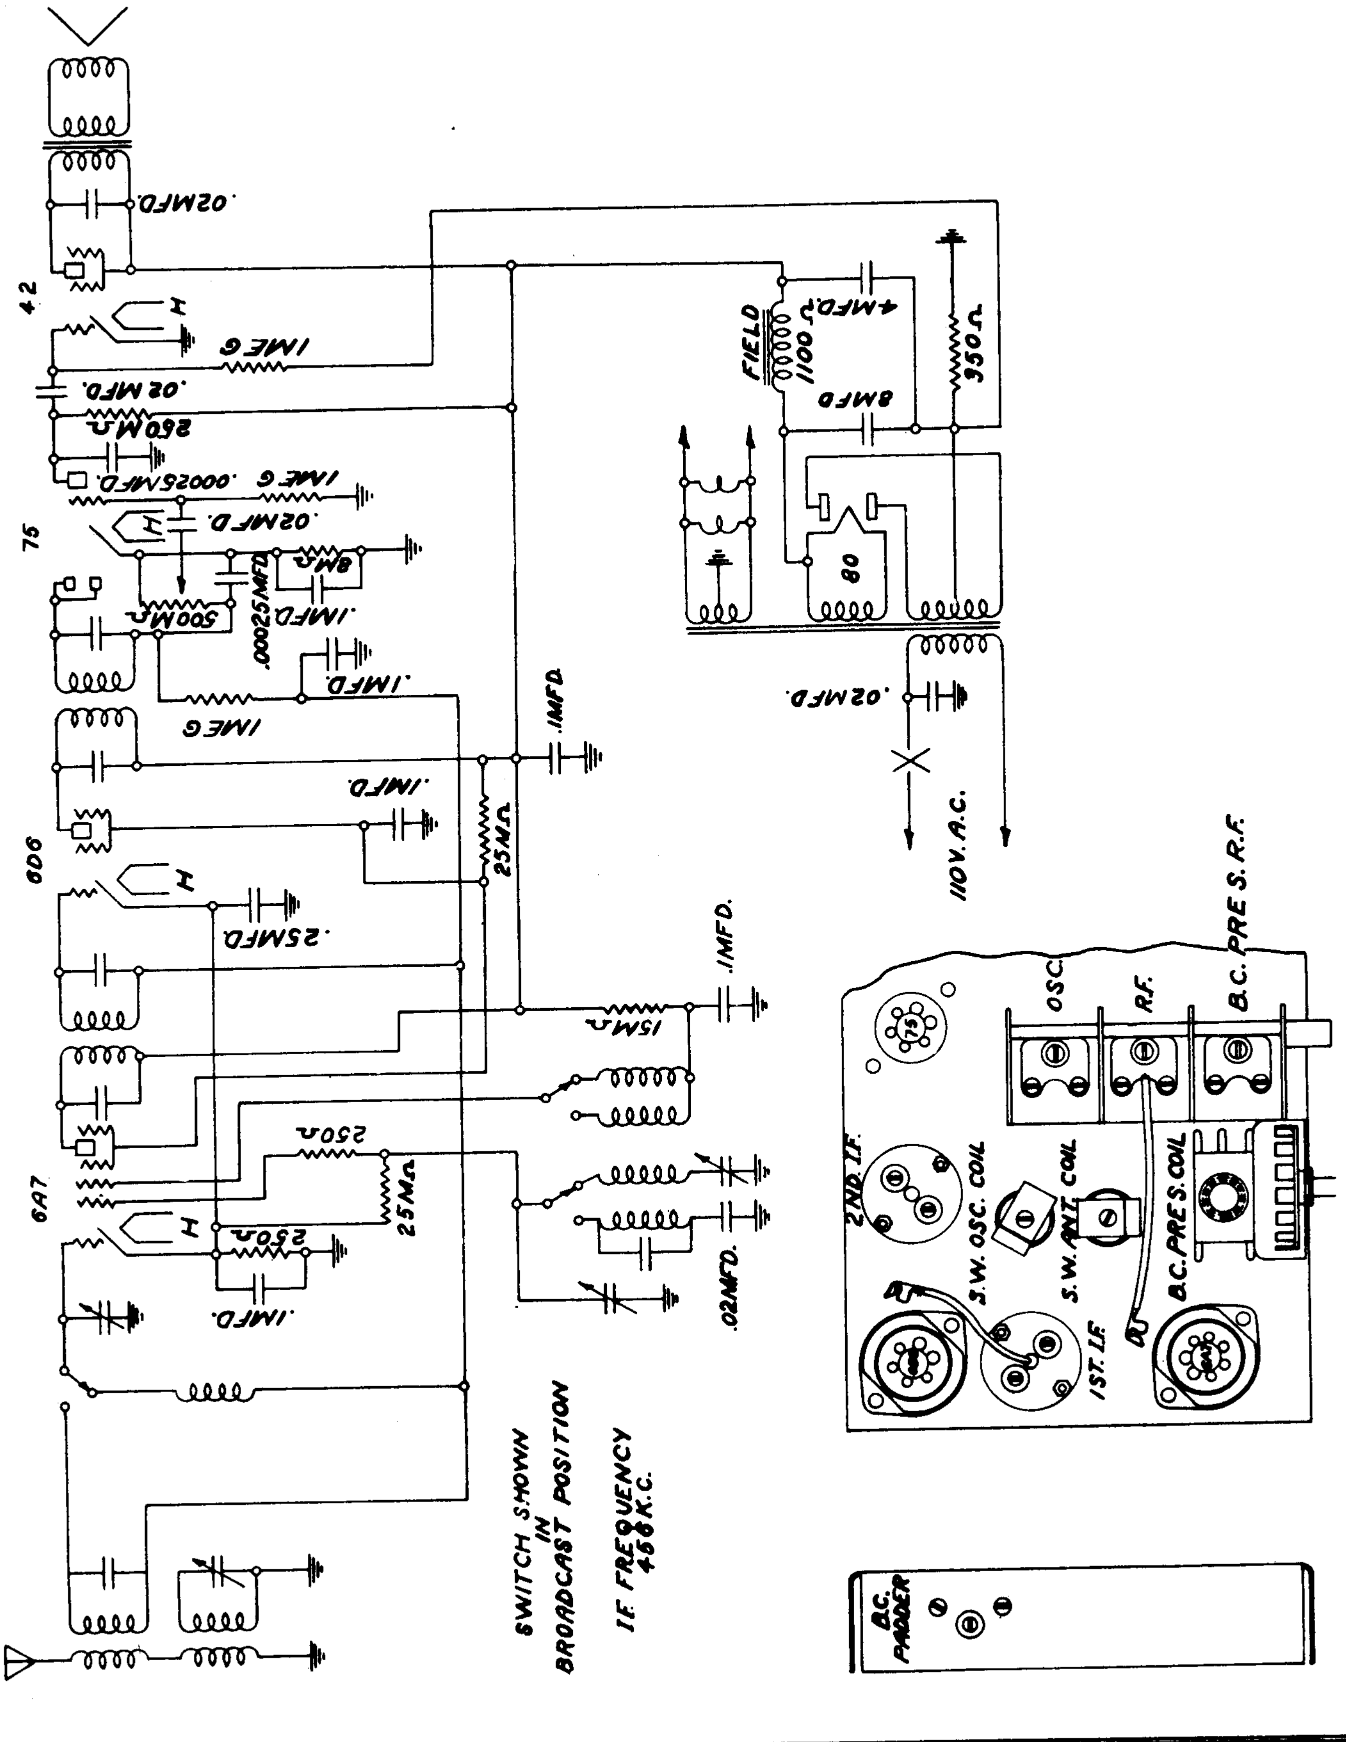
SEARS, ROEBUCK & CO.

MODELS 1907, 1939 & 1957



SEARS, ROEBUCK & CO.

MODELS 1907, 1939 & 1957

The alignment of this receiver requires the use of a test oscillator that will cover the frequencies of 456, 600, 1400, 6000 and 14,000 K.C. and output meter to be connected across the primary or secondary of the output transformers. If possible, all alignment should be made with the volume control on maximum and the test oscillator output as low as possible, to prevent the AVC from operating and giving false readings.

I. F. ALIGNMENT: Adjust the test oscillator to 456 K.C. and connect the output to the grid of the first detector tubes (6A7) through a .05 or .1 mfd. condenser. The ground on the test oscillator can be connected to the chassis ground. Align all four I. F. trimmers to peak or maximum reading on the output meter.

R. F. ALIGNMENT: Adjust the oscillator to 1400 K. C. and connect the output to the antenna post through a .0001 mfd. mica condenser to give the equivalent of an antenna about 60 feet. Set the receiver pointer to 1400 K. C. and adjust the rear gang condenser trimmer to peak. Next re-set the dial pointer on the receiver and the test oscillator to 600 K. C. Slowly increase or decrease the oscillator padding condenser and at the same time continuously tuning back and forth across the signal with the receiver until the maximum reading is obtained on the output meter. This adjustment seems a little complicated but is the easiest way to adjust the oscillator to the pre-selector or R. F. section. The padding condenser is located on the left-hand end of the chassis. Return to 1400 K. C. and again go over the adjustments at that frequency to be sure they have not been thrown out of adjustment.

SHORT WAVE BANDS

The foreign band of 19 to 49 meters can be adjusted by the two trimmers on the short wave coil located on the top of the chassis. Set the test oscillator to 14 megacycles. The oscillator coil is located near the 1st I. F. transformer.

The gang condenser trimmers are not to be used for alignment of the short wave band.

SERVICE HINTS

LOW VOLUME: This may be caused by weak or defective tubes (replace with set of tubes known to be in good condition), antenna disconnected from the receiver , open antenna coil, open or shorted by-pass condensers, or defective wave change switch.

LOW VOLTAGE: Low voltage may be caused by a defective 80 rectifier, low line voltage, a defective power transformer, or shorted by-pass condensers.

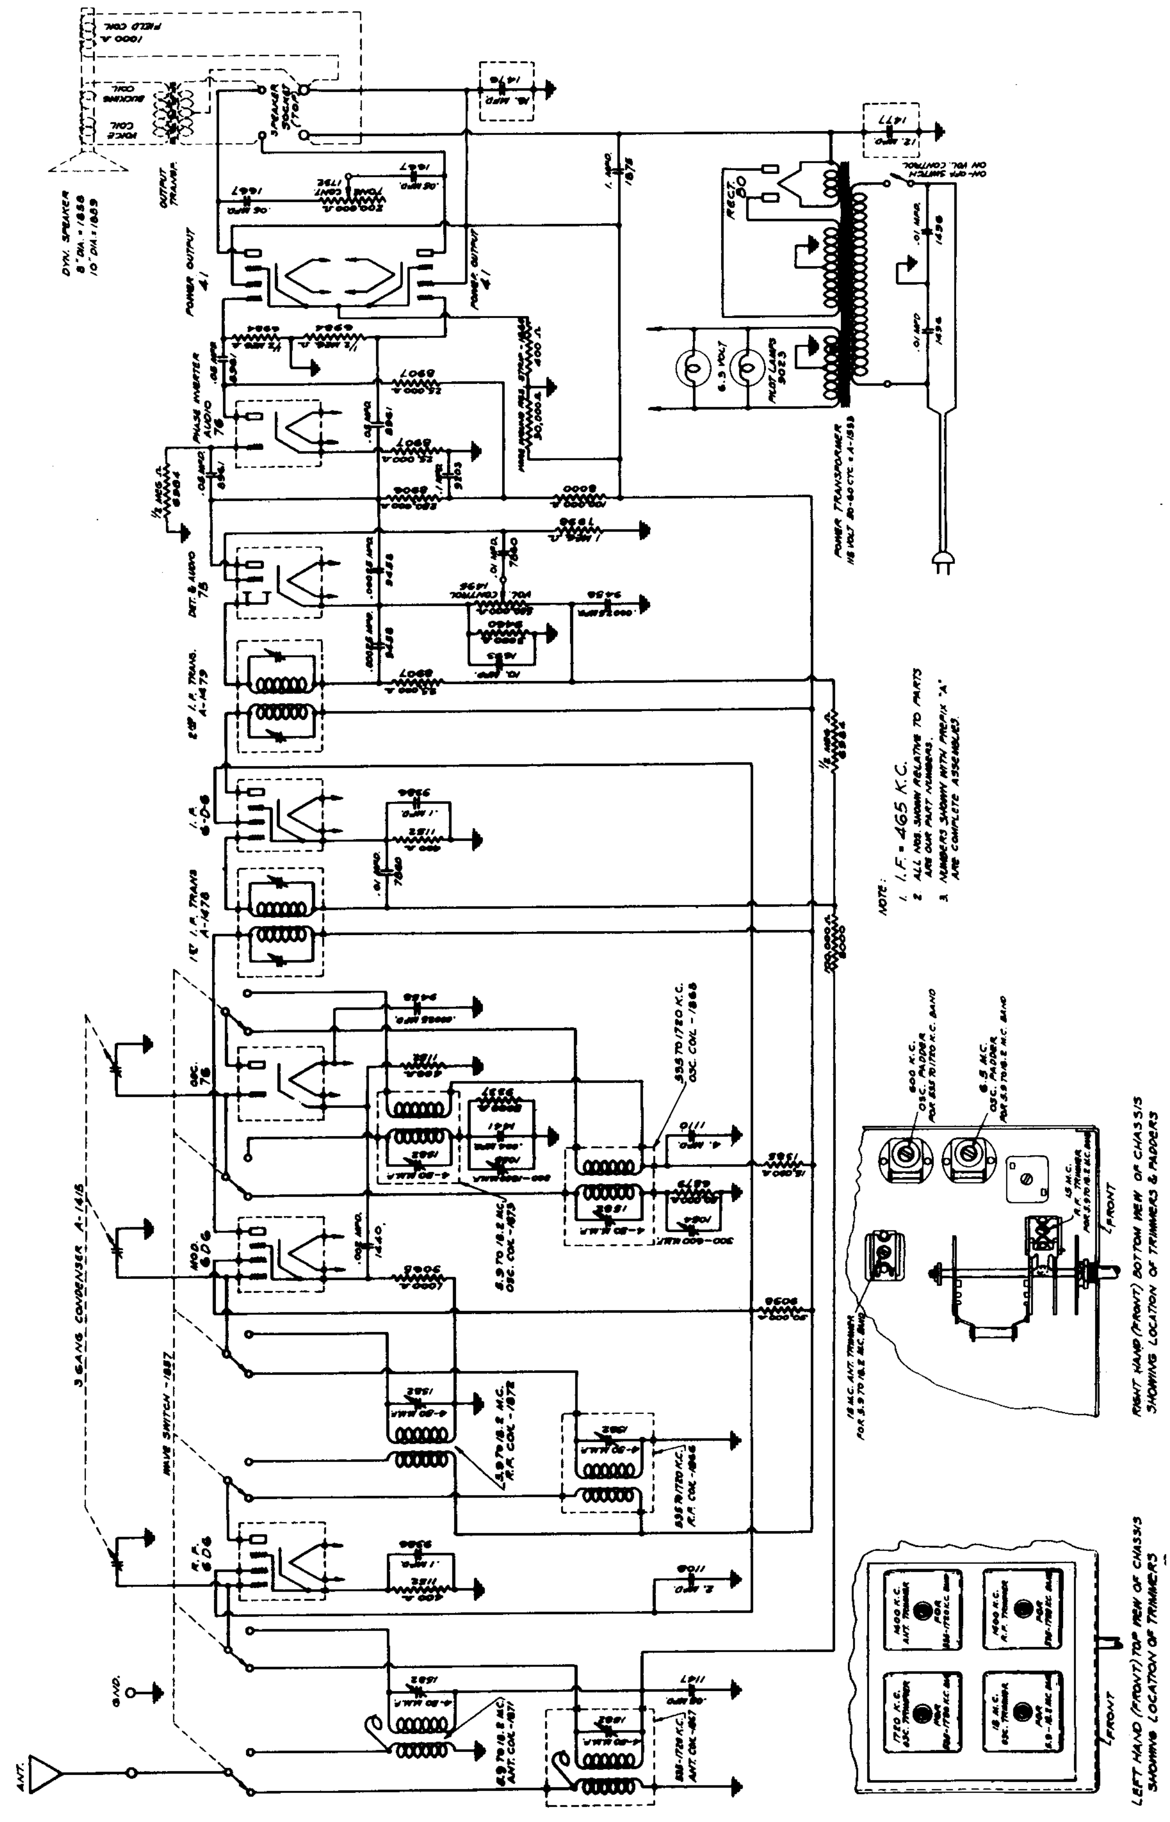
HUM: Excessive hum may be caused by a defective 80 tube, open filter condenser, or open audio grid lead.

DISTORTED REPRODUCTION: This may be caused by a defective 75 or 42 tube or a ground or open in the automatic volume control circuit. Check all circuits with an ohmmeter or continuity tester.

OSCILLATION: Most trouble from oscillation is due to open by-pass or defective filter condenser. The grid lead on the 75 tube may also cause a howl if it runs too close to the 42 tube.

SENTINEL RADIO CORP.

MODEL 6A



SENTINEL RADIO CORP.

MODEL 6A

INTERMEDIATE ALIGNMENT:

1. Connect the high side of the test oscillator output to the control grid of the 6D6 modulator tube. Leave the grid cap disconnected and connect a 1 meg ohm resistor from the modulator grid to the chassis base. Connect the ground side of the test oscillator to the receiver ground.

2. Set the test oscillator frequency to 465 kilocycles (this must be accurate).

3. Align the first intermediate transformer by turning one of the trimmer screws accessible through holes in the top of the transformer shields up and down (increasing and decreasing capacity) until maximum reading is obtained on the output meter, after which adjust the other trimmer screw of the same transformer for maximum sensitivity.

4. Adjust the other intermediate transformer in the same manner as the first IF transformer.

TO ALIGN THE VARIABLE CONDENSER:

It is important when aligning the gang condenser, padding and trimmer condensers to follow the procedure carefully, otherwise the receiver will be insensitive and the dial calibration will be incorrect. The coils located on the top of the chassis which have trimmer condensers mounted on them and the padding and trimmer condensers located underneath the chassis will be referred to by their function as indicated on the circuit diagram.

1. Connect the high output side of the test oscillator through a .00025 Mfd. condenser to the set antenna lead and the ground to the set ground.

2. Place the band selector switch for operation on the 18.2 to 5.9 megacycle band, tune the receiver dial, and set the test oscillator frequency to EXACTLY 18 MEGACYCLES. THEN TUNE IN THE 18 MEGACYCLE SIGNAL TO MAXIMUM OUTPUT BY ADJUSTING THE 18 MEGACYCLE OSCILLATOR TRIMMER. When adjusting this trimmer two peaks, the fundamental and the image peak, will be noticed. CARE MUST BE TAKEN SO THAT THE FUNDAMENTAL PEAK AND NOT THE IMAGE PEAK IS USED FOR ALIGNING THE RECEIVER AT 18 MEGACYCLES. Always back off the trimmer to minimum capacity, then screw down the trimmer (add capacity) until the first peak which is the fundamental and the proper one to use is tuned in. If the trimmer is screwed down beyond the point where the first peak is received the incorrect image peak will be tuned in. After completing adjustment of the oscillator trimmer at 18 megacycles always check to see if the proper peak has been used. To do this leave the test oscillator frequency at 18 megacycles, increase the output of the test oscillator and tune the receiver dial to approximately 17 megacycles. Vary the receiver dial slightly to the right and left of 17 megacycles, and if the fundamental peak was used in aligning at 18 megacycles the test oscillator signal will be heard at approximately 17 megacycles on the receiver dial. If it is not possible to receive the signal then the fundemental peak was not used and the 18 megecycle oscillator trimmer must be properly readjusted.

3. Leave the band selector switch for operation on the 18.2 to 5.9 megacycle band, tune the receiver dial and the test oscillator frequency to approximately 15 megacycles. Then, while rocking the gang condenser slightly to the right and left adjust the 15 megacycle antenna and R1 trimmer for maximum sensitivity.

4. With the band selector switch set for operation on the 5.9 to 18.2 megacycle band, tune the receiver dial, and set the test oscillator frequency to approximately 6.5 megacycles. While rocking the gang condenser slightly to the right and left adjust the 6.5 megacycle oscillator padder condenser for maximum 6.5 megacycle signal sensitivity.

5. Set the band selector switch for operation on the 535 to 1720 kilocycle band, turn the gang condenser to MINIMUM capacity, and set the test oscillator frequency to EXACTLY 1720 KILOCYCLES. BRING IN THIS 1720 KILOCYCLE SIGNAL TO MAXIMUM OUTPUT BY ADJUSTING THE 1720 KILOCYCLE OSCILLATOR TRIMMER.

6. With the band selector switch adjusted for operation on the 535 to 1720 kilocycle band tune the receiver dial and set the test oscillator frequency to EXACTLY 1400 KILOCYCLES. Adjust the 1400 kilocycle antenna and RF trimmers for maximum 1400 kilocycle sensitivity.

7. Leave the band selector switch for operation on the 1720 to 535 kilocycle band, tune the receiver dial, and set the test oscillator frequency to approximately 600 kilocycles. Then, while rocking the gang condenser slightly to the right and left adjust the 600 kilocycle oscillator padder for maximum 600 kilocycle signal sensitivity.

This completes the alignment and it is recommended that all the adjustments be gone over again, as generally it will be found that improved results can be obtained if this is done. Assuming that all tubes and component parts of the set are okeh, then extreme inaccuracies in the dial calibration, low sensitivity, and poor selectivity are indications that the alignment procedure has not been followed.

MODELS 73-AX & 73-BX

A. ALIGNMENT OF INTERMEDIATE-FREQUENCY STAGES.

(1) Turn on receiver and test oscillator, and allow both to operate several minutes before attempting to align any condensers.

(2) Connect "antenna" of test oscillator to grid cap of Type 78 first detector-oscillator tube and "ground" of test oscillator to chassis frame of receiver.

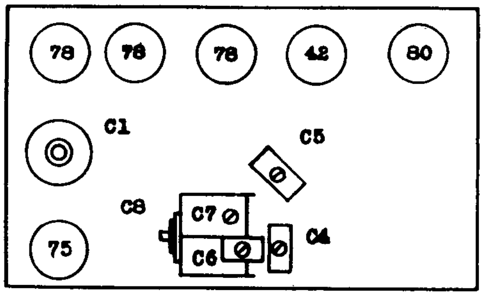
(3) Turn the band selector switch to the "broadcast" position and adjust the tone control completely to the left so that the "brilliant" tone is obtained.

(4) Adjust condenser C_4 (see Fig.) so that the adjusting nut is screwed all the way down and then turned back one-quarter turn.

(5) Adjust condenser C_5 so that the nut is turned about one-half way down.

(6) The dial pointer should point to the last line on the scale past 550 meters when the variable condenser rotor plates are completely meshed with the stator plates. If the dial pointer reads incorrectly it may be reset by first loosening the set-screws on the hub of the dial scale, holding the rotor plates fully in mesh and moving the dial scale until the last line on the scale past 550 meters is opposite the pointer on the escutcheon.

(7) Turn the condenser rotor plates all the way out and with the test oscillator adjusted for generating a signal of 456 kilocycles (657.8 meters) adjust condensers C_1, C_2, and C_3.



TOP VIEW

B. ALIGNMENT OF BROADCAST BAND AND LONG-WAVE BAND.

(1) Disconnect "antenna" lead of test oscillator from grid cap of first detector-oscillator tube and connect to the antenna terminal of the chassis.

(2) Tune the test oscillator and receiver to a wave-length of 200 meters (1500 kilocycles) and adjust condensers C_6 and C_7.

CAUTION: Extreme care should be taken in the preceding step so that the condensers are not adjusted to any other signal except the 200 meter wave-length of the signal generator or test oscillator.

(3) Turn the band selector switch to the "long-wave" position.

(4) Tune the test oscillator and receiver to 1,000 meters (300 kilocycles) and adjust condenser C_4.

(5) Adjust condenser C_8 (mounted on the side of the variable condensers) for maximum deflection of the output meter with the test oscillator adjusted for 1,000 meters.

(6) Tune the test oscillator and receiver to 1740 meters (172.5 kilocycles) and adjust condenser C_5 for maximum deflection of the output meter regardless of the dial setting.

(7) Repeat steps 5 and 6 until the adjustment of condenser C_5 does not affect the adjustment made in Step 5 (1,000 meters).

(8) Tune test oscillator and receiver for a wave length of 2,000 meters (150 kilocycles) and check for operation of the receiver.

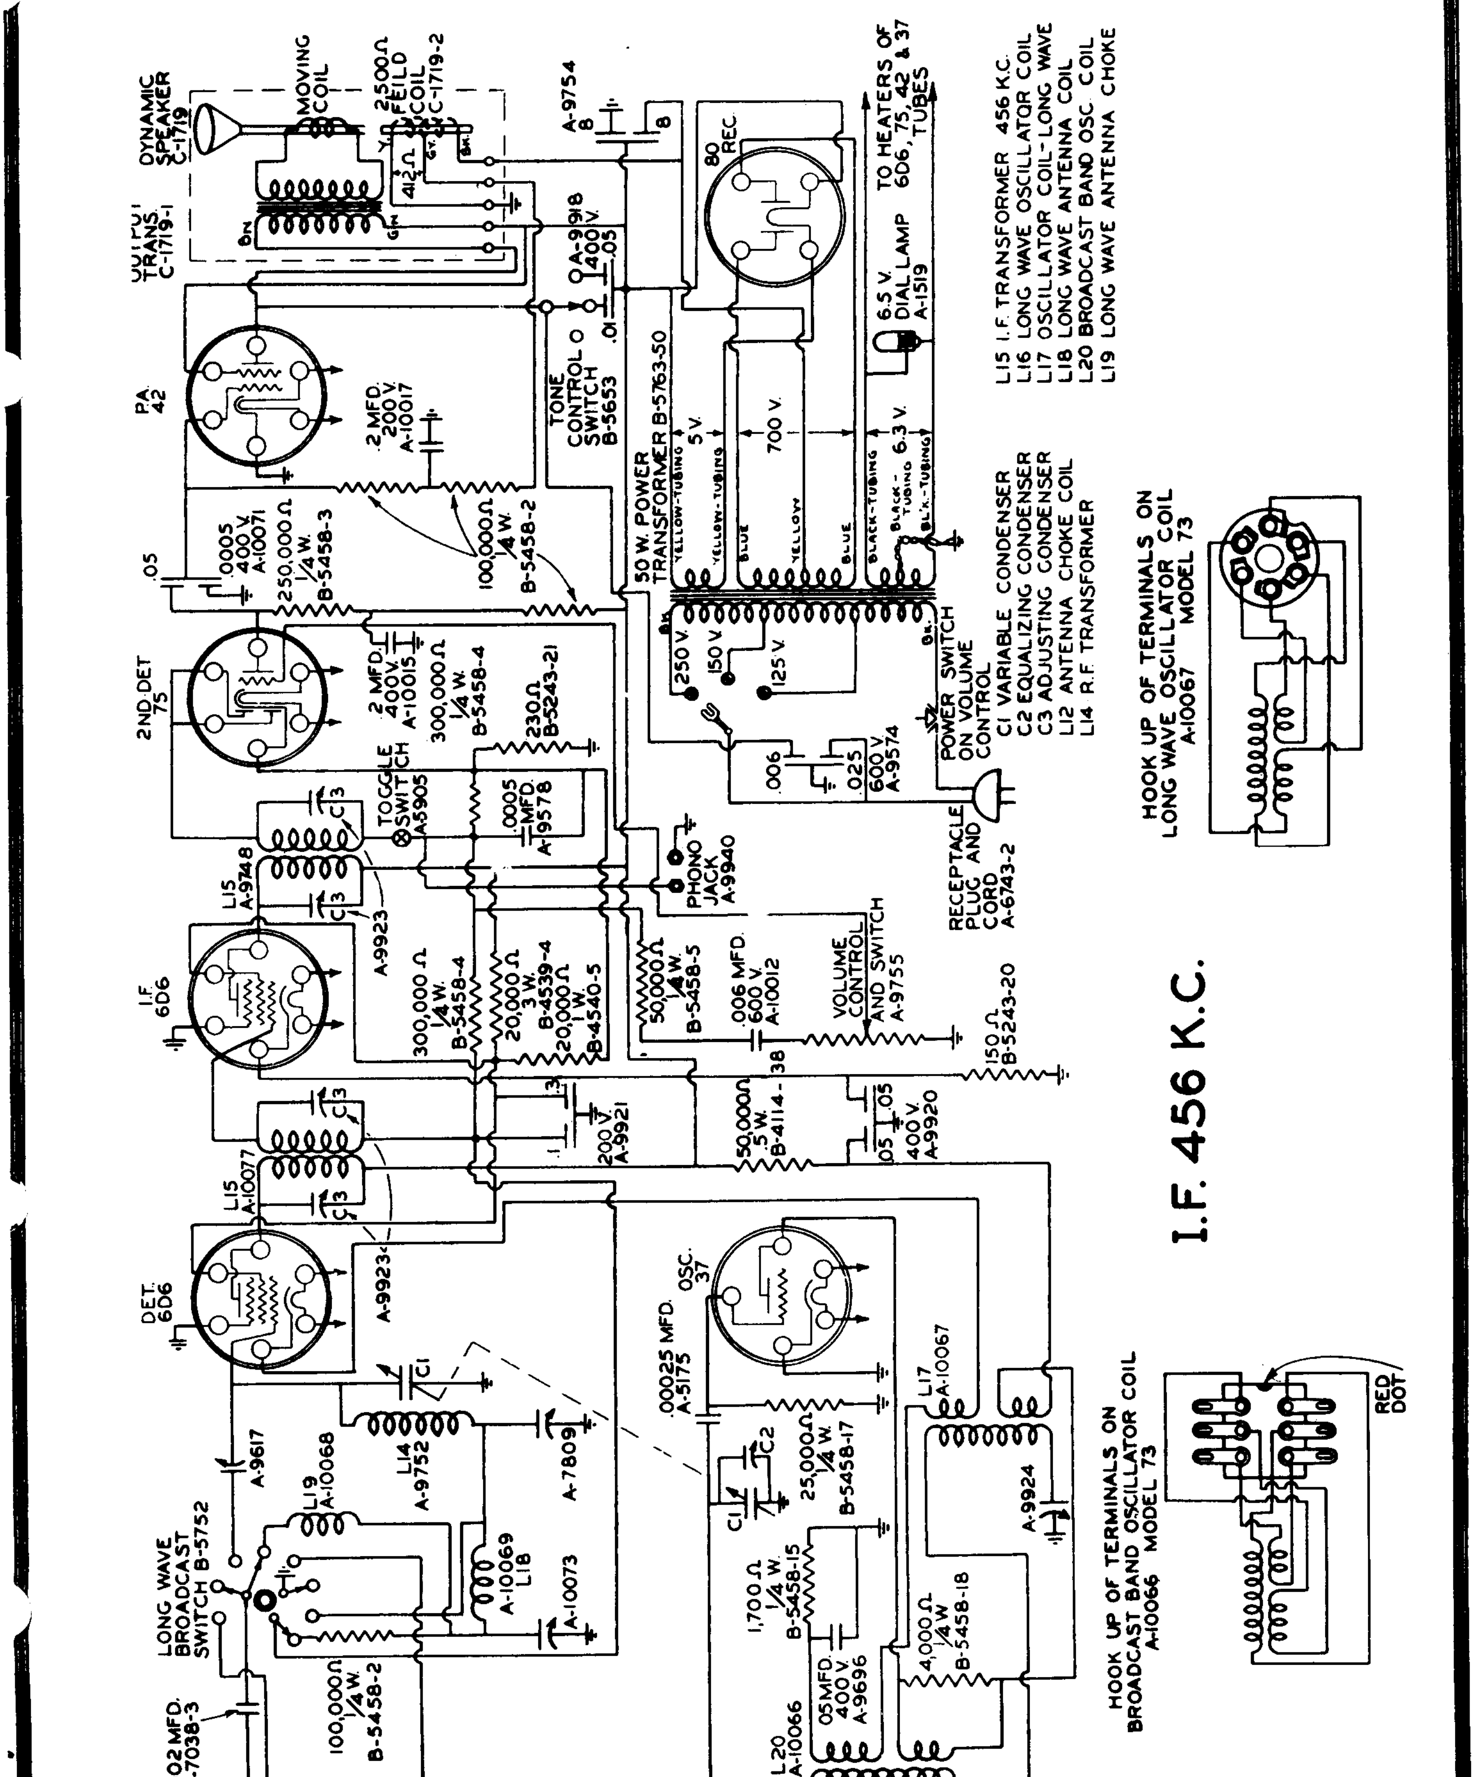
(9) Turn band selector switch back to "broadcast" position and tune test oscillator and receiver to 500 meters (600 kilocycles) and readjust condenser C_1 for maximum deflection of the output meter.

(10) Tune test oscillator and receiver to 200 meters (1500 kilocycles) and check for calibration and operation of the receiver. Repeat this procedure at 333 meters (900 kilocycles) and 500 meters (600 kilocycles.)

NOTE: Slight readjustments of the condenser C_6 will be required after the receiver is connected to the antenna with which it is to be used. This condenser should be adjusted by tuning in a weak distant station between 200 and 250 meters, and adjusting the condenser to a point of maximum volume. Once adjusted, it need not be changed unless the antenna system is altered. This adjustment ideally matches the receiver to operate on any antenna.

SPARKS-WITHINGTON COMPANY

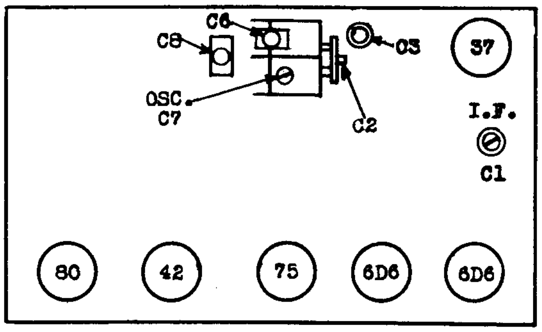
MODEL 73



SPARKS-WITHINGTON COMPANY
MODEL 73

A. ALIGNMENT OF INTERMEDIATE-FREQUENCY STAGES.

(1) Turn on receiver and test oscillator, and allow both to operate several minutes before attempting to align any condensers.



(2) Connect "antenna" of test oscillator to grid cap of Type 6D6 first detector tube and "ground" of test oscillator to chassis frame of receiver.

NOTE: It is advisable to read carefully the operating instructions included with the test oscillator.

(3) Turn the band selector switch to the "broadcast" position and adjust the tone control completely to the left so that the "brilliant" tone is obtained Connect the black lead and the black and red tracer lead to chassis.

(4) Adjust condenser C_4 so that the adjusting nut is screwed all the way down and then turned back one-quarter turn.

(5) Adjust condenser C_5 so that the nut is turned about one-half way down.

(6) The dial pointer should point to the last line on the scale past 550 meters when the variable condenser rotor plates are completely meshed with the stator plates. If the dial pointer reads incorrectly it may be reset by first loosening the set-screws on the hub of the dial scale, holding the rotor plates fully in mesh and moving the dial scale until the last line on the scale past 550 meters is opposite the pointer on the escutcheon.

(7) Turn the condenser rotor plates all the way out and with the test oscillator adjusted for generating a signal of 456 kilocycles (657.8 meters) adjust I.F. trimmers for maximum output.

B. ADJUSTING 456 KC REJECTOR CIRCUIT.

(1) Connect oscillator antenna lead to yellow wire (antenna) of set and ground of oscillator to chassis.

(2) Tune test oscillator to 456 KC.

(3) With volume control on full position adjust wave trap condenser C_2 for <u>minimum</u> output.

C. ALIGNMENT OF BROADCAST BAND AND LONG-WAVE BAND.

(1) Disconnect "antenna" lead of test oscillator from grid cap of first detector tube and connect to the antenna terminal of the chassis.

(2) Tune the test oscillator and receiver to a wave-length of 200 meters (1500 kilocycles) and adjust condensers C_6 and C_7.

CAUTION: Extreme care should be taken in the preceding step so that the condensers are not adjusted to any other signal except the 200 meter wave-length of the signal generator or test oscillator.

(3) Turn the band selector switch to the "long-wave" position.

(4) Tune the test oscillator and receiver to 1,000 meters (300 kilocycles) and adjust condenser C_4.

(5) Adjust condenser C_8 and C_4 for maximum deflection of the output meter with the test oscillator adjusted for 1,000 meters.

(6) Tune the test oscillator and receiver to 1740 meters (172.5 kilocycles) and adjust condenser C_5 for maximum deflection of the output meter regardless of the dial setting.

(7) Repeat steps 5 and 6 until the adjustment of condenser C_5 does not affect the adjustment made in Step 5 (1,000 meters).

(8) Tune test oscillator and receiver for a wave length of 2,000 meters (150 kilocycles) and check for operation of the receiver.

(9) Turn band selector switch back to "broadcast" position and tune test oscillator and receiver to 500 meters (600 kilocycles) and readjust condenser C_1 for maximum deflection of the output meter.

(10) Tune test oscillator and receiver to 200 meters (1500 kilocycles) and check for calibration and operation of the receiver. Repeat this procedure at 333 meters (900 kilocycles) and 500 meters (600 kilocycles).

NOTE: Slight readjustments of the condenser C_6 will be required after the receiver is connected to the antenna with which it is to be used. This condenser should be adjusted by tuning in a weak distant station between 200 and 250 meters, and adjusting the condenser to a point of maximum volume. Once adjusted, it need not be changed unless the antenna system is altered. This adjustment ideally matches the receiver to operate on any antenna.

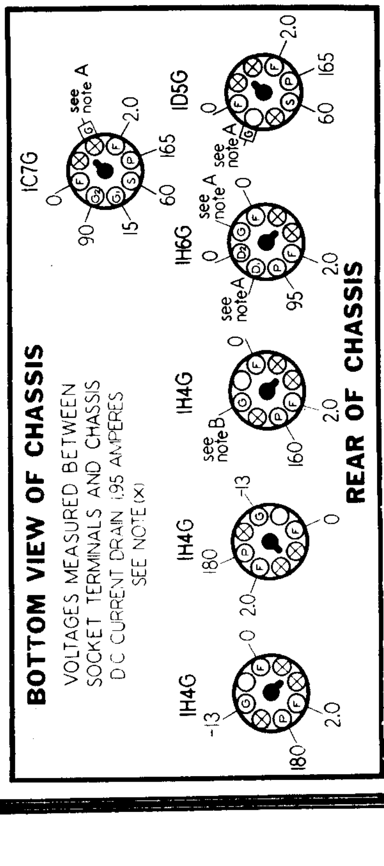
SOCKET VOLTAGES

A BATTERY VOLTAGE 6.0 VOLTS DIAL TUNED TO 530 KC.



IMPORTANT: Use a high resistance voltmeter of 1,000 ohms per volt.

NOTE A: The grid bias for the 1C7G, 1D5G, 1H6G and the A.V.C. delay voltage for one diode of the 1H6G is —2.7 volts measured across resistor 63.

NOTE B: The grid bias on the 1H4G 1st audio tube is —13.0 volts measured across resistors 27 and 63.

NOTE (X): These terminals indicate tube pins which are not internally connected to any element.

STEWART-WARNER CORPORATION

MODELS R-164-D CHASSIS, 1641-D TO 1649-D

CALIBRATION AND ALIGNMENT

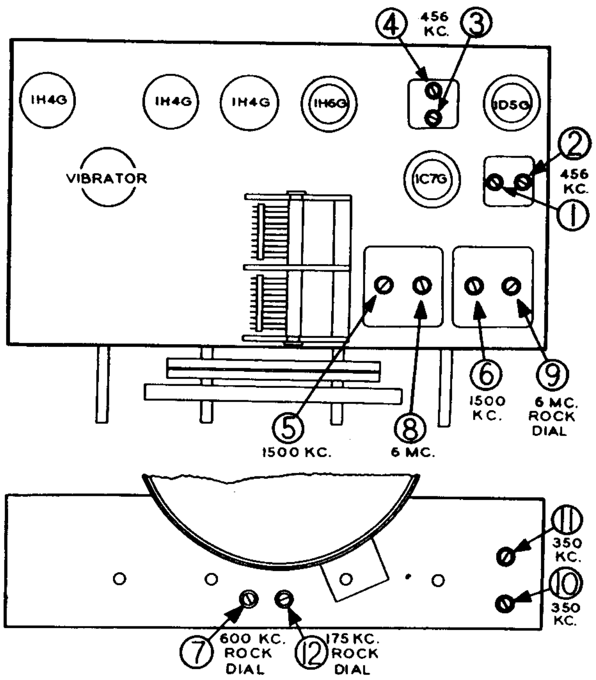
ALIGNING EQUIPMENT: For proper alignment, an output meter and an accurately calibrated oscillator with a tuning range from 175 KC. to 6 MC. are required.

Connect the output meter across the plates of the output tubes. Convenient points to make the plate connections are the yellow wires on the speaker terminal strip.

ALIGNING THE I.F. AMPLIFIER: Turn the volume control to maximum volume position and keep it in this position throughout the entire alignment procedure. Turn the range switch to the broadcast position (center position).

Connect the test oscillator output leads to the 1C7G control grid and chassis with a .1 mfd. condenser in series with the oscillator output. Set the oscillator to exactly 456 KC. Set the receiver dial at any point where it has no tuning effect on the oscillator signal.

Adjust the four I.F. trimmers, Nos. 1, 2, 3 and 4, for maximum output meter deflection, then repeat the trimmer adjustment.



TRIMMER LOCATIONS

Trimmer Number		Alignment Frequency
1-2-3-4	1st and 2nd I.F. transformer trimmers	456 KC.
5	Broadcast oscillator shunt trimmer	1500 KC.
6	Broadcast antenna shunt trimmer	1500 KC.
7	Broadcast oscillator series padder	600 KC.
8	Short wave oscillator shunt trimmer	6 MC.
9	Short wave antenna shunt trimmer	6 MC.
10	Long wave oscillator shunt trimmer	350 KC.
11	Long wave antenna shunt trimmer	350 KC.
12	Long wave oscillator series padder	175 KC.

BROADCAST BAND CALIBRATION AND ALIGNMENT: With the gang condenser in full mesh, the dial pointer should be on the yellow horizontal line below 530 KC. on the dial scale.

Leave the range switch in the center position. Connect a 400 or 500 ohm carbon resistor in series with the oscillator output and the receiver antenna lead (blue wire in the back of the chassis). Connect the grounded oscillator output wire to the receiver ground lead (black wire in back of chassis).

Adjust the test oscillator to exactly 1500 KC. Tune in the 1500 KC. oscillator signal or a station above 1300 KC. on the dial and determine whether the dial calibration is correct at the high frequency end of the dial. If the calibration is correct, do not adjust the broadcast oscillator shunt trimmer No. 5. If the calibration is incorrect, adjust trimmer No. 5 to give proper calibration.

Carefully tune the receiver to the 1500 KC. oscillator signal and adjust trimmer No. 6 for maximum output.

Adjust the test oscillator to 600 KC. and tune the receiver to the signal. Adjust trimmer No. 7 for maximum output. Then try to increase the output meter reading by detuning No. 7 slightly and retuning the receiver dial. If the output goes down, detune the trimmer in the opposite direction. Continue detuning the trimmer and retuning the receiver dial until maximum output meter deflection is secured. This operation is commonly known as "rocking" and when performed as described will give maximum selectivity and sensitivity even though the dial may be slightly off calibration at 600 KC.

Repeat the adjustment of Nos. 5 and 6 at 1500 KC.

SHORT WAVE BAND CALIBRATION AND ALIGNMENT: Turn the range switch to the short wave band (maximum counter-clockwise position).

Adjust the test oscillator to exactly 6.0 MC.

Tune in the 6 MC. oscillator signal at or near 6 MC. on the receiver dial to determine whether the receiver dial calibration is correct at 6 MC. If it is, do not adjust the short wave band oscillator shunt trimmer No. 8. If the calibration is incorrect, set the dial pointer to 6 MC. on the dial, and adjust the oscillator shunt trimmer No. 8 until the oscillator signal comes in at this point. If there are two peaks, the proper one is that with the trimmer screw farthest out.

Carefully tune the receiver to the signal and adjust trimmer No. 9 for maximum output. Then try to increase the output by detuning No. 9 slightly and retuning the receiver. Continue detuning No. 9 and retuning the receiver until the output meter deflection is a maximum.

LONG WAVE BAND CALIBRATION AND ALIGNMENT: Turn the range switch to the long wave band position (maximum clockwise position) and adjust the test oscillator to exactly 350 KC.

Tune in the oscillator signal at or near 350 KC. on the receiver dial to determine whether the dial calibration is correct at this point. If it is, do not adjust trimmer No. 10. If the calibration is incorrect, set the receiver dial pointer to 350 KC. and adjust trimmer No. 10 for maximum output.

Carefully tune the receiver to the signal, then adjust trimmer No. 11 for maximum output.

Adjust the test oscillator to 175 KC. and tune in the signal at or near 175 KC. on the receiver dial. Adjust padder No. 12 for maximum output, then try to increase the output by detuning padder No. 12 and retuning the receiver dial.

Repeat the adjustment of trimmers Nos. 10 and 11 at 350 KC.

PROPER SIZE OF FUSE

The early production of this model was equipped with 3-ampere fuses. If one of these blow out, and if there is nothing wrong in the set to cause it to blow, replace with a 4-ampere fuse.

MISCELLANEOUS PARTS

Part Number	Description	List Price
67032	Felt washer for back of knobs, per C	$0.35

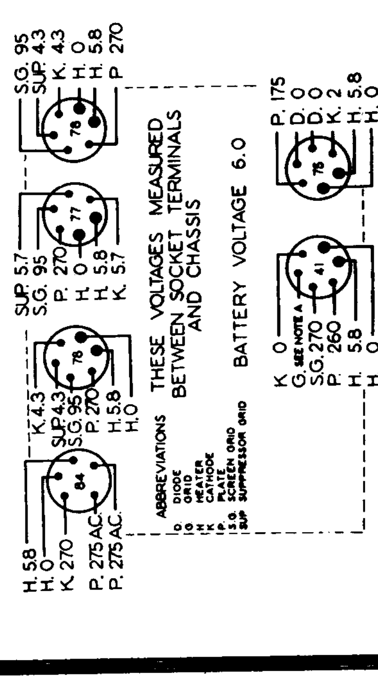
SOCKET VOLTAGES

BOTTOM VIEW OF CHASSIS



IMPORTANT: Use high resistance voltmeter of 1000 ohms per volt. Readings will vary depending upon range of meter. Make allowances for battery voltage variations.

NOTE A: The actual bias on the grid of the 41 tube is —23 volts which must be measured from chassis to the ungrounded filter choke terminal. Due to the high resistance of the grid leak, the voltmeter will show only about —1 volt at the grid.

STEWART-WARNER CORPORATION

MODEL 1312 AUTO RADIO

CIRCUIT DESCRIPTION

In the R-131 Chassis, the incoming signal is tuned and amplified in the 78 R.F. stage. Further amplification and frequency conversion to 177.5 KC. take place in the 77 combination first detector and oscillator tube.

The 177.5 KC. signal is amplified in the I.F. stage, using a 78 type tube, and then rectified in the diode section of the 75 second detector tube. The rectified current produces a modulated D.C. voltage across the diode load resistor No. 7. The audio component of this voltage appears across the 500,000 ohm volume control. Any part or all of this audio signal may be impressed on the triode section of the 75 tube where amplification takes place.

The modulated drop across resistor No. 7 is filtered and applied to the grids of the 78 R.F. and I.F. tubes to provide A.V.C.

POWER SUPPLY PROTECTIVE RESISTOR

The filter system and the rectifier tube are protected against breakdown during the warming-up period by the Globar resistor connected across the high voltage secondary of the power transformer (No. 12 in the circuit diagram). This resistor drops rapidly in resistance as the voltage across it rises, so that it acts as a load on the power transformer during the warm-up period and keeps the voltage below the danger point until the tubes are heated and take their normal current. Because of its unique voltage characteristics, the Globar resistor cannot be tested with an ordinary ohmmeter, since it will show a resistance of several megohms.

CALIBRATION AND ALIGNMENT

A good modulated oscillator and a sensitive output meter are necessary for proper calibration and alignment of the R.F. and I.F. stages of this receiver. The output of the oscillator must be adjustable to give a very weak signal which will not actuate the A.V.C. of the receiver. The output meter must be sensitive enough to give sufficient reading with such a weak signal.

The output meter should be connected from the 41 plate to ground through a .25 mfd. condenser or across the voice coil, depending upon its sensitivity. A convenient point to connect the 41 plate is the terminal of the tone control switch.

During all calibration and alignment adjustments, keep the volume control full on.

I. F. ALIGNMENT

The I.F. trimmers are located on the top of the I.F. transformers which may be reached by removing the front cover. The modulated oscillator should be set to exactly 177.5 K.C. and connected from the 77 control grid to ground. Adjust the oscillator output to give about half-scale reading of the output meter. Tune the set to make certain that no station or signal is tuned in since this would affect the output meter reading. Adjust all three I.F. trimmers to give maximum output reading.

In adjusting the I.F. transformer trimmers, it is desirable to use a bakelite screw driver or one having only a small metal tip. After the I.F. trimmers have been aligned once, go back and repeat the procedure, since any adjustment of one will affect the others to some extent.

DIAL CALIBRATION

The dial of the Auto Radio is calibrated in kilocycles, except that the last two zeros have been omitted. Inasmuch as changes in the position of the flexible shafts may cause the calibration to vary, the dial can be calibrated as follows:

Tune in a station of known frequency between 800 and 1100 K.C. Insert a screw driver in the slotted shaft on the rear of the control head. Hold the tuning control knob so that the station remains tuned in properly and by turning the screw driver adjust the dial pointer so that it indicates the station frequency.

If the set is badly out of calibration such that it calibrates correctly at one part of the dial but not at another, it is necessary to adjust the oscillator shunt trimmer as explained below.

The gang condenser trimmers can be reached by removing the back cover. Connect a .00025 mfd. mica condenser in series with the output of the test oscillator and the aerial lead of the receiver. This condenser is absolutely necessary to secure proper alignment of the antenna stage.

Set the test oscillator to exactly 600 K.C. Tune the radio set to maximum volume. Calibrate the dial at the low frequency end by setting the pointer to read exactly 6.0 (600 K.C.).

Set the test oscillator to exactly 1400 K.C. Turn the tuning knob until the dial pointer indicates 14.0 (1400 K.C.) and then adjust the oscillator shunt trimmer (third one from shaft end of the variable condenser) until the signal is received with maximum output. Then adjust the other two gang condenser trimmers as directed under R.F. alignment.

R. F. ALIGNMENT

With the test oscillator set to approximately 1400 K.C., tune the set very carefully for maximum output.

Adjust the output of the oscillator to the minimum value which will give sufficient output meter deflection. Adjust the two trimmers nearest to the shaft end of the gang condenser to give maximum output meter reading.

MISCELLANEOUS PARTS NOT SHOWN ON DIAGRAM

Part No.	Description	List Price
12606	Receiver mtg. nut (5/16—18 hex.)	$0.02
81346	1 lug terminal strip	.04

WELLS-GARDNER & CO.

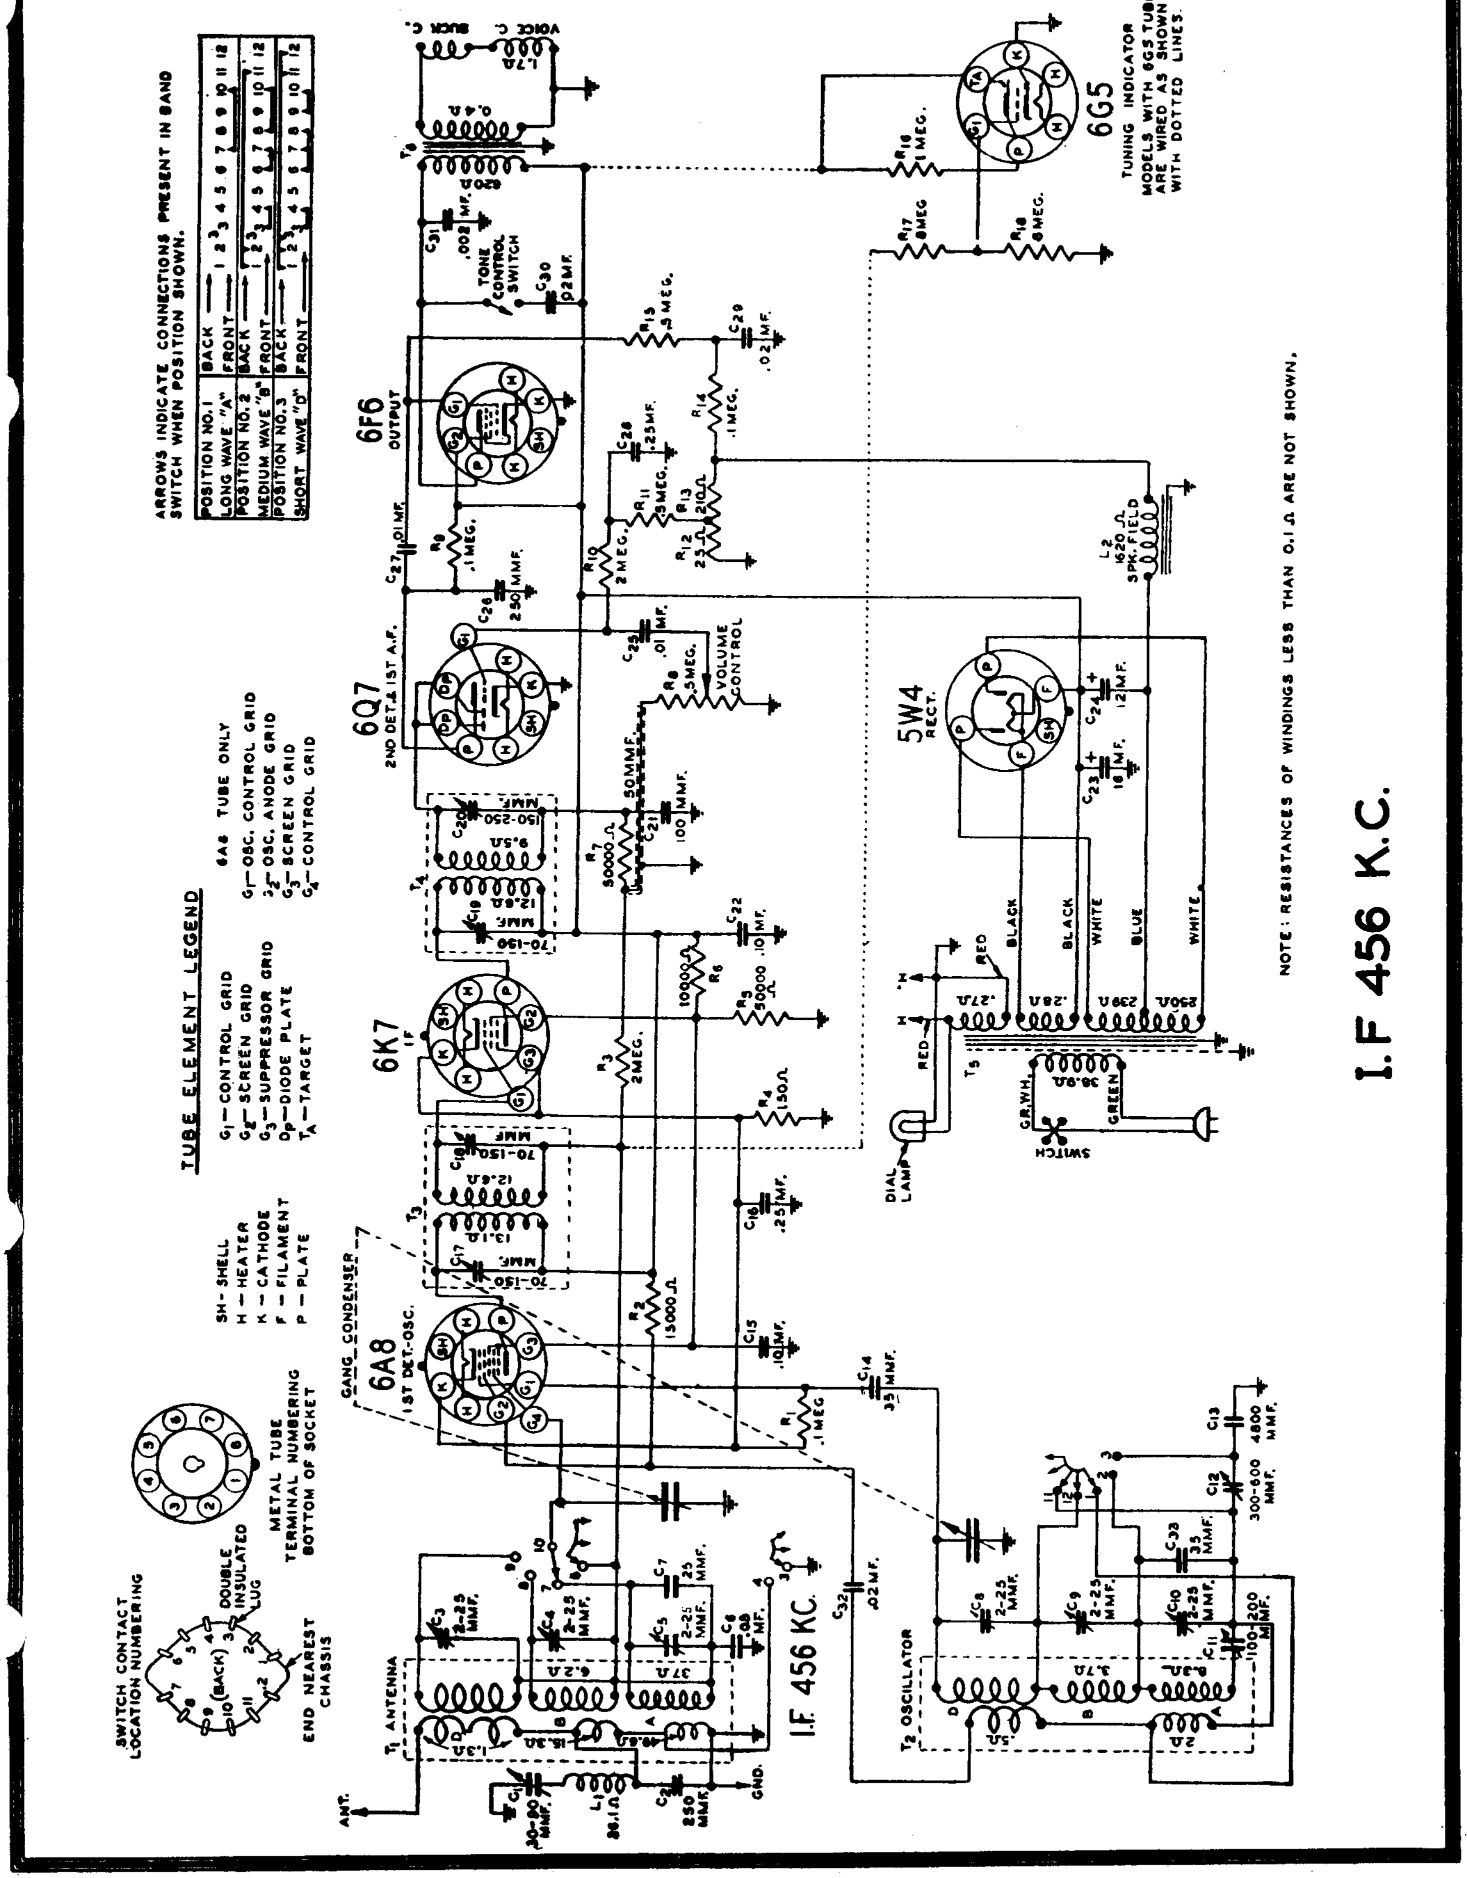
MODELS 5F & 5FL



WELLS-GARDNER & CO.

MODELS 5F & 5FL

Correct alignment is extremely important in connection with multi-band radios. The receivers are all properly aligned at the factory with precision instruments and realignment should not be attempted unless all other possible causes of the faulty operation have first been investigated and unless the service technician has the proper equipment.

A signal generator that will provide an accurately calibrated signal at 456, 380, 350, 165, 1730, 1500, 600, 18,300 and 15,000 KC and an output indicating meter are required. It will be practically impossible to align the receiver if unsatisfactory apparatus is used.

Use a non-metallic screwdriver for the adjustments. **Be sure to align the radio in the order as given below.**

I. F. Adjustment

Set the signal generator for a signal of 456 KC.

Connect the output of the signal generator through a .1 mf. condenser to the grid of the 1st detector.

Connect the ground lead of the receiver to the ground post of the signal generator.

Turn the band switch to the Range B position (medium wave band).

Turn the volume control to the maximum position.

Attenuate the signal from the signal generator to prevent the levelling-off action of the AVC.

Then adjust the four I.F. trimmers until maximum output is obtained. The adjusting screws for these condensers are reached from the top of the chassis, and the location is shown in Fig. 3.

Connect the antenna lead of the receiver through a 200 mmf. condenser to the output of the signal generator, and adjust the I.F. wave trap trimmer (C1) for minimum output. The location of this trimmer is shown in Fig. 3.

Range D Alignment

After the procedure for the alignment of each range, as explained below, is completed, it is advisable to repeat the procedure as a final check.

CAUTION—When aligning the short wave bands be sure NOT to adjust at the image frequency. This can be checked as follows: Let us say the signal generator is set for 15000 KC. The signal will then be heard at 15000 KC on the dial of the radio. The image signal, which is much weaker, will be heard at 15000 less 912 KC, or 14088 KC. It may be necessary to increase the input signal to hear the image.

18,300 KC Adjustment

Set the signal generator for 18,300 KC.

Connect the antenna lead of the receiver through a 400 ohm resistor to the output of the signal generator.

Turn the rotor of the tuning condenser to the full open position.

Turn the band switch to the Range D position (short wave band).

For this and **all** subsequent adjustments keep the volume control at the maximum position and attenuate the signal from the signal generator to prevent AVC action.

Adjust the oscillator Range D trimmer (C8) until maximum output is obtained. See Fig. 3 for location of this trimmer.

15,000 KC Adjustment

Set the signal generator for 15,000 KC.

Turn the rotor of the tuning condenser carefully until maximum output is obtained.

Adjust the antenna Range D trimmer (C3) to maximum.

When adjusting the antenna Range D trimmer, it will be necessary at the same time to turn the tuning condenser rotor slowly back and forth until the peak of greatest intensity is obtained.

Do not change the setting of the oscillator Range D trimmer.

Range B Alignment

1730 KC Adjustment

Set the signal generator for 1730 KC.

Turn the rotor of the tuning condenser to the full open position.

Turn the band switch to the medium wave position.

Connect the antenna lead of the receiver through a 200 mmf. condenser to the output of the signal generator.

Adjust the oscillator Range B trimmer (C9) until maximum output is obtained. The location of this trimmer is shown in Fig. 3.

1500 KC Adjustment

Set the signal generator for 1500 KC.

Turn the rotor of the tuning condenser carefully until maximum output is obtained.

Loosen the screw of the large pointer and set the pointer at the 1500 KC mark on the standard wave band scale. Retighten the screw.

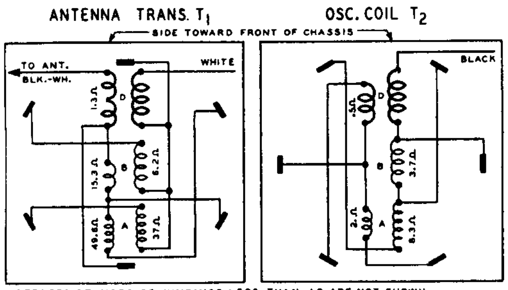
Adjust the antenna Range B trimmer (C4) to maximum.

Do not change the setting of the oscillator Range B trimmer.

600 KC Adjustment

Set the signal generator for 600 KC.

Turn the tuning condenser rotor until maximum output is obtained.



NOTE: RESISTANCES OF WINDINGS LESS THAN .1Ω ARE NOT SHOWN

R.F. and Oscillator Coil Base Terminal Arrangement and D.C. Resistance

Turn the rotor slowly back and forth at the same time adjusting the 600 KC trimmer (C12) until the peak of greatest intensity is obtained. See Fig. 3 for location of this trimmer.

Range A Alignment

380 KC Adjustment

Set the signal generator for 380 KC.

Turn the rotor of the tuning condenser to the full open position.

Turn the band switch to the Range A position (long wave band).

Adjust the oscillator Range A trimmer (C10) until maximum output is obtained. The location of this trimmer is shown in Fig. 3.

350 KC Adjustment

Set the signal generator for 350 KC.

Turn the rotor of the tuning condenser carefully until maximum output is obtained.

Adjust the antenna Range A trimmer (C5) to maximum.

Do not change the setting of the oscillator Range A trimmer.

165 KC Adjustment

Set the signal generator for 165 KC.

Turn the tuning condenser rotor until maximum output is obtained.

Turn the rotor slowly back and forth at the same time adjusting the 165 KC trimmer (C11) until the peak of greatest intensity is obtained. See Fig. 3 for location of this trimmer.

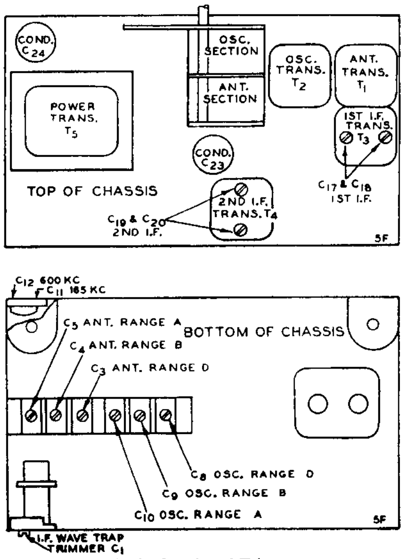


Fig. 3—Location of Trimmers

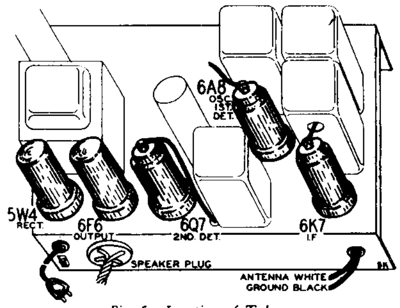

Fig. 5—Location of Tubes

Voltage Chart

The voltage readings are taken with a voltmeter having a resistance of 1000 ohms per volt.

The standard metal tube socket terminal numbering system (bottom of socket) is shown in Fig. 6. On the schematic circuit diagram, Fig. 2, is a list giving the complete names of the tube elements and the corresponding symbols as used on the sockets on the schematic.

Correct alignment is extremely important in connection with all wave radios. The receivers are all properly aligned at the factory with precision instruments and realignment should not be attempted unless all other possible causes of the faulty operation have first been investigated and unless the service technician has the proper equipment.

A signal generator that will provide an accurately calibrated signal at 456, 1730, 1500, 600, 5800, 5000, 18,300 and 15,000 KC and an output indicating meter are required. It will be practically impossible to align the receiver if unsatisfactory apparatus is used.

Use a non-metallic screwdriver for the adjustments. **Be sure to align the radio in the order as given below.**

I. F. Adjustment

Set the signal generator for a signal of 456 KC.

Connect the output of the signal generator through a .1 mf. condenser to the grid of the 1st detector.

Connect the ground lead of the receiver to the ground post of the signal generator.

Turn the band switch to the Range B position (standard wave band).

Turn the volume control to the maximum position.

Attenuate the signal from the signal generator to prevent the levelling-off action of the AVC.

Then adjust the four I.F. trimmers until maximum output is obtained. The adjusting screws for these condensers are reached from the top of the chassis, and the location is shown in Fig. 3.

Connect the antenna lead of the receiver through a 200 mmf. condenser to the output of the signal generator, and adjust the I.F. wave trap trimmer (C1) for minimum output. The location of this trimmer is shown in Fig. 3.

Range D Alignment

After the procedure for the alignment of each range, as explained below, is completed, it is advisable to repeat the procedure as a final check.

CAUTION—When aligning the short wave bands be sure NOT to adjust at the image frequency. This can be checked as follows: Let us say the signal generator is set for 5000 KC. The signal will then be heard at 5000 KC on the dial of the radio. The image signal, which is much weaker, will be heard at 5000 less 912 KC, or 4088 KC. It may be necessary to increase the input signal to hear the image.

18,300 KC Adjustment

Set the signal generator for 18,300 KC.

Connect the antenna lead of the receiver through a 400 ohm resistor to the output of the signal generator.

Turn the rotor of the tuning condenser to the full open position.

Turn the band switch to the Range D position (2nd short wave band).

For this and all subsequent adjustments keep the volume control at the maximum position and attenuate the signal from the signal generator to prevent AVC action.

Adjust the oscillator Range D trimmer (C8) until maximum output is obtained. See Fig. 3 for location of this trimmer.

15,000 KC Adjustment

Set the signal generator for 15,000 KC.

Turn the rotor of the tuning condenser carefully until maximum output is obtained.

Adjust the antenna Range D trimmer (C3) to maximum.

When adjusting the antenna Range D trimmer, it will be necessary at the same time to turn the tuning condenser rotor slowly back and forth until the peak of greatest intensity is obtained.

Do not change the setting of the oscillator Range D trimmer.

Range C Alignment

5800 KC Adjustment

Set the signal generator for 5800 KC.

Keep the antenna lead of the receiver connected through the 400 ohm resistor to the output of the signal generator.

Turn the rotor of the tuning condenser to the full open position.

Turn the band switch to the Range C position (1st short wave band).

Adjust the oscillator Range C trimmer (C9) until maximum output is obtained. See Fig. 3 for location of this trimmer.

5000 KC Adjustment

Set the signal generator for 5000 KC.

Turn the rotor of the tuning condenser carefully until maximum output is obtained.

Adjust the antenna Range C trimmer (C4) to maximum.

Do not change the setting of the oscillator Range C trimmer.

Range B Alignment

1730 KC Adjustment

Set the signal generator for 1730 KC.

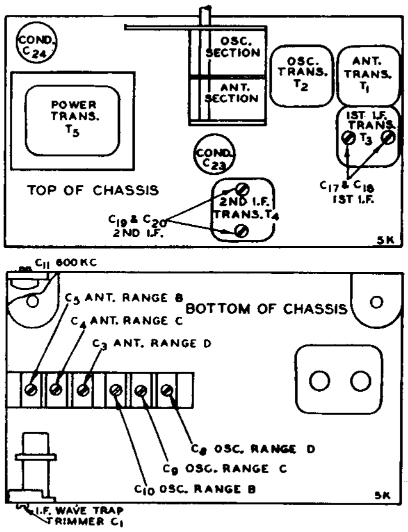

Fig. 3—Location of Trimmers

Turn the rotor of the tuning condenser to the full open position.

Turn the band switch to the standard wave position.

Connect the antenna lead of the receiver through a 200 mmf. condenser to the output of the signal generator.

Adjust the oscillator Range B trimmer (C10) until maximum output is obtained. The location of this trimmer is shown in Fig. 3.

1500 KC Adjustment

Set the signal generator for 1500 KC

Turn the rotor of the tuning condenser carefully until maximum output is obtained.

Loosen the screw of the large pointer and set the pointer at the 1500 KC mark on the standard wave band scale. Retighten the screw.

Adjust the antenna Range B trimmer (C5) to maximum.

Do not change the setting of the oscillator Range B trimmer.

600 KC Adjustment

Set the signal generator for 600 KC.

Turn the tuning condenser rotor until maximum output is obtained.

Turn the rotor slowly back and forth at the same time adjusting the 600 KC trimmer (C11) until the peak of greatest intensity is obtained. See Fig. 3 for location of this trimmer.

Power Consumption .... 47 Watts
Tuning Ranges .... 540 to 1550 and 1500 to 3200 KC.
Maximum Output .... .75 Watt
Maximum Undistorted Output .... 1 Watt
Line-Up Frequencies .... I.F. 465 KC., 1400 KC.

GENERAL DESCRIPTION

This model is a six-tube, A.C.-D.C., two-band superheterodyne receiver whose circuit comprises a combined first detector-oscillator, an intermediate frequency amplifier, a combined second detector, A.V.C. and first audio amplifier, a power pentode output stage and a rectifier with its associated filter circuit, plus a ballast tube.

This model is designed to work over two bands, the Broadcast Band extending from 540 to 1550 KC., and a Police Band which extends from 1500 to 3200 KC.

LINE-UP CAPACITOR ADJUSTMENTS

To align the circuits of this receiver, it is essential to use a high grade modulated test oscillator, the output of which can be continuously varied with absence from overload when the individual circuits of the receiver are brought into alignment.

A conventional output meter can be connected across the terminals of the speaker voice coil to indicate when the circuits are aligned. The sensitivity of the output meter must be sufficient to give satisfactory reading with a low input signal.

Before attempting to align the receiver, the service man should familiarize himself with the general layout of the chassis, the location of the tubes and various alignment condensers. Top and bottom views of the chassis are shown in Figs. #1 and #2 and should be carefully studied before the actual work is started.

ADJUSTMENT OF I.F. (465 KC.)

1. Set volume control on full, the wave-change switch on the Broadcast (treble position) and the dial indicator at approximately 600 KC.
2. Connect output meter across voice coil of speaker.
3. Set test oscillator to 465 KC., and adjust its output to produce a measurable reading on output meter when test signal is applied to the grid of the 6D6 I.F. tube through a .5 mfd. blocking condenser.
4. Adjust #24 (see Fig. #2) to maximum output, reducing output of test oscillator as required.
5. Apply test signal to grid of 6A7 first detector-oscillator tube and adjust #13 and #15 (Fig. #1) to maximum output.
6. With test signal still on the grid of 6F7 tube, repeat the above adjustments for greatest sensitivity.
7. Apply strong 465 KC. signal to the antenna and adjust trap coil trimmer #3 to a minimum output.

ADJUSTMENT OF BROADCAST BAND

1. Apply test signal on grid of 6A7 tube and set the test oscillator to 1400 KC.
2. Turn the gang condenser to its maximum position. Adjust dial indicator until either end is directly over the long horizontal lines on the dial scale. Then set dial indicator to 1400 KC.
3. Adjust trimmer #7 to maximum output.
4. Apply test signal to antenna of set through a .0002 mfd. condenser and adjust trimmer #8 to maximum output.

ADJUSTMENT OF POLICE BAND

When adjustments as outlined under the Broadcast Band are completed, the Police Band requires no adjustment unless the coil has been changed. In this event, set test oscillator and station indicator to 1700 KC., and apply test signal to antenna lead. The Police Band winding is indicated by "A" in Fig. #2. Adjust the position of this winding by sliding it back and forth on the coil until maximum output is indicated on the output meter. This winding should then be secured in place by applying a thin coat of coil cement.

Five-Tube, Superheterodyne Receiver

SERVICE NOTES

ELECTRICAL SPECIFICATIONS

Type and Number of Tubes ---------------- 1 #6F7, 1 #6D6, 1 #75, 1 #42, 1 #80 - Total 5
Power Supply ---------------------------------- 105 to 125 volts, 50 to 60 cycles A.C.
Power Consumption -- 46 Watts
Tuning Ranges ------------------------------ 540 to 1500 K.C. and 1500 to 3200 K.C.
Maximum Undistorted Output -- 1.5 Watts
Maximum Output -- 2.8 Watts
Line-Up Frequencies ------------------------------ I.F. 465 K.C., 1400 K.C.

GENERAL DESCRIPTION

This model is a five-tube, A.C., two-band superheterodyne receiver whose circuit comprises a combined first detector-oscillator an intermediate frequency amplifier, a combined second detector, A.V.C. and first audio amplifier, a power pentode output stage and a rectifier with its associated filter circuit and power transformer.

This model is designed to work over two bands, the broadcast band extending from 540 to 1500 K.C. and a police band which extends from 1400 to 3200 K.C.

LINE-UP CAPACITOR ADJUSTMENTS

To align the circuits of this receiver it is essential to use a high grade modulated test oscillator, the output of which can be continuously varied with absence from overload when the individual circuits of the receiver are brought into alignment.

A conventional output meter can be connected across the terminals of the speaker voice coil to indicate when the circuits are aligned. The sensitivity of the output meter must be sufficient to give satisfactory reading with a low input signal.

Before attempting to align the receiver, the service man should familiarize himself with the general layout of the chassis, location of the tubes and various alignment condensers. Top and bottom views of the chassis are shown in Fig. #1 and #2 and should be carefully studied before the actual work is started.

ADJUSTMENT OF I.F. (465 K.C.)

1. Set volume control on full, turn tone control knob to the right hand position. Set wave-change switch on the broadcast position and the dial indicator at approximately 600 K.C.
2. Connect output meter across voice coil of speaker.
3. Set test oscillator to 465 K.C. and adjust its output to produce a measurable reading on output meter when test signal is applied to the grid of the 6D6 I.F. tube thru a .5 mfd. blocking condenser.
4. Adjust #26 (see Fig. #2) to maximum output reducing output of test oscillator as required.
5. Apply test signal to grid of 6F7 first detector-oscillator tube and adjust #18 and #19 (Fig. #1) to maximum output.
6. With test signal still on the grid of 6F7 tube, repeat the above adjustments for greatest sensitivity.

ADJUSTMENT OF BROADCAST BAND

1. Leave test signal on grid of 6F7 tube and set the test oscillator to1400 K.C.
2. Turn the gang condenser to its maximum position. Adjust dial indicator until either end is directly over the long horizontal lines on the dial scale. Then set dial indicator to 1400 K.C.
3. Adjust trimmer #8 to maximum output.
4. Apply test signal to antenna of set thru a .0002 mfd. condenser and adjust trimmer #7 to maximum output.

ADJUSTMENT OF POLICE BAND

When adjustments as outlined under the broadcast band are completed, the police band requires no adjustment unless the coil had been changed. In this event, set test oscillator and station indicator to 1700 K.C. and apply test signal to antenna lead. The police band winding is indicated by "A" in Fig. #2. Adjust the position of this winding by sliding it back and forth on the core until maximum output is indicated on the output meter. This winding should then be secured in place by applying a thin coat of coil cement.

WESTINGHOUSE RADIO MODEL WR-209

SERVICE PARTS LIST

Dia. #	Part #	Description of Parts	List Price
1	RC 9588	Antenna coil assembly	$ 1.10
2		.05 mfd., 200 V. condenser - part of SA 105327 (dual).	.30
3	CM 958	400 mmfd. mica condenser	.20
4		Police pre-selector coil - part of RC 9588	
5	SW 9519	Switch assembly	.85
6	CG 9522	Variable gang condenser	2.45
7		Trimmer condenser - part of CG 9522	
8		Trimmer condenser - part of CG 9522	
9	RC 9589	Oscillator coil assembly	.95
10	SA 106417	100 mmfd. mica condenser	.20
11	SA 105276	50,000 ohm, 1/4 W. resistor	.15

INSTRUCTIONS MODEL 209 6T AC 3 BAND SUPERHETERODYNE RECEIVER

ANTENNA AND GROUND CONNECTIONS. An antenna from 50 to 100 feet long is recommended. A good ground wire is absolutely essential on this receiver.

POWER SUPPLY. This receiver is designed to operate from the 115-135 or 220 A.C. 50 cycle lines. The voltage change is accomplished by removing the cover from the power transformer and connecting the flexible lead to the desired voltage terminal.

LOCATION OF CONTROLS. The knob on the lower right is the on-off switch and the tone control. The knob on the lower left is the volume control and the knob directly below the selector knob is the wave change switch.

OPERATION. Turn station selector knob to secure desired stations. When tuning in a set, set tuning control carefully to maximum station volume, then adjust volume to desired level with volume control knob.

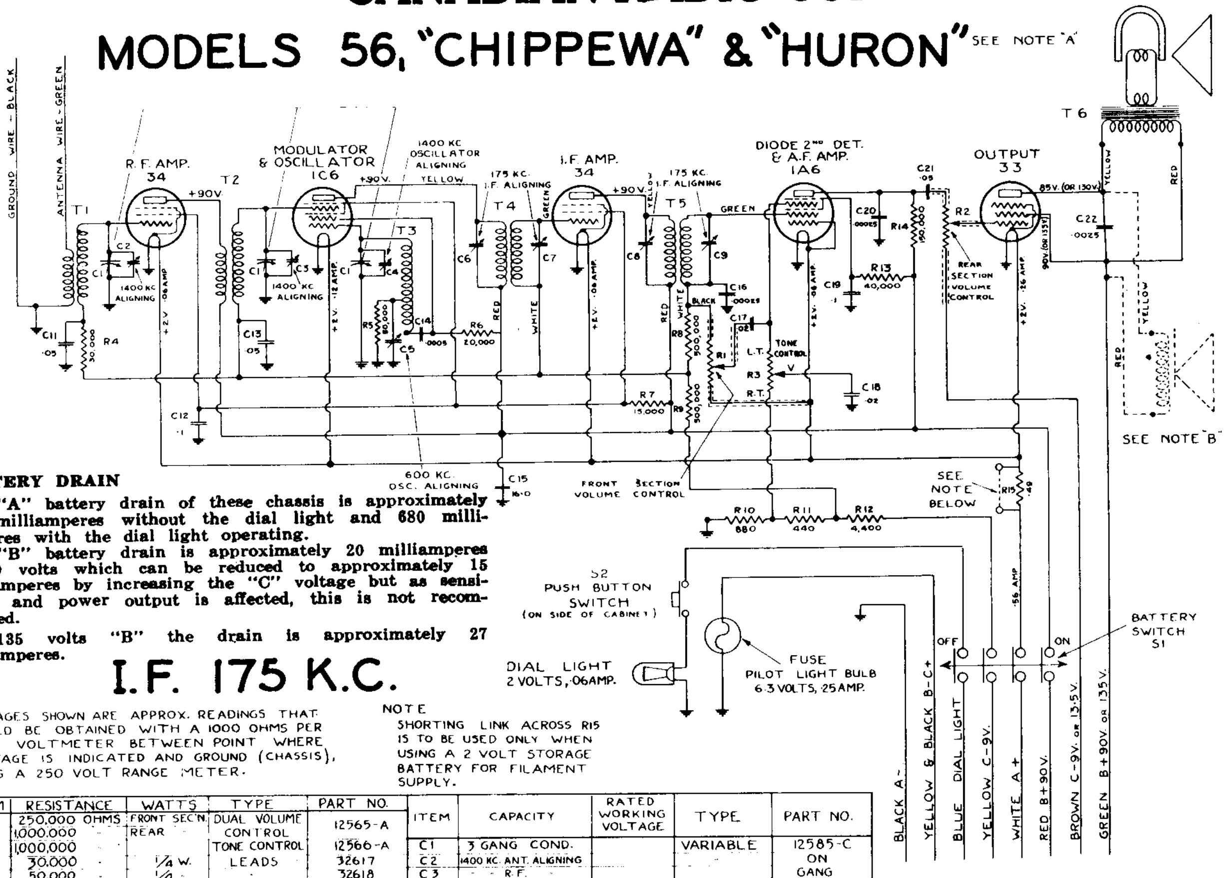
MODELS 56, "CHIPPEWA" & "HURON" SEE NOTE "A"



BATTERY DRAIN

The "A" battery drain of these chassis is approximately 500 milliamperes without the dial light and 680 milliamperes with the dial light operating.

The "B" battery drain is approximately 20 milliamperes at 90 volts which can be reduced to approximately 15 milliamperes by increasing the "C" voltage but as sensitivity and power output is affected, this is not recommended.

At 135 volts "B" the drain is approximately 27 milliamperes.

I.F. 175 K.C.

NOTE
VOLTAGES SHOWN ARE APPROX. READINGS THAT SHOULD BE OBTAINED WITH A 1000 OHMS PER VOLT VOLTMETER BETWEEN POINT WHERE VOLTAGE IS INDICATED AND GROUND (CHASSIS), USING A 250 VOLT RANGE METER.

NOTE
SHORTING LINK ACROSS R15 IS TO BE USED ONLY WHEN USING A 2 VOLT STORAGE BATTERY FOR FILAMENT SUPPLY.

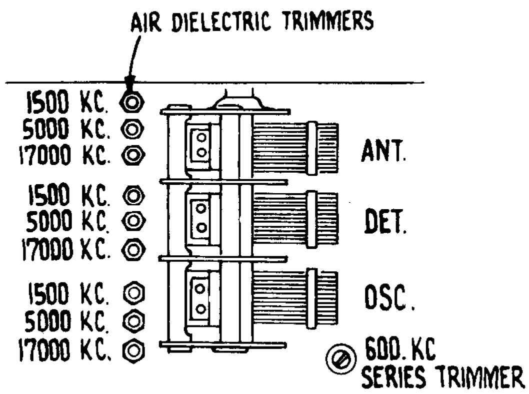
Radiotron Socket Voltages and I.F. Trimmer Locations

The meter readings given in the diagram are taken with the antenna and ground binding posts short circuited and with 120 volts line. All readings are actual operating conditions and in some cases it will be necessary to allow for meter resistance. All D.C. voltage readings are taken with respect to the chassis frame. All readings are given for normal operation. If readings are taken with a set analyser circuits that are not intended to oscillate, may oscillate, thus increasing plate or screen voltages and decreasing plate or screen current. The set analyser cable may also cause the oscillator radiotron to cease oscillating, thus increasing current and decreasing voltage.

In some cases the socket contacts of "blank" radiotron pins are used as terminals for chassis parts. The voltages shown above on such contacts are circuit voltages, not radiotron voltages.



R.F. Alignment Points

When adjusting the Air Dielectric R.F. trimmers, it is necessary to use a special tool (See H-29644 in parts list) to slacken the lock nut on the trimmer, previous to the adjustment, and to tighten it again after the adjustment. Another special tool (See H-29643 in parts list) is available for making the actual adjustment to the trimmer. The adjustment should be made upward or downward on the plunger with a twisting motion. The special tool designed by the Canadian Westinghouse Company for this purpose is double ended; one end having a pin for the R.F. adjustments, the other end is a special socket screw driver for use in making I.F. adjustments.

	Frequency Ranges	*Alignment Frequencies*
Broadcast (BC)	530–1720 kc.	600 kc. (osc.,) 1500 kc. (osc., ant. det.)
Medium Wave (MW)	1720–5500 kc.	5000 kc. (osc. ant. det.)
Short Wave (SW)	5500–18000 kc.	17000 kc. (osc. ant. det.)
Intermediate Frequency		460 kc.

SERVICE DATA

The various diagrams of this booklet contain such information as will be needed to isolate causes for defective operation if such develops. The ratings of the resistors, capacitors, coils, etc., are indicated adjacent to the symbols signifying these parts on the diagrams. Identification titles, such as R3, L2, C1, etc., are provided for reference between the illustrations and the Replacement Parts List. The coils, reactors, and transformer windings are rated in terms of their d-c resistances only. Ratings of less than one ohm are generally omitted.

Alignment Procedure

There are ten alignment trimmers provided in the R.F., first detector and oscillator tuned circuits. The four i-f transformer adjustments are made by means of screws attached to molded magnetite cores. All of these circuits have been accurately adjusted during manufacture and should remain properly aligned unless affected by abnormal conditions or altered during servicing. Loss of sensitivity, improper tone quality, and poor selectivity are the usual indications of improper alignment.

The correct performance of this receiver can only be obtained when the aligning has been done with adequate and reliable apparatus. It is not absolutely necessary to use a frequency modulated oscillator and cathode ray oscillograph to align this receiver. Those service men that have this equipment will probably prefer to use it and for their convenience we have indicated on the socket voltage diagram the proper connection point for the cathode ray vertical amplifier input terminal.

A special tool (See H-29643 in parts list) is available for adjusting the I.F. trimmers. This tool has at one end a socket screw driver which aids in locating the head of the I.F. trimmer screw, and will not slip off the screw. It is recommended that two of these tools be used simultaneously, particularly when a Cathode Ray Oscillograph is being used for alignment purposes. With the chassis standing on one end, and both primary and secondary I.F. trimmer screws accessible, much more rapid work can be done by simultaneously adjusting the primary and secondary I.F. trimmers.

A test oscillator is required as a source of the specified alignment frequencies. Visual indication of receiver output during the adjustment is necessary and should be accomplished by the use of an indicator or meter.

The procedure outlined below should be followed in adjusting the various trimmer capacitors and molded cores:

WHEN ALIGNING THE R.F. CIRCUITS, THE CHASSIS BOTTOM SHIELD MUST BE IN PLACE ON THE CHASSIS AND SECURELY FASTENED WITH ALL OF THE RETAINING SCREWS. IF THE CHASSIS BOTTOM PLATE IS REMOVED, COIL SHIELDING WILL BE INCOMPLETE AND THE R.F. CIRCUIT WILL OSCILLATE. WHEN ADJUSTING I.F. CORES WITH THE CHASSIS BOTTOM PLATE REMOVED OR DOING TROUBLE SHOOTING ON THE CHASSIS, OSCILLATION MAY BE PREVENTED BY USING A SHORT LENGTH OF WIRE WITH TWO CLIPS TO CONNECT TOGETHER THE PARTITION SHIELDS BETWEEN THE ANTENNA AND DETECTOR COILS, AND BETWEEN THE DETECTOR AND OSCILLATOR COILS.

I.F. ADJUSTMENTS USING CATHODE RAY EQUIPMENT

1. Set up the Cathode Ray Equipment in the manner recommended by the manufacturer of the equipment. The frequency modulated oscillator should be connected to the control grid cap of the W-6K7 I.F. radiotron (with grid lead in place), through a .001 Mfd. capacitor. The grounded side of the test oscillator output should be connected to the receiver chassis frame. The cathode ray oscillograph vertical terminals should be connected to points indicated on the radiotron socket voltage diagram.

2. Place the receiver in operating condition. The antenna and ground terminal should be short circuited and if necessary the gang condenser adjusted so that no stray signals are fed into the I.F. amplifier during the adjustment.

Adjust the test oscillator to supply a 460 Kc. audio-modulated signal. Increase the output of the test oscillator until a deflection is noticeable on the oscillograph screen. The figures obtained represent several waves of the detected signal, the amplitude of which may be observed as an indication of output. Cause the wave-image formed to be spread completely across the screen by adjusting the "Horizontal gain" control. The image should be synchronized and made to remain motionless by adjusting the proper oscillograph controls.

3. Adjust the two magnetite core screws of the second I.F. transformer (see radiotron socket voltage and I.F. terminal location diagram) to produce maximum vertical deflection of the oscillograph image. This adjustment places the transformer in exact resonance with the 460 Kc. signal.

4. Set up the cathode ray and test oscillator equipment in the standard manner to provide a frequency modulated signal and a "double trace" image.

5. Adjust the frequency of the test oscillator until the two traces move together and overlap with their highest points exactly coinciding.

6. Now readjust the two magnetite core screws on the second I.F. transformer so as to cause the two traces on the oscillograph screen to coincide throughout their lengths and have maximum amplitude.

7. Without altering the adjustments of the apparatus, shift the "Ant." output of the test oscillator to the input of the I.F. system; i.e., to the grid cap of the W-6L7 first detector (with grid lead in place) through the .001 mfd. capacitor. Regulate the test oscillator output so that the amplitude of the oscillograph image is approximately the same as used for adjustment (6) above.

8. The two first I.F. transformer magnetite core screws should then be adjusted so as to cause the forward and reverse waves to become coincident throughout their lengths and have maximum amplitude.

I.F. ADJUSTMENT WITHOUT CATHODE RAY EQUIPMENT

In most cases provided the I.F. transformers have not been very badly put out of adjustment, it is possible to secure reasonably good results by alignment with a simple 460 K.C. audio modulated oscillator and standard output indicator. The adjustment should be made in a similar manner described for the cathode ray equipment, but of, course, the I.F. cores should be adjusted for maximum output indication only. The adjustments must be done in the order given and must be done carefully.

R.F. ADJUSTMENT

Before attempting R.F. alignment it is necessary to set the pointer in the correct position with relation to the gang condenser plates. This is done by setting the pointer to the angle of the border line of the dial immediately below the 530 K.C. calibration point, with the gang tuning condenser in full mesh.

"Broadcast" Trimmer Adjustments.

The output indicator should be left connected to the system. Connect the test oscillator to antenna and ground terminals of the chassis through a 200 mmfd. condenser. Adjust the test oscillator to 1500 kc. and set the receiver tuning control to a dial reading of 1500 kc. Leave the volume control of the receiver at its maximum position. Make sure that the Range Selector is at its broadcast position. and the high fidelity switch in the counter clockwise position. Regulate the output of the test oscillator until a slight indication is perceptible at the receiver output. Then adjust the three 1500 kc. trimmers (see diagram) of the oscillator and antenna transformer coils so that each produces maximum (peak) receiver output. After this maximum has been accurately obtained, shift the test oscillator to 600 kc. Tune the receiver to pick up this signal, disregarding the dial reading at which it is best received. Then, adjust the receiver 600 kc. series trimmer, simultaneously rocking the tuning control backward and forward through the signal until maximum receiver output results from these combined operations. The adjustment at 1,500 kc. should then be repeated to correct for any change which may have been caused by the oscillator series trimmer adjustment.

"Medium Wave" Trimmer Adjustment:

Use same equipment and layout as for "broadcast" alignment. Place the receiver range selector switch to its "medium wave" position with the dial pointer set at 5000 Kc. Tune the test oscillator to 5000 Kc. Adjust the oscillator 5,000 Kc. air-trimmer to produce maximum output. Two peaks may be found with this circuit; the peak with minimum capacitance (plunger nearly out) should be used. Tighten locknut. Adjust the detector 5000 Kc. air-trimmer for maximum output while slightly rocking the gang condenser. Two peaks may be found with this circuit; the peak with maximum capacitance (plunger nearly in) should be used. Tighten locknut. Adjust antenna 5000 Kc. air-trimmer to produce maximum output. Tighten locknut.

"Short-Wave" Trimmer Adjustments

Connect the "ANT" output of the test oscillator to the antenna terminal of the receiver through a 400 ohm resistor. Set the receiver range selector switch to its "short wave" position and its dial pointer to 17000 Kc. Adjust the test oscillator to 17000 Kc. Adjust oscillator 17000 Kc. trimmer until maximum output is reached. Two peaks may be found with this circuit. The peak with minimum capacitance (plunger nearly out) should be used. Tighten locknut. Adjust detector 17000 Kc. trimmer until maximum output is reached while slightly rocking the gang condenser. Two peaks may be found with this circuit; the peak with maximum capacitance (plunger nearly in) should be used. Tighten locknut. Adjust antenna 17000 Kc. trimmer until maximum output is reached, while slightly rocking the gang condenser. Two peaks may be found with this circuit; the peak with maximum capacitance (plunger nearly in) should be used. Tighten locknut. Check the image frequency by changing the receiver dial setting to 16,080 Kc. the image signal should be received at this position, indicating that the adjustments have been correctly made. No adjustments should be made while checking for the image signal.

LOUDSPEAKER

The reproducer centering adjustment will be obvious if the field coil shield is removed. One screw in the centre of the back of the reproducer holds the shield in place. Two screws hold the voice coil centering spider in place and must of course be loosened while adjustment is being made.

I.F. = 456 K.C.
SWITCH SHOWN IN B.C. POSITION
ALL VOLTAGES SHOWN TO GROUND

ALIGNMENT DATA AND SERVICING

GENERAL DATA The alignment of this receiver requires the use of a test oscillator that will cover the frequencies of 456, 600, 1400, and 6000 KC and an output meter to be connected across the primary or secondary of the output transformers. If possible, all alignments should be made with the volume control on maximum and the test oscillator output as low as possible, to prevent the AVC from operating and giving false readings.

CORRECT ALIGNMENT PROCEDURE The intermediate frequency (I.F.) stage should be aligned properly as the first step. After the I.F. transformers have been properly adjusted and peaked, the Broadcast Band should always be the next procedure; after which, the Short Wave Band may be aligned.

I.F. ALIGNMENT Adjust the test oscillator to 456 KC and connect the output to the grid of the first detector tubes (6A7) through a .05 or .1 mfd. condenser. The ground on the test oscillator can be connected to the chassis ground. Align all four I.F. trimmers to peak or maximum reading on the ouput meter.

BROADCAST BAND ALIGNMENT Adjust the oscillator to 1400 KC and connect the output to the antenna lead (Blue) through a .0001 mfd. mica condenser to give the equivalent of an antenna about 60 feet. Set the receiver pointer to 1400 KC and adjust the rear gang condenser trimmer (oscillator circuit) to peak. After this has been carefully done, the next step is to adjust the front trimmer of the gang condenser to peak.

Next, re-set the dial pointer on the receiver and the test oscillator to 600 KC. Slowly increase or decrease the oscillator padding condenser and at the same time continuously tune back and forth across the signal with the receiver until the maximum reading is obtained on the output meter. This adjustment seems a little complicated but is the easiest way to adjust the oscillator to the pre-selector or R.F. section. The padding condenser is located on the right hand end of the chassis

Return to 1400 KC and again go over the adjustments of this frequency to be certain that they were not put slightly out of alignment when adjustment was made at 600 KC.

This completes the correct sequence of operations in properly aligning the receiver for the Broadcast Band, and **must always be done before** attempting to align the Short Wave Band.

SHORT WAVE BAND There is only one adjustment to be made in the alignment of the Short Wave Band. Due to the circuit design and correct matching of the coils, no oscillator adjustment is necessary.

Set the dial pointer to 600 KC (also the test oscillator) and adjust the antenna and antenna trimmer to resonance. The short wave band coils are under the chassis and are located at the right front corner along side of wave band switch.

IMPORTANT: This is the only adjustment necessary for the Short Wave Band. Do not attempt any adjustment of the gang condenser trimmers in aligning the Short Wave Band, otherwise the Broadcast Band will be thrown out of alignment.

Return to 1400 KC and again go over the adjustments of this frequency to be certain that they were not put slightly out of alignment when adjustment was made at 6000 KC.

This completes the correct sequence of operations Band, and MUST ALWAYS BE DONE BEFORE attempting to align the Short Wave Band.

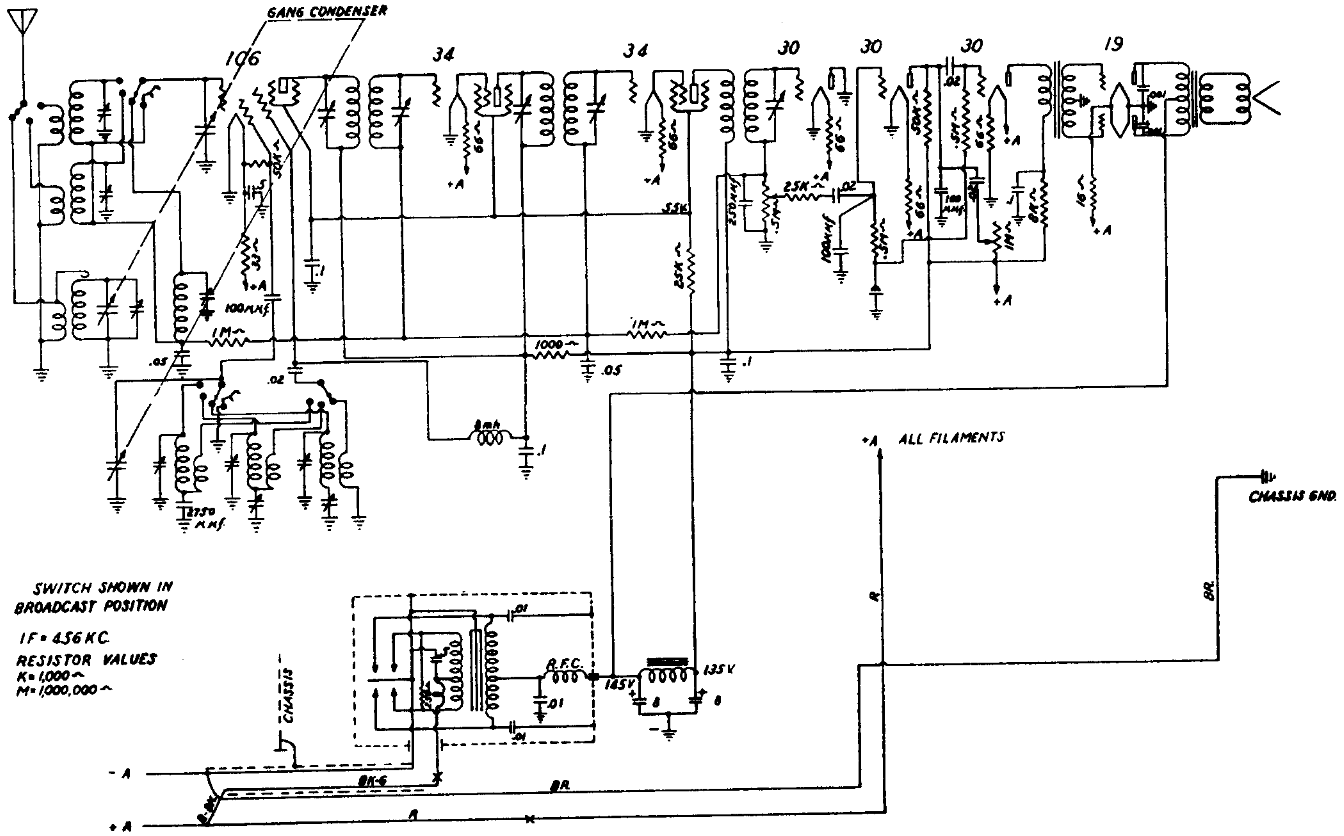
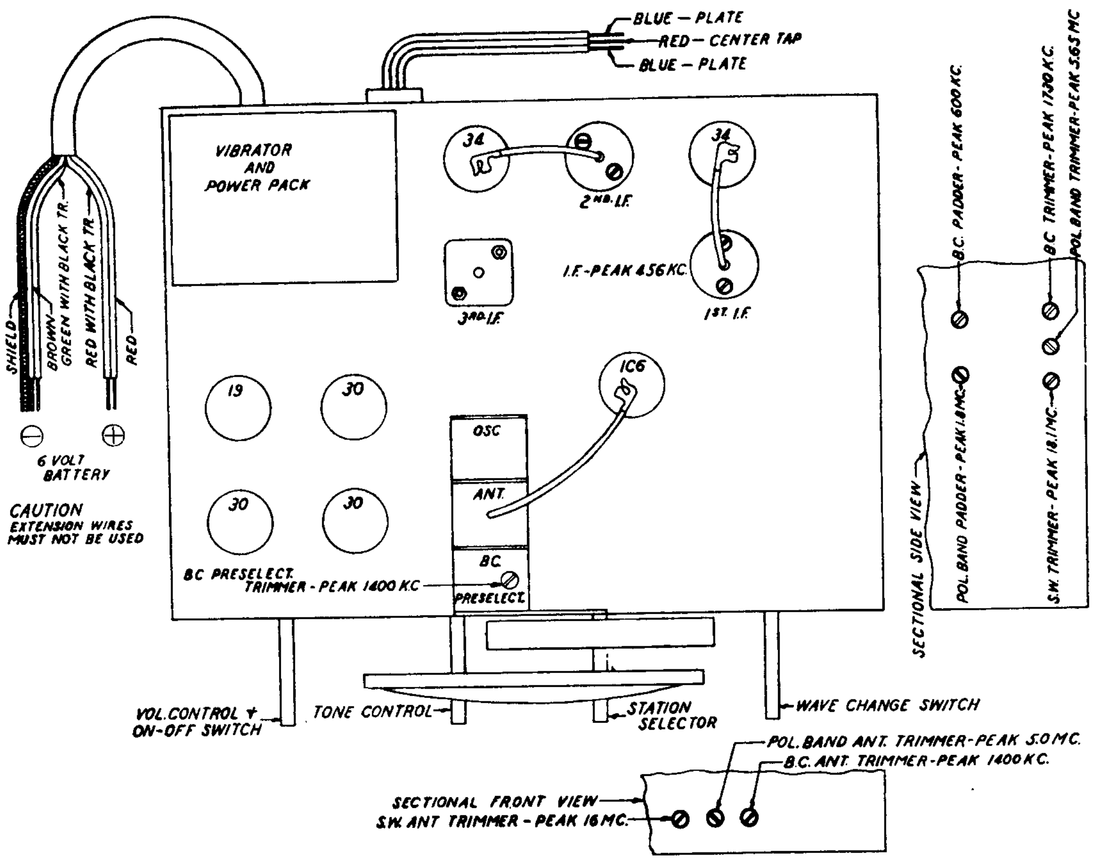
MODEL M5 SERIES



I.F. 456 K.C.



CONTINENTAL RADIO & TELEVISION CORP.

MODEL M5 SERIES

ALIGNMENT DATA AND SERVICING

GENERAL DATA

The alignment of this receiver requires the use of a test oscillator which will cover the frequencies of 456, 600, 1400, 1800, 4000, 6000, and 14,000 KC and an output meter which is to be connected across the primary or secondary of the output transformer. If possible, all alignments should be made with the volume control on maximum and the test oscillator output as low as possible, to prevent the AVC from operating and giving false readings.

CORRECT ALIGNMENT PROCEDURE

The intermediate frequency (I.F.) stages should be aligned properly as the first step. After the I.F. transformers have been properly adjusted and peaked, the Broadcast Band should always be the next procedure; after which, either or both of the Short Wave Bands may be aligned.

I.F. ALIGNMENT

Adjust the test oscillator to 456 KC and connect the output to the grid of the first detector tube (1C6) through a .05 or .1 mfd. condenser. The ground on the test oscillator can be connected to the chassis ground. Align all five I.F. trimmers to peak or maximum reading on the output meter. As there are two stages of I.F. in this receiver, there will be consequently three I.F. transformers to align. The I.F. transformer nearest the type (30) diode detector has only one trimmer, (single tuned) and should be the first adjustment. Next adjust the center I.F. transformer, which has two trimmers (double tuned) for maximum output; then adjust the two trimmers on the input I.F. transformer (double tuned) for peak.

BROADCAST BAND ALIGNMENT

Adjust the oscillator to 1400 KC and connect the output to the antenna post marked "A" through a .0001 mfd. mica condenser to give the equivalent of an antenna about 60 feet. Set the receiver pointer to 1400 KC and adjust the broadcast oscillator trimmer to peak. (See drawing for location.) After this has been carefully done, the next step is to adjust the front trimmer of the gang condenser to peak. The front condenser section tunes the preselector circuit. Then adjust the Broadcast Band R. F. trimmer to peak. This trimmer aligns the grid or input circuit of the 1C6 tube, (See drawing for position of Broadcast R. F. trimmer). Next, re-set the dial pointer on the receiver and the test oscillator to 600 KC. Slowly increase or decrease the B. C. oscillator padding condenser and at the same time continuously tune back and forth across the signal with the receiver until the maximum reading is obtained on the output meter. This adjustment may seem a little complicated but is the easiest way to adjust the oscillator to the R.F. section. (For location of B.C. padding condenser see drawing.) Return to 1400 KC and again go over the adjustments of this frequency to be certain that they were not put slightly out of alignment when adjustment was made at 600 KC.

This completes the correct sequence of operations in properly aligning the receiver for the Broadcast Band.

FOREIGN BAND ALIGNMENT

The Foreign Band of 19 to 49 meters can be adjusted by the two trimmers marked and illustrated in the drawing as S.W. oscillator and S.W. trimmer. In preparing the test oscillator for alignment of this band, connect a 400 ohm carbon resistor in series with the .0001 mfd. condenser on the output lead of the test oscillator. Set the receiver pointer to 14,000 KC (also test oscillator).

Then proceed to adjust these two trimmers for peak at 14,000 KC (adjust oscillator trimmer first) and as the inherent design of the circuit has been expressly developed for simplicity in servicing, no other adjustments are necessary for aligning this band.

Note: Always start this procedure by having the oscillator coil trimmer loose (out all the way), and the antenna coil trimmer fairly tight (in all the way); otherwise it is possible to make a false alignment on the image frequency. In order to prevent alignment on the image frequency, it is suggested that the following check be made: Readjust the pointer to 13,100 KC where the image frequency should be found. If properly aligned, the image frequency will be found to be weaker. If, however, the signal at 13,100 KC is found to be stronger than the signal at 14,000 KC, it signifies that alignment was incorrectly made on the image frequency.

POLICE BAND

In preparing the test oscillator for alignment of this band, connect a 400 ohm carbon resistor in series with a .0001 mfd. condenser on the output lead of the test oscillator. This resistor is used with the test oscillator only on the Short Wave Bands and should not be used for Broadcast Band alignment.

Set the receiver pointer to 4000 KC (also test oscillator) and adjust the Police Band oscillator circuit trimmer to peak.

After this has been carefully done, the next step is to adjust the Police Band antenna trimmer to peak.

Now reset the dial pointer and the test oscillator to 1800 KC in preparation for adjusting the police band padding condenser.

Slowly increase or decrease the oscillator padding condenser and at the same time continuously tune back and forth across the signal with the receiver until the maximum reading is obtained on the output meter. This adjustment may seem a little complicated, but is the easiest way to correctly adjust the oscillator to the R.F. or antenna section. Return to 4000 KC and again go over the adjustments of this frequency to be certain that they were not put slightly out of alignment when adjustment was made 1800 KC.

If it is found that in returning to 4000 KC the pointer is accurately on scale, no further adjustment should be necessary (in this recheck). If the pointer is found off scale, it may be corrected and put on scale by readjustment of the police band oscillator trimmer. Alignment of the pointer can only be corrected by adjustment of the oscillator trimmer.

Important: The adjustment, the Police Band Oscillator Trimmer, Police Band Antenna Trimmers and Police Band Padding Trimmers are the only three adjustments required in aligning this band.

SERVICE DATA FOR ALL BANDS

If it is suspected that the oscillator has stopped but is doubtful due to the presence of the usual amount of noise level, it is suggested that the oscillator plate voltage be checked. To ascertain whether the tube is oscillating, ground the oscillator grid of the 1C6 (short stator and rotor plates of oscillator section on gang condenser). If oscillating properly, grounding the grid will cause an appreciable drop in oscillator voltage.

BATTERY CONNECTIONS

At the rear of the receiver there will be found extending from the left end of the chassis, the battery connecting cable. Observation will show that 5 wires are brought out from the braided cable. The **red** and **red with black tracer** wires are joined together and should **both** be securely fastened to the positive (+) terminal of the 6 volt storage battery. The other 3 wires which are **brown, black with green tracer** and **Metallic shield lead** are also joined together and should be securely connected to the negative (—) post of the battery.

Note: It is extremely important that only the best possible means of obtaining a secure connection to the battery terminals be employed. If a battery with automobile terminal posts is used, the **large** post is the positive (+) post; the **smaller post** is the **negative** (—) terminal. It is suggested, when using a battery with auto type posts that large heavy lead covered battery clips be used in making connections. Make sure that **all wires** are firmly connected to clips (solder if possible). Also see that the jaw teeth of the clips are clean, and firmly bite into the post. It is very important that the battery posts and battery clip teeth be cleaned at frequent intervals to assure maintaining good connections. Corrosion may be readily removed by cleaning with a solution of 3 tablespoons of bicarbonate of soda (baking soda) and one cup of water. This solution neutralizes the acid coating that causes the corrosion and leaves a protective condition that retards further corrosion. It is important that this solution does not in any way enter the interior of the battery.

THE CROSLEY RADIO CORPORATION

MODELS 506 & C-516

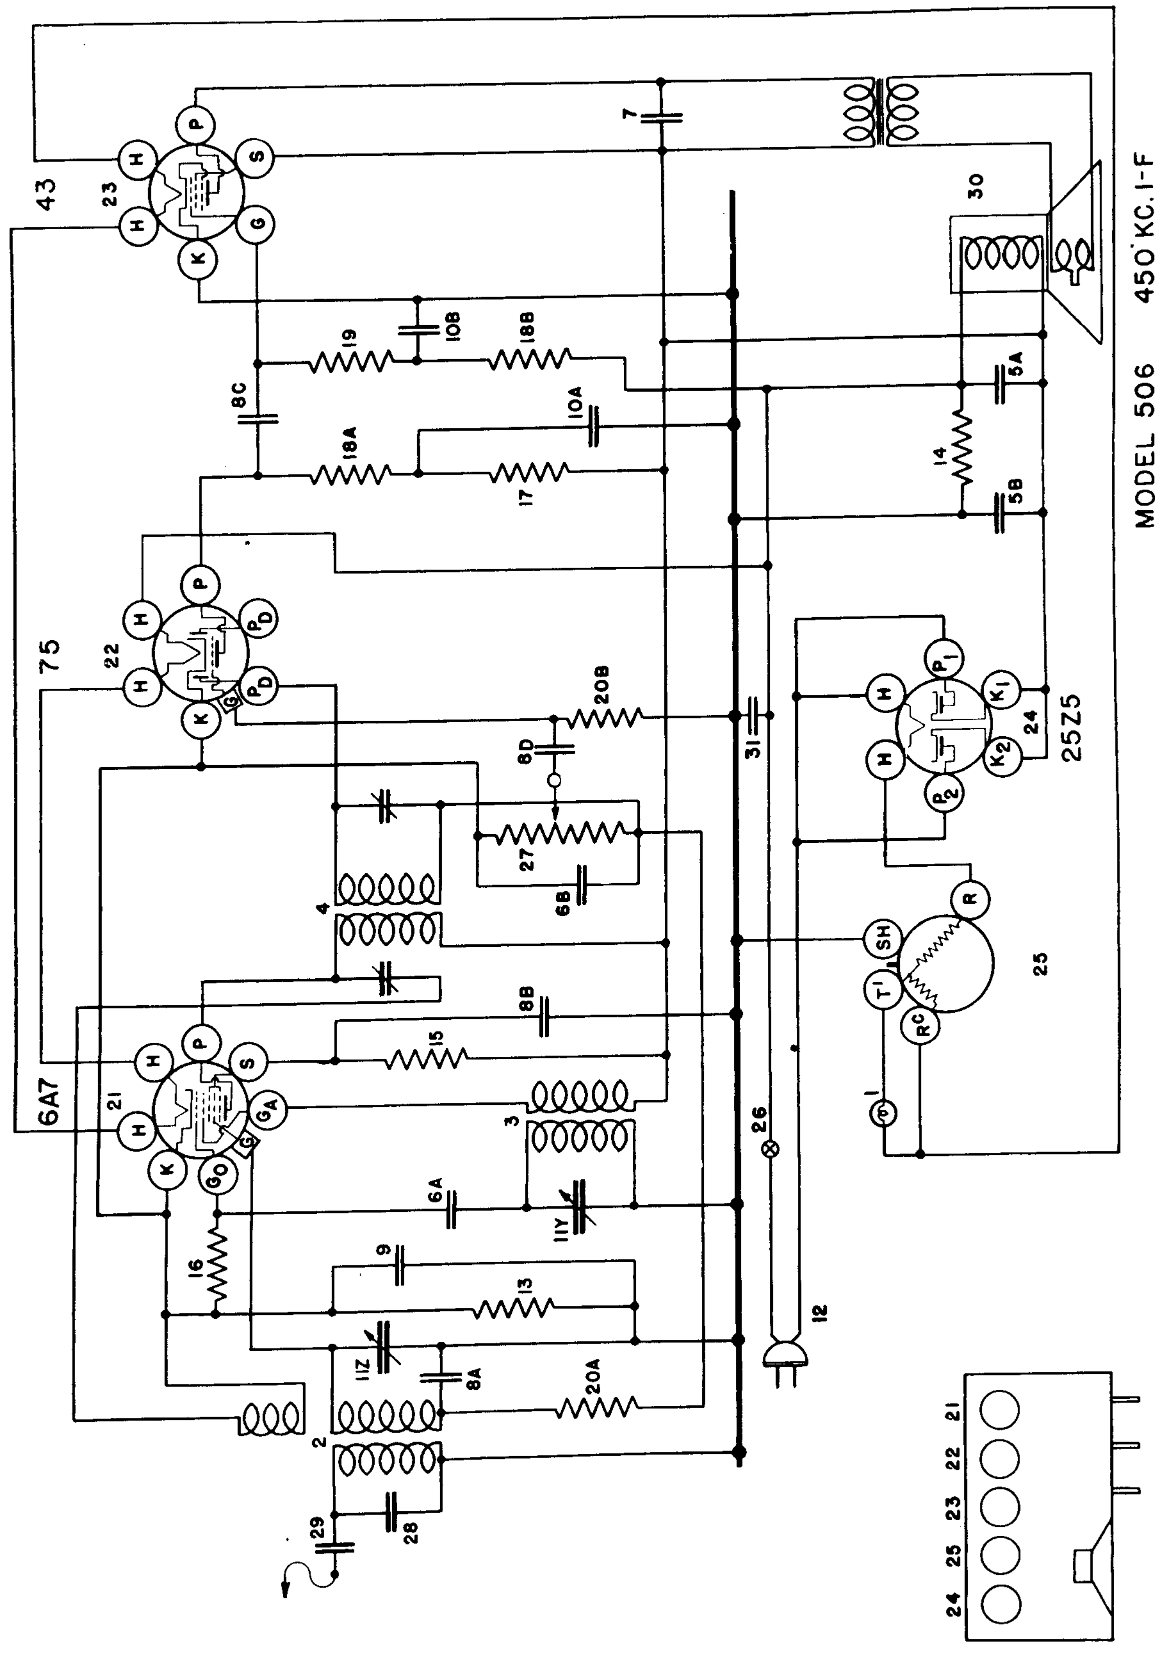


FIG. 1—WIRING DIAGRAM—MODEL 506

THE CROSLEY RADIO CORPORATION

MODELS 506 & C-516

ALIGNMENT PROCEDURE

The chassis of this receiver is connected through a resistor to one side of the power supply and for this reason all test equipment should be thoroughly isolated in order that the power supply will not be short circuited while attempting to align the receiver.

CONNECTING OUTPUT METER

Connect one terminal of the output meter to the plate and the other terminal to the screen of the 93 Output tube. Be sure the meter is protected from D.C. by connecting a condenser (.1 mfd. or larger—not electrolytic) in series with one of the leads.

1. Tuning I-F Amplifier to 450 Kilocycles.

(a) Connect the output of the signal generator through a .02 condenser to the top cap of the 6A7 Oscillator-Modulator tube, leaving the tube's grid clip in place. Connect the ground lead from the signal generator direct to the receiver chassis **but do not run a wire direct to ground.** KEEP THE GENERATOR LEADS AS FAR AS POSSIBLE FROM THE GRID LEADS OF THE OTHER SCREEN GRID TUBES.

(b) Set the station selector so that the plates of the condenser gang are completely out of mesh and turn the volume control to the right (ON).

(c) Set the signal generator to 450 kilocycles.

(d) Adjust the I-F trimmer condensers for maximum reading on the output meter.

ALWAYS USE THE LOWEST SIGNAL GENERATOR OUTPUT THAT WILL GIVE A REASONABLE OUTPUT METER READING.

2. Aligning R-F Amplifier.

(a) Connect the output lead from the signal generator through a .00025 mfd. condenser to the antenna lead on the chassis.

(b) Set the signal generator to 1400 kilocycles.

(c) Adjust the station selector to 140 on the dial.

(d) Adjust the trimmer located on the "OSC" section of the condenser gang for maximum output.

(e) Adjust the trimmer located on the "ANT" section of the condenser gang for maximum output.

(f) Readjust the station selector slightly for maximum output.

(g) Repeat operation (e) for more accurate adjustment.

The tuning range of the receiver is approximately from 540 to 1725 kilocycles (555 to 173 meters).

TUBES AND VOLTAGE LIMITS

The following table gives the functions of the tubes used, together with the voltage readings between the tube socket contacts and B—. Voltage readings should be taken with a 1000 ohm per volt, 250 volt voltmeter (except filaments) with volume control full on and no signal input. The filament voltages should be measured with an accurate low range voltmeter. Voltage limits may vary plus or minus 10% of values given.

ALIGNMENT PROCEDURE

The chassis of this receiver is connected through a resistor to one side of the power supply and for this reason all test equipment should be thoroughly isolated in order that the power supply will not be short circuited while attempting to align the receiver.

CONNECTING OUTPUT METER

Connect one terminal of the output meter to the plate and the other terminal to the screen of the 43 Output tube. Be sure the meter is protected from D.C. by connecting a condenser (.1 mfd. or larger—not electrolytic) in series with one of the leads.

1. Tuning I-F Amplifier to 450 Kilocycles.

(a) Connect the output of the signal generator through a .02 condenser to the top cap of the 6A7 Oscillator-Modulator tube, leaving the tube's grid clip in place. Connect the ground lead from the signal generator direct to the receiver chassis **but do not run a wire direct to ground.** KEEP THE GENERATOR LEADS AS FAR AS POSSIBLE FROM THE GRID LEADS OF THE OTHER SCREEN GRID TUBES.

(b) Set the station selector so that the plates of the condenser gang are completely out of mesh and turn the volume control to the right (ON).

(c) Set the signal generator to 450 kilocycles.

(d) Adjust the I-F trimmer condensers for maximum reading on the output meter.

ALWAYS USE THE LOWEST SIGNAL GENERATOR OUTPUT THAT WILL GIVE A REASONABLE OUTPUT METER READING.

2. Aligning R-F Amplifier.

(a) Connect the output lead of the signal generator through a .00005 mf. condenser to the **junction of the antenna and antenna blocking condenser** (Items 34 and 29)

(b) Set the signal generator to 1725 kilocycles.

(c) Open gang all the way (minimum capacity).

(d) Adjust the trimmer located on the "Osc" section of the gang for maximum output.

(e) Set signal generator to 1400 Kc.

(f) Tune station selector to 1400 kc. signal.

(g) Adjust the trimmer located on the "Ant" section of the gang for maximum output.

(h) Repeat e, f, and g for more accurate adjustment.

The tuning range of the receiver is approximately from 540 to 1725 kilocycles (555 to 173 meters).

TUBES AND VOLTAGE LIMITS

The following table gives the functions of the tubes used, together with the voltage readings between the tube socket contacts and B—. Voltage readings should be taken with a 1000 ohm per volt, 250 volt voltmeter (except filaments) with volume control full on and no signal input. The filament voltages should be measured with an accurate low range voltmeter. Voltage limits may vary plus or minus 10% of values given.

450 KC. I-F

FIG. 1.—WIRING DIAGRAM—MODELS 666 AND 5666

THE CROSLEY RADIO CORPORATION

MODELS 629, 644, 666 & 5666

The frequency ranges covered are from 540 to 1710 kilocycles in the broadcast band and from 2350 to approximately 7500 kilocycles in the high frequency band.

TUBES AND VOLTAGE LIMITS

The following table gives the functions of the tubes used, together with the voltage readings between tube socket contacts and chassis. Voltage readings should be taken with a 1000 ohm per volt, 500 volt D.C. voltmeter (except filaments) with receiver in operating condition and no signal input. The filament voltages should be measured with an accurate low range A-C voltmeter (Approximately 0 to 10 volts). Voltage limits may vary plus or minus 10% of values given.

TUBE SOCKET VOLTAGE READINGS

Tube	Where Used	H	P	P2	S	Su	K	Ga	Go
6A7	Osc-Mod	6.3	235	—	128	—	6.2	154	—5 to —20

5Y3	Rectifier	5.0	--	—	—	—	335	—	—

Power Output Approximately 4 Watts.
Power Consumption Approximately 68 Watts at 117.5 Volts.
Voltage Drop Across Speaker Field Approximately 95 Volts.

ALIGNMENT PROCEDURE

Connect the output meter to P. and P2 of the 6B5 Output Tube. Be sure the meter is protected from D.C. by connecting a condenser (.1 mfd. or larger--not electrolytic) in series with one of the leads.

1. Tuning I-F Amplifier to 450 Kilocycles.

(a) Connect the output of the signal generator through a .02 mfd. condenser to the top cap of the 6A7 tube, leaving the tube's grid clip in place. Connect the ground lead from the signal generator to the "GND" terminal of the receiver. KEEP THE GENERATOR LEADS AS FAR AS POSSIBLE FROM THE GRID LEADS OF THE OTHER SCREEN GRID TUBES.

(b) Set the station selector so that the tuning condenser plates are completely out of mesh. Turn the volume control knob to the right (ON) and turn the tone control knob to the left (TREBLE).

(c) Turn the band selector switch to the right (High Frequency).

(d) Set the signal generator to 450 kilocycles.

(e) Adjust both trimmers located on top of the 2nd I-F Transformer for maximum output. (Fig. 2).

(f) Adjust both trimmers located on top of the 1st I-F Transformer for maximum output.

(g) Check operations (e) and (f) for more accurate adjustments.

ALWAYS USE THE LOWEST SIGNAL GENERATOR OUTPUT THAT WILL GIVE A REASONABLE OUTPUT METER READING.

2. Aligning R-F Amplifier.

(a) When aligning the R-F Amplifier the output lead from the signal generator should be connected through a dummy antenna to the "ANT" terminal of the receiver. For the broadcast band the dummy antenna should be a .00025 mfd. condenser and for the high frequency band this condenser should be replaced by a 400 ohm (Non Inductive) carbon resistor.

Each band should be shunt aligned, series aligned and then shunt aligned again in the order given. The band selector switch should be set for the band being aligned and the signal generator should be set to the frequency indicated below for each adjustment.

Adjust the "OSC" and "ANT" shunt trimmers (Shunt alignment. See Fig. 3) in the order given for maximum output. Tune the station selector to the generator signal for maximum output and then check the adjustment of the "ANT" trimmer. NOTE: When aligning the high frequency band care should be exercised so that the circuits will be aligned on the fundamental frequency rather than on the image frequency which is approximately 900 kilocycles less than the fundamental. To check on this, increase the output of the signal generator approximately 10 times and try to tune-in the signal both at the generator frequency as indicated on the station selector dial and at approximately 900 kilocycles below the correct frequency. If the circuits have been properly aligned the signal can be tuned-in at both positions but much stronger at the correct dial setting.

To adjust the "series" trimmers (Fig. 3) set the signal generator to the frequency indicated below and then tune-in this signal with the station selector for maximum output. Adjust the series trimmer while rocking the tuning condenser back and forth slightly, until no further improvement in output can be obtained.

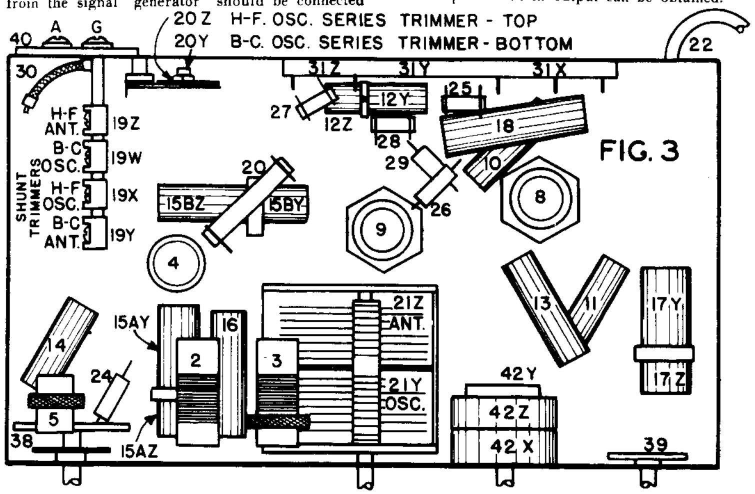

FIG. 3

(b) Signal Generator Frequencies.

	Shunt Alignment	Series Alignment
Broadcast Band	1400 Kc.	600 Kc.
High Frequency Band	6000 Kc.	1500 Kc.

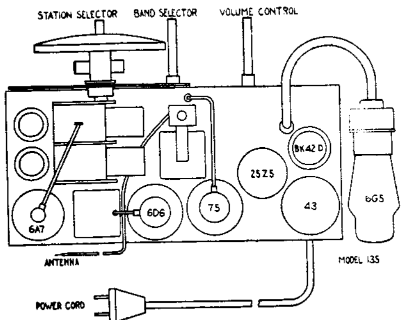
MODEL 135



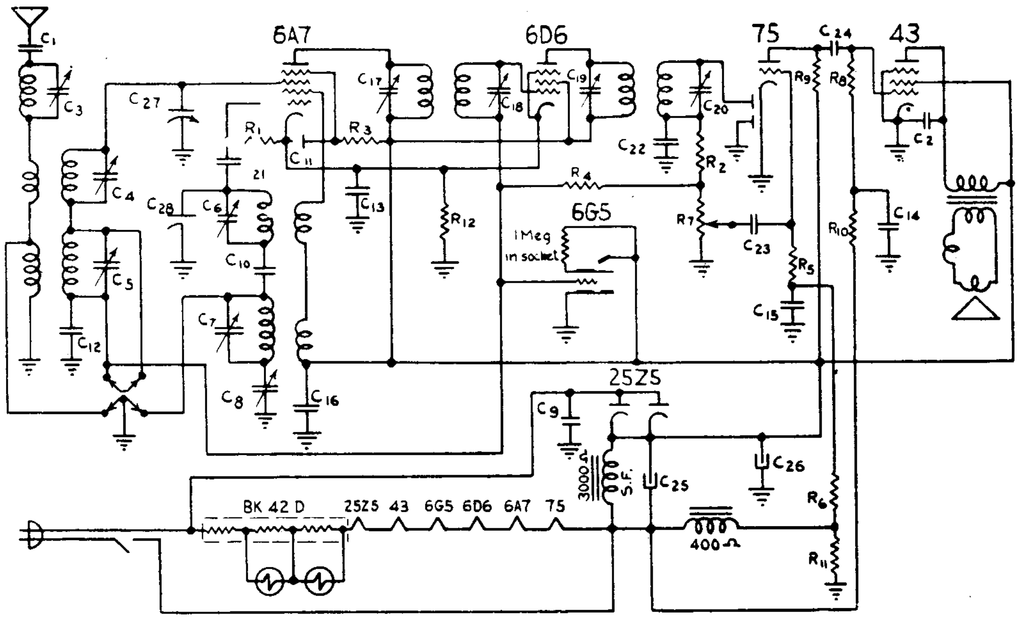
I. F. 456 K.C.

TUBE LAYOUT CHART — MODEL 135

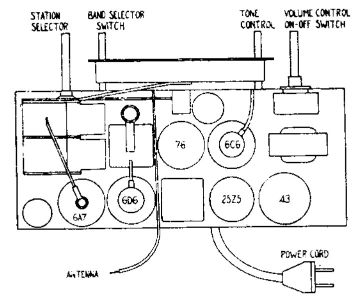
Tubes must be in proper sockets and connected as shown.

- C1, C2 .005 - 600 v.
- C3 180 mmf. trimmer
- C4, C5, C6, C7, 1 - 10 mmf. trimmer
- C8 350 mmf. padder
- C9 .02 - 600
- C10 1150 mmf. mica
- C11, C12 .05 - 200
- C13, C14, C15, C16 .1 - 200 v.
- C17, C18, C19, C20 100 - 125 trimmer
- C21 50 mmf. mica
- C22 250 mmf. mica
- C23, C24 .01 - 600 v.
- C25 16 mfd. 150 v.
- C26 24 mfd. 150 v.
- C27, C28 variable air
- R1, R2, 50M 1/3 w.
- R3 20M 1/3 w.
- R4, R5, R6 1 meg. 1/3 w
- R7 500M volume control and switch
- R8 500M 1/3 w.
- R9 200M 1/3 w.
- R10 300M 1/3 w.
- R11 20 ohms. 1/2 w.
- R12 100 ohms. 1/3 w.

When ordering replacement parts, give symbol, description, and model number of set. For example: "C14.1 - 200 Volt Condenser, Model 135."



MODEL 140



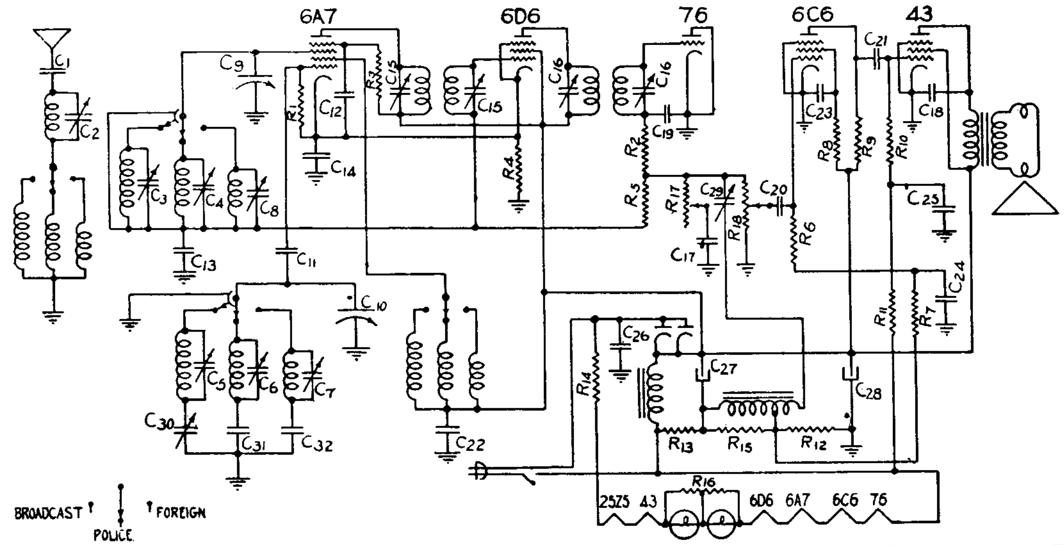
I.F. 456 K.C.

TUBE LAYOUT CHART — MODEL 140

Tubes must be in proper sockets and connected as shown.

- C1 .005 600 v.
- C2 180 mmf. trimmer
- C3, C4, C5, C6, C7, 1 to 10 mmf. trimmer
- C8 3 to 35 mmf. trimmer
- C9, C-10 350 mmf. air variable
- C11 50 mmf. mica
- C12, C13, .05-200 v.
- C14 .2 200
- C15, C16 120 mmf. trimmer
- C17, C18 .003 600 v.
- C19 250 mmf. mica
- C20 .01 200 v.
- C21 .01 400 v.
- C22, C23, C24 .1 200 v.
- C25 .2 200 v.
- C26 .02 600 v.
- C27 16 mfd. 150 v. wet electrolytic
- C28 24 mfd. 150 v. wet electrolytic
- C29 3 to 35 mmf. trimmer
- C30 220 to 550 mmf. padder
- C31 1330 mmf. padder
- C32 3850 mmf. padder
- R1, R2 50M ohms
- R3 20M ohms
- R4 200 ohms
- R5, R6, R7, R8 1 megohm
- R9 250M ohms
- R10 500M ohms
- R11 300M ohms
- R12, R13 35 ohms
- R14 100 ohms line cord
- R15 10M ohms
- R16 45 ohms center tapped
- R17 2 megohms tone control
- R18 500M ohms vol. control

When ordering replacement parts, give symbol, description, and model number of set. For example: "C22, .1 - 200 Volt Condenser, Model 140."



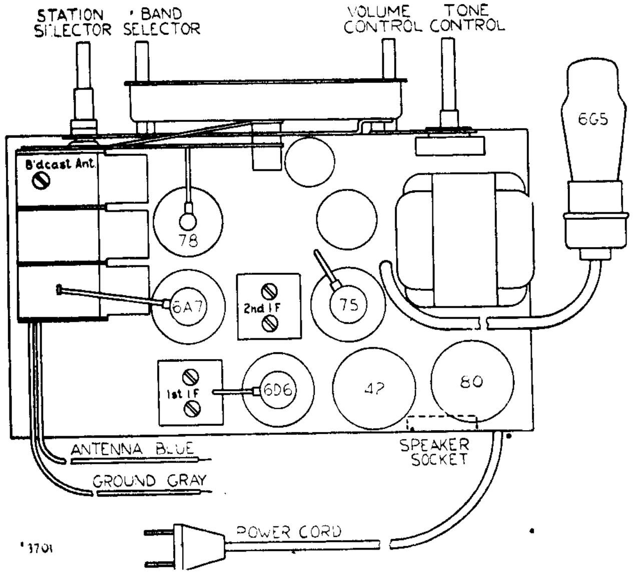
DETROLA RADIO AND TELEVISION CORPORATION

MODEL DETROLA 146E

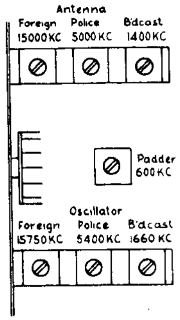
The I.F. frequency of this receiver is 456 K.C. For realignment, use the following procedure.

It is necessary to use an accurately calibrated signal generator. Couple the signal generator to the grid of the 6A7 tube with a tenth microfarad condenser in series with the "high" lead of the signal generator. Connect the ground side of the signal generator to the chassis. Set the signal generator to 456 K.C. Be sure the wave switch of the set is in the broadcast position and the volume control set at maximum. Attenuate the signal generator so that the signal is just audible in the speaker. If an ouput meter is used, it should be connected across the voice coil terminals of the speaker. Use ½ volt as standard output.

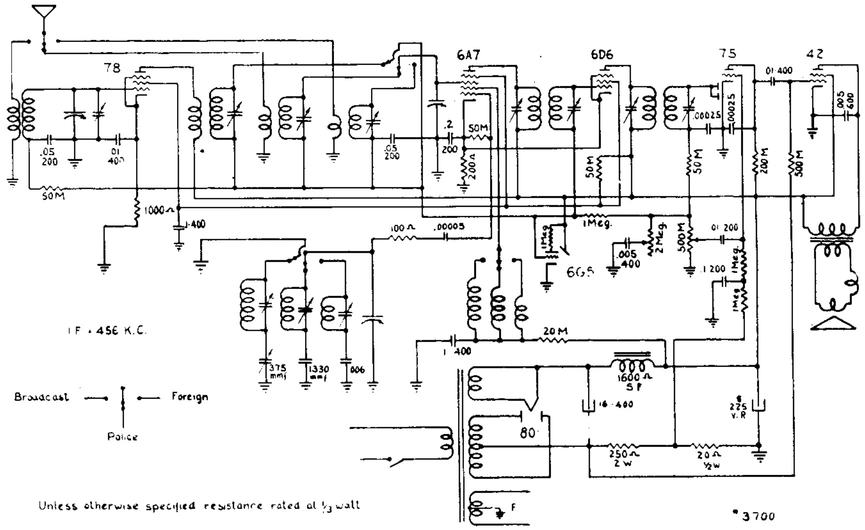
Adjust the 2nd I.F. transformer first. Each screw should be adjusted for maximum output. After number two I.F. has been adjusted, number one I.F. should be adjusted for maximum output. After both transformers have been adjusted, it is necessary to recheck No. 2 transformer and then recheck No. 1.



*3701



TRIMMER ADJUSTMENT



Unless otherwise specified resistance rated at ⅓ watt

*3700

RF. (See above diagram for location of trimmers.) Using 200 mmf condenser in series with the generator, feed 1660 kc to antenna lead and adjust broadcast oscillator trimmer for top frequency. Set generator to 1400 kc, tune receiver and adjust the *two* antenna trimmers. Set generator to 600 kc, tune receiver to signal and adjust padder. The tuning condenser should be rocked back and forth through the signal while the padder is being set in order to secure perfect alinement.

Using 400 ohm resistor in series with generator, set band selector in center position, set generator to 5400 kc and adjust oscillator trimmer for top frequency. Set generator to 5000 kc, tune receiver to signal and adjust antenna trimmer

Turn band selector to extreme clockwise position. Using 400 ohm resistor in series with generator, set oscillator top frequency for 15,750 kc—screw trimmer down tight, then unscrew to *second* peak. Set generator to 15,000 kc, tune receiver to signal and adjust antenna trimmer—Screw trimmer down tight, then unscrew to *first* peak, rocking the tuning condenser back and forth through the signal while the adjustment is being made. **Above procedure for alinement at 15,000 kc must be followed exactly to insure proper tracking. A dead spot at about 12,000 kc will result if antenna and oscillator circuits are not set in proper relation to each other.**

Tube Data

The tube complement for receivers bearing serial numbers **below** 1,266,501 is as follows:

1—6A7 pentagrid oscillator-modulator
1—6D6 first i-f amplifier
1—75 diode detector, a.v.c., audio amplifier
1—43 pentode power output
1—25Z5 dual half-wave rectifier
1—3CR-241 ballast tube.

The tube complement for receivers bearing serial numbers **above** 1,266,501 is as follows:

1—6A7 pentagrid oscillator-modulator
1—6D6 first i-f amplifier
1—6Q7 diode detector, a.v.c., audio amplifier
1—25L6 beam power output
1—25Z5 dual half-wave rectifier
1—2UR-224 ballast tube.

NOTE—Except when otherwise specified all octal base tubes may be replaced with either metal or octal base glass tubes.

EMERSON RADIO AND PHONOGRAPH CORPORATION

MODELS AA & AA-131

ADJUSTMENTS

An oscillator with frequencies of 150, 350, 456, 600, 1500 and 15,000 kc should be used.

An output meter should be used across the voice coil or output transformer for observing maximum response.

Use a standard dummy antenna when aligning either the long-wave or medium-wave bands. A .0002 mf condenser may be used as a substitute. When aligning the short-wave band use a 400 ohm dummy antenna (a 400 ohm resistor in series with antenna lead).

The set's oscillator is higher in frequency than the signal, so images should be observed on the low frequency side of the signals.

Always choose the minimum capacity peak on oscillator trimmers and maximum capacity peaks on antenna trimmers. The last motion is adjusting trimmers should always be a tightening one, not a loosening one.

Never leave a trimmer with the outside plate so loose that there is no tension on the screw. Either bend the plate up or remove the screw entirely.

Always use as weak a test signal as possible during alignment.

Location of Coils and Trimmers

The antenna coils for the three bands are wound on one form and mounted underneath the chassis deck to the right of the variable condenser. The trimmers for these coils are accessible through three holes in the top of the chassis. The trimmer farthest from the front of the chassis is for the long-wave antenna coil. The trimmer closest to the front of the chassis is for the medium-wave antenna coil, and the central trimmer is for the short-wave antenna coil.

The oscillator coils for the three bands are wound on one form and mounted on the inside of the rear chassis wall. The trimmers for these coils are accessible through holes in the rear chassis wall. The trimmer farthest from the end of the chassis is for the long-wave oscillator coil. The trimmer nearest the end of the chassis is for the medium-wave oscillator coil, and the central trimmer is for the short-wave oscillator coil.

The two i-f transformers are in oblong coil cans located on the top of the chassis. The first i-f transformer is the one behind the variable condenser. The trimmers for these transformers are accessible through holes in the tops of the cans.

The series padding condensers for the long-wave and medium-wave bands are located on the rear chassis wall below the 6A7 tube.

I-f Alignment

Rotate the wave-band switch to the medium-wave (central) position and set the variable condenser to minimum. Feed 456 kc to the grid cap of the 6A7 tube through a .02 mf paper condenser, (do not remove the grid clip from the tube). Adjust the four i-f trimmers for maximum response.

Long-Wave Alignment

With the wave-band switch at long-wave (clockwise) position set the dial pointer at 15 and feed 150 kc to antenna. Adjust the long-wave series padder (hex nut on dual padder) for maximum response. Move pointer to 35 and feed 350 kc to antenna. Adjust the long-wave oscillator trimmer then the long-wave antenna trimmer for maximum response. Reset pointer to 15, feed 150 kc and rock (rotate back and forth through a small arc) the variable condenser while adjusting long-wave series padder for maximum response. Reset pointer to 35, feed 350 kc and check alignment. If readjustment is necessary return to 150 kc and repeat entire procedure.

Medium-Wave Alignment

Set switch at medium-wave (central) position and dial pointer at 60. Feed 600 kc to antenna and adjust medium-wave series padder (slotted screw on dual padder) for maximum response. Move pointer to 150, feed 1500 kc and adjust medium-wave oscillator trimmer and then the medium-wave antenna trimmer for maximum response. Reset pointer to 60, feed 600 kc and rock variable condenser while readjusting medium-wave series padder for maximum response. Reset pointer to 150, feed 1500 kc and check alignment. If readjustment is necessary return to 600 and repeat entire procedure.

Short-Wave Alignment

Set wave-band switch at short-wave (counter-clockwise) position. Set pointer at 15, feed 15 megacycles to antenna and adjust short-wave oscillator trimmer and then short-wave antenna trimmer for maximum response.

GENERAL NOTES

1. If replacements are made or the wiring disturbed in the r-f portion of the circuit, the receiver should be carefully re-aligned.
2. One side of the power line is directly grounded to the chassis base. Under no circumstances, therefore, should a ground wire be permitted to come in contact with any metal part of the receiver.
3. The filament dropping resistor is in a special metal tube at the rear of the chassis. This tube will become quite hot under normal operating conditions. For voltage drop specifications, see below.
4. The power supply for this receiver may be either a.c. or d.c. The standard line voltage rating is 105 to 125 volts. With special external line ballast resistors this receiver may be operated on higher voltages.
5. When operating the receiver on d.c. it may be necessary to reverse the line plug to obtain the correct polarity.
6. The two i-f transformers are held to the chassis by snap-on fasteners. To remove an i-f, unsolder all the leads under the chassis, pinch together the prongs of the snap-on fastener and lift the i-f can from the chassis.
7. The color coding of the i-f transformer leads is as follows:

   Grid—green — Plate—blue
   Grid return—black — B plus—red
8. An efficient antenna system is necessary to enable a full realization of the merits of the receiver. For reductions of noise and achievement of high efficiency on all frequency ranges the Emerson All-Wave High-Fidelity Antenna, Model W-78, and the Emerson All-Wave Antenna System, Model W-89, are recommended. Instructions for the installation of these antennas are supplied with each kit.

   In congested areas where the installation of a large antenna is not desirable we recommend the use of the Emerson Flexible Mast Antenna, Model W-82. Instructions for the installation of this compact and efficient antenna are supplied with each kit.

VOLTAGE ANALYSIS

Readings should be taken with a 1000 ohms-per-volt meter. Voltages listed below are from point indicated to ground (chassis) with the volume control turned on full and no signal. Line voltage for these readings was 117.5 volts, 60 cycles, a.c.

The following are voltages for receivers bearing serial numbers *below* 1,266,501:

Tube	*Plate*	*Screen*	*Cathode*	*Osc. Plate*	*Fil.*
6A7	96	35	0.6	57	6.3
6D6	96	78	2	—	6.3
75	35	—	0	—	6.3
43	85	96	0	—	24

Voltage across speaker field—125
Voltage across filter choke—11.1

The bias for the 75 and 43 is developed across resistors R22 and R23 (see schematic diagram). The voltage across R22 is 11 volts and the voltage across R23 is 1 volt.

The voltage drop across the ballast resistor (R16—see schematic) is 49 volts between pins 3 and 7.

The following are voltages for receivers bearing serial numbers *above* 1,266,501:

Tube	*Plate*	*Screen*	*Cathode*	*Osc. Plate*	*Fil.*
6A7	100	42	1.6	75	6.3
6D6	100	100	3.6	—	6.3
6Q7	36	—	0.8	—	6.3
25L6	95	100	6.7	—	24

Voltage across speaker field—27.5

The voltage drop across the ballast resistor (R15—see schematic) is 49 volts between pins 3 and 7.

REPLACEMENT PARTS LIST

NOTE: Schematic No. 1 applies to receivers bearing serial numbers below 1,266,501. Schematic No. 2 applies to receivers bearing serial numbers above 1,266,501.

VOLTAGE ANALYSIS

Readings should be taken with a 1000 ohms-per-volt meter. Voltages listed below are from point indicated to ground (chassis) with the volume control turned on full and no signal. Line voltage for these readings was 117.5 volts, 60 cycles, a.c.

Tube	*Plate*	*Screen*	*Cathode*	*Osc. Plate*	*Fil.*
6A7	100	50	2.3	100	6.3
6D6	100	100	3.5	—	6.3
6Q7	43	—	1.2	—	6.3
25L6	92	100	6.5	—	25.0

Voltage at 25Z5 cathode—128 volts.

Voltage across speaker field—28 volts.

Location of Coils and Trimmer Adjustments

The first i-f transformer is mounted on top of the chassis deck beside the speaker. The trimmers are accessible through holes in the top of the can.

The second i-f transformer is mounted underneath the chassis in the right hand front corner. The trimmers are accessible through holes in the top of the chassis directly in front of the first i-f transformer.

The trimmers for the antenna and oscillator coils are located on the variable condenser. The trimmer on the front section is for the antenna coil.

The 456 kc wave-trap is mounted on the metal strip at the rear of the chassis directly behind the variable condenser. The trimmer for the 456 kc wave-trap is mounted on the coil and is accessible from the bottom of the chassis.

I-f and Wave-trap Alignment

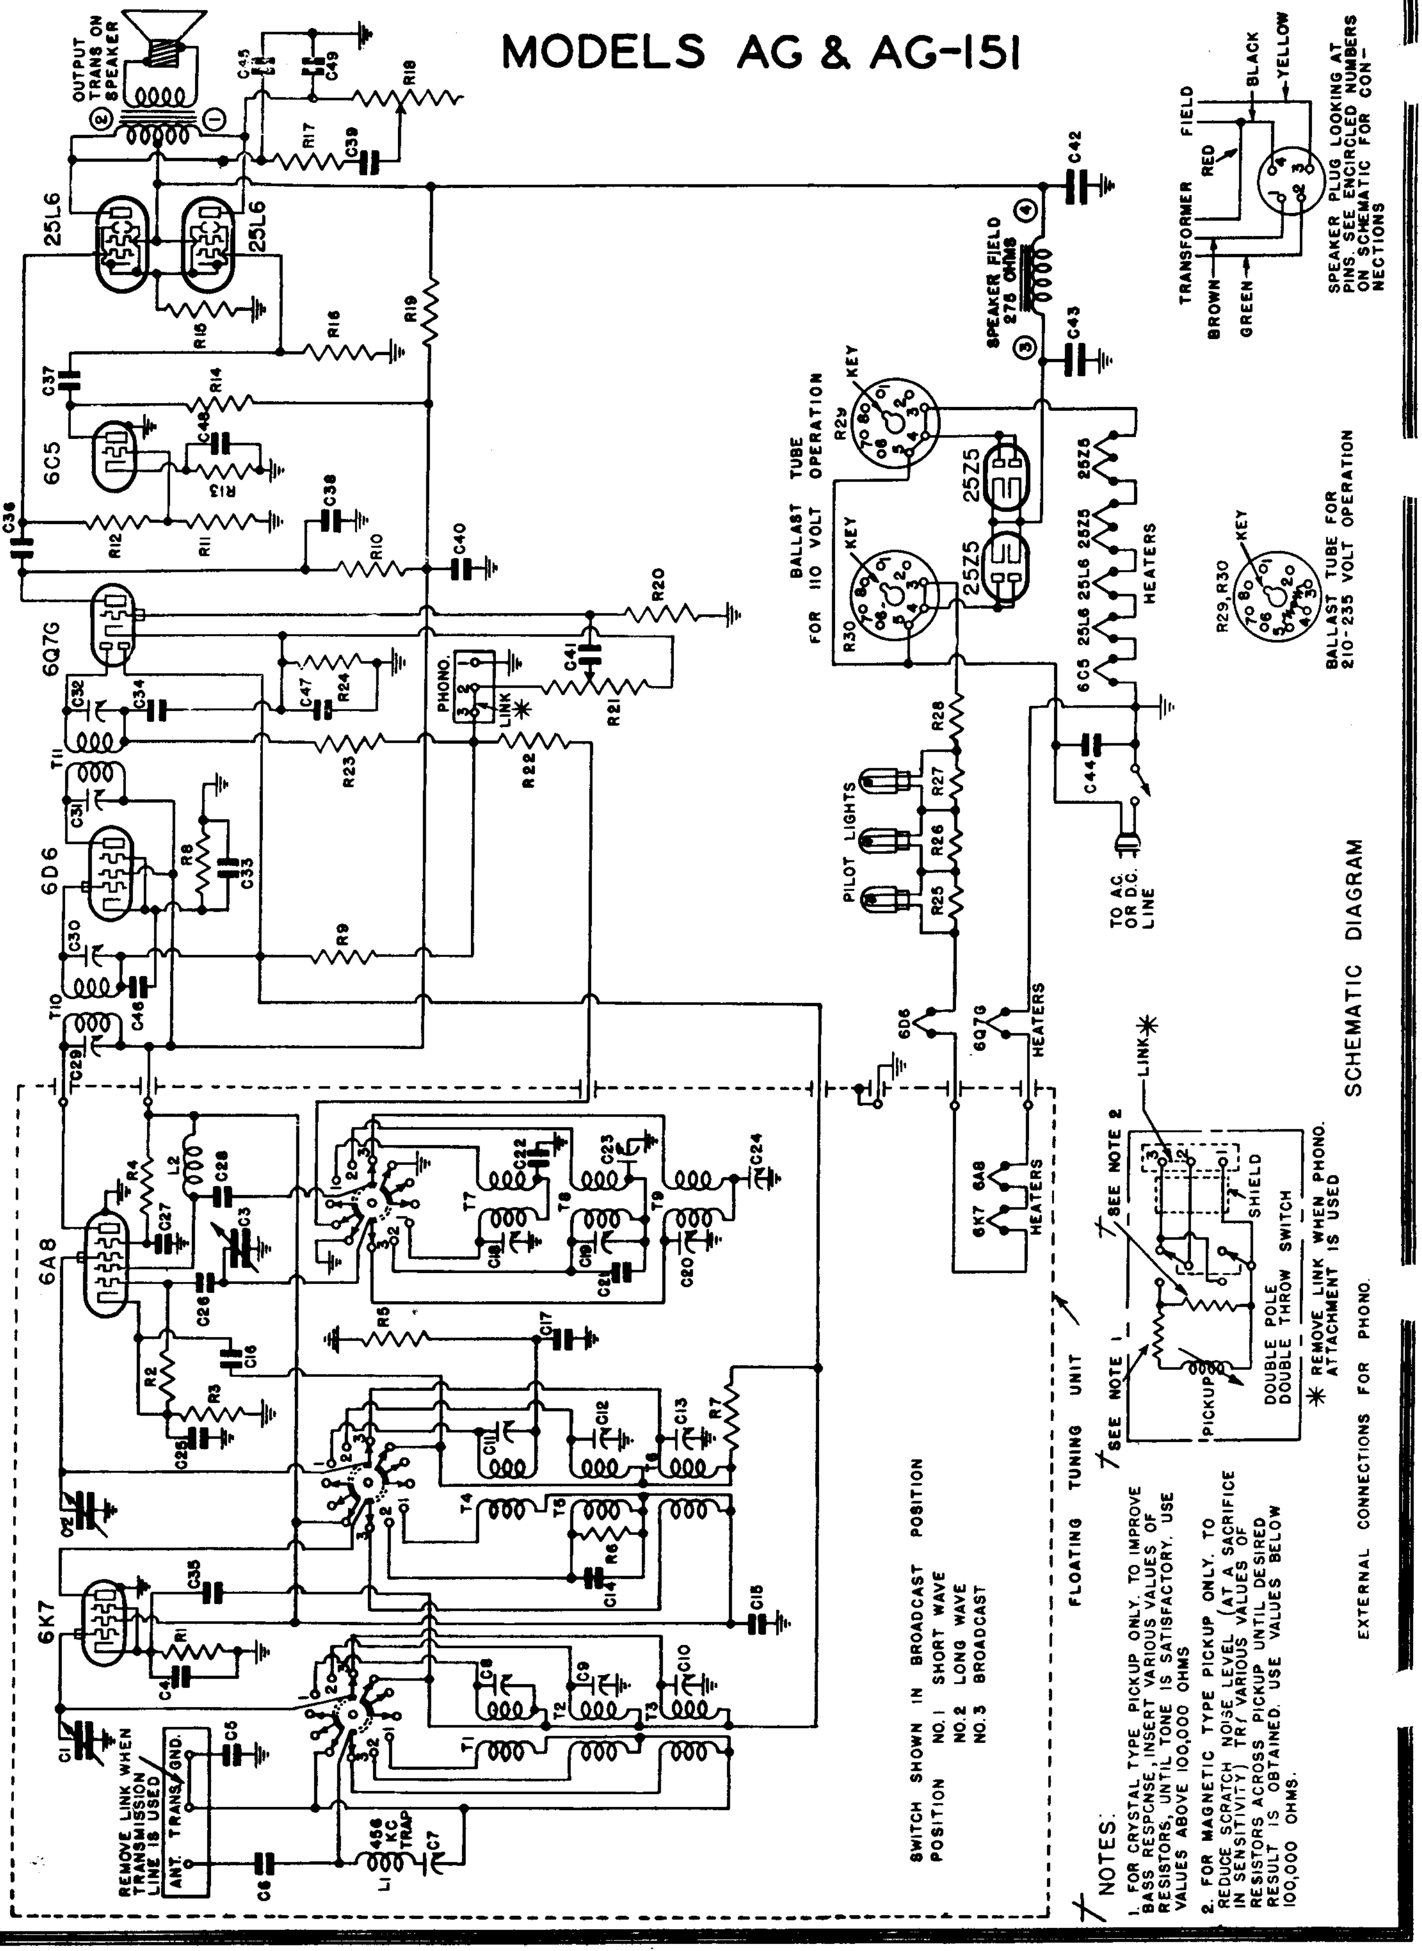
Rotate the wave-band switch (located at the rear of the chassis) to the broadcast position, clockwise, and swing the variable condenser to the minimum capacity position. Feed 456 kc to the grid-cap of the 6A7 tube and adjust the four i-f trimmers for maximum response. Feed 456 kc through a dummy antenna (a .0002 mf condenser may be used as a substitute) to the antenna lead and adjust the wave-trap trimmer for *minimum* response. (See General Notes, paragraph No. 7.)

R-f Alignment

With the wave-band switch in the broadcast position, clockwise, set the dial pointer at 140. Feed 1400 kc through a standard dummy antenna (a .0002 mf condenser may be used as a substitute) to the antenna lead and adjust first the oscillator trimmer (on rear section of variable condenser) then the antenna trimmer (on front section of variable condenser) for maximum response. The police band is self-tracking and does not require any adjustment.

EMERSON RADIO AND PHONOGRAPH CORPORATION

MODELS AG & AG-151



EMERSON RADIO AND PHONOGRAPH CORPORATION

MODELS AG & AG-151

ADJUSTMENTS

An oscillator with frequencies of 150, 345, 456, 600, 1600 and 16000 kc should be used.

An output meter should be used across the voice coil or speaker output transformer for observing maximum response.

Use a standard dummy antenna for aligning any of the three bands. A .0002 mf condenser may be used for the medium-wave band and the long-wave band dummy antenna and a 400 ohm non-inductive resistor for the short-wave dummy antenna.

Always use as weak a test signal as possible when aligning the receiver.

The set's oscillator is higher in frequency than the signal on all three bands. Images, therefore, should be observed on the low-frequency side of the signals.

Always choose the minimum capacity peak on oscillator trimmer and maximum capacity peaks on antenna and r-f trimmers. The last motion in adjusting trimmers should always be a tightening one.

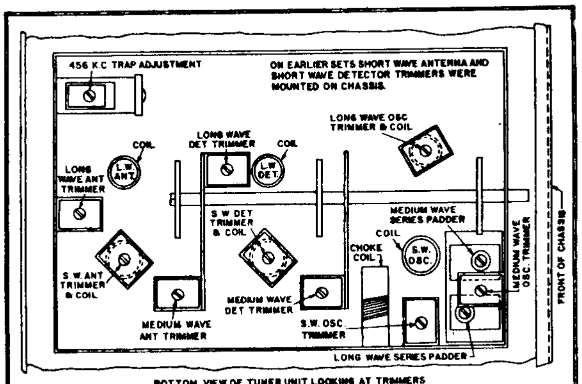
Never leave a trimmer with the outside plate so loose that there is no tension on the screw. Either bend the plate up or remove the screw entirely. Loose screws are a source of noise, frequency drift and microphonism.

In aligning antenna trimmers on the high-frequency signals there is usually a tendency for the oscillator to drift, due to interlocking. To compensate for this always keep re-tuning the variable condenser as you align.

Location of Coils and Trimmer Adjustments

The i-f transformers are located on the extreme left side of the chassis. The transformer nearest the front of the chassis is the first i-f transformer. The four trimmers for the i-f adjustment are available through holes in the tops of the cans.

The medium-wave, long-wave and short-wave coils are all located on the tuner unit. The tuner unit is the separate chassis section floated on rubber and mounted in center of chassis. The location of the trimmers for the coils is shown in the illustration at the right. The three coils for the medium-wave band are in separate cans on top of the tuner unit.



BOTTOM VIEW OF TUNER UNIT LOOKING AT TRIMMERS

I-f Alignment

Set the wave-band switch at the medium-wave (clockwise) position and the variable condenser at the minimum capacity position. Feed 456 kc to the grid cap of the 6A8 tube. Adjust the four i-f trimmers carefully for maximum response. Feed 456 kc through a dummy antenna into the antenna terminal and adjust the 456 kc wave-trap for *minimum response.* (See General Notes.)

Medium-Wave Alignment

Both pointers on the dial should coincide vertically at 890 kc. For adjustment, the gold pointer may be slipped around its shaft. With the wave-band switch at the medium-wave (clockwise) position, set the pointer at 60, feed 600 kc through the antenna (using a standard dummy antenna), and adjust the medium-wave series padder for maximum response. Move pointer to 160, feed 1600 kc to the antenna and adjust the oscillator trimmer for maximum response, then adjust detector and antenna trimmers. Reset the pointer to 60, feed 600 kc to antenna and rock the variable condenser (rotate the condenser back and forth through a small arc) while resetting the oscillator padder for maximum response. Return to 1600 and check alignment. If readjustment is necessary, return to 600 and repeat entire procedure.

Long-Wave Alignment

Set the wave-band switch at the long-wave (central) position and the pointer to 150. Feed 150 kc through a standard dummy antenna to the antenna terminal and adjust the long-wave series padder for maximum response. Move the pointer to 345, feed 345 kc and adjust the long-wave oscillator trimmer, then the r-f trimmer and then the antenna trimmer for maximum response. Return to 150 kc and re-adjust the long-wave series padder for maximum response. Return to 345 kc and re-adjust all three trimmers. Return again to 150 and check the alignment. Repeat the entire procedure until no appreciable re-adjustment is required.

Short-Wave Alignment

Set the wave-band switch at the short-wave (counter-clockwise) position. Move pointer to 16, feed 16000 kc to antenna (using a 400 ohm dummy antenna) and adjust the short-wave oscillator for maximum response. If two peaks are obtained choose minimum capacity peak. Then adjust the detector and antenna trimmers for maximum response. If two peaks are obtained choose the maximum capacity peak.

VOLTAGE ANALYSIS

Readings should be taken with a 1000 ohms-per-volt meter. Voltages listed below are from point indicated to ground, with no signal, volume control turned on full, and variable condenser at minimum capacity position. The line voltage for these readings was 117.5 volts, 60 cycles, a.c.

Tube	*Plate*	*Screen*	*Osc. Plate*	*Cathode*	*Fil.*
6K7	80	80	—	2.6	6.3

25Z5	—	—	—	105	25.0

Voltage across speaker field—82.

EMERSON RADIO AND PHONOGRAPH CORPORATION

MODELS AG-AG-151

1. An electrical phonograph pick-up may be connected to this receiver for playing records. Connections to the receiver may be made at the "phono" terminal strip which is located on the rear wall of the receiver chassis. A double-pole, double throw-switch is necessary in addition to the phonograph pick-up and motor. The receiver volume control may be used to control the phonograph volume. Remove the link connecting two of the terminals on the phono strip. The switch should be wired to the pick-up and terminal strip so that in the phonograph position the switch should short terminals 1 and 3 and at the same time connect the high side of the pick-up to a lead from terminal 2. (The ground side of the pick-up may be permanently wired to terminal 1.) When the switch is in the radio position terminals 2 and 3 should be shorted together and the pick-up disconnected from terminal 2. A matching input transformer must be used if the pick-up is of the low impedance type. If the phonograph be permanently disconnected, the small connecting link must be replaced across terminals 2 and 3. (See schematic diagram.)
2. The receiver should never be turned on with the speaker plug out of its socket, since the rapid rise in rectifier voltage would damage the electrolytic condenser.
3. Pilot lights may be replaced by slipping the push-on sockets off the dial and unscrewing the bulbs. It is not necessary to remove either the dial or chassis from cabinet.
4. In replacing chassis in cabinet do not tighten mounting screws so much that chassis will not float freely, and do not allow any part of the dial assembly to touch the cabinet. Do not push control knobs on so far that they touch the cabinet front panel. If these precautions are not observed the receiver may become microphonic.
5. One side of the power line is connected to the chassis. Under no condition, therefore, should a ground wire be allowed to come in contact with any metal part of the receiver.
6. An efficient antenna system is necessary to enable a full realization of the merits of the receiver. For reduction of noise and achievement of high efficiency on all frequency ranges the Emerson All-Wave High Fidelity Antenna, Model W-78, or the Emerson All-Wave Antenna System, Model W-89, are recommended. Complete instructions for the installation of these antennas are supplied with each kit.
7. The wave-trap in the receiver has been adjusted for maximum signal rejection at 456 kc. If, however, persistent interference is experienced from some particular telegraphic station, readjust the wave-trap trimmer until the response from the interfering station is at a minimum.
8. The receiver for 105-125 volt operation may be easily converted for 210-250 volt operation by substituting ballast tubes part no 3MR-253 for ballast tubes part no. 3MZ-419.

Voltage rating .... 105-125 volts, a.c. or d.c. (with ballast tubes part no. 3MZ-419).
210-250 volts, a.c. or d.c. (with ballast tubes part no. 3MR-253).

Current drain .... 0.7 amps.

Frequency ranges .... 140 to 375 kc, 540 to 1800 kc, 5.5 to 18.0 megacycles.

MODELS 4A & 4B

ALIGNMENT

Alignment procedure is given below in chart form (Figure 4). Make adjustments in the order given. Any low range AC voltmeter, preferably about 0-15 volts, may be used for an output meter. It should be connected from the plate of the 1F5G tube to ground with a .1 mfd. condenser in series with one of the leads. The volume control should be set at maximum during the alignment and the output from the signal generator should be decreased as the meter hand tends to go off scale. If too strong a signal is used and the volume control is used to keep the hand on scale, the A.V.C. will operate and inaccurate alignment will result.

ALIGNMENT PROCEDURE CHART

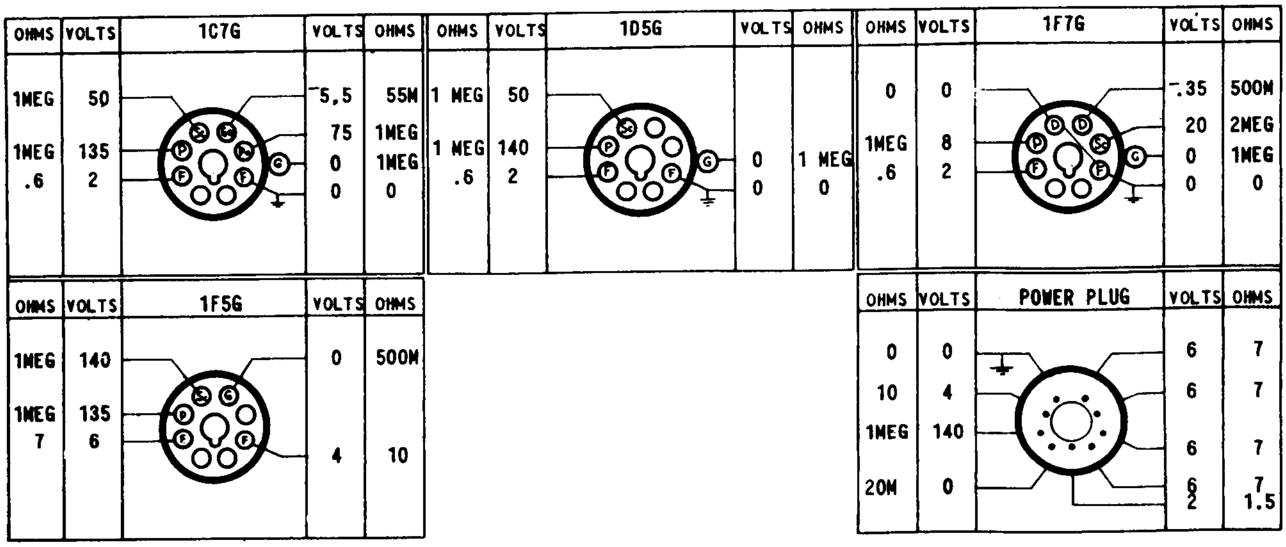

FIGURE 5
VOLTAGE AND RESISTANCE ANALYSIS CHART MODEL 4B

FAIRBANKS, MORSE & CO., HOME APPLIANCE DIVISION

MODELS 4A & 4B

The model 4A-4B chassis employs a superhetrodyne circuit with automatic volume control (Figure 2). The receiver operates equally well on a six-volt storage battery or on any of the conventional A, B and C battery arrangements (Figure 1). New high-gain, octal-base tubes are used (Figures 3 and 5), making possible a receiver of high sensitivity with low battery drain.

On six-volt operation the current consumption is only approximately 1.3 amperes. As a two-volt receiver the "A" and "B" currents are approximately .55 amperes and 20 milliamperes respectively.

In order to make interchangeability as simple as possible, a nine-prong socket and plug power connection is employed (Figure 2). Only part of these prongs are used on either battery arrangement. A careful study of the circuit diagram should be made before any attempt is made to replace defective parts in the receiver, since the purpose of the various connections may not be readily apparent from a chassis inspection alone.

"B" AND "C" BATTERIES

Four Standard Battery Plugs will be found on the battery cable. Three of these are identical to each other and are to be plugged into the Standard Receptacles on the three "B" batteries. The remaining plug, the one with one large prong, should be plugged into the "C" battery.

DO NOT ALLOW THE "A" BATTERY LEADS TO COME IN CONTACT WITH ANY OF THE "B" BATTERY TERMINALS. IF THIS HAPPENS, THE TUBES, RECEIVER AND BATTERIES MAY BE SERIOUSLY DAMAGED.

32 VOLTS D.C. RECEIVER

VOLTAGES

Tolerances of about 10% plus or minus are allowable on the following list of measured voltages. In the event all voltages are low try replacing the 25Z5 rectifier tube or vibrator. All measurements are made to ground except on filament voltage.

TUBE		PLATE	GRID	SCREEN	CATHODE	HEATER
39	1st Det.	205	0	120	12.5	6.3
39	R. F.	205	0	120	5	6.3
39	I. F.	205	0	120	5	6.3
37	Osc.	120	0	-	0	6.3
37	A. F.	185	0	-	12.5	6.3
85	2nd Det.	45	0	-	0	6.3
79	A. F.	205 each	0 each	-	0	6.3
25Z5	Rect.	-	-	-	-	-

ALIGNMENT PROCEDURE

If the set is weak or broad it is possibly out of alignment and the following adjustments should be made.

1. A 177.5 kilocycle signal, from a good service oscillator, should be supplied to the grid of the 39 first detector tube thru a small condenser. The trimmers on the first and second I. F. transformers should be adjusted for maximum output with minimum input from the service oscillator. The first I. F. transformer is located at the left of the chassis and the second I. F. at the right of the chassis, viewed from the front. These trimmers may be reached from the bottom of the chassis.

2. Supply a 1500 kilocycle signal to the antenna of the set. Tune the dial to 1500 kilocycles. Adjust the trimmer on the oscillator section of the gang condenser (the rear section) for maximum output with minimum input from the service oscillator.

3. Adjust the trimmers on the R. F. and first detector sections of the gang condenser for maximum output with minimum input from the service oscillator.

VIBRATOR NOISE PICKUP

In the event vibrator noise pickup is present the various ground connections on the set should be carefully checked. Special attention should be given the grounds on the large, fin type, separator shield on top of the chassis, and on the center fin of the gang condenser. In the event all grounds are satisfactory and noise is still present try placing the antenna lead as far as possible from the vibrator can. In some cases it is helpful to place an eight or ten inch shield over the antenna lead and ground the end of this shield on the chassis at the point where the antenna lead enters. In some cases it is helpful to use an additional ground on the large separator shield at a point even with the center section of the gang condenser.

HOWL AND VIBRATION

Howl is usually due to a defective tube. This may be checked by replacing the tubes in the receiver one by one. The type 37 oscillator and the type 37 first audio tube should be checked first. Do not, under any condition, remove a tube from the receiver without first turning the set off.

Excessive vibration, after the set has warmed up, is usually due to a loose part or screw. A careful checkup will usually reveal the source of trouble. On early models excessive mechanical vibration may be eliminated by replacing vibrator or by mounting vibrator on sponge rubber.

All voltages except filament, are measured from socket terminals to chassis and with a 1000 Ohms per volt voltmeter. The set must be in operation and the sensitivity control in its maximum clockwise position.

Filament voltages are taken from filament prong to filament prong at tube socket and measured with a low impedance AC voltmeter.

ALIGNMENT PROCEDURE

Realignment of this receiver should not be attempted unless all other possible causes of faulty operation have been thoroughly investigated. An accurately calibrated signal generator which will cover the necessary wave-bands and an output meter for indicating the effect of adjustments are required.

It is important to remember that in receivers of this kind which are equipped with automatic volume control it is necessary to use the minimum possible signal from the signal generator; otherwise the A.V.C. action will tend to nullify the variations in output as the trimmers are adjusted.

I.F. ADJUSTMENT - The signal generator is set at 456 kc. and is connected to the grid of the first detector (6A8). With the oscillator section of the tuning condenser short-circuited and the receiver volume control at its maximum position, the i.f. trimmers are adjusted for maximum output. These trimmers may be found on the tops of the I.F. Transformers.

18 MEGACYCLE ADJUSTMENT - The high side of the signal generator is connected to the antenna lead of the receiver and the low side to the ground lead. The receiver and the signal are both tuned to a frequency of 18 mc. with the selector switch in position for band no. 1. The oscillator trimmer condenser is adjusted so that the 18 mc. signal is tuned in exactly at the 18 mc. calibration point, with the volume control on full and the signal generator adjusted for minimum input. The antenna preselector and interstage trimmers are then adjusted in the order named for maximum output. These trimmers are located as indicated in the bottom view of the chassis.

6 MEGACYCLE ADJUSTMENT - The signal generator is set at 6 megacycle and the signal tuned in on the dial. The short wave padding condenser is adjusted for maximum output, while the gang condenser is rocked slightly to the right and left. The 18 megacycle adjustment should then be rechecked.

5 MC. ADJUSTMENT - With the band selector switch in position for operation on band no. 2. and the receiver and signal generator both set at 5 mc. the procedure outlined above is repeated.

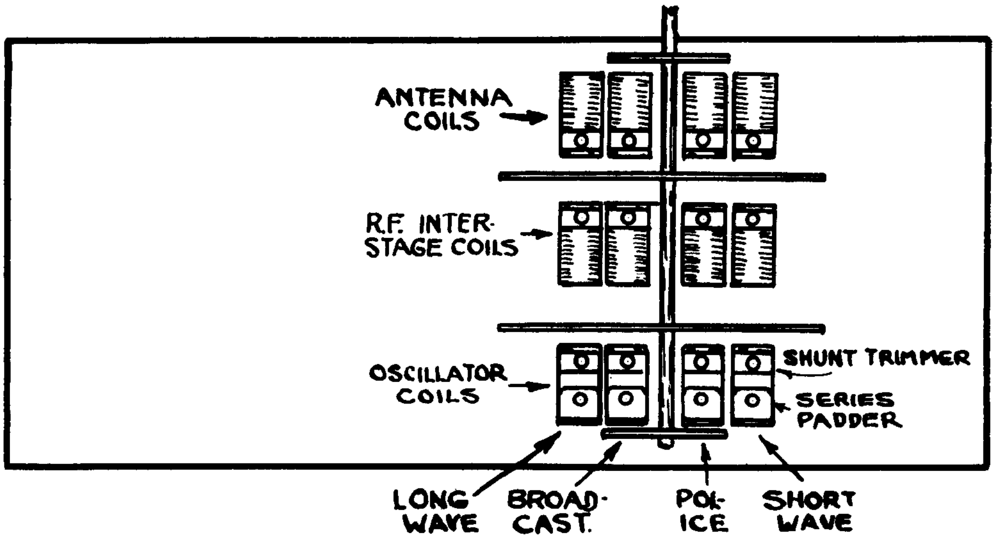
The signal generator is set at 1.8 mc. and the signal tuned in on the dial. The police band padder condenser is adjusted for maximum gain while the gang tuning condenser is rocked slightly to the right and left. The 5 mc. adjustment should then be rechecked.

1500 KC. ADJUSTMENT - The band selector switch is set in position for operation on the no. 3. band. The receiver and signal generator are both set at 1500 kc. and the procedure outlined above is repeated.

The signal generator is set at 600 kc. and the signal tuned in on the dial. The broadcast padder condenser is adjusted for maximum response while the gang tuning condenser is rocked slightly to the right and left. The 1500 kc. adjustment should then be rechecked.

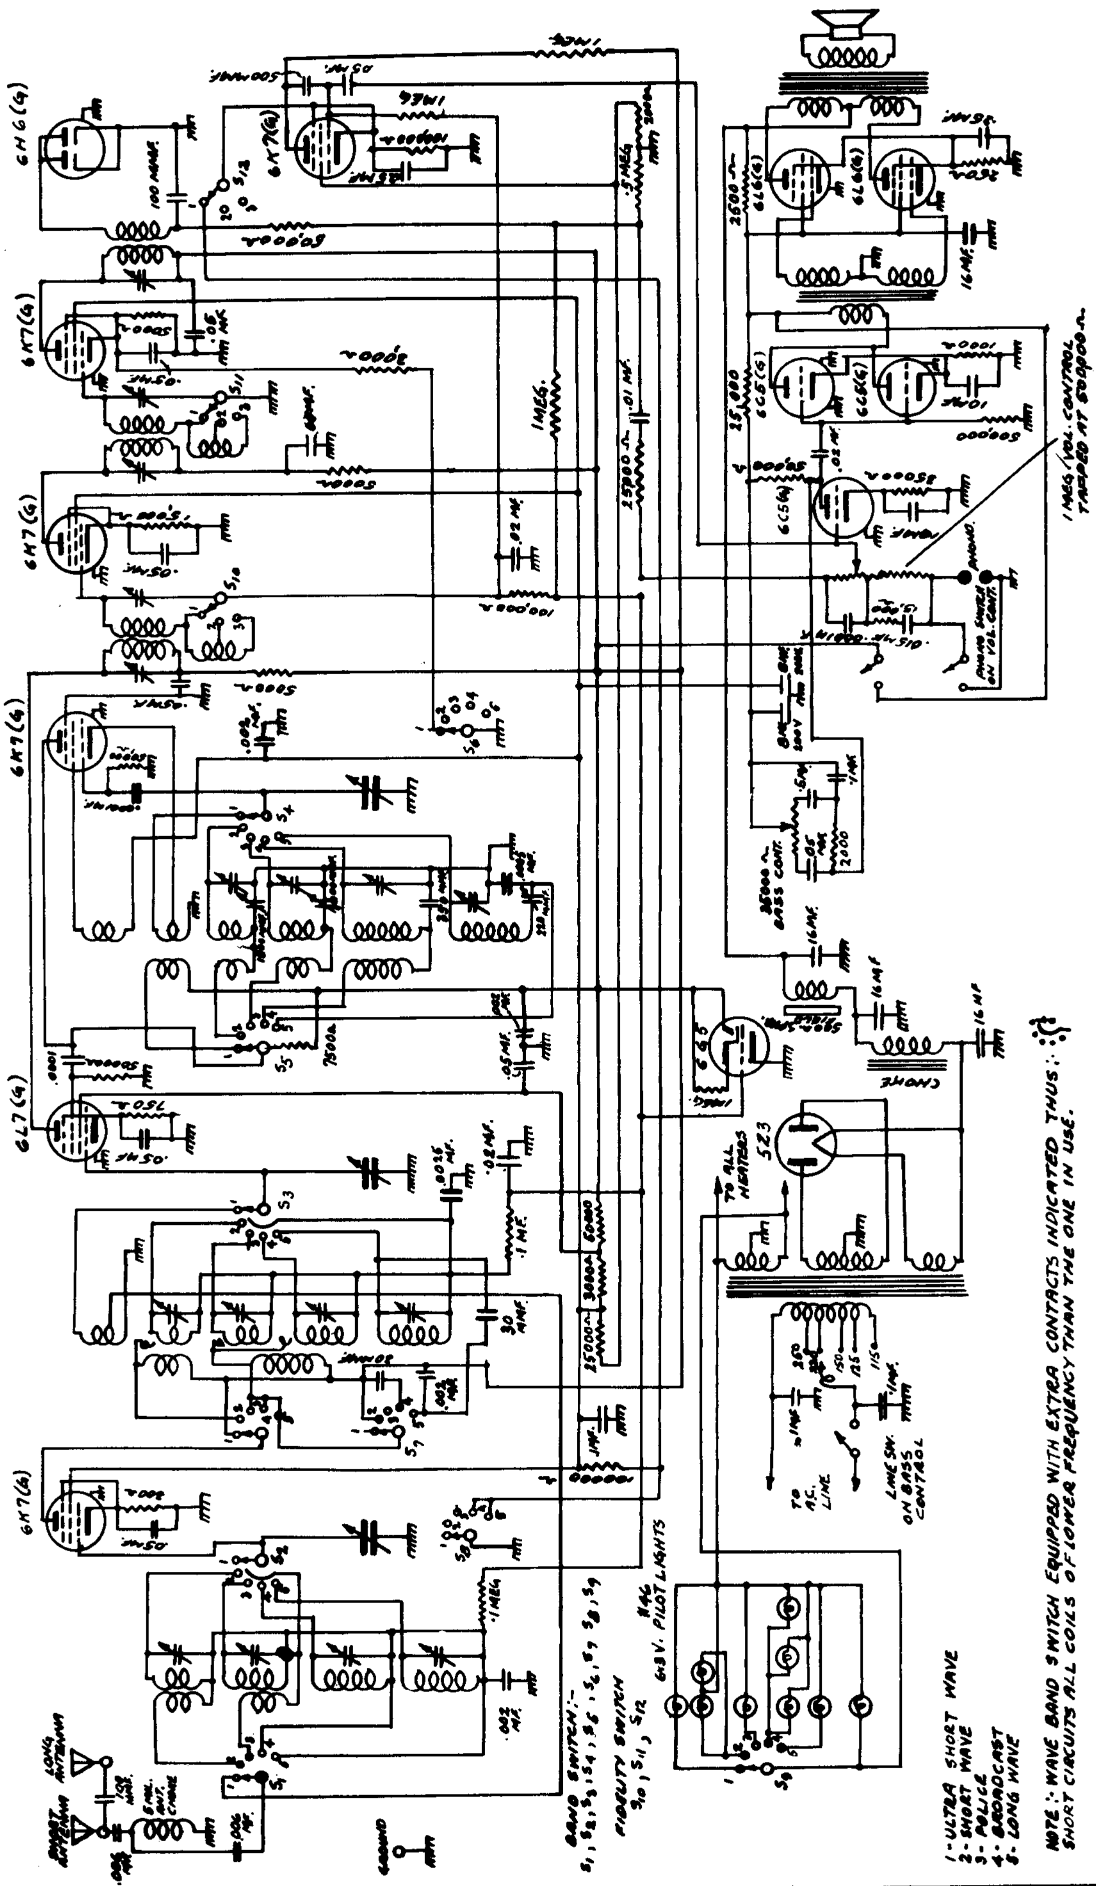
300 KC. ADJUSTMENT - The band selector switch is set in position for operation on band no. 4. The receiver and generator are both tuned to 300 kc. and the procedure outlined above is repeated.

The signal generator is set at 150 kc. and the signal is tuned in on the dial. The long wave padder condenser is adjusted for maximum response while the gang tuning condenser is rocked slightly to the right and left. The 300 kc. adjustment should then be rechecked.



GAROD RADIO CORPORATION

MODELS 5140, 5140H & 5140LC



I.F. 456 K.C.

GAROD RADIO CORPORATION

MODELS 5140, 5140H & 5140LC

Realignment of this receiver should not be attempted unless all other possible causes of faulty operation have been thoroughly investigated. An accurately calibrated signal generator which will cover the necessary wave-bands and an output meter for indicating the effect of adjustments are required.

It is important to remember that in receivers of this kind which are equipped with automatic volume control it is necessary to use the minimum possible signal from the signal generator; otherwise the avc action will tend to nullify the variations in output as the trimmers are adjusted. A surer method is to make the avc tube inoperative. This may be done by shorting return of RF trimmers to ground.

I.F. ADJUSTMENT: The signal generator is set at 456 kc. and is connected to the grid of the first detector (6L7). With the oscillator section of the tuning condenser short-circuited and the receiver volume control at its maximum position, the i.f. trimmers are adjusted for maximum output. These trimmers may be found on the tops of the I.F. transformers.

18 MEGACYCLE ADJUSTMENT: The high side of the signal generator is connected to the antenna lead of the receiver and the low side to the ground lead. The receiver and the signal are both tuned to a frequency of 18 mc. with the selector switch in position for band no. 2 (Short Wave). The oscillator trimmer condenser is adjusted so that the 18 mc. signal is tuned in exactly at the 18 mc. calibration point, with the volume control on full and the signal generator adjusted for minimum input. The antenna preselector and interstage trimmers are then adjusted in the order named for maximum output. These trimmers are located as indicated in the bottom view of the chassis.

6 MEGACYCLE ADJUSTMENT: The signal generator is set at 6 megacycles and the signal tuned in on the dial. The Short Wave padding condenser is adjusted for maximum gain while the gang tuning condenser is rocked slightly to the right and left.

5 MC. ADJUSTMENT: With the band selector switch in position for operation on band no. 3 (Police) and the receiver and signal generator both set at 5 mc. the procedure outlined above is repeated.

The signal generator is set at 1.8 mc. and the signal tuned in on the dial. The padder condenser for this band is adjusted for maximum gain while the gang tuning condenser is rocked slightly to the right and left. The 5 mc. adjustment should then be rechecked.

1500 KC. ADJUSTMENT: The band selector switch is set in position for operation on the no. 4 band. (Broadcast). The receiver and signal generator are both set at 1500 kc. and the procedure outlined above is repeated.

The signal generator is set at 600 kc. and the signal tuned in on the dial. The padder condenser for this band is adjusted for maximum response while the gang tuning condenser is rocked slightly to the right and left. The 1500 kc. adjustment should then be rechecked.

300 KC. ADJUSTMENT: The band selector switch is set in position for operation on band no. 5. The receiver and generator are both tuned to 300 kc. and the procedure outlined above is repeated.

The signal generator is set at 150 kc. and the signal is tuned in on the dial. The Long Wave padder condenser is adjusted for maximum response while the gang tuning condenser is rocked slightly to the right and left. The 300 kc. adjustment should then be rechecked.

GENERAL INFORMATION

The model E-115 is a three-band superheterodyne employing eleven G.E. Metal Tubes described above. It incorporates two stages of I.F., push-pull output, three-point tone control, and a high and low note compensated volume control. Full wave rectification is obtained from two 5W4's connected as half-wave rectifiers. L1 is the "D" band antenna coil. L2 is the "B" and "C" band antenna coil. The rear section of the gang condenser, L3, and a 6K7 tube are the essential elements of an R.F. stage, used only in the "B" band. L4 and L5 are the oscillator coils for the "D," "B" and "C" bands respectively. The antenna secondary and oscillator plate coils on the next lower frequency band to the one in use are shunted out by the wave switch contacts which are connected to C3 and B+.

