	46AX254J
C-64,75,85	.1 mfd. 600 V., tubular	46AY104J
C-70	680 mmf. 500 V., mica	CM20A681M
C-71,72	.0005 mfd. 6000 V., tubular	46A145
C-73,74	.03 mfd. 6000 V., tubular	46B149
C-80	Trimmer, adjustable, HV osc.	44A359
C-81,82	.001 mfd. 6000 V., tubular	46A146
C-95	.01 mfd. 600 V., tubular	46AZ103J
C-98	10 mfd. 25 V., electrolytic	45A121
C-101	5000 mmf. 500 V., ceramic	47A168
	RESISTORS	
R-1,3,4,6	3300 ohms 1 watt, carbon, part of coils L-12, 10, 8, 6.	
R-2	2200 ohms 1 watt, carbon, part of coil L-11	
R-5	2200 ohms 1 watt, carbon, part of coil L-7

RESISTORS (Cont.)

Ref. No.	Part Number	Description
R-7, 8,9		1 megohm 1 watt, carbon, part of coils L-4, 3 and 2.
R-10,11,12		1 megohm 1/2 watt, carbon, part of coils L-9, 5 and 1.
R-13,91	RC20AE154M	150,000 ohms ½ watt, carbon
R-14,18,21, 52,62,76	RC20AF333M	33,000 ohms ½ watt, carbon
R-15,39	RC20AE123K	12,000 ohms ½ watt, carbon
R-16,17	RC20AE103J	10,000 ohms ½ watt, carbon
R-19	25B721	1 megohm, VOLUME control
R-20,26,27	RC20AE151M	150 ohms ½ watt, carbon
R-23,24,55	RC20AE474M	470,000 ohms ½ watt, carbon
R-25	RC30AE101M	100 ohms 1 watt, carbon
R-28,32,88	RC20AE225M	2.2 megohms ½ watt, carbon
R-30,36,37, 38,57,120	RC20AE101M	100 ohms ½ watt, carbon
R-31,44, 49,66	RC20AE105M	1 megohm ½ watt, carbon
R-33,40	RC20AE183K	18,000 ohms ½ watt, carbon
R-34,35	RC20AE124K	120,000 ohms ½ watt, carbon
R-41		1 megohm ½ watt, carbon, part of coil L-19
R-42,83	RC20AE564M	560,000 ohms ½ watt, carbon
R-43,89 113	RC20AE562K	5600 ohms ½ watt, carbon
R-45		68,000 ohms 1 watt, carbon, part of coil L-20
R-46		1 megohm 1 watt, carbon, part of coil L-21
R-47	RC20AE822M	8200 ohms ½ watt, carbon
R-48	25B739	1000 ohms WW, CONTRAST control. (Includes SW-2)
R-50,54	RC20AE334M	330,000 ohms ½ watt, carbon
R-51	RC20AE823M	82,000 ohms ½ watt, carbon
R-53,117	RC20AE682M	6800 ohms ½ watt, carbon
R-56	25B722	25,000 ohms, BRIGHTNESS control
R-58	24BG332E	3300 ohms 10 watts, WW
R-59	RC20AE223M	22,000 ohms ½ watt, carbon
R-60,77, 85,86	RC30AE104M	100,000 ohms 1 watt, carbon
R-61,79	RC30AE473M	47,000 ohms 1 watt, carbon
R-63,81	RC30AE681M	680 ohms 1 watt, carbon
R-64	25B720	500,000 ohms, HORIZONTAL control
R-65	RC20AE334M	270,000 ohms ½ watt, carbon
R-67,68	RC40AE473M	47,000 ohms 2 watts, carbon
R-69,70	RC20AE475M	4.7 megohms ½ watt, carbon
R-71,119	RC20AE224K	220,000 ohms ½ watt, carbon
R-72	RC40AE681M	680 ohms 2 watt, carbon
R-73	RC40AE180M	18 ohms 2 watts, carbon
R-74	RC30AE122M	1200 ohms 1 watt, carbon
R-75	RC20AE471M	470 ohms ½ watt, carbon
R-78	RC20AE155M	1.5 megohm ½ watt, carbon
R-80	RC20AE472M	4700 ohms ½ watt, carbon
R-82	25B720	500,000 ohms, VERTICAL control
R-84	25B724	2.5 megohms, HEIGHT control
R-87	RC30AE272M	2700 ohms 1 watt, carbon
R-90	RC30AE124K	120,000 ohms 1 watt, carbon
R-92,93	RC30AE395M	3.9 megohms 1 watt, carbon
R-94	25B723	5 megohms, FOCUS control
R-95,96 100,106	RC30AE475M	4.7 megohms 1 watt, carbon
R-97,98 101,102	RC30AE335M	3.3 megohms 1 watt, carbon
R-99,104	RC30AE565M	5.6 megohms 1 watt, carbon
R-103	25B723	5 megohms, VERTICAL POSITION control
R-105	25B723	5 megohms, HORIZONTAL POSITION control
R-107	24BG180E	18 ohms 10 watts, WW
R-108	RC40AE121M	120 ohms 2 watts, carbon
R-109	RC30AE470K	47 ohms 1 watt, carbon
R-110	RC30AE390K	39 ohms 1 watt, carbon
R-112		33,000 ohms 1 watt, carbon, part of coil L-18
R-114	25B724	2.5 megohms, WIDTH control
R-115		470 ohms 1 watt, carbon, part of coil L-22

TRANSFORMERS AND COILS

T-1	Transformer, FM sound detector	50B406
T-2	Transformer, audio output	55B080-3
T-3	Transformer, H.V. osc.	51B1038
L-1,5	Coil, osc. and mixer stages	51A1041
L-2	Coil, osc. stage	51A1042
L-3	Coil, osc. stage	51A1043
L-4	Coil, osc. stage	51A1044
L-6	Coil, mixer stage	51A1046
L-7	Coil, mixer stage	51A1047
L-8,12	Coil, mixer and r-f stages	51A1048
L-9	Coil, r-f amp. stage	51A1049
L-10	Coil, r-f amp. stage	51A1050
L-11	Coil, r-f amp. stage	51A1051
L-13,29	Choke, RF (Red color code)	53B008
L-14,15 16,17	Coil, i-f amplifier	50A372
L-18	Coil, video peaking, video detector	51A1053
L-19	Coil, video peaking, video detector	51A1054
L-20	Coil, video peaking, video amp.	51A1055
L-21	Coil, video peaking, video amp.	51A1057
L-22	Coil, sync. shaping	51B1040
L-23	Coil, 4.5 mc. sound trap	51B1037
L-25	Choke, filter	56C093
L-26	Choke, dual winding, HV oscillator	53A134
L-27	Choke, dual winding, 6C4 oscillator fil.	53A133
L-28	Antenna coil	51A1039

PLUGS AND SOCKETS

	Socket, octal (tube)	6A296
	Socket, miniature (tube)	6A297
	Socket, kinescope (tube)	6B298
PL-1	Line cord and plug PL2 (Model T-54)	87B1668
PL-1	Line cord and plug PL2 (Model 505, 506 and 506M)	87B1668-1
SO-2	Connector, line cord	10A286
PL-3	Connector and cord assembly, speaker	87A1670
	Receptacle, fuse	6A287

TUBES, RECTIFIERS AND FUSES

V-1,7,8,9, 11	Type 6AU6, audio IF; 1st, 2nd and 3rd IF amp; video amp.	90X6AU6
V-2	Type 6AL5, FM detector	90X6AL5
V-3	Type 6AV6, audio amp.	90X6AV6
V-4	Type 25L6GT, audio output	90X25L6GT
V-5,6	Type 6AG5, mixer, R.F. amp.	90X6AG5
V-10	Type 6H6, video detector	90X6H6
V-12,17, 18,19,20	Type 12SN7GT, video output; horizontal osc; vertical osc; horizontal amp.; vertical amp.	90X12SN7GT
V-13	Type 7JP4, kinescope	90X7JP4
V-14,21	Type 6C4, RF oscillator, H.V. osc.	90X6C4
V-15	Type 25Z6GT, rectifier	90X25Z6GT
V-16	Type 6X5GT, rectifier	90X6X5GT
V-22	Type, 1B3GT, H.V. rectifier	90X1B3GT
CR-1	Rectifier, silenium	27B147
F-1	Fuse, 2 amp., type 3AG	39A307

MISCELLANEOUS

	Channel selector assembly complete (Includes PB switch, trimmers, coils, etc.)	41X11203
LS-1	Speaker assembly (Includes SO-1)	85B070
	Baffle, speaker (Model T-54)	78B314
	Knob, rear chassis controls	15B141
	Knob, front panel controls (Model T-54)	15B068-4
	Knob, front panel controls (Model 505 & 506M)	15B068-3
	Knob, front panel controls (Model 506)	15B093-1
	Knob, push button & FINE TUNING (Model T-54 & 506)	17A041
	Knob, push button & FINE TUNING (Model 505 & 506M)	17A041-1
	Escutcheon, kinescope tube (Model T-54, 506 & 506M)	7DO71
	Escutcheon, kinescope tube (Model 505)	7DO71-1
	Window, escutcheon	22B206
	Foot, rubber (Model T-54)	16A029
	Plate, foot reinforcing (Model T-54)	63A334
	Cabinet back (Model 505, 506 & 506M)	8D844
	Mounting plate, chassis apron controls	8A786
	Mounting plate, front panel controls	8B788
	Insulating plate, mounting foot brackets	8A787
	Bracket, mounting foot	67A797
	Bracket, selenium rectifier mounting	67A807
	Bracket, kinescope tube mounting	67A809
	Bracket, a-c receptacle mtg. (505, 506 & 506M)	67B894
	Ring, kinescope tube mounting	76A393
	Terminal board, resistor mounting	88A574

SERVICE NOTES

SPECIFICATIONS

FREQUENCY RANGES:

Channel Number	Channel Frequency (mc.)	Video Carrier Frequency (mc.)	Audio Carrier Frequency (mc.)	Receiver H-F Oscillator Frequency (mc.)
1	not used	--	--	--
2	54 - 60	55.25	59.75	81.35
3	60 - 66	61.25	65.75	87.35
4	66 - 72	67.25	71.75	93.35
5	76 - 82	77.25	81.75	103.35
6	82 - 88	83.25	87.75	109.35
7	174 - 180	175.25	179.75	201.35
8	180 - 186	181.25	185.75	207.35
9	186 - 192	187.25	191.75	213.35
10	192 - 198	193.25	197.75	219.35
11	198 - 204	199.25	203.75	225.35
12	204 - 210	205.25	209.75	231.35
13	210 - 216	211.25	215.75	237.35

FINE TUNING RANGE:

Plus or minus 400 kc. on Channel 2;
Plus or minus 2 mc. on Channel 13.

OPERATING VOLTAGE:

105 to 120 volts, 60 cycles.

POWER CONSUMPTION: .... 300 watts

AUDIO POWER OUTPUT:

Undistorted .... 3.5 watts
Maximum .... 4.5 watts

LOUDSPEAKER:

Type .... 12" P.M.
Voice Coil Impedance ..... 3.2 ohms at 400 cycles

RECEIVER ANTENNA INPUT IMPEDANCE:

.. 300 ohms balanced or 72 ohms unbalanced

TUBE COMPLEMENT:

1	1B3/GT	High Voltage Rectifier
2	5U4G	Low Voltage Rectifier
1	6AH6	Video Output
1	6AG5	Mixer
1	6AG5	R.F. Amplifier
1	6AL5	Video Detector and Noise Clipper
1	6AL5	Ratio Detector
1	6AL5	Horizontal A. F. C.
1	6AQ5	Vertical Output
2	6AU5/GT	Horizontal Output
1	6AV6	1st Audio Amplifier
1	6BH6	1st I. F. Amplifier
1	6BH6	2nd I. F. Amplifier
1	6BH6	3rd I. F. Amplifier
1	6BH6	1st Sound I. F. Amplifier
1	6BH6	2nd Sound I. F. Amplifier
1	6BH6	Keyed AGC
1	6BJ6	4th I. F. Amplifier
1	6C4	H. F. Oscillator
1	6Y6G	High Voltage Oscillator
1	6Y6G	Audio Output
1	6W4/GT	Horizontal Damper
1	12AT7	1st Sync. Amp. & Sync. Separator
1	12AU7	Vertical Multivibrator
1	12AU7	Horizontal Multivibrator
1	12AU7	2nd Sync. Amp. & Phase Invertor
1	12LP4 or 12LP4A	Cathode Ray Tube

VIDEO CARRIER INTERMEDIATE FREQUENCY: .... 26.1 mc.

VIDEO RESPONSE: .... 3.6 mc.

AUDIO CARRIER INTERMEDIATE FREQUENCY: .... 4.5 mc.

AUDIO DISCRIMINATOR BAND WIDTH: (between peaks) .... 150 kc.

FOCUS: .... Magnetic

SWEEP DEFLECTION: .... Magnetic

SCANNING: .... Interlaced 525 line

HORIZONTAL SCANNING FREQUENCY: .... 15,750 CPS

VERTICAL SCANNING FREQUENCY: .... 60 CPS

FRAME FREQUENCY (picture repetition rate): .... 30 CPS

CATHODE RAY TUBE HANDLING PRECAUTIONS

Shatterproof goggles and heavy gloves should be worn at all times when handling the cathode ray tube. The tube should not be handled in the vicinity of any person not so equipped. When handling the cathode ray tube, always keep it away from the body.

The cathode ray tube bulb, due to its large surface area and high vacuum contained within, is subjected to high air pressure. More than ordinary care is required to prevent shattering the tube. The large end of the bulb, particularly the rim of the viewing surface, must not be struck, scratched, or subjected to more than moderate pressure at any time. If the tube sticks or fails to slip smoothly into place during installation, remove the tube and determine the cause of the trouble - - DO NOT FORCE THE TUBE.

©John F. Rider

World Radio History

HIGH VOLTAGE WARNING

The danger accompanying shock is always present when the receiver is operated outside the cabinet or when the rear cover is removed from the cabinet. Only a person familiar with the precautions to be observed when working with high-voltage equipment should service this receiver.

INSTALLATION INSTRUCTIONS

TO PREPARE THE RECEIVER FOR OPERATION:

1. Remove the screws that secure the rear cover to the cabinet.

2. Remove the rear cover by pulling it straight out from the cabinet.

3. Check the operation of the Electronic Magnifier. If the shutters bind, *do not force the control*. Re-position the chassis to allow smooth operation of the control. If the shutters still bind, remove the chassis from the cabinet as outlined under CHASSIS REMOVAL to determine the cause of the binding.

4. Models H-606K12 and H-607K12 contain a built-in antenna for use in areas of normal reception. In such areas where the built-in antenna provides good reception, no antenna connections are required. However, in weak signal areas or under adverse conditions, it may be necessary to use an external antenna. In this event, the antenna lead-in can be connected to the antenna terminals on the back of the receiver after disconnecting the built-in antenna wires that normally connect to these terminals. The lugs on the built-in antenna should be insulated and dressed in such a position that they do not touch the chassis or components. The clamp located at the top, inside, rear of the cabinet may be used to hold the built-in antenna feeder out of the way.

5. Apply power to the receiver by connecting a temporary line cord between the receptacle on the chassis and a 105 to 120 volt 60 cycle A-C outlet.

TO CHECK THE OPERATION:

1. Turn the magnifier switch to the clockwise (magnified) position.

2. Rotate the brightness and contrast controls completely counterclockwise.

3. Turn on the receiver by rotating the off-on-volume control clockwise.

4. Rotate the channel selector to the channel number of the desired station.

5. Rotate the brightness control clockwise until the screen is well lighted.

6. Rotate the contrast control clockwise until a picture appears on the screen.

7. If the built-in antenna is in use adjust the television antenna control for maximum picture contrast. If an external antenna is in use, this step is not required.

8. If the picture is moving up or down or quivering adjust the vertical hold control to stabilize the image.

9. If vertical or diagonal bars or a folded over picture appears on the screen, adjust the horizontal hold control to obtain a stable picture.

10. Adjust the fine tuning control for best picture detail.

11. Readjust the brightness and contrast controls until pleasing shades ranging from clear white to intense black are attained.

12. If shadows appear on the face of the tube or the picture is not properly centered, adjust the ion trap magnet and focus coil as outlined under ADJUSTMENTS.

13. Adjust the volume control for the desired sound volume.

14. Turn the magnifier switch to the counterclockwise (normal) position.

15. If vertical or diagonal bars appear on the screen, adjust the width control as described under ADJUSTMENTS. *Do not readjust the horizontal hold control.*

16. If necessary, adjust the height, height magnifier, vertical linearity, vertical linearity magnifier, and focus controls as explained under ADJUSTMENTS.

17. Check the operation on all available television stations. Note that if the built-in antenna is in use, the television antenna control must be readjusted for maximum picture contrast each time the receiver is tuned to a different channel.

18. Turn off the receiver, disconnect the temporary line cord and external antenna (if used), and replace the rear cover.

19. Re-connect the external antenna (if used) to the antenna terminals on the rear of the chassis, and connect the A-C plug to a 105 to 120 volt 60 cycle power outlet.

20. Re-check the operation on all available stations.

ADJUSTMENTS

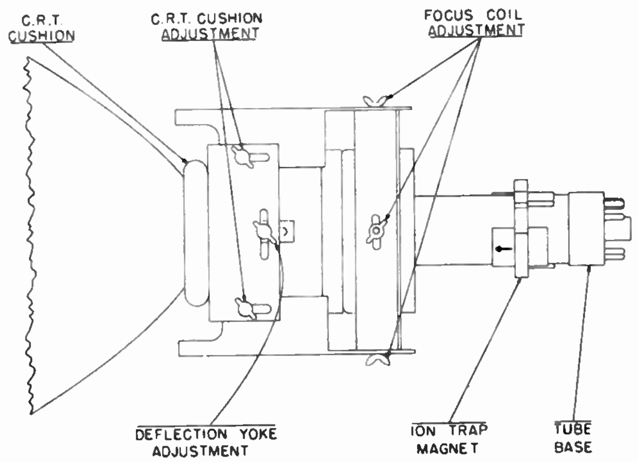

FIG. 1 — CRT ADJUSTMENTS

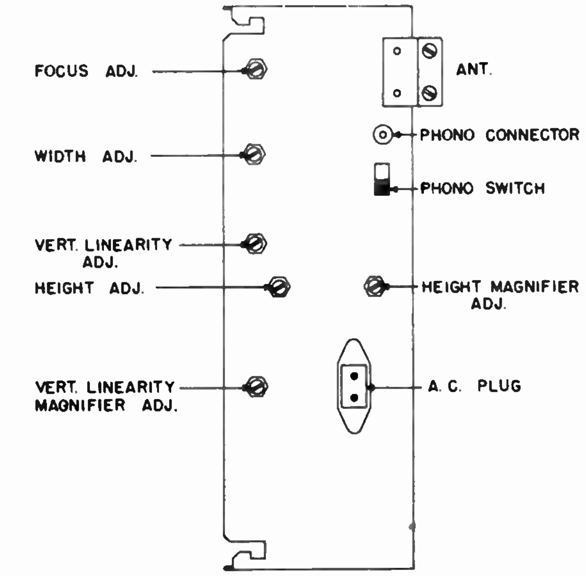

FIG. 2 — ADJUSTMENTS ON REAR OF CHASSIS

The picture adjustments are located on the rear of the chassis and are accessible through cut-outs in the back cover.

An insulated, long shank screwdriver is preferred for making the ringing coil and H.V. oscillator adjustments.

ION TRAP MAGNET

CAUTION: When adjusting the ion trap magnet, care must be exercised to avoid breaking the neck of the C.R.T.

The ion trap magnet must always be adjusted for maximum picture brightness. With the magnet oriented approximately as shown in Fig. 1, rotate it around the neck of the tube and move it forward and backward until the position is found where the brightest raster is obtained.

FOCUS COIL

If a shadow falls on one corner of the picture or if the picture is not centered, adjustment of the focus coil will be necessary. To adjust, loosen the focus coil adjustment wing screws and slightly rotate the coil about its vertical and horizontal axis until a position is found where the picture is centered and there are no shadowed corners. Tighten the wing screws with the coil in this position.

CATHODE RAY TUBE CUSHION

The cushion must fit snugly against the flare of the cathode ray tube in order that the rear of the tube will be supported firmly.

DEFLECTION YOKE

This adjustment controls the angle of the picture with respect to the horizontal. If the picture is not squared in the picture mask, loosen the wing nut and move it to the left or right so as to rotate the deflection yoke. The picture will tilt to the left or right with the deflection yoke rotation.

FOCUS CONTROL

The focus control (Fig. 2) should be adjusted with the brightness and contrast controls in their normal positions. If correct focusing cannot be obtained, the high voltage oscillator may require adjustment.

HEIGHT AND VERTICAL LINEARITY (NORMAL)

The height adjustment controls the overall height of the picture, while the vertical linearity adjustment governs contraction or expansion of the upper portion only. For this reason, a balance between the two controls is necessary to make the picture symmetrical and fill the mask vertically.

©John F. Rider

World Radio History

HEIGHT AND VERTICAL LINEARITY (MAGNIFIED)

The height magnifier adjustment controls the overall height of the magnified picture, while the vertical linearity magnifier adjustment governs contraction or expansion of the upper portion only. For this reason, a balance between the two controls is necessary to make the picture symmetrical and fill the mask vertically. *These controls must be reset if the height and vertical linearity controls governing the normal picture are changed.*

WIDTH

The width adjustment must always be made with the magnifier control set for a normal size picture. The correct adjustment is made as follows:

1. Rotate the magnifier control to the magnified position, and adjust the horizontal hold control until magnified picture hold holds horizontal sync.

2. Set the magnifier control for a normal size picture, and *without re-adjusting the horizontal hold control* adjust the width control until the picture holds horizontal sync and fills the mask horizontally.

HORIZONTAL RINGING COIL

To adjust the horizontal ringing coil.

1. Turn the magnifier switch to the clockwise (magnified) position.

2. Tune in the weakest station in your area.

3. Set the horizontal hold control at approximately the center of its range.

4. Adjust the ringing coil (L403) until the picture is properly "locked-in".

HIGH VOLTAGE OSCILLATOR

1. *Turn off the receiver* and disconnect the high voltage lead from the CRT.

2. Connect 18 one megohm, one watt resistors in series between the high voltage lead and the chassis.

3. Connect a kilovoltmeter across the 18 megohms of resistance.

4. Turn on the receiver and adjust C507 (location shown on Fig. 8) for maximum voltage indication on the meter. When C507 is peaked using an 18 megohm load, the voltage across the load should be 9.3 kilovolts (approximately).

5. *Turn off the receiver,* disconnect the kilovoltmeter, remove the 18 megohms of resistance, and connect the high voltage lead to the CRT. Note that when the 18 megohm load is removed and the high voltage lead is connected to the CRT, the output voltage of the H.V. power supply will rise because of the higher load resistance offered by the CRT.

13. Tighten the CRT strap and the wing nut on the stud at the top of the CRT strap.

14. Adjust the CRT cushion and tighten the CRT cushion screws.

15. Replace the ion trap magnet and the CRT socket.

16. Adjust the ion trap magnet and focus coil as outlined under ADJUSTMENTS.

17. Turn the magnifier switch to the clockwise (magnified) position. Open the shutters completely and tighten the set screw to lock the shutter actuating link to the control shaft.

18. Check the operation of the shutters to make certain there is no binding.

19. Replace the chassis in the cabinet.

CHASSIS REMOVAL

To remove the chassis from the cabinet:

1. Remove the control knobs from the front of the cabinet.

2. Remove the wood screws that hold the rear cover to the cabinet, and remove the rear cover.

3. Remove the two red-headed wood screws from the block located on the top (inside) of the cabinet, and remove the block.

4. Disconnect the built-in antenna feeder from the antenna terminals.

5. Release the antenna stub from the top of the cabinet by pulling out the thumbtack.

6. Remove the two screws that secure the antenna trimmer assembly to the top of the cabinet.

7. Remove the trimmer assembly and rubber coupling sleeve by carefully pulling the coupling sleeve off the drive shaft.

8. Temporarily tape the drive shaft to the top of the cabinet to avoid breakage.

9. Remove the bracket that clamps the shutter frame to the bottom of the cabinet. This bracket is located near the front (inside) of the cabinet and can be released by removing the screw from the under side of the cabinet.

10. Remove the hex-head chassis bolts from the under side of the cabinet.

11. Remove the chassis by pushing the front of the chassis against the left side of the cabinet and then easing the chassis out of the cabinet while moving the rear of the chassis gradually toward the right. The chassis must leave the cabinet at an angle so that the shutter mechanism will clear the antenna drive pulleys. This step must be performed cautiously to prevent scratching the plastic front plate.

CATHODE RAY TUBE REPLACEMENT

1. Remove the chassis from the cabinet as explained under CHASSIS REMOVAL.

2. Back off the screw locking the shutter actuating link to the magnifier control shaft.

3. Remove the two self-tapping screws that secure the shutter assembly frame to the chassis.

4. Remove the two self-tapping screws that secure the shutter assembly frame to the brace bars.

5. Remove the wing nut and lock washer from the stud on top of the CRT strap.

6. Remove the shutter assembly by lifting the bronze strap over the stud and sliding the complete assembly forward.

7. Remove the ion trap magnet and the CRT socket.

8. Loosen the CRT cushion screws, the focus coil wing screws, and remove the screw from the CRT strap.

9. Remove the defective CRT and insert the replacement through the deflection yoke and focus coil, exercising the caution necessary when handling cathode ray tubes.

10. Replace the screw in the CRT strap and tighten the strap about the tube just enough to hold the tube in place.

11. Replace the shutter assembly and tighten the self-tapping screws only. Do not tighten the CRT strap wing nut or the set screws on the magnifier control shaft.

12. Position the CRT so that the clearance between the tube and the mask is approximately 1/32".

ALIGNMENT

TEST EQUIPMENT—To properly service this chassis, the following test equipment should be available:

1. R-F sweep generator which meets the following requirements:

a. Frequency range from 18 to 30 mc. with a sweep width of 10 mc.

b. Output adjustable with at least 100,000 microvolts maximum and a very low minimum.

c. Output "flat" on all attenuator positions.

2. Cathode-ray oscilloscope, preferably one with a wide band vertical deflection amplifier and a low-capacitance input probe.

3. Signal generator capable of providing output frequencies listed below.

21.6 mc. 4th I-F trap
22.6 mc. 1st I-F
25.9 mc. 2nd I-F
25.6 mc. 3rd I-F
23.8 mc. 4th I-F
23.0 mc. 5th I-F
4.5 mc. Audio I-F and ratio detector (the frequency must be extremely accurate, preferably crystal controlled.)

©John F. Rider

World Radio History

NOTE—The R-F output level on all the above frequencies should be adjustable with at least 100,000 microvolts maximum and a very low minimum.

4. Heterodyne frequency meter with crystal calibrator (if the signal generator does not include a crystal calibrator).

5. Electronic voltmeter (vacuum tube voltmeter), with a high voltage multiplier probe for measurements up to 15,000 volts and an R-F probe for measuring R-F voltages.

GENERAL INFORMATION—All test equipment and the chassis should be bonded together by short lengths of heavy (½ inch) braided copper ribbon. The interconnecting leads should be shielded (72 ohms coaxial cable) and should be as short as possible consistent with ease of making connections. The effectiveness of the bonding can be checked during alignment by placing the hand on the metal chsssis or test equipment case. If the response pattern or meter reading changes visibly, the bonding must be improved before the circuits are aligned.

COMMON I-F ALIGNMENT PROCEDURE

1. Rotate the channel selector switch to channel 3.

2. Connect the signal generator to the mixer tube through the coupling device shown in Fig. 4. The device is constructed by squeezing together a miniature tube shield until it fits the tube snugly and does not ground to the chassis. A .005 mfd capacitor is then soldered to the side of the shield. By sliding the tube shield up or down on the tube, the capacitance between the shield and the tube elements can be varied to obtain additional control of the coupling over that provided by the attenuator in the generator itself. The ground side of the generator output cable should be connected to the receiver chassis.

3. Connect a vacuum tube voltmeter to the video test jack on the receiver chassis, and set the meter to its 5 volt scale.

4. Set the signal generator to 21.6 mc. (unmodulated), and adjust C329 for *minimum* voltage on the VTVM. Use a strong signal for this adjustment.

5. Set the signal generator to 22.6 mc. (unmodulated), and adjust L306 for maximum voltage on the VTVM. *During this adjustment, keep the signal generator output adjusted so that the VTVM reading does not exceed 2 volts.*

6. Set the signal generator to 25.9 mc. (unmodulated), and adjust L307 for maximum voltage on the VTVM. *During this adjustment, keep the signal generator output adjusted so that the VTVM reading does not exceed 2 volts.*

7. Set the signal generator to 25.6 mc. (unmodulated), and adjust L308 for maximum voltage on the VTVM. *During this adjustment, keep the signal generator output adjusted so that the VTVM reading does not exceed 2 volts.*

8. Set the signal generator to 23.8 mc. (unmodulated), and adjust L309 for maximum voltage on the VTVM. *During this adjustment, keep the signal generator output adjusted so that the VTVM reading does not exceed 2 volts.*

9. Set the signal generator to 23.0 mc. (unmodulated), and adjust L313 for maximum voltage on the VTVM. *During this adjustment, keep the signal generator output adjusted so that the VTVM reading does not exceed 2 volts.*

10. Connect the *sweep* generator to the mixer tube through the coupling device previously described. The *signal* generator will be used in the following steps to provide marker indications at various frequencies on the response curve. In this application, the signal generator input to the set must be low in amplitude to avoid distorting the response curve. To reduce the signal generator input accordingly, the signal generator should be *loosely* coupled to the set by wrapping a few turns of insulated wire around the coupling capacitor "pigtail" and connecting the signal generator to this wire.

11. Connect the vertical input of the oscilloscope to the video test jack through the de-coupling network shown in Fig. 5. The oscilloscope horizontal input should be connected to the sweep output from the sweep generator; turn the sweep control on the oscilloscope to the "X" or "OFF" position.

12. Adjust the sweep generator for a center frequency of 25.3 mc. with a 10 mc. deviation. Adjust the sweep generator output until a setting is found where there is very little noise on the oscilloscope pattern.

The oscilloscope pattern obtained should be similar to that shown in Fig. 6. Use the signal generator as a marker to check at the frequencies indicated. If the pattern obtained is not similar to Fig. 6, L306, L307, L308, L309, and L313 should be re-adjusted to produce the correct pattern. The affect of the adjustments will be as follows:

L306 affects the low frequency side of the curve.
L307 affects the high frequency side of the curve and the position of the video I-F carrier.
L308 affects the center of the curve.
L309 affects the tilt of the "shelf" of the curve.
L313 affects the center and the low frequency side of the curve.

SOUND I-F AND 4.5 MC. TRAP ALIGNMENT PROCEDURE

1. Connect the "high" side of the signal generator to the video test jack through a .001 mfd capacitor, and ground the "low" side to the chassis.

2. Connect the vacuum tube voltmeter to the points indicated on the bottom view of the chassis, Fig. 8. The common lead should connect to point "C", and the "high" lead should connect to point "A". Set the meter on its 5 volt (-DC) scale.

3. Adjust the signal generator to 4.5 mc. (unmodulated). The accuracy of this frequency is very important. If a crystal controlled signal generator is not available, the frequency should be checked using a frequency meter with a crystal calibrator.

4. Adjust T201 and the primary of T202 for maximum voltage on the VTVM. *During this adjustment keep the signal generator output adjusted so that the VTVM reading does not exceed 5 volts.*

5. Connect the common lead from the VTVM to point "A" (Fig. 8), and connect the "high" lead to point "B". Here it is important that the case and components of the VTVM are *not* grounded to the receiver chassis; otherwise, point "A" would be shorted to the chassis through the common lead.

6. Using the same signal generator amplitude and frequency as in step 4, adjust the secondary of T202 for *zero* voltage on the VTVM. As the adjustment is tuned through resonance, the voltage will rapidly change from one polarity to the opposite polarity. The point where the voltage is zero is the correct setting.

7. Connect the common lead from the VTVM to the chassis, and connect the *R-F probe* from the VTVM to the junction of R332 and R326. This point is shown as point "D" on Fig. 8. *Note that this point is 150 volts above ground and, therefore, the R-F probe must contain a blocking capacitor.*

8. Using a strong 4.5 mc. signal applied as in step 1, adjust C321 for *minimum* indication on the meter.

H. F. OSCILLATOR ALIGNMENT PROCEDURE

If the 6C4 H-F oscillator tube is replaced the different inter-electrode capacitance of the new tube may change the oscillator frequency enough to necessitate re-alignment of the oscillator.

The oscillator adjusting screws are located on the front of the tuner assembly, and this procedure should be followed for their adjustment:

1. Remove the channel selector and fine tuning knobs. Remove the selector escutcheon plate and escutcheon mounting plate by removing the Phillips head screws securing them to the cabinet. The adjustments are accessible through the hole in the cabinet.

2. Set the fine tuning control to the middle of its range, and leave it in this position during the following adjustments.

3. Set the channel selector switch to the highest of the low band (channels 2 through 6) stations operating in your locality.

4. Peak the appropriate oscillator slug for the best picture detail.

5. Repeat step 4 for each progressively lower channel on which a station transmits in your area.

6. Set the channel selector switch to the highest of the high band (channels 7 through 13) stations operating in your locality.

7. Peak the appropriate oscillator slug for the best picture detail.

8. Repeat step 7 for each progressively lower channel in the high band on which a nearby station transmits.

9. Check the previously made low band adjustments, and if the tuning has changed repeat steps 3 through 8.

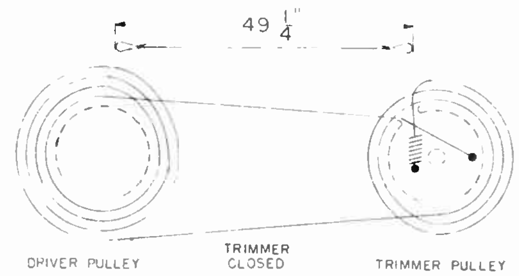

FIG. 3 — DRIVE STRING ARRANGEMENT FOR ANTENNA TRIMMER

I-F ALIGNMENT CHART

Turn the channel selector to channel 3 to avoid undesirable beat response during alignment.

COMMON I-F SECTION

Couple the sweep and marker generators to the mixer tube as shown in Fig. 4.

Step	*Sweep Gen. Frequency*	*Marker Gen. Frequency*	*Remarks*	*Indicator Connection*	*Adjust*
1.	Not used	21.6 mc. unmodulated	Use a strong signal	Connect VTVM to video test jack	C-329 for *minimum* voltage
2.	Not used	22.6 mc. unmodulated	Keep marker output adjusted so VTVM reading does not exceed 2 v.	Same as step 1	L-306 for maximum voltage
3.	Not used	25.9 mc. unmodulated	Same as step 2	Same as step 1	L-307 for maximum voltage
4.	Not used	25.6 mc. unmodulated	Same as step 2	Same as step 1	L-308 for maximum voltage
5.	Not used	23.8 mc. unmodulated	Same as step 2	Same as step 1	L-309 for maximum voltage
6.	Not used	23.0 mc. unmodulated	Same as step 2	Same as step 1	L-313 for maximum voltage
7.	25.3 mc. with 10 mc. deviation	check at: 21.6 mc. 22.5 mc. 23.5 mc. 25.3 mc. 26.1 mc.	Keep sweep output low enough so that very little noise appears on the oscilloscope trace	Connect oscilloscope to video test jack. See Fig. 5.	If necessary, adjust L-306, L-307, L-308, L-309, and L-313 to obtain correct response curve. See Fig. 6.

SOUND I-F SECTION AND 4.5 MC. TRAP

Connect the signal generator to the video test jack through a .001 mfd mica capacitor.

Step	*Signal Gen. Frequency*	*VTVM Connection*	*Remarks*	*Adjust*
1.	4.5 mc. unmodulated	See Fig. 8. Common lead to point "C" and high lead to point "A".	Use 5 v. (−DC) scale on meter. Set sig. gen. output accordingly.	T-201 and pri. of T-202 for maximum voltage
2.	4.5 mc. unmodulated	See Fig. 8. Common lead to point "A" and high lead to point "B".	Use same sig. gen. output as in step 1.	Sec. of T-202 for *zero* voltage
3.	4.5 mc. unmodulated	See Fig. 8. R-F probe to point "D" and common lead to chassis.	Use strong signal from generator.	C-321 for *minimum* voltage

L-312	V-5902-1	Coil	Video peaking
L-313	V-6459	Coil	I-F peaking
*R-301	V-9235-2 assy	Control, 1500 ohms (assy consists of R-301 and R-302)	Contrast
*R-302	V-9235-2 assy	Control, 50,000 ohms (assy consists of R-301 and R-302)	Brightness
R-306	RC41AE103K	Resistor, 10,000 ohms 2 w.	Cathode bias
R-307	V-6984-1	Resistor, 2000 ohms 5 w.	Decoupling
R-309	RC20AE680K	Resistor, 68 ohms ½ w.	Cathode bias
R-310	RC20AE680K	Resistor, 68 ohms ½ w.	Cathode bias
R-311	RC20AE101K	Resistor, 100 ohms ½ w.	Cathode bias
R-312	RC20AE101K	Resistor, 100 ohms ½ w.	Cathode bias
R-313	RC20AE102M	Resistor, 1000 ohms ½ w.	Plate decoupling
R-314	RC20AE102M	Resistor, 1000 ohms ½ w.	Screen load
R-315	RC20AE102M	Resistor, 1000 ohms ½ w.	Plate decoupling
R-316	RC20AE102M	Resistor, 1000 ohms ½ w.	Screen load
R-317	RC20AE472K	Resistor, 4700 ohms ½ w.	Grid return
R-318	RC20AE472K	Resistor, 4700 ohms ½ w.	Grid bias
R-319	RC20AE472K	Resistor, 4700 ohms ½ w.	Grid return
R-320	RC20AE103K	Resistor, 10,000 ohms ½ w.	Grid return
R-321	RC20AE103K	Resistor, 10,000 ohms ½ w.	Plate decoupling
R-322	RC20AE103M	Resistor, 10,000 ohms ½ w.	AGC decoupling
R-323	RC20AE103M	Resistor, 10,000 ohms ½ w.	AGC decoupling
R-324	RC20AE223K	Resistor, 22,000 ohms ½ w.	4.5 mc trap loading
R-325	RC20AE473K	Resistor, 47,000 ohms ½ w.	DC divider
R-326	RC20AE104K	Resistor, 100,000 ohms ½ w.	DC divider
R-327	RC20AE682K	Resistor, 6800 ohms ½ w.	Grid return
R-328	RC20AE102M	Resistor, 1000 ohms ½ w.	Plate decoupling
R-329	RC20AE225K	Resistor, 2.2 megs ½ w.	AGC decoupling
R-331	RC20AE123K	Resistor, 12,000 ohms ½ w.	Grid return
R-332	RC20AE154K	Resistor, 150,000 ohms ½ w.	DC divider
R-333	RC30AE473K	Resistor, 47,000 ohms 1 w.	Screen load
R-334	RC30AE224K	Resistor, 220,000 ohms 1 w.	AGC filter
R-335	RC30AE683K	Resistor, 68,000 ohms 1 w.	Screen load
R-336	RC30AE104K	Resistor, 100,000 ohms 1 w.	Screen load
R-337	RC30AE362J	Resistor, 3600 ohms 1 w.	Plate load
R-338	RC41AE103K	Resistor, 10,000 ohms 2 w.	Plate decoupling
R-339	RC20AE222K	Resistor, 2200 ohms ½ w.	Cathode bias

PARTS LIST FOR MODELS H-606K12 AND H-607K12 (*Continued*)

Item	Part No.	Description	Function
*C-403	V-6978 assy	Capacitor, electrolytic 30 mfd 450 v. (assy consists of C-403 and C-501 and C-502)	Filter
C-404	V-9009-1	Capacitor, electrolytic 150 mfd 50 v.	Cathode by-pass
C-405	V-6570	Capacitor, electrolytic 30 mfd 450 v.	Filter
C-406	RCP10W4104M	Capacitor, .1 mfd 400 v.	H.V. supply decoupling
C-407	V-5596	Capacitor, hi-kap .005 mfd	Filament by-pass
C-408	V-5596	Capacitor, hi-kap .005 mfd	Filament by-pass
C-409	V-5596	Capacitor, hi-kap .005 mfd	Filament by-pass
C-410	V-6023-6102M	Capacitor, .001 mfd 600 v.	AFC coupling
C-411	V-6023-6102M	Capacitor, .001 mfd 600 v.	AFC coupling
C-412	V-6023-4472M	Capacitor, .0047 mfd 400 v.	AFC delay
C-413	V-6023-6222M	Capacitor, .0022 mfd 600 v.	Pulse divider
C-414	V-6023-4103M	Capacitor, .01 mfd 400 v.	Vert. sync. coupling
C-415	V-6023-4103M	Capacitor, .01 mfd 400 v.	H. MV coupling
C-416	V-6023-4503M	Capacitor, .05 mfd 400 v.	Sync coupling
C-417	V-6023-4503M	Capacitor, .05 mfd 400 v.	Cathode by-pass
C-418	V-6023-4503M	Capacitor, .05 mfd 400 v.	AFC delay
C-419	V-6023-4104M	Capacitor, .1 mfd 400 v.	Grid by-pass
C-420	V-6023-4104M	Capacitor, .1 mfd 400 v.	V. MV coupling
C-421	V-6023-4104M	Capacitor, .1 mfd 400 v.	Plate decoupling
C-422	V-6023-4104M	Capacitor, .1 mfd 400 v.	Plate decoupling
C-423	V-6066-4254M	Capacitor, .25 mfd 400 v.	Sync coupling
C-424	V-6023-4104M	Capacitor, .1 mfd 400 v.	Coupling
C-425	V-6023-4104M	Capacitor, .1 mfd 400 v.	Cathode by-pass
C-426	V-6023-4104M	Capacitor, .1 mfd 400 v.	Screen by-pass
C-427	V-6066-4254M	Capacitor, .25 mfd 400 v.	Plate by-pass
C-428	V-6023-4104K	Capacitor, .1 mfd 400 v.	Vertical discharge
C-429	V-6023-4103K	Capacitor, .01 mfd	MV coupling
C-430	RCM20B271K	Capacitor, 270 mmf	Grid by-pass
C-431	RCM20B101K	Capacitor, 100 mmf	Plate by-pass
C-432	RCM20B681M	Capacitor, 680 mmf	Horiz. discharge
C-433	RCM20C331J	Capacitor, 330 mmf	Error volt. coupling
C-434	RCM20C331J	Capacitor, 330 mmf	H. MV coupling
C-435	RCM30C392K	Capacitor, 3900 mmf	MV plate tank
C-436	V-9176-15560K	Capacitor, 56 mmf	Transient by-pass
C-437	RCM20B391K	Capacitor, 390 mmf	H. sync coupling
C-438	V-6023-4503M	Capacitor, .05 mfd	Sync coupling
C-442	V-6023-4104M	Capacitor, .1 mfd	Grid by-pass
C-443	RCM20B101K	Capacitor, 100 mmf	Plate by-pass
C-444	V-9465-2	Capacitor, 7 mmf (twin lead 150 ohms)	AGC coupling
L-401	V-9230-2	Choke, feed	Plate load
L-402	V-5900-2	Coil	Focus
L-403	V-6764	Coil	Ringing
L-404	V-4886-2	Choke, RF	Filament
L-405	V-4886-2	Choke	Filament
L-406	V-4886-2	Choke	Filament
L-407	V-4886-2	Choke	Filament
L-413	V-4886-2	Choke, RF	Filament
R-401	V-5908	Control, 400 ohms	Focus
R-402	V-6462	Control, 1 meg	Height
R-403	V-6463	Control, 5,000 ohms	Vert. Lin.
*R-404	V-6464-1 assy	Control, 100,000 ohms (assy consists of R-404 and R-405)	Horizontal hold
*R-405	V-6464-1 assy	Control, 500,000 ohms (assy consists of R-404 and R-405)	Vertical hold
R-406	V-6500-1	Control, 5000 ohms	Width
R-407	RC20AE561K	Resistor, 560 ohms ½ w.	Transient damping
R-408	RC20AE561K	Resistor, 560 ohms ½ w.	Transient damping
R-409	V-6984-6	Resistor, 560 ohms 5 w.	Plate load
R-410	V-6984-5	Resistor, 10,000 ohms 5 w.	Screen load
R-411	V-6984-1	Resistor, 2000 ohms 5 w.	Plate load
R-412	V-4758	Resistor, 110 ohms 3 w.	Focus coil shunt
R-415	RC20AE105K	Resistor, 1 megohm ½ w.	Positive bias limiting
R-418	RC20AE101K	Resistor, 100 ohms ½ w.	Hor. sweep stabilizer
R-419	RC20AE331K	Resistor, 330 ohms ½ w.	Cathode bias
R-420	RC20AE471K	Resistor, 470 ohms ½ w.	Cathode bias
R-421	RC20AE471K	Resistor, 470 ohms ½ w.	Focus coil shunt
R-422	RC20AE102K	Resistor, 1000 ohms ½ w.	Limiting
R-423	RC20AE102K	Resistor, 1000 ohms ½ w.	Cathode bias
R-424	RC20AE182K	Resistor, 1800 ohms ½ w.	Cathode bias
R-425	RC20AE272K	Resistor, 2700 ohms ½ w.	Cathode bias
R-426	RC20AE272K	Resistor, 2700 ohms ½ w.	Plate load
R-427	RC20AE392K	Resistor, 3900 ohms ½ w.	Waveform correction
R-428	RC20AE223K	Resistor, 22,000 ohms ½ w.	Plate load
R-429	RC20AE562K	Resistor, 5600 ohms ½ w.	Plate load
R-430	RC30AE333K	Resistor, 33,000 ohms 1 w.	H. MV decoupling
R-431	RC30AE333K	Resistor, 33,000 ohms 1 w.	H. MV decoupling
R-432	RC20AE273K	Resistor, 27,000 ohms ½ w.	Waveform correction
R-433	RC20AE333K	Resistor, 33,000 ohms ½ w.	Voltage divider
R-434	RC20AE473K	Resistor, 47,000 ohms ½ w.	Plate decoupling
R-436	RC20AE683K	Resistor, 68,000 ohms ½ w.	Error voltage load
R-437	RC20AE104J	Resistor, 100,000 ohms ½ w.	AFC diode load
R-438	RC20AE104J	Resistor, 100,000 ohms ½ w.	AFC diode load
R-439	RC20AE225K	Resistor, 2.2 megohms ½ w.	Grid return
R-440	RC20AE104K	Resistor, 100,000 ohms ½ w.	Plate load
R-441	RC20AE224J	Resistor, 220,000 ohms ½ w.	Grid bias
R-442	RC20AE394J	Resistor, 390,000 ohms ½ w.	Plate load
R-443	RC20AE474K	Resistor, 470,000 ohms ½ w.	Charge limiting
R-444	RC20AE474K	Resistor, 470,000 ohms ½ w.	Grid return
R-445	RC20AE474K	Resistor, 470,000 ohms ½ w.	AFC delay
R-446	RC20AE104K	Resistor, 100,000 ohms ½ w.	Grid return
R-447	RC20AE105K	Resistor, 1.0 megohms ½ w.	Grid return
R-448	RC20AE105K	Resistor, 1.0 megohms ½ w.	Grid return
R-449	RC20AE225K	Resistor, 2.2 megohms ½ w.	Grid return
R-450	RC20AE475K	Resistor, 4.7 megohms ½ w.	Plate load
R-451	RC20AE224K	Resistor, 220,000 ohms ½ w.	Plate load
R-452	RC20AE154K	Resistor, 150,000 ohms ½ w.	Plate load
R-453	RC30AE224K	Resistor, 220,000 ohms 1 w.	Limiting
R-455	RC20AE153K	Resistor, 15,000 ohms ½ w.	Plate load
R-456	V-6067-4	Resistor, glasohm, 150 ohms 3 w.	Cathode bias
R-464	V-5909	Control, 2.5 megohms	Height magnifier
R-465	V-5910	Control, 25,000 ohms	V. lin magnifier
R-469	RC20AE225K	Resistor, 2.2 megohms ½ w.	Diode shunt
R-470	RC20AE101K	Resistor, 100 ohms ½ w.	Parasitic suppressor
R-471	RC20AE101K	Resistor, 100 ohms ½ w.	Parasitic suppressor
SW-401	V-9482-1 assy	Magnifier (assy consists of R-201, SW-401 and SW-501)	
T-401	V-6981-1	Transformer	Vertical output
T-402	V-6481-2	Transformer	Filament
Z-401	V-9213	Filter	Integrating
Z-402	V-6486-2	Yoke assembly	Deflection

Section 5—Power

Item	Part No.	Description	Function
C-501	V-6978 assy	Capacitor, electrolytic 30 mfd 450 v. (assy consists of C-501, C-502 and C-403)	Filter
C-502	V-6978 assy	Capacitor, electrolytic 30 mfd 450 v. (assy consists of C-501, C-502 and C-403)	Filter
C-503	V-5040-15	Capacitor, .01 mfd 600 v.	A-C line by-pass
C-504	V-5040-15	Capacitor, .01 mfd 600 v.	A-C line by-pass
C-505	V-6023-4503M	Capacitor, .05 mfd 400 v.	Screen by-pass
C-506	V-6023-4503M	Capacitor, .05 mfd 400 v.	Plate decoupling
C-507	V-6454	Capacitor	Osc trimmer
C-508	RCM20B271K	Capacitor, 270 mmf	Grid bias
C-509	V-5895	Capacitor, 500 mmf	HV filter
C-510	V-5895	Capacitor, 500 mmf	HV filter
L-501	V-6471	Choke	Filter
L-502	V-9279-1	Choke	RF
R-501	RC41AE333K	Resistor, 33,000 ohms 2 w.	Screen drop
R-502	RC20AE680K	Resistor, 68 ohms ½ w.	Plate decoupling
R-503	RC20AE683K	Resistor, 68,000 ohms ½ w.	Grid bias
R-504	RC20AE104K	Resistor, 100,000 ohms ½ w.	HV filter
SW-501	V-9482-1 assy	Switch, on-off (assy consists of R-201, SW-401 and SW-501)	
T-501	V-6988	Transformer	Power
T-502	V-9278	Transformer, HV	RF

INDEX

FREQUENCY RANGES:

Channel Number	Channel Frequency (mc.)	Video Carrier Frequency (mc.)	Audio Carrier Frequency (mc.)	Receiver H-F Oscillator Frequency (mc.)
1	not used	--	--	--
2	54 - 60	55.25	59.75	81.35
3	60 - 66	61.25	65.75	87.35
4	66 - 72	67.25	71.75	93.35
5	76 - 82	77.25	81.75	103.35
6	82 - 88	83.25	87.75	109.35
7	174 - 180	175.25	179.75	201.35
8	180 - 186	181.25	185.75	207.35
9	186 - 192	187.25	191.75	213.35
10	192 - 198	193.25	197.75	219.35
11	198 - 204	199.25	203.75	225.35
12	204 - 210	205.25	209.75	231.35
13	210 - 216	211.25	215.75	237.35

FINE TUNING RANGE:
Plus or minus 400 kc. on Channel 2;
Plus or minus 2 mc. on Channel 13.

OPERATING VOLTAGE:
105 to 120 volts, 60 cycles.

POWER CONSUMPTION: .... 185 watts

AUDIO POWER OUTPUT:
Undistorted .... 1.2 watts
Maximum .... 1.5 watts

LOUDSPEAKER:
Type .... 4" E. M.
Voice Coil Impedance .... 3.2 ohms at 400 cycles

RECEIVER ANTENNA INPUT IMPEDANCE:
.. 300 ohms balanced or 72 ohms unbalanced

TUBE COMPLEMENT:
1 1B3/GT .... High Voltage Rectifier
1 5U4G .... Low Voltage Rectifier
1 6AH6 .... Video Output
1 6AG5 .... Mixer
1 6AG5 .... R.F. Amplifier
1 6AL5 . Video Detector and Noise Clipper
1 6AL5 .... Ratio Detector
1 6AL5 .... Horizontal A. F. C.
1 6K6GT .... Audio Output
1 6AQ5 .... Vertical Output
1 6AV6 .... 1st Audio Amplifier
1 6BH6 .... 1st I. F. Amplifier
1 6BH6 .... 2nd I. F. Amplifier
1 6BH6 .... 3rd I. F. Amplifier
1 6BH6 .... 1st Sound I. F. Amplifier
1 6BH6 .... 2nd Sound I. F. Amplifier
1 6BH6 .... Keyed AGC
1 6BJ6 .... 4th I. F. Amplifier
1 6C4 .... H. F. Oscillator
1 6V6/GT .... High Voltage Oscillator
1 6W4/GT .... Horizontal Damper
1 6BQ6/GT .... Horizontal Output
1 12AT7 1st Sync. Amp. & Sync. Separator
1 12AU7 .... Vertical Multivibrator
1 12AU7 .... Horizontal Multivibrator
1 12AU7 2nd Sync. Amp. & Phase Inverter
1 10BP4 .... Cathode Ray Tube

VIDEO CARRIER INTERMEDIATE FREQUENCY: .... 26.1 mc.

VIDEO RESPONSE: .... 3.6 mc.

AUDIO CARRIER INTERMEDIATE FREQUENCY: .... 4.5 mc.

AUDIO DISCRIMINATOR BAND WIDTH:
(between peaks) .... 150 kc.

FOCUS: .... Magnetic

SWEEP DEFLECTION: .... Magnetic

SCANNING: .... Interlaced 525 line

HORIZONTAL SCANNING FREQUENCY: .... 15,750 CPS

VERTICAL SCANNING FREQUENCY: .... 60 CPS

FRAME FREQUENCY (picture repetition rate): .... 30 CPS

HIGH VOLTAGE WARNING

The danger accompanying shock is always present when the receiver is operated outside the cabinet or when the rear cover is removed from the cabinet. Only a person familiar with the precautions to be observed when working with high-voltage equipment should service this receiver.

CATHODE RAY TUBE HANDLING PRECAUTIONS

Shatterproof goggles and heavy gloves should be worn at all times when handling the cathode ray tube. The tube should not be handled in the vicinity of any person not so equipped. When handling the cathode ray tube, always keep it away from the body.

The cathode ray tube bulb, due to its large surface area and high vacuum contained within, is subjected to high air pressure. More than ordinary care is required to prevent shattering the tube. The large end of the bulb, particularly the rim of the viewing surface, must not be struck, scratched, or subjected to more than moderate pressure at any time. If the tube sticks or fails to slip smoothly into place during installation, remove the tube and determine the cause of the trouble - - **DO NOT FORCE THE TUBE.**

INSTALLATION INSTRUCTIONS

TO PREPARE THE RECEIVER FOR OPERATION:

Model H-609T10 is shipped in operating condition. There is no shipping material to be removed. Simply remove the receiver from its carton, and connect the A-C plug to a 105 to 120 volt 60 cycle A-C outlet.

