BRITAINS LEADING JOURNAL FOR THE RADIO & ELECTRONIC CONSTRUCTOR

Published by IPC Magazines Ltd., Westover House, West Quay Rd., POOLE, Dorset BH151JG

COPYRIGHT

© IPC Magazines Limited 1978. Copyright in all drawings, photographs and articles published in *Practical Wireless* is fully protected and reproduction or imitation in whole or in part is expressly forbidden. All reasonable precautions are taken by *Practical Wireless* to ensure that the advice and data given to readers are reliable. We cannot however guarantee it and we cannot accept legal responsibility for it. Prices are those current as we go to press.

CORRESPONDENCE

All correspondence regarding advertisements should be addressed to the Advertisement Manager, "Practical Wireless", King's Reach Tower, Stamford Street, London SE1 9LS. All other correspondence should be addressed to the Editor, "Practical Wireless", Westover House, West Quay Road, Poole, Dorset BH15 1JG.

BINDERS AND INDEXES

Binders (£2.85) and Indexes (45p) can be supplied by the Post Sales Department, IPC Magazines Ltd., Lavington House, 25 Lavington Street, London SE1 OPF. Both prices include postage and VAT. Overseas orders for binders should include 60p to cover despatch and postage. All remittances should be made payable to IPC Magazines Limited. Commencing with Volume 52, the Index is included in Number 1 of the following Volume.

BACK NUMBERS

Some back issues, mostly those published during the last two years, are available from our Post Sales Department (address above) at 65p each, including postage and packing to both home and overseas destinations. Remittances should be made payable to IPC Magazines Limited.

SUBSCRIPTIONS

Subscriptions are available to both home and overseas addresses at £10.60 per annum, from "Practical Wireless" Subscription Department, Oakfield House, Perrymount Road, Haywards Heath, West Sussex RH16 3DH. Remittances should be made payable to IPC Services Limited.

QUERIES

We do not operate a Technical Query Service except on matters concerning constructional articles published in *PW*. We cannot offer advice on modifications to our published designs, nor comment on alternative ways of using them. We do not supply service sheets nor information on commercial radios, TVs or electronic equipment.

All queries must be accompanied by a stamped self-addressed envelope, otherwise a reply cannot be guaranteed. We cannot answer technical queries over the telephone.

LOOK! Here's how you master electronics.

.... the practical way.

Build an oscilloscope.

As the first stage of your training, you actually build your own Cathode ray oscilloscope! This is no toy, but a test instrument that you will need not only for the course's practical experiments, but also later if you decide to develop your k nowledge and enter the profession. It remains your property and represents a very large saving over buying a similar piece of essential equipment.

2 Read, draw and understand circuit diagrams.

In a short time you will be able to read and draw circuit diagrams, understand the very fundamentals of television, radio, computors and countless other electronic devices and their servicing procedures,

This new style course will enable anyone to have a real understanding of electronics by a modern, practical and visual method. No previous knowledge is required, no maths, and an absolute minimum of theory.

You learn the practical way in easy steps mastering all the essentials of your hobby or to further your career in electronics or as a selfemployed electronics engineer.

All the training can be carried out in the comfort of your own home and at your own pace. A tutor is available to whom you can write, at any time, for advice or help during your work. A Certificate is given at the end of every course.

3 Carry out over 40 experiments on basic circuits.

We show you how to conduct experiments on a wide variety of different circuits and turn the information gained into a working knowledge of testing, servicing and maintaining all types of electronic equipment, radio, t.v etc.

All students enrolling in our courses receive a free circuit board originating from a computer and containing many different components that can be used in experiments and provide an excellent example of current electronic practice.

To find out more about how to learn electronics in a new, exciting and absorbing way, just clip the coupon for a free colour brochure and full details of enrolment. British National Radio & Electronic School P.O. Box 156, Jersey, Channel Islands.

SRX-30 For the advanced, keen short wave listener, the choice of receiver has usually been between cheap and nasty or very good but very expensive equipment. We think that the SRX-30 will provide that listener with excellent performance at a reason-able cost and is the answer to this eternal problem.

able cost and is the answer to this eternal problem. The SRX-30 provides AM. CW. USB and LSB reception on all frequencies from 500 kHz to 30MHz. All right, so does your Sooper Blooper Mk. 3 but you can't set the Sooper Blooper dial to the frequency you want and be sure that it's correct! The SRX-30 tuning system is so simple to operate. You have a dial reading in MHz from 0-29 and a main tuning dial reading 0-1000 kHz. So---if you know that Radio Slobovia is broadcasting on 10.255 MHz, you set the MHz dial to 10, the kHz dial to 295 and there you are. The MHz dial setting is not critical, as stability is guaranced by a triple mixing drift cancelling system, thereby overcoming another problem in your Sooper Blooper Mk. 3; drift.

another problem in your Sooper Biooper Mk. 3: drift. A further drawback to cheap receivers is massive image interference on the higher frequencies due to the use of a low IF, typically 455 kHz. The cure for this problem is the use of a high IF and the SRX-30 employs a first IF of around 40 MHz—so goodbye to first IF images. You could of course find the same system as this in the Racal RA17 series receivers: after all, the SRX-30 has copied the basic idea from this very receiver. The big drawback to the RA17 (apart from the price 1!) is that unless you have the muscles of a prize fighter, lifting the RA17 may send you for a holiday at Hernia Bay (staying at the Truss House?).

House?). To summarize, the SRX-30 covers 500 kHz to 30 MHz with excellent dial readout and reset accuracy; it has all mode (AM, CW, SSB) reception and is equally at home in broadcast or amateur bands; it has all the facilities of a top class com-munications receiver, RF gain, fine tuning, selectable sidebands, built in loud-speaker, operation from ac mains or 12v. Dc, rugged construction and super styling and all at an attractive price—£158 inc. VAT. Carr £3. See it soon at your nearest stockist, you will be agreeably impressed.

all that's good in Amateur Radio, contact:

GREENWEL

443 Millbrook Road Southampton Tel:(0703) 772501 SO1 OHX

All prices quoted include VAT. Add 25p UK/BFPO postage. Most orders des-patched on day of receipt. SAE with enquiries picese. MINIMUM ORDER VALUE £1. Official orders accepted

DIODE SCOOP!!!

We have been fortunate to obtain a large quantity of untested, mostly unmarked glass silicon diodes. Testing a sample batch revealed about 70% useable devices-signal diodes, high voltage rects and zeners may all be included. These are being offered at the incredibly low price of £1.25/1000-or a bag of 2500 for £2.25. Bag of 10,000 £8. Box of 25,000 £17.50. Box of 100,000

DISC CERAMIC PACK

Amazing variety of values and voltages from a few pF to 2.2uF! 3V to 3kV! 200 £1 500 £2.25 1000 £4.00.

TTL PANEL

52 logic IC's including 32 \times 74161 (4 bit binary counter) + 16 tant bead caps, R's, C's, etc. Over £30 worth of TTL alone!! ONLY £3.00.

PC ETCHING KIT MK III

Now contains 200 sq. ins. copper clad board, 11b. Ferric Chloride, DALO etch-resist pen, abrasive cleaner, two mini-ature drill bits, etching dish and instruc-tions. £3-90

VEROBOARD

Our packs of vero offcuts are one of our biggest sellers—and no wonder, they are amazing valuel! Each pack contains 7 or 8 pieces to make up a total area of 100 sq. Ins. All packs are the same price. £1:30 each and are available as follows:

Pack A all 0·1″ pitch Pack B all 0·15″ pitch Pack C mixed 0·1 & 0·15″ Pack D all 0·1″ plain

Also available by weight 11b £3·95 101bs £32·50

Regular size vero 17×3≩×0·1″ £2·00, 10 strips £15 17×3≩×0·15″ £1·76; 0·1″ plain £1·63 DIP Breadboard size 6, 15×4 5", can accommodate 20×14 pin ICs £2 35 VQ Board, size 148 × 75mm 0.1" pitch. Copper strips in rows of 4 to facilitate construction with IC's. Layout sheet construction provided 85p

EDGE CONNECTORS

Special purchase of these 0.1" pitch double-sided gold-plated connectors enables us to offer them at less than one-third their original list price! 15 way 41p; 32 way 47p; 32 way 72p; 40 way 90p.

SOLDERING IRONS

Antex model C—15W gen. purpose iron. Our bestseller at £3.50

Antex model CCN-15W element with ceramic shaft. Very low leakage. **£3:90** Antex MLX12. This is a 12V iron, ideal for car and boat use. 25W rating. Comes complete with large crocodile clips fitted + booklet "How to solder" and strong PVC carrying case **£4:29**

COMING SOON . . .

The amazing automatic Logic Monitor I M-1

Just clip it over your IC. It instantly and accurately shows both static and dynamic logic states, on a bright, 16-LED display. It finds its own

power.

It cuts out guesswork, saves time, and eliminates the risk of short-circuits.

LM-1 is suitable for all dual-inline logic ICs; DTL, TTL, HTL, CMOS; up to 16 pins.

LED on = logic state 1 (high), LED off = logic state 0 (low), and each LED is clearly numbered 1 to 16 in the conventional IC pattern.

Brief specification

Input Threshold Input Impedance Input Voltage Range

Maximum Current Drain Maximum Input Frequency* Operating Temperature Range Weight Maximum Dimensions $2V \pm 0.2$ volts. 100,000 Ohms 4 volts minimum 15 volts maximum across any two or more input leads 200 mA @ 10 volts 10,000 Hz 50% duty cycle 0° C to 50° C 3 ounces (85 grams) $4.0 \times 2.0 \times 1.8''$ $102 \times 51 \times 45 \text{ mm}$

*LM-1 will respond to signals up to 0.1MHz when the input signal swing exceeds the threshold voltage by more than 0.5 volts.

Applications

Design, breadboarding, testing and checking new logic systems. Direct real-time monitoring of logic function in operating equipment. Long-term testing of individual ICs. Identification of unused elements, to find room for an extra gate, clock etc. Observing relationships between ICs on different boards of multiple board systems (you need more than one LM-1 to observe simultaneously, of course).

Plus dozens of other uses. You'll find them.

Plus 8% VAT, plus post and packaging, total £32.35, including box and instruction manual. Try the LM-1 and you won't know how you ever managed without it!

It's Easy to Order

Ring us (01-890 0782) with your Access, Barclaycard or American Express number and your order will be in the post that night. Alternatively, send a cheque, or postal order (don't send credit cards!) and it still only takes a few days.

Otherwise ask for our complete catalogue.

<u>Chicken & Egg</u>

NEW developments in electronics tend to fall broadly into two categories. Some appear to be the result of someone saying "Here's an idea or an i.c. that will do something that's never been possible before—what can we use it for? The results are often rather gimmicky and pointless and remind me of a course in "Design" which I attended a few years back. There, each project team was given a portable videotape recorder and camera and told to go out and find something to record. A definite case of a means looking for an application.

Other new pieces of equipment seem to announce that their designers have done a tremendous amount of research into what people need, and then proceeded to pack the maximum facilities possible into the product.

Happily there were several examples of the latter type among new items on display at the recent round of London radio and TV trade shows. Perhaps it is a little unfair to mention some without mentioning all, but two particularly took my fancy. From Ferguson somes a clock radio which they have nicknamed (with some justification) "The Great Little Time Machine". This has two time zone settings (BST and GMT?), two alarm time settings (husband and wife?), day and month calendar, forward and reverse setting facility (no more advancing $23\frac{1}{2}$ hours to achieve a half-hour earlier call) and Long, Medium and v.h.f. bands, (ready for the new frequency plan in November). Add to this all the usual facilities and the bonus of auto-dimming of the clock display and you have a very handy item for the bedside table.

Those of you who have ever caught the end of a radio announcement and thought "That sounded as if it could be of interest, I wonder what it was", may find their salvation in a fascinating new system by Intermetall Semiconductors of the ITT group. Based on "bucket-brigade" i.c.s., this continuously stores the last 15 seconds or so of a sound transmission, which may be repeated at the press of a button. So that subsequent announcements are not missed, the recorded speech is compressed in time by removing pauses between words. This process continues until the replayed speech catches up with real time and then normal speech is resumed. Altogether very cunning, and a delightful example of someone recognising that a new technique could be adopted to solve an age-old problem!

Geoffrey C. Arnold

Practical Wireless, August 1978

RAE

The Mid-Warwickshire College of Further Education notify us that they will be offering the City & Guilds, RAE Course No. 765 in September 1978.

Enrolment will be on September 7th and 8th. The course will be one evening each week for approximately 30 weeks and is intended to prepare students for examination No. 765-1-02. *Mid-Warwickshire College of Further Education, Department of Engineering, Warwick New Road, Learnington Spa CV32 5JE. Tel: (0926) 311711.*

Hello Thistle

North Sea oilmen in the Brent oilfield will soon be able to telephone each other thanks to new equipment now being installed by Marconi engineers.

Shell (UK) Ltd placed a contract worth over £300,000 with Marconi Communications Ltd, a GEC-Marconi Electronics company, for the installation of radio equipment that will establish a communications link between offshore stations, and also back to the mainland.

Phase one of the contract will be to link Dunlin and Brent A, B and D by line-of-sight radio equipment and also to connect Dunlin to BNOC's Thistle platform, Thistle having a troposcatter terminal relaying back to the new Post Office terminal in South Shetland. Phase two will connect Brent C and Cormorant into the system and establish a line-of-sight microwave link between Cormorant and Thistle.

Finally, there will also be a troposcatter link from Cormorant to South Shetland and the line-of-sight microwave link between this platform and Thistle will complete the triangulation for alternate path operation.

Practical Wireless, August 1978

Computer Clubs

I am informed of the existence of two northern sub-groups of the Amateur Computer Club, whose object is to help anyone who has an interest in computers, microprocessors etc.

For details of joining the groups those in the North East should contact: Thomas Turnbull, $49 \times 9th$ Row, Ashington, Northumberland NE63 8JY, and those in the North West: David Wade, 26 Wolsey Close, Radcliffe, Manchester M26 0AG.

Special Event

Yeovil Amateur Radio Club will be running a special event station for Air Day at RNAS Yeovilton, Somerset on Saturday 5th August. Call-sign GB3FAA. For further information contact: John Howard, 127 Goldcroft, Yeovil, Somerset BA21 4DD.

Diary notes

The Telford Mobile Rally Group are organising a rally for radio amateurs at Town Centre Malls of Telford, New Town, Salop, on Sunday 10th September, 1978—starting at 11am. There will be many trade stands and exhibits. Details from: *Martyn Vincent G3UKV*, 9 Sleapford, Long Lane, Telford, Salop.

The British Amateur Electronics Club are holding their Amateur Electronics Exhibition this year at the Centre of the Esplanade, Penarth, S. Glamorgan, between 15th and 22nd July 1978. As before all proceeds will be given to the Cancer Research Campaign. Further information from: Cyril Bogod, "Dickens", 26 Forrest Road, Penarth, Glam.

