# TELEVISION SUPERSTATION, AFFILIATE OR INDEPENDENT... ADM MAKES YOUR CHANGE TO STEREO EASY

When you're making the transition to stereo TV, make the move to ADM. In addition to stereo, you can have the traditional ease of operation, reliability and quality available only with ADM consoles.

ADM's top of the line BCS has proven to be a best seller at major networks, affiliates and independents. The console features input pre-selection and bussing, dual cue, group mute and Slidex® VCA control of all main program paths provide superior stereo tracking... making ADM your logical choice.

BCS SERIES

For any broadcaster who needs ADM quality at a price that will be gentle on your equipment budget, the S/TV fills the bill.

With the ADM five year warranty on parts and labor you can buy it and forget it. It will handle your stereo needs now and in the future. Call us, we like to make life easier for our friends.

# Professionals on the Road in Florida Midwest and JVC

As the leader in the United States in the design and manufacture of mobile units, Midwest utilizes the finest in video equipment — and that means JVC. We know that when you're on the road you need a camera that will give you top-quality performance.

So when WXEL Public Television in West Palm Beach, Florida ordered two mobile units, we knew how to respond to their need. Utilizing our basic M30 and M1 Mobile Units, we custom designed both units to meet all of WXEL's remote production demands.

Plumbicon\* pickup tubes.

WXEL's M1 Mobile Production Unit utilizes two JVC KY320U Color Cameras. The KY320U also uses the newly designed 2/3" electrostatic focus/electromagnetic deflection Plumbicon\* tubes to give it excellent dynamic range suitable for the wide variety of applications demanded in on-location work.

So join with WXEL and get on the road with the Professionals—Midwest and JVC. Midwest has the expertise to custom design a mobile unit that fits all of YOUR production needs!

WXEL's M30 Mobile Unit carries four JVC KY950U Color Cameras which produce broadcast quality signal-to-noise ratio, resolution and performance. The KY950U uses a prism optical system and

## ON THE COVER

New power devices are giving broadcasters new ways of generating RF power. Advancements in tube and solid-state designs have revolutionized transmission technology for radio and television. Shown on our cover this month is a Klystrode device intended for application in UHF TV transmitters. The Klystrode represents a marriage of klystron and tetrode technology to achieve high efficiency in the UHF TV bands. (Photo courtesy of Varian EIMAC).

## BROADCAST engineering

### TRANSMISSION SYSTEMS SPECIAL REPORT:

*The transmission plant is the heart of any radio or TV facility. The most basic requirement of the engineering staff is to keep the transmission system—from the STL to the antenna—in good working order. Our first annual Transmission Systems Special Report examines this critical area of station operation.*

### 22 New Developments in RF Technology

By Brad Dick, technical editor  
Recent advancements in power technology have revolutionized the generation of RF energy for broadcasting. This article examines the latest developments in tube and solid-state devices. A sidebar looks at:

- Power-Grid Tubes

### 42 Broadcast Transmission Systems

By Carl Bentz, TV technical editor  
The tower is a critical component in the transmission chain of any broadcast station, but one that is often neglected until a problem occurs.

### 62 Television on Ice

By Robert Dean, WSAZ-TV, and Gary Krohe, KLDH-TV  
To a radio or TV station engineer, there is no greater fear than a failure of the transmission tower structure. This article reviews two case histories of tower failure because of excessive ice buildup:

- The 58-Hour Miracle
- Gone in 30 Seconds

### 74 Using Circular Waveguide

By Gary Krohe, KLDH-TV  
Circular waveguide is gaining popularity in UHF TV transmission systems for a variety of reasons, including efficiency and ease of installation.

### 82 Complying with RF Emissions Standards

Compliance with FCC regulations on non-ionizing radiation is a subject of great concern to radio and TV engineers. This article tells how to check the compliance of your station. Other aspects of the topic covered include:

- Reducing Downward Radiation

When the Hitachi HR-230's real-time diagnostic system spots a potential problem during operation, it tells you what happened, and exactly where it happened. And it tells you in plain English.

The HR-230's computer controlled self-diagnostics continually monitors 49 different operational, maintenance, and troubleshooting parameters during both playback and recording. And it gives you the whole story up front on a console display and on the monitor.

Plus, you don't have to keep your eyes glued to the machine. Because the HR-230 stores it all in memory—along with the exact location—so you can go back and check later on.

But the HR-230 has a lot more going for it than just a great memory. Our retracting tape guides and tension arms—along with a non-contact

air scanner system dramatically reduce head and tape wear. It's compatible with all major editing systems. And such features as master/slave operation of up to 48 VTRs through its built-in editor, complete autoseup, pre-aligned replacement scanner, and a built-in TBC save you a lot of time and trouble.

And the HR-230 will save you money. Because nobody offers you so complete a machine for so modest a price.

# THE FIRST 1-INCH VTR THAT TELLS YOU WHERE TO GO.

## NAB requests federal pre-emptions

The NAB has asked the FCC to federally pre-empt state or local RF radiation regulations that arbitrarily restrict broadcast and other interstate communication services. In a growing number of instances, non-federal authorities have placed restrictions on placement and/or use of broadcast facilities. Such a federal pre-emption would ensure the FCC goal of interstate communications. The lack of pre-emptory action may see those goals thwarted by non-federal regulatory or legislative action.

In particular, the NAB has called for a commission policy statement that pre-empts state and local standards more stringent than those of ANSI non-ionizing radiation guidelines. No additional scientific evidence showing potential harm by public exposure to RF radio frequency energy below ANSI levels has been provided. The FCC adopted ANSI guidelines for its own regulatory purposes.

A stronger TVRO policy also has been requested by NAB. Previously, the FCC announced pre-emption policies for

satellite master antenna TV (SMATV) operations and amateur radio. Those policies stated that local regulation generally must not interfere with the delivery of interstate signals, and that regulations directly conflicting with federal objectives should be pre-empted.

The NAB indicated that a major federal objective is to diversify the means of program distribution to radio and TV stations. A stronger policy toward non-federal zoning and other restrictions applied to broadcast and auxiliary facilities would further the objective.

## BE goes electronic

Publications from the Intertec Electronics Group — **Broadcast Engineering, Video Systems, Sound & Video Contractor, Recording Engineer/Producer and Land Mobile Product News** — have been added to information services on the CompuServe Network. Initial material provided includes highlights of feature stories and column topics. Additional information is planned for the future.

In order to take advantage of this service, you must have a CompuServe

membership. A membership package can be obtained at most any computer store across the country. To access the professional publications area, enter GO INCUE at any (!) prompt.

Readers also may wish to enroll with Broadcasters Data Base (BDB). BE has already provided several computer programs to the Houston-based data service. For more information about BDB, call 713-623-4011 or write BDB, 3935 Westheimer, Ste 305, Houston, TX 77027.

## EBU panel views MUSE

Demonstrations presented by RAI and NHK (the Italian and Japanese national broadcasting networks) compared MAC and MUSE HDTV transmission systems for an EBU technical panel in March. MAC (multiplexed analog components) is the British-developed encoding system proposed for DBS broadcasting of 625-line TV signals for Europe. MUSE (multiple sub-Nyquist sampling encoding) is a development of NHK.

The tests compared MUSE-encoded pictures to the original HDTV pictures, as

## Deregulation affects business practices

By Harry C. Martin

The commission noted that the harmful effects of fraudulent billing and network clipping practices are *de minimis* to consumers and viewers. Thus, the commission reasoned, there is a strong incentive for the business entities that are victimized by such practices to monitor station activities and protect themselves. With a wide range of remedies available for resolution of business disputes, the commission decided the public interest does not mandate the retention of its rules in these areas. However, the commission indicated it would refer allegations regarding fraudulent billing and network clipping to the Federal Trade Commission or the U.S. Attorney, where appropriate.

The most significant policy change is in the area of combination advertising rates and joint sales practices. Up to now, the commission has prohibited competing stations from using the same sales personnel and does not permit stations in the same region, except commonly owned AM/FM operations, to offer advertising rates in combination with other stations in the same community or market.

These rules have been eliminated by the commission's deregulatory move. However, stations wishing to engage in combination advertising rate setting and joint sales with other stations should check with antitrust counsel to make sure federal law is not violated by specific combination agreements.

The commission said that licensees that engage in the previously prohibited practices in the future will not be subject to FCC scrutiny unless there is a final adjudication, civil or criminal, that misconduct has occurred.

### UHF-UHF and VHF-VHF channel exchanges permitted

The commission has adopted rules that will permit channel exchanges between commercial and non-commercial educational TV stations that are intra-banned: UHF for UHF or VHF for VHF.

Under current FCC rules, commercial and non-commercial licensees are permitted to exchange channels, but any interested party is free to apply for any channel newly made available for com-

mercial use. Because existing commercial stations fear they will lose their authorizations in resulting comparative hearings, few channel switches have ever occurred.

The commission believes that permitting exchanges without subjecting the parties to competing applications will result in more efficient use of the spectrum and the initiation of new services on both commercial and non-commercial channels.

The commission has placed certain restrictions on exchanges, however. Agreements involving payments to non-commercial stations will be scrutinized to make sure that proceeds are used only for the purpose of improving broadcast operations. The commission said it would be self-defeating if funds obtained through a channel exchange were used for other purposes, because the new rules are intended to help educational stations improve their facilities, not to fund outside projects.

In this connection, the commission will examine not only proposed changes in the signal reach of non-commercial stations, but also the extent to which signal quality will be affected by a channel change.

Under the new rule, commercial or non-commercial stations assigned to different communities in the same market would be permitted to exchange channels. The commission saw no reason to limit the scope of the proposed rule to situations where both channels are assigned to the same community. However, under no circumstances will the commission permit a channel exchange arrangement to go forward if it involves a net loss of one or more allocations reserved for non-commercial use.

To take advantage of the rule change, it will be necessary for parties agreeing to an exchange to submit a formal petition for rulemaking. The standards discussed above will be applied during the resulting rulemaking proceeding.

### Forfeiture proceedings

Even in the era of deregulation, commission enforcement actions continue. If

anything, commission-assessed fines for rule violations are now even higher.

The commission recently ordered a Pompano Beach, FL, station to pay \$10,000 for repeated violations of the commission's rules regarding fraudulent billing practices. This fine was imposed even though the commission, as noted here, now has eliminated the rule on which it was based.

In another case, the commission issued a notice of apparent liability to a La Plata, MD, AM/FM combination for \$10,000 for failing to originate a majority of its non-network programming from its main studio (or elsewhere within the community of license), failing to maintain its main studio in the community of license, failing to apply to the commission for approval to relocate its main studio outside the community of license and failing to make its public inspection file available during business hours.

### Issues/programs lists still required

The commission still requires all commercial and non-commercial broadcast stations, on a quarterly basis, to place in their public inspection files lists of public issues and the programs broadcast to address such issues. The lists must be placed in the public inspection file by the 10th day of each calendar quarter (January 10, April 10, July 10 and October 10).

The commission requires that the lists contain a brief description of at least five to 10 significant issues to which the station gave particular programming attention during the preceding quarter. A broadcaster may list as few as five issues, but the FCC's staff recommends that more than five be listed. There is no maximum limit on the number of issues a broadcaster may list.

The list must include, but is not limited to, the broadcast time, date and duration of each program, and the title and type of program in which the issue was treated (i.e., public service announcements or call-in program).

All programming broadcast for each issue need not be listed. However, licensees should maintain a record of any unlisted programs aired to meet a specific problem in the event a question is raised at renewal time regarding responsiveness to community problems.

# In the year 2003, this system will be less obsolete than any other master control system available today.

Not even Grass Valley Group knows all the features you'll need in your master control system in 2003.

But we *do* know you'll need stereo audio, second audio program and still store interface. And the only

master control system that has them all today — plus BETACART™ interface — is the Grass Valley Group 1600-4S/M200.

As your needs grow, so will your system — because it's designed,

built and backed by Grass Valley Group.

Check out the 1600-4S/M200. In 2003, you'll still be glad you did.

## By the book

By Carl Bentz, TV technical editor

Few TV stations will find difficulty in complying with the recently adopted rules regarding electromagnetic non-ionizing radiation. In case you need to consider antenna or tower alterations, be aware that changes in location, overall height and directional radiation characteristics of the antenna system must be reported to the FCC.

The transmitting antenna should be the most reliable element of the entire transmission system. If not, it is certainly one of the most difficult elements to work on. Subject to year-round weather and a certain amount of stress from the RF energy being transmitted, antennas generally present fewer problems than other parts of the transmitting plant.

### Pattern proof

When the original documents for your station were filed with the FCC, the manufacturer and model number of the antenna were included. An exhibit showing the directional pattern may have been required as well. Full-power VHF stations seldom use directional antennas. If any type of pattern control is employed (including mechanical beam tilt) to provide improved coverage of a particular area, the directional plane cannot exceed 10dB. The variation for UHF transmissions over 1kW is 15dB maximum.

Now that temperatures have moderated, a check on signal strengths radiated from the antenna might prove interesting. You may discover that the pattern has changed, perhaps the result of ice damage. In theory the VSWR of the antenna will have changed as well, but preventive observations won't hurt.

Low-power TV stations should check the accuracy of the pattern in order to comply with their license. Because the directional characteristics are specified to avoid interference with other stations,

maintaining the correct pattern is essential. Remember that weather does not differentiate between a full- and low-power station.

### Painting and lighting

If an FCC inspector pays a visit to your station, he will be particularly interested in the condition of the tower and the visibility of the structure in terms of the paint and lighting. Any antenna support structure exceeding 200 feet above ground must be painted and lighted. In general, the paint must be aviation surface orange and white in alternating bands. FCC rules specify that the uppermost and bottom bands must be orange. The widths of the bands must be equal and approximately one-seventh of the structure height.

Tower lighting is determined by the height. In all cases, however, a code beacon equipped with two 620W or 700W PS-40 lamps and aviation red color filters must be located at the top of the tower and antenna structure. Both lamps are to illuminate simultaneously at a rate of at least 12 flashes per minute, but not more than 40 flashes per minute. The period of darkness should be approximately one-half the luminous period.

Additional beacons are required on towers greater than 450 feet in height, and at least one set of two continuously burning lamps of 116W or 125W rating are required at intermediate levels. (See Table 1.) These running lights also must have aviation red filters.

All tower lighting must be operating continuously or controlled by a light-sensitive device. The device should activate the tower lighting when north sky illumination falls to 35fc. The lighting system should remain in operation until north sky illumination rises to 58fc.

High-intensity white obstruction lights may be used instead of incandescent beacons and running lights. When such equipment is authorized by the FCC, the flashing units at the top of the structure must produce an effective intensity of 200,000fc during the day, 20,000fc at twilight and 4,000fc at night. Intermediate units will produce an effective intensity of 20,000fc during the day and twilight with 4,000fc at night. As with incandescent units, the number of intermediate flashers depends upon the structure height.

The tower lighting should be inspected at least once every 24 hours to assure proper operation. An automatic monitoring system may be used. Alternatively, an alarm system that will detect any failure of the tower lighting is acceptable. At intervals not exceeding three months, all portions of the lighting-control system and alarms must be inspected for proper operation.

In the event that any flashing beacon or top steady burning light fails or is extinguished and cannot be repaired or re-illuminated within 30 minutes, the operator on duty must contact the nearest Federal Aviation Administration office or Flight Service Station.

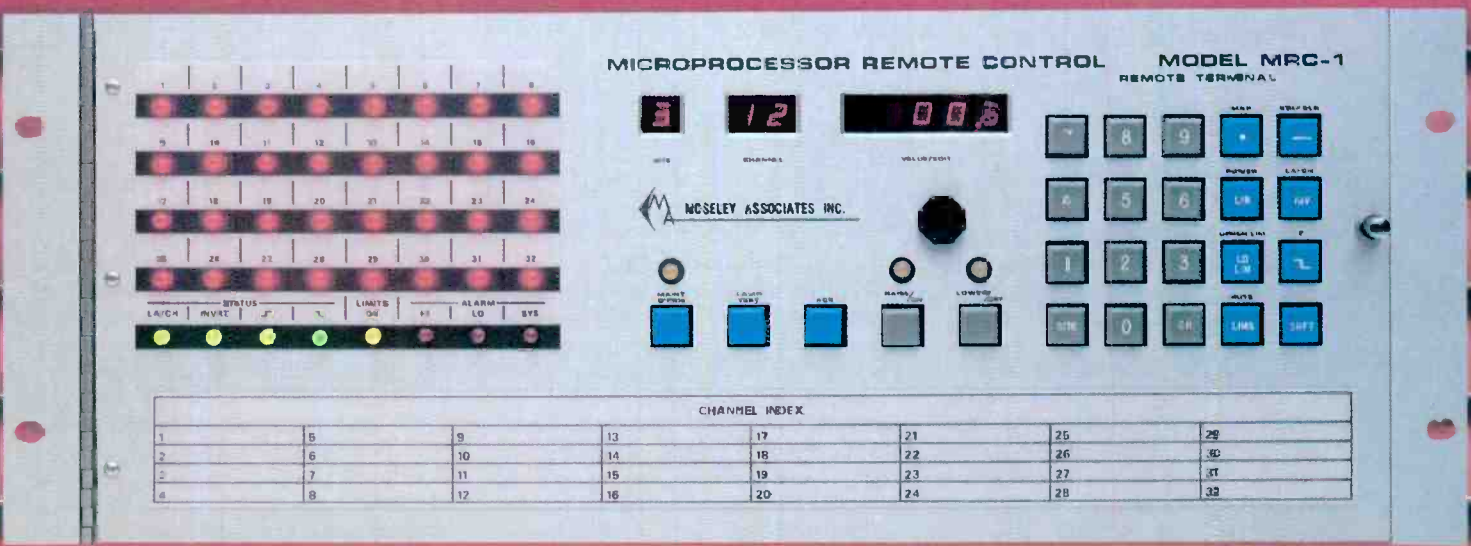

Notification also should be made when improper lighting conditions have been corrected. For the convenience of the operator, the telephone number of the appropriate aviation office should be posted at the master-control operating position.

Station records should reflect any failure of the tower lighting system. The entry of such reports should include the nature of the failure, the time and date the failure was first observed and the date, time and nature of repair made to the system.

When several stations use the same support structure for their transmitting antennas, the owner/licensee of the structure should provide copies of the quarterly tower inspection report to the other occupants of the tower. If all users share in ownership of the tower, one licensee will be designated to provide the quarterly inspection report.

		ANTENNA AND SUPPORT STRUCTURE HEIGHT					
		450-600	600-750	750-900	900-1,050	1,050-1,200	1,200-1,350

# The Moseley MRC-1. Creative Control.

No two stations are exactly alike, and neither are their remote control needs. The MRC-1 Microprocessor Remote Control is easily tailored to your specific application, be it for radio, TV or earth satellite transmitter control, to keep your system running at the peak efficiency you expect.

*Optional CRT and Logger.*

## Specify Your Options

The optional Moseley Memory protects your setups for up to 10 years in the event of an extended shutdown. An optional Logger records status and telemetry data, while the CRT provides a plain-language display of all status and telemetry inputs from any site and duplicates all MRC-1 command functions from the keyboard. Field-proven for reliability and performance, the MRC-1 lets you create control where you need it. For full details, contact Moseley Marketing or your Authorized Moseley Distributor.

## The FMX system

By Emil Torick

Last month we looked at some of the reasons why stereophonic transmission causes a loss in S/N and a reduction in stereophonic reception range. Although simply companding the audio would help the coverage and S/N problem, standard receivers would not be able to properly decode the signal.

One proposed companding system, FMX, developed by the author and Ed Keller at NAB, resolves the incompatibility problem. A companded audio stereophonic (L-R) signal is transmitted in quadrature with the normal stereophonic channel (Figure 1). A 10Hz pilot tone identifies the availability of the companded signal and properly equipped receivers can decode the encoded stereophonic signal.

Figure 1. An effective FMX system lies in transmitting a second (companded) subchannel in quadrature with the normal stereo subchannel.

### Noise reduction by companding

Companding systems achieve noise reduction by compressing the dynamic range of an audio program before transmission and expanding it to its original dynamic range at the receiver. Companding systems have achieved success in various audio applications, including tape and disk recording. Because of recent, significant improvements in companding system technology, there is new interest in broadcast applications.

The recently adopted MTS standard for stereophonic TV sound relies on companding techniques. In this system, both the stereophonic (L-R) and second audio channel (SAP) rely on companding to preserve the audio quality. Although the stereo noise penalty is less severe in television (15dB) than in radio, companding permits reception with acceptable sound quality at least to the geographical limits of acceptable picture quality.

Torick is vice president, Audio Technology, for CBS, Stamford, CT.

### FM companding

Given the recent advances in the art of audio companding, it is once again appropriate to examine the potential application to FM radio broadcasting. Some broadcasters have experimented with companding in the left and right audio channels to provide modest noise reduction in receivers equipped with appropriate expanders, and through simple receivers without expanding capability, acceptable reproduction of program material.

However, the need to maintain compatibility with existing receivers inhibits the potential for truly significant noise reduction in new receivers. Alternatively, the use of companding in the S channel of an FM broadcast would allow full compatibility with monophonic reception and the potential for a significant reduction of the stereophonic reception noise penalty. Unfortunately, this process would seriously degrade the quality of stereophonic reception in existing receivers not equipped with expanders.

The FMX system provides an alternative approach that achieves better noise reduction and compatibility with existing receivers. It also avoids any modification of the audio signals in either

S channel.) This new S' channel is transmitted in quadrature with existing stereophonic subcarrier (Figure 1).

Figure 2 depicts a block diagram of the encoder for the new composite signal. A conventional audio matrix is used to derive the sum and difference signals. A carrier generator provides the 19kHz pilot tone and the sine and cosine functions of the 38kHz subcarrier. The L-R difference signal modulates the sine carrier. The same L-R difference signal—but compressed—along with an identification tone of approximately 10Hz, modulates the cosine subcarrier producing the new stereophonic (S') signal. The monaural, stereo and companded stereo signals and pilot are added together to constitute the complete composite signal.

The reception benefits offered by the broadcast service may be viewed both as improving receiver S/N and extending the useful range of reception. In strong signal areas, the monophonic and stereophonic S/N ratios in most receivers are greater than 75dB, and only a little improvement can be expected. For stereo reception below 60dB S/N, the service offers a dramatic improvement for the user. Near the limit of effectiveness (less than 35dB S/N) some improvement is theoretically possible but potentially subject to audio noise modulation. In this area, a fixed blend or monophonic reproduction is preferred.

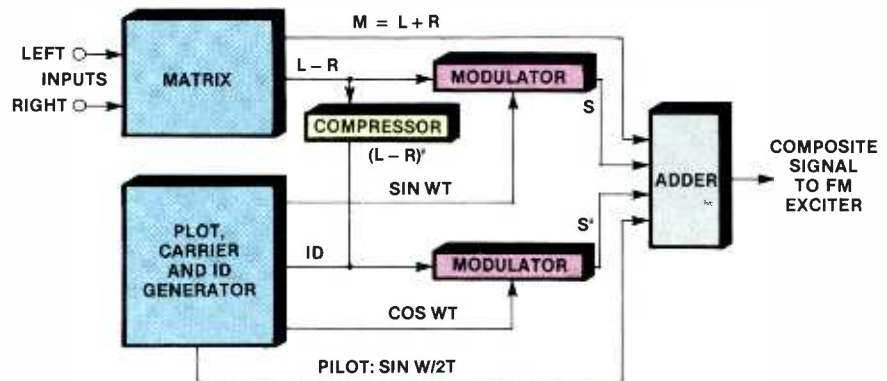

Figure 2. Block diagram of an FMX exciter.

the M or S channel. In this scheme, a companded S' channel is transmitted, to provide noise-free stereo reception to a new class of receivers. (Existing receivers will continue to use the conventional

Editor's note: This material was adapted from an Audio Engineering Society paper presented by Torick at the 70th AES convention, Oct. 12-16, 1985. Torick presented an update on the latest field tests of FMX at the 1986 NAB convention. A copy of his paper is available from the NAB.

## **CRL** makes your sound stand out from the crowd

You can't compete effectively for listeners if your station sounds just like everyone else's. And the way to stand out is with outstanding sound of the kind you get with CRL's outstanding FM-4 system.

CRL's FM-4 gives you the spectral shaping flexibility you need to sound different from other stations using the single unit processor. The CRL advantage comes from our intelligent building block approach. An approach that gives you the options you want.

Begin with our SPP 800 Stereo Preparation Processor and our SEP 800 Spectral Energy Processor for individually selectable four-band compression. Then add our SMP 800 Stereo Modulation Processor and our SG 800 Stereo Generator and you are equipped to stand out on the airwaves as never before.

If you haven't heard what CRL technology can do, you don't know what you're missing. For a *10-day free trial* at your station just call CRL toll-free at (800) 535-7648 and we'll make immediate arrangements for your local CRL dealer to give you a demonstration.

Call CRL today for sound that stands out tomorrow.

## Terrestrial interference

By Elmer Smalling, III

The greatest fear on the part of most C-band satellite earth station owners and operators is *terrestrial interference* (TI). Ku-band reception is virtually interference free, but C-band satellite downlink frequencies are co-assigned with common-carrier microwave users. If your earth station is located close to a metropolitan area, or in the path of a common-carrier microwave relay system, TI can occur, rendering your system marginal or useless.

If you have licensed your downlink with the FCC, you have some protection from interference caused by new microwave relay systems, but, in many cases, the nature and origin of the interference takes time to investigate, especially if the TI is intermittent. If you have not filed for licensing with the FCC, thereby proving you were there first, you have limited legal recourse.

Even if you have filed, interference from a licensed carrier can occur if a previously unused part of the licensed spectrum is employed to handle peak loads. Many telephone-type carriers increase their microwave bandwidth during peak hours of the day, causing time-dependent TI.

### Tracing TI

How do you know if you are experiencing TI? Symptoms range from the least offensive level of interference to a level that renders your C-band downlink useless. Before you begin the search for TI, check your downlink equipment to determine that it is not causing TI-like effects.

The following signal levels are referenced to a maximum video S/N ratio of -52dB for the desired satellite signal at the output of a receiver. For instance, a decrease in the video S/N ratio of 10dB would place the output video S/N at -42dB rather than -52dB. The more positive the S/N number becomes, when measured at the output of the video receiver, the greater the noise and the worse the picture. Noise may be a combination of snow, random bright sparkles and other degradations.

#### • Very light TI

As a general rule of thumb, a decrease in the video S/N ratio by less than 5dB results in slight snow in the video. This level of TI may be overlooked as natural

Smalling, BE's consultant on cable/satellite systems, is president of Jenel Systems and Design, Dallas.

signal or equipment degradation. It is usually not considered objectionable.

#### • Light TI

A decrease in the video S/N ratio of 7dB to 20dB causes noticeable snow in the video. Pictures remain stable on the screen and images continue to be recognizable.

#### • Medium TI

A 20dB to 25dB decrease in the S/N ratio causes objectionable snow and possible picture tearing. From this level

of interference upward, the TI is strong enough to capture receiver AGC and/or ALC circuits.

#### • Heavy TI

A 25dB to 35dB decrease in the video S/N ratio results in an almost total loss of picture and synchronization. It is sometimes possible to see the picture of the offending signal at this level of TI.

#### • Very heavy TI

A 35dB to 52dB decrease in S/N ratio removes all vestiges of the original signal. TI at a level this high is usually bad news for an earth-station owner, because it is expensive and complicated to eliminate.

Next month we'll investigate solutions to various TI problems and discuss the costs involved in eliminating TI.

Signal-to-noise (S/N) in dB =  $20 \log x$

$\frac{100 \text{ IRE units}}{\text{peak-to-peak noise voltage}}$

The ratio of 100IRE units (0.7V) video-to-noise voltage is multiplied by  $20 \log_{10}$  to get decibels.

# ONE LESS ALLIGATOR

The Broadcast Engineer works with time-line responsibilities few of us will ever experience. He knows that equipment problems can wreck production schedules.

That's why the Otari BII audio machine is so widely used for broadcast, news editing, and production.

Three speed operation, front panel record calibrations, a microprocessor controlled tape counter with LED display, and variable speed control, coupled with "bulletproof" reliability and high level product support all add up to one less alligator snapping at your heels. From Otari: The Technology You Can Trust.

## Power amplifier neutralization

By Jerry Whitaker, editor

Neutralization of power-grid tubes operating at VHF frequencies provides special challenges and opportunities to the transmitter design engineer. At VHF frequencies and above, significant RF voltages can develop in the residual inductance of the screen, grid and cathode circuits. If managed properly, these inductances can be used to accomplish neutralization in a simple, straightforward manner.

Figure 1 shows a PA stage employing stray inductance of the screen grid to achieve neutralization. In this grounded-screen application, the screen is tied to the cavity deck using six short connecting straps. Two additional adjustable ground straps are set to achieve neutralization.

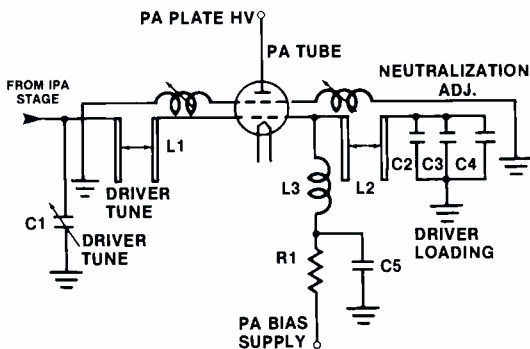

Figure 1. A grounded-screen PA stage neutralized through the use of stray inductance between the screen connector and the cavity deck.

### Grounded-grid circuits

Triode amplifiers operating in a grounded-grid configuration offer an interesting alternative to the more common grounded-cathode system. When the control grid is operated at ground potential, it serves to shield capacitive currents from the output to the input circuit. Typically, provisions for neutralization are not required until the point at which grid lead inductance becomes significant. This point is determined by the frequency of operation and the mechanical construction of the stage.

Two methods of neutralization are commonly used in grounded-grid RF amplifiers. The first method requires an inductance between the grid and ground or between the grids of a push-pull amplifier. This inductance can be used to compensate for the internal capacitance

of the tubes and cancel out coupling between the input and output circuits.

The second method involves connection of the grids of a push-pull amplifier to a point having zero impedance to ground. A bridge circuit of neutralizing capacitances is then added that is equal to the plate-to-filament capacitances of the tubes, thus achieving neutralization.