Colorama Tuning

This receiver is equipped with a novel tuning device which indicates the point of exact resonance by the color of the dial illumination. When no signal is tuned-in, the dial illumination is red, but as the receiver is tuned, a smooth change to green occurs. Powerful stations will produce the darkest green color. Weak stations may only change the dial illumination to pink. The point at which any station is exactly in tune is indicated by the greatest color change obtainable.

The colored light is produced by a red and a green pilot bulb mounted behind the dial scale. These are controlled by a saturable reactor in a circuit which is shown in the schematic diagram, Fig. 2. The two bulbs are placed in series across one of the secondaries on the power transformer. In shunt with the green bulb is a reactor whose impedance is varied by a d-c coil wound on the same core. The plate current of the AVC controlled tubes flows through the d-c coil. At a condition of no-signal, the bias on the AVC controlled tubes is at minimum and their plate current is at maximum causing saturation of the reactor, which in turn shunts out and nearly extinguishes the green bulb. This causes most of the a-c supply voltage to be impressed across the RED bulb and its parallel resistor. At no signal, then, the dial is deepest red. When a station is tuned-in, the above conditions are reversed and the GREEN bulb is illuminated brightly. The impedance of the reactor changes in exact relationship with the incoming signal resulting in a smooth change from red to green or from green to red.

Phase Inverter

A 6C5, used as a phase-inverter, makes it possible to use push-pull output without the use of an inter-stage transformer. The audio signal from the volume control is impressed on the grid of the 6C5 audio amplifier. A portion of the 6C5 output is taken from a tap on one of the 6F6 grid resistors, and impressed on the grid of the phase inverter. (The ratio of R-19 and R-20 is chosen so that the excitation on the grid of the phase inverter is equal to that applied to the grid of the 6C5 audio amplifier.) Thus, the input signal to one of the 6F6's passes through two tubes while the input to the other 6F6 passes through one tube. As a result, the excitation on the 6F6 grids is 180 degrees out of phase, which is the requirement for push-pull operation.

To realize all the performance built into these receivers at the factory, alignment using cathode ray equipment is to be preferred.

On the "D" band (5400 to 18,000 K.C.), the oscillator operates on the *LOW* frequency side of the incoming signal; therefore, adjust the oscillator trimmer until the second peak is reached as the trimmer is *INCREASED* in capacity. When the correct adjustment is made, it will be possible to tune the image of any signal on the "D" band 930 K.C. *HIGHER* than the signal if the input is sufficiently high. Example: The image of 15 M.C. should be heard at 15,970 K.C.

The alignment procedure is given in table form on page 3. The "Dummy Antenna" is the capacitor or capacitor and resistor used in series with the signal generator antenna lead.

ADJUSTMENT OF DIAL MECHANISM

The dial mechanism (Fig. 4) is mounted to the chassis by means of two brackets and four self-tapping screws. Motion is imparted to the gang condenser rotor through a series of pulleys and an interconnecting cable to the dial pointer slider which is supported on a rail above the dial scale.

To Replace Drive Cable

Rotate the drive drum (14) counter-clockwise until the gang condenser plates are fully open. Place the end of the cable having an eyelet in slot (A). Thread the cable as shown in Fig. 4, making certain that the cable passes *over* the pin (B) and runs along the *correct* grooves, the looped end hooking over the tension spring (16). Check the position of the drive wheel (14) on the condenser shaft to make sure that the cable coming off the right-hand idler pulley lines up with the groove in the drive pulley. Also, as the condenser plates become fully meshed, the drive wheel (14) should just meet the bushing (D) of the reduction drive unit (13). With the drive wheel in this position, place the pointer on the rail (E) and, with the tip of the pointer (11) on the extreme left-hand dial scale division of Broadcast band, crimp the pointer tab on the drive cable.

To Adjust Pointer or Scale Calibration

Three positions of the dial pointer cable are provided on the drive drum (14) to adjust the dial pointer up or down scale. The position shown in Fig. 4 with the cable over pin (B) is the medium position. Changing the cable to the position between pins (B) and (C) moves the pointer *down* scale. The position below the pin (C) moves the pointer *up* scale from the medium position. With the gang plates closed, set the pointer at the extreme left-hand dial scale marking on the Broadcast band.

To Replace Scale

Remove the band change cable (12) by unhooking it from the fork (F) on bracket (3). Remove the end support bracket (8) held by a single self-tapping screw and withdraw the scale assembly from its housing. Replace the end caps (5) and (6) on the new scale and reassemble. Before reattaching the band change cable to the fork (F) the tension spring (7) should be given two full turns to provide proper tension for the cable.

To Ajdust Rotation of Scale

The bracket arm (3) may be moved up or down by means of the set screw to give the correct position of the scale divisions with respect to the dial pointer. The pointer tip should slightly overlap the scale divisions.

To Change Dial Lamps

Lift the lamp bracket (17) from the housing (20) to which it is clipped. With the lamp bracket laid back horizontally, the lamps may be replaced.

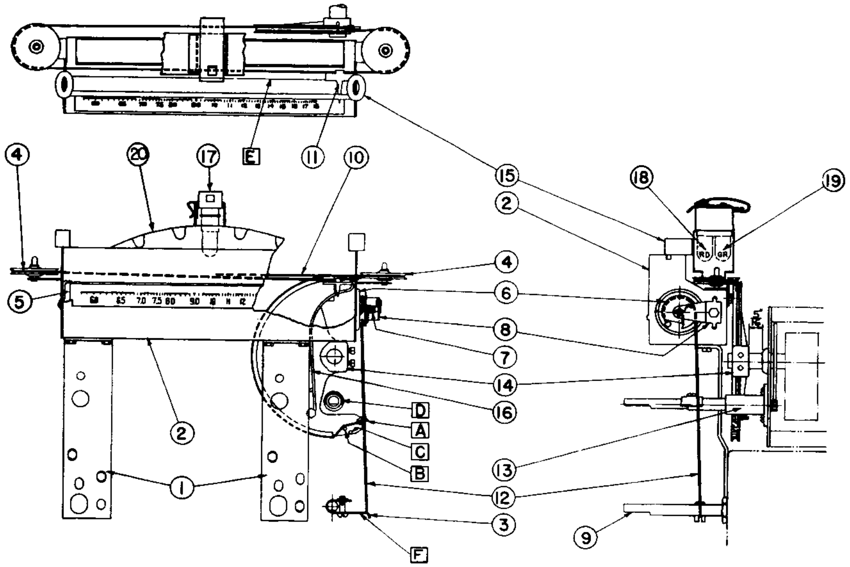

Fig. 4. Dial Mechanism

SERVICE DATA

Electrical Specifications

Voltage Rating............................105–125 Volts
Power Consumption..........................100 Watts
Type and Number of Radiotrons..3 RCA-58, 1 RCA-56, 1 RCA-55, 2 RCA-2A5, 1 UX-280—Total, 8
Type of Circuit..Super-Heterodyne with A.V.C., tone control and push-pull Universal Output Tubes
Undistorted Output............................3 Watts
R. F. and Oscillator Alignment Frequency 600 K. C., and 1400 K. C.
Intermediate Frequency.......................175 K. C.

This receiver is an eight tube Super-Heterodyne incorporating Automatic volume control, tone control and Universal Output tubes operated as a push-pull pentode stage. Service Data will be found to be similar to that of other Super-Heterodyne receivers incorporating similar features.

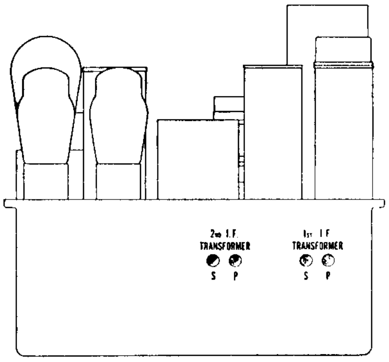

Figure C—I. F. Alignment Location

Line-up Adjustments

I. F. Tuning Adjustments—Two transformers comprising four tuned circuits are used in the intermediate amplifier. These are tuned to 175 K. C., and the adjustment screws are accessible from the rear of the chassis. See Figure C for location of the adjustment screws and proceed as follows:

(a) Procure a modulated oscillator giving a signal at 175 K. C., a non-metallic screwdriver such as Stock No. 7065 and an output meter.

(b) Remove the oscillator tube and connect a ground to the chassis.

(c) Connect the oscillator output between the 1st detector control grid and chassis ground. Connect the output meter across the voice coil of the loudspeaker and adjust the oscillator output so that with the receiver volume control at maximum, a slight deflection is obtained in the output meter.

(d) Adjust the secondary and then the primary of the second and then the first I. F. transformers until a maximum deflection is obtained. Keep the oscillator output at a low value so that only a slight deflection is obtained on the output meter at all times. Go over these adjustments a second time as there is a slight interlocking of adjustments. This completes the I. F. Adjustments.

R. F. and Oscillator Adjustments—The three gang capacitor screws are accessible through the bottom cover and the 600 K. C. oscillator trimmer through the top of the chassis adjacent to the R. F. coil. Proceed as follows:

(a) Procure a modulated oscillator giving a signal at 1400 K. C. and 600 K. C., a non-metallic screwdriver such as Stock No. 7065 and an output meter.

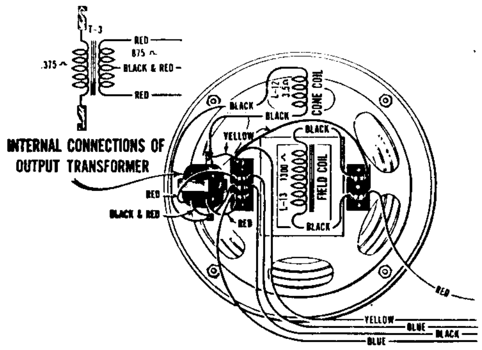

Figure D—Loudspeaker Wiring

(b) Connect the output of the oscillator to the antenna and ground lead of the receiver. Check the dial at the extreme maximum position of the tuning capacitor. The indicator should be at the short line on the dial. Then set the dial at 1400 K. C., the oscillator at 1400 K. C. and connect the output meter across the cone coil. Adjust the oscillator output so that a slight deflection is obtained when the receiver volume control is at maximum.

(c) Adjust the three line-up capacitors, accessible at the bottom of the receiver until maximum deflection is obtained in the output meter.

(d) Shift the oscillator frequency to 600 K. C. and tune the signal. Then adjust the 600 K. C. capacitor, accessible through the top, until maximum deflection is obtained. The main tuning capacitor must be rocked back and forth while making this adjustment.

(e) Then realign at 1400 K. C. This completes the adjustments.

When making both the I. F. and R. F. adjustments, the important point to remember is that the receiver volume control must be at its maximum position and the minimum input signal necessary from the oscillator must be used.

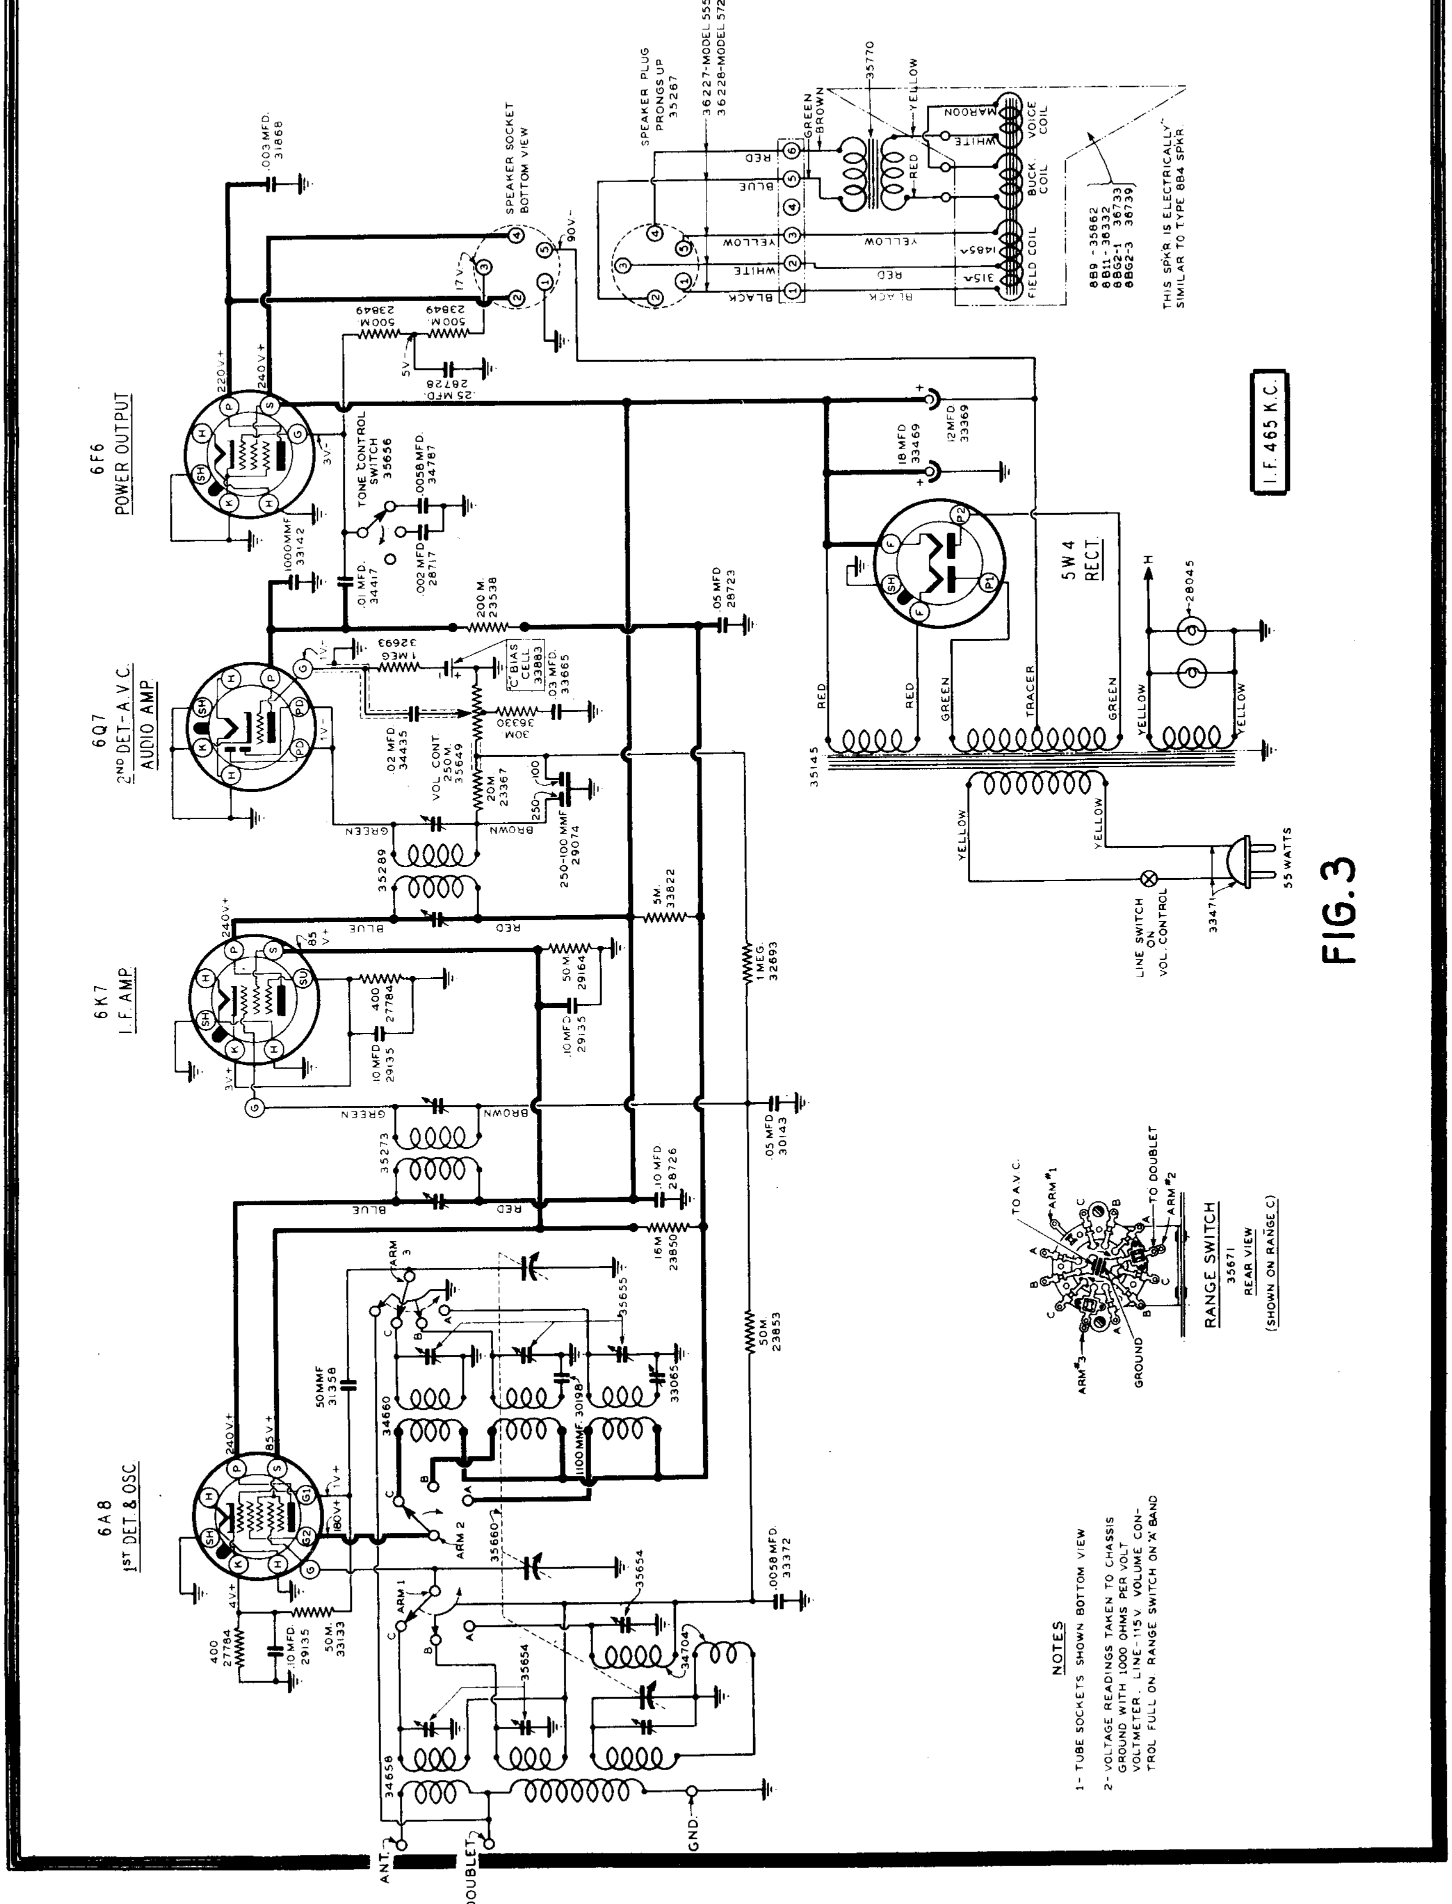

FIG. 3

GENERAL HOUSEHOLD UTILITIES COMPANY
MODELS 5L, 555 & 572

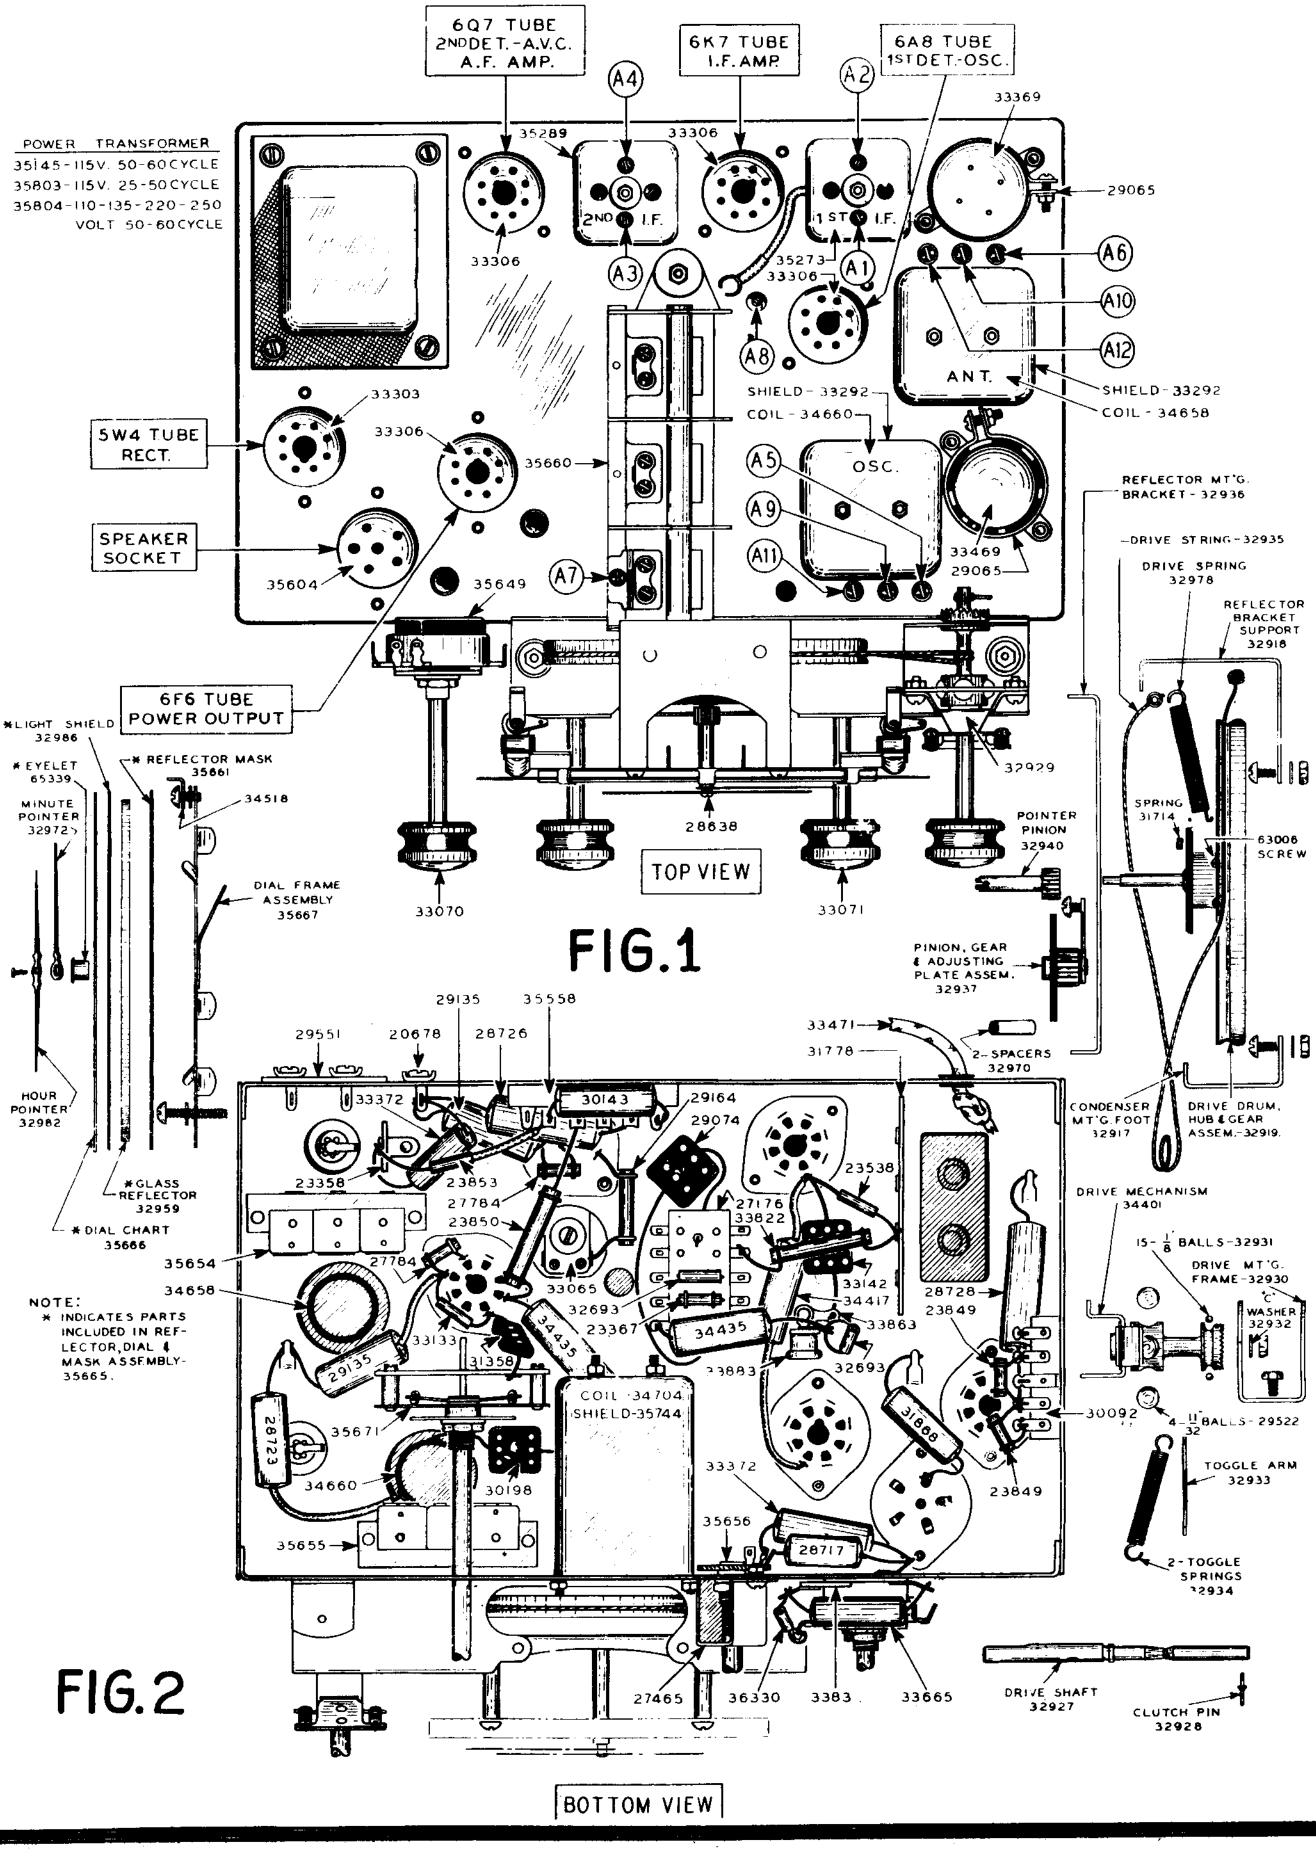

FIG.1

FIG.2

GENERAL HOUSEHOLD UTILITIES COMPANY

MODELS 5L, 555 & 572

The Grunow 5L Chassis is a Five Metal tube, 115 V. 50-60 cycles A. C., three band receiver with A. V. C., Tone Control and a "Band spread" dial. The tubes used are: 1-6A8 1st Detector and Oscillator, 1-6K7 I. F. Amplifier, 1-6Q7 2nd Detector, A. V. C. and 1st Audio Amplifier, 1-6F6 Power Output tube and a 5W4 Rectifier tube.

The frequency range is divided into three bands or divisions, one covering the band of 550 to 1750 K. C. (A), one the band from 1750 to 550 K. C. (B) and the other from 5.5 to 18.20 megacycles (C).

SERVICE DATA

Continuity and voltage readings should be taken from the underside of the chassis. The values given on the schematic diagram are average and allow the serviceman to make a quick check of the chassis constants. The socket layouts given on the schematic diagram show each socket from the underside. This Chassis uses a single unit "C" Bias cell in the grid of the 6Q7 A. F. Amplifier tube. This cell will in time have to be replaced, and in so doing be sure that the carbon (+) side of the cell is connected to the ground side of the cell terminal clip. An indication of the faulty cell will be distorted tone quality and the quickest check is a substitution of the old cell with a new one. For testing purposes a "C" battery may be used—using a 1½ volt battery in place of the single cell. The bias cell has a voltage of about 1.2 volts but due to their low current output they cannot be measured by any ordinary volt meter.

ALIGNMENT PROCEDURE

Do not attempt to align the 5L Chassis without the proper equipment. Alignment condensers are shown in the accompanying illustrations and are numbered in order of procedure—I. F. Condensers on top of the I. F. Transformers.

1. EQUIPMENT:

(A) Test Oscillator.

A modulated Oscillator capable of producing signals at the I. F., Broadcast and Short-Wave frequencies is necessary for alignment of the 5L Chassis.

(B) Insulated Screw Driver—(all bakelite or fibre) about 6" long.

(C) Output Meter.

This may be any of the standard Output Meters, but should be sufficiently sensitive to provide a good deflection at low signal strength.

(D) Coupling Means.

Coupling Condensers of 200 mmf., .05 mfd., and a 400 ohm resistor should be used when coupling oscillator to receiver during alignment as specified in the procedure.

(E) The Receiver should be aligned in a location free from local interference (interference caused by motors—flashers—automobile ignition, etc.) as high frequency disturbances will cause difficulties when the short wave section is being adjusted. (A screen room is to be recommended.)

2. DIAL SETTING:

Turn dial knob until condensers are fully meshed. The dial pointer (Hour Hand) should be on the horizontal line of the dial, pointing to 9 and 3 o'clock. The minute hand should be at 12 o'clock or in a vertical position.

3. I. F. ALIGNMENT:

(A) Connect signal lead of test oscillator to grid of 6A8 (1st detector tube) through .05 mfd. condenser. Connect the ground lead to the chassis.

(B) Set dial pointer to 1500 K. C. and range switch on "A" position.

(C) Place test Oscillator in operation at 465 K. C. Turn receiver volume control to maximum.

(D) Attenuate test Oscillator output to lowest value, consistent with obtaining a readable indication on output meter.

(E) Adjust four I.F. Trimmers, (A1, A2, A3, A4) located on the I. F. Transformers on top of Chassis (Fig. 1) until maximum output is obtained. During alignment maintain as low a value of signal as will allow obtaining of accurate adjustment.

4. 1500 K. C. ALIGNMENT:

(A) Connect signal lead of test Oscillator through 200 mmf. Condenser to Antenna binding post on Chassis.

(B) Connect the test Oscillator ground lead to the ground post of Chassis.

(C) Place test oscillator in operation at 1500 K. C.

(D) Turn dial pointer to 1500 K. C.

(E) Adjust broadcast oscillator trimmer (A5) to maximum output.

(F) Adjust 1st Detector Trimmer (A6) to maximum output.

(G) Adjust Antenna Trimmer (A7) to maximum output.

5. 600 K. C. ALIGNMENT:

(A) Place test oscillator in operation at 600 K.C.

(B) Tune in signal to maximum (this point does not have to be exactly at 600 K. C. dial setting.)

(C) Adjust the 600 K. C. Padding Condenser (A8) in direction of signal increases. At same time rock the tuning condenser back and forth through resonance while adjusting padding condenser until maximum output is obtained.

6. 5000 K. C. ALIGNMENT:

(A) Set Range Switch to "B" position.

(B) Place test Oscillators in operation at 5000 K. C.

(C) Turn Dial Pointer to 5000 K. C.

(D) Adjust Set Oscillator Trimmer (A9) to maximum output.

(E) Adjust Detector Trimmer (A10) to maximum output.

7. 18 M. C. ALIGNMENT:

(A) Connect signal lead of test oscillator through 400 Ohm Resistor to Antenna binding post of Chassis.

(B) Connect the ground lead to ground terminal of Chassis.

(C) Set Range Switch to "C" position and turn dial pointer to 18 M. C.

(D) Place test Oscillator in operation at 18 M. C.

(E) Adjust set oscillator Trimmer (A11) to maximum output.

(F) Adjust Detector Trimmer (A12) to maximum output.

(G) On the 18 M. C. Oscillator Alignment it will be noted that there are two settings at which the signal will be received. Use the lower of the images for alignment point that is the setting giving most capacity or the point at which the trimmer screw is farthest in.

I.F. 448 K.C.

ALIGNMENT

ESSENTIAL DATA: The intermediate frequency employed is 448 Kc.

The standard type of output meter should be used to indicate signal strength. It should be connected from the output plate of the 25B5 tube to ground.

Poor sensitivity may be an indication of incorrectly adjusted I.F. trimmers.

Aligning of Broadcast band should be done on 1400, 1000 and 600 kilocycles.

INTERMEDIATES: To align the I.F. circuits, set the signal generator to 448 Kc. and feed its modulated signal direct to the antenna. Adjust the first I.F. transformer trimmers for maximum meter reading. Go over both adjustments at least three or four times for accuracy. Repeat this process on the second I.F. transformer. If adjustments are not made accurately, selectivity will be poor and I.F. oscillation may result. Finally, adjust the trimmer in the tuned wave trap for *minimum meter reading.*

BROADCAST BAND: Place the band change switch on the Broadcast position. Turn the dial to 1400 Kc. and feed a very weak 1400 Kc. modulated signal from your signal generator to the antenna. Adjust the broadcast oscillator trimmer and detector trimmer (on condenser gang) for maximum reading.

There is no adjustable padder condenser in this model so resonance on lower frequencies is accomplished by bending plates on tuning condensers.

SHORT WAVE BAND: No alignment necessary.

ALIGNMENT

I.F. AMPLIFIER

All I.F. transformers are aligned for a band pass effect, and may not be realigned without a cathode ray oscilloscope for visual examination of the response curve. In brief, THE I.F. SHOULD NEVER BE TOUCHED, for they CANNOT be aligned by ear or output meter.

If the I.F. amplifier must be re-aligned, this MUST be done with a 465 K.C. "wobulated" oscillator and cathode ray oscillograph. The oscillator is connected between the 2nd I.F. grid and ground, FIDELITY knob set "HI.FI." and 3rd and 4th I.F. trimmers adjusted to provide a flat-topped selectivity curve on the cathode ray screen 15 K.C. wide between peaks. This done, the FIDELITY knob is set "SHARP," the test oscillator connected from 1st detector grid to ground, and the 1st and 2nd I.F. trimmers ONLY adjusted to give a selectivity curve 3 K.C. wide across its peak. In each case, the "high" lead from oscilloscope is connected to the join between R13a and R13b in the diagram, with a 10 mh. R.F. choke in this "high" lead. The 2nd lead from the oscilloscope connects to the tuner chassis.

A.V.C. alignment is made, AFTER I.F. alignment, by increasing test oscillator signal to 7,000 to 10,000 microvolts and adjusting the "A.V.C." trimmer ONLY for MINIMUM output meter deflection.

The beat oscillator may be aligned by ear with FIDELITY knob set at "B. OSC." to give the desired beat note upon a received carrier. For telephone reception it should be adjusted for zero beat with properly tuned carrier, while for single signal code reception it should be offset or adjusted for 800 to 1,000 cycle beat note after a modulated carrier has been accurately tuned in. This will result in a very considerable reduction in the "other side" or 2nd audio beat note, which is desirable for telegraph reception.

R.F. ALIGNMENT

At the left of the photo all trimmers are labeled for bands A, B, C, D and E, and for 1st and 2nd R.F. stages, 1st detector and oscillator. All high frequency trimmers should be aligned upon test signals at frequencies specified below with the main tuning dial set to these frequencies:

A. 350 K.C.
B. 1400 K.C.
C. 5000 K.C.
D. 16,000 K.C.

After the above high frequency alignment the low frequency oscillator trimmers must be set. This is done on the following test frequencies:

A. 175 K.C.
B. 600 K.C.
C. 2000 K.C.
D. 6000 K.C.

In this low frequency oscillator alignment, ONLY the oscillator low frequency trimmers are adjusted. The method involves, for an example applicable to all 4 bands, tuning in on band B a 600 K.C. signal with the tuning dial set at 600 K.C. and then adjusting the B low frequency oscillator trimmer at the same time that the tuning dial is rocked very slightly around its 600 K.C. setting in order to obtain the maximum output meter deflection. In this low frequency alignment, dial calibration is of secondary importance, and the alignment is intended to permit of accurate tracking between the UNTOUCHED R.F. and the varied oscillator circuit by means of the low frequency oscillator trimmer adjustment in conjunction with dial rocking to bring all 4 circuits into track. After the above low frequency oscillator alignment, high frequency alignment should be rechecked for the above bands.

Band E has no trimmers. It is aligned by movement of its labeled oscillator grid lead, toward or from nearby metal shielding, at 60,000 K.C.

All above alignment instructions will require the use of an insulated screw driver or one having a very short metal shank, particularly in D and E band alignment where the insulated screw driver is practically essential.

Voltage check data is found in sufficient amount to indicate voltages to be anticipated at different points in the circuit directly upon the diagram herewith. All voltage measurements must be made with a high resistance voltmeter and should be within plus or minus 10% of specified values.

For data on Setting Telephone Dial Stations, see model 62-271 on page 680.

BAND	DIAL COLOR	FREQUENCY RANGE
Standard Wave	White	528 to 1730 KC. (Kilocycles)
1st Short Wave	Amber	1.71 to 5.8 MC. (Megacycles)
2nd Short Wave	Green	5.75 to 18.3 MC. (Megacycles)

Service Data

In Fig. 12 is shown the schematic circuit diagram of the radio. Values of the condensers and resistors used are given. In the following paragraphs is given the complete aligning procedure. If a station is tuned in with the selectivity control in the broad position and this control is then turned to the sharp position, the station may disappear. This is not an indication that the receiver is out of alignment. If additional service information is required, write to us for a complete service manual.

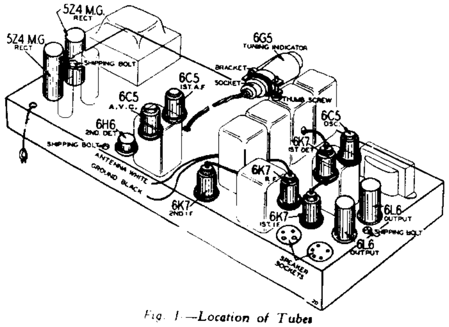

Fig. 1—Location of Tubes

Alignment Procedure

Correct alignment is extremely important in connection with all wave radios. The receivers are all properly aligned at the factory with precision instruments and realignment should not be attempted unless all other possible causes of the faulty operation have first been investigated and unless the service technician has the proper equipment.

A signal generator that will provide an accurately calibrated signal at 456, 1730, 1500, 600, 5800, 5000, 1800, 18,300, 15,000 and 6000 KC and an output indicating meter are required. It will be practically impossible to align the receiver if unsatisfactory apparatus is used.

Use a non-metallic screwdriver for the adjustments. The complete procedure is as follows:

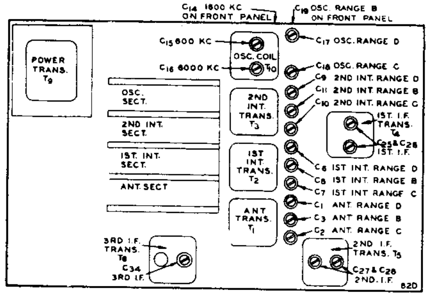

Fig. 11—Location of Trimmers

I. F. Adjustment

Set the signal generator for a signal of 456 KC.

Connect the output of the signal generator through a .1 mf. condenser to the grid of the 1st detector.

Connect the ground lead of the receiver to the ground post of the signal generator.

Turn the band switch to the Range B position (standard wave band).

Turn the selectivity control to the sharp position and keep it in this position for all adjustments.

Turn the volume control to the maximum position.

Attenuate the signal from the signal generator to prevent the levelling-off action of the AVC.

Then adjust the five I.F. trimmers until maximum output is obtained. The adjusting screws for these condensers are reached from the top of the chassis and the location is shown in Fig. 11.

Range B Alignment

After the procedure for the alignment of each range, as explained below, is completed, it is advisable to repeat the procedure as a final check.

1730 KC Adjustment

Set the signal generator for 1730 KC.

Turn the rotor of the tuning condenser to the full open position.

Keep the band switch in the standard wave position.

Connect the antenna lead of the receiver through a 200 mmf. condenser to the output of the signal generator.

For this and all subsequent adjustments keep the volume control at the maximum position and attenuate the signal from the signal generator to prevent AVC action.

Adjust the oscillator Range B trimmer (C19) until maximum output is obtained. The location of this trimmer is shown in Fig. 11.

1500 KC Adjustment

Set the signal generator for 1500 KC.

Turn the rotor of the tuning condenser carefully until maximum output is obtained.

Turn the calibration screw (under color filter—See Fig. 10) until the 1500 KC mark on the dial scale is at the vertical red line on the screen.

Adjust the 1st and 2nd interstage Range B trimmers (C8 and C11) and antenna Range B trimmer (C3) to maximum.

Do not change the setting of the oscillator Range B trimmer.

600 KC Adjustment

Set the signal generator for 600 KC.

Turn the tuning condenser rotor until maximum output is obtained.

Turn the rotor slowly back and forth at the same time adjusting the 600 KC trimmer until the peak of greatest intensity is obtained. See Fig. 11 for location of this trimmer.

Range C Alignment

CAUTION—When aligning the short wave bands be sure NOT to adjust at the image frequency. This can be checked as follows: Let us say the signal generator is set for 5000 KC. The signal will then be heard at 5000 KC on the dial of the radio. The image signal, which is much weaker, will be heard at 5000 less 912 KC, or 4088 KC. It may be necessary to increase the input signal to hear the image.

5800 KC Adjustment

Set the signal generator for 5800 KC.

Connect the antenna lead of the receiver through a 400 ohm resistor to the output of the signal generator.

Turn the rotor of the tuning condenser to the full open position.

Turn the band switch to the Range C position (first short wave band).

Adjust the oscillator Range C trimmer (C18) until maximum output is obtained. See Fig. 11 for location of this trimmer.

5000 KC Adjustment

Set the signal generator for 5000 KC.

Turn the rotor of the tuning condenser carefully until maximum output is obtained.

Adjust the 1st and 2nd interstage Range C trimmers (C7 and C10) and antenna Range C trimmer (C2) to maximum.

Do not change the setting of the oscillator Range C trimmer.

1800 KC Adjustment

Set the signal generator for 1800 KC.

Turn the tuning condenser rotor until maximum output is obtained.

Turn the rotor slowly back and forth at the same time adjusting the 1800 KC trimmer until the peak of greatest intensity is obtained. See Fig. 11 for location of this trimmer.

Range D Alignment

18,300 KC Adjustment

Set the signal generator for 18,300 KC.

Keep the antenna lead of the receiver connected through the 400 ohm resistor to the output of the signal generator.

Turn the rotor of the tuning condenser to the full open position.

Turn the band switch to the Range D position (second short wave band).

Adjust the oscillator Range D trimmer (C17) until maximum output is obtained. See Fig. 11 for location of this trimmer.

15,000 KC Adjustment

Set the signal generator for 15,000 KC.

Turn the rotor of the tuning condenser carefully until maximum output is obtained.

Adjust the 1st and 2nd interstage Range D trimmers (C6 and C9) and antenna Range D trimmer (C1) to maximum.

When adjusting the 2nd interstage Range D trimmer, it will be necessary at the same time to turn the tuning condenser rotor slowly back and forth until the peak of greatest intensity is obtained.

Do not change the setting of the oscillator Range D trimmer.

6000 KC Adjustment

Set the signal generator for 6000 KC.

Turn the tuning condenser rotor until maximum output is obtained.

Turn the rotor slowly back and forth at the same time adjusting the 6000 KC trimmer until the peak of greatest intensity is obtained. See Fig. 11 for location of this trimmer.

BE 134-40	Rubber Grommet	2	.02

Note: Speakers cannot be ordered, defective speakers must be repaired.
All resistors and mica condensers are RMA color coded — specify value and/or resistor or condenser (per schematic diagram) and model number.
Mica condensers are coded with an additional dot indicating tolerance:

Tolerance Percent	Color of Dot
2½%	White
5%	Green
10%	Blue
15%	Yellow
20%	Red
More than—20%	None

When ordering parts, always specify part and model number as well as serial number of chassis.
When ordering condensers, specify part number, tolerance and/or schematic reference number.

MONTGOMERY WARD & CO.

BAND	DIAL SCALE	FREQUENCY RANGE
Broadcast	Outer Scale—Blue	535 to 1720 K.C. (Kilocycles)
Middle Wave	Center Scale—Green	1695 to 5500 K.C. (Kilocycles)
Short Wave	Inner Scale —Buff	5.2 to 18.3 M.C. (Megacycles)

Service Data

DESCRIPTION:

TUBES:

The tube complement of this chassis consists of the latest metal type tubes.

The type and function of each tube is as follows:
1—Type 6L7 Pentagrid Mixer, First Detector.
1—Type 6C5 Oscillator.
1—Type 6K7 Remote Cut-Off Pentode, I. F. Amplifier (465 K.C.)
1—Type 6Q7 Duplex Diode Triode Second Detector, A.V.C. and First Audio.
1—Type 6F6 Pentode Output Amplifier.
1—Type 5W4 High Vacuum Rectifier.
1—Type 6G5 Cathode-Ray Tuning Eye.
(Note:—6G5 available in all glass only.)

Transformers are available and chassis are sometimes equipped with universal transformers for operation on 40 and 60 cycles and with primary taps for 108, 125, 150, 220 and 250 volts (see parts list) and also sometimes equipped with 25 cycle transformers with 105-115 volt or 220 volt primaries, not universals.

SERVICE NOTES:

Voltages taken from different points of circuit to chassis are measured with volume control full on, all tubes in their sockets and speaker connected, with a volt meter having a resistance of 1000 ohms per volt.

All voltages as indicated on diagram are measured with 119 volts on the primary of the power transformer.

Resistances of coil windings are indicated in ohms on the schematic circuit diagram.

To check for open by-pass condensers, shunt each condenser with another condenser of the same capacity and voltage rating, which is known to be good, until the defective unit is located.

Excessive hum, stuttering, low volume and a reduction in all D.C. voltages is usually caused by a shorted electrolytic condenser; open by-pass condensers frequently cause oscillation and distorted tone.

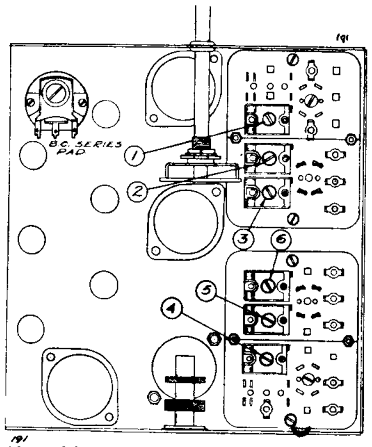

FIG. 3—BOTTOM VIEW SHOWING TRIMMERS

ALIGNING INSTRUCTIONS:

CAUTION:—No aligning adjustments should be attempted without first thoroughly checking over all other possible causes of trouble, such as poor installations, open or grounded antenna systems, low line voltages, defective tubes, condensers and resistors. In order to properly align this chassis, an oscillator (generator) is absolutely necessary. No aligning adjustments should be attempted with the chassis in the cabinet. Remove the knobs and the four bolts which are used to fasten the chassis.

All adjustments should be made with a non-metallic screw driver.

RESONANCE INDICATOR:

Use as a resonance indicator an output meter connected across the primary of the speaker input transformer, or by means of an adapter between the plate and screen terminals of the type 6F6 output tube. Maximum deflection of the meter indicates resonance. Use only enough signal to get a readily readable output. A low range output meter or the low scale of a multi-range meter should be used.

DUMMY ANTENNAS:

The following dummy antennas are used in aligning and are referred to in the following alignment instructions as "Dummy 1," "Dummy 2," and "Dummy 3."

Dummy 1: (I.F.)—Consists of a .1 mfd. condenser connected in series with the external oscillator.

Dummy 2: (Broadcast—Consists of a 200 mmfd. condenser and a 20 ohm resistor connected in series with each other and in series with the external oscillator.

Dummy 3: (Middle and Short Wave)—Consists of a .1 mfd. condenser and a 400 ohm resistor connected in series with each other and in series with the external oscillator.

ALIGNING I.F. TRANSFORMERS: (465 K.C.):

Part No. 108-73 Output I.F. Transformer
Part No. 108-74 Input I.F. Transformer
These I.F. transformers have two adjustments, both of which are accessible from the top of chassis (see top view).

1. With volume control full on (the extreme right of its rotation), the band changing switch in the broadcast position, (extreme left of its rotation), and with the variable condenser set to approximately 1400 kilocycles, make the following adjustments:
   (a) Connect external oscillator set at 465 kilocycles, in series with "Dummy 1," to the control grid cap of the type 6K7 tube, and adjust the output I.F. transformer (No. 108-73) to resonance.
   (b) With "Dummy 1" still connected, move oscillator output clip from grid of 6K7 to grid cap to 6L7 and adjust input I.F. transformer (No. 108-74) to resonance.
   (c) With oscillator still connected to 6L7, readjust output I.F. transformer (108-73) if necessary.

BROADCAST BAND ALIGNMENT:
535 to 1720 Kilocycles

1. With band changing switch in the broadcast position, extreme left of its rotation, and with gang condenser in its minimum capacity position, plates entirely out of mesh, and with external oscillator connected in series with "Dummy 2" to tan antenna lead and black ground lead, make following adjustments:
   (a) Set external oscillator to 1720 K.C. and adjust broadcast oscillator trimmer to resonance (Adjustment number 1; see bottom view of coil assembly, Fig. 3).
   (b) Re-set external oscillator to 1550 K.C., rotate variable gang condenser and pick up signal. Adjust broadcast antenna trimmer (Adjustment number 4) to resonance; also adjust preselector trimmer which is mounted on the top of the rear section of the three gang variable tuning condenser to resonance. (See top view of chassis; Fig. 1, for location of this adjustment).
   (c) Re-set external oscillator to 600 K.C., and adjust broadcast series pad to resonance by rotating condenser to approximately 600 K.C., rocking it slowly to and fro until by adjusting series pad maximum output is attained. This adjustment is located on the bottom of the chassis directly under the variable gang condenser. (See bottom view of chassis, Fig. 3).
   (d) Repeat adjustments "a" and "b" until sensitivity is at its maximum.
   (e) Check for tracking and sensitivity at 1000 kilocycles. Under no circumstances bend plates of variable condenser sections to correct tracking.

SHORT WAVE BAND ALIGNMENT:
5.2 to 18.3 Megacycles

1. With band changing switch in the short wave position, extreme right of its rotation, and with external oscillator set at 17 megacycles and connected in series with "Dummy 3" to the tan antenna and black ground lead, make the following adjustments:
   (a) Move dial pointer to 17 megacycles and adjust short wave oscillator (Adjustment number 3) and short wave antenna (Adjustment number 6) to resonance.
   (b) Re-set external oscillator to 6 megacycles and pick up signal by rotating variable condenser and check sensitivity.
   (c) Re-set external oscillator and check set at 18.1 megacycles and 5.3 megacycles for band coverage.

NOTE: It is extremely necessary in making all of these adjustments that the fundamental oscillator signal be tuned in and not the image frequency which will fall below the fundamental on the receiver dial. As an example of this a fundamental 18.3 megacycle can be tuned in not only at 18.3 on the dial, but also at approximately 17.4 megacycles.

MIDDLE WAVE BAND ALIGNMENT:
1695 to 5500 Kilocycles

1. With band changing switch in the middle wave position, center of its rotation, and with external oscillator set at 5000 kilocycles and connected in series with "Dummy 3" to the tan antenna and black ground lead, make the following adjustments:
   (a) Move dial pointer to 5000 kilocycles and adjust middle wave oscillator (adjustment number 2) and middle wave antenna (adjustment number 5) to resonance.
   (b) Re-set external oscillator to 1800 kilocycles and pick up signal by rotating variable condenser and check sensitivity.
   (c) Re-set external oscillator and check set at 5400 kilocycles and 1700 kilocycles for band coverage.

PHILCO RADIO & TELEVISION CORPORATION

MODEL 37-9

Electrical Specifications

Type of Circuit: Superheterodyne, with magnetic tuning control on the broadcast range, and a push-pull pentode audio output circuit.

Dial Mechanism: Philco Automatic Dial Tuning System.

Power Supply: Voltage	Frequency Cycles	Consumption
115	50 to 60	110 watts
115	25 to 40	110 watts

Intermediate Frequency: 470 K. C.

Undistorted Output: 5 watts.

Philco Tubes Used: Nine. Two 6K7G; one 6A8G; one 6N7G; one 6H6G; one 6Q7G; two 6F6G, and one 5Y4G.

Tuning Ranges: Three. Range 1—530 to 1720 K. C.; Range 2—2.3 to 7.4 M. C.; Range 3—7.35 to 22 M. C.

Tone Control: 3 positions.

Speaker: H-30.

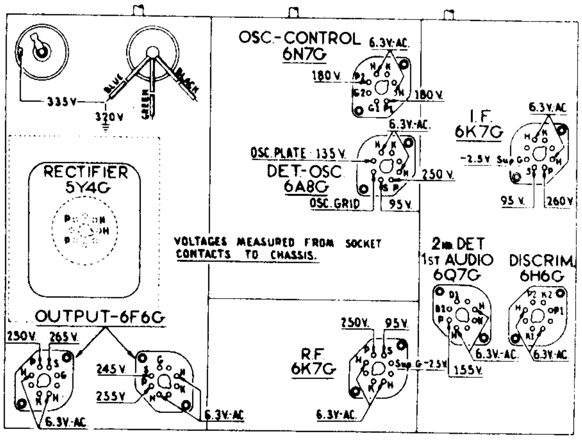

Fig. 1—Receiver Socket Voltages

The voltages indicated by arrows were measured with a Philco 025 Circuit Tester which contains a voltmeter having a resistance of 1000 ohms per volt. Volume Control at minimum, range switch in broadcast position, line voltage 115 A. C.

Alignment of Compensators

EQUIPMENT REQUIRED: (1) Signal Generator; **Philco Model 088** (fundamental frequency 110 to 20,000 K. C.) is the correct instrument for this purpose; (2) Output meter; **Philco Model 025** Circuit Tester incorporates a sensitive output meter and is recommended; (3) Fibre handle screw-driver (Philco Part No. 27-7059); (4) Special variable condenser (Philco Part No. 45-2325).

OUTPUT METER: The 025 Output Meter is connected to the plate and cathode terminals of one of the (6F6G) tubes. Adjust the meter to use the (0-30) volt scale.

INTERMEDIATE FREQUENCY CIRCUIT

1. Set controls as follows:
   - a. Magnetic Tuning "off" (19)
   - b. Bass compensation minimum
   - c. Volume control maximum (67)
   - d. Receiver Dial 580 K. C.
   - e. Signal Generator 470 K. C
   - f. Range switch position 1

2. Adjust the I. F. compensators for maximum with signal generator output lead connected through a .1 mfd. condenser to the grid of the tubes as follows:

Input Point	Compensators in Order
6A8G—1st Det.	(54) (53P) (43S) (43P)

RADIO FREQUENCY CIRCUIT

Tuning Range 530 to 1720 K. C.

1. Connect the signal generator output lead through a .1 mfd. condenser to terminal 1 and the generator ground to terminal 3 on aerial input panel. Terminals 2 and 3 must be connected with the shorting link provided on the aerial panel.

2. Other controls set as given under intermediate frequency circuit, with the exception of those as follows:

Adjust compensators for maximum output as follows:

Range Switch	Signal Generator	Receiver Dial	Compensators in Order
1	1600 K. C.	1600 K. C.	(21) (36B) (36A)
1	580 K. C.	580 K. C.	(22) Roll gang through signal when padding this compensator
1	1600 K. C.	1600 K. C.	(21)
1	1500 K. C.	1500 K. C.	(36A) (36B)

Tuning Range 2.3 to 7.4 M. C.

Adjust compensators for maximum output as follows:

Range Switch	Signal Generator	Receiver Dial	Compensators in Order
2	6 M. C.	6 M. C.	(21A)

Tuning Range 7.35 to 22 M. C.

Adjust compensators for maximum output as follows:

Range Switch	Signal Generator	Receiver Dial	Compensators in Order
3	18 M. C.	18 M. C.	(21B) Check image at 17.06 M. C.
3	18 M. C.	18 M. C.	(10) (4) Use shunt condenser on (21B) or rock gang through signal when padding compensator No. 10
3	18 M. C.	18 M. C.	(21B)

MAGNETIC TUNING ADJUSTMENT—Set the range switch in position one (530 to 1720 K. C.) and the magnetic tuning switch in the "out" position. Now turn the signal generator and receiver dial to any frequency in the Broadcast band. The receiver dial must be adjusted very accurately for maximum output.

Set the magnetic tuning control in the "on" position (clockwise) Compensator (53S) of the magnetic tuning transformer is now adjusted for maximum output.

The above adjustment is now checked for accuracy, by turning the magnetic tuning control "off" and "on." When this is done, there should be no change in the tone of the received signal. If a change of tone or hiss develops, it indicates a shift in frequency and the adjustment must be made again.

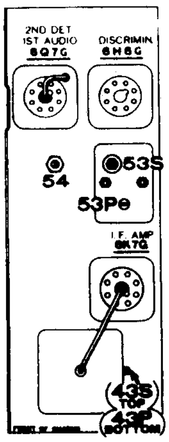

Fig. 2—I. F. Compensators

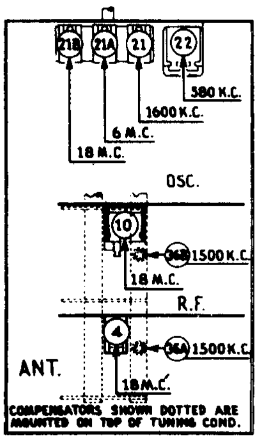

Fig. 3—R. F. Compensators

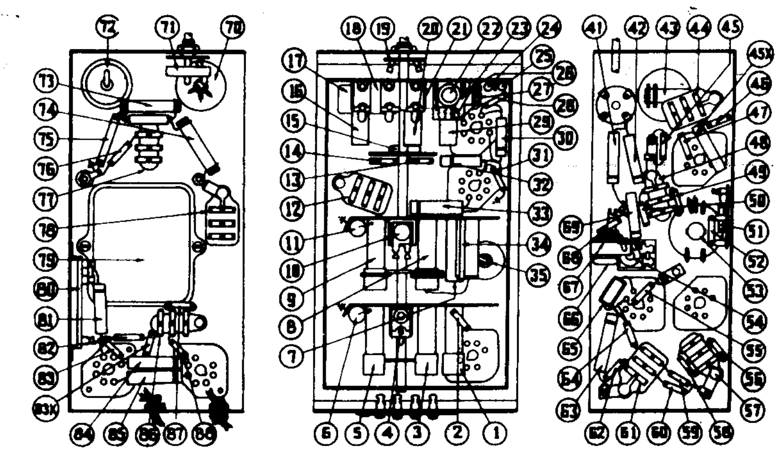

Fig. 4—Part Locations, Underside of Chassis

NOTE: See page 237 before servicing this set.

PHILCO RADIO & TELEVISION CORPORATION

MODEL 37-34

Electrical Specifications

Type of Circuit: Superheterodyne, with Push-Pull Pe tode Audio Output, using a vibrator unit operated by a 6 volt storage battery for supplying "B" power to the receiver.

Power Supply: 6 volt storage battery Philco Type 116-R.

Current Drain: 1.3 Amps.

Philco Tubes Used: 1D7G, Det.-Osc.; 1D5G, I.F. Amp.; 1H6G, 2nd Det. 1st Audio; 1H4G, Phase Inverter; 1E7G Output.

Frequency Range: 530—1720 K.C.

Intermediate Frequency: 470 K.C.

Speaker: Permanent Magnet Model L2B.

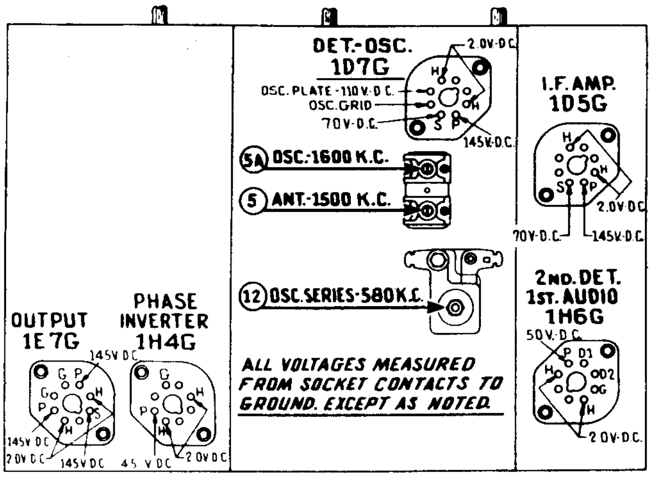

Fig. 1—Socket Voltages and R. F. Compensators

The voltages indicated by arrows were measured with a **Philco 025 Circuit Tester** which contains a voltmeter having a resistance of 1000 ohms per volt. Volume Control at minimum, Storage Battery fully charged.

Aligning Compensators

To accurately adjust this receiver precision test equipment is necessary. A signal generator such as the **Philco Model 088**, covering from 110 to 20,000 K.C. is recommended for adjusting the various compensators at the frequencies specified. A visual indication of the receiver output is also necessary. **Philco Model 025 Circuit Tester** contains a sensitive output meter and is recommended for this purpose.

Philco fibre handle screw-driver **No. 27-7059** and wrench **Part No. 3164** complete the equipment necessary for the following adjustments. The locations of the various compensators are shown in Figs. 1 and 2.

OUTPUT METER—The 025 Output Meter is connected between one of the plate contacts of the 1E7G tube and ground. Adjust the meter to use the (0-30) volt scale.

DIAL ADJUSTMENT—The tuning condenser is set at the maximum capacity position, by turning the knob clockwise. Loosen the set screw of dial hub and set dial, with Glowing Indicator centered between the first and second index lines at the low frequency end of the scale.

INTERMEDIATE FREQUENCY CIRCUIT

1. Connect the 088 Signal Generator output lead through a .1 mfd. condenser to the grid of the 1D7G tube and the generator ground lead to the chassis. Set the generator for 470 K.C. and turn the receiver dial to approximately 580 K.C.
2. Now adjust compensators 18S, 18P, 17S, and 17P for maximum output.

RADIO FREQUENCY CIRCUIT

1. Remove the signal generator output lead from the 1D7G tube and connect it through a 200 mmfd condenser to the receiver aerial post.
2. Set the 088 Signal Generator indicator and the receiver dial to 1600 K.C.
3. Now adjust compensators 5A and 5 for maximum output.
4. The low frequency end of the tuning scale is now adjusted as follows: Set the signal generator at and turn the receiver dial to 580 K.C. Now adjust compensator 12 for maximum output, then vary the tuning condenser of the receiver for maximum output about the 580 K.C. dial mark. Now turn compensator 12 slightly to the right or left and again vary the receiver tuning condenser for maximum output. If the output reading increases, turn compensator 12 in the same direction a trifle more, and vary the tuning condenser again for maximum output. If a decrease in output is noted turn the compensator 12 in the opposite direction. This procedure of first setting the compensator and then varying the tuning condenser is continued until there is no further gain in the output reading.
5. Set the signal generator and receiver dials as given in Paragraph 2 above and adjust compensator 5A for maximum output.
6. Rotate the signal generator and receiver dials to 1500 K.C. and adjust compensator 5 for maximum output.

PHILCO RADIO & TELEVISION CORPORATION

MODEL 37-62

Electrical Specifications

Type of Circuit: Superheterodyne, with pentode audio output Circuit.

Power Supply:

Voltage	Frequency	Connection
115	50 to 60 cycles	60 watts
115	25 to 40 cycles	60 watts

Intermediate Frequency: 470 K. C.

Undistorted Output: 3 watts.

Philco Tubes Used: Five; one 6A8G, one 6F6G, one 6K7G, one 5Y4G, one 6Q7G.

Tuning Ranges: Two; Range 1—530 to 1720 K. C. Range 2—2.3 to 2.5 M. C.

Speaker: S-7.

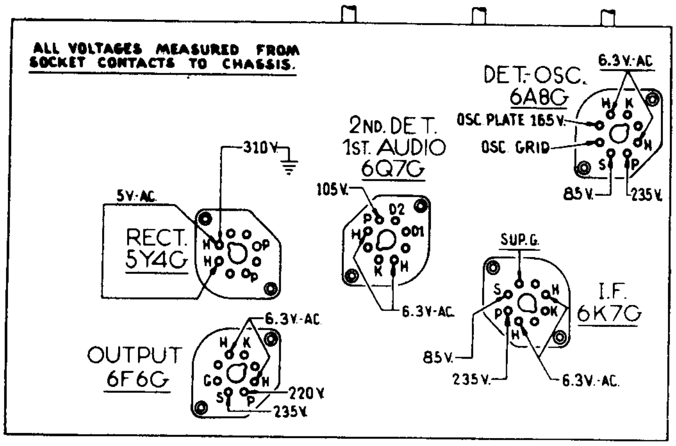

Fig. 1. View of Sockets from Underside Chassis

The voltages indicated by arrows were measured with a **Philco 025 Circuit Tester** which contains a voltmeter having a resistance of 1000 ohms per volt. Volume Control at minimum, range switch in broadcast position, line voltage 115 A. C.

Alignment of Compensators

Equipment Required: (1) Signal Generator; Philco Model 088 (fundamental frequency 110 to 20000 K. C.) is the correct instrument for this purpose; (2) output meter. **Philco Model (025) Circuit Tester** incorporates a Sensitive output meter and is recommended; (3) Fibre handle screwdriver (Philco Part No. 27-7059); (4) Fibre wrench Part No. 3164.

Dial Calibration: Set the tuning condenser at the maximum capacity position. Loosen the set screw of the dial hub and set dial, with the glowing indicator centered between the first and second index lines, at the low frequency end of the broadcast scale. Tighten set screw in this position.

Output Meter: The 025 Output Meter is connected to the plate and cathode terminals of the (6F6G) tube. Adjust the meter to use the (0-30) Volt Scale.

INTERMEDIATE FREQUENCY CIRCUIT

1. Set controls as follows:
   a. Volume control maximum
   b. Receiver Dial 580 K. C.
   c. Signal generator 470 K. C.
   d. Range Switch Broadcast position

2. Connect the signal generator output lead through a .1 mfd. condenser to the 6A8G Grid and adjust the Compensators as follows for maximum output (17S), (17P), (12S), and (12P).

RADIO FREQUENCY CIRCUIT

Tuning Range: 520 to 1720 K. C.

1. Connect the signal generator output lead through a 200 mmfd. condenser to the ant. terminal of the receiver and the generator ground to the chassis. Set the range switch in the broadcast position.

2. Adjust compensators as follows for maximum output.

Signal generator	Receiver dial	Compensators in order
1600 K. C.	1600 K. C.	(3B), (3A)
580 K. C.	580 K. C.	(10) Note A
1600 K. C.	1600 K. C.	(3B), (3A)

No adjustments are required for Range 2 as Range 1 adjustments compensate for this circuit.

Note A—First tune compensator (10) for maximum output, then vary the tuning condenser of the receiver for maximum output about the 580 K. C. dial mark. Now turn compensator (10) slightly to the right or left and vary the receiver tuning condenser for maximum output. If the out reading increases, turn compensator (10) in the same direction a trifle more, and again vary the tuning condenser for maximum output. If the output decreases, set the compensator in the opposite direction. This procedure of first setting the compensator and then varying the tuning condenser is continued until there is no further gain in output reading.

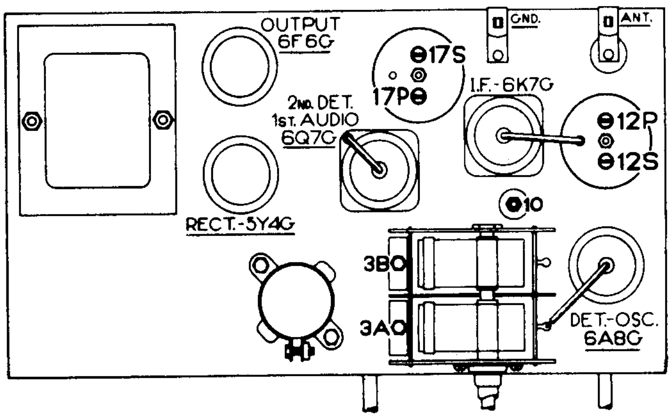

Fig. 2. Locations of R. F. & I. F. Compensators

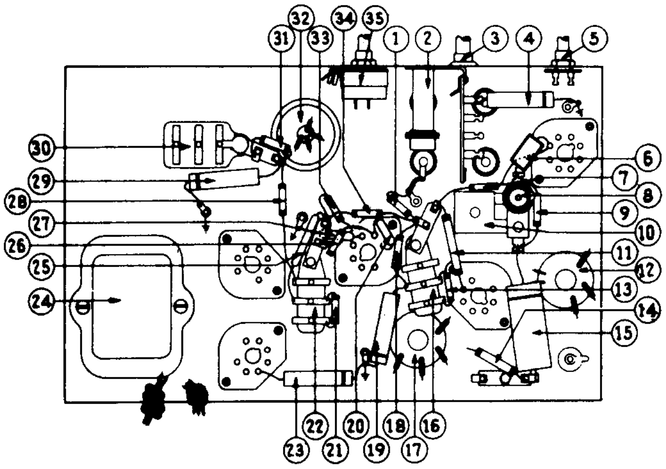

Fig. 3. Parts locations, Underside of chassis view

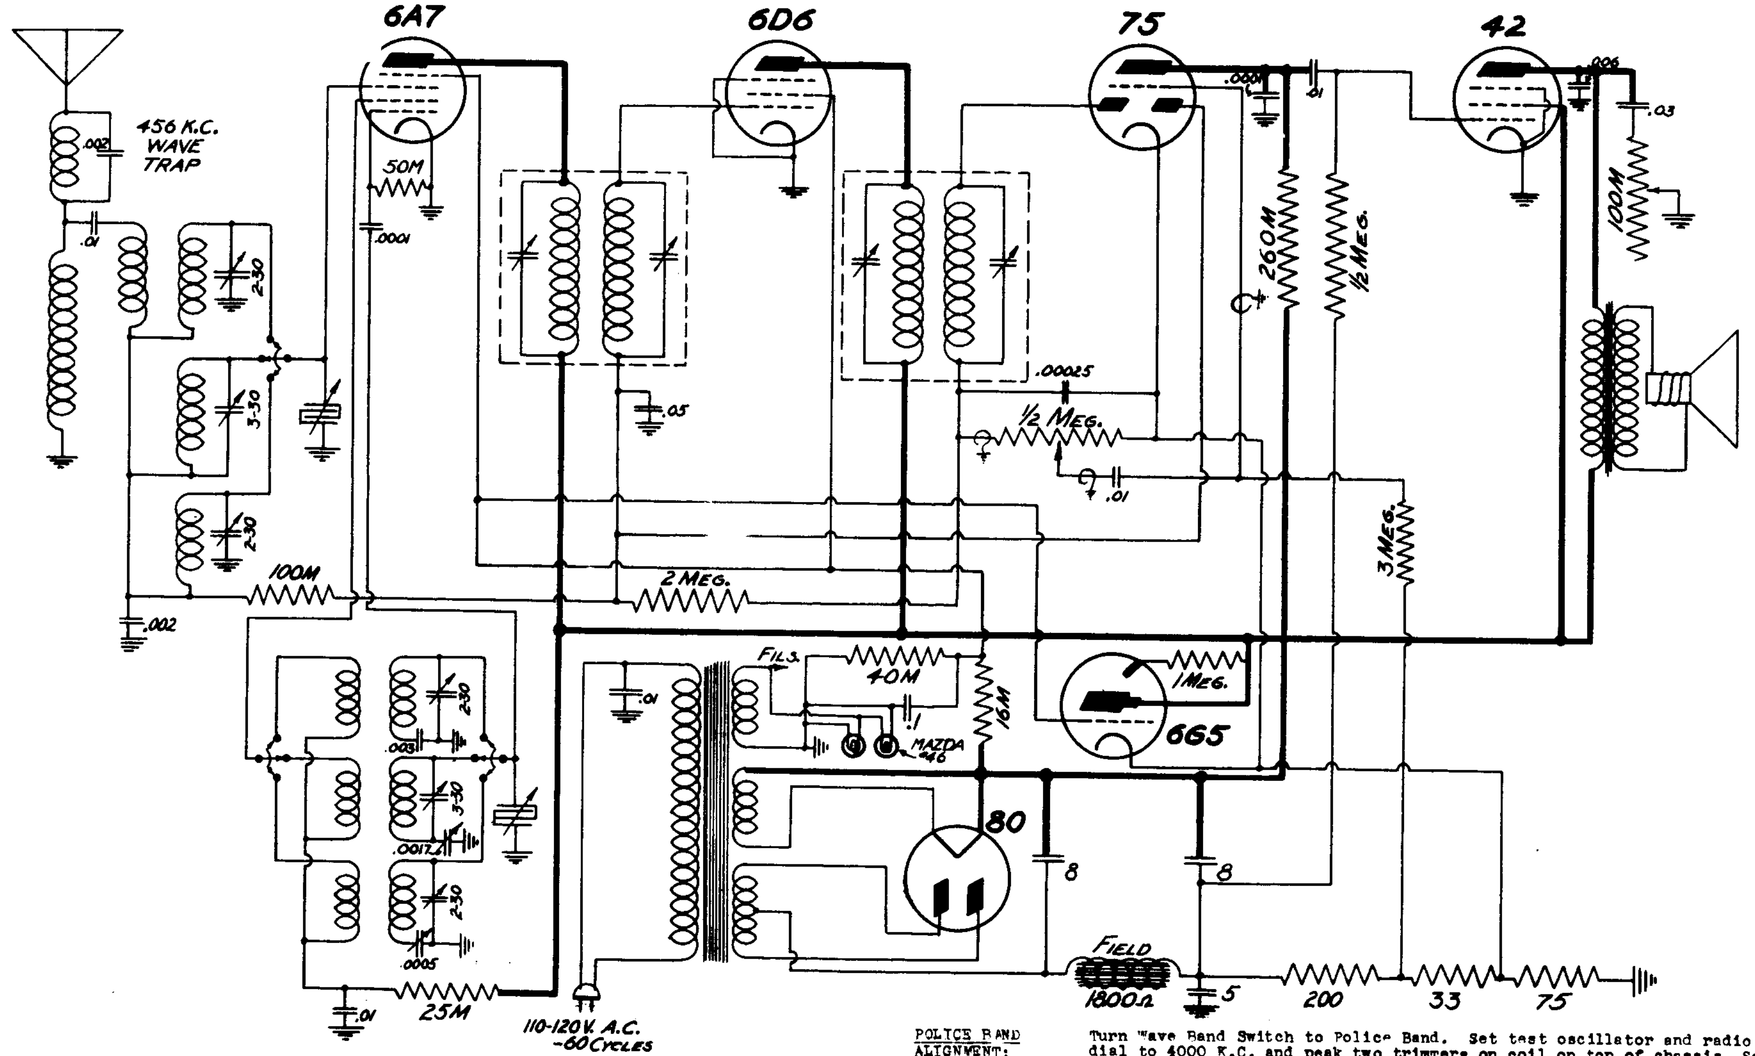
NOTE: See page 237 before servicing this set.

PIERCE AIRO, Inc.

MODELS 635 & 635LW



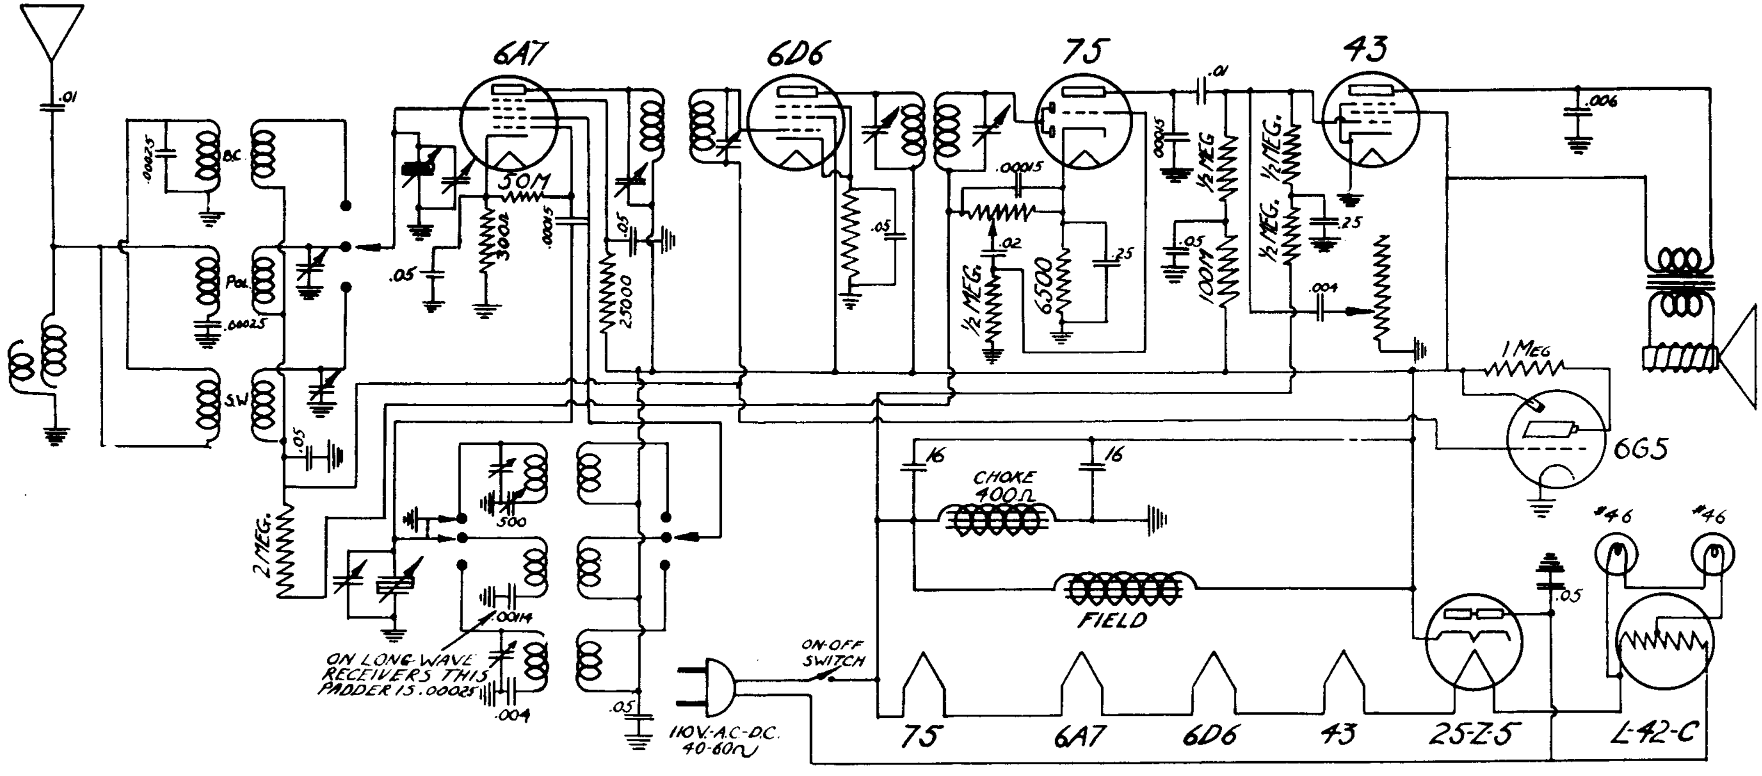
I. F. ALIGNMENT: Intermediate frequency peaked at 456 K.C. Connect test oscillator to grid of 6A7 and chassis. Short circuit stator of front section of variable condenser during this operation. Then peak I.F. trimmers for maximum signal.

R. F. ALIGNMENT: Remove short from stator of variable condenser. Turn Wave Band Switch to Broadcast. Connect test oscillator to antenna and chassis. Set test oscillator and radio dial to 1500 K.C. and peak two trimmers underneath chassis, (toward rear) for maximum signal. Set test oscillator at 600 K.C. and adjust padder condenser (nut side) in front of chassis for maximum signal. During this operation, the variable condenser must be rocked. Readjust 1500 K.C.

POLICE BAND ALIGNMENT: Turn Wave Band Switch to Police Band. Set test oscillator and radio dial to 4000 K.C. and peak two trimmers on coil on top of chassis. Set test oscillator and radio to 1700 K.C. and adjust padder (screw side) for maximum signal. The variable condenser must be rocked during the operation. If receiver has long waves instead of police band, calibrate same trimming condenser as on Police Band, but set oscillator and receiver at 300 K.C. for alignment.

SHORT WAVE ALIGNMENT: Turn wave band switch to short wave. Set test oscillator and radio dial to 15 Megacycles and peak trimmers on bottom of chassis (toward front) for maximum signal. Low frequency setting is automatically taken care of by short wave coils which are carefully matched for this setting by a fixed calibrated padder.

PIERCE AIRO, Inc.
MODELS 700 & 700LW



SERVICE NOTES

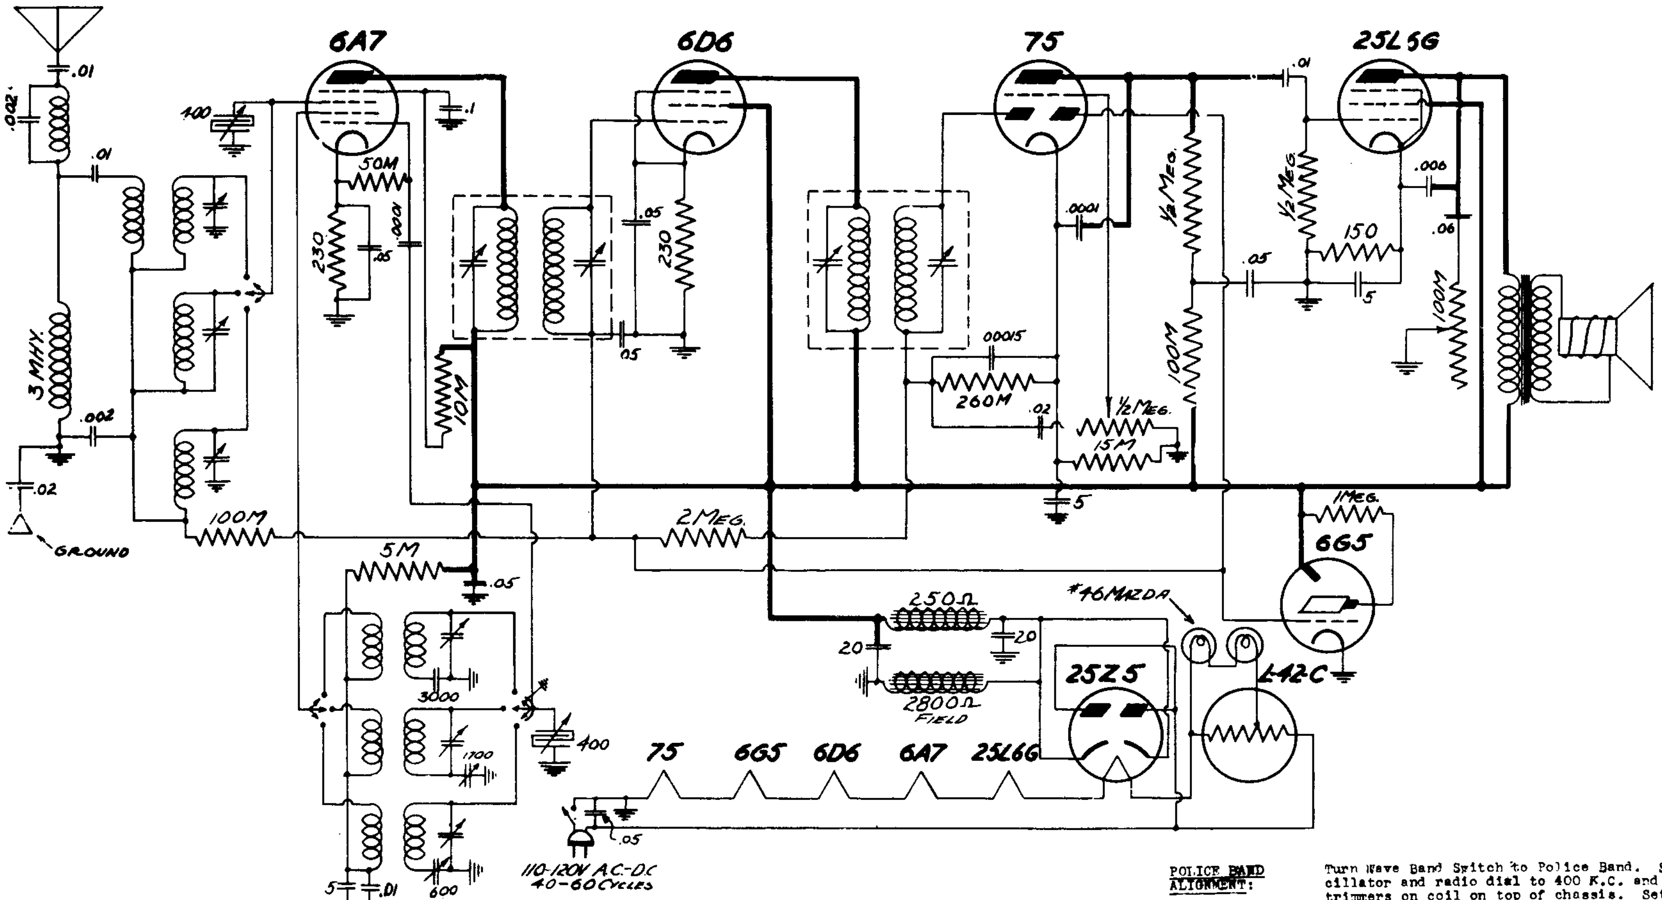
I.F. ALIGNMENT- Intermediate Frequency Peaked At 456 K.C. Connect Test Oscillator To Grid of 6A7 And Chassis. Short Circuit Stator of Front Section of Variable Condenser During This Operation. Then Peak I.F. Trimmers For Maximum Signal.

R.F. ALIGNMENT- Remove Short From Stator of Variable Condenser. Turn Wave Band Switch To Broadcast. Connect Test Oscillator To Antenna And Chassis. Set Test Oscillator And Radio Dial To 1500 K.C. And Peak Var. Cond. Trimmers For Maximum Signal. Set Test Oscil. at 600 K.C. And Adjust Padder Condenser in Front of Chassis For Max. Signal. During This Operation The Var. Cond. Must Be Rocked. Readjust 1500 K.C.

POLICE BAND ALIGNMENT- Turn Wave Band Switch To Police Band Set Test Osc. And Radio Dial To 4000 K.C. And Peak 2 Trimmers Near Front Of Chassis For Max. Sig. The Low Freq. Setting is Automatically Adjusted By A Fixed Calibrated Padder. If Receiver Has Long Waves Instead of Police Band Calibrate Same Trimming Cond. As on Police Band But Set Oscillator And Receiver At 300 K.C. For Alignment.

SHORT WAVE ALIGNMENT- Turn W.B. Switch To Short Wave. Set Test Osc. And Radio Dial To 15 Megacycles And Peak Trimmers Near Center of Chassis For Max. Sig. Low Freq. Setting is Automatically Taken Care Of By Short Wave Coils Which Are Carefully Matched For This Setting By A Fixed Calibrated Padder.

PIERCE AIRO, Inc.
MODELS 700A & 700ALW



I. F. ALIGNMENT: Intermediate frequency peaked at 456 K. C. Connect test oscillator to grid of 6A7 and chassis. Short circuit stator of front section of variable condenser during this operation. Then peak I.F. trimmers for maximum signal.

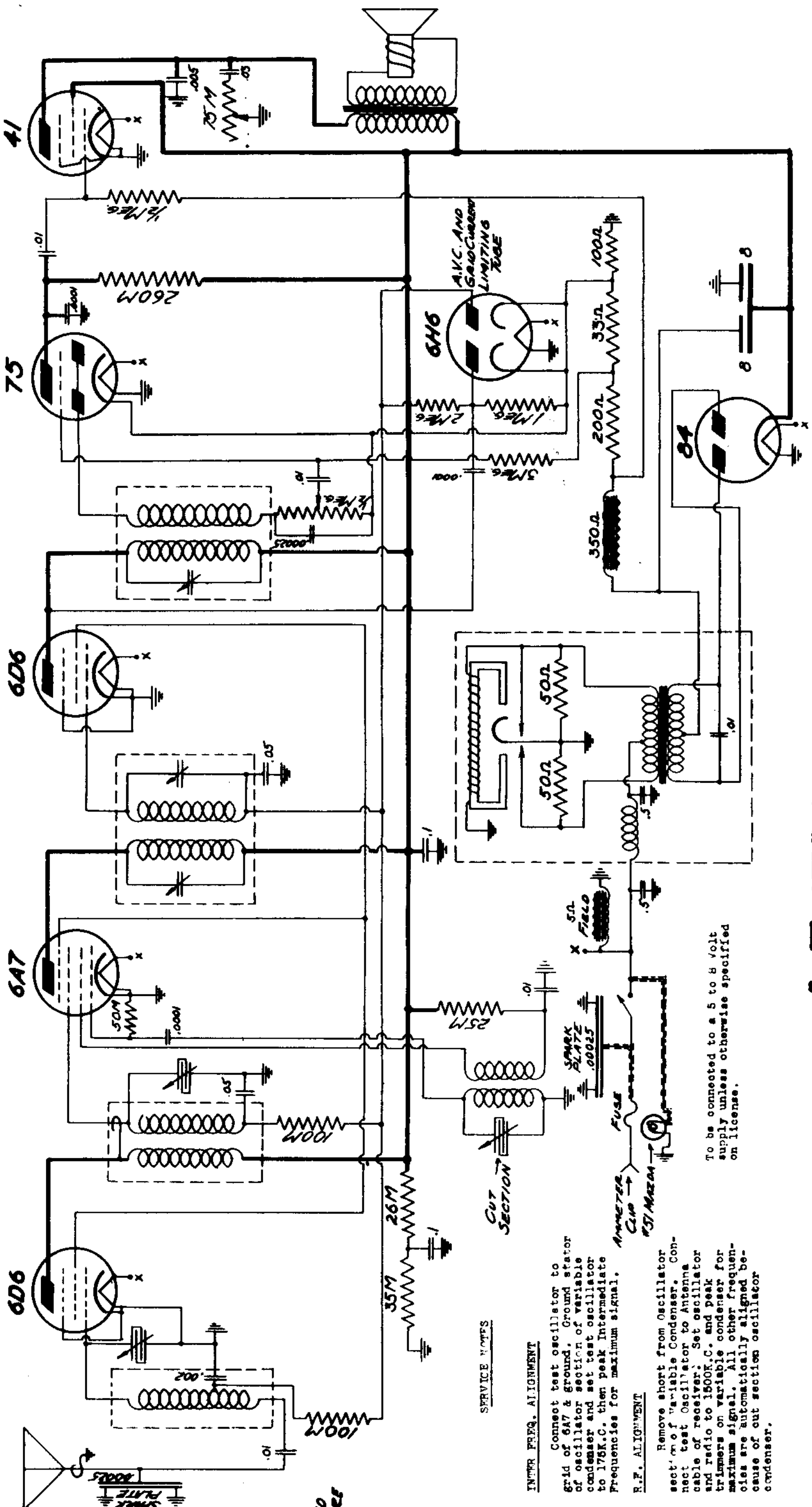
R. F. ALIGNMENT: Remove short from stator of variable condenser. Turn Wave Band Switch to Broadcast. Connect test oscillator to antenna and chassis. Set test oscillator and radio dial to 1500 K.C. and peak two trimmers underneath chassis, (toward rear) for maximum signal. Set test oscillator at 600 K.C. and adjust padder condenser (nut side) in front of chassis for maximum signal. During this operation, the variable condenser must be rocked. Readjust 1500 K. C.

POLICE BAND ALIGNMENT: Turn Wave Band Switch to Police Band. Set test oscillator and radio dial to 400 K.C. and peak two trimmers on coil on top of chassis. Set test oscillator and radio to 1700 K.C. and adjust padder (screw side) for maximum signal. The variable condenser must be rocked during the operation. If receiver has long waves instead of police band, calibrate same trimming condenser as on Police Band, but set oscillator and receiver at 300 K.C. for alignment.

SHORT WAVE ALIGNMENT: Turn Wave band switch to short wave. Set test oscillator and radio dial to 15 Megacycles and peak trimmers on bottom of chassis (toward front) for maximum signal. Low frequency setting is automatically taken care of by short wave coils which are carefully matched for this setting by a fixed calibrated padder.

PIERCE AIRO, Inc.

MODEL 702 AUTO RADIO



To be connected to a 5 to 8 volt supply unless otherwise specified on license.

SERVICE NOTES

INTER FREQ. ALIGNMENT

Connect test oscillator to grid of 6A7 & ground. Ground stator of oscillator section of variable condenser and set test oscillator to 175K.C. then peak Intermediate Frequencies for maximum signal.

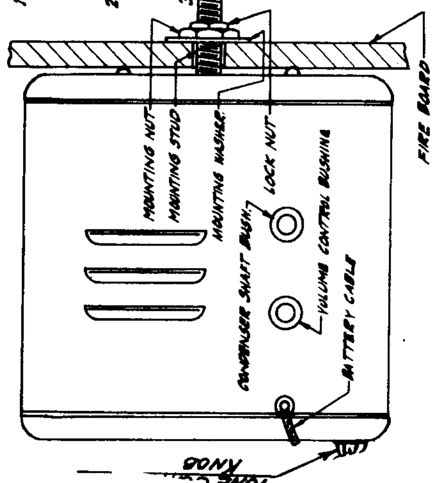
R.F. ALIGNMENT

Remove short from Oscillator section of variable Condenser. Connect test Oscillator to Antenna cable of receiver. Set oscillator and radio to 1500K.C. and peak trimmers on variable condenser for maximum signal. All other frequencies are automatically aligned because of cut section oscillator condenser.

MOUNTING INSTRUCTIONS

1-SCREW UNSLOTTED END OF MOUNTING BOLT TIGHTLY (UP TO THE NICKS) INTO LARGE THREADED HOLE IN REAR OF RECEIVER CASE.
2-DETERMINE LOCATION OF RECEIVER AND DRILL 1/2 INCH HOLE IN FIRE BOARD TO PASS THE MOUNTING BOLT.
3-SCREW ON THE MOUNTING NUT SO THAT RECEIVER IS HELD FIRMLY IN PLACE. SCREW ON LOCK NUT FIRMLY OVER MOUNTING NUT.

PILOT LAMP: MAZDA #51, 6-8 VOLTS



TO REPLACE VIBRATOR TURN TENSION SPRING TO THE LEFT 90° THEN WITH A SLIGHT UPWARD PULL VIBRATOR CAN BE REMOVED. AFTER THE VIBRATOR HAS BEEN REPLACED MAKE CERTAIN THAT TENSION SPRING IS RETURNED TO NORMAL POSITION.

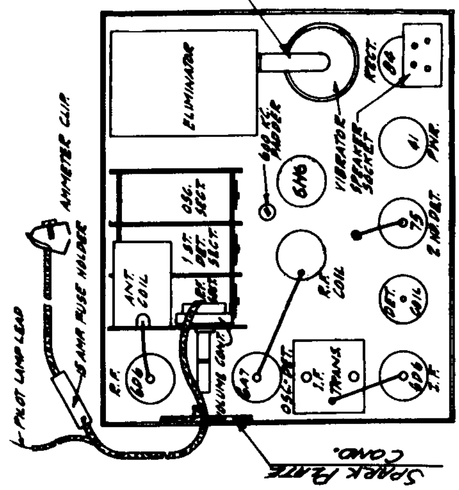


FIG. 1

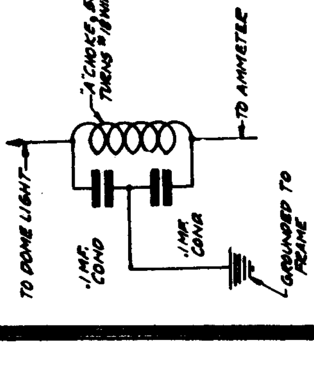

FIG. 3

8. Dome Light Wire: If dome light wire is radiating it may be necessary to shield this wire. A single .5mfd. condenser or a double condenser and choke as shown in fig. #3 connected at the point where the dome light wire enters the upright post will clear up this trouble.

PILOT RADIO CORPORATION

MODELS 420 SERIES, 423 & 425

SERVICE INFORMATION FOR PILOT MODELS 423 AND 425

REMOVAL OF CHASSIS FROM CABINET:

To remove the chassis from the cabinet proceed as follows:

Be certain that the line cord is removed from the power outlet socket.

Remove the "slip-on" knobs and felt washers from the controls and loosen the set screw on the tuning knob.

Remove the speaker plug from the cable socket.

Remove the four mounting screws, located underneath the cabinet.

REALIGNMENT: Should the receiver require re-alignment, the procedure outlined below should be followed. For best results an external modulated oscillator with adequate frequency range, and a visual output meter, should be used.

Before connecting the chassis to the power line, reconnect the speaker cable in its socket.

The R. F. alignment trimmer condensers are mounted on the side of the R. F. shields.

I. F. ALIGNMENT: When aligning the Intermediate Frequency Amplifier, the external oscillator must be set at 456 kc. The Band Selector Switch should be in the position marked "Broadcast", and the tuning condenser should be set at maximum capacity. Connect the "antenna" lead of the external oscillator to the control grid of the type 6K7 tube in the I. F. Amplifier stage through a .1 mfd. fixed condenser. Connect the "ground" lead of the external oscillator to the receiver ground lead. The I. F. alignment capacitors are located at the side of the shielded I. F. Transformers. Rotate the adjusting screw of each capacitor on I. F. Unit No. 2 slowly until maximum output is noted. On completion of this operation, remove the external oscillator lead from the type 6K7 I. F. amplifier tube and connect it in the same manner to the control grid at the top of the type 6A8 tube.

Now rotate each adjustment screw on I. F. Unit No. 1 for maximum output. During these operations, use the least possible input to prevent broadening of the resonance peaks.

In order to obtain the most accurate realignment of the I. F. amplifier, it is essential to repeat the alignment process in both I. F. Units.

BROADCAST ALIGNMENT: After the I. F. amplifier is completely realigned, connect the external oscillator leads to the receiver antenna and ground leads. Insert a 200 mmf. condenser in series with the antenna lead. Set the Band Selector Switch in the "Broadcast" position and place the tuning control pointer at the 1500 kc. mark. Adjust the broadcast band oscillator trimmer.

Next adjust the interstage alignment trimmer for maximum response. Finally adjust the antenna section trimmer in the same manner.

Next adjust the 600 kc. padder condenser, located on the top of the oscillator coil. Set the external oscillator at 600 kc. Rotate the receiver tuning control until resonance is indicated. Then rock the tuning control back and forth about this resonance position, and at the same time adjust the padder condenser for the highest resonance peak.

Now repeat the 1500 kc. trimmer adjustment, following in every detail the procedure previously described.

ALIGNMENT OF THE SHORT WAVE-BANDS:— The procedure in aligning the short wave-bands is identical with that for the broadcast with the exception of the adjustment of the padder condenser. Insert a 400 ohm non-inductive resistor in series with the antenna lead. The alignment frequencies are as follows:

Band 2: 50 Meters—(6,000 kc.)
Band 1: 16.6 Meters—(18,000 kc.)

When aligning Band 2, set the Band Selector Switch in the position marked "Band 2". Set the tuning control pointer at 50 meters. Adjust the oscillator alignment capacitor on Band 2 for maximum output. Next adjust the interstage and antenna section alignment capacitors for maximum output.

To align Band 1, set the Band Selector Switch in the position marked "Band 1" Set the tuning control pointer at the 16.6 meter mark. Set the external oscillator at 16.6 meters. Adjust the oscillator section alignment capacitor on Band 1 for maximum output.

Proceed next to align the interstage section of Band 1. In doing this, it is essential to rock the tuning control back and forth about the resonance position and at the same time to adjust the trimmer for the highest resonance peak. Next align the antenna section for maximum sensitivity.

LONG WAVE MODEL 425

The above alignment positions refer to the Model 423 only, which is calibrated in frequency. The alignment points for the Model 425, which is calibrated in meters only, is as follows:

Long Wave	Align at 750 meters.
	Pad at 2,000 meters.
Broadcast	Align at 200 meters.
	Pad at 500 meters.
Band 1	Align at 17 meters.

The Long Wave alignment procedure is similar to that for the Broadcast. A 200 mmf. condenser should be used in series with the antenna lead in aligning this band.

CAUTION: When making repairs on the receiver, use only ROSIN CORE SOLDER. NEVER USE SOLDERING PASTE OR ACID FLUXES OF ANY TYPE.

REMOVAL OF CHASSIS FROM CABINET:

To remove the chassis from the cabinet proceed as follows:

Be certain that the line cord is removed from the power outlet socket.

Remove the "slip-on" knobs and felt washers from the controls and loosen the set screw on the tuning knob.

Remove the speaker plug from the socket at the rear of the chassis.

Remove the four mounting screws, located underneath the cabinet.

Remove the tuning beam plug from the socket at the front of the chassis.

REALIGNMENT: Should the receiver require re-alignment, the procedure outlined below should be followed. For best results an external modulated oscillator with adequate frequency range, and a visual output meter, should be used.

Before connecting the chassis to the power line, reconnect the speaker cable in its socket at the rear of the chassis.

The R. F. alignment trimmer condensers are mounted on the side of the coil shields.

I. F. ALIGNMENT: When aligning the Intermediate Frequency Amplifier, the external oscillator must be set at 456 kc. The Band Selector Switch should be in the position marked "Broadcast", and the tuning condenser should be set at maximum capacity. Connect the "antenna" lead of the external oscillator to the control grid of the type 6K7 tube in the I. F. Amplifier stage through a .1 mfd. fixed condenser. Connect the "ground" lead of the external oscillator to the receiver ground lead. The I. F. alignment capacitors are located at the side of the shielded I. F. Transformers. Rotate the adjusting screw of each capacitor on I. F. Unit No. 2 slowly until maximum output is noted. On completion of this operation, remove the external oscillator lead from the type 6K7 I. F. amplifier tube and connect it in the same manner to the control grid at the top of the type 6A8 tube.

Now rotate each adjustment screw on I. F. Unit No. 1 for maximum output. During these operations, use the least possible input to prevent broadening of the resonance peaks

In order to obtain the most accurate realignment of the I. F. amplifier, it is essential to repeat the alignment process in both I. F. Units.

BROADCAST ALIGNMENT: After the I. F. amplifier is completely realigned, connect the external oscillator leads to the receiver antenna and ground leads. Insert a 200 mmf. condenser in series with the antenna lead. Set the Band Selector Switch in the "Broadcast" position and place the tuning control pointer at the 1500 kc. mark. Adjust the broadcast band oscillator trimmer.

Next adjust the interstage alignment trimmer for maximum response. Finally adjust the antenna section trimmer in the same manner.

Next adjust the 600 kc. padder condenser, located on the top of the oscillator coil. Set the external oscillator at 600 kc. Rotate the receiver tuning control until resonance is indicated. Then rock the tuning control back and forth about this resonance position, and at the same time adjust the padder condenser for the highest resonance peak.

Now repeat the 1500 kc. trimmer adjustment, following in every detail the procedure previously described.

ALIGNMENT OF THE SHORT WAVE-BANDS:— The procedure in aligning the short wave-bands is identical with that for the broadcast with the exception of the adjustment of the padder condenser. Insert a 400 ohm non-inductive resistor in series with the antenna lead. The alignment frequencies are as follows:

Band 2: 50 Meters—(6,000 kc.)
Band 1: 16.6 Meters—(18,000 kc.)

When aligning Band 2, set the Band Selector Switch in the position marked "Band 2". Set the tuning control pointer at 50 meters. Adjust the oscillator alignment capacitor on Band 2 for maximum output. Next adjust the interstage and antenna section alignment capacitors for maximum output.

To align Band 1, set the Band Selector Switch in the position marked "Band 1". Set the tuning control pointer at the 16.6 meter mark. Set the external oscillator at 16.6 meters. Adjust the oscillator section alignment capacitor on Band 1 for maximum output.

Proceed next to align the interstage section of Band 1. In doing this, it is essential to rock the tuning control back and forth about the resonance position and at the same time to adjust the trimmer for the highest resonance peak. Next align the antenna section for maximum sensitivity.

LONG WAVE MODEL 625

The above alignment positions refer to the Model 623 only, which is calibrated in frequency. The alignment points for the Model 625, which is calibrated in meters only, is as follows:

Long Wave	Align at 750 meters.
	Pad at 2,000 meters.
Broadcast	Align at 200 meters.
	Pad at 500 meters.
Band 1	Align at 17 meters.

The Long Wave alignment procedure is similar to that for the Broadcast. A 200 mmf. condenser should be used in series with the antenna lead in aligning this band.

CAUTION: When making repairs on the receiver, use only ROSIN CORE SOLDER. NEVER USE SOLDERING PASTE OR ACID FLUXES OF ANY TYPE.

RCA MANUFACTURING COMPANY, Inc.

MODEL 5X2

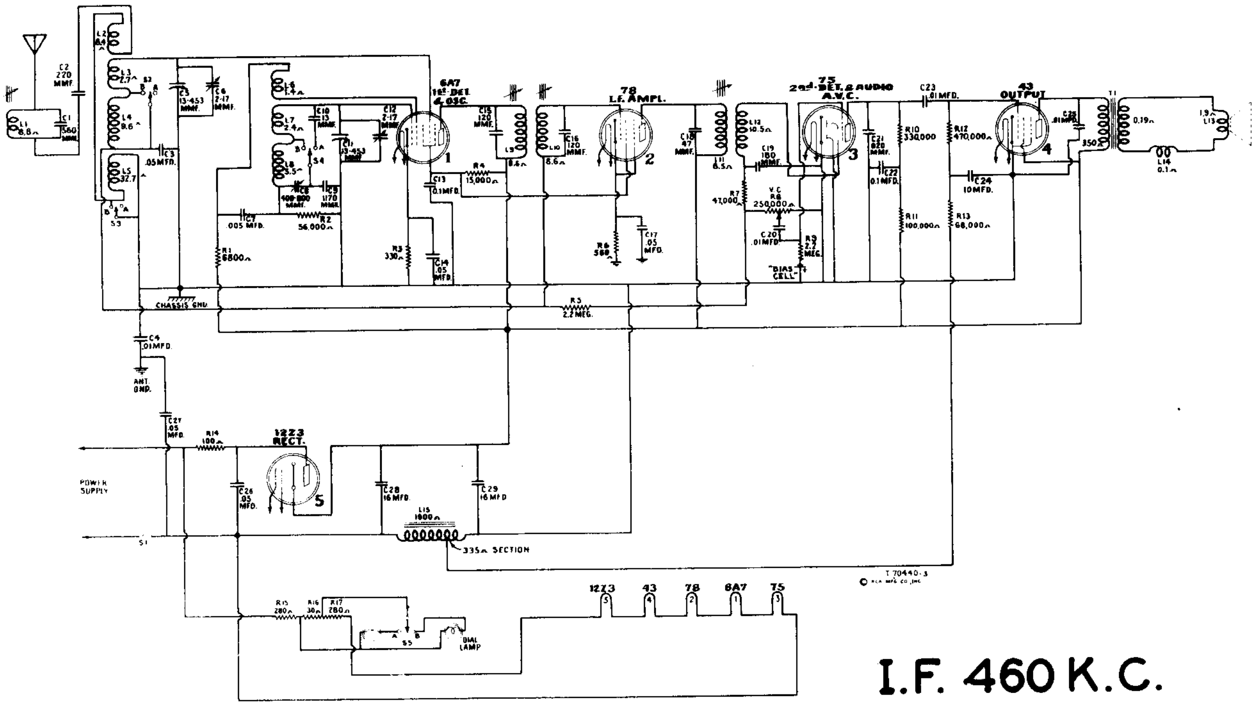

Figure 1—Schematic Circuit Diagram

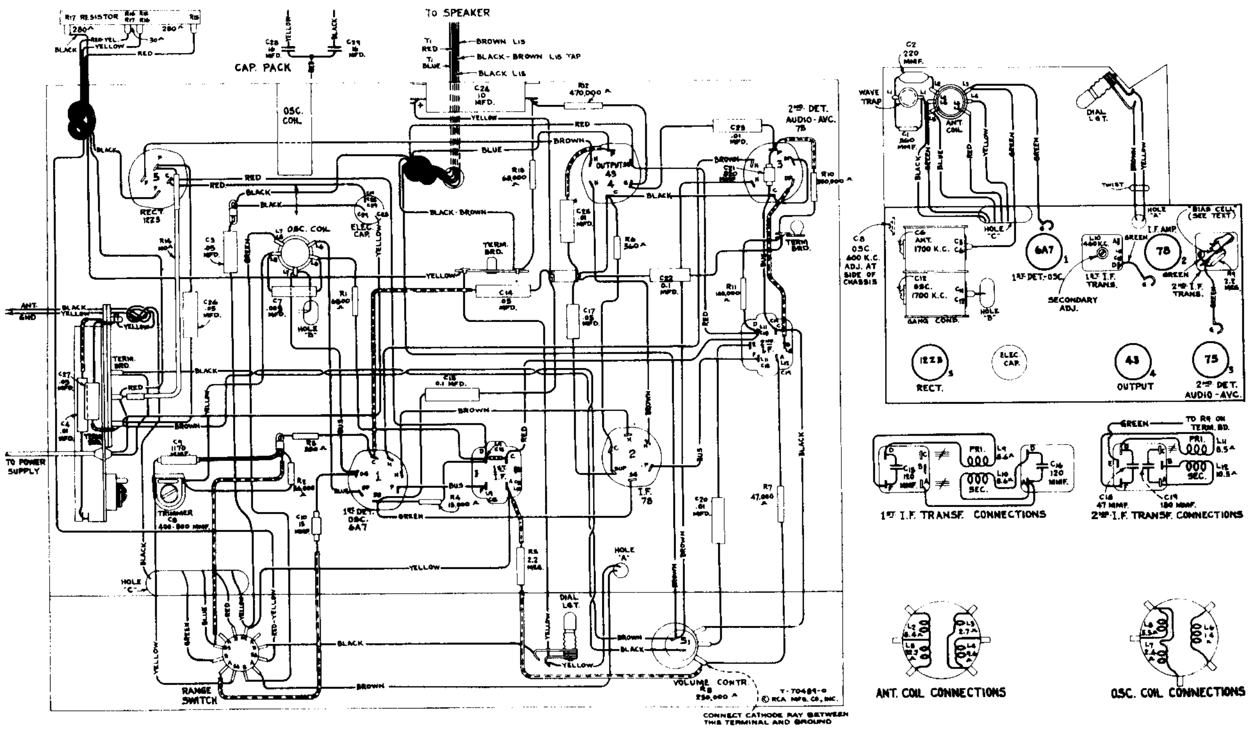

Figure 2—Chassis Wiring Diagram, Radiotron, Coil, and Trimmer Locations

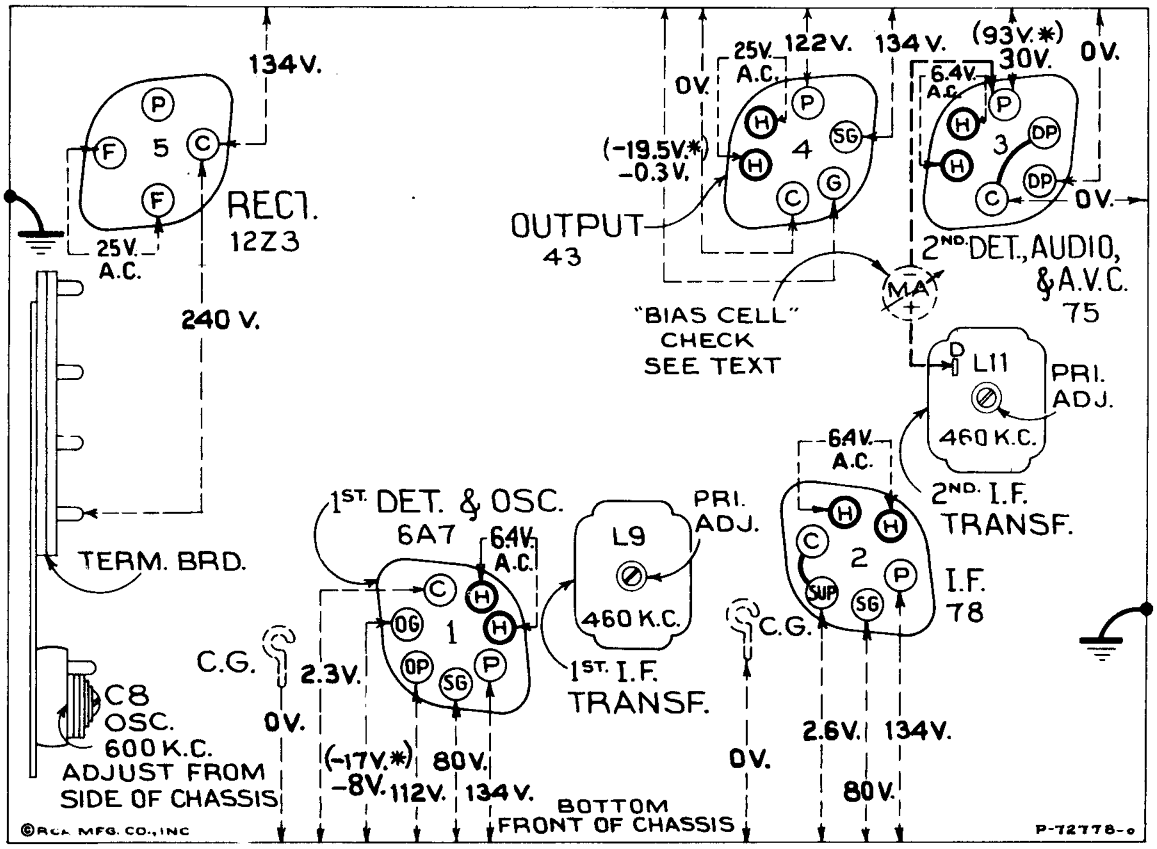
RCA MANUFACTURING COMPANY, Inc.

MODEL 5X2



CAUTION: NEVER CONNECT VOLTMETER TO CONTROL GRID OF TUBE No. 3 (RCA-75)-SEE TEXT.

Figure 6—Radiotron Socket Voltages and Trimmer Locations

Measured at 230 volts, 60 cycle supply—For 230 volt D-C approximately 10% lower
Tuned to approximately 1,000 kc. ("Standard broadcast" position)—No signal being received—
Volume control setting optional

Radiotron Socket Voltages

Note: *Two voltage values are shown for some readings. The higher value shown in parenthesis with asterisk (*) indicates operating conditions without voltmeter loading. The lower value is the actual measured voltage and differs from the higher value because of the additional loading of the voltmeter through the high series circuit resistance.*

CAUTION: The voltage between the RCA-75 control grid and ground should never be measured. All ordinary meters will paralyze the "Bias Cell," see figures 1 and 2, in this circuit for a period of approximately one to two hours. To check "Bias Cell," connect 0-1 M.A. milliameter as shown on figure 6. A satisfactory cell should give a steady reading on the meter between 0.3 and 0.65 M.A. when used with a good RCA-75 tube.

The voltage values indicated from the Radiotron socket contacts, grid caps, resistors and terminals to receiver chassis ground on figure 6 will assist in locating cause for faulty operation. Each value as specified should hold within ± 20% when the receiver is normally operative at its rated line voltage. Variations in excess of this limit will usually be indicative of trouble in the basic circuits. These voltages were measured with set tuned to approximately 1,000 kc. ("Standard broadcast" range); no signal being received and volume control setting optional. To duplicate the conditions under which the voltages were measured requires a 1,000 ohm-per-volt d-c meter, having ranges of 10, 50 and 250 volts. Voltages between 0 and 10 read on 10-volt scale, between 10 and 50 on 50-volt scale, and between 50 and 250 on 250-volt scale. A-C voltages were measured with a corresponding a-c meter.

Detector and A.V.C.

The modulated signal, as obtained from the output of the i-f stage, is detected by one of the diodes in the RCA-75 tube. The audio frequency component, secured by this process, is transferred from the movable arm of the volume control R8 through coupling capacitor C20 to the control grid of the RCA-75 for voltage amplification. The d-c voltage which results from detection of the signal is used for automatic volume control. This voltage which develops across resistor R8 is applied as automatic control grid bias to the first-detector and i-f tube through a suitable resistance filter circuit.

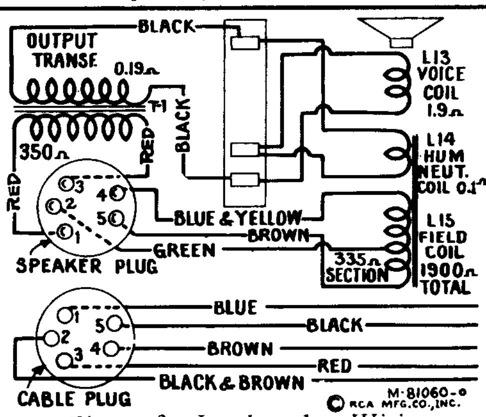


Figure 3—Loudspeaker Wiring

CAUTION: REMOVE BIAS CELL BEFORE MAKING RESISTANCE MEASUREMENTS.
NOTE: * OPEN CIRCUIT (LEAKAGE ELECTROLYTIC CAPACITORS ONLY).

Figure 5—Resistance Diagram

Power supply disconnected—Tuning condenser in full mesh—Volume control at maximum
Radiotrons in sockets

Resistance Measurement

CAUTION: The "Bias Cell," see figures 1 and 2, should be carefully removed before any resistance measurements are made. Do not allow the spring contact clips to short-circuit "Bias Cell" during its removal or insertion.

The resistance values shown between Radiotron socket contacts, grid caps, resistors, terminals, and receiver chassis ground, on figure 5 have been carefully selected so as to facilitate a rapid check of the circuit for defective parts, bad joints, etc. The use of this diagram in conjunction with the Schematic Circuit Diagram, figure 1, and the Chassis Wiring Diagram, figure 2, will permit the location of certain troubles which would otherwise be difficult to ascertain. Each value as specified should hold within ± 20%. Variations in excess of this limit will usually be indicative of trouble in the basic circuits. Resistance values were measured with the Radiotrons in sockets; power supply disconnected; tuning condenser in full mesh, and volume control set at maximum except where otherwise noted. In all cases of measuring the resistance between points of the circuit and ground, it will be necessary to connect the negative (–) terminal of the resistance meter to the chassis ground. If the polarity of the resistance meter is not known, it may be readily ascertained by connecting a d-c voltmeter of indicated polarity across the terminals of the device.

Electrical Specifications

Frequency Ranges
"Standard broadcast" .... 540-1,800 kc.
"Short-wave" .... 1,800-6,500 kc.

Alignment Frequencies
"Standard broadcast" ...... 600 kc. (osc.); 1,700 kc. (osc. and ant.)
"Short-wave" .... None Required

Intermediate Frequency .... 460 kc.

Radiotron Complement
(1) RCA-6A7 .... First Detector–Oscillator
(2) RCA-78 .... Intermediate Amplifier
(3) RCA-75 ..... Second Detector, A-F, and A.V.C.
(4) RCA-43 .... Power Output
(5) RCA-12Z3 .... Rectifier

Power Supply
200-250 volts, 50-100 cycles .... 120 watts
200-250 volts, D-C .... 110 watts

Power Output
Undistorted .... 0.9 watts A-C, 0.7 watts D-C
Maximum .... 2 watts A-C, 1.6 watts D-C

Loudspeaker
Type .... Electrodynamic
Voice Coil Impedance .... 2.2 ohms at 400 cycles

Pilot Lamps (2) .... Mazda No. 40, 6.3 volts, 0.15 amperes

MODEL 5X2

SERVICE DATA

CAUTION: Certain tests (e.g. alignment and voltage measurement) require operation of receiver with chassis removed from cabinet. Avoid external grounding of receiver chassis or associated equipment since the power supply is now connected to receiver chassis through the speaker field. Carelessness may cause serious damage to equipment.

Alignment Procedure

There are three alignment trimmers provided in the antenna coil and oscillator coil tuned circuits. The i-f transformer adjustments are made by means of three screws attached to molded magnetite cores.

Improper alignment usually causes the impairment of sensitivity, selectivity, and tone quality. Such conditions will usually exist simultaneously.

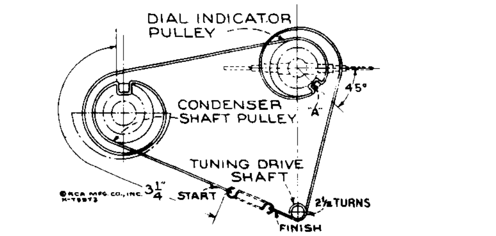

Figure 4—Tuning Drive Cord Mechanism

Rear view of drive assembly showing threading of drive cord with variable condenser plates in full mesh. To perform this operation, unsolder the four leads (connected between antenna coil and range selector switch) from the range selector switch, unsolder antenna lead-in wire from wave-trap terminal, unsolder lead from rear section of gang tuning condenser, and remove the four screws which secure the tuning drive frame to the chassis proper. This frame with gang tuning condenser still attached may now be easily removed for the threading operation. The relative position of the parts and method of threading are shown on the above diagram. In case the cord is too long for proper tension, it may be effectively shortened by first releasing finish end of cord, inserting a match or other shim under the cord at point "A" and then re-hooking the end of the cord to the tension spring. Replace drive assembly and re-solder leads.

In re-adjusting the tuned circuits, it is important to apply a definite procedure and to use adequate and reliable test equipment. A standard test oscillator, such as the **RCA Stock No. 9595** will be required as the source of the signal at the specified alignment frequencies. Visual indication of the receiver output during alignment is also necessary to accurately show when the correct point of adjustment is reached. The **RCA Stock No. 4317 Neon Output Indicator** is especially suitable for this use.

The procedure outlined below should be followed in adjusting the various trimming capacitors and molded magnetite cores.

I-F Core Adjustments

The three adjustment screws (one on top and one on bottom of first i-f transformer and one on bottom of second i-f transformer) are located as shown by figures 2 and 6. Each circuit must be aligned to a basic frequency of **460 kc.** To do this attach the output indicator across the loudspeaker voice coil or across the output transformer primary. Connect the output of the test oscillator through a **.05 mfd.** capacitor to the RCA-6A7 control grid, the ground of the test oscillator being connected to the receiver external yellow ground lead. Set the test oscillator to **460 kc.** Place the range selector in "Short wave" position. Advance the receiver volume control to its full-on position and adjust the receiver tuning control to a point within its range where no interference is encountered either from local broadcast stations or heterodyne oscillator. Increase the output of the test oscillator until a slight indication is apparent on the output indicator.

Adjust the bottom magnetite core screw of the second i-f transformer to produce maximum (peak) indicated receiver output. Then adjust the two magnetite core screws of the first i-f transformer for maximum (peak) receiver output as shown by the indicating device.

During these adjustments regulate the test oscillator output so the indication is always as low as possible. By doing so, broadness of tuning due to A.V.C. action will be avoided. It is advisable to repeat the adjustment of all i-f magnetite core screws to assure that the interaction between them has not disturbed the original adjustment.

Wave-Trap Adjustment

Attach the output of the test oscillator to the black antenna lead through a **200 mmfd.** capacitor, the ground connection of the test oscillator and receiver being connected as before.

Leave the test oscillator adjusted to **460 kc.,** and range selector in "Short wave" position as before. Then adjust the wave-trap trimmer to the point which causes maximum suppression of the **460 kc.** signal.

R-F Trimmer Adjustments

Roughly calibrate the tuning dial by setting the pointer to the bottom horizontal line at the low frequency end of the broadcast scale with the two-gang tuning condenser at its maximum capacity. The output indicator should be left connected to the output system. The connections for the test oscillator remain the same as for "Wave-trap" adjustment. Volume control should be in maximum position. Set range selector to "Standard broadcast" position.

Set oscillator and antenna trimming capacitors **C12** and C6, respectively, to a position near minimum capacitance (plates near out). Adjust the test oscillator to 1,700 kc.

Tune the receiver to pick up this signal (near **1,700 kc.** on dial) for maximum response disregarding dial reading. Always keep test oscillator output as low as is possible and still obtain visual indication. Adjust trimming capacitors **C12** and **C6** so that each produces maximum (peak) receiver output, re-adjusting receiver tuning slightly if necessary, but using the minimum trimming capacitance possible to obtain peaks. Adjust the dial pointer (without disturbing gang tuning condenser) to a dial reading of **1,700 kc.** Shift the test oscillator to **600 kc.** Tune the receiver to receive the signal disregarding the dial reading at which it is best received. Then adjust the oscillator series capacitor, **C8,** simultaneously rocking the tuning control backward and forward through the signal until maximum receiver output results from these combined operations. The adjustment at **1,700 kc.** should then be repeated to correct for any change which may have been caused by the oscillator series trimming capacitor adjustment.

Loudspeaker

Centering of the loudspeaker voice coil is made in the usual manner with three narrow paper feelers after first removing the front paper dust cover. This may be removed either permanently by cutting it away with a sharp knife, or by softening its cement with a very light application of acetone using care not to allow the acetone to flow down into the air gap The dust cover may be cemented back in place with ambroid upon completion of adjustment.

Circuit Arrangement

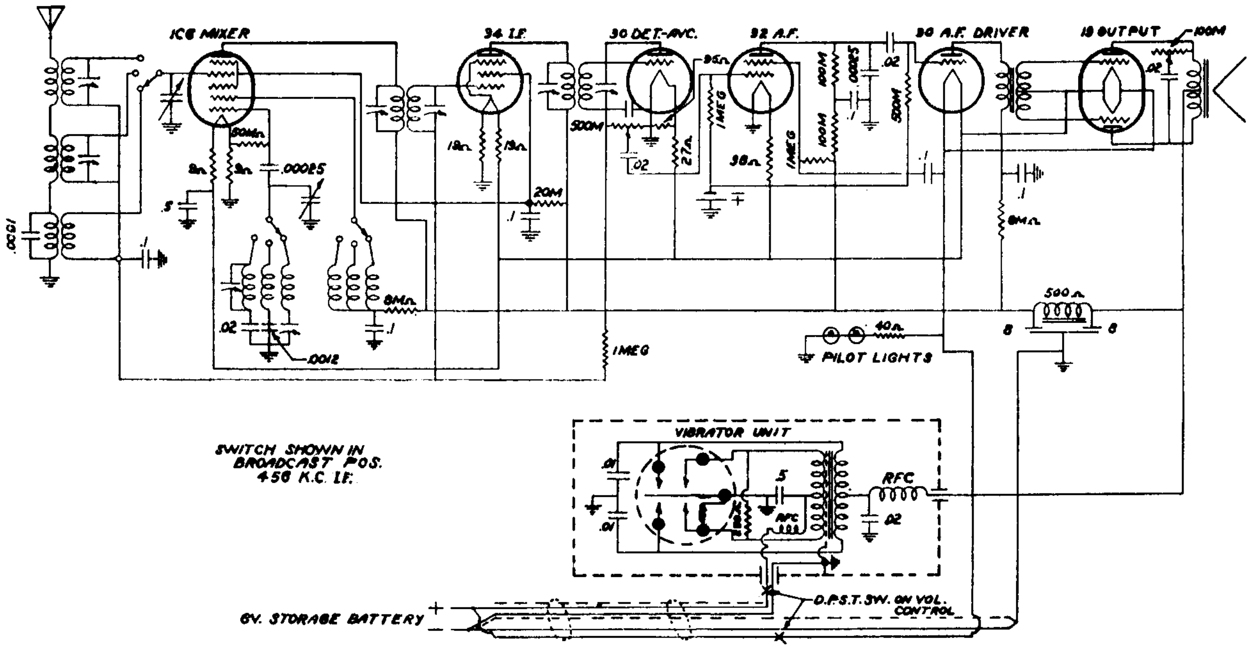
The conventional superheterodyne type of circuit, consisting of a combined first-detector–oscillator stage, a single i-f stage, a diode-detector automatic-volume-control stage, an audio voltage amplifier stage, an audio power output stage, and a half-wave rectifier power supply stage, is used.

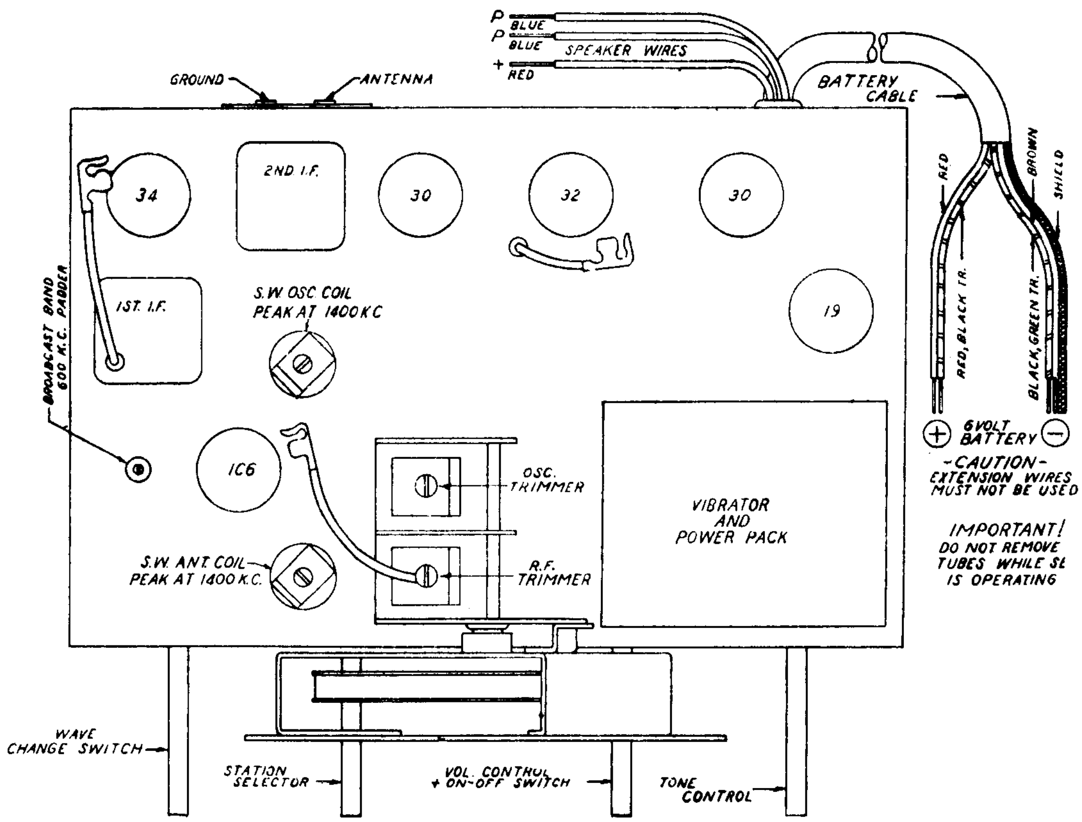
Tuned Circuits

The antenna coil system consists of two series-connected primary and two series-connected secondary windings to provide the two ranges of tuning. The oscillator coil is similarly wound on a single form. A multi-pole range selector switch, consisting of S2, S3, S4, and S5, is used to connect the various sections of these coil systems and to illuminate the proper tuning dial scale for the band in operation. The coils are tuned by a variable two-section gang condenser having trimming capacitors in shunt with each section. A series trimming capacitor is also associated with the "Standard broadcast" oscillator coil.

The intermediate frequency amplifier system consists of an RCA-78 in a transformer coupled circuit. This stage operates at a basic frequency of **460 kc** Adjustable magnetite cores are provided for adjusting inductance of the input i-f transformer (primary and secondary) and the output transformer (primary) windings.

RADOLEK COMPANY
MODEL K16743





This receiver is designed to operate over three tuning ranges. The broadcast range which extends from 545 to 1715 Kilocycles (KC) (175 to 550 meters), Police and Aviation Band which extends from 1715 to 5350 Kilocycles (KC) (56 to 175 Meters) and the International Short Wave Band which extends from 5760 to 16200 Kilocycles (KC) (18.5 to 52 meters). This short wave range is the one which includes the four internationally assigned bands—the 19, 25, 31 and 49 meter bands.

RADOLEK COMPANY
MODEL K16743

ALIGNMENT DATA AND SERVICING

GENERAL DATA

The alignment of this receiver requires the use of a test oscillator which will cover the frequencies of 456, 600, 1400, 1800, 4000, 6000, and 14,000 KC and an output meter which is to be connected across the primary or secondary of the output transformer. If possible, all alignments should be made with the volume control on maximum and the test oscillator output as low as possible, to prevent the AVC from operating and giving false readings.

CORRECT ALIGNMENT PROCEDURE

The intermediate frequency (I.F.) stage should be aligned properly as the first step. After the I.F. transformers have been properly adjusted and peaked, the Broadcast Band should always be the next procedure; after which, either or both of the Short Wave Bands may be aligned.

I.F. ALIGNMENT

Adjust the test oscillator to 456 KC and connect the output to the grid of the first detector tube (1C6) through a .05 or .1 mfd. condenser. The ground on the test oscillator can be connected to the chassis ground. Align all four I.F. trimmers to peak or maximum reading on the output meter.

BROADCAST BAND ALIGNMENT

Adjust the oscillator to 1400 KC and connect the output to the antenna post marked "A" through a .0001 mfd. mica condenser to give the equivalent of an antenna about 60 feet. Set the receiver pointer to 1400 KC and adjust the rear gang condenser trimmer (oscillator circuit) to peak. After this has been carefully done, the next step is to adjust the front trimmer of the gang condenser to peak. The front condenser section tunes the RF or grid circuit of the 1C6 tube. Next, re-set the dial pointer on the receiver and the test oscillator to 600 KC. Slowly increase or decrease the oscillator padding condenser and at the same time continuously tune back and forth across the signal with the receiver until the maximum reading is obtained on the output meter. This adjustment may seem a little complicated but is the easiest way to adjust the oscillator to the R.F. section. The padding condenser is located on the left hand side of the chassis, directly to the left of the 1C6 tube and in front of the first I.F. transformer. Return to 1400 KC and again go over the adjustments of this frequency to be certain that they were not put slightly out of alignment when adjustment was made at 600 KC.

This completes the correct sequence of operations in properly aligning the receiver for the Broadcast Band, and **must always be done before** attempting to align the Short Wave Bands.

FOREIGN BAND ALIGNMENT

The Foreign Band of 19 to 49 meters can be adjusted by the two trimmers on the short wave coils located on the top of the chassis. Set the test oscillator to 14,000 KC. In preparing the test oscillator for alignment of this band, connect a 400 ohm carbon resistor in series with the .0001 mfd. condenser on the output lead of the test oscillator. The oscillator coil is located near the 1st I.F. Transformer and the antenna or R.F. coil is located directly in front of the Short Wave oscillator coil and alongside the front section of the gang condenser. These two trimmers should be adjusted for peak at 14,000 KC and as the inherent design of the circuit has been expressly developed for simplicity in servicing, no other adjustments are necessary for aligning this band. **Note:** Always start this procedure by having the oscillator coil trimmer loose (out all the way), and the antenna coil trimmer fairly tight (in all the way); otherwise it is possible to make a false alignment on the image frequency. In order to prevent alignment on the image frequency, it is suggested that the following check be made: Readjust the pointer to 13,100 KC where the image frequency should be found. If properly aligned, the image frequency will be found to be weaker. If, however, the signal at 13,100 KC is found to be stronger than the signal at 14,000 KC, it signifies that alignment was incorrectly made on the image frequency.

IMPORTANT: Do not attempt any adjustment of the gang condenser trimmers in aligning the Foreign Band as this will throw the Broadcast Band out of alignment.

POLICE BAND ALIGNMENT

There is only one adjustment to be made in the alignment of the Police Band. Due to the circuit design and correct matching of the coils, no oscillator adjustment is necessary. Set the dial pointer to 4000 KC (also the test oscillator) and adjust the antenna coil trimmer to resonance. In preparing the test oscillator for alignment of this band, connect a 400 ohm carbon resistor in series with the .0001 mfd. condenser on the output lead of the test oscillator. This resistor is used with the test oscillator only on the Short Wave Bands and should not be used for Broadcast Band alignment. The two police band coils are under the chassis and the antenna coil trimmer is mounted on the end of the antenna coil. **Important:** This is the only adjustment necessary for the Police Band. Do not attempt any adjustment of the gang condenser trimmers in aligning the Police Band, otherwise the Broadcast Band will be thrown out of alignment.

SERVICE DATA FOR ALL BANDS

If it is suspected that the oscillator has stopped but is doubtful due to the presence of the usual amount of noise level, it is suggested that the oscillator plate voltage be checked. To ascertain whether the tube is oscillating, ground the oscillator grid of the 1C6 (short stator and rotor plates of oscillator section on gang condenser). If oscillating properly, grounding the grid will cause an appreciable drop in oscillator voltage.

REASONS FOR UNSATISFACTORY OPERATION

FAILURE TO OPERATE

1. Check connections from battery cable to storage battery. If connections are reversed, set will not operate. Proper instructions for connecting the battery are given on the first page.
2. Check all tubes. Have them tested by meter equipped to test the type of tubes used in this receiver.
3. Check tube shields for good ground connections. Check grid caps for good connection. See that grid caps and tube shields are not shorted to each other (touching).
4. Reversed connections on Antenna and ground terminals. Try both ways for best results.
5. Oscillator tube (1C6) not oscillating.
6. Vibrator unit not securely in socket.

HUM

A minimum amount of hum, equivalent to A.C. receivers, may be present. Excessive hum may be traced to the following causes:

1. Omitting the use of a ground or a poor ground connection.
2. Vibrator unit not securely fitted in socket.
3. Antenna picking up interference from high tension power lines.
4. Weak or rundown battery. Battery with defective cell.
5. Poor battery connections.
6. Extending or lengthening battery leads cause an enormous increase in "hum." The battery cable attached to the receiver is of special design and its ends **must** be connected directly to the battery terminals. **(See battery connection data on first page.)**

HOWLS AND SQUEALS

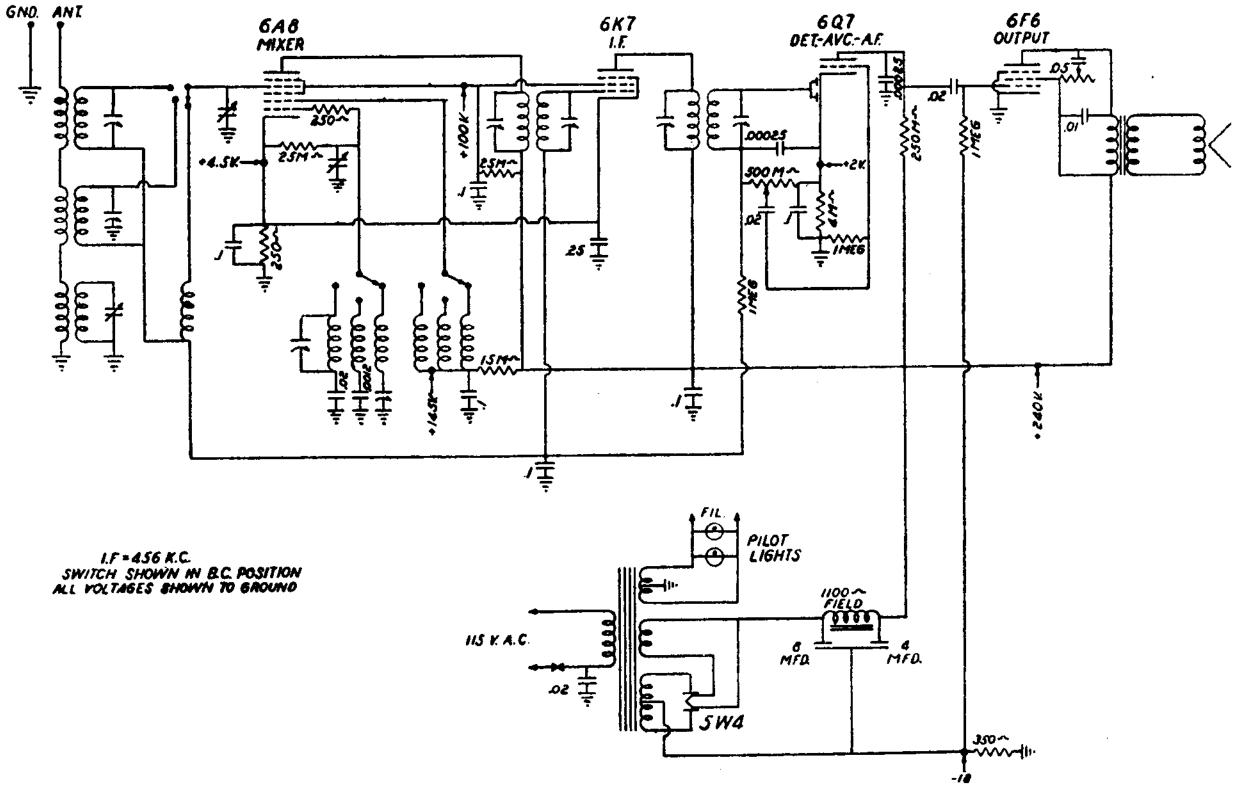
1. Omitting the use of a ground or poor ground connections.
2. Speaker leads placed near the (32) tube. These leads should be kept away from this locality. Speaker leads should be kept along the end of chassis and front corner of cabinet.
3. Check shield on (34) tube for good connection to chassis.

WINDCHARGERS

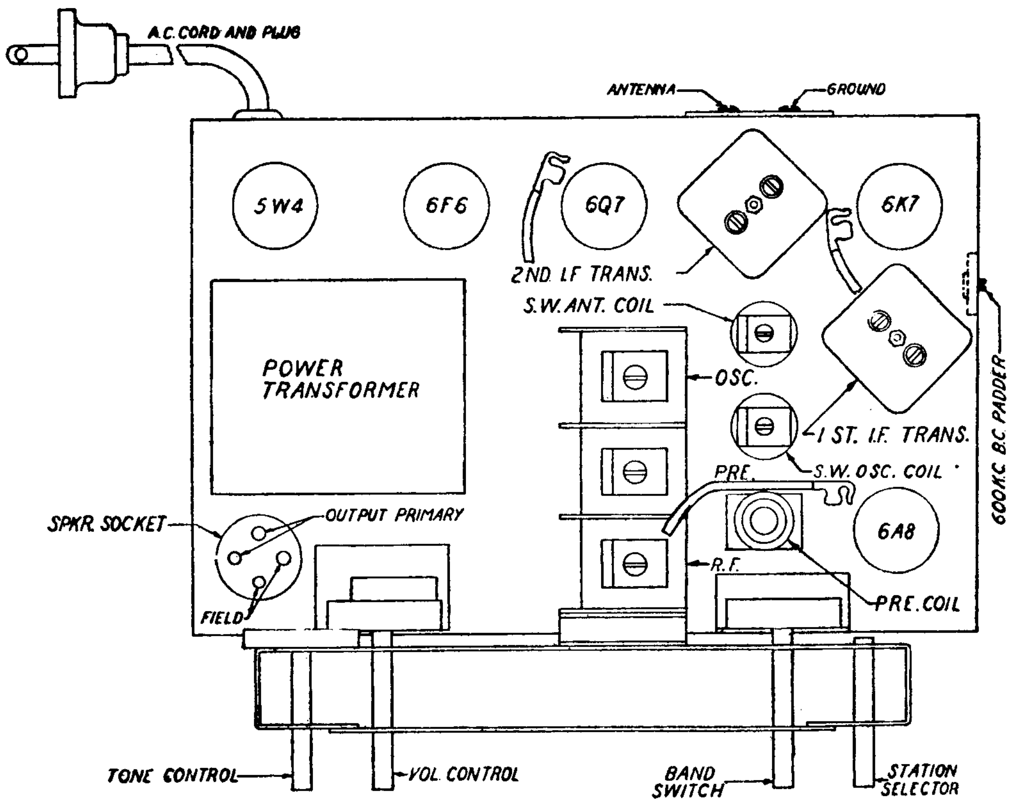
There are many types of windchargers now on the market which may be used to advantage for greater economy of receiver operation. Such chargers will pay for themselves over a period of time; by saving the cost of battery recharging; removing the inconvenience of taking the battery to a charging station; non-operation of the receiver during the charging period.

IMPORTANT NOTE: The battery must never be charged while set is in operation. If a windcharger is used, it should always be disconnected from the battery when the receiver is being used. An inexpensive single pole switch can be used for disconnecting the windcharger from the battery. This will increase the life of the tubes and give additional economy to the use of the receiver.

RADOLEK COMPANY
MODEL K16747

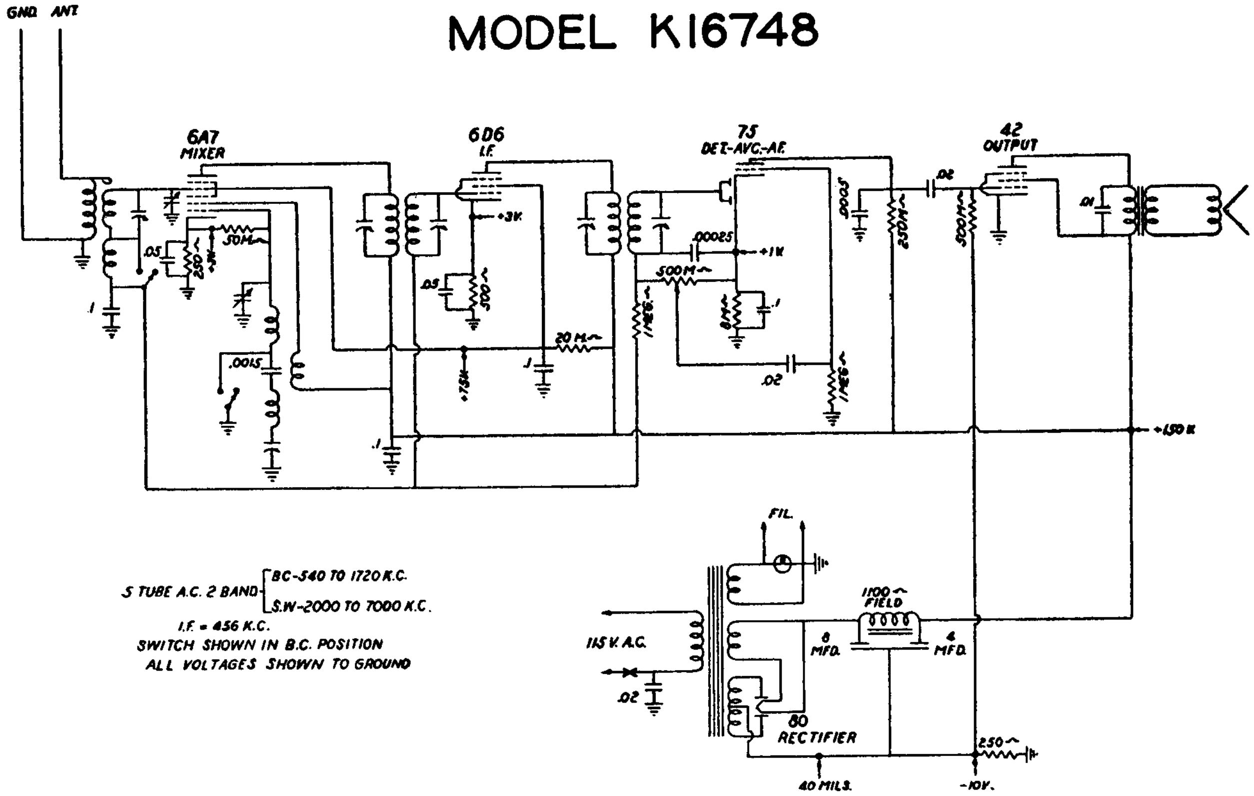


This receiver is designed to operate over three tuning ranges. The broadcast range which extends from 545 to 1715 Kilocycles (KC) (175 to 550 meters), Police and Aviation Band which extends from 1715 to 5350 Kilocycles (KC) (56 to 175 Meters) and the International Short Wave Band which extends from 5760 to 16200 Kilocycles (KC) (18.5 to 52 meters). This short wave range is the one which includes the four internationally assigned bands—the 19, 25, 31 and 49 meter bands.



RADOLEK COMPANY

MODEL K16748



This receiver is designed to operate over two tuning ranges. Upper band which covers the broadcast range, extends from 545 to 1750 kilocycles (175 to 550 meters), lower band which covers Police, Aviation, and the International 49 Meter Foreign Band.

1400 kc	1400 kc	.0002 mfd.	Antenna Conn.	C1,C21	Ant. Transl.	1
600 kc (rock)	600 kc	.0002 mfd.	Antenna Conn.	C8	Padder	2

IMPORTANT ALIGNMENT NOTES

The variable should be rocked back and forth a degree or two while making the 600 kc adjustment.

The alignment procedure should be repeated in the original order, step by step, to insure greater accuracy.

Always keep the output power from the generator at its lowest possible value to prevent the AVC of the receiver from interfering with accurate alignment.

ALIGNMENT PROCEDURE: FOR PROPERLY ALIGNING EITHER THE INTERMEDIATE TRANSFORMER OR THE VARIABLE CONDENSER IT IS NECESSARY THAT AN ACCURATELY CALIBRATED TEST OSCILLATOR BE USED WITH SOME TYPE OF OUTPUT MEASURING DEVICE.

INTERMEDIATE ALIGNMENT:

1. ATTACH THE HIGH SIDE OF THE TEST OSCILLATOR OUTPUT TO THE CONTROL GRID OF THE 6A7 TUBE, LEAVING THE CONTROL GRID DISCONNECTED. CONNECT A 1 MEGOHM RESISTOR FROM THE CONTROL GRID TO CHASSIS. CONNECT THE GROUND SIDE OF THE OSCILLATOR TO THE RECEIVER CHASSIS.

2. SET THE TEST OSCILLATOR FREQUENCY AT 370 KILOCYCLES (THIS MUST BE ACCURATE) AND ADJUST THE OUTPUT OF THE OSCILLATOR SO THAT A CONVENIENT READING IS OBTAINED ON THE OUTPUT METER.

3. ALIGN THE FIRST INTERMEDIATE TRANSFORMER BY TURNING ONE OF THE TRIMMER SCREWS UP AND DOWN UNTIL MAXIMUM READING IS OBTAINED ON THE OUTPUT METER, AND THEN ADJUST THE OTHER TRIMMER SCREW OF THE INTERMEDIATE FOR MAXIMUM SENSITIVITY.

4. ADJUST THE SECOND INTERMEDIATE TRANSFORMER IN THE SAME MANNER.

NOTE: TWO TYPES OF INTERMEDIATE TRANSFORMER TRIMMERS HAVE BEEN USED IN THIS MODEL RECEIVER. ONE TYPE HAS TWO PARALLEL HOLES IN THE TOP OF THE SHIELD, ONE FOR EACH TRIMMER. THE OTHER TYPE HAS A BRASS HEX NUT FOR ADJUSTING ONE INTERMEDIATE TRIMMER, THE OTHER INTERMEDIATE TRIMMER BEING ADJUSTED WITH THE TRIMMER SCREW LOCATED INSIDE OF THE BRASS HEX NUT. REGARDLESS OF WHICH TYPE TRIMMER IS USED, THE PROCEDURE IS THE SAME.

TO ALIGN THE VARIABLE CONDENSER: IT IS NECESSARY TO REMOVE THE RECEIVER CHASSIS FROM THE SET HOUSING TO ALIGN THE VARIABLE GANG CONDENSER AND PADDING CONDENSER. TO DO THIS REMOVE THE 12 MACHINE SCREWS LOCATED AROUND THE EDGE OF THE FRONT COVER OF THE SET HOUSING AND THE SINGLE MACHINE SCREW UNDERNEATH THE HOUSING, AFTER WHICH THE CHASSIS MAY BE PULLED OUT OF THE SET HOUSING BY GRASPING THE RECEIVER METAL FRONT PANEL AND PULLING OUTWARD.

1. PROPERLY CONNECT THE REMOTE CONTROL HEAD AND SHAFTS AND ADJUST THE DIAL NEEDLE ON THE DIAL FACE FROM THE BACK SO THAT THE DIAL CALIBRATION IS CORRECT.

2. CONNECT THE HIGH OUTPUT SIDE OF THE TEST OSCILLATOR TO THE ANTENNA AND THE GROUND TO THE RECEIVER CHASSIS.

3. TUNE THE RECEIVER DIAL AND SET THE TEST OSCILLATOR FREQUENCY TO EXACTLY 1400 KILOCYCLES. BRING IN THE 1400 KILOCYCLE SIGNAL TO MAXIMUM OUTPUT BY ADJUSTING THE TRIMMER LOCATED ON TOP OF THE OSCILLATOR SECTION (FRONT SECTION) OF THE GANG CONDENSER. NEXT ADJUST THE ANTENNA SECTION (REAR SECTION) FOR MAXIMUM 1400 KILOCYCLE SIGNAL SENSITIVITY.

4. TUNE THE RECEIVER DIAL AND SET THE TEST OSCILLATOR FREQUENCY TO APPROXIMATELY 600 KILOCYCLES AND WHILE ROCKING THE GANG CONDENSER SLIGHTLY TO THE RIGHT AND LEFT ADJUST THE 600 KILOCYCLE PADDING CONDENSER, WHICH IS LOCATED ON AND ACCESSIBLE THROUGH THE HOLE IN THE LEFT HAND SIDE OF THE CHASSIS, FOR MAXIMUM OUTPUT.

RECEIVERS SHIPPED TO CERTAIN SECTIONS OF THE COUNTRY THAT HAVE LOCAL AEROPLANE BEACON STATIONS BROADCASTING ON A FREQUENCY OF APPROXIMATELY 370 KILOCYCLES HAVE A COMBINATION WAVE TRAP AND ANTENNA COIL TO ELIMINATE INTERFERENCE FROM THESE BEACON STATIONS. ALL RECEIVERS EQUIPPED WITH THE COMBINATION WAVE TRAP AND ANTENNA COIL CAN BE IDENTIFIED BY THE LETTER "T" MARKED ON THE CHASSIS. THE STANDARD COIL AND THE COMBINATION WAVE TRAP AND ANTENNA COIL ARE INTERCHANGEABLE. THE STANDARD ANTENNA COIL IS PART #1898, AND THE COMBINATION ANTENNA COIL AND WAVE TRAP IS PART #1898T.

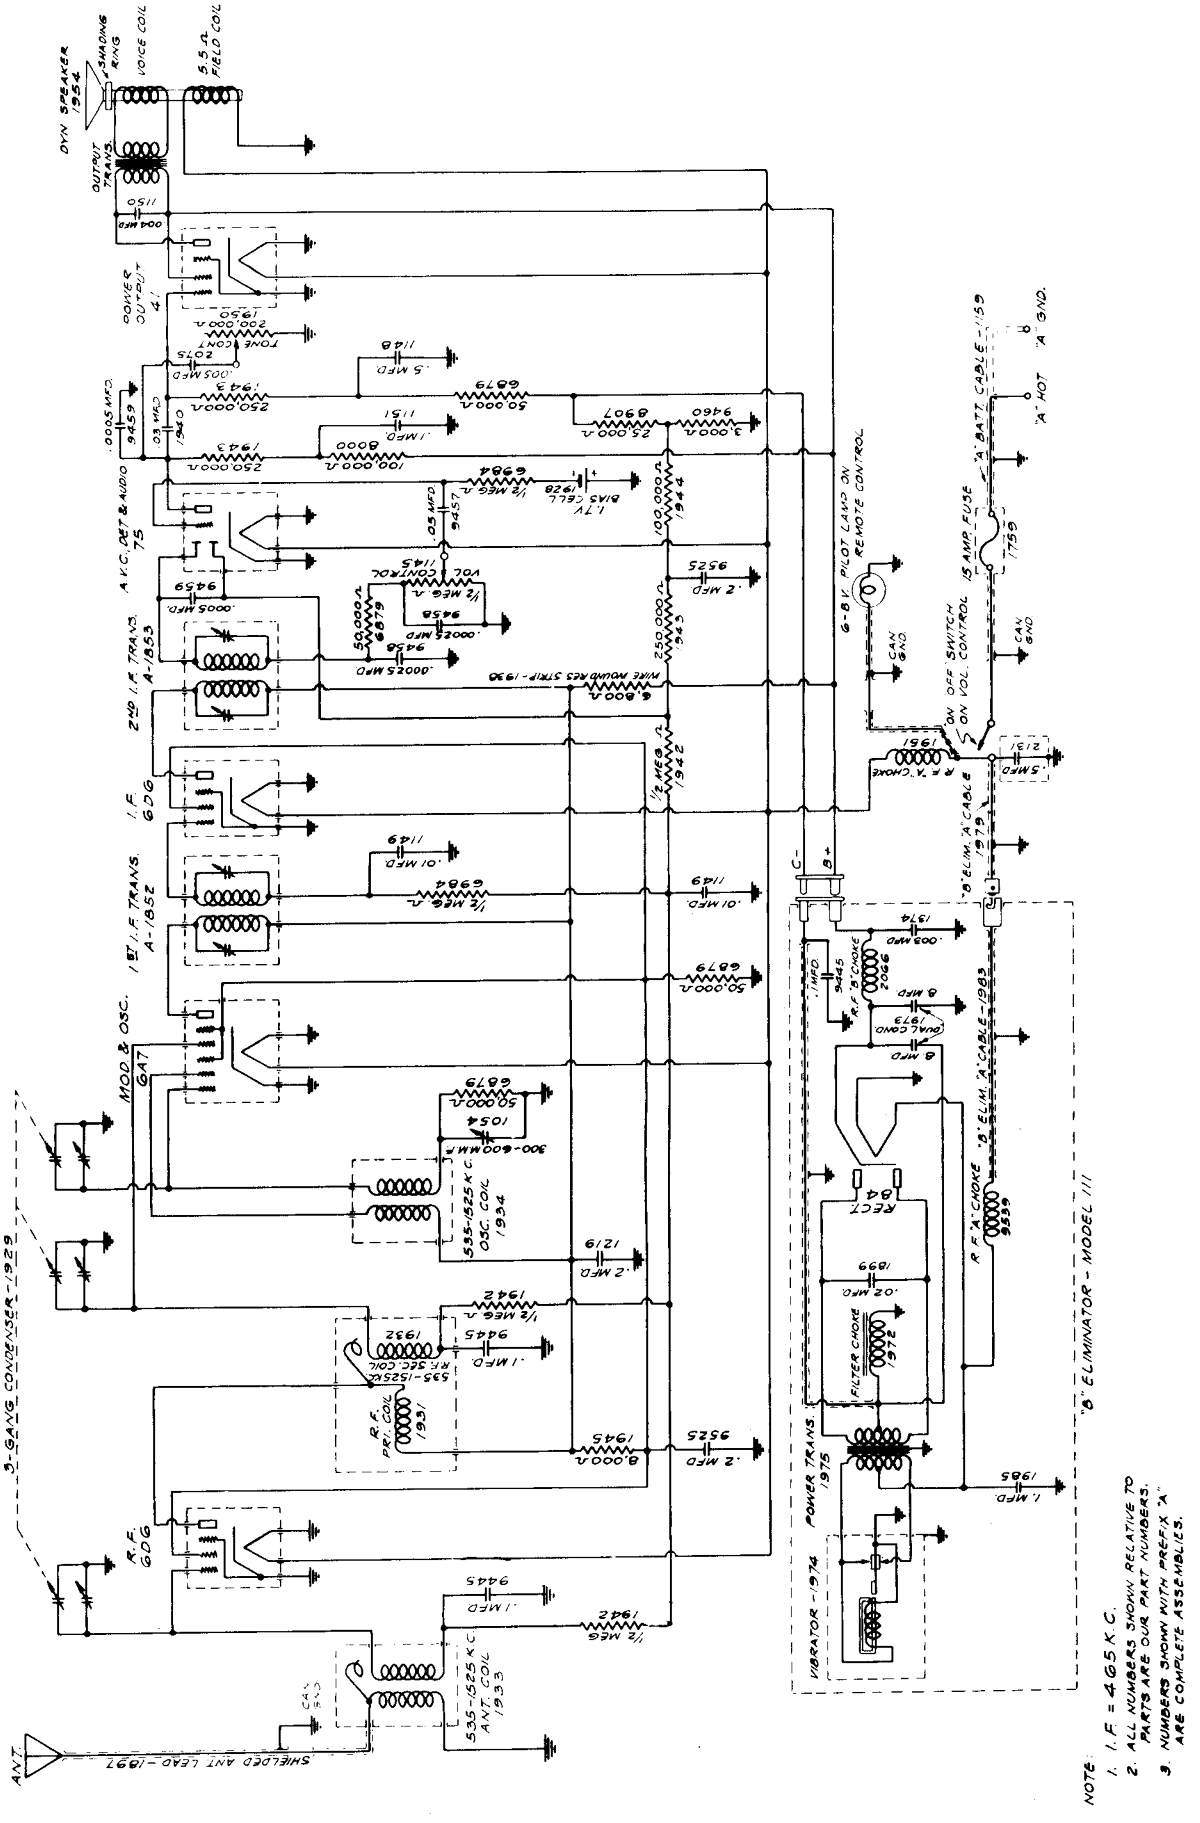
SENTINEL RADIO CORP.

MODEL 11M



SENTINEL RADIO CORP.

MODEL 11M

IGNITION NOISE: ELECTRICAL AND IGNITION INTERFERENCE CREATED BY THE SPARK PLUGS, HIGH TENSION COIL, DISTRIBUTOR, AND GENERATOR CAN BE MINIMIZED IN MOST INSTALLATIONS TO A POINT WHERE RADIO RECEPTION IS NOT IMPAIRED BY JUST INSTALLING THE DISTRIBUTOR SUPPRESSOR, GENERATOR AND AMMETER CONDENSERS SUPPLIED. IT WILL GENERALLY BE FOUND THAT WHATEVER IGNITION NOISE IS PRESENT AFTER INSTALLING THE DISTRIBUTOR SUPPRESSOR AND GENERATOR CONDENSER IS BEING PICKED UP BY THE ANTENNA. OFTEN THE INTERFERENCE IS FED INTO THE ROOF TYPE ANTENNA THROUGH THE DOME LIGHT WIRING, AND IN UNDERCAR AERIALS BY THE TAIL LIGHT WIRE (SEE "UNDERCAR AERIAL" PARAGRAPH). TO DETERMINE IF THESE WIRES ARE THE CAUSE OF THE ANTENNA PICKING UP THE INTERFERENCE, TRY BYPASSING THE LEAD AT THE POINT WHERE IT CONNECTS EITHER TO THE AMMETER OR THE LIGHTING SWITCH TERMINAL BLOCK TO THE CAR FRAME WITH ONE OF THE CONDENSERS SUPPLIED. IF THIS IS NOT EFFECTIVE WITH THE ROOF TYPE ANTENNA TRY BYPASSING THE DOME LIGHT LEAD AS NEAR AS POSSIBLE TO THE POINT WHERE IT ENTERS THE FRONT CORNER BODY POST. WHENEVER A NOTICEABLE REDUCTION IN IGNITION NOISE IS MADE, PERMANENTLY CONNECT THE CONDENSER AT THE POINT WHERE THIS REDUCTION WAS OBTAINED. IF THE IGNITION NOISE AFTER BYPASSING THE LIGHT LEAD STILL INTERFERES WITH RADIO RECEPTION, PROCEED AS FOLLOWS:

1. CONNECT THE "A" BATTERY LEADS DIRECT TO THE 6 VOLT STORAGE BATTERY POSTS INSTEAD OF THE AMMETER OR TERMINAL BLOCK.

2. PLACE A PIECE OF COPPER SCREENING SUFFICIENTLY LARGE TO COVER ALL OF THE FRONT FLOOR UP TO THE BULKHEAD UNDERNEATH THE FRONT FLOOR MAT, GROUNDING IT IN SEVERAL PLACES TO THE FRAME OF THE CAR.

3. BYPASSING THE IGNITION SWITCH, LOW TENSION SIDE OF THE DISTRIBUTOR COIL, CIGAR LIGHTER, ETC. MAY BE HELPFUL.

4. IF THE LOW TENSION WIRE BETWEEN THE IGNITION COIL AND DISTRIBUTOR RUN PARALLEL OR IN THE SAME HOUSING WITH THE HIGH TENSION LEAD, REMOVE IT OR SHIELD THE HIGH TENSION LEAD WITH A METAL SHIELD SIMILAR TO THE TYPE USED IN SHIELDING THE ANTENNA LEAD, GROUNDING THE SHIELDING AT SEVERAL POINTS TO THE FRAME OF THE CAR OR MOTOR.

5. ALL METAL TUBES AND RODS SUCH AS GAS AND OIL LINES, THROTTLE AND SPARK CONTROL CABLES, SPEEDOMETER CABLES, FREE WHEELING CABLES, ETC. THAT PASS THROUGH THE BULKHEAD SHOULD BE BONDED TO THE MOTOR WITH A HEAVY COPPER BRAIDED SHIELDING. THE SHIELDING SHOULD BE MADE AS SHORT AS POSSIBLE AND MUST BE SOLDERED TO THE METAL TUBES OR RODS, ETC., AND GROUNDED BY FASTENING IT TO THE MOTOR SIDE OF THE BULKHEAD, THE FRAME OF THE CAR, OR MOTOR.

6. REMOVE ROTOR FROM THE DISTRIBUTOR AND PEEN THE ROTOR CONTACT SO THAT THERE IS A CLEARANCE OF ONLY .004 INCHES BETWEEN THE ROTOR AND DISTRIBUTOR HEAD CONTACTS.

IN VERY RARE INSTANCES IT MAY BE FOUND THAT EVEN AFTER FOLLOWING THE ABOVE SUGGESTIONS THAT THE IGNITION INTERFERENCE IS STILL EXCESSIVE, IN WHICH EVENT IT MAY BE ADVISABLE TO INSTALL SPARK PLUG SUPPRESSORS ON EACH SPARK PLUG (SEE GENERAL INSTALLATION OF RECEIVER AND ACCESSORIES DRAWING).

ALIGNMENT PROCEDURE: FOR PROPERLY ALIGNING EITHER THE INTERMEDIATE TRANSFORMERS OR THE VARIABLE CONDENSER IT IS NECESSARY THAT AN ACCURATELY CALIBRATED OSCILLATOR BE USED WITH SOME TYPE OF OUTPUT MEASURING DEVICE.

INTERMEDIATE ALIGNMENT:

1. CONNECT THE HIGH SIDE OF THE OSCILLATOR OUTPUT TO THE CONTROL GRID OF THE 6A7 TUBE LEAVING THE CONTROL GRID CAP DISCONNECTED, AND ATTACH A 1 MEG OHM RESISTOR FROM GRID TO GROUND. CONNECT THE GROUND SIDE OF THE OSCILLATOR TO THE RECEIVER CHASSIS.

2. SET THE OSCILLATOR FREQUENCY AT 465 KILOCYCLES (THIS MUST BE ACCURATE) AND ADJUST THE OUTPUT OF THE OSCILLATOR SO THAT A CONVENIENT READING IS OBTAINED ON THE OUTPUT METER.

3. ALIGN THE FIRST INTERMEDIATE TRANSFORMER BY TURNING ONE OF THE TRIMMER SCREWS UP AND DOWN UNTIL MAXIMUM READING IS OBTAINED ON THE OUTPUT METER, AND THEN ADJUST THE OTHER TRIMMER SCREW OF THE INTERMEDIATE TRANSFORMER FOR MAXIMUM SENSITIVITY.

4. ADJUST THE SECOND INTERMEDIATE TRANSFORMER IN THE SAME MANNER.

NOTE: TWO TYPES OF INTERMEDIATE TRANSFORMER TRIMMERS HAVE BEEN USED IN THIS MODEL RECEIVER. ONE TYPE HAS TWO PARALLEL HOLES IN THE TOP OF THE SHIELD, ONE FOR EACH TRIMMER. THE OTHER TYPE HAS A BRASS HEX NUT FOR ADJUSTING ONE INTERMEDIATE TRIMMER, THE OTHER INTERMEDIATE TRIMMER BEING ADJUSTED WITH THE TRIMMER SCREW LOCATED INSIDE OF THE BRASS HEXNUT. REGARDLESS OF WHICH TYPE TRIMMER IS USED THE PROCEDURE IS THE SAME.

TO ALIGN THE VARIABLE CONDENSER: IT IS NECESSARY TO REMOVE THE RECEIVER CHASSIS FROM THE SET HOUSING TO ALIGN THE GANG AND PADDING CONDENSERS.

1. PROPERLY CONNECT THE REMOTE CONTROL HEAD AND SHAFTS AND ADJUST THE DIAL NEEDLE ON THE DIAL FACE SO THAT THE DIAL CALIBRATION IS CORRECT.

2. CONNECT THE HIGH OUTPUT SIDE OF THE OSCILLATOR TO THE ANTENNA AND THE GROUND TO THE RECEIVER CHASSIS.

3. TUNE THE RECEIVER TO EXACTLY 1400 KILOCYCLES ON THE DIAL AND ADJUST THE OSCILLATOR TO THIS FREQUENCY. <u>BRING IN THE 1400 KILOCYCLE SIGNAL TO MAXIMUM OUTPUT BY ADJUSTING THE OSCILLATOR SECTION GANG CONDENSER TRIMMER.</u> LOOKING AT THE TOP OF THE GANG CONDENSER AND READING FROM FRONT TO REAR, THE TRIMMER CONDENSERS ARE: R. F., OSCILLATOR, AND ANTENNA SECTIONS. NEXT, ADJUST THE R. F. AND ANTENNA SECTIONS OF THE GANG CONDENSER FOR MAXIMUM SENSITIVITY.

4. TUNE THE RECEIVER TO APPROXIMATELY 600 KILOCYCLES ON THE DIAL AND SET THE OSCILLATOR TO THIS FREQUENCY. THEN ADJUST THE 600 KILOCYCLE PADDING CONDENSER, WHICH IS LOCATED ON AN ACCESSIBLE THROUGH THE HOLE IN THE LEFT SIDE OF THE CHASSIS FOR MAXIMUM OUTPUT. ALWAYS ROCK THE CONDENSER SLIGHTLY TO THE RIGHT AND LEFT WHEN MAKING THIS ADJUSTMENT USING THE POSITION OF GREATEST OUTPUT.

SPARKS-WITHINGTON COMPANY

MODELS 43-S, 43-S-1600, 43-S-2400, 44-P & 46-P

A. ALIGNING THE INTERMEDIATE FREQUENCY ADJUSTABLE CONDENSERS.

1. Connect the aerial terminal of the oscillator to the control grid terminal (terminal on top of tube) of the first detector-oscillator tube, and the ground terminal to the ground connection of the receiver and tune oscillator to 172.5 K.C.

2. Turn the volume control on full.

3. Turn the attenuator or volume control on the oscillator to the position where the oscillator is heard faintly. If the oscillator is not heard at all, even with the control full on, the condensers of the stage requiring adjustment should be manipulated until it is heard at the loudest. The control should then be reduced so that only a faint sound from the oscillator is audible.

4. All intermediate frequency adjustable condensers should be adjusted if the adjustment of one is necessary. When adjustment of the stage that requires such has been made, the other stages should be adjusted in rotation. Each pair of condensers should be adjusted before proceeding to the next.

5. Correct alignment is obtained when reduction of the oscillator output and readjustment of the condensers is continued until maximum deflection of the output meter is obtained with a minimum of oscillator input. The numerical value of the deflection on the output meter scale is of no consequence, for the object is to set the output of the oscillator at a certain value and adjust the condenser until maximum deflection is obtained. If the meter goes off scale or does not give a large enough reading, adjust the oscillator accordingly.

6. It may be necessary to repeat the entire adjustment once or twice, to be sure the adjustments are correct.

B. ALIGNING THE OSCILLATOR EQUALIZING CONDENSER.

1. Connect the crystal controlled oscillator (adjusted to 172.5 kilocycles) to the antenna and ground connections of the receiver.

2. Align the oscillator equalizing condenser to a frequency of 2200 K.C. on Model 46-P.

NOTE: ON MODEL 44-P ALIGN OSCILLATOR TRIMMER TO THE FREQUENCY FOR WHICH THE SET IS DESIGNED.

C. ALIGNING THE R. F. ADJUSTABLE CONDENSERS.

1. Turn the volume control on full and the tone and static control all the way to the left or to the position where low tone is obtained

2. Set oscillator for the frequency for which the set is designed.

NOTE: ON MODEL 46-P SET OSCILLATOR FOR A FREQUENCY OF 2200 K.C.

3. Adjust R.F. trimmers for maximum output.

D. ALIGNING THE ANTENNA EQUALIZING CONDENSER.

The antenna equalizing condenser should always be adjusted when the receiver is installed and with the regular aerial and ground connected. It is the purpose of this condenser to resonate the first tuned circuit with the antenna system to which the receiver is connected, thereby providing a maximum transfer of energy. The procedure of adjustment is as follows:

1. Tune in the desired signal and turn volume control on full position.

NOTE: ON MODEL 46-P TUNE IN A SIGNAL AT APPROXIMATELY 2200 K.C.

2. Next, with a hex-socket insulated wrench, turn the hex-nut on the condenser or the screw in the condenser with an insulated handle screw driver to the position where the volume from the station "tuned-in" or the oscillator signal is the loudest. Once made, this adjustment need not be changed unless the antenna system is altered, the receiver is moved from one location to another, or the other condensers are re-adjusted.

NOTE: When antenna equalizing condenser is adjusted on oscillator signal, adjustment will not hold true when receiver is connected to aerial; this condenser must be aligned to antenna system.

MODELS R-167-S, R-168 & 1671 TO 1689

CIRCUIT DESCRIPTION

The R-167-S and R-168 chassis are identical with the exception of the size and location of the speaker and the physical location of a few other parts. The R-167-S, which is used in the table model cabinet, has a 5 inch speaker mounted on the chassis and the variable condenser, dial and the control shafts are located on the right side of the chassis. The R-168 is used in the console with a separate 8 inch speaker while the variable condenser, dial, and shafts are in the center of the chassis.

These receivers use a superheterodyne circuit which employs five glass tubes with octal bases. The intermediate frequency is 456 KC. The tuning range of this chassis includes, in addition to the standard broadcast band, the two police radio bands. The 2500 KC. police band can be tuned in around 1600 KC. on the broadcast dial with the range switch in the short-wave position (counter clockwise).

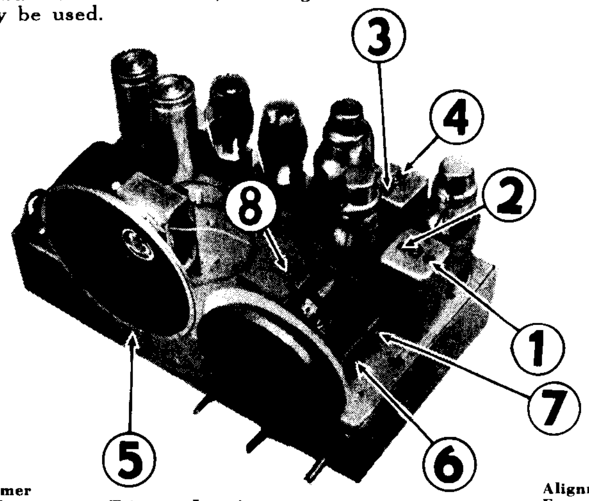
The volume control is double acting. It simultaneously changes the antenna signal input and the I. F. stage bias. Because of the sensitivity of this receiver, and due to the fact that it does not have A. V. C., it requires an antenna that is shorter than usual. The short antenna is particularly necessary where interference from powerful local stations is encountered, and where difficulty is experienced in properly controlling the volume.

When tuning on the short wave band, local broadcast stations can be heard in the background at their regular positions on the dial. This is a normal condition, and is due to the tapped coil method of tuning the antenna coil secondary to the short wave band. No aligning adjustments are required on the short wave band.

A wave trap is connected across the primary of the antenna coil to reduce code interference from stations with a frequency near 456 KC.

ALIGNING EQUIPMENT

For proper alignment of this receiver, an output meter and a high grade modulated service oscillator are essential. The oscillator should be capable of generating the frequencies of 456 KC., 600 KC. and 1400 KC. The test oscillator calibration should be checked, using broadcast station signals as standards. For trimmer adjustment, it is advisable to use an all bakelite screwdriver, although one with a small metal tip may be used.



Trimmer Number	Trimmer Location	Alignment Frequency
1, 2, 3, 4	I.F. Trimmers	456 KC.
5	Wave trap trimmer	456 KC.
6	Oscillator shunt trimmer	1400 KC.
7	Antenna trimmer	1400 KC.
8	Oscillator padding trimmer	600 KC.

ALIGNING THE I.F. CIRCUIT

1. (a) Connect the output meter in series with a .25 mfd. condenser between the plate of the 6K6G tube and ground, or across the voice coil, depending on the type of meter.

(b) Turn the volume control to the maximum volume position. (Note: The volume control should be kept in this position throughout the entire alignment procedure.) Ground the antenna lead to the chassis.

(c) Turn the range switch to the right (clockwise) to the broadcast position.

(d) Adjust the test oscillator to exactly 456 KC. and connect its output in series with a .1 mfd. condenser to the control grid of the 6K7G first detector tube and the chassis.

(e) Align I. F. trimmers No. 1, 2, 3 and 4 for maximu output as indicated on the output meter. No inward or side ward pressure should be applied to the alignment tool, or the condenser may spring back to a different setting as soon as the tool is removed.

(f) Repeat all I. F. trimmer adjustments since the changing of each trimmer may affect the others.

456 KC. WAVE TRAP ADJUSTMENT

2. (a) Disconnect the antenna lead from ground.

(b) Connect the test oscillator output in series with a .00025 mfd. condenser to the antenna lead, and connect the test oscillator ground lead to the receiver chassis. Ground the chassis.

(c) Without changing the test oscillator from the frequency setting used in aligning the I. F. stage, adjust trimmer No. 5 for **MINIMUM** output. Increase the test oscillator output as a minimum is reached, in order to obtain a clearly defined setting of the trimmer. NOTE: If code interference transmitted on a frequency slightly different than 456 KC. is troublesome, the wave trap should be adjusted for **MINIMUM** output with the test oscillator set to the same frequency as the signal that is causing interference.

DIAL CALIBRATION

3. (a) The dial pointer should indicate 530 KC. with the gang condenser in full mesh.

(b) Adjust the test oscillator to exactly 1400 KC.

(c) Tune in a broadcast station with a known frequency of about 1300 to 1400 KC. to determine whether the dial calibration is correct at the high frequency end of the dial. If no such station can be heard, tune in the 1400 KC. oscillator signal to check calibration.

(d) If the calibration is correct, do not adjust trimmer No. 6 (oscillator shunt trimmer). If the calibration is not correct, adjust trimmer No. 6 to give proper calibration at the high frequency end of the dial.

ALIGNMENT

4. (a) With the test oscillator set at 1400 KC. tune the receiver to the signal for maximum output.

(b) Adjust trimmer No. 7 for maximum output. Do not touch trimmer No. 6 as this will change the calibration.

(c) Adjust the test oscillator to exactly 600 KC. and tune the receiver to the signal. Adjust trimmer No. 8 for maximum output. Then try to increase the output by detuning the trimmer and retuning the receiver dial. If this reduces the output, detune the trimmer in the opposite direction. Continue detuning the trimmer and retuning the dial until a maximum output meter deflection is secured. This operation is commonly known as "rocking." The object of this adjustment is to find the combination of trimmer adjustment and tuning condenser position which gives the maximum output. This adjustment should not be changed regardless of whether the dial reads exactly 600 KC. or slightly off 600 KC. for maximum output.

(d) Check the adjustment of trimmers No. 6 and 7 at 1400 KC.

No trimmers are provided for alignment on the short wave band.

TUNING DRIVE AND DIAL PARTS

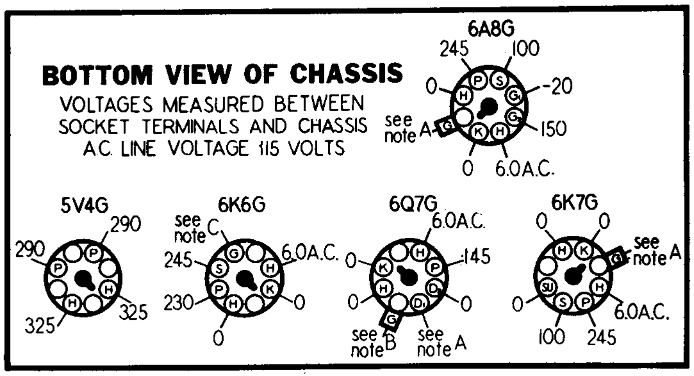
SOCKET VOLTAGES

VOLUME CONTROL ON FULL — ANTENNA GROUNDED
RANGE SWITCH SET ON BROADCAST POSITION — DIAL TUNED TO 530 KC.



IMPORTANT: Use a high resistance voltmeter of 1000 ohms per volt.

NOTE A: The grid bias for the 6A8G, 6K7G, and the anode voltage of the A.V.C. section of the 6Q7G is —3 volts measured across resistors 11 and 42.

NOTE B: The grid bias for the audio section of the 6Q7G is —2 volts measured across resistor 41.

NOTE C: The grid bias for the 6K6G output tube is —18 volts measured across resistors 41, 42 and 20.

STEWART-WARNER CORPORATION

MODELS R-169 & 1691 TO 1695

CALIBRATION AND ALIGNMENT

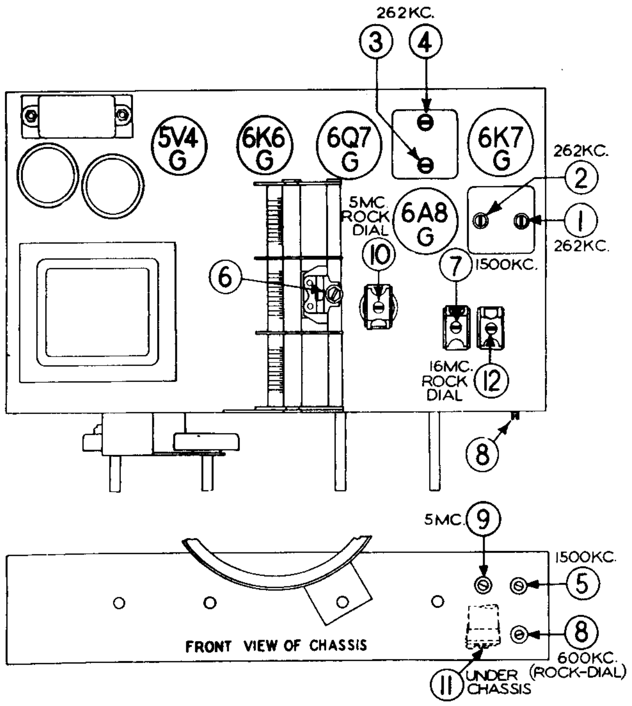
ALIGNING EQUIPMENT: For proper alignment, an output meter and an accurately calibrated oscillator with a tuning range from 262 KC. to 16 MC. are required.

Connect the output meter from the plate of the output tube to chassis. A convenient point to make the plate connection is to the yellow wire on the speaker socket.

ALIGNING THE I. F. AMPLIFIER: Turn the volume control to maximum volume position and keep it in this position throughout the entire alignment procedure. Turn the range switch to the broadcast position (fully clockwise).

Connect the test oscillator output leads to the 6A8 control grid and chassis with a .1 mfd. condenser in series with the oscillator output. Set the oscillator to exactly 262 KC. Set the receiver dial at any point where it has no tuning effect on the oscillator signal.

Adjust the four I.F. trimmers, Nos. 1, 2, 3 and 4, for maximum output meter deflection, then repeat the trimmer adjustment.



TRIMMER LOCATIONS

Trimmer Number		Alignment Frequency
1.	2nd I.F. transformer trimmer	262 KC.
2.	2nd I.F. transformer trimmer	262 KC.
3.	1st I.F. transformer trimmer	262 KC.
4.	1st I.F. transformer trimmer	262 KC.
5.	Broadcast oscillator shunt trimmer	1500 KC.
6.	Broadcast antenna shunt trimmer	1500 KC.
7.	Broadcast detector shunt trimmer	1500 KC.
8.	Broadcast oscillator series padder	600 KC.
9.	Police oscillator shunt trimmer	5 MC.
10.	Police antenna shunt trimmer	5 MC.
11.	Short wave oscillator shunt trimmer	16 MC.
12.	Short wave antenna shunt trimmer	16 MC.

BROADCAST BAND CALIBRATION AND ALIGNMENT

With the gang condenser in full mesh, the dial pointer should be on the white horizontal line below 530 KC. on the dial scale. If it does not, hold the dial gear and turn the pointer to the correct position.

Turn the range switch to the extreme clockwise position and connect the test oscillator output to the A and G terminals of the receiver with a 400 ohm carbon resistor in series with the A terminal and the oscillator output.

Adjust the test oscillator to exactly 1500 KC.

Tune in the 1500 KC. oscillator signal or a station above 1300 KC. on the dial and determine whether the dial calibration is correct at the high frequency end of the dial. If the calibration is correct, do not adjust the broadcast oscillator shunt trimmer No. 5. If the calibration is incorrect, adjust trimmer No. 5 to give proper calibration.

Carefully tune the receiver to the signal and adjust trimmers Nos. 6 and 7 for maximum output.

Adjust the test oscillator to 600 KC. and tune the receiver to the signal. Adjust trimmer No. 8 for maximum output. Then try to increase the output meter reading by detuning No. 8 slightly and retuning the receiver dial. If the output goes down, detune the trimmer in the opposite direction. Continue detuning the trimmer and retuning the receiver dial until maximum output meter deflection is secured. This operation is commonly known as "rocking" and when performed as described will give maximum selectivity and sensitivity even though the dial may be slightly off calibration at 600 KC.

POLICE BAND CALIBRATION AND ALIGNMENT

Turn the range switch to the center position. Adjust the test oscillator to exactly 5.0 MC. Tune in the 5 MC. oscillator signal at or near 5 MC. on the receiver dial to determine whether the receiver dial calibration is correct at 5 MC. If it is, do not adjust police band oscillator shunt trimmer No. 9. If the calibration is incorrect, set the dial pointer to 5 MC. on the dial, and adjust the oscillator shunt trimmer No. 9 until the oscillator signal comes in at this point. If there are two peaks, the proper one is that with the trimmer screw farthest out.

Carefully tune the receiver to the signal and adjust trimmer No. 10 for maximum output. Then try to increase the output by detuning No. 10 slightly and retuning the receiver dial. Continue detuning No. 10 and retuning the dial until the output meter deflection is a maximum.

SHORT WAVE BAND CALIBRATION AND ALIGNMENT

Turn the range switch to the extreme counter-clockwise position. Set the test oscillator to 16 MC. Tune in the 16 MC. oscillator signal at 16 MC. on the receiver dial to determine whether the receiver dial calibration is correct at 16 MC. If it is, do not adjust the short wave band oscillator shunt trimmer No. 11. If the calibration is incorrect, set the receiver dial pointer exactly at 16 MC. and adjust the oscillator shunt trimmer No. 11 until the oscillator signal comes in at this point.