The British Amateur Radio Teleprinter Group is holding its annual convention at Harpenden Public Hall, Harpenden, Herts. on Saturday 15th July, 1978—starting at 11am. There will be trade stalls, demonstrations and lectures, including one on Microprocessors by G3PLX, which is expected to attract particular attention. Details from: J. P. G. Jones GW3IGG, Heywood, 40 Lower Quay Road, Hook, Haverfordwest, Dyfed SA62 4LR.

The 1978 Harrogate International Festival of Sound is to be held at The Harrogate Exhibition Centre, Harrogate. The public are invited on Saturday 19th and Sunday 20th August from 11.00am until 9.00pm and admission will be free of charge. Trade days are Monday 21st and Tuesday 22nd August, when admission will be by ticket, available from the organisers in a special dealer invitation pack. Further information from Stan Smith and Peter Hainsworth of: Exhibition and Conference Services Ltd., Claremont House, Victoria Avenue, Harrogate, North Yorkshire. Tel: (0423) 62677.

Microprocessor terminal

Soon to be launched on the home market is the SR100 series Minitype computer terminal from Warren Logic Ltd.

Designed specifically as a low cost teletype or v.d.t. replacement, it is expected to cost less than \pounds 300.

A teletype compatible keyboard with full ASCII capabilities is used. The display section consists of fifteen alphanumeric sixteen segment l.e.d. elements which utilize a sixty-four character ASCII subset. The On-Line mode of operation is full duplex and a local facility is also provided. Both E.I.A. and 20mA current loop operation are standard and any baud rate between 50 and 240 baud may be selected by an eight pin d.i.l. module.

For further details contact: Warren Logic Ltd., Hockley Road, Brosley, Salop, TF12 5HT. Tel: (0952) 883010.

PW "Avon"

Those constructors of the "Avon" 2m Transmitter, who intend purchasing transistor types 2N4427 and BLY83 from Watford Electronics should note that the prices quoted in their advertisement are wrong. The correct prices for these transistors are: 2N4427 90p plus 8% VAT and BLY83 £8.50 plus 8% VAT.

Part 5

IAN HICKMAN

This month's instalment deals with the trigger circuits, timebase generator and X output amplifier, all contained on board 4. Figs. 2 and 4 show the component and wiring side of the board and Fig. 1 gives the complete circuit diagram.

The trigger input (either from front panel SKT5 or 6 or from the trigger pick-off stage of the Y amplifier board) is first buffered, amplified and squared up and then passed to a polarity selector gate IC403a which inverts it or not under control or front panel switch 85.

So now we have a squared-up waveform at standard TTL logic levels applied to trigger gate IC402d.

Let's assume the time base hasn't been triggered for some time, so that flyback is complete. Then the output of the control bistable will be a logic 0 (about +0.2V) and the emitter of Tr406 will be negative by a few hundred millivolts.

As the current through its emitter resistor always exceeds the current supplied by the constant current generator Tr404, diode D404 will hold C12 at about 0V and the inverting input of the end-of-flyback comparator IC406 will be slightly negative. IC406 will therefore apply a logic 1 (about +3.8V) to the trigger gate.

The control bistable IC404a is positive edge triggered. Therefore when the output from IC403a goes negative, causing the output of the 2 input nand gate IC402 to go positive, IC404a's Q output will go to a logic 1. D404 will therefore be cut off and the constant current source will start to charge up C12 linearly.

Meanwhile, once triggered, further edges will have no effect on the control bistable and anyway, shortly after the start of the scan, the inverting input of IC406 will go positive, putting a logic 0 on IC402d. The latter's output will therefore sit at logic 1 until the end of retrace (flyback). When the scan reaches +3V, the output of IC405 will change from a logic 1 to logic 0, resetting IC404a. The Q output will therefore fall to 0V, cutting off Tr406, the whole of the current through R429 then being available to charge C12 back down negative.

As soon as the recharge commences, of course, the output of IC405 returns to a logic 1, removing the reset from IC404a.

However, not until the end of flyback will IC406 re-enable IC402d by applying a logic 1 to it, preventing early retriggering of the scan. It doesn't matter whether IC403a output is positive or negative when IC406 re-enables trigger gate IC402d, either way the first edge out of the latter will be negative going.

The control bistable will only be retriggered on a positive edge, i.e. on the first negative edge from IC403a following the appearance at IC402d of a logic 1 from end-of-flyback comparator IC406.

With a basic understanding of the circuit operation, we can now look in more detail at the complete circuit diagram. Emitter follower Tr401 drives the trigger amplifier IC401 via two 150Ω resistors in

Fig. 1: The circuit diagram of the trigger circuits, timebase generator and X output amplifier, all on board 4

series, providing a low source impedance.

At their junction a current injected via R405 provides a variable offset voltage at pin 3, giving control of the trigger level. The gain and bandwidth of the 710 are so great that despite the low source impedance there is a possibility of oscillation as a low frequency input is passing through the triggering point.

This would lead to false triggering and is prevented by applying a small amount of positive feedback via R406, thus introducing a small hysteresis. The output of IC401 drives IC402a, a two input nand Schmitt trigger circuit used as a buffer. The 710 will only drive one standard TTL load and so cannot drive both IC402b and IC403a directly.

The sudden change in loading on the 710 when IC402a switches can cause the 710 to retrigger falsely. This is prevented by the retardation network R407, C404.

The brightline circuit IC402b to IC403b works as follows. If IC402a is producing a squared-up trigger waveform, the output of IC402b will be detected by D401 and 402, charging C406 up positive. Current through R409 will keep Tr402 bottomed and the output of IC402c must therefore remain permanently high (logic 1). If the other input of exclusive or gate C403b is low, its output will be high. Under these conditions the output of IC403a will be an inverted version of its input. Conversely, if pin 12 of IC403b is high, IC403a output will not be inverted. This provides trigger polarity selection.

If there is no trigger input to the board or RV1 is right at either end of its travel, IC402a output will sit permanently at either a logic 0 or a 1. With no a.c. output from IC402b for the diodes to detect, after about a second, C406 will be discharged and Tr402 will turn off.

With pin 1 now high, IC402c will oscillate, since if its output is high, C407 will charge up via R410 until pin 2 reaches the trigger point and the output drops to a 0 and conversely. As IC403a and b are exclusiveor gates, the output must change whenever one of the inputs changes.

The square wave generated by IC402c will thus be passed to the trigger gate IC402d, operating the timebase and providing a trace when there is no trigger available.

If the square wave produced by Tr402c were of a very low frequency, on the fast time-base setting a very rapid scan would be followed by a much longer pause before retriggering.

This would result in a very dim trace. IC402c therefore oscillates at a very high frequency, giving a nontriggered trace brightness independent of time-base speed setting.

Note that IC402c output could have been taken straight to pin 10 of IC403a and IC403b inserted between the latter and IC402d.

However, mixing the polarity control in with IC402c "off line" minimises the number of gate delays in the main trigger path. This in turn enables more of the leading edge of a wave form to be seen.

The basic operation of the ramp generator section has already been described, but there are several points of detail worth noting. The D input, pin 13, of IC404a is tied to +5V, i.e. logical. Therefore the "Q" output, pin 9, will go high when a positive edge appears at pin 11. IC403c is a non-inverting buffer and the pull-up resistor R415 takes its output right up to +5V when high, taking the emitter of Tr406 to about $+4\cdot4V$.

The end of trace comparator IC405 resets the control bistable when the ramp reaches +3V, so there is no danger of D404 tending to turn on before the end of the ramp. VR401 is set so the end-of-flyback comparator only re-enables the trigger gate when the ramp voltage is within a per cent or so of the value at which it would rest if IC404a was never triggered.

and 1 on alternate traces. IC403d also drives Tr403, which is cut off during the scan and bottomed during retrace. The collector wave-form is used to blank the c.r.t. during flyback.

Besides driving the comparators IC405 and 406, emitter follower Tr404 makes the ramp wave form available at SKT 7 (sweep output) via R416 and drives the X deflection amplifier.

This is basically similar to the Y deflection amplifier, but driven unbalanced at Tr408 with the X shift voltage fed in at Tr409.

In view of the more limited frequency response

WARNING Extra care must be taken when working on any part of this instrument while power is switched on. 1100 volts can kill. When delving into the insides of the scope for any reason with power on keep one hand in your pocket. which suffices for the X amplifier, a single frequency compensation capacitor C411 is used in the emitter circuit. The Calibrated position for VR407 is fully anticlockwise, corresponding to minimum gain. RV408 allows this value of gain to be set to the required value.

Owing to the larger deflection voltage required for the X plates, the collector resistors of TR410 and 411 are returned directly to +150V.

With a higher supply voltage than the Y amplifier, the current is reduced, about 10mA in each transistor, to keep the dissipation of the BF336s the same.

Having completed the construction of Board 4, check each power supply pin to 0V with an ohmmeter to make sure none is short circuit and centre all preset potentiometers except VR401, which should be set with the wiper at the earthy end. Set VR407 fully anticlockwise.

Plug the board into the mainframe, remove the temporary $47k\Omega$ and $100k\Omega$ resistor chain and con-

Fig. 4: Back wiring of board 4 in relation to the components. This layout of the wiring should be followed to avoid any possibility of instability occurring

nect the X plates via R21 and R22 and sockets to pins X1 and X2 of the board.

Connect one lead of C18 to c.r.t. pin 3 (one of the tube base mounting holes—which are not used—can be fitted with a solder tag to support the lead) and the other via a socket to the blanking output of the board.

Set RV3 fully clockwise, S4 to position 2 and S401 to position 5. Plug in briefly and check that all stabilised supply voltages are normal, indicating no shorts anywhere.

A trace should appear on the screen—the tube may need rotating a little if it is not horizontal, but the spigot should be somewhere near the top. It is safest to turn off first, remember there is -800V around! Next, set S401 to position 2 and connect SKT3 to SKT1. With S3 and S301 both in position 3, two or

three cycles of the 50Hz Cal. square wave should appear on the screen.

If the waveform is running through, adjusting RV1 should synchronise it, provided of course that S6 is in the Internal position.

The trace should start with a positive or with a negative edge according to the position of S5. Now set S401, Timebase Multiplier, to position 5 (X 0.5). Rotate the wiper of RV401 away from the earthy end of its track until the trace stops running and then set it back just a few degrees beyond the point where the trace starts to run again.

These tests show that Board 4 is basically operational; setting up is covered in next month's instalment.

Next month we will deal with the case and other mechanical details.

Mains Cable Detector

This month's circuit uses the 741 op. amp. in a closed loop inverting mode to form a sensitive mains cable detector. A simple but very useful device it can save certain disaster when deciding where to bang nails, etc., into walls.

When a.c. mains current flows in a conductor there is a magnetic/electric field surrounding the conductor, albeit a very weak field. If this field comes within range of our search coil (L1) then the fluctuating 50Hz field from the conductor will induce tiny voltages and currents in the coil L1. These can be quite clearly heard in the earpiece.

On test, the circuit shown could easily and positively detect the presence of a mains cable to a small Ni Cad battery charger laid on a bench at a distance of 12 inches. A simple, small bar magnet could also be 'heard' when passed within some 3 to 4 inches of the search coil.

The complete circuit of the mains cable detector is shown in Fig. 1, it can be built on a μ DeC in less than 15 minutes and takes only 20 minutes to transfer to a piece of matching Blob Board. The inverting closed loop amplifier IC1 has its output fed to C3. By connecting the earpiece recommended between the positive plate of C3 and the negative line the circuit will function well, although it would be wise to reverse the polarity of C3 if this circuit configuration is settled as permanent. In Fig. 1 an additional stage of amplification is afforded by the addition of only two components, R4 and Tr1.

The total measured current drawn by the circuit with 3V applied was only 0.6 mA and battery life should be very long indeed if the device is used intermittently. A magnetic microphone was tried as a small loudspeaker in place of the earpiece. This worked well but increased the current drawn to 1.4 mA. The microphone had an impedance of 300Ω . Note that a lower impedance should not be used and that small 8Ω loudspeakers would be unsuitable in the circuit as shown.

The value of C2 should be found by experiment for optimum results. This is extremely simple with the μ DeC because one simply 'plugs in' different values of capacitor in turn. The capacitance shown will work well but various values from 10pF to 0.1μ F were tried. In general, the best value will lie between about 80pF and 350pF. The effect of adding this capacitor across the feedback resistor R3 is to make it frequency conscious and to attenuate the higher frequencies.

This is sensible for two reasons. Firstly we are only interested in 50Hz, which is a very low frequency. Secondly, without this capacitor the circuit becomes a h.n.c. circuit (Horrible Noise Oscillator!). The values of the input and output capacitors C1 and C3 are not all critical. Low values were selected because they would present less resistance/impedance to the lower frequency of interest. However, even using 0.1μ F in each case still gave excellent results.

Fig. 2: Layout of the mains cable detector on a µDeC. The same layout can be used to build the circuit permanently on a matching Blob Board

The search coil L1 was simply an old relay. The contacts connections were ignored. The one used was a midget 700Ω type, but almost any kind should work well. For the constructionally-minded a few hundred turns of, say, 30 s.w.g. enamelled copper wire wound higgledy-piggledy on a 2 inch piece of ferrite rod (any diameter) should also work.

The circuit might also be used as a telephone amplifier. This can be useful where you might require another person to listen to a conversation. One of the small telephone pick-up devices with a little rubber sucker may be plugged in directly in place of L1. The

telephone pick-up could also double as the search coil for the cable detector operation.

Sensitivity of the circuit can be damped by reducing the value of R3 to $820k\Omega$. Experimenters might like to insert a potentiometer in place of R3. Connect the outer tags on the potentiometer to μ DeC holes L32 and 035 (i.e. in place of R3), and connect the middle tag to either of the others. It is suggested that a 1M Ω potentiometer be used.

For best results, the earpiece should be an Acos red spot $lk\Omega$ type. All others tried were found to be inferior in terms of sensitivity. A crystal microphone was also tried in place of the earpiece and this worked tolerably well provided that a 560k Ω resistor was wired in parallel with it to provide a d.c. path for the collector of Tr1.

If (like the writer) a permanent circuit is required, the device could be transferred to a matching piece of Blob Board and the components then soldered into position. The Blob Board is then stuck directly to the

Practical Wireless, August 1978

inner wall of the case using a generous blob of Bostick to its plain side. You will also need an on/off switch—not shown in Fig. 1, the search coil should be mounted inside the case for protection and two small (3mm) holes drilled just above the coil and in both sides of the box.

When using the device, the wall is swept for maximum pick up. A long knitting needle is then pushed gently through both holes and the container drawn away up the knitting needle to reveal a locating point. This can then be marked lightly with a pencil and a further sweep made to trace the cable.

27

Introduction to S.A.MONEY

Last month we started our exploration of digital logic by examining the characteristics of digital signals and the AND gate circuit. In a real logic system the AND type gate alone will not allow us to perform all of the operations that we might need. Obviously we shall need some other types of logic gate if we are to produce a logic system.

The OR Gate

Let's go back to our simple electrical lamp and switch circuit. This time however, instead of having the two switches connected in series, we shall have them in parallel as shown in Fig. 9. Now we have produced a different type of logic gate function. Here the lamp will light if either of the switches is closed. In logical terms, the output is 1 when input A OR B is at 1. As one might expect, this type of gate is called an OR gate.