However, it is desirable that the adjustment of the ion trap magnet be checked in order to obtain best performance from the receiver. A check of this adjustment will also avoid the possibility of C.R.T. damage resulting from prolonged operation with an incorrectly adjusted ion trap magnet. To check the adjustment, proceed as follows:

1. Remove the screws that secure the rear cover to the cabinet.

2. Remove the rear cover by pulling it straight out from the cabinet.

3. Apply power to the receiver using a temporary line cord connected between the A-C receptacle on the chassis and an A-C outlet.

4. Adjust the ion trap magnet as explained under ADJUSTMENTS.

Model H-609T10 contains a built-in antenna for use in areas of normal reception. In such areas when the built-in antenna provides good reception, no antenna connections are required. However, in weak signal areas or under adverse conditions, it may be necessary to use an external antenna. In this event, the antenna lead-in can be connected to the antenna terminals on the back of the receiver after disconnecting the built-in antenna wires that normally connect to these terminals. The lugs on the built-in antenna should then be insulated and dressed in such a position that they do not touch the chassis or components. If desired, the clamp located on the left side (facing the rear) of the cabinet can be used to hold the built-in antenna feeder out of the way.

TO CHECK THE OPERATION OF THE RECEIVER:

1. Rotate the BRIGHTNESS and CONTRAST controls completely counterclockwise.

2. Turn on the receiver by rotating the OFF-ON-VOLUME control clockwise.

3. Rotate the CHANNEL SELECTOR to the channel number of the desired station.

4. Rotate the BRIGHTNESS control clockwise until the screen is well lighted.

5. Rotate the CONTRAST control clockwise until a picture appears on the screen.

6. If the built-in antenna is in use, adjust the TELEVISION ANTENNA control for maximum picture contrast. If an external antenna is in use, this step is not required.

7. If the picture is moving up or down or quivering, adjust the VERTICAL HOLD control to stabilize the image.

8. If horizontal or diagonal bars or a folded-over picture appears on the screen, adjust the HORIZONTAL HOLD control to obtain a clear picture.

9. Adjust the FINE TUNING control for the best picture detail.

10. Readjust the BRIGHTNESS and CONTRAST controls until pleasing shades ranging from clear white to intense black are attained.

11. Adjust the VOLUME control for the desired sound volume.

12. Check the operation on all available television stations. Note that if the built-in antenna is in use, the TELEVISION ANTENNA control must be readjusted for maximum picture contrast each time the receiver is tuned to a different channel.

13. If necessary, adjust the vertical linearity, height, width, and focus controls as explained under ADJUSTMENTS.

ADJUSTMENTS

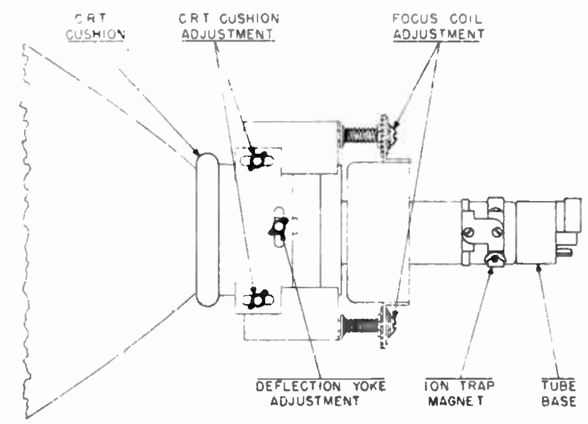

FIG. 1 — TOP VIEW OF C.R.T.

The picture adjustments are located on the rear of the chassis and are accessible through cut-outs in the back cover.

ION TRAP MAGNET

CAUTION: When adjusting the ion trap magnet, care must be exercised to avoid breaking the neck of the C.R.T.

The ion trap magnet must always be adjusted for maximum picture brightness. With the magnet oriented approximately as shown in Fig. 1, rotate it around the neck of the tube and move it forward and backward until the position is found where the brightest raster is obtained.

FOCUS COIL

Incorrect centering of the picture or a shadow on one corner of the picture may indicate that the focus coil is in need of adjustment. If only a slight adjustment is required, it can be made by turning the focus coil adjustment screws in or out as required.

If a major adjustment of the focus coil is required, the procedure is as follows:

1. Turn the focus coil adjustment screws in or out until the focus coil is positioned at right angles to the neck of the C.R.T. and there is a slight separation between the deflection yoke and the focus coil.

2. Loosen the lock nuts located under the heads of the adjustment screws and slide the focus coil up or down or sideways until the picture is correctly centered. Large holes in the focus coil brackets permit this movement of the coil.

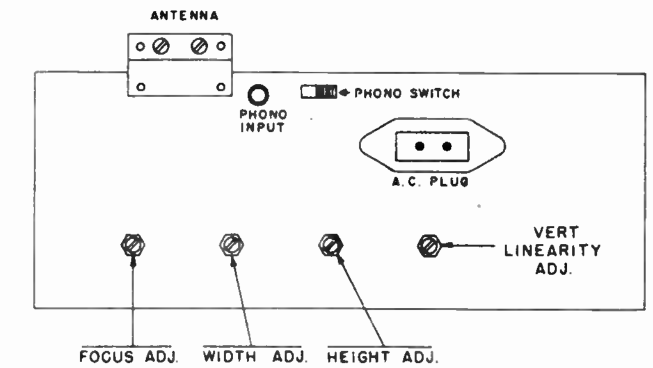

FIG. 2 — REAR VIEW OF CHASSIS

3. Tighten the lock nuts while taking care that the screws do not turn during the process.

4. Fine centering adjustments can be made by turning one or more of the screws in or out.

CATHODE RAY TUBE CUSHION

The cushion must fit snugly against the flare of the cathode ray tube in order that the rear of the tube will be supported firmly.

DEFLECTION YOKE

This adjustment controls the angle of the picture with respect to the horizontal. If the picture is not squared in the picture mask, loosen the wing nut and move it to the left or right so as to rotate the deflection yoke. The picture will tilt to the left or right with the deflection yoke rotation.

FOCUS CONTROL

The focus control (Fig. 2) should be adjusted with the brightness and contrast controls in their normal positions. If correct focusing cannot be obtained, the high voltage oscillator may require adjustments.

HEIGHT AND VERTICAL LINEARITY

The height adjustment controls the overall height of the picture, while the vertical linearity adjustment governs contraction or expansion of the upper portion only. For this reason, a balance between the two controls is necessary to make the picture symmetrical and fill the mask vertically.

©John F. Rider

World Radio History

WIDTH

The width control should be adjusted so that the picture fills the mask horizontally.

HORIZONTAL RINGING COIL

To adjust the horizontal ringing coil (L403), tune in the weakest station in the area, set the horizontal hold control at approximately the middle of its range, and adjust L403 (location shown on Fig. 8) until the picture is properly "locked-in".

HIGH VOLTAGE OSCILLATOR

1. *Turn off the receiver* and disconnect the high voltage lead from the C.R.T.

2. Connect 13 one megohm, one watt resistors in series between the high voltage lead and the chassis.

3. Connect a kilovoltmeter across the 13 megohms of resistance.

4. Turn on the receiver and adjust C507 (location shown on Fig. 8) for maximum voltage indication on the meter.

5. *Turn off the receiver*, disconnect the kilovoltmeter, remove the 13 megohms of resistance, and connect the high voltage lead to the C.R.T.

CHASSIS REMOVAL

Removal of the chassis is complicated somewhat by the built-in antenna. The recommended procedure is as follows:

1. Remove the control knobs from the front of the receiver.

2. Remove the wood screws that secure the back cover, and remove the back cover by pulling it away from the cabinet.

3. Remove the built-in antenna feeder from the antenna terminals on the rear of the chassis.

4. Remove the thumb tack that secures the end of the antenna tuning stub to the top of the cabinet.

5. Remove the two screws that secure the antenna trimmer brackets to the top of the cabinet.

6. Using care to avoid bending the antenna tuning stub, pull the trimmer shaft and rubber coupling off the pulley shaft thus detaching the trimmer and tuning stub assembly.

7. Remove the hex-head chassis mounting bolts from the bottom of the cabinet.

8. Remove the chassis from the cabinet. The pulley shaft is sufficiently flexible to allow passage of the chassis.

To replace the chassis, the above procedure should be reversed.

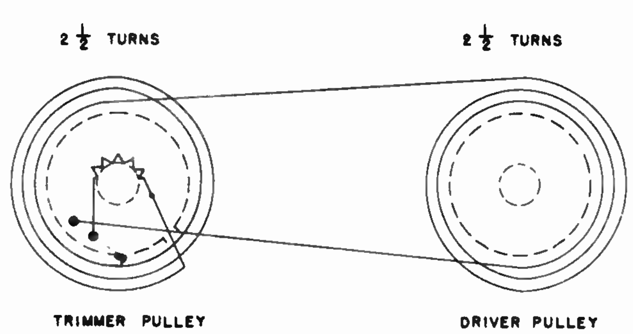

FIG. 3 — DRIVE STRING ARRANGEMENT

ALIGNMENT

TEST EQUIPMENT—To properly service the chassis, the following test equipment should be available:

1. R-F sweep generator which meets the following requirements:

   a. Frequency range from 18 to 30 mc. with a sweep width of 10 mc.

   b. Output adjustable with at least 100,000 microvolts maximum and a very low minimum.

   c. Output "flat" on all attenuator positions.

2. Cathode-ray oscilloscope, preferably one with a wide band vertical deflection amplifier and a low-capacitance input probe.

3. Signal generator capable of providing output frequencies listed below.

21.6 mc.	4th I-F trap
22.6 mc.	1st I-F
25.9 mc.	2nd I-F
25.6 mc.	3rd I-F
23.8 mc.	4th I-F
23.0 mc.	5th I-F
4.5 mc.	Audio I-F and ratio detector (the frequency must be extremely accurate, preferably crystal controlled.)

NOTE: The R-F output level on all the above frequencies should be adjustable with at least 100,000 microvolts maximum and a very low minimum.

4. Heterodyne frequency meter with crystal calibrator (if the signal generator does not include a crystal calibrator).

5. Electronic voltmeter (vacuum tube voltmeter), with a high voltage multiplier probe for measurements up to 15,000 volts and an R-F probe for measuring R-F voltages.

GENERAL INFORMATION—All test equipment and the chassis should be bonded together by short lengths of heavy (½ inch) braided copper ribbon. The interconnecting leads should be shielded (72 ohms coaxial cable) and should be as short as possible consistent with ease of making connections. The effectiveness of the bonding can be checked during alignment by placing the hand on the metal chassis or test equipment case. If the response pattern or meter reading changes visibly, the bonding must be improved before the circuits are aligned.

COMMON I-F ALIGNMENT PROCEDURE

1. Rotate the channel selector switch to channel 3.

2. Connect the signal generator to the mixer tube through the coupling device shown in Fig. 4. The device is constructed by squeezing together a miniature tube shield until it fits the tube snugly and does not ground to the chassis. A .005 mfd capacitor is then soldered to the side of the shield. By sliding the tube shield up or down on the tube, the capacitance between the shield and the tube elements can be varied to obtain additional control of the coupling over that provided by the attenuator in the generator itself. The ground side of the generator output cable should be connected to the receiver chassis.

3. Connect a vacuum tube voltmeter to the video test jack on the receiver chassis, and set the meter to its 5 volt scale.

4. Set the signal generator to 21.6 mc. (unmodulated), and adjust C329 for ***minimum*** voltage on the VTVM. Use a strong signal for this adjustment.

5. Set the signal generator to 22.6 mc. (unmodulated), and adjust L306 for maximum voltage on the VTVM. *During this adjustment, keep the signal generator output adjusted so that the VTVM reading does not exceed 2 volts.*

6. Set the signal generator to 25.9 mc. (unmodulated), and adjust L307 for maximum voltage on the VTVM. *During this adjustment, keep the signal generator output adjusted so that the VTVM reading does not exceed 2 volts.*

7. Set the signal generator to 25.6 mc. (unmodulated), and adjust L308 for maximum voltage on the VTVM. *During this adjustment, keep the signal generator output adjusted so that the VTVM reading does not exceed 2 volts.*

8. Set the signal generator to 23.8 mc. (unmodulated), and adjust L309 for maximum voltage on the VTVM. *During this adjustment,*

©John F. Rider

World Radio History

keep the signal generator output adjusted so that the VTVM reading does not exceed 2 volts.

9. Set the signal generator to 23.0 mc. (unmodulated), and adjust L313 for maximum voltage on the VTVM. *During this adjustment, keep the signal generator output adjusted so that the VTVM reading does not exceed 2 volts.*

10. Connect the *sweep* generator to the mixer tube through the coupling device previously described. The *signal* generator will be used in the following steps to provide marker indications at various frequencies on the response curve. In this application, the signal generator input to the set must be low in amplitude to avoid distorting the response curve. To reduce the signal generator input accordingly, the signal generator should be *loosely* coupled to the set by wrapping a few turns of insulated wire around the coupling capacitor "pigtail" and connecting the signal generator to this wire.

11. Connect the vertical input of the oscilloscope to the video test jack through the de-coupling network shown in Fig. 5. The oscilloscope horizontal input should be connected to the sweep output from the sweep generator; turn the sweep control on the oscilloscope to the "X" or "OFF" position.

12. Adjust the sweep generator for a center frequency of 25.3 mc. with a 10 mc. deviation. Adjust the sweep generator output until a setting is found where there is very little noise on the oscilloscope pattern.

The oscilloscope pattern obtained should be similar to that shown in Fig. 6. Use the signal generator as a marker to check at the frequencies indicated. If the pattern obtained is not similar to Fig. 6, L306, L307, L308, L309, and L313 should be re-adjusted to produce the correct pattern. The affect of the adjustments will be as follows:

- L306 affects the low frequency side of the curve.
- L307 affects the high frequency side of the curve and the position of the video I-F carrier.
- L308 affects the center of the curve.
- L309 affects the tilt of the "shelf" of the curve.
- L313 affects the center and the low frequency side of the curve.

SOUND I-F AND 4.5 MC. TRAP ALIGNMENT PROCEDURE

1. Connect the "high" side of the signal generator to the video test jack through a .001 mfd capacitor, and ground the "low" side to the chassis.

2. Connect the vacuum tube voltmeter to the points indicated on the bottom view of the chassis, Fig. 8. The common lead should connect to point "C" and the "high" lead should connect to point "A". Set the meter on its 5 volt (-DC) scale.

3. Adjust the signal generator to 4.5 mc. (unmodulated). The accuracy of this frequency is very important. If a crystal controlled signal generator is not available, the frequency should be checked using a frequency meter with a crystal calibrator.

4. Adjust T201 and the primary of T202 for maximum voltage on the VTVM. *During this adjustment, keep the signal generator output adjusted so that the VTVM reading does not exceed 5 volts.*

5. Connect the common lead from the VTVM to point "A" (Fig. 8), and connect the "high" lead to point "B". Here it is important that the case and components of the VTVM are *not* grounded to the receiver chassis; otherwise, point "A" would be shorted to the chassis through the common lead.

6. Using the same signal generator amplitude and frequency as in step 4, adjust the secondary of T202 for *zero* voltage on the VTVM. As the adjustment is tuned through resonance, the voltage will rapidly change from one polarity to the opposite polarity. The point where the voltage is zero is the correct setting.

7. Connect the common lead from the VTVM to the chassis, and connect the *R-F probe* from the VTVM to the junction of R324 and R325. This point is shown as point "D" on Fig. 8. *Note that point "D" is 150 volts above ground and, therefore, the R-F probe must contain a blocking capacitor.*

8. Using a strong 4.5 mc. signal applied as in step 1, adjust C321 for ***minimum*** voltage on the meter.

H.F. OSCILLATOR ALIGNMENT PROCEDURE

If the 6C4 H-F oscillator tube is replaced in this tuner, the different inter-electrode capacitance of the new tube may change the oscillator frequency enough to necessitate re-alignment of the oscillator.

The oscillator adjusting screws are located on the front of the tuner assembly, and this procedure should be followed for their adjustment:

1. Remove the channel selector and fine tuning knobs. Remove the selector escutcheon plate and escutcheon mounting plate by removing the Phillips head screws securing them to the cabinet. The adjustments are accessible through the hole in the cabinet.

2. Set the fine tuning control to the middle of its range, and leave it in this position during the following adjustments.

3. Set the channel selector switch to the highest of the low band (channels 2 through 6) stations operating in your locality.

4. Peak the appropriate oscillator slug for the best picture detail.

5. Repeat step 4 for each progressively lower channel on which a station transmits in your area.

6. Set the channel selector switch to the highest of the high band (channels 7 through 13) stations operating in your locality.

7. Peak the appropriate oscillator slug for the best picture detail.

8. Repeat step 7 for each progressively lower channel in the high band on which a nearby station transmits.

9. Check the previously made low band adjustments, and if the tuning has changed repeat steps 3 through 8.

I-F ALIGNMENT CHART

Turn the channel selector to channel 3 to avoid undesirable beat response during alignment.

COMMON I-F SECTION

Couple the sweep and marker generators to the mixer tube as shown in Fig. 4.

Step	*Sweep Gen. Frequency*	*Marker Gen. Frequency*	*Remarks*	*Indicator Connection*	*Adjust*
1.	Not used	21.6 mc. unmodulated	Use a strong signal	Connect VTVM to video test jack	C329 for *minimum* voltage
2.	Not used	22.6 mc. unmodulated	Keep marker output adjusted so VTVM reading does not exceed 2 v.	Same as step 1	L306 for maximum voltage
3.	Not used	25.9 mc. unmodulated	Same as step 2	Same as step 1	L307 for maximum voltage
4.	Not used	25.6 mc. unmodulated	Same as step 2	Same as step 1	L308 for maximum voltage
5.	Not used	23.8 mc. unmodulated	Same as step 2	Same as step 1	L309 for maximum voltage
6.	Not used	23.0 mc. unmodulated	Same as step 2	Same as step 1	L313 for maximum voltage
7.	25.3 mc. with 10 mc. deviation	check at: 21.6 mc. 22.5 mc. 23.5 mc. 25.3 mc. 26.1 mc.	Keep sweep output low enough so that very little noise appears on the oscilloscope trace	Connect oscilloscope to video test jack. See Fig. 5.	If necessary, adjust L306, L307, L308, L309, and L313 to obtain correct response curve. See Fig. 6.

L313	V-6459	Coil	I-F peaking
L314	V-5902-1	Coil, 140 microhenries	Video peaking
R301	Part of V-9235-2 assy	Control, 1500 ohms (assy consists of R301 and R302)	Contrast control
R302	Part of V-9235-2 assy	Control, 50,000 ohms (assy consists of R301 and R302)	Brightness control
R303	V-6984-8	Resistor, 2700 ohms 5 w.	Screen bus dropping
R304	RC20AE683K	Resistor, 68,000 ohms ½ w.	Screen dropping
R305	RC20AE680K	Resistor, 68 ohms ½ w.	Cathode bias
R306	RC20AE680K	Resistor, 68 ohms ½ w.	Cathode bias
R307	RC20AE101K	Resistor, 100 ohms ½ w.	Cathode bias
R308	RC20AE101K	Resistor, 100 ohms ½ w.	Cathode bias
R309	RC20AE102M	Resistor, 1000 ohms ½ w.	I-F decoupling
R310	RC20AE102M	Resistor, 1000 ohms ½ w.	Plate decoupling
R311	RC20AE102M	Resistor, 1000 ohms ½ w.	Plate decoupling
R312	RC20AE102M	Resistor, 1000 ohms ½ w.	Plate decoupling
R314	RC20AE472K	Resistor, 4700 ohms ½ w.	Grid return
R316	RC20AE562K	Resistor, 5600 ohms ½ w.	Grid return
R317	RC20AE103K	Resistor, 10,000 ohms ½ w.	Grid return
R318	RC20AE103K	Resistor, 10,000 ohms ½ w.	AGC decoupling
R319	RC20AE103K	Resistor, 10,000 ohms ½ w.	AGC decoupling
R320	RC20AE333K	Resistor, 33,000 ohms ½ w.	4.5 mc trap load
R324	RC20AE104K	Resistor, 100,000 ohms ½ w.	DC divider
R325	RC20AE154K	Resistor, 150,000 ohms ½ w.	Cathode bias
R327	RC20AE225K	Resistor, 2.2 megs ½ w.	DC divider
R329	RC20AE123K	Resistor, 12,000 ohms ½ w.	Grid return
R330	RC30AE362J	Resistor, 3600 ohms 1 w.	Plate load
R331	RC30AE392K	Resistor, 3900 ohms 1 w.	Screen drop
R332	RC20AE223K	Resistor, 22,000 ohms ½ w.	Bass Boost
R334	RC20AE473K	Resistor, 47,000 ohms ½ w.	DC divider
R335	RC20AE222K	Resistor, 2200 ohms ½ w.	Contrast control shunt
R336	RC20AE103K	Resistor, 10,000 ohms ½ w.	Decoupling
R337	RC20AE472K	Resistor, 4700 ohms ½ w.	Grid return
R338	RC30AE334K	Resistor, 330,000 ohms 1 w.	AGC filter
R339	RC20AE472K	Resistor, 4700 ohms ½ w.	Grid AGC keyer
R340	RC20AE103K	Resistor, 10,000 ohms ½ w.	Cathode bias
R341	RC20AE473K	Resistor, 47,000 ohms ½ w.	Cathode bias

PARTS LIST FOR MODEL H-609T10 *(Continued)*

Section 4—Sweep

Ref. No.	Part No.	Description	Function
C401	Part of V-5891 assy	Capacitor, electrolytic, 80 mfd 350 v. (assy consists of C401, C402, C403 and C301)	Filter
C402	Part of V-5891 assy	Capacitor, electrolytic 10 mfd 350 v. (assy consists of C401, C402, C403 and C301)	Filter
C403	Part of V-5891 assy	Capacitor, electrolytic 10 mfd 350 v. (assy consists of C401, C402, C403 and C301)	Filter
C404	Part of V-6509 assy	Capacitor, electrolytic 40 mfd 350 v. (assy consists of C404, C405, C406 and C501)	Filter
C405	Part of V-6509 assy	Capacitor, electrolytic 40 mfd 350 v. (assy consists of C404, C405, C406 and C501)	Filter
C406	Part of V-6509 assy	Capacitor, electrolytic 150 mfd 50 v. (assy consists of C404, C405, C406 and C501)	Cathode by-pass
C407	V-6066-4254M	Capacitor, midget .25 mfd	Sync clip coupling
C409	V-6023-4104K	Capacitor, hi-temp 0.1 mfd	Vertical discharge
C410	V-6023-4104M	Capacitor, hi-temp 0.1 mfd	Yoke coupling
C411	R5CC21ZY151M	Capacitor, hi-temp 150 mmf	Grid by-pass
C412	RCP10W6102M	Capacitor, .001 mfd	AFC coupling
C413	RCP10W6102M	Capacitor, .001 mfd	AFC coupling
C415	RCP10W4502M	Capacitor, .005 mfd	AFC delay
C416	RCP10W4103M	Capacitor, .01 mfd	Horizontal output coupling
C417	RCP10W4503M	Capacitor, .05 mfd	Coupling
C418	RCP10W4503M	Capacitor, .05 mfd	AFC delay
C420	RCP10W4104M	Capacitor, .01 mfd	Vertical output coupling
C422	RCP10W4104M	Capacitor, 0.1 mfd	Screen by-pass
C423	RCP10W4104M	Capacitor, 0.1 mfd	Horizontal discharge
C424	RCP10W4254M	Capacitor, .25 mfd	Plate by-pass
C425	R5CC26ZY152M	Capacitor, 1500 mmf	Heater by-pass
C427	R2CC26SL560J	Capacitor, 56 mmf	Transient by-pass
C430	RCM20C331J	Capacitor, 330 mmf	Error voltage coupling
C431	RCM20C331J	Capacitor, 330 mmf	MV coupling
C432	RCM20C331J	Capacitor, 330 mmf	Horizontal discharge
C434	RCM30C392K	Capacitor, 3900 mmf	Ringing coil tuning
C438	RCM20B681M	Capacitor, 680 mmf	Plate by-pass
C439	RCP10W4104M	Capacitor, .1 mfd	Plate by-pass
C440	RCP10W4103M	Capacitor, .01 mfd	Vert. sync. coupling
C441	RCM20B391M	Capacitor, 390 mmf	Horiz. sync. coupling
C442	RCM20B101M	Capacitor, 100 mmf	Plate by-pass
C443	V-9465-2	Capacitor, 7 mmf (150 ohm twin lead)	AGC coupling
C444	RCP10W4503M	Capacitor, .05 mfd	Sync. coupling
C445	V-6023-4103M	Capacitor, hi-temp .01 mfd	V. MV coupling
C446	RCP10W4503M	Capacitor, .05 mfd	Cathode by-pass
C447	RCP10W4104M	Capacitor, .1 mfd	Plate by-pass
C448	RCP10W4104M	Capacitor, .1 mfd	HV supply decoupling
C449	RCP10W6102M	Capacitor, .001 mfd	Pulse divider
L401	V-9230-1	Coil	Plate load
L402	V-6639-2	Coil	Focus coil
L403	V-6764	Coil, ringing	Horizontal coarse tuning
L404	V-9501-1	Coil	Filament
L405	V-9501-1	Coil	Filament
R401	V-9232	Control, 600 ohms	Focus control
R402	V-6462	Control, 1 meg	Height control
R403	V-6463	Control, 5000 ohms	Vertical lin. control
R404	Part of V-9233 assy	Control, 100,000 ohms (assy consists of R404 and R405)	Horizontal hold control
R405	Part of V-9233 assy	Control, 500,000 ohms (assy consists of R404 and R405)	Vertical hold control
R406	V-6500-1	Control, 5000 ohms	Width control
R407	V-9002-4822K	Resistor, 8200 ohms 2 w.	Horiz. output screen drop
R408	V-4758	Resistor, 110 ohms 3 w.	Focus coil shunt
R410	RC20AE330M	Resistor, 33 ohms ½ w.	Plate load
R411	RC20AE121K	Resistor, 120 ohms ½ w.	Grid parasitic suppressor
R412	RC20AE151K	Resistor, 150 ohms ½ w.	Damper diode decoupling
R413	RC20AE471K	Resistor, 470 ohms ½ w.	Cathode bias
R414	RC20AE102M	Resistor, 1000 ohms ½ w.	Vert. output decoupling
R417	RC20AE122K	Resistor, 1200 ohms ½ w.	Cathode bias
R418	RC20AE182K	Resistor, 1800 ohms ½ w.	Cathode bias
R420	RC20AE272K	Resistor, 2700 ohms ½ w.	Cathode bias
R421	RC20AE392K	Resistor, 3900 ohms ½ w.	Plate load
R424	RC20AE562K	Resistor, 5600 ohms ½ w.	Plate load
R426	RC20AE153K	Resistor, 15,000 ohms ½ w.	Waveform correction
R427	RC20AE101K	Resistor, 100 ohms ½ w.	Horiz. sweep stabilizer
R430	RC20AE473K	Resistor, 47,000 ohms ½ w.	Plate decoupling
R431	RC20AE683K	Resistor, 68,000 ohms ½ w.	Phase reference
R432	RC20AE104J	Resistor, 100,000 ohms ½ w.	Diode load
R433	RC20AE104J	Resistor, 100,000 ohms ½ w.	Diode load
R434	RC20AE224J	Resistor, 220,000 ohms ½ w.	Grid return
R435	RC20AE154K	Resistor, 150,000 ohms ½ w.	DC divider
R436	RC20AE224K	Resistor, 220,000 ohms ½ w.	Plate load
R437	RC20AE394K	Resistor, 390,000 ohms ½ w.	Plate load
R438	RC20AE474K	Resistor, 470,000 ohms ½ w.	AFC delay
R440	RC20AE103K	Resistor, 10,000 ohms ½ w.	Plate load
R441	RC20AE105K	Resistor, 1 meg ½ w.	Grid return
R442	RC20AE105K	Resistor, 1 meg ½ w.	Grid return
R443	RC20AE225K	Resistor, 2.2 meg ½ w.	Grid return
R445	RC20AE475M	Resistor, 4.7 meg ½ w.	Grid return
R446	V-9002-4151K	Resistor, 150 ohms 2 w.	Cathode bias
R448	RC40AE153K	Resistor, 15,000 ohms 2 w.	Plate load
R449	RC20AE561K	Resistor, 560 ohms ½ w.	Transient damping
R450	RC20AE561K	Resistor, 560 ohms ½ w.	Transient damping
R455	RC20AE223K	Resistor, 22,000 ohms ½ w.	Plate load
R456	RC20AE225K	Resistor, 2.2 megohms ½ w.	Diode shunt
R457	RC20AE105K	Resistor, 1 megohm ½ w.	Positive bias limiting
R459	RC20AE474K	Resistor, 470,000 ohms ½ w.	Charge limiting
R460	RC20AE333K	Resistor, 33,000 ohms ½ w.	DC divider
R461	RC20AE225K	Resistor, 2.2 megohms ½ w.	Grid return
R462	RC20AE102K	Resistor, 1000 ohms ½ w.	Limiting
R463	RC20AE331K	Resistor, 330 ohms ½ w.	Cathode bias
R464	RC20AE474K	Resistor, 470,000 ohms ½ w.	Grid return
R465	RC20AE104K	Resistor, 100,000 ohms ½ w.	Plate load
R466	RC20AE680K	Resistor, 68 ohms ½ w.	Plate load
R467	RC20AE104K	Resistor, 100,000 ohms ½ w.	Grid return
R468	RC30AE224K	Resistor, 220,000 ohms 1 w.	Horiz. error take off
R469	RC20AE333K	Resistor, 33,000 ohms ½ w.	H. MV decoupling
T401	V-6981-2	Transformer	Vertical output
T402	V-6481-3	Transformer	Filament
Z401	V-9213-1	Network	Integrating
Z402	V-6486-3	Yoke assembly, complete	Deflection

Section 5—Power

Ref. No.	Part No.	Description	Function
C501	Part of V-6509 assy	Capacitor, electrolytic, 40 mfd 350 v. (assy consists of C501, C404, C405, and C406)	Filter HV
C502	V-6023-4503M	Capacitor, hi-temp .05	Screen by-pass
C503	V-6023-4503M	Capacitor, hi-temp .05	Plate decoupling
C504	V-6023-4503M	Capacitor, hi-temp .05	Grid bias
C505	V-5895	Capacitor, hi-voltage 500 mmf	HV filter
C507	V-6454	Capacitor, osc. trimmer	HV osc. trimmer
R501	RC20AE680K	Resistor, 68 ohms ½ w.	Plate decoupling
R502	RC20AE104K	Resistor, 100,000 ohms ½ w.	HV filter
R503	RC20AE222K	Resistor, 2200 ohms ½ w.	Grid return
R504	RC30AE103K	Resistor, 10,000 ohms 1 w.	Screen dropping
SW501	V-6465-1	Switch, on-off	
T501	V-9395	Transformer	Power L. V.
T502	V-6457	Transformer	Hi-voltage
	V-9445	High voltage supply assy, R-F

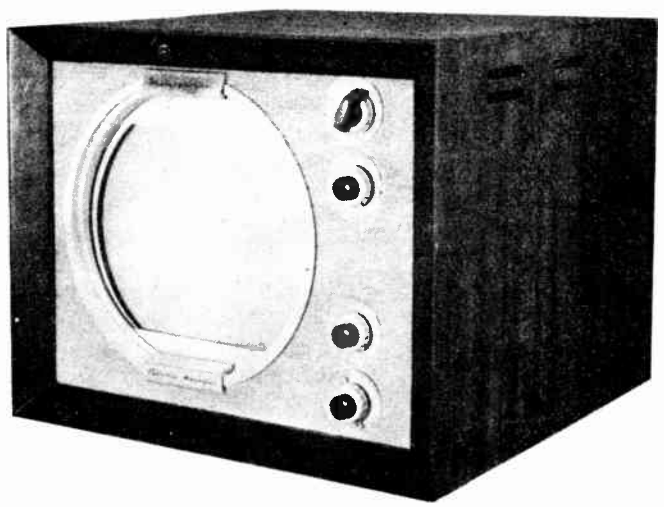
INDEX



SPECIFICATIONS

FREQUENCY RANGES:

Channel Number	Channel Frequency (mc.)	Video Carrier Frequency (mc.)	Audio Carrier Frequency (mc.)	Receiver H-F Oscillator Frequency (mc.)
1	not used	--	--	--
2	54 - 60	55.25	59.75	81.35
3	60 - 66	61.25	65.75	87.35
4	66 - 72	67.25	71.75	93.35
5	76 - 82	77.25	81.75	103.35
6	82 - 88	83.25	87.75	109.35
7	174 - 180	175.25	179.75	201.35
8	180 - 186	181.25	185.75	207.35
9	186 - 192	187.25	191.75	213.35
10	192 - 198	193.25	197.75	219.35
11	198 - 204	199.25	203.75	225.35
12	204 - 210	205.25	209.75	231.35
13	210 - 216	211.25	215.75	237.35

FINE TUNING RANGE:
Plus or minus 1 mc. minimum
Plus or minus 2 mc. maximum

OPERATING VOLTAGE:
105 to 120 volts, 60 cycles

POWER CONSUMPTION: .... 275 watts

AUDIO POWER OUTPUT:
Undistorted .... 1.5 watts
Maximum .... 2.5 watts

LOUDSPEAKER:
Type .... 5" E. M.
Voice Coil Impedance—3.2 ohms at 400 cycles

RECEIVER ANTENNA INPUT IMPEDANCE:
... 300 ohms balanced or 72 ohms unbalanced

TUBE COMPLEMENT:

1	1B3/GT	High Voltage Rectifier
2	5U4G	Low Voltage Rectifier
1	6AH6	Video Output
1	6AK5	R.F. Amplifier
1	6AL5	Video Detector and Noise Clipper
1	6AL5	Ratio Detector
1	6AL5	Horizontal A. F. C.
1	6AQ5	Vertical Output
2	6AU5/GT	Horizontal Output
1	6AU6	1st Audio I. F. Amplifier
1	6AU6	2nd Audio I. F. Amplifier
1	6AU6	Keyed A. G. C.
1	6AV6	1st Audio Amplifier
1	6BH6	1st I. F. Amplifier
1	6BH6	2nd I. F. Amplifier
1	6BH6	3rd I. F. Amplifier
1	6BJ6	4th I. F. Amplifier
1	6J6	H. F. Oscillator and Mixer
1	6W4/GT	Horizontal Damper
1	6Y6G	High Voltage Oscillator
1	6Y6G	Audio Output
1	12AT7	Sync. Amp. & Sync. Separator
1	12AU7	Vertical Multivibrator
1	12AU7	Horizontal Multivibrator
1	12AU7	D. C. Restorer & Phase Invertor
1	12LP4 or 12LP4A	Cathode Ray Tube

VIDEO CARRIER INTERMEDIATE FREQUENCY: .... 26.1 mc.

VIDEO RESPONSE: .... 4.0 mc.

AUDIO CARRIER INTERMEDIATE FREQUENCY: .... 4.5 mc.

AUDIO DISCRIMINATOR BAND WIDTH: (between peaks) .... 150 kc.

FOCUS: .... Magnetic

SWEEP DEFLECTION: .... Magnetic

SCANNING: .... Interlaced 525 line

HORIZONTAL SCANNING FREQUENCY: .... 15,750 CPS

VERTICAL SCANNING FREQUENCY: .... 60 CPS

FRAME FREQUENCY (picture repetition rate): .... 30 CPS

HIGH VOLTAGE WARNING

The danger accompanying shock is always present when the receiver is operated outside the cabinet or when the rear cover is removed from the cabinet. Only a person familiar with the precautions to be observed when working with high-voltage equipment should service this receiver.

CATHODE RAY TUBE HANDLING PRECAUTIONS

Shatterproof goggles and heavy gloves should be worn at all times when handling the cathode ray tube. The tube should not be handled in the vicinity of any person not so equipped. When handling the cathode ray tube, always keep it away from the body.

The cathode ray tube bulb, due to its large surface area and high vacuum contained within, is subjected to high air pressure. More than ordinary care is required to prevent shattering the tube. The large end of the bulb, particularly the rim of the viewing surface, must not be struck, scratched, or subjected to more than moderate pressure at any time. If the tube sticks or fails to slip smoothly into place during installation, remove the tube and determine the cause of the trouble - - DO NOT FORCE THE TUBE.

©John F. Rider

World Radio History

INSTALLATION INSTRUCTIONS

TO PREPARE THE RECEIVER FOR OPERATION:

Later production models are shipped in operating condition, and there is no shipping material to be removed.

Early production models contain shipping precautions, however, and these steps should be followed to prepare the receiver for operation:

1. Remove the screws that hold the rear cover to the cabinet, and remove the rear cover by pulling it away from the cabinet.

2. Remove the red-headed wood screw from the shipping block located on the top (inside) of the cabinet, and remove the shipping block.

3. Remove the two red-headed wood screws from the shipping block located between the upper left side of the cabinet and the chassis, and remove the shipping block.

4. Inspect the face of the CRT and the glass window for dust or smudges. If the face of the CRT or the inside of the glass window is smudged, refer to REMOVAL OF FRONT GLASS FOR CLEANING.

5. Loosen the two, red, hex-head bolts on the under side of the cabinet.

6. In some models, a wood shipping strip is located between the chassis and the bottom of the cabinet. This strip should be removed.

7. Loosen the screws that secure the upper chassis mounting bracket to the top inside of the cabinet.

8. Adjust the position of the chassis so that the knobs and the face of the CRT are properly aligned with respect to the holes in the front of the cabinet.

9. Re-tighten the two, red, hex-head bolts on the under side of the cabinet, and the two screws of the upper chassis mounting bracket.

10. Make certain that all tubes are secure in their sockets.

11. These models contain a built-in antenna for use in areas of normal reception. In such areas when the built-in antenna provides good reception, no additional antenna connections are required. However, in weak signal areas or under adverse conditions, it may be necessary to use an external antenna. If an external antenna is to be used, the built-in antenna should be disconnected from the antenna terminals on the back of the chassis, and the lugs of the built-in antenna should be insulated and dressed in such a position that they do not touch the chassis or components.

12. If an outside antenna is to be used, connect the lead-in to the antenna terminals on the back of the set.

13. Connect the A-C plug to a 105 to 120 volt 60 cycles A-C power outlet.

14. Refer to REMOVAL OF FRONT GLASS FOR CLEANING. If the receiver contains a removable front glass plate, instruct the owner as to the correct procedure for removing the glass and cleaning the face of the CRT and the inside of the glass.

TO CHECK THE OPERATION OF THE RECEIVER:

1. Turn the magnifier switch to the clockwise (magnified) position.

2. Rotate the brightness and contrast controls completely counterclockwise.

3. Turn on the receiver by rotating the off-on-volume control clockwise.

4. Rotate the channel selector to the channel number of the desired station.

5. Rotate the brightness control clockwise until the screen is barely lighted. Check the adjustment of the ion trap magnet as outlined under ADJUSTMENTS.

6. Rotate the contrast control clockwise until a picture appears on the screen.

7. If the built-in antenna is in use, adjust the television antenna control for maximum picture contrast. If an external antenna is in use, this step is not required.

8. If the picture is moving up or down or quivering, adjust the vertical hold control to stabilize the image.

9. If vertical or diagonal bars or a folded-over picture appears on the screen, adjust the horizontal hold control to obtain a stable picture.

10. Adjust the fine tuning control for best picture detail.

11. Re-adjust the brightness and contrast controls until pleasing shades ranging from clear white to intense black are attained.

12. Check the adjustment of the focus coil as outlined under ADJUSTMENTS.

13. Adjust the volume control for the desired sound volume (phono switch on back of set must be in TV position).

14. Turn the magnifier switch to the counter-clockwise (normal) position.

15. If vertical or diagonal bars appear on the screen, adjust the width control as described under ADJUSTMENTS. *Do not re-adjust the horizontal hold control.*

16. If necessary, adjust the height, height magnifier, vertical linearity, vertical linearity magnifier, and focus controls as explained under ADJUSTMENTS.

17. Check the operation on all available television stations. Note that if the built-in antenna is in use, the television antenna control must be readjusted for maximum picture contrast each time the receiver is tuned to a different channel.

18. Replace the rear cover.

ADJUSTMENTS

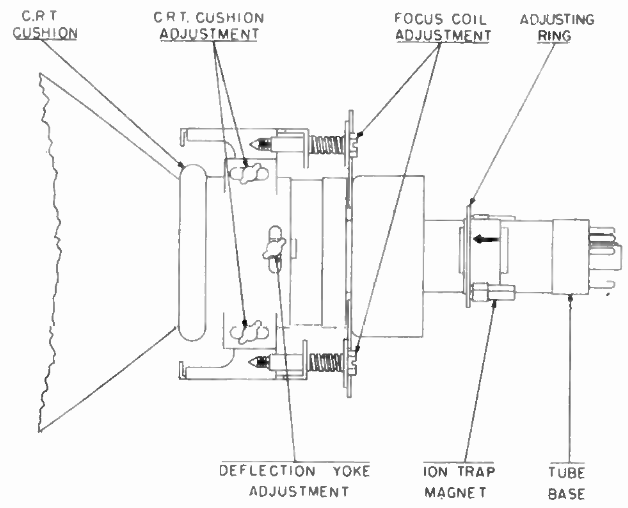


FIG. 1 – CRT ADJUSTMENTS

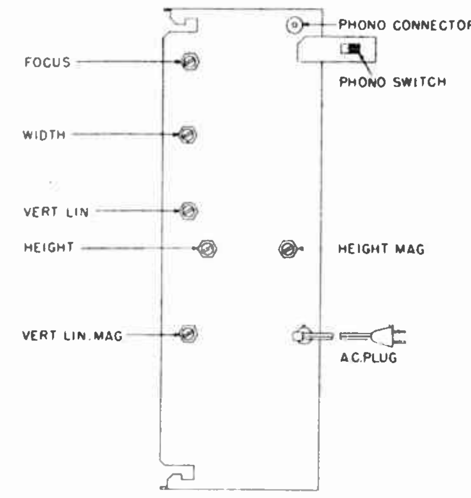

FIG. 2 – ADJUSTMENTS ON REAR OF CHASSIS

The picture adjustments are located on the rear of the chassis and are accessible through cut-outs in the back cover.

An insulated, long shank screwdriver is preferred for making the ringing coil and H. V. oscillator adjustments.

ION TRAP MAGNET

Caution: When adjusting the ion trap magnet, care should be exercised to avoid breaking the neck of the cathode ray tube.

The magnet should first be oriented approximately as shown in Fig. 1. Then, with the brightness control rotated completely clockwise, adjust the magnet by rotating it about the neck of the tube and moving it forward and backward until the raster is brightest on the screen.

If shadows on the face of the tube are not completely removed by either coarse or fine adjustment of the focus coil as outlined below, rotate the adjusting ring on the front of the ion trap magnet to remove the shadows.

FOCUS COIL

If a shadow falls on one corner of the picture, or the picture is not properly centered, adjustment of the focus coil will be necessary. To adjust, loosen the short hex head bolts that lock the coil to the adapter plates, and move the coil horizontally and vertically until the position is found where the picture is properly centered and shadows are removed. Tighten the short hex head bolts to lock the coil in this position. Fine adjustment is provided by the long hex head bolts at each corner of the focus coil.

If shadows cannot be completely removed by adjustment of the focus coil, refer to *ION TRAP MAGNET* above.

CATHODE RAY TUBE CUSHION

The cushion must fit snugly against the flare of the cathode ray tube in order that the rear of the tube will be supported firmly.

DEFLECTION YOKE

This adjustment controls the angle of the picture with respect to the horizontal. If the picture is not squared in the picture mask, loosen the wing nut and move it up or down so as to rotate the deflection yoke. The picture will tilt to the left or right with the deflection yoke rotation.

FOCUS CONTROL

The focus control (Fig. 2) should be adjusted with the brightness and contrast controls in their normal positions. If correct focusing cannot be obtained, the high voltage oscillator may require adjustment.

HEIGHT AND VERTICAL LINEARITY (NORMAL)

The height adjustment controls the over-all height of the picture, while the vertical linearity adjustment governs contraction or expansion of the upper portion only. For this reason, a balance between the two controls is necessary to make the picture symmetrical and fill the mask vertically.

©John F. Rider

HEIGHT AND VERTICAL LINEARITY (MAGNIFIED)

The height magnifier adjustment controls the over-all height of the magnified picture, while the vertical linearity magnifier adjustment governs contraction or expansion of the upper portion only. For this reason, a balance between the two controls is necessary to make the picture symmetrical and fill the mask vertically. *These controls must be reset if the height and vertical linearity controls governing the normal picture are changed.*

WIDTH

The width adjustment must always be made with the magnifier control set for a normal size picture. The correct adjustment is made as follows:

1. Rotate the magnifier control to the magnified position, and adjust the horizontal hold control until the magnified picture holds horizontal sync.

2. Set the magnifier control for a normal size picture, and *without re-adjusting the horizontal hold control* adjust the width control until the picture holds horizontal sync and fills the mask horizontally.

HORIZONTAL RINGING COIL

The horizontal ringing coil is accessible through a hole in the bottom of the cabinet. To adjust the coil:

1. Turn the magnifier switch to the clockwise (magnified) position.

2. Tune in the weakest station in your area.

3. Set the horizontal hold control at approximately the center of its range.

4. Adjust the ringing coil (L403) until the picture is properly "locked-in."

HIGH VOLTAGE OSCILLATOR

1. *Turn off the receiver* and disconnect the high voltage lead from the CRT.

2. Connect 18 one megohm, one watt resistors in series between the high voltage lead and the chassis.

3. Connect a kilovoltmeter across the 18 megohms of resistance.

4. Turn on the receiver and adjust C507 (location shown on Fig. 7) for maximum voltage indication on the meter. When C507 is peaked using an 18 megohm load, the voltage across the load should be 9.3 kilovolts (approximately).

5. *Turn off the receiver*, disconnect the kilovoltmeter, remove the 18 megohms of resistance, and connect the high voltage lead to the CRT. Note that when the 18 megohm load is removed and the high voltage lead is connected to the CRT, the output voltage of the H.V. power supply will rise because of the higher load resistance offered by the CRT.

CATHODE RAY TUBE REPLACEMENT

1. Remove the chassis from the cabinet as explained under CHASSIS REMOVAL.

2. Back off the set screw locking the shutter actuating link to the magnifier control shaft.

3. Remove the two self-tapping screws that secure the shutter assembly frame to the chassis.

4. Remove the two self-tapping screws that secure the shutter assembly frame to the brace bars.

5. Remove the wing nut and lock washer from the stud on top of the CRT strap.

6. Remove the shutter assembly by lifting the bronze strap over the stud and sliding the complete assembly forward.

7. Remove the ion trap magnet and the CRT socket.

8. Loosen the CRT cushion screws and the focus coil mounting screws, and remove the screw from the CRT strap.

9. Remove the defective CRT and insert the replacement through the deflection yoke and focus coil, exercising the caution necessary when handling cathode ray tubes.

10. Replace the screw in the CRT strap and tighten the strap about the tube just enough to hold the tube in place.

11. Replace the shutter assembly and tighten the self-tapping screws only. Do not tighten the CRT strap wing nut or the set screw on the magnifier control shaft.

12. Position the CRT so that the clearance between the tube and the mask is approximately 1/32".

13. Tighten the CRT strap and the wing nut on the stud at the top of the CRT strap.

14. Adjust the CRT cushion and tighten the CRT cushion screws.

15. Replace the ion trap magnet and the CRT socket.

16. Adjust the ion trap magnet and focus coil as outlined under ADJUSTMENTS.

17. Turn the magnifier switch to the clockwise (magnified) position. Open the shutters completely and tighten the set screws to lock the shutter actuating link to the control shaft.

18. Check the operation of the shutters to make certain there is no binding.

19. Replace the chassis in the cabinet.

CHASSIS REMOVAL

To remove the chassis from the cabinet:

1. Remove the control knobs.

2. Remove the wood screws that secure the rear cover to the cabinet and remove the rear cover.

3. Disconnect the antenna feed line from the antenna terminals.

4. Release the antenna terminal mounting plate by removing the screws that secure the plate to the rear of the cabinet.

5. Remove the two bolts that hold the upper chassis mounting bracket to the top inside of the cabinet, and swing the bracket clear of the cabinet. On some models, a wood block is used instead of the bracket; the two screws that hold the block in place should be removed to remove the block.

6. Remove the clamp that secures the shutter frame to the bottom of the cabinet by removing the machine screw that holds the clamp in place. This screw is accessible from beneath the cabinet.

7. Remove the two hex head chassis mounting bolts from beneath the cabinet.

8. Remove the chassis from the cabinet carefully to avoid damaging the built-in antenna system. Removal may be facilitated by turning the cabinet on its side so that the chassis is upright during removal.

NOTE: When replacing the chassis in the cabinet, make certain that the shutter mechanism operates freely and that the control shafts and the face of the CRT is correctly aligned with respect to the holes in the front of the cabinet before tightening the chassis mounting bolts and the upper support bracket bolts.

REMOVAL OF FRONT GLASS FOR CLEANING

With early production Models, it is necessary to remove the chassis from the cabinet in order to clean the inside of the front glass plate or the face of the CRT. Later Models, however, contain provisions for removing the front glass plate for cleaning purposes.

Whether or not the glass is removable from the front of the cabinet can be determined by inspecting the brass retainers at the top and bottom of the glass. If two screw heads are visible on the face of each retainer, the glass is removable from the front of the cabinet. Otherwise, the chassis must be removed to clean the inside of the glass.

For Models that contain the removable glass, the removal procedure is as follows:

1. Remove the power plug from the outlet.

2. Remove the two screws from each of the brass retainers. This will detach the retainers from the cabinet.

3. Remove the glass by lifting it straight out from the front. *Use care to avoid scratching paint off the mask.*

ALIGNMENT

TEST EQUIPMENT—To properly service this chassis, the following test equipment should be available:

1. R-F sweep generator which meets the following requirements:

a. Frequency range from 18 to 30 mc. with a sweep width of 10 mc.

b. Output adjustable with at least 100,000 microvolts maximum and a very low minimum.

c. Output "flat" on all attenuator positions.

2. Cathode-ray oscilloscope, preferably one with a wide band vertical deflection amplifier and a low-capacitance input probe.

©John F. Rider

World Radio History

3. Signal generator capable of providing output frequencies listed below.

21.6 mc. 4th I-F trap
22.6 mc. 1st I-F
25.9 mc. 2nd I-F
25.6 mc. 3rd I-F
24.7 mc. 4th I-F
23.0 mc. 5th I-F
4.5 mc. Audio I-F and ratio detector (the frequency must be extremely accurate, preferably crystal controlled.)

NOTE—The R-F output level on all the above frequencies should be adjustable with at least 100,000 microvolts maximum and a very low minimum.

4. Heterodyne frequency meter with crystal calibrator (if the signal generator does not include a crystal calibrator).

5. Electronic voltmeter (vacuum tube voltmeter), with a high voltage multiplier probe for measurements up to 15,000 volts and an R-F probe for measuring R-F voltages.

GENERAL INFORMATION—All test equipment and the chassis should be bonded together by short lengths of heavy (½ inch) braided copper ribbon. The interconnecting leads should be shielded (72 ohms coaxial cable) and should be as short as possible consistent with ease of making connections. The effectiveness of the bonding can be checked during alignment by placing the hand on the metal chassis or test equipment case. If the response pattern or meter reading changes visibly, the bonding must be improved before the circuits are aligned.

COMMON I-F ALIGNMENT PROCEDURE

1. Remove the 6AK5 R-F amplifier tube from its socket, and rotate the channel selector to channel 13 to avoid undesirable beat response during alignment. The channel selector is at channel 13 when the flat of the shaft faces the top of the tuner.

2. Connect the signal generator to the mixer tube through the coupling device shown in Fig. 3. The device is constructed by squeezing together a miniature tube shield until it fits the tube snugly and does not ground to the chassis. A .005 mfd capacitor is then soldered to the side of the shield. By sliding the tube shield up or down on the tube, the capacitance between the shield and the tube elements can be varied to obtain additional control of the coupling over that provided by the attenuator in the generator itself. The ground side of the generator output cable should be connected to the receiver chassis.

3. Connect a vacuum tube voltmeter to the video test jack on the receiver chassis, and set the meter to its 5 volt scale.

4. Set the signal generator to 21.6 mc. (unmodulated), and adjust T305 for *minimum* voltage on the VTVM. Use a strong signal for this adjustment.

5. Set the signal generator to 22.6 mc. (unmodulated), and adjust L110 for maximum voltage on the VTVM. *During this adjustment, keep the single generator output adjusted so that the VTVM reading does not exceed 2 volts.*

6. Set the signal generator to 25.9 mc. (unmodulated), and adjust T301 for maximum voltage on the VTVM. *During this adjustment, keep the signal generator output adjusted so that the VTVM reading does not exceed 2 volts.*

7. Set the signal generator to 25.6 mc. (unmodulated), and adjust T302 for maximum voltage on the VTVM. *During this adjustment, keep the signal generator output adjusted so that the VTVM reading does not exceed 2 volts.*

8. Set the signal generator to 24.7 mc. (unmodulated), and adjust T303 for maximum voltage on the VTVM. *During this adjustment, keep the signal generator output adjusted so that the VTVM reading does not exceed 2 volts.*

9. Set the signal generator to 23.0 mc. (unmodulated), and adjust T304 for maximum voltage on the VTVM. *During this adjustment, keep the signal generator output adjusted so that the VTVM reading does not exceed 2 volts.*

10. Connect the *sweep* generator to the mixer tube through the coupling device previously described. The *signal* generator will be used in the following steps to provide marker indications at various frequencies on the response curve. In this application, the signal generator input to the set must be low in amplitude to avoid distorting the response curve. To reduce the signal generator input accordingly, the signal generator should be *loosely* coupled to the set by wrapping a few turns of insulated wire around the coupling capacitor "pigtail" and connecting the signal generator to this wire.

11. Connect the vertical input of the oscilloscope to the video test jack through the decoupling network shown in Fig. 4. The oscilloscope horizontal input should be connected to the sweep output from the sweep generator; turn the sweep control on the oscilloscope to the "X" or "OFF" position.

12. Adjust the sweep generator for a center frequency of 25.3 mc. with a 10 mc. deviation. Adjust the sweep generator output until a setting is found where there is very little noise on the oscilloscope pattern.