Check to see that it has been adjusted to the proper peak by tuning the receiver to approximately 15.5 MC. A repeat signal should be heard at this point. If none is present, even with greatly increased oscillator output, retune the receiver to 16 MC. and adjust trimmer No. 11 to the proper peak with the trimmer screw farther **out.**

Carefully tune the receiver to the signal and adjust trimmer No. 12 to a peak. Then try to increase the output by detuning the trimmer slightly and retuning the dial until a maximum output meter deflection is secured. Check the adjustment by tuning the receiver to the image at about 15.5 MC. The image should be much weaker than the 16 MC. signal. If the signal at 15.5 MC. dial setting is equal to or stronger than the 16 MC. signal, trimmer No. 12 is not set to the proper peak. Turn the trimmer in a turn or so, then readjust as above.

TUNING DRIVE AND DIAL PARTS

Power Frequency (For AC Operation).................. 50-60 Cycles
Input Power Rating.................. 50 Watts
Intermediate Frequency.................. 465 Kilocycles

APPARATUS SPECIFICATIONS

No. 225 Receiver.......... 50 to 60 Cycles (For AC Operation).......... P-27285 Chassis Assembly

CIRCUIT DESCRIPTION

This triple range, superheterodyne receiver has five tubes and may be operated on a power supply circuit of either alternating or direct current at the voltages and frequency (for A. C. operation) specified above.

The various tubes are used in this receiver as follows: One No. 6A8 tube functions as both Oscillator and Modulator; one No. 6K7 tube is used in the I. F. Amplifier; the No. 6Q7 tube is used as the Demodulator, A. V. C., and Audio Amplifier tube. The No. 25A6-G tube is used in the Audio Power Output stage, and the No. 25Z6-G tube is used as the Rectifier tube for the receiver "B" voltage supply. In addition to these tubes a voltage divider resistance tube of the plug-in type is used.

NORMAL VOLTAGE READINGS

These voltage readings are obtained by measuring between the various tube socket contacts and the heavy bus wire with the tubes in their respective sockets. The receiver is, therefore, in operation when the measurements are made. The heavy bus wire, which is the negative side of the grid and plate voltages, is plainly marked on the schematic and wiring diagram shown on pages three and five. Figure 1 shows the terminal layout of the sockets with the proper terminal numbers.

Voltages are given for a line voltage of 120 volts, A. C. Allowance should be made for the difference when the line voltage is higher or lower.

IMPORTANT—If the receiver is operated from a direct current power supply circuit, the various voltages measured will be slightly lower than those listed in the table for A. C. operation. A meter having a resistance of 1000 ohms per volt should be used for measuring the D. C. voltages. Voltage values shown are those obtained on the lowest possible scale of a meter having the following ranges: 0-2.5, 0-10, 0-100, 0-250, 0-500, 0-1000 volts except when an asterisk appears after any given voltage value in which case the 1000 volt scale was used.

When the receiver is being operated from an alternating current power supply circuit, it will be necessary to have a high resistance A. C. voltmeter for checking the A. C. voltages.

Tube	Circuit	Cap	Terminals of Sockets								Heater Voltages Between Heater Terminals	
			1	2	3	4	5	6	7	8	Socket Terminal Numbers	Volts
6A8	Mod.—Osc.	0	0	*13*	+97	+65	—7	+59	*6*	+1.5	2–7	*6.4*
6K7	I. F. Amp.	0	0	*12.8*	+94	+85	+2.5	—	*19*	+2.5	2–7	*6.4*
6Q7	Dem.—A.V.C.—Audio	0	0	0	+40	0	0	—	*6*	+1	2–7	*6*
25A6-G	Audio Output	—	0	*45*	+93	+99	0	—	*19*	+14	2–7	*26*
25Z6-G	Rectifier	—	0	*73*	*115*	+105	*115*	—	*47*	+105	2–7	*26*
Resistor	Voltage Divider	—	—	—	*73*	*120*	—	—	*120*	*107*		
Voltage across pilot lamps—*13* volts												

A. C. voltages are indicated by italics; when the receiver is operated from a D. C. power supply, D. C. voltages will be obtained in place of the A. C. voltages.
Receiver tuned to 1000 kc., no signal.

ALIGNMENT DATA

All alignment adjustments are accurately made at the factory on these receivers and ordinarily no re-adjustments are necessary. However, should it become necessary to make any readjustments, this alignment procedure should be carefully followed.

In making any alignment adjustments always adjust the signal generator's output to the minimum value where a good alignment may still be obtained. Never attempt to make any alignment adjustments using a strong signal.

Figure 1 shows the location of all the aligning capacitors used in this receiver. In making any alignment adjustments on this receiver it will not be necessary to remove the chassis from the cabinet. The aligning capacitors for the intermediate circuits of the receiver are easily accessible from the rear of the receiver, and the aligning capacitors for the radio frequency circuits are easily accessible through the apertures located in the bottom of the cabinet (see Figure 2). To reach these aligning capacitors for the radio frequency circuits, simply turn the receiver cabinet upside-down. When making any alignment adjustments on this receiver, it is recommended that the Stromberg-Carlson, P-24608 Insulated Screwdriver be used in order to obtain accurate adjustments.

Intermediate Frequency Adjustments

The intermediate frequency used in these receivers is 465 kilocycles. In making these I. F. circuit adjustments always align in the following order:

1. Secondary of 2nd I. F. Transformer (Capacitor C-10).
2. Primary of 2nd I. F. Transformer (Capacitor C-9).
3. Secondary of 1st I. F. Transformer (Capacitor C-8).
4. Primary of 1st I. F. Transformer (Capacitor C-7).

Radio Frequency Adjustments

The adjustments of the aligning capacitors used in the radio frequency circuits in this receiver should be very carefully made in the following order and at the frequencies specified below:

1. Oscillator's "C" Band Shunt Aligner at 17 Megacycles (Capacitor C-4).
2. Antenna "C" Band Shunt Aligner at 17 Megacycles (Capacitor C-1).
3. Oscillator's "B" Band Shunt Aligner at 3.4 Megacycles (Capacitor C-5).
4. Antenna "B" Band Shunt Aligner at 3.4 Megacycles (Capacitor C-2).
5. Oscillator's "A" Band Shunt Aligner at 1400 Kilocycles (Capacitor C-6).
6. Antenna "A" Band Shunt Aligner at 1400 Kilocycles (Capacitor C-3).
7. Oscillator's "A" Band Series Aligner at 600 Kilocycles (Capacitor (36)).
8. Oscillator's "A" Band Shunt Aligner at 1400 Kilocycles (Capacitor C-6).
9. Antenna "A" Band Shunt Aligner at 1400 Kilocycles (Capacitor C-3).

MODEL FT6 "FORD"

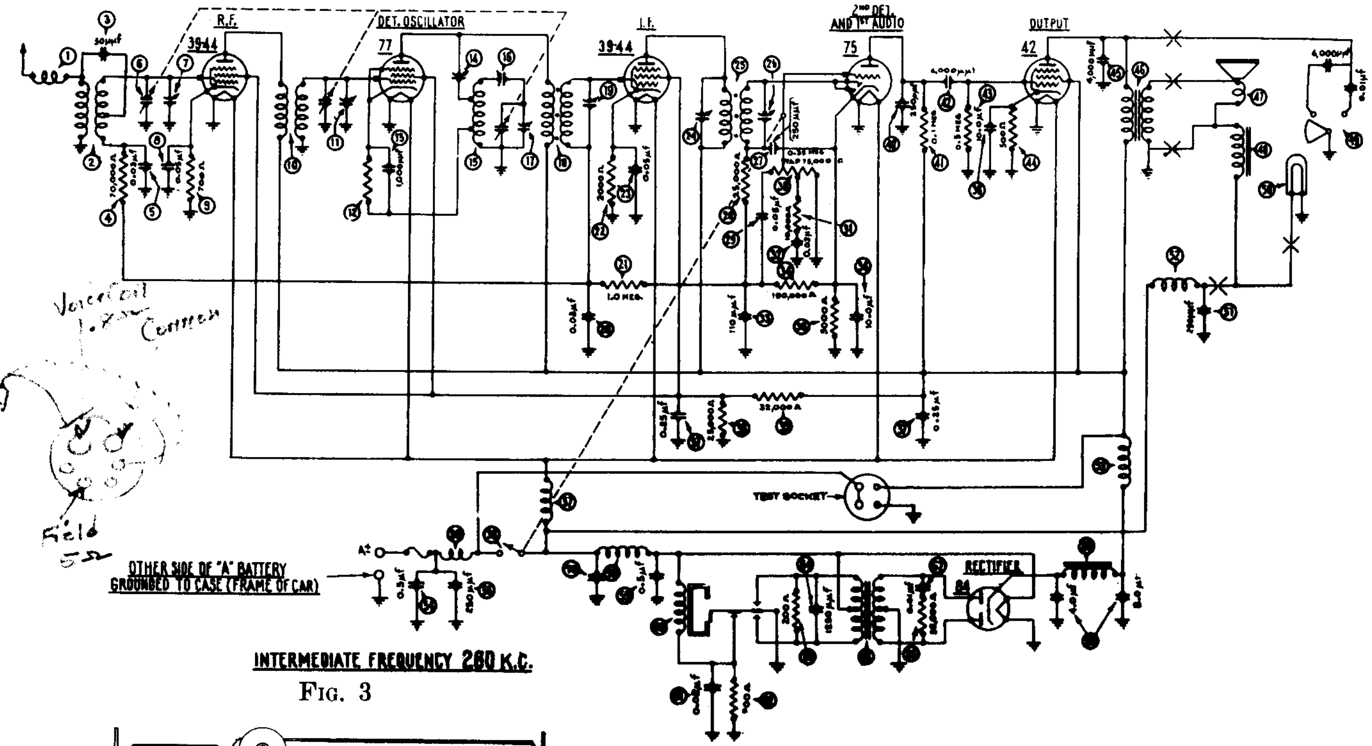

FIG. 3

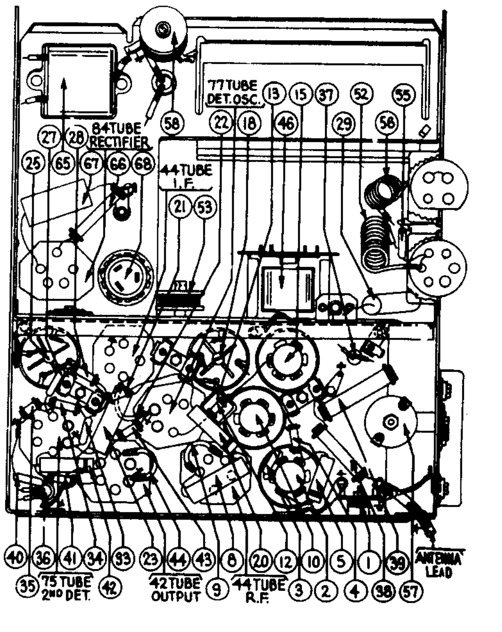

FIG. 4

With the tuning condenser in this position, adjust the high-frequency padder (17) until the maximum reading is obtained in the output meter. This is the true setting for 1580 K.C., 158 on the dial scale. Adjust condensers (11) and (7) in the same manner.

Remove the paper and turn the tuning condenser plates in mesh to approximately 60 on the scale, and adjust the signal generator to 600 K.C. Roll the tuning condenser and adjust the series padder (16) for the maximum meter reading.

Readjust the padder (17) at 1580 K.C.

Tune the gang to 1400 K.C. and adjust padders (11) and (7) to maximum.

If this procedure has been carefully followed and an accurately calibrated oscillator or signal generator used, the receiver will be adjusted properly.

MODEL LT14X3 "LINCOLN"

I. F. Transformers and Padders
Model LT14X3

The I. F. transformers are assembled complete with padding condensers.

Both the primary and the secondary padders are placed side by side in the top of the transformer shield can. The adjusting screws are accessible thru the holes in the top of the shield. (See Fig. 2).

The coil windings terminate in leads instead of terminals or lugs. The color scheme of the leads is given in Fig. 1.

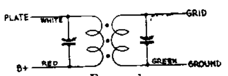

FIGURE 1

If replacements are ever necessary, replace the entire coil assembly, 32-1928 for the first I. F. stage and 32-1929 for the second I. F. stage. Neither the coil nor the padders will be furnished separately. Order only by the above numbers.

Model LT14X3 Adjustments

All padding adjustments are carefully made at the factory and ordinarily no readjustments are necessary. However, when readjustments to the Model LT14X3 are required, the procedure given below must be followed in detail.

Equipment

Fully charged heavy duty storage battery or 6-volt power pack, 048A Philco Set Tester, 3164 Padding wrench, 27-7159 Padding screw driver.

General

OUTPUT METER. — The output meter must be connected by means of an adapter to the plate of the type 41 output tube and to the Receiver chassis.

SIGNAL GENERATOR — With the Receiver and signal generator set up for operation at the prescribed frequency, turn the Receiver volume control on full and set the signal generator attenuator so that a half scale reading is obtained on the output meter. The signal in the speaker should be audible but not loud.

The shielding on the signal generator output lead must be connected to the Receiver housing.

The tone control should be turned to the brilliant position.

Remove the cover from the Receiver. The antenna lead must be disconnected.

I. F. — Adjust the signal generator to exactly 260 K. C. Connect the generator lead to the grid cap of the 78 I. F. tube in series with a .1 mfd. condenser.

Adjust the secondary screw padder (25) on the second I. F transformer for maximum reading on the output meter. Then adjust the primary screw padder (23) for maximum reading. (See Fig. 2 for location of padders).

Remove the generator lead from the 78 tube.

Connect the generator lead to the grid cap of the 6A7 tube in series with a .1 mfd. condenser. Adjust the secondary screw padder (22) on the first I. F. transformer for maximum reading on the output meter. Then adjust the primary screw padder (20) for maximum reading. (See Figure 2 for location of padders).

HIGH FREQUENCY AND R. F. — After padding the first I. F. stage remove the generator lead from the 6A7 tube. Adjust the signal generator to 1600 K. C. and then connect the generator lead to the grid cap of the 78 R. F. tube in series with a .1 mfd. condenser.

Turn the tuning condenser plates out of mesh as far as they will go. With the tuning condenser in this position, adjust the high frequency padder (14) and the R. F. padder (13) until the maximum reading is obtained on the output meter. This is the true setting for 1600 K. C., 160 on the dial scale.

LOW FREQUENCY — Turn the tuning condenser plates in mesh to approximately 580 K. C., 58 on the dial scale and adjust the signal generator to 580 K. C. Roll the tuning condenser and adjust the low frequency padder (18) for maximum reading on the output meter.

HIGH FREQUENCY RE-ADJUSTMENT — Turn the tuning condenser plates out of mesh as far as they will go and adjust the signal generator to 1600 K. C. Then adjust the high frequency padder (14) again for maximum reading on the output meter.

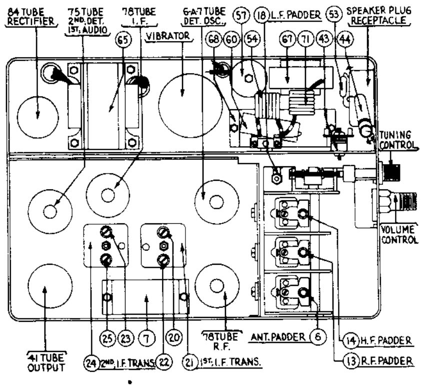

FIGURE 2

ANTENNA — Connect the generator lead to the antenna cable assembly (made up of Part No. L1963 loom, 1-27-7133 terminal and 64 inches of 16 strand No. 30 wire), using a 530 mmfd. condenser in series between the two leads. Plug the cable into the antenna socket.

Turn the tuning condenser to 1400 K. C. and set the generator at 1400 K. C. Adjust the padders (13) and (6) for the maximum reading on the output meter.

When the antenna stage adjustment is made with the Receiver installed in the car, the Receiver antenna lead must be connected to the car antenna in the usual manner. Connect the signal generator output lead to a wire placed near the car antenna but not connected to it.

If this procedure has been carefully followed and an accurately calibrated oscillator or signal generator has been used, the Receiver will be adjusted properly.

MODEL FT6 "FORD"

The new Ford auto radio incorporates new advanced principles of circuit and tube design. A totally new idea in sound distribution and musical fidelity is built into a dynamic speaker located above the occupants' heads in the header-bar of the car. Other features of the set are two-unit construction with separate speaker, highly developed Automatic Volume Control, illuminated custom-built instrument panel control, mounting in the ash receptacle opening.

The Receiver is mounted directly above the steering column out of sight and out of the way.

I. F. TRANSFORMER AND PADDERS

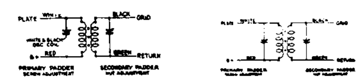
The padders are placed in the top of the shield can one above the other.

The I. F. transformers are assembled complete with padding condensers.

The primary padder is adjusted by means of the screw slot, accessible through the hole in the top of the shield can. The secondary padder is adjusted by means of the small hex nut, also accessible through the hole in the top of the shield. (See Figs. 1 and 2.)

The coil windings terminate in leads instead of terminals or lugs. The color scheme of the leads is given in Fig. 1.

If replacements are ever necessary, replace the entire coil assembly 32-1329 for the first I. F. stage and 32-1237 for the second I. F. stage. Neither the coil nor the padders will be furnished separately. Order only by the above numbers.



1st I. F. Transformer 32-1329

2nd I. F. Transformer 32-1237

FIG. 1

MODEL FT-6 ADJUSTMENTS

All adjustments have been carefully checked at the factory. If, however, it is found necessary to re-adjust the padding condensers, this procedure must be followed carefully. Do not attempt to make any adjustments until the procedure is clearly understood or without the use of a good oscillator or signal generator and output meter. The PHILCO Set Tester 048 is highly recommended for this procedure and for all service work.

The Receiver must be connected to a six-volt storage battery and set up for operation. It is assumed that tubes have been checked and that the Receiver is in good condition except for the padding adjustments.

Remove the cover from the Receiver and disconnect the grid clip from the 77 tube. (For location see Fig. 2.)

Set up the signal generator and adjust it to exactly 260 K.C. Connect the generator lead to the grid cap of the 77 tube, and ground the shield to the Receiver housing.

Connect one lead from the output meter to the plate of the 42 tube and the other lead to the receiver housing. The Receiver volume control must be turned to approximately full volume and the attenuator in the generator set for a half-scale reading of the output meter.

The primary screw padders (34) and (14) must be screwed all the way in. (Figs. 2 and 3.) The secondary nut padders (36) and (16) must then be adjusted. These padders should be adjusted for maximum reading on the output meter.

The screw padders (24) and (14) must be adjusted next.

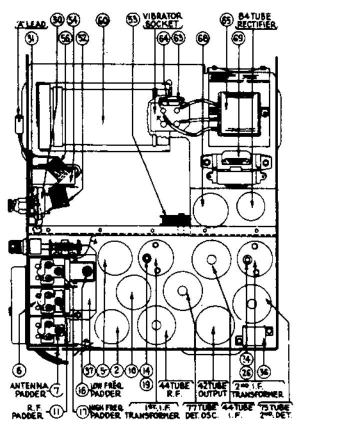


FIG. 2

Adjust the screw on each padder for maximum reading on the meter. This adjustment is critical. Note the maximum reading obtainable. Turn the screw in again and readjust, just bringing the adjustment up to the maximum reading. Do not pass it and then back off.

After padding the I. F. stages, remove the generator lead from the 77 tube and reconnect the grid clip to the 77 tube. Adjust the generator to 1580 K.C. and then connect the generator lead to the antenna lead. Ground the shield to the receiver housing.

Using a piece of paper approximately .006 inch in thickness, place it under the heel of the tuning condenser between the stator and rotor plates and turn the tuning condenser until the rotor plates strike this paper.

MODELS 119-129 MOTORCYCLE POLICE RADIO

TUNING

The receiver as delivered will be tuned to the station frequency requested. Due to unavoidable differences between the frequency adjustment made at the factory and that of the station, it will be necessary to re-align the tuning condensers slightly. One of the following methods of procedure should be followed depending on whether or not a tuning meter is available. The method of tuning using a tuning meter is preferable since more accurate adjustment is possible.

A. With Tuning Meter: With the receiver installed on the motorcycle and turned on, plug the tuning meter into the jack provided for the purpose. If the station desired is not heard, drive the motorcycle (with the radio set in operation), toward the broadcasting station. When the station is heard stop the motorcycle and proceed as follows:

(1) Remove both small circular cover plates from the top of the receiver housing, thus exposing the tuning adjustment screws.

(2) Loosen the brass lock nuts (which can be seen through the two holes), using a 7/16" socket wrench. This operation must be observed or damage will be done to the tuning condensers when alignment is attempted with a screw driver.

(3) Insert a screw driver into the slot in the shaft of the left hand condenser (when the receiver is in such a position that the volume control is toward the operator), and adjust this condenser until maximum deflection of the tuning meter in the direction indicated by the arrow on the dial is obtained for the station being heard.

(4) Repeat operation "3" with the right hand condenser.

(5) Lock the condensers with the 7/16" socket wrench and replace the circular cover plates.

B. Without Tuning Meter: With the receiver installed on the motorcycle and turned on, drive the machine toward the broadcasting station. When the station is heard faintly, stop the motorcycle and proceed as follows:

(1) Remove both small circular cover plates from the top of the receiver housing, thus exposing the tuning adjustment screws.

(2) Loosen the brass lock nuts (which can be seen through the two holes), using a 7/16" socket wrench. This operation must be observed or damage will be done to the tuning condensers when alignment is attempted with a screw driver.

(3) Insert a screw driver into the slot in the shaft of the left hand condenser (when the receiver is in such a position that the volume control knob is toward the operator), and adjust this condenser until the station is heard loudest.

(4) Reduce the volume with the volume control.

(5) Repeat operations "3" and "4" with the right hand condenser.

(6) Lock the condensers with the 7/16" socket wrench and replace the circular cover plates.

Alignment by the above operations will be approximate only. To obtain the exact alignment required for successful operation, proceed as follows:

Drive the motorcycle with the receiver operating at maximum volume to a "dead" spot, or to a place sufficiently remote from the transmitter to produce a weak signal. In such a location repeat operations "1", "2", "3", "5" and "6" under "B". Under no circumstances should the volume of the signal be reduced by adjusting the volume control knob. Keep the volume control in its maximum position. Do not neglect to lock the condensers with the socket wrench after alignment and before replacing the cover plates.

When these tuning operations have been properly executed, the receiver installation on the motorcycle is then ready for suppression of ignition interference and subsequently ready for service.

UNITED AMERICAN BOSCH CORPORATION

MODELS 119-129 MOTORCYCLE POLICE RADIO

IGNITION NOISE SUPPRESSION

Shielded ignition cable, spark plug suppressors, spark plug shields, and bypass condensers are furnished as auxiliary equipment with the Models 119 and 129 receivers. These items are necessary for the suppression of ignition interference.

In attempting to suppress ignition interference, the following must be observed:

(1) Damp the oscillations at the spark plugs and across distributor caps by putting resistors (suppressors) in the cables at these points.

(2) Prevent the cables, spark plugs, etc., from radiating to the antenna by enclosing them in grounded metal shields.

(3) Minimize the effect of auxiliary or secondary radiating systems by a judicious choice of grounding points and by making ground connections in the proper way. A ground connection for high frequency currents cannot be made by running wires between the cable shield to be grounded and the engine block or the frame of the machine. The cable shield to be grounded must be brought down against the surfaces of the frame and clamped or soldered in place as required by the circumstances. The choice of ground points is commonly accomplished by trial and error-experience with the phenomena governing such circuits being extremely helpful.

Before proceeding with the work of suppressing ignition noise, the ignition system of the motorcycle should be checked thoroughly to make certain that all high-tension leads make good connections at their terminals, that the spacing of the spark plug electrodes is the minimum amount consistent with good motor performance, that the gap between the distributor electrode and the rotor electrode is a minimum, that all leaky high-tension cables are replaced, etc.

The specific procedure for suppressing ignition noise with either two or four cylinder motorcycles and with either battery or magneto ignition is as stated below:

A. Two-Cylinder Motorcycle - Battery Ignition:

(1) Install suppressor in series with each spark plug lead as close as possible to the spark plug.

(2) Replace each spark plug lead with a shielded cable.

(3) Connect .5 mfd. bypass condenser from the generator to ground.

(4) Disconnect the lead between coil and breaker and replace with a shielded lead running directly from the coil to the breaker (length approximately 10").

(5) Ground the housing of the ignition coil to the frame.

(6) Install a spark plug shield on each spark plug whenever possible.

B. Two-Cylinder Motorcycle - Magneto Ignition:

(1) Install suppressor in series with each spark plug lead as close as possible to the spark plug.

(2) Replace each spark plug lead with a shielded cable.

(3) Connect .5 mfd. bypass condenser from the generator to ground.

(4) Install a spark plug shield on each spark plug whenever possible.

C. Four-Cylinder Motorcycle - Battery Ignition:

(1) Install suppressor in series with each spark plug lead as close as possible to the spark plug.

(2) Install suppressor in series with the lead to the center contact of the distributor as close as possible to the distributor.

(3) Replace each spark plug lead with a shielded cable.

(4) Ground the spark plug cables in the tube which carries them over the motor.

(5) Connect .5 mfd. bypass condenser from the generator to ground.

CONTINUED ON NEXT PAGE

UNITED AMERICAN BOSCH CORPORATION
MODELS 119-129 MOTORCYCLE POLICE RADIO
CONTINUED FROM PRECEDING PAGE

(6) Install a spark plug shield on each spark plug.

(7) Connect .5 mfd. bypass condenser from the "hot" side of the ignition coil to ground.

D. Four-Cylinder Motorcycle - Magneto Ignition:

(1) Install suppressor in series with each spark plug lead as close as possible to the spark plug.

(2) Replace each spark plug lead with a shielded cable.

(3) Ground the spark plug cables in the tube which carries them over the motor.

(4) Connect .5 mfd. bypass condenser from the generator to ground.

(5) Install a spark plug shield on each spark plug.

ELECTRICAL CHARACTERISTICS

Frequency range:	Model 119 - 1500 to 1800 kilocycles Model 129 - 2250 to 2500 kilocycles
Sensitivity:	Designed to be adequate for special nature of police radio service.
Maximum output:	1.3 watts.
Intermediate frequency:	456 kilocycles.
Total battery drain:	4.5 amperes at 6.0 volts.

OPERATING VOLTAGES AND TUBE COMPLEMENT

Tube Type	Tube Function	Plate Voltage	Screen Voltage	Voltage Cathode to Ground	Heater Voltage
78	R.F. Amp.	45	95	2.3	6.0
6A7	Det., Osc.	170	95	2.3	6.0
78	I.F. Amp.	175	95	2.3	6.0
75	Det.,A.V.C., A.F. Amp.	73		0.6	6.0
41	A.F. Amp.	165	175	13	6.0

NOTE: The above readings were taken from the various socket points to ground using a Weston Model 663 volt-ohmmeter which has a resistance as a voltmeter of 1000 ohms per volt full scale. For meters of other ratings, these voltages may not be as indicated.

"B" POWER SUPPLY UNIT

The "B" power for operation of the receiver is supplied by the American-Bosch magmotor. This magmotor unit is turned on and off simultaneously with the receiver and receives its energy from the storage battery of the motorcycle.

The magmotor is essentially a dynamotor, the armature having two windings, one to supply the driving force for rotating the armature and the other for generating the desired "B" power. The armature is fitted with a commutator at each end. The brushes which contact the commutators look alike, but the material of those operating at the 6-volt end is quite different from that of those operating at the high voltage end. If, for any reason, the brush holders are removed from the frame, they must be returned to their original positions when re-assembled. Failure to do this will cause shortened commutator life and improper operation of the magmotor unit.

The magmotor is provided with a permanent magnet, rather than field coils, for excitation. This makes possible the extreme compactness of the unit and also conserves the battery energy. Should it be necessary to remove the magnet during service operations, some marking should be made on adjacent sides of the frame and magnet so that the magnet can be returned to its original position and not inverted. If it is assembled in an inverted position, the polarity of the output will be reversed and the radio receiver will not function. A large soft iron "keeper" should be placed across the poles of the magnet when it is removed in order to conserve the magnetism. It is well to remagnetize the magnet after re-assembling the magmotor in order that it may give completely satisfactory service. If the magnet is not remagnetized, the output of the magmotor will be reduced.

Condenser Alignment

Misalignment or mistracking of condensers generally manifests itself in broad tuning and lack of volume at portions or all of the broadcast band. The receivers are all properly aligned at the factory with precision instruments and realignment should not be attempted unless all other possible causes of the faulty operation have first been investigated and unless the service technician has the proper equipment. A signal generator that will provide accurately calibrated signals over the broadcast band and accurately calibrated signals at and around 262 K.C., the intermediate frequency and an output indicating meter are desirable.

First set the signal generator at approximately 262 K.C. Connect the antenna lead from the generator to the control grid of the I.F. 78 tube, through a .05 mfd. condenser. The ground lead of the generator goes to the ground of the receiver. Turn the rotor plates of the tuning condenser completely out and keep the signal weak enough to prevent A.V.C. action. Note from Fig. 10 that the second I.F. transformer is self tuned and cannot be adjusted. Adjust the frequency of the signal generator until the output meter shows maximum output. The intermediate frequency setting of the generator is then correct, although it may be a very small percentage higher or lower than 262 K.C.

Next connect the signal lead from the signal generator to the grid of the 1st detector tube through a .05 mfd. condenser. Then adjust the two intermediate frequency condensers for maximum output. One of the I.F. condenser screws is reached through the hole on the top of the 1st I.F. assembly can. The other I.F. condenser screw is reached from the bottom of the sub-panel through a hole at the bottom of this assembly.

Now set the signal generator for a signal of exactly 1400 K.C. The antenna lead from the generator is, in this instance, connected to the antenna lead of the receiver. Connect the flexible drive shaft to the chassis if it has been disconnected. As explained previously, the dial scale should be at the low frequency end stop when the rotor is completely in mesh. Then turn the station selector knob until the dial scale is at 1400 K.C.

Then adjust the three trimmer condensers on the gang tuning condenser for maximum output, adjusting the oscillator section first.

Next, set the signal generator for a signal of 600 K.C. and adjust the oscillator 600 K.C. trimmer. The adjusting screw for this condenser is reached through a hole in the back wall of the sub-panel.

A non-metallic screwdriver is necessary for this adjustment. Turn the tuning condenser rotor until maximum output is obtained. Then turn the rotor slowly back and forth over this settin at the same time adjusting the 600 K.C. trimmer ew until the highest output is obtained.

Then set the signal generator again for a signal of 1400 K.C. and check the adjustment of the tuning condenser trimmers at this frequency for maximum output.

Voltages at Sockets

In the following chart are given the voltages at the sockets with all the tubes in, all units connected, and the set in operating condition, but with no signal being received. The antenna should be grounded.

A thousand ohm-per-volt meter of 0-250 volt range is required for the plate and screen voltages.

Lower ranges will be necessary for the grid and heater voltages. It is not absolutely necessary to have a high resistance meter for the heater or "A" battery reading.

These voltages will vary with variations in receivers, tubes, test equipment used, and "B" eliminator output voltage.

Type of Tube	Function	Across Heater	Plate to Cathode	Screen to Cathode	Grid to Cathode	Normal Plate MA
78	R. F.	6.1	182	80	3.(1)	7.0

Alignment and Calibration

Misalignment of condensers generally manifests itself as broad tuning and lack of volume at portions or all of the standard wave band. The radios are all properly aligned at the factory with precision instruments and realignment should not be attempted unless all other possible causes of the faulty operation have first been investigated and unless the service technician has the proper equipment.

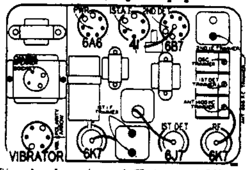

Fig. 3—Location of Tubes and Vibrator

A signal generator that will provide accurately calibrated signals over the standard wave band and at the intermediate frequency and an output meter are required for indicating the effect of adjustments.

Use a non-metallic screwdriver for the adjustments. The complete procedure is as follows:

I. F. Adjustment

Set the signal generator for a signal of 175 KC.

Connect the output of the signal generator through a .05 mf. condenser to the stator of the 1st detector section of the tuning condenser. (See Fig. 3 for location of this section.)

Connect the ground lead of the signal generator to the chassis. The chassis should be in the case.

Set the volume control at the maximum position.

Attenuate the signal from the signal generator to prevent the levelling-off action of the AVC.

Then adjust the three I.F. trimmers until maximum output is obtained. The location of these trimmers is shown in Fig. 3.

1581 KC Adjustment

Set the signal generator for 1581 KC.

Turn the rotor of the tuning condenser to the full open position.

Insert the antenna plug with the mark on the high capacity (HC) side. Connect the shielded antenna lead from the chassis through a 120 mmf. condenser to the antenna post of the signal generator.

For this and all subsequent adjustments, keep the volume control at the maximum position and attenuate the signal from the signal generator to prevent AVC action.

Adjust the trimmer of the oscillator section of the three gang condenser until maximum output is obtained—see Fig. 3 for location of this trimmer.

1400 KC Adjustment

Set the signal generator for 1400 KC.

Turn the rotor of the tuning condenser carefully until maximum output is obtained.

Adjust the 1st detector and antenna 1400 KC trimmers for maximum output.

Do not change the setting of the oscillator trimmer.

600 KC Adjustment

Set the signal generator for 600 KC.

Tune in this signal and adjust the 600 KC antenna trimmer to maximum. (See Fig. 5 for location of this trimmer).

After the alignment procedure is completed, the antenna plug may be withdrawn and reinserted on the LC side if a low capacity (70 mmf.) car antenna is used.

Adjusting Antenna 600 KC Trimmer

After the radio is installed and the car antenna is connected, it will be necessary to readjust the antenna trimmer. Tune in a weak signal at approximately 600 KC with the volume control about three-fourths on. Turn the adjusting screw of the antenna 600 KC trimmer up or down until maximum output is obtained. See Fig. 5 for location of this trimmer.

Calibrating the Radio

To calibrate the radio, tune in a station of known frequency. At the back of the control head is the calibration screw. Remove the pilot lamp assembly. Hold the tuning knob. Insert a fine blade screwdriver and turn this screw until the pointer on the dial scale is at the frequency of the station being received.

A very short insulated screwdriver will be helpful.

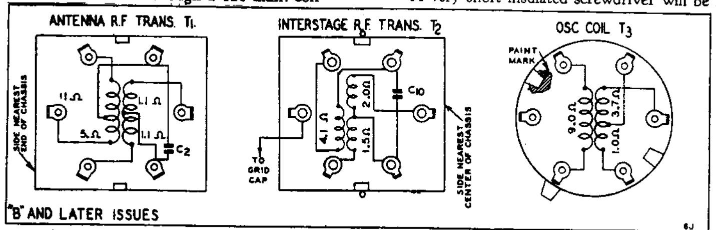

Fig. 4—R.F. and Oscillator Coil Base Terminal Arrangement and D.C. Resistance of Windings

Inserting Antenna Plug

IMPORTANT—The antenna plug can be inserted in two ways depending on whether the antenna is of high or low capacity.

If the total capacity of the antenna and shielded lead is approximately 200 mmf., which would be the case in a running board or ordinary roof antenna (not metal roof), insert the antenna plug with the mark on the HC side—See Fig. 5.

If the total capacity of the antenna and shielded lead is approximately 70 mmf., such as may be the case if a "fish pole" antenna is used, insert the antenna plug with the mark on the LC side.

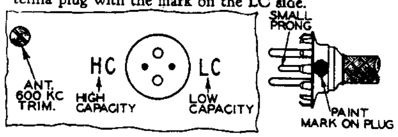

Fig. 5—Antenna Plug Insertion

The 1936 Chrysler Motors cars (except Plymouth—but including Chrysler, Dodge and DeSoto) have a steel roof, separated from the body proper, which is used as an antenna. The capacity of these antennas is about 1500 mmf. If this radio is installed in these cars, it will be necessary to use a running board or "fish pole" antenna.

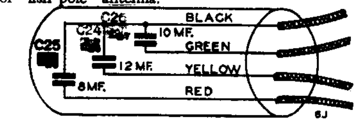

Fig. 6—Electrolytic Condenser Internal Connections

Most 1937 General Motors cars are equipped with an antenna built into the running board which is insulated from the body proper.

If a running board or under-car antenna is used, it must be one which is covered with a suitable insulation, to prevent short circuiting in wet weather.

VOLTAGES AT SOCKETS ("A" ISSUE)

Battery—6.3 Volts Under Load — L-D Switch in Distance Position

Type of Tube	Function	Across Heater	Plate to Ground	Screen to Ground	Cathode to Ground
6K7	R.F.	5.8	270	120	2.0
6J7	1st Det. and Osc.	5.8	268	120	0
6K7	I.F.	5.8	270	120	2.0
6B7	2nd Det. & 1st A.F.	5.8	70(1)	50(1)	0
41	2nd A.F.	6.0	260	260	28
6A6	Power	6.0	275		0

(1) As read with 1000 ohm per volt meter—500 volt scale.

VOLTAGES AT SOCKETS ("B" AND LATER ISSUES)

Battery—6.3 Volts Under Load — L-D Switch in Distance Position

Type of Tube	Function	Across Heater	Plate to Ground	Screen to Ground	Cathode to Ground
6K7	R.F.	5.8	250	132	3.6

41	2nd A.F.	6.0	240	240	26
6A6	Power	6.0	262		0

(1) As read with 1000 ohm per volt meter—500 volt scale.

Changes in Later Models

The "B" and later issues of this series have changes incorporated in them as explained in this article. The issue letter is a large letter stamped on the chassis base.

The "B" and later issue models are different from the "A" issue models in the following respects: The antenna, interstage and oscillator assemblies have been redesigned; condensers C13, 21, 22, and 32 have been changed to a different type with a new part number; the value of condenser C8 has been changed from 70 mmf. to 35 mmf.; condenser C35, 250 mmf., has been added to the circuit. On radios with the letter "C" stamped on the chassis base, the 7 mmf. condenser used as an oscillator padder on early models has been removed.

The circuit connections of the "B" and later issues have been changed at the following points: R1 and C8 in the interstage coil are now connected to one side of the secondary coil instead of to the midpoint of the secondary winding; R4 in the AVC line is now connected in series with R17 with a condenser C35 connected at the junction of the two resistors; R15 is shown connected on the chassis side of the speaker socket, while on early models this resistor was shown connected on the speaker side of this socket. At that time it was mounted on the local-distance switch.

Some of the later models use a P.M. dynamic speaker. The connections for both types of speakers are shown in the "B" and Later Issues schematic diagram.

When ordering parts, therefore, it is important that the issue letter on the chassis be noted and the correct part number as shown in the parts list be specified.

Circuit

This model is a 6 tube automobile radio covering the standard wave band. It has a tuning range as shown in the specifications above. The signal is fed through an antenna transformer with tuned secondary into a 6K7 tube which functions as an R.F. amplifier. A connection is provided in the primary of the antenna transformer for installations in cars in which a low capacity antenna is used.

The output of the R.F. tube is fed through another R.F. transformer with tuned secondary into a 6J7 tube which functions as the first detector and oscillator. The oscillating circuit is tuned by the oscillator section of the gang condenser and is always resonant at a frequency 175 KC above the frequency to which the R.F. circuits are tuned.

One stage of I.F. amplification is employed using a 6K7 tube. The primary and secondary of the first I.F. transformer and the primary of the second I.F. transformer are tuned by small trimmer condensers.

A local-distance switch is employed to reduce the sensitivity for city driving. When the switch is in the local position, resistor R15 is in series with R.F. and I.F. bias resistor R8, causing a reduction in sensitivity. When the switch is in the distance position, resistor R15 is short circuited and full sensitivity is obtained.

A 6B7 duo diode-pentode tube functions as a diode 2nd detector, AVC tube and a one-stage audio amplifier. AVC voltage is applied to the control grid circuits of the 6K7 R.F. and I.F. tubes. The manual volume control varies the audio voltage applied to the grid of the 6B7 tube.

Resistance coupling is used between the 1st audio stage and the 2nd audio stage which employs a 41 tube. The latter is transformer coupled to the output stage which uses a 6A6 tube. This tube is a Class "B" power amplifier and combines 2 triodes in one envelope. A dynamic reproducer is used.

Provision is made for single roof speaker and dual speaker (chassis and roof) connections. The electrical connections for the different speaker installations are shown in the schematic and explained more fully in the article on that subject in this manual. When single chassis or roof speakers are used the entire output transformer secondary is connected to the speaker voice coil. When dual 5¼ inch roof and 6 inch chassis speakers are used, the 5¼ inch speaker voice coil is across the entire output tranformer secondary and the 6 inch speaker voice coil is connected to the tap on this secondary. When dual 8 inch roof and 6 inch chassis speakers are used, the voice coils of both speakers are connected to the output transformer secondary tap.

A synchronous type vibrator is used in the power unit. This vibrator interrupts the current through the primary of the power transformer and also rectifies the current in the secondary circuit.

Polarity in inserting the vibrator must be observed. It can be inserted in two ways, and the correct method depends on which terminal of the car storage battery is grounded. Full instructions are on the vibrator.

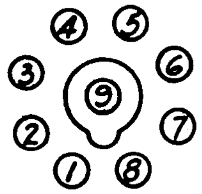
1F5	Power	0	2	122	126	0	—	0	0	—



BOTTOM VIEW OF SOCKET

All voltages measured with a 1000 ohm per volt D.C. meter and using the Zenith 6 V Economy Pack—Antenna and ground disconnected.

Battery Voltage—6.3 V.

Battery Drain—.98 amp.

ALIGNMENT

(1) Connect the output leads of the signal generator to the grid of the first detector and receiver ground lead. Also connect an output meter across the speaker leads.

(2) Set the signal generator at 456 K.C. and carefully adjust the four I.F. trimmers to the point giving the greatest output reading. These I.F. transformers are of a very high gain, selective type, and the adjustments should be repeated several times for greatest accuracy.

(3) Change the signal generator leads to the antenna and ground terminals of the receiver.

(4) Set the signal generator at 1400 K.C. Set the pointer on the receiver dial at the same frequency. First adjust the oscillator and then the detector trimmers on the gang condenser to the point giving the maximum reading on the output meter, using as small a signal from the generator as possible so as to prevent the A.V.C. action from affecting the output readings.

(5) Reset the signal generator to 600 K.C.

(6) Slowly rock the pointer past 600 K.C. on dial meanwhile adjusting the osc. padder (located in rear of gang condenser) to the combination giving the greatest output reading.

(7) Repeat operation No. 4.

BOTTOM VIEW OF SOCKET

All voltages measured with a 1000 ohm per volt D.C. meter and using the Zenith 6 V Economy Pack—Antenna and ground disconnected.

Battery Voltage—6.3 V.

Battery Drain—1.1 ampere

ALIGNMENT PROCEDURE

(1) Connect the output leads of the signal generator to grid of the first detector and receiver chassis. Also connect an output meter across the speaker transformer leads.

(2) Set the signal generator at 456 K.C. and carefully adjust the four I.F. trimmers to the point giving the highest reading on the output meter. The I. F transformers are of a very high gain, selective type, and these adjustments should be repeated several times in order to secure maximum accuracy.

All adjustments should be made using as weak an output from the signal generator as possible in order to prevent the A.V.C. action from affecting the output readings.

(3) Change the signal generator leads to the antenna and ground terminals of the receiver.

(4) Set signal generator at 5 M.C. Switch receiver to band B and adjust osc. trimmer on gang for correct dial reading.

(5) Set signal generator at 1400 K.C. Switch receiver to band A and adjust broadcast trimmer (located at front of chassis—see diagram below) for correct dial reading. Also adjust antenna trimmer on gang to resonance.

(6) Set signal generator at 18 M.C.—Switch receiver to band C and adjust the short wave trimmer while rocking the pointer past 18 M.C. on the dial to the combination giving the greatest output.

(7) Set signal generator at 600 K.C.—Switch receiver to band A and rock pointer past 600 on dial while adjusting the broadcast padder (located adjacent to gang condenser) to combination giving the greatest output reading.

(8) Readjust broadcast and ant. trimmers at 1400 K.C. (Same as No. 5).

112-212	Dial Scale		.40
131-43	Cinch Buttons for Fastening Scale		.03
112-151	Dial Pointer with 132-19 Screw and 117-62 Washer		.05
112-143	Oval Escutcheon Complete with Crystal		.85

Tubes are coded and guaranteed by the tube manufacturer.

Prompter service can be rendered on adjustments if defective tubes are returned direct to the tube manufacturer rather than through our factory.

Note: We cannot supply speaker cones or coils only. We can replace a damaged speaker for $2.00 net, if defective speaker is returned.

All resistors and mica condensers are RMA color coded—specify value and/or resistor or condenser (per schematic diagram) and model number. Mica condensers are coded with an additional dot indicating tolerance:

Tolerance Percent	Color of Dot
2½%	White
5%	Green
10%	Blue
15%	Yellow
20%	Red
More Than 20%	None

When ordering condensers, specify part number, model and/or capacitor (per schematic diagram) and model number.

When ordering parts, always specify part and model number as well as serial number of chassis.

All prices quoted are list and are subject to the usual trade discounts. Shipments are F. O. B. our Factory. When remitting in advance, please include postage.

Prices subject to change without notice.

BELMONT RADIO CORPORATION

MODEL 523

WHAT TO DO IF RECEPTION IS POOR, OR RECEIVER WILL NOT OPERATE

TUBES

See that all tubes are in their proper places. Tubes are very fragile and are the most frequent cause of a radio set not playing. Take your tubes to your dealer and have him test them for you.

BATTERIES

Look over all battery connections and see that they are all tight and clean. Take them to the nearest dealer where you can have them tested.

ANTENNA AND GROUND

Check over all connections to be sure that they are all clean and tight. Make sure that the antenna is not rubbing against a metal eavestrough or against trees.

HOWLING

See if the bolts holding the chassis to the cabinet have been removed. These bolts will be found underneath the cabinet.

STATION INTERFERENCE AND WHISTLING

As you use your radio you will notice that the sound from most stations comes clear, but that with a few there is a continuous background noise or whistling. This is no fault of the radio—but is caused by two or more stations operating on practically the same wave length or frequency, and occurs with all radios, no matter how selective they may be.

Interference is caused by the fact that there are more broadcasting stations than broadcasting channels. On some channels there are several stations operating at the same time. This condition is particularly noticeable in the shorter wave lengths (higher frequencies) which is one reason why all radio sets are noisy on the lower portion of the dial. Usually, noisy stations are small and of local range. Better reception can usually be obtained by turning to another portion of the dial.

FADING

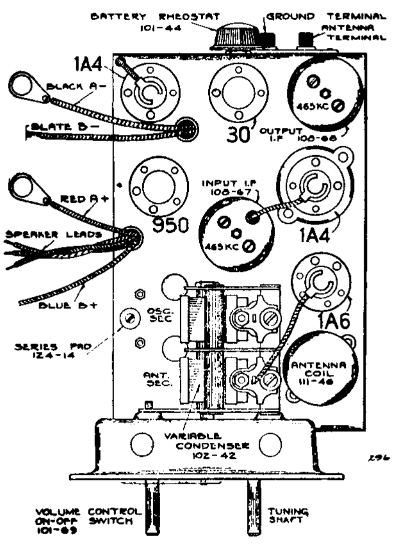
There is one curious and confusing condition known as "fading" which you will probably encounter from time to time when receiving distant stations.

A program may be tuned in loud and clear. Then without any change in the adjustment of the set, the music will begin to fade, gradually becoming weaker and weaker until it may die out altogether. Then it may increase again in volume until the program is once more loud and clear. All of this can happen in one or two minutes and may occur only once or twice in an evening. On the other hand it might happen many times.

Fading is much more noticeable on some nights than others and is more pronounced with certain stations.

The cause of fading is not definitely known. If you are bothered by it the only thing to do is wait for the program to strengthen or turn to another station.

TOP VIEW MODEL 523



GROUND

Although the radio will operate without a ground wire a good ground is absolutely necessary for proper operation. The ground wire should be attached to a metal pipe driven into the ground or to the metal jacket on a water pump. Be sure that the connection is clean at the point where the wire connects to the metal. If necessary use a file to insure a clean contact and if possible solder the wire to the metal. Remember that a poor connection to either the aerial or the ground will make the receiver very noisy.

BATTERIES REQUIRED

The following batteries are needed.

2........45 volt "B" Batteries.

1........3 Volt Dry "A" Battery or 2 Volt Storage Battery.

IMPORTANT

This radio must be used with a good aerial and ground. Unless you are careful to make all connections clean and tight the set will not operate properly.

CARE AND MAINTENANCE

There are no adjustments of any kind to be made on the chassis or speaker. There is nothing to get out of order and no attention to these items is required.

TUBES

The tubes in the receiver should be checked occasionally, either by taking them out and having them tested or by obtaining a new set of tubes and inserting them in the sockets, one at a time, noting any difference in performance.

ANTENNA AND GROUND

Periodic inspection of the antenna and ground system is recommended, to be sure that all connections are clean and tight, and that the antenna is well insulated from the ground at all points.

DRY "A" BATTERY

The long life dry "A" battery will need very little attention other than to keep the top of the battery clean and to see that the connections to the terminals are clean and tight at all times.

At all times, whether in use or not, endeavor to have the battery in a cool dry place.

Be careful not to leave your set turned on over night — it discharges the battery very quickly.

STORAGE "A" BATTERY

If your set uses a storage "A" battery, you will notice that when the battery is new *it does not have its full rated life* — this is characteristic of new storage batteries. They reach their maximum capacity after being charged and discharged several times in service.

The proper care of a storage battery will enable you to receive several years of good service. Neglect will ruin it very quickly. Check frequently to see that the water level is about one-half inch above the plates. Add only pure distilled water, as often as needed. A little too much water will do no harm. Too little is very harmful to the battery.

Do not let the battery become completely discharged, but if it should, have it charged again as soon as possible. A battery can be ruined very quickly by permitting it to lie around unused, in a fully discharged condition.

Keep the top of the battery clean and dry and grease the terminals occasionally with a little vaseline.

In testing your battery use only the indicator on your battery or a hydrometer. These indicators measure the specific gravity of the electrolyte. Do not, under any circumstances, use so-called "magic" charging powders or liquids, or you may completely ruin your battery.

When you have your battery recharged at a charging station tell the operator that the battery must not be charged at a faster rate than 5 amperes. If the battery is charged above this it will take the charge too quickly and will not hold it when put into service again. If this precaution is not followed you will have to have your battery charged much more often than necessary.

"B" BATTERIES

Whether in service or not, endeavor to keep the batteries in a cool dry place.

The top of the batteries should be wiped off occasionally with a dry cloth and the connections should be checked to see that they are clean and tight.

Most of the newer types of radio sets are designed to use less battery current when the set is operated at low volume and to use maximum battery current only when large volume is desired. For this reason you will obtain longer life from your "B" batteries by not operating your set louder than is necessary.

Be careful not to leave your set turned on over night. The long drain uses a lot of current and gives the batteries no chance to recuperate. Remember also that the life of your "B" batteries will depend upon the number of hours each day that you use your set. Turning the set off when it is not needed saves the batteries accordingly.

SERVICE DATA FOR PROFESSIONAL SERVICE MEN

DESCRIPTION

TUBES:

The tube complement of this chassis is as follows:

1 Type 1A6—first detector oscillator.
1 Type 1A4—I.F. amplifier. 465 K. C
1 Type 30—second detector. A. V. C.
1 Type 1A4—audio.
1 Type 950—output.

SERVICE NOTES

Voltages taken from different points of circuit to chassis are measured with volume control full on, all tubes in their sockets and speaker connected, with a volt meter having a resistance of 1000 ohms per volt.

All voltages as indicated on diagram, are measured with a new set of batteries.

Resistances of coil windings are indicated in ohms on the schematic circuit diagram.

To check for open by-pass condensers, shunt each condenser with another condenser of the same capacity and voltage rating, which is known to be good, until the defective unit is located.

ALIGNING INSTRUCTIONS

CAUTION: No aligning adjustments should be attempted without first thoroughly checking over all other possible causes of trouble, such as run down batteries, defective tubes, poor installations, open or grounded antenna systems, defective condensers and resistors.

In order to properly align this chassis, an oscillator (generator) is necessary.

All adjustments should be made with a non-metallic screw driver.

ALIGNING I.F. TRANSFORMERS: (465 K.C.)

1. With volume control full on and with variable condenser at its minimum capacity position, plates entirely out of mesh, and with external oscillator set at 465 K.C. connected in series with a .1 mfd. condenser, to the grid of the 1A6 tube (cap at top of tube), adjust I.F. transformers, parts number 108-67 and 108-68, to resonance. Both of these transformers have two (2) adjustments each, they are accessible from the tops of the cans (for location see top view).

   Use as a resonance indicator an output meter connected across the outside terminals of the speaker or by means of an adapter to the plate and screen of the type 950 output tube. Maximum deflection of the volt meter indicates resonance.

   Use only enough signal to get a readily readable output.

   A low range output meter or the low scale of a multi-range meter should be used.

BROADCAST BAND ALIGNMENT:

1. Set external oscillator to 1720 K.C. and connect it in series with a 200 mmfd. condenser to the antenna and ground posts.
   (a) With variable condenser in its minimum capacity position, plates entirely out of mesh, adjust oscillator trimmer (rear section of variable condenser) to resonance.
   (b) Re-set external oscillator to 1400 K.C. Rotate variable condenser, pick up signal and adjust antenna trimmer (front section of variable condenser) to resonance.
   (c) Re-set external oscillator to 600 K.C., move dial pointer to 600 K.C., and adjust series pad, part number 124-14 (see top view), to resonance. While making this adjustment, slowly rock variable condenser to and fro until maximum output is obtained.
   (d) Check for sensitivity at 1400, 1000, 600 K.C. DO NOT BEND PLATES.

BELMONT RADIO CORPORATION

MODEL 555

DESCRIPTION

Tubes:

The Tube complement of this chassis is as follows:

1 Type 6A7—pentagrid converter.

1 Type 6D6—remote cut-off pentode as I.F. amplifier.

1 Type 6B7—duplex diode pentode as diode detector, A.V.C and A.F.

1 Type 42E—pentode output tube.

1 Type 80—high vacuum rectifier.

Voltages taken from different points of circuit to chassis are measured with volume control full on, all tubes in their sockets and speaker connected, with a voltmeter having a resistance of 1000 ohms per volt. These voltages are clearly indicated on circuit diagram.

All voltages are measured with 235 volts 50-100 cycles on the primary of the power transformer.

Resistance of coils and transformer windings are indicated in ohms on schematic circuit diagram.

Transformers are available and chassis are sometimes equipped with universal transformers for operation on 40 and 60 cycles and with primary taps for 108, 125, 150, 220 and 250 volts (see illustrations) and also sometimes equipped with 25 cycle transformers with 105-115 volt or 235 volt primaries, not universals.

Should the receiver be equipped with a special transformer, connect primary tap on voltage terminal which corresponds as nearly as possible to the actual line voltage. If an exact agreement cannot be secured, suitable allowances of other measured voltages must be made.

ALIGNING INSTRUCTIONS—SERIES A

Description of various dummy antennas used and referred to in these instructions:

(1) I.F. Dummy—Consists of a .1 mfd. condenser connected in series with the external oscillator

(2) Broadcast Dummy—Consists of a 200 mmfd. condenser and a 20 ohm resistor connected in series with each other and in series with the external oscillator

(3) Intermediate and Short Wave Dummy—Consists of a .1 mfd. condenser and a 400 ohm resistor connected in series with each other and in series with the external oscillator.

Resonance Indicator:

Use as a resonance indicator an output meter connected across the primary of the speaker input transformer, or by means of an adapter between the plate and screen terminals of the type 42E output tube. Maximum deflection of the meter indicates resonance. Use only enough signal to get a readily readable output. A low range output meter or the low scale of a multi-range volt meter should be used.

TEST FREQUENCIES

	Wave Length Meters	Frequency Kilocycles
Long Wave	2000	150
	923	325
I.F.	645.1	465
Broadcast	500	600
	300	1000
	214.3	1400
Short Wave	50.0	6000
	16.7	18000

ALIGNMENT:

No aligning adjustments should be attempted without first thoroughly checking over all other possible causes of trouble, such as poor installations, open or grounded antenna systems, low line voltages, defective tubes, condensers and resistors. In order to properly align this chassis, an oscillator (generator) is absolutely necessary. No aligning adjustments should be attempted with the chassis in the cabinet. To remove the knobs, pull them off and to take the chassis out of the cabinet, remove the three bolts by which it is fastened and the speaker plug which you will find on the front flange of the chassis panel.

ALIGNING I. F. TRANSFORMERS:

1. With volume control full on, the extreme right of its rotation, and with wave changing switch in the broadcast position, center of its rotation, and with variable condenser at its minimum capacity position, plates entirely out of mesh, adjust the I.F. transformers (two adjustments at the top of parts number 108-47 and 108-53—see top view).

(a) Connect external oscillator which has been adjusted to 645.1 meters in series with I.F. dummy antenna, to the control grid cap of the type 6D6 tube and chassis ground. Adjust output I.F. transformer, part number 108-47, to resonance.

(b) Move generator output clip from grid of 6D6 to grid cap of 6A7 tube and align input I.F. transformer, part number 108-53.

(c) With generator connected to grid of type 6A7 tube, re-adjust output I.F. transformer, part number 108-47, to resonance.

BROADCAST BAND ALIGNMENT:

(188-595 meters)

1 With wave changing switch in the broadcast position, center of its rotation, and with gang condenser in its minimum capacity position, plates entirely out of mesh, connect an external oscillator in series with broadcast dummy antenna to tan antenna and black ground leads and make the following adjustments:

(a) With external oscillator set at 187.5 meters, adjust oscillator trimmer to resonance, for location of this adjustment, number 5, see diagram.

(b) Re-set external oscillator to 214.3 meters, rotate condenser, pick up oscillator signal and adjust antenna trimmer to resonance. For location of this adjustment, number 2, see diagram.

(c) Re-set external oscillator to 500 meters and adjust series pad to resonance, rotate condenser and move dial pointer to 500 meters by gently rocking condenser to and fro. Pick up oscillator signal while adjusting series pad to resonance, maximum deflection on an output meter. This adjustment is accessible from the top of the chassis and is located between variable condenser and power transformer, rear hole see top view—part number 124-19.

(d) Check for tracking and sensitivity at 300 meters.

SHORT WAVE BAND ALIGNMENT:

(16.5-56.6 meters)

1. Set wave changing switch to short wave position, extreme right of its rotation, set dial pointer to 16.7 meters.

(a) With external oscillator adjusted to 16.7 meters and connected in series with short wave dummy antenna to tan antenna and black ground leads, adjust the oscillator short wave trimmer until generator signal is picked up. For location of this adjustment, number 4, see diagram.

(b) Adjust short wave antenna trimmer to resonance. For location of this adjustment, number 1, see diagram.

(c) Re-set external oscillator to 50 meters, rotate condenser, move dial pointer to 50 meters, and check for tracking and sensitivity. Do not bend plates. **Note: It is extremely necessary in making all of the above adjustments that the fundamental signal of the oscillator be tuned in and not the image frequency, which will fall at a higher wave length.**

LONG WAVE BAND ALIGNMENT:

(925-2140 Meters)

1. With wave changing switch in long wave position (extreme left of its rotation) and with variable condenser in its minimum capacity position (plates entirely out of mesh), make the following adjustments:

(a) With external oscillator set at 923 meters and connected in series with "Dummy 2" to the tan antenna lead, adjust rear trimmer of oscillator coil (adjustment No. 6, see diagram) until oscillator signal is picked up.

(b) Adjust rear trimmer of antenna coil to resonance with oscillator (adjustment No. 3, see diagram).

(c) Re-set external oscillator to 2000 meters and rotate variable condenser (move pointer) and pick up oscillator signal, adjust L.W. pad (front adjustment accessible from top of chassis and located between variable condenser and power transformer) to resonance. While making this adjustment, slowly rock variable condenser to and fro until maximum output is obtained.

SERVICE NOTES:

To check for open by-pass condensers, shunt each condenser with another of similar capacity and of the same voltage rating, which is known to be good, until the defective unit is located. Open by-pass condensers frequently cause oscillation and distorted tone. Defective and shorted electrolytic filter condensers cause excessive hum, motor-boating, low volume and a reduction in all D.C. voltages. Open or shorted electrolytic and by-pass condensers (across bias resistor of type 42E tube) will cause low volume and distorted tone.

Should the planetary vernier dial drive mechanism fail to function properly, it will probably be found to be due to a cracked or broken compression spring. The drive may be disassembled to replace the compression spring (part number 112-31) by removing the two screws which fasten it to the dial bracket. Before re-assembling all parts should be carefully cleaned and a small amount of vaseline applied to the ball bearings. All other dial parts are hardened and should cause no trouble.

All resistors and mica condensers are RMA color coded—specify value and/or resistor or condenser (per schematic diagram) and model number.

Mica condensers are coded with an additional dot indicating tolerance:

Tolerance Percent	Color of Dot
2½%	White
5%	Green
10%	Blue
15%	Yellow
20%	Red
More than 20%	None

When ordering condensers, specify part number, model and/or capacitor (per schematic diagram) and model number.

When ordering parts, always specify part and model number as well as serial number of chassis.

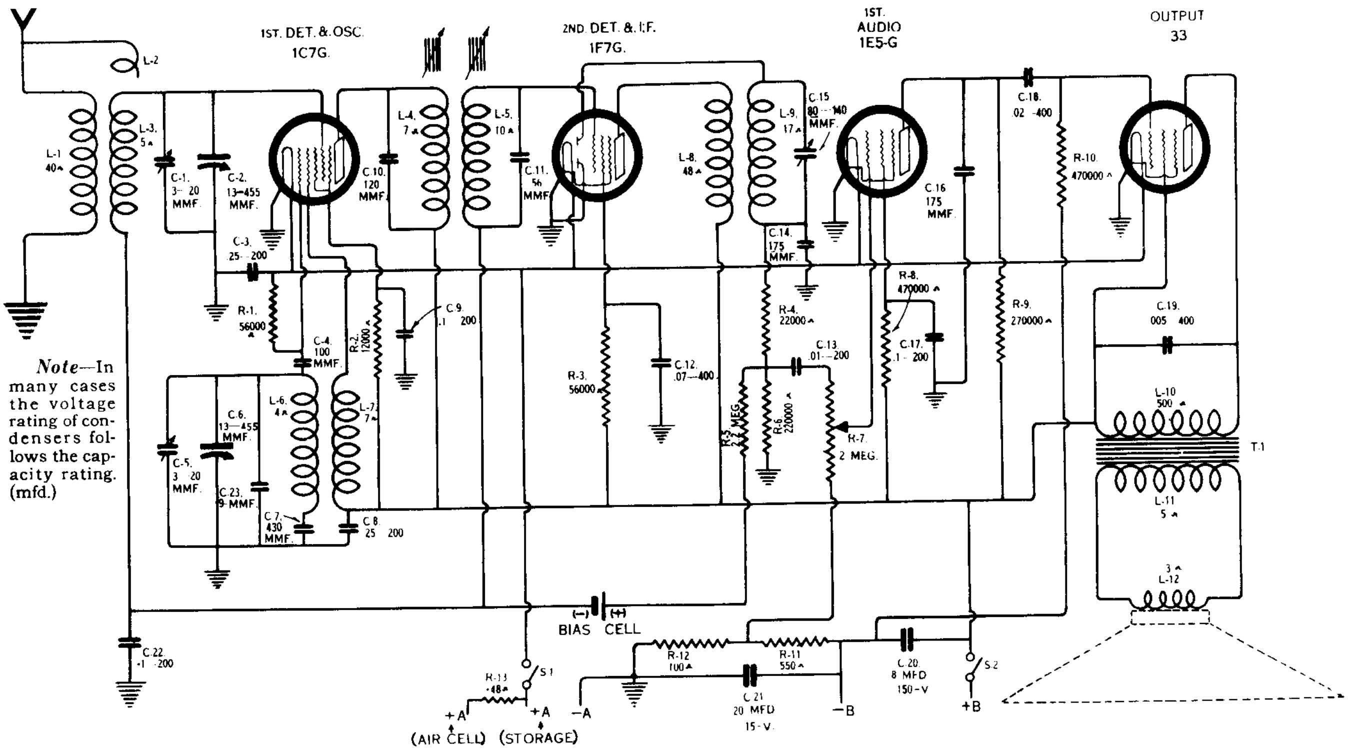
WHEN ORDERING SPEAKER PARTS: CONES, FIELD COILS, OUTPUT TRANSFORMERS SPECIFY PART NUMBER OF SPEAKER AND MAKE.

Note—On some chassis part 108-53 was in error marked 108-38.

Part 108-53 is the correct number for this input I. F. transformer.

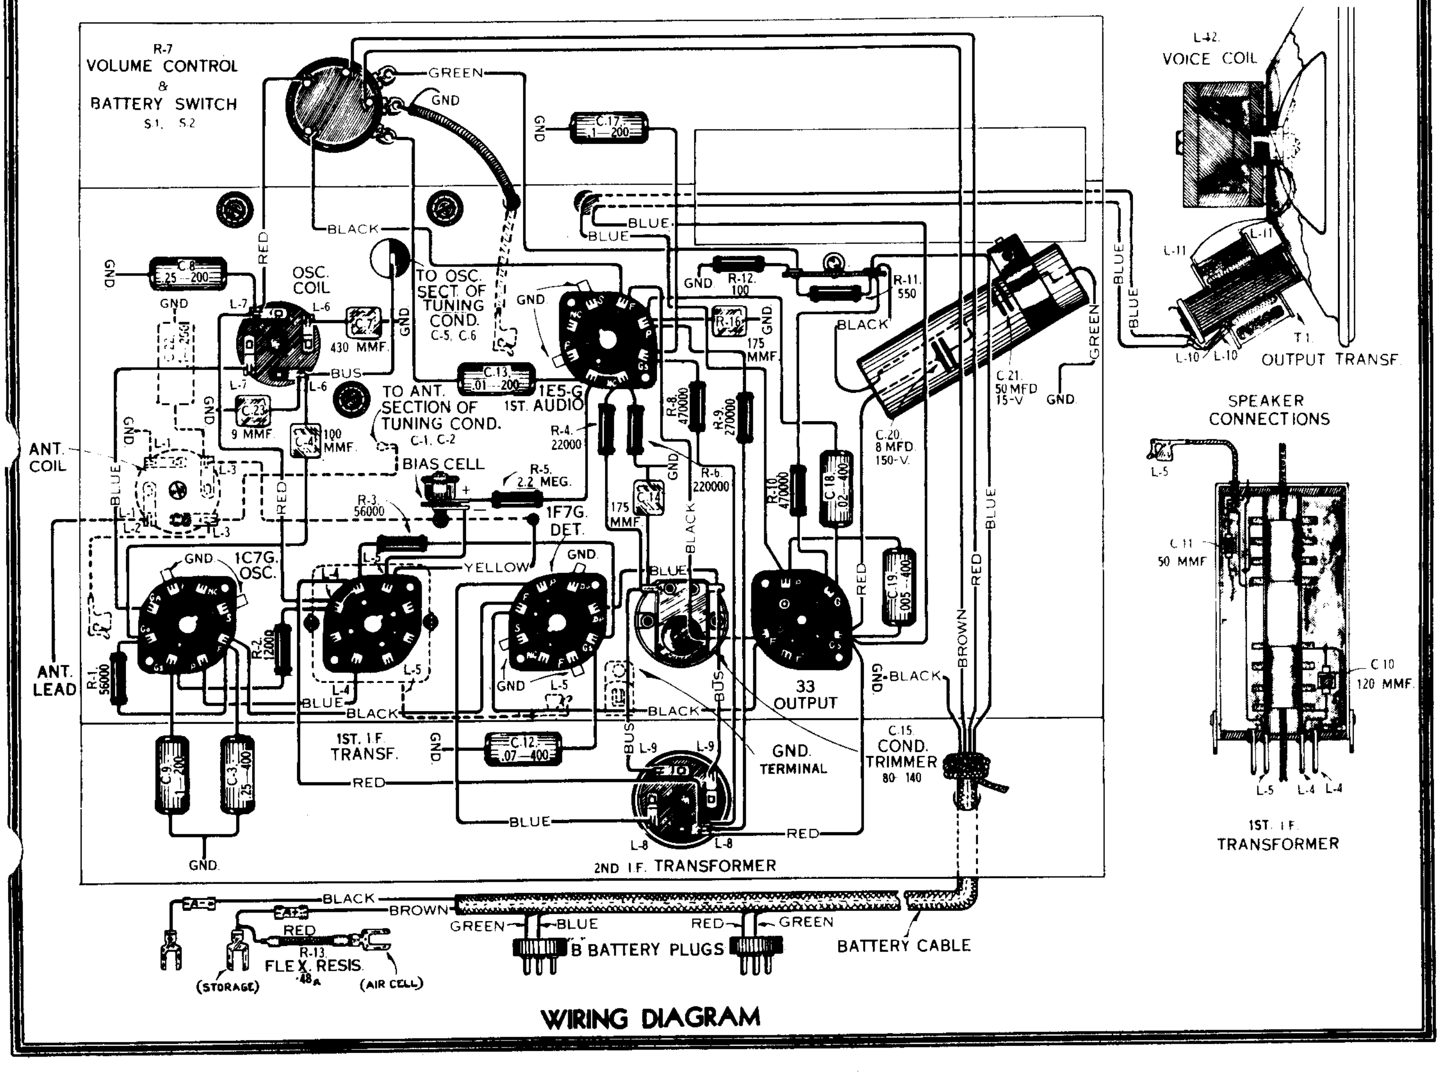
CANADIAN WESTINGHOUSE COMPANY Limited

MODEL B-428A



Note—In many cases the voltage rating of condensers follows the capacity rating. (mfd.)

SCHEMATIC CIRCUIT DIAGRAM



WIRING DIAGRAM

CANADIAN WESTINGHOUSE COMPANY Limited

MODEL B-428A

"A" Battery—1 plug-in 2½ volt Air-cell Eveready A-600 (or equivalent) or 1 2.0 volt storage battery.

"B" Battery—2 45 volt, heavy duty plug-in type.

"C" Battery—(Audio)—None required.

Battery Current—"A"=500 milliamperes; "B"=14 milliamperes.

Cabinet Dimensions—7½" x 14½" x 8½".

Shipping Weight—13 lbs.

Controls—Upper Knob: Station Selector. Lower Knob: Operating Switch and Volume Control.

Station Selector Drive Ratio .... 5½:1 (planetary type).

Number and types of radiotrons—1-W-1C7G; 1-W-E5G; 1-W-1F7G; 1-W33. Total 4.

Undistorted output .... 0.2 Watt
Frequency range .... 530 K.C. to 1720 K.C.

This Receiver is a 4 tube superheterodyne incorporating such features as wide broadcast range, Alnico dynamic speaker, one "iron core" I.F. transformer, one "air core" I.F. transformer, automatic volume control "Cell" type "C" bias, unexcelled battery economy, special circuit for securing audio "C" bias without the use of a "C" battery and the inherent sensitivity, selectivity and tone quality of the superheterodyne circuit.

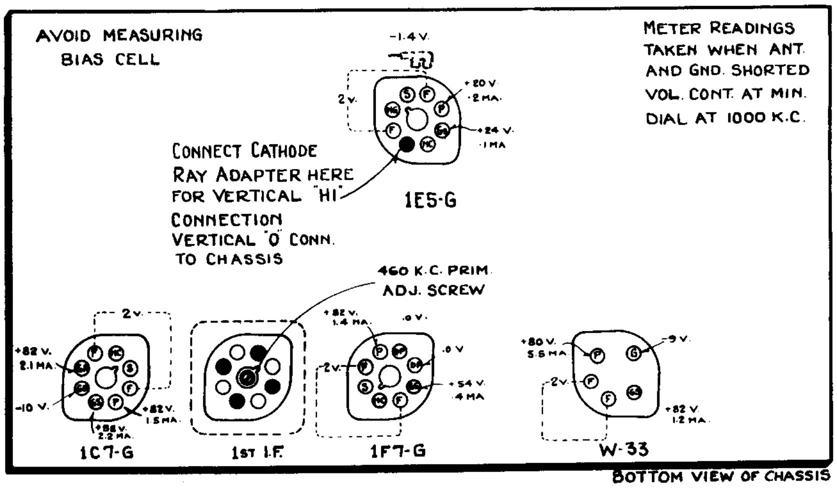
The following description of the circuit includes several new design features which are incorporated in this receiver. The first tube (Radiotron W-1C7G) is used as a combined first detector and oscillator. Separate tuned circuits are provided for each function. The second tube (Radiotron W-1F7G) is used as an I.F. amplifier with one diode plate acting as detector and A.V.C.

The I.F. transformer feeding the control grid of the W-1F7G is tuned by fixed primary and secondary condensers and adjusted by movement of the two "iron cores." The use of the "iron core" I.F. transformer results in considerably improved sensitivity, selectivity and stability of adjustment.

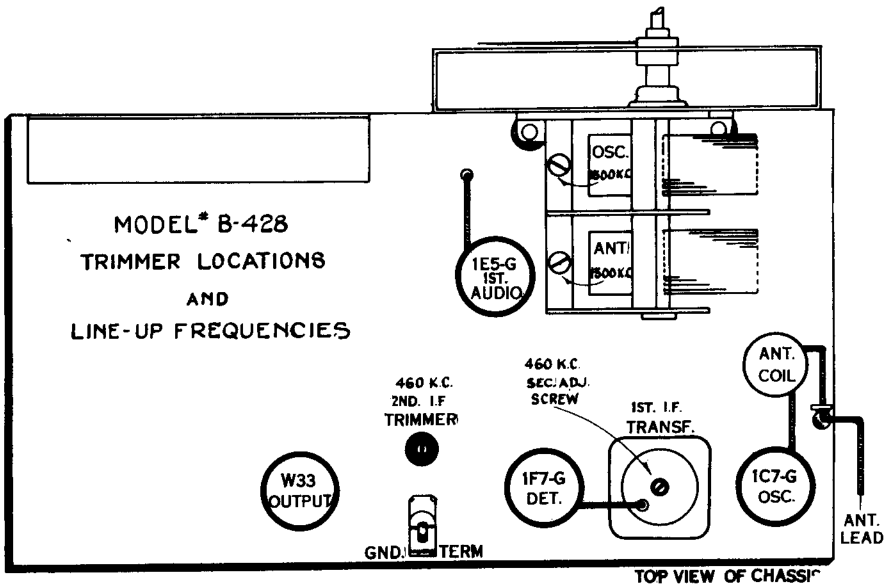
The I.F. transformer feeding the diode detector and A.V.C. circuit is an "air core" transformer with the secondary only tuned by an adjustable trimmer capacitor.

The volume control is used to control the amount of audio voltage applied to the control grid of the Radiotron W-1E5G first audio stage which is resistance-capacitance, coupled in the usual manner to the Radiotron W-33 pentode output stage.

The line up adjustment is made in the usual way to the adjustment screws shown in the trimmer location diagram. When making adjustment the test oscillator frequency and receiver dial setting should correspond to the indicated line up frequency. When making I.F. adjustment the oscillator should be connected to the W-1C7G control grid through a .001 mfd. condenser and ground, with the antenna wire grounded.



BOTTOM VIEW OF CHASSIS



TOP VIEW OF CHASSIS

RADIOTRON SOCKET VOLTAGES AND TRIMMER LOCATIONS

Caution—Do not attempt to measure voltages on the control grids of the W-1C7G or W-1F7G with any conventional voltmeter as paralysis of the "C-bias" cell will result.

Check "C" cell by noting whether plate current is abnormally high on tubes biased by cells.

A further check on the C bias cell, particularly if it is suspected that the control grid leads have been grounded, is to connect a 1½ volt C battery between the control grid cap of one of the tubes on the C cell circuit and the chassis frame. The negative of the C battery should be connected to control grid, positive to chassis frame. This connection should be momentarily made only, and if the C cell had been weakened before, it will now be found to be recharged and ordinarily will not need to be replaced.

All voltages are measured with respect to chassis frame, with all batteries at normal voltage — tuned to approximately 1000 K.C. — no signal being received.

MODELS B-624A & B-624X

"A" Battery—1-2½ volt Air-cell Eveready A-600 (or equivalent) or 1-2.0 volt storage battery.
"B" Battery—2 (or 3) 45 volt, heavy duty plug-in type.
"C" Battery—(Audio)—1 (or 2) 4½ volt plug-in type such as Eveready 771 or Burgess 536.
Pilot Lamp Battery—Eveready 409 or Burgess 1042.
Battery Current—"A"=540 milliamperes; "B"=14.5 milliamperes. (Average at 90 volts.)
Cabinet Dimensions—B-624A, 11" x 22¾" x 9"; B-624X, 39" x 22" x 11¼".
Shipping Weight—B-624A, 28 lbs.; B-624X, 58 lbs.
Controls—(1) Off-Speech-Music Switch, (2) Station Selector, (3) Treble Tone Control and Dial Light Switch, (4) Volume Control.
Station Selector Drive Ratio 18:1
Number and types of radiotrons—(1)-W-1C7G; (1)-W-1F7G; (1)-W-E5G; (1)-W-1H4; (2)-W-49. Total 6.
Pilot Lamps (2)—Mazda No. 40, 6.3 V., 0.15 Amp.
Undistorted output ..... 0.5 Watt
Frequency range ..... 530 K.C. to 1720 K.C.

These receivers are 6 tube superheterodynes incorporating such features as wide broadcast range, Alnico dynamic speaker, "iron core" I.F. transformers, bass and treble tone controls, automatic volume control, "Cell" type "C" bias, unexcelled battery economy, plug-in batteries, compensated manual volume control, class B output circuit, dust-proof loudspeaker, wave trap and the inherent sensitivity, selectivity and tone quality of the superheterodyne circuit.

The following description of the circuit includes several new design features which are incorporated in this receiver. The first tube (Radiotron W-1C7G) is used as a combined first detector and oscillator. Separate tuned circuits are provided for each function. The second tube (Radiotron W-1F7G) is used as an I.F. amplifier with one diode plate acting as detector and A.V.C..

The audio frequency voltage appearing across the diode load resistor of the W-1F7G Radiotron is coupled to an acoustically tapered and compensated volume control. The moving tap of the volume control is connected to the control grid of the W-1E5G first audio amplifier Radiotron, which is in turn resistance-capacitance coupled to a W-1H4G driver Radiotron.

The output of the driver stage is transformer-coupled to the Class B, push-pull output stage which uses two W-49 Radiotrons.

The treble tone control consists of a variable resistance in series with a fixed capacity connected across the secondary of the driver transformer.

The amount of bass response is controlled by the speech-music switch S7. When this switch-pole S7 is closed, the amount of compensation on the volume control is decreased—thus reducing the bass response at low and moderate volume.

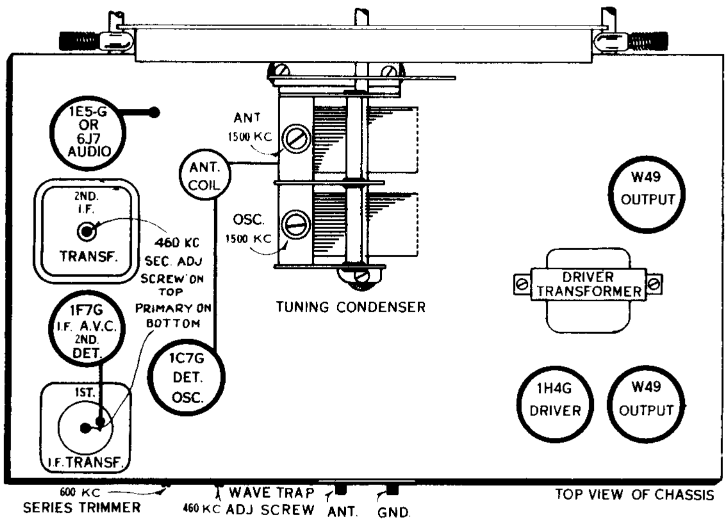
The line up adjustment is made in the usual way to the adjustment screws shown in the trimmer location diagram. When making adjustment the test oscillator frequency and receiver dial setting should correspond to the indicated line up frequency. When making I.F. adjustment the oscillator should be connected to the W-1C7G control grid through a .001 mfd. condenser and ground, with the antenna trminal grounded.

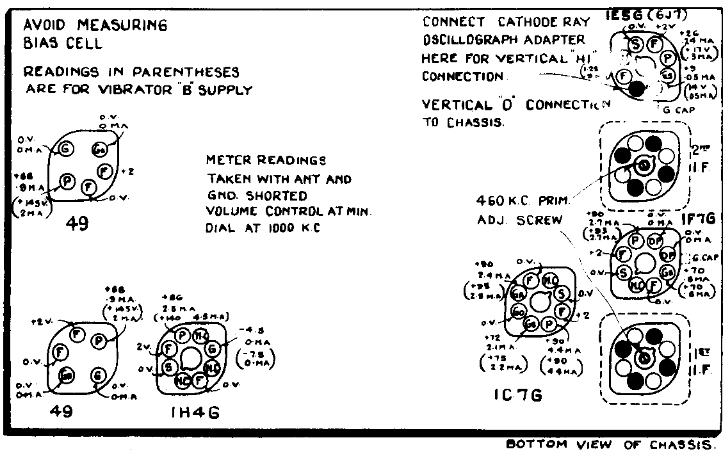
Use With Vibrator "B" Supply

These receivers may be used with Westinghouse Style No. H-36133 vibrator "B" supply if a 6.0 volt storage battery is available. The necessary changes are very simple. Follow the instructions given with the vibrator "B" supply, noting also the following points:

The W-1E5G tube must be removed and a W-6J7G radiotron substituted. No Pilot Lamp Battery is required.

Refer to schematic circuit diagram in this leaflet and note the internal connection of the vibrator plug. When vibrator H-36133 is used with Model B-624, it is necessary to connect together pins No. 1 and No. 5, on the diagram. This may be done by dissembling the vibrator plug and soldering a jumper in place. It will be more convenient, however, to use a special adapter, Style No. H-38178. (See parts list.)





Socket Voltage and Trimmer Locations

For service data (or operating instructions) on vibrator "B" supply H-36133, see radio service manual, section RS-170.

Caution — Do not attempt to measure voltages on the control grids of the W-1C7G or W-1F7G with any conventional voltmeter as paralysis of the "C-bias" cell will result.

Check "C" cell by noting whether plate current is abnormally high on tubes biased by cells.

A further check on the C bias cell, particularly if it is suspected that the control grid leads have been grounded, is to connect a 1½ volt C battery between the control grid cap of one of the tubes on the C cell circuit and the chassis frame. The negative of the C battery should be connected to control grid, positive to chassis frame. This connection should be momentarily made only, and if the C cell had been weakened before, it will now be found to be recharged and ordinarily will not need to be replaced.

All voltages are operating voltages with respect to chassis frame, with all batteries at normal voltage —tuned to approximately 1000 K.C. —no signal being received. Due allowance must be made for current

CONTINENTAL RADIO & TELEVISION CORP.

MODELS Z3 & Z344

This receiver is designed to operate over three tuning ranges. The broadcast range which extends from 545 to 1715 Kilocycles (KC) (175 to 550 meters), Police and Aviation Band which extends from 1715 to 5350 Kilocycles (KC) (56 to 175 Meters) and the International Short Wave Band which extends from 5760 to 16200 Kilocycles (KC) (18.5 to 52 meters). This short wave range is the one which includes the four internationally assigned bands—the 19, 25, 31 and 49 meter bands.

ALIGNMENT DATA AND SERVICING

GENERAL DATA The alignment of this receiver requires the use of a test oscillator that will cover the frequencies of 456, 600, 1400, 1800, 4000, 6000, and 14,000 KC and an output meter to be connected across the primary or secondary of the output transformers. If possible, all alignments should be made with the volume control on maximum and the test oscillator output as low as possible, to prevent the AVC from operating and giving false readings.

CORRECT ALIGNMENT PROCEDURE The intermediate frequency (I.F.) stage should be aligned properly as the first step. After the I.F. transformers have been properly adjusted and peaked, the Broadcast Band should always be the next procedure; after which, either or both of the Short Wave Bands may be aligned.

I.F. ALIGNMENT Adjust the test oscillator to 456 KC and connect the output to the grid of the first detector tubes (6L7) through a .05 or .1 mfd. condenser. The ground on the test oscillator can be connected to the chassis ground. Align all six I.F. trimmers to peak or maximum reading on the output meter.

BROADCAST BAND ALIGNMENT Adjust the oscillator to 1400 KC and connect the output to the antenna post marked "A" through a .0001 mfd. mica condenser to give the equivalent of an antenna about 60 feet. Set the receiver pointer to 1400 KC and adjust the rear gang condenser trimmer (oscillator circuit) to peak. After this has been carefully done, the next step is to adjust the center and front trimmers of the gang condenser to peak. The front gang section tunes the R.F. or grid coil of the 6A8 tube and the center condenser section tunes the pre-selector stage circuit.

Next, re-set the dial pointer on the receiver and the test oscillator to 600 KC. Slowly increase or decrease the oscillator padding condenser and at the same time continuously tune back and forth across the signal with the receiver until the maximum reading is obtained on the output meter. This adjustment seems a little complicated but is the easiest way to adjust the oscillator to the pre-selector or R.F. section. The padding condenser is located on the right hand end of the chassis near the 6K7 tube.

Return to 1400 KC and again go over the adjustments of this frequency to be certain that they were not put slightly out of alignment when adjustment was made at 600 KC.

This completes the correct sequence of operations in properly aligning the receiver for the Broadcast Band, and **must always be done before** attempting to align the Short Wave Bands.

FOREIGN BAND The Foreign Band of 19 to 49 meters can be adjusted by the two trimmers on the short wave coil located on the top of the chassis. Set the test oscillator to 14,000 KC. The oscillator coil is located near the 1st I.F. Transformer and the antenna or R.F. coil is located directly in front of the Short Wave oscillator coil and about midway between the 1st I.F. Transformer and the 6A7 tube. These two trimmers should be adjusted for peak at 14,000 KC and as the inherent design of the circuit has been expressly designed for simplicity in servicing, no other adjustments are necessary for aligning this band. **Note:** Always start this procedure by having the oscillator coil trimmer loose (out all the way), and the antenna coil trimmer fairly tight (in all the way); otherwise it is possible to make a false alignment on the image frequency.

Important: Do not attempt any adjustment of the gang condenser trimmers in aligning the Foreign Band as this will throw the Broadcast Band out of alignment.

POLICE BAND There is only one adjustment to be made in the alignment of the Police Band. Due to the circuit design and correct matching of the coils, no oscillator adjustment is necessary.

Set the dial pointer to 4000 KC (also the test oscillator) and adjust the antenna coil trimmer to resonance. In preparing the test oscillator for alignment of this band, connect a 400 ohm carbon resistor in series with the .0001 mfd. condenser on the output lead of the test oscillator. This resistor is used with the test oscillator only on the Short Wave Bands and should not be used for Broadcast Band alignment. The two police band coils are under the chassis and the antenna coil trimmer is mounted on the end of the antenna coil.

Important: This is the only adjustment necessary for the Police Band. Do not attempt any adjustment of the gang condenser trimmers in aligning the Police Band, otherwise the Broadcast Band will be thrown out of alignment.

CONTINENTAL RADIO & TELEVISION CORP.

MODEL Z5

This receiver is designed to operate over three tuning ranges. The broadcast range which extends from 545 to 1715 Kilocycles (KC) (175 to 550 meters), Police and Aviation Band which extends from 1715 to 5350 Kilocycles (KC) (56 to 175 Meters) and the International Short Wave Band which extends from 5760 to 16200 Kilocycles (KC) (18.5 to 52 meters). This short wave range is the one which includes the four internationally assigned bands—the 19, 25, 31 and 49 meter bands.

REASONS FOR UNSATISFACTORY OPERATION

FAILURE TO OPERATE 1. Check connections from battery cable to storage battery. If connections are reversed, set will not operate. Proper instructions for connecting the battery are given on the first page.
2. Check all tubes. Have them tested by meter equipped to test the type of tubes used in this receiver.
3. Check tube shields for good ground connections. Check grid caps for good connection. See that grid caps and tube shields are not shorted to each other (touching).
4. Reversed connections on Antenna and ground terminals. Try both ways for best results.
5. Oscillator tube (1C6) not oscillating.
6. Vibrator unit not securely in socket.

HUM A minimum amount of hum, equivalent to A.C. receivers, may be present. Excessive hum may be traced to the following causes:
1. Omitting the use of a ground or a poor ground connection.
2. Vibrator unit not securely fitted in socket.
3. Antenna picking up interference from high tension power lines.
4. Weak or rundown battery. Battery with defective cell.
5. Poor battery connections.
6. Extending or lengthening battery leads cause an enormous increase in "hum." The battery cable attached to the receiver is of special design and its ends **must** be connected directly to the battery terminals. **(See battery connection data on first page.)**

HOWLS AND SQUEALS 1. Omitting the use of a ground or poor ground connections.
2. Speaker leads placed near the (32) tube. These leads should be kept away from this locality. Speaker leads should be kept along the end of chassis and front corner of cabinet.
3. Check shield on (34) tube for good connection to chassis.

WINDCHARGERS

There are many types of windchargers now on the market which may be used to advantage for greater economy of receiver operation. **Such chargers will pay for themselves over a period of time; by saving the cost of battery recharging; removing the inconvenience of taking the battery to a charging station; non-operation of the receiver during the charging period.**
IMPORTANT NOTE: The battery must never be charged while set is in operation. If a windcharger is used, it should always be disconnected from the battery when the receiver is being used. An inexpensive single pole switch can be used for disconnecting the windcharger from the battery. This will increase the life of the tubes and give additional economy to the use of the receiver.

ALIGNMENT DATA AND SERVICING

GENERAL DATA The alignment of this receiver requires the use of a test oscillator which will cover the frequencies of 456, 600, 1400, 1800, 4000, 6000, and 14,000 KC and an output meter which is to be connected across the primary or secondary of the output transformer. If possible, all alignments should be made with the volume control on maximum and the test oscillator output as low as possible, to prevent the AVC from operating and giving false readings.

CORRECT ALIGNMENT PROCEDURE The intermediate frequency (I.F.) stage should be aligned properly as the first step. After the I.F. transformers have been properly adjusted and peaked, the Broadcast Band should always be the next procedure; after which, either or both of the Short Wave Bands may be aligned.

I.F. ALIGNMENT Adjust the test oscillator to 456 KC and connect the output to the grid of the first detector tube (1C6) through a .05 or .1 mfd. condenser. The ground on the test oscillator can be connected to the chassis ground. Align all four I.F. trimmers to peak or maximum reading on the output meter.

BROADCAST BAND ALIGNMENT Adjust the oscillator to 1400 KC and connect the output to the antenna post marked "A" through a .0001 mfd. mica condenser to give the equivalent of an antenna about 60 feet. Set the receiver pointer to 1400 KC and adjust the rear gang condenser trimmer (oscillator circuit) to peak. After this has been carefully done, the next step is to adjust the front trimmer of the gang condenser to peak. The front condenser section tunes the RF or grid circuit of the 1C6 tube. Next, re-set the dial pointer on the receiver and the test oscillator to 600 KC. Slowly increase or decrease the oscillator padding condenser and at the same time continuously tune back and forth across the signal with the receiver until the maximum reading is obtained on the output meter. This adjustment may seem a little complicated but is the easiest way to adjust the oscillator to the R.F. section. The padding condenser is located on the left hand side of the chassis, directly to the left of the 1C6 tube and in front of the first I.F. transformer. Return to 1400 KC and again go over the adjustments of this frequency to be certain that they were not put slightly out of alignment when adjustment was made at 600 KC.
This completes the correct sequence of operations in properly aligning the receiver for the Broadcast Band, and **must always be done before** attempting to align the Short Wave Bands.

FOREIGN BAND ALIGNMENT The Foreign Band of 19 to 49 meters can be adjusted by the two trimmers on the short wave coils located on the top of the chassis. Set the test oscillator to 14,000 KC. In preparing the test oscillator for alignment of this band, connect a 400 ohm carbon resistor in series with the .0001 mfd. condenser on the output lead of the test oscillator. The oscillator coil is located near the 1st I.F. Transformer and the antenna or R.F. coil is located directly in front of the Short Wave oscillator coil and alongside the front section of the gang condenser. These two trimmers should be adjusted for peak at 14,000 KC and as the inherent design of the circuit has been expressly developed for simplicity in servicing, no other adjustments are necessary for aligning this band.
Note: Always start this procedure by having the oscillator coil trimmer loose (out all the way), and the antenna coil trimmer fairly tight (in all the way); otherwise it is possible to make a false alignment on the image frequency. In order to prevent alignment on the image frequency, it is suggested that the following check be made: Readjust the pointer to 13,100 KC where the image frequency should be found. If properly aligned, the image frequency will be found to be weaker. If, however, the signal at 13,100 KC is found to be stronger than the signal at 14,000 KC, it signifies that alignment was incorrectly made on the image frequency.
IMPORTANT: Do not attempt any adjustment of the gang condenser trimmers in aligning the Foreign Band as this will throw the Broadcast Band out of alignment.

POLICE BAND ALIGNMENT There is only one adjustment to be made in the alignment of the Police Band. Due to the circuit design and correct matching of the coils, no oscillator adjustment is necessary. Set the dial pointer to 4000 KC (also the test oscillator) and adjust the antenna coil trimmer to resonance. In preparing the test oscillator for alignment of this band, connect a 400 ohm carbon resistor in series with the .0001 mfd. condenser on the output lead of the test oscillator. This resistor is used with the test oscillator only on the Short Wave Bands and should not be used for Broadcast Band alignment. The two police band coils are under the chassis and the antenna coil trimmer is mounted on the end of the antenna coil. **Important:** This is the only adjustment necessary for the Police Band. Do not attempt any adjustment of the gang condenser trimmers in aligning the Police Band, otherwise the Broadcast Band will be thrown out of alignment.

SERVICE DATA FOR ALL BANDS

If it is suspected that the oscillator has stopped but is doubtful due to the presence of the usual amount of noise level, it is suggested that the oscillator plate voltage be checked. To ascertain whether the tube is oscillating, ground the oscillator grid of the 1C6 (short stator and rotor plates of oscillator section on gang condenser). If oscillating properly, grounding the grid will cause an appreciable drop in oscillator voltage.

MODEL -- A-157

TUBES AND VOLTAGE LIMITS

The following table gives the functions of the tubes used, together with the voltage readings between the tube socket contacts and the receiver chassis. Voltage readings taken with a 1000 ohm per volt, 500 volt voltmeter (except filaments) with receiver in operating condition and no signal input. The filament voltages should be measured with an accurate low range D-C voltmeter (approximately 0 to 10 volts). Voltage limits may vary plus or minus 10% of values given.

THE CROSLEY RADIO CORPORATION

MODELS A-157 & FIVER ROAMIO

SPECIFICATIONS

The Crosley Model A-157 auto radio is a single unit, five-tube superheterodyne receiver, incorporating A. V. C. and many advanced features in circuit design. The power supply unit is an integral part of the receiver chassis and uses a primary type vibrator.

ALIGNMENT PROCEDURE

All the circuits in this receiver are very accurately adjusted at the factory and normally should need no further adjustment. However, if it is definitely known that an adjustment is necessary the circuits can best be properly aligned with the use of a modulated signal generator and an output meter.

CONNECTING OUTPUT METER

Connect the output meter to P and S of the 6K6G Output tube. Be sure the meter is protected from D.C. by connecting a condenser (.1 mfd. or larger—not electrolytic) in series with one of the leads.

1. Tuning I-F Amplifier To 455 Kilocycles.

(a) Connect the output of the signal generator through a .02 mfd., or larger, condenser to the top cap of the 6A8G Osc-Mod. tube, leaving the tube's grid clip in place. Connect the ground lead from the signal generator to the receiver chassis frame. KEEP THE GENERATOR LEADS AS FAR AS POSSIBLE FROM THE GRID LEADS OF THE OTHER SCREEN GRID TUBES.

(b) Adjust the station selector so that the rotor plates of the tuning condenser are completely disengaged and turn Vol. Cont. to maximum position (RIGHT).

(c) Set the signal generator to 455 kilocycles.

(d) Adjust both trimmers located on the 2nd I-F transformer for maximum output. Fig. 2.

(e) Adjust both trimmers located on the 1st I-F transformer for maximum output.

(f) Repeat operations (d) and (e) for more accurate adjustments.

IN ORDER TO PREVENT A. V. C. ACTION ALWAYS USE THE LOWEST SIGNAL GENERATOR OUTPUT THAT WILL GIVE A REASONABLE OUTPUT METER READING.

2. Aligning R-F Amplifier.

(a) Connect the output lead from the signal generator through a .00025 mfd. condenser to the "ANT" connection of the receiver.

(b) Set the signal generator to 1400 kilocycles.

(c) Adjust the station selector to 140 on the dial.

(d) Adjust the trimmer on the "OSC" section of the tuning condenser for maximum output.

(e) Adjust the trimmer on the "ANT" section of the tuning condenser for maximum output.

(f) Readjust the station selector for maximum output. DO NOT READJUST THE OSC. TRIMMER.

(g) Repeat operation (e) for more accurate adjustment.

3. Adjusting Antenna Compensating Condenser.

(a) Set the signal generator to 600 kilocycyes.

(b) Tune in the 600 kilocycle signal with the station selector for maximum output.

(c) Adjust the antenna compensating condenser, Illustration No. 9, Fig. 3, for maximum output.

(d) Repeat operations (b) and (c) alternately until no further improvement can be obtained.

(e) Set the signal generator to 1400 kilocycles again.

(f) Tune-in the 1400 kilocycle signal with the station selector for maximum output.

(g) Readjust the trimmer on the "ANT" section of the tuning condenser for maximum output.

It will be necessary to adjust the antenna compensating condenser to the car antenna after the receiver has been installed in the car.

(a) After the installation is complete, tune-in a WEAK station between 55 and 65 on the dial.

(b) Adjust the antenna compensating condenser for maximum volume in the speaker.

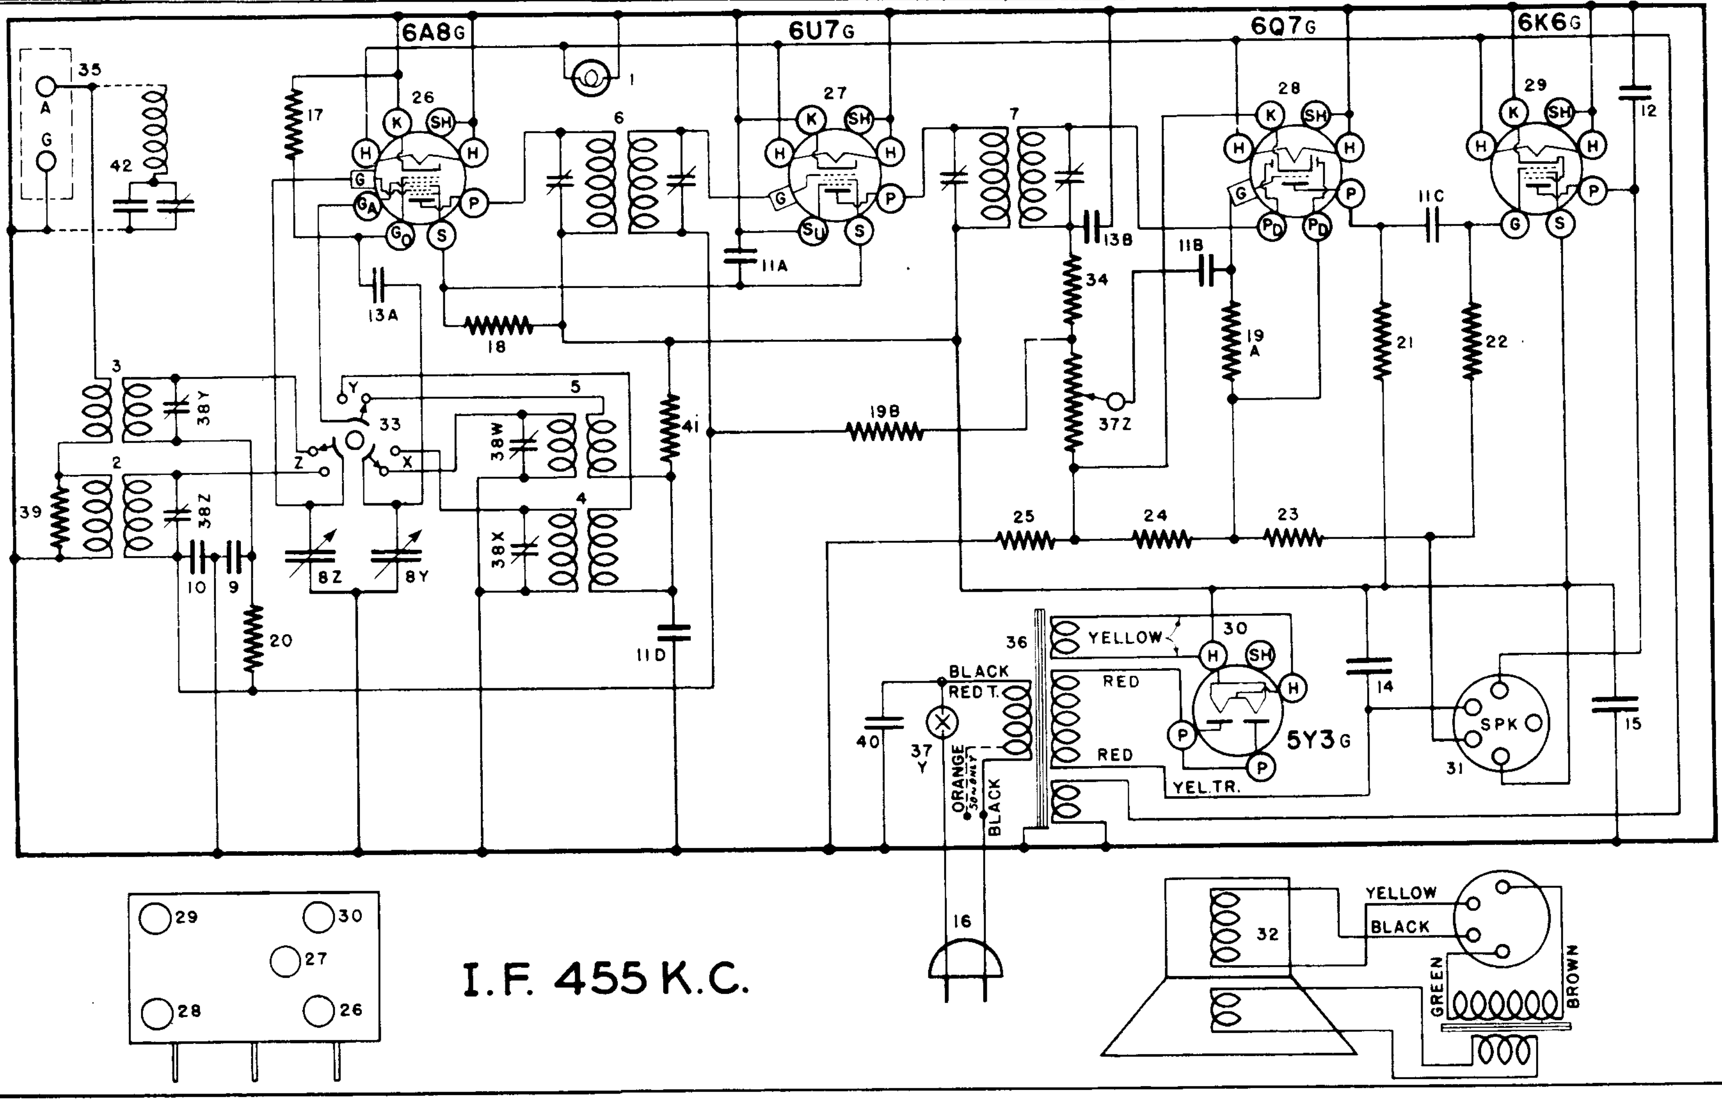
THE CROSLEY RADIO CORPORATION

MODEL 567



SOCKET VOLTAGES

The tube socket voltages are measured from the tube socket contacts to the chassis with a 1000 ohm per volt 500 volt d. c. voltmeter (except filaments) with the receiver in operating condition and no signal input. The filament voltages should be measured with an accurate low range a. c. voltmeter (approximately 0-10 volts). Readings may vary plus or minus 10% of values given.

TUBE SOCKET VOLTAGE READINGS

Tube	Function	H	P	S	K	G	Ga
6A8G	Oscillator-Modulator	6.3	160	115	0	-1.2	160
6U7G	I-F Amplifier	6.3	160	115	0	-1.2	—
6Q7G	Diode Detector & A-F Amplifier	6.3	80	—	2.5	-2.5	—
6K6G	Output	6.3	160	160	0	-5.0	—
5Y3G	Rectifier	5.0	—	—	225	—	—

Power output approximately 2 watts.
Power consumption approximately 40 watts at 117.5 volts.
Voltage drop across speaker field 35 volts.

THE CROSLEY RADIO CORPORATION

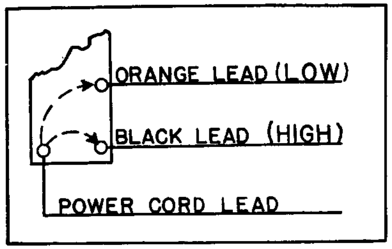
MODEL 567

Tuning Range

540-1725 Kilocycles or 555-173 Metres
5.9-15.3 Megacycles or 51- 18 Metres

50 CYCLE POWER TRANSFORMER ADJUSTMENT

Receivers equipped with a 50 cycle power transformer have a "high" and "low" voltage tap on the under side



of the chassis. The "high" voltage lead (BLACK) and the "low" voltage lead (ORANGE) are connected to a terminal strip near the transformer.

The voltage range of the "low" tap of the 95-130 volt transformer is from 95 to 112½ volts and of the "high" tap is from 112½ to 130 volts. The range of the "low" tap of the 190-260 volt transformer is from 190 to 225 volts and of the "high" tap is from 225 to 260 volts.

The accompanying illustration shows the connections for changing from high to low or low to high line voltage. Note the "jumper" wire which is attached to the terminal at which one side of the power cord is attached. The other end of this jumper wire should be connected to the ORANGE or BLACK lead of the transformer primary, according to the line voltage the receiver is to be used on.

NOTE: Any change made in the power supply circuit of the receiver should be plainly stamped or otherwise permanently recorded on the rear of the chassis.

ALIGNMENT PROCEDURE

All the circuits in this receiver are very accurately adjusted at the factory and normally should need no further adjustment. However, if it is definitely known that an adjustment is necessary the circuits can best be properly aligned with the use of a modulated signal generator and output meter.

CONNECTING OUTPUT METER

Connect the output meter to P and S of the 6K6G output tube. Be certain that the meter is protected from d. c. by connecting a condenser (.1 mfd. or larger—not electrolytic) in series with one of the leads.

Tuning I-F Amplifier To 455 Kilocycles.

(a) Connect the output of the signal generator through a .02 mfd. condenser to the top cap of the 6A8G tube, leaving the tube's grid clip in place. Connect the ground lead from the signal generator to the "GND" terminal of the receiver. KEEP THE GENERATOR LEADS AS FAR AS POSSIBLE FROM THE GRID LEADS OF THE OTHER SCREEN GRID TUBES.

(b) Set the station selector so that the tuning condenser plates are completely out of mesh and turn the volume control knob to the right (ON).

(c) Turn the band selector switch to the left (Broadcast Band).

(d) Set the signal generator to 455 kilocycles.

(e) Adjust both trimmers located on top of the 2nd I-F transformer for maximum output. See Fig. 2.

(f) Adjust both trimmers located on the top of the 1st I-F transformer for maximum output.

ALWAYS USE THE LOWEST SIGNAL GENERATOR OUTPUT THAT WILL GIVE A REASONABLE READING ON THE OUTPUT METER.

Aligning The R-F Amplifier.

When aligning the R-F amplifier the output lead from the signal generator is connected to the antenna (A) terminal of the receiver. For the Broadcast Band a .00025 mfd. condenser should be connected in series with the output lead of the signal generator and for the High Frequency Band a 400 ohm carbon resistor should be used in place of the condenser.

(a) With the station selector adjusted so that the tuning condenser plates are completely out of mesh and the band selector switch set for the band being aligned, adjust the "OSC" shunt trimmer so that the MINIMUM CAPACITY SIGNAL (C), is heard. It is not necessary that the receiver tune through this signal.

(b) Adjust the station selector so that the SHUNT ALIGNMENT signal is tuned-in with maximum output. Then adjust the "ANT" shunt trimmer for maximum output. Readjust the station selector slightly so that the generaor signal is tuned-in with maximum output and check the adjustment of the "ANT" trimmer. DO NOT READJUST THE "OSC" TRIMMER.

NOTE 1: When shunt aligning the High Frequency Band care should be exercised so that the circuits will be aligned on the correct frequency rather than on the image frequency which is approximately 910 kilocycles less than the fundamental. To check on this, increase the output of the signal generator 10 times, or more, and try to tune-in the signal both at the generator frequency as indicated on the station selector dial and at approximately 910 kilocycles less than the correct frequency. If the circuits have been properly aligned the signal can be tuned-in at both positions but much stronger at the correct frequency.

NOTE 2: If at any time the H-F coils are replaced, it may be necessary to vary the inductance of the "OSC" coil by moving the cross-over turn of wire at the gap to make the set track at the 6 megacycle end. Moving the turn toward the short end of the coil will decrease the inductance and moving it toward the long end will increase the inductance. If the signal is weak at 6 megacycles, a similar slight change in the inductance of the "ANT" coil should bring up the signal strength. THIS IS A CRITICAL OPERATION AND SHOULD NOT BE DONE ON ANY SET UNLESS CHANGING COILS MAKES IT NECESSARY.

(C) SIGNAL INPUT FREQUENCIES

	Minimum Capacity	Shunt Alignment
American Broadcast Band	1725 Kilocycles	1400 Kilocycles
High Frequency Band	15400 Kilocycles	15000 Kilocycles

WAVE TRAP

Some chassis of this model are equipped with a wave trap for the purpose of eliminating interference from code stations which operate on a frequency of approximatly 455 kilocycles. This assembly is located on the underneath side of the chassis and consists of a coil, a fixed condenser and a trimmer condenser as illustrated by dotted lines in the Wiring diagram.

The wave trap should not be adjusted until all other adjustments have been made. To make the adjustment, feed a 455 kilocycle signal from the signal generator through a .00025 mfd. condenser into the antenna terminal of the receiver. With the band selector switch turned to the Broadcast Band position, the gang condenser open and the volume control full on, adjust the trimmer condenser on the wave trap for minimum output.

Should the interfering station be operating on a frequency of slightly more or less than 455 kilocycles, the exact frequency should be determined with the aid of the signal generator. Then, instead of feeding a 455 kilocycle signal into the receiver the exact frequency of the interfering signal should be used. If it is not possible to determine the exact frequency of the interfering signal the antenna may be attached to the receiver and the receiver tuned to the position where the interfering signal is most noticeable. Then adjust the wave trap for minimum interference.

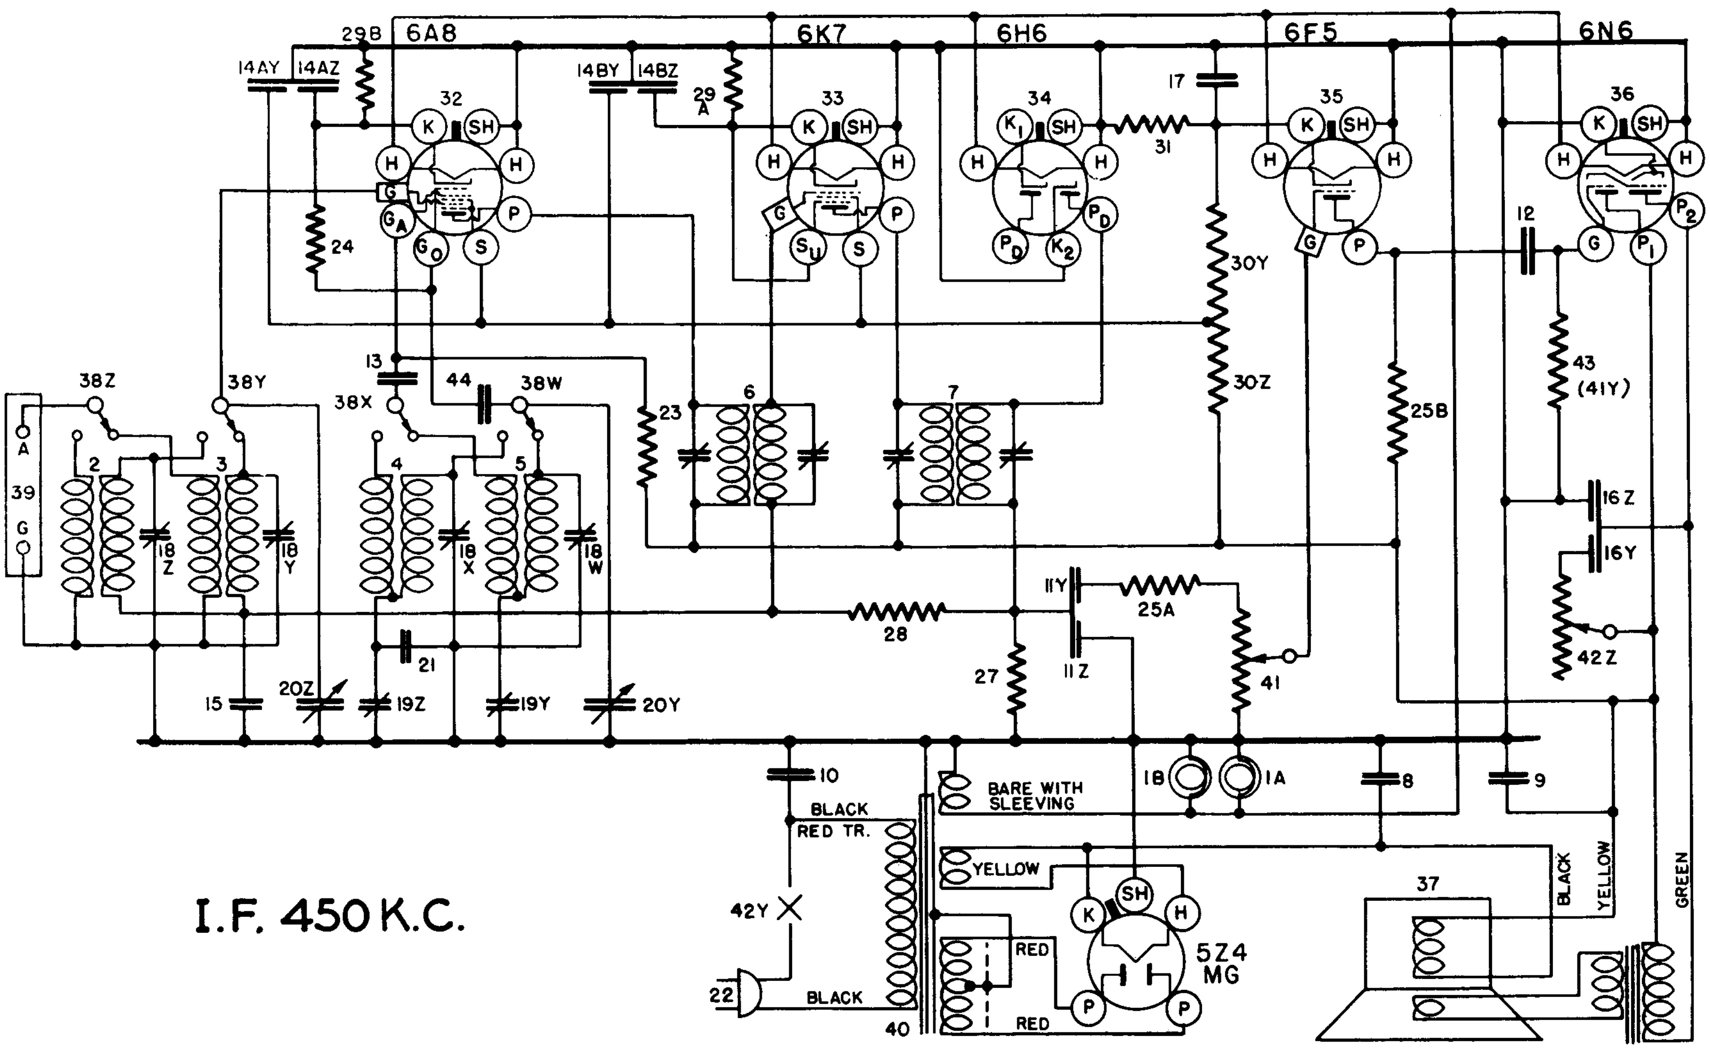
THE CROSLEY RADIO CORPORATION

MODELS 634, 649, 656 & 5656



TUBES AND VOLTAGE LIMITS

The following table gives the functions of the tubes used, together with the voltage readings between tube socket contacts and chassis. Voltage readings should be taken with a 1000 ohm per volt, 500 volt D.C. voltmeter (except filaments) with receiver in operating condition and no signal input. The filament voltages should be measured with an accurate low range A-C voltmeter (Approximately 0 to 10 volts). Voltage limits may vary plus or minus 10% of values given.

TUBE SOCKET VOLTAGE READINGS

Tube	Where Used	H	P	P2	S	Su	K	Ga	Go

Power Output Approximately 4 Watts.
Power Consumption Approximately 85 Watts at 117.5 Volts.
Voltage Drop Across Speaker Field Approximately 78 Volts.

THE CROSLEY RADIO CORPORATION

MODELS 634, 649, 656 & 5656

SPECIFICATIONS

The Crosley Radio Models 656 and 5656 are companion models employing the same circuit. The Model 656 is supplied in a table cabinet having the speaker mounted on the chassis and the Model 5656 is a console type having the speaker mounted in the cabinet.

The frequency ranges covered are from 540 to 1710 kilocycles in the broadcast band and from 6,000 to approximately 18,000 kilocycles in the high frequency band.

ALIGNMENT PROCEDURE

All the circuits in this receiver are very accurately adjusted at the factory and normally should need no further adjustment. However, if it is definitely known that an adjustment is necessary the circuits can best be properly aligned with the use of a modulated signal generator and an output meter.

CONNECTING OUTPUT METER

Connect the output meter to P. and P2 of the 6N6 Output Tube. Be sure the meter is protected from D.C. by connecting a condenser (.1 mfd. or larger—not electrolytic) in series with one of the leads.

1. Tuning I-F Amplifier to 450 Kilocycles.

(a) Connect the output of the signal generator through a .02 mfd. condenser to the top cap of the 6A8 tube, leaving the tube's grid clip in place. Connect the ground lead from the signal generator to the "GND" terminal of the receiver. KEEP THE GENERATOR LEADS AS FAR AS POSSIBLE FROM THE GRID LEADS OF THE OTHER SCREEN GRID TUBES.

(b) Set the station selector so that the tuning condenser plates are completely out of mesh. Turn the volume control knob to the right (ON) and turn the tone control knob to the left (TREBLE).

(c) Turn the band selector switch to the right (High Frequency).

(d) Set the signal generator to 450 kilocycles.

(e) Adjust both trimmers located on top of the 2nd I-F Transformer for maximum output. (Fig. 2).

(f) Adjust both trimmers located on top of the 1st I-F Transformer for maximum output.

(g) Check operations (e) and (f) for more accurate adjustments.

ALWAYS USE THE LOWEST SIGNAL GENERATOR OUTPUT THAT WILL GIVE A REASONABLE OUTPUT METER READING.

2. Aligning R-F Amplifier.

(a) When aligning the R-F Amplifier the output lead from the signal generator should be connected through a dummy antenna to the "ANT" terminal of the receiver. For the broadcast band the dummy antenna should be a .00025 mfd. condenser and for the high frequency band this condenser should be replaced by a 400 ohm (Non Inductive) carbon resistor.

Each band should be shunt aligned, series aligned and then shunt aligned again in the order given. The band selector switch should be set for the band being aligned and the signal generator should be set to the frequency indicated below for each adjustment.

Adjust the "OSC" and "ANT" shunt trimmers (Shunt alignment. See Fig. 3) in the order given for maximum output. Tune the station selector to the generator signal for maximum output and then check the adjustment of the "ANT" trimmer. NOTE: When aligning the high frequency band care should be exercised so that the circuits will be aligned on the fundamental frequency rather than on the image frequency which is approximately 900 kilocycles less than the fundamental. To check on this, increase the output of the signal generator approximately 10 times and try to tune-in the signal both at the generator frequency as indicated on the station selector dial and at approximately 900 kilocycles below the correct frequency. If the circuits have been properly aligned the signal can be tuned-in at both positions but much stronger at the correct dial setting.

To adjust the "series" trimmers (Fig. 3) set the signal generator to the frequency indicated below and then tune-in this signal with the station selector for maximum output. Adjust the series trimmer while rocking the tuning condenser back and forth slightly, until no further improvement in output can be obtained.

(b) Signal Generator Frequencies.

	Shunt Alignment	Series Alignment
Broadcast Band	1400 Kc.	600 Kc.
High Frequency Band	18000 Kc.	6000 Kc.

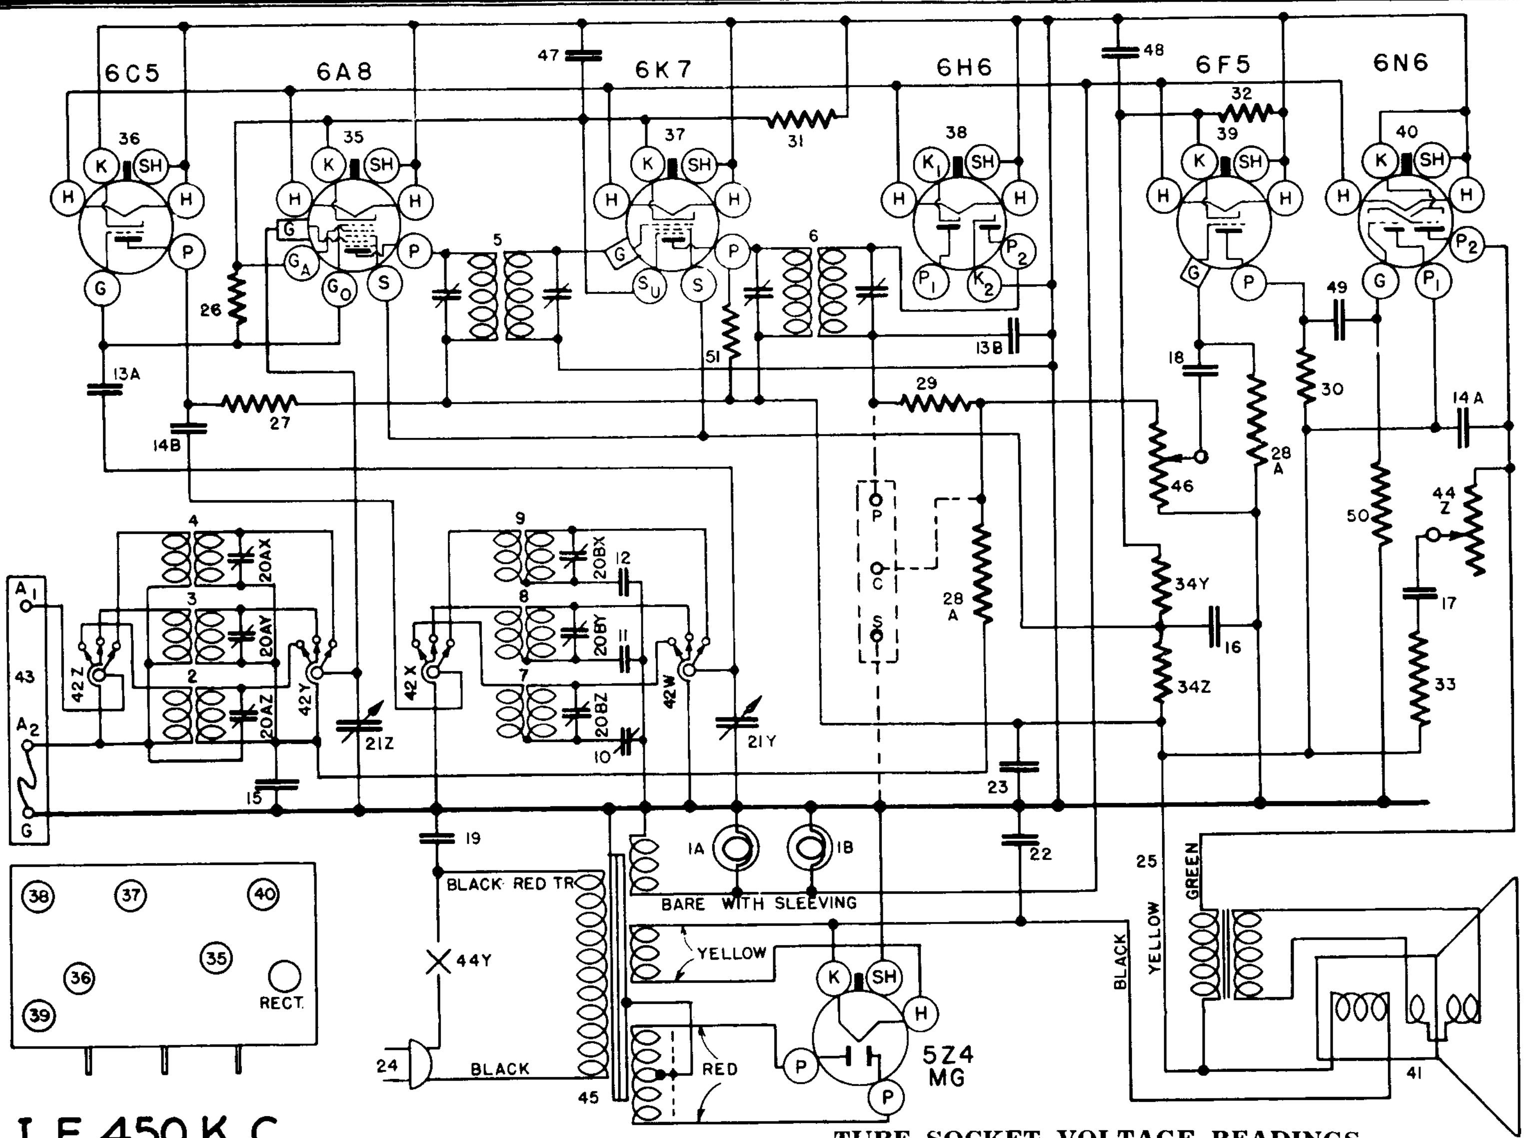
THE CROSLEY RADIO CORPORATION

MODELS 716, 744 & 745



I.F. 450 K.C.

SOCKET VOLTAGES

The tube socket voltages are measured from the tube socket contacts to the chassis with a 1000 ohm per volt, 500 volt D.C. voltmeter (except filaments) with the receiver in operating condition and no signal input. The filament voltages should be measured with an accurate low range A-C voltmeter (Approximately 0-10 volts). Readings may vary plus or minus 10% of values given.

TUBE SOCKET VOLTAGE READINGS

Tube	Where Used	H	P	P2	S	G	K	Go
6C5	Oscillator	6.3	165	—	—	0	0	—
6A8	Modulator	6.3	270	—	120	0	2.85	—5 to —30
6K7	I. F. Amp.	6.3	270	—	120	0	2.85	—
6H6	Diode Detector	6.3	0	—	—	—	—	—
6F5	A. F. Amp.	6.3	170	—	—	0	1.75	—
6N6	Output	6.3	270	255	—	0	0	—
5Z4MG	Rectifier	5.0	—	—	—	—	330	—

Power Consumption Approximately 80 Watts at 117.5 Volts.
Power Output Approximately 6 Watts.
Voltage Drop Across Speaker Field Approximately 60 Volts.

THE CROSLEY RADIO CORPORATION

MODELS 716, 744 & 745

SPECIFICATIONS

The Crosley Radio Model 716 is a seven-tube superheterodyne receiver designed to operate on an ALTERNATING CURRENT power supply.

It is a three band receiver and the dial is divided into three sections as follows:

BLUE 540-1800 Kilocycles (American Broadcast Band)
RED 1.8- 6.0 Megacycles (Police and Amateurs)
GREEN 6.0- 18.0 Megacycles (High Frequency Bands)

ALIGNMENT PROCEDURE

All the circuits in this receiver are very accurately adjusted at the factory and normally should need no further adjustment. However, if it is definitely known that an adjustment is necessary the circuits can best be properly aligned with the use of a modulated signal generator and an output meter.

CONNECTING OUTPUT METER

Connect the output meter to the two plates of the 6N6 Output Tube. Be sure the meter is protected from D. C. by connecting a condenser (.1 mfd. or larger—not electrolytic) in series with one of the leads.

1. Tuning I-F Amplifier to 450 Kilocycles.

(a) Connect the output of the signal generator through a .02 mfd. condenser to the top cap of the 6A8 tube, leaving the tube's grid clip in place. Connect the ground lead from the signal generator to the "GND" terminal of the receiver. KEEP THE GENERATOR LEADS AS FAR AS POSSIBLE FROM THE GRID LEADS OF THE OTHER SCREEN GRID TUBES.

(b) Set the station selector so that the tuning condenser plates are completely out of mesh. Turn the volume control knob to the right (ON) and turn the tone control knob to the left (TREBLE).

(c) Turn the band selector switch to the High Frequency Band.

(d) Set the signal generator to 450 kilocycles.

(e) Adjust both trimmers located on top of the 2nd I-F Transformer for maximum output.

(f) Adjust both trimmers located on top of the 1st I-F Transformer for maximum output.

(g) Check operations (e) and (f) for more accurate adjustments.

ALWAYS USE THE LOWEST SIGNAL GENERATOR OUTPUT THAT WILL GIVE A REASONABLE OUTPUT METER READING.

Aligning R-F Amplifier.

When aligning the R-F Amplifier the output lead of the signal generator is connected to the "Ant" terminal of the receiver. For the BLUE and RED bands a .00025 mfd. condenser must be connected in series with the output lead of the signal generator and for the high-frequency band a 400 ohm carbon resistor should be used in place of the condenser.

Each band should first be shunt aligned and then series aligned, where provision is made for series alignment (BLUE band). The band selector switch should be set for the band being aligned and the station selector and signal generator should be set to the frequency indicated (c) for each adjustment.

(a) Adjust the "Osc" and "ANT" shunt trimmers in the order given for maximum output. Readjust the station selector slightly so that the generator signal is tuned-in with maximum output and then check the adjustments of the "ANT" trimmers. Do NOT READJUST the "OSC" TRIMMER.

NOTE: When shunt aligning the RED and GREEN bands care must be exercised so that the circuits will be aligned on the correct frequency rather than on the image frequency which is approximately 900 kilocycles less than the fundamental. To check on this, increase the output of the signal generator ten times, or more, and try to tune-in the signal both at the generator frequency as indicated on the station selector dial and at approximately 900 kilocycles less than the correct frequency. If the circuits have been properly aligned the signal can be tuned-in at both positions but much stronger at the correct position.

(b) To align the series trimmer (Item 10, Fig. 2) set the signal generator to the frequency indicated (c) and then tune-in this signal with the station selector for maximum output. To obtain the best adjustment for the series trimmer it will be necessary to rotate the station selector back and forth slightly while adjusting the trimmer for maximum output.

(c) Signal Input Frequencies:

	Shunt Alignment	Series Alignment
American Broadcast Band (BLUE)	1700 Kilocycles	600 Kilocycles
Police Band (RED)	6000 Kilocycles	....
High-Frequency Band (GREEN)	18000 Kilocycles	....

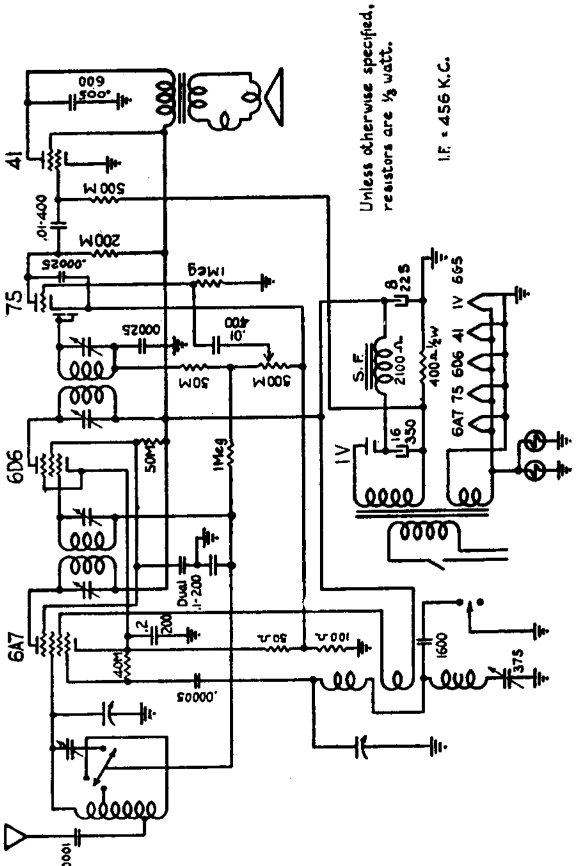
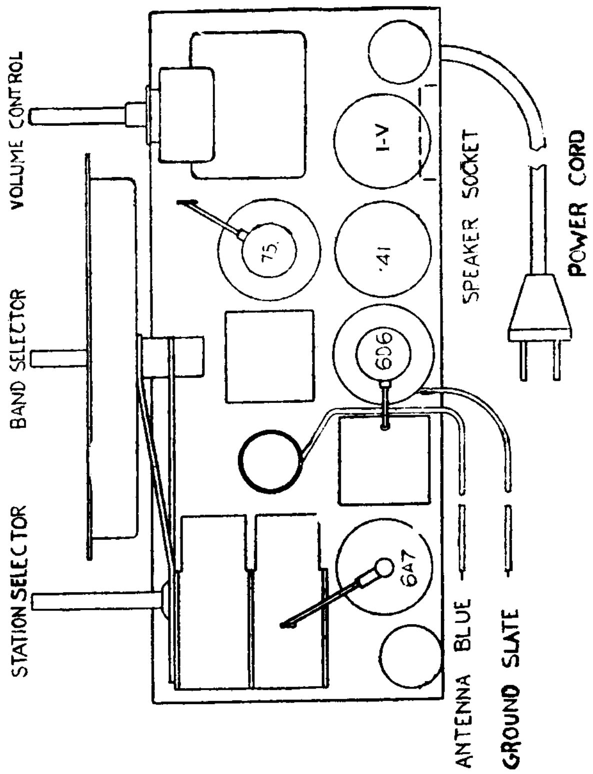
DETROLA RADIO AND TELEVISION CORPORATION

MODEL 149





SERVICE SUGGESTIONS

Be *sure* that antenna and ground connections are made according to instructions.

See that all tubes are in the proper sockets, that they are in good operating condition, and that clips are attached to the small caps on top of those tubes requiring them. Make sure that tube shields are not shorting the clips to the chassis.

Be sure that the Band Selector Switch is in the proper position for the type of reception desired.

See that all plugs are making proper contact. (SEE INSTALLATION NOTES.)

If the receiver remains inoperative after the above suggestions have been tried, TURN THE POWER SWITCH "OFF." Never leave the switch turned on when signs of abnormal heating are present. A minor circuit trouble may cause an expensive repair bill if the set is allowed to run for any length of time after the trouble develops.

Occasionally a loud hum will be heard as stations are tuned in. Reverse the power supply plug. If the hum persists, remove the cause by properly grounding other sets or appliances in the house.

RECEIVER ALIGNMENT

I. F. Alignment

The I.F. frequency of this receiver is 456 K.C. For realignment, use the following procedure.

It is necessary to use an accurately calibrated signal generator. Couple the signal generator to the grid of the 6A7 tube with a tenth microfarad condenser in series with the "high" lead of the signal generator. Connect the ground side of the signal generator to the chassis. Set the signal generator to 456 K.C. Be sure the wave switch of the set is in the broadcast position and the volume control set at maximum. Attenuate the signal generator so that the signal is just audible in the speaker. If an output meter is used, it should be connected across the voice coil terminals of the speaker. Use ½ volt as standard output.

Adjust the 2nd I.F. transformer first. Each screw should be adjusted for maximum output. After number two I.F. has been adjusted, number one I.F. should be adjusted for maximum output. After both transformers have been adjusted, it is necessary to recheck No. 2 transformer and then recheck No. 1.

See TUBE LAYOUT for location of I.F. and R.F. trimmers and padder.

R. F. Alignment

To align the broadcast band, proceed as follows: First, connect the ground side of the signal generator to the chassis. Connect the high side of the signal generator with a .00025 condenser, in series, to the antenna lead of the set. Make sure the band switch of the set is in the broadcast position. Set the volume control to maximum. Turn the station selector to the highest frequency (as far as it will go). Set the signal generator to 1720 K.C. Adjust the oscillator trimmer until the signal is heard. After the oscillator has been set at 1720 K.C., turn the station selector to 1400 K.C. Set the signal generator to 1400 K.C. When the signal is heard, adjust the first detector trimmer for maximum output.

When the set has been adjusted at 1400 K.C., turn the station selector dial to 600 K.C. Set the signal generator to 600 K.C. When the signal is heard, adjust the padder condenser by rocking the selector back and forth. While adjusting the padder screw, it is necessary to move the selector so that the signal may be kept in tune while adjusting the padder screw. This procedure should be followed until maximum output is obtained.

The foregoing procedure should be repeated. That is, the set is to be rechecked at 1720, 1400 and 600 K.C.

When aligning the R.F., use the same output standard as was used on the I.F. alignment.

Short Wave Alignment

Turn the band selector switch of the set to short wave. Set the signal generator to 6000 K.C. Connect a 400 ohm resistor in series with the .00025 condenser. Tune the set until the signal is heard. If two signals are heard, always align to the highest frequency heard on the receiver. Adjust the small trimmer on the antenna coil for maximum output.

SERVICE SUGGESTIONS

Be *sure* that antenna and ground connections are made according to instructions.

See that all tubes are in the proper sockets, that they are in good operating condition, and that clips are attached to the small caps on top of those tubes requiring them. Make sure that tube shields are not shorting the clips to the chassis.

Be sure that the Band Selector Switch is in the proper position for the type of reception desired.

If the receiver remains inoperative after the above suggestions have been tried, TURN THE POWER SWITCH "OFF." Never leave the switch turned on when signs of abnormal heating are present. A minor circuit trouble may cause an expensive repair bill if the set is allowed to run for any length of time after the trouble develops.

Occasionally a loud hum will be heard as stations are tuned in. Reverse the power supply plug. If the hum persists, remove the cause by properly grounding other sets or appliances in the house.

RECEIVER ALIGNMENT

WARNING — This information is to be used by competent service men only. This information is not to be used by an untrained person.

I. F. Alignment

The I.F. frequency of this receiver is 456 K.C. For realignment, use the following procedure.

It is necessary to use an accurately calibrated signal generator. Couple the signal generator to the grid of the 6A7 tube with a tenth microfarad condenser in series with the "high" lead of the signal generator. Connect the ground side of the signal generator to the chassis. Set the signal generator to 456 K.C. Be sure the wave switch of the set is in the broadcast position and the volume control set at maximum. Attenuate the signal generator so that the signal is just audible in the speaker. If an output meter is used, it should be connected across the voice coil terminals of the speaker. Use ½ volt as standard output.

Adjust the 2nd I.F. transformer first. Each screw should be adjusted for maximum output. After number two I.F. has been adjusted, number one I.F. should be adjusted for maximum output. After both transformers have been adjusted, it is necessary to recheck No. 2 transformer and then recheck No. 1.

See TUBE LAYOUT for location of I.F. and R.F. trimmers and padder.

R. F. Alignment

To align the broadcast band, proceed as follows:

First, connect the ground side of the signal generator to the chassis. Connect the high side of the signal generator with a .00025 condenser, in series, to the antenna lead of the set. Make sure the band switch of the set is in the broadcast position. Set the volume control to maximum. Turn the station selector to the highest frequency (as far as it will go). Set the signal generator to 1720 K.C. Adjust the oscillator trimmer until the signal is heard. After the oscillator has been set at 1720 K.C., turn the station selector to 1400 K.C. Set the signal generator to 1400 K.C. When the signal is heard, adjust the first detector trimmer for maximum output.

When the set has been adjusted at 1400 K.C., turn the station selector dial to 600 K.C. Set the signal generator to 600 K.C. When the signal is heard, adjust the padder condenser by rocking the selector back and forth. While adjusting the padder screw, it is necessary to move the selector so that the signal may be kept in tune while adjusting the padder screw. This procedure should be followed until maximum output is obtained.

The foregoing procedure should be repeated. That is, the set is to be rechecked at 1720, 1400 and 600 K.C.

When aligning the R.F., use the same output standard as was used on the I.F. alignment.

Short Wave Alignment

Turn the band selector switch of the set to short wave. Set the signal generator to 6000 K.C. Connect a 400 ohm resistor in series with the .00025 condenser. Tune the set until the signal is heard. If two signals are heard, always align to the highest frequency heard on the receiver. Adjust the small trimmer on the antenna coil for maximum output.

*Item number indicates article on schematic diagram.

EMERSON RADIO AND PHONOGRAPH CORPORATION

MODELS L, L117, L122, L133, L135 & L141

Voltage rating .... 105 to 125 volts, a.c.
Current drain .... 0.5 amps.
Frequency range .... 540 to 1750 kc, 2200 to 7500 kc.

GENERAL NOTES

1. The receiver should never be turned on with either the speaker plug or the 41 tube out of its respective socket, since the rapid rise in rectifier voltage will damage the electrolytic condenser.
2. When replacing the chassis in the cabinet take precautions to keep any part of the dial and condenser assembly from touching the cabinet, otherwise microphonism will result.
3. The color coding of the i-f transformers is as follows:
   Grid—green / Grid return—black
   B plus—red / Plate—blue
4. The color coding of the power transformer is as follows:
   Primary—two black leads
   High-voltage secondary—two red leads
   High-voltage secondary center tap—red and yellow lead
   6.3 volt secondary—two green leads
   5 volt secondary—two yellow leads.
5. The adjustable padding condenser for the broadcast band is mounted underneath the chassis (in the corner near the wave-band switch) with the screw adjustment accessible through a hole in the top of the chassis. The short-wave band has a fixed padder which is a 1350 mmf molded mica condenser. (Note that this condenser is coded 1300 mmf.) When replacing this fixed padder be careful to use a condenser which has a capacity within 2% of 1350 mmf, otherwise the short-wave coils may not track.
6. With a few exceptions, the color coding of the general wiring is as follows:
   Plate—blue / Cathode—white or yellow
   B plus—red / Grid—green
   Screen—brown / Fil. and ground—black.

VOLTAGE ANALYSIS

Readings should be taken with a 1000 ohms-per-volt meter. Voltages listed below are from point indicated to ground (chassis). Line voltage for these readings was 117.5 volts, 60 cycles, a.c.

Tube	Plate	Screen	Cathode	Osc. Plate	Fil.
6A7	255	90	3.5	170	6.3 a.c.
6D6	255	90	3.5	—	6.3 a.c.
35	37	—	5.5	—	6.3 a.c.
41	240	255	15.0	—	6.3 a.c.

B plus at filament of 80 tube—325 volts
Voltage across speaker field—70 volts.

ADJUSTMENTS

An oscillator with frequencies of 456, 600, 1600 and 6000 kc should be used.
An output meter should be used across the voice coil or output transformer for observing maximum response.
If the circuit is at all disturbed, both the broadcast and short-wave bands must be realigned.

Location of Coils and Trimmer Adjustments

The two i-f transformers are located on top of the chassis deck. The second i-f is the one directly behind the variable condenser. The four trimmers, two for each transformer, are accessible through holes in the tops of the cans.

The 456 kc wave trap is located on top of the chassis deck between the 6A7 tube and the first i-f transformer.

The adjustable padding condenser for the broadcast band is mounted underneath the chassis (in the corner near the 6A7 tube) with the screw adjustment accessible through a hole in the top of the chassis.

The antenna coils for the broadcast and short-wave bands are wound on one form and mounted underneath the chassis deck directly behind the adjustable padding condenser. The trimmers for these coils are also accessible through holes in the top of the chassis. The trimmer nearest the front of the chassis is the short-wave antenna trimmer. The trimmer farthest from the front of the chassis is the broadcast antenna trimmer.

The oscillator coils for the broadcast and short-wave bands are wound on one form and mounted underneath the chassis deck near the variable condenser. The trimmers for these coils are accessible through holes in the top of the chassis. The trimmer nearest the front of the chassis is for the short-wave oscillator coil and the trimmer farthest from the front is for the broadcast oscillator coil.

I-f and Wave-trap Alignment

Rotate the wave-band switch to the broadcast position, clockwise. Set the variable condenser at the minimum capacity position and feed 456 kc to the grid cap of the 6A7 tube. Adjust the four i-f trimmers for maximum response. Feed 456 kc to the antenna lead and adjust the wave-trap trimmer (mounted on wave-trap) for *minimum response.*

Short-wave Alignment (Alignment of the short-wave band should precede broadcast alignment)

Use a 400 ohm dummy antenna (a 400 ohm resistor in series with the test oscillator antenna lead) in aligning the short-wave coils. Rotate the wave-band switch to the short-wave position (counter-clockwise) and set the dial pointer exactly at 6 megacycles. Feed 6000 kc and adjust the short-wave oscillator trimmer (closest to front beside the variable condenser) for maximum response and then adjust the antenna trimmer (left side of top of chassis, closest to front). Be very careful to choose the minimum capacity peak on the oscillator trimmer. (See General Instructions below.)

Broadcast Alignment

Use a standard dummy antenna in aligning the broadcast coils. (A .0002 condenser may be used as a substitute.) Rotate the wave-band switch to the broadcast position, clockwise. Set the dial pointer at 600 and feed 600 kc. Adjust the broadcast series padder (in corner near 6A7 tube) for maximum response. Move the dial pointer to 1600 and feed 1600 kc. Adjust the broadcast oscillator trimmer (farthest from front beside the variable condenser) for maximum response and then adjust the broadcast antenna trimmer (farthest from front at left side of chassis). Return pointer to 600, feed 600 kc and readjust the broadcast series padder, rocking the variable condenser (rotate the variable condenser shaft back and forth through a small arc) for maximum response.

GENERAL INSTRUCTIONS

The set's oscillator is higher in frequency than the signal, so images should be observed on the low frequency side of the signals.

Always choose the minimum capacity peak on oscillator trimmers and maximum capacity peaks on antenna trimmers. The last motion in adjusting trimmers should always be a tightening one, not a loosening one.

Never leave a trimmer with the outside plate so loose that there is no tension on the screw. Either bend the plate up or remove the screw entirely.

Always use as weak a test signal as possible during alignment.

MODELS U6F, 107 & 111 "CHASSIS U6F"

Voltage rating .... 105-130 volts ac-dc
Current drain .... 0.43 amps.
Frequency ranges .... 540 to 1660 kc, 1580 to 4750 kc, 5.5 to 16 mc.

GENERAL NOTES

1. To take the chassis out of the Model 107 cabinet first remove the knobs (knobs are of push-on type), and then the cabinet bottom. Remove the two wood screws and four nuts holding the chassis to the cabinet. With the receiver bottom side up, slide the chassis towards the back and lift out of cabinet.
2. If replacements are made or the wiring disturbed in the r-f section of the circuit, the receiver should be carefully realigned.
3. The filament dropping resistor, part number 2LR-212, is of the cylindrical plug-in type and is located on top of the chassis between the 6H6 and 25Z5 tubes.
4. The output transformer, part no. 2LT-221 (T9 on schematic diagram) and the filter choke, part no. 2CT-207A (L2 on schematic diagram) are located in the square can on top of the chassis to the left of the speaker.

VOLTAGE ANALYSIS

Readings should be taken with a 1000 ohms-per-volt meter. Voltages listed below are from point indicated to the cathode of the 43 tube (B minus). Line voltage for these readings was 117.5 volts, 60 cycles, a.c.

Tube	Plate	Screen	Cathode	Osc. Plate	Fil.
6A7	99	43	1.1	80	6.3
6K7	99	80	1.8	—	6.3
6H6	—	—	0	—	6.3
6F5	50	—	0	—	6.3
43	87	99	0	—	24

Voltage across speaker field (black and yellow leads)—120
Voltage across filter choke—9.5

The 250 ohm bias resistor, R16 and R17 on schematic diagram, is located underneath the chassis deck near the volume control.

Voltage across the two outside terminals of this resistor—11.5
Voltage from cathode of 43 tube to central terminal of resistor—1.0

ADJUSTMENTS

An oscillator with frequencies of 456, 600, 1600, 1700, 4500 and 15,000 kc should be used. In addition, an output meter should be used across the voice coil or output transformer for observing maximum response.

I-f and Wave-trap Alignment

The i-f transformers are located on the top of the chassis. The four trimmers, two for each i-f transformer, are located at the tops of the cans. Set the wave-band switch to broadcast (extreme clockwise position) and rotate variable condenser to minimum capacity. Feed 456 kc to grid of the 6A8 tube and adjust the four i-f trimmers for maximum response. Then feed 456 kc through the antenna and adjust the wave-trap trimmer for *minimum response.* The trimmer is on the wave-trap, which is located on top of the chassis behind the speaker. This reduces telegraphic code interference.

Location of Coils

The antenna coils for the three bands are wound on one form and mounted on the top of the chassis to the right of the speaker. The three trimmers for these coils are mounted on the bakelite strip fastened to the coil form. The upper trimmer is for the short-wave coil, the central trimmer for the police coil and the lower trimmer for the broadcast coil.

The oscillator coils for the three bands are wound on one form and mounted underneath the chassis deck on the right-hand wall with the trimmers facing out. The trimmer screws are available through three holes in the chassis wall. The trimmer closest to front is for the broadcast oscillator coil, the central trimmer is for the police oscillator coil and the trimmer furthest from front is for the short-wave oscillator coil.

The adjusting screws for the dual padder are also available at the right-hand chassis wall. The screw closer to the front is for the broadcast band and the other is for the police band. The short-wave band has no adjustable padder.

Broadcast Alignment

Set the wave-band switch to broadcast position (extreme clockwise) and dial pointer to 600. Feed 600 kc through antenna lead and adjust broadcast padder (lower row on right wall, closest to front) for maximum response. Set pointer to 1600, feed 1600 kc and adjust the broadcast oscillator trimmer (top row on right wall, closest to front) for maximum response, and then the broadcast antenna trimmer (on antenna coil, lower trimmer). Return pointer to 600 and rock the variable condenser (rotate condenser back and forth through small arc) while adjusting the broadcast padder for maximum response. If a readjustment is necessary return to 1600 and realign the antenna and oscillator trimmers.

Police Alignment

Set the wave-band switch to police (central position), pointer to 1700 and feed 1700 kc through antenna lead. Adjust police band padder (furthest from front on right wall, lower row) for maximum response. Set pointer to 4500 and feed 4500 kc. Adjust police band oscillator trimmer (central trimmer on right wall, upper row) for maximum response. If two peaks are heard, select the one of minimum capacity (see General Instructions below). Then adjust police band antenna trimmer (central one on top) for maximum response, selecting the peak of maximum capacity. Again feed 1700 kc, with pointer at 1700, rock variable condenser and adjust police band padder for maximum response. Realign at 4500 if necessary.

Short-wave Alignment

Set wave-band switch to short-wave (counter-clockwise) position and pointer at 15 megacycles. Feed 15,000 kc through antenna. Adjust short-wave oscillator trimmer (furthest from front on right wall, top row) for maximum response. If two peaks are obtained, select the one of minimum capacity. Adjust the short-wave antenna trimmer (upper trimmer on antenna coil) for maximum response while rocking the variable condenser.

Check all three bands for dead spots or incorrect image responses.

General Instructions

The set's oscillator is higher in frequency than the signal on all three bands. Images, therefore, should be observed on the low-frequency side of the signals.

Always choose the minimum capacity peak on oscillator trimmers and maximum capacity peak on the antenna trimmers. The last motion in adjusting trimmers should always be a tightening one.

Never leave a trimmer with the outside plate so loose that there is no tension on the screw. Either bend the plate up or remove the screw entirely. Loose screws are a source of noise, frequency drift and microphonism.

In aligning antenna trimmers on the high-frequency signals there is usually a tendency for the oscillator to drift, due to interlocking. To compensate for this, always keep re-tuning the variable condenser.

When ordering replacement parts specify part number.

*Item number locates the article on the schematic diagram.

‡ In the Model L150, C28 and C29 are dry electrolytic condensers as follows:
C29—12 mf, 450 volt dry electrolytic condenser 1.60
C28—8 mf, 450 volt dry electrolytic condenser 1.35

† These trimmers are part of coil assemblies and can not be supplied separately.

PRODUCTION CHANGES

In receivers bearing serial numbers below 961,900:

a. The two primaries of the antenna coil T1 were in parallel from antenna to ground, and a 0.00005 mf mica condenser was in series with the antenna lead and the short-wave primary.

b. C17 was an 0.00135 mf mica condenser.

EMERSON RADIO AND PHONOGRAPH CORPORATION

MODELS L, L117, L122, L133, L135 & L141 "BELOW SERIAL № 895,962"

These service notes apply only to receivers bearing serial numbers below 895,962. Different service notes are available for receivers bearing serial numbers above 895,962.

Voltage rating .... 105 to 125 volts, a.c.
Current drain .... 0.5 amps.
Frequency range .... 540 to 1750 kc, 2200 to 7500 kc.

GENERAL NOTES

1. The receiver should never be turned on with either the speaker plug or the 41 tube out of its respective socket, since the rapid rise in rectifier voltage will damage the electrolytic condenser.
2. When replacing the chassis in the cabinet take precautions to keep any part of the dial and condenser assembly from touching the cabinet, otherwise microphonism will result.
3. The color coding of the i-f transformers is as follows:
   Grid—green; Grid return—black
   B plus—red; Plate—blue
4. The color coding of the power transformer is as follows:
   Primary—two black leads
   High-voltage secondary—two red leads
   High-voltage secondary center tap—red and yellow lead
   6.3 volt secondary—two green leads
   5 volt secondary—two yellow leads.
5. The adjustable padding condenser for the broadcast band is mounted underneath the chassis (in the corner near the wave-band switch) with the screw adjustment accessible through a hole in the top of the chassis. The short-wave band has a fixed padder which is a 1350 mmf molded mica condenser. (Note that this condenser is coded 1300 mmf.) When replacing this fixed padder be careful to use a condenser which has a capacity within 2% of 1350 mmf, otherwise the short-wave coils may not track.
6. With a few exceptions, the color coding of the general wiring is as follows:
   Plate—blue; Cathode—white or yellow
   B plus—red; Grid—green
   Screen—brown; Fil. and ground—black.

VOLTAGE ANALYSIS

Readings should be taken with a 1000 ohms-per-volt meter. Voltages listed below are from point indicated to ground (chassis). Line voltage for these readings was 117.5 volts, 60 cycles, a.c.

Tube	Plate	Screen	Cathode	Osc. Plate	Fil.
6A7	255	90	3.5	170	6.3 a.c.
6D6	255	90	3.5	—	6.3 a.c.
85	37	—	5.5	—	6.3 a.c.
41	240	255	15.0	—	6.3 a.c.

B plus at filament of 80 tube—325 volts
Voltage across speaker field—70 volts.

ADJUSTMENTS

An oscillator with frequencies of 456, 600, 1600 and 6000 kc should be used.
An output meter should be used across the voice coil or output transformer for observing maximum response.
If the circuit is at all disturbed, both the broadcast and short-wave bands must be realigned.

Location of Coils and Trimmer Adjustments

The two i-f transformers are located on top of the chassis deck. The second i-f is the one directly behind the variable condenser. The four trimmers, two for each transformer, are accessible through holes in the tops of the cans.

The 456 kc wave trap is located on top of the chassis deck between the 6A7 tube and the first i-f transformer.

The adjustable padding condenser for the broadcast band is mounted underneath the chassis (in the corner near the 6A7 tube) with the screw adjustment accessible through a hole in the top of the chassis.

The antenna coils for the broadcast and short-wave bands are wound on one form and mounted underneath the chassis deck directly behind the adjustable padding condenser. The trimmers for these coils are also accessible through holes in the top of the chassis. The trimmer nearest the front of the chassis is the short-wave antenna trimmer. The trimmer farthest from the front of the chassis is the broadcast antenna trimmer.

The oscillator coils for the broadcast and short-wave bands are wound on one form and mounted underneath the chassis deck near the variable condenser. The trimmers for these coils are accessible through holes in the top of the chassis. The trimmer nearest the front of the chassis is for the short-wave oscillator coil and the trimmer farthest from the front is for the broadcast oscillator coil.

I-f and Wave-trap Alignment

Rotate the wave-band switch to the broadcast position, clockwise. Set the variable condenser at the minimum capacity position and feed 456 kc to the grid cap of the 6A7 tube. Adjust the four i-f trimmers for maximum response. Feed 456 kc to the antenna lead and adjust the wave-trap trimmer (mounted on wave-trap) for *minimum response.*

Short-wave Alignment (Alignment of the short-wave band should precede broadcast alignment)

Use a 400 ohm dummy antenna (a 400 ohm resistor in series with the test oscillator antenna lead) in aligning the short-wave coils. Rotate the wave-band switch to the short-wave position (counter-clockwise) and set the dial pointer exactly at 6 megacycles. Feed 6000 kc and adjust the short-wave oscillator trimmer (closest to front beside the variable condenser) for maximum response and then adjust the antenna trimmer (left side of top of chassis, closest to front). Be very careful to choose the minimum capacity peak on the oscillator trimmer. (See General Instructions below.)

Broadcast Alignment

Use a standard dummy antenna in aligning the broadcast coils. (A .0002 condenser may be used as a substitute.) Rotate the wave-band switch to the broadcast position, clockwise. Set the dial pointer at 600 and feed 600 kc. Adjust the broadcast series padder (in corner near 6A7 tube) for maximum response. Move the dial pointer to 1600 and feed 1600 kc. Adjust the broadcast oscillator trimmer (farthest from front beside the variable condenser) for maximum response and then adjust the broadcast antenna trimmer (farthest from front at left side of chassis). Return pointer to 600, feed 600 kc and readjust the broadcast series padder, rocking the variable condenser (rotate the variable condenser shaft back and forth through a small arc) for maximum response.

GENERAL INSTRUCTIONS

The set's oscillator is higher in frequency than the signal, so images should be observed on the low frequency side of the signals.

Always choose the minimum capacity peak on oscillator trimmers and maximum capacity peaks on antenna trimmers. The last motion in adjusting trimmers should always be a tightening one, not a loosening one.

Never leave a trimmer with the outside plate so loose that there is no tension on the screw. Either bend the plate up or remove the screw entirely.

Alw[illegible]se as weak a test signal as possible during alignment.

MODELS L, L117, L122, L133, L135 & L141 "ABOVE SERIAL № 895,962"

These service notes apply only to receivers bearing serial numbers above 895,962. Different service notes are available for receivers bearing serial numbers below 895,962.

Voltage rating .... 105 to 125 volts, a.c.
Current drain .... 0.5 amps.
Frequency range .... 540 to 1750 kc, 2200 to 7500 kc.

GENERAL NOTES

1. The receiver should never be turned on with either the speaker plug or the 41 tube out of its respective socket, since the rapid rise in rectifier voltage will damage the electrolytic condenser.
2. When replacing the chassis in the cabinet take precautions to keep any part of the dial and condenser assembly from touching the cabinet, otherwise microphonism will result.
3. The color coding of the i-f transformers is as follows:
   Grid—green; Grid return—black
   B plus—red; Plate—blue
4. The color coding of the power transformer is as follows:
   Primary—two black leads
   High-voltage secondary—two red leads
   High-voltage secondary center tap—red and yellow lead
   6.3 volt secondary—two green leads
   5 volt secondary—two yellow leads.
5. The adjustable padding condenser for the broadcast band is mounted underneath the chassis (in the corner near the wave-band switch) with the screw adjustment accessible through a hole in the top of the chassis. The short-wave band has a fixed padder which is a 1800 mmf molded mica condenser. When replacing this fixed padder be careful to use a condenser which has a capacity within 2% of 1800 mmf, otherwise the short-wave coils may not track.
6. With a few exceptions, the color coding of the general wiring is as follows:
   Plate—blue; Cathode—white or yellow
   B plus—red; Grid—green
   Screen—brown; Fil. and ground—black.

VOLTAGE ANALYSIS

Readings should be taken with a 1000 ohms-per-volt meter. Voltages listed below are from point indicated to ground (chassis). Line voltage for these readings was 117.5 volts, 60 cycles, a.c.

Tube	Plate	Screen	Cathode	Osc. Plate	Fil.

ALIGNMENT PROCEDURE CHART

ALIGNMENT

The model 5A is a five-tube AC operated, superhetrodyne. Alignment is given below in chart form. Make adjustments in the order given. The output meter may be any low range AC voltmeter, preferably about 0-15 volts. It should be connected from the plate of the 6F6G tube to ground with a .1 mfd. condenser in series with one of the leads. When the hand tends to go off scale, reduce the input from the signal generator and keep the volume control at maximum. Inaccurate alignment is likely to result if too strong a signal is used.

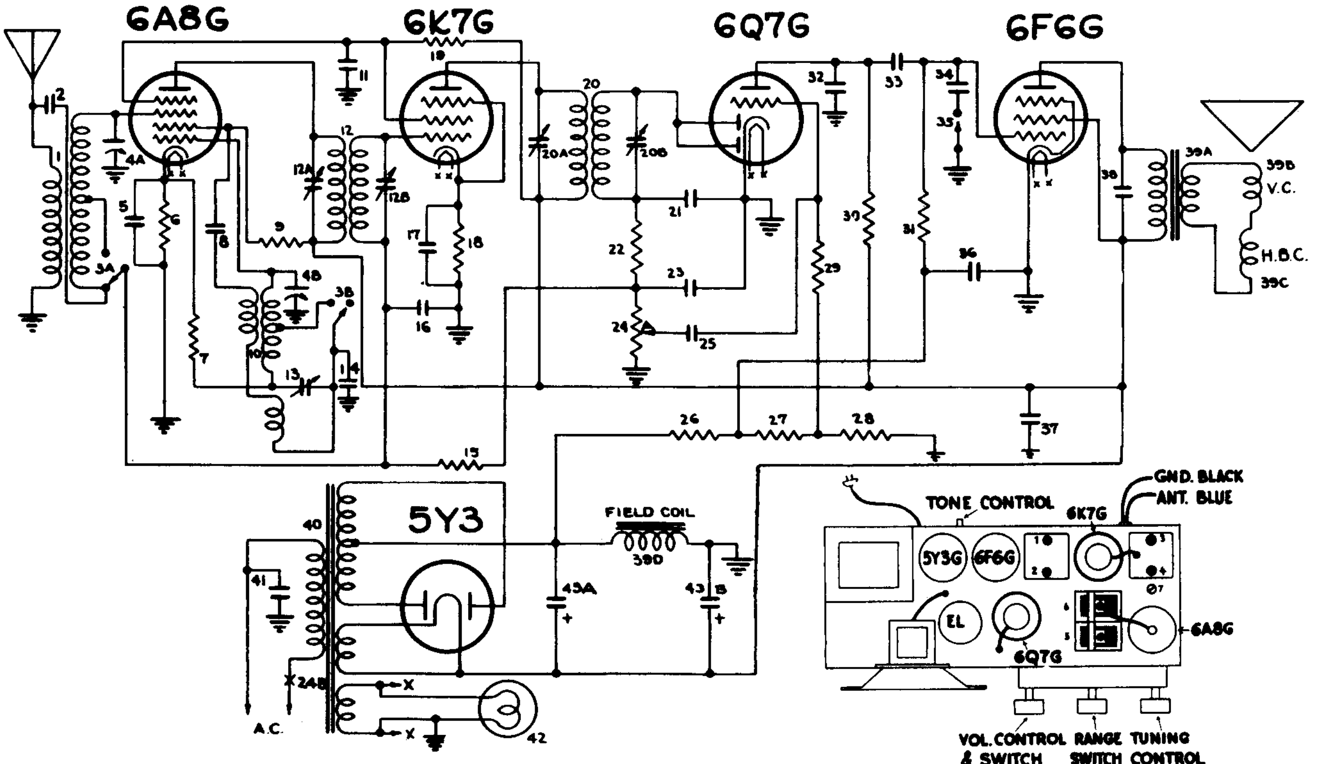
MODEL 5B



TOP VIEW OF CHASSIS SHOWING LOCATION OF TRIMMERS AND TUBES AS WELL AS OTHER COMPONENT PARTS

ALIGNMENT

The model 5B is a five-tube AC operated, superhetrodyne. It is capable of receiving signals on the standard broadcast band, 540 to 1750 kilocycles, and on the police-amateur band, 2.35 to 7.8 megacycles.

Alignment procedure is given below in chart form. Make adjustments in the order given. The output meter may be any low range AC voltmeter, preferably about 0-15 volts. It should be connected from the plate of the 6F6G tube to ground with a .1 mfd. condenser in series with one of the leads. When the hand tends to go off scale, reduce the input from the signal generator and keep the volume control at maximum. If too 'trong a signal is fed to the receiver and the volume control is used to keep the output meter hand on scale, the A.V.C. will operate and inccurate alignment will result.

THE CIRCUIT

Models 51, 52, and 53 are 5 tube superheterodynes. The circuits are very similar, the only differences being those made necessary in order to cover different wave bands. These sets are in many ways a radical departure from conventional design. Maximum performance with a minimum number of tubes is accomplished thru the use of new multi-purpose tubes and new type, high efficiency, I. F. transformers. Due to the use of a high impedance primary, a litz wire secondary, and a wave trap, very good pre-selection and high gain are obtained in the tuned antenna stage. The antenna circuit is fed into a 2A7 which serves the triple purpose of R. F. amplifier, electron coupled oscillator, and first detector. The I. F. output of this tube is fed into the double tuned, first I. F. transformer and from there into the 58 I. F. amplifier. The output of this tube is fed into the second, double tuned, I. F. transformer. The output of this transformer is fed into the 2A6 where three functions are accomplished. Detection, automatic volume control, and audio amplification. The A. F. output of this tube is resistance coupled to the grid circuit of the 2A5, high gain, output tube from where it is transfered to the loudspeaker. A familiar type 80 rectifier is used in a conventional power supply circuit.

WAVE BANDS

The model 51 chassis is a standard broadcast receiver covering a frequency range of 540 to 1725 kilocycles. The model 52 is a dual band chassis covering frequency ranges of 540 to 1700 kilocycles and 1600 to 3500 kilocycles. The model 53 is a split band chassis covering frequency ranges of 540 to 1725 kilocycles and 5 to 16.5 megacycles.

SUGGESTED SERVICE PROCEDURE

If the set does not operate test all tubes. If no tube tester is available replace the tubes in the set, one by one, with tubes known to be good. A noisy tube cannot always be found by checking in a tube tester, however by sharply tapping each of the tubes in the set the bad tube can usually be located.

If, after replacing any defective tubes, the set is still inoperative follow the instructions given under Resistance and voltage analysis.

ALIGNMENT PROCEDURE

Proper adjustment of the tuned circuits will only be possible thru the use of a good service oscillator and output meter.

The gang condenser plates are properly adjusted in the factory and under no condition should it be necessary to bend them.

All adjustments should be made with the volume control full "on". The wave band switch on models 52 and 53 should be in the broadcast position.

1. Supply a 456 kilocycle signal to the grid of the 2A7 thru a .00005 Mfd. condenser. Carefully adjust both trimmers on the first I. F. transformer. The center screw will peak the grid side and the hexagon nut will peak the plate side. **Next adjust the second I. F. transformer in the same manner. Since these adjustments are very critical it is advisable to go back over them to make sure they are correct.**

2. Turn the gang condenser until it is fully meshed. The dial should read 540 kilocycles, if it is incorrect loosen the set screw and move the dial until the reading is correct.

3. Supply a 1500 kilocycle signal from the test oscillator to the antenna of the set. Tune the set until the dial reads 1500 kilocycles. Adjust the trimmer on the oscillator section of the gang condenser (front section) until the signal comes in at 1500 on the dial. Adjust the trimmer on the R. F. section, of the gang condenser, for maximum output with minimum input from the service oscillator. Some sets do not have a trimmer on the oscillator section and in this case it will only be necessary to adjust the R. F. trimmer for maximum output with the set tuned to the correct frequency reading.

4. On the model 53 a low frequency padding condenser will be found located on the front of the chassis. To adjust this condenser tune the set and the service oscillator to 600 kilocycles. Adjust the padding condenser for maximum output at the same time tune the set back and forth across the 600 kilocycle signal to make sure the correct peak is obtained.

5. If all adjustments have been carefully made the dial readings will be approximately correct on all frequencies If not it will be necessary to go over the entire procedure again.

6. On models 51 and 53 it will sometimes be necessary to make high frequency adjustments at 1200 kilocycles rather than 1500 in the event police calls do not come in properly after alignment.

7. On the model 53 a small trimmer condenser will be found under the chassis and connected across the secondary of the short wave R. F. coil. This condenser should be peaked at 16 megacycles. Turn the band selector to the short wave position and tune the set to 16 megacycles. Supply a 16 megacycle signal to the antenna and adjust the trimmer for maximum output. If no oscillator, supplying a 16 megacycle signal, is available it may be possible to pick up the tenth harmonic of the 1500 kilocycle signal (15 megacycles) from a standard service oscillator. If neither is available it will be necessary to use the signal from a short wave station, near 16 megacycles, or adjust for maximum noise level.

RESISTORS

The body color represents the **first figure** of the resistance value.

The end color represents the **second figure** of the resistance value.

The dot color represents the **number of ciphers** following the first two figures.

MICA CONDENSERS

The **first dot** on the condenser represents the **first figure** of the capacity.

The **second dot** on the condenser represents the **second figure** of the capacity.

The **third dot** on the condenser represents the **number of ciphers** following the first two figures.

RESISTANCE AND VOLTAGE ANALYSIS

The following chart gives detailed information regarding the resistance from various points to various other points on the chassis. The measured voltage from the various tube socket contacts to ground is also given. When this chart is faithfully followed little difficulty should be experienced in finding almost any fault that may develop.

Resistance Tests. These tests should be made with an accurate ohm-meter. The speaker should be connected. All tubes should be removed from the set. The volume and tone controls should be full "on". The A. C. line plug must be removed from the A. C. outlet.

Voltage Tests. These readings should be taken with all tubes in their sockets. The volume and tone controls should be full "on". The antenna should be disconnected. Tune the set to a point where no signal is received.

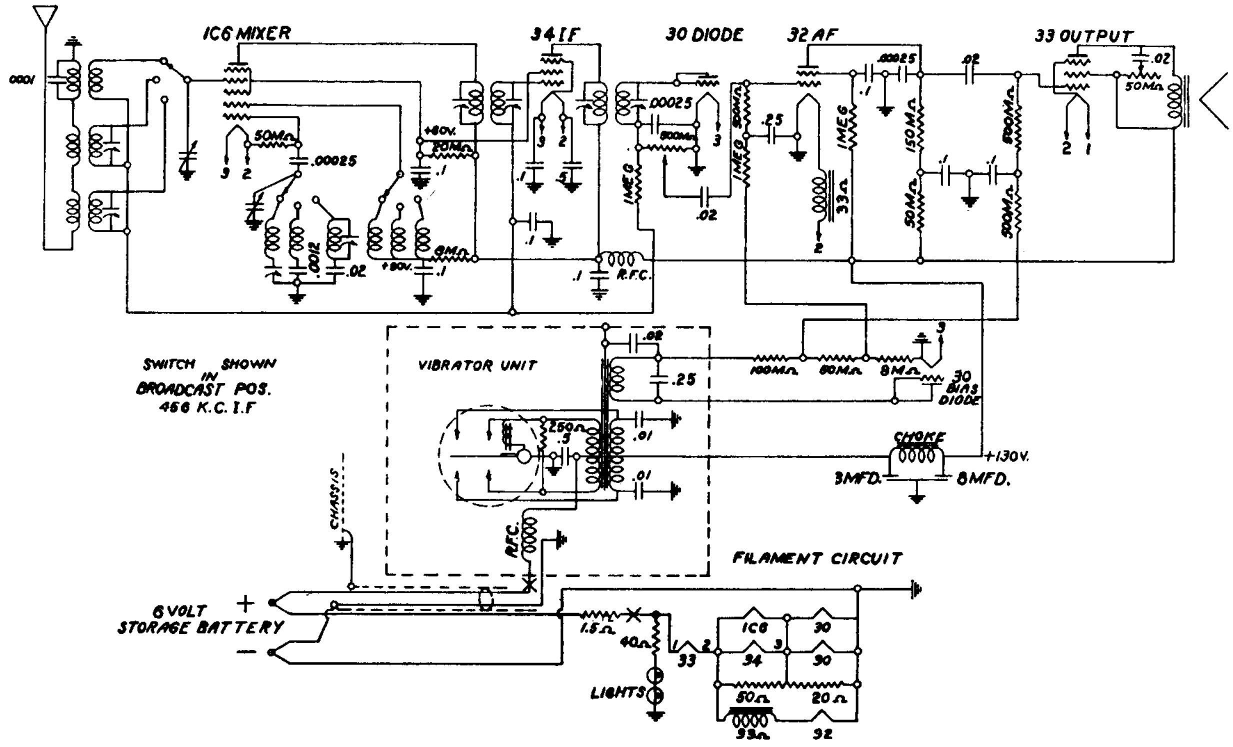
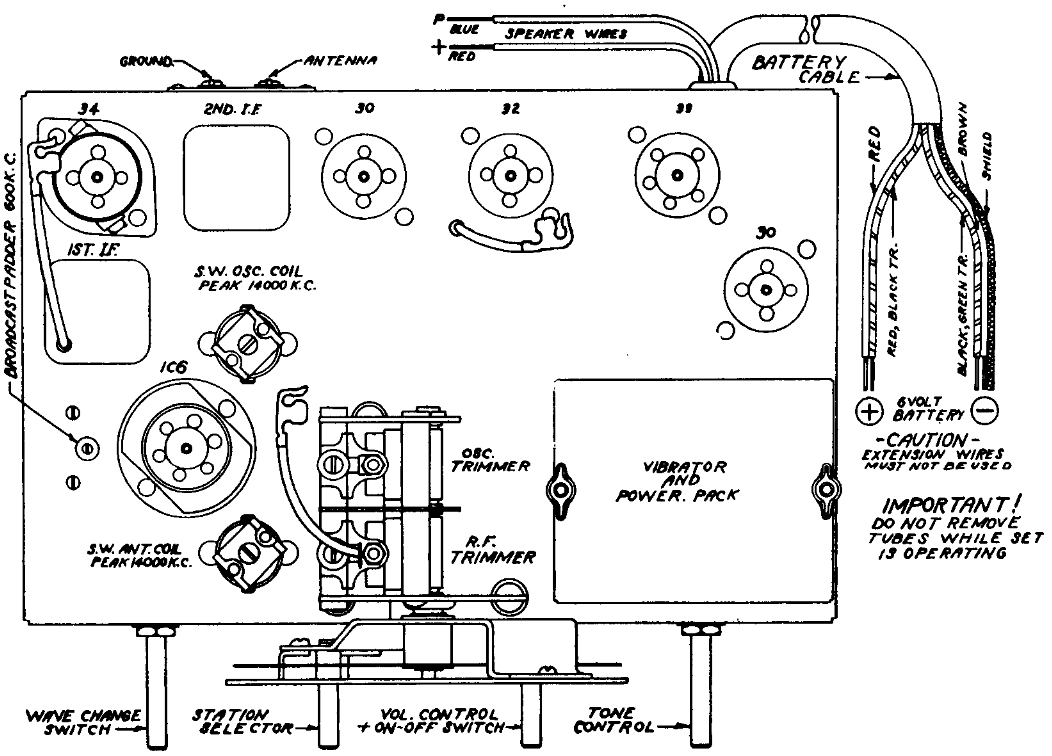
FEDERATED PURCHASER INC.

MODELS 53D & 54D

This receiver is designed to operate over three tuning ranges: the broadcast range which extends from 540 to 1700 Kilocycles (KC) (175 to 550 meters), Police and Aviation Band which extends from 1700 to 5000 Kilocycles (KC) (52 to 175 Meters) and the International Short Wave Band which extends from 5800 to 15,200 Kilocycles (KC) (18.5 to 52 meters). This latter range is the one which includes the four internationally assigned bands —the 19, 25, 31 and 49 meter bands.





FEDERATED PURCHASER INC.
MODELS 53D & 54D
REASONS FOR UNSATISFACTORY OPERATION

FAILURE TO OPERATE 1. Check connections from battery cable to storage battery. If connections are reversed, set will not operate. Proper instructions for connecting the battery are given on the first page.
2. Check all tubes. Have them tested by meter equipped to test the type of tubes used in this receiver.
3. Check tube shields for good ground connections. Check grid caps for good connection. See that grid caps and tube shields are not shorted to each other (touching).
4. Reversed connections on Antenna and ground terminals. Try both ways for best results.
5. Oscillator tube (1C6) not oscillating.
6. Vibrator unit not securely in socket.

HOWLS AND SQUEALS 1. Omitting the use of a ground or poor ground connections.
2. Speaker leads placed near the (32) tube. These leads should be kept away from this locality. Speaker leads should be kept along the end of chassis and front corner of cabinet.
3. Check shield on (34) tube for good connection to chassis.

WINDCHARGERS

There are many types of windchargers now on the market which may be used to advantage for greater economy of receiver operation. Such chargers will pay for themselves over a period of time; by saving the cost of battery recharging; removing the inconvenience of taking the battery to a charging station; non-operation of the receiver during the charging period.

IMPORTANT NOTE: The battery must never be charged while set is in operation. If a windcharger is used, it should always be disconnected from the battery when the receiver is being used. An inexpensive single pole switch can be used for disconnecting the windcharger from the battery. This will increase the life of the tubes and give additional economy to the use of the receiver.

HUM A minimum amount of hum, equivalent to A.C. receivers, may be present. Excessive hum may be traced to the following causes:
1. Omitting the use of a ground or a poor ground connection.
2. Vibrator unit not securely fitted in socket.
3. Antenna picking up interference from high tension power lines.
4. Weak or rundown battery. Battery with defective cell.
5. Poor battery connections.
6. Extending or lengthening battery leads cause an enormous increase in "hum." The battery cable attached to the receiver is of special design and its ends **must** be connected directly to the battery terminals. **(See battery connection data on first page.)**

ALIGNMENT DATA AND SERVICING
INFORMATION FOR THE RADIO SERVICE MAN

GENERAL DATA The alignment of this receiver requires the use of a test oscillator which will cover the frequencies of 456, 600, 1400, 1800, 4000, 6000, and 14,000 KC and an output meter which is to be connected across the primary or secondary of the output transformer. If possible, all alignments should be made with the volume control on maximum and the test oscillator output as low as possible, to prevent the AVC from operating and giving false readings.

CORRECT ALIGNMENT PROCEDURE The intermediate frequency (I.F.) stage should be aligned properly as the first step. After the I.F. transformers have been properly adjusted and peaked, the Broadcast Band should always be the next procedure; after which, either or both of the Short Wave Bands may be aligned.

I.F. ALIGNMENT Adjust the test oscillator to 456 KC and connect the output to the grid of the first detector tube (1C6) through a .05 or .1 mfd. condenser. The ground on the test oscillator can be connected to the chassis ground. Align all four I.F. trimmers to peak or maximum reading on the output meter.

BROADCAST BAND ALIGNMENT Adjust the oscillator to 1400 KC and connect the output to the antenna post marked "A" through a .0001 mfd. mica condenser to give the equivalent of an antenna about 60 feet. Set the receiver pointer to 1400 KC and adjust the rear gang condenser trimmer (oscillator circuit) to peak. After this has been carefully done, the next step is to adjust the front trimmer of the gang condenser to peak. The front condenser section tunes the RF or grid circuit of the 1C6 tube. Next, re-set the dial pointer on the receiver and the test oscillator to 600 KC. Slowly increase or decrease the oscillator padding condenser and at the same time continuously tune back and forth across the signal with the receiver until the maximum reading is obtained on the output meter. This adjustment may seem a little complicated but is the easiest way to adjust the oscillator to the R.F. section. The padding condenser is located on the left hand side of the chassis, directly to the left of the 1C6 tube and in front of the first I.F. transformer. Return to 1400 KC and again go over the adjustments of this frequency to be certain that they were not put slightly out of alignment when adjustment was made at 600 KC.
This completes the correct sequence of operations in properly aligning the receiver for the Broadcast Band, and **must always be done before** attempting to align the Short Wave Bands.

FOREIGN BAND ALIGNMENT The Foreign Band of 19 to 49 meters can be adjusted by the two trimmers on the short wave coils located on the top of the chassis. Set the test oscillator to 14,000 KC. In preparing the test oscillator for alignment of this band, connect a 400 ohm carbon resistor in series with the .0001 mfd. condenser on the output lead of the test oscillator. The oscillator coil is located near the 1st I.F. Transformer and the antenna or R.F. coil is located directly in front of the Short Wave oscillator coil and alongside the front section of the gang condenser. These two trimmers should be adjusted for peak at 14,000 KC and as the inherent design of the circuit has been expressly developed for simplicity in servicing, no other adjustments are necessary for aligning this band. **Note:** Always start this procedure by having the oscillator coil trimmer loose (out all the way), and the antenna coil trimmer fairly tight (in all the way); otherwise it is possible to make a false alignment on the image frequency. In order to prevent alignment on the image frequency, it is suggested, that the following check be made: Readjust the pointer to 13,100 KC where the image frequency should be found. If properly aligned, the image frequency will be found to be weaker. If, however, the signal at 13,100 KC is found to be stronger than the signal at 14,000 KC, it signifies that alignment was incorrectly made on the image frequency.

IMPORTANT: Do not attempt any adjustment of the gang condenser trimmers in aligning the Foreign Band as this will throw the Broadcast Band out of alignment.

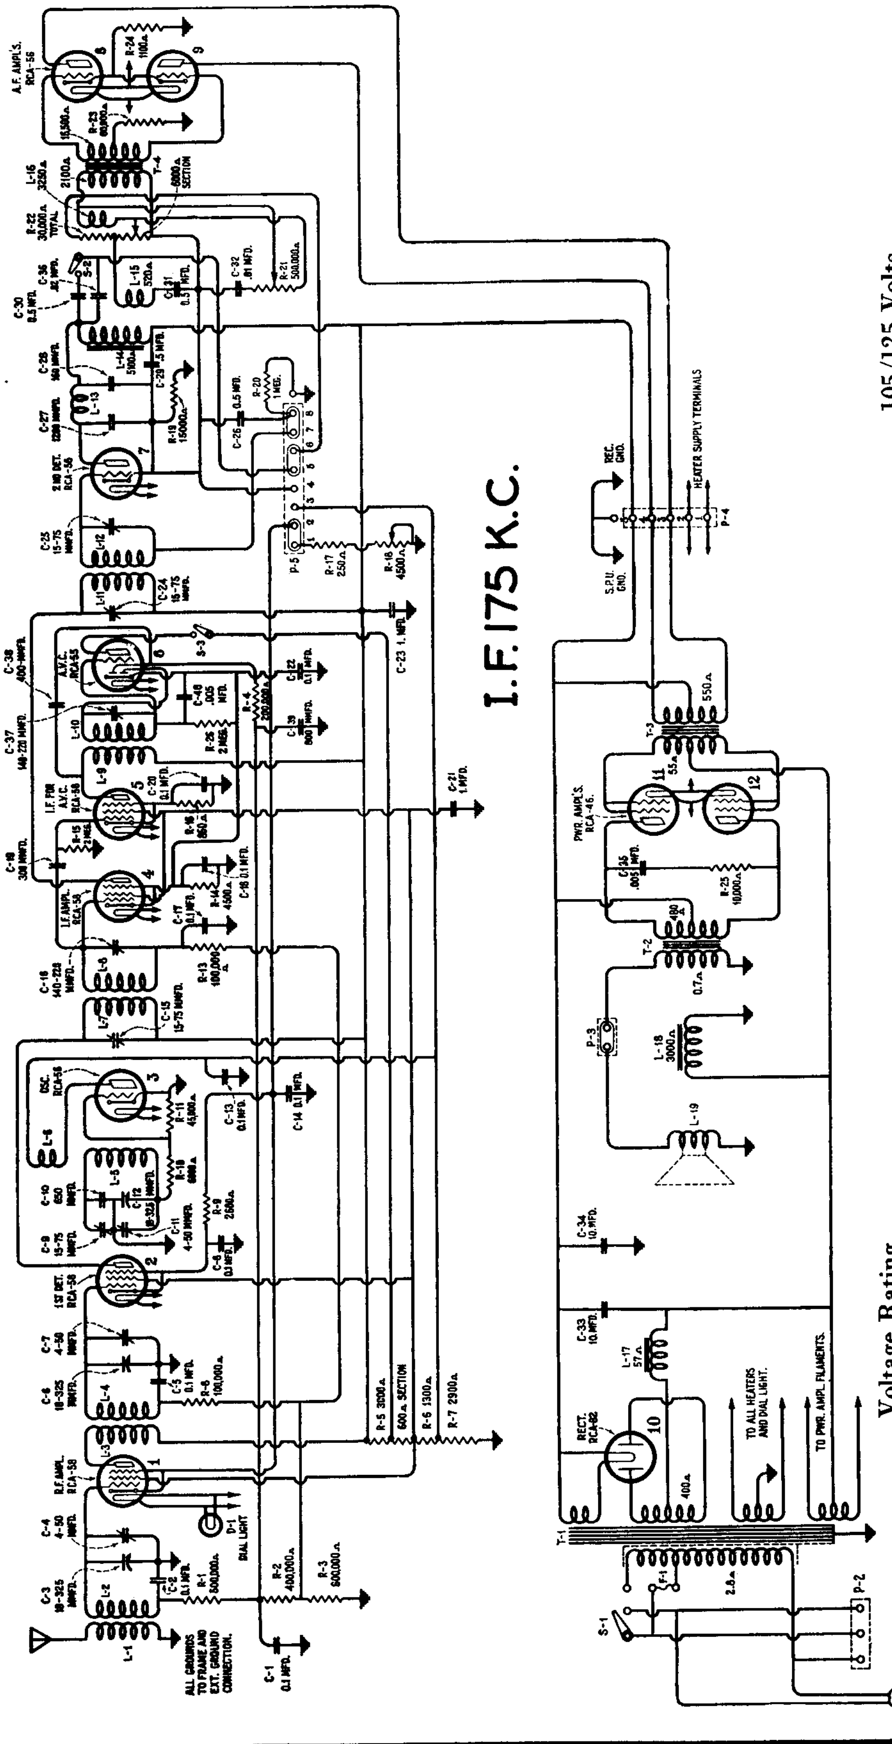
POLICE BAND ALIGNMENT There is only one adjustment to be made in the alignment of the Police Band. Due to the circuit design and correct matching of the coils, no oscillator adjustment is necessary. Set the dial pointer to 4000 KC (also the test oscillator) and adjust the antenna coil trimmer to resonance. In preparing the test oscillator for alignment of this band, connect a 400 ohm carbon resistor in series with the .0001 mfd. condenser on the output lead of the test oscillator. This resistor is used with the test oscillator only on the Short Wave Bands and should not be used for Broadcast Band alignment. The two police band coils are under the chassis and the antenna coil trimmer is mounted on the end of the antenna coil. **Important:** This is the only adjustment necessary for the Police Band. Do not attempt any adjustment of the gang condenser trimmers in aligning the Police Band, otherwise the Broadcast Band will be thrown out of alignment.