We can of course make up an OR gate by using discrete diodes, using the circuit shown in Fig. 10. If we compare this with a diode AND gate, we see that it is in effect an AND gate which has been turned upside down whilst the diodes have had their polarity reversed.

If input A goes to 1 diode D1 conducts and pulls the output up to 1 by driving current through resistor R. Input B will have the same effect upon the output. Only if both A and B inputs are at 0 will both diodes turn off to leave the output at the 0 level.

We can now draw up a truth table to show the various logic states that can exist in a 2-input OR gate (Table 3).

Table	3
-------	---

A	out	Output
A	B	Y
0	0	0
1	0	1
0	1	1
1	1	1

In fact the OR gate is effectively complementary to the AND gate. For an AND gate the output is 1only when all of the inputs are at 1, whilst for the OR gate the output is at 0 only when all of the inputs are at 0. If we changed all of the 1s for 0s and vice versa in the OR-gate truth table, we should end up with the same set of logic conditions as we had in the AND-gate truth table. For an OR gate we can also say that if any one or more of the inputs is at 1 the output will be at 1.

Fig. 12: A typical TTL OR gate

In CMOS logic devices, the OR gate arrangement looks similar to the CMOS AND gate except that it has effectively been turned upside down so that the p transistors are now in series and the n transistors are in parallel. A circuit for a typical CMOS 2-input OR gate is shown in Fig. 11. If either of the inputs is at 1, then either Tr3 or Tr4 will be turned on to bring point X down to the 0 level. This produces a 1 level at the output because of the inverting action of the output stage itself.

In the case of the TTL type devices, the circuit of an OR gate is rather different from that of an AND gate and is shown in Fig. 12.

OR Gate Symbol

Once again, because of the complex nature of the gate circuit, a special symbol is used to denote an OR gate. This one takes the shape of a shield, with the output line coming from the pointed end of the shield as shown in Fig. 13(a). For convenience in drawing an OR gate with a large number of inputs this symbol may be modified to that shown in Fig. 13(b). The symbols we shall use in this series are those of American MIL STD 806B. Alternative symbols are used in other standard systems.

Actual OR-gate integrated circuits come in a similar range of combinations to the AND-gate types. In the CMOS range we have the 4071 which is a quadruple 2-input OR gate arrangement. Then there are the 4075 (triple 3-input OR gate) and the 4072 which contains two separate 4-input OR gates. These are shown together with their connections in Fig. 14.

In the TTL series, the OR gate is not very popular and only one variety is available. This is the 7432 which contains four separate 2-input OR gates as shown in Fig. 14(d).

When designing actual logic systems we shall, from time to time, want to use OR gates which have more inputs than those available as standard circuits. These larger OR gates can be built up by cascading several smaller OR gates as shown in Fig. 15. Here an 8input OR gate has been produced by using two 4-input gates feeding a 2-input gate. If any input of G1 goes to 1 then its output goes to 1 and hence the output of G3 will also go to 1. Similarly a 1 applied to any of the inputs of G2 will produce a 1 at the output. Thus the combination will behave as if it is an 8-input OR gate.

Using OR Gates

How might we use OR gates in practice? Let us once again consider our automatic hot drinks machine, and see how it might be organised using logic. For a start we'll assume that some mechanical valves are used to control the flow of coffee, tea, milk etc. into the cup and that these valves are operated by solenoids driven from the logic.

When a 1 signal is applied to a solenoid the associated valve will deliver a metered amount of coffee, tea, etc. into the cup. If a 0 signal is applied to the solenoid the valve will remain closed.

Suppose we allow for six basic drink combinations, each of which is selected by a push button on the front of the machine. In this case these will give black or white coffee, which may be sweet or not as desired. Other options will be tea (with milk) which may be either with or without sugar. There are six inputs to our logic system and four outputs to control the valves for tea, coffee, milk and sugar. A suitable arrangement for the logic is shown in Fig. 16.

Let us start by looking at the coffee output line. This must go to 1 whenever any of the buttons calling for a coffee drink is pressed. We can produce the output required by feeding the signals from the four buttons selecting coffee combinations to a 4-input OR gate (G1). The output from this gate drives the coffee control valve.

If we consider the milk output signal this must be set to 1 when white coffee or tea has been selected. Again we have four inputs which are fed to an OR gate G2 to provide the drive for the milk control solenoid.

Practical Wireless, August 1978

Fig. 13: OR gate symbols

Fig. 14: Some actual OR gates

Fig. 15: Cascading OR gates to provide more inputs

Fig. 16: Logic circuit for a hot drinks machine

For tea there are only two combinations which need a 1 output so here a 2-input OR gate G4 is used for the tea control signal. Finally for sugar control we can OR together all of the inputs that require sugar and here we need a 3-input OR gate G3 to produce the output. This basic logic scheme could now be extended to allow for more combinations such as lemon tea, chocolate and maybe even cold drinks such as Coca Cola or lemonade by adding more inputs and more OR gates.

The Inverter

Apart from the AND and OR type gates, we need one more basic logic function which is called the inverter. This produces a 1 output for 0 input and vice versa.

Suppose we have a 2-input AND gate with signals A and B applied to its inputs. Now assume that we want to achieve a 1 output when A is at 1 but B is at 0. In a simple AND gate the output would be 0. Now suppose we invert the B input so that a 1 is applied to the input of the gate when the actual B input is 0, then we shall get a 1 out of the gate if A is 1 and B is 0.

A logic inverter might be a simple transistor stage as shown in Fig. 17. When 0 is applied at the input the transistor is cut off and the output line will go to the *1* level. If a *1* input is applied, the transistor will turn on and its collector voltage will fall to zero to give a 0 output. Such an inverter stage might have been used with discrete diode logic in the days before integrated logic circuits appeared.

In TTL and CMOS logic an inverter usually consists of simply the output stages of a gate circuit which with most logic types gives a logical inversion.

The symbol used for an inverter is shown in Fig. 18. Here the triangle indicates an amplifier whilst the small circle on the output line indicates that the logic signal has been inverted.

Actual inverter devices usually come in groups of six to a package. In the TTL range the standard version is the 7404 which is shown in Fig. 19(a) whilst the CMOS equivalent is the 4049 shown in Fig. 19(b).

Logic Equations

The theory of logic systems is by no means new. The ancient Greeks had already worked out many of the ideas but in the mid 19th century mathematicians, such as George Boole, developed logic as a branch of mathematics. Now a logic system could be reduced to mathematical equations and operated upon by special algebra called Boolean algebra. We shall not go into the theory of logic in a mathematical sense, but it is useful to understand the shorthand used to describe a logic system.

If we take a simple 2-input AND gate we can write down its operation as the equation

Y = A.B

Here the inputs have been named as A and B and the output is called Y. In a logic system the signals may be denoted by letters such as A, B, etc. or they may be given names such as DATA, CLOCK etc. In the equation for the AND gate the full stop between A and B signifies an AND function, so the equation can be translated as output Y equals input A AND input B.

For the OR function a + sign is used, so that for a 2-input OR gate the logic equation would become,

Y = A + B

If there were three inputs to the OR gate the equation would then become,

$$Y = A + B + C$$

We can make up much more complex logic equations by mixing both OR and AND functions so that we might have,

Y = (A.B) + (C.D)

Here brackets have been added to make it clear which of the logic operations go together. In this case if both A AND B go to 1, OR, if both C AND D go to 1, the output Y will go to 1. The logic arrangement which will produce this equation is shown in Fig. 20.

What happens if we put an inverter into the system? Any logic signal which has been inverted is denoted by a bar drawn over the name of the signal. So for a simple inverter the logic equation will be

$$Y = A$$

Such an inverted signal might be referred to as BAR A or alternatively NOT A, where A is the name of the signal. Thus we might have,

$$Y = \bar{A}.B$$

This means that output Y will go to 1 when input A is 0 ($\bar{A}=1$) AND B is at 1.

Now by using only these three types of logic unit, the AND gate, the OR gate and the INVERTER we can build up virtually any logic system.

The NAND Gate

If you look up a data book of TTL devices, the first one you are likely to meet is the 7400 which is described as a quadruple 2-input NAND gate. So what is a NAND gate and why should we need one anyway? Basically the NAND gate is simply an AND gate followed by an inverter, built up as a single device. One advantage of this type of gate is that we can produce all of our logic systems by using just one type of gate rather than three.

In the NAND gate the function is similar to that of an AND gate except that the output is inverted so that the truth table becomes as shown in Table 4.

Table 4

Ing	out	Output
A	B	Y
0	0	1
1	0	1
0	1	1
1	1	0

The symbol used for a NAND gate is similar to that for the AND type except that it has a circle at its output to indicate logic inversion. This is shown in Fig. 21. The logic equation for a NAND gate will be,

 $Y = \overline{A.B}$

where the bar over the A.B indicates the inversion of the complete logic signal at the output of the gate.

If we take a NAND gate and join all of its inputs together in parallel it will become a simple inverter. If we feed the output of a NAND gate through an inverter it will perform the same function as an AND gate, since the extra inverter will cancel out the action of the one inside the NAND gate. By inverting each of the input signals to a NAND gate we can produce the OR function. Here if any of the inputs goes to 1 the actual signal applied to the NAND gate goes to 0 and hence the output of the NAND gate must go to 1, thus producing the same result as an OR gate. You can check all of these actions by looking at the truth tables and working out the various states of the inputs and outputs of these combinations of NAND gates.

In TTL the NAND gates come in the same combinations as the AND types, giving four 2-input gates (7400) three 3-input gates (7410) and two 4-input gates (7420). Each of these arrangements has the same pin layout as the AND counterpart. In NAND gates however we can also have an 8-input gate (the 7430). For CMOS the 2, 3 and 4-input gates are the 4011, 4023 and 4012 respectively, and they have the same pin configuration as the AND versions. There is an 8-input gate in CMOS which has the number 4068.

The NOR Gate

Having produced a NAND gate we might now consider the possibility of combining an OR gate with an inverter. This will in fact produce what is called a NOR gate. Like the NAND gate it has the advantage that you could build up any logic system by using just NOR gates instead of having AND, OR and INVERT functions.

In the NOR gate a 1 applied to any of its inputs will produce a 0 to the output. Conversely the output can only become 1 when both inputs are at 0. This produces the truth table shown in Table 5.

A	out	Output
Inj	B	Y
0	0	1

0

0

0

1

Table 5

As we might expect, the symbol for a NOR gate is like that for OR but with a circle on the output line to show that the output is inverted. This is shown in Fig. 22. We can write down the action of a NOR gate as

 $Y = \overline{A + B}$

Practical devices are the 4001, 4025 and 4002 in CMOS, which are the NOR equivalents of the 4071, 4075 and 4072 respectively and have the same pin connections. In addition to these there is the 4078 which is an 8-input NOR gate. In TTL there is also quite a range of NOR gates giving two inputs (7402), three inputs (7427) and four inputs (7425).

By inverting the output of a NOR gate we can get an OR gate and by inverting its inputs we can produce an AND gate, so the NOR gate alone can be used to build up almost any logic function.

Changeover Gate

Let's see how we might use some of the gates that have been described. One frequently used function is to simulate a changeover switch. Here we want to pass either input A or input B through to the output according to the state of a control line C. Such a circuit can be built up from NAND gates as shown in Fig. 23, which also shows the equivalent switch circuit.

When control input C is a 0, gate G3 is effectively closed and its output remains at 1 irrespective of the state of the B input. Gate G1 acts as an inverter and G2 is therefore held open and allows input A to pass through to the input of G4. Since the other input of G4 is at 1, signal A passes through to the output. The inversions in gates G2 and G4 cancel out to leave A uninverted at the output. When C goes to 1, G2 closes and G3 opens to let input B pass through to the output.

Fig. 23: Logic circuit of a changeover gate, and its electrical equivalent

Practical Wireless, August 1978

1

0

This changeover gate function can of course be made up by using other combinations of gates and inverters and as an exercise you might like to work out some of these alternatives. Generally the circuit shown is convenient because it can be implemented by using a single 7400.

The Multiplexer

We can expand the idea of a changeover switch to produce a multiway switch similar to our old friend the rotary switch. Such an arrangement of logic is normally called a multiplexer.

In Fig. 24 we show the logic for a 4-way multiplex switch. The control signals C1 to C4 are arranged so that only one of them can be at 1 at any time. If C1 were at 1 then signal A would pass through G1 and since G5 is an OR gate it will also pass through G5 to the output. Gates G2, G3 and G4 will be off because one of their inputs is at 0 and hence they will have no effect on the state of G5. The number of inputs can be expanded by adding more AND gates and having more inputs to the final OR gate. If desired, multibank switches can be produced by having a series of parallel multiplexer circuits with the control inputs connected in parallel across the banks.

Because multiplexers are often used, special logic devices are available such as the 74151 which is an 8-input single-bank multiplexer in one package.

The EXCLUSIVE OR Gate

There is one further special gate function which it is worthwhile to investigate. When we looked at the OR gate you will remember that the output went to 1 when either input A or input B or both went to 1. There are occasions however when we would like the output to go to 1 if A or B was at 1 but to remain at 0 if both of the inputs went to 1. A gate that performs this action is called the EXCLUSIVE OR gate.

Such a gate arrangement can be built up as shown in Fig. 25. Here the two AND gates are detecting the input conditions A = 1, B = 0 and A = 0, B = 1and these are the only states where there will be a 1 at the output.

The EXCLUSIVE OR gate has its own special symbol as shown in Fig. 26. In logic equations too it uses a special symbol which is a + enclosed in a circle so that for a 2-input gate we get the equation, Y=A(+)B

The truth table for this type of gate is shown in Table 6.

Table 6

Ing	out	Output
A	B	Y
0	0	0
1	0	1
0	1	1
1	1	0

Normally, EXCLUSIVE OR gates are produced with only two inputs and the standard package is to have four separate 2-input gates in one device. In TTL this is the 7486, and in CMOS it is the 4070.

We shall see later that the EXCLUSIVE OR gate is useful when comparing patterns of bits, and can also be used as a switched inverter device which will allow us to invert a signal on command from another signal.

At this point we have looked at most of the useful types of gate, although there are of course many other combinations in both TTL and CMOS which can sometimes be useful, but whose functions can be reproduced by a mixture of the gates we have looked at already.

Next month we shall go on to look at the other major group of logic devices, namely the flip-flops.

M. J. DARBY

The construction of an amplitude modulation (a.m.) receiver can be considerably simplified by the use of one of the semiconductor devices which have been especially developed for this particular application. This and future articles will review the various types of device available and include a selection of typical circuits which the reader can construct and with which he can experiment.

Practical constructional details will not be included, since a variety of circuits are covered and constructional details for specific receivers are regularly included in our pages. Audio amplifier sections will not be included since the audio output from any of the receiver circuits can be fed into a standard audio amplifier. Integrated circuits will be used throughout, since this reduces the number of components used compared with discrete (separate) transistor designs.