The oscilloscope pattern obtained should be similar to that shown in Fig. 5. Use the signal generator as a marker to check at the frequencies indicated. If the pattern obtained is not similar to Fig. 5, L110, T301, T302, T303, and T304 should be re-adjusted to produce the correct pattern.

SOUND I-F AND 4.5 MC. TRAP ALIGNMENT PROCEDURE

1. Connect the "high" side of the signal generator to the video test jack through a .001 mfd capacitor, and ground the "low" side to the chassis.

2. Connect the vacuum tube voltmeter to the points indicated on the bottom view of the chassis, Fig. 7. The common lead should connect to point "C", and the "high" lead should connect to point "A". Set the meter on its 5 volt (-DC) scale.

3. Adjust the signal generator to 4.5 mc. (unmodulated). The accuracy of this frequency is very important. If a crystal controlled signal generator is not available, the frequency should be checked using a frequency meter with a crystal calibrator.

4. Adjust T201 and the primary of T202 for maximum voltage on the VTVM. *During this adjustment, keep the signal generator output adjusted so that the VTVM reading does not exceed 5 volts.*

5. Connect the common lead from the VTVM to point "A" (Fig. 7, and connect the "high" lead to point "B". Here it is important that the case and components of the VTVM are *not* grounded to the receiver chassis; otherwise, point "A" would be shorted to the chassis through the common lead.

6. Using the same signal generator amplitude and frequency as in step 4, adjust the secondary of T202 for *zero* voltage on the VTVM. As the adjustment is tuned through resonance, the voltage will rapidly change from one polarity to the opposite polarity. The point where the voltage is zero is the correct setting.

7. Connect the common lead from the VTVM to the chassis, and connect the *R-F probe* from the VTVM to the CRT cathode terminal. This point is shown as point "D" on Fig. 7. *Note that this point is above ground and, therefore, the R-F probe must contain a blocking capacitor.*

8. Using a strong 4.5 mc. signal applied as in step 1, adjust Z301 for *minimum* indication on the meter.

H. F. OSCILLATOR ALIGNMENT PROCEDURE:

If the 6J6 oscillator tube is replaced, the different inter-electrode capacity of the new tube may change the oscillator frequency enough to necessitate realignment of the oscillator.

Alignment of the oscillator on the high band is accomplished by adjusting the brass slug located adjacent to the vernier drive wheel on the front of the tuner. Alignment of the oscillator on the low band is accomplished by adjusting the brass slug on the lower front of the tuner. *A non-metallic screwdriver is required.*

The oscillator alignment procedure is as follows:

1. Set the fine tuning control at the middle of its range, and leave it in this position during the following adjustments.

2. Set the selector switch to the highest of the low-band (channels 2 through 6) stations operating in your vicinity.

3. Peak the low band adjustment slug for the best picture detail.

4. Set the selector switch to the highest of the high-band (channels 7 through 13) stations operating in your vicinity.

5. Peak the high band adjustment slug for best picture detail.

6. Check the previously made low band adjustment, and if the tuning has changed, repeat steps 2 and 3.

I-F ALIGNMENT CHART

Remove the 6AK5 R-F amplifier tube and turn the channel selector to channel 13 to avoid undesirable beat response during alignment.

COMMON I-F SECTION

Couple the sweep and marker generators to the mixer tube as shown in Fig. 3.

Step	*Sweep Gen. Frequency*	*Marker Gen. Frequency*	*Remarks*	*Indicator Connection*	*Adjust*
1.	Not used	21.6 mc. unmodulated	Use a strong signal	Connect VTVM to video test jack	T305 for *minimum* voltage
2.	Not used	22.6 mc. unmodulated	Keep marker output adjusted so VTVM reading does not exceed 2 v.	Same as step 1	L110 for maximum voltage
3.	Not used	25.9 mc. unmodulated	Same as step 2	Same as step 1	T301 for maximum voltage
4.	Not used	25.6 mc. unmodulated	Same as step 2	Same as step 1	T302 for maximum voltage
5.	Not used	24.7 mc. unmodulated	Same as step 2	Same as step 1	T303 for maximum voltage
6.	Not used	23.0 mc. unmodulated	Same as step 2	Same as step 1	T304 for maximum voltage
7.	25.3 mc. with 10 mc. deviation	Check at: 21.6 mc. 22.5 mc. 23.5 mc. 25.3 mc. 26.1 mc.	Keep sweep output high enough so that very little noise appears on the oscilloscope trace	Connect oscilloscope to video test jack. See Fig. 4.	If necessary, adjust L110, T301, T302, T303 and T304 to obtain correct response curve. See Fig. 5.

SOUND I-F SECTION AND 4.5 MC. TRAP

Connect the signal generator to the video test jack through a .001 mfd mica capacito

Step	*Signal Gen. Frequency*	*VTVM Connection*	*Remarks*	*Adjust*
1.	4.5 mc. unmodulated	See Fig. 7. Common lead to point "C" and high lead to point "A".	Use 5 v. (−DC) scale on meter. Set sig. gen. output accordingly.	T201 and the primary of T202 for maximum voltage
2.	4.5 mc. unmodulated	See Fig. 7. Common lead to point "A" and high lead to point "B".	Use same sig. gen. output as in step 1.	The secondary of T202 for *zero* voltage
3.	4.5 mc. unmodulated	See Fig. 7. R-F probe to point "D" and common lead to chassis.	Use strong signal from generator.	Z301 for minimum voltage

11	198 - 204	199.25	203.75	225.35
12	204 - 210	205.25	209.75	231.35
13	210 - 216	211.25	215.75	237.35

NOTE: The fine tuning range is plus or minus 1 mc. on channel 2 and plus or minus 2 mc. on channel 13.

AM/FM FREQUENCY RANGES:

Standard Broadcast .... 540 to 1600 kc.
Frequency Modulation .... 88 to 108 mc.

INTERMEDIATE FREQUENCIES:

Television Video Carrier .... 26.1 mc.
TV sound and FM .... 4.5 mc.
AM .... 455 kc.

OPERATING VOLTAGE: .... 105 to 120 volts, 60 cycles A-C

POWER CONSUMPTION: .... 325 watts

TV RECEIVER ANTENNA INPUT IMPEDANCE:

.. 300 ohms balanced or 72 ohms unbalanced

PILOT LAMP:

Westinghouse No. 44 .... 6.3 v., 0.25 amp.

AUDIO POWER OUTPUT:

Undistorted .... 3 watts
Maximum .... 4.5 watts

SPEAKER:

Size and Type .... 10" PM
Voice Coil Impedance-3.2 ohms at 400 cycles

TUBE COMPLEMENT:

1	1B3GT	High Voltage Rectifier
2	5U4G	Low Voltage Rectifier
1	6AH6	Video Output
1	6AK5	R-F Amplifier (TV)
1	6AL5	Video Detector and Noise Clipper
1	6AL5	Ratio Detector
1	6AL5	Horizontal AFC
2	6AU5GT	Horizontal Output
1	6AV6	1st A-F Amplifier and AM Det. — AVC
1	6BE6	FM HF Oscillator/AM Converter
1	6BH6	1st I-F Amplifier (TV)
1	6BH6	2nd I-F Amplifier (TV)
1	6BH6	3rd I-F Amplifier (TV)
1	6BH6	2nd Sound I-F Amplifier And FM AVC
1	6BH6	AGC Keying
1	6BJ6	1st Sound I-F Amplifier
1	6BJ6	4th I-F Amplifier (TV)
1	6J6	HF Oscillator and Mixer (TV)
1	6V6GT	Vertical Output
1	6W4GT	Horizontal Damper
1	6Y6G	H.V. Oscillator
1	6Y6G	Audio Output
1	12AT7	FM R-F Amplifier and Mixer
1	12AT7	Sync Amplifier and Sync Separator
1	12AU7	Vertical Multivibrator
1	12AU7	Horizontal Multivibrator
1	12AU7	DC Restorer and Phase Inverter
1	12KP4, 12KP4A, or 12LP4	Cathode Ray Tube

VIDEO RESPONSE: .... 3.6 mc.

AUDIO DISCRIMINATOR BAND WIDTH (between peaks): .... 180 kc.

FOCUS: .... Magnetic

SWEEP DEFLECTION: .... Magnetic

SCANNING: .... Interlaced, 525 line

HORIZONTAL SCANNING FREQUENCY: .... 15,750 CPS

VERTICAL SCANNING FREQUENCY: .... 60 CPS

FRAME FREQUENCY (picture repetition rate): .... 30 CPS

INSTALLATION INSTRUCTIONS

TO PREPARE THE RECEIVER FOR OPERATION:

1. Remove the red screw and wood spacer located at the rear of the record changer slide mechanism.

2. Remove all packing from the record changer compartment.

3. Remove the phono needle guard if one is used.

4. Remove the turntable by lifting it straight up.

5. Turn the two large, round-head screws, located under the turntable, *clockwise* to the limit of their travel.

6. Replace the turntable.

7. Remove the screws that secure the rear cover of the television section to the cabinet, and remove the rear cover by pulling it away from the cabinet.

8. Remove the red headed wood screw from the shipping block located on the top (inside) of the cabinet, and remove the shipping block.

9. Remove the two red headed wood screws from the shipping block located between the upper left side of the cabinet and the chassis, and remove the shipping block.

10. Inspect the face of the C.R.T. and the glass window for dust or smudges. If the face of the C.R.T. or the inside of the glass window is smudged, it will be necessary to remove the chassis to clean the smudged surface. In this event, refer to CHASSIS REMOVAL.

11. Loosen the two hex-head bolts on the under side of the cabinet, and remove the

©John F. Rider

World Radio History

wood shipping strip located between the chassis and the bottom of the cabinet.

12. Loosen the two screws securing the shock mounting bracket to the top (inside) of the cabinet.

13. Adjust the position of the chassis so that the knobs and the face of the C.R.T. are properly aligned with respect to the holes in the front of the cabinet.

14. Re-tighten the two red headed bolts on the under side of the cabinet and the two screws securing the shock mount bracket on the top of the cabinet.

15. Make certain that all tubes are secure in their socket.

16. Models H-611C12 and H-615C12 contain a built-in antenna for use in areas of normal reception. In such areas when the built-in antenna provides good reception, no additional antenna connections are required. However, in weak signal areas or under adverse conditions, it may be necessary to use an external antenna. If an external antenna is used the built-in antenna should be disconnected from the antenna terminals on the rear of the cabinet, and the lugs of the built-in antenna should be insulated and dressed in such a position that they do not touch the chassis or components. The spring clamp located on the top (inside) of the cabinet can be used to hold the built-in antenna feeder out of the way.

17. Replace the rear cover.

18. If an outside antenna is to be used, connect the lead-in to the antenna terminals on the back of the set.

19. Connect the A-C plug to a 105 to 120 volt 60 cycle A-C power outlet.

TO CHECK THE OPERATION:

1. Rotate the selector to the TV position.

2. Turn the magnifier switch to the clockwise (magnified) position.

3. Rotate the brightness, and contrast controls completely counterclockwise.

4. Turn on the receiver by rotating the off-on-volume control clockwise.

5. Rotate the channel selector to the channel number of the desired station.

6. Rotate the brightness control clockwise until the screen is well lighted.

7. Rotate the contrast control clockwise until a picture appears on the screen.

8. If the built-in antenna is in use, adjust the television antenna control for maximum picture contrast. If an external antenna is in use, this step is not required.

9. If the picture is moving up or down or quivering, adjust the vertical hold control to stabilize the image.

10. If vertical or diagonal bars or a folded over picture appears on the screen, adjust the horizontal hold control to obtain a stable picture.

11. Adjust the fine tuning control for best picture detail.

12. Readjust the brightness and contrast controls until pleasing shades ranging from clear white to intense black are attained.

13. Adjust the volume control for the desired sound volume.

14. Turn the magnifier switch to the counterclockwise (normal) position. If vertical or diagonal bars appear on the screen, adjust the width control as described under TELEVISION ADJUSTMENTS. *Do not readjust the horizontal hold control.*

15. If necessary, adjust the height, height magnifier, vertical linearity, vertical linearity magnifier, and focus controls as explained under TELEVISION ADJUSTMENTS.

16. Check the operation on all available television stations. Note that if the built-in antenna is in use, the television antenna control must be readjusted for maximum picture contrast each time the receiver is tuned to a different channel.

17. Rotate the selector to the FM position, and check the operation of the radio section on the FM band.

18. Rotate the selector to the AM position, and check the operation of the radio section on the broadcast band.

19. Rotate the selector to the PHONO position, and completely check the operation of the record changer using 78 RPM intermixed 10" and 12" records, 33-1/3 RPM intermixed 10" and 12" records, and 45 RPM 7" records.

TELEVISION ADJUSTMENTS

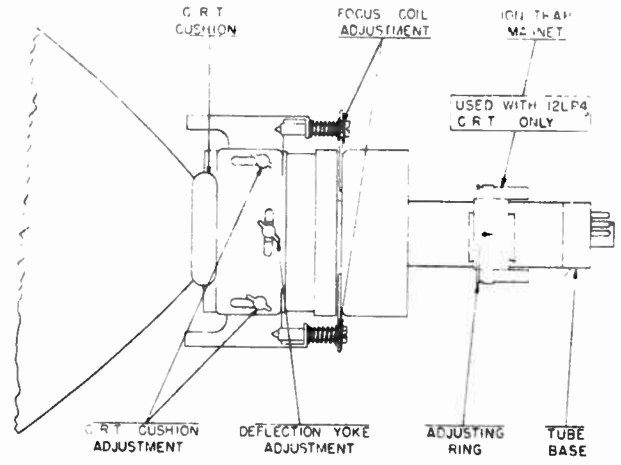

FIG. 1 — CRT ADJUSTMENTS

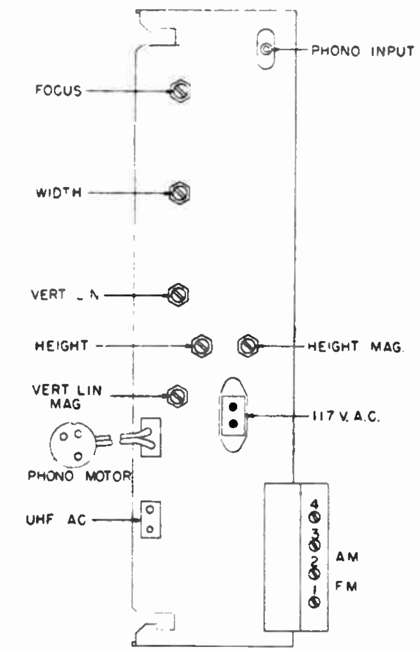

FIG. 2 — ADJUSTMENTS ON REAR OF CHASSIS

The picture adjustments are located on the rear of the chassis and are accessible through cut-outs in the back cover.

ION TRAP MAGNET

Adjustment of the ion trap magnet is required only when a 12LP4 cathode ray tube is used. An ion trap magnet is not used with 12KP4 or 12KP4A cathode ray tubes.

The ion trap magnet must always be adjusted for maximum picture brightness. With the magnet oriented approximately as shown in Fig. 1, rotate it around the neck of the tube and move it forward and backward until the position is found where the brightest raster is obtained.

CAUTION: When adjusting the ion trap magnet, care must be exercised to avoid breaking the neck of the CRT.

FOCUS COIL

If a shadow falls on one corner of the picture or the picture is not properly centered, adjustment of the focus coil is required. To adjust, loosen the short hex-head bolts that lock the focus coil to the adapter plates and move the coil up and down and to the left and right until the position is found where the picture is properly centered and there are no shadowed corners. Tighten the short hex-head bolts to lock the coil in this position. Fine adjustment is provided by the long hex-head bolts at each corner of the focus coil.

If a 12LP4 CRT is in use and shadows cannot be removed completely by adjusting the focus coil, the ion trap magnet may be in need of adjustment.

CATHODE RAY TUBE CUSHION

The cushion must fit snugly against the flare of the cathode ray tube in order that the rear of the tube will be supported firmly.

DEFLECTION YOKE

This adjustment controls the angle of the picture with respect to the horizontal. If the picture is not squared in the picture mask, loosen the wing nut and move it up or down so as to rotate the deflection yoke. The picture will tilt to the left or right with the deflection yoke rotation.

FOCUS CONTROL

The focus control (Fig. 2) should be adjusted with the brightness and contrast controls in their normal positions. If correct focusing cannot be obtained, the high voltage oscillator may require adjustment.

HEIGHT AND VERTICAL LINEARITY (NORMAL)

The height adjustment controls the overall height of the picture, while the vertical

©John F. Rider

World Radio History

linearity adjustment governs contraction or expansion of the upper portion only. For this reason, a balance between the two controls is necessary to make the picture symmetrical and fill the mask vertically.

HEIGHT AND VERTICAL LINEARITY (MAGNIFIED)

The height magnifier adjustment controls the overall height of the magnified picture, while the vertical linearity magnifier adjustment governs contraction or expansion of the upper portion only. For this reason, a balance between the two controls is necessary to make the picture symmetrical and fill the mask vertically. *These controls must be reset if the height and vertical linearity controls governing the normal picture are changed.*

WIDTH

The width adjustment must always be made with the magnifier control set for a normal size picture. The correct adjustment is made as follows:

1. Rotate the magnifier control to the magnified position, and adjust the horizontal hold control until the magnified picture holds horizontal sync.

2. Set the magnifier control for a normal size picture, and *without re-adjusting the horizontal hold control* adjust the width control until the picture holds horizontal sync and fills the mask horizontally.

HORIZONTAL RINGING COIL

To adjust the horizontal ringing coil:

1. Turn the magnifier switch to the magnified (clockwise) position.

2. Tune in the weakest TV station in your area.

3. Set the horizontal hold control at approximately the center of its range.

4. Adjust the ringing coil (L403) until the picture is properly "locked-in".

HIGH VOLTAGE OSCILLATOR

An insulated, long-shank screwdriver is preferred for making the H.V. oscillator adjustment The procedure is as follows:

1. *Turn off the receiver* and disconnect the high voltage lead from the CRT.

2. Connect 18 one megohm, one watt resistors in series between the high voltage lead and the chassis.

3. Connect a kilovoltmeter across the 18 megohms of resistance.

4. Turn on the receiver and adjust C507 for maximum voltage indication on the meter. When C507 is peaked using an 18 megohm load, the voltage across the load should be 9.3 kilovolts (approximately).

5. *Turn off the receiver*, disconnect the kilovoltmeter, remove the 18 megohms of resistance, and connect the high voltage lead to the CRT. Note that when the 18 megohm load is removed and the high voltage lead is connected to the CRT, the output voltage of the H.V. power supply will rise because of the higher load resistance offered by the CRT.

CHASSIS REMOVAL

To remove the chassis from the cabinet, proceed as follows:

1. Remove the control knobs.

2. If an external antenna is in use, disconnect the transmission line from the antenna terminals.

3. Remove the screws that secure the rear cover, and remove the rear cover by pulling it straight out.

4. Disconnect the FM dipole and the AM loop from the antenna terminals on the rear of the chassis.

5. Disconnect the built-in TV antenna (if in use) from the TV antenna terminals, and release the TV antenna terminal strip from the cabinet.

6. Disconnect the phono cable from the connector on the chassis.

7. Disconnect the A-C power cord from the record changer

8. Disconnect the speaker leads from the terminals on the chassis.

9. Open the record changer drawer by pulling it out to the limit of its travel.

10. Remove the pilot lamp socket located under the AM/FM dial scale by removing the screw that secures it to the underside of the supporting shelf.

11. Pull the pilot lamp socket and leads up through the hole in the supporting shelf, and dress it clear of the cabinet.

12. Remove the clamp that secures the shutter frame to the supporting shelf after removing the machine screw that holds the clamp in place. The screw is accessible from the underside of the supporting shelf.

13. Remove the two bolts that hold the upper chassis mounting bracket to the top (inside) of the cabinet.

14. Remove the two red headed chassis mounting bolts from the underside of the supporting shelf.

15. Slide the chassis out of the cabinet, keeping the front of the chassis against the cabinet partition and progressively moving the rear of the chassis to the right so that the chassis components will clear the cabinet accessories.

CATHODE RAY TUBE REPLACEMENT

To remove the CRT from the chassis, it is not necessary to remove the shutter assembly or the radio dial cord. The CRT can most readily be removed as follows:

1. Remove the chassis from the cabinet as explained under CHASSIS REMOVAL.

2. Remove the wing nut that holds the shutter assembly to the CRT strap. This wing nut is located at the top front of the CRT.

3. Remove the CRT strap bolt.

4. Slide the upper section of the CRT strap free from the bracket on the shutter assembly, and bend the strap away from the CRT.

5. Release the deflection yoke connector socket from the superstructure by removing the two screws that hold it in place.

6. Remove the CRT socket and the ion trap magnet (if used).

7. Remove the two short hex-head bolts from the focus coil, and slide the focus coil and its mounting bracket off the neck of the CRT.

8. Remove the CRT cushion adjustment wing screws. These are the screws that secure the deflection yoke and hood to the superstructure.

9. Slide the deflection yoke and hood assembly toward the base of the CRT until the yoke and hood are clear of the superstructure and the neck of the CRT.

10. Remove the CRT by pulling it slightly toward the rear of the chassis to clear the shutter mechanism and then lifting it straight up from the chassis. Care must be exercised to avoid damaging the aquadag of scratching the face of the tube.

ALIGNMENT INFORMATION

TEST EQUIPMENT REQUIRED

To properly service the chassis, the following test equipment should be available:

1. R-F sweep generator which meets the following requirements:
   a. Frequency range from 18 to 30 mc. with a sweep width of 10 mc.
   b. Output adjustable with at least 100,000 microvolts maximum and a very low minimum.
   c. Output "flat" on all attenuator positions.

2. Cathode-ray oscilloscope, preferably one with a wide band vertical deflection amplifier and a low-capacitance input probe.

3. Signal generator or generators capable of providing output at various frequencies between 455 kc. and 108.5 mc. The R-F output level should be adjustable with at least 100,000 microvolts maximum and a very low minimum. Amplitude modulation is required on the frequencies between 455 kc. and 1615 kc.

4. Heterodyne frequency meter with crystal calibrator (if the signal generator does not include a crystal calibrator.

5. Electronic voltmeter (vacuum tube voltmeter), with a high voltage multiplier probe for measurements up to 15,000 volts and an R-F probe for measuring R-F voltages.

INTERCONNECTIONS AND BONDING

The test equipment and the chassis should be bonded together by short lengths of heavy, braided copper ribbon. The effectiveness of the bonding can be checked during alignment by placing the hand on the metal chassis or test equipment case. If the response pattern

World Radio History

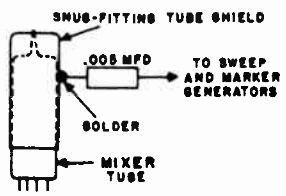

FIG. 3 — COUPLING SIGNAL GENERATORS TO TV MIXER TUBE

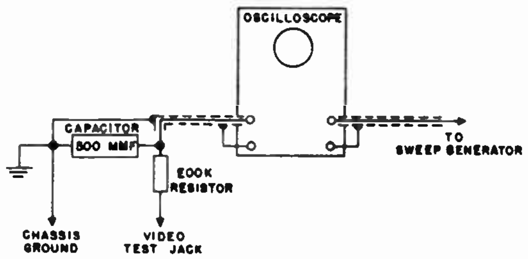

FIG. 4 — OSCILLOSCOPE CONNECTIONS

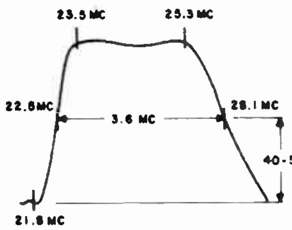

FIG. 5 — TV COMMON I-F RESPONSE CURVE

or meter reading changes visibly, the bonding should be improved before the circuits are aligned.

An exception to this general bonding rule is the instrument case of the VTVM. Difficulty will be encountered during the ratio detector zero adjustment if the common terminal of the VTVM is bonded (either directly or through the instrument case) to the television chassis. During this adjustment, both connection points for the VTVM are above ground in the television chassis, and both VTVM terminals must therefore be isolated from ground.

The interconnecting leads should be shielded (72 ohms coaxial cable) and should be as short as possible consistent with ease of making connections.

SIGNAL GENERATOR COUPLING FOR TV ALIGNMENT

In steps 1 to 7 of the TV common I-F procedure, an unmodulated signal is applied to the TV mixer tube through the coupling device illustrated in Fig. 3. The device is constructed by squeezing together a miniature tube shield until it fits the tube snugly and does not ground to the chassis. A .005 mfd capacitor is then soldered to the side of the shield. By sliding the tube shield up or down on the tube, the capacitance between the shield and the tube elements can be varied to obtain additional control of the coupling over that provided by the attenuator in the generator itself. The ground side of the generator output cable should be connected to the receiver chassis.

In step 8 of the TV common I-F alignment procedure, a sweep generator is connected to the coupling device described above. An unmodulated signal generator is used to provide marker indications at various frequencies on the response curve. In this application, the signal generator input of the set must be low in amplitude to avoid distorting the response curve. To reduce the signal generator input accordingly, the signal generator should be *loosely* coupled to the set by wrapping a few turns of insulated wire around the coupling capacitor "pigtail" and connecting the signal generator to this wire. The sweep generator should be connected directly to the coupling device.

USE OF OSCILLOSCOPE

In step 8 of the TV common I-F alignment procedure, the I-F response pattern on the oscilloscope screen serves as a check on the I-F alignment. The vertical input to the oscilloscope is connected to the video test jack on the receiver chassis through the de-coupling network illustrated in Fig. 4. The horizontal input of the oscilloscope should be connected to the sweep output from the sweep generator, and the sweep control on the oscilloscope should be turned to the "X" or "OFF" position.

The oscilloscope pattern obtained in step 8 of the TV common I-F alignment procedure should be similar to that shown in Fig. 5. Use the signal generator as a marker to check at the frequencies indicated. If the pattern obtained is not similar to Fig. 5, it will be necessary to re-adjust L110, T301, T302, T303, and T304 to produce the correct pattern.

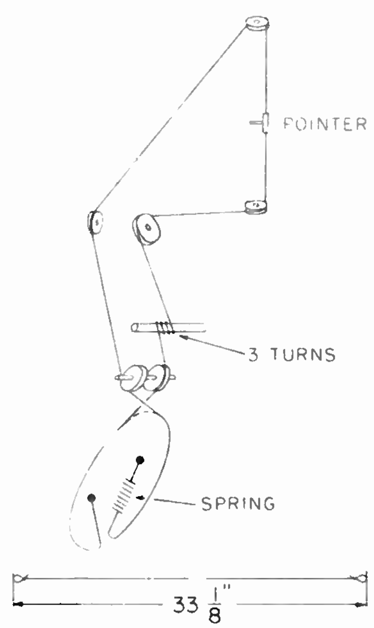

FIG. 6 — AM/FM DIAL DRIVE

ALIGNMENT PROCEDURE

AM RADIO SECTION

Set the selector switch to the "AM" position.

Connect an output meter across the speaker voice coil.

While making the following adjustments, keep the volume control set for maximum output, the tone control set for maximum treble, and the signal generator output attenuated to avoid AVC action.

Step	Connect Signal Generator to—	Sig. Gen. Freq.	Radio Dial Setting	Adjust for Maximum Output —
1.	Stator of AM ant. section (C250E) of tuning gang thru a 0.1 mfd capacitor	455 kc. amplitude modulated	minimum capacity	Primary and secondary of T204 and T205
	NOTE: If the I-F transformers are badly mis-aligned, it may be impossible to obtain sufficient output using the above system. In this event it will be necessary to align each transformer separately. Start with T205 and work forward, connecting the signal generator through a 0.1 mfd capacitor to the control grid of the tube preceding the transformer under alignment.			
2.	Same as step 1	1615 kc. amplitude modulated	minimum capacity	AM oscillator trimmer.
3.	Radiated signal (no actual connection)	1400 kc. amplitude modulated	tune for maximum signal	AM antenna trimmer (rock-in adjustment).

NOTE: The alignment of T204 and T205 affects the alignment of T201 and T202. Therefore, it will be necessary to check the alignment of the 4.5 mc. I-F system whenever T204 or T205 are adjusted. The check can be made by performing steps 3 and 4 under "FM Radio Section."

FM RADIO SECTION

If AM adjustments are required, do not align the FM circuits until the AM adjustments have been completed.

Set the selector switch to the "FM" position.

Step	Connect Signal Generator to—	Sig. Gen. Frequency	Radio Dial Setting	Adjust —
1.	Connect a VTVM between points "A" and "B" (shown on Fig. 8) with the common lead to point "A" and the high lead to point "B".			
2.	Stator of FM mixer section (C250B) of tuning gang thru a .01 mfd mica capacitor.	4.5 mc. unmodulated	maximum capacity	Secondary (top slug) of T203 for *zero* voltage.
3.	Connect the VTVM between points "A" and "C" with the common lead to point "C" and the high lead to point "A". Set the VTVM on the 5 volt (-DC) scale, and keep the signal generator output adjusted accordingly.			
4.	Same as step 2.	4.5 mc. unmodulated	maximum capacity	Primary and secondary of T201 and T202 and primary of T203 for maximum voltage.
5.	Repeat steps 1 and 2.			
6.	Re-connect the VTVM as in step 3.			
7.	Ant. terminal No. 1 thru a 300 ohm non-inductive resistor.	108.5 mc. unmodulated	minimum capacity	FM oscillator trimmer (C247) for maximum voltage*.
	NOTE: If two peaks appear, use the one that occurs with the trimmer nearest maximum capacity.			
8.	Same as step 7.	105 mc. unmodulated	tune for maximum signal	FM R-F amp. trimmer for maximum voltage (rock-in adjustment).
9.	Same as step 7.	105 mc. unmodulated	tune for maximum signal	FM mixer trimmer for maximum voltage (rock-in adjustment).

* To check the dial calibration after adjusting the FM oscillator trimmer (C247), set the tuning gang at maximum capacity and adjust the signal generator frequency in the vicinity of 87.5 mc. for maximum voltage on the VTVM. If maximum response occurs at a generator frequency of 87.5 mc., no further adjustments are necessary. If maximum response occurs when the generator frequency is lower than 87.5 mc., slightly expand the FM oscillator coil (L203); if the generator frequency is higher than 87.5 mc., slightly compress the FM oscillator coil (L203). Re-adjust the FM oscillator trimmer (C247) at 108.5, and again check the calibration. Repeat this process until correct calibration is obtained.

ALIGNMENT PROCEDURE (continued)

TV SOUND I-F SECTION

The 4.5 mc. circuits serve as an I-F channel for both the TV sound and the FM radio. Alignment of the TV sound I-F section is therefore accomplished when steps 1 to 5 inclusive under "FM Radio Section" have been performed.

TV COMMON I-F AND 4.5 MC. TRAP

Set the selector switch to the "TV" position.

Turn the TV channel selector to channel 13 to avoid undesirable beat response during alignment.

Step	*Sweep Gen. Frequency*	*Marker Gen. Frequency*	*Remarks*	*Indicator Connection*	*Adjust*
1.	Couple the sweep and marker generators to the TV mixer tube as shown in Fig. 3.				
2.	Not used	21.6 mc. unmodulated	Use a strong signal	Connect VTVM to video test jack	T305 for *minimum* voltage
3.	Not used	22.6 mc. unmodulated	Keep marker output adjusted so VTVM reading does not exceed 2 v.	Same as step 2	L110 for maximum voltage
4.	Not used	25.9 mc. unmodulated	Same as step 3	Same as step 2	T301 for maximum voltage
5.	Not used	25.6 mc. unmodulated	Same as step 3	Same as step 2	T302 for maximum voltage
6.	Not used	23.8 mc. unmodulated	Same as step 3	Same as step 2	T303 for maximum voltage
7.	Not used	23.0 mc. unmodulated	Same as step 3	Same as step 2	T304 for maximum voltage
8.	25.3 mc. with 10 mc. deviation	check at: 21.6 mc. 22.5 mc. 23.5 mc. 25.3 mc. 26.1 mc.	Keep sweep output low enough so that very little noise appears on the oscillo-scope trace	Connect oscilloscope to video test jack. See Fig. 4.	If necessary, adjust L110, T301, T302, T303, and T304 to obtain correct response curve. See Fig. 5.
9.	Connect the signal generator to the video test jack through a .001 mfd mica capacitor.				
10.	Not used	4.5 mc. unmodulated	Use a strong signal	Connect high side of R-F probe from VTVM to point "D" (see Fig. 8) and common lead to chassis	Z301 for *minimum* voltage

TV HIGH FREQUENCY OSCILLATOR

If the 6J6 oscillator tube is replaced, the different inter-electrode capacity of the new tube may change the oscillator frequency enough to necessitate realignment of the oscillator.

Alignment of the oscillator on the high band is accomplished by adjusting the brass slug located adjacent to the vernier drive wheel on the front of the tuner. Alignment of the oscillator on the low band is accomplished by adjusting the brass slug on the lower front of the tuner. *A non-metallic screwdriver is required.*

The oscillator alignment procedure is as follows.

1. Set the fine tuning control at the middle of its range, and leave it in this position during the following adjustments.
2. Set the selector switch to the highest of the low-band (channels 2 through 6) stations operating in your vicinity.
3. Peak the low band adjustment slug for the best picture detail.
4. Set the selector switch to the highest of the high-band (channels 7 through 13) stations operating in your vicinity.
5. Peak the high band adjustment slug for best picture detail.
6. Check the previously made low band adjustment, and if the tuning has changed, repeat steps 2 and 3.

R218	RC20AE333K	Resistor, 33,000 ohms ½ w.	De-emphasis
R219	RC20AE473K	Resistor, 47,000 ohms ½ w.	455 kc filter
R220	RC20AE104K	Resistor, 100,000 ohms ½ w.	Grid return
R221	RC20AE154K	Resistor, 150,000 ohms ½ w.	Decoupling
R222	RC20AE474K	Resistor, 470,000 ohms ½ w.	Plate load
R223	RC20AE105K	Resistor, 1 megohm ½ w.	AVC load
R224	RC20AE105K	Resistor, 1 megohm ½ w.	AVC load
R225	RC20AE106M	Resistor, 10 megohms ½ w.	Grid return
R226	RC30AE562K	Resistor, 5600 ohms 1 w.	Plate load
R227	RC30AE683K	Resistor, 68,000 ohms 1 w.	Decoupling
R228	RC30AE473K	Resistor, 47,000 ohms ½ w.	Screen dropping
R229	RC30AE473K	Resistor, 47,000 ohms ½ w.	Screen dropping
R230	RC40AE181K	Resistor, 180 ohms 2 w.	Cathode bias
R231	RC40AE223K	Resistor, 22,000 ohms 2 w.	Screen dropping
R232	RC20AE225K	Resistor, 2.2 megohms ½ w.	455 kc diode load
R233	V-9085-4	Resistor, glasohm, 1670 ohms 10 w.	Screen bus load
R235	V-6067-6	Resistor, glasohm, 470 ohms 4 w.	Screen load
R236	RC20AE101K	Resistor, 100 ohms ½ w.	Ratio det.
R237	RC40AE103K	Resistor, 10,000 ohms 2 w.	Plate dropping
R240	RC20AE224K	Resistor, 220,000 ohms ½ w.	Grid return
SW201	V-9618	Switch, selector (consists of wafer A, B and C)	
T201	V-9370	Transformer (complete)	FM 1st I-F (4.5 mc)
T202	V-9371	Transformer (complete)	FM 2nd I-F (4.5 mc)
T203	V-9340	Transformer (complete)	Ratio detector
T204	V-6130-1	Transformer (complete)	AM 1st I-F (455 kc)
T205	V-6130-2	Transformer (complete)	AM 2nd I-F (455 kc)
T206	V-9685	Transformer (complete)	Audio output
Z201	V-4886-7	Parasitic suppressor	

Section 3—Video

Item	Part No.	Description	Function
C301	V-5596	Capacitor, hi-kap .005 mfd	AGC filter
*C302	V-9577 assy	Capacitor, electrolytic, 20 mfd 400 v. (assy consists of C238, C302, C421 and C417)	Screen by-pass
C303	R5CC26ZY152M	Capacitor, .0015 mfd	
C304	V-5596	Capacitor, hi-kap .005 mfd	R-F by-pass
C305	V-5658-6	Capacitor, 4.7 mmf	Diode plate by-pass
C307	V-6066-4254M	Capacitor, .25 mfd 400 v.	AGC filter
C308	V-5596	Capacitor, hi-kap .005 mfd	Screen by-pass
C309	R5CC26ZY152M	Capacitor, .0015 mfd	Plate decoupling
C310	R5CC21ZY151M	Capacitor, 150 mmf	I-F coupling
C311	V-5596	Capacitor, hi-kap .005 mfd	Cathode by-pass
C312	V-6023-4223K	Capacitor, hi-temp .022 mfd 400 v.	Coupling (DC restorer)

PARTS LIST FOR MODELS H-611C12 AND H-615C12 (*Continued*)

Item	Part No.	Description	Function
C313	V-5596	Capacitor, hi-kap .005 mfd	Screen by-pass
C314	V-5596	Capacitor, hi-kap .005 mfd	Screen by-pass
C315	R5CC26ZY152M	Capacitor, .0015 mfd	Grid by-pass
C317	V-6066-4254M	Capacitor, .25 mfd 400 v.	Video coupling
C318	V-6023-4104M	Capacitor, hi-temp .1 mfd 400 v.	Cathode by-pass
C319	R5CC26ZY152M	Capacitor, .0015 mfd	Grid by-pass
C320	V-5596	Capacitor, hi-kap .005 mfd	Screen by-pass
C322	R5CC26ZY152M	Capacitor, .0015 mfd	Plate decoupling
C323	V-5596	Capacitor, hi-kap .005 mfd	Cathode by-pass
C329	R5CC26ZY152M	Capacitor, .0015 mfd	Plate decoupling
L301	V-5902-4	Coil, 100 microhenries	Video peaking
L302	V-5902-1	Coil, 140 microhenries	Video peaking
L303	V-5902-5	Coil, 250 microhenries	Video peaking
*R301	V-9235-2 assy	Control, 1500 ohms (assy consists of R301 and R302)	Contrast
*R302	V-9235-2 assy	Control, 50,000 ohms (assy consists of R301 and R302)	Brightness
R303	RC20AE474K	Resistor, 470,000 ohms ½ w.	AGC divider
R304	RC30AE473K	Resistor, 47,000 ohms ½ w.	Screen dropping
R305	RC20AE680K	Resistor, 68 ohms ½ w.	Cathode bias
R306	RC20AE680K	Resistor, 68 ohms ½ w.	Cathode bias
R307	RC20AE101K	Resistor, 100 ohms ½ w.	Cathode bias
R308	RC20AE101K	Resistor, 100 ohms ½ w.	Cathode bias
R309	RC20AE223K	Resistor, 22,000 ohms ½ w.	Video peaking shunt
R310	RC20AE102M	Resistor, 1000 ohms ½ w.	Screen dropping
R311	RC20AE102M	Resistor, 1000 ohms ½ w.	Plate decoupling
R312	RC20AE102M	Resistor, 1000 ohms ½ w.	Screen dropping
R313	RC20AE102M	Resistor, 1000 ohms ½ w.	Plate decoupling
R314	RC20AE102M	Resistor, 1000 ohms ½ w.	Plate decoupling
R315	RC20AE102M	Resistor, 1000 ohms ½ w.	Plate decoupling
R316	RC30AE362J	Resistor, 3600 ohms 1 w.	Plate decoupling
R317	RC20AE472K	Resistor, 4700 ohms ½ w.	Screen dropping
R318	RC20AE472K	Resistor, 4700 ohms ½ w.	Grid return
R319	RC20AE472K	Resistor, 4700 ohms ½ w.	Grid return
R320	RC20AE123K	Resistor, 12,000 ohms ½ w.	Grid return
R321	RC20AE822K	Resistor, 8200 ohms ½ w.	Grid return
R322	RC20AE182K	Resistor, 1800 ohms ½ w.	Screen bias
R323	RC20AE223K	Resistor, 22,000 ohms ½ w.	Isolating
R324	RC20AE103M	Resistor, 10,000 ohms ½ w.	AGC decoupling
R325	RC20AE103M	Resistor, 10,000 ohms ½ w.	AGC decoupling
R326	RC30AE224K	Resistor, 220,000 ohms 1 w.	Plate load
R327	RC20AE473K	Resistor, 47,000 ohms ½ w.	Isolating
R328	RC20AE105K	Resistor, 1 megohm ½ w.	Grid return
R329	RC20AE473K	Resistor, 47,000 ohms ½ w.	DC divider
R330	RC20AE105K	Resistor, 1 megohm ½ w.	Cathode bias
R331	RC20AE473K	Resistor, 47,000 ohms ½ w.	Cathode bias
R332	RC20AE474K	Resistor, 470,000 ohms ½ w.	AGC divider
R333	RC30AE683K	Resistor, 68,000 ohms 1 w.	Screen dropping
R334	RC20AE104K	Resistor, 100,000 ohms ½ w.	AGC divider
R335	RC30AE104K	Resistor, 100,000 ohms 1 w.	Screen dropping
R336	RC20AE682K	Resistor, 6800 ohms ½ w.	DC divider
R337	RC20AE472K	Resistor, 4700 ohms	Grid return
R339	RC20AE103K	Resistor, 10,000 ohms ½ w.	Cathode bias
T301	V-9586-3	Transformer (complete)	1st I-F
T302	V-9586-2	Transformer (complete)	2nd I-F
T303	V-9586-2	Transformer (complete)	3rd I-F
T304	V-9586-3	Transformer (complete)	4th I-F
T305	V-9592	Transformer (complete)	Cathode trap
Z301	V-9591	Trap	4.5 mc trap

Section 4—Sweep

Item	Part No.	Description	Function
C401	RCM20C331J	Capacitor, 330 mmf	Keyed AGC coupling
C402	V-6023-6102M	Capacitor, hi-temp .001 mfd 600 v.	AFC coupling
C403	V-6023-6102M	Capacitor, hi-temp .001 mfd 600 v.	AFC coupling
C404	RCM20C331J	Capacitor, 330 mmf	Error voltage coupling
C405	V-6023-4472M	Capacitor, hi-temp .0047 mfd 400 v.	AFC delay
C406	V-6023-4503M	Capacitor, hi-temp .05 mfd 400 v.	AFC delay
C407	V-6023-6102M	Capacitor, hi-temp .001 mfd 600 v.	Transient by-pass
C408	V-6066-4254M	Capacitor, .25 mfd 400 v.	Noise clipper coupling
C409	RCM20B271K	Capacitor, 270 mmf	Horizontal sync coupling
C410	V-6023-4503M	Capacitor, hi-temp .05 mfd 400 v.	Sync coupling
C411	V-6023-4103M	Capacitor, hi-temp .01 mfd 400 v.	Vertical sync coupling
C412	V-6023-4104M	Capacitor, hi-temp .1 mfd 400 v.	Plate decoupling
C413	RCM20C331J	Capacitor, 330 mmf	Horizontal mv coupling
C414	RCM20B101K	Capacitor, 100 mmf	Charge limiting
C415	V-6023-4104M	Capacitor, hi-temp .1 mfd 400 v.	Grid by-pass
C416	V-6023-4104M	Capacitor, hi-temp .1 mfd 400 v.	R-F by-pass
C417	V-6023-4104M	Capacitor, hi-temp .1 mfd 400 v.	Decoupling
C418	V-6023-4103M	Capacitor, hi-temp .01 mfd 400 v.	Horizontal coupling
C419	RCM20B681M	Capacitor, 680 mmf	Horizontal discharge
C420	RCM20B271K	Capacitor, 270 mmf	Grid by-pass
*C421	V-9577 assy	Capacitor, electrolytic 20 mfd 400 v. (assy consists of C421, C302, C417 and C238)	Decoupling
C422	V-6023-4104M	Capacitor, hi-temp .1 mfd 400 v.	Horiz. output coupling
C423	V-6023-4104M	Capacitor, hi-temp .1 mfd 400 v.	Cathode by-pass
C424	V-6023-4104M	Capacitor, hi-temp .1 mfd 400 v.	Decoupling
C425	V-6023-4103K	Capacitor, hi-temp .01 mfd 400 v.	Vertical mv coupling
C426	V-6023-4104M	Capacitor, hi-temp .1 mfd 400 v.	Vertical coupling
C427	V-6023-4104M	Capacitor, hi-temp .1 mfd 400 v.	Grid by-pass
C428	V-6023-4503M	Capacitor, hi-temp .05 mfd 400 v.	Cathode by-pass
C429	V-6023-4683K	Capacitor, hi-temp .068 mfd 400 v.	Vertical discharge
C430	V-6066-4254M	Capacitor, .25 mfd 400 v.	Plate by-pass
C431	V-6023-4104M	Capacitor, hi-temp .1 mfd 400 v.	HV osc. decoupling
C432	V-6023-4104M	Capacitor, hi-temp .1 mfd 400 v.	Vertical mv decoupling
*C433	V-9575 assy	Capacitor, electrolytic, 20 mfd 450 v. (assy consists of C501, C502 and C433)	Filter
C434	V-9009-1	Capacitor, electrolytic 150 mfd 50 v.	Cathode by-pass
C435	V-6570	Capacitor, electrolytic 30 mfd 450 v.	Filter
C436	V-9792-15560K	Capacitor, 56 mmf	Transient by-pass
C440	V-5596	Capacitor, hi-kap .005 mfd	Filament by-pass
C441	RCM30C392K	Capacitor, 3900 mmf	Horiz. mv plate tank
C442	RCM20B681K	Capacitor, 680 mmf	Cathode by-pass
L401	V-6764	Coil	Horizontal ringing
L402	V-9590-3	Coil	Focus
L403	V-9230-2	Choke	Horizontal feed
L404	V-9099-1	Choke	Filament
L405	V-9099-1	Choke	Filament
L406	V-9099-1	Choke	Filament
L407	V-9099-1	Choke	Filament
L408	V-9099-2	Choke	Filament
R401	RC20AE223K	Resistor, 22,000 ohms ½ w.	Plate load
R402	RC20AE225K	Resistor, 2.2 megohms ½ w.	Diode load
R403	RC20AE105K	Resistor, 1 megohm ½ w.	Voltage divider
R404	RC30AE224K	Resistor, 220,000 ohms 1 w.	Limiting
R405	RC30AE224K	Resistor, 220,000 ohms 1 w.	Limiting
R406	RC20AE683K	Resistor, 68,000 ohms ½ w.	Phase reference
R407	RC20AE104J	Resistor, 100,000 ohms ½ w.	AFC diode load
R408	RC20AE474K	Resistor, 470,000 ohms ½ w.	AFC delay
R409	RC20AE104J	Resistor, 100,000 ohms ½ w.	AFC diode load
R410	RC20AE475M	Resistor, 4.7 megohms ½ w.	Grid return
R411	RC20AE182K	Resistor, 1800 ohms ½ w.	Cathode bias
*R412	V-9233 assy	Control, 100,000 ohms (assy consists of R412 and R434)	Horizontal hold
R413	RC20AE224J	Resistor, 220,000 ohms ½ w.	Grid return
R414	RC20AE562K	Resistor, 5600 ohms ½ w.	Plate load
R415	RC30AE333K	Resistor, 33,000 ohms 1 w.	Decoupling
R416	RC20AE474K	Resistor, 470,000 ohms ½ w.	Charge limiting
R417	RC20AE154K	Resistor, 150,000 ohms ½ w.	Plate load
R418	RC20AE272K	Resistor, 2700 ohms ½ w.	Plate load
R419	RC20AE223K	Resistor, 22,000 ohms ½ w.	DC divider
R420	RC20AE105K	Resistor, 1 megohm ½ w.	Grid return
R421	RC20AE272K	Resistor, 2700 ohms ½ w.	Limiting
R422	RC20AE471K	Resistor, 470 ohms ½ w.	Cathode bias
R423	V-6500-2	Control, 5000 ohms	Width
R424	RC30AE333K	Resistor, 33,000 ohms 1 w.	Decoupling
R425	RC20AE224K	Resistor, 220,000 ohms ½ w.	Horiz. mv plate load
R426	RC20AE273K	Resistor, 27,000 ohms ½ w.	Horizontal discharge
R427	RC20AE104K	Resistor, 100,000 ohms ½ w.	Grid return
R428	V-6067-4	Resistor, glasohm, 150 ohms 3 w.	Cathode bias
R429	RC20AE101K	Resistor, 100 ohms ½ w.	Parasitic suppressor
R430	RC20AE101K	Resistor, 100 ohms ½ w.	Parasitic suppressor
R431	V-5909	Control, 2.5 megohms	Height mag.
R432	V-5910	Control, 2500 ohms	Vertical linearity
R433	RC20AE104K	Resistor, 100,000 ohms ½ w.	Plate load
*R434	V-9233 assy	Control, 500,000 ohms (assy consists of R412 and R434)	Vertical hold
R435	RC20AE474K	Resistor, 470,000 ohms ½ w.	Grid return
R436	RC20AE394J	Resistor, 390,000 ohms ½ w.	Plate load
R437	V-6462	Control, 1 megohm	Height
R438	RC20AE102K	Resistor, 1000 ohms ½ w.	Cathode bias
R439	RC20AE473K	Resistor, 47,000 ohms ½ w.	Plate decoupling
R440	V-6984-1	Resistor, 2000 ohms 5 w. w.w.	Plate load
R441	V-6984-6	Resistor, 560 ohms 5 w. w.w.	Decoupling
R442	V-4758	Resistor, 110 ohms 3 w.	Focus coil shunt
R443	V-6984-5	Resistor, 10,000 ohms 5 w. w.w.	Screen dropping
R444	V-5908	Control, 400 ohms	Focus
R445	RC20AE225K	Resistor, 2.2 megohms ½ w.	Grid return
R446	RC30AE471K	Resistor, 470 ohms 1 w.	Cathode bias
R447	RC20AE472K	Resistor, 4700 ohms ½ w.	Vertical discharge
R448	V-6463	Control, 5000 ohms	Vertical linearity
R449	RC30AE471K	Resistor, 470 ohms 1 w.	Plate decoupling
R450	RC20AE561K	Resistor, 560 ohms ½ w.	Transient damping
R451	RC20AE561K	Resistor, 560 ohms ½ w.	Transient damping
R452	V-9085-5	Resistor, 680 ohms 10 w.	Current limiting
R453	RC40AE102K	Resistor, 1000 ohms 2 w.	Focus shunt
R460	RC20AE105K	Resistor, 1 megohm ½ w.	Grid return
*SW401	V-9607-2 assy	Switch, (assy consists of R201 and SW401 and SW501)	Magnifier
T401	V-6481-2	Transformer	Filament
T402	V-9584-1	Transformer	Vertical output
Z401	V-9213	Filter	Integrating
Z402	V-6486-4	Yoke assembly	Deflection

Section 5—Power

Item	Part No.	Description	Function
*C501	V-9575 assy	Capacitor, electrolytic 60 mfd 400 v. (assy consists of C501, C502 and C433)	Filter
*C502	V-9575 assy	Capacitor, electrolytic 20 mfd 400 v. (assy consists of C501, C502 and C433)	Filter
C505	V-6023-4503M	Capacitor, hi-temp .05 mfd 400 v.	Screen by-pass
C506	V-6023-4503M	Capacitor, hi-temp .05 mfd 400 v.	Screen by-pass
C507	V-6454	Capacitor	Hi-volt osc. trimmer
C508	RCM20B271K	Capacitor, 270 mmf	Osc. feed back
C509	V-5895	Capacitor, 500 mmf	Hi-volt filter
C510	V-5895	Capacitor, 500 mmf	Hi-volt filter
L501	V-6471	Choke	Filter
L502	V-9279-1	Choke, R-F	HV osc. load
R502	RC41AE333K	Resistor, 33,000 ohms 2 w.	Screen drop
R503	RC20AE680K	Resistor, 68 ohms ½ w.	Grid bias
R504	RC20AE683K	Resistor, 68,000 ohms ½ w.	Plate decoupling
R505	RC20AE104K	Resistor, 100,000 ohms ½ w.	Hi-volt filter
*SW501	V-9607-2 assy	Switch, on-off (assy consists of SW501, R201, and SW401)	
T501	V-6988	Transformer	Power L. V.
T502	V-9278	Transformer	Hi-voltage R-F

*Sold only as complete assembly.

HIGH VOLTAGE WARNING

The danger accompanying shock is always present when the receiver is operated outside the cabinet or when the rear cover is removed from the cabinet. Only a person familiar with the precautions to be observed when working with high-voltage equipment should service this receiver.

CATHODE RAY TUBE HANDLING PRECAUTIONS

Shatterproof goggles and heavy gloves should be worn at all times when handling the cathode ray tube. The tube should not be handled in the vicinity of any person not so equipped. When handling the cathode ray tube, always keep it away from the body.

The cathode ray tube bulb, due to its large surface area and high vacuum contained within, is subjected to high air pressure. More than ordinary care is required to prevent shattering the tube. The large end of the bulb, particularly the rim of the viewing surface, must not be struck, scratched, or subjected to more than moderate pressure at any time. If the tube sticks or fails to slip smoothly into place during installation, remove the tube and determine the cause of the trouble.—DO NOT FORCE THE TUBE.