These two neutralization schemes behave quite differently. They are special forms of neutralization in which the neutralizing capacitors have values differing from the internal capacitances of the tubes, and in which an appropriate reactance is inserted between the control grids.

The purpose of neutralization is to make the tube input and output circuits independent of each other with respect to reactive currents. Isolation is necessary to ensure independent tuning of the input and output circuits. If variations in the output voltage of the stage produce variations of phase angle of the input impedance, phase modulation will result.

A circuit exhibiting independence between the input and output circuits is only half of the equation required for proper operation at RF frequencies. The effects of incidental inductance of the control grid must be cancelled out for complete stability. This condition is required because the suppression of coupling by capacitive currents between the input and output circuits is not, by itself, sufficient to negate the effects of the output signal on the cathode-to-grid circuit. Both conditions, input and output circuit independence and compensation for control grid lead inductance, must be met for complete stage stability.

### Symmetrical RF stages

Figure 2 illustrates a common symmetrical or push-pull RF stage that is grid-driven with grounded cathodes. If the inductance of the leads is negligible, because of either operating frequency or circuit construction, neutralization can be accomplished by simply cross-coupling the stage. The value of  $C_n$  from each grid to its opposite plate is equal to

the internal grid-to-plate capacitance of the power tubes. As pointed out in last month's column, this capacitor can consist of a simple wire probe that is positioned near the plate of the opposite tube in the push-pull pair.

Figure 2. Push-pull (symmetrical) stage neutralization for a grounded-cathode circuit.

Figure 3. Symmetrical stage neutralization for the grounded-grid circuit.

A similar method of neutralization can be used for cathode-driven symmetrical stages. (See Figure 3.) Note that the neutralization capacitors,  $C_n$ , are connected from the cathode of one tube to the plate of the opposite tube. The neutralizing capacitors have a value equal to the internal cathode-to-plate capacitance of the PA tubes. This neutralization method is used for applications in which the lead inductance of the circuit can be considered negligible.

Editor's note: This column is based on information contained in the publication, "The Care and Feeding of Power Grid Tubes," prepared by the laboratory staff of Varian EIMAC, San Carlos, CA.

# OPTIMOD-FM: BECAUSE MUSIC MATTERS.

Even though loudness was considered of vital importance in the design of OPTIMOD-FM Model 8100A/1, something else had even higher priority.

**Music.** Because music is what your listeners care about passionately.

OPTIMOD-FM was designed and built by people who have worked professionally in the recording industry. People with educated ears who *know* natural, musical sound—and who aren't satisfied with anything less. And people who are also skilled in the art of sophisticated, mathematical design techniques.

In OPTIMOD-FM, the math and the music come together in perfect harmony.

There are no bells and whistles. The few flashing lights are functional, not cosmetic. The sophistication is on the inside, where it belongs—assuring *listener satisfaction* by never mangling the music.

That's why OPTIMOD-FM is the best-selling FM processor ever. Use it alone, or adapt it to special needs with its optional Six-Band Limiter (for the more aggressive sound demanded by certain formats) and/or Studio Accessory Chassis (for dual STLs). OPTIMOD's versatility makes it the right choice for *your* station, regardless of format.

If you believe that music matters to your listeners, why wait any longer to bring them the best? Call your favorite Orban Broadcast Dealer, or contact us direct.

## Using power tubes

By Jerry Whitaker, editor

There are many variables that can affect the life of a PA tube in a transmitter, including tuning, filament voltage and cooling system efficiency. Heat is a frequent source of trouble for a transmitter, resulting from degradation of the internal cooling system or poor design of the air intake and output ports and ducting.

### Cooling system design

The layout of a transmitter room HVAC (heating, ventilation and air conditioning) system can have a significant impact on the life of the PA tube(s) and the ultimate reliability of the transmitter.

Air intake and output ports must be designed with care to avoid airflow restrictions and back-pressure problems. This process, however, is not as easy as it may seem. The science of airflow is complex and often requires the advice of a qualified HVAC consultant.

To help illustrate the importance of proper cooling system design and the real-world problems that some stations have experienced, consider the following examples taken from actual case histories.<sup>1</sup>

**Figure 1.** A case study in which excessive summertime heating was eliminated through the addition of a 1hp exhaust blower to the building.

**Figure 2.** A case study in which excessive back pressure to the PA cavity during winter periods (when the rooftop damper was closed) was eliminated by repositioning the damper as shown.

### Case 1:

A fully automatic building ventilation system (Figure 1) was installed to maintain room temperature at 20°C during the fall, winter and spring. During the summer, however, ambient room temperature would increase to as much as 60°C.

A field survey showed that the only room exhaust for the system was through the transmitter. Therefore, air entering the room was heated by test equipment, people, solar radiation on the building and radiation from the transmitter itself before entering the transmitter.

The problem was resolved through the addition of an exhaust fan (3,000 cfm). The 1hp fan lowered room temperature by 20°C.

### Case 2:

A simple remote installation was constructed with a heat recirculating feature for the winter (Figure 2). Outside supply air was drawn by the transmitter cooling system blowers through a bank of air filters and hot air was exhausted through the roof. A small blower and damper were installed near the roof exit point. The damper allowed hot exhaust air to blow back into the room through a tee duct during winter months.

For summer operation, the fan was activated, roof damper switched open and tee damper closed. For winter operation, the arrangement was reversed. The station, however, experienced short tube life during winter operation, even

though the ambient room temperature during winter was not excessive.

The solution involved moving the roof damper 12 feet down to just above the tee. This significantly reduced cavity exhaust back pressure. With this relatively simple modification, the problem of short tube life disappeared.

### Case 3:

An inconsistency regarding test data was discovered within a transmitter manufacturer's plant. Units tested in the engineering lab typically ran cooler than those at the manufacturing test facility.

Pride would have it that design engineers tune better; however, an investigation showed otherwise. Figure 3 shows the test station difference, a 4-foot exhaust stack that was used in the engineering lab. The addition of this stack would increase airflow by 20% because of reduced air turbulence at the output port and result in a 20°C decrease in tube temperature.

These examples point out how easily a cooling problem can be caused during HVAC system design. All power delivered to the transmitter is either converted to RF energy and sent to the antenna or becomes heated air. Proper design of a cooling system, therefore, is a part of transmitter installation that should not be taken lightly.

**Figure 3.** A case study in which air turbulence at the exhaust duct resulted in reduced airflow through the PA compartment. The problem was eliminated by adding a 4-foot extension to the output duct.

**Acknowledgment:** 1. The examples included in this column were adapted from the Harris Corporation engineering department paper, "Keeping Your Cool."

# Management for engineers

## Working with others

By Brad Dick, radio technical editor

Joe was aware there were problems between the programming and engineering departments. However, it seemed that ever since the new program director was hired, things had gotten worse. Now, both departments were engaged in a constant battle about something. The problems, when viewed later, seldom seemed to be serious. Unfortunately, at the time, everyone thought so. Recently, Joe spent most of his time playing fireman, putting out equipment-related brush fires.

### The problem

As director of engineering, Joe was responsible for a staff of engineers and operations people. It was his responsibility to keep the technical side of the station in good condition and see that his operations staff kept up with the needs of other departments. The latter task appeared to be the major part of the problem.

One of engineering's jobs was to record the numerous network feeds from the satellite system. While the task appeared simple enough, a week seldom went by without a glitch.

In recent months, several special feeds had been missed. When Joe inquired why, the operational staff said that the recording schedule was wrong. The special feeds were not listed. The program director stated that yes, the printed schedule had not called for the recordings. This was because notification of their availability wasn't received until later in the week. However, she noted that she had personally talked with the recording engineer about the late feeds and assumed, that based on the verbal request, the programs would be recorded. Unfortunately, they weren't.

### Different personalities

This scenario is not that different from what happens in many radio and TV stations. Although the particular circumstances may be different, the conflict is typical. Many engineering and programming departments seem to be constantly at war with each other, usually for reasons not easily identified.

Engineers often place great faith in their equipment. If a failure occurs, an engineer will often blame a person before he blames the equipment. A non-technical person may look at the same problem in exactly the opposite manner. A programmer may blame the equipment before blaming a person.

### Working toward a solution

The first step in resolving a problem like the one described is to establish a friendly relationship with the other department manager. Even if you don't have many personal common interests, station activities make it possible for you to communicate on business matters of

other department. Your staff also should be told that its cooperation is not an option, but rather a requirement.

Make it clear that you are not interested in attaching blame for mistakes. Rather, that you want to identify what went wrong so that a similar problem can be prevented in the future. The other department staff may have heard this line of reasoning before and may be skeptical. Even so, follow through on your promise. Attack the problem, not the person.

When problems occur, despite your best efforts, hold a special meeting. The meeting should be organized by you and the other department head. Make it plain that the meeting is being held to examine a specific incident, not as a general gripe session.

### Mutual resolution

It's important that any proposed resolution be developed by those who will have to implement it. It makes little sense to mandate a change if that change will have to be carried out by people who don't want it to occur. Better results will be obtained when you involve those who will implement any change in the decision-making process.

Be flexible. When you open yourself up to this type of decision-making process, the specific results may be different than you anticipated. Granted, you are still the manager, but you get your work accomplished *through* the efforts of others. If you want to complete your tasks, you need their cooperation.

### Mutual cooperation

Studies show that when members of disparate groups see the need to cooperate with each other for mutual survival, they usually will do so. In other words, if you make it plain to your staff that cooperation is necessary for the benefit of each person, positive results are likely. Without being threatening, let your staff know that you feel strongly on this matter. Be visible in your dealings with others and show your own cooperation. Don't be guilty of preaching one line while practicing another.

Initial results probably will not be spectacular. Bad feelings and bad habits are difficult to overcome and difficult to break. However, if you make the effort, you can succeed in resolving the type of problem that too many stations tolerate. The results will be worth the effort.

[ :- ) ]

Figure 1. Visualize a step-by-step resolution process for interdepartmental or employee conflicts.

mutual importance. Make a point to drop by the other person's office on a regular basis. Perhaps you occasionally can arrange to go to lunch. These encounters allow both of you to develop lines of communication that may help to reduce conflicts and prevent future mistakes. At the very least, they can help tear down the wall of distrust that often develops.

As a departmental manager, it's vital that you make it evident to your staff that you are trying to work *with* the

# Dazzle 'm with technical brilliance.

Everybody's talking about CD's and digital. It's as if all analog tape technology and the cart machine were obsolete. Although CD's are a terrific new program source, it should come as no surprise that carts are still the best way to handle the huge quantity of individual program elements that comprise a typical day in radio broadcasting.

What else can play spots, promos, sound effects, news actualities, ID's and music so easily?

Carts have been around for thirty years because they're a great package—easy to handle and store, easy to record and re-record, easy to label and identify. Best of all, they're cued-up from the moment you put them in the machine. Try that with a CD, turntable or reel tape!

The engineer's challenge is not CD versus the cart, vinyl LP or reel tape—but improving all broadcast

source and delivery systems. Digital audio technology is here with exciting potential for the future. For today's programming needs though, you can't beat the features and performance of our Tomcat and Micromax cart machines.

Tomcat and Micromax are equipped with our Maxtrax® wide-track tape heads which give you nearly twice the stereo track width. This track format, coupled with our superior recording and reproduction circuitry, maintains the fidelity of

master quality sound sources better than any other cart machine.

A lot of #1 stations depend on Tomcats. For stations on a tighter budget, our Micromax is the best choice. Both are built rugged to last—designed with the best components money can buy. Both will make your station sound great with everything you cart-up, especially CD's.

Give us a call now for all the technical details on the "Digital Age" cart machines.

## Cart 'em-up with Tomcat™ & Micromax.™

# New developments in RF technology

By Brad Dick, technical editor

**High-performance klystrons, Klystrodes and solid-state RF amplifiers are reducing operating costs and improving broadcast transmitter quality.**

**H**igh-power transmitter tubes are critical to the operation of most stations. FM and VHF TV transmitters usually operate with power-grid tubes. UHF TV transmitters often rely on klystrons. It is only the AM and low-power FM broadcaster who has recently been able to reap the advantages of semiconductor

development through all solid-state transmitters.

VHF transmitters were developed and in service long before the first UHF transmitters came along. When the first UHF transmitters were designed, special power-grid tubes had to be developed. Unfortunately, the performance and

reliability of early UHF transmitters were far from satisfactory. Because of the high frequencies involved, UHF tubes had to be physically smaller for a given power level than their VHF counterparts. The high power density in these small tubes stressed the elements to the limit, severely compromising the reliability and life of the tubes.

As a result of market demand, the klystron was developed and perfected for broadcast applications. The refinement efforts on the part of klystron manufacturers continue, with the objectives of increased operating efficiency, higher operating power, longer life and improved reliability.

## High-power klystrons

In the United States, UHF TV transmitters tend to be sized at 30kW, 55kW and 110kW power ratings. Until recently, the only way a transmitter could reach the 110kW and 220kW power levels was through the use of multiple 55kW klystrons. In these systems, each 55kW tube requires its own dedicated high-voltage power supply, command and control circuitry, interlocks, heater supplies, focus magnet supplies and other support circuits. This added complexity increases the cost of the transmitter.

The key to reducing the price tag for such high-power transmitters is to reduce the number of tubes, hence the need for high-power klystrons. Today, it is possible to build a transmitter around a klystron that is capable of producing 110kW of output power.

## Klystron design

The principle of *velocity modulation* is the basis on which klystrons operate. The concept describes how a long continuous electron beam is converted into a density-modulated beam at UHF frequencies.

Velocity modulation applied to a long continuous electron beam gives the klystron an important feature: high gain. Klystron design also uses a collector that can be made large and independent of

the operating frequency. In addition, the power density is kept low throughout the tube, which provides long life and reliability. These advantages were so significant that, historically, the klystron soon dominated UHF broadcasting. Of the more than 500 UHF TV stations in the United States, at least 90% use klystrons.

Figure 1 is a simplified diagram of a typical integral cavity klystron used as the final amplifier in a UHF TV transmitter. The RF input signal is coupled into the input cavity by an inductive loop. The RF voltage impressed across the cavity's capacitive gap applies an RF component to the beam current. The intermediate cavities enhance this process until, at the output cavity gap, the electron plasma is formed into more or less tight bunches. By judicious design of the output cavity, output cavity gap, and output loading loop, the energy in the bunched beam can be efficiently extracted and delivered to the RF transmission line.

The physical advantage of the klystron over the tetrode is that it makes the cathode-grid-collector structure virtually independent of the transit time effects. Therefore, the cathode can be made large and the electron beam density kept low. The result is high grid reliability and long tube life with a simpler structure.

High conversion efficiency requires the formation of electron bunches, which occupy a small region in velocity space, and the formation of interbunch regions with low electron density. The latter is particularly important because these electrons are phased to be accelerated into the collector at the expense of the RF field. Studies show that the energy loss due to an electron accelerated into the collector can exceed the energy delivered to the field by an equal but properly phased electron. Herein lies a key in improving the efficiency of the klystron: recover a portion of this wasted energy.

#### Low perveance

The *perveance* of an electron beam is defined by the equation  $I_b = k(E_b)^{3/2}$  where  $I_b$  is equal to the beam voltage in kV and  $k$  is a constant called microperveance, which is a function of the dimensions of the electron gun. It has been recognized for some time that klystrons with lower perveance are more efficient than tubes that operate at low voltage and high current.

High efficiency in low-perveance beams is mainly due to the charge density in a bunched electron beam, which is limited by the mutual repulsion of the electrons in that bunch. This mutual repulsion tends to deform the bunches, causing low efficiency.

Table 1 summarizes the perveance of three klystron tubes available today.

Notice that the 110kW klystron has a perveance one-half that of an older style klystron. Unfortunately, the bandwidth decreases and the linearity degrades with decreasing beam current for a constant output power. There are other practical reasons to limit the operating beam voltage to manageable levels. Attempting to reduce perveance just to enhance efficiency is really a matter of design tradeoffs.

Another important element in the design of high-power klystrons centers on the tube's external circuitry. Although excellent bandwidth can be obtained from a 5-cavity klystron design, it requires significant amounts of *precorrection*. The precorrection is necessitated by the higher levels of differential phase and gain generated within the low-perveance tubes. Additional drive is also

needed to meet the tube's input requirements.

#### Phased electrons

Other changes in klystron design can produce additional gain. The phase or degree of bunching of electrons in the beam current holds an answer for increased efficiency, and hence, more output power.

Studies show that by properly phasing the second-harmonic fields, an electron density distribution pattern can be established at the output gap and can produce additional RF energy. This condition can be established by replacing the harmonic cavities with the extended *drift tube* in the pre-buncher region. The idea works because the second harmonic of the spacer-charge acts upon the interbunch region in a manner similar to

Figure 1. Simplified diagram of an integral cavity klystron used as an amplifier in a UHF TV transmitter.

Table 1. Perveance of three commonly used klystrons.

TYPE	DESCRIPTION	PERVEANCE
VA-953-H	COMMONLY USED 55kW KLYSTRON	$2.0 \times 10^4$
VKP-7553S	NEW HIGH-EFFICIENCY VARIANT OF VA-953H	$1.5 \times 10^4$
VKP-7853	110kW KLYSTRON	$1.0 \times 10^4$

second-harmonic RF fields. The significance of the discovery is that wide-band klystrons for TV service can be designed using this technique.

A phase-space diagram for a high-power klystron is shown in Figure 2. The curves represent a plot of the relative phase of the reference electrons as a function of axial distance along the tube. Electrons having negative slope have been decelerated. Electrons having positive slope have been accelerated with respect to unaccelerated electrons parallel to the axis. The diagram shows how the electrons are nicely grouped at the output cavity gap while the interbunch regions are relatively free of electrons.

This interaction can be viewed another way, as shown in Figure 3, a plot of the normalized RF beam currents as a function of distance along the tube. The curves show that the fundamental component of the plasma wave has a negative slope at the third gap. This normally would be a poor condition, but because of the drift of the interbunch electrons, the fundamental current peaks at nearly 1.8 times the dc beam current. The theoretical limit for perfect bunching in a delta function is 2. The second

harmonic of the plasma wave also peaks at the output gap, which adds to the conversion efficiency.

Typical operating parameters for this klystron are 33kV beam voltage and 6.2A beam current. Gain at saturation output power is 37dB, requiring 50W of RF drive power. Conversion efficiency at saturation is typically 58%. Under pulsed conditions, peak-of-sync efficiency is approximately 70%. Other performance characteristics are shown in Table 2.

The primary advantage of this design is that it can help UHF TV stations reduce their power-consumption costs. The tube may also bring down the overall cost of new transmitters because of the reduction in the required number of final amplifier tubes and associated support circuits for high-power (110kW and above) systems.

#### The Klystrode

As the name implies, the Klystrode is a hybrid between a klystron and a tetrode. The high reliability and power-handling capability of the klystron results, in part, from the fact that electron beam dissipation takes place in the collector electrode, quite separate from the RF cir-

Introducing the ADO 1000 Digital Optics system: The full array of ADO effects. Single button access to 30 on-line effects. Multi-channel capability. All as standard equipment, and all with the picture quality that made the ADO family the industry standard for digital effects.

Even when you add perspective and rotation, for effects like the famous *ADO page turn*, the price is

still only \$67,000.

When you need even more power, options like Digi-Matte™, a key processing channel, and RGB input/output are available. And for the ultimate in convenience, you can integrate your ADO system with an Ampex AVC switcher and run effects right from the switcher control panel.

So call your nearest Ampex representative for a demo of the

ADO system's amazing effects. From Ampex, with product support and service, worldwide.

cuitry. The electron dissipation elements of a tetrode are the anode (primary) and screen grid (secondary), both of which are an inherent part of the RF circuit and must, therefore, remain small at UHF frequencies.

In the Klystrode, shown schematically in Figure 4, the electron beam is formed at the cathode, density-modulated with the input RF signal by a grid, then accelerated through the anode aperture. In its bunched form, the beam drifts through a field-free region, then interacts with the RF field in the output cavity. Power is extracted from the beam in the same way as in a klystron.

In operation, an alternating RF voltage is applied between the cathode and grid. The resulting bunched, or density-modulated, electron beam then accelerates toward the aperture anode at high potential and passes through without being intercepted. Continuing through a field-free region at a constant velocity, the beam then passes through an output gap in the resonant cavity as the electric field induced by its passing is decelerating.

Finally, the beam passes through a second field-free region (tail pipe), again with minimal interception, and then crosses the gap between the tail pipe and the collector.

The difference between the Klystrode and a conventional tetrode can be demonstrated graphically in a comparison of their potential electric fields and electron velocity (see Figure 5). The Klystrode acts similar to a klystron between the anode and collector, but closely resembles a tetrode between the cathode and anode. Six important differences should be noted:

- The Klystrode's anode potential is higher than the tetrode's screen-grid potential.

- There is a strong decelerating field in the output gap of the Klystrode compared with an almost-zero field associated with the tetrode at the time of maximum current flow. These different profiles for the potential and field (potential gradient) reveal fundamental differences in operation. Think of the tetrode as a switch that closes every half-cycle, allowing current to flow from the power supply through the resonant load. By taking advantage of the energy storage properties of the resonant circuit, the dc energy is converted to RF energy.

In contrast, the Klystrode (and klystron) change the kinetic energy of the high-velocity electrons directly to electromagnetic energy in the output gap. Tetrode conversion efficiency is maximized at low frequencies, and efficiency is decreased markedly at higher frequencies when the screen-grid voltage must be made high to supply sufficient electron beam velocity.

- The field-free regions before and after

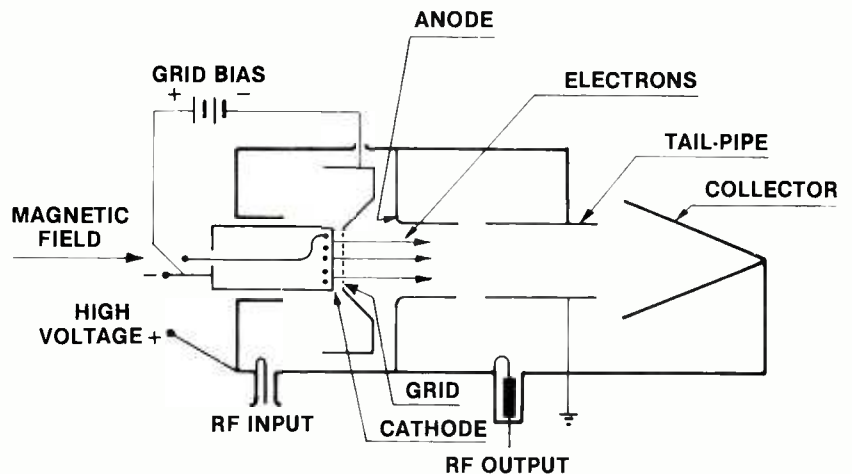

*The Klystrode is really a hybrid of the klystron and tetrode.*

the Klystrode output gap ensure that the output interaction space is isolated from the input space (grid-anode) as well as from the collector. In practice this isolation is important because, without it, input circuit conditions could be affected adversely by variations in tuning or loading of the output circuit.

- The Klystrode tail pipe is essentially non-intercepting when compared with the tetrode's anode, which also functions as a collector. The Klystrode's collector can then be made large (unlike the tetrode's anode) and, therefore, can be operated at lower power density and greater power output.

- With the Klystrode, there is no need for a blocking or bypass capacitor.

**Figure 4.** Schematic representation of a Klystrode, which combines the features of a klystron and a tetrode.

# WHAT'S NEW IN ARRAKIS SYSTEMS

## 5000 SERIES MODULAR CONSOLE \$9,999 Complete

- 16 CHANNEL MAINFRAME
- PROGRAM, AUDITION & MONO
- TELEPHONE MIX-MINUS
- CONTROL ROOM MODULES
- PROCESSING/EQ MODULES
- CLOCK AND TIMER STANDARD

Advanced engineering brings the radio industry its first no-compromise under \$10,000 audio console.

(303) 224-2248

because there is no dc voltage across the output gap. The high-voltage dc and RF fields are separated; therefore the gradient in each gap is about half the gradient in the output space of a conventional tetrode. This, coupled with the fact that no blocking capacitor is needed to carry the RF circulating current in the output cavity, is an advantageous operational feature of the Klystrode.

- Unlike the tetrode, the Klystrode uses a magnetic field. Although the Klystrode would perform well without such a field, the advantages of a magnetic field are considerable. The beam's natural

tendency is to spread out and the magnetic field prevents this from happening. Also, without focusing, the tail pipe would have to be much larger in diameter to avoid interception of the beam. If interception took place, secondary electrons could cross the gap in a direction opposite that of the main beam and tap energy from the main load. A larger tail pipe would also increase the output gap capacitance and decrease bandwidth. Finally, the beam-to-gap coupling coefficient between the beam and cavity fields would be reduced, decreasing conversion efficiency.

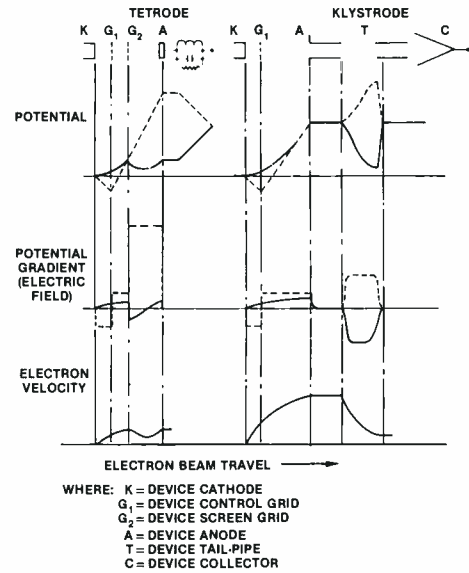

Figure 5. The potential, potential gradient and electron velocity vs. beam distance for a tetrode and a Klystrode.

### Operating class

The klystron requires class A operation. In a class B amplifier, the power taken from the power supply is a function of the signal level. In a class A amplifier, power-supply current is constant and must be high to support the peak power output.

High-power VHF TV transmitters are typically built with power-grid tubes operating in class B. This is the reason VHF transmitters are smaller, less costly and less expensive to operate than UHF transmitters of the same power class.

Modern UHF transmitters use klystrons operating in class A, with the tube biased to draw a continuous dc current equal to the highest value necessary to meet instantaneous RF output requirements. The Klystrode, on the other hand, can operate as a class B amplifier.

### Beam pulsing

In class A operation, the tube is biased to draw high current whether or not RF drive is applied and regardless of the drive level. Successful attempts have been made to reduce this inefficient mode of operation by applying a pulsing technique to the tube bias. The technique switches the tube bias between peak sync and black level operating points coincident with the video drive requirements. The most successful effort this technology has achieved is a 77% beam efficiency or *figure of merit*.

Beam pulsing the klystron involves the external control of beam current and its improvements are limited to the ratio between black level and peak sync power. Some thought has been given to full-time beam modulation of klystrons, but the linearity correction requirements, including frequency response change and ICPM generation, are currently beyond

# HIGH PERFORMANCE

System One is HIGH PERFORMANCE. Combined generator-analyzer thd + n guaranteed below 18 ppm (0.0018%) 20 Hz to 20 kHz; typical mid-band residuals below 5 ppm. Flatness 0.05 dB 20 Hz-20 kHz, noise typically below -118 dBu (1 microvolt) in a 22 kHz bandwidth. System One measures 16-bit digital audio systems to manufacturer's specs; in the mid-'80s, should you invest in equipment that can't?

the state of the art.

In class B operation, because of the klystron's geometry, the RF drive power automatically controls beam current. Thus, when the video is at white level, the beam current is low and as the picture power increases toward black level, the beam current automatically follows. For a 64kW peak sync power output, the instantaneous beam current will be 3.9A. At black level, it will be 2.7A and at middle gray levels, the beam current is only 1.4A.

Under these conditions, the figure of merit will equal 123%, where:

Peak RF sync power out

Figure of merit =  $\frac{\text{Average picture power dc input including sync and blanking}}{\text{Average picture power dc input including sync and blanking}}$

Class B operation, therefore, gives the UHF broadcaster a power cost that is based on *actual* transmitted RF power output, not on a fixed dc tube power consumption.

The figure of merit is more meaningful than other measures of transmitter performance. The broadcaster is not interested in the average power output of the transmitter or in many of the other parameters important to tube engineers. A broadcaster is only interested in the

peak sync power output of the transmitter and the power bill that arrives each month. Any expression used to accurately measure these elements need only include two parameters, the peak sync power output and the average power input. For our discussions, we will rely on the figure of merit for comparisons between tube performance.

The Klystrode uses a convergent-beam gun to form the electron beam. This beam, being self-focusing to some extent, requires relatively low focus power. In fact, only one air-cooled focus coil is employed. The focus power is 50Vdc at 6A maximum for a 64kW tube. This represents another power savings over a klystron with a similar power rating.

In class B operation, the Klystrode will have a turn-on non-linearity at small signal levels. This effect can be corrected by providing enough idle dc current to place the tube on its midrange characteristic. At 64kW, an idle current of less than 200mA is sufficient. Then, the Klystrode is actually operating as a class AB amplifier.

#### Other Klystrode features

The Klystrode has other potential advantages over the klystron. For one, the Klystrode is expected to be easier to tune. With the Klystrode, you need only

to observe the beam current while sweeping the drive frequency and adjust the input circuit to provide a flat frequency response over slightly more than the required band. Then, the output cavity can be adjusted to provide symmetrical response centered on the mid frequency of the pass band.

Another important characteristic of the Klystrode is the high isolation between the input and the output circuits. The drift tube effectively isolates the input and output circuits because of its length and narrow diameter.

A comparison of the class A klystron and the class B Klystrode shows that today's UHF broadcaster can expect to reduce the part of the power bill attributable to the tubes by up to 50%. UHF transmitters are expected to be supplied with Klystrode amplifiers capable of figures of merit that exceed 120%.

#### Depressed collector

Another change in klystron design may be in the near future. The depressed collector klystron, introduced in Europe as early as 1961, has found its most practical application in radar. Beam electrons impacting the collector revert to heat, making cooling systems mandatory. For a device designed for TV service and rated at 50kW, using a 25kV cathode-

# COMBAT TRAINING

The Otari MTR-90, the MTR-10/12 and the MX-70, taught inside and out by an Otari audio service engineer!