Amplitude Modulation

The amplitude of an a.m. signal varies at the frequency of the audio signal concerned. For example, one may consider a 1MHz radio frequency carrier wave (which is far above the level of human hearing) and which varies in amplitude at an audio frequency of 1kHz. When a receiver is tuned to this signal, the 1kHz frequency will be heard from the loudspeaker.

Amplitude modulation is used on long, medium and short wave transmissions. Frequency modulation can be used at much higher frequencies (e.g. f.m. sound at about 90MHz) for high quality reception, but cannot be used with advantage at relatively low frequencies.

A.M. receivers are usually simpler than f.m. receivers and it is therefore sensible for a beginner to commence with a.m. circuits. Signals at the high f.m. frequencies cannot be received from distant transmitters, so if you wish to receive a signal from a station more than about 50 to 100 miles away, it will be an a.m. signal you will select. However, the fact that distant a.m. signals can reach your aerial inevitably means that one is much more likely to experience interference from unwanted signals than with f.m. reception.

T.R.F. or Superhet?

There are two main types of a.m. receiver, the socalled "t.r.f." (tuned radio frequency) and the superheterodyne or "superhet". The t.r.f. type is far simpler than the superhet, so the beginner who wishes to experiment is strongly advised to commence with a t.r.f. circuit.

In a t.r.f. receiver the incoming signal is amplified, detected or demodulated in a stage which converts the radio frequency wave into an audio signal and the audio signal is then amplified so that it can feed a loudspeaker or an earphone.

In a superhet the incoming signal is changed in frequency to another radio frequency signal known as the intermediate frequency. It is convenient to obtain most of the selectivity (or ability to reject interference from adjacent signals) at this intermediate frequency before the signal is demodulated and fed to an audio amplifier and hence to a loudspeaker.

A t.r.f. receiver can give good audio quality provided there are no interfering signals, thus if you require a simple bed-side or kitchen receiver for local programmes, a t.r.f. circuit will be satisfactory.

If, however, you wish to receive stations from Europe on medium waves or even from other continents on short waves, one will normally obtain much better results using a superheterodyne receiver.

T.R.F. Circuits

The remainder of this article will be devoted to t.r.f. circuits mainly for the purpose of helping the beginner. Numerous t.r.f. circuits have been published using discrete transistors, but a unique integrated circuit was released some years ago which has been designed especially for use in t.r.f. receivers.

This device is the Ferranti ZN414 which is ideal for use by the home constructor and is readily available. It requires only a low voltage power supply and provides a very high gain when used in a simple circuit.

The ZN414 is encapsulated in a simple transistor metal envelope, and the pin connections are shown in Fig. 1. There are only three leads, these being input, earth, and a common lead for output and the positive voltage supply.

Fig. 1: Pin connections of the ZN414

ZN414 basic circuit

A basic t.r.f. receiver circuit using the ZN414 device is shown in Fig. 2. The inductance L1 is a winding on a ferrite rod or slab aerial which will be described in detail later. This inductance must

Macdonald and Jane's

It is normally preferable to employ at least a single transistor amplifier stage (such as that shown in Fig. 5) so that the requirements of the earpiece are far less critical and a cheaper earpiece is satisfactory. A volume control is also incorporated in the Fig. 5 circuit, whilst the two forward biased diodes limit the voltage across the ZN414; the Ferranti BAW 37A double diode may be used here.

Loudspeaker circuits

The audio output from a ZN414 circuit can be fed to almost any audio amplifier which can drive a loudspeaker. Audio amplifiers using discrete transistors have been published for use with the ZN414, but simpler circuits can be made using an integrated circuit audio amplifier.

A small loudspeaker radio receiver circuit is shown in Fig. 6. In this circuit the ZN414 device is fed from a simple single transistor voltage stabiliser circuit so that the gain is almost independent of the power supply voltage used. If no stabiliser circuit is used, the gain will fall considerably as the battery ages. The supply voltage to the ZN414, and therefore the gain, can be set by means of VR2. The audio signal passes through the d.c. blocking capacitor C3 to the input of an integrated circuit audio amplifier. C4 helps to remove any radio frequencies from the audio signal and prevents spurious noise.

The LM380 was selected for this circuit partly because an extremely simple circuit can be employed, but also because it contains protection circuits. If the output of this device is shorted to ground accidentally, the output current will be limited to a safe value so that the device is not destroyed. In addition, if the device becomes so hot that it is in danger of failing, the output current is automatically reduced until it cools to a safer temperature.

Diode stabilisers

An alternative to the transistor voltage stabiliser of Fig. 6 involves the use of two series connected forward biased silicon diodes in the circuit of Fig. 6(a). The larger the value of R, the greater the gain

Fig. 6(a): An alternative voltage stabiliser using two silicon diodes

of the ZN414. The voltage drop across this resistor is added to the voltage drop of about 1.3V across the two forward biased diodes.

It is also possible to employ a small light emitting diode instead of the two silicon diodes of Fig. 6(a), but the current required to enable the light emitting diode to provide a reasonable light output will be greater than that required by the Fig. 6(a) circuit. In other words, the value of R must be reduced.

Frequencies

The variation of the ZN414 gain with frequency is typically similar to that shown in Fig. 7. The peak gain is at about 1MHz, but the device can be used with a reasonable gain from about 100kHz up to about 3MHz. However, one should remember that the gain is much reduced near these limiting frequencies. The lowest frequency for reasonable gain is set by the values of the internal coupling capacitors shown in Fig. 2, whilst the maximum practicable frequency is determined by the properties of the internal transistors in the device.

It can be seen from Fig. 7 that there is a considerable difference in the output voltage as the input rises from 1mV up to 3mV, but any further increase in the input voltage produces a relatively small change in the audio output level owing to the a.g.c. action.

Aerial

The aerial may consist of a ferrite rod about 12cm in length with 55 to 65 turns of 28 gauge wire wound as a single layer for medium wave. The long wave coil may consist of some 250 turns of 38 gauge single silk covered wire wound in a random way with turns on top of one another, as indicated in Fig. 8. The exact number of turns will depend on the value of the tuning capacitor placed in parallel with the coil (typically 200pF).

Fig. 8: The ferrite rod aerial with I.w. and m.w. coils

Only one aerial coil has been shown in the circuits of Figs. 2, 4, 5 and 6. If both medium and long wave coils are required, the switched circuit of Fig. 9 may be used with any of these circuits. It is important that the aerial coil should have a high Q (magnification) so that reasonable selectivity is obtained.

If one requires an extremely small receiver (possibly using the circuit of Fig. 4), there will not be

enough space for a reasonably long ferrite rod aerial in the case. One can employ a ferrite slab with only a medium wave coil wound on it in such receivers; the slab should not be less than about 3cm in length unless one intends to use the receiver only fairly close to a transmitter. A longer ferrite slab will produce a greater signal voltage.

Fig. 10: A double tuned circuit for greater selectivity

If greater selectivity is required, a double tuned circuit can be used before the ZN414 as shown in Fig. 10, but this requires careful alignment for optimum performance. The Q factors of the two tuned circuits should be similar. If the two tuned circuits are not correctly matched, each station may be received at two points in the band. This type of double tuned circuilt is especially useful when one has a larger external aerial coupled to the ferrite rod. The lead from the external aerial should be connected to a few turns of wire around the ferrite rod, the other end of the winding preferably being connected to earth.

Fig. 11: A six position switching circuit

The circuit of Fig. 11 shows how four pre-selected stations may be selected by the push buttons S1 to S4. The buttons S5 and S6 enable the normal medium and long wave bands respectively to be tuned by means of the variable capacitor C5.

Next month we will consider superheterodyne receivers for a.m. reception.

This attractive unit incorporates three-speed turntable with choice of magnetic or ceramic cartridge, stereo cassette deck, and long-wave, medium-wave and f.m. stereo tuner with automatic frequency control. The high-quality amplifier provides an output of 11 watts per channel into 4 ohms.

Cabinet parts will be available, to let you build a music centre fit to grace your lounge.

SIMPLE HIGH-RESISTANCE VOLTMETER

An economical design based on the CA3130 operational amplifier, with ranges of 100mV, 1V, 10V and 100V d.c. full scale. Input impedance is $10M\Omega$ on all ranges.

ELECTRONIC FISH~FEEDER

Does your fish go hungry while you're away getting your suntan? Build our automatic fishfeeder and ensure that just the right amount of food reaches him at regular mealtimes. Easy to build, it suits all fish from guppies to piranhas!

In official lists of the "Q" codes—the comprehensive system of abbreviations used by professional telegraphy operators to speed the exchange of traffic —the meaning of each code is clearly defined.

Many of these codes have been adopted by other services, such as broadcasting, and by the amateur radio fraternity. For each class of user, the same abbreviation can have a quite significantly different shade of meaning.

To the transmitting amateur, a QSL is an acknowledgment of a successful two-way radio contact established with another amateur, and normally takes the form of a specially printed card. To this are added a note of the date, time and frequency of the contact, and brief technical details of the equipment used.

For the broadcast band listener, the radio contact is, of course, strictly one way, and the situation therefore differs again.

Broadcast Band QSLs

What is a QSL? is a question sometimes asked by newcomers to the hobby. According to the March 1978 bulletin of the International Short Wave Club, "a QSL is an acknowledgement". International broadcasters like to hear from their listeners, many of whom are not DXers and in reply these stations issue QSL cards which are really mementos of the occasion. The cards themselves are often colourful. On one side there may be a photograph, a design of some sort or even the station's callsign, while on the other side there will be the acknowledgement and perhaps some information that would confirm that the listener did in fact hear the broadcast.

It is the last factor that causes difficulty for some DXers. Though many will be content to have a card that can be shown to others and perhaps kept in a photograph album, the serious DXer who is interested in obtaining a diploma from a DX club, or who simply wants to be able to prove his reception, will be disappointed. As the ISWC puts it, "To prove reception the document that one receives from the station should be plainly endorsed with the date, time and frequency". Such a reply is called a verification (verie for short) and this is what the majority of DXers hope to receive in return for a reception report.

The current QSL card from Radio Australia is an example of a pleasant QSL that is also a verie. It is a card with a colour photo on one side and the sort of details that the serious DXer would want, on the other side. Even here, the purist might complain that it should have stated my address. The card came inside an envelope!

DX clubs consider QSLs and Veries to be a major part of their activities. The Twickenham DX Club for example, recently produced a 16-page QSL Survey which summarises verification details submitted to their "QSL Report". Broadcasting stations are listed by country. The frequency band verified, number of verifications received from 1974-76 and 1976 to March 1978, the type of verification (card, letter, folder), whether return postage is recommended and the time taken to receive a reply, are all listed in this comprehensive survey. Copies can be obtained from the TDXC, 13 Tennyson Avenue, Twickenham, TW1 4QX for four 7p stamps in the UK or for 3IRCs surface mail or 5IRCs airmail to any other part of the world.

Practical Wireless, August 1978

A final word on QSLs comes from Peter Gatenouse of Buckingham, who refers to a recent communication from Radio Canada International which says that to receive a QSL card from Radio Canada International one has to be on the mailing list! Programme schedules will be sent free but QSLs will not be sent to people not on the mailing list. Write to RCI Publicity and Audience Relations, PO Box 6000, Montreal, Canada H3C 3A8. Clearly, this type of QSL is intended for listeners rather than DXers.

Medium Wave

The medium wave DXer invariably resides outside the service area of his DX and this should be kept in mind when writing to a station. The reception report is unlikely to be of any value to the station and one is depending on goodwill for a reply. So, always include return postage, either an International Reply Coupon, currently 25p at main Post Offices, or as unused postage stamps of the country concerned. These are obtainable from stamp dealers (philatelist shops).

Send the reception report to the Chief Engineer, if possible in the language of the country, as there will not be an international department to deal with listeners' letters. Many radio clubs supply report forms in a number of languages, Spanish and Portuguese being the most useful. Try to convince the station that you really did hear them as they may be surprised to hear from you. Station announcements, slogans, weather report details, time checks, news items are the sort of material to mention and these can be heard at programme changes which usually occur on the hour or half hour.

Introduction to the Problem

Many model railways use the solenoid type of point motor to operate the point blades from a central control panel. Although the manufacturers claim that these units will operate at a supply of 12 to 20 volts they rarely do so reliably and it is generally better to operate them at around 30 volts. This ensures that they throw properly and overcomes any resistance due to mechanical deficiencies inherent in the design. A typical point motor is shown in the photograph, along with the unit which forms the subject of this article.

The coils forming the solenoids have a d.c. resistance of around 2Ω each and it does not take much imagination to see what happens when 30 volts is applied to the motor. If the armature sticks or the operator leaves the switch on for any length of time then some 15 amps will flow (assuming that the power supply is capable of delivering this current) and 450W will be generated as heat. The end result is that the solenoid coil burns out.

Solution and Circuit Description

The situation can be avoided by using a capacitor discharge system to provide enough energy to ensure that the armature is thrown over but not enough to burn out the coils if the operating switch is left on.

The circuit shown in Fig. 1 uses a transistor to switch off the charging current to the operating capacitor C2 whenever the output is connected to the 0V line by a low resistance such as a motor coil.

Fig. 1 The complete circuit diagram

When the load is removed from the output the base of Tr1 is unclamped and Tr1 is turned on allowing current to flow through R2 to charge C2. The low value resistor R2 is used to limit the maximum charging current and its value is not critical. R1 limits the current which flows when the load is left applied and C2 has fully discharged. When C2 is fully charged and there is no load on the output, Tr1 is turned off via D6. Any small loss of charge due to leakage is made up automatically. Diode D5 provides reverse voltage protection for C2, preventing back e.m.f. damage due to the transients produced when the current in the solenoid coil changes rapidly.

Power Supply and Switching

The power supply is a conventional bridge rectifier circuit with a large reservoir capacitor C1. The input

PARIS Components HOW DAVID GIBSON

With a record attendance by nearly 82,000 visitors, the Salon International des Composants Electroniques 1978 chalked up yet another international success. This giant electronics exhibition, held each year in Paris, attracted over 1345 registered exhibitors from 30 countries and spread itself over an area of 60,900m².

Exhibits ranged from Ham radio equipment and accessories to laser trimming equipment, from single components to highly complex instrumentation and of course. microprocessors.

In this latter area it was interesting to see a microprocessor timer kit. This offered a choice of 21 programmes plus a digital readout of time. The unit has many applications but suggested text included ideas like, automatically waking you up in the morning (you can programme in different times for different mornings), switching on your egg and boiling it to perfection, switching the heating on and off plus putting lights on an off during the evenings to deter burglars. The input keyboard (supplied with the kit) has buttons for each day of the week, a one to nine set of tabs, plus an am/pm button although the digital clock can be switched to read either 12 hours or 24 hours.

Readers wanting to conduct underwater experiments in the bath (?) or elsewhere will be pleased to hear of a special transducer shown by a French company. An electret (an electrostatic transducer) for underwater applications has been developed. The air gap which is commonly present in such transducers has been replaced by a compressible, very high resistivity

material which is held in intimate contact (lovely wording those French use!) with the electret. This design suppresses the drawbacks which result from the presence of air in such transducers-variation of sensitivity as a function of immersion depth for example. The advantages claimed for the new device are a sensivity higher than 30μ V/ μ Bar (-90dB relative to 1V/ μ Bar), broad bandwidth, and an acoustic impedance close to that of water. The company is understood to be making some experiments with an array/antenna of electrets which could prove interesting for listening underwater.