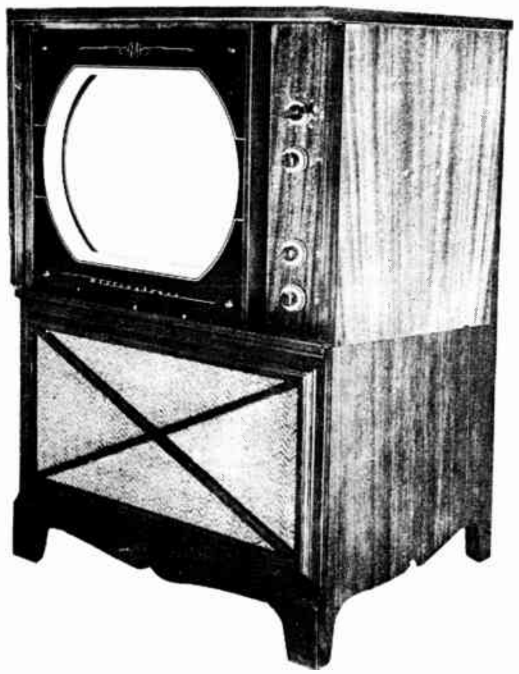
INDEX



SPECIFICATIONS

FREQUENCY RANGES:

Channel Number	Channel Frequency (mc.)	Video Carrier Frequency (mc.)	Audio Carrier Frequency (mc.)	Receiver H-F Oscillator Frequency (mc.)
1	not used	--	--	--
2	54 - 60	55.25	59.75	81.35
3	60 - 66	61.25	65.75	87.35
4	66 - 72	67.25	71.75	93.35
5	76 - 82	77.25	81.75	103.35
6	82 - 88	83.25	87.75	109.35
7	174 - 180	175.25	179.75	201.35
8	180 - 186	181.25	185.75	207.35
9	186 - 192	187.25	191.75	213.35
10	192 - 198	193.25	197.75	219.35
11	198 - 204	199.25	203.75	225.35
12	204 - 210	205.25	209.75	231.35
13	210 - 216	211.25	215.75	237.35

FINE TUNING RANGE:

Plus or minus 1 mc. on Channel 2 (minimum)
Plus or minus 2 mc. on Channel 13 (maximum)

OPERATING VOLTAGE:

105 to 120 volts, 60 cycles

POWER CONSUMPTION: .... 275 watts

AUDIO POWER OUTPUT:

Undistorted .... 1.5 watts
Maximum .... 2.5 watts

LOUDSPEAKER:

Type .... 12" P.M.
Voice Coil Impedance-3.2 ohms at 400 cycles

RECEIVER ANTENNA INPUT IMPEDANCE:

... 300 ohms balanced or 72 ohms unbalanced

TUBE COMPLEMENT:

1 1B3GT .... High Voltage Rectifier

HIGH VOLTAGE WARNING

The danger accompanying shock is always present when the receiver is operated outside the cabinet or when the rear cover is removed from the cabinet. Only a person familiar with the precautions to be observed when working with high-voltage equipment should service this receiver.

CATHODE RAY TUBE HANDLING PRECAUTIONS

Shatterproof goggles and heavy gloves should be worn at all times when handling the cathode ray tube. The tube should not be handled in the vicinity of any person not so equipped. When handling the cathode ray tube, always keep it away from the body.

The cathode ray tube bulb, due to its large surface area and high vacuum contained within, is subjected to high air pressure. More than ordinary care is required to prevent shattering the tube. The large end of the bulb, particularly the rim of the viewing surface, must not be struck, scratched, or subjected to more than moderate pressure at any time. If the tube sticks or fails to slip smoothly into place during installation, remove the tube and determine the cause of the trouble - - DO NOT FORCE THE TUBE.

World Radio History

INSTALLATION INSTRUCTIONS

TO PREPARE THE RECEIVER FOR OPERATION:

1. Remove the screws that hold the rear cover to the cabinet, and remove the rear cover by pulling it away from the cabinet.

2. Inspect the face of the CRT and the glass window for dust or smudges. If the face of the CRT or the inside of the glass window is smudged, it will be necessary to remove the front glass to clean the smudged surfaces. In this event, refer to REMOVAL OF FRONT GLASS FOR CLEANING.

3. If the control shafts and CRT face are not properly aligned with the holes in the front of the cabinet, loosen the two hex-head bolts on the under side of the chassis shelf and adjust the position of the chassis accordingly. Then re-tighten the two hex-head bolts.

4. Make certain that all tubes are secure in their sockets.

5. Connect the A-C plug to a 105 to 120 volt, 60 cycles A-C, power outlet, and adjust the ion trap magnet as outlined under ADJUSTMENTS.

6. Model H-613K16 contains a built-in antenna for use in areas of normal reception. In such areas when the built-in antenna provides good reception, no additional antenna connections are required. However, in weak signal areas or under adverse conditions, it may be necessary to use an external antenna. If an external antenna is to be used, the built-in antenna should be disconnected from the antenna terminals on the back of the chassis, and the lugs of the built-in antenna should be insulated and dressed in such a position that they do not touch the chassis or components.

7. Replace the rear cover.

8. If an outside antenna is to be used, connect the lead-in to the antenna terminals on the back of the set.

TO CHECK THE OPERATION OF THE RECEIVER:

1. Rotate the volume, brightness, and contrast controls completely counterclockwise.

2. Turn on the receiver by rotating the off-on-tone control clockwise.

3. Rotate the channel selector to the channel number of the desired station.

4. Rotate the brightness control clockwise until light becomes barely visible on the picture screen.

5. Rotate the contrast control clockwise until a picture appears on the screen.

6. If the built-in antenna is in use, adjust the television antenna control for maximum picture contrast. If an external antenna is in use, this step is not required.

7. If the picture is moving up or down or quivering adjust the vertical hold control to stabilize the image.

8. If vertical or diagonal bars or a folded over picture appears on the screen, adjust the horizontal hold control to obtain a stable picture.

9. Adjust the fine tuning control for best picture detail.

10. Readjust the brightness and contrast controls until pleasing shades ranging from clear white to intense black are attained.

11. Adjust the volume control for the desired sound volume.

12. If necessary, adjust the height, width, vertical linearity, and focus controls as explained under ADJUSTMENTS.

13. Check the operation on all available television stations. Note that if the built-in antenna is in use, the television antenna control must be readjusted for maximum picture contrast each time the receiver is tuned to a different channel.

ADJUSTMENTS

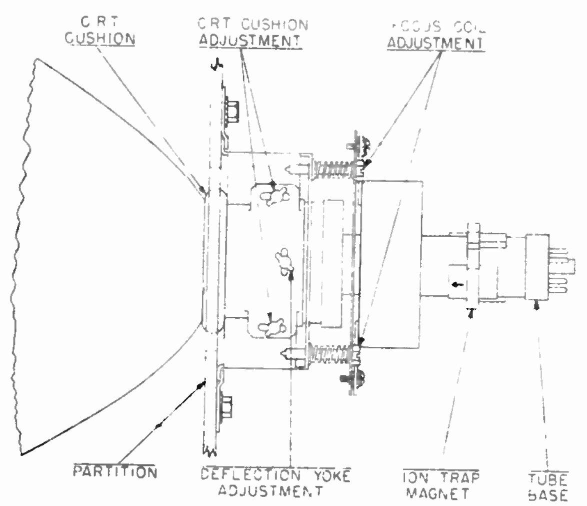

FIG. 1 — CRT ADJUSTMENTS

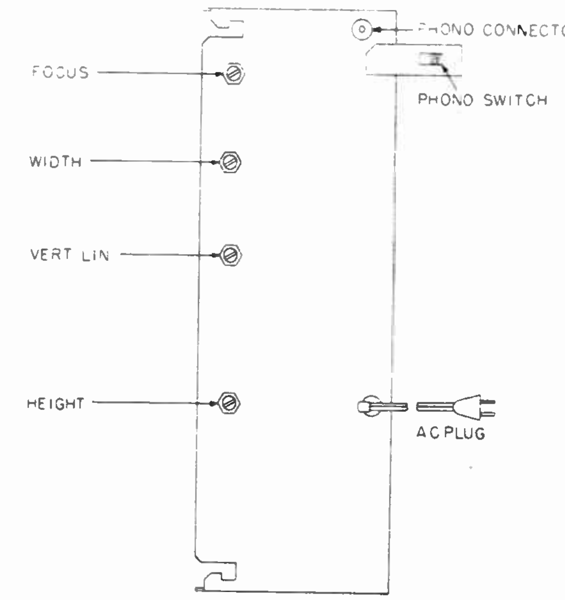

FIG. 2 — ADJUSTMENTS ON REAR OF CHASSIS

The picture adjustments are located on the rear of the chassis and are accessible through cut-outs in the back cover.

An insulated, long shank screwdriver is preferred for making the ringing coil and H.V. oscillator adjustments.

ION TRAP MAGNET

The magnet should be oriented approximately as shown in Fig. 1 with the arrow on the magnet pointing toward the large end of the CRT and the bar magnets lined up with the "flags" inside the neck of the cathode ray tube. Starting from this position, adjust the magnet by rotating it around the neck of the tube and moving it forward and backward until the raster is brightest on the screen.

CAUTION: When adjusting the ion trap magnet, care should be exercised to avoid breaking the neck of the cathode ray tube.

FOCUS COIL

If a shadow falls on one corner of the picture or if the picture is not centered, adjustment of the focus coil is required.

A coarse adjustment is made by loosening the two hex-head bolts that secure the focus coil to its mounting plate and shifting the position of the coil around the neck of the tube until the picture is centered and there are no shadowed edges. Re-adjustment of the ion trap magnet may be required to obtain these conditions.

A fine adjustment of picture centering is made by adjusting the three bolts marked FOCUS COIL ADJUSTMENT on Fig. 1.

CATHODE RAY TUBE CUSHION

The cushion must fit snugly against the flare of the cathode ray tube in order that the rear of the tube will be supported firmly.

DEFLECTION YOKE

This adjustment controls the angle of the picture with respect to the horizontal. If the picture is not squared in the picture mask, loosen the wing nut and move it to the left or right so as to rotate the deflection yoke. The picture will tilt to the left or right with the deflection yoke rotation.

FOCUS CONTROL

The focus control (Fig. 2) should be adjusted with the brightness and contrast controls in their normal positions. If correct focusing cannot be obtained, the high voltage oscillator may require adjustment.

HEIGHT AND VERTICAL LINEARITY

The height adjustment controls the overall height of the picture, while the vertical linearity adjustment governs contraction or expansion of the upper portion only. For this reason, a balance between the two controls

©John F. Rider

World Radio History

is necessary to make the picture symmetrical and fill the mask vertically.

WIDTH

Adjust the width control (Fig. 2) until the picture fills the mask horizontally.

HORIZONTAL RINGING COIL

To adjust the horizontal ringing coil:

1. Tune in the weakest station in your area.

2. Set the horizontal hold control at approximately the center of its range.

3. Adjust the ringing coil (L403), which is accessible through a hold in the bottom of the cabinet, until the picture is properly "locked-in".

HIGH VOLTAGE OSCILLATOR

1. *Turn off the receiver* and disconnect the high voltage lead from the CRT.

2. Connect 18 one megohm, one watt resistors in series between the high voltage lead and the chassis.

3. Connect a kilovoltmeter across the 18 megohms of resistance.

4. Turn on the receiver and adjust C507 (location shown on Fig. 7) for maximum voltage indication on the meter. When C507 is peaked using an 18 megohm load, the voltage across the load should be 9.3 kilovolts (approximately).

5. *Turn off the receiver*, disconnect the kilovoltmeter, remove the 18 megohms of resistance, and connect the high voltage lead to the CRT. Note that when the 18 megohm load is removed and the high voltage lead is connected to the CRT, the output voltage of the H.V. power supply will rise because of the higher load resistance offered by the CRT.

REMOVAL OF FRONT GLASS FOR CLEANING

If it is necessary to clean dust or smudges off the face of the CRT or the inside of the front glass plate, the front glass plate can be removed from the front of the cabinet. To remove the glass, first remove the four screws from the corners of the glass plate, and then carefully lift out the glass plate and CRT mask assembly.

CATHODE RAY TUBE REPLACEMENT

1. Remove the screws that hold the rear cover to the cabinet, and remove the rear cover.

2. Remove the CRT socket, ion trap magnet, and high voltage anode connector from the CRT.

3. Loosen the two wing bolts that secure the deflection yoke assembly.

4. Remove the four screws from the corners of the front glass plate, and carefully lift out the front glass plate and the CRT mask assembly.

5. Remove the four hex-head bolts that secure the CRT mounting strap to the front bulkhead.

6. Grasp the CRT and mounting strap securely from the front of the cabinet, and remove the CRT by pulling it straight out.

7. Remove the mounting strap from the CRT, and replace it in exactly the same position on the replacement CRT. The strap must be replaced in the same position to provide correct orientation of the high voltage anode contact.

8. Insert the replacement CRT through the yoke and focus coil assemblies, and replace the four washers and bolts that secure the mounting strap to the forward mounting bulkhead.

9. Replace the front glass plate and CRT mask assembly, and replace the four screws in the corners of the glass.

10. Position the deflection yoke assembly snugly against the flare of the CRT, and tighten the two wing bolts that secure the yoke assembly.

11. Replace the ion trap magnet, CRT socket, and high voltage anode connector.

12. Adjust the focus coil and ion trap magnet as described under ADJUSTMENTS.

13. Replace the rear cover.

CHASSIS REMOVAL

To remove the chassis from the cabinet:

1. Remove the control knobs from the front of the cabinet.

2. Remove the wood screws that hold the rear cover to the cabinet, and remove the rear cover.

3. Disconnect the built-in antenna feeder from the antenna terminals, and release the antenna terminal bracket from the cabinet by removing the two screws that hold it in place.

4. Loosen the bracket at the top (inside) of the cabinet by removing the two screws that secure it to the top of the cabinet.

5. Disconnect the CRT socket from the base of the CRT, the deflection yoke plug from its socket on the chassis, the ground lead from the yoke assembly, the speaker leads from the speaker, and the H.V. connector from the CRT high voltage contact.

6. Remove the hex-head chassis bolts from the under side of the chassis shelf.

7. Remove the chassis by pushing it to the left of the cabinet and then pulling it straight back until clear of the cabinet.

ALIGNMENT

TEST EQUIPMENT—To properly service this chassis, the following test equipment should be available:

1. R-F sweep generator which meets the following requirements:

a. Frequency range from 18 to 30 mc. with a sweep width of 10 mc.

b. Output adjustable with at least 100,000 microvolts maximum and a very low minimum.

c. Output "flat" on all attenuator positions.

2. Cathode-ray oscilloscope, preferably one with a wide band vertical deflection amplifier and a low-capacitance input probe.

3. Signal generator capable of providing output frequencies listed below.

21.6 mc.	4th I-F trap
22.6 mc.	1st I-F
25.9 mc.	2nd I-F
25.6 mc.	3rd I-F
24.7 mc.	4th I-F
23.0 mc.	5th I-F
4.5 mc.	Audio I-F and ratio detector (the frequency must be extremely accurate, preferably crystal controlled.)

NOTE—The R-F output level on all the above frequencies should be adjustable with at least 100,000 microvolts maximum and a very low minimum.

4. Heterodyne frequency meter with crystal calibrator (if the signal generator does not include a crystal calibrator).

5. Electronic voltmeter (vacuum tube voltmeter), with a high voltage multiplier probe for measurements up to 15,000 volts and an R-F probe for measuring R-F voltages.

GENERAL INFORMATION—All test equipment and the chassis should be bonded together by short lengths of heavy (½ inch) braided copper ribbon. The interconnecting leads should be shielded (72 ohms coaxial cable) and should be as short as possible consistent with ease of making connections. The effectiveness of the bonding can be checked during alignment by placing the hand on the metal chassis or test equipment case. If the response pattern or meter reading changes visibly, the bonding must be improved before the circuits are aligned.

COMMON I-F ALIGNMENT PROCEDURE

If a common I-F transformer is replaced or, for any other reason, is badly out of adjustment, it is advisable to turn the slug out (counterclockwise) as far as possible before beginning alignment. Then starting from this position, turn the slug in a clockwise direction until the *first* peak is reached. This procedure is recommended to obtain the correct peak rather than an undesired second peak which is sometimes obtained when the slug is turned clockwise past the first peak.

The common I-F alignment procedure is as follows:

1. Rotate the channel selector to the position where the flat of the shaft is parallel with the top of the tuner, thus selecting channel 13. Remove the 6AK5 R-F amplifier tube from its socket to avoid

©John F. Rider

World Radio History

undesirable noise pickup and beat response during alignment.

2. Connect the signal generator to the mixer tube through the coupling device shown in Fig. 3. The device is constructed by squeezing together a miniature tube shield until it fits the tube snugly and does not ground to the chassis. A .005 mfd capacitor is then soldered to the side of the shield. By sliding the tube shield up or down on the tube, the capacitance between the shield and the tube elements can be varied to obtain additional control of the coupling over that provided by the attenuator in the generator itself. The ground side of the generator output cable should be connected to the receiver chassis.

3. Connect a vacuum tube voltmeter to the video test jack on the receiver chassis, and set the meter to its 5 volt scale.

4. Set the signal generator to 21.6 mc. (unmodulated), and adjust T305 for *minimum* voltage on the VTVM. Use a strong signal for this adjustment.

5. Set the signal generator to 22.6 mc. (unmodulated), and adjust L110 for maximum voltage on the VTVM. *During this adjustment, keep the signal generator output adjusted so that the VTVM reading does not exceed 2 volts.*

6. Set the signal generator to 25.9 mc. (unmodulated), and adjust T301 for maximum voltage on the VTVM. *During this adjustment, keep the signal generator output adjusted so that the VTVM reading does not exceed 2 volts.*

7. Set the signal generator to 25.6 mc. (unmodulated), and adjust T302 for maximum voltage on the VTVM. *During this adjustment, keep the signal generator output adjusted so that the VTVM reading does not exceed 2 volts.*

8. Set the signal generator to 24.7 mc. (unmodulated), and adjust T303 for maximum voltage on the VTVM. *During this adjustment, keep the signal generator output adjusted so that the VTVM reading does not exceed 2 volts.*

9. Set the signal generator to 23.0 mc. (unmodulated), and adjust T304 for maximum voltage on the VTVM. *During this adjustment, keep the signal generator output adjusted so that the VTVM reading does not exceed 2 volts.*

10. Connect the *sweep* generator to the mixer tube through the coupling device previously described. The *signal* generator will be used in the following steps to provide marker indications at various frequencies on the response curve. In this application, the signal generator input to the set must be low in amplitude to avoid distorting the response curve. To reduce the signal generator input accordingly, the signal generator should be *loosely* coupled to the set by wrapping a few turns of insulated wire around the coupling capacitor "pigtail" and connecting the signal generator to this wire.

11. Connect the vertical input of the oscilloscope to the video test jack through the de-coupling network shown in Fig. 4. The oscilloscope horizontal input should be connected to the sweep output from the sweep generator; turn the sweep control on the oscilloscope to the "X" or "OFF" position.

12. Adjust the sweep generator for a center frequency of 25.3 mc. with a 10 mc. deviation. Adjust the sweep generator output until a setting is found where there is very little noise on the oscilloscope pattern.

The oscilloscope pattern obtained should be similar to that shown in Fig. 5. Use the signal generator as a marker to check at the frequencies indicated. If the pattern obtained is not similar to Fig. 5, L110, T301, T302, T303, and T304 should be re-adjusted to produce the correct pattern.

SOUND I-F AND 4.5 MC. TRAP ALIGNMENT PROCEDURE

1. Connect the "high" side of the signal generator to the video test jack through a .001 mfd capacitor, and ground the "low" side to the chassis.

2. Connect the vacuum tube voltmeter to the points indicated on the bottom view of the chassis, Fig. 7. The common lead should connect to point "C", and the "high" lead should connect to point "A". Set the meter on its 5 volt (-DC) scale.

3. Adjust the signal generator to 4.5 mc. (unmodulated). The accuracy of this frequency is very important. If a crystal controlled signal generator is not available, the frequency should be checked using a frequency meter with a crystal calibrator.

4. Adjust T201 and the primary of T202 for maximum voltage on the VTVM. *During this adjustment, keep the signal generator output adjusted so that the VTVM reading does not exceed 5 volts.*

5. Connect the common lead from the VTVM to point "A" (Fig. 7), and connect the "high" lead to point "B". Here it is important that the case and components of the VTVM are *not* grounded to the receiver chassis; otherwise, point "A" would be shorted to the chassis through the common lead.

6. Using the same signal generator amplitude and frequency as in step 4, adjust the secondary of T202 for *zero* voltage on the VTVM. As the adjustment is tuned through resonance, the voltage will rapidly change from one polarity to the opposite polarity. The point where the voltage is zero is the correct setting.

7. Connect the common lead from the VTVM to the chassis, and connect the *R-F probe* from the VTVM to the junction of C338 and R343. This point is shown as point "D" on on Fig. 7. *Note that this point is above ground and, therefore, the R-F probe must contain a blocking capacitor.*

8. Using a strong 4.5 mc. signal applied as in step 1, adjust Z301 for *minimum* indication on the meter.

H.F. OSCILLATOR ALIGNMENT PROCEDURE

If the 6J6 oscillator tube is replaced, the different inter-electrode capacity of the new tube may change the oscillator frequency enough to necessitate realignment of the oscillator.

Alignment of the oscillator on the high band is accomplished by adjusting the brass slug located adjacent to the vernier drive wheel on the front of the tuner. Alignment of the oscillator on the low band is accomplished by adjusting the brass slug on the lower front of the tuner. *A non-metallic screwdriver is required.*

The oscillator alignment procedure is as follows:

1. Set the fine tuning control at the middle of its range, and leave it in this position during the following adjustments.

2. Set the selector switch to the highest of the low-band (channels 2 through 6) stations operating in your vicinity.

3. Peak the low band adjustment slug for the best picture detail.

4. Set the selector switch to the highest of the high-band (channels 7 through 13) stations operating in your vicinity.

5. Peak the high band adjustment slug for best picture detail.

6. Check the previously made low band adjustment, and if the tuning has changed, repeat steps 2 and 3.

I-F ALIGNMENT CHART

Turn the channel selector to channel 13 to avoid undesirable beat response during alignment.

COMMON I-F SECTION

Couple the sweep and marker generators to the mixer tube as shown in Fig. 3.

Step	*Sweep Gen. Frequency*	*Marker Gen. Frequency*	*Remarks*	*Indicator Connection*	*Adjust*
1.	Not used	21.6 mc. unmodulated	Use a strong signal	Connect VTVM to video test jack	T305 for *minimum* voltage
2.	Not used	22.6 mc. unmodulated	Keep marker output adjusted so VTVM reading does not exceed 2 v.	Same as step 1	L110 for maximum voltage
3.	Not used	25.9 mc. unmodulated	Same as step 2	Same as step 1	T301 for maximum voltage
4.	Not used	25.6 mc. unmodulated	Same as step 2	Same as step 1	T302 for maximum voltage
5.	Not used	24.7 mc. unmodulated	Same as step 2	Same as step 1	T303 for maximum voltage
6.	Not used	23.0 mc. unmodulated	Same as step 2	Same as step 1	T304 for maximum voltage
7.	25.3 mc. with 10 mc. deviation	check at: 21.6 mc. 22.5 mc. 23.5 mc. 25.3 mc. 26.1 mc.	Keep sweep output high enough so that very little noise appears on the oscilloscope trace	Connect oscilloscope to video test jack. See Fig. 4.	If necessary, adjust L110, T301, T302, T303, and T304 to obtain correct response curve. See Fig. 5.

C316	V-5596	Capacitor, hi-kap .005 mfd	Cathode by-pass
C318	V-5596	Capacitor, hi-kap .005 mfd	I-F decoupling
C319	V-5596	Capacitor, hi-kap .005 mfd	AGC delay
C328	R5CC21ZY151M	Capacitor, 150 mmf	I-F coupling
C335	V-5596	Capacitor, hi-kap .005 mfd	Screen by-pass
C336	V-6023-4203M	Capacitor, hi-temp .02 mfd 400 v.	Coupling
C338	V-6066-4254M	Capacitor, .25 mfd 400 v.	CRT-coupling
*C339	V-9577 assy	Capacitor, electrolytic, 20 mfd 400 v. (assy consists of C354, C402, C339 and C301)	Decoupling
C340	V-6023-4104M	Capacitor, hi-temp .1 mfd 400 v.	Cathode by-pass
C341	R5CC26ZY152M	Capacitor, .0015 mmf	Screen by-pass
C342	V-6066-4254M	Capacitor, 25 mfd 400 v.	AGC filter
*C354	V-9577 assy	Capacitor, electrolytic 30 mfd 400 v. (assy consists of C354, C402, C339 and C301)	Filter
C355	V-5596	Capacitor, hi-kap .005 mfd	Cathode bias
L310	V-5902-4	Coil	Video peaking
L311	V-5902-5	Coil	Video peaking
L312	V-5902-1	Coil	Video peaking
*R301	V-9235-2 assy	Control, 1500 ohms (assy consists of R301 and R302)	Contrast
*R302	V-9235-2 assy	Control, 50,000 ohms (assy consists of R301 and R302)	Brightness
R306	RC20AE473K	Resistor, 47,000 ohms ½ w.	Cathode bias
R309	RC20AE101K	Resistor, 100 ohms ½ w.	Cathode bias
R310	RC20AE101K	Resistor, 100 ohms ½ w.	Cathode bias
R311	RC20AE121K	Resistor, 120 ohms ½ w.	Cathode bias
R312	RC20AE121K	Resistor, 120 ohms ½ w.	Cathode bias
R314	RC20AE272K	Resistor, 2700 ohms ½ w.	I-F decoupling
R316	RC20AE272K	Resistor, 2700 ohms ½ w.	I-F decoupling
R317	RC20AE472K	Resistor, 4700 ohms ½ w.	Grid return
R318	RC20AE472K	Resistor, 4700 ohms ½ w.	Grid return
R319	RC20AE472K	Resistor, 4700 ohms ½ w.	Plate load
R322	RC20AE103K	Resistor, 10,000 ohms ½ w.	AGC decoupling
R323	RC20AE103K	Resistor, 10,000 ohms ½ w.	AGC decoupling
R327	RC20AE472K	Resistor, 4700 ohms ½ w.	Grid return
R329	RC20AE104K	Resistor, 100,000 ohms ½ w.	AGC filter
R331	RC20AE123K	Resistor, 12,000 ohms ½ w.	Grid rdturn
R334	RC30AE224K	Resistor, 220,000 ohms 1 w.	Plate load
R336	RC20AE272K	Resistor, 2700 ohms ½ w.	I-F decoupling
R339	RC20AE153K	Resistor, 15,000 ohms ½ w.	Cathode bias
R340	RC20AE102M	Resistor, 1000 ohms ½ w.	I-F decoupling
R341	RC20AE822K	Resistor, 8200 ohms ½ w.	Grid return
R342	RC20AE473K	Resistor, 47,000 ohms ½ w.	Decoupling
R343	RC20AE104K	Resistor, 100,000 ohms ½ w.	Cathode bias
R344	RC20AE682K	Resistor, 6800 ohms ½ w.	Series brightness
R345	RC20AE104K	Resistor, 100,000 ohms ½ w.	Series brightness
R346	RC20AE105K	Resistor, 1 megohm ½ w.	Grid return
R347	RC20AE105K	Resistor, 1 megohm ½ w.	Cathode bias
R348	RC30AE362J	Resistor, 3600 ohms 1 w.	Decoupling
R349	RC20AE223K	Resistor, 22,000 ohms ½ w.	Plate load
R350	RC30AE683K	Resistor, 68,000 ohms 1 w.	Screen load
R351	RC20AE474K	Resistor, 470,000 ohms ½ w.	AGC divider
R352	RC20AE153K	Resistor, 15,000 ohms ½ w.	Screen load
R353	RC20AE104K	Resistor, 100,000 ohms ½ w.	AGC divider
T301	V-9586-1	Transformer	1st I-F
T302	V-9586-1	Transformer	2nd I-F
T303	V-9586-1	Transformer	3rd I-F
T304	V-9586-2	Transformer	4th I-F
T305	V-9592	Transformer	Sound trap
Z301	V-9591	4.5 mc trap	

Section 4—Sweep

Ref. No.	Part No.	Description	Function
C401	V-6023-4104M	Capacitor, hi-temp .1 mfd 400 v.	Horiz MV decoupling
*C402	V-9577 assy	Capacitor, electrolytic, 20 mfd 400 v. (assy consists of C354, C402, C339 and C301)	Filter
*C403	V-9575 assy	Capacitor, electrolytic, 20 mfd 450 v. (assy consists of C403, C501 and C502)	Filter
C404	V-9576-1	Capacitor, electrolytic, 150 mfd 50 v.	Cathode by-pass
C410	V-6023-6102M	Capacitor, hi-temp .001 mfd 600 v.	AFC coupling
C411	V-6023-6102M	Capacitor, hi-temp .001 mfd 600 v.	AFC coupling
C412	V-6023-4472M	Capacitor, hi-temp .0047 mfd 400 v.	AFC delay
C413	V-6023-6102M	Capacitor, hi-temp .001 mfd 600 v.	Pulse divider
C414	V-6023-4103M	Capacitor, hi-temp .01 mfd 400 v.	Vert sync coupling
C415	V-6023-4103M	Capacitor, hi-temp .01 mfd 400 v.	Horiz output coupling
C417	V-6023-4503M	Capacitor, hi-temp .05 mfd 400 v.	Cathode by-pass
C418	V-6023-4503M	Capacitor, hi-temp .05 mfd 400 v.	AFC delay

L415	V-9099-1	Choke, R-F	I-F filament
R401	V-9232	Control, 600 ohms	Focus
R402	V-6462	Control, 1 megohm	Height
R403	V-6463	Control, 5000 ohms	Vert linearity
*R404	V-9233 assy	Control, 100,000 ohms (assy consists of R405 and R404)	Horiz hold
*R405	V-9233 assy	Control, 500,000 ohms (assy consists of R405 and R404)	Vert hold
R406	V-6500-2	Control, 3000 ohms	Width
R407	RC20AE561K	Resistor, 560 ohms ½ w.	Transient damping
R408	RC20AE561K	Resistor, 560 ohms ½ w.	Transient damping
R409	RC40AE221K	Resistor, 220 ohms 2 w.	Plate load
R410	V-6984-5	Resistor, 10,000 ohms 5 w. w.w.	Screen load
R411	V-9600-3	Resistor, 7500 ohms 10 w. ww.	Plate load
R412	V-9002-4900K	Resistor, 90 ohms 2 w.	Focus coil shunt
R420	RC20AE471K	Resistor, 470 ohms ½ w.	Cathode bias
R421	RC20AE471K	Resistor, 470 ohms ½ w.	Decoupling
R423	RC20AE102K	Resistor, 1000 ohms ½ w.	Cathode bias
R424	RC20AE182K	Resistor, 1800 ohms ½ w.	Cathode bias
R427	RC20AE562K	Resistor, 5600 ohms ½ w.	Waveform correction
R428	RC20AE153K	Resistor, 15,000 ohms ½ w.	Plate load
R429	RC20AE562K	Resistor, 5600 ohms ½ w.	Plate load
R430	RC30AE333K	Resistor, 33,000 ohms 1 w.	MV decoupling
R431	RC20AE333K	Resistor, 33,000 ohms ½ w.	MV decoupling
R432	RC20AE273K	Resistor, 27,000 ohms ½ w.	Waveform correction
R433	RC20AE223K	Resistor, 22,000 ohms ½ w.	DC divider
R434	RC20AE473K	Resistor, 47,000 ohms ½ w.	Vert MV decoupling
R436	RC20AE683K	Resistor, 68,000 ohms ½ w.	Phase reference
R437	RC20AE104J	Resistor, 100,000 ohms ½ w.	AFC diode load
R438	RC20AE104J	Resistor, 100,000 ohms ½ w.	AFC diode load
R440	RC20AE104K	Resistor, 100,000 ohms ½ w.	Plate load
R441	RC20AE224J	Resistor, 220,000 ohms ½ w.	Grid return
R442	RC20AE394J	Resistor, 390,000 ohms ½ w.	Plate load
R443	RC20AE474K	Resistor, 470,000 ohms ½ w.	Charge limiting
R444	RC20AE474K	Resistor, 470,000 ohms ½ w.	Grid return
R445	RC20AE474K	Resistor, 470,000 ohms ½ w.	AFC delay
R446	RC20AE104K	Resistor, 100,000 ohms ½ w.	Grid return
R447	RC20AE105K	Resistor, 1 megohm ½ w.	Grid return
R449	RC20AE225K	Resistor, 2.2 megohms ½ w.	Grid return
R450	RC20AE475M	Resistor, 4.7 megohms ½ w.	Cathode bias
R451	RC20AE224K	Resistor, 220,000 ohms ½ w.	MV plate load
R453	RC30AE224K	Resistor, 220,000 ohms 1 w.	Error volt take off
R454	RC30AE224K	Resistor, 220,000 ohms 1 w.	Error volt take off
R456	V-6067-4	Resistor, glasohm, 150 ohms 3 w.	Cathode bias
R466	RC20AE103K	Resistor, 10,000 ohms ½ w.	Decoupling
R467	RC20AE105K	Resistor, 1 megohm ½ w.	Positive bias limiting
R468	RC20AE154K	Resistor, 150,000 ohms ½ w.	Plate load
R469	RC20AE225K	Resistor, 2.2 megohms ½ w.	Grid return
R470	RC20AE272K	Resistor, 2700 ohms ½ w.	Plate load
R471	RC20AE272K	Resistor, 2700 ohms ½ w.	Limiting
R472	RC20AE331K	Resistor, 330 ohms ½ w.	Cathode bias
R474	RC20AE225K	Resistor, 2.2 megohms ½ w.	Diode shunt
R475	RC20AE101K	Resistor, 100 ohms ½ w.	Parasitic suppressor
R476	RC20AE101K	Resistor, 100 ohms ½ w.	Parasitic suppressor
T401	V-9584-1	Transformer	Vert output
Z401	V-9213	Filter	Integrating
Z402	V-8298	Yoke assembly (complete)	Deflection

Section 5—Power

*C501	V-9575 assy	Capacitor, electrolytic, 60 mfd 450 v. (assy consists of C403, C501 and C502)	Filter
*C502	V-9575 assy	Capacitor, electrolytic, 20 mfd 450 v. (assy consists of C403, C501 and C502)	Filter
C505	V-6023-4503M	Capacitor, hi-temp .05 mfd 400 v.	Screen by-pass
C506	V-6023-4503M	Capacitor, hi-temp .05 mfd 400 v.	Plate decoupling
C507	V-6454	Capacitor	Osc. trimmer
C508	RCM20B271K	Capacitor, 270 mmf	Grid bias
C509	V-5895	Capacitor, 500 mmf	HV filter
L501	V-6471	Choke	Filter
L502	V-9279-1	Coil	R-F
R501	RC41AE333K	Resistor, 33,000 ohms 2 w.	Screen load
R502	RC20AE680K	Resistor, 68 ohms ½ w.	Plate decoupling
R503	RC20AE683K	Resistor, 68,000 ohms ½ w.	Grid return
R504	RC20AE104K	Resistor, 100,000 ohms ½ w.	HV filter
*SW501	V-9686-1 assy	Switch (assy consists of SW501, R200 and R201	On-off
T501	V-9595-1	Transformer	Power
T502	V-9278	Transformer	Hi-voltage

*Sold only as complete assembly.

SPECIFICATIONS

FREQUENCY RANGES:

Channel Number	*Channel Frequency (mc.)*	*Video Carrier Frequency (mc.)*	*Audio Carrier Frequency (mc.)*	*Receiver H-F Oscillator Frequency (mc.)*
1	not used	--	--	--
2	54 - 60	55.25	59.75	81.35
3	60 - 66	61.25	65.75	87.35
4	66 - 72	67.25	71.75	93.35
5	76 - 82	77.25	81.75	103.35
6	82 - 88	83.25	87.75	109.35
7	174 - 180	175.25	179.75	201.35
8	180 - 186	181.25	185.75	207.35
9	186 - 192	187.25	191.75	213.35
10	192 - 198	193.25	197.75	219.35
11	198 - 204	199.25	203.75	225.35
12	204 - 210	205.25	209.75	231.35
13	210 - 216	211.25	215.75	237.35

FINE TUNING RANGE:

1 mc. minimum; 2 mc. maximum

OPERATING VOLTAGE:

105 to 120 volts, 60 cycles.

POWER CONSUMPTION: .... 230 watts

AUDIO POWER OUTPUT:

Undistorted .... 1.5 watts
Maximum .... 3.5 watts

LOUDSPEAKER:

Type .... 4" E.M.
Voice Coil Impedance-3.2 ohms at 400 cycles

RECEIVER ANTENNA INPUT IMPEDANCE:

... 300 ohms balanced or 72 ohms unbalanced

TUBE COMPLEMENT:

2 1V2 .... High voltage rectifier
1 6AK5 .... R-F amplifier
1 6AL5 ... Video detector and noise clipper
1 6AL5 .... Ratio detector
1 6AL5 .... Horizontal AFC
1 6AQ5 .... Vertical output
1 6AU5GT .... Horizontal output
1 6AU6 .... Sound I-F amplifier
1 6AU6 .... Keyed AGC
1 6AV6 .... 1st. audio amplifier
1 6C4 .... Phase inverter
1 6CB6 .... Video output
1 6CB6 .... 1st. I-F amplifier
1 6CB6 .... 2nd. I-F amplifier
1 6CB6 .... 3rd. I-F amplifier
1 6J6 .... H-F oscillator and mixer
1 6K6GT .... Audio output
1 6W4GT or 6U4GT .... Horizontal damper
2 6W4GT or 6U4GT ... Low voltage rectifier
1 12AU7 .... Vertical multivibrator
1 12AU7 .... Horizontal multivibrator
1 12AT7 ..... Sync separator and amplifier
1 12LP4 or 12LP4A .... Cathode ray tube

VIDEO CARRIER INTERMEDIATE FREQUENCY: .... 26.1 mc.

VIDEO RESPONSE: .... 2.7 mc.

AUDIO CARRIER INTERMEDIATE FREQUENCY: .... 4.5 mc.

AUDIO DISCRIMINATOR BAND WIDTH:

(between peaks) .... 150 kc.

FOCUS: .... Magnetic

SWEEP DEFLECTION: .... Magnetic

SCANNING: .... Interlaced 525 line

HORIZONTAL SCANNING FREQUENCY: .... 15,750 CPS

VERTICAL SCANNING FREQUENCY: .... 60 CPS

FRAME FREQUENCY

(picture repetition rate): .... 30 CPS

HIGH VOLTAGE WARNING

The danger accompanying shock is always present when the receiver is operated outside the cabinet or when the rear cover is removed from the cabinet. Only a person familiar with the precautions to be observed when working with high-voltage equipment should service this receiver.

CATHODE RAY TUBE HANDLING PRECAUTIONS

Shatterproof goggles and heavy gloves should be worn at all times when handling the cathode ray tube. The tube should not be handled in the vicinity of any person not so equipped. When handling the cathode ray tube, always keep it away from the body.

The cathode ray tube bulb, due to its large surface area and high vacuum contained within, is subjected to high air pressure. More than ordinary care is required to prevent shattering the tube. The large end of the bulb, particularly the rim of the viewing surface, must not be struck, scratched, or subjected to more than moderate pressure at any time. If the tube sticks or fails to slip smoothly into place during installation, remove the tube and determine the cause of the trouble - - DO NOT FORCE THE TUBE.

INSTALLATION INSTRUCTIONS

TO PREPARE THE RECEIVER FOR OPERATION:

Models H-617T12 and H-619T12 are shipped in operating condition. There is no shipping material to be removed. Simply remove the receiver from its carton, and connect the A-C plug to a 105 to 120 volt 60 cycle A-C outlet.

However, it is desirable that the adjustment of the ion trap magnet be checked in order to obtain best performance from the receiver. A check of this adjustment will also avoid the possibility of C.R.T. damage resulting from prolonged operation with an incorrectly adjusted ion trap magnet. To check the adjustment, proceed as follows:

1. Remove the screws that secure the rear cover to the cabinet.

2. Remove the rear cover by pulling it straight out from the cabinet.

3. Apply power to the receiver.

4. Adjust the ion trap magnet as explained under ADJUSTMENTS.

These models contain a built-in antenna for use in areas of normal reception. In such areas when the built-in antenna provides good reception, no antenna connections are required. However, in weak signal areas or under adverse conditions, it may be necessary to use an external antenna. In this event, the antenna lead-in can be connected to the antenna terminals on the back of the receiver after disconnecting the built-in antenna wires that normally connect to these terminals. The lugs on the built-in antenna should then be insulated and dressed in such a position that they do not touch the chassis or components.

TO CHECK THE OPERATION OF THE RECEIVER:

1. Rotate the BRIGHTNESS and CONTRAST controls completely counterclockwise.

2. Turn on the receiver by rotating the OFF-ON-VOLUME control clockwise.

3. Rotate the CHANNEL SELECTOR to the channel number of the desired station.

4. Rotate the BRIGHTNESS control clockwise until the screen is well lighted.

5. Rotate the CONTRAST control clockwise until a picture appears on the screen.

6. If the built-in antenna is in use, adjust the TELEVISION ANTENNA control for maximum picture contrast. If an external antenna is in use, this step is not required.

7. If the picture is moving up or down or quivering, adjust the VERTICAL HOLD control to stabilize the image.

8. If horizontal or diagonal bars or a folded-over picture appears on the screen, adjust the HORIZONTAL HOLD control to obtain a clear picture.

9. Adjust the FINE TUNING control to the best picture detail.

10. Readjust the BRIGHTNESS and CONTRAST controls until pleasing shades ranging from clear white to intense black are attained.

11. Adjust the VOLUME control for the desired sound volume.

12. Check the operation on all available television stations. Note that if the built-in antenna is in use, the TELEVISION ANTENNA control must be readjusted for maximum picture contrast each time the receiver is tuned to a different channel.

13. If necessary, adjust the vertical linearity, height, width, and focus controls as explained under ADJUSTMENTS.

ADJUSTMENTS

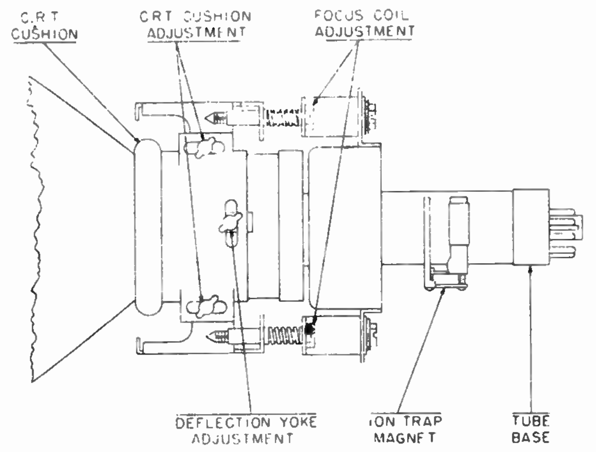

FIG. 1 — TOP VIEW OF C.R.T.

The picture adjustments are located on the rear of the chassis and are accessible through cut-outs in the back cover.

ION TRAP MAGNET

Caution: When adjusting the ion trap magnet, care must be exercised to avoid breaking the neck of the C.R.T.

The ion trap magnet must always be adjusted for maximum picture brightness. With the magnet oriented approximately as shown in Fig. 1, rotate it around the neck of the tube and move it forward and backward until the position is found where the brightest raster is obtained.

FOCUS COIL

If a shadow falls on one corner of the picture or if the picture is not properly centered, adjustment of the focus coil will be necessary. To adjust, loosen the short hex head bolts that lock the coil to the adapter plates, and move the coil horizontally and vertically until the position is found where the picture is properly centered and shadows are removed. Tighten the short hex head bolts to lock the coil in this position. Fine adjustment is provided by adjustment of the four hex head bolts at each corner of the focus coil.

If shadows cannot be removed completely, refer to ION TRAP MAGNET.

CATHODE RAY TUBE CUSHION

The cushion must fit snugly against the flare of the cathode ray tube in order that the rear of the tube will be supported firmly.

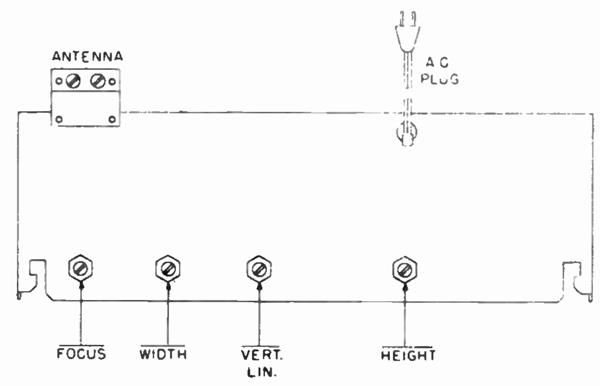

FIG. 2 — REAR VIEW OF CHASSIS

DEFLECTION YOKE

This adjustment controls the angle of the picture with respect to the horizontal. If the picture is not squared in the picture mask, loosen the wing nut and move it to the left or right so as to rotate the deflection yoke. The picture will tilt to the left or right with the deflection yoke rotation.

FOCUS CONTROL

The focus control (Fig. 2) should be adjusted with the brightness and contrast controls in their normal positions. If correct focusing cannot be obtained, the high voltage oscillator may require adjustment.

HEIGHT AND VERTICAL LINEARITY

The height adjustment controls the overall height of the picture, while the vertical linearity adjustment governs contraction or expansion of the upper portion only. For this reason, a balance between the two controls is necessary to make the picture symmetrical and fill the mask vertically.

WIDTH

The width control should be adjusted so that the picture fills the mask horizontally.

HORIZONTAL RINGING COIL

To adjust the horizontal ringing coil (L403), tune in the weakest station in the area, set the horizontal hold control at approximately the middle of its range, and adjust L403 (location shown on Fig. 7) until the picture is properly "locked-in".

World Radio History

ALIGNMENT

TEST EQUIPMENT—To properly service the chassis, the following test equipment should be available:

1. R-F sweep generator which meets the following requirements:

   a. Frequency range from 18 to 30 mc. with a sweep width of 10 mc.

   b. Output adjustable with at least 100,000 microvolts maximum and a very low minimum.

   c. Output "flat" on all attenuator positions.

2. Cathode-ray oscilloscope, preferably one with a wide band vertical deflection amplifier and a low-capacitance input probe.

3. Signal generator capable of providing output frequencies listed below.

   25.6 mc. 1st I-F
   24.1 mc. 2nd I-F
   23.6 mc. 3rd I-F
   24.7 mc. 4th I-F
   4.5 mc. Audio I-F and ratio detector (the frequency must be extremely accurate, preferably crystal controlled.)

NOTE: The R-F output level on all the above frequencies should be adjustable with at least 100,000 microvolts maximum and a very low minimum.

4. Heterodyne frequency meter with crystal calibrator (if the signal generator does not include a crystal calibrator).

5. Electronic voltmeter (vacuum tube voltmeter), with a high voltage multiplier probe for measurements up to 15,000 volts and an R-F probe for measuring R-F voltages.

GENERAL INFORMATION—All test equipment and the chassis should be bonded together by short lengths of heavy (¼ inch) braided copper ribbon. The interconnecting leads should be shielded (72 ohm coaxial cable) and should be as short as possible consistent with ease of making connections. The effectiveness of the bonding can be checked during alignment of placing the hand on the metal chassis or test equipment case. If the response pattern or meter reading changes visibly, the bonding must be improved before the circuits are aligned.

COMMON I-F ALIGNMENT PROCEDURE

If a common I-F transformer is replaced or, for any other reason, is badly out of adjustment, it is advisable to turn the slug out (counterclockwise) as far as possible before beginning alignment. Then starting from this position, turn the slug in a clockwise direction until the *first* peak is reached. This procedure is recommended to obtain the correct peak rather than an undesired second peak which is sometimes obtained when the slug is turned clockwise past the first peak.

The common I-F alignment procedure is as follows:

1. Rotate the channel selector to the position where the flat of the shaft is parallel with the top of the tuner, thus selecting channel 13. Remove the 6AK5 R-F amplifier tube from its socket to avoid undesirable beat response during alignment.

2. Connect the signal generator to the mixer tube through the coupling device shown in Fig. 3. The device is constructed by squeezing together a miniature tube shield until it fits the tube snugly and does not ground to the chassis. A .005 mfd capacitor is then soldered to the side of the shield. By sliding the tube shield up or down on the tube, the capacitance between the shield and the tube elements can be varied to obtain additional control of the coupling over that provided by the attenuator in the generator itself. The ground side of the generator output cable should be connected to the receiver chassis.

3. Connect a vacuum tube voltmeter to the video test jack on the receiver chassis, and set the meter to its 5 volt scale.

4. Set the signal generator to 25.6 mc. (unmodulated), and adjust L110 for maximum voltage on the VTVM. *During this adjustment, keep the signal generator output adjusted so that the VTVM reading does not exceed 2 volts.*

5. Set the signal generator to 24.1 mc. (unmodulated), and adjust T301 for maximum voltage on the VTVM. *During this adjustment, keep the signal generator output adjusted so that the VTVM reading does not exceed 2 volts.*

6. Set the signal generator to 23.6 mc. (unmodulated), and adjust T302 for maximum voltage on the VTVM. *During this adjustment, keep the signal generator output adjusted so that the VTVM reading does not exceed 2 volts.*

7. Set the signal generator 24.7 mc. (unmodulated), and adjust T303 for maximum voltage on the VTVM. *During this adjustment, keep the signal generator output adjusted so that the VTVM reading does not exceed 2 volts.*

8. Connect the *sweep* generator to the mixer tube through the coupling device previously described. The *signal* generator will be used in the following steps to provide marker indications at various frequencies on the response curve. In this application, the signal generator input to the set must be low in amplitude to avoid distorting the response curve. To reduce the signal generator input accordingly, the signal generator should be *loosely* coupled to the set by wrapping a few turns of insulated wire around the coupling capacitor "pigtail" and connecting the signal generator to this wire.

9. Connect the vertical input of the oscilloscope to the video test jack through the de-coupling network shown in Fig. 4. The oscilloscope horizontal input should be connected to the sweep output from the sweep generator; turn the sweep control on the oscilloscope to the "X" or "OFF" position.

10. Adjust the sweep generator for a center frequency of 25.3 mc. with a 10 mc. deviation. Adjust the sweep generator output until a setting is found where there is very little noise on the oscilloscope pattern.

The oscilloscope pattern obtained should be similar to that shown in Fig. 5. Use the signal generator as a marker to check at the frequencies indicated. If the pattern obtained is not similar to Fig. 5, L110, T301, T302 and T303 should be re-adjusted to produce the correct pattern.

SOUND I-F ALIGNMENT PROCEDURE

1. Connect the "high" side of the signal generator to the video test jack through a .001 mfd capacitor, and ground the "low" side to the chassis.

2. Connect the vacuum tube voltmeter to the points indicated on the bottom view of the chassis, Fig. 7. The common lead should connect to point "C", and the "high" lead should connect to point "A". Set the meter on its 5 volt (-DC) scale.

3. Adjust the signal generator to 4.5 mc. (unmodulated). The accuracy of this frequency is very important. If a crystal controlled signal generator is not available, the frequency should be checked using a frequency meter with a crystal calibrator.

4. Adjust primary and secondary slugs of T201 and primary of T202 for maximum voltage on the VTVM. During this adjustment, keep the signal generator output adjusted so that the VTVM reading does not exceed 5 volts. The primary adjustments are made from the bottom of the chassis while secondary adjustments are made from the top.

5. Connect the common lead from the VTVM to point "A" (Fig. 7), and connect the "high" lead to point "B". Here it is important that the case and components of the VTVM are *not* grounded to the receiver chassis; otherwise, point "A" would be shorted to the chassis through the common lead.

6. Using the same signal generator amplitude and frequency as in step 4, adjust the secondary of T202 for *zero* voltage on the VTVM. As the adjustment is tuned through resonance, the voltage will rapidly change from one polarity to the opposite polarity. The point where the voltage is zero is the correct setting.

H.F. OSCILLATOR ALIGNMENT PROCEDURE

If the 6J6 oscillator tube is replaced, the different inter-electrode capacity of the new tube may change the oscillator frequency enough to necessitate realignment of the oscillator.

Alignment of the oscillator on the high band is accomplished by adjusting the brass slug located adjacent to the vernier drive wheel on the front of the tuner. Alignment of the oscillator on the low band is accomplished by adjusting the brass slug on the lower front of the tuner. A *non-metallic screwdriver is required.*

The oscillator alignment procedure is as follows:

1. Set the fine tuning control at the middle of its range, and leave it in this position during the following adjustments.

2. Set the selector switch to the highest of the low-band (channels 2 through 6) stations operating in your vicinity.

3. Peak the low band adjustment slug for the best picture detail.

4. Set the selector switch to the highest of the high-band (channels 7 through 13) stations operating in your vicinity.

5. Peak the high band adjustment slug for best picture detail.

6. Check the previously made low band adjustment, and if the tuning has changed, repeat steps 2 and 3.

I-F ALIGNMENT CHART

Turn the channel selector to channel 13, and remove the 6AK5 R-F amplifier tube.

COMMON I-F SECTION

Couple the sweep and marker generators to the mixer tube as shown in Fig. 3.

Step	Sweep Gen. Frequency	Marker Gen. Frequency	Remarks	Indicator Connections	Adjust
1.	Not used	25.6 mc. unmodulated	Keep marker output adjusted so VTVM reading does not exceed 2 v.	Connect VTVM to video test jack	L110 for maximum voltage
2.	Not used	24.1 mc. unmodulated	Same as step 1	Same as step 1	T301 for maximum voltage
3.	Not used	23.6 mc. unmodulated	Same as step 1	Same as step 1	T302 for maximum voltage
4.	Not used	24.7 mc. unmodulated	Same as step 1	Same as step 1	T303 for maximum voltage
5.	25.3 mc. with 10 mc. deviation	Check at: 23.0 mc. 23.4 mc. 24.0 mc. 25.3 mc. 26.1 mc.	Keep sweep output high enough so that very little noise appears on the oscilloscope trace	Connect oscilloscope to video test jack. See Fig. 4.	If necessary, adjust L110, T301, T302 and T303 to obtain correct response curve. See Fig. 5.

SOUND I-F SECTION

Connect the signal generator to the video test jack through a .001 mfd mica capacitor.

Step	Signal Gen. Frequency	VTVM Connection	Remarks	Adjust
1.	4.5 mc. unmodulated	See Fig. 7. Common lead to point "C" and high lead to point "A".	Use 5 v. (−DC) scale on meter. Set sig. gen. output accordingly.	Pri. and sec. of T201 and pri. of T202 for maximum voltage
2.	4.5 mc. unmodulated	See Fig. 7. Common lead to point "A" and high lead to point "B".	Use same sig. gen. output as in step 1.	Sec. of T202 for *zero* voltage

R442	RC20AE225M	Resistor, 2.2 megohms ½ w.	Grid return
R443	RC20AE475M	Resistor, 4.7 megohms ½ w.	DC return
R444	RC20AE561K	Resistor, 560 ohms ½ w.	Transient damp.
R445	RC20AE561K	Resistor, 560 ohms ½ w.	Transient damp.
R446	RC40AE103K	Resistor, 10,000 ohms 2 w.	Cathode bias
R447	RC20AE222K	Resistor, 2200 ohms ½ w.	Limiting
R448	RC20AE471K	Resistor, 470 ohms ½ w.	Cathode bias
R449	RC20AE102M	Resistor, 1000 ohms ½ w.	Plate decoupling
R450	RC30AE334M	Resistor, 330,000 ohms 1 w.	Plate load
R451	V-9600-3	Resistor, 7500 ohms 10 w.	Plate load
R452	RC20AE225M	Resistor, 2.2 megohms ½ w.	Grid return
R453	V-9612-1	Control, 1000 ohms	Focus
R456	V-5134	Resistor, glasohm 190 ohms 3 w.	Focus coil shunt
R457	V-9612-1	Control, 1000 ohms	Width
R458	RC20AE474M	Resistor, 470,000 ohms ½ w.	AGC filter
R459	V-9002-4822K	Resistor, 8200 ohms 2 w.	Screen load
R461	RC30AE224K	Resistor, 220,000 ohms 1 w.	H. error take off
R463	RC20AE333K	Resistor, 33,000 ohms ½ w.	Mv. decoupling
T401	V-9584-1	Transformer	Vertical output
Z401	V-9213	Filter	Integrating
Z402	V-9210-2	Yoke assembly (complete)	Deflection

*Sold only as complete assembly.