A 3-day course on each machine, covering schematics to the component level, electronic and mechanical alignment, and assembly/disassembly, will be presented at several locations beginning June 23, 1986.

# PERFORMANCE AND ECONOMY. SIDE BY SIDE!

Now get more performance for the money in two new additions to Tek's 1700 Series family: the 1720 Vectorscope and 1730 Waveform Monitor. For years television facilities have looked to the Tek 528A and 1420 for reliable, consistent signal monitoring. Our two new monitors do the job faster, better—and at a substantial reduction in cost. Even easier to use. Now four front panel setups can be stored—from the front panel—and recalled at the touch of a button. You get complete line select capabilities including field selection,

15-line display and CR<sup>2</sup> read-out of field arc line number. You can display Channel A and Channel B inputs simultaneously. The information you need is there at a glance. Each monitor includes its own advanced feature set. There's an X-Y input for stereo audio monitoring in the 1720. Dual filter operation in the 1730. Plus proven 1700 Series family advantages. Excellent viewability. Low power consumption. All in a compact package suited for stand alone use or rack-

mounting and available in NTSC and PAL versions.

The new 1720 Vectorscope can also be combined with a 1710B Waveform Monitor—for even greater side-by-side economy!

Get the full story from your Tektronix representative. Ask for a demo and see what makes the 1720 and 1730 the leading price/performance values on the market today!

www.americanradiohistory.com

collector potential difference and a beam current of 6A, 100kW of heat energy remains after the final cavity extracts the RF signal.

The residual beam consists of electrons of varying velocities, most being much less than the equivalent 24kV collector potential. If the collector voltage matched the velocity still in the beam, reduced collector dissipation would result. A multistage collection process with various potentials would logically be more effective.

Once past the final cavity and magnetic assemblies, electrons in the

beam diverge. Slower electrons diverge more quickly to the positive collector field than faster ones because of the inertia. If the slowest electrons carried a 5kV potential, then a section of the collector at 5kV could dissipate them with less heat loss. Faster electrons might require a 10kV section of the collector to be used. Not every electron would be collected at its most favorable potential, but a significant change would result.

Depressed collector devices serve airborne radar equipment well, an application in which efficiency is more critical than in broadcasting. Two- and even

A 4kW solid-state FM amplifier.

3-stage devices are in use, although the operating powers are significantly less than a full-power UHF TV station. The power levels required for TV service have kept depressed collector klystrons in the computer model stage, but such units could appear relatively soon, perhaps within two or three years.

#### Solid-state devices

Tubes are not the only RF power devices that have undergone changes in the past few years. Solid-state devices also play an important role in modern broadcast transmitters.

Several currently available FM transmitters rely on solid-state amplifiers. These amplifiers are typically used as driver stages for the final amplifier tube. In FM applications that do not require more than about 4kW of output power, a completely solid-state transmitter is attainable. Both FM and TV transmitters regularly use solid-state IPA modules, and solid-state AM transmitters have now reached the 50kW level.

By combining modules, almost any power level could conceivably be obtained. In practice, however, current technology limits the output level to approximately 10kW of power in VHF broadcast equipment.

#### Combining networks

In order to obtain the needed RF drive levels for high-power transmitters, several semiconductor devices are usually assembled together in a single module. The 50Ω modular building blocks can then be combined to provide whatever power level is required.

One design, shown in Figure 6, uses eight 125W FETs combined into a single chassis. This particular configuration

# EIMAC Tubes Provide Superior Reliability at radio station KWAV — over 112,000 hours of service!

Ken Warren, Chief Engineer at KWAV reports that their 10 kW FM transmitter went on the air in November, 1972, equipped with EIMAC power tubes. The original tubes are still in operation after over 13 years of continuous duty!

Ken says, "In spite of terrible power line regulation, we've had no problems with EIMAC tubes. In fact, in the last two years, our standby transmitter has operated less than two hours!"

Transmitter downtime means less revenue. EIMAC tube reliability gives you *more* of what you need and *less* of what you don't want. More operating time and less downtime!

EIMAC backs their proven tube

reliability with the longest and best warranty program in the business. Up to 10,000 hours for selected types.

Quality is a top priority at EIMAC, where our 50-year charter is to produce long-life products.

Send for our free Extended Warranty Brochure which covers this program in detail.

provides as much as 600W per module. The appropriate number of modules are then combined to obtain the desired output power level.

### Protection circuits

Because of the unpredictable conditions a broadcast transmitter periodically encounters, sophisticated protection circuits are needed. Each module must be self-protected against voltage transients, thermal overloads and severe load VSWR. Some designs also incorporate a soft start-up feature. In this case, as the

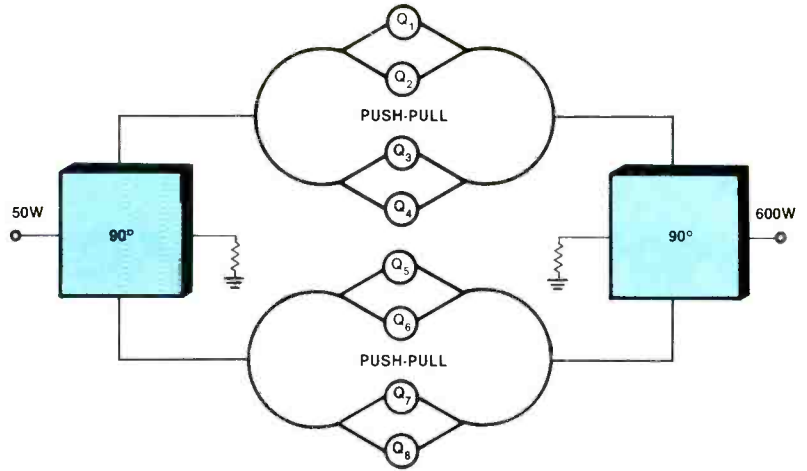

Figure 6. Schematic representation of an 8-FET 600W VHF amplifier.

## At Last, a 200 Watt Coax!

Everyone knows the benefit of a well designed coaxial loudspeaker... a single-point sound source. Until now, the most popular coaxials presented severe power limitations... had to have "trick" crossovers... and needed time compensation. Gauss technology has changed all that.

The new Gauss 3588 is the first computer designed coaxial. But, we know computers can't hear, so we used a panel of "golden ears" at the fall AES to help determine the final sound of the loudspeaker. This combination of computer design and great ears gives you a coax with the sound and the power you want!

With a conservative power rating of 200 watts RMS, this new Gauss coaxial has been tested to 750 watts delivering clean sound... and can "coast" along at control room levels still delivering great sound. Metric sensitivity is 95dB for the low frequency and 109dB HF.

Because of our proprietary design parameters, both drivers are virtually in the same acoustic plane, eliminating the

need for costly time compensation networks. For bi-amp operation, you can use any standard professional quality crossover.

The unique *cosh* horn was designed using Gauss's exclusive Computer Aided Time Spectrometry (CATS™) program. This design provides an extremely stable image... reduced second harmonic distortion... and virtually no midrange shadowing.

For additional information on the new Gauss coaxial loudspeaker, call or write Cetec Gauss, 9130 Glenoaks Blvd., Sun Valley, CA 91352. (818) 875-1900. Or better yet, hear it at a selected sound specialist soon.

system is turned on, the modules do not simultaneously draw current from the power supply. Rather, each module switches on at a different time, thereby reducing the initial surge applied to the power supply. The time delay is only a few milliseconds, so it is not noticed by the operator. However, even this short time delay is sufficient to protect the supply from the initial high current demand that would otherwise be present.

One advantage of current solid-state designs is that catastrophic failure need not occur. With a tube final amplifier, if the tube fails, the station is off the air. With a well-designed solid-state system using combined power devices, the failure of a single semiconductor usually will not shut down the station. Instead, only a small reduction in radiated power results (typically less than 1dB).

Each of the modules in a typical design is combined through a high-power combining network. In addition to coupling the devices together to obtain higher power levels, the networks also protect the modules. Failure of any of the modules does not affect the other modules but simply reduces the output power by a fractional amount. Repairs can usually be completed by unplugging

A 600W solid-state VHF module.

The PR99 MKII is a fully professional, balanced in/out ATR that's priced perfectly for broadcasters on a budget. Although compact in size, the PR99 MKII scores big on production features, audio performance, and long term reliability.

**Help for Deadline Dodgers** When deadline pressure hits, the PR99 MKII comes to your rescue with new microprocessor-controlled cueing and editing features: A highly accurate real time counter. Zero locate and address locate to find your cue and stop right on the money. Plus auto repeat for timing and rehearsing. The seconds you save will show in your production quality ... and your blood pressure. Other features include edit mode, tape dump, self-sync, input and output mode switching, input and output level calibration, and front-panel vari-speed. Console, remote control, and monitor panel available as options.

**Count on It** The Swiss-engineered PR99 MKII has earned its reputation for reliability. From the massive die-cast chassis to the servo capstan motor, every part is milled and drilled

to fit right and stay put. For a long time. Modular electronics simplify maintenance and servicing.

#### Pure Performance

Purity of sound reproduction has long been a hallmark of Studer Revox recorders, and the PR99 MKII is no exception. Noise, distortion, and frequency response specs rival those of recorders costing far more.

**All This for Not Much** Competitively priced, the PR99 MKII carries the lowest suggested list price in the under-\$2500 class. For more information, contact your Revox Professional Products Dealer. Find out how easily you can fit the PR99 MKII's balanced performance into your station's budget.

the defective module and installing a replacement unit.

### Advantages

There are a number of advantages to solid-state amplifiers. Reduced power consumption is one that broadcasters look for. Another advantage is that they usually provide wider fixed-tuned bandwidths. For instance, an FM IPA may use a module that is sufficiently broad to cover the FM broadcast band. In this design, no tuning is required when a module is replaced. In some systems, it is not even necessary to shut down the

transmitter. The modules can be replaced while the transmitter is on. This feature greatly reduces downtime from module failure.

With modern technology, it is much easier to provide reliable, and economically operating transmitters. The engineer no longer needs to be concerned about monthly—or even weekly—changes in circuit parameters. Solid-state circuits tend to be stable and, for the most part, maintenance-free.

Through the use of solid-state technology, computer modeling and manufacturing, it may not be too long

before engineers see completely solid-state 20kW (or more) FM and TV transmitters. Until then, new tube designs will continue to improve the efficiency and reliability of broadcast transmitters.

## The alternative to our "double isolation" headsets.

The Shure SM1 and SM2 Headsets isolate you from sound in two exclusive ways.

First, these headsets use extra-large, pillow-soft ear pads for superior noise isolation and comfort. Second, they feature a noise-reducing mic, with a precision cardioid polar pattern, to leave background noises where they belong... in the background. The mic's tailored frequency response insures outstanding voice reproduction.

Other features include: an all-metal boom and double-braced, all-metal headband for greater durability and comfort; a patented boom mount for total mic position flexibility; detachable cable; and a stylish matte chrome and black finish that looks great "on camera".

The SM2 is a dual-ear headset, the SM1—single. For complete information, write or call Shure Brothers Inc., 222 Hartrey Avenue, Evanston, IL 60202-3696. (312) 866-2553.

## Inside power-grid tubes

A power-grid tube is a device using the flow of free electrons in a vacuum. It has an emitting surface called the cathode, one or more grids that control the flow of electrons, and an element that collects the electrons, called the anode.

### Triodes

Most tubes used today are cylindrically symmetrical. The filament or cathode structure, the grid and the anode are all cylindrical in shape and are mounted with the axis of each cylinder along the center line of the tube. Some triodes (3-element tubes) are manufactured with the cathode, grid and the anode in the shape of a flat surface. Triodes so constructed are called planar triodes. This construction technique is used when it's necessary to provide short lead lengths within the tube. The close spacing reduces electron transit time and, therefore, allows the tube to be used at high frequencies (up to 3GHz). The 3CX100A5 and 8755 series triodes are representative of this type of tube.

### Tetrodes

The tetrode is a 4-element tube with two grids. The control grid serves the same purpose as the grid in a triode, while a second grid with the same number of bars as the control grid is mounted between the control grid and the anode. The grid bars of the second grid are mounted directly behind the control grid bars as observed from the cathode surface and serve as a shield or screen between the input circuit and the output circuits of the tetrode.

The main advantages of a tetrode over a triode include:

# UNWANTED FRAME GRABBING STOPS HERE

DFS-3000N Digital Frame Synchronizer

If your video synchronizer lets you down on a noisy feed, you need the new Leitch DFS-3000N. This digital frame synchronizer incorporates input processing circuitry that uses the latest in digital auto-correlation techniques to prevent intermittent frame grabbing or switching to black. Only Leitch offers this capability.

Now you know one of the features of the Leitch DFS-3000N. But the advantages don't stop there. Neither should you. Write or call (toll free) for further information.

A critical part of power tube construction involves the bake-out procedure, in which residual gas is burned out of the assembly.

Testing of power-grid tubes involves both dc and RF measurements. Through careful design and construction, production variations in operating parameters can be minimized.

- Lower internal plate-to-grid feedback.
- Lower driving power requirements. In most cases, the driving circuit need supply only 1% of the output power.
- More efficient operation. Tetrodes allow the design of compact, simple, flexible equipment with little spurious radiation and low IM.

#### Pentodes

The pentode is a 5-electrode tube with three grids. The control grid and screen grids perform the same function as in a tetrode. The third grid, the suppressor grid, is mounted in the region between the screen grid and the anode. The suppressor grid produces a potential minimum, which prevents secondary electrons from being interchanged between screen and plate.

The pentode's main advantages are that:

- secondary emission effects are reduced;
- it is well suited for linear amplifier service; and
- plate voltage can swing below the screen voltage without exceeding screen dissipation, allowing slightly higher power output for a given plate voltage.

#### Cathode emitters

The typical production-type oxide cathode is a coating of barium and strontium oxides on a base metal such as nickel. The oxide layer is formed by first coating a nickel can or disc with a mixture of barium and strontium carbonates, suspended in a binder material. The mixture is approximately 60% barium carbonate and 40% strontium carbonate. During vacuum processing of the tubes, they are baked out at high temperatures. As the binder is burned away, the carbonates are subsequently reduced to oxides. The cathode is now activated and will emit electrons.

The typical oxide cathode operates CW at about 1,000°K and is capable of roughly 200mA to 300mA per cm<sup>2</sup> at a typical emission efficiency of 200mA to

The production of power vacuum tubes is perhaps as much art as science. Shown is one of the glass-blowing stages used in making the envelope for a medium-power tube.

A mesh tungsten filament before mounting in the tube base. Mesh filament construction provides a rugged structure that is resistant to shock and vibration.

300mA per watt of heater power. The high emission current capability for each watt of heating power is one of the main advantages of the oxide cathode. Other advantages include high peak emission capability for short pulses and a low operating temperature.

A thoriated tungsten filament is one form of an atomic-film emitter. Thorium is added to the tungsten in the process of making tungsten wire. Typically, about 1.5% of thorium in the form of thoria is added. By proper processing during vacuum pumping of the tube envelope, the metallic thorium is brought to the surface of the filament wire, and emission increases approximately 1,000 times.

At a typical operating temperature of approximately 1,900°K, a thoriated tungsten filament will produce a specific peak emission of about 70mA to 100mA per watt of filament heating power. This is normally 5mA to 10mA of CW plate current per watt of filament power.

Thoriated tungsten filaments can be assembled in several different configurations. The spiral filament is used extensively in lower-power tubes. As the size of the tube increases, mechanical considerations dictate a bar-type filament construction technique with spring loading to compensate for thermal expansion. A mesh filament can be used for both small and large tubes. It is more rugged than other designs and less subject to damage from shock and vibration.

#### Gun-type emitters

Some power tubes are designed as a series of electron gun structures arranged in a cylinder around a center line. This construction allows large amounts of plate current to flow and to be controlled with a minimum amount of grid interception. With reduced grid interception, less power is dissipated in the grid structures. In the case of the control grid, less driving power is required for the tube.

# THIS IS THE ONE.

# THIS IS THE ONLY.

The nature of ENG and EFP business demands that you have one and only one chance to capture an event the moment it happens.

And when you're talking one and only, you're thinking Sony.

The Sony Betacam system is the one to record with, and Sony's Betacam BCT series cassette is the only one to record on. Our exclusive VIVAX™ magnetic particles, special binder system, new surface treatment and anti-static shell are all specifically designed to ensure the highest level of durability and reliability. And most of all, the best audio and video signal performance possible.

Your Sony Professional Tape Dealer will be glad to give you all the impressive facts and figures on Betacam BCT series cassettes. But the most important fact is: No Sony recorder should have to tape on anything less than Sony tape.

# Broadcast transmission systems

By Carl Bentz, TV technical editor

**Constructing a broadcast transmission system involves critical engineering-intensive design considerations.**

**T**he tower is the most visible part of the broadcast transmission system that supports the TV or FM antenna or forms the AM antenna. Many aspects of tower design and construction, however, are not as obvious.

## Tower types

Planning the transmission system is usually more critical to a successful operation than planning the studio. Not only must the system work right, it must withstand years of constantly varying weather conditions and present the fewest possible hazards to the surrounding area and population.

The choice of tower type—self-supported or guyed—is made primarily upon the basis of the available real estate at the tower site. Self-supported towers do not require as much space as guyed structures. However, the non-guyed tower must be structurally heavier because its stability is a function of design and the foundation provided. The cost of a self-supported tower will be greater than a guyed type by a factor of two or more, increasing with the height. If properly designed, a self-supported tower is no less or more reliable than a guyed tower.

To achieve the necessary strength, all structural members must be heavier than those of guyed counterparts. When wind strikes the tower, side-mounted antennas or attachments may cause torque. The tendency to twist is counteracted by the strength of the legs and the manner in which bracing is attached between the legs. At the same time, the entire height of the tower tends to pivot around the leeward side of the base. The center of balance and foundation attachment keep the tower from tipping.

## Guyed designs

Guyed structures present a different set of problems. Considering only static forces on a tower without wind, the designer is presented with a complex closed mechanical system. (See Figure 1.) Adding dynamic forces caused by wind and variations from seasonal conditions increases the complexity.

The lower portion of the tower itself must be capable of withstanding the weight of the material above it. The entire length of the tower also must sustain the downward compression force resulting from the weights and tensions of several sets of guys. Naturally, top- or

side-mounted antennas add to the total weight, along with feedlines for those antennas. The base pier and surrounding earth must withstand and support the entire downward force of the tower.

Tensions presented by guy cables differ with the height at which a set of guys is attached. In the simplest case, the lengths and tensions of all guys attached at a particular level should be equal. (Some engineers will allow variations from guy to guy of less than  $\pm 10\%$ . Unequal tensions may result in non-linearity of the tower along its length and lead to a tower that is out of plumb.

*Figure 1. A complex, but balanced, system of static forces exists in a properly designed tower. When windloading is considered, many dynamic forces come into play.*

## Continental FM Antennas Meet Your Power And Coverage Requirements

Continental offers FM broadcasters a wide variety of models to meet commercial or educational station requirements: from low power to high power, including circularly and horizontally polarized, and dual polarized directional designs.

### G5 Series

The most popular FM antenna in the United States today, this circularly polarized antenna was introduced in 1976. The G5 is available from 1 to 16 bays, in super power and medium power versions.

### G8 Series

Similar to the G5, but designed to achieve maximum circularity of coverage, especially when mounted on tower sections that have a 24" face.

### G4 CPH/M Series

A rugged, heavy-duty circularly polarized antenna capable of handling powers from 5 kW to 40 kW. It's available from 1 to 16 bays.

### G4CPL Series

Similar to the G4CPH/M series, but available only in 1 to 8 bays, and for low power applications.

### G4D Series

This dual polarized directional antenna comes with a custom matching pole. It does not require deicing in normal environmental conditions; from 1 to 8 bays.

### Move up with Continental

Whatever your antenna needs may be, your local Continental Sales Representative can help you with a choice of the best FM antennas available today.

May 1986 *Broadcast Engineering* 43

Tension also depends upon the distance of the guy anchors from the base, ranging from 50% to 100% of the tower height. The greater the distance of the anchor from the base, the less tension that must be placed on the guy for the desired amount of tower stability. However, towers with distant anchors require longer and heavier guy cable.

The number of guying levels needed is based upon the tensile strength of the tower itself, and the need to control end-to-end linearity. Curvature in the tower can add stress to one or two legs, leading to buckling.

The *plumb* of the tower also is controlled largely by guying and should be as close to zero deviation as possible. A leaning tower places stress on the base and guys. If not corrected, this can lead to catastrophic failure of the structure.

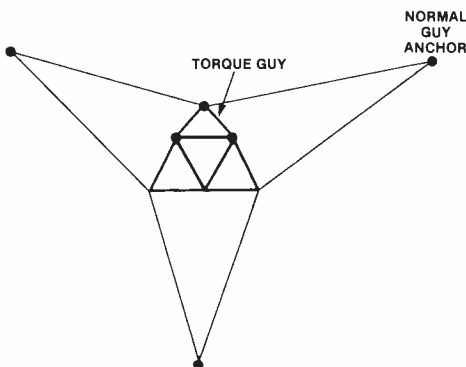

Icing of a tower presents an entirely different picture. How ice collects depends upon many factors, including height and wind direction. Icing is included in the EIA RS-222C standards for tower structures, but the unpredictability of ice collection on the tower and guys allows only approximations of its effects. The increase in loading by ice uses a factor of  $\frac{2}{3}$  for the width added to rectangular or circular tower members. Design calculations sum this amount to the clean tower windload values.

Tower designs require temperature considerations as well. For any location, maximum and minimum average temperatures determine approximately how tight (in winter) or loose (in midsummer) guys at a given tension will become. Guy weight is not changed, but forces on the tower are increased in cold weather, because of the greater tension on each guy.

Because changes in guy length occur with temperature, the natural resonant frequency of the guy cables also experiences seasonal change. (Icloading of guys also alters the natural resonance.) Although a resonant or vibrating guy is usually not a critical factor, it should be noted in the design.

### Twist

When wind is brought into the design

**Figure 2.** Torsion guys, extending from tower faces, aid in reducing tower twisting.

model, dynamic forces are added. Side attachments of any kind cause torque or a twisting of the tower. The torque may be reduced by adding torque arms to the structure. (See Figure 2.) Because the torque arms extend beyond the faces of the tower, they effectively add to the torque.

Torque is important in all situations because of the stress it places on the structure. Torque has other significance for towers supporting microwave antennas and reflectors. The half-power beam width of an STL antenna, for example, is relatively narrow. The angular width of the beam is determined from the frequency of operation ( $\lambda$ ) and the parabolic reflector diameter (D), that is:

$$2\theta = (70\lambda)/D.$$

The angle is approximately  $1.5^\circ$  for a 6-foot dish on a 7MHz video STL link. Twisting of the tower by more than  $0.75^\circ$  in either direction from the no-wind condition degrades signal reception.

When passive reflectors redirect the signal from a ground-mounted transmitting or receiving dish, the allowable tolerance of the tower-twisting rotation is further reduced. Additional factors of angular tower sway and linear displacement also must be minimized for reliable link operation.

*Turning moments* around possible pivot points (that is, any guy level on the tower) are additional stresses placed on the tower by wind. The entire tower tends to pivot around the base. The portion above the lowest guy tends to pivot around that point, and so forth. This additional set of dynamic forces significantly increases the complexity of the design project.

Tower non-linearity may increase the effect of such moments, increasing the likelihood of buckling. The collapse of a tower from the failure of one guy is probably more related to turning moments, increased by the sudden inequality of tensions at the guy point involved, than any other single factor.

Additional moments may result when wind blows against the tower. The entire structure, acting as an extension of a guy, attempts to pivot around the guy anchor, creating an additional downward force on the base pier.

### Other attachments

Coaxial feedlines and circular or rectangular waveguides provide additional weight considerations to the entire design model. They also increase torque and straight windload forces. If the feedline is placed in the angle of a leg, both types of loading are increased, with torque being the greatest. If the feedline is nearer the middle of a tower face, windload will be greater than torque.

The type of feedline also will change the amount of force. Rectangular (including square) waveguide produces a larger windload factor than circular feedline. Circular material causes only

*Cross-bracing in the tower for KTZZ-TV 22 (Seattle) adds structural strength to faces and the cross-section.*

two-thirds the load of rectangular material.

Wind also can have an effect on the operating characteristics of the waveguide. Because wind tends to deform the shape of either type of waveguide, it may be desirable to provide some type of protection for the feedline. In this case, windloading by the protective material will take precedence over the feedline itself.

### Construction

Just as the final tower specifications should be handled by a qualified design engineer, the actual construction should be contracted to a reputable and insured tower builder. As chief engineer for the station, however, you must take part in every phase of the project. Even if the tower, antenna and feedline installation is a turnkey project, you or another member of the engineering staff should monitor the progress.

Monitoring the project requires the ability to interpret specifications and to observe each step. Any deviation from good engineering practices should be pointed out to the contracting foreman and to station management. Be familiar with the EIA RS-222C publication.

As each guy point is reached during the project, observation of tower linearity, plumb and twist should be noted and corrected. All three factors may result from incorrectly manufactured materials as well as improper construction procedures. Guying tensions, as the tower grows, should be accurately set to avoid creating new linearity and plumbness

# CONTROL

*That A Ballerina Would Appreciate.....*

Is by way of introducing a new era in video switching *control*. Like the ballerina whose quality of dance expression demands absolute control, broadcasters can now achieve new levels of *control* over their video switching matrix.

To become a "video choreographer", start with just 21 buttons. Add our Series I Control Computer. Select from a library of firmware. Put it all in a 1 3/4" package and call it the PCA-904A. Now you've got a swifter *control* tailored for today's job... reprogrammable for tomorrow's. Choice of functions is limitless, and most features are available for EVERY Series 10, Series 25 and System 21 matrix **EVER BUILT!**

- **Simple Operation**—downloadable input assignments, one per button
  - **More Inputs**—reprogrammable as 100 input, downloadable alpha-numeric controller
  - **Compact**—a multi-bus controller in a 1 3/4" package
  - **Rearrange Matrix**—stores up to 20 salvos, one per button
  - **Sequential Control**—individual dwell adjustment with random order sequencing
  - **Restricted Access**—downloaded from system controller
- Try *THAT* in any other 1 3/4" rack-mounted panel!

And that's only a sample of what the powerful Series I Control Computer can do in just one configuration. Multi-level control, alpha displays and VDT interfaces are offered in other packages. The Series I can also give **YOUR** custom *control* panel all these features plus others you program yourself.

Isn't it time you assumed absolute control!

Leaders in

Signal Switching and Control

Circle (27) on Reply Card

**Figure 3.** Without cross-bracing, the rectangular form is structurally less rigid than the triangular form. Tendencies toward rotation and a flattening deformation of the rectangular structure are caused by external forces applied to an edge. In the triangular structure, the force is translated primarily to rotation. These tendencies apply for such structures either as tower face bracing or as tower cross-sections.

problems as the height adds more stress.

Any deformation of tower members should be noted and discussed with the designer prior to putting the element into place. It is possible that a bent element will not have an effect upon the final project. However, any bending of metal may signal a point of metal fatigue that could result in a disaster.

Every fastener in the tower structure should be securely tightened. A conscientious foreman will cooperate by having each fastener rechecked by the crew.

If you have any question about progress of the project, request an explanation and proof. The tower presents the greatest liability for which the station is

responsible. Concerns during the construction phase are more easily answered and dispelled at the time they occur, rather than later, when a failure produces court hearings, insurance investigations, a loss of public confidence in the station, property damage and possible injury or death.

#### Rules for safety

A number of regulations in regard to towers and support structures must be observed. In Volume 1, Part 17, the FCC spells out painting and lighting requirements for towers ranging from less than 250 feet to more than 2,000 feet.

By naming paints, colors, lamps and

lighting filters, the FCC provides the greatest measure of safety in conjunction with aircraft. The Occupational Safety and Health Administration focuses on personnel safety matters. OSHA's main concern is for the people who must work on and around the tower structure.

Many cities have statutes applying to broadcast facilities in regard to antennas and towers and safety of the general public. In some cases, the local regulations may be far more stringent than any demands from the FCC and OSHA.

The various tiers of regulations may seem to be overkill to some. Yet, the tower represents a liability for which the broadcaster is solely responsible. The regulatory efforts at each level are intended to aid the broadcast industry in reducing such liability.

#### On the tower

The majority of work to be done on existing towers will be limited to two projects: replacing lamps and/or colored lighting filters and occasional painting. Ideally, a reliable tower service company will be contracted to perform these tasks. Replacement lamps should be kept in stock to assure that any failures can be corrected quickly.

Painting is a long-term project. Even if a known service company is contracted to do the work, the station engineer should oversee the project. Not only must the paint and its application answer FCC and FAA requirements (see FCC 17.53), but painting may have a direct effect on the longevity of the structure. Galvanized metal usually does not require painting as non-coated metals do. Even so, the zinc coating of galvanizing will eventually wear away.

Seven points are suggested by NAB in regard to contracting the tower painting project:

- purchase the paint yourself, in accordance with FCC rules;
- require brushing, scraping and priming of the structure before the final coat of paint is applied;
- require painting to be done only when the tower is dry and the relative humidity is low;
- require painting to be done only if the tower temperature is at least 50°;
- apply paint as specified by the manufacturer;
- inform the painters that the job will be inspected as the work progresses; and
- require evidence of insurance coverage of the painting company for its employees. The coverage should include worker's liability, contractor's public liability, contractor's protective liability, automobile liability and direct-damage insurances. Request your insurance representative to investigate the evidence of coverage.

#### Inspections

As with other equipment around the station, preventive maintenance may aid

# AMEK announces the "soft" solution.

## Introducing the APC1000™. . .

Over twenty years ago, the concept of multi-track recording for stereo went from two to three tracks. Today, mixing 64 tracks is not unusual. The nature of audio, with digital sources and programmable electronic instruments, and the wide variety of functions demanded in recording have radically changed the requirements for an audio console.

Clearly, the answer to today's needs for audio control does not lay in yesterday's thinking. **AMEK**, long the leader in audio console innovation, has just re-defined audio control — the virtual console.