One device causing raised eyebrows was the "Snapistor". This is a thick

Signs of things to come. A complete data terminal in an attache case. It comprises a full keyboard, all necessary electronics, and a small collapsible television screen which folds down. The station may be used over a standard telephone via a modem, and can chat to computers and data terminals anywhere in the world

film resistor network on a ceramic substrate. Pre-scribed lines on the back of the substrate divide it into ten parts. Each part can be snapped off, one by one, and each snap increases the remaining resistance by 20%. This gives a five-fold increase in resistance when all nine parts have been broken off. Applications suggested are; to set the gain of a transistor stage, or to set up the voltage of a voltage regulator. Here, one could use one Snapistor for coarse adjustment, and another for fine setting. Various ranges of resistance values were offered. These inincluded; 100 Ω to 520 Ω , 10k Ω to 52k Ω , 33k Ω to 520k Ω , and 100k Ω to 520k Ω . The resistance values are +20%, TCR +100p.p.m./°C and operating temperature range -40° C to $+125^{\circ}$ C. Power handling capability depends on how much snapping you've done. If they are unsnapped (i.e. all sections are in circuit) then the power capability is 250mW; with just a lonely one segment, power is 50mW. Maximum voltage is 100V.

Trends were not hard to spot. Many people offered microprocessors either a single chip, or with a complementary keyboard, or as a complete kit of parts with a manual,

Motorised rotation of f.m. antennas featured strongly. These came complete with a nicely styled box. The box shows you which way your aerial is pointing and the whole array is controllable from your living room. Many companies showed results, including a BBC2 test card which had superb definition.

One dealer displayed an impressive array of Yaesu Ham equipment. Interesting to see the FT-301D solid state transceiver. It has a digital readout and uses no valves at all, not even those ubiquitous 6146's in the final. The unit runs from 12V direct—ideal for mobile work, although a separate mains p.s.u. is available which includes a digital clock and an automatic callsign sender for the c.w. enthusiast. Price was horrendous and interest high!

French giant Thomson-CSF took a huge number of stands, indeed their particular alleyway was signposted "Avenue de Thomson-CSF". Along this Avenue was found an "Easy-touse Super-Noticon". This turned out to be Thomson's latest addition to its range of low-level TV camera tubes. The Super-Noticon really is super, too. It can view a scene without trouble even on a cloudy and moonless night. The French boffins mumbled something about sensitivity down to 10⁻⁵ lux.

Also on the Thomson stand were a number of quartz resonators which achieve 300MHz in fundamental mode. Close by were a number of devices described as piezoelectric but using Lithium Tantalate and not quartz. These synthetic single crystal devices have inherent properties suited to the production of wideband filters in the 0.08 to 35MHz band. A stand spokesman hinted at possibilities that this frequency could be raised to 400MHz in the not-too-distant future.

Surface wave filters were a feature on the Siemens stand. The company has succeeded in laying these down on a lithium nobate substrate. The technique is to lay down tiny fingers of conducting pattern which intermesh (but do not touch) rather like the teeth of a comb. The result is that the signal can be made to pass along these closely coupled subminiature antennas which are frequency sensitive and thus have a filtering action. Although other materials made the surface wave filter a reality, high cost and low consistency were deterrents. Lithium Nobate is claimed to overcome these problems The filter has the great advantage that it has no coils or capacitors. First applications are in the i.f. strips of TV sets. Siemens has already manufactured filters to suit British standards and markets. The standard package size on the stand was 19 imes 16 imes 5mm with five terminals brought out at one side.

The French Amateur Radio Association—Reseau des Emetteurs Français —had a real live repeater satellite on show. Unlike other repeater stations which are fired aloft from places like Cape Canaveral, the French decided to try a much cheaper method. They attached their 144MHz repeater station to a balloon and let it loose. The

Practical Wireless, August 1978

The French Ham v.h.f. radio repeater Anjou 009, which was sent up by balloon on September 25th 1977 and returned to earth via parachute. It is one of a series which have been launched by French Amateur Radio enthusiasts.

highest one of these repeaters (there have been about nine) has reached is 31,400 metres. The "flight" can be up to 24 hours long, then the balloon bursts and the repeater parachutes back to earth. The REF has around 12,000 members in France in some 250 Ham radio clubs. Annual subscription is 120 French Francs.

One normally associates Sprague with capacitors, but visitors to the stand in Paris found quite a number of useful i.c.s on display. A good one to watch for is the ULN-2283B. This is a little audio chip which offers 1W output with 12V applied. It will function from -40°C right up to a very hot +85°C. Gain is claimed to be 43dB and the i.c. will function at voltages down to only 3V. The circuit shown on the Sprague stand gave an idea of the simplicity when using the ULN-2283B. Apart from the chip and loudspeaker, only two capacitors plus a volume control are required.

The new Philips personal bleeper system looked a good idea. The tiny pocket receiver, besides have a bleep "you're wanted" facility, also boasts an alphanumeric readout. Speech facilities can be added, too, if required. By using a standard code, say from one to nine, a message can be sent very easily. Thus a number 3 displayed would mean outside telphone call; number 6 might mean return to the office etc.

At more official levels, the exhibition literature had some intriguing headings. How about "Universal elastic banana plug"? Upon my breathless arrival I was shown a banana plug whose spring arrangement assures good electrical contact with any diameter socket from 3.9mm to 4.5mm in diameter. After 100,000 pluggings in and out (no, I didn't) the plug still has a contact resistance between it and its socket of only 0.8 milliohms. Maximum current is 15A.

A fascinating device was one which varied the inductance of a coil---useful in tuning up aerials no doubt. The main coil has its windings composed of silver-plated tape-like metal. One end of this is fixed, but the other goes across to another former, which is motor driven. When power is applied to the motor, it simply unwinds turns off the coil onto the secondary former and thus the original coil has its inductance decreased. By deriving the motor power drive command from a signal fed back from an s.w.r. bridge, aerials may be loaded automatically from transmitters even when the frequency is changed by quite a large amount.

Solar cell enthusiasts will be pleased to hear that production of professional industrial components is driving the prices down and they could well make an appearance on the Amateur market before very long. One French company is talking of 500,000 cells of 57mm diameter for 1978, and the production has already dropped the price by 30% at the beginning of this year.

Still in terms of economical power, Lithium batteries were commonly offered. One of these would give 300μ A for 100,000 hours. Couple this with a CMOS circuit and your battery replacement problems could be over. Carrying this capacity to the 30mA mark would give 1,000 hours of operation. The operating temperature range of these batteries is impressive; from -65° C up to $+160^{\circ}$ C.

Smallest radar I've seen was on the Jay Electronique stand. It measures 126mm \times 60mm \times 70mm. It's called a guarding radar because its power dissipation is 22mA at 12V, and it is undisturbed by small things, such as passing birds, insects etc. Its range is fully adjustable from 0 to 15 metres.

In the heavier machinery part of the exhibition was a machine for winding wire onto toroids. It does this at the rate of 2,000 turns/minute. Have you ever thought—how do you automatically wind onto a ring or toroid?

Experimental software Broadcasting Satellite

A new high-power experimental broadcast satellite was launched from Cape Canaveral in April for the National Space Development Agency (NASDA) of Japan. It will doubtless be the forerunner of many new satellites designed to provide high-quality experimental colour television reception in regions of the world where the terrain makes it difficult or impossible to receive high-quality signals from normal earthbound television transmitters. The spacecraft was constructed for NASDA by the Space Division of the US General Electric Company of Valley Forge, Pennsylvania under contract to the Tokyo Shibaura Electric Company (Toshiba).

This BSE (Broadcast Satellite Experimental) craft weighs 678kg and was sent into orbit by a Delta 2194 rocket. Onboard propulsion jets propelled the satellite into a geosynchronous orbital position at longitude 110° E, and the control system will be able to maintain its position to $\pm 0.1^{\circ}$ in latitude and longtitude.

Television and voice signals will be sent from the Japanese mainland to the satellite using frequencies in the $14 \cdot 0$ to $14 \cdot 5$ GHz band, and the satellite will then relay these signals back to ground using frequencies in the $11 \cdot 7$ to $12 \cdot 2$ GHz band. It will provide two high-quality colour television channels and also voice communication circuits over the whole of the Japanese mainland and over many remote islands and mountainous regions. About two per cent of the Japanese population are outside the area where reception from existing transmitters is satisfactory. Japan has many islands spread over a wide area and it is thought that a high-power relay satellite will provide an economic and effective means of sending television signals to such regions.

Receiving stations

If a satellite relay system is to be an economical proposition, it is essential that the cost of each of the numerous small receiving stations shall be minimised. This implies that the power transmitted by the satellite must be quite high—especially if the power is beamed to cover a relatively wide area of a country.

The experimental broadcast satellite has been designed with this particular objective in mind. Many satellites use a cylindrical array of solar cells which are spinning in space so that the spacecraft is stabilised. However, such spin-stabilised craft have the disadvantage that only a small proportion of the solar cells are receiving the maximum amount of energy from the sun at any one time. The experimental broadcast satellite therefore employs three-axis stabilisation with its solar cells on arrays of extended arms; all of the solar cells in such a satellite can be directed towards the sun at all times (except during eclipses of the satellite by the earth) and therefore maximum power is available. The solar cells of the satellite provide a minimum power of at least 780W.

The Japanese BSE satellite. The aerial reflector can be seen in the centre and the solar cells on each side.

The receiving stations will employ parabolic antennae, but owing to the high power level transmitted by the satellite and the fact that only Japan will be included in the transmitted beam, the parabolic reflectors of the receiving aerials can be as small as 1m in diameter. (This may be contrasted with the huge 30m diameter aerials used for international satellite communications which provide about 900 times the gain of a lm aerial). In many cases, a single receiving station will be able to feed the received signals to a whole district, but cheap receivers will be able to be used in individual homes in remote districts. The satellite has an expected life of three years and many signal strength measurements will be made at various points in the reception area so that this experimental satellite can be used as a model for future craft.

Command and control signals will be transmitted to the satellite from ground stations in Japan in the S and Ku microwave bands. It is interesting to note the tendency to use higher and higher frequencies for satellite communications with earth stations in order to obtain more bandwidth and hence a greater information carrying capacity.

Future developments

The basic design of this satellite can be readily adapted to provide both expanded telephone, data and television services and in addition to incorporate educational and health care transmissions to the developing countries in future satellites. Some satellites of the future will be operated by one nation, whereas others will be jointly operated by a group of small nations. All are situated in a geostationary orbit some 36,000km above the equator where they remain at the same position above the earth's surface. They are expected to have a very great impact on health and medical care in many of the developing countries.

PRINTED CIRCUIT BOARDS SERVICE FOR PW PROJECTS

It has now been decided, commencing with our issue dated September 1978, to enlarge the facilities for the supply of p.c.b.s to readers by authorising additional suppliers. It is hoped that readers may benefit from being able to purchase boards as part of component kits, thereby reducing the number of separate orders for a project.

For some time, most p.c.b.s published in *Practical Wireless* have been available exclusively from Reader's PCB Services Ltd., P.O. Box 11, Worksop, Notts, who will continue to be a supplier and to whom we would wish to say thank you for helping us to get the service started.

Applications for permission to reproduce boards for resale purposes must be made to the editor.

Go West

If inflation is hitting you and/or you are intending to take a job in electronics, think about the USA. The IEEE (Institution of Electronic and Electrical Engineers) out there reckons that its members' salaries have kept well ahead of inflation over the past two difficult years—and they're still well ahead. Average annual salary is put at around 27,500 dollars, and some members have confessed to raking in 70,000 dollars.

No, I don't have any membership forms!

Watch what you say

Microprocessors seem to be creeping into practically everything these days. There's even one lurking in a new system under development which will recognise continuous speech. The basic unit has a 16 word vocabulary. Each word is converted/translated into a pattern generated by a spectrum analyser. This pattern, representing the word, is then stored in a memory bank.

When the system hears words, it nips along to its memory bank and rummages around comparing the words it's hearing with the words it's "learned". If it finds a match you get a response.

One particular version of the system was hooked up for a demonstration and arranged to respond to single word commands. The whole affair was coupled to the telephone network via a suitable interface. When the system was instructed to hunt through the files of the New York Times Information Bank (which was hundreds of miles away) it did just that. It took less than a minute to display, on a video terminal, abstracts of the particular topic selected.

Intelligent to credit cards

And that's not the end of the microprocessor—yet. They're doing things with them in France, too. Like one company that is actually putting one (albeit a mighty thin one) into a bank credit card. When you think that the familiar 14 or 16-pin in-line package contains only a very tiny, thin chip, then if one can do away with all that bulky packaging a very thin circuit indeed can be had. The exact method of fabrication is still under wraps but the future looks extremely promising. Unlike many credit type cards which can only "store" a very limited amount of information on magnetic stripe, these microprocessor beasties will be able to store lots of things, like the balance in the account which would be easily updated at every transaction. Perhaps they might even put a radio receiver chip in there somewhere: do I recognise someone saying "Hear hear"?

High Power

Hams (radio Amateurs) will remember their first experiments with transistors, particularly using them to generate r.f. Some of the early Ginsberg experiments on 1.8MHz with these three-wire fuses were, to put it kindly, expensively disastrous! One watt was, in the early days, guite something. This contrasts with the new power field effect transistors just out which will happily give 100W of c.w. at 175MHz. Certain advantages are claimed by the manufacturers. For example they tell that the devices draw very little input current and things like biasing and modulating are simpler than with bipolar devices. They also tolerate load mismatches and in terms of distortion they are ahead of bipolars. Third order distortion is reckoned to be about the same as a similar size bipolar component, but because the f.e.t. devices have a square law characteristic the higher order distortion is between 5 and 10dB less.

Spot your Tank

So there you are, peering at your video screen, looking for the enemy. But its difficult. Tanks, for example, can be camouflaged quite cunningly. One answer is to employ a computer with built-in edge detection routines. These things take the data from the sensor and tell the computer to enhance all the straight lines. This crafty dodge has the effect of outlining man-made objects quite dramatically. But we have a problem—the process involves using things called algorithms and these can take some 10 seconds. By that time, our unfriendly

A REVIEW OF RECENT DEVELOPMENTS In general, the author does not have any more information on products than appears in the article.

> tank crew could have done some very nasty things to both you and your algorithm.

> However, tank spotters among you can now rest easy because a solution is at hand. The answer has been to use a charge-coupled device which acts extremely fast—almost in real time to all intents and purposes. If you want to be more precise, the manufacturers say it works up to 1,000 times faster than a general purpose computer. The technique employed is subject to a patent and is quite ingenious.

> The chip receives the image signal from the electronic camera (another c.c.d. used for the sensor) and gives it to three separate parallel shift registers. Each register takes just one line at a time and so at any instant these registers hold three contiguous lines of the image. Backing these are 20 edgedetection algorithms which are so arranged that they are able to treat the three lines held by the registers as a 3×3 array of nine separate little picture elements.