Section 5—Power

Item	Part No.	Description	Function
*C501	V-6509 assy	Capacitor, electrolytic, 40 mfd 350 v. (assy consists of C501, C213, C402 and C441)	Filter
*C502	V-5891	Capacitor, electrolytic, 80 mfd 350 v. (assy consists of C502, C401, C417 and C302)	Filter
C503	V-9571-1	Capacitor, .001 mfd	Filter
C504	V-9571-1	Capacitor, .001 mfd	Filament by-pass
C505	V-9571-1	Capacitor, .001 mfd	Coupling
C506	RCP10W4104M	Capacitor, .1 mfd	RF by-pass
R501	V-9016-2514J	Resistor, 510,000 ohms ½ w.	Voltage doubler
R502	V-9016-2514J	Resistor, 510,000 ohms ½ w.	Voltage doubler
R503	RC20AE104M	Resistor, 100,000 ohms ½ w.	Filter
R504	V-6597	Resistor, 50 ohms 10 w.	Input filter
T501	V-9723	Transformer	Power
T502	V-9572-1	Transformer	High voltage
*SW501	V-6198-4 assy	Switch, on-off (assy consists of R201 and SW501)	

*Sold only as complete assembly.

When ordering parts, specify model number of set in addition to part number and description of part.

CHANGES IN V-2150-176 CHASSIS

In later production of the V-2150-176 chassis used in Models H-617T12 and H-619T12, the following changes are incorporated:

1. To reduce horizontal wobble under strong signal conditions and increase the contrast range, R437 (connected between pins 6 and 7 of the 6AU6 AGC tube) is 3300 ohms 1 watt (RC30AE332K) rather than 5600 ohms.

2. To improve horizontal linearity, C427 (horizontal discharge capacitor) is 330 mmf (RCM20C331K) rather than 680 mmf.

NOTE: The information given above under "CHANGES IN V-2150-176 CHASSIS" applies also to the V-2150-176U chassis.

HORIZONTAL DAMPING TUBE

The H-617T12 and H-619T12 service notes specify a type 6U4GT or 6W4GT as the horizontal damping tube. Only a 6U4GT tube should be used in this application, however, and all references to a 6W4GT as the horizontal damping tube should be deleted from the service notes.

MODEL H-619T12U — CHASSIS V-2150-176U AND V-2150-177U

The difference between the two chassis is in the use of different R-F amplifier tubes; the V-2150-176U chassis uses a 6AK5 while the V-2150-177U uses a 6AG5.

With the exception of parts that correspond in function or item number to the parts listed below, the H-617T12 and H-619T12 parts list applies to Model H-619T12U. When ordering parts for Model H-619T12U (V-2150-176U and V-2150-177U chassis), the following parts should be ordered in lieu of the corresponding parts listed in the H-617T12 and H-619T12 service notes.

Item	*Part No.*	*Description*
	V-5522	Cord, A-C power ....
	V-9805-1	Cover assembly, black ....
	V-9756-2	Mask, CRT (H-619T12 and H-619T12U)
R209	RC30AE471K	Resistor, 470 ohms, 1 w ....
T203	V-9814	Transformer, audio output ....
T301	V-9798	Transformer, video I-F ....
T302	V-9798	Transformer, video I-F ....
T303	V-9798	Transformer, video I-F ....
C443	RCP10W6202M	Capacitor, .002 mfd ....
C462	RCP10W4104M	Capacitor, 0.1 mfd ....
C463	V-5596	Capacitor, hi-kap, .005 mfd ......
R401	V-9813	Control, height (1 megohm) ....
R416	RC20AE152K	Resistor, 1500 ohms ½ w. ....
R417	RC20AE392K	Resistor, 3900 ohms ½ w. ....
R433	RC20AE334J	Resistor, 330,000 ohms ½ w. ....
R437	RC30AE332K	Resistor, 3300 ohms 1 w. ....
R439	RC30AE224K	Resistor, 220,000 ohms 1 w. ....
R447	RC20AE392K	Resistor, 3900 ohms ½ w. ....
R461	RC30AE104K	Resistor, 100,000 ohms 1 w. ....
R464	V-5924-2	Resistor, 10,000 ohms 10 w (used when V-9759 HV Trans., T502, is used) ....
R464	RC40AE183K	Resistor, 18000 ohms 2 w. (used when V-9803 HV Trans., T502, is used) ....
R505	RC30AE224K	Resistor, 220,000 ohms 1 w ....
*T502	V-9759	Transformer, high voltage ....

*Some chassis use a V-9803 HV transformer (T502) instead of a V-9759. Only the V-9759 HV transformer is stocked as a replacement. When replacing a V-9803 with a V-9759, refer to note 8 on the V-2150-176U and V-2150-177U chassis schematic.

CHANGES IN V-2150-176 CHASSIS

The schematic diagram, Fig. 8 in the original H-617T12 and H-619T12 service notes, should be altered to include later production changes as follows:

1. Add a fuse between the center tap of the power transformer (T501) and ground, and label the fuse F501.

2. Add a 510,000 ohm resistor in series with R501 and R502 in the H.V. power supply, and label the resistor R506. This reduces heating in the network.

3. Change the capacitance of C427 in the pin 6 plate circuit of the 12AU7 horizontal multivibrator to 330 mmf. This improves the horizontal linearity.

4. Change the resistance of R437 connected between pins 6 and 7 of the 6AU6 AGC tube to 3.3K. This reduces horizontal wobble under strong signal conditions and increases the contrast range.

5. Delete R333 located between the AGC line and ground, and change the resistance of R458 in the AGC line to 10K. These changes improve the signal to noise ratio at medium signal levels. *Note, however, that these changes are effective in medium or low signal areas only. If receiver overload occurs in strong signal areas, R333 should be re-inserted and R458 should be 470K as shown on the schematic.*

In accordance with the preceding information, the parts list in the original H-617T12 and H-619T12 service notes should be altered as follows:

1. Change R303 to read RC40AE472K Resistor, 4700 ohms 2 w.

2. Change C427 to read RCM20C331K Capacitor, 330 mmf

3. Change R437 to read RC30AE332K Resistor, 3300 ohms 1 w.

4. Add the following parts to the list:

R458	RC20AE103M	Resistor, 10,000 ohms ½ w. (see change #5)	$.05
F501	V-6171-4	Fuse, 0.5 amp. 250 v.	.20
R506	V-9016-2514J	Resistor, 510,000 ohms ½ w.	.11

CHANGES IN V-2150-176U AND V-2150-177U CHASSIS

The schematic diagram of the V-2150-176U and V-2150-177U chassis given in supplement #2 to the H-617T12 and H-619T12 service notes should be altered to include production changes as follows:

1. Add a fuse between the center tap of the power transformer (T501) and ground, and label the fuse F501.

2. Add a 680 mmf capacitor connected in parallel with R416 in the cathode circuit of the 12AU7 horizontal multivibrator, and label the capacitor C464.

3. Change the resistance of R463 in the plate supply circuit (pin 1) for the 12AU7 horizontal multivibrator to 47K. This along with the preceding change improves the horizontal sweep stability.

4. Delete R333 located between the AGC line and ground, and change the resistance of R458 in the AGC line to 10K. These changes improve the signal to noise ratio at medium signal levels. *Note, however, that these are effective in medium or low signal areas only. If receiver overload occurs in strong signal areas, R333 should be re-inserted and R458 should be 470K as shown on the schematic.*

In accordance with the preceding information, the following parts should be added to the parts list in supplement #2 to the H-617T12 and H-619T12 service notes:

C427	RCM20B681K	Capacitor, 680 mmf ...
C464	RCM20B681M	Capacitor, 680 mmf ...
R463	RC30AE473K	Resistor, 47,000 ohms 1 w. ....

World Radio History

INDEX

The 22H20/23H22/24H20-21 series of direct view TV receivers have many outstanding features. These include Remote Control, Turret Tuning with replaceable channel strips, main chassis construction using interchangeable sub-chassis and provision for easy addition of Phonevision.

In addition, provisions are made for reception, under present standards, of the new ultra high frequencies by the simple addition of ultra high frequency channel strips as required.

For the convenience of the serviceman, a built-in oscillator adjustment wrench and easily accessible test points are provided for use during alignment and test of the receiver.

Zenith television receivers are being manufactured with the new Glare-Ban "Black" tubes. These tubes are constructed with a special glass containing certain metallic oxides which reduce halations and provide much better contrast.

The etched surface on the picture tube face coupled with the precise tilt of the protective glass, virtually eliminates undesirable reflections from windows, room lights, etc.

On those receivers equipped with the Remote Control Unit, station selection can be made with ease from any point in the room within reach of the 17-foot extension cable.

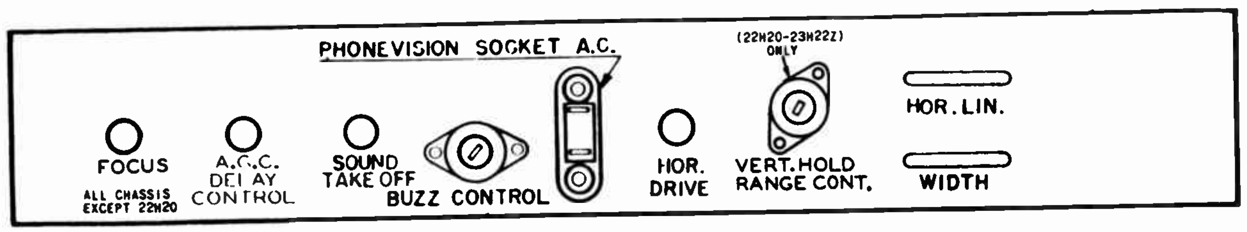
*All model numbers with the suffix letter "Q" identify receivers equipped with the S17268 Remote Control Unit.

Power Consumption: 22H-Series 225 Watts; 23H-Series 250 Watts; 24H-Series 275 Watts

Antenna Impedance - 300 Ohms

Power Supply - 110 V 60 Cycles AC
Audio Output-TV Undistorted 1.8 Watts
Maximum 3.2 Watts



CONTROLS AT REAR OF CHASSIS

CONTROLS AND FUNCTIONS

Location of the various receiver controls is shown in Fig. 2 After the receiver has been properly adjusted, the serviceman should remove the Horizontal Hold, Brightness, Fine Tuning, Vertical Hold, and Contrast Control knobs and re-position them so that the white dot stamped on the outer edge of each knob faces upward. (As in Fig. 2). The positioning of the knobs will aid the customer in resetting the controls should they be accidentally moved. A brief description of each control follows:

CHANNEL SELECTOR SWITCH: Switches into operating position the pre-tuned RF strip for reception of the particular channel desired.

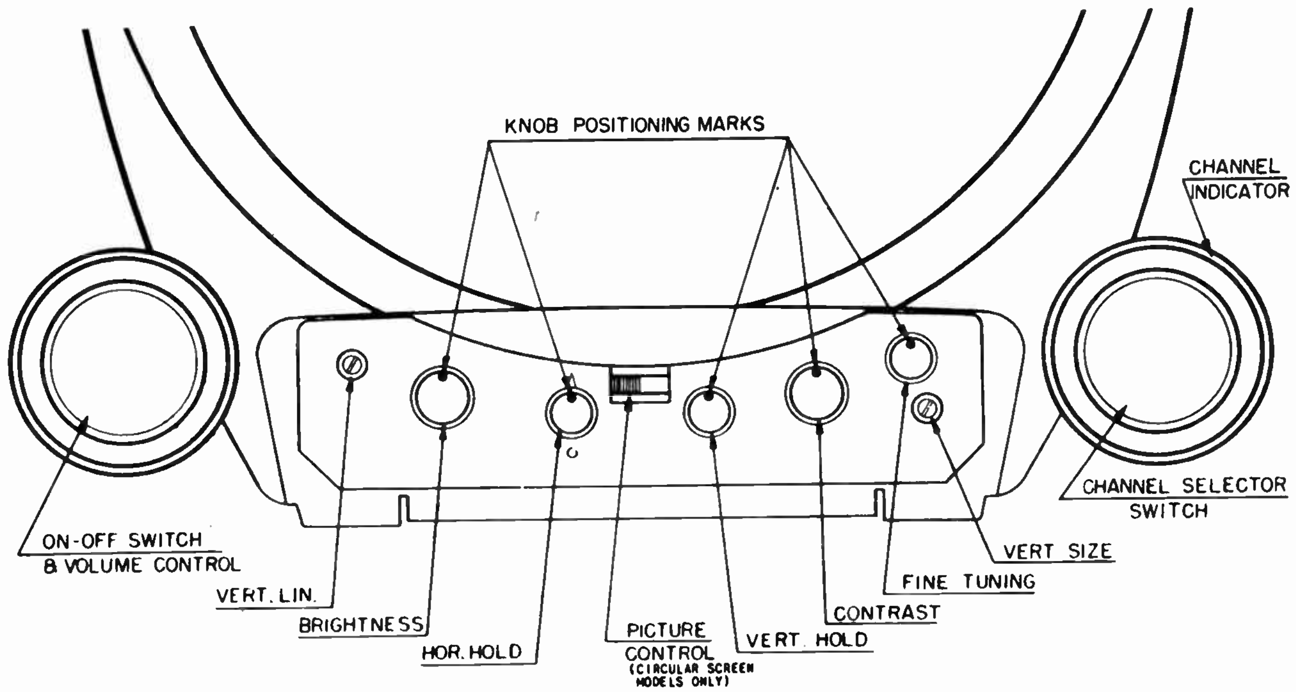
FINE TUNING CONTROL: Provides a means of varying the frequency of the local oscillator to compensate for any frequency deviation which may result from tube and circuit variations. In operating this control it will be found that the range of sound is quite broad. Proper setting is the point where the best picture is obtained within the range of best sound.

VERTICAL HOLD CONTROL
VERTICAL HOLD RANGE CONTROL: The combination of these controls provide a means of changing the cathode resistance of the vertical oscillator to effect synchronization of the vertical sweep with the transmitted sync pulses. Adjustment is made by setting the vertical hold control in the center of its range and adjusting the vertical hold range control for proper sync. Improper adjustment will cause the picture to "roll" vertically.

BRIGHTNESS CONTROL: Controls the cathode voltage of the picture tube to afford control of picture brilliance. Must be operated in conjunction with the Contrast Control for maximum picture clarity.

CONTRAST CONTROL: Control is in the plate circuit of the 12AU7 second video amplifier. It regulates the magnitude of video signal applied to the picture tube.

PICTURE CONTROL SWITCH: The Picture Control Switch changes the magnitude of the sweep voltage into the vertical deflection coils thereby allowing the choice of either a Giant Circle or "conventional" picture.



FRONT PANEL CONTROLS

Fig. 2 Controls

©John F. Rider

World Radio History

HORIZONTAL HOLD CONTROL: The Horizontal Hold Control is used to tune the horizontal oscillator to the frequency of the transmitted sync pulses.

VERTICAL SIZE CONTROL: The Vertical Size Control is part of the vertical oscillator plate load. It is used in conjunction with the vertical linearity control to adjust the size of the picture vertically.

VERTICAL LINEARITY CONTROL: The Vertical Linearity Control is in the cathode circuit of the vertical output tube and is used to shift the operating point of the tube so that the sweep is amplified along that portion of the plate current curve which results in a linear output.

HORIZONTAL DRIVE CONTROL: Regulates the magnitude of the horizontal sweep voltage applied to the grid of the horizontal output tube. Care must be exercised not to advance this control to a point where the right side of picture begins to fold.

HORIZONTAL LINEARITY CONTROL: The Horizontal Linearity Control should be adjusted for best horizontal symmetry while observing a test pattern on the screen. The position of the horizontal drive and width controls also affect linearity and possible interaction of these controls must be taken into consideration when making linearity adjustments.

WIDTH CONTROL: A variable inductance L75 shunted across a portion of the secondary winding of the horizontal output transformer T14. Varying this shunt inductance changes the magnitude of the sweep voltage across the horizontal deflection coils thus causing the picture to widen or narrow accordingly.

FOCUS CONTROL: (22H20) A mechanical shunt which regulates the flux density of the ring type permanent magnet to effect proper focus.

FOCUS CONTROL: (23H & 24H series) A combination electro-permanent magnet is used. Focus is accomplished electrically by adjustment of the Focus Control at the rear of the chassis.

ADJUSTMENTS AND ALIGNMENT

FOCUS AND CENTERING ADJUSTMENTS

The 22H series receivers incorporate mechanical means of centering and focusing while the 24H series utilize mechanical centering and electrical focus.

The centering control lever is used for centering the picture both vertically and horizontally. An up-down movement of the lever moves the picture horizontally while a left-right movement shifts it vertically.

Complete focus, centering and beam bender adjustments are made as follows:

1. Loosen the deflection yoke adjustment locknut (See Fig. 4) and move the yoke as far as possible toward the front of the picture tube. Check for picture tilt and tighten locknut.

2. Adjust the magnet positioning screws until the assembly is approximately 1/8" from the yoke. Be certain that the focus coil sleeve is inserted inside the magnet assembly for proper mechanical centering of the picture tube.

3. Set the centering lever to a position where the locking screw is centered inside its slot.

4. Rotate and slide the beam bender along the neck of the tube for a raster of maximum brilliance. (The beam bender has an identifying arrow which must point towards the front of the picture tube when installed. On double ring type beam benders, the air gaps should be 180° removed with the heavier ring nearest the picture tube socket.)

5. Adjust the focus shunt ring (22H series only), or the focus control for sharpest picture definition.

6. With the centering lever, center the picture vertically and horizontally. A slight readjustment of the beam bender may be necessary to obtain a full raster of maximum brilliance.

After adjustments are made, tighten the centering lever locknut.

BULLS EYE TUNER ADJUSTMENTS

With an intercarrier receiver of this type, a VTVM cannot be effectively used as a resonance indicator when oscillator adjustments are made with the built-in wrench.

Satisfactory adjustments can be made by setting the fine tuning control in the center of its range, observing a test pattern and adjusting the oscillator for best sound and picture. It will be noted that tuning to one side of resonance results in a faded, washed-out picture with the spacings between the wedge lines fogged and tuning in the opposite direction causes the spaces

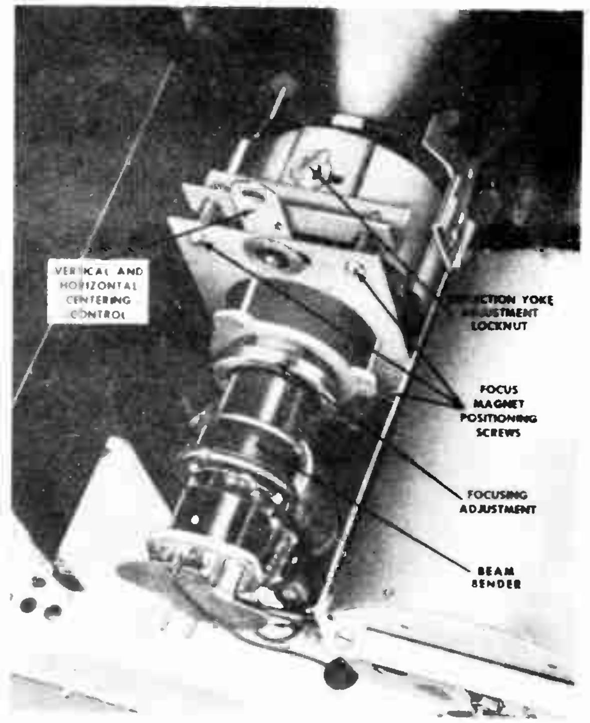

Fig. 4 Adjustments on Neck of Picture Tube.

between the lines to clear up. However, going beyond this point causes the picture to take on a "wormy" appearance from sound getting into the picture. Correct adjustment is obtained by tuning to the "wormy" picture and then backing the control off slightly until the picture clears up.

AFC ADJUSTMENTS

The AFC adjustment can effectively be made by setting the horizontal hold control (L74) to a position where it is virtually impossible to "throw" the receiver out of horizontal sync when switching from channel to channel.

AGC ADJUSTMENTS

Connect the calibrated oscilloscope through a 10K isolation resistor to the grid (Pin 7) of the 12AT7 limiter-inverter. Select the strongest TV signal and observe the deflection on the scope screen. Adjust the AGC delay control R50 for 2.5V peak output.

Satisfactory adjustment can also be made by observing the picture and backing off the AGC control from its maximum clockwise position to a point comfortably below the level of intercarrier buzz, picture distortion, improper sync or excessive contrast at maximum contrast setting.

CAUTION: Misadjustment of the AGC delay control can result in a washed-out picture, distorted picture, buzz in sound OR COMPLETE LOSS OF PICTURE AND SOUND.

SOUND ALIGNMENT

Proper alignment of the 4.5 Mc intercarrier sound channel can only be obtained if the signal to the receiver antenna terminals is reduced to a level below the limiting point of the 6BN6 Gated Beam Detector. This level can be easily identified by the "hiss" which then accompanies the sound.

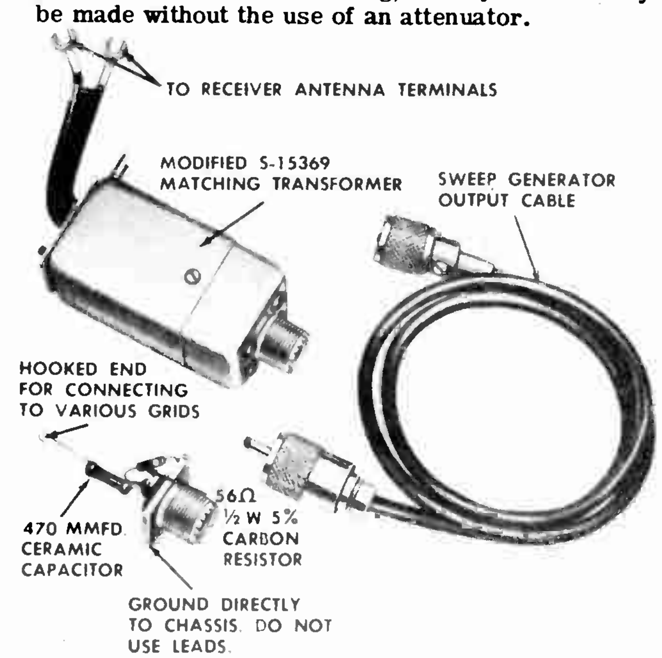
Various methods may be used to reduce the signal level, however, it is recommended that a S17203 step attenuator be used for most satisfactory results. To prevent leakage, certain precautions must be taken when connections are made. Use as short a lead as possible between the attenuator and receiver antenna terminals and approximately 6 feet of 300 ohm shielded line between the antenna transmission line and the attenuator. The shield from the transmission line should be connected to the attenuator and the attenuator itself grounded to the TV chassis under test.

After the connections are made, proceed as follows:

1. Tune in a tone modulated TV signal and adjust the step attenuator until the signal is reduced to a level where "hiss" is heard with the sound.

2. Adjust the sound take-off coil L60, input coil L57, quadrature coil L58 and buzz control R19 for the cleanest sound and minimum buzz. It must be remembered that any of these adjustments may cause the "hiss" to disappear and further reduction of the signal is necessary so that the "hiss" never disappears during alignment.

In weak signal areas, where the signal amplitude is not sufficient to cause limiting, the adjustments may be made without the use of an attenuator.



If intercarrier buzz is in evidence, after all normal sound adjustments have been made, the cause may be attributed to one or more of the following.

1. Improper adjustment of the AGC delay control.
2. Defective 12AT7 inverter-limiter tube.
3. Extremely high signal levels which require attenuation in the antenna circuit.
4. Transmitter overmodulation.

CALIBRATING THE OSCILLOSCOPE

When aligning RF-IF stages and when making AGC adjustments, it is necessary to measure detector peak output voltage. This may be done with an oscilloscope which has been calibrated with a known DC voltage. To calibrate any oscilloscope proceed as follows:

Connect the ground lead of the scope vertical input cable to the negative side of a 3 volt battery supply. Turn the horizontal gain control fully counter-clockwise. With the "hot" lead, make a momentary contact to the positive connection on the battery and observe the instantaneous spot deflection on the screen. Discharge the scope input capacitor by shorting out the leads and then repeat the procedure, each time readjusting the scope vertical gain until the spot deflects 3 large divisions on the screen. Each division will then represent 1 volt peak. The position of the vertical gain control must be noted for future reference.

IF ALIGNMENT

When aligning the 40 Mc IF, it is of utmost importance to keep the sweep generator connections as short as possible. (See Fig. 5). Clip the negative lead of a 4.5V battery to test point "A" and the positive lead to chassis. Connect the oscilloscope to the grid (Pin 7) of the 12AT7 limiter-inverter through a 10K isolation resistor. During alignment keep the output from the sweep generator at a level which develops approximately 3V peak output at the detector as viewed on the calibrated oscilloscope. It is important that the voltage be maintained at this 3V level.

After the bias and scope connections have been made and the receiver allowed a 15 minutes warm-up period, proceed as follows:

1. Feed the output from the sweep generator through a connector, as shown in Fig. 5, into the converter grid (terminal "F"). This terminal is immediately adjacent to the 6CB6 converter tube.

2. Remove oscillator tube V3 and switch channel selector to channel 12.

3. Adjust the IF transformers to obtain an overall pattern of maximum amplitude with linearity, similar to the illustration in Fig. 6. It will be noted that adjustment of L51, T1 and T3 will have maximum effect on the low frequency portion of the pattern (42.75 - 43.5 Mc) whereas adjustment of T2 and T4 will have

©John F. Rider

World Radio History

maximum effect on the high frequency side (45.75 and 45 Mc.) T5 tilts the top and is adjusted to obtain best symmetry.

After the correct overall pattern is obtained, turn the channel selector to channel 2 and inject a 47.25 Mc marker into the sweep. Adjust the low channel adjacent sound trap L53 for minimum indication on the scope or on a VTVM connected to the video detector.

4. Feed a 4.5 Mc crystal calibrated signal to terminal "C" Fig. 20 and connect the RF probe of a VTVM to the cathode (Pin 11) of the picture tube. Advance the contrast control for approximately 1 volt indication on the meter and adjust trap L63 for minimum indication.

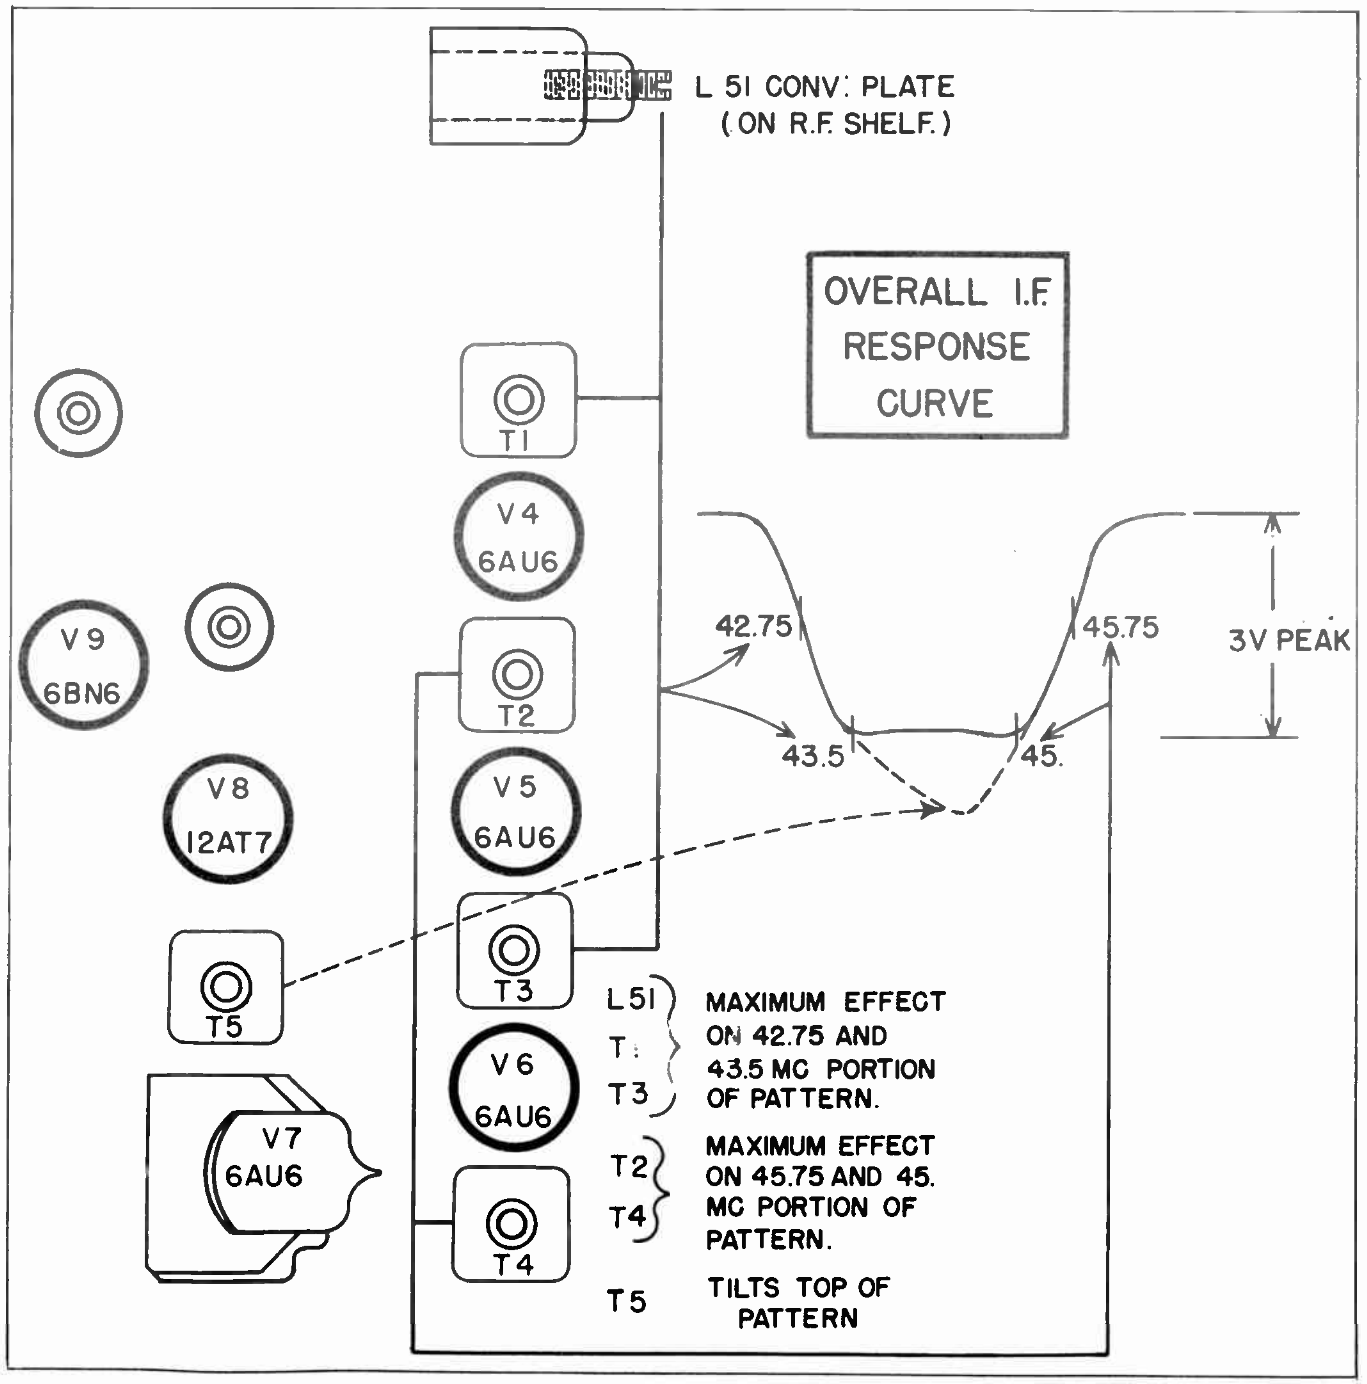


Fig. 6 IF Alignment Guide

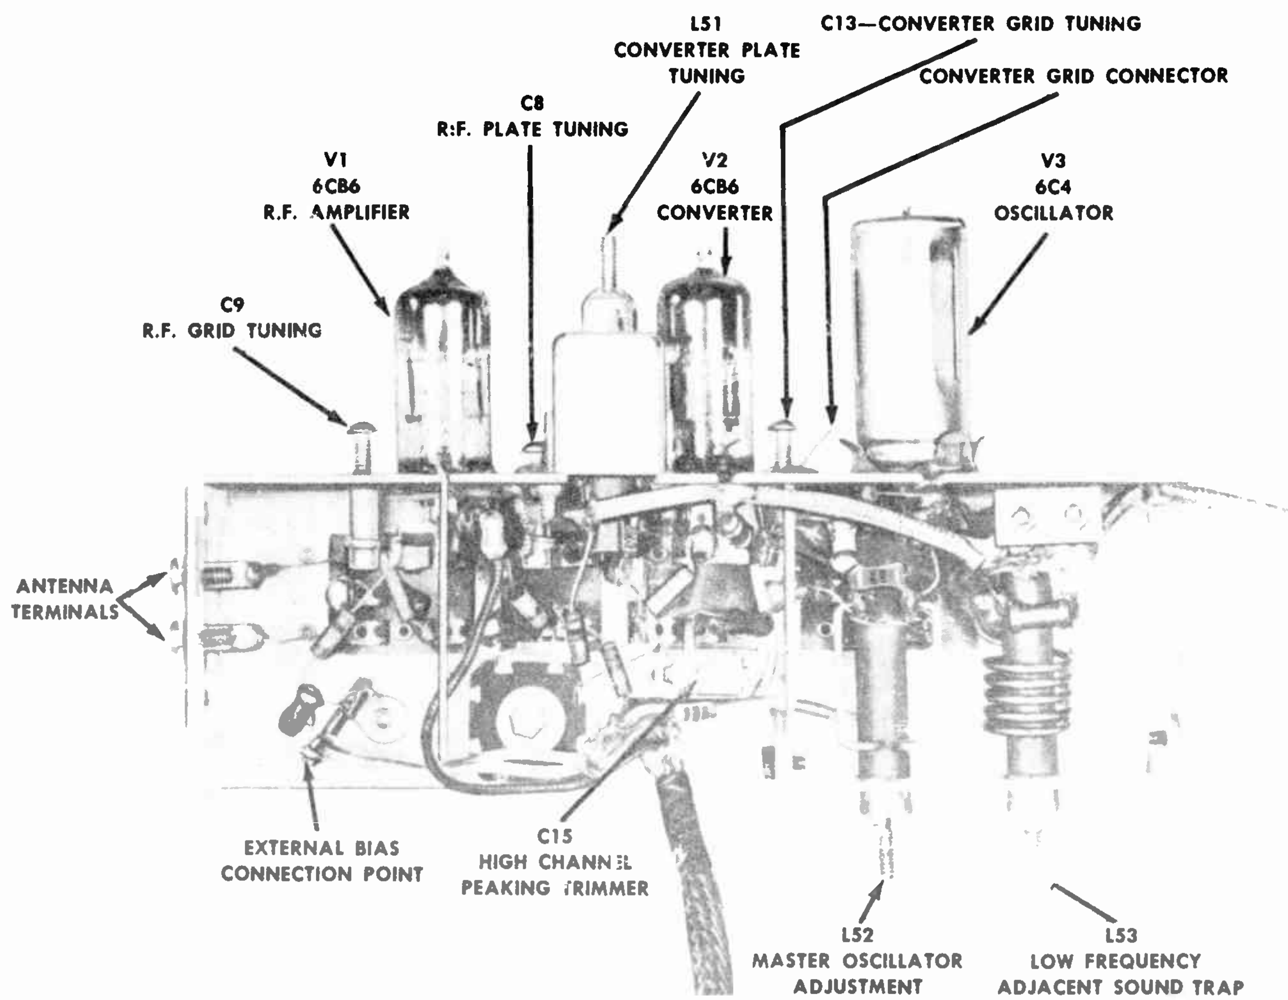

Fig. 7 RF Shelf

MASTER OSCILLATOR ALIGNMENT

The 6C4 master oscillator operates above the incoming frequency on the low channels (2-6) and below on the high channels (7-13). Slug L52 is used to pre-set the master oscillator on channel 7 since the channel 7 strip itself does not have an oscillator adjustment.

The master oscillator adjustment is to be made only if resonance cannot be obtained with the strip oscillator adjustment wrench when the fine tuning control is in its center position (open end of pulley on the RF shelf facing up) and after it has been determined that the channel strip itself is not at fault.

Although it is possible to set the master oscillator L52 by tuning in a station and alternating the master and strip oscillator adjustments until proper tuning results, the use of the Mega-Sweep and Mega-Marker Sr. is preferred. The Mega-Marker Sr. is provided with crystals for the sound carrier frequencies of all 12 existing channels. The sound carrier frequencies can be used in adjusting the master oscillators, however, it is recommended that the Mega-Marker Sr. be equipped with a crystal for the picture carrier frequency for channel 7 (175.25 Mc). This crystal may be inserted into one of the extra positions and adjustments made as follows:

1. Connect the negative lead of a 4.5V battery to point "A" (See Fig. 20) and the positive lead to chassis.

2. Feed the signal generator through a S-15369 matching transformer to the antenna terminals of the receiver. Fig. 5.

3. Set the channel selector to channel 7 and turn the fine tuning control until the open end of the RF shelf pulley faces upward.

©John F. Rider
World Radio History

4. Adjust the sweep generator for an RF response curve (similar to Fig. 6). Set the Mega-Marker Sr. on channel 7 and observe the video marker on the response curve. Adjust L52 until this marker falls at approximately 50% on the response curve.

In adjusting the master oscillator on the sound carrier frequency for channel 7, the above procedure is followed, with the exception that the sound marker is placed at approximately 20 times down on the response curve.

TURRET TUNER AND RF SHELF ALIGNMENT

The RF shelf adjustments are made at the factory and normally do not require readjustment unless the unit has been tampered with. If adjustments become necessary, they are made as follows:

1. Connect the negative lead of a 4.5V bias supply to point "A" (See Fig. 20) and the positive lead to chassis. Connect the oscilloscope through a 10K isolation resistor to terminal "C" and chassis.

2. Feed the output of the Mega-Sweep through a S-15369 matching transformer to the antenna terminals of the receiver.

3. Adjust the Mega-Sweep and check the RF response curve (See Fig. 6) on each channel. If all the response curves are tilted approximately the same amount, first check the IF response to see that it has a reasonably flat top (See Fig. 6) before an attempt is made to adjust the RF trimmers. If the IF response is correct, set the channel selector switch to channel 4 and adjust the RF grid (C9), RF plate (C8), converter grid (C13) for symmetry and amplitude of the response curve.

4. If the receiver sensitivity is satisfactory on the low channels (2 to 6) and is down on the high channels, adjust the high channel peaking trimmer (C15) for maximum sensitivity with band pass.

SERVICE HINTS

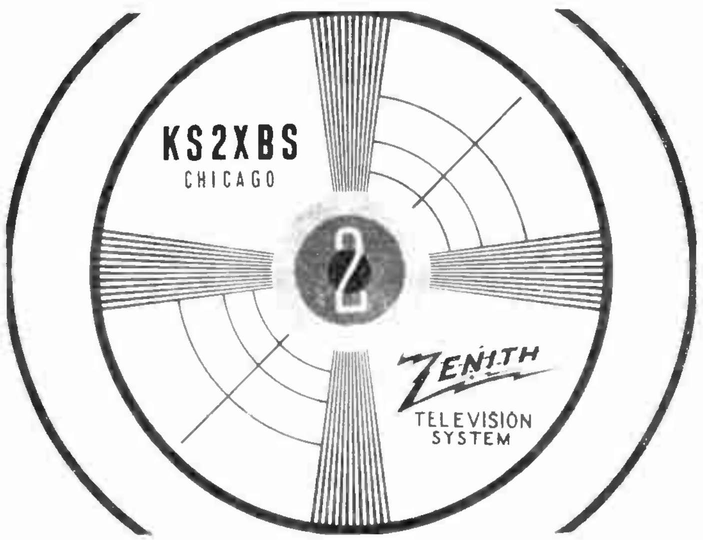
FRINGE RECEPTION - Vertical synchronization in weak signal areas may be improved by lowering the value of the resistor in the grid circuit of the sync clipper from its normal 1 Meg. value. Values as low as 10,000 ohms may be used, however, care must be exercised as too great a reduction of this resistance may introduce horizontal distortion into the picture on some signals.

POOR VERTICAL LINEARITY - (22H20 - 23H22Z) If this condition cannot be corrected by adjustment of the vertical linearity and height adjustments, the fault will probably lie in a defective 6BL7GT vertical sweep tube.

S-17268 REMOTE CONTROL UNIT - Locking of the manual control can be caused by failure of the worm drive gear to disengage. This condition can be the result of a weak solenoid armature actuating spring or misalignment of the magnet mounting bracket. It will be noted that the solenoid mounting bracket has slotted mounting holes which allows for horizontal as well as vertical alignment. Improper seating of the solenoid clapper plate on the magnet core will cause excessive buzz.

IMPORTANT: Any receiver equipped with the remote control unit must be perfectly "bulls eyed" to insure its most satisfactory operation with the remote control unit.

TESTING GERMANIUM CRYSTALS - If, after all normal adjustments have been made, the picture appears washed out, the cause may be low detector output due to a defective germanium crystal. The crystal may be disconnected and tested with an ohmmeter for front-to-back ratio. The resistance in one direction should be lower than 400 ohms and at least 25 times this resistance (10,000 ohms) or higher in the other direction. Any ratio less than 25 to 1 would indicate a below standard crystal.



Rectangular Screen Models properly adjusted on Test Pattern.

SPECIAL TEST EQUIPMENT FOR TV

Part No.	Description
68-7	Alignment Wrench
68-13	Alignment Tool
68-14	Tuning Wand
68-17	Adjustment Wrench for Master Oscillator and Sound Trap Adjustments
	Trap Adjustments on RF Shelf
68-18	18" Insulated Screwdriver for Hum and AGC adjustments
68-19	Nylon Alignment Wrench
95-1234	250 Watt Isolation Transformer
S-15369	Generator Test Unit
S-15371	Coupling Ring
S-15521	AC Test Cord for TV Chassis
S-15627	Balance Transformer (Ant)
S-15729	Balance Transformer (Receiver)
S-17303	Step Attenuator

PARTS SUPPLEMENT

S-17635 VIDEO I.F. ASSEMBLY

(Also refer to Parts List for S-17064 I.F. Assembly)

The S-17635 Video I.F. Assembly is interchangeable with the S-17064 units used in early production "H" series receivers. The new I.F. can be identified by the oblong shaped can which houses the 5th IF transformer.

MODEL H3475R CABINET PARTS

Model H3475R is the same as Model H3469E except the following:

OMIT:

Part No.	Description
2-199	Cabinet Back (Phono Section)
14-1263E	Cabinet for H3469E Console Combination Model
16-644	Packing Carton - Inner Pack
16-645	Packing Carton - Outer Pack
46-833	Vol. Control Knob
46-889	Channel Selector Knob
126-650	Heat Shield
166-57	Tack Bumper (2 used)

ADD:

Part No.	Description
2-197	Cabinet Back (Phono Section)
14-1261R	Cabinet for H3475R Console Combination
16-642	Packing Carton - Inner Pack
16-643	Packing Carton - Outer Pack
46-888	Channel Selector Knob
46-890	Vol. Control Knob
126-649	Heat Shield
166-55	Tack Bumper

MODELS H3267 & H3267R CABINET PARTS

Part No.	Description
2-209	Cabinet Back (Phono Section)
11-106	Line Cord & Plug - 9 ft. lg. (TV Back)
11-109	Line Cord & Plug - 3 ft. lg. (Radio Back)
12-1797	Clamping Guide Brkt. (2 used on TV Esc. Mtg.)
14-1271	Cabinet for H3267 Console Combination
14-1271R	Cabinet for H3267R Console Combination
16-654	Packing Carton - Inner Pack
16-655	Packing Carton - Outer Pack
19-169	Record Changer Mtg. Clip (2 used)
24-535	Line Cord Plug Cover
46-873	Tone Control Knob
46-876	Tuning Control Knob
46-885	Contrast Control Knob
46-887	Horizontal Hold Knob
46-888	Channel Selector Knob
46-890	Vol. Control Knob
46-893	Brightness Control Knob
46-895	Fine Tuning Knob
46-896	Vertical Hold Knob
46-899	Band Switch Knob
49-694	12" P.M. Speaker ZC12161 Cone & Voice Coil
56-286	Cover Hinge Pin
57-1284	Strike Plate (2 Used)
57-1481	Esc. Clamping Plate
57-1658	Radio Dial Esc.
57-1670	Glass Retaining Plate (TV)
57-1671	Television Esc.
57-1678	Esc. (Vol. Control)
57-1679	Esc. (Channel Selector)
70-86	#6 x 5/8 Washer Hd. Wood Screw St. Br. (15 used to mt. backs)
72-81	#8 x 3/4" Phill. Flt. Hd. Wood Screw St. Br. (4 used to mt. S-16890)
74-58	Ventilating Screen
74-75	Ventilating Screen
78-787	Two Contact Socket (TV Back)
78-847	Two Contact Socket (Radio Back)
80-604	Hinge Spring (2 used)
80-826	Grounding Spring
80-828	Door Return Spring
80-830	Record Changer Mtg. Spring (4 used)
93-1059	Felt Washer (used on 46-873)
97-293	Chassis Mtg. Insulating Stud (3 used)
100-97	Pilot Light Bulb
112-809	Record Changer Mtg. Screw (3 used)
112-813	4-40 x 5/16" R.H.S.T. (8 used on TV Esc. Mtg.)
114-80	1/4-20 x 1-3/8" Hex Hd. (4 used to mt. TV Chassis) (3 used to mt. Pwr. Supply)
114-128	#10 x 1-1/16" Hex Washer Hd. S.T. (3 used to mt. radio chassis)
114-201	#8 x 5/16 Hex Hd. S. T. (used on pwr. supply)
114-341	#6 x 3/8 Hex Hd. S. T. (used on 80-826)
114-350	#8 x 7/16" Hex Hd. Sl. S. T. (4 used on Radio Esc. Mtg.)
126-648	Heat Shield
156-35	Bullet Catch (2 used)
159-50	Plug Button (2 used)
165-9	Metal Glide (2 used)
165-14	Metal Glide (2 used)
166-55	Tack Bumper (2 used)
188-54	Knob Clamping Ring (46-876)
192-137	Protective Glass (TV)
192-138	Dial Glass (Radio)
196-149	Glass Gasket (TV)
202-829	Television Instruction Book
202-850	Radio-Phono Instruction Book
S-14029	Variable Speed Record Changer
S-15536	Record Changer Compt. Hinge Brkt. & Link Assy. (2 used)
S-15737	Socket Cap & Brkt.
S-15780	Cobra Cartridge
S-16419	Record Adapter Plug & Envelope Assembly
S-16890	Cabinet Antenna Assy.
S-17005	Record Changer Mtg. Frame Assembly
S-17167	Vol. Control Knob
S-17189	Power Supply Assembly (Complete)
S-17218	Low Impedance Loop Assy.
S-17264	Cabinet Back Assy. (TV)
S-17328	Loop Loading Coil Assy.
S-17399	Cabinet Back Assy. (Radio)
S-17497	Cover & Nameplate Assy.
S-17556	Antenna Terminal & Wire Assembly

24H21 Main Chassis (cont'd.)

Part No.	Description
73-114	8-32x5/16 Slab Hd. Set Screw (2 used S-17083 & 4 used S-16529)
76-604	Fine Tuning Ext. Shaft
76-605	Horiz. Hold Control Shaft
78-250	Elect. Cond. Socket
78-580	Nine Contact Socket
78-706	Octal Socket
78-709	Octal Tube Socket
78-755	Octal Tube Socket (5 used)
78-807	Miniature Tube Socket (2 used)
78-834	Octal Tube Socket
78-840	A.C. Socket
78-875	C.R. Tube Socket
78-876	Noval Miniature Tube Socket
78-883	Nine Contact Socket
78-900	Pilot Light Socket & Wire
80-744	Focus Mtg. Spring (4 used)
80-802	Retaining Spring (1 ea. used on 149-100 & 149-101)
80-822	Dial Cord Tension Spring
80-823	Shaft Guide Spring
80-824	Tube Plate Connector Spring (2 used)
80-825	C. R. Tube Retaining Spring
80-843	Tension Spring
80-846	Fine Tuning Limiting Spring
83-1802	Fuse Mounting Strip
85-488	Picture Control Switch
93-2	Brass Washer (used on 22-2154)
93-525	Fibre Washer (2 used on 78-709)
93-961	Insulating Washer (used on Contrast Control)
93-971	Shell Support Washer (used on Horiz. Sweep)
93-1057	Insulating Washer (used on Contrast Control)
95-1240	Vertical Output Trans.
95-1267	Deflection Coil
100-67	Pilot Light
103-1	Crystal Diode
112-88	Thumb Screw #8-32 (Deflection Coil)
112-758	#4-40x1/4" R.H.S.T. (used on 85-488)
114-45	#8x3/8 Hex. Hd. S. T. (2 used on S-17289)(or 114-313)
114-268	#6x1/4 Hex Hd. S. T. (2 used on 24-554)
114-310	#8x5/16 Hex. Washer Hd. S. T. (4 used S-17100 & 2 used on Defl. Coil Mtg.)
125-26	Rubber Grommet (2 used on 78-709)
126-652	Pilot Light Shield
136-22	Fuse 1/4 amp
149-89	Iron Core (1 ea. used on S-16855 & S-17116)
149-98	Iron Core & Screw (used on S-17400)
149-100	Iron Core & Spring (used on S-17177)
149-101	Iron Core & Spring (used on S-17177)
149-102	Iron Core & Screw (use S-17114)
188-131	Retaining Ring (used on S-17097)
188-137	Retaining Ring (used on (S-17362)
196-147	Plastic Gasket

	S-17497	Cover & Nameplate Assy.

CABINET PARTS FOR H2445R & RQ

Model H2445R & RQ is the same as H2447R & RQ except the following:

OMIT:

Part No.	Description
14-1262R	Cabinet for H2447R & RQ Console Model
16-646	Packing Carton

ADD:

Part No.	Description
14-1269R	Cabinet for H2445R & RQ Console Model
16-650	Packing Carton
57-1284	Strike Plate (2 used)
74-76	Ventilating Screen
156-35	Bullet Catch
166-55	Tack Bumper (2 used)

CABINET PARTS FOR H3478E & EQ

Part No.	Description
2-207	Cabinet Back (Phono Sect.)
11-106	Line Cord & Plug 9 ft. lg.
14-1270E	Cabinet for H3478E & EQ Console CombinationModel
16-652	Packing Carton - Inner Pack
16-653	Packing Carton - Outer Pack
19-9	Cable Clip
19-169	Record Changer Mtg. Clip (2 used)
19-210	Loop Connector Clip (2 used)
24-535	Line Cord Plug Cover
46-833	Volume Control Knob
46-876	Tuning Control Knob
46-885	Contrast Control Knob
46-887	Horiz. Control Knob
46-889	Channel Selector Knob
46-893	Brightness Control Knob
46-895	Fine Tuning Knob
46-896	Vertical Hold Knob
46-899	Band Switch Knob
49-694	12" PM Speaker ZC12161 Cone & Voice Coil
56-286	Cover Hinge Pin
57-1270	Strike Plate (2 used)
57-1481	Esc. Clamping Plate (7 used)
57-1666	Radio Dial Esc.
57-1670	Glass Retaining Plate (4 used)
57-1674	TV Escutcheon
57-1678	Esc. (Vol. Control)
57-1679	Esc. (Channel Selector)
70-3	#5x1/2" R.H.W.S. Steel N.P. (2 used S-17305 & 1 used 19-9)
70-86	#6x5/8 Washer Hd. Wood Screw - St. Br. (11 used to mt. Backs)
72-3	#5x5/8" Flt. Hd. W. Steel N.P. (2 used on EQ Models)
72-81	#8x3/4" Phill. Flt. Hd. Wood Screw - St. Br. (4 used on S-17293)
74-58	Ventilating Screen
74-71	Ventilating Screen
78-787	Two Contact Socket
80-604	Hinge Spring (2 used)
80-826	Grounding Spring
80-828	Door Return Spring
80-830	Record Changer Mtg. Spring (4 used)
93-168	Rubber Shoulder Washer (4 used)
94-295	Mtg. Bushing (4 used on EQ Models)
112-809	Record Changer Mtg. Screw (3 used)
112-813	4-40x5/16" R.H.S.T. (8 used on TV Esc. Mtg.)
114-80	1/4-20x1-3/8" Hex. Hd. M.S. (4 used Mtg. TV Chassis & 3 used Mtg. Pwr. Supply)
114-201	#8x5/16 Hex. Hd. S. T. (used on Pwr. Supply)
114-341	#6x3/8 Hex Hd. S. T. (used on 80-826)
114-350	#8x7/16" Hex. Hd. Sl. S. T. (used on Radio Esc. Mtg.)
114-354	Radio Chassis Mtg. Screw (4 used)
114-358	#6x1/2" Hex Hd. Sl. S. T. (4 used on EQ Models)
126-653	Heat Shield
156-33	Bullet Catch (2 used)
159-50	Plug Button - Black Oxide (2 used)
165-14	Metal Glide (2 used)
166-57	Tack Bumper (2 used)
188-54	Knob Clamping Ring (46-876)
192-138	Dial Glass (Radio)
192-139	Protective Glass (TV)
196-150	Glass Gasket (TV)

CABINET PARTS FOR H3478E & EQ (cont'd.)