By removing the constraints of twenty-year-old console philosophy, **AMEK** has designed the obvious solution for recording, sweetening, TV Stereo, and film. The need for operational features and instant repeatability has grown but has yielded consoles of out-sized proportions and excessive electro-mechanical complexity. In-line or split monitors, and hard-wired systems, limit the operator's capabilities.

The **AMEK APC1000 Large Architecture Console™** System is the "soft console" we've all waited for. Centralizing all redundant switch and control functions into one simple logic driven key entry panel has greatly expanded the flexibility, while reducing the overall size of the console and dramatically increasing accessibility. **Dynamic Reset™**, **Synchronous Reset™** and **simplified Recall**, up to 128 inputs and 64 busses are just a few of the features of an **APC1000**.

And, in keeping with the **APC** concept, **AMEK** has introduced the **BCII**, a cost-effective open architecture console system for all broadcast or production applications, featuring audio-follows-video capabilities. The **AMEK BCII** is customizable for your operation, yet is totally user reconfigurable.

Take a closer look at the **APC1000** and the **BCII** . . . the soft solutions to today's serious engineering needs.

Distributed by:

**AMEK CONSOLES INC.**, 10815 Burbank Blvd., North Hollywood, CA 91601 Tel: 818-508-9788 Telex: 662526 AMEK USA

Circle (29) on Reply Card

in avoiding tower problems. In theory, a stainless or galvanized steel tower should stand for an extended time without causing concern. Frequent fluctuations in weather and its varied effects on out-of-door segments of broadcast facilities significantly shorten the time that a tower should go without attention.

Insurance requirements often specify that complete inspections of the tower be made annually as a requisite for renewing coverage. In some areas, local statutes also require inspections to be made and the results approved by a professional engineer. During such inspections, search for any sign of wear, stress or corrosion of the tower, all attachments and hardware.

Check guys, guy attachments on the tower, guy anchors and insulators (if used). Greasing the guys may be desirable if a trend toward excessive rusting is noted. Include all ladders, catwalks, ice bridges and other ancillary parts of the tower in the inspection. Pay special attention to concrete foundations, the ball gap of AM towers and weep holes on base insulators.

In addition, check guy tensions, linearity and plumb of the tower. These factors can be checked occasionally by station personnel, if the proper equipment is available. Your tower structural consultant should be able to assist in developing an inspection plan. Checks throughout

the year and especially after storms or high winds can help you to locate a potential tower failure and prevent it.

#### Tower security

Security at the tower site is essential in regard to a station's liability. AM towers, for example, require that locks are provided both on the tuning house and fence at the base. See section 73.40(b). Failure to keep the area secured violates the FCC regulation. Even more critical, however, is the liability of the station, if an unauthorized person enters an unsecured area and is injured or killed. An unlocked gate or insufficient fence makes the station directly responsible.

If proper security of a compound at the base of the tower is breached by unauthorized personnel, the responsibility and liability of the station should be minimal. The station may have to show that the security arrangements were sufficient. However, if the individual broke or climbed the fence for access, the case would most likely be considered burglary.

Guy points should also be secure. Because the tower structure and its guys form a complex system of forces, any change in the system produces an imbalance that may be disastrous. There are a number of cases in which guys have been cut by vandals, social fanatics or disgruntled employees.

Many remote-control systems include control and feedback channels that may be used for security monitoring purposes. Sensing for such applications can be expensive, but the cost is insignificant when compared with the investment that a transmitting tower represents.

#### From transmitter to antenna

The link from the transmitter to the antenna is the feed or transmission line. The type of line used depends upon several criteria:

- How much power will the line be expected to carry?
- What is the frequency of operation?
- What efficiency is desirable?

From these questions, a choice between coaxial line and rectangular or circular waveguide can be made.

Current designs for VHF TV and FM broadcast use coaxial feedline almost exclusively. UHF TV may use either coax or waveguide, although a preference for waveguide is noted for higher UHF channels. Microwave frequencies are more efficiently carried through waveguide.

#### Coax

The power to be carried by a coaxial line dictates the size of the cable. The greater the power requirement, the larger the diameter. At a given power level, increasing the operating frequency

## Get safe storage and transport of edit decision lists.

**C**MX systems compatibility is one of the unique features of the Greco Systems' EDL Minifile—a high capacity disk storage system used in video edit applications for storing, retrieving and transporting edit decision lists on disks.

Edit decision lists stored on the Minifile can be read by CMX systems. In turn, the lists created with a CMX system can be read by the Minifile and transferred to other video edit systems. This makes for substantial savings on your video "rough cut."

Greco Systems EDL Minifile interfaces with all video edit systems including Convergence, EECO, Paltex and Sony among others. It can also be interfaced with off-line editing systems, printers and computer systems.

**EDL Minifile. The CMX compatible system.**

Greco Systems is the leading manufacturer of specialized mass storage systems for the video edit industry. EDL Minifiles are currently being used by such leading companies as Grumman Aerospace, AT&T Technologies and Lucasfilm Ltd.

For safe storage and transport of edit decision lists, you don't have to call Brinks, call Greco Systems and talk to **Bill Barnett** at 800-621-0852 Ext. 395.

PRERECORDED TAPE

# SEVEN WAYS WE'RE

Continued from page 48

also means increasing the size of the coax to reduce attenuation.

Coaxial feedline is manufactured to meet a characteristic impedance ( $Z_0$ ), which is used throughout the system. The characteristic impedance results from either a voltage and current or from lumped capacitive and inductive values;

$$Z_0 = (L/C)^{1/2} = V' / I'$$

L and C are reactively related to frequency. As frequency increases, inductive reactance increases, while capacitive effects are reduced, according to the formulas:

$$X_L = 2\pi fL \text{ and } X_C = (2\pi fC)^{-1}$$

The change in attenuation with frequency also is related to the skin effect of conductors. At higher frequencies, the signal penetrates less deeply into the center and outer conductors of the coax. Because the signal current must travel through a smaller cross-sectional area of the conductor, more resistance is, in effect, observed.

The outside diameter of the center conductor and the inside diameter of the outer conductor also relate to the  $Z_0$  of the line. Any variation in the relationship between the two dimensions and the spacing of the center to outer conductor results in a change of  $Z_0$ . Such variations may occur at joints in a rigid coax run, a

$$Z_0 = 138 \log_{10} \frac{D}{d}$$

AIR DIELECTRIC

Figure 4. The outside diameter of the inner conductor and the inside diameter of the outer conductor determine the characteristic impedance of the coaxial material line.

mismatched load (antenna) or dents in the feedline.

### VSWR

Variations in  $Z_0$  are the cause of the phenomenon of standing waves. The amount of power sent toward the load and the amount of power reflected (the return loss) by the load forms the standing wave ratio (VSWR). Reflections occur at any time that  $Z_0$  changes, forcing some portion of the RF energy to be returned toward the transmitter. At the transmitter connection, the signal is reflected again toward the antenna. Because of the delays caused by reflection times, the reflected signal will not be in time with the primary signal. In television the results are echoes or ghosts in the picture. In radio, VSWR problems cause a degradation in stereo separation and subcarrier performance.

### Burnout

The constant motion of coaxial feedline, as a result of wind and temperature, can have a grinding effect upon the connections of the transmission line sections. In severe cases, a powder

Main article continues on page 56

Metallic particles, collecting on this coaxial spacer over several years, finally resulted in a feedline burnout.

If you're gearing up for greater capability, used equipment from Ampex can save you money. You'll save time searching, too, because we have a wide selection from virtually every manufacturer—for post-production, broadcast or in-house operations.

Give your nearest Ampex sales engineer a call. His list of used equipment ranges from "as is, where is" to reconditioned—so

there's bound to be something that fits your needs and your budget.

# THE FIRST INTELLIGENT BROADCAST COLOR MONITOR

BARCO INDUSTRIES' new CVS professional broadcast monitor is microprocessor-based to make it intelligent in operation and easy to use.

It has both a digital and an analog bus for maximum flexibility. Plus four "open" slots that let you plug in today's options and those yet to come. As new features do come along, you'll be able to add them through software - no hardware changes!

All CVS functions are controlled from the front of the monitor or from a remote keyboard. An optional master remote permits control of a series of monitors.

WE PUT THE FUTURE IN THE PICTURE.

**BARCO  
INDUSTRIES**

You can also store, and automatically call up, either calibrated presets or your own preferred presets.

Like our best master control monitors, the CVS has Automatic Kinescope Biasing (AKB) to maintain color and black level stability.

The CVS also generates more internal test patterns than any other monitor. They include white field, crosshatch and color bars.

The CVS is available in both 14 inch and 20 inch versions, and provides outstanding picture quality in any TV standard.

For complete specifications, contact your local BARCO INDUSTRIES Dealer or BARCO INDUSTRIES, 170 Knowles Drive, Suite 212, Los Gatos, CA 95030. Phone: (408) 370-3721.

BARCO INDUSTRIES is a member of the ACEC-group.

## Upon closer inspection

Are you planning changes to your transmission system? If such changes will alter the loading of the tower in any way, you should first have the structure thoroughly inspected. A number of reliable professional engineers provide such inspection serv-

This damage may have resulted during the tower construction or during the 1972 antenna installation. Deformation indicated by the top arrow is obvious. The bottom arrow indicates bending of the vertical portion of the horizontal member.

ices. You may discover that structural work is required before any additional stresses are placed on the tower. If prevention of a catastrophic collapse results, however, every penny of the inspection and repair cost is well spent. The tower shown here was originally

erected in 1969. When the initial owner was forced off the air in 1972, the channel assignment of the new owner required an antenna change. An inspection was made in 1973. The next inspection occurred in 1980, at which time these photographs were taken. Have these bolts been loose since the 1969 construction? The tower was painted at least once between the inspections, but the painting crew would not have been looking for this type of problem.

Rusting of ungalvanized fasteners holding the electrical conduit might not have major consequences. However, if rusting continues, weakening the feedline hangers, the coaxial line could become detached and, subsequently, suffer wind damage.

## Will Your Station Be Next?

One violent strike and you're fried—downtime and lost revenue. Only our unique surge protection truly handles the big hits without exposing your equipment. Competitive systems can't. Before you get hit...call us.

## Hardening the tower

The tower will stand, no matter what. That, in short, was one of the prime specifications for the Gannett site 441 tower just outside Miami. The 1,045-foot structure serves WINZ-FM and eight other FM stations using a community antenna, and supports two side-mounted UHF TV antennas as well.

Miami broadcasters and others situated along the Atlantic and Caribbean shores have a problem that the rest of the United States doesn't usually face. When hurricane season comes, even early warnings can't help a station to weatherproof the tower and antenna. However, these broadcasters have already taken precautions against these winds, which can exceed 120mph.

The Gannett tower design specified a windload factor of 100psf on the flat 12-foot faces. Circular forms exhibit a 66.7psf loading factor. Using the standard equation to relate wind pressure and velocity:

$$P = KV^2$$

a 100psf pressure results from a wind of 158mph.  $K = 0.004$  and includes a gust factor and drag coefficient for flat

The WINZ-FM transmitting facility stands between Miami and Fort Lauderdale, away from high-rise congestion.

surfaces.

An original design for the structure included a candelabra top arrangement of three masts. One would support two FM antennas, a Class C1 at the 984-foot level and a Class C above at 1,010 feet. The other two masts were planned for television.

This design was dropped because the structure would compromise the FM vertical characteristics that were desired. The tower was intended primarily for FM and TV, therefore, would take second place with side-mounted antennas below the top. Meanwhile, all FM stations would be handled by a 6-bay directional antenna that would allow the signal to be shaped to cover the coast of Florida and the Bahamas.

The second plan involved two 6-bay arrays, one for the C's and one for the C1s. The system consultants determined a third plan that simplified structural design even more. The FCC approved allowing the C1 stations to operate at 96kW ERP and the C's at 100kW ERP, all stations using a single

Three million pounds of tower are supported by a base structure that is approximately 2' 8" in diameter. Unseen is the 16-foot-square cement base pier. The legs are 10-inch-solid steel.

antenna capable of a 180kW input.

The tower, as constructed, includes 10-inch-solid steel legs, supported by a base, almost 2.4 feet in diameter, that allows the tower to rotate. The base pier cap is 16 feet square and five feet thick, poured over an array of 25 37-foot pilings.

Six guy anchor points provide three inner and outer attachment locations for the five sets of 3-inch guys. Inner anchor points for level one and two guys include 10'x13' pile caps over eight 37-foot piles. Outer points are 16 feet square, poured over 16 37-foot piles. Post-tensions arrangements are provided on outer points.

The directional characteristics of the transmission pattern require that excessive twisting of the tower is minimized. While the stress of torque on the tower structure is reduced by the rotatable base, guys at levels four and five (767' 6" and 962' 6", respectively) include dual guys attached to torque guy points. In addition, the anti-torsion controls avoid communication failures to the several STL microwave dishes mounted below the 500-foot level.

To the side of the tower, a bridge structure supports and protects the feedlines. The top-most guys can be seen attached to a torque arm.

Courtesy of Lewis T. Fineman

Continued from page 52

of copper forms inside the line, settling on the non-conductive spacers that keep the center and outside conductors properly separated. As the copper dust collects, it changes the characteristic impedance and VSWR of the line.

VSWR indicates inefficiency and may result in heat being generated at the point of the mismatch and other points along the line. Arcing also may occur, particularly if a partial electrical path is created by such copper dust on the spacer. When an arc occurs, heating at the point of the arc may establish a conductive path. The heat of the arc may melt or even char the spacer, allowing the two conductors to come in contact with one another. This mechanism

results in a burnout failure in FM and TV transmission systems.

### Waveguides

Signal propagation in waveguide occurs much differently than in coax. A radio signal in free space exists as electrical and magnetic fields oriented at right angles to the direction the signal is traveling. An RF signal confined to waveguide travels in much the same manner, although different modes may exist.

The propagation mode in waveguide defines the electrical and/or magnetic fields that may be at 90° angles to the path of signal travel. Each mode has characteristics that may be advantageous to or detrimental to signal transmission. A detrimental mode means

reduced efficiency and possible heat generation.

The frequency and mode applicable to waveguide are determined by the dimensions of the material. For higher frequencies, Part of the 9-station combining network for the Gannett site 441, Miami. All stations are Class C or C1.

cies, smaller dimensions may be used to prevent wrong modes from occurring.

Just as with coax, changes in dimension of a waveguide run may produce changes in the system VSWR. The pressure of wind blowing on the waveguide may be sufficient to cause a deformation. A varying VSWR along the run may produce reflections in the same manner as coax, but another reflection produced by mismatched polarization also may occur.

When signals leave an antenna, they are given a characteristic polarization by the antenna design. When signals enter the waveguide from the transmitter, they also are given a certain polarization. As the signals reach the antenna, signals in the waveguide of the proper polarization are transferred to the load. Changes in polarization result from dimensional changes in the waveguide.

Transmission lines are usually pressurized primarily to keep the air inside the line dry. Rectangular waveguide cannot withstand the same amount of pressure that circular waveguide allows. As a result, deformation from outside forces, such as wind, may have a greater effect on rectangular material.

Care must be used when installing any type of feedline system. Because any change in the shape of the line alters the operating characteristics, dents should

be avoided. Connections between sections must be properly seated and secured with the specified number of bolts. For more information on circular waveguide, see the article, "Using Circular Waveguide," page 74 in this issue.

#### RF combining

The FCC's 80-90 decision regarding FM power levels has resulted in a significantly increased interest in constructing tall towers and operating several stations into a single transmitting antenna. The primary requirement of such combining systems is isolation from input to input. Insufficient isolation may result in high-power intermodulation or conversion products that radiate on frequencies not assigned to any of the stations. Intermodulation and signal spurs must be at -80dB, relative to the transmitter output power.

Filtering circuits used to achieve the required separation must be linear across the passband of any one FM channel, and the overall combiner linear across the entire FM band used by the stations. Filters, by nature, usually cause some phase-shifting or group delay and band-pass reduction. Such phase shifts result in degradation to stereo separation and subcarriers of the individual carriers.

Filters are characteristically frequency-selective. In a combiner, however, the

frequency response of the network must remain flat over an FM channel. Significant signal amplitude changes of individual channels, as well as throughout the entire network, should be avoided.

Figure 5. The operation of a generalized 3dB coupler.

#### Directional coupling

The method currently found most applicable for multiple FM signal combining uses the *balanced* or *constant impedance* approach. A series of high-power hybrid 3dB directional couplers allows an efficient combining of several individual signals into a single feed to the community antenna.

In essence, the directional coupler consists of a low-loss through-path between an input and the output. A second input, the *tap*, allows an additional signal to be injected into the through-path without letting energy from the through-path leak back toward the tap input.

## Talk To Us First... about a Downstream Keyer

### It could save you a bundle!

**Model 1231**

- Up to 6 simultaneous key signals over one background
- Internal matte and masking generators
- Rack or console mount control panels
- Timed key dissolves, or key cuts
- Fade or cut to black
- Edit system control capability
- Optional Analog key bordering

**Model 1235**

- Mix or cut a single key source
- Fade to black
- Matte generator for colorizing keys
- Optional Analog key bordering

TRUTH...

OR  
CONSEQUENCES.

If you haven't heard JBL's new generation of Studio Monitors, you haven't heard the "truth" about your sound.

**TRUTH:** A lot of monitors "color" their sound. They don't deliver truly flat response. Their technology is full of compromises. Their components are from a variety of sources, and not designed to precisely integrate with each other.

**CONSEQUENCES:** Bad mixes. Re-mixes. Having to "trash" an entire session. Or worst of all, no mixes because clients simply don't come back.

**TRUTH:** JBL eliminates these consequences by achieving a new "truth" in sound: JBL's remarkable new 4400 Series. The design, size, and materials have been specifically tailored to each monitor's function. For example, the 2-way 4406 6" Monitor is ideally designed for console or close-in listening. While the 2-way 8" 4408 is ideal for broadcast applications. The 3-way 10" 4410 Monitor captures maximum spatial detail at greater listening distances. And the 3-way 12" 4412 Monitor is mounted with a tight-cluster arrangement for close-in monitoring.

**CONSEQUENCES:** "Universal" monitors, those not specifically designed for a precise application or environment, invariably compromise technology, with inferior sound the result.

**TRUTH:** JBL's 4400 Series Studio Monitors achieve a new "truth" in sound with

an extended high frequency response that remains effortlessly smooth through the critical 3,000 to 20,000 Hz range. And even extends beyond audibility to 27 kHz, reducing phase shift within the audible band for a more open and natural sound. The 4400 Series' incomparable high end clarity is the result of JBL's use of pure titanium for its unique ribbed-dome tweeter and diamond surround, capable of withstanding forces surpassing a phenomenal 1000 G's.

**CONSEQUENCES:** When pushed hard, most tweeters simply fail. Transient detail blurs, and the material itself deforms and breaks down. Other materials can't take the stress, and crack under pressure.

**TRUTH:** The Frequency Dividing Network in each 4400 Series monitor allows optimum transitions between drivers in both amplitude and phase. The precisely calibrated reference controls let you adjust for personal preferences, room variations, and specific equalization.

**CONSEQUENCES:** When the interaction between drivers is not carefully orchestrated, the results can be edgy, indistinctive, or simply "false" sound.

**TRUTH:** All 4400 Studio Monitors feature JBL's exclusive Symmetrical Field Geometry magnetic structure, which dramatically reduces second harmonic

Circle (38) on Reply Card

distortion, and is key in producing the 4400's deep, powerful, clean bass.

**CONSEQUENCES:** Conventional magnetic structures utilize non-symmetrical magnetic fields, which add significantly to distortion due to a nonlinear pull on the voice coil.

**TRUTH:** 4400 Series monitors also feature special low diffraction grill frame designs, which reduce time delay distortion. Extra-large voice coils and ultra-rigid cast frames result in both mechanical and thermal stability under heavy professional use.

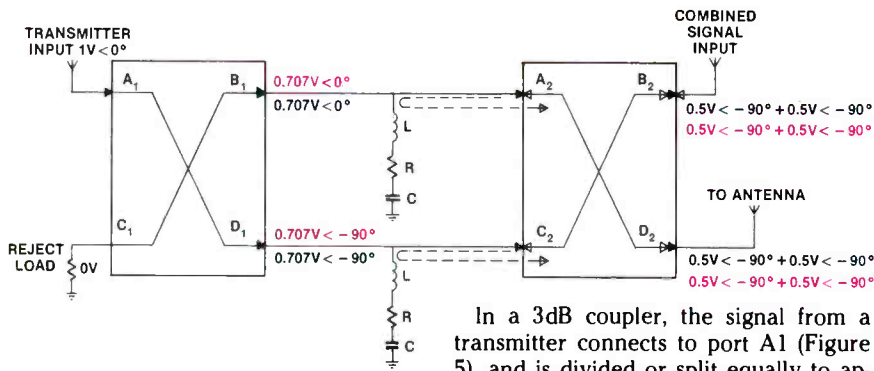

**CONSEQUENCES:** For reasons of economics, monitors will often use stamped rather than cast frames, resulting in both mechanical distortion and power compression.

**TRUTH:** The JBL 4400 Studio Monitor Series captures the full dynamic range, extended high frequency, and precise character of your sound as no other monitors in the business. Experience the 4400 Series Studio Monitors at your JBL dealer's today.

**CONSEQUENCES:** You'll never know the "truth" until you do.

JBL Professional  
8500 Balboa Boulevard  
Northridge, CA 91329

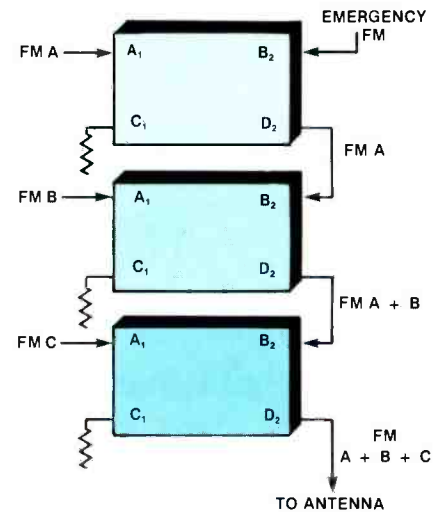

**Figure 6.** Two cascaded 3dB couplers allow separate signals to be injected at ports A1 and B2 with a combined output at port D2.

In a 3dB coupler, the signal from a transmitter connects to port A1 (Figure 5), and is divided or split equally to appear at ports B1 and D1. The signal appearing at port D1 differs from that at port B1 by a phase lag of  $-90^\circ$ . Any

signal appearing at port C1 is attenuated by 30dB, if ports B1 and C1 are terminated with the correct impedance. By connecting a second coupler section, as in Figure 6, through frequency-selective LRC circuits, the signals entering port A2 and C2 are again split and phase-shifted. At B2, the resultants, being  $-180^\circ$  out of phase, cancel; at D2, two signals, which are each  $-90^\circ$  shifted, add.

For an FM multiple transmitter combiner, individual station inputs are made through port A1 of each combiner section. Signals from an emergency transmitter or previous combiner sections enter the network through port B2. The output sum is developed at each port D2, for connection to the next section or to the antenna feedline. (See Figure 7.)

**Figure 7.** A number of dual-coupler blocks may be connected to combine several FM transmitters for application to one antenna.

By using this configuration, handling of increasing RF power levels is necessary only in the second portion of each coupler section. The LRC networks in the coupler sections must each deal only with a small bandwidth.

Group delay specifications of less than 50ns between  $\pm 150$ kHz from an FM carrier can be achieved, even with only 800kHz carrier separation. Corresponding frequency response values at  $\pm 200$ kHz from the FM carrier have been measured from 0.08dB to 0.5dB as a worst-case figure. Insertion loss for each section of the entire system can be held to 0.4dB or less.

The engineering expertise needed to specify, design and install the complete transmission system covers several engineering disciplines. Careful attention to detail in the integration of RF and structural requirements, however, results in a reliable, long-lasting facility.

Pappas Telecasting

# Comark performance satisfies the most exacting customers...again and again.

**Harry Pappas was so impressed with his first Comark "S" Series 220kW Transmitter, he bought a second.**

You don't get to be a leader in the independent television broadcast industry by making the wrong decisions about TV transmitters. When Harry Pappas was ready to build his New Super-power station, WHNS-TV in Asheville, N.C., he chose the Comark "S" Series 220kW Transmitter. In Harry's own words: "The transmitter lived up to the promises made by the Comark people...and then some. In terms of performance, specifications and efficiency ratings, I couldn't have asked for more."

Naturally when it came to choosing the transmitter for his next station in Omaha, Nebraska, there was only one choice: Comark's "S" Series 240kW rig.

At Comark, we are especially proud to have gained the confidence of a knowledgeable industry leader like Mr. Pappas. But building superior transmitters is only a part of our story. We continue to work even harder at building a superior transmitter company.

Customer service backed by engineering in depth is Comark's formula for satisfying the needs of the most exacting user.

Services and Equipment that Comark supplies include:

- Klystron UHF Transmitters from 10kW to 240kW
- A complete line of Tetrode TV Transmitters from 1 to 10kW
- Turnkey Installations
- On-site Retrofit Programs
- 24-hour Field Engineering and Customer Service
- RF Transmission Line, Components and Hardware
- Site Surveys

Whether your requirements are simple or complex, Comark stands ready to professionally satisfy your needs. Call (215) 822-0777 or write Comark, P.O. Box 506, Route 309 and Advance Lane, Colmar, PA 18915.

# Television on ice

What do you do when your world crashes down around your ears?

Many people find winter enjoyable. But for broadcasters, winter brings inevitable travel inconveniences and the ever-present possibility of storm-related damage to transmission facilities. The item most prone to winter damage, ex-

cluding vehicles, also is one of the most expensive necessities of the station: the transmission tower.

Towers are exposed to potentially damaging winds throughout the year. Winter icing, however, adds to the

windloading, increasing the vulnerability of the structure.

No station is ever really prepared for the disaster that is a tower collapse. The following accounts of two ice-related incidents tell the effects of such a loss.

## The 58-hour miracle

By Robert Dean

At 9:38 a.m. on March 11, 1983, the 1,295-foot WCSH-TV transmitting tower collapsed under an unprecedented iceload. For several days before the incident, the Portland area experienced mist, freezing rain and temperatures at or just below 32°.

We were aware of problems at the antenna site atop the 1,300-foot Winn Mountain, but poor visibility prevented our knowing just how bad the icing really was. Our only clue at the time was rising VSWR, forcing us to operate at greatly reduced power and resulting in a multitude of calls from irate viewers. Later, we would find chunks of ice up to 10 inches thick amid the wreckage of our transmitting tower.

When the tower fell, both WCSH-TV and WMEA-FM, an NPR affiliate, were immediately knocked off the air. Fortunately, our transmitter building, with the transmitter engineer inside, escaped nearly unscathed, as did a newly constructed earth station. As the structure collapsed around the downlink, the dish sustained only slight damage and remained operational. Two loggers, working about 200 feet from the base of the tower, heard the guys snapping and took refuge under their truck.

### Rebuild preparations

After assessing the situation, we were faced with two immediate problems: first, getting some type of antenna operational as quickly as possible, and second, re-establishing the microwave link to our Portland studio.

Three telephone calls brightened the day. The first successfully arranged for

Dean is the former assistant chief engineer at WCSH-TV, Portland, ME.

Part of the 1,295-foot tower on Winn Mountain that served WCSH-TV and WMEA-FM.

The temporary turnstile antenna with its custom-built utility pole mount.

Little was salvageable from the twisted wreckage.

## FORTEL'S AFFORDABLE NEW TURBO 2 TBC. PEAK PERFORMANCE AT ANY SPEED.

From freeze to shuttle. Now you can get Y-688 performance from an affordable signal processor...with Fortel's new TURBO 2 Time Base Corrector. Slim-lined and feature-packed, TURBO 2 is the first in a new generation of Fortel products...products designed to give you peak performance in signal processing.

No other TBC gives you so many features. Features like Y-688 component processing, field freeze, frame freeze, high speed shuttle and dynamic tracking, all at CCIR-601 sampling. TURBO 2 also gives you luma noise reduction, horizontal enhancement, drop-out compensation and switcher-compatible Y/R-Y/B-Y outputs...features you would normally expect from our Y-688 T.E.C.

Fortel's new TURBO 2 is built for serviceability. Self-diagnostics and interchangeable PC boards in an 1 3/4 inch rack space makes troubleshooting a breeze.

It's the signal processor you can depend on for the long run.

### TURBO 2

The new industry standard.

an available superturnstile antenna and a hybrid coupler to provide the necessary dual 90° line feed. The antenna was to be at the transmitter site the following morning.

The second call located a 100-foot tower and a crew available to begin its construction at dawn the following day. Concerned whether the tower would support both the microwave and TV transmitting antennas, we decided to mount the antennas on separate structures. The tower could easily hold the microwave dish. Meanwhile, the power company confirmed that a 70-foot utility pole would support a 3,000-pound antenna and offered an installation crew to set the pole with only an hour's notice.

The third call went to our sister station, WLBZ-TV, Bangor, ME, which came to the rescue with the needed microwave equipment.

### Hard at work

Workers were hampered by more sleet, rain and fog throughout the day following the collapse. However, by nightfall the tower was nearly completed and the notch diplexer was replaced with a hybrid coupler. The wreckage was scavenged for usable parts. The sales staff and some of the talent brought food to the site, while other staffers stayed at the station to answer telephones and explain the situation. The news department provided their 4-wheel-drive vehicles in what became a stationwide effort to get back on the air as soon as possible.

Welders worked throughout the night preparing a custom utility pole mount for the antenna. At dawn the power company arrived and the process of mounting and erecting the pole and antenna began.

Meanwhile, others salvaged the old microwave dish mount from the rubble and adapted it to the reflector provided by WLBZ. Finally the top section of the tower, with the microwave antenna attached, went into place. The old radome had survived the fall and was installed to reduce windloading on the temporary tower.

By 2:40 p.m. on the second day after the tower had fallen, microwave signals with the studio were re-established. We could now turn our attention to the antenna.

Only six 20-foot sections of transmission line were available, which created definite restrictions on placement of the antenna and pole. A spot about 18 feet from the transmitter building was selected, giving a couple of feet of leeway inside the building. As the pole was being installed, workers stood by with a backhoe and chainsaw to help with any necessary height fine-tuning.