SERVICE DATA FOR ALL BANDS

If it is suspected that the oscillator has stopped but is doubtful due to the presence of the usual amount of noise level, it is suggested that the oscillator plate voltage be checked. To ascertain whether the tube is oscillating, ground the oscillator grid of the 1C6 (short stator and rotor plates of oscillator section on gang condenser). If oscillating properly, grounding the grid will cause an appreciable drop in oscillator voltage.

GENERAL ELECTRIC COMPANY

MODEL J-125A



Voltage Rating .... 105/125 Volts
Frequency Rating .... 50/60 Cycles
Power Consumption .... 110 Watts Average
(The input wattage may vary from 70 to 130 watts, depending on the output volume being used)
Recommended Antenna Length .... 25-100 Feet
Type of Circuit .... Super-Heterodyne with A. V. C., Compensated A. F. System, Class "B" Output Stage and Noise Suppressor
Type and Number of Radiotrons . . 1 RCA-55, 4 RCA-58, 4 RCA-56, 2 RCA-46, 1 RCA-82—Total 12
Number of R. F. Stages .... One
Type of First Detector .... Exponential with Control Grid Voltage Varied by A. V. C. Tube
Number of Intermediate Stages .... Two: One for Signal and One for A. V. C.
Type of Second Detector .... Power Grid Bias

GENERAL ELECTRIC COMPANY

MODEL J-125A

Number of A. F. Stages............Two: One Push-Pull Driver and One Class "B" Output

Type of Tone Control............Reactor Capacitor and Variable Resistance for Reducing High Frequency Response

Type of Rectifier............Mercury Vapor Full Wave RCA-82

Undistorted Output............Approximately 20 Watts Maximum

GENERAL ELECTRIC COMPANY

MODEL J-125A

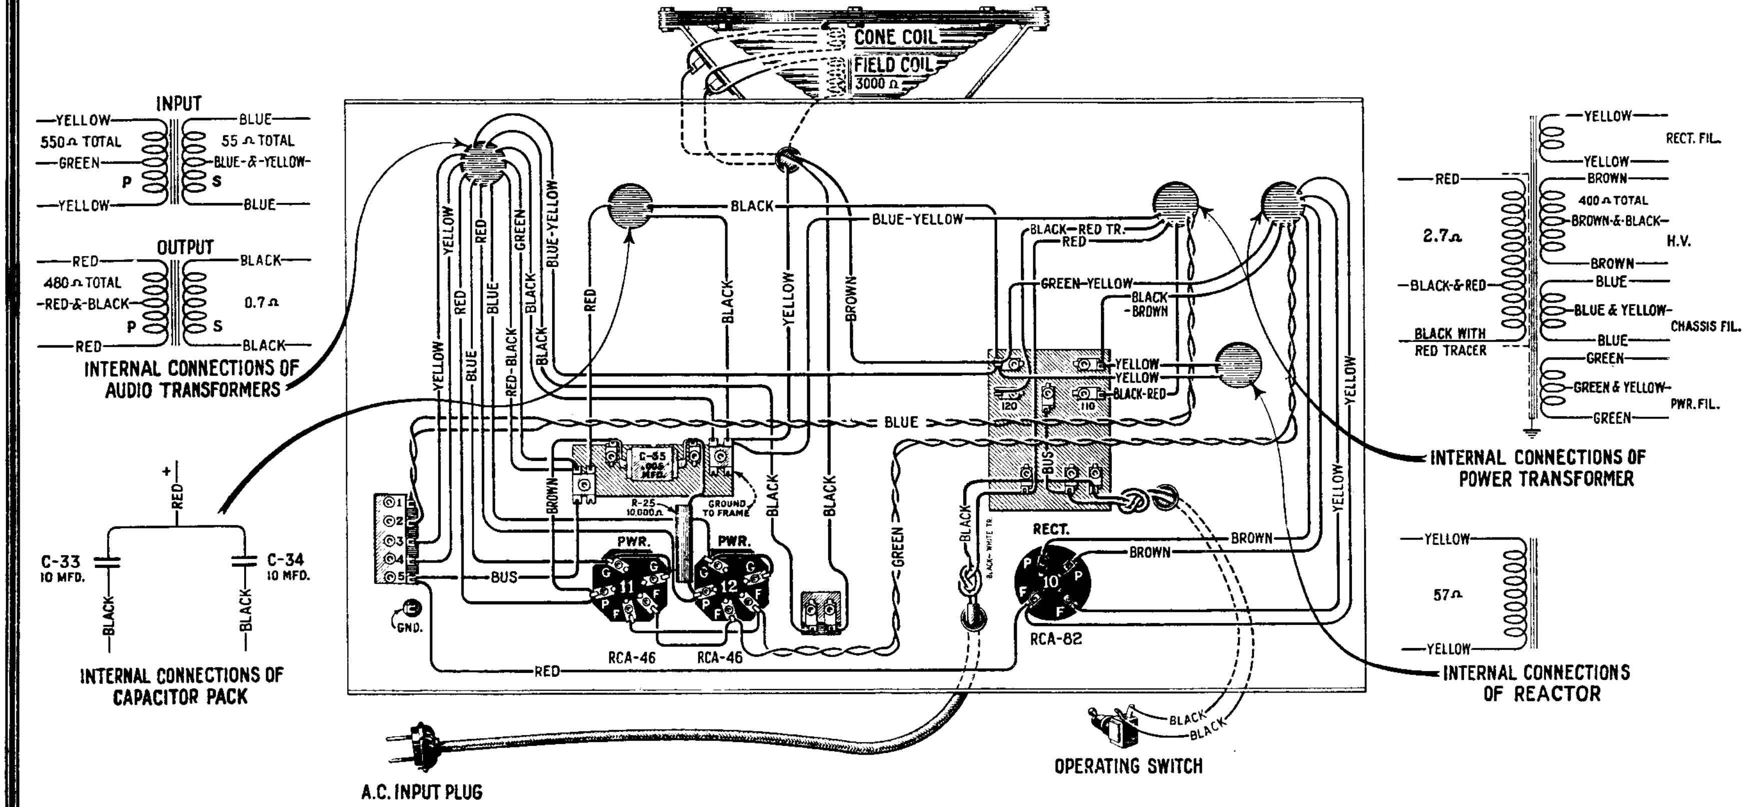

Figure 3—Amplifier Wiring Diagram

When the receiver is tuned to a signal, the signal voltage is amplified in the A. V. C. amplifier and impressed on coils L-9 and L-10. On the positive half of the signal voltage, the signal is rectified in the suppressor circuit which generates a negative potential on the grid of the Radiotron RCA-55. The plate current is thereby reduced to approximately zero which releases the high bias potential on the signal channel I. F. amplifier. Signal voltage will then be impressed on the second detector.

A. V. C. bias for the R. F., first detector and I. F. tubes will be generated when the I. F. voltage on the A. V. C. Diode overcomes and exceeds the positive potential on the cathode of the Radiotron RCA-55. This bias is approximately 10 volts when the receiver is tuned to signal.

The second I. F. transformer feeding the second detector has been changed to two high impedance circuits in order to provide the proper amplification with the increased bias resistor in the I. F. cathode circuit.

The suppressor circuit L-10 has been designed to be a sharp circuit so that the action of the suppressor comes as near the center of the carrier as possible.

The sensitivity control is in the cathode circuit of the R. F. and first detector and reduces the sensitivity of the receiver by increasing the residual bias on these Radiotrons. One end of the sensitivity control has a switch which is provided so that the noise suppressor circuit may be cut out. Under this condition the full sensitivity of the receiver is obtained.

GENERAL ELECTRIC COMPANY

MODEL J-125A

(1) I. F. TUNING ADJUSTMENTS

Although this receiver has two I. F. stages, one for the second detector and one for the A. V. C., only five of the circuits are tuned by adjustable capacitors and require adjustment. The coil used for the A. V. C. is broadly tuned and does not require any adjustment, while the one used for the noise suppressor circuit is sharply tuned. Refer to Figure 4 for location of the adjusting screws.

The transformers are all tuned to 175 K. C., and adjustments are made for maximum output.

A detailed procedure for making this adjustment follows:

(a) Procure a modulated R. F. oscillator that gives a modulated 175 K. C. signal. Also procure a non-metallic screw driver such as Stock No. 7065.

(b) An output meter is necessary. This may be a current squared galvanometer connected to the secondary of the output transformer instead of the cone coil, or a low range A. C. voltmeter connected across the reproducer unit cone coil.

(c) Remove the oscillator tube and make a good ground connection to the chassis. Place the test oscillator in operation and couple its output from the control grid of the first detector to ground. With the receiver volume control at maximum, the noise suppressor control at its extreme counter-clockwise position and the noise suppressor switch open, adjust the oscillator output until a deflection is obtained in the output meter.

(d) Adjust the secondary and primary of the second and then the first I. F. transformer until a maximum deflection is obtained in the output meter. Go through these adjustments a second time as a slight readjustment may be necessary.

(e) Then close the noise suppression control switch by advancing slightly clockwise, but do not advance the control beyond the snapping of the switch. The single noise suppressor circuit should then be adjusted for maximum output.

The points to remember when making these adjustments are that no dummy Radiotron is used and a minimum of input signal is necessary. An excessive signal will make it impossible to get correct adjustments of the signal channel I. F. and especially the suppressor circuit.

It is necessary, when adjusting the suppressor circuit, that the input signal be kept just as low as possible so that the output meter follows every change in the adjustment of the suppressor I. F. circuit.

When the adjustments are made the set should perform at its maximum efficiency. However, due to the interlocking of adjustments, it is good practice to follow the I. F. adjustments with the R. F. and oscillator line-up capacitor adjustments. The correct method of doing this is given in the J-125 Service Notes.

(2) RADIOTRON SOCKET VOLTAGES

Due to the wide variation in Set Analyzers, the General Electric Company will, in the future, list the actual voltages at which the Radiotrons operate, rather than those that will be obtained with a particular Set Analyzer. It is therefore necessary that the serviceman allow corrections for circuits having high resistance and for meter scales having a relative low resistance. Usually an application of Ohms Law will give an approximate value of the voltage that will be read on a particular meter, assuming that the resistance of the meter is known.

RADIOTRON SOCKET VOLTAGES

10. RCA-46—Power	0	0	400	—	—	6.0	2.5
11. RCA-46—Power	0	0	400	—	—	6.0	2.5
12. RCA-82—Rectifier	462.5 Volts R. M. S. Each Plate.—72 M. A. Total Plate Current.						

The untuned intermediate I. F. transformer used in the older Model J-125 has been changed to a natural period plate coil L-9 and a sharply tuned secondary coil L-10. Coil L-9 supplies the voltage to operate the A. V. C. circuit, while coil L-10 supplies that used to operate the suppressor circuits. An examination of this circuit will show that with no signal voltage impressed on coil L-10, no current is rectified in the Diode plate and hence the grid of the Radiotron RCA-55 operates at zero bias. The plate current is then at a maximum value—approximately 10 M. A.—and since the cathodes of the Radiotron RCA-55 and the signal channel I. F. tube are common, the I. F. tube is biased to cut-off. This, therefore, prevents signal voltage from reaching the second detector.

REPLACEMENT PARTS

Stock No.	DESCRIPTION	List Price
	RECEIVER ASSEMBLIES	
2723	Switch—Fidelity switch—Package of 5	$3.00
2746	Socket—Dial lamp socket	.50
2747	Contact cap—Package of 5	.50
3047	Resistor—1,500 ohms—Carbon type—½ watt—Package of 5	2.50

3441	Resistor—850 ohms—Carbon type—½ watt—Package of 5	2.50
6142	Resistor—6,000 ohms—Carbon type—½ watt—Package of 5	2.00
6188	Resistor—2 megohm—Carbon type—½ watt—Package of 5	2.00
6189	Bracket—Dial lamp bracket and indicator—Package of 2	.65
6192	Spring—3 gang tuning capacitor drive cord tension spring—Package of 10	.50
6251	Capacitor—1200 mmfd.—Package of 5	2.30
6276	Tone control—Complete with mounting nut and washer	2.10
6277	Capacitor—0.1 mfd. capacitor—Located in back of oscillator tube socket	.75
6279	Resistor—15,000 ohms—Carbon type—½ watt—Package of 5	2.50
6280	Resistor—400,000 ohms—Carbon type—½ watt—Package of 5	2.50
6281	Resistor—1,100 ohms—Carbon type—½ watt—Package of 5	2.50
6282	Resistor—60,000 ohms—Carbon type—½ watt—Package of 5	2.50
6284	Reactor—Tone control reactor	1.35
6285	Choke coil—Second detector plate choke coil	1.10
6288	Knob—Station selector, tone control, radio or phonograph, volume control knob—Package of 5	1.50
6298	Cord—3 gang tuning capacitor drive cord—Package of 5	1.00
6306	Coil—R. F. coil complete with mounting bracket	1.90
6312	Capacitor—650 mmfd.—Oscillator series—Package of 5	2.50
6314	Capacitor—160 mmfd.—Package of 5	2.50
6315	Resistor—45,000 ohms—Carbon type—½ watt—Package of 5	2.50
6316	Resistor—2,500 ohms—Carbon type—½ watt—Package of 5	2.50
6323	Shaft—Tuning condenser drive shaft with one flat washer and two "C" washers—Package of 2	.85
6351	Resistor—Voltage divider resistor	1.00
6352	Transformer—Third intermediate transformer	3.00
6353	Transformer—Second intermediate transformer	3.00
6354	Rheostat—Noise suppressor rheostat	1.90
6355	Volume control—Complete with mounting nut	1.90
6356	Capacitor—0.1 mfd. capacitor—Located on resistor board	.70
7062	Capacitor—Adjustable trimming capacitor—15 to 70 mmfd.	1.00
7065	Screw driver—Non-metallic screw driver for oscillator and I. F. adjustments	1.10
7298	Capacitor—0.01 mfd. capacitor—Located on resistor board	.80
7438	Capacitor—3 gang variable tuning capacitor complete with mounting screws and washers	5.20
7439	Drum—Dial drum with set screws and 3 dial mounting nuts	.50
7440	Scale—Dial and dial scale	.75
7477	Capacitor pack—Comprising two 1.0 mfd. and five 0.1 mfd. capacitors in metal container	2.90
7478	Capacitor pack—Comprising four 0.5 mfd., one 0.02 mfd., and one 0.1 mfd. capacitors in metal container	3.00
7479	Transformer—Interstage audio transformer in metal container	3.90
7480	Transformer—First intermediate frequency transformer	3.15
7483	Reactor—Compensating reactor	$1.00
7484	Socket—UY type Radiotron socket—4 used	.65
7485	Socket—Radiotron six contact socket—5 used	.70
7486	Board—Phonograph terminal board—8 terminals and 3 links	1.00
7490	Board—Resistor board—Less resistors and capacitors	1.10
7498	Reactor—Coupling reactor	2.50
7500	Cable—Six conductor—From receiver to S. P. U.	1.50
7505	Shield—Tube shield top—1 used—Maroon	.50
7506	Shield—Radiotron tube shield—7 used—Maroon	.55
7540	Coil—Detector and oscillator coil complete with mounting bracket	3.50
	AMPLIFIER ASSEMBLIES	
2725	Fuse—1.5 ampere—Cartridge type fuse—Package of 5	.50
2731	Resistor—10,000 ohms—1 watt—Carbon resistor—Package of 5	2.00
2757	Strip—Terminal strip—2 terminals	.50
3032	Socket—UX type Radiotron socket with insulator	.50
3056	Shield—Radiotron tube shield—Package of 2	.50
3099	Capacitor—0.005 mfd. capacitor	.75
3147	Cover—Fuse cover with bushing and insulator	.95
6289	Strip—Terminal strip—5 terminals	.85
6290	Board—Terminal board complete with terminals, fuse clips, and insulator	1.00
6291	Board—Terminal board complete with terminals and insulator—Less capacitor	.90
6292	Switch—Operating switch	1.25
7054	Cord—Power cord	1.00
7370	Cover—Terminal strip cover with insulator—5 terminals	.55
7491	Socket—UY type Radiotron socket with insulator	.70
8910	Capacitor pack—Comprising two 10 mfd. capacitors in metal container	7.00
8911	Reactor—Filter reactor	4.75
8912	Transformer—Audio transformer pack comprising input and output transformer in metal container	6.50
8913	Transformer—Power transformer—105/125 volts, 50/60 cycles	12.50
8914	Transformer—Power transformer—105/125 volts, 25/50 cycles	16.00
8915	Transformer—Power transformer—200/250 volts, 50/60 cycles	13.50
10907	Fuse—3 ampere fuse (for 25 cycle use)—Package of 5.	.50
	CABINET ASSEMBLIES Prices Furnished Upon Request	
X104	Foot—Cabinet foot	
X106	Board—Baffle board with grille cloth—Assembled	
X107	Stretcher—Stretcher rail—Comprising front, center, side, and back rails	
2776	Catch—Door catch with strike and nail—Package of 2 sets	
G5015	Pull—Door pull with mounting screw—Package of 2.	
G5023	Station Selector Escutcheon	
6294	Hinges—Door hinges—One set of 4 hinges with mounting screws	
G8939	Ornament—Front end top rail ornaments—1 pair	
G8940	Overlay—Door overlay—Right and left hand—One pair	
G8976	Panel—Control panel	
G9579	Top—Cabinet top	
G9580	Doors—Left and right—1 pair—Short doors	
G9581	Leg—Cabinet leg	
G9589	Cabinet—Cabinet complete—Less all equipment—Short doors	
	REPRODUCER ASSEMBLIES	
7292	Screw assembly—Comprising two screws, two nuts, two lock-washers, and 1 plate—For mounting speaker to amplifier	.95
8559	Ring—Cone retaining ring	.80
8916	Cone—Reproducer cone complete with voice coil—Package of 5	15.00
9418	Coil assembly—Comprising field coil, magnet, and cone support	12.00

GENERAL HOUSEHOLD UTILITIES COMPANY

MODELS 5NB & 510

The Grunow Chassis 5NB is a five tube battery operated Superheterodyne receiver using 1—1A4 R. F. Amplifier, 1—1A6 1st Detector and Oscillator, 1—1A4 I. F. Amplifier, 1—1B5 2nd Detector, A. V. C. and A. F. Amplifier and 1—33 Power Output. The tuning range covers the Broadcast Band from 550 kc. to 1750 kc.

REPAIRS

When servicing this chassis, it is IMPERATIVE that parts replacements are made in EXACTLY the same way as the original parts were connected and located. This applies particularly to all ground points.

All parts replacements in the R.F. end of the circuit must be exact duplicates of the originals, especially coils, R.F. by-pass, and coupling condensers.

Any repairs in the R.F. circuit will make a complete re-alignment of the entire tuned circuit necessary.

BIAS CELLS

This Chassis uses "C" bias cell units in both the A.V.C. and Audio Amplification Circuits. These cells may have to be replaced occasionally, and when doing so, note that the carbon or (+) side is connected to the ground side of the cell terminal clip. An indication of a faulty cell will be distorted tone quality. This may be checked by the substitution of new cells in place of the old, or for testing purposes a "C" battery may be used—using 1½ volt tap for a single cell or 4½ volts for the 4 unit cell. This bias cell has a voltage of 1½ volts, but due to its low current output it cannot be measured by any ordinary volt meter.

ALIGNMENT

CIRCUIT ALIGNMENT EQUIPMENT

Do not attempt to align the chassis without the following:

1. Signal Generator.
   A modulated oscillator capable of delivering frequencies from 465 kc. to 1750 kc.
2. Alignment Tool.
   A non-metallic screw driver.
3. Dummy Antenna.
   .05 Mfd. Condenser (I. F. Alignment).
   200 Mmfd. Condenser (Broadcast Alignment).
4. Output Meter.
   A meter of sufficient sensitivity to give a good deflection at very low signal input.

Note: The receiver should be aligned in a location free from local interference. A screen room is recommended.

1. HEATING.
   (A) Allow the receiver to heat up for at least 15 minutes. This is necessary in order to eliminate possible alignment variations due to thermal expansion and contraction of the capacitors and inductances.
   (B) Allow the signal generator to warm up in order to prevent frequency drift during alignment.
2. DIAL CALIBRATION.
   (A) Turn the tuning condenser until plates are fully meshed, set the dial pointer to the horizontal line on the dial chart.
3. SIGNAL GENERATOR ADJUSTMENT.
   During the entire alignment procedure the signal input from the generator to the receiver must be continually attenuated at the generator as the various trimmers are brought into resonance. This is necessary in order to hold the signal at the lowest intensity so that the A.V.C. circuit will remain at its most sensitive point.
4. I. F. ALIGNMENT.
   (A) Set the generator to 465 kc. and connect the output to the grid of the 1A6 tube through the .05 mfd. dummy. Connect the ground to the chassis ground post.
   (B) Set the receiver to 600 kc.
   (C) Adjust the trimmers A1, A2, A3, and A4 to maximum output.
5. 1500 K. C. ALIGNMENT.
   (A) Set the generator to 1500 kc. and connect the output to the chassis antenna post through the 200. mmfd. dummy.
   (B) Set the receiver to 1500 kc.
   (C) Adjust trimmer A5 to maximum output.
   (D) Adjust trimmer A6 in the direction of signal increase and at the same time slowly rock the tuning condenser back and forth through resonance until the combined resonant point of both is determined.
   (E) Repeat operation "C."
   (F) Adjust trimmer A7 to maximum output.

MODELS 5R & 564

The following characteristics apply to the GRUNOW Radio—Chassis 5R:

This model is a 5 tube Super-Heterodyne Broadcast (540 to 1720 K.C.) Receiver using 1-6A7 tube as a 1st Detector and Oscillator, 1-6D6 tube as an I.F. Amplifier, 1-76 tube as a 2nd Detector and audio Amplifier. The 41 output tube is a power amplifier pentode and is capable of producing large power output with a relatively small signal input. The rectifier tube is an 80, the output of which is well filtered through the action of the speaker field and the two 8 mfd. electrolytic condensers.

The following three variable circuits are used: R.F. input, detector or mixer input and oscillator. These circuits are tuned by a 2 gang variable condenser of rugged construction.

The remainder of the circuit is typical and has been designed along lines of what is considered the best engineering practice to date. Parts are all oversize and of the finest quality.

SERVICE DATA

CONTINUITY AND VOLTAGE

Continuity and voltage readings should be taken from the underside of the chassis. The values given on the schematic diagram are average and allow the service man to make a quick check of the chassis constants. The socket layouts given on the schematic diagram show each socket from the underside.

ALIGNMENT

1. EQUIPMENT.

A—Test Oscillator.

A modulated oscillator capable of producing signals at 465 K.C., 600 K.C., 1500 K.C. and 1700 K.C. is necessary for alignment of the 5R Grunow Receiver.

B—Output Meter.

This may be any of the standard output meters on the market but should be sufficiently sensitive to provide a good deflection at low signal strength.

C—Coupling Means.

Coupling condensers of .25 Mfd. and 200 Mmf. should be used when coupling oscillator to receiver during alignment as specified in following paragraphs.

2. DIAL SETTING.

Turn dial pointer until condensers are fully meshed. The dial pointer should be on the horizontal line of the dial.

3. I.F. ALIGNMENT.

A—Connect signal lead of oscillator through .25 Mfd. condenser to grid of 6A7 (1st Detector Tube.) Connect the ground lead to the Chassis.

B—Place oscillator in operation at 465 K.C. and turn receiver volume control to maximum. (Volume Control should remain at maximum during entire alignment procedure and signal should be attenuated at oscillator to lowest value consistent with obtaining a readable indication on output meter.)

C—Align four I.F. trimmers (A1—A2—A3—A4) located on top of I.F. Transformers.

4. 1700 K.C. ALIGNMENT.

A—Connect signal lead of oscillator to antenna lead (the yellow wire leading from rear of chassis) through 200 Mmf. Condenser.

B—Set dial pointer at 1700 K.C. and place oscillator in operation at 1700 K.C.

C—Align oscillator trimmer (A5) which is the second of the two on the variable condenser as you face chassis.

5. 1500 K.C. ALIGNMENT.

A—Place oscillator in operation at 1500 K.C.

B—Set dial pointer at 1500 K.C.

C—Align antenna trimmer (A6). This operation may require rocking the variable condenser back and forth through resonance. The object of this operation is to be sure that the receiver will reach 1712 K.C. and at the same time have maximum sensitivity on the rest of the broadcast band.

MODELS 5S & 566

The following characteristics apply to the GRUNOW Radio—Chassis 5S:

This model is a 5 Tube Super-Heterodyne Dual Wave (540 to 1725 K.C. and 1725 to 4000 K.C.) Receiver, using 1-6A7 tube as 1st Detector and Oscillator, 1-6D6 tube as an I. F. Amplifier, 1-76 tube as 2nd Detector and Audio Amplifier. The 41 output tube is a power amplified pentode and is capable of producing large power output with relatively small signal input. The rectifier tube is an 80, the output of which is well filtered through the action of the speaker field and the two 8 mfd. electrolytic condensers.

SERVICE DATA

CONTINUITY AND VOLTAGE

Continuity and voltage readings should be taken from the underside of the chassis. The values given on the schematic diagram are average and allow the service man to make a quick check of the chassis constants. The socket layouts given on the schematic diagram show each socket from the under side.

ALIGNMENT

1. EQUIPMENT

A—Test Oscillator.

A modulated oscillator capable of producing signals at 465 K. C., 1500 K. C., 1000 K. C., 600 K. C. and 3500 K. C. is necessary for alignment of the 5S Grunow Receiver.

B—Output Meter.

This may be any of the standard output meters on the market, but should be sufficiently sensitive to provide a good deflection at low signal strength.

C—Coupling Means.

Coupling condensers of .05 Mfd. and 200 Mmf. should be used when coupling oscillator to receiver during alignment as specified in following paragraphs.

2. DIAL SETTING.

Turn dial pointer until condensers are fully meshed. The dial pointer should be on the horizontal line of the dial chart.

3. I. F. ALIGNMENT.

A—Connect signal lead of oscillator through .05 Mfd. condenser to grid of 6A7 (1st Detector tube), connect the ground lead to the chassis.

B—Place oscillator in operation of 465 K. C. and turn receiver Volume Control to maximum (Volume Control should remain at maximum during the entire alignment procedure and signal should be attenuated at oscillator to lowest value consistent with obtaining a readable indication on output meter).

C—Align four I. F. trimmers (A1-A2-A3-A4) located on top of I. F. Transformers.

4. 1500 K. C. ALIGNMENT.

A—Connect signal lead of oscillator to antenna lead (the yellow wire) through 200 Mmf. condenser.

B—Set dial pointer at 1500 K. C. and place oscillator in operation at 1500 K. C. Set Range switch on broadcast position. Knob to the left.

C—Align oscillator trimmer (A5), which is the second trimmer on variable condenser as you face the chassis.

D—Align antenna trimmer (A6), which is the first trimmer on Variable Condenser, in direction of signal increase and at the same time rock the tuning condenser back and forth thru resonance. Continue this procedure until maximum signal is obtained on the output meter.

5. 3500 K. C. ALIGNMENT.

A—Set Range Switch to Short Wave Position. Set test oscillator in operation at 3500 K. C. Turn Dial pointer to 3500 K. C. (3.5 M. C.).

B—Adjust Oscillator Trimmer (A7), located on range switch, to maximum output. (Use the higher of the images for alignment point—the setting giving the least capacity—screw farthest out.)

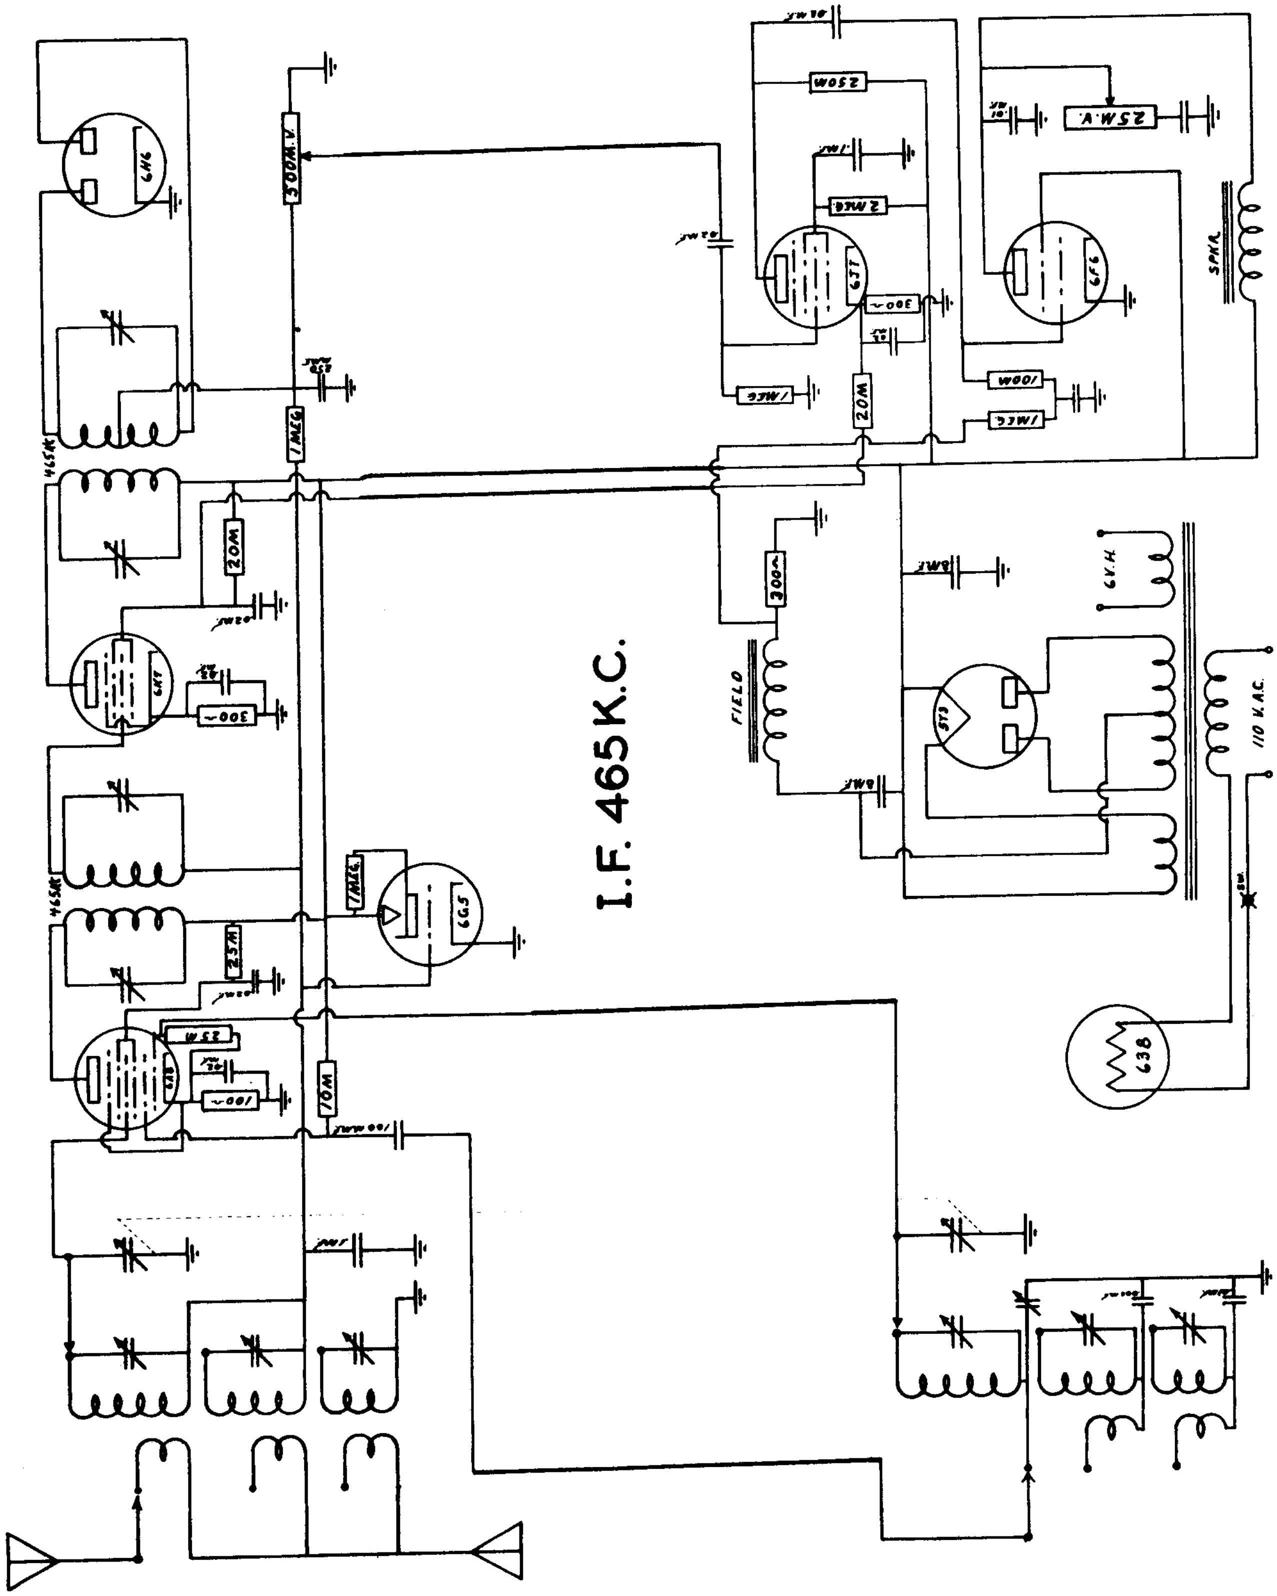
C—Adjust antenna trimmer (A8), located on top of antenna coil, to maximum output while rocking tuning condenser thru resonance.

D—Check at 1500 K. C.

Note: Best results may be had with this receiver when using a high, long antenna.

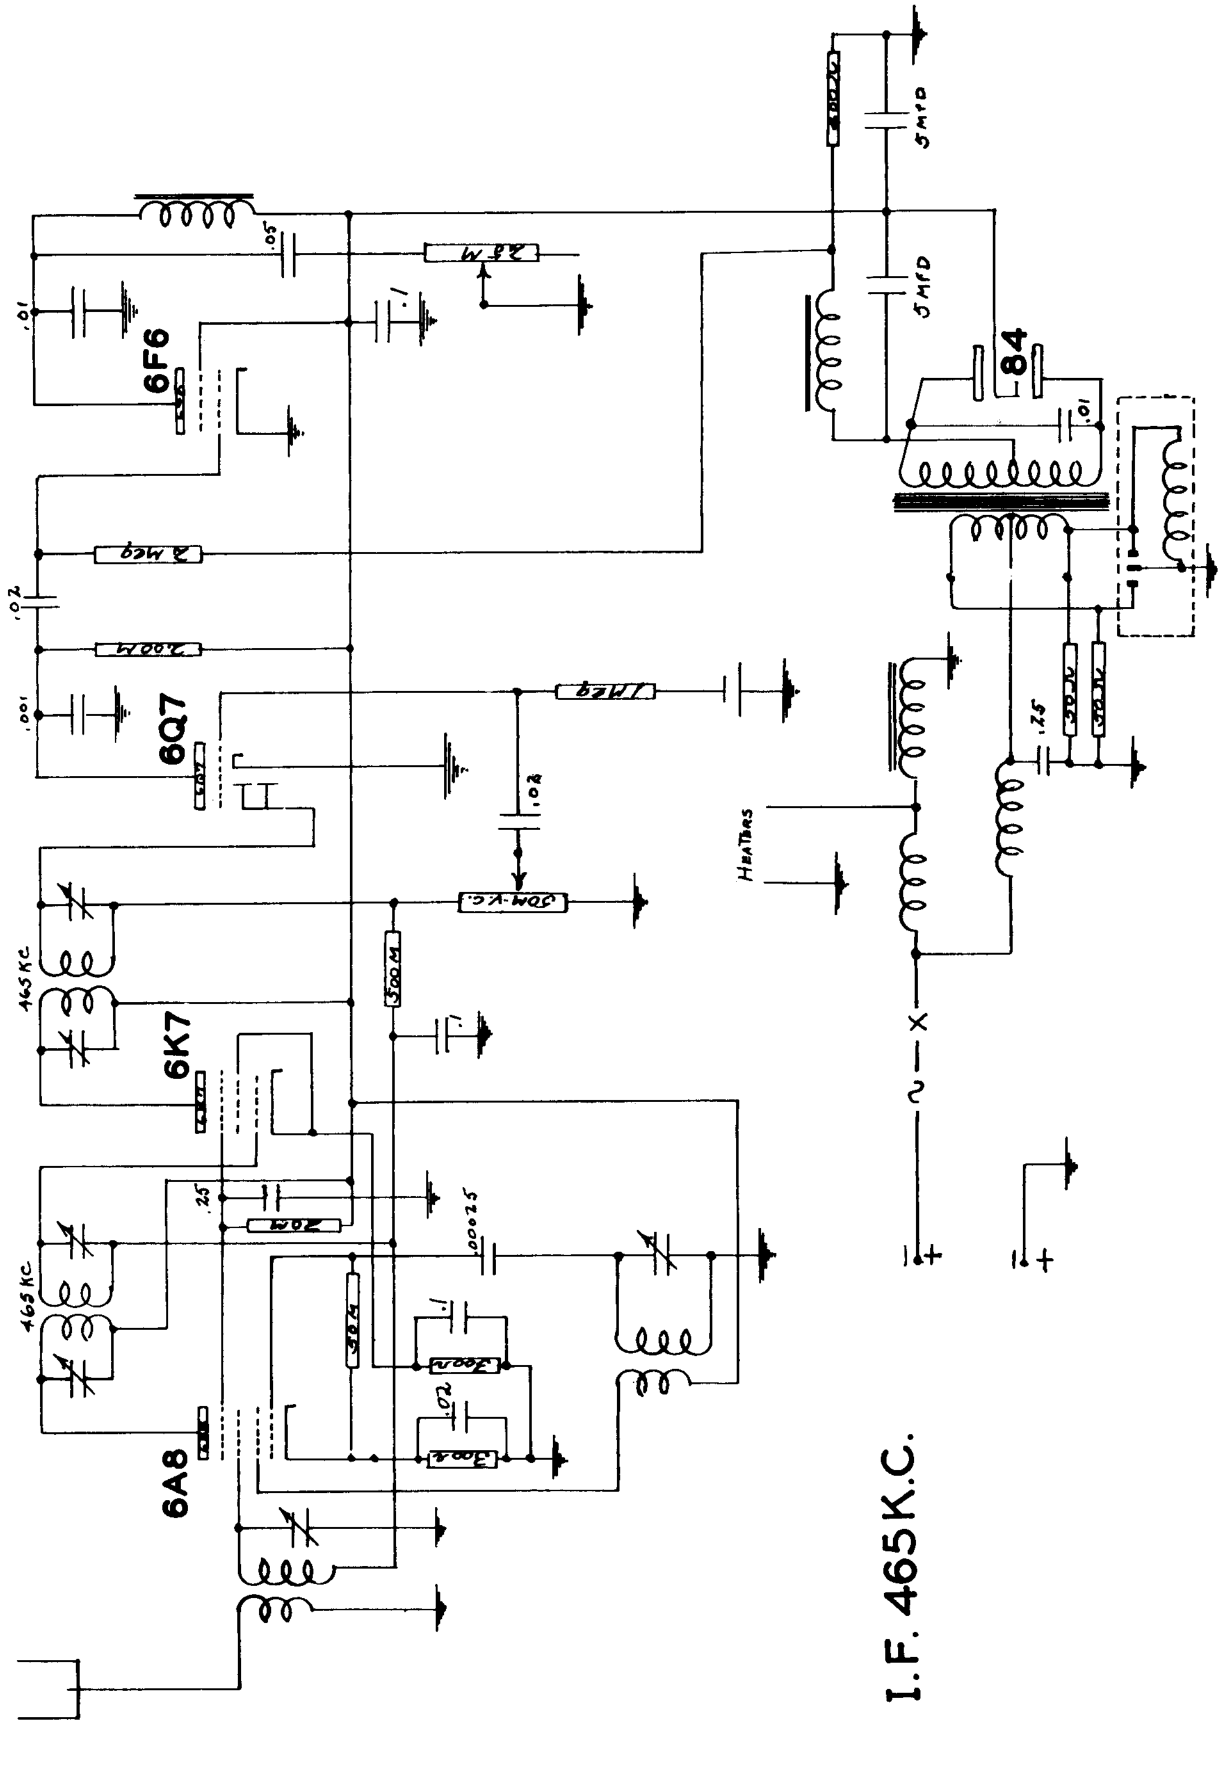
HERBERT H. HORN RADIO MFG. CO.

MODEL 83



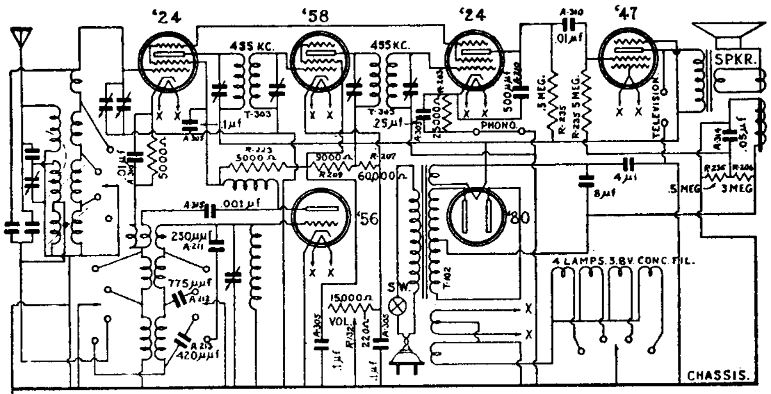
HERBERT H. HORN RADIO MFG. CO.

MODELS 537 & 538



INTERNATIONAL RADIO CORP.

MODEL AW-55



MODEL AW-55

VOLTAGE READINGS:

NOTE: Voltages should be measured with volume control all the way "ON" and the range selector in position 3 (broadcast). Use a 250-volt D. C. meter with a resistance of 1000 ohms per volt.

The following are average voltages measured on 118 volt 60 cycle A. C. line. A slight variation is allowable for variations in meters, tubes, and line voltage.

	Plate	Screen	Cathode
'47 Tube —ground to	235	245	......
'24 Tube —ground to (Tube next to '47)	70	40	6
58 Tube —ground to	240	100	3
'24 Tube —ground to	240	40	8
56 Tube —ground to	40	......	0

The grid of the '47 is biased through such high resistances that only an indication of negative bias can be read with an ordinary meter.

MODEL J-S

Voltage Readings:

NOTE: Voltages should be measured with volume control all the way "ON" and the band selector switch at the "long" wave position using zero to 250 volt D. C. voltmeter with resistance of 1,000 ohms per volt.

The following are average voltages taken on 118 volts 60 cycle A. C. line. A slight variation is allowable for variation in meters and line voltage.

	Plate	Screen	Cathode
Pentode tube —ground to	240	245	None
235 R. F. tube —ground to	245	70	2.5
224 1st. Detector tube —ground to (center tube)	245	70	7
224 2nd. Detector —ground to	75	70	10

The grid of the Pentode is biased through such high resistance that only an indication of negative bias can be read with an ordinary high resistance meter.

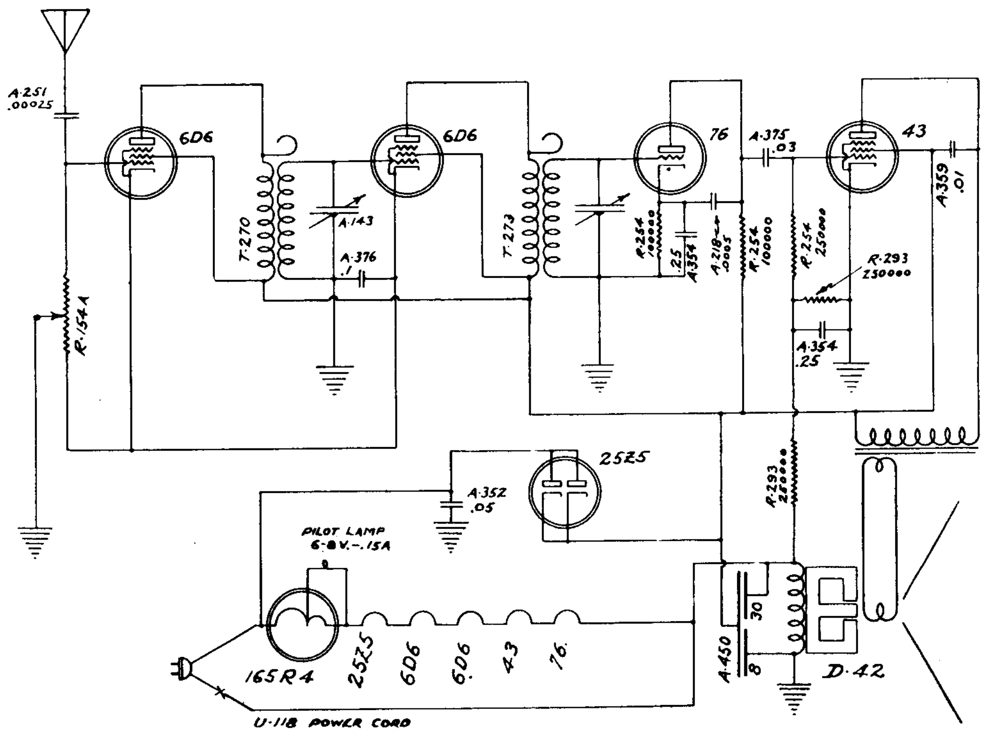
MODELS 76X & 676X



ALIGNMENT

Alignment may be accomplished using either a signal generator or weak broadcast signals although the signal generator is preferable. An output meter should be connected from the plate of the 43 tube to ground.

Set signal generator at 1500 kilocycles and feed signal to antenna. Keep the output from signal generator as low as possible. Tune in signal on radio and make adjustments for maximum output. Rock the tuning condenser back and forth across the signal while adjusting the R.F. trimmer for resonance.

Next check the alignment at 1000 Kc. Insert a thin bakelite, celluloid or mica feeler strip between the plates of the variable condensers to determine whether the circuits are properly matched. The action is this—the dielectric constant of the celluloid feeler strip being higher than that of the air it displaces, results in an increase of capacity. Open the variable condenser just enough to indicate two or three points below maximum signal. As the feeler is inserted the meter reading should indicate increasing signal and then decreasing as the feeler is inserted farther. This procedure should be followed on both sections. Should the meter fail to show an increase in signal as the strip is inserted in one section this indicates too great a capacity for the section. This may be corrected by bending the outside rotor plates out at the point where they begin to mesh with the stator.

After checking the alignment at 1000 Kc. repeat the process at 600 Kc.

Alignment and Calibration

Correct alignment is extremely important in connection with standard and short wave radios. The receivers are all properly aligned at the factory with precision instruments and re-alignment should not be attempted unless all other possible causes of the faulty operation have first been investigated and unless the service technician has the proper equipment.

A signal generator which will provide an accurately calibrated signal at 456, 1730, 1500, 600, 18,300, 15,000 and 6000 KC and an output indicating meter are required. It will be practically impossible to align the receiver if unsatisfactory apparatus is used.

Use a non-metallic screwdriver for the adjustments. The complete procedure is as follows:

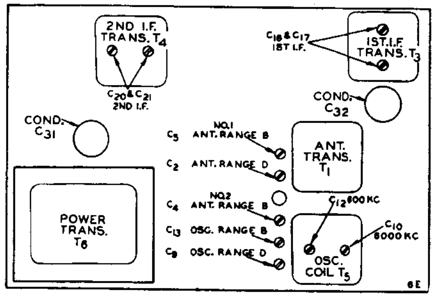

Fig. 3—Location of Trimmers

I. F. Adjustment

Set the signal generator for a signal of 456 KC.

Connect the output of the signal generator through a .1 mf. condenser to the grid of the 1st detector.

Connect the ground lead of the radio to the ground post of the signal generator.

Turn the band switch to the Range B position (standard wave band).

Turn the selectivity control to the sharp position and keep it in this position for all adjustments.

Turn the volume control to the maximum position.

Attenuate the signal from the signal generator to prevent the levelling-off action of the AVC.

Then adjust the four I.F. trimmers until maximum output is obtained. The adjusting screws for these condensers are reached from the top of the chassis, and the location is shown in Fig. 3.

1500 KC Adjustment

Set the signal generator for 1500 KC.

Turn the rotor of the tuning condenser carefully until maximum output is obtained.

Loosen the two screws inside of the film drum at the bottom which hold the drum in place. Set the drum at the 1500 KC mark and retighten the screws.

Adjust the antenna Range B trimmers (C4) and (C5) to maximum.

Do not change the setting of the oscillator Range B trimmer.

600 KC Adjustment

Set the signal generator for 600 KC.

Turn the tuning condenser rotor until maximum output is obtained.

Turn the rotor slowly back and forth at the same time adjusting the 600 KC trimmer (C12) until the peak of greatest intensity is obtained. See Fig. 3 for location of this trimmer.

Range B Alignment

After the procedure for the alignment of each range, as explained below, is completed, it is advisable to repeat the procedure as a final check.

1730 KC Adjustment

Set the signal generator for 1730 KC.

Turn the rotor of the tuning condenser to the full open position.

Keep the band switch in the standard wave position.

Connect the antenna lead of the radio through a 200 mmf. condenser to the output of the signal generator.

For this and all subsequent adjustments keep the volume control at the maximum position and attenuate the signal from the signal generator to prevent AVC action.

Adjust the oscillator Range B trimmer (C13) until maximum output is obtained. The location of this trimmer is shown in Fig. 3.

Range D Alignment

CAUTION—When aligning the short wave band be sure NOT to adjust at the image frequency. This can be checked as follows: Let us say the signal generator is set for 15,000 KC. The signal will then be heard at 15,000 on the dial of the radio. The image signal, which is much weaker, will be heard at 15,000 less 912 KC, or 14,088 KC. It may be necessary to increase the input signal to hear the image.

18,300 KC Adjustment

Set the signal generator for 18,300 KC.

Connect the antenna lead of the receiver through a 400 ohm resistor to the output of the signal generator.

Turn the rotor of the tuning condenser to the full open position.

Turn the band switch to the Range D position (short wave band).

Adjust the oscillator Range D trimmer (C9) until maximum output is obtained. See Fig. 3 for location of this trimmer.

15,000 KC Adjustment

Set the signal generator for 15,000 KC.

Turn the rotor of the tuning condenser carefully until maximum output is obtained.

Adjust the antenna Range D trimmer (C2) to maximum.

When adjusting this trimmer, it will be necessary at the same time to turn the tuning condenser rotor slowly back and forth until the peak of greatest intensity is obtained.

Do not change the setting of the oscillator Range D trimmer.

6000 KC Adjustment

Set the signal generator for 6000 KC.

Turn the tuning condenser rotor until maximum output is obtained.

Turn the rotor slowly back and forth at the same time adjusting the 6000 KC trimmer (C10) until the peak of greatest intensity is obtained. See Fig. 3 for location of this trimmer.

General Service Data

Twenty-five Cycle Radios

The twenty-five cycle model differs from the sixty cycle model only in the fact that a different power transformer is used. The correct power transformer is shown in the parts list.

The twenty-five cycle receiver can be operated satisfactorily from a sixty cycle power supply. However, the reverse is not true, the sixty cycle receiver cannot be operated from a twenty-five cycle power supply.

A 115-230 volt, 40 to 60 cycle as well as other power transformers with special power ratings are also available for this model.

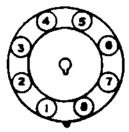

Fig. 4—Metal Tube Terminal Numbering (bottom of socket)

Trimmer Replacement

If one trimmer of the gang trimmer strip should become defective, it is not necessary to replace the entire strip. A single trimmer 17A36, as shown in the

CON'T FROM PRECEDING PAGE

replacement parts list, may be used. Disconnect the lead from the coil side (side not grounded) of the defective trimmer in the strip. This connection is then made to the single trimmer. Connect it to the side of the trimmer not in contact with the adjusting screw.

The other side of the single trimmer is then connected to a good ground, using a piece of heavy wire in order to support the trimmer adequately. In replacing a trimmer, be sure to keep both leads as short as possible and keep the ungrounded lead as far from ground as possible.

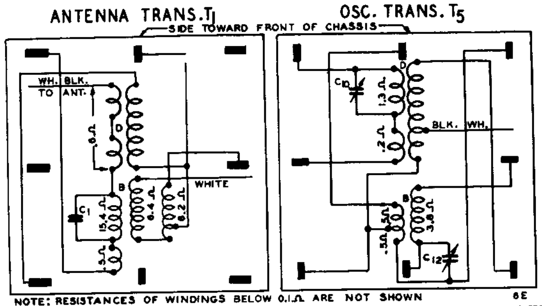

Fig. 6—R.F. and Oscillator Coil Base Terminal Arrangement and D.C. Resistance of Windings.

Movie Dial Adjustments and Replacements

Issue Letter of Radio

The issue letter is the large letter appearing on the under side of the chassis which identifies the chassis as to major part changes. There are two distinct types of chassis known as Issue A and Issue B. The adjustments, as decribed in the following paragraphs, cover both issues unless otherwise specified.

A chassis bearing the issue letter "A" may be further identified by the die stamped Light and Projector Lens Bracket and the separate die stamped Condenser Lens and Aperture Bracket. See Fig. 9.

The chassis bearing the issue letter "B" may be further identified by a die cast combination Lens, Light and Aperture Bracket. See Fig. 10.

Bringing Lens Adjustment to a Focus

Important—Turn the band switch to the standard wave position.

Move the focusing lever (see Fig. 9) up or down until the image on the screen is clearest. In Fig. 7 is shown the effect of correct and incorrect focusing.

Replacing and Positioning the Dial Lamp

Caution—If a new lamp is required, use only a G. E. lamp, Wards catalogue No. 61P8204. Get this from your nearest Ward store or Ward Mail Order House.

First, turn the radio off.

Loosen the thumb screw and lift the lamp socket assembly out of the light tube—see Fig. 9. This can be lifted vertically by grasping the insulated top of the assembly through which the wire runs.

Remove the old lamp from the socket and put in the new one.

Replace the lamp socket assembly in the light tube with the light tube embossing in the groove of the lamp socket assembly—see Fig. 9. Do not tighten the thumb screw yet.

Turn the radio on.

Then grasp the top of the lamp socket assembly and move it up or down until the image on the screen is clearest and the lines are horizontal. The effect of having the lamp assembly too high or low is shown in Fig. 8. Tighten the thumb screw.

Dial Calibration

The radio is properly calibrated if, when a station is correctly tuned in, the vertical red line on the screen crosses the call letters of that station. If the red line is found to be on one side of the call letters of a large number of stations on the standard wave band (the same side in each case), the dial is out of calibration.

To re-calibrate, carefully tune in the signal of one of the larger nearby stations in accordance with the instructions under "Tuning in a Signal." Choose a station which is near the middle of the dial. Loosen the two screws seen at the inside of the film drum at the bottom. Adjust the position of the drum and tighten the screws.

The dial will then be properly calibrated and this adjustment should not be changed unless re-calibration again becomes necessary. It should be remembered that after calibration a few stations may be tuned in when the vertical red line is near one end or the other of the call letters and city of a station. That is because of slight variations in the film.

Adjusting Film Drum Position to Raise or Lower Image

If the raising and lowering mechanism is not adjusted properly, the image will be too high or too low on the screen and part of the image may be cut off.

If this condition exists, turn the radio on and turn the band switch to the standard wave position. Then loosen the two set screws in the collar on the band switch shaft—See Fig. 9. Move the elevator assembly up or down by means of the fibre arm until the image on the screen is centered from top to bottom. Then tighten the two set screws.

Cleaning the Lenses

It is very seldom necessary to clean the lenses. Occasionally, however, dust or dirt on the lens may cause the image on the screen to be spotted or foggy. If this is the case, the lenses may be removed as explained below and may then be cleaned by wiping carefully with a clean chamois or soft cloth.

Removing Condenser Lens—Remove the four screws which hold the projector compartment and glass screen to the glass screen mounting bracket. Remove the screw at the top and back of the projector compartment. See Fig. 9. Lift the projector compartment up and away from the chassis. Remove the screw from the bottom of the lens and light bracket and take out this bracket, being careful not to scratch the film.

Issue A—Remove the condenser lens bracket from the lens and light bracket—See Fig. 9. The lens can then be cleaned without removal, or it may be forced out of the tube with a wood block. After the lens has been cleaned, reinsert it in the lens tube until the end of the lens barrel is about $\frac{1}{16}$ inch inside the tube.

Issue B—Remove the aperture cap—See Fig. 10. Insert a fine blade screw driver into the slot and then push the condenser lens away from the light tube until it is possible to remove the lens. Clean the lens carefully. Replace the lens so that the lens barrel projects about 1/32 inch beyond the lens tube. Re-

CON'T ON NEXT PAGE

CON'T FROM PRECEDING PAGE

place the aperture cap so that the square notch of the aperture cap fits over the square rib as illustrated.

Removing Projector Lens—Remove the projector compartment and lens and light bracket as explained in the first paragraph of the article "Removing Condenser Lens."

The projector lens may then be removed by first unscrewing the focusing lever assembly (Issue A radios have focusing lever only). Then push the lens barrel out of the projector lens tube. Clean the lens carefully. Replace the lens barrel so that the threaded hole will coincide with the slot opening of the bracket. Replace the focusing lever assembly.

Reassembling—Replace the lens and light bracket taking care not to scratch the inside of the film.

Replace the projector compartment, glass screen and dial lamp assembly.

When replacing the glass screen, the glass is put on with the frosted side toward the inside of the assembly.

Refocus the projector lens.

Cleaning the Film and Glass Screen

As in the case of the lenses, it is very seldom necessary to clean the film or glass screen. If, however, the image on the screen is spotted or foggy, it may be necessary to clean these items as explained below.

Film—The film may be dusted with a camel hair brush or fine cloth. CAUTION—Extreme care must be taken not to scratch the film.

Glass Screen—If the screen should become dirty, the front may be cleaned by wiping with a clean, dry cloth. If the back of the screen becomes dirty, it should be cleaned with alcohol. Care should be taken not to get any alcohol on the red line at the front of the screen.

Replacing the Film Drum Assembly

Remove the lamp socket assembly from the light tube by lifting it out in accordance with instructions in "Replacing and Positioning the Dial Lamp."

Remove the glass screen, projector compartment and lens and light bracket as described in the article "Removing Condenser Lens."

Remove the film drum assembly by unscrewing the two small screws located inside the drum at the bottom.

Mount the new film drum assembly on the film drum supports leaving the paper around the film for protection, and insert the clamping plate within the film drum. The film drum and clamping plate should then be so placed that the small screws are in the center of the two slots.

Replace the lens and light bracket taking care not to scratch the inside of the film.

Replace the projector compartment, glass screen and dial lamp assembly.

Now remove the paper from the film, turn the radio on and calibrate the dial in accordance with the instructions in the article "Dial Calibration."

The film and mounting drum are sold as one assembly and cannot be ordered separately.

Replacing Rubber Friction Drive Pinion

Loosen the set screw on the brass bushing which holds the rubber pinion—See Fig. 11. Push out the small horseshoe washer on the tuning shaft in back and below the glass screen. Pull the tuning shaft from the front until the brass bushing may be removed. Place the new rubber pinion over the brass bushing and replace the bushing on the tuning shaft. Tighten the set screw on the brass bushing after the bushing has been returned to its original position. Replace the horseshoe washer.

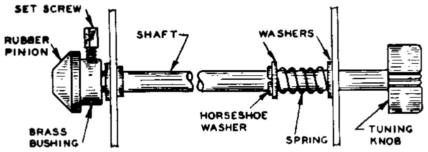

Fig. 11—Drive Shaft Assembly

Replacing Friction Drive Drum

If it is ever necessary to replace the friction drive drum, be sure that the stop on the drum hits the stop on the condenser before the gang rotor is either completely meshed or completely open (maximum or minimum position).

Replacement Parts List

RETAIL STORES: Order any parts from division superintendent at Chicago or Oakland, on stock order. Order by bin number and description. If no bin number is shown, order by part number and description.

Return defective parts to division superintendent only.

There is a large letter on the chassis which identifies the set to major part changes. When ordering parts please be sure to mention the model number and this large letter.

DIAL AND DRIVE ASSEMBLY

When ordering Dial and Drive Parts, be sure to mention the Issue Letter. If the letter appearing in the issue letter column for any one item is A, that part is to be used on Issue A radios only; if it is B, it is to be used on Issue B radios only; and if it is A-B, it is used on both Issue A and Issue B radios.

Bin No.	Part No.	Issue Letter	Description	Selling Price
	25X334	A-B	Support Bracket for Gang Condenser	$0.24

SPECIFICATIONS

Power Consumption - 60 Watts (At 115 volts 60 cycles)

Power Output - - - - - 2.5 Watts Undistorted

Selectivity - 30 KC Broad at 1000 times Signal (Sharp)

Intermediate Frequency - - - - - - 456 KC

Speaker - - - - - - - - - - 8" Dynamic

Tuning Frequency Range

B Range 528 to 1730 KC

D Range 5750 to 18300 KC

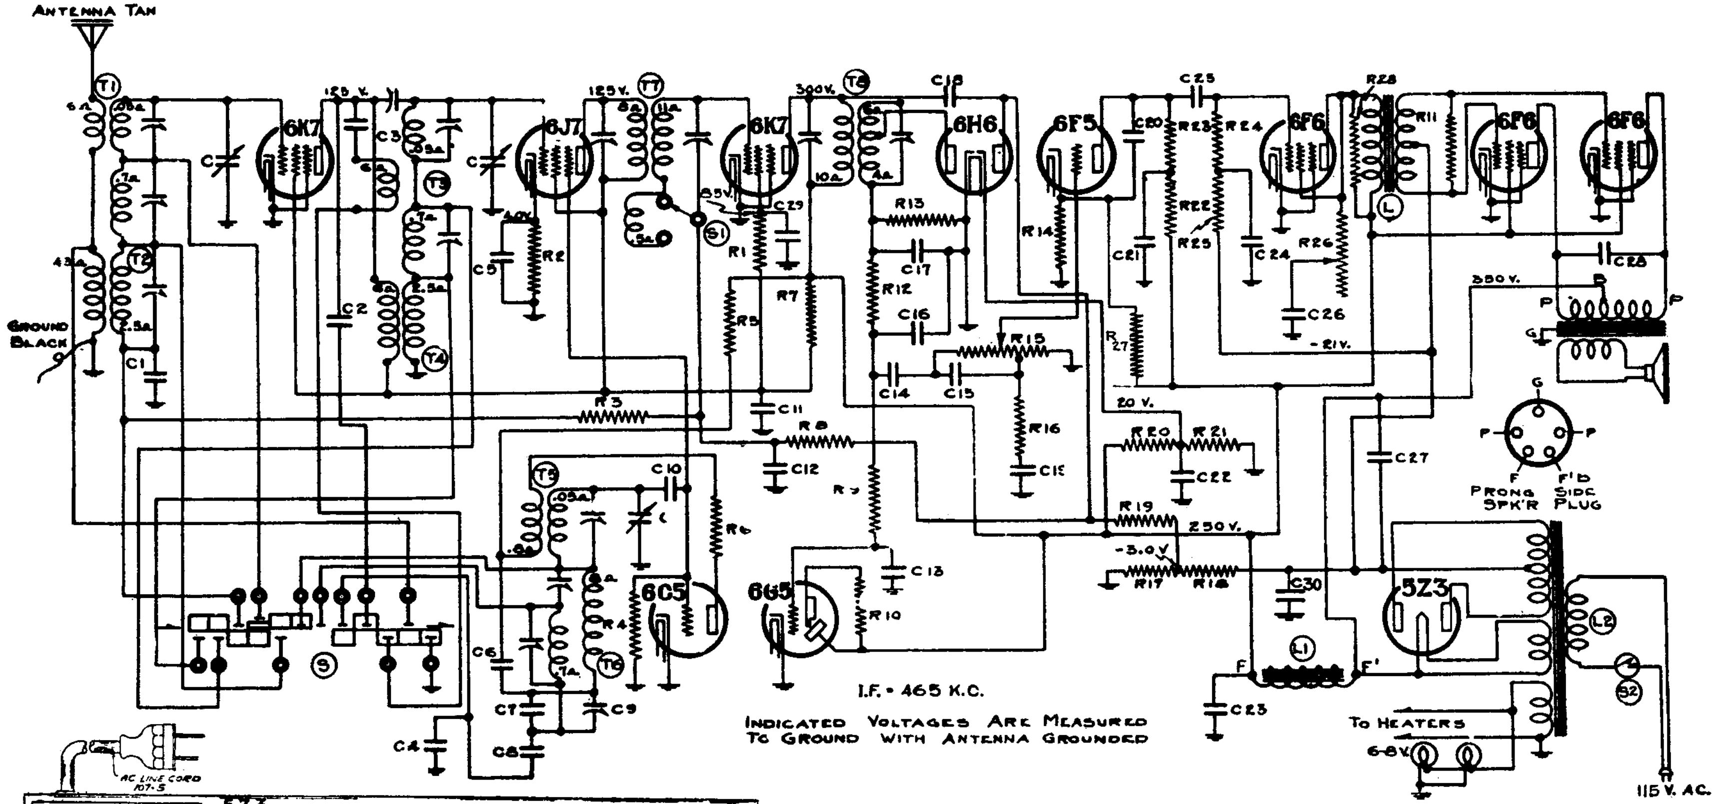
Sensitivity

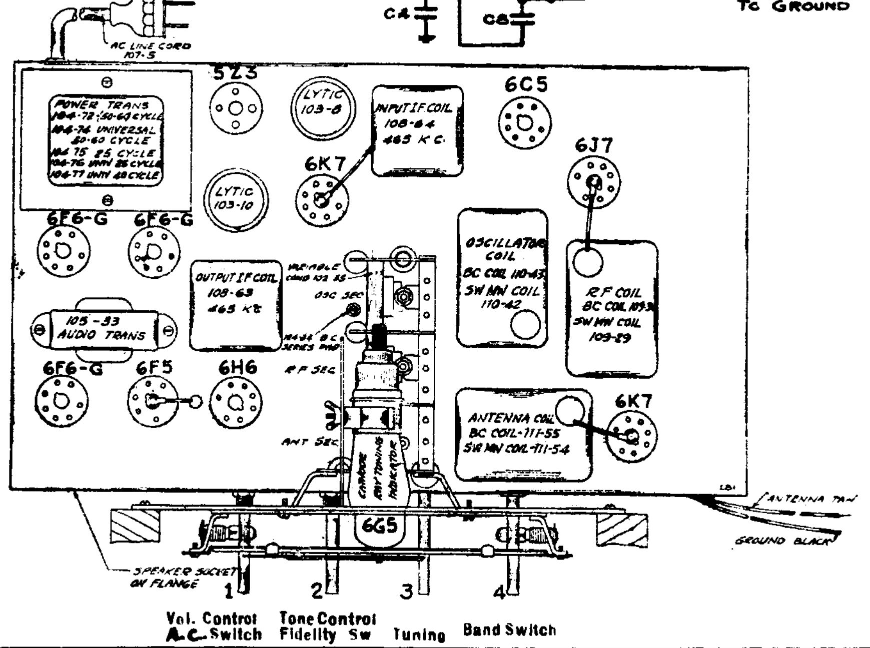
B Range 4 to 5 Microvolts Absolute

D Range 5 to 6 Microvolts Absolute

MONTGOMERY WARD & CO.

MODELS 62-301 & 62-301X





FREQUENCY RANGE

535 to 1720 K. C. (Kilocycles)
1690 to 5300 K. C. (Kilocycles)
5.2 to 18.1 M. C. (Megacycles)

LOCAL INTERFERENCE:

Local interference or "man-made" static is a form of interference often confused with static. It is due to electrical apparatus which, due to arcing or high leakage, radiates interference.

The principal sources of "man-made" noise are nigh voltage power lines, ignition systems of automobiles, brush type motors, street car trolley lines, flasher signs and electrical appliances. The noise from these sources is distributed throughout the entire frequency range used in radio, and is always strong in cities and particularly in business and industrial areas.

In rural areas "man-made" forms of interference are not as common as in cities; however, farm lighting systems, rural telephone systems and nearby high tension transmission lines often develop trouble which make radio reception noisy.

The power companies are willing to co-operate in hunting down and eliminating sources of interference, especially where their equipment is at fault.

MONTGOMERY WARD & CO.
MODELS 62-301 & 62-301X

The tube complement of this chassis consists of the latest metal and octal base glass type amplifying tubes

The type and function of each tube is as follows:

1—Type 6K7 Remote cut-off pentode R.F. amplifier.
1—Type 6J7 Pentode first detector.
1—Type 6C5 Oscillator.
1—Type 6K7 Remote cut-off pentode I.F. amplifier (465 K.C.)
1—Type 6H6 Duplex diode second detector and A.V.C.
1—Type 6F5 First audio amplifier.
1—Type 6F6G Triode driver stage.
2—Type 6F6G Class AB Output pentodes in push-pull
1—Type 5Z3 High vacuum rectifier.
1—Type 6G5 Cathode ray tuning eye.

Transformers are available and chassis are sometimes equipped with universal transformers for operation on 25, 40 and 60 cycles and with primary taps for 108, 127, 150, 225, and 260 volts, (see parts list) and also sometimes equipped with 25 cycle transformers with 105-115 volt or 220 volt primaries, not universals.

SERVICE NOTES:

Voltages taken from different points of circuit to chassis are measured with volume control full on, all tubes in their sockets and speaker connected, with a volt meter having a resistance of 1000 ohms per volt.

All voltages as indicated on diagram are measured with 115 volts on the primary of the power transformer.

Resistances of coil windings are indicated in ohms on the schematic circuit diagram.

To check for open by-pass condensers, shunt each condenser with another condenser of the same capacity and voltage rating, which is known to be good, until the defective unit is located.

Excessive hum, stuttering, low volume and a reduction in all D.C. voltages is usually caused by a shorted electrolytic condenser; open by-pass condensers frequently cause oscillation and distorted tone.

ALIGNING INSTRUCTIONS:

CAUTION:—No aligning adjustments should be attempted without first thoroughly checking over all other possible causes of trouble, such as poor installations, open or grounded antenna systems, low line voltages, defective tubes, condensers and resistors. In order to properly align this chassis, an oscillator (generator) is absolutely necessary.

No aligning adjustments should be attempted with the chassis in the cabinet. Remove the knobs and the four bolts which are used to fasten the chassis.

All adjustments should be made with a non-metallic screw driver.

RESONANCE INDICATOR:

Use as a resonance indicator an output meter connected across the primary of the speaker input transformer or by means of an adapter between the plate and cathode terminals of the 5 prong speaker socket. Maximum deflection of the meter indicates resonance. Use only enough signal to get a readily readable output. A low range output meter or the low scale of a multi-range meter should be used

DUMMY ANTENNAS:

The following dummy antennas are used in aligning and are referred to in the following alignment instructions as "Dummy 1," "Dummy 2," and "Dummy 3."

Dummy 1: (I.F.)—Consists of a .1 mfd. condenser connected in series with the external oscillator.

Dummy 2: (Broadcast—Consists of a 200 mmfd. condenser and a 20 ohm resistor connected in series with each other and in series with the external oscillator.

Dummy 3: (Middle and Short Wave)—Consists of a .1 mfd. condenser and a 400 ohm resistor connected in series with each other and in series with the external oscillator.

ALIGNING I.F. TRANSFORMERS: (465 K.C.):

Part No. 108-63 Output I.F. Transformer
Part No. 108-64 Input I.F. Transformer

These I.F. transformers have two adjustments, both of which are accessible from the underside of chassis (see bottom view, Fig. 3).

1. With volume control full on, (the extreme right of its rotation), the wave changing switch in the broadcast position, (extreme left of its rotation), the tone control on "Hi" part of the sharp position (as much right rotation as possible without operating the Hi Fidelity switch), and with the variable condenser set to approximately 1400 kilocycles, make the following adjustments:

(a) Connect external oscillator set at 465 kilocycles, in series with "Dummy 1", to the control grid cap of the type 6K7 tube, located between the two I.F. transformers, and adjust the output I.F. transformer 108-63 to resonance.

(b) With "Dummy 1" still connected, move oscillator output clip from grid of 6K7 to grid cap to 6J7 and adjust input I.F. transformer (108-64) to resonance.

(c) With oscillator still connected to 6J7, re-adjust output I.F. transformer if necessary.

(Continued on next page)

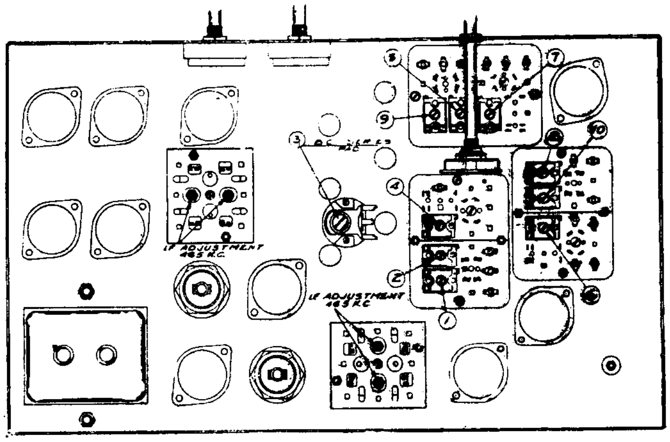


FIG. 3 — BOTTOM VIEW SHOWING TRIMMERS

MONTGOMERY WARD & CO.
MODELS 62-301 & 62-301X

(Continued from preceding page)

BROADCAST BAND ALIGNMENT:
585 to 1720 Kilocycles

1. **With band changing switch in the broadcast position, extreme left of its rotation, and with external oscillator set at 600 kilocycles and connected in series with "Dummy 2" to the tan antenna and black ground lead, make the following adjustments:**

   (a) **Adjust broadcast series pad (adjustment number 3) to resonance with oscillator.** Keep set in tune with oscillator by slowly rocking to and fro the variable condenser until maximum output is obtained. Note: This adjustment is accessible from the top of the chassis and is located between the variable condenser and the 108-63 output I.F. transformer. See top view, Fig. 1.

   (b) Re-set external oscillator to 1400 K.C., **move dial** pointer to 1400 K.C. and adjust oscillator (adjustment number 4), R.F. (adjustment number 6) and antenna (adjustment number 7) to resonance. See bottom view for location of these adjustments, Fig. 3.

   (c) Repeat adjustments "a" and "b" until sensitivity is at its maximum.

   (d) Check for tracking and sensitivity at 1000 kilocycles. **Under no circumstances bend plates of variable condenser sections to correct tracking.**

SHORT WAVE BAND ALIGNMENT:
5.2 to 18.1 Megacycles

1. With band changing switch in the short wave position, extreme right of its rotation, and with external oscillator set at 17 megacycles and connected in series with "Dummy 3" to the tan antenna and black ground lead, make the following adjustments:

   (a) Move dial pointer to 17 megacycles and adjust short wave oscillator (adjustment number 1), short wave R.F. (adjustment number 8) and short wave antenna (adjustment number 9) to resonance.

   (b) Re-set external oscillator to 6 megacycles and pick up signal by rotating variable condenser and check for sensitivity.

NOTE: **It is extremely necessary in making all of these adjustments that the fundamental oscillator signal be tuned in and not the image frequency which will fall below the fundamental on the receiver dial. As an example of this a fundamental 18.3 megacycle can be tuned in not only at 18.3 on the dial, but also at approximately 17.4 megacycles.**

MIDDLE WAVE BAND ALIGNMENT:
1690 to 5300 Kilocycles

1. With band changing switch in the middle wave position, center of its rotation, and with external oscillator set at 5 M.C. and connected in series with "Dummy 3" to the tan antenna and black ground lead, make the following adjustments:

   (a) Rotate condenser, pick up signal and adjust middle wave R.F. (adjustment number 10), middle wave antenna (adjustment number 5) and middle wave oscillator (adjustment number 2) to resonance.

PHILCO RADIO & TELEVISION CORPORATION

MODEL 37-624

Electrical Specifications

Type Circuit: Superheterodyne, using a vibrator unit operated by a 6 volt storage battery for supplying "B" power to the receiver, and a Class B audio output circuit.

Power Supply: 6 volt storage battery, Philco Type 116R.

Current Drain: 1.5 Amps.

Philco Tubes Used: 6-1D5G, R. F. Amp.; 1C7G, Det. Osc.; 1D5G I. F. Amp.; 1F7G, 2nd Det.—1st Audio A. V. C.; 1H4G, Audio Driver; 1J6G, Output.

Frequency Ranges: Three. Range 1—530 to 1720 K. C.; Range 2—2.3 to 7.4 M. C.; Range 3—7.35 to 22 M. C.

Intermediate Frequency: 470 K. C.

Speakers: KR-17. "B" Cabinet; HR-12. "J" Cabinet.

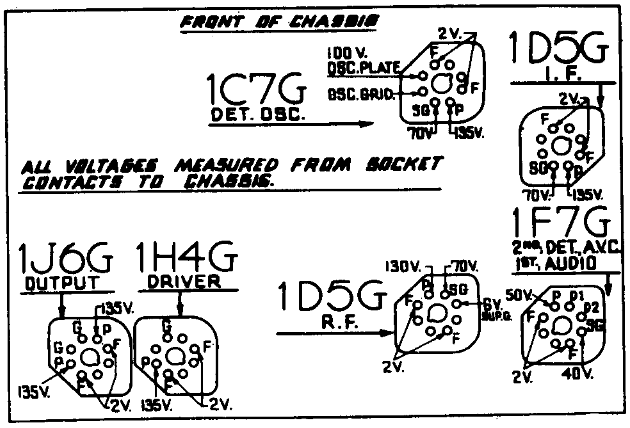

Fig. 1—Socket Voltages and R. F. Compensators

The voltages indicated by arrows were measured with a Philco 025 Circuit Tester which contains a voltmeter having a resistance of 1000 ohms per volt. Volume Control at maximum, Storage Battery fully charged.

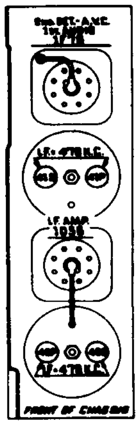

Fig. 2—I. F. Compensators

Alignment of Compensators

EQUIPMENT REQUIRED: (1) Signal Generator; Philco Model 088 (fundamental frequency 110 to 20000 K. C.) is the correct instrument for this purpose; (2) output meter. **Philco Model 025 Circuit Tester** incorporates an accurate, Sensitive output meter and is recommended; (3) Fibre handle screwdriver (Philco Part No. 27-7059); (4) Special variable condenser (Philco Part No. 45-2325).

DIAL CALIBRATION: Set the tuning condenser at the maximum capacity position. Loosen the set screw of the dial hub and set dial, with the glowing indicator centered between the first and second index lines, at the low frequency end of the broadcast scale. Tighten set screw in this position.

INTERMEDIATE FREQUENCY CIRCUIT

Frequency 470 K. C.

1. Connect the 088 Signal Generator output lead through a .1 mfd. condenser to the control grid of the 1C7G tube, and the ground connection of the Generator to the chassis. Turn the Volume Control to maximum volume position.

2. Set the range switch in position No. 1 (Broadcast), then rotate the tuning condenser of the receiver to approximately 580 K. C. and adjust the signal generator for 470 K. C.

3. Adjust compensators (41S) 2nd I. F. Sec., (41P) 2nd I. F. Pri., (40S) 1st I. F. Sec., and (40P) 1st I. F. Pri. for maximum reading on the output meter.

RADIO FREQUENCY CIRCUIT

Tuning Range (7.35) to (22.0) M. C.

1. Remove the signal generator output lead from the grid of the 1C7G tube and connect it through the .1 mfd. condenser to terminal No. 1 on aerial input panel and the generator ground lead to terminal No. 3, rear of chassis. Terminals 2 and 3 must be connected by the shorting link provided on the panel.

2. Set the range switch in position No. 3. Turn the receiver and signal generator dials to 18 M. C. Now adjust compensator (24B) by turning the screw (clockwise) to the maximum capacity position, then slowly turning it (counter-clockwise) until a second peak signal is reached on the output meter. The first peak from maximum capacity is the image signal and must not be used. **Note**—In adjusting some receivers only one peak will be observed, therefore, tune the compensator to maximum on this peak. If the above procedure is correctly performed, the image signal will be found at 17.06 M. C. by advancing the signal generator attenuator and turning the receiver dial to this frequency mark on the dial.

3. The antenna and R. F. Compensators (6B) and (20B) are now adjusted by connecting a variable condenser of approximately 350 mmfd., Philco Part No. 45-2325 across the oscillator section of the gang condenser and ground. Leaving the signal generator and receiver dials at 18 M. C., tune the added condenser from the maximum capacity point until the second harmonic of the receiver oscillator beats against the signal from the generator thereby bringing in the signal. The antenna and R. F. compensators (6B) and (20B) are then adjusted for maximum output. Now remove the external condenser and readjust compensator (24B) for maximum output.

Tuning Range (2.3) to (7.4) M. C.

1. Set range switch in position 2. Rotate signal generator and receiver dials to 7.0 M. C. Now adjust compensator (24A) for maximum output.

2. Turn the signal generator and receiver dials to 6.0 M. C. and adjust compensators (20A) R. F. and (6A) Ant. for maximum output.

Tuning Range (530) to (1720) K. C.

1. Set range switch in position No. 1 (Broadcast). Rotate the signal generator and receiver dials to 1600 K. C. Now adjust compensators (24) Osc., (20) R. F. and (6) Ant. for maximum output.

2. Rotate the signal generator and receiver dials to 580 K. C. Compensator (25) Osc. series is now adjusted for maximum output as follows:

First tune compensator (25) for maximum output, then vary the tuning condenser of the receiver for maximum output about the 580 K. C. dial mark. Now turn compensator (25) slightly to the right or left and vary the receiver tuning condenser for maximum output. If the out reading increases, turn compensator (25) in the same direction a trifle more, and again vary the tuning condenser for maximum output. If the output decreases, set the compensator in the opposite direction. This procedure of first setting the compensator and then varying the tuning condenser is continued until there is no further gain in output reading.

3. Readjust compensator (24) for maximum output, by turning the signal generator and receiver dials to 1600 K. C.

4. Turn the signal generator and receiver dials to 1500 K. C. and adjust compensators (20) R. F. and (6) Ant. for maximum output.

PHILCO RADIO & TELEVISION CORPORATION

MODEL 37-650

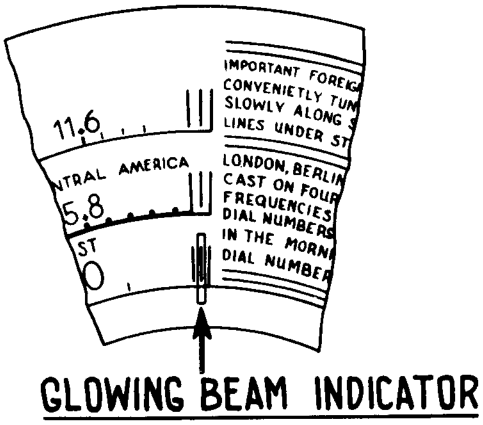

Fig. 4—Dial Calibration

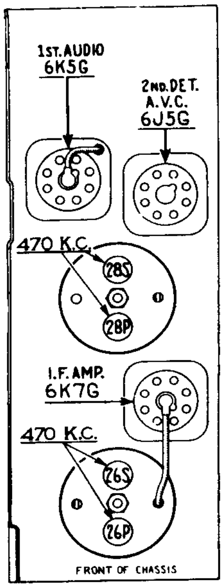

Fig. 5—I. F. Compensators—Top of Chassis

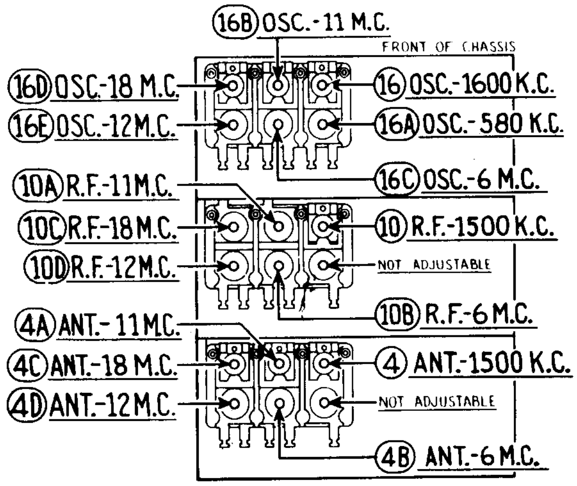

Fig. 6—R. F. Compensators—Underside of Chassis

Alignment of Compensators

The accurate adjustment of the various compensating condensers is vital to the proper functioning of this receiver. There are four compensating condensers in the I. F. Circuit, six in the Oscillator Circuit, five in the R. F. Amplifier Circuit and five in the Antenna Circuit. Incorrect adjustment will cause loss of sensitivity, unsatisfactory tone, and poor selectivity.

To accurately adjust this receiver, precision test equipment is necessary. A signal generator such as the PHILCO MODEL 088 SIGNAL GENERATOR, covering from 110 to 20,000 K. C. is recommended to adjust the compensators at the various frequencies specified. A visual indication of the receiver output is also necessary to obtain correct adjustment of the compensators. PHILCO MODEL 025 CIRCUIT TESTER contains a sensitive output meter and is recommended for these adjustments.

Philco Fibre Handle Screw-driver No. 27-7059 completes the necessary equipment for these adjustments. The locations of the various compensators are shown in Figs. 5 and 6.

The following procedure must be observed in adjusting the compensators:—

SHADOWMETER ADJUSTMENT

1. Remove the aerial and allow tubes to warm up. Then adjust shadowmeter as follows: Move the coil backward and forward until opposite edges of the shadow are ⅛ of an inch from each end of shadow screen, measuring along bottom edge. Adjustment of the shadowmeter light bracket may be necessary for perfect centering.
2. Remove the (5Y4G) rectifier tube from its socket and rotate coil until shadow reaches minimum width. This width is not to exceed $\frac{1}{32}$".
3. Replace the (5Y4G) rectifier tube. Shadow must not widen to more than $\frac{1}{16}$" or less than $\frac{1}{16}$" from each side of screen. If these limits are not obtained readjust the shadowmeter as given in paragraphs 1 and 2 until they are reached.

OUTPUT METER—The 025 Output Meter is connected to the plate and cathode terminals of one of the (6F6G) tubes. Adjust the meter to use the (0-30) volt scale.

DIAL CALIBRATION—Rotate the tuning condenser control to the extreme counter-clockwise position (maximum capacity). Loosen the screw of dial hub, then turn dial until the glowing indicator is centered on the second index line of dial scale (see Fig. 4). Then tighten the dial hub set screw in this position.

INTERMEDIATE FREQUENCY CIRCUIT

Frequency 470 K. C.

1. Turn volume control to maximum volume position. Connect the 088 Signal Generator output through a .1 mfd. condenser, to the control grid of the 6A8G tube and the ground connection of the output lead to the chassis.
2. Set the range switch in position No. 1 (Broadcast), then rotate the tuning condenser of the receiver to the maximum capacity position (counter-clockwise) and adjust the signal generator for 470 K. C.
3. Adjust compensators (28S) 2nd I. F. Sec., (28P) 2nd I. F. Pri., (26S) 1st I. F. Sec. and (26P) 1st I. F. Pri. for maximum reading on the output meter.

RADIO FREQUENCY CIRCUIT

Tuning Range—7.3 to 18.0 M. C.

1. Remove the signal generator output lead from the grid of the 6A8G tube and connect it through the .1 mfd. condenser to terminal No. 1 on aerial input panel and the generator ground lead to terminal No. 3, rear of chassis. Terminals 2 and 3 must be connected with the shorting link provided on the panel during these adjustments.
2. Set the range switch in position No. 3. Turn the receiver and signal generator dials to 18 M. C. Now adjust compensator (16D) by turning the screw (clockwise) to the maximum capacity position. Then slowly turn it counter-clockwise until a second peak signal is reached on the output meter. The first peak from maximum capacity is the image signal and must not be used. NOTE: In some cases only one peak will be found, therefore, tune the compensator to this peak. If the above procedure is correctly performed, the image signal will be found at 17.060 M. C., by advancing signal generator input and turning receiver dial to this frequency mark on the dial.
3. The antenna and R. F. compensators (4C) and (10C) are now adjusted by connecting a variable condenser of approximately 350 mmfd.,—having a good vernier drive—across the oscillator compensator (16D) contact (first contact from left side of receiver facing rear underside view of chassis) and ground. Leaving the signal generator and receiver dials at 18 M. C., tune the added condenser until the second harmonic of the receiver oscillator beats against the signal from the generator, thereby giving an indication on the output meter. It may be necessary to increase the signal generator output to obtain a signal of sufficient strength for reading on the output meter. The antenna and R. F. compensators (4C) and (10C) should then be adjusted for maximum output. Then remove external condenser and readjust compensator (16D) as given in paragraph 2 above.
4. Turn signal generator and receiver dials to 12 M. C. and adjust compensators (16E), (10D), (4D) for maximum output.
5. Now turn signal generator and receiver dials to 18 M. C. and readjust compensators (16D), (10C) and (4C) as given in Paragraphs 2 and 3 above.

Tuning Range—5.7 to 11.6

1. Set range switch in position No. 2. Rotate signal generator and receiver dials to 11 M. C. Compensator (16B) is now adjusted as given in Paragraph 2, under tuning range 7.3 to 18 M. C. above. ***Check image signal on the 10.06 dial mark.*** The only difference in the two procedures is the frequency used.
2. Turn the signal generator to 11 M. C. Then connect a 350 mmfd. variable condenser from the oscillator compensator (16B) contact (third contact from left side of the receiver, facing rear underside view of chassis) and ground. Tune the added condenser, as given in Paragraph 3 under tuning range 7.3 to 18 M. C. Now adjust compensators (10A) and (4A) for maximum output. The only difference in the two procedures is in the connection of the variable condenser and the frequency used.
3. Readjust compensator (16B) as given in Paragraph 1 for maximum output.
4. Turn signal generator and receiver dials to 6 M. C. and adjust compensators (16C), (10B) and (4B) for maximum output.
5. After the 6 M. C. end of scale is adjusted, the high frequency end is readjusted as given in Paragraphs 1, 2 and 3 above.

Tuning Range—530 to 1720 K. C.

1. Turn signal generator and receiver dials to 1600 K. C.—If signal generator scale is not calibrated for 1600 K. C. the dial of the generator may be rotated to 800 K. C. and the second harmonic of this frequency (1600 K. C.) may be used for following adjustments. Compensators (16), (10) and (4) are now adjusted for maximum output.
2. Turn signal generator and receiver dials to 580 K. C. and adjust compensator (16A) for maximum output. This is accomplished as follows:
First tune compensator (16A) for maximum output. Then vary the tuning condenser for maximum output about the 580 K. C. scale mark. Now retune compensator (16A), and again vary the tuning condenser back and forth about 580 K. C. for maximum output. This operation of first tuning the compensator, then the tuning condenser is continued until maximum output is obtained on or about the 580 K. C. dial mark.
3. Turn signal generator and receiver dials to 1600 K. C. and readjust compensator (16) for maximum output.
4. Now rotate signal generator and receiver dials to 1500 K. C. and adjust compensators (10) and (4) for maximum output.

NOTE: See page 237 before servicing this set.

PHILCO RADIO & TELEVISION CORPORATION

MODEL 37-650

SERVICE DATA

DESCRIPTION

Model 37-650 is an 8 tube superheterodyne receiver for operation on alternating current. It has three tuning ranges, covering standard broadcast and short-wave frequencies. The chassis is constructed in four basic assembly units, concentrating the R. F., I. F., Audio and Power Circuits in individual units.

The circuit includes the **Philco Foreign Tuning System**—controlled by the range switch—providing maximum sensitivity and noise reduction, when used with the **Philco High Efficiency Aerial;** one stage of radio frequency amplification before the Detector-Oscillator tube; Automatic Bass Compensation in the Volume Control Circuit; Shadow Tuning; Automatic Volume Control, and a Push-Pull Pentode Output Circuit

AERIAL CONNECTIONS

The red and black leads of the High-Efficiency Aerial "transmission line" are connected to terminals 1 and 2 respectively, of the terminal panel provided at the rear of the chassis. Connect the jumper on the terminal panel across terminals 3 and 4.

If a temporary aerial is used, the jumper should be across terminals 2 and 3. The aerial connects to terminal 1 and the ground lead to terminal 3. A good ground connection is desirable in all installations.

REPLACING DIAL

To replace the dial, remove the clamp holding the dial to the hub by turning clamp counter-clockwise, using the two holes provided on the clamp for this purpose.

REMOVING MASK ARM & LINK ASSEMBLY

First remove dial, then loosen set screw of dial hub and remove the hub and felt washer from the shaft. Now loosen screws holding indicator bracket and lens assembly, and move bracket forward about ½ inch. The assembly may now be removed by loosening set screw of range switch arm, then pull arm off of range switch shaft.

REMOVING SWITCH & COIL ASSEMBLIES OF R. F. UNIT

To replace any part in the switch and coil assemblies of the R. F. Unit, each assembly can be removed separately as follows:

First remove the tuning dial, mask and arm assembly. Remove the center mounting screw on the rear of the R. F. Unit. Then lift the rear of the unit and push forward until the rubber mounting grommets, on each side of the unit, clear the mounting slots. The unit is then lifted far enough from the chassis for removal of the two screws holding the selector switch indexing plate and shaft (front of unit). Then pull shaft straight out from the unit. Also, remove the volume control shaft by releasing the retaining clip, inside the chassis, from the shaft.

IMPORTANT—When selector switch shaft is replaced, care should be taken to have all wafer rotors in the same position, so that the key on the switch shaft will slide freely into the notched hole in each wafer rotor. *NEVER* force shaft into rotors.

Servicing Stages—It is necessary to unsolder some connecting leads in order to release the stage for servicing. If all the following connections are unfastened the stage will be entirely released. Ordinarily only one or two leads need be loosened in order to change coils, replace coupling condensers, or replace switch sections.

Antenna Stage Assembly—Rear Section of Unit

A. Remove screw holding shield plate to the unit base. This screw is located in the right hand corner of the shield plate, facing rear underside of the chassis.

B. Unsolder the wires at the I. F. and Aerial terminal panels which connect to the range switch, also wires from tuning condenser housing to tubular condenser (6); tuning condenser stator plate to selector switch contact (B3), and ground lead from assembly shield to unit frame. After disconnecting these wires assembly may be removed

R. F. Stage Assembly—Middle Section

A. Remove screw (right side of assembly) holding shield plate to unit base.

B. Unsolder the two wires connecting the I. F. Unit to range switch contacts (C3) and (D12); also wires connecting tuning condenser housing to tubular condenser (13) and stator plates to selector switch contact (D3); selector switch contact (D2) to the grid of the 6A8G tube, and ground lead from shield to unit frame. Remove assembly from the unit.

Oscillator Stage Assembly—Front Section

A. The oscillator assembly may be removed by unscrewing the four screws holding shield to R. F. base. These screws are located on each side of the R. F. Unit.

B. Unsolder the wires connecting range switch contacts (E2) and (F2) to the 6A8G socket; tuning condenser stator plates to range switch contact (F3); mica condenser (19) to the tuning condenser housing; range switch to resistor (60) and (61), and ground lead to I. F. Unit. With these leads disconnect unit may be removed.

Replace the units by following the above procedure in the reverse order.

Electrical Specifications

Power Supply:

	Voltage	Frequency Cycles	Consumption
	115	50–60	110 watts
	115	25–40	110 watts

Intermediate Frequency: 470 K. C

Output: Undistorted 7 watts.

Philco Tubes: 6K7G—R. F. Amplifier; 6A8G—Oscillator and first detector; 6K7G—I. F. Amplifier; 6J5G—2nd Detector, A. V. C.; 6K5G—1st Audio; 2-6F6G—Output; 5Y4G—Rectifier.

Tuning Ranges: Range 1—530 to 1720 K. C.; Range 2—5.7 to 11.6 M. C.; Range 3—11.5 to 18.2 M. C.

Speakers: X Cabinet—H-26; B Cabinet—K-35.

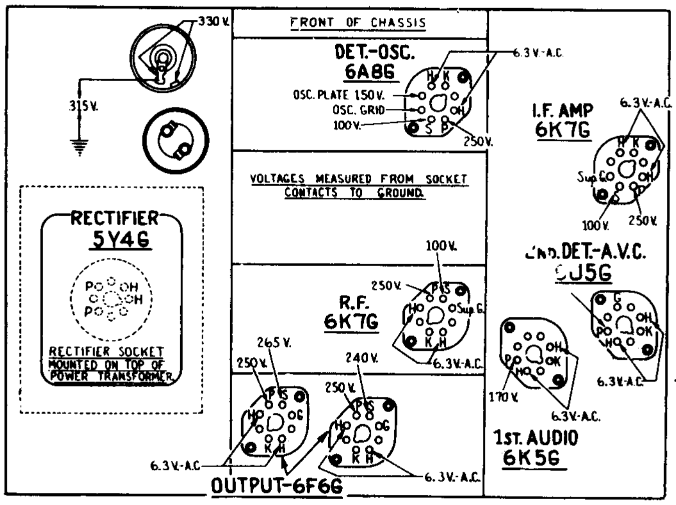
Schematic Lead No.	A. C. Volts	Current	Circuit	Color	Resistance
1-2	120	—	Pri.	White	2.0 ohm
3-4	5.	2.0A	Rect. Fil.	Blue	Less than 0.1 ohm
5-7	700	135 MA	High Volt. Sec.	Yellow	55 ohms 60 ohms
6	—	—	Center Tap 5-7	Yellow Green tr.	—
8-9	6.7	3.3 A	Fil	Black	Less than 0.1 ohm



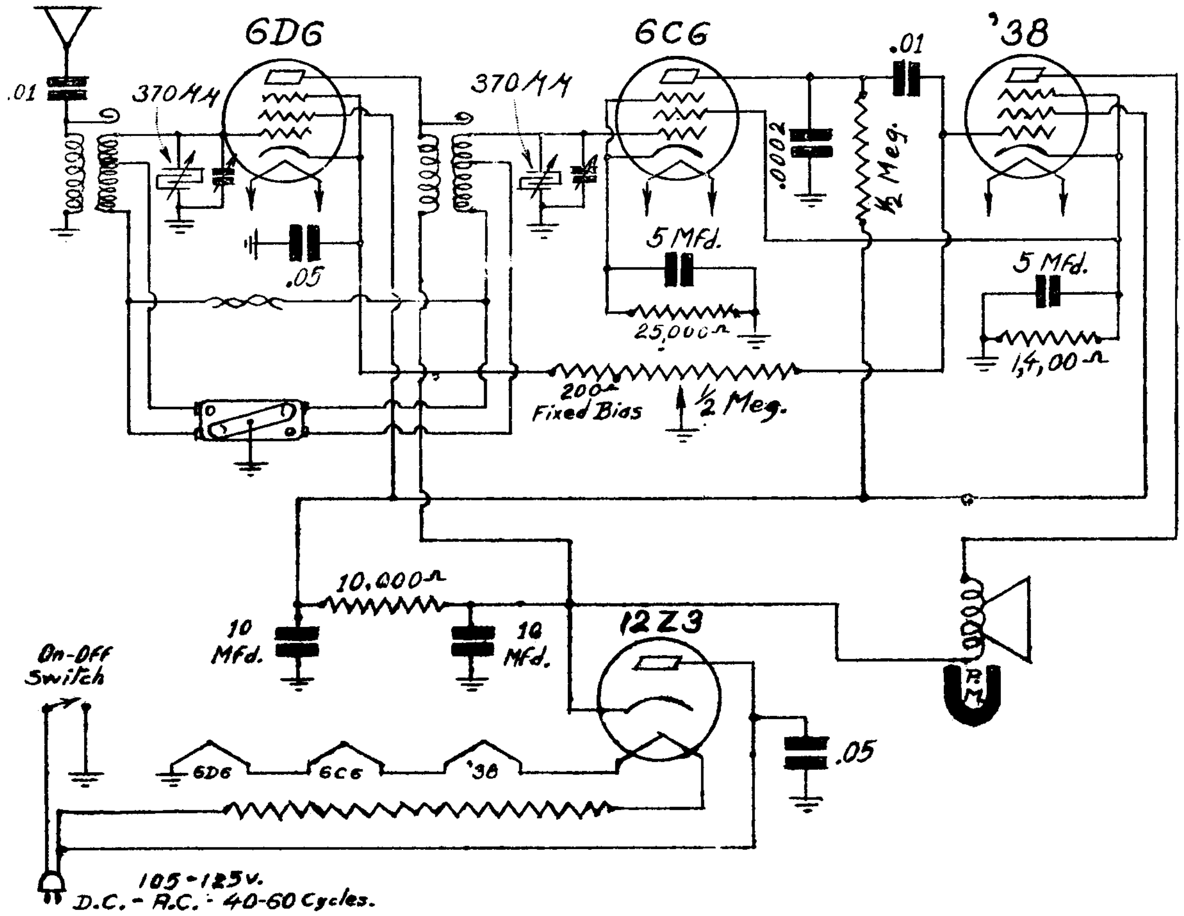
Socket Voltages—Underside of Chassis View

The voltages indicated by arrows were measured with a **Philco 025 Circuit Tester** which contains a voltmeter having a resistance of 1000 ohms per volt. Volume Control at minimum, range switch in broadcast position, line voltage 115 A. C.

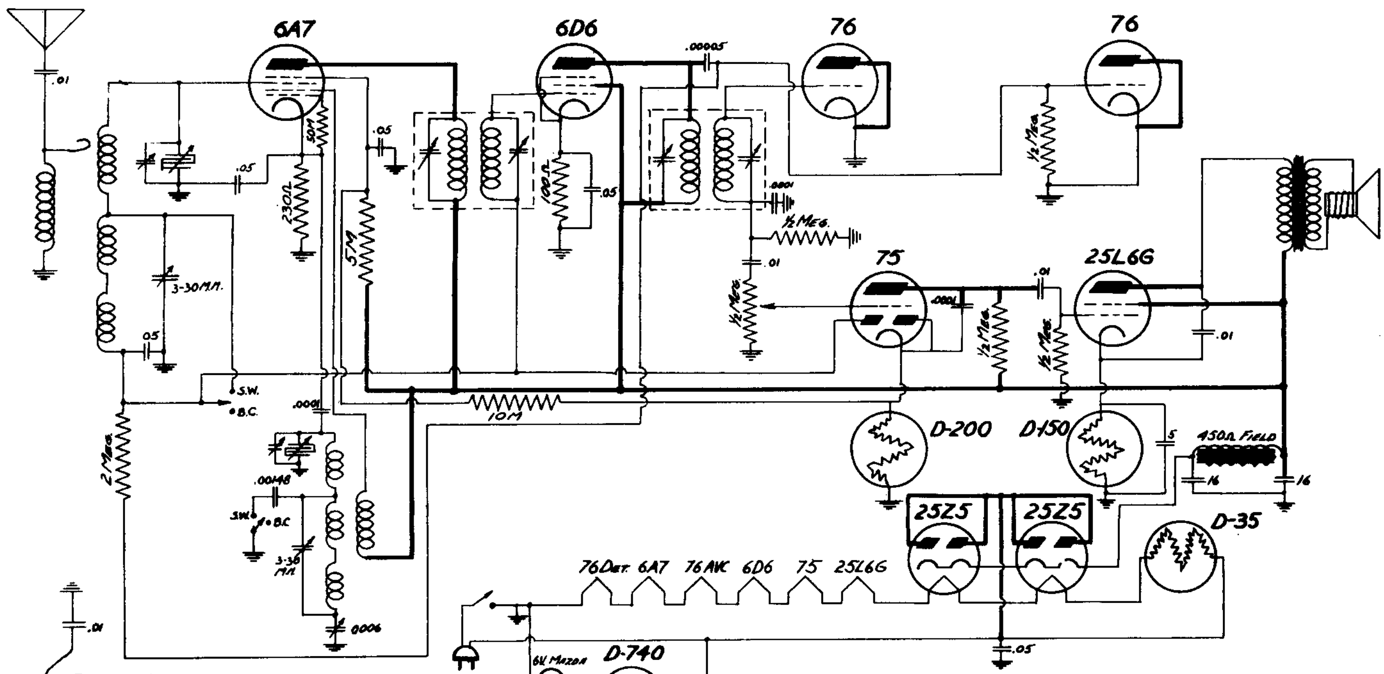
NOTE: See page 237 before servicing this set.

PIERCE AIRO, Inc.

MODEL 401



MODEL 1200



TO CALIBRATE:

Set service oscillator to 456 K.C. and connect "HOT" lead to grid of 6A7 tube. Ground stator of front (oscillator) section of variable condenser. Turn volume control for maximum output and peak intermediate frequency trimmers for maximum gain. Turn wave band switch knob toward right. Adjust service oscillator and receiver to 7 megacycles and peak variable condenser trimmers for maximum gain. Turn wave band switch toward left and adjust oscillator (service) and receiver to 1500 K.C. Peak both trimmers underneath chassis for maximum gain. Then adjust service oscillator and receiver to 600 K.C. and "rock" the variable condenser and adjust the padder (near front of chassis on top) at the same time for maximum gain.

SERVICE NOTES

REALIGNMENT The procedure outlined below should be followed should the receiver require realignment. For location aligning trimmers and padders, see Fig. 2.

I. F. ALIGNMENT To align the Intermediate Frequency stages, first place the wave Band Switch in Pos. Blue and Short Circuit the Oscillator Section of the Variable Condenser. Set the test Oscillator to 456 K.C. and connect its output through A .00025 MFD fixed Condenser to the grid cap of the 6A8G Tube and chassis ground. Adjust the six I. F. Compensators (Three on each I.F. Transformer) for Max Signal. (Volume Control must be in maximum position during all adjustments. Use the least possibe input to the receiver to prevent broadening of the resonance peaks.)

BLUE BAND (BROADCAST) ALIGNMENT After the Intermediate Frequency stages have been completely aligned, connect external test oscillator to the Antenna and Ground binding posts of the set. Set the band switch to Blue position. Set test Oscillator to 1500 K.C. and adjust the three Bl Band Compensators for maximum gain. Next, set dial at 600 K.C. and adjust Bl. Band Paddler for maximum signal, rocking Variable Condenser at the same time. Now repeat repeaking operation at 1500 K. C.

White Band ALIGNMENT Turn Wave Band Switch to White Position and set Variable Condenser to 5000 K. C. Adjust test oscillator to this frequency and adjust 3 Wh. Band Trimmers for maximum gain. Next set dial at 1900 K. C. and adjust Wh. Band Paddler for maximum signal. Now repeat repeaking operation at 5000 K. C.

Red Band (SHORT WAVE) ALIGNMENT Turn Wave Band Switch to Red position and set Variable Condenser to 16 megacycles. Adjust test oscillator to this frequency and adjust three Red Band Trimmers.

Green Band (LONG WAVE) ALIGNMENT Turn wave Band Switch to GR. position and align Trimmers on long wave coils at 375 K.C. Adjust GR. Band Padder at 160 K. C.

SERVICE NOTES.

RE-ALIGNMENT The procedure outlined below should be followed should the receiver require re-alignment. For location aligning trimmers and padders, see Fig. 2.

I. F. ALIGNMENT To align the Intermediate Frequency stages, first place the Wave Band Switch in Pos. Green and Short Circuit the Oscillator Section of the Variable Condenser. Set the test Oscillator to 456 K.C. and connect its output through A .00025 MFD fixed Condenser to the grid cap of the 6A8G Tube and chassis ground. Adjust the six I.F. Compensators (Three on each I.F. Trans.) for Max Signal (Volume Control must be in maximum position during all adjustments. Use the least possible input to the receiver to prevent broadening of the resonance peaks.)

GREEN BAND (BROADCAST) ALIGNMENT After the Intermediate Frequency states have been completely aligned, connect external test oscillator to the Antenna and Ground binding posts of the set. Set the band switch to green position. Set test Oscillator to 1500 K.C. and adjust the three Green Band Compensators for maximum gain. Next, set dial at 600 K.C. and adjust Green Band Paddler for maximum signal, rocking Variable Condenser at the same time. Now repeat repeaking operation at 1500 K.C.

WHITE BAND ALIGNMENT Turn Wave Band Switch to White Position and set Variable Condenser to 5000 K.C. Adjust test oscillator to this frequency and adjust 3 Wh. Band Trimmers for maximum gain. Next set dial at 1900 K.C. and adjust White Band Padder for maximum signal. Now repeat repeaking operation at 5000 K.C.

RED BAND (SHORT WAVE) ALIGNMENT Turn Wave Band Switch to Red position and set Variable Condenser to 16 megacycles. Adjust test oscillator to the frequency and adjust three Red Band Trimmers.

BLUE BAND (LONG WAVE) ALIGNMENT Turn Wave Band Switch to Blue position and align Trimmers on long wave coils at 375 K.C. Adjust Blue Band Padder at 160 K.C.

MODELS 2250 SERIES, 2253 & 2255

SERVICE INFORMATION FOR PILOT MODELS 2253 AND 2255

REMOVAL OF CHASSIS FROM CABINET:

To remove the chassis from the cabinet proceed as follows:

Be certain that the line cord is removed from the power outlet socket.

Remove the "slip-on" knobs and felt washers from the controls and loosen the set screw on the tuning knob.

Remove the speaker plug from the socket at the rear of the chassis.

Remove the four mounting screws, located underneath the cabinet.

REALIGNMENT: Should the receiver require re-alignment, the procedure outlined below should be followed. For best results an external modulated oscillator with adequate frequency range, and a visual output meter, should be used.

Before connecting the chassis to the power line, reconnect the speaker cable in its socket at the rear of the chassis.

The location of the R. F. alignment trimmer condensers is on the side of the band switch. The trimmers in the lowest row are those for aligning Band 1. Those in the second row from the bottom are for Band 2. Those in the third row up are for the Broadcast. In the Model 2255 there is an additional row of trimmers located immediately above those for the Broadcast.

The padder condenser is located under the rear section of the band switch. In the Model 2255 an additional padder for the long wave range is located at the right of the Broadcast padder. Access to the padder condenser is made through a hole provided in the rear of the chassis frame.

I. F. ALIGNMENT: When aligning the Intermediate Frequency Amplifier, the external oscillator must be set at 456 kc. The Band Selector Switch should be in the position marked "Broadcast", and the tuning condenser should be set at maximum capacity. Connect the "antenna" lead of the external oscillator to the control grid of the type 6D6 tube in the I. F. Amplifier stage through a .1 mfd. fixed condenser. Connect the "ground" lead of the external oscillator to the receiver ground lead. The I. F. alignment capacitors are located at the side of the shielded I. F. Transformers. Rotate the adjusting screw of each capacitor on I. F. Unit No. 2 slowly until maximum output is noted. On completion of this operation, remove the external oscillator lead from the type 6D6 I. F. amplifier tube and connect it in the same manner to the control grid at the top of the type 6A7 tube.

Now rotate each adjustment screw on I. F. Unit No. 1 for maximum output. During these operations, use the least possible input to prevent broadening of the resonance peaks.

In order to obtain the most accurate realignment of the I. F. amplifier, it is essential to repeat the alignment process in both I. F. Units.

BROADCAST ALIGNMENT: After the I. F. amplifier is completely realigned, connect the external oscillator leads to the receiver antenna and ground leads. Insert a 200 mmf. condenser in series with the antenna lead. Set the Band Selector Switch in the "Broadcast" position and place the tuning control pointer at the 1500 kc. mark. Adjust the broadcast band oscillator trimmer.

Next adjust the interstage alignment trimmer for maximum response. Finally adjust the antenna section trimmer in the same manner.

Next adjust the 600 kc. padder condenser, located in the lower rear section of the band switch, under the chassis. Set the external oscillator at 600 kc. Rotate the receiver tuning control until resonance is indicated. Then rock the tuning control back and forth about this resonance position, and at the same time adjust the padder condenser for the highest resonance peak.

Now repeat the 1500 kc. trimmer adjustment, following in every detail the procedure previously described.

ALIGNMENT OF THE SHORT-WAVE BANDS:— The procedure in aligning the short-wave bands is identical with that for the broadcast with the exception of the adjustment of the padder condenser. Insert a 400 ohm non-inductive resistor in series with the antenna lead The alignment frequencies are as follows:

Band 2: 50 Meters—(6,000 kc.)
Band 1: 16.6 Meters—(18,000 kc.)

When aligning Band 2, set the Band Selector Switch in the position marked "Band 2". Set the tuning control pointer at 50 meters. Adjust the oscillator alignment capacitor on Band 2 for maximum output. Next adjust the interstage and antenna section alignment capacitors for maximum output.

To align Band 1, set the Band Selector Switch in the position marked "Band 1". Set the tuning control pointer at the 16.6 meter mark. Set the external oscillator at 16.6 meters. Adjust the oscillator section alignment capacitor on Band 1 for maximum output.

Proceed next to align the interstage section of Band 1. In doing this, it is essential to rock the tuning control back and forth about the resonance position and at the same time to adjust the trimmer for the highest resonance peak. Next align the antenna section for maximum sensitivity.

LONG WAVE MODEL 2255

The above alignment positions refer to the Model 2253 only, which is calibrated in frequency. The alignment points for the Model 2255, which is calibrated in meters only, is as follows:

Long Wave	Align at 750 meters.
	Pad at 2,000 meters.
Broadcast	Align at 200 meters.
	Pad at 500 meters.
Band 2	Align at 49 meters.
Band 1	Align at 17 meters.

The Long Wave alignment procedure is similar to that for the Broadcast. A 200 mmf. condenser should be used in series with the antenna lead in aligning this band.

REMOVAL OF BAND SELECTOR SWITCH ASSEMBLY: Should it be necessary to remove the switch assembly, this is easily done by removing the supporting screws. Before doing this, however, it is essential to unsolder the leads between the switch and the chassis.

It is advisable to realign the receiver after reinstalling the switch assembly.

CAUTION: When making repairs on the receiver, use only ROSIN CORE SOLDER. NEVER USE SOLDERING PASTE OR ACID FLUXES OF ANY TYPE.

MODELS U-101 & U-103

Chassis Wiring Diagram
(Model U-103)

General Description

The Model U-103 combination instrument consists of a five-tube superheterodyne receiver and an automatically operated phonograph combined in console-type cabinet. Its design includes magnetic-core adjusted i-f transformers, automatic volume control, resistance-coupled audio system, phonograph compensation pack, self-starting constant-speed motor, improved magnetic pickup, and a twelve-inch dust-proof electrodynamic loudspeaker. The phonograph mechanism will change seven 10-inch records or repeat 12-inch records automatically. It may be operated manually if desired.

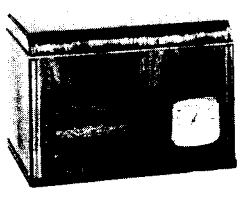
The Model U-101 instrument consists of a similar radio receiver combined with a manually operated phonograph in a table-type cabinet. The loudspeaker is an eight-inch dust-proof electrodynamic unit. The motor is of the synchronous induction type. The circuit arrangement of both receivers is shown on figure 1.

Service Data

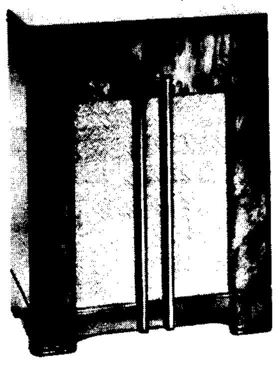
The various diagrams of this model contain such information as will be needed to isolate causes for defective operation if such develops. The ratings of the resistors, capacitors, coils, etc., are indicated adjacent to the symbols signifying these parts on the diagrams. Identification titles such as R1, L1, C1, etc., provide reference between the illustrations and Replacement Parts List. The coils, transformer windings, and reactors are rated in terms of d-c resistance to permit continuity checks.

Precautionary Lead Dress—(1) Dress power line leads to the on-off switch away from grid connection terminal on volume control to reduce hum pickup. (2) Keep leads of capacitor C3 as short as possible. (3) Bus leads from range selector (ter. 6) to oscillator coil tap L6L8 should be maintained 3½ inches long for proper alignment. (4) Capacitor C25 should be dressed free of adjacent parts to maintain correct alignment at high-frequency end of "A" band. (5) Bus lead from range selector (ter. 3) to antenna coil L1 should be maintained 2¼ inches long for proper alignment. (6) The RCA-6A7 grid-cap lead (50-ohm resistor R18) to top of tuning capacitor C2 should be dressed properly to prevent shorts and should be maintained flexible to prevent acoustic howl.

Loudspeaker.—Centering of the loudspeaker is made in the usual manner with three narrow paper feelers after first removing the front dust cover. This may be removed by softening its cement with a light application of acetone, using care not to allow the acetone to flow into the air gap. The dust cover should be cemented back in place with ambroid upon completion of adjustment.



Model U-101



Model U-103 →

Phonograph Mechanism
(Model U-101)

This phonograph motor is of the synchronous type. Under normal operating conditions, service difficulties should be

(Continued on next page)

RCA MANUFACTURING COMPANY, Inc.

MODELS U-101 & U-103

(Continued from preceding page)

negligible. Occasionally, however, certain adjustments may be required. These adjustments are illustrated and explained in figure 7. Refer to figure 1 for motor coil connections.

Automatic Record Mechanism

(Model U-103)

The record changing mechanism is designed to be simple and fool-proof. Certain adjustments may be required occasionally. The adjustments are illustrated and explained in figures 4 and 5.

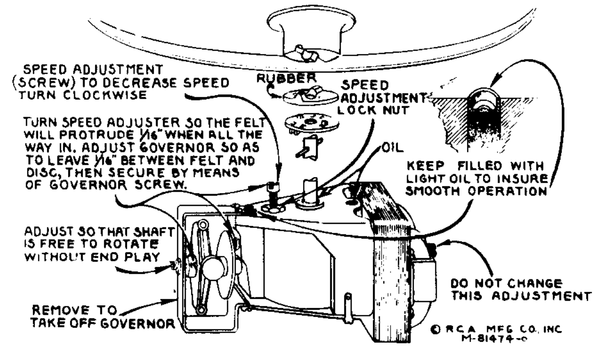


Figure 5—Details of Motor
(Model U-103)

It is important when servicing the automatic mechanism, to have it placed on a level support. It is also important to refrain from forcing the mechanism if there is a tendency to bind or jam, since bent levers and possible broken parts may result.

CAUTION.—**Do not leave records stacked on the record holder posts, when not in use, as they are liable to warp, particularly so in warm climates.**

MAGNETIC PICKUP

The pickup used in the phonograph unit is of an improved design. The horseshoe magnet is rigidly welded to the pole pieces and is irremovable. There is a centering spring attached to the armature to maintain proper adjustment and to provide a limiting effect on the movement of the armature. The frequency response is substantially uniform over a wide range. Service operations which may be necessary on the pickup are as follows:

Centering Armature.—Refer to figure 6 showing the pickup inner structure. The armature is shown in its proper relation to the magnet pole pieces, i. e., exactly centered. Whenever this centering adjustment has been disturbed it will be necessary to remove the pickup mechanism from the tone arm by removing the needle holding screw and the two mounting screws from the front of the tone arm, holding the pickup assembly to keep it from dropping. Unsolder the two leads from the lugs on the terminal board at the rear of the pickup. Insert a small rod or nail into the armature needle hole and replace the needle holding screw, tightening it to hold the rod securely. If the armature clamping screws A and B have not been disturbed, screws C should be loosened which will permit the armature to be moved from side to side, the rod acting as a lever to perform this operation. The proper adjustment is obtained when the armature is moved to the extreme position on each side (the movement being

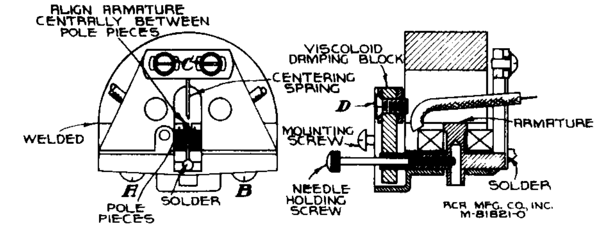

Figure 6—Details of Pickup

limited by the armature striking the pole pieces) and then brought to the mid position between these two extremes. Screws C should then be tightened. The armature position should then be central between the pole pieces and at right angles to them. With a little practice, the correct adjustment of the armature will be obtained. The air gap between the pole pieces and the armature should be kept free from dust, filings, and other foreign material which would obstruct the movement of the pickup armature.

Damping Block.—The viscoloid damping block which is attached to the front end of the armature shank serves as a mechanical filter to eliminate undesirable resonances and to cause the frequency response to be uniform. Should it be necessary to replace this damping block, the pickup mechanism should be removed from the tone arm as explained above. Remove screw D and the damping block from the pickup assembly. Make sure that the shaft of the armature which contacts the viscoloid is clean. Then insert the new damping block so that it occupies the same position as that of the origi-

(Continued from preceding page)

nal block, and is in correct vertical alignment with the armature. The hole in the block is somewhat smaller than the diameter of the armature in order to permit a snug fit. With the damping block properly aligned on the armature, screw D with its washer should then be replaced. Heat should be applied to the armature (viscoloid side) so that the damping block will fuse at the point of contact and become rigidly attached to the armature. A special-tip soldering iron, constructed as shown in figure 8 will be found very useful in performing this operation. The iron should be applied only long enough to slightly melt the block, causing a small bulge on both sides.

Replacing Coil.—Whenever there is defective operation due to an open or shorted pickup coil, this coil should be replaced. Remove the pickup mechanism and terminal board as described above. Remove screws A and B and the magnet assembly. Remove the bakelite coil support (with coil attached) and insert the new coil support assembly in its place, after which replace the magnet assembly and center the armature as described above, then re-assemble the remainder of the unit.

Magnetizing.—In case it becomes necessary to re-magnetize the unit, first remove the pickup mechanism from the tone arm, and then remove the magnet assembly. Place the mag-

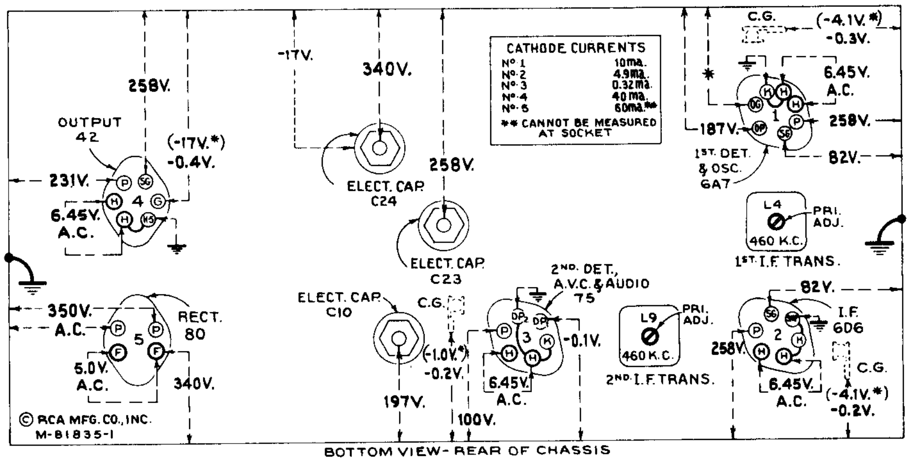

Figure 9—Radiotron Socket Voltages, Coil, and Trimmer Locations
(Model U-101)

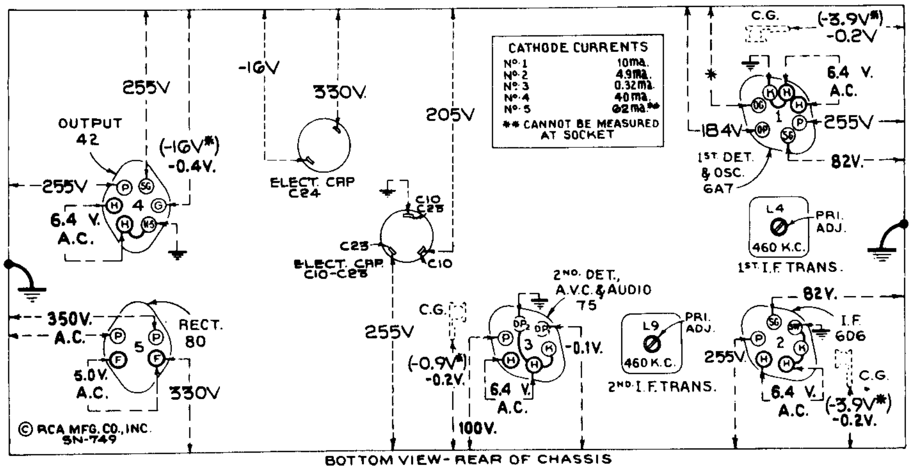

Figure 10—Radiotron Socket Voltages, Coil, and Trimmer Locations
(Model U-103)

Measured at 115 volts, 60-cycle supply—Tuned to approximately 1,000 kc ("Broadcast")—
No signal being received—Volume control minimum

Note: Two voltage values are shown for some readings. The value shown in parentheses with asterisk (*) indicates operating conditions without voltmeter loading. The other value (generally lower) is the actual measured voltage and differs from the value shown in parentheses because of the additional loading of the voltmeter through the high series circuit resistance.

Voltage values as specified should hold within ±20% when the receiver is normally operative at its rated line voltage. To duplicate the conditions under which the voltages were measured requires a 1,000-ohm-per-volt d-c meter, having ranges of 10, 50, 250, and 500 volts. Use the nearest range above the specified measured voltage. A-c voltages were measured with a corresponding a-c meter.

net assembly on the poles of a standard pickup magnetizer such as the RCA Stock No. 9549 Pickup Magnetizer and charge the magnet in accordance with the instructions accompanying the magnetizer. It is preferable to check the polarity of the pickup magnet and to remagnetize it so that the same polarity is maintained.

Alignment Procedure

Calibrate the tuning dial by adjusting dial pointer to the center horizontal line with the gang tuning-condenser plates in full-mesh position. This is a screw-driver adjustment

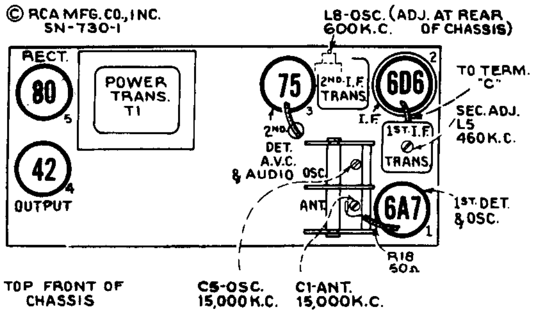

Figure 11—Radiotron, Coil, and Trimmer Locations

Perform alignment in proper order, tabulated below, starting with No. 1 and following all operations across, then No. 2, etc. Adjustment locations are shown on figures 9, 10, and 11.

Cathode-ray alignment is preferable; the connections to the chassis are shown on figures 2 and 3. If an output indicator is used, connect it across the loudspeaker voice-coil and advance the receiver volume control to full-volume position.

Connect the "low" output terminal of the test oscillator to the receiver chassis for all alignment operations. Regulate the output of the test oscillator so that minimum signal is applied to the receiver to obtain an observable output indication. This will avoid a-v-c action.

The term "Dummy antenna" means the device which must be connected between the "high" test-oscillator output and the point of connection to the receiver in order to obtain ideal alignment. "No signal, 550-750 kc" means that the receiver should be tuned to a point between 550 and 750 kc where no signal or interference is received from a station or local (heterodyne) oscillator.

For further details on alignment, refer to booklet "RCA Victor Receiver Alignment."

Order of Alignment	Test Oscillator			Range-Selector	Receiver Dial Setting	Circuit to Adjust	Adjustment Symbols	Adjust to Obtain
	Connection to Receiver	Dummy Antenna	Frequency Setting					
1	6D6 I-F Grid Cap	.001 Mfd.	460 kc	"A" Left	No Signal 550-750 kc	2nd I-F Trans.	L9	Max. (peak)
2	6A7 Det. Grid Cap	.001 Mfd.	460 kc	"A" Left	No Signal 550-750 kc	1st I-F Trans.	L4 and L5	Max. (peak)
3	Ant. Lead (blue)	300 Ohms	15,000 kc	"C" Right	15,000 kc	"C" Osc.	C5	Max. (peak)†
4	Ant. Lead (blue)	300 Ohms	15,000 kc	"C" Right	Rock Through 15,000 kc	"C" Ant.	C1	Max. (peak)*‡
5	Ant. Lead (blue)	200 Mmfd.	600 kc	"A" Left	600 kc	"A" Osc.	L8	Max. (peak)

† Use maximum capacity peak if two peaks can be obtained.
* Use minimum capacity peak if two peaks can be obtained.
‡ After this adjustment, check for image signal by shifting receiver dial to 15,920 kc.

REPLACEMENT PARTS

Insist on genuine factory tested parts which are readily identified and may be purchased from authorized dealers.

14640	Switch—Range switch (S2, S3)
14376	Transformer—First I.F. transformer (L4, L5, C11, C12)
14642	Transformer—Second I.F. transformer (L9, L10, C14, C16)
14655	Transformer—Power transformer, 105-125 volts, 50-60 cycle (T1)
14656	Transformer—Power transformer, 105-125 volts, 25-60 cycle (T1)
14657	Transformer—Power transformer, 100-125/200-250 volts, 50-60 cycle (T1)
14826	Volume Control—and power switch (R5, S1)

OPERATING MECHANISM ASSEMBLIES MODEL U-103

STOCK No.	DESCRIPTION
14199	Bushing—Record separator rotating shaft bushing
14183	Cam—Cam and gear assembly
6808	Clutch—Trip lever friction clutch
14197	Finger—Friction finger assembly
14186	Hub—Rotating hub and record separator complete with set screw
14189	Lever—Locating lever assembly
14184	Lever—Main lever and link assembly
14201	Lever—Manual index lever assembly
14193	Lever—Pickup lift cable lever
14194	Lever—Pickup arm lever complete with set screws
14198	Lever—Reject lever assembly
14185	Lever—Trip lever and friction clutch assembly
14196	Pawl—Trip pawl assembly
4563	Screw—Cable lever screw and two locknuts
4059	Screw—Trip lever clutch tension adjustment screw
14200	Screw—No. 8-32 special hex head screw and lockwasher for record separator shaft mounting
14195	Screw—No. 10-32x5/16 fillister-head, cone-pointed set screw for pickup arm lever
14188	Screw—No. 10-32x7/16 fillister-head, cone-pointed set screw for rotating hub
14187	Shaft—Rotating shaft for record separator
3676	Spring—Cam pawl tension spring
3666	Spring—Lift cable tension spring
14190	Spring—Locating lever pawl tension spring
14191	Spring—Locating lever or reject lever tension spring
14192	Spring—Main lever tension spring

MOTORBOARD ASSEMBLIES MODEL U-101

STOCK No.	DESCRIPTION
14803	Brake—Turntable brake and motor switch
14805	Connector—2-contact male connector for motor and switch leads
3261	Rest—Pickup rest
14235	Screw—Motor mounting screw and washer
30100	Springs—Tension springs for brake Stock No. 14803—comprising 1 long and 1 short spring
14804	Switch—Motor switch (S4)—located on turntable brake Stock No. 14803

MOTORBOARD ASSEMBLIES MODEL U-103

STOCK No.	DESCRIPTION
14208	Bracket—Bumper bracket and bumper complete
14209	Bumper—Rubber bumper
14830	Cable—Shielded cable 13-in. long complete with single contact male connector — connects pickup shorting switch to input transformer or compensator
11704	Damper—Turntable damper and damper plate
14212	Escutcheon—Manual index lever and switch escutcheon
14203	Post—Record post—located on front left hand corner of motorboard
14210	Rest—Pickup arm rest
14207	Roller—Pickup lift cable roller and bracket
14211	Socket—Motorboard socket and shell
14205	Support—Pickup arm mounting spacer, washers and nut
14206	Switch—Motor toggle switch (S4)
14629	Switch—Pickup shorting switch (S6)
14204	Turntable Complete
14213	Washer—Pickup arm stop washer and spacing washer

MOTOR ASSEMBLIES MODEL U-101

STOCK No.	DESCRIPTION
10194	Ball—Steel ball bearing
14233	Base—Motor base and bearing assembly
14232	Cap—Turntable spindle cap
14223	Coil—Stator assembly—comprising coils and laminations—105-125 volts, 60 cycle
14224	Coil—Stator assembly—comprising coils and laminations—105-125 volts, 50 cycle
14225	Coil—Stator assembly—comprising coils and laminations—105-125 volts, 25 cycle
14228	Damper—Motor damper assembly comprising one damper, one damper plate, one screw and one "C" washer
14806	Motor—105-125 volts, 60 cycle (M1)
14807	Motor—105-125 volts, 50 cycle (M1)
14808	Motor—105-125 volts, 25 cycle (M1)
14227	Shield—Terminal board shield and nuts
14229	Stop—Turntable stop, lockwasher and nut—prevents removal of turntable
14809	Turntable—Turntable assembly complete with rotor laminations—60 cycle operation
14810	Turntable—Turntable assembly complete with rotor laminations—50 cycle operation
14811	Turntable—Turntable assembly complete with rotor laminations—25 cycle operation
14812	Turntable—10-in. turntable plate only
4083	Washer—Leather washer for turntable bearing
14230	Washer—Metal washer for turntable bearing
14231	Washer—Metal shim washer for turntable bearing

MOTOR ASSEMBLIES MODEL U-103

STOCK No.	DESCRIPTION
14215	Governor—Governor complete for motor Stock No. 9799, No. 14465 and No. 14466
14466	Motor—105-125 volts, 25 cycle (M1)
14465	Motor—105-125 volts, 50-60 cycle (M1)
9799	Motor—105-125 volts, 60 cycle (M1)
14214	Screw—Motor mounting screw and spacer assembly

PICKUP AND ARM ASSEMBLIES MODEL U-101

STOCK No.	DESCRIPTION
14291	Armature—Pickup armature
11732	Coil—Pickup coil (L14)
14292	Damper—Pickup damper assembly — comprising one damper, one clamp and one screw
14933	Pickup and Arm complete
3811	Screw—Needle holding screw

PICKUP AND ARM ASSEMBLIES MODEL U-103

STOCK No.	DESCRIPTION
14291	Armature—Pickup armature assembly
4064	Cable—Pickup lift cable
11732	Coil—Pickup coil (L14)
14292	Damper—Pickup damper block complete with clamp and screw
14290	Pickup and Arm complete
3811	Screw—Needle holding screw
4387	Screw—No. 6-32x¼-in. headless set screw for pickup arm pivot shaft

REPRODUCER ASSEMBLIES (RL63F-1) MODEL U-101

STOCK No.	DESCRIPTION
14356	Board—3-contact reproducer terminal board
13866	Cap—Cone center dust cap
12012	Coil—Field coil (L13)
11469	Coil—Hum neutralizing coil (L12)
12642	Cone—Reproducer cone and dust cap (L11)
5118	Plug—3-contact male plug for reproducer
14360	Reproducer—Complete
14358	Screw—Screw, washer and lockwasher to hold core in yoke
14355	Transformer—Output transformer (T2)
14357	Washer—Spring washer to hold field coil

REPRODUCER ASSEMBLIES (RL70E-1) MODEL U-103

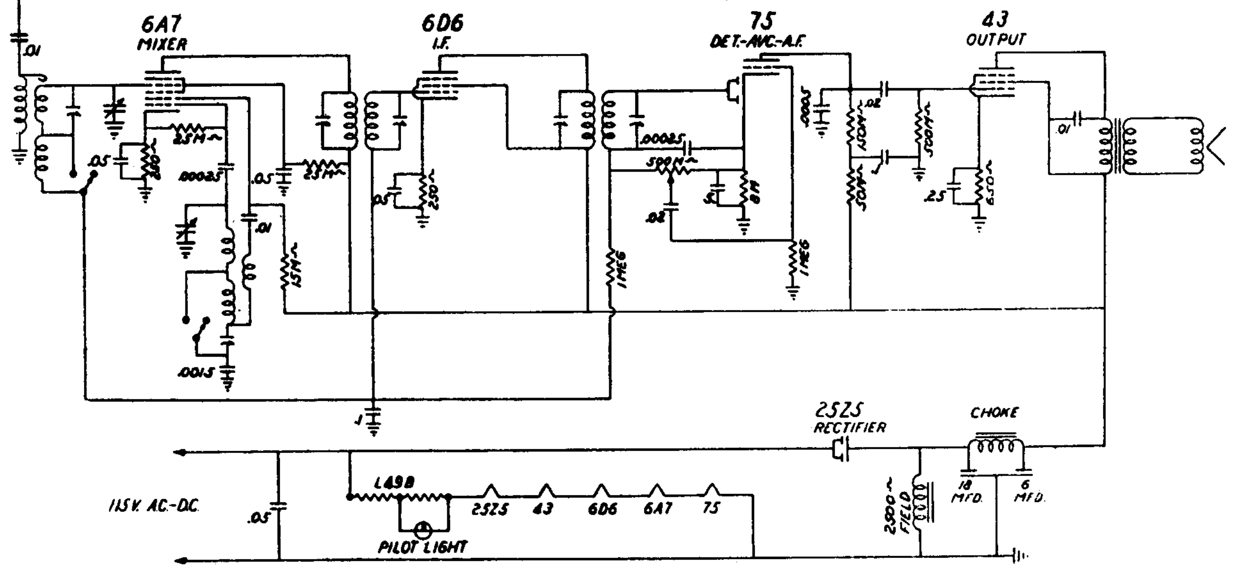
STOCK No.	DESCRIPTION
13866	Cap—Dust cap for cone center
14354	Coil—Field coil (L13)
11469	Coil—Hum neutralizing coil (L12)
12667	Cone—Reproducer cone and dust cap (L11)
5118	Plug—3-contact male plug for reproducer
14395	Reproducer—Complete
14358	Screw—Screw, washer and lockwasher to hold core in yoke
14355	Transformer—Output transformer (T2)
14357	Washer—Spring washer to hold field coil

MISCELLANEOUS ASSEMBLIES

STOCK No.	DESCRIPTION
11762	Box—Needle box—for Model U-101 only
4391	Box—Needle box—for Model U-103 only
14817	Cable—Shielded pickup cable complete with female connector—compensator end
5107	Capacitor—.0025 Mfd. (C50)
13138	Capacitor—.01 Mfd. (C30)
4841	Capacitor—0.1 Mfd. (C51, C52)
14654	Escutcheon—Station selector escutcheon and crystal
12673	Knob—Station selector, range switch, radio volume control or phonograph volume control knob
13716	Resistor—2,200 ohms, insulated, ½ watt (R51, R52, R53)
14267	Screw—Chassis mounting screw and washer—for Model U101 only
13573	Screw—Chassis mounting screw and washer—for Model U103 only
14816	Screw—Motorboard mounting screw and spacer—for Model U103 only
4119	Screw—No. 8-32 headless set screw for knob Stock No. 12673
14815	Volume Control—Phonograph volume control and radio-record switch (R50, S5)

RADOLEK COMPANY

MODEL K16,740



6 TUBE AC-DC 2 BAND — BC.-540 TO 1720 KC. / S.W. 2000 TO 7000 KC

I.F. 456 K.C.

SWITCH SHOWN IN B.C. POSITION

This receiver is designed to operate over two tuning ranges. Upper band which covers the broadcast range, extends from 545 to 1750 kilocycles (175 to 550 meters), lower band which covers Police, Aviation, and the International 49 Meter Foreign Band.

ALIGNMENT DATA AND SERVICING

GENERAL DATA The alignment of this receiver requires the use of a test oscillator that will cover the frequencies of 456, 600, 1400, and 6000 KC and an output meter to be connected across the primary or secondary of the output transformers. If possible, all alignments should be made with the volume control on maximum and the test oscillator output as low as possible, to prevent the AVC from operating and giving false readings.

CORRECT ALIGNMENT PROCEDURE The intermediate frequency (I.F.) stage should be aligned properly as the first step. After the I.F. transformers have been properly adjusted and peaked, the Broadcast Band should always be the next procedure; after which, the Short Wave Band may be aligned.

I.F. ALIGNMENT Adjust the test oscillator to 456 KC and connect the output to the grid of the first detector tubes (6A7) through a .05 or .1 mfd. condenser. The ground on the test oscillator can be connected to the chassis ground. Align all four I.F. trimmers to peak or maximum reading on the ouput meter.

BROADCAST BAND ALIGNMENT Adjust the oscillator to 1400 KC and connect the output to the antenna lead (Blue) through a .0001 mfd. mica condenser to give the equivalent of an antenna about 60 feet. Set the receiver pointer to 1400 KC and adjust the rear gang condenser trimmer (oscillator circuit) to peak. After this has been carefully done, the next step is to adjust the front trimmer of the gang condenser to peak.

Next, re-set the dial pointer on the receiver and the test oscillator to 600 KC. Slowly increase or decrease the oscillator padding condenser and at the same time continuously tune back and forth across the signal with the receiver until the maximum reading is obtained on the output meter. This adjustment seems a little complicated but is the easiest way to adjust the oscillator to the pre-selector or R.F. section. The padding condenser is located on the right hand end of the chassis near the 6A7 tube.

Return to 1400 KC and again go over the adjustments of this frequency to be certain that they were not put slightly out of alignment when adjustment was made at 600 KC.

This completes the correct sequence of operations in properly aligning the receiver for the Broadcast Band, and **must always be done before** attempting to align the Short Wave Band.

SHORT WAVE BAND There is only one adjustment to be made in the alignment of the Short Wave Band. Due to the circuit design and correct matching of the coils, no oscillator adjustment is necessary.

Set the dial pointer to 600 KC (also the test oscillator) and adjust the antenna and antenna trimmer to resonance. The short wave band coils are under the chassis and are located at the right front corner along side of wave band switch.

IMPORTANT: This is the only adjustment necessary for the Short Wave Band. Do not attempt any adjustment of the gang condenser trimmers in aligning the Short Wave Band, otherwise the Broadcast Band will be thrown out of alignment.

Return to 1400 KC and again go over the adjustments of this frequency to be certain that they were not put slightly out of alignment when adjustment was made at 6000 KC.

This completes the correct sequence of operations in properly aligning the receiver for the Broadcast Band, and MUST ALWAYS BE DONE BEFORE attempting to align the Short Wave Band.

Part No.	Description	List Price

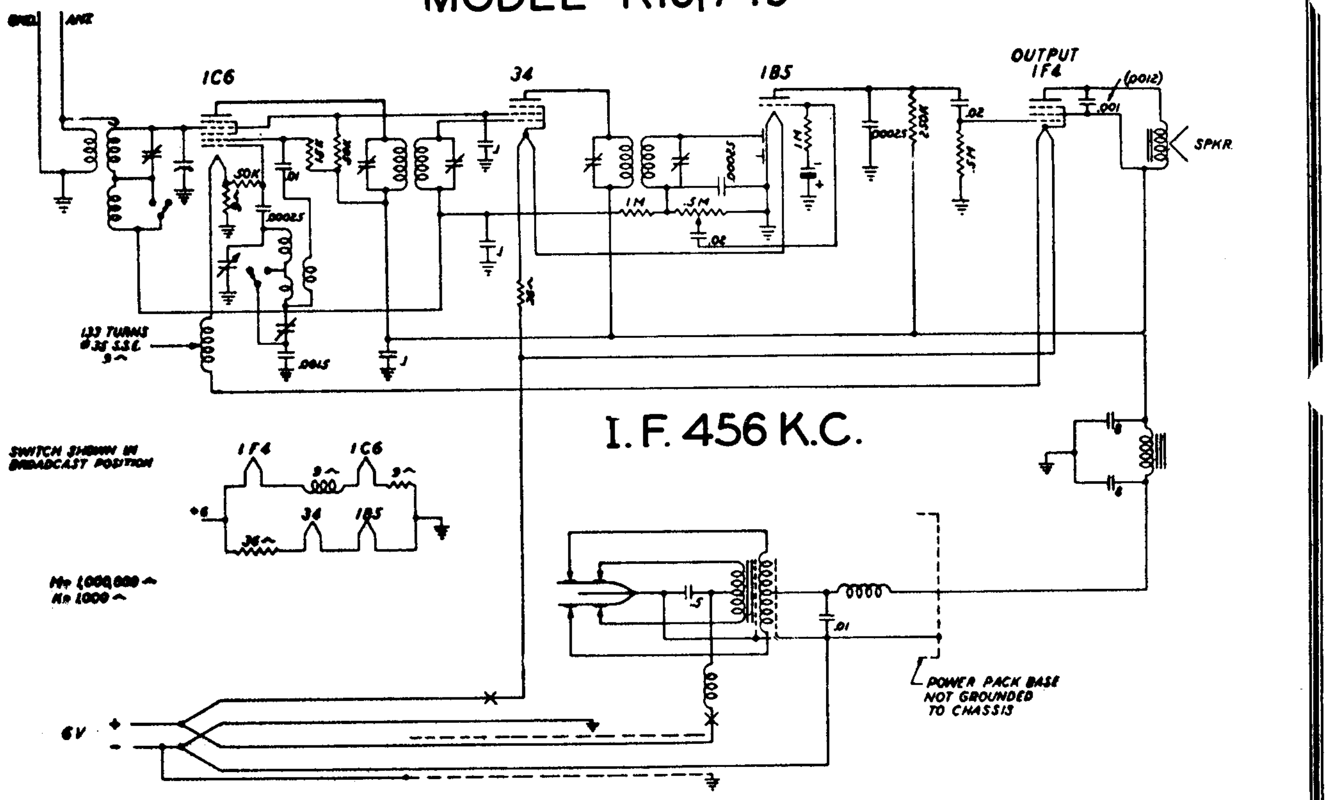
MODEL K16,749



This receiver is designed to operate over two tuning ranges. Upper band which covers the broadcast range, extends from 545 to 1750 kilocycles (175 to 550 meters), lower band which covers Police, Aviation, and the International 49 Meter Foreign Band

ALIGNMENT DATA AND SERVICING

GENERAL DATA The alignment of this receiver requires the use of a test oscillator that will cover the frequencies of 456, 600, 1400, and 6000 KC and an output meter to be connected across the primary or secondary of the output transformers. If possible, all alignments should be made with the volume control on maximum and the test oscillator output as low as possible, to prevent the AVC from operating and giving false readings.

CORRECT ALIGNMENT PROCEDURE The intermediate frequency (I.F.) stage should be aligned properly as the first step. After the I.F. transformers have been properly adjusted and peaked, the Broadcast Band should always be the next procedure; after which, the Short Wave Band may be aligned.

I.F. ALIGNMENT Adjust the test oscillator to 456 KC and connect the output to the grid of the first detector tubes through a .05 or .1 mfd. condenser. The ground on the test oscillator can be connected to the chassis ground. Align all four I.F. trimmers to peak or maximum reading on the ouput meter.

BROADCAST BAND ALIGNMENT Adjust the oscillator to 1400 KC and connect the output to the antenna lead (Blue) through a .0001 mfd. mica condenser to give the equivalent of an antenna about 60 feet. Set the receiver pointer to 1400 KC and adjust the rear gang condenser trimmer (oscillator circuit) to peak. After this has been carefully done, the next step is to adjust the front trimmer of the gang condenser to peak.

Next, re-set the dial pointer on the receiver and the test oscillator to 600 KC. Slowly increase or decrease the oscillator padding condenser and at the same time continuously tune back and forth across the signal with the receiver until the maximum reading is obobtained on the output meter. This adjustment seems a little complicated but is the easiest way to adjust the oscillator to the pre-selector or R.F. section. The padding condenser is located on the right hand end of the chassis

Return to 1400 KC and again go over the adjustments of this frequency to be certain that they were not put slightly out of alignment when adjustment was made at 600 KC.

This completes the correct sequence of operations in properly aligning the receiver for the Broadcast Band, and **must always be done before** attempting to align the Short Wave Band.

SHORT WAVE BAND There is only one adjustment to be made in the alignment of the Short Wave Band. Due to the circuit design and correct matching of the coils, no oscillator adjustment is necessary.

Set the dial pointer to 6000 KC (also the test oscillator) and adjust the antenna and antenna trimmer to resonance. The short wave band coils are under the chassis and are located at the right front corner along side of wave band switch.

IMPORTANT: This is the only adjustment necessary for the Short Wave Band. Do not attempt any adjustment of the gang condenser trimmers in aligning the Short Wave Band, otherwise the Broadcast Band will be thrown out of alignment.

Return to 1400 KC and again go over the adjustments of this frequency to be certain that they were not put slightly out of alignment when adjustment was made at 6000 KC.

This completes the correct sequence of operations Band, and MUST ALWAYS BE DONE BEFORE at-
nal with the receiver until the maximum reading is
tempting to align the Short Wave Band.

GENERAL INFORMATION

THE FILAMENT CIRCUIT:

The 1G5G tube and the 1C7G tube are connected in series with each other. The 1D5GP and 1F7G also are connected in series with each other. Accordingly, if any one tube burns out its companion tube also will not light. It is necessary to replace merely the burned out tube; the other then will light. The burned out tube can be identified through the fact that the full voltage of the "A" battery will appear across its filament prongs.

BATTERY CONNECTIONS:

A-	Black and yellow
A+	Yellow and blue
B-	Red and black
B+ 67½V.	Red

SPEAKER ADJUSTMENT:

Two types of speaker have been used. One has a single adjusting screw at the back; the other has two adjusting screws. Speaker rattle can be corrected by turning these screws. In the speaker having two adjusting screws, tighten one screw and loosen the other screw slightly until the rattle is eliminated.

THE BIAS CELL:

The bias cell is filled with thick liquid. When the receiver is in its normal position the liquid in the bias cell will come in contact with the carbon block and the inside of the metal container. However, the receiver may be stood on its end when working on it on the service bench. In this position the bias cell may be upright and the liquid may not touch the carbon block. If this happens, it will cause severe distortion. Accordingly, the necessary precaution should be observed when working on the receiver on the service bench.

ELIMINATING WHISTLE AT 930 KC:

A whistle, due to a beat between the second harmonic (930 kc) of the 465 kc IF, and a 930 kc signal may be experienced. In localities where the 930 kc station is one that is frequently listened to, it will be desirable to shift the whistle to some other point where it will not be objectionable. This can be done by shifting the IF frequency of the receiver.

Determine at what point between 900 kc and 960 kc the whistle will be least objectionable. Dividing this frequency by two will give the new IF frequency to which the receiver should be aligned. For example, if it is determined that a whistle at 915 kc would not be objectionable, the IF should be realigned at 915/2 or 457.5 kc. Try to select the new IF frequency as near as possible to 465 kc.

Align the IF at the new frequency and then realign the rest of the receiver as described under, "ALIGNMENT PROCEDURE".

THE AVC CIRCUIT:

The diode current of the 1F7G tube, flowing through the 500M ohm resistor, R6, creates a voltage drop across it. This voltage is applied to the control grid of the 1C7G tube to provide AVC.

BATTERY REPLACEMENT:

The dry "A" battery should be replaced when its voltage drops to 3.4 volts, under load. The "B" battery should be replaced when its total voltage has dropped to 51 volts, under load.

ALIGNMENT PROCEDURE

PRELIMINARY:

Output meter connections . . . . 4000 ohm Weston meter, across speaker terminals

Output meter reading to indicate 50 milliwatts . . . . 9.4 volts

Average sensitivity in microvolts for 50 milliwatts output . . . . See chart below

Generator ground lead connection . . . . Receiver chassis

Dummy antenna value to be in series with generator output . . . . See chart below

Connection of generator output lead . . . . See chart below

Generator modulation . . . . 30%, 400 cycles

Position of Volume Control . . . . Fully on

POSITION OF VARIABLE	GENERATOR FREQUENCY	DUMMY ANTENNA	GENERATOR CONNECTION	TRIMMER ADJUSTMENTS (IN ORDER SHOWN)	TRIMMER FUNCTION	APPROXIMATE MICROVOLTS
Closed	465 kc	.1 mfd.	1C7G Transl. Grid	T2, T1	IF	225
1400 kc *	1400 kc	.0002 mfd.	Antenna Term.	C1, C4	Translator Oscillator	85
600 kc (rock)	600 kc	.0003 mfd.	Antenna Term.	C5	Padder	60

IMPORTANT ALIGNMENT NOTES

* Using the dial as a template make a dummy dial of cardboard with only the 1400 kc calibration on it. Slip this dummy dial over the shaft, hold it horizontal so that the 1400 mark will come at the same position as the 1400 mark of the actual dial and turn the dial pointer to the 1400 kc mark. (The dial pointer should be horizontal when the condenser is fully open or fully meshed.)

The variable should be rocked back and forth a degree or two while making the 600 kc adjustment.

The alignment procedure should be repeated in the original order, step by step, to insure greater accuracy.

Always keep the output power from the generator at its lowest possible value to prevent the AVC of the receiver from interfering with accurate alignment.

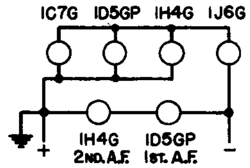
GENERAL INFORMATION

These models may be used with either a 4½ volt dry "A" battery or a 4 volt storage "A" battery. Catalog #6000 adapter is necessary to make the connection between the "A" plug and the terminals of a storage battery.

THE FILAMENT CIRCUIT:

Since the tubes have two volt filaments and the "A" supply is four volts, a series parallel arrangement is used for the filament circuit. The 1C7G, the 1D5GP IF and the 1H4G Detector-AVC tubes are connected as one parallel group. This group is connected in series with the 1J6G tube across the "A" supply. The 1H4G second AF and 1D5GP first AF tubes are connected in series with each other across the "A" supply. If any one tube burns out, it will affect the filament voltage and current of its companion tube. The simplified diagram of the filament circuit is shown below.



THE AVC CIRCUIT:

The 1H4G Detector-AVC tube is used as a diode with its grid acting as the diode plate. Diode current, flowing through the 500M ohm resistor, R6, creates a voltage drop across it. This voltage is applied to the control grid of the 1C7G tube to provide AVC.

BATTERY REPLACEMENT:

The dry "A" battery should be replaced when its voltage drops to 3.4 volts, under load. "B" batteries should be replaced when the voltage of each battery has dropped to 34 volts, under load. Because of the class "B" output circuit the "B" drain will vary with volume at which the set is played. Accordingly, the user should be told that for longest battery service the set should not be played louder than necessary.

ELIMINATING WHISTLE AT 930 KC:

A whistle, due to a beat between the second harmonic (930 kc) of the 465 kc IF, and a 930 kc signal may be experienced. In localities where the 930 kc station is one that is frequently listened to, it will be desirable to shift the whistle to some other point where it will not be objectionable. This can be done by shifting the IF frequency of the receiver.

Determine at what point between 900 kc and 960 kc the whistle will be least objectionable. Dividing this frequency by two will give the new IF frequency to which the receiver should be aligned. For example, if it is determined that a whistle at 915 kc would not be objectionable, the IF should be realigned at 915/2 or 457.5 kc. Try to select the new IF frequency as near to 465 kc as possible.

Align the IF at the new frequency and then realign the rest of the receiver as described under, "ALIGNMENT PROCEDURE".

ALIGNMENT PROCEDURE

PRELIMINARY:

Output meter connection . . . . Across loud speaker voice coil

Output meter reading to indicate 50 milliwatts . . . . 0.37 volts

Generator ground lead connection . . . . Receiver chassis

Dummy antenna value to be in series with generator output . . . . See chart below

Connection of generator output lead . . . . See chart below

Generator modulation . . . . 30%, 400 cycles

Approximate average sensitivity in microvolts for 50 milliwatts output . . . See chart below

Position of Volume Control . . . . Fully clockwise

Position of Tone Control . . . . Fully clockwise

POSITION OF VARIABLE	GENERATOR FREQUENCY	DUMMY ANTENNA	GENERATOR CONNECTION	TRIMMER ADJUSTMENTS (IN ORDER SHOWN)	TRIMMER FUNCTION	APPROXIMATE MICROVOLTS
Closed	465 kc	.1 mfd.	1C7G Transl. Grid	T2,T1	IF	160
1400 kc *	1400 kc	.0002 mfd.	Antenna Term.	C4,C1	Oscillator Translator	50
600 kc (rock)	600 kc	.0002 mfd.	Antenna Term.	C5	Padder	25

IMPORTANT ALIGNMENT NOTES

* Using the dial as a template make a dummy dial of cardboard with only the 1400 kc calibration on it. Slip this dummy dial over the shaft, hold it horizontal so that the 1400 mark will come at the same position as the 1400 mark of the actual dial and turn the dial pointer to the 1400 kc mark. (The dial pointer should be horizontal when the condenser is fully open or fully meshed.)

The variable should be rocked back and forth a degree or two while making the 600 kc adjustment.

The alignment procedure should be repeated in the original order, step by step, to insure greater accuracy.

Always keep the output power from the generator at its lowest possible value to prevent the AVC of the receiver from interfering with accurate alignment.

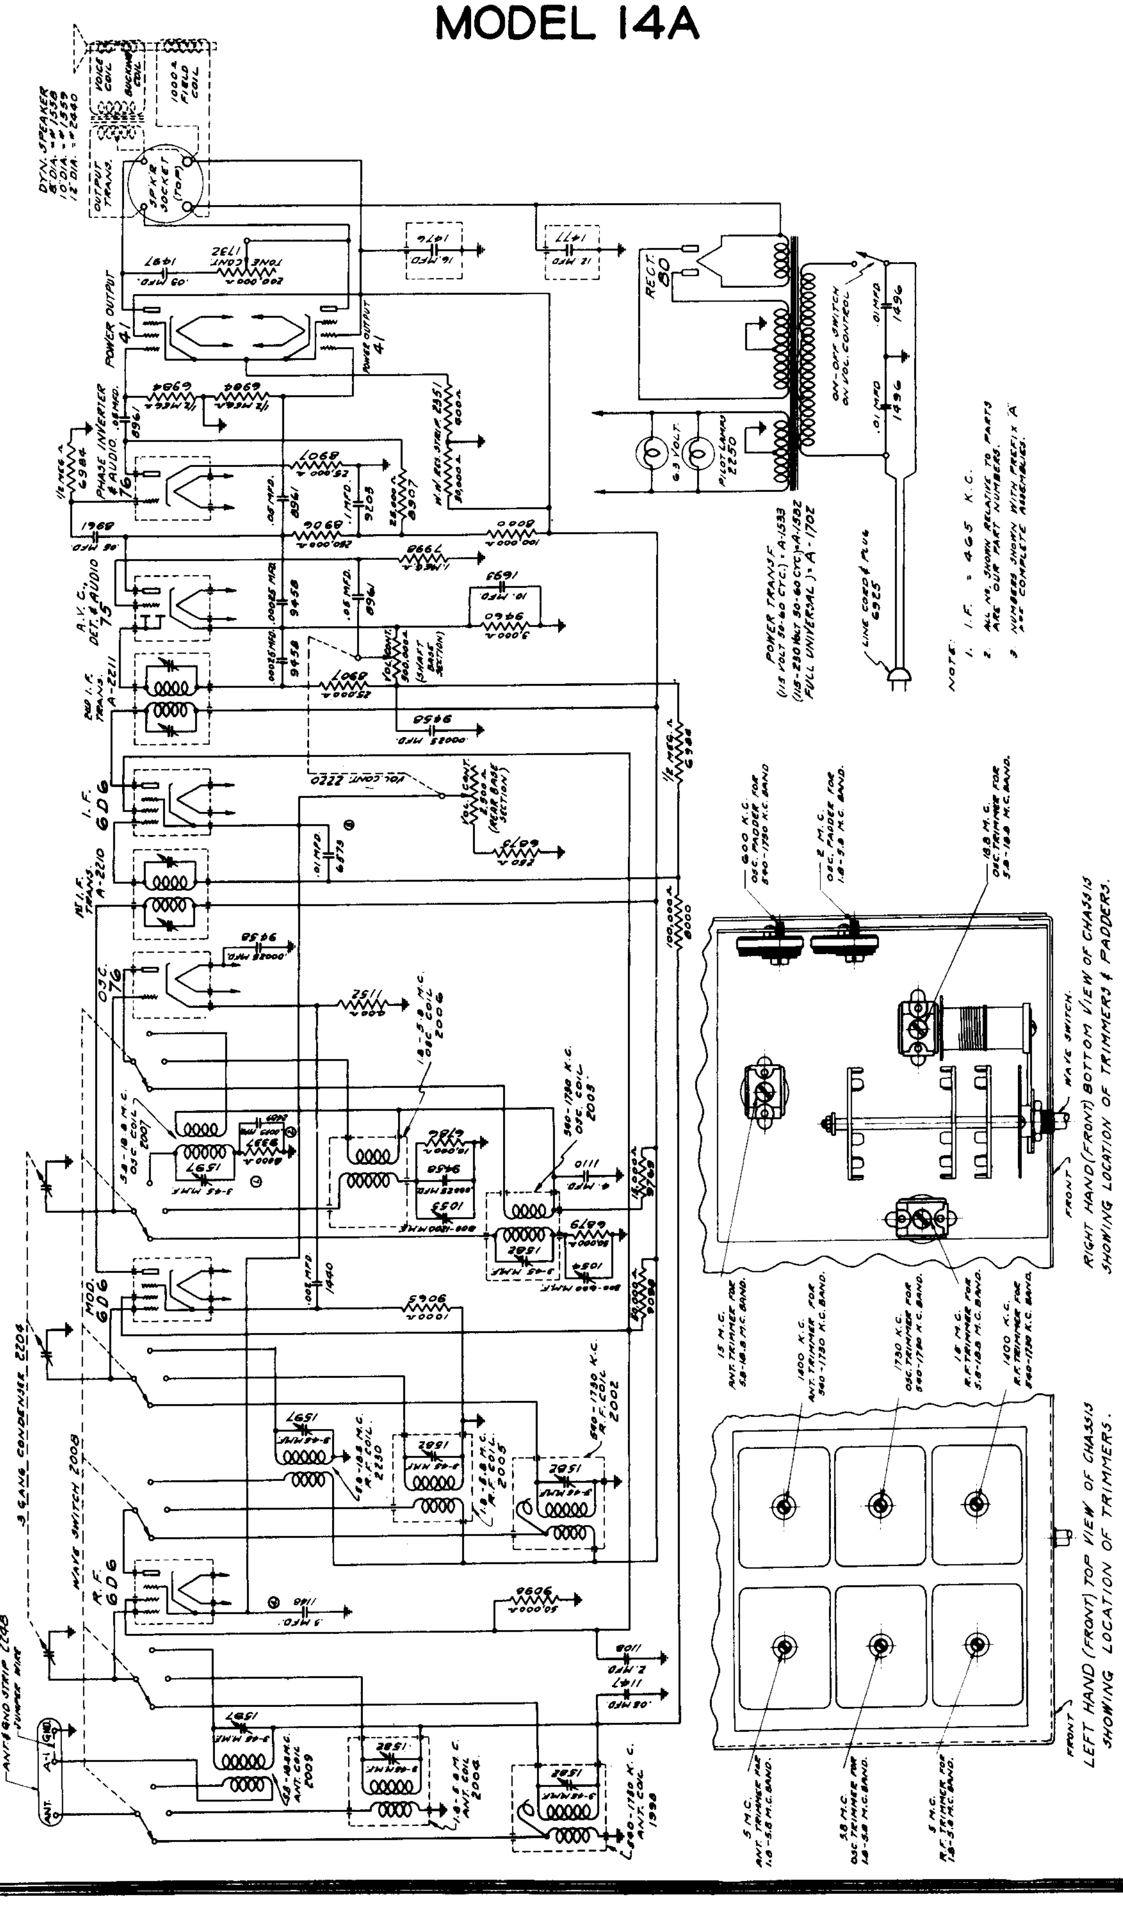
SENTINEL RADIO CORP.

MODEL 14A



SENTINEL RADIO CORP.

MODEL 14A

ALIGNMENT PROCEDURE:

Realignment of this receiver should never be necessary unless one of the oscillator, antenna, or I. F. coils has been replaced. Lack of sensitivity, selectivity, and poor tone quality may be due to any one or a combination of causes, such as weak or defective tubes or speaker, inadequate or excessively long antenna, open or grounded bias resistor, bypass condenser, etc. Under no circumstances should realignment be attempted until all other possible sources have been first thoroughly investigated and have been definitely proven not to be the cause.

If an I. F. tube is replaced it is advisable to realign the I. F. amplifier, particularly if the replacement tube is one of a different manufacture than the one in the receiver. It is important when aligning to carefully follow the procedure in the order given, otherwise the receiver will lack sensitivity and the dial calibration will be incorrect.

IT IS IMPERATIVE THAT AN ACCURATELY CALIBRATED OSCILLATOR BE USED WITH SOME TYPE OF OUTPUT MEASURING DEVICE.

INTERMEDIATE ALIGNMENT:

1. Connect the high side of the test oscillator output to the control grid of the 6D6 modulator tube through a .02 Mfd. condenser. Leave the grid cap connected to the grid terminal of the tube, and connect the ground side of the test oscillator to the receiver ground.
2. Set the test oscillator frequency to 465 kilocycles (this must be accurate).
3. Align the second intermediate transformer by turning one of the trimmer screws accessible through holes in the top of the transformer shields up and down (increasing and decreasing capacity) until maximum reading is obtained on the output meter, after which adjust the other trimmer screw of the same transformer for maximum sensitivity.
4. Adjust the first intermediate transformer in the same manner as the second I. F. transformer.

TO ALIGN THE VARIABLE CONDENSER:

It is important when aligning the gang condenser, padding and trimmer condensers to follow the procedure carefully, otherwise the receiver will be insensitive and the dial calibration will be incorrect. The padding and trimmer condensers located underneath the chassis and inside of and accessible through the holes found in the top of the catacomb shield (mounted on top and in the left front corner of the receiver) will be referred to by their function as indicated on the circuit diagram.

1. Connect the high output side of the test oscillator through a 400 ohm resistor to the receiver antenna lead and the low side to the set ground.

2. Place the band selector switch for operation on the 5.8 to 18.8 megacycle band, tune the receiver dial, and set the test oscillator frequency to EXACTLY 18.8 MEGACYCLES.

Rotate gang condenser so that plates are completely out of mesh and then tune in the 18.8 MEGACYCLE SIGNAL TO MAXIMUM OUTPUT BY ADJUSTING THE 18.8 MEGACYCLE OSCILLATOR TRIMMER. When adjusting this trimmer two peaks, the fundamental and the image peak will be noticed. CARE MUST BE TAKEN THAT THE FUNDAMENTAL PEAK AND NOT THE IMAGE PEAK IS USED FOR ALIGNING THE RECEIVER AT 18.8 MEGACYCLES. Always back off the trimmer to minimum capacity, then screw down the trimmer (add capacity) until the first peak which is the fundamental and the proper one to use is tuned in. If the trimmer is screwed down beyond the point where the first peak is received, the incorrect image peak will be tuned in. After completing adjustment of the oscillation trimmer at 18 megacycles always check to see if the proper peak has been used. To do this leave the test oscillator frequency at 18.8 megacycles, increase the output of the test oscillator and tune the receiver dial to approximately 17.8 megacycles. Then vary the receiver dial slightly to the right and left of 17.8 megacycles, and if the fundamental peak was used in aligning at 18.8 megacycles the test oscillator signal will be heard at approximately 17.8 megacycles on the receiver dial. If it is not possible to receive the signal, then the fundamental peak was not used and the 18.8 megacycle oscillator trimmer must be properly readjusted.

3. With band selector switch set for operation on 5.8 to 18.8 megacycle band tune the receiver dial and set test oscillator frequency to EXACTLY 15 MEGACYCLES. Adjust 15 megacycle antenna and R.F. trimmers to maximum 15 megacycle signal sensitivity.

4. Leave band selector switch for operation on the 5.8 to 18.8 megacycle band, tune the receiver dial and set the test oscillator frequency to approximately 6 megacycles. While rocking gang condenser slightly to right and left adjust 6 megacycle oscillator padder for maximum sensitivity.

5. Place band selector switch for operation on 1.8 to 5.8 megacycle band, tune the receiver dial, and set test oscillator frequency to EXACTLY 5.8 MEGACYCLES.

Rotate gang condenser so that plates are completely out of mesh and then BRING IN 5.8 MEGACYCLE SIGNAL TO MAXIMUM OUTPUT by adjusting 5.8 megacycle oscillator trimmer.

6. With the band selector switch set for operating on 1.8 to 5.8 Megacycle band tune receiver dial and set test oscillator frequency to EXACTLY 5 MEGACYCLES. Then adjust 5 megacycle antenna and R.F. trimmers for maximum 5 megacycle signal sensitivity.

7. Leave band selector switch for operation on 1.8 to 5.8 megacycle band, tune receiver dial and set test oscillator frequency to approximately 2 megacycles. While rocking gang condenser slightly to right and left adjust 2 megacycle oscillator padder for maximum sensitivity.

8. Replace the 400 ohm resistor in series with test oscillator lead with a 200 Mmfd. condenser, place the band selector switch for operation on the 540 to 1730 kilocycle band and set test oscillator frequency to EXACTLY 1730 KILOCYCLES.

Rotate gang condenser so that plates are completely out of mesh and BRING IN THE 1730 KILOCYCLE SIGNAL TO MAXIMUM OUTPUT BY ADJUSTING 1730 KILOCYCLE OSCILLATOR TRIMMER.

9. With band selector switch placed for operation on the 540 to 1730 kilocycle band set test oscillator frequency and receiver dial to EXACTLY 1400 KILOCYCLES. Adjust 1400 kilocycles R. F. and antenna trimmers for maximum 1400 kilocycle signal sensitivity.

10. Leave band selector switch for operation on 540 to 1720 kilocycle band, tune receiver dial and set test oscillator frequency to approximately 600 kilocycles. While rocking gang condenser slightly to right and left adjust 600 kilocycle oscillator padder for maximum sensitivity.

ALIGNMENT PROCEDURE: Realignment of this receiver should never be necessary unless one of the oscillator, antenna, or I. F. coils has been replaced. Lack of sensitivity, selectivity, and poor tone quality may be due to any one or a combination of causes, such as weak or defective tubes or speaker, inadequate or excessively long antenna, open or grounded resistor, bypass condenser, etc. Under no circumstances should realignment be attempted until all other possible sources have been first thoroughly investigated and have been definitely proven not to be the cause. If an I. F. tube is replaced, it is advisable to realign the I. F. amplifier, particularly if the replacement tube is one of a different manufacture than the one in the receiver. It is important when aligning to carefully follow the procedure in the order given, otherwise the receiver will lack sensitivity and the dial calibration will be incorrect.

IT IS IMPERATIVE THAT AN ACCURATELY CALIBRATED OSCILLATOR BE USED WITH SOME TYPE OF OUTPUT MEASURING DEVICE.

INTERMEDIATE ALIGNMENT:

1. Connect the high side of the test oscillator output to the control grid of the 6A7 oscillator-modulator tube through a .02 Mfd. condenser. Leave the grid cap connected to the grid terminal of the tube, and connect the ground side of the test oscillator to the receiver ground.

2. Set the test oscillator frequency to 465 kilocycles (this must be accurate).

3. Align the second intermediate transformer by turning one of the trimmer screws accessible through holes in the top of the transformer shields up and down (increasing and decreasing capacity) until maximum reading is obtained on the output meter, after which adjust the other trimmer screw of the same transformer for maximum sensitivity.

4. Adjust the first intermediate transformer in the same manner as the second I. F. transformer.

TO ALIGN VARIABLE CONDENSER: It is important when aligning the gang condenser, padding condenser, and wave trap to follow the procedure carefully, otherwise the receiver will be insensitive and the dial calibration will be incorrect. The trimmer and padding condensers will be referred to by their function as indicated on the circuit diagram.

1. Connect the high output side of the test oscillator through a .00025 Mfd. condenser to the receiver antenna lead and the low side to the set ground.

2. Place band selector switch for operation on the 1720-535 kilocycle band, rotate gang condenser so that plates are completely out of mesh, set test oscillator frequency to EXACTLY 1720 KILOCYCLES. Adjust 1720 kilocycle oscillator trimmer for maximum 1720 kilocycle signal output.

3. With band selector switch set for operation on the 1720-535 kilocycle band, set the test oscillator frequency and receiver tuning dial to EXACTLY 1400 KILOCYCLES. Then adjust 1400 kilocycle preselector trimmers for maximum 1400 kilocycle response.

4. Tune receiver dial and set test oscillator frequency to approximately 600 kilocycles. While rocking gang condenser slightly to right and left adjust 600 kilocycle oscillator padder for maximum sensitivity.

5. Place band selector switch for operation on the 390-140 kilocycle band, rotate gang condenser so plates are completely out of mesh, and set test oscillator frequency to EXACTLY 390 KILOCYCLES. Bring in 390 kilocycle signal to maximum output with 390 kilocycle oscillator trimmer.

6. With band selector switch for operation on 390-140 kilocycle band, tune receiver dial and set test oscillator frequency to EXACTLY 350 KILOCYCLES. Adjust 350 kilocycle preselector trimmers for maximum 350 kilocycle signal response.

7. Leave band selector switch for operation on the 390-140 kilocycle band, tune receiver dial and set test oscillator frequency to approximately 160 kilocycles. Then while rocking gang condenser slightly to right and left adjust 160 kilocycle padding condenser for maximum sensitivity.

SPARKS-WITHINGTON COMPANY

MODELS 537 & 577

Foreword: The use of quality test equipment is highly recommended and a good test oscillator becomes a virtual necessity when aligning the all-wave or short-wave type of receiver. Due to the fact that the ear cannot distinguish small changes in sound intensity, an output meter is essential to the proper adjustment of the various condensers.

Unless otherwise specified, the adjusting of any condenser consists of turning the adjusting screw or nut to the right or left until the output meter registers the greatest deflection.

1. EQUIPMENT REQUIRED

A. Modulated test oscillator (crystal controlled or accurately calibrated) capable of generating frequencies from 456 to 15,000 kilocycles.

B. Output meter.

C. Part A-5732 adjusting wrench.

D. Dummy antennas, consisting of a 150 mmf. condenser and a 400 ohm non-inductive resistor.

2. STEP BY STEP PROCEDURE

NOTE: For proper alignment of these chassis, the procedure should be followed in the same order as given.

With the condenser plates fully meshed, the dial pointer should point to the first calibration marks immediately to the right of the band identification letters "P", "B" and "F". Any necessary correction may be made simply by moving the pointer on the shaft.

A. Alignment of Intermediate-Frequency Stages

(1) Turn on receiver and test oscillator and allow both to operate several minutes before attempting to adjust any condensers.

(2) Turn the band selector switch to the broadcast "B" position and turn the station selector knob until the rotor plates are completely out of mesh with the stator plates.

(3) Connect "antenna" of test oscillator to grid cap of Type 6A8G 1st detector-oscillator tube and "ground" of test oscillator to chassis frame of receiver. Connect output meter "high tap" from plate of Type 6F6G tube to ground. NOTE: It is advisable to read carefully the operating instructions included with the test oscillator.

(4) Tune test oscillator to obtain a signal of 456 KC.

(5) Turn the volume control of receiver on full and adjust I.F. condensers C3 and C2. NOTE: The intermediate frequency circuits are quite selective and care must be taken to insure proper adjustment.

(6) Connect "antenna" of test oscillator to "A" post on chassis and "ground" of test oscillator to "G" post.

(7) Tune test oscillator to 456 KC. and adjust condenser C4 for minimum output.

NOTE: This adjustment is in the code rejector circuit and proper adjustment of this condenser is essential to satisfactory operation of the receiver.

B. Alignment of Broadcast Band

(1) Disconnect "antenna" lead of test oscillator from grid cap of first detector-oscillator tube and connect in series with a 150 mmf. condenser dummy antenna to the antenna terminal of the chassis.

(2) Tune test oscillator and receiver to a frequency of 1500 KC., and without disturbing the setting of the test oscillator or the station selector, adjust condensers C8 and C5 in the order given.

(3) Tune test oscillator and receiver to 600 KC. and adjust condenser C9.

(4) Retune test oscillator and receiver to 1500 KC. and check the adjustments of condensers C8 and C5.

(5) Calibration of the broadcast band should also be checked at 900 kilocycles and 600 kilocycles.

C. Alignment of Police Band

(1) Turn the band selector switch to the Police Band "P".

(2) Remove the 150 mmf. condenser from the "antenna" lead of test oscillator and replace with a 400 ohm non-inductive resistor dummy antenna.

(3) Tune test oscillator and receiver to 4.5 MC. and adjust condenser C7.

NOTE: There are no other adjustments in this band.

D. Alignment of Foreign Band

(1) Turn the band selector switch to the Foreign Band "F".

(2) Tune test oscillator and receiver to 15 MC. and adjust condenser C6.

CAUTION: On this band care must be taken to adjust the condenser to the fundamental of the signal and not to the image. The image signal is equal to the fundamental minus twice the intermediate frequency of the receiver.

A set that is adjusted to the image frequency instead of to the fundamental may be detected by tuning over the band and checking the sensitivity at various points. If a dead spot appears near the center of the band, the adjustable condensers for that band have probably been adjusted to the image instead of the fundamental.

This type of mis-alignment may also be detected by tuning the test oscillator to a frequency of 15 megacycles and the station selector to approximately 15,900 KC. If a strong signal is found approximately at this frequency, it indicates that the band has been adjusted to the image frequency. The normal image frequency for 15,000 kilocycles would be 15,000 KC. minus twice 456 KC. or approximately 14,100 KC. Therefore a signal of this frequency may be found with the test oscillator generating a 15,000 KC. signal.

(3) Retune the test oscillator and receiver to 7.5 MC. and check sensitivity and calibration. (There are no other adjustments for this band.)

CAUTION: All adjustments should be rechecked to assure accuracy and stability of adjustment and calibration.

SPARKS-WITHINGTON COMPANY
MODEL 547X

Foreword: The SPARTON Model 547-X is equipped with an adjustable power transformer for operation on various line voltages as indicated under the transformer terminal cover plate.

Before attempting to realign the circuits, be sure that the transformer tap is correctly adjusted for the line voltage to be used.

The use of quality test equipment is highly recommended and a good test oscillator becomes a virtual necessity when aligning the all-wave or short-wave type of receiver. Due to the fact that the ear cannot distinguish small changes in sound intensity, an output meter is essential to the proper adjustment of the various condensers.

Unless otherwise specified, the adjusting of any condenser consists of turning the adjusting screw or nut to the right or left until the output meter registers the greatest deflection.

1. EQUIPMENT REQUIRED

A. Modulated test oscillator (crystal controlled or accurately calibrated) capable of generating frequencies from 150 to 15,000 kilocycles.

B. Output meter.

C. Part A-5732 adjusting wrench.

D. Dummy antennas, consisting of a 150 mmf. condenser and a 400 ohm non-inductive resistor

2. STEP BY STEP PROCEDURE

NOTE: For proper alignment of these chassis, the procedure should be followed in the same order as given.

The dial pointer should point to the first calibration mark immediately to the right of the band indicating letters "L", "B" or "S" when the condenser plates are fully meshed. If the pointer does not read correctly, hold the rotor plates fully meshed with the stator plates and set the pointer so that it reads correctly.

A. Alignment of Intermediate-Frequency Stages.

(1) Turn on receiver and test oscillator and allow both to operate several minutes before attempting to adjust any condensers.

(2) Turn the band selector switch to the Broadcast Band "B" position and turn the station selector knob until the rotor plates are completely out of mesh with the stator plates.

(3) Connect "antenna" of test oscillator in series with 150 mmf. condenser dummy antenna to grid cap of Type 6A8G 1st detector-oscillator tube and "ground" of test oscillator to chassis frame of receiver. Connect output meter "high tap" from plate of Type 6F6G tube to ground. NOTE: It is advisable to read carefully the operating instructions included with the test oscillator.

(4) Tune test oscillator to obtain a signal of 456 kilocycles.

(5) Turn the volume control of receiver on full and adjust IF condensers C3 and C2. NOTE: The intermediate frequency circuits are quite selective and care must be taken to insure proper adjustment.

(6) Disconnect test oscillator "antenna" and 150 mmf. condenser from grid cap of 6A8G tube, and connect oscillator "antenna" to antenna post of chassis.

(7) With the test oscillator generating a 456 KC. signal, adjust condenser C4 until a minimum of output is obtained. NOTE: This adjustment is in the code rejector circuit, and care should be taken to see that proper adjustment is made, otherwise the receiver will not operate with maximum efficiency.

B. Alignment of Long-Wave Band

(1) Insert the 150 mmf. condenser in series with the "antenna" lead of test oscillator and the antenna terminal of the chassis.

(2) Turn the band selector switch to the long wave "L" position, tune test oscillator and receiver to a wave length of 870 meters (345 KC.) and without disturbing the setting of the test oscillator or the station selector, adjust condensers C25 and C7 in the order given.

(3) Tune test oscillator and receiver to 2000 meters (150 KC.) and adjust condenser C26.

(4) Retune test oscillator and receiver to 345 kilocycles and check the adjustments of condensers C25 and C7.

C. Alignment of Broadcast Band

(1) Turn band selector switch to the broadcast band "B" position.

(2) Tune test oscillator and receiver to a wave length of 200 meters (1500 kilocycles) and adjust condenser C8 (oscillator trimmer) and condenser C5 (antenna trimmer).

(3) Tune test oscillator and receiver to 500 meters (600 kilocycles) and adjust condenser C9 (oscillator padder).

(4) Retune test oscillator and receiver to 200 meters and check the adjustments of condensers C8 and C5.

(Continued from preceding page)

D. Alignment of Short-Wave Band.

(1) Turn the band selector switch to the short wave band "S" position.

(2) Remove the 150 mmf. condenser from "antenna" lead of test oscillator and replace with a 400 ohm non-inductive resistor dummy antenna.

(3) Tune test oscillator and receiver to 20 meters (15 megacycles) and adjust condenser C6.

CAUTION: On this band care must be taken to adjust the condenser to the fundamental of the signal and not to the image. The image signal is equal to the fundamental minus twice the intermediate frequency of the receiver. A set that is adjusted to the image frequency instead of to the fundamental may be detected by tuning over the band and checking the sensitivity at various points. If a dead spot appears near the center of the band, the adjustable condensers for that band have probably been adjusted to the image instead of the fundamental.

This type of mis-alignment may also be detected by tuning the test oscillator to a frequency of 15 megacycles and the station selector to approximately 15,900 kilocycles. If a strong signal is found approximately at this frequency, it indicates that the band has been adjusted to the image frequency. The normal image frequency for 15,000 kilocycles would be 15,000 kilocycles minus twice 456 kilocycles or approximately 14,100 kilocycles. Therefore a signal of this frequency may be found with the test oscillator generating a 15,000 kilocycle signal.

MODELS R171 & 1711 TO 1719

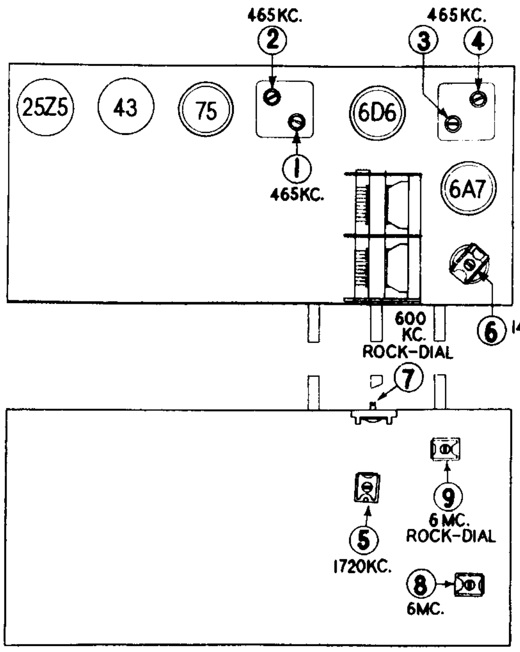
CIRCUIT DESCRIPTION

The model R-171 chassis is a 115 volt A.C. or D.C. five tube superheterodyne receiver. It has an intermediate frequency of 465 K.C.; and tuning ranges of 535 to 1720 K.C.; 2.3 to 6.15 M.C. respectively.

The incoming signal picked up by the antenna is induced in the tuned secondary of the antenna coil and impressed upon the control grid of the 6 A 7 first detector and oscillator. The 465 K.C. output of the 6 A 7 is amplified in the I.F. stage using a 6 D 6 tube. The amplified voltage is then impressed upon the diodes of the 75 twin diode triode tube. The two diodes are tied together and function as a linear second detector and A.V.C. The direct current voltage developed across the fixed ends of the volume control is used as A.V.C. voltage and applied to the control grids of the 6 D 6 and 6 A 7 tubes through a resistance capacity filter.

The potentiometer type of volume control 33A serves as a load resistance for the diode section of the 75 tube and a continuous voltage divider of the audio frequency voltage developed. Hence any portion of the audio voltage developed can be applied to the control grid of the triode section of the 75 tube. It should be noted the grid bias of the 75 tube is obtained from a bias cell. The 75 tube is resistance coupled to the 43 power output tube. Grid bias for the output tube is obtained across the filter choke number 13.

The heaters of all the tubes in the receiver are connected in series. The 25 Z 5 tube is used as a conventional half wave rectifier. When the receiver is operated on direct current the line cord plug must be so inserted that the plates of the rectifier are on the positive side of the line. Under this condition the rectifier acts as a device passing direct current to the plates of the other tubes.



TRIMMER LOCATIONS

Trimmer Number		Alignment Frequency
1.	2nd I.F. Transformer Trimmer	465 KC.
2.	2nd I.F. Transformer Trimmer	465 KC.
3.	1st I.F. Transformer Trimmer	465 KC.
4.	1st I.F. Transformer Trimmer	465 KC.
5.	Broadcast oscillator shunt trimmer	1720 KC.
6.	Broadcast antenna trimmer	1400 KC.
7.	Broadcast oscillator series padder	600 KC.
8.	Short-wave oscillator shunt trimmer	6 MC.
9.	Short-wave antenna shunt trimmer	6 MC.

CALIBRATION AND ALIGNMENT

ALIGNING EQUIPMENT

For proper alignment, an output meter and an accurately calibrated oscillator with a tuning range from 465 KC. to 6 MC. are required.

Connect the output meter from the plate of the output tube to chassis.

ALIGNING THE I.F. AMPLIFIER

(a) Turn the volume control to maximum volume position and keep it in this position throughout the entire alignment procedure.

(b) Turn the range switch to the broadcast position (fully clockwise).

(c) Connect the test oscillator output leads to the 6A7 control grid and chassis with a .1 mfd. condenser in series with the oscillator output.

(d) Set the oscillator to exactly 465 KC.

(e) Set the receiver dial at any point where it has no tuning effect on the oscillator signal.

(f) Adjust the four I.F. trimmers, Nos. 1, 2, 3 and 4, for maximum output meter deflection, then repeat the trimmer adjustment.

BROADCAST BAND CALIBRATION AND ALIGNMENT

(a) With the gang condenser in full mesh, the dial pointer should be on the horizontal line below 540 KC. on the dial scale.