Diag. No.	Part No.	Description
	202-829	Instruction Book (TV)
	202-849	Instruction Book (EQ Model)
	202-851	Instruction Book (Radio-Phono)
	S-14029	Variable Speed Record Changer
	S-15536	Record Changer Compt. Hinge Brkt. & Link Assy. (2 used)
	S-15780	Cobra Tone Arm Cartridge
	S-16419	Record Adapter Plug & Envelope Assembly
	S-17005	Record Changer Mtg. Frame Assembly
	S-17167	Volume Control Knob Assy.
	S-17189	Power Supply Assy. (Complete)
	S-17255	Radiorgan Cable Assy.
	S-17266	Remote Control Assy. (used on EQ Models)
	S-17267	Hand Control & Cable Assy. (used on EQ Models)
	S-17293	Cabinet Antenna Assy.
	S-17305	Antenna Terminal & Wire Assembly
	S-17325	Low Impedance Loop Assembly
	S-17328	Loop Loading Coil Assy.
	S-17351	Cabinet Back (TV)
	S-17497	Cover & Nameplate Assy.

RADIORGAN ESCUTCHEON PARTS

Part No.	Description
76-444	Radiorgan Knob Shaft
114-297	#6x1/4 Hex. Hd. Sl. S. T. (2 ea. used on S-17252 & S-17253)
S-14255	Radiorgan Mtg. Brkt. Assy. (2 used)
S-17246	Radiorgan Knob & Eyelet Assembly (Treble)
S-17247	Radiorgan Knob & Eyelet Assembly (Voice)
S-17248	Radiorgan Knob & Eyelet Assembly (Alto)
S-17249	Radiorgan Knob & Eyelet Assembly (Bass)
S-17250	Radiorgan Knob & Eyelet Assembly (Lo-Bass)
S-17251	Radiorgan Knob & Eyelet Assembly (Normal)
S-17252	Radiorgan Esc. & Knob Assembly (R.H.)
S-17253	Radiorgan Esc. & Knob Assembly (L.H.)

CABINET PARTS FOR H3477R & RQ

Model H3477R & RQ is the same as H3478E & EQ except the following:

OMIT:

Part No.	Description
2-207	Cabinet Back (Phono Section)
14-1270E	Cabinet for H3478E & EQ Console Combination Model
16-652	Packing Carton - Inner Pack
16-653	Packing Carton - Outer Pack
46-833	Volume Control Knob
46-889	Channel Selector Knob
57-1270	Strike Plate (2 used)
156-33	Bullet Catch (2 used)
166-57	Tack Bumper (2 used)
S-17351	Cabinet Back Assy. (TV)

ADD:

1 - 6AL5	1 - 12AU7
1 - 6BF5	1 - 6BL7GT

For parts on S-17100 R.F. Shelf & Turret Tuner refer to 22H20 Chassis

Parts for the Video I.F. Assembly are listed under Part Numbers S-17064 or S-17635.

For parts on S-17230 Mechanical Centering & Focus Assembly, refer to parts list for 24H20 Chassis.

CABINET PARTS H2328RZ & RQZ

Part No.	Description
11-106	Line Cord & Plug 9 ft. lg.
12-1798	Support Brkt. (4 used to mt. 192-140)
14-1278R	Cabinet for H2328RZ & RQZ Table Model
16-665	Packing Carton
19-196	Clip (2 used on 188-134)
24-446	AC Line Cord Plug Cover
43-196	Control Housing
46-885	Contrast Control Knob
46-887	Horiz. Hold Knob
46-888	Channel Selector Knob
46-890	Volume Control Knob
46-893	Brightness Control Knob
46-895	Fine Tuning Knob
46-896	Vertical Hold Knob
49-696	5-1/4" PM Speaker ZC5093 Cone & Voice Coil
54-129	Speed Nut (3 used on 188-133)
54-269	#8-32x11/32 (1 used on ea. S-17422)
56-286	Cover Hinge Pin
57-1481	Clamping Plate (4 used to mt. S-17422)
57-1620	Retaining Plate (used on 188-134)
70-3	#5x1/2" R.H.W.S. Steel N.P. (2 used on S-17306)
70-86	#6x5/8" Washer Hd. Wood Screw St. Br. (5 used to mt. back)
70-153	#5x1/4" R. H. W. S. Steel (2 used on 57-1620)
72-3	#5x5/8" Flt. Hd. W.S. (2 used on QZ Models Only)

CABINET PARTS H2328RZ & RQZ (cont'd.)

Part No.	Description
72-81	#8x3/4 Phill. Flt. Hd. Wood Screw St. Br. (4 used on S-17307)
72-90	#4x3/4 Phill. Flt. Hd. Wood Screw St. Br. (4 used to mt. 43-196)
74-58	Ventillating Screen
78-787	Two Contact Socket (Cabt. Backs)
80-828	Cover Return Spring
94-295	Mtg. Bushing (4 used on RQZ Models only)
114-80	1/4-20x1-3/8 Hex Washer Hd. M.S. (4 used Chassis Mtg.)
114-358	#6x1/2" Hex Hd. Sl. S. T. (4 used on RQZ Models only)
188-133	Trim Ring
188-134	Trim Ring
192-140	Protective Glass
196-163	Rectangular Gasket
202-844	Instruction Book
202-849	Instruction Book (RQZ Models only)
S-17266	Remote Control Assy. (used on RQZ Models only)
S-17267	Hand Control & Cable Assy. (used on RQZ Models only)
S-17306	Antenna Terminal & Wire Assembly
S-17307	Cabinet Antenna Assy.
S-17422	Brkt. & Screw Assy. (4 used to mt. 192-140)
S-17443	Cabinet Back Assembly
S-17497	Cover & Nameplate Assy.

CABINET PARTS H2329RZ

Part No.	Description
11-106	Line Cord & Plug 9 ft. lg.
14-1285R	Cabinet for H2329RZ Table Model
16-773	Packing Carton
19-196	Clip (2 used on 188-134)
24-446	AC Line Cord Plug Cover
43-196	Control Housing
46-885	Contrast Control Knob
46-887	Horiz. Hold Knob
46-888	Channel Selector Knob
46-890	Volume Control Knob
46-893	Brightness Control Knob
46-895	Fine Tuning Knob
46-896	Vertical Hold Knob
49-696	5-1/4" PM Speaker ZC5093 Cone & Voice Coil
54-129	Speed Nut (3 used on 188-133)
54-269	#8-32x11/32" Palnut (4 used on dial glass mtg.)
56-286	Cover Hinge Pin
57-1620	Retaining Plate (used on 188-134)
70-3	#5x1/2" R.H.W.S. Steel N.P. (2 used on S-17306)
70-86	#6x5/8" Washer Hd. Wood Screw St. Br (5 used to mt. back)
70-153	#5x1/4" R.H.W.S. Steel (2 used on 57-1620)
72-81	#8x3/4 Phillips Flt. Hd. Wood Screw St. Br. (4 used on S-17307)
72-90	#4x3/4 Phill. Flt. Hd. Wood Screw St. Br. (4 used to mt. 43-196)
74-58	Ventilating Screen
78-787	Two Contact Socket
80-828	Cover Return Spring
83-1844	Trim Strip
112-818	#4-40x1/4" Rd. Hd. S.T. Screw (2 used on S-17510)
114-80	1/4-20x1-3/8" Hex Washer Hd. M.S. (4 used chassis mtg.)
188-133	Trim Ring
188-134	Trim Ring
192-142	Protective Glass
196-166	Rectangular Gasket
202-844	Instruction Book
S-17306	Antenna Terminal & Wire Assembly
S-17307	Cabinet Antenna Assembly
S-17497	Control Cover Assembly
S-17510	Frame & Stud Assembly
S-17616	Cabinet Back Assy.(Compl.)

CABINET PARTS H2352RZ & RQZ

Part No.	Description
11-106	Line Cord & Plug - 9 ft. lg.
14-1282R	Cabinet for H2352RZ & RQZ Console Model
16-771	Packing Carton
19-196	Clip (2 used on 188-134)
24-446	AC Line Cord Plug Cover
43-196	Control Housing
46-885	Contrast Control Knob
46-887	Horiz. Hold Knob
46-888	Channel Selector Knob
46-890	Volume Control Knob
46-893	Brightness Control Knob
46-895	Fine Tuning Knob
46-896	Vertical Hold Knob
49-649	10" PM Speaker ZC10161 Cone & Voice Coil
54-129	Speed Nut (3 used on 188-133)
54-269	#8-32x11/32" Palnut (4 used on dial glass mtg.)
56-286	Cover Hinge Pin
57-1481	Clamping Plate (4 used on glass mtg.)
57-1620	Retaining Plate (used on 188-134)
70-3	#5x1/2" R.H.W.S. Steel N.P. (2 used to mt. S-17556)
70-86	#6x5/8" Washer Hd. Wood Screw St. Br. (7 used to mt. S-17511)
70-153	#5x1/4" R. H.W.S. Steel (2 used on 57-1620)
72-3	#5x5/8" Flt. Hd. W. S. (2 used on RQZ Models only)
72-81	#8x3/4 Phill. Flt. Hd. Wood Screw St. Br. (4 used to mt. S-16890)
72-90	#4x3/4 Phill. Flt. Hd. Wood Screw St. Br. (4 used on 43-196)
74-58	Ventilating Screen
78-787	Two Contact Socket
80-828	Cover Return Spring
83-1844	Trim Strip
94-295	Mtg. Bushing (4 used on RQZ Model only)
112-818	#4-40x1/4" Rd. Hd. S. T. Screw (2 used on glass & gasket mtg.)
114-80	1/4-20x1-3/8" Hex Washer Hd. M.S. (4 used chassis mtg.)
114-358	#6x1/2" Hex. Hd. Sl. S. T. (4 used on RQZ Models only)
165-9	Metal Glide (4 used)
188-133	Trim Ring
188-134	Trim Ring
192-142	Protective Glass
196-166	Rectangular Gasket
202-844	Instruction Book
202-849	Instruction Book (used on RQZ Models only)
S-16890	Cabinet Antenna Assy.
S-17266	Remote Control Assy. (used on RQZ Models only)
S-17267	Hand Control & Cable Assy. (used on RQZ Models only)
S-17497	Control Cover Assy.
S-17510	Frame & Stud Assy.
S-17511	Cabinet Back Assy. (Complete)
S-17556	Antenna Terminal & Wire Assembly

CABINET PARTS H2353EZ & EQZ

Diag. No.	Part No.	Description
	11-106	Line Cord & Plug 9 ft. lg.
	14-1284E	Cabinet for H2353EZ & EQZ Console Model
	16-772	Packing Carton
	19-196	Clip (2 used on 188-134)
	24-446	AC Line Cord Plug Cover
	43-195	Control Housing
	46-833	Volume Control Knob

	S-17497	Cover & Nameplate Assy.

H2328R & RQ - H2328E - H2329R & RQ - H2352R & RQ - H2353E & EQ

CHASSIS 23H22

MAIN CHASSIS

Chassis 23H22 is the same as 23H22Z except for the following:

OMIT:

Part No.	Description
94-746	C.R. Tube Support Bushing (2 used)
S-17064	Video I.F. Strip Assy. (Complete)
S-17521	C.R. Tube Support & Alignment Brkt. Assembly

TUBES

1 - 16TP4

ADD:

Part No.	Description
94-745	C.R. Tube Support Bushing (2 used)
S-17531	C.R. Tube Support & Alignment Brkt. Assembly
S-17635	Video I.F. Strip Assy. (Compl.)

TUBES

1 - 17BP4

For parts on S-17635 refer to page 33.

CABINET PARTS H2328R & RQ

Model H2328R & RQ is the same as H2328RZ & RQZ except for the following:

OMIT:

196-163 Rectangular Gasket

ADD:

196-157 Rectangular Gasket

CABINET PARTS H2329R & RQ

Model H2329R & RQ is the same as H2329RZ & RQZ except for the following:

OMIT:

196-166 Rectangular Gasket

ADD:

196-165 Rectangular Gasket

CABINET PARTS H2352R & RQ

Model H2352R & RQ is the same as H2352RZ & RQZ except for the following:

OMIT:

196-166 Rectangular Gasket

ADD:

196-165 Rectangular Gasket

CABINET PARTS H2353E & EQ

Model H2353E & EQ is the same as H2353EZ & EQZ except for the following:

OMIT:

196-166 Rectangular Gasket

ADD:

196-165 Rectangular Gasket

CABINET PARTS H2328E

Model H2328E is the same as H2328EZ except for the following:

OMIT:

196-163 Rectangular Gasket

ADD:

196-157 Rectangular Gasket

©John F. Rider

World Radio History

Admiral Ch. 20A1, 20B1, 21A1

R-f oscillation on the a-m band of 4J1 and 4K1 radio tuners usually may be corrected by replacing the a-m peaking coil. The early peaking coil is coded with a blue dot and the new type peaking coil (part no. 73A5-10) is coded with a black dot.

If oscillations are present when the new type peaking coil is used, it is possible that the trouble is caused by the first a-m i-f transformer T604. In some instances the silver mica capacitors in T604 have become open causing the converter to oscillate. The replacement of transformer T604 (part no. 72B92) will cure the trouble.

Under the heading "Tunable Audio Hum," the resistor mentioned should be 22,000 ohms instead of 2,200 ohms.

In areas where any two adjacent channels may be received, the sound transmission from the lower channel may cause interference on the picture of the higher channel. This type of interference may be reduced to a minimum or eliminated by means of an adjacent channel trap fitted to the transformer T302 of the 2nd vidio i-f amplifier.

The trap is constructed by using another sound trap, L308, part number 72A88-1, which should be modified and installed in the receiver in the following manner:

1. Procure this sound trap (part no. 72A88-1) and remove two turns from the coil at the end farthest from the slug screw and resolder the coil to the lug on the form (do not remove the capacitor).
2. Clip the white lead and the bare tinned lead from the coil.
3. Remove the cover from the video i-f strip and locate T302.
4. Procure a short length (approximately 3 inches) of insulated 24- or 26-guage wire and wind approximately 1½ turns in a clockwise direction on T302. These turns should be positioned on the small diameter portion of T302 at the end farthest from the slug screw, with one end of the wire looped under itself to hold the coil in position in a manner similar to the coupling coil of T301.
5. Connect one end of the 1½-turn coil to the ground connection of T302.
6. In a large number of these chassis, an unused ¼-inch hole will be found between V302 and V303, but if the hole has not been punched, one should be drilled and the new trap inserted.
7. Connect the black lead from the new trap to the ground lug of T302 and connect the loose end of the 1½-turn coupling coil to the other lug on the new trap.
8. Realign the video i-f stages. Due to the slope of the video i-f curve, it is difficult to align the new trap to 27.25 Mc with a signal generator, so the slug should be adjusted for minimum interference on the picture. However, care must be used when making this adjustment since it is possible to affect the video i-f bandpass if the adjustment is incorrectly made.
9. Use a sweep generator and scope to check the video i-f bandpass after adjustment to be sure the trap has not affected the i-f bandpass.

Admiral Ch. 20X1

This chassis appears on *pages 4-38 through 4-62 of Rider's TV Manual Volume 4.* Weak sound may be due to the use of an incorrect type speaker or misalignment of the 4.5-Mc sound i. f.

1. 20X1 chassis made for combinations models are wired for permanent-magnet type speakers part number 78B52-1 and these chassis may be identified by the letter "C" stamped on the rear of the chassis.
2. 20X1 chassis made for straight TV models are wired for an electro dynamic speaker part number 78B50-1 or 78B51-1 and these chassis are not stamped with letter "C".

If the electrodynamic type speaker is used with a combination model chassis (stamped with the letter "C"), weak sound will result. If a permanent-magnet speaker is used with a chassis wired for an electrodynamic speaker the chassis will be inoperative. Note that the 20Y1 (12-inch) chassis in straight TV models is wired only for an electrodynamic speaker.

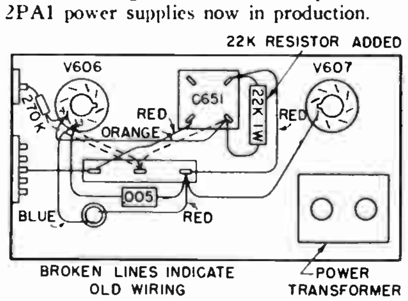
Should the sound level be weak in sets with the correct speaker in use, careful realignment of the 4.5 Mc should be made.

Admiral 32X26, 32X27, 32X35, 32X36, Ch. 20Z1, Radio Ch. 5B2

A change has been made in the 2PA1 power supply filter circuit to reduce residual hum. This power supply is used with the 20Z1 chassis in combination models using the 5B2 radio tuner. The following changes will reduce hum to a low level.

1. Remove the lead that connects pin 4 of V606 to center tap of R638-R639 candohm resistor. Remove lead that connects C651B to center tap of R638-R639.
2. Disconnect 270,000-ohm resistor R635 from center tap of candohm and reconnect to pin 4 of V606. Leave center tap of candohm unconnected.
3. Connect a 1-watt, 22,000-ohm resistor (60B14-223) from C651C to C651B and a lead from C651B to pin 4 of V606, as shown in the accompanying diagram.

These changes have been incorporated in 2PA1 power supplies now in production.



Changes for Admiral Models 32X26, 32X27, 32X35, and 32X36.

Associated Merchants 114C, 114T, 116C, 116CD, 16RCT

The service data for these models are the same as those for Bendix Models 2051, 3051, 6001, 6003, and 6100 except for the parts listed below:

Stock No.	*Description*
BZ0D50	Baffle, wood & grille cloth (16" console w/o doors)
BZ0D51	Baffle, wood & grille cloth (16" console w, w/o doors)
FW0P02	Frame, wood, 16" picture (16" console w, w/o doors)
FW0P03	Frame, wood, 16" picture (16" console comb.)
FW0P05	Frame, wood, 14" picture (14" table model)
FW0P07	Frame, wood, 14" picture (14" console)
HK0R21	Knob, door pull (16" console comb.)
HZ0H21	Handle, door (16" console w doors)
KB0B06	Knob, control channel indicator (all models)
KC0B24	Knob, control, fine tuning (all models except 16" console comb.)
KC0B24	Knob, control, fine tuning, radio tuning (16" console comb.)
KC0B25	Knob, control, hor. hold (all models except 16" console comb.)
KC0B25	Knob, control, hor. hold, TV Vol Radio Vol (16" console comb.)
KC0B26	Knob, control, contrast (all models except 16" console comb.)
KC0B26	Knob, control, TV contrast, radio tone, Radio-Off-TV (16" console comb.)
KC0B27	Knob, control, Off-On-Volume (all models except 16" console comb.)
KC0B29	Knob, control, radio bandswitch (16" console comb.)
S0D15	Socket, dial light (16" console comb.)
ZW1T09	Cabinet (14" table model)
ZW1V10	Cabinet (16" console model w/o doors)
ZW1V11	Cabinet (16" console model w doors)
ZW1V13	Cabinet (16" console comb.)
ZW1V17	Cabinet (14" console model).

Associated Merchants 12T1, 12T2, 12T3, 120C1, 120C2, 120C3, 160C1, 160C2, 160C3

The service data for these models are the same as those for Bendix Models 2025, 3033, and 6002 except for the changes in the parts list that are shown below. For all service data and change notices see Bendix 2025, 3033, and 6002.

Stock No.	*Description*
FP0P07	Frame, paper, decorative (12½" table and console models)
FP0P08	Frame, paper, 12½" picture tube
FW0P05	Frame, wood, 16" picture tube
HP0M08	Plate, metal, decorative (12½" and 16" console models)
KC0B26	Knob, control, contrast
KC0B27	Knob, control, Off-On-Volume
ZW1T06	Cabinet, table model, mahogany
ZE1V08	Cabinet, console model, mahogany (12½")
ZW1V09	Cabinet, console model, mahogany (16").

Automatic P-490, TV-707, TV-709, TV-710, TV-712, TVX313, TVX404

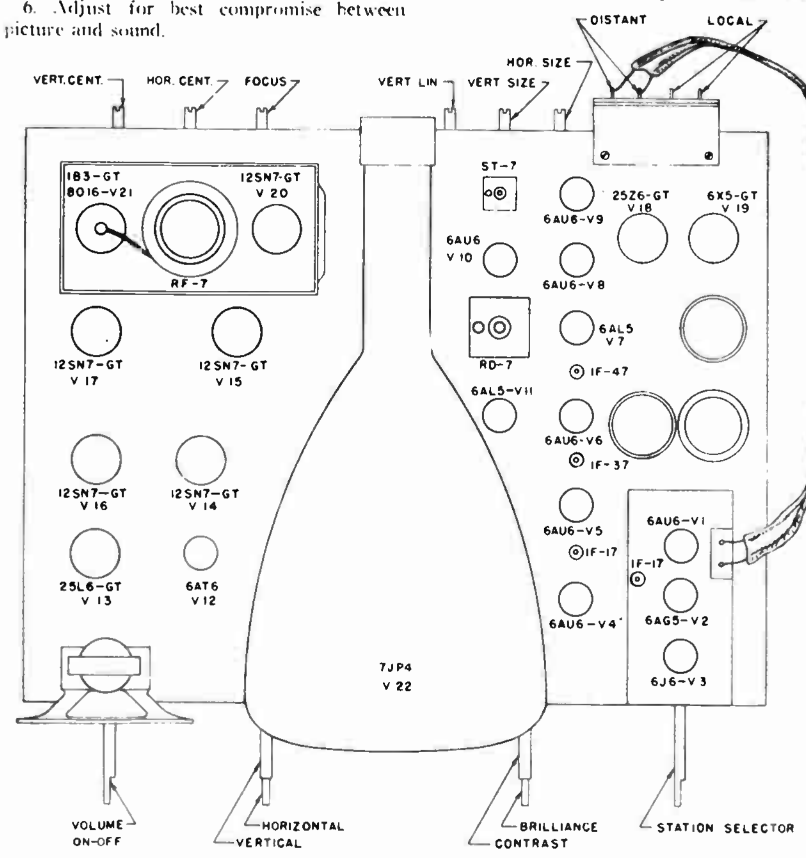
These models all use Chassis AR-TV-709. A final oscillator adjustment for each channel should be made on the receiver at the time of installation and whenever the 6J6 oscillator tube is changed. This oscillator adjustment can be made for each channel without removing the receiver from the cabinet. The following procedure should be followed in setting the oscillator frequency for each channel:

1. Turn channel selector to the required channel.
2. Remove channel selector knob.
3. Remove two wood screws securing channel selector indicating plate.
4. Locate oscillator coil to be adjusted by noting channel number on chassis around switch.
5. Insert fiber or bakelite-type screw driver carefully in slotted brass slug in oscillator coil.
6. Adjust for best compromise between picture and sound.

(Caution: Do not apply excessive pressure while adjusting!)

7. Turn Channel Selector switch to other channels and repeat above procedure.
8. Replace selector plate and knob.

The accompanying figure shows the tube layout.



Tube layout for Automatic Chassis AR-TV-709.

Bendix 2025, 3033, 6002, Codes C and D

In order to improve electrical centering of the raster and to facilitate easier mechanical adjustment of the focus coil, a revision of the horizontal oscillator and phase detector circuit has been made.

1. Remove lead of capacitor C39 from the junction of capacitors C40 and C41.
2. Connect this lead of capacitor C39 to the junction of resistors R59, R60, and R61.
3. Remove lead of resistor R58 from pin number three of V14, 6SN7GT, horizontal oscillator and phase detector.
4. Connect this lead of resistor R58 to the junction of resistor R55 and capacitor C36.

Bendix 2025, 3033, 6002

These models use tuner assemblies AROTO4 (type 1), AROTO5 (type 2) and AROTO3 (type 3) as mentioned in the parts lists for the models. The schematic for AROTO4 and alignment notes are given in the service data for Models 2025, 3033, and 6002. The schematic and alignment notes for tuners AROTO3 and AROTO5 are given in the service data for Models 2051, 3051, 6001, 6003, and 6100.

Belmont M-1101, C-1102, C-1104, M-1105, Ch. 12AX22

This chassis appears on *pages 4-6 through 4-10 of Rider's TV Manual Volume 4.* Model M-1101 "The Suburban" is a table model with a white picture tube. Model C-1102 "The Consolette" is a floor model with a white picture tube. Model C-1104 "The Console" is a floor model with a glareless grey picture tube. Model M-1105 "The Suburban" is a table model with a glareless grey picture tube. As changes were made in the production of the 12AX22 chassis, code numbers were assigned to distinguish the differences in the sets. The differences between the different code numbers are explained below:

Code 1. Code 1 chassis are wired as shown in the schematic diagram in Volume 4, except for the tuner chassis filament wiring. Only terminals 6 and 7 should be connected to H. Terminals 5, 8, and 10 should be grounded. There should be no direct connection between C32 and C31, as indicated in Volume 4, C32 should go directly to terminal 6, and C31 should go directly to terminal 7.

Code 2. A 1,000-μμf capacitor is used in place of C111. The value of resistor R92 is changed from 270,000 ohms to 220,000 ohms, and the lead from R92 now goes to the +350-volt line instead of to the +250-volt line. The value of R63 is changed from 560 ohms to 680 ohms, 1 watt.

Code 3. This is similar to Code 2 except that capacitor C109, 47 μμf has been deleted from pin 1 tube 16 to ground.

Code 4. This is similar to Code 3 except that C117 is no longer connected to terminal 1 of T6. It is now grounded.

Code 5. C111, 680 μμf, and C109, 80-480 (A-8E-18508) are now connected in parallel from the junction of C110 and R95 to ground.

Code 6. C116, 0.2 μμf (coil form, A5D-18507) has been added from pin 3 to tube 9-B, the 6SL7 agc amplifier, to pin 5 of tube 18, the 6W4.

Code 7. R48 is no longer connected to the +350-volt line, instead it now goes directly to tap 3 of T6.

Code 8. R98 now goes to the +350-volt line, instead of to tap 3 of T6. C113 is grounded instead of going to the junction of C114 and the +350-volt line. Capacitor C119, 1,000 μμf, has been added from ground to the junction of C118-A and the lead from C114 that goes to tap 3 of T6.

Code 9. The value of R73 is changed from 100,000 ohms to 68,000 ohms.

The following additions have been made to the parts list in Codes 1 through 9:

Parts No.	*Description*
C-12M-18285	Horizontal-deflection transformer
B-55P-18282	Focus magnet
A-19A-14275	Yoke plug
B-15B-14274	Yoke socket
C-2B-18056	Power-supply shield can
A-5B-18446-74	Knob (5 used)
A-6M-18412	Indicator plate.

The deflection-yoke socket is now numbered in the following way: pin 1 is now designated as pin 4, 2 is now 5, 3 is now 1, 4 is now 2.

Code 10. The value of R47 is changed to 68,000 ohms (C-9B1-84), and a switch on volume-contrast control has been added from R47 to the +250-volt line. R73 is changed to 18,000 ohms (C-9B1-77). R76 is changed to 560,000 ohms (C-9B1-95). R100 has been removed from its position at pin 6 of tube 19 and is now located from the junction of pin 11 of tube 10 and C67 to the tap of R46, brightness control. The value of R100 is 100,000 ohms. R103 is changed to 5,600 ohms, 2 watts (C-9B4-74). R108, 5,600 ohms, 2 watts (C-9B4-74), has been added from C61-D to the +350-volt line. R105 and F-1 have been deleted from the circuit. C118-A is now located from pin 1 of the power-jumper plug to ground; C119 goes from ground to pin 1 of the jumper plug and C114. A ¼-amp fuse has been inserted from pin 6 to pin 1 of the jumper plug.

Code 11. Resistor R107, 3,900 ohms, 2 watts (C-9B4-69) is added from pin 3 of tube 18, the 6W4, to the minus side of C115. The horizontal-deflection transformer T6 has been changed from C-12M-18285 to C-201-18530.

Code 12. Capacitor C120, 7 μf (ceramic, C-8G-11790) has been added in parallel across coil L10.

Code 13. Capacitor C56 has been deleted. R32, contrast control, and R34 are now located as shown in Fig. 1. Additional changes in component location in this circuit are also shown in Fig. 1. The lead from R34 goes to pin 1 of tube 9-B, the agc amplifier. The lead from R37 goes to L16. The lead from pin 1 goes to the junction of C64 and L21. R37 has been relocated, as shown in Fig. 1, and its value is changed from 1,000 ohms to 8,200 ohms. C61-A has been deleted. R35 and C60 have been added. R32, R38, R40, and C63 are changed to 5,000 ohms, 3,300 ohms, 100 ohms, and 22 μμf, respectively. Since the contrast control was moved to a new location after Code 12, the output connection of an oscilloscope or meter will not be connected across the contrast control, but now across resistor R37 (pin 7 of tube 7 to ground).

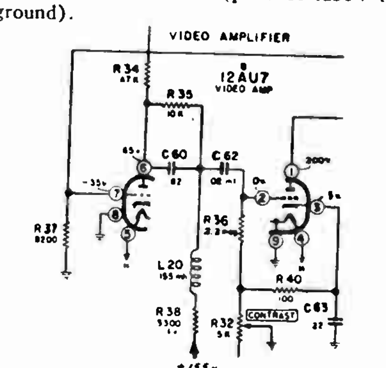


Fig. 1. Changes in the video amplifier circuit of the Belmont 12AX22.

R53 has been deleted and C59 has been added. Additional changes in component location are shown in Fig. 2. The lead from R50 and C59 goes to the agc line. The lead from C71 goes to C116, and the other side of C116 goes to pin 4 of tube 9-A, the 6SL7 sync amplifier. The lead from pin 2 goes to tap 6 (an additional winding which is described below), of T6. C71 is now 1 μμf, and R50 is 2,200 ohms.

R54, which went from R17 to pick-off coil T8, has been deleted. C72 has also been deleted. R99, to tap 5 of T6, has been deleted. T6 has been changed (see parts-list changes listed below), and now has an additional winding which is located between the winding for the filaments on the 1X2 and the winding going to the plate of the 1X2.

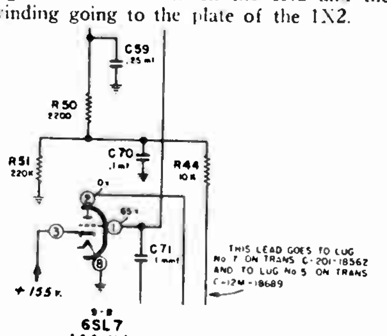

Fig. 2. Changes in the agc circuit of the Belmont 12AX22.

©John F. Rider

World Radio History

The value of R82 is changed from 1 megohm to 220,000 ohms, and the lead goes to tap 6 of T6, instead of to tap 5. C98 is changed from 75 $\mu\mu f$ to 82 $\mu\mu f$. R87 is changed from 1.5 megohms to 680,000 ohms. C110 has been relocated and now goes from R87 to the junction of C112, R96, and R97. The value of C110 is changed from 220 $\mu\mu f$ to 22 $\mu\mu f$, 500 volts. R95 has been deleted and the value of C111 is changed from 680 ohms to 820 ohms. Pin 8 of tube 17, the 6BQ6 pulse amplifier, is now tied to pin 2 of the same tube.

The change in parts list is as follows:

Ref. No.	*Part No.*	*Description*
C60	C-8F3-112	82 $\mu\mu f$, mica
C63	C-8F-18569	22 $\mu\mu f$, mica
C70	B-8D-18491	0.1 μf, paper
C71	A-8G-12495-2	1 $\mu\mu f$, ceramic
C98	C-8F3-112	82 $\mu\mu f$, mica
C110	C-8G-11892	22 $\mu\mu f$, 500 volts, ceramic
C111	C-8F6-124	820 $\mu\mu f$, mica
R34	C-9B1-82	47,000 ohms, ½ watt
R35	C-9B1-74	10,000 ohms, ½ watt
R37	C-9B1-73	8,200 ohms, ½ watt
R38	C-9B2-68	3,300 ohms, 1 watt
R40	C-9B1-74	100 ohms, ½ watt
R50	C-9B1-66	2,200 ohms, ½ watt
R82	C-9B1-90	220,000 ohms, ½ watt
R87	C-9B1-96	680,000 ohms, ½ watt
T6	C-201-18562	Horizontal-deflection transformer
	C-12M-18689	Horizontal-deflection transformer, R107 not used with C-12M-18689.

Code 14. R44 is changed from 3.3 megohms to 10,000 ohms, ½ watt (C-9B1-74).

Code 15. The value of R56 is changed from 68 ohms to 120 ohms, ½ watt (C-9B1-51).

Ref. No.	*Part No.*	*Description*
C61	A-8C-18487	30-30 μf x 450 volts, 125 μf x 25 volts
	B-5B-18552-85	Tuning knob (vernier)
	B-2M-18553	Vernier disk
	B-55P-18638	Focus magnet
	A-51A-15713	Iron core, for L4, 8, 9
	A-10B-18794	Vertical size control (screwdriver shaft)
	A-10B-18795	Linearity size control (screwdriver shaft).

In later production, group numbers (chassis identification numbers) were assigned to each set. The production changes made are explained below:

Code 16 or Group Numbers 6,700 to 8,999. Video trap coil L19 was relocated and connected to pin 7 of the 12AU7 video amplifier, tube 8, and L16. Peaking coil L21 (A-16A-17961) was replaced with A-16A-18685 (white dot). The high-voltage capacitor and socket assembly (N-201-18161) was removed and replaced with a wafer tube socket (A-15C-18735), high-voltage ring (A-62C-18734), two insulators (A-5M-18733), and mounting hardware. A 2.2 ohm, ½-watt, wire wound resistor (C-9C1-1067) or a filament choke (A-16A-18785) was added in series with the 1X2 filament lead as shown in Fig. 3.

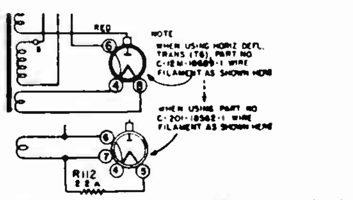

Fig. 3. Wiring for the 1X2 filament lead of the Belmont 12AX22.

Code 17 or Group Numbers 9,000 to 12,399. To reduce "snow" in the pictures, the yellow lead from the tuner (terminal 9) was disconnected from agc and reconnected to ground. To reduce capacitor failures, capacitor C64 is replaced with a 0.01-μf, 600-volt capacitor (C-8D-11128).

Code 18 or Group Numbers 12,400 to 14,199. To reduce horizontal size, the white and black leads to the horizontal-deflection transformer T6, lugs 2 and 3, respectively, were interchanged, black to lug 2 and white to lug 3.

Code 19 or Group Numbers 14,200 and above. Both the C-12M-18689 and C-201-18562 horizontal-deflection transformers were removed and replaced with new transformers. The part numbers are the same with the addition of a dash one (—1). The black and white horizontal-deflection-transformer leads are connected as in Code 17. Resistor R4 is changed to 10,000 ohms. Resistors R8 and R10 are grounded, C33 has been deleted, and the tuner chassis filament wiring has been changed. Pin 4 of the 6AG5 is grounded, pin 3 of the same tube and pin 3 of the 6J6 are tied to tuner terminal 8 and go to H. Pin 4 of the 6J6 is grounded. C30, C31, and C32 have been deleted. C25 has been deleted. The value of R45 is changed to 220,000 ohms (C-9B1-90), and a resistor R110, 220,000 ohms, ½ watt (C-9B1-90) has been added from pin 5 of the 6SL7 sync amplifier, tube 9-A, to ground. R28 is changed to 120 ohms.

To elimihate vertical jitters, R73 is changed to 68,000 ohms (C-9B1-84). R72 is changed to 1.5 megohms (C-9B1-100). C95 is changed to 0.02 μf (C-8D-17607). C106 is changed to 0.1 μf (C-8D-10771). Capacitor C91 is deleted. C90 has been relocated to between R77 and C95, and its value has been changed to 0.005 μf (C-8D-17608). A 27-inch, 300-ohm jumper is connected in parallel between the high- and low-band antenna terminals. The changes applying to C90, C91, C95, C106, R45, R72, and R110 were made to remove horizontal waver and to improve vertical sync. A dual control and switch (A-10A-18441) have been added to the parts list.

Capehart-Farnsworth CX-33

Sometimes a "whistle" occurs in the sound and/or lines (similar to a Barkhausen effect) appear in the picture, although both symptoms do not always appear. The cause in most cases is due to the fact that C-242D (electrolytic, between —90-volt point and chassis ground) has a higher than normal impedance at the horizontal oscillator frequency. To improve by-passing at this frequency, a 0.1-μf, 200-volt capacitor is connected from the —90-volt point (junction of R-291 and R-290 near the 6BG6 tube) and chassis ground. This capacitor will be added in production.

If difficulty is encountered in accurately aligning the primary of transformer T-204, to the 4.5 Mc, it is possible that the tuning range has deviated, due to variations in material. A 5-$\mu\mu f$ capacitor connected from terminals 3 and 4 of T-204 should correct this condition.

If the picture focus lacks sharpness, it may possibly be improved by connecting a 2,200-ohm 2-watt resistor in parallel with R-297 (focus control) and R-296B. This connection can be made at the terminals of the filter capacitors C-243C and C-264B. This change should be tried only after carefully making normal adjustment to obtain proper focus.

Where vertical instability occurs, check capacitor C-230 from the cathode of the 12AU7 pre-sync separator. The lead may have been broken in shipment. Check the value of R-256 grid resistor of the 6SN7 sync-clipper to ground, and if it is higher than 3.9 megohms, replace. Check R-269, the 38,000-ohm temperature compensating resistor in series with the vertical hold control. Its normal value (at 25° C) is 38,000 ohms, plus or minus 20%. As the chassis operating temperature rises, its value will decrease to a minimum of 18,500 ohms, plus or minus 20% (at 65° C). Replace this resistor if it is out of these limits, and especially if it increases in value.

Crosley 10-401

To prevent breakdown due to arcing between the plate leads of the 6BG6 tube and the damper, install 3½ inches of fiberglass sleeving (part no. 39468-14) over the 6BG6 plate lead. This sleeving should be placed toward the terminal on the horizontal deflection transformer.

Horizontal sweep sing can be caused by vibration of the mounting bracket on the horizontal output transformer, T107. This mounting bracket occasionally vibrates at a sub-harmonic of the 15,750-cps horizontal sweep frequency. On later production sets this condition has been corrected by dipping the core and mounting bracket in a high melting point wax. Receivers that do not have this wax treatment can be corrected by inserting small wedges between each end of the transformer and the chassis. It is not necessary to remove the chassis from the cabinet to make this correction.

Crosley 10-414MU, 10-416MU, 10-416MIU, 10-429MU

On later sets resistor R151, 150,000 ohm, 10%, ½ w (part No. 39374-51) was changed to 220,000 ohm, 10%, ½ w (part No. 39374-53). This change was made to increase the horizontal hold control range.

DuMont RA-101B, RA-102, RA-103

If vertical jitter occurs in these chassis the following modification is suggested: (See the schematic for the deflection chassis.)

1. Disconnect the blue lead of the vertical BTO transformer from the B+ supply point.
2. Disconnect the red lead of the vertical BTO transformer from the end of the integrator network, and ground the red lead to the chassis.
3. Connect one terminal of a 0.01-400-v (0.01-450 volt for RA-103 only) paper tubular capacitor to the point from which the red transformer lead was removed in Step 2.
4. Connect the blue transformer lead to the remaining lead of the 0.01 capacitor.
5. Connect a 27,000-ohm, 2-watt carbon resistor to the plate (pin 8) of the vertical sync amplifier V6 (V216-A in RA-103).
6. To the open end of the 27,000-ohm resistor, connect a 4700-ohm, 1-watt, carbon resistor and the positive terminal of an 8-μf, 450-v, electrolytic capacitor.
7. Ground the negative terminal of the 8-μf capacitor to the chassis.
8. Connect the open end of the 4700-ohm resistor to the point from which the blue transformer lead was removed in Step 1.
9. Remove resistor R270, 12,000 ohms. (This step applies to Chassis RA-103 only.)

DuMont RA-101B

The connection from the 4.5-Mc trap (V17) to the junction of L47 and R91 has been deleted. Resistor R91 which goes from L47 to the junction of R89 and R94 has also been deleted.

DuMont RA-109A, RA-111A

Type 6CB6 tubes may be substituted for 6AU6's in the 2nd sound i-f amplifiers of the RA-109A and RA-111A sets. This substitution requires the addition of a tube shield (part number 42002530) and a shield base (part number 42002540). The latter may be readily soldered in place, rather than riveted or bolted.

A 6BC5 may be substituted for the 6AU6 first sync clipper, V219, in the RA-111A set. This change does not require the addition of parts or wiring.

Type 6BA6 tubes may be used in place of the 6AU6's in the 1st and 2nd video i-f of the RA-109A and RA-111A sets, providing both 6AU6's are replaced by two 6BA6's simultaneously. It is not advisable to use one 6BA6 and one 6AU6 in these positions.

DuMont RA-102 Series

These chassis appear on *pages *1-34 through *1-57 of Rider's TV Manual Volume 1.* Low picture i-f sensitivity will cause the picture level to drop when the sound carrier is properly tuned in. The condition will be most apparent on stations with low signal strength. If this occurs, check the vacuum tubes in i-f chain. Also a defective 1N34 video rectifier or a poor vacuum tube in the inputuner may be the cause.

The following list are given as an aid for servicing RA-102 Telesets:

Indication	*Cause*
No bigh voltage.	Defective 8016 or 807 in power supply. Defective high-voltage transformer.
Picture has horizontal wobble.	Defective 6AC7 (video amplifier), 807's (horizontal output stage), or 6SN7 (1st sync amplifier).
Notches in picture or raster (moving up and down).	Bad 6AS7.
Picture size varies excessively during evening's operation.	Improperly adjusted high voltage.
Poor definition.	Bad crystal.

DuMont RA-102

The large amount of noise flashes on the cathode-ray-tube screen has been traced to corona discharge in the high-voltage r-f power supply. The remedies suggested are: (1) lead dressing to lengthen discharge path; (2) insulating sleeving on leads; (3) painting exposed high-voltage points with insulating compound.

Evenly spaced carriers across the broadcast band every 17 kc are caused by continuously running h-v r-f oscillator or horizontal sweep oscillator. Causes may be:

1. Bias on h-v oscillator has dropped so that oscillator is free running without triggering from sweep circuits. Check cathode resistor, grid resistor.
2. Beam cut-off relay not opening when television is switched off. Clean contacts or adjust armature return spring tension.

The front-to-back resistance ratio of the 1N34 crystal rectifier should be at least 100 to 1. If the ratio falls below this, the crystal should be replaced. These resistance ratios may be measured with a common ohmmeter.

Emerson 651C, 651D, 658B, 658C, Ch. 120124

In the event that this chassis causes interference on a-m radio sets, the following change will eliminate it:

1. Add a 0.05-μf, 400-volt capacitor from line switch side of a-c input plug.
2. Add a 100,000-ohm, 1-watt resistor in parallel with above capacitor.

The following changes will reduce internal radiation effects upon sync stability:

1. Remove the lead from junction of R-6 (1000 ohms), R-31 (1 megohm), C-37 (0.25 μf), to V-8 (6T8) pin 6.
2. Add a 1500-$\mu\mu f$ capacitor from the B+ side of fuse F-1, to chassis. The leads should be ¼" long.
3. One side of R-35 (100,000 ohms) now goes to the chassis, instead of to pin 7 (V-4, 6AU6).
4. Remove the 225-volt B+ lead from the fuse to the dummy lug under T-8, the horizontal oscillator transformer.

5. From the fuse on the dummy lug, add a B+ lead through the high-voltage box, along the top of the chassis to the chassis hole near the power transformer, through this hole to the plus terminal of C-51. C-51 is part of C-49 and is designated by a square on the top of the can.
6. Remove the secondary of the vertical output transformer (T-7) leads from the dummy lug under the deflection yoke.
7. Reroute the leads through the high-voltage box and along the top of the chassis, solder back to the same dummy lugs. These lugs also hold leads from the vertical deflection coils L-8.
8. Reroute the lead from the horizontal size coil L-11 to the horizontal deflection coil L-9 through the high-voltage box and along the top of the chassis.
9. Add a metal shield 4" long by 2" along the side of the i-f dummy-lug strip.
10. Change C-73 from 50 $\mu\mu f$, mica capacitor, to 42 $\mu\mu f$, ceramic, 2000 volts, (part #928058).

Sets coded with triangle 4 have all above changes except Step 10.

Sets coded with triangle 5 have all above changes including Step 10.

Emerson 66B, 86B; 611, Ch. 87B

In the Oscillator Alignment Chart, under the column headed VTVM, the VTVM goes to the junction of R41, C28 and C29 for Chassis 66B, only. For Chassis 86B and 87B, the VTVM should go to point C.

Farnsworth B504P16, Ch. U-12

The B504P16 is a television, a-m—f-m radio and phonograph combination similar to the 504P16. The picture tube used in this instrument is the Farnsworth "160" type (16½ inch direct view). The instrument employs the U-12 television chassis, C-265 h-v supply chassis, P7 a-m—f-m chassis with a separate pre-amplified chassis, and the P777 three-speed record changer. The cabinet has been revised from the original 504P cabinet to provide a "truncated circle" opening for the 16½-inch picture tube.

The C-265 h-v supply chassis is identical to the C-266 chassis which is used in Model 462P12. The C-265 version uses the long cables, whereas in the C-266 the power cable, deflection cable and anode connector are of the short type.

Farnsworth, Capehart Models 461P, 501P, 502P, 504P, Ch. U-12

Models 501P, 502P, and 504P use the Capehart P-7 a-m—f-m radio tuner chassis and the Capehart Automatic Intermix Record Changer, Model P-71. Model 461P is a television receiver only, and uses, in conjunction with the U-12 Chassis, the Capehart A-13 Audio Amplifier. The schematic for the A-13 is given in Fig. 1. There have been incorporated in production, three versions of the 12-kv high-voltage supply, which were necessitated by the use of three different focus coils.

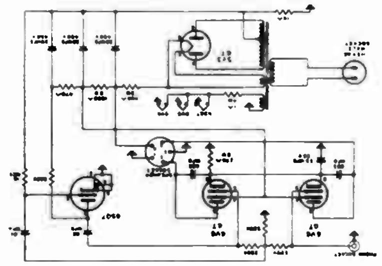

Fig. 1. Schematic diagram for the Capehart A-13 Audio Amplifier.

The focus coil originally used, part number 38955, is an electromagnetic coil. Focus coils part numbers 650001A-1 and 650001A-2 shown in Fig. 2 (for 10- and 12-inch picture tubes, respectively) are part electromagnet and part permanent magnet, therefore the latter two require much less current than the former.

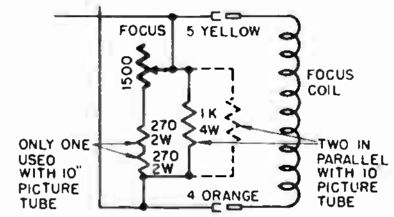

Fig. 2. Focus coils used in the U-12 Chassis.

Two types of r-f sub-assemblies have been incorporated: (1) that switching coils in selection of channels, and (2) that using continuous variable capacitor tuning. The latter, provides 12 channel reception (channel 1 is deleted since this channel is no longer assigned to telecasting service by order of the FCC) and channel identification is by a brass pin extending from the selector switch. The schematic for the 12-channel r-f unit, part number 13900, is shown in Fig. 3.

Additional changes have been made in the U-12 Chassis. A 100,000-ohm resistor has

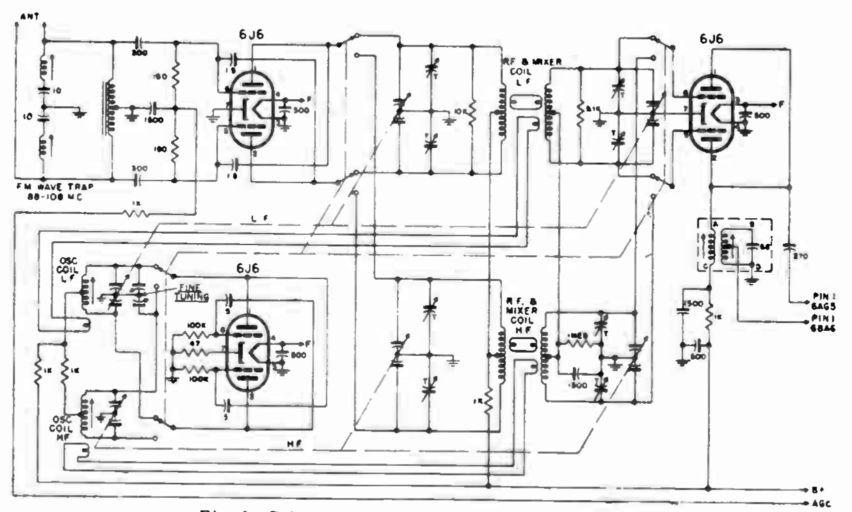

Fig. 3. Schematic for the r-f unit Part No. 13900.

©John F. Rider

been inserted from R42 to +270 volts. A 0.2-μf capacitor has been inserted from the junction of the 100,000-ohm resistor and R42 to the 3-megohm volume control and C39. Resistors R204 and R208 have been deleted. A 47-ohm, ½-watt resistor has been inserted from tap 2 of T201 to the plate of the 6BG6 Pin 5 of the audio socket is now connected to the junction of the power transformer and C34, and pin 7 is connected to the junction of the jumper and the transformer. (The jumper is removed on Model 461P.) A 9,000-ohm, 5-watt resistor has been inserted from tap 1 of T201 to the junction of R205 and R209. R203 is now connected to the junction of the ¼-amp fuse and the cathode of the 5V4G. The tube socket voltage readings are shown in the accompanying chart.

Gamble-Skogmo "Preview," 05TV1-43-9002A

The "Preview" model 05TV1-43-9002A is electrically identical to Model 94TV1-43-8940A. The 05TV1-43-9002A replacement parts list is identical to the 94TV1-43-8940A except for cabinet parts which are listed below:

Part No.	*Description*
R-24D-18709	Cabinet
C-2M-18191	Escutcheon
C-2M-18187	Escutcheon mask
B-30M-18201	Picture glass
B-2M-17067-1	Channel indicator plate
B-2M-17068-1	Contrast off-volume plate
B-5B-18552-76	Tuning knob
B3B-18555	Tuning knob bushing
A-2M-18558	Tuning knob spring
A-6M-17803	Indicator, tuning knob
B-5B-17761-76	Knob, volume
B-5B-17762-76	Knob, contrast
B-5B-18244-76	Knob, 3 used
B-2M-18553	Vernier arm
B-3B-18554	Vernier bushing
A-3C-18551	Vernier stud
A-2M-18557	Vernier spring
C-23J-18722	Cabinet back
B-14M-17758	Line cord and plugs
C-18A-18157	10" p-m speaker
N-201-8386	TV Antenna assembly
B-5B-18382-36	Antenna knob.

*Has a.c. component of approx. 6000 volts.
**Has a.c. component of approx. 10000 volts.
All voltages measured from terminal to ground.
Line voltage, 117 volts, 60 cycles a.c.

Power transformer tap switch set to 115 volt position.
All controls set for normal operation except where otherwise specified.
No signal received.
All voltages measured with Vacuum-Tube-Voltmeter.

Gamble-Skogmo 05TV1-43-8940B, 05TV1-43-9002B

These models are similar to Model 94TV1-43-8940A and Model 05TV1-43-9002A except for the following changes. Models 8940B and 9002B are 12½-inch television receivers, and the 9002B employs a 10-inch p-m speaker. A chassis identification number is assigned to each receiver in production. After identification number (group number) 14,200, a wiring change was made to improve the vertical sync, reduce "snow" in the picture, and to remove the tendency toward horizontal wavering. This wiring change was accompanied by a model number series change from A to B in both the 8940 and 9002 receivers.

The models 8940B and 9002B are identical to the 8940A and 9002A with the exception of the tuner input wiring and the changes listed for Model 94TV1-43-8940A. The changes in the parts lists are as follows:

	C-23J-18722	Back cover (9002)

Gamble-Skogmo 94TV1-43-8940A

Improper neutralization of the sync amplifier may result in a severe horizontal shift of the entire picture with contrast control adjustments and may also start hunt oscillation (squegging) of the horizontal afc circuit. Squegging, evidenced by white lines or streaks running diagonally across the picture, ringing from the speaker, or singing from the horizontal deflection transformer, may cause damage to the 6BQ6, 6W3, 1X2, or horizontal deflection transformer. If this condition is noticed, it will be necessary to adjust the neutralization of the sync amplifier as shown below:

1. Disconnect the antenna.
2. Ground pin 5 of V7.
3. Rotate the contrast control to its normal operating position.
4. Connect a vtvm (±10-volt range) across capacitor C-106 (near pin 4 of horizontal multivibrator 6SN7).
5. Short pin 5 of 6SL7 to ground.
6. Turn set on and check vtvm reading. (Should be within ±0.5 of zero volts. If not within this, check capacitors C-99, C-100, C-101, C-102, and resistors R-82 and R-87.)
7. Remove the short at pin 5 of 6SL7 from ground and note vtvm reading. If the voltage goes positive, move the two neutralizing capacitors C-71 and C-116 closer together to reduce the voltage to zero. Should this adjustment be insufficient, spread the black and blue leads connected to pins 2 and 4 of the 6SL7. If the voltage is negative, do the opposite.
8. When the vtvm reading is zero, the receiver is properly neutralized.

Garod 12T6, 14C4, 14T2, 14T6, 16C6, Series 94

Except for cabinet designs or picture tube size, Models 12T6, 14T2, and 14T6 are the same as Model 12T2, Model 14C4 is the same as Model 12C4, and Model 16C6 is the same as 16C4.

General Electric 814, 820, 830, 840

A new ceramic-core sweep transformer, Stock No. RTO-071, is recommended as a substitute for the original molded horizontal-sweep output transformers for these models. It has several electrical design improvements over the originally specified transformer, among them are higher efficiency and better high-voltage insulation.

The transformer is equipped with a 470,000-ohm resistor in shunt with a 0.0022-μf capacitor, connected between the primary and high-voltage windings. In order to provide identical electrical characteristics to the original transformers, a few circuit revisions are necessary when the substitution is made. Kits

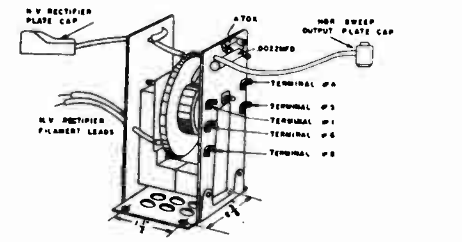

Fig. 1. RTO-071 transformer used in General Electric Models 814, 820, 830, and 840.

are available which contain all the additional components, except transformers or tube, which are required to make the conversions. Fig. 1 is a sketch of the RTO-071 transformer.