By 6:30 p.m., after many challenges to our ingenuity, the transmitter engineers turned on the filaments and exciters for the parallel transmitter system. An hour

later, power was slowly applied to the untested, temporary antenna and feed system. With constant checks for signs of

arcing or heating, power was increased to the full rated output.

At 7:42 p.m., all tests had positive results and a telephone call to the

Portland studio brought normal program signals back on the air. Only 58 hours after disaster struck, teamwork successfully put us back in business.

# Gone in 30 seconds

By Gary L. Krohe

**T**he tower was only nine months old, and although it was originally built to hold one UHF-TV and two FM antennas, the FM equipment was not yet installed. We thought a wide safety margin existed. But sometime between midnight and 4 a.m. on March 19, 1984, the 1,439-foot tower was reduced to a pile of rubble, the victim of ice.

Problems arose the previous afternoon, and by 4:30 p.m. icing had become too heavy for the radome to shed, causing the aural VSWR to rise slowly.

Krohe is the director of engineering for KLDH-TV, Topeka, KS.

Responding to the call for assistance, I proceeded to the transmitter site about 6:15 p.m., noting on my way that the power lines were already showing signs of strain from ice.

A half-hour later, one leg of the 3-phase ac service failed, shutting the transmitter down. Without power, de-icing was impossible. Not long after, the other two phases failed as well, leaving no power at the transmitter site.

## The morning after

We had waited at the transmitter site in hopes that power would be returned. By 11:30 p.m. the maintenance engineer

and I left, planning to return at 5 a.m. to restart the system and check for damage.

On my return to the site at 4:45 a.m., power line and tree damage told me that there was little chance of power being restored. I didn't expect to see the tower lights as I approached the site. I also didn't expect to find the top plate of the tower and the bottom of the antenna lying across the access road 400 feet inside the KLDH property line.

As I approached the site, I found a 10-foot-high pile of steel where the tower base pier once stood. The transmitter building appeared undamaged. Later, however, we would find that the collapse

*Within 30 to 45 seconds, approximately 900 feet of the tower collapsed into a 100-foot-long pile of rubble. Guys remained intact through most of the fall, forcing a near-vertical position of the tower.*

*The top section and antenna from the 1,439-foot tower landed 400 feet away from the base. One of the top guys apparently caught on the rubble, causing the top part to fall in the opposite direction.*

*With its radome partially removed for inspection, the antenna shows a bend in the body resulting from the fall. Damage to the climbing ladder occurred as it was moved. Rectangular-to-circular transition at the tower top plate had been twisted badly.*

*From the 800-foot level, flanges were broken from the WC-1500 waveguide and the solid tower leg.*

# INTRODUCING AN AUTOMATIC CAMERA DESIGNED TO BEAT THE COMPETITION HANDS DOWN.

The new Sharp XC-A1 weight distribution and shoulder fit are so exceptional, it can balance on your shoulder without being held. (Something we suggest you don't try with the competition.)

And weight isn't the only thing well-balanced about it.

The XC-A1 has the most advanced 2/3" compact tube technology in the business. With three Low Capacitance Diode Gun/Mixed Field Saticons\* to give you 750 lines of resolution. Plus a high 57db signal-to-noise ratio, for an amazingly quiet picture even when you go to 9db or 18db gain.

It also has a full range of automatic features.

Like computer controlled auto-centering, auto-white and auto-black. A new auto-iris with NAM, to handle those intense color fields. Plus center weighting, so the iris isn't fooled by off-center light sources, reducing the need to manually override.

What the XC-A1 can't do alone, it coaches

you to do. With step-by-step instructions that appear in the viewfinder, then disappear or move to one corner automatically.

It's virtually rainproof and immune to radio frequency interference, too. And with a rugged die-cast frame, crack-resistant glass epoxy circuit boards and gold-plated connectors, it'll take great pictures for years to come.

All of which makes its suggested list price of under \$6,500 truly remarkable.

# Using circular waveguide

By Gary L. Krohe

A look inside circular waveguide, how it works and how it can be used.

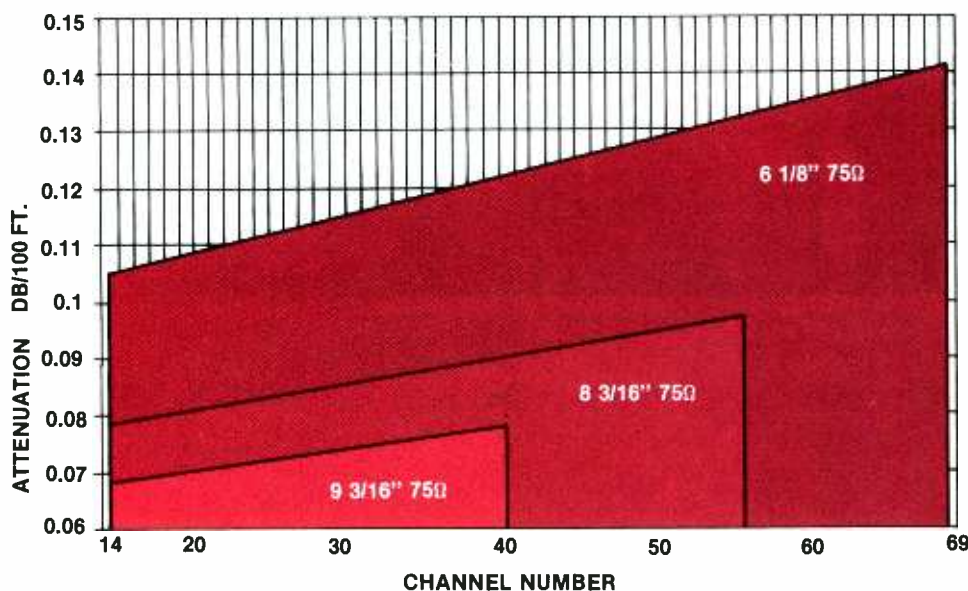

Figure 1. Attenuation vs. UHF TV frequencies for different coax materials.

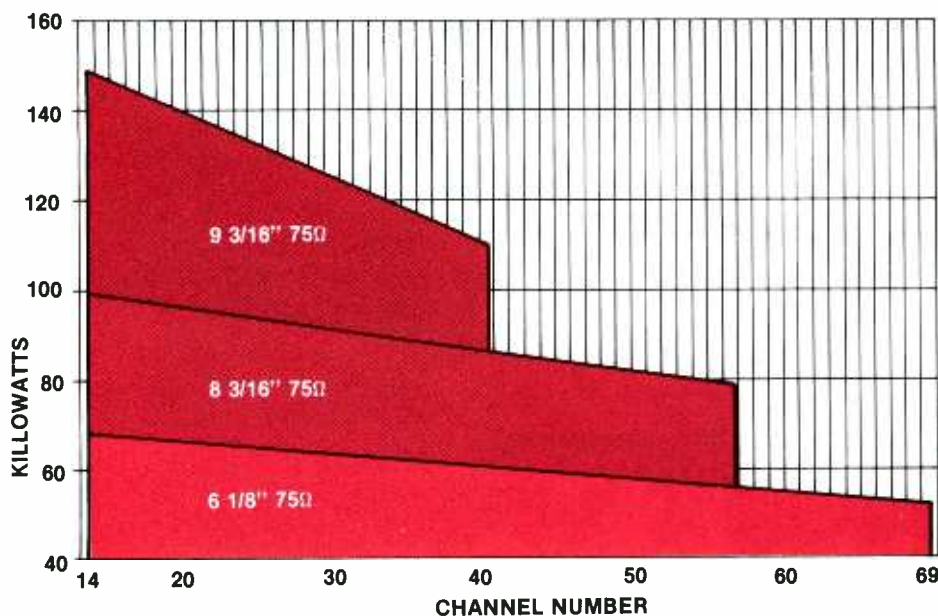

Figure 2. Power handling vs. UHF TV frequencies for different coax materials.

Although considered a new technology in broadcasting, circular waveguide systems have worked successfully for 20 years in telephone communications. Since the 1930s, when the attenuation characteristics of *overmoded* waveguide were discovered, Bell Labs has been exploring its applications. Currently, most AT&T long-lines facilities use circular waveguide to carry three frequency bands in two polarizations to feed one broadband horn antenna. In Japan, extremely long runs of circular waveguide have carried intra-city communication signals successfully. With the advent of fiber-optical systems, however, waveguide is being phased out in telecommunications applications.

The first application of circular waveguide to feed a UHF broadcast antenna was at WLFL-TV, Durham, NC, in November 1981. Currently, more than a dozen stations have installed circular transmission systems.

### Feedline types

Three types of feed systems are used to drive UHF TV broadcast antennas: rectangular and circular waveguide and coaxial transmission line. Coaxial line is the most conventional, but it has several drawbacks. A transmission line with a center conductor may be subject to burn-out through natural or induced causes. As the operating frequency increases, the power-handling capacity decreases.

Coax also has a frequency limit, where high-frequency operation can cause higher-order moding problems (the line tries to act as if it were waveguide). Finally, as frequency increases, so does line attenuation with a decrease in efficiency. On the positive side, transmission line, although weighing more than waveguide, presents the smallest cross-sectional windload of the three methods.

Rectangular waveguide offers several advantages over coax, but has inherent problems of its own. Rectangular

*"With 3M Switchers, We've Got  
Control Right At Our Fingertips."*

John Owen, VP Engineering, Taft Broadcasting

When you've got your finger on the pulse of a dozen stations scattered across the country, you can't simply install routing switcher equipment and then hope for the best.

You have to be sure it's the best.

With the best specs in the industry. With keyboard controls that are fast and easy to use. And software that's as flexible as it is friendly.

That's why John Owen, VP of Engineering for Taft Broadcasting, chose 3M Series H Routing Switchers when six of Taft's stations recently underwent plant redesigns.

"We wanted to quadruple our capacity, and the Series H provided the means of doing it. This system is expandable and has excellent flexibility while providing clean signal switching. It was a major improvement.

"The Series H is based on a primary switching matrix increment of 16 x 16, so you can install a switching frame configured for initial needs, and have room for a good deal of expansion later on.

"We have a concept at Taft that is somewhat different from most. We look at routing systems for more than distribution from point to point. We try to use the system creatively, and we use it for quality control as well as switching diversity. We believe we are on the leading edge of technology, and we wanted equipment that best reflected that.

"If you want to be one of the premier broadcasting groups, you'll be working closely with a lot of different component companies. 3M took the time to listen when we talked about switchers and was right here in the trenches every step of the way. If I were doing it again, I'd look to 3M in a minute."

More information about 3M Series H Routing Switchers, switching systems, machine control systems and master controls is right at your fingertips as well. Just call toll free: 1-800-328-1684 (in Minnesota 1-800-792-1072).

waveguide, unlike coax, can carry more power as the operating frequency increases and will generally handle a minimum of 150kW using WR-1150 on channel 40, compared to a maximum of 150kW for 9 3/16-inch coax on channel 14. System efficiency is significantly better with rectangular waveguide at higher frequencies.

Rectangular waveguide, however, presents a large, non-uniform windload surface, which places additional demands upon the tower. Rectangular waveguide can only be pressurized to 0.5psi. Any greater pressure will deform

the guide shape and result in an increasing VSWR. Wind also may cause deformation and ensuing VSWR problems.

Circular guide improves on the advantages of rectangular guide, by yielding higher power ratings and lower signal attenuation. It can be pressurized to 2.5psi, like transmission line. The antenna may be pressurized through the guide, rather than through a separate pressure line, as rectangular guide requires. As the pressure inside the waveguide increases, the shape tends to become more uniformly circular, improving guide characteristics. Finally, circular waveguide presents lower and more

uniform windloading than rectangular waveguide, thus reducing tower structural requirements.

The same physical properties of circular waveguide that give it superior power handling and low attenuation also are the cause of its electrical complexities. Circular waveguide has two potentially unwanted modes of propagation, the cross-polarized  $TE_{11}$  and  $TM_{01}$  modes.

Circular waveguide, by definition, has no short or long dimension and, consequently, no method to prevent the development of *cross-polar* or *orthogonal* energies. Cross-polar energy is formed by small ellipticities in the waveguide. If the cross-polar energy is not trapped out, this parasitic energy form can recombine with the dominant mode energy to cause ghosting. Manufacturers of circular waveguide for broadcast incorporate some form of cross-polar filter or attenuator in their systems.

#### More on modes

In a discussion of waveguides, some understanding of the modes of propagation is necessary. There are four common modes in coax and waveguides:  $TE_{01}$ ,  $TM_{01}$ ,  $TE_{11}$ , and TEM. Each mode has a cutoff frequency, the lowest frequency at which a particular type of guide will propagate a signal without undue attenuation.

$TE_{01}$  mode, or *transverse electric* mode, has an electric field transverse (at right angles) to the direction of propagation. Of the four modes, it also has the highest cutoff frequency.

$TE_{11}$  also has an electric field that is transverse to the direction of propagation. In circular guide, however,  $TE_{11}$  develops a more complex propagation pattern with electric vectors curving inside the guide. This mode exhibits the lowest cutoff frequency of all modes, which allows a smaller guide diameter for a specified operating frequency.

The third mode,  $TM_{01}$ , unlike TE modes, has its magnetic field transverse to the direction of propagation.  $TM_{01}$  also has a slightly higher cutoff frequency than  $TE_{11}$ , for the same size guide. Developed as a result of discontinuities in the waveguide, such as flanges and transitions,  $TM_{01}$  energy is not coupled out by either dominant or cross-polar transitions. Such parasitic energy must be filtered out or the waveguide diameter picked carefully to reduce the unwanted mode.

The fourth mode functions in coaxial transmission line. TEM mode has both electrical and magnetic fields transverse to the direction of propagation. Signals can range from dc to a frequency where higher-order moding occurs. As a result, 9 3/16-inch and 8 3/16-inch transmission lines can't be used throughout the UHF TV band.

## Super Flexible ADA

These Utah Scientific Audio DAs provide eight isolated outputs from one input—or four isolated outputs from each of two separate mono or stereo inputs—or can be used as remotely controlled mixers\*—or with remote gain control.\*

They mount ten-to-the-frame with single or redundant power supplies, and feature specs like .00% IMD/THD and  $\pm .05$  dB flatness, all at +24 dBm/20 KHz.

INTERCOMMUNICATIONS

Circle (52) on Reply Card

**Figure 3.** Attenuation vs. UHF TV frequencies for different waveguide materials.

**Figure 4.** Power handling vs. UHF TV frequencies for different waveguide materials.

**Waveguide pros and cons**

Waveguide system installation is both easier and more difficult than traditional transmission line systems. There is no inner conductor to align, but alignment pins and more bolts are required per flange. Transition hardware to accommodate loads and coaxial-to-waveguide interfacing are required, but the additional installation requires less than a day's time.

Tuning circular waveguide is a 2-step procedure. First, the cross-polar TE<sub>11</sub>

component is reduced primarily through axial ratio compensators or mode optimizers. These devices counteract the net system ellipticity and indirectly minimize cross-polar energy. The cross-polar filters are also rotated at this time to achieve the greatest isolation between the dominant and cross-polar modes. Cross-polar energy manifests itself as a net signal rotation at the end of the waveguide run. The perfect system would have a net rotation of zero.

In the second step, tuning slugs at both

the top and bottom of the waveguide run reduce the overall system VSWR. Tuning the waveguide can be a several-day procedure, but normally, once set, tuning does not drift and must be redone only if major components changes are made.

As more UHF stations move toward the full 5MW ERP power limit, change to circular polarization and experience rising costs of electricity, the efficiency and cost effectiveness of circular waveguide make it an attractive option.

# Complying with RF emission standards

By Donald L. Markley

## Is your station in compliance with the FCC's new guidelines on non-ionizing radiation?

When broadcasters were notified by the FCC that they would have to comply with standards for non-ionizing radiation, they raised a great cry. Many feared that new and significant restrictions upon broadcasters would be expensive to meet.

The commission has issued further information allowing engineers to evaluate their compliance with the guidelines. The good news is that most stations will find few problems meeting the required standard. The bad news is that some local governments are issuing their own versions of the standard.

### NEPA mandate

The National Environmental Policy Act of 1969 required the commission to place controls on electromagnetic or non-ionizing radiation. The purpose was to prevent possible harm to the public at large and to those who must work near sources of the radiation.

Action was delayed because no hard and fast evidence existed that low- and medium-level RF energy is harmful to human life. Also, there was no evidence showing that radio waves from radio and TV stations did not constitute a health hazard.

During the delay, many studies were carried out in an attempt to identify those levels of radiation that might be harmful. From the research suggested, limits were developed by the American National Standards Institute (ANSI) and stated in the document known as ANSI C95.1-1982. The protection criteria stated in the standard are shown in Figure 1.

The energy level criteria were developed by representatives from a number of industries and educational institutions after performing research on the possible effects of non-ionizing radiation. The projects all concerned the absorption of RF energy by the human body, based upon simulated human body models. In preparing the document,

ANSI attempted to determine those levels of incident radiation that would cause the body to absorb less than 0.4W/kg of mass (averaged over the whole body) or peak absorption values of 8W/kg over any one gram of body tissue.

From the data, the researchers found that energy would be absorbed more readily at some frequencies than at others. The absorption rates were found to be functions of the size of a specific individual and the frequency of the signal being evaluated. It was the result of these absorption rates that culminated in the shape of the *safe curve* of Figure 1.

ANSI concluded that no harm would occur to individuals exposed to radio energy fields, as long as specific values were not exceeded when averaged over a period of 0.1 hours. Also, higher values for a brief period would not pose difficulties, if the levels shown in the standard document were not exceeded when

averaged over the 0.1-hour time period.

### FCC action

The commission adopted ANSI C95.1-1982 as a standard that would provide adequate protection to the public and to industry personnel who are involved in working around antenna structures. The regulation provides the industry with established criteria to protect the population at large, as well as broadcasters. As long as a broadcast facility complies with the ANSI document, a reasonable response can be offered to those who express fears about the possible effects of a station's operation.

Unfortunately, not all communities have agreed with the ANSI standard. In several areas, specific communities are attempting to enforce their own standards, which involve less realistic and far more stringent values. The eventual outcome of this action is still in question, as

**Figure 1.** For compliance with ANSI C95.1-1982, the electromagnetic radiation level encountered by an individual must fall below the heavy line at any frequency. For quick reference, particular frequency segments are noted.

# The SSL Stereo Video System Makes Multichannel Television Sound. Easy.

Solutions to the problems of Multichannel Television Sound once required compromise. Skillful engineers could improvise around the obstacles of equipment designed for mono, but speed and flexibility inevitably suffered.

The SL 6000 E Series changes all of that. Its unique multi-format mix matrix, stereo signal processors and patchfree subgrouping provide unrivalled operational efficiency and creative precision, on-the-air and in post-production.

SSL's Studio Computer adds the most powerful audio software ever developed. Mix automation, integral five-machine synchronisation, events control and Total Recall™ provide rapid central command over the most complex stereo setups.

Simply stated, no other console or collection of equipment can do the job faster or better. Which makes one more thing easy — your choice. For more information on the SL 6000 E Series, write or call today for our 40 page colour brochure.

the commission appears to be reluctant to become involved in local disputes.

### To the broadcaster

In adopting the standard, the commission has placed a requirement on all broadcast stations to comply with ANSI C95.1-1982. Existing stations are grandfathered without having to show compliance until a major action occurs with regard to that station. A *major action* is defined as a renewal or modification that requires a new application to be filed with the commission. Therefore, all stations must eventually show compliance.

The commission has ruled that compliance with the standard will be handled through self-certification. That is, if station personnel believe that they have complied with the regulations, it is necessary only that they mark a box on the application to indicate that it is not a major environmental action. A brief statement of explanation must be filed with the application. Then, unless an objection is filed, or the commission has reason to believe that the operation does not comply, no further action will be necessary.

To assist individual stations, the commission has published a series of curves and graphs for engineers to use as rough guidelines to determine compliance status. Any assumptions that have been made in the preparation of the tables and

NEC

NEC

TECHNOLOGY  
SOLUTIONS

## THE ANSWER

The DVE® System 100. The \$29,500 answer from NEC. For TV stations and production facilities concerned about image quality but limited in budget. With the DVE System 100, the sacrifice is over. You get NEC reliability, versatility, and quality in a moderately priced system. Because the DVE System 100 has many of the features that made the DVE System 10 a winner. It doesn't have 3-D rotation or perspective, but

it has pattern select and can be more easily used live. So, if you think you'd have to settle for a lot less in moderately priced effects equipment, think again. And don't think image quality is a high stakes game for high rollers alone, because NEC has turned up a new card.

The DVE System 100. Affordable technology, from an expected source. NEC.

[www.americanradiohistory.com](http://www.americanradiohistory.com)

graphs have been weighted toward greater amounts of protection.

As an example, for AM directional arrays, total power is assumed to be radiated by each element of the array. Because the total power is actually determined from the combined powers of all elements, it is obvious that the assumption affords far more protection to people in the vicinity of the array than is realistically required. However, if the station complies with the standard based on the assumption, there can be no serious question concerning compliance when a more realistic set of factors and assumptions is applied.

Compliance can be determined by

means other than the curves or tables in the guidelines. If the station's operation does not comply according to the tables, compliance may be shown through a more detailed analysis. Such an analysis requires calculations or measurements with an explanation of the assumptions or data upon which the calculations are based.

#### FM

Consider a standard Class B FM station operating a 20kW transmitter and driving a 6-bay antenna mounted on a 500-foot tower. For this full-power station, the effective radiated power is the sum of the horizontally and vertically

polarized components, totaling 100kW. In Table 1, the absolute worst-case installation using the worst transmitting antenna would require the example 6-bay antenna's center of radiation to be 57.8m (190 feet) above ground. Because the vast majority of Class B FM stations have their antennas at heights greater than 190 feet, even the most offending antennas pose little problem.

#### TV

Table 2 applies to a VHF station. A lowband VHF station operating with 100kW visual and 10kW aural ERP levels would not exceed the ANSI standard at any point more than 40.9m (134 feet) distant from the center of radiation.

As with FM stations, few channel 2 through 6 TV stations have antennas that close to the ground. As a result, the impact of the regulation for lowband VHF TV will be minimal.

Because the effects of electromagnetic radiation decline at frequencies above 300MHz, highband TV VHF channels 7 through 13 and UHF stations face less of a problem in meeting the ANSI standard. However, the impact of higher ERP, particularly for UHF operations, must be considered when determining compliance with the exposure limits.

#### AM

For standard broadcast stations, the ANSI guidelines require that the *electric field strength squared* is less than 400,000 or that the *magnetic field strength squared* is less than 2.5. Assuming that all energy is radiated from the bottom of the antenna, Table 3 shows the necessary distance from an AM tower for compliance with the field-strength limits.

An electric field strength of 40,000V/m<sup>2</sup> corresponds to a magnetic field strength of 632V/m. For a 1kW station, this distance is 3m (9.8 feet). Because most 1kW stations probably have fences around the tower at that distance (or at a greater distance), such stations are probably already in compliance with the guidelines.

For a 50kW radio station, the safe measurement is 39.4 feet. This distance is normally either on, or close to, the ground screen that surrounds the tower.

From these examples, it is apparent that the vast majority of normally operated AM, FM and TV stations will not be affected by the ANSI standard.

#### Special cases

It should be noted that the standard concerns only areas that are accessible and where excessive levels may exist. For stations where problems are found, it may only be necessary to construct a fence around the tower at the required distance. In addition, no unauthorized personnel may be permitted inside that fence. For engineers who need to enter the area for a brief period, the exposure

# MINOLTA INDUSTRIAL METERS

REMARKABLE VERSATILITY COMBINED WITH SUPERB ACCURACY—  
MINOLTA METERS CONFORM TO CIE SPECTRAL RESPONSE STANDARDS.

## MINOLTA TV COLOR ANALYZER II

- Enables objective white-balance measurement and adjustment of color monitors.
- Clear, accurate digital and analog displays simplify adjustment of monitors on production lines.
- The analyzer has four memory channels for white standard plus four CRT memory channels. This enables measurement and adjustment of different models of CRT's.

## LUMINANCE METERS

- The Luminance Meter ft-1°, nt-1°, or nt-1/3° is the perfect choice for readings of light source or surface brightness. The single-lens-reflex viewing system provides a bright, magnified circular view with a clearly marked 1° or 1/3° center spot to measure the light with no influence from surrounding areas.
- The meter instantly displays foot-lamberts (or cd/m<sup>2</sup>) on the viewfinder's LED digital display.
- The ability to read flickering sources makes the Luminance Meter ideal for measuring TV and movie screens, cathode-ray tubes, etc.

## ILLUMINANCE METERS

- Accurate light measuring capabilities in a versatile, hand-held meter.
- A custom-designed liquid crystal display indicates illuminance in either foot-candles or lux.
- Measuring range of .001 fcd to 9,990 fcd enables measurements in virtually any situation.
- Stores a single reading for simplified comparison with other sources or monitoring of single source illumination.

## CHROMA METER CL-100

- Ability to measure light source color and color difference between sources.
- Chromaticity and color difference are measured instantly and displayed as Yxy (CIE 1931), Yu'v' (CIE 1976), or Δ (Yxy), Δ (Yu'v'), or Δ u'v'.
- The user can calibrate the meter to their own standard. Once input into memory, the user calibration value remains until changed. Several meters can be unified to eliminate any variations in their spectral response.
- Built-in terminals for remote operation or attachment to Minolta Data Processor DP-100.

is averaged over 0.1-hour intervals.

On the other hand, there may be locations where compliance with C95.1-1982 will prove to be expensive or difficult for broadcast licensees. In particular, multistation sites located on large towers and large buildings may require auxiliary antennas mounted at a second level to allow adjustment and maintenance of the primary systems. Also,

problems may be encountered on mountaintop facilities where the tower is only tall enough to keep the antenna clear of the transmitter building.

The complete radiation report, prepared by the FCC Office of Science and Technology, is detailed and lengthy. However, it is recommended that engineers obtain and read a copy of this, as well as the ANSI C95.1-1982 document. By reviewing both documents, you can obtain a full understanding of

# The Sexy, Universal BTSC TV Stereo Modulation Monitor

If you want to get intimate, you've got to "push the right buttons."

That's the idea behind TET's new Model 850. **Everything\*** you wanted to know about your BTSC TV Stereo signal is a pushbutton away.

The 850 was created with the TV broadcaster in mind. TET's design team actively sought TV engineers' critiques and suggestions in conceiving and developing the 850. The result is a microprocessor-controlled BTSC stereo monitor with unending diagnostic capabilities, including built-in off-air monitoring, split-sound mode, inter-carrier mode demodulation... plus the required standards and characteristics as defined in the BTSC recommended practices.\*

The top-of-the-line 850 Monitor comes with a built-in distortion analyzer, digital AC voltmeter, and ratio meter. The 850 is also available without the analyzer, but with an output to drive an external distortion analyzer.

Get intimate with your TV aural signal. Contact your favorite TET dealer for details on the complete—and sexy—850.

\*As required by BTSC Standards, EIA Systems Bulletin No. 5, Section 3.2, Monitoring and Measuring.

the thoroughness with which the standard was determined and the reasonable approach that the commission has taken in allowing the self-certification process. The sad part of the story of non-

ionizing radiation is not that some broadcasters may have a financial liability. It is that some communities have refused to acknowledge reasonable standards that are based upon research and facts.

Rather, they are rushing to proclaim their own standards that are based not upon safety or environmental considerations, but rather, upon unrealistic, incomplete or incorrect information.

# If you need rigid line, here's where to get it fast.

**CABLEWAVE rigid coaxial transmission line is available in sizes from 7/8 inch to 3 1/8 inches in 50 ohm impedance and 6 1/8 inches in both 50 and 75 ohm impedances.**

Not only available, but in most cases, we can ship from stock. You will rarely have to wait more than two weeks.

You can order twenty foot lengths or any shorter length cut to your specifications. You can request that line be fitted with flanges on both ends, one end or without the flanges. Hardware and other installation accessories are also available from stock. Aluminum outer conductor is available, as well.

Quality? You can count on it. Every inch is constructed of high conductivity, hard drawn copper tubing and fitted with pin-type Teflon dielectric insulators produced to exacting standards.

And, all rigid line, flanges and conductors are manufactured in accordance with Mil-L-3980, EIA Standard RS-225 and international IEC recommendations.

While purchasing rigid line for system upgrading and repair may be a simple matter, you may encounter layout and design problems in new installation. We can help here too, with appropriate technical and engineering assistance. Just ask.

the new RF exposure requirements, what are the possible solutions? Although there may be several ways to resolve a non-compliance problem, building a new tower or moving to

Radiation pattern for a 6-bay antenna with conventional spacing. The downward radiation from the antenna is obvious, especially at the 70° points.

Figure 2

another location may not be options you want to choose.

**New antennas**

Studies have shown that some types of antennas possess more desirable radiation characteristics (smaller downward components) than others. In some instances, these antennas can

be used to replace existing antennas that are producing excessive downward radiation. In general, cycloid-type ring antennas, which are uniformly and symmetrically fed, produce

Radiation pattern for a 10-bay antenna with 1/2-wavelength spacing. Note that the downward radiation problem has been significantly reduced.

Figure 3

# Who Cares If The Announcer Lisps?

You won't, if you use the Valley 415 Dual Dynamic Sibilance Processor. Sibilance problems are effectively handled without detriment to the sound.

Previously, the solution was worse than the problem; when you de-essed a sibilant, you were left with a hole in the program material. Now, the DSP 415 uses a dynamic new technology that processes the sibilance, so that only the annoying whistle is removed.

So, who cares if the announcer lisps, or if the newscaster wears dentures? The Valley 415 is on the job. Hire one today from your local Valley People dealer.

# If you can't fix your board with the enhanced 9000 Series, it's beyond repair.

## Introducing a new dimension of test capabilities for the Fluke 9000 Series Micro-System Troubleshooter line.

Finally there's a way to conquer some of the most difficult board testing problems imaginable. Take control of the situation with Fluke's 9000 Series and new **Asynchronous Signature Probe option**. You'll be able to pinpoint virtually every digital hardware fault on the entire board. Even those frustrating faults in circuits that operate independently of the microprocessor bus cycle.

Begin testing boards with the 9000 Series' built-in, preprogrammed test routines. In a single keystroke, you can automatically check the entire microprocessor kernel—Bus, ROM, RAM and I/O.