(b) Turn the range switch to the clockwise position and connect the test oscillator output to the antenna lead of the receiver with a 400 ohm carbon resistor in series with the antenna lead and the oscillator output.

(c) Adjust the test oscillator to exactly 1720 KC. and turn the receiver dial pointer to 1720 KC. on the tuning dial.

(d) To calibrate the dial, adjust trimmer No. 5 for maximum output.

(e) Adjust the test oscillator to 1400 KC. and carefully tune the receiver to the signal.

(f) Adjust trimmer No. 6 for maximum output.

(g) Adjust the test oscillator to 600 KC. and tune the receiver to the signal.

(h) Adjust trimmer No. 7 for maximum output. Then try to increase the output meter reading by detuning No. 7 slightly and retuning the receiver dial. If the output goes down, detune the trimmer in the opposite direction. Continue detuning the trimmer and retuning the receiver dial until maximum output meter deflection is secured. This operation is commonly known as "rocking" and when performed as described will give maximum selectivity and sensitivity, even though the dial may be slightly off calibration at 600 KC.

(i) Check the adjustment of trimmer 5 at 1720 KC. and trimmer 6 at 1400 KC.

SHORT WAVE BAND CALIBRATION AND ALIGNMENT

(a) Turn the range switch to the short wave position (counter-clockwise).

(b) Adjust the test oscillator to exactly 6.0 MC.

(c) Tune in the 6 MC. oscillator signal at or near 6 MC. on the receiver dial to determine whether the receiver dial calibration is correct at 6 MC. If it is, do not adjust the oscillator shunt trimmer No. 8.

(d) If the calibration is incorrect, set the dial pointer to 6 MC. on the dial, and adjust the oscillator shunt trimmer No. 8, until the oscillator signal comes in at this point. If there are two peaks, the proper one is that with the trimmed screw farthest out.

(e) Carefully tune the receiver to the signal and adjust trimmer No. 9 for maximum output. Then try to increase the output by detuning No. 9 slightly and retuning the receiver dial. Continue detuning No. 9 and retuning the dial until the output meter deflection is a maximum

MODELS R172 & 1721 TO 1729

CALIBRATION AND ALIGNMENT

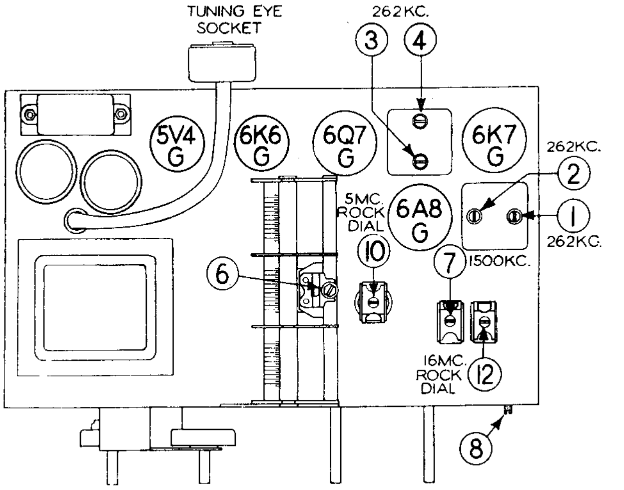
ALIGNING EQUIPMENT: For proper alignment, an output meter and an accurately calibrated oscillator with a tuning range from 262 KC. to 16 MC. are required.

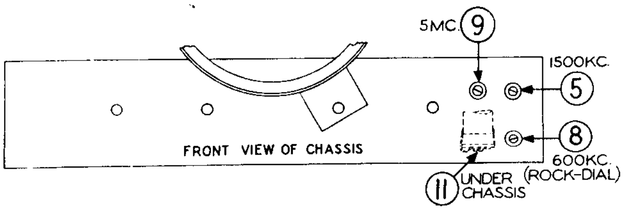
Connect the output meter from the plate of the output tube to chassis. A convenient point to make the plate connection is to the yellow wire on the speaker socket.

ALIGNING THE I. F. AMPLIFIER: Turn the volume control to maximum volume position and keep it in this position throughout the entire alignment procedure. Turn the range switch to the broadcast position (fully clockwise).

Connect the test oscillator output leads to the 6A8 control grid and chassis with a **.1 mfd. condenser in series with the oscillator output.** Set the oscillator to exactly 262 KC. Set the receiver dial at any point where it has no tuning effect on the oscillator signal.

Adjust the four I.F. trimmers, Nos. 1, 2, 3 and 4, for maximum output meter deflection, then repeat the trimmer adjustment.





FRONT VIEW OF CHASSIS

TRIMMER LOCATIONS

Trimmer Number		Alignment Frequency
1.	2nd I.F. transformer trimmer	262 KC.
2.	2nd I.F. transformer trimmer	262 KC.
3.	1st I.F. transformer trimmer	262 KC.
4.	1st I.F. transformer trimmer	262 KC.
5.	Broadcast oscillator shunt trimmer	1500 KC.
6.	Broadcast antenna shunt trimmer	1500 KC.
7.	Broadcast detector shunt trimmer	1500 KC.
8.	Broadcast oscillator series padder	600 KC.
9.	Police oscillator shunt trimmer	5 MC.
10.	Police antenna shunt trimmer	5 MC.
11.	Short wave oscillator shunt trimmer	16 MC.
12.	Short wave antenna shunt trimmer	16 MC.

BROADCAST BAND CALIBRATION AND ALIGNMENT

With the gang condenser in full mesh, the dial pointer should be on the white horizontal line below 530 KC. on the dial scale. If it does not, hold the dial gear and turn the pointer to the correct position.

Turn the range switch to the extreme clockwise position and connect the test oscillator output to the A and G terminals of the receiver with a 400 ohm carbon resistor in series with the A terminal and the oscillator output.

Adjust the test oscillator to exactly 1500 KC.

Tune in the 1500 KC. oscillator signal or a station above 1300 KC. on the dial and determine whether the dial calibration is correct at the high frequency end of the dial. If the calibration is correct, do not adjust the broadcast oscillator shunt trimmer No. 5. If the calibration is incorrect, adjust trimmer No. 5 to give proper calibration.

Carefully tune the receiver to the signal and adjust trimmers Nos. 6 and 7 for maximum output.

Adjust the test oscillator to 600 KC. and tune the receiver to the signal. Adjust trimmer No. 8 for maximum output. Then try to increase the output meter reading by detuning No. 8 slightly and retuning the receiver dial. If the output goes down, detune the trimmer in the opposite direction. Continue detuning the trimmer and retuning the receiver dial until maximum output meter deflection is secured. This operation is commonly known as "rocking" and when performed as described will give maximum selectivity and sensitivity even though the dial may be slightly off calibration at 600 KC.

POLICE BAND CALIBRATION AND ALIGNMENT

Turn the range switch to the center position. Adjust the test oscillator to exactly 5.0 MC. Tune in the 5 MC. oscillator signal at or near 5 MC. on the receiver dial to determine whether the receiver dial calibration is correct at 5 MC. If it is, do not adjust police band oscillator shunt trimmer No. 9. If the calibration is incorrect, set the dial pointer to 5 MC. on the dial, and adjust the oscillator shunt trimmer No. 9 until the oscillator signal comes in at this point. If there are two peaks, the proper one is that with the trimmer screw farthest out.

Carefully tune the receiver to the signal and adjust trimmer No. 10 for maximum output. Then try to increase the output by detuning No. 10 slightly and retuning the receiver dial. Continue detuning No. 10 and retuning the dial until the output meter deflection is a maximum.

SHORT WAVE BAND CALIBRATION AND ALIGNMENT

Turn the range switch to the extreme counter-clockwise position. Set the test oscillator to 16 MC. Tune in the 16 MC. oscillator signal at 16 MC. on the receiver dial to determine whether the receiver dial calibration is correct at 16 MC. If it is, do not adjust the short wave band oscillator shunt trimmer No. 11. If the calibration is incorrect, set the receiver dial pointer exactly at 16 MC. and adjust the oscillator shunt trimmer No. 11 until the oscillator signal comes in at this point.

Check to see that it has been adjusted to the proper peak by tuning the receiver to approximately 15.5 MC. A repeat signal should be heard at this point. If none is present, even with greatly increased oscillator output, retune the receiver to 16 MC. and adjust trimmer No. 11 to the proper peak with the trimmer screw farther **out.**

Carefully tune the receiver to the signal and adjust trimmer No. 12 to a peak. Then try to increase the output by detuning the trimmer slightly and retuning the dial until a maximum output meter deflection is secured. Check the adjustment by tuning the receiver to the image at about 15.5 MC. The image should be much weaker than the 16 MC. signal. If the signal at 15.5 MC. dial setting is equal to or stronger than the 16 MC. signal, trimmer No. 12 is not set to the proper peak. Turn the trimmer in a turn or so, then readjust as above.

CALIBRATION AND ALIGNMENT

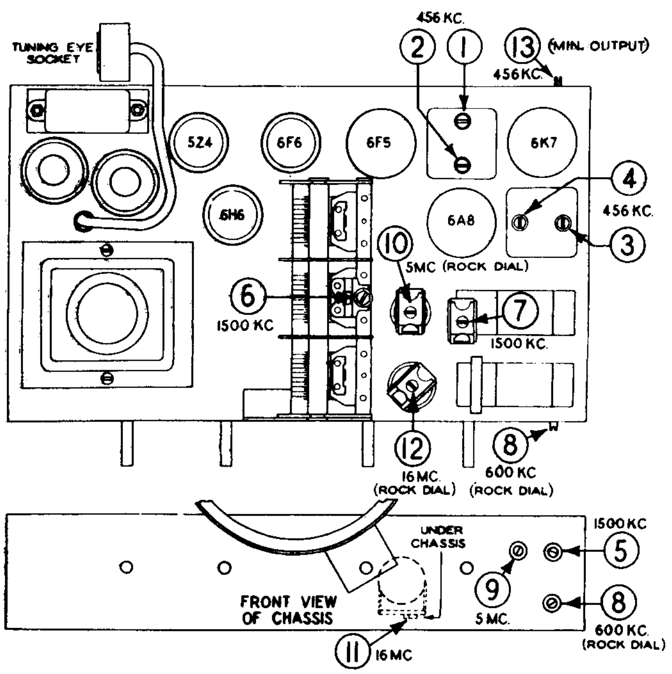
ALIGNING EQUIPMENT: For proper alignment, an output meter and an accurately calibrated oscillator with a tuning range from 456 KC. to 16 MC. are required.

Connect the output meter from the plate of the output tube to chassis. A convenient point to make the plate connection is to the yellow wire on the speaker socket.

ALIGNING THE I. F. AMPLIFIER: Turn the volume control to maximum volume position and keep it in this position throughout the entire alignment procedure. Turn the range switch to the broadcast position (fully clockwise).

Connect the test oscillator output leads to the 6A8 control grid and chassis with a .1 mfd. condenser in series with the oscillator output. Set the oscillator to exactly 456 KC. Set the receiver dial at any point where it has no tuning effect on the oscillator signal.

Adjust the four I.F. trimmers, Nos. 1, 2, 3 and 4, for maximum output meter deflection, then repeat the trimmer adjustment.



TRIMMER LOCATIONS

Trimmer Number		Alignment Frequency
1.	2nd I.F. transformer trimmer	456 KC.
2.	2nd I.F. transformer trimmer	456 KC.
3.	1st I.F. transformer trimmer	456 KC.
4.	1st I.F. transformer trimmer	456 KC.
5.	Broadcast oscillator shunt trimmer	1500 KC.
6.	Broadcast antenna shunt trimmer	1500 KC.
7.	Broadcast detector shunt trimmer	1500 KC.
8.	Broadcast oscillator series padder	600 KC.
9.	Police oscillator shunt trimmer	5 MC.
10.	Police antenna shunt trimmer	5 MC.
11.	Short wave oscillator shunt trimmer	16 MC.
12.	Short wave antenna shunt trimmer	16 MC.
13.	Wave-trap trimmer	456 KC.

BROADCAST BAND CALIBRATION AND ALIGNMENT: With the gang condenser in full mesh, the dial pointer should be on the white horizontal line below 530 KC. on the dial scale.

Turn the range switch to the extreme clockwise position and connect the test oscillator output to the A and G terminals of the receiver with a 400 ohm carbon resistor in series with the A terminal and the oscillator output.

Adjust the test oscillator to exactly 1500 KC. and turn the receiver dial pointer to 1500 KC. on the tuning dial. To calibrate the dial, adjust trimmer No. 5 for maximum output.

Carefully tune the receiver to the signal and adjust trimmers Nos. 6 and 7 for maximum output.

Adjust the test oscillator to 600 KC. and tune the receiver to the signal. Adjust trimmer No. 8 for maximum output. Then try to increase the output meter reading by detuning No. 8 slightly and retuning the receiver dial. If the output goes down, detune the trimmer in the opposite direction. Continue detuning the trimmer and retuning the receiver dial until maximum output meter deflection is secured. This operation is commonly known as "rocking" and when performed as described will give maximum selectivity and sensitivity even though the dial may be slightly off calibration at 600 KC.

WAVE-TRAP ADJUSTMENT: The wave-trap adjusting trimmer, No. 13, is located on the back of the chassis. Leave the test oscillator connected to the A and G terminals through a 400 ohm resistor and set the oscillator at 456 KC. Then adjust the wave-trap trimmer No. 13 for minimum output. If some particular station with a frequency near 456 KC. causes code interference, it may be desirable to adjust the wave-trap on the actual frequency of the interfering station.

Check the adjustment of trimmers 5, 6, and 7 at 1500 KC.

BAND NO. 2 CALIBRATION AND ALIGNMENT: Turn the range switch to the center position.

Adjust the test oscillator to exactly 5.0 MC. and turn the receiver dial pointer to exactly 5.0 MC. on the tuning dial.

To calibrate the dial, adjust trimmer No. 9 for maximum output. If two peaks are found, the proper one is that with the trimmer screw farthest out.

Carefully tune the receiver to the signal and adjust trimmer No. 10 for maximum output. Then try to increase the output by detuning No. 10 slightly and retuning the receiver dial. Continue detuning No. 10 and retuning the dial until the output meter deflection is a maximum.

BAND NO. 3 CALIBRATION AND ALIGNMENT: Turn the range switch to the extreme counter-clockwise position. Be sure the D and G terminals on the antenna terminal strip are connected together.

Set the test oscillator to 16 MC. and turn the receiver dial pointer to exactly 16 MC. on the tuning dial.

To calibrate the dial, adjust trimmer No. 11 for maximum output. Check to see that it has been adjusted to the proper peak by tuning the receiver to approximately 15.1 MC. A repeat signal should be heard at this point. If none is present, even with greatly increased oscillator output, retune the receiver to 16 MC. and adjust trimmer No. 11 to the proper peak with the trimmer screw farther out.

Carefully tune the receiver to the signal and adjust trimmer No. 12 to a peak. Then try to increase the output by detuning the trimmer slightly and retuning the dial until a maximum output meter deflection is secured. Check the adjustment by tuning the receiver to the image at about 15.1 MC. The image should be much weaker than the 16 MC. signal. If the signal at 15.1 MC. dial setting is equal to or stronger than the 16 MC. signal, trimmer No. 12 is not set to the proper peak. Turn the trimmer in a turn or so, then readjust as above.

- Input Power Rating — 56 Watts
- Frequency of Intermediate Amplifier — 465 Kilocycles

STROMBERG-CARLSON TELEPHONE MFG. CO.

MODELS 228H, 228HB, 228L & 228LB

CIRCUIT DESCRIPTION

These receivers are six tube superheterodyne receivers employing metal tubes and a highly efficient dynamic speaker. There are three tuning ranges; the limits of each tuning range are listed under the "Electrical Specifications" given above. These receivers are also equipped with a low level bass frequency compensating network, which in conjunction with the volume control circuit gives balanced reproduction at any setting of the volume control.

The various tubes are used in these receivers as follows: The No. 6A8 tube functions as both Modulator and Oscillator. The No. 6K7 tube is used in the I. F. Amplifier and the No. 6Q7 tube is used as the Demodulator, A. V. C., and Audio Amplifier tube. The No. 6F6G tube is used in the Audio Power Output Stage and the No. 6G5 tube is used for indicating resonance in the Tuning Indicator System. The No. 5Y4G is the Rectifier tube of the power supply unit.

NORMAL VOLTAGE READINGS

The various values of voltages listed in the following table are obtained by measuring between the various tube socket contacts and the chassis base, with the tubes in their respective sockets. The receiver is, therefore, in operation when the measurements are made. Figure 1, shows the terminal layout of the sockets with the proper terminal numbers.

Voltages are given for a line voltage of 120 volts, and allowance should be made for differences when the line voltage is higher or lower. A meter having a resistance of 1000 ohms per volt should be used for measuring the D. C. voltages. Voltage values shown are those obtained on the lowest possible scale of a meter having the following ranges: O-2.5, O-10, O-100, O-250, O-500, O-1000 volts except when an asterisk appears after any given voltage value in which case the 250 volt scale was used.

			Terminals of Sockets								*Heater Voltages Between Heater Terminals*

Speaker Socket		—	+340	0	0	+340	+340	—	+220			

Receiver tuned to 1000 Kc., no signal. A. C. voltages are indicated by italics.

ALIGNMENT DATA

All alignment adjustments are accurately made at the factory on these receivers, and ordinarily no readjustments are necessary. However, should it become necessary to make any readjustments, the alignment procedure given in the following paragraphs should be carefully followed. In order to make these aligning adjustments in an easy and satisfactory manner, it is recommended that the Stromberg-Carlson P-24608 aligning tool be used.

To accurately align the circuits in these receivers, it is necessary to use a high grade, modulated test oscillator (Signal Generator), the output voltage of which can be varied. In conjunction with this test oscillator, a sensitive output meter should be used for determining the maximum signal voltage developed across the voice coil of the loud speaker.

In making any alignment adjustments, always adjust the test oscillator's output voltage to the minimum value where a good alignment may still be obtained. Never attempt to make any alignment adjustments using a strong signal. Before proceeding with the alignment of any circuits in these receivers be sure that the "Off-On-Tone" control knob is set for maximum treble response (position where knob is rotated from its maximum counter-clockwise position, slightly clockwise to position where set turns "on"). Figure 1, shows the location of all the aligning capacitors in these receivers.

In making any alignment adjustments on these receivers, it will not be necessary to remove the chassis from the cabinet. The aligning capacitors for the intermediate frequency circuits of these receivers are easily accessible from the rear of the receiver, and the aligning capacitors for the radio frequency circuits are accessible through the aperture located in the bottom metal base plate of the chassis. These apertures are easily accessible either through the bottom of the cabinet or through the bottom of the cabinet shelf depending upon the style of cabinet. See Figure 2.

Dial Adjustment

Before aligning the circuits of any of these receivers, the tuning dial must be properly aligned to track with the gang tuning capacitors. To check whether the dial is set correctly with respect to the gang tuning capacitor, rotate the "Station Selector" knob in a clockwise direction so that the gang tuning capacitor is set to its maximum capacity position. Then, with the gang tuning capacitor in this position, the dial pointer should center over the middle vertical line of the three vertical lines located on the glass dial and the vertical lines located on the metal pan of the dial frame. Now, rotate the "Station Selector" knob so that the dial pointer lines up with the horizontal lines located on the metal pan of the dial frame; with the pointer in this position the two horizontal center marks of the glass dial (located at approximately 9.3 megacycles on the right hand scale and 2.16 megacycles on the left hand scale) should also be in alignment with the dial pointer. If the above conditions are not obtained, loosen the four clamps which hold the glass dial to the dial pan by slightly loosening the four screws, and shift the glass dial so that a good alignment between the dial pointer, the glass dial, and alignment marks located on the metal pan of the dial frame is obtained for both the horizontal and vertical position of the dial pointer.

Intermediate Frequency Adjustments

The intermediate frequency used in these receivers is 465 kilocycles. In making these circuit adjustments always align the circuits in the order given in these instructions.

1. Operate the "Range" switch of the receiver to the "A" range position. Set the receiver's tuning dial at its extreme low frequency position, and operate the Tone Control knob to the "Normal" position. Rotate the Volume Control knob to its maximum clockwise position (maximum volume).
2. Apply between the chassis base (or ground binding post) of the receiver and the grid of the No. 6A8 modulator-oscillator tube, a modulated signal of 465 kilocycles from the test oscillator, using a 0.1 microfarad capacitor in series with the connection between the output terminal of the test oscillator and the grid of the No. 6A8 tube. Do not remove the chassis grid lead connecting to this tube. The ground (or low side) terminal of the test oscillator should be connected to either the chassis base or the ground binding post terminal.
3. Now, noting from Figure 1, the aligning capacitors for the first and second I. F. transformers, align the I. F. circuits in the following manner:
   Secondary of second I. F. transformer.
   Primary of second I. F. transformer.
   Secondary of first I. F. transformer.
   Primary of first I. F. transformer.
   Adjusting the circuits to obtain maximum reading on the output meter, reducing the output of the test oscillator as required.

Radio Frequency Adjustments

The alignment of the radio frequency circuits of the various ranges in these receivers should be very carefully made and in the order specified.

Alignment of Short Wave Range (Also Referred to as "C" Band)

In aligning the radio frequency circuits for this range, replace the 0.1-microfarad capacitor which was placed in series with the test oscillator's output lead for the I. F. alignments, with a 400-ohm carbon type resistor. This lead should then be connected to the antenna binding post located on the rear of the receiver chassis. The ground terminal (or low side) of the test oscillator should be connected to the ground binding post on the receiver.

1. Operate the Range Switch on the receiver chassis to the "C" range position, and set the test oscillator's frequency and the receiver's tuning dial to 17 megacycles.
2. Adjust the oscillator's "C" band high frequency aligner for maximum output.
3. Adjust the antenna's "C" band high frequency aligner for maximum output, at the same time rotate the gang tuning capacitor back and forth through resonance until maximum output is obtained.

Alignment of Aircraft, Amateur, and Police Range (Also Referred to as "B" Band)

In aligning the radio frequency circuits for this range, use the same artificial antenna (400-ohm carbon type resistor) in series with the output terminal of the test oscillator as was used for aligning the short-wave range.

1. Operate the Range Switch on the receiver chassis to the "B" range position, and set the test oscillator's frequency and the receiver's tuning dial to 3.4 megacycles.
2. Adjust the oscillator's "B" band high frequency aligner for maximum output.
3. Adjust the antenna's "B" band high frequency aligner for maximum output, and at the same time rotate the gang tuning capacitor back and forth through resonance until maximum output is obtained.

Alignment of Standard Broadcast Range (Also Referred to as "A" Band)

In aligning the radio frequency circuits for this range, replace the 400-ohm carbon type resistor in series with the test oscillator's output lead with a 200-micro-microfarad capacitor and align these circuits as follows:

1. Operate the Range Switch to the "A" range position and set the test oscillator's frequency and the receiver's tuning dial to 1.4 megacycles.
2. Adjust the oscillator's "A" band high frequency aligner for maximum output.
3. Adjust the antenna's "A" band high frequency aligner for maximum output.
4. Set the test oscillator's frequency and the receiver's tuning dial to 0.6 megacycles.
5. Adjust the oscillator's "A" band low frequency aligner (series aligner) for maximum output, and at the same time rotate the gang tuning capacitor slightly back and forth through resonance until maximum output is obtained.
6. Reset both the test oscillator's frequency and receiver's tuning dial to 1.4 megacycles and repeat operations Nos. 2 and 3.

Input Power Rating	90 Watts
Frequency of Intermediate Amplifier	465 Kilocycles

STROMBERG-CARLSON TELEPHONE MFG. CO.
MODELS 229P, 229PB, 229PD & 229PE

CIRCUIT DESCRIPTION

The Stromberg-Carlson No. 229-P Radio Receivers are eight tube, superheterodyne receivers employing metal tubes and a highly efficient dynamic speaker. These receivers have three tuning ranges which are quickly interchangeable by means of a rotary switch, the control knob of which is located on the control panel. Ease and convenience of operation are assured by the vernier drive with its associated double knob. Resonance with a signal is indicated by means of the tuning indicator tube which operates on the cathode-ray principle. The strength of a received signal may be determined by observing the size of the aperture appearing on the target of the tuning indicator tube, the stronger a received signal the greater the reduction in the size of the aperture. A low level bass frequency compensating circuit is also provided in the volume control circuit of these receivers, which operates to give balanced reproduction at any setting of the volume control.

These receivers are also equipped with a single record playing phonograph unit which uses a crystal type pick-up in conjunction with a specially equalized circuit.

In order to obtain maximum performance from these receivers, a sensitivity control is provided for use on the standard broadcast range only. Its control knob is located on the rear of the chassis base. When either the "B" or "C" ranges are in operation, this sensitivity control is automatically cut out of the circuit so that the receiver will function at its maximum sensitivity on these two ranges. In some localities it will be found that without the use of this control, it will be impossible to eliminate adjacent channel interference. When this condition is obtained, the receiver should be tuned accurately to the desired station, and this sensitivity control adjusted so that minimum interference is obtained from the interfering station. See Figure 1.

The various tubes are used in these receivers as follows: One No. 6K7 tube is used in the R. F. Amplifier, and the other No. 6K7 tube is used in the I. F. Amplifier. The No. 6A8 tube functions as both Oscillator and Modulator tube. The No. 6H6 tube is used as a Demodulator and Automatic Volume Control tube. The No. 6F5 tube is used in the Audio Frequency Amplifier Stage (Driver), and the No. 6F6 tube is used in the Audio Power Output Stage. The No. 80 tube is the Rectifier tube of the power supply unit, and the No. 6G5 tube is used for indicating resonance in the Tuning Indicator System.

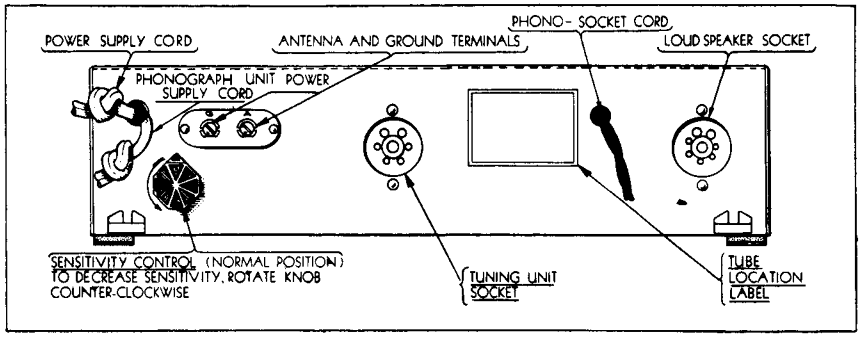

Fig. 1. Location and Operation of Sensitivity Control.

NORMAL VOLTAGE READINGS

The various values of voltages listed in the following table are obtained by measuring between the various tube socket contacts and the chassis base, with the tubes in their respective sockets. The receiver is, therefore, in operation when the measurements are made. Figure 2 shows the terminal layout of the sockets with the proper terminal numbers.

Voltages are given for a line voltage of 120 volts, and allowance should be made for differences when the line voltage is higher or lower. A meter having a resistance of 1000 ohms per volt should be used for measuring the D. C. voltages. Voltage values shown are those obtained on the lowest possible scale of a meter having the following ranges: O-2.5, O-10, O-100, O-250, O-500, O-1000 volts except when an asterisk appears after any given voltage value in which case the 1000 volt scale was used.

			Terminals of Sockets								Heater Voltages Between Heater Terminals

Receiver tuned to 1000 Kc., no signal. A. C. voltages are indicated by italics.

ALIGNMENT DATA

All alignment adjustments are accurately made at the factory on these receivers and ordinarily no readjustments are necessary. However, should it become necessary to make any readjustments, this alignment procedure should be carefully followed.

In making any alignment adjustments always adjust the signal generator's output to the minimum value where a good alignment may still be obtained. Never attempt to make any alignment adjustments using a strong signal.

Figure 2 shows the location of all the aligning capacitors used in this receiver.

Intermediate Frequency Amplifier Adjustments

The intermediate frequency used in these receivers is 465 kilocycles. In making these I. F. circuit adjustments always align in the following order:

1. Secondary of 2nd I. F. Transformer (Capacitor C-13).
2. Primary of 2nd I. F. Transformer (Capacitor C-12).
3. Secondary of 1st I. F. Transformer (Capacitor C-11).
4. Primary of 1st I. F. Transformer (Capacitor C-10).

Radio Frequency Adjustments

The adjustments of the aligning capacitors used in the radio frequency circuits in this receiver should be very carefully made in the following order and at the frequencies specified below:

1. Oscillator's "C" Band Shunt Aligner at 17 Megacycles (Capacitor C-7).
2. R. F. Interstage "C" Band Shunt Aligner at 17 Megacycles (Capacitor C-6).
3. Antenna "C" Band Shunt Aligner at 17 Megacycles (Capacitor C-3).
4. Oscillator's "B" Band Shunt Aligner at 3.4 Megacycles (Capacitor C-8).
5. R. F. Interstage "B" Band Shunt Aligner at 3.4 Megacycles (Capacitor C-5).
6. Antenna "B" Band Shunt Aligner at 3.4 Megacycles (Capacitor C-2).
7. Oscillator's "A" Band Shunt Aligner at 1.4 Megacycles (Capacitor C-9).
8. R. F. Interstage "A" Band Shunt Aligner at 1.4 Megacycles (Capacitor C-4).
9. Antenna "A" Band Shunt Aligner at 1.4 Megacycles (Capacitor C-1).
10. Oscillator's "A" Band Series Aligner at 0.6 Megacycles (Capacitor-23).
11. Oscillator's "A" Band Shunt Aligner at 1.4 Megacycles (Capacitor C-9).
12. R. F. Interstage "A" Band Shunt Aligner at 1.4 Megacycles (Capacitor C-4).
13. Antenna "A" Band Shunt Aligner at 1.4 Megacycles (Capacitor C-1).

TRANSITONE AUTOMOBILE RADIO CORP.

MODEL P1421 "PACKARD"

I. F. TRANSFORMERS AND PADDERS

The I. F. transformers are assembled complete with padding condensers.

Both the primary and the secondary padders are placed side by side in the top of the transformer shield can. The adjusting screws are accessible thru the holes in the top of the shield. (See Figure 4).

The coil windings terminate in leads instead of terminals or lugs. The color scheme of the leads is given in Figure 8.

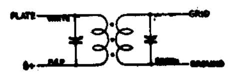

Figure 8

If replacements are ever necessary, replace the entire coil assembly, 32-2252 for the first I. F. stage and 32-2167 for the second I. F. stage. Neither the coil nor the padders will be furnished separately. Order only by the above numbers.

MODEL P-1421 ADJUSTMENTS

All padding adjustments are carefully made at the factory and ordinarily no readjustments are necessary. However, when readjustments are required, the procedure given below must be followed in detail.

Equipment

Fully charged heavy duty storage battery or 6-volt power pack, 048A Philco Set Tester, 8164 Padding wrench, 27-7159 Padding screw driver.

General

OUTPUT METER—The output meter must be connected by means of an adapter to the plate of the type 79 output tube and to the Receiver chassis.

SIGNAL GENERATOR—With the Receiver and signal generator set up for operation at the prescribed frequency, turn the Receiver volume control on full and set the signal generator attenuator so that a half scale reading is obtained on the output meter. The signal in the speaker should be audible but not loud.

The shielding on the signal generator output lead must be connected to the Receiver housing.

Procedure

I. F.—Set the signal generator at exactly 260 K. C. Connect the generator lead to the grid cap of the 78 I. F. tube in series with a .1 mfd. condenser (without removing the grid cap).

Adjust the secondary screw padder (27) on the second I. F. transformer for maximum reading on the output meter. Then adjust the primary screw padder (26) for maximum reading (See Figure 4 for location of padders).

Remove the generator lead from the 78 tube.

Connect the generator lead to the grid cap of the 6A7 tube in series with a .1 mfd. condenser (without removing the grid cap). Adjust the secondary screw padder (24) on the first I. F. transformer for maximum reading on the output meter. Then adjust the primary screw padder (23) for maximum reading. Readjust padders (26) and (27) with the generator lead connected to the type 6A7 tube. (See Figure 4 for location of padders).

HIGH FREQUENCY AND R. F.—After padding the first I. F. stage remove the generator lead from the 6A7 tube. Set the signal generator at 1550 K. C. and then connect the generator lead to the grid cap of the 78 R. F. tube in series with a .1 mfd. condenser (without removing the grid cap).

Using a piece of paper approximately .006" thick as a gauge between the heel of the rotor plates and the stator plates, turn the rotor plates in mesh until they strike against the paper.

With the tuning condenser in this position, adjust the high frequency padder (18) and the R. F. padder (13) until the maximum reading is obtained on the output meter. This is the true setting for 1550 K. C., 155 on the dial scale.

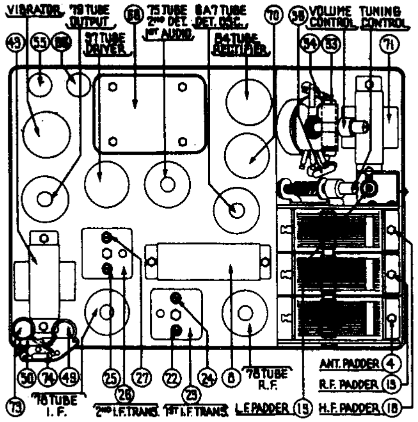

Figure 4

LOW FREQUENCY—Turn the tuning condenser plates in mesh to approximately 600 K. C., 60 on the dial scale and set the signal generator at 600 K. C. Roll the tuning condenser and adjust the low frequency padder screw (15) for maximum reading on the output meter.

HIGH FREQUENCY READJUSTMENT—Turn the tuning condenser plates out of mesh to 1550 K. C. and set the signal generator at 1550 K. C. Then adjust the high frequency padder (18) again for maximum reading on the output meter.

Remove the generator lead from the 78 R. F. tube.

ANTENNA — WHEN PADDING THE ANTENNA STAGE IT IS EXTREMELY IMPORTANT THAT THE PROPER DUMMY ANTENNA BE USED.

Connect the signal generator lead to the antenna lead on the Receiver using a 280 mmfd. condenser in series between the two leads.

Turn the tuning condenser to 1400 K. C. and set the generator at 1400 K. C. Adjust the padders (13) and (4) for the maximum reading on the output meter.

When the antenna stage adjustment is made with the Receiver installed in the car, the Receiver antenna lead must be connected to the car antenna in the usual manner. Connect the signal generator output lead to a wire placed near the car antenna but not connected to it.

MODEL PHXD "PACKARD DeLUXE"

I. F. Transformers and Padders
Model PHXD

The I. F. transformers are assembled complete with padding condensers.

The padders are placed in the top of the shield can, one above the other.

The primary padder is adjusted by means of the screw slot, accessible through the hole in the top of the shield can. The secondary padder is adjusted by means of the small hex nut, also accessible through the hole in the top of the shield. (See Figure 8).

The coil windings terminate in leads instead of terminals or lugs. The color scheme of the leads is given in Figure 7.

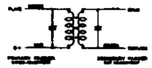

Figure 7

If replacements are ever necessary, replace the entire coil assembly, 32-1471 for the first I. F. stage and 32-1449 for the second I. F. stage. Neither the coil nor the padders will be furnished separately. Order only by the above numbers.

Model PHXD Adjustments

All padding adjustments are carefully made at the factory and ordinarily no readjustments are necessary. However, when readjustments to the Model PHXD are required, the procedure given below must be followed in detail.

Equipment

Full charged heavy duty storage battery or 6-volt power pack, 048 Philco Set Tester, 8164 Padding Wrench, 27-7159 Padding Screw Driver.

General

OUTPUT METER — The output meter must be connected by means of an adapter to one of the plates of the type 79 output tube and to the Receiver chassis.

SIGNAL GENERATOR — With the Receiver and signal generator set up for operation at the prescribed frequency, turn the Receiver volume control on full and set the signal generator attenuator so that a half scale reading is obtained on the output meter. The signal in the speaker should be audible but not loud.

The shielding on the signal generator output lead must be connected to the Receiver housing.

The sensitivity switch must be in the "distance" position. The tone control should be turned to the brilliant position.

Remove the cover from the Receiver. The antenna lead must be disconnected.

I. F.—Adjust the signal generator to exactly 260 K. C. Connect the generator lead to the grid cap of the 89-44 I. F. tube, in series with a .1 mfd. condenser.

Adjust the secondary nut padder (27) on the second I. F. transformer for maximum reading on the output meter. Then adjust the primary screw padder (25) for maximum reading. (See Figure 8 for location of padders). Note the maximum reading obtained and then turn the screw in again and readjust, just bringing the adjustment up to the maximum reading. Do not pass it and then back off. This adjustment is critical.

Remove the generator lead from the 89-44 tube.

Connect the generator lead to the grid cap of the 6A7 tube in series with a .1 mfd. condenser. Adjust the secondary nut padder (18) on the first I. F. transformer for maximum reading on the output meter. Then adjust the primary screw padder (19) for maximum reading. (See Figure 8 for location of padders). Note the maximum reading obtained and then turn the screw in again and readjust, just bringing the adjustment up to the maximum reading. Do not pass it and then back off. This adjustment is critical.

HIGH FREQUENCY AND R. F. — After padding the first I. F. stage remove the generator lead from the 6A7 tube. Adjust the signal generator to 1500 K. C., and then connect the generator lead to the grid cap of the 89-44 R. F. tube in series with a .1 mfd. condenser.

Using a piece of paper approximately .006" thick as a gauge between the heel of the rotor plates and the stator plates, turn the rotor plates until they strike against the paper. With the tuning condenser in this position, adjust the high frequency padder (10) and the R. F. padder (9) until the maximum reading is obtained on the output meter. This is the true setting for the 1500 K. C., 150 on the dial scale.

HIGH FREQUENCY READJUSTMENT—Next turn the tuning condenser plates out of mesh to 1500 K. C., 150 on the dial scale, and adjust the signal generator to 1500 K. C. Then adjust the high frequency padder (10) for maximum reading on the output meter.

LOW FREQUENCY—Turn the tuning condenser plates in mesh to approximately 580 K. C., 58 on the dial scale and adjust the signal generator to 580 K. C. Roll the tuning condenser and adjust the low frequency padder (14) for maximum reading on the output meter.

ANTENNA AND R. F.—Connect the generator lead to the antenna lead using a 200 mmfd. condenser in series between the two leads and the .1 mfd. condenser. Turn the tuning condenser to 1400 K. C., and set the generator for 1400 K. C. Adjust the padders (9) and (3) for maximum reading on the output meter.

If this procedure has been carefully followed and an accurately calibrated oscillator or signal generator has been used, the Receiver will be adjusted properly.

Note: When the antenna stage adjustment is made with the Receiver installed in the car, the Receiver antenna lead must be connected to the car antenna in the usual manner. The signal generator output lead should be connected to a wire placed near the car antenna but not connected to it.

MODEL ST12 "STUDEBAKER"

I. F. Transformers and Padders
Model ST12

The I. F. transformers are assembled complete with padding condensers.

Both the primary and the secondary padders are placed side by side in the top of the transformer shield can. The adjusting screws are accessible thru the holes in the top of the shield. (See Figure 8).

The coil windings terminate in leads instead of terminals or lugs. The color scheme of the leads is given in Figure 7.

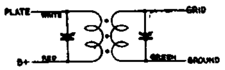

FIGURE 7

If replacements are ever necessary, replace the entire coil assembly, 32-1928 for the first I. F. stage and 32-1929 for the second I. F. stage. Neither the coil nor the padders will be furnished separately. Order only by the above numbers.

Model ST12 Adjustments

All padding adjustments are carefully made at the factory and ordinarily no readjustments are necessary. However, when readjustments to the Model ST12 are required, the procedure given below must be followed in detail.

Equipment

Fully charged heavy duty storage battery or 6-volt power pack, 048A Philco Set Tester, 3164 Padding wrench, 27-7159 Padding screw driver.

General

OUTPUT METER — The output meter must be connected by means of an adapter to the plate of the type 41 output tube and to the Receiver chassis.

SIGNAL GENERATOR — With the Receiver and signal generator set up for operation at the prescribed frequency, turn the Receiver volume control on full and set the signal generator attenuator so that a half scale reading is obtained on the output meter. The signal in the speaker should be audible but not loud.

The shielding on the signal generator output lead must be connected to the Receiver housing.

The sensitivity switch must be in the "distance" position. The tone control should be turned to the brilliant position.

Procedure

I. F. — Adjust the signal generator to exactly 260 K. C. Connect the generator lead to the grid cap of the 78 I. F. tube in series with a .1 mfd. condenser.

Adjust the secondary screw padder ⑳ on the second I. F. transformer for maximum reading on the output meter. Then adjust the primary screw padder ㉑ for maximum reading. (See Figure 8 for location of padders).

Remove the generator lead from the 78 tube.

Connect the generator lead to the grid cap of the 6A7 tube in series with a .1 mfd. condenser. Adjust the secondary screw padder ㉔ on the first I. F. transformer for maximum reading on the output meter. Then adjust the primary screw padder ㉕ for maximum reading. (See Figure 8 for location of padders).

HIGH FREQUENCY AND R. F. — After padding the first I. F. stage remove the generator lead from the 6A7 tube.

Adjust the signal generator to 1600 K. C. and then connect the generator lead to the grid cap of the 78 R. F. tube in series with a .1 mfd. condenser.

Turn the tuning condenser plates out of mesh as far as they will go. With the tuning condenser in this position, adjust the high frequency padder ⑯ and the R. F. padder ⑬ until the maximum reading is obtained on the output meter. This is the true setting for 1600 K. C., 160 on the dial scale.

LOW FREQUENCY — Turn the tuning condenser plates in mesh to approximately 580 K. C., 58 on the dial scale and adjust the signal generator to the 580 K. C. Roll the tuning condenser and adjust the low frequency padder screw ⑮ for maximum reading on the ouput meter.

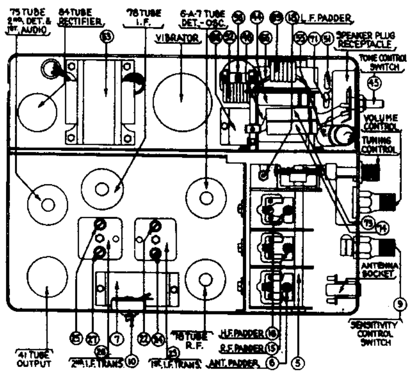

FIGURE 8

HIGH FREQUENCY RE-ADJUSTMENT — Turn the tuning condenser plates out of mesh as far as they will go and adjust the signal generator to 1600 K. C. Then adjust the high frequency padder ⑯ again for maximum reading on the output meter.

ANTENNA — Connect the generator lead to the antenna cable assembly (made up of Part No. L1915 loom, 1-27-7133 terminal and 40 inches of 16 strand No. 30 wire), using a 200 mmfd. condenser in series between the two leads. Plug the cable into the antenna socket.

Turn the tuning condenser to 1400 K. C. and set the generator for 1400 K. C. Adjust the padders ⑬ and ⑥ for the maximum reading on the output meter.

When the antenna stage adjustment is made with the Receiver installed in the car, the Receiver antenna lead must be connected to the car antenna in the usual manner. The signal generator output lead should be connected to a wire placed near the car antenna but not connected to it.

If this procedure has been carefully followed and an accurately calibrated oscillator or signal generator has been used, the Receiver will be adjusted properly.

MODEL ST15 "STUDEBAKER"

I. F. Transformers and Padders
Model ST15

The I. F. transformers are assembled complete with padding condensers.

Both the primary and the secondary padders are placed side by side in the top of the transformer shield can. The adjusting screws are accessible thru the holes in the top of the shield. (See Figure 6).

The coil windings terminate in leads instead of terminals or lugs. The color scheme of the leads is given in Figure 5.

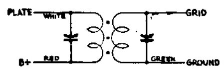

FIGURE 5

If replacements are ever necessary, replace the entire coil assembly, 32-1928 for the first I. F. stage and 32-1929 for the second I. F. stage. Neither the coil nor the padders will be furnished separately. Order only by the above numbers.

Model ST15 Adjustments

All padding adjustments are carefully made at the factory and ordinarily no readjustments are necessary. However, when readjustments to the Model ST15 are required, the procedure given below must be followed in detail.

Equipment

Fully charged heavy duty storage battery or 6-volt power pack, 048A Philco Set Tester, 3164 Padding wrench, 27-7159 Padding screw driver.

General

OUTPUT METER — The output meter must be connected by means of an adapter to the plate of the type 41 output tube and to the Receiver chassis.

SIGNAL GENERATOR — With the Receiver and signal generator set up for operation at the prescribed frequency, turn the Receiver volume control on full and set the signal generator attenuator so that a half scale reading is obtained on the output meter. The signal in the speaker should be audible but not loud.

The shielding on the signal generator output lead must be connected to the Receiver housing.

Procedure

I. F. — Adjust the signal generator to exactly 260 K. C. Connect the generator lead to the grid cap of the 78 I. F. tube in series with a .1 mfd. condenser.

Adjust the secondary screw padder ⑳ on the second I. F. transformer for maximum reading on the output meter. Then adjust the primary screw padder ㉑ for maximum reading. (See Figure 6 for location of padders).

Remove the generator lead from the 78 tube.

Connect the generator lead to the grid cap of the 6A7 tube in series with a .1 mfd. condenser. Adjust the secondary screw padder ㉔ on the first I. F. transformer for maximum reading on the output meter. Then adjust the primary screw padder ㉕ for maximum reading. (See Figure 6 for location of padders).

HIGH FREQUENCY AND R. F. — After padding the first I. F. stage remove the generator lead from the 6A7 tube.

Adjust the signal generator to 1600 K. C. and then connect the generator lead to the grid cap of the 78 R. F. tube in series with a .1 mfd. condenser.

Turn the tuning condenser plates out of mesh as far as they will go. With the tuning condenser in this position, adjust the high frequency padder ⑯ and the R. F. padder ⑬ until the maximum reading is obtained on the output meter. This is the true setting for 1600 K. C., 160 on the dial scale.

LOW FREQUENCY — Turn the tuning condenser plates in mesh to approximately 580 K. C., 58 on the dial scale and adjust the signal generator to the 580 K. C. Roll the tuning condenser and adjust the low frequency padder screw ⑮ for maximum reading on the output meter.

HIGH FREQUENCY RE-ADJUSTMENT — Turn the tuning condenser plates out of mesh as far as they will go and adjust the signal generator to 1600 K. C. Then adjust the high frequency padder ⑯ again for maximum reading on the output meter.

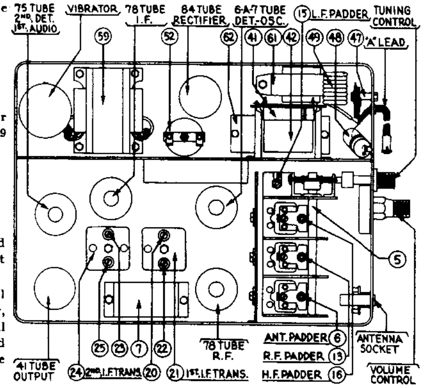

FIGURE 6

ANTENNA — Connect the generator lead to the antenna cable assembly (made up of Part No. L1915 loom, 1-27-7133 terminal and 40 inches of 16 strand No. 30 wire), using a 200 mmfd. condenser in series between the two leads. Plug the cable into the antenna socket.

Turn the tuning condenser to 1400 K. C. and set the generator for 1400 K. C. Adjust the padders ⑬ and ⑥ for the maximum reading on the output meter.

When the antenna stage adjustment is made with the Receiver installed in the car, the Receiver antenna lead must be connected to the car antenna in the usual manner. The signal generator output lead should be connected to a wire placed near the car antenna but not connected to it.

If this procedure has been carefully followed and an accurately calibrated oscillator or signal generator has been used, the Receiver will be adjusted properly.

MODEL 224

ELECTRICAL SPECIFICATIONS

Type and Number of Tubes .... 4 #39, 1 #37, 1 #71A, 2 #52 - Total 8
Power Supply Characteristics .... 105 to 125 Volts D.C.
Power Consumption .... 200 Watts
Tuning Range .... 550 to 1500 K.C.
Maximum Undistorted Output .... 3. Watts
Line-Up Frequencies .... I.F. 175 K.C., 1400 K.C., 600 K.C.

GENERAL DESCRIPTION

The Model 224 is an eight tube direct current superheterodyne receiver whose circuit consists of a stage of radio frequency amplification, an oscillator, a stage of intermediate frequency amplification, a second detector, a driver and a push-pull stage of class B audio amplification.

The receiver is designed to operate on the standard broadcast band extending from 550 to 1500 K.C.

LINE-UP CAPACITOR ADJUSTMENTS

To properly align the chassis, it is essential to use a high grade modulated test oscillator and a sensitive output meter. The R.F. signal fed into the receiver must be relatively weak or it will cause the A.V.C. to function making correct alignment difficult. The sensitivity of the output meter must be sufficient to give satisfactory reading with a low input signal. Before attempting to align the receiver, the service man should familiarize himself with the general layout of the chassis, the location of the tubes and the various alignment condensers. A top view is shown in Figure #1 and should be carefully studied before the actual work is started.

I.F. ADJUSTMENTS - 175 K.C.

1. Set volume control on full.
2. Set test oscillator to 175 K.C. and apply test signal to grid of 39 I.F. tube through a .5 mfd. blocking condenser.
3. Adjust the two trimmers on top of second I.F. transformer to maximum output reducing output of test oscillator as required.
4. Apply test signal to grid of 39 first detector tube and adjust the two trimmers on top of first I.F. transformer to maximum output.
5. Repeat above operations for accuracy.

OSCILLATOR & R.F. ADJUSTMENTS

1. Set test oscillator and dial scale to 1400 K.C.
2. With test signal still applied to the grid of the first detector, adjust oscillator trim condenser A to maximum output.
3. Apply test signal to antenna lead of the set and adjust trimmer B and the antenna adjustment screw to maximum output.
4. Set test oscillator and dial scale to 600 K.C. and adjust oscillator lagging condenser on top of oscillator coil to maximum output.
5. Return to 1400 K.C. setting and readjust A, B and the antenna adjustment screw as the adjustment of the oscillator lagging condenser may have altered these settings.
6. Check the sensitivity and calibration at several different positions of the dial scale.

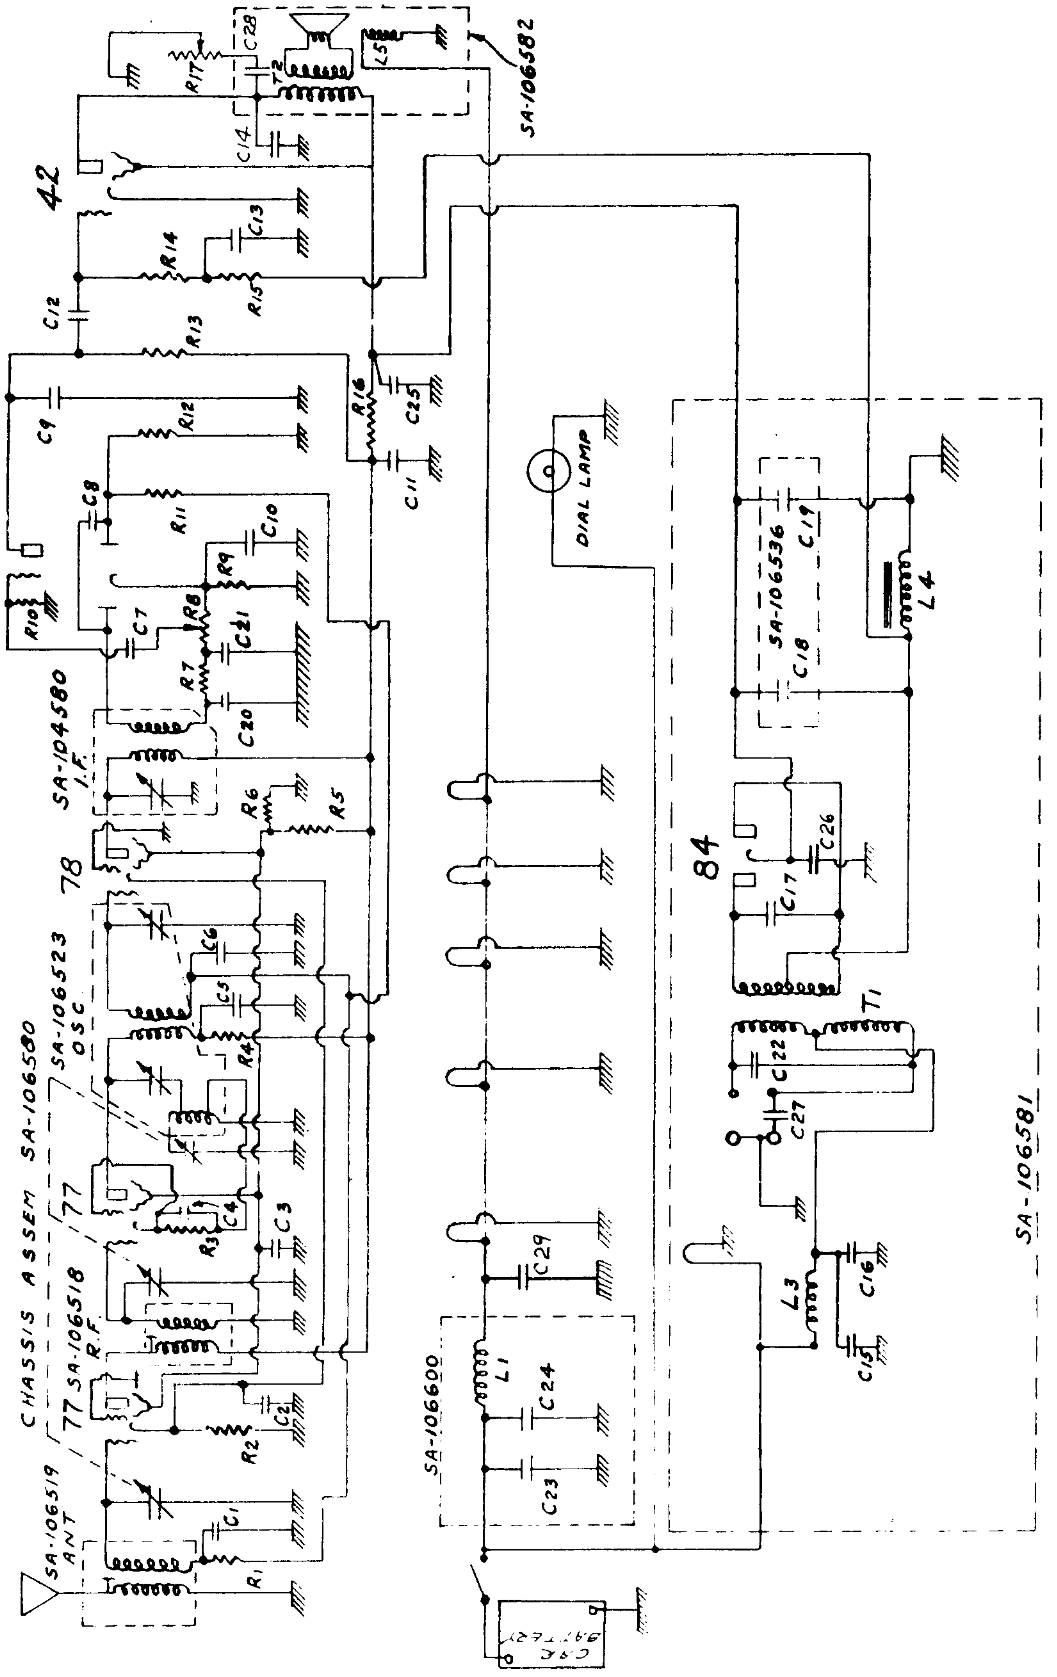
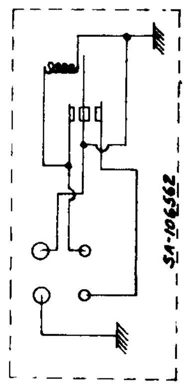
UNITED AMERICAN BOSCH CORPORATION

MODEL 79C CAR RADIO



The tubes employed in this circuit are as follows:

1 type 77 radio frequency amplifier.
1 type 77 detector oscillator.
1 type 78 intermediate frequency amplifier.
1 type 75 second detector, A.V.C. and audio amplifier.
1 type 42 output tube.
1 type 84 rectifier.



UNITED AMERICAN BOSCH CORPORATION

MODEL 79C CAR RADIO

GENERAL DESCRIPTION

This receiver consists of 6-tube superheterodyne circuit with 3-gang condenser, electro-dynamic speaker, and self-contained power pack.

The antenna is coupled to the first stage by means of a transformer. The R.F. stage is also coupled to the oscillator by means of a transformer. Resistance coupling is employed between the audio portion of the type 75 tube and the output tube. The intermediate frequency employed is 175 kilocycles.

Automatic volume control is provided by utilizing the potential drop in the collector circuit of the type 75 tube. The A.V.C. is made a part of the D.C. grid circuits of the R.F. and I.F. amplifiers.
An electro-dynamic speaker is used with this set. This speaker has a field resistance of 5.6 ohms and a voice coil resistance of approximately 3 ohms.

A tone control is provided in the plate circuit of the output tube. This consists of a condenser and variable resistor in series.

TROUBLE CHART

A few general classes of trouble in the Model 79C set are listed below, together with the probable reasons. These should serve as a general guide in checking set trouble.

I. NO RECEPTION (Dial light not illuminated)
- (a) Fuse in "A" battery cable burned out:
  - (1) Short in "A" line or circuit.
  - (2) Shorted elements in vibrator.
  - (3) Shorted elements in tube.
- (b) Poor connection at ammeter.
- (c) Defective switch:
  - (1) Switch is not actuated by shaft due to loose clamp screw.
  - (2) Switch not making contact.

II. NO RECEPTION (Dial light illuminated)
- (a) Car antenna grounded.
- (b) Loose antenna connection.
- (c) Antenna coil open or other coils defective.
- (d) One or more defective tubes.
- (e) Open in voltage supply to tube sockets.
- (f) Vibrator not working or intermitten.

III. WEAK OR INTERMITTENT RECEPTION
- (a) Poor antenna or antenna connections.
- (b) One or more defective tubes.
- (c) Low voltage output of vibrator.
- (d) Open speaker field.
- (e) Grid bell off of tube cap.
- (f) Defective oscillator coil.
- (g) Trimmer condensers out of alignment. (See instructions for alignment)
- (h) Shorted turns in power transformer, giving low "B" voltage.
- (i) Lack of plate voltage on some tube.

IV. POOR TONE QUALITY
- (a) Low car storage battery.
- (b) One or more defective tubes.
- (c) Defective speaker
  - (1) Buzzing in speaker caused by foreign material between voice coil winding and pole piece. Blow out with air pressure.
  - (2) Buzzing in speaker caused by loose voice coil winding. Winding can be tightened by cementing with household cement.
  - (3) Speaker rattle caused by diaphragm hitting screen in front. Remedy - Space speaker away from screen by inserting extra card-board ring. Rattle caused by loose paper inside of voice coil form. Remedy - Take thin metal shim and run around inside of voice coil form to clear out loose paper.
- (d) Low "B" voltage (should be at least 220 at output from power pack).
- (e) Defective tone control.
- (f) Defective tone control .05 condenser.

V. DEAD OVER CERTAIN PORTIONS OF DIAL
- (a) Defective oscillator tube.
- (b) Trimmers not aligned properly.
- (c) Gang condenser shorted for certain positions of rotation.
- (d) Gang condenser wiper contacts dirty.
- (e) Metal chips or foreign metal particles in gang condenser.

VI. OSCILLATION
- (a) I.F. grid lead moved out of position.
- (b) Open in some bypass condenser circuit.

TESTING

(a) ANTENNA: Substitute a piece of insulated wire 6 to 8 feet long and lay on ground; if reception is normal, the regulator antenna is at fault and should be checked for grounds, opens, etc. (Somewhat better reception should be expected with wire aerial than with car antenna.)

(b) TUBES: Remove and test, or substitute known good tubes, one at a time.

(c) VIBRATOR: Remove and substitute known good unit.

(d) SPEAKER: Using voltohmmeter check voltage supplied to speaker field (should be 5.8 V. or more). Disconnect lead from transformer to speaker at #47 (Fig. #1.). Measure resistance between #47 and #48 (should be about 3 ohms).

(e) SECONDARY OUTPUT TRANSFORMER: After unsoldering lead from terminal #47 (Fig. #1), test with ohmmeter between this lead and terminal #48 (full scale reading - ohmmeter).
(f) CHASSIS: After checking the components listed above, test the voltages as they appear on "Voltage Chart" and Fig. #4, and the resistance measurements as found in "Resistance Chart" and Fig. #5. If any particular reading obtained is very different from the chart reading, the trouble is located in the portion of the circuit associated with the points at which this discrepancy occurs. Referring to diagram shown and location drawings (Figs. #1, 2 and 3), each part making up the circuit may be individually tested until the faulty part is specifically located.

ALIGNMENT INSTRUCTIONS

All the adjustable condensers, commonly called trimmer condensers, are very accurately adjusted at the factory and will not need any further adjustment unless a coil or I.F. transformer is changed, or the adjustments tampered with in the field. Therefore, DO NOT attempt to change the setting of any of the trimmer condensers unless it is definitely known that adjustment is necessary, and a test oscillator is available, then proceed as follows and refer to Fig. #1.

(A) I.F. ADJUSTMENT

(Use .1 mfd. antenna condenser)

1. Connect test oscillator to grid of 1st I.F. (78) tube.
2. Adjust small I.F. coil (between 78 and 75 tube) to maximum output.
3. Connect test oscillator to grid of 1st detector (77) tube.
4. Adjust condensers on coil in left hand corner of receiver for maximum output.
5. Repeat the above operations for accuracy.

(B) OSCILLATOR ADJUSTMENT

(Use .1 mfd. condenser on grid - .002 mfd. on antenna)

1. Connect test oscillator to grid of 1st detector (77) tube. Set at 1500 K.C.
2. Set gang to 1500 K.C. as follows:
   (a) Open gang to fullest extent.
   (b) Close slowly to thickness of approximately .015 of an inch.
3. Peak oscillator condenser on end of gang.
4. Connect test oscillator to antenna lead.
5. Peak other two condensers on gang.
6. Check sensitivity at several points on dial scale.

The set is now fully aligned and normal sensitivity prevails.

SERVICE INSTRUCTIONS

When set fails to perform properly, always check the voltage of the batteries. Run down batteries will cause weak and poor reception.

Noises may develop from defective tubes and condensers.

This set has been carefully aligned at the factory, but if realignment should become necessary, the following procedure should be followed.

Use a test oscillator and connect an output meter from plate of 41 to B plus.

I. F. Alignment:

Connect the oscillator through a .1 condenser to the grid of the 6A7 tube and set the oscillator to 456 kilocycles. Peak each I. F. stage to resonance as indicated by maximum output on the output meter.

R. F. Alignment:

With the wave change switch in the broadcast position, set oscillator to 1700 kilocycles and connect in series with a .00025 condenser to the antenna of the receiver. Rotate the variable condenser to the 1700 setting of the dial and adjust the trimmer condenser of the broadcast oscillator to resonance. The location of oscillator trimmer is on rear section of variable condenser. Reset the test oscillator to 1400 kilocycles and adjust antenna trimmer located in corner front section of variable condenser. Now set oscillator to 600 kilocycles and adjust padder located on top of the chassis. Check alignment at 1000 kilocycles.

For alignment police band, set test oscillator to 6 megacycles. Turn bandswitch to short wave. Rotate variable condenser until signal is heard. Peak antenna trimmer (across antenna coil under chassis) to maximum. Rock variable condenser slightly backward and forward until maximum peak is reached.

TUBE LOCATION

A special feature of this receiver is the "SENSITIZER". The incorporation of this advanced engineering design enables you to obtain maximum sensitivity and efficiency from the receiver regardless of the location in which it is used. No attempt should be made to adjust the "SENSITIZER" until you have familiarized yourself with the proper method of tuning for maximum volume as explained above.

To adjust the "SENSITIZER" carefully tune in a station, preferably one which is received weakly in your locality at or around 600 kilocycles, then with a non metallic rod shaped on one end like a screw driver (a metal screw driver can be used if care is taken), turn the small screw which is visible through the hole at the rear of the set marked "SENSITIZER" to the right for about one-half turn. Retune the station again going back and forth slowly through the station and listen carefully for a whistling sound. If no whistling is heard turn the "SENSITIZER" screw another fraction of a turn to the right and retune. Repeat this procedure until the whistling noise is heard and then unscrew the "SENSITIZER" screw just sufficiently to eliminate the whistle which is heard when tuning. This point of adjustment at which the whistling just disappears is the most sensitive position of the receiver and once properly adjusted, the "SENSITIZER" should not have to be touched again except when using the set in a different location, or with a different aerial, or when either of the type 6C6 or 6A7 tubes has been replaced.

MODEL A1 SERIES

ALIGNMENT PROCEDURE

Volume Control—Maximum All Adjustments.
Selectivity Control—Sharp Position All Adjustments.
Connect Radio Chassis to Ground Post of Signal Generator with a Short Heavy Lead.
Allow Chassis and Signal Generator to "Heat Up" for Several Minutes.

The following equipment is required for aligning:
An All Wave Signal Generator which will provide an accurately calibrated signal at the test frequencies as listed.
Output Indicating Meter — Non-Metallic Screwdriver.
Dummy Antennas — .1 mf., 200 mmf., and 400 ohms.

STEP (Follow Order as Given)	BAND SWITCH SETTING	DUMMY ANTENNA	SIGNAL GENERATOR FREQUENCY SETTING	SIGNAL GENERATOR CONNECTION AT RADIO	TRIMMERS ADJUSTED See Illustration	PROCEDURE INITIAL STEPS	PROCEDURE ADJUSTMENT
I. F.							
2nd I.F. Adj.	Range B	.1 mf.	456 KC	Grid of I.F. Tube	2nd I.F. (C29) & (C30)	Turn Rotor to Full Open	Adjust to Maximum Output
1st I.F. Adj.	Range B	.1 mf.	456 KC	Grid of 1st Det.	1st I.F. (C23) & (C24)	Turn Rotor to Full Open	Adjust to Maximum Output

2000 KC	Range C	400 Ohm	2000 KC	Antenna Lead	2000 KC (C11)	Turn Rotor to Max. Output	Adjust to Maximum Output Rock Rotor — See Note B
RANGE D							
22,000 KC	Range D	400 Ohm	22,000 KC	Antenna Lead	Oscillator Range D (C9)	Turn Rotor to Full Open	Adjust to Maximum Output
20,000 KC	Range D	400 Ohm	20,000 KC	Antenna Lead	Antenna Range D (C2)	Turn Rotor to Max. Output	Adjust to Maximum Output Rock Rotor — See Note B
7000 KC	Range D	400 Ohm	7000 KC	Antenna Lead	7000 KC (C8)	Turn Rotor to Max. Output	Adjust to Maximum Output Rock Rotor — See Note B

Attenuate the signal from the signal generator to prevent the leveling-off action of the AVC.

After each range is completed, repeat the procedure as a final check.

NOTE A—In sets using the telephone dial tuning, there will be seen inside the telephone dial button ring an escutcheon plate held in place by four screws. Loosen the 2 screws nearest the pointer. An extension of the pointer will be seen protruding over the edge of this escutcheon plate. Move the pointer to the 1500 KC mark on the dial and then tighten the 2 escutcheon screws. (Do not tighten these screws too much.)

In sets using the moving beam of light indicator, there is a moving light assembly held to the front of the drive drum by means of a screw. Loosen this screw and move the light assembly until the beam is at the 1500 KC mark on the dial. Retighten the screw.

NOTE B—Turn the rotor back and forth and adjust the trimmer until the peak of greatest intensity is obtained.

CAUTION—When aligning the short wave bands, be sure NOT to adjust at the image frequency. This can be checked as follows: Let us say the signal generator is set for 5000 KC. The signal will then be heard at 5000 KC on the dial of the radio. The image signal, which is much weaker, will be heard at 5000 less 912 KC, or 4088 KC on the dial. It may be necessary to increase the input signal to hear the image.

NOTICE—Re-alignment is necessary if glass tubes are replaced by their equivalent in metal tubes, or vice versa, in the R.F. and I.F. stages.

MODEL AI SERIES

SPECIFICATIONS

Power Consumption - 67 Watts (At 117 volts 60 cycles)
Power Output - - - - 2.5 Watts Undistorted, 4.5 Watts Maximum
Selectivity - 30 KC Broad at 1000 times Signal (Sharp)
Intermediate Frequency - - - - 456 KC.
Speakers - - - - 8", 10" or 12" Dynamic

Tuning Frequency Range
B Range .... 528 to 1830 KC.
C Range .... 1810 to 6350 KC.
D Range .... 6300 to 22000 KC.

Sensitivity
B Range .... 8 Microvolts Average
C Range .... 13 Microvolts Average
D Range .... 9 Microvolts Average

Circuit

This model is a three band AC operated radio with a tuning range as shown in the specifications above.

Referring to the schematic circuit diagram, Fig. 2, T1 and T7 are the antenna coil assemblies and T2 is the oscillator coil assembly. The standard wave, 1st and 2nd short wave coils in each assembly are indicated by the letters B, C and D respectively

The band switch completes connections to the coils in use. When it is in the Range B position, a double tuned antenna R.F. stage is used while for the C and D Ranges, a single tuned secondary is used.

A type 6J7 tube functions as the 1st detector.

A separate type 6C5 tube is employed in the oscillator circuit. The oscillating circuit is always resonant at 456 KC above the frequency to which the R.F. amplifier is tuned.

One stage of I.F. amplification is employed using a 6K7 tube. The primaries and secondaries of the 1st and 2nd I.F. transformers are tuned by small trimmer condensers.

Referring to Fig. 2, it will be noted that there is a coupling winding connected in series with the secondary of I.F. transformer T3. When the selectivity control is in the sharp position, the coupling winding is open circuited and the loose coupling which exists between the primary and secondary of this transformer results in high selectivity.

When the selectivity control is in the broad position, the coupling winding which is wound under the primary is connected in series with the secondary. This provides overcoupling which results in a greatly widened resonance curve. Passage of a wide range of audio frequencies is thus obtained.

A 6H6 tube functions as a diode 2nd detector. AVC voltage is applied to the control grid circuits of the 1st detector and I.F. tubes.

A 6F5 triode tube functions as the first audio amplifier while the output stage uses a 6F6 output pentode tube. A dynamic reproducer is employed.

The power unit uses a 5Y3G full wave rectifier. A 6G5 tuning indicator tube is employed.

Glass and Metal Tubes

All sets of this series use a 6H6 metal tube and 5Y3G and 6G5 glass tubes.

It will be noted in the schematic that there are two tube type numbers shown at the other sockets. The "metal" tube sets use the upper tube type numbers which are for metal tubes while the "glass" tube sets use the lower tube type numbers which are for glass tubes.

Re-alignment is necessary if glass tubes are replaced by their equivalent in metal tubes, or vice versa, in the R.F. and I.F. stages.

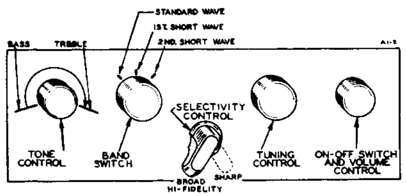

Fig. 1—Arrangement of Controls

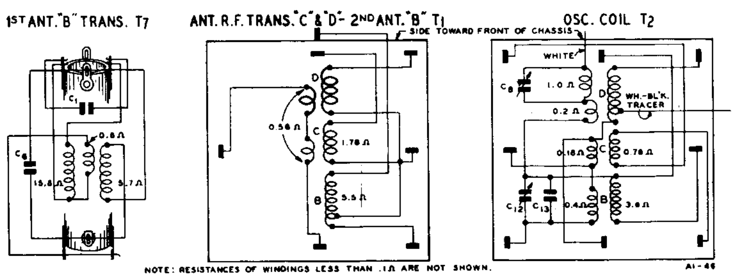

Fig. 7—Coil Terminal Arrangement and D.C. Resistance of Windings

Phonograph Connections

Phonograph connections are made as shown in the schematic circuit diagram Fig. 2. On the side panel of the chassis base is a round knockout 1⅛ inches in diameter. An octal base socket is mounted in this knockout opening and wired as shown in the schematic.

A phono cable assembly may then be purchased (see parts list). On one end of this cable is an octal plug and on the other end is a phonograph-radio switch and double tip jack.

Some models are shipped from the factory equipped with the phono socket. A jumper is inserted in this socket which must be removed if the phonograph installation is made—See Fig. 2.

Early Models—A few of the early models did not have the circular knockout for the phonograph socket as mentioned above. If a phonograph installation is to be made in connection with one of these early models, write the factory for detailed instructions.

117-234 Volt Power Transformers

Some models are equipped with a 117-234 volt 40 to 60 cycle power transformer. Connections as shown in Fig. 2 are completed to a special octal socket mounted on the back panel of the chassis. A plug which goes with this socket may then be inserted for either the 117 volt or 234 volt connection.

If one of these transformers is to be installed in a chassis equipped with a regular transformer, there is a 1⅛ inch round knockout on the back panel which may be removed to permit installation of the octal socket mentioned above.

Dial and Drive Assembly

Complete information regarding the dial and drive assemblies will be found in the Dial and Drive Service Manual issued for this chassis.

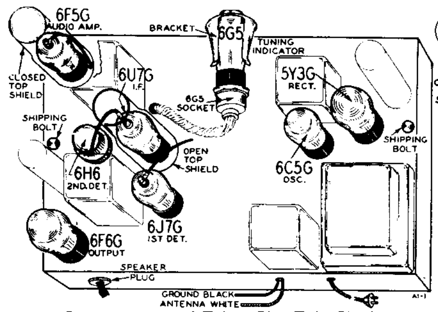

Fig. 4—Location of Tubes—Glass Tube Chassis

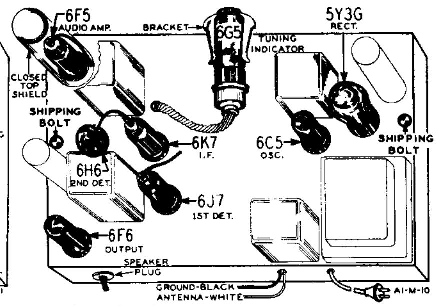

Fig. 6—Location of Tubes—Metal Tube Chassis

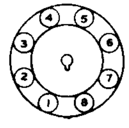

Fig. 5—Octal Tube Terminal Numbering (bottom of socket)

Twenty-five Cycle Models

The twenty-five cycle receiver differs from the sixty cycle receiver only in the fact that a different power transformer is used.

The twenty-five cycle receiver can be operated satisfactorily from a sixty cycle power supply. However, the reverse is not true, the sixty cycle receiver cannot be operated from a twenty-five cycle power supply.

VOLTAGES AT SOCKETS

Line Voltage: 117—Volume Control: Maximum
Readings taken with 1000 Ohm-per-volt meter.

WESTINGHOUSE ELECTRIC SUPPLY COMPANY
MODEL WR-211

GENERAL DESCRIPTION

This model is a six-tube, three-band superheterodyne receiver whose circuits employ all-metal tubes. The circuit employs a type 6A8 tube as a combined first detector-oscillator, a type 6K7 tube as an intermediate frequency amplifier, a type 6H6 tube as a second detector and automatic volume control, a type 6F5 tube as a first audio frequency amplifier, a type 6F6 as an output amplifier, and a type 5Y3 tube as a rectifier.

LINE-UP CAPACITOR ADJUSTMENTS

To align the circuits of this receiver it is essential to use a high grade modulated test oscillator, the output of which can be continuously varied with absence from overload, when the individual circuits of the receiver are brought into alignment. A conventional output meter should be connected across the terminals of the speaker voice coil to indicate when the circuits are aligned. The sensitivity of the output meter must be sufficient to give satisfactory reading with a low input signal.

Before attempting to align the receiver, the service man should familiarize himself with the general layout of the chassis, the location of the tubes and various alignment condensers. Top and bottom views of the chassis are shown in Figures #1 and #2 and should be carefully studied before the actual work is started.

ADJUSTMENT OF I.F. (465 KC.)

1. Set volume control to maximum position, the tone control to treble, the wave switch on broadcast and the dial indicator at approximately 600 KC.
2. Connect output meter across voice coil of speaker.
3. Set test oscillator to 465 KC., apply signal to grid of 6K7 I.F. tube through a 0.5 mfd. blocking condenser.
4. Adjust trimmers #25 and #26 to maximum output, reducing output of test oscillator as required.
5. Apply test signal to grid of 6A8 first detector-oscillator tube and adjust trimmers #21 and #22 to maximum output.
6. Apply test signal to antenna of receiver.
7. Adjust trap coil trimmer #5 to minimum output.

ADJUSTMENT OF BROADCAST BAND
(540 to 1550 KC.)

1. Set wave-change switch to standard broadcast band position.
2. Set test oscillator and dial indicator to 1400 KC.
3. Apply the test signal to the antenna of the receiver through a .0002 mfd. blocking condenser and adjust the oscillator trimmer condenser #14 until the signal is received.
4. Adjust the preselector trimmer #4 to maximum output.
5. Set the test oscillator and dial indicator to 600 KC., and adjust the oscillator series condenser #17 until the signal is received. Tune the variable condenser to a slightly lower frequency and readjust trimmer #17 to maximum output. If the sensitivity increases, continue this trial and error method in the same direction until no further improvement in sensitivity can be made.

If the sensitivity decreases, try this adjustment at slightly higher frequencies.

ADJUSTMENT OF GREEN BAND

1. Set the wave-change switch to the green band position.
2. Set the test oscillator and dial indicator to 4000 KC., and adjust the oscillator trimmer condenser #13 until the signal is tuned in.
3. Adjust the preselector trimmer condenser #3 to maximum output.
4. Check the sensitivity and calibration over scale.

ADJUSTMENT OF RED BAND

1. Set the wave-change switch to the red band position.
2. Set the test oscillator and dial indicator to 15000 KC., and adjust the oscillator trimmer condenser #12 until the signal is received. Two positions may be found at which the signal may be tuned in. Use the position with the lower capacity trimmer setting or with the alignment screw turned farther out.
3. Adjust the preselector trimmer #2 to maximum output.
4. Check the receiver over scale for calibration and sensitivity.

Power Consumption	47 Watts
Maximum Output	3 Watts
Maximum Undistorted Output	2.4 Watts
Tuning Ranges	(White Band - 540 to 1550 KC.
	(Green Band - 1500 to 4500 KC.
	(Red Band - - 5500 to 15500 KC.
Line-Up Frequencies	I.F. 465 KC., 1400 KC., 600 KC., 4000 KC.

ALIGNMENT PROCEDURE

I. F. Alignment. Connect a signal generator set at 456kc to the 6A7 input and connect an output meter to the speaker output. Using a weak signal tune the two I. F. condensers on the first I. F. coil and the two I. F. condensers on the output I. F. coil for maximum response.

R. F. Alignment. Connect the signal generator set at 1400kc to the antenna lead using a dummy antenna of 200mmf. Tune the set by means of the dial to 1400kc position. Adjust oscillator trimmer for this frequency. Pad at 600kc. Recheck 1400kc and trim antenna stage for maximum response. Repeating the alignment may result in improved sensitivity.

ALIGNMENT PROCEDURE

I. F. Alignment. Connect a signal generator set at 456 kc to the 6A7 grid. Connect an output meter across the secondary terminals of the speaker output transformer. With the weakest signal from the generator necessary to obtain .5 volt deflection on the output meter, peak the two trimmers on the first I. F. transformer and the single trimmer on the second I. F. transformer. This second I. F. transformer is located on the under side of the chassis.

R. F. Alignment. Insert a 200mmfd condenser in series with the antenna lead of the receiver and the signal generator. Set the receiver dial to 1400kc and the signal generator to the same frequency. Again with the weakest signal necessary to obtain .5 volt deflection of the output meter, adjust the terminals on both sections of the variable condenser. It is the utmost importance in making these various adjustments that the signal level be attenuated as far as possible in order to overcome the AVC action which would otherwise introduce serious errors and prevent obtaining optimum results.

ALIGNMENT PROCEDURE

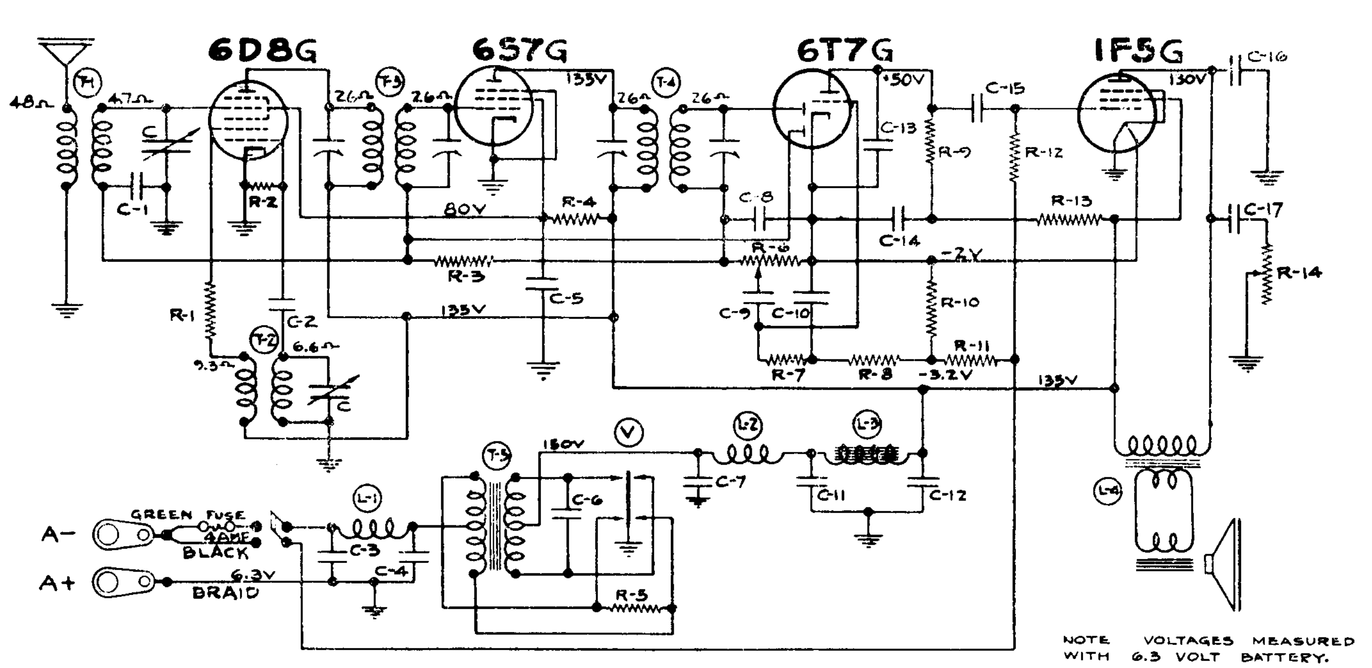
I. F. Alignment. Connect a signal generator set at 456 kc to the 6A7 grid. Connect an output meter across the secondary terminals of the speaker output transformer. With the weakest signal from the generator necessary to obtain .5 volt deflection on the output meter, peak the trimmers on both I. F. transformers.

R. F. Alignment. Insert a 200mmfd condenser in series with the antenna lead of the receiver and the signal generator. Set the receiver dial to 1400kc and the signal generator to the same frequency. Again with the weakest signal necessary to obtain 1 volt deflection of the output meter, adjust the trimmers on the oscillator, antenna and interstage sections of the variable condenser. Tune the receiver to 600kc and set the signal generator to this frequency. Adjust the padder condenser for maximum signal response to minimum signal input. Repeat the high frequency alignment.

It is of the utmost importance in making these various adjustments that the signal level be attenuated as far as possible in order to overcome the AVC action which would otherwise introduce serious errors and prevent obtaining optimum results.

BELMONT RADIO CORPORATION

MODEL 415-SERIES B "SERIAL No 7B542,500 UP"



NOTE VOLTAGES MEASURED WITH 6.3 VOLT BATTERY. ALL VOLTAGES TAKEN FROM GROUND WITH 1000Ω PER VOLT METER. * MEASURED WITH 0-300V SCALE.

112-147	Tuning Shaft Including 117-86 Pulley	.10
112-199	Dial Drum Including 117-84 Bushing and Set Screw	.20
120-7B	Take-Up Coil Spring	.03
120-9	Black Irish Linen String	.05
112-171	Dial Scale	.40
131-43	Cinch Buttons for Fastening Scale	.03
112-151	Dial Pointer with 132-19 Screw	.05
112-143	Oval Escutcheon Complete with Crystal	.85

Vibrators can be reconditioned at a cost of $3.00 each list, if the old unit is returned.

All resistors are RMA color coded—specify value and/or resistor number (per schematic diagram) and model number.

When ordering condensers, specify part number, model number and/or capacitor (per schematic diagram) and model number.

Mica condensers are coded with an additional dot indicating tolerance:

Tolerance Percent	Color of Dot
2½%	White
5%	Green
10%	Blue
15%	Yellow
20%	Red
More Than 20%	None.

All prices quoted are list and are subject to the usual trade discounts. Shipments are F.O.B. our Factory. When remitting in advance, please include postage.

WE CANNOT SUPPLY SPEAKER PARTS, CONES, TRANSFORMERS OR FIELDS SEPARATELY. WE CAN REPLACE OR REPAIR A DAMAGED SPEAKER FOR $2.00 NET, IF IT IS RETURNED TO OUR FACTORY TRANSPORTATION CHARGES PREPAID.

PRICES SUBJECT TO CHANGE WITHOUT NOTICE.

BELMONT RADIO CORPORATION

MODEL 415-SERIES B "SERIAL № 7B542,500 UP"

Frequency Range 535-1720 Kilocycles
I. F. Frequency 465 K. C.

BATTERY CONNECTIONS:

Referring to Fig. 1, Page 2, of this manual, connect the battery cable to the storage battery in the following manner:

(a) **The storage battery should be located as far from the receiver as the battery cable will permit.**

(b) **Connect the lead (containing the fuse receptacle) marked A negative (—) to the negative (—) post of the storage battery.**

(c) **Connect the lead marked A positive (+) to the positive (+) post of the storage battery.**

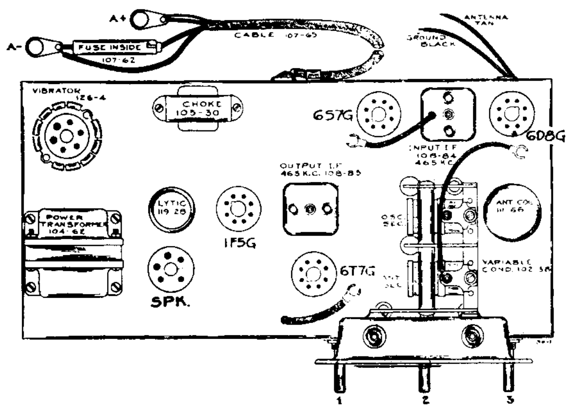

FIG. 1—TOP VIEW

STORAGE "A" BATTERY:

The storage "A" battery, you will notice that when it is new, **does not have its full rated life—this is characteristic of new storage batteries. They reach their maximum capacity after being charged and discharged several times in service. The proper care of a storage battery will enable you to receive several years of good service. Neglect will ruin it very quickly. Check frequently to see that the water level is about one-half inch above the plates. Add only pure distilled water, as often as needed. A little too much water will do no harm. Too little is very harmful to the battery.**

Do not let the battery become completely discharged, but if it should, have it charged again as soon as possible. A battery can be ruined very quickly by permitting it to lie around unused in a fully discharged condition.

Keep the top of the battery clean and dry and grease the terminals occasionally with a little vaseline.

Service Data

DESCRIPTION:

TUBES:

The tube complement of this chassis consists of the following octal base glass tubes which are interchangeable with metal tubes.

The type and function of each tube is as follows:

1—Type 6D8G Pentagrid Mixer, First Detector-oscillator.
1—Type 6S7G Remote Cut-off Pentode I. F. Amplifier (465 K.C.)
1—Type 6T7G Duplex Diode Triode, Second Detector, A.V.C. and First Audio.
1—Type 1F5G Pentode Output Amplifier.

SERVICE NOTES:

Voltages taken from different points of circuit to chassis are measured with volume control full on, all tubes in their sockets and speaker connected, with a volt meter having a resistance of 1000 ohms per volt. These voltages are clearly indicated on the circuit diagram.

In order to prevent signal from acting upon A.V.C. and affecting accuracy of voltage measurements, aerial and ground leads should be short circuited while making measurements.

All voltages are to be measured with 6.3 volts input to receiver. Resistances of coils and transformer windings are indicated in ohms on schematic circuit diagram.

To check for open by-pass condensers, shunt each condenser with another condenser of the same capacity and voltage rating, which is known to be good, until the defective unit is located.

Failure to operate, noisy or weak reception is usually due to defective tubes, the tubes making poor contact with sockets or grid clips making poor contact with the caps of the tubes. Tubes may be checked very easily by replacing with other tubes which are known to be good. If fuse blows out frequently and insulating sleeve has been properly placed over fuse, the trouble is probably in the vibrator, it should be replaced. Do not attempt to make any adjustments on the vibrators.

GROUND:

To obtain the best performance (freedom from radiated noise), a ground **must** be used.

ALIGNING INSTRUCTIONS:

CAUTION—No aligning adjustments should be attempted without first thoroughly checking over all other possible causes of trouble, such as poor installations, open or grounded antenna systems, low storage battery, defective tubes, condensers and resistors. In order to properly align this chassis, an oscillator (generator) is absolutely necessary. No aligning adjustments should be attempted with the chassis in the cabinet. Remove the knobs and the four bolts which are used to fasten the chassis.

All adjustments should be made with a non-metallic screw driver.

RESONANCE INDICATOR:

Use as a resonance indicator an output meter connected across the primary of the speaker input transformer, or by means of an adapter between the plate and screen terminals of the type 1F5G output tube. Maximum deflection of the meter indicates resonance. Use only enough signal to get a readily readable output. A low range output meter or the low scale of a multi-range meter should be used.

ALIGNING I.F. TRANSFORMERS: (465 K. C.):

Part No. 108-85 Output I.F. Transformer.
Part No. 108-84 Input I.F. Transformer.

These I.F. Transformers have two adjustments, both of which are accessible from the top of chassis (see fig. 1, top view page 2).

1. With volume control full on (the extreme right of its rotation), and with the variable condenser set to approximately 1400 kilocycles, make the following adjustments.

   (a) Connect external oscillator set at 465 kilocycles, in series with .1 mfd. condenser, to the control grid cap of the type 6S7G tube, and adjust the output I.F. transformer (No. 108-85) to resonance.

   (b) Move oscillator output clip from grid of 6S7G to grid cap of 6D8G and adjust input I.F. transformer (No. 108-84) to resonance.

   (c) With oscillator still connected to 6D8G readjust output I.F. transformer (108-85) if necessary.

R. F. ALIGNMENT: (535-1720 K.C.)

1. With gang condenser in its minimum capacity position, plates entirely out of mesh, connect an external oscillator in series with a 200 mmf. condenser to tan antenna and black ground leads and make the following adjustments:

   (a) With external oscillator set at 1720 kilocycles, adjust oscillator trimmer (rear of gang condenser).

   (b) Re-set external oscillator to 1400 kilocycles, rotate condenser, pick-up oscillator signal and adjust antenna trimmer to resonance (front section of gang condenser).

   (c) Check sensitivity at 600 and 1000 kilocycles.

BELMONT RADIO CORPORATION

MODEL 588-SERIES A "SERIAL No 7D569,700 UP"

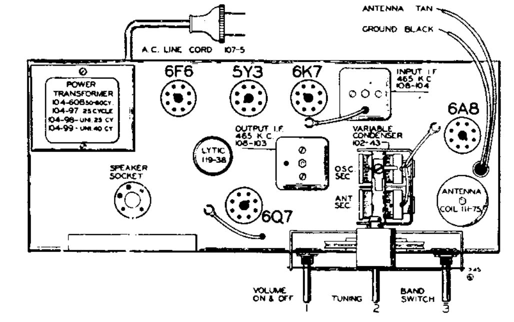
BAND	DIAL SCALE	FREQUENCY RANGE
Broadcast	Upper	535 to 1720 K.C. (Kilocycles)
Short Wave	Lower	2000 to 7000 K.C. (Kilocycles)

I.F. Frequency 465 K.C.

POWER SUPPLY:

Caution:—This radio, unless otherwise marked, must be operated from 105-115 volts, 60 cycle A.C. supply only. If you are in doubt as to the voltage and frequency rating of the power supply, consult your local power company before inserting plug. Do not insert plug unless all tubes and speaker plug are in their proper sockets.

Receivers of this model which are to be used on voltages or frequencies other than 105-115 volts, 60 cycles are so marked. The power consumption of this receiver is 55 watts.



Vol. Control On-Off Switch | Tuning Control | Band Switch

FIG. 1—TOP VIEW

Service Data

DESCRIPTION:
The tube complement of this chassis consists of the following octal base glass tubes which are interchangeable with metal tubes:
1—Type 6A8G Pentagrid mixer, first detector-oscillator.
1—Type 6K7G Remote cut-off pentode I.F. amplifier (465 K.C.)
1—Type 6Q7G duplex diode triode second detector, A.V.C. and audio.
1—Type 6F6G—pentode output amplifier.
1—Type 5Y3G or 5W4—high vacuum rectifier.

Transformers are available and chassis are sometimes equipped with universal transformers for operation on 25, 40 and 60 cycles and with primary taps for 108, 127, 150, 225, and 260 volts, (see instructions) and also sometimes equipped with 25 cycle transformers with 105-115 volt or 220 volt primaries, no universals.

SERVICE NOTES:
Voltages taken from different points of circuit to chassis are measured with volume control full on, all tubes in their sockets and speaker connected, with a volt meter having a resistance of 1000 ohms per volt. These voltages are clearly indicated on the circuit diagram.

IN ORDER TO PREVENT SIGNAL FROM ACTING UPON AVC AND AFFECTING ACCURACY OF VOLTAGE MEASUREMENTS, AERIAL AND GROUND LEADS SHOULD BE SHORT CIRCUITED WHILE MAKING MEASUREMENTS.

All voltages are to be measured with 115 volts on the primary of the power transformer.

Resistances of coils and transformer windings are indicated in ohms on schematic circuit diagrams.

To check for open by-pass condensers, shunt each condenser with another condenser of the same capacity and voltage rating, which is known to be good, until the defective unit is located.

Excessive hum, stuttering, low volume and a reduction in all D.C. voltages is usually caused by a shorted electrolytic condenser, open by-pass condensers frequently cause oscillation and distorted tone.

ALIGNING INSTRUCTIONS:
CAUTION: No aligning adjustments should be attempted without first thoroughly checking over all other possible causes of trouble, such as defective tubes, poor installations, open or grounded antenna systems, defective condensers and resistors.

In order to properly align this chassis, an oscillator (generator) is necessary.

All adjustments should be made with a non-metallic screw driver.

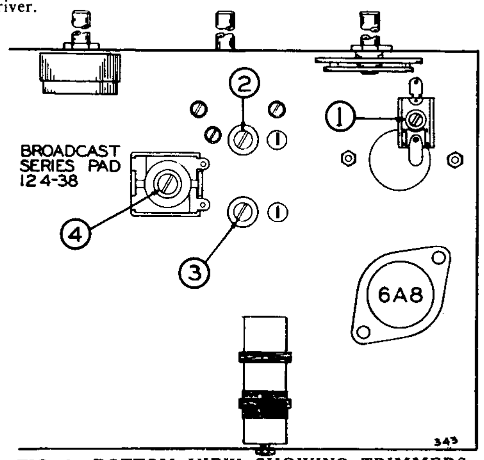


FIG. 3.—BOTTOM VIEW SHOWING TRIMMERS

RESONANCE INDICATOR:
Use as a resonance indicator an output meter connected across the primary of the speaker input transformer or by means of an adapter between the plate and screen terminals of the type 6F6G output tube. Maximum deflection of the meter indicates resonance. Use only enough signal to get a readily readable output. A low range output meter or the low scale of a multi-range meter should be used.

DUMMY ANTENNAS:
The following dummy antennas are used in aligning and are referred to in the following alignment instructions as "Dummy 1", "Dummy 2", and "Dummy 3".

Dummy 1: (I.F.)—Consists of a .1 mfd. condenser connected in series with the external oscillator.

Dummy 2: (Broadcast)—Consists of a 200 mmfd. condenser and a 20 ohm resistor connected in series with each other and in series with the external oscillator.

Dummy 3: (Short Wave)—Consists of a .1 mfd. condenser and a 400 ohm resistor connected in series with each other and in series with the external oscillator.

ALIGNING I.F. TRANSFORMERS: (465 K.C.):

Part No. 108-103 Output I.F. Transformer
Part No. 108-104 Input I.F. Transformer

These I.F. transformers have two adjustments, both of which are accessible from the top of chassis (see top view).

1. With volume control full on, (the extreme right of its rotation), the band changing switch in the broadcast position, (extreme left of its rotation), and with the variable condenser in its minimum capacity position, plates entirely out of mesh, make the following adjustments:
   (a) Connect external oscillator set at 465 kilocycles, in series with "Dummy 1", to the control grid cap of the type 6K7G tube, and adjust the output I.F. transformer (No. 108-103) to resonance.
   (b) With "Dummy 1" still connected, move oscillator output clip from grid of 6K7G to grid cap of 6A8G and adjust input I.F. transformer (No. 108-104) to resonance.

SHORT WAVE BAND ALIGNMENT:

2000 to 7000 Kilocycles

1. With band changing switch in the short wave position, extreme right of its rotation, and with external oscillator set at 6 megacycles and connected in series with "Dummy 3" to the antenna and ground leads, make the following adjustments:
   (a) Move dial pointer to 6 megacycles and adjust short wave oscillator trimmer to resonance.
   This adjustment is the trimmer mounted on the top of rear section of the variable gang condenser (see Fig. 1, top view).
   (b) Adjust short wave antenna trimmer (Adjustment Number 1), to resonance (see Fig. 3, bottom view).

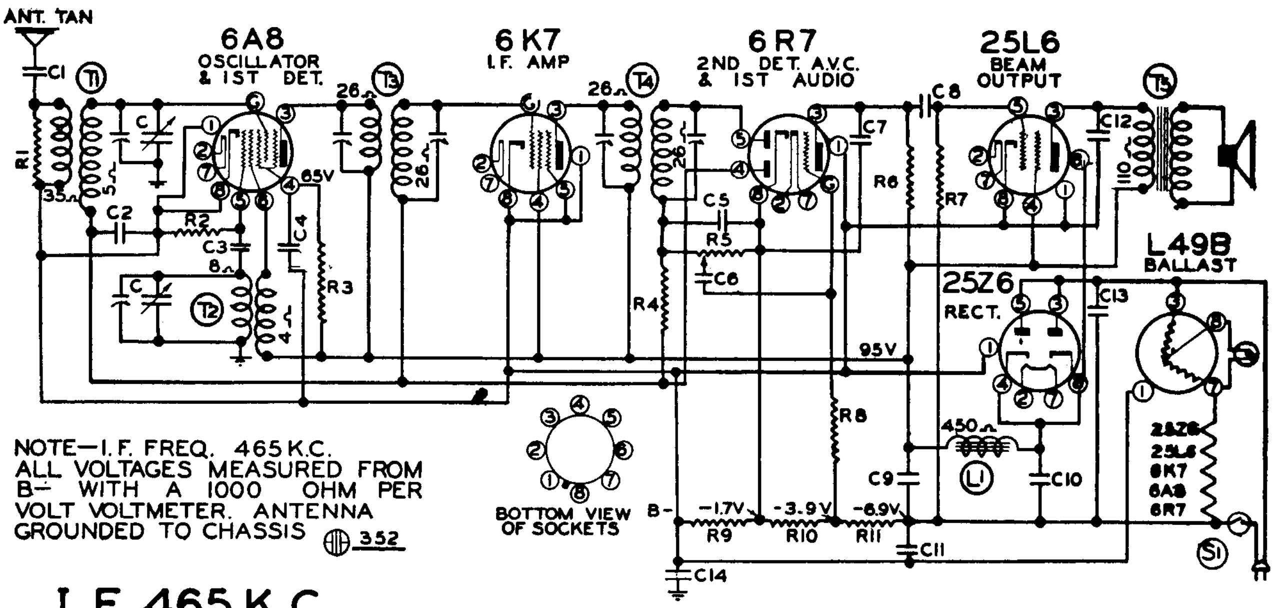
BROADCAST BAND ALIGNMENT:

535 to 1720 Kilocycles

1. With band changing switch in the broadcast position, extreme left of its rotation, and with gang condenser in its minimum capacity position, plates entirely out of mesh, and with external oscillator connected in series with "Dummy 2" to antenna and ground leads make following adjustments:
   (a) Set external oscillator to 1720 K.C. and adjust broadcast oscillator trimmer to resonance. (Adjustment number 3, see bottom view of chassis, Fig. 3).
   (b) Re-set external oscillator to 1400 K.C., rotate variable gang condenser and pick up signal. Adjust broadcast antenna trimmer (adjustment number 2), to resonance.
   (c) Re-set external oscillator to 600 K.C., and adjust broadcast series pad (adjustment number 4), to resonance by rotating condenser to approximately 600 K.C., rocking it slowly to and fro until by adjusting series pad maximum output is attained. This adjustment is located on the bottom of the chassis directly under the variable gang condenser. (See bottom view of chassis, Fig. 3).
   (d) Repeat adjustments "a" and "b" until sensitivity is at its maximum.
   (e) Check for tracking and sensitivity at 1400, 1000, and 600 kilocycles. **Under no circumstances bend plates of variable condenser sections to correct tracking.**

BELMONT RADIO CORPORATION

MODEL 602 "SERIAL Nº 7D600,100 UP"



I. F. 465 K.C.

Frequency Range 535-1720 Kilocycles

112-160B	Pointer with 132-19 Pointer Screw	.05
131-43	Cinch Button for Fastening Dial Scale	.01
112-257	Celluloid Crystal for Dial	.25
107-106	Pilot Light Socket and Bracket	.10
107-107	Shield for Pilot Light	.01
107-97	6-8 volt T51 Pilot Light (Bayonet Base)	.10

Tubes are coded and guaranteed by the tube manufacturer.

Prompter service can be rendered on adjustments if defective tubes are returned direct to the tube manufacturer rather than through our factory.

All resistors are RMA color coded—specify value and/or resistor number (per schematic diagram) and model number.

When ordering condensers, specify part number, model number and/or capacitor (per schematic diagram) and model number.

Mica condensers are coded with an additional dot indicating tolerance:

Tolerance percent	Color of Dot
2½%	White
5%	Green
10%	Blue
15%	Yellow
20%	Red
More Than 20%	None

All prices quoted are list and are subject to the usual trade discounts.

Shipments are F.O.B. our Factory. When remitting in advance, please include postage.

WE CANNOT SUPPLY SPEAKER PARTS, CONES, TRANSFORMERS, OR FIELDS SEPARATELY. WE CAN REPLACE OR REPAIR A DAMAGED SPEAKER FOR $1.25 NET, IF IT IS RETURNED TO OUR FACTORY, TRANSPORTATION CHARGES PREPAID.

PRICES SUBJECT TO CHANGE WITHOUT NOTICE.

BELMONT RADIO CORPORATION

MODEL 602 "SERIAL No 7D600,100 UP"

POWER SUPPLY:

Caution:—This radio, unless otherwise marked, must be operated from 105-125 volts, A.C. or D.C. supply only. If you are in doubt as to the voltage rating of the power supply, consult your local power company before inserting plug. Do not insert plug unless all tubes and speaker plug are in their proper sockets.

Receivers of this model which are to be used on voltages other than 105-125 volts, are so marked. The power consumption of this receiver is 40 watts.

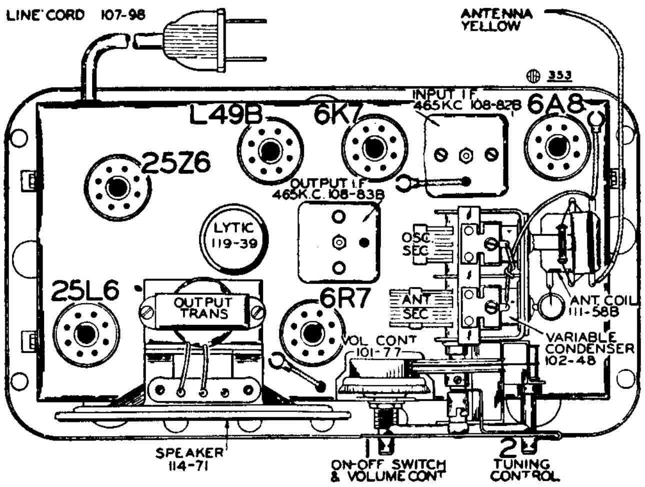

FIG. 1—TOP VIEW

SERVICE DATA

DESCRIPTION:

The tube complement of this chassis consists of the following octal base glass tubes which are interchangeable with metal tubes:

The type and function of each tube is as follows:

1—Type 6A8G Pentagrid Mixer, First Detector-oscillator.
1—Type 6K7G Remote Cut-Off Pentode, I.F. Amplifier (465 K.C.)
1—Type 6R7G Duplex Diode Triode Second Detector, A.V.C. and First Audio.
1—Type 25L6G Beam Output Amplifier.
1—Type 25Z6G High Vacuum Rectifier.
1—Type L49B Ballast Tube.

SERVICE NOTES:

Voltages taken from different points of circuit to chassis are measured with volume control full on, all tubes in their sockets and speaker connected, with a volt meter having a resistance of 1000 ohms per volt.

All voltages as indicated on diagram are measured with 119 volt A.C. or D.C. line.

Resistances of coil windings are indicated in ohms on the schematic circuit diagram.

To check for open by-pass condensers, shunt each condenser with another condenser of the same capacity and voltage rating, which is known to be good, until the defective unit is located.

Excessive hum, stuttering, low volume and a reduction in all D.C. voltages is usually caused by a shorted electrolytic condenser; open by-pass condensers frequently cause oscillation and distorted tone.

ALIGNING INSTRUCTIONS:

CAUTION:—No aligning adjustments should be attempted without first thoroughly checking over all other possible causes of trouble, such as poor installations, open or grounded antenna systems, low line voltages, defective tubes, condensers and resistors. In order to properly align this chassis, an oscillator (generator) is absolutely necessary. No aligning adjustments should be attempted with the chassis in the cabinet.

All adjustments should be made with a non-metallic screw driver.

RESONANCE INDICATOR:

Use as a resonance indicator an output meter connected across the primary of the speaker input transformer or by means of an adapter between the plate and screen terminals of the type 25L6G output tube. Maximum deflection of the meter indicates resonance. Use only enough signal to get a readily readable output. A low range output meter or the low scale of a multi-range meter should be used.

ALIGNING I.F. TRANSFORMERS: (465 K.C.):

Part No. 108-83B Output I.F. Transformer
Part No. 108-82B Input I.F. Transformer

These I.F. transformers have two adjustments, both of which are accessible from the top of chassis (see Fig. 1).

1. With volume control full on (the extreme right of its rotation), and with the variable condenser set to approximately 1400 kilocycles, make the following adjustments:
   (a) Connect external oscillator set at 465 kilocycles, in series with .1 mfd. condenser, to the control grid cap of the type 6K7G tube, and adjust the output I.F. transformer (No. 108-83B) to resonance.
   (b) Move oscillator output clip from grid of 6K7G to grid of 6A8G and adjust input I.F. transformer (No. 108-82B) to resonance.
   (c) With oscillator still connected to 6A8G, readjust output I.F. transformer (108-83B) if necessary.

R.F. ALIGNMENT: (535-1720 K.C.)

1. With gang condenser in its minimum capacity position, plates entirely out of mesh, connect an external oscillator in series with a 200 mmf. condenser to the antenna lead and chassis ground and make the following adjustments:
   (a) With external oscillator set at 1720 kilocycles, adjust oscillator trimmer to resonance. This adjustment is on the top of rear section of variable gang condenser. (See Fig. 1).
   (b) Re-set external oscillator to 1400 kilocycles, rotate condenser, pick up oscillator signal and adjust antenna trimmer to resonance. (Top of front section of gang condenser).
   (c) Check sensitivity at 600 and 1000 kilocycles.

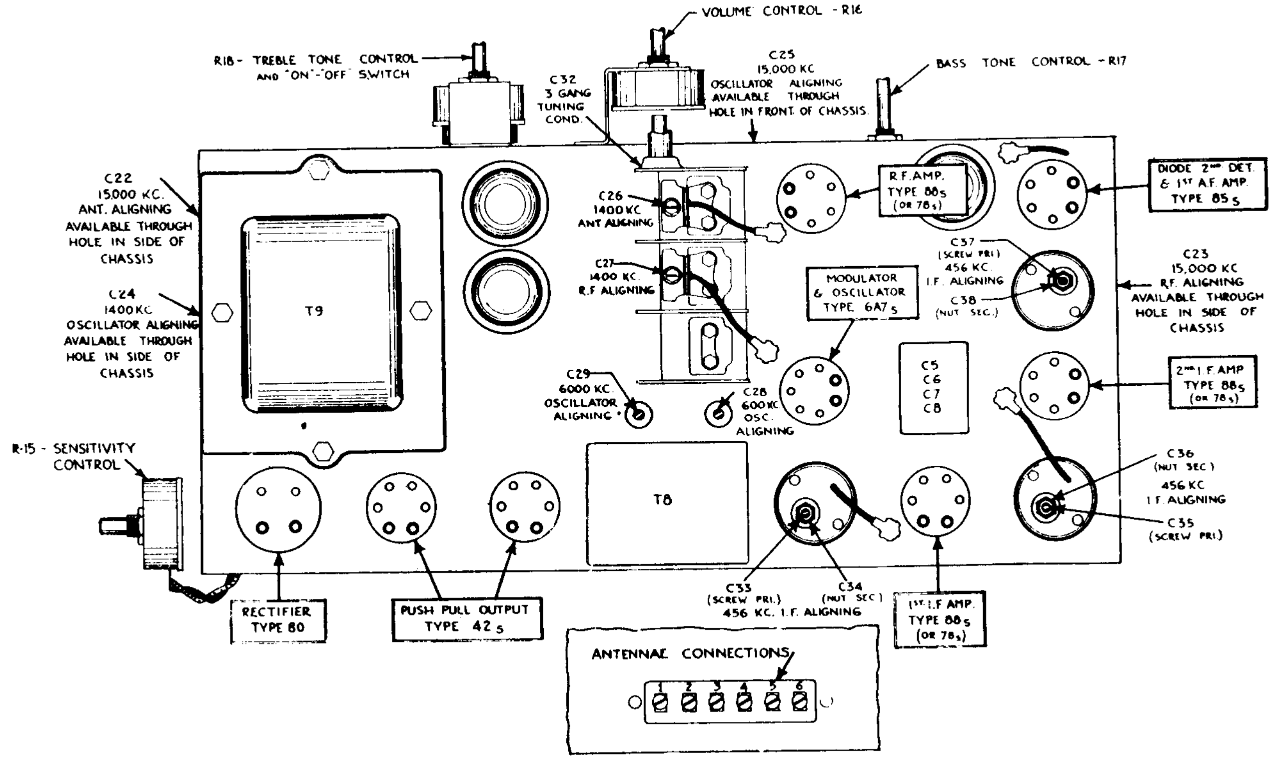
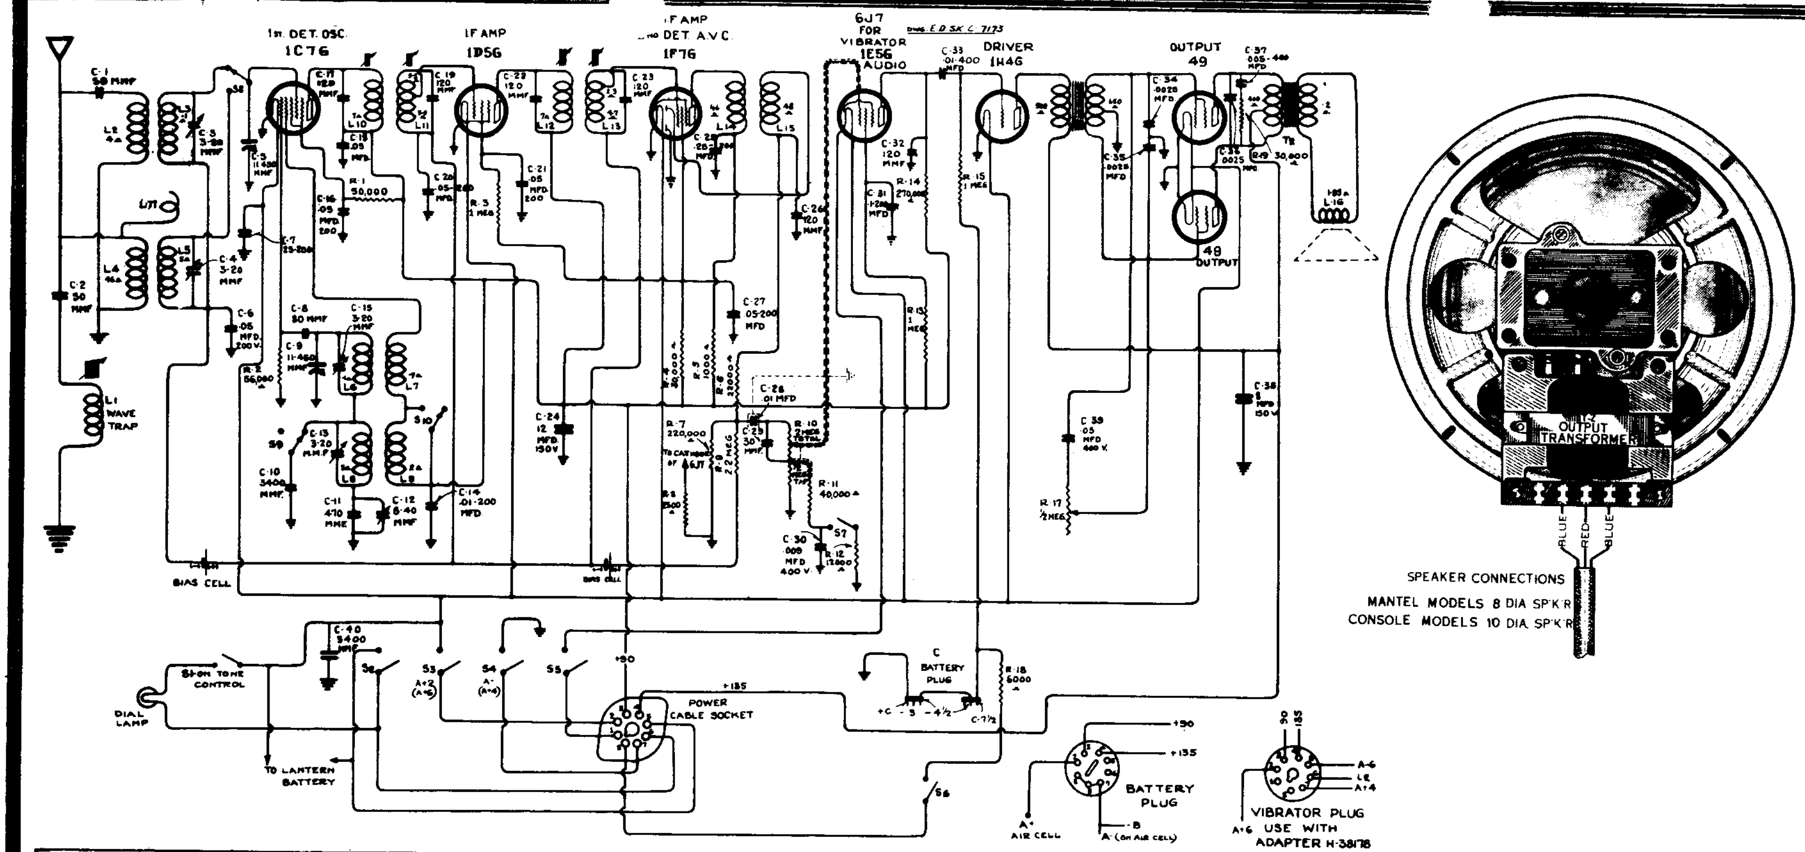
VOLTAGES SHOWN ARE APPROX. READINGS THAT SHOULD BE OBTAINED BETWEEN POINTS WHERE VOLTAGE IS INDICATED AND GROUND (CHASSIS), UNLESS SHOWN OTHERWISE. VOLTAGES ARE MEASURED WITH A 1000 OHMS PER. VOLT VOLTMETER USING 250 VOLT RANGE.
VOLTAGES MARKED * CHANGE WITH SETTING OF SENSITIVITY CONTROL.
VOLTAGES ARE MEASURED WITH SENSITIVITY CONTROL AT MAX.



Note: In late releases C27 is located on band switch in chassis.

CANADIAN WESTINGHOUSE COMPANY Limited

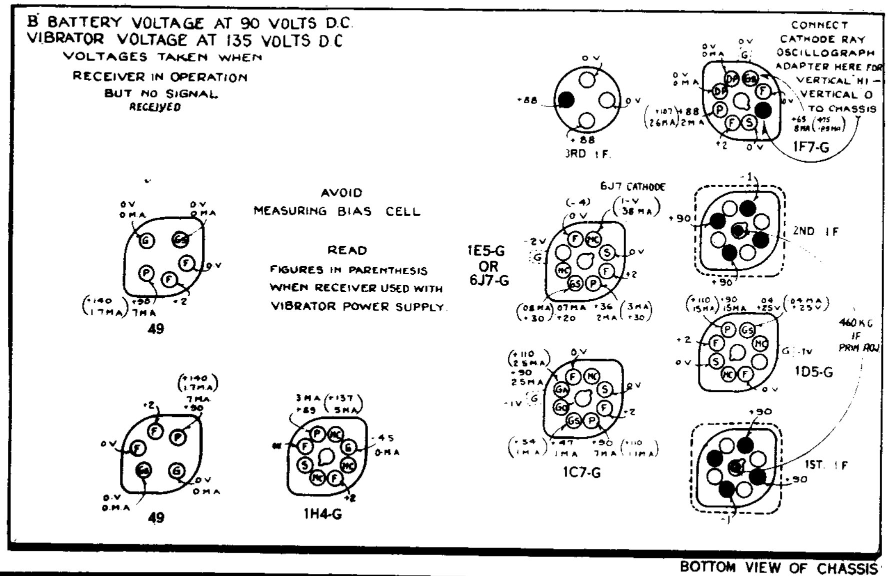
MODELS B-725A & B-725X



Note 1—In many cases the voltage rating of condensers follows the capacity rating (mfd.)

Note 2—On a few of the first chassis built R1 was 82,000 ohms not 50,000 as shown. The lower valve should be installed if oscillation failure occurs when the W-1C7G is replaced.

Note 3—Range Selector Switch is shown above in the S.W. position.



Socket Meter Readings

Caution — Do not attempt to measure voltages on the control grids of the W-1D5G or W-1F7G with any conventional voltmeter as paralysis of the "C-bias" cell will result.

Check "C" cell by noting whether plate current is abnormally high on tubes biased by cells.

A further check on the C bias cell, particularly if it is suspected that the control grid leads have been grounded, is to connect a 3 volt C battery between the control grid cap of the W-1C7G and the chassis frame. The negative of the C battery should be connected to control grid, positive to chassis frame. This connection should be momentarily made only, and if the C cell had been weakened before, it will now be found to be recharged and ordinarily will not need to be replaced.

All voltages are operating voltages with respect to chassis frame, with all batteries at normal voltage—tuned to approximately 1000 K.C.—no signal being received. Due allowance must be made for current drawn by the meter used.

MODELS B-725A & B-725X

SERVICE DATA

"A" Battery—1-2½ volt Air-cell Eveready A-600 (or equivalent) or 1-2.0 volt storage battery.

"B" Battery—2 (or 3) 45 volt, heavy duty plug-in type.

"C" Battery—(Audio)—1 (or 2) 4½ volt plug-in type such as Eveready 771 or Burgess 536.

Pilot Lamp Battery—Eveready 409 or Burgess 1042.

Battery Current—"A"—600 milliamperes; "B" 10 milliamperes. (Average at 90 volts.)

Cabinet Dimensions—B-725A, 11" x 22¾" x 9"; B-725X, 39¾" x 22" x 11½".

Shipping Weight—B-725A, 37 lbs.; B-725X, 67 lbs.

Controls—(1) Off-Speech-Music Switch, (2) Treble Tone Control and Dial Light Switch, (3) Station Selector, (4) Range Selector Switch, (5) Volume Control.

Station Selector Drive Ratio .... 90:1 and 18:1

Number and types of radiotrons—(1)-W-1C7G; (1)-W-1D5G; (1)-W-1F7G; (1)-W-E5G; (1)-W-1H4G; (2)-W-49. Total 7.

Pilot Lamps (2)—Mazda No. 40, 6.3 V., 0.15 Amp.

Undistorted output .... 0.2 Watt

Frequency range .... 530 K.C. to 1720 K.C., and 5.5 M.C. to 18.0 M.C.

These receivers are 7 tube superheterodynes incorporating such features as wide broadcast range, the more popular short wave bands, Alnico dynamic speaker, "iron core" I.F. transformers, bass and treble tone controls, automatic volume control, "Cell" type "C" bias, unexcelled battery economy, plug-in batteries, compensated manual volume control, class B output circuit, dust-proof loudspeaker, wave trap and the inherent sensitivity, selectivity and tone quality of the superheterodyne circuit.

The following description of the circuit includes several new design features which are incorporated in this receiver. The first tube (Radiotron W-1C7G) is used as a combined first detector and oscillator. Separate coil assemblies are provided for each function. The antenna, or first detector coil assembly, has two primary coils. Both of these coils are connected in parallel to the antenna at all times. The short wave primary coil has a small condenser in series with it to prevent it absorbing energy at broadcast frequencies. Pole S-8 of the range selector switch selects either of two antenna secondary windings, depending on whether short wave or broadcast range reception is required. Separate trimmers are provided for each coil for adjustment at the high frequency ends of their respective ranges. As the two frequency ranges are so widely separated, there is no necessity to have the range switch short-circuit unused coils to prevent absorption of energy by resonance.

The oscillator plate and grid coils are wound in two sections. Each section of the grid coil has its own high frequency trimmer. There is also a low frequency trimmer for the broadcast range. In the short wave position pole S-10 short-circuits the broadcast portion of the oscillator plate coil, and pole S-2, practically speaking, short-circuits the broadcast grid coil through C-13, which then functions as the oscillator fixed series padding condenser.

The second tube (Radiotron W-1D5G) is an I.F. amplifier. The third tube (Radiotron W-1F7G) is an I.F. amplifier with one diode plate acting as second detector and automatic volume control.

It will be noted that the first two I.F. transformers are of the "Iron-core" type and the third is a non-adjustable "air-core" transformer. The control grids of the I.F. amplifier radiotrons are not connected to the "high" ends of the I.F. transformer secondary windings, but are connected to taps on their respective windings. This arrangement gives the maximum permissible selectivity without excessive I.F. amplification which would result in high background noise level.

The rectified D.C. voltage developed across the diode load resistor (R-7) is applied as A.V.C. voltage through a resistor (R-9) to the control grids of the first detector and both I.F. radiotrons. Two bias cells are also used to give a residual bias of 1.0 volt to the I.F. radiotrons and 2.0 volts to the first detector.

The audio frequency voltage appearing across the diode load resistor of the W-1F7G Radiotron is coupled to an acoustically tapered and compensated volume control. The moving tap of the volume control is connected to the control grid of the W-1E5G first audio amplifier Radiotron, which is in turn resistance-capacitance coupled to a W-1H4G driver Radiotron.

The output of the driver stage is transformer-coupled to the Class B, push-pull output stage which uses two W-49 Radiotrons.

The treble tone control consists of a variable resistance in series with a fixed capacity connected across the secondary of the driver transformer.

The amount of bass response is controlled by the speech-music switch S7. When this switch-pole S7 is closed, the amount of compensation on the volume control is decreased—thus reducing the bass response at low and moderate volume.

Use With Vibrator "B" Supply

These receivers may be used with Westinghouse Style No. H-36133 vibrator "B" supply if a 6.0 volt storage battery is available. The necessary changes are very simple. Follow the instructions given with the vibrator "B" supply, noting also the following points:

The W-1E5G tube must be removed and a W-6J7G radiotron substituted. No Pilot Lamp Battery is required.

Refer to schematic circuit diagram in this leaflet and note the internal connection of the vibrator plug. When vibrator H-36133 is used it is necessary to connect together pins No. 1 and No. 5, on the diagram. This may be done by dissembling the vibrator plug and soldering a jumper in place. It will be more convenient, however, to use a special adapter, Style No. H-38178. (See parts list.)

ALIGNMENT PROCEDURE

There are various alignment trimmers provided in the antenna transformer and oscillator coil tuned circuits. One adjustment is also provided for the wave trap. The i-f transformer adjustments are made by means of screws attached to molded magnetite cores. All of these circuits have been accurately adjusted during manufacture and should remain properly aligned unless affected by abnormal conditions or altered during servicing. Loss of sensitivity, improper tone quality, and poor selectivity are the usual indications of improper alignment.

The correct performance of this receiver can only be obtained when the aligning has been done with adequate and reliable apparatus. It is not necessary to use a frequency modulated oscillator and cathode ray oscillograph to align this receiver. Those service men that have this equipment will probably prefer to use it and for their convenience we have indicated on the socket voltage diagram the proper connection point for the cathode ray vertical amplifier input terminal.

By using the Cathode Ray Adapter shown in the Replacement Parts List the cathode ray connections may be made without removing or opening the chassis.

A test oscillator is required as a source of the specified alignment frequencies. Visual indication of receiver output during the adjustment is necessary and should be accomplished by the use of an indicator or meter.

The procedure outlined below should be followed in adjusting the various trimmer capacitors and molded cores:

Calibrate the tuning dial by adjusting pointer to the low frequency end of scale with gang condenser plates fully meshed. The pointer should be horizontal with its painted section resting at the end of the vertical index line. This is a friction adjustment. At the same time set the vernier dial scale (this is secured by two set screws) to read "o".

Perform alignment in proper order as shown by the accompanying chart, starting with No. 1, and following all operations across, then No. 2, etc. The chassis bottom shield must be securely in place when making R.F. adjustments. Adjustment locations and frequencies are shown on a sticker fastened to the bottom side of the chassis shield. These trimmer locations are also shown in one of the accompanying illustrations.

Connect the "low" output terminal of the test oscillator to the receiver chassis for all alignment operations. Regulate the output of the test oscillator so that minimum signal is applied to the receiver to obtain an observable output indication. This will avoid a-v-c action.

The term "Dummy antenna" means the device which must be connected between the "high" test-oscillator output terminal and the point of connection to the receiver in order to obtain ideal alignment. "No signal, 550-750 kc." means that the receiver should be tuned to a point between 550 and 750 kc. where no signal or interference is received from a station or the receiver (heterodyne) oscillator.

The term "Rock Through" indicates that the receiver station selector should be rocked back and forth while making the indicated adjustment. The adjustment and rocking should be continued until the combined action results in the maximum deflection on the output meter.

When adjusting oscillator circuits that have both series and shunt trimmers it is good practice to repeat the adjustment on the oscillator shunt trimmer after making the adjustment on the oscillator series trimmer. On some tuning ranges it is found that more than one peak may be secured if the trimmer is adjusted over a wide enough range. When this occurs it should be noted that oscillator circuits should be aligned, using that peak which occurs at the lower capacity setting of the trimmer. On R.F. or first detector trimmers the peak occurring with the larger capacity setting of the trimmer should be used.

It is also good practice to make sure that the trimmers on the short-wave ranges are set so that the oscillator stage develops its signal at a higher frequency than the signal to which the R.F. stage (or stages) is tuned. This check can be made by advancing the test oscillator output control and tuning the receiver above and below the frequency of the test oscillator, noting at what frequency the test signal reappears. It should reappear at a frequency setting on the receiver dial lower than the test oscillator frequency by an amount equal to twice the intermediate frequency.

ALIGNMENT CHART

Order of Alignment	Connection To Receiver	Test Oscillator Dummy Antenna	Frequency Setting	Receiver Dial Setting	Circuit To Adjust	Adjustment Symbols	Adjust to Obtain

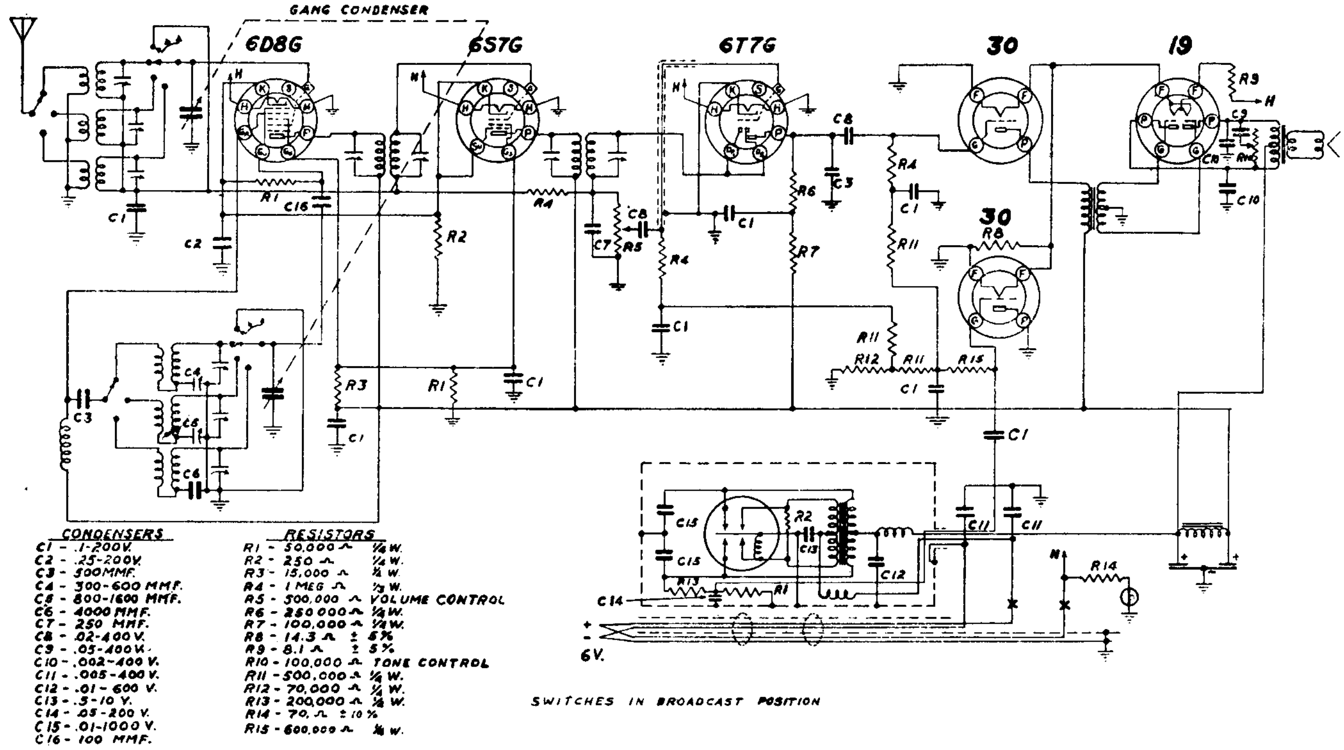
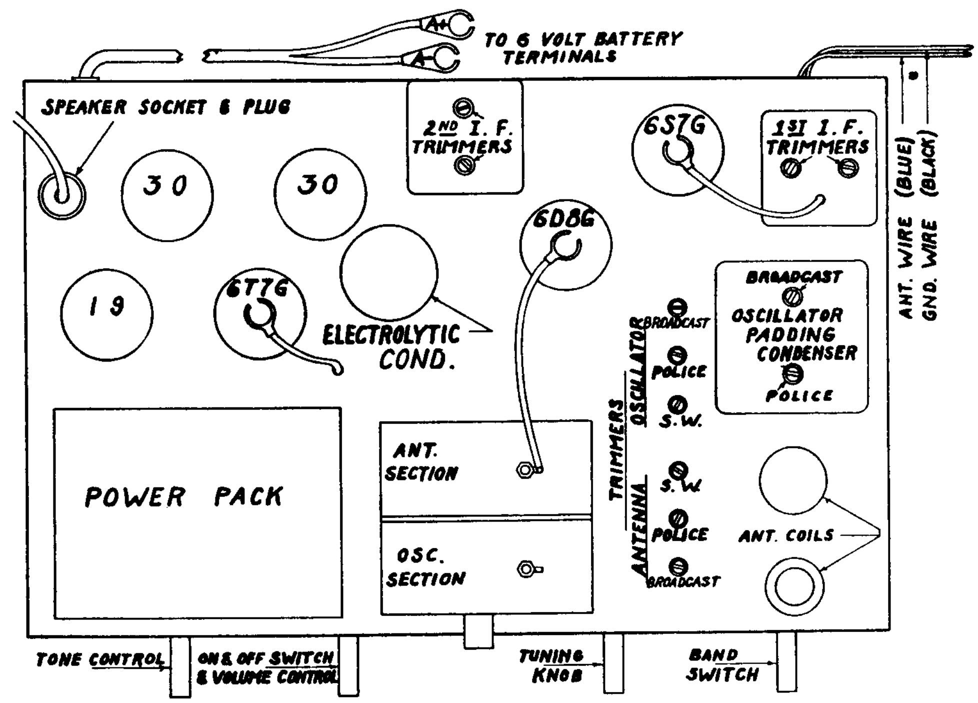
CONTINENTAL RADIO & TELEVISION CORP.

MODEL 6P





This receiver is designed to operate over three tuning. ranges; the broadcast range which extends from 550 to 1700 Kilocycles (KC) (176 to 545 meters), Police and Aviation Band which extends from 1700 to 5400 Kilocycles (KC) (56 to 176 Meters) and the International Short Wave Band which extends from 5600 to 18,100 Kilocycles (KC) 16.5 to 53 Meters). This latter range is the one which includes the four internationally assigned bands —the 19, 25, 31 and 49 meter bands.

CONTINENTAL RADIO & TELEVISION CORP.

MODEL 6P

REASONS FOR UNSATISFACTORY OPERATION

FAILURE TO OPERATE

1. Check connections from battery cable to storage battery. If connections are reversed, set will not operate. Proper instructions for connecting the battery are given on the first page.
2. Check all tubes. Have them tested by meter equipped to test the type of tubes used in this receiver.
3. Check tube shields for good ground connections. Check grid caps for good connection. See that grid caps and tube shields are not shorted to each other (touching).
4. Reversed connections on Antenna and ground terminals. Try both ways for best results.
5. Oscillator tube (6D8G) not oscillating.
6. Vibrator unit not securely in socket.

HUM

A minimum amount of hum, equivalent to A.C. receivers, may be present. Excessive hum may be traced to the following causes:

1. Omitting the use of a ground or a poor ground connection.
2. Vibrator unit not securely fitted in socket.
3. Antenna picking up interference from high tension power lines.
4. Weak or rundown battery. Battery with defective cell.
5. Poor battery connections.
6. Extending or lengthening battery leads causes an enormous increase in "hum." The battery cable attached to the receiver is of special design and its ends **must** be connected directly to the battery terminals.

HOWLS AND SQUEALS

1. Omitting the use of a ground or poor ground connections.
2. Speaker leads placed near the (6T7G) tube. These leads should be kept away from this locality. Speaker leads should be kept along the end of chassis and front corner of cabinet.
3. Check shield on (6S7G) tube for good connection to chassis.

NOTICE — MICROPHONIC NOISE CORRECTION

If this radio instrument appears to be microphonic during operation, loosen the four (4) mounting screws that secure the chassis to the cabinet and remove the two (2) wooden strips that are underneath the chassis. This allows the chassis to float and rest on the four (4) rubber pads used for this purpose.

After the strips have been removed, adjust the chassis in the cabinet so that the dial will be in the center of the front escutcheon plate. Do not retighten the mounting screws.

"Should this radio set be moved any great distance, it is best to put the wooden strips back under the chassis and have the mounting screws securely tightened. If this is not done, damage may be done to the instrument, cabinet or tubes."

WINDCHARGERS

There are many types of windchargers now on the market which may be used to advantage for greater economy of receiver operation. Such chargers will pay for themselves over a period of time; by saving the cost of battery recharging; removing the inconvenience of taking the battery to a charging station; non-operation of the receiver during the charging period.

IMPORTANT NOTE: The battery must never be charged while set is in operation. If a windcharger is used, it should always be disconnected from the battery when the receiver is being used. An inexpensive single pole switch can be used for disconnecting the windcharged from the battery. This will increase the life of the tubes and give additional economy to the use of the receiver.

ALIGNMENT DATA AND SERVICING

GENERAL DATA

The alignment of this receiver requires the use of a test oscillator which will cover the frequencies of 456, 600, 1400, 1730, 1800, 4000, 5600, 6000, and 18,000 KC and an output meter which is to be connected across the primary or secondary of the output transformer. If possible, all alignments should be made with the volume control on maximum and the test oscillator output as low as possible, to prevent the AVC from operating and giving false readings.

CORRECT ALIGNMENT PROCEDURE

The intermediate frequency (I.F. stage should be aligned properly as the first step. After the I.F. transformers have been properly adjusted and peaked, the Broadcast Band should always be the next procedure; after which, both of the Short Wave Bands may be aligned.

I.F. ALIGNMENT

With the wave switch in the broadcast band and the gang condenser set at minimum, adjust the test oscillator to 456 KC and connect the output to the grid of the first detector tube (6D8G) through a .05 or .1 mfd. condenser. The ground on the test oscillator can be connected to the chassis ground. Align all four I.F. trimmers to peak or maximum reading on the output meter.

BROADCAST BAND ALIGNMENT

Connect the output of the signal generator to the antenna lead (blue) through a .0002 mfd. mica condenser. Set the gang condenser to minimum and the oscillator to 1730 KC and adjust the "oscillator trimmer" to receive this signal. Make no other adjustments at this frequency. Then set the generator to 1400 KC and tune in this signal by rotating the gang to 1400 on the dial. Adjust the "antenna" trimmer to maximum signal. Set the signal generator to 600 KC and tune in the signal on the receiver. **Note:** Approximately the same sensitivity should be noted at this point as was at 1400 KC. The signal strength may sometimes be improved by padding the circuits. This is done by slowly increasing or decreasing the oscillator padding condenser and, at the same time, continuously tuning back and forth across the signal with the receiver until the maximum reading is obtained on the output meter. This adjustment may seem a little complicated but is the easiest way to adjust the oscillator to the antenna. Return to 1400 KC and again go over the adjustments of this frequency to be certain that they were not put slightly out of alignment when adjustment was made at 600 KC.

POLICE BAND ALIGNMENT

The police band is adjusted by first replacing the .0002 dummy with a 400 ohm resistor and setting the generator to 5600 KC. With the gang set at minimum, adjust the "police oscillator trimmer" to receive this signal, then set the signal generator to 4000 KC and adjust "police antenna trimmer" to give maximum output. Next, set the oscillator to 1800 KC and "pad" the circuit at this frequency as described in the instructions for padding the broadcast circuits.

SHORT WAVE BAND ALIGNMENT

The short wave band is adjusted by setting the generator to 18,100 KC and with the gang at minimum, adjust the "short wave oscillator trimmer" to receive the signal. Set the generator at 16,000 KC and adjust the "short wave antenna" to give maximum output. As there is no variable low frequency padding condenser on this band, the sensitivity of the receiver should be checked at 6000 KC to determine whether the circuits are in line at this frequency. Should the receiver lack sensitivity at 6000 KC, the antenna and oscillator coils, as well as the .004 mica padding condenser, should be tested for defects as sometimes these components become subject to mechanical or electrical injuries, despite their rugged construction and liberal ratings.

SERVICE DATA FOR ALL BANDS

If it is suspected that the oscillator has stopped but is doubtful due to the presence of the usual amount of noise level, it is suggested that the oscillator plate voltage be checked. To ascertain whether the tube is oscillating, ground the oscillator grid of the 6D8G (short stator and rotor plates of oscillator section on gang condenser). If oscillating properly, grounding the grid will cause an appreciable drop in oscillator voltage.

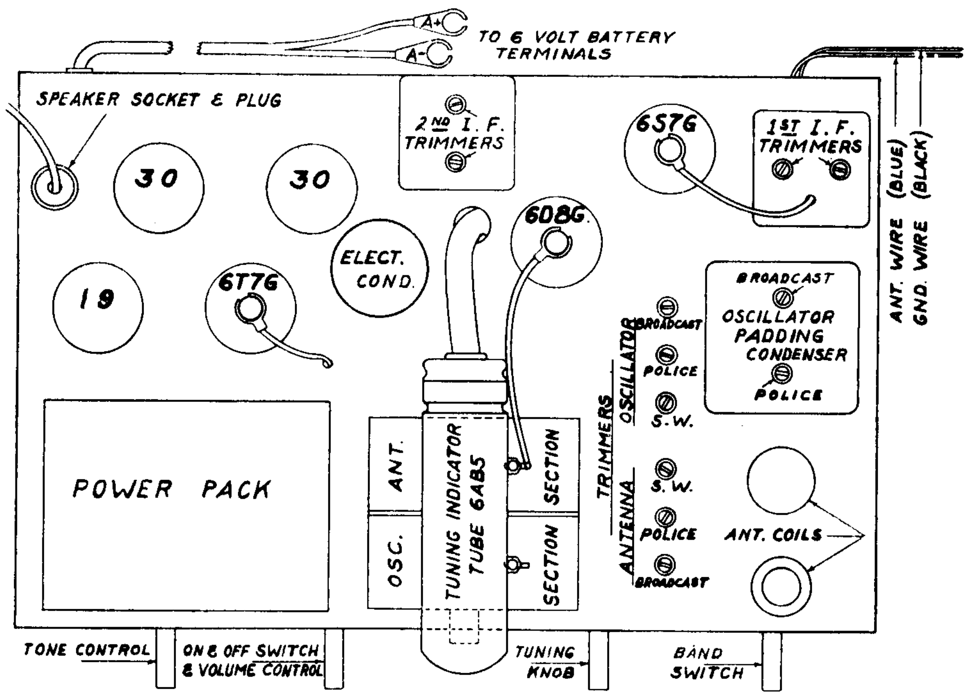
SWITCHES IN BROADCAST POSITION



This receiver is designed to operate over three tuning ranges; the broadcast range which extends from 550 to 1700 Kilocycles (KC) (176 to 545 meters), Police and Aviation Band which extends from 1700 to 5400 Kilocycles (KC) (56 to 176 Meters) and the International Short Wave Band which extends from 5600 to 18,100 Kilocycles (KC) 16.5 to 53 Meters). This latter range is the one which includes the four internationally assigned bands —the 19, 25, 31 and 49 meter bands.

CONTINENTAL RADIO & TELEVISION CORP.

MODEL 7J

REASONS FOR UNSATISFACTORY OPERATION

FAILURE TO OPERATE

1. Check connections from battery cable to storage battery. If connections are reversed, set will not operate. Proper instructions for connecting the battery are given on the first page.
2. Check all tubes. Have them tested by meter equipped to test the type of tubes used in this receiver.
3. Check tube shields for good ground connections. Check grid caps for good connection. See that grid caps and tube shields are not shorted to each other (touching).
4. Reversed connections on Antenna and ground terminals. Try both ways for best results.
5. Oscillator tube (6D8G) not oscillating.
6. Vibrator unit not securely in socket.

HUM

A minimum amount of hum equivalent to A.C. receivers may be present. Excessive hum may be traced to the following causes:

1. Omitting the use of a ground or a poor ground connection
2. Vibrator unit not securely fitted in socket.
3. Antenna picking up interference from high tension power lines.
4. Weak or rundown battery. Battery with defective cell.
5. Poor battery connections.
6. Extending or lengthening battery leads causes an enormous increase in "hum." The battery cable attached to the receiver is of special design and its ends **must** be connected directly to the battery terminals.

HOWLS AND SQUEALS

1. Omitting the use of a ground or poor ground connections.
2. Speaker leads placed near the (6T7G) tube. These leads should be kept away from this locality. Speaker leads should be kept along the end of chassis and front corner of cabinet.
3. Check shield on (6S7G) tube for good connection to chassis.

NOTICE — MICROPHONIC NOISE CORRECTION

If this radio instrument appears to be microphonic during operation, loosen the four (4) mounting screws that secure the chassis to the cabinet and remove the two (2) wooden strips that are underneath the chassis. This allows the chassis to float and rest on the four (4) rubber pads used for this purpose.

After the strips have been removed, adjust the chassis in the cabinet so that the dial will be in the center of the front escutcheon plate. Do not retighten the mounting screws.

"Should this radio set be moved any great distance, it is best to put the wooden strips back under the chassis and have the mounting screws securely tightened. If this is not done, damage may be done to the instrument, cabinet or tubes."

WINDCHARGERS

There are many types of windchargers now on the market which may be used to advantage for greater economy of receiver operation. Such chargers will pay for themselves over a period of time; by saving the cost of battery recharging; removing the inconvenience of taking the battery to a charging station; non-operation of the receiver during the charging period.

IMPORTANT NOTE: The battery must never be charged while set is in operation. If a windcharger is used, it should always be disconnected from the battery when the receiver is being used. An inexpensive single pole switch can be used for disconnecting the windcharged from the battery. This will increase the life of the tubes and give additional economy to the use of the receiver.

ALIGNMENT DATA AND SERVICING

GENERAL DATA

The alignment of this receiver requires the use of a test oscillator which will cover the frequencies of 456, 600, 1400, 1730, 1800, 4000, 5600, 6000, and 18,000 KC and an output meter which is to be connected across the primary or secondary of the output transformer. If possible, all alignments should be made with the volume control on maximum and the test oscillator output as low as possible, to prevent the AVC from operating and giving false readings.

CORRECT ALIGNMENT PROCEDURE

The intermediate frequency (I.F. stage should be aligned properly as the first step. After the I.F. transformers have been properly adjusted and peaked, the Broadcast Band should always be the next procedure; after which, both of the Short Wave Bands may be aligned.

I.F. ALIGNMENT

With the wave switch in the broadcast band and the gang condenser set at minimum, adjust the test ocillator to 456 KC and connect the output to the grid of the first detector tube (6D8G) through a .05 or .1 mfd. condenser. The ground on the test oscillator can be connected to the chassis ground. Align all four I.F. trimmers to peak or maximum reading on the output meter.

BROADCAST BAND ALIGNMENT

Connect the output of the signal generator to the antenna lead (blue) through a .0002 mfd. mica condenser. Set the gang condenser to minimum and the oscillator to 1730 KC and adjust the "oscillator trimmer" to receive this signal. Make no other adjustments at this frequency. Then set the generator to 1400 KC and tune in this signal by rotating the gang to 1400 on the dial. Adjust the "antenna" trimmer to maximum signal. Set the signal generator to 600 KC and tune in the signal on the receiver. **Note:** Approximately the same sensitivity should be noted at this point as was at 1400 KC. The signal strength may sometimes be improved by padding the circuits. This is done by slowly increasing or decreasing the oscillator padding condenser and, at the same time, continuously tuning back and forth across the signal with the receiver until the maximum reading is obtained on the output meter. This adjustment may seem a little complicated but is the easiest way to adjust the oscillator to the antenna. Return to 1400 KC and again go over the adjustments of this frequency to be certain that they were not put slightly out of alignment when adjustment was made at 600 KC.

POLICE BAND ALIGNMENT

The police band is adjusted by first replacing the .0002 dummy with a 400 ohm resistor and setting the generator to 5600 KC. With the gang set at minimum, adjust the "police oscillator trimmer" to receive this signal, then set the signal generator to 4000 KC and adjust "police antenna trimmer" to give maximum output. Next, set the oscillator to 1800 KC and "pad" the circuit at this frequency as described in the instructions for padding the broadcast circuits.

SHORT WAVE BAND ALIGNMENT

The short wave band is adjusted by setting the generator to 18,100 KC and with the gang at minimum, adjust the "short wave oscillator trimmer" to receive the signal. Set the generator at 16,000 KC and adjust the "short wave antenna" to give maximum output. As there is no variable low frequency padding condenser on this band, the sensitivity of the receiver should be checked at 6000 KC to determine whether the circuits are in line at this frequency. Should the receiver lack sensitivity at 6000 KC, the antenna and oscillator coils, as well as the .004 mica padding condenser, should be tested for defects as sometimes these components become subject to mechanical or electrical injuries, despite their rugged construction and liberal ratings.

SERVICE DATA FOR ALL BANDS

If it is suspected that the oscillator has stopped but is doubtful due to the presence of the usual amount of noise level, it is suggested that the oscillator plate voltage be checked. To ascertain whether the tube is oscillating, ground the oscillator grid of the 6D8G (short stator and rotor plates of oscillator section on gang condenser). If oscillating properly, grounding the grid will cause an appreciable drop in oscillator voltage.

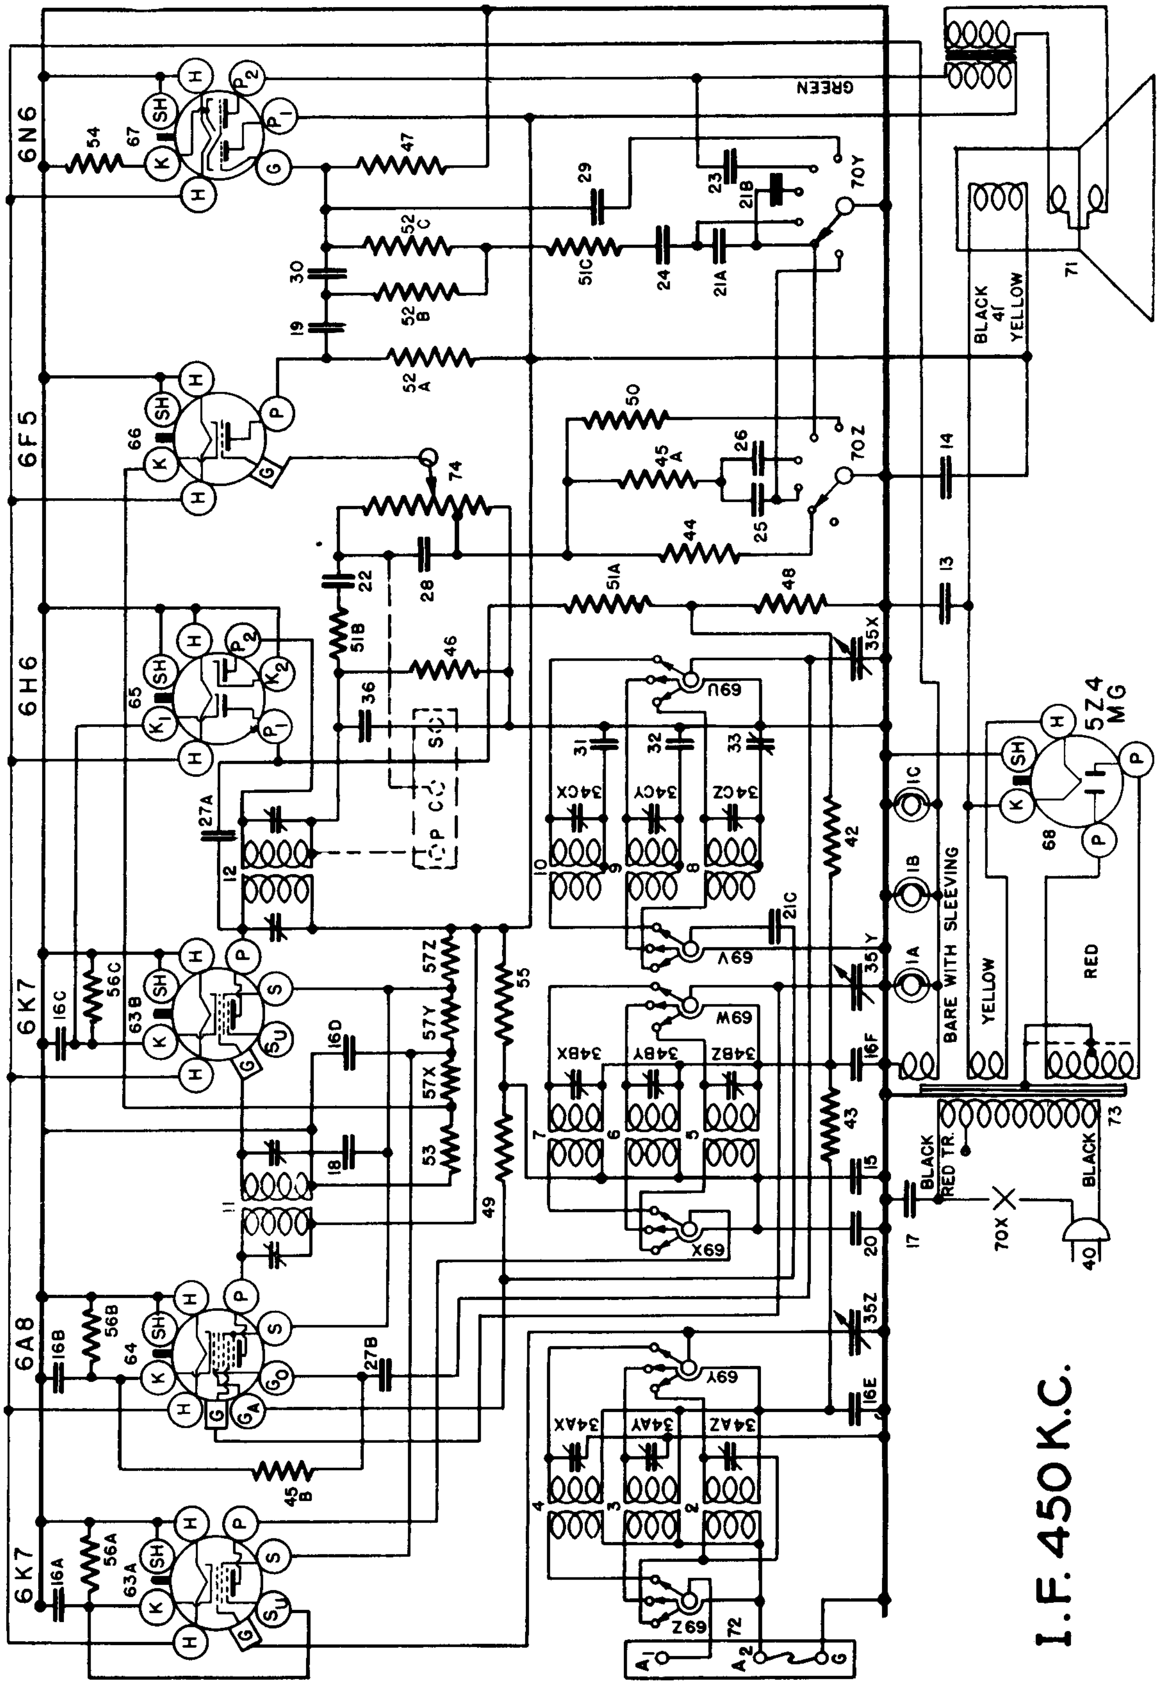
MODELS 726 & 769



I.F. 450 K.C.

THE CROSLEY RADIO CORPORATION

MODELS 726 & 769

SPECIFICATIONS

The Crosley Radio Model 726 is a seven tube superheterodyne receiver designed to operate on an ALTERNATING CURRENT power supply. It is available with either 110 V., 60 Cy., or 110 V., 25 Cy., Transformers.

It is a three band receiver and the dial is divided into three sections as follows:

BLUE 540-1800 Kilocycles (American Broadcast Band)
RED 1.8- 6.0 Megacycles (Police and Amateurs)
GREEN 6.0- 18.0 Megacycles (High Frequency Band)

SOCKET VOLTAGES

The tube socket voltages are measured from the tube socket contacts to the chassis with a 1000 ohm per volt. 5 0 volt D.C. voltmeter (except filaments) with the receiver in operating condition and no signal input. The filament voltages should be measured with an accurate low range A-C voltmeter (Approximately 0-10 volts). Readings may vary plus or minus 10% of values given.

TUBE SOCKET VOLTAGE READINGS

Tube	Where Used	H	P	P_2	S	G	Su	K	Ga
6K7	R. F. Amplifier	6.3	235	--	73	0	3.0	3.0	
6A8	Osc.-Mod.	6.3	270	--	96	0	--	3.5	145
6K7	I. F. Amplifier	6.3	270	--	96	0	2.7	2.7	
6H6	Det. & AVC	6.3	0	--	--	--	--	0	---
6F5	A. F. Amplifier	6.3	135		—	0	-	2.5	--
6N6	Output	6.3	270	260	—	0		2.2	---
5Z4MG	Rectifier	5.0	---	---	-	—	-	350	

Power Output Approximately 6 Watts.
Power Consumption Approximately 83 Watts at 117.5 Volts.
Voltage Drop Across Speaker Field 77 Volts

ALIGNMENT PROCEDURE

All the circuits in this receiver are very accurately adjusted at the factory and normally should need no further adjustment. However, if it is definitely known that an adjustment is necessary the circuits may be properly aligned with the use of a modulated signal generator and an output meter.

CONNECTING OUTPUT METER

Connect the output meter to the two plates of the 6N6 Output Tube. Be sure the meter is protected from D.C. by connecting a condenser (.1 mfd. or larger—not electrolytic) in series with one of the leads.

1. Tuning I-F Amplifier to 450 Kilocycles.

(a) Connect the output of the signal generator through a .02 mfd. condenser to the top cap of the 6A8 tube, leaving the tube's grid clip in place. Connect the ground lead from the signal generator to the "GND" terminal of the receiver. KEEP THE GENERATOR LEADS AS FAR AS POSSIBLE FROM THE GRID LEADS OF THE OTHER SCREEN GRID TUBES.

(b) Set the station selector so that the tuning condenser plates are completely out of mesh. Turn the volume control knob to the right (ON) and turn the fidelity control knob to the left (NORMAL).

(c) Turn the band selector switch to the High Frequency Band.

(d) Set the signal generator to 450 kilocycles.

(e) Adjust both trimmers located on top of the 2nd I-F transformer for maximum output.

(f) Adjust both trimmers located on top of the 1st I-F Transformer for maximum output.

(g) Check operations (e) and (f) for more accurate adjustments.

ALWAYS USE THE LOWEST SIGNAL GENERATOR OUTPUT THAT WILL GIVE A REASONABLE OUTPUT METER READING.

Aligning R-F Amplifier.

When aligning the R-F Amplifier the output lead of the signal generator is connected to the "ANT" terminal of the receiver. For the BLUE and RED bands a .00025 mfd. condenser must be connected in series with the output lead of the signal generator and for the high-frequency band a 400 ohm carbon resistor should be used in place of the condenser.

Each band should first be shunt aligned and then series aligned, where provision is made for series alignment (BLUE band). The band selector switch should be set for the band being aligned and the station selector and signal generator should be set to the frequency indicated (c) for each adjustment.

(a) Adjust the "OSC.," "ANT" and "R-F" shunt trimmers in the order given for maximum output. Readjust the station selector slightly so that the generator signal is tuned-in with maximum output and then check the adjustments of the "ANT" and "R-F" trimmers. DO NOT READJUST the "OSC" TRIMMER.

NOTE: When shunt aligning the RED and GREEN bands care must be exercised so that the circuits will be aligned on the correct frequency rather than on the image frequency which is approximately 900 kilocycles less than the fundamental. To check on this, increase the output of the signal generator ten times, or more, and try to tune-in the signal both at the generator frequency as indicated on the station selector dial and at approximately 900 kilocycles less than the correct frequency. If the circuits have been properly aligned the signal can be tuned-in at both positions but much stronger at the correct position.

(b) To align the series trimmer (Item 33, Fig. 2) set the signal generator to the frequency indicated (c) and then tune-in this signal with the station selector for maximum output. To obtain the best adjustment for the series trimmer it will be necessary to rotate the station selector back and forth slightly while adjusting the trimmer for maximum output.

(c) Signal Input Frequencies:

	Shunt Alignment	Series Alignment
American Broadcast Band (BLUE)	1700 Kilocycles	600 Kilocycles
Police Band (RED)	6000 Kilocycles	....
High-Frequency Band (GREEN)	18000 Kilocycles	....

THE CROSLEY RADIO CORPORATION

MODELS 736 & 759

SPECIFICATIONS

The Crosley Receiver Model 736 is a seven tube superheterodyne radio designed to operate on an ALTERNATING CURRENT power supply. It incorporates a WAVE-TRAP in its construction so that interfering signals between the frequencies of approximately 440 and 480 Kilocycles may be reduced so that they are not objectionable if not entirely eliminated from over riding station being received.

It is a three band receiver and the dial is divided into three sections as follows:

BLUE	540-1800 Kilocycles	(American Broadcast Band)
RED	1.8- 6.0 Megacycles	(Police and Amateurs)
GREEN	6.0- 18.0 Megacycles	(High Frequency Band)

ALIGNMENT PROCEDURE

All the circuits in this receiver are very accurately adjusted at the factory and normally should need no further adjustment. However, if it is definitely known that an adjustment is necessary the circuits can best be properly aligned with the use of a modulated signal generator and an output meter.

CONNECTING OUTPUT METER

Connect the output meter to the two plates of the 6N6 Output Tube. Be sure the meter is protected from D.C. by connecting a condenser (.1 mfd. or larger—not electrolytic) in series with one of the leads.

1. Tuning I-F Amplifier to 450 Kilocycles.

(a) Connect the output of the signal generator through a .02 mfd. condenser to the top cap of the 6A8 tube, leaving the tube's grid clip in place. Connect the ground lead from the signal generator to the "GND" terminal of the receiver. KEEP THE GENERATOR LEADS AS FAR AS POSSIBLE FROM THE GRID LEADS OF THE OTHER SCREEN GRID TUBES.

(b) Set the station selector so that the tuning condenser plates are completely out of mesh. Turn the volume control knob to the right (ON) and turn the tone control knob to the left (TREBLE).

(c) Turn the band selector switch to the High Frequency Band.

(d) Set the signal generator to 450 kilocycles.

(e) Adjust both trimmers located on the top of the 3rd I-F Transformer for maximum output.

(f) Adjust both trimmers located on top of the 2nd I-F Transformer for maximum output.

(g) Adjust both trimmers located on top of the 1st I-F Transformer for maximum output.

(h) Check operations (e), (f) and (g) for more accurate adjustments.

ALWAYS USE THE LOWEST SIGNAL GENERATOR OUTPUT THAT WILL GIVE A REASONABLE OUTPUT METER READING.

Aligning R-F Amplifier.

When aligning the R-F Amplifier the output lead of the signal generator is connected to the "ANT" terminal of the receiver. For the BLUE and RED bands a .0002 mfd. condenser must be connected in series with the output lead of the signal generator and for the high-frequency band a 400 ohm carbon resistor should be used in place of the condenser.

Each band should first be shunt aligned and then series aligned, where provision is made for series alignment (BLUE band). The band selector switch should be set for the band being aligned and the station selector and signal generator should be set to the frequency indicated (c) for each adjustment.

(a) Adjust the "OSC" and "ANT" shunt trimmers in the order given for maximum output. Readjust the station selector slightly so that the generator signal is tuned-in with maximum output and then check the adjustments of the "ANT" trimmers. DO NOT READJUST the "OSC" TRIMMER.

NOTE: When shunt aligning the RED and GREEN bands care must be exercised so that the circuits will be aligned on the correct frequency rather than on the image frequency which is approximately 900 kilocycles less than the fundamental. To check on this, increase the output of the signal generator ten times, or more, and try to tune-in the signal both at the generator frequency as indicated on the station selector dial and at approximately 900 kilocycles less than the correct frequency. If the circuits have been properly aligned the signal can be tuned-in at both positions but much stronger at the correct position.

(b) To align the series trimmer (Item 13, Fig. 2) set the signal generator to the frequency indicated (c) and then tune-in this signal with the station selector for maximum output. To obtain the best adjustment for the series trimmer it will be necessary to rotate the station selector back and forth slightly while adjusting the trimmer for maximum output.

(c) Signal Input Frequencies:

	Shunt Alignment	Series Alignment
American Broadcast Band (BLUE)	1700 Kilocycles	600 Kilocycles
Police Band (RED)	6000 Kilocycles	....
High-Frequency Band (GREEN)	18000 Kilocycles	....

TO ADJUST WAVE TRAP

Connect the output of the signal generator through an .02 Mf. condenser to the ANT. terminal on the chassis and the other lead to GND. terminal.

(a) Adjust signal generator to frequency of interfering signal.

(b) Set station selector to approximately 650 Kilocycles with the band selector in the Broadcast position.

(c) Adjust Wave Trap trimmer (Item 12, Fig. 2) to minimum signal.

For simple adjustment tune-in station with maximum interference and adjust Wave Trap Trimmer for minimum interference.

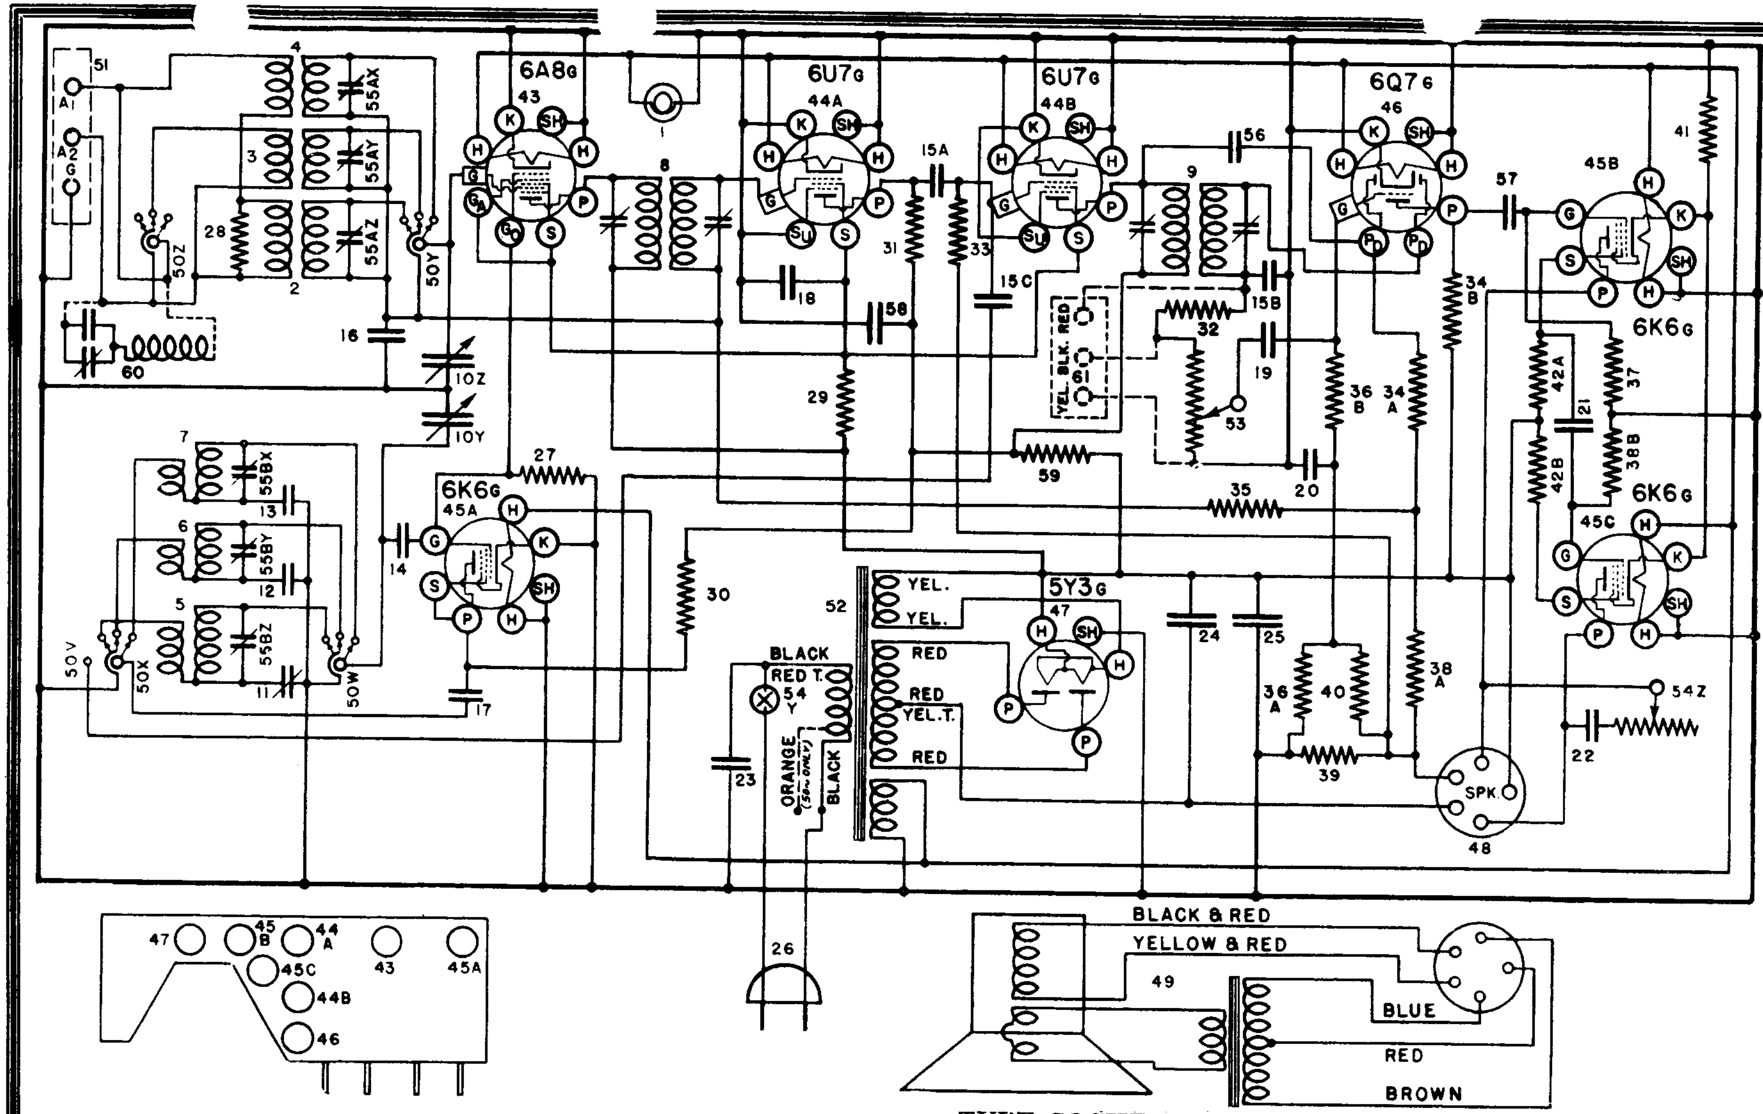
THE CROSLEY RADIO CORPORATION

MODEL 817



I. F. 456 K.C.

SOCKET VOLTAGES

The tube socket voltages are measured from the tube socket contacts to the chassis with a 1000 ohm per volt, 500-volt D. C. voltmeter (except filaments) with receiver in operating condition and no signal input. The filament voltages should be measured with an accurate low range A. C. voltmeter (approximately 0-10 volts). Readings may vary plus or minus 10% of values given.

TUBE SOCKET VOLTAGE READINGS

Tube	Function	H	P	S	G	K	Go	Ga
6A8G	Modulator	6.3	240	85	Neg	0	Neg	85
6K6G	Oscillator	6.3	145	145	Neg	0	—	—
6U7G	1st I-F Amp	6.3	240	85	Neg	0	—	—
6U7G	2nd I-F Amp	6.3	210	85	Neg	0	—	—
6Q7G	Det., AVC & 1st A-F Amp	6.3	120	—	Neg	0	—	—
6K6G	Output	6.3	235	230	0	18.5	—	—
6K6G	Output	6.3	235	230	0	18.5	—	—
5Y3G	Rectifier	5.0	—	—	—	240	—	—

Power output approximately 5.5 watts.
Power consumption approximately 70 watts at 117.5 volts
Voltage drop across speaker field 80 volts

THE CROSLEY RADIO CORPORATION

MODEL 817

This model Crosley radio is an 8-tube AC receiver designed for American and Foreign broadcast reception.

The tuning range is from 540 kilocycles to 22 megacycles and is divided into three bands as follows:

540-1850 Kilocycles or 555-162 Metres (American Broadcast Band)
1.9- 6.6 Megacycles or 158-45.5 Metres (Police & Amateur Band)
6.4- 22 Megacycles or 47-13.5 Metres (High Frequency or Foreign Band)

Circuit Description

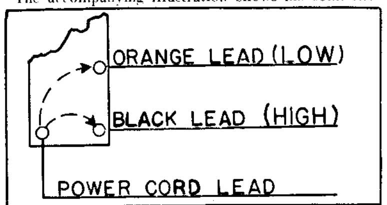
Eight octal base glass tubes are employed in a superheterodyne circuit which consists of separate oscillator and modulator tubes, two stages of I-F amplification—the second of which is resistance coupled, a combination AVC and diode detector and 1st A-F amplifier tube, push pull output and power supply. The speaker field is located in the negative leg of the power supply. The bias for all tubes except the output is developed across a 40 ohm resistor, item 39, located between the speaker field and ground. Phase inversion is obtained in the output circuit by the voltage developed across a 3000 ohm resistor, item 42A, located in the screen circuit of one of the output tubes, item 45B.

50 CYCLE POWER TRANSFORMER ADJUSTMENT

Receivers equipped with a 50 cycle power transformer have a "high" and "low" voltage tap on the under side of the chassis. The "high" voltage lead (BLACK) and the "low" voltage lead (ORANGE) are connected to a terminal strip near the transformer.

The voltage range of the "low" tap of the 95-130 volt transformer is from 95 to 112½ volts and of the "high" tap is from 112½ to 130 volts. The range of the "low" tap of the 190-260 volt transformer is from 190 to 225 volts and of the "high" tap is from 225 to 260 volts.

The accompanying illustration shows the connections



for changing from high to low or low to high line voltage. Note the "jumper" wire which is attached to the terminal at which one side of the power cord is attached. The other end of this jumper wire should be connected to the ORANGE or BLACK lead of the transformer primary, according to the line voltage the receiver is to be used on.

NOTE: Any change made in the power supply circuit of the receiver should be plainly stamped or otherwise permanently recorded on the rear of the chassis.

ALIGNMENT PROCEDURE

All the circuits in this receiver are very accurately adjusted at the factory and normally should need no further adjustment. However, if it is definitely known that an adjustment is necessary the circuits may be properly aligned with the use of a modulated signal generator and an output meter.

CONNECTING OUTPUT METER

Connect the output meter to the plates of the two 6K6G Output tubes. Be certain that the meter is protected from D. C. by connecting a condenser (.1 mfd. or larger—not electrolytic) in series with one of the leads.

Tuning I-F Amplifier to 455 Kilocycles.

(a) Connect the output of the signal generator through a .02 mfd. condenser to the top cap of the 6A8G tube, leaving the tube's grid lead in place. Connect the ground lead from the signal generator to the ground terminal of the receiver. KEEP THE GENERATOR LEADS AS FAR AS POSSIBLE FROM THE GRID LEADS OF THE OTHER SCREEN GRID TUBES.

(b) Set the station selector so that the tuning condenser plates are completely out of mesh. Turn the volume control knob to the right (ON) and turn the tone control knob to the left (TREBLE).

(c) Turn the band selector switch to the High Frequency Band.

(d) Set the signal generator to 455 kilocycles.

(e) Adjust both trimmers located on top of the 2nd I-F assm. for maximum output. (Item 9, Fig. 2)

(f) Adjust both trimmers located on top of the 1st I-F assm. for maximum output. (Item 8, Fig. 2)

(g) Check operations (e) and (f) for more accurate adjustment.

ALWAYS USE THE LOWEST SIGNAL GENERATOR OUTPUT THAT WILL GIVE A REASONABLE OUTPUT METER READING.

Aligning R-F Amplifier.

When aligning the R-F amplifier the output lead from the signal generator is connected to the "ANT" terminal of the receiver. For the Broadcast and Police Bands a .00025 mfd. condenser should be connected in series with the output lead of the signal generator and for the High Frequency band a 400 ohm carbon resistor should be used in place of the condenser.

Each band should first be shunt aligned and then series aligned where provision is made for series alignment (Broadcast Band). The band selector switch should be set for the band being aligned and the station selector and signal generator should be set to the frequency indicated for each adjustment, paragraph (c) below.

(a) Adjust the "OSC" and "ANT" shunt trimmers in the order given for maximum output. Readjust the station selector slightly so that the generator signal is tuned-in with maximum output and then check the adjustment of the "ANT" trimmer. DO NOT READJUST THE "OSC" TRIMMER.

NOTE: When shunt aligning the Police and High Frequency Bands care must be exercised so that the circuits will be aligned on the correct frequency rather than on the image frequency which is approximately 910 kilocycles less than the fundamental. To check on this, increase the output of the signal generator ten times, or more, to try to tune-in the signal both at the generator frequency as indicated on the station selector dial and at approximately 910 kilocycles less than the correct frequency. If the circuits have been properly aligned the signal can be tuned-in at both positions but much stronger at the correct frequency.

(b) To align the B. C. OSC. series trimmer (Fig 2), set the signal generator to the frequency indicated below and then tune-in this signal with the station selector for maximum output. To obtain the best adjustment for the series trimmer, it will be necessary to rotate the station selector back and forth slightly while adjusting the trimmer for maximum output.

(C) SIGNAL INPUT FREQUENCIES

	Shunt Alignment	Series Align.
American Broadcast Band	1700 Kilocycles	600 Kilocycles
Police & Amateur Band	6000 "	
Foreign Band	18 Megacycles	

WAVE TRAP

Some chassis of this model are equipped with a wave trap for the purpose of eliminating interference from code stations which operate on a frequency of approximately 455 kilocycles. This assembly is located on the underneath side of the chassis and consists of a coil, a fixed condenser and a trimmer condenser as illustrated by dotted lines in the Wiring Diagram (item 60).

The wave trap should not be adjusted until all other adjustments have been made. To make the adjustment, feed a 455 kilocycle signal from the signal generator through a .00025 mfd. condenser into the antenna terminal of the receiver. With the band selector switch turned to the Broadcast Band position, the gang condenser open and the volume control full on, adjust the trimmer condenser on the wave trap for minimum output.

Should the interfering station be operating on a frequency of slightly more or less than 455 kilocycles, the exact frequency should be determined with the aid of the signal generator. Then, instead of feeding a 455 kilocycle signal into the receiver the exact frequency of the interfering signal should be used. If it is not possible to determine the exact frequency of the interfering signal the antenna may be attached to the receiver and the receiver tuned to the position where the interfering signal is most noticeable. Then adjust the wave trap for minimum interference.

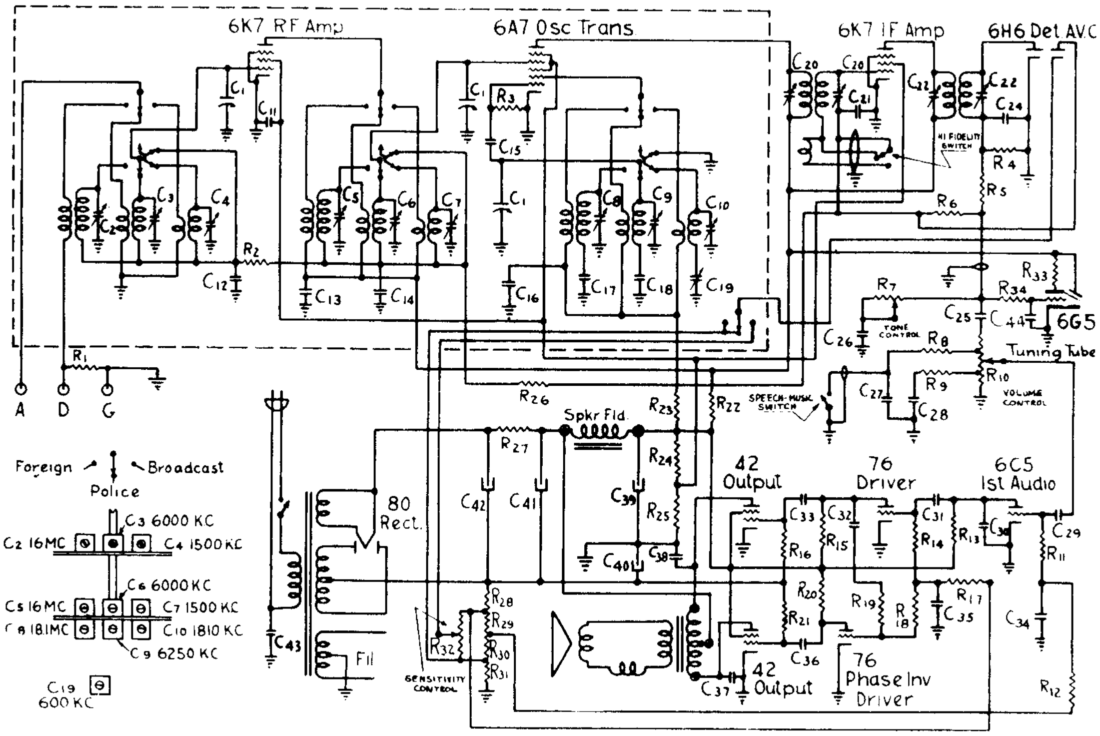
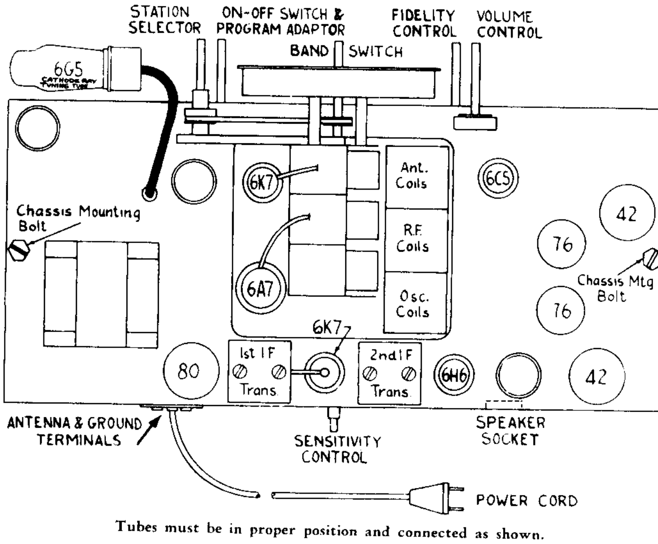
DETROLA RADIO AND TELEVISION CORPORATION

MODEL 155X



TUBE LAYOUT *and* CONNECTION DIAGRAM



Tubes must be in proper position and connected as shown.

ALINEMENT PROCEDURE

Connect a high impedance AC voltmeter across the loudspeaker terminals. Volume control should be set a few degrees back of maximum volume position. Use a weak signal from the generator, strong signals tend to cause improper adjustments.

Be sure that the fidelity control is NOT in the HIGH FIDELITY position. It will not be possible to properly aline the receiver unless this control is turned part way toward its "bass" position.

IF. Connect the generator ground to receiver chassis. Using .1 mfd. condenser in series with high side of the generator, apply 456 kc. signal to the grid of the 6K7 IF amplifier tube and aline second IF transformer trimmers. Repeat for first IF transformer, applying signal to grid of the 6A7 tube. (See above diagram for location of tubes and transformers.)

RF. (See circuit diagram for location of trimmers.) Using a 200 mmf. condenser in series with the high side of the generator, turn band selector switch all the way to the left, tuning condenser to minimum capacity, feed 1810 kc. signal to antenna terminal and adjust broadcast oscillator trimmer for top frequency. Set generator frequency at some point around 1500 1600 kc., and adjust broadcast antenna and RF trimmers. Set generator for 600 kc., tune receiver to signal and adjust the padder. The tuning condenser should be rocked back and forth through the signal while varying the padder in order to assure perfect alinement.

A 400 ohm resistor must be used in series with the generator as a "dummy" antenna for proper alinement of the two short wave bands. Set the band selector switch in the center position, adjust the oscillator top frequency for 6250 kc., then aline the antenna and RF trimmers at about 6000 kc. With the band selector in the extreme right position, adjust the top frequency of the high frequency to 18,100 kc., and aline the antenna and RF trimmers at about 16,000 kc. In order to make sure that the top end of the last band is set properly, it is best to screw the oscillator trimmer down tight, then unscrew to the second peak. The antenna and RF trimmers should be screwed down tight, then unscrewed to the first peak. This procedure must be followed in order that the oscillator and RF circuits will be set in the correct relation to each other, otherwise a "dead" spot at a lower frequency will result, and the dial calibration will not be correct. Usually, it is best to rock the tuning condenser back and forth slightly while making these adjustments at high frequencies.

