

GRATING GENERATOR
TYPE WA-3A
MI-30003-A

TEST AND MEASURING EQUIPMENT SECTION RADIO CORPORATION OF AMERICA engineering products department Camden, New Jersey, U.S.A.

# ADDENDA TO INSTRUCTIONS IB-4003-6 FOR Grating Generator <br> Type WA-3A 

MI-30003-A

To correspond to the latest circuit improvements, modify instruction book IB-4003-6 as follows:

1. On page 1, under Electrical Characteristics, Vertical Bars substitute "40 bars" for "64 bars".
2. 'On page 2 under Installation, add the following:
"When the equipment is mounted directly over a power supply, an asbestos baffle should be placed directly under the grating generator to prevent direct flow of heat to components under the chassis."
3. On page 3, Figure 1, under 6AG5 Multivibrator, delete " $109 \mathrm{KC}-1000 \mathrm{KC}^{\prime}$ and substitute " $125 \mathrm{KC}-835 \mathrm{KC}$. ${ }^{\text {. Also }}$ under $6 \mathrm{SN}_{7}$ Multivibrator, delete "500-2500 cps" and substitute "720-2500 cps".
4. On page 4 delete figure 2 , and paragraph starting with: "When the synchronizing input voltage is too high......"
5. On page 5, substitute the following for information in table headed Vertical Bar MV:

| Range <br> Switch <br> Position | Multiple No. with <br> Frequency Cont rol at |  |
| :---: | :---: | :---: |
|  | Minimum | Maximum |
| 1 | 8 | 10 |
| 2 | 10 | 13 |
| 3 | 12 | 17 |
| 4 | 16 | 25 |
| 5 | 24 | 53 |

6. On pages 6 and 7, modify Replacement parts List to include following information:

C-23 is changed to "Capacitor mica, $2200 \mathrm{mmf}, 500 \mathrm{v}$, stock number $39660^{\prime \prime}$

C-24 is changed to "Capacitor, mica $1000 \mathrm{mmf}, 500 \mathrm{v}$, stock number 39652".
R-53 is changed to "Resistor, 10,000 ohms $1 / 2 \mathrm{w}, \pm 10 \%$ ".
7. On page 8, Figure 5, delete dashed line, and following note:
"First space too wide because of too high a level of vertical sync voltage."
8. Substitute schematic diagram included in this addenda for Figure 9 on page 13.

## TEST and MEASURING EQUIPMENT SECTION

RADIO CORPORATION OF AMERICA

WA- 3A Grating Generator, Front Vi ew

## TYPE WA-3A GRATING GENERATOR

## TECHNICAL SUMMARY

## ELECTRICAL CHARACTERISTICS

## MECHANICAL SPECIFICATIONS

## DESCRIPTION

A uniforn distribution ofpicture detail on the kinescope of a receiveror monitor requires a constant uniform velocity of scanning by the deflection circuits since this characteristic is standard in the operation of television cameras. If the scanning characteristic deviates from the standard, picture detail will be compressed over part of the area and expanded over the balance of the area of the kinescope. The WA-3AGrating Generator provides a convenient means for checking and adjusting the linearity of television deflection circuits.

The WA-3A Grating Generator generates a timing signal synchronized by standard television synchronizing pulses and injects this signal into the video circuit under test. The pattern produced on the kinescope has the appearance of a grating. The number of vertical bars is a multiple of the horizontal scanning frequency minus 15 - 18 percent which are lost during the horizontal blanking interval. The number of horizontal bars is a multiple of the vertical scanning frequency minus 7-8 percent which are lost during the vertical blanking interval. Separate switches are provided for independent operation of the horizontal bar, vertical bar and blanking signal circuits. Control of the bar pulse level independent of the output (blanking) level provides for contrast control.

Equal spacing between the vertical bars over the width of the raster shows linearity of scanning by the horizontal deflection circuit. Equal spacing between the horizontal bars over the height of the raster shows linearity of scanning by the vertical deflection circuit. See Figures 5, 6 , and 7.