For testing beyond the bus, Fluke's new probe option eliminates the need for a logic analyzer or scope to test asynchronous circuits. One complete package, easily installed into either new or existing 9000 Series units, offers signature analysis, waveform capture and event counting. These three vital troubleshooting functions give any 9000 Series the power to diagnose:

- DMA Controllers
- Disk Controllers
- Video Controllers
- Video-Generation Circuits
- Communication Circuits
- Peripheral Controllers
- Dynamic RAM timing relationships

Not only does the 9000 Series test more of the board, it also supports more 8-bit and 16-bit processors than any other tester on the market.

Call Fluke toll-free **1-800-426-0361** or contact your local representative, and put your most challenging board to the 9000 Series test. If it can't be fixed with the enhanced 9000, it's probably beyond repair.

smaller downward radiation lobes than those fed non-symmetrically.

Perhaps the most effective solution consists of modifying the antenna pattern through element spacing. Here, element spacing is changed from the normal one-wavelength to  $\frac{1}{2}$ -wavelength spacing. Figure 1 illustrates the effectiveness of this.

The graph on the left shows the theoretical elevation pattern of a 6-bay antenna using conventional spacing. The graph on the right is the

measured elevation pattern for an identical antenna but with 10 bays spaced at  $\frac{1}{2}$ -wavelength intervals. The resulting dramatic reduction in downward radiation is perhaps better shown in Figures 2 and 3. Here, the patterns are translated into an artist's representation (vertical profile) of signal densities radiating from a typical tower.

Although the technical basis for  $\frac{1}{2}$ -wave spacing is well known, some features of the technique are less ob-

vious and may need some elaboration. In Office of Science and Technology bulletin No. 65, Dr. Cleveland notes that  $\frac{1}{2}$ -wave spacing results in an overall gain loss for a particular antenna. To maintain gain, the number of bays must be increased. Fortunately, due to the reduced spacing, virtually identical gain can be achieved in the same aperture as that occupied by a conventionally spaced antenna.

Referring again to Figure 1, observe that the gain for the 10-bay  $\frac{1}{2}$ -wave-spaced antenna is nearly equal to that of the 6-bay antenna. In addition, the 10-bay array actually occupies approximately six feet less space on the tower. Obtaining the equivalent gain in the same aperture results from reshaping the array pattern and redirecting the downward radiation into the main beam.

The effect of  $\frac{1}{2}$ -wave spacing is even more obvious in Figures 4 and 5. The downward radiation from a 1-wavelength-spaced 2-bay antenna is apparent at the  $55^\circ$  points in Figure 4. The same antenna with  $\frac{1}{2}$ -wave spacing is shown in Figure 5. In this case, the downward radiation is practically eliminated.

Another important fact to those considering  $\frac{1}{2}$ -wave spacing is the simple reality that not all antennas really lend themselves to the technique. Antennas that use direct-coupled-feed or those with non-symmetrical feeds will require either cumbersome mechanical feedline re-arrangement or some power-dividing scheme to maintain proper phasing.

On the other hand, antennas that are inductively loop coupled are relatively simple to manipulate into a  $\frac{1}{2}$ -wave configuration. Usually a shorter feedline and a simple repositioning of the inductive loop is all that is needed.

Another advantage of inductive coupling is that odd numbers of antenna elements are possible. This not only yields a significant cost savings if gain figures can be satisfied, but also can be of great value if windload or tower considerations are critical.

This method of reducing downward radiation may not be possible for all situations. It does, however, provide another tool for the station unfortunate enough to be required to take corrective action under the new rules.

Station engineers should become familiar with their station's particular situation with respect to the new radiation standards. Even if your station is not exceeding the standards, you need to understand how the ANSI requirements apply to your station. As more publicity results from the FCC action, residents around your transmitter site may raise legitimate questions. You should be prepared to answer any questions that might be raised. In this way, you may save the station from any misunderstandings by a misinformed public.

# Spark Gaps!

## For Overvoltage Protection and High Energy Switching

You'll see EG&G spark gaps working wherever there's a need for overvoltage protection of critical system components.

For high energy protection where a very wide range of operating voltages is required—up to 50:1

Gaps designed specifically for military CO<sub>2</sub> lasers

Gaps designed for series switching in medical and pulsed laser applications.

Two element (overvoltage) and three element (triggered) devices, gas-filled and vacuum, all hermetically-sealed units—all EG&G gaps are rugged, reliable, and readily available.

# Did you know... that with a UHF TV transmitter from Philips you pay for a lot less?

- ... a lot less space to house it
- ... a lot less attention to keep it maintained
- ... and a lot less money to run it

Every business wants to keep its costs down. So it's hardly surprising that so many people have already chosen our UHF television transmitters.

There are plenty of reasons: the tremendous quality of our equipment, their compact size, the design concept with everything built-in, easy maintenance, easy adjustment, high efficiency and excellent stability.

The result for you is substantial savings on the cost of housing the transmitter, of maintaining it and of running it. The result for us is that we're now the largest off-shore supplier in America – and have well over 2000 installations world wide.

See the UHF 1790 range with high power

klystron tubes for outputs between 30 and 240kW. You'll soon see the value of getting a lot less for your money.

Reliability through Quality

# FM/TV power density analysis

The power density at any point within the RF field of a TV or FM transmitting antenna may be calculated by determining the parameters shown in the diagram below and following a simple procedure. Outlined by TV Ontario in Toronto, this method may be applied to U.S. stations as well.

First, determine the dimensions  $E_1$ ,  $E_2$ ,  $h_2$  and  $d$ . From these, calculate the vertical angles  $V_1$  and  $V_2$  for direct and reflected RF rays from formulas 1 and 2. Then, from antenna radiation patterns, determine the antenna relative vertical field at  $V_1$  and  $V_2$  and relative horizontal field in the direction of the test point.

Next, calculate the path distances  $D_1$  and  $D_2$  for the direct and reflected rays by using formulas 3 and 4. The direct and reflected field intensities  $F_d$  and  $F_r$  are found from formulas 5 and 6, using values found in formulas 1 through 4. Finally, calculate the maximum power density at the test location with formula 7.

For installations with multiple antennas, the calculations must be performed on each antenna separately. Additional information is available in FCC publication OST-65.

1. Calculate vertical angle,  $V_1$ , for direct ray:

$$V_1 = \tan^{-1} \left[ \frac{E_1 - (E_2 + h_2)}{d} \right] \text{ degrees}$$

2. Calculate vertical angle,  $V_2$ , for reflected ray:

$$V_2 = \tan^{-1} \left[ \frac{(E_1 - E_2) + h_2}{d} \right] \text{ degrees}$$

3. Calculate path distance,  $D_1$ , for direct ray:

$$D_1 = [d^2 + (E_1 - (E_2 + h_2))^2]^{1/2} \text{ meters}$$

4. Calculate path distance,  $D_2$ , for reflected ray:

$$D_2 = [d^2 + (E_1 - E_2 + h_2)^2]^{1/2} \text{ meters}$$

5. Calculate direct ray field intensity ( $F_d$ ) at test point location:

$$F_d = \frac{7 \times F(V_1) \times F(H)}{D_1} \times (\text{ERP max})^{1/2} \text{ V/m}$$

6. Calculate reflected ray field intensity ( $F_r$ ) at test point location:

$$F_r = \frac{7 \times F(V_2) \times F(H)}{D_2} \times (\text{ERP max})^{1/2} \text{ V/m}$$

7. Calculate maximum power density at test point location:

$$\left[ \frac{(F_d + F_r)^2}{\pi \times 1,200} \right] \text{ mW/cm}^2$$

Repeat steps 1-7 for other locations, as required.

Generalized geometry for FM/TV power density analysis, using 2-ray method.

# SONEX CONTROLS SOUND.

With its patented anechoic foam wedge, SONEX absorbs and diffuses unwanted sound in your studio. And it can effectively replace traditional acoustic materials at a fraction of the cost. SONEX blends with almost any pro audio decor and looks

# The Outperformer!

IKEGAMI'S HL-79E IS MORE VERSATILE THAN EVER

Ikegami's HL-79E has lived up to its billing as the greatest achievement in hand-held camera technology, a claim supported by an increasing number of 79 series purchasers, presently in excess of 5000.

And yet, today, the engineers at Ikegami have found a way to improve the camera. Now, when equipped with the new VBA-1 adapter, the HL-79E is totally compatible with the Sony Beta recorder.

On your shoulder, the HL-79E is still unmatched in performance with features that include Dynamic Detail Correction, Chroma Aperture Correction, Highlight Aperture Correction and Auto Contrast Compression. Plus the HL-79E offers superior contrast range, S/N ratio, registration accuracy, resolution and more.

On a tripod, the HL-79E becomes the premier EFP camera which can be used in various systems configurations and controlled remotely by the MA-79 Multicore Adapter, through multi-core cable (up to 300 meters) or by the TA-79E triax adapter through triax cable (up to 2000 meters).

The camera can be set up using conventional manual techniques or an optional microprocessor assist.

For a complete demonstration of the HL-79E and other Ikegami cameras and monitors, contact us or visit your local Ikegami dealer.

# Selecting speakers for TV stereo

By Thomas Sahara

If you are going to broadcast high-quality TV stereo, you must first be able to properly monitor it.

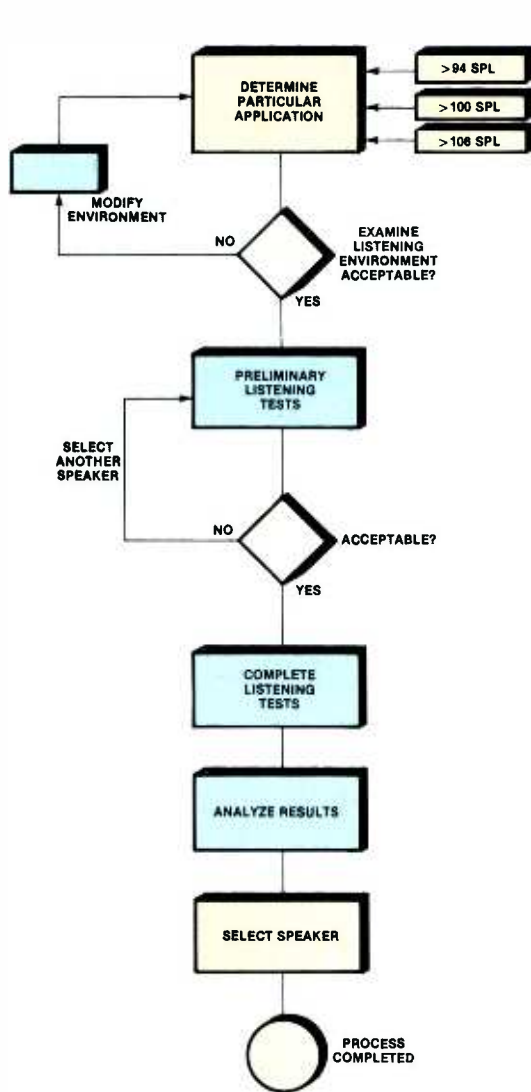

Figure 1. The process of selecting monitor speakers.

The advent of TV stereo has placed additional responsibility on TV audio engineers. And these engineers must be more concerned than ever before about the quality of the speakers used for monitoring audio. The selection of the proper speakers for mixing and monitoring stereo TV requires time and effort if the best results are to be obtained.

## Procedures

Choosing a monitor loudspeaker system is probably one of the most difficult tasks an audio engineer will encounter. The system you choose must sound good to everyone involved with audio production. Although it may seem next to impossible to obtain general agreement on speaker selection, by following a few procedures, a universally accepted loudspeaker system can usually be found.

Even though there are no standard practices established for selecting monitor loudspeakers, a few guidelines are available. Many of the following definitions and procedures are based on the recommendations of David Bennet of the Canadian Broadcast Corporation and Floyd Toole of the National Research Council. Their research and experimentation will be used for the tests.

## Types of rooms

The first step in selecting a monitor loudspeaker system is to determine the particular application. There are three classifications of loudspeakers, each classification defining a different application. This ensures that the loudspeakers are being compared with others intended for similar applications and that the loudspeaker selected will be capable of delivering what you expect.

The first application is the small control room where the maximum sound pressure level generated by the loudspeaker is greater than 94dB at one

meter. This application also includes remote vans and other small environments. Most of the so-called *mini monitors* and compact loudspeakers fall into this classification.

The second application is the small-to-medium-sized control room, where the desired maximum sound pressure level is more than 100dB at one meter. A few of the mini monitors fall into this category, but most loudspeakers in this application are the larger bookshelf and medium-sized loudspeakers.

The third application is the large control room or music production facility, where the maximum sound pressure level is greater than 106dB at one meter. This application includes all of the large monitor loudspeaker systems and a few of the higher-powered medium-sized systems.

Three sizes of rooms have been defined by Bennet. A small room has a volume of less than 50 cubic meters, or approximately 1,765 cubic feet. The medium-sized room has a volume between 50 cubic meters and 150 cubic meters, or approximately 1,765 cubic feet to 5,300 cubic feet. The large room has a volume of more than 150 cubic meters, or 5,300 cubic feet.

These room sizes cover a wide range of room environments. But no distinction is made with regard to the acoustical environment of each room classification. It is assumed most control rooms within a station will exhibit somewhat similar acoustical characteristics.

Once you have determined the class of loudspeaker required, you can start specifying loudspeakers for comparative testing. In most stations, each listening area may have slightly different acoustical characteristics. For this reason, you must keep in mind that the loudspeakers specified must be able to provide acceptable performance in each area. If there is any doubt, then a

Sahara is an audio engineer for KITV, Honolulu.

# YOUR BEST BET FOR BETACAM® AND BETACART™ SYSTEMS

✓ Flat, peak-free frequency response within narrow limits throughout the audible range. A loudspeaker that does not have a flat anechoic response may have a fairly flat response in the acoustic environment. Conversely, a loudspeaker that exhibits excellent free-field frequency response may produce large frequency anomalies in the acoustic environment.

✓ Broad and uniform sound dispersion to provide identical sound over the entire listening area.

✓ Low harmonic, intermodulation and transient distortion throughout the audible range at all listening levels.

✓ Sufficient output level capability to meet the requirement of each class of monitor.

✓ Electrical and mechanical durability to assure continued service without changes in the sound characteristics over long periods of time and under heavy use.

✓ Loudspeaker-to-loudspeaker uniformity to guarantee identical sound characteristics from any two units.

**Table 1.** In order to provide a high-quality monitoring system, the speakers must meet several important criteria.

series of preliminary tests should be conducted to ensure that all loudspeakers meet minimum requirements.

The ideal loudspeaker, according to Toole, must meet several criteria (see Table 1). These criteria define the basic performance that can be obtained from the speaker. Unfortunately, even these criteria are not absolute in that two loudspeakers can have similar specifications and yet have different sonic

characteristics. This is the reason why the only reliable method of choosing a monitor loudspeaker is to audition a number of units. Once you know what your specific requirements are going to be, you are in a position to make an informed choice.

There have been numerous listening tests performed on almost every loudspeaker on the market, with each test having its own objective results.

However, it has been determined that many of the tests are not without their share of questionable data. Data that have been collected or analyzed in an inconsistent, uncontrollable manner may cause the test to favor a particular outcome. It is this inconsistency and uncontrollability that the following procedure seeks to minimize.

#### Listening tests

A panel of listeners must be assembled to perform the actual listening tests. Select the panel with caution. It is important that a fair representation of all factions contributing to the evaluation of the audio quality be included. This helps prevent unintentional bias toward a particular outcome because of overrepresentation by a particular group.

There is some evidence that a listener with impaired hearing can cause significantly higher variations in responses than a listener with normal hearing. Also, a listener with previous experience in critical listening may produce a more consistent set of responses than a person without any previous critical listening experience.

A preliminary test should be carried out to ensure that every loudspeaker selected for testing will meet the minimum performance requirements. This is called the *coarse filter*. Loudspeakers that do not rate as high as

## This new portable UHF Field Strength Meter gives you accurate readings across the entire band.

Someone once said that "Certainty is Security." That is the main idea behind field strength measurements. They verify the signal level and rf environment at the point of reception. You know for certain what's out there.

It is now easy for UHF stations to achieve this certainty. With the new FIM-72 from Potomac Instruments.

#### Tune the entire UHF band

From 470 to 960 MHz. The received signal strength is shown in volts and dB, with a 140 dB measurement range. Select peak or averaging detection; wide or narrow IF bandwidth. Seven 20dB logarithmic ranges assures precise readings. Internal demodulators (AM and FM) provide audio monitoring of the selected signal.

#### It is easy to use

Find the desired signal on the spiral dial. Calibrate the meter using the internal generator, then read the signal strength from the mirrored meter. The field strength is easily determined from the supplied calibration data.

#### Laboratory applications

The FIM-72 includes a precision rf generator that tracks the tuned frequency. Typical measurements include insertion loss, VSWR, and filter response.

#### Call Potomac Today

Place your order for this new UHF field intensity meter. Put it to work. And then you will know for certain.

# The Wait is Over!

## IKEGAMI UNVEILS THE 2/3" FIELD/STUDIO CAMERA STANDARD

When Ikegami engineered the all new HK-323 field/studio camera, their first priority was to make this advanced technology camera available to all preferences.

The result: the HK-323 1" and the HK-323 2/3"—two tube sizes to meet the broadest range of preference, application or budget.

Like the 1", the HK-323 2/3" features self-contained operation, numerous auto set-ups in any mode, a built-in encoder and sync generator, high performance prism optics, self-diagnostic functions, a control panel that connects directly to the camera head, a S/N ratio of 60dB and more—all in a camera weighing only 55 lbs.

The HK-323 2/3" is equipped with a 7" viewfinder featuring pan and tilt, and special functions that include Chroma Aperture for sharpest picture quality regardless of color or lighting; Highlight Compression Circuitry for broadest contrast range; Soft Detail to eliminate harsh or overwhelming presence; Auto Beam Control, and more.

A companion hand-held camera is also available, and is operational off the same base station.

Optional remote control is available in: triax, multicore and fiber optics.

Compare the HK-323 2/3" to any camera in its class and find out why the lightest field/studio camera is also the biggest value.

Circle 72 on Reply Card

Selecting speakers for a video production studio requires careful planning.

the other units should be removed from further testing. This helps limit the number of loudspeakers to a manageable number. The remaining loudspeakers are then subjected to a more rigorous test sequence of longer listening sessions with various program materials.

The source material used for the evaluation process should be representative of that used within the facility. For example, do not use only rock music to evaluate a loudspeaker if the majority of the applications do not contain rock music. Use as wide a variety of program materials as practical.

All of the testing material should be monophonic. This helps eliminate inconsistencies in the data resulting from variations in the stereo image caused by room acoustics, listener position or some other uncontrollable phenomenon. It is reasonable to conclude that a loudspeaker exhibiting a high degree of fidelity with monophonic program material will also perform well with stereophonic program material.

#### The setup

Conduct the listening session in a location that is free from extraneous noises and activity. Make the test period long enough that the setup won't have to be changed or moved for the duration of the evaluation. It is important that all loudspeakers be evaluated in a stable environment.

Each test session should last for about 30 minutes so each listener has sufficient time to formulate a response. If several sessions are needed, then a 30-minute rest period between tests will help prevent listener fatigue.

To prevent bias in the results because of a familiarity with a particular monitor, all loudspeakers must be hidden from view. Use an acoustically transparent screen and match the output levels with pink noise and a sound-level meter. Because of variations in speaker radiation patterns, measure the sound pressure at ear level near the center of the listening area.

A double-blind procedure, in which neither the person conducting the listening session nor the listeners know what loudspeaker is being tested, is recommended. The listeners should not discuss their listening experience with others. This helps prevent any one person from influencing the responses of other panelists. To prevent inconsistencies in the results, all of the listeners should be given identical and complete instructions on the objectives and procedures to be used in the test.

#### Obtaining the data

Direct the participants to rate each loudspeaker on a uniform scale. The lowest possible score is zero, which represents the worst possible reproduction. The highest possible score is 10,

Circle (77) on Reply Card

representing the best possible reproduction—the ideal loudspeaker. A rating of five represents the midpoint of the scale. On the rating form, be sure to label the loudspeakers by numbers, not by brands or names. This prevents any preconceived notions of quality from influencing the results because of familiarity with a particular brand or model.

After all of the test data have been collected and analyzed, the loudspeakers receiving the highest ratings should be subjected to a final round of testing. This step helps validate the test results. The final round is more of a check of the procedure than a test of the loudspeakers. If there are large variations among the test results, there is a possibility that an outside influence was introduced somewhere in the test procedure.

If, however, there is a high degree of consistency among the test results, the engineer is assured that the loudspeaker receiving the highest rating is capable of reproducing almost any material without introducing coloration or masking subtle details of the material.

#### Analyzing the data

After all of the test results are in, the task of interpreting the test data begins. Record the test data by test group, noting the order of the loudspeakers being auditioned and the program material used in the listening tests. By comparing the results among groups, trends and tendencies are noted and variations in individual ratings are analyzed.

If there are significant differences among test groups reviewing the same loudspeaker/program material combination, a determination must be made regarding the validity of the test. Is the variation because of a listener variable or is it a fault in the test method? If you determine that there is a fault in the test procedure, you must determine how much of the variation is due to this procedural defect.

After the test data are compiled, several speakers may have similar high ratings. If so, then secondary considerations such as size, efficiency, impedance characteristics and long-term availability will play a more significant role in the final selection. Minor differences in the sonic character of the loudspeakers may rate a lower priority than speaker availability. Factory support should also play a role in the selection process.

By following a set procedure and taking the necessary precautions, you can select a monitor speaker that will be accepted by all involved in the audio process. The advantages of going to this effort extend across departmental boundaries, which of itself may prove advantageous. If you follow the basic guidelines, your station will have a monitoring system adequate to meet the critical audio demands of a high-tech audience. [:-)]]

## The choice of Radio Station KGLT

David Peters, Assistant Engineer KGLT Radio Station, Bozeman, Montana.

# THE EIMAC 5CX1500B FOR LONG LIFE, QUALITY AND ECONOMY

Varian EIMAC has been in the business of broadcasting for over 50 years, producing durable, reliable and long-lasting tubes that a non-profit radio station like KGLT in Bozeman, Montana, can afford.

### Longevity

KGLT engineers use the EIMAC 5CX1500B tube in their transmitter, reporting a life span of 18-19 months—approximately 13,000 hours of service!

### Quality and Savings

This would be impressive under ideal conditions, but KGLT operates under rugged and adverse mountain-top conditions. Just as important is the 40% cost

savings attributable to the 5CX1500B's extended life.

In FM broadcasting, EIMAC tubes are customer-proven.

EIMAC's 5CX1500B broadcasting tube in KGLT radio station's transmitter.

Varian EIMAC offers a 5,000-hour warranty on 5CX1500B tubes.

May 1986 *Broadcast Engineering* 107

**W**e know that one basic VTR, modified many ways to fit many recording applications, is the most cost-effective way for a manufacturer to *build* a line of VTRs. But we also know that this approach may result in compromised performance and concessions on the part of the user — concessions that at first seem small, but add up quickly in terms of inefficient operation and lost business.

Ampex, video recording, and the

business of video have been synonymous since 1956. And though we've seen the "expedient approach" come and go over the years, the professionals in the video business have repeatedly assured us that their standards leave no room for compromise.

For these professionals, we build a complete line of the very best video tape recorders in the world.

The VPR-3: 500 ips<sup>2</sup> acceleration/deceleration profile and 20 milli-second single field lockup make it the

fastest and most precise video tape recorder ever designed. With its multitude of sophisticated features, the VPR-3 is ideal for demanding post-production applications.

The VPR-6: Superb video and audio performance, along with the features most users ask for, make the VPR-6 the choice of video professionals for a wide range of applications. Its price, performance and reliability offer a package that makes good business sense for broadcast, production and

post-production users.

The VPR-80: Low cost, but high quality. Ampex brought decades of VTR experience to bear on this most difficult of design tasks. We know that every video facility at some time or other needs a "workhorse" — a VTR that can produce high quality video and audio, and at the same time not strain the budget. The VPR-80 is that machine.

The VPR-5: The video quality and features of a Type C VTR in a pack-

age no larger than a briefcase, allow you to record tapes in the field and edit the same format in the studio. When your productions begin in the field, where rugged and reliable performance is demanded, you need the VPR-5.

Call your nearest Ampex field office for a demo of *the* VTR that fits your needs. We know that one will be a *perfect* fit, either as a stand-alone performer, or teamed with an ACE editor, AVC switcher and an ADO™

in an Ampex Creative Command Center™. And remember, you can count on Ampex product support, worldwide.

# Stereo audio production techniques

By Todd A. Boettcher

## Producing quality stereo audio involves more than just adding another microphone.

With the advent of MTS (multichannel television sound), a number of concerns need to be addressed to ensure consistent audio quality for locally originated stereo programming. With programming originated both in-studio and on-location, all areas of station operation are involved in the move to MTS.

This article will not discuss wiring standards, signal distribution and routing or the recording medium. It will assume that the wiring and recording equipment is properly installed and maintained. The scope of this article is limited to the audio production engineer's operational concerns. It seeks to help develop an understanding of stereo audio concepts and values, while leaving the final choice of microphones and microphone placement up to the creative abilities of the individual audio engineer.

### Compatibility

Just as with stereo broadcast on radio, the primary concern with MTS stereo is monaural compatibility without signal degradation. The most severe form of signal degradation occurs when the two program channels are  $180^\circ$  out of phase. This causes nearly total loss of the monaural (summed) signal and an undefined stereo image.

More subtle, yet just as important, are phase cancellations caused by improper microphone placement. These phase differences can cause a loss of high-frequency response, erratic stereo imaging and a *swishing* (or comb filter) effect in the monaural summed signal. This can be a difficult problem to uncover when monitoring in stereo because the phase differences can be interpreted creatively as an *airy* or *open* sound.

Appropriate monitoring is critical to the production process. The environment should be quiet enough to allow critical monitoring decisions. When loudspeakers are used for monitoring, the units should be located to the front of the audio mixing engineer, and elevated to approximately ear level or slightly above. They should develop an arc of approximately  $60^\circ$  ( $30^\circ$  to either side of the center axis line) for best monitoring of stereo imaging. (See Figure 1.)

Figure 1. Regardless of the distance from the speakers to the audio engineer, the angle between the speakers should be about  $60^\circ$ .

If the angle is greater than  $60^\circ$ , the listener tends to hear the monitored audio as two independent sound sources rather than as a panoramic wall of sound between speakers. This is known as the *hole-in-the-middle* effect. This condition makes correct stereo imaging difficult.

If the angle is too small (because the speakers are too close to each other), the sound sources tend to be heard as a single point source. Again, this makes proper stereo imaging difficult because there is little perceived stereo spread. Ideally, the monitor speakers should be

$\frac{1}{3}$ -octave equalized to the room to reduce resonant room peaks. This also helps smooth out the room-response curve.

Alternatively, high-quality stereo headphones can be used for monitoring. However, stereo imaging tends to exaggerate the spread toward extreme left and extreme right. This is because the left and right channel information remains segregated until mixed within the engineer's head. When speakers are used

Figure 2. Because sound travels at a uniform speed, the different distances traveled ( $L_1$ ,  $L_2$  and  $R_1$ ,  $R_2$ ) result in a sense of directionality.

for monitoring, some acoustic blending takes place prior to reception at the mixer's ears, tending to centralize the stereo image.

Technically, when speakers are used for monitoring, the left ear hears full left channel, plus the right channel delayed and at a slightly reduced intensity because of a slightly longer path length. The right ear hears full right channel, plus the left channel delayed and at a slightly reduced intensity. (See Figure 2.)

The distance between the eardrums (approximately 19cm to 21cm) is

Boettcher is a staff engineer at WTMJ radio and TV, Milwaukee.

[www.americanradiohistory.com](http://www.americanradiohistory.com)

microphone by one-half for every 3dB of difference in source-sound level in order to maintain the same degree of compatibility. Alternatively, the sources and their respective microphones could be separated by a greater distance. A third choice would be to insert some type of sound-absorbing baffle between the sources to maintain the needed acoustical separation. A fourth option, if the sound sources must be in close proximity to maintain visual production values, is to have these sources share one microphone.

#### Near-field imaging

*Stereo imaging* involves the placement of various sound sources in the stereo spectrum to produce apparent direction and localization (hard left, left center, center, right center, hard right). This is normally accomplished through adjustment of the mixing console pan pots. By definition, near-field sound includes negligible ambient information, so there is virtually no chance for phase incoherence when placed in the stereo spectrum. This creates a sort of pseudostereo—a stereo determined only by intensity differences. Near-field stereo can regain an artificial ambience through digital delays, echo chambers or reverberation units, and other forms of signal manipulation.

As previously mentioned, near-field

stereo imaging can be controlled to establish left-right directional cues. The signal can also be manipulated to provide depth, or a sense of distance from the foreground. For example, a dry (unprocessed) signal will sound *up front*, while the same signal with reverberation added will sound distant. By varying the amount of delay and reverberation to the various signals, a 3-D effect can be achieved (side to side and front to back).

#### Far-field sound

As its name implies, far-field sound pertains to sound that is picked up by microphones placed at a distance from the source. Because of this increased distance, room acoustics become an important consideration in actual placement of the microphones. In addition, the possibility is great for interaction among multiple far-field microphones. Far-field microphone placement is most commonly used for classical and religious music, as well as for picking up natural sound. In addition, far-field microphone placement can be used for dialogue when natural sounds are to be specifically included as part of the production. Examples are soap operas and theatrical productions.

When placing primary microphones in the far-field in a reverberant room, such as a church or concert hall, you must be careful in final placement to retain

source clarity and intelligibility. However, you must include enough ambient sound to make the final product a satisfying listening experience. Such placement work requires the ability to make creative decisions. If the microphones are placed too close, the ambience is lost. The best way to determine final placement is through critical listening, first in the studio or location environment, then through the monitoring system. Experience will help you make these decisions more quickly.

Because far-field sound includes the sound of the acoustical environment, it will also include any extraneous noise, such as that from loud radiators or air-conditioning blowers, from the crew and cast, prop movements, and bleedthrough of outside noises such as trucks, trains or aircraft. Care should be taken to reduce these intrusions as much as possible.

Far-field stereo is simply picking up the sound source in stereo by placing the microphones in the far field. There are three basic ways to place microphones for far-field stereo: spaced, coincident and near-coincident.