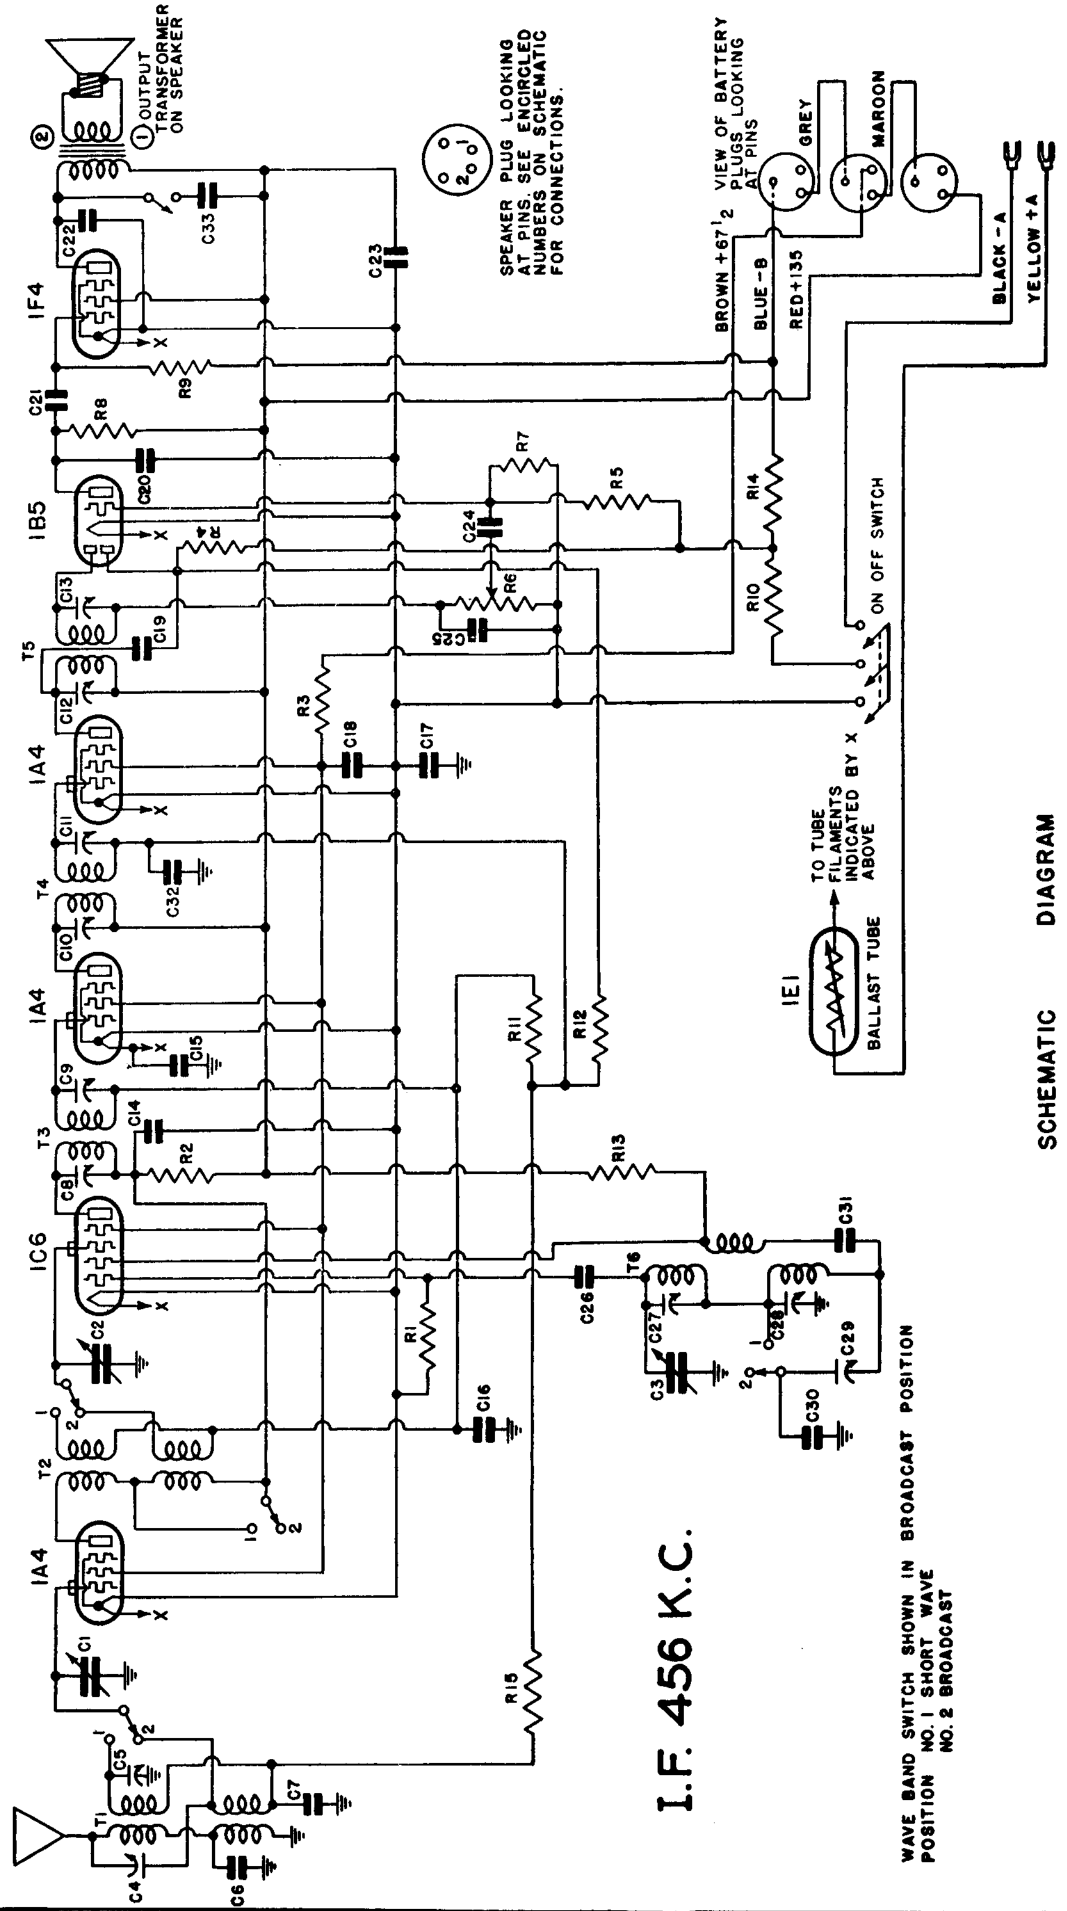
EMERSON RADIO AND PHONOGRAPH CORPORATION

MODELS AF, AF-171, AF-173, AF-176, AF-179, AF-180 & AF-185



EMERSON RADIO AND PHONOGRAPH CORPORATION
MODELS AF, AF-171, AF-173, AF-176, AF-179, AF-180 & AF-185

Current drain	"A" battery—0.48 amps. "B" battery—0.013 amps. with no signal
Frequency range	540 to 1730 kc and 5.6 to 18.0 mc

GENERAL NOTES

1. The battery complement should be as follows:

Type	*No. Required*	*Battery Manufacturer* Eveready *Part No.*	Burgess *Part No.*	Ray-o-vac *Part No.*
3 volt "A"	1	X-125 or A-600	20F2	P9403
45 volt "B"	3	385 (plug-in type)	22308 (plug-in type)	P9303 (plug-in type)

2. The receiver is designed for an "A" supply of 2 to 3 volts. A 2 volt storage battery may be used, in which case the 1E1 (ballast) tube, in the chassis becomes unnecessary and may be eliminated as follows:
   If it is definitely known that a 2 volt storage battery will always be used it is permissable and advisable to short-circuit the two heavy prongs on the 1E1 tube by connecting them with a short piece of bare wire. *Be sure that the two small prongs on the tube are free of this bare wire.*

3. The color coding of the i-f transformer leads is as follows:
   Grid—green — Plate—blue
   Grid return—black — B plus—red

4. Note that all leads in the battery cable are color coded. The two "A" leads are tagged with small metal markers giving the polarity. The battery cable is equipped with three plugs for "B" battery connections. These plugs are all alike and may be inserted in any order in the sockets of the three "B" batteries. The color coding of the battery cable is as follows:

Red	B plus 135
Brown	B plus 67.5
Blue	B neg.
Yellow	A plus 3
Black	A neg.

5. If replacements are made in the r-f section of the circuit, the receiver should be carefully re-aligned.

6. Be very careful not to remove any of the tubes from their sockets with the power switch turned on, as the rapid rise in filament voltage will damage the remainder of the tubes.

Tube Data

The tube complement is as follows:
1—1A4, r-f amplifier (to right of variable condenser)
1—1C6, oscillator-modulator
1—1A4, 1st i-f amplifier (to left of variable condenser)
1—1A4, 2nd i-f amplifier (behind variable condenser)
1—1B5-25S, 2nd detector, a.v.c., a-f amplifier
1—1F4, pentode output
1—1E1, ballast tube.

VOLTAGE ANALYSIS

Readings should be taken with a 1000 ohms-per-volt meter. Voltages listed are from point indicated to A neg. with volume control turned on full and no signal. The battery voltages for these readings were: "A" 3 volts, "B" 135 volts.

Tube	*Plate*	*Screen*	*Osc. Plate*	*Fil.*
1A4 r-f	130	57	—	2.0
1C6	130	57	100	2.0
1A4 1st i-f	130	57	—	2.0
1A4 2nd i-f	130	57	—	2.0
1B5-25S	65	—	—	2.0
1F4	130	130	—	2.0

Bias for the three 1A4 and the 1C6 tubes is obtained across the resistor R10. The voltage drop across this resistor should be 5 volts. Bias for the output tube (1F4) is obtained across resistors R10 and R14 in series. Voltage drop across these resistors should be 7.5 volts.

ADJUSTMENTS

An oscillator with frequencies of 456, 600, 1600 and 15,000 kc should be used.
An output meter should be used across the voice coil or output transformer for observing maximum response.
If the circuit is at all disturbed, both the broadcast and short-wave bands must be realigned.
The set's oscillator is higher in frequency than the signal, so images should be observed on the low frequency side of the signals.
Always choose the minimum capacity peak on oscillator trimmers and maximum capacity peaks on antenna trimmers. The last motion in adjusting trimmers should always be a tightening one, not a loosening one.
Never leave a trimmer with the outside plate so loose that there is no tension on the screw. Either bend the plate up or remove the screw entirely.
Always use as weak a test signal as possible during alignment.
Use a standard dummy antenna for aligning either of the bands. A .0002 mf condenser may be used for the broadcast band dummy antenna and a 400 ohm non-inductive resistor for the short-wave dummy antenna.

Location of Coils and Trimmer Adjustments

The three i-f transformers are in oblong coil cans located on top of the chassis deck.
The first i-f transformer, part number 4ET-350B, is located to the left of the variable condenser.
The second i-f transformer, part number 4ET-350B, is located behind the variable condenser.
The third i-f transformer, part number 4FT-382, is located to the right of the variable condenser. The trimmers, two for each transformer, are accessible through holes in the top of the cans.
The broadcast series padder is located underneath the chassis (in the corner near the 1C6 tube). The screw adjustment is accessible through a hole in the top of the chassis.
The antenna coil for the two bands is wound on one coil form and mounted underneath the chassis to the right of the variable condenser. The trimmers are accessible through holes in the top of the chassis. The trimmer nearest the front of the chassis is for the short-wave antenna coil.
The r-f interstage coils for the two bands are wound on one form and mounted underneath the chassis to the left of the first i-f transformer. The trimmers are accessible through holes in the top of the chassis. The trimmer nearest the front of the chassis is for the short-wave interstage coil.
The oscillator coils for the two bands are wound on one coil form and mounted underneath the chassis to the left of the variable condenser. The trimmers are accessible through holes in the top of the chassis. The trimmer nearest the front of the chassis is for the short-wave oscillator coil.

I-f Alignment

Rotate the wave-band switch to the broadcast (clockwise) position. Set the variable condenser at the minimum capacity position and feed 456 kc through a 0.02 mf paper condenser, to the grid cap of the 1C6 tube (do not remove the grid clip from the tube). Adjust the six i-f trimmers for maximum response.

Short-Wave Alignment (Short-wave alignment should precede broadcast alignment.)

Set the wave-band switch at the short-wave (counter-clockwise) position. Move pointer to 15, feed 15,000 kc to antenna (using a 400 ohm dummy antenna) and adjust the short-wave oscillator for maximum response. If two peaks are obtained choose minimum capacity peak. Then adjust the interstage and antenna trimmers for maximum response. If two peaks are obtained choose the maximum capacity peak.

Broadcast Alignment

With the wave-band switch at the broadcast (clockwise) position, set the pointer at 600, feed 600 kc through the antenna (using a standard dummy antenna), and adjust the broadcast series padder for maximum response. Move pointer to 1600, feed 1600 kc to the antenna and adjust the oscillator trimmer for maximum response, then adjust interstage and antenna trimmers. Reset the pointer to 600, feed 600 kc to antenna and rock the variable condenser (rotate the condenser back and forth through a small arc) while resetting the oscillator padder for maximum response. Return to 1600 and check alignment. If readjustment is necessary, return to 600 and repeat entire procedure.

REPLACEMENT PARTS LIST

List Price Ea. Effective as of Aug. 15th, 1937 (Subject to change without notice)

*Item	Part No.	DESCRIPTION	PRICE
T1	4FT-380	Two band antenna coil	$1.55

	4RZ-595	Escutcheon with crystal	1.95

When ordering replacement parts specify part numbers.

*Item number locates the article on the schematic diagram.

†These trimmers are part of the coil assemblies and cannot be supplied separately.

PRODUCTION CHANGES

Receivers bearing serial numbers above 1,244,716 differ from the schematic diagram as follows:
a. C17 is omitted, and the negative side of the filament circuit is grounded to the chassis.

EMERSON RADIO AND PHONOGRAPH CORPORATION

EMERSON RADIO AND PHONOGRAPH CORPORATION
MODELS AL, AL-130, AL-132, AL-149, AL-168, ALLW, ALLW-130, ALLW-132, ALLW-149 & ALLW-168

Voltage rating	105 to 125 volts, a.c. or d.c.
Power consumption	43 watts.
Frequency ranges	Model AL: 540 to 1580 kc and 1580 to 4200 kc. Model ALLW: 135 to 360 kc and 530 to 1550 kc.

GENERAL NOTES

1. If replacements are made or the wiring disturbed in the r-f portion of the circuit, the receiver should be carefully re-aligned.
2. One side of the power line is directly grounded to the chassis base. Under no circumstances, therefore, should a ground wire be permitted to come in contact with any metal part of the receiver.
3. The filament dropping resistor (R12 on schematic) is in a special metal tube at the rear of the chassis. This tube will become quite hot under normal operating conditions. For voltage drop specifications, see below.
4. When operating the receiver on d.c. it may be necessary to reverse the line plug to obtain the correct polarity.
5. The two i-f transformers are held to the chassis by snap-on fasteners. To remove an i-f, unsolder all the leads under the chassis, pinch together the prongs of the snap-on fastener and lift the i-f can from the chassis.
6. The color coding of the i-f transformer leads is as follows:
   Grid—green Plate—blue
   Grid return—black B plus—red
7. The receiver is shipped with an attached antenna wire. In some locations near powerful local stations the addition of a very large antenna may be detrimental to reception, because of the resulting interference. The Emerson Flexible Mast Antenna, Model W-82, has been especially designed for Emerson receivers, featuring compactness and portability while at the same time retaining a high efficiency from the standpoint of performance. Since it functions as an outside antenna the Flexible Mast will substantially improve the receiver performance. Where the Flexible Mast is installed permanently, it is urgently recommended that the receiver antenna wire be cut. Leave just enough of this wire to reach from the receiver to the window strip connector. Instructions for the installation of this compact and efficient outside antenna are supplied with each kit.
8. The wave-trap in the receiver has been adjusted for maximum signal rejection at 456 kc. If, however, persistent interference is experienced from some particular telegraphic station, readjust the wave-trap trimmer until the response from the interfering station is at a minimum.

Tube Data

The tube complement is as follows:

1—6A7 pentagrid oscillator-modulator.
1—6D6 first i-f amplifier.
1—6Q7 diode detector, a-f amplifier, a.v.c.
1—25L6 beam power output.
1—25Z5 dual half-wave rectifier.
1—2UR-224 ballast tube (R12 on schematic).

NOTE: Metal tubes may be replaced with equivalent octal-base glass tubes.

VOLTAGE ANALYSIS

Readings should be taken with a 1000 ohms-per-volt meter. Voltages listed below are from point indicated to ground (chassis) with the volume control turned on full and no signal. Line voltage for these readings was 117.5 volts, 60 cycles, a.c.

Tube	*Plate*	*Screen*	*Cathode*	*Osc. Plate*	*Fil.*
6A7	100	50	2.3	100	6.3
6D6	100	100	3.5	—	6.3
6Q7	43	0	1.2	—	6.3
25L6	92	100	6.5	—	25.0

Voltage at 25Z5 cathode—130 volts.
Voltage across speaker field—28 volts.
Voltage drop across ballast tube (pins Nos. 3, 7)—49 volts.
Voltage drop across pilot light section (pins Nos. 8 and 7)—4 volts.

ADJUSTMENTS

An oscillator with frequencies of 172, 345, 456, 600 and 1400 kc should be used.

An output meter should be used across the voice coil or output transformer for observing maximum response.

If the circuit is at all disturbed, both the broadcast and long-wave bands must be realigned.

The set's oscillator is higher in frequency than the signal, so images should be observed on the low frequency side of the signals.

The last motion in adjusting trimmers should always be a tightening one, not a loosening one.

Never leave a trimmer with the outside plate so loose that there is no tension on the screw. Either bend the plate up or remove the screw entirely.

Always use as weak a test signal as possible during alignment.

Use a standard dummy antenna for aligning either of the bands. A .0001 mf condenser may be used for either the broadcast or long-wave band dummy antennas.

CHASSIS MODEL AL

Location of Coil and Trimmer Adjustments on the Model AL

The two i-f transformers are in oblong coil cans located on top of the chassis deck. The first i-f transformer is the one behind the variable condenser. The trimmers for these transformers are accessible through holes in the tops of the cans.

The 456 kc wave-trap is mounted on the right side of the front chassis wall. Its trimmer is accessible through a hole in the bottom plate.

The antenna coils for the broadcast and police bands are wound on one form and are mounted underneath the chassis deck below the variable condenser.

The oscillator coils for the broadcast and police bands are wound on one form and are mounted on the rear wall of the chassis deck near the variable condenser.

The trimmers for the broadcast antenna and oscillator coils are located on the variable condenser. The trimmer on the front sections is for the antenna coil.

I-f Transformer and Wave-Trap Alignment for Model AL

Turn the switch clockwise to the broadcast position and rotate the variable condenser to the minimum capacity position. Feed 456 kc to the grid cap of the 6A7 tube and adjust the four i-f trimmers for maximum response. Feed 456 kc to the antenna and adjust the wave-trap trimmer for *minimum* response.

R-f Alignment for Model AL

With the wave-band switch in the broadcast position, clockwise, set the dial pointer at 140. Feed 1400 kc through a standard dummy antenna (a .0001 mf condenser may be used as a substitute) to the antenna lead and adjust first the oscillator trimmer (on rear section of variable condenser) then the antenna trimmer (on front section of variable condenser) for maximum response. The police band is self-tracking and does not require any adjustment.

CHASSIS MODEL ALLW

Location of Coils and Trimmer Adjustments on the Model ALLW

The two i-f transformers are in oblong coil cans located on top of the chassis deck. The first i-f transformer is the one behind the variable condenser. The trimmers for these transformers are accessible through holes in the tops of the cans.

The broadcast antenna coil, the long-wave antenna coil and the 456 kc wave-trap are one assembly mounted underneath the chassis deck to the right of the variable condenser. The trimmers for these coils are accessible through three holes in the top of chassis. The trimmer closest to the front of the chassis is for the 456 kc wave-trap, the central trimmer is for the long-wave oscillator coil and the rear trimmer is for the long-wave antenna coil.

The oscillator coils for the broadcast and long-wave bands are wound on one form and are mounted underneath the chassis below the variable condenser.

The trimmers for the broadcast antenna and oscillator coils are located on the variable condenser. The trimmer on the front section is for the antenna coil.

The dual adjustable padding condenser is mounted on the left side of the rear chassis wall. The hexagon nut is the adjustment for the long-wave band and the screw in the center of this nut is for the broadcast band.

I-f Transformer and Wave-Trap Alignment for ALLW

Turn the switch clockwise to the broadcast position and rotate the variable condenser to the minimum capacity position. Feed 456 kc to the grid cap of the 6A7 tube and adjust the four i-f trimmers for maximum response. Feed 456 kc to the antenna and adjust the wave-trap trimmer for *minimum* response.

Broadcast Alignment for Model ALLW

Rotate the wave-band switch clockwise to the broadcast position and set dial pointer to 60. Feed 600 kc through a .0001 mf condenser. Adjust padding condenser (slotted screw on dual unit) for maximum response. Move pointer to 140. Feed 1400 kc and adjust broadcast oscillator trimmer (on front section of gang) and broadcast antenna trimmer (on rear section of gang) for maximum response. Return pointer to 60, feed 600 kc and readjust padding condenser while rocking variable condenser.

Long-Wave Alignment for Model ALLW

Rotate the wave-band switch to the long-wave position, counter-clockwise, and set the dial pointer to 345. Feed 345 kc through the dummy antenna and adjust the long-wave oscillator trimmer for maximum response and then adjust the long-wave antenna trimmer. Move the pointer to 172.5 kc and feed 172.5 kc. Adjust the long-wave series padder (hexagon nut on dual unit) for maximum response. Return the pointer to 345 kc and adjust the long-wave oscillator and antenna trimmers. Check at 600 kc on broadcast band and readjust if necessary.

		4MZ-588	Dial pointer	.25
		3FZ-351	Escutcheon with crystal (for Models AL-130, AL-168, ALLW-130 and ALLW-168)	1.05
		3FZ-398	Dial crystal (for Models AL-132, AL-169, ALLW-132 and ALLW-169)	.50
		3FZ-399	Clip for dial crystal (for Models AL-132, AL-169, ALLW-132 and ALLW-169)	.01

When ordering replacement parts specify part numbers.

*Item number locates the article on the schematic diagram.

†These trimmers are part of coil assemblies and can not be supplied separately.

‡These trimmers are part of variable condenser and can not be supplied **separately.**

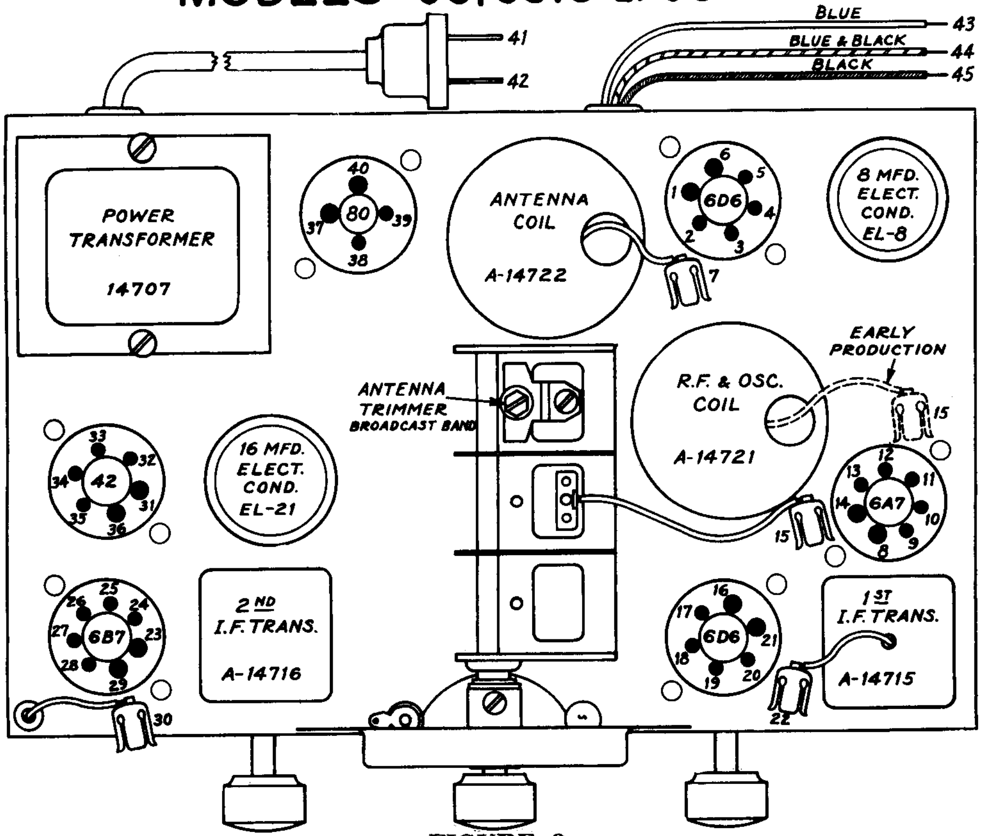

FIGURE 3
TOP VIEW OF THE CHASSIS SHOWING NUMBERS WHICH REFER TO COLUMN ONE OF THE CHART ON THE OPPOSITE PAGE

ALIGNMENT PROCEDURE

To insure the performance the Model 60 is capable of delivering the following instructions should be carefully studied before any alignment adjustments are attempted.

Proper adjustment of the tuned circuits will only be possible through the use of a reliable, all wave, service oscillator and an output meter. Tests have been made in our laboratory on several All Wave service oscillators and it was found that the new Clough-Brengle, continuously variable, Model OC; manufactured by the Clough-Brengle Company, 1134 West Austin Avenue, Chicago, Illinois, was the most satisfactory of the units submitted for the test.

The output meter should be connected across the secondary of the output transformer. The voice coil may be left connected but a larger meter indication will be obtained, on a given signal, if the voice coil is disconnected.

All adjustments should be made with the volume control "full on." Any desired variations in signal strength should be obtained by adjusting the output of the service oscillator.

I. F. ALIGNMENT

All Intermediate Frequency alignment adjustments must be made with the band selector switch in the broadcast (left hand) position.

1. Supply a 456 Kilocycle signal from an accurate service oscillator, to the grid of the 6A7 tube. It is advisable to connect a small condenser, about .00005 Mfd. (50 MMFD) in series with the lead from the service oscillator to prevent the characteristics of the service oscillator circuit from affecting the set.

2. Adjust the grid circuit trimmer condenser of the first intermediate frequency transformer, carefully, for maximum output with minimum input from the service oscillator. The grid circuit trimmer condenser of the first intermediate frequency transformer is controlled by the left hand adjustment screw located on the front of the intermediate frequency transformer can (see Figure 4).

3. Adjust the plate circuit trimmer condenser of the first intermediate frequency transformer, carefully, for maximum output with minimum input from the service oscillator. The plate circuit trimmer condenser of the first intermediate frequency transformer is contolled by the right hand adjustment screw located on the front of the intermediate frequency transformer can (see Figure 4).

4. Adjust the diode circuit trimmer condenser of the second intermediate frequency transformer, carefully, for maximum output with minimum input from the service oscillator. The diode plate circuit trimmer condenser of the second intermediate frequency transformer is controlled by the right hand adjustment screw located on the front of the intermediate frequency transformer can (Grid Trimmer Figure 4).

5. Adjust the plate circuit trimmer condenser of the second intermediate frequency transformer carefully, for maximum output with minimum input from the service oscillator. The plate circuit trimmer condenser of the second intermediate frequency transformer is controlled by the left hand adjustment screw located on the front of the intermediate frequency transformer can (see Figure 4).

6. Much of the sensitivity and selectivity of the receiver depends upon the proper setting of these critical adjustments, for this reason it is necessary to go back over them to make sure they are correct.

R. F. AND OSCILLATOR ALIGNMENT

An alignment jig is available for use in aligning the broadcast and short wave bands of the Model 60. The part number of this jig is 14726, it may be obtained through any Fairbanks-Morse jobber.

BROADCAST BAND

ALIGN AT 1400 INSTEAD OF 1700

1. Place the alignment jig on the front of the chassis. Tune the gang condenser to 1700 Kilocycles. Supply a 1700 Kilocycle signal from the service oscillator to the antenna of the set. Adjust the broadcast band oscillator trimmer (see Figure 3) for maximum output with minimum input from the service oscillator. It is advisable to turn the gang condenser back and forth across the signal while this adjustment is being made to make sure the peak of greatest intensity is obtained. This is necessary to bring the oscillator into track with the R. F. circuit since, in most cases, the R. F. circuit has no trimmer. If the dial reading is incorrect after this adjustment has been made the travelite disc should be adjusted until the reading is correct.

2. Adjust the broadcast band antenna trimmer (Figure 3) for maximum output with minimum input from the service oscillator.

3. Supply a 600 Kilocycle signal to the antenna of the set. Turn the gang condenser to 600 Kilocycles. Adjust the low frequency padding condenser (Figure 4) for maximum output with minimum input from the service oscillator. While making this adjustment turn the gang condenser back and forth across the signal to make sure the peak of greatest intensity is obtained.

SHORT WAVE BAND

1. Supply a 15 megacycle signal to the antenna of the set. Turn the gang condenser to 15 megacycles. Adjust the short wave oscillator trimmer (Figure 5) for maximum output with minimum input from the service oscillator.

2. Adjust the short wave R. F. trimmer (Figure 5) for maximum output with minimum input from the service oscillator. While making this adjustment it is advisable to turn the gang condenser back and forth across the signal to make sure the peak of greatest intensity is obtained. This is desirable because

(Continued from preceding page)

of the reflected effect of the adjustment of one stage on the other.

NOTE: After all alignment adjustments have been completed the set should be tuned slowly from one end of the dial to the other, on the short wave band. If a howl or "squak" is heard at any point, the set is "crossing track." To remedy this condition loosen the short wave oscillator trimmer (Figure 5) slowly and carefully to the point where the howl disappears.

DIAL CALIBRATION IN CABINET

After the set has been aligned in accordance with the foregoing instructions the dial readings will be approximately correct on all frequencies. When the chassis is placed in the cabinet it should be bolted down and any differences in calibration should be adjusted by loosening the set screw in the travelite disc hub and turning the travelite disc until the reading is correct and then tightening the set screw.

GANG CONDENSER PLATES

The adjustment of the slotted end plates on the gang condenser is very critical since it must be accurate on both bands. These adjustments are made in the factory with precision equipment and under no condition should it be necessary to change them by bending plates.

RESISTANCE AND VOLTAGE ANALYSIS

The following chart gives detailed information regarding the resistance from various points to various other points on the chassis. The measured voltage from the various tube socket contacts to ground is also given. When this chart is faithfully followed little difficulty should be experienced in finding almost any fault that may develop.

RESISTANCE TESTS

These tests should be made with an accurate ohm-meter. The speaker should be connected. All tubes should be removed from the set. The volume and tone controls should be full "on." The A. C. line plug must be removed from the A. C. outlet.

VOLTAGE TESTS

These readings should be taken with all tubes in their sockets. The volume and tone controls should be full "on." The antenna should be disconnected. Tune the set to a point where no signal is received.

DESCRIPTION OF ELECTRICAL CIRCUIT—RADIO

Model E-79 employs seven metal envelope tubes to perform the above functions in a superheterodyne circuit, giving the excellent selectivity and sensitivity inherent in this type circuit. The "B" and "C" band coils are wound on a common form, while the "D" band coils have individual forms. Ample undistorted output is obtained through diode detection and two audio amplifier stages.

The signal from the antenna is applied to the control grid of the 6A8 converter tube through the antenna coil, the secondary of which is tuned to the incoming signal by the rear section of the main tuning condenser. The secondary of the coil for the band next lower in frequency to the one in use is short-circuited through a capacitor to prevent absorption of energy at its resonant frequency which falls in the next higher band. (NOTE.—On the schematic diagram, Fig. 1, the center portion of the wave band switch supporting the two shorting lugs rotates simultaneously with the four contact pins.) In the 6A8 tube the incoming signal is combined with the local oscillator signal which is 465 kc. different in frequency. The local signal is generated by the oscillator elements of this tube and the proper frequency difference is maintained throughout the tuning range by the front section of the main tuning condenser in conjunction with the oscillator coil and padding capacitors.

The combination of the signal frequency with the local oscillator frequency in the converter tube produces the intermediate frequency of 465 kilocycles. This particular intermediate frequency is chosen to reduce image response and improve short-wave performance. The intermediate frequency amplifier consists of two 6K7 tubes and three transformers, each with two tuned circuits.

The output of the I. F. amplifier is applied to the 6H6 diode rectifier, which is a combined detector and automatic volume control tube. The direct current component of the rectified signal produces a voltage drop across R-14. This voltage drop provides automatic bias for the R. F. and I. F. amplifier and converter tubes and so gives automatic volume control action. Full automatic bias voltage is applied to the pentagrid converter tube and to the first I. F. amplifier tube. The second I. F. tube is operated on self bias, obtained by the drop through R-8. This enables the second I. F. tube to provide maximum power to the 6H6 diode rectifier.

The manual volume control, R-13, selects the amount of audio signal applied to the grid of the 6F5 audio amplifier tube and this regulates the output of the receiver. The output of the 6F5 tube is resistance coupled to the grid of the 6F6 power amplifier pentode. The plate circuit of the 6F6 is suitably matched to the loud-speaker by means of a step-down output transformer.

The tone control circuit consists of a .003-mfd. capacitor connected in series with a grounding switch S-3 in the grid circuit of the 6F6 output tube. When it is desired to reduce the high frequency output of this receiver the switch S-3 is closed to ground.

Plate and grid voltages for all tubes are supplied by the power supply system employing a 5W4 full-wave rectifier tube which, together with a suitable network of resistors and capacitors, supplies the required voltages and filtering action.

PHONOGRAPH

The record reproducing facilities consist of a high impedance magnetic pickup with its associated balanced tone-arm, a compensated volume control, audio amplifier and loud-speaker of the receiver. In changing from radio reception to phonograph reproduction the phono-radio switch simultaneously disconnects the 6H6 diode from the volume control, connects the phono-pickup across this control, and shorts the 6H6 diode output, rendering the R. F. and I. F. sections inoperative.

The turntable assembly consists of a combination line switch which is simultaneously turned on when the phono-radio switch is turned on the phonograph position. A separate motor switch is provided to permit starting and an adjustable automatic stop.

ALIGNMENT PROCEDURE

The receiver should first be allowed to run for fifteen minutes in order to reach its approximate normal operating temperature. Before making any adjustments, it is wise to determine the correctness of the existing alignment. This may be done by supplying a signal at the alignment frequency from the test oscillator to the receiver and inserting a "Tuning Wand" into the coil involved. The "Tuning Wand" consists of a bakelite rod having a brass cylinder attached to one end, and a small core of finely divided iron compacted into the opposite end. For use on this receiver, it is recommended that a "Tuning Wand" having a flexible center portion be employed. The standard "Tuning Wand" may be adapted by cutting the bakelite rod in half and joining the two resulting pieces with a short length of rubber tubing. By inserting the brass cylinder end into the center of a particular coil, the inductance of the coil is lowered, increasing its resonant frequency. Inserting the iron-filled end into the coil raises its inductance, lowering its resonant frequency. If the circuits are in exact alignment, inserting either end of the tuning wand in any coil will result in a decrease in output. When an increase in signal is obtained with the iron-filled end of the wand, a decrease in resonant frequency of that circuit by increasing its trimmer capacity is indicated. When an increase in signal is obtained with the brass cylinder, a decrease in trimmer capacity is indicated.

Changes Indicated by Wand

Wand	Signal	Trimmer Adjustment Required
Brass cylinder	Decrease	None
Iron filings	Decrease	
Brass cylinder	Increase	Decrease capacity
Iron filings	Decrease	
Brass cylinder	Decrease	Increase capacity
Iron filings	Increase

MODEL E-79

(Continued from preceding page)

ALIGNMENT FREQUENCIES

I. F.	Band "B"	Band "D"	Wave Trap
465 kc.	580 kc. 1500 kc.	18,000 kc.	465 kc

In order to align these receivers properly, it is necessary to have available the following test equipment:

1. A modulated test oscillator with frequencies available of 465, 580, 1500, and 18,000 kc.
2. An output indicator, such as a high resistance a-c. voltmeter with a maximum scale reading of 3 to 5 volts, or a neon lamp output indicator.
3. An alignment tool consisting of an insulating shaft with a small screwdriver blade.
4. A tuning wand.

The location of all trimmer capacitors, as well as socket voltages to chassis, is shown in Figs. 2 and 3.

1. I. F. Alignment

Set the frequency band switch of the receiver to Band "B," short-circuit the antenna and ground terminals and tune the receiver to some point where no signal is heard. Set the volume control at its maximum position and ground the chassis.

The I. F. amplifier is tuned to 465 kc.; set the test oscillator dial at this frequency. Connect the test oscillator output between the converter tube (6A8) control grid and chassis. Connect the output meter across the cone coil of the speaker and adjust the test oscillator output control so that, with the receiver volume control at maximum, a small deflection is observed on the output meter. During both I. F. and R. F. alignment, the test oscillator signal should be maintained at the lowest level that will give a good readable output indication.

Adjust the secondary trimmer of the third I. F. transformer until a maximum output reading is obtained. Maintain a small deflection on the output meter throughout alignment by adjusting the test oscillator output. Next, adjust the primary trimmer of the third I. F. transformer for maximum output. Continue this procedure, adjusting the secondary and primary trimmers, respectively, of the second I. F. transformer. The secondary trimmer of the first I. F. transformer may then be adjusted and, lastly, the primary trimmer of the first I. F. transformer. After completing this procedure, repeat it a second time for final alignment. The I. F. alignment will then be complete.

I. F. Wave Trap Alignment

After completion of the I. F. alignment, with the test oscillator still set on 465 kc., apply this frequency to the antenna post of the receiver through a dummy antenna. This dummy antenna consists of a 400-ohm resistor in series with a 250-mmfd. capacitor and should be connected in series between the test oscillator output and the receiver antenna post. With the 465-kc. signal applied to the receiver antenna post, adjust the I. F. Wave Trap trimmer for *minimum* output indication.

2. R. F. Alignment

First of all, check the position of the dial pointer. To do this, rotate the gang condenser to the maximum capacity position, i.e., plates fully meshed. While in this position, align the pointer with the last black line on the scale by loosening the dial drum set screws and rotating the drum on the gang shaft. Make sure the antenna and ground terminals of the receiver are not short-circuited and connect to them the output of the test oscillator, preferably using the dummy antenna described above between the test oscillator and the receiver antenna terminal. Connect the output indicator across the speaker cone coil.

"D" Band (5.6-18.0 mc.)

Because of the R. F. circuit used in this receiver the "D" band must be aligned first. Set the frequency band switch to the "D" band position by rotating it to its most clockwise position. Tune the test oscillator to 18,000 kc. (18 mc.) and set the dial pointer on the receiver at this frequency. Adjust the "D" band oscillator trimmer, located on the front section of the gang condenser, for maximum output. (NOTE.—The oscillator operates on the *low* frequency side of the incoming signal; therefore adjust the trimmer until the second oscillator peak is reached as the trimmer is *increased* in capacity. A check for the correctness of this adjustment may be made by rotating the gang to the 17,070 kc. calibration mark. If, with increased input from the test oscillator, no signal is detected, the correct oscillator peak has been used.) Keep the receiver volume control at its extreme clockwise position and adjust the test oscillator output to maintain a small reading on the output indicator. When the optimum adjustment on the oscillator trimmer has been obtained, adjust the "D" band antenna trimmer on the rear section of the gang for maximum output while rocking the tuning condenser through the signal.

"C" Band (1.56-5.80 mc.)

No separate trimmers are provided for adjustment of this band. The correct adjustment of the "D" band and "B" band automatically aligns the "C" band. The adjustment procedure for the "B" band follows immediately.

"B" Band (540-1600 kc.)

Set the frequency band switch to the broadcast position. Rotate the gang condenser until the dial pointer indicates the 1500 kc. calibration point, and adjust the test oscillator to this frequency. The "B" band trimmers are located underneath the chassis. (See Fig. 2.) Adjust the broadcast oscillator trimmer for maximum output. This trimmer is the one nearest the volume control. When the oscillator has been peaked, adjust the antenna trimmer for maximum output. Here again, as pointed out previously, it is necessary to maintain a small R. F. input from the test oscillator to avoid erratic action of the output indicator due to automatic volume control action.

Now set the test oscillator at 580 kc. and tune the receiver to that frequency. Slowly, rocking the tuning condenser back and forth through the signal, adjust the 580-kc. padding capacitor for maximum output. When this has been done, return to 1500 kc. on the receiver and test oscillator and recheck the alignment at that frequency for maximum output. The broadcast band should now be in alignment.

ADJUSTMENT OF DIAL MECHANISM

The dial mechanism is rigidly mounted to the frame of the tuning condenser by means of two removable, self-tapping screws. The complete assembly is rubber-mounted on rubber cushions at the points of support.

The dial mechanism consists of the following parts:

1. Dial Scale.
2. Reflector.
3. Mounting Bracket.
4. Dial Pointer.
5. Dial Pointer Drive Cable.
6. Drive Cable Tension Spring.
7. Two Idler Pulleys.
8. Cable Drum (mounted on condenser shaft).
9. Vernier Drive.

To Replace Dial Scale or Reflector

Twist the supporting tabs at either end of the scale into alignment with the slots and remove the scale and reflector. Disengage the old scale from the reflector and insert the new scale in its place with the mounting slots in alignment. Replace scale and reflector on the bracket and twist the inner corner of each tab over the outer edge of the slot with which it is engaged.

To Replace Dial Pointer

Disengage the clamping tabs at the rear of the slider from the cable by bending down the center one of the three tabs. Place the new pointer on the scale in a position to agree with the calibration. Secure the pointer to the cable by pinching together the clamping tabs with enough pressure to hold firmly without damaging the cable.

To Replace Dial Pointer Drive Cable

Remove the dial pointer as explained above and set the tuning condenser gang for maximum capacity (plates all meshed). Remove the old cable from the cable drum and engage one end of the new cable with the upper end of the keyhole slot in the drum circumference. Draw the cable clockwise over the top of the drum and through the notch in the right-hand end of the bracket, then around the idler pulley and to the left, close to the scale, passing around the idler pulley mounted in the tension spring and clockwise over the top of the drum. Note that the pulleys are held in place by the tension on the cable. Release the spring tension on the drive cable by pressing inwardly on the tension idler pulley, then insert the free end of the cable in the keyhole slot.

To Replace Cable Drum

Remove the dial scale and reflector bracket as explained elsewhere. The cable drum can then be removed by loosening the two set screws in the hub. When replacing the cable drum, set the condenser so that all plates are fully meshed. The right-hand end of the radial slot in the drum web should then be approximately $\frac{1}{16}$ of an inch clear of the tuning knob shaft bearing bushing. Locate the cable drum axially on the condenser shaft so as to clear the heads of the two mounting bracket screws.

To Replace Mounting Bracket

Remove the dial scale and reflector bracket, also the cable drum. Access may be had to the mounting bracket self-tapping screws when this is done. In replacing the mounting bracket it is necessary to insure that the lower edge of the bracket is parallel to and at height above the top of the cabinet chassis support panel of 5¾ inches.

To Adjust the "Automatic Vernier" Drive

The vernier drive used on this receiver includes a planetary reduction unit equipped with a clutch which automatically changes the reduction ratio. This clutch consists of a sleeve mounted on the knob shaft. To adjust, loosen the locking screw and move the sleeve axially along the shaft until the cam surface in the end of the sleeve engages with the pin in the knob shaft. This engagement should take place at a point on the cam surface as near to the stop as possible and still allow complete release of the clutch.

PHONOGRAPH

The phonograph mechanism in this receiver has been designed to be simple and foolproof. Under normal operating conditions, service difficulties should be negligible. Occasionally, however, certain adjustments may be required. These adjustments are explained in the following paragraphs.

SOCKET VOLTAGES

Measured at 115 volts supply. No signal input. Volume control maximum. Voltmeter 1000 ohms per volt; measurements taken on highest scale giving accurate readable deflection.
*Supply voltage minus drop in load resistor.

MOTOR ADJUSTMENTS

The speed of the turntable motor is controlled by a governor which allows correct adjustment of the turntable rotation to 78 revolutions per minute. A pointer is provided under the turntable and the base plate is marked "F" and "S" to indicate direction to move pointer for faster or slower operation. A check of the turntable rotational speed may be made by placing a piece of paper under a record on the turntable and counting the number of times it rotates

(Continued on next page)

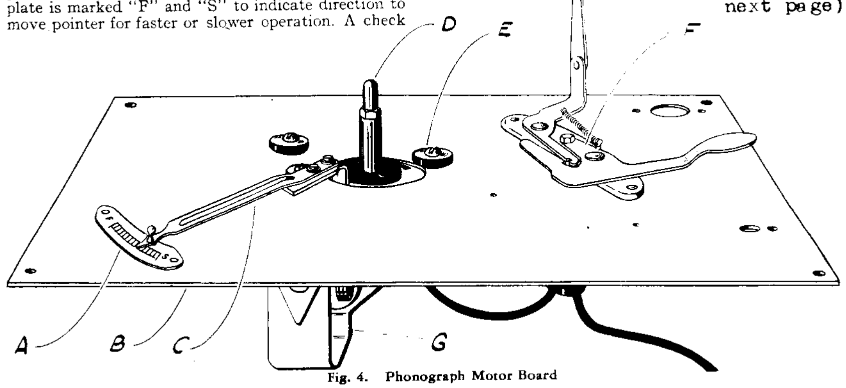

Fig. 4. Phonograph Motor Board

GENERAL ELECTRIC COMPANY

MODEL E-79

(Continued from preceding page)
past a fixed point in one minute.

There is another type motor used in some sets of this model that does not have a speed control on the base plate. The speed of this motor is regulated by an adjustable collar on the governor. This is adjusted to 78 RPM at the factory and should not require attention.

The motor bearings and gears are properly lubricated for long operation under normal weather conditions. If the motor chatters or runs uneven, place a few drops of light machine oil on the governor felt.

TRIP MECHANISM

The trip mechanism is of simple design and consists of a latch bar connected to the motor switch and a trip lever. The latch is held closed by means of a spring between the latch bar and the trip lever. Be sure the parts work freely without binding.

The trip is actuated by an adjustable arm on the trip lever. When the eccentric groove in the record swings the tonearm back and forth, it pushes the latch out of engagement.

MAGNETIC PICKUP

The pickup used in the phonograph is of an improved design. It is horizontally mounted in the tonearm and is held by a single set screw. The horseshoe magnet is fastened to the pole pieces by means of a set screw and clamp. The armature is centered by means of a split rubber block, which also provides a damping effect on the armature movement. The frequency response is uniform over a wide range.

Service operations which may be necessary on the pickup are as follows:

CENTERING ARMATURE

Refer to Fig. 6 showing the pickup inner structure. The armature (11) is shown in its proper relation to the magnet pole pieces, i.e., exactly centered. Whenever this centering adjustment has been disturbed, the screws (5) and (10) should be loosened and the armature rubber cushion (12) adjusted so the vertical axis of the armature is at right angles to the horizontal axis of the pole piece (8). Adjust the tension on the armature until there is a slight rocking motion. The spacing between the pole pieces and armature should be .0125 inch on each side.

DAMPING BLOCK

The top projection of the armature is imbedded in a rubber block (6) attached to the top of the pole pieces. This damping block acts as a mechanical filter to eliminate undesirable resonances and to cause the frequency reponse to be uniform. Should it be necessary to replace this damping block, it may be done by removing the yoke (7).

REPLACING COILS

In case of an open or shorted pickup coil, the method of replacement is obvious upon inspection of the pickup assembly and by study of Fig. 6. It is important to adjust the armature as previously explained after reassembly of the mechanism. Only rosin core solder should be used in soldering the coil leads to the lugs.

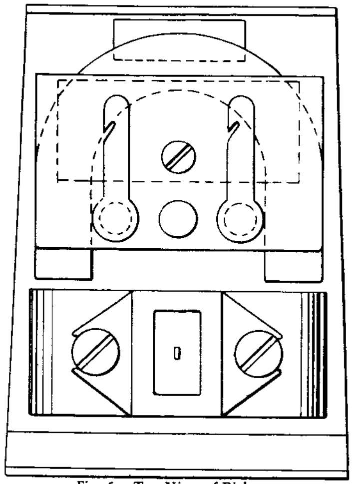

Fig. 5. Top View of Pickup

MAGNETIZING

The loss of magnetization will not occur when the pickup has received normal care, due to the fact that the magnet and pole pieces are one unit and the magnetic circuit remains closed at all times. When the pickup has been mishandled, subjected to a strong AC field, jolted or dropped, there may be an appreciable loss of magnetic strength, in which case it will be necessary to remagnetize the entire structure. This should be done by placing the pickup assembly on the poles of a standard pickup magnetizer and changing the pickup in accordance with the instructions accompanying the magnetizer. It is preferable to check the polarity of the pickup magnet and to remagnetize it so that the same polarity is maintained.

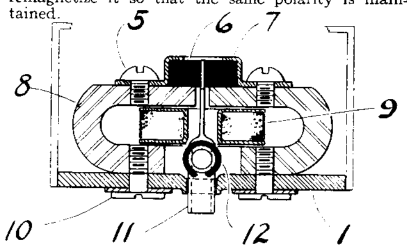

Fig. 6. Front View of Pickup

REPLACEMENT PARTS

INSIST ON GENUINE FACTORY-TESTED PARTS, WHICH MAY BE PURCHASED FROM AUTHORIZED DEALERS

Stock No.	Description	List Price
*RB-026	BOARD—Antenna & Ground Terminal Board	$0.10
RB-040	BOARD—Terminal Board Near Oscill. Padder	.10
RB-054	BOARD—Terminal Board on Front Wall near Volume Control	.10
RB-134	BRACKET—Dial Light Bracket	.15
RB-135	BRACKET—Dial Support Bracket	.15
RC-014	CAPACITOR—.003 mfd., 200 volt, Paper (C-22)	.25
RC-017	CAPACITOR—.0045 mfd., 200 volt, Paper (C-16)	.25
RC-018	CAPACITOR—.004 mfd., 600 volt, Paper (C-19)	.30

8-D CHASSIS TUBE LAYOUT

FIGURE 1

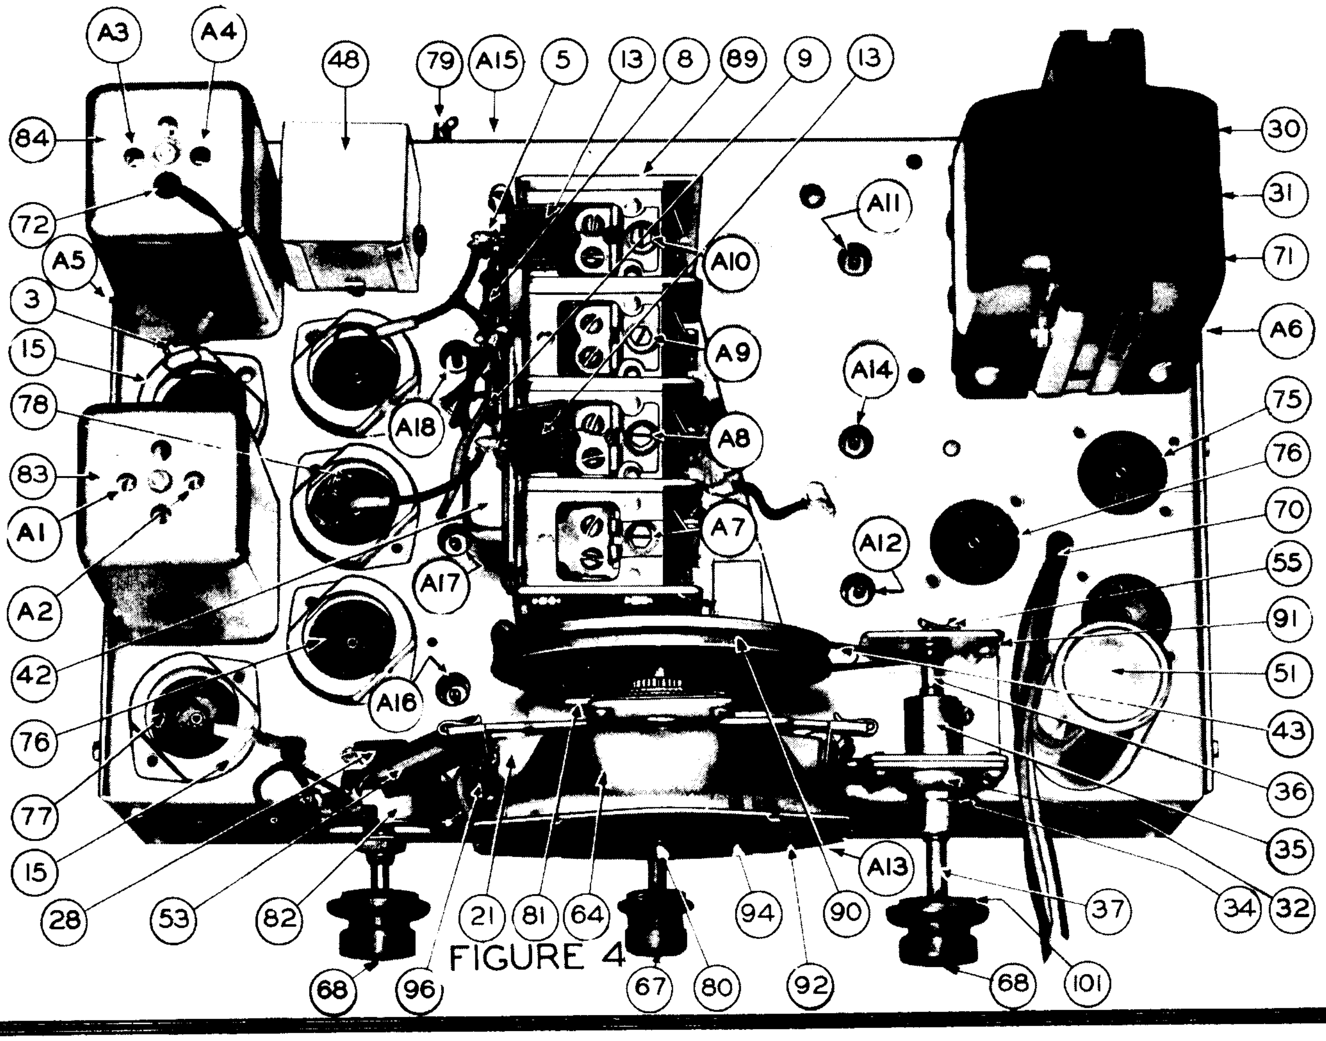

FIGURE 4

GENERAL HOUSEHOLD UTILITIES COMPANY

MODELS 8D, 8DX, 8DZ & 861

Chassis 8D —115 volt 50-60 cycle

Chassis 8DX—115 volt 25-50 cycle

Power Consumption 75 watts.

Chassis 8DZ { 110—135—220—250 volt; 50-60 cycle }

Tubes—2-6D6, 1-6A7, 1-75, 1-42, 2-76, 1-80

The following characteristics apply to the Grunow Radio—Chassis Type 8D:

This model is an 8 tube Super-Heterodyne All Wave (550 to 21,000 KC) Receiver, using 1-6D6 tube as an R. F. Amplifier, 1-6A7 tube as a 1st Detector or mixer—being electronicly coupled to a 76 Oscillator tube, 1-6D6 tube as an I.F. amplifier with the 1st I.F. Transformer of the Bi-Selector type and both 1st and 2nd transformers tuned to 455 K. C. A 75 tube (double diode high mu Triode) is used as a diode detector, delayed Automatic Volume Control (AVC) and a high gain audio amplifier. The 42 output tube receives its bias through the voltage drop produced in the tapped speaker field. A type 76 tube is used as a Signal Beacon or beat oscillator. Plate voltage to the Signal Beacon being applied by closing the switch on the tone control. The rectifier tube is an 80, the output of which is well filtered through the choke action of the speaker field and the 8, 16 and 18 mfd. electrolytic condensers.

The broadcast section of the receiver consists of the following 4 variable tuned circuits: R.F. input, bi-selector, mixed input and oscillator. These circuits are tuned with a 4-gang variable condenser of rugged construction.

The short wave section of the receiver consists of 3 variable tuned circuits, the bi-selector being cut out to prevent losses when the receiver is working at the higher frequencies.

The Signal Beacon is a beat oscillator using a 76 tube, and is a feature of the 8D chassis. When this tube is brought into operation it acts as a local oscillator, with a frequency of 455 K.C. The signal of this oscillating circuit is fed into the I.F. circuit through a short lead that acts as a radiator and beats against the incoming signal at the I.F. frequency. The presence of a station's signal will be indicated by a high pitched "whistle," becoming lower in pitch as "resonance" or exact tuning is approached. The Signal Beacon is also used to receive telegraph or continuous wave signals.

A sensitivity Control is incorporated in the 8D chassis and consists of a switch on the rear of the Chassis. This switch when in position No. 1 reduces the sensitivity by allowing the total resistance of 850 Ohms to be used as a grid bias on the 6D6 R.F. tube and the 6A7 1st Det. tube. When on position No. 2, the bias is changed to 250 Ohms by grounding out the 600-Ohm section and increasing the sensitivity of the receiver. It will be noted by referring to schematic diagram that this control is effective only on the "D" or broadcast range.

The remainder of the circuit is typical and has been designed along the lines of what is considered the best engineering practice to date. Parts are all oversize and of the finest quality.

SERVICE DATA

Continuity and Voltage

Continuity and voltage readings should be taken from the underside of the Chassis. The values given on the schematic diagram are average and allow the service man to make a quick check of the Chassis Constants. The socket layouts given on the schematic diagram show each socket from the underside.

The Range Switch

In servicing the 8D Receiver consider the radio frequency end as four different and distinct radios:

One working from 550 to 1500 K.C. (D Range)
One working from 1500 to 4200 K.C. (C Range)
One working from 4100 to 10000 K.C. (B Range)
One working from 8500 to 21500 K.C. (A Range)

These four radios are put into operation as desired by means of the Range Switch.

When on position "A" the short wave coils covering the range from 8,500 to 21,500 K.C. are connected into the three tuned circuits of the receiver, one coil as an R.F. Transformer, one as the Detector Coupler, and one as the Oscillator Transformer.

On position "B" the 4100 to 10,000 K.C. coils are put into operation.

On position "C" the 1500 to 4200 K.C. coils are shunted across the 550 to 1500 K.C. coils in such a manner as to lower the total inductance of the combined coils and reduce the losses caused by open end coils.

On both the "C" and "D" positions, four coil sets are put into the circuit and the receiver operates as a four-tuned circuit radio. On all four ranges the receiver works at maximum sensitivity and selectivity. All coils and condensers are of such construction that atmospheric and temperature changes have minimum effect.

Each circuit is completely shielded from each other, and the complete range switch and coil assembly may be removed for inspection or repair.

ALIGNMENT

Do not attempt to align the 8D Chassis without the proper equipment. Alignment condensers are shown in the accompanying illustrations and are numbered in order of procedure.

1. EQUIPMENT

A—Test Oscillator.

A modulated oscillator capable of producing signals at 455 K.C.—600 K.C.—1400 K.C.—3700 K.C.—10 M.C. and 18 M.C. is necessary for alignment of the 8D Chassis.

B—Insulated screw driver—(All bakelite or fibre) about 6" long.

C—Output Meter.

This may be any of the standard output meters on the market, but should be sufficiently sensitive to provide a good deflection at low signal strength, and should also incorporate an adjustable shunt so that extremely strong signals may be read.

D—Coupling Means.

Coupling Condensers of 200 mmf., .25 Mfd., and a 400 Ohm resistor should be used when coupling oscillator to receiver during alignment as specified in the following paragraphs.

E—The receiver should be aligned in a location free from local interference (man-made static)—as high frequency disturbances will cause difficulties when the short wave section is being adjusted. (A screen room is to be recommended.)

2. DIAL SETTING

Turn dial knob until condensers are fully meshed. The dial pointer (hour hand) should be on the horizontal line of the dial, pointing to 9 and 3 o'clock. The minute hand should be at 12 o'clock or in a vertical position.

3. I. F. ALIGNMENT

Connect signal lead of test oscillator to grid of the 6A7 (1st Detector Tube) through .25 Mfd. Condenser. Connect the ground lead to the chassis.

A—Set Dial pointer to 1400 K.C. and range switch on position D.

B—Place test Oscillator in operation at 455 K.C. Turn receiver volume control and tone control to maximum.

C—Attenuate test oscillator output to lowest valve consistent with obtaining a readable indication on output meter.

D—Adjust five I.F. Trimmers, A1-A2-A3-A4-A5 (Fig 4), located on the I.F. transformers on top of chassis (2 trimmers are on top of each transformer and one, the Bi-Selector, is at the lower side of the 1st I.F. Transformer), until maximum output is obtained. During alignment, maintain as low a value of signal as will allow obtaining of accurate adjustment.

E—Turn the tone control counter clockwise until the Signal Beacon switch snaps on.

F—Adjust Signal Beacon trimmer A6 (Fig. 4), which is located on right hand face of Chassis, to zero beat with the 455 K.C. incoming signal.

4. 1400 K. C. ALIGNMENT

A—Place test oscillator in operation at 1400 K.C.

B—Turn dial pointer to 1400 K.C.

C—Turn range switch to range D.

D—Adjust broadcast oscillator trimmer A7, which is on the variable condenser section nearest the dial to maximum output. (It may be necessary to reduce the capacity of the 600 K.C. padder (A11) to about half its capacity, before the oscillator will peak at 1400 K.C.).

E—Adjust 1st Det. Trimmer A8 (Fig. 4), which is the second from front on top of variable condenser.

F—Adjust Bi-Selector Trimmer A9 (Fig. 4), which is the third from front on top of variable condenser.

G—Adjust Antenna Trimmer A10 (Fig. 4), which is the fourth from the front on top of variable condenser.

5. 600 K. C. ALIGNMENT

A—Place test oscillator in operation at 600 K.C.

B—Tune in signal to maximum (this point does not have to be exactly at 600 K.C. dial setting).

C—Adjust the 600 K.C. Padding Condenser A11 (Fig. 4) (which is on top of chassis on right-hand side third from front as you face chassis) in direction of signal increases. At same time rock the tuning condenser back and forth through resonance while adjusting padding condenser until maximum output is obtained.

D—Readjust Oscillator Trimmer (A7) for maximum output with pointer and signal set at 1400 K.C. (see 1400 K.C. Alignment).

6. 3700 K. C. ALIGNMENT

A—Connect signal lead of test oscillator through 200 Mmf. condenser to antenna binding post.

B—Connect the test oscillator ground lead to the ground post of chassis.

C—Turn range switch to range "C" and set dial pointer to 3700 K.C.

D—Adjust the 3700 K.C. Oscillator Trimmer A12 (Fig. 4) (which is the first of the three located on top of chassis on the right-hand side as you face it) in direction of signal increase. At same time work the tuning condenser back and forth through resonance while adjusting trimmer condenser until maximum output is obtained.

7. 10 M. C. ALIGNMENT

A—Connect signal lead of test oscillator through 400 Ohm resistor to antenna binding post of chassis.

B—Connect the ground lead to ground terminal of chassis.

C—Set range switch to range "B" and turn dial pointer to 10 M.C.

D—Place Test Oscillator in operation at 10 M.C.

E—Adjust Set Oscillator Trimmer A13 (Fig. 4), (located on front face of chassis).

F—Adjust Detector Trimmer A14 (Fig. 4), (located on right-hand side on top of chassis, second from front).

G—Adjust Antenna Trimmer A15 (Fig. 4), (located on rear face of chassis).

8. 18 M. C. ALIGNMENT

A—Set Range Switch on Range "A".

B—Place Test Oscillator in operation at 18 M.C.

C—Turn Dial Pointer to 18 M.C.

D—Adjust Set Oscillator Trimmer A16 (Fig. 4), (located on top of chassis on left of gang condenser, first from front).

E—Adjust Detector Trimmer A17 (Fig. 4), (located second from front on top of chassis on left-hand side).

F—Adjust Antenna Trimmer A18 (Fig. 4), (located third from front on top of chassis on left-hand side).

G—It may be necessary to rock the variable condenser back and forth through resonance while adjusting the Detector (A17) and the Antenna (A18) for maximum output.

WHSS18	Shielded antenna wire (2 ft.)	.20

INTERNATIONAL RADIO CORP.

MODEL K-60

Motor Noise Suppression

Every automobile motor generates high frequency electrical interference due to its ignition coil, distributor, and spark plugs. To satisfactorily operate an automobile receiver this motor interference must be suppressed. A standard suppressor kit is supplied with each receiver. Each car, however, is a somewhat different problem, and the service man must use his own ingenuity in addition to following definite instructions.

First, apply the standard suppression parts furnished. A suppressor should be placed on each spark plug and one in the center lead of the distributor. Keep as close to motor as possible. Next, place condenser on generator to eliminate the high pitched "whine" from this source.

Afer standard suppression has been applied check the receiver for chassis pick-up. The antenna wire should not be connected during this test. Turn volume control to FULL ON position and start motor. If any motor noise is heard in the receiver it is originating through the battery circuit. It will be necessary to eliminate this interference before attaching the antenna. One or more of the following should correct this condition. Try one at a time and check for reduction in interference.

Attach condenser (such as supplied for generator) from ammeter to ground (instrument panel).

Attach condenser from battery side of ignition coil primary to ground. Do not put a condenser on the distributor side of the coil primary as this will affect motor operation.

Reduce the gap between the distributor rotor and contacts. This may be done by carefully peening out the end of the distributor arm or building it up with solder. Put the distributor arm and distributor cap back in position but do not clamp the cap down. With ignition OFF turn the motor over slowly with its crank to determine if the rotor arm is touching the contacts. The gap should be small (.001" to .004") but under no circumstances should it touch or cut into the stator contacts.

Badly worn or burned breaker points will cause interference as will also a leaky or defective distributor condenser.

If high and low tension leads from the coil to distributor are run together they should be separated. The low tension lead may be shielded if necessary with copper braid and this shielding bonded to the bulkhead at one end and the motor at the other.

If the coil is located inside the driving compartment it may be necessary to shield the high tension lead from the coil to the point where it passes through the bulkhead. The shielding should terminate at least one and one-half inches from the coil terminal. The shielding should be bonded to the bulkhead and in some cases to the instrument panel also. Wherever possible it helps to move the coil to the motor side of the bulkhead or mount it on the motor.

Cars with rubber mounted motors must have the motor bonded to the bulkhead at the rear and the chassis at the front. Use heavy copper braid for bonding and be sure it is long enough to allow for motor vibration. In many cars without rubber mounted motors it is also very helpful to bond the motor in this manner. Insulated bodies should be grounded in the same way.

A remedy which is effective on one car may not be on another car of the same make and model. Noise suppression is largely a process of elimination. The above suggestions if carefully followed should eliminate chassis pick up of interference. In very stubborn cases it may be necessary to bond the various control rods and wires to the bulkhead at the points where they pass through into the driver's compartment Sometimes reversing the primary leads on the coil will help.

When chassis pickup is eliminated the antenna lead should be connected. The shielding on the antenna lead should be grounded at the point where it enters the windshield post. The hood must be clamped down to prevent radiation. Any motor noise now heard is being picked up by the antenna. The dome light wiring may be bringing the interference up to the antenna. In this case it will be necessary to bypass the dome light wire with a condenser at the point where the dome light wire enters the windshield post. If this is not sufficient a so called dome light filter should be connected in the wire at this point. The dome light filter consists of a condenser and RF choke.

Interference may be picked up by the antenna from the following if poorly grounded: steering column, pedals, brake lever, instrument panel, windshield wiper tube, body, motor hood, etc. The wiring to electrical devices such as cigar lighter, electric clock, electric windshield wiper, etc., may be carrying interference. Bypassing these to ground should correct this condition.

If all the usual methods of eliminating motor noise have been tried without obtaining quiet operation check for the following: weak storage battery, leaky or poorly adjusted spark plugs, leaky distributor cap or case, arc in ignition coil between secondary and primary or ground, leaks in high tension wiring to plugs, distributor or coil.

In some cars having wooden floor boards it may be necessary to cover the floor boards with metal screen or a metal plate and ground to the car frame.

Service

The following headings cover briefly the probable causes and remedies encountered in servicing

1. INOPERATIVE
   - (a) Examine fuse and replace if open. If fuses continue to blow, a probable short circuit exists.
   - (b) Loose or corroded power connection.
   - (c) Defective tube.
   - (d) Defective buzzer.
   - (e) Tube out of socket
   - (f) Broken connection or short circuit in chassis.
2. WEAK
   - (a) Grounded or partially grounded antenna.
   - (b) Defective tube.
   - (c) Weak storage battery.
   - (d) Broken connection.
3. DISTORTION
   - (a) Defective tube.
   - (b) Defective speaker.
4. RATTLES
   - (a) Loose instruments, wires, rods, etc., on instrument panel or bulkhead.
   - (b) Loose speaker or case screws.
   - (c) Loose tube shields.
   - (d) Defective speaker.
5. INTERMITTENT
   - (a) Loose power connection.
   - (b) Grounded or partially grounded antenna or lead-in.
   - (c) Poor contact in fuse container.
   - (d) Defective tubes.
   - (e) Loose connection or short in chassis.
6. MOTOR NOISE
   - (a) Defective suppressor.
   - (b) Defective condenser at generator, coil, ammeter, etc.
   - (c) Loose bonding of any shielding, bonding, etc., which was applied at time of original motor noise elimination.
   - (d) Open ground to lead-in shielding.
   - (e) Burned or pitted distributor rotor or breaker points or defective condenser across breaker points.
   - (f) Leaky distributor head.
   - (g) Leaky ignition wiring or defective coil.
   - (h) Defective dome light filter.

TO REPLACE DIAL LIGHT

Dial light socket assembly may be pried out from the rear of control head by using a small screw driver or knife blade.

AVERAGE TUBE VOLTAGES:

Measurements made from indicated points to chassis. Battery voltage 6 volts.

POSITION	TUBE	Ef	Ek	Eg	Eg	Eg	Ep

f—Filament; k—Cathode; g—Control Grid; g—Suppressor Grid; g—Screen Grid; p—Plate; *—Depends on applied signal strength.

Balancing and Aligning

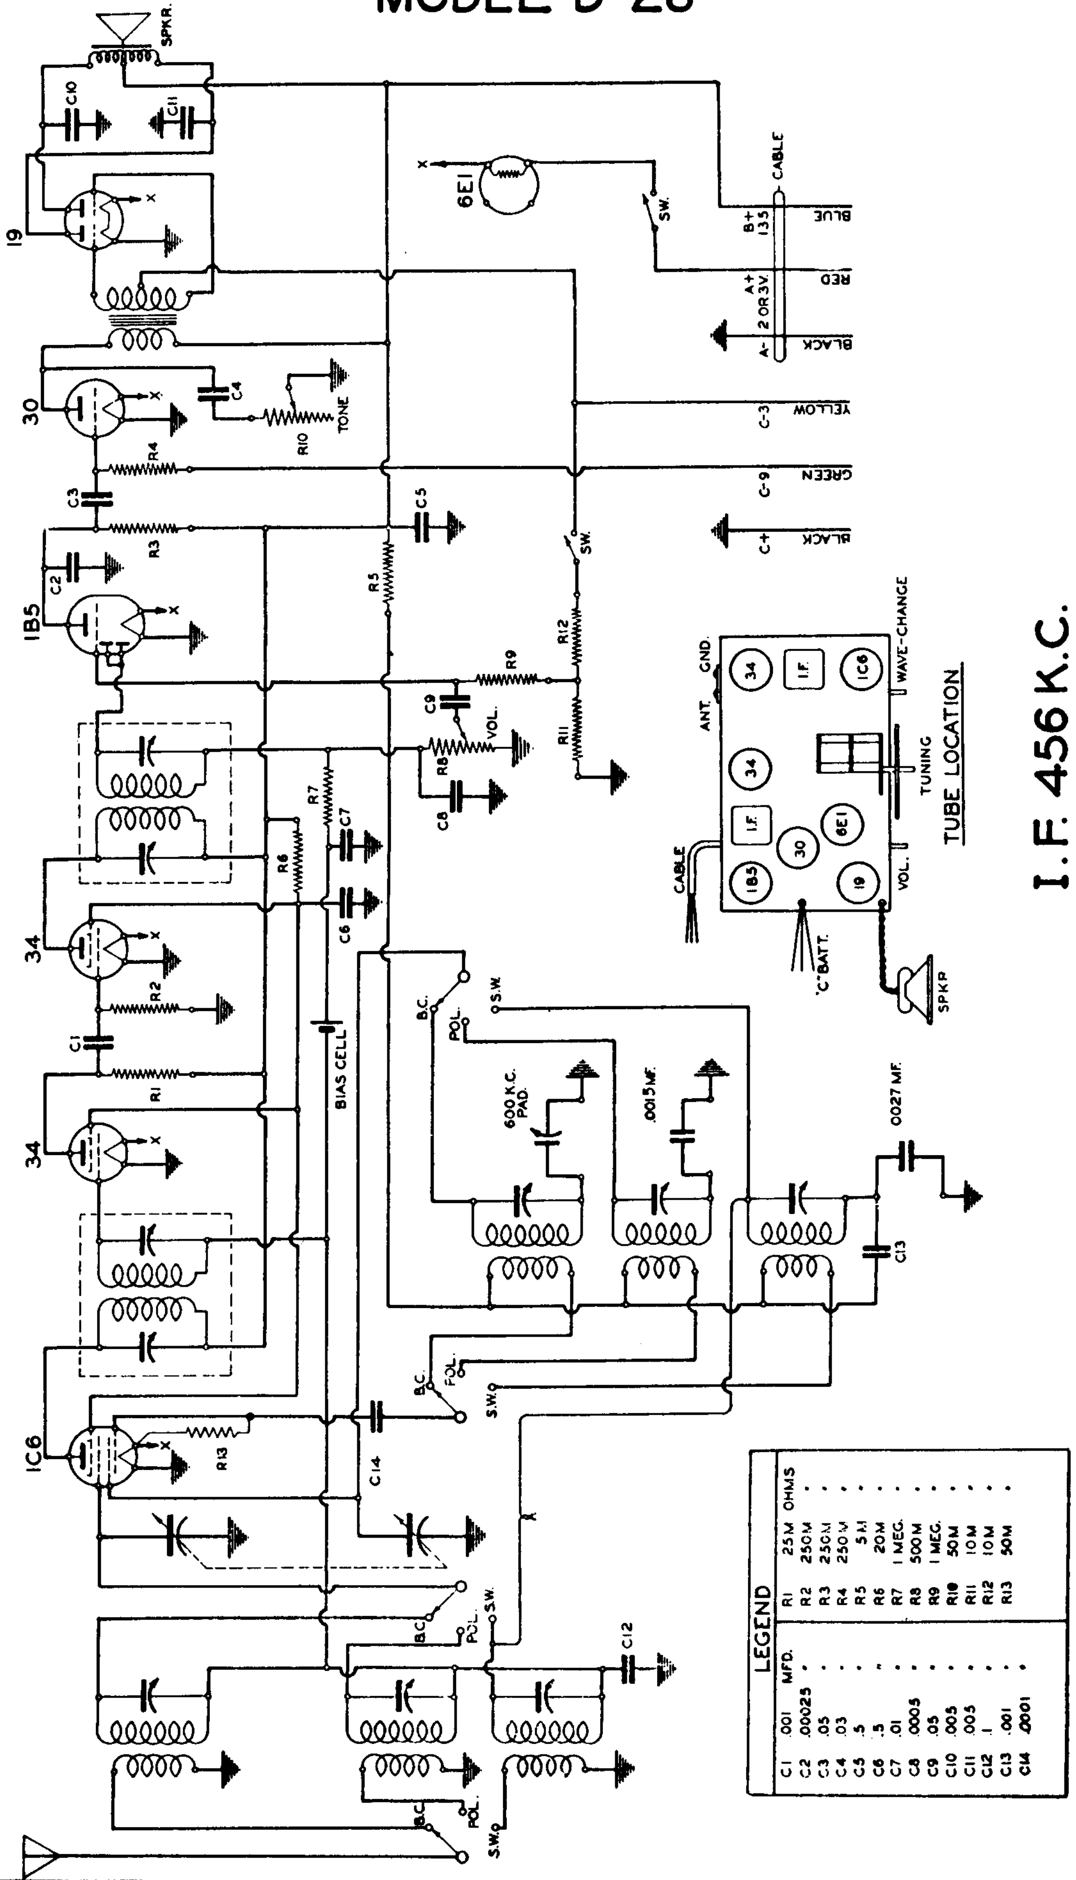
Each automobile radio is carefully balanced on accurate oscillators before leaving the factory. If it is necessary to rebalance because of part changes or other causes a good test oscillator capable of delivering modulated signals at 262½, 1500 and 600 Kc. will be needed. The customary audio out-put meter may be used IF the out-put of the test oscillator is weak enough to get below the A.V.C. action. Otherwise a microammeter will be needed to measure the A.V.C. voltage developed. It should be connected from ground to the junction of two 100M resistors and one condenser in the center bottom of the chassis.

To balance the I.F. circuits, attach the antenna wire to the test oscillator. Short out the oscillator section of the tuning condenser in the radio by inserting a thin piece of metal between the plates. Set the test oscillator to 262½ Kc. and adjust the trimmers on the I.F. transformers for maximum output. Go over all four adjustments at least twice for accuracy.

Next set the test oscillator at 1500 Kc. and open the tuning condenser until it is tuned to the test signal as indicated by maximum output. Adjust the small trimmers on top of the condenser gang for maximum output.

Set the test oscillator at 600 Kc. and, while rocking the tuning condenser slowly back and forth across this setting, adjust the padder condenser for maximum output. Go over the adjustments at least twice for accuracy.

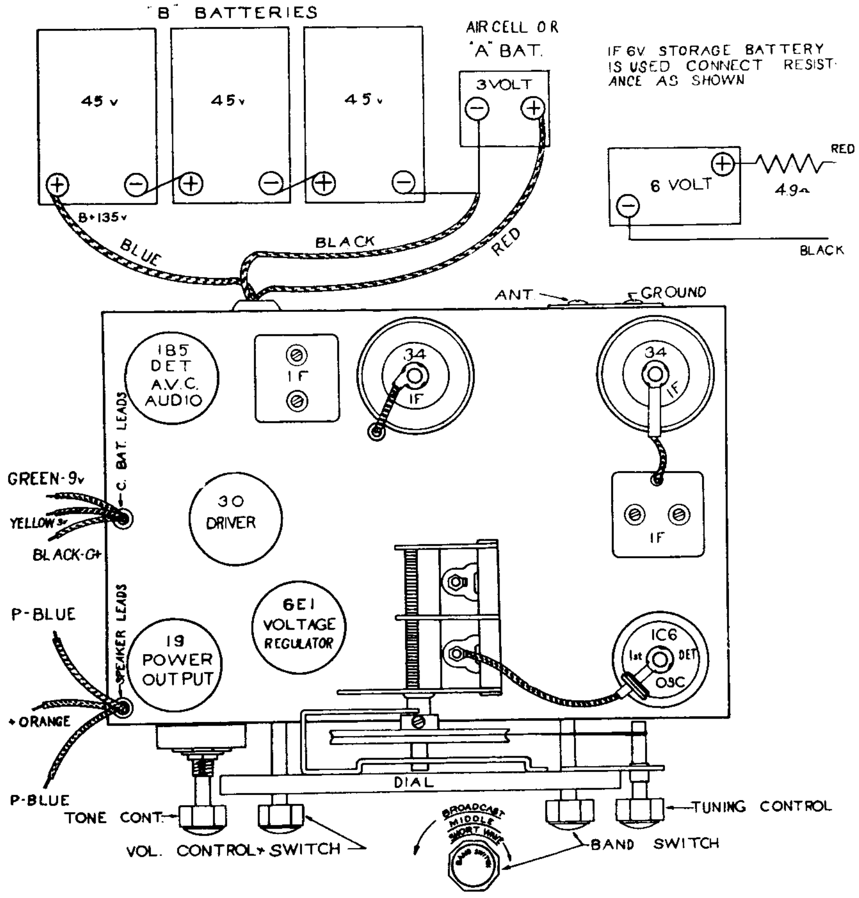
LAFAYETTE RADIO MFG. CO.
MODEL D-28



LAFAYETTE RADIO MFG. CO.

MODEL D-28

The frequercy range covered by this receiver is as follows: Broadcast band 537 KC to 1730 KC. Middle wav band 1.8 megacycles to 5.7 megacycles, short wave band 5.7 megacycles to 18.3 megacycles and any of thes bands are selected at will by a flip of the band change switch. To the left for broadcast. Center for 75M c police. To the right for short wave.



SERVICE INSTRUCTIONS

When set fails to perform properly, always check the voltage of the batteries. Run down batteries wi cause weak and poor reception.

Noises may develope from defective tubes and condensers.

This set has been carefully aligned at the factory, but if realignment should become necessary, the followin procedure should be followed.

Use a test oscillator and connect an output meter from plate to plate of the 19 output tube.

I. F. Alignment:

Connect the oscillator through a .1 condenser to the grid of the 1C6 tube and set the oscillator to 456 kilocycles. Peak each I. F. stage to resonance as indicated by maximum output on the output meter.

R. F. Alignment:

With the wave change switch in the broadcast position, set the oscillator to 1700 kilocycles and connect in series with a .00025 condenser to the antenna of the receiver. Rotate the variable condenser to the 1700 setting of the dial and adjust the trimmer condenser of the broadcast oscillator to resonance. This trimmer is located on the right side of the chassis, second position from the front. Reset the test oscillator to 1400 kilocycles and adjust antenna trimmer located under the chassis. Now set oscillator to 600 kilocycles and adjust padder located on top of the chassis. Check alignment at 1000 kilocycles.

For aligning the police band, set test oscillator to 5 megacycles and switch to the police band position on the set. With the condenser rotated to this frequency setting as indicated on the dial, adjust oscillator trimmer located on the right side of the chassis, first position from the front. Now adjust antenna trimmer located on the front of the chassis, left position, to resonance.

The short wave band is aligned by setting the condenser to 18 megacycles and adjust the oscillator trimmer located on the right side of the chassis, third position from the front to resonance with an 18 megacycle signal from the test oscillator. Turn dial to 16 M. C. Set test oscillator to 16 M. C. and adjust antenna trimmer through right hand hole in front of chassis, rocking variable condenser slightly back and forth to get maximum peak.

LAFAYETTE RADIO MFG. CO.

MODELS D-30 & D-31

The frequency range covered by this receiver is as follows: Broadcast band 540 KC to 1550 KC; middle wave band 1.5 megacycles to 4.6 megacycles. Short wave band 5.8 to 16.5 megacycles. These ranges are selected by turning the range switch knob. Turning this knob to the left switches to the broadcast band; in the center, to the middle wave band; and to the right, to the short wave band.

SERVICE INSTRUCTIONS

In case of faulty operation of the receiver, first make sure that the antenna and ground are in good condition and properly attached to the receiver. Then determine if any of the tubes are faulty. In case of trouble within the receiver itself, the circuit diagram shown on the opposite page will be useful to the service man in locating and correcting the trouble.

I. F. Alignment:
Connect a test oscillator or signal generator through a .1 mfd. condenser to the grid of the 6A7 tube and set the oscillator to 456 KC. Use an output meter connected to the speaker if possible, to obtain the most accurate adjustments. Peak each I. F. stage to maximum response, reducing the output of the oscillator as far as possible for final adjustments.

R. F. Alignment:
With test oscillator set at 1400 KC, feed this signal into the antenna lead of the receiver through a .00025 condenser. With band switch in broadcast position, set the dial pointer to 1400 KC.
Adjust the broadcast oscillator trimmer (the small trimmer attached to the coil located approximately in front of the range switch) to peak at 1400 KC. Next adjust the trimmer on the preselector (this coil is mounted in the center at the front of the chassis). Then adjust the one trimmer on top of the gang condenser.

Now set the test oscillator to 600 KC. Adjust the broadcast padder condenser (the ceramic-base condenser adjustable through the right hand end of the chassis) in this manner: Move the dial slowly and repeatedly back and forth across the signal while adjusting the padder. Adjust for maximum gain.
Now set the range switch to middle wave band. Adjust the test oscillator to 4000 KC, and set the dial to 400 KC. Adjust the two trimmers located on the tops of the two short wave coils, on top of the chassis, for maximum gain.

Now set the range switch to the short wave position, adjust the test oscillator to 15 megacycles. Turn the dial to read 15 megacycles. Adjust for maximum gain the two trimmers located at the bases of the short wave coils.

MONTGOMERY WARD & CO.

MODELS 62-261, 62-311, 62-411 & OEL SERIES

Tuning Frequency Range

B Range	528 to 1730 KC.
C Range	1715 to 5800 KC.
D Range	5750 to 18300 KC.

Alignment and Calibration

The receivers are properly aligned at the factory with precision instruments and realignment should not be attempted unless all other possible causes of the faulty operation have first been investigated and unless the service technician has the proper equipment.

A signal generator that will provide an accurately calibrated signal at 456, 1730, 1500, 600, 5800, 5000, 1800, 18,300, 15,000 and 6000 KC and an output indicating meter are required. It will be practically impossible to align the receiver if unsatisfactory apparatus is used.

Use a non-metallic screwdriver for the adjustments. The complete procedure is as follows:

I. F. Adjustment

Set the signal generator for a signal of 456 KC.

Connect the output of the signal generator through a .1 mf. condenser to the grid of the 1st detector.

Connect the ground lead of the receiver to the ground post of the signal generator.

Turn the band switch to the Range B position (standard wave band).

Turn the selectivity control to the sharp position and keep it in this position for all adjustments.

Turn the volume control to the maximum position.

Attenuate the signal from the signal generator to prevent the levelling-off action of the AVC.

Then adjust the five I.F. trimmers until maximum output is obtained. The adjusting screws for these condensers are reached from the top of the chassis and the location is shown in Fig. 3.

Range B Alignment

After the procedure for the alignment of each range, as explained below, is completed, it is advisable to repeat the procedure as a final check.

1730 KC Adjustment

Set the signal generator for 1730 KC.

Turn the rotor of the tuning condenser to the full open position.

Keep the band switch in the standard wave position.

Connect the antenna lead of the receiver through a 200 mmf. condenser to the output of the signal generator.

For this and **all** subsequent adjustments keep the volume control at the maximum position and attenuate the signal from the signal generator to prevent AVC action.

Adjust the oscillator Range B trimmer (C18) until maximum output is obtained. The location of this trimmer is shown in Fig. 3.

1500 KC Adjustment

Set the signal generator for 1500 KC.

Turn the rotor of the tuning condenser carefully until maximum output is obtained.

Turn the calibration screw (under color filter) until the 1500 KC mark on the dial scale is at the vertical red line on the screen. If the film drum cannot be turned a sufficient amount by means of the calibration screw, loosen the 2 screws inside the drum which hold it in place. Adjust the position of the drum and tighten the screws. The early models do not have the calibration screw mentioned above. These models must be adjusted by loosening the drum screws.

Adjust the interstage Range B trimmer (C10) and antenna Range B trimmer (C4) to maximum.

Do not change the setting of the oscillator Range B trimmer.

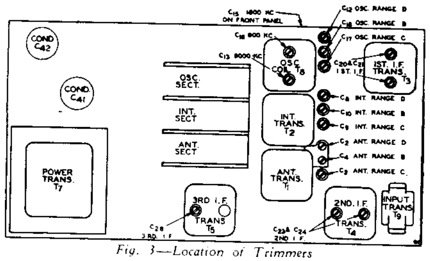

Fig. 3—Location of Trimmers

600 KC Adjustment

Set the signal generator for 600 KC.

Turn the tuning condenser rotor until maximum output is obtained.

Turn the rotor slowly back and forth at the same time adjusting the 600 KC trimmer until the peak of greatest intensity is obtained. See Fig. 3 for location of this trimmer.

Range C Alignment

CAUTION—When aligning the short wave bands be sure NOT to adjust at the image frequency. This can be checked as follows: Let us say the signal generator is set for 5000 KC. The signal will then be heard at 5000 KC on the dial of the radio. The image signal, which is much weaker, will be heard at 5000 less 912 KC, or 4088 KC. It may be necessary to increase the input signal to hear the image.

5800 KC Adjustment

Set the signal generator for 5800 KC.

Connect the antenna lead of the receiver through a 400 ohm resistor to the output of the signal generator.

Turn the rotor of the tuning condenser to the full open position.

Turn the band switch to the Range C position (first short wave band).

Adjust the oscillator Range C trimmer (C17) until maximum output is obtained. See Fig. 3 for location of this trimmer.

5000 KC Adjustment

Set the signal generator for 5000 KC.

Turn the rotor of the tuning condenser carefully until maximum output is obtained.

Adjust the interstage Range C trimmer (C9) and antenna Range C trimmer (C3) to maximum.

Do not change the setting of the oscillator Range C trimmer.

1800 KC Adjustment

Set the signal generator for 1800 KC.

Turn the tuning condenser rotor until maximum output is obtained.

Turn the rotor slowly back and forth at the same time adjusting the 1800 KC trimmer until the peak of greatest intensity is obtained. See Fig. 3 for location of this trimmer.

Range D Alignment

18,300 KC Adjustment

Set the signal generator for 18,300 KC.

Keep the antenna lead of the receiver connected through the 400 ohm resistor to the output of the signal generator.

Turn the rotor of the tuning condenser to the full open position.

Turn the band switch to the Range D position (second short wave band).

Adjust the oscillator Range D trimmer (C12) until maximum output is obtained. See Fig. 3 for location of this trimmer.

15,000 KC Adjustment

Set the signal generator for 15,000 KC.

Turn the rotor of the tuning condenser carefully until maximum output is obtained.

Adjust the interstage Range D trimmer (C8) and antenna Range D trimmer (C2) to maximum.

When adjusting the interstage and antenna Range D trimmers, it will be necessary at the same time to turn the tuning condenser rotor slowly back and forth until the peak of greatest intensity is obtained.

Do not change the setting of the oscillator Range D trimmer.

6000 KC Adjustment

Set the signal generator for 6000 KC.

Turn the tuning condenser rotor until maximum output is obtained.

Turn the rotor slowly back and forth at the same time adjusting the 6000 KC trimmer until the peak of greatest intensity is obtained. See Fig. 3 for location of this trimmer.

General Service Data

Twenty-five Cycle Models

The twenty-five cycle receiver differs from the sixty cycle receiver only in the fact that a different power transformer is used. The correct power transformer is shown in the parts list.

The twenty-five cycle receiver can be operated satisfactorily from a sixty cycle power supply. However, the reverse is not true, the sixty cycle receiver cannot be operated from a twenty-five cycle power supply.

A 115-230 volt, 40 to 60 cycle as well as other power transformers with special power ratings are also available for this model.

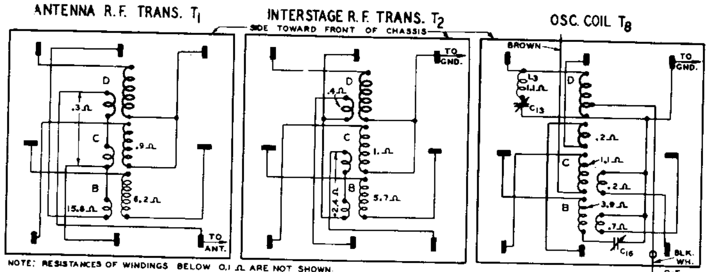

Fig. 4—R. F. and Oscillator Coil Base Terminal Arrangement and D. C. Resistance of Windings

Switch Contact Location Numbering

A standard arrangement for switch contact location numbering has been adopted. This numbering is illustrated in Fig. 2. In contact locations not used, the number applying to that particular location is not employed.

Voltage Chart

The voltage readings are taken with a voltmeter having a resistance of 1000 ohms per volt.

The standard metal tube socket terminal numbering system (bottom of socket) is shown in Fig. 5. On the schematic circuit diagram, Fig. 2, is a list giving the complete names of the tube elements and the corresponding symbols as used on the sockets on the schematic.

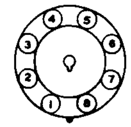

Fig. 5—Metal Tube Terminal numbering (bottom of socket)

Dial and Drive Assembly

Complete information regarding the movie dial and drive assembly will be found in the Movie Dial Manual No. 108.

(5) As read with 500,000 ohm meter.

Trimmer Replacement

If one trimmer of the gang trimmer strip should become defective, it is not necessary to replace the entire strip. A single trimmer P-17A36, as shown in the replacement parts list, may be used. Disconnect the lead from the coil side (side not grounded) of the defective trimmer in the strip. This connection is then made to the single trimmer. Connect it to the side of the trimmer not in contact with the adjusting screw. The other side of the single trimmer is then connected to a good ground, using a piece of heavy wire in order to support the trimmer adequately. In replacing a trimmer, be sure to keep both leads as short as possible and keep the ungrounded lead as far from ground as possible.

Planetary Drive Assembly

The planetary assembly is the unit that is integral with the tuning shaft.

If the nut on the back end of this assembly is too tight, the drive will be jerky and will turn hard in high speed. If this condition exists, back off this nut one or two turns and note the effect.

If this nut is too loose, the drive will slip in slow speed. The remedy in this case, of course, is to tighten the nut.

Should the condenser drive cord slip when the planetary pulley is turning, inspect the tuning condenser, drive drum and film drum to see if they are turning properly or if they are being obstructed in some way.

If the drive turns unevenly (rough in spots), this may mean that the planetary assembly is defective or damaged internally and a new unit will be required.

Phonograph Connections

Phonograph connections can be made as shown in Fig. 7. The parts required are shown in the parts list. Knockouts are provided in the back panel of the chassis for mounting the phono jack and phono switch—See Fig. 8.

The phono switch must be mounted with one set of terminals nearest the bottom of the chassis base.

The connections are made by opening the diode return circuit at the volume control. This is done by removing the white wire connected to the insulated lug of the terminal strip on which one end of condenser C32 is also connected. The terminal strip is located at the back of the volume control. This wire is then connected to the phono switch as shown in Fig. 7. A wire is then connected from the lug on the above mentioned terminal strip to the phono switch, as shown in Fig. 7. Both of the above wires are connected to the switch terminals nearest the chassis base and should be twisted together as far as possible and run as close to the back of the chassis base as possible.

The lead to condenser C32, after turning away from the back of the chassis base, should be run close to the 6C5 tube sockets.

Complete the other connections as illustrated in Fig. 7, using the lugs in the chassis base, located near the phono switch and jack, for grounding purposes.

The control grid lead of the 6F6 power tube nearest the back of the chassis should be removed and a longer lead substituted. This lead is run from the tone control to the back of the chassis, along the lower edge and is then brought to the grid terminal by being routed between the speaker socket and the tubular condenser next to it.

If a hum is heard when the phono pickup is touched, reverse the two pickup leads.

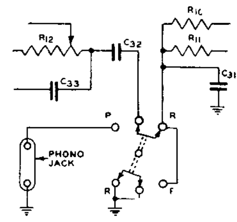

Fig. 7—Phonograph Connections

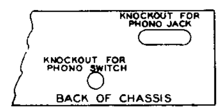

Fig. 8—Location of Phono Knockouts

Replacement Parts List

There is a large letter on the chassis which identifies the set as to major part changes. When ordering parts please be sure to mention the model number and this large letter.

MONTGOMERY WARD & CO.
MODELS 62-261,62-311,62-411 & OEL SERIES; 62-308,62-318,62-408,62-418 & 7LL SERIES; 62-310,62-410 & OF SERIES; 62-313,62-413 & 2DL SERIES; 62-327,62-337,62-427,62-437 & 7Q SERIES; 62-332, 62-432 & 7P SERIES.

Caution

In all work on the chassis and movie dial, extreme care must be taken not to scratch the film or damage the color filter. The film is easily scratched and should not be touched by the hand or any other object.

Adjustments and Service Data

Bringing Lens Adjustment to a Focus

Important—Turn the band switch to the standard wave position.

Move the focusing lever (see Fig. 2) up or down until the image on the screen is clearest. In Fig. 1 is shown the effect of correct and incorrect focusing. Care should be taken not to touch the color filter

Adjusting Reflecting Mirror

On the back wall of the projector compartment are two screws as shown in Fig. 2, the purpose of which is to adjust the position of the reflecting mirror vertically and horizontally.

If the raising and lowering adjustment screw (see Fig. 2) is not adjusted properly, the image will be too high or too low on the screen and the kilocycle or megacycle lines will not be horizontal. Also, part of the image may be cut off. If this condition exists loosen the nut which holds this screw in place. Back this nut off about one turn and then carefully turn this screw until the image is centered on the screen and the lines are horizontal. Use a fine blade screwdriver for this adjustment. Retighten the nut.

If the image cannot be centered from top to bottom, it may be necessary to adjust the elevator height in accordance with the article on this subject in this manual.

If the image on the screen is too far to the right, there will be a space at the left of the screen without light. If the image is too far to the left the same condition is true on the right side of the screen. In either case, loosen the nut which holds the left and right adjusting screw in place—see Fig. 2. Back this nut off about one turn and then carefully turn this screw with a fine blade screwdriver until the image is centered. Retighten the nut.

Tighten the calibration screw to secure the required cord tension. When this is done the radio might be out of calibration. If this condition occurs, the film drum may be shifted to the proper position by loosening the two screws inside the drum at the bottom. After these two screws are tightened, a fine calibration adjustment may then be obtained by turning the calibration screw.

Dial Calibration

The radio is properly calibrated if, when a station is correctly tuned in, the vertical red line on the screen crosses the call letters of that station. If the red line is found to be on one side of the call letters of a large number of stations on the standard wave band (the same side in each case), the dial is out of calibration.

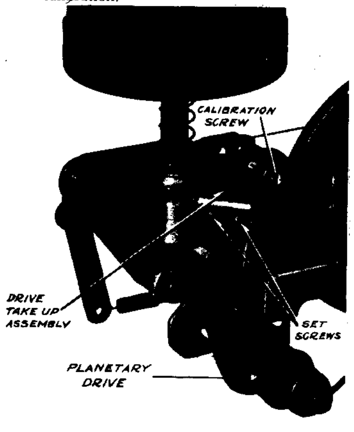

Fig. 3—Drive Takeup Assembly

To re-calibrate, tune in the signal of one of the larger nearby stations. Choose a station which is near the 1500 KC end of the dial and tune carefully to resonance. Turn the calibration screw (see Fig. 2, 3 or 7) until the vertical red line on the screen is at the center of the call letters of that station.

If the film drum cannot be turned a sufficient amount by means of the calibration screw, loosen the 2 screws at the bottom of the drum which hold it in place. Adjust the position of the drum and tighten the screws. The early models do not have the cord take-up calibration screw mentioned above. These models must be calibrated by loosening the drum screws.

The dial will then be properly calibrated and this adjustment should not be changed unless re-calibration again becomes necessary. It should be remembered that after calibration a few of the stations will be tuned in when the vertical red line is near the end of the call letters and city of a station. That is because of slight variations in the film.

Fig. 1—Effect of Lens Focus

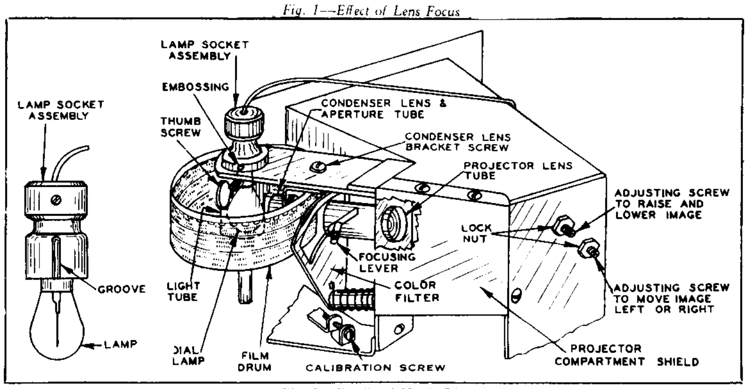

Fig. 2—Details of Movie Dial

Drive Takeup Assembly

Later models are equipped with a drive takeup assembly illustrated in Fig. 7, by means of which the dial drum can be rotated a slight amount for calibration purposes. The earlier models do not have this adjustment. However, a special unit illustrated in Fig. 3 can be put on.

This unit is assembled to the film drum bracket and drive cord as shown in Fig. 3. Unscrew the two set screws and open the slot to the maximum position by turning the adjusting screw in a counter-clockwise direction. Place the unit in position on the bracket.

Push it as far to the left as possible (from back of chassis) and tighten the two set screws. These will extend beneath the film drum bracket. Then place the drive cord between the two pulleys as shown.

Adjusting Elevator to Raise or Lower Image

Adjust the lamp assembly height until the lines on the screen are straight—see article on this adjustment in this manual.

Turn the upper reflecting mirror adjusting screw—see Fig. 2, until the lines on the screen are horizontal.

Turn the band switch to the second short wave position (green).

Loosen the elevator adjusting screw—see Fig. 4.

Raise and lower the elevator until the megacycle line (at bottom) is between the letters "S" and "T" of the word "West" on the glass at either side of the glass screen.

Tighten the elevator adjusting screw.

Removing Play between Band Switch and Elevator

If the elevator arm stops and the band switch stops do not coincide, there will be a certain amount of play between the band switch and the elevator. When this condition occurs, the position of the image on the screen will not be fixed, but can be moved up or down by turning the band switch knob.

To remedy this condition, first turn the band switch to the second short wave position (green).

Loosen the set screw and square head screw on the band switch shaft collar, see Fig. 4. Turn the band switch shaft clockwise as far as it will go. Push the collar arm clockwise as far as it will go without pulling the elevator arm ball bearing out of the bottom slot.

Then tighten the square head screw and set screw in the elevator arm collar.

Planetary Drive Assembly

The planetary assembly is the unit that is integral with the tuning shaft. It is illustrated in Fig. 3.

If the nut of this assembly is too tight, the drive will be jerky and will turn hard in high speed. If this condition exists, back off this nut one or two turns and note the effect.

If this nut is too loose, the drive will slip in slow speed. The remedy in this case, of course, is to tighten the nut.

Should the condenser drive cord slip when the planetary pulley is turning, inspect the tuning condenser, drive drum and film drum to see if they are turning properly or if they are being obstructed in some way.

If the drive turns unevenly (rough in spots), this may mean that the planetary assembly is defective or damaged internally and a new unit will be required.

Changes in Early Models

Film Drum Base In the early models a metal film drum base was used. This was replaced in later models with a molded base. The latter type is used in filling orders and is interchangeable with the early type. A clamping plate is now included with the molded base Film Drum Assembly.

Lamp Socket Assembly—Two changes were made in the lamp socket assemblies in the early models The type used with each receiver is illustrated in the instruction book packed with that model. For further information regarding this assembly see the article "Replacing and Positioning the Dial Lamp"

Cleaning Light Reflecting and Transmitting Parts

Cleaning the Lenses

It is very seldom necessary to clean the lenses. Occasionally, however, dust or dirt on the lens may cause the image on the screen to be spotted or foggy. If this is the case, the lenses may be removed as explained below and may then be cleaned by wiping carefully with a clean chamois or soft cloth.

Removing Condenser Lens This lens is inside the film drum as shown in Fig. 2. Turn the band switch to the standard wave position. Take out screw (C) holding the condenser lens bracket in place see Fig. 4. Turn this bracket in a clockwise direction (from top) and lift it out carefully to avoid scratching the film.

This lens can be cleaned without removal or may be forced out of the tube with a wood block. When the lens is replaced, line up the end of the lens barrel with the edge of the tube.

(Continued on next page)

MONTGOMERY WARD & CO.

MODELS 62-261, 62-311, 62-411 & OEL SERIES; 62-308 62-318, 62-408, 62-418 & 7LL SERIES; 62-310, 62-410 & OF SERIES; 62-313, 62-413 & 2DL SERIES; 62-327, 62-337, 62-427, 62-437 & 7Q SERIES; 62-332, 62-432 & 7P SERIES.

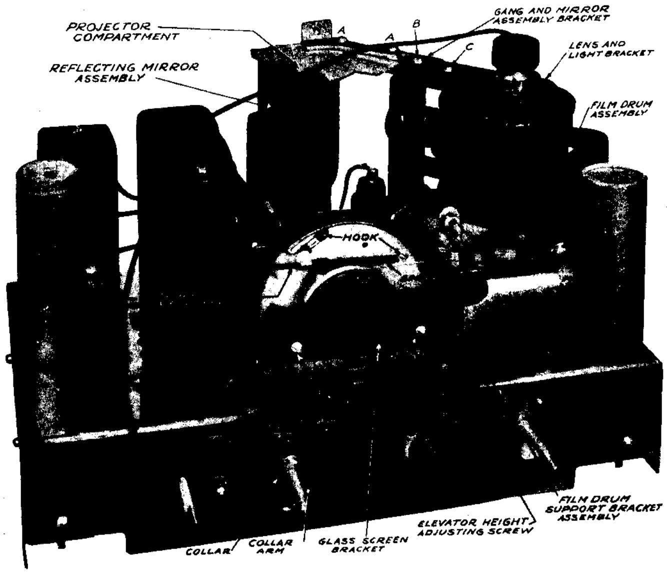

Fig. 4—Movie Dial Chassis

(Continued from preceding page)

In replacing the condenser lens bracket, shift this bracket until the end of the condenser lens tube is about ⅛ inch from the dial lamp.

Removing Projector Lens—This lens is inside the projector lens tube as shown in Fig. 2. Turn the band switch to the standard wave position. Take out the three screws which hold the projector compartment shield in place. Then remove the projector compartment shield by tilting the top slightly to the back and toward the right (from back of shield). Move the focusing lever to the highest position. Unscrew and remove this lever.

Push the color filter in a counter-clockwise direction (from front) as far as it will go. Insert a fine blade screwdriver into the projector lens tube (from the front). The blade of the screwdriver should engage the end of the barrel of this lens and push against it until it has been pushed a slight distance toward the projector compartment. CAUTION—Do not let the screwdriver touch the glass. Then insert the screwdriver through the slot in the side of this tube, again engaging the barrel of the lens. Push against the barrel until the lens can be removed by hand from the projector compartment.

Cleaning the Reflecting Mirror, Film, Color Filter and Glass Screen

As in the case of the lenses, it is very seldom necessary to clean the reflecting mirror, film, color filter or glass screen. If, however, the image on the screen is spotted or foggy, it may be necessary to clean these items as explained below.

Reflecting Mirror—The reflecting mirror is located within the projector compartment. Remove the projector compartment shield as described above under "Removing Projector Lens". The glass may then be cleaned without removal of this assembly. Wipe the glass carefully with a clean chamois or soft cloth.

Film—The film may be dusted with a camel hair brush or fine cloth. CAUTION—Extreme care must be taken not to scratch the film.

Color Filter—To clean the color filter, turn the band switch to the second short wave position (green). Clean the filter using a fine cloth or chamois. CAUTION—Extreme care must be taken not to damage the filter.

Glass Screen—If the screen should become dirty, the front may be cleaned by wiping with a clean, dry cloth. If the back of the screen becomes dirty, it should be cleaned with alcohol. Care should be taken not to get any alcohol on the paint on the letters at the sides of the screen, or on the red line at the front of the screen.

Replacing Parts

Replacing and Positioning the Dial Lamp

Caution—If a new lamp is required, use only the correct lamp as shown in the parts list and on the label on each radio. These are special lamps and can be purchased only through Wards stores and mail order houses. The life of the lamp is somewhat less than that of a radio tube.

First, turn the radio off.

Loosen the thumb screw and lift the lamp socket assembly out of the light tube—see Fig. 2. This can be lifted vertically by grasping the insulated top of the assembly through which the wire runs.

Remove the old lamp from the socket and put in the new one.

Replace the lamp socket assembly in the light tube with the light tube embossing in the groove of the lamp socket assembly—see Fig. 2. Do not tighten the thumb screw yet.

Turn the radio on.

Then grasp the top of the lamp socket assembly and move it up or down until the image on the screen is clearest and the lines are horizontal. The effect of having the lamp assembly too high or low is shown in Fig. 5. Tighten the thumb screw.

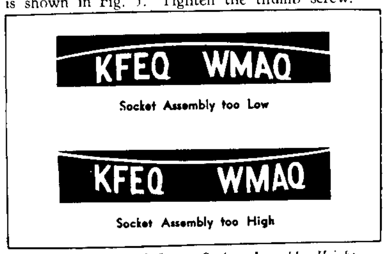

Fig. 5—Effect of Lamp Socket Assembly Height

Early Types—There were two earlier types of lamp socket assemblies.

In the assembly shown in Fig. 6(A) the procedure differs from the above as follows:

To remove the socket assembly from the light tube, grasp the locking ring and turn it in a counter-clockwise direction until the pins are at the vertical portion of the slots. Then lift it out.

When replacing the lamp socket assembly in the light tube, line up the slots in the locking ring over the pins at the top of the light tube. Push the locking ring down and turn it clockwise until the pins move as far as possible into the horizontal portion of the slot—See Fig. 6(A).

To make the image on the screen clear and the lines horizontal, turn the adjusting nut. This moves the lamp assembly up or down depending on the direction of rotation.

In the assembly shown in Fig. 6(B), the procedure differs from that used in the (A) type as follows:

To remove the lamp socket assembly, unscrew the locking ring screw until it is free of the locking ring. Then pry the locking ring upward with a screw driver and lift the assembly out of the light tube.

When replacing the assembly in the light tube, line up one of the holes in the locking ring with the screw in the bracket. Push the locking ring down on the light tube and tighten the locking ring screw until it enters the hole in the locking ring.

Turn the adjusting nut as explained for the type (A) assembly. If the adjusting nut turns hard, grasp the black insulated top of the assembly and lift upward slightly until the nut turns freely.

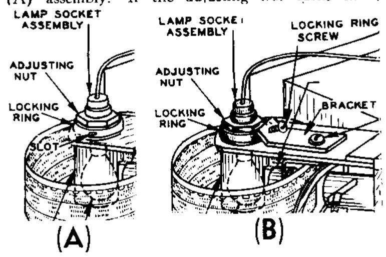

Fig. 6—Early Dial Lamp Assemblies

Important—Latest type used for parts orders. In filling orders for this assembly the latest type, illustrated in the parts list, is shipped. This is interchangeable with all early types.

The early types of lamp socket and light tube did not have the groove and embossing illustrated in Fig. 2. When one of the latest type of socket assembly is used in these models, it will be necessary to turn the assembly until the filament is at right angles to the lens.

Replacing the Film Drum Assembly

Remove the lamp socket assembly from the light tube by lifting it out in accordance with instructions in "Replacing and Positioning the Dial Lamp".

Remove the projector compartment shield by taking out the three screws which hold it in place—See Fig. 2.

Take out the two screws (B and D) which hold the lens and light bracket in place—See Fig. 4. Now remove the lens and light bracket taking care not to scratch the inside of the film.

Remove the film drum assembly by unscrewing the two small screws located inside the drum at the bottom.

Mount the new film drum assembly on the film drum supports leaving the paper around the film for protection, and insert the clamping plate within the film drum. The film drum and clamping plate should then be so placed that the small screws are in the center of the two slots.

Replace the lens and light bracket taking care not to scratch the inside of the film.

Replace the projector compartment shield and dial lamp assembly.

Now remove the paper from the film, turn the radio on and calibrate the dial in accordance with the instructions in the article "Dial Calibration".

The film and mounting drum are sold as one assembly and cannot be ordered separately

Replacing the Glass Screen

Loosen the screws holding the glass screen clamps on each side of the screen. Loosen these only enough to enable the glass screen to be removed by lifting it out from the top.

Mount the new screen from the top being very careful not to touch the back of the screen, as touching the screen will leave fingerprints on the roughened or ground portion.

Push the glass screen down until it rests on the shelves provided for it.

Tighten the four screws holding the screen clamps just enough so that the glass is held firmly in place.

Replacing Film Drum Drive Cord

Remove the projector compartment and glass screen assembly together. To do this, take out the 2 screws (A) see Fig. 4, at the back of the top of the projector compartment, the 2 screws (E) at the bottom of the glass screen bracket, and the 2 brass collars from the volume control and tone control shafts.

Disconnect the tension spring from the arm at the right side of drive mechanism—see Fig. 7.

Remove the old cord by unsoldering it from the

(Continued on next page)

MONTGOMERY WARD & CO.

MODELS 62-261, 62-311, 62-411 & OEL SERIES; 62-308, 62-318, 62-408, 62-418 & 7LL SERIES; 62-310, 62-410 & OF SERIES; 62-313, 62-413 & 2DL SERIES; 62-327, 62-337, 62-427, 62-437 & 7Q SERIES; 62-332, 62-432 & 7P SERIES.

(Continued from preceding page)
small lug on the film pulley. Clean the excess solder off of this lug. With a narrow blade screwdriver carefully bend this lug out toward the vertical position, a slight amount.

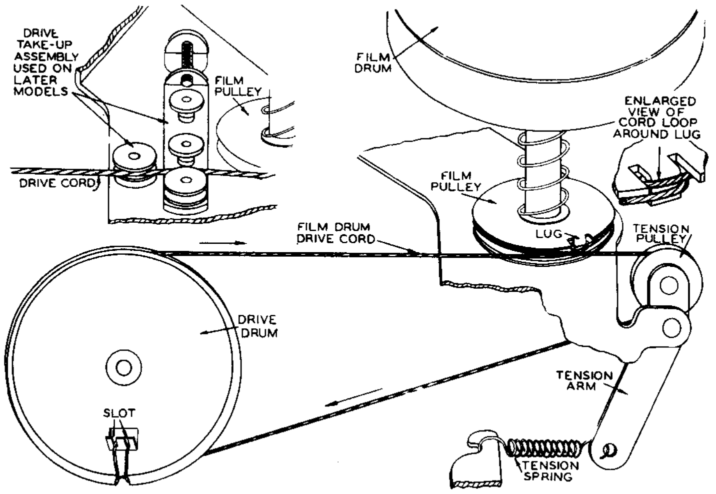

Fig. 7—Replacement of Film Drum Drive Cord

Turn the tuning shaft until the condenser plates are completely in mesh.

Turn the film drum so that the lug on the film pulley is in the position shown in Fig. 7. This is important.

Insert the new drive cord in the left slot in the drive drum (from front) and wind the cord in a clockwise direction one half turn around the drive drum.

Continue the cord horizontally to the lug on the film pulley. Loop the cord around this lug in the manner shown in Fig. 7.

Wind the cord on the film pulley one turn counter-clockwise, being sure that the end coming from the pulley passes over the cord from the drive drum.

Bring the cord over the brass tension pulley and back again to the left. Insert the end in the right slot in the drive drum.

Replace tension spring and reassemble projector compartment, glass screen and collars to the chassis.

Set the signal generator to 600 KC and carefully tune in the signal. Adjust the position of the film drum in accordance with the article "Dial Calibration" in this manual until the 600 KC mark on the dial is at the red line on the screen. **Do not touch the film with the fingers.**

When the above adjustments have been made, carefully bend the lug on the film pulley down over the cord and solder, being sure that the upper cord leaving the pulley receives no solder.

Replacing Condenser Drive Cord

Remove the projector compartment and glass screen assembly together. To do this, take out the 2 screws (A) see Fig. 4, at the back of the top of the projector compartment, the 2 screws (E) at the bottom of the glass screen bracket and the 2 brass collars from the volume control and tone control shafts.

Turn the drive drum until it is in the position shown in Fig. 4.

Place the loop at the end of the drive cord (without the spring) over the small hook nearest the cut out part of the drive drum.

Now turn the chassis on its back. Bring the cord down over the right side (from front) of the drive drum and over the planetary drive pulley, keeping the cord in the groove provided for it. Bring the drive cord up over the left side (from front) of the drive drum to the cut out part of the drum. While holding the cord in place, return the chassis to normal position.

Then bring the cord in toward the inside of the drum, attaching the tension spring to the small hook provided for it.

Reassemble the projector compartment, glass screen and collars to the chassis.

Replacing the Color Filter Semaphore

Push the focusing lever up as far as it will go.

Cut a strip of paper the width of the film drum assembly and place this around the film holding it on with a string wound around the drum. This will protect the film from being scratched on the outside.

Remove the projector compartment shield by taking out the three screws which hold it in place—See Fig. 2

Remove the lens and light bracket by taking out screws (B and D) which hold it in place—See Fig. 4. Care must be taken not to scratch the inside of the film when removing this bracket.

Remove the horseshoe washer from the stud holding the color filter semaphore in place. Then take off the color filter semaphore.

Take the spring off of the old assembly. Put this spring on the new assembly, the straight end of the spring being placed under the small clip provided for it on the color filter semaphore.

Now replace the color filter semaphore on the stud on which it mounts. Put on the horseshoe washer, pinching the open ends together. The free end of the spring should catch the edge of the lens and light bracket

Next turn the color filter one complete turn in a counter-clockwise direction (from front) to provide tension on the spring.

Holding the semaphore in this position, replace the entire assembly with the semaphore stop placed under the film drum (drum in second short wave or highest position). Care must be taken not to scratch the inside of the film when replacing the lens and light bracket assembly.

Now replace the projector compartment shield and remove the paper from around the film.

Turn the radio on and bring the letters on the screen into proper focus by means of the focusing lever—See Fig. 2. The effects of incorrect focusing are shown in Fig. 1.

Movie Dial Parts List

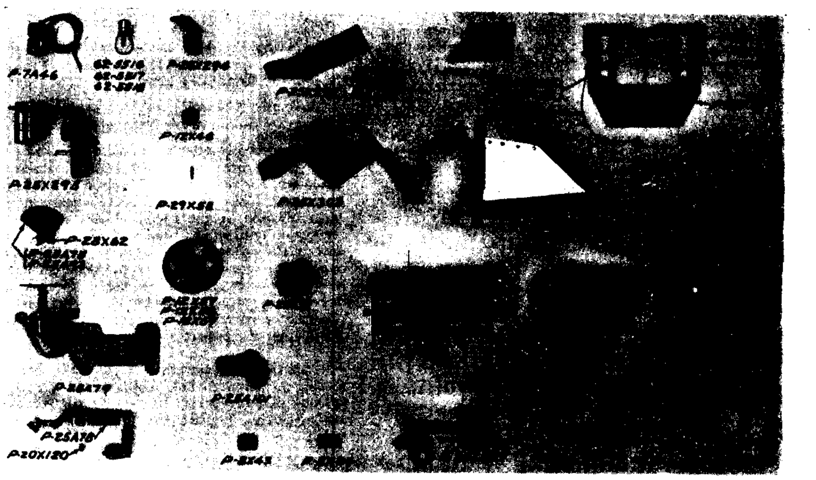

Fig. 8—Replacement Parts

The Series 7LL and OEL radios use the parts shown in the list below.
The Series 2DL, OF, 7P and 7Q radios use the same parts with the exception of the items shown in the four columns to the right.

SUPPLEMENTARY MOVIE DIAL AND DIAL DRIVE DATA

The greatest point of difference between the early and late models is the use of die castings instead of die stampings for the following parts: Drive Drum and Pulley Assembly, Film Drum Support Bracket, Lens and Light Bracket, and Elevator Arm Assembly. A cardboard projector compartment and shield is now used in place of the early metal type compartment.

The models in which the latest changes have been made may be identified in most cases by this cardboard projector compartment.

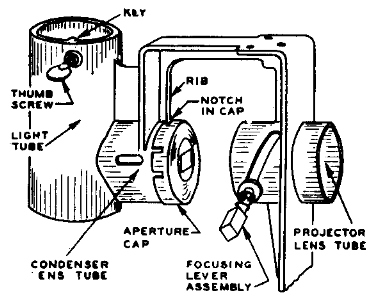
However, this identifying characteristic is not positive. Some models not using die cast parts have the cardboard projector compartment and some models with die cast parts have the metal compartment or a combination of metal and cardboard. When ordering movie dial parts, therefore, determine whether the chassis uses die cast or stamped parts.

Revised Movie Dial Procedures

The changes in design of certain parts of the movie dial assembly have necessitated a revision in the procedure for making some adjustments and replacements. The new instructions are as follows:

Cleaning the Lenses (When die cast lens and light bracket is used)

Removing Condenser Lens—Turn the band switch to the standard wave position. Remove the dial lamp assembly. Take out the two screws holding the lens



Lens and Light Bracket.

and light bracket in place. Take out the three screws holding the projector compartment shield in place. Remove this shield. If a one-piece cardboard compartment is used, remove two screws only and bend the shield down. Turn the lens and light bracket in a clockwise direction (from top) and lift it out carefully to avoid scratching the film.

Remove the aperture cap—See illustration. Insert a fine blade screwdriver into the slot and then push the condenser lens away from the light tube until it is possible to remove the lens. Clean the lens carefully. Replace the lens so that the lens barrel projects about 1/32 inch beyond the lens tube. Replace the aperture cap so that the square notch of the aperture caps fits over the square rib as illustrated.

Reassembling—Replace the lens and light bracket taking care not to scratch the inside of the film.

Replace the projector compartment shield and dial lamp assembly.

Refocus the projector lens.

Removing Projector Lens—Remove the projector shield as explained in the first paragraph of the article "Removing Condenser Lens."

Move the focusing lever to the highest position. Unscrew and remove the focusing lever assembly.

Push the color filter in a counter-clockwise direction (from front) as far as it will go. Insert a fine blade screwdriver into the projector lens tube (from the front). The blade of the screwdriver should engage the end of the barrel of this lens and push against it until it has been pushed a slight distance toward the projector compartment. CAUTION—Do not let the screwdriver touch the glass. Then insert the screwdriver through the slot in the side of this tube, again engaging the barrel of the lens. Push against the barrel until the lens can be removed by hand from the projector compartment.

Clean the lens carefully. Replace the lens barrel so that the threaded hole will coincide with the slot opening of the bracket. Reassemble the focusing lever assembly. Replace the projector compartment shield

Replacing the Film Drum Assembly (When die cast lens and light bracket is used)

Remove the lamp socket assembly from the light tube by lifting it out in accordance with instructions in "Replacing and Positioning the Dial Lamp"

Remove the lens and light bracket as described in the article "Removing Condenser Lens."

Remove the film drum assembly by unscrewing the two small screws located inside the drum at the bottom.

Mount the new film drum assembly on the film drum supports leaving the paper around the film for protection, and insert the clamping plate within the film drum. The film drum and clamping plate should then be so placed that the small screws are in the center of the two slots.

Replace the lens and light bracket taking care not to scratch the inside of the film.

Replace the dial lamp assembly.

Now remove the paper from the film, turn the radio on and calibrate the dial in accordance with the instructions in the article "Dial Calibration"

The film and mounting drum are sold as one assembly and cannot be ordered separately.

Adjusting Elevator to Raise or Lower Image

The elevator adjusting method, utilizing a screw moving in a slot, has been changed to the method explained in the following paragraphs:

Turn the band switch to the standard wave band position (white).

Adjust the lamp assembly height until the lines on the screen are straight—See article on this adjustment

Turn the upper adjusting screw of the reflecting mirror (See Fig. 2 until the lines on the screen are horizontal.

At the bottom of the film drum assembly shaft is an adjustable screw arrangement. To adjust the height of the elevator, loosen the locknut on the adjustable screw. This nut is the smallest hex nut on this shaft. Then turn the adjustable screw, by means of the larger hex head, in a clockwise direction to lower the image on the screen and counter-clockwise to raise the image.

When the correct position has been obtained, tighten the locknut.

Drive Cord Replacements

When ordering the film drum drive cord or the condenser drive cord, it is important that the type of drive drum (die cast or stamped) be noted. The cords used with the die cast drum are not interchangeable with those used with the die stamped drum. The two drive drum assemblies may be differentiated as follows: The die cast drive drum and the smaller pulley which drives the film drum are one piece. The die stamped drum and pulley assembly is composed of two separate pulleys held together with a brass bushing.

Lubrication Necessary

After a period of time some light grease should be placed on the film drum shaft at the point where it passes through the film pulley (See Fig. 7.

Movie Dial Supplementary Parts List

Bin No.	Part No.	Description	Selling Price
11119	*7A42	Lamp Socket (Interchangeable with P-7A46)	$ .32
	‡25X295J	Lens and Light Bracket (Die Cast)	.46
	‡12X54	Aperture Cap for Above Bracket	.06
	†12X64	Condenser Lens (Used instead of P-12X46)	.50
	**12X64	Projector Lens Only (Used instead of P-12X46)	.50
	†29X77	Focusing Lever Assembly for Projector Lens (Used instead of P-29X58)	.06
	†10X21	Condenser Drive Cord—Black (Used instead of P-10X14)	.12
	†24X240D	Drive Drum and Pulley (Die Cast)	.22
	†25A106	Film Drum Support Bracket Assembly (Used instead of P-25A79)	1.04
	†10X22	Film Drum Drive Cord Only—Phosphor-bronze (Used instead of P-10X15)	.10
	†28X104	Film Drum Drive Tension Spring (Used instead of P-28X19)	.04
	*32X83	Cardboard Projector Compartment (One piece—Interchangeable with all early types)	.08
11397	*25A105	Elevator Assembly Complete less Ball Bearing (Die Cast—Interchangeable with P-25A78)	.22

*Interchangeable with early models.

†Not interchangeable with early models.

‡These two items when used together are interchangeable with the combination of P-25X294—Aperture Bracket and P-25X295—Lens and Light Bracket on early models.

**Interchangeable with P-12X46—Projector Lens (Used on early models) if used with 29X77—Focusing Lever Assembly.

PHILCO RADIO & TELEVISION CORPORATION

MODEL 37-641 "CODE 121"

Electrical Specifications

Type of Circuit: Superheterodyne, with push-pull pentode audio output.
Power Supply: 115 volts, A. C. or D. C.
Power Consumption: 60 watts.
Power Output: 1.4 watts.
Philco Tubes Used: Seven. One 6A8G; one 6Q7G; one 25Z6G; two 6K7G; two 25A6G.
Tuning Ranges: Three. Range 1—530 to 1720 K. C.; Range 2—2.3 to 7.4 M. C.; Range 3— 7.35 to 22 M. C.
Tone Control: Three Point.
Speaker: "B" Cabinet KR-18. "X" and "MX" Cabinets HR-13.

Alignment of Compensators

EQUIPMENT REQUIRED: (1) Signal Generator; Philco Model 088 (fundamental frequency 110 to 20,000 K. C.) is the correct instrument for this purpose; (2) Output meter. **Philco Model 025 Circuit Tester** incorporates a sensitive output meter and is recommended; (3) Fibre handle screw driver (Philco Part No. 27-7059); (4) Special variable condenser (Philco Part No. 45-2325).

OUTPUT METER—The 025 Output Meter is connected between the plate and cathode prongs of one of the 25A6G tubes. Then adjust the meter to use the (0-30) volt scale.

INTERMEDIATE FREQUENCY CIRCUIT

Set controls as follows:

a. Range Switch position one (broadcast).
b. Volume control maximum.
c. Connect the 088 signal generator output lead through a .1 mfd. condenser to the control grid of the 6A8G tube and the ground connection of the output lead to the chassis.
d. Receiver dial at 580 K. C.
e. Signal generator 470 K. C.
f. Adjust compensators (38P), (38S), (35P), (35S).

RADIO FREQUENCY CIRCUIT

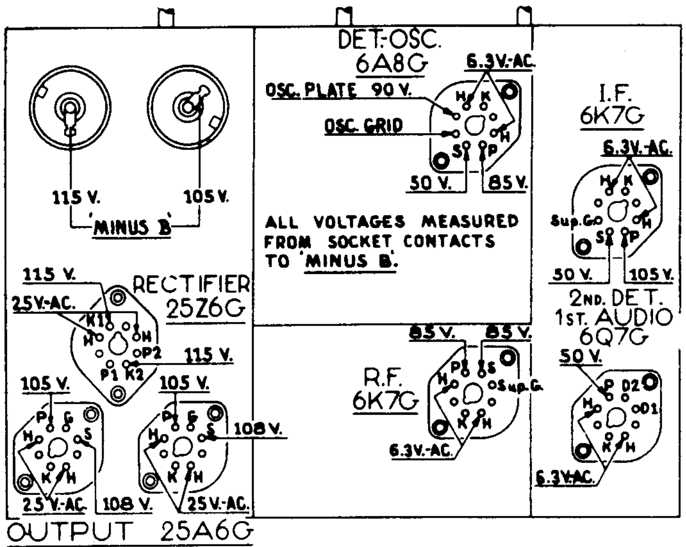
Tuning Range 7.35 to 22 M. C.

1. Connect signal generator output lead with the .1 mfd. condenser to terminal No. 1 and the ground lead to terminal No. 3. Terminals 2 and 3 must be connected with the shorting link provided on the aerial panel.
2. Adjust compensators as follows:

Range Switch	Signal Generator	Receiver Dial	Compensators In Order
3	18 M. C.	18 M. C.	(18B) check image at 17.06 M. C. on receiver dial. (See note B)
3	18 M. C.	18 M. C.	(11B), (2B) use shunt condenser on (18B) (See Note A)
3	18 M. C.	18 M. C.	(18B)

Tuning Range 2.3 to 7.4 M. C.

Range Switch	Signal Generator	Receiver Dial	Compensators In Order
2	7 M. C.	7 M. C.	(18A)
2	6 M. C.	6 M. C.	(11A), (2A)



Socket Voltages—Underside of Chassis View

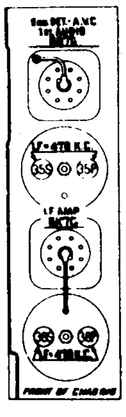
The voltages indicated by arrows were measured with a **Philco 025 Circuit Tester** which contains a voltmeter having a resistance of 1000 ohms per volt. Volume Control at minimum, range switch in broadcast position, line voltage 115 A. C.

Tuning Range 530 to 1720 K. C.

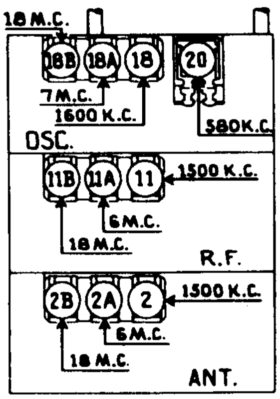
Range Switch	Signal Generator	Receiver Dial	Compensators In Order
1	1600 K. C.	1600 K. C.	(18), (11), (2)
1	580 K. C.	580 K. C.	(20) roll gang
1	1600 K. C.	1600 K. C.	(18)
1	1500 K. C.	1500 K. C.	(11), (2)

NOTE "A"—To eliminate the effect of the R. F. compensator detuning the Osc. circuit, a variable tuning condenser, Philco Part No. 45-2325 is connected from the oscillator compensator to ground when designated in the padding instruction above. Tune the added condenser from the minimum capacity position until the second harmonic of the receiver oscillator beats against the signal from the generator, resulting in a maximum indication on the output meter. Then adjust compensators as noted for maximum output.

NOTE "B"—To accurately adjust the compensator to the fundamental and not the image signal, turn the oscillator compensator to the maximum capacity position clockwise. Then slowly turn the compensators counter-clockwise until a second maximum peak is obtained on the output meter. The first peak is the image signal and the receiver must not be adjusted to it. If the above procedure is correctly performed, the image signal will be found 940 K. C. below the frequency being used on any high frequency band.



I. F. Compensators



R. F. Compensators

PHILCO RADIO & TELEVISION CORPORATION

MODEL 37-665

Electrical Specifications

TYPE CIRCUIT:

Superheterodyne, with a High-Frequency tuning range; covering from 25 to 42 megacycles and a Push-Pull pentode audio output circuit.

POWER SUPPLY:

Voltage	Frequency	Power Consumption
115	50 to 60	130 watts
115	25 to 40	130 watts

Power transformers for the different voltage and frequency ratings are listed in the parts list.

INTERMEDIATE FREQUENCY:
470 K. C.

TUNING RANGES: Four.
Range 1—530 to 1720 K. C.
Range 2—2.3 to 7.4 M. C.
Range 3—7.35 to 22 M. C.
Range 4—25 to 42 M. C.

UNDISTORTED OUTPUT: 7 watts.

PHILCO TUBES USED: Nine.
Two 6K7G; two 6F6G; two 6J5G; one 6A8G; one 6K5G and one 5Y4G.

SPEAKERS: B Cabinet, K35. Part No. 36-1231.
X Cabinet, H26. Part No. 36-1238.

Aerial Connections

To obtain the full advantage of the sensitivity of this receiver the Philco High Efficiency Aerial supplied with the receiver must be used. The connections for the aerial are as follows:

The red and black leads of the High-Efficiency Aerial "transmission line" are connected to terminals 1 and 2 respectively, of the terminal panel provided on the rear of the chassis. Connect the jumper on the terminal panel across terminals 3 and 4.

If a temporary aerial is used, the jumper should be across terminals 2 and 3. The aerial connects to terminal 1 and the ground lead to terminal 3. A good ground connection is desirable in all installations.

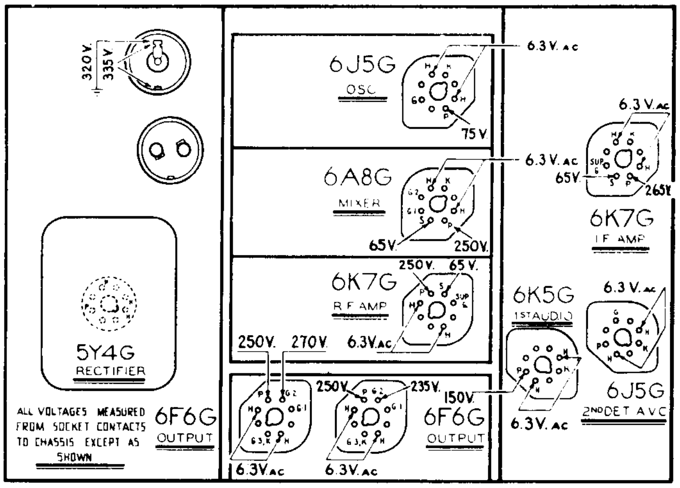
Shadow Meter Adjustment

Remove aerial and allow tubes to warm up. Then adjust shadow meter as follows:

1. Move the shadow meter coil backwards and forwards, until the opposite edges of the shadow are ⅛ of an inch from end of the shadow screen, measuring along the bottom edge of the screen. Adjustment of the shadow meter light bracket may be necessary for perfect centering.

2. Remove the rectifier tube from its socket, and rotate coil until shadow reaches minimum width. This width must not exceed 3/32 of an inch.

3. Replace the 5Y4G rectifier tube in its socket. The shadow should then widen to not more than 3/16 of an inch or less than 1/16 inch from each side of the screen measuring along the bottom edge. If these limits are not obtained readjust the shadow meter as given in paragraphs 1 and 2 until they are reached.



Socket Voltages—Underside of Chassis View

The voltages indicated by arrows were measured with a **Philco 025 Circuit Tester** which contains a voltmeter having a resistance of 1000 ohms per volt. Volume Control at minimum, range switch in broadcast position, line voltage 115 A. C.

Dial Calibration

In order to adjust this receiver correctly, the dial must be aligned to track properly with the tuning condenser. To do this rotate the tuning control to the extreme counter-clockwise position (maximum capacity). Loosen the set screw of the dial hub, then turn dial until the glowing indicator is centered on the middle index line of dial scale (see Fig. 5). Now tighten the dial hub set screw in this position.

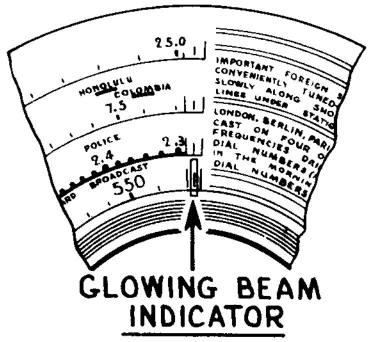


Fig. 5—Dial Calibration

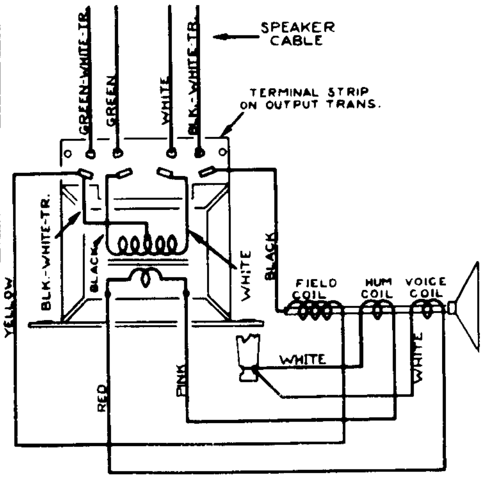
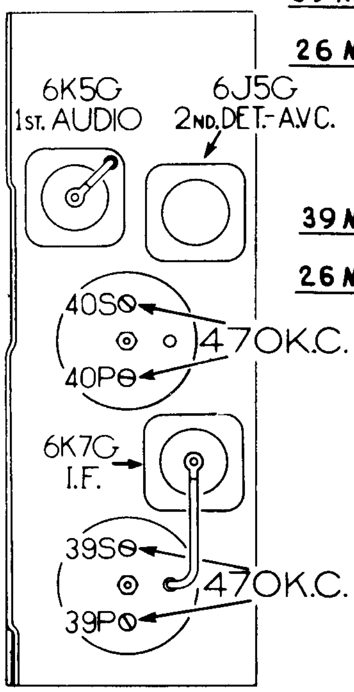
NOTE: See page 237 before servicing this set.

PHILCO RADIO & TELEVISION CORPORATION

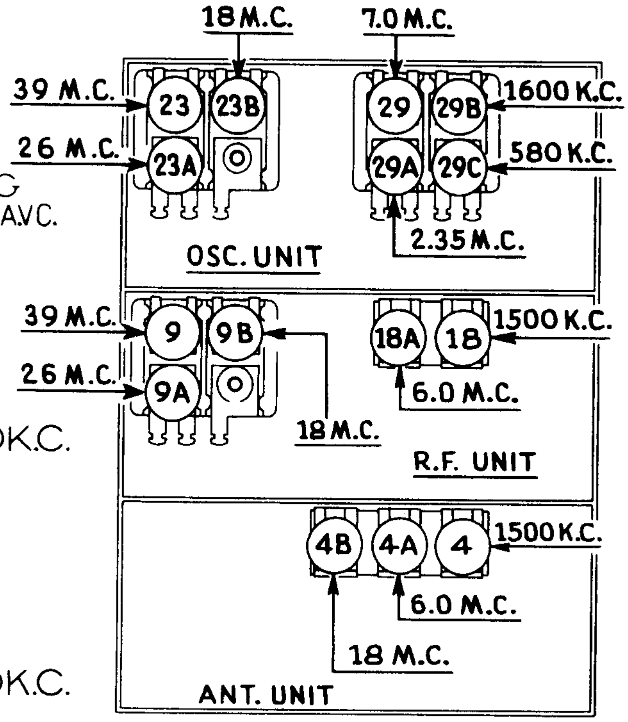
MODEL 37-665



Speaker Wiring, K-35, H-26



I. F. Compensators



R. F. Compensators

Alignment of Compensators

EQUIPMENT REQUIRED: (1) Signal Generator; Philco **Model 088** (fundamental frequency 110 to 20000 K. C.) is the correct instrument for this purpose; (2) output meter. **Philco Model 025 Circuit Tester** incorporates an accurate, sensitive output meter and is recommended; (3) Fibre handle screw-driver (Philco Part No. 27-7059); (4) Special variable condenser (Philco Part No. 45-2325).

OUTPUT METER: The 025 Output Meter is connected between the plate and cathode prongs of one of the 6F6G tubes. The meter is adjusted to use the (0-30) volt scale.

INTERMEDIATE FREQUENCY CIRCUIT

1. Set controls as follows:
   a. Range switch position one (broadcast)
   b. Receiver dial 580 K. C.
   c. Volume control maximum
   d. Signal generator 470 K. C.
   e. Connect the 088 signal generator output lead through a .1 mfd. condenser to the control grid of the 6A8G tube and the generator ground connection to the chassis.
2. Adjust the following I. F. compensators for maximum output: (39P), (39S), (40P) and (40S).

RADIO FREQUENCY CIRCUIT

Tuning Range (28 to 42 M. C.)

1. Set controls as follows:
   a. Range switch position 4
   b. Connect the signal generator output lead and ground to terminals 1 and 3 respectively on the aerial input panel. Terminals 2 and 3 must be connected with the shorting link provided on the aerial panel.
2. Adjust compensators as follows for maximum output:

Signal Generator	Receiver Dial	Compensators in Order
13 M. C.	39 M. C.	(23) Check image signal at 38.06 on the Receiver Dial. (See Note A)
13 M. C.	39 M. C.	(9) Roll gang
13 M. C.	26 M. C.	(23A)
13 M. C.	26 M. C.	(9A)
13 M. C.	39 M. C.	(23) check image (Note A)
13 M. C.	39 M. C.	(9) Roll gang

Tuning Range 7.35 to 22 M. C.

1. Set controls and adjust compensators for maximum output as follows:
   Range Switch Position 3.

Signal Generator & Receiver Dials	Compensators in Order
18 M. C.	(23B) check image 17.06 M. C.
18 M. C.	(9B), (4B) use shunt condenser on (23B) See Note B

Tuning Range 2.3 to 7.4 M. C.

1. Range Switch Position 2
2. Signal Generator & Receiver Dials / Compensators in Order

Signal Generator & Receiver Dials	Compensators in Order
7.0 M. C.	(29), (18A), (4A)
2.35 M. C.	(29A)
7.0 M. C.	(29)
6.0 M. C.	(18A), (4A)

Tuning Range 530 to 1720 K. C.

1. Range Switch Position 1
2. Signal Generator & Receiver Dials / Compensators in Order

Signal Generator & Receiver Dials	Compensators in Order
1600 K. C.	(29B), (18), (4)
580 K. C.	(29C) Roll gang
1600 K. C.	(29B)
1500 K. C.	(18), (4)

NOTE "A"—To accurately adjust the compensator to the fundamental and not the image signal, turn the oscillator compensator to the maximum capacity position clockwise. Then slowly turn the compensators counter-clockwise until a second maximum peak is obtained on the output meter. The first peak is the image signal and the receiver must not be adjusted to it. If the above procedure is correctly performed, the image signal will be found 940 K. C. below the frequency being used on any high frequency band.

NOTE "B"—To eliminate the effect of the Ant. and R. F. compensators detuning the Osc. circuit, a variable tuning condenser, Philco Part No. 43-2325 is connected from the oscillator compensators to ground when designated in the padding instruction above. Tune the added condenser from the minimum capacity position until the second harmonic of the receiver oscillator beats against the signal from the generator, resulting in a maximum indication on the output meter. Then adjust compensators as noted for maximum output.

NOTE: See page 237 before servicing this set.

PILOT RADIO CORPORATION
MODEL X-41

Range: 170 Meters—550 Meters (1,770 kc.—545 kc.)

HOW TO OPERATE THE PILOT X41

1. Examine the label on the rear of the chassis to make sure that the voltage and frequency are correct for the power supply in your home.
2. Connect the blue wire at the rear of the chassis to your antenna. For best results use an antenna of the type described in the PILOT antenna instruction sheet. If you are not experienced in erecting antennas, we strongly advise having this done by your radio service man. Good results can be obtained from a single wire about fifty feet long, and as high above surrounding objects as possible.
3. Connect the clip at the rear of the chassis to the ground. This lead should be as short as possible, connected to the nearest water pipe.
4. When the connections have been made, switch on the set by turning the left-hand knob clockwise. This is the volume control knob as well as the line switch On the right is the tuning knob for the compass dial and at the center, the Tone Control.
5. When tuning in a station, be very careful to adjust the dial to the center of the response with the volume control set at the lowest position that will give sufficient volume. Unless that is done, the tone will be distorted.
6. If signals from local stations are loud enough to overload the speaker, reducing the volume slightly will clear up the tone.

NOTE: This PILOT set, in design, the quality of the materials, and the workmanship, is a fine musical instrument. It deserves careful treatment. Protect it from excessive dampness and from dry heat. Have it inspected and have the tubes checked twice a year by your radio dealer, to assure the maintenance of its fine musical quality.

SERVICE INFORMATION

REMOVAL OF CHASSIS FROM CABINET:

To remove the chassis from the cabinet proceed as follows:

Be certain that the line cord is removed from the power outlet socket.

Remove the slip-on knobs and felt washers from the controls on the front panel.

Remove the speaker plug from the socket at the rear of the chassis.

Remove the four mounting screws, located underneath the cabinet.

REALIGNMENT: Should the receiver require realignment, the procedure outlined below should be followed. For best results an external modulated oscillator with adequate frequency range, and a visual output meter, should be used.

Before connecting the chassis to the power line, reconnect the speaker cable in its socket at the rear of the chassis.

I. F. ALIGNMENT: When aligning the intermediate Frequency Amplifier, the external oscillator must be set at 456 kc. The tuning condenser should be set at maximum capacity. Connect the antenna lead of the external oscillator to the control grid of the type 6F7 tube in the I. F. Amplifier stage through a 0.1 mfd. fixed condenser. Connect the ground lead of the external oscillator to the receiver ground clip. The I. F. alignment capacitors are located at the top of the shielded I. F. Transformers. Rotate the adjusting screw of each capacitor on I. F. Unit No. 2 slowly until maximum output is noted. On completion of this operation, remove the external oscillator leads from the type 6F7 I. F. Amplifier tube and connect it in the same manner to the control grid at the top of the type 6A7 tube.

Now rotate each adjustment screw on I. F. Unit No. 1 for maximum output. During these operations, use the least possible input to prevent broadening of the resonance peaks.

In order to obtain the most accurate realignment of the I. F. Amplifier, it is essential to repeat the alignment process in both I. F. units with the external oscillator leads connected across the control grid of the 6A7 tube.

BROADCAST ALIGNMENT: After the I. F. Amplifier is completely realigned, connect the external oscillator leads to the receiver antenna and ground leads, this time with a .0002 mfd. condenser in the antenna lead. Adjust the tuning control pointer at the 1500 kc. mark. Adjust the broadcast band oscillator trimmer to maximum response. Adjust the signal section trimmer in the same manner.

Next adjust the 600 kc. padder condenser. Set the external oscillator at 600 kc. Rotate the receiver tuning control until resonance is indicated. Then rock the tuning control back and forth about this resonance position, and at the same time adjust the padder condenser for the highest resonance peak.

Now repeat the 1500 kc. trimmer adjustment, following in every detail the procedure previously described.

CAUTION: When making repairs on the receiver, use only ROSIN CORE SOLDER. NEVER USE SOLDERING PASTE OR ACID FLUXES OF ANY TYPE.

VOLTAGES MEASURED AT TUBE SOCKETS

	Det. Osc. 6A7	Amp. Det. 6F7	Audio Output 42	Rectifier 80
PLATE	220	220	210	335 Volts D.C. from Filament to transformer center tap.

Plate and screen voltages measured to cathode.
Cathode voltages measured to chassis frame.

Speaker field volts—85 volts.
Anode grid of 6A7—150 volts.
Triode plate of 6F7—95 volts.

***Measured across 250 ohm resistor, R-11.**
Measurements made with voltmeter of 1,000 ohms per volt.

RCA MANUFACTURING COMPANY, Inc.

MODEL U-103

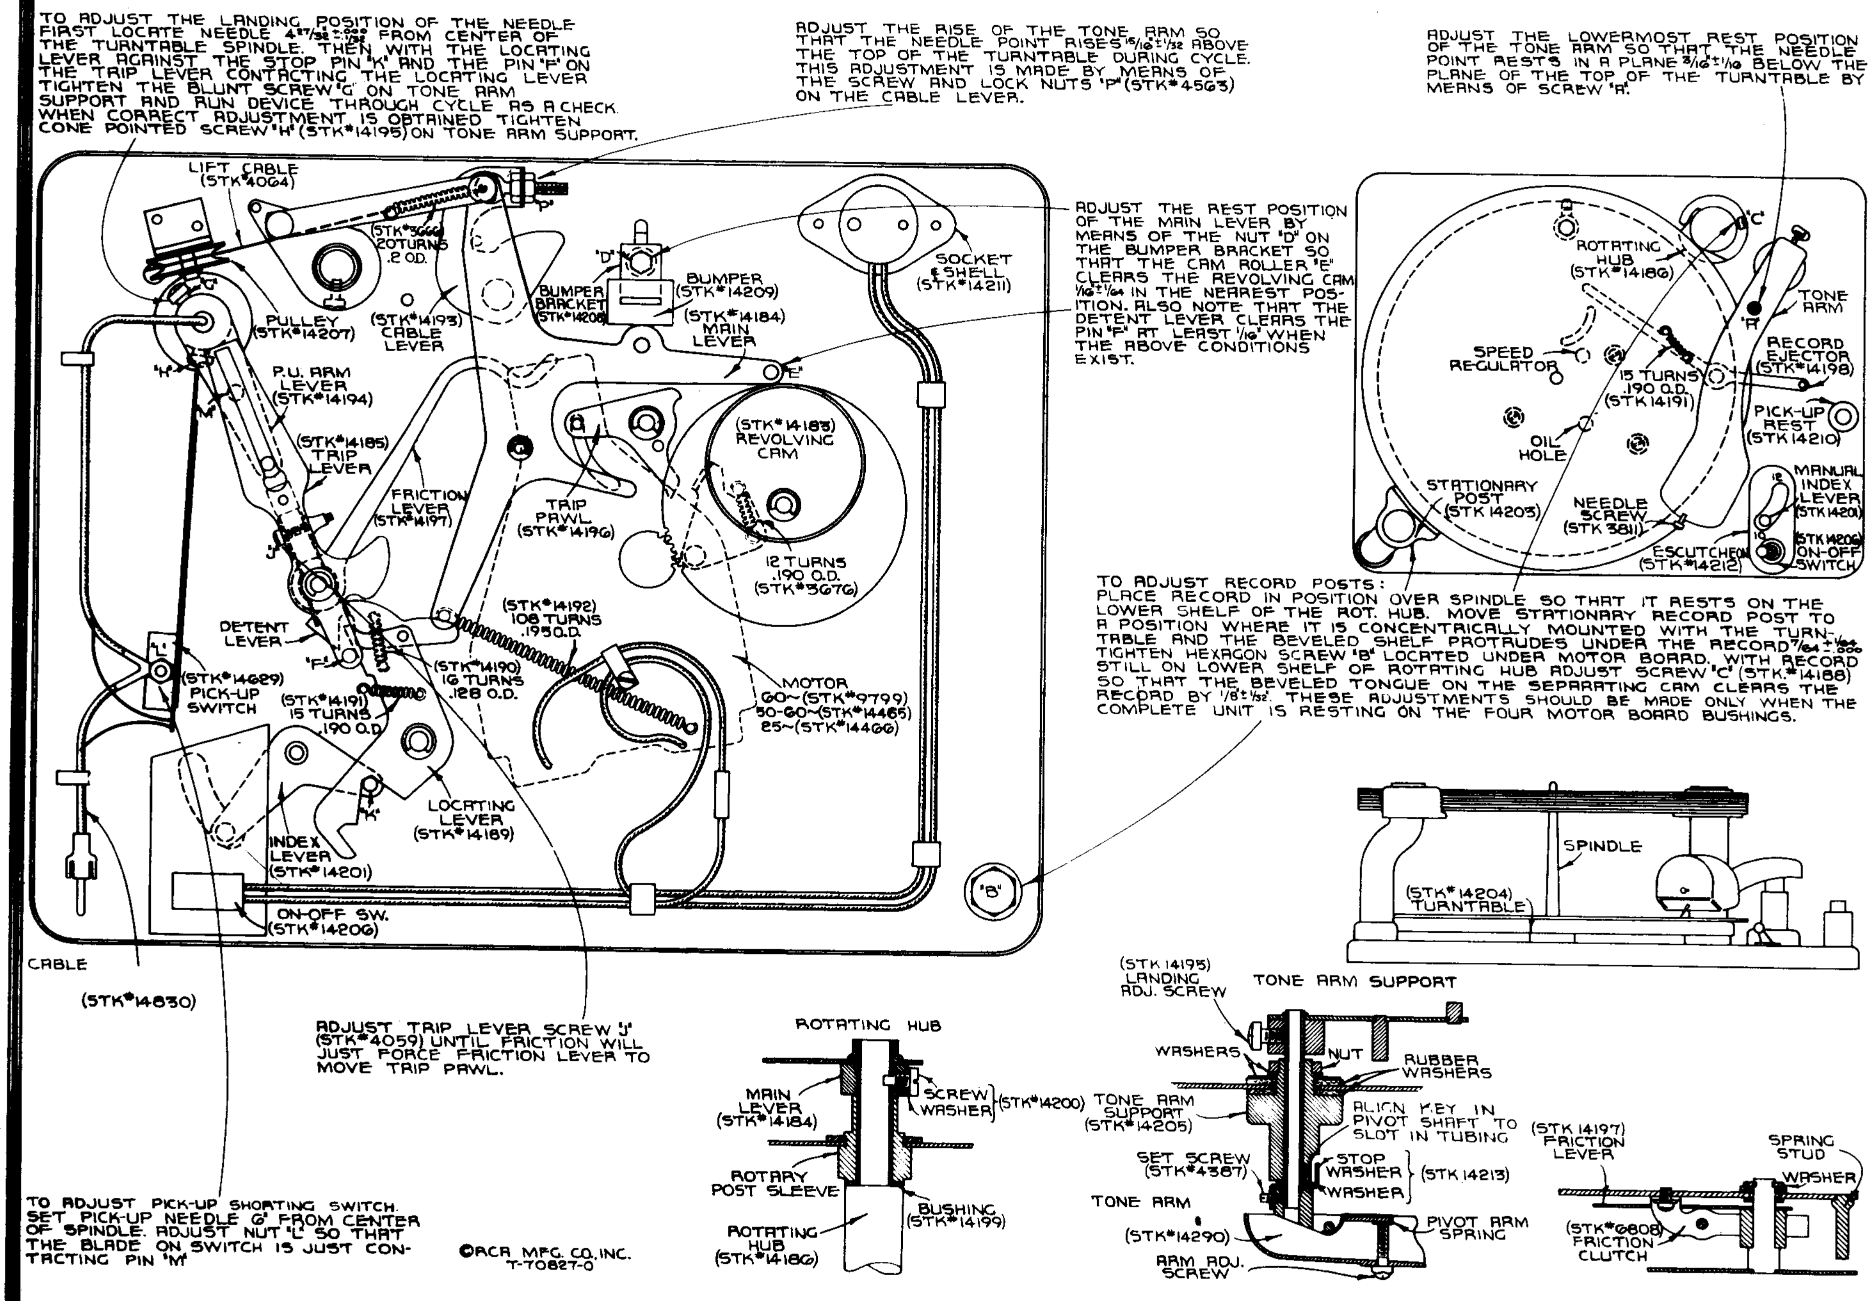

Figure 4—Automatic Record Changer Adjustments
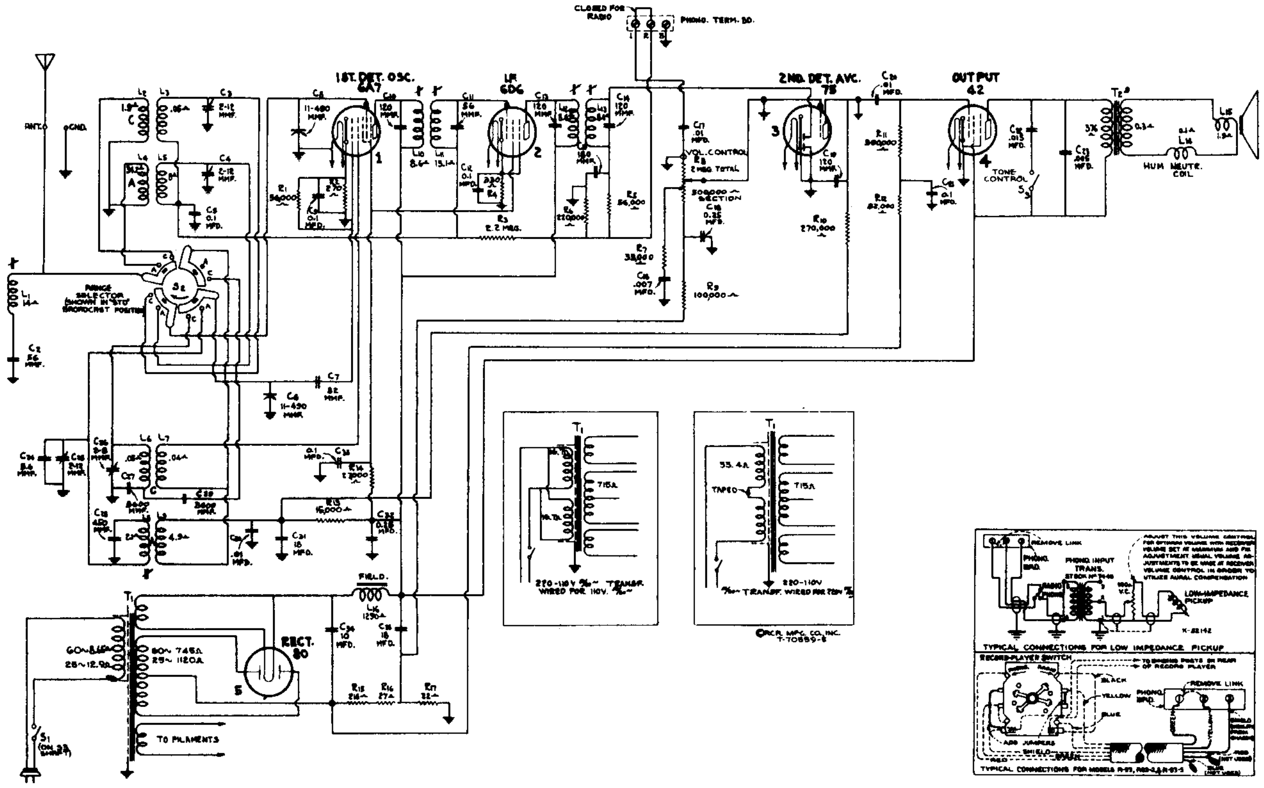
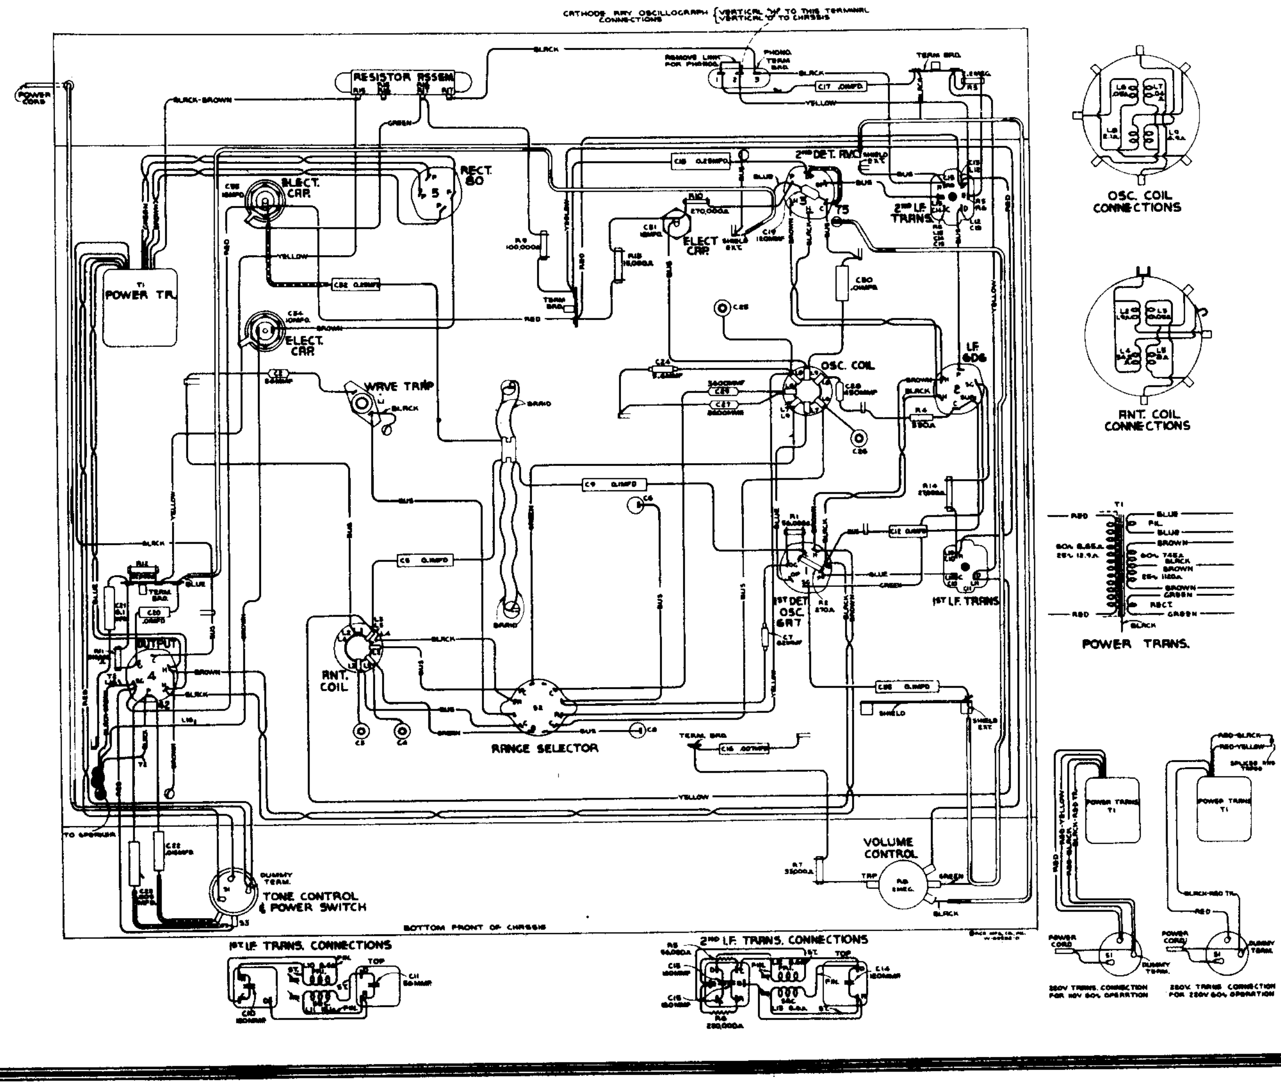
(Model U-103)

RCA MANUFACTURING COMPANY, Inc.
MODEL 5T5





RCA MANUFACTURING COMPANY, Inc.
MODEL 5T5

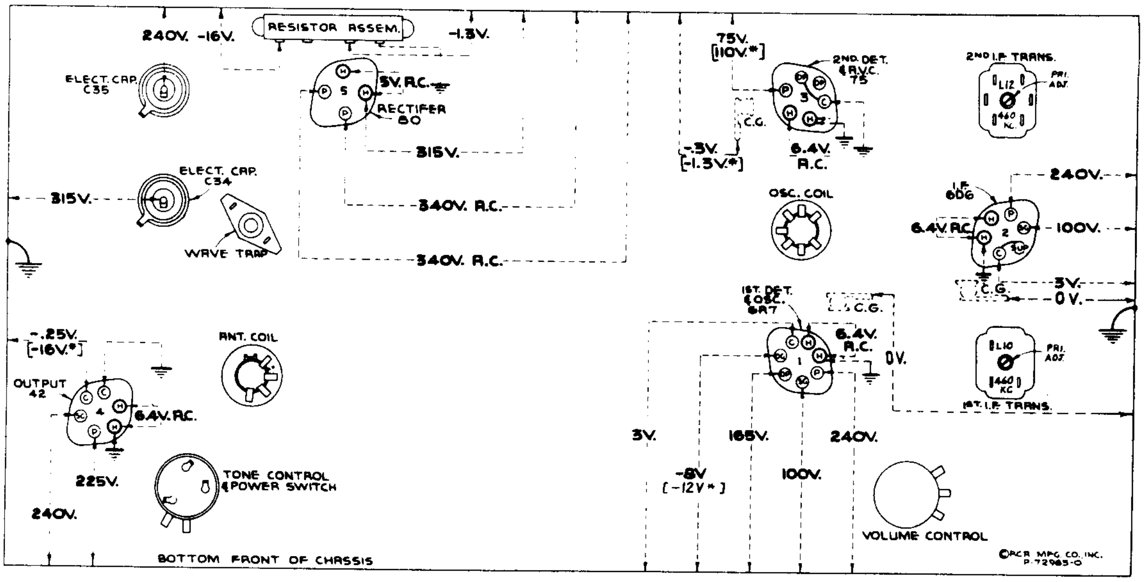


Figure 6—Radiotron Socket Voltages, Coil and Trimmer Locations.

Measured at 115 volts, 60-cycle supply—Tuned to approximately 1,000 kc ("Standard broadcast")—

Radiotron Socket Voltages

Note: Two voltage values are shown for some readings. The value shown in parentheses with asterisk (*) indicates operating conditions without voltmeter loading. The other value (generally lower) is the actual measured voltage and differs from the value shown in parentheses because of the additional loading of the voltmeter through the high series circuit resistance.

The voltage values indicated from the Radiotron socket contacts, grid caps, resistors, and terminals to receiver chassis ground on figure 6 will assist in locating cause of faulty operation. Each value as specified should hold within ± 20% when the receiver is normally operative at its rated line voltage. Variations in excess of this limit will usually be indicative of trouble in the basic circuits. To duplicate the conditions under which the voltages were measured requires a 1,000-ohm-per-volt d-c meter, having ranges of 10, 50, 250, and 500 volts. Use the nearest range above the specified measured voltage. A-c voltages were measured with a corresponding a-c meter.

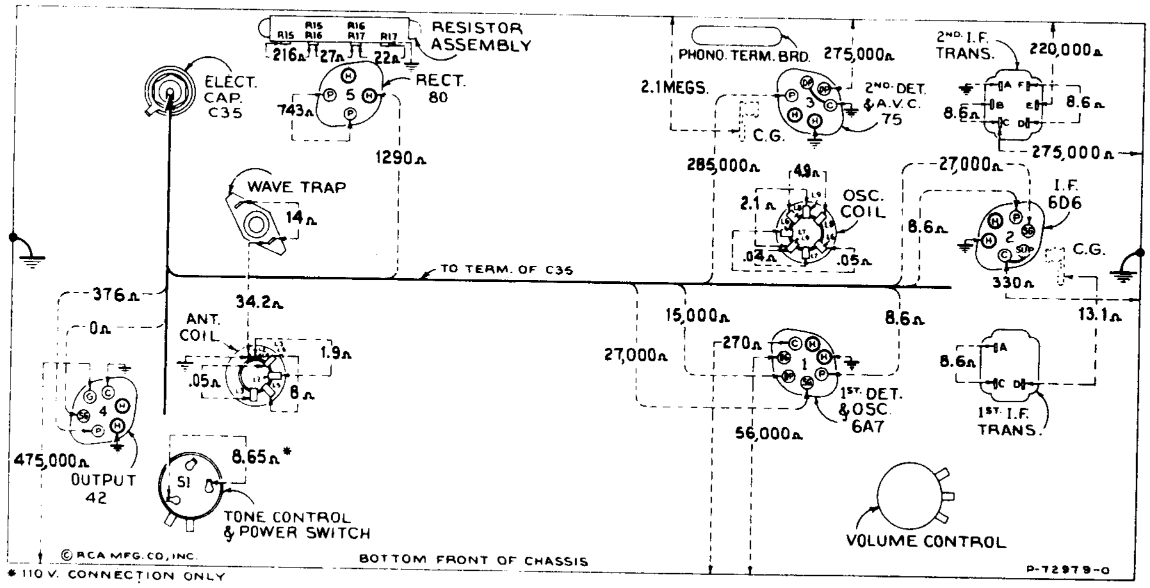

Figure 4—Resistance Diagram

Resistance Measurements

The resistance values shown between Radiotron socket contacts, grid caps, resistors, and terminals to receiver chassis-ground or other pertinent point on figure 4, permit a rapid continuity check of the circuits. The use of this diagram in conjunction with the Schematic Circuit Diagram, figure 1, and Wiring Diagram, figure 2, will permit the location of certain troubles which might otherwise be difficult to ascertain. Each value as specified should hold within ± 20%. Variations in excess of this limit will usually be indicative of trouble in circuit under test. When measuring the resistance between points of the circuit and ground, it will be necessary to connect the negative terminal of the resistance meter to the chassis-ground. If the polarity of the resistance meter is not known, it may be readily ascertained by connecting a d-c voltmeter of indicated polarity across the terminals of the device.

Type .... Electrodynamic
Voice Coil Impedance .... 2.2 ohms at 400 cycles

General Features

This receiver is of the superheterodyne type and has many distinctive features. Its design includes magnetite core adjusted i-f transformers and wave-trap, aural compensated volume control, tone control, resistance-coupled audio system, phonograph terminal board, and an 8-inch dust-proof electrodynamic loudspeaker.

Tuning range includes the "Standard broadcast" (A) and "Short wave" (C) bands. The "Short wave" (C) position of this extensive range includes channels assigned for amateur, and international short-wave broadcast on 49, 31, 25, 19, 16 and 13 meters. Trimming adjustments are located at accessible points. Their number is reduced to the least that is consistent with efficient operation. The tuning dial ratio of 10 to 1, with a 50 to 1 vernier, permits ease of tuning, especially in the "Short wave" band.

Circuit Arrangement

The first-detector and oscillator functions are accomplished in a single tube, an RCA-6A7. The input of this tube is coupled to the antenna through a tuned transformer. A shunt (magnetite core adjusted) wave-trap is connected across the primary of this transformer to prevent signals of intermediate frequency (460 kc) from being introduced into the first stage as interference. A two-section gang condenser tunes the antenna transformer secondary and the heterodyne oscillator coils. These coils are shunted by improved plunger-type, air-dielectric, adjustable trimming capacitors, for obtaining exact alignment.

The intermediate frequency stage is coupled to the RCA-6A7 and to the RCA-75 by means of tuned transformers. These transformers resonate with fixed capacitors and are adjusted by molded magnetite cores to tune to 460 kc.

The modulated signal as obtained from the output of the i-f system is detected by one of the diodes of the RCA-75 tube. Audio frequency secured by this process is passed on to the control grid of this same tube for amplification before final reproduction. The d-c voltage, which results from detection of the signal, is used for automatic volume control. This voltage, which develops across resistor R6, is applied as automatic control grid bias to the first-detector and i-f tubes through a suitable resistance filter.

Manual volume control is effected by means of an acoustically tapered potentiometer connected as a variable coupling element between the output of the second detector and the first audio control grid. After amplification by the RCA-75, the audio signal is transmitted by resistance-capacitance coupling to the input of the RCA-42 power output stage, which, in turn, is transformer-coupled to the dynamic speaker. High-frequency tone control is provided by means of a shunt capacitor across the plate circuit of the output tube, which may be cut in or out of the circuit with a control switch S3.

The power supply system consists of an RCA-80 rectifier tube, power transformer, and filter.

SERVICE DATA

The various diagrams of this booklet contain such information as will be needed to isolate causes for defective operation if such develops. The ratings of the resistors, capacitors, coils, etc., are indicated adjacent to the symbols signifying these parts on the diagrams. Identification titles, such as L1, C2, R1,

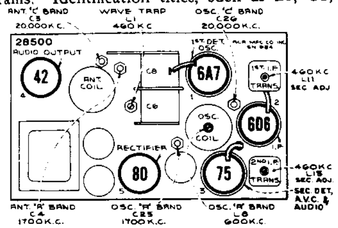

Figure 3—Radiotron, Coil, and Trimmer Locations

etc., are provided for reference between the illustrations and the Replacement Parts List. The coils, reactors, and transformer windings are rated in terms of their d-c resistances only. Ratings of less than one ohm are generally omitted.

Alignment Procedure

There are five alignment trimmers provided in the antenna transformer and oscillator coil tuned circuits. The i-f transformer and wave-trap adjustments are made by means of screws attached to molded magnetite cores. All of these circuits have been accurately adjusted during manufacture and should remain properly aligned unless affected by abnormal conditions or altered during servicing. Loss of sensitivity, improper tone quality, and poor selectivity are the usual indications of improper alignment.

The correct performance of this receiver can only be obtained when the aligning has been done with adequate and reliable apparatus. The manufacturer of this receiver has available for sale, through its distributors and dealers, a complete assortment of such service equipment as may be needed for the alignment operation.

A test oscillator, such as the **RCA Stock No. 9595**, is required as a source of the specified alignment frequencies. Visual indication of receiver output during the adjustment is necessary and should be accomplished by the use of an indicator such as the **RCA Stock No. 4317 Neon Output Indicator.**

The procedure outlined below should be followed in adjusting the various trimmer capacitors and molded cores:

I-F Adjustments

The four adjustment screws (attached to molded magnetite cores) of the two i-f transformers (one on top and one on bottom of each i-f transformer) are located as shown by figures 3 and 6. Each circuit must be aligned to a basic frequency of **460 kc.** To do this, attach the output indicator across the loudspeaker voice coil.

Connect the output of the test oscillator to the control grid of the RCA-6A7 through a **.001 mfd.** capacitor. Connect the test oscillator **"Gnd"** terminal to the ground terminal of the receiver chassis. Tune the oscillator to **460 kc.** Advance the receiver volume control to its full-on position and adjust the receiver tuning control to a point, within its range, where no interference is encountered from local broadcast stations or from the local (heterodyne) oscillator. To eliminate signals from the local oscillator short stator of C6 to chassis-ground. Increase the output of the test oscillator until a slight indication is present on the output indicator. Adjust the two magnetite core screws of the second i-f transformer L13 and L12 to produce maximum (peak) indicated receiver output. Then adjust the two magnetite core screws L11 and L10 of the first i-f transformer for maximum (peak) receiver output as shown by the indicating device. During these adjustments, regulate the test oscillator output so that the indication is always as low as possible. By doing so, broadness of tuning due to a.v.c. action will be avoided. It is advisable to repeat the adjustment of all i-f magnetite core screws to assure that the interaction between them has not disturbed the original adjustment.

R-F Adjustments

Calibrate the tuning dial by adjusting the scale pointer to the extreme end calibration mark (beyond 55 on dial) while the two-gang tuning condenser plates are in full mesh.

Wave-Trap Adjustment

Attach the output of the test oscillator to the receiver "Antenna" terminal through a **200 mmfd. (important)** capacitor. The ground connections remain connected together. Leave the test oscillator tuned to **460 kc.** Adjust range selector to "Short wave" (C) position. Then adjust the wave-trap screw to the point which causes maximum suppression (minimum received) of the **460 kc** signal.

"Standard Broadcast" Band

(a) Adjust range selector to "Standard broadcast" (A) position. Reduce output of test oscillator to a minimum. Tune the test oscillator to **600 kc** and set receiver dial pointer to **600 kc.** Adjust output of test oscillator until a slight indication of output is visible.

(b) Adjust the oscillator magnetite core screw **L8** (top of oscillator coil) so that maximum (peak) indicated output results.

(c) Set receiver dial pointer to **1,700 kc.** Tune the test oscillator to **1,700 kc.** Carefully adjust the oscillator and antenna trimmers **C25** and **C4** respectively so that each brings about maximum (peak) indicated output.

(d) Tune the test oscillator to **600 kc.** Adjust the receiver to pick up this signal disregarding the dial reading at which it is best received. Adjust oscillator magnetite core screw **L8** (top of oscillator coil) for maximum (peak) output while rocking gang tuning condenser. After completing this adjustment, the trimmers **C25** and **C4** should be re-adjusted as in (c) to correct for any change in the oscillator high-frequency tuning which has been caused by the preceding adjustment.

"Short-Wave" Band

(e) Connect the "Ant." output of the test oscillator to the "Antenna" terminal through a **300-ohm** resistor, leaving the "Gnd." of the oscillator connected to the receiver chassis.

(f) Adjust range selector to its "Short wave" (C) position. Set receiver dial pointer to **20,000 kc.**

Tune test oscillator to **20,000 kc.** Set oscillator trimmer C26 to minimum capacity (plunger full out), and antenna trimmer C3 to maximum capacity (plunger full in). Slowly push in oscillator trimmer C26 until maximum (peak) output is reached. Two peaks may be found. Adjust C26 to the peak with minimum capacity (plunger near out) for maximum indication. Tighten lock nut. Slowly pull out plunger of antenna trimmer C3 until maximum (peak) indicated output is reached while slightly rocking the gang tuning condenser back and forth through the signal. Two peaks may be found with this circuit. The peak with maximum capacity (plunger near in) should be used. Tighten lock nut.

Radiotron Plate Current Readings

Measured with Milliammeter Connected at Tube Socket Plate Terminals Under Conditions Similar to Those of Voltage Measurements

(1) RCA-6A7—1st Det.—Osc.	11.0 ma.
(2) RCA-6D6—I. F. Amp.	10.0 ma.
(3) RCA-75—2nd Det., A.V.C. and A. F.	0.22 ma.
(4) RCA-42—Power Amp.	42.0 ma.
(5) RCA-80—Rectifier	—

Loudspeaker

Centering of the loudspeaker voice coil is made in the usual manner with three narrow paper feelers after first removing the front paper dust cover. This may be removed by softening its cement with a very

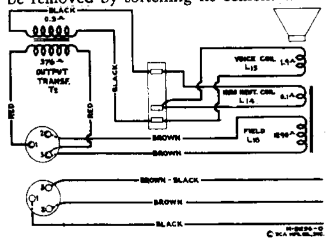

Figure 5—Loudspeaker Wiring

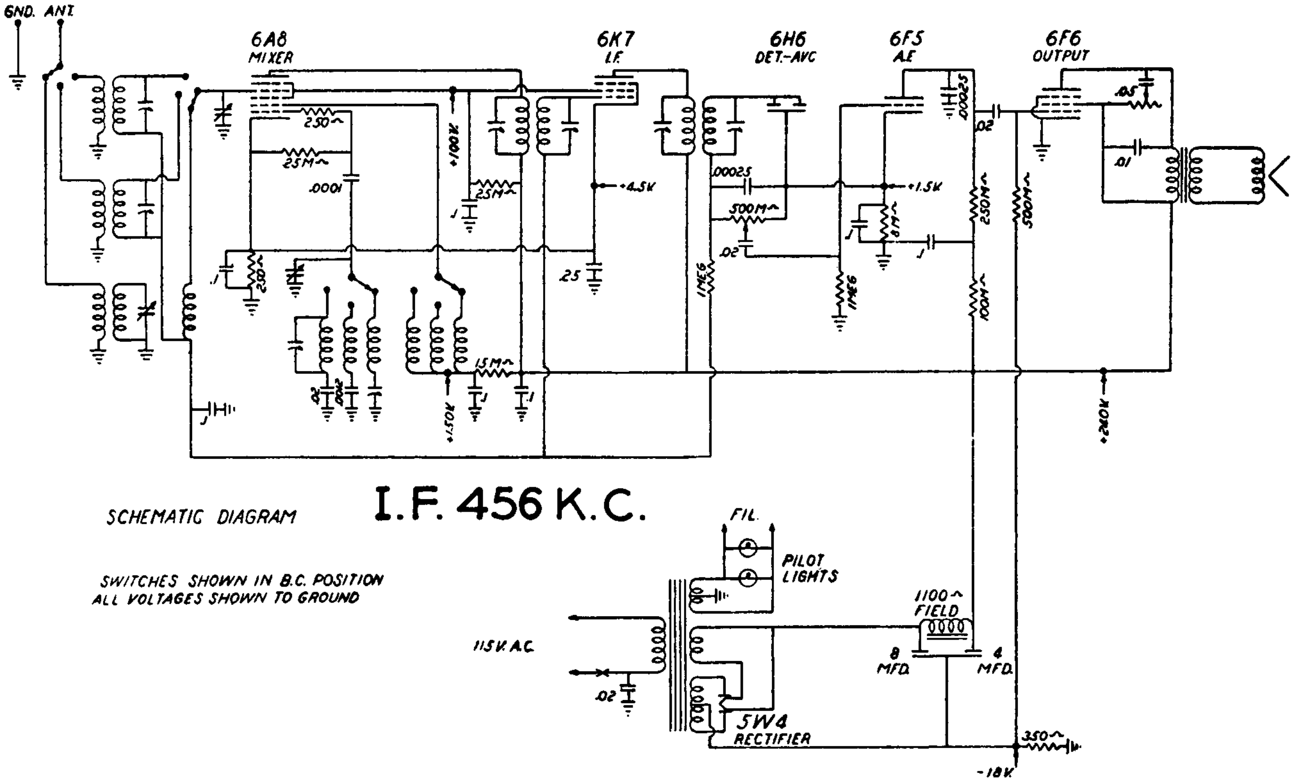
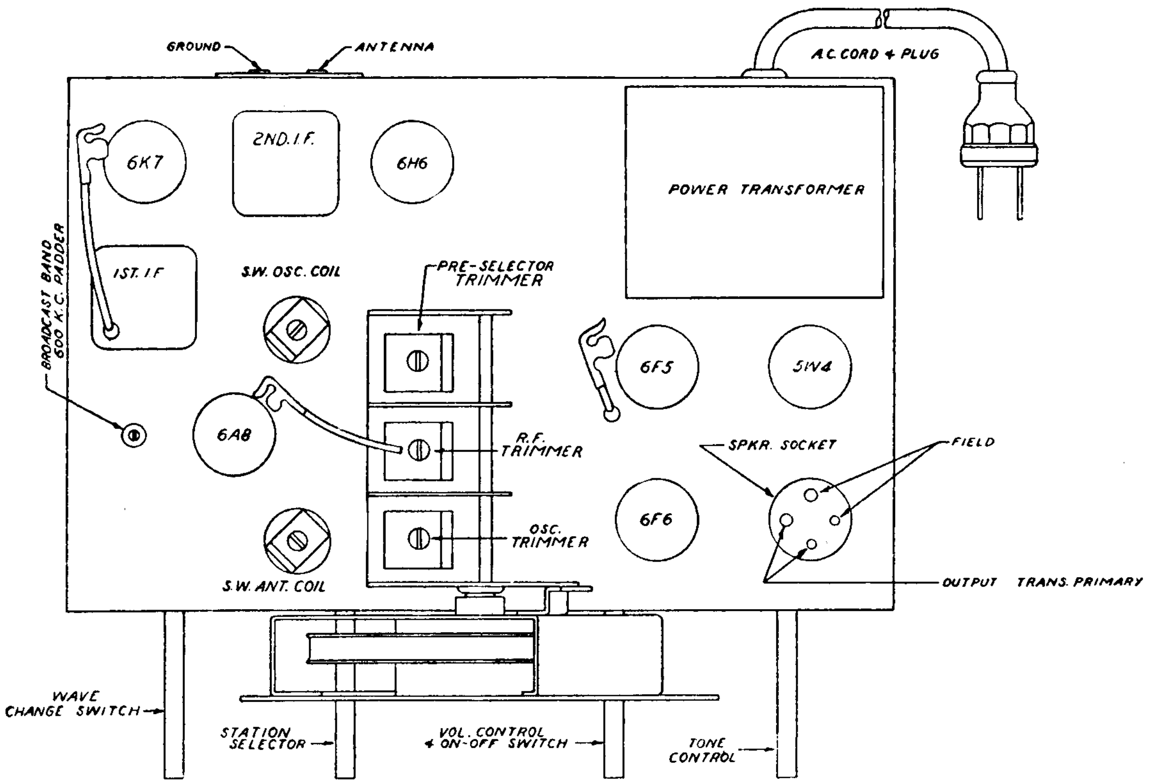
light application of acetone, using care not to allow the acetone to flow down into the air gap. The dust cover may be cemented back in place with ambroid upon completion of adjustment.

RADOLEK COMPANY

MODEL K16,756





This receiver is designed to operate over three tuning ranges. The broadcast range which extends from 545 to 1715 Kilocycles (KC) (175 to 550 meters), Police and Aviation Band which extends from 1715 to 5350 Kilocycles (KC) (56 to 175 Meters) and the International Short Wave Band which extends from 5760 to 16200 Kilocycles (KC) (18.5 to 52 meters). This short wave range is the one which includes the four internationally assigned bands—the 19, 25, 31 and 49 meter bands.

RADOLEK COMPANY
MODEL K16,756
ALIGNMENT DATA AND SERVICING

GENERAL DATA The alignment of this receiver requires the use of a test oscillator that will cover the frequencies of 456, 600, 1400, 1800, 4000, 6000, and 14,000 KC and an output meter to be connected across the primary or secondary of the output transformers. If possible, all alignments should be made with the volume control on maximum and the test oscillator output as low as possible, to prevent the AVC from operating and giving false readings.

CORRECT ALIGNMENT PROCEDURE The intermediate frequency (I.F.) stage should be aligned properly as the first step. After the I.F. transformers have been properly adjusted and peaked, the Broadcast Band should always be the next procedure; after which, either or both of the Short Wave Bands may be aligned.

I.F. ALIGNMENT Adjust the test oscillator to 456 KC and connect the output to the grid of the first detector tubes (6L7) through a .05 or .1 mfd. condenser. The ground on the test oscillator can be connected to the chassis ground. Align all six I.F. trimmers to peak or maximum reading on the output meter.

BROADCAST BAND ALIGNMENT Adjust the oscillator to 1400 KC and connect the output to the antenna post marked "A" through a .0001 mfd. mica condenser to give the equivalent of an antenna about 60 feet. Set the receiver pointer to 1400 KC and adjust the rear gang condenser trimmer (oscillator circuit) to peak. After this has been carefully done, the next step is to adjust the center and front trimmers of the gang condenser to peak. The front gang section tunes the R.F. or grid coil of the 6A8 tube and the center condenser section tunes the pre-selector stage circuit.

Next, re-set the dial pointer on the receiver and the test oscillator to 600 KC. Slowly increase or decrease the oscillator padding condenser and at the same time continuously tune back and forth across the signal with the receiver until the maximum reading is obtained on the output meter. This adjustment seems a little complicated but is the easiest way to adjust the oscillator to the pre-selector or R.F. section. The padding condenser is located on the right hand end of the chassis near the 6K7 tube.

Return to 1400 KC and again go over the adjustments of this frequency to be certain that they were not put slightly out of alignment whon adjustment was made at 600 KC.

This completes the correct sequence of operations in properly aligning the receiver for the Broadcast Band, and **must always be done before** attempting to align the Short Wave Bands.

FOREIGN BAND The Foreign Band of 19 to 49 meters can be adjusted by the two trimmers on the short wave coil located on the top of the chassis. Set the test oscillator to 14,000 KC. The oscillator coil is located near the 1st I.F. Transformer and the antenna or R.F. coil is located directly in front of the Short Wave oscillator coil and about midway between the 1st I.F. Transformer and the 6A7 tube. These two trimmers should be adjusted for peak at 14,000 KC and as the inherent design of the circuit has been expressly designed for simplicity in servicing, no other adjustments are necessary for aligning this band. **Note:** Always start this procedure by having the oscillator coil trimmer loose (out all the way), and the antenna coil trimmer fairly tight (in all the way); otherwise it is possible to make a false alignment on the image frequency.

Important: Do not attempt any adjustment of the gang condenser trimmers in aligning the Foreign Band as this will throw the Broadcast Band out of alignment.

POLICE BAND There is only one adjustment to be made in the alignment of the Police Band. Due to the circuit design and correct matching of the coils, no oscillator adjustment is necessary.

Set the dial pointer to 4000 KC (also the test oscillator) and adjust the antenna coil trimmer to resonance. In preparing the test oscillator for alignment of this band, connect a 400 ohm carbon resistor in series with the .0001 mfd. condenser on the output lead of the test oscillator. This resistor is used with the test oscillator only on the Short Wave Bands and should not be used for Broadcast Band alignment. The two police band coils are under the chassis and the antenna coil trimmer is mounted on the end of the antenna coil.

Important: This is the only adjustment necessary for the Police Band. Do not attempt any adjustment of the gang condenser trimmers in aligning the Police Band, otherwise the Broadcast Band will be thrown out of alignment.