> The straight edge components of the signal are located simultaneously in 2D i.e. in both vertical and horizontal planes. This is achieved by part of the chip continuously calculating the difference in picture signal between the separate picture elements in the little 3×3 array.

And to think I was impressed by the first op amp.

Micropot

If I mention the word "potentiometer" you will probably have a mental picture of a pot about 25mm diameter with a spindle which is always too long and has to be hacked off! But what about the latest potentiometers which are so small you can get a dozen or so on your fingernail? These truly minute pots are only 0.172in. in diameter and 0.1in. high. Presumably a magnifying glass and micro-screwdriver come with each.

Practical Wireless, August 1978

THE PU SAVON' 2 Metre f.m. F.m. F.m. PART 2 BRIAN L. PHILLIPS G8FVM

Board 3—Power Amplifier (Fig. 7)

If a greater power output is required, then Board 3 may be fully constructed as shown and will be found to deliver around 10 watts r.f. output with a 25 volt supply to the final two stages. It is also quite feasible to construct just one amplifier, or two, or three, etc., depending on requirements.

Merely using the single Tr1 on this board will produce about ${}^{1}_{4}$ -watt, whereas including Tr2 will increase this to about 1 watt. In each case, the aerial filter will connect adjacent to the appropriate tuning capacitors and the remainder of the circuit is omitted.

Do not apply more than 15 volts to Tr1 and Tr2 as in this configuration Tr2 especially is running near to its maximum rating.

In the completed power amplifier, the two BLY83 transistors are bolted direct to the metal case and holes are drilled in the board for the transistor body to sit in ensuring good heat transfer. Push-on heat sinks are fitted to Tr1 and Tr2, which are wired to the board conventionally.

Readers who intend to operate the Avon Transmitter should be in possession of the appropriate licence issued by the Home Office to those who have passed the City and Guilds Radio Amateurs' Examination. Details may be obtained from: The Home Office, Radio Regulatory Department, Amateur Licensing Section, Waterloo Bridge House, Waterloo Road, London SE1 8UA.

The board layout for etching is shown in Fig. 8 and Fig. 9 illustrates the component positions.

The aerial filter consists of a parallel-tuned circuit offering low attenuation to the 2m signal, but is effective in reducing harmonic and spurious emissions to an acceptable level.

Practical Wireless, August 1978

Two small inductors either side of the tuned element resonate at the second and third harmonics respectively and further reduce the possibility of radiation at these frequencies.

A small, separate board supports the filter and is mounted close to the chosen output stage.

The low level r.f. input from Board 2 is coupled to Tr1 base via a short length of miniature 50Ω co-axial cable. Inductor L1 provides a match into the base/emitter junction of the transistor with L3, L5 and L7 of the following stages.

Each stage is in class C and there is therefore no d.c. bias required. Each positive half-cycle of the r.f. sinewave input turns the transistors on and the flywheel effect of the collector tuned circuits modifies this pulsed signal to a sinewave again.

To allow a d.c. path from base to emitter, small ferrite-cored r.f. chokes are used from base to ground. These are marked "r.f.c." on the diagrams and they are all wound in a smiliar manner, including the three used in the supply line decoupling.

The inductors RFC1 and $\tilde{R}FC2$ are wound on $^{1}2$ watt 1M Ω resistors, their leads being used to anchor the windings.

All remaining r.f. chokes are air-spaced types and pictorial details are given in Fig. 12.

Note that the high-power output and driver are fed directly from the 25 volt d.c. supply whilst the remainder of the transmitter, with the exception of the display, is fed from an integrated circuit regulator type 7815. This device has short-circuit and overtemperature protection, and delivers a constant 15 volts at up to 1 amp.

Its inclusion is not necessary if a reasonably stable d.c. supply is available, and of course the entire transmitter can be operated from 12 volts at reduced output.

Relay Switching (Fig. 10)

The incoming 25 volt supply has a diode D1 (BY127) inserted in series with its positive line as protection against polarity reversals. Relay RLA is the keying relay, and is operated by the microphone pressel switch or by the "send" toggle on the facia of the transmitter. The co-axial relay CO is the aerial changeover, and operates through contact RLA3 of the keying relay.

On operating the microphone pressel switch, RLA operates, RLA1 completes the circuit to the 15 volt regulator, RLA2 illuminates the status l.e.d. "send", RLA3 energises the co-axial changeover relay CO and RLA4 applies the 25V to the BLY83 final amplifiers.

The "send" switch S3, located on the front of the transmitter merely overrides the microphone switch and provides a latching facility, enabling the transmitter to be permanently keyed.

Switch S1 "cal" enables the transmitter to be keyed at very low power by removing the 25 volts to the power amplifiers. Contacts S1a close, completing the RLA coil circuit; RLA1 closes, RLA2 changes over but the "send" l.e.d. is prevented from operating by S1c. The CO relay circuit is completed by RLA3, RLA4 closes but the 25 volts is prevented from reaching the power amplifiers by S1b, which is open.

The "tune" facility S2a again energises RLA; S2b disables the 25 volt supply to the power amplifiers and operates the "net" l.e.d., whilst S2c prevents the aerial changeover relay CO from operating.

An additional contact set on RLA can be used to provide a loop make or break facility for receiver muting and sufficient contacts on the d.c. input plug have been provided for this option.

Tuning

Each transistor collector is series-tuned to give a low impedance feed to the following stage and ultimately to the aerial. The trimmer furthest from the board edge in each section—i.e. TC1—tunes the coil, and the other—TC2—is adjusted for maximum drive into the next stage.

This arrangement has proved to be both reliable and stable in operation. Tests with the prototype indicated that however badly out of alignment the board was, negligible stray oscillations or spurious signals were produced. Should the board be well off tune, there will be no output.

Fig. 10: Circuit diagram of the switch and relay wiring

Decoupling

Notice on the circuit diagram the extensive use of capacitive decoupling on the power supply lines. Various values are used to give broadened effectiveness and the specified types are particularly important here.

A characteristic of the r.f. power transistor is that generally speaking it will not withstand high switching transients, such as those produced by relays. Filters are therefore included from the supply rail to ground thus reducing the charging effects on the line as the voltage is applied and removed.

Hardware Notes

The prototype was constructed in a Foxall T4108 instrument case on a Foxall T2004 chassis specifically made for this enclosure (see Fig. 11).

The boards are bolted directly to the chassis, with the exception of the oscillator (Board 1), which is supported by small insulated pillars and secured by 6BA PK screws. Construction is not too critical, provided clearance for the switches etc on the front panel is allowed and sufficient room is made available for the relays, co-axial sockets and power jack.

Three different types of 50Ω co-axial connector were used to avoid confusion or the accidental insertion of wrong cables. The aerial input is an SO239, the aerial output (to receiver) a BNC and the v.f.o. input a miniature BNC: power is applied via a 4-way McMurdo connector.

Tuning (Boards 1 and 2)

After checking for correct values and component positioning, power can be applied to Boards 1 and 2 having first made the necessary r.f. connections with miniature 50Ω co-axial cable. Temporarily solder a $60-80\Omega$ $^{1}_{2}$ watt resistor across the output and ground, i.e. across TC7. Set all trimmers mid-way and the slugs in L1 (Board 1) and L1 (Board 2) to the centres of their respective coils. Do not connect Board 3 at this stage.

With a diode probe connected to a suitable meter (f.s.d. 50-150mA) and with power applied to both boards, check the oscillator output and tune TC1 on board 2 for maximum signal at the base of Tr2. Loosely couple L1 to a receiver tuned to 24MHz and a strong signal should be detected. Establish that TC1 tunes this frequency by turning it through 360°, when a rise and fall in output should be produced.

Place the probe on the base of Tr3 and adjust TC2 or maximum. Now transfer it across TC7, adjust TC4 and TC5 for maximum level, peaking TC6 and TC7. Repeat all tuning until no further improvement can be obtained.

Signs of erratic tuning indicates either an incorrect crystal harmonic from L1 or some other source of instability.

quite hot, as they are designed for temperatures of 150°C. The section of chassis around the power output transistors will become warm after a few minutes operation.

Remove the power from the transmitter and the link across the aerial filter. Re-apply voltage and adjust TC9 for maximum output: a sharp point should occur where maximum power is reached.

Remove the dummy load and couple an aerial via an s.w.r. bridge to the transmitter. Key the unit and re-adjust TC7, TC8, TC9 for maximum forward reading. The setting will most likely differ from that used when tuning into the dummy load, due to a variation of impedances.

Channel Frequencies

As previously discussed, a number of crystals covering several frequencies within the 2-metre band can be utilised. Each crystal will have an associated trimmer and capacitor, the precise frequency being set by means of a counter or calibrated receiver.

NOTE: In compiling the components lists for part 1, a few inconsistencies occurred. The following values are correct:

Board 1. R5-15k Ω , R6–8·2k Ω , R11–68k Ω , R15–10k Ω Board 2. R4–10k Ω , R13–56 Ω , C3–0·1 μ F

Also on Fig. 3 page 46; C18 should be shown in parallel with R15.

Next month we will consider the digital display and power supplies for the Avon.

54

If, like myself, you live on the top floor of a highrise block of flats then you will appreciate the problems involved in using the *PW* Economy Timing Strobe featured last February.

The need to use the mains supply to power the strobe tube seriously limits its use to those who have easy access to a suitable mains socket.

If the strobe could be made to operate from the car battery then its usefulness would be improved immensely.

The power supply described here is both simple to build, cheap and can be fitted into the case used for the original version.

The inverter shown in the circuit diagram produces around 400V and is a conventional inverter circuit using one transistor to convert the d.c. supply to a.c. ready for transforming up to 400V at the secondary of the transformer.

As the circuit is so simple and uses few components the construction can take any convenient form such as Veroboard or a small tag strip.

The transformer bobbin is wound with about 150 turns of 29 s.w.g. enamelled copper wire which is covered with a layer of insulating tape. This winding, which is the secondary, should almost fill the bobbin leaving just enough room for the primary and feedback windings (8 turns and 4 turns respectively). Take care to note the start and finish of the primary and feedback windings as this is important to ensure that the inverter oscillates.

The two ferrite pot cores can then be bolted together with the bobbin inside and the finished transformer secured by the central bolt to a convenient place in the box.

The small piece of Veroboard or tag strip can be bolted using the same bolt as shown in the drawing.

A standard line fuse should be inserted in the cable which is to be attached to the live terminal of the car battery to give protection against short circuits and other disasters which might possibly occur during use.

The basic circuit of the inverter can be used to power a standard 2 foot long fluorescent tube as an emergency lighting unit. In this case D1 and C1 should be omitted and R1 changed to 220Ω . The unit can then be run from a 6V lantern battery.

The method of connecting the strobe unit to the Number 1 plug lead suggested in the original article and the subsequent Extra Data published in the April issue may prove difficult to use on some engines and a modification is to use a length of Bowden cable outer sleeving to provide a flexible take-off point instead of the rigid 4BA stud. The 4BA stud should of course be fitted to the end of the flexible cable.

Circuit diagram and layout for battery-powered strobe

Practical Wireless, August 1978

resist coated epoxy glass laminate sheets, developing and etching trays, label and panel materials, high-speed drill, and all the requisite developers.

The Photolab Kit has been designed for use by both the amateur constructor and the professional engineer. It has been introduced to fill the gap between commonly used '1-off' prototype p.c.b. production methods and the facilities offered by the existing, larger kits currently available. However, with its pricing at only £49.50,

Telephone Charge Clock

Trying to calculate the cost of a telephone call while you are actually making it is an almost impossible mental exercise. An attractive new unit by Monitel now makes the process simplicity itself. All that is required of the caller is to select the appropriate charge band, as listed in the Post Office dialling code book, and start the clock at the appropriate moment. The microprocessor-based circuitry does the rest, displayed the accumulating charge continuously on an l.e.d. display, and taking account of the time of day, and the day of the week. The unit is programmed by means of a punched card, and in the event of a change in charge rates, can be reprogrammed by inserting a new card supplied by the makers.

When not in use, the display functions as a conventional digital clock. Produced in similar style and colours to Post Office telephones, the Monitel Telephone Charge Clock is available in a UK version, retailing at about $\pounds 29$, and an International version at about $\pounds 39$. The latter also copes with a selection of the charge bands for overseas calls.

Further details are available from Monitel Limited, Berechurch Road, Colchester CO2 7QH.

Light work

Mega Electronics Ltd. have introduced a comprehensive kit which enables the preparation of artwork for, and the production of, both printed circuit boards and front panels or labels.

Known as the Photolab Kit, it consists of an ultraviolet exposure unit, draughting aids and film, positive

Tele-View Module

Texas Instruments have recently announced the production in quantity of their VDP11 combined Viewdata/ Teletext decoder module. It uses a microprocessor system based on the familiar TMS 9980, which performs Viewdata decoding, and if used with a remote control system, a codeconverting PROM on the input lines enables the codes to be chosen by each customer. An internal TV sync. generator is included, and this is automatically switched in when Viewdata is selected. Auto-dialler telephone numbers are controlled by a fourpole DIL switch, and the unit also features terminal identification.

The complete p.c.b. module ($300 \times$ 165mm) is available from *Texas Instruments Ltd.*, *Manton Lane*, *Bedford*, priced at approximately £250, depend-

complete, and its ability to handle p.c. boards and labels of up to 228 \times 152mm, it is anticipated that the kit will have wide ranging appeal in both sectors of the market.

Available from: Mega Electronics, Ltd., 9 Radwinter Road, Saffron Walden, Essex CB11 3HU. Tel: (7099) 21918.

ing upon options selected; a version of the VDP11 with expanded memory in the microprocessor system, suitable for editing terminals, is expected to be available shortly.

PCB aids

A comparatively new product is available which will be of great benefit to engineers and amateurs who need to make their own printed circuit boards.

The Alfac Electro range of dry transfers contains almost 100 different patterns for making printed circuit layouts, quickly and accurately. As the symbols are etch resistant, they can be used for making 'one-off' printed circuits by direct application on to copper clad boards.

They are simple to use, and need no

special 'fixing' since the double action adhesive used, prevents the patterns from moving once they are laid down. The quality of the ink used avoids any cracking enabling users to obtain a very fine detailed finish.

They are available in a range of patterns and sizes and give correct spacing for integrated circuits and transistors. Also available are a range of lines and rounded corners etc., thus enabling a highly professional standard of finish to be achieved. Alfac Electro transfers are economical in price and are available in handy blister packs which are ideal for storage. They do not deteriorate with age and if left on their backing sheets can be used after months of storage. Each blister pack contains 5 sheets of patterns and costs $\pounds 1.30$.

Further details and catalogue can be obtained by writing to the sole UK agents for Alfac; *Pelltech Ltd., Alfac Electro Division, 6 Church Green, Witney, Nr. Oxford.*

A selection of some of the patterns available

LETTERS

Pen-Pal

Sir: I am a Ghanaian boy of seventeen years old. I am a first year apprentice in radio and TV servicing. I plan to start a course in radio and TV servicing, and I would be happy if you can help me to correspond with any beginner or experienced radio and TV technician from anywhere and of any age.