#### Spaced technique

Using the spaced microphone technique, the microphones are literally spaced a distance apart from each other, possibly by several meters or more (see Figure 4). The intention is to use this distance to provide different localizations in order to provide varied information to the stereo channels. Normally, spaced stereo microphones have omnidirectional patterns. Many amateur and some professional recordings use spaced stereo, because it provides a lot of ambient information with a good amount of setup flexibility. The sound is generally airy or open. It is usually pleasing to hear in stereo.

Figure 4. Spaced stereo microphone placement produces noticeable phase cancellation in the summed-monaural signal.

Spaced stereo microphones are acceptable for broadcast *only* when the sound source is a point source placed exactly equidistant from the spaced microphone pair. If the sound source is located off-center, the sound will reach the microphones at slightly different times. This timing (or phase) difference will add or subtract signal level in the monaural sum, depending on the source frequency, the distance between microphones and the sound arrival time difference at the two microphones. Known as *comb filter*

**How can  
Grass Valley Group  
sync so low?**

By building application-specific models centered around the revolutionary SPG Gate Array integrated circuit, that's how.

The 9510 Reference Synchronizing Generator is a compact master featuring protected video genlock. With the

phase preset option, it can even store genlock phase settings. Add an optional test signal generator and source ID, and you've got a full-featured master or source sync generator.

The 9510 is only one of our landmark 9500 Series Sync Generators.

## FINISH UP ON TIME WITHOUT SACRIFICING QUALITY.

You want it quick and you want it good. In today's competitive post-production audio/visual scene, the rewards go to those who can produce results that are quick *and* good. That's why TASCAM designed the MS-16 1" 16-track recorder—to bring together top-notch audio quality plus premium features that streamline production and move you ahead of schedule.

Quality reproduction starts with the heads, and TASCAM has three decades of design experience behind the MS-16's new micro-radii heads. They bring "head bumps" under control and ensure flat frequency response. And unlike most tape machines, the MS-16 record/sync and playback heads are identical in performance. Because sync response equals repro response on the MS-16, you can make critical EQ and processing decisions on overdubs or punch-ins without having to go back and listen a second time. You get what you want sooner and with fewer headaches.

The MS-16 cuts down on the time you spend locking up with other audio and video machines as well. A 38-pin standard SMPTE/EBU interface affords speedy, single-cable connection with most popular synchronizers and editing systems. It's the easy, efficient way to get the most out of today's sophisticated synchronization equipment. The MS-16's new Omega Drive transport is tough enough to stand up to long days of constant shuttling... while handling tapes with the kid-glove kindness they deserve.

Record/Function switches for each track allow effortless, one-button punch-ins. Input Enable allows instant talkback during rewinds, fast forwards and cue searches. These features speed you through sessions and let you concentrate on the project at hand... not on your tape machine.

Take a closer look at the MS-16. See your TASCAM dealer for a demo or write us for more information at 7733 Telegraph Road Montebello, CA 90640.

THE TASCAM MS-16 SIXTEEN TRACK

**TASCAM** THE SCIENCE OF BRINGING ART TO LIFE.

effect, the result is unacceptable for broadcast because it is noticeable over a broad portion of the audio frequency spectrum.

The only situation in which spaced microphones will not create comb filter problems is if the sound source is *non-coherent*. All of the sound source pickups illustrated so far have been of *coherent sound*. Coherent sound originates as an apparent point source that has definable shape and characteristics such as a leading edge, frequency, envelope and decay. It is intelligible and can convey meaning, whether it is the sound of a hammer striking a nail, a human voice, a musical instrument or a car crash.

In contrast, non-coherent sound is a non-definable sound—one that is created by the summation of random signals originating at many points, or over a broad area. Ready examples of non-coherent sound are the rumble of an earthquake or the cheering of a crowd.

For a baseball game, the crowd could be picked up by two, three or five widely spaced microphones that can be panned across the stereo image without phase cancellation. In essence, there would be little true stereo in such a crowd pickup. Instead, it could be thought of as picking up two, three or five independent monaural crowds. The only coherent audio reaching the crowd microphones would be the sound of the public address

system. Generally, any cancellation of that signal would be an advantage to the broadcaster, not a concern.

#### Coincident technique

The coincident microphone technique uses two directional (usually cardioid) microphone capsules placed in *perfect-time* alignment. This ensures that there will be absolutely no phase differences based on differing arrival times or sound source locations. To obtain true coincidence, both capsules are mounted in the same microphone. Because these stereo microphones have true coincidence, there is no summed-monaural cancellation, making this choice the unquestioned best form of stereo pickup for broadcast. Directionality is accomplished through intensity differences based on source location with respect to the positioning of the capsule pickup patterns. It's important that the capsules have smooth polar response curves, so that there will be no off-axis coloration of sound.

A subcategory of true coincident microphone technique was developed by Alan Blumlein of E.M.I in the 1930s. In his research, Blumlein found excellent results with a crossed pair of bidirectional capsules set at 90° to each other, with both front (positive) capsule patterns set at 45° off-axis to the center of the sound source. One microphone ac-

cepts left-front and right-back information, while the other microphone accepts right-front and left-back information. (See Figures 5 and 6.) This provides clarity and ambience even in highly reverberant rooms and improves the ambient perception of a dry room.

Figure 5. Coincident microphone placement locates both capsule elements in perfect time alignment, resulting in no phase cancellation in the summed-monaural signal.

Figure 6. The Blumlein coincident technique uses a pair of bidirectional microphones with axes positioned at 90° to each other.

#### Near-coincident technique

Near-coincident technique uses two directional microphones placed in close proximity to each other, but not in true coincidence. As might be expected, this slight separation causes some minor comb filtering, but the effect occurs only at extremely high frequencies. For all practical purposes, the effect is negligible, and therefore, is not a serious concern for most broadcast programming. As a result, a wide variety of cardioid and hypercardioid microphones can be used with success. Again, smooth polar pattern response is essential to colorless pickup and smooth sound.

The most often-used near-coincident format is one developed by the Office of Radio and Television in France (ORTF). Also known as X-Y stereo, it has gained international acceptance for broadcast compatibility. With the ORTF standard, capsules are separated by a distance of 17cm. When hypercardioid microphones are used, the angle between microphone axes should be 110° to maintain constant intensity across the stereo image. (See Figure 7.) For cardioid microphones, the angle between axes must be opened up

**\$1800**

**How can Grass Valley Group sync so low?**

By designing the SPG Gate Array, our new integrated circuit, we use fewer parts and less support circuitry. And that means reduced maintenance and higher performance — at an unbelievable price.

SC/H Phase will never be a problem

with the 9505 — it's always correct. And you can add to its capability with an optional test signal generator and source ID.

The 9505 is only one of our landmark 9500 Series Sync Generators.

**Figure 7.** The ORTF near-coincident placement technique uses hypercardioid microphones placed together and facing  $110^\circ$  from each other.

**Figure 8.** Cardioid microphones can also be used in near-coincident placement. Note that they are located closer to the sound source than in Figure 7.

**Figure 9.** Coincident microphone placement can affect stereo imaging. In position A, the shaded areas are located only hard left or hard right. In position B, the source is evenly spread between the speakers. In position C, the stereo image will not reach from speaker to speaker, thereby reducing the size of the source.

to  $135^\circ$  to maintain constant stereo image intensity because the cardioid polar lobe is much broader than the hypercardioid polar lobe. (See Figure 8.)

With both coincident and near-coincident techniques, the forward-facing axes should mark the outer limits of the sound source for even distribution of sound through the stereo image. If the microphones are backed farther away from the source, the source will tend to have less spread, while still picking up ambience. This may be desirable for a solo piano, but not for a large choir. On the other hand, moving in too close, where the source spreads beyond the axes, will tend to exaggerate the spread by placing more information hard left and hard right. (See Figure 9.)

Both coincident and near-coincident techniques provide excellent directional cues and exceptional realism. Proponents of spaced stereo claim that X-Y stereo lacks crisp, clear, intelligible sound. Because X-Y microphones are generally placed farther from the sound source than spaced microphones, the increased distance can provide the answer. Although sound travels at a constant velocity, it has been found that high frequencies are attenuated more quickly than low frequencies. Also, high frequencies are attenuated more rapidly than low frequencies with increasing humidity. Because of this, it is not uncommon to equalize the high frequencies in a far-field pickup to compensate for these losses.

### Practical stereo imaging for TV

When creating stereo TV programming, consider the size of the visual medium and how it relates to the viewing room. When compared to the large viewing screens in movie theaters, where the viewing angle is wide (approaching  $90^\circ$  or more), the viewing angle of a TV screen in the typical home environment is narrow (normally  $10^\circ$  to  $20^\circ$ ). The left-to-right visual cue is significantly smaller for television than it is for theater motion picture viewing. Theater speakers are located behind the projection screen. As a result, all directional audio cues (except for some specialized effects sounds) fall realistically within the visual perspective of the screen.

Many stereo TV sets have speakers on both sides of the picture tube, or aiming out the sides of the cabinet, or even underneath the picture tube. Some have stereo headphone outputs. Many stereo TV viewers also have stereo audio systems in the same room and connect the TV audio outputs to the audio system to benefit from the higher-quality amplifier and speakers. In any case, the stereo sound field will be moderately to considerably wider than the viewing angle. As a result, television does not lend itself to dramatic motion within the stereo field. Therefore, stereo imaging decisions need to be made that differ from traditional large-screen concepts.

### Dialogue

Dialogue refers to all forms of foreground speech, whether it is news reporting, sports play by play or the spoken portions of entertainment programming.

Because of the narrow viewing angle, placement of these primary voices hard left or hard right would be visually inappropriate. In fact, nothing would be gained by placing dialogue anywhere

# TV Stereo's Missing Link.

## THE NEW ORBAN AUTOMATIC STEREO SYNTHESIZER

For years, Orban's popular 245F Stereo Synthesizer has proven its worth to broadcast professionals by generating compelling, dramatic pseudo-stereo from mono sources.

Now, Orban introduces the new Model 275A **Automatic Stereo Synthesizer**, precisely tailored to the needs of TV broadcasters. The unit will smoothly crossfade between true and synthesized stereo when triggered by internal automatic mono/stereo detection and/or single-channel recognition circuits; upon receipt of local or remote commands; or, upon commands from your automation system, tally, or vertical interval decoder.

Orban's switch-defeatable center-channel mono/stereo recognition circuit is carefully designed to eliminate many of the false-triggering problems of competitive units. However, because it is difficult for any electronic circuitry to distinguish between true mono and hard-center information in "stereo" sources, we offer a rational alternative—single-channel recognition. By recording or feeding mono material to **one track only**, you can use the single-channel recognition to automatically and **reliably** fade in synthesized stereo when this condition is detected. It also remains continuously alert to guard against dead channels.

The 275A employs Orban's patented, allpass-derived, complementary comb filter stereo synthesis technique. It's fully mono-compatible, and its logarithmically-spaced frequency bands avoid the disturbing and unnatural harmonic cancellation problems of delay-line-derived stereo simulators. **Two** synthesis modes are available to assure proper spatial perspective: "Wide" creates a dramatic sound similar

to our 245F. The new "Narrow" mode creates a more subtle ambience which properly centers dialog. While the two modes are remote-selectable, "Narrow" can safely and effectively be used with all program material.

Single-ended Noise Reduction can be applied to the synthesized signal to reduce hiss and other noise by about 10dB without "pumping" or "breathing" while preserving low-level ambience and dialog intelligibility. This function is ideal for cleaning up older material and optical soundtracks because no encoding is required.

When not in a stereo mode, the 275A ordinarily routes its inputs directly to its outputs. In this mode ("Bypass") the 275A can detect and correct "out-of-phase" stereo material before your mono audience notices any degradation. Our sophisticated Auto Polarity detection circuitry is highly resistant to "falsing"—even with Dolby MP Matrix® material containing substantial out-of-phase surround information.

The 275A complements Orban's complete audio processing and baseband generation system for stereo TV, and provides the stability, reliability, and superb performance which have made Orban **the choice** for the TV broadcaster who is evolving to meet the needs of the contemporary audience.

Contact your local Orban dealer for more information.

automatic analysis of all sync parameters of the video signal \* video monitor output \* local liquid crystal display \* two independent video inputs \* manual/automatic testing modes \* alarm indicators for parameters out of tolerance \* self-test software \* RS 232 output to feed printer or PC \* PAL/NTSC version.

### Standard Measurements

#### Watcher-Analyzer:

- \* sync and burst amplitude
- \* field period
- \* number of lines
- \* horizontal sync width
- \* number of cycles in burst
- \* breezeway
- \* number of vertical sync pulses
- \* equalizer width
- \* vertical pulse width
- \* SC/H phase up to two degrees
- \* SC frequency error up to 0.2 Hz

#### Timer:

- \* H and V lock
- \* PAL lock
- \* H delay and SC phase delay between inputs A and B
- \* Sync
- \* Watcher
- \* Analyzer
- \* Timer

Continued from page 118

other than dead center. A stereo spread of 10° to 20° is too small an angle for effective perception of directional dialogue cues. Therefore, all dialogue should be placed center channel (or very near center channel) for all programming. The only exception would be if dialogue were intentionally planned to originate off-stage (off-screen). In that case, dialogue cues could appear hard left or hard right, whichever is appropriate. In most broadcast applications, dialogue will be picked up using near-field techniques to increase intelligibility.

### Music

Music includes all forms of musical pickup, including acoustic and electronic instruments, and all vocal renditions associated with the musical selection being performed. Musical production may use all the creative flexibility normally associated with music recording to enhance the final video product. The full stereo spread may be used, in addition to special processing (reverb, delay, flanging, chorusing, compressing and limiting) that is considered creatively appropriate to enhancing the final product.

For more traditional music rendition,

the natural room ambience should be exploited through proper far-field microphone techniques to create a natural, pleasing product. Even though a lot of creative freedom is available, lead vocal solos are generally still placed center or near-center.

### Effects

The term effects refers to the wide variety of sound effects and natural sounds that can be used to enhance the TV production's dramatic or entertainment value. This includes effects that have been prerecorded on disc or tape as well as those effects that are captured live. They could include anything, from the subtle presence of gentle wind with softly chirping crickets, to the swish of a basketball gliding through the net to the roar of the crowd, to the thunder of a passing train.

These effects help develop the character of the programming and also can exploit the full capabilities of stereo imaging. Remember that these effects need to be treated as coherent sound and should be miced accordingly, using coincident or near-coincident techniques.

### Prerecorded stereo material

Prerecorded stereo material includes video programming from the network, syndicators or other outside sources. It also includes prerecorded music or effects on audio disc, cassette, cartridge or reel-to-reel tape. Although it seems reasonable to assume that prerecorded material has been recorded properly, experience has proved that this is not always true. One major artist, recorded on a reputable label, sounded great in stereo. However, when monitoring in summed-monaural, the singer disappeared. Clearly, this recording was not verified in summed-monaural prior to commercial release. All prerecorded sources should be verified for summed-monaural compatibility, and rejected as unsuitable for broadcast if a phase incompatibility problem is noticed.

### Putting it all together

The primary concern for broadcast stereo is summed-monaural compatibility. To achieve this compatibility, stereo microphone placement should always be coincident or near-coincident, never spaced. Dialogue should always be placed center or near-center. Music and effects may exploit stereo imaging to provide a sense of width, depth and movement to the sound field.

Finally, good monitoring is essential to developing effective stereo imaging. The capability to instantly switch from stereo to summed-monaural monitoring is necessary to verify compatibility. Armed with this information, and the audio engineer's creative abilities, interesting and exciting stereo programming can be produced.

Look. We know that for PC board mounting you want a receptacle that keeps a low profile and turns in a top quality performance.

Now you can get it...just about any way you want it...from Neutrik® Ag, the leader in innovative XLR technology.

You want to make the right connections?

Easily? Then you'll appreciate the D series' compact design. It saves time with a quick-connecting contact assembly that's removable from the rear of the housing just by turning a cam with any slotted screwdriver. While the housing sits tight...right on the panel.

You're after more options? D series receptacles give you a stockpile. Three pin types. Silver or gold contacts. Front or rear mounting. Vertical or horizontal PCB styling. Solder cups for wire connections. Your choice of locking or non-locking receptacles. In fact, you get options right down to the satin nickel or black chrome finish.

You just need a little more information? Learn all the angles by contacting: Kulka Smith, Inc., Sales Dept., 1913 Atlantic Ave., Manasquan, NJ 08736. (201) 223-9400. TLX: 244536.

## QEI OFFERS EVERYTHING YOU EXPECT IN A HIGH TECHNOLOGY FM TRANSMITTER WITHOUT THE HIGH PRICE TAG

**ASK ABOUT  
QEI'S 15000 HOUR  
TUBE WARRANTY!**

**W**ith a QEI FM transmitter you won't have to compromise quality to meet your budget.

A one-kilowatt transmitter that is completely solid-state. Higher power models that have only one tube . . . a stable, reliable, efficient grounded grid triode.

A full remote control system along with microprocessor-based diagnostics built into every transmitter.

A super-low distortion "transparent" exciter with automatic power and modulation control.

Advanced technology at a price you can afford. Why settle for anything else?

For more information contact John Tiedeck at 609-728-2020. He will describe the many features of these unique transmitters.

We make the famous 691 too! A stereo and SCA monitor that can give you accurate readings, even on clipped composite. Over 40 tests performed in minutes on your station, or the competition.

## NEC PCU-780KS UHF transmitter

By Karl Paulsen

Seattle's first commercial UHF TV station signed on the air on Saturday, June 22, 1985, following a long planning period. It took almost three years from the time the original construction permit was granted until sign-on of KTZZ-TV.

Certainly one of the key elements in any new TV installation is the transmitter. Because this station was being built from the ground up, we had the opportunity to survey the entire broadcast

Paulsen is chief engineer at KTZZ-TV, Seattle, and KTDZ-TV, Portland, OR.

### Performance at a glance

- High-efficiency klystron operation
- Stereo- and SAP-compatible
- Solid-state exciter and driver
- Automatic redundancy, transmitter switches to backup mode and bypasses defective circuits
- Differential gain  $\pm 5\%$  at 3.58MHz
- Differential phase  $\pm 3^\circ$  at 3.58MHz
- Group delay with precorrection is 50ns up to 2MHz; 40ns up to 3.58 MHz; and 80ns up to 4.18MHz.

equipment market for our transmitter. After a thorough investigation, we selected the NEC PCU-780KS 80kW transmitter.

### Inside the transmitter

As most engineering managers know, UHF transmitters are the local utility company's best friend. A UHF transmitter consumes a tremendous amount of power, especially when compared to a VHF transmitter. The selection of the PCU-780KS transmitter with mod-anode pulser was perfect for our application.

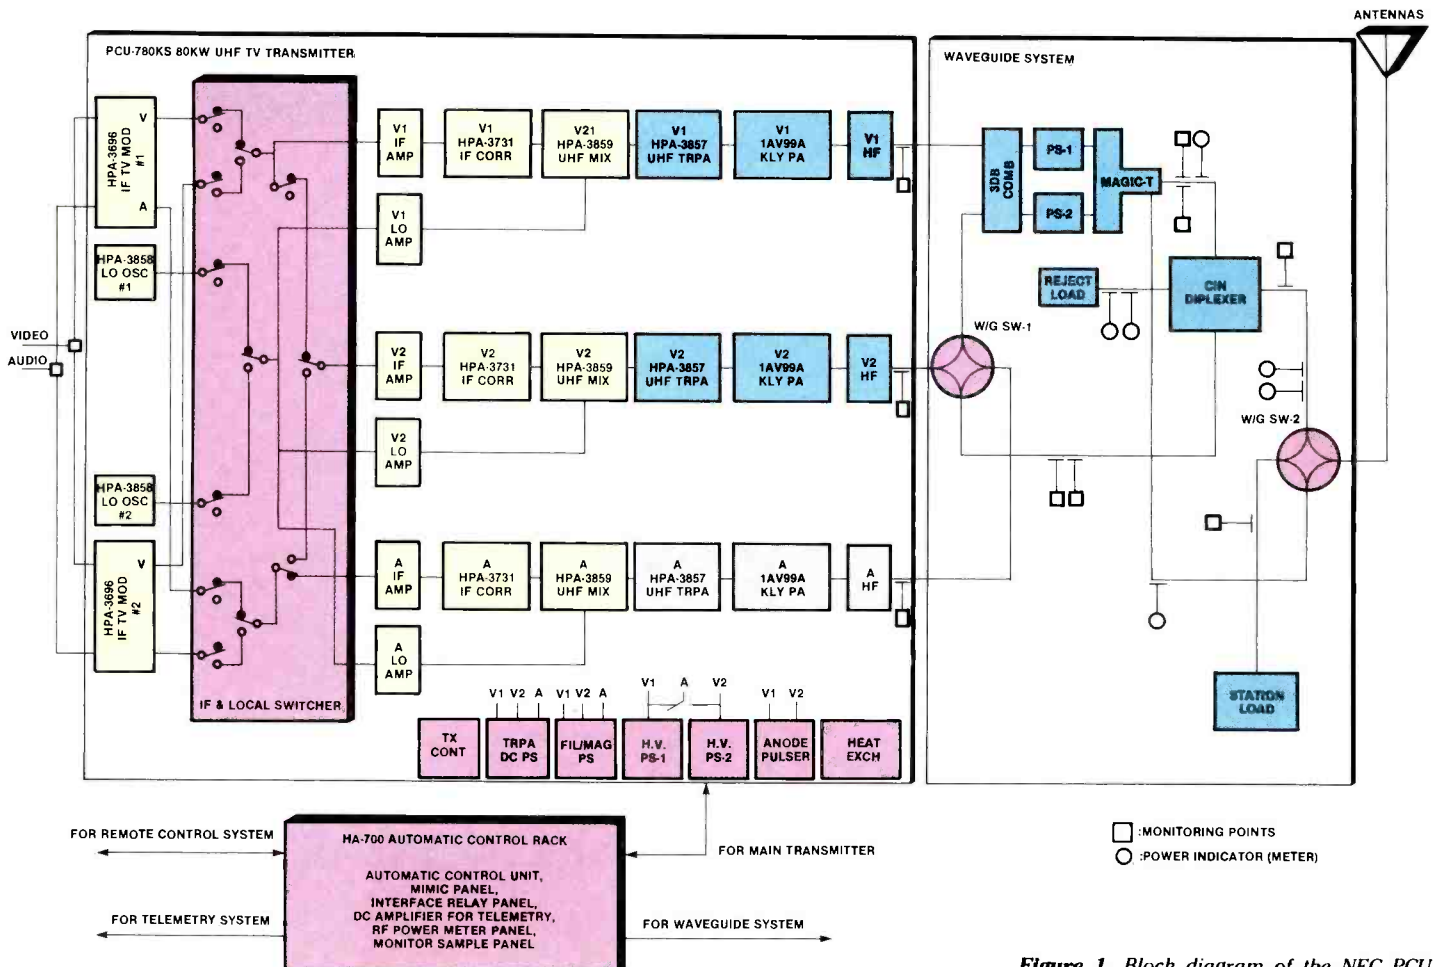

Figure 1. Block diagram of the NEC PCU-780KS 80kW UHF transmitter system.

When combined with circular waveguide, we were able to reach 5,000kW +10% aural ERP without needing a more costly 110kW or 120kW transmitter.

The transmitter (see Figure 1) is built around three 40kW vapor phase 1AV97A klystrons. Two of the klystrons are operated in parallel to provide the visual signal and one klystron is used for the aural signal. The visual amplifiers are connected in a backup configuration so that failure of the aural klystron will not force the station off the air. If the aural section fails, the transmitter drops to one-half visual power and uses either visual klystron as the aural amplifier.

The klystrons operate at 55% efficiency. The total power consumption is 213kW at 480V/3-phase. In order to obtain this efficiency, an anode pulser is used (see Figure 2). In a conventional UHF transmitter, the beam power input to the klystron amplifier is greater than actually required for most of the signal. It's only during the transmission of the sync signal that the transmitter must reach full output power. The anode pulser circuit allows the transmitter to operate with less input power during the non-sync periods of the signal. Then, when sync is transmitted, the anode pulser boosts the transmitter output to the proper level. The results of this transmission scheme are reduced power consumption and

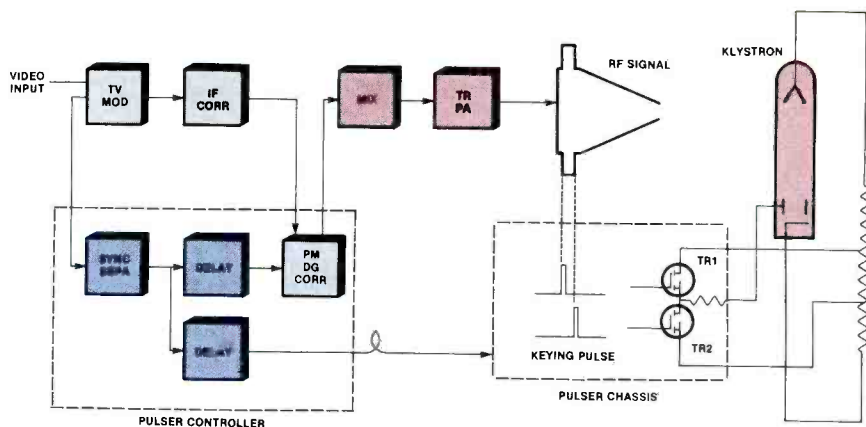

Figure 2. This illustration shows where the anode pulser is connected in the transmitter circuit to increase the output during sync.

lower utility bills. Unfortunately, pulsed-anode operation does require more non-linearity correction in the exciter. This transmitter provides ample correction within the exciter module. Furthermore, once the system has been properly adjusted, it remains stable and needs no attention. In our case, after the anode pulser circuits were properly adjusted, we left them alone. (See the accompanying sidebar on pulsed-klystron operation.)

#### Operation features

The transmitter uses two discrete ex-

citer systems including separate modular oscillators, IF modulators and common buffer amplifiers. Each subsystem is designed to be transparent to the other when cross-switched. The automatic control system incorporates all of the required subsystems into one complete assembly. It also allows independent control of any subsystem in the event of failure or during maintenance.

A mimic panel provides a highlighted schematic of the actual transmission path. A warning indicator panel helps the operator identify the location of any problem. If a fault arises within the

transmitter, it can automatically sense the cause, isolate that portion of the circuit and in some cases switch auxiliary circuits into the system. The defective stages are shut down and bypassed so the station can stay on the air. Of course, there are circumstances in which no backup provisions are available. In these cases, the transmitter sequences through a safe shutdown and awaits operator instructions. All telemetry and fault information is available for interfacing to a transmitter remote control.

The signal flow is diagrammed on the front of each module, making troubleshooting easier. Sample test points are brought out to the front panel for connection to test equipment. Each module also has its own internal power supply. While this may not seem to be an important feature, consider how much trouble it is to rig up several different power supplies just to bench test a module.

The transmitter employs a pedestal AGC circuit to maintain the proper power output level. The output signal is first sampled and detected through a directional coupler. The signal is then sampled at blanking intervals, producing a correction voltage that can be used to adjust the transmitter output power. The feedback circuit provides a constant blanking level and is effective through a range of  $\pm 1$ dB. If the output variation exceeds this limit, the transmitter

*The limited available space meant the CIN diplexer, waveguide switch, Magic-Tee phaser and hybrid switching system had to be squeezed into an overhanging mezzanine.*

automatically reverts to normal settings to prevent any power amplifier problem.

#### Installation

The KTZZ engineering staff installed the transmitter with the assistance of NEC's technical engineers. We felt there was an important advantage to having the station's engineering staff involved in the installation process. The knowledge

gained from participating in the installation of a transmitter is invaluable when it comes time to maintain the unit. At no other time will the engineers be able to take their time to slowly go through each section of the transmitter learning how each part works within the system.

The station's transmitter building is a 3-level, multi-user structure designed specifically to house the transmitter and

its associated equipment. The building also supports a future office complex located directly overhead. Because our downtown Seattle location was expensive, the waveguide combiner, phaser and diplexer were stacked into an overhanging mezzanine. Another problem, caused by the limited space, required us to develop a detailed plan to receive the equipment and components in a specific order so we would not paint ourselves into a corner. A key element in this process was the information supplied by the transmitter company on component sizes. Detailed drawings were sent to us far in advance of the actual building design.

Because of the limited space within our

## Pulsed anode operation

*In the search for efficiency, new approaches to klystron operation have been suggested. One concerns the licensed maximum output signal power transmitted during peak of sync. The inverted polarity of video, when modulated, avoids excessive noise in the picture. With sync producing 100% modulation, noise spikes cause greater than 100% modulation, but are disguised in black. (Noise with positive polarity would result in piercing whites.) However, effective transmission of picture does not require that the same level of dc power (relative to the sync pulse) be maintained during the active video line time.*

*In a standard configuration, the potential on the klystron cathode is approximately -24kV (below ground). The mod anode voltage is much closer to ground, perhaps -1kV to -3kV. For safety purposes, the collector and the tube body are at ground potential.*

*By operating the modulating anode at about -7kV during active video, and pulsing it to the -3kV level during sync time, the average dc input beam power to the visual amplifier may be reduced. Switching to the less negative voltage for sync increases the acceleration and therefore the current. This increases beam power during horizontal sync or about 7% or 8% of the total line time. If the beam current was set to 7A initially and turned back to 5A with the pulsing, the power formula would show an immediate change of 48kW (the product of 24x24kV).*

*In essence, a pulser system changes the operating class of the amplifier. The klystron should be as linear as possible during active video, the most inefficient class A mode. During sync, maintaining class A biasing wastes energy. If, for the approximate 4µs period, we change the klystron bias point, we can improve efficiency. Because the sync interval is primarily a pulse, strict linearity is not necessary.*

new building, the entire transmitter was delivered, uncrated and prestaged in a warehouse five blocks from the site. This process allowed us to become familiar with just how much assembly would be required after the numerous wooden crates and pallets were removed.

The station's chief operator and assistant chief engineer, Chuck Johnson, was responsible for overseeing the actual transmitter installation process. He worked with the company engineers to ensure the proper coordination of our staff and the outside support needed to complete the work.