The effect of stray magnetic fields in the vicinity of the kinescopeis shown by curvature of the bars
ilonoscope scanning linearity can be checked by injecting its signal and the grating genera-
tor signal into a monitor. The monoscope test pattern will have the grating pattern superimposed on it, and, with the horizontal and vertical bars set at a convenient number, the blocks of the test pattern will be subdivided by the bars. The same number of bars will divide each block equally when the scanning is linear.

Figure 1 shows a block diagram of the WA-3A Grating Generator.

A negative driving pulse of 15,750 cycles is amplified, clipped and differentiated to synchronize a multivibrator. With a pulse of short duration the multivibrator synchronizes over its entire range. The pulse output of this multivibrator which is the vertical bar signal is amplified and fed into a mixer stage.

A negative driving pulse of 60 cycles is amplified, clipped and differentiated to synchronize another multivibrator, the output of which is a multiple of 60 cycles. The multivibrator output is fed to a width control circuit where the pulse width can be adjusted to be 10 percent of the cycle over the entire frequency range. This pulse is the horizontal bar signal and is mixed with the vertical bar signal. The mixed signals are held to approximately equal levels by a limiter stage whose output can be adjusted to provide a range of contrast.

A standard blanking signal from the video sync generator is connected to a polarity control stage with output taken from the cathode or plate circuit (depending on the polarity desired). Separate tubes having a comsmon load combined the blanking and bar signals. A limiter stage prevents the bar signal from exceeding the blanking signal level.

The output of positive polarity is taken from the cathode of one output stage, with coupling from its plate to a second output stage. The output of negative polarity is taken from the cathode of the second output stage.

## INSTALLATION

The Type WA-MA Grating Generator is designed for mounting on a standard 19-inch rack. It may also be installed in a standard cabinet 21 inches $x 101 / 2$ inches $x 15$ inches. The
power supply is self contained, and connected for operation at 115 volts. Terminals are provided on the power transformer for operation at 105 or 125 volts.

The Type Wa-3A Grating Generator is designed for use in a video signal test system. Signals of negative polarity consisting of a horizontal drive of 15,750 cycles per second, a vertical drive of 60 cycles per second, and mixed blanking are obtained from a video synchronizing signal generator and fed to the appropriate connectors at the rear of the WA-3A chassis. The output is connected to a distribution amplifier channel. The video synchronizing signal from the synchronizing generator is connected to a second distribution amplifier channel from a 75 -ohm control with which the correct sync level can be adjusted. The output of the two distribution amplifier channels are connected together to provide a composite signal made up of grating, blanking and synchronizing signals. This composite signal is then connected to the input of each distribution amplifier channel serving a distribution line.

Television camera deflection linearity can be checked and adjusted in a similar manner by focusing the camera on a test chart.

Television receiver deflection linearity can be checked and adjusted by injecting the composite grating signal into the receiver video circuit or by remote pict-up of a transmitter modulated with the composite grating signal or grating signal and video test pattern superimposed.

For setting the linearity of monoscope canera and monitor equipment, the output of the WA-3A may be fed into one channel of a distribution amplifier, the monoscope camera fed into another channel and the output of the two channels from the distribution amplifier tied together and fed into the master monitor. To check the linearity of the monoscope camera it is necessary to adjust the master monitor linearity controls with the Grating Generator. Then adjust the monoscope linearity to conform. Field equipment may be preset by this method before remote pickup.

For a signal of standard negative polarity, with black bars, proceed as follows:

1. Turn "POWER" switch to "ON" and allow a short time for warm-up.
2. Turn the "CONTRAST" control fully counterclockwise.
3. Switch the output at the monitoring control switch panel to the monitor oscilloscope or to a separate oscilloscope.
4. Turn "BLANKING" switch to "ON" and adjust "OUIPUT" control until the output is between 1 and 2 volts. Blanking polarity should be set at the negative position at the rear of the chassis.
5. Adjust the sync signal level until it is 20 to 25 percent greater than the blanking level.
6. Turn "VERT. BARS" and "HOR BARS" switches to "ON" and adjust the "CONTRAST" control until the bar level is nearly the same as the blanking level.
7. Switch the signal to the monitor and adjust the number of horizontal and vertical bars by means of the respective "RANGE" and "FREQ." controls. If the return trace is observed, the blanking and sync level should be increased until it disappears.