Fig. 2 shows the seven steps required to change the circuit for the use of the substitute transformer. The procedure is as follows:

1. Disconnect leads of defective sweep output transformer, including filament loop for 1B3GT rectifier tube. Note that R67, R62, and C103 contained in lead of sweep transformer are removed and discarded.
2. Remove old size control L18 and its shunt resistor R64. Replace it with the new horizontal size control (Stock No. RLD-014). Before installing new control, the mounting hole will have to be enlarged to accommodate the shoulder of RLD-014.
3. Remove old linearity control L19 and its shunting resistor, R65. Replace it by the new linearity control (Stock No. RLD-014).
4. Mount new sweep output transformer (Stock No. RTO-071) in place. See sketch for lead identity so as to effect most satisfactory placement of transformer. Wire the new transformer to the circuit according to the diagram, Fig. 2.
5. Remove type 5V4G tube, V15, and discard. Reconnect V15 socket for new type 6W4GT tube as shown on diagram. Connect the heater of the 6W4GT tube in parallel with the picture tube heater winding. Note: If line voltage remains above 105 volts, the filament of the 6W4GT tube may be connected to the 5-volt winding that supplied the 5V4G damper tube.
6. Remove R60 and R61. Replace them with two 27,000-ohm resistors connected in parallel.
7. Reconnect the h-v capacitor, C53, so that the connection from the stand-off which was disconnected in Step 1, reconnects to chassis ground as shown in Fig. 2.

The conversion components required are:—
1 Stock RTO-071 transformer
1 Type 6W4GT tube
1 Stock RKT-004 kit.
The kit consists of:—
2 URF-083, 27,000, 2 watts, carbon
2 RLD-014, controls.

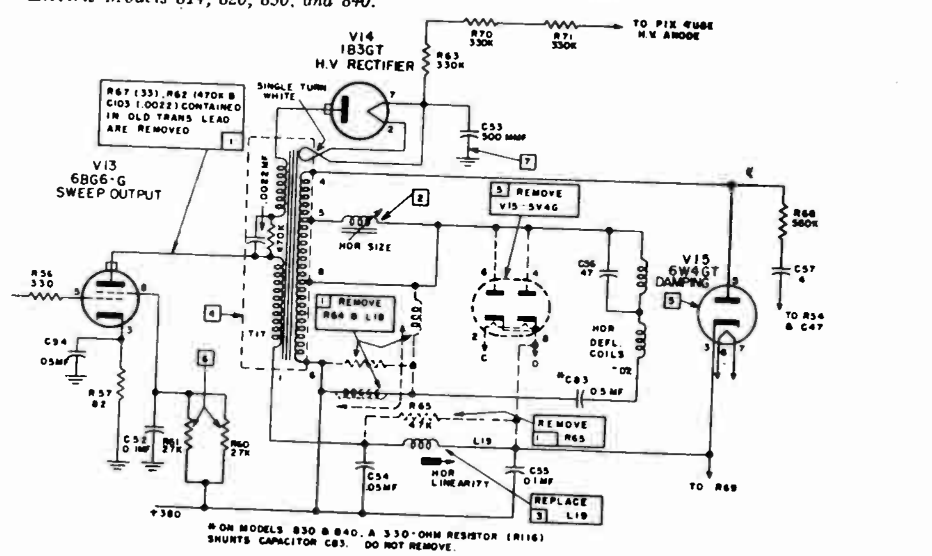

Fig. 2. The seven steps required to change the circuit of General Electric Models 814, 820, 830, and 840, for the use of transformer RTO-071.

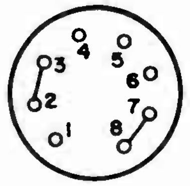
©John F. Rider

General Electric 12K1, 818

An adapter plug may be made which makes it unnecessary to remove the television chassis when service has to be rendered on the radio chassis only of Models 818 and 12K1. A standard octal tube base is wired as shown in the sketch below. A jumper is connected between pins 7 and 8 and also between pins 2 and 3. This plug is then inserted into the J-4 socket on the radio chassis to re-instate audio continuity and to energize the tube filaments when the radio is separated from the TV chassis. A-c power is furnished at pin 3-4 of P3 or with a suitable plug in receptacle J-2. *Precaution*—When using the latter point for power connection, it requires a male pin jack which makes the pins "hot" at 110 volts.



Wiring for standard octal tube base for General Electric 12K1 and 818.

The plug shown above may also be used when servicing the television chassis separated from the radio chassis. When this plug is inserted into the octal socket J5 on the television chassis, it permits application of power to the television chassis for alignment or trouble shooting purposes.

General Electric 810, 811, 835

A new ceramic-core sweep transformer, Stock No. RTO-071, is recommended as a substitute for the original molded horizontal sweep output transformers for these models. It has several electrical design improvements over the original specified transformer, among them are higher efficiency and better high-voltage insulation.

The transformer is equipped with a 470,000-ohm resistor in shunt with a 0.0022-μf capacitor, connected between the primary and high-voltage windings. In order to provide identical electrical characteristics to the original transformer, a few circuit revisions are necessary when the substitution is made. Kits are available which contain all the additional components, except transformers or tube, which are required to make the conversions. Fig. 1 is a sketch of the RTO-071 transformer.

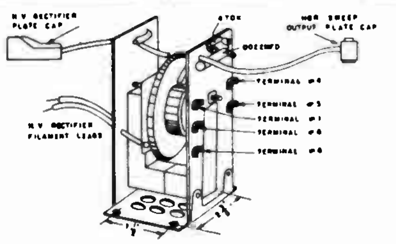


Fig. 1. RTO-071 transformer used in General Electric Models 810, 811, and 835.

Fig. 2 shows the five steps required to change the circuit for the use of the substitute transformer. The procedure is as follows:

1. Disconnect leads of defective sweep output transformer, including filament loop for 1B3GT tube. Notice that R67, R62, and C103 are removed with it. Mount new transformer on chassis. See Fig. 1 for lead identity to effect most satisfactory placement of transformer. Wire new transformer into the circuit according to the diagram in Fig. 2.
2. Add a 27,000-ohm resistor, URF-083, in parallel with R60 and R61 as shown.
3. Disconnect the white lead of the horizontal size control, L18, that connects to pins 4 and 6 of V15, and reconnect it to terminal 8 of the sweep transformer. Make sure that the leads from the horizontal size coil do not short to the frame of the sweep transformer. Connections from terminals 5 and 8 of the high-voltage transformer should be made with the high-voltage insulation wire.
4. Connect the 1,200-$\mu\mu$f capacitor, UCU-2054, in series with the 1,500-$\mu\mu$f capacitor, RCU-285. This series combination is then connected between terminals 6 and 8.
5. Remove the 4,700-ohm resistor, R65, from across the horizontal linearity control L19.

The conversion components required are:
1—Stock RTO-071 transformer
1—Stock RKT-003 kit.

The kit consists of:
1—URF-083, resistor, 27,000 ohms 2 w, carbon
1—USU-2054 capacitor, 1,200 $\mu\mu$f, mica
1—RCU-285, capacitor, 1,500 $\mu\mu$f mica.

Readjustment of the blocking oscillator transformer, T16, may be necessary. In some cases, if proper centering of the horizontal hold control cannot be had, it may be necessary to reduce or increase the value of R52 somewhat to effect the correct adjustment of the blocking oscillator transformer. This change should be limited to values between 35,000 and 82,000.

There will probably be two settings of the horizontal linearity control which will be found to give good linearity. The proper setting is the one with the slug withdrawn from the center of the coil, or minimum inductance. The other position may cause some "squaring" of the outside circle of a test pattern.

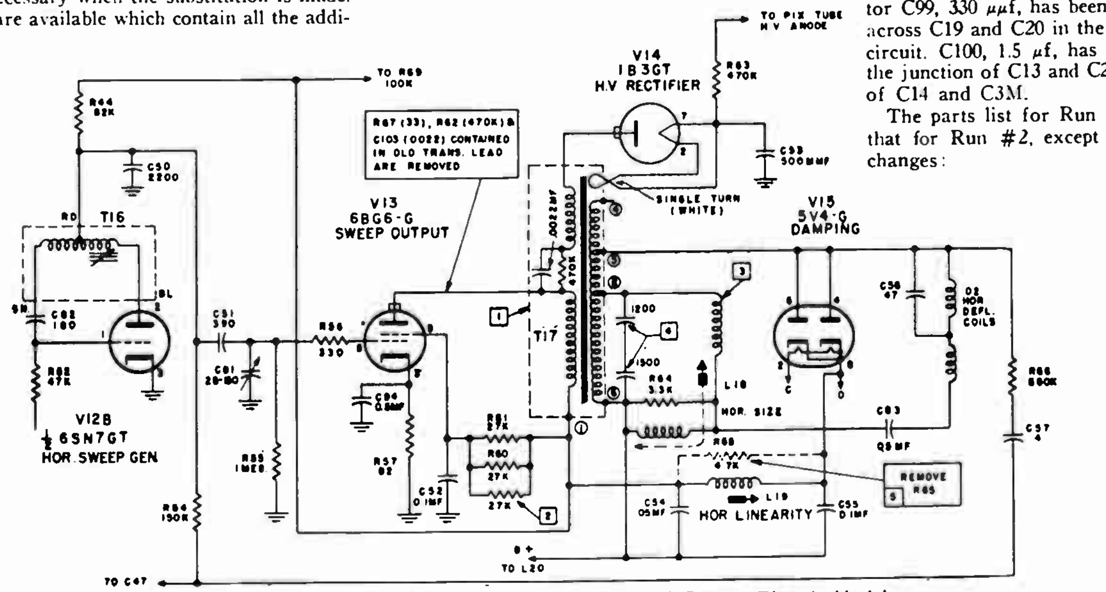

Fig. 2. The five steps required to change the circuit of General Electric Models 810, 811, and 835, for the use of transformer RTO-071.

General Electric 810, 814, 820, 830, 835, 840

The following miscellaneous repair parts are added for the head-end unit of the above receivers:

Part No.	Description
RBI-001	Strip, textolite bearing strip for selector switch shaft
RHM-070	Washer, oversize "C" washer (47 mils) to remove end play from the switch shaft
RSC-001	Wafer, front switch wafer of head-end unit
RSC-002	Wafer, center switch wafer of head-end
RSC-003	Wafer, rear switch wafer of head-end unit.

General Electric 817, 821

Under PRESET CONTROLS, the description of the TILT control was omitted. The following should be added:

TILT—if raster is slightly tilted and does not square with the picture-tube mask, rotate the deflection yoke in its clamp bracket by loosening the wing screw.

Hallicrafters T-54, 505, 506, Run #3

Model 506 is the same as Models T-54 and 505. Run #3 is the same as Run #2 except for the following changes:

Resistor R29 from pin 5 to pin 6 of the r-f amplifier, V5, has been deleted. C61, a 0.005-μf capacitor in the vertical oscillator circuit has been deleted. C23, a 0.05-μf capacitor connected from ground to the volume control has also been deleted. R119, a 220,000-ohm resistor has been added in place of C23, from the volume control to ground. Capacitor C99, 330 $\mu\mu$f, has been added in parallel across C19 and C20 in the f-m detector, V2, circuit. C100, 1.5 μf, has been added from the junction of C13 and C2M to the junction of C14 and C3M.

The parts list for Run #3 is the same as that for Run #2, except for the following changes:

Hallicrafters Ref. No.	Part No.	Description
C1, 2	44B358	Trimmer assembly, mixer and r-f amp. stage, 13 sections
C3	44B357	Trimmer assembly, osc. stage, 13 sections
C100	47A160-3	1.5 $\mu\mu$f, 500 v, bakelite
C51, 66	46AU503J	0.05 μf, 200 v, tubular
C101	47A168	5,000 $\mu\mu$f, 500 v, ceramic
R120	RC20AE101M	100 ohms, ½ w, carbon
R119	RC20AE224K	220,000 ohms, ½ w, carbon.

Hallicrafters T-54, 505, Run #2

Run #2 is similar to Run #1 except for the following changes:

Tube V3, the audio amplifier has been changed for a 6SH7 to a 6AV6; and R22, 680,000 ohms, and C24, 0.05 μf, that were connected to pin 6 of the 6SH7 have been deleted. The tap from the volume control goes to pin 1 of the 6AV6. R20 goes from ground to the cathode, and R21 goes from the cathode to the 110-volt bus. The value of R23 has been changed from 100,000 ohms to 470,000 ohms. Capacitor C98, 10 μf has been added in parallel across cathode resistor (V4) R25.

Tubes 1, 7, 8, 9, 11, have been changed from type 6SH7 to type 6AU6. R33, connected to pin 1 of V7, has been changed from 27,000 ohms to 18,000 ohms. R39, connected to pin 1 of V8, has been changed from 27,000 ohms to 12,000 ohms. R40, connected to pin 1 of V9 has been changed from 27,000 ohms to 18,000 ohms. L24 has been deleted from the 3rd i-f circuit and R117, 6,800 ohms, substituted in its place, from pin 5 to pin 6 of V9. The value of C52, connected from pin 1 of V12 to pin 5 of VII, has been changed from 0.25 μf to 0.1 μf. The value of C17, connected from pin 3 of V12 to pin 2 of V13, has been changed from 0.25 μf to 0.1 μf.

R55 in the cathode circuit of the picture tube V13, has been changed from 150,000 ohms to 470,000 ohms. R11, 5,600 ohms, connected from ground to the brightness control R56, has been deleted. R56 now goes directly to ground.

R116, 6,800 ohms, in the circuit of V14 and in parallel with R58, has been deleted. The value of R58 has been changed from 6,800 ohms to 3,300 ohms. The value of R83, connected from pin 4 of V18 to the vertical hold, has been changed from 680,000 ohms to 560,000 ohms. The values of C73 and C74, connected to pins 2 and 5, respectively, of V20, have been changed from 0.05 μf to 0.03 μf. The value of R108, connected from pin 3 to pin 4 of V12, has been changed from 68 ohms to 120 ohms.

The following changes in the parts list for Run #1 should be made for Run #2:

Hallicrafters Ref. No.	Part No.	Description
C17,52	46AU104J	0.1 μf, 200 v, tubular
C73,74	46B149	0.03 μf, 6000 v, tubular
C98	45A121	10 μf, 25 v, electroytic
R39	RC20AE123K	12,000 ohms ½ w, carbon
R23,55	RC20AE474M	470,000 ohms ½ w, carbon
R33,40	RC20AE183K	18,000 ohms ½ w, carbon
R83	RC20AE564M	560,000 ohms ½ w, carbon
R117	RC20AE682M	6,800 ohms ½ w, carbon
R58	24BG332E	3,300 ohms 10 w, ww
R108	RC40AE121M	120 ohms 2 w, carbon
V1,7,8, 9, 11	90X6AU6	Type 6AU6, audio i-f; 1st, 2nd and 3rd i-f amp; video amp
V3	90X6AV6	Type 6AV6, audio amp.

Hoffman CT800, CT801, CT802, CT900, CT901, Ch. 135

The following trouble symptoms and their probable causes also apply to Model CT902, Ch. 141, and Models CT816, CT817, Ch. 145.

Trouble	Cause
A. No raster, Sound o.k.	1. Fuse blown. (Usually caused by shortened V126 or shorting T109.) 2. Shorted or open V126. 3. Open V127. 4. Open or shorted V120B. 5. Shorted C176. 6. Shorted C187. 7. Open or intermittent R235. (Causes picture to bloom when defective.) 8. Defective picture tube. 9. Shorted V128. 10. T109 open or shorted. 11. Check leads going to V126 and V127 in h-v cage to see that they are not touching each other or not arcing to metal cage. 12. Defective V125. 13. Open R199 or R200. 14. Check high-voltage lead going to picture tube. (Voice coil open.)
B. No sound, weak or distorted sound. Picture o.k.	1. Defective or open V104, V105, V106, V107, V108, or V109. 2. Defective speaker. Voice coil open.) 3. Defective T114. 4. Open C206. 5. Defective C208 or C209.
C. A film-like distortion on left side of picture as contrast turned up.	Usually one turn of primary sync lock transformer will phase correctly. This adjustment of sync transformer is under chassis.
D. Picture unstable horizontally.	1. Defective V124. 2. R200 changed value. 3. Open C170—gives sawtooth effect throughout picture. 4. Weak V123. 5. R188 changed value. 6. Arcing under V126. 7. T108 frequency off. 8. Defective C169 and C171. 9. Defective C144. 10. Defective V118-V119. (Usually causes picture to travel sideways.)
E. No picture. Raster o.k. Sound o.k.	1. Shorted C116, C123, C128, C134, C138, or C140. 2. Open L187, L190, or L192. 3. Defective V110, V111, V112, V113, V114, V115, or V116. 4. R127, R134, or R140. If any of these resistors burned, check for cause.
F. Hum.	1. If hum is caused by head end use 5,000-ohm resistor from test loop to ground. 2. V108 for bad contact. 3. 6J6 oscillator. 4. V107, V108, V109. 5. C208 leaky. 6. 6J6 oscillator may induce a slow starting motor-boating effect and increase rapidly until maximum is reached, then become normal.
G. Vertical sync.	1. Defective R171, R166, R167. 2. Defective V121. 3. Defective C151, C152, C153. 4. R162, R163, R164, R165 off value. 5. C149 open.
H. Noisy or chattering sound.	1. Be sure tubes are tight. 2. Check tightness of T111, T112, and T113. 3. Check contact of r-f tubes to bead-end sockets. 4. V108, V109 intermittent. 5. Breaking down of C208 and C209. 6. Control shafts rubbing against front metal plate.
I. Hum in picture.	1. Shorted V116 or V114. 2. Loose grid connections on V110, V111, V112, V113. 3. Faulty C224, C223.
J. Insufficient width.	1. Weak V126. Also causes fold over of picture. 2. T109 defective. 3. Open C180. 4. If all above is o.k. then proceed as follows: a. Add 0.05-400v across terminals 5 and 6 of T109. b. Open width coil at terminal 5. This removes shunting effect of width coil.
K. Insufficient height.	1. Leaky C157 and C158. 2. R177 changes value. 3. Weak V122. 4. If vertical linear circuit is normal, parallel R177 with like value for more height.
L. Picture blooms and goes out.	1. R235 intermittent. 2. 1B3 defective. 3. Check high-voltage through following parts: V126, T109, V120, R204.
M. Sound in picture after adjustments made on cathode trap and converter coil.	1. Microphonic V124. 2. V119, V118, V121, V122. 3. Microphonic tubes in r-f unit. 4. Microphonic tubes in picture circuit.
N. Horizontal white line. No picture.	1. Defective V121, V122. 2. If both tubes o.k., check connections under same tubes.
O. Horizontal white line through picture. Also in raster.	1. Irregular characteristic of V122; replace. 2. Replace V121.
P. Horizontal white line accompanied by white flashes.	1. Intermittent V126. 2. Also causes small sawtooth noticeable on black border of pattern.
Q. Dark vertical lines left side of picture on high channels.	1. Replace 6BG6, V126. Lines caused by transients at start of sweep.

Hoffman 820, 821, 822, Ch. 146

These models appear on *pages 3-1 through 3-19 of Rider's TV Manual Volume 3*. Natural springiness of the backboard on Models 820, 821 and 822 tends to pull the power plug from the interlock socket even when all parts are in their normal positions. To prevent the plug from unintentionally being removed from the socket, sets manufactured after Serial No. E 906729 will have a redesigned power-plug mounting.

On sets of prior manufacture, the problem can be satisfactorily solved by putting an additional wood screw, #6-1" length through the backboard and into the wood chassis shelf at a point below the power plug. This additional screw will spring the backboard in, and hold the power plug firmly in place.

Hoffman 826, 827, 828, Ch. 143

A vertical white line sometimes appears in the left portion of the picture, about two- to four-inches in from the left side on some receivers with 16-inch picture tubes. The vertical disturbance may appear in any form from two light, slightly displaced traces to a broad, fuzzy band. The actual condition is a foldover of the raster, and the edge of the raster appears as if it were behind the picture a few inches from the edge. If the horizontal sync pulses are viewed on an oscilloscope, the position of the vertical line will be indicated by two small pips on the sawtooth portion of the horizontal sync trace.

The coupling capacitor C161, to the grid of the 6BG6G horizontal output tube, is at present a 0.01-μf, 400-v paper tubular capacitor (part no. 4112). A capacitor change to 0.001-μf, 500-v, ceramic tubular capacitor will eliminate most cases of the left-side vertical white line. Do not decrease the capacity below 0.001 μf, as coupling capacitance below this value tends to cause a right side foldover. The part number of the new capacitor is 4025.

This also applies to Models 830 and 831, Ch. 151 and Models 917 and 918, Ch. 152.

Hoffman Ch. 140, 142, 143, 146, 147

The video i-f string may be peaked for additional gain at a sacrifice of bandwidth to aid reception in low-signal areas.

The procedure is set up on the basis that the adjustments may be made in the field without the aid of a sweep generator or 'scope. All adjustments on the i-f coils are reached from the top of the chassis and may be accomplished without removing the chassis from the cabinet, in sets produced prior to Serial No. E 906732

Ref. No.	Circuit Position	Adjustment
L102	Plate circuit 2nd video i-f	Counterclockwise, 1½ turns
L103	Plate circuit 3rd video i-f	Clockwise ½ turn
L104	Plate circuit 4th video i-f	Counterclockwise, 1 turn.

Fine trimming of the i-f tuning may be accomplished with a sweep generator and 'scope. The resultant i-f characteristic will have approximately twice the gain of the normal amplifier, and will have a bandpass of about 3 megacycles between 50% points. This bandpass characteristic applies to all sets, regardless of sound i-f take-off point.

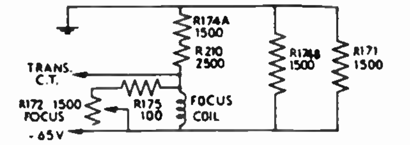
World Radio History

Hoffman 612, Ch. 142; 820, 821, 822, Ch. 146

Insufficient adjustment range of the focus control R172 has occurred in 12-inch chassis using the DuMont 12QP4 picture tube. The 12QP4 tube requires more focusing current through the focus coil than other 12-inch tube types, and maximum counterclockwise rotation of the focus control will not bring the tube to its optimum focus.

Circuit changes to increase the amount of current through the focus coil can be accomplished by changing one resistor and adding another resistor, as shown in the accompanying diagram.



Circuit changes for Hoffman Chassis 142 and 146.

The 2,500-ohm resistor formerly used as R171 may be used as R210. The 1,500-ohm resistor now used as R171 should be the wire-wound type. R174A and B are a single large Candohm resistor, center tapped to form the two sections.

Old Part	New Part	Difference
R171 (4714)	R171 (4715)	Decreased from 2,500 ohms to 1,500 ohms 5 watts
——	R210 (4714)	Added 2,500 ohms in series with R174A (1,500 ohms)

These changes will increase the current through the focus coil, and bring the adjustment of the focus control near the center of its range. These changes have been made on all sets produced after Serial No. H 913661.

This also applies to Models 601, Ch. 154; 613, Ch. 149, 914, 915, Ch. 150.

Hoffman Service Hints

Symptom: Quivering of the picture due to partial loss of both vertical and horizontal sync pulses has been observed in strong signal areas. This occurs when a strong signal overloads the video i-f amplifiers and a limiting action occurs which clips the sync pulses. *Remedy*: An increase in the agc action, which will produce more agc bias with strong signals, can be accomplished by decreasing the delay bias voltage on the agc diode. This delay bias voltage is derived from the plate, pin 2 of V113A, 2nd sync separator.

Reference to the circuit diagram for Chassis 140, 142, and 146 on *page 3-8*, and for Chassis 143 and 147 on *page 3-9 of Rider's TV-Manual Volume 3*, will show that a 10,000-ohm plate stabilizing resistor, R150, is connected from pin 2 to ground. A smaller diode delay bias can be obtained by effectively tapping down on this resistor.

R150 at present is a 10,000-ohm, ½-watt, 10%, composition resistor. Remove this resistor from the circuit and replace with two 4700-ohm, ½-watt, 10%, composition resistors in series. The junction of the two new resistors provides a centertap for connection of the delay bias lead, a green wire from pin 5 of V110. This green wire is at present connected to pin 2 of V113.

This modification can be made on any Hoffman receiver produced with signal keyed agc and will aid materially in the stabilizing of picture sync in strong signal areas. Factory modification has been accomplished on all sets produced after Serial No. J 921278.

Industrial Television Ch. IT-21R

This Chassis appears on *pages 4-1 through 4-6 of Rider's TV Manual Volume 4.* The following is recommended in all cases where trouble is experienced with hum or buzz in audio, and will eliminate such trouble and improve the quality of sound and picture:

1. Disconnect primary of T1 from plate circuit of V9.
2. Connect L17 direct to pin 8 of V9.
3. Remove jumper from pin 6, V9 and junction of R51-52 and R53.
4. Connect terminal of T1 which previously was connected to pin 8, to pin 6 of V9.
5. Connect terminal of T1 which previously connected to L17 to junction of R51-52 and R53.
6. Connect 20,000-ohm-per-volt meter across C51, and with meter on 10-volt range, antenna in local plug, and signal tuned in, readjust the top and bottom slugs of T1 for maximum voltage across C51.

Majestic 12T6, 14C4, 14T2, 14T6, 16C6, Series 94

Except for cabinet designs or picture tube size, Models 12T6, 14T2, and 14T6 are the same as Model 12T2, Model 14C4 is the same as Model 12C4, and Model 16C6 is the same as 16C4.

Majestic 14CT4, 16CT5, 19C6, 19C7, 1671, 1672, 1673, 1674, 1675, 1900, 1974, 1975, 16CT4, 97 & 98 Series

Model 14CT4 is a consolette with a mahogany finish and employs a 14" rectangular picture tube. Model 1671 has a table cabinet with a mahogany finish and employs a 16" rectangular tube. Models 16CT4 and 16CT5 are consolettes using 16" round tubes. Model 16CT4 has a mahogany finish, while Model 16CT5 has a bleached finish. Model 1900 is also a consolette with a mahogany finish, although it employs a 19" round tube. A total of 20 tubes including the picture tube is used in these receivers.

The service data for these models in the 97 and 98 Series are the same as the data for the 94 and 97 Series except for the differences and additions mentioned in the following paragraphs.

Under the section titled "Picture Tube Installation in 16" Receivers," add:

For receiver Models 1672 or 1673, remove the two screws which hold the front mask assembly. These pass through the two corner blocks on the inside of the cabinet at the top. When these screws are removed, the front panel may be lifted out. For receiver Models 1671, 1674, or 1675, remove the four decorative screws which hold the front panel and mask assembly. These pass through the four corners of the picture frame. Carefully lift out the front panel and mask assembly. For Model 1671, loosen the two screws which fasten the metal picture-tube retaining band sufficiently so that the picture tube may be slipped through the opening. The high-voltage connector should be located on the right side of the chassis, as viewed from the front. Secure the metal band over the top of the tube by tightening the two screws alternately and evenly, so that the rectangular picture tube is not forced to rotate or twist in its mounting.

The picture tube installation in 19" receivers is as follows:

The bulblike glass separation between the neck of the picture tube and its metal cone is treated with an anti-corona coating to reduce high-voltage leakage under humid atmospheric conditions. Avoid touching this treated area since perspiration may reduce its effectiveness. If handled accidentally, wash with water or mild soap and water. Remove all traces of soap. Use no chemical solvents or abrasives for cleaning.

1. Remove the slotted head P.K. screws retaining the back and release with the interlocked line cord.

2. Remove the bag containing the beam bender, the hardware for deflection and focus coil assembly, and the front plug buttons, if used.

3. Remove the deflection and focus coil assembly which is fastened to a shelf for shipping purposes. Remove retaining wires that are wrapped around focus coil adjustment screws.

4. Carefully slide the deflection yoke and focus coil assembly over the neck of the picture tube, so that the deflection yoke adjustment thumb screw faces the top of the cabinet.

5. Assemble the deflection yoke and focus coil assembly to the support bracket using the hardware provided. See Fig. 1 for proper hardware assembly and mounting procedure.

6. Remove the 6-32 grounding screw from the yoke frame (see Fig. 1 for location). Attach the ground lug on the brown wire coming from the chassis, and replace the screw.

7. Slide the beam bender over the neck of the picture tube.

8. Connect the picture tube socket to the tube base.

9. Connect the male octal plug from the deflection yoke and focus coil assembly to the female octal socket from the chassis.

The rear panel adjustments that are illustrated for Models 1672, 1673, 1674, 1675, 19C6, 19C7, 1974, and 1975 apply to the other models mentioned in this article. The location of the front panel controls are shown for Models 1974 and 1975 in Fig. 2, and for the rest of the models in Fig. 3.

The circuit description for these models is the same as that for the 94 Series, except that in the section titled "Vertical Deflection Circuit (Block H)," the generated sawtooth voltage is amplified by the 6K6 output tube (V20), rather than the "other half of the 6SN7 duo-triode (V14)."

The Alignment Procedure, Video I-F and Sound Alignment, and the R-F and Oscillator Alignment for the 97 and 98 Series is the same as that found for the 94 Series. The Voltage Chart for all models except 14CT4, 1674, and 1900, is the same as that shown on page 5-13. The voltage readings for Model 1900 are the same as those shown on page 5-13, except for the following changes: Picture tube (V1)—pin 2 is 2 v, pin 10 is 230 v. Audio output (V4, 6V6)—pin 1 is N.C., pins 5 and 6 are —6 v. Ratio detector driver (V6, 6AU6)—pin 1 is 4.5 v, pin 7 is 5 v. The voltages on pins 5 and 6 of the 1st, 2nd, and 3rd video i-f tubes (V7 6AU6, V8 6AG5, V9 6AG5) are 115 v. Video amplifier (V11, 6AC7)—pins 3 and 5 are 0.2 v, pin 4 is —2 v, pin 6 is 145 v, and pin 8 is 115 v. D-c restorer-clipper-separator-amplifier (V12, 12AU7)—pin 1 is 90 v, pins 2 and 6 are 24 v, and pin 3 is 25 v. Vertical sweep oscillator (V14, 6C4)—no voltage on pin 1, pin 5 is 100 v, and pin 6 is —25 v. Horizontal sweep output (V16, 6BQ6-GT)—pins 3 and 4 are 155 v, pins 5 and 6 are —26 v, and pin 8 is 7 v. High-voltage rectifier (V17, 1B3)—pins 2, 6, and 7 are 11.5 kv. Horizontal damper (V18, 6W4)—pins 2 and 4 are N.C., pin 3 is 370 v, pins 5 and 6 are 210 v, pin 7 is 6.3 vac, and pin 8 is 0 v. Power rectifier (V19, 5U4G)—pins 2 and 8 are 380 v, and pins 4 and 6 are 365 vac. Vertical output (V20, 6K6)—pin 1 is 0 v.

The voltage readings for Models 14CT4 and 1674 are the same as those on page 5-13 except for the following changes: Picture tube (V1)—pin 2 is 4.3 v, pin 10 is 245 v, and pin 11 is 17 v. Oscillator-converter (V3, 6J6)—pin 1 is —0.7 v, pin 2 is 0 v. Audio output (V4, 6V6)—pin 1 is —138 v, pin 3 is 195 v, pin 4 is 210 v, and pins 5 and 6 are —9 v. Ratio detector-audio amplifier (V5, 6T8)—pin 6 is —0.5 v, pin 9 is 115 v. Ratio detector driver (V6, 6AU6)—pin 1 is 8 v, pin 2 is 8.5 v, pin 5 is 220 v, pin 6 is 105 v, and pin 7 is 9 v. Third video i.f. (V9, 6AG5/6BC5)—pin 7 is 1.2 v. D-c restorer-clipper-separator-amplifier (V12, 12AU7)—pins 2 and 6 are 160 v, pin 3 is 162 v. Horizontal phase detector (V13, 6AL5)—pin 1 is 6 v, pin 2 is —6 v. Horizontal sweep oscillator (V15, 6SN7)—pin 5 is 100 v. Horizontal sweep output (V16, 6BQ6-GT)—pins 3 and 4 are 210 v, pin 5 is 48 v, no voltage on pin 6, and pin 8 is 72 v. High-voltage rectifier (V17, 1B3)—pins 2, 6, and 7 are 10.1 kv. Horizontal damper (V18, 6W4)—pin is —85 v, pins 5 and 6 are 225 v.

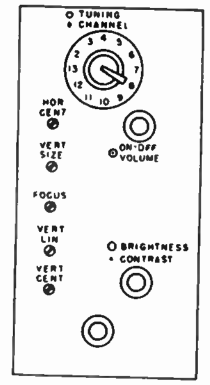


Fig. 2. Front panel layout for Models 1974 and 1975.

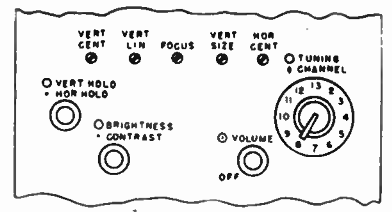

Fig. 3. Front panel layout for Series 97 and 98.

Model 1671 uses a single 5" p-m speaker. Models 16CT4 and 16CT5 use a single 10" p-m speaker. The schematic for Series 97 and 98 is the same as that which appears on page 5-14 except for the following changes in the ratio detector driver stage. A 100-ohm resistor, R10, is inserted from the junction of R28 and C49 to pin 1 of V6, the 6AU6 ratio detector driver. Capacitor C55, the 0.02-μf capacitor connected from pin C of ratio detector transformer T6 to ground, has been relocated and now goes from pin C to pin 7 of V6, the ratio detector driver. The value of C55 has been changed to 5000 μμf. A 5000-μμf capacitor C32 has been added from pin 7 to pin 2 of V6. An 82-ohm resistor R26 has been inserted from pin 7 to R27, the 1,000-ohm grid resistor.

The schematic for models 14CT4 and 1674 is the same as that described above for Series 97 and 98 except for a change in the sweep circuit. Resistor R18, 390,000 ohms now goes from the junction of R83, 100,000 ohms, and C79, 13 μμf, 2 kv, to the junction of R48 (the 250-ohm resistor going from ground to pin 8 of the horizontal sweep output tube V16) and R80 (mentioned below), instead of from R83 and C79 to ground. Resistor R80, that was connected from ground to capacitor C92 (connected to pin 8 of V16), was relocated and now goes from the junction of R18 and R84 to R85 (mentioned below), and the value of R80 has been changed from 47 ohms to 470 ohms, 7 watts. Resistor R85, the 30,000-ohm resistor that was connected in parallel with R87 (30,000 ohms) going to the +360-volt buss, has been relocated. It noes goes from ground to R80, and the value has been changed to 100 ohms, 2 watts. The value of R87 has been changed from 30,000 ohms, 2 watts, to 12,000 ohms, 2 watts.

The schematic for Model 1900 is the same as that for the 97 and 98 Series appearing on page 5-14 except for the following changes. The value of C88, connected to pin 2 of V10A, the 1/2-6AL5 video detector, has been changed from 10 μμf to 15 μμf. Capacitor C67, 10 μf, 150 v, connected to pin 6 of the video amplifier V11 and ground has been removed, and C77C, 10 μf, 450 v, inserted in its place. The value of R108 connected to pin 8 of V12A, the 1/2-12AU7 d-c restorer sync clipper, has been changed from 8,200 ohms to 7,000 ohms; and the value of resistor R52, connected from R53 to the +360-volt buss in the same circuit has been changed from 12,000 ohms to 11,000 ohms. The value of resistor R100, connected from the junction of pin 2 of V12B and pin 6 of V12A to R116 has been changed from 1 megohm to 2.2 megohms. The 470,000-ohm resistor R116 has been deleted from the circuit and a direct connection used in its place.

Model 1900 is the only receiver which is not equipped with a built-in antenna. The two connections from the terminal strip go to the tuner. Since the built-in high-frequency antenna is not used, the 300-ohm transmission-line matching section, the two 5000-μμf capacitors C112 and C113 attached to this section, and the line choke L21 (that are shown in the schematic on page 5-14) are also omitted in this model. In place of C114 and C115, 5000 μμf, two 0.01 μf capacitors, C78 and C79 are connected from the terminals of the primary of T11 to ground. The vertical centering control R14, 10 ohms, has been relocated as shown in Fig. 4. On all other models in the 97 and 98 Series it goes from coil L12, connected to the power rectifier, to the yellow lead of focus coil L14. In Model 1900 L12 is connected directly to the junction of C81A and the yellow lead of the focus coil, and capacitor C89, 500 μf, that was connected in parallel across the vertical centering coil, has been deleted. The vertical centering coil is connected, as shown in Fig. 4, from ground to the 3.3-ohm resistor R60 (going to the —2.5-volt line). The taps from the vertical centering control are connected as in the 97 and 98 Series schematic.

Additional changes in Model 1900 are shown in Fig. 4. The lead from C77B and C goes directly to the green lead of the focus coil. The lead and the 270,000-ohm resistor R79, from the yellow lead of the focus coil to pin 5 of V15 the horizontal sweep oscillator, have been deleted. The lead from the horizontal size coil L10 and capacitor C79 to R83 have been deleted. Tap 2 or T12 goes to the 470,000-ohm resistor R96, the lead from pin 1 of V15 goes to the junction of C100 and R90. C74 goes to the red lead of the vertical oscillator transformer T8, R74 goes to the red lead of T9, and R85 and R87 go to the tap on the horizontal centering control R12.

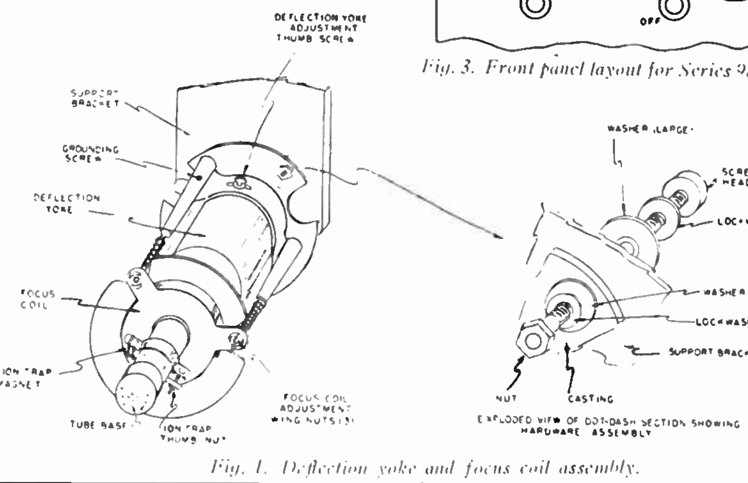

Fig. 1. Deflection yoke and focus coil assembly.

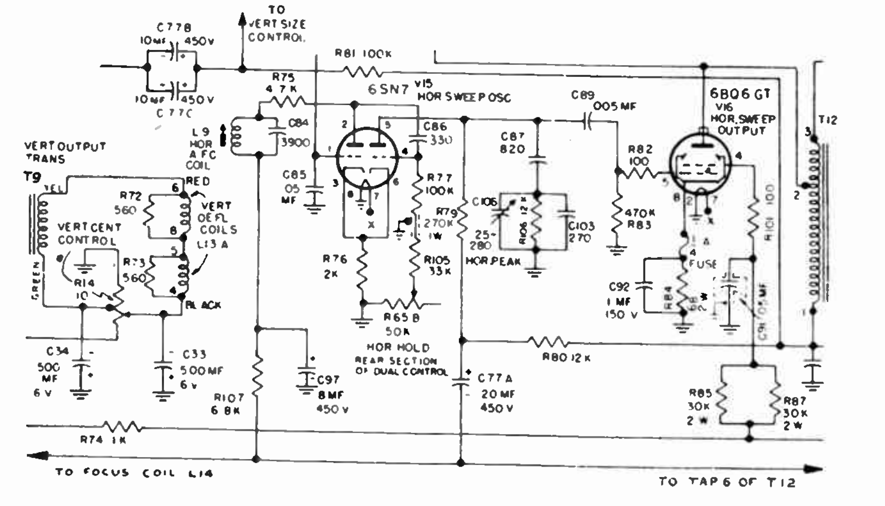

Fig. 4. Additional circuit changes for Majestic Series 97 and 98.

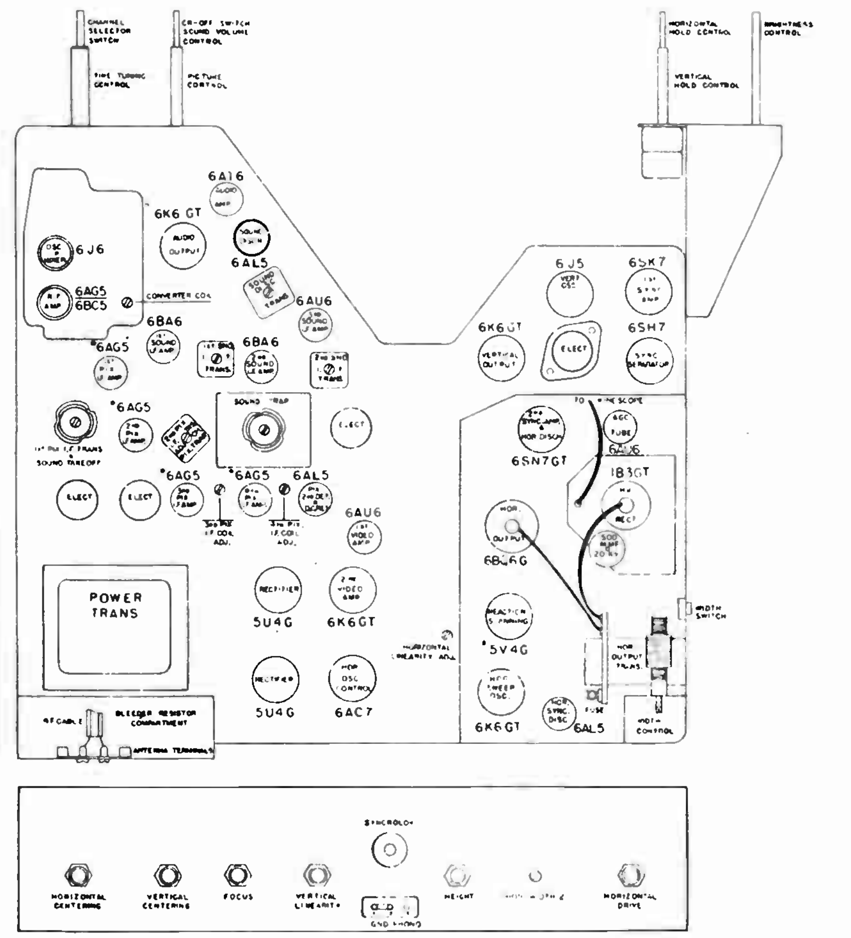
World Radio History

Mars Dartmouth, Hampton, Oriental, Versailles, Ch. K-2

The chassis layout for the K-2 chassis is shown in the accompanying figure. 6CB6 tubes can be substituted for the 6AG5 tubes shown marked with asterisks, and a 6W4GT can be substituted for the 5V4G reaction scanning tube. The rear chassis controls are shown at the bottom of the illustration.



Chassis layout and rear chassis controls for Mars K-2.

Montgomery Ward 94WG-3006B, 94WG-3009B

Models 94WG-3006B and 94WG-3009B are similar to Models 94WG-3006A and 94WG-3009A except for the following information which replaces the Response Curves section and the R-F Response Curves section for these latter models. All other service information for Models 94WG-3006A and 94WG-3009A is applicable to Models 94WG-3006B and 94WG-3009B.

R-F Response Curves—The response curves shown in Figure 18, for the "A" Series" may be observed by connecting the sweep generator and the marker signal generator (loosely coupled) to the antenna input and by connecting the oscilloscope to the TEST POINT (junction of R-6 and R-7) on the tuner. This TEST POINT is accessible from the top of the tuner chassis and appears as a small insulated tip between the oscillator and mixer tubes as shown in Fig. 1, shown below. An S-25A3 tuner may be used in these models.

The response curves obtained in this check indicate the accuracy of adjustment of the r-f and converter coils. Any appreciable variation from the curves shown in Figure 18

Montgomery Ward 94GSE-3011B

Model 94GSE-3011B differs from Model 84GSE-3011A only in type of cabinet covering and cabinet hardware as listed below:

Part Number	*Description*
MW7E179-3	Cabinet
MW20E449-2	Rear door with hinges, antenna post and line cord
MW20E461	Handle with mounting brackets.

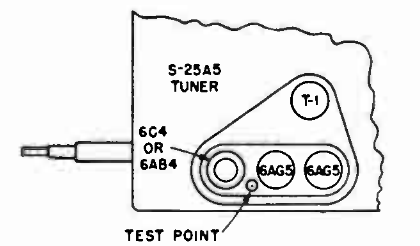


Fig. 1. Test point for Montgomery Ward Models 94WG-3006B and 94WG-3009B.

indicates coil misalignment. To check for correct oscillator coil adjustment on each channel connect the sweep generator and the marker signal generator (loosely coupled) to the antenna input. Connect the oscilloscope to the junction of L-8 and R-51. The response curve should be approximately the same as for the i-f response check. The picture carrier marker should be approximately 45% down and the sound carrier at zero level.

To adjust each oscillator coil, set the Fine Tuning control in the center of its range and adjust each coil screw to properly position the markers.

Montgomery Ward 94WG-3006A, 94WG-3009A

The following information supplements the Picture I-F and Trap Adjustment Alignment Table and replaces the Retouching of Picture I-F Adjustments and Response Curves section.

Checking Picture I-F Adjustments — The response curve, secured after completing steps 5 through 12, may be observed by connecting the sweep generator to the junction of C-31 and R-23 (through hole in tuner side of chassis) and by connecting the oscilloscope to the junction of L-8 and R-51. The marker signal generator should be loosely coupled to the sweep generator output leads.

With the Contrast control set at —3 volts as in Step 5, the response curve should be approximately flat topped as shown in Fig. 1.

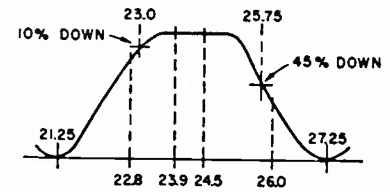

Fig. 1. I-f response for —3 volts on contrast control of Models 94WG-3006A and 94WG-3009A.

A 25.75-Mc (picture carrier) marker signal should appear approximately 45% down, and a 23.0-Mc marker should appear approximately 10% down. A 21.25-Mc signal (sound carrier) and a 27.25-Mc signal (adjacent sound carrier) should have zero response. Some final adjustment of T-1 (bottom), L-5, T-10 (top), and L-7 may be required to secure an ideal response curve. The portions of the curve affected by these adjustments are shown in Fig. 1. Do not change trap adjustments T-1 (top), T-5 or T-10 (bottom) after they have been set according to steps 6, 7 and 8.

In areas of low signal strength it may be desirable to increase the i-f sensitivity by aligning the i-f with a —1 volt setting of the contrast control. If this is done the response curve will be approximately as shown in Fig. 2. The 25.75-Mc (picture carrier) marker and 23.0-Mc marker should have the same relative positions as for —3 volt alignment.

Fig. 2. I-f response for —1 volt on contrast control of Models 94WG-3006A and 94WG-3009A.

R-F Response Curves—The response curves shown in Figure 18 were taken at the input of the converter circuit of the tuner, using a crystal diode probe and a sensitive oscilloscope. Since such equipment is not generally available to the service man these curves cannot be observed. However the over-all response of the set may be observed by connecting the sweep generator and marker signal generator (loosely coupled) to the antenna input and the oscilloscope to the junction of L-8 and R-51. The response curve for each channel should be approximately the same as the i-f response curve, with the picture carrier frequency appearing 45% down and the sound carrier frequency at the zero base line. Be sure the Fine Tuning Control is set in the center of its range. The picture carrier and sound carrier frequencies can be properly positioned for each channel by adjusting the proper oscillator coil screw, as shown in Figure 8.

Note: — All response curves have been shown in the classical manner, with the curve up and the frequency increasing from left to right. The manner in which the curves will appear on any alignment check will depend upon the equipment used, i.e., curves may appear inverted or reversed from the manner shown.

Motorola VT73, VT73A, Ch. TS-4J

Model VT-73 is a portable television receiver which uses chassis TS-4J and is similar to Model VT-71. Model VT-73A is the same as VT-73 except that a fiber-board back cover is used in the VT-73A, while the VT-73 has a metal back cover. The late version TS-4J is the same as the early one except for the following changes:

The value of radio-frequency choke L-34 is 2 μh. Coils L-81 and L-82 have been substituted for L-29 and L-35, respectively. A 10-megohm resistor, R-158, has been added from pin 3 of the 12AT7 converter, V-17A, to tap 2 of T-1. In the video amplifier stage, R-137, R-146, L-58, and L-59 have been deleted and the changes in the schematic are shown in Fig. 1.

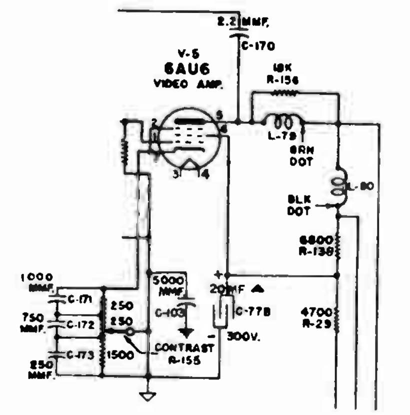

Fig. 1. Circuit changes in the video amplifier stage of Motorola VT73, VT73A,

Ballast tube R-159 has been substituted for R-80. Resistor E has been deleted, and resistors A, B, and D are now connected to pin 6, instead of to 5. The values of the resistors have not been changed.

An 8,200-ohm resistor, R-153, has been substituted for R-134, 10,000 ohms, which was connected from pin 2 of T-8 to the horizontal-hold control. The horizontal-hold control has been changed from R-49, 20,000 ohms, to R-154, 10,000 ohms. Resistor R-132, 220,000 ohms, that goes from pin 1 of the horizontal-sweep oscillator to T-10, has been deleted. Capacitor C-137 is now connected to the high side of R-55, the horizontal-size control, instead of to the brown lead from T-10. Additional circuit changes are shown in Fig. 2.

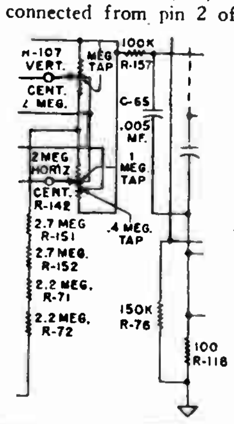

Fig. 2. Circuit changes in the Motorola VT73, VT73A, Ch. TS-4J.

The replacement parts list supplement is as follows:

Ref. No.	*Part No.*	*Description*
C-171	21K780599	Capacitor, ceramic, 1,000 $\mu\mu$f
C-172	21K780598	Capacitor, ceramic, 750 $\mu\mu$f
C-173	21K77375	Capacitor, ceramic, 250 $\mu\mu$f, 20%, 500 v
L-79	24A780602	Video compensating coil, wound on 18,000-ohm resistor
	5K790196	Rivet, bi-furcated, ½" long, polished brass (hinges & catches)
	5A470755	Rivet, shoulder, ⅜" long, (line cord mtg. VT-73)
	5K790482	Rivet, shoulder, ½" long (line cord mtg VT-73A)
	5S7721	Rivet, 0.122 x ¼, brass (line cord clamp mtg VT-73A)
	3S7362	Screw, machine, 6-32 x ½ slotted binderhead, cad pl
	3S7258	Screw, machine, 8-32 x ½ slotted binderhead, cad pl (line cord clamp mtg)
	3S6943	Screw, machine, 8-32 x 1¼ slotted round head, blk nkl (bumper on back cover)
	3K780454	Screw, machine, 8-32 x 1½, (spkr & picture tube mtg)
	3S490333	Screw, sheet metal, #4 x ⅝ PKA slotted acorn head, statuary bronze finish (back mtg)
	3S7453	Screw, sheet metal, #8 x 1 PKZ plain hex head (chassis mtg, 1 used)
	3S7534	Screw, sheet metal, #8 x 1⅜ PKA plain hex head (chassis mtg, 3 used)
	3S7455	Screw, wood, #8 x ⅜ slotted acorn head, antique copper finish
	26K780497	Shield, chassis bottom
	9K790405	Socket, strap, brass
	46K790404	Stud, strap, brass
	4K790402	Washer, finishing, brass (antenna holding strap)
	4S7557	Washer, flat, ⅜ x 11/64 x 0.033 stl, cad pl
	4S1745	Washer, flat, 7/16 x 0.203 x 0.030, antique copper finish
	4S488317	Washer, flat, ⅜ x 0.390 x 0.020, bright brass finish (ant jack)
	4A780458	Washer, insulating (ant jack)
	4A482130	Washer, shoulder, fiber (back cover).
L-80	24A780601	Video compensating coil
L-81	24A780142	R-f coil, channels #12 & 13, less form & core
L-82	24A90197	1st i-f plate coil, less core

Note: All resistors are insulated carbon type unless specified otherwise.

Ref. No.	*Part No.*	*Description*

	5S3139	Eyelet, 0.202 x 0.475, brass (back cover VT-73A)
	32C471295	Gasket, rubber (picture tube)
	36K790199	Handle, cabinet, complete with posts
	55K790401	Hinge, "come-apart" type, complete, polished brass
	14A482129	Insulator, fiber (on cabinet back VT-73 only)
	9A780457	Jack, antenna plug
	29A790117	Lug, spade (on antenna jack leads)
	2A780465	Nut, knurled, bright dip finish (ant jack)
	35A780119	Pad, tube neck
	64A780440	Plate, jack mtg, cad pl

Motorola Ch. TS-67A

The TS-67A differs from the TS-67 in several tube types and tube functions. A 6AG5 sync segregator was added to replace the sync clipper V-6B (½ 6AL5). The latter became the first of a new two-stage agc circuit. The second stage is a 6AU6 which replaces the 12AX7 of the TS-67. In addition, a sensitivity control was added to the agc circuit. The control, located on the top of the chassis, permits the agc to be pre-set at the desired level. The function of V-15A (½ 6SN7GT) was changed from a squelch diode to a pulse shaper. The chassis contains 24 tubes plus a 19" picture tube.

Information on the TS-67 apply to television chassis TS-67A with the following addition:

Sensitivity Control

The sensitivity control determines the level of the agc curve and is adjusted as follows:

1. Turn receiver to channel on which the strongest signal is received.

2. Turn sensitivity control until the video amplifier overloads (picture starts to tear), and then back off until the picture is stable. The sensitivity control is located on approximately top center of chassis.

3. The audio should also be checked during this adjustment. Although there may be no evidence of tearing in the picture after step 2, the signal may still be strong enough to cause sync buzz. If this is the case, back off the sensitivity control until sync buzz disappears.

Alignment

The alignment procedure for chassis TS-67A is the same as that for TS-67, with the following exceptions:

1.5 Mc Trap Alignment

In step 1. Connect the signal generator to the grid, pin 2 or 5, of the 2nd video amplifier tube V-8 (6AS5).

In step 2. Remove the agc tube V-10 (6AU6).

In step 3. Connect 3 volts of battery bias between the plate, pin 5, of the agc tube V-10 (6AU6) and ground. The positive terminal of the battery is on the plate.