The entire transmitter and its remote-control interface was assembled and pretested in Japan. Those familiar with other transmitter installations may recall the problems usually encountered with connecting transmitters to remote-control systems. The connection process usually requires out-board sampling units, driver amplifiers and interfaces to the transmitter. With the PCU-780KS, the entire transmitter interface from the transmitter automatic control unit (ACU) to the remote control was merely wire connections. No outside load resistors, sampling units or other devices were required.

### Performance

KTZZ was NEC's first stereo UHF installation in the United States. The com-

pany is, however, familiar with the problems associated with multichannel broadcasting because Japan uses bilingual broadcasting. It was a relief to know that the transmitter was already capable of producing the wide aural bandwidth and required deviation without special modifications.

The aural bandwidth is flat out to 270kHz. The -3dB point is 320kHz. This performance is more than acceptable for BTSC operation. Modulator performance was measured both with 600Ω balanced (mono operation) and with 75Ω (stereo composite) inputs. Although we do not use the pro channel or SAP, performance measurements show that the transmitter easily meets all of those requirements.

It is important to reduce incidental phase modulation (ICPM) in order to minimize the potential for aural buzz during peak white signals. Because of our concern about providing a quality signal, we specified a maximum of 2° ICPM as measured through the entire transmitter before placing the transmitter order. Tests show that our transmitter exceeds that specification, with ICPM typically running approximately 1°.

### Company support

By the time the full checkout and performance proof was completed, all automatic and transfer systems connected to the remote control and every-

thing tested, the transmitter had been run nearly 250 hours. This burn-in period ensured that early mortality problems were caught by the factory engineers.

We haven't needed much assistance from the company since the transmitter was installed. At one point, when a glitch developed in the control-sensing system, we called for help. They were able to point us in the right direction and we quickly solved the problem. After the flow sensor was properly adjusted, they checked back with us to make sure everything was OK.

The transmitter continues to provide us with excellent service. The combination of factory support and a good product has made the NEC PCU-780KS an excellent choice for our station.

**Editor's note:** The field report is an exclusive BE feature for broadcasters. Each report is prepared by the staff of a broadcast station, production facility or consulting firm.

In essence, these reports are prepared by the industry and for the industry. Manufacturer's support is limited to providing loan equipment and to aiding the author if support is requested in some area.

It is the responsibility of **Broadcast Engineering** to publish the results of any piece tested, whether positive or negative. No report should be considered an endorsement or disapproval by **Broadcast Engineering** magazine.

**Acknowledgment:** Portions of this article were adapted from "KTZZ-TV (Seattle) Goes All-Stereo With NEC's PCU-780KS UHF Transmitter," printed in the Fall 1985 issue of the *NEC Synchronizer*. [:-:~:~:~]]

## Committee advocates rulemaking on LPAS

By Bob Van Buhler

Continuing a pattern of SBE advocacy before the FCC, the society filed comments on the commission's notice of proposed rulemaking (NPRM) on broadcast low-powered auxiliary stations (LPAS).

The NPRM proposed to expand the use of LPAS, which include wireless microphones and short-range production control equipment, into additional unused TV channels. Previously authorized for use on unused spectrum on channels 7 to 13, the FCC now proposes to permit them on unused channels 2 to 6 and 14 to 16.

The society's comments point out the conflict between expanding the use of LPAS into channels 14 to 36, and the recent moves to introduce land mobile licenses on channels 15 to 18. The possibility of mutual interference between these two services is great.

The SBE also suggested that additional measures be imposed on the use of wireless microphones to permit better local frequency coordination. The microphones are often rented rather than purchased. Because they are usually not labeled with operating frequencies, the user seldom knows at what frequency the units operate. This aspect can cause many problems in the field. SBE recommends that labels be required showing transmit frequency, owner's name, address and telephone number.

### Other filings

During the last year SBE filed the following documents with the FCC:

- Comments on the amendment of Part 90 to allocate additional channels in 470MHz to 512MHz to public safety and other land mobile services (June 13, 1985).
- Comments on review of technical operations requirements in Part 74 regarding aural STL/ICR and TV auxiliary stations (June 28 and July 29, 1985).
- Comments on remote pickup and low-power auxiliary stations.
- Proposed rulemaking to amend frequency coordination requirements in Part 74 (September 24, 1985).
- Comments on above rulemaking (November 7, 1985).
- Reply comments on above rulemaking (November 20, 1985).
- Comments on the problem of com-

patibility of broadcast services and VHF aeronautical mobile equipment (December 17, 1985).

•Comments on the review of technical operations regulations in Part 73 regarding AM broadcast stations (July 1, 1985).

A total of 10 filings were made by president Richard Rudman and SBE counsel Chris Imlay on behalf of the SBE membership. This level of national activity speaks well for our organization. The FCC as well as other national organizations and companies have come to respect our opinion and seek our advice on important industry matters.

### Check your status

Many SBE members may not be aware that they are eligible for upgraded membership status. Check the following criteria to see if you are eligible for an upgrade:

- Life membership—when retired from full-time employment, a person can apply for life membership. The person must have been an SBE member continuously for five years at the time of application. Life members are exempt from further dues payment.
- Senior membership—available to anyone who has been an SBE member for three consecutive years, participated in broadcast engineering for 15 years and has demonstrated professional responsibility in the areas of supervision, equipment design, plant layout or projects directly related to broadcasting for at least six years.
- Life certification—this certification level requires that a number of steps be completed in the application process. See your certification chairman or call the national office for details.

### Membership

The February issue of **Broadcast Engineering** carried a full page membership application blank. So far, 56 new members took advantage of that application form. The April issue of **BE** also contained a tear-out, self-addressed application blank. If you want to pay by Visa or Mastercard, simply complete the form, stamp it and mail it. If you want to

pay by check or money order, please enclose the application form inside an envelope.

Almost 200 new members were added to our ranks this year. We also gained one new life member.

### Computer news

The new SBE computers were installed in mid-January by Gerry Dalton, member of the Dallas chapter who co-chairs the National Frequency-Coordinating Committee. The installation represents more than a year of work by Dalton and Jack McKain, vice president.

The administrative system uses a Compaq computer and 30Mb drive with streaming tape backup. This computer is used to store and to process all administrative work, certification information and frequency-coordination data. A second computer system, consisting of a Compaq 20Mb Desk Pro and modem, is used for certification and the SBE electronic bulletin board. Members can call the bulletin board after office hours at 317-842-0896.

Both computers are connected to a pair of printers. The dot matrix printer is used for reports and other non-letter documents. The laser jet printer is used for correspondence and reports that require high-quality output. This printer will generate all of the certification examinations, including schematics. The purchase of the computer equipment was financed by chapter rebates (40%) and sustaining membership fees (60%).

In other computer-related news, SBE can now provide members with access to CompuServe, a time-share database. CompuServe will maintain a separate database for SBE information, computer programs and listings of chapter chairmen and frequency coordinators. The information will be updated regularly by Gerry Dalton, the systems operator (SYSOP). Members of CompuServe can send messages or transmit electronic mail to other SBE/CompuServe members through the system.

SBE members who do not yet have access to CompuServe can obtain introductory kits for \$21.95. This price represents a discount of \$18 from the retail price of \$39.95. The kits provide \$25 worth of free time on the system. All of the standard CompuServe services are available to SBE members who sign up with the company. Contact the national office for more information. (:-:-))

Van Buhler is chief engineer for WBAL-AM and WITY-FM, Baltimore.

## Color character generator

*ICM Video* has introduced the model CG-7000P color character generator. The unit has high-resolution characters, and character fonts are generated by a plug-in module. The unit will generate an unlimited number of colors for the characters, and for the internally generated background.

The generator can gen-lock to any video source, including 3/4-inch and 1/2-inch videotape. The characters and graphics can then be keyed over the external video with a built-in keyer. The unit contains 80 pages of built-in memory. Additional features include: program and preview outputs, four character sizes, scrolling, auto-sequencing, drop shadow, flashing effect and battery backup.

Circle (350) on Reply Card

## Component downstream keyer/ RGB chromakeyer

*Shintron* has announced the DK3/CK3 component downstream keyer/RGB chromakeyer, a combination shadow keyer and chromakeyer built into one enclosure. It can be used as a stand-alone unit or as an accessory to a component switcher. It is compatible with all standard component formats.

The unit employs super-linear extra wideband technology, which performs key fades and program preset fades with almost immeasurable degradation in differential phase ( $<0.25^\circ$ ), differential gain ( $<0.5\%$ ) or frequency response ( $0\text{dB} \pm 0.25\text{dB}$  to 5MHz).

The unit can generate independent video keys on the program and preview buses. Dropshadows in any of eight different directions are possible, as well as full borders and outlines. The downstream keyer on the program bus can be independently faded into the foreground, while a new program preset fade allows 1-step fading between videos in the background.

Circle (351) on Reply Card

## Demodulator adapter

*TFT* has announced that its 850 BTSC aural modulation monitor has been adapted to operate directly from the output of the Tektronix 1450 TV demodulator (updated versions). This configuration is the 850-1450. The adaption of the 850 makes it more universally acceptable and usable in satisfying the NAB/EIA recommended practices for measurement and monitoring of BTSC performance parameters. This configuration of the monitor is like the basic unit, without the front-end RF and IF circuits.

Circle (352) on Reply Card

## Digital voice announcer system

*Granite Telcom* has introduced the digital voice announcer 1000 (DVA-1000), which digitally records, stores and plays back outgoing telephone messages. The unit is a microprocessor-based system with a full-fraction membrane keyboard for system control and an FCC-registered telephone interface. Features include variable voice digitizing rates, selectable announcement repeats before disconnect, call counter(s), elapsed time indicators for each message, calling party disconnect detection and self-contained system diagnostics.

Circle (353) on Reply Card

## Microwave booster/UPS/and SCPC systems

*Marti Electronics* has introduced the MW-500 microwave booster; the UPS-12 uninterruptible power system; and the STL-10 narrowband SCPC.

The MW-500 receives, amplifies and redirects an aural STL signal over or around an obstructing object in the direct path between the transmitting and receiving antennas. The booster uses the same frequency for retransmitting and provides a maximum of 500mW output power. The booster also provides 60dB power gain at any point it is inserted in the microwave path.

The UPS-12 has a dc-dc system that provides automatic battery backup for the STL-10/R-10 radio link systems as well as the RPT-15/BR-10 automatic relay stations and TSL-15 data links. The unit is equipped with a precision constant voltage taper battery charger to maintain a 24, 36 or 60 amp-hour sealed maintenance-free battery in a charged condition.

The STL-10 uses 125kHz for mono and 250kHz for FM stereo STL.

Circle (354) on Reply Card

## Condenser microphones

*Shure* has introduced the SM94 and SM96 electret condenser microphones. The SM94 has a flat frequency response and the SM96 has a slight presence rise and smooth low-end rolloff. Both mics have cardioid polar patterns that will not collapse at high frequencies. Both mics also feature a shock-mounting system that isolates the transducer element. The mics may be powered by any standard phantom power source (12Vdc-48Vdc), or internally by a standard 1.5V AA battery. The SM96 has a built-in 3-stage pop filter. Both mics have a nonreflective gray finish and come in a vinyl bag.

Circle (355) on Reply Card

## Precision digital multimeters

*Spanta* has introduced models 540 and 530 4½-digit and 3½-digit hand-held digital multimeters. Both models are drop-proof and provide true rms ac readings using LSI circuitry, yielding accurate results on non-sinusoidal waveforms as well as sine waves. Model 540 provides 0.05% accuracy. The frequency measurement capability of the model 540 provides fast readings from 12Hz to 200kHz, with readings updated 2½ times per second.

With the data hold feature, the final reading of any measurement can be held on the display indefinitely. A standard feature of both models is an instant continuity test using a visible solid bar display and an audible beep signal. Other features include a diode test and triple overload protection. The model 530 provides direct reading decibel measurements for amplifiers, filters and attenuators.

## Replacement parts, repair products

*Black Audio Devices* has announced a line of replacement parts and repair products for microphone booms. They are the swivel levers which replace the dumbbell on the AKG- and Beyer-type mic booms. The lockscrews replace lost or hard to find lockscrews on most makes of mic booms. They come in several styles and colors. The thread strips are used on the 5/8 to 27 threads on booms, stands and accessories.

### TBC and video switcher

For-A Corporation of America has introduced the FA-440 TBC, the FA-450 TBC and the CVM-500 video mixer.

The FA-440 TBC features 8-bit chroma signal component encoding and is compatible with all 1/2-inch and 3/4-inch format VTRs. Digital effects include quarter-size compression with five positions. The unit also includes a built-in effects keyer, full-frame time base correction; built-in dropout compensation, full-color frame memory that provides field and frame freeze; strobe freeze and an adjustable auto freeze and pro-amp controls.

The FA-450 TBC is capable of transcoding signals in any format to any other format. The unit provides input and output capability for handling component RGB, YIQ; Y, R-Y, B-Y; Y/C dub and composite (NTSC) on a full cross-matrix basis. The TBC has full-frame correction and color picture freeze. Features include a gen-lock sync generator, black-burst output, comp sync and subcarrier outputs. A remote control console provides control of time base correction and video level functions.

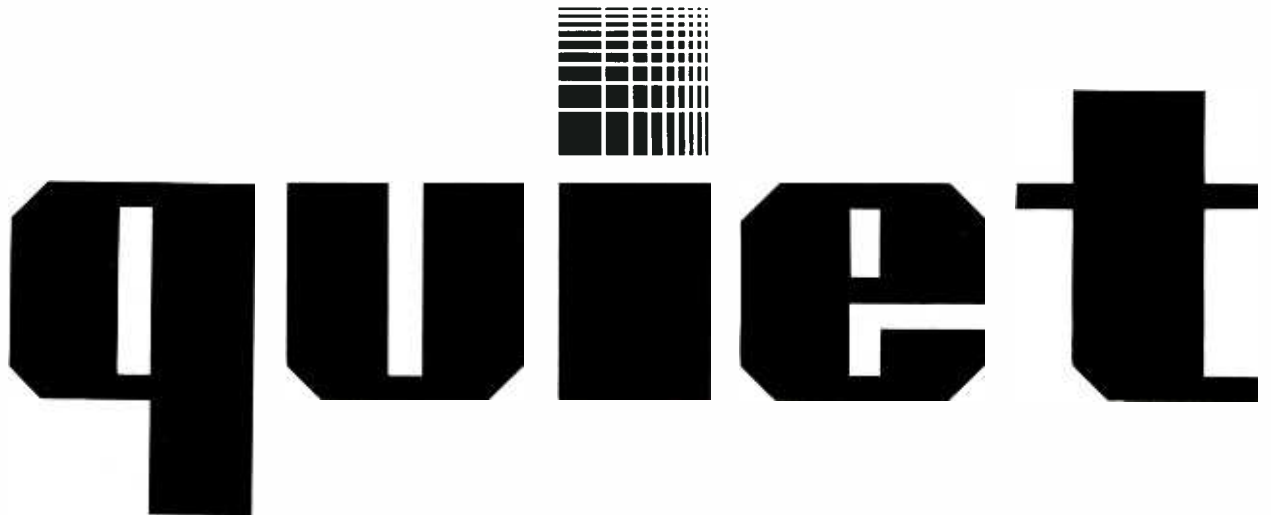

The CVM-500 video switcher features 6-inputs plus black and color background; and reduces edge noise during keying, matting and wipe effects. A high-resolution picture is possible at all times since component VTR and component camera inputs require no decoding or encoding prior to processing.

digital dimmers via 960 blocks of cue storage memory. The console offers a real time clock/calendar on screen, a local area network, and 72-hour memory retention without batteries or extra power supplies. The console has a high-resolution 13-inch color video display with direct-etched antiglare screen and is mounted on a tilt/swivel case. The unit also has a 3½-inch floppy disk drive for library storage. There are two time faders, one split-level manual cross fader and 10 submasters.

The PII/III RAM board is equipped with 32K of CMOS memory chips and is designed to replace the existing memory board of the Performer II/III. The board features 4-day memory retention. During a power stoppage, large capacitors provide enough power to sustain memory contents, eliminating the need for batteries.

### Audio/video products

*Ampex* has introduced a series of audio and video products.

The 467 professional U-matic digital audio cassette for PCM converters feature a cross-linked copolymer oxide binder system that withstands repeated plays without signal loss or error build-up. No realignment or special adjustment is necessary, and the cassettes can be used in all digital U-matic systems with standard factory adjustment.

The ATX-100 digital repositioner with zoom can connect to telecines with little or no modification. The unit consists of a control keyboard, computer system and a signal system and provides control of five positioning parameters. Parameters are entered via a joystick or keypad and can be stored in the system's memory for real time or recall.

### Video test and measurement equipment

*Magni Systems* has announced the 1527 integrated measurement package (IMP) and the 1510 digital signal generator.

The 1527 IMP adds SCH phase capability to the waveform/vectorscope monitoring and test signal generation found in the 1520 IMP. The system measures absolute SCH phase of a single video signal, relative SCH phase of two signals or wrong color-frame matching between two video signals.

The 1510 digital signal generator is a new version of the 1520 IMP generator. A precision 10-bit digital test signal generator, generates 16 required signals. It contains 12-character overlay for signal source identification gen-lock capability and programmable offset of +45µs to -15µs to provide a time synchronous video source through a remote device under test.

# Creating a colorful image

The FA-430 Digital TBC combines the best features of the component-structured FA-410 TBC with a digital image processor for full-feature processing of all color under formats. Time-Base and Color correction, Noise Reduction, Image Enhancement and Y/C Dub In and Out capability—all in a single unit for excellent program quality control.

**Color Correction** compensates for camera black and white levels, gamma and camera-to-camera colorimetry differences. Tint mode lets you "paint" scenes and create moods by changing picture color content. Black Stretch delivers optimum contrast in low light level scenes.

**Image Enhancement** combines H detail enhancement and selective noise reduction with improved V detail for sharper and subjectively more pleasing pictures.

**Noise Reduction** minimizes chroma noise and streaking as well as luminance noise in recorded signals to produce higher quality, multi-generation tapes. Result: lower editing and production costs.

**Y/C Dub** interfaces directly with VTRs to reduce ringing and distortion effects caused by cascaded filters.

Circle (110) on Reply Card

Wider bandwidth, greater resolution and sharper luminance and chroma transitions build quality into your programs.

More than a high-performance TBC, the FA-430 with Image Processing, Dropout Compensation and Y/C Dub features moves picture processing to a new level. FOR-A regional and local sales offices are ready to take you up. Now.

### Ku-band portable uplink

Modulation Associates has announced the Ku 02, a suitcase-sized, completely portable satellite uplink designed specifically for remote broadcast and satellite news gathering applications that require quick deployment anywhere in North America.

The Ku 02 has been configured to provide continuous 2-way, multichannel communications between remote locations throughout the country and a master control center. Two-way communications is possible without interruption of the broadcast programming.

The unit comes with selective signaling, audio monitoring and telephone termination equipment. It has been designed to be used with a micro, 1.2 meter antenna.

### Headset stations

HM Electronics has introduced the HME BH720 and BH721 belt pacs, which feature a contoured aluminum extrusion housing. These belt pacs are light, compact and rugged for long-term reliability.

Both models feature soft compression limiting to eliminate distortion from high microphone input levels. A user-accessible switch allows the use of headsets with dynamic microphone or the lightweight HME 700-18 electret headset.

The single-channel BH720 belt pac is compatible with all HME 700 series intercoms and other 3-wire systems.

The BH721 includes the same features in addition to 2-channel capability over 4-conductor cable. A top panel toggle switch permits selection of either channel.

# Agile Omni, the industry's most advanced receiver designed by the most relied upon name in the business... Standard.

**W**ith the new Agile Omni, you need no other receiver.

Standard designed it for cable TV operators, broadcasters, CATV, SMATV, and business and special teleconferencing networks—now and in the future.

An onboard microprocessor permits selection of any band available from domestic satellites, including the 32-channel ANIK C2. Channel tuning provides direct reading of the transponder-assigned channel number and a format control permits selection of six frequency band formats—24-channel C-band, SBS/USAT and Spacenet already installed. Select channel and format, and the microprocessor controls frequency, channel spacing, transponder bandwidth, audio

frequency and bandwidth, and antenna and video polarity—automatically.

Omni's flexible design can handle up to three separate subcarriers including stereo programming or data. Omni also will accept descrambling modules—eliminating the need for expensive add-on descramblers.

For CATV and SMATV applications, severe microwave terrestrial interference is minimized by optional internal SAW notch filters, automatically programmed to switch in. A 30 MHz low DG/DP LC bandwidth filter is standard, and a second internally installed optional filter of 18, 22, 26, or 36 MHz bandwidth can be controlled by the microprocessor, or manually switched.

Standard's proven RF

loop-thru circuitry and blockdown conversion technology combine, with better image rejection and lower differential gain and phase, to provide excellent video performance. C/N threshold is an impressive 6.5 dB at the wide 30 MHz bandwidth.

Agile Omni is an affordable, flexible receiver designed to keep you in business, a commitment Standard backs with its unique 5-year warranty program. Contact us for further information.

regional sales manager. His territory includes the north-central United States. Olimski is field service technician and provides post-sale service in the southern California and Los Angeles areas.

**Philip J. Lantry** has been named sales manager of pro products at Audio-Technica, Stow, OH. Lantry will be coordinating sales efforts with the company's national sales representatives.

**Bob Bergfeld** has been appointed national sales manager of the electronics division of Lenco, Jackson, MO. He is a former senior district manager of Sony Video Communications.

**Ray Updike** has been named sales manager at Circuit Research Labs, Tempe, AZ. Updike is responsible for limiters, stereo generators and spectral energy processors.

**Kevin J. Barry** has been appointed national sales manager of PRO Battery, Atlanta. He is a former telemarketing manager in the company. [:(=)]

**Seeing is believing**

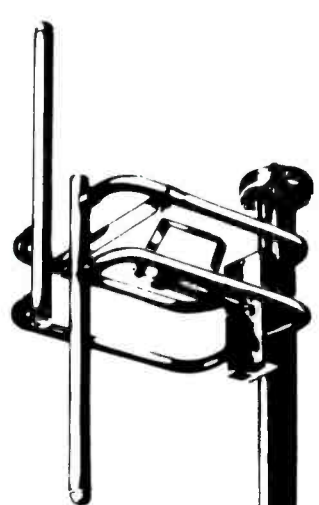

Look at what's available now!  
The new AN-1000 has been adapted to fit the Tektronix half-rack.

That empty space next to your waveform monitor can be put to use. It can house an AN-1400, an unbelievably powerful small speaker.

Mosfet output, DC servo offset control and electro-acoustic signal processing are all combined with the acoustically tuned enclosure, producing quality sound that you have to hear to believe.

Anchor Audio, Inc. • 913 W. 223rd St. • Torrance, California 90502 • 213-533-5984 • 1-800-ANCHOR-1

**PATTERN WORK ....**

In over a dozen years of providing formal directional patterns to both the FCC and DOC, Shively has never had a pattern rejected; ever. We've earned the trust of the industry in all aspects of pattern work. What are your requirements?

INFORMATION ABOUT SAVING YOUR ELECTRONIC EQUIPMENT

## Your Broadcast Operations are in Danger!

**The danger is serious and ever-present. In a split second you could be off the air...or operating with a scrambled program-control system ...or totally shut down with equipment catastrophically damaged. It's a threat you live with day after day and one that merits your closest attention.**

**The Threat** Abnormal voltage surges that occur on AC power lines, communications lines and data lines are a major cause of misinformation and equipment failure for the broadcaster. Broadcasting equipment is especially vulnerable, with tall antennas reaching up into the skies and with electronic units of unusual sensitivity.

Difficulties manifest themselves in two ways: (1) as physical *damage*...this is obvious damage that occurs directly as the result of an electrical storm, or less obvious failures that seem to occur almost at random; (2) as *misinformation*... where the power surge is coupled into the equipment causing improper events to occur or incorrect data to be presented.

These problems are familiar ones to broadcasters. And now, with the ever-expanding dependence on computer control and the corresponding increase in the susceptibility of these sensitive devices to damage from voltage surges, overvoltages must be controlled and eliminated.

\*Allen & Segall/IBM, 1974

# MCG

ELECTRONICS INC.

12 Burt Drive, Deer Park, NY 11729 • 516-586-5125

Specialists in Circuit Protectors, Transients, Lightning & Surges.

Call or write for our  
FREE CATALOG

**The Causes** Transient power problems originate outside buildings from lightning, ground faults, and public utility switching, and inside buildings from inductive loads, transmitters, air conditioners, fluorescent lights, etc. A study at IBM\* identified transients as the cause of 88.5% of all line disturbances. Transients, sudden and extreme "spikes" in voltage, can be as short as a few nanoseconds or as long as several milliseconds. Their effect can range from total failure to the gradual degradation and breakdown of electronic components or systems.

**The Solution** MCG Electronics provides total protection against these transients for your broadcasting operation. AC power lines and data lines that serve your internal communications network are guarded day and night.

### AC Power Line Protection

MCG's Surge-Master™ provides high speed (5ns), heavy-duty protection that limits AC overvoltage spikes to safe levels. Surge-Master protectors are your first line of defense, and are available in configurations designed to meet your needs, from complete building protection to individual equipment protection.

**Data Line Protection** Interfaced between network equipment and data lines, MCG's Data Line Protectors provide a sophisticated blend of high speed (less than 5ns) and brute force protection against induced transient voltage surges. Available in multiple configurations, they are designed to meet your every need, and will keep your data network out of danger.

**MCG Protectors** Your most cost effective insurance against downtime and data loss caused by voltage surges and transients.

## Wold chooses Wegener Panda II system

Wold Communications has chosen the Communications Panda II audio transmission system from *Wegener Communications*, Norcross, GA, to deliver stereo programming over the Wold Satellite TV Network. Left channel, right channel and multilingual monaural audio are transmitted as separate subcarriers to affiliate TV stations receiving Wold stereo broadcasts through the United States. Equipment to receive this programming is available directly from Wegener.

The system provides the transparent transmission of the full dynamic range and transient properties of digital audio source material over satellite, terrestrial microwave and fiber-optic links.

## Harris plans new product and services for ADDA

Harris, Quincy, IL, will provide full support of four new products as a result of the acquisition of ADDA. Parts and services for all other ADDA products are offered on a best effort basis.

The model 560 (Vision) and the model AC-20A time base correctors, the VW-3 frame synchronizer and the ESP-II still store will be manufactured and are offered for sale under the Harris name.

## Dynatech acquires Quanta

Dynatech, Burlington, MA, has acquired Quanta, Salt Lake City. Quanta manufactures video character generators, video

graphics systems and related products. Quanta was founded as Systems Concepts in 1974.

Quanta will add new products and marketing strengths to Dynatech's Video Communications Division. Dynatech's Video Companies include Utah Scientific and ColorGraphics Systems.

## MCL relocates

MCL, La Grange, IL, has expanded and moved to the Bolingbrook, IL, Industrial Park, Wood Creek Centre. It will occupy more than six acres and more than a 60,000-square-foot building. MCL's first phase building is a 2-story office building. The manufacturing facilities will be behind the offices.

## DCC installs computerized newsrooms

Data Communications Corporation, Memphis, TN, has announced two installations of its BIAS newsroom computerized newsroom system at WREG-TV, Memphis and KOB-TV, Albuquerque, NM.

The system is IBM PC-XT or AT-based. IBM PCs may serve as stand-alone units or share files with other PCs. BIAS newsroom uses modular software and hardware to allow news departments a comprehensive system, with the capacity to add on work stations, file storage and other features.

Software resides on the computer's hard disk and is self-loading when the unit is turned on. Programs are called up by means of selecting from a menu on the screen.

## STOP GROUND-LOOP HUM!

### VIDEO HUM STOP COIL...HSC 1

Will ELIMINATE HUM and other INTERFERENCE in Video Lines caused by differences in Ground Potential.

- For Color and Black and White.
- FLAT-DC to 6.5 MHz.
- No Low-Freq. or Hi-Freq. Roll-off.
- No Differential Phase Distortion.
- No Differential Gain Distortion.
- No Envelope Delay.
- Passive Device - Failure Free-Low Price.
- Small Compact Package 4" x 4" x 2-1/4".

### ELIMINATES HUM AND INTERFERENCE:

#### IN STUDIO

- Between Buildings
- On long runs in Buildings
- Between Studio and Transmitter
- On Incoming Telco circuits
- On Outgoing Telco circuits

#### IN FIELD

- Betw. Remote Truck and Telco
- Betw. Remote Truck and Microwave
- For Intertruck Hookup
- For VTR Units
- For Monitoring Lines

NEW!

\$190  
F.O.B.

# Multiple Choice:

## What do you need in an audio console?

Every application is different; what are your requirements? Should the input section be stereo or mono, mic or line? What kind of outputs and subgrouping do you need? Is a matrix mix important? Do you require mix-minus capabilities? What about metering, timers, tape remotes, mainframes, future expansion?

A-500 Radio  
On-Air

TV-80 Television Master

So whatever your application, stereo or multi-track production, television master control, on-air, video edit, or mobile installation, consult WHEATSTONE.

WHEATSTONE consoles give you all the choices. Our sales engineers listen to your requirements, then work with you and plan your console from the first module to the last VU meter. The result is custom-configured equipment built specifically to your needs.

The truth is, there's only one choice when specifying broadcast equipment: **QUALITY**. There's simply no room in broadcast for cutting corners; when you're on-the-air the phrase "Time is Money" takes on real meaning.

SP-5 Stereo  
Production

3224 Multi-Track

**QUALITY**  
*There's No Better  
Choice.*

# The ST Series by Ward-Beck. Television's first true Stereo Console!

Ward-Beck proudly introduces the first purebred  
Stereo Television Console.

This is no ordinary mixing board modified and adapted for stereo TV. The ST Series has been designed, without compromise, from the ground up to give television broadcasters full stereo facilities.

The ST evolved from extensive consultation with end-users, resulting in a microprocessor controlled system incorporating totally new circuitry, new module designs, and a unique console profile for enhanced operational simplicity.

The ST3642 has ample capacity for major production facilities, while the ST2442 is ideal for on-air and smaller production applications.

The ST Series... Legendary Ward-Beck quality, competitively priced, for every television market!

First by Design.

Ward-Beck Systems Ltd.,  
841 Progress Avenue, Scarborough, Ontario, Canada M1H 2X4.