Francis K. Acquaye c/o Mr. K. Agyei Box 756 Takoradi GHANA

CQ-CQ

Sir: It seems a long time since I saw a "CQ" column in PW, and I wondered whether any reader could loan me for no more than just a few hours, the assembly instructions, or even just the circuit-diagram only, of the Tandy's "ArcharKit" Timing-light Kit, Cat. No. 28-4061.

This kit is discontinued, and the instructions were missing. In spite of exhaustive enquiries, Tandy have been unable to turn a replacement set up.

Jim Robson 47 Rosewood Crescent Newcastle upon Tyne NE6 4PR

Band II FM

Sir: I would like to hear from any of your readers who are interested in long-distance Band II v.h.f. (f.m.) reception. I have made contact with several people in the immediate locality, and feel sure that there are others who find the possibility of alternative goodquality programmes (both mono and stereo) interesting.

Some years ago a series of articles on Band II topics, written by Mr. Austin H. Uden, appeared in *Hi-Fi News*. If any reader knows of an address where Mr. Uden can be contacted, I would be grateful if they could send me details.

G. P. Stanbury 275 Meadgate Avenue Great Baddow Chelmsford Essex CM2 7NJ

Mains Plugs

Sir: I read with interest your editorial about plugs and fuses (PW, May, p 18).

It may be of interest to compare the situation here with that in America. Over there, there is only one kind of plug configuration, so all appliances come with the plug already fitted. However, there are no fuses in plugs, nor switches on outlets. Most appliances have two-pin plugs, with no earth pin, though all outlets accept three-pin plugs.

Perhaps this country could combine the advantages of the two systems by standardising on a single type of plug. Then manufacturers could supply equipment with plugs and fuses already in place.

M. A. Covington Cambridge

The proposed 16A "International" plug and socket has most of the features of the American plug described in this letter. Ed.

Sir: The recent comments in PW about 13A plugs have been most interesting.

May I point out that it is good practice to wire such a plug so that there is more slack in the earth lead than in the other two. Then, if the cable is wrenched from the plug, the earth lead is the last to part company, maintaining the safety of the equipment.

Plugs like those mentioned in May's PW, which accommodate equal length leads, do not encourage this practice. They should have the earth connection point even nearer the cable grip.

E. F. Chase Titchfield, Hants

Practical Wireless, August 1978

Image Rejection Filter

Use of the superheterodyne principle enables highly efficient communications receivers to be produced, but these sets are not totally free from flaws. The main drawback experienced with most s.w. superhet receivers is what is termed the "image response." This is a secondary response of the set which at high frequencies is often nearly equal to the main response, or "primary" signal.

The image response is produced because there are actually two possible difference frequencies for each oscillator frequency. One is equal to the oscillator frequency minus the i.f., and this is conventionally the main response. The other is equal to the oscillator frequency plus the i.f. Thus in order to convert a 1MHz signal to an i.f. of 455kHz, the oscillator would operate at 1.455MHz, and the image response would be at 1.91MHz (1.455MHz+0.455MHz).

Reducing the Image Response

Usually the image response is attenuated by using one or more parallel tuned circuits ahead of the mixer in the basic manner shown in Fig. 1(a). Theoretically, a parallel tuned circuit has a very high impedance

Fig. 1(a) Parallel-tuned, parallel-connected tuned circuit, and Fig.1(b) parallel-tuned, series-connected tuned circuit

at its resonant frequency and a low impedance at other frequencies. By tuning the circuit to the desired input frequency the input signal should pass unhindered and the image signal should be largely shunted to earth.

A practical tuned circuit does not achieve anything like perfection, and there will be some attenuation of the desired signal and perhaps only modest attenuation of the image signal. Several factors determine just how much attenuation of the image signal can be obtained, and one of the most important is the ratio of the input signal frequency to i.f.

In our example of an image response at 1.91MHz, produced by a 455kHz i.f. this response is at virtually double the original. Even a single tuned circuit would be sufficient to greatly attenuate the image response. If the same receiver were to be tuned to a frequency of 10MHz the image response would be at 10.91MHz, which is less than 10% higher than the primary signal. Therefore, the image rejection of a receiver falls away with increasing frequency, and on many sets it falls to a surprisingly low level. For example, a typical s.w. receiver might have two tuned circuits ahead of the mixer, an i.f. of 455kHz, and an image rejection of about 20dB at 14MHz, which means that the set is only ten times more sensitive on the primary frequency than it is on the image frequency. At higher frequencies the image rejection would be further reduced.

Problem Area

In practice it tends to be on the 20 metre amateur band that a lack of image rejection becomes most troublesome. This is because the image response overlaps the 19 metre broadcast band, and strong signals from that band can often largely obliterate the h.f. end of the 20 metre band. This only occurs with receivers having an i.f. in the 455 to 470kHz range, but unfortunately this probably includes the majority of communications receivers in amateur hands. The author experienced this difficulty with his Trio QR666 receiver, and it was this that prompted the construction of the simple filter which forms the subject of this article.

Rejection Filter

Probably the most obvious way of increasing the image rejection of a set is to insert an extra parallel tuned circuit in the r.f. signal path, as in Fig. 2.

Here the tuned circuit responds to the image frequency rather than the primary signal. As mentioned earlier, a parallel tuned circuit has a very high impedance at resonance, and so this should result in almost total suppression of the image signal and the wanted signal can pass with virtually zero losses.

The practical circuit of Fig. 3 clearly does not achieve perfection, but can provide a high degree of image rejection. A signal breaking through at about S9 or so can be reduced to less than S1, and the wanted signal is only very slightly attenuated.

The circuit is very straightforward with VC1 and L1 forming a variable tuned circuit which can be adjusted over the range 12MHz to 30MHz approximately. S1 enables the tuned circuit to be shorted out when the filter is not required.

Construction

L1 consists of 6^{1}_{2} turns of 0.9mm diameter enamelled copper wire wound around the bottom part of a Denco 38in (9.5mm) coil former. This is fitted with an iron dust core which is adjusted so that the threaded part of the core is flush with the top of the coil. If preferred, a ready made coil can be used. Suitable types are Denco Range 5 blue aerial or yellow r.f. coils. Use the winding between pins 1 and 6, and ignore any others. The tuning capacitor can be any good quality air spaced type having a maximum value in the range 300 to 400pF.

Using the Filter

The filter is coupled to the receiver via a short length of coaxial cable. When an interfering signal is noted, it is merely necessary to switch the filter in and adjust VCl to null this signal.

Don't keep a good Antenna down!

.... put it up instead! And put a really good one up, in your shack, in the loft, on the roof or (dare we say it) up the pole. Put up the Joystick VFA and note the difference. Six bands for the price of one antenna (not forgetting to mention that it tunes continuously from .5-30 MHz) and other benefits include the fact that it acts as a ground-plane on all bands, substantially reduces TVI and other spurious emissions including harmonic supression. SWL's shouldn't be without one --transmitting amateurs will prove that "to work them you have to hear them"

by Eric Dowdeswell G4AR

As promised last month I should like to discuss the question of what makes a callsign or prefix "rare". It arises with those listeners who start to keep a log of stations heard in the amateur bands.

The newcomer who has just heard his first American amateur, probably on 20m s.s.b., is a little put out when more experienced listeners do not share his initial excitement. In fact, thousands of such stations can be heard, as our beginner will soon appreciate!

He'll go on to log calls from around the world and tick them off against a prefix list. He'll notice that some countries, like the US, are divided into call areas comprising groups of states. On the other hand G2, G3, G4, G5, G6, G8 and several other derivatives could all be in the same block of flats, in England!

Some of the prefixes are hard to find but periods spent listening during the wee small hours will always produce a few more. Certain countries do not appear to have any amateurs at all, frequently due to political reasons. Some "countries" are no more than reefs or small islands that are uninhabited until a group of amateurs form themselves into a DXpedition in order to put a new country in the log of thousands of amateurs.

It is very important to note that **distance** does not come into the question as to whether a call is rare or not. Due to skip it might be next to impossible to log a station in GU (Guernsey) on 20m, while capturing all the VK areas without difficulty. The purpose of the log extracts each month is to alert readers to the comparatively few rare calls that have appeared recently.

Details of time and precise frequency are not required because of the time that the information takes to get into print. The date and band and mode is sufficient. An excellent prefix list with much other useful information costs just 40p from Geoff Watts, 62 Belmore Road, Norwich NR7 0PU. No amateur can afford to be without it.

Talking about sunspot curves, a plot of rainfall against letters received here would be very interesting! Lousy weather so plenty of mail this month!

Practical Wireless, August 1978

Newcomers

Having read this column for the last three years **Paul Bown** at 2 Sunnyside, Theale, Reading, Berks has at last acquired a receiver. Unfortunately it seems to need a bit of attention, not doing much above 20MHz, and Paul is very keen to get on 10 and 15m. So, can anyone help with a manual for the Skywood CX203? Replies direct to Paul, please.

Four months on the bands with an FRG7, and a good log, hardly qualifies **J. S. Goodier** of Marple, Cheshire as a newcomer. He is now keen enough to start studying for the RAE! He thinks he may have to go it alone but I hope my advice to contact his local radio club and technical college may avoid that.

Round the Shacks

Dave Greenhalgh BRS39965 in Poynton, Cheshire found two goodies in VK9NGE on Norfolk Is. and VR1AR in the Gilbert Is. on 10m. I hope **Bill Rendell** down in Truro, Cornwall won't mind if I mention him in this section. He has been lapsed for seven years but is hard at it again with a 1961 Heathkit AR3 fourvalve set plus preselector and a very short wire in the attic. Naturally, selectivity is a problem and I fear that something a bit better may be the only answer. Bill reckons the lads and lasses would do a better job communicating if they stuck to the proper phonetic alphabet instead of the "homebrew" variety.

An AR88 and 120ft of wire brought in strings of Japs on 10m for **Brian Harrison** in Hastings, Sussex while in Tetbury, Glos. **Jim Rowland** is putting the finishing touches to a Heathkit HR1680. He finds the components a bit "fiddly" compared to those of the '20s! **Dick Smith** reckons he is the only SWL in Porthcawl, Mid-Glamorgan but I doubt it very much! He has a Codar MC3 t.r.f. set with pre-selector, a.t.u., 100ft of wire and an "artificial earth" whatever that is! Could be a collection of quarter wave wires all joined to the set's chassis. A CR100 will, hopefully, be added to the strength in the holidays.

Army type Sgt. Anderson, Dennis, also BRS36591, reports back to the column after wandering around Jamaica and the Sudan. Wonder if he saw my old tribander still up there in Khartoum? Dennis now has a Venus SS2 for SSTV and getting good results, with RAE studies going on apace aided by G8LVB. John Whiting, Fareham, Hants, has done well in the Pacific area with a sort of vee beam with 90ft legs, with the feed from one end.

G. M. Davies of Rhyl, N. Wales has been SWLing for 25 years and has reached the FRG7 stage, but wishes the Fine Tune were a lot finer and doesn"t and two rather sharp nulls. It is the nulls that are of use to the DXer. A loop is used to null out QRM. It is not used to peak up DX.

How to use the Loop

A loop is very easy to use. For example, with the loop pointing in any direction, tune the receiver to 782kHz and peak up the mixture of stations heard, using the loop's tuning control. East Germany and Portugal are on 782. Now rotate the loop slowly around its vertical axis. In one position East Germany should be heard reasonably clear of QRM while in another position Portugal will appear. Similarly on 989kHz where from this QTH Madrid can be heard clear of the jamming that is normally on this channel. Similar results can be obtained with a transistor portable that has an internal aerial. The whole receiver must be rotated and the two nulls on most models will be along the length of the receiver parallel to the tuning scale.

When DXing with a loop, rotate it for optimum results. North American DX often suffers from QRM from Latin America and the two are easily separated. The loop may not always null out QRM. North American DX sometimes has European QRM coming from the opposite direction from the DXer and the loop cannot help on this occasion. On the other hand European QRM can nearly always be nulled out when listening to South America.

Advantages and Disadvantages of Loops

The only disadvantage the loop has is its low pickup compared with a long wire. My 40 inch loop has a pick-up somewhere between that of my 90ft longwire and a ferrite rod aerial. It is claimed that the standard 40 inch loop has a pick-up equivalent to a 30ft longwire 10ft above the ground and although I have not done comparative tests I think this value is about right.

The loop has a number of advantages in addition to its ability to reduce QRM. It is an indoor aerial and can be used in locations where a long wire could not be erected. Some excellent DX comes from readers who live in multi-storey flats. A loop will nearly always improve the signal-to-noise ratio and if static is coming from one direction, perhaps from tropical thunderstorms in the south in summer, then the static can be eliminated when listening to North America to the west. DXers claim that a "cleaner" signal is sometimes obtained when using a loop and surprisingly, this is true. Overloading, sideband splatter, crossmodulation, when reduced can leave a much cleaner DX signal on some receivers. Loops are not made commercially in the UK so you will have to make your own. This is not a disadvantage. A lot of satisfaction is to be had from quite a simple device that you can easily make yourself and that will on occasion produce quite startling results.

Problems with Loops

Reader John Cook of Southend-on-Sea has constructed the loop described in the 1976 edition of the World Radio and TV Handbook. The tuning capacitor is a 365pF variable ant the loop works well between 525kHz and 1250kHz, but on higher frequencies John has to switch out the tuning capacitor. Try reducing the number of turns. You should then be able to tune to 1605kHz but you may then not be able to tune as low as 525kHz. If so, switch in additional capacitance (220pF should do) whenever you want to reach the l.f. end of the band. The general rule is; if you cannot tune to the h.f. end, remove turns and if you cannot reach the l.f. end, increase the tuning capacitance.

As a rough guide, 100ft of wire will be found to be the correct length to wind most loops irrespective of size. On this basis a loop of 4ft size would have six turns, though it might be possible to squeeze in another turn or two if the self capacitance of the winding and the minimum value of the tuning capacitor are low.

A number of readers, including John, ask for details of a suitable pre-amplifier for use with a loop. My advice is, do not use a pre-amp, at least until you have some experience handling a loop. Even then a pre-amp is of limited value. The same applies to the use of a preselector on the medium waves. DX on this band is often quite strong and it is interference, some 80 megawatts in Europe, that is the problem. High selectivity, not high gain, is what is required and a loop pre-amp or preselector may easily overload the receiver.

SHORT WAVE BROADCASTS by Charles Molloy G8BUS

During the early days of wireless, Saturday was aerial cleaning day when enthusiasts used to scrub their aerials with steel wool to remove corrosion and hopefully, bring about improved reception. While it is not suggested that this practice should be resurrected it is a fact that outdoor aerials do require maintenance now and again and summertime, when the days are long and the weather is kind, is the time to do it. Several years ago I discovered with horror that my long wire was no more than a 10ft lead-in, as the joint between lead and aerial had corroded away!