In step 8. Connect an oscilloscope between chassis and the plate, pin 5, of the 1st video amplifier V-7 (6BA6).

The following parts should be added to the parts list. For components not mentioned here, refer to TS-67 Replacement Parts List.

Muntz M158, M159, M159A, M159B, M169

Alignment and service data given for Model M169 apply also to the Models M158, M159, M159A, and M159B. The following voltages were taken with the line voltage set at 117 volts, and are subject to ±20%. The meter used is an RCA VoltOhmyst. All voltages were taken from chassis ground to the socket pin contacts.

Pulsed high voltages are present on the cap of the 6BH6 and 1B3 tubes. No attempt should be made to measure voltage at these points. A continuity check of the high-voltage winding will quickly reveal an open winding. Resistance values are given on the various schematics. The high voltage of the picture tube anode can be measured with a kilovoltmeter if necessary. Following is a list of resistances of various components not given on the schematics.

HORIZ. OSC. OUTPUT TRANS. PART #TO-17A

Terminals	*Resistance*
1 — 2	180 ohms
2 — 3	180 ohms
1 — 3	360 ohms
4 — 5	10 ohms
5 — 6	0.9 ohms
4 — 6	11 ohms
Filament	0.2 ohms

National TV-1601, TV-1602, TV-1625, TV-1627

Models TV-1602 and TV-1627 are similar to Models TV-1601 and TV-1625. The following changes have been made in these National models.

In the audio output circuit (V-22), capacitor C-101, that went from pin 8 to the junction R-106, R-107 and R-108, has been relocated and is now inserted in the lead from pin 8 to R-109. The value of C-101 has been changed from 0.05 μf to 10 μf. R-106 has been removed from its position (from the junction of C-101, R-108, and R-107, to socket X-1 pin 6) and relocated in parallel with C-101. The value of R-106 has been changed from 330,000 ohms to 270 ohms. Resistor R-107, 180,000 ohms, has been removed. In the audio amplifier circuit, R-104, 470,000 ohms, connected from pin 8 of V-21B to R-105, 470,000 ohms, has been removed from the circuit. The value of resistor R-99 connected to pin E of transformer T-5, has been changed from 220 ohms to 120 ohms.

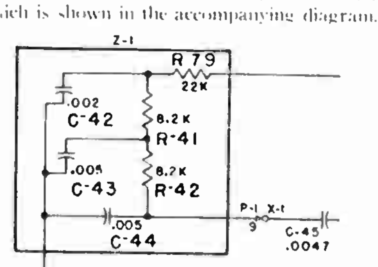
In the ratio-detector driver circuit resistor, R-96, that went from pin 7 of V20 to R-97, 1000 ohms, has been relocated and now is connected in parallel with capacitor C-89, 0.005 μf, from pin 6 to R-97. The value of R-96 has been changed from 68 ohms to 18,000 ohms. Capacitor C-88, 0.005 μf from pin 7 to R-97 has been removed from the circuit and pin 7 is tied directly to R-97.

The value of resistor R-13, connected to the junction of pin 6 of V-3 the first video i.f. and L-8, has been changed from 100 ohms to 220 ohms. The value of resistor R-31, connected to pin 4 of V-8 the video amplifier, has been changed from 120 ohms to 100 ohms. A centering control, R-41, 8200 ohms, has been added from L-18 to socket X-2, pins 2-10. Tap 6 of transformer T-4 is connected to pin 7 instead of to pin 5 of socket X-2. The pins for the X-2 P-2 connections (in the lead that goes to the horizontal deflection coil), are designated 2-10.

Resistor R-48, 470 ohms, has been removed from across the focus control. Capacitor C-58, 20 μf, connected to the vertical size control tap now goes to pin 7 of socket X-2, instead of to ground. A 47-μμf capacitor, C-44, has been added from pin 4 of the horizontal sweep oscillator to ground. Resistor R-62, 22,000 ohms, is now connected to pin 7 of socket X-2 instead of to fuse F-2. The value of R-64 connected to pin 5 of the horizontal sweep oscillator has been changed from 220,000 ohms to 150,000 ohms. The value of resistor R-68, connected to pin 8 of the horizontal sweep output, has been changed from 1500 ohms to 5600 ohms.

The 1000-μμf capacitor C-49, going from tap 5 to tap 8 of T-4, the horizontal output transformer, has been replaced by a direct connection. The value of R-73, connected to pin 2 of the horizontal phase detector, has been changed from 4700 ohms to 10,000 ohms.

The 22,000-ohm resistor, R-79, connected from pin 3 of the sync amplifier-splitter to pin 9 of socket X-1 is now included in Z-1 which is shown in the accompanying diagram.



Circuit changes in National Models.

Connection P-1 X-1 is now located as shown in the accompanying diagram, and pin of the sync amplifier-splitter is connected directly to the 22,000-ohm resistor of Z-1. The value of C-43 has been changed from 0.002 μf to 0.005 μf.

Philco 48-2500

Many cases of apparent lid warpage have been traced to cabinet distortion, which occurs when the cabinet rests on an uneven floor. This distortion may be corrected by simply leveling the cabinet, by placing blocks under the legs.

Before adjusting the keystone magnets, it is advisable to ground the metallic magnet band clamp, to eliminate the static high-voltage charge on the magnets. Where a plastic magnet band clamp is encountered, it is necessary to ground the individual magnets themselves momentarily.

Philco 50-T Series

Operating the 50-T Series with the deflection yoke disconnected removes the load from the 6BG6G tube, causing excessive screen current and damage to the screen dropping resistor. A deflection yoke should always be connected when the receiver is in operation. If a complete picture-tube assembly is not available, a yoke by itself will be satisfactory.

In some cases, horizontal streaks may be caused by video or a-c voltage being fed back into the first v-i-f stage. One cause of this coupling is the leads running to the contrast control, which carry video voltage, being to close to the 28.1-Mc trap. In this case, these wires should be dressed away from the trap, and as close to the chassis as possible. In some extreme cases, it may be necessary to reroute these wires as in later production of Model 50-T1443, Code 123. In this chassis, the wires are routed from the contrast control out through a hole near the control, down the front of the chassis, into a ventilation hole near the bottom-right corner, and thence to the output stage. In all cases, all leads must be dressed away from the 28.1-Mc trap.

Philco 50-T1403, 50-T1404, 50-T1406

The chassis of Models 50-T1403, 50-T1404, and 50-T1406 are similar to that used in Model 50-T1400.

RCA T121, KCS34C

Poor vertical sync may be caused by capacitor C-136 (cathode bypass V-108) breaking loose from ground. Some vertical oscillator transformers, marked 274011, with too high a Q may cause a white condition at the top of the picture and possible instability of sync. If this is the case, lower the transformer Q by connecting a 1-megohm resistor across the green and yellow transformer leads.

Radio Merchandise SP-5

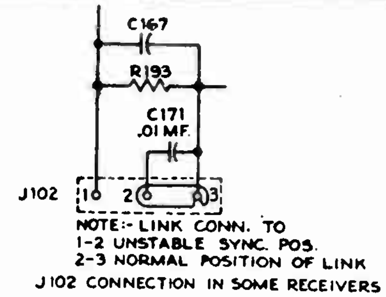
TV booster SP-5 is similar to the SP-4 which appears on *pages 4-1 and 4-2 of Rider's TV Manual Volume 4*. In the SP-5, the one pilot light used is a #47 and is connected directly to pin 4 of the 6AK5.

Regal TV-1030, TV-1031

In later production models, an e-m speaker is employed with a hum-bucking coil and voice coil, whose impedance is 3 ohms. The three-prong plug has been deleted. The jumper across R232 has been deleted.

J104 is now designated as J102. Filter choke 1,200 is now a 62-ohm field. In some receivers C19 is omitted. In some receivers C14 is fixed. R239 is omitted in some receivers.

In some receivers J102 is connected to the cathode lead of V123, 6AL5, horizontal sync discriminator, as shown in the accompanying figure.



Circuit change for Regal TV-1030, TV-1031.

Sears Ch. 101.846, 101.854, 101.864, 101.867, 101.868

Low-frequency microphonics (rumble in sound, little or no disturbance of picture) in Chassis 101.864 and 101.868 can be attributed to oversize inserts in the core slide assembly. The view of the core slide assembly shown in Fig. 1 shows one of the four inserts which is affixed to the core slide. These inserts are assembled on each of the four ends or ears of the slides. Due to the push button pressure exerted against the core slide, there can be no forward or backward play of the core slide to cause vibration. However, occasionally there is a sideward clearance between the core slide and the carriage rod to permit mechanical vibration. This movement is what often produces microphonism.

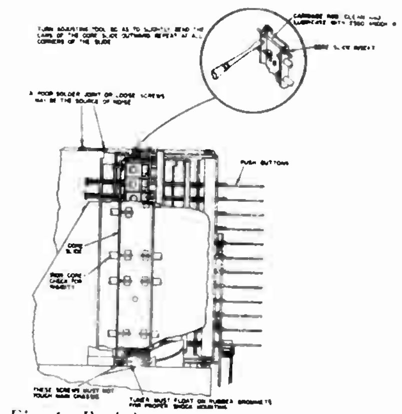


Fig. 1. Push-button tuner for Sears Chassis 101.846, 101.854, 101.864, 101.867, and 101.868.

A very effective and simple remedy can be applied to the tuner without removing it from the main chassis or even removing the tuner cover. Take a 6- to 6½-inch screwdriver having a blade not wider than ¼-inch. File or grind a notch .062- to .067-inch wide and ⅛-inch deep in the end of the blade. Insert the tool into tuner so that the slot in the blade is over one ear of the core slide assembly as shown in Fig. 1. With a slight twisting motion, rotate the tool so the ear of the core slide is bent outward. Only a slight bend should be made insofar as this procedure must be repeated on all four ears or inserts. After each adjustment, work push buttons to make sure core slide will return to normal setting when released. Failure of this will indicate adjustment is too tight. Movement of these slide inserts may necessitate the resetting of the push buttons due to possible shifting of the core slide assembly in relation to the carriage rod supports which also act as stops. If resetting of any push buttons is done, the channel under adjustment should be alternately pushed several times to insure correct setting of the adjusting screw.

Another possible source of low-frequency mircrophonics may come from loose coil dampers on high-band or low-band oscillator coils. Also check all cores, particularly the oscillator cores for rigid mounting.

Three rubber grommets shock mount the push button tuner to the main chassis. Refer to Fig. 1 and note that the grommet mounting nearest the 6AT6 first audio tube may cause the two screws mounted to the tuner to touch the main chassis. If this occurs, add sufficient spacer washers to the grommets to properly shock mount the push button tuner. Likewise the push buttons themselves may make contact with the cabinet escutcheon plate. Remedy by loosening chassis mounting screws and repositioning the chassis so that push buttons are completely free from cabinet.

For the treatment of high-frequency microphonics (high-frequency howl in sound, little or no disturbance of picture), change high-band oscillator tube 7F8. A check should also be made for broken mica on oscillator trimmer.

The following suggestions are offered for the case of noisy tuners in Chassis 101.846, 101.864, 101.867, and 101.868.

Occasionally when the push buttons are actuated, noise may occur due to the grounding braid scraping the chassis base at a different place than where soldered. This grounding braid must make contact with the main chassis only at the soldered joint. Noise will occur particularly at the high-frequency channels.

Another source of noise is the cable clamp shown in Fig. 2. All cables joining at this point have their shields grounded at the antenna coils and also joined together near the clamp itself. However, the shields do not and must not ground to the clamp. Check the cables for frayed insulation. If the insulation needs repair, open the clamp, wrap the cables with insulating tape, and replace the cables in the clamp.

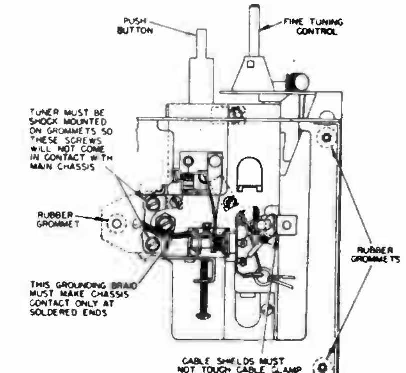

Fig. 2. Tuner for Sears Chassis 101.846, 101.854, 101.864, 101.867, and 101.868.

Check all hold-down screws on the tuner for tightness, especially the screws attaching the cover over the high band coils. Loose screws as well as poor solder joint may be a source of noise.

Sears 125, Ch. 478.257; 9125, Ch. 478.252; 9125A, Ch. 478.253

In some localities due to the degree of modulation of the local stations, a variable amount of buzz will be heard in the sound of these models at certain picture levels during transmission. This buzz can be minimized by the following substitutions:

1. In the video amplifier V9, the plate load resistor R47, a 3,300-ohm resistor, should be changed to 1,800 ohms, ½ w, 10 per cent.
2. In the same tube circuit, the plate resistor R42 should be changed to 4,700 ohms, 1 w, 10 per cent.

©John F. Rider

World Radio History

Sears 110.499 Series

Model 9135 employs a 16-inch kinescope, 16AP4, V12. The 16-inch tube has a metal cone that is connected to the high-voltage supply. The tube is insulated from the chassis by mounting it directly to the cabinet. The tube should be installed as follows:

(1) Remove the back cover by removing the screws holding it to the cabinet.

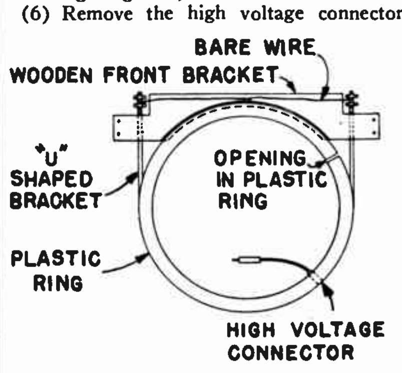
(2) Be sure that the kinescope tube protector (cup) is mounted on the outside of the cabinet back. If it is mounted on the inside, turn it around.

(3) There should be a wooden block mounted in the center of the lower back rail to protect the portion of the kinescope tube extending beyond the cabinet. If it is not there, it will be found in back of the power transformer, remove it, and mount it on the rail.

(4) Unscrew top panel and pull straight out. Do not remove the focus and deflection coils from the panel.

(5) Remove the plastic insulating ring by loosening the two nuts holding the kinescope "U" shape mounting ring and unwrapping the bare wire from the top ends of the mounting ring. (It is not necessary to take the nuts off. Loosen them until you can take the plastic insulating ring out.)

(6) Remove the high voltage connector



TUBE MOUNT

Fig. 1. Front mounting of kinescope, Sears 110.499 Series.

from the ring.

(7) Remove the wire from the plastic ring. The wire will be used later.

(8) Remove the 5U4 tube.

(9) Place plastic ring on kinescope tube with trade mark facing the neck of the tube.

(10) Place high-voltage connector under the plastic ring in the position indicated in Fig. 1.

(11) Place bare wire in the outer groove of the plastic ring and twist, leaving two equal ends as indicated in Fig. 1.

(12) Place kinescope tube and plastic ring into the "U" shaped bracket. The top of the plastic ring will fit into the wooden bracket at the front of the cabinet. Support the tube with your hand.

(13) Slide the top panel into place with the deflection and focus coils over the neck of the tube.

(14) Take up slack in "U" shaped bracket by tightening the nuts.

(15) Wrap one end of the bare wire (circling the plastic ring) around the left-hand end of the "U" shaped bracket, add a second nut and tighten.

(16) Wrap remaining end of bare wire around right end of "U" shaped bracket.

(17) Place terminal lug on one end of ground harness over right end of "U" shaped bracket, add second nut and tighten.

(18) Remove one wing nut from the deflection yoke mounting bracket, place second terminal lug on ground harness under this nut and replace.

(19) Remove one wing nut from the focus coil bracket, place third terminal lug on ground harness under this nut and replace.

(20) Be sure that the remaining end of this ground harness is connected to the chassis.

NOTE: Wire around plastice ring, "U" shaped bracket, deflection and focus coil mounting brackets must all be connected together and grounded to the chassis.

(21) Replace screws in top wooden bracket.

(22) Replace screws in top panel.

(23) Connect high voltage male plug to the female socket coming from the high voltage compartment.

(24) Place ion trap on neck of kinescope tube. (Ion trap will work best near the socket of the kinescope tube.)

(25) Place the socket on the kinescope tube.

(26) Make sure that the hood on the deflection yoke is pushed as far forward as possible.

(27) Push the deflection yoke as far up in the hood as possible.

(28) Place the focus coil as close to the deflection yoke as possible.

(29) Make sure that the focus and deflection cables do not come in contact with the cone of the kinescope tube. (Outer surface of the kinescope is at high potential.)

(30) Proceed with all other adjustments in the same manner as you do on the 10- or 12½-inch models.

Caution: The metal cone of the picture tube is connected directly to the high voltage. Extreme care must be used so as not to come in contact with this cone when the receiver is in operation.

The following changes were made in the schematic diagram of Chassis 110.499, 110.499-1, 110.499-2. The changes are not retroactive, and should not be necessary on early production chassis except for improving a particular function.

Section (2), under Parts Removal, To Remove the Chassis from the Cabinet, should be changed to read: "On all models except 9126 remove the screws holding the antenna terminal strip to the cabinet. On Model 9126 remove the antenna connector plugs connecting the antenna terminal strip and the built-in antenna to the chassis."

The tube chart should have the following changes made:

Tube No.	Pin No.	Old Voltage	New Voltage
V4	5,6	130	140
V5	5,6	132	142
V6	5,6	135	145
V13A	6,7,8	Add 30, 0, 3, respectively, when using new horizontal afc circuit	
V13B	1,2,3	Add 125, 0, 30, respectively, when using new horizontal afc circuit	
V14B	5	350	390
V15	1	3.2	6
	2	-1.6	-6
V16	3,8	10	13
V19	5	—	340
V20	2,8	360	370.

Improve Focus Range

(1.) Change R20 and R85 from 47,000 ohms to 18,000 ohms, 2 watts.

(2) Connect R20 and R85 to the low-voltage side of the focus coil instead of to terminal 3 of the yoke.

(3) Change focus control R38 from 1,500 ohms to 2,500 ohms.

Improve Contrast and Hold in Fringe Area

This change increases the agc delay voltage from 2.5 volts to 5 volts.

(1) Change R15 from 39,000 ohms to 18,000 ohms, 2 watts.

Increase Vertical Height

(1) Change R64 from 6,800 to 3,900 ohms, and R59 from 1.5 megohms to 1 megohm.

Improve Interlace

(1) Move C45, 4,700 $\mu\mu f$, from the grid lead of the vertical oscillator transformer T4 to the grid return lead.

Reduce Drift of Horizontal AFC and the Ratio Detector

(1) Add R91, a 1.1-ohm, 1-watt resistor, in series with the heater of V15, 6AL5, and V10, 6T8.

Changed Fuse Position

(1) Remove all fuses.

(2) Add a ¼-amp pigtail fuse between pin 5 of the 6W4 damper tube and terminal 4 of the horizontal output transformer T6.

Added Horizontal Centering Control

(1) Add horizontal centering control R90, 750 ohms, to rear of chassis.

(2) Run R39, 1,500 ohms, from focus coil to top of horizontal centering control, instead of from focus coils to plus 360 volts.

(3) Connect R81 from screen of 6BG6B to terminal 1 of the horizontal output transformer, instead of to terminal 3 of the yoke.

(4) Connect top of horizontal centering control to terminal 3 of the yoke.

(5) Connect arm of horizontal centering control to plus 360 volts.

(6) Under Adjustments, Focus and Centering, add: "On later model receivers using electrical centering proceed as follows: (1) Swing the focus coils to center the picture vertically. (2) Turn the horizontal centering control R90 to center the picture horizontally. (3) Adjust the focus control R38 on the rear of the chassis until the lines are in sharp focus. It may be necessary to readjust the ion trap magnet as indicated in step 8 above."

Improve Vertical Flutter

(1) Change C43 from 0.005 μf to 0.01 μf.

Additional changes that have been made are as follows: C2, 10 μf, 150 volts, has been removed from the tap of R30A, contrast control and now goes to -2.5 volts. R16 is also connected to -2.5 volts; and C25 and R30A go directly to pin 1 of V7B. L1, L2, L3, L4, L5, and L6, are 0.1 ohms. Figs. 2 and 3 show additions that have been made to the wave forms.

A new horizontal-hold-control circuit is found in all sets having the chassis number 110.499-3 or those having a higher dash number, such as -10, -11, -12, etc. There are, however, a quantity of receivers with the numbers 110.499, 110.499-1, and 110.449-2 that contain the new horizontal hold circuit. These chassis are identified with the stamped or written letter "O" on the rear apron of the chassis. To convert to the new circuit proceed as follows:

(1) Remove C39, a 0.01-μf capacitor.

(2) Remove C38, a 22-$\mu\mu f$ capacitor.

(3) Remove R47, a 1.0-megohm resistor.

(4) Remove R46, a 47,000-ohm resistor.

(5) Remove R69, a 2,200-ohm resistor.

(6) Remove R45 and add R93, a 3.3-megohm resistor in its place.

(7) Remove R68 and add R94, a 1,800-ohm resistor, in its place.

(8) Change C65 from 0.1 μf to 0.05 μf.

(9) Add C71, a 0.005-μf capacitor from pin 3 of the horizontal damper tube, 6W4GT, to pins 5 and 7 of the horizontal phase detector tube, 6AL5.

(10) Connect pin 6 to pin 2 of the 12AU7 d-c restorer, sync clipper, sync amplifier and phase splitter tube.

(11) Add R96, 68,000 ohms across R77.

(12) Short out C49, a 0.01-μf capacitor.

The horizontal linearity control is used in all chassis having the chassis number 110.499-

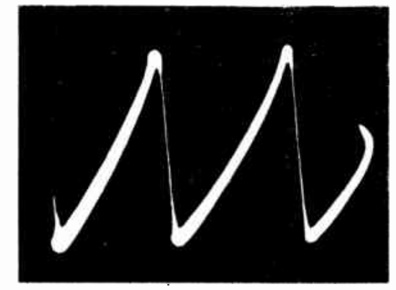


Fig. 2. Waveform at grid of sync amplifier, V13 pin 2, applies to Model 499-3 and all later models.

20 or higher, such as -21, 22, etc, and 110.499-33 including type "A" and "B" only. To add a horizontal linearity coil to other chassis proceed as follows:

(1) Mount the horizontal linearity coil in the hole provided on the top of the main chassis, using the figure showing the top of the chassis as a guide, near the high-voltage shield and the picture tube.

(2) Change C61 from 0.25 μf to 0.1 μf, 600 volts.

(3) Change R87 from a 22,000-ohm resistor to an 18,000-ohm resistor.

(4) Change R75 from 1,500 ohms to 2,200 ohms.

(5) Remove wire from terminal 1 of the horizontal output transformer T6 and pin 3 of the horizontal damper tube 6W4.

(6) Add a 0.05-μf, 600-volt capacitor, C100, from terminal 1 of the horizontal output transformer and chassis.

(7) Add a 36-$\mu\mu f$ capacitor, C110, in series with C57 and C68 so as to reduce the total value to 12 $\mu\mu f$.

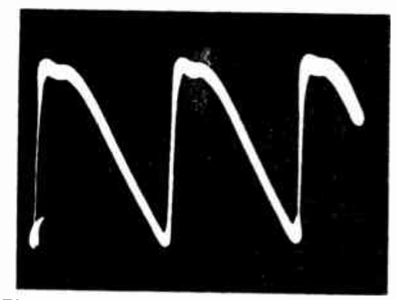

Fig. 3. Waveform of the horizontal phase detector, V15 pins 5 and 7, applies to Model 499-3 and all later models.

(8) Connect one side of the horizontal linearity coil L21 to terminal 1 of the horizontal output transformer T6.

(9) Connect the other side of the horizontal linearity coil to pin 3 of the horizontal damper tube 6W4.

(10) Under Alignment Procedure, Width and Horizontal Drive, add: "(3) On later model receivers having a horizontal linearity control located on top of chassis next to the high voltage shield, adjust this control for the best shaped picture horizontally." When using the horizontal linearity control, use terminal 1 of the horizontal output transformer T6.

A description of the chassis in the 110.499 series is given below.

Chassis No.	Description
110.499	Original 10-in. television chassis with tuner #1
110.499A	Original 10-in. television chassis with tuner #3
110.499B	Original 10-in. television chassis with tuner #4
110.499-1	Original 12½-in. television chassis with tuner #1
110.499-1A	Original 12½-in. television chassis with tuner #3
110.499-1B	Original 12½-in. television chassis with tuner #4
110.499-2	Original 12½-in. television chassis with built in antenna switch and tuner #1
110.499-2A	Original 12½-in. TV chassis with built in antenna switch and tuner #3
110.499-2B	Original 12½-in. TV chassis with built in antenna switch and tuner #4
110.499-3	16-in. round metal tube TV chassis with tuner #1
110.499-3A	16-in. round metal tube TV chassis with tuner #3
110.499-3B	16-in. round metal tube TV chassis with tuner #4
110.499-10	Revised 10-in. TV chassis with new horizontal afc and tuner #1
110.499-10A	Revised 10-in. TV chassis with new horizontal afc and tuner #3
110.499-10B	Revised 10-in. TV chassis with new horizontal afc and tuner #4
110.499-11	Revised 12½-in. TV chassis with new horizontal afc and tuner #1
110.499-11A	Revised 12½-in. TV chassis with new horizontal afc and tuner #3
110.499-11B	Revised 12½-in. TV chassis with new horizontal afc and tuner #4
110.499-12	Revised 12½-in. TV chassis with antenna switch, new horizontal afc, and tuner #1
110.499-12A	Revised 12½-in. TV chassis with antenna switch, new horizontal afc, and tuner #3
110.499-12B	Revised 12½-in. TV chassis with antenna switch, new horizontal afc, and tuner #4
110.499-20	Revised 10-in. TV chassis with horizontal linearity control and tuner #1
110.499-20A	Revised 10-in. TV chassis with horizontal linearity control and tuner #3
110.499-20B	Revised 10-in. TV chassis with horizontal linearity control and tuner #4
110.499-21	Revised 12½-in. TV chassis with horizontal linearity control and tuner #1
110.499-21A	Revised 12½-in. TV chassis with horizontal linearity control and tuner #3
110.499-21B	Revised 12½-in. TV chassis with horizontal linearity control and tuner #4
110.499-22	Revised 12½-in. TV chassis with antenna switch, linearity control, and tuner #1
110.499-22A	Revised 12½-in. TV chassis with antenna switch, linearity control, and tuner #3
110.499-22B	Revised 12½-in. TV chassis with antenna switch, linearity control, and tuner #4
110.499-33	Revised 16-in. TV chassis with round metal tube, linearity control, and tuner #1
110.499-33A	Revised 16-in. TV chassis with round metal tube, linearity control, and tuner #3
110.499-33B	Revised 16-in. TV chassis with round metal tube, linearity control, and tuner #4.

The following list is a supplement to the parts list for the 110.499 series:

Ref. No.	Part No.	Description
•C43	A194-179	Capacitor, paper, 0.01 μf, 600 v, ±10%
C58	A19108	Capacitor, paper, 0.25 μf, 600 v, +30% – 10% 85°C
•C61	A19121	Capacitor, paper, 0.1 μf, 600 v, ±10%, 85°C
•C57, C68		Capacitor, mica, 24 $\mu\mu f$, 1,500 v a.c., 400 v d.c.
C100	A1996	Capacitor, paper, 0.05 μf, 600 v, + 30% — 10%, 85°C
C63	A1998-1	Capacitor, mica, 500 $\mu\mu f$, 10,000 v, 10- & 12½-in set only
C63	A1998	Capacitor, mica, 500 $\mu\mu f$, 15,000 v, 16-in. set only
•C65	A1996	Capacitor, paper, 0.05 μf, 600 v, +30% – 10% 85°C
C70	A194-151	Capacitor, paper, 0.005 μf, 600 v, ±20%
L5	A28253	Coil, i-f choke
L18, L19, L20	A28264	Coil, filament choke
L11	A28273	Coil, focus, p.m., 16-in. set only
L21	A28259	Coil, linearity, horizontal
L14	A28258-1	Coil, width, 10 & 12½-in. set only
L14	A28258-2	Coil, width, 16-in. set only
	A55131	Connector, anode, 16-in. set only
R90	A24106	Control, centering

Sears Ch. 101.865, 101.866, 101.867, 101.868

Due to variation in design of horizontal output transformers, in some sets, the voltage output of the high-voltage power supply is reduced by grounding one side of capacitor C102 instead of returning it to the high side (secondary) of the transformer T11. This reduction of the high voltage (about 800 volts) gives wider scan with certain horizontal output transformers.

In some sets resistor R147 is omitted in the screen grid circuit of the 6BG6G horizontal output tube. This results in lower screen voltage on the 6BG6G which also affects the horizontal scan.

If under low-line voltage conditions the picture is too dim and it is difficult to get the correct focus, the grounded side of C102 may be returned to transformer T11 as in the original chassis and R147 installed in its original position in the 6BG6G screen circuit. The high voltage will be back to normal. If insufficient scan is experienced, then the horizontal output transformer will have to be replaced. Transformer #70155 is, in all probability, the only one that will require this replacement. There are two transformers currently used—#70930 and #70372, which will be satisfactory replacements where absolutely necessary.

©John F. Rider

World Radio History

Sears Ch. 101.865

The following is a revision and supersedes "Ion Trap Magnet Adjustment" under "Television Service Adjustments":

Loosen thumb nut sufficiently to slip ion trap magnet on neck of picture tube from the rear with the narrow magnet ring toward the front of the tube. Tighten thumb nut as required to make magnet adjustable on neck of picture tube. Position the ion trap magnet so that the open part of the "U" is in the direction of the second anode contact. The ion trap rear ring magnet should be approximately over the ion trap flags in the picture tube. The ion trap flags are small, rectangular plates in the neck of the picture tube about 1 inch from the black base of the tube. Starting from this position, adjust the magnet by moving it forward or backward until the raster is observed. Rotate it slightly around the neck of the picture tube for the brightest raster on the screen, and at the same time reduce the brightness-control setting until the raster is slightly above average brilliance. Adjust the focus control (on rear apron) until the line structure of the raster is clearly visible. Readjust the ion trap magnet for maximum raster brilliance. The final touches on this adjustment should be made with the brightness control at the maximum position with which good line focus can be maintained. Tighten thumb nut to permanently hold magnet in adjusted position. Refrain from tightening too much however, since excess pressure may break neck of picture tube.

Under Step 4 of "*Video I-F Alignment*," the first tuning slug adjustment with the generator set at 23.5 Mc. refers to transformer T8. This transformer should be T9.

The following paragraphs should be added under "Picture Tube Installation":

There are two possible approved methods of installing the web strap around the top of the picture tube. With the picture tube in place, the strap may hang over the flare of the tube. Fasten each end of the strap to the mounting springs attached to the mounting bracket. Carefully pull the strap up the flare of the picture tube until it is in position near the front of the tube. The alternate method is to connect the mounting springs to the strap with the strap in front of the tube. strap with the strap in front of the tube. slip the mounting strap in position around the top of the tube. Never connect one side of the strap and attempt to stretch it around the top of the picture tube before connecting to the other spring.

The following changes have been made to the 101.865 chassis. The Parts List should be revised accordingly.

Ref. No.	*Part No. Delete*	*Description*
C24		Capacitor, 1.5 $\mu\mu f$, ceramic
C33		Capacitor, 680 $\mu\mu f$, ceramic
C41	R70581	Capacitor, 10 μf, 450 v
L24	R65641	Coil, yoke, deflection
	R67849	Glass, picture bezel
	R65489	Magnet, ion trap
R6		Resistor, 1,000 ohm, ½ w
T3	R65427	Transformer, input i-f.

Add

C33		Capacitor, 1.5 $\mu\mu f$, ceramic
C24		Capacitor, 15 $\mu\mu f$, ceramic
C30		Capacitor, 25 $\mu\mu f$, ceramic
C41	R70581	Capacitor, electrolytic, 10 μf, 450 v
L24	R65461	Coil, yoke, deflection
	R67849	Glass, picture bezel, 12½"
	R67863	Glass, picture bezel, 10"
	R70842	Magnet, ion trap
R6		Resistor, 150 ohm, ½ w
	R65473	Socket, tube, 8 prong, octal, ring lock
T3	R70656	Transformer, input i-f.

Sparton 4935, 4942, 4954, 4960, Ch. 23TC10; 5002, 5003, 5006, 5007, Ch. 23TD10

Additional sync amplification and improved receiver performance can be provided for all models using the 23TC10 and 23TD10 chassis by following the procedure outlined below:

On V11 (12AU7 Tube)

1. Disconnect resistors R53 (100,000 ohms), R52 (1.0 megohm) and capacitor C47 (0.05 μf) from pin 8.
2. Connect the 1N34 crystal diode (cathode end) to R52, R53 and C47.
3. Move ground from pin 7 to pin 8.
4. Move C48 (22 $\mu\mu f$) from pin 6 to pin 7.
5. Remove R54 (47,000 ohms) on pin 6.
6. Use new R83 (4,700 ohms) from pin 7 to ground.
7. Connect plate side of 1N34 diode crystal to pin 7.
8. Replace R48 (1.0 megohm) from pin 6 to +135-volt line with new R48 (4,700 ohms).
9. Move R115 (22,000 ohms) from pin 1 to pin 3.

On V16 (6AL5 Tube)

10. Interchange C100 and C101 capacitor leads on pins 5 and 7.

New Parts Required

1. 1N34 Germanium crystal diode (Part No. PA4206).
2. 4,700-ohm resistor, ½ watt (Part No. BR12S-472).

Sparton 5068, 5069, Ch. 24TV9C

Model 5068 and 5069 are consoles using receiver chassis 24TV9C and power supply chassis 3TV9C.

Standard Coil TV-100 Series, TV-201, TV-202, TV-203

In all models C1 is eliminated on some tuners by the use of a 3- to 9-$\mu\mu f$ trimmer at C2.

Description

1. Type of r-f amplifier—6AG5 with double-tuned bandpass coupling to converter grid.
2. Type of converter—Triode using one setting of a 6J6. Oscillator excitation is inductively coupled to the control grid.
3. Type of oscillator—Grounded Cathode Colpitts type using the second section of the 6J6.
4. Type of tuning—Switched inductances in a turret-type tuner. Normal channel sequence is progressive, channel 2 to 13; with clockwise rotation, but due to clip in design of the coil assemblies the channel sequence may be changed at will.
5. Vernier tuning—Vernier oscillator tuning is provided by an auxiliary capacitor shunted across the plate portion of the tank circuit. Average coverage on the low range is ±0.5 megacycles; on the high range, ±1.6 megacycles.

Approximate Gain Readings

	Input	*Output*
Channel 13	7,000 μv	100,000 μv
Channel 12	7,000 μv	100,000 μv
Channel 7	5,500 μv	100,000 μv
Channel 6	4,400 μv	100,000 μv
Channel 2	3,500 μv	100,000 μv.

Output measured on Measurements Corporation VTVM #62 at point C to ground on Tuner. Point C loaded to ground with a 15,000-ohm resistor only no i-f tube in circuit. Points A, A_1 and C shown on schematic.

Channel	*I-F Rejection Ratio*	*Image Rejection Ratio*	*Signal/Noise Ratio*
2	1000:1	2000:1	8.1
6	2000:1	550:1	11.7
7	4000:1	590:1	14.2
12	5000:1	240:1	14.6
13	5000:1	240:1	14.6.

1. Input Balance Ratio

1. Input balance ratios measured:

Channel	*Ratio*	*Channel*	*Ratio*
2	43.5	8	8.37
3	8.42	9	11.1
4	9.76	10	14.8
5	6.9	11	24
6	13.2	12	21
7	1.9	13	22.3.

2. Oscillator Radiation

Radiation as measured at the antenna terminals with a tuned r-f voltmeter.

Channel	*Push-Pull*	*Push-Pull*
2	57,500	17,000
3	28,000	12,000
4	18,000	16,000
5	16,500	16,000
6	75,000	45,000
7	16,000	11,000
8	20,000	22,500
9	30,000	22,000
10	42,000	45,000
11	45,000	40,000
12	100,000	43,000
13	100,000	25,000.

Selectivity

The selectivity of the r-f response shall be defined in terms of the attenuation at a bandwidth of 4.5 Mc and of the bandwidth at an attenuation of 6 db. With a sweep generator connected to the antenna terminals and an oscilloscope connected to terminal G (see schematic), the sound and picture carriers are held to within 3-db attenuation from the peak of the r-f curve. Maximum bandwidth 6 db down is 11 Mc.

Antenna Impedance Match

Channel	*Standing Wave Ratio*
2	2.3:1
6	1.8:1
7	2.5:1
13	2.5:1.

Intermediate Frequencies

TV-101 and TV-103 Tuners

Models are aligned to give frequencies of 21.25 Mc and 25.75 Mc for the sound and picture carriers at the i-f output of the tuner. Split sound i-f assemblies have the following ranges:—

Sound trap: 21.0 Mc to 22.0 Mc
Plate circuit: 19.5 Mc to 27.5 Mc.

Adjustment of the brass-oscillator tuning slugs over plus and minus one turn from the aligned position provide a range of 4 Mc on all channels so that the tuner may be used to produce intermediate frequencies of 21.0 Mc to 22.0 Mc for the sound carrier and 25.5 Mc to 26.5 Mc for the picture carrier.

TV-100 and TV-102 tuners are single peaked at approximately 23 Mc. Tuning range is from approximately 18.0 Mc to 27.0 Mc.

TV-104 and TV-111 are double peaked with peaks tuned to approximately 22 and 25.5 Mc.

Oscillator Characteristics

Stability—After one minute from starting the long time warm-up drift is approximately 150 kc on channel 13 and 50 kc on channel 6.

Switch resetability—Maximum detuning of oscillator circuit when switched is approximately 100 kc on channel 13. Minimum B+ voltage, 120 volts, without loss of gain of tuner. Reduction of B+ to 90 v results in approximately 2:1 loss of gain. Change of oscillator frequency from 150 volts to 90 volts results in slightly detectable change in sound

Torque

Torque is held to a maximum of 90 inch-ounces.

Stromberg-Carlson TC10, TC125 Series

The series capacitors C90 and C91 in the low-band coupling network have been changed from 4.2 $\mu\mu f$ to 4.5 $\mu\mu f$ (part no. 110668).

Capacitor C43 in the horizontal-sweep output stage has been changed from 0.22 μf, 400 volts, to 5 μf, 50 volts (part no. 111030).

Resistor R59 has been changed from 22,000 ohms, ½ watt in TC10 and from 22,000 ohms, 1 watt in TC125, to 22,000 ohms, 2 watts. The required dissipation of about 1 watt was too great for the half-watt value.

A bent metal shield has been added to cover the underside of the first audio-amplifier tube socket to prevent extraneous audio pickup. This shield is designated part number 151104, and mounts with a PK screw which is already in use at that point.

Light vertical fold lines in the picture can usually be corrected by slight readjustment of the horizontal-size-control trimmer capacitor. This capacitor is located in the grid circuit of the 6BG6 horizontal sweep output tubes and bears the symbol of C40. The adjustment is accessible from the underside of the chassis.

To obtain a greater range of contrast, the 750-ohm potentiometer (part no. 145085) has been changed to a 3,000-ohm potentiometer (part no. 145105) in the R19A position. The 3,000-ohm potentiometer will be substituted on all replacement orders in a package assembly, number 81539, which also includes a 47-$\mu\mu f$ capacitor (part no. 110597) and instructions for making the change.

Stromberg-Carlson TC10 Series

The R68, 1-megohm, ½-watt resistor, in series with the high voltage, has been changed to a 680,000-ohm, 1-watt value (part no. 149202). If flashing horizontal streaks or lines are observed in a TC10H picture when the brightness control is advanced, the receiver may have a defective 1-megohm resistor in the R68 position which should be changed to the 680,000-ohm value, even though the resistor outwardly appears to be good. This resistor will be found on the 1B3 socket terminal in the high-voltage case.

A 150,000-ohm, ½-watt resistor (part no. 27640) has been substituted for the 39,000-ohm, 1-watt resistor in the R15 position.

The first i-f screen resistor R23 has been changed from 33,000 ohms, ½ watt, to 56,000 ohms, ½ watt (part no. 28178).

Resistor R66 in the 1B3 filament circuit has been changed from 3.3 ohms to 5.6 ohms (part no. 149271).

Resistor R43 may be a 1.8-megohm or a 1.5-megohm resistor, if the R57 potentiometer in the vertical sweep oscillator is part number 145086 or 145102, respectively.

Stromberg-Carlson TC and TS Series

Following are the part numbers of the movable iron cores and the respective coils used in the tuning assembly on TS and TC receivers:

Low-band oscillator	Core no. 118039 with coil no. 114065
Hi-band oscillator	Core no. 118030 with coil no. 114066
Low-band converter	Core no. 118029 with coil no. 114065
Hi-band converter	Core no. 118035 with coil no. 114066
Low-band r.f.	Core no. 118029 with coil no. 114065
Hi-band r.f.	Core no. 118035 with coil no. 114066.

Note: The glass coil forms are color coded (red, blue, and yellow) to indicate the range of diameter size.

In model TC receivers, to assure maximum sensitivity of the high-band section of the television tuner in TC receivers, a 6BC5 tube (part no. 110675) is being used, in place of the 6AG5 tube in the r-f amplifier position. The circuit remains unchanged.

Stromberg-Carlson TC125 Series

The following modifications have been made to improve the apparent resolution of these instruments:

1. Resistor R14 changed from 56,000 ohms to 680,000 ohms (part no. 149118).
2. Resistor R73, 22,000 ohms (part no. 27407) has been added across the secondary of the video detector transformer.
3. Capacitor C36 has been changed from 0.01 μf to 0.047 μf (part no. 110544).

A 0.0022-μf capacitor (part no. 110536) has been shunted across C30, the 0.0047-μf capacitor, when the R57B potentiometer in the vertical oscillator is part no. 145078. When a 2-megohm potentiometer (part no. 145101) is used, this shunt capacitor is not used.

The 80-μf capacitors (part no. 111067) in the B-plus power supply, and the 2-μf capacitor (part no. 110675) in C7 position in the agc line are now being supported in position by a center mounting strap. Other heavy tubular-type capacitors are being dressed in such a manner as to prevent transit breakage of the capacitor leads.

To obtain sufficient vertical size under low-line voltage conditions, the value of R52 (vertical-oscillator charging resistor) may be changed from 1.8 megohms and 2.2 megohms to 1.5 megohms. This applies to TC125 receivers not having the opera glass feature.

©John F. Rider

World Radio History

Stromberg-Carlson TC125

To improve the signal-to-noise level at the ratio-detector stage for clearer audio reproduction, capacitor C56 has been increased from 1 μf to 5 μf, 50 volts (part no. 111030).

Kinescope tubes using the grey-filter face plate (dark-faced) will be used in the subject receivers. These new tube types are identified by the following code numbers: 12½-inch tubes are denoted as 12LP4A (part no. 162075) or 12QP4A (part no. 162080), and the 19-inch tubes as 19AP4A (part no. 162083).

Cases of horizontal instability or jitter in the picture have been encountered where L4, horizontal-oscillator coil (part no. 114069), has developed short-circuited turns. This condition lowers the Q of the coil, in turn lowering the stability of the horizontal oscillator. This situation is best remedied by replacement of the coil.

In the L31 position, focus-coil assembly, part number 114660, is used when a 12LP4 kinescope tube is employed. Focus-coil assembly, part number 114661, is used when a 12KP4 or 12QP4 tube is employed.

Stromberg-Carlson TC125H, TC125L, TC125LM-2, TC125LSM

These models are similar to Model TC125. The following list should be added to the Parts List:

†Indicates metallic brown finish.

Stromberg-Carlson TC125H, TC125L

These models are similar to Model TC125 which appears on *pages 4-5 through 4-8 of Rider's TV Manual Volume 4.* The differences are given on *page 4-5 of the same volume.*

Stromberg-Carlson TS125 Series

The 5.6-ohm resistor R395 has been removed, and the 5.6-ohm resistor R396 has been changed to a 15-ohm, 1-watt value (part no. 149158), to reduce picture background noise.

Microphonics in the TS125H and TS125L models have been encountered when the audio feeds back to the r-f oscillators. It can be eliminated in the following manner:

1. Check that the tuner mounting screws do not clamp the tuner too rigidly to the main chassis.
2. Try substituting 6J6 r-f oscillator tubes. The Sylvania 6J6/TV tubes (part no. 162085) are especially good in these two oscillator positions.
3. To dampen possible movement within the oscillator trimmers, a rubber band or a spring (part no. 29628) may be stretched across the two trimmer shafts that project through the top side of the tuner chassis.

Stromberg-Carlson TS125, TS16 Series

When tolerances accumulate, the 1.5-megohm resistor R403, in the grid circuit of the vertical blocking oscillator, is sometimes too large in value to permit full control range adjustment. In these cases a 10-megohm resistor may be shunted across R403.

The 1,800-ohm, 1-watt resistor, R412, in the cathode of the vertical output tube has been changed to 3,300 ohms, 1 watt (part no. 149181).

Vertical dark lines at the left side of the picture area, caused by Barkhausen oscillations, can usually be eliminated by adjustment of the horizontal drive control. If the lines persist, changing 6BG6 tubes in the horizontal output stage should be tried. Often the lines are present on the raster, but disappear when the picture is present, so be sure to check under picture conditions.

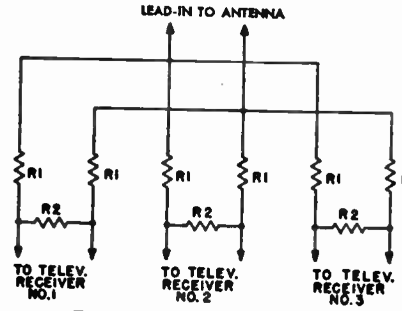
Stromberg-Carlson TV-12 Series

In case noise appears as a growl in the r-f tuner as the tuning shaft is rotated, making it difficult to tune in the desired station, especially in the high-frequency channels, the tuner is in need of cleaning and re-lubrication which is done as follows:

1. Remove the cover from the ganged coils in a clean, dust-free location.
2. With a soft small brush and some carbon tetrachloride, clean all the turns of the coils, the end rings, and the coil tracks.
3. Re-lubricate with a small amount of Lubriplate 105, covering all the surfaces just cleaned.
4. Replace the dust cover.

Stromberg-Carlson TV-12 Series

To connect more than one television receiver to one antenna without the use of switches, resistor pads will be necessary to match the impedance of the lead-in to the impedance of the receiver.



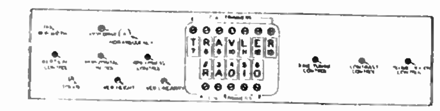
Examples for three receivers.

The table shown below is a chart of the resistors to use with each specified number of receivers. The figures are based on a 75-ohm impedance which is the input impedance of the TV-12 and also the characteristic impedance of the coaxial lead-in (RG-59U or equivalent). Use noninductive carbon resistors and place the pads at the junction point and not at the receiver terminals, as shown in the accompanying figure.

Number of Receivers	R1	R2
2	56	100
3	100	100
4	120	82
5	150	82
6	180	82
7	240	82
8	270	82.

Trav-ler 10T, 12T

Resistor R8, 10,000 ohms, has been removed from the plate circuit of VT2. Capacitor C103, 10 $\mu\mu f$, and L16B have been added from the plate of the picture tube to grid 1 of the same tube. Resistor R102, 22,000 ohms, has been inserted from grid 1 to the plate of VT11. C102, 0.05 μf has been inserted from grid 1 to the junction of R73 and the vertical output transformer. The accompanying diagram shows the placement of the front panel controls.



Front panel controls for Trav-ler 10T and 12T.

Westinghouse H-223, Ch. V-2150-01, V-2150-02, V-2150-04

Chassis V-2150-01, V-2150-02 and V-2150-04 are used in model H-223. The differences in these chassis are in the r-f tuner assembly.

The V-2150-01 chassis uses a tuner assembly marked V-6771-2. The V-2150-02 chassis uses a tuner marked V-6850. This tuner is electrically the same as the V-6771-2 tuner, but one wafer of the channel selector is mounted on the outside of the tuner housing.

The V-2150-04 chassis uses a tuner marked V-6238. This is the same tuner that is used in Model H-251. The high-frequency oscillator alignment procedure given for Model H-223 applies to the V-2150-01 chassis only. For high-frequency oscillator alignment information on the other two chassis refer to the data on Model H-251.

In early chassis, the resistance values of the V 6464 horizontal hold R403 and vertical hold R404 controls are 250,000 ohms for both sections. With these 250,000-ohm controls, the resistors that are connected in series with each control, R433 and R436, should have the resistances 100,000 and 330,000 ohms respectively. However, in later production the hold-control resistance values were changed to 100,000 ohms for R403 and 500,000 ohms for R404. When the 100,000- and 500,000-ohm controls are used, the values indicated for R433 and R436 are not correct; both R433 and R436 should be 220,000 ohms (RC20AE-224J). Since the controls furnished as replacements under part number V-6464 are the later type, R433 and R436 must be 220,000 ohms when a replacement control is installed.

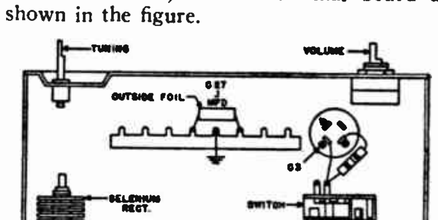
The following changes should be made in the parts list:

Part No.	Description
V-6889-1	Indicator, channel (use with V-2150-01 or V-2150-02 chassis)
V-6282-1	Indicator, channel (use with V-2150-04 chassis only)
V-8200	Tuner assembly, complete less mounting (V-2150-01 and V-2150-02 chassis only)
V-8215	Tuner assembly, complete less mounting (V-2150-04 only).

Westinghouse H-303P4, H-304P4, Ch. V-2153

The chassis used in later production contains modifications that eliminate the possibility of burning out the filament of the 3V4 tube by inserting the a-c plug in position for battery operation with the on-off switch in off position. Sets that contain the modified chassis are identified by a warning label pasted on the inside of the back cover. The warning, which reads, "Always remove plug from wall socket before operating battery change-over switch," serves as a further precaution against damage. Sets that do not contain the revisions can be modified in the following manner:

1. Remove the chassis from the cabinet.
2. Refer to the accompanying figure, and remove enough components from their positions over C3 to permit ease in performing steps 3, 4, and 5.
3. Remove the 3 red B+ wires from the C3 section lug of the filter capacitor.
4. Solder the 3 wires together and apply tape to the joint until they are well insulated.
5. Connect a single red wire between C3 lug and the battery switch terminal to which R16 is connected. The wire should be the same type as the wires that were removed.
6. Connect a 0.1-μf, 200-v, capacitor (C27, RCP10W2104M) to the terminal board as shown in the figure.



Bottom view of Westinghouse Chassis V-2153 showing wiring revisions.

7. Replace the components that were removed in step 2.

Westinghouse H-600T16, Ch. V-2150-61; H-601K12, H-602K12, Ch. V-2150-41

The following changes should be made in the schematic drawings which appear for Chassis V-2150-61 and V-2150-41:

1. In the tube heater schematic in the lower left portion of the drawing, the five filament chokes that are not numbered should be labeled L404, L405, L406, L407, and L408. In addition, the capacitor across the 6AL5 tube heater should be labeled C406, and the capacitor across the 6BJ6 heater is C407. The capacitor across the 6BH6 heater should be deleted.
2. The 6.3-v line that extends from the heater schematic should connect to terminal 5 of the terminal strip in the tuner section rather than to terminal 3. C306 which is connected to this line on the drawing should be connected between terminal 3 and ground.
3. The plate dropping resistor for the 6BH6 2nd audio a-f amplifier should be labeled R214 rather than R219.
4. The capacitor that is connected between the grid of the 6AV6 1st audio amplifier and ground should be labeled C217 rather than C216.
5. The unnumbered resistor that is connected between the horizontal hold control and the grid of the horizontal multivibrator should be labeled R436, 220,000 ohms.

The parts list for the H-600T16 should be changed as follows:

Ref. No.	Change—
R301, R302, L401	Part number to V-9235-2
L404, L405, L406, L407, L408	Part number to V-9099-1
L409, L410, L411, L412	Part number to V-9210-1.

Westinghouse H-604T10, Ch. V-2150-94; H-604T10A, Ch. V-2150-94A

The schematic diagram for these chassis should be altered to show a decoupling network in the B+ supply lead to the h-v power supply. The network consists of a 68-ohm resistor, R505, inserted in series with the B+ lead that connects from the junction of R501 and R524 to ground. These items are added in later production chassis to eliminate diagonal bars in the picture.

The parts list should be altered as follows. Change R504 to read R524. Add:

Ref. No.	Part No.	Description
—	V-9323-2	Pulley assembly, TV antenna (side H-604T10A)
—	V-9324-2	Pulley assembly, TV antenna (top H-604T10A)
C508	RCP10W4104M	Capacitor, 0.1 μf, 400 v
R505	RC20AE680K	Resistor, 68 ohms, ½ w.

Wilcox-Gay G306, G402, G403, G404, G426, G427, G624, G914

Wilcox-Gay Model G306 is similar to Majestic Model 12T6. Model G402 is similar to Majestic 12C4. Model G403 is similar to Majestic 14T2. Model G404 is similar to Majestic 14C4. Model G426 is similar to Majestic 16C4, and Model G427 is similar to Majestic 16C6. Except for cabinet designs or picture tube size, Majestic Models 12T6 and 14T2 are the same as Majestic Model 12T2. Majestic Model 14C4 is the same as Majestic Model 12C4, and Majestic Model 16C6 is the same as 16C4.

Wilcox-Gay Model G624 is similar to Majestic Model 1674, and Model G914 is similar to Majestic Model 1974.

TEST PATTERNS

Abnormalities in the patterns appearing on the scope can be classified as being caused by either:-

1. Internal effects - i.e. misadjustment of one or more controls, incorrect voltages, deterioration of components, etc., or -
2. External effects - i.e. interfering signals, multiple signals, too strong or too weak a signal, etc.

Many of the internal defects, causing abnormalities in the test pattern can be corrected by the simple adjustment of the pre-set or front panel controls.

The following test patterns have been arranged firstly as to internal and then the external causes for abnormalities. It should be born in mind that whereas only one cause is given for each defect, it is possible to have more than one simultaneously, necessating several adjustments.

These patterns are reproduced through the courtesy of the following companies: Radio Corporation of America, General Electric Company, Allen B. DuMont Laboratories, Inc., Capehart - Farnsworth Corporation, Motorola, Inc., and others