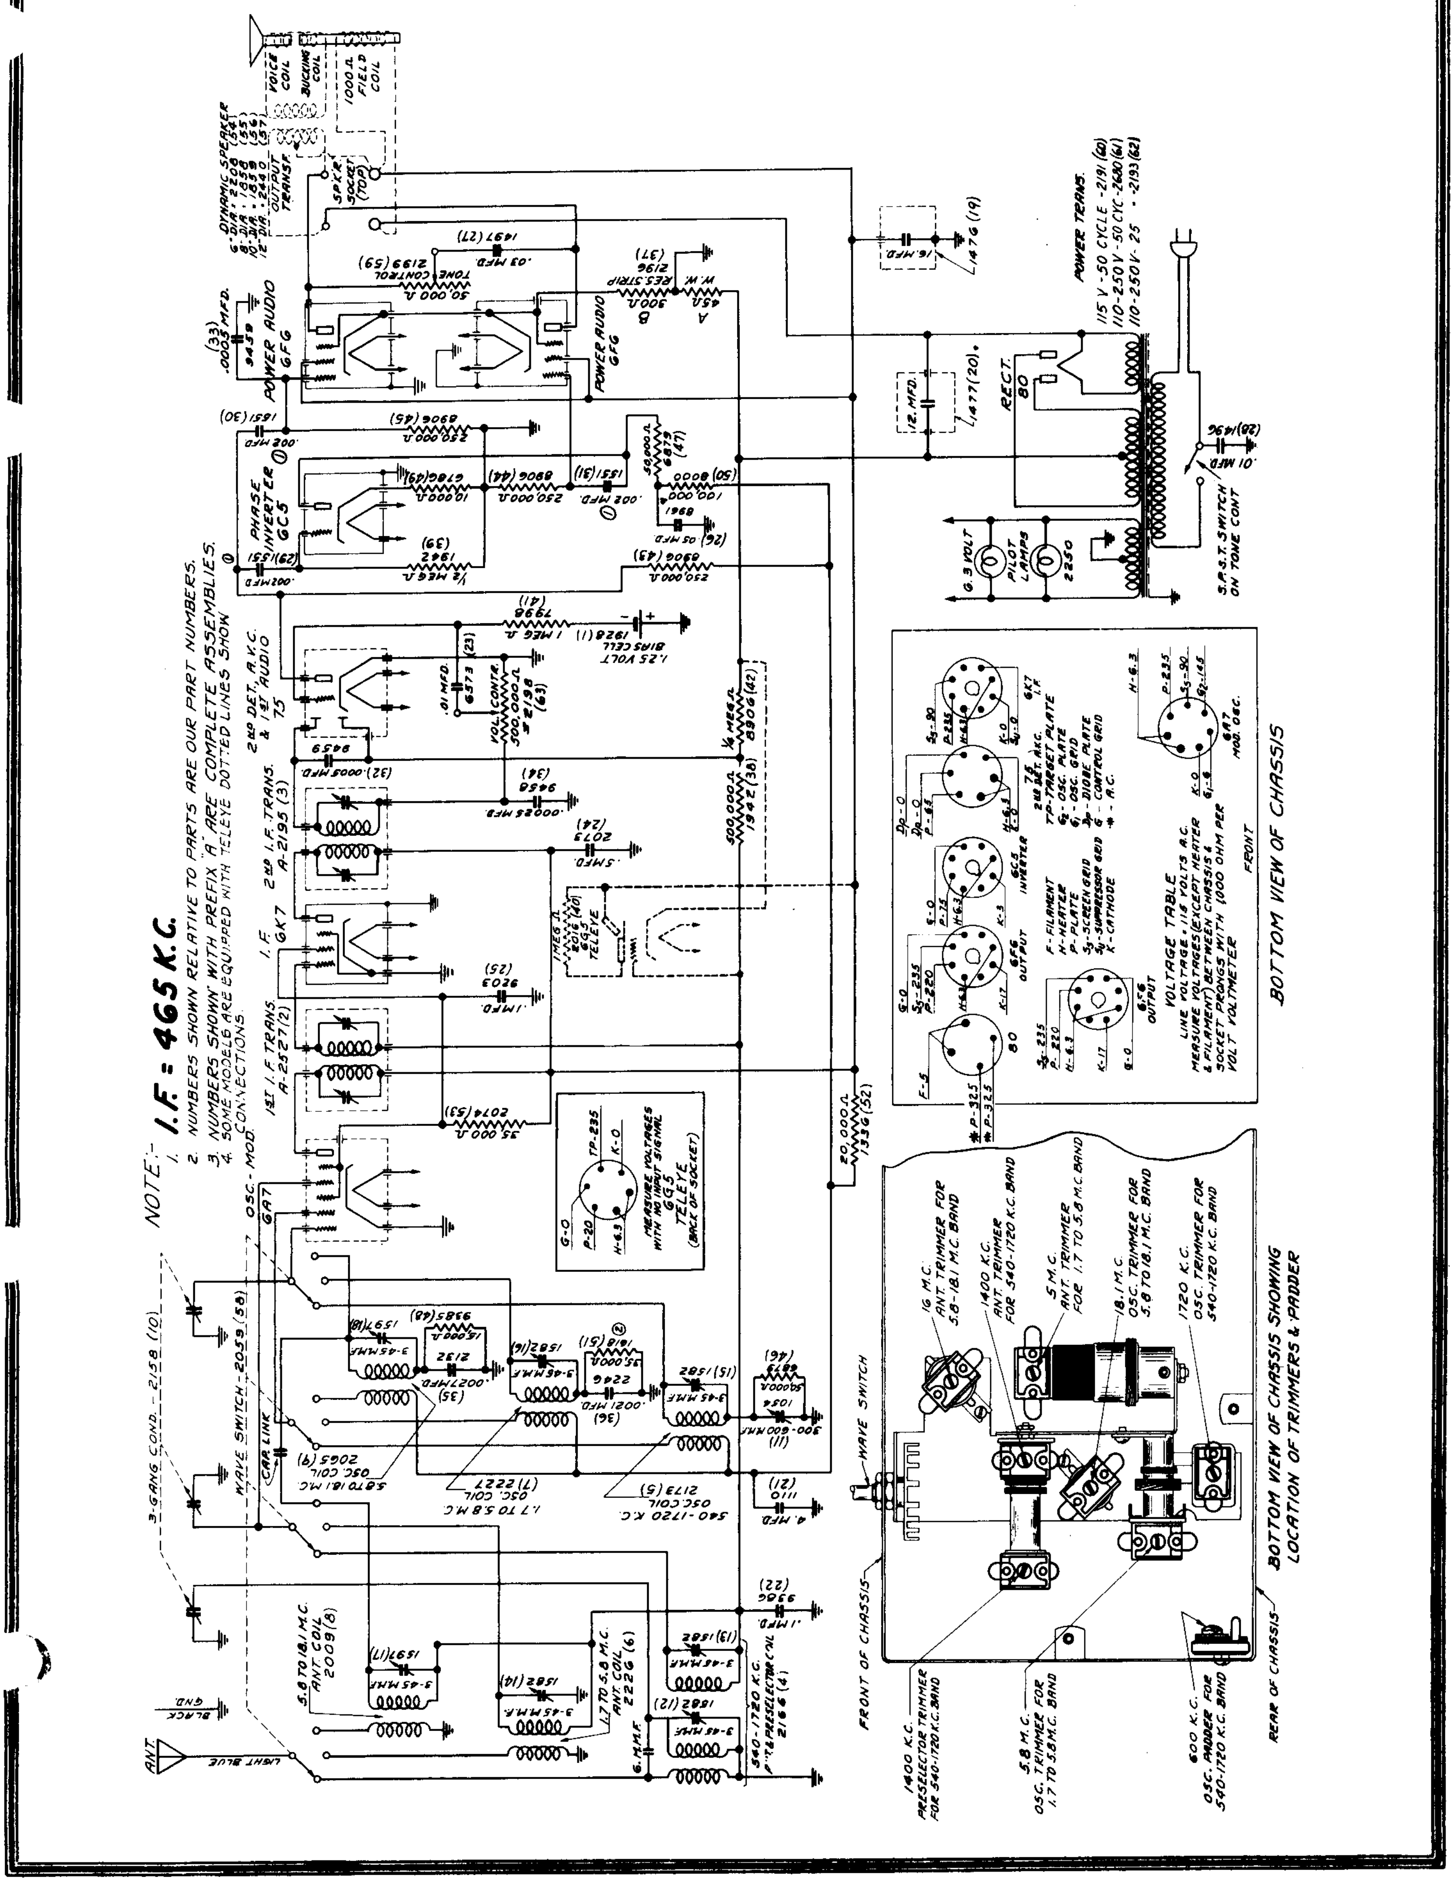
RADOLEK COMPANY
MODELS K16,770, K16,771 & K16,772

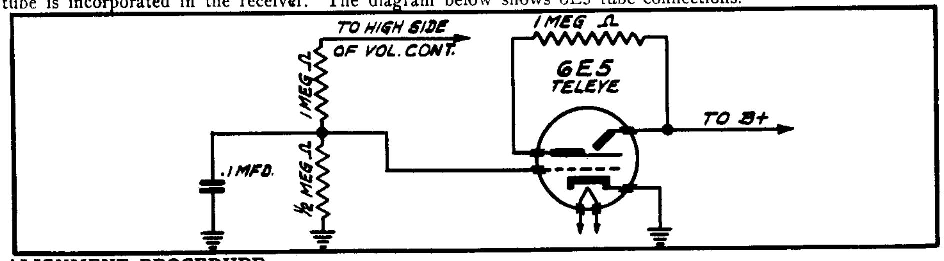


RADOLEK COMPANY

MODELS K16,770, K16,771 & K16,772

NOTE:

Some of these model receivers were equipped with "Teleye" the cathode ray visual tuning indicator. A 6E5 tube was used in early production models, which was replaced by a 6G5 tube in later production. The parts and connections shown in the dotted lines on the complete circuit diagram are used only when a 6G5 "Teleye" tube is incorporated in the receiver. The diagram below shows 6E5 tube connections.



ALIGNMENT PROCEDURE:

Realignment of this receiver should never be necessary unless one of the oscillator, antenna, or I. F. coils has been replaced. Lack of sensitivity, selectivity, and poor tone quality may be due to any one or a combination of causes, such as weak or defective tubes or speaker, inadequate or excessively long antenna, open or grounded bias resistor, bypass condenser, etc. Under no circumstances should realignment be attempted until all other possible sources have been first thoroughly investigated and have been definitely proven not to be the cause.

If an I. F. tube is replaced it is advisable to realign the I. F. Amplifier particularly if the replacement tube is one of a different manufacture than the one in the receiver. It is important when aligning to carefully follow the procedure in the order given, otherwise the receiver will lack sensitivity and the dial calibration will be incorrect.

IT IS IMPERATIVE THAT AN ACCURATELY CALIBRATED OSCILLATOR BE USED WITH SOME TYPE OF OUTPUT MEASURING DEVICE.

INTERMEDIATE ALIGNMENT:

1. Connect the high side of the test oscillator output to the control grid of the 6D6 modulator tube through a .02 Mfd. condenser. Leave the grid cap connected to the grid terminal of the tube, and connect the ground side of the test oscillator to the receiver ground.

2. Set the test oscillator frequency to 465 kilocycles (this must be accurate).

3. Align the second intermediate transformer by turning one of the trimmer screws accessible through holes in the top of the transformer shields up and down (increasing and decreasing capacity) until maximum reading is obtained on the output meter, after which adjust the other trimmer screw of the same transformer for maximum sensitivity.

4. Adjust the first intermediate transformer in the same manner as the second I. F. transformer.

TO ALIGN THE VARIABLE CONDENSER:

It is important when aligning the gang condenser, padding and trimmer condensers to follow the procedure carefully, otherwise the receiver will be insensitive and the dial calibration will be incorrect. The padding and trimmer condensers located underneath the chassis will be referred to by their function as indicated on the circuit diagram.

1. Connect the high output side of the test oscillator through a 400 ohm resistor to the receiver antenna lead and the low side to the set ground.

2. Place the band selector switch for operation on the 5.8 to 18.1 megacycle band, tune the receiver dial, and set the test oscillator frequency to EXACTLY 18.1 MEGACYCLES.

Tune in the 18.1 MEGACYCLE SIGNAL TO MAXIMUM OUTPUT BY ADJUSTING THE 18.1 MEGACYCLE OSCILLATOR TRIMMER. When adjusting this trimmer two peaks, the fundamental and the image peak will be noticed. CARE MUST BE TAKEN THAT THE FUNDAMENTAL PEAK AND NOT THE IMAGE PEAK IS USED FOR ALIGNING THE RECEIVER at 18.1 MEGACYCLES. Always back off the trimmer to minimum capacity, then screw down the trimmer (add capacity) until the first peak which is the fundamental and the proper one to use is tuned in. If the trimmer is screwed down beyond the point where the first peak is received, the incorrect image peak will be tuned in. After completing adjustment of the oscillator trimmer at 18.1 megacycles always check to see if the proper peak has been used. To do this leave the test oscillator frequency at 18.1 megacycles, increase the output of the test oscillator and tune the receiver dial to approximately 17.1 megacycles, and if the fundamental peak was used in aligning at 18.1 megacycles the test oscillator signal will be heard at approximately 17.1 megacycles on the receiver dial. If it is not possible to receive the signal, then the fundamental peak was not used and the 18.1 megacycle oscillator trimmer must be properly re-adjusted.

3. With band selector switch set for operation on 5.8 to 18.1 megacycle band tune the receiver dial and set test oscillator frequency to EXACTLY 16 MEGACYCLES. Adjust 16 megacycle antenna trimmer for maximum 16 megacycle signal sensitivity.

4. Place band selector switch for operation on 1.7 to 5.8 megacycle band, tune the receiver dial, and set test oscillator frequency to EXACTLY 5.8 MEGACYCLES. BRING IN 5.8 MEGACYCLE SIGNAL TO MAXIMUM OUTPUT by adjusting 5.8 megacycle oscillator trimmer.

5. With the band selector switch set for operation on the 1.7 to 5.8 megacycle band tune receiver dial and set test oscillator frequency to EXACTLY 5 MEGACYCLES. Then adjust 5 megacycle antenna trimmer for maximum 5 megacycle signal sensitivity.

6. Replace the 400 ohm resister in series with test oscillator lead with a 200 Mmfd. condenser, place the band selector switch for operation on the 540 to 1720 kilocycle band, tune receiver dial, and set test oscillator frequency to EXACTLY 1720 KILOCYCLES. NEXT BRING IN THE 1720 KILOCYCLE SIGNAL TO MAXIMUM OUTPUT BY ADJUSTING 1720 KILOCYCLE OSCILLATOR TRIMMER.

7. With band selector switch placed for operation on the 540 to 1720 kilocycle band set test oscillator frequency and receiver dial to EXACTLY 1400 KILOCYCLES. Adjust 1400 kilocycle preselector and antenna trimmers for maximum 1400 kilocycle signal sensitivity.

8. Leave band selector switch for operation on 540 to 1720 kilocycle band, tune receiver dial and set test oscillator frequency to approximately 600 kilocycles. While rocking gang condenser slightly to right and left adjust 600 kilocycle oscillator padder for maximum sensitivity.

SERVICE DATA

The antenna-R.F. coil is located over the variable condenser and is trimmed by the trimmer on the rear section of the variable condenser. The oscillator coil is mounted under the chassis and is trimmed by the front trimmer section. The I.F. transformers and trimmers are mounted under the chassis. The I.F. frequency is 450 K.C.

The output transformer and filter choke are in the can on the left of the chassis. To take the chassis out of the cabinet - first, remove the knobs, then the back, and finally the hold down screw in the base of the cabinet. To replace tubes it is only necessary to remove the back.

SERVICE DATA

The following tubes are used in this receiver;

6K7-R.F. Amplifier
6L7-Mixer
6C5-Oscillator
6K7-I.F. Amplifier
6H6-Diode Detector
6F5-A.F. Amplifier
6F5-A.F. Amplifier
6V6G-Beam Power Amplifier
6V6G-Beam Power Amplifier
6E5-Tuning Indicator
5X4G-Rectifier

I.F. 450 K.C.

The R.F., Mixer and oscillator coils are located in the large square shields on the right end of the chassis.
Trimmers for these circuits are mounted along the end of the chassis, beneath the coils in the following order; R.F. short wave, Mixer short wave, Oscillator broadcast, Oscillator medium wave, Oscillator short wave. From front to rear.
The R.F. broadcast and Mixer broadcast trimmers are mounted on the range switch assembly. Oscillator pads are located at the back of the variable condenser. The pad nearest the end of the chassis is for the broadcast band and the medium wave is next.
Trimmers for the I.F. transformers are adjustable thru holes in the I.F. transformer shield cans. The I.F. frequency is 450 K.C.

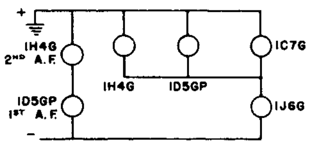
GENERAL INFORMATION

THE "A" SUPPLY:

These models may be used with either a 4½ volt dry "A" battery or a 4 volt storage "A" battery. If a storage "A" battery is used, it will be necessary to use a Catalog #5000 adapter to permit connecting the "A" plug to the storage battery terminals. The customer should be cautioned against using a 6 volt automobile storage battery.

THE FILAMENT CIRCUIT:

Since the tubes have two volt filaments and the "A" supply is four volts, a series parallel arrangement is used for the circuit. A simplified diagram of the filament circuit is shown below. If any one tube burns out, it will affect the filament voltage and current of its companion tubes.



THE AVC CIRCUIT:

The 1H4G Detector-AVC tube is used as a diode with its grid acting as the diode plate. Diode current, flowing through the 50M ohm resistor, R5, and the 500M ohm resistor, R6, create a voltage drop across them. This voltage is applied to the control grid of the 1C7G tube to provide AVC.

BATTERY REPLACEMENT:

The dry "A" battery should be replaced when its voltage drops to 3.4 volts, under load. Approximately 610 hours of service can be expected before the "A" battery voltage drops to this value (based on 3 to 4 hours a day use). If the storage "A" battery is used, it should be recharged every 3 to 4 weeks. Approximately 375 hours of service can be expected from the "B" batteries supplied. Since this receiver uses a class "B" output stage the "B" drain will vary with the volume at which the radio is played. The customer should be informed of this fact and told that for longest "B" battery life the radio should not be played louder than necessary. The "B" batteries should be replaced when the voltage of the 90 volt block has dropped to 68 volts, under load. For longer uninterrupted service, heavy duty "B" batteries should be recommended.

ELIMINATING WHISTLE AT 930 KC:

A whistle, due to a beat between the second harmonic (930 kc) of the 465 kc IF, and a 930 kc signal may be experienced. In localities where the 930 kc station is one that is frequently listened to, it will be desirable to shift the whistle to some other point where it will not be objectionable. This can be done by shifting the IF frequency of the receiver.

Determine at what point between 900 kc and 960 kc the whistle will be least objectionable. Dividing this frequency by two will give the new IF frequency to which the receiver should be aligned. For example, if it is determined that a whistle at 915 kc would not be objectionable, the IF should be realigned at 915/2 or 457.5 kc.

Align the IF at the new frequency and then realign the rest of the receiver as described under, "ALIGNMENT PROCEDURE".

DIFFERENCES IN TONE CONTROLS:

Earlier production used a tone control knob having only two positions marked, "HI", "LO". Later production used three positions marked, "HI", "MED", "LO". In both types of set the Tone Control switch is a three position one and the medium tone adjustment can be had with the two position knob by turning the knob so that the marker pin is between "HI" and "LO".

THE DIAL FLASH-O-LITE:

Pushing down on the Volume Control knob closes the switch to light the dial. Two Flash-Light cells supply the voltage for the dial light. Be sure that they are mounted in their holder so that the center contact of one cell touches the bottom of the shell of the other cell. Otherwise, the cells will buck each other and no voltage will be applied to the dial light.

ALIGNMENT PROCEDURE

PRELIMINARY:

- Output meter connection . . . . Across loud speaker voice coil
- Output meter reading to indicate 50 milliwatts . . . . 0.42 volts
- Generator ground lead connection . . . . Receiver chassis
- Dummy antenna value to be in series with generator output . . . . . See chart below
- Connection of generator output lead . . . . See chart below
- Generator modulation . . . . 30%, 400 cycles
- Approximate average sensitivity in microvolts for 50 milliwatts output . . . See chart below
- Position of Volume Control . . . . Fully clockwise
- Position of Tone Control . . . . Fully clockwise
- Position of Dial Pointer with variable fully closed . . . To fall in center of embossed gold block that is about 1/4" to the left of the letters, "MC", at the low frequency end of the FOREIGN scale.

WAVE BAND SWITCH POSITION	POSITION OF VARIABLE	GENERATOR FREQUENCY	DUMMY ANTENNA	GENERATOR CONNECTION	TRIMMERS ADJUSTED (IN ORDER SHOWN)	TRIMMER FUNCTION	APPROXIMATE MICROVOLTS
"A"	550 kc	465 kc	.1 mfd.	1C7G Grid	12,T1	IF Output, IF Input	150
"A"	1400 kc	1400 kc	.0002 mfd.	Ant. Term.	C1,C5	Antenna Oscillator	65
"A"	600 kc (rock)	600 kc	.0002 mfd.	Ant. Term.	C6	Padder	30
"A"	1400 kc	1400 kc	.0002 mfd.	Ant. Term.	C1,C5	Antenna Oscillator	65
"F"	15 mc (rock)	15 mc	400 ohms	Ant. Term.	C2	Translator	40
"F"	6 mc	6 mc	400 ohms	Ant. Term.	-	-	250

IMPORTANT ALIGNMENT NOTES

Where indicated by the word, "Rock", the variable should be rocked back and forth a degree or two while making the adjustment.

The figures given in the "Microvolts" column are only approximate.

Note that the 1400 kc alignment is to be repeated after the 600 kc padder adjustment.

The alignment procedure should be repeated stage by stage, in the original order, for greatest accuracy. Always keep the output from the test oscillator at its lowest possible value to make the AVC action of the receiver ineffective.

The high frequency limit of the Broadcast band is 1750 kc although the last dial marking is 1800 kc. This dial marking is only to obtain symmetry of appearance in the dial.

SPEAKER PLUG COLOR CODE

Wave Band Indicator

CHASSIS FEATURES:
Number RF stages . . One on Broadcast Band
Number IF stages . . . . Two
Number condensers in gang . . . . Three
Antenna . . . . Conventional
Plugs attached to battery cable

THE DIAL FLASH-O-LIGHT:

The Dial Flash-O-Light is operated by pushing down on the Volume Control knob. Two flash light batteries provide the voltage for the two dial lights. It is important that both flash light batteries face in the same direction when put in the holder. That is, the top center contact of one battery must touch the bottom of the shell of the other battery. Otherwise, the voltages of the batteries will buck each other and there will be no voltage available for the dial light.

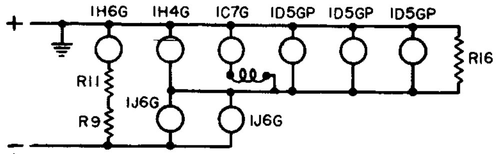
THE AVC CIRCUIT:

The diode current of one of the diode plates of the 1H6G tube, flowing through the one megohm resistor, R10, creates a voltage drop across it. This voltage is applied to the control grids of the RF, translator, and first IF tubes to provide AVC.

THE FILAMENT CIRCUIT:

Since the "A" supply is four volts and the tube filaments are rated at two volts, a series parallel arrangement is used for the filament circuit. A simplified diagram is shown below. If any one tube burns out (except the 1H6G) the filament voltage and current of the other tubes will be affected.

A catalog #5000 adapter must be used on the "A" cable plug when a storage "A" battery is used. The owner should be warned not to attempt the use of a six volt automobile storage battery. Only a four volt storage "A" battery should be used.



ELIMINATING WHISTLE AT 930 KC:

A whistle, due to a beat between the second harmonic (930 kc) of the 465 kc IF, and a 930 kc signal may be experienced. In localities where the 930 kc station is one that is frequently listened to, it will be desirable to shift the whistle to some other point where it will not be objectionable. This can be done by shifting the IF frequency of the receiver.

Determine at what point between 900 kc and 960 kc the whistle will be least objectionable. Dividing this frequency by two will give the new IF frequency to which the receiver should be aligned. For example, if it is determined that a whistle at 915 kc would not be objectionable, the IF should be realigned at 915/2 or 457.5 kc. Try to select the new IF frequency as near as possible to 465 kc.

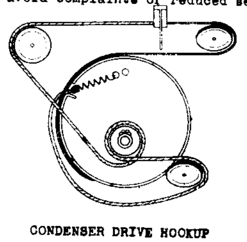
Align the IF at the new frequency and then realign the rest of the receiver as described under, "ALIGNMENT PROCEDURE".

WAVE-TRAP TO ELIMINATE INTERFERENCE FROM SHIP OR AIRPORT TRANSMITTERS:

In locations near ship transmitters or airports or air beacon stations, code interference may be experienced. Part #1013114356 wave-trap is designed to eliminate such interference.

Mount the trap, by means of two wood screws, at any convenient place on the chassis shelf or cabinet where it will be near the antenna terminal of the receiver. Connect the yellow lead of the wave-trap to the antenna downlead. Connect the green lead of the wave-trap to the antenna terminal of the receiver. Cut off any excess length of green wire from the trap so that the green lead from the wave-trap to the chassis is as short as possible. The yellow lead from the wave-trap should be run so that it is as far as possible from the green lead. Splice one of the black leads from the wave-trap to the black ground lead of the receiver. Connect the other wave-trap black lead to the ground used for the installation.

The trap is pre-tuned to the IF frequency so that normally no further adjustment is necessary. However, should interference still be experienced, tune the reciever between approximately 550 and 600 kc. Then adjust the wave-trap, by means of the trimmer screw at the bottom of the container, until the interference is eliminated. Addition of the trap will reduce the sensitivity of the receiver around 600 kc by approximately 50%. The customer should be forewarned of this to avoid complaints of reduced sensitivity.



CONDENSER DRIVE HOOKUP

ALIGNMENT PROCEDURE

PRELIMINARY:

Output meter connection . . . . Across speaker voice coil
Output meter reading to indicate 50 milliwatts . . . . 0.4 volts
Average sensitivity in microvolts for 50 milliwatts output . . . . See chart below
Dummy antenna value to be in series with generator output . . . . See chart below
Connection of generator output lead . . . . See chart below
Connection of generator ground lead . . . . Receiver chassis
Generator modulation . . . . 30%, 400 cycles
Position of Volume Control . . . . Fully on
Position of Tone Control . . . . Fully clockwise
Position of Dial Pointer . . . . .To fall on end line of scale (low frequency end). Loosen dial drum set screws and rotate drum if necessary. Tighten set screws after pointer is properly set.

WAVE BAND SWITCH POSITION	POSITION OF DIAL POINTER	GENERATOR FREQUENCY	DUMMY ANTENNA	GENERATOR CONNECTION	TRIMMERS ADJUSTED (IN ORDER SHOWN)	TRIMMER FUNCTION	APPROXIMATE MICROVOLTS
"P"	6 mc	465 kc	.1 mfd.	1C7G Grid	T3, T2, T1	IF	20
"A"	1400 kc	1400 kc	.0002 mfd.	Ant. Term.	C8, C5, C2	Osc., Transl., Antenna	7
"A"	600 kc (rock)	600 kc	.0002 mfd.	Ant. Term.	C9	Padder	7
"P"	5 mc	5 mc	400 ohms	Ant. Term.	C10, C6	Oscillator Translator	10
"F"	15 mc	15 mc	400 ohms	Ant. Term.	C7	Translator	15

IMPORTANT ALIGNMENT NOTES

Note that the IF must be adjusted with the Wave Band Switch in the "P" position.

Where indicated by the word, "Rock", the variable should be rocked back and forth a degree or two while making the adjustment.

Always keep the output from the signal generator at its lowest possible value to prevent the AVC action of the receiver from interfering with accurate alignment. As the receiver sensitivity is increased through alignment, the output from the generator should be decreased to compensate.

SENTINEL RADIO CORP.

MODEL 22U

ALIGNMENT PROCEDURE: Realignment of this receiver should never be necessary unless one of the oscillator, antenna, or I. F. coils has been replaced. Lack of sensitivity, selectivity and poor tone quality may be due to any one or a combination of causes, such as weak or defective tubes or speaker, inadequate or excessively long antenna, open or grounded bias resistor, by-pass condenser, etc. Under no circumstances should realignment be attempted until all other possible sources have been first thoroughly investigated and have been definitely proven not to be the cause.

If an I. F. tube is replaced it is advisable to realign the I. F. amplifier, particularly if the replacement tube is one of a different manufacture than the one in the receiver. It is important when aligning to carefully follow the procedure in the order given, otherwise the receiver will lack sensitivity and the dial calibration will be incorrect.

IT IS IMPERATIVE THAT AN ACCURATELY CALIBRATED OSCILLATOR BE USED WITH SOME TYPE OF OUTPUT MEASURING DEVICE.

INTERMEDIATE ALIGNMENT:

1. Connect the high side of the test oscillator output to the control grid of the 6A7 oscillator-modulator tube through a .02 Mfd. condenser. Leave the grid cap connected to the grid terminal of the tube, and connect the ground side of the test oscillator to the receiver ground.
2. Set the test oscillator frequency to 465 kilocycles (this must be accurate).
3. Align the second intermediate transformer by turning one of the trimmer screws accessible through holes in the top of the transformer shields up and down (increasing and decreasing capacity) until maximum reading is obtained on the output meter, after which adjust the other trimmer screw of the same transformer for maximum sensitivity.
4. Adjust the first intermediate transformer in the same manner as the second I. F. transformer.

TO ALIGN THE VARIABLE CONDENSER: It is important when aligning the gang condenser, padding and trimmer condensers to follow the procedure carefully, otherwise the receiver will be insensitive and the dial calibration will be incorrect. The padding and trimmer condensers located underneath the chassis will be referred to by their function as indicated on the circuit diagram.

1. Connect the high output side of the test oscillator through a 400 ohm resistor to the receiver antenna lead and the low side to the set ground.
2. Place the band selector switch for operation on the 5.8 to 18.3 megacycle band, tune the receiver dial, and set the test oscillator frequency to EXACTLY 18.3 MEGACYCLES. In this receiver on the high frequency band the oscillator frequency is tracked LOWER in frequency than the signal frequency instead of higher as ordinarily. This must be borne in mind in retracking.

   Rotate gang condenser so that plates are completely out of mesh and then tune in the 18.3 MEGACYCLE SIGNAL TO MAXIMUM OUTPUT BY ADJUSTING THE 18.3 MEGACYCLE OSCILLATOR TRIMMER. When adjusting this trimmer two peaks will be noticed. CARE MUST BE TAKEN SO THAT THE PROPER PEAK IS USED FOR ALIGNING THE RECEIVER AT 18.3 MEGACYCLES. Always back off the trimmer to minimum capacity, then screw down the trimmer (add capacity) until the SECOND PEAK which is the proper one to use is tuned in. After completing adjustment of the oscillator trimmer at 18.3 megacycles always check to see if the proper peak has been used. To do this leave the receiver dial set at 18.3 megacycles, increase the output of the test oscillator and tune the test oscillator frequency to approximately 17.3 megacycles. Then vary the receiver dial slightly to the right and left of 17.3 megacycles, and if the proper peak was used in aligning at 18.3 megacycles the test oscillator signal will be heard at approximately 18.3 megacycles on the receiver dial. If it is not possible to receive the signal, then the fundamental peak was not used and the 18.3 megacycle oscillator trimmer must be properly readjusted.
3. With band selector switch set for operation on 5.8 to 18.3 megacycle band tune the receiver dial and set test oscillator frequency to EXACTLY 15 MEGACYCLES and adjust 15 megacycle antenna trimmer for maximum 15 megacycle signal sensitivity.
4. Replace the 400 OHM resistor in series with test oscillator lead with a 200 mmfd. condenser, place the band selector switch for operation on the 535 to 1720 kilocycle band and set test oscillator frequency to EXACTLY 1720 KILOCYCLES.

   Rotate gang condenser so that plates are completely out of mesh and BRING IN THE 1720 KILOCYCLE SIGNAL TO MAXIMUM OUTPUT BY ADJUSTING 1720 KILOCYCLE OSCILLATOR TRIMMER.
5. With band selector switch placed for operation on the 535 to 1720 kilocycle band set test oscillator frequency and receiver dial to EXACTLY 1400 KILOCYCLES. Adjust 1400 kilocycle preselector trimmers for maximum 1400 kilocycle signal sensitivity.
6. Leave band selector switch for operation on 535 to 1720 kilocycle band, tune receiver dial and set test oscillator frequency to approximately 600 kilocycles. While rocking gang condenser slightly to right and left adjust 600 kilocycle oscillator padder for maximum sensitivity.

Notes; Voltage and resistance readings are for schematic diagram shown on back of sheet. Allow 15% + or - on all measurements. Always use meter scale which will give greatest deflection within scale limits. All measurements made with Weston Selective Analyzer No. 665, Type 2.

* Reading will be zero or 6 volts, depending on twist of heater hook-up wire.

** Cannot be measured with Weston Selective Analyzer No. 665, Type 2.

The SPARTON Model 417-X (Export) is equipped with an adjustable power transformer for operation on various line voltages as indicated under the transformer terminal cover plate. The Receivers are shipped from the factory to operate on a line voltage of 220 volts, unless other specifications are found on the chassis. Before attempting to re-align the circuits, be sure that the transformer tap is correctly adjusted for the line voltage to be used.

The Model 417-X is a single band (Broadcast) Receiver with an Airplane-type dial calibrated to show station readings in Meters and Kilocycles simultaneously.

For proper alignment of this model, the procedure should be followed in the same order as given.

(1) Turn on receiver and test oscillator and allow both to operate several minutes before attempting to adjust any condensers.

(2) The dial pointer should point to the horizontal lines on the scale when the variable condensers are turned all the way in (rotor plates flush with stator plates). The pointer can be adjusted by holding the condenser plates firmly meshed and then turning the pointer hub which projects through the back of the scale.

(3) Tune test oscillator and receiver to 1400 kilocycles.

(4) Connect the "antenna" lead of the test oscillator to the grid-cap of the Type 6A7 1st. Detector-Oscillator tube, and the test oscillator ground to the chassis frame.

(5) Connect output meter from Plate connection of the Type 41 tube to ground.

(6) Adjust Condensers C4 and C3 until the output meter registers the greatest deflection. It is advisable to keep the output of the receiver down to a low value with the volume control as this permits more exact adjustments.

(7) If necessary, the wirewound condenser (C15 in the schematic diagram) may be adjusted to obtain maximum gain with good stability. If greater gain is required, the wire may be bent to to form more turns results in greater capacity. This wirewound condenser is located on the terminal strip underneath the chassis.

After making any changes in this condenser, it should be waxed thoroughly and condensers C4 and C3 should be re-adjusted.

(1) Disconnect "antenna" lead of test oscillator from grid-cap of Type 6A7 tube and connect it in series with a 250 uuf. (.00025 uf.) condenser to the Antenna terminal (Blue wire) of the receiver. Condenser Part No. C-720-217 may be used.

(2) Tune test oscillator and receiver to 1500 kilocycles and adjust condensers C2 (RF) and C2 (Osc.)

(3) Tune test oscillator and receiver to 900 kilocycles and 600 kilocycles and check sensitivity and calibration. If necessary, the variable condenser plates may be bent slightly to provide correct operation at these frequencies.

(4) Tune test oscillator to 456 kilocycles and adjust condenser C5 to a point where the output meter registers the minimum deflection.

All adjustments should be rechecked to assure accuracy and stability of adjustment and calibration.

MODELS 427X, 437X & 457X

CHASSIS DIAGRAM

FOREWORD: The SPARTON Models 427-X, 437-X and 457-X (Export) are equipped with an adjustable power transformer for operation on various line voltages as indicated under the transformer terminal cover plate.

Before attempting to realign the circuits, be sure that the transformer tap is correctly adjusted for the line voltage to be used. Unless otherwise specified, the adjusting of any condenser consists of turning the adjusting screw or nut to the right or left until the output meter registers the greatest deflection.

STEP BY STEP PROCEDURE

Note: For proper alignment of these chasses, the procedure should be followed in the same order as given.

The dial pointer should be exactly parallel with the horizontal line of the dial scale when the condenser plates are fully meshed. If the pointer does not read correctly, remove the dial cover and move the pointer until it shows a correct reading.

A. Alignment of Intermediate-Frequency

1. Turn on receiver and test oscillator and allow both to operate several minutes before attempting to adjust any condenser.

2. Turn the band selector switch to the "Broadcast" position and turn the station selector knob until the rotor plates are completely out of mesh with the stator plates.

3. Connect antenna of test oscillator to grid cap of Type 6A7 1st detector-oscillator tube and ground of test oscillator to chassis frame of receiver. Connect output meter "high tap" from plate terminal of Type 42 tube to ground.

Note: It is advisable to read carefully the operating instructions included with the test oscillator.

4. Tune test oscillator to obtain a signal of 456 kilocycles.

5. Turn the volume control of receiver on full and adjust I-F condensers C5 and C6.

B. Alignment of Broadcast Band

1. Disconnect "antenna" lead of test oscillator from grid cap of Type 6A7 tube and connect it in series with a 150 mmf. condenser dummy antenna to the antenna terminal of the chassis.

2. Tune test oscillator and receiver to a wave length of 200 meters (1500 kilocycles) and adjust condenser C2-B (oscillator trimmer) and condenser C2-A (antenna trimmer).

3. Tune test oscillator and receiver to 500 meters (600 kilocycles) and adjust condenser C4 (oscillator padder).

4. Retune test oscillator and receiver to 200 meters and check the adjustments of condensers C2B and C2A.

5. Calibration of the broadcast band should also be checked at 330 meters (900 kilocycles).

C. Alignment of Long-Wave Band

1. Turn the band selector switch to the "long-wave" band, tune test oscillator and receiver to a wave length of 870 meters (345 kilocycles) and adjust condenser C7-B (long-wave oscillator trimmer) and condenser C7-A (long-wave antenna trimmer).

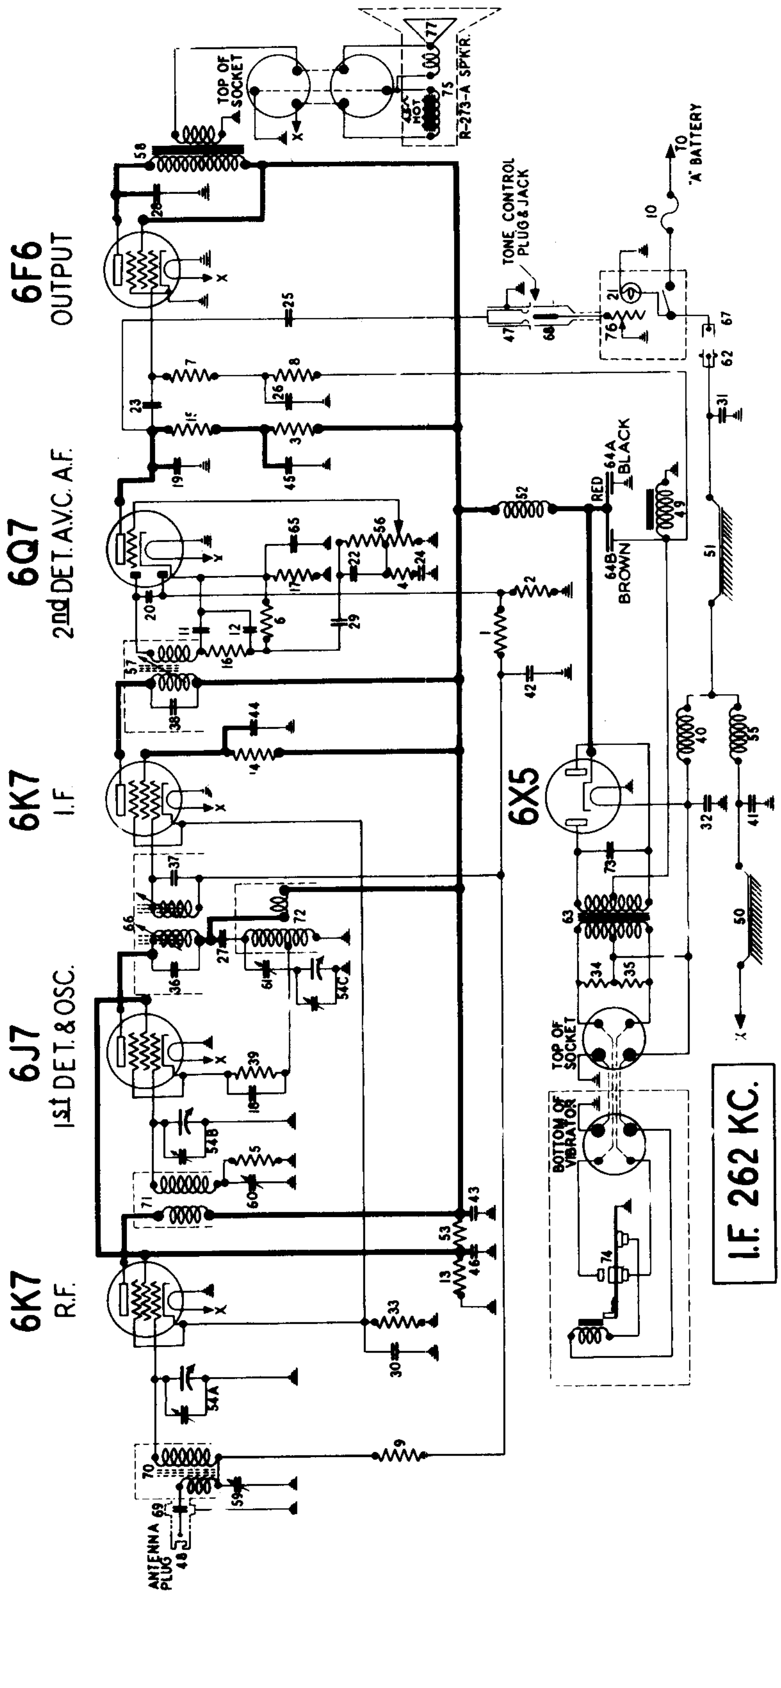
2. Tune test oscillator and receiver to a wave length of 2000 meters (150 kilocycles) and adjust condenser C3 (long-wave oscillator padder).

3. Retune test oscillator and receiver to 870 meters (345 kilocycles) and check the adjustment of condensers C7-B and C7-A.

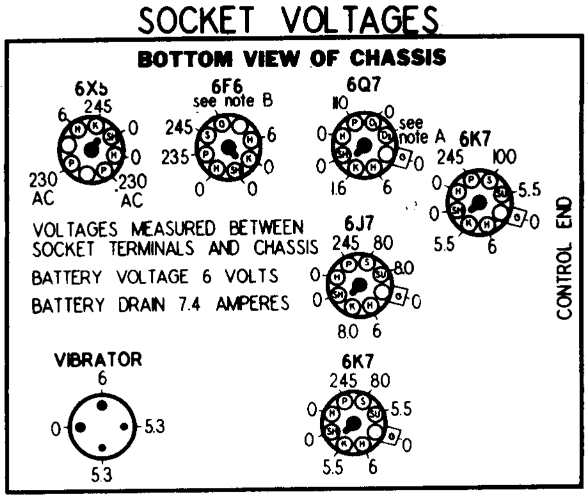
Caution: All adjustments should be rechecked to assure accuracy and stability of adjustment and calibration.

STEWART-WARNER CORPORATION

MODEL R1781 AUTO RADIO



SOCKET VOLTAGES



IMPORTANT: Use a high resistance voltmeter of 1,000 ohms per volt. Make allowances for battery voltage variation.

NOTE A: This voltage is 1.6 volts measured across resistor No. 17.

NOTE B: The grid bias of the 6F6 output tube is -14 volts measured between chassis and ungrounded filter choke terminal.

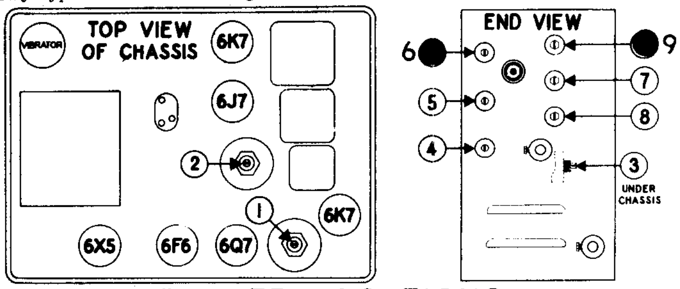
MODEL R1781 AUTO RADIO

CIRCUIT DESCRIPTION

This receiver employs several outstanding circuit refinements such as permeability-tuned iron core I.F. transformers, iron core antenna coil, bass-compensated volume control, high and low frequency R.F. trimmers, adjustable "antenna compensator", and improved "hash" and ignition interference elimination filters.

IMPORTANT: No check for storage battery polarity is necessary as the receiver works with equal efficiency on cars with negative or positive grounds. This convenient self-contained power unit utilizes a primary type vibrator and a high vacuum full wave rectifier tube.



TRIMMER LOCATIONS

Trimmer Number		Alignment Frequency
1	1st I.F. transformer trimmer (top)	262 KC.
2	2nd I.F. transformer trimmer	262 KC.
3	1st I.F. transformer trimmer (bottom)	262 KC.
4	Oscillator series padder	600 KC.
5	R.F. series padder	600 KC.
6	Antenna compensator (padder)	600 KC.
7	Oscillator shunt trimmer	1400 KC.
8	R.F. Shunt trimmer	1400 KC.
9	Antenna shunt trimmer	1400 KC.

ALIGNMENT

The equipment necessary for proper alignment of this receiver consists of a good modulated oscillator, a sensitive output meter and an insulated screw driver.

The test oscillator must be accurately calibrated and its output must be adjustable to give a very weak signal which will not actuate the A.V.C. of the receiver. The insulated screw driver should be made of fibre or bakelite although a small metal blade inserted at the tip is permissible. A long blade in an insulated handle is not suitable and will prevent accurate adjustment.

An output meter with a full scale reading of four volts or less is desirable so that it can be connected directly across the voice coil terminals of the speaker. Any A.C. voltmeter with such a range will be satisfactory. If your output meter is not equipped with such a low scale, it should be connected from the plate of the output tube to chassis.

During alignment, the volume control should be turned full on and the receiver case should be in place. The front cover can be removed to permit the connection of the output meter. Keep rear cover in place.

I.F. ALIGNMENT

1– (a) Set the test oscillator to exactly 262 KC.

(b) Connect the output terminal of the oscillator to the grid of the 6J7 tube through a .1 to .5 mfd. condenser. Do not remove the grid lead from the tube.

(c) Connect the grounded output lead of the oscillator to the receiver case.

(d) Turn the gang condenser of the receiver to any point where it has no tuning effect on the 262 KC. signal.

(e) Adjust trimmers 1, 2 and 3 for maximum output. Trimmer No. 3 is located under the chassis but can be reached through a hole in the rear cover.

(f) Repeat the adjust of trimmers 1, 2 and 3.

R.F. CALIBRATION AND ALIGNMENT

This receiver employs an unusual circuit which allows the antenna, the R.F. and the oscillator circuits to be adjusted near the low frequency end of the dial in addition to the high frequency end. To get maximum sensitivity and accurate dial calibration, the following procedure must be followed exactly.

2– Low Frequency Alignment.

(a) Connect the output of the test oscillator to the antenna socket of the receiver through a 200 mmfd. (.0002 mfd.) mica condenser. This condenser must not be omitted or alignment will be incorrect.

(b) Connect the control head to the receiver, then turn the tuning knob until the variable condenser plates are in full mesh.

Adjust the dial calibration so that the dial pointer is on the last dial calibration mark below 550 KC. The relative position of the control head, the control shaft, and the receiver must remain unchanged until the alignment is completed.

(c) Turn the tuning knob until the dial pointer indicates that the set is tuned to 600 KC.

(d) Set the test oscillator at exactly 600 KC.

(e) Adjust trimmer No. 4 for maximum output. The adjustment of this trimmer must be made with an insulated screw driver having no more than a small metal tip.

(f) Retune the receiver to the oscillator signal.

(g) Adjust trimmers 5 and 6 for maximum output.

3– High Frequency Alignment.

(a) Tune the receiver to exactly 1400 KC. on the tuning dial.

(b) Adjust the test oscillator to exactly 1400 KC.

(c) Adjust trimmer No. 7 for maximum output.

(d) Carefully tune the receiver to the 1400 KC. oscillator signal.

(e) Adjust trimmers 8 and 9 for maximum output.

4– Final Adjustment.

(a) Repeat operations 2 (c) to (g) and 3 (a) to (e) in the same order until no further improvement in output can be made. Adjustments must be repeated at least once and if the set is badly out of alignment, a second repetition is necessary.

ANTENNA COMPENSATOR AJUSTMENT

The antenna compensator must be adjusted after the installation of the receiver has been completed in order to match the receiver to the antenna. If this adjustment is made for an old under-car aerial, care must be taken that the aerial and its insulators are clean and free from mud or slush which would alter the capacity and resistance. More accurate adjustment is possible if the aerial and its insulators are washed and allowed to dry before attempting adjustment.

The adjustment is to be made as follows:

(a) Carefully tune the receiver to some fairly weak signal between 550 and 650 KC.

(b) Remove the chrome plated button adjacent to the antenna jack. (Covering trimmer No. 6).

(c) Adjust the antenna compensator, trimmer No. 6 for maximum volume. Carefully retune the receiver to the signal, then again adjust the compensator.

Do not attempt to adjust any of the other trimmers on stations at this time or the entire alignment will be upset since an oscillator must be used for all adjustments except the antenna compensator.

Note: If you do not get a peak when adjusting this trimmer and if the car has a built-in antenna of unusually high capacity such as an insulated running board or insulated metal roof, it will be necessary to insert a special plug-in adapter in series with the antenna lead. These adapters are made in two types and can be obtained from United Motors Service Stations. For aerials having a capacity between 400 and 900 micro-microfarads (insulated running boards), the adapter United Motors Part No. 7231410 (marked with red band) should be used. For aerials between 900 and 2,000 micro-microfarads (metal roof tops) their Part No. 1210915 should be used.

MISCELLANEOUS PARTS

Part Number	Description	List Price
83319	Fuse insulator tube	$ .02
83722	Rubber grommet for gang condenser mounting	.03
85427	Eight prong tube socket	.15
88262	Four prong vibrator socket	.14
110075	Cup washer for gang condenser mtg.	.02

27685	Dry Electrolytic Capacitor, 12 Mf., 25 Volts
27782	Capacitor, .03 Mf.

ELECTRICAL SPECIFICATIONS

Type of Circuit	Superheterodyne
Tuning Ranges	A—530 to 1700 Kc.; B—1700 to 5600 Kc.; C—5600 to 18,000 Kc.
Number and Type of Tubes	1 No. 6A8, 1 No. 6K7, 1 No. 6H6, 1 No. 6F5, 1 No. 6F6, 1 No. 6G5, 1 No. 5Y4G
Voltage Rating	105 to 125 Volts
Frequency Rating	25 to 60 Cycles and 50 to 60 Cycles
Input Power Rating	65 Watts
Frequency of Intermediate Amplifier	465 Kilocycles

STROMBERG-CARLSON TELEPHONE MFG. CO.
MODELS 230 SERIES, 230-H, 230-HB, 230-L, 230-LB; 231 SERIES, 231-F, 231-FB, 231-P, 231-PB, 231-R & 231-RB

NORMAL VOLTAGE READINGS

The various values of voltages listed in the following table are obtained by measuring between the various tube socket contacts and the chassis base with the tubes in their respective sockets. The receiver is, therefore, in operation when the measurements are made. Figure 1 shows the terminal layouts of the sockets with the proper terminal numbers.

Voltages are given for a line voltage of 120 volts, and an allowance should be made for differences when the line voltage is higher or lower. A meter having a resistance of 1000 ohms per volt should be used for measuring the D. C. voltages. Voltage values shown are those obtained on the lowest scale of a meter having the following ranges: 0-2.5, 0-10, 0-100, 0-250, 0-500, 0-1000 volts.

ALIGNMENT DATA

All alignment adjustments are accurately made at the factory on these receivers, and ordinarily no readjustments are necessary. However, should it become necessary to make any readjustments, the alignment procedure given in the following paragraphs should be carefully followed. In order to make these aligning adjustments in an easy and satisfactory manner, it is recommended that the Stromberg-Carlson P-27657 and P-27658 aligning tools be used.

To accurately align the circuits in these receivers, it is necessary to use a high grade, modulated test oscillator (Signal Generator), the output voltage of which can be varied. In conjunction with this test oscillator, a sensitive output meter should be used for determining the maximum signal voltage developed across the voice coil of the loud speaker.

In making any alignment adjustments, always adjust the test oscillator's output voltage to the minimum value where a good alignment may still be obtained. Never attempt to make any alignment adjustments using a strong signal. Before proceeding with the alignment of any circuits in these receivers be sure that the "Signal Admission Control" is set for the maximum sensitivity position and that the "Off-On-Tone" control knob is set for maximum treble response (position where knob is rotated from its maximum counter-clockwise position, slightly clockwise to position where set turns "on"). Figure 1 shows the location of all the aligning capacitors or adjustments for this receiver.

Except in the case of making any aligning adjustments of the radio frequency circuits in the No. 231-P Receivers, it will not be necessary to remove the chassis in these receivers from their cabinets in order to make any alignment adjustments. If it is necessary to make any alignment adjustments of the radio frequency circuits in the No. 231-P Receivers, it will be necessary to remove the chassis from the cabinet. To remove the chassis in these receivers, it is only necessary to remove the two bolts which hold the chassis shelf to the cabinet. In making any radio frequency circuit alignment adjustments in the No. 231-P Receivers, the chassis should be set at approximately the same position which it occupies when in the cabinet. With the exception of the Nos. 231-F and 231-R Receivers, the alignment adjustments for the intermediate frequency circuits are accessible from the rear of the receiver, and the adjustments for the radio frequency circuits are accessible through the apertures located in the bottom metal base plate of the chassis; these apertures are easily accessible either through the bottom of the cabinet or through the bottom of the cabinet shelf, depending upon the particular style of cabinet. In the Nos. 231-F and 231-R Receivers, the adjustments for the intermediate frequency circuits are accessible through the bottom of the cabinet, while the adjustments for the radio frequency circuits are not accessible until the backs of the cabinets are removed. See Figure 2. Never align any of these receivers without having the metal base plate fastened to the chassis base. In the Nos. 231-F and 231-R Receivers, it is important that the final alignment be made with the chassis mounted in the cabinet.

Dial Adjustment

Before aligning the circuits of these receivers, the tuning dial must be properly aligned to "track" with the gang tuning capacitor. To check whether the dial is set correctly with respect to the gang tuning capacitor, rotate the "Rapid Station Selector" knob in a clockwise direction so that the gang tuning capacitor is set to its maximum capacity position. Then, with the receiver turned "on", the illuminated dial indicator line should be exactly centered over the dial alignment lines (black lines) which are located at the extreme low frequency end of each scale on the dial. If these lines do not center over the illuminated dial indicator line, loosen the two set screws located on the hub of the dial. Then, rotate the dial so that these alignment lines are centered over the illuminated dial indicator line. The two set screws of the dial hub should then be securely tightened.

Intermediate Frequency Adjustments

The intermediate frequency used in these receivers is 465 kilocycles. In making these circuit adjustments always align the circuits in the order given in these instructions.

1. Operate the "Range" switch of the receiver to the "A" range position. Set the receiver's tuning dial at its extreme low frequency position, and operate the Tone Control knob to the "Normal" position. Rotate the Volume Control knob to its maximum clockwise position (maximum volume).
2. Apply between the chassis base (or ground binding post) of the receiver and the grid of the No. 6A8 modulator-oscillator tube, a modulated signal of 465 kilocycles from the test oscillator, using a 0.1-microfarad capacitor in series with the connection between the output terminal of the test oscillator and the grid of the No. 6A8 tube. Do not remove the chassis grid lead connecting to this tube. The ground (or low side) terminal of the test oscillator should be connected to either the chassis base or the ground binding post terminal.
3. Now, noting from Figure 1 the aligning adjustments for the first and second I. F. transformers, align the I. F. circuits in the following manner:
   Secondary of second I. F. transformer.
   Primary of second I. F. transformer.
   Secondary of first I. F. transformer.
   Primary of first I. F. transformer.
   Adjusting the circuits to obtain maximum reading on the output meter, reducing the output of the test oscillator as required.

Radio Frequency Adjustments

The alignment of the radio frequency circuits of the various ranges in these receivers should be very carefully made and in the order specified.

Alignment of Short Wave Range (Also Referred to as "C" Band)

In aligning the radio frequency circuits for this range, replace the 0.1-microfarad capacitor which was placed in series with the test oscillator's output lead for the I. F. alignments, with a 400-ohm carbon type resistor. This lead should then be connected to the antenna binding post located on the rear of the receiver chassis. The ground terminal (or low side) of the test oscillator should be connected to the ground binding post on the receiver.

1. Operate the Range Switch on the receiver chassis to the "C" range position, and set the test oscillator's frequency and the receiver's tuning dial to 17 megacycles.
2. Adjust the oscillator's "C" band high frequency aligner for maximum output.
3. Adjust the antenna's "C" band high frequency aligner for maximum output, at the same time rotate the gang tuning capacitor back and forth through resonance until maximum output is obtained.

Alignment of Aircraft, Amateur, and Police Range (Also Referred to as "B" Band)

In aligning the radio frequency circuits for this range, use the same artificial antenna (400-ohm carbon type resistor) in series with the output terminal of the test oscillator as was used for aligning the short-wave range.

1. Operate the Range Switch on the receiver chassis to the "B" range position, and set the test oscillator's frequency and the receiver's tuning dial to five megacycles.
2. Adjust the oscillator's "B" band high frequency aligner for maximum output.
3. Adjust the antenna's "B" band high frequency aligner for maximum output, and at the same time rotate the gang tuning capacitor back and forth through resonance until maximum output is obtained.
4. Set the test oscillator's frequency and the receiver's tuning dial to 1.8 megacycles.

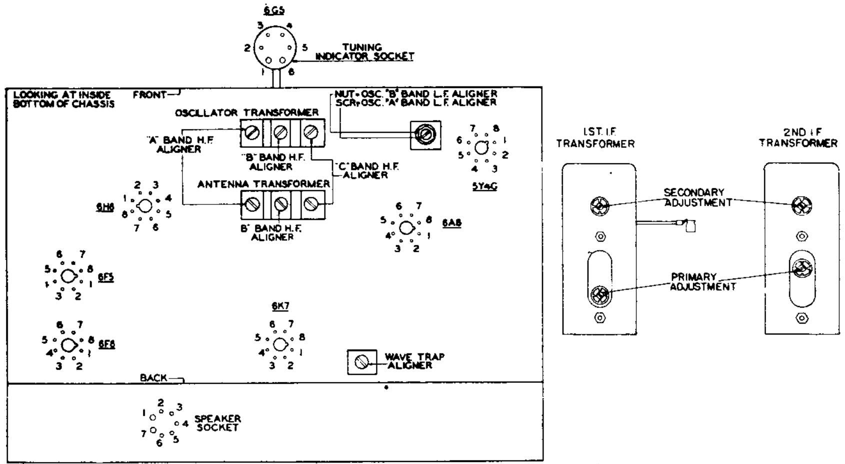

Fig. 1.—Terminal Layout for Voltage Measurement Chart and Location of the Various Aligning Capacitors.

5. Adjust the oscillator's "B" band low frequency aligner (series aligner), and at the same time rotate the gang tuning capacitor back and forth through resonance until maximum output is obtained.
6. Reset both the test oscillator's frequency and the receiver's tuning dial to 5 megacycles and repeat operations Nos. 2 and 3.

Alignment of Standard Broadcast Range (Also Referred to as "A" Band)

In aligning the radio frequency circuits for this range, replace the 400-ohm carbon type resistor in series with the test oscillator's output lead with a 200-micro-microfarad capacitor and align these circuits as follows:

1. Operate the Range Switch to the "A" range position and set the test oscillator's frequency and the receiver's tuning dial to 1.4 megacycles.
2. Adjust the oscillator's "A" band high frequency aligner for maximum output.
3. Adjust the antenna's "A" band high frequency aligner for maximum output.
4. Set the test oscillator's frequency and the receiver's tuning dial to 0.6 megacycles.
5. Adjust the oscillator's "A" band low frequency aligner (series aligner) for maximum output, and at the same time rotate the gang tuning capacitor slightly back and forth through resonance until maximum output is obtained.
6. Reset both the test oscillator's frequency and receiver's tuning dial to 1.4 megacycles and repeat operations Nos. 2 and 3.

Wave Trap Adjustment

In adjusting the wave trap circuit, the "Signal Admission Control" should be set for the most sensitive position (shaft rotated in the most counter-clockwise direction). Set the Range Switch of the receiver to the "A" range position and the tuning dial to 1000 kilocycles. Connect a 200-micro-microfarad capacitor in series with the output terminal of the modulated test oscillator and the antenna binding post on the receiver, and the ground terminal of the test oscillator to the ground binding post on the receiver. Then, with the modulated test oscillator set at the frequency of the intermediate amplifier, 465 kilocycles, supply a fairly strong signal to the receiver and adjust the wave trap aligner until a minimum indication is obtained on the output meter.

NOTE: The items marked with an asterisk are rarely required for service and in many cases will not be carried in stock by the local service station. In such cases it will be necessary to order these parts from Philco Transitone, Philadelphia or Chicago.

TRANSITONE AUTOMOBILE RADIO CORP.

MODEL G1418 GRAHAM-PAIGE 91

I. F. TRANSFORMERS AND PADDERS

The I. F. transformers are assembled complete with padding condensers.

Both the primary and the secondary padders are placed side by side in the top of the transformer shield can. The adjusting screws are accessible thru the holes in the top of the shield. (See Figure 8).

The coil windings terminate in leads instead of terminals or lugs. The color scheme of the leads is given in Figure 7.

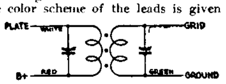

Figure 7

If replacements are ever necessary, replace the entire coil assembly, 32-2026 for the first I. F. stage and 32-2027 for the second I. F. stage. Neither the coil nor the padders will be furnished separately. Order only by the above numbers.

MODEL G-1418 ADJUSTMENTS

All padding adjustments are carefully made at the factory and ordinarily no readjustments are necessary. However, when readjustments are required, the procedure given below must be followed in detail.

Equipment

Fully charged heavy duty storage battery or 6-volt power pack, 048A Philco Set Tester, 3164 Padding wrench, 27-7159 Padding screw driver.

General

OUTPUT METER—The output meter must be connected by means of an adapter to the plate of the type 41 output tube and to the Receiver chassis.

SIGNAL GENERATOR—With the Receiver and signal generator set up for operation at the prescribed frequency, turn the Receiver volume control on full and set the signal generator attenuator so that a half scale reading is obtained on the output meter. The signal in the speaker should be audible but not loud.

The shielding on the signal generator output lead must be connected to the Receiver housing.

Procedure

I. F.—Set the signal generator at exactly 260 K. C. Connect the generator lead to the grid cap of the 78 I. F. tube in series with a .1 mfd. condenser (without removing the grid cap).

Adjust the secondary screw padder (27) on the second I. F. transformer for maximum reading on the output meter. Then adjust the primary screw padder (25) for maximum reading. (See Figure 8 for location of padders).

Remove the generator lead from the 78 tube.

Connect the generator lead to the grid cap of the 6A7 tube in series with a .1 mfd. condenser (without removing the grid cap). Adjust the secondary screw padder (24) on the first I. F. transformer for maximum reading on the output meter. Then adjust the primary screw padder (22) for maximum reading. Readjust padders (25) and (27) with the generator lead connected to the type 6A7 tube. (See Figure 8 for location of padders).

HIGH FREQUENCY AND R. F.—After padding the first I. F. stage remove the generator lead from the 6A7 tube.

Set the signal generator at 1550 K. C. and then connect the generator lead to the grid cap of the 78 R. F. tube in series with a .1 mfd. condenser (without removing the grid cap).

Turn the tuning condenser plates out of mesh as far as they will go.

With the tuning condenser in this position, adjust the high frequency padder (16) and the R. F. padder (11) until the maximum reading is obtained on the output meter. This is the true setting for 1550 K. C., 155 on the dial scale.

LOW FREQUENCY—Turn the tuning condenser plates in mesh to approximately 600 K. C., 60 on the dial scale and set the signal generator at 600 K. C. Roll the tuning condenser and adjust the low frequency padder screw (20) for maximum reading on the output meter.

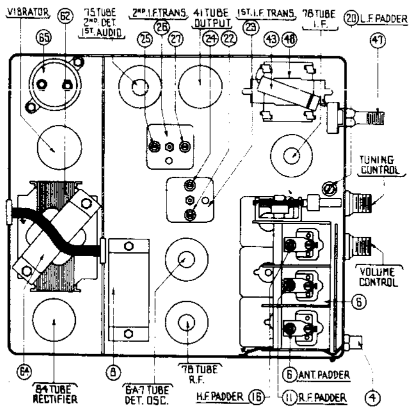

Figure 8

HIGH FREQUENCY READJUSTMENT—Turn the tuning condenser plates out of mesh to 1550 K. C. and set the signal generator at 1550 K. C. Then adjust the high frequency padder (16) again for maximum reading on the output meter.

Remove the generator lead from the 78 R. F. tube.

ANTENNA—WHEN PADDING THE ANTENNA STAGE IT IS EXTREMELY IMPORTANT THAT THE PROPER DUMMY ANTENNA BE CONSTRUCTED AND USED.

Connect the signal generator lead to the antenna cable assembly (made up of Part No. 38-7295 cable, and a 155 mmfd. condenser in series between the lead and the signal generator. Plug the cable into the antenna receptacle on the bottom of the Receiver.

Turn the tuning condenser to 1400 K. C. and set the generator at 1400 K. C. Adjust the padders (11) and (6) for the maximum reading on the output meter.

When the antenna stage adjustment is made with the Receiver installed in the car, the Receiver antenna lead must be connected to the car antenna in the usual manner. Connect the signal generator output lead to a wire placed near the car antenna but not connected to it.

MODEL G1436 GRAHAM-PAIGE 86, 87, 88 & 89

I. F. TRANSFORMERS AND PADDERS

The I. F. transformers are assembled complete with padding condensers.

Both the primary and the secondary padders are placed side by side in the top of the transformer shield can. The adjusting screws are accessible thru the holes in the top of the shield can. (See Figure 4).

The coil windings terminate in leads instead of terminals or lugs. The color scheme of the leads is given in Figure 3.

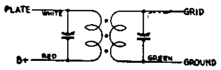

Figure 3

If replacements are ever necessary, replace the entire coil assembly, 32-2286 for the first I. F. stage and 32-2167 for the second I. F. stage. Neither the coil nor the padders will be furnished separately. Order only by the above numbers.

MODEL G-1436 ADJUSTMENTS

All padding instruments are carefully made at the factory and ordinarily no readjustments are necessary. However, when readjustments are required, the procedure given below must be followed in detail.

Equipment

Fully charged heavy duty storage battery or 6-volt power pack, 048A Philco Set Tester, 3164 Padding Wrench, 27-7159 Padding screw driver.

General

OUTPUT METER—The output meter must be connected by means of an adapter to the plate of the type 41 output tube and to the Receiver chassis.

SIGNAL GENERATOR—With the Receiver and signal generator set up for operation at the prescribed frequency, turn the Receiver volume control on full and set the signal generator attenuator so that a half scale reading is obtained on the output meter. The signal in the speaker should be audible but not loud.

The shielding on the signal generator output lead must be connected to the Receiver housing.

Procedure

I. F.—Set the signal generator at exactly 260 K. C. Connect the generator lead to the grid cap of the 78 I. F. tube in series with a .1 mfd. condenser (without removing the grid cap).

Adjust the secondary screw padder (26) on the second I. F. transformer for maximum reading on the output meter. Then adjust the primary screw padder (24) for maximum reading. (See Figure 4 for location of padders).

Remove the generator lead from the 78 tube.

Connect the generator lead to the grid cap of the 6A7 tube in series with a .1 mfd. condenser (without removing the grid cap). Adjust the secondary screw padder (22) on the first I. F. transformer for maximum reading on the output meter. Then adjust the primary screw padder (20) for maximum reading. Readjust padders (24) and (26) with the generator lead connected to the type 6A7 tube. (See Figure 4 for location of padders.)

HIGH FREQUENCY AND R. F.—After padding the first I. F. stage remove the generator lead from the 6A7 tube.

Set the signal generator at 1550 K. C. and then connect the generator lead to the grid cap of the 78 R. F. tube in series with a .1 mfd. condenser (without removing the grid cap).

Using a piece of paper approximately .006″ thick as a gauge between the heel of the rotor plates and the stator plates, turn the rotor plates in mesh until they strike against the paper.

With the tuning condenser in this position, adjust the high frequency padder (14) and the R. F. padder (10) until the maximum reading is obtained on the output meter. This is the true setting for 1550 K. C., 155 on the dial scale.

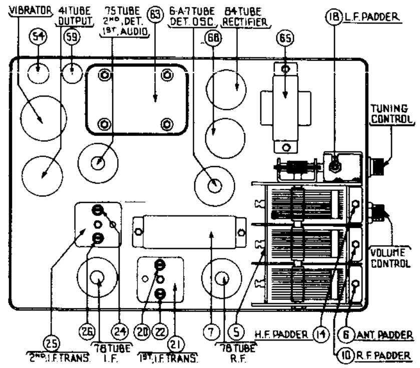

Figure 4

LOW FREQUENCY—Turn the tuning condenser plates in mesh to approximately 600 K. C., 60 on the dial scale and set the signal generator at 600 K. C. Roll the tuning condenser and adjust the low frequency padder screw (18) for maximum reading on the output meter.

HIGH FREQUENCY READJUSTMENT—Turn the tuning condenser plates out of mesh to 1550 K. C. and set the signal generator at 1550 K. C. Then adjust the high frequency padder (14) again for maximum reading on the output meter.

Remove the generator lead from the 78 R. F. tube.

ANTENNA—WHEN PADDING THE ANTENNA STAGE IT IS EXTREMELY IMPORTANT THAT THE PROPER DUMMY ANTENNA BE CONSTRUCTED AND USED.

Connect the signal generator lead to the antenna cable assembly (made up of Part No. 38-7295 cable and a 1650 mmfd. condenser in series between the lead and the signal generator. Plug the cable into the antenna lead connector on the end of the Receiver.

Turn the tuning condenser to 1400 K. C. and set the generator at 1400 K. C. Adjust the padders (10) and (6) for the maximum reading on the output meter.

When the antenna stage adjustment is made with the Receiver installed in the car, the Receiver antenna lead must be connected to the car antenna in the usual manner. Connect the signal generator output lead to a wire placed near the car antenna but not connected to it.

TRANSITONE AUTOMOBILE RADIO CORP.

MODEL N1418, "LAFAYETTE 3710", "NASH 3720 & 3780"

I. F. TRANSFORMERS AND PADDERS

The I. F. transformers are assembled complete with padding condensers.

Both the primary and the secondary padders are placed side by side in the top of the transformer shield can. The adjusting screws are accessible thru the holes in the top of the shield. (See Figure 8).

The coil windings terminate in leads instead of terminals or lugs. The color scheme of the leads is given in Figure 7.

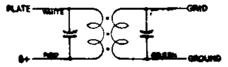

Figure 7

If replacements are ever necessary, replace the entire coil, assembly, 32-2026 for the first I. F. stage and 32-2027 for the second I. F. stage. Neither the coil nor the padders will be furnished separately. Order only by the above numbers.

MODEL N-1418 ADJUSTMENTS

All padding adjustments are carefully made at the factory and ordinarily no readjustments are necessary. However, when readjustments are required, the procedure given below must be followed in detail.

Equipment

Fully charged heavy duty storage battery or 6-volt power pack, 048A Philco Set Tester, 3164 Padding wrench, 27-7159 Padding screw driver.

General

OUTPUT METER—The output meter must be connected by means of an adapter to the plate of the type 41 output tube and to the Receiver chassis.

SIGNAL GENERATOR—With the Receiver and signal generator set up for operation at the prescribed frequency, turn the Receiver volume control on full and set the signal generator attenuator so that a half scale reading is obtained on the output meter. The signal in the speaker should be audible but not loud.

The shielding on the signal generator output lead must be connected to the Receiver housing.

Procedure

I. F.—Set the signal generator at exactly 260 K. C. Connect the generator lead to the grid cap of the 78 I. F. tube in series with a .1 mfd. condenser (without removing the grid cap).

Adjust the secondary screw padder (27) on the second I. F. transformer for maximum reading on the output meter. Then adjust the primary screw padder (25) for maximum reading. (See Figure 8 for location of padders).

Remove the generator lead from the 78 tube.

Connect the generator lead to the grid cap of the 6A7 tube in series with a .1 mfd. condenser (without removing the grid cap). Adjust the secondary screw padder (24) on the first I. F. transformer for maximum reading on the output meter. Then adjust the primary screw padder (22) for maximum reading. Readjust padders (25) and (27) with the generator lead connected to the type 6A7 tube. (See Figure 8 for location of padders).

HIGH FREQUENCY AND R. F.—After padding the first I. F. stage remove the generator lead from the 6A7 tube. Set the signal generator at 1550 K. C. and then connect the generator lead to the grid cap of the 78 R. F. tube in series with a .1 mfd. condenser (without removing the grid cap).

Turn the tuning condenser plates out of mesh as far as they will go.

With the tuning condenser in this position, adjust the high frequency padder (16) and the R. F. padder (11) until the maximum reading is obtained on the output meter. This is the true setting for 1550 K. C., 155 on the dial scale.

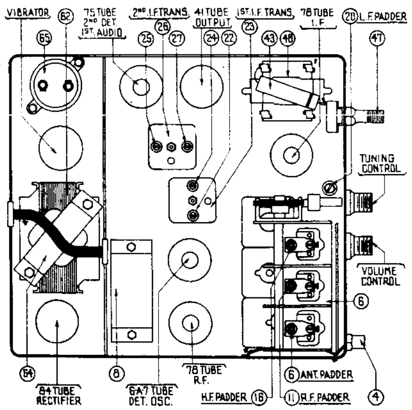

Figure 8

LOW FREQUENCY—Turn the tuning condenser plates in mesh to approximately 600 K. C., 60 on the dial scale and set the signal generator at 600 K. C. Roll the tuning condenser and adjust the low frequency padder screw (20) for maximum reading on the output meter.

HIGH FREQUENCY READJUSTMENT—Turn the tuning condenser plates out of mesh to 1550 K. C. and set the signal generator at 1550 K. C. Then adjust the high frequency padder (16) again for maximum reading on the output meter.

Remove the generator lead from the 78 R. F. tube.

ANTENNA—WHEN PADDING THE ANTENNA STAGE IT IS EXTREMELY IMPORTANT THAT THE PROPER DUMMY ANTENNA BE CONSTRUCTED AND USED.

Connect the signal generator lead to the antenna cable assembly (made up of Part No. 38-7295 cable and a 155 mmfd. condenser in series between the lead and the signal generator. Plug the cable into the antenna receptacle on the top of the Receiver.

Turn the tuning condenser to 1400 K. C. and set the generator at 1400 K. C. Adjust the padders (11) and (6) for the maximum reading on the output meter.

When the antenna stage adjustment is made with the Receiver installed in the car, the Receiver antenna lead must be connected to the car antenna in the usual manner. Connect the signal generator output lead to a wire placed near the car antenna but not connected to it.

MODEL N1433H

I. F. TRANSFORMERS AND PADDERS

The I. F. transformers are assembled complete with padding condensers.

Both the primary and secondary padders are placed side by side in the top of the transformer shield can. The adjusting screws are accessible thru the holes in the top of the shield. (See Figure 4).

The coil windings terminate in leads instead of terminals or lugs. The color scheme of the leads is given in Figure 3.

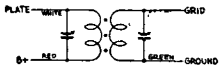

Figure 3

If replacements are ever necessary, replace the entire coil assembly, 32-2286 for the first I. F. stage and 32-2167 for the second I. F. stage. Neither the coil nor the paddlers will be furnished separately. Order only by the above numbers.

MODEL N-1433 ADJUSTMENTS

All padding adjustments are carefully made at the factory and ordinarily no readjustments are necessary. However, when readjustments are required, the procedure given below must be followed in detail.

Equipment

Fully charged heavy duty storage battery or 6-volt power pack, 048A Philco Set Tester, 3164 Padding wrench, 27-7159 Padding screw driver.

General

OUTPUT METER—The output meter must be connected by means of an adapter to the plate of the type 41 output tube and to the Receiver chassis.

SIGNAL GENERATOR—With the Receiver and signal generator set up for operation at the prescribed frequency, turn the Receiver volume control on full and set the signal generator attenuator so that a half scale reading is obtained on the output meter. The signal in the speaker should be audible but not loud.

The shielding on the signal generator output lead must be connected to the Receiver housing.

Procedure

I. F.—Set the signal generator at exactly 260 K. C. Connect the generator lead to the grid cap of the 78 I. F. tube in series with a .1 mfd. condenser (without removing the grid cap).

Adjust the secondary screw padder (27) on the second I. F. transformer for maximum reading on the output meter. Then adjust the primary screw padder (25) for maximum reading. (See Figure 4 for location of padders).

Remove the generator lead from the 78 tube.

Connect the generator lead to the grid cap of the 6A7 tube in series with a .1 mfd. condenser (without removing the grid cap.) Adjust the secondary screw padder (23) on the first I. F. transformer for maximum reading on the output meter. Then adjust the primary screw padder (21) for maximum reading. Readjust padders (25) and (27) with the generator lead connected to the type 6A7 tube. (See Figure 4 for location of padders).

HIGH FREQUENCY AND R. F.—After padding the first I. F. stage remove the generator lead from the 6A7 tube. Set the signal generator at 1550 K. C. and then connect the generator lead to the grid cap of the 78 R. F. tube in series with a .1 mfd. condenser (without removing the grid cap).

Using a piece of paper approximately .006" thick as a gauge between the heel of the rotor plates and the stator plates, turn the rotor plates in mesh until they strike against the paper.

With the tuning condenser in this position, adjust the high frequency padder (15) and the R. F. padder (11) until the maximum reading is obtained on the output meter. This is the true setting for 1550 K. C., 155 on the dial scale.

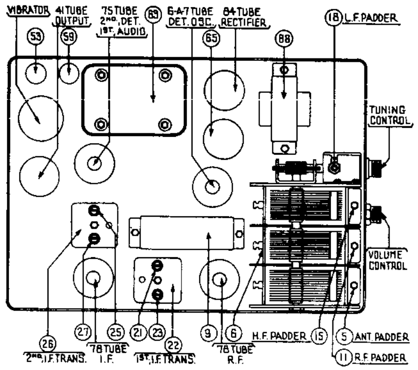

Figure 4

LOW FREQUENCY—Turn the tuning condenser plates in mesh to approximately 600 K. C., 60 on the dial scale and set the signal generator at 600 K. C. Roll the tuning condenser and adjust the low frequency padder screw (18) for maximum reading on the output meter.

HIGH FREQUENCY READJUSTMENT—Turn the tuning condenser plates out of mesh to 1550 K. C. and set the signal generator at 1550 K. C. Then adjust the high frequency padder (15) again for maximum reading on the output meter.

Remove the generator lead from the 78 R. F. tube.

ANTENNA—WHEN PADDING THE ANTENNA STAGE IT IS EXTREMELY IMPORTANT THAT THE PROPER DUMMY ANTENNA BE CONSTRUCTED AND USED.

Connect the signal generator lead to the antenna cable assembly (made up of Part No. L-2320 lead, and a 64 mmfd. condenser in series between the lead and the signal generator. Plug the cable into the ROOF ANTENNA CONNECTOR on the end of the Receiver.

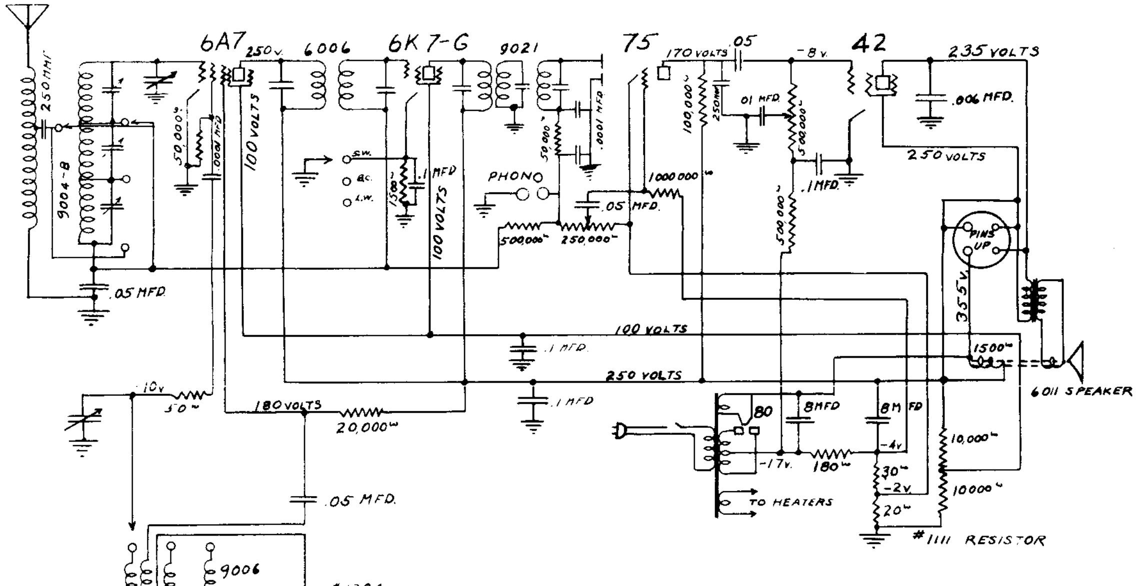
Follow this padding procedure regardless of whether the Receiver is used with the Roof or Under-car antenna.

Turn the tuning condenser to 1400 K. C. and set the generator at 1400 K. C. Adjust the padders (11) and (5) for the maximum reading on the output meter.

When the antenna stage adjustment is made with the Receiver installed in the car, the Receiver antenna lead must be connected to the car antenna in the usual manner. Connect the signal generator output lead to a wire placed near the car antenna but not connected to it.

ULTRAMAR MANUFACTURING CORPORATION

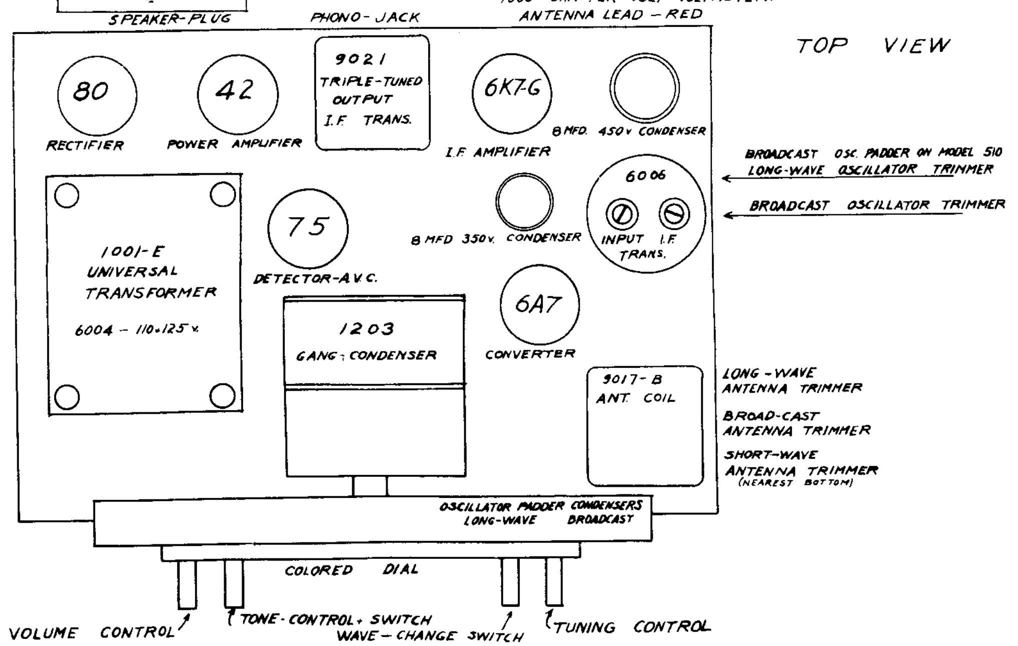
MODELS 510 & 520



WIRING DIAGRAM OF MODELS 510 AND 520

NOTE

LONG-WAVE BAND IS OMITTED ON MODEL 510
VOLTAGES INDICATED ARE MEASURED WITH A
1000 OHM PER VOLT VOLTMETER.
ANTENNA LEAD - RED



TOP VIEW

A calibrated oscillator such as Model 180, covering the ranges from 20 to 2000 meters and an output meter (connected between plate and screen prongs of the 42 tube) will be required. Use low values of output to prevent false readings due to the operation of the automatic volume control while aligning.

The output meter may also be connected across the two small prongs of the speaker plug.

INTERMEDIATE STAGE ALIGNMENT

1. Connect the output of the test oscillator to the grid of the 6A7 converter tube, and connect a 1 megohm resistor from this grid to the chassis. Connect the ground side of the oscillator (the shielding) to the receiver chassis.

2. Set the test oscillator to 465 K.C. Refer to Curve B on the calibration chart to obtain the proper setting of the test oscillator dial.

3. Align the output intermediate transformer by turning one of the trimmer screws accessible at the top of the coil shield until the response is at a maximum. Adjust the other trimmer screws in the same manner.

4. Adjust the input intermediate frequency transformer in the same manner.

SHORT-WAVE ALIGNMENT

5. Set the dial of the test oscillator and the receiver to 20 meters. Connect the output (insulated lead) of the test oscillator to the antenna lead (red) thru a 400 ohm resistor.

6. Adjust the lowest trimmer in the square shield near the front of the chassis till maximum response is obtained while rocking the gang condenser at the same time. By rocking the gang condenser is meant tuning to a point just above and just below the oscillator frequency while making some other adjustment. Set the test oscillator and receiver to 50 meters and check sensitivity.

BROADCAST BAND ALIGNMENT

7. Set the test oscillator and receiver to 214 meters (1400 K.C.). Replace the 400 ohm resistor connected to the antenna lead by a .00025 MFD condenser. Adjust the B.C. oscillator trimmer and the center trimmer in the square shield near the front of the chassis (B.C. antenna trimmer) till maximum response is obtained. Set the test oscillator and receiver to 500 meters (600 K.C.) and adjust B.C. padder for maximum response while rocking the gang at the same time. Repeat this entire procedure.

LONG-WAVE BAND ALIGNMENT (MODEL 520 ONLY)

8. Set the test oscillator and receiver to 900 meters and adjust the long-wave oscillator trimmer and long-wave antenna trimmer (highest trimmer in square shield near front of chassis) till maximum response is obtained. Set the test oscillator and receiver to 1800 meters. Adjust the long-wave oscillator padder condenser till maximum response is obtained, rocking the gang condenser at the same time. Repeat the above procedure for this band.

Assuming that all of the component parts are not defective, poor sensitivity, selectivity, or extremely inaccurate dial calibration are an indication that the procedure has not been carefully followed and should be repeated following each step carefully in the above order.

ULTRAMAR MANUFACTURING CORPORATION

N O T E:

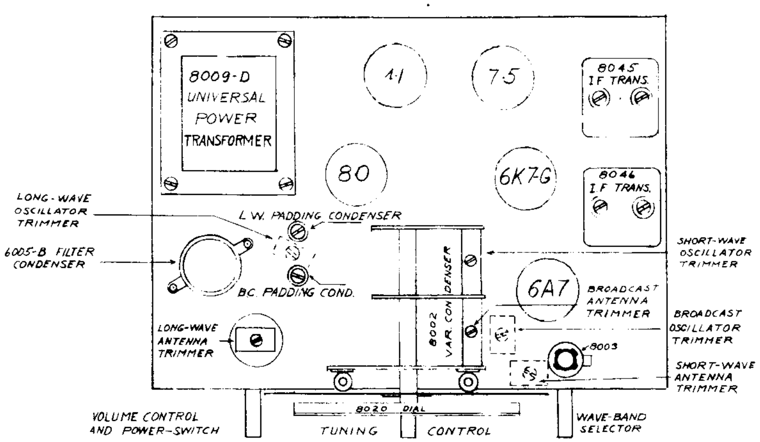
1.- ALL NUMBERS SHOWN RELATIVE TO PARTS ARE OUR PART NUMBERS.

2.- INTERMEDIATE FREQUENCY = 456 K.C.

3.- SWITCH ON POSITION A 18 TO 53 METERS (GREEN)
SWITCH ON POSITION B 540 TO 1700 KILOCYCLES (YELLOW)
SWITCH ON POSITION C 800 TO 2000 METERS (RED)

4.- ON MODEL 525 THE LONG-WAVE BAND (C) IS OMITTED. THE CATHODES OF THE 6A7 AND 6K7-G TUBE ARE CONNECTED TOGETHER AND BY-PASSED WITH A 1/2 MFD CUB CONDENSER.

TOP VIEW of CHASSIS



A calibrated oscillator such as Model 180, covering the ranges from 20 to 2000 meters and an output meter (connected between plate and screen prongs of the 41 tube) will be required. Use low values of output to prevent false readings due to the operation of the automatic volume control while aligning.

The output meter may also be connected across the two small prongs of the speaker plug.

INTERMEDIATE STAGE ALIGNMENT:

1. Connect the output of the test oscillator to the grid of the 6A7 converter tube, and connect a 1 megohm resistor from this grid to the chassis. Connect the ground side of the oscillator (the shielding) to the receiver chassis.

2. Set the test oscillator to 456 K.C. Refer to Curve B on the calibration chart to obtain the proper setting of the test oscilator dial.

3. Align the output intermediate transformer by turning one of the trimmer screws accessible at the top of the coil shield until the response is at a maximum. Adjust the other trimmer screws in the same manner.

4. Adjust the input intermediate frequency transformer in the same manner.

SHORT-WAVE ALIGNMENT

5. Set the dial of the test oscillator and the receiver to 20 meters. Connect the output (insulated lead) of the test oscillator to the antenna lead (red) thru a 400 ohm resistor.

6. Adjust the short-wave oscillator trimmer located on the wave-band switch till maximum response is obtained while rocking the gang condenser at the same time. By rocking the gang condenser is meant tuning to a point just above and just below the oscillator frequency while making some other adjustment. Set the test oscillator to 50 meters and check sensitivity.

BROADCAST BAND ALIGNMENT

7. Set the test oscillator and receiver to 214 meters (1400 K.C.). Replace the 400 ohm resistor connected to the antenna lead by a .00025 MFD condenser. Adjust the broadcast oscillator trimmer located to the left of the band switch (see diagram for location of all trimmers and padders) and the broadcast antenna trimmer located on the top of the gang condenser till maximum response is obtained. Set the test oscillator and receiver to 500 meters (600 K.C.) and adjust the B.C. padder for maximum response while rocking the gang condenser at the same time. Repeat this entire procedure.

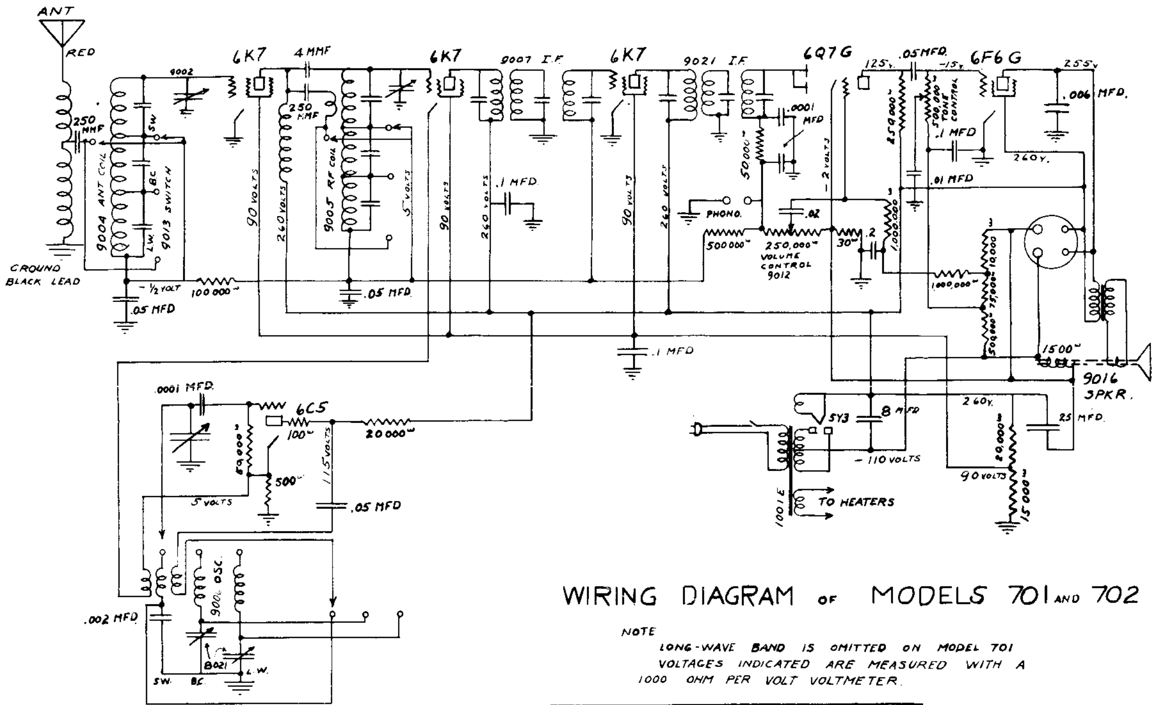
LONG-WAVE BAND (MODEL 526 ONLY)

8. Set the test oscillator and receiver to 900 meters and adjust the long-wave oscillator trimmer and the long-wave antenna trimmer located on top of their respective coils till maximum response is obtained. Set the test oscillator and receiver to 1800 meters. Adjust the long-wave padder condenser till maximum response is obtained, rocking the gang condenser at the same time. Repeat the entire procedure for this band.

Assuming that all of the component parts are not defective, poor sensitivity, selectivity, or extremely inaccurate dial calibration are an indication that the procedure has not been carefully followed and should be repeated following each step carefully in the above order.

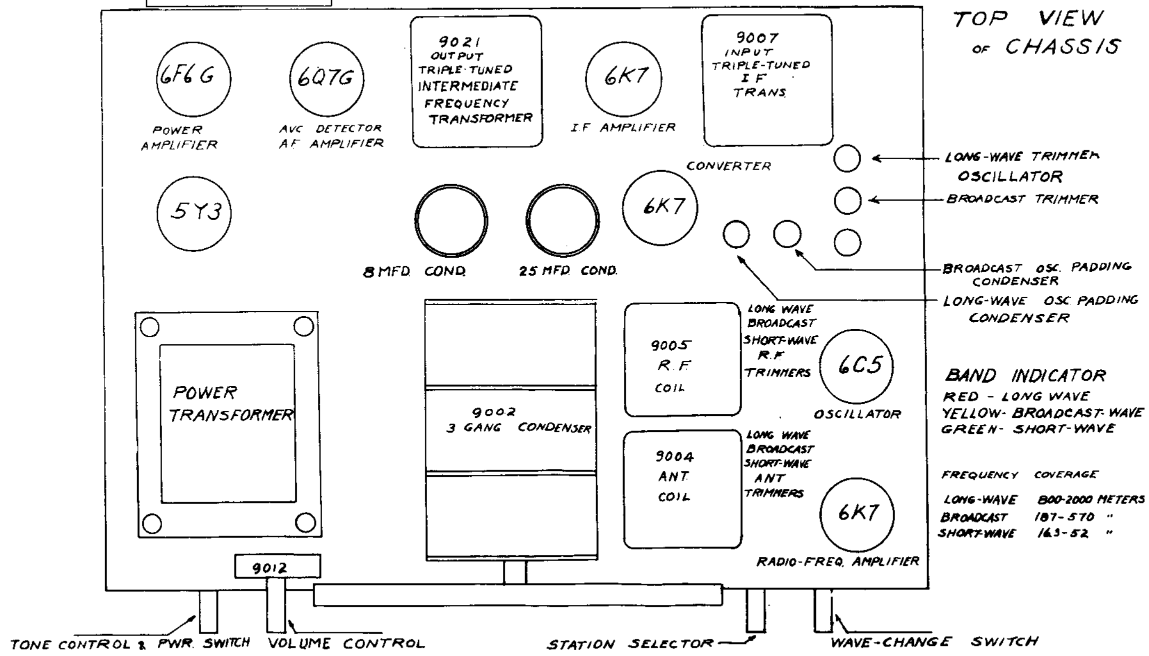
ULTRAMAR MANUFACTURING CORPORATION

MODELS 701 & 702



WIRING DIAGRAM OF MODELS 701 AND 702

NOTE
LONG-WAVE BAND IS OMITTED ON MODEL 701
VOLTAGES INDICATED ARE MEASURED WITH A 1000 OHM PER VOLT VOLTMETER.



A calibrated oscillator such as Model 180, covering the ranges from 20 to 2,000 meters and an output meter (connected between plate and screen prongs of the 6F6G tube) will be required. Use low values of output to prevent false readings due to the operation of the automatic volume control while aligning.

The output meter may also be connected across the two small prongs of the speaker plug.

INTERMEDIATE STAGE ALIGNMENT

1. Connect the output of the test oscillator to the grid of the 6K7 converter tube (located behind tuning condenser), and connect a 1 megohm resistor from this grid to the chassis. Connect the ground side of the oscillator (the shielding) to the receiver chassis.

2. Set the test oscillator to 465 K.C. Refer to Curve B on the calibration chart to obtain the proper setting of the test oscillator dial.

3. Align the output intermediate transformer by turning one of the trimmer screws accessible at the rear of the coil shield until the response is at a maximum. Adjust the other trimmer screws in the same manner.

4. Adjust the input intermediate frequency transformer in the same manner.

SHORT-WAVE ALIGNMENT

5. Set the dials of the test oscillator and the receiver to 20 meters. Connect the output (insulated lead) of the test oscillator to the antenna lead (red) through a 400 ohm resistor.

6. Adjust the two lowest trimmers in the square shields near the front of the chassis till maximum response is obtained while rocking the gang condenser at the same time. By rocking the gang condenser is meant tuning to a point just above and just below the oscillator frequency while making some other adjustment. Set the test oscillator for frequency while making some other adjustment. Set the test oscillator and receiver to 50 meters and check sensitivity.

BROADCAST BAND ALIGNMENT

7. Set the test oscillator and receiver to 214 meters (1400 K.C.). Replace the 400 ohm resistor connected to the antenna lead by a .00025 MFD condenser. Adjust the B.C. oscillator trimmer and center trimmers in the square shields near the front of the chassis (B.C. - R.F. and B.C. antenna trimmers) till maximum response is obtained. Set the test oscillator and receiver to 500 meters (600 K.C.) and adjust the B.C. padder for maximum response while rocking the gang at the same time. Repeat this entire procedure.

LONG-WAVE BAND ALIGNMENT (Model 702 only).

8. Set the test oscillator and receiver to 900 meters and adjust the L.W. oscillator trimmer and the L.W. antenna and R.F. trimmers (highest trimmers in the square shields near the front of the chassis) till maximum response is obtained. Set the test oscillator and receiver to 1800 meters. Adjust the long-wave oscillator padder condenser at the same time. Repeat the above procedure for this band.

Assuming that all of the component parts are not defective, poor sensitivity, selectivity, or extremely inaccurate dial calibration are an indication that the procedure has not been carefully followed and should be repeated following each step carefully in the above order.

OPERATING INSTRUCTIONS

Installation: Remove all packing material from inside the cabinet and be sure the speaker cord is plugged into the socket at the rear of the chassis. Replace the back panel. Do not ever remove this back unless the line-cord has been disconnected from the source of supply.

Current Supply: This receiver can be used with either alternating or direct current. The power supply voltage must correspond to the number of the ballast tube. For 110 volts a #910-110 ballast tube is used. For 230 volts a #910-230 tube is used, in place of the #910-110.

Antenna: Use an outside antenna about fifty feet in length, including the lead-in wire. Connect it to the red wire coming out of the rear of the receiver. No ground connection is necessary with this receiver.

ALIGNING NOTES

1.- Align the IF Transformers at 465 kilocycles (645 meters).
2.- Align the Short-wave Band (Green) at 20 meters by adjusting the SW Antenna and SW R.F. trimmers (at bottom of square cans, at side of chassis).
3.- Align the Broadcast Band (Yellow) by adjusting the BC Oscillator trimmers and also the BC Antenna and BC R.F. trimmers (center trimmers in the square cans), at 1400 kilocycles (214 meters). Adjust the BC padder condenser at 600 kc. (500 meters).
4.- Align the Long-wave Band (Red) at 900 meters by adjusting the LW Oscillator trimmer and also the LW Antenna and R.F. trimmers (the top trimmers in the square cans). Adjust the LW padder at 1800 meters.

All aligning adjustments are to be made with a standard Signal Generator, and Output Meter.

Caution: Be sure that the four bolts under the cabinet are loosened and that no part of the dial touches the front of the cabinet.

UNITED AMERICAN BOSCH CORPORATION
MODELS 139H, 139HC, 139HT, 139HTC, 139L, 139LC, 139LT, 139LTC, 149H, 149HC, 149HT, 149HTC, 149L, 149LC, 149LT & 149LTC "POLICE RADIO"

The Models 139 and 149 are designed especially for police use in motor cars. The Model 139 is for frequency settings between 1500 and 1800 kilocycles, and the Model 149 for settings between 2250 and 2500 kilocycles. The receiver equipment consists of three units:

(1) Receiver unit
(2) "B" power supply unit
(3) Speaker

The receiver is arranged to be mounted on the steering column which is preferable, or on the bulkhead, whereas, the "B" power supply unit and the speaker are arranged to be mounted on the bulkhead. The mounting construction of each unit is such as to simplify removal for servicing.

The receiver unit employs a superheterodyne circuit with five tubes arranged as follows:
1 Type 77 used as an R.F. amplifier
1 Type 6A7 used as a 1st detector and oscillator
1 Type 78 used as an I.F. amplifier
1 Type 75 used as a 2nd detector, AVC tube, and audio amplifier
1 Type 41 used as an audio output tube

The oscillator is tuned to a frequency differing from the signal frequency by 456 KC., the intermediate frequency. The oscillator in Model 139 receiver generates a frequency 456 KC. higher than the signal frequency, whereas, the oscillator in the Model 149 receiver generates a frequency 456 KC. lower than the signal frequency. Accordingly, one model is convertible to the other by merely changing the preselector coil.

1. CONNECT POWER SUPPLY UNIT FOR SUPPLY POLARITY:
(a) Model GM-A-Ed.2 or GM-B-Ed.2. The power supply unit as provided has a terminal plate to which a black wire and a blue wire are connected. These connections are made for the condition where the power supply unit is to be used in a motor car whose storage battery has the positive terminal grounded. If it is desired to use the power supply unit in a car whose storage battery has the negative terminal grounded, it will be necessary to reverse the connections of the blue and black wires on the terminal strip. To gain access to this terminal plate it is necessary to remove the housing and the bottom cover on the power supply unit. The terminal plate will be found on the under side of the sub-base inside of the unit. The terminals on the terminal plate are designated "+" and "-". As furnished, the black wire is connected to the " " terminal and the blue wire is connected to the "-" terminal, to accommodate a positive storage battery ground. When the negative terminal of the storage battery is grounded these wires should be reversed so that the blue wire is connected to the "+" terminal and the black wire is connected to the "-" terminal.
(b) Model GM-EA or GM-EB. The power supply unit as provided is connected for the condition where it is to be used in a motor car whose storage battery has the positive terminal grounded. If it is desired to use the power supply unit in a car whose storage battery has the negative terminal grounded, it will be necessary to remove the end cap from the end, of the dynamotor which is away from the filter unit and interchange the red and black wires which make connections with the brushes.

It is IMPORTANT to observe these instructions since the receiver will not operate if the polarity connection is not correct and serious damage to some of the electrical components may result.

2. INSTALL THE STANDARD SUPPRESSION EQUIPMENT: The method of eliminating ignition noise is the same for practically all of the later model cars. Eight spark plug suppressors, one distributor suppressor, and three shielded condensers are provided in the bag of accessories. Using this material and observing the following procedure in installation, the desired results will be obtained in the majority of cases.

A. Connect a spark plug suppressor in series with each spark plug connection as close to the spark plug as possible. To do this, remove the nuts which secure the ignition wires to the spark plugs and screw a suppressor on each plug. The top of the suppressor is a stud fitted with a push-type clip which can be removed, thereby making the suppressor universally adaptable to all types of spark plug wire connectors.

B. Insert a distributor or suppressor in series with the center lead of the distributor (high tension lead from coil) as close as possible to the distributor. This is done by first cutting the lead to the center of the distributor about 1-1/2 inches above the distributor cap, then remove the short end of this lead from the distributor and screw the suppressor into this short end. Next screw the other end of the suppressor into the long end of the ignition wire to the coil. Plug the lead assembly thus completed back into the distributor. If the weight of the suppressor causes excessive vibration of the wire, it should be taped to some mechanical support to prevent the strands of the wire from breaking. This wire should not be placed close to any metal part.

C. Mount a condenser on the generator housing, in such a manner as to make a good ground as well as a secure mounting. Connect the condenser lead to the battery side of the cutout. (Note: On cars where the generator cutout is mounted on the bulkhead, and there are two terminals on the generator, connect the condenser lead to the terminal carrying the heaviest wire.)

D. In all cars equipped with a roof antenna, it is absolutely necessary to connect a condenser to the dome light lead at the point where the lead enters the post in back of the dash. This condenser may be mounted and grounded on the under lip of the dash. The condenser lead to the dome light should be as short as possible.

E. In many installations it will be necessary to connect a condenser to the battery side of the ignition switch. This condenser can be mounted and grounded at the rear of the dash.

On a Ford V8, this condenser should be mounted on the ignition coil and distributor unit, which is located directly in back of the car radiator, in the motor compartment. The condenser mounting bracket should be bent out straight and clipped off to the edge of the mounting hole, with a pair of cutters. This permits the condenser to be secured under the distributor cap screw nearest the car radiator, without striking it. The condenser lead is then connected to the primary terminal in back of the distributor cap.

3. INSTALL SPARK NOISE TRAP AND CONNECT BATTERY CABLE TO THE AMMETER: A spark noise trap has been included among the accessories. The cable on this trap terminates in a female bayonet connector while the cover at the other end of the trap is fitted with a male bayonet connector. The battery cable on the receiver unit should be disconnected at the fuse container and the spark noise trap inserted, being careful not to let the fuse drop out of the container. The free end of the battery cable should then be connected to the ammeter or to the ammeter side of the automobile fuse. This connection should be made so that the current drawn by the receiver will be registered on the ammeter. When the receiver is turned on, a slight humming noise will be heard from the power supply unit, and a slight sound should be heard in the loudspeaker.

4. INSTALL THE ANTENNA: There are a number of different types of car antennas.
ROOF TYPE: This usually consists of a copper screen, similar to window screening, and is secured to the wooden bracing members of the top, between the top upholstery and the outer top fabric. This type of antenna has been standard equipment in most closed cars without turret tops, and is generally agreed to be the best type for automobile use. To obtain the best results from your radio receiver, this type antenna should be installed.

CAPACITOR PLATE: A metal plate, sometimes adjustable in length with insulated adjustable mounting brackets can be mounted conveniently under the chassis frame or running board of the car. For best results, the height of the plate should be determined by trial with the receiver turned on and connected to it. The height has to be a compromise between sufficient clearance to ground and good reception.

UNDER CAR WIRE TYPE: A length of wire is suspended from insulators attached to various parts of the chassis frame.

All under car antennas should be mounted as far to the rear of the motor and as far from the car storage battery as possible, in order to minimize the ignition noise pickup.

FISH POLE TYPE: A collapsible metal rod similar in construction to a fish pole is mounted on insulators and attached to the rear bumper. This type of antenna is very efficient, particularly at police frequencies.

STREAMLINE TYPE: A length of metal tubing is attached to the top of the car by means of insulators fastened to suction cups. The tubing is bent to conform to the curvature of the car top. This type of antenna is particularly advantageous for use with turret top cars.

5. INSTALL THE ANTENNA LEAD-IN: The proper installation of an antenna lead-in is a VERY IMPORTANT CONSIDERATION FOR GOOD MOTOR NOISE SUPPRESSION. It is essential, therefore, to observe the following instructions:

The antenna lead-in must be kept away from any car cable wiring, choke rods, etc., under the dash. Never coil up excess antenna lead near the dashboard, and do not run the antenna lead near or parallel to the receiver battery cable. Be sure that the antenna lead shielding is completed from the receiver to within 6 or 8 inches from the antenna, and that this shield is grounded about every two feet along its entire length. Always use a good grade of shielded antenna lead-in on all types of antenna, such as Belden Braid or its equivalent.

ROOF ANTENNA LEAD-IN: The lead-in from the roof type of antenna should be led down either the right or left hand windshield post depending upon which is nearer to the receiver. The portion of the lead-in which extends outside of the windshield post should be shielded. Where a roof type of antenna has been installed by the car manufacturer, a lead-in will also have been provided.

UNDER CAR ANTENNA LEAD-IN: Run the shielded lead up through the floor board as near to the edge of the front seat as possible to keep it away from the motor. Most cars have a metal weather strip inside the car at the bottom of the doors. Continue the lead along this strip, and ground the shielding to it. From there the lead should be run up the toe board, and then at right angles to it along the floor where the toe board joins the bulkhead to the receiver.

6. TUNE THE RECEIVER TO THE DESIRED STATION: The radio receiver as delivered will be tuned to the station frequency requested. Due to unavoidable differences between the frequency adjustment made at the factory and that of the station, it will be necessary to realign the tuning condensers slightly. One of the following methods of procedure should be followed depending upon whether or not a tuning meter is available. The method of tuning using a tuning meter is preferable since more accurate adjustment is possible.

A. With Tuning Meter.
With the receiver in the motor car, and connected to the car antenna and battery, turn the receiver fully on and allow it to get into operation which will be indicated by a slight hum heard in the speaker. Plug the tuning meter (SA 107610) into the jack in the receiver housing. If the station desired is not heard, drive the machine (with the radio set in operation), toward the broadcasting station. When the station is heard, stop the motor car and proceed as follows:

(a) Loosen the brass condenser lock nuts (which can be seen through the two holes in the top cover of the housing) using a 7/16" socket wrench (ST 450). This operation must be observed or damage will be done to the tuning condensers when alignment is attempted with a screw driver.

(b) With a screw driver inserted into the slot in the shaft of the left hand condenser (#8-Fig. #1), adjust this condenser until maximum deflection of the tuning meter in the direction indicated by the arrow on the dial is obtained on the station being heard.

(c) Repeat operation "b" with the right hand condenser (#2-Fig. #1).
(d) Lock the condensers with the 7/16" socket wrench.

B. Without Tuning Meter:
With the receiver in the motor car, and connected to the car antenna and battery, turn the receiver fully on and allow it to get into operation which will be indicated by a slight hum heard in the speaker.

If the station desired is not heard, drive the machine (with radio set in operation) toward the broadcasting station. When the

(Continued on next page)

UNITED AMERICAN BOSCH CORPORATION

MODELS 139H, 139HC, 139HT, 139HTC, 139L, 139LC, 139LT, 139LTC, 149H, 149HC, 149HT, 149HTC, 149L, 149LC, 149LT & 149LTC "POLICE RADIO"

(Continued from preceding page)
station is heard faintly, stop the motor car and proceed as follows:

(a) Loosen the brass condenser lock nuts (which can be seen through the two holes in the top cover of the housing) using a 7/16" socket wrench. This operation must be observed or damage will be done to the tuning condensers when alignment is attempted with a screw driver.

(b) With a screw driver inserted into the slot in the shaft of the left hand condenser (#8-Fig. #1), adjust this condenser until the station is heard loudest.

(c) Reduce the volume by rotating the volume control knob on the face of the receiver housing counter-clockwise.

(d) Repeat operations (b) and (c) with the right hand condenser (#2-Fig. #1).

(e) Lock the condensers with the 7/16" socket wrench.

Alignment by the above operations will be only approximate. To attain the exact alignment required for successful operation proceed as follows:

(a) Drive the motor car (with radio operating with volume control on full) to a "dead" spot or to a place sufficiently remote from the transmitter to produce a weak signal. In such a location repeat operations "a", "b", "d" and "e". In this case under no circumstances should the volume of the signal be reduced by adjusting the volume control knob. Keep the volume control in its maximum position. Do not neglect to lock the condensers with the socket wrench after alignment and before replacing cover plates.

C. WITH EXTERNAL TRIMMER CONDENSER - Types HT, LT, HTC, LTC, Only. These models are provided with an auxiliary tuning condenser which permits fine adjustments of the tuning while the receiver is in operation. This condenser is connected in parallel with the main oscillator tuning condenser. The shaft of the trimmer condenser extends through the top cover of the receiver and is provided with a suitable knob. An arrow on the knob indicates the position of the trimmer condenser with respect to a small scale on the cover.

When the receiver is tuned, the trimmer condenser should be adjusted to its mid-position and the information given in Section #5 should be followed. The trimmer condenser knob must be removed before the top cover of the receiver can be taken off.

Before replacing the cover, it is very important to make certain that the trimmer condenser is in its mid-capacity position, i.e. with the rotor plate turned half way into the stator. Then place the cover on the receiver and without turning the trimmer condenser shaft, replace the knob in such a position that the arrow points to the center of the scale. Tighten the set screw securely.

7. REMOVE REMAINING IGNITION NOISE INTERFERENCE: In certain older models of cars, some difficulty may be experienced in the elimination of ignition noise, the expedients described under sections nos. 2, 4 and 5 having proved to be insufficient. In order to facilitate the elimination of noise in the extreme cases of older cars, the following generalities pertaining to ignition noise elimination are stated.

Motor noise gets into radio receivers in automobiles in the following manner:

1. Picked up by the antenna.
2. Picked up by the antenna lead-in.
3. Carried into the receiver on the battery cable.
4. Admitted to the receiver through openings in the housing.

The Models 139 - 149 have been carefully designed to eliminate items #3 and #4 above and to minimize to a very great extent items #1 and #2 above. If, however, it is found in the older cars that there is still some motor noise present, it may be localized and in most cases remedied in accordance with the following procedure:

TO CHECK FOR THE SOURCE: Start the motor and turn on the receiver to full volume. Now turn the motor off and on to make sure that it is motor noise and not some extraneous local interference. Having determined the interference to be motor noise, keep the engine running at a speed where the noise is loudest. Disconnect the antenna lead-in from the receiver. If the noise ceases it is being picked up by the antenna or the antenna lead-in. If the noise continues, it is very rare and can usually be remedied by changing the location of the cable in respect to other car wiring under the dash.

Conditions #1 and #2, although closely related, can be treated separately, by disconnecting the car antenna from the lead-in attached to the set. If the noise still persists, it is in the lead-in, and can be eliminated by following the directions under Section #5 above. In the case of a roof antenna, as stated before, the pickup is usually by the antenna itself. The corrections for antenna pickup vary widely with cars of different makes, and no attempt will be made to list them here. However, the following expedients, if made in the order in which they are set down, will cure the majority of cases.

1. Shield the primary wire from the ignition switch to the ignition coil, running the lead separately from the other wiring and grounding the shield.

2. If the car is equipped with an Electro-Lock System, the cable wiring from it to the motor compartment must be shielded through the bulkhead to the switch.

3. Check the distributor contacts for too wide a gap.
4. Check the spark plugs for too wide a gap.

5. Be sure that the high tension center coil lead does not run closely parallel or in same conduit with the spark plug wires.

6. If the ignition coil is mounted on the driver's side of the bulkhead, move it out in to the motor compartment, close to the distributor, and shield the extended primary lead back to the ignition switch.

IMPORTANT

Material and workmanship represented in this receiver are of the best obtainable. The results obtained from the receiver, however, are dependent upon many features, of which the following are perhaps the most important items:

1. Proper mechanical and electrical installation.
2. Efficient suppression of electrical interference.
3. Adequate source of power or battery supply.

The last one mentioned is perhaps responsible for more complaints than any other item. Battery and generator are supplied with the vehicle and the customer, as a rule, considers them adequate to handle every new appliance he adds to the installation. The efficiency of the receiver will be materially affected in all cases where too small a battery is employed or where the charging equipment is inadequate. Therefore, do not blame the receiver for possible poor performance unless and until you definitely know that your battery and generator equipment are ample to supply the power needed for this installation.

Where cars are on 24 hour service, the standard generator with which the car is equipped, is usually replaced with a volt-omatic generator, which will keep the storage battery fully charged under all ordinary operating conditions.

We will be glad to help you with your battery and generator problems.

TOOLS AND EQUIPMENT

1 Weston Model #564 Volt-Ohmmeter.
1 Test oscillator covering 456 kilocycles.
1 Screw driver with insulated handle.
1 Socket wrench #4.
1 Tuning meter with cord and plug #SA 107610.
1 Socket wrench 7/16" hex. #ST 450.
1 Soldering iron.
1 Long nose pliers.
1 Cutting pliers.

ALIGNMENT INSTRUCTIONS

All of the adjustable condensers, commonly called trimmer condensers, are very accurately adjusted at the factory and will not need any further adjustments unless an I.F. transformer is changed, or the adjustments tampered within the field. Therefore, DO NOT attempt to change the setting of any of the trimmer condensers unless it is definitely known that adjustment is necessary, and a test oscillator is available, then proceed as follows: (See Fig. #1.)

1. Connect output meter across terminals of speaker voice coil.
2. Set test oscillator at 456 kilocycles.
3. Connect test oscillator lead to grid of I.F. amplifier tube, type 78.
4. Adjust condenser on primary of second I.F. transformer, (Point #15) to peak on output meter.
5. Adjust condenser on secondary of second I.F. transformer, (Point #14) to peak on output meter.
6. Connect ~~test~~ oscillator lead to grid of detector-oscillator tube, type 6A7.
7. Adjust condenser on primary of first I.F. transformer (Point #12) to peak on output meter.
8. Adjust condenser on secondary of first I.F. transformer, (Point #11) to peak on output meter.

The above procedure lines up the I.F. stages properly, so that all that remains is to tune the oscillator and preselector circuits to the frequency of the station it is desired to receive. This has been covered in the section headed TUNING.

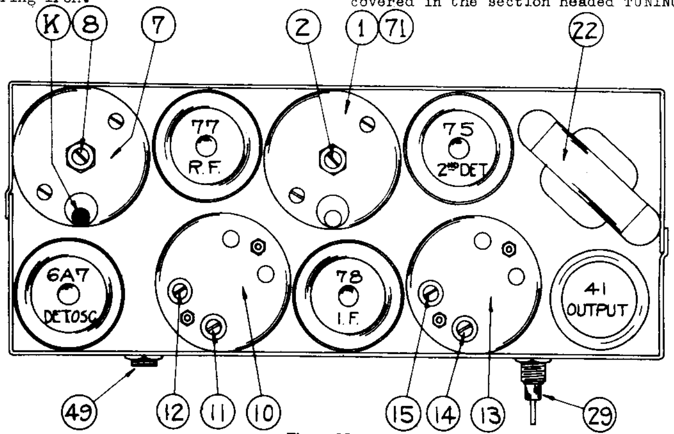

Figure No. 1

TROUBLE CHART

A few general classes of trouble are listed below with the probable reasons. These are intended to serve as a general guide in checking trouble.

1. No reception - power supply unit not operating.
   (a) Fuse in "A" battery cable burned out.
      (1) Short in "A" line or circuit.
      (2) Shorted elements in power supply unit.
      (3) Shorted elements in tube.
   (b) Poor connection at storage battery.
   (c) Connections not made in double cable between chassis and power supply unit.
   (d) Defective switch.
2. No reception - power supply unit operating.
   (a) Car antenna grounded.
   (b) Loose antenna connection.
   (c) Connections not made in double cable between chassis and power supply unit.
   (d) Antenna coil open or other coils defective.
   (e) One or more defective tubes.
   (f) Open circuit in voltage supply to tube sockets.
   (g) Open connection in speaker cable.
   (h) Open voice coil in speaker.
   (i) Contacts in tuning meter jack not

(Continued from preceding page)
making contact when plug is removed.
(j) Grid bell off of tube cap.

3. Weak reception.
(a) Poor antenna or antenna connections.
(b) Incorrect adjustment of oscillator and preselector tuning condensers.
(c) One or more defective tubes.
(d) Low voltage output of power supply unit.
(e) Defective oscillator coil.
(f) Trimmer condensers on I.F. transformers out of alignment. (See Alignment Instructions.)

4. Poor tone quality.
(a) Low storage battery voltage.
(b) One or more defective tubes.
(c) Defective speaker.
(d) Low "B" voltage.

"B" POWER SUPPLY UNIT

The dynamotor contained in the power supply unit will give several thousand hours of satisfactory service under normal conditions of operation. However, it is very important to inspect the dynamotor unit at least ONCE A MONTH in order to insure satisfactory operation. Occasionally due to mistreatment the unit may fail to function properly and a little attention will, in most cases, eliminate the difficulty. However, repairs to the dynamotor should be confined to the replacement of brushes, brush holders and the cleaning of the armature commutators with very fine sandpaper. NEVER attempt to turn the armature commutators on a lathe. Service work should be done carefully, since the guarantee is cancelled on any unit that shows evidence of improper handling. For all other repairs such as the replacement of field coils, armature, bearings, etc., the complete dynamotor should be returned to the United American Bosch Corporation for repairs.

The principal causes of trouble are as follows:

A. LOW OUTPUT:
1. Short or overload in receiver. Indicated by high output current.
2. Low input voltage.
3. Short or ground in power supply unit. Indicated by high input current.
4. Dirty commutators. Clean with very fine sand paper while running.
5. Dirt between bars of commutators.
6. Tight bearings.
7. Armature laminations rubbing on the field laminations.
8. Brushes not free to move and not exerting proper pressure on commutator.
9. Defective filter components. Check condensers and continuity of choke coils.

B. MECHANICAL NOISE:
1. Loose or defective bearings.
2. Brushes chattering.
3. Armature rubbing.
4. Rubber bumpers worn, permitting motor to vibrate against container.

C. ELECTRICAL NOISE IN SPEAKER:
If the receiver has been operated with "B" batteries so that it is certain that the power supply unit is the source of the noise, one of the following conditions in the power supply unit may be the cause.

1. Rough commutator.
2. Brushes not seating properly.
3. Loose connections.
4. Short between primary and secondary armature windings.
5. Defective filter components. Check condensers and resistance of choke coil windings.

In re-assembling the motors apply a small quantity of dynamotor lubricant (BM 1057) to each bearing, and be sure to remove all oil or grease from the commutators. Replace brushes in original position and be sure they are seated properly and are free to move, exerting proper pressure against the commutators.

If new brushes are installed, they should be "run in" a short time to insure proper seating. Any new brushes or springs should be purchased only from the United American Bosch Corporation, since the grade of the brushes and the degree of spring tension is important to insure satisfactory operation.

Make certain that the rubber bumpers supporting the motor do not bind, and that the motor floats freely in rubber.

Observe the precautions with respect to polarity connections given in Section #1 of the Installation Instructions. This is very important.

8-	79-113	SPEAKER
10-	2054	S.W. ANT. TRIMMER

This receiver is a 5 tube dry battery operated superheterodyne.

The tubes used are a 1C6 as oscillator modulator, a 34 as I.F. amplifier, a 1B5 as A.V.C. and audio rectifier and audio voltage amplifier, a 33 as power audio amplifier, and a 5E1 as a filament ballast tube.

This receiver is made to cover two tuning bands, the standard broadcast band which ranges from 1730 K.C. to 535 K.C. and the middle or police band which has a frequency range of from 6.4 M.C. to 2.1 M.C.

ALIGNMENT PROCEDURE

The following alignment procedure is for use only by competent service men having the proper equipment. Re-alignment is very seldom needed and is usually only required after some major part has been replaced because of damage to the receiver.

The equipment required for re-aligning this receiver is an out-put meter and a modulated source of radio frequency (a signal generator or microvolter). This source of radio frequency must be accurately calibrated in frequency and must have a method of varying the output.

All alignments must be made with the volume control turned full on and with the signal input reduced to as low a value as possible while still giving a reasonably accurate output indication.

Connect the output meter, through a .5 M. F. condenser and a resistance of such a value as to make the total meter resistance approximately 7000 ohms, to the two small pins of the speaker plug. The output meter remains connected during the entire alignment procedure.

Connect the signal generator to the grid cap of the 1C6 tube through a .1 M.F. condenser. Connect the ground of the generator to the ground lead of the receiver. With the wave switch on broadcast position and the dial set to about 1000 K. C., feed in a 456 K.C. signal. Adjust the trimmers on top of the first and second I.F. transformers until the maximum output is obtained. This aligns the I.F.

The short wave band is aligned while feeding a 6.0 M.C. signal to the frequency end. Feed a 1730 K.C. signal to the receiver antenna lead through a .00025 M.F. mica condenser. Adjust the 1730 K.C. broadcast oscillator trimmer until maximum output is shown. Set the generator to 1400 K.C. and tune in this signal on the receiver. Then adjust the 1400 K.C. broadcast antenna trimmer to maximum output. Set the generator to 600 K.C. and adjust the 600 K.C. broadcast oscillator pad to maximum output **while tuning the receiver back and forth across the signal** from the generator. This completes the alignment of the broadcast band.

The short wave band is aligned while feeding a 6.0 M.C. signal the to receiver antenna lead through a .00025 M.F. mica condenser. Turn the wave switch to short wave position and tune in the 6.0 M.C. signal. Adjust the 6.0 M.C. short wave trimmer to maximum output.

I.F. 456 K.C.

TUBE COMPLEMENT:

1—Type 6C6—Oscillator and first detector.

1—Type 6D6—Intermediate frequency amplifier (456 KC).

1—Type 75 —Second detector, A.V.C. and first audio.

1—Type 42 —Pentode output tube.

1—Type 84 —Rectifier.

RECEIVER INSTALLATION:

This receiver is designed to mount to the instrument panel of any automobile. Select the most convenient location, preferably to the left or right of the steering column. A mounting bracket attached to the auto case above the dial, mounts flush with the lower edge of the instrument panel. Hold the receiver in the most suitable position and mark off the two mounting holes. Drill these holes about one-fourth inch diameter. A long threaded rod is provided to suspend the back of the set from the fire wall. Locate and drill a one-half inch hole in line with the rod. The two nuts and washers must be drawn up tight to each side of the fire wall.

Connect the heavy insulated wire to the battery terminal of the ammeter and splice the shielded antenna lead to the auto antenna. A lug provided on the end of the shield should be fastened to a suitable ground.

OPERATION:

The left hand knob is the switch and volume control. Rotate this knob about half-way to the right and allow a few seconds for the tubes to heat up. The right hand knob is the station selector.

Never de-tune a station off resonance to decrease the volume since this will affect the tone quality and cause noisy reception.

MOTOR NOISE ELIMINATION:

Every auto radio installation presents an individual problem in the elimination of motor noise interference. However, there is a definite procedure to follow which reduces motor noise in every case. First, obtain and attach a distributor suppressor as required for the particular car installation. Then attach a generator condenser from the generator cut-out relay to ground.

Should there be any objectional motor noise after the standard method of suppression is used, it is then advisable to check the ignition system. Spark plugs and distributor points should be properly adjusted.

Below is a list of noise elimination methods which may prove helpful in extreme cases:

1. Shield high tension leads.
2. Bond motor with copper braid to frame of car at points where noise pick-up is reduced to minimum, especially on cars with a floating motor.
3. Isolate low tension battery leads from high-tension leads on cars where these leads are grouped together.
4. Connect a condenser from the battery side of the ammeter to ground.
5. Connect a condenser from dome light wire to ground.
6. Bond together all rods extending through fire-wall and connect to a suitable ground on the motor side of the fire-wall. Use one-half inch copper braid for this purpose.
7. Connect a condenser at electrically operated oil, gas and water gauges to ground.
8. Bond brake-rods or any other possible conductor of high frequency interference.

SERVICE NOTES:

When the set fails to operate, check all external connections before removing set from the car.

A loose battery or antenna connection will cause noisy intermittent reception.

If set is weak check for a weak storage battery, shorted antenna or defective tubes.

A defective vibrator may cause weak and noisy operation.

I. F. ALIGNMENT:

Rotate the variable condenser to its maximum capacity and turn volume control on full. Set a test oscillator to 456 kilocycles and connect in series with a .1 mfd. condenser to the grid of the 6C6 tube. Adjust I. F. trimmers to resonance as indicated on an output meter connected across the voice coil of the speaker or from plate to screen of the 42 tube.

R. F. ALIGNMENT:

Rotate the variable condenser to full open position and connect the test oscillator in series with a .00015 mfd. condenser to the antenna lead of receiver. Feed a 1550 Kilocycle signal to the set and adjust the oscillator trimmer on the gang condenser to resonance. Reset test oscillator to 1400 Kilocycles and adjust R.F. trimmer on gang condenser to resonance. Also check at 1000 KC, 600KC. and 550 KC.

8 tube—Series A1	11 Tube—Series A2
9 tube—Series A5	13 Tube—Series A3

Telephone Dial Assembly

The telephone dial assembly provides a means of pre-setting a number of broadcasting stations and tuning in these stations at any time by depressing a button and rotating the dial to a stop position.

The apparatus is mounted on an assembly attached at the front of the chassis. An examination of this assembly will clearly show the method of operation.

Silencer Circuit—A silencer circuit is provided which results in silent tuning between stations when using the telephone dial buttons.

When a telephone dial button is depressed, a circuit is established between the ungrounded end of the volume control and the chassis ground. Referring to Fig. 1 it will be noted that contact is made between the line from the volume control, contact ring, contact washer arm (when button is depressed), spring and pulley ring stud. Since the pulley ring is at ground potential, this grounds the audio voltage and no signal will be heard until the button is released to break the contact.

It should be noted that the contact ring is part of the pulley ring assembly, but is insulated from it.

In the case of powerful local stations a slight amount of signal may be heard when the button is depressed.

Telephone Dial Adjustments

Noise When Tuning in a Signal with a Telephone Dial Button

As explained in the article on "Silencer Circuit" no noise or signal should be heard when tuning in a signal with a telephone dial button until the button is released. If noise is heard while tuning in a signal with one of these buttons, it can be corrected as follows:

If Noise Occurs on All Buttons—This is probably due to a poor contact between the flat contact spring and the contact ring—See Fig. 1. Clean the flat contact spring and contact ring to insure a good electrical connection. Ordinary cleaning fluid may be used and will be effective in most cases in cleaning the surface without affecting the plating. If the contact is still not satisfactory, a piece of fine emery cloth may be used.

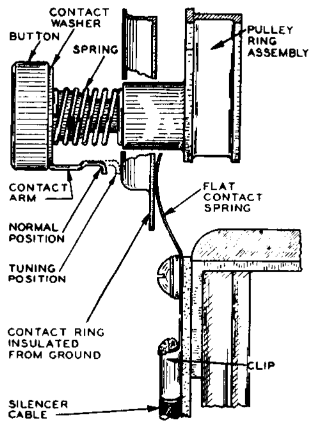

Fig. 1—Silencer Assembly

If Noise Occurs on One Button Only—This is due to a poor contact between the pulley ring stud, spring, contact washer, and contact ring—See Fig. 1. Clean all of these items of the particular button, in the same manner as mentioned previously, so as to provide a good electrical connection.

Telephone Dial Drive Cord Slipping

If the telephone dial drive cord slips on the tuning shaft pulley, this may be remedied by adjusting the drive cord tension pulley. Loosen the tension pulley bracket screw and adjust pulley assembly until the desired tension is obtained.

Position of Stop Pin

When the telephone dial assembly is on the chassis, the gang condenser rotor should not completely open or close. The travel of the rotor in this respect is controlled by the gang stop pin on the pulley ring—See Fig. 4. This is necessary to protect the gang condenser in case the telephone dial is swung rapidly to either of the extreme positions. When the gang stop pin is properly set, it will serve as the stop at both extreme positions. If the rotor is seen to open completely or close completely, the stop pin should be pulled back and re-set to overcome this condition.

Greasing and Oiling

After a period of time, put some light grease on the pulley ring shaft and on the teeth of the pulley ring. Use light oil on the drive shaft assembly bearing, care being taken not to get any on the drive cord.

Telephone Dial Replacements

Replacing Complete Dial and Condenser Assembly

Remove the grid lead clip from tube grid cap.

Remove silencer cable from the contact spring assembly. Unsolder dial lamp lead from terminal of tube socket.

Unsolder the three stator section connections of the gang condenser. Unsolder the three braided shield leads which ground the gang condenser frame to the chassis, taking care not to loosen the connections of any other units which are grounded at these common points.

At the back of the gang condenser is a stud which secures the assembly to an "L" bracket which is secured to the chassis.

Through this stud is a cotter pin. Remove only the cotter pin, metal washer, and rubber washer.

Viewing the assembly from the back, on the left is a brass bolt which holds the dial support bracket to the chassis—remove this bolt from underneath the chassis.

Grasp the dial support brace and move entire assembly toward the front of the chassis. When the support casting rubber cushions slip clear of the slot in front of chassis, lift entire assembly clear of chassis.

To replace this assembly, reverse the procedure as given above.

Replacing Pulley and Button Ring Assembly Only

Remove drive cord.

From underneath the chassis, unsolder the dial lamp lead from prong of the tube socket. Pull this lead through and out to the front of the assembly.

Remove the four escutcheon screws which hold the escutcheon ring and glass crystal in place. The dial scale pointer is removed by unhooking it from the center stud. Unscrew and remove center stud, washers, and dial scale. Slide pulley ring assembly off the center shaft.

On the No. 10 dial, two strips of celluloid between the escutcheon ring and the glass crystal will have to be removed.

To replace the pulley ring assembly, proceed as follows: Lay the assembly face down and adjust the stop pin. The stop pin (Fig. 2) is directly in

WELLS GARDNER & CO.
MODELS A1 SERIES, A2 SERIES, A3 SERIES, A4 SERIES, A5 SERIES & A7 SERIES

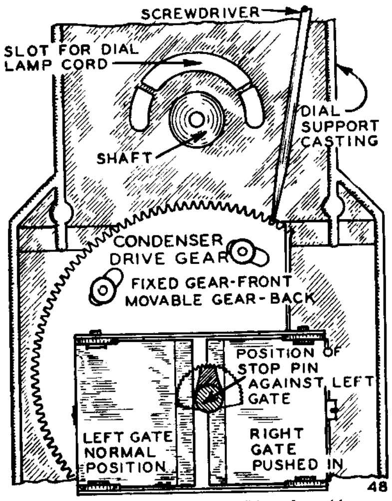

Fig. 2—Replacing Pulley Ring Assembly

back of the wide spacer on the dial button ring. Pull this pin back and adjust it to the center position —See Fig. 2.

Rotate tuning condenser rotor counter-clockwise (from front) as far as possible—See. Fig. 2.

Place the pulley ring assembly on the shaft with the knot of the dial lamp lead at the top—do not engage the gears.

Pull the dial lamp lead through the slot in the pulley ring gear and through the long slot in the dial support casting. Then place this lead through the clip under the dial support brace and out through the opening in the back of this brace.

With the gears still disengaged, rotate the pulley ring clockwise (from front) ½ revolution until the stop pin passes over the right gate and comes to rest against the left gate—See Fig. 2.

With the condenser rotor fully closed, push the pulley ring on the shaft until the pulley ring gear engages the *fixed gear only* (front) of the condenser drive gear assembly. Hold the pulley ring assembly and with a fine blade screw driver, move the movable (back) gear clockwise one tooth relative to the fixed gear—See Fig. 2. Then push the pulley ring all of the way on, engaging the movable gear.

Now lay the chassis on its back. Replace in the order given the large washer with rectangular hole, dial scale, washers, center stud, dial pointer, glass crystal, and escutcheon. Resolder the lamp lead.

For the No. 10 dial, before putting the escutcheon on, lay the two celluloid strips on the glass crystal with the inside flange facing away from the glass. Then lay the escutcheon on top of the celluloid strips. The section not cut out for station call letters should be at the wide spacer in the button spacer ring. Center the small holes in the celluloid discs in the station call letter openings and then tighten the escutcheon screws.

The stop pin must now be adjusted, as explained in article "Position of Stop Pin," until the condenser does not open or close fully. Injury to the condenser will result if allowed to open or close fully.

Replace the drive cord as explained in the article "Replacing Drive Cord."

Replacing Gates

After a great amount of use, one or both of the stop gates may wear, making it necessary to replace the stop gate assembly. This is done by first removing the pulley ring assembly as explained in

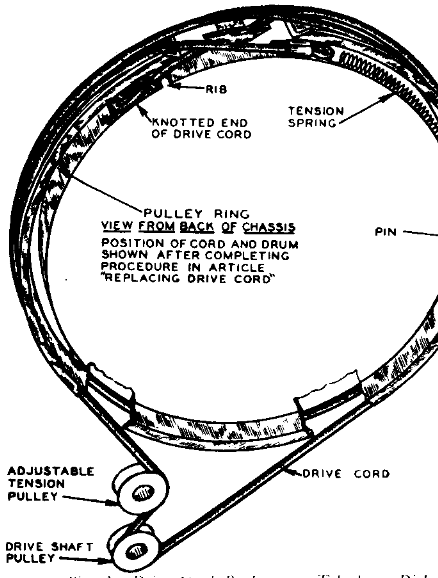

Fig. 3—Drive Cord Replacement-Telephone Dial

the article "Replacing Pulley and Button Ring Assembly."

The stop gate assembly is then removed by taking out the two screws at the bottom of the assembly.

Replacing Drive Cord

Remove the old drive cord and tension spring Rotate telephone dial clockwise (from back of chassis) as far as it will go.

Viewing the pulley ring drum from above and to the back, place the knotted end of the drive cord in the slot provided for it, catching the knot in back of the rib as shown in Fig. 3.

Bring the cord down and around the right side (from back) of the drum at front part of groove in pulley ring drum and under the drive shaft pulley making one-half turn on this pulley. Then bring the cord around the right side (from back) of the adjustable tension pulley and up to the upper left side of the pulley ring drum in front of the cord already on.

Hold the cord in the left hand and rotate the dial counter-clockwise with the right hand. Feed the cord on the drum in such a way that after passing the two openings at the top of the pulley ring drum, it passes to the back of the groove in the drum. After the pulley ring drum makes one complete revolution, place the cord through the left drum opening into the slot and secure the tension spring hook over the pin provided for it—See Fig. 3.

Replacing a Telephone Dial Button or Button Shaft

A telephone dial button or button shaft may be replaced without removing the chassis from the cabinet.

Rotate the dial until the button shaft to be replaced is in the position shown in Fig. 4. Using a wooden wedge block or any other wedge, hold this button shaft in place as shown. Remove the clear celluloid disc and the call letter disc with the point of a pin from the button of the shaft to be replaced (No. 10 dial—brown opaque celluloid disc only).

Remove the hairpin spring from the front of this shaft, spreading it with an ice pick or screwdriver. Take off the button, metal washer, molded bushing, and spring. Take out the wedge block, remove the button shaft to be replaced from the back of the dial assembly and put in the new one. Then put

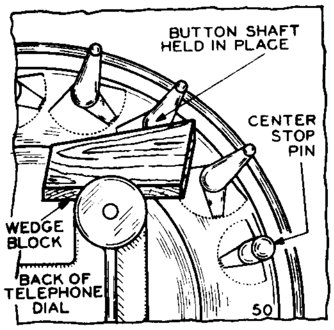

Fig. 4—Holding a Push Button Shaft in Place

the wedge block back in place again as illustrated.

Lay the cabinet back down against a chair so that it will be about 30 degrees from the vertical position.

Assemble the spring, molded bushing, metal washer, and button in the order shown in Fig. 5. (Last three items may be in one unit). Push the button and spring assembly over the button shaft with the tab of the metal washer in the normal

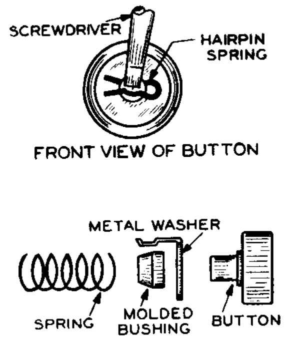

Fig. 5 Putting a Hair Spring on a Push Button Shaft

position—See illustration in instruction book. Hold the tab and rotate the button until the flat in the shank coincides with the flat on the shaft. Push the button all of the way on.

Put the hairpin spring in place, as shown in Fig. 5, with the upper part of the slot near the end of the button shaft and the lower part over the end of the shaft. Place the blade of a screwdriver at the center of the lower part of the spring and push down until the spring snaps into place in the slot on the shaft. Remove the wedge block.

Phantom Light Dial - Replacing Drive Cord

Remove the dial assembly as follows: Take out the screw which secures the dial frame brace to the back of the gang condenser. Take out the two screws which secure the brackets on the bottom of the dial frame to the chassis. Lay the dial assembly face down in front of the chassis—it is not necessary to remove the volume control and tone control indicator cords.

Remove the phantom light assembly from the

WELLS GARDNER & CO.

MODELS A1 SERIES, A2 SERIES, A3 SERIES, A4 SERIES, A5 SERIES & A7 SERIES

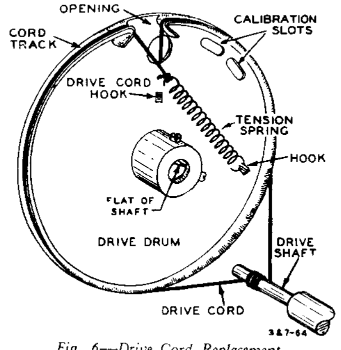

Fig. 6—Drive Cord Replacement. Phantom Light Dial

drive drum by taking out the screw.

Take off the old cord and tension spring. Tie a knot with a small loop in it in one end of the new cord. Then tie the other end of this cord to the hook on the tension spring. The distance from the loop on one end to the tension spring is 17¾ inches.

From the front of the chassis, place the looped end of the cord through the drum hole located near the cord track opening, and hook it over the hook provided for it at the back of the drum.

Bring the cord up and around the right side of the drum, keeping the cord in the grooved track of the drum.

Bring the cord down to the right side of the drive shaft and wind it three and one-third times around this shaft progressing toward the back.

Then bring the cord up and around the left side of the drive drum. Hook the tension spring on the hook of the drive drum.

Replace the phantom light and the dial assembly.

Phantom Light Dial Replacement Parts

See article "Identification of Dial and Chassis" in order to determine the correct dial and chassis assembly number.

The No. 3 Dial is used on the Series A1, A4, and A5 chassis. The No. 7 Dial is used on the Series A1 and A4 chassis only. The following parts are common to both groups unless otherwise specified.

Tuning Frequency Range
B Range .... 528 to 1730 KC
D Range .... 5650 to 16000 KC

Sensitivity
B Range .... 4 Microvolts Absolute
D Range .... 6 Microvolts Absolute

Circuit

This radio is designed to operate from a power supply source of 32 volts DC. With the exception of the type 43 tube, which has a 25 volt heater, all of the tubes are of the 6 volt type. The heaters of these tubes and the dial lamps are connected across the 32 volt line in a series-parallel arrangement as shown in Figs. 2 and 7. The speaker field winding is also across the line. Plate and screen voltages are obtained directly from the 32 volt line. In working on the set, certain precautions, as explained below and in one of the following articles must be observed.

The chassis base is connected to one side of the line as shown in Fig. 2. Either side of a 32 volt line may be grounded. For that reason the external ground lead is connected to the chassis base through a .02 mf. condenser. Contacts between the antenna or external ground lead and the chassis base must be avoided as the side of the line not connected to the chassis base may be grounded and a line short circuit would result.

Two bands are covered with a tuning range in each band as shown in the specifications above. Two band coverage is accomplished by means of two sets of R.F. and oscillator coils and a single section double throw switch.

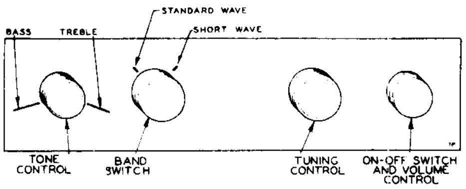

Fig. 1—Arrangement of Controls

Referring to the schematic circuit diagram, Fig. 2, T1 and T2 are the antenna and interstage R.F. transformer assemblies and T3 is the oscillator coil assembly. The standard wave and short wave coils are indicated by the letters B and D respectively.

The band switch completes connections to the coils in use. It also short circuits the interstage R.F. transformer B Range primary and oscillator B Range grid coil when it is in the D Range position.

The antenna transformer with tuned secondary feeds into a type 6K7 R.F. amplifier tube. The output of this tube is fed through the interstage R.F. transformer with tuned secondary into the control grid circuit of a 6A8 pentagrid converter tube which functions as the oscillator and 1st detector.

The oscillator potential on the oscillator control grid of this tube modulates the electron stream from the cathode in such a manner as to impress on it the oscillator frequency which is always 456 KC above the frequency to which the R.F. amplifier is tuned. The electron stream is also modulated at the signal frequency by the detector control grid. As a result of the beating of the two frequencies, the intermediate or beat frequency of 456 KC is present in the plate circuit of this tube.

Two stages of I.F. amplification are employed using 6K7 tubes. The primaries and secondaries of the first and second I.F. transformers and the primary of the 3rd I.F. transformer are tuned by small trimmer condensers.

A type 85 duo-diode triode tube functions as the second detector and a one stage audio amplifier. AVC voltage is applied through isolating resistors to the control grid circuits of the R.F. and I.F. tubes. The audio voltage developed across volume control resistor R10 is applied through the movable arm to the control grid of the 85 tube.

Resistance coupling is used between the 1st audio stage and the driver stage which employs a 43 tube. The latter is transformer coupled to the output stage which uses a 6A6 tube. This tube combines 2 triodes in one envelope. Push-pull amplification is used. A dynamic reproducer is employed.

Alignment and Calibration

Alignment Procedure

Correct alignment is extremely important in connection with standard and short wave radios. The receivers are all properly aligned at the factory with precision instruments and re-alignment should not be attempted unless all other possible causes of the faulty operation have first been investigated and unless the service technician has the proper equipment.

A signal generator that will provide an accurately calibrated signal at 456, 1730, 1500, 600, 16,000, 15,000 and 6000 KC and an output indicating meter are required. It will be practically impossible to align the radio if unsatisfactory apparatus is used.

Use a non-metallic screwdriver for the adjustments. The complete procedure is as follows:

I. F. Adjustment

Set the signal generator for a signal of 456 KC.

Connect the output of the signal generator through a .1 mf. condenser to the grid of the 1st detector (G_4).

Connect the ground lead of the radio to the ground post of the signal generator.

Turn the band switch to the Range B position (standard wave band).

Turn the volume control to the maximum position.

Attenuate the signal from the signal generator to prevent the levelling-off action of the AVC.

Then adjust the five I.F. trimmers until maximum output is obtained. The adjusting screws for these condensers are reached from the top of the chassis, and the location is shown in Fig. 3.

Range B Alignment

After the procedure for the alignment of each range, as explained below, is completed, it is advisable to repeat the procedure as a final check.

1730 KC Adjustment

Set the signal generator for 1730 KC.

Turn the rotor of the tuning condenser to the full open position.

Keep the band switch in the standard wave position.

Connect the antenna lead of the radio through a 200 mmf. condenser to the output of the signal generator.

For this and all subsequent adjustments keep the volume control at the maximum position and attenuate the signal from the signal generator to prevent AVC action.

Adjust the oscillator Range B trimmer (C32) until maximum output is obtained. The location of this trimmer is shown in Fig. 3.

1500 KC Adjustment

Set the signal generator for 1500 KC.

Turn the rotor of the tuning condenser carefully until maximum output is obtained.

Loosen the pointer screw and set the pointer at the 1500 KC mark on the standard wave band scale. Retighten the screw.

Adjust the interstage Range B trimmer (C10) and antenna Range B trimmer (C2) to maximum.

Do not change the setting of the oscillator Range B trimmer.

600 KC Adjustment

Set the signal generator for 600 KC.

Turn the tuning condenser rotor until maximum output is obtained.

Turn the rotor slowly back and forth at the same time adjusting the 600 KC trimmer (C30) until the peak of greatest intensity is obtained. See Fig. 3 for location of this trimmer.

Range D Alignment

CAUTION—When aligning the short wave band be sure NOT to adjust at the image frequency. This can be checked as follows: Let us say the signal generator is set for 15,000 KC. The signal will then be heard at 15,000 on the dial of the radio. The image signal, which is much weaker, will be heard at 15,000 less 912 KC, or 14,088 KC. It may be necessary to increase the input signal to hear the image.

16,000 KC Adjustment

Set the signal generator for 16,000 KC.

Connect the antenna lead of the radio through a 400 ohm resistor to the output of the signal generator.

Turn the rotor of the tuning condenser to the full open position.

Turn the band switch to the Range D position (short wave band).

Adjust the oscillator Range D trimmer (C31) until maximum output is obtained. See Fig. 3 for location of this trimmer

15,000 KC Adjustment

Set the signal generator for 15,000 KC.

Turn the rotor of the tuning condenser carefully until maximum output is obtained.

Adjust the interstage Range D trimmer (C9) and antenna Range D trimmer (C1) to maximum. When adjusting these trimmers, it will be necessary at the same time to turn the tuning condenser rotor slowly back and forth until the peak of greatest intensity is obtained.

Do not change the setting of the oscillator Range D trimmer.

6000 KC Adjustment

Set the signal generator for 6000 KC.

Turn the tuning condenser rotor until maximum output is obtained.

Turn the rotor slowly back and forth at the same

(Continued on next page)

WELLS GARDNER & CO.

MODEL 7P SERIES

(Continued from preceding page)

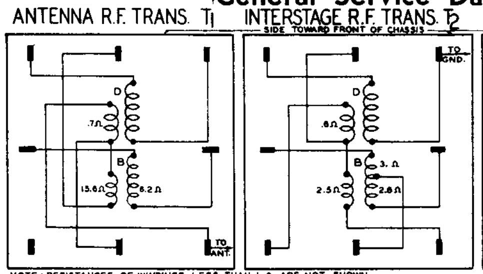
time adjusting the 6000 KC (C28) trimmer until the peak of greatest intensity is obtained. See Fig. 3 for location of this trimmer.

Polarity of Power Supply

There is a red mark on the plug at the end of the power supply cord of the radio. The prong of the plug at which the red mark is placed must be plugged into the positive side of the line.

Use a receptacle on the 32 volt line from which the plug will not have to be removed after it has once been inserted correctly.

General Service Data



NOTE: RESISTANCES OF WINDINGS LESS THAN .1 Ω ARE NOT SHOWN.

Fig. 4—R.F. and Oscillator Coil Base Terminal Arrangement and D.C. Resistance of Windings

CAUTION–Read the Following

To avoid the danger of damage to the radio and accidental short circuit, the following facts should be understood.

The metal chassis is connected to one side of the line—See Fig. 2. 32 volt lines are generally grounded on one side — either side may be used. If the side of the line, not connected to the metal chassis, is grounded and the metal chassis comes in contact with the external ground, the line will be short circuited and an excessive current may result.

In any service work, therefore, on this chassis keep it on a wood or other insulated surface. Disconnect the antenna and ground leads to avoid the possibility of any external ground contacts with the chassis. The person working on the set should avoid coming in contact with any ground.

Eliminating Ignition and Generator Noise

After the radio is in working order, the following procedure must be followed in practically all cases to eliminate ignition and generator noise caused by the charging plant. If the charging plant causes no noise, then of course, these steps do not have to be taken.

One spark plug suppressor must be placed on each spark plug of the engine. One spark plug for example would be required on a one-cylinder engine and four must be used on a four-cylinder engine. To connect the spark plug suppressor, remove the wire from the top of the plug, put the suppressor on and attach the wire to the other end of the suppressor.

A generator condenser must be used. This consists of two .5 mf. sections in one unit. The two sections have one side grounded to the metal case of the condenser. Mount the condenser on the frame of the charging plant. This will ground it. Then connect the two leads to the charging switch, one on each side of the line.

In some large installations, where the charging unit is on only two or three times a week, the above steps do not have to be taken as interference is caused only when the generating plant is in operation.

Noisy Operation

Noisy operation may be due to a faulty antenna system. The action of the automatic volume control, due to the low pickup, causes the radio to operate at its maximum sensitivity, thereby increasing noisy reception due both to external pickup and internal conditions.

The radio may be partially detuned, causing it to operate at maximum sensitivity. The signal should be very carefully tuned in until it is clearest and strongest.

If the reception is noisy only when the generating plant is in operation, then the noise is due to the latter and several things can be done. There may be loose parts in the generator plant rubbing together. Tighten up all parts and be sure that all parts of the

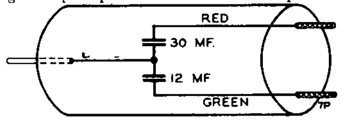


Fig. 5—Electrolytic Condenser Internal Connections

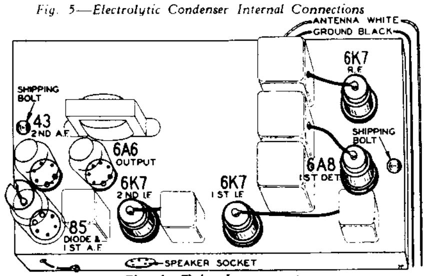

Fig. 6—Tube Arrangement

engine are well grounded. Dirty spark plugs may cause noise. Clean and respace the plugs or try out a new set. In some instances it may be necessary to filter the power supply line to the radio.

If any motor driven devices, such as pumps, are operated from the 32 volt line, the motor may cause noisy reception in the radio. This can be corrected in most cases by connecting one of the dual .5 mf. condensers mentioned above across the line at the motor. The common connection to the two condensers which is grounded to the can is grounded externally by mounting the unit on the motor frame.

Trimmer Replacement

If one trimmer of the gang trimmer strip should become defective, it is not necessary to replace the entire strip. A single trimmer P-17A36, as shown in the replacement parts list, may be used. Disconnect the lead from the coil side (side not grounded) of the defective trimmer in the strip. This connection is then made to the single trimmer. Connect it to the side of the trimmer not in contact with the adjusting screw. The other side of the single trimmer is then connected to a good ground, using a piece of heavy wire in order to support the trimmer adequately.

There are two trimmers in the strip that are not grounded (2nd and 4th from front of chassis). When replacing either of these trimmers, the side of the replacement trimmer connected to the adjusting screw should be connected to the same terminal as the corresponding side of the defective trimmer after this trimmer has been cut out of the circuit.

In replacing a trimmer, be sure to keep both leads as short as possible and keep the ungrounded lead as far from ground as possible.

Dial Lamps

For the dial lamps, No. 51 bayonet pin base lamps must be used. These lamps are part of one section of the tube heater circuit (See Fig. 7) and any other lamps having a different current drain would upset the voltage system of this section.

Voltages

Check the voltages at the sockets to see if correct values are being delivered to the tubes. The antenna and ground should be disconnected and the antenna and ground leads from the radio connected together. The volume control should be turned to the right or maximum position.

All of the voltage readings as shown in the chart are read with a 1,000 ohm-per-volt meter. As high a range as possible should be used. In general, the higher the resistance of the meter, the more accurate the reading will be.

The voltage chart gives the voltages with all tubes in, the speaker connected and the set in operating condition. These voltages are typical of the sets but will vary slightly with variations in individual radios tubes, test equipment used and line voltage.

Switch Contact Location Numbering

A standard arrangement for switch contact location numbering has been adopted. This numbering is illustrated in Fig. 2. In contact locations not used, the number applying to that particular location is not employed.

Parts

NOTICE—There is a large letter on the chassis which identifies the set as to major part changes. When ordering parts, please be sure to mention the series number and this large letter.

LINE-UP CAPACITOR ADJUSTMENTS

To properly align the circuits of the receiver it is essential to use a high grade modulated test oscillator, the output of which can be continuously varied when the individual circuits are brought into alignment. A conventional output meter can be connected across the terminals of the speaker voice coil to indicate when the circuits are aligned. The sensitivity of the output meter must be sufficient to give satisfactory reading with a low input signal. It is also necessary to use an 0-5 microammeter in order to align the discriminator circuits.

Before attempting to align the receiver, the service man should familiarize himself with the general layout of the chassis, the location of the tubes and various alignment condensers. Top and bottom views of the chassis are shown in Figures #1 and #2 and should be carefully studied before the actual work is started.

ADJUSTMENT OF I.F., CONTROL OSCILLATOR AND DISCRIMINATOR

1. Set the volume control on full and turn the bass control to the bass position (position immediately after set is turned .
2. Connect the output meter across the voice coil of the speaker.
3. Set the test oscillator to 100 KC., and adjust the output to give a readable deflection on the output meter when the signal is applied to the grid of the 6K7 I.F. amplifier tube through a 0.5 mfd. blocking condensor.
4. Connect a 10,000 ohm resistor across the primary winding of the third I.F. coil #62. This should be connected to terminals marked "A" and "B" in Figure #2.
5. Adjust trimmer #64 to maximum output, reducing the output of the test oscillator as required.
6. Remove the 10,000 ohm resistor from the primary side of I.F. coil #62 and connect across the secondary winding from terminals marked "C" and "D".
7. Adjust trimmer #63 to maximum output, reducing the output of the test oscillator as required. Remove 10,000 ohm resistor.
8. Turn switch #98 to the left-hand position (viewed from rear of chassis).
9. Set the output of the test oscillator to a high level.
10. Connect a 0 to 5 microammeter across resistor #149 and adjust trimmer condenser #111 to maximum swing of the microammeter, keeping the output of the signal generator set to a point which will give a deflection of approximately 5 microamperes when condenser #111 is tuned to maximum deflection. WHEN THE SIGNAL GENERATOR IS SET TO THIS OUTPUT, DO NOT ALTER THE OUTPUT OF THE SIGNAL GENERATOR UNTIL THE ALIGNMENT OF THE DISCRIMINATOR CIRCUIT IS COMPLETED.
11. Adjust trimmer #110 until the microammeter reading is reduced exactly to zero.
12. Turn switch #98 to the right-hand position and proceed with the alignment of the I.F.
13. Apply the test signal to the grid of the 6A8 oscillator-modulator tube.
14. Connect the 10,000 ohm resistor across the primary of I.F. coil #50 by connecting it to the terminals marked "E" and "F" in Figure #2.
15. Adjust trimmer #52 to maximum output, reducing the output of the test oscillator as required.
16. Remove the 10,000 ohm resistor and connect across the secondary of I.F. transformer #50. Connect to terminals marked "G" and "H".
17. Adjust trimmer #51 to maximum output, reducing the output of the test oscillator as required.
18. Remove the 10,000 ohm resistor.

19. Set the test oscillator to 465 KC., and adjust the control oscillator trimmer #92 to maximum output.
20. Apply the test signal to the grid of the type 6A8 oscillator-detector tube.
21. Connect the 10,000 ohm resistor across the primary of I.F. transformer #26 by connecting it to the points marked "J" and "K" in Figure #2.
22. Adjust trimmer #28 to maximum output, reducing the output of the test oscillator as required.
23. Remove the 10,000 ohm resistor and connect across the secondary of the I.F. transformer #26 by connecting it to the points marked "L" and "M" in Figures #1 and #2.
24. Adjust trimmer #27 to maximum output, reducing the output of the test oscillator as required. Remove the 10,000 ohm resistor.

ADJUSTMENT OF BROADCAST BAND

1. Set the wave-change switch to the White or Broadcast Band position.

2. Set the test oscillator and dial indicator to 1600 KC.

3. Apply the test signal to the antenna terminal of the chassis through a .0002 mfd. series condenser and adjust the oscillator trimmer condenser #30 until the signal is received at a maximum.

4. Adjust trimmers #17 and #5 to maximum output.

5. Set the test oscillator and dial indicator to 570 KC., and adjust the oscillator series condenser #31 to maximum output, at the same time rocking the condenser gang.

6. Return both the test oscillator and dial indicator to 1600 KC., and check the adjustment of trimmers #30, #17 and #5 for accuracy.

ADJUSTMENT OF GREEN BAND

NOTE: In adjusting the two short-wave bands (Green and Red) a .0002 mfd. condenser and a 400 ohm resistor connected in series should be inserted in the high side of the test oscillator leads. This combination of condenser-resistor combination is the approximate equivalent of a short-wave antenna.

1. Set the wave-change switch to the Green Band position.
2. Set the test oscillator and dial indicator to 5500 KC., and adjust the oscillator trimmer condenser #39 until the signal is received at a maximum.

3. Adjust trimmer condensers #22 and #10 to maximum output.

4. Set the test oscillator and dial indicator to 1900 KC., and adjust the oscillator series condenser #40 to maximum output, at the same time rocking the condenser gang.

5. Return both the test oscillator and dial indicator to 5500 KC., and check the adjustment of trimmers #39, #22 and #10 for accuracy.

ADJUSTMENT OF RED BAND

1. Set the wave-change switch to the Red Band position.

2. Set the test oscillator and dial indicator to 17000 KC., and adjust the oscillator trimmer condenser #35 until the signal is received.

NOTE: When adjusting the oscillator trimmer condenser #35 it will be possible to secure two peaks. The peak secured with the trimmer screw turned farthest out should be used. When aligned on the correct peak a strong signal will be heard at 17000 KC., and a weaker signal at approximately 16000 KC. No signal should be heard at 18000 KC.

3. Adjust trimmer condensers #20 and #7 to maximum output.

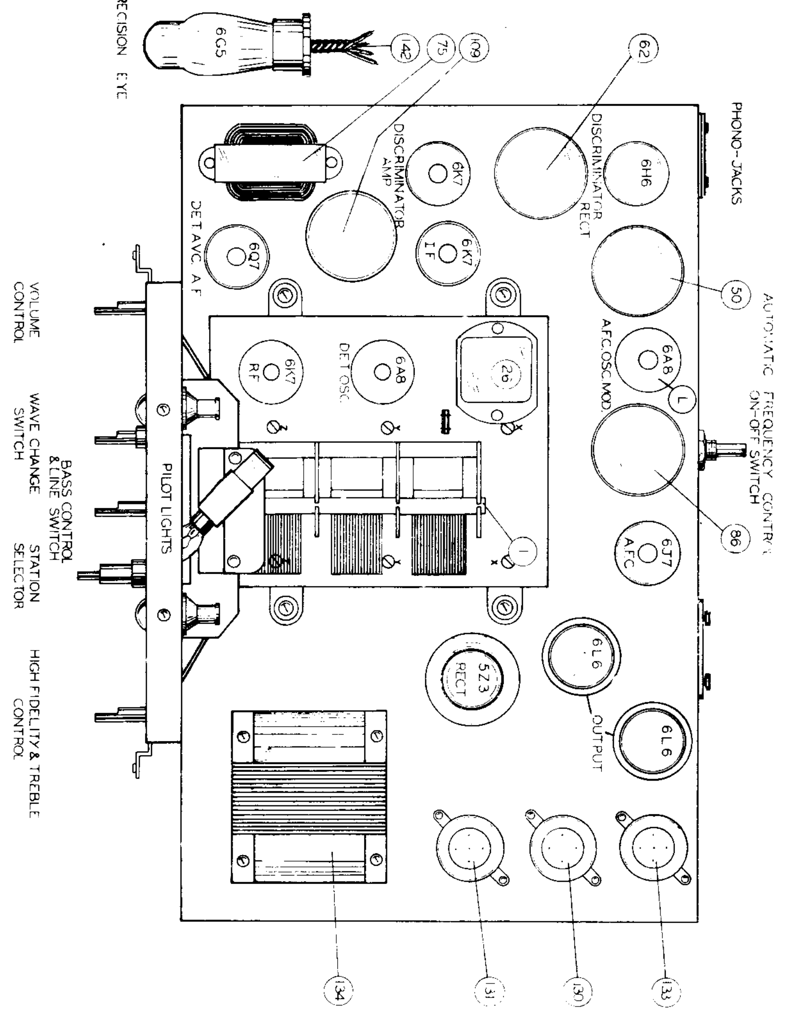

Figure No. 1

WESTINGHOUSE ELECTRIC SUPPLY COMPANY

MODEL WR-315

4. Set the test oscillator and dial indicator to 6000 KC., and adjust the oscillator series condenser #36 to maximum output, at the same time rocking the condenser gang.

5. Return both the test oscillator and dial indicator to 17000 KC., and check adjustment of trimmers #35, #20 and #7 for accuracy.

IMPORTANT: While testing or making pairs on this receiver, the chassis should not be turned upside down or on its side for any long period of time while the set is turned on as the chemicals in the electrolytic filter condensers will come through the air vents, making the condenser appear to be defective. If left in this position too long the condenser may be injured.

BOTTOM VIEW OF SOCKET

Voltage at Battery 6V.
Voltage at Receiver 5.9 V.
Antenna disconnected
All voltages measured with 1000 ohms per volt D. C. meter
Total current consumption 5.5 amperes
Sensitivity at 1 watt out put 5 M. V.
Maximum power output 3.2 watts.

IMPORTANT ANTENNA INFORMATION

Some cars are factory equipped with an antenna. If this is the case, the lead should be checked to make certain that it is not grounded, and after being shielded by a large diameter loom, ground this loom to the instrument panel, and attach the Delco-Remy male connector to the end of the antenna wire. This should be done carefully so as to insure a good solder joint, and prevent any grounding at this point to the braided shielding. Insert the antenna lead-in connector into the female Delco-Remy receptacle directly below the tuning cable shoulder on the receiver case.

Where a car is not equipped with an antenna, such as convertible models, or those with all steel turret top, any one of the following Zenith antennas may be used:

Undercar antenna—part No. S-4800 and S-4801.
Over the Top Antenna (Sedan) S-4802.
Over the Top Antenna (Coupe) S-4803.
Zenith Fleet Wing Antenna S-4821.
Zenith Bumper Pole Antenna S-4822.

Complete instructions covering the installation of each of the above antennas is furnished with the various kits.

IMPORTANT: BALANCING SET TO ANTENNA. There is such an extremely wide variation in antenna capacities that it is difficult to match this condition without some means of variable antenna alignment. To accomplish this, an antenna compensating adjustment is provided through the small hole directly above the antenna cable connector on the receiver case. In addition to this, a tapped antenna transformer is also incorporated (see Figure No. 2). The proper method of alignment is as follows: After completely connecting receiver, tune in a signal between 1400 and 1450 K.C. and adjust the antenna compensator shown in Figure 3, for either the roof antenna, or single or double under-car antenna. The receiver is shipped from the factory with the antenna tap shown in Figure 2 set to the No. 2 position, and, therefore, need not be changed for either of the two types of antennas mentioned.

For Zenith Fleet Wing, and Over the Top Antennas, unsolder the antenna lead from the No. 2 lug, and resolder it to the No. 3 lug. After this is done, tune in a station between 1450 and 1400 K.C., and adjust the antenna compensator shown in Figure 3 to resonance.

For high capacity antennas such as the 1936 Dodge solid steel roof, or the Lincoln Zephyr luggage compartment, drawer antenna, etc., remove the antenna lead from the No. 2 lug, as it comes from the factory, and resolder it to the No. 1 connector. After this is done, the same procedure of tuning in a signal from 1450 to 1400 K.C., and balancing to resonance with the antenna compensator, as described above, should be followed.

This system of tapped transformer, and variable compensating adjustment gives an extremely flexible means of resonating the receiver to any type of antenna, and it should be noted that the tap need only be changed in two cases. Of course, it is necessary to remove the bottom cover in order to shift the antenna tap where necessary.

MODEL 855

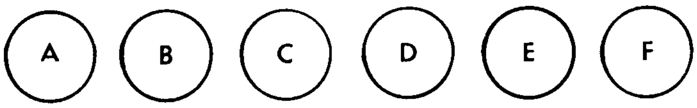
INSTRUCTIONS FOR ADJUSTING THE AUTOMATIC SELECTOR UNITS

The Automatic Station Selector mechanism incorporated in this receiver has been designed to provide a compact, rugged and efficient unit, which will stand up under the severest use without drift or deviation. Its operation and adjustment is so simple that even the layman can make the necessary adjustments in setting up the device without the use of tools or special equipment. By rigidly adhering to the following instructions, any difficulty in aligning the unit will be obviated.

It is first necessary to determine the stations which are to be controlled by the Automatic Selector mechanism. The six stations which comprise the principal source of entertainment should be chosen. These must be local stations that can be depended upon to provide good reception at all times. Arrange them in the sequence of their frequency assignment. This may be determined by consulting a newspaper or station log. Designate each of the stations selected by the alphabetical series of letters from "A" to "F", inclusive. That station with the highest frequency assignment (nearest the 1500 K.C. end of the broadcast band) should bear designation "A". "B" in the series would be applied to the station of the next highest frequency. This arrangement is followed through the series of letters and terminates with the assignment of the letter "F" to the station of lowest frequency allocation (nearest the 550 K.C. end of the band). The purpose of this series of alphabetical designations is to coordinate the selected stations with the proper adjustment screws, as indicated on the index strip which is mounted on the back of the selector unit. Examination of the index strip will disclose that there are two adjustments for each letter or station; one, is the Oscillator adjustment, and the other the Antenna adjustment. For example, 'A' osc, 'A' ant; 'B' osc, 'B' ant, etc.

It is essential that the frequency of each of the selected stations should fall within the range of frequencies encompassed by the button unit which is being assigned to any particular station. Listed below are the frequency limits of each button position.



POSITION	FREQUENCY RANGE
A	1520 KC to 830 KC
B	1520 KC to 830 KC
C	1250 KC to 740 KC
D	1220 KC to 670 KC
E	970 KC to 580 KC
F	770 KC to 540 KC

Switch the set on by rotating the volume control knob to the right. Rotate the band switch to the intermediate or broadcast position as indicated on the front card, and carefully tune in the station which has been selected for position "A". Note the program emanating from that station. This will provide a simple method of identifying the station while adjusting the selector unit. Rotate the band switch to the left, which is indicated on the front card as the Automatic position. Depress the extreme left hand selector button on the front panel. This is the control for station "A". With a small screw driver adjust the setting marked "A" Osc. until the desired program is heard. Now carefully adjust the screw which is marked "A" Ant. for complete resonance. It is desirable to repeat these adjustments to insure accuracy. Next rotate the band switch to the broadcast position again. Then tune in the station which has been selected for position "B". Observe the nature of its program and rotate band switch to the Automatic position. Depress control button "B", which is the second from the left. Adjust the screws marked "B" Osc. and "B" Ant. in the same manner as was previously done for position "A". The same procedure is followed for each of the other four stations selected. In making the various adjustments keep the volume control turned to the minimum volume necessary for audibility. This will enable more accurate adjustment to be secured. For extreme accuracy in adjustment, a very short antenna should be employed. After the adjustments have been made, the antenna with which the set is to be used may be permanently connected. It is suggested that these adjustments be checked about a week after the original settings are made. No corrections will be necessary thereafter unless it is desired to alter the station selections. The permanent designation of the selected stations can be made through the use of the accompanying station call letter card. Detach the call letters of the stations selected and paste them in the depressions of the appropriate buttons.

ALIGNMENT PROCEDURE

The following instructions are for the sole use of professional radio service men in the event that the receiver should require serviceing.

I. F. Alignment. The intermediate frequency to which this set should be adjusted is 456 K.C. To align the intermediate frequency transformers properly, a signal generator emitting a signal of 456 K.C. should be coupled to the signal control grid of the 6A7 tube through a .5 mmfd condenser. An output meter should be connected across the voice coil of the speaker. The four trimmers mounted internally in the top of the two I. F. cans should be adjusted to resonance. The output of the signal generator should be attentuated so as to provide the weakest possible signal necessary to produce a .5 volt deflection on the output meter.

R. F. Alignment. Adjust the signal generator to 17.4 MC. Feed this signal into the antenna lead of the receiver through a 400 ohm resistor. Rotate the band switch on the receiver to the Short Wave position and set the tuning dial to 17.4 on the Short Wave Scale. Adjust the trimmer on the rear section for maximum signal output. Rotate the Band Switch to the broadcast position. Replace the 400 ohm resistor in the Oscillator lead with a 200 mmfd condenser. Set the signal generator to 1560 K.C. and tune the receiver to the same frequency. Adjust the small trimmer condenser which is located near the Oscillator coil underneath the Chassis, to maximum signal response. Attentuate the output of the signal generator to the extent necessary for maintaining a deflection of .5 volts on the output meter and adjust the trimmer mounted on the front section of the variable condenser to resonance. Set the signal generator and the receiver at 600 K.C. and adjust the padder condenser for optimum response. Repeat the last two adjustments to insure accuracy of alignment. Rotate the Band Switch to the Short Wave position and with the signal generator and receiver tuned to 15 MC, adjust the small trimmer condenser which is located near the Short Wave Antenna coil. This last operation should be made with the 400 ohm resistor in the antenna circuit.

It is imperative that all adjustments be made with the minimum signal necessary to obtain the designated deflection on the output meter. This will obviate any difficulty arising from the A.V.C. action of the receiver, and will permit adjustment to absolute resonance.

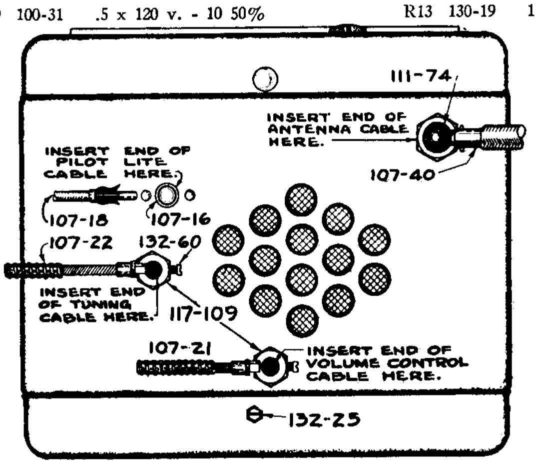

FIG. 1—SIDE VIEW

DIAL ADJUSTMENT

Tune set to some station of a known frequency (between 800 and 1200 K.C.), hold selector knob, then remove pilot light assembly from back of remote head and with a screw driver adjust the slotted screw through this opening and in this way adjust the dial pointer to the correct frequency setting.

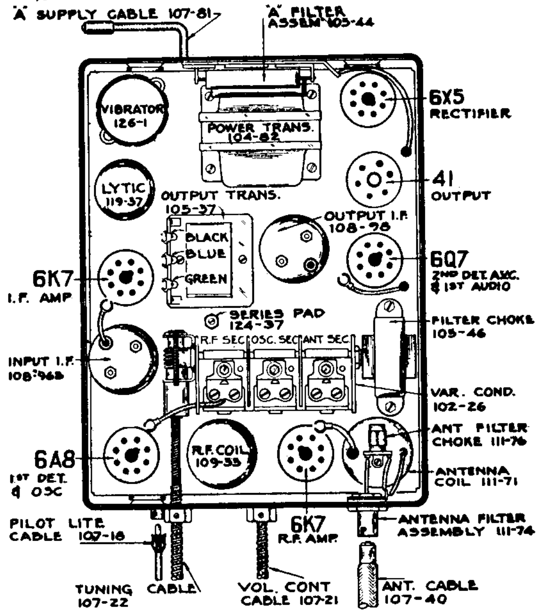

FIG. 2—TOP VIEW

MODEL 661 (SERIAL No W1000 UP)

TUBE COMPLEMENT

The tube complement of this chassis consists of the following octal base glass tubes which are interchangeable with metal tubes.

1—Type No. 6K7G—Remote Cut-off Pentode as an R.F. Amplifier
1—Type No. 6A8G—Pentagrid Converter (composite first detector and oscillator)
1—Type No. 6K7G—Remote Cut-off Pentode as an I.F. Amplifier (465 K. C.)
1—Type No. 6Q7G—Duplex Diode Triode Second Detector, A.V.C. and First Audio
1—Type No. 41—Pentode Output Amplifier
1—Type No. 6X5G—High Vacuum Rectifier.

MOTOR NOISE SUPPRESSION

The ignition system of every automobile generates high frequency electrical disturbances which interfere to some extent with the operation of the radio receiver. This disturbance arises from the ignition coil, the distributor and associated wiring. It must either be suppressed at its origin or must be prevented from feeding into the input of the radio receiver through the common storage battery. By proper shielding and by-passing these disturbances are prevented from entering the receiver.

DISTRIBUTOR SUPPRESSOR

The first essential procedure toward minimizing this disturbance is to disconnect the high tension lead to the distributor and insert a distributor suppressor, part number 168-2.

Note: For Ford V-8's, no distributor suppressor is used.

For cap type distributors, exchange standard type 168-2 for a special cable type suppressor, part 168-3, from your dealer.

IGNITION COILS

In cars where the ignition coil is located on the back side of the instrument panel it is often necessary to use an additional capacitor, part number 148-3, obtainable from your dealer. It must be installed from the battery side of the ignition coil to the closest ground on the instrument panel.

Short leads are very important. Where coils are mounted either on the instrument panel or in the driver's compartment, it may be necessary to shield the high tension lead from the coil to the distributor.

HIGH AND LOW TENSION WIRES

This can be done by covering the lead first with flexible loom and then with shielded braid, grounding one side of the braid to the instrument panel and the other to a point on the motor block closest to the distributor. This lead should be run as nearly as possible directly from the coil to the distributor, even if it is necessary to drill an extra hole in the fire wall. It may even be necessary in some stubborn cases to move the coil from the driver's compartment and mount it on the motor block as close as possible to the distributor. The new primary wire should be No. 14 shielded low tension cable. Do not run wires close to the high tension leads and make certain that shields are well grounded.

Make certain that the instrument panel has a ground connection to the frame of the car.

For Ford V-8's, it may be necessary to remove from the high tension housing attached to the left bank of 4 cylinders the master cable containing the generator wire (yellow wire with black tracer) and the red low tension wire connecting ignition coil to the ignition switch.

These two wires must be removed from high tension housing and shielded. Shielding must be grounded at both ends. A capacitor must be connected between the primary of the ignition coil and ground. Your dealer can supply a special type capacitor for this purpose.

BONDING

Cars with floating power must have the motor bonded to the bulkhead and again to the frame to provide a direct path for the high frequency interference developed in the ignition system. 5/8" copper braid will be necessary, SMALL DIAMETER WIRE WILL NOT DO. Bond flexible shaft leads, such as free wheeling, choke wires, etc., which pick up motor noise and reradiate it into the car. Free wheeling cables should be grounded at the point at which they go through the fire wall of the car. In extreme cases it has been found necessary to ground the steering column.

Great care of design has been given the Model No. 661 to minimize motor noise pick-up. Three sources of motor noise pick-up are antenna pick-up, "A" line pick-up, and chassis pick-up. Chassis pick-up is reduced to an absolute minimum by completely insulating the inner chassis from the outer case and grounded at carefully selected points to outer case so as to get minimum impedance drops induced by eddy currents around the R.F. end of the chassis. The "A" line pick-up was eliminated by a carefully designed low pass filter. Antenna pick-up was reduced to a minimum by removing all capacity coupling in the antenna stage.

A further precaution that was taken against motor noise is the insulated couplings used on the end of the volume control shaft and variable condenser shaft. This completely kills any motor noise loop that would have been caused by the grounding of the flexible control cables through Variable Condenser.

CHECK FOR MOTOR NOISE (Chassis Pickup)

After the above instructions have been followed, with the hood clamped down to prevent radiation and the motor running, the receiver should be turned on and the dial turned off a station, with volume control at maximum, and local distance switch in distance position. If motor noise is objectionable the next step is to determine whether the interference is originating through chassis pickup or from the antenna.

To check for chassis pickup, disconnect the antenna from the antenna cable and ground the antenna lead to shield of cable. Chassis pickup is due to the electrical interference being radiated or fed back through the frame of the car into the receiver or through the storage battery to the receiver.

It may be necessary when chassis pickup is present to ground the choke and gas throttle rods securely to the firewall at the point which they enter the drivers compartment.

DISTRIBUTOR ROTOR

Chassis pickup can be reduced by reducing the gap between contacts and the rotating arm in the distributor head. To do this, apply solder to the end of the rotor arm. Replace the rotor in the distributor and turn the engine over slowly with the crank in order to clean the excess solder. The rotor should not brush or wipe the contacts inside the distributor cap, but should just clear them. As an additional precaution check the breaker points. They should be thoroughly cleaned and adjusted or new points installed if they are badly worn. In stubborn cases a good grade mica .002 to .006 condenser connected across the breaker points will reduce interference.

HIGH AND LOW TENSION LEADS

The ignition system of a car must be kept in good condition and leaky cracked high tension wires and bad spark plugs should be replaced. In many cars the low tension battery leads, etc., are grouped together with the high tension wires. These leads will very often pick up motor noise and feed it into the receiver through the battery circuit. In cases such as these it will be necessary to separate the low tension from the high tension wires and run them through another hole if they run from the engine compartment up to the instrument panel. This condition, as explained previously, is particularly true on the V-8 Ford as the battery and primary leads run through a special tube which also houses the high tension leads. Shield and ground these leads.

IGNITION COILS

Where ignition coils are mounted in motor compartments a .5 mfd cond (148-1 or 148-3) connected between primary coil terminal and receiver mounting bolt will often reduce motor noise.

ELECTRICAL ACCESSORIES

Accessories such as lighters, electric motor heaters, horns, light switches, automatic relays, electrical gauges such as oil, water and gas are often a source of interference. In these cases the procedure is to try a condenser from ground to various accessories until the interference is eliminated, then install the condensers in those places permanently. Spark intensifiers should not be used.

CHECK FOR MOTOR NOISE (Antenna Pickup)

Now connect the antenna to the receiver and test for motor noise pick-up, it is entirely probable that if any noise is present it will be very slight and only noticeable between stations. No absolute rule for complete motor noise elimination can be specified inasmuch as many times two cars of the same make present entirely different problems and require bonding or shielding at different points. If motor noise is objectionable, it is due to the interference being radiated and picked up through the antenna system. Motor noise can be radiated into the drivers compartment through the drivers body due to the fact that in the majority of cars the toe board is wood. This can be remedied by covering the entire floor board with copper screen grounded in several places to the frame of the car. This condition is only true in cars which have roof antennas. Under-slung antennas, either of the strap or plate type, will very often pick up motor noise if mounted too far forward on the frame of the car, the noise naturally being picked up due to the close proximity of the antenna to the engine. It is recommended that if an under-slung antenna is used, that it be mounted as far towards the rear of the car as possible.

ANTENNA

Naturally the performance of any radio depends on the effectiveness of the antenna. Many of the older cars on the market today have a wire network in the roof which is nothing more than ordinary chicken wire. This wire network acts as a support to the roof and is in the majority of cases grounded directly to the body of the car at the point at which the roof meets the sides of the body. Service men frequently tack antennas to the underside of the top material in these cars, this is not satisfactory. There are but two things to do. Either an underslung (plate or strap) antenna must be used or the wire network must be cut from all grounds to the car. If this is done this network will in itself make a very good antenna, but it will be necessary to cut the wire network back for a distance of at least three inches from all sides of the car.

When running the lead-in up the corner post of the car to the roof antenna ground it every few inches to the frame of the body of the car. If this is not possible, insulate it, otherwise scratchy noises will result.

STEEL TOP OR TURRET TOP CARS do not contain built-in roof antennas. In cars of this type an under-slung, strap or plate, antenna must be used.

DOME LIGHT LEAD

If after all standard methods to reduce motor noise, as outlined above, have been tried and trouble still persists, carefully check the following: the dome light is usually the greatest source of antenna pick-up interference. First check the dome light by disconnecting the dome light connection on the back of the dash and grounding the wire (for location of this wire see car wiring diagram). If this eliminates the interference it indicates clearly that motor noise is being picked up by the dome light wire and radiated into the antenna. A small R.F. choke connected in series with the dome light wire and by-passed to ground at the dome light side of the choke with a .5 or 1 mfd. condenser, will eliminate this source of interference.

WHEEL STATIC

Wheel or brake noise is probably the most peculiar type of interference and is due to accumulated static charges. This type of interference is only noticeable while the car is in motion and could very easily be confused with ignition interference. Check for this with car running at a good speed, turn the ignition switch off and the clutch disengaged, apply the brakes. If the noise stops, the source of the static is in the wheels. To overcome the wheel static condition, use graphite grease in the wheel bearings or insert grounding springs in the hub caps. In the case of external brakes, it may be necessary to ground the brake bands to the frame of the car.

LOOSE CONNECTIONS

Loose connections are a frequent cause of interference. Make certain that light bulb contacts are clean and that they fit tight in their sockets, that all battery cable connections are tight and well grounded. Secondary high tension leads at the distributor cap or the coil very often work loose and a sparking contact results. Make certain that clips on all high tension wires are clean and bright and are pressed firmly into the receptacies on the distributor cap and the ignition coil.

Ignition noise should, if possible, be checked in a location that is free from electrical disturbances such as power lines, electrical equipment, neon signs, street car and elevated lines. This receiver is a very sensitive instrument and will pick up over its antenna system electrical disturbances in its immediate vicinity.

PILOT LAMP AND FUSE

PILOT LAMP—A 6-8 volt lamp is used (Bulb No. 116-13 Bulb).

Fuse—A 15 ampere automobile fuse is used. CAUTION: BE SURE THE FUSE SHIELD IS ON THE FUSE BEFORE THE LATTER IS INSERTED IN THE RECEPTACLE.

SERVICE DATA

SERVICE NOTES

Voltages taken from different points of circuit to chassis are measured with volume control full on, all tubes in their sockets and speaker connected, with a volt meter having a resistance of 1000 ohms per volt. These voltages are clearly indicated on the circuit diagram.

In order to prevent signal from acting upon A.V.C. and affecting accuracy of voltage measurements, aerial and ground leads should be short circuited while making measurements.

All voltages are to be measured with 6.3 volts input to receiver. Resistances of coils and transformer windings are indicated in ohms on schematic circuit diagram.

To check for open by-pass condensers, shunt each condenser with another condenser of the same capacity and voltage rating, which is known to be good, until the defective unit is located.

Failure to operate, noisy or weak reception is usually due to defective tubes, the tubes making poor contact with sockets or grid clips making poor contact with the caps of the tubes. Tubes may be checked very easily by replacing with other tubes which are known to be good. If fuse blows out frequently and insulating sleeve has been properly placed over fuse, the trouble is probably in the vibrator, it should be replaced. Do not attempt to make any adjustments on the vibrators.

ALIGNING INSTRUCTIONS

All of the adjustments have been very carefully set with signal generators at the factory and require no further adjustment, unless it becomes necessary to replace a coil or transformer, or if the adjustments have been tampered with in the field. Under no circumstances attempt any adjustments without first making certain that adjustment is necessary and only after voltages, tubes and condensers have been checked and found to be normal. To properly re-align this receiver, a test oscillator, as well as an output meter, must be used.

DUMMY ANTENNAS

The dummy antennas referred to in the following instructions are:

"I.F. Dummy" —A .5 mfd. condenser connected in series with the test oscillator output lead.

"Broadcast Dummy"—A 175 mmfd. condenser connected in series with the output lead of the test oscillator.

RESONANCE INDICATOR

Use as a resonance indicator an output meter connected across the primary of the speaker input transformer, or by means of an adapter between the plate and screen terminals of the type 41 output tube. Maximum deflection of the meter indicates resonance. Use only enough signal to get a readily readable output. A low range output meter or the low scale of a multi-range meter should be used.

I.F. ALIGNMENT: (465 K.C.)

1. With variable condenser in its minimum capacity position (plates entirely out of mesh) and with volume control full on, connect test oscillator set at 465 K.C. in series with I.F. dummy antenna, to grid of 6K7 I.F. tube.
2. Adjust trimmer condensers of output I.F. transformer No. 108-98 to resonance with oscillator.
3. Move test oscillator connection to grid of 6A8 tube and adjust trimmer condensers of input I.F. transformer No. 108-96B to resonance with oscillator. See top view for location of these transformers. There are two adjustments on each and they are accessible from the top of the transformer shield and should be adjusted with an insulated screw driver.

BROADCAST ALIGNMENT

1. With variable condenser in its minimum capacity position, connect test oscillator set at 1550 K.C. in series with broadcast dummy to the antenna lead of receiver.
2. Adjust oscillator trimmer of variable condenser to resonance. (This adjustment is on the middle section of the three-gang condenser—see top view, Fig. 2).
3. Shift test oscillator to 1400 K.C. and pick up signal by rotating condenser and adjust R.F. and antenna trimmers to resonance (see top view, Fig. 2).
4. Re-set test oscillator to 600 K.C. and rotate variable condenser to 600 K.C. Adjust series pad, rocking gang condenser to and fro, at the same time adjusting series pad for maximum gain. This adjustment is accessible from the top of chassis—see top view.
5. Go back and check 1400 K.C. If adjustment is made here, check 600 K.C. again.
6. Check for sensitivity at 1000 K.C. by setting test oscillator to this frequency and picking up the signal by rotating variable condenser. Under no circumstances bend plates of variable condenser sections to correct tracking.