It can be rather annoying if an aerial comes down during the winter when the weather makes repair work difficult and even hazardous. I take down my long wire every summer to examine it for mechanical weakness or breakage. It is only the active part of the aerial between the insulators, that needs to be copper wire. The parts between insulators and supports can be of stronger material such as steel wire or nylon rope. Leakage is not a great problem when an aerial is used with a modern receiver but if the aerial is down then it only takes a moment or two to clean the insulators and it might just make a difference when you are chasing weak DX. Dirty insulators and bad connections can also cause crackles.

Summer is also the time to experiment with aerials. If you have a long wire then why not try a vertical or a whip? An ounce of practice is worth a ton of theory. If you have the space, try making your aerial longer to see if it makes any difference. Height is usually

Solar noise was frequently heard at 28 and 50MHz with normal communications receivers and dipole aerials on May 3rd, 5th, and 7th and large bursts were recorded at 136MHz at 1201 (8 mins) on the 6th and 1213 (37 mins) on the 8th. Noise storms were recorded on May 1st, 4th, and 18th. On April 30th, Henry, using his spectrohelioscope, counted 5 large sunspots, 6 small ones, 3 bright plages and on May 3rd he saw a baby flare. Another look on the 17th revealed 10 spots in 5 separate groups.

Aurora

After that April 28th burst, and with more solar activity on May 1st and 3rd, it was not surprising that auroral events began during the afternoon of April 30th and rolled around, with varying intensity until the small hours of May 4th. Between 1555 and 1720 on April 30th, John Branegan, GM8OXQ, Saline, Fife, heard tone-A, c.w., signals from G, GI, GM, PA0, SM and beacon signals from GB3ANG, GI, LER, and VHF on 2m. John found it impossible to access OSCAR-8 during the aurora while the satellite was to the north of his QTH. Alan Baker heard GMs on the 30th and around midnight on May 1st/2nd, Barry Ainsworth had s.s.b. contacts with GM4COX and GM8ODN and a c.w. contact with GM4CXM. At 2354 on May 2nd, Alan worked GI5SJ, at 0013 on the 3rd he worked GM4BYF and heard GI4GVS and GM8FFX.

Around 2215 on May 1st, Neil Clarke heard tone-A beacon signals from GB3CTC, GB3GI, DL0PR and SK7VHF and auroral s.s.b. from 7 Gs, 5 GMs, 1 GI, 1 GW, 1 ON, 1 PA0 and 3 DCs. At the same time John Branegan heard several of his GM colleagues "piling up the Continentals on both c.w. and s.s.b., with Gs in the London area very prominent". Between 1645 and 1850 on May 3rd John heard tone-A c.w. from Russian and Swedish amateurs, meanwhile I heard auroral signals from G8LIC, Middlesbrough, G8AZA, broadcast Scarborough, 11 east-European f.m. stations (67-73MHz), Meldrum TV sound (58.25MHz), GI4GVK and Mike Rowe, G8JVE, some 10 miles south of me at East Preston, Sussex. Mike also heard GI4GVK and GI4GVS, while at nearby Lancing, Roy Bannister worked GW2HIY and GM4EYF on c.w., and further east in Newhaven, Alan Baker heard 4 Gs, 1 GI. 1 GM and a GW.

Around 0249 on the 4th Alan had auroral QSOs with a couple of GMs and a GW, and agreed with Barry, Roy and myself that GM4COK was the most consistent auroral signal in southern England. Having weighed all this up, **Charlie Newton**, G2FKZ, London, RSGB auroral co-ordinator, is studying the relationship between large individual solar bursts and aurora and would appreciate any information you can give him. Between 1534 and 1738 on May 9th John Branegan worked G8LIC and G8MJG via aurora and heard strong c.w. signals from G, GI, GW, LA, and beacons DL0PR, GB3GI, LER, and VHF.

10m Band

Harold Brodribb, St. Leonards-On-Sea, Sussex and Alan Baker reported that the 10m band was dead on April 20th and, periodically, on other days ionospheric disturbances menaced the BBC's World Service transmissions on the h.f. bands. On most days between April 20th and May 18th, John Branegan, Gordon Goodyer, BRS37345, Petworth, Sussex, Neil Clarke, and myself received strong signals from the Cyprus beacon, 5B4CY, project TESSA beacon ZE2JV, and occasionally A9XC, Bahrain, and DL0IGI when sporadic-E was present. Neil reports that on April 29th and May 3rd, 10m was open from 0800 until 2000 with signals from South Africa, South America, Israel and Russia. Gordon logged a host of Ws around 1840 on May 6th and Middle East stations during the afternoon of the 7th, while on the 14th he received s.s.b. signals from 30 countries from Japan to South America and Russia to South Africa.

Sporadic-E

The 1978 Sporadic-E season (northern-Hemisphere) began at 0800 on April 26th when I received both sound (56.25MHz) and picture (49.75MHz) on the B1 television channel with only dipole aerials feeding my R216 v.h.f. receiver and JVC 3060 television receiver. At the same time I heard strong f.m. signals from seven east-European broadcast stations (66-72MHz) and during the morning of May 1st, I watched part of Russia's May Day parade on R1. A most intense Es disturbance occurred between 0900-1100 on May 13th when I received very strong signals from 33 broadcast stations (65-73MHz), European radiotelephone signals in Band I and on Ch.Rl I watched an ice hockey match. There are many transmitters on the R1 system and periodically (typically sporadic-E) one picture would fade out and another take its place. At 1241 on the 15th, a test card appeared on R1, and reference to Roger Bunney's book, Long Distance Television, revealed that the station was Televidnie Sovietskogo Soiuza (USSR) using test card pattern 0249.

Tropospheric

Conditions on v.h.f. improved greatly between May 6th and 18th, during which time the atmospheric pressure fluctuated from $30 \cdot 0$ in to $30 \cdot 5$ in and down again. On the 6th, Mike Rowe worked 3 Ds, 8 Fs, 5 ONs, and 6 PA0s on 2m s.s.b. and during the afternoon of the 7th he had a 59 QSO with DK8VRA. Mike runs a TS700G, with a home-brew 50 watt linear to an 8element crossed Yagi. At 2240 on the 9th, Neil Clarke heard a PA0 calling through his local 2m repeater, GB3NA, R3, and on s.s.b. he heard 17 PA0s and 7 DCs working UK stations from Kent to Wales and north to Scotland.

During the afternoon of the 7th G4GNX had 2m s.s.b. QSOs with PA0WRL/P, F1ENH/P and DC9DZA, and on the 10th both **Andrew "Jim" Lyon**, G8LPY, Worthing, and G4GNX heard signals through the French repeater, FZ3THF, R4. On the 11th, Jim worked Roy Bannister, holidaying in Yorkshire, via GB3PI, R6. Like Mike Rowe, Jim uses a TS700G to an 8-element crossed Yagi and they are both now equipped for 70cm operation. In a c.w. contact on the 10th PA0DOG told G4GNX that PA0MI had worked into Russia via the aurora on May 1st, and at 2028 on the 15th G4GNX had a 2m c.w. QSO with F6BCK.

Band II FM DX

Guy Stanbury, Chelmsford and Bob Dewick, Southminster, Essex, are keenly interested in Band II DX. Guy uses a home-brew receiver built from Ambit International modules and Bob has a Trio KT7001. Both stations use two Fuba Uka Stereo '8's aerials stacked vertically and rotatable. Guy sent a detailed

15-240 Watts!

HY5 Preamplifier

The HY5 is a mono hybrid amplifier ideally suited for all applications. All common input functions (mag Cartridge, tuner, etc) are catered for internally. The desired function is achieved either by a multi-way switch or direct connection to the appropriate pins. The internal volume and tone circuits merely require connecting to external potentiometers (not included). The HY5 is compatible with all L.P. power amplifiers and power supplies. To ease construction and mounting a P.C. connector is supplied with each pre-amplifier. To ease construction and mounting a P.C. connector is supplied with each pre-amplifier. In equalization—Low noise —Low distortion—High overload—Two simply combined for stereo.

APPLICATIONS : Hi-Fi-Mixers-Disco-Guitar and Organ-Public address

The HY30 is an exciting New kit from I.L.P. It features a virtually indestructible I.C. with short circuit and thermal protection. The kit consists of I.C., heatsink, P.C. board. 4 resistors, 6 capacitors, mounting kit, together with easy to follow construction and operating instructions. This amplifier is ideally suited to the beginner in audio who wishes to use the most up-to-date

technology available. FEATURES: Complete Kit—Low Distortion—Short, Open and Thermal Protection—Easy to

APPLICATIONS: Updating audio equipment-Guitar practice amplifier-Test amplifier-

log containing some 49 stations heard, both mono and stereo, between 87-104MHz on May 9th, and 68 stations on the 10th. His logs are impressive and give comparable signal strength for the British and Continental stations. The strongest signal on these two days was Lopik 3s, $96 \cdot 80$ MHz. Guy, Bob and myself would like to hear more from readers on this subject.

Microwaves

On April 2nd, Peter Kerry, G8ARO and Don Hayter, G3JHM, established their portable 3cm equipment, with an 18in dish, on the Hogs Back, Surrey, and worked G8BDJ and G8GKV, situated 40km away on Chanctonbury Ring, Sussex, at good strength. On May 1st, Peter set up the same gear on top of an 80ft high residential tower block, 320ft a.s.l., at Highgate and received the London 3cm beacon, GB3LBH, at 25km, 48dB above the noise. Peter points out that only 30dB of this was produced by the 18in dish. At 0950 on May 3rd he recorded a 2dB increase in noise when he pointed the dish towards the sun compared with cold sky.

OSCAR

John Branegan told me on May 6th "As of today, I have worked 20 countries by satellite" and at 1310 on May 9th he made his first transatlantic QSO with W2BAX, New Jersey, through OSCAR-8. John is now operational on OSCAR-7, Mode A and OSCAR-8, Modes A and J and has had over 70 QSOs via satellite in his first 10 weeks on the air.

Down under

Anthony Mann, Applecross, Western Australia, says "If sunspot activity keeps on increasing, the start of the next sporadic-E season (southern hemisphere) in October or November ought to see some really high MUFs to the north". Between 1325-1545 on April 16th he received for the first time, via F2, signals on Ch.R1 (Russian) sound, Ch.E3 video and Japanese amateurs on $50 \cdot 1$ and $52 \cdot 0$ MHz.

April 13th was another memorable day for Anthony with E2 and R1 in around 1100 and out at 1810, and late night transequatorial skip producing Korean Broadcast Service, $44 \cdot 3$ MHz, and Ch.E2 West Malaysia from 2220 to 2255. The only other evening T.E. skip observed by Anthony this autumn was on March 12th from 1915-2015, with KBS $44 \cdot 3$ MHz and $44 \cdot 9$ MHz and Radio Peking, $45 \cdot 3$ MHz. Around 35MHz on April 3rd, 8th, and 9th he heard "This is Radio Call Paging Service of Oklahoma City".

From your letters

"I have just come back to radio as a hobby" writes **R. Horsfield**, Sandbach, Cheshire, "having started in the early 50s with an R1155, and after using a R210 have ordered an FRG7 digital", he is also looking for a y.h.f. receiver.

Eleven members of the Brighton and District Radio Society visited the *Practical Wireless* stand at the RSGB show at Alexandra Palace on May 6th. The mini-bus used for the journey was equipped with an IC240 and an Antec window-mount, ground plane aerial for contacting the exhibition talk-in station, GB2VHF, organised by the Grafton Radio Society.

Many reports exist that static-like radio interference is heard prior to an earthquake, any readers

Reports on the various bands are welcome and should be sent direct, by the 15th of the month, to:-
 AMATEUR BANDS Eric Dowdeswell G4AR, Silver Firs, Leatherhead Road, Ashtead, Surrey KT21 2TW, Logs by bands, each in alphabetical order.
MEDIUM and SW BANDS Charles Molloy G8BUS, 132 Segars Lane, Southport, PR8 3JG. Reports for both bands must be kept separate.
VHF BANDS Ron Ham BRS15744, Faraday, Grey- triars, Storrington, Sussex RH20 4HE.

who have experienced this, please let we know because **Richard Hill** of Tunbridge Wells is making a special study of this.

Geoff Drewe, G4CAO, Weybridge, Surrey, is operational on c.w., 625-line TV, Slow Scan TV, and Facsimile. Geoff had a 2m FAX contact with G8ONE on April 17th using sync for the first time. The frequency is 144.700MHz and Geoff says "We can now transmit two-way FAX in fine detail in sync without too much stress". He also hopes that more amateurs will become active in this field.

Many thanks for all your interesting reports on such a wide range of subjects.

PW PERSONALITY VISITS WEST KENT ARS

Richard Leman, G8CDD, challenged fellow members of the West Kent Amateur Radio Society to make a crystal set, to look again at the first principles and provide a competitive activity for the Society.

The completed set had to receive the 200kHz BBC transmitter and any medium wave station, excluding the BBC World Service transmitter at Crowborough which pounds a signal into Tunbridge Wells. Bonus marks (10%) were awarded for not using new components, and (15%) for using wireless parts of the pre-1940 era.

Judging by G8CDD, for loudness, clarity, construction and originality (one competitor used a 30 amp antenna fuse), was carried out on top of a local multistorey car park using a long wire aerial and a connection to the fire hose rising main for earth.

The prizes were presented on May 12th, at the fortnightly meeting of WKARS, by Ron Ham, our VHF Columnist, who was the visiting speaker seen here fourth from left.

Practical Wireless, August 1978

Situations Vacant

Radio Technicians

Government Communications Headquarters has vacancies for Radio Technicians. Applicants should be 19 or over.

STANDARDS required call for a sound knowledge of the principles of electricity and radio, together with 2 years experience of using and maintaining radio and electronic test gear.

DUTIES cover highly skilled telecommunications/electronic work, including the construction, installation, maintenance and testing of radio and radar telecommunications equipment and advanced computer and analytic machinery.

QUALIFICATIONS: Candidates must hold either the City and Guilds Telecommunications Part 1 (Intermediate) Certificate or equivalent HM Forces qualification.

SALARY (inc. supps.) from £2,673 at 19 to £3,379 at 25 (highest pay on entry) rising to £3,883 with opportunity for advancement to higher grades up to £4,297 with a few posts carrying still higher salaries.

Opportunities for service overseas.

Further particulars and application forms available from:

Practical Wireless, August 1978

Your career in Electronics?

Enrol in the BNR & E School and you'll have an entertaining and fascinating hobby. Stick with it and the opportunities and the big money await you, if qualified, in every field of Electronics today. We offer the finest home study training for all subjects in radio, television, etc., especially for the CITY AND GUILDS EXAMS (Technicians' Certificates); the Grad. Brit. I.E.R. Exam; the RADIO AMATEUR'S LICENCE; P.M.G. Certificates; the R.T.E.B. Servicing Certificates; etc. Also courses in Television; Transistors; Radar; Computers; Servo-mechanisms; Mathematics and Practical Transistor Radio course with equipment. We have OVER 20 YEARS' experience in teaching radio subjects and an unbroken record of exam successes. We are the only privately run British home study College specialising in electronics subjects only. Fullest details will be gladly sent without any obligation.