The width of the vertical bars can be adjusted and is usually satisfactory between 50 and 100 percent of the cloclowise setting of the "WIDTH" control. This control affects the vertical bar frequency which necessitates readjustment of the "FREQ." control for the desired number of lines. The width of the horizontal bars can be adjusted to be equal to the width of the vertical bars. In some applications it may be desirable to produce white bars, in which case the "POLARITY" and "BLANKING" (rear of chassis) switches should be set at the $n+n$ position.

In an application where a signal of positive polarity is desired the "POLARITY" switch should be set to the $n+n$ and the "BLANKING" (rear of chassis) switch should be set to the n-n position.

When the grating signal is to be superimposed on a video test pattern, the "BLANKING" switch should be off.

When the synchronizing input voltage is too high the first space of the grating pattern may be wider than the succeeding spaces (see Figure 5). This can be corrected by inserting a sync level control at the WA-3A sync input circuit. A schematic of such a control is shown in Figure 2.

Each input signal circuit is brought out to two connectors at the rear of the chassis. When the generator is used at the end of a 75 -ohm line which is normally terminated, remove the termination and connect the line to its respective input connector. To terminate the line connect one of the special 75-ohm
terminating resistors (furnished with the WA-3A) to the other connector.

To use the generator at any point in a line, open the line and connect the ends to their respective input connectors.

## MAINTENANCE

## A schematic diagram of the WA-3A is shown

 in Figure 9.A table of operating voltages is shown in Figure 8. All voltages are measured with the plate voltage supply set at 250 volts, and are measured to ground unless otherwise noted. Any abnormal deviation from the values indicated should be investigated and corrective steps taken.

$$
\begin{aligned}
& f_{s .}=15750 \text { OR } 60 \\
& f_{M V}=15750(\mathrm{~N}) \text { OR } 60(\mathrm{~N}) \\
& \text { T.S. }=\frac{1}{f s}=\frac{1}{15750} \text { OR } \frac{1}{60} \\
& \text { T.MV }=\frac{1}{15750(\mathrm{~N})} \text { OR } \frac{1}{60(\mathrm{~N})} \\
& \begin{array}{l}
\text { Figure } 3
\end{array} \\
& \text { Frequeq94 } \\
& \text { Freck Pattern }
\end{aligned}
$$

The frequency range of the multivibrator can be checked by connecting a square wave generator set at 15750 or 60 cycles to the respective input circuits of the WA-3A. An oscilloscope is connected at the junction of the coupling capacitors between the clipper and the mul tivibrator. The pattern produced on the oscilloscope will be similar to that shown in Figure 3. The number of pips during one cycle $T_{s}$ is the multiple of the sync frequency at which the multivibrator is operating, and depends mainly on the RC circuit values and operating voltages. The multiple of the synchronizing frequency for the vertical and horizontal multivibrator is approximately as given in Figure 4.

The percent blanking times the multiple number equals the number of bars which will be lost when observed on a monitor or receiver kinescope.

When circuit checking the WA-3A with an oscilloscope, a low capacity attenuating cable will be required for all high frequency vertical bar signals. The signal pattern on the oscilloscope should be as shown on the schematic (Figure 8). A check of the width control circuit with an oscilloscope will show whether the horizontal bar signal pulse width can be

| VERTICAL BAR MV |  |  |
| :---: | :---: | :---: |
| Sync. Freq. $=15750$ cps |  |  |
| Width | Control at Minimum |  |

| HORI ZONTAL BAR MV |  |  |
| :---: | :---: | :---: |
| Sync. Freq. $=60 \mathrm{cps}$ |  |  |
| Range <br> Switch <br> Position | Multiple No. with <br> Frequency |  |
|  | Minimum | Maximum |
| 1 | 12 | 27 |
| 2 | 25 | 36 |
| 3 | 33 | 43 |
|  |  |  |
|  |  |  |

adjusted to approximately 10 percent of the period at the minimum and maximum frequency. The pulse width range is determined largely by the coupling capacity (390 mmfd.), grid resistance and bias.

With an oscilloscope connected to the WA-3A output (75-ohm load) a 60 cycld square wave signal applied to the blanking signal input should show a good square wave response. The response is affected by RC coupling values and electrolytic capacity values.

## REPLACEMENT PARTS LIST