BELMONT RADIO CORP.

MODEL 661 (SERIAL Nº W1000 UP)

DESCRIPTION

Model No. 661 is a six-tube superheterodyne receiver having a tuning range of 530 K.C. to 1550 K.C., operates from a 6.0 volt storage battery and uses the automotive type 6.3 volt tubes. The "B" supply is obtained from a vibrator with a tube rectifier.

The I.F. frequency used is 465 K.C., the R.F. end of the receiver consisting of a high gain iron core antenna coil which gives high signal to noise ratio and an R.F. stage especially designed to give high image rejection and high I.F. attenuation. The I.F. transformers are designed to give high gain and selectivity and yet to have a broad nose for ease of tuning and hi-fidelity response. They are of the air core type and wound with solid wire to give *minimum* drift and variation of gain due to climatic changes.

This receiver has been carefully designed to facilitate servicing, the top and bottom covers are both removable and are fastened in place by spring clips, self tapping screws and trimount buttons.

All adjustments are accessible and any part replaceable without removing the chassis from the case.

Dash kits for the remote control head are available for 1935, 1936, 1937 cars drilled for dash plates.

PARTS

Part No.	Circuit Diagram Reference	Description	List Price Each
		CONDENSERS	
100-11	C15, C16, C20	.01 x 400 volt Tubular	.25
100-13	C3	.05 x 400 volt Tubular	.25
100-20	C7, C10	.1 x 200 volt Tubular	.25
100-22	C4	.05 x 200 volt Tubular	.25
100-31	C8, C19, C23	.5 x 120 volt Tubular (Oval Type)	.60
100-54	C22	.006 x 600 volt Tubular	.25

117-42		Knurled, Threaded Coupling for Flexible Control Cable	.05
116-13		6 - 8 Volt Pilot Light Bulb, T-50, Round, Bayonet Base	.10

Tubes are coded and guaranteed by the tube manufacturer. Prompter service can be rendered on adjustments if defective tubes are returned direct to the tube manufacturer rather than through our factory.

Vibrators can be reconditioned at a cost of $3.00 each, if the old unit is returned.

All resistors are RMA color coded - specify value and/or resistor number (per schematic diagram) and model number.

When ordering condensers, specify part number, model number and/or capacitor (per schematic diagram) and model number.

Mica condensers are coded with an additional dot indicating tolerance:

Tolerance Percent	Color of Dot
2½%	White
5%	Green
10%	Blue
15%	Yellow
20%	Red
More Than 20%	None.

All prices quoted are list and are subject to the usual trade discounts. Shipments are F.O.B. our Factory. When remitting in advance, please include postage.

WE CANNOT SUPPLY SPEAKER PARTS, CONES, TRANSFORMERS OR FIELDS SEPARATELY. WE CAN REPLACE OR REPAIR A DAMAGED SPEAKER FOR $1.00 NET, IF IT IS RETURNED TO OUR FACTORY TRANSPORTATION CHARGES PREPAID.

Socket Voltage and Trimmer Locations

Caution—Do not attempt to measure voltages on the control grids of the W-1D5G, W-1C7G, or W-1F7G with any conventional voltmeter as paralysis of the "C-bias" cell will result.

Check "C" cell by noting whether plate current is abnormally high on tubes biased by cells.

A further check on the C bias cell, particularly if it is suspected that the control grid leads have been grounded, is to connect a 1½ volt C battery between the control grid cap of one of the tubes on the C cell circuit and the chassis frame. The negative of the C battery should be connected to control grid, positive to chassis frame. This connection should be momentarily made only, and if the C cell had been weakened before, it will now be found to be recharged and ordinarily will not need to be replaced.

All voltages are operating voltages with respect to chassis frame, with all batteries at normal voltage—tuned to approximately 1000 K.C.—no signal being received. Due allowance must be made for current drawn by the meter used.

MODELS B-826A & B-826X

SERVICE DATA

"A" Battery—1-2¼ volt Air-cell Eveready A-600 (or equivalent) or 1-2.0 volt storage battery.

"B" Battery—2 (or 3) 45 volt, heavy duty plug-in type.

"C" Battery—(Audio)—1 (or 2) 4½ volt plug-in type such as Eveready 771 or Burgess 536.

Pilot Lamp Battery—Eveready 409 or Burgess 1042.

Battery Current—"A"=660 milliamperes; "B"=13½ milliamperes. (Average at 90 volts.)

Cabinet Dimensions—B-826A, 11¼ x 22½ x 9"; B-826X, 40" x 23" x 12".

Shipping Weight—B-826A, 30 lbs.; B-826X, 75 lbs.

Controls—(1) Off-Speech-Music Switch, (2) Treble Tone Control and Dial Light Switch, (3) Station Selector, (4) Range Selector Switch, (5) Volume Control.

Station Selector Drive Ratio .... 90:1 and 18:1

Number and types of radiotrons—(1)-W-1C7G; (1)-W-1D5G; (1)-W-1F7G; (1)-W-1E5G; (2)-W-1H4G; (2)-W-49. Total 8.

Pilot Lamps (3)—Mazda No. 40, 6.3 V., 0.15 Amp.

Undistorted output .... 0.4 Watt

Frequency range .... 530 K.C. to 1720 K.C., and 1.7 to 6.0 M.C. and 5.9 to 19 M.C.

These receivers are 8 tube superheterodynes incorporating such features as wide broadcast range, the more popular short wave and police bands, unusually powerful Alnico dynamic speaker, "iron core" I.F. transformers, bass and treble tone controls, automatic volume control, "Cell" type "C" bias, unexcelled battery economy, plug-in batteries, compensated manual volume control, two tube driver stage, class B output circuit, dust-proof loudspeaker, and the inherent sensitivity, selectivity and tone quality of the superheterodyne circuit.

R. F. COIL SYSTEM

Ample R.F. selectivity is secured by the R.F. pre-selector stage, which renders a wave trap unnecessary. This stage uses a W-1D5G Radiotron.

Referring to the schematic circuit diagram, it will be seen that four coils are used to cover the three ranges. Coil L4 is the broadcast antenna primary coil, which is connected to the antenna terminal permanently. In the "BC" position of the range selector, pole S2 is open and pole S1 connects coil L3 to the control grid of the W-1D5G to act as the broadcast antenna secondary coil.

In the "MW" position coil L3 is connected (through condenser C4) to the antenna and acts as the medium wave antenna primary coil. Coil L2, at the same time, becomes the medium wave antenna secondary coil.

In the "SW" position, coil L2 acts as the short wave antenna primary coil, and L1 the antenna secondary coil.

Three air dielectric trimmers are used to align each range of antenna coil circuit.

Radiotron W-1C7G is used as both first detector and oscillator. Poles S3 and S4 of the range selector switch make the necessary circuit changes to the coils coupling the R.F. amplifier to the first detector circuit. Coil L5 is the R.F. broadcast primary coil and is permanently in the plate circuit. In the "BC" position, pole S3 is open, and pole S4 connects coil L8 to the first detector control grid. An air dielectric trimmer is provided to align the R.F. secondary coil L8. In the "MW" position, coil L8 is coupled through condenser C6 to the R.F. amplifier tube plate, and becomes the medium wave R.F. primary winding. (It should be noted that the normal plate current of the R.F. Radiotron does not flow through this coil, but only through coil L5.) At the same time, coil L7 becomes the R.F. secondary coil.

In the "SW" position, the broadcast primary coil L5 acts as a choke, feeding the normal plate current to the R.F. amplifier Radiotron. The amplified R.F. signal is reactance-capacitance, coupled by C6 and L6 to the first detector.

At the same time, the shorting bars on switches S3 and S4 together short-circuit the unused coils L7 and L8 to prevent absorption of energy.

Precision manufacture permits the medium and short wave R.F. coils to be in proper alignment without additional trimmers.

The oscillator circuit is conventional. Pole S6 selects either of three separate grid coils and short-circuits the unused lower frequency windings. Pole S7 selects either of three plate coils and short-circuits the unused lower frequency windings. A series trimmer of the mica compression type is used for 600 K.C. alignment, and a shunt trimmer of the air dielectric type for 1500 K.C. alignment. No trimmers are used on the medium and short wave ranges of the oscillator circuit.

"GENERAL CIRCUIT DETAILS"

The third tube (Radiotron W-1F7G) is an I.F. amplifier with one diode plate acting as second detector and automatic volume control.

It will be noted that the two I.F. transformers are of the "Iron-core" type.

The rectified D.C. voltage developed across the diode load resistor (R-9) is applied as A.V.C. voltage through a resistor (R-10) to the control grids of the R.F., first detector, and I.F. radiotrons. Two bias cells are also used to give a residual bias of 2.0 volts.

The audio frequency voltage appearing across the diode load resistor of the W-1F7G Radiotron is coupled to an acoustically tapered and compensated volume control. The moving tap of the volume control is connected to the control grid of the W-1E5G first audio amplifier Radiotron, which is in turn resistance-capacitance coupled to the driver stage which uses two W-1H4G Radiotrons in parallel.

The output of the driver stage is transformer-coupled to the Class B, push-pull output stage which uses two W-49 Radiotrons.

The treble tone control consists of a variable resistance in series with a fixed capacity connected across the secondary of the driver transformer.

The amount of bass response is controlled by the speech-music switch S14. When this switch-pole is closed, the amount of compensation on the volume control is decreased—thus reducing the bass response at low and moderate volume.

Use With Vibrator "B" Supply

These receivers may be used with Westinghouse Style No. H-36133 vibrator "B" supply if a 6.0 volt storage battery is available. The necessary changes are very simple. Follow the instructions given with the vibrator "B" supply, noting also the following points:

The W-1E5G tube must be removed and a W-6J7G radiotron substituted. No Pilot Lamp Battery is required.

Refer to schematic circuit diagram in this leaflet and note the internal connection of the vibrator plug. When vibrator H-36133 is used, it is necessary to connect together pins No. 1 and No. 5, on the diagram. This may be done by dissembling the vibrator plug and soldering a jumper in place. It will be more convenient, however, to use a special adapter, Style No. H-38178. (See parts list.)

For service data (or operating instructions) on vibrator "B" supply H-36133, see radio service manual, section RS-170.

ALIGNMENT PROCEDURE

There are various alignment trimmers provided in the R.F. tuned circuits. The i-f transformer adjustments are made by means of screws attached to molded magnetite cores. All of these circuits have been accurately adjusted during manufacture and should remain properly aligned, unless affected by abnormal conditions or altered during servicing. Loss of sensitivity, improper tone quality, and poor selectivity are the usual indications of improper alignment.

The correct performance of this receiver can only be obtained when the aligning has been done with adequate and reliable apparatus. It is not necessary to use a frequency modulated oscillator and cathode ray oscillograph to align this receiver. Those service men that have this equipment will probably prefer to use it and, for their convenience, we have indicated on the socket voltage diagram the proper connection point for the cathode ray vertical amplifier input terminal.

By using the Cathode Ray Adapter shown in the Replacement Parts List, the cathode ray connections may be made without removing or opening the chassis.

A test oscillator is required as a source of the specified alignment frequencies. Visual indication of receiver output during the adjustment is necessary, and should be accomplished by the use of an indicator or meter.

The procedure outlined below should be followed in adjusting the various trimmer capacitors and molded cores:

Calibrate the tuning dial by adjusting pointer to the low frequency end of scale, with gang condenser plates fully meshed. The pointer should be horizontal with its painted section resting at the end of the vertical index line. This is a friction adjustment. At the same time, set the vernier dial scale (this is secured by two set screws) to read "o".

Perform alignment in proper order, as shown by the accompanying chart, starting with No. 1, and following all operations across, then No. 2, etc. The chassis bottom shield must be securely in place when making R.F. adjustments. Adjustment locations and frequencies are shown on a sticker fastened to the bottom side of the chassis shield. These trimmer locations are also shown in one of the accompanying illustrations.

Connect the "low" output terminal of the test oscillator to the receiver chassis for all alignment operations. Regulate the output of the test oscillator so that minimum signal is applied to the receiver to obtain an observable output indication. This will avoid a-v-c action.

The term "Dummy antenna" means the device which must be connected between the "high" test-oscillator output terminal and the point of connection to the receiver in order to obtain ideal alignment. "No signal, 550-750 kc." means that the receiver should be tuned to a point between 550 and 750 kc. where no signal or interference is received from a station or the receiver (heterodyne) oscillator.

The term "Rock Through" indicates that the receiver station selector should be rocked back and forth while making the indicated adjustment. The adjustment and rocking should be continued until the combined action results in the maximum deflection on the output meter.

When adjusting oscillator circuits that have both series and shunt trimmers, it is good practice to repeat the adjustment on the oscillator shunt trimmer after making the adjustment on the oscillator series trimmer. On some tuning ranges, it is found that more than one peak may be secured if the trimmer is adjusted over a wide enough range. When this occurs, it should be noted that oscillator circuits should be aligned, using that peak which occurs at the lower capacity setting of the trimmer. On R.F. or first detector trimmers, the peak occurring with the larger capacity setting of the trimmer should be used.

It is also good practice to make sure that the trimmers on the short-wave ranges are set so that the oscillator stage develops its signal at a higher frequency than the signal to which the R.F. stage (or stages) is tuned. This check can be made by advancing the test oscillator output control and tuning the receiver above and below the frequency of the test oscillator, noting at what frequency the test signal reappears. It should reappear at a frequency setting on the receiver dial lower than the test oscillator frequency by an amount equal to twice the intermediate frequency.

Due to the small number of trimmers, it may be necessary to replace a coil assembly if, due to accident, serious mis-alignment occurs which cannot be corrected by the trimmers available.

It is possible to use a tuning wand (such as stock RCA-6679) in the usual way as a check-up on coil alignment, but, in order to do this, it will be necessary to drill two openings in the chassis shield to permit insertion of the tuning wand into the coils, under operating conditions. This check with the tuning wand should be made, in all cases, before replacing any coil assemblies.

ALIGNMENT CHART

Order of Alignment	Connection To Receiver	Dummy Antenna	Oscillator Setting	Receiver Dial Setting	Circuit To Adjust.	Adjustment Symbols	Adjust to Obtain

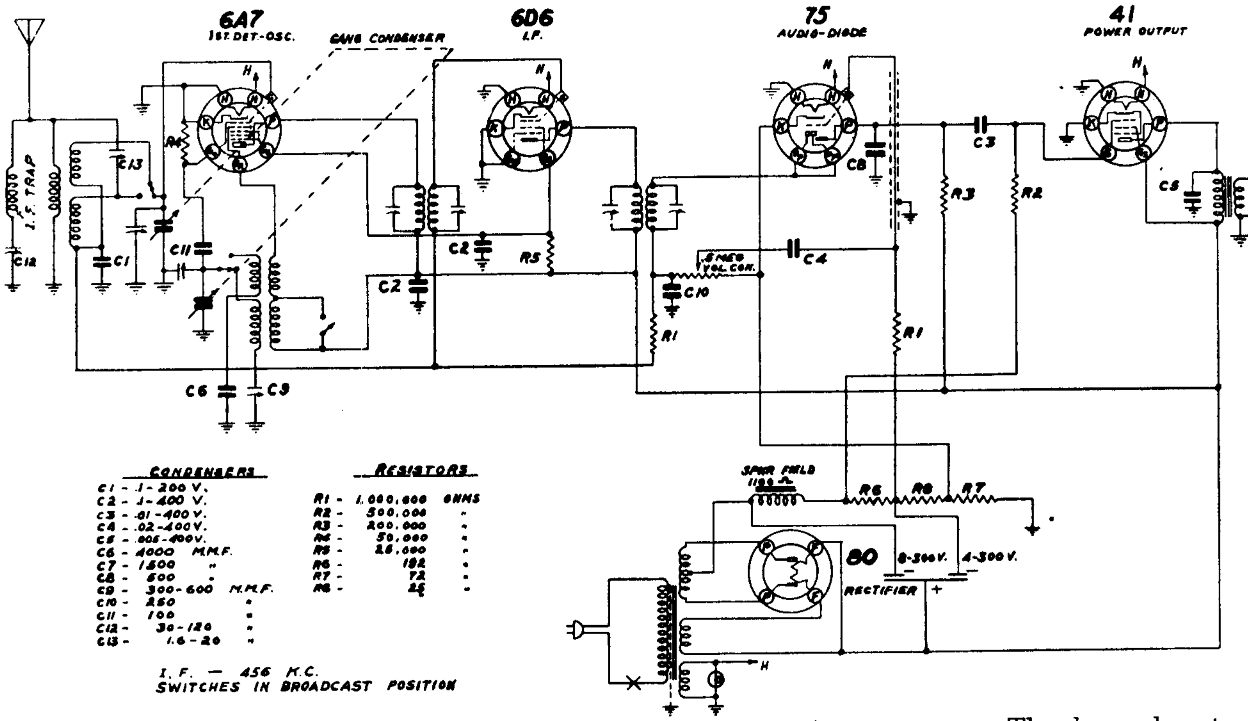
CONTINENTAL RADIO & TELEVISION CORP.

MODEL 5M



This receiver is designed to operate over two tuning ranges. The broadcast range, which extends from 535 to 1750 kilocycles (175 to 550 meters) and the International Short Wave Band which extends from 5600 to 18100 Kilocycles (KC) (16.5 to 53.5 meters). This short wave range is one which includes the four internationally assigned bands—the 19, 25, 31 and 49 meter bands.

CONTINENTAL RADIO & TELEVISION CORP.

MODEL 5M

GENERAL DATA The alignment of this receiver requires the use of a test oscillator that will cover the frequencies of 456, 600 1400, and 16000 KC and an output meter to be connected across the primary or secondary of the output transformers. If possible, all alignments should be made with the volume control on maximum and the test oscillator output as low as possible, to prevent the AVC from operating and giving false readings.

CORRECT ALIGNMENT PROCEDURE The intermediate frequency (I.F.) stage should be aligned properly as the first step. After the I.F. transformers have been properly adjusted and peaked, the Broadcast Band should always be the next procedure; after which the Short Wave Band may be aligned.

I.F. ALIGNMENT Adjust the test oscillator to 456 KC and connect the output to the grid of the first detector tube (6A7) through a .05 or .1 mfd. condenser. Align all four I.F. trimmers to peak or maximum reading on the output meter The four trimmers are located in the two I.F. cans on the top of the chassis.

BROADCAST BAND ALIGNMENT Adjust the oscillator to 1400 KC and connect the output to the antenna lead (Blue) through a .0002 mfd. mica condenser to give the equivalent of a normal antenna. Set the receiver pointer to 1400 KC and adjust the front gang condenser trimmer (oscillator circuit) to peak. After this has been carefully done, the next step is to adjust the rear trimmer of the gang condenser to peak. Next, re-set the dial pointer on the receiver and the test oscillator to 600 KC. Slowly increase or decrease the oscillator padding condenser and at the same time continuously tune back and forth across the signal with the receiver until the maximum reading is obtained on the output meter. This adjustment seems a little complicated but is the easiest way to adjust the oscillator to the pre-selector or R.F. section. The padding condenser is located on the front apron of the chassis.
Return to 1400 KC and again go over the adjustments of this frequency to be certain that they were not put slightly out of alignment when adjustment was made at 600 KC.
This completes the correct sequence of operations in properly aligning the receiver for the Broadcast Band, and **must always be done before** attempting to align the Short Wave Band.

SHORT WAVE BAND There is only one adjustment to be made in the alignment of the Short Wave Band. Due to the circuit design and correct matching of the coils, no oscillator adjustment is necessary.
Set the test oscillator to 16000 KC and start rotating the tuning condenser from the high frequency end of the dial until the signal of the test oscillator is heard. Adjust the trimmer on the antenna coil located under the chassis to give maximum signal. Be sure to align the antenna coil on the first signal heard as the condenser is turned from the high frequency end of the dial.
IMPORTANT: This is the only adjustment necessary for the Short Wave Band. Do not attempt any adjustment of the gang condenser trimmers in aligning the Short Wave Band, otherwise the Broadcast Band will be thrown out of alignment.
Return to 1400 KC and again go over the adjustments of this frequency to be certain that they were not put slightly out of alignment when adjustment was made at 16000 KC.

MODEL 6L

This receiver is designed to operate over two tuning ranges. The Outer band, which covers the broadcast range, extends from 535 to 1650 kilocycles (182 to 560 meters); the Inner band, which covers the Longwave band, extends from 800 to 2000 Meters (375 kilocycles to 150 kilocycles).

BALLAST TUBES This receiver is designed to operate from any 60 cycle AC (alternating current) or DC (direct current) power supply main of 110 to 120 volts. However by the use of the proper tube (listed below) any one of the following line voltages can be employed: 115, 130, 150, 230.

Type Tube	Line Voltage
L49BJ	115 Volts
L61BJ	130 Volts
L81BJ	150 Volts
L151BJ	230 Volts

ALIGNMENT DATA AND SERVICING

GENERAL DATA The alignment of this receiver requires the use of a test oscillator that will cover the frequencies of 160, 325, 375, 456, 600 and 1400 KC and an output meter to be connected across the primary or secondary of the output transformer. If possible, all alignments should be made with the volume control on maximum and the test oscillator output as low as possible, to prevent the AVC from operating and giving false readings.

CORRECT ALIGNMENT PROCEDURE The intermediate frequency (I.F.) stage should be aligned properly as the first step. After the I.F. transformers have been properly adjusted and peaked, the Broadcast Band should always be the next procedure; after which, the Long Wave Band may be aligned.

I.F. ALIGNMENT Adjust the test oscillator to 456 KC and connect the output to the grid of the first detector tubes (6A7) through a .05 or .1 mfd. condenser. The ground on the test oscillator can be connected to the chassis ground if the test oscillator is not grounded to one side of the power line. In case one side is not connected to ground, connect a large condenser from ground on the test oscillator to ground of the chassis. Align all three I.F. trimmers to peak or maximum reading on the output meter. The three trimmers are located as follows: two are located in the I.F. can on top of the chassis, and the third is located on the front apron of the chassis and is the left hand section of the double trimmer.

BROADCAST BAND ALIGNMENT Adjust the oscillator to 1400 KC and connect the output to the antenna lead (Blue) through a .0001 mfd. mica condenser to give the equivalent of an antenna about 60 feet. Set the receiver pointer to 1400 KC and adjust the rear gang condenser trimmer (oscillator circuit) to peak. After this has been carefully done, the next step is to adjust the front trimmer of the gang condenser to peak.
Next, re-set the dial pointer on the receiver and the test oscillator to 600 KC. Slowly increase or decrease the oscillator padding condenser and at the same time continuously tune back and forth across the signal with the receiver until the maximum reading is obtained on the output meter. This adjustment seems a little complicated but is the easiest way to adjust the oscillator to the pre-selector or R.F. section. The padding condenser is located on the right hand side of the double trimmer on the front of the chassis.
Return to 1400 KC and again go over the adjustments of this frequency to be certain that they were not put slightly out of alignment when adjustment was made at 600 KC.
This completes the correct sequence of operations in properly aligning the receiver for the Broadcast Band, and **must always be done before** attempting to align the Long Wave Band.

LONG WAVE BAND ALIGNMENT Set the test oscillator to 375 KC and with the gang condenser all the way out, adjust the long wave oscillator trimmer to peak. Next set the test oscillator to 325 KC and turn the gang towards the low end of the dial until the signal is heard. Peak the antenna at 325 KC. Set the test oscillator to 160 KC and tune in the signal. Adjust the 160 KC pad while rocking the gang back and forth to secure maximum output. Since the long wave pad has considerable effect on the high frequency end of the long wave, it is necessary to repeat the above procedure to secure correct alignment. Use the same antenna dummy on the long wave band as used on the broadcast band.

CONTINENTAL RADIO & TELEVISION CORP.

MODEL 5VU

This receiver is designed to operate over two tuning ranges. The Outer band, which covers the Broadcast range, extends from 535 to 1650 kilocycles (182 to 560 meters); the Inner band, which covers the Longwave band, extends from 800 to 2000 Meters (375 kilocycles to 150 kilocycles).

ALIGNMENT DATA AND SERVICING

GENERAL DATA The alignment of this receiver requires the use of a test oscillator that will cover the frequencies of 160, 325, 375, 456, 600 and 1400 KC and an output meter to be connected across the primary or secondary of the output transformer. If possible, all alignments should be made with the volume control on maximum and the test oscillator output as low as possible, to prevent the AVC from operating and giving false readings.

CORRECT ALIGNMENT PROCEDURE The intermediate frequency (I.F.) stage should be aligned properly as the first step. After the I.F. transformers have been properly adjusted and peaked, the Broadcast Band should always be the next procedure; after which, the Long Wave Band may be aligned.

I.F. ALIGNMENT Adjust the test oscillator to 456 KC and connect the output to the grid of the first detector tube (6A7) through a .05 or .1 mfd. condenser. The ground on the test oscillator should be connected to the Black wire on the chassis. Align all four I.F. trimmers to peak or maximum reading on the output meter. The four trimmers are located as follows: two in each I.F. can on top of the chassis.

BROADCAST BAND ALIGNMENT Adjust the oscillator to 1400 KC and connect the output to the antenna lead (Blue) through a .0001 mfd. mica condenser to give the equivalent of an antenna about 60 feet. Set the receiver pointer to 1400 KC and adjust the front gang condenser trimmer (oscillator circuit) to peak. After this has been carefully done, the next step is to adjust the rear trimmer of the gang condenser to peak.

Next, re-set the dial pointer on the receiver and the test oscillator to 600 KC. Slowly increase or decrease the oscillator padding condenser and at the same time continuously tune back and forth across the signal with the receiver until the maximum reading is obtained on the output meter. This adjustment seems a little complicated but is the easiest way to adjust the oscillator to the pre-selector or R.F. section. The padding condenser is located on the front apron of the chassis.

Return to 1400 KC and again go over the adjustments of this frequency to be certain that they were not put slightly out of alignment when adjustment was made at 600 KC.

This completes the correct sequence of operations in properly aligning the receiver for the Broadcast Band, and **must always be done before** attempting to align the Long Wave Band.

LONG WAVE BAND ALIGNMENT Set the test oscillator to 375 KC and with the gang condenser all the way out, adjust the long wave oscillator trimmer to peak. Next set the test oscillator to 325 KC and turn the gang towards the low end of the dial until the signal is heard. Peak the antenna at 325 KC. Set the test oscillator to 160 KC and tune in the signal. Adjust the 160 KC pad while rocking the gang back and forth to secure maximum output. Since the long wave pad has considerable effect on the high frequency end of the long wave, it is necessary to repeat the above procedure to secure correct alignment. Use the same antenna dummy on the long wave band as used on the broadcast band.

MODEL 6PU

This receiver is designed to operate over three tuning ranges; the broadcast range which extends from 550 to 1700 Kilocycles (KC) (173 to 562 meters), Longwave Band which extends from 150 to 375 Kilocycles (KC) (800 to 2000 Meters) and the International Short Wave Band which extends from 5600 to 18,100 Kilocycles (KC) (16.5 to 53 Meters). This latter range is the one which includes the four internationally assigned bands — the 19, 25, 31 and 49 meter bands.

REASONS FOR UNSATISFACTORY OPERATION

FAILURE TO OPERATE

1. Check connections from battery cable to storage battery. If connections are reversed, set will not operate. Proper instructions for connecting the battery are given on the first page.
2. Check all tubes. Have them tested by meter equipped to test the type of tubes used in this receiver.
3. Check tube shields for good ground connections. Check grid caps for good connection. See that grid caps and tube shields are not shorted to each other (touching).
4. Reversed connections on Antenna and ground terminals. Try both ways for best results.
5. Oscillator tube (6D8G) not oscillating.
6. Vibrator unit not securely in socket.

HUM A minimum amount of hum, equivalent to A.C. receivers, may be present. Excessive hum may be traced to the following causes:

1. Omitting the use of a ground or a poor ground connection.
2. Vibrator unit not securely fitted in socket.
3. Antenna picking up interference from high tension power lines.
4. Weak or rundown battery. Battery with defective cell.
5. Poor battery connections.
6. Extending or lengthening battery leads causes an enormous increase in "hum." The battery cable attached to the receiver is of special design and its ends **must** be connected directly to the battery terminals. **(See battery connection data on first page.)**

HOWLS AND SQUEALS

1. Omitting the use of a ground or poor ground connections.
2. Speaker leads placed near the (6T7G) tube. These leads should be kept away from this locality. Speaker leads should be kept along the end of chassis and front corner of cabinet.
3. Check shield on (6S7G) tube for good connection to chassis.

NOTICE — MICROPHONIC NOISE CORRECTION

If this radio instrument appears to be microphonic during operation, loosen the four (4) mounting screws that secure the chassis to the cabinet and remove the two (2) wooden strips that are underneath the chassis. This allows the chassis to float and rest on the four (4) rubber pads used for this purpose.

After the strips have been removed, adjust the chassis in the cabinet so that the dial will be in the center of the front escutcheon plate. Do not retighten the mounting screws.

"Should this radio set be moved any great distance, it is best to put the wooden strips back under the chassis and have the mounting screws securely tightened. If this is not done, damage may be done to the instrument, cabinet or tubes."

WINDCHARGERS

There are many types of windchargers now on the market which may be used to advantage for greater economy of receiver operation. Such chargers will pay for themselves over a period of time by saving the cost of battery recharging; removing the inconvenience of taking the battery to a charging station, non-operation of the receiver during the charging period.

IMPORTANT NOTE: The battery must never be charged while set is in operation. If a windcharger is used, it should always be disconnected from the battery when the receiver is being used. An inexpensive single pole switch can be used for disconnecting the windcharger from the battery. This will increase the life of the tubes and give additional economy to the use of the receiver.

ALIGNMENT DATA AND SERVICING

GENERAL DATA The alignment of this receiver requires the use of a test oscillator that will cover the frequencies of 160, 325, 380, 456, 600 1400, 1730, 6000, 16,000 and 18,100 KC and an output meter to be connected across the primary or secondary of the output transformers. If possible, all alignments should be made with the volume control on maximum and the test oscillator output as low as possible, to prevent the AVC from operating and giving false readings

CORRECT ALIGNMENT PROCEDURE The intermediate frequency (I.F.) stage should be aligned properly as the first step. After the I.F. transformers have been properly adjusted and peaked, the Broadcast Band should always be the next procedure; after which, either or both of the Short Wave Bands may be aligned

I.F. ALIGNMENT With the wave switch in the Broadcast Band and the gang condenser set at minimum. Adjust the test oscillator to 456 KC and connect the output to the grid of the first detector tube (6D8G) through a .05 or .1 mfd. condenser. The ground on the test oscillator can be connected to the chassis ground. Align all four I.F. trimmers to peak or maximum reading on the output meter.

BROADCAST BAND ALIGNMENT Connect the output of the signal generator to the antenna lead (blue) through a .0002 mfd. mica condenser. Set the gang condenser to minimum and the oscillator to 1730 KC and adjust the "oscillator trimmer" to receive this signal. Make no other adjustments at this frequency. Then set the generator to 1400 KC and tune in this signal by rotating the gang to 1400 on the dial. Adjust the "preselector" and "antenna" trimmer to maximum signal. Set the signal generator to 600 KC and tune in the signal on the receiver. **Note:** approximately the same sensitivity should be noted at this point as was at 1400 KC. The signal strength may sometimes be improved by padding the circuits. This is done by slowly increasing or decreasing the oscillator padding condenser and, at the same time, continuously tuning back and forth across the signal with the receiver until the maximum reading is obtained on the output meter. This adjustment may seem a little complicated but is the easiest way to adjust the oscillator to the preselector of the R.F. section. Return to 1400 KC and again go over the adjustments of this frequency to be certain that they were not put slightly out of alignment when adjustment was made at 600 KC.

SHORT WAVE BAND ALIGNMENT The short wave band is adjusted by setting the generator to 18,100 KC and with the gang at minimum, adjust the "short wave oscillator trimmer" to receive the signal. Set the generator at 16,000 KC, tune in the signal and adjust the "short wave antenna" trimmer to give maximum output. As there is no variable low frequency padding condenser on this band, the sensitivity of the receiver should be checked at 6000 KC to determine whether the circuits are in line at this frequency. Should the receiver lack sensitivity at 6000 KC, the antenna and the oscillator coils, as well as the .004 mica padding condenser, should be tested for defects as sometimes these components become subject to mechanical or electrical injuries, despite their rugged construction and liberal ratings.

LONG WAVE BAND ALIGNMENT The long wave band is adjusted by connecting the output of the signal generator through a .002 Mfd. mica condenser to the blue antenna lead. Then set the gang to minimum and the generator to 380 KC and adjust the long wave oscillator trimmer to receive this signal. Then set the generator to 325 KC and adjust the long wave antenna trimmer to give maximum output. Next set generator to 160 KC and pad the circuits to maximum output. Owing to the nature of the long wave band, the trimmer and padding condensers react upon each other to quite a degree; consequently, several re-adjustments at the trimming and padding positions are required before the circuits are adjusted properly.

CROSLEY RADIO CORP.

MODELS 926 & 989

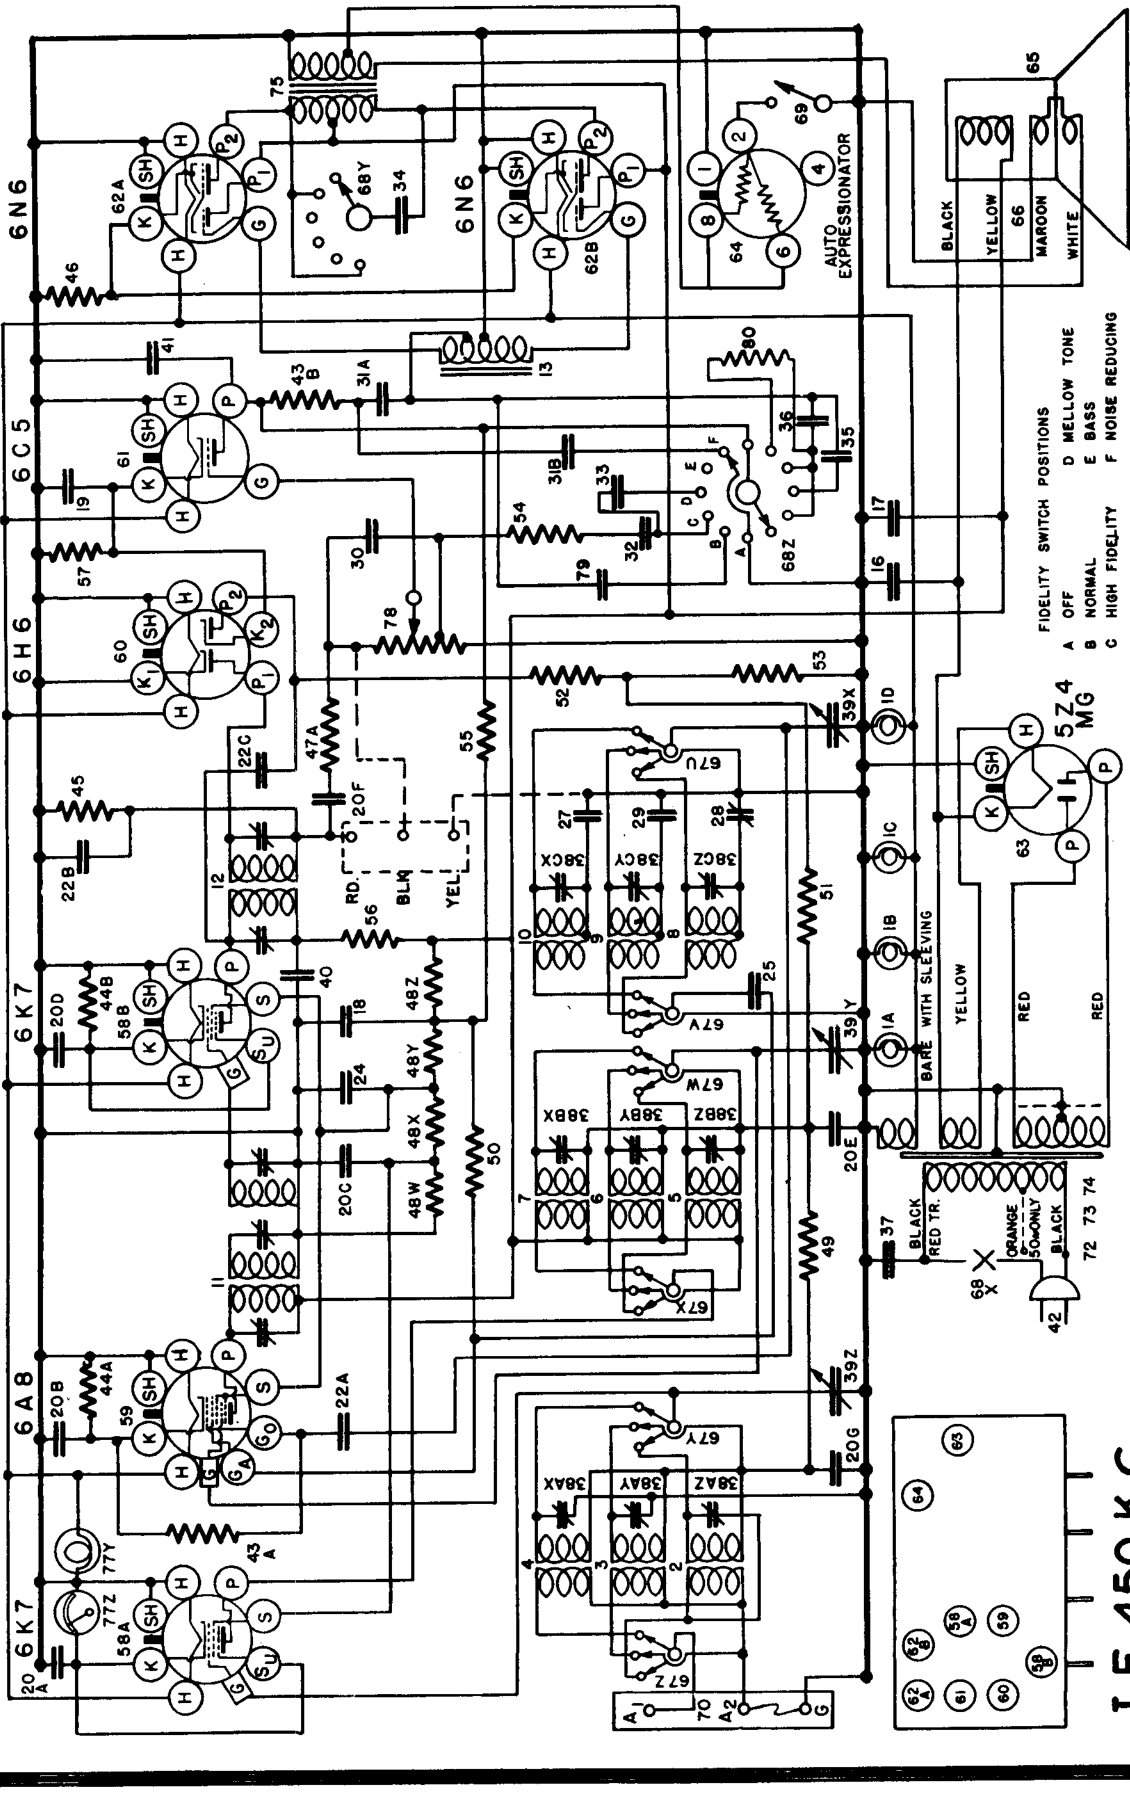

FIG. 1—WIRING DIAGRAM

I.F. 450 K.C.

CROSLEY RADIO CORP.

MODELS 926 & 989

SPECIFICATIONS

The Crosley Model 926 radio is a nine-tube super-heterodyne receiver and uses metal tubes, except the Auto Expressionator tube which is always glass and the 5Z4 rectifier which should always be the MG type. Chassis are available either with a standard 110 Volt-60 Cycle, or 110 Volt—25 Cycle Power Transformer.

The tuning range of the receiver is from 540 to 18100 Kilocycles and is divided into three bands as follows:

BLUE	540-1800 Kc.	or 555-170 Meters (Standard American Broadcast)
RED	1.8- 6.0 Mc.	or 158- 50 Meters (Police and Amateurs)
GREEN	6.0-18.0 Mc.	or 50- 17 Meters (High Frequency)

AUTO EXPRESSIONATOR

The Auto-Expressionator, Item 64, Fig. 1, is connected across the voice coil of the speaker. When operating its resistance varies so as to increase the volume of loud tones, thus giving a wider volume range to reproduced music which tends to compensate for the electrical limitations of broadcasting equipment.

ALIGNMENT PROCEDURE

This is a High Fidelity receiver and in order to secure maximum performance the alignment of its circuits should be done with precision instruments.

Tuning I-F Amplifier to 450 Kilocycles.

The I-F amplifier employs one triple-tuned and one double-tuned I-F transformers and under no condition should their trimmer condensers be readjusted just to determine if they are properly tuned. Fig. 5 shows the selectivity curve of a receiver whose I-F amplifier was slightly mis-tuned while Fig. 6 shows a curve made from actual measurements of a receiver which was properly aligned with the use of an oscilloscope. (See Note 3,

1. Conventional Method—

(a) Connect one terminal of the output meter to P2 of one of the 6N6 Output tubes and the other terminal through a .1 mf., or larger, condenser—Not Electrolytic—to P2 of the other Output Tube.

(b) Connect the output of the signal generator through a .02 mf. condenser, to the top cap of the 6K7 I-F Amp. tube, leaving the tube's grid clip in place. Connect the ground lead from the signal generator to the GND. terminal of the receiver chassis. KEEP THE GENERATOR OUTPUT LEAD AS FAR AS POSSIBLE FROM THE GRID LEADS OF THE OTHER SCREEN GRID TUBES.

(c) Set the band selector switch to the Broadcast Band and rotate the station selector to approximately 60 on the dial. Turn the volume control knob to the right (ON), turn the fidelity control knob to (NORMAL), and turn the Auto-Expressionator Control Switch to the left (NORMAL).

(d) Set the signal generator to 450 Kilocycles.

(e) Adjust the trimmer condensers on the top of the 2nd. I-F transformer for maximum output. Fig. 2 (Item 12).

ALWAYS USE THE LOWEST SIGNAL GENERATOR OUTPUT THAT WILL GIVE A REASONABLE READING ON THE OUTPUT METER.

(f) Transfer the output lead of the signal generator from the 6K7 tube to the top cap of the 6A8 Osc.-Mod. tube, leaving the tube's grid clip in place.

(g) Close the middle trimmer condenser on the 1st. I-F transformer (Tert. Fig. 4) so that it is moderately tight. (DO NOT FORCE ADJUSTING SCREW)

(h) Adjust the top (Sec) and then the bottom (Pri) trimmers of the 1st I-F transformer for maximum output.

(i) Transfer the lead of the signal generator from the 6A8 tube to the "ANT" terminal of the receiver and increase the output of the signal generator if necessary.

(j) Check the adjustment of the bottom (Pri) trimmer of the 1st. I-F transformer. Then adjust the middle trimmer by opening until maximum output is obtained. DO NOT READJUST TOP OR BOTTOM TRIMMERS AFTER THE MIDDLE TRIMMER HAS BEEN ADJUSTED.

2. Oscilloscope Method—

(a) Connect the output of the signal generator through a .02 mf. condenser to the top cap of the 6K7 I-F amplifier tube, leaving the tube's grid clip in place. Connect the ground lead from the signal generator to the receiver chassis. KEEP THE GENERATOR OUTPUT LEAD AS FAR AS POSSIBLE FROM THE GRID LEADS OF THE OTHER SCREEN GRID TUBES.

(b) Connect the vertical plates of the cathode ray oscilloscope to the receiver as follows: The binding post marked "GND" should be connected to the receiver chassis and the other binding post should be connected to the plate terminal of the 6C5 tube, (Fig. 1). (Be sure the oscilloscope is protected from D. C. by connecting a condenser, 0.1 to .05 mf., in series with the lead to the plate of the 6C5 tube).

(c) Set the band selector switch to the Broadcast Band and rotate the station selector to approximately 60 on the dial. The exact setting should be at a position where no broadcast signal will be received. Turn the volume control to the right (ON), turn the fidelity control to the left (NORMAL) and turn the Auto-Expressionator switch to the left (NORMAL).

(d) Set the signal generator to 450 kilocycles. See Instructions supplied with signal generator and oscilloscope.

(e) Adjust the trimmer condensers located on top of the 2nd. I-F transformer for maximum amplitude and symmetry of the selectivity curve on the resonance line (R).

NOTE: Keep the signal generator output as low as possible in order to prevent AVC action in the receiver.

(f) Transfer the output lead of the signal generator from the 6K7 tube to the top cap of the 6A8 oscillator-modulator tube, leaving the tube's grid clip in place.

(g) Close the middle trimmer (TERT) of the 1st. I-F transformer so that it is moderately tight. (Do not force adjustment screw).

(h) Increase the output of the signal generator and adjust the top trimmer (Sec) of the 1st. I-F transformer for maximum symmetry and amplitude.

(i) Adjust the bottom trimmer (Pri) of the 1st. I-F transformer for maximum amplitude.

(j) Reduce the output of the signal generator and adjust the middle trimmer of the 1st. I-F transformer for maximum symmetry and amplitude.

Aligning R-F Amplifier.

The R-F amplifier can best be aligned in the conventional manner, using a modulated signal generator and output meter.

When aligning the R-F amplifier the output lead of the signal generator is connected to the antenna terminal of the receiver. For the BLUE and RED bands a .0002 mf. condenser must be in series with the output lead of the signal generator and for the high-frequency band a 400 Ohm carbon resistor should be used in place of the condenser.

Each band should be shunt aligned and then series aligned, where provision is made for series alignment (BLUE band). The band selector switch should be set for the band being aligned and the signal generator should be set to the frequency indicated (c) for each adjustment.

(a) Adjust the "Osc.," "R-F" (Fig. 4) and "Ant." (Fig. 2) shunt trimmers in the order given for maximum output. Readjust the station selector slightly so that the generator signal is tuned-in with maximum output and then check the adjustments of the "R-F" and "Ant." trimmers in the order given. DO NOT READJUST THE "OSC" TRIMMER.

NOTE: When shunt aligning the RED and GREEN bands care must be exercised so that the circuits will be aligned on the fundamental frequency rather than on the image frequency which is approximately 900 Kilocycles less than the fundamental frequency. To check on this, increase the output of the signal generator ten times or more and try to tune-in the signal both at the generator frequency as indicated on the station selector dial and at approximately 900 Kilocycles less than the correct frequency. If the circuits have been properly aligned the signal can be tuned-in at both positions but much stronger at the correct position.

(b) To align the B-C "OSC" series trimmer, Item 28, Fig. 4, set the signal generator to 600 Kilocycles and then tune-in this signal with the station selector for maximum output. While the series trimmer is being adjusted rotate the station selector back and forth slightly until no further improvement in output can be obtained.

(C) SIGNAL INPUT FREQUNCIES

		Shunt Aligned	Series Aligned
American Broadcast	(BLUE)	1700 Kc.	600 Kc.
Pol. & Amateur	(RED)	6000 Kc.	
High-Frequency	(GREEN)	18000 Kc.	

NOTE 3: The high frequency oscillator on this receiver is neutralized by the addition of some small capacity coupling between the oscillator grid and the R-F grid of the 6A8 tube. This is accomplished by loosely wrapping a piece of insulated hook-up wire around the R-F grid lug and connecting it to the oscillator grid lug on the band selector switch.

It is necessary on some sets to adjust or even remove this coupling, in which case the wire should be unwrapped and threaded through the extra hole in the grid end of the R-F coil.

Figures in first column refer to parts in Diagrams.

SOCKET VOLTAGES

The tube socket voltages are measured from the tube socket contacts to the chassis with a 1000 ohm per volt, 500 volt D.C. voltmeter (except filaments) with the receiver in operating condition and no signal input. The filaments should be measured with an accurate low range A.C. voltmeter. Readings may vary plus or minus 10% of values given.

TUBE SOCKET VOLTAGE READINGS

Tube	Function	H	P	P_2	S	Su	G	K	Ga	Go
6K7	R-F Amplifier	6.3	225	—	90	4.0	—	4.0	—	—

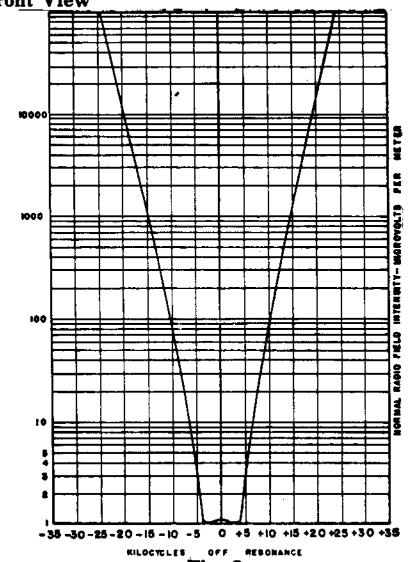

Fig. 6

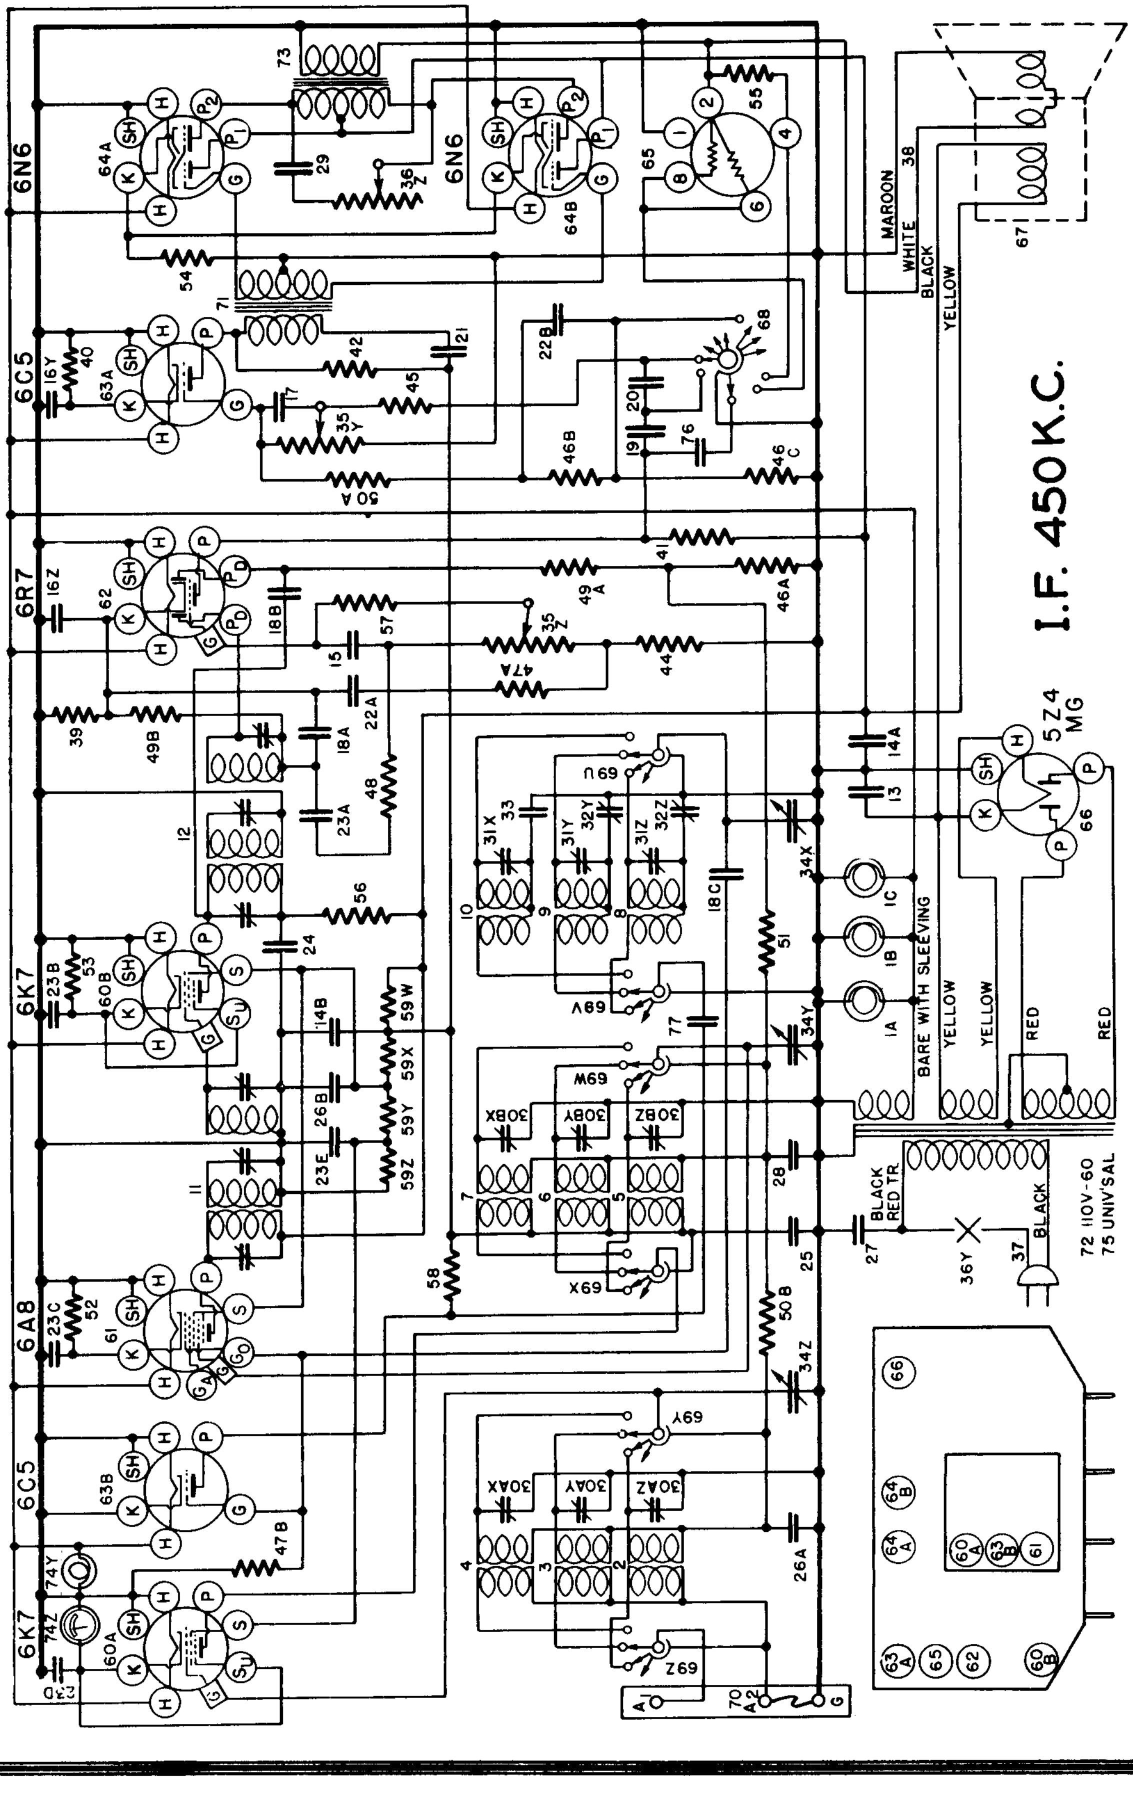
CROSLEY RADIO CORP.

MODEL 1026



CROSLEY RADIO CORP.

MODEL 1026

The tuning range of the receiver is from 540 to 19000 Kilocycles and is divided into three bands as follows:

BLUE	540-1900	Kc.	or	555-158 Meters (American Broadcast Band)
RED	1.9-6.5	Megacycles	or	158- 46 Meters (Police & Amateurs)
GREEN	6.0-19	Megacycles	or	50- 16 Meters (High Frequency Band)

AUTO-EXPRESSIONATOR

The Auto-Expressionator tube, Illustration No. 65, is connected across the voice coil of the speaker. When it is operating its resistance varies so as to increase the volume of loud tones, thus giving a wider volume range to reproduced music which tends to compensate for the electrical limitations of broadcasting equipment.

UNIVERSAL POWER TRANSFORMER

The Model 1026 chassis for use on other than 110 volts —60 cycles, is supplied with a universal power transformer designed to operate on a power supply of from 95 to 267 volts and any commercial frequency of 25 cycles or above. To adapt the set to a different line voltage it is necessary to remove the chassis from the cabinet, remove the bottom from the chassis, locate the terminal strip on the bottom of the power transformer and locate the wire leading from the power switch to the terminal strip. After careful measurement of the maximum values of line voltage, unsolder the wire described above, from the lug on the terminal strip and solder it to the correct lug. The correct lug will be the one marked so as to cover or nearly cover the maximum line voltage. THE MAXIMUM LINE VOLTAGE SHOULD NOT EXCEED THE HIGHEST VOLTAGE STAMPED ON THE TERMINAL STRIP BESIDE THE LUG TO BE USED BY MORE THAN 3%.

PHONOGRAPH PICKUP

Chasses equipped with a universal power transformer also have three terminals on the back for connecting a phonograph pickup. These terminals are marked P C S and the pickup is connected through a double pole—single throw switch to these terminals as shown in Fig. 7.

ALIGNMENT PROCEDURE

This is a High Fidelity receiver and in order to secure maximum performance the alignment of its circuits should be done with precision instruments.

Tuning I-F Amplifier to 450 Kilocycles

The I-F amplifier employs two triple-tuned I-F transformers and under no condition should their trimmer condensers be readjusted just to determine if they are properly tuned. Fig. 5 shows the selectivity curve of a receiver whose I-F amplifier was slightly mis-tuned while Fig. 6 shows a curve made from actual measurements of a receiver which was properly aligned with the use of an oscilloscope.

I. Conventional Method—

(a) Connect one terminal of the output meter to P2 of one of the 6N6 Output tubes and the other terminal through a .1 mf., or larger, condenser—not electrolytic —to P2 of the other 6N6 Output tube.

(b) Connect the output of the signal generator through a .02 mf. condenser to the top cap of the 6K7 I-F Amplifier tube, leaving the tube's grid clip in place. Connect the ground lead from the signal generator to the "GND" terminal of the receiver chassis. KEEP THE GENERATOR OUTPUT LEAD AS FAR AS POSSIBLE FROM THE GRID LEADS OF THE OTHER SCREEN GRID TUBES.

(c) Set the band selector switch to the Broadcast Band and rotate the station selector to approximately 60 on the dial. Turn the volume control knob to the right (ON), turn the tone control knob to the left (TREBLE) and turn the Multivox control knob to the Auditorium Position (Third position in the clockwise direction).

(d) Set the signal generator to 450 kilocycles.

(e) Close the middle trimmer condenser on the 2nd. I-F transformer (Tert. Fig. 4) so that it is moderately tight. (Do not force the adjustment screw).

(f) Adjust the top trimmer and then the bottom trimmer (Sec. & Pri) of the 2nd. I-F transformer for maximum output. ALWAYS USE THE LOWEST SIGNAL GENERATOR OUTPUT THAT WILL GIVE A REASONABLE READING ON THE OUTPUT METER.

(g) Transfer the output lead of the signal generator from the 6K7 tube to the top cap of the 6A8 Modulator tube, leaving the tube's grid clip in place.

(h) Open the middle trimmer of the 1st I-F transformer three or four turns from the closed position. (Care should be taken that the adjustment screw does not become dislodged from the nut).

(i) Adjust the top trimmer and then the bottom trimmer of the 1st I-F transformer for maximum output.

(j) Transfer the output lead of the signal generator from the 6A8 tube to the "ANT" terminal of the receiver and increase the output of the signal generator, if necessary.

(k) Adjust the middle trimmer of the 2nd. I-F transformer by opening until maximum output is obtained. DO NOT READJUST THE TOP AND BOTTOM TRIMMERS.

(l) Adjust the middle trimmer of the 1st I-F transformer by closing until maximum output is obtained. DO NOT READJUST TOP AND BOTTOM TRIMMERS.

II. Oscilloscope Method.

(a) Connect the output of the signal generator through a .02 mf. condenser to the top cap of the 6K7 I-F amplifier tube, leaving the tube's grid clip in place. Connect the ground lead from the signal generator to the receiver chassis. KEEP THE GENERATOR OUTPUT LEAD AS FAR AS POSSIBLE FROM THE GRID LEADS OF THE OTHER SCREEN GRID TUBES.

(b) Connect the vertical plates of the cathode ray oscilloscope to the receiver as follows: The binding post marked "GND" should be connected to the receiver chassis and the other binding post should be connected to the terminal marked "P" of the 6R7 tube. (Be sure the oscilloscope is protected from D. C. by connecting a condenser, .1 to .05 mf., in series with the lead connected to the plate of the 6R7 tube).

(c) Set the band selector switch to the Broadcast Band and rotate the station selector to approximately 60 on the dial. The exact setting should be at a position where no broadcast signal will be received. Turn the volume control knob to the right (ON), turn the tone control knob to the left (TREBLE) and turn the Multivox control knob to the Auditorium Position (Third position in the clockwise direction).

(d) Set the signal generator to 450 kilocycles. See Instructions supplied with signal generator and oscilloscope.

(e) Close the middle trimmer condenser on the 2nd. I-F transformer (Tert. Fig. 4) so that it is moderately tight. (Do not force adjustment screw).

(f) Adjust the top trimmer (Sec) of the 2nd. I-F transformer so that the nose of the selectivity curves is centered on the resonance axis (R) of the transparent scale supplied with the oscilloscope.

(g) Adjust the bottom trimmer (Pri) of the 2nd. I-F transformer for maximum amplitude of the selectivity curve on resonance line (R).

(h) Reduce the output of the signal generator and adjust the middle trimmer of the 2nd. I-F transformer for maximum amplitude and symmetry of the selectivity curve about the resonance line.

NOTE: Keep the base of the selectivity curve centered on the transparent scale from —15 to +15 and keep the signal generator output as low as possible in order to prevent AVC action in the receiver.

(i) Readjust the bottom trimmer of the 2nd. I-F transformer for maximum symmetry and amplitude.

(j) Transfer the output lead of the signal generator from the 6K7 tube to the top cap of the 6A8 Modulator tube, leaving the tube's grid clip in place.

(k) Open the middle trimmer of the 1st. I-F transformer three or four turns from the closed position. (Care should be taken that the adjustment screw does not become dislodged from the nut).

(l) Increase the output of the signal generator and adjust the top trimmer (Sec) of the 1st. I-F transformer for maximum symmetry and amplitude.

(m) Adjust the bottom trimmer of the 1st I-F transformer for maximum amplitude.

(n) Reduce the output of the signal generator and adjust the middle trimmer of the 1st. I-F transformer for maximum symmetry and amplitude.

(o) Carefully repeat operations (h), (i) and (n) for more accurate adjustments.

Aligning R-F Amplifier.

The R-F amplifier can best be aligned in the conventional manner, using a modulated signal generator and output meter.

When aligning the R-F amplifier the output lead of the signal generator is connected to the antenna terminal of the receiver. For the BLUE and RED bands a .00025 mfd. condenser must be connected in series with the output lead of the signal generator and for the high-frequency band a 400 ohm carbon resistor should be used in place of the condenser.

Each band should first be shunt aligned and then series aligned, where provision is made for series alignment (BLUE and RED bands). The band selector switch should be set for the band being aligned and the signal generator should be set to the frequency indicated (c) for each adjustment.

(a) Adjust the "OSC", "R-F" and "ANT" shunt trimmers in the order given for maximum output. Readjust the station selector slightly so that the generator signal is tuned-in with maximum output and then check the adjustments of the "R-F" and "ANT" trimmers in the order given. DO NOT READJUST THE "OSC" TRIMMER.

NOTE: When shunt aligning the RED and GREEN bands care must be exercised so that the circuits will be aligned on the fundamental frequency rather than on the image frequency which is approximately 900 kilocycles less than the fundamental. To check on this, increase the output of the signal generator ten times or more and try to tune-in the signal both at the generator frequency as indicated on the station selector dial and at approximately 900 kilocycles less than the correct frequency. If the circuits have been properly aligned the signal can be tuned-in at both positions but much stronger at the correct position.

(b) To align the series trimmers, 32Y and 32Z Fig. 2, set the signal generator to the frequency indicated below and then tune-in this signal with the station selector for maximum output. At the time that any series trimmer is being adjusted rotate the station selector back and forth slightly until no further improvement in output can be obtained.

(c) Signal Input Frequencies:

	Shunt Aligned	Series Aligned
American Broadcast Band (BLUE)	1700 Kc.	600 Kc.
Police Band (RED)	6000 Kc.	2000 Kc.
High-Frequency Band (GREEN)	18000 Kc.	....

SOCKET VOLTAGES

The tube socket voltages are measured from the tube socket contacts to the chassis with a 1000 ohm per volt, 500 volt D.-C. voltmeter (except filaments) with the receiver in operating condition and no signal input. The filament voltages should be measured with an accurate low range A.-C. voltmeter. Readings may vary plus or minus 10% of values given.

ALINEMENT PROCEDURE

Connect a high impedance AC voltmeter across the loudspeaker terminals Volume control should be set a few degrees back of maximum volume position. Use a weak signal from the generator, strong signals tend to cause improper adjustments.

Be sure that the fidelity control is NOT in the HIGH FIDELITY position. It will not be possible to properly aline the receiver unless this control is turned part way toward its "bass" position.

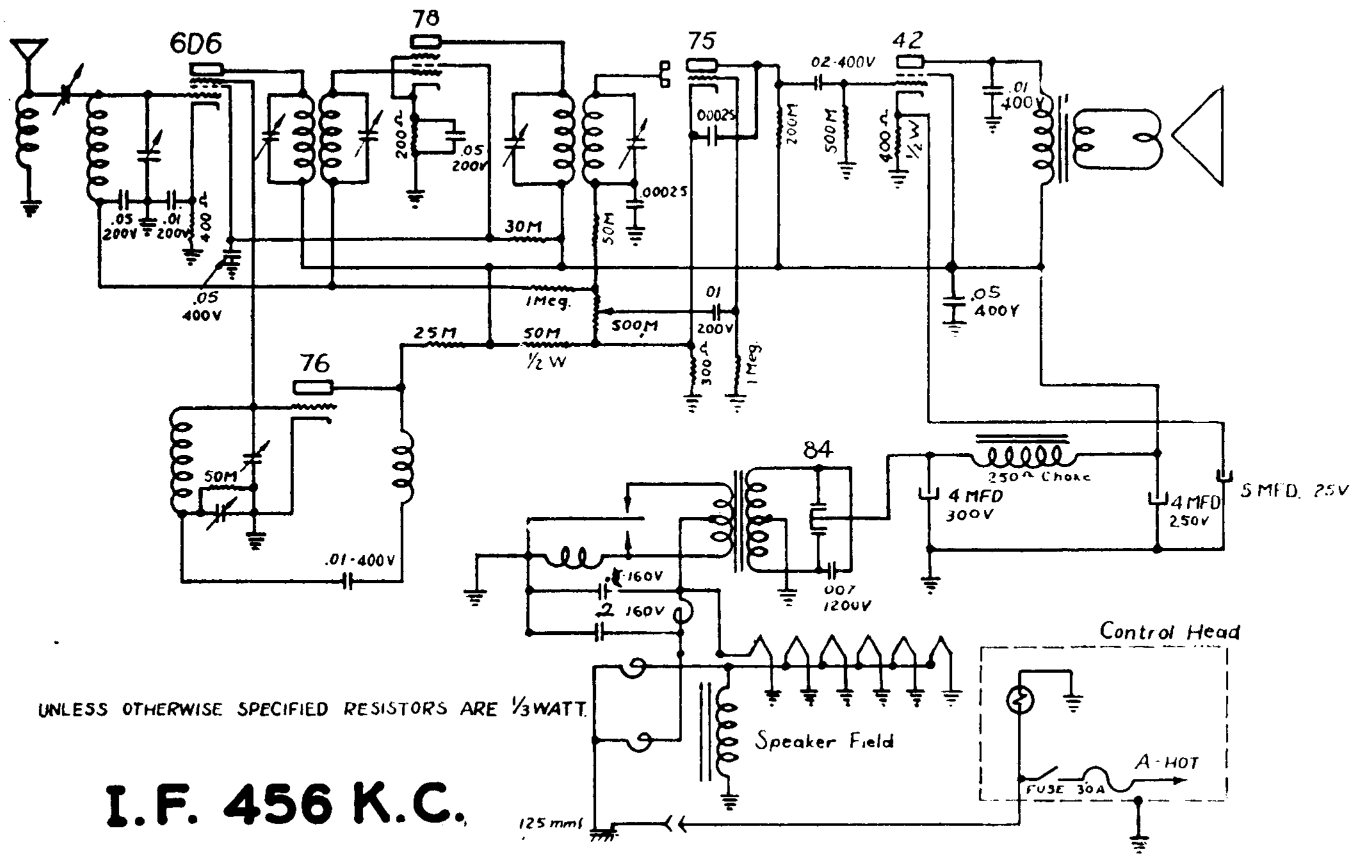
IF. Connect the generator ground to receiver chassis. Using .1 mfd condenser in series with high side of generator, apply 456 kc signal to grid of 6D6 second IF amplifier and aline transformer No. 3. Repeat for transformer No. 2, applying signal to grid of 6D6 first IF amplifier. Repeat for transformer No. 1 applying signal to grid of 6A7 translator. (See above diagram for location of tubes and transformers.)

RF. (See circuit diagram for location of trimmers.) Using a 200 mmf. condenser in series with the high side of the generator, turn band selector switch all the way to the left, tuning condenser to minimum capacity, feed 1810 kc. signal to antenna terminal and adjust broadcast oscillator trimmer for top frequency. Set generator frequency at some point around 1500-1600 kc., and adjust broadcast antenna and RF trimmers. Set generator for 600 kc., tune receiver to signal and adjust the padder. The tuning condenser should be rocked back and forth through the signal while varying the padder in order to assure perfect alinement.

A 400 ohm resistor must be used in series with the generator as a "dummy" antenna for proper alinement of the two short wave bands. Set the band selector switch in the center position, adjust the oscillator top frequency for 6250 kc., then aline the antenna and RF trimmers at about 6000 kc. With the band selector in the extreme right position, adjust the top frequency of the high frequency to 18,100 kc., and aline the antenna and RF trimmers at about 16,000 kc. In order to make sure that the top end of the last band is set properly, it is best to screw the oscillator trimmer down tight, then unscrew to the second peak. The antenna and RF trimmers should be screwed down tight, then unscrewed to the first peak. This procedure must be followed in order that the oscillator and RF circuits will be set in the correct relation to each other, otherwise a "dead" spot at a lower frequency will result, and the dial calibration will not be correct. Usually, it is best to rock the tuning condenser back and forth slightly while making these adjustments at high frequencies.

DETROLA RADIO AND TELEVISION CORPORATION

MODEL 166



I. F. Alignment

The I.F. frequency of this receiver is 456 K.C. For realignment, use the following procedure.

It is necessary to use an accurately calibrated signal generator. Couple the signal generator to the grid of the 6D6 tube with a tenth microfarad condenser in series with the "high" lead of the signal generator. Connect the ground side of the signal generator to the chassis. Set the signal generator to 456 K.C. Be sure the volume control is set at maximum. Attenuate the signal generator so that the signal is just audible in the speaker. If an output meter is used, it should be connected across the voice coil terminals of the speaker. Use ½ volt as standard output.

Adjust the 2nd I.F. transformer first. Each screw should be adjusted for maximum output. After number two I.F. has been adjusted, number one I.F. should be adjusted for maximum output. After both transformers have been adjusted, it is necessary to recheck No. 2 transformer and then recheck No. 1.

See TUBE LAYOUT for location of I.F. and R.F. trimmers and padder.

R. F. Alignment

To align the broadcast band, proceed as follows:

First, connect the ground side of the signal generator to the chassis. Connect the high side of the signal generator with a .00025 condenser, in series, to the antenna lead of the set. Set the volume control to maximum. Turn the station selector to the highest frequency (as far as it will go). Set the signal generator to 1570 K.C. Adjust the oscillator trimmer until the signal is heard. After the oscillator has been set at 1570 K.C., turn the station selector to 1400 K.C. Set the signal generator to 1400 K.C. When the signal is heard, adjust the antenna trimmer for maximum output.

When the set has been adjusted at 1400 K.C., turn the station selector dial to 600 K.C. Set the signal generator to 600 K.C. When the signal is heard, adjust the padder condenser by rocking the selector back and forth. While adjusting the padder screw, it is necessary to move the selector so that the signal may be kept in tune while adjusting the padder screw. This procedure should be followed until maximum output is obtained.

The foregoing procedure should be repeated. That is, the set is to be rechecked at 1570, 1400 and 600 K.C.

When aligning the R.F., use the same output standard as was used on the I.F. alignment.

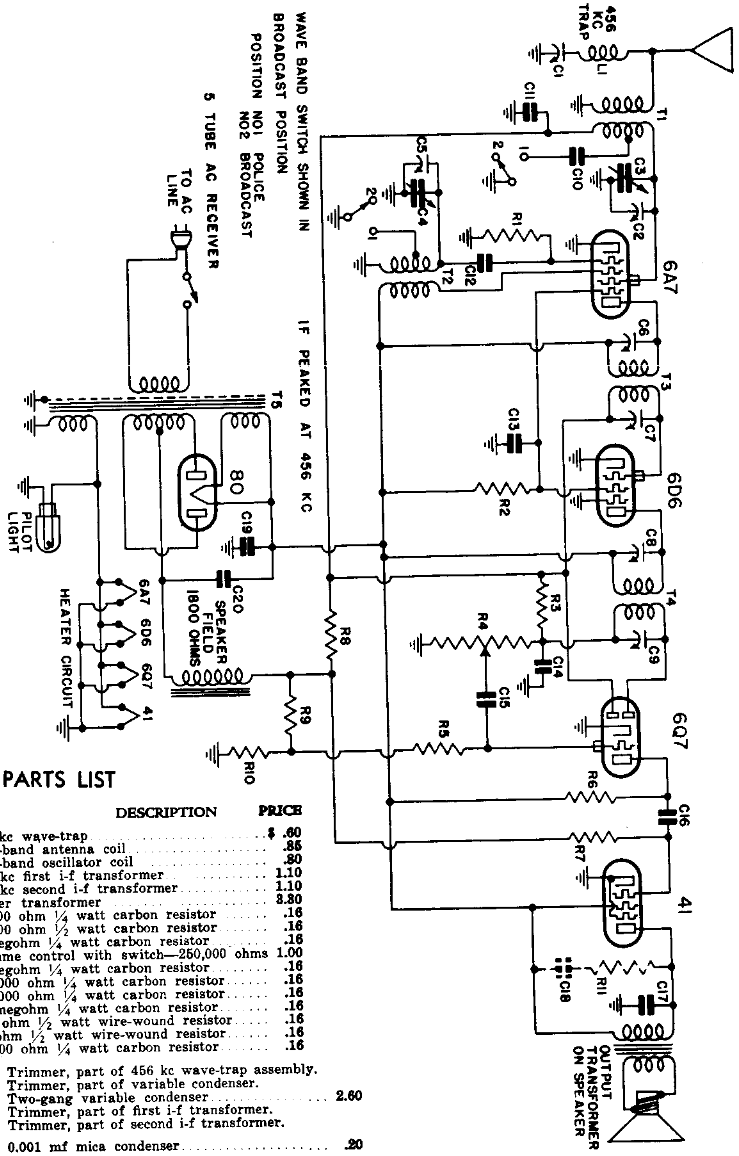
EMERSON RADIO AND PHONOGRAPH CORPORATION

MODELS AC, AC-130, AC-149 & AC-168



Voltage rating		105-125 volts, 60 cycles, a.c.
Power consumption		45 watts.
Frequency ranges		540 to 1580 kc. and 1580 to 4200 kc.

GENERAL NOTES

1. The wave-trap in the receiver has been adjusted for maximum signal rejection at 456 kc. If, however, persistent interference is experienced from some particular telegraphic station, readjust the wave-trap trimmer until the response from the interfering station is at a minimum.
2. The receiver should never be turned on with the 41 tube out of its socket since the rapid rise in rectifier voltage would damage the electrolytic condensers.
3. The two i-f transformers are held to the chassis by snap-on fasteners. To remove an i-f, unsolder all the leads under the chassis, pinch together the prongs of the snap-on fastener and lift the i-f can from the chassis.
4. The color coding of the leads of the i-f transformers, is as follows:
   Grid—green Plate—blue
   Grid return—black B plus—red
5. The color coding of the power transformer leads is as follows:
   Primary—two green leads 6.3 v. sec.—two heavy blue leads
   High voltage sec.—two black leads 5 v. sec.—two heavy red leads
   High voltage sec. center tap—yellow
6. With a few exceptions, the color coding of the general wiring is as follows:
   Plate—blue A.v.c. and cathode—white or yellow
   B plus—red Grid—green
   Screen—brown Filament and ground—black
7. An efficient antenna system is necessary to enable a full realization of the merits of the receiver. For reduction of noise and achievement of high efficiency on all frequency ranges the Emerson All-Wave High-Fidelity Antenna, Model W-78, and the Emerson All-Wave Antenna System, Model W-89, are recommended. Instructions for the installation of these antennas are supplied with each kit.

   In congested areas where the installation of a large antenna is not desirable we recommend the use of the Emerson Flexible Mast Antenna, Model W-82. Instructions for the installation of this compact and efficient antenna are supplied with each kit.

Tube Data

The tube complement is as follows:

1—6A7 pentagrid oscillator-modulator
1—6D6 i-f amplifier
*1—6Q7 diode detector, audio amplifier, automatic volume control
1—41 pentode power output
1—80 full-wave rectifier

Unless otherwise specified all octal-base tubes may be replaced with either metal or octal-base glass tubes.

VOLTAGE ANALYSIS

Readings should be taken with a 1000 ohms-per-volt meter. Voltages listed below are from point indicated to ground (chassis) with the volume control turned on full and no signal. Line voltage for these readings was 117.5 volts, 60 cycles, a.c.

Tube	*Plate*	*Screen*	*Cathode*	*Osc. Plate*	*Fil.*
6A7	182	70	0	182	6.3
6D6	182	70	0	—	6.3
6Q7	87	—	0	—	6.3
41	165	182	0	—	6.3

Voltage across speaker field—70.
Voltage from B minus to chassis—80.
B plus at 80 tube filament—262.

*See production changes

ADJUSTMENTS

An oscillator with frequencies of 456 and 1400 kc is required.

An output meter should be used across the voice coil or output transformer for observing maximum response.

Always use as weak a test signal as possible when aligning the receiver.

Location of Coils and Trimmer Adjustments

The two i-f transformers are located on top of the chassis deck. The first i-f transformer is the one directly behind the variable condenser. The trimmers for the two i-f transformers are available through holes in the tops of the cans.

The trimmers for the antenna and oscillator coils are located on the variable condenser. The trimmer on the front section is for the antenna coil.

The 456 kc wave-trap is mounted on the front chassis wall beneath the variable condenser. The trimmer for the 456 kc wave-trap is mounted on the coil and is accessible from the bottom of the chassis.

I-f and Wave-Trap Alignment

Rotate the wave-band switch to the broadcast (clockwise) position. Set the variable condenser at the minimum capacity position and feed 456 kc, through a 0.02 mf paper condenser, to the grid cap of the 6A7 tube (do not remove the grid clip from the tube). Adjust the four i-f trimmers for maximum response. Feed 456 kc to the antenna through a standard dummy antenna (a .0002 mf condenser may be used as a substitute) and adjust the wave-trap trimmer for *minimum* response. (See General Notes.)

R-f Alignment

With the wave-band switch in the broadcast position, clockwise, set the dial pointer at 140. Feed 1400 kc through a standard dummy antenna (a .0002 mf condenser m. be used as a substitute) to the antenna lead and adjust first the oscillator trimmer (on rear section of variable condenser) then the antenna trimmer (on front section of variable condenser) for maximum response. The police band is self-tracking and does not require any adjustment.

NOTE: The Model AC-149 should be aligned with the chassis bottom plate in place.

PRODUCTION CHANGES

In receivers bearing serial numbers below 1,258,237:

a. C17 was a .001 mf, 600 volt tubular condenser.
b. R11 and C18 were connected from the plate of the 41 tube to B plus as shown by the dotted lines on the schematic diagram.

In receivers bearing serial numbers below 1,333,800:

a. The second detector and first audio amplifier was a type 75.
b. R9 was a 310 ohm ½ watt wire-wound resistor, part number 3RR-276.
c. R10 was a 23 ohm ½ watt wire-wound resistor, part number 3RR-266.

	4MZ-644	Dial crystal (for Model AM-187)	.50

When ordering replacement parts specify part numbers.

*Item number locates the article on the schematic diagram.

†These trimmers cannot be supplied separately.

PRODUCTION CHANGES

In receivers bearing serial numbers below 1,184,290:

The variable condenser was part number 3CC-275. The dial pointer was part number 4MZ-590.

EMERSON RADIO AND PHONOGRAPH CORPORATION

MODELS AJ, AJ-130, AJ-137 & AJ-149

Current drain .... "A" battery—.42 amps.
"B" battery—.016 amps. with no signal
Frequency range .... 540 to 1730 kc.

1. The battery complement should be as follows:

Portable (Small Batteries)

Type	No. Req.	Eveready Part No.	Burgess Part No.	Ray-o-vac Part No.
1½ volt "A"	2	7111	4FA	6 Railroad
45 volt "B"	3	762 (plug-in type)	5308 (plug-in type)	5303 (plug-in type)

Home (Heavy Duty Batteries)

Type	No. Req.	Eveready Part No.	Burgess Part No.	Ray-o-vac Part No.
3 volt "A"	1	X-125	20F2	P9403
45 volt "B"	3	385 (plug-in type)	22308 (plug-in type)	P9303 (plug-in type)

The batteries indicated above for portable use are chosen for size so that the entire complement can be housed by the portable cabinet. In general, it will be found that the "B" batteries will last somewhat longer than the "A" batteries.

2. The receiver is designed for an "A" supply of 2 to 3 volts. If a 2 volt storage battery is used, its positive terminal should be connected to the terminal marked "2" on the metal clad ballast resistor. If a 2½ volt air-cell battery is used, it should be connected to the terminal marked "2.5". A 3 volt supply should be connected to the terminal marked "3".

3. The i-f transformers are of the snap-on type. To remove, unsolder all leads under the chassis, pinch together the prongs of the snap-on fastener and lift out.

4. The color coding of the i-f transformer leads is as follows:
Grid—green Plate—blue
Grid return—black B plus—red

5. An efficient antenna system is necessary to enable a full realization of the merits of the receiver. For reduction of noise and achievement of high efficiency on all frequency ranges the Emerson All-Wave High-Fidelity Antenna, Model W-78, and the Emerson All-Wave Antenna System, Model W-89, are recommended. Instructions for the installation of these antennas are supplied with each kit.

Tube Data

The tube complement is as follows:
1—1C6 oscillator-modulator
1—1A4 1st i-f amplifier
1—1B5-25S 2nd detector, a.v.c., a-f amplifier
1—30 a-f amplifier
1—1F4 pentode output

VOLTAGE ANALYSIS

Readings should be taken with a 1,000 ohms-per-volt meter. The voltages listed below are from point indicated to A minus with volume control turned on full and no signal. The battery voltages for these readings were as follows: "A" battery 3 volts, "B" battery 135 volts.

Tube	Plate	Screen	Osc. Plate	Fil.
1C6	105	105	57	2.0
1A4	105	57	—	2.0
1B5-25S	75	—	—	2.0
30	90	—	—	2.0
1F4	127	135	—	2.0

ADJUSTMENTS

An oscillator with frequencies of 456 and 1600 kc should be used.
An output meter should be used across the voice coil or output transformer for observing maximum response.
If the circuit is at all disturbed, the receivers must be realigned.
The set's oscillator is higher in frequency than the signal, so images should be observed on the low frequency side of the signals.
Always choose the minimum capacity peak on the oscillator trimmer and the maximum capacity peak on the antenna trimmer. The last motion in adjusting trimmers should always be a tightening one, not a loosening one.
Never leave a trimmer with the outside plate so loose that there is no tension on the screw. Either bend the plate up or remove the screw entirely.
Always use as weak a test signal as possible during alignment.

Location of Coils and Trimmer Adjustments

The two i-f transformers are located on top of the chassis deck. The first i-f is the one directly behind the variable condenser. The four trimmers, two for each transformer, are accessible through holes in the tops of the cans.
The antenna and oscillator trimmers are located on the right hand side of the variable condenser. The rear trimmer is the oscillator trimmer.
On portable model AJ-137, the 456 kc wave-trap is located below the chassis deck, directly underneath the variable condenser. Its trimmer is accessible through a hole in the bottom plate.

Alignment Procedure

1. Rotate the variable condenser to the minimum capacity position.
2. Feed 456 kc to the grid cap of the 1C6 tube.
3. Adjust the four i-f trimmers, repeating for maximum response.
4. If the receiver is portable model AJ-137, feed 456 kc to the antenna through a standard dummy antenna (a .0002 mf mica condenser may be substituted) and adjust the wave-trap trimmer for minimum response.
5. Set dial pointer to 1600 and feed 1600 kc to the antenna lead through a standard broadcast dummy antenna (a .0002 mf mica condenser may be used as a substitute).
6. Adjust the oscillator trimmer (on rear section of variable condenser) for maximum response.
7. Adjust the r-f trimmer (on front section of variable condenser) for maximum response.

MODELS AM, AM-131, AM-169 & AM-187

Voltage rating .... 105-125 volts, a.c. or d.c.
Power consumption .... 50 watts.
Frequency ranges .... 540 to 1,730 kc, and 5.6 to 18.0 megacycles.

1. If replacements are made or the wiring disturbed in the r-f portion of the circuit, the receiver should be carefully re-aligned.
2. One side of the power line is directly grounded to the chassis base. Under no circumstances, therefore, should a ground wire be permitted to come in contact with any metal part of the receiver.
3. The filament dropping resistor (R13 on schematic) is in a special metal tube at the rear of the chassis. This tube will become quite hot under normal operating conditions. For voltage drop specifications, see below.
4. When operating the receiver on d.c. it may be necessary to reverse the line plug to obtain the correct polarity.
5. The two i-f transformers are held to the chassis by snap-on fasteners. To remove an i-f, unsolder all the leads under the chassis, pinch together the prongs of the snap-on fastener and lift the i-f can from the chassis.
6. The color coding of the i-f transformer leads is as follows:
Grid—green Plate—blue
Grid return—black B plus—red
7. An efficient antenna system is necessary to enable a full realization of the merits of the receiver. For reduction of noise and achievement of high efficiency on all frequency ranges the Emerson All-Wave High Fidelity Antenna, Model W-78, and the Emerson All-Wave Antenna System, Model W-89, are recommended. Instructions for the installation of these antennas are supplied with each kit.
In congested areas where the installation of a large antenna is not desirable we recommend the use of the Emerson Flexible Mast Antenna, Model W-82. Instructions for the installation of this compact and efficient antenna are supplied with each kit.
8. The wave-trap in the receiver has been adjusted for maximum signal rejection at 456 kc. If, however, persistent interference is experienced from some particular telegraphic station, readjust the wave-trap trimmer until the response from the interfering station is at a minimum.

Tube Data

The tube complement is as follows:
1—6A7 pentagrid oscillator-modulator.
1—6D6 first i-f amplifier.
1—6Q7 diode detector, a-f amplifier, a.v.c.
1—25L6 beam power output.
1—25Z5 dual half-wave rectifier.
1—2UR-224 ballast tube (R13 on schematic).
NOTE: All metal tubes may be replaced with equivalent octal base glass tubes.

VOLTAGE ANALYSIS

Readings should be taken with a 1000 ohms-per-volt meter. Voltages listed below are from point indicated to ground (chassis) with the volume control turned on full and no signal. Line voltage for these readings was 117.5 volts, 60 cycles, a.c.

Tube	Plate	Screen	Cathode	Osc. Plate	Fil.
6A7	96	45	2.3	74	6.3
6D6	96	96	4.5	—	6.3
6Q7	40	—	1.0	—	6.3
25L6	92	100	6.2	—	25.0

Voltage at 25Z5 cathode—125 volts.
Voltage across speaker field—29 volts.
Voltage drop across ballast tube (pins Nos. 3, 7)—49 volts.
Voltage drop across pilot light section (pins Nos. 8, 7)—4 volts.

ADJUSTMENTS

An oscillator with frequencies of 456, 600, 1425 and 15,000 kc should be used.
In addition an output meter should be used across the voice coil or output transformer for observing maximum response.
The set's oscillator is higher in frequency than the signal, so images should be observed on the low frequency side of the signals.
Always choose the minimum capacity peak on oscillator trimmers and maximum capacity peaks on antenna trimmers. The last motion in adjusting trimmers should always be a tightening one, not a loosening one.
Always use as weak a test signal as possible during alignment.
Never leave a trimmer with the outside plate so loose that there is no tension on the screw. Either bend the plate up or remove the screw entirely.

Location of Coils and Trimmer Adjustments

The broadcast antenna coil, the short-wave antenna coil and the 456 kc wave trap are one assembly mounted underneath the chassis deck to the right of the variable condenser. The trimmers for these coils are accessible through three holes in the top of the chassis. The trimmer closest to the front of the chassis is for the short-wave antenna coil. The central trimmer is for the broadcast antenna coil and the trimmer farthest from the chassis front is for the 456 kc wave trap.
The broadcast oscillator and short-wave oscillator coils are wound on one form and mounted on the inside of the rear chassis wall. The trimmers for these coils are accessible through two holes in the rear chassis wall. The left-hand trimmer (looking at the rear wall) is for the short-wave oscillator coil and the right-hand trimmer is for the broadcast oscillator coil.
The two i-f transformers are in oblong coil cans located on the top of the chassis. The first i-f transformer is the one behind the variable condenser. The trimmers for these transformers are accessible through holes in the tops of the cans.
The broadcast series padding condenser is located on the rear wall of the chassis below the 6A7 tube.

I-f Transformer and Wave-Trap Alignment

Turn the switch clockwise to the broadcast position and rotate the variable condenser to the minimum capacity position. Feed 456 kc to the grid cap of the 6A7 tube and adjust the four i-f trimmers for maximum response. Feed 456 kc to the antenna and adjust the wave-trap trimmer (rear screw beside variable condenser) for minimum response.

Short-Wave Alignment

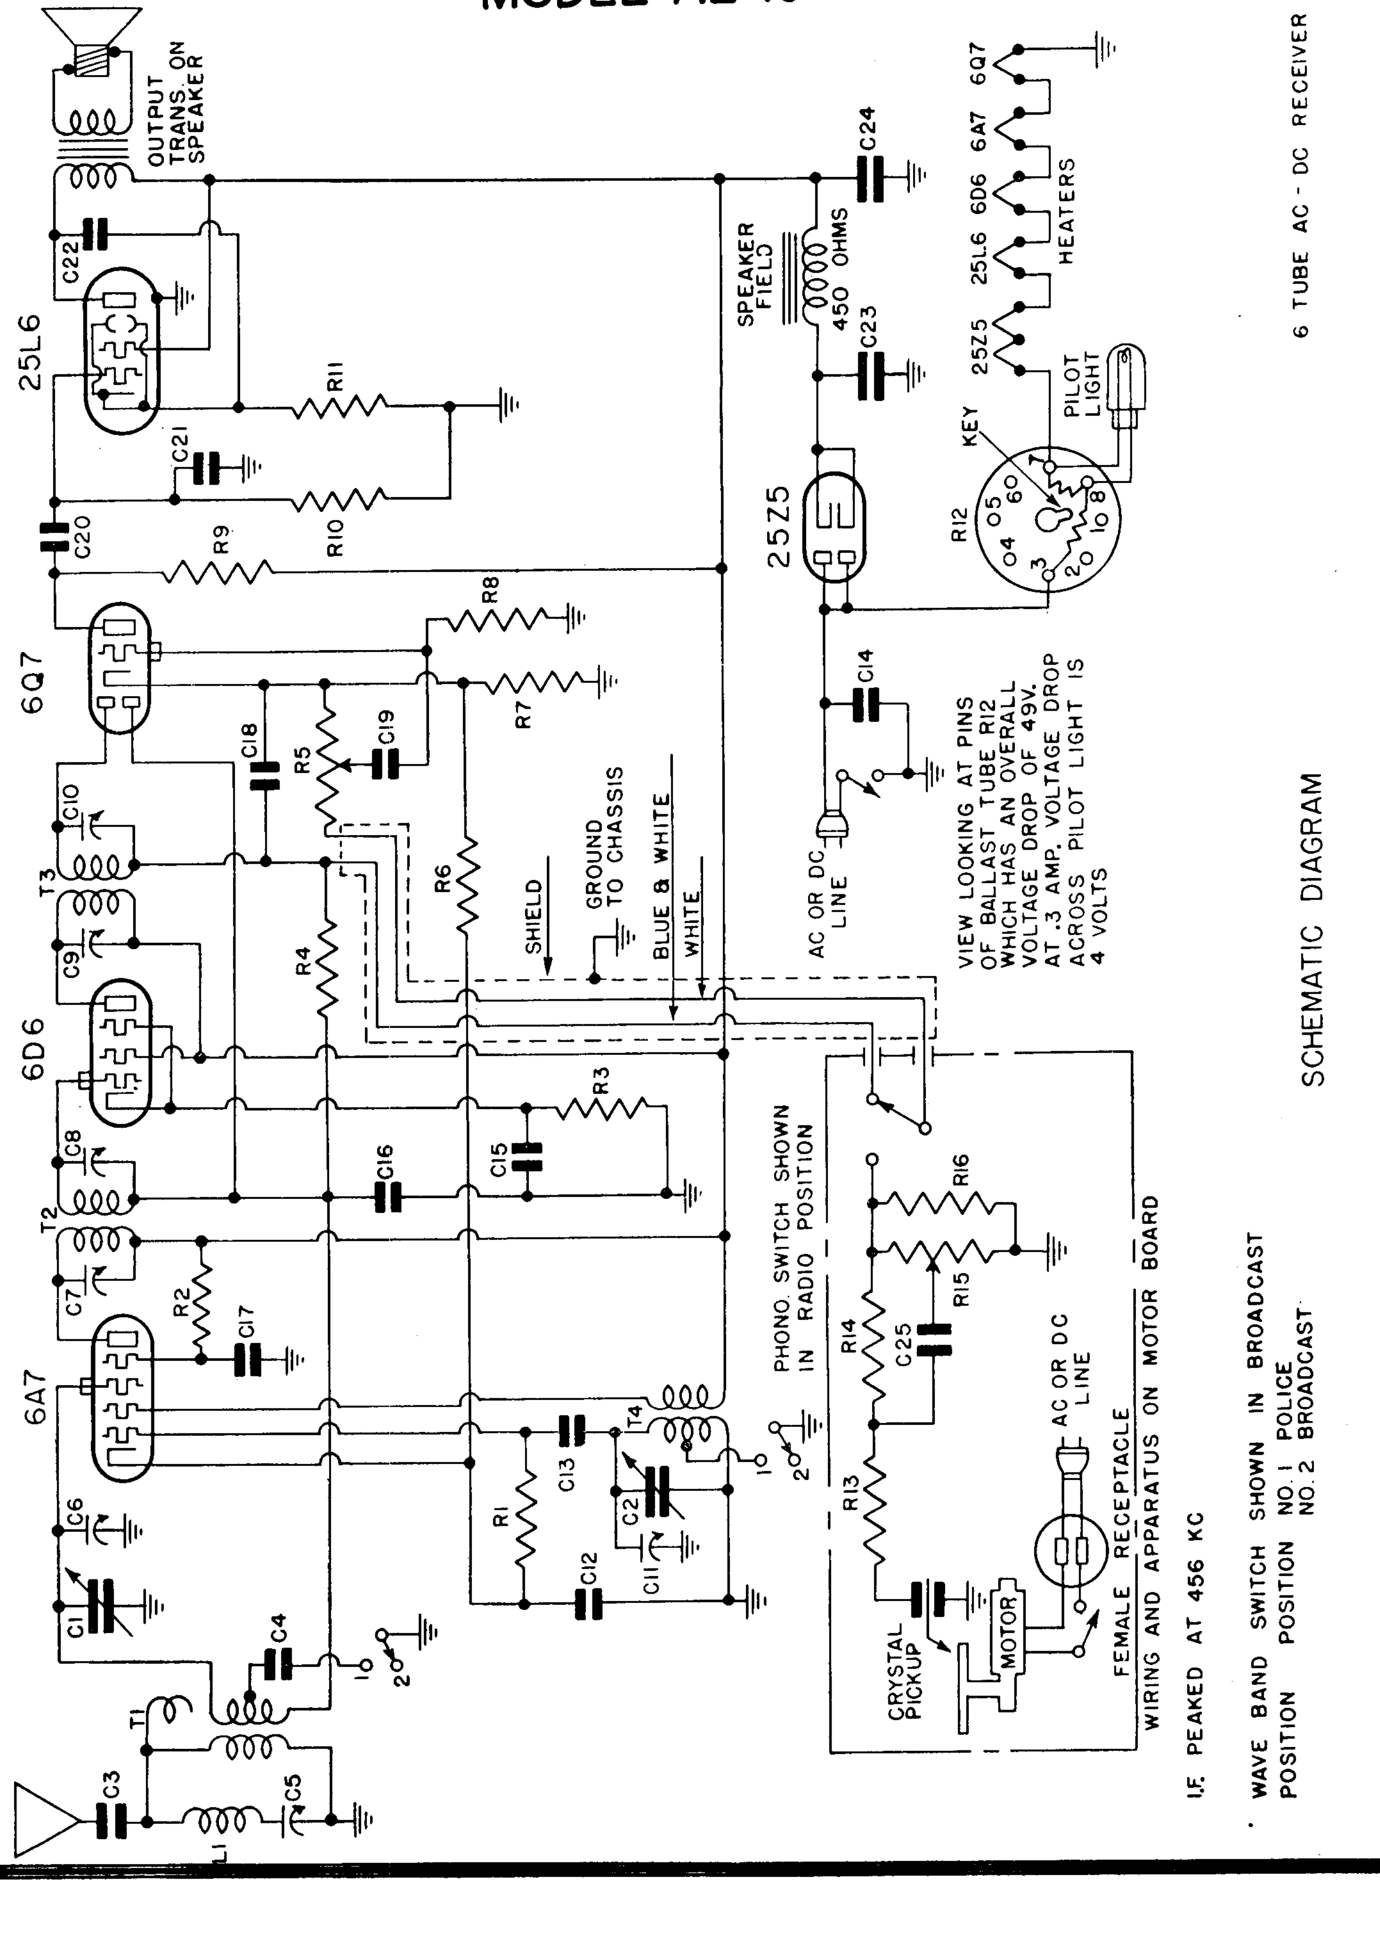
Use a dummy antenna (400 ohm resistor) when aligning the short-wave coils.
Rotate the wave-band switch counter-clockwise to the short-wave position and set the dial pointer to 15 megacycles. Feed 15 megacycles through the dummy antenna and adjust the short-wave oscillator trimmer (left-hand screw on rear chassis wall) for maximum response and then adjust the short-wave antenna trimmer (front screw beside variable condenser) for maximum response. The variable condenser should be rocked while adjusting the antenna trimmer. (Rotate variable condenser rotor shaft back and forth through a small arc).

Broadcast Alignment

Rotate the wave-band switch to the broadcast position, clockwise, and set the dial pointer at 60. Feed 600 kc through a standard dummy antenna (a .0002 mf condenser may be used as a substitute).
Adjust the broadcast series padding condenser (on rear chassis wall, below 6A7 tube) for maximum response. Move pointer to 142.5, feed 1425 kc and adjust the broadcast oscillator trimmer (right-hand screw on rear chassis wall) for maximum response and then adjust the broadcast antenna trimmer (central screw beside variable condenser) for maximum response. Return pointer to 60, feed 600 kc and readjust the series padding condenser rocking the variable condenser for maximum response.

EMERSON RADIO AND PHONOGRAPH CORPORATION

MODEL AL-164



EMERSON RADIO AND PHONOGRAPH CORPORATION

MODEL AL-164

Voltage rating	105 to 125 volts a.c. or d.c.
Power consumption	43 watts for receiver and 26 watts for motor
Frequency range	540 to 1580 kc (See paragraph 11 in General Notes below)

GENERAL NOTES

1. If replacements are made or the wiring disturbed in the r-f portion of the circuit, the receiver should be carefully re-aligned.
2. One side of the power line is directly grounded to the chassis base. Under no circumstances, therefore, should a ground wire be permitted to come in contact with any metal part of the receiver.
3. The filament dropping resistor (R12 on schematic) is in a special metal tube at the rear of the chassis. This tube will become quite hot under normal operating conditions. For voltage drop specifications, see below.
4. When operating the receiver on d.c. it may be necessary to reverse the line plug to obtain the correct polarity.
5. The two i-f transformers are held to the chassis by snap-on fasteners. To remove an i-f, unsolder its leads under the chassis, pinch together the prongs of the snap-on fastener and lift the i-f can from the chassis.
6. The color coding of the i-f transformer leads is as follows:
   Grid—green Plate—blue
   Grid return—black B plus—red
7. The receiver is shipped with an attached antenna wire. In some locations near powerful local stations the addition of a very large antenna may be detrimental to reception, because of the resulting interference. The Emerson Flexible Mast Antenna, Model W-82, has been especially designed for Emerson receivers, featuring compactness and portability while at the same time retaining a high efficiency from the standpoint of performance. Since it functions as an outside antenna the Flexible Mast will substantially improve the receiver performance. Where the Flexible Mast is installed permanently, it is urgently recommended that the receiver antenna wire be cut. Leave just enough of this wire to reach from the receiver to the window strip connector. Instructions for the installation of this compact and efficient outside antenna are supplied with each kit.
8. The wave-trap in the receiver has been adjusted for maximum signal rejection at 456 kc. If, however, persistent interference is experienced from some particular telegraphic station, readjust the wave-trap trimmer until the response from the interfering station is at a minimum.
9. The phonograph motor has been adjusted at the factory, to turn at a speed of 78 r.p.m. The speed may be checked by counting the turns per minute or by using a stroboscope disc and a neon light (the stroboscope method will only work when the neon bulb is lighted from a 60 cycle a.c. supply).
10. An a.c.-d.c. switch is provided to switch the motor for a.c. or d.c. power supply. It is important that this switch be in the proper position for the power supply available.
11. The receiver in this combination is designed to cover two frequency ranges, but since it is represented as a single band receiver only, the short-wave band, although available, may be ignored.

Tube Data

The tube complement is as follows:
1—6A7 pentagrid oscillator-modulator.
1—6D6 first i-f amplifier.
1—6Q7 diode detector, a-f amplifier, a.v.c.
1—25L6 beam power output.
1—25Z5 dual half-wave rectifier.
1—2UR-224 ballast tube (R12 on schematic).

Unless otherwise specified all octal-base tubes may be replaced with either metal or octal-base glass tubes.

VOLTAGE ANALYSIS

Readings should be taken with a 1000 ohms-per-volt meter. Voltages listed below are from point indicated to ground (chassis) with the volume control turned on full and no signal. Line voltage for these readings was 117.5 volts, 60 cycles, a.c.

Tube	*Plate*	*Screen*	*Cathode*	*Osc. Plate*	*Fil.*
6A7	100	50	2.3	100	6.3
6D6	100	100	3.5	—	6.3
6Q7	43	—	1.2	—	6.3
25L6	92	100	6.5	—	25.0

Voltage at 25Z5 cathode—130 volts.
Voltage across speaker field—28 volts.
Voltage drop across ballast tube (pins Nos. 3, 7)—49 volts.
Voltage drop across pilot light section (pins Nos. 8 and 7)—4 volts.

ADJUSTMENTS

An oscillator with frequencies of 456, 600 and 1400 kc should be used.

An output meter should be used across the voice coil or output transformer for observing maximum response.

The set's oscillator is higher in frequency than the signal, so images should be observed on the low frequency side of the signals.

The last motion in adjusting trimmers should always be a tightening one, not a loosening one.

Never leave a trimmer with the outside plate so loose that there is no tension on the screw. Either bend the plate up or remove the screw entirely.

Always use as weak a test signal as possible during alignment.

Use a .0001 mf mica condenser as a dummy antenna during alignment.

Location of Coils and Trimmer Adjustments

The two i-f transformers are in oblong coil cans located on top of the chassis deck. The first i-f transformer is the one behind the variable condenser. The trimmers for these transformers are accessible through holes in the tops of the cans.

The 456 kc wave-trap is mounted on the right side of the front chassis wall. Its trimmer is accessible at the bottom of the chassis.

The antenna coils for the broadcast and police bands are wound on one form and are mounted underneath the chassis deck below the variable condenser.

The oscillator coils for the broadcast and police bands are wound on one form and are mounted on the rear wall of the chassis deck near the variable condenser.

The trimmers for the broadcast antenna and oscillator coils are located on the variable condenser. The trimmer on the front section is for the antenna coil.

I-f Transformer and Wave-Trap Alignment

Turn the switch clockwise to the broadcast position and rotate the variable condenser to the minimum capacity position. Feed 456 kc to the grid cap of the 6A7 tube and adjust the four i-f trimmers for maximum response. Feed 456 kc to the antenna and adjust the wave-trap trimmer for *minimum* response.

R-f Alignment

With the wave-band switch in the broadcast position, clockwise, set the dial pointer at 140. Feed 1400 kc through a .0001 mf condenser to the antenna lead and adjust first the oscillator trimmer (on rear section of variable condenser) then the antenna trimmer (on front section of variable condenser) for maximum response. The police band is self-tracking and does not require any adjustment.

PARTS LIST

List Price as. Effective as of Sept. 1st, 1937 (Subject to change without notice)

*Item	Part No.	DESCRIPTION	PRICE
T1	3RT-384	Two-band antenna coil	$ .85
T2	3RT-320B	456 kc first i-f transformer	1.10

MODELS 5C & 6A

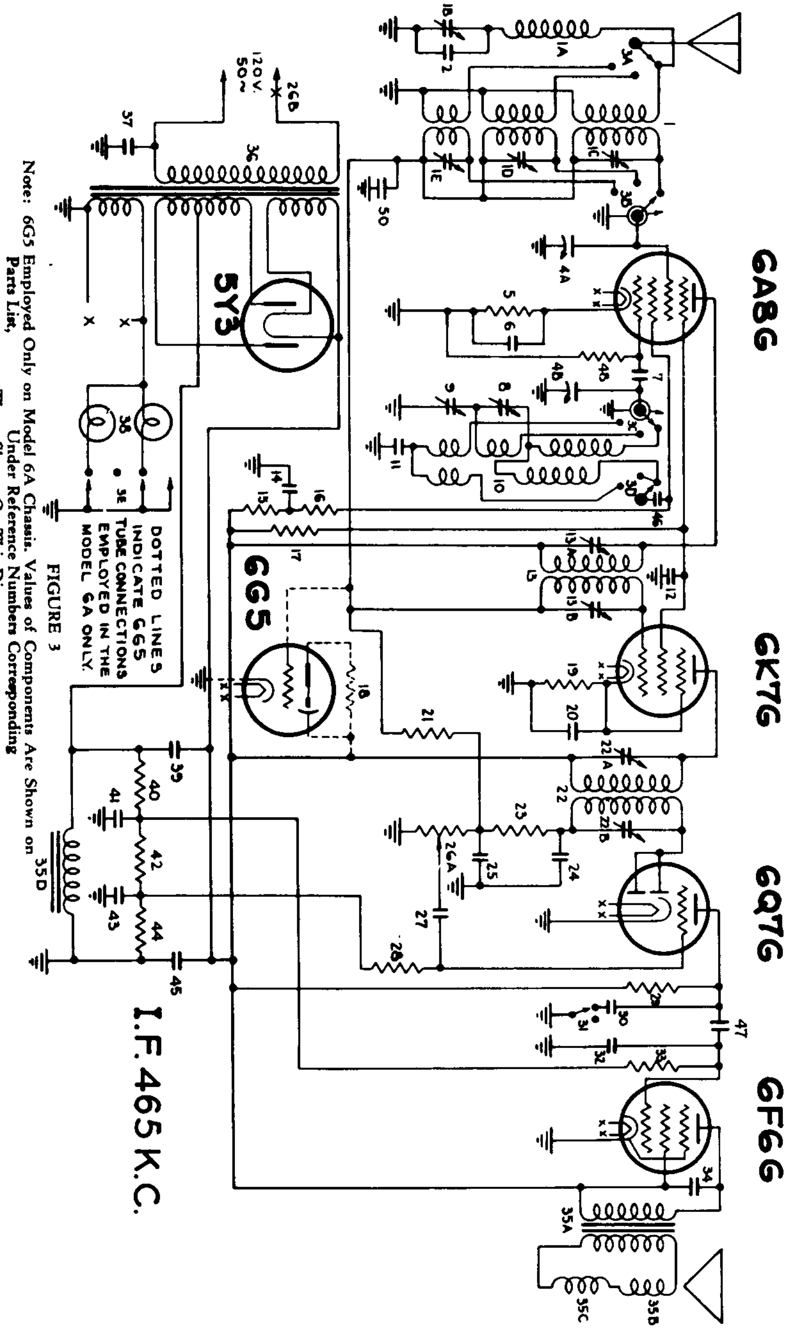

FIGURE 3

Note: 6G5 Employed Only on Model 6A Chassis. Values of Components Are Shown on Parts List, Under Reference Numbers Corresponding to Those Shown On This Diagram.

ELECTROLYTIC CONDENSER COLOR CODE

(ALL OTHER COLOR CODES—STANDARD R. M. A.)

With the positive (+) or center solder lug toward you, read the colored markings as follows from left to right:

LEFT HAND OR CAPACITY COLOR

Black	0 to 9 mfd.
Brown	9 to 19 mfd.
Red	19 to 29 mfd.
Orange	29 to 39 mfd.
Yellow	39 to 49 mfd.

SECOND FROM LEFT OR MAXIMUM VOLTAGE COLOR

Black	0 to 99 volts
Brown	99 to 199 volts
Red	199 to 299 volts
Orange	299 to 399 volts
Yellow	399 to 499 volts
Green	499 to 599 volts

If a third (blue) stripe is shown, the condenser is a regulator and should be in the position farthest from the rectifier tube in the filter circuit.

FAIRBANKS, MORSE & CO., HOME APPLIANCE DIVISION
MODELS 5C & 6A

The models 5C and 6A are AC operated, superheterodyne chassis with automatic volume control. These receivers operate on three bands—broadcast, police-amateur, and short wave. The 6A has the tuning eye, Figures 3 and 4; the 5C does not. Otherwise, the two chassis are identical.

Alignment procedure is given below in chart form, Figures 1 and 2. Make adjustments in the order given. The output meter may be any low range AC voltmeter, preferably about 0-15 volts. It should be connected from the plate of the 6F6G tube to ground with a .1 mfd. condenser in series with one of the leads. When the hand tends to go off scale, reduce the input from the signal generator and keep the volume control at maximum. If too strong a signal is fed to the receiver and the volume control is used to keep the output meter hand on scale, the A. V. C. will operate and inaccurate alignment will result.

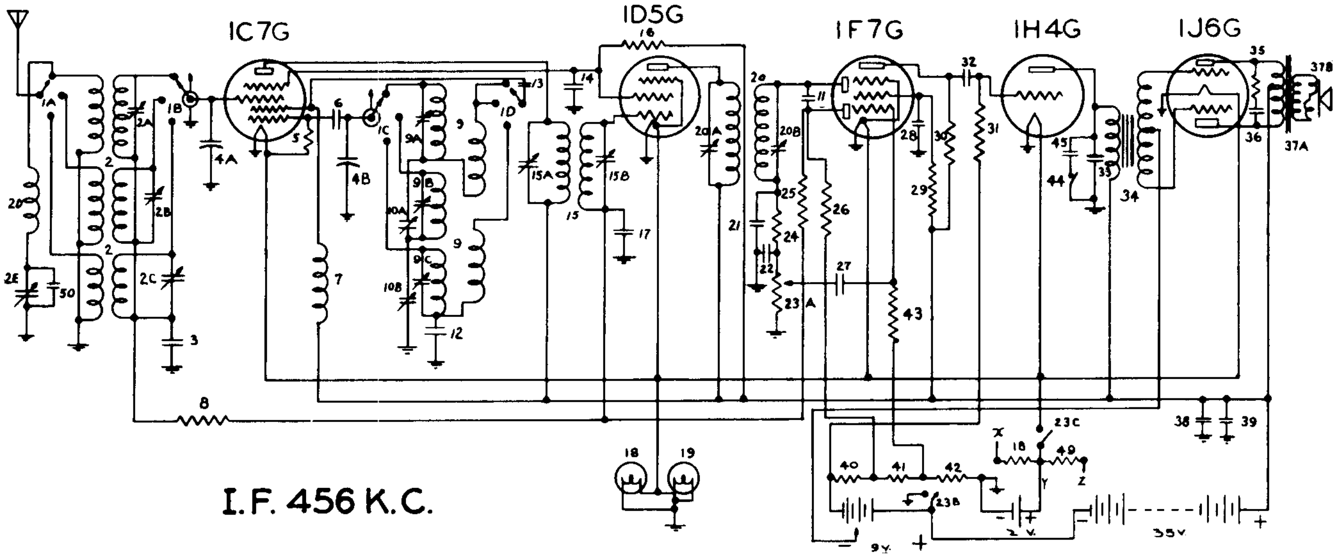
MODEL 5D



I. F. 456 K.C.

The model 5D is a battery operated superhetrodyne with automatic volume control. It receives signals on three bands—broadcast, police-amateur, and short wave.

Alignment procedure is given below in chart form, figures 1 and 2. Make adjustments in the order given. The output meter may be any low range AC voltmeter, preferably about 0-15 volts. It should be connected across the two plates of the 1J6G tube with a .1 mfd. condenser in series with one of the leads. Set the volume at maximum during the alignment and as the meter hand tends to go off scale, decrease the output from the signal generator. If too strong a signal is fed to the receiver and the volume control is used to keep the output meter hand on scale, the AVC will operate and inaccurate alignment will result.

BATTERIES AND CONNECTIONS

AIR CELL "A" BATTERY. If the receiver is to be operated on an Air Cell Battery, only one section of the "resistance link" circuit should be connected. (See "X," Figure 2.) The remaining two leads from the positive (+) "A" lead should be taped or otherwise insulated so they will not come in contact with any of the battery terminals.

TWO-VOLT STORAGE "A" BATTERY. If the receiver is to operate on a Two-Volt Storage "A" Battery, none of the "resistance link" circuit is to be used. The positive (+) "A" connection is to be made as shown under "Y" of Figure 2. The unused leads should be taped so they will not come in contact with the other battery terminals.

THREE-VOLT "A" BATTERY (DRY). If the receiver is to be operated on a Three-Volt "A" Battery, the "resistance link" circuit should be connected as shown under "Z" of Figure 2. The unused leads should be taped so they will not come in contact with any of the battery terminals.

When the Three-Volt "A" Battery becomes so low or weak that the receiver will no longer operate satisfactorily, the connections may then be changed to conform with "X" under Figure 2, thus obtaining a little more operating time from the battery.

When the Three-Volt "A" Battery again becomes so low that the receiver will not operate satisfactorily, the connections may once again be changed to conform with "Y," Figure 2, thus obtaining more operating time from the battery.

NOTE—These changes must not be made until the battery becomes so low that the receiver does not operate properly, and then the change must be made one step at a time as described above, otherwise the tubes in the receiver may be damaged.

"A" battery current consumption may be reduced approximately 18 per cent. by removing both dial light bulbs.

"B" BATTERIES. Three 45-volt "B" Batteries, with standard plug receptacles, are required with the receiver. Good quality, HEAVY DUTY batteries are recommended.

"C" BATTERIES. Two 4½-volt "C" Batteries, with standard plug receptacles are required with the receiver.

"A" BATTERY (2-VOLT). The Black battery lead is to be connected to "A" minus (—). The Red battery lead is to be connected to "A" plus (+).

"B" AND "C" BATTERIES. Five standard battery plugs will be found on the battery cable. While each has three prongs, it will be noted that three of the plugs have prongs which are all the same size. These are the "B" battery plugs and are to be plugged into the standard receptacles on the three 45-volt "B" batteries. The remaining plugs, each having one large prong and two small ones are to be plugged into the standard receptacles on the $4\frac{1}{2}$-volt "C" batteries.

WARNING—DO NOT ALLOW THE "A" BATTERY LEADS TO COME IN CONTACT WITH ANY OF THE "B" BATTERY TERMINALS. IF THIS HAPPENS THE TUBES, RECEIVER, AND BATTERIES MAY BE SERIOUSLY DAMAGED.

ALIGNMENT PROCEDURE

Volume Control—Maximum All Adjustments.
Selectivity Control—Sharp Position All Adjustments.
Connect Radio Chassis to Ground Post of Signal Generator with a Short Heavy Lead.
Allow Chassis and Signal Generator to "Heat Up" for Several Minutes.

The following equipment is required for aligning:
An All Wave Signal Generator which will provide an accurately calibrated signal at the test frequencies as listed.
Output Indicating Meter — Non-Metallic Screwdriver.
Dummy Antennas — .1 mf., 200 mmf., and 400 ohms.

STEP (Follow Order as Given)	BAND SWITCH SETTING	DUMMY ANTENNA	SIGNAL GENERATOR FREQUENCY SETTING	SIGNAL GENERATOR CONNECTION AT RADIO	TRIMMERS ADJUSTED See Illustration	PROCEDURE INITIAL STEPS	PROCEDURE ADJUSTMENT
I. F.							
2nd I.F. Adj.	Range B	.1 mf.	456 KC	Grid of I.F. Tube	2nd I.F. (C29) & (C30)	Turn Rotor to Full Open	Adjust to Maximum Output
1st I.F. Adj.	Range B	.1 mf.	456 KC	Grid of 1st Det.	1st I.F. (C23) & (C24)	Turn Rotor to Full Open	Adjust to Maximum Output
RANGE B

20,000 KC	Range D	400 Ohm	20,000 KC	Antenna Lead	Antenna Range D (C2)	Turn Rotor to Max. Output	Adjust to Maximum Output Rock Rotor — See Note B
7000 KC	Range D	400 Ohm	7000 KC	Antenna Lead	7000 KC (C8)	Turn Rotor to Max. Output	Adjust to Maximum Output Rock Rotor — See Note B

Attenuate the signal from the signal generator to prevent the leveling-off action of the AVC.

After each range is completed, repeat the procedure as a final check.

NOTE A—In sets using the telephone dial tuning, there will be seen inside the telephone dial button ring an escutcheon plate held in place by four screws. Loosen the 2 screws nearest the pointer. An extension of the pointer will be seen protruding over the edge of this escutcheon plate. Move the pointer to the 1500 KC mark on the dial and then tighten the 2 escutcheon screws. (Do not tighten these screws too much.)

In sets using the moving beam of light indicator, there is a moving light assembly held to the front of the drive drum by means of a screw. Loosen this screw and move the light assembly until the beam is at the 1500 KC mark on the dial. Retighten the screw.

NOTE B—Turn the rotor back and forth and adjust the trimmer until the peak of greatest intensity is obtained.

CAUTION—When aligning the short wave bands, be sure NOT to adjust at the image frequency. This can be checked as follows: Let us say the signal generator is set for 5000 KC. The signal will then be heard at 5000 KC on the dial of the radio. The image signal, which is much weaker, will be heard at 5000 less 912 KC, or 4088 KC on the dial. It may be necessary to increase the input signal to hear the image.

NOTICE—Re-alignment is necessary if glass tubes are replaced by their equivalent in metal tubes, or vice versa, in the R.F. and I.F. stages.

MODEL AI SERIES

SPECIFICATIONS

Power Consumption - 67 Watts (At 117 volts 60 cycles)
Power Output - - - - 2.5 Watts Undistorted, 4.5 Watts Maximum
Selectivity - 30 KC Broad at 1000 times Signal (Sharp)
Intermediate Frequency - - - - 456 KC.
Speakers - - - - 8", 10" or 12" Dynamic

Tuning Frequency Range
B Range .... 528 to 1830 KC.
C Range .... 1810 to 6350 KC.
D Range .... 6300 to 22000 KC.

Sensitivity
B Range .... 8 Microvolts Average
C Range .... 13 Microvolts Average
D Range .... 9 Microvolts Average

Circuit

This model is a three band AC operated radio with a tuning range as shown in the specifications above.

Referring to the schematic circuit diagram, Fig. 2, T1 and T7 are the antenna coil assemblies and T2 is the oscillator coil assembly. The standard wave, 1st and 2nd short wave coils in each assembly are indicated by the letters B, C and D respectively.

The band switch completes connections to the coils in use. When it is in the Range B position, a double tuned antenna R.F. stage is used while for the C and D Ranges, a single tuned secondary is used.

A type 6J7 tube functions as the 1st detector.

A separate type 6C5 tube is employed in the oscillator circuit. The oscillating circuit is always resonant at 456 KC above the frequency to which the R.F. amplifier is tuned.

One stage of I.F. amplification is employed using a 6K7 tube. The primaries and secondaries of the 1st and 2nd I.F. transformers are tuned by small trimmer condensers.

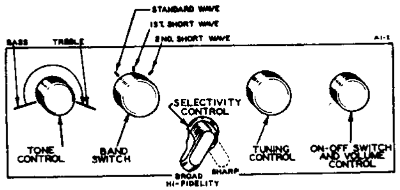

Fig. 1—Arrangement of Controls

Referring to Fig. 2, it will be noted that there is a coupling winding connected in series with the secondary of I.F. transformer T3. When the selectivity control is in the sharp position, the coupling winding is open circuited and the loose coupling which exists between the primary and secondary of this transformer results in high selectivity.

When the selectivity control is in the broad position, the coupling winding which is wound under the primary is connected in series with the secondary. This provides overcoupling which results in a greatly widened resonance curve. Passage of a wide range of audio frequencies is thus obtained.

A 6H6 tube functions as a diode 2nd detector. AVC voltage is applied to the control grid circuits of the 1st detector and I.F. tubes.

A 6F5 triode tube functions as the first audio amplifier while the output stage uses a 6F6 output pentode tube. A dynamic reproducer is employed.

The power unit uses a 5Y3G full wave rectifier. A 6G5 tuning indicator tube is employed.

Glass and Metal Tubes

All sets of this series use a 6H6 metal tube and 5Y3G and 6G5 glass tubes.

It will be noted in the schematic that there are two tube type numbers shown at the other sockets. The "metal" tube sets use the upper tube type numbers which are for metal tubes while the "glass" tube sets use the lower tube type numbers which are for glass tubes.

Re-alignment is necessary if glass tubes are replaced by their equivalent in metal tubes, or vice versa, in the R.F. and I.F. stages.

General Service Data

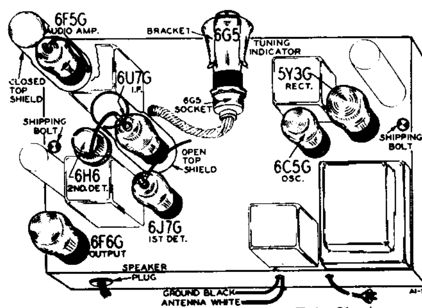

Fig. 4—Location of Tubes—Glass Tube Chassis

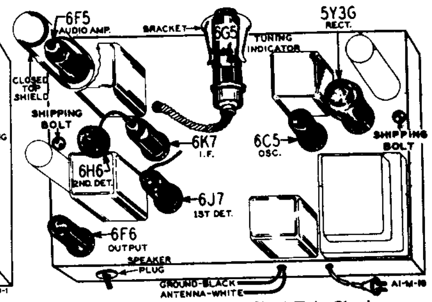

Fig. 6—Location of Tubes—Metal Tube Chassis

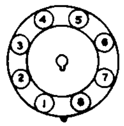

Fig. 5—Octal Tube Terminal Numbering (bottom of socket)

Twenty-five Cycle Models

The twenty-five cycle receiver differs from the sixty cycle receiver only in the fact that a different power transformer is used.

The twenty-five cycle receiver can be operated satisfactorily from a sixty cycle power supply. However, the reverse is not true, the sixty cycle receiver cannot be operated from a twenty-five cycle power supply.

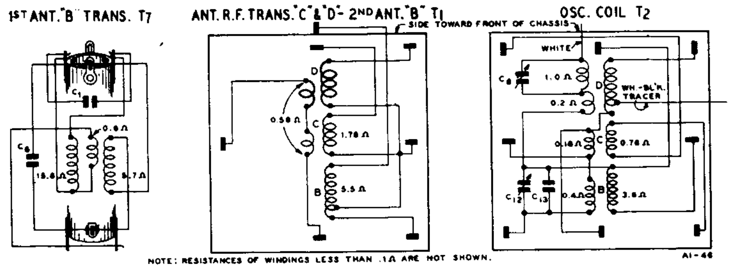

Fig. 7—Coil Terminal Arrangement and D.C. Resistance of Windings

Phonograph Connections

Phonograph connections are made as shown in the schematic circuit diagram Fig. 2. On the side panel of the chassis base is a round knockout 1⅛ inches in diameter. An octal base socket is mounted in this knockout opening and wired as shown in the schematic.

A phono cable assembly may then be purchased (see parts list). On one end of this cable is an octal plug and on the other end is a phonograph-radio switch and double tip jack.

Some models are shipped from the factory equipped with the phono socket. A jumper is inserted in this socket which must be removed if the phonograph installation is made—See Fig. 2.

Early Models—A few of the early models did not have the circular knockout for the phonograph socket as mentioned above. If a phonograph installation is to be made in connection with one of these early models, write the factory for detailed instructions.

117-234 Volt Power Transformers

Some models are equipped with a 117-234 volt 40 to 60 cycle power transformer. Connections as shown in Fig. 2 are completed to a special octal socket mounted on the back panel of the chassis. A plug which goes with this socket may then be inserted for either the 117 volt or 234 volt connection.

If one of these transformers is to be installed in a chassis equipped with a regular transformer, there is a 1⅛ inch round knockout on the back panel which may be removed to permit installation of the octal socket mentioned above.

Dial and Drive Assembly

Complete information regarding the dial and drive assemblies will be found in the Dial and Drive Service Manual issued for this chassis.

DESCRIPTION OF ELECTRICAL CIRCUIT

The signal from the antenna is applied to the control grid of the 6A8 tube through the R.F. transformer, the secondary of which is tuned to the incoming signal by the rear section of the main tuning condenser. In the 6A8 tube the incoming signal is combined with the local oscillator signal which is 465 kc. higher in frequency. The local signal is generated by the oscillator section of this tube, and the proper frequency difference is maintained throughout the tuning range by the front section of the tuning condenser in conjunction with the oscillator coils. The special-cut rotor of the front condenser section permits dispensing with the usual padding capacitor.

The combination of the two signals produces the intermediate frequency of 465 kc. This particular frequency is chosen to reduce image response and improve short-wave performance. The intermediate frequency amplifier consists of a 6K7 tube and two transformers, both of which have tuned primaries and secondaries. Volume is controlled by the 4500-ohm variable resistor, R-1, which varies the bias applied to the control grids of the 6A8 and 6K7 tubes.

The output of the I.F. amplifier is applied to the grid of the 6C5 detector which is properly biased for this service by the .1 megohm cathode resistor, R-6.

The output of the 6C5 detector is resistance coupled to the grid of the 6F6 power amplifier pentode. The plate circuit of the 6F6 is suitably matched to the loud-speaker by means of a step-down output transformer.

The tone control circuit consists of a .002 mfd. capacitor, connected in series with a two-point grounding switch, S-3, in the grid circuit of the 6F6 power pentode. When it is desired to reduce the high frequency output of the receiver, the switch, S-3, is turned to its counterclockwise grounding position.

Plate and grid voltages for all tubes are supplied by the power supply system employing a 5W4 full-wave rectifier tube which, together with a suitable network of resistors and capacitors, supplied the required voltages and filtering action.

ALIGNMENT PROCEDURE

Before making any adjustments to the R.F. circuits, it is wise to determine the correctness of the existing alignment. This may be done by supplying a signal from the test oscillator to the receiver and inserting a "tuning wand" into the antenna coil. The "tuning wand" consists of a bakelite rod having a brass cylinder attached to one end, and a small core of finely divided iron compacted into the opposite end. By inserting the brass cylinder end into the antenna coil, the inductance is lowered, increasing its resonant frequency. Inserting the iron-filled end into the coil raises its inductance, lowering its resonant frequency. If the circuits are in exact alignment, inserting either end of the tuning wand in the coil will result in a decrease in output. When an increase in signal is obtained with the iron-filled end of the wand at the 1500-kc. point or the 4.0-mc. point, a decrease in resonant frequency of that circuit by increasing the antenna trimmer capacity is indicated. When an increase in signal is obtained with the brass cylinder, a decrease in antenna trimmer capacity is indicated.

Changes Indicated by Wand

Wand	Signal	Trimmer Adjustment Required
Brass cylinder Iron filings	Decrease Decrease	None
Brass cylinder Iron filings	Increase Decrease	Decrease capacity
Brass cylinder Iron filings	Decrease Increase	Increase capacity

ALIGNMENT FREQUENCIES

I.F.	Broadcast	Short-wave
465 Kc.	1500 Kc.	4000 Kc.

In order to align these receivers properly it is necessary to have available:

1. A modulated test oscillator capable of producing the above alignment frequencies.
2. An output indicator, such as a high-resistance a-c voltmeter with a maximum scale reading of 3 to 5 volts, or a neon lamp indicator.
3. An alignment tool consisting of an insulating shaft with a small screwdriver blade.

The location of all alignment trimmer capacitors are illustrated in Fig. 2.

(1) *I.F. Alignment*

Set the frequency band switch of the receiver to the broadcast position and turn the volume control to maximum (extreme clockwise position). Tune the receiver to a point where no signal comes in and short-circuit the antenna and ground leads.

Connect the test oscillator output between the chassis and the control grid of the 6A8 tube. Connect the output meter across the cone coil of the speaker. Set the test oscillator to 465 kc. and adjust the output until a small deflection is observed in the output meter.

The four I.F. trimmers, see Fig. 2, are adjusted in the following sequence:

1. Secondary trimmer on second I.F. transformer.
2. Primary trimmer on second I.F. transformer.
3. Secondary trimmer on first I.F. transformer.
4. Primary trimmer on first I.F. transformer.

Throughout all adjustments the output should be maintained at a low level by decreasing the test oscillator output as the various stages are brought in line. After these adjustments have been made, the same procedure should be repeated as a final check. The I.F. alignment will then be complete.

(2) *I.F. Wave Trap*

No adjustable trimmer is provided for the I.F. trap adjustment in this receiver. The capacitor C-27, in conjunction with the inductance, L-1, automatically provides rejection of incoming I.F. signals.

(3) *R.F. Alignment*

The Ant. and oscillator trimmers are aligned at 1500 kc. First of all, check the position of the dial pointer. To do this, rotate the gang condenser to the maximum capacity position, i.e., plates fully meshed. While in this position, align the pointer with the last black line on the scale by loosening the dial drum set screws and rotating the drum on the gang shaft. Remove the short-circuit from the antenna and ground terminals and connect the test oscillator to same through a dummy antenna consisting of a 400-ohm resistor in series with a 250-mmf. capacitor. Connect the output indicator across the speaker cone coil.

(*a*) *Broadcast Band—(540-1800 Kc.)*

With the band switch in the clockwise position, set the tuning indicator to 1500 kc. Set the test oscillator at 1500 kc. and adjust the broadcast band oscillator trimmer, C-4 for maximum output. Next, set the Ant. trimmer, C-3, for maximum output, taking care that the output from the test oscillator is not high enough to overload any part of the set. No padding adjustment is required.

To complete the broadcast band line-up, repeat the Ant. trimmer adjustment after aligning the short-wave band.

(*b*) *Short-wave Band (1800-4000 Kc.)*

Turn the band switch to its counterclockwise position. Set the test oscillator at 4000 kc. and tune the receiver to resonate at this frequency. No trimmer is provided for short-wave oscillator alignment. To perform the Ant. short-wave adjustment, rock the tuning condenser back and forth through resonance while adjusting the short-wave Ant. trimmer, C-5, for maximum output indication on the tuning meter. It may now be necessary to readjust the broadcast band Ant. trimmer as indicated above.

Alignment of the receiver is now complete.

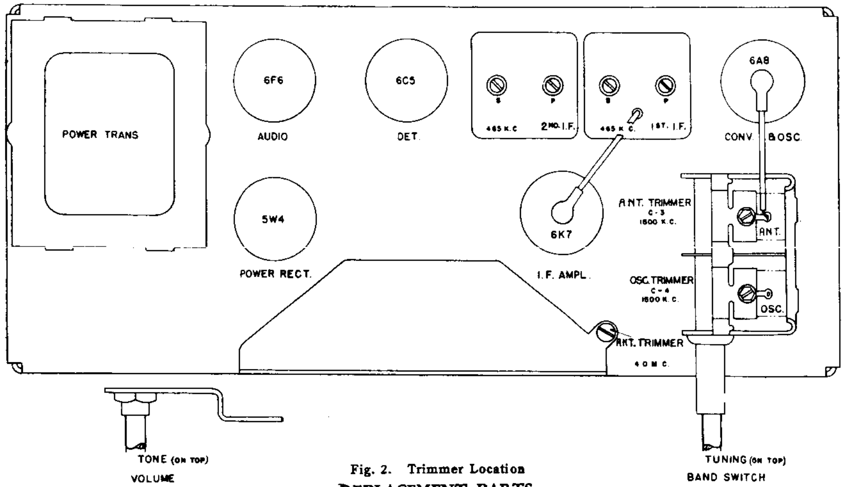

Fig. 2. Trimmer Location

REPLACEMENT PARTS

GENERAL INFORMATION

These two-band receivers employ six General Electric tubes described above in a superheterodyne circuit which includes a single stage of I.F., automatic volume control, four-point tone control, wave trap and pentode output.

L1, L2 and L3 are the components of the "B" band antenna coil and are wound on the same coil form. When operating in the "C" band, L3 and a part of L2 are shorted out by the wave change switch. L4–L5 and L6–L7 are the "B" and "C" band oscillator coils respectively and are wound on the same coil form. The "B" band oscillator grid coil is shorted out by a contact of S-1 when the set is operating on the "C" band.

The intermediate frequency amplifier consists of a 6K7 tube and two transformers, both of which have tuned primaries and secondaries. The output of this amplifier is applied to one plate of the 6H6 diode which is a combined detector, initial bias and automatic volume control tube.

Volume is controlled by the variable potentiometer R-5 in the grid circuit of the 6F5 1st audio amplifier tube. The output of the 6F5 tube is resistance coupled to the grid of the type 41 power amplifier pentode. The plate circuit of the 41 tube is suitably matched to the loud-speaker by means of a step-down output transformer.

Proper bias voltages for the various tubes are obtained by the use of a tapped bleeder circuit across the speaker field L14. One of the cathodes of the 6H6 diode is returned to −3.1 volts on this bleeder circuit in order to provide initial bias to all the tubes controlled by the A.V.C.

Tone Control

When the tone control switch is in the "normal" position, a portion of the output voltage of the receiver is fed back through a resistor-capacitor network consisting of C-15, R-16 and R-6 to a tap on the volume control. This feed back voltage is out of phase with the input and the resulting degeneration improves the frequency characteristic and reduces distortion. In the "bass" position, the tone control switch connects C-19 in parallel with the above network. The value of C-19 is such that more degeneration of the high than the low frequency notes occurs, thereby increasing the bass response. The "foreign" position of the switch shorts out C-15 and R-16 and places C-19 and R-6 in parallel which gives a frequency response best suited for short-wave reception. In the "speech" position, C-15 and R-16 are shorted out, C-19 is removed from the circuit, leaving R-6, thereby providing flat degeneration at all frequencies which is the most desirable condition for the reception of programs predominating in speech. The tone control switching described can be traced on the schematic diagram shown in Fig. 1.

ALIGNMENT PROCEDURE

In order to align these receivers properly, it is necessary to have the following test equipment:

1. A modulated test oscillator.

2. An output indicator such as an a-c voltmeter with a scale reading of 3 to 5 volts.

3. A screwdriver-type alignment tool.

To realize all the performance built into these receivers at the factory, alignment using cathode-ray equipment is to be preferred. The alignment procedure is given in table form on page 5 along with a trimmer location drawing Fig. 3. The "Dummy Antenna" is the capacitor or capacitor and resistor used in series with the signal generator antenna lead. The grid lead should not be removed from the tube to which the input signal is applied when aligning the I.F.

SOCKET VOLTAGES

Tube No.	Plate to Ground Volts D-C	Screen Grid to Ground Volts D-C	Cathode to Ground Volts D-C	Cathode Current M.A.	Heater Volts A-C
6A8 Oscillator	98	....	0	....	6.3
6A8 Converter	250	98	0	12.0	6.3
6K7 I.F. Amplifier	250	98	0	9.0	6.3
6H6 Detector and AVC	....	....	....	....	6.3

Audio Power Amplifier . . . . . 42 Power Amplifier Pentode
Rectifier . . . . . 80 Full-wave Rectifier
Dial Lamp . . . . . MAZDA No. 46

GENERAL INFORMATION

The Models F-70 and F-75 employ seven General Electric tubes described above in a superheterodyne circuit, which includes two stages of I.F and wave trap, compensated volume control, four-point tone control, and ample pentode power output.

The "B," "C" and "D" band antenna coils are wound on a single coil form designated as T-3 in Fig. 1. Coils L4, L5 and L6 are the components of the "B" band antenna coil. When operating in the "C" band, L4 is used for the grid coil while L3 acts as the antenna primary. L2 is the "D" band antenna grid coil using L3, as in the "C" band, for the antenna primary coil. T4 consisting of plate and grid coils L7 and L8 are the components of the "D" band oscillator coil. L12, L13 and L14, L15 are the "C" and "B" band oscillator coils respectively and are wound on the same coil form. The "B" and "C" band oscillator grid coils are shorted out by a contact of S1 when the set is operating in the "C" and "D" bands respectively.

The intermediate frequency amplifier consists of two 6K7 tubes and three tuned transformers. The output of the third I.F. transformer is applied to one plate of the 6H6 diode, which is a combined detector, initial bias and automatic volume control tube.

Volume is controlled by the variable potentiometer R1 in the grid circuit of the 6F5 audio amplifier tube. The output of the 6F5 is resistance coupled to the grid of the type 42 power amplifier pentode. The plate circuit of the 42 tube is matched to the loud-speaker by means of a suitable step-down output transformer.

Proper bias for the various tubes are obtained by the use of a tapped bleeder resistance (R-11). One of the cathodes of the 6H6 diode is returned to −5 volts on this bleeder in order to provide initial bias to all tubes controlled by the AVC.

Tone Control

When the tone control is in the "normal" position, a portion of the output voltage of the receiver is fed back through a resistor-capacitor network consisting of C-25, R-14 and R-13 to a tap on the volume control. This feedback voltage is out of phase with the input and the resulting degeneration reduces the speaker resonance boom due to pentode output, gives an extended and relatively flat response to a wide range of low frequencies, and reduces distortion arising in the audio amplifier. In the "bass" position, the tone control switch connects C-26 in parallel with the above network. The value of C-26 is such that more degeneration of the high than the low frequency notes occurs, thereby increasing the bass response. The "foreign" position of the switch shorts out Capacitor C-25 and Resistor R-14 and places C-26 and R-13 in parallel which gives a frequency response best suited for short-wave reception. In the speech position, C-25 and R-14 are shorted out; C-26 is removed from the circuit, leaving R-13, thereby providing flat degeneration at all frequencies which is the most desirable condition for the reception of programs predominating in speech. The tone control switching described can be traced on the schematic diagram shown in Fig. 1.

Speaker

Two different types of voice coil suspensions are used in both the 8-inch and 12-inch speakers.

The 8-inch cone assemblies are designated as early and late production and are not interchangeable. The early production voice coil suspension is 4⅝ in. between points of clamping while the later production voice coil suspension is 2⅜ in. between points of clamping.

The 12-inch cone assemblies which were changed in design during production are interchangeable.

ALIGNMENT PROCEDURE

In order to align these receivers properly, it is necessary to have the following test equipment:

1. A modulated test oscillator.
2. An output indicator such as an a-c voltmeter with a scale reading of 3 to 5 volts. A cathode-ray oscilloscope is preferred for I.F. alignment.
3. A screwdriver-type alignment tool.

The alignment procedure is given in table form on page 5 along with the trimmer location drawing, Fig. 4. A "dummy antenna" should be used in all alignments and is the capacitor or capacitor and resistor used in series with the signal generator. The grid lead should not be removed from the tube to which the input signal is applied when aligning the I.F. as this would remove the grid bias from the tube.

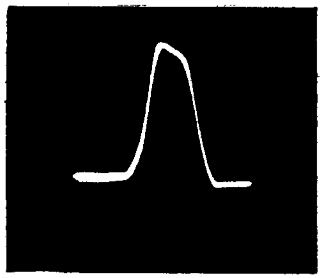

Fig. 3. Overall I.F. Curve

SOCKET VOLTAGES

Tube No.	Plate to Ground Volts D-C	Screen Grid to Ground Volts D-C	Cathode to Ground Volts D-C	Cathode Current M.A.	Heater Volts A-C
6A8 Oscillator	190	....	....	....	....
6A8 Converter	235	100	0	11	6.3
6K7 1st I.F. Amplifier	235	105	0	5	6.3
6K7 2nd I.F. Amplifier	235	105	0	7	6.3
6H6 Detector and A.V.C.	0 sig. −6 delay	....	0 sig. −6 delay	0 0	6.3
6F5 Audio Amplifier	120*	....	1.2	0.2	6.3
42 Output	250	265	16	39	6.3
80 Power Rectifier	640/320 RMS	....	335 D-C	70	5.0

A-C line voltage 120—No signal input—1000 ohms per volt-meter—dial pointer at 530 K.C.
* Measured on 500-volt scale.

ALIGNMENT PROCEDURE

Band Switch Setting	Input Freq.	Point of Input	Dummy Antenna	Trimmer	Comments
I. F. ALIGNMENT WITH OSCILLOSCOPE					
1. Band "B"	465 K.C. Sweep	2nd I.F. Grid	.05 Mfd.	3rd I.F. Sec. (C-22) 3rd I.F. Pri. (C-21)	Gang condenser plates wide open—connect vertical input of oscilloscope to ground and the junction of C-24 and R-9 on 3rd I.F. transformer. Adjust trimmers for a single symmetrical curve of maximum amplitude. The resulting curve with input at converter grid is shown in Figure 3.
2. Band "B"	465 K.C. Sweep	1st I.F. Grid	.05 Mfd.	2nd I.F. Sec. (C-20) 2nd I.F. Pri. (C-19)	
3. Band "B"	465 K.C. Sweep	Converter Grid	.05 Mfd.	1st I.F. Sec. (C-18) 1st I.F. Pri. (C-17)	
4. Band "B'	465 K.C. Sweep	Antenna Post	250 Mmf. 400 ohms	Wave Trap Trimmer (C-4)	Adjust for minimum amplitude.
I. F. ALIGNMENT WITH OUTPUT METER					
1. Band "B"	465 K.C. with Modulation	2nd I.F. Grid	.05 Mfd.	3rd I.F. Sec. (C-22) 3rd I.F. Pri. (C-21)	Gang condenser plates wide open—connect output meter across voice coil—keep input signal low and volume control at maximum. Adjust all trimmers in order mentioned for maximum output. Do not attempt an overall realignment after stage by stage alignment has been accomplished.
2. Band "B"	465 K.C. with Modulation	1st I.F. Grid	.05 Mfd.	2nd I.F. Sec. (C-20) 2nd I.F. Pri. (C-19)	
3. Band "B"	465 K.C. with Modulation	Converter	.05 Mfd.	1st I.F. Sec. (C-18) 1st I.F. Pri. (C-17)	
4. Band "B"	465 K.C. with Modulation	Antenna Post	250 Mmf. 400 ohms	Wave Trap Trimmer (C-4)	Adjust for minimum output.
R. F. ALIGNMENT					
1. Band "B"					Close gang plates—adjust pointer to first line at left end of tuning scale.
2. Band "D"	18 M.C. with Modulation	Antenna Post	250 Mmf. 400 ohms	Osc. (C-3) Ant. (C-2)	Connect output meter across voice coil—tone control on "Bass" position. The image of any "D" band signal should be heard 930 K.C. above input signal when (C-3) is on proper peak. Example: 15 M.C. image—15,930 K.C. Peak (C-2) while rocking the gang condenser.
3. Band "C"	No adjustments necessary.				
4. Band "B"	1500 K.C. with Modulation	Antenna Post	250 Mmf. 400 ohms	Osc. (C-12) Ant. (C-7)	Peak trimmers for maximum output with a low input signal.
5. Band "B"	580 K.C. with Modulation	Antenna Post	250 Mmf. 400 ohms	Osc. Padder (C-13)	Adjust padder for maximum output in vicinity of 580 K.C. while rocking the gang condenser.
6. Band "B"	1500 K.C. with Modulation	Antenna Post	250 Mmf. 400 ohms	Osc. (C-12) Ant. (C-7)	Peak trimmers for maximum output with a low input signal.

INTRODUCTION

The Grunow Chassis 6M is a six tube, three band superheterodyne receiver, using 1-6A8 1st Detector and Oscillator, 1-6K7 1st I. F. Amplifier, 1-6K7 2nd I. F. Amplifier, 1-6Q7 2nd Detector, A. V. C. and Audio Amplifier, 1-6F6 Power Output, and 1-5W4 Rectifier. The tuning range is divided into three divisions or bands covering from 550 K. C. to 1750 K. C. on the "A" or Broadcast Band, 1750 K. C. to 5.5 M. C. on the "B" or Police Amateur Band and 5.5 M. C. to 18.2 M. C. on the "C" or Foreign Broadcast Band.

SERVICE DATA

CONTINUITY AND VOLTAGE

Tube sockets on the schematic diagram (Fig. 3) are shown bottom view, each element being in its actual position in respect to the guide pin. The voltage measurements shown are average and were taken with a line voltage of 115 V., the volume control "full on" and the range switch in position "A" using a 1000 ohms per volt meter.

REPAIRS

When servicing this chassis it is IMPERATIVE that the service man make all parts replacements in EXACTLY the same way as the original part was located and connected. This applies particularly to ground points. All parts replacements in the R. F. end of the circuit must be exact duplicates of the originals, especially so in the case of coils, R. F. by-pass or coupling condensers. Any repairs in the R. F. circuit will make a complete realignment of the tuned circuit necessary.

BIAS CELL

This Chassis uses a "C" bias cell unit in the control grid of the 6Q7 tube. This type bias cell has an exceedingly long life but occasionally may have to be replaced. When replacing the cell note that the carbon or (+) side is connected to the ground side of all terminal clips. To check the bias cell a new cell or a 1½ volt battery must be substituted, as the cell voltage cannot be measured with an ordinary voltmeter due to its low current rating.

CIRCUIT ALIGNMENT EQUIPMENT

Do not attempt to align the 6M Chassis without the equipment specified below:

1. Signal Generator—A modulated oscillator capable of delivering signals from 465 K.C. to 18.2 M.C.

2. Alignment Tool—A non-metallic screw driver.

3. Dummy Antenna — .05 Mfd. Condenser (I. F. Alignment); 200 Mmfd. Condenser (Broadcast Alignment); 400 Ohm Carbon Resistor (Short Wave Alignment).

4. Output Meter—A meter of sufficient sensitivity to give a good deflection at very low signal input.

Note: The receiver should be aligned in a location free from local interference. A screen room is recommended.

ALIGNMENT PROCEDURE

1. HEATING

(A) Allow the receiver to heat up for a period of 20 to 30 minutes. This is necessary in order to eliminate possible alignment variations due to the thermal expansion and contraction of the capacitors and inductances.

(B) Allow the signal generator to warm up in order to prevent frequency drift during alignment.

2. DIAL CALIBRATION

Turn the condenser until the plates are fully meshed, set the pointer (Hour Hand) to 9 and 3 on the outer edge of dial chart. Set the vernier pointer (Minute Hand) to the line pointing to 12.

3. SIGNAL GENERATOR ADJUSTMENT

During the entire alignment procedure the signal input from the generator to the receiver must be continually attenuated at the generator as the various trimmers are brought into resonance. This is necessary in order to hold the signal at the lowest intensity so that the A. V. C. Circuit will remain at the most sensitive point.

4. I. F. ALIGNMENT

(A) Set the generator to 465 K.C. and connect the output lead to the control grid of the 6A8 tube through the .05 Mfd. dummy and the generator ground to the chassis ground post.

(B) Set the receiver dial pointer to 600 K.C., the range switch to position "A" and turn the volume control full on.

(C) Connect the output meter across the two primary terminals on the output transformer.

(D) Adjust the I. F. Trimmers A1, A2, A3, A4, A5, and A6 to maximum output.

5. 1500 K.C. ALIGNMENT

(A) Set the generator to 1500 K.C. and connect the output to the antenna post on the chassis through the 200 Mmfd. dummy.

(B) Set the receiver dial pointer to 1500 K.C.

(C) Adjust the trimmers (A7) Oscillator, (A8) Detector and (A9) Antenna to maximum output.

6. 600 K.C. ALIGNMENT

(A) Set generator to 600 K.C.

(B) Set receiver dial pointer to 600 K.C.

(C) Turn trimmer (A10) in direction of signal increase and at the same time rock tuning condenser slowly back and forth through resonance until the exact resonant point on both is obtained.

7. 5 M.C. ALIGNMENT

(A) Set generator to 5 M.C.

(B) Set receiver range switch to position "B" and dial pointer to 5 M.C.

(C) Adjust trimmer (A11) Oscillator and (A12) Antenna to maximum output.

8. 18 M.C. ALIGNMENT

(A) Set generator to 18 M.C. and connect the output to the chassis Antenna post through the 400 Ohm dummy.

(B) Set the receiver range switch to position "C" and the dial pointer to 18 M.C.

(C) Screw the Oscillator trimmer (A13) down tight and back off until signal is heard, then rock the tuning condenser slowly back and forth through resonance uhtil exact resonant point is determined.

(D) Adjust Antenna trimmer (A14) to maximum output.

(E) Readjust Oscillator trimmer(A13) to maximum output.

INTRODUCTION

The Grunow Chassis 7M is a seven tube, three band superheterodyne receiver using 1-6E5 Beacon Eye tuning indicator, 1-6A8 1st Detector and Oscillator, 1-6K7 1st I. F. Amplifier, 1-6K7 2nd I. F. Amplifier, 1-6Q7 2nd Detector, A. V. C. and Audio Amplifier, 1-6F6 Power Output and 1-5W4 Rectifier. The tuning range is divided into three divisions or bands covering from 550 K.C. to 1750 K.C. on "A" Broadcast Band, 1750 K.C. to 5.5 M.C. on the "B" Police Amateur Band, and 5.5 M.C. to 18.2 M.C. on the "C" Foreign Broadcast Band.

SERVICE DATA

CONTINUITY AND VOLTAGE

Tube sockets on the schematic diagram (Fig. 3) are shown bottom view, each element being in its actual position in respect to the guide pin. The voltage measurements shown are average and were taken with a line voltage of 115 V., the volume control "full on" and the range switch in position "A" using a 1000 ohms per volt meter.

REPAIRS

When servicing this chassis it is IMPERATIVE that the service man make all parts replacements in EXACTLY the same way as the original part was located and connected. This applies particularly to ground points. All parts replacements in the R.F. end of the circuit must be exact duplicates of the originals, especially so in the case of coils, R.F. by-pass or coupling condensers. Any repairs in the R.F. circuit will make a complete re-alignment of the tuned circuit necessary.

BIAS CELL

This Chassis uses a "C" bias cell unit in the control grid of the 6Q7 tube. This type bias cell has an exceedingly long life, but occasionally may have to be replaced. When replacing the cell, note that the carbon or (+) side is connected to the ground side of cell terminal clip. To check the bias cell, a new cell or a 1½ volt battery must be substituted, as the cell voltage cannot be measured with an ordinary voltmeter due to its low current rating.

BEACON EYE SENSITIVITY ADJUSTMENTS

The 6E5 Beacon Eye tube is designed to give the best results with the proper size antenna. However, where a full sized antenna cannot be erected or an inside antenna must be used, a type 6G5 Beacon Eye Tube can be substituted by making the following changes in the wiring of the circuit:

Refer to schematic diagram Fig. 3 and disconnect the "Green" grid wire at point "A" and connect to point "B". This change can be made quickly and will give a maximum sensitivity on the weaker signals.

CIRCUIT ALIGNMENT EQUIPMENT — Do not attempt to align the 7M Chassis without the equipment specified below:

1. Signal Generator—A modulated oscillator capable of delivering signals from 465 K.C. to 18.2 M.C.

2. Alignment Tool—A non-metallic screw driver.

3. Dummy Antenna — .05 Mfd. Condenser (I. F. Alignment); 200 Mmfd. Condenser (Broadcast Alignment); 400 Ohm Carbon Resistor (Short Wave Alignment).

4. Output Meter—A meter of sufficient sensitivity to give a good deflection at very low signal input.

Note: The receiver should be aligned in a location free from local interference. A screen room is recommended.

ALIGNMENT PROCEDURE

1. HEATING

(A) Allow the receiver to heat up for a period of 20 to 30 minutes. This is necessary in order to eliminate possible alignment variations due to the thermal expansion and contraction of the capacitors and inductances.

(B) Allow the signal generator to warm up in order to prevent frequency drift during alignment.

2. DIAL CALIBRATION

Turn the condenser until the plates are fully meshed, set the pointer (Hour Hand) to 9 and 3 on the outer edge of dial chart. Set the vernier pointer (Minute Hand) to the line pointing to 12.

3. SIGNAL GENERATOR ADJUSTMENT

During the entire alignment procedure the signal input from the generator to the receiver must be continually attenuated at the generator as the various trimmers are brought into resonance. This is necessary in order to hold the signal at the lowest intensity so that the A. V. C. Circuit will remain at the most sensitive point.

4. I. F. ALIGNMENT

(A) Set the generator to 465 K.C. and connect the output lead to the control grid of the 6A8 tube through the .05 Mfd. dummy and the generator ground to the chassis ground post.

(B) Set the receiver dial pointer to 600 K.C., the range switch to position "A" and turn the volume control full on.

(C) Connect the output meter across the two primary terminals on the output transformer.

(D) Adjust the I. F. Trimmers A1, A2, A3, A4, A5, and A6 to maximum output.

5. 1500 K.C. ALIGNMENT

(A) Set the generator to 1500 K.C. and connect the output to the antenna post on the chassis through the 200 Mmfd. dummy.

(B) Set the receiver dial pointer to 1500 K.C.

(C) Adjust the trimmers (A7) Oscillator, (A8) Detector and (A9) Antenna to maximum output.

6. 600 K.C. ALIGNMENT

(A) Set generator to 600 K.C.

(B) Set receiver dial pointer to 600 K.C.

(C) Turn trimmer (A10) in direction of signal increase and at the same time rock tuning condenser slowly back and forth through resonance until the exact resonant point on both is obtained.

7. 5 M.C. ALIGNMENT

(A) Set generator to 5 M.C.

(B) Set receiver range switch to position "B" and dial pointer to 5 M.C.

(C) Adjust trimmer (A11) Oscillator and (A12) Antenna to maximum output.

8. 18 M.C. ALIGNMENT

(A) Set generator to 18 M.C. and connect the output to the chassis Antenna post through the 400 Ohm dummy.

(B) Set the receiver range switch to position "C" and the dial pointer to 18 M.C.

(C) Screw the Oscillator trimmer (A13) down tight and back off until signal is heard, then rock the tuning condenser slowly back and forth through resonance until exact resonant point is determined.

(D) Adjust Antenna trimmer (A14) to maximum output.

(E) Readjust Oscillator trimmer(A13) to maximum output,

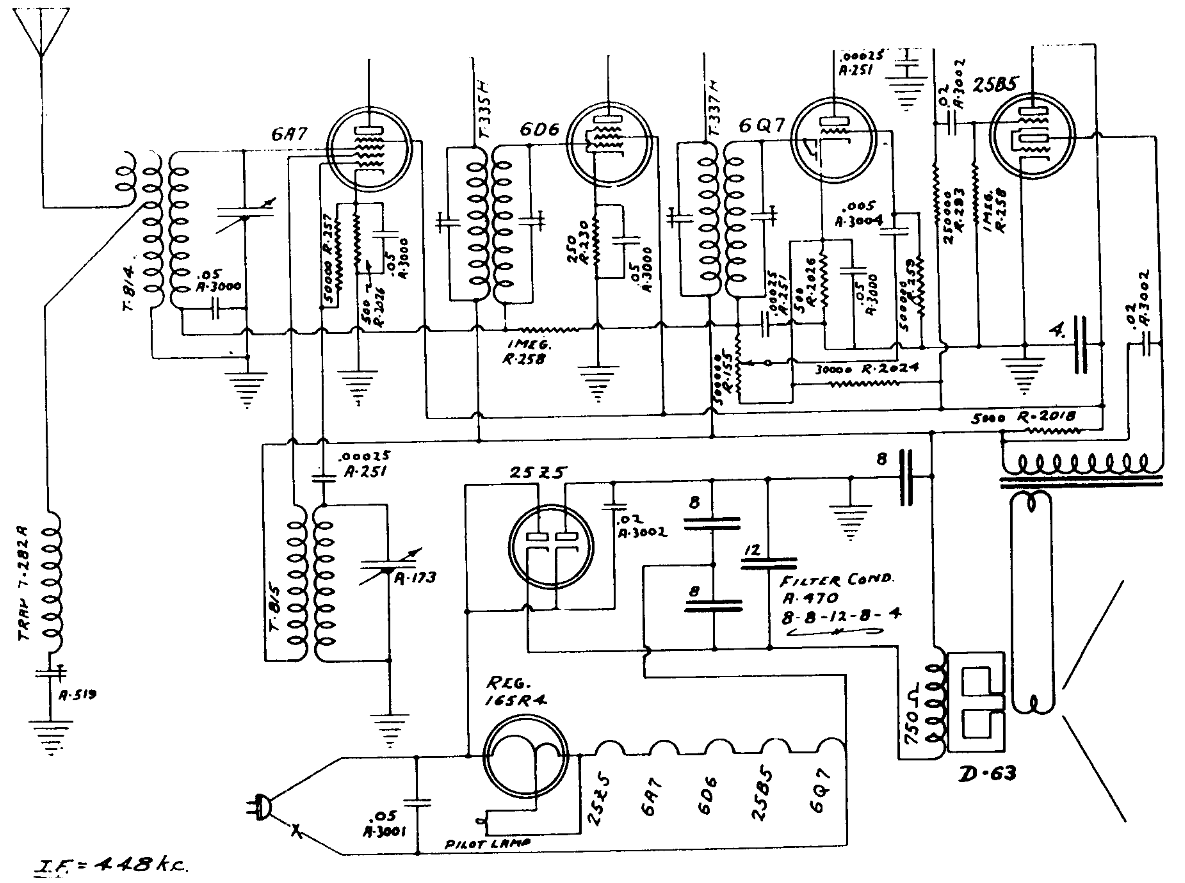
INTERNATIONAL RADIO CORP.
MODEL K-10



This chassis is designed to operate from 110-125 volt, 60 cycle, alternating current power lines. It is a single band receiver covering the American broadcast band.

The following tubes are employed:

6A7 —Mixer-Oscillator
6D6 —I. F. Amplifier
6Q7 —2nd Detector-AVC-1st A. F. (Metal)
25B5 - Pentode Output
25Z5 —Rectifier
165 1R—Regulator

ALIGNMENT

ESSENTIAL DATA: The intermediate frequency employed is 448 Kc.

The standard type of output meter should be used to indicate signal strength. It should be connected from the output plate of the 25B5 tube to ground.

Poor sensitivity may be an indication of incorrectly adjusted I. F. trimmers.

Aligning should be done on 1400 1000 and 600 kilocycles.

INTERMEDIATES: To align the I. F. circuits, set the signal generator to 448 Kc and feed its modulated signal direct to the antenna. Adjust the first I. F. transformer trimmers for maximum meter reading. Go over both adjustments at least three or four times for accuracy. Repeat this process on the second I. F. transformer. If adjustments are not made accurately, selectivity will be poor and I. F. oscillation may result. Finally, adjust the trimmer in the tuned wave trap for *minimum* meter reading.

BROADCAST: Turn the dial to 1400 Kc and feed a *very weak* 1400 Kc modulated signal from your signal generator to the antenna. Adjust the broadcast oscillator trimmer and detector trimmer (on condenser gang) for maximum reading.

There is no adjustable padder condenser in this model so resonance on lower frequencies is accomplished by bending plates on tuning condensers.

INTERNATIONAL RADIO CORP.
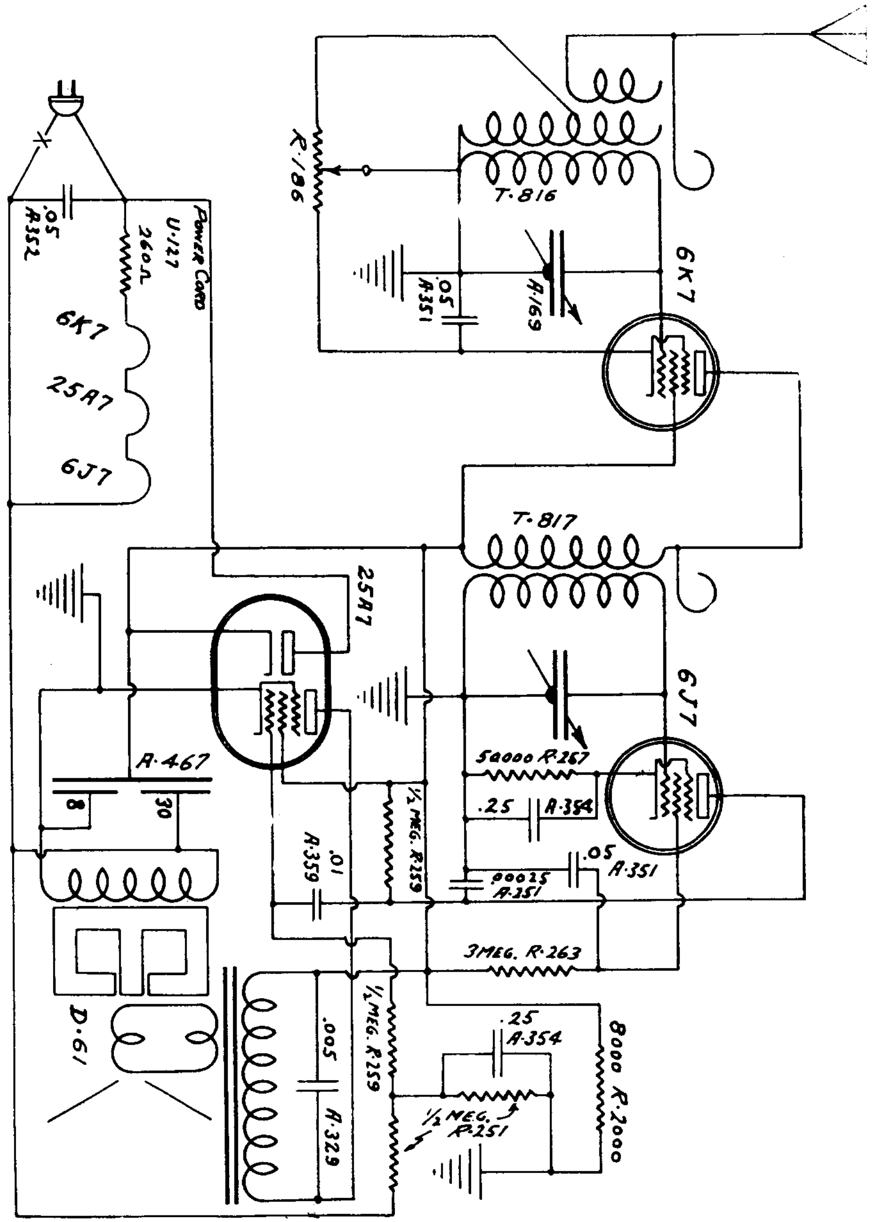
MODEL K-43



This chassis is designed to operate from 110-125 volt power lines, either alternating or direct current. It is a single band receiver covering the American broadcast band.

The following tubes are employed:

6K7M —Tuned R. F.
6J7M —Detector
25A7G—Pentode output and Rectifier

ALIGNMENT

Alignment may be accomplished using either a signal generator or weak broadcast signals although the signal generator is preferable. An output meter should be connected from the plate of the 25A7G tube to ground.

Set signal generator at 1500 kilocycles and feed signal to antenna. Keep the output from signal generator as low as possible. Tune in signal on radio and set detector to calibrate to the dial. Rock the tuning condenser back and forth across the signal while adjusting the R. F. trimmer for resonance.

Next check the alignment at 1000 Kc. Insert a thin bakelite, celluloid or mica feeler strip between the plates of the variable condensers to determine whether the circuits are properly matched. The action is this—the dielectric constant of the celluloid feeler strip being higher than that of the air it displaces, results in an increase of capacity. Open the variable condenser just enough to indicate two or three points below maximum signal. As the feeler is inserted the meter reading should indicate increasing signal and the decreasing as the feeler is inserted farther. This procedure should be followed on both sections. Should the meter fail to show an increase in signal as the strip is inserted in one section this indicated too great a capacity for the section. This may be corrected by bending the outside rotor plates out at the point where they begin to mesh with the stator.

After checking the alignment at 1000 Kc. repeat the process at 600 K

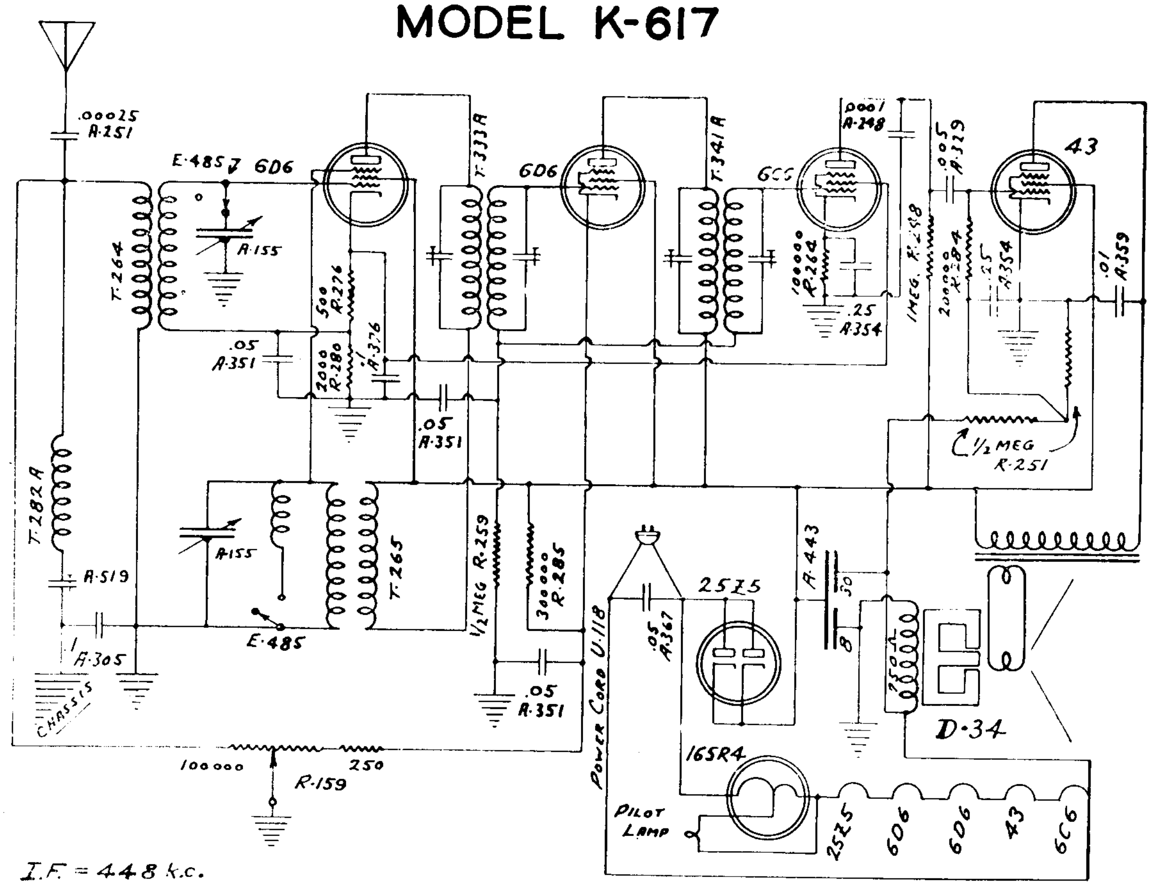
INTERNATIONAL RADIO CORP.
MODEL K-617



I.F. = 448 k.c.

This chassis is designed to operate from 110-125 volt power lines, either alternating or direct current. It is a two band receiver covering the American broadcast and police and airport bands.

The following tubes are employed:

6D6 —1st Detector-Oscillator
6D6 —I. F. Amplifier
6C6 —2nd Detector
43 —Pentode Output
25Z5 —Rectifier
165R4—Regulator

ALIGNMENT

ESSENTIAL DATA: The intermediate frequency employed is 448 Kc.

The standard type of output meter should be used to indicate signal strength. It should be connected from the plate of the 43 tube to ground.

Poor sensitivity may be an indication of incorrectly adjusted I. F. trimmers.

Aligning of broadcast band should be done on 1400, 1000 and 600 kilocycles

INTERMEDIATES: To align the I. F. circuits, set the signal generator to 448 Kc. and feed its modulated signal direct to the antenna. Adjust the first I. F. transformer trimmers for maximum meter reading. Go over both adjustments at least three or four times for accuracy. Repeat this process on the second I. F. transformer. If adjustments are not made accurately, selectivity will be poor and I. F. oscillation may result. Finally, adjust the trimmer in the tuned wave trap for minimum meter reading.

BROADCAST BAND: Place the band change switch on the Broadcast position. Turn the dial to 1400 Kc. and feed a *very weak* 1400 Kc. modulated signal from your signal generator to the antenna. Adjust the oscillator trimmer for maximum reading. Then peak the antenna trimmer to this setting.

There is no adjustable padder condenser in this model so resonance on lower frequencies is accomplished by bending plates on tuning condensers.

SHORT WAVE BAND: No alignment necessary.

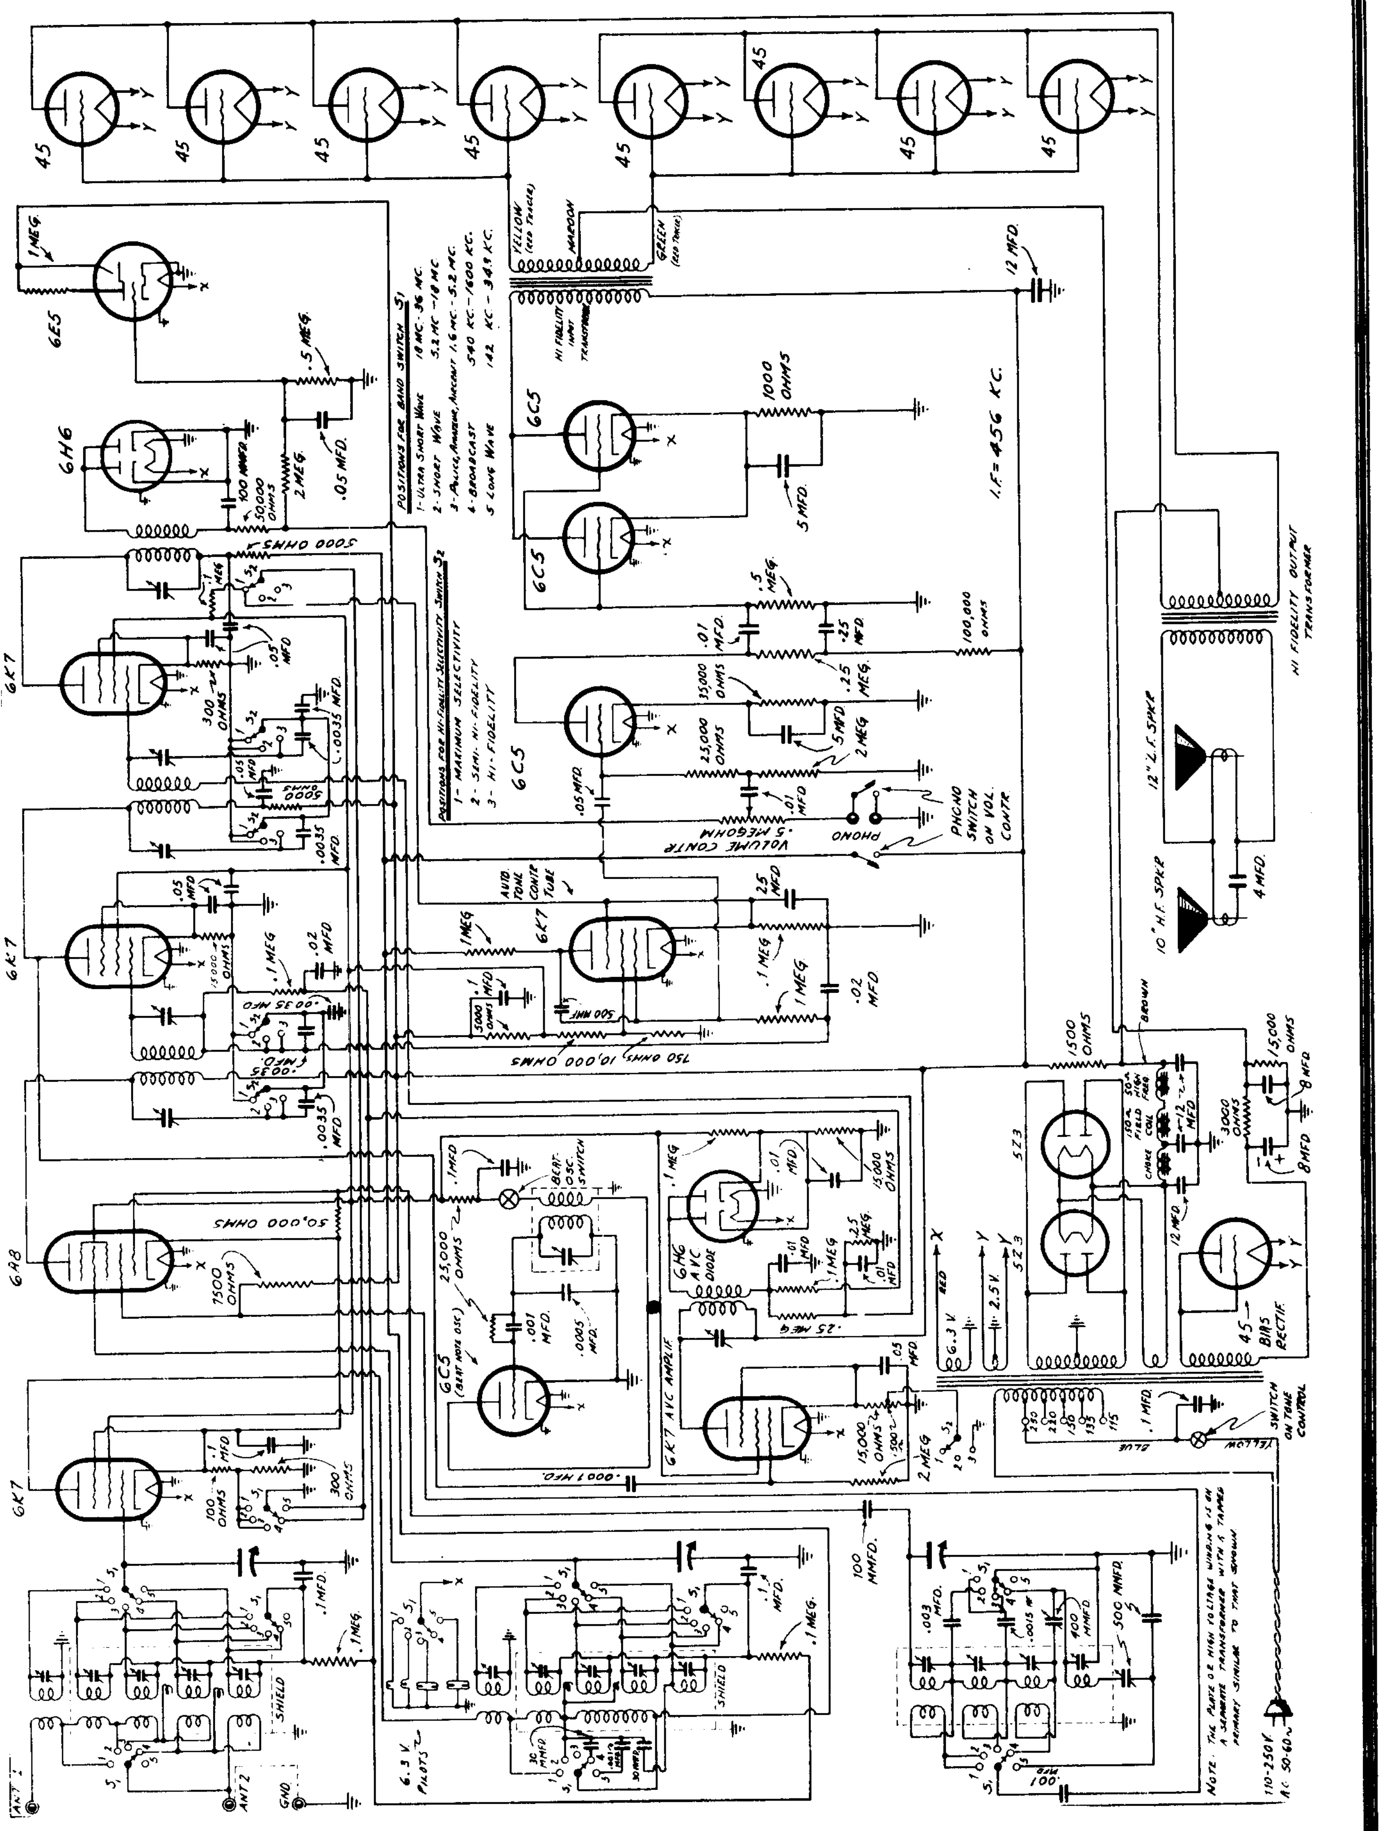
MODEL C-95



LAFAYETTE RADIO MFG. CO.

MODEL C-95

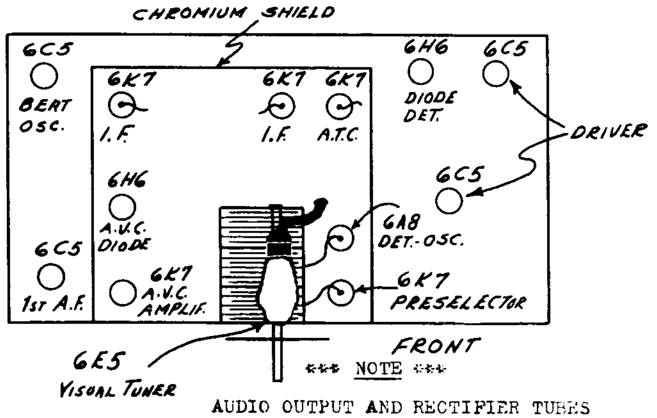
ALIGNMENT PROCEDURE

Realignment of this receiver should not be attempted except by an experienced serviceman and only after all other possible causes of faulty operation have first been thoroughly investigated. An accurately calibrated signal generator which will cover the necessary wave bands is required. Either a suitable output meter or the cathode-ray tuning indicator may be used for indicating the effects of adjustments. It is necessary, in all of the ensuing procedure, that the signal generator be attenuated as much as possible.

I.F. ADJUSTMENT - The i.f. transformers are housed in the polished metal shield on the chassis. The location of these transformers is indicated in the accompanying diagram. The trimmers are on the tops of the transformer cans. The first and second i.f. transformers have two trimmers each and the detector coupling transformer has only one trimmer. These trimmers are adjusted at 456 kc. for maximum gain. In making this adjustment, the oscillator (rear) section of the tuning condenser should be short-circuited, and the signal generator connected between the grid cap of the 6A8 and the ground post of the receiver. The selectivity switch should of course be in the high selectivity position.

SHORT WAVE BAND - With the output from the signal generator connected across the aerial and ground terminals of the receiver, and the volume control in position for maximum volume, the oscillator trimmer for this band is adjusted for maximum response as indicated by the 6E5. This adjustment must be made with the dial set at exactly 17 mc., otherwise the calibration will be off. The series padder for this band should then be adjusted by setting the signal generator at a frequency of 5.5 megacycles and tuning the signal in on the receiver. The tuning condenser is rotated slightly back and forth as the padder screw is adjusted for maximum output. The 17 mc. adjustment should then be rechecked. If the dial calibration is off, the procedure should be repeated again.

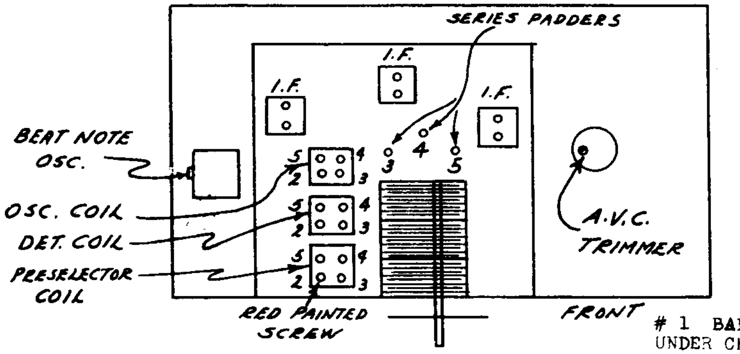
TOP VIEW OF CHASSIS SHOWING LOCATION OF TUBES



*** NOTE ***

AUDIO OUTPUT AND RECTIFIER TUBES ARE IN POWER SUPPLY CHASSIS.

TOP VIEW OF CHASSIS SHOWING LOCATION OF ALIGNING TRIMMERS



1 BAND TRIMMERS UNDER CHASSIS

WAVE BANDS:- The wave bands covered by this receiver are as follows:

	Kilocycles or Megacycles		Meters	
(1) Ultra Short Wave	36.25	18	8.125	-16.6
(2) Foreign & American Short Wave, Airplanes	18	5.2	16.6	-57.5
(3) Police, Amateur, Airplanes	5.2	1.6	57.5	-187.5
(4) Broadcast	1600-540		187.5	-554
(5) Long Wave	343-142		872	-2100

ULTRA SHORT WAVE BAND - The trimmers for this band are adjusted at 36 megacycles in the manner described above. They are located on the under side of the chassis and are not shown on the chassis layout diagram. There are only two trimmers for this band, the oscillator operating on a harmonic of another band.

POLICE BAND ADJUSTMENT - The trimmers for this band are adjusted at 4.8 megacycles in the manner described and the series padder at 1.7 mc. exactly as indicated in the SHORT WAVE BAND ADJUSTMENT procedure.

BROADCAST BAND - The adjustments for this band are as described above. The trimmers are adjusted at 1400 kc. and the padder at 600 kc.

LONG WAVE BAND - The adjustments for this band are made in the prescribed manner, the trimmers being adjusted at 340 kc. and the padder at approximately 150 kc.

A.V.C. AMPLIFIER ADJUSTMENT - The a.v.c. has a separate amplifier which is tuned as follows: The signal generator is set at 1400 kc. and the signal tuned in on the receiver, as indicated by the minimum opening in the 6E5 beam. The a.v.c. trimmer is then adjusted to give the WIDEST opening in the beam. The receiver is then carefully retuned and the adjustment repeated.

BEAT NOTE OSCILLATOR ADJUSTMENT - A weak signal from the signal generator is tuned in on the receiver as indicated by the minimum opening in the 6E5 beam. The beat oscillator switch is then turned on. An audible note should be heard whose pitch may be varied by adjusting the screw on the small square can on the left side of the chassis. This should be so adjusted that when the station is tuned in exactly, no beat is heard (zero beat). If no beat note is audible when first turned on, rotation of this same screw should bring in the note.

VOLTAGE TABLE

All voltages are measured between socket terminals and chassis: set in operation: volume control full on; antenna disconnected. voltmeter sensitivity - 1000-ohms-per volt. Line voltage measured:- 115.0 Power Consumption: 250 watts

The frequency range covered by this receiver is as follows: Broadcast band 537 KC to 1730 KC. The short wave band covers a range of 2.2 megacycles to 6.4 megacycles and either of these bands are selected at will by a flip of the band change switch. To the left for broadcast—To the right for short wave.

SERVICE INSTRUCTIONS

When set fails to perform properly, always check the voltage of the batteries. Run down batteries will cause weak and poor reception.

Noises may develope from defective tubes and condensers.

This set has been carefully aligned at the factory, but if realignment should become necessary, the following procedure should be followed.

Use a test oscillator and connect an output meter from plate of 33 to B plus.

I. F. Alignment:

Connect the oscillator through a .1 condenser to the grid of the 1C6 tube and set the oscillator to 456 kilocycles. Peak each I. F. stage to resonance as indicated by maximum output on the output meter.

R. F. Alignment:

With the wave change switch in the broadcast position, set the oscillator to 1700 kilocycles and connect in series with a .00025 condenser to the antenna of the receiver. Rotate the variable condenser to the 1700 setting of the dial and adjust the trimmer condenser of the broadcast oscillator to resonance. The location of oscillator trimmer is on rear section of variable condenser. Reset the test oscillator to 1400 kilocycles and adjust antenna trimmer located corner front section of variable condenser. Now set oscillator to 600 kilocycles and adjust padder located on side of chassis. Check alignment at 1000 kilocycles.

For aligning police band, set test oscillator to 6 megacycles. Turn band switch to short wave. Rotate variable condenser until signal is heard. Peak antenna trimmer (across antenna coil under chassis) to maximum. Rock variable condenser slightly backward and forward until maximum peak is reached.

I. F. ALIGNMENT:

With volume control on full and variable gang condenser at maximum capacity, attach test oscillator lead in series with a .1 mfd. condenser to stator of R. F. section of gang condenser (center section). Set test oscillator at 262.5 KC and adjust I.F. trimmers for maximum output as indicated on an output meter connected across voice coil of speakers or from plate and screen of 42 tube.

Set test oscillator to 600 KC and adjust oscillator padding (located on bakelite strip, 2nd from front). Also adjust 600 KC antenna padding condenser (located on bakelite strip, 1st condenser). Reset test oscillator to 1400 KC and readjust antenna and R. F. trimmers.

R. F. ALIGNMENT:

Set test oscillator at 1550 KC and connect through a 150 mmf. condenser to antenna of reciever. Rotate variable gang condenser to minimum capacity and back off slightly. Adjust trimmer on oscillator section of gang condenser (third section from shaft end) to resonance indicated by maximum output. Re-set test oscillator of 1400 KC and rotate variable condenser until oscillator signal is picked up. Adjust antenna trimmer (front section) and R. F. trimmer (center section) to resonance.

ANTENNA ADJUSTMENT:

When set is in operation, tune to a station on or about 1400 KC and adjust antenna trimmer to maximum volume. This trimmer is accessable by removing the plug button on the front cover of the receiver.

Proper adjustment of this trimmer matches the particular antenna used in the auto to the receiver which increases the sensitivity of the receiver.
